the area of the stope face.

A comparative analysis of the SSS components of spatial models is conducted, where, for example, the minimum value of the average daily velocity $V_d = 5$ m/day of the stope face advance is taken as the base. For it, the main parameters of rock pressure anomalies are determined in the form of concentrations of stress components (or the degree of their destressing) and the propagation distances of these concentrations into the mass. At two other values of V_d (10 m/day and 15 m/day), the same order of research is set and the result is presented in relative units of change (increase, decrease) of certain parameters of rock pressure anomalies.

The obtained results in terms of the V_d influence on the dimensions of the frontal bearing pressure zone are presented in the form of graphs (figure 7) for a more visual representation of the correlation degree between the studied parameters. The non-linearity of the growth in the relative dimensions of the frontal bearing pressure zone with an increase in the average daily velocity V_d of the stope face advance is clearly observed. At the V_c of 10 m/day, there is a decrease in the increase gradient P. It should be clarified that when constructing these graphs and subsequent ones, average values of P are taken in each range of vertical stress σ_y concentration coefficients K_y. The general conclusion on the frontal bearing pressure zone dimensions is such that the velocity V_d has a very significant influence (in the range of $V_d = 5$ – 15 m/day), varying in the range from 132 percent to 281 percent.

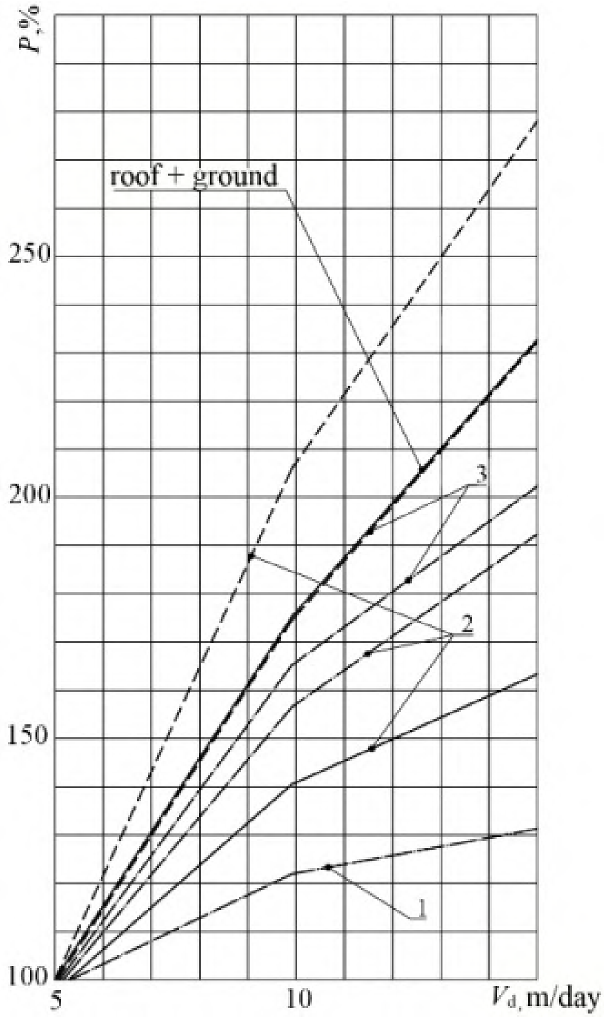

Figure 7. Patterns of the average daily velocity V_d influence of the stope face advance on the growth of the relative dimensions P of the frontal bearing pressure zone at concentration coefficients σ_y.

Similar patterns of the average daily velocity V_d influence of the stope face advance are shown in figure 8 for the dimensions P (at different concentration coefficients K_y) of the lateral bearing pressure zone. The main difference is in the relatively lower degree of influence from 100 percent (no link between P and V_d) to 163 percent for most dimensions of this zone. The only exception is the propagation distance of the concentration $K_y = 1.25 - 1.35$ into the seam bottom. It is noteworthy that the concentration $K_y = 2.0$, which is capable of weakening the border rocks, practically does not change its propagation with an increase in V_d by 3 times (from 5 to 15 m/day). This means a sufficient constancy of the dimensions of weakened rocks from the side of the undisturbed rock mass and, at least, the absence of an increase in the mass displacements (in this direction), if the time factor of their development is not taken into account (limitation of displacements at high values of V_d). Lower concentrations σ_y propagate to more remote areas at $V_d = 10 - 15$ m/day, but it is their moving away (up to 13–15 m along the strike) that makes it possible to predict the minimum impact from the undisturbed rock mass on the rock pressure manifestations in the extraction drift.

In the destressing zone behind the stope face, similar tendencies in the velocity V_d influence on this rock pressure anomaly values are observed (figure 9).

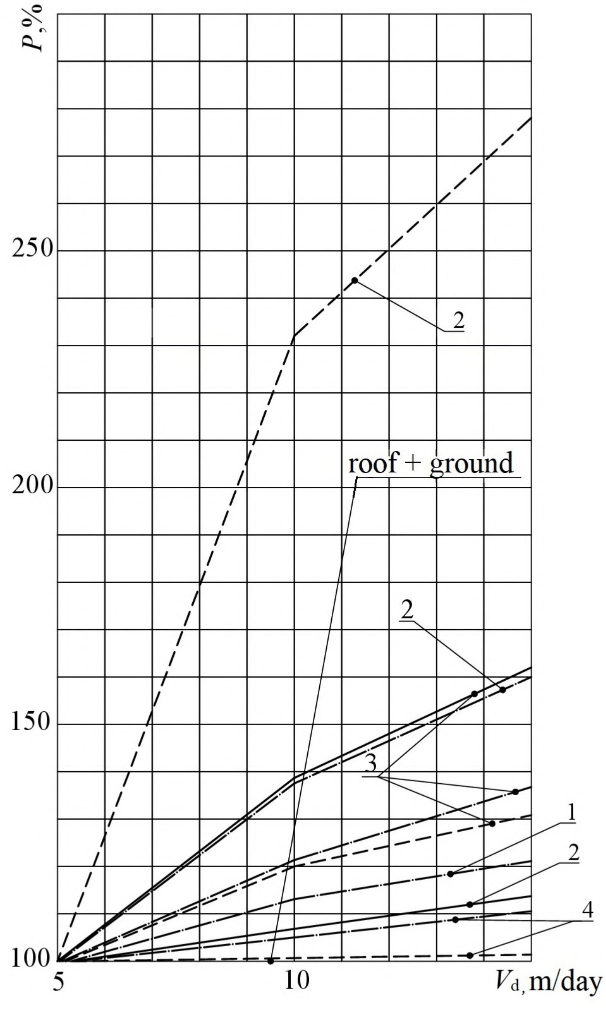

Figure 8. Patterns of the average daily velocity V_d influence of the stope face advance on the growth of the relative dimensions P of the destressing zone at concentration coefficients σ_y.

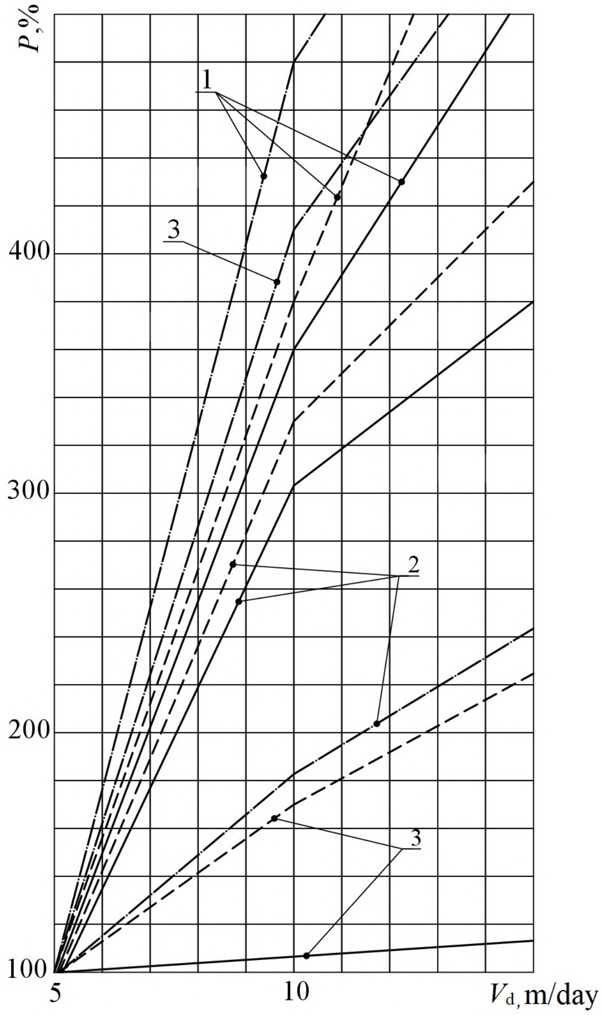

Figure 9. Patterns of the average daily velocity V_d influence of the stope face advance on the growth of the relative dimensions P of the lateral bearing pressure zone at concentration coefficients σ_y.

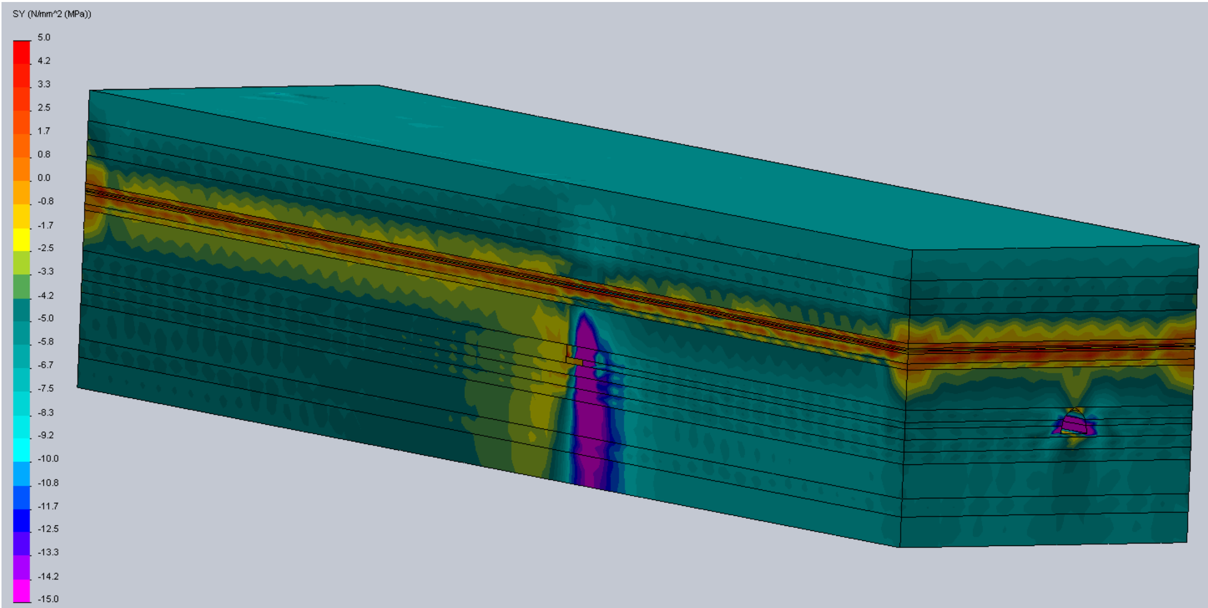
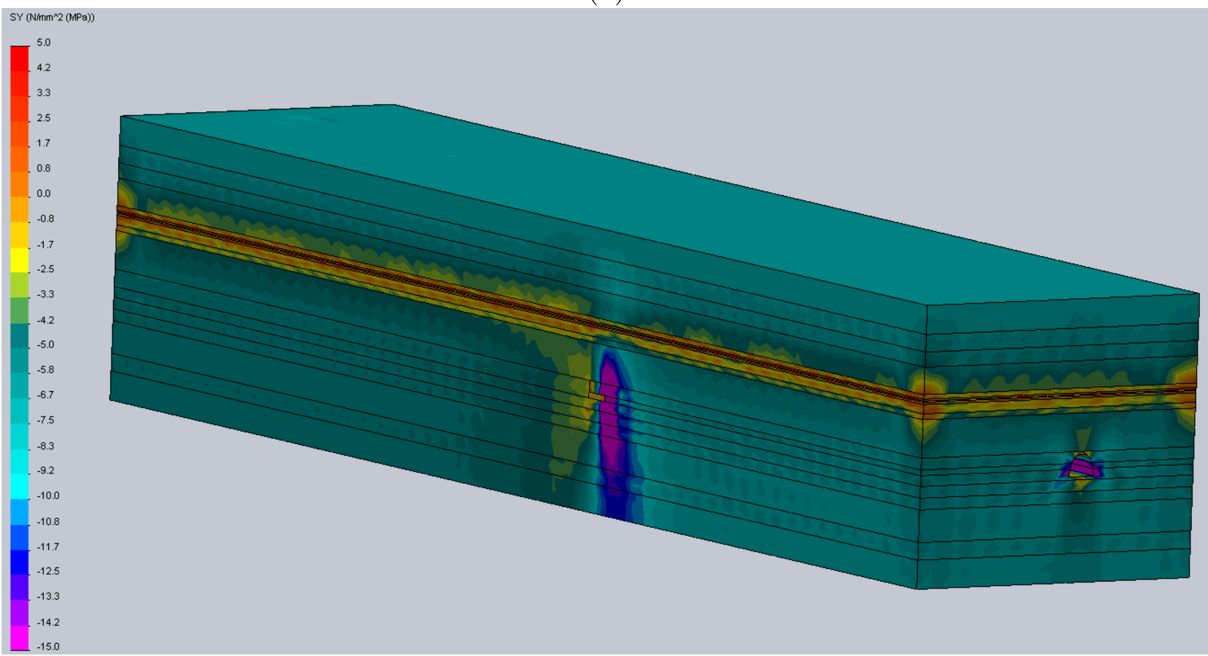
6. Influence of the coal-bearing mass texture on the stress-strain state of spatial models

The studies accumulated to date on the stratified coal-bearing mass stress-strain state, including the Western Donbass weak rocks, convincingly prove the presence of the influence of its texture on the parameters of distributing stress components in the area of stope operations. Therefore, this factor is subjected to a detailed study in combination with a variable velocity of the stope face advance. The studies are illustrated by the example of spatial curves of the three stress components distribution: vertical σ_y, horizontal σ_z (in the plane of the cross-section of extraction workings) and stress intensity σ.

First of all, the peculiarities of vertical stress distribution are studied, the curve of which is shown in figure 10 for the minimum ($V_d = 5$ m/day) and maximum ($V_d = 15$ m/day) stope face advance velocities in the studied range of their change. Since the analysis of the distribution parameters σ_y for a predominantly thick-bedded and medium-bedded structure has already been presented, the results of comparison with the peculiarities of the curve σ_y for a predominantly thin-bedded and medium-bedded structure are presented below.



(a)



(b)

Figure 10. Curves of vertical stresses σ_y in a spatial model of a predominantly thin-bedded and medium-bedded mass at an increased (a) and decreased (b) stope face advance velocity.

At the minimum stope face advance velocity ($V_d = 5$ m/day), the following differences in the distribution curve σ_y for predominantly thin-bedded and medium- bedded texture of the coal-bearing stratum have been revealed.

In the frontal bearing pressure zone, the change in the mass texture has caused a number of transformations in the vertical stress σ_y distribution. Thus, the minimum influence of the approaching stope face ($K_y = 1.05 - 1.25$) is noted at a distance of $13 - 15$ m to the rise of the seam. This is by 35 – 40 percent closer to the stope face than with predominantly thick-bedded and medium-bedded texture. This is quite consistent with the results of mine observations of rock pressure manifestations and is explained as follows: less thick rock layers that are not capable of developing a high repulse reaction to vertical rock pressure weaken and break into blocks with a small length of a stable cantilever, which deform the underlying layers at a greater distance (to the rise) from the stope face.

The minimum concentration of $K_y = 1.05 - 1.25$ propagates into the seam roof up to 23 – 24 m, which practically coincides with the results of the predominantly thick-bedded and medium-bedded texture variant. Into the seam bottom, the minimum concentrations are distributed to an equivalent depth and go beyond the boundaries of the spatial model.

More significant concentrations of the $K_y = 1.46 - 1.56$ level reach 2.5 – 4.6 m to the rise from the stope face plane, that is, they reduce their impact by 23 – 52 percent. This concentration in the roof reaches 6.7 m (decrease by 39 percent), and in the bottom – 18.6 m, which is by 2.04 times higher than in the predominantly thick-bedded and medium-bedded texture.

The most dangerous concentrations of $K_y = 2.0$ level are located near the stope face and are characterized by the following dimensions: to the rise of the seam – 2.1 – 2.6 m (81 – 87 percent); throughout the height into the roof – up to 4.6 m (by 1.19 times greater); in depth of the bottom – up to 11 m (by 2.29 times greater).

Summing up the above data, one should pay attention to the tendencies of reducing the propagation of concentrations σ_y to the rise of the seam and mainly the growth of their dimensions into the roof and bottom of the seam.

The obtained tendencies in terms of the development of rock pressure manifestations in the extraction workings make it possible to predict the following:

- reduction not only of the distance (ahead of the stope face) of the coal-bearing mass displacement intensity into the cavity of mine workings, but also the value of their displacements;
- directly near the junction of the stope face with the drift, an increase in the displacement velocity of the rocks in the roof and the bottom of the seam.

In general, according to the results of the performed studies on the stress-strain state of spatial models, a number of influence patterns of the coal-bearing mass texture type and the average daily velocity of the stope face advance on the parameters of the three main rock pressure anomalies in the area of conducting stope operations have been determined: frontal and lateral bearing pressure zones, as well as destressing zone behind the stope face.

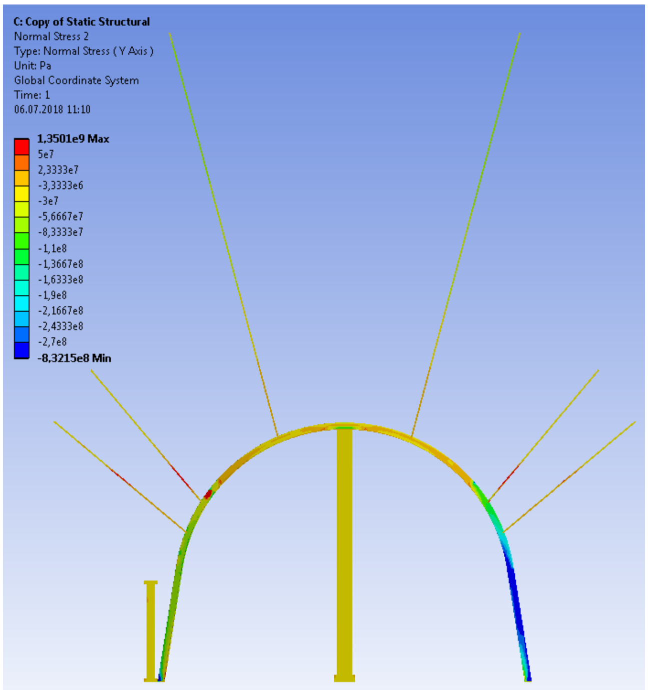
These studies are used in the development of recommendations for the selection of rational design parameters for high-rate mining of coal seams in the Western Donbass conditions.

Based on the performed research, the state of modern fastening and security structures has been studied, which provides the possibility of reusing the mine working at high velocities of stope face advance in order to improve the schemes for maintaining extraction workings.

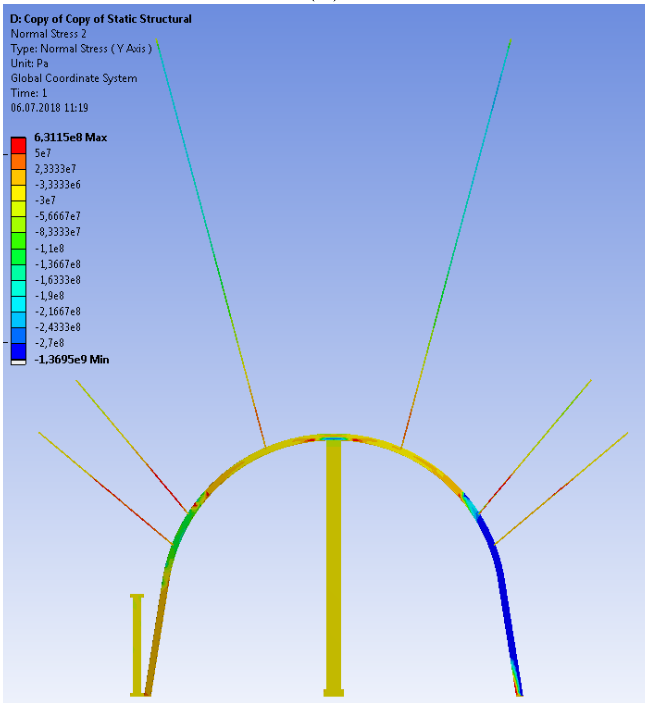
The state of the fastening and security structures is studied in terms of three main stress components. The SSS analysis is performed sequentially for each of the studied areas of the mine working maintenance.

For example, a curve of the vertical stress σ_y components is studied (figure 11).

The conducted comparative analysis of the vertical stress distribution in all fastening structure elements proves the significance of the influence of the stope face advance velocity and the mass texture. The identified tendencies should be taken into account when substantiating the fastening parameters. The patterns determined during the performance of multivariate computational observations have been confirmed in the course of instrumental observations in the mine workings of the Western Donbass mines (figure 12).



(a)



(b)

Figure 11. Curves of vertical stresses σ_y iin the fastening structure of the extraction drift in the frontal bearing pressure zone at the stope face advance velocities V_d: (a) $V_d = 15$ m/day; (b) $V_d = 5$ m/day.

Figure 12. The state of mine working at the experimental site.

Experimental studies have been performed in various mining-geological and mining-technical conditions.

The decrease in the material consumption of fastening and security structures at high velocities of advancing stope faces has been substantiated and confirmed by calculations. It is recommended to fasten with the lightweight SCP-22 profile and with an increase in the step of setting the frame support and resin-grouted rockbolts up to 1.0 m, the rope bolts are placed in a checkerboard pattern with a step of 4.0 m, the permissible diameter and the number of rows of side prop stays of the strengthening support and the breaker-prop row are reduced. The use of such a highly efficient scheme for maintaining extraction workings provides a reduction in the time and cost spent on end operations. Thus, this creates an opportunity for the full operation of modern high-performance stope equipment and, as a result, the intensification of mining operations in difficult mining-geological conditions.

7. Conclusions

Generalization of the research results makes it possible to formulate the following conclusions.

The analysis of existing analytical studies and experimental measurements of the rock pressure manifestation parameters has convincingly proved the significance of the influence of technological parameters of coal seam mining on the formation of SSS anomalies (frontal and lateral bearing pressure, destressing zone behind the stope face) in the coal-bearing mass adjacent to stope operations. For indicated three main SSS anomalies, a set of parameters has been substantiated that completely characterize this research object. On the other hand, two technological parameters have been distinguished that not only significantly influence on the formation and development of SSS anomalies, but are also inextricably linked with the intensification of mining the coal seams: the average daily velocity V_d of the stope face advance and the duration of its stoppage t.

Based on the analysis of existing scientific-practical developments, the most expedient three-stage structure for performing research has been substantiated, where mine instrumental observations and multivariate computational experiments are combined and complement each other through a linking element – the mechanism for coal-bearing mass displacement in terms of the impact of the selected technological parameters for conducting stope operations.

A new methodological approach has been developed in the technology of conducting computational experiments, which ensures the research continuity when separating and sequentially solving two groups of problems on a common macromodel and subordinate models with a more detailed reflection of real conditions. Such a two-stage research structure makes it possible to more adequately and reliably determine two groups of patterns of the influence of technological parameters on the indicators of rock pressure anomalies and stress-strain state of fastening, security elements in the latest schemes for resource-saving maintenance of extraction workings in the conditions of highly stressed stope faces.

Six main peculiarities of the substantiation and construction of geomechanical models have been formulated and systematized, with account of which it is possible to ensure a sufficient degree of adequacy and reliability of the results of computational experiments for studying the correlation between the rock pressure anomaly parameters and mining-geological, technological factors of highly-productive mining of coal seams.

It has been proved that the results of calculating the SSS of spatial geomechanical models correspond to the prevailing ideas about the mechanism and nature of the coal-bearing stratum displacement process in the zone of stope operations. The consistency of the results and their objectivity has been determined based on the analysis of the parameters of rock pressure anomalies.

A very significant influence of the average daily velocity V_d of the stope face advance (in the range of changing $V_d = 5 - 15$ m/day) on the dimensions P of the frontal bearing pressure zone has been determined. The link between P and V_d is non-linear with some damping of the growth gradient of the zone dimensions at $V_c = 10$ m/day. The average values of increasing P at $V_d =$ 15 m/day are from 132 percent (to the rise of the seam at $K_y = 1.05 - 1.25$) to 281 percent (in depth of the bottom at $K_y = 1.46 - 1.56$). The revealed patterns should be taken into account when choosing the mode for conducting stope operations and, especially, when substantiating the parameters of the fastening structures and the means of their strengthening (ahead of the stope face) for the extraction drifts.

A reduced influence of V_d on the dimensions P of the lateral bearing pressure zone has been revealed. Moreover, the distribution of "destructive" vertical stress σ_y concentrations practically does not change in the range of 5 m/day V_c 15 m/day. On the other hand, reduced concentrations σ_y that are influenced by V_d cannot significantly affect the rock pressure manifestations in the extraction drift due to their remoteness. This brings to the fore the pattern for limiting the adjacent mass displacement at high velocities of the stope face advance.

A tendency to reduce the influence of the stope face advance velocity on the dimensions of the frontal bearing pressure zone with a more thin-bedded mass texture compared to a thick-bedded texture has been revealed. This is conditioned by the reduced stability of less thick lithotypes, which, during their bending, "react" to a lesser extent to limiting the period of acting bending loads at increased stope face movement velocities. At the same time, in the zone of lateral bearing pressure (in the area of the drift ahead of the stope face, where the maximum frontal bearing pressure acts), the opposite tendency has been determined – an almost universal increase in the degree of V_d influence on the dimensions of the zone under conditions of a more thin-bedded mass texture. In the destressing zone, there is a decrease in the degree of V_d influence, similar to the tendencies in the frontal bearing pressure zone.

The results of research in various mining-geological conditions are experimentally confirmed, as well as recommendations for the implementation of resource-saving fastening and security systems are presented.

Abstract. Mining waste can generate environment pollution including acid mine drainage (AMD). AMD is dangerous for its surroundings and can pollute surface and groundwater it is contacting with. Nanomaterials are advanced materials used in all fields of human activity and development. However, their production is still expensive and may pollute the environment due to the chemicals' used and/or production of the energy needed for their synthesis. A smart solution could be use of mining waste and AMD to produce nanomaterials with properties similar to the properties of nanomaterials obtained from clean chemicals. Thus both waste will be valorised / decontaminated and useful and needed materials produced. This paper presents production of nanoparticles and nanomaterials from mining waste and AMD with emphasis on iron- and copper-based materials, as well as some applications of the obtained materials.

1. Introduction

Mining and minerals beneficiation are fundamental activities that provide raw materials for the production of goods and services necessary for the daily life of every person, as well as for the sustainable development of all humanity.

However, large amounts of solid rocky waste and tailings are generated that, apart from their unaesthetic appearance, can be a source of dangerous environmental pollutants resulting from the leaching of usually present toxic metals, metalloids and/or non-metals under the influence of precipitation [1, 2]. This type of waste has been accumulated for hundreds and thousands years and some authors estimate that its yearly production rate is 350x109 t [3] while other give the value of 100x109 t waste from primary production of mineral and metal commodities [4]. Although the mining waste disposal decreases in some well-developed countries, due to their ability to treat, recycle or use for energy recovery part of this waste this is not the case with all countries worldwide.

Scientific and engineering community has already been working on the technologies for mining waste management [4,5] and for extraction of valuable metals from mining and mineral processing waste [6–10].

Mining activities and mine waste can be a source of mine drainages that can be four types (neutral, acid, basic and saline) in dependence of the ores composition and local hydro-geological and physicochemical conditions. Among the mentioned types, acid mine drainage (AMD) represents the major concern. Generally, its formation can be presented by the following chemical equations [11, 12]:

$$2FeS_{2(s)} + 7O_{2(g)} + 2H_2O \rightarrow 2Fe^{2+}_{(aq)} + 4SO^{2-}_{4(aq)} + 4H^{+}_{(aq)},$$
$$4Fe^{2+}_{(aq)} + O_{2(g)} + 4H^{+}_{(aq)} \rightarrow 4Fe^{3+}_{(aq)} + 2H_2O,$$
$$FeS_{2(s)} + 14Fe^{3+}_{(aq)} + 8H_2O \rightarrow 15Fe^{2+} + 2SO^{2-}_{4(aq)} + 16H^{+},$$
$$Fe^{3+}_{(aq)} + 3H_2O \rightarrow Fe(OH)_{3(s)} + 3H^{+}.$$

The pyrite (FeS_2) oxidation can be facilitated by the presence of sulphur-oxidizing bacteria. The acidic nature of the AMD leads to the leaching of the ores that it is contacting with and thus different metals, such as aluminium (Al), cadmium (Cd), chromium (Cr), cobalt (Co), copper (Cu), manganese (Mn), nickel (Ni), lead (Pb), zinc (Zn), etc. and metalloids (for example, arsenic – As) appeared in the AMD, besides iron (Fe). AMD is dangerous for the surrounding environment or when it mixes with surface or groundwater bodies. The composition and characteristics of AMD depends on the local geological, hydro-geological and climate conditions, availability of pyrite ores and the rate of their oxidation. Without any claims for comprehensiveness, table 1 gives an idea about the ranges of some AMD parameters.

Table 1. Concentration ranges of some metals and As in AMD from different mines worldwide.

Parameter, Pollutants concentration range, mg L^{-1}	Coal mines [11–15]	Sulfide ores mines* [12, 13, 16, 17]	Copper mines [12, 18, 19]	Pyrite mines [12, 13, 17]

* Cu-Zn, Pb-Zn, Cu-Pb-Zn, and polymetallic ores; n.i. – no information

It is difficult to prevent formation of AMD because it is a natural oxidation process accelerated by the increase in pyrite-bearing minerals surface area that is exposed to water and oxygen during mining operations [14]. The already formed AMD is treated in active and/or passive systems. Constructed wetlands, limestone drains, permeable reactive barriers, and use of natural sulphate reduction processes are the main passive treatment methods. They could be more cost effective and environmentally friendly, compared to active methods, but are slow and depend on the site conditions [12]. Most often the active treatment is based on addition of neutralizing and alkalizing reagents, mainly lime, limestone, magnesite, etc. [11, 20]. However, alkalization precipitation of metals-pollutants results in big amount of sludge. In addition, the metals in the sludge could be relatively easily mobilized by contacting with acidic or even fresh water. Thus, this type of treatment needs corresponding handling and storage. Adsorption is considered as a cost-effective and efficient method in treating AMD. Different adsorbents are used, among them natural mineral materials such as clays and zeolites. Their low mechanical strength and poor ion selectivity can be pointed as drawbacks. Membrane technologies such as nanofiltration and reverse osmosis possess high separation efficiency, automatic operation and produce good water quality. However they are still relatively expensive and need a preliminary treatment of the water in order to reduce membrane system pollution and unstable work [12].

Recovery of the valuable metals from AMD and solid mining waste is needed in order to achieve sustainable use of resources jointly with sustainable remediation and the environment protection.

Nanomaterials are materials that have at least one dimension at nanoscale. Due to their size, nanomaterials have a number of different properties compared to bulk materials of the same chemical composition [14]. They are used in different areas such as electronics, power generation and storage, mechanical industries, water treatment, pharmaceutical and medical activities and products, etc. [21, 22]. Recently magnetic zeolite nanocomposites have been studied as reusable green adsorbents for removal of different pollutants from wastewater [23, 24].

Two approaches are applied to synthesize nanoparticles (NPs). The "top-down" approach is based on a physical miniaturization of materials to the nanometer scale by applying high-energy inputs. Mechanical milling, laser ablation, ion sputtering, etc. are included in this approach. The "bottom-up" approach is based mainly on chemical reaction of precursors and precipitation of the obtained NPs or evaporation followed by deposition. Both techniques for NPs production are expensive and can pollute the environment by using chemicals and/or due to the production of the energy needed. The basis of the NPs biosynthesis is the use of biochemical redox reactions where the ion is transformed to its solid phase by using as chemicals extracts of different microbes and plants. This approach is considered environmentally-friendly, cost effective and scalable [21, 25] but usually the NPs yield is low.

This paper aim is to present recovery of the valuable metals from mining waste and AMD under the form of useful nanoparticles and nanocomposites and some applications of the produced materials, which is a relatively new scientific field being developed in recent years.

2. Nanoparticles from mining waste

Mining waste contains diverse valuable metals and various technologies have been and are being developed and applied to extract metals. Recent 10-15 years with the burst of nanoscience and nanotechnologies the number of studies on NPs production from mining waste is also increasing. Mainly iron (Fe) mining waste has attracted the scientists' attention probably due to the two reasons: a) diverse unique properties of iron-based nanoparticles and especially of the magnetite nanoparticles (MNPs) and b) due to the mineral beneficiation technology usually this waste is rich in Fe that could be used as a cheap precursor for preparing MNPs.

2.1. Iron-based nanoparticles

Iron based materials and especially magnetite (Fe_3O_4) nanoparticles have found wide application. Back in 2004 Hu and co-workers [26] prepared MNPs ($\sim$ 10 nm) by sol-gel method and studied their ability to remove Cr(VI) from wastewater by adsorption. Adsorption on MNPs is regarded as an effective and economically vital method for removing different pollutants (such as metal ions, dyes) from water [20]. Besides their use as adsorbents MNPs are used as catalysts, paint pigments, additives to ceramics, in electronic materials fabrication, ferrofluid technology, controlled drug delivery, etc. [20, 27].

MNPs are able to remove most divalent and some trivalent metal ions (forming stable precipitates) from water (including AMD) at easy application and recovery by magnetic filtration. In addition, most of them do not change their magnetic properties when used as adsorbents and thus they can be reused [20]. MNPs are synthesized by different methods, such as thermal decomposition, milling, chemical precipitation, sonochemical synthesis. Chemical precipitation is the most widely used approach because the produced MNPs are with controlled size and morphology. Co-precipitation of Fe^{3+} and Fe^{2+} (from aqueous solutions, at a ratio of 2:1) is usually applied to prepare the MNPs.

It is carried out under anaerobic alkaline (pH 9–12) conditions [27]. The cost of iron precursor salts used is the main component contributing to the price of nanoparticles. For this reason, as a source of Fe ions, mining wastes from iron ore mining and processing are of interest for the production of MNPs. In addition, in recent years an increasing attention is paid to the synthesis of iron-based materials, especially aimed to be used in energy storage applications.

2.1.1. Materials based on iron oxides. Wu et al [28] synthesized magnetic Fe_3O_4 nano-powder by applying ultrasonic chemical co-precipitation in presence or absence of a surfactant sodium dodecyl sulfate ($C_{12}H_{25}OSO_3Na$). They used high purity Fe that was separated from iron ore tailings by acidic leaching (with 37.5 wt. % hydrochloric acid – HCl). Further, hydrogen peroxide (H_2O_2) was added to the filtrate (i.e. to the pregnant leach solution – PLS) in order to ensure that all iron exists as Fe^{3+}. The solution was heated to 60°C and concentrated ammonia solution (NH_4OH) was added to achieve pH 3.2. Thus iron was separated from tailings and precipitated as $Fe(OH)_3$. The precipitate formed was washed and re-dissolved in HCl. Measured amount of $FeSO_4 \cdot 7H_2O$ was added in order to ensure Fe^{3+} and Fe^{2+} molar ratio of 1.5:1. Then sodium hydroxide (NaOH) solution was added under ultrasonic agitation to form black precipitate of Fe_3O_4 by the reaction

$$Fe^{2+} + 2Fe^{3+} + 8OH^- \rightarrow Fe_3O_4 + 4H_2O.$$

The produced MNPs (with an average diameter of 15 nm) possessed high crystallinity and super-paramagnetism (74.86 emu g^{-1} saturation magnetization). Fe_3O_4 NPs coated with $C_{12}H_{25}OSO_3Na$ were with uniform size and exhibited better dispersion, compared to uncoated.

Giri and co-authors synthesized MNPs using ferric iron ions obtained by treatment of tailing of iron ore industries [29]. The material containing ≈39.01% Fe was digested in HCl solution to produce $FeCl_3$ solution. Concentrated NH_4OH solution was added to produce $Fe(OH)_3$ that was washed, dried and dissolved in 50% HCl solution together with $FeCl_2 \cdot 4H_2O$ at $Fe^{3+} : Fe^{2+}$ molar ratio of 2:1. Then NaOH solution was added to reach pH 11, under continuous stirring, nitrogen (N_2) atmosphere and 70°C. Further, temperature was risen to 90°C, sodium dodecyl sulphonate was added to stabilize the formed MNPs. After cooling to ambient temperature, the produced MNPs were magnetically separated, washed with acetone and distilled water and sonicated. The dispersed MNPs (from 8.3 to 23.0 nm) were used in adsorption studies. They were found effective in removing anionic (Congo red) and cationic (methylene blue) dyes from their aqueous solutions with adsorption capacities of 70.4 and 172.4 mg g^{-1} for methylene blue and Congo red, correspondingly.

Kumar et al prepared MNPs using as a Fe source the waste from the iron ore processing plant [30]. The waste material contained 26.8% Fe_2O_3, 72.4% SiO_2 and 0.7% Al_2O_3. Metallic iron was added at the ratio of Fe to Fe_2O_3 content of tailings = 1:4 and the mixture was subjected to ball milling followed by leaching with HCl solution. Thus, chloride solution was produced that contained iron (III) and iron (II) at ratio of 2:1 M. Urea was added to the solution and its hydrolysis at 95°C released ammonia (NH_3) that alkalized the medium and black MNPs were formed in the suspension. After the suspension was cooled to room temperature, the NPs were removed by magnetic separation, washed and dried in a vacuum desiccator (at room temperature). The produced MNPs were coated with silver (Ag) nanoparticles by wet impregnation with aqueous silver acetate followed by washing and drying. The antibacterial activity of the prepared Ag–Fe_3O_4 nano-composite was studied against *Escherichia coli*. Silver coated MNPs possessed antibacterial activity. Silver NPs anchored to the Fe_3O_4 can be easily separated from the water by a suitable magnet in order to be reused. Thus, waste can be converted into useful resource and the produced product can be applied in water treatment.

Suh et al started from a low-grade iron ore and prepared MNPs (with a purity of 99.8%) and a Mg-rich solution that were used as a nano-adsorbent and a coagulant for water treatment, correspondingly [31]. Aqueous HCl solution was used to leach the ore. After solid/liquid separation, 30% H_2O_2 was added to convert all iron available in the solution to Fe^{3+} ions. Impurities that passed to the PLS were removed by solvent extraction with tri-n-butyl phosphate as an extractant. Therefore, the amounts of Mg and Si that are able to inhibit the formation of MNPs, were reduced from 15.5 wt.% and 10.3 wt.% to less than 1.4 mg L^{-1} and 28.1 mg L^{-1}, respectively. As a result, the Fe content increased from 68.6 wt. % to 99.8 wt. %. This high-purity Fe^{3+} solution was used to synthesize 5-15 nm MNPs. The high-purity Fe^{3+} solution was mixed with ferrous solution (obtained by reducing one-third of the high-purity Fe^{3+} solution with sodium borohydride – $NaBH_4$ aqueous solution) in the ratio of 2:1 and the obtained mixture was added to NaOH solution. The following reactions took place at 40°C to produce MNPs:

$$\begin{gathered}
Fe^{2+} + 2OH^- \to Fe(OH)_2, \\
Fe^{3+} + 3OH^- \to Fe(OH)_3, \\
Fe(OH)_3 \to \alpha - FeOOH + H_2O, \\
Fe(OH)_2 + 2\alpha - FeOOH \to Fe_3O_4 + 2H_2O.
\end{gathered}$$

The synthesized NPs were washed with distilled water and separated by using a magnet. Thus, MNPs adsorbent can be produced in large quantities at low cost and at the same time the cost of iron-ore-wastewater treatment could be decreased.

Ren and co-authors [32] used ferrous sulphate heptahydrate ($FeSO_4 \cdot 7H_2O$, 92.45%) that is an industrial by-product from titanium dioxide production by sulphuric acid (H_2SO_4) method and pyrite (FeS_2, 75.62%) that is a by-product of mineral processing plants. Ferrous sulphate was reduced with pyrite under N_2 protection to produce porous MNPs (with particle size of 25–50 nm).

Iron ore tailings (containing 43.47% Fe, 7.99% Si, 9.07% Ca, 3.8% Mg, and 2.4% Al) were ball milled and leached in mixture of 5 M H_2SO_4 and 2 M NaCl at 85°C [33]. The use of H_2SO_4/NaCl hybrid lixiviant resulted in decreased Ca^{2+} ions impurity in PLS because of precipitation of gypsum. Then Fe^{3+} ions in the produced PLS were reduced by adding sodium thiosulfate pentahydrate ($Na_2S_2O_3 \cdot 5H_2O$), under N_2 atmosphere, in such stoichiometric amount to obtain and maintain the $Fe^{3+}/Fe^{2+} = 2$. Further NH_4OH was added to reach pH=9.5, under N_2 atmosphere at room temperature. Greenish black precipitate was formed that was heated at 85°C and then the magnetic precipitate was gathered with a magnet, washed with distilled water and ethanol, and dried at 44°C. The XRD and ICP-OES analyses showed that the produced magnetite nanoparticles (with an average diameter of 19±3 nm) were pure (impurities $< 3\%$). The VSM analysis showed that the powder behaved as ferromagnetic at room temperature with a saturation magnetization of 63.27 emu g^{-1}. The proposed reduction-precipitation method is suitable and economic for producing MNPs when low amount of iron ions present in the tailings ($< 25\%$).

Microorganisms have also been studied for their ability to produce iron oxide NPs from mining waste. The bacterium *Rhodococcuserythropolis* ATCC 4277 was used in stirred tank reactor to extract residual iron from rhomboclase (found in coal tailings) and to transform it into magnetic nanoparticles [34]. The prepared NPs were composed of β-Fe_2O_3 and α-Fe_2O_3. The proposed process is environment-friendly and sustainable.

2.1.2. Other iron-based materials. Two organic-inorganic hybrid materials with magnetic properties were synthesized, using as precursors the iron ions obtained from Fe ore mining tailings [35]. The first precursor material consisted mainly of ferric sulphate. It was from iron mine tailings of a company. The second precursor resulted from the acid extraction of iron mine sludge gathered from the Doce River watercourse near the Fundão dam in Mariana, after its rupture in 2015. The hybrid materials were produced in the following way: $CoCl_2 \cdot 6H_2O$ and waste iron salts were dissolved in natural organic material (NOM)-rich water. Then the solution was alkalized to pH 9 with 1 M NaOH solution, the precipitate formed was washed and dried. SEM and TEM images pointed at the formation of nanostructures, while XRD analyses disclosed formation of the cobalt ferrite phase ($CoFe_2O_4$). The hybrids obtained (NOM-$CoFe_2O_4$) exhibited conversion rate of 99% of nitrophenol in short times (1-2 min). They also showed high performance in the adsorption of PAHs, achieving removals in the range of 75–80%.

Other study has presented synthesis of manganese ferrite ($MnFe_2O_4$) from a low-grade mining waste bearing both iron and manganese [36]. Initially the material was heated at 700°C and then leached in H_2SO_4 medium. Further, the leachate was purified and its composition adjusted to reach the Fe : Mn molar ratio of 2:1. The $MnFe_2O_4$ synthesis was achieved through co-precipitation from the solution at temperature of 90°C. The obtained nano-sized particles (45 nm) possessed a saturation magnetization of 51.03 emu g^{-1} and are candidates for energy storage devices.

Yao et al synthesized interconnected α-Fe_2O_3 nanoparticles using tin ore tailings as Fe source [37]. The ore tailings (containing 20.9% Fe) were leached in 1.5 mol L^{-1} H_2SO_4 at 70°C, the liquid-solid ratio of 4:1 (mL:g) for 90 min. Further, sodium carbonate (Na_2CO_3), NaOH, and NH_4OH solutions were added to the equal volumes of the PLS to precipitate iron hydroxide. The precipitate was washed and calcinated at 800 ^oC to obtain α-Fe_2O_3 nanoparticles. The α-Fe_2O_3 nanostructures synthesized by using $NaCO_3$ as precipitating reagent showed the best lithium storage performance with a reversible discharge capacity of 1146 mAh g^{-1} at 0.5 A g^{-1} after 300 cycles and stable discharge capacity of 377 mAh g^{-1} at a high current density of 4 A g^{-1}. The obtained results point at the possibility to use the ore tailings to produce high-value products.

Natural pyrite NPs were prepared by grinding pyrite taken from real mine waste to micro particles (< 50 μm), washing them with 0.5 M HNO_3 and additional grinding in ceramic mortar followed by ball milling in a planetary ball mill.

Thus produced NPs were rinsed with a mixture of ethanol and deionized water (50/50) and dried at 105°C [38]. The obtained NPs were studied for their ability to function as a catalyst for the activation of peroxymonosulfate (PMS) and peroxydisulfate (PDS) to oxidize tetracycline (TTC). A degradation of 98.3% and mineralization up to 46% of TTC were achieved using the produced pyrite catalyst. In addition, biochemical and histopathological assays pointed that nephrotoxicity and hepatotoxicity effect of TTC were decreased by 90% and 85% respectively. The pyrite NPs catalyst was used in four consecutive cycles with no significant decrease in process efficiency (<3% decrease in TTC removal). Furthermore, it was found that the pyrite presence in the water had not any significant toxic effects. The generalized route used for the preparation of MNP from mining waste is presented in figure 1.

2.2. Nanoparticles based on other metals

Mining waste material contains other valuable elements besides iron and have to be considered for their utilization in the NPs preparation. However, until our days no many efforts appeared in this direction.

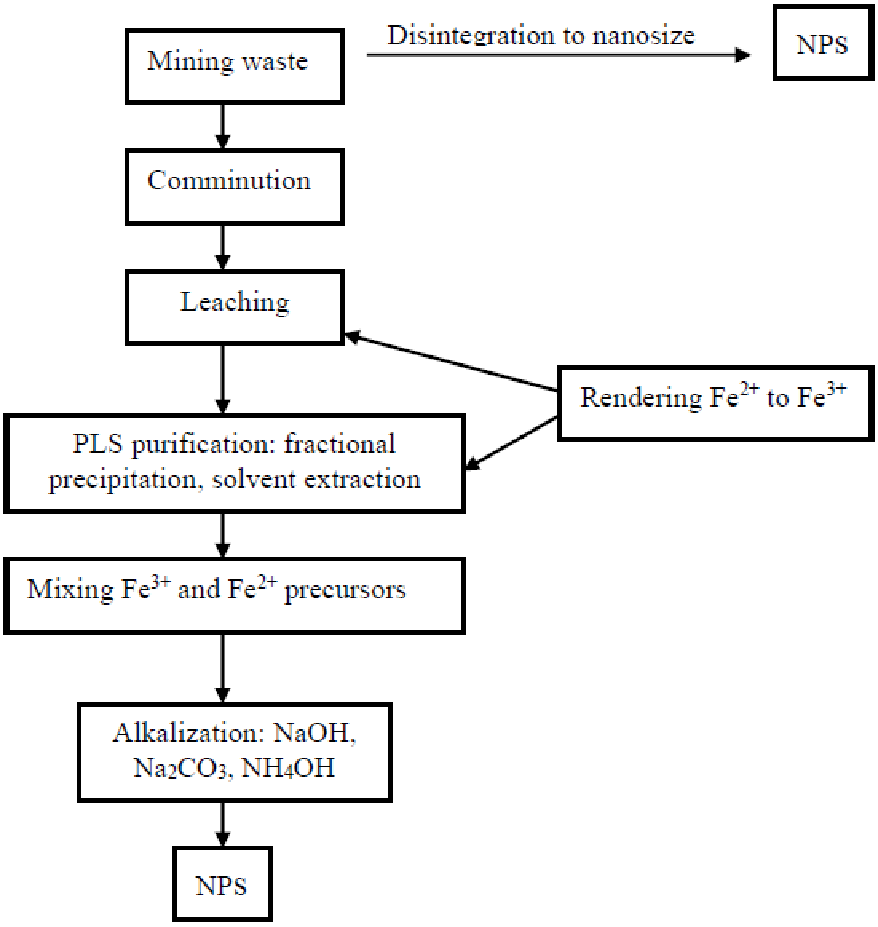

Figure 1. Generalized route for preparation of magnetic nanoparticles from mining waste.

Wong-Pinto et al utilized a real effluent produced by the leaching of sulfide ore tailings as a copper source to synthesize copper nanoparticles (CuNPs) using the non-pathogenic bacteria *Pseudomonasstutzeri* DSM 5190 as a bio-reducing agent [21]. In order to extract the Cu from the chalcopyrite-bearing tailings, they were treated with H_2SO_4 solution (120 g L^{-1}) in presence of sodium nitrate (1 g L^{-1}) that acted as an oxidizing reagent able to enhance Cu dissolution. A copper recovery of 50% was achieved in 8 h. Further, the PLS was purified by solvent extraction (using Acorga PT5050 diluted with Escaid 110) and then Cu was stripped with H_2SO_4 solution (120 g L^{-1}). The obtained solution was used as a precursor for CuNPs synthesis after raising its pH to 4 by addition of NaOH solution. Then, pellets of cultured *Pseudomonasstutzeri* DSM 5190 were added to the Cu-bearing solution. Some of the produced CuNPs (1–2 nm) were attached to the pellets of the biomass, other were left in the solution which after drying produced Na_2SO_4 – CuNPs mixture. The obtained products are intermediate. Different techniques have been proposed to separate CuNPs from the biomass (such as washing-vacuum filtration, density gradient centrifugation, sonication), which are relatively cheap and clean methods.

Recently a study appeared on the synthesis of selenium NPs (SeNPs) using mining waste that contained 6.11% Se, 4.97% Sb, 4.69% Pb, 4.12% Ag, 3.61% Cu and 70.01% barium sulphate ($BaSO_4$) [39]. In order to prepare pure solution for SeNPs synthesis the following stages were taken: (a) gravity separation to remove $BaSO_4$, (b) Leaching of the obtained concentrate by 3M nitric acid (HNO_3), (c) Chloride solution addition to precipitate Ag and Pb as insoluble salts, and (d) removal of other impurities such as tellurium, strontium and arsenic by different reagents addition, followed by solid/liquid separation. The purified solution was utilized as a precursor for the green synthesis of SeNPs using different fruit extracts with the orange extract being found to be the most efficient reducing and stabilizing reagent leading to the formation of stable SeNPs with particle size between 70 and 80 nm.

3. Nanoparticles from acid mine drainage

Recently various efforts have been done to handle AMD with the aim not only to decrease the content of hazardous elements that present in it but also to produce valuable minerals and metals by the AMD treatment. In this line, efforts to produce NPs have their place. Studies on the synthesis of iron based materials are prevailing but also other metals and minerals are aimed at.

3.1. Iron based materials

Efforts to use AMD to synthesize MNPs started also 15-17 years ago. One of the pioneering works was that of Wei and Viadero [27]. They recovered ferric iron from AMD pumped out from abandoned underground coal mines. Hydrogen peroxide was added to the raw AMD to oxidize the eventually available Fe^{2+} to Fe^{3+}. Then the AMD pH value was raised from the natural 2.6 to 3.5–4.0 by addition of 4 M NaOH solution. At this iron was precipitated as ferric hydroxide/oxyhydroxide. At pH 3.5 other metals remained in the solution. The precipitate was separated from AMD by centrifugation. The ferric precipitate was resolubilized and used as a ferric iron source. Reagent-grade $FeSO_4 \cdot 7H_2O$ was the ferrous iron source. Solution containing $Fe^{3+} : Fe^{2+} = 2 : 1$ was prepared under a $N_{2(g)}$ atmosphere to prevent oxidation and mixed for a certain time to remove the dissolved oxygen. Further, pH was risen to 9.5 by addition of 6.4 M NH_4OH solution. NPs were allowed to grow for 30 min, under N_2 atmosphere. The black precipitate (magnetite NPs with size of 10-15 nm) was separated from solution with the aid of an external magnetic field and washed. The prepared MNPs were of the same quality as the MNPs prepared using chemicals (pure iron salts) under the similar conditions.

Cheng et al studied microbial fuel cells that can be used to treat AMD and generate electricity [40]. The dissolved oxygen reacts with Fe^{2+} in AMD and iron oxide precipitates are produced that at frying are transformed to goethite (α-FeOOH) NPs with size in the range from 120 to 700 nm. The size of the produced NPs could be controlled by changing the conditions in the fuel cell – initial Fe^{2+} concentration (50–1000 mg L^{-1}), pH (4–7.5) and the cell current density (0.04–0.12 mA cm^{-2}).

Kefeni et al initially optimized the conditions for synthesis of MNPs from analytical grade chemicals at low pH and temperature and then applied the optimized conditions to treat real AMD with the aim to produce valuable commercial NPs [20]. They have proved that it is possible to synthesize Fe_3O_4 and $CoFe_2O_4$ from their corresponding binary salts. However, the direct application of the same conditions to both simulated and real AMD did not result in the MNPs formation. The reason was the presence of many other cations that can hinder that process. Beside iron oxides, Mn_3O_4, MnO_2 and ZnO were formed from real AMD. It is found that in order to produce MNPs from AMD higher pH and heat are needed in comparison with the model binary solutions. The study showed that $NH_4OH_{(aq)}$ was better alkalizing reagent than NaOH solution. It is proved that if the AMD is treated with MNPs the formation of ferrites is accelerated which resulted in an increased magnetic moment of ferrite sludge produced.

A study was conducted with the aim to recover Fe^{2+} and Fe^{3+} from Fe^{2+} rich acidic mine water that resulted from coal mining and washing processes, and to use the recovered Fe^{2+} and Fe^{3+} sludge as precursor for magnetite synthesis [11]. Only real AMD and soda ash were used. A sequential and fractional precipitation procedure was used to recover different Fe-species. In order to precipitate Fe^{3+} the pH value of the AMD was raised by Na_2CO_3 addition to pH$\geq$4.5 and to obtain Fe^{2+} the pH was increased to pH$\geq$8.3. Afterwards, the two recovered and collected sludges were used to synthesize magnetite. The reaction can be described as it follows:

$$Fe^{2+}_{(aq)} + 2Fe^{3+}_{(aq)} + 8OH^{-}_{(aq)} \rightarrow Fe_3O_4 + 4H_2O.$$

The formed magnetite (with a purity of 28%) was separated by centrifuging. The optimum conditions for the recovery of MNPs were mol ratio of Fe^{3+} / Fe^{2+}=2:1, pH≥10 and temperature ranging from 25 to 100°C.

Moreira et al prepared acicular goethite nanoparticles from AMD and studied their ability to adsorb arsenate, phosphate and humic acids [41]. The AMD was collected from a coal mine. It was treated using the following steps (the procedure is similar to that used at industrial scale to treat AMD): a) pre-neutralization by lime ($Ca(OH)_2$) addition to pH 2.7 to precipitate selectively aluminium hydroxides and $CaSO_4$, b) addition of NaOH to pH 3.2 to precipitate acicular goethite nanoparticles (AGNs). The AGNs were washed, filtered, dried at 90^{o}C for 5 h and stored. The obtained AGNs were similar in composition to the product derived at industrial scale at treatment of that AMD. The size of the AGNs was 23 nm, the material specific surface area was 102 m^2 g^{-1}. The AGNs adsorbed humic acid (37.30 mg C g^{-1}), arsenate (19.91 mg As(V) g^{-1}) and (12.98 mg PO_4^{3-} g^{-1}).

Further, a study has been carried out with the aim to explore the use of AMD as a source of Fe^{3+} ions as a precursor for synthesis of iron NPs and use of the produced NPs to remove pollutants from the same AMD [14]. A coal mine AMD (containing 4219.14 mg L^{-1} iron and 21,317.79 mg L^{-1} sulphate as the predominant anion) was used as feedstock. Initially the ferrous ion that present in the mine water was converted to ferric ion by addition of hydrogen peroxide solution:

$$2Fe^{2+} + H_2O_{2(aq)} + 2H^{+}_{(aq)} \rightarrow 2Fe^{3+} + 2H_2O_{(l)}.$$

In order to remove dissolved oxygen from the thus treated AMD, nitrogen gas was bubbled. Iron(III) ions that present in the mine water were reduced at room temperature using 0.5 M $NaBH_4$ solution to produce the iron nanoparticles.

$$4Fe^{3+} + 3BH_4^- + 9H_2O \rightarrow 4FeO + 3H_2BO_3^- + 12H^+ + 6H_2.$$

The synthesized black particles were separated from the mixture by using a strong external magnet, washed and dried. Their size was 31.8 nm and BET surface area was 88±3.16 m^2g^{-1}. For comparison iron NPs were synthesized under the similar conditions from pure chemicals as precursors. Their size and BET surface area were 28.05 nm and 91±3.08 mm^2g^{-1} correspondingly. The morphology of NPs prepared by starting from the different precursors was the same. The NPs synthesized by using AMD have been applied to remove toxic elements that present in the raw AMD. An average removal efficiency of 75% has been achieved due to combination of the different properties of the produced NPs, namely chemical stability, high redox potential and specific surface area as well as the presence of easily accessible adsorption sites. The main reactions leading to the pollutants removal have been identified as adsorption, co-precipitation and reduction.

Another study has used plant extracts to recover iron NPs from AMD [42]. Real wastewater from an industrial iron-ore processing company was used. Extracts of different plants were added to the wastewater at ratio of 1:1 v/v (determined as optimal in preliminary experiments) and temperature and contact time were varied. The precipitates formed were dried and annealed. Their analyses disclosed presence of maghemite-C (Fe_2O_3) and magnetite ($FeFe_2O_4$) nanoparticles. Best results at room temperature have been obtained when *Eucalyptus globulus* extract was used. In addition, the quality of treated mine water was improved and thus it was made reusable for other purposes.

Real AMD from a coal mine was used to synthesize goethite, hematite, and magnetite NPs [43]. Recovery of Fe^{3+} sludge and recovery of Fe^{2+} sludge was achieved by selective precipitation. The pH of the AMD was increased from 2 to 4.5 by addition of 10% Na_2CO_3 solution to obtain Fe^{3+} rich precipitates / sludge. The filtrate from the sludge / water separation was used for ferrous (Fe^{2+}) sludge production by raising the pH from 4.5 to $\geq$ 8.5 via addition of 10% NaOH solution. For goethite synthesis the Fe^{3+} rich slurry was heated at 80°C and then dried at room temperature for 24 h. For hematite synthesis the Fe^{3+} rich slurry was heated at 700°C and then cooled to room temperature. Magnetite nanoparticles were synthesized by mixing the preliminary obtained Fe^{3+} and Fe^{2+} sludge at 2:1 M ratio and adding NaOH solution to reach pH > 9 under oxygen-free environment achieved by N_2 gas bubbling into the reactor. High purity (>99%, =100% for goethite) has been observed for the recovered Fe-species, which indicates that they are suitable for industrial applications.

A recent study has applied hydrazine as reductant in order to produce iron nanoparticles using iron-rich AMD solution as a ferric iron source [44]. In order to prepare NPs 0.9 M hydrazine solution was added to AMD sample (4492.1 mg L^{-1} iron, pH=2.14) from a coal mine under stirring at a temperature of 70°C. A brownish yellow precipitate was formed that was identified by the XRD analysis as goethite. The SEM images of the iron nanoparticles revealed spherical morphology. The HRTEM analysis showed nanoparticles with size 8.66±0.58 nm and the XRF analysis results revealed that the samples were very rich in iron. It is concluded that Fe-rich AMD is a very good substitute material for commercial reagent grade salts for synthesizing iron NPs.

Another recent study proposed preparation of stabilized iron NPs from AMD applying rooibos tea extract as reagent used to reduce Fe^{2+}/Fe^{3+} to zero-valent Fe [45]. Ambient temperature (~25°C), a rooibos tea extract dosage of 5 g L^{-1}, a pH of 6, and 6 h of reaction time are found as optimal conditions. The average particle size was 36 nm, as determined by TEM analysis and the NPs were stabilized by tea polyphenols that partially coated the surface of the nano-iron. When the synthesized iron NPs were used as a Fenton like catalyst for the degradation of textile dye (orange II sodium salt), 94% removal efficiency was achieved in only 30 min.

3.2. Copper based materials

Schaffie and Hosseini proposed a biosynthesis of semiconductor copper sulfide nanoparticles from mine wastewaters with the aid of *Fusarium oxysporum* fungus [18]. Study was conducted with wastewater collected from a copper mine. The wastewater contained 56.75 mg L^{-1} Cu and its pH was 5.2. The bio-reduction of Cu ions occurred at 30°C for 96 h. The analysis of the separated and washed nanoparticles revealed that they possessed a covelite composition and the particle size was in the range of 10–40 nm. For comparative purpose NPs were synthesized also using 10^{-3} M $CuSO_4$ under the same conditions as when AMD was used. Analyses pointed that the properties of the NPs produced from AMD were the same as the properties of the NPs synthesized from the pure $CuSO_4$ solution.

Crane and Sapsford produced Cu nanoparticles from AMD using nanoscale zerovalent iron (nZVI) as a selective reducing reagent [16]. The AMD used was collected from abandoned open pit Cu-Pb-Zn mine. Its pH was 2.67 and the copper concentration – 45.41 mg L^{-1}. The used nZVI was prepared from $FeSO_4 \cdot 7H_2O$ by addition of 4 M NaOH solution. Two types of batch experiments were carried out – with unbuffered (pH 2.67 at t = 0) and pH buffered (pH < 3.1) AMD that was contacted with nZVI (with concentrations in the range of 0.1 – 2.0 g L^{-1}). It is found that addition of nZVI at concentrations $\geq$ 1 g L^{-1} to the unbuffered AMD lead to rapid and nearly total removal of Cu, Al and Cd from the water solution (> 99.9% removal within 1 h) through cementation (for Cu), precipitation and sorption to iron corrosion products (for Al and Cd). Other metals that present in the AMD were not immobilized. When buffered AMD was used Cu was selectively precipitated at addition of nZVI. The maximum removal of Cd and Al were only < 1.5% and < 0.5% correspondingly. Spherical nanoparticles (with diameter of 20–100 nm) were formed, containing up to 68 wt.% Cu, as revealed by HRTEM-EDS analysis.

The study showed that highly selective formation of Cu bearing nanoparticles from real AMD can be achieved by tuning the synthesis conditions.

3.3. Sulphides based materials
Below are presented some examples of metal sulphides NPs synthesis at contacting the AMD with sulphide ions produced by microorganisms.

Vitor et al studied the possibility to treat AMD at simultaneous bio-synthesis of zinc sulphide (ZnS) nanoparticles and ZnS / TiO_2 nanocomposites by using a combined process, developed by the members of this research group [19]. It consists of two consecutive steps – water neutralization in a calcite tailing column, and treatment of the neutralized water in an anaerobic sulphate reducing bioreactor. That process was planned to use locally available wastes and/or natural cheap materials, with the aim to develop as simple as possible, working at normal pressure and ambient temperature environmentally friendly and economically viable treatment of an AMD. The AMD used was collected from the region of an abandoned copper mine. The neutralizing column was filled with a mixture of small pieces of calcite tailing (from a marble stone cutting and polishing industry) and coarse sand, in a 1:2 (w/w) ratio. For the second stage the Upflow anaerobic packed-bed reactor was filled in with coarse sand. It was inoculated with sulphate reducing bacteria (SRB). The effluent from the bioreactor contained biologically generated sulphide. The biosynthesis of ZnS was realized by allowing the effluent from the biotreatment process to flow into a reaction vessel, containing a zinc sulphate solution. Composites were prepared by adding commercial titanium oxide (TiO_2) powder to the zinc solution. Over 90% of the zinc initially available in the AMD was removed as ZnS nanoparticles (with an average size in the range of 29 – 39 nm) or ZnS/TiO_2. Water going out of the system complied with legal irrigation requirements. The results obtained confirmed the possibility of coupling the synthesis of ZnS nanoparticles and nanocomposites with the AMD bioremediation.

Kumar and Pakshirajan studied the ability of biomass with SRB from an anaerobic rotating biological contactor to remove metals – (Cu(II), Cd(II), Ni(II), Fe(II), Pb(II), Mn(II) and Zn(II)) from simulated AMD while simultaneously rendering them in metal- sulphide nanoparticles [15]. The main mechanism of metal sulphide formation was the binding of metals to sulphide produced outside bacterial cell surface as a result of sulphate reduction by the bacteria. Heavy metals recovery by sulphide precipitation was over 70% for Cu and Pb. The recovery was a little bit lower for the other metals. Studies on the particle size distribution of the different NPs revealed that the size of NiS and ZnS nanoparticles was 15–17 nm, the size of CdS and CuS nanoparticles was 12–14 nm, the MnS NPs were 9–11 nm, while the size of FeS and PbS NPs was in the range 8–10 nm.

4. Conclusions and outlook
Studies carried out in recent 10-20 years have proved that:

(i) Mine tailings can be successfully used as iron source for producing different nanoparticles: magnetite, interconnected α-Fe_2O_3, ferrites and their composites, as well as copper and selenium nanoparticles – all with properties and prospective applications similar to the properties and applications of nanoparticles and composites fabricated from clean chemicals.

(ii) AMD can be utilized as an iron source for synthesizing magnetic, zerovalent iron, goethite and hematite nanoparticles, along with being a resource for copper and sulfide (copper, zinc, lead) nanoparticles and their nanocomposites. Besides NPs synthesis, remediation of the AMD is the other achieved positive result. The obtained materials showed ability to remove different pollutants from contaminated water.

The positive feature of the studies carried out is that most of them have used real waste material and AMD.

The following drawbacks could be pointed out: (i) The experiments are conducted at small laboratory scale, (ii) Most often solutions of strong acids are used as leaching reagents for mining waste, and strong alkaline solution (NaOH) is used as pH raising reagent in treating both the AMD and the PLS; (iii) Stabilization of the produced non-magnetic nanoparticles in different composites or on various carries (for example, clay, zeolite) is practically not studied, while it could contribute to easier separation and multiple use of those nanocomposites.

In short – production of nanoparticles and nanocomposites from mining waste and AMD seems promising environmentally friendly and feasible approach to minimize the negative impact of these waste streams and utilize them. However, there is still long way till their real implementation.

Abstract. It is not possible to determine the type of coal in terms of reducibility from thermal decomposition without access to air for volatile maters to dry ash-free mass, which provides establishing the ratio between oxygen content and other essential components of organic mass. The hazards of coal mine operations depend to a large extent on the ratio of the main components, both in organic matter and in mineral impurities. Methods for determining the yield of volatile maters make it impossible to assess the effect of the main components of organic matter and mineral impurities on the hazard characteristics of coal seams. The volatile maters index reflects only the sum of the thermal decomposition gases: hydrogen, methane, carbon monoxide and carbon dioxide without considering the ratio between them. The determination of the hazard properties of a seam in relation to metamorphic transformations factor should include a case-by-case examination of the relationship between the major components of fuel both the organic and mineral, including the moisture content, for each coal seams.

1. Introduction

All current Ukrainian regulations on safe mining [1–8] do not use indicators that directly characterize changes in the elemental composition of coals due to metamorphic processes. For this reason, the influence of coal elemental composition on hazard expression remains largely unknown [9, 10]. Changes in the elemental composition of organic (combustion) mass during geological processes are established for most coal seams in Donetsk and Lviv-Volyn basins when determining the consumer properties of coal [11, 12]. The organic (combustible) mass, which characterizes consumer qualities, undergoes preliminary preparation, which consists in enriching coal and removing external moisture from it.

All types of solid fuels contain, in addition to the organic (combustion) mass, a mixture of mineral substances. When the fuel is burned, its organic mass is removed as CO_2 and H_2O, and the mineral components undergo a series of transformations to form ash. Ash is an inorganic residue from the complete combustion of coal [13]. The purpose of enrichment is to reduce the yield of ash. Coal is typically enriched with more than 10 % ash.

External moisture is a part of the total moisture of the fuel that is removed when it is dried to an air-dry state. The "total moisture" term is determined as the total external moisture content and the total moisture content of the air-dry fuel. The term is used to describe the humidity of coal as a whole (humidity content of coal). When drying coal in the air, free moisture from the outer surface of the pieces and capillary moisture from open cracks and pores (external moisture) shall be removed. Capillary moisture of closed pores, adsorption and hydrate moisture remain in the dry coal. When drying crushed coal at 105°C, the capillary moisture and adsorption moisture is removed from the pores opened by grinding [13]. In order to properly evaluate the results of the coal analysis in order to establish its consumption characteristics, it is necessary to know the humidity of the sample in which the indicators are measured. To this end, the concept of "analytical sample moisture" has been introduced, i.e. a moisture content in a sample of less than 212 µm (0.2 mm).

From the analysis reviewed, it is clear that the indicators in the handbooks [11, 12] are not directly relevant to the hazard characteristics of coal seams in underground mining, given the methods used to define them. They characterize only one part of the dry ash-free organic (combustible) component of coal. The proportion of mineral impurities, taking into accounts the ash yield, may exceed 40% [11, 12] in some cases, which can certainly affect the hazards of coal seams.

2. Research procedure

The elemental composition of the organic (combustible) mass is determined without considering the moisture content on which the physico-mechanical and physico-chemical properties of coal mine miners largely depend. One of the main elements that can influence the hazard behaviour of miners is oxygen. It is present in both organic and mineral mass of fuels and is largely responsible for coal restorability.

The methodology is based on the fact that the consumer qualities of solid fuels are determined on the basis of analytical samples brought to an air-dry state (analytical state). The results, which are expressed in other fuel conditions are calculative. Recalculation is made on the basis of ash content, humidity and mineral mass [13].

In the present case, the formulae for conversion are(%):

- from a dry, ash-free state:

$$O^r = O_c \cdot \frac{100 - (W_t^r + A^r)}{100}, H^r = H_c \cdot \frac{100 - (W_t^r + A^r)}{100}; \tag{1}$$

- organic mass:

$$O^r = O_c \cdot \frac{100 - (W_t^r + MM^r)}{100}, H^r = H_c \cdot \frac{100 - (W_t^r + MM^r)}{100} \tag{2}$$

where O_c, H_c – oxygen and hydrogen content in the combusted mass, %; O_r, H_r – oxygen and hydrogen content for the operating condition of the fuel, %; W_t^r – total moisture for the operating condition of the fuel, %; A^r – ash content of the sample, %; MM^r – mineral mass for the working condition, %.

The total moisture for the working condition of the fuel for each coal seam is given in the references [11, 12]. There is also information on the ash content of the seam (A_s^r) and enriched (A_e^r) samples.

The calculation of oxygen content to the operating state of the fuel O^r according to equation (2) is difficult due to the lack of a reliable method for determining mineral impurities in coals [6].

For all coal seams listed in the guide [11], using data on the ash content of enriched (A_e^r) and seam (A_s^r) samples and the total moisture content (W_t^r), the oxygen content was calculated according to equation (1) for enriched (O_e^c) and seam (O_s^c) samples respectively. Similar calculations have been made for coal seams in the guide [12], but only for the sum of oxygen and nitrogen for enriched ($\sum O_e^c, N_e^c$) and formation ($\sum O_s^c, N_s^c$) samples respectively.

The influence of coal enrichment and analytical sampling on changes in oxygen content on the operating state of the fuel was determined by comparing the graphs for enriched (figure 1) and formation (figure 2) samples, respectively.

The enrichment process contributes to the removal of some mineral impurities, which improves the quality of coal consumption properties. The ideal hypothetical enrichment option is to remove almost all (100 %) mineral impurities. The bisectrics (2) of the coordinate grid (figure 1) correspond ($O_e^r = O_c$) to this case. The mutual location of the bisectress (2) and the average line (1), as well as the regression coefficient (0.93) and the free term (0.04) of equation (1) indicate that the mineral impurities residue after enrichment causes a relative decrease of oxygen content on average from 3 to 7.0 %. This relative decrease increases with the oxygen content of the combustible mass. At absolute value $O_e^r = 1.0$ %, the average relative oxygen value drops by 3 % and at $O_e^r = 15.0$ % – by 6.7 %. With an absolute oxygen content of [11] in the combusted mass of 0.3 to 14.6 % in most cases, the maximum absolute reduction for individual coal seams is in limits beetwin 0.02÷0.98 %. These figures are derived from the position of the bisectress (2), the average line (1) and the standard deviations of the individual data ($\sigma = 0.27\%$) from the average line under the “three sigma” rule (figure 1). This accuracy in the determination of oxygen content is quite satisfactory when the organic (combusted) mass element composition is determined to a dry, ash-free state in order to clarify the consumer properties of coals.

An entirely different error is obtained when the oxygen content is recalculated to conditions close to the mining (working r) conditions under which the hazard properties of coal seams occur. For this case, the trendline (1) is also characterized by a high correlation coefficient (0.98), but it is much further away from the bisectress (2) of the coordinate grid (figure 2). This follows from the values of the regression coefficient of equation 1 (0.81) and the absence of a free term.

The influence of the natural content of mineral impurities and total moisture on the relative

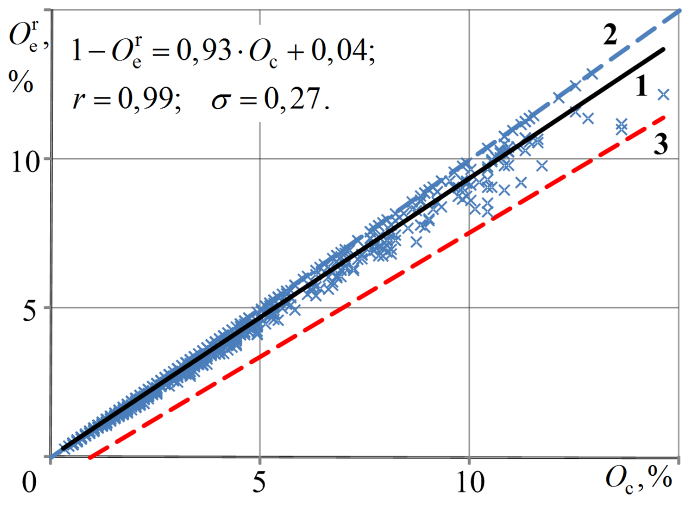

Figure 1. Oxygen Recalculation Results in combusted mass for working conditions of the fuel for enriched O_e^r samples of coal: 1 – the average trend lines; 2 – the bisectors of coordinate grids; 3 – a straight line defining the possible limit of maximum deviations of individual values from the trendlines (1) according to the “three sigma” rule; r, σ – correlation coefficients and standard deviations, respectively; × – experimental data [11] on the combustible mass of oxygen (O_c) converted to working condition according to [13].

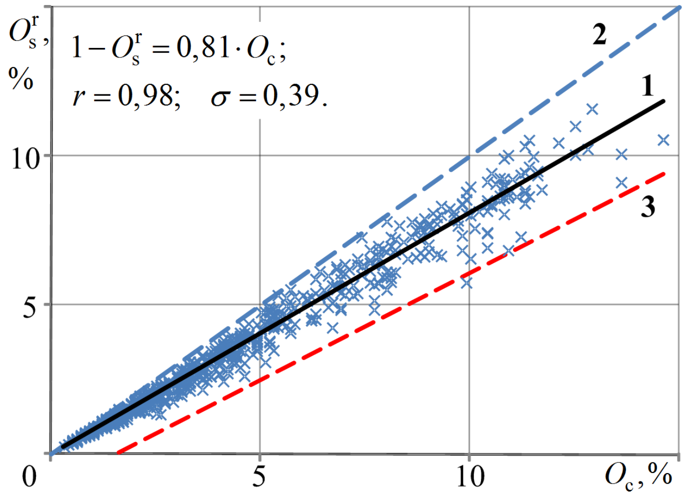

Figure 2. Oxygen Recalculation Results in combusted mass for working conditions of the fuel for seam O_s^r samples of coal: 1 – the average trend lines; 2 – the bisectors of coordinate grids; 3 – a straight line defining the possible limit of maximum deviations of individual values from the trendlines (1) according to the "three sigma" rule; r, σ – correlation coefficients and standard deviations, respectively; $\times$ – experimental data [11] on the combustible mass of oxygen (O_c) converted to working condition according to [13].

average decrease in oxygen content when converted to the working condition of coal is estimated on average to be 19.0 %. For the considered sample of coal seams (734), the absolute oxygen content of the combusted mass was in the range of 0.3 ÷ 14.6 %. The reduction in its content, when measured by the working condition, taking into account the actual discharge of ash and total moisture in the coals of each mine, is in absolute terms within the range of 0.00÷10.66 %. This follows from the resulting dependency (1) and related graphs (figure 2).

The ideal hypothetical enrichment option is to remove almost all (100 %) mineral impurities. The bisectrics (2) of the coordinate grid (figure 3) correspond ($H_e^r = H_c$) to this case. The mutual location of the bisectress (2) and the average line (1), as well as the regression coefficient (0.85) and the free term (0.09) of equation (1) indicate that the mineral impurities residue after enrichment causes a relative decrease of hydrogen content on average from 6 to 13.5 %. This relative decrease increases with the hydrogen content of the combustible mass.

At absolute value $H_e^r = 1.0$ %, the average relative hydrogen value drops by 6 % and at $H_e^r = 6.0$ % – by 13.5 %. With an absolute hydrogen content of in the combusted mass of 1.2 to 5.9 % in most cases, the maximum absolute reduction for individual coal seams is in limits beetwin 0.51 ÷ 1.71 %. These figures are derived from the position of the bisectress (2), the average line (1) and the standard deviations of the individual data ($\sigma = 0.15$ %) from the average line under the "three sigma" rule (figure 3). This accuracy in the determination of hydrogen content is quite satisfactory when the organic (combusted) mass element composition is determined to a dry, ash-free state in order to clarify the consumer properties of coals. An entirely different error is obtained when the hydrogen content is recalculated to conditions close to the mining (working r) conditions under which the hazard properties of coal seams occur. For this case, the trendline (1) is also characterized by a high correlation coefficient (0.95), but it is much further away from the bisectress (2) of the coordinate grid (figure 4). This follows from the values of the regression coefficient of equation 1 (0.68) and its free term (0.15).

The influence of the natural content of mineral impurities and total moisture on the relative average decrease in hydrogen content when converted to the working condition of coal is

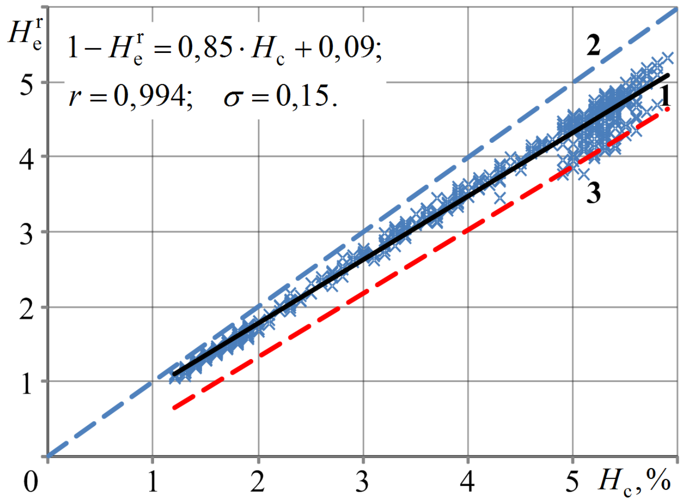

Figure 3. Hydrogen Recalculation Results in combusted mass for working conditions of the fuel for seam H_e^r samples of coal: 1 – the average trend lines; 2 – the bisectors of coordinate grids; 3 – a straight line defining the possible limit of maximum deviations of individual values from the trendlines (1) according to the "three sigma" rule; r, σ – correlation coefficients and standard deviations, respectively; × – experimental data [11] on the combustible mass of hydrogen (H_c) converted to working condition according to [13].

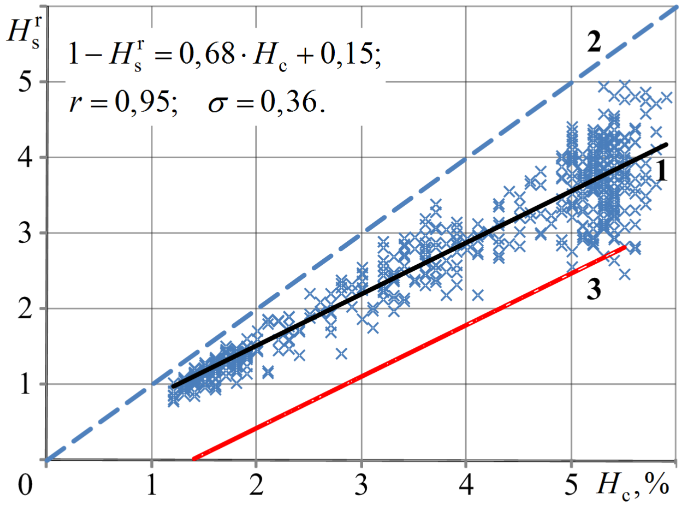

Figure 4. Hydrogen Recalculation Results in combusted mass for working conditions of the fuel for seam H_s^r samples of coal: 1 – the average trend lines; 2 – the bisectors of coordinate grids; 3 – a straight line defining the possible limit of maximum deviations of individual values from the trendlines (1) according to the "three sigma" rule; r, σ – correlation coefficients and standard deviations, respectively; × – experimental data [11] on the combustible mass of hydrogen (H_c) converted to working condition according to [13].

estimated from 17.0 to 29.5 %. For the considered sample of coal seams (557), the absolute hydrogen content of the combusted mass was in the range of 1.2÷5.9 %. The reduction in its content, when measured by the working condition, taking into account the actual discharge of ash and total moisture in the coals of each seam, is in absolute terms within the range of

1.25÷2.85 %. This follows from the resulting dependency (1) and related graphs (figure 4).

3. Discussion

A comparison of the graphs (figure 1, figure 3) and (figure 2, figure 4) shows that pre-enrichment and consideration of the elemental composition for dry ash-free coal samples predetermines a practical functional dependency from oxygen and hydrogen content. The removal of some random quantity of mineral impurities and completely external moisture has largely systematized the ratio between the oxygen and hydrogen content of the combustible mass and its reconsidered values by the working condition. However, the reference state of the samples taken for calculation does not correspond to the natural state of coal in the work area, as the actual mineral impurities and moisture content are not taken into account. For this reason, despite the almost functional dependancy (1) and the low standard deviations (figure 1 and figure 3), there is no reason to use the recalculated results for this case to predict the hazards of coal seams.

The presence of natural mineral impurities and total moisture in the seam's samples significantly influences the results of recalculation to working condition (figure 2 and figure 4). Primarily, this caused large deviations of individual values from the trend line (1), which makes it impossible to use the average oxygen and hydrogen values, recalculated by the working state of coal, to determine the hazards of a particular coal seam.

The total moisture content is one of the main indicators of the degree of coals' metamorphism, but it is generally not used in regulations to predict the hazards of miners [14]. The dependence of mineral impurities on the degree of metamorphic transformation is not generally established, but their presence in seam samples of coals of individual coal seams to be folowing a pattern [13]. This indicates that it is possible to individually characterise a coal seam by oxygen and hydrogen content, calculated by the working condition, taking into account the values of total moisture and total ash. The oxygen content of the organic (combustible) mass at a dry, ash-free state is an auxiliary indicator of one side of its metamorphic transformations. The carbon content in organic (combustible) mass is one of the main indicators of metamorphic transformation [14] because it functionally controls the sum of the other main components (oxygen, hydrogen, nitrogen, sulphur). The dependence of individual organic matter components on carbon is less clear. This applies in particular to the oxygen content of the organic (combustible) mass. This dependence is purely non-linear and is characterised by a high deterministic coefficient (R^2=0.87). The co-dependence of oxygen content with carbon, which is calculated as working-level ash output and total moisture content in enriched samples, is substantially lower.

For this case $r = -0.64$ and doubled the standard deviation of the individual values from the trend line ($\sigma = 2.21$). No specific relationship of oxygen content to carbon can be established in case of recovery from seam samples. It is characterized by a practical lack of correlation ($r = -0.34$) and a large standard deviation of the individual values ($\sigma = 2.39$). The reduction of mineral impurities ($A^r < 10.0$ %) after coal enrichment and their joint consideration with seam moisture has led to a significant reduction in the correlation between considered components when converted to working condition. The weakening of this dependence is caused by the partial enrichment of coals (the presence of a random residue of mineral impurities) and total moisture's presence, which are individually different for each mine. Consideration of the ratio between the components after they have been brought to working condition on the basis of the actual ash content and total humidity has led to an unpredictable redistribution of the influence of factors on oxygen content [15]. The natural accidental presence of mineral impurities and the different values of total moisture in the seam's samples have eliminated the monopolistic metamorphic ratio of oxygen in the organic, dry, ash-free mass to carbon. This resulted in a redistribution of the influence of factors on the components of O^r and C^r. Consideration of seam's samples with mineral inpurities and total moisture content has increased the number of influencing factors.

4. Conclusions

The formation and manifestation of dangerous properties of coal seams, judging by the requirements of current regulatory documents, are determined by the degree of metamorphic transformations of fossil coal. The use of indicators of mass ($V^d af$) and volume ($V_V^d af$) output of volatile substances, which are set for dry ashless combustible (organic) mass, excludes the possibility of analyzing the influence of moisture and mineral impurities on the manifestation of dangerous properties of coal seams. The use of these indicators for the prediction of dangerous properties of coal seams, instead of indicators for the working condition (r), can lead to errors in their determination by 50 and 45 %, respectively. The conducted research made it possible to reveal the important role of mineral impurities in the formation of dangerous properties of coal seams. This is caused both by the significant possible content of mineral impurities in fossil coal, and by the simultaneous presence of the main components that determine the dangerous properties of coal seams (carbon, hydrogen, sulfur, oxygen and moisture), both in the organic and mineral parts of fossil coal. The influence of the natural content of mineral impurities and total moisture on the relative average decrease in oxygen content when converted to the state of coal is estimated at 19.0 % on average.

Abstract. In mining iron ore, over 60% of underground mines at Kryvyi Rih iron ore basin apply a system with the bulk caving of ore and overlying rocks. However, when the deposit dip is 45-60 degrees, application of this mining system leads to losses of about 30-40% of the footwall ore. Available methods of the loss reduction result in an increase in production costs or a decrease in the iron content in the mined ore mass. After analyzing the mechanism of forming the figure of drawing, it is proposed to change its parameters without significant costs due to the use of an inclined plane and an overcompacted ore layer. The presented study enables stating that with an increase in the inclined plane angle from 45 to 75 degrees the draw crater radius increases from 2 to 7.5 m, and a decrease in the factor of first loosening of ore leads to an increase in the radius of the crater to 10 m. Thus, for the first time it is proved that a decrease in the first loosening factor leads to the increased semi-minor axis of the ellipsoid of drawing and the width of the active drawing area, which will reduce losses of caved ore when drawing it from the stoping block in the footwall area. It is established that in order to minimize losses and dilution of ore when using level mining systems, the drawpoint should be located in the block sill at a distance ensuring formation of the 20 to 25 m high ellipsoid of drawing. In case of an overcompacted 22 m thick ore layer, it is possible to significantly reduce ore losses from 14 to 10% and ore dilution from 16 to 9%, thereby enhancing ore mass extraction indices without additional costs.

1. Introduction

Kryvyi Rih iron ore deposit is a narrow strip of metamorphic rocks and it is an integral part of Kryvyi Rih-Kremenchuk deposit extending from south to north. The length of the ore deposits along the strike varies from 0.8 to 2.5 km due to different mining and geological conditions at different enterprises, [1–4].

Kryvyi Rih deposit consists of four suites: schist-amphibolite (K_0); lower arkose-phyllite (K_1); middle iron ore (K_2); upper schist (K_3) ones [1, 4–7]. The main productive thickness is (K_2) which embraces seven pairs of interchanging ore and schist layers [8–10].

The underground mines are working out the fourth, fifth and sixth ferruginous levels with rich iron ores (the average iron content is 60-63%) represented by various forms: stratal, layer-shaped, lenticular, pillar-like and nested, and in some cases their combinations within the mining block [11–15].

The geological cross-section of the deposit along the shaft of the KRYVORIZKA underground mine of the joint-stock company KRYVBASZALIZRUDKOM is given (figure 1).

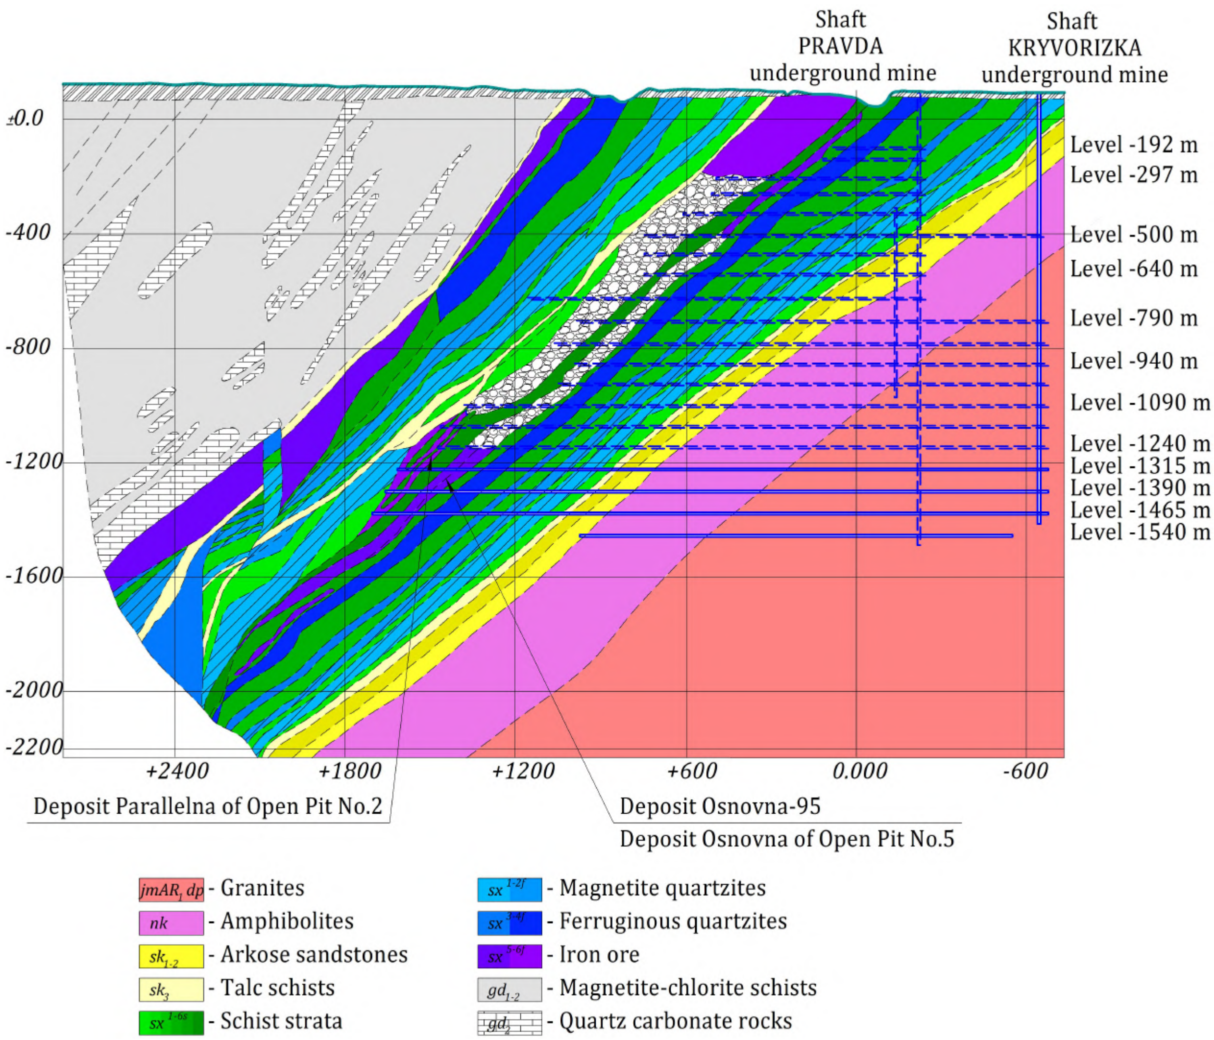

Figure 1. Geological cross-section of Kryvyi Rih iron ore basin along the shaft of the mine KRYVORIZKA, the JSC KRYVBASZALIZRUDKOM.

As is seen from figure 1, mining operations are carried out below level -1350 m. The analysis of mining enterprises shows that physical and mechanical properties, the shape of occurrence, the dip angle and stability change depending on the mining depth. In mining blocks there occur inclusions of waste rocks with the horizontal thickness of 0.5-12.0 m [16–20].

Rocks of the hanging wall and footwall are represented by strong, stable martite hornfels with ultimate compression strength of 100-130 MPa and goethite-hematite-martite hornfels with ultimate compression strength of 70-90 MPa. Physical properties of rocks are given in table 1.

As is seen from table 1, physical and mechanical properties of the rocks are wide in range. According to the geological data [1, 21, 22], the rich ores are of hematite composition and differ only in the number and proportion of mineral varieties [23–26].

Strength of iron ores declines with depth, and this deteriorates mining conditions. Thus,

Schistous rocks		
Quartz-chlorite-biotite, PR_1Sx^{1s}	-	130-150
Quartz-sericite-chlorite, PR_1Sx^{2s}	-	90-110
Quartz-mica, silicate, PR_1Sx^{3-5s}	-	70-120
Colored quartzite with martite crystals, PR_1Sx^{6s}	-	90-130
Chlorite-amphibole-hematite, carbonate-magnetite-chlorite, PR_1Sx^{7s}	-	120-160

every 500 m of the depth increase reduces the gradient of the compression strength of rocks by 0.6–0.7, and for the central part it makes 0.9–1.0 [27–30].

When mining iron ore, over 60% of underground mines of Kryvyi Rih iron ore basin apply a system with the bulk caving of ore and overlying rocks [31–34].

These mining systems have the following disadvantages [35–38]: ore losses on the footwall (up to 30-50% of the total ore losses); ore dilution (by 3-5% more than standard); reduced content of the useful component in the mined ore mass.

When the deposit dip is 45-60 degrees, application of these mining systems results in about 30-40% of ore lost on the footwall [39–43]. Increased losses of ore during mining lead to an increase in the specific volume of mining and capital works, pre-term mining of levels [21].

In this regard, the scientific and technical task of studying and enhancing the technology of mining ore deposits by the underground method for Kryvyi Rih iron ore basin in the “triangle” of the footwall (in the “dead” area) when working out ore deposits with a dip of 45-60 degrees to minimize ore losses is topical.

2. Purpose

One of the solutions for this scientific and technical problem involves developing a method to reduce ore losses in the footwall “triangle” without increasing the cost of caved ore drawing.

The present work aims to study and enhance the technology of mining ore deposits by enhancing the mode of drawing, which will reduce ore losses on the footwall in underground mining at Kryvyi Rih iron ore basin.

To achieve this goal it is necessary to solve the following tasks:

(i) Analyzing iron ore mining practices and ways to reduce ore losses in the footwall influence area.

(ii) Conducting studies to reduce ore losses in the “dead” area of the ore deposit.

The idea behind the work is to use regularities of ore movement under an inclined plane when working out ore deposits with a 45-60 degrees dip by bulk caving systems.

3. Analysis of researches and publications

Caved ore drawing from blocks when using systems with the bulk caving of ore is one of the most important production processes. Depending on the accepted method of ore drawing, ore losses and dilution are calculated, and the main parameters of the mining system are determined. This is due to the fact that 30-45% of the caved ore reserves is drawn from a block under overlying rocks, while losses in the block make 14-16%, and ore dilution is 12-20% [44–48].

A significant number of publications are devoted to the issue of reducing losses and dilution of caved ore from the stoping block [49–53]. Scientists of Kryvyi Rih National University (Ukraine) have made a significant contribution concerning ore drawing under caved rocks [54–61]. The panel enclosed by vertical walls of the ore massif from four sides is more favorable in terms of drawing from blocks as such conditions increase extraction indicators.

According to studies, the following factors significantly impact extraction indices [31, 62, 63]:

- intensification of ore drawing under caved rocks;
- the distance between the axes of drawpoints;
- structural elements of the mining system.

It is proved that the optimal distance between the axes of drawpoints is 4-6 m when drawing ore using scraper winches or vibration equipment, and 8-12 m – when using self-propelled loading machines or underground excavators. This enables significant reduction of ore losses and dilution but increases costs for driving and maintaining workings.

The authors of [1, 6, 31, 54] argue that the distance between drawpoints is inversely proportional to the height of the sublevel and proportional to losses in ore drawing. Therefore, depending on the height of the sublevel, the ore deposit thickness and the dip angle, it is necessary to use the appropriate drawing mode: even, sequential, advance and others, thus allowing reduction of ore losses on: the stoping block sill; the footwall of the ore deposit.

However, when working out a block, a significant amount of broken ore remains in the footwall influence area, especially when using the bulk caving system in unstable rocks. When drawing ore under caved rocks, about 25-35% of the reserves remains in the footwall influence area, and when working out deposits in unstable rocks of the hanging wall, ore losses reach 50% [64–67].

Practices of mining ore deposits with a dip of over 75 degrees applying systems with the bulk caving of ore and country rocks show that ore losses in the footwall influence area are minimal and do not exceed 5-7%. However, the number of such deposits in Kryvyi Rih iron ore basin is less than 15-17% [68–70].

To reduce ore losses on the footwall when mining deposits with a dip of less than 60 degrees. the following technological solutions are applied (figure 2) [31, 32, 54, 64, 71]:

- working out the "triangle" of the footwall as the first stage (figure 2(a));
- extracting the "triangle" of the footwall as the second stage (figure 2(b));
- cutting waste rocks in the footwall (figure 2(c));
- creating an additional receiving level with the complete working out of the ore massif and a single compensation room (figure 2(d)).

When working out the "triangle" of the footwall as the first stage (figure 2(a)), a scraper drift is driven 10-20 m above the main receiving level in the footwall of the deposit. An additional working of the receiving level can be driven in both ore and rocks of the footwall with drawpoints on one side.

Disadvantages include:

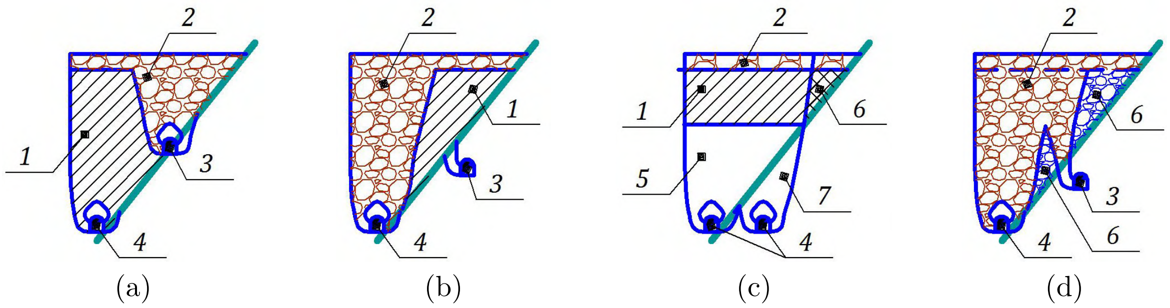

Figure 2. Methods of mining ore reserves in the footwall influence area: 1 – the ore massif; 2 – overlying rocks; 3 – the working of the additional receiving level; 4 – the delivery working of the main receiving level; 5 – the compensation room; 6 – losses of ore in the footwall influence area; 7 – cutting footwall rocks.

- significant costs for creation and maintenance of an additional receiving level;
- the specific volume of subsidiary development increased by 1.0-1.2 m/kt of reserves;
- significant dilution of ore with waste rocks as the height of the drawn ore layer increases.

The idea behind the method of mining the “triangle” of the footwall as the second stage (figure 2(b)) involves extraction of the main reserves of the panel with the help of delivery workings of the main receiving level, and the reserves of the footwall are broken and drawn afterwards. It should be noted that mining the “triangle” of the footwall in this way is carried out in difficult mining conditions, and in some cases it is hardly possible at all.

Disadvantages of this method of mining the footwall “triangle” include:

- increased unsafety of stoping; significant ore losses (up to 30-50%);
- a significant amount of subsidiary development (10-15 m/kt);
- low efficiency;
- high labor intensity and material costs.

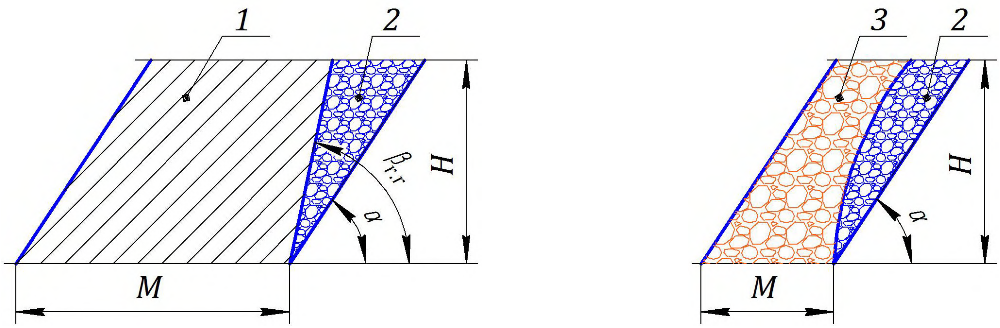
Extracting ore from the “triangle” of the footwall with cutting footwall waste rocks (selective mining) (figure 2(c)) involves creating a compensation room at the footwall on which the ore massif is broken. Due to movement of the massif, the broken ore is shifted from the footwall to the center at the level of undercutting. Thus, the broken ore enters the drawing area and is located on the footwall. The ore is drawn from the first row of drawpoints located in the footwall. After extracting the ore mass from the first row of drawpoints, drawing continues from the second row, and so on.

Advantages of this method consists in the following: on the footwall, the minimum amount of ore remains (up to 10%); driving additional workings in the footwall allows an increase in the size of the compensation room; a simplified scheme of preparatory-development operations is applied; a small part of the “triangle” at the top of the panel remains unmined; location of workings on the same level enhances occupational safety.

Disadvantages include the following: additional costs for creating a compensation room; a significant amount of additional work on driving workings in the footwall rocks; increased costs for maintaining additional workings; increased volume of mined waste rocks due to creation of the compensation room in the footwall.

To reduce ore losses on the footwall of the panels, the method of driving additional draw workings in footwall rocks is used (figure 2(d)). This scheme has found wide application in complete mining of the ore massif within the stoping block. The main requirements for application of this scheme of mining the “triangle” of the footwall are [54, 64]: relatively stable rocks of the hanging wall; medium thickness of ore deposits; the distance between the rows of drawpoints of additional receiving levels is determined such that ellipsoids of drawing touch waste rocks.

According to [54, 55], depending on the horizontal thickness of the ore deposit and the height of the caved layer, ore losses are formed in different ways (figure 3).



(a) (b)

Figure 3. Ore losses in the footwall influence: a) formation of a "triangle" of the footwall at an ore drawing angle of 75-81 degrees; b) formation of a "triangle" of the footwall parallel to the hanging wall; 1 – the ore massif; 2 – losses of ore in the footwall influence area; 3 – overlying rocks.

It is proved that when ore is being drawn, the figure of drawing is formed to the maximum height equal to the vertical thickness of the deposit. After reaching the contact with the inclined surface, the axis of the ellipsoid of drawing deviates and runs parallel to the footwall, forming a draw crater with the radius R_r.

4. Methods

A significant contribution to development of the theory of ore drawing has been made by Agoshkov et al [31], Malakhov et al [54], Korzh [64]. According to the results of their research, it is established that when caved ore is drawn from the mining block, the following figures are formed: ellipsoid of drawing, ellipsoid of loosening and draw crater (figure 4) [31, 54, 72, 73].

At the first stage, before the ellipsoid of drawing reaches the inclined surface, the figure of drawing is formed according to previous studies [1, 18, 54].

According to [31,32,54], the small and large semi-minor and semi-major axes of the ellipsoid of drawing are determined by empirical expressions (1) and (2) for fine and coarse ores respectively, m:

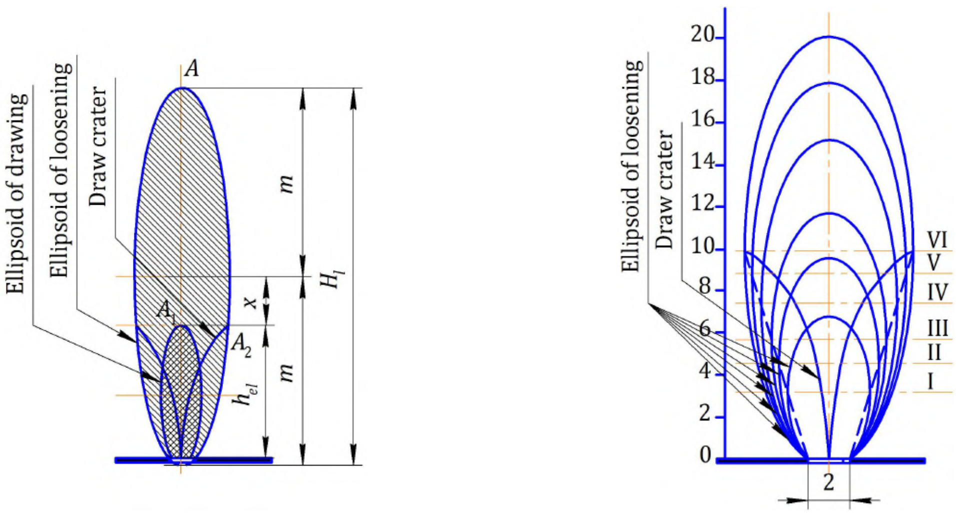
$$b = 0.007 \times h_{el} + 0.5 \times d, \qquad a = 0.512 \times h_{el}, \tag{1}$$

$$b = 0.1515 \times h_{el} + 0.5 \times d, \qquad a = 0.51 \times h_{el}, \tag{2}$$

where b is the semi-minor axis of the ellipsoid of drawing, m; h_{el} is the height of the caved ore layer (height of the ellipsoid of drawing), m; d is the diameter of the drawpoint, m; a is the semi-major axis of the ellipsoid of drawing, m.

The volume of the ellipsoid of drawing for ores with homogeneous loose properties is determined by the empirical formula, m^3

$$q = \left(\frac{h_{el}}{k_1} + k_2 \times d\right)^3, \tag{3}$$



(a) (b)

Figure 4. Formation of figures of drawing and loosening in drawing caved ore.

where k_1 is the tangent of the straight line inclination angle; k_2 is the empirical coefficient.

The volume of the ellipsoid of loosening Q_l is about fifteen times larger than that of the ellipsoid of drawing for loose non-compacted materials [21, 74, 75]. Therefore, the volume of the ellipsoid of loosening can be determined by the expression, m^3

$$Q_l = \mu_0 \times h_{el} \times b^2, \tag{4}$$

where μ_0 is the volume factor, assumed to be equal to 2.11.

Knowing the ratio of the volume of the ellipsoid of loosening to that of drawing, the latter can be determined according to the expression, m^3

$$q = \frac{Q_l}{n}, \tag{5}$$

where Q_l is the volume of the ellipsoid of loosening, m^3; n is the ratio of the volume of the ellipsoid of loosening Q_l to the volume of the ellipsoid of drawing q.

The ratio of the volume of the ellipsoid of loosening Q_l to that of the ellipsoid of drawing q that are formed during caved ore drawing depends on loose properties of the ore and is described by the dependency [33, 62, 71]

$$n = \frac{1}{1 - \dfrac{k_l}{\epsilon_{dyn} \times \epsilon_{kl} \times k_{l.is}}}, \tag{6}$$

where n is the angular caved ore drawing factor; k_l is the first loosening factor, unit fr.; ϵ_{dyn} is the dynamic component of subsequent loosening; ϵ_{kl} is the component of the subsequent loosening; $k_{l.is}$ is the subsequent loosening factor.

For magnetite ore, the indicators k_l and ϵ_{dyn}, are 1.0204 and 1.05 respectively [21, 33], the calculation results are given in table 2.

As is seen from table 2, when the caved ore first loosening factor decreases from 1.5 to 1.25, the ratio of the volume of the loosening figure to the volume of the drawing figure changes from 15.0 to 2.84.

Table 2. Volume to volume ratio for loosening and drawing figures.

First loosening factor, k_1	Subsequent loosening factor, ϵ_{kl}						
	1.50	1.55	1.60	1.65	1.70	1.75	1.80
1.50	15.00	10.33	8.00	6.60	5.67	5.00	4.50
1.45	10.23	7.88	6.49	5.56	4.90	4.41	4.03
1.40	7.76	6.37	5.45	4.81	4.32	3.95	3.65
1.35	6.25	5.35	4.71	4.23	3.86	3.57	3.33
1.30	5.23	4.60	4.14	3.78	3.49	3.26	3.07
1.25	4.50	4.04	3.69	3.41	3.19	3.00	2.84

In compacted ore, there is an intensive extinction of an increase in the volume of figures of loosening and ore drawing. Consequently, extinction of the increase in the volume of loosening figures is more intensive than that of the figure of drawing, as a result of which the ratio of their volumes decreases [76–79].

According to Korzh [33], the semi-minor axis of the ellipsoid of drawing is determined by the expression, m

$$b = r + m_0 \times \left(\frac{k_{exl} \times h_{el}}{h_0}\right)^n, \tag{7}$$

where r is the radius of the ore drawing flow, m; m_0 is the factor of increase in the semi-minor axis of the ellipsoid of drawing, m; k_{ext} is the factor of intensity extinction for the semi-minor axis increase; h_0 is the minimum height of the ellipsoid of drawing, m.

When drawing caved ore under overlying rocks [5, 21, 54], particle flow velocities throughout the entire period remain phase shifted by the constant value φ.

The trajectory of particles (the boundary of the ellipsoid of loosening) is determined by the expression [32]

$$y_1 = \sqrt{\varphi \times (x_1 + k) \times (1 - \epsilon^2)}, \tag{8}$$

where φ is the distance between points A0 and A1, m; y, x are coordinates of a point relative to the horizontal and vertical axes of the ellipsoid of loosening, m; k is the distance to which a piece of ore moves vertically, m; ϵ is eccentricity of the ellipsoid of loosening.

The second stage of ore drawing from a single drawpoint is characterized by the fact that with further caved ore drawing, parameters of the ellipsoid of drawing remain unchanged, and subsequent formation of the ellipsoid of drawing occurs parallel to the hanging wall, thus forming the draw crater.

It is proved that the normal ellipsoid of loosening is formed until the cutoff height $h = m \times \tan\alpha$ [31].

The draw crater radius R_r, which is equal to the vertical thickness of the ore body, is determined by the formula

$$R_r = \sqrt{(H_l - h) \times h \times (1 - \epsilon^2)}, \tag{9}$$

where H_l is the height of the ellipsoid of loosening, m; h is the height of the caved ore layer, m.

In [4, 33, 62, 64] it is argued that the curve forming the draw crater within the range $H_l - H$ moves parallel to the footwall. Thus, ore losses in the "triangle" of the deposit footwall are calculated by the expression, unit fractions

$$P = 1 - \frac{R_r}{M} - \frac{0.5 \times M \times \tan\alpha}{H} \times \left(1 - \frac{2 \times R_r}{M} + \frac{R_r^2}{M^2}\right), \tag{10}$$

where M is the horizontal thickness of the ore deposit, m; α is the dip angle of the ore deposit, degrees; H is the height of the caved ore, m.

5. Results

Laboratory studies enable establishing that the figure of drawing changes depending on the surface inclination angle. The results of studying changes in ore drawing angles depending on the surface inclination, distances between the drawpoint and the inclined surface and the width of the caved layer in the lower and upper parts of the "triangle" of the footwall are given in table 3.

Table 3. The angle of the caved ore movement under the inclined plane.

Ore deposit dip, degrees	Distance between a drawpoint and the inclined surface, m	Ore drawing angle, degrees, depending on on the caved layer width in the lower part of the mining block of the footwall "triangle"			
		4	6	8	10
45	10	57.2	66.0	72.4	76.4
	15	52.5	58.0	63.6	70.0
	20	50.5	54.1	58.0	62.3
50	10	63.5	73.5	75.0	78.0
	15	59.0	64.7	71.5	77.4
	20	56.5	60.5	65.3	70.0
55	10	70.5	75.7	77.0	78.3
	15	65.4	72.0	75.5	78.0
	20	62.5	67.0	72.5	77.3
60	10	77.2	77.5	78.0	78.5
	15	71.0	75.2	77.9	78.1
	20	68.1	73.2	76.6	77.6

Based on the results of the calculations performed, dependencies of the angle of the caved ore flow under the inclined plane on the angle of the ore deposit dip and the distance between a drawpoint and the inclined surface can be built (figure 5).

The graphs in figure 5 enable the conclusion that an increase in the ore deposit dip angle results in an increased angle of ore drawing under the inclined plane. Thus, an increase in the deposit dip from 45 to 60 degrees leads to increases of the angle of drawing from 57.2 to 77.2 at the distance of 10 m between a drawpoit and the inclined surface. When the distance between a drawpoint and the inclined surface increases from 10 to 20 m at the ore deposit dip of 60 degrees, the angle of ore drawing decreases from 77.2 to 68.1 degrees.

The dependency of the change in the angle of ore drawing under the inclined plane on the distance between a drawpoint and the inclined surface and the caved layer width in the lower part of the mining block of the "triangle" of the footwall shown in figure 6.

Figure 6 enables the conclusion that an increase in the distance between a drawpoint and the inclined surface from 10 to 20 m results in a decrease of the angle of caved ore drawing from 76.4 to 50.5 degrees. The graph shows that changing the caved layer in the lower part of the mining block of the "triangle" of the footwall and the distance between a drawpoint and the inclined surface approximate the angle of ore drawing to that of the deposit dip.

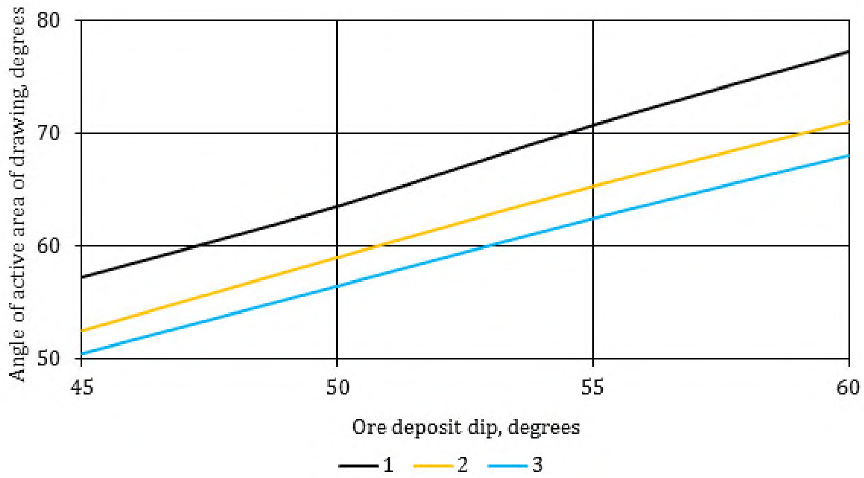


Figure 5. Dependency of the ore drawing angle on the ore deposit dip and the distance between a drawpoint and the inclined surface when the caved layer width at the lower part of the mining block is 4 m: 1, 2, 3 – the distance between a drawpoint and the inclined surface, 10, 15 and 20 m respectively.

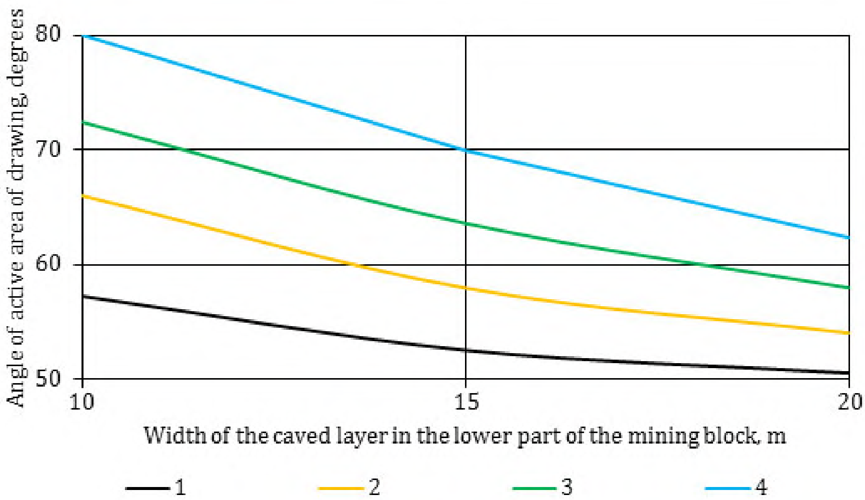

Figure 6. Dependency of the angle of ore drawing on the distance between a drawpoint and the inclined surface at the ore deposit dip of 45 degrees and the width of the caved layer in the lower part of the mining block of the "triangle" of the footwall: 1, 2, 3 and 4 – the width of the caved layer, 4, 6, 8 and 10 m respectively.

Let us consider how the angle of inclination of the enclosing plane and the angle of caved ore drawing impact the draw crater radius. The calculation scheme is given in figure 7.

Considering the right triangle ABC and knowing the width of the ore layer under breaking, the angle of inclination of the enclosing plane, the radius of the draw crater R_r (triangle BCD) is determined by the formula

$$R_r = h_{el} \times \tan\gamma = d \times \tan\beta_{r.r} \times \tan(90 - \beta_{r.r}), \quad (11)$$

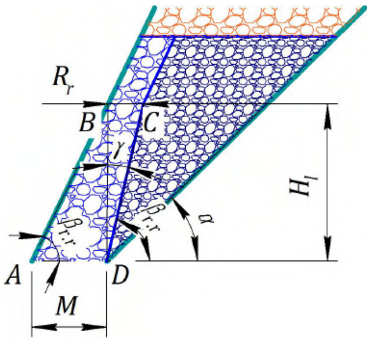

Figure 7. Scheme for determining the radius of the draw crater depending on the angle of the inclined plane.

where γ is the angle of internal friction, degrees; $\beta_{r.r}$ is the angle of inclination of the enclosing plane, degrees; d is the width of the base of the ore layer under breaking, m.

Thus, according to the known values from the theory of drawing caved ore under the country rocks, the radius of the draw crater is determined. The results of the calculations are given in table 4.

Table 4. Change in the radius of the drawing crater depending on the angle of the enclosing plane inclination.

Angle of the enclosing plane inclination, degrees	Radius of the drawing crater depending on the first loosening factor, m				
	1.1	1.2	1.3	1.4	1.5
45	4.4	4.1	3.3	2.5	2.0
50	4.8	4.5	3.7	2.9	2.4
55	5.3	5.0	4.2	3.4	2.9
60	6.0	5.6	4.8	4.0	3.5
65	7.0	6.5	5.6	4.9	4.4
70	8.2	7.7	6.8	6.1	5.5
75	10.0	9.7	8.9	8.2	7.5

According to the obtained values, the dependency of the drawing crater radius on the angle of the enclosing plane inclination can be built (figure 8).

As is seen in figure 8, an increase in the angle of plane inclination leads to the increase of the draw crater radius from 2.0 to 7.5 m at the first loosening factor of 1.5. A decrease in the first loosening factor from 1.5 to 1.1 results in the increase of the draw crater radius from 2.0-7.5 m to 4.4-10.0 m.

Thus, by changing the angle of plane inclination and increasing the width of the active drawing area, it is possible to reduce ore losses on the footwall.

Ore reserves remaining outside the active drawing area are determined by the expression, t

$$Q_l = (3 \times b + 0.5 \times h_{el} \times (\coth \alpha - \coth \beta_{r.r})) \times H \times L \times \gamma_o. \tag{12}$$

The volume of diluting rocks, when drawing caved ore, is determined by the formula, m^3

$$V_r = \frac{\pi \times h_l \times b^2}{3} \times \left(2 - \frac{3 \times (l_d - h_l \times k_l)}{b} + \frac{3 \times (l_d - h_l \times k_l)}{b}\right), \tag{13}$$

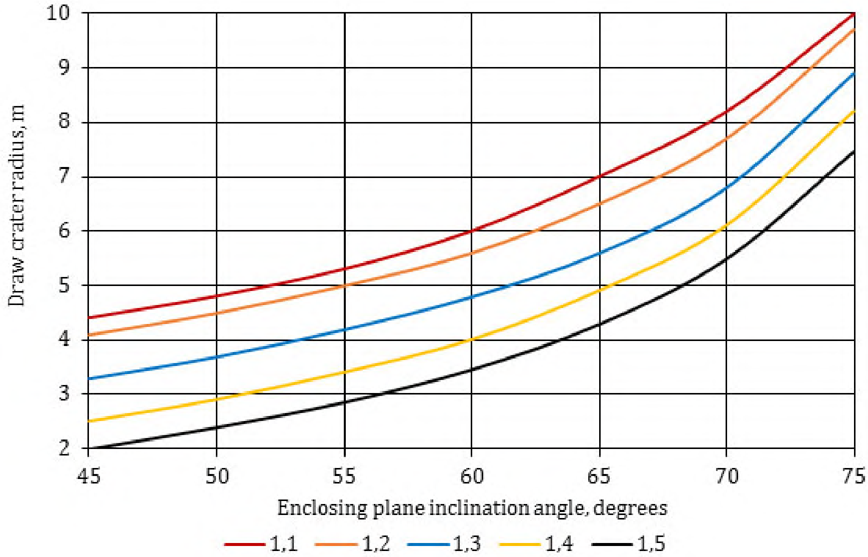

Figure 8. Dependencies of the change in the radius of the draw crater on the angle of the plane inclinatione.

where l_d is the distance between the drawpoint and the inclined plane, m.

Caved ore losses during its drawing under the overcompacted layer are determined by the expression, %

$$V = \frac{k_r \times Q_r + \left(L \times M - \frac{\pi \times N}{12} \times \left(d_{cr}^2 + d_{cr} \times d + d^2\right)\right) \times \frac{d_{cr} - d}{2} \times \gamma_{r.o} \times \tan \beta_{r.r}}{Q}, \quad (14)$$

where k_r is the ratio of ore extraction from the overcompacted layer, unit fr.; Q_r is the ore reserve in the overcompacted layer, t; N is the number of drawpoints; $\gamma_{r.o}$ is the volumetric weight of loosened ore, t/m^3; d_{cr} is the diameter of the draw crater, m.

Depending on physical and mechanical properties of the caved ore, ridges remaining on the block sill depend on the angle of ore drawing. At Kryvyi Rih iron ore basin, the angle of ore drawing does not exceed 68 degrees.

Analytical calculations of losses and dilution of ore during deposit mining using an overcompacted layer for the ore deposit dip of 60 degrees and an angle of the inclined plane of 70 degrees are given in table 5.

Based on the results of the analytical calculations performed, dependencies of changes in losses and dilution of ore during its drawing under the overcompacted layer are built figure 9.

As is seen in figure 9, an increase in the thickness of the overcompacted layer of ore decreases ore losses from 15 to 8%, and dilution increases from 6 to 16%. This is due to the fact that a decrease in the thickness of the overcompacted layer decreases the semi-minor axis of the ellipsoid of drawing, and the radius of the drawing flow under the inclined plane decreases accordingly. To minimize ore losses and dilution, it is advisable to locate the drawpoint in the block sill at a distance that provides formation of the 20 to 25 m high ellipsoid of drawing.

Thus, when applying the sublevel forced caving system using an overcompacted ore layer, it is possible to significantly reduce ore losses and dilution to enhance extraction of ore mass without additional costs. With the 22 m thick overcompacted layer, ore losses and dilution can be reduced from the actual 14 and 16% to 10 and 9% respectively.

Table 5. Ore losses and dilution during deposit mining using the overcompacted layer under the inclined plane.

Thickness of the overcompacted layer, m	Ore clogging, tons	Ore losses, tons
5	2088	5987
10	1605	4427
15	1337	3067
20	966	1256
25	854	1103
30	635	966

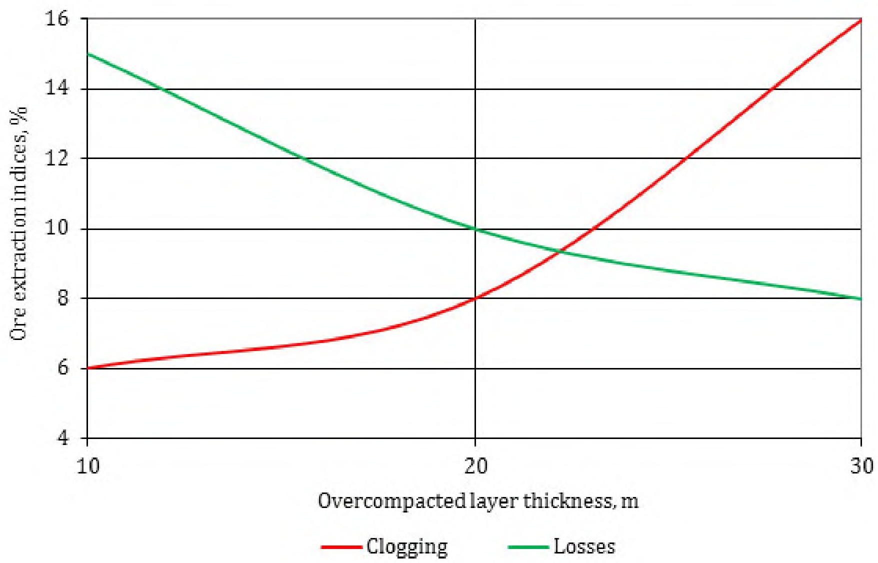

Figure 9. Dependencies of changes in losses and dilution of ore during its drawing under the over-compacted layer and the inclined plane located at the angle of 70 degrees and with the ore deposit dip of 60 degrees.

6. Conclusions

The results of the analysis of methods for determining parameters of figures of caved ore drawing from stoping blocks enable the conclusion that there is no single methodology. Each of the methods has its own conditions of application. However, parameters of the figure of drawing are significantly impacted by the degree of crushing, the material mobility ratio, the shape and condition of the surface, the compaction factor, the mode of drawing.

The results of the studies performed enable proving that the width of the active drawing area is impacted by not only rock pressure, but also the ore deposit dip angle and the enclosing surface represented by the hanging wall or created by gradual ore breaking. Thus, losses of ore on the footwall can be reduced by changing the angle of inclination of the plane and increasing the width of the active drawing area.

It is established for the first time that an increase in the thickness of the overcompacted ore layer leads to increases in the semi-minor axis of the ellipsoid of drawing and the width of the active area, which results in decreased losses and dilution of ore during its drawing from the stoping block. It is established that in order to minimize ore losses and dilution when using level mining systems, the drawpoint should be located in the block sill at a distance that provides formation of the 20 to 25 m high ellipsoid of drawing.

Using an overcompacted ore layer can significantly reduce ore losses and dilution and enhance extraction of ore mass without additional costs. Thus, the 22 m thick overcompacted layer enables ore losses and dilution reduction from the actual 14 and 16% to 10 and 9% respectively.

Abstract. There is a problem of increasing the durability of the roller cone bit of the drilling rigs used in the quarries of Ukraine. One of the effective ways to solve it is to apply the control method of maintaining a constant flow of mechanical power in the bottom hole zone. The implementation of such a control method leads to the necessity of controlling and limiting the resistance torque on the roller cone bit. To solve the problem of determining the resistance torque, we used methods of parameter identification: the Luenberger observation device with adaptation to external influences; estimation of the resistance torque using an extended observation object; the theory of regulators adapting to perturbations. It has been established that the most rational method of identifying the resistance torque on a roller cone bit is an astatic monitoring device, which allows to implement a method of controlling the rotation of the drill rod by a drive mechanism that maintains a constant flow of mechanical energy through the roller cone bit and increases the durability of the roller cone bit.

1. Introduction

The operation of the drilling rig is characterized by the transformation of the flow of electromagnetic energy coming from the power supply system into a flow of mechanical energy, which is released in the form of non-productive losses and turned into useful work, going to the destruction of rock and transportation of drilling fines onto the wellhead [1]. Energy flows are formed and directed through the following channels: axial force – power of linear movement of the drilling rod; rotation frequency – rock destruction power; compressed air pressure and flow rate – drilling fines evacuation (cuttings) power. Each channel has an individual type of energy converter; these are: adjustable electro-hydro-mechanical drive of drill bit supplying; adjustable electromechanical drive of roller cone bit rotation; nonadjustable electromechanical drive of compressor to remove drilling fines from the surface of the hole bottom.

Figure 1 shows a diagram of the formation and transformation of the electromagnetic energy flow of the power supply system into the mechanical energy flow on a roller cone.

There is a problem of improving the working capacity of a roller cone bit, since it wears most of all, since its cutting structure and supports work in an abrasive environment. During operation, the bit absorbs high static and dynamic loads, and is also subjected to intensive destruction from material fatigue and abrasive wear. The flow of rotational energy is directed not only to the destruction of the rock, but also to the destruction of the bit itself.

In order to increase the performance of a roller cone bit by maintaining the power flow in the bottom hole zone, the method of drilling process control [2] with control of the drives for the feeding and rotating mechanisms has been developed, where hard mechanical characteristics

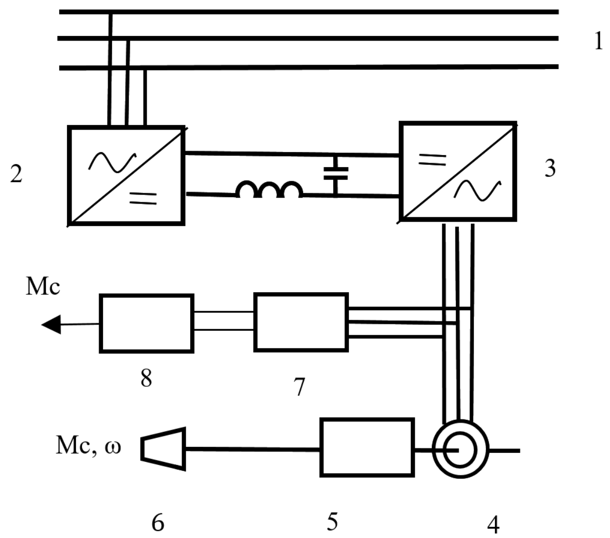

Figure 1. Diagram of the formation, transformation and control of the flow of mechanical energy on the cone bit by the rotation drive of the drilling rig rod. Designate: 1 – power supply network; 2 – rectifier; 3 – inverter; 4 – asynchronous motor; 5 – reducer; 6 – cone bit; 7 – coordinate converter of the ABC axes to the d-q system; 8 – identifier of the resistance torque on the cone bit.

are formed on the roller cone bit when penetrating soft formations and soft mechanical characteristics – in stronger formations.

When drilling rocks with intermittent physical and mechanical properties, the control method provides automatic selection of mechanical characteristics depending on the strength characteristics of the rock.

Implementation of the developed method of drilling process control leads to the necessity of measuring, controlling and limiting on permissible levels of resistance torque on the roller cone bit.

2. Related work

The need to modernize the park of drilling rigs for blasting wells used in quarries in Ukraine is an actual task, since they have exhausted their physical reserves, being in operation for 1.5 – 2 normative time limits.

Machine-building and electro-technical plants of Ukraine have modern technologies, on the basis of which they are capable of serial production of new generation drilling rigs on their own. Since 2003 the Novokramatorsk Machine-Building Plant has been working on the development of a new generation drill rig SBShS-250H with AC drive systems.

The essential question when developing the control system of the drilling rig rotation drive is the choice of its control method. There are known methods of control, realizing the support at a constant level of one of the parameters: bit rotation frequency, resistance torque on the bit [3], linear speed of bit movement, axial pressure on the bit, consumed power of rotation drive.

There are kinematic and energy criteria of the working capacity of a roller cone bit. The kinematic criterion monitors bit speed or linear penetration rate per bit, which is an indirect evidence of bit cutting structure wear.

Energy criterion of the working capacity of a roller cone bit is proposed in [2]. In this case, it is necessary to control the resistance torque on the bit and its rotation frequency. The time integral of their product is the energy released by the bit armament on the bottom hole. By stabilizing the energy release rate at a constant level, it is possible to get the maximum bit durability, since the cutting structure material is under a constant load. This can be achieved by keeping the power of destruction of the rock at a constant level with varying strength of the drilled rocks. The power delivered will depend on the resistance torque on the bit and the rotational speed of the bit. If the rotational speed is easy to measure, then measuring the resistance torque on the bit is in principle impossible due to the aggressive environment in the bottom hole area. Measuring power by voltage and current of the drive system will lead to errors due to their nonlinear dependence and dynamic torque presents.

Based on the energy criterion of bit durability, we choose the most rational way of controlling the rotation drive of the roller cone drill bit, which controls the power released in the bottom hole zone of the roller cone bit. With this approach, it is necessary to determine the resistance torque on the bit, using one of the methods of identifying the external influences based on the state observer [4, 5].

3. Results

The system of differential equations describing the dynamics of an induction motor in the d-q coordinate system, tied to the vector of the main flux linkage, has the form [5]:

$$\frac{d\psi_r}{dt} = -\frac{R_r}{L_r}\psi_r + k_r R_r I_d; \frac{dI_d}{dt} = \frac{R_s + k_r^2 R_r}{L_s'} I_d + \frac{k_r R_r}{L_s' L_r}\psi_r + \omega_{\psi r} I_d + \frac{1}{L_s'} U_d;$$

$$\frac{dI_q}{dt} = -\frac{R_s + k_r R_r}{L_s'} I_d - \omega_{\psi r} I_d - \frac{k_r}{L_s'} p_n \psi_r \omega + \frac{1}{L_s'} U_d; \frac{d\omega}{dt} = \frac{k_m \psi_r I_q - M_c}{J},$$

where ψ_r, L_r, R_r – the rotor flux linkage, inductance and active resistance; I_d, I_q – transverse and longitudinal components of the motor stator current; R_s, L_s' – stator resistance and inductance; ω, $\omega_{\psi r}, p_n$ – angular frequency of rotation of the rotor, flux linkage of the rotor and the number of pole pairs of the stator winding; U_d, U_q – transverse and longitudinal components of the stator voltage; M_m – mutual induction between the stator and the rotor (inductance of the magnetization circuit); denoted: $k_r = M_m/L_r, k_s = M_m/L_s, L_s' = \sigma L_s, \sigma = 1 - k_s Kr, k_m = 3p_n k_r/2$; σ – leakage coefficient; J is the dynamic moment inertia of the drive mechanical link.

The coordinate system is oriented in the direction of the vector of the main flux linkage, which makes it possible to separately control the flux linkage of the rotor and the transverse component of the stator current. This makes it possible to synthesize a system with normalized dynamic parameters, which controls the flux coupling and the longitudinal stator current on one channel, and the rotor speed and the transverse component of the stator current on the other channel (vector control system for induction squirrel-cage motor).

Equations describing dynamic processes in the control channel by the active (torque-forming) component of induction motor stator current [6]

$$\begin{cases} \frac{dI_q}{dt} = -\frac{R_s + k_r R_r}{L_s'} I_d - \omega_{\psi r} I_d - \frac{k_r}{L_s'} p_n \psi_r \omega + \frac{1}{L_s'} U_d; \\ \frac{d\omega}{dt} = \frac{k_m \psi_r I_q - M_c}{J}. \end{cases} \tag{1}$$

The coordinate system is oriented in the direction of the vector of the main flux linkage, which makes it possible to separately control the flux linkage of the rotor and the transverse component of the stator current. This makes it possible to synthesize a system with normalized dynamic parameters, which controls the flux coupling and the longitudinal stator current on one channel, and the rotor speed and the transverse component of the stator current on the other channel (vector control system for induction squirrel-cage motor).

Equations describing dynamic processes in the control channel by the active (torque-forming) component of induction motor stator current [6]

$$\begin{cases} \frac{dI_q}{dt} = -\frac{R_s+k_rR_r}{L'_s}I_d - \omega_{\psi r}I_d - \frac{k_r}{L'_s}p_n\psi_r\omega + \frac{1}{L'_s}U_d; \\ \frac{d\omega}{dt} = \frac{k_m\psi_r I_q - M_c}{J}. \end{cases} \tag{2}$$

There are four disturbing signals in the control object: rotor flux linkage – ψ_r; resistance torque – M_c; cross-coupling – $\omega_{\psi r}I_d$; electromotive force of rotation frequency – $k_r\psi_r p_n\omega/L'_s$.

We believe that the rotor flux linkage is maintained at a constant level through the control channel of the reactive (flux-forming) current of the motor stator. Compensation of the cross-coupling and the electromotive force of the rotation frequency is carried out by introducing additional links, zeroing out the perturbing actions from the indicated influences. Compensation of the cross-coupling is achieved by decoupling of the control channels. The direct compensation uses signals proportional to the product of the instantaneous frequency rotation of the rotor flux linkage vector $\omega_{\psi r}$ and the reactive component of the stator current, as well as the product of the rotor frequency rotation and the current value of the rotor flux linkage. Therefore, these perturbations on the control object are not taken into account when identifying the torque of resistance [7, 8].

After these simplifications one can forming the state vector

$$X = \begin{pmatrix} x_1 \\ x \end{pmatrix} = \begin{pmatrix} I_d \\ \omega \end{pmatrix}$$

and denoting $k_m = 3p_nk_r/2$ it is convenient to represent the object under consideration by a system of linear differential equations written in matrix form:

$$\begin{cases} \dot{X} = AX + Bu + W; \\ Y = CX, \end{cases} \tag{3}$$

where the matrix coefficients are defined

$$A = \begin{pmatrix} -\ (R_s + k_rR_r)/L'_s & -k_rp_n\psi_r/L'_s \\ k_m\psi_r/J & 0 \end{pmatrix}, B = \begin{pmatrix} 1/L'_s \\ 0 \end{pmatrix}, W = \begin{pmatrix} 0 \\ M_c/J \end{pmatrix}, C = (1\ 0).$$

Let us study the problem of determining the resistance torque on the bit M_c, using various methods of identifying the external influences that cannot be directly measured. The methods under consideration apply the so-called observer, i.e., its mathematical model working in parallel with the object. The main attention is paid to the stability of the system, which is ensured by a proper choice of its natural frequencies (modes) on the complex plane.

The extended object method assumes [9] that the change in the external action is subject to some differential equations, which together with the equations of the main object define the extended system. In this case perturbing influences become state variables of the extended object.

In our case, taking into account that the rate of transient processes in the object exceeds the rate of change M_c, we obtain $M_c \approx const$.

The original system of equations presented in vector-matrix form

$$\begin{cases} \dot{X} = AX + Bu + W; \\ Y = CX; \\ \dot{W} = 0, \end{cases}$$

transform to a form convenient for further analysis:

$$\begin{cases} \dot{X}^{*} = A^{*}X^{*} + B^{*}u + W; \\ Y^{*} = C^{*}X^{*}, \end{cases} \tag{4}$$

where the notation for matrix coefficients is accepted

$$A^{*} = \begin{pmatrix} -\ (R_s + k_r R_r)/L'_s & -k_r p_n \psi_r / L'_s & 0 \\ k_m \psi_r / J & 0 & -1/J \\ 0 & 0 & 0 \end{pmatrix},$$

$$B^{*} = \begin{pmatrix} 1/L'_s \\ 0 \\ 0 \end{pmatrix}, X^{*} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} I_s 2 \\ \omega \\ M_c \end{pmatrix}, C^{*} = (1\ 0\ 0).$$

We construct the observing device in the form of a mathematical model, which is described by the equation

$$\dot{\hat{X}} = A^{*}X + B^{*}u + W + L(Y - C^{*}\ \hat{X}), \tag{5}$$

where L – some unknown matrix of size $n \times 1$; n is system order.

The last term in (4), taking into account the difference between the outputs of the object and the model, corrects the observer so that the condition is fulfilled $\hat{X}\ (t) - X^{*}(t) \to 0$ when $t \to \infty$. Such an observer is called an asymptotic identifier.

If we denote $\widetilde{X} = \hat{X} - X^{*}$, then from (3) and (4) we obtain equations for the estimation error:

$$\dot{\widetilde{X}} = A^{*}\widetilde{X} + L(Y - C^{*}\widetilde{X}) \text{ or } \dot{\widetilde{X}} = (A^{*}\widetilde{X} - LC^{*})\widetilde{X}.$$

In accordance with the scientific statements put forward in [10,11], which establish the relation between the total observability and the characteristic polynomial of a matrix $A^{*} - LC^{*}$ with an arbitrary desired set of roots, we check for the system (3) the observability condition, which consists in that the rank of the observation matrix

$$Q_n = (C^T \vdots A^{*T} C^T \vdots\ (A^{*T})^2 C^T \vdots \ldots \vdots\ (A^{*T})^{n-1} C^T)$$

must match the order of the system n.

For the system under study, we obtain:

$$Q_n = (C^T \vdots A^{*T} C^T \vdots\ (A^{*T})^2 C^T) = \begin{pmatrix} 1 & -(R_s + k_r R_r)/L'_s & ((R_s + k_r R_r)/L'_s)^2 - k_r k_m p_n \psi_r^2 / J L'_s \\ 0 & -k_r p_n \psi_r / L'_s & k_r p_n \psi_r (R_s + k_r R_r)/(L'_s)^2 \\ 0 & 0 & k_r p_n \psi_r / L'_s J \end{pmatrix}.$$

The matrix rank Q_n is 3, that is, it coincides with the order of the system. In this case, the condition of complete observability is satisfied.

The characteristic polynomial for the matrix $A^{*} - LC^{*}$, (where $det[\lambda I - A^{*} + LC^{*}]$, where I is the identity matrix) is determined by the expression:

$$\det \begin{pmatrix} \lambda + (R_s + k_r R_r)/L'_s + l_1 & k_r p_n \psi_r / L'_s & 0 \\ -k_m \psi_r / J + l_2 & \lambda & 1/J \\ l_3 & 0 & \lambda \end{pmatrix} =$$

$$= \lambda^3 + (\frac{R_s + k_r R_r}{L'_s} + l_1)\lambda^2 + \frac{k_r p_n \psi_r}{L'_s}(\frac{k_m \psi_r}{J} - l_2)\lambda + \frac{k_r p_n \psi_r}{J L'_s} l_3 \quad (6)$$

We select the elements of the matrix $L = (l_1\ l_2\ l_3)^T$ in such a way that the polynomial turns into the Newton binomial

$$(\lambda + \beta)^3 = \lambda^3 + 3\lambda\beta^2 + 3\lambda^2\beta + \beta^3; (\beta > 0).$$

Whence, by equating the coefficients at the same degrees of the polynomial, we obtain

$$\begin{cases} (R_s + k_r R_r)/L'_s + l_1 = 3\beta; \\ (k_r p_n \psi_r / L'_s)(k_m \psi_r / J - l_2) = 3\beta^2; \\ k_r p_n \psi_r l_3 / J L'_s = \beta^3. \end{cases} \quad (7)$$

To solve system (6), it is necessary to choose the value determines the position of the matrix eigenvalues $A^* - LC^*$ on the complex plane and, consequently, the rate of convergence $\hat{X}(t)$ to $X^*(t)$.

Usually, values β are used in 2...3 times greater than the maximum of the numbers $|Re\lambda_0|$, where λ_0 is the eigenvalues of the object's matrix. Let's find them by solving the equation

$$\det |Re\lambda_0 I - A| = 0$$

$$\begin{vmatrix} \lambda_0 + (R_s + k_r R_r)/L'_s & k_r p_n \psi_r / L'_s \\ -k_m \psi_r / J & \lambda_0 \end{vmatrix} = \lambda_0^2 + \lambda_0 (R_s + k_r R_r)/L'_s + k_m k_r p_n \psi_r^2 / J L'_s = 0$$

$$\lambda_0(1,2) = -(R_s + k_r R_r)/2L'_s \pm \sqrt{(R_s + k_r R_r)/2L'_s)^2 - k_m k_r p_n \psi_r^2 / J L'_s}.$$

We choose $\beta = \gamma (R_s + k_r R_r)/2L'_s$, where the value γ within 2. . . 3 is accepted.

Then, in accordance with the obtained equations of system (6), we find the values of the correction coefficients:

$$\begin{cases} l_1 = \frac{3\gamma}{2}\frac{R_s + k_r R_r}{L'_s} - \frac{R_s + k_r R_r}{L'_s} = \frac{R_s + k_r R_r}{L'_s}(\frac{3\gamma}{2} - 1); \\ l_2 = \frac{k_m \psi_r}{j} - \frac{3}{4}\gamma^2 \frac{(R_s + k_r R_r)^2}{k_r p_n \psi_r L'_s}; \\ l_3 = \frac{1}{8}\gamma^3 \frac{J(R_s + k_r R_r)^3}{k_r p_n \psi_r (L'_s)^2}. \end{cases} \quad (8)$$

Consequently, the structural diagram and the values of the correction coefficients are generally defined for the observing device (4).

It is known that the method of transition to an extended object requires complete observability of this object [5]. An astatic observing device [11] is free from this restriction [12], the construction of which we will consider for the problem to be solved when the vector of disturbing influences contains one nonzero element.

For system (2) in this case it is possible to construct an observing device described by equations:

$$\dot{\widetilde{X}} = A\widetilde{X} + Bu + L(Y - C\widetilde{X}) + K\int_0^t (Y - C\widetilde{X})dt, \quad (9)$$

where $L = (l_1\ l_2)^T$ and $K = (0\ k)^T$ are matrices with yet unknown coefficients.

From (8) and the structure of the matrix, we see that the integral term is added only to the equation of system (8) that corresponds to the equation of system (2) containing a nonzero perturbation.

The equation for the estimation error $\widetilde{X}(t) = \hat{X}(t) - X(t)$ takes the form:

$$\dot{\widetilde{X}} = (A - LC)\widetilde{X} - kC\int_0^t \widetilde{X}(t)dt - W. \tag{10}$$

It follows from the last relation that the condition $\hat{X}(t) \to X(t)$ or $\widetilde{X} \to 0$ when $t \to \infty$ (and actually for the damping time of the natural component of the transient) is satisfied if

$$-kC\int_0^t (\hat{X}(t) - X(t))dt = W.$$

Thus, the observer (8) allows us to identify the perturbation W. The choice of matrices L and K makes it possible to control the rate of this process.

When applied to the object under consideration (2), the described technique leads to the following result. Let us differentiate equation (9), assuming that the perturbation the perturbation does not change over the transition time:

$$\dot{\widetilde{X}} = (A - LC)\widetilde{X} - kCX.. \tag{11}$$

Let's write the system (10) in the expanded form:

$$\begin{cases} \ddot{\widetilde{x}}_1 = (a_{11} - l_1)\,\dot{\widetilde{x}}_1 + a_{12}x_2; \\ \ddot{\widetilde{x}}_2 = (a_{21} - l_2)\,\dot{\widetilde{x}}_1 - k\widetilde{x}_1, \end{cases} \tag{12}$$

where a_{ij} is matrix A element.

Using the method of excluding the unknowns, we transform the system (11) into a third-order differential equation:

$$\dddot{\widetilde{x}}_1 - (a_{11} - l_1)\,\ddot{\widetilde{x}}_1 - a_{12}(a_{21} - l_2)\,\dot{\widetilde{x}}_1 - a_{12}k\widetilde{x}_1 = 0,$$

whose characteristic polynomial has the form (taking into account values of a_{11}, a_{12}, a_{21})

$$\lambda^3 + (\frac{R_s + k_r R_r}{L'_s} - l_1)\lambda^2 + \frac{k_r p_n \psi_r}{L'_s}(\frac{k_m \psi_r}{j} - l_1)\lambda + \frac{k_r p_n \psi_r}{L'_s}k = 0. \tag{13}$$

$$\lambda^3 + (\frac{R_s + k_r R_r}{L'_s} - l_1)\lambda^2 + \frac{k_r p_n \psi_r}{L'_s}(\frac{k_m \psi_r}{j} - l_1)\lambda + \frac{k_r p_n \psi_r}{L'_s}k = 0. \tag{14}$$

The polynomial (12) coincides completely with the characteristic polynomial (5). This allows one, if a binomial arrangement of the roots $(\alpha + \beta)^3$ is desired, to write down, using the solution obtained earlier (7):

$$\begin{cases} l_1 = \frac{R_s + k_r R_r}{L'_s}(\frac{3\gamma}{2} - 1); \\ l_2 = \frac{k_m \psi_r}{j} - \frac{3}{4}\gamma^2 \frac{(R_s + k_r R_r)^2}{k_r p_n \psi_r L'_s}; \\ l_3 = \frac{1}{8}\gamma^3 \frac{J(R_s + k_r R_r)^3}{k_r p_n \psi_r (L'_s)^2}. \end{cases}$$

where γ has the same meaning as in (7).

Equations (8) written element by element in expanded form:

$$\begin{cases} \dot{\hat{x}}_1 = a_{11}\,\hat{x}_1 + a_{12}\,\hat{x}_2 + l_1(x_1 - \hat{x}_1) + \frac{1}{L'_s}u_q; \\ \dot{\hat{x}}_2 = a_{21}\,\hat{x}_1 + l_2(x_1 - \hat{x}_1) + k\int_0^t (x_1 - \hat{x}_1)dt, \end{cases}$$

$R_s + k_r R_r$	L'_s	k_r	k_m	p_n	ψ_r	J	M
ohm	mH	p.u.	p.u.	p.u.	wb	kg m^2	kg m
0.152	2.73	0.977	0.842	2.0	1.502	1.2	580

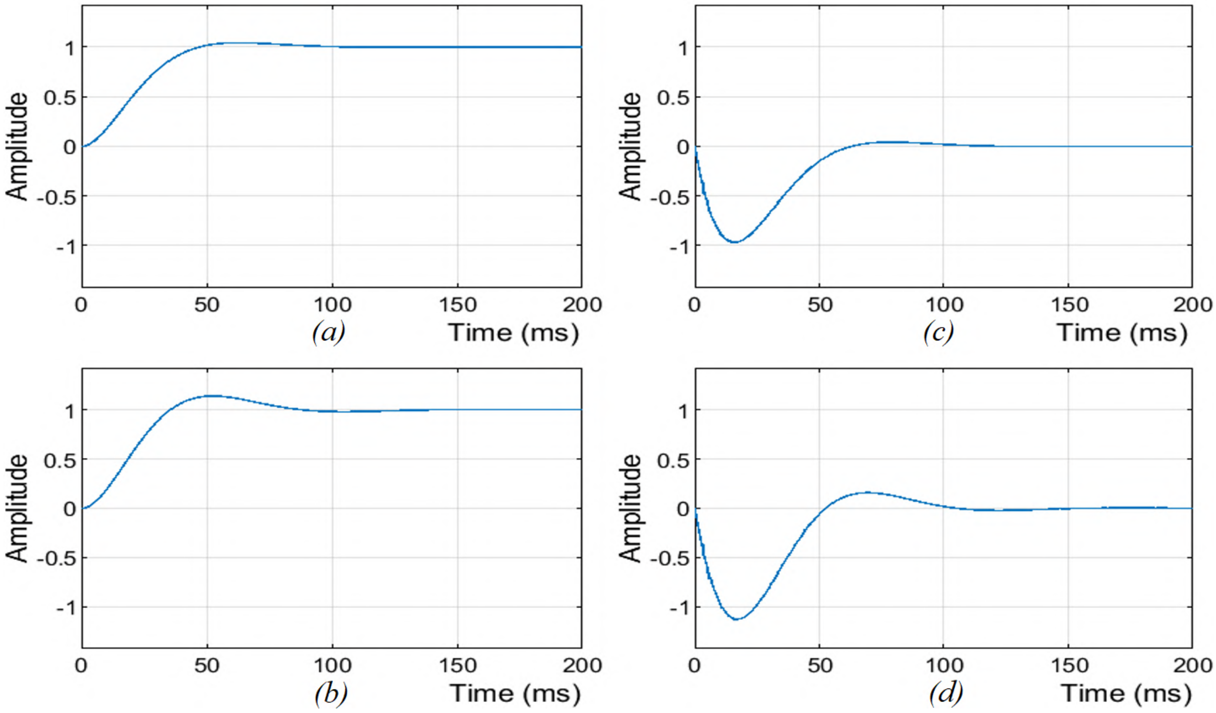

Figure 3. Graphs of the resistance torque (a, b) and the determination error (c, d) during their identification on a roller bit, given in p.u.

1480 rpm, 90 kW. Technical data are given in the table 1.

Calculated plots of resistance torque identification on the roller cone bit using the astatic observer and the binomial root distribution ($\beta = 55.6$; figure 3(a)) and the Butterworth distribution (($\beta = 83.4$; figure 3(b)), are shown in figure 3.

Figure 3 shows the calculated graphs of the error in finding the resistance torque by an astatic observer with a binomial distribution of roots ($\beta = 55.6$; figure 3(c)) and the Butterworth distribution ($\beta = 83.4$; figure 3(d)), In all graphs, the torque amplitudes are shown in relative units (p.u.). Torques are reduced to the rated motor torque $M = 580$ kg m.

4. Conclusions

1. The disturbing influence from the load in the system of electric drive can be effectively restored by the observer, to which the signals of the supply voltage and current of motor. Beside it is necessary to introduce three corrective links: two of which have proportional and one has integral dynamic characteristics. At the output of the observer, a signal that is proportional to the ratio of the resistance torque on the working body of the drive system to the moment of inertia is explicitly allocated.

2. Identification of the resistance torque on the roller cone bit allows to realize the way of controlling the drive of the drill rod rotation when the mechanical energy constant flow on the roller cone bit is maintained by forming "hard" mechanical characteristics in the drive of the rotation when drilling in soft and broken formations and "soft" mechanical characteristics when drilling in hard undisturbed formations that will increase the life of the bit.

Abstract. Mining and geometrical prediction of iron ore deposit quality indices to solve problems of long-term and current planning intended to provide the most efficient performance of mining enterprises in terms of ore blending quality and increase rationalization of deposit development is an important aspect of geometrization. Investigations carried out to develop a mining-geometrical method for predicting indices of iron ore deposit quality are topical nowadays. The present study aims to enhance the methodology for geometrization of iron ore deposit quality indices for developing a mining-geometrical method of their prediction to provide rational mining. The research methodology consists in mining and geometrical modeling of quality indices and properties of the deposit, thus enabling determination of a certain relationship between components of a mineral, and, thereby, identification of the nature of these components' location in the mineral. The latter is essential in design, construction and operation of a mineral deposit. The obtained results allow predicting quality indices of the deposit, assessing mineral reserves and consequently planning and optimizing performance of mining enterprises. The developed methods enable increased efficiency of mining iron ore deposits of Kryvbas.

1. Introduction

Ukraine ranks third in the world as to calculated iron ore reserves which make over 62 Bn t. Most of these reserves (over 32 Bn t) are concentrated in Kryvyi Rih iron ore basin [1–5] and mined by open pit and underground methods. Distribution of iron ore reserves by enterprises of the Kryvyi Rih Basin is given in table 1. According to the US Geological Survey, during the past 15 years, Ukraine ranks sixth in terms of the amount of the ore mass mined (70-86 M t/y) [6–10].

To maintain a high level of annual ore production, mining enterprises are continuously enhancing technological processes.

Thus, in open pit mining, special attention is paid to drilling and blasting (enhancement of explosives and initiation methods) and technological operations (application of imported equipment during loading and transportation of the broken ore mass).

Underground mining systems are constantly being enhanced as well. To ensure appropriate quality of the extracted ore mass, enterprises widely apply open stoping systems. Imported self-propelled delivery equipment used in mining at considerable depths (over 1250 m) helps provide annual productivity of 2-3 M t [11–14].

Together	9.15
Total	32.2

It should be noted that in working out Kryvyi Rih iron ore deposit, mining enterprises fail to increase annual ore production due to the fact that when designing or enhancing the technology, they use the data of mining and geometrical assessment of the deposit obtained in the previous century.

Planning mining production processes and performance of a mining enterprise is an important task even at the stage of deposit opening [15–19]. It can be ensured by application of mining and geometrical methods. At this, an important role is played by mining, geological and geometrical parameters and the nature of the deposit position which can be determined by methods of subsoil geometry [20–23].

A very important task that can be solved by geometrization methods is to determine stability of a rock massif under the stress-strain state. This enables determining measures to maintain rock massif stability [24–27].

A significant task of subsoil geometrization consists in increasing efficiency of drilling and blasting as an important factor for mining enterprise performance [28–32]. This task, in turn, is associated with that of monitoring the state of the rock massif [33–37] and closely related to methods of mining processes control [38–42].

Another important task involves selective mining based on assessment of geological, geochemical and geomechanical fields [43–47]. Methods of geometrization provide assessment and rational processing of man-made mineral formations [48–52].

Planning operation of a mining enterprise on the basis of mining and geometrical methods results in high economic indicators [53–57] ensured by rationalizing and optimizing mining operations.

Mining and geometrical assessment of the deposit is the most expedient when based on methods of analyzing geological data, among which geostatistical methods are the most effective [58–62]. This problem is closely related to the task of assessing and predicting the quality of reserves applying self-organization methods [63–65].

2. Purpose

The purpose of the study is geometrization of the iron ore deposit. A particularly important aspect of geometrization of iron ore mineral deposits involves mining and geometrical prediction of their quality indices to solve problems of long-term and current planning intended to provide the most efficient performance of mining enterprises in terms of ore blending and increase rationalization of deposit development.

The most promising methods for assessing indicators of the deposit include geometrization ones based on the use of a set of self-organizing methods and geostatistical methods of assessment [66, 67] which are developed and enhanced in the present work.

3. Methods

Processing the initial geological data requires a lot of sampling; the content of samples influences the quality in a certain block or area of the deposit. The problem of sampling is associated with application of various methods for determining weighted averages. The following two aspects of the problem are of great importance: the search procedure and a criterion for its completion. This criterion can be based on the value of the distance from the sample to the block or to the point where the composition is to be determined. In the most complex programs for calculating weighted averages, the search for points in an area is carried out on a plane or in a cone to ensure relative representativeness of all directions. This enables avoiding the effect of accumulation of samples in certain directions and their absence in others.

This step is, however, superfluous in case of kriging, since with accumulation of points, introduction of sample covariances allows considering automatically the influence of components of the cluster eliminating its excessive influence. Kriging helps to distribute weights among the nearest samples, if a constant density of sampling is not provided.

The grid density does not really influence the number of samples to be considered. Any kriging method does not indicate the number of samples required when assessing the ore composition in this block. From a theoretical standpoint, all available samples should be used. Nevertheless, it is clear that far-removed samples are of little interest. Therefore, it is obvious that the number of samples should not be too large. For example, considering sixteen points instead of twelve increases the calculation time by a factor of about 3, and sixteen samples instead of eight – by a factor of 8.

A sample removed from the block in a given direction for more than an influence interval (if any) is assumed to have a zero weight and should not be used. As an example, let us assess the exploration grid of Skelevatske deposit of ferruginous quartzites mined by the PivdGZK open pit. The deposit has for a long time been sampled in two ways. Detailed exploration is carried out by sampling the sludge of boreholes located irregularly with an interval of 50 to 200 meters. Operational exploration is carried out in the exploded mass by the point method. In case of homogeneous ores, pieces from an area of about a 50 m long (in the direction parallel to the bench slope) with a width determined by the size of the block to be exploded are selected in one sample. In case of heterogeneous ores, each type of quartzites is sampled separately. The sample weight is about 30 kg.

The data for assessment were selected along axis 77 along the strike towards the main direction of mining operations advance. The best method of assessment for actual conditions of Kryvbas iron ore deposits can be chosen by comparison. First, dependency of the natural component of variability on the sampling interval is assessed (figure 1-6), and then autocorrelation coefficients are determined at different sampling intervals (figure 7-12).

According to figures 1-6, at Skelevatske deposit, the minimum critical interval of geological exploration for both magnetite and total iron is 600 m. This enables the conclusion that

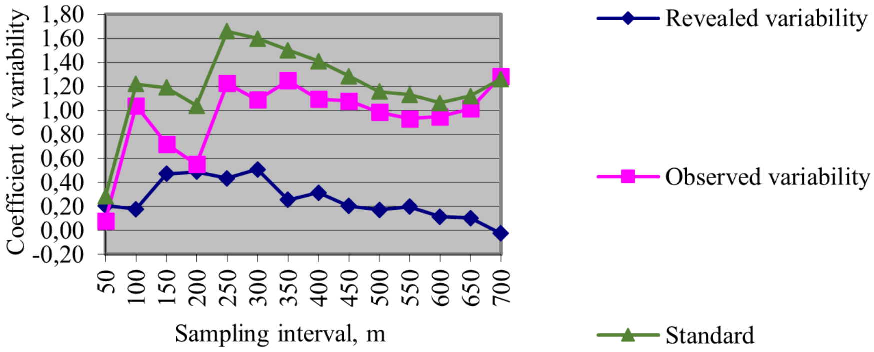

Figure 1. Dependency of the magnetite iron content variability on the sampling interval, hor. –165÷–180 m.

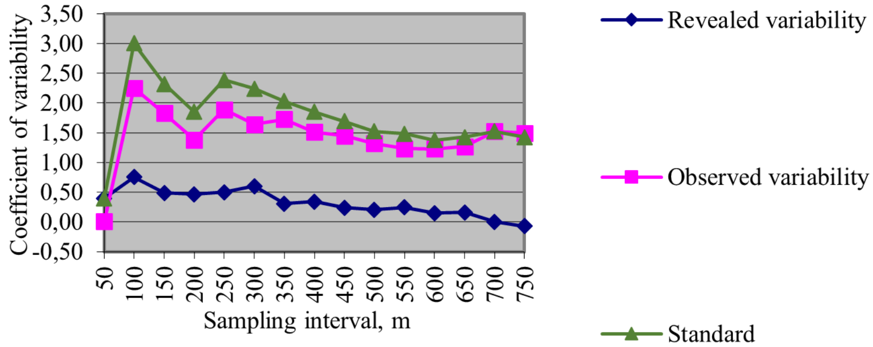

Figure 2. Dependency of the magnetite iron content variability on the sampling interval, hor. -180÷-195 m.

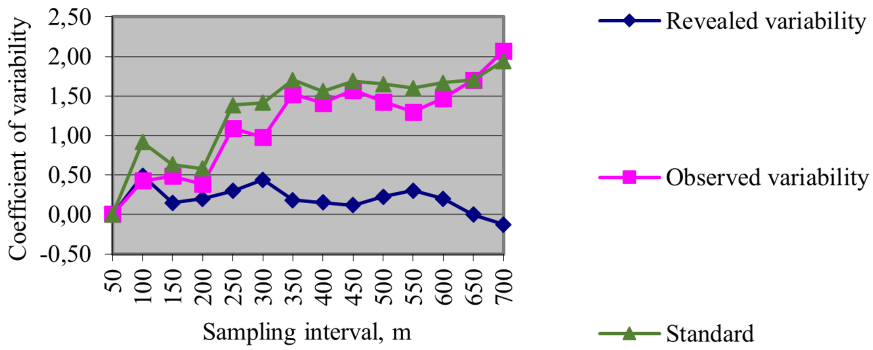

Figure 3. Dependency of the magnetite iron content variability on the sampling interval, hor. -195÷-210 m.

parameters of the exploration grid meet the requirements to them.

As is seen from figure 7-12, the autocorrelation coefficient provides ambiguous results. This is due to the fact that this coefficient inherently estimates, to this or that degree, deviation from the sample average value. Thus, in order to qualitatively assess a deposit with a nonlinear nature of index variability, the volume and interval of the sample should be selected with great accuracy and the initial data should be smoothed over as well, this being very time consuming and not always possible. In this very case, the graphs are sine curves with a growing amplitude.

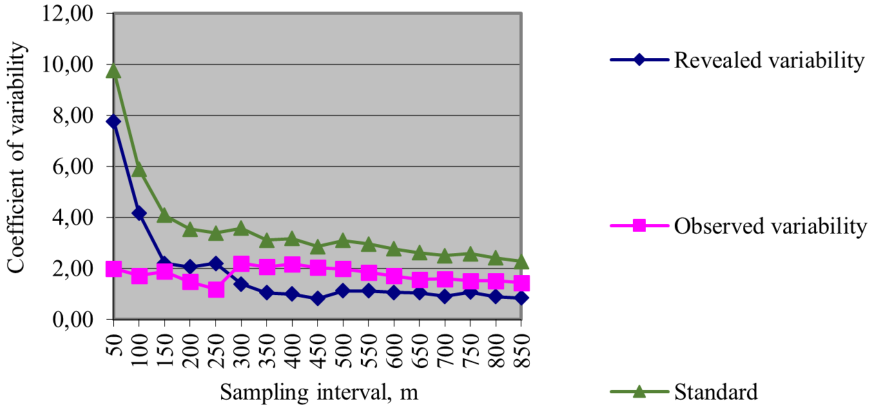

Figure 4. Dependency of the total iron content variability on the sampling interval, hor. -165÷-180 m.

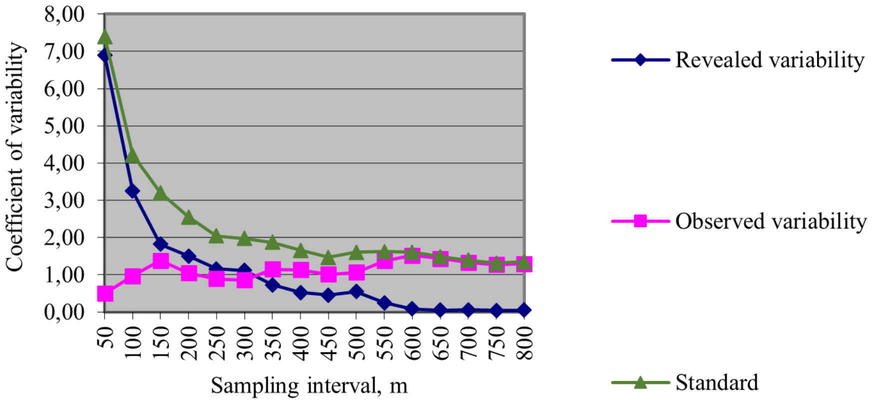

Figure 5. Dependency of the total iron content variability on the sampling interval, hor. -180÷-195 m.

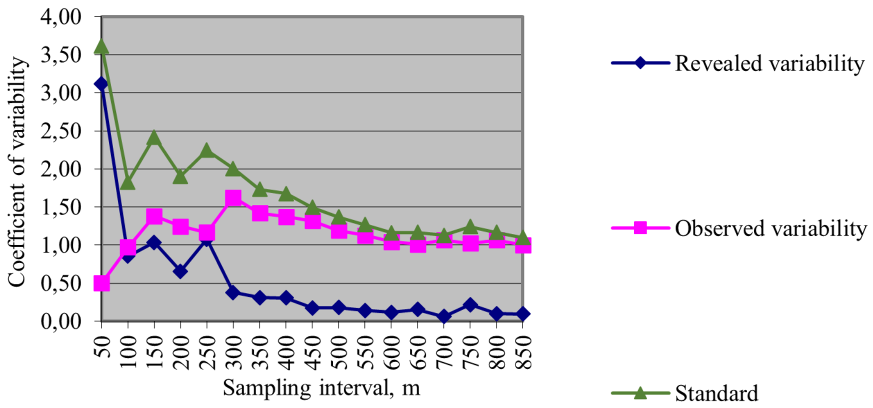

Figure 6. Dependency of the total iron content variability on the sampling interval, hor. -195÷-210 m.

Deviations of the indices of nearby points from the average also change in the close to sinusoidal manner, so the deposit can be said to actually have a sinusoidal component when obtaining the indices, and the autocorrelation coefficient is not quite relevant for assessing the exploration grid

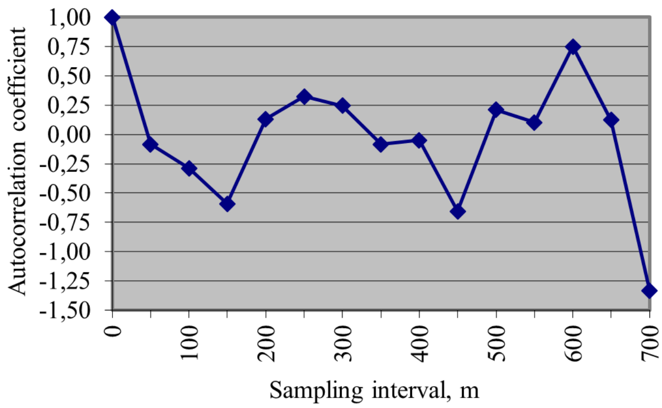

Figure 7. Dependency of the autocorrelation coefficient for the magnetite iron content on the sampling interval, hor. -165÷-180 m.

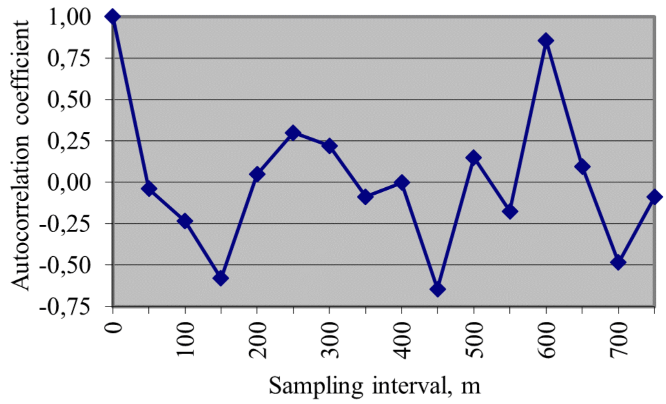

Figure 8. Dependency of the autocorrelation coefficient for the magnetite iron content on the sampling interval, hor. -180÷-195 m.

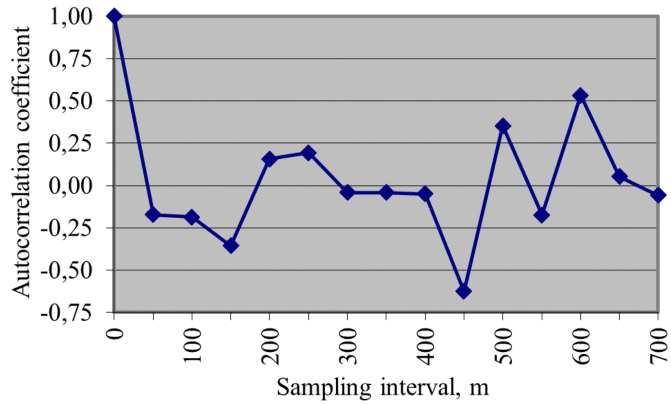

Figure 9. Dependency of the autocorrelation coefficient for the magnetite iron content on the sampling interval, hor. -195÷-210 m.

of Kryvbas iron ore deposits.

Determining the size of blocks under assessment can be set as a detailed assessment task,

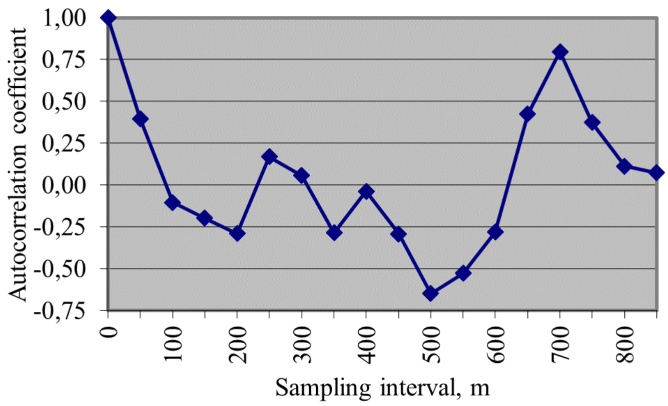

Figure 10. Dependency of the autocorrelation coefficient for the total iron content on the sampling interval, hor. -165÷-180 m.

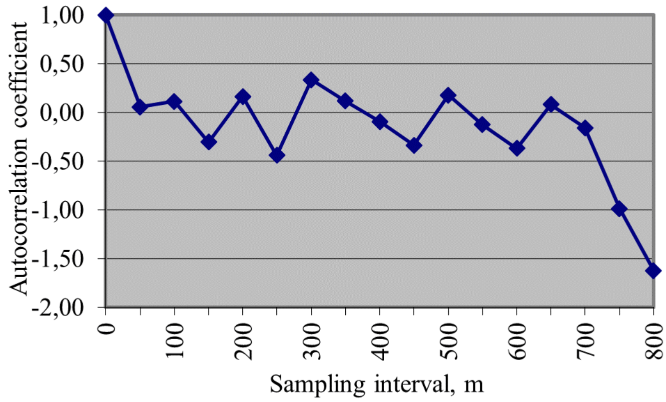

Figure 11. Dependency of the autocorrelation coefficient for the total iron content on the sampling interval, hor. -180÷-195 m.

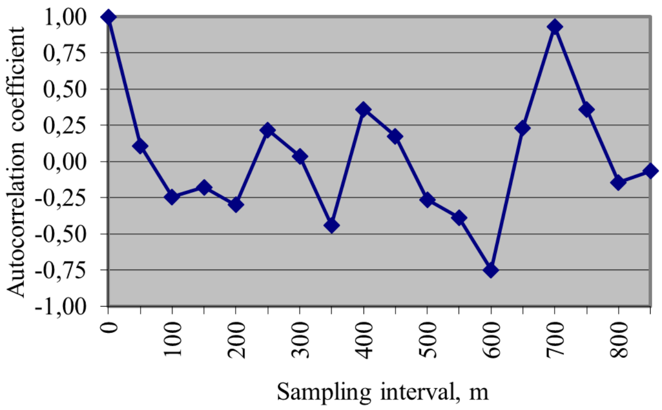

Figure 12. Dependency of the autocorrelation coefficient for the total iron content on the sampling interval, hor. -195÷-210 m.

distinguishing blocks of the smallest possible sizes. But this trend leads to an inexpedient cost of work and unreliable results. It turns out that small closely located blocks are characterized by very similar estimates. It should be kept in mind that as the block sizes decrease, estimation errors increase. Thus, a halving in linear dimensions of blocks leads to an 8-fold increase in the number of blocks to be assessed and, probably, the number of systems of linear equations to be solved. Accordingly, it can be assumed that the minimum block size should be at least a quarter of the average interval of the drilling grid. For example, blocks should have a side of 50 meters with a drilling grid pitch of 200 meters or a side of 200 meters at a pitch of 800 meters.

The most important geological and technological indices of ores of Skelevatske deposit of ferruginous quartzites include the content of magnetic iron which is associated with the total iron content. The nature of magnetic iron content in the exploded mass can be predicted based on the borehole sample data. At that, it is advisable to take the content of total and magnetic iron according to borehole sample data as arguments of prediction. Argument values in the inter-hole space can be determined through interpolation. It is advisable to use kriging as an interpolation method.

4. Results and discussion

The experiment was carried out at the PivdGZK open pit within axes 80-108 along and 89-109 across the strike at horizons -165÷-180 m, -180÷-195 m and -195÷-210 m. The area is located in the north-eastern part of the deposit, the area of oxidized ores makes its southern boundary. Structurally, the area is the eastern wing of the deposit synclinal. In the east, it is bounded by Tarapakiv fault, and its western border coincides with the deposit boundary.

The area is characterized by a sustained occurrence of rocks, weak development of folded deformations. Rocks dip to the north-north-east according to the general deposit sinking.

In the southern part of the area, i.e. on the boundary between the fourth ferruginous quartzites horizon and the fourth schistous horizon, there emerge a number of open folds the size and position of which are clearly seen on the map of the deposit as alternative outbreaks of schists (anticlinal) and quartzites (synclinal).

The initial geological data was obtained from horizon mining plans at a scale of 1:1000. Operational exploration was carried out to sample the exploded mass. At that, sampling areas were of irregular shape and different sizes. The dimensions of the areas ranged from 20 to 50 meters across. The content of total and magnetic iron by detailed exploration boreholes data and horizontal and vertical coordinates of the centers of the sampling areas were taken as arguments for prediction using the multidimensional heuristic prediction algorithm (MHPA). An irregular sampling grid was used for drilling detailed exploration boreholes. Distances between the boreholes ranged from 50 to 200 meters. With the help of kriging, isolines of the content of magnetic iron in the inter-hole space were built. In the center of each sampling area of the exploded mass, the value of magnetic iron was determined based on the available electronic model of isolines. All the acquired values were summarized in spreadsheets, which made the basis for building a predictive function according to the MHPA method. At that, at each stage of its building, credibility of the results obtained was proportional to the inverse distance between the center of the area of sampling the exploded mass and the nearest borehole of detailed exploration, as the greater this distance is, the greater the interpolation error becomes. Thus, the results of building a more accurate function had a greater priority in assessing the quality of the built predictive function.

The basic set of initial data enabled determining dependencies of the magnetic iron content in the exploded mass on that of magnetic iron determined by boreholes of detailed exploration and on the horizontal and vertical coordinates of the points. Three equations of predictive functions obtained by the MHPA method are presented in figures 13-15.

The found dependencies demonstrate that there is a dependency of the magnetic iron content in the exploded mass on that of the sampling data of detailed exploration boreholes, as of all the arguments involved in the MHPA procedure, significant numerical coefficients were determined

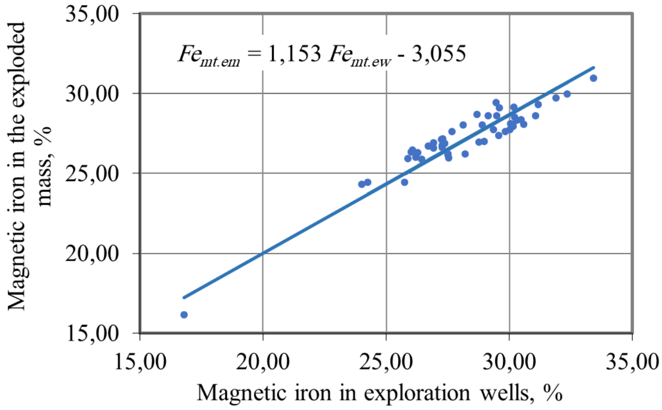

Figure 13. Relationship between the magnetic iron content according to the exploded rock mass sampling data and that of detailed exploration borehole data at hor. -165÷-180 m.

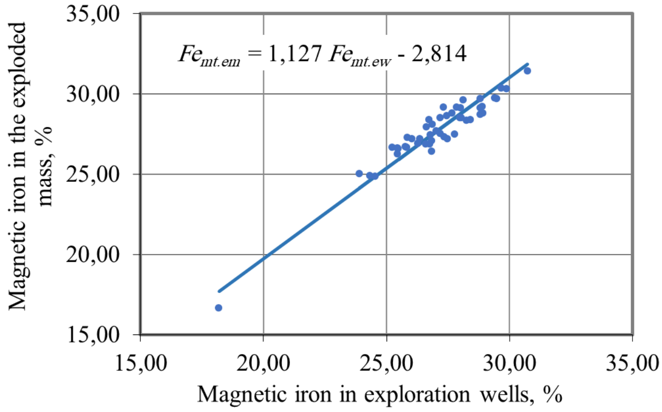

Figure 14. Relationship between the magnetic iron content according to the exploded rock mass sampling data and that of detailed exploration borehole data at hor. -180÷-195 m.

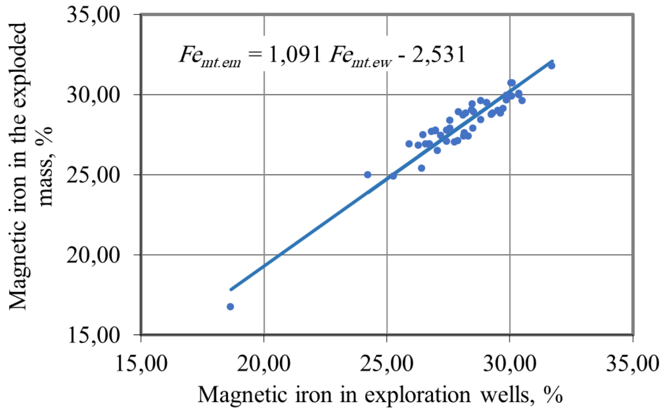

Figure 15. Relationship between the magnetic iron content according to the exploded rock mass sampling data and that of detailed exploration borehole data at hor. -195÷-210 m.

only for this value. During calculations, several types of ores with different properties were identified in the area under consideration and that resulted in determining different functional dependencies.

Areas with properties corresponding to these dependencies on a simulated set of data were obtained and grouped according to the MHPA procedure. At that, the iron content data obtained from detailed exploration boreholes were interpolated for 50 by 50 m square grid nodes.

Interpolation was performed using kriging. Predictive values of the content of magnetic iron associated with the content of magnetic iron in the exploded mass were determined in the square-grid nodes applying the MHPA procedure. Via kriging, these values were interpolated, which became the basis for long-term planning. Based on the interpolation, there were built plans of isolines of the predicted magnetite iron content which are presented in figures 16-18. Predicted data for current planning was received by adjusting the obtained electronic model according to operational exploration data at points spatial position of which was determined on the basis of production needs and was irregular.

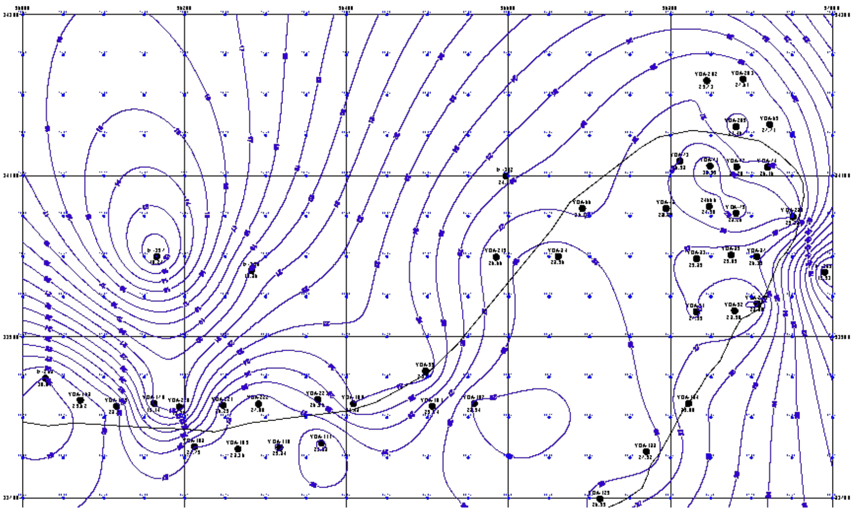

Figure 16. Plan of isolines of the predicted magnetic iron content at hor. -165÷-180 m.

5. Author contributions

The contributions of each author to this research are summarized as follows:

- As the author of the research concept, *Andrii Peremetchyk* played a pivotal role in developing the research methodology, collecting data, and setting the direction for the research. His contributions span across multiple sections of the article, including Introduction, Purpose, Methods, Results and discussion, and Conclusions.
- *Serhii Pysmennyi* actively participated in shaping the research methodology, conducting data analysis, and gaining a comprehensive understanding of the scientific essence of the research. His contributions are prominently featured in the Introduction, Purpose, Methods, and Results and discussion sections.
- *Serhii Chukharev* took charge of data analysis and was responsible for drafting the initial version of the article. His contributions are particularly evident in the Purpose, Methods, and Results and discussion sections.

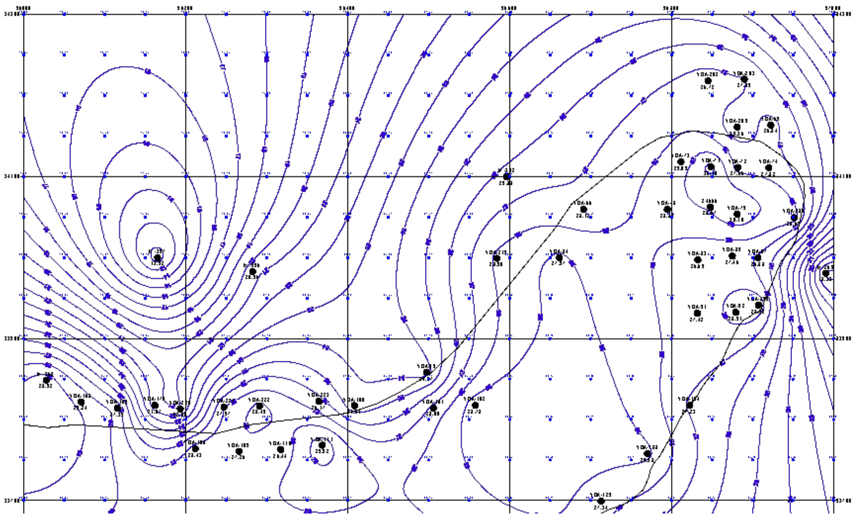

Figure 17. Plan of isolines of the predicted magnetic iron content at hor. -180÷-195 m.

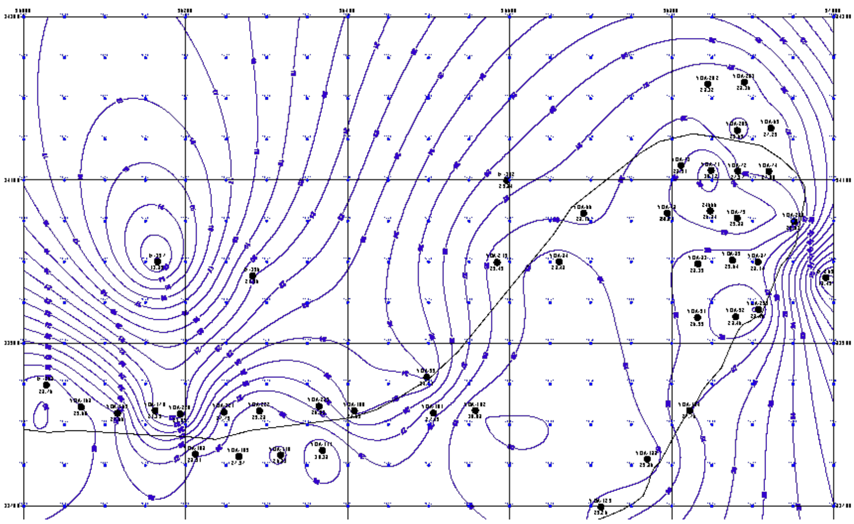

Figure 18. Plan of isolines of the predicted magnetic iron content at hor. -195÷-210 m.

- *Nataliia Shvaher* meticulously processed the raw data obtained during the study and conducted a thorough evaluation of the research results. Her significant contributions are concentrated in the Methods and Results and discussion sections.
- *Serhii Fedorenko* conducted a rigorous statistical assessment of the data's reliability and accuracy of the results obtained. His invaluable contributions are prominent in the Methods and Results and discussion sections.
- *Roland Iosif Moraru* held the responsibility for the overall design of the research methodology, ensuring its coherence and effectiveness. His primary contribution is in the Methods section.

Each author's specific role and expertise greatly enriched the research across various stages, ultimately leading to the comprehensive findings and conclusions presented in this article.

6. Conclusions

As a result of the study, an effective geometrization technique has been developed that meets the requirements of mining production. It enables assessment of mineral reserves and significantly increases efficiency of planning mining operations. The use of geostatistical methods makes it possible to assess and process the initial geological data. The developed self-organizing prediction algorithm is flexible in application, efficient, and can be used in various mining and geological conditions for geometrization of the deposit in order to provide planning and assessment of various mining technologies.

The relative error of the predicted value of the magnetic iron content in the exploded mass according to the developed method for long-term planning does not exceed 6.8%.

The positive results of prediction at the area under consideration are the basis for using the developed methods in other areas of the PivdGZK open pit.

Proceeding from the results, methods of geometrization of mineral deposits based on self-organization and geostatistical assessment are a very promising direction for further research. The considered methods require further development and enhancement in order to increase their efficiency and application at deposits of Kryvbas as well as other regions that produce both ore and non-metallic minerals.

Abstract. The paper describes topical issues of a prospective method for coalmine methane utilization for obtaining an additional valuable energy resource for the regional development of coal-mining areas. It is noted that the development of the extraction of methane resources is very urgent and is of great economic importance for ensuring the energy independence of Ukraine. The experience and technologies of using methane and coalmine gas by global coal-mining companies are analyzed. Modern prospects and opportunities for using coal gas are studied. There is a need to transform the coalmine methane removal system and directions for maximizing the use of its resources in a wide range of concentrations in the composition of gas-air mixtures based on the development of innovative technologies to improve the efficiency and cost-effectiveness of functioning coal-mining enterprises. Attention is focused on the advantages of using gas hydrate technologies for obtaining additional energy resource under conditions of changing coalmine methane concentrations. The specifics of the process of mixed gas hydrate formation from gas mixtures of various geneses have been studied. It has been revealed that it is the coalmine gas-methane composition that determines and forms the basic condition for hydrate formation. The thermobaric conditions for the hydrate formation process at different methane concentrations in gas mixtures of degassing systems have been experimentally determined. The results obtained are the basis for further research on efficiency of creating gas hydrates from coalmine methane and determining its minimum permissible concentration in the gas mixture of degassing systems according to the technological and economic criteria of hydrate formation.

1. Introduction

Rational use of natural resources is the main prerequisite for ensuring sustainable social and economic development [1, 2]. In this regard, state regulation of resource consumption as a tool for environmental management is of great importance in most countries of the world, which is evidenced by a number of international agreements adopted within the framework of the United Nations. For Ukraine, such a tool can be not only the transformation of the coal industry, but also the reduction of operational losses of energy resources of coal-mining and coal-processing enterprises by involving in the economic turnover of associated resources of gas-coal deposits. As for today, coal, oil and natural gas continue to be the main fuel and energy resources [3–7].

In recent years, the energy market has undergone significant changes, which are primarily caused by the ever-increasing needs of society for energy, due to economic and technological development. Leading countries are beginning to fight for the right to develop energy resource deposits on neutral Arctic and Antarctic territories. More stringent environmental regulations are becoming an impetus for the transition to cleaner fuel types [8, 9]. There is a need to search for new alternative energy sources and develop technologies for their mining and use, as well as to improve the efficiency of existing technologies in the energy sector [10–12]. Thus, ensuring energy security is becoming an increasingly complex and multifaceted task.

According to existing predictions and reports, energy consumption is growing every year. Thus, in 2021, the global demand for electricity increased by almost 50% [13]. Analyzing the World Energy Outlook report for 2022, the situation has almost remained unchanged, demand continues to rise, but at a somewhat slower pace, given today's high prices for energy carriers and market instability due to Russia's aggression on the territory of Ukraine [14]. Having faced with market uncertainty and high prices, consumers are withdrawing some of their gas purchases, and industry is reducing production. Despite a strong post-pandemic economic recovery in 2021, the average annual GDP growth rate for the rest of the decade assumed by the Stated Policies Scenario in 2020 has been slightly revised. As a result, energy demand is growing at a slower pace and the fuels used to meet this demand growth are different from previous projections (figure 1) [14].

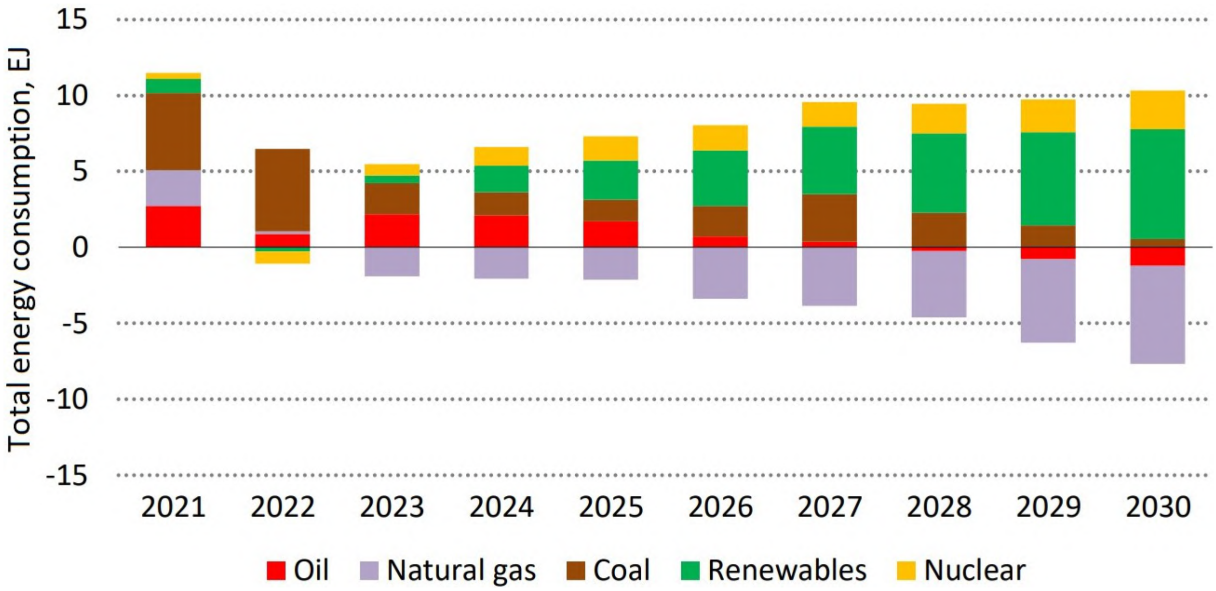

Figure 1. Predicted global consumption of fuel and energy resources [14].

As it can be seen, in the context of the diversification of hydrocarbon sources and the war unleashed by Russia in Ukraine, an unstable situation has developed on the global fuel and energy market. Of particular importance is the issue of determining the energy security prospects of many countries, including Ukraine, by increasing the volumes of domestic gas production or searching for renewable and alternative fuel types [15, 16]. Despite the significant potential of the major types of renewable energy sources, their practical use today is only a small part in the fuel-energy balance (figure 1). Nevertheless, the interest in the development of production technologies for new types of energy raw materials is increasing significantly. Currently, alternative types of gas fuel include methane from coal deposits and coalmine methane [17]; gas obtained from the processing of solid fuel (hard and brown coal, oil shale, peat) [18, 19]; producer gas, other gaseous fuel derived from biological raw materials [20]. Special attention should be paid to the development and implementation of gas production technologies by underground coal gasification [21, 22]. However, according to many scientists, the most promising source of hydrocarbon fuels are gas hydrate deposits found in many countries of the world [23–29].

On an industrial scale, methane is not produced from gas hydrate deposits in the world today.

However, a number of leading countries, such as Japan, the USA, Canada, India, China, Norway, South Korea, Australia, Turkey, Bulgaria and Ukraine, are implementing large-scale research programs and are actively engaged in studying the issue of gas hydrates, both artificial and natural, as well as in the development of hydrate formation and dissociation technologies [30–36]. Assessment of the economic efficiency of gas hydrate projects requires certain clarifications. This uncertainty is aggravated by the ongoing search for both optimal technologies for the development of gas hydrate deposits, as well as obtaining gas hydrates for their use when transporting hydrocarbon raw materials.

Obviously, natural gas remains the most commercially prepared energy carrier [37]. Therefore, consideration of issues related to the development of hydrocarbons [38–40] and the industrial utilization of natural reserves of methane – the most demanded fuel in Ukraine – is extremely relevant and is of great economic importance for ensuring the energy independence of our country [41, 42].

2. Prospects and opportunities of using coal gas

Given the interest in non-conventional energy sources, more and more attention has recently been paid to coal seam gas, which can be extracted by implementing innovative coal-mining technologies. The successful experience of gas companies in the United States has even led to the announcement of the creation of a gas subsector dedicated to the methane production from coal seams [43–45]. By combining the interests of the gas and coal industries, it is possible to ensure and significantly improve the technical, economic, ecological and social conditions of the population in industrial regions.

Over the past 15-20 years, this area has received significant attention and intensive development in the United States, where the average volume of gas production from coal seams is 55 billion m^3 annually, in Canada – more than 9 billion m^3, in Australia – 5.5 billion m^3, in China – 1.2 billion m^3, Russia – 6 million m^3 [46–48].

Natural gas from coal seams is 90% or more methane. Methane is the purest hydrocarbon energy source with almost no harmful impurities, such as nitrogen or sulphur compounds. Currently, commercial production of methane from coal seams is carried out only in the United States. Over 9 thousand wells are in operation, of which more than 40% are located in the San Juan Basin. About 10% of wells in this basin provide 75% of its production and 60% of the total annual coalmine methane production in the United States [49, 50].

Also, in recent years, technologies for using ventilation gas removed from the mine along with the ventilation air flow have gained significant development. The first major project of this kind in the world is the Australian West Cliff Ventilation Air Methane Project (WestVAMP), which converts a part of the ventilation jet into heat and electricity using the VOCSIDIZER™ energy system from the Megtec Company (Sweden) [51]. This technology involves the use of ventilation gas with an extremely low methane concentration of 0.3-1.2%, but requires further improvement due to low economic efficiency. The Natural Resources Company (Canada) developments use reverse-flow reactors (Catalytic Flow Reversal Reactor, CFRR), which are also designed to generate heat by utilizing an off-standard gas mixture with 0.5-1.0% methane content [52].

When mining coal deposits, outgoing gas-air flows occur, which are formed in the process of diluting the released gas with atmospheric air and methane-air mixture sucked from the mined-out area and drilled wells in the coal-rock mass (figure 2) [53]. Under the conditions of high methane-bearing capacity of coal deposits, degassing is the main way of ensuring the coal-mining safety. Therefore (regardless of other possibilities of using the methane-air mixture), the main condition remains the extraction of gas from the coal-rock mass and the mined-out area, its localization and removal to the surface or to the outgoing jet.

In Ukraine, coal mines emit most of the methane (up to 90%) into the atmosphere in the form of a low-concentration gas-air mixture from mine ventilation units. In 2016, about 517

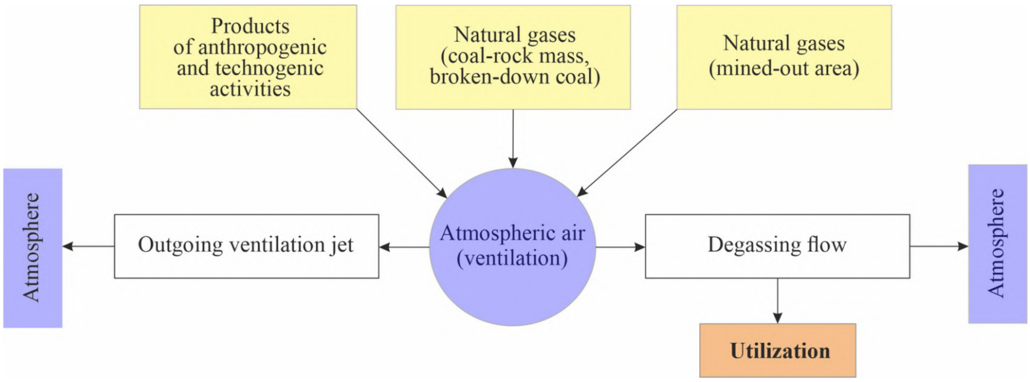

Figure 2. Scheme of formation of the outgoing gas-air flows [53].

million m^3 of methane gas was released during coal mining by 50 mines [54], which is equivalent to the production of 3.3 billion kWh or 3.0 billion m^3 of burned natural gas and exceeds the electricity consumption of all coal-mining enterprises in Ukraine. In global practice, mixtures with a methane concentration above 25-50% are most efficiently utilized. Therefore, it can be concluded that the energy potential of coalmine gas-methane during mining operations is extracted from the bowels, and its potential is not fully utilized for the needs of industry and the population.

Thus, in the conditions of the most powerful coal-mining enterprise in Ukraine, PJSC Mine Administration "Pokrovske", a universal combined degassing method is used – underground method, which extracts about 60% of coal methane, and degassing from the surface, extracting 40% of methane. The underground degassing system is represented by a network of degassing pipelines in mine workings, through which, using two vacuum-pump stations on the surface, coalmine methane is extracted through drilled wells from the mined-out area and the coal mass of the extraction sites. The methane concentration in the gas-air mixture during underground degassing varies widely, ranging from 15 to 70%. Surface degassing involves drilling degassing wells every 300 m in extraction panels ahead of the stoping faces in highly stressed longwall faces. The methane concentration in the gas-air mixture with this method is extremely high, since the mass is not de-stressed and ranges between 90-98%. For gas utilization, a cogeneration plant with a capacity of 18 MW has been implemented at the enterprise, but only up to 40% of methane is utilized, because its flow rate and concentrations are variable, making it difficult to utilize it.

In most other coal mines in Ukraine, coal methane is currently extracted to the surface as part of ventilation jets and underground degassing systems. In this case, the methane-air mixture coming to the surface is usually substandard and is released into the atmosphere or burned. Only if the methane content in the gas-air mixture exceeds 25%, it becomes possible to use cogeneration plants. Thus, at the Stepova mine (PJSC "DTEK Pavlohradvuhillia") for a year, about 6 million kW of electricity has been generated from 1.3 million m^3 of extracted coalmine methane using a cogeneration plant [55].

In this regard, the problem of the large scale of coalmine gas utilization is becoming increasingly important, the great difficulties of which are associated with the variability of its flow rates and the different methane content in the extracted mixtures, as well as the limitated possibility of using cogeneration plants to generate electrical or thermal energy [56, 57].

Therefore, today it is required to transform the coalmine methane removal system and the directions for maximizing the use of its resources in a wide range of concentrations in the composition of gas-air mixtures (15-98%) based on the development of innovative technologies to improve the efficiency and cost-effectiveness of functioning coal-mining enterprises.

3. Advantages of using gas hydrate technologies for obtaining additional energy resource

As a result of significant variations in methane concentration in the gas mixtures of degassing wells, its widespread use is becoming more difficult. Therefore, it becomes necessary to create a method for producing methane in the final chain of mining gas-coal deposits, for which the component composition of the outgoing gas would not be a stringent condition. This method, according to the authors, is the conversion of gas into a solid gas-hydrate state, since gas-hydrate technology makes it possible to convert various gases into hydrates, including their mixtures. In this case, only the equilibrium conditions of the hydrate formation process will change [58, 59]. It is easier and safer to store and transport methane in the state of gas hydrates to industrial and energy companies for its further use as an energy carrier, which is another advantage of gas hydrate technologies [60, 61].

Hydrates are formed and stably exist in a wide range of thermobaric parameters. But each individual gas is characterized by certain variants of pressures and temperatures of the hydrate phase stability existence. The main factors determining the conditions for hydrate formation and storage of gas hydrates, first of all, should be considered the composition of gases, their moisture saturation, phase state, composition and state of water, its mineralization, external pressure and temperature [62]. The gas composition determines the basic condition for hydrate formation – the higher the molecular weight of an individual gas or mixture of gases, the lower the pressure required for hydrate formation at the same temperature. Natural gases, consisting of a combination of individual components, form mixed gas hydrates. In this case, during hydrate formation, crystals are simultaneously formed, which are characteristic of both methane and other hydrocarbon and associated gases in the mixture. That is, for the conditions of gas-air mixtures of degassing systems in coal mines, it is possible to apply the concept of mixed gas hydrates.

The following characteristic stages are distinguished during hydrate formation:

1) formation of gas hydrate crystallization centers;
2) sorption growth of crystalline hydrates around crystallization centers;
3) mass crystallization or simultaneous increase of a large number of formed crystallization centers.

Further in the research, the possibility of creating methane gas hydrates from degassing gas mixtures of a coal mine with a wide variation of methane concentrations is experimentally studied.

4. Research methods

The conversion of methane-air mixtures of degassing systems into the gas-hydrate state, when mining gas-coal deposits, would solve a number of difficulties related to their utilization and subsequent use. However, the specificity of the component composition of gas mixtures necessitate the development of optimal parameters for the hydrate formation process. The process of nucleation and formation of gas hydrates from gas mixtures of various geneses is more complex than from individual gases, which manifests itself in the changing value of equilibrium parameters for hydrate formation and its rate.

In order to determine the patterns of the hydrate formation process and the influence of various technological and regime parameters on it, a bench unit has been developed, consisting of an ILKA KTK-3000 Climatic-Thermal Chamber and a number of other measuring equipment. The Climatic-Thermal Chamber allows conducting research in different temperature conditions and with different humidity. Structurally, the Climatic-Thermal Chamber has four main parts:

the working volume, in which the NPO-5 hydrate formation reactor is directly located, the automatic control panel, the refrigeration unit and the steam generator. The NPO-5 unit is equipped with a reducer, which makes it possible to regulate the pressure of the gas mixture from 0 to 10 MPa and maintain it constant throughout the entire duration of the experiment [63].

A transparent polymer pipe with a wall thickness of 2.5 mm is used for conducting experimental research and visual observation of the hydrate formation and hydrate accumulation processes. To record the pressure and velocity of the water and gas flowing out of the high-pressure nozzles, the unit is equipped with a measuring system consisting of a direct-acting indicating pressure gauge, a thermometer, an anemometer and a PC-based measuring station. To conduct experimental research on the process of hydrate formation from gas mixtures, jet-forming nozzles of an original design are used.

5. Research results

For reasons of clarity of the experiment and the comparison of the obtained further results, the process of hydrate formation from pure methane is studied as a standard at the first stage, the actual volume fraction of which is 99.7%. The hydrate formation curve and process parameters are given in figure 3.

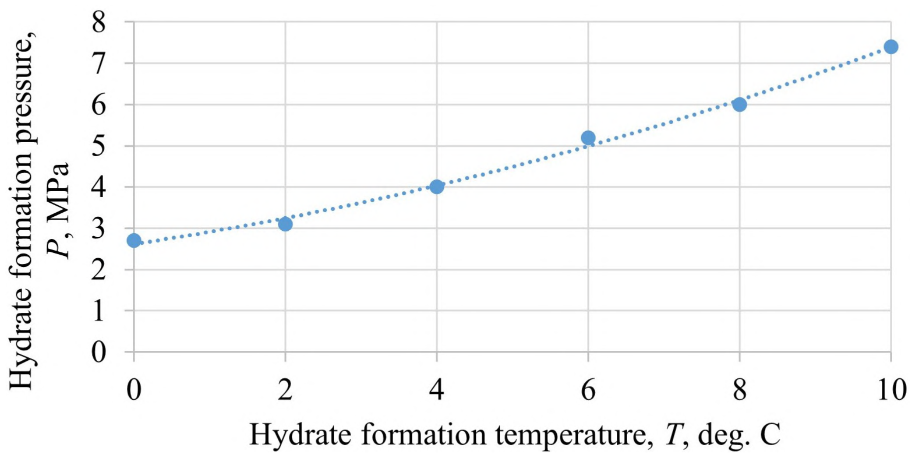

Figure 3. Parameters of the methane hydrate formation process.

The resulting pattern of methane gas hydrate formation (Fig. 3) has a polynomial character with the value of approximation reliability $R^2 = 0.99$ and is described by the equation $y = 0.02x^2 + 0.27x + 2.62$. The pressure range varies from 3 to 7.5 MPa. This has experimentally proven the fact that at pressures below 3 MPa, the hydrate formation process using pure methane is difficult and requires a sufficiently long time to start crystallization with the formation of crystalline hydrate nuclei (according to existing data, up to several days). Accordingly, it is inexpedient to conduct research under such pressures. The increase in temperature parameters occurs naturally with increasing pressure and reaches its maximum value at +10°C.

In order to study the influence of thermobaric parameters on the conditions for the formation of gas hydrates, depending on methane concentration in gas mixtures of degassing systems, samples have been taken directly from the Western Donbas coal-mining enterprises. Their compositions are given in table 1.

The thermobaric parameters of the hydrate formation process from gas mixtures of degassing systems have been obtained experimentally (figure 4). Methane concentrations in the selected mixtures range from 47 to 95%, reflecting their real wide variation with degassing methods in

Table 1. Compositions of gas mixtures obtained from degassing systems.

No.	Methane	Ethane	Propane	Butane	Carbon dioxide	Nitrogen
Mixture 1	0.95	0.02	0.025	–	0.005	–
Mixture 2	0.86	0.06	0.04	0.01	–	0.03
Mixture 3	0.75	0.06	0.04	–	0.01	0.14
Mixture 4	0.54	0.15	–	–	0.21	0.10
Mixture 5	0.47	0.08	0.07	–	0.33	0.05

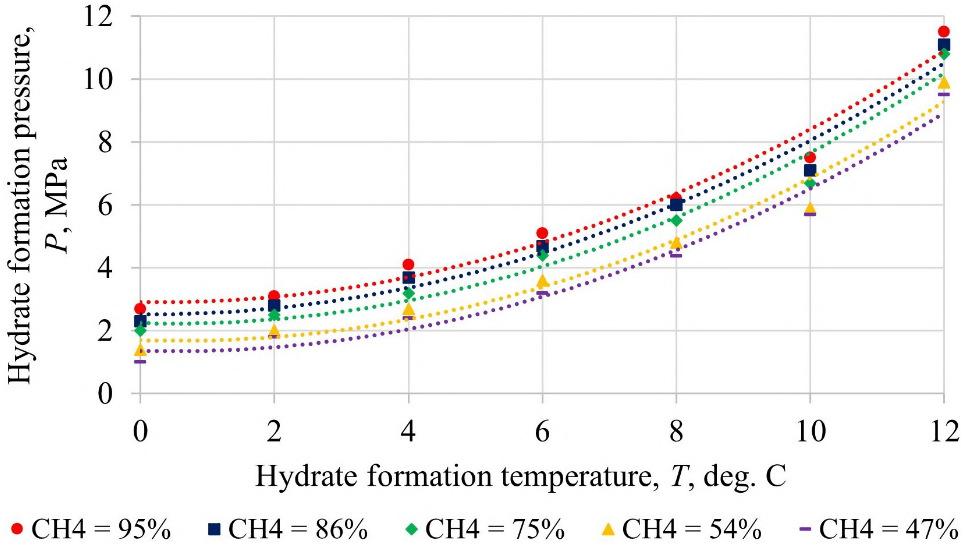

Figure 4. Parameters of hydrate formation of gas mixtures in degassing systems in the Western Donbas mines.

coal mine conditions. The resulting dependences of pressure on temperature change according to a polynomial law with an approximation value of $R^2 = 0.97$ for each separately selected mixture.

At the same time, the highest pressures of hydrate formation are for a mixture with a methane concentration of 95%, and the lowest, respectively, for a mixture with 47% methane in the gas mixture (figure 4).

The patterns of the gas hydrate formation process from mixtures of various genesis, depending on pressure and temperature, are described by the following equations:

– at $CH_4 = 47\% - y = 0.06x^2 - 0.06x + 1.37$;
– at $CH_4 = 54\% - y = 0.06x^2 - 0.07x + 1.70$;
– at $CH_4 = 75\% - y = 0.06x^2 - 0.06x + 2.25$;
– at $CH_4 = 86\% - y = 0.06x^2 - 0.02x + 2.53$;
– at $CH_4 = 95\% - y = 0.06x^2 - 0.04x + 2.92$.

Also, the formation parameters of mixed gas hydrates are influenced by the presence of carbon dioxide in the mixture, in addition to hydrocarbon gases. It has been found in the previous research that the pressure required to form carbon dioxide hydrates is by 20-30% lower than for methane hydrates, depending on the conditions of hydrate formation. This fact is also observed during the formation of mixed gas hydrates, although the CO_2 share in the mixtures is quite low.

In the future, for the production of gas hydrates from coalmine methane, it is proposed to build a hydrate formation complex near the facilities of degassing systems in the surface mine complex, followed by their transportation by mobile refrigerators to consumers (industry, population, etc.) and settlements located near the coal mine.

To evaluate the economic efficiency of the proposed technological solutions in the future, it is planned to use the methods of economic and mathematical modeling, taking into account the capital investments in equipment, the cost of the final product, the determination of operating costs, the reduction of charges for atmospheric pollution, the level of consumption by the population or industrial enterprises of gas obtained by the gas hydrate method.

6. Conclusions

The energy market has undergone significant changes in recent years, which are caused by the growing needs of society for energy resources. In the context of diversification of hydrocarbon sources, the issue of ensuring the energy security of many countries of the world and Europe is of great importance. This encourages the search for new alternative energy sources and the development of innovative technologies, in particular, gas hydrate technologies.

The prospects and possibilities of using coal gas in the implementation of innovative technologies for mining gas-coal deposits have been studied. The experience and technologies of using methane and coalmine gas by global coal-mining companies have been analyzed. The experience of many American enterprises and companies has even made it possible to declare the formation of a gas subsector dedicated to the methane production from coal seams. The experience of Australia and Canada on the use of ventilation gas carried out of the mine together with the ventilation air flow has been studied.

The experience of using degassing systems at Ukraine's largest coal enterprise PJSC Mine Administration "Pokrovske", which uses both underground degassing and surface degassing methods, has been analyzed. For gas utilization, a cogeneration plant has been implemented at the enterprise, but only up to 40% of methane is utilized, because its flow rate and concentrations are variable, making it difficult to utilize it. Thus, in most other coal mines in Ukraine today, the methane-air mixture coming to the surface is usually substandard and is released into the atmosphere or burned. Therefore, it becomes necessary to create a method for producing methane in the final chain of mining gas-coal deposits, for which the component composition of the outgoing gas would not be a stringent condition. This method is the implementation of gas hydrate technologies for obtaining the final product.

The main factors influencing the conditions for the hydrate formation process and storage of gas hydrates, as well as their thermobaric parameters have been determined, which should be further taken into account when developing a technological scheme for the utilization of methane mixtures. The specifics of the process of mixed gas hydrate formation from gas mixtures of various geneses have been studied. It has been revealed that it is gas composition that determines the basic condition for hydrate formation.

A number of experimental researches on the process of obtaining gas hydrates from methane-air mixtures of various geneses have been conducted. In addition, the peculiarities of hydrate formation, which are typical for the formation of mixed gas hydrates, have been determined. For reasons of clarity of the experiment, the process of hydrate formation from pure methane has been studied as a standard, the actual volume fraction of which is 99.7%. The hydrate formation pressure varies in the range of 3.0-7.5 MPa, since at pressures lower than 3.0 MPa, the process of crystal hydrate nuclei formation takes a long time.

The thermobaric conditions have been determined for the hydrate formation process at various methane concentrations in gas mixtures of degassing systems (47-95%), indicating their wide variation depending on the method of degassing in different coal mines. The dependence of the methane concentration on the hydrate formation pressure has been revealed: the higher the CH_4 concentration in the mixture, the higher the gas hydrate formation pressure should be.

Abstract. The aim of the research is the analysis and modeling of the process of sedimentation of the solid phase of the pulp in the technological units of processing plants to assess the density of particles of crushed ore. The paper analyzes domestic and foreign experience; methods of mathematical modeling were used, as well as methods of mathematical statistics and probability theory for processing the results of experiments. Scientific novelty consists in developing and substantiating a method for estimating the density of crushed ore particles in the process of their sedimentation directly in the process units of beneficiation plants. Practical value consists in developing a methodology for determining the characteristics of the enriched raw materials, which make it possible to form the degree of grinding necessary for the full disclosure of mineral formations. It was proposed to use the density of ore particles as an indicator of changes in the quality characteristics of the ore received for beneficiation, which is determined on the basis of measurements of the attenuation of volumetric ultrasonic waves and Lamb waves propagating in the pulp and the wall of the technological sump that is in contact with it. These measurements must be synchronized with the results of measurements of the pulp level in the sump during its working operation. The proposed method makes it possible to dynamically correct the parameters of the model of a closed ore grinding cycle, depending on the quality characteristics of the feedstock, and thereby form the conditions for the full disclosure of inclusions of the useful component in the product entering the magnetic separation or flotation.

1. Introduction

In the world practice of extraction and processing of minerals, geological reserves of ore with a high content of a valuable component are constantly declining [1, 2]. In this regard, mining and metallurgical enterprises are faced with the problem of rational use of ore with a high content of useful minerals and the development of technologies that allow efficient processing of low-grade ores [3]. Many efforts are being made to rationally use poor ores to extend the life of developed deposits and achieve acceptable financial results, such as optimizing the cut-off grade of a useful component [4, 5], mining production schedule optimization [6, 7], improvement of technologies for enrichment of extracted raw materials [8, 9].

In mineral processing, grinding is used to reduce the particle size of the ore in order to expose the valuable mineral component and recover it in subsequent processing operations such as flotation or magnetic separation [10]. The specific particle size of the crushed ore is the most important production indicator, which is a prerequisite for ensuring the quality of the resulting concentrate. The difficulty of achieving this condition is due to the fact that the process of grinding ore depends on a large number of operating parameters. In addition, the composition of iron ore is unstable and its quality deteriorates with a decrease in geological reserves [1].

Because of these difficulties, much attention has been paid to research into the grinding process [11]. With the development of new intelligent modeling and control methods, many of them have been successfully implemented in the field of mineral processing. Recently, advanced methods based on predictive control with a model have been widely discussed [12,13], supervisory control with intelligent decision support system [14, 15] and others to optimize the technological operations of ore beneficiation.

However, the grinding process is difficult to describe using mathematical models, since the real technological complex that implements it is a multiple input multiple output (MIMO) system with large inertia, nonlinearities, strong feedbacks, uncertainty, and the presence of a large number of perturbing factors [16]. Moreover, due to the lack of high-quality information support, which makes it possible to obtain real-time data on the main variables of the grinding process, its optimal control cannot be realized even on the basis of the most advanced models [17].

Under these conditions, the combination of the advantages of various methods of analysis and modeling makes it possible to more accurately and comprehensively simulate the real operating conditions of technological units [18, 19].

As the importance of process information grows [20, 21], there is a growing need to develop methods that can automate the processing and interpretation of the received data.

In work [22] the importance of data quality assessment for the development of semi-rigorous and empirical models of the primary grinding scheme at the concentrator is emphasized.

The key task of information support for the effective management of ore grinding-classification processes is the operational measurement of its granulometric composition and determination of the degree of grinding required, depending on the physical-mechanical and chemical-mineralogical properties of the enriched raw material. A promising direction in the development of methods to solve this problem is the use of non-contact non-destructive testing tools based on ultrasonic, magnetometric and nuclear-physical measurements [23].

There are different mineralogical varieties of ore that enters the beneficiation process. These varieties differ in several characteristics of inclusions of a useful component (fineness of inclusions), which requires various degrees of grinding for its complete disclosure. As a marker of the changed qualitative composition of the crushed ore, it is proposed to use the density of particles of the solid phase of the pulp in the process of its deposition directly in the technological units of concentrating plants. This parameter is determined based on the results of measuring the attenuation of bulk ultrasonic waves and Lamb waves propagating in the iron ore pulp and metal platinum that is in contact with it, as well as the level of the pulp in the process tank in which it is located.

2. Results

In many technological units of the processing plant, during their operation, particles of crushed ore are deposited in the pulp, i.e. in certain volumes, sedimentation and thickening of the solid phase of the pulp occurs. When performing operations such as desliming, thickening and clarification, these processes are part of the technology used, while in intermediate process tanks, sumps, they are a factor that introduces a disturbing effect, the effect of which on the technological process, in this regard, should be taken into account.

On figure 1 it is shown a typical technological scheme of the process of grinding ore during its enrichment, which is widely used in processing plants [22]. Initial ore and water are supplied to the mill, which operates in a closed cycle with hydrocyclones. Their flow is monitored by WT, FT sensors and controlled by closed local automatic control systems (ACS) based on proportional-integral-derivative (PID) controllers. The ore crushed in the mill is pumped through the Mill Discharge Sump to the Cyclone Clusters. Hydrocyclone sands are returned to the mill, and the overflow through the Rougher Feed Tank is fed further to flotation or magnetic separation. The diagram provides for the control of the mill rotation speed and the control loops for the additional water flow to the process sump and the performance of the pump supplying the pulp to the hydrocyclones. The control strategy and its technical implementation by the grinding cycle can differ significantly at different concentrators,

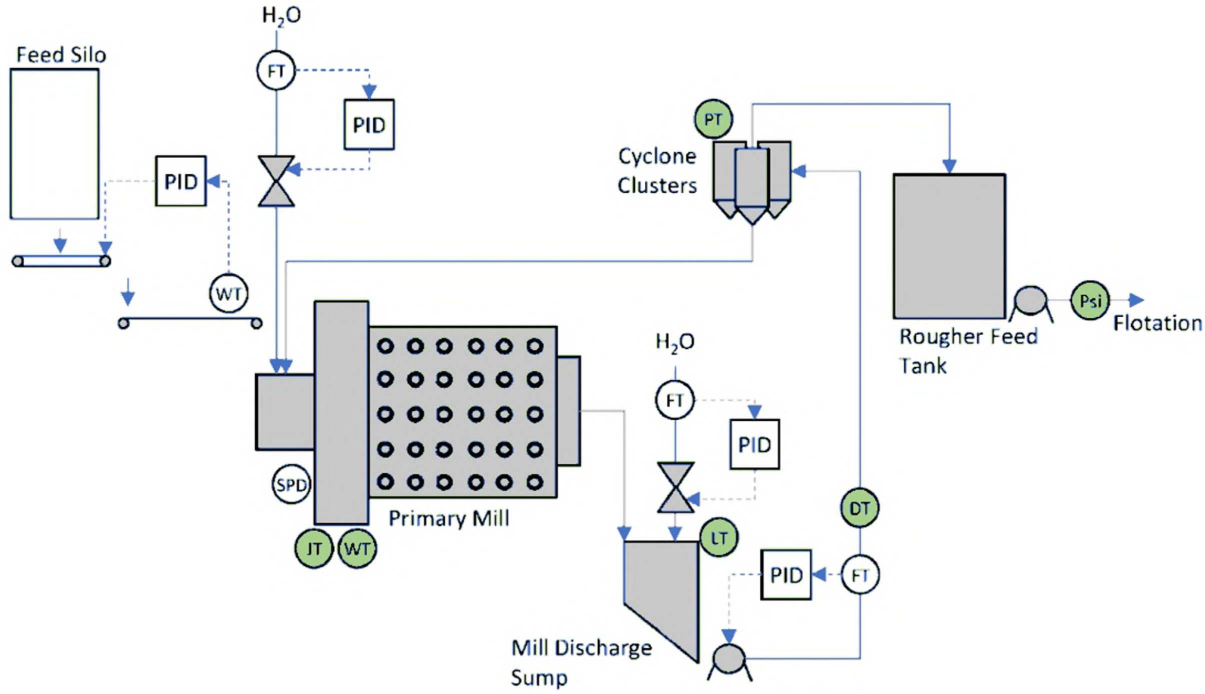

Figure 1. Technological scheme of the closed cycle of ore grinding [22].

As shown above, the task of the ore grinding cycle is the complete disclosure of inclusions of a useful mineral in the original ore for its subsequent extraction in concentrators. It follows from the above diagram that the characteristics of the product entering the hydrocyclones have a decisive influence on the conditions for its classification by size and specific gravity (density) of ore particles, and, consequently, on the results of extracting the useful component in the enrichment apparatus. Thus, the conditions and characteristics of the process of sedimentation of the solid phase of the pulp in the Mill Discharge Sump (taking into account the characteristics and conditions of the formation of input and output products, as well as additional water consumption) directly affect the quality indicators of the entire ore grinding cycle.

In accordance with the main position of the kinematic theory of sedimentation [24, 25] the relative velocity v_r of particles of the solid phase and liquid depends only on their local concentration. In this case, the flux density function is determined by the expression:

$$h(u) = u(1-u)v_r(u), \tag{1}$$

where u is the dimensionless volume fraction of solid particles.

For calculations of the designs of sedimentation tanks (thickeners) of continuous action, the transport term $q(t)u$ is used, where $q(t)$ is the controlled flow rate of the mixture [26, 27]. This leads to the equation of continuous suspension settling:

$$\frac{\partial u}{\partial t} + \frac{\partial\left(q(t)u + h(u)\right)}{\partial x} = 0, \tag{2}$$

where t is time and x is depth.

The function $h(u)$ depends on the material properties of the studied suspension [25, 28]. However, in order to use (2) to simulate continuous deposition, it is necessary to explicitly model the feed and discharge mechanisms and provide the boundary conditions [29].

On figure 2 it is shown the main notation and variables used in the mathematical model of the sump in the technological chain of the closed grinding cycle [22, 30, 31].

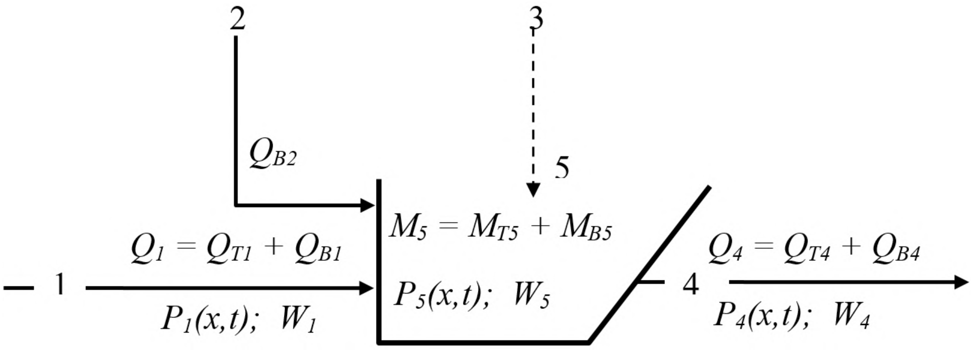

Figure 2. Balance of ore flows and granulometric composition of processed ore in the technological sump.

$Q(t)$ denotes the flows at the corresponding points of the technological process, W is the content of the solid phase of the pulp, $M(t)$ is the mass of material in the technological units at time t. In addition, when modeling the grinding cycle, the following designations were adopted: $P(x,t)$ is the cumulative yield of solid particles whose size is less than x; $\bar{X}_i = \left[\frac{\partial P(x,t)}{\partial x}\right]_i \Delta x$ – fraction of the crushed material, the particle size of which belongs to the size interval i. Consider the movement of crushed material through the technological sump. We will assume:

$$W_5 = \frac{M_{T_5}}{M_5} = \frac{Q_4}{Q_4} = W_4. \tag{3}$$

Material mass balance equations in the technological sump [22, 30]:

$$\bar{M}_5 = Q_{B_2}(t) + Q_1(t) - Q_4(t); \tag{4}$$

$$\bar{M}_{T_5} = Q_{B}1(t) - Q_4(t); \tag{5}$$

$$\bar{M}_{B_5} = Q_{B_1}(t) + Q_{B_2}(t) - Q_{B_4}(t); \tag{6}$$

$$M_5 = M_{T_5} + M_{B_5}; \tag{7}$$

$$Q_4 = Q_4 + Q_4. \tag{8}$$

Equation for the balance of mass and fineness of the crushed material for the technological sump:

$$\frac{\partial\left[P_5(x,t)M_5(t)\right]}{\partial t} = P_1(x,t)Q_1(t) - P_4(x,t), \tag{9}$$

or in discrete form:

$$\begin{array}{c}\bar{X}_5 = \left[-\frac{Q_{T_1}}{M_{T_5}} I\right] X_5 + \frac{Q_{T_1}}{M_{T_5}} X_1 \\ X_4 = X_5.\end{array} \qquad (10)$$

In this expression, X_1, X_5 and X_4 characterize the dynamics of the granulometric composition of the loaded, internal and output products of the technological sump [30].

System (10) can be written in the following form:

$$\begin{array}{c}\bar{X}_5 = A_5 X_5 - A_5 X_1 \\ X_4 = X_5.\end{array} \qquad (11)$$

where $A_5 = -\frac{Q_{T_1}}{M_{T_5}} I$.

In steady state:

$$\bar{X}_5 = \bar{M}_5 = 0; \qquad (12)$$

$$X_5 = X_1. \qquad (13)$$

Taking into account the fact that the output flow of the sump Q_4 is determined by the performance of the hydrocyclone feed pump, we can write:

$$\bar{M}_{T_5} = Q_{T_1} - Q_4 \frac{M_{T_5}}{M_{T_5} + M_{B_5}}; \qquad (14)$$

$$\bar{M}_{B_5} = Q_{B_2} + Q_{B_1} - Q_4 \frac{M_{B_2}}{M_{B_5} + M_{T_5}}. \qquad (15)$$

In the table 1 it is shown the density and grindability for 7 types of ores, which are mined and processed from one of the deposits of the Krivoy Rog iron ore basin. In this case, the following designations of ore types are accepted [32]: 1 – magnetite hornfelses; 2 – silicate-carbonate-magnetite hornfelses; 3 – red-banded magnetite; 4 – semi-oxidized and oxidized hornfelses; 5 – silicate schists, barren hornfelses, and quartz; 6 – magnetite-silicate-carbonate (poor) hornfelses; 7 – hematite-magnetite hornfelses.

Table 1. The results of the analysis of ores of various types.

Ore type	Quartz, %	Magnetite, %	Martit, %	Hematite, %	Siderite, %	Density, kg/m^3	Grindability, K
1	63.7	30.9	0	1.4	3.8	3431	1.06
2	68.4	21.7	0	0.4	9.1	3248	1.25
3	64.5	30.2	0	1.5	3.8	3414	1.48
4	65.4	24.4	3.3	3.7	3.2	3412	1.76
5	74.6	4.5	0	0.7	20.2	2989	1.29
6	75.2	6.8	0	0.8	17.2	3009	1.64
7	60.8	31.4	0	5.4	2.5	3530	1.18

The density of a particular type of ore with known values of the mass fraction of minerals is calculated by the formula [32]:

$$\rho = \frac{\rho \rho \beta}{\rho \alpha + \rho \left(\beta - \alpha\right)}, \qquad (16)$$

where ρ_m, ρ_n – mineral and rock density; β_m, α – mass fraction of the component in the mineral and ore; V_m, V_p – the volume of the mineral and rock in the ore.

Variations in the qualitative properties of enriched raw materials lead to changes in the results of grinding, opening of mineral formations and precipitation conditions (function $h(u)$) in the expression 2 particles of crushed ore in the technological sump.

The basic level of modern automatic process control systems (APCS) for grinding are local automatic control systems (ACS) of individual process variables (figure 1). At the same time, the models of regulated objects are approximated by an aperiodic link of the first order with sufficient accuracy for practical problems. Variations of the mineralogical varieties and characteristics of the ore received for enrichment lead to ambiguous results of the operation of the mill, technological sump and hydrocyclones, as well as their models, as objects of automatic control [32]. On figure 3 it is shown the results of the influence of this ambiguity based on the analysis of expressions (10), (14), (15).

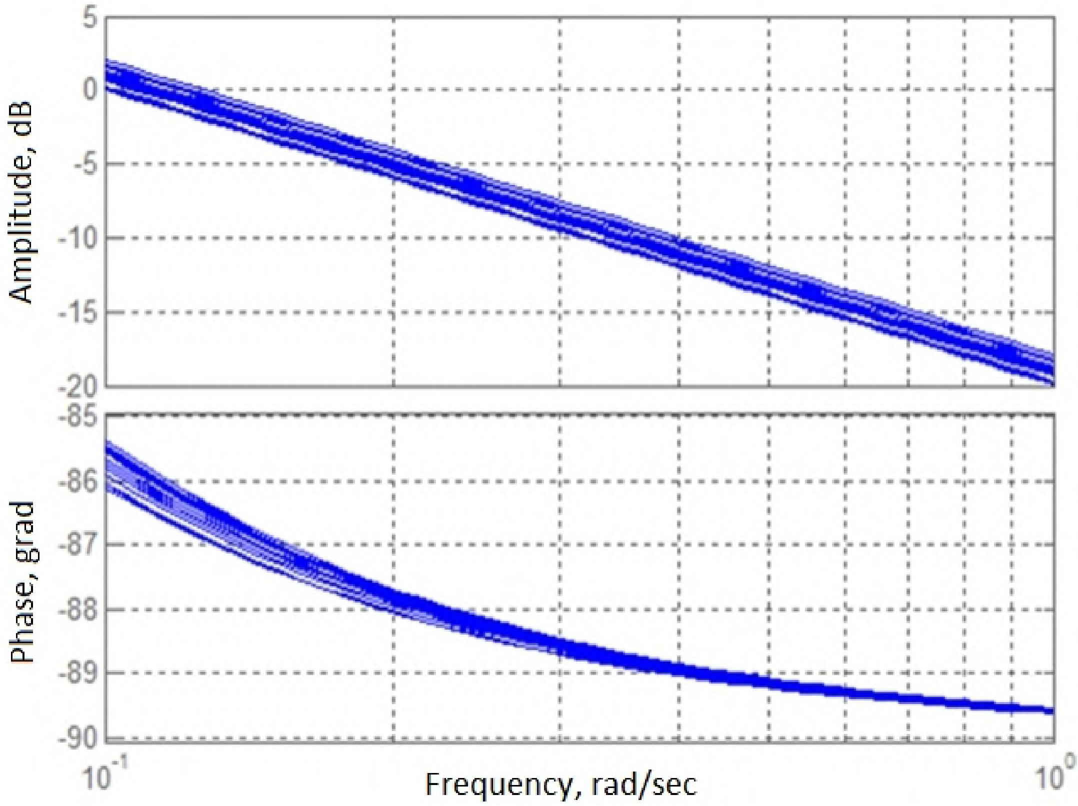

Figure 3. The family of frequency characteristics of the object of treatment with variation of parameters in the model.

To maintain the degree of grinding of the initial ore necessary for the full disclosure of the useful component, when $h(u)$ changes, the amount of additional water supplied to the technological sump is corrected.

It is proposed to estimate the changes in $h(u)$ based on the results of determining the density of particles of the solid phase of the pulp during its working settling in technological sumps of the grinding cycle.

Consider the process of movement of the pulp in the technological sump (figure 4).

The Bernoulli equation for the flow of a viscous liquid (pulp) has the form:

$$\rho g Z_1 + P_1 + \alpha_1 \rho \frac{V_1^2}{2} = \rho g Z_2 + P_2 + \alpha_2 \rho \frac{V_2^2}{2} + \rho g \sum h_n, \tag{17}$$

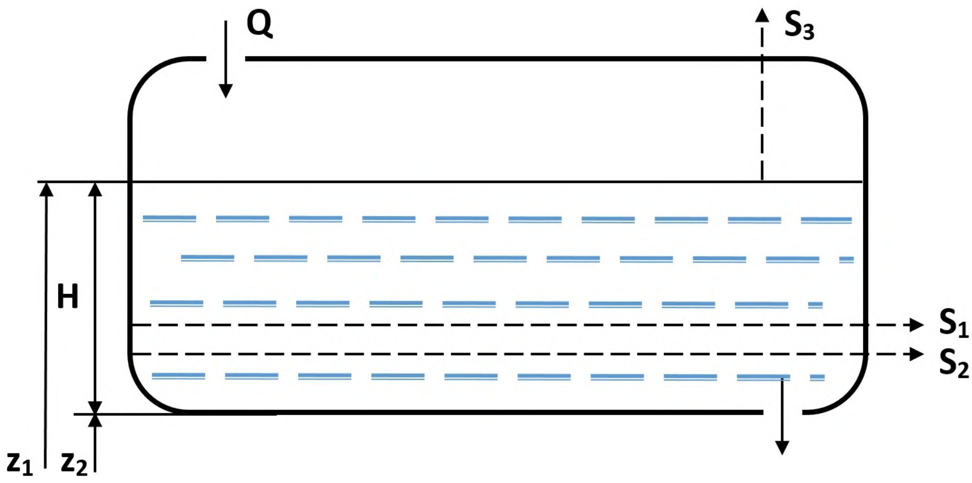

Figure 4. Scheme of measurements and movement of the pulp in the technological sump.

where ρ – pulp density.

Let the conditions:

$$P_1 = P_2, V_1 = 0. \tag{18}$$

In this case, expression 17 will take the form:

$$\rho g(Z_1 - Z_2) = \alpha_2 \rho \frac{V_2^2}{2} + (\sum h_n) g\rho; \tag{19}$$

$$\sum h_n = \xi_. \frac{V_2^2}{2g} + \xi_c \frac{V_2^2}{2g}, \tag{20}$$

where $\xi_{TP} = \xi_{TP}(W, \rho_T, \eta)$; $\eta_c = const$; η – controlled size class of crushed material in the pulp flow; $H = Z_1 - Z_2$; W – volume fraction of the solid phase of the pulp; ρ_T is the density of particles of the solid phase of the pulp.

Then:

$$H = (\alpha_2 + \xi_c + \xi_.) \frac{V_2^2}{2g}. \tag{21}$$

Let us denote by Q the volume of incoming pulp per unit time. From the condition of equality of the volumes of incoming and outgoing pulp for the velocity V_2, the relation:

$$V_2 = \frac{Q}{\sqrt{\alpha_2} S_{c2}}. \tag{22}$$

Taking into account (21), we have:

$$H = (\alpha_2 + \xi_C + \xi_{TP}) \frac{Q^2}{\alpha_2 S_{c2}^2} = (1 + \frac{\xi_c}{\alpha_2}) \frac{Q^2}{S_{c2}^2} + \xi_{TP}(W, \rho_T, \eta) \frac{Q^2}{\alpha_2 S_{c2}^2}. \tag{23}$$

Let the distance from the top edge of the sump to the pulp surface be determined by the signal S_3, which is a linear function of H, i.e.:

$$S_3 = A + BH, \tag{24}$$

where A and B are constants.

Then, taking into account expression 23, S_3 can be represented as:

$$S_3 = A' + \xi_{TP}(W, \rho_T, \eta)B', \tag{25}$$

where $A' = A + (1 + \frac{\xi_C}{\alpha_2})\frac{Q^2}{S_{c2}^2}$; $B' = B\frac{Q^2}{\alpha_2 S_{c2}^2}$.

Thus, the signal S_3 is a function of three variables W,ρ_T,η.

In accordance with the scheme shown in figure 4 according to the method described in the works [33], two more signals can be formed: S_2 – based on measurements of the attenuation of Lamb waves propagating in the wall of the technological sump in contact with the pulp and S_1 – based on measurements of the amplitude of high-frequency volumetric ultrasonic waves that have traveled a fixed distance in the pulp. Thus, the following system of functional dependencies can be formed:

$$\begin{gathered} S_3 = A' + \xi_{tr}(W, \rho T, \eta)B' \\ S_2 = W(\rho_T - \rho_V)C \\ S_1 = W_f(\eta). \end{gathered} \tag{26}$$

Let's pretend that ξ_{TP} – friction loss coefficient, directly proportional to pulp viscosity, i.e.:

$$\xi_{TP} = \lambda\frac{l}{d} = [(1 - W)\eta_B + W\phi(\rho_T, \eta)]\, D = D + WD\,[\phi(\rho_T, \eta) - \eta_B]\,, \tag{27}$$

where D is a constant value; η_B is the viscosity of water.

In this case:

$$S_3 = (A' + DB') + W(DB')[\phi(\rho_T, \eta) - \eta_B]. \tag{28}$$

If $W = 0$, then the pure water signal is equal to:

$$S_3^o = A' + DB'; \tag{29}$$

$$\tilde{S}_3 = S_3 - S_3^o = W\,[\phi(\rho_T, \eta) - \eta_B]\,A_2, \tag{30}$$

where $A_2 = DB'$.

Let's find the signal ratio $\tilde{S}_3$ and S_2 as well as S_1 and S_2:

$$\begin{gathered} S_{32} = \frac{\tilde{S}_3}{S_2} = \frac{[\phi(\rho_T,\eta)-\eta_B]A_2}{(\rho_T-\rho_B)c} = \frac{[\phi(\rho_T,\eta)-\eta_B]}{(\rho_T-\rho_B)}A_3 \\ S_{23} = \frac{S_1}{S_2} = \frac{f(\eta)}{(\rho_T-\rho_B)}\frac{1}{C}. \end{gathered} \tag{31}$$

The resulting expressions relate the content of the control size class of the crushed material with the density of the solid phase of the pulp. Thus, measuring the value, in accordance with the methodology described in the works [33], and the magnitude of the signal. S_3, you can determine the value t.

In connection with the fundamental importance for solving the problem of controlling the parameters of the fineness of the processed raw materials [34], supplied for enrichment, on the basis of the results obtained, the procedure for correcting the flow rate of additional water supplied to the process sump and the effect of this control action on the content of class -74 μm in the hydrocyclone discharge was modeled. On figure 5 it is shown the results of modeling the mass balance and dynamics of the granulometric composition of the processed ore in a closed grinding cycle. The root-mean-square discrepancy between the model and experiment was 0.92%.

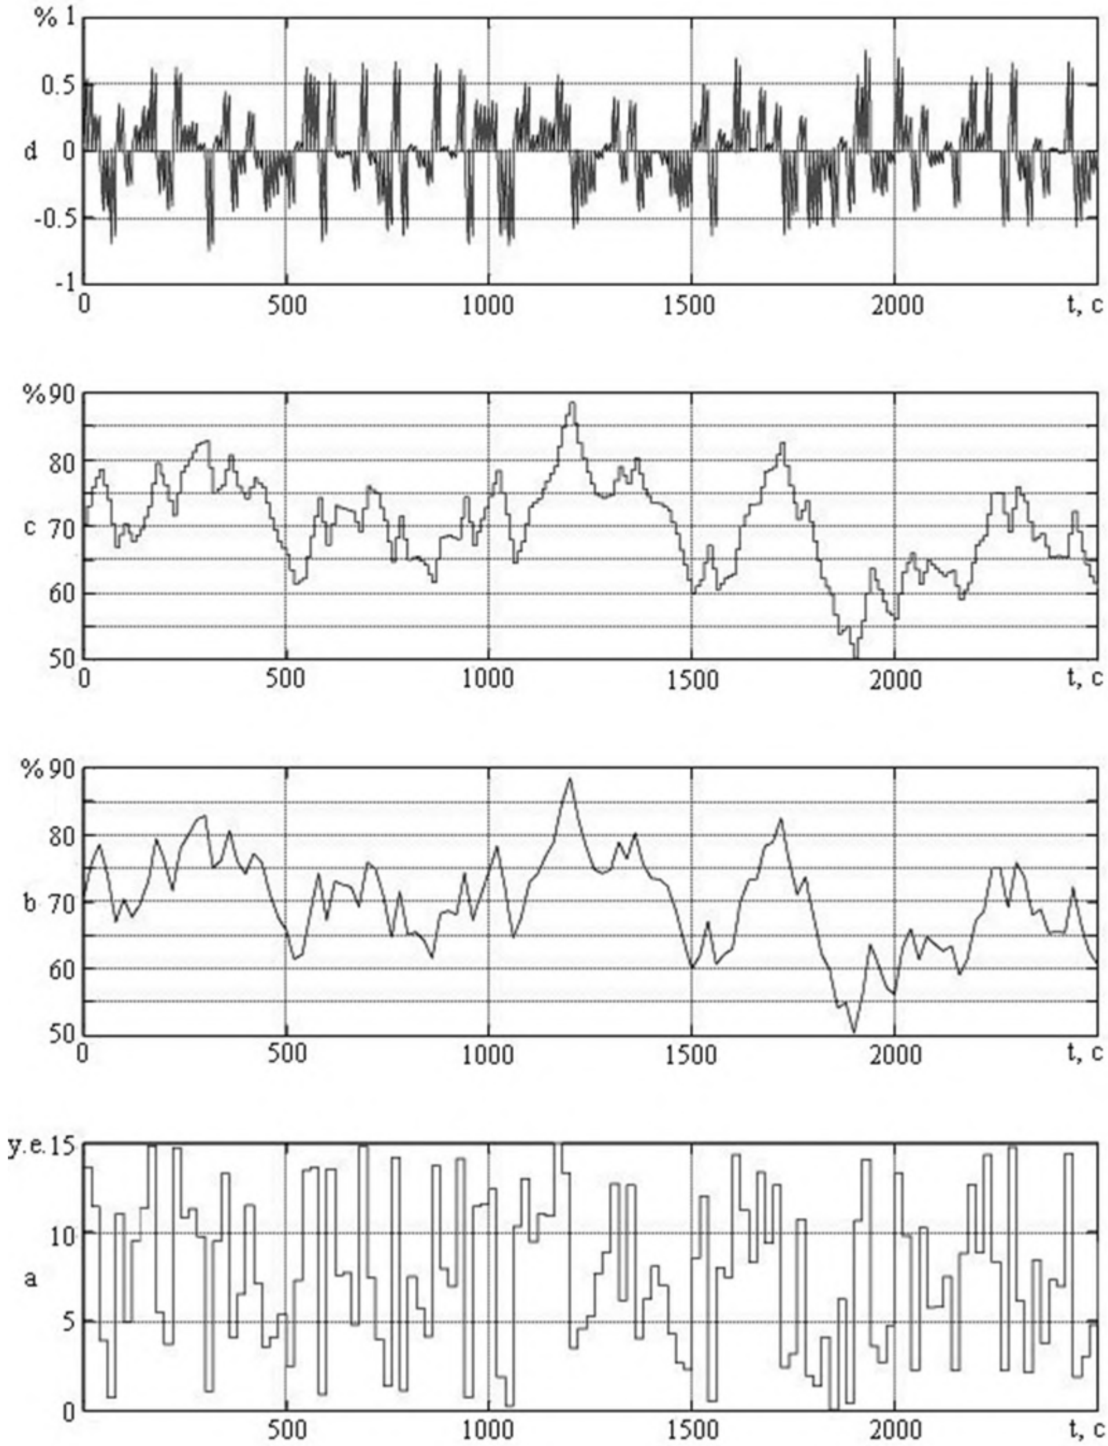

Figure 5. The results of modeling the mass balance and dynamics of the granulometric composition of the processed ore in a closed grinding cycle: *a* – input signal (consumption of additional water in the technological sump, c.u.); *b* – object output (class content -74 μm in the hydrocyclone drain, %); *c* is the output of the model (the content of the -74 μm class in the hydrocyclone drain, %); *d* – error signal, %.

3. Conclusions and further research

Under the conditions of the changing quality of the initial ore and the state of the technological equipment, in order to ensure the optimal operation of the subsequent technological stage - magnetic separation or flotation, the mathematical model of a closed grinding cycle, including a mill, a sump and a hydrocyclone, must contain a circuit that corrects its parameters depending on current physical-mechanical and chemical-mineralogical characteristics of processed raw materials.

It is proposed to use the density of its particles as an indicator of changes in the quality characteristics of the ore received for beneficiation, which is determined on the basis of measurements of the attenuation of volumetric ultrasonic waves and Lamb waves propagating in the pulp and the wall of the technological sump that is in contact with it. These measurements must be synchronized with the results of measurements of the pulp level in the sump during its working operation.

The proposed method makes it possible to dynamically correct the parameters of the model of a closed ore grinding cycle, depending on the quality characteristics of the feedstock, and thereby form the conditions for the full disclosure of inclusions of the useful component in the product entering the magnetic separation or flotation. The root-mean-square discrepancy between the model and experiment was 0.92%.

The direction of further research should be the approbation of the proposed approach in relation to spiral classifiers and concentrators.

Abstract. In Kryvyi Rih iron ore basin, long-term and intensive mining of deposits applying open pit methods have resulted in significant areas disturbed by open pits, dumps and tailings storage facilities. Hundreds of thousands of hectares of fertile arable land are already unsuitable for agriculture and sometimes for living. Thousands of tonnes of dust from dumps and tailing ponds deteriorate the surrounding nature every year and pollute the atmosphere in mining basins. Industrial ore breaking in open pits using bulk blasting causes emissions of a significant amount of harmful dust and carcinogenic substances. The environmental situation in open pit mining areas is often close to critical. In addition, bulk blasting forms a seismic wave, which in some cases destruct civil buildings and industrial facilities. The article proposes ways of gradual transition from mining mineral deposits by open pit methods to environmentally friendly technologies of open pit-underground and underground mining. It is established that such transition is a forced and at the same time choiceless way of developing mining areas, in particular Kryvyi Rih iron ore basin. The paper notes that the main problems of this transition include geomechanical stabilization of the rock massif during construction of underground mines in areas of possible impacts of open pit fields. The paper develops the fundamental study of the problems of controlling the stress-strain state of the massif during transition from the open pit to combined technology of deposit mining. Technologies of combined mining that involve formation of a transition belt with backfilling the worked-out space with compound mixtures are studied as well. It is proved that development of theoretical foundations for controlling the stress-strain state of the massif during transition from the open-pit to combined technology of deposit mining, study and design of technological solutions that contribute to transition to open pit-underground and underground mining, is an urgent scientific, technical and practical problem of great importance.

1. Introduction

In terms of explored iron ore reserves Ukraine ranks first-second among the most powerful mining countries. The main reserves of iron ores are located on the Ukrainian crystalline shield in Kryvyi Rih iron ore basin. This basin along with Kremenchuk and Bilozersk iron ore districts forms the region of Greater Kryvyi Rih, or Kryvyi Rih iron ore basin – Kryvbas.

Iron ores are represented mainly by three geological and industrial types: rich magnetite-hematite-martite ores, ferruginous quartzites and oolite brown iron ores [1].

Rich ores are used without processing.

Magnetite and cumingtonite-magnetite quartzites, brown iron ores of Kryvbas and brown iron ores of Kerch basin are processed by simple methods – washing and magnetic separation [2].

Oxidized quartzites and brown iron ores are difficult to process and require roasting-magnetic or gravitational-flotation processing methods [2].

The thickness of magnetite and oxidized ferruginous quartzites is up to 100–200 m, occasionally up to 500 m, the content of iron oxides in ore is from -15 to 46%, phosphorus – from -0.03 to 0.16%, sulfur – from -0.02 to 0.24% [3].

Of the total volume of iron ore raw materials (IORM) mined in Ukraine, Kryvbas accounts for about 80%, at that the share of the open pit mining method is about 70–80% [4].

Ferruginous quartzites are mined mainly by open pit and partly underground methods.

The dynamics of iron ore production by mining enterprises of Ukraine over the past ten years is shown in figure 1.

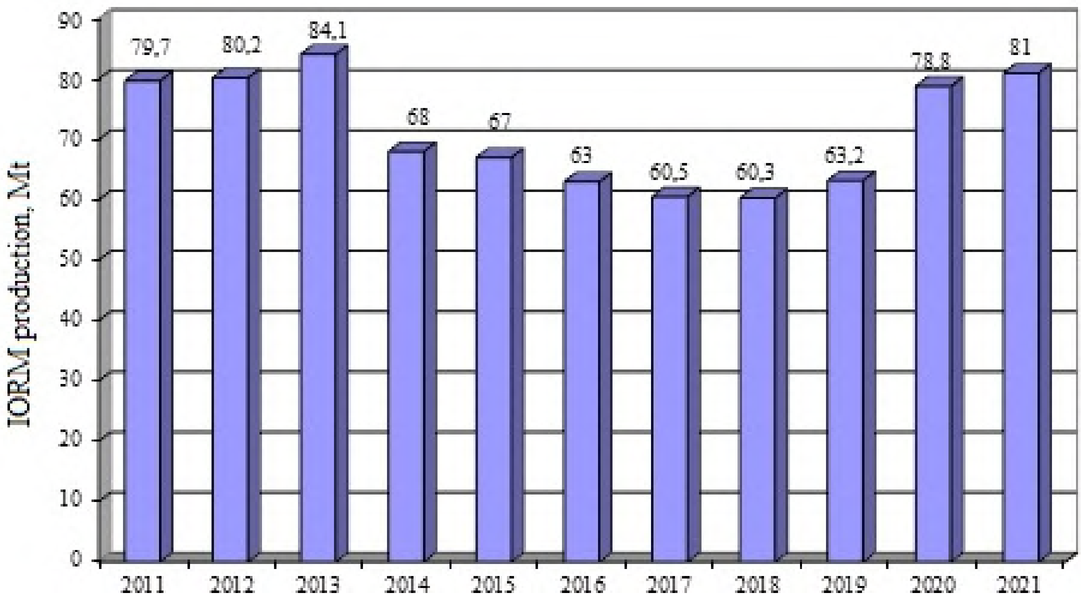

Figure 1. Dynamics of iron ore raw material production by mining enterprises of Ukraine in 2011–2021.

In the base year of 2013, mining enterprises of Ukraine produced 84110.4 kt of iron ore and concentrate. which is by 4.8% more than in 2012, including: non-sintered iron ore – 14242.2 kt (+6.0%); iron ore concentrate 69868.2 kt (+4.6%), of which 30431.5 kt (at the level of the previous year) of marketable concentrate; iron ore sinter of the PJSC "PivdGZK" – 2413.8 kt (+19.3%); iron ore pellets – 23965.3 kt (+9.1%); fluxing metallurgical limestone – 15437.5 kt (-7.1%), including 2109.5 kt (-19.7%) of the dolomitic one [1].

According to the U.S. Geological Survey, Mineral Commodity Summaries, January 2022, Ukraine mined 78.8 and 81.0 Mt of in 2020 – 2021 respectively [5].

In Kryvyi Rih basin, lean iron ores or magnetite quartzites are mined by open pit methods by the PrJSC "Inhulets GZK", the PrJSC "PivdGZK", the Mine Administration for open pit ore mining of the PJSC "ArcelorMittal Kryvyi Rih", the PrJSC "Central GZK" and the PrJSC PivnGZK".

The open pit method of mining causes alienation of much more land. In Kryvyi Rih basin, which accounts for up to 85% of marketable IORM production in Ukraine, mining has disturbed thousands of hectares of fertile arable land.

According to the State Enterprise "State Institute for Design of mining enterprises "Kryvbasproekt", in Kryvyi Rih basin land expenditure per unit of marketable products is 13 times larger when applying open pit mining methods than in underground mining. Air pollution by dust and gas emissions is also much greater as compared to underground works.

During open pit mining, the damage caused to the environment per 1 t of marketable products is 3.5 times greater than in underground mining, and considering the quality of marketable products it is 3 times larger [6].

The above-mentioned conditions of iron ore deposits operation and their impact on the environment deterioration when applying the open pit mining method are summarized (table 1).

Table 1. Conditions of iron ore deposits operation and the impact of production processes on the environment in open pit mining.

Deposit operation conditions	Production processes	Implications for the environment
Depth of ore deposits (up to 450 m)	Opening operations while stoping	The Earth's surface disturbance, soil quality deterioration, storage of significant overburden volumes in dumps, change in the hydrological conditions of the area
High strength of overburden and ores	Application of drilling and blasting	Large volumes of dust and gas emissions into the atmospheric air, seismic impact
Qualitative characteristics of ores (22–38% Fe)	Necessity of processing ore raw materials mined	Storage of processing wastes, creation of tailings storage facilities, harmful emissions into the air, use and pollution of significant amounts of water resources

Every 1 kt of rock mass mined by GZKs produces just about 200 t of iron ore products. At that, 40 m^2 of land is alienated and 50 m^2 of land is flooded, 110 m3 of highly mineralized waters is consumed, 2.5 t of fine dust and 1.8 t of poisonous gases are emitted into the atmosphere.

As compared to the open pit methods, underground mining of deposits demonstrates the following significant environmental advantages:

- reduction of area losses caused by formation of open pits and waste dumps;
- possible separate extraction of rich iron ores of different varieties;
- use of overburden rocks as raw materials for by-product production;
- lower losses of ore raw materials in the subsoil;
- possible creation of nature reserve areas, recreational areas after completion of the deposit operation.

Thus, one of the main ways to reduce the negative impact of open pit mining on the environment of the basin consists in gradual transition from the open pit mining of mineral deposits to environmentally friendly technologies of open pit-underground and underground mining. Such a transition is found to be a forced and at the same time choiceless way of developing mining areas, in particular Kryvyi Rih iron ore basin. The main problems of such transition will include those of geomechanical stabilization of the rock massif during construction of underground mines in areas of possible impact of open pit fields.

2. Purpose

The paper develops the fundamental study of the problems of controlling the stress-strain state (SSS) of the massif during transition from the open pit to combined technology of deposit mining. Technologies of combined mining that involve formation of a transition belt with backfilling the worked-out space with compound mixtures are studied as well.

So, the paper aims to develop theoretical foundations for controlling the stress-strain state of the massif during transition from the open-pit to combined technology of deposit mining, study and design technological solutions that contribute to transition to open pit-underground and underground mining.

3. Analysis of researches and publications

Deterioration of mining conditions (increased depth of mining, reduced thickness of ore deposits) with a simultaneous increase in energy consumption leads to reduction in parameters of working sites, an increase in angles of the working wall and conservation of a significant part of the open pit [1]. Deconservation of the open pit reserves after completion of every stage of mining results in a sharp increase in the volume of stripping, and given limited investments and a long period of their return, technical and economic indicators deteriorate significantly. The environmental problems of the open pit method of mining add to the already difficult condition of modern mining and processing plants (GZKs).

One of the directions of solving this theoretical and technical problem is the wider applicationt of combined mining with the integrated use of open pit-underground and underground methods of deposit mining.

Combined open pit-underground mining allows for maintaining the production capacity of mining enterprises for a long time. Along with that, introduction of scientific recommendations and technological solutions for combined mining of reserves has enabled a number of foreign companies that traditionally applied the open pit method to involve areas of deposits considered unpromising into intensive operation [7].

The sequence of application of open pit and underground mining methods is determined considering the required productivity of the enterprise and specifics of the deposit [8].

Depending on the location of underground mine and open pit fields within the deposit, three characteristic schemes can be distinguished [7]:

- with a combination of work in one vertical plane (underground mining operations (UMO) are carried out under the open pit);
- with a combination of works in the horizontal plane (UMO are carried out in the pit wall);
- with a partial combination in both the vertical and horizontal planes.

The Kidd Creek Mine in Ontario (Canada) is an example of a systematic transition from open pit to underground mining, [9].

Construction of the underground mine started when the depth of the open pit was actually 150 m (the design depth is 250 m), i.e. 7-10 years before completion of open pit mining operations (OPMO).

The Australian copper-gold deposit Osborne located in Queensland has been mined by underground methods in the pit wall since 1996. The pit was decommissioned the same year. The underground work site is opened out through an inclined adit with a portal at hor. 80 m of the depleted pit, and vertical shafts [10].

The Australian Northparkes deposit operated by a group of mines that conduct UMO not after completion of OPMO but simultaneously with them is of particular interest. The company produces high-quality copper-gold concentrate [11].

Considerable experience in the simultaneous conduct of open pit and underground operations has been accumulated at the largest copper-gold deposit Grasberg which was explored in 1988.

Grasberg is the largest gold mine and the third largest copper open pit, as well as the world's highest located open pit. It is located in the province of Central Papua, Indonesia [12].

The mine consists of an open pit and an underground mine. The pit provides high production at low cost. The underground mine operates the under-pit ore massif and several individual deposits near the pit.

Mines "Vihanti", "Hammaslahti", "Pyhäsalmi", "Luikonlahti" and "Kotalahti" (Finland) are mining a number of deposits of polymetallic ores by open pit, underground and combined open pit-underground methods. Pyhäsalmi Mine Oy is the deepest non-ferrous metal mine in Europe (1444 m deep).

The Pyhäsalmi mine operates a copper polymetallic deposit with the 3-4% copper content in the ore and also extracts lead, zinc, sulfur and rare earth elements. The upper part of the deposit is worked out by a pit to the depth of 120 m, the lower part – by the underground method, using room systems with backfilling, as well as a system of horizontal layers with consolidating backfill [11].

The Virtasalmi copper mine operates a polymetallic ore deposit and is being worked out by open pit and underground methods. To the depth of 175 m, the deposit was worked out by both open pit and underground methods with taking the rock mass from the underground part to the daylight surface along the ramp. With transition to underground mining, ventilation raises were created from the non-operating wall of the pit to air underground mining operations [13].

"Sherrit Gordon" (Canada) has transited from the open pit method to the underground one. The Ruttan mine operates the copper ore deposit by the open pit to the depth of 120-160 m. The orebody thickness is 36 m, its length is 820 m, the dip is 70 degrees. The explored reserves for UMO are 27 Mt of ore with the copper content of 1.74%. The development system is room mining with subsequent backfilling of the worked-out space with processing tailings [14].

The copper-cobalt deposit Kamoto in Katanga is also mined by the open pit-underground method. The steeply dipping part of the deposit directly under the pit is worked out by a room system with backfilling, and the flat part is worked out by a room-and-pillar method [15].

To the depth of 170 m the deposit was mined during 15 years, then 10 years later they started underground mining operations. The period of simultaneous OPMO and UMO made 8 years [16].

The Tishinske polymetallic deposit (Kazakhstan) is represented by two steeply dipping orebodies "Osnovne" and "Paralelne" with a dip of 80-85 degrees and the thickness of 10-70 m [17].

Initially, the deposit was supposed to be worked out in combination, by an open pit to the depth of 380 m and an underground mine with a 60 m high safety ore pillar left in the bottom of the pit, which is equal to the height of a level. At the underground mine, room systems are applied with the backfilling of the worked-out space and the use of self-propelled equipment.

The Gaiske copper-pyrite deposit is represented by a series of orebodies with the thickness of 35-40 m and over. It is mined by the combined open pit and underground method in one vertical plane [18].

Finsch deposit is another good example of combined mining. It was developed by the open pit method until the 1990s [19]. Since 1991, mining has been carried out by the underground method under the shell of the depleted open pit.

The Kiruna Mine is the world's largest and most modern mine with open pit-underground iron ore mining (figure 2). The mine is located in Kiruna, Sweden, and owned by the Swedish mining company Luossavaara-Kiirunavaara AB. In 2018, the mine produced 26.9 Mt of iron ore.

Until the 1960s, the mine applied the open pit ore mining method. Now iron ores are mined by the underground method [20].

Based on the analysis performed, it is established that the choice of combined mining technology is to a great extent impacted by the stress-strain state of the rock massif.

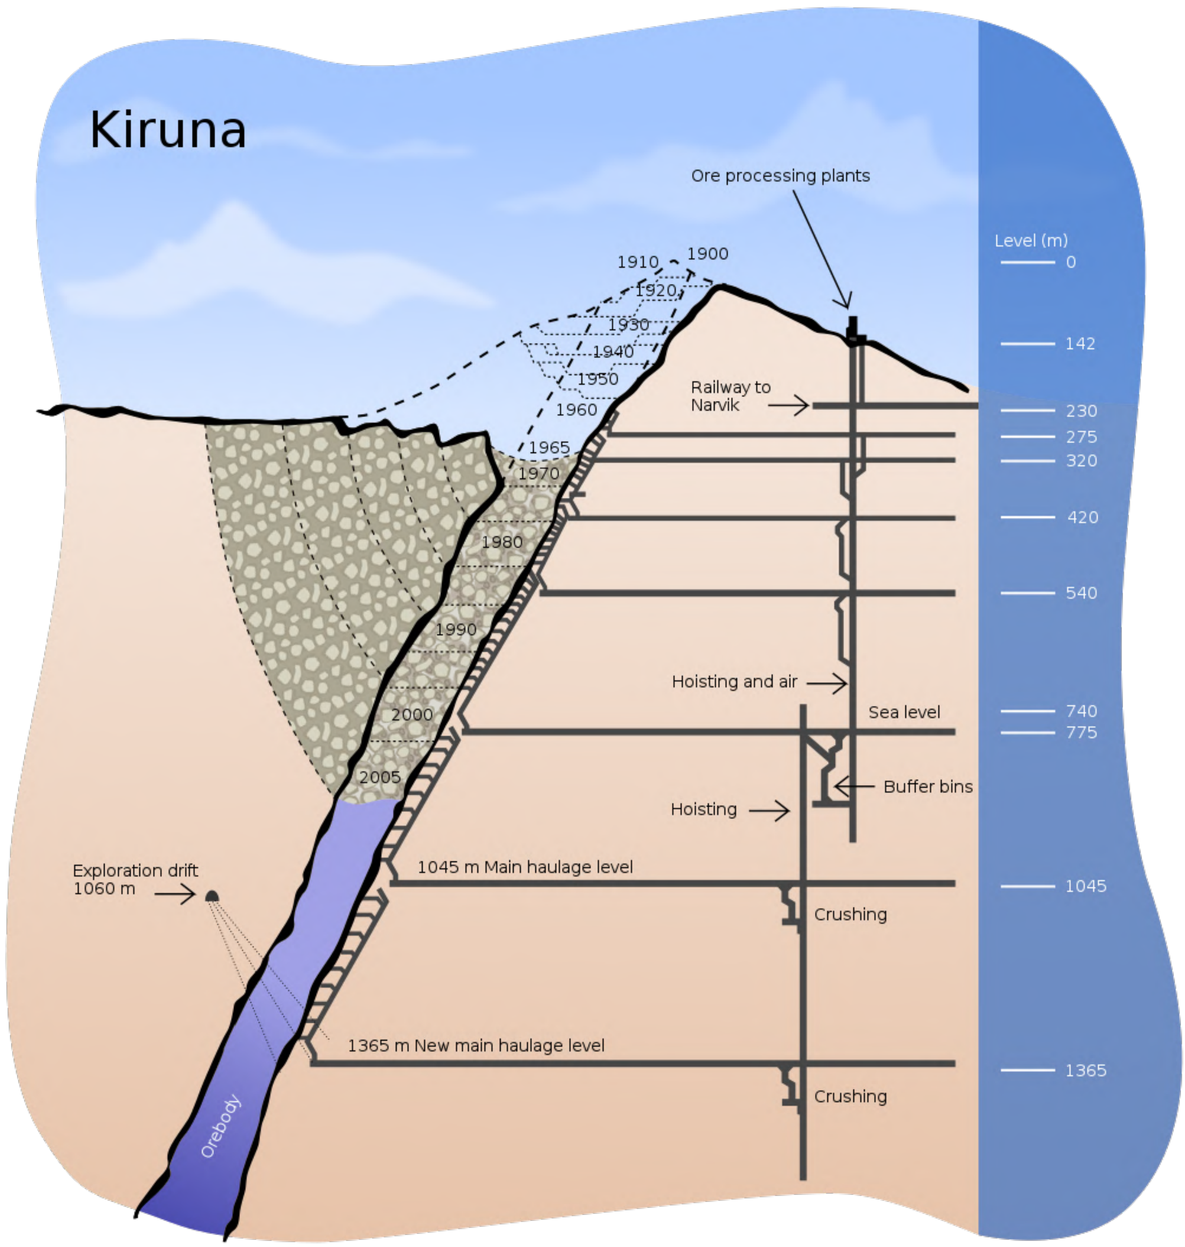

Figure 2. Kiruna mine of Luossavaara-Kiirunavaara AB.

Mathematical methods enable assessing current conditions and obtaining predicted data for enhancement and development of new mining methods, improvement of the flowsheet, selection of optimal parameters for stoping.

4. Methods

An important element of transition from technologies of open pit mining of magnetite quartzites to those of open pit-underground and underground mining is the control of rock landslides in areas of pit fields undermined by underground workings. Such areas may be potential sources of man-made disasters.

The stress-strain state of the massif is known to significantly depend on both natural and artificial conditions of the mining environment.

Among natural properties, geological heterogeneities, in particular the availability of structural, tectonic and other disturbances, are of special significance.

Among artificial disturbances of the rock massif, those occuring during the preparatory-development and especially stoping operations have the greatest impact [21]. In combined open pit-underground mining, the nature of the massif SSS change is impacted by both underground and open pit mining operations. Therefore, information about such disturbances is extremely necessary both at the design stage and in the process of deposit mining [22].

Consequently, a comprehensive assessment of values of current stresses in the massif, prediction of their nature and causes of their change during combined open pit-underground and underground stoping are necessary. This information will enable assessing current conditions and obtaining initial data for improvement of the applied and development of new combined flowsheets of open pit-underground mining, selecting optimal parameters for stoping operations and determining their rational sequence [23].

Consider application of mathematical methods on the example of the impact of the Pershotravnevyi open pit of the PrJSC "PivnGZK" on geomechanical properties of the rock massif at the bottom and in walls of the open pit.

Consider the geomechanical conditions for transition to underground operations during mining the reserves of the Pershotravneve deposit by the open pit-underground method. Minerals are mined by the H_k deep open pit with the angle of the walls ϕ_k. Underground mining operations are supposed to be carried out under the pit at the depth h from the daylight surface.

Assess the deposit area adjacent to the open pit on the basis of solving the plane problem of the theory of elasticity. The components of the stress fields are determined in stages. First, determine the amount of load removed from the pit bottom. It is a uniformly distributed load with an intensity $\gamma_p H_k$.

The values of the stress components can be written as

$$\sigma_{X_1} = \frac{\gamma_p H_k}{\pi}\left(arctg\frac{a_k - x_1}{z_1} + arctg\frac{a_k + x_1}{z_1}\right) + \frac{2a_k\gamma_p H_k z_1(x_1^2 - z_1^2 - a_k^2)}{\pi((x_1^2 + z_1^2 - a_k^2) + 4a_k^2 z_1^2)}, \tag{1}$$

$$\sigma_{Z_1} = \frac{\gamma_p H_k}{\pi}\left(arctg\frac{a_k - x_1}{z_1} + arctg\frac{a_k + x_1}{z_1}\right) - \frac{2a\gamma_p H_k z_1(x_1^2 - z_1^2 - a_k^2)}{\pi((x_1^2 + z_1^2 - a_k^2) + 4a_k^2 z_1^2)}, \tag{2}$$

$$\tau_{X_1 Z_1} = \frac{4a_k\gamma_p H_k x_1 z_1^2}{\pi((x_1^2 + z_1^2 - a_k^2) + 4a_k^2 z_1^2}, \tag{3}$$

where a_k is half the width of the pit bottom; γ_p is the volumetric weight of ore in the massif; x_1, z_1 are the coordinates along the corresponding axes.

Analysis of the results obtained shows that the value of the horizontal component grows with an increase in the pit bottom depth and width. The value of the vertical component increases only with an increase in the width of the pit bottom, and the change in the pit depth does not impact the value of this parameter.

The values of the lateral earth pressure coefficient λ_f are also maximum in the area that is directly adjacent to the contour of the open pit and decreases as the depth and width of the pit bottom increase [24].

In this paper, SolidWorks 2015 software is used to determine the SSS of a rock massif related to the determination of the stress field [25].

Table 2 presents initial physical and mechanical properties of rocks and the backfill material for calculating stresses and strains applying SolidWorks 2015.

Table 2. Physical and mechanical properties of rocks and backfill material.

Parameters	Magnetite quartzites, waste rock	Backfill
Young's modulus, MPa	15000–60000	500
Volumetric weight, kg/m^3	3400	2000
Tensile strength, MPa	6–18	0,5–1,0
Compression strength, MPa	60–180	5–10
Poisson's ratio	0.25	0.15

To calculate the stress-strain state of the combined massif, options of the classical scheme of open pit-underground mining of magnetite quartzites are accepted for the average statistical conditions of transition from open pit to underground mining.

The current average depth of open pits at the level of 350 m is accepted as the final pit depth (or the boundary of transition from open pit to underground mining).

The second stage of the deposit opening during transition from the open pit to underground mining method is carried out by a vertical shaft located outside the open pit in the footwall of the deposit.

The scheme of this kind is expedient for opening at the deposit depths of over 800 – 1000 m, which is characteristic of all Kryvbas deposits. In addition, Kryvbas mining enterprises have accumulated a huge experience of applying this particular scheme for underground opening of deposits.

With less than 800 m depths of deposits, or in case of no funds for construction of mine shafts and absence of prospects for long-term mining by the open pit-underground or underground method, other opening schemes are applied.

Creation of ramps or spiral ramps from technological platforms in the open pit is the main scheme. It is expedient if self-propelled drilling, loading, and transport equipment is used. But in case of low costs of magnetite quartzites, such a scheme may not always be economically viable.

A grid of finite elements of the initial design model is given in figure 3. The model is adequate in size to the site where the technology under study is applied and is used to calculate stresses during open pit-underground mining.

Below are given the results of calculating stress fields in the rock massif when stoping under the open pit bottom, as well as when backfilling stopes with consolidating backfill mixtures.

Isolines of the main stress field around the rooms with an open stoping space and rooms backfilled with a consolidating mixture and collapsed waste rocks are presented in figure 4.

To visually determine the stresses, all isolines have a certain stress value in Pa and correspond to a certain color scale.

All the options proposed by the authors have the following general characteristics.

The vertical shaft of the mine is located in the footwall of the deposit. The height of the underground level is 90 m.

The main crosscuts, drifts of the foot- and hanging walls are driven from the shaft to the orebody at levels –440 m and –530 m.

The level-room system is used for stoping.

Three fundamental schemes of work development are investigated.

The idea behind the first flowsheet of transition from the open pit to underground method of mining an ore deposit is illustrated in figure 4.

After the complete drawing of the broken ore, the stoping space of the worked-out room is filled with waste rocks resulted from driving underground and open workings.

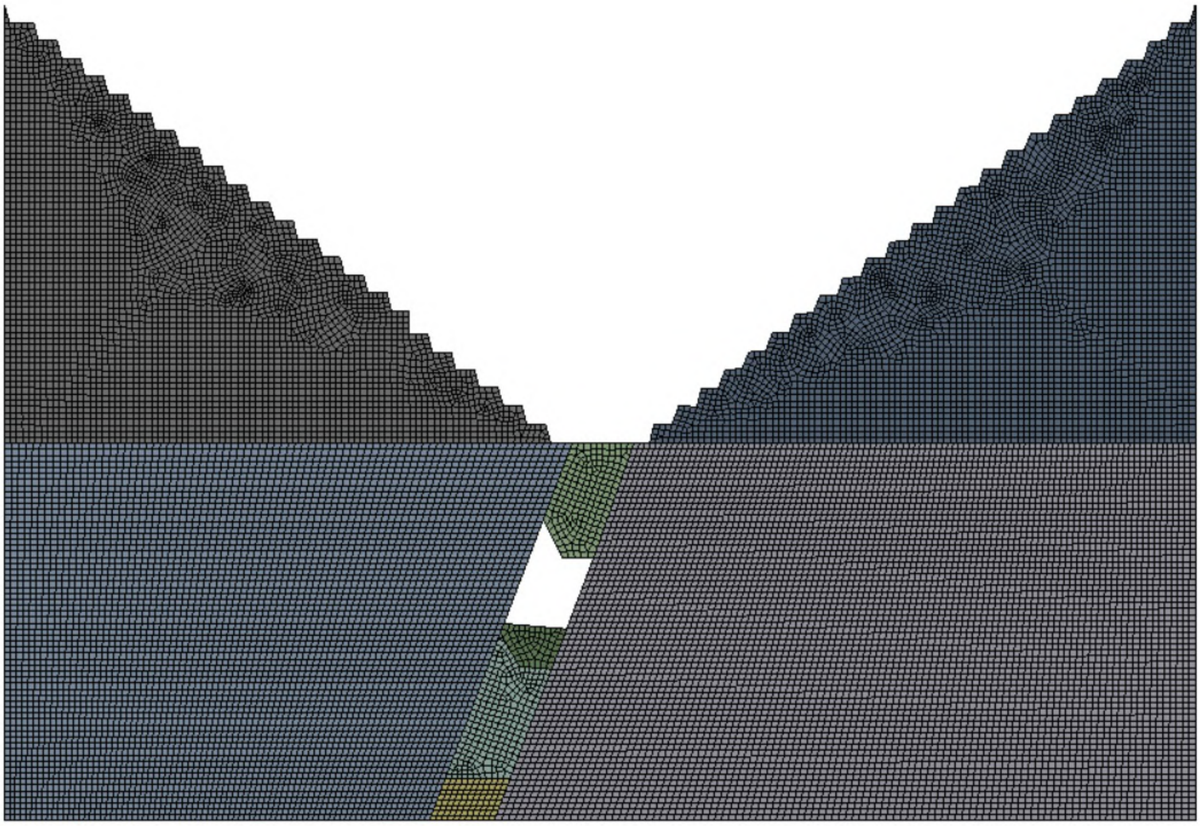

Figure 3. Grid of finite elements of the initial design model adequate in size to the site where the technology under study is applied to mine magnetite quartzites.

The calculated isolines of the main stresses σ_1 of the rock massif when applying open pit-underground mining of the magnetite quartzites deposit with ore breaking and drawing and subsequent backfilling the stoping space of the worked-out room with waste rocks are presented in figure 4.

As is seen in figure 4, the general picture of the distribution of the field of stresses is classic: the greatest absolute magnitude of stress occurs near the angles of the formed stope from the side of the ore massif. Small concentration of stresses is observed in the corners on the bottom of the room.

Significant maximum stresses σ_1 in the corners of the room appear due to the action of compressive stresses. The stresses σ_1 decrease depthward into the ore massif, and their distribution becomes more uniform.

Concentration of maximum stresses σ_1 is observed in the upper and lower corners of the rooms that are not backfilled, and only in the lower part of the backfilled ones.

In some cases, lateral exsposures of the unfilled stope may be distinguished by the fact that tensile stresses σ_3 appear in the central part of the lateral generatrix. In this case stresses σ_1 are reduced from the boundary of the room depthward into the ore massif.

5. Results

Today, development of deposits of ferruginous quartzites of Kryvbas by underground mining has equaled the cost of open pit operations. At the same time, the cost of open pit operations will steadily increase, but in underground mining it will remain rather stable.

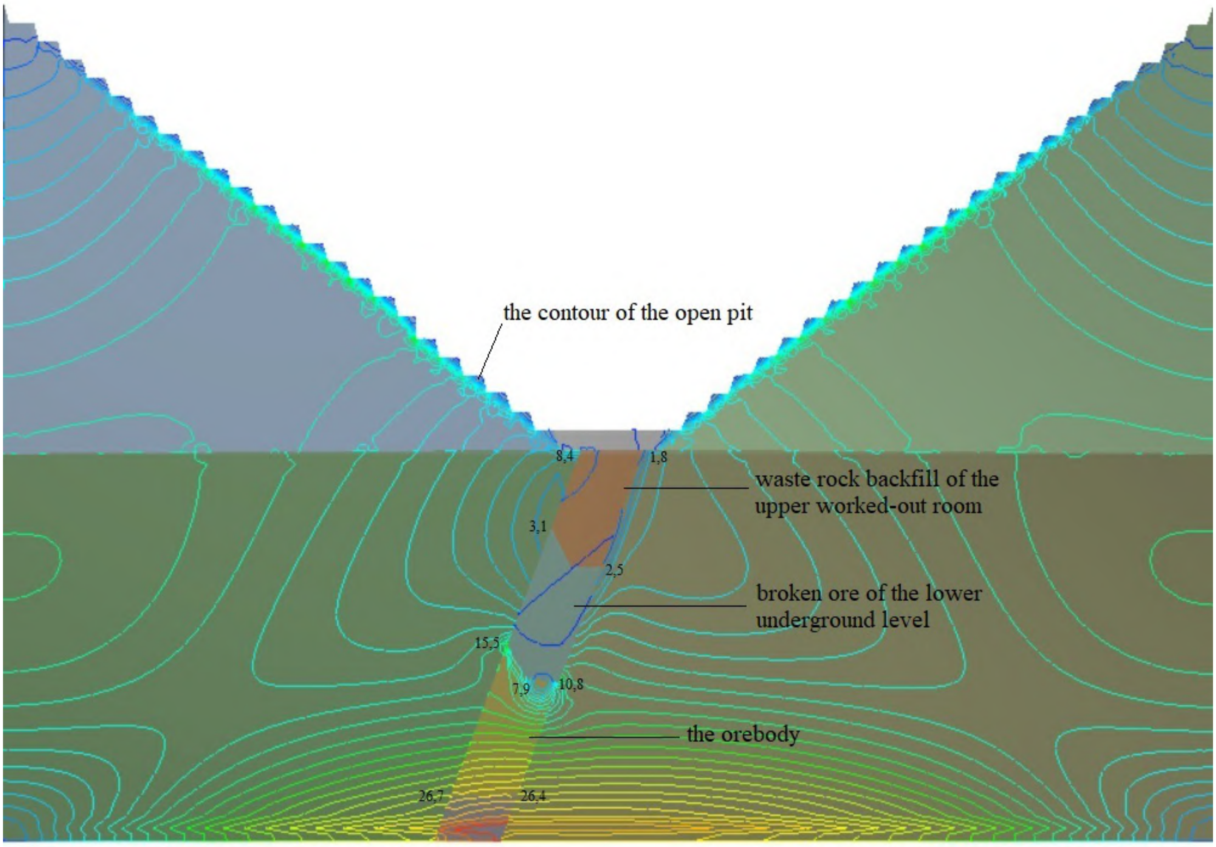

Figure 4. Results of calculation of the main stresses σ_1 when applying open-underground mining of the magnetite quartzites deposit with ore breaking and drawing and subsequent backfilling the stoping space of the worked-out room with waste rocks: 1 – the contour of the open pit; 2 – waste rock backfill of the upper worked-out room; 3 – broken ore of the lower underground level; 4 – the orebody.

In order to improve the technologies of transition from open pit to underground mining of magnetite quartzites, on the example of Kryvyi Rih iron ore basin, three fundamental technological schemes are proposed.

The idea behind the first flowsheet of transition from the open pit to underground method of mining an ore deposit is illustrated in figure 5.

In addition, the proposed solution to store waste rocks in the worked-out space of underground mines has a significant environmental effect, improving the environment of the mining basin.

In the future, in order to develop the environmental safety of the region, it is proposed to store all available waste rock, including overburden at possible parallel ore mining by the open pit method, in the worked-out space of underground mines.

Further underground extraction of magnetite quartzites will be carried out by systems of level caving of ore under overlying waste rocks.

This technology is the cheapest due to no consolidating backfill used that is provided for in the following flowsheets.

The idea behind the second flowsheet of the transition from the open pit to underground method of mining an ore deposit consists in backfilling the stoping space of the room with consolidating backfill after the complete drawing of broken ore. After the consolidating backfill

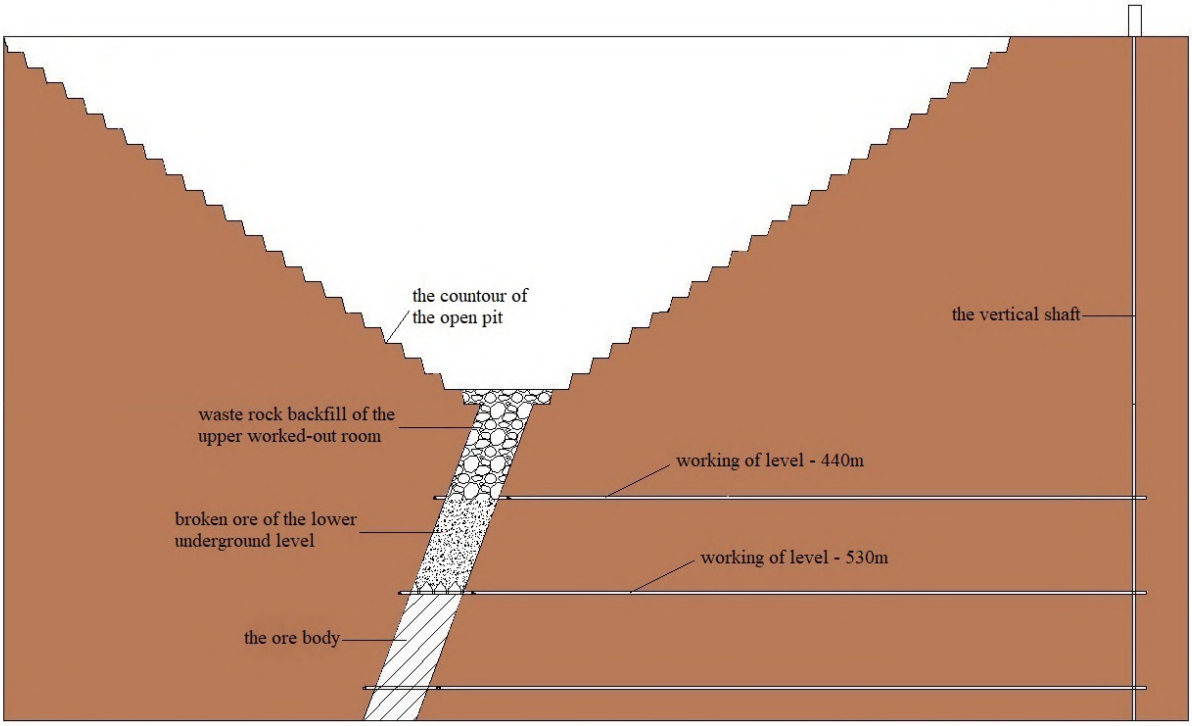

Figure 5. The proposed technology of open pit-underground mining of the deposit of magnetite quartzites with backfilling the worked-out room with waste rocks: 1 – the contour of the open pit, 2 – the vertical shaft, 3 – workings of level – 440m, 4 – workings of level -530 m, 5 – waste rock backfill of the upper worked-out room, 6 – broken ore of the lower underground level, 7 – the orebody.

gains its standard strength, an internal dump of waste rocks can be created on the bottom of the open pit.

Further underground extraction of magnetite quartzites will be carried out by level-room mining under protection of an artificial pillar made of consolidating backfill.

To reduce costs for consolidating backfill in case of its necessary application in the initial version of the combined open pit-underground mining of magnetite quartzites, the third flowsheet with a partial artificial pillar made of consolidating backfill is proposed.

The idea behind the third flowsheet consists in backfilling the bottom of the worked-out room with extra strong consolidating backfill after the complete drawing of broken ore. After the consolidating backfill gains its standard strength, it can be overlaid with waste rocks as an inert backfill.

Formation of an artificial pillar of consolidating backfill on the bottom of the stope requires a much smaller amount of the backfill material. At the transitional stage, this volume can be obtained by using a mobile backfilling complex. Consequently, no need for construction of a stationary backfilling complex significantly reduces the cost of the proposed technology, the cost of magnetite quartzites production by the proposed option of the technology of combined open pit-underground mining.

6. Conclusions

It is determined that nowadays development of deposits of ferruginous quartzites of Kryvbas by underground mining has equaled the cost of open pit operations. At the same time, the cost of open pit operations will steadily increase, but in underground mining it will remain rather stable.

The nature of distribution of the maximum stresses σ_1 in the massif is determined. Mathematical modeling is performed and the results of calculating the main stresses σ_1 are presented in the proposed variantions of the open pit-underground mining of the magnetite quartzites deposit.

It is proved that transition to open pit-underground, and over time to underground mining will reduce environmental tensions in the region.

Highly efficient technologies of transition from open pit extraction of magnetite quartzites to open pit-underground and underground mining of iron ore raw materials within the mining basins of Ukraine are developed and improved.

7. Author contributions

The author contributions are as follows:

- *Mykola Stupnik* conceived the idea of the study, designed the research methodology, and supervised the project.
- *Vsevolod Kalinichenko* performed the numerical simulations, analyzed the data, and wrote the first draft of the manuscript.
- *Olena Kalinichenko* conducted the field experiments, collected and processed the samples, and contributed to the data interpretation.
- *Oleksandr Shepel* assisted with the numerical simulations, and revised the manuscript.
- *Mykhailo Hryshchenko* helped with the field experiments, prepared the figures and tables, and edited the manuscript.

All authors read and approved the final version of the manuscript.

Acknowledgments

The work was supported by the Ministry of Education and Science of Ukraine within the framework of the state scientific theme “Development of technologies for transition from technogenically destructive, environmentally hazardous technologies for mining magnetite quartzites by the open pit method to resource-saving and environmentally friendly technologies of open pit-underground and underground mining of iron ore raw materials” (state registration RK No. 0121U111709).

Abstract. The research is aimed to the analysis and modeling of the process of propagation of ultrasonic waves in iron ore samples to assess its mineralogical varieties. The paper analyzes domestic and foreign experience in modeling of ultrasonic waves propagation; methods of mathematical and computer modeling were used, as well as methods of mathematical statistics and probability theory for analysis of the results. Scientific novelty consists in developing and substantiating a method for recognizing the mineralogical and technological varieties of iron ore of a developed deposit based on spectrograms of a backscattered ultrasonic probing signal. Practical valueconsists in developing a methodology for non-contact non-destructive mineralogical analysis of iron ore to improve the efficiency and quality of its further processing and preparation for metallurgical processing. results. As measurable characteristic estimates of textural and structural features of iron ore varieties the results of spectral analysis of the reversed radiant ultrasonic signal were used.To implement the measurement results classification procedure, Adaptive Neuro-Fuzzy Inference System is used. At the vector of parameters of membership functions of terms of input variables and the vector of coefficients of linear functions in the conclusions of the rules was formed based on the characteristics of the processed ore and the spectrograms of the backscattered ultrasonic signal. The average accuracy of recognition of magnetite, chlorite-carbonate-magnetite, hematite-magnetite, magnetite-cummngtonite-chlorite-siderite mineral varieties of iron ore of the studied deposit was 93%.

1. Introduction

Information about the mineralogical varieties of iron ore can be effectively used to improve the quality of its preparation for metallurgical processing [1]. The technologies of mineralogical analysis that exist and are used in practice take a lot of time and require significant labor costs for preparatory operations. Ultrasonic measurement is a widely used tool for the detection, localization and characterization of materials with important applications in many fields [2]. However, the solution of these problems is associated with great difficulties in relation to inhomogeneous media in which the ultrasonic wave is scattered by the microstructure of the material [3]. The data obtained in this case directly from the results of raw measurements is difficult to analyze, since they depend on many interrelated characteristics of the medium under study. In fact, the maximum information that can be experimentally obtained from each area of the material under study consists of the parameters of the transmitted and reflected probing signals. Thus, the actual problem is to substantiate the necessary and sufficient set of estimated characteristics of the process of propagation of ultrasound in randomly inhomogeneous media, as well as the development of effective methods for their processing for operational non-contact non-destructive mineralogical analysis of iron ore.

2. Literature review

Measurement methods based on the evaluation of the characteristics of backscattered ultrasonic waves in the medium under study are widely used [4, 5]. In work [6] a new formulation is presented to derive the absolute backscatter coefficient from pulse echo measurements. The diffraction correction function for measuring the backscattering coefficient and the acoustic coupling function for the echo-pulse system are determined. The elements of these functions are presented for a flat disk transducer and a transducer with spherical focusing. Approximations of these functions are also given. For a flat disk transducer, the final formulation looks like a modification of the well-known Siegelmann-Reid formulation [7]. For a focused transducer, the final correction is a weak function of frequency when the scattering volume is close to the focal region.

Velichko et al [8] proposed to use a set of measurement results to achieve a complete spatiotemporal separation of the data of the transmitter-receiver structure corresponding to different local areas of ultrasonic signal scattering. It is expected that access to local scattering data can provide valuable benefits for many applications. This method makes it possible to use the angular distribution of the scattering amplitude and phase of each local scattering region to detect small inclusions in various highly scattering materials.

To recognize the characteristics of the interaction of elastic vibrations with the medium in which they propagate, many methods have been proposed, for example, cepstral frequency coefficients (MFCC) are widely used, which describe the shape of the spectrum of an acoustic signal [9–11]. The problem is that individual elements of the acoustic interaction signal are noise-like with a wide flat spectrum and may include strong signatures in the time domain. At present, only a few features in the time domain are known to characterize such diverse audio signals. In work [12] an empirical feature analysis is presented to characterize acoustic signals and it is proposed to use a tracking matching (MP) algorithm to obtain effective time-frequency responses. The MP-based method uses a dictionary for feature selection, resulting in a flexible, intuitive, and physically interpretable set of features. The MP-based function is used as an addition to the MFCC functions in order to provide a higher accuracy of recognition of the characteristics of the analyzed environment.

Traditional acoustic event recognition methods based on informative input characteristics or with internal sequencing methods tend to perform poorly in the presence of interfering acoustic noise. Since noise distortion may be unavoidable in practical situations, it is important to develop more robust analysis models and classifiers [13, 14]. Recent advances in this field use powerful machine learning techniques with multivariate input features such as spectrograms or auditory images. They increase reliability largely due to the discriminatory capabilities of internal classifiers. In work [15] new features derived from spectrogram characteristics are proposed, combined with the powerful classification capabilities of a convolutional neural network (CNN). The proposed method demonstrates high performance under noise conditions compared to current approaches to standard acoustic event analysis and recognition problems.

A number of works propose methods for classifying the parameters of acoustic signals based on the support vector machine (SVM) [16–18]. Tran and Li [19] uses a parametric approach to the characterization of acoustic signals based on subband time envelope distribution (STE) and kernel techniques to determine the subband probabilistic distance (SPD) within SVM. It is shown that the generalized gamma model is well suited for characterizing acoustic events, and the determination of the probabilistic distance provides a closed-form solution for calculating the magnitude of the discrepancy, which significantly reduces computational costs. The results show that the proposed classification method is superior to traditional SVM classifiers with Mel-frequency cepstral coefficients (MFCC).

A promising biological method for classifying acoustic events, which combines spike coding with a spike neural network (SNN) [20]. Peak encoding extracts key points that represent the local maximum components of the acoustic spectrogram and are encoded based on their local time-frequency information. Thus, both position information and spectral characteristics are extracted. The proposed method simultaneously increases the sparseness of the acoustic event spectrogram, producing a noise-tolerant representation, and also maximizes the distinguishability of the spike encoding input data in terms of their temporal information [21].

An important element of the analysis of the results of acoustic interaction is the method of its qualitative description. Mesaros et al [3] presents and discusses various metrics proposed for evaluating acoustic event detection systems used in real situations. An overview of the most common metrics in the field and how they are adapted and interpreted in the polyphonic case is presented. Each metric is defined based on segments and events, and the consequences of averaging based on instances and classes are analyzed using a case study.

Acoustic events can occur both as a result of the purposeful formation of a probing signal, and as a side effect [22–24]. In work [25] a concept is presented that uses acoustic signals to classify instrument-tissue interactions during diathermy. This is done by training a CNN classification pipeline based on a logarithmic spectrogram of acoustic signals recorded directly from the operation area. The presented model achieved an accuracy of up to 89.90% on the data set obtained in the experimental setup.

Another use caseacoustic events, as a side effect, is a system toterrain classification implemented as a component of an autonomous mobile robotic system operating in unknown real conditions [26]. Recently, several proprioceptive terrain classification techniques have been developed to improve reliability or act as a fallback to traditional approaches [27, 28]. However, they lack quality adaptation due to various factors including lack of accuracy, reliability, and slow execution times. Valada and Burgard [26] uses the sounds of vehicle interaction with the ground as a proprioceptive modality and proposes a recurrent model based on deep short-term memory that captures both the spatial and temporal dynamics of such an operation. The model has a new convolutional neural network architecture that allows for deep spatial features, and is supplemented with long-term memory to account for complex temporal dynamics. In addition, a training scheme is proposed that takes into account noise effects, which allows you to synthesize generalized models necessary for reliable operation in real conditions.

The tasks of analyzing the characteristics of rocks have much in common with the evaluation of suspension parameters. Heterogeneous mixtures of solids in liquids play an important role in various industries. Online methods for analyzing the concentration and size of solid particles in given suspensions are of great interest in chemistry, mining and processing industries, for example, for monitoring and controlling mineral processing processes [29]. In work [30] a method for determining the concentration and size of particles using a parametric approach is proposed. This is achieved by selecting an analytical model for the spectra of the received echo signals and determining their quantitative parameters. It is shown that the values of amplitude, center frequency and bandwidth, which are obtained from the fitted model, have great potential for evaluating the characteristics of the suspension.

Thus, the development of methods for measuring characteristics, modeling, classification and recognition of randomly inhomogeneous media is an urgent scientific and technical problem. However, the complexity of solving this problem does not allow creating a universal theoretical and software-technical base for practical application in various industries. A promising approach in the implementation of the mineralogical analysis of iron ore is the use of the parameters of the backscattered ultrasonic signal propagating in the studied samples, and modern methods of their interpretation and analysis.

3. Problem statement

The article presents the results of the development, justification and approbation of the method for recognizing the main mineralogical and technological varieties of iron ore of the developed deposit based on the spectrograms of the backscattered ultrasonic probing signal using the ANFIS neuro-fuzzy classifier.

4. Materials and results

In work [31] the characteristic of the mineral composition, as well as the size of mineral formations in the iron ore of magnetite deposits of the Kryvyi Rih basin is given. In the varieties of iron ore, the grains and aggregates that form them are distributed unevenly both in quantity and size. However, they differ with its physico-mechanical and chemical-mineralogical properties. Magnetite is one of the most common minerals in the Kryvyi Rih basin.

It is included in iron ores and ferruginous rocks as an important ore-forming mineral. Tables 1 and 2 show the characteristics of the mineral composition, as well as the size of individuals and aggregates of mineral varieties of hornfelses and jaspilites of the Skelevatsky magnetite deposit (Kryvyi Rih, Ukraine) [31]. The characteristics are given in relation to the main iron-bearing mineral – magnetite and the main accompanying – quartz.

In mineral varieties, individual types of magnetite aggregates are unevenly distributed (table 2) and have different configurations (figure 1).

When ultrasonic waves propagate in a randomly inhomogeneous medium, with the characteristics given in table 1, their attenuation occurs due to the absorption and scattering of elastic vibrations on the mineral formations of iron ore. Fluctuations in the number and size of mineral inclusions in a controlled volume V of the medium under study affect the parameters of the ultrasonic signal measured by the detector D.

Table 1. Characteristics of the mineral composition, as well as the size of individuals and aggregates in iron ore.

Hornfels and Jaspilites	Magnetite			Quartz	
	Size, mm		Content, %	Grain size, mm	Content, %
	grain	unit			
Magnetite	0.15	0.35	90	0.04	8.5
Chlorite-carbonate-magnetite	0.18	0.45	85	0.05	8
Hematite-magnetite	0.15	0.6	87	0.03	5.5
Magnetite-cummingtonite-chlorite-siderite	0.15	0.2	76	0.08	four

Table 2. Distribution of types of magnetite aggregates in iron ore [31].

Hornfels and Jaspilites	Unit type			
	polyhedral	branched	tape	solid and interspersed
Magnetite	50	40	5	5
Chlorite-carbonate-magnetite	50	35	15	0
Hematite-magnetite	80	10	5	5
Magnetite-cummingtonite-chlorite-siderite	60	20	10	10

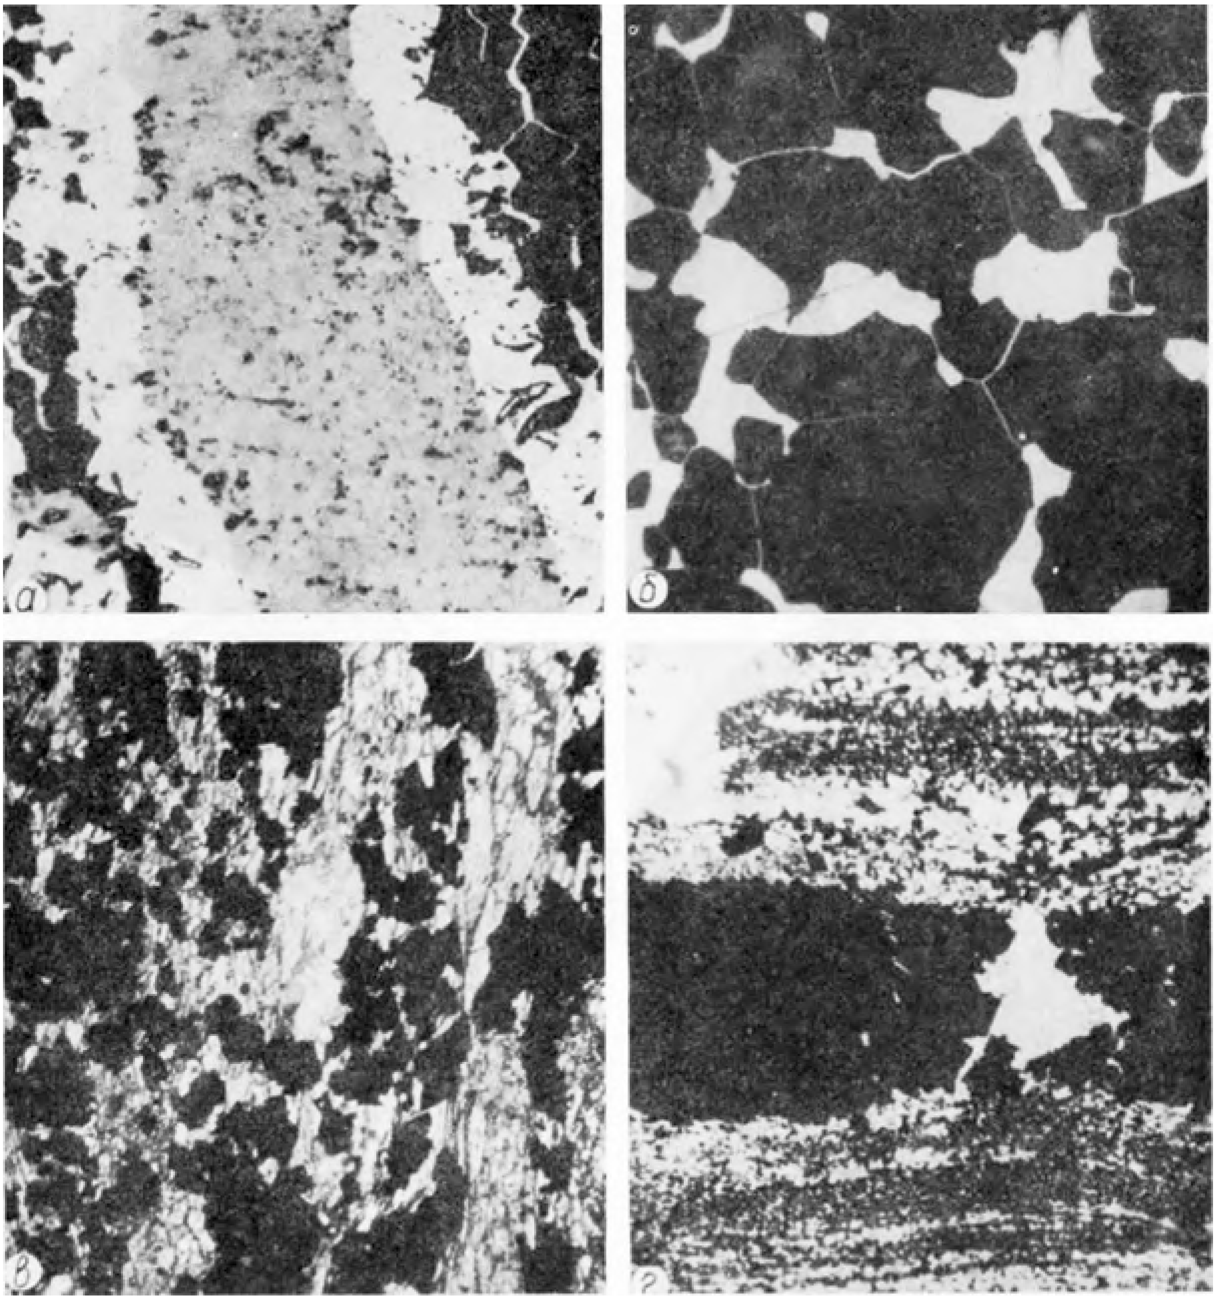

Figure 1. Distribution and configuration of magnetite aggregate types in various varieties of iron ore.

Let us determine the concentration of mineral inclusions of magnetite in the studied sample of iron ore through their number in volume V:

$$n_1 = N_1/V. \tag{1}$$

Since the number of inclusions fluctuates, then N_1 is a random number with Poisson distribution:

$$P_{N1}(k) = \frac{< N_1 >^k e^{-<N_1>}}{k!}, k = 0, 1, 2, ... \tag{2}$$

where $< N_1 >$ is the average value of the number N_1 in the volume V, which can be determined through the average value of the concentration $\vec{n}_1$:

$$< N_1 > \; = \bar{n}_1 V. \tag{3}$$

Then the integral intensity of ultrasonic waves with wavelength λ, passing the distance Z in the medium, will be determined by the expression:

$$I_\lambda^\circ(Z) = I_\lambda \exp\left(-\frac{1}{V}\sum_{i=1}^{N_1}\sigma_p(\lambda, R_i)Z\right), \tag{4}$$

where I_λ is the intensity of the ultrasonic signal emitted into the medium under study; $\sigma_p(\lambda, R)$ is the attenuation cross section of ultrasonic vibrations with a wavelength λ on a mineral inclusion of size R_i.

The detector reading D will be proportional to the value $I_\lambda^\circ(Z)$, averaged over fluctuations in the number and size of inclusions, i.e. in proportion to the value:

$$< I_\lambda^\circ(Z) >= I_\lambda < \exp\left\{-\frac{1}{V}\sum_{i=1}^{N_1}\sigma_p(\lambda, R_i)Z\right\} >, \tag{5}$$

Denote by ξ random variable:

$$\xi = \exp\left\{-\frac{1}{V}\sum_{i=1}^{N_1}\sigma_p(\lambda, R_i)Z\right\}. \tag{6}$$

To find the average value of the ξ apply the formula for the total mathematical expectation:

$$M\xi = \sum_{k=0}^{\infty} M\left(\frac{\xi}{k}\right)P_{N_1}(k). \tag{7}$$

In this expression $M\left(\frac{\xi}{k}\right)$ stands for conditional expectation. It is easy to show that:

$$M\left(\frac{\xi}{k}\right) = \left[M\exp\left\{-\frac{1}{V}\sigma_p(\lambda, R)Z\right\}\right]^k, \tag{8}$$

where:

$$M\exp\left\{-\frac{1}{V}\sigma_p(\lambda, R)Z\right\} = \int_0^\infty \exp\left\{-\frac{Z}{V}\sigma_p(\lambda, R)Z\right\}f(R)dR = \eta_1. \tag{9}$$

Here $f(R)$ is a distribution function of mineral inclusions by size.

Substituting expressions (2) and (9) into (7), we obtain

$$M\xi = \sum_{k=0}^{\infty} \cdot\eta_1^k \frac{(n_1 V)^k}{k!}e^{-\bar{n}_1 V} = e^{-\bar{n}v}\exp\{\bar{n}_1 V\eta_1\} = e^{-\bar{n}_1 V(1-\eta_1)}. \tag{10}$$

In the same way, the influence of fluctuations in the concentration and size distribution of other mineral formations on the intensity of the ultrasonic signal propagating in the rock can be determined.

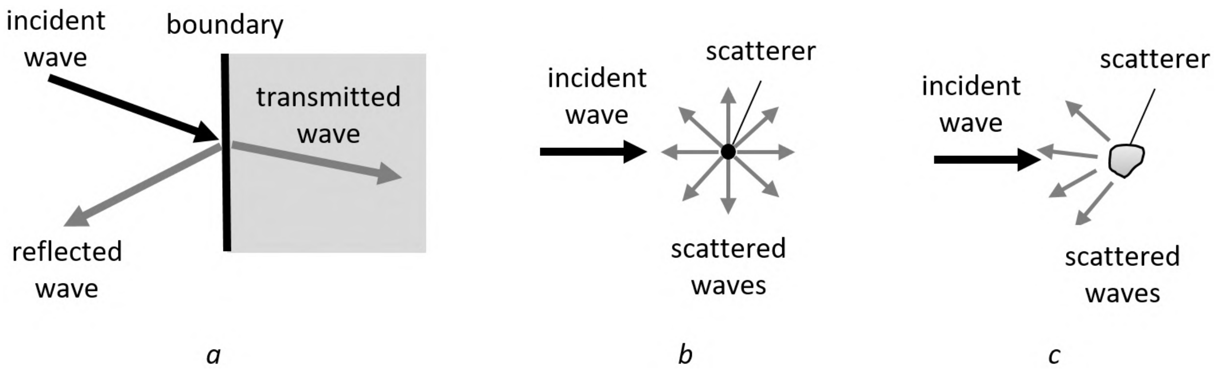

Figure 2. Types of ultrasound scattering in an inhomogeneous medium.

In the expression (4) attenuation cross section of ultrasonic vibrations with wavelength λ is the sum of two terms:

$$\sigma_p(\lambda, R) = \sigma_c(\lambda, R) + \sigma_s(\lambda, R), \tag{11}$$

where $\sigma_c(\lambda, R)$ is the absorption cross section; $\sigma_s(\lambda, R)$ is the scattering cross section.

Let us consider in more detail the scattering of ultrasonic waves on mineral inclusions in iron ore. On figure 2 it is shown the types of ultrasound scattering depending on the ratio of its wavelength and the size of the scattering structure [32].

Specular scattering (figure 2, a) occurs when an object is much larger than the ultrasound wavelength. The ultrasonic wave can be reflected or refracted through the boundary between the object and its environment. Diffuse scattering (figure 2, b) occurs when the structure is much smaller than the ultrasound wavelength. Diffraction scattering (figure 2, c) occurs when the wavelength and size of the object are comparable. In this case, the incident wave scatters equally in all directions.

We will assume that the electrical transducer of ultrasonic waves combines the functions of transmission (generation) and reception of ultrasonic waves. In the transmission mode, the transducer surface is driven into oscillation by electrical excitation, and at the same time, a falling pressure field $P_{in}(\mathbf{r}; w)$ is formed at the point $\mathbf{r}$ of the medium under study [6]:

$$P_{in}\left(\mathbf{r}w\right) = P_0(w) D_T(\mathbf{r}; w)), \tag{12}$$

where $P_0(w)$ is the pressure amplitude on the transducer surface; $D_T(\mathbf{r}; w)$ is the transducer directivity diagram; $w = 2\pi f$ is the angular frequency of the acoustic wave.

Using the electrical equivalent [6], can be written:

$$\left\langle |V_s\left(\mathbf{r} \in V; w\right)|^2 \right\rangle = |V_{in}(w) \bullet X_T(w) \bullet X_R(w)|^2 \bullet \theta(w) \bullet \overline{l \bullet D_s}(\mathbf{r} \in V; w), \tag{13}$$

where $V_s\left(\mathbf{r} \in V; w\right)$ is the received voltage signal from the scattering volume; $V_{in}(w)$ – electrical signal that excites the transducer; $X_T(w) = P_0(w)/V_{in}(w)$ – coefficient of electromechanical connection of the transducer in the transmission mode; $X_R(w) = V_s(\mathbf{r}; w)/\overline{P_s}\left(\mathbf{r}; w\right)$ – coefficient of electromechanical coupling of the transducer in the receive mode.

Since $\overline{D_s}(\mathbf{r} \in V; w)$ can be obtained both analytically and numerically, the backscatter coefficient $\theta(w)$ can be calculated if the system response function $|V_{in}(w) \bullet X_T(w) \bullet X_R(w)|^2$ is defined. In work [7] the response function of the system is measured by placing a reference plate with an ideal reflective surface at the location of the sample volume. There are techniques based on placing the reference plate at half this distance, as well as in the near field for a flat transducer and in the geometric focal plane for a focused transducer [4].

Assuming that the received signal is integrated over the surface of the receiver, and $\frac{U_R(\mathbf{r}_R;w)}{U(w)}$ is the relative sensitivity of the receiving element with coordinates $\mathbf{r}_R$, we can write:

$$D_{ref}\left(2z_{ref};w\right)=\frac{\exp\left(-2ikz_{ref}\right)}{S_R}\int\limits_{S_R}\frac{U_R\left(\mathbf{r}_R;w\right)}{U(w)}D_T\left(2z_{ref};w\right)dS(\mathbf{r}_R). \tag{14}$$

This expression defines the acoustic coupling function from the transducer surface (S_R – active transducer area) to the reference plane and back to the transducer surface [33].

Using the same electromechanical coupling coefficients, the output voltage of the converter due to the reflected wave:

$$V_{ref}\left(z_{ref};w\right)=V_{in}(w)X_T(w)X_R(w)\exp(i2kz_{ref})D_{ref}(2z_{ref};w). \tag{15}$$

Taking into account (13) and (15), it is possible to determine the backscattering coefficient of ultrasonic waves:

$$\theta(w)=\frac{\left\langle|V_s(\mathbf{r}\in V;w)|^2\right\rangle}{|V_{ref}(2z_{ref};w)|^2}\bullet\frac{|D_{ref}(2z_{ref};w)|^2}{l\bullet\overline{D_s}\left(\mathbf{r}\in V;w\right)}. \tag{16}$$

As follows from the above expressions, the parameters of the process of scattering of ultrasound on the structural inhomogeneities of the medium characterize its structural and textural properties. This allows them to be used to recognize the main mineralogical and technological varieties of iron ore in relation to certain of its deposits [34].

The scheme of functioning of the system for recognition of mineralogical and technological varieties of iron ore is shown in figure 3. The functioning algorithm includes the processing of ultrasonic signals and annotations, as well as training the recognition system [3]. Acoustic characteristics are extracted from the measurement results, and at the training stage, a correspondence is found between them and the characteristics of the iron ore samples indicated in the annotations. The testing chain includes processing test signals as for training, testing the system, and, if necessary, post-processing the output of the system to obtain a representation similar to annotations.

In practice, there are three main methods for analyzing acoustic signals in the clock and frequency domains. The watch area has parameters that are taken from the statistics of the output. In the frequency domain, Four's transformations are performed for frequency spectroscopy and cepstral analysis [35]. Let's look at the possibility of victorious results in the

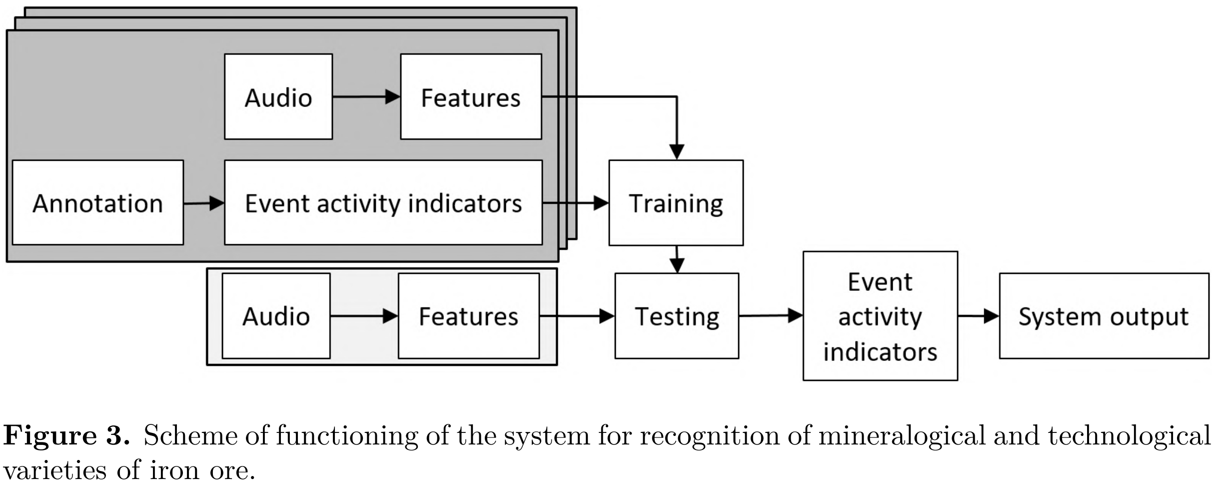

Figure 3. Scheme of functioning of the system for recognition of mineralogical and technological varieties of iron ore.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012071 doi:10.1088/1755-1315/1254/1/012071

spectral analysis of the turning pink ultrasonic signal for the task of recognizing the mineralogy and technological diversity of the flood.

Spectrograms are two-dimensional visualizations of spectral sequences with time on the abscissa and frequency on the ordinate. The color intensity of each pixel is related to the amplitude of the corresponding frequency. When ultrasonic waves propagate in a rock, due to their multiple reflection and scattering on mineral formations, a spectral characteristic of the medium in which they propagate is formed. Thus, the spectrogram of a backscattered probing signal is a spatial (in a certain area) amplitude-frequency characteristic of the medium under study or its acoustic structural-textural image.

To obtain spectrograms in accordance with the methodology used in the works [25, 26], a short-time Fourier transform (STFT) was performed for each window segment of the recorded probing signal:

$$X\ (i,\ j) = \sum_{p=0}^{N_f-1} x[n]w[n-j]\exp\left(-p\frac{2\pi k}{N_f}n\right), p = 0, \ldots, N_f - 1, \tag{17}$$

where $x[n]$ is the signal consisting of N_f samples, $w[n-j]$ is the window function in frame $n-j$, p are iteration variables, $2\pi k$ is the frequency.

In this expression, $X(i;j)$ is the matrix representation of the spectrogram of the received signal with $f(k) = kf_s/N_f$; $x[n]$ is the recorded raw received signal with sample length N_f and sampling rate f_s. The sliding window step size was set to 512 samples, resulting in a window overlap of 50%.

To compensate for the Gibbs effect during STFT by smoothing out discontinuities at the beginning and end of the received signal, the Hamming window function was used:

$$w[n] = 0.54 - 0.46\cos\left(2\pi\frac{n}{M-1}\right), n = 0, \ldots,\ M-1. \tag{18}$$

Then the power spectrum log is calculated:

$$S_{\log}(i,j) = 20\log_{10}(|X(i,j)|). \tag{19}$$

In order to reduce the effect of disturbing noise effects, the spectrograms are normalized by dividing by the maximum amplitude.

$$S(i;j) = S_{\log}(i,j)/\max S_{\log}(i,j). \tag{20}$$

Then the average spectrum over the entire data set is calculated and subtracted from the normalized spectrogram.

On figure 4 it is shown spectrograms of various mineral varieties of iron ore: the x-axis represents time, (ms); y-axis – frequency scale, (Hz); pixel intensity – amplitude, (dB).

As shown in work [36], due to the peculiarities of acoustic interaction, spectrograms provide qualitative characteristics of the classification of research objects.

To implement this procedure, ANFIS (Adaptive Neuro-Fuzzy Inference System) is used – the editor of the Matlab package.In the task of recognizing the main varieties of iron ore of the developed deposit, the vector of parameters of the membership functions of the terms of the input variables and the vector of coefficients of linear functions in the conclusions of the rules are formedbased on the characteristics of the processed ore and the spectrograms of the backscattered ultrasonic signal. ANFIS – the editor automatically synthesizes a neuro-fuzzy network from experimental data, which can be considered as one of the varieties of fuzzy inference of the typeTakagi-Sugeno.

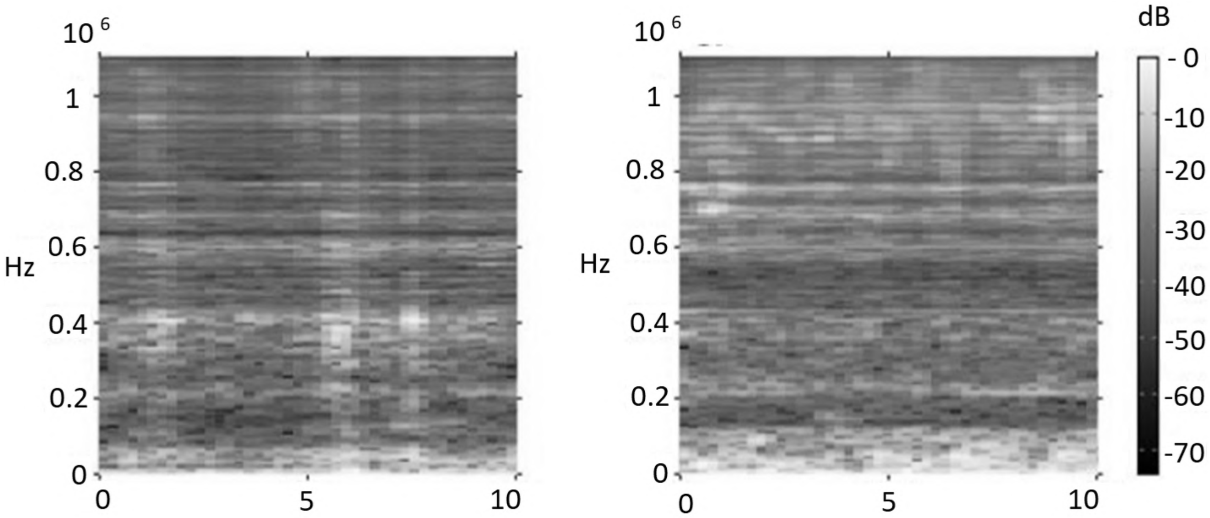

Figure 4. Spectrograms of various mineral varieties of iron ore.

In the process of approbation of the used recognition method, we evaluatedadding the number of epochs of learning, types and number of functions of occurrence of input fuzzy terms in the ANFIS-model for the accuracy of classification.

To study the influence of the number of training epochs of the ANFIS model, the following constant parameters were adopted: the number of input functions of the membership of fuzzy terms – 3; type of input membership functions – bell-shaped (‘gbellmf’); the type of output membership functions is linear (‘linear’) – the only possible option for fuzzy Sugeno-type derivation. Classification accuracy and time spent on model training were calculated. The results of this experiment are shown on figure 5.

With the number of epochs 20 spent 6.9512 s for training. During training for 50 epochs – 11.7630 s were spent. At the same time, the accuracy increases from 0.9410 to 0.9524. A conclusion was made regarding the expediency of further researching the model by training it for 20 epochs.

In the process of researching the influence of the types of membership functions of the input fuzzy terms of the ANFIS model, the following constant parameters were adopted: the number of learning epochs – 20; the number of input functions belonging to fuzzy terms is 3; type of output membership functions – linear (‘linear’). The type of input membership functions that were investigated is given in table 3.

Table 3. Type of studied input membership functions.

“gbellmf”	Generalized bell-shaped membership function
“gaussmf”	Gaussian membership function
“gauss2mf”	Gaussian combination membership function
“trimf”	triangular membership
“trapmf”	Trapezoidal membership

The results of the study of the influence of the types of membership functions of the input fuzzy terms of the ANFIS model on the classification accuracy and the time spent on training the model are shown in figure 6.

Among the tested membership functions, the best results were shown by the bell-shaped

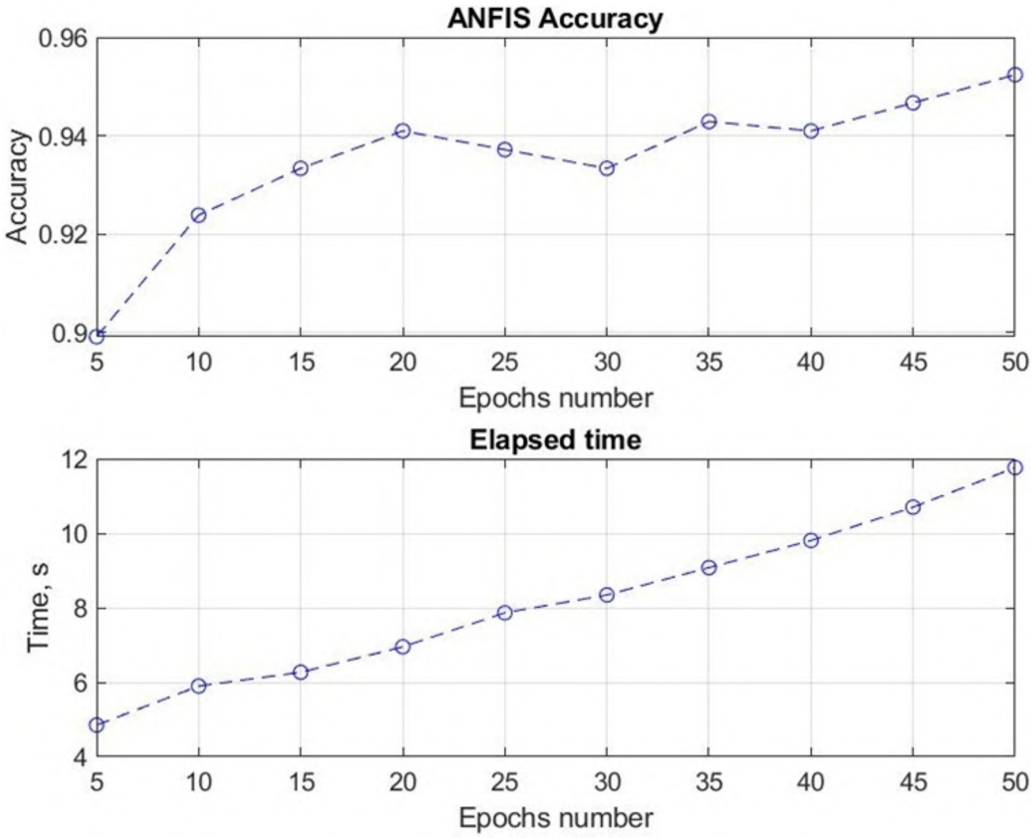

Figure 5. The influence of the number of epochs of ANFIS model training on classification accuracy and time spent on training.

function – accuracy 0.94. At the same time, it also shows one of the best results – 7.13 in terms of duration of study. Therefore, the choice is made in favor of the bell-shaped (Bell-shaped) function of the membership of the terms of the input variables.

In the process of studying the influence of the number of membership functions of the input fuzzy terms of the ANFIS model on the classification accuracy and the time spent on training, the following constant parameters were adopted: the number of training epochs – 20; type of input membership functions – bell-shaped ('gbellmf'); type of output membership functions – linear ('linear'). Variable parameters: the number of fuzzy terms of the input membership functions (2, 3, 4, 5).

The results of calculations of the influence of the number of membership functions of the input fuzzy terms of the ANFIS model on the classification accuracy and the time spent on training are given in the table 4. The option with four membership functions is selected.

Table 4. The influence of the number of membership functions of the input fuzzy terms of the ANFIS model on the classification accuracy and the time spent on training.

Number of functions	Accuracy	Time, s
2	0.777143	1.013732
3	0.940952	6.795064
4	0.966190	47.14676
5	0.968095	291.4074

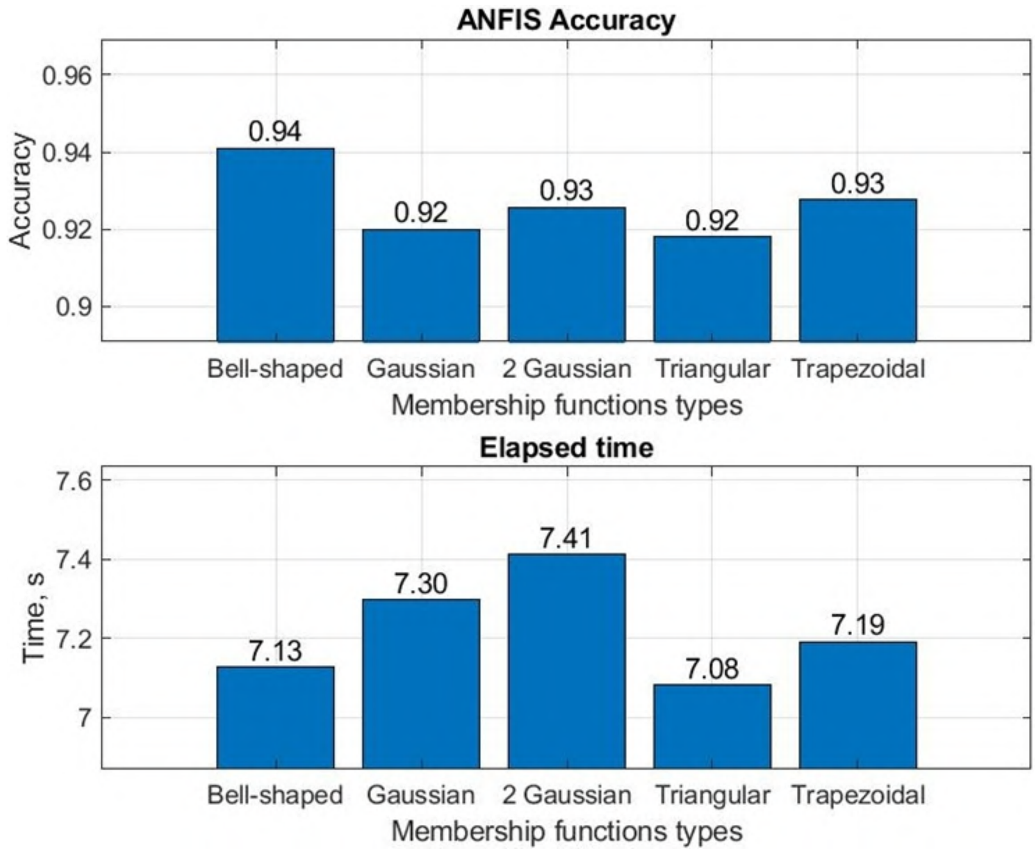

Figure 6. The influence of the types of membership functions of the input fuzzy terms of the ANFIS model on the accuracy of classification and the time spent on training.

Therefore, a model trained for 20 epochs out of 4 was further investigated bell-shaped membership functions of the input fuzzy terms of the ANFIS model.

The average accuracy of recognition of magnetite, chlorite-carbonate-magnetite, hematite-magnetite, magnetite-kummngtonite-chlorite-siderite mineral varieties of iron ore, the characteristics of which are given in tables 1 and 2 was 93%.

5. Conclusions and further research

As measurable characteristic estimates of textural and structural features of iron ore varietiesthe results of spectral analysis of the reversed radiant ultrasonic signal were used.

To implement the measurement results classification procedure, ANFIS (Adaptive Neuro-Fuzzy Inference System) is used – the editor of the Matlab package. At the vector of parameters of membership functions of terms of input variables and the vector of coefficients of linear functions in the conclusions of the rules was formedbased on the characteristics of the processed ore and the spectrograms of the backscattered ultrasonic signal.

The average accuracy of recognition of magnetite, chlorite-carbonate-magnetite, hematite-magnetite, magnetite-cummngtonite-chlorite-siderite mineral varieties of iron ore of the studied deposit was 93%.

Due to the variety of physical-mechanical and chemical-mineralogical characteristics of rocks, the proposed method for recognizing the mineral varieties of iron ore requires tuning the ANFIS model on samples of a particular deposit. To increase the possibility of its more universal use, it is necessary to increase the number of characteristic parameters used to build the model. It is also advisable to consider more advanced methods for building and training the used model, for example, convolutional neural networks (CNN), transfer learning, etc.

Abstract. The development of a sufficiently reliable forecast of the values of trough parameters on the earth's surface and the displacement of undermined rocks using mathematical modeling methods is an urgent problem for mining. Not only the protection of objects on the earth's surface depends on its successful solution, but also the choice of the location of mine workings and rational ways to protect them from the influence of rock pressure, the forecast of gas release from undermined sources, the occurrence of gas-dynamic phenomena, the rationale for rational ventilation schemes for excavation areas, the calculation of the bearing capacity supports and many other engineering tasks. The study is based on the use of experimental data obtained during the operation of a separate extraction area, respectively, at the first stage when the working face is removed from the split furnace and at the second stage above the working face when it is sufficiently removed from the open working. This makes it possible to obtain all the necessary experimental data for constructing a general scheme for the development of clearing operations and the formation of a trough for the displacement of the earth's surface in two stages. On the basis of the studies carried out, it was found that the maximum subsidence of the earth's surface above the cut working with a sufficient distance from the production face is equal to the subsidence above the production face at the stage of attenuation of the processes of displacement of undermined rocks and the earth's surface. This gives grounds to make an assumption about the closeness of the displacement parameters of the stationary and dynamic semitroughs.

1. Problem statement

Conducting cleaning operations in coal mines, even at depths of more than 1000 m, has an impact on changes in the state of the earth's surface. Initially, the study of the processes of formation of shear troughs on the earth's surface was aimed at solving one problem -of protecting buildings, structures and other objects from destruction and the harmful effects of mine workings [1–4]. Based on the results of these studies, a regulatory document [5] was developed, which regulated the rules for protecting structures and natural objects from the harmful effects of underground mine workings. Currently, in the coal mines of Ukraine, the requirements of the current rules [6] are mandatory for use, which determine only the conditions for underworking earth's surface. The calculation of displacements and deformations of the earth's surface and rock mass is a complex problem that has not yet received its fundamental solution. For this reason, empirical calculation methods and separate analytical dependencies are used in practice. In recent years, taking into account the possibilities of computer technology, mathematical modeling of the processes of shifting underworked rocks and the earth's surface. This direction of scientific research is the most promising and relevant, since its implementation does not require long and laborious observations both on the earth's surface and in mine workings.

In addition, such an approach to solving the issue under consideration makes it possible to significantly expand the range of engineering tasks to be solved, related not only to the protection of objects on the earth's surface, but also to the safety of mining operations and the manifestation of rock pressure on the lining of workings. The development of a sufficiently reliable forecast of the values of trough parameters on the earth's surface and the displacement of undermined rocks using mathematical modeling methods is an urgent problem for mining. Not only the protection of objects on the earth's surface depends on its successful solution, but also the choice of the location of mine workings and rational ways to protect them from the influence of rock pressure, the forecast of gas release from undermined sources, the occurrence of gas-dynamic phenomena, the rationale for rational ventilation schemes for excavation areas, the calculation of the bearing capacity supports and many other engineering tasks.

In the general case, the formation of a shear trough on the earth's surface consists of two stages [5, 6]. The first is related to the start of operation of the excavation area and the development of stope work when separating the stope from the open cut. At this stage, the process of shifting the undermined rocks of the earth's surface is achieved and a stationary half-trough is formed above the open cut. The second characterizes the shift of the undermined rocks and the earth's surface above the moving stope. The relationship between the stages of the formation of a shear trough on the earth's surface and the development of stopping operations in the excavation area is characterized [7] by a graph (figure 1).

Normative documents [5, 6] do not consider the logical transition from the first stage of the formation of the trough of the earth's surface displacement to the second. In addition, there are ambiguous recommendations for determining individual parameters. It is envisaged that the stage of attenuation of the process of shifting the earth's surface ends when the stope is removed from the projection considered point at a distance that exceeds the depth of work (H) by 1.2÷1.4 times. There is also no exact definition of the location of the point of the beginning of the displacement of the earth's surface.

By a similar principle, mathematical models have been constructed that separately describe the processes of displacement of the earth's surface at different stages of the development of clearing operations. At the initial stage of operation of the excavation area, the maximum subsidence of the earth's surface (η_m) is considered when the stope is removed from the open cut [8]. In parallel with this, mathematical models [9–11] make it possible to predict the subsidence of points on the earth's surface above the stope in time, when its advance no longer has a significant effect on the maximum subsidence of the earth's surface.

Preliminary analysis [12, 13] based on the processing of experimental data [4, 8, 14–18] showed that in some mining and geological conditions, with little changing values of the thickness of the developed seam (m), the depth of mining operations (H) and strength properties undermined rocks, maximum subsidence of points on the earth's surface η_m (Figure 1, curve 8) is close to functional dependence on the distance (L_p) of the stope from the cut working:

$$\eta_m = a_p - b_p \cdot \exp(c_p \cdot L_p) \tag{1}$$

where a_p, b_p, c_p are empirical coefficients typical for some mining-geological and mining-technical conditions. In addition to the least squares method, to determine the coefficients a_p, b_p, c_p of equation 1, the following equations were proposed [12, 13]:

$$a_p = 374 + 7.4 \cdot 10^4 \cdot \frac{m}{H}, r = 0.78 \tag{2}$$

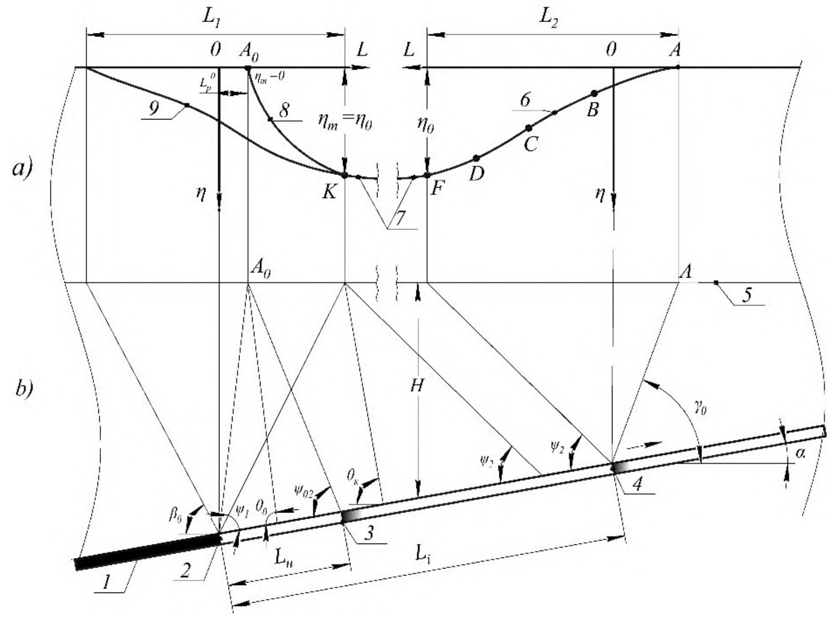

Figure 1. Scheme of the formation of a trough of the earth's surface displacement (a) and its correspondence to the parameters of stopes and the displacement of rocks (b). 1 – the developed layer; 2 – split production; 3 – the position of the treatment face relatively to the split furnace at which the movement of the earth surface begins ($\eta_m = 0$); 4 – *i-e* position of the treatment face after a complete study of the earth's surface (formation of a flat bottom of the mold); 5 – the earth's surface; 6 – dynamic half – mold over the treatment face; 7 – flat bottom of the mold movement; 8 – the trajectory of the maximum points of the earth surface subsidence; 9 – stationary half- mold from the side of the split furnace; β_0, γ_0 – boundary angles, respectively, from the fall and rise of the formation; ψ_1, ψ_2 – angles of complete displacements, respectively, from the fall and rise of the formation; – the angle of full displacements, corresponding to the beginning of the displacement of the earth's surface when removing the face from the split production at a distance; L_H, θ_0, θ_k – the angles of maximum subsidence, respectively, when the processes of displacement of the earth's surface rocks ($\eta_m = 0$) and the formation of a flat bottom ($\eta_m = \eta_0$) ; H – the average depth of conducting cleaning works; α- the angle of the fall of the formation; η, η_m – respectively, subsidence and maximum subsidence of the earth's surface; η_0 – the depth of the flat bottom of the mold ; A_0, A – points of the beginning of the movement of the earth's surface, respectively, is a distance from the split furnace with leaning face and in front of it; *B, C, D, F* – the characteristic point displacement under the influence of clearing face movement; $\longrightarrow$ – is a direction of clearing face movement.

$$b_p = 717 - 41 \cdot v_{ox}, r = 0.96 \tag{3}$$

$$c_p = \frac{1}{-0.5 \cdot H + 14.6}, R = 0.90 \tag{4}$$

where v_{ox} – speed of advancement of the stope, m/month; r and R – respectively, the correlation coefficient and the correlation ratio.

For an analytical description of the dynamics of subsidence of the earth's surface under the influence of a moving stope, it was previously proposed to use logistic [7], exponential [9], or hyperbolic tangent [10] dependences. Comparative analysis of these dependences showed approximately the same, almost functional, convergence with experimental data.

Above the stope, the subsidence of the earth's surface (η_{ox}) in the case of applying the logistic curve, corresponds to the equation:

$$c_p = \frac{a_{ox}}{1 + b_{ox} \cdot \exp(c_{ox} \cdot L_{ox})} \tag{5}$$

where L_{ox} – is the distance from the projection of a point on the earth's surface to the production face, m.

The coefficients a_p, b_p, c_p of equation (5) are also determined in two ways – by the least squares method and using the results of the correlation analysis between the displacement trough parameters and the mining-geological and mining-technical operating conditions of the extraction areas:

$$a_p = \frac{1}{-2.64 \cdot 10^{-4} \cdot m + 1.54 \cdot 10^{-3}}, R = 0.88 \tag{6}$$

$$b_p = \frac{1}{-0.14 \cdot \dfrac{v_{ox}}{H} + 19}, R = 0.88 \tag{7}$$

$$c_p = 0.205 + 0.0148 \cdot \ln(\frac{1}{m \cdot L_l \cdot H}), R = 0.99 \tag{8}$$

where L_l is the lava length.

In addition to equation (5), dependencies were proposed [7] to determine the coordinates of the characteristic points of the earth's surface displacement (figure 1) using the coefficients a_p, b_p, c_p. The coordinates of point A (the beginning of the earth's surface displacement) in front of the stope, respectively, along the abscissa and ordinate axes:

$$x = \frac{4.595 - \ln b}{-c}, y = 0 \tag{9}$$

Similarly, for other characteristic points:

Point O (origin)

$$x = 0, y = \frac{\eta_k}{1 + b} \tag{10}$$

Point B (the beginning of the active stage of the earth's surface displacement)

$$x = \frac{\ln(3.73/b)}{-c}, y = 0.21 \cdot \eta_k \tag{11}$$

Point C (maximum settling rate and curve inflection)

$$x = \frac{\ln b}{c}, y = 0.5 \cdot \eta_k \tag{12}$$

Point D (completion of the active stage and the beginning of the attenuation of the displacement processes)

$$x = \frac{\ln 0.268/b}{-c}, y = 0.79 \cdot \eta_k \tag{13}$$

Point F (beginning of the residual influence of the side job)

$$x = \frac{3.892 \;\; - - \ln b}{c}, y = \frac{0.97}{0.99} \cdot \eta_k \tag{14}$$

In the scheme under consideration (figure 1), the decay stage is limited by the point F. Her settling η_0 is approximately 0.97÷0.99 of the final value η at the end of rock compaction processes [9].

Approximate values of the duration of the active stage of the earth's surface displacement are given in the regulatory documents [5, 6] depending on the depth of the mining operation (H) and the speed of advance of the mining faces. According to mathematical models [9–11], the characteristic features of the processes of displacement of rocks and the earth's surface are also considered in time. This approach does not allow, in the general case, to link the process of displacement of the earth's surface with the development of clearing operations in the excavation area. For this reason, in the general scheme (figure 1), instead of time along the abscissa, we considered the distance L_{ox} from the projection of the stope lines onto the earth's surface to the observation points. Using the method [9] with the use of derivatives, the coordinates of the characteristic points were determined from the extrema of the obtained dependences (equations 9 – 14). The coefficients (a_p, b_p, c_p and a_ox, b_ox, c_ox) of equations 1 and 5 are determined by the most reliable least squares method. For a separate excavation area, when using these coefficients, dependencies 1 and 5 are inherently are functional.

The initial data for calculating the coefficients according to equations 2, 3, 4 and 6, 7, 8 are calculated using the known values of m, H, v_{ox} and m, H, v_{ox}, L respectively. This greatly simplifies the necessary calculations of the parameters of the displacement of the earth's surface troughs, but these dependencies are not functional.

If we prove the closeness of the results obtained by the least squares method, and using empirical equations established on the basis of correlation analysis, then with high reliability it is possible to predict the processes of displacement of undermined rocks and the parameters of the trough displacement of the earth's surface. In this case, there is no need to simultaneously conduct long-term and labor-intensive observations, both on the earth's surface and in mine workings.

2. Purpose, idea and research methodology

2.1. The goal of the research

Given the state of the issue under consideration, the purpose of this work is:

- on the basis of theoretical assumptions and experimental data, to establish a logical relationship between the parameters of the shear half-trough above the cut working and above the stope at its sufficient distance from the cut furnace;

Table 1. The results of determining the coefficients of equation 1 by the least squares method (a_p^k, b_p^k, c_p^k)and based on their correlation dependences (2, 3, 4) on mining-geological and mining engineering factors (a_p^a, b_p^a, c_p^a).

2.2. The idea

The idea of the work is to determine the dependencies obtained on the basis of experimental data for a separate excavation area and processed by the least squares method, and compare them with the dependencies established by the general results of the correlation analysis for different mining, geological and mining conditions.

Table 2. The results of determining the coefficients of equation 5 by the least squares method ($a^k_{ox}, c^k_{ox}, c^k_{ox}$) and on the basis of correlation dependences (6, 7, 8) on mining-geological and mining-technical factors.

2.3. Methodology
The methodology is based on the use of experimental data obtained during the operation of a separate extraction area, respectively, at the first stage when the stope is removed from the split furnace and at the second stage above the stope with its sufficient distance from the open cut. This makes it possible to obtain all the necessary experimental data for constructing a general scheme (figure 1) for the development of stope work (removal of the stope from the split furnace) and the formation of a trough of earth surface displacement in two stages. The necessary amount of experimental observations to achieve the goals was carried out at the Stepnaya mine when the seam was mined with longwall No. 604 [17] and at the Yubileynaya mine when the seam was mined with longwall No. 530 [8].

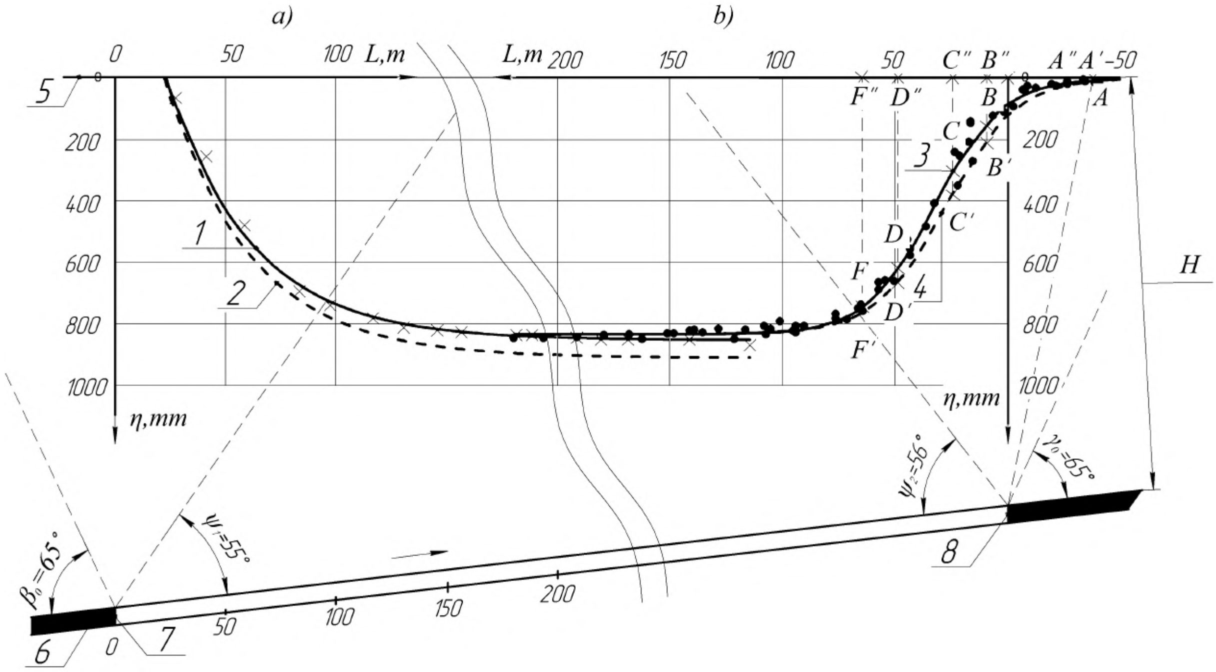

Figure 2. Dependence of the change in the parameters of the displacement trough on the earth's surface with distance from the stope of Chapter No. 604 (Stepnaya mine) on the open working (a) and above the stope (b): 1, 2 – curves of the trajectory of the maximum subsidence of points when the working face is removed from the split furnace, calculated respectively by the least squares method and according to the results of the correlation analysis; 3, 4 – curves of subsidence of points on the earth's surface above the stope, respectively, calculated by the least squares method and according to the results of correlation analysis (they coincide on the graph); η – subsidence of the earth's surface; H – depth of cleaning operations; *A, B, C, D, F* – the position of the characteristic points calculated according to equations (9-14) using the coefficients a, b, c; A', B', C', D', F' – positions of characteristic points calculated according to equation (9-14) using coefficients a_a, b_a, c_a; A'', B'', C'', D'', F'' – the position of the abscissas of the characteristic points of subsidence of the earth's surface according to their dependence on the depth of the clearing operations [19]; 5, 6 – respectively, the earth's surface and the reservoir being developed; 7 – surface of the coal massif of the open cut; 8 – conditional position of the stope in relation to the reference points R25, K30, R35, R40 and R45 as it moves [17]. ψ_1, ψ_2 – angles of total displacements [6]; β_0, γ_0 – boundary angles [6]; + – direction of advance of the stope; •, × – experimental data, respectively, of the maximum subsidence of points on the earth's surface above the cut working and subsidence above the stope [17].

According to the general design scheme, the influence of stopes on the earth's surface (figure 1) was calculated in two ways using the equation of curves for the maximum subsidence of points on the earth's surface. In the first case, the coefficients of equation (1) are determined from the experimental data [17] and [8] by the least squares method (a_p^k, b_p^k, c_p^k). In the second, using the operating conditions of the excavation sites (m, H, v_{ox}), according to equations (2, 3, 4), the empirical coefficients (a_p^a, b_p^a, c_p^a) equations 1, respectively) were calculated.

3. The research results

When determining the empirical coefficient calculated according to equation (2), it is necessary to take into account the value of the reservoir thickness m. The relation $\leq m$ must always hold between them a_p^a. If according to the calculations received $a_p^a > m$, then its value is taken equal to the thickness of the developed reservoir.

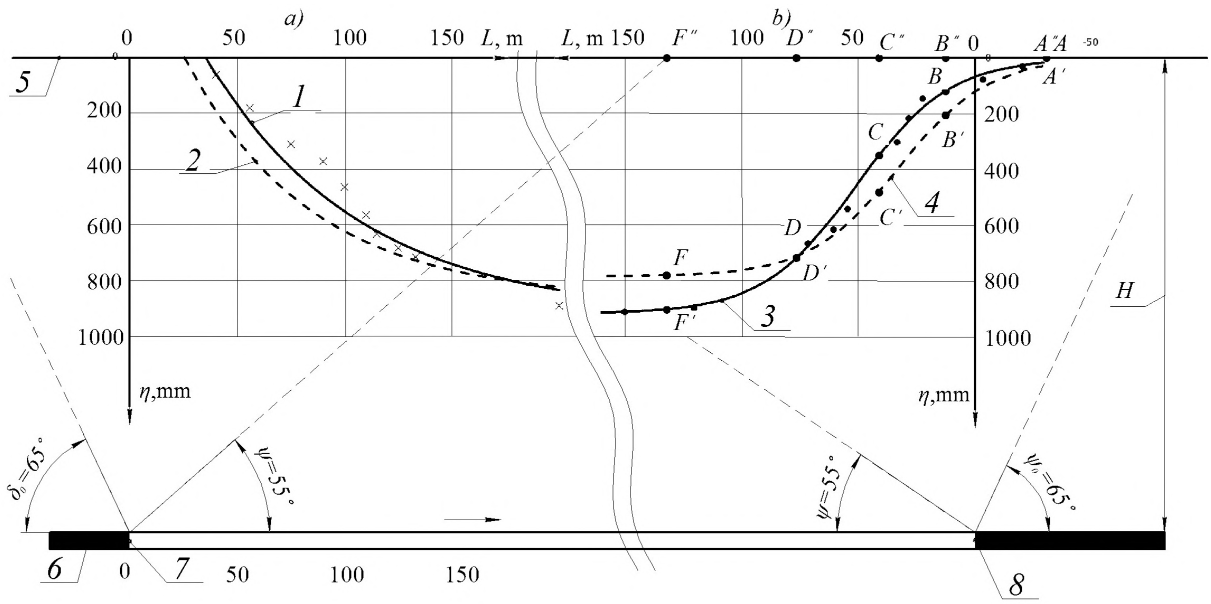

Figure 3. Dependence of the change in the parameters of the trough of the earth's surface displacement as the stope of longwall No. 530 (Yubileynaya mine) is removed from the cut working (a) and above the stope (b): 1, 2 – curves of the trajectory of the maximum subsidence of points when the stope is removed from the split furnace, calculated respectively by the least squares method and according to the results of the correlation analysis; 3, 4 – curves of subsidence of points of the earth's surface above the stope, respectively, calculated by the least squares method and according to the results of the correlation analysis; 5, 6 – respectively, the earth's surface and the reservoir being developed; 7 – surface of the coal massif of the open cut; 8 – conditional position of the stope as it moves relative to points on the earth's surface [8]; η – subsidence of the earth's surface; H – depth of cleaning operations; A, B, C, D, F – the position of the characteristic points calculated according to equations (9-14) using the coefficients a_k, b_k, c_k; A', B', C', D', F' – positions of characteristic points calculated according to equations (9-14) using the coefficients a_k, b_k, c_k; A'', B'', C'', D'', F'' – the position of the abscissas of the characteristic points of subsidence of the earth's surface according to their dependence on the depth of the clearing operations [19]; ψ – angle of full movements [6]; δ_a – boundary angle; $\longrightarrow$ – direction of advance of the stope; $\bullet$, $\times$ – experimental data, respectively, the maximum subsidence of points on the earth's surface above the cut working and subsidence above the stope [8].

It was also established that when the stope advance rate is less than 50 m/month, the value of the empirical coefficient b_p^a is approximately equal to 1330. Similarly, according to equations (2, 3, 4), the empirical coefficients a_p^a, b_p^a, c_p^a were calculated for the operating conditions of longwall No. 530 $C_6^{'}$ of the Yubileynaya mine seam (table 1).

The coefficients of equation (5) were also determined in two ways – by the least squares method and using dependencies (6, 7, 8) obtained from the results of correlation analysis (table 2).

Having determined the empirical coefficients in two ways ($a_{ox}^k, c_{ox}^k, c_{ox}^k$ and $a_{ox}^a, c_{ox}^a, c_{ox}^a$)we calculated, using equations (9-14), the coordinates of the characteristic points of subsidence of the earth's surface above the stopes of the considered longwalls (table 3 and table 4). In addition to these data indicated in the tables, there are also the average values of the characteristic points abscissas. They are calculated depending on the depth of the mining operations according to the method [19], which combines the exponential, hyperbolic tangent and logistic equations recommended respectively [7, 9–11], to describe the curve of subsidence of points on the earth's surface above the moving stope.

On the basis of experimental data [17] and empirical coefficients, graphs of possible changes in the trajectories of maximum subsidence of points were plotted when the longwall of longwall No. 604 of the Stepnaya mine was removed from the open cut and subsidence of points on the earth's surface above the stope (figure 2).

To assess the convergence of the results, we analyzed the relationship between the coordinates of the characteristic points of subsidence of the earth's surface above the production faces,

Table 4. Estimated values of the coordinates ($\eta_o x, L_o x$) of the characteristic points of the earth surface subsidence curve above the stope when processing the 530th lava of the seam $C_6^{'}$, Yubileynaya mine.

Characteristic points of the curve	Coordinates of characteristic points according to equations 9-14				Subsidence of the earth's surface according to equation (5) for different methods of determining empirical coefficients $a_o x, b_o x, c_o x$		Average distances from points to the projection of the production face along the abscissa axis [19], $L_o x, m$		
	Determination of empirical coefficients by the method of least squares		Empirical coefficients are determined by a method based on correlation analysis						
	L_{ox}^{1k}, m	η_{ox}^{1k}, mm	L_{ox}^{a}, m	η_{ox}^{a}, mm	η_{ox}^{k}, mm	η_{ox}^{a}, mm	Empirical Equations	r	L_{ox}, m
A	-41	0	-56	0	9	8	$L_A = -0.264H$	-0.96	-40
O	0	68	0	124	68	124	-	-	0
B	24	192	7	164	192	167	$L_B = 0.107H$	0.92	16
C	51	458	32	392	463	391	$L_C = 0.290H$	0.98	44
D	77	723	57	619	723	615	$L_D = 0.466H$	0.99	70
F	128	897	107	767	896	767	$L_F = 0.862H$	0.99	129

determined in different ways (table 3 and table 4).

The most reliable are the results obtained on the basis of experimental data and their processing by the least squares method.

These results include the coordinates of the characteristic points of subsidence of the earth's surface above the stope when they are calculated according to equations 9-14 using the empirical coefficients of equation 5 calculated by the least squares method ($L_{ox}^{1k}, \eta_{ox}^{1k}$). For this case, the determination of the coordinates of the characteristic points (*A, B, C, D, F*) used the original equation 5 and its derivatives. For this reason, a practical coincidence of the results of determination with (table 3 and table 4) was obtained. Values close to them were also obtained using the results of correlation analysis (figure 4a), as evidenced by the close location of the bisector of the coordinate grid (1) and the averaging line (2).

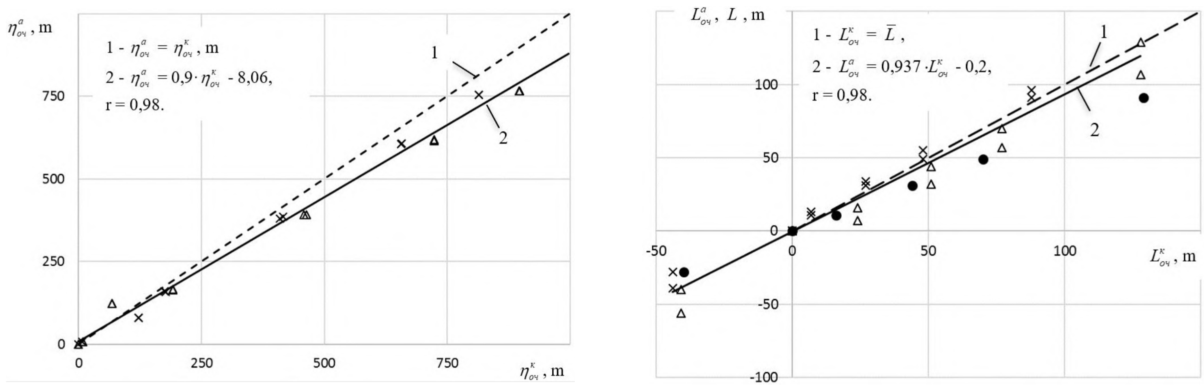
Similar results were obtained when determining the values of the coordinates of characteristic points along the abscissa axis (figure 4b). The values L_{ox}^{1k} are near the bisector of the coordinate grid (1), as is the averaging straight line (2).

Close to the coordinates along the abscissa axis (L_{ox}^{1k}) are and their average values (L_{ox}) calculated [19] depending on the depth of treatment (table 3 and table 4).

4. Conclusions

The conducted research allowed to draw the following conclusions:

- the maximum subsidence of the earth's surface from the side of the split furnace at a



(*a*) (*b*)

Figure 4. (*a*) – along the ordinate axis (subsidence of the earth's surface at the corresponding points); (*b*) – along the abscissa axis (distance from the projection of production faces to the considered points); 1 – bisectors of coordinate grids; $L_{ox}^{1k}, \eta_{ox}^{1k}$ – coordinates established according to equations (9-14), for which the empirical coordinates are calculated by the least squares method according to equation 5; $L_{ox}^{1a}, \eta_{ox}^{1a}$ – coordinates set according to equations (9-14), for which empirical coefficients are calculated using correlation analysis and equation 6-8; L_{ox} – certain distances from the characteristic points to the projection of the stope [19]; $\eta_{ox}^{k}, \eta_{ox}^{a}$ – subsidence of the earth's surface according to equation 5 and empirical coefficients calculated respectively by the least squares method and on the principles of correlation analysis; $\times, \triangle$ – calculated values respectively for the conditions of mines 'Stepnaya' and 'Yubileynaya'; $\times, \triangle$ – calculated values, $L_o^{1a}x$ – respectively, for the conditions of the Stepnaya and Yubileinaya mines; x, y- calculated values, $\eta_o^{ox}x, \eta_o^{k}x, \eta_o^{a}x$ respectively, for the conditions of the Stepnaya and Yubileinaya mines; • – averaged values for the location of characteristic points depending on the depth of work (table 3 and table 4).

sufficient distance from the cutter furnace coincides with the subsidence above the stope at the stage of attenuation of the processes of displacement of undermined rocks, which gives reason to consider the displacement parameters of the stationary and dynamic semitrough close to each other;

- dependencies established by the methodology using the results of correlation analysis are close in their accuracy to the results obtained by the least squares method, which greatly simplifies engineering calculations and obtaining initial data for their production;
- the averaged abscissas of the characteristic points of subsidence of the earth's surface above the stope are determined quite accurately from empirical dependencies and data on the depth of the stope.

Abstract. Based on the design assumptions according to Eurocode 2, the concept of determining the value of the design strength of reinforced concrete has been developed for calculating the bearing capacity of reinforced concrete members subjected to biaxial bending. The theorem on the parallelism of the planes of internal and external forces action is applied. The considered design cases are for the most expected forms of the compressed concrete areas, which are characteristic for biaxial bending of beam members. The value of the coefficient of influence of biaxial bending on the characteristics of the member of rectangular section with triangular and trapezoidal forms of the compressed concrete area is obtained. A methodology for calculating the bearing capacity of biaxially bended members based on the application of the design strength of reinforced concrete is brought to the engineering level of application. An example of a calculation is presented, which demonstrates the convenience and effectiveness of the developed method. The proposed method of calculating the bearing capacity of beam member under biaxial bending is approved by comparing the results of calculations with experimental data for 12 samples of biaxially bended beams.

1. Introduction

Complex deformation of reinforced concrete members is widespread in the practice of operation of many building structures. Wherein, it may be caused by both force and random factors of a constructive, technological or operational nature. As a rule, the main attention of scientists is devoted to the study of reinforced concrete members subjected to axial load and biaxial bending. Proposals were developed for the construction of universal diagrams for determination the bearing capacity of columns under biaxial bending [1–5], while not always acceptable simplifications were used.

Meanwhile, many bending members that are operated in the absence of axial force are subjected to complex deformation. Biaxial bending is exposed by individual members, for example, reinforced concrete girders, crane beams, horizontal elements of frameworks, elements of shells, bridges, staircases and underground structures, crossbars of transport galleries and overpasses, foundation and framing beams, wall panels, etc. and entire spatial systems of buildings and structures.

The application of numerical methods for calculating the bearing capacity of biaxially bended members is considered in works [6–15] for cross-sections of arbitrary shape with different

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012073 doi:10.1088/1755-1315/1254/1/012073

arrangement of reinforcement. The diagrams for strength estimation were presented in the form of moment-curvature curves, ultimate strength interaction curves, and three-dimensional fracture surfaces [16].

The results of studies of the strength of biaxially bended reinforced concrete members are given in publications [17, 18]. The developed strength calculation algorithms and their results are compared with experimental data.

The concept of the design strength of reinforced concrete and its application are given in the work [19] for calculating the bearing capacity of members subjected to plane bending. The essence of the considered approach is that reinforced concrete is considered as a composite that has a certain strength characteristic – the design strength of reinforced concrete. At the same time, the strength problems for reinforced concrete members are solved on the basis of the classical theory of resistance of materials. The implemented characteristic is an integral value that takes into account the strength characteristics of concrete and reinforcement, the amount of reinforcement in the section and its location.

It is obvious that it can be used for any type of deformation of a reinforced concrete member, in particular for biaxial bending. The problem of this implementation is complicated by an additional unknown parameter, namely the angle of inclination of the neutral axis, as well as the presence of different forms of the compressed concrete area in the cross-section of the member. To date, no practical proposals have been developed regarding the application of the theory of design reinforced concrete strength for biaxially bended members in this aspect.

2. Results

Obtaining the design strength of reinforced concrete in biaxial bending is considered for members of rectangular section with single reinforcement. At the same time, the assumptions for design according to Eurocode 2 [20] are used. In particular, a rectangular stress distribution in the concrete of the compressed area is accepted, the stress-strain diagram of the reinforcing steel with a physical yield point is assumed to be bilinear with a horizontal section of unlimited length. The deformation criterion is used as a failure criterion.

In general, it is proposed to solve strength problems using the design strength of reinforced concrete on the basis of the dependence

$$M_{Ed} \leq M_{Rd} = f_{zM} W \gamma, \tag{1}$$

where f_{zM} is the design strength of a reinforced concrete member of rectangular section with single reinforcement in plane bending; $W = bd^2/6$ – moment of resistance of a rectangular section; γ is a reducing coefficient for the design strength of a reinforced concrete at biaxial bending.

On the basis of the work [19], the design strength of reinforced concrete for a rectangular section, taking into account the accepted assumptions, is obtained in the form

$$f_{zM} = 6 f_{yd} \rho_l \left(1 - \frac{f_{yd} \rho_l}{2 f_{cd}}\right), \tag{2}$$

where ρ_l is the longitudinal reinforcement ratio.

Using dependence (2), it is possible to tabulate the design strength of reinforced concrete for different classes of concrete and reinforcement at different of reinforcement ratios. For example, table 1 shows the value of f_{zM} for reinforcement of A500C class. It should be noted that the values in table 1 are determined under the condition that at the moment of failure, the stresses in the tensile reinforcement reach the yield point.

To determine the coefficient γ, which takes into account the decreasing of the design strength of reinforced concrete of biaxially bended members, it is first considered the case of biaxial

bending of a reinforced concrete beam, in which the compressed concrete area has the form of a trapezoid. According to the accepted prerequisites, the design scheme of the section has the form presented in figure 1.

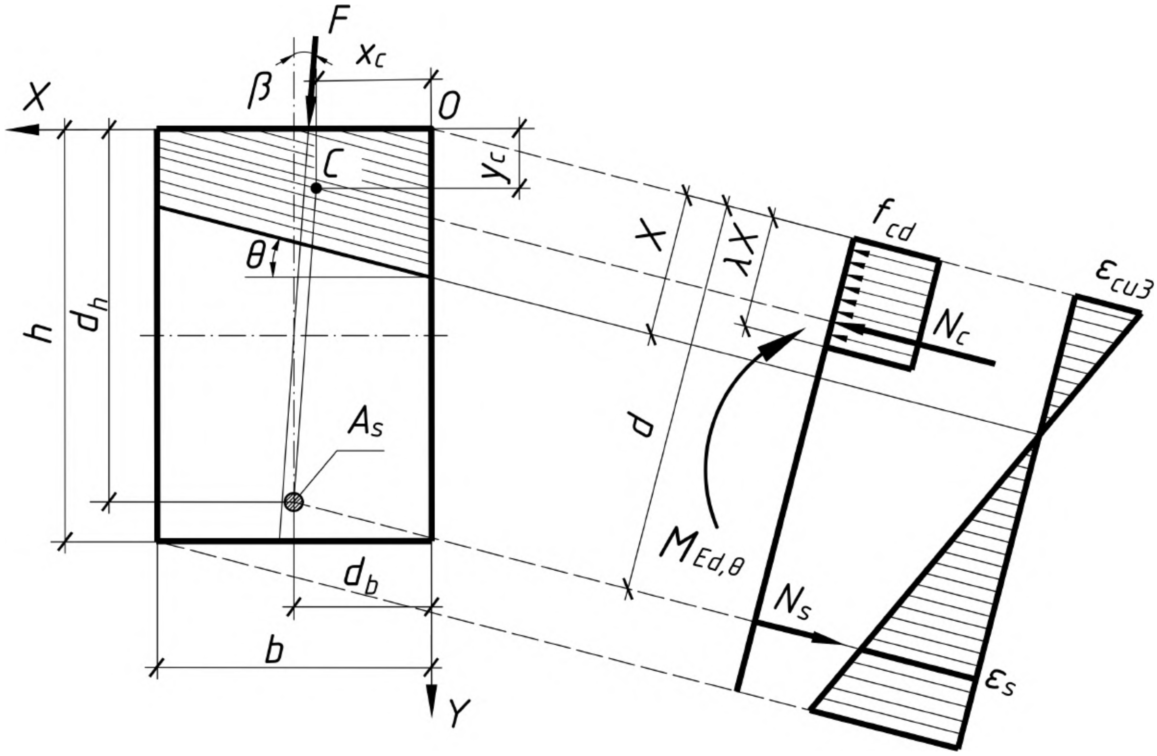

Figure 1. Design diagram of the cross-section of a biaxially bended member with a trapezoidal form of a compressed concrete area.

Taking into account the assumptions outlined above and figure 1, the design equations of equilibrium in the plane of the vertical coordinate axis Y are written in the form:

$$\sum Z = N_s - N_c = 0; \tag{3}$$

$$\sum M_C = M_{Rd,Y} - M_{Ed,Y} = 0, \tag{4}$$

where

$$M_{Rd,Y} = N_s\left(d_h - y_c\right), \tag{5}$$

N_s, N_c – resultant forces, in the reinforcement and in the compressed concrete area, respectively; d_h is the distance from the most compressed concrete fiber of the section to the point of application of the resultant N_s; y_c is the coordinate of application of the resultant N_c; $M_{Rd,Y}, M_{Ed,Y}$ – values of bending moments from the action of internal and external forces, respectively, in the plane of the coordinate axis Y at the moment of exhaustion of the strength of the reinforced concrete member in the normal section.

To obtain the necessary design formulas, the expressions of the resultant N_c, as well as the distance y_c from the most compressed concrete fiber to the point of application of N_c, were first realized. The desired expressions for the trapezoidal form of the compressed concrete area (figure 1) are obtained in the following form:

$$N_c = \frac{f_{cd}b}{\cos\theta}\left(\lambda X - \frac{b\sin\theta}{2}\right), \tag{6}$$

$$y_c = \frac{3\lambda^2X^2 - 3\lambda Xb\sin\theta + b^2\sin^2\theta}{3\cos\theta\left(2\lambda X - b\sin\theta\right)}, \tag{7}$$

where θ is the angle of inclination of the neutral axis; X is the neutral axis depth.

Since the problem is solved for the case when the stresses in the reinforcement of the tensile area reach the values $\sigma_s = f_{yd}$, then the resultant force in the tensile reinforcement is determined by the dependence

$$N_s = f_{yd}A_s. \tag{8}$$

After substituting (6) – (7) in (3) and (5) for the trapezoidal form of the compressed area, the formulas for determining the neutral axis depth X and the ultimate value of the moment $M_{Rd,Y}$ in the plane of the coordinate axis Y are obtained:

$$X = \frac{f_{yd}A_s\cos\theta}{f_{cd}\lambda b} + \frac{b\sin\theta}{2\lambda}, \tag{9}$$

$$M_{Rd,Y} = f_{yd}A_s\left(d_h - \frac{3\lambda^2X^2 - 3\lambda Xb\sin\theta + b^2\sin^2\theta}{3\cos\theta\left(2\lambda X - b\sin\theta\right)}\right). \tag{10}$$

Substituting the value of X from equation (9) into equation (10) and making the substitution $\rho_l = A_s/(bd_h)$, it is obtained

$$M_{Rd,Y} = f_{yd}\rho_l bd_h\left(d_h - \frac{f_{yd}\rho_l d_h}{2f_{cd}} + \frac{f_{cd}b^2tan^2\theta}{24f_{yd}\rho_l d_h}\right). \tag{11}$$

By equating the right-hand side of inequality (1) and equation (9) taking into account (2), it is possible to obtain the coefficient of reduction of the design strength of reinforced concrete at biaxial bending for a rectangular cross-section with a trapezoidal form of the compressed concrete area

$$\gamma = 1 - \frac{f_{cd}^2\tan^2\theta}{12f_{yd}\rho_l\left(2f_{cd} - f_{yd}\rho_l\right)}\left(\frac{b^2}{d_h^2}\right). \tag{12}$$

To obtain the dependence $\theta = f(\beta)$, which can be used to calculate the angle θ of inclination of the neutral axis, the condition of parallelism of the planes of the internal $M_{Rd,\beta}$ and external $M_{Ed,\beta}$ bending moments action is applied. Those planes are inclined at an angle β to the vertical

Y axis of symmetry of the section. According to this condition in the XOY coordinate system (figure 1) the ratio is valid

$$\tan\beta = \frac{d_b - x_c}{d_h - y_c}, \tag{13}$$

where d_b, d_h are the effective heights, respectively, in the direction of the X and Y axes of the cross-section of the biaxially bended member; x_c, y_c are the coordinates of the point of application of the resultant in the compressed concrete area in XOY coordinate system. The coordinate y_c is determined by dependence (7), and the coordinate x_c is determined by the following dependence

$$x_c = \frac{b\,(3\lambda X - 2b\sin\theta)}{3\,(2\lambda X - b\sin\theta)}. \tag{14}$$

After substituting (9) into (7) and (14), it is obtained that the formulas for calculating the coordinates of the application of resultant force in the compressed area take the form

$$x_c = \frac{b}{2} - \frac{f_{cd} b^3 \tan\theta}{12 f_{yd} A_s}, \tag{15}$$

$$y_c = \frac{f_{yd} A_s}{2 f_{cd} b} + \frac{f_{cd} b^3 \tan^2\theta}{24 f_{yd} A_s}. \tag{16}$$

Substituting (15) and (16) into the original formula (13) makes it possible to obtain an equation whose solution with respect to $\tan\theta$ will be a formula that allows calculating the angle θ depending on the angle β of inclination of the external load plane

$$\tan\theta = -\cot\beta + \sqrt{\cot^2\beta - \frac{24 t f_{yd} A_s \cot\beta}{f_{cd} b^3}}, \tag{17}$$

where $t = d_b - d_h \tan\beta + \frac{f_{yd} A_s \tan\beta}{2 f_{cd} b} - \frac{b}{2}$.

Having singled out the ratio b/d_h as one that can be specified, and performing the substitution ρ_l, the formula for determining the angle θ is written in the form

$$\tan\theta = -\cot\beta + \sqrt{\cot^2\beta - \frac{24 f_{yd}\rho_l \cot\beta}{f_{cd}} \left(\left(k - \frac{1}{2}\right)\frac{b}{d_h} - \tan\beta\left(1 - \frac{f_{yd}\rho_l}{2 f_{cd}}\right)\right)\left(\frac{d_h}{b}\right)^2}, \tag{18}$$

where $k = d_b/b$.

Thus, using dependencies (12) and (18), it is possible to tabulate the coefficient of decreasing of the strength of reinforced concrete at biaxial bending when the angle β of the external load plane inclination to the vertical axis of symmetry of the section is changed for a certain value of the b/d_h ratio.

In a similar way, the dependencies for the triangular form of the compressed concrete area are found. In this case the design scheme is shown in figure 2.

The general equilibrium equations for the considered design diagram (figure 2) will have the form (3) – (4).

The sought expressions of the resultant N_c in (3), as well as the coordinates y_c of its application in (4) for the triangular form of the compressed concrete area (figure 2) take the following form:

$$N_c = \frac{f_{cd}\lambda^2 X^2}{\sin 2\theta}, \tag{19}$$

$$y_c = \frac{\lambda X}{3\cos\theta}. \tag{20}$$

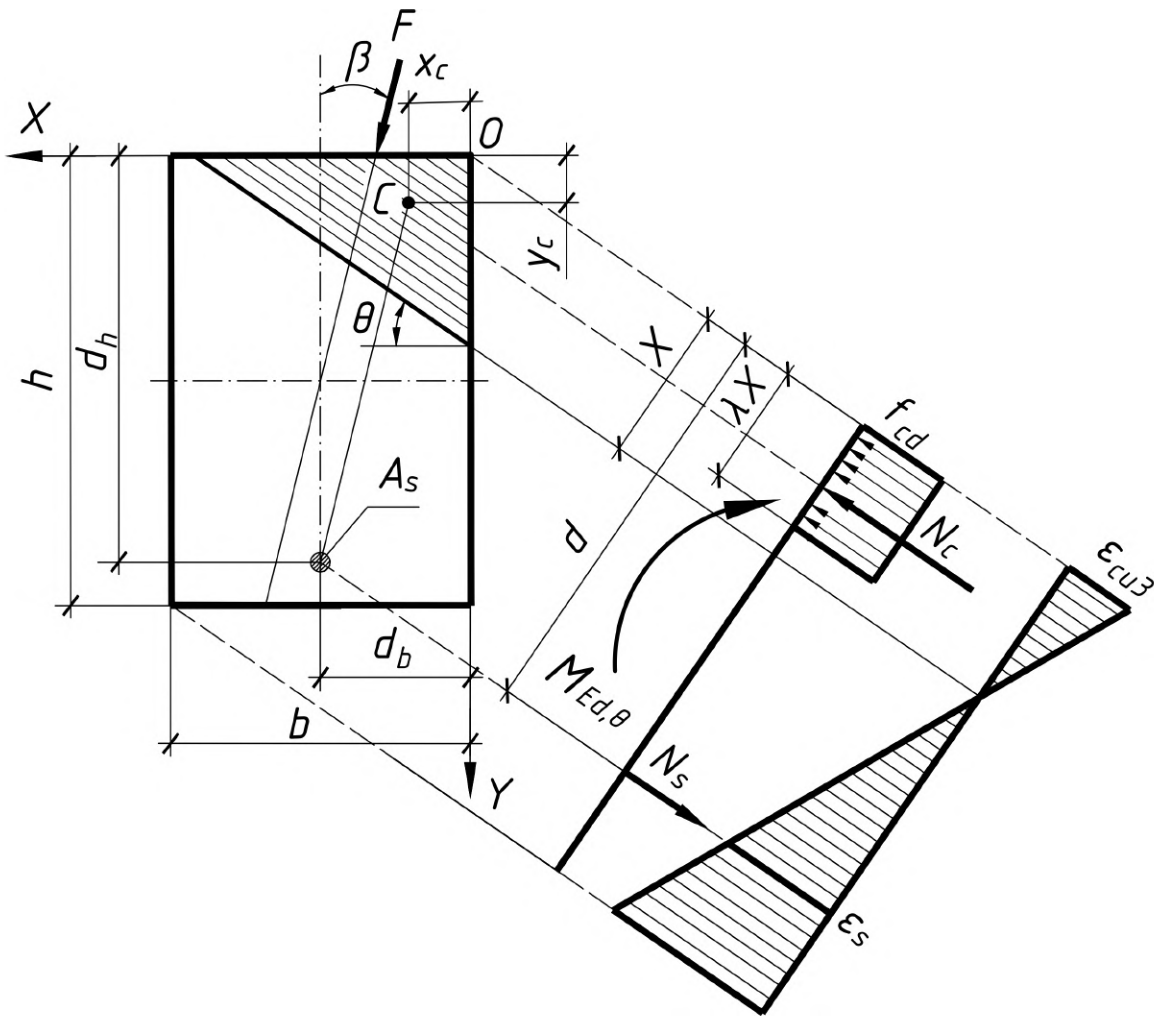

Figure 2. Design diagram of the cross-section of a biaxially bended member with a triangular form of a compressed concrete area.

Since the problem is solved for the case when the stresses in the reinforcing steel of the tensile area reach the values $\sigma_s = f_{yd}$, the resultant force in the tensile reinforcement is determined by dependence (8).

After substituting (19) – (20) in (3) and (5) for the triangular form of the compressed area, the formulas for determining the neutral axis depth X and the ultimate value of the moment $M_{Rd,Y}$ in the plane of the coordinate axis Y are obtained:

$$X = \sqrt{\frac{f_{yd} A_s \sin 2\theta}{f_{cd} \lambda^2}}, \tag{21}$$

$$M_{Rd,Y} = f_{yd} A_s \left(d_h - \frac{\lambda X}{3 \cos \theta} \right). \tag{22}$$

By substituting the value of X from equation (21) into equation (22) and performing the substitution ρ_l, it is obtained

$$M_{Rd,Y} = f_{yd} \rho_l b d_h \left(d_h - \frac{1}{3} \sqrt{\frac{2 f_{yd} \rho_l b d_h \tan \theta}{f_{cd}}} \right). \tag{23}$$

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012073 doi:10.1088/1755-1315/1254/1/012073

By equating the right-hand side of inequality (1) and equation (23) taking into account (2), an expression for calculating the coefficient γ is obtained, which takes into account the influence of biaxial bending on the values of the member characteristics in (1) for a rectangular cross-section with a triangular form of a compressed concrete area

$$\gamma = \frac{2f_{cd}}{2f_{cd} - f_{yd}\rho_l} - \sqrt{\frac{8f_{cd}f_{yd}\rho_l \tan\theta}{9(2f_{cd} - f_{yd}\rho_l)^2}\frac{b}{d_h}}. \tag{24}$$

To obtain the dependence $\theta = f(\beta)$, condition (13) is applied, in which the coordinate y_c is determined by dependence (20), and the coordinate x_c is determined by the following dependence

$$x_c = \frac{\lambda X}{3\sin\theta}. \tag{25}$$

After substituting (21) into (20) and (25), it is obtained that the formulas for calculating the coordinates of the application of resultant force N_c in the compressed area take the form:

$$x_c = \frac{1}{3}\sqrt{\frac{2f_{yd}A_s}{f_{cd}\tan\theta}}, \tag{26}$$

$$y_c = \frac{1}{3}\sqrt{\frac{2f_{yd}A_s}{f_{cd}}\tan\theta}. \tag{27}$$

Substituting (26) and (27) into the original formula (13) makes it possible to find an equation whose solution with respect to $\tan\theta$ will be a formula that allows calculating the angle θ depending on the angle β of inclination of the external load plane

$$\tan\theta = \frac{f_{cd}\left(\sqrt{c^2 + 8\frac{f_{yd}A_s}{f_{cd}}\tan\beta} - c\right)^2}{8f_{yd}A_s\tan^2\beta}, \tag{28}$$

where $c = 3d_b - 3d_h\tan\beta$.

Having singled out the ratio b/d_h as one that can be specified, the formula for determining the angle θ is written in the form

$$\tan\theta = \frac{d_h}{b}\frac{f_{cd}l^2}{8f_{yd}\rho_l\tan^2\beta}\left(\sqrt{1 + \frac{8f_{yd}\rho_l}{f_{cd}l^2}\frac{b}{d_h}\tan\beta} - 1\right)^2, \tag{29}$$

where $l = 3kb/d_h 3\tan\beta; k = d_b/b$.

Full calculation of biaxially bended members according to the described method is possible only if the form of the compressed concrete area is known. For its definition, a prerequisite is adopted, on the transformation of the trapezoidal form of the compressed area into a triangular one on the border of the limiting state of its existence. The considered state is characterized by one case of the position of the neutral axis, namely, when the neutral axis crosses the less compressed edge. This position of the neutral axis, as can be seen from the comparison of the design diagrams shown in figure 1 and figure 2, is the boundary between these schemes.

According to the design diagram (figure 2), at the limit position of the neutral axis, the equation (3) using (19) and (8) will have the form

$$\frac{f_{cd}X^2\lambda^2}{\sin 2\theta} = f_{yd}A_s. \tag{30}$$

From the analysis of equation (30), it is obvious that the condition for delimiting the forms of the compressed area will be inequality

$$\frac{f_{cd}X^2\lambda^2}{\sin 2\theta} \geq f_{yd}A_s. \tag{31}$$

If condition (31) is fulfilled, the compressed concrete area has the form of a triangle, if it is not fulfilled, the compressed area has the form of a trapezoid. To use this condition in practice, it is necessary to know all the parameters included in inequality (31). When solving the bearing capacity check problem, two parameters X and θ are unknown.

To determine the unknowns, the condition of the parallelism of the planes of action of internal and external forces is applied, which, based on the design diagram, is written in the form (13).

Substituting (25) and (20) into (13) under the condition that for the limiting case of the position of the neutral axis $\lambda X = b\sin\theta$ it is obtained

$$\frac{\lambda X}{\cos\theta} = 3d_h - (3d_b - b)\cot\beta. \tag{32}$$

After substituting (32) into inequality (31) and performing mathematical transformations, the condition for delimiting the forms of the compressed area is reduced to a simple form

$$\cot\beta \leq \frac{3f_{cd} - 2f_{yd}\rho_l}{f_{cd}\,(3k-1)}\frac{d_h}{b}. \tag{33}$$

Therefore, if inequality (33) is fulfilled, the form of the compressed area of concrete is triangular, if it is not fulfilled, it is trapezoidal.

Using the obtained dependencies (12), (18), (24), (29) and (33), it is possible to determine the coefficient γ of taking into account the influence of biaxial bending on the values of the member characteristics in (1) for a rectangular section depending on the angle of inclination of the external load plane. At the same time, the geometric characteristics of the cross-section in the form of ratios b/d_h and $k = d_b/b$ (figures 1, 2) and the longitudinal reinforcement ratio ρ_l of the cross-section are also taken into account. The values of the coefficient γ for reinforcement of class A500C are given in table 2 for the case of the tensile reinforcement reaching the yield point at the time of member failure.

Using the developed method, the bearing capacity of the biaxially bended beams studied in [18] was determined. The calculation results and experimental data are shown in table 3.

To illustrate the developed calculation method, the following example is considered.

Given: a reinforced concrete beam of a rectangular profile with cross-sectional dimensions $b = 200$ mm, $h = 450$ mm, the beam is made of concrete class C25/30 ($f_{cd} = 17$ MPa); in the beam, tensile reinforcement (4Ø16) with a cross-sectional area of $A_s = 804$ mm^2 of class A500C ($f_{yd} = 435$ MPa) is located symmetrically relative to the vertical axis at a distance of its centre of gravity from the lower face of the cross-section $a = 50$ mm, the angle between the vertical axis of symmetry of the cross-section and the plane of action of the external load $\beta = 5°$. It is necessary to determine the maximum value of the bending moment that the beam may perceive.

Calculation: Determination of the geometric characteristics of the section

$d_h = h - a = 450 - 50 = 400$ mm; $d_b = b/2 = 200/2 = 100$ mm,

$b/d_h = 200/400 = 0.5$; $d_b/b = 100/200 = 0.5$.

Determination of the longitudinal reinforcement ratio

$\rho_l = A_s/(bd_h) \times 100\% = 804/(200 \times 400) \times 100\% = 1\%$.

The design strength of reinforced concrete is determined from table 1 $f_{zM} = 22.76$ MPa.

According to table 2, the coefficient $\gamma = 0.962$.

Modulus of the section is $W = bd_h^2/6 = 200 \times 400^2/6 = 5333333$ mm^3.

Table 2. The coefficient γ of taking into account the influence of biaxial bending on the design strength of reinforced concrete for members of a rectangular section with single reinforcement of class A500C (f_{yd}=435 MPa, ρ_l= 1, b/d_h= 0.5, k= 0.5).

BR-4-4	581	462	1.44	21	13.36	40.28	0.964	41.40	40.28	43.65	7.7

Using formula (1), the bending moment that might be perceived by the beam in the vertical plane is calculated $M_{Rd,Y} = f_{zM}W\gamma = 22.76 \times 5333333 \times 0.962 = 116.77 \times 10^6$ Nmm = =116.77kNm.

The moment in the external load plane action passing at an angle β to the vertical axis of symmetry of the section is $M_{Rd,\beta} = M_{Rd,Y} \cos\beta = 116.77 \times \cos 5° = 116.33$ kNm.

3. Conclusions

The concept of determining the value of the design strength of reinforced concrete for calculating the bearing capacity of reinforced concrete members subjected to biaxial bending has been developed. The value of the coefficient of influence of biaxial bending on the characteristics of the member of rectangular section with triangular and trapezoidal forms of the compressed concrete area is obtained. The methodology is brought to the engineering level of application. The proposed method of calculating the bearing capacity of beam members under biaxial bending ensures a satisfactory convergence of the calculation and experimental data.

Abstract. Phytofiltration is the most sustainable way to achieve a better quality of inlet air in buildings in a polluted environment. But they don't take into account the biorhythms of plants and pollute the inlet air with CO_2 during breathing only time. We collected and analysed data about the biorhythms of plants. As a result, a new bi-directional phytofilter was offered for cleaning and oxygenation of the inlet ventilation air, and also to protect the environment by cleaning the exhaust air from different pollutants. The device has spaces with shifted illumination rhythms and a valve system. A controller directs the inlet air to the space(s), where plants release CO_2. The outlet air runs through other spaces. Literature data show that in the less favourable case, the CO_2 and oxygen emissions are balanced per day without overall CO_2 gain to the environment. When plants are growing, they sequestrate CO_2 to catch greenhouse gas emissions. Either natural light, artificial light, or a combination of the two can be used. While the second option simply demands one plant metabolism type, the first option needs a combination of CAM metabolism and other plants

1. Introduction

The fundamental issue with contemporary dense construction and high levels of traffic is their detrimental impact on the environment, which lowers the quality of the outdoor air. Outdoor air in industrial areas or near congested roadways is too filthy to be used for ventilation. The air is passed to an air handling unit, which can remove dust, and change temperature and humidity, but can't effectively eliminate the gas pollutants. Thus, dirty inlet air pollutes the indoor one. The last one is additionally polluted by indoor sources such as furniture, water supply, equipment, finishing materials, etc. And finally, the more polluted indoor air is released into the environment through exhaust ventilation and makes the environment dirtier. To solve the problem, we can use a biotechnological approach – green structures that connect living plants and building structures [1–7]. The most perspective solution for inlet/internal ait treatment is fytofilters with living plants. Modern phytofiltration systems in rooms or ventilation systems run independently on the biorhythms of plants. At the time when plants don't release oxygen, they cause secondary CO_2 pollution.

2. The current state of phytoremediation of indoor air

2.1. Mechanisms of removal of air pollutants by plants

Indoor air pollution can be remedied using methods such as chemical cleaning, assimilation by ventilation, insulation, and plant decontamination (phytoremediation). Plants are autotrophic organisms that perform intensive gas exchange to carry out cellular vital activities, thanks to which air pollutants can be absorbed or accumulated inside [8–10]. The term "Phytoremediation" means bioremediation of polluted air, soil and water with the help of plants [11].

Plants reduce the mobility, toxicity, and volume of pollutants through a variety of mechanisms, such as accumulation, volatilization, and degradation. These biological processes ultimately require light energy (solar, high-efficient LED phytolamps), and therefore phytoremediation is a cheaper method than engineering ones. Phytoremediation is considered an alternative or additional air purification technology [11].

More than 35 years ago, the US National Aeronautics and Space Administration (NASA) faced health problems related to poor indoor air in fully enclosed systems in outer space. More than 300 volatile organic compounds (VOCs) were found in the environment of the spacecraft, which were cause the deterioration of the astronauts' health. To solve this problem, NASA researched the use of plants to remove pollutants and maintain a safe breathing environment. The first studies on the purifying properties of plants were conducted within the framework of NASA's Clean Air project in cooperation with the Association of Landscape Contractors of America (ALCA) [12].

The results of these studies have shown that some common indoor plants in combination with activated carbon as a substrate contribute to the natural purification of the air from several of toxic substances for humans, such as benzene, formaldehyde and trichloroethylene, helping to neutralize the sick building syndrome. The first list of air-purifying plants was formed by NASA and published in 1989 [12–14], which was aimed at research on air purification in the closed conditions of space stations. The plants included in the first list, in addition to the absorption of carbon dioxide and the release of oxygen, also eliminated a significant amount of benzene, formaldehyde and trichloroethylene.

The second and third lists were formed later by Wolverton in the book [15] and article [16]. These works provide information about plants that remove more specific chemicals from the air. NASA researchers suggest that effective air purification can be achieved with at least one plant per 100 square feet (approximately 9.29 square meters) of a home or office space. At the initial stage of research, only plants grown hydroponically (that is, without soil) were considered, in later studies it was shown that microorganisms in a soil mixture in a pot can remove benzene from the air. Certain types of plants also contribute to the removal of benzene. Given the surface area required, using leaves alone was impractical, so the NASA team investigated the possibility of toxin removal by microorganisms in the rhizosphere. In addition, research conducted at NASA's National Space Technology Laboratories has shown that phytoremediation is effective in treating residential wastewater and in removing compounds containing radioactive components from both soil and wastewater [16, 17].

In 1985, fundamental research that revealed the ability of indoor plants and their root microorganisms to clean indoor air from chemical pollutants received further development. However, the removal time of pollutants can be long [18].

There are different forms of plant pollution removal. One of them is absorption of pollutants by roots from soil and water. Root uptake is related to contaminant concentration and properties, plant species/composition, time of exposure, and other system variables. When organic pollutants (such as trichloroethylene) are present in the shoots, they can be transported to the roots by the phloem. The transformation or degradation of the pollutant by plant tissues is another important issue in phytoremediation [19] gaseous pollutants and particles such as dust and bioaerosols are adsorbed on the leaf surface, gaseous pollutants are absorbed by stomata and accumulate in various internal structures, photosynthesis can remove CO_2 and produce O_2. Leaf transpiration and evaporation from the environment for rooting (soil, precipitation, sludge, sewage) [20] increase the moisture content.

2.2. Removal of volatile organic compounds (VOCs) from indoor air by plants

Volatile organic compounds (VOCs)are an important class of indoor air pollutants because they cause a wide range of harmful effects on human health, even at low concentrations. Despite this, currently available techniques for removing VOCs from indoor air are often ineffective, especially when it comes to gaseous compounds [21].

The idea of the removal of volatile organic compounds from indoor air by plants was also presented by Wolverton et al [12] in 1989, as discussed above. These studies confirmed that potted plants can remove significant or large amounts of gaseous VOCs in sealed chambers, reducing VOCs from 10 % to 90 % in 24 h [22].

Wolverton et al studied 12 plants for removing VOCs and demonstrated the possibility of improving indoor air quality by removing traces of organic pollutants from the air in energy-efficient buildings. They showed that contact of the root area with air has a higher efficiency in removing organic pollutants [12, 23].

The work [24] describes the following possible ways of removal of volatile organic compounds by plants:

- removal of the above-ground zone of plants;
- removal of VOCs by microorganisms in the soil;
- removal through the root system;
- removal by the plant environment (substrate).

Highlighting the method of VOC removal by microorganisms in the soil is worthwhile, which is a subspecies of phytoremediation and phytodegradation, which describes the breakdown of complex organic pollutants into simple compounds or the metabolism of pollutants in the phyllosphere and rhizosphere [11].

Transformation in the rhizosphere, also called rhizodegradation (or considered phytostimulation), is carried out by soil organisms such as bacteria, fungi or enzymes released from plants or microorganisms. Pollutants are degraded in the rhizosphere as well as inside plants by specific plant enzymes such as nitroreductases, dehalogenases, and laccases [25]. Compounds secreted from plants, such as sugars, amino acids or enzymes, can stimulate the growth of bacteria in the soil and vice versa – stimulate microbial and fungal degradation by releasing enzymes into the rhizosphere. That is why rhizodegradation is also called phytoremediation or bioremediation with the help of plants [11].

During photosynthesis, plants absorb VOCs through stomata and cuticle wax, subsequently converting them into amino acids through the Calvin cycle [26]. In the intercellular spaces of plants, absorbed pollutants are stored or react with the inner surface of leaves and the water film, then decompose or are released to the outside [26].

Other common gaseous air pollutants such as SO_2, CO_2, NO_x and O_3 also accumulate in plant cells and tissues, mainly through stomata, wax and cuticle. Photosynthesis is the basic plant mechanism in which plants absorb CO_2 and convert it into oxygen. Stomata located on the epidermis of leaves and stems of plants are the primary zone where the process of gas exchange takes place [27].

Considering the potential of plants to remove VOCs, there is some research on benzene removal. In [28], it was shown that the main agents for removing benzene, as one of the model VOCs, are microorganisms of the rhizosphere of potting mix. These studies were the first demonstration of microbial degradation of soil VOCs from the gaseous phase. The results demonstrate the ability of the microcosm created in the pots to contribute to indoor air purification and lay the foundation for the development of the plant and substrate system as an additional biofiltration system.

Sriprapat and Thiravetyan [29] provided experimental data for eight types of plants, including *Sansevieria trifasciata*, *Euphorbia milii*, *Epipremnum aureum*, *Syngonium podophyllum*, *Hedera helix*, *Chlorophytum comosum*, *Dracaena sanderiana* and *Clitoria ternatea* used to remove benzene from air and water. These houseplants are well known for their high tolerance to toxic pollutants. Within 96 hours, *C. comosum* was found to have the greatest potential among other plants to remove benzene from indoor air. The addition of bacteria showed a lower rate of benzene removal than in the absence of bacteria. Also, the efficiency of benzene removal by Chlorophytum comosum under conditions of light and darkness was considered in the work [23].

Some studies revealed that bacteria, which are concentrated on the surfaces of plant leaves, contribute to the biodegradation of VOCs [30]. Wetzel and Doucette [31] state that wax coating of cuticles on leaves can provide a simple, cost-effective way to sample indoor air for VOCs and help improve indoor air quality.

Correct selection of plant species plays an important role in removing VOCs from indoor air. Thus, in work [32], about 120 species of indoor plants were analysed by various researchers for the degree of VOC removal, which made it possible to draw the following conclusions:

- tropical indoor plants such as *Dracaena Janet Craig* and *Spathiphyllum* have low VOC removal activity [33];
- the best plants with high VOC removal: *Hemigraphis Alternata*, *Hosta* Purpleheart, *Hedera helix*, *Asparagus fern*, *Senecio Macroglossus 'Variegatus'*, and *Crassula portulacea.*

There is an interesting study that evaluated the potential of a *Spathiphyllum wallisii* to remove cigarette-derived VOCs and all particle size fractions [34], achieving a single-pass removal efficiency of 43.26 % for the total VOCs and 34.37 % for the total number of suspended particles. A botanical biofilter with a selected type of vegetation allowed the reduction of the concentration of many of harmful chemicals in tobacco smoke, including nicotine, limonene and toluene.

Usually, among volatile organic compounds, the main research of the scientific community is focused on formaldehyde. And phytoremediation is still the simplest and most environmentally safe technology for removing formaldehyde from indoor air [35]. Being toxic to humans and other living organisms due to, for example, DNA damage, formaldehyde is also an indispensable substance in plant metabolism [36]. According to the mass balance of water-air plant systems, the main mechanism of formaldehyde loss is the decomposition of formaldehyde in plant tissue caused by enzyme and redox reactions [37]. The redox mechanism shows that the rate of formaldehyde removal can be accelerated by increasing reactive oxygen species caused by ambient pressure [38].

Historically, the above-mentioned NASA studies on the purification of plants from formaldehyde in a closed environment used methods of formaldehyde absorption by plants in hanging pots, which also contributed to the study of formaldehyde absorption by leaf stomata [39] These methods have evolved into a modern automatic system for monitoring formaldehyde uptake by plants, which shows how fumigation increases hydroponic plants that are the most efficient for formaldehyde uptake [40]. Other factors affecting formaldehyde removal are the type of plants and the environment for their cultivation [28].

In [41], a number of experiments are given that demonstrate the absorption of formaldehyde by 376 different types of plants. Only five species ($\sim$1.3%) absorb more than 10 mg/m^2 of formaldehyde, while 90% of plants absorb less than 5 mg/m^2 of formaldehyde, with the majority of plant species belonging to the genus Tillandsia having a level of 97%, so can be recommended for indoor use.

The work [42] showed that *Epipremnum aureum* is one of the most effective plant species for formaldehyde absorption due to its high stomata and leaf area. In addition, in [43], an experiment was conducted on the removal of formaldehyde by such plant species as *Epipremnum aureum* and *Rohdea japonica* in a hermetic chamber. The results showed that the stems can also effectively remove formaldehyde. The results also showed that when plant leaves were exposed to formaldehyde, CO_2 concentration increased with decreasing formaldehyde concentration, and the change in CO_2 concentration could be used as an indicator of the degree of formaldehyde decontamination by plants.

In general, the ability of succulent plants and plants with lanceolate, hard, leathery leaves to absorb formaldehyde is relatively low [44].

Similarly, 50 terrestrial and 15 hydroponic plant species exhibiting high formaldehyde uptake capacity were also found to be related to light intensity, photosynthesis, and biomass [45]. Substrates for potted plants with high porosity, such as diatomite, peat, bark, sawdust, perlite, and bacterial residues, have a strong capacity to absorb formaldehyde [46]. In addition, it has been confirmed [47] that leaf age is very important for formaldehyde absorption efficiency, since young leaves have low stomatal conductance, while mature leaves have higher stomatal conductance for formaldehyde absorption.

Formaldehyde gas accumulates in the leaves of plants and transported to the roots from the rhizosphere zone. This transport mainly depends on the absorption time and formaldehyde content in the leaves. Microorganisms on the surface of the leaves also absorb formaldehyde, further enhancing this process.

Indoors with continuous release of formaldehyde, early-stage uptake is mainly by roots and soil, while plant leaves play a smaller role in the early stage and a greater role in the later stages [48].

Plants are known to be associated with symbiotic microbes such as fungi and bacteria that mitigate abiotic and biotic stresses in them and enhance their growth. Plant-microbe interactions also play an important role during phytoremediation by degrading, detoxifying, or sequestering pollutants [49].

Therefore, the composition of soil rhizosphere microorganisms also plays an important role in the absorption and metabolism of gaseous formaldehyde by plants [50]. In systems without rhizosphere microorganisms, formaldehyde is not removed, while in systems with a rhizosphere microbiome (10–45 mg/dm^3), all formaldehyde is removed [51].

Understanding the influence of rhizosphere microflora on formaldehyde metabolism is important to increase the efficiency of uptake and removal by houseplants [52].

The use of microorganisms can improve the remediation capacity of potted plants. The addition of cultivated microorganisms to the rhizosphere of such plant species as *Aloe vera* and *Tradescantia zebrine* improved the efficiency of formaldehyde removal [53]. In addition, a hydroponic system was developed that consisted of plants of the species *Ophiopogon japonicus*, phenol-degrading bacteria such as *Staphylococcus epidermis* and *Pseudomonas spp.* and air compressor. This system showed a high capacity for phenol decomposition of about 1000 g/dm^3 daily [53].

The authors [54] showed that the rate of formaldehyde removal is not only related to the size of plants in pots but also closely related to air dynamics. They used the parameter of equivalent clean air supply rate, which is commonly used to quantify air cleaning capacity, and showed that the investigated parameter is only 5.1 m^3/h per m^2 room for static air, and 233 m^3/h per m^2 room when the air was transported through potted plants.

On the other hand, work [55] shows that, according to the ASHRAE standard 62.1-2016, the minimum ventilation rate in the working zones of office premises is 0.3 dm^3/s for every m^2 of space (1.08 m^3/h for every square meter of space) [56]; similarly to the NEN-EN 15251-2007 standard, the minimum ventilation rate for new or reconstructed buildings is 0.35 dm^3/s for each m^2 of the room area (1.26 m^3/h for each square meter of area) [57].

In the standard [56], it was established that the rate of supply of clean air for formaldehyde removal by potted plants is 0.03 m^3/h, therefore, to meet the standards without an additional ventilation system, it is necessary to have 42 plants for every square meter of the room area.

In addition, the authors established [55] that the rate of supply of clean air for CO_2 depletion by plants in pots is 0.01 m^3/h (*Reace lily*) and 0.02 m^3/h (*Nephrolepis exaltata*). Therefore, it is necessary to have >100 plants for every square meter of room area to meet the standards without an additional ventilation system.

Despite the large number of works devoted to the study of the removal of VOCs from indoor air by plants [58, 59], there is still a need for additional research on the modification of plant physiology by, for example, rhizosphere modification to increase phytoremediation of indoor gaseous formaldehyde.

There is an inaccuracy related to volatile organic compounds. There is a subclass of it called volatile phytoorganic compounds, which contain healthy substances – phytoncides, odorants etc. But gas analysers often display total volatile organic compounds (TVOC) without division. When the authors perform experiments with plants, D91 gas analyser alerts the deadly content of TVOC, but the experimenters feel very good and stay healthy. Thus, we should be very careful interpreting the measuring results in greened rooms. When measuring the absorption of total volatile organic compounds by plants, the result will be always strictly underestimated or inverted. Thus, we can perform experiments only on individual compounds and only after testing the measuring sensors for the influence of volatile phytoorganic compounds. For example, we can bring the sensors to plants in a clean room and check the insignificance of rising the readings.

Phytoremediation was evaluated in [64] as a solution for trimethylamine (TMA) removal. Trimethylamine (TMA, N(CH3)3) is a volatile tertiary amine, which is a decomposition product of nitrogen-containing organic substances of animal and plant origin. It is a colourless gas that has a fishy odour at low concentrations and an ammonia-like odour at higher concentrations. Eight species of pot plants were used in the research: *Opuntia*, *Dracaena sanderiana*, *Dieffenbachia camilla*, *Tradescantia spathacea*, *Peperomia magnoliifolia*, *Chlorophytum comosum*, *Cereus hexagonus* (L.) Mill., and *Scindapsus aureus*, which were selected as candidates for TMA removal under light and dark conditions.

According to the research results, the authors divided the selected plants into two groups: plants with high TMA removal efficiency under light conditions and plants with high removal efficiency under light and dark conditions. The results showed that *S. aureus* had the highest TMA removal efficiency under light conditions after 72 hours (> 95 %). However, it had very low efficiency under dark conditions, suggesting that *S. aureus* should be housed in areas with 24-hour light sources. On the other hand, *cactus* species (*C. hexagonus* (L.) Mill. and *Opuntia*) remove TMA highly efficiently in both light and dark conditions after 72 hours (> 90 %) and therefore may be more suitable for real-world use. In addition, the ANOVA (analysis of variance) results confirm with 95 % confidence that plant type (chosen from 8 types) and lighting conditions (e.g., LED lighting, fluorescent lighting, or dark conditions) have a significant effect on TMA removal after 24 h.

2.3. Reducing the level of CO_2 *in a room*

Regarding the reduction of carbon dioxide (CO_2) levels and the expected level of air quality, the results showed a positive effect of indoor green spaces in reducing CO_2 levels [60]. In addition, the authors also found that the concentration of CO_2 changes depending on human activity inside the living space.

Thus, work [61] shows that in non-industrial premises, such as offices, schools and houses, the main source of CO_2 is human metabolism. In addition, it is justified that CO_2 is no longer considered a pollutant, but an indicator of the presence of pollutants associated with the presence of people indoors.

It has been proven [62] that indoor plants improve the indoor atmosphere, relieve anxiety and reduce CO_2 concentration. In addition, there are a number of studies that confirm the removal of other types of indoor air pollutants by potted plants. For example, in [63] the mechanisms of nitrogen oxide removal by dry deposition by potted plants were considered. The principle of absorption of pollutants by leaves and the factors affecting the removal of nitrogen oxides are substantiated, providing a theoretical basis for the selection of urban green vegetation.

2.4. Microorganisms

The work [1] shows the results of research based on the microbiota factor. The impact of plants on air quality was determined by monitoring the microbiological state of the air in several office premises in order to select promising plant species for creating health-improving interiors. Observational data demonstrate the bactericidal effect of the investigated phytoncide plants. It has been experimentally established that the microbial count in rooms with plants is significantly lower than in a reference room without plants. In the room with plants, the number of microorganisms was 1.5 ... 5 times less, depending on the period of observation. In addition, work [1] offers an assortment of plants, namely: *Ficus benjamina*, *Ficus benjamina Wiandi*, *Zamioculcas Zamiifolia*, *Dracaena marginata*, *Dracaena fragrans*, *Yucca elephantipes*, *Schefflera digitata*, *Aspidistra elatior*, *Crassula ovata*, *Spathiphyllum wallisii*.

2.5. Technology of active "green" structures for indoor air purification

Active "green" structures are one of the newest varieties of phytoremediation systems, which include ventilation, heating and cooling of the house using evaporative cooling – by the same principle as the cooling effect of outdoor green structures [3]. It operates on full recirculation, taking and returning the air to the room (figure 1).

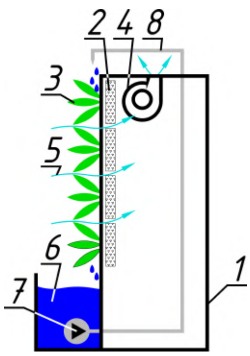

Figure 1. Active phytowall [65]: 1 – box; 2 – planting media; 3 – plants; 4 – fan; 5 – air movement; 6 – water tray; 7 – pump; 8 – pipe for watering.

The system of "green" walls, which cleans the air inside, also acts as a temperature and humidity control.

The authors [65] studied the system over 300 days. Satisfactory efficiency was found to remove formaldehyde and toluene (90 % and more than 33 %, respectively, during the first four days). In addition, this ACBB system successfully reduced the indoor air temperature by 0.5 °C in the real environment, while the temperature reduction was 1 °C in the laboratory. The increase in relative humidity for realistic and laboratory conditions was 17.7 and 9-13 %, respectively. In addition, a 20 % reduction in outside air supply was achieved with the ACBB system, saving the energy required by the building, given that the toluene and formaldehyde concentrations determined the standard ventilation rate for this case. Also, the analysis of the studied data confirmed the reduction of particulate matter (PM) concentrations to a level that the current indoor HVAC system could not achieve under normal conditions.

The same authors [65] also conducted many studies in laboratory conditions. The efficiency of the system in removing PM was evaluated exclusively in a static chamber, where a general observation recorded that the efficiency of PM removal increased with an increase in the airflow rate. Experiments were conducted with five different air flow rates to evaluate the efficiency of the ACBB system for filtering total suspended particles, PM 2.5 and PM 10. Based on the collected data and further analysis, this study estimates that for four workers in an office space, 1 m^2 of the system can sufficiently provide the necessary ventilation.

Therefore, since indoor air quality in buildings contributes to human health problems on a large scale, implementing sustainable solutions to maintain indoor air quality has become a particular challenge for the scientific community. Active botanical biofiltration systems are effective in removing pollutants along with the potential to increase humidity and cool the air. It is also well-studied that these systems do not promote the spread of fungi if they are maintained in a well-controlled state [66]. Moreover, the aesthetic value of the systems is an additional advantage for positive mental effects.

Since there is currently no software or computational methods capable of recognizing plants as indoor “air cleaners”, the impact of phytoremediation on the operation of HVAC systems and the energy sector is still poorly researched.

In the work [67], *Azolla filiculoides* was integrated into building walls for bioremediation of indoor air and a new protocol for assessing the effectiveness of a “green” wall using the “Indoor Air Quality” and “Ventilation Rate” techniques was proposed, which are recognized as practical engineering methods for determining the efficiency of air exchange using mechanical equipment. *Azolla filiculoides* has been observed to help absorb indoor CO_2, while under the Indoor Air Quality methodology, this results in a reduction in the building’s ventilation rate and, as a result, a reduction in the building’s overall energy consumption. In addition, the cooling effect of a green wall with *Azolla filiculoides* as a natural shading component was evaluated by applying its latent heat capacity to the thermal convection/conductivity of the facade, compared to aluminium louvres of the same size and spacing to computationally assess the thermal benefits of plants for improvement of cavity/inner space overheating.

So, based on the work [55], it is possible to define advantages regarding the effectiveness of the use of vegetation in rooms, which are based on scientific research over the past 30 years, of which the main ones are:

- Biophilic design and vegetation have a positive effect on people who spend a long time indoors, which is manifested in an increase in the general psychological satisfaction and mood of people.
- Evaporation of plants has been found to help lower ambient temperature, so this property of plants can be used to cool air and control humidity.
- It has been shown that green plants can be used to reduce the sound level – as a passive acoustic insulation system.
- The effect of vegetation on improving indoor air quality was analysed. However, there is still a lack of reliable and relevant data to understand the true pollutant removal mechanisms and factors in these systems (plant species, microorganism species, gas composition, light source, number of plants).
- It has been shown that in an active vegetation system (”green” systems in combination with mechanical fans) the rate of air purification can be significantly higher than in a passive vegetation system (potted plants).

Nevertheless, no attention is paid to the time, when plants don’t release oxygen. The daily biorythms of plants weren’t analysed, which can principally change the conclusions. Thus, we need to focus on this challenge to avoid troubles in the corresponding daytime.

3. Materials and methods

The literature review shows the most naturally promising approach for air quality control – plants [1, 2, 11, 68, 69]. They continuously humidify the air, remove volatile chemicals, dust, and other impurities, and release valuable volatile phytoorganic substances such as odorants and phytoncides. The last ones are the immunity substances that kill viruses and bacteria.

During active oxygen release time, plants emit oxygen while absorbing CO_2 [70, 71]. At other times, plants breathe only and pollute the surrounding air by CO_2. Except for [72] Crassulacean acid metabolism (CAM), which releases oxygen at night, most plants produce oxygen during the day.

To check the overall effect, we can analyse the outcomes of the *Aglaonema roebelinii* testing conducted by Intell House [73]. To control illumination, the researchers use two packets – light-tight and transparent. The measurements were performed using NetAtmo Weather Station. In the first packet, the CO_2 content increases from 796 to 2311 ppm within 40 minutes. The concentration in the transparent packet under the sun decreases from 1060 to 315 ppm. The concentration starts to rise at 16:06, reaches 1572 ppm at 6:54 and decreases to 263 ppm in the morning. The researchers concluded of no overall oxygenation during the day. The experimental method is very simple and didn't take into account many factors such as the dependency of photosynthesis on CO_2 content. But we can conclude that in the less favourable case, the CO_2 and oxygen emissions are balanced per day without overall CO_2 gain to the environment. It's good for us because phytofiltration will never cause greenhouse gas emissions. The second important conclusion is that we should develop a new phytofilter that operates accordingly to the plant's biorhythms to avoid temporary pollution of the inlet/indoor air. To continuously reduce indoor and outdoor air pollution and oxygenate the inlet/indoor air, active oxygen release should be carried out in the inlet air and breathing only in the exhaust.

4. Results and discussion

We suggest a design for an inlet-exhaust ventilation phytofilter module (figure 2). The phytofilter contains a valve system 4, which controls the airflow through spaces with plants 3 and the corresponding illumination 5. Ducts 1 should be connected to inlet and outlet ventilation ducts or an air handling unit. Controller 6 switches illumination 5 by rotation to keep artificial biorhythms of the plants inside. Some spaces 3 can be equipped with glazing to utilize natural light. The valves are opened-closed together with the illumination to pass inlet air through space(s) 3 with oxygen release and outlet one – through other spaces 3. For 24/7 operation with most plants, the phytofilter should contain at least three cameras. But for working time up to 16 h/day two cameras will be enough.

The main problem is the energy consumption of phytolamps. It's impossible to split oxyden and carbon from CO_2 without energy consumption because in the opposite case, we will obtain perpetum mobile by burning the carbon. Thus we should find opportunities to use free accessible energy for illumination or utilise the heat from the lamp. There are some ways:

- utilizing natural illumination only through transparent walls demands the combination of CAM and other plants, but this raises biomass requirements due to CAM's reduced efficiency as a result of its overnight energy discharge and daily energy charge, so the exergy destruction will occur twice;
- the use of natural illumination for spaces with daily oxygen release;
- the phytofilter should be installed after an air-handling unit with the heater, cooler, and re-heater (figure 2), thus the heat from illumination will reduce the requirement for energy

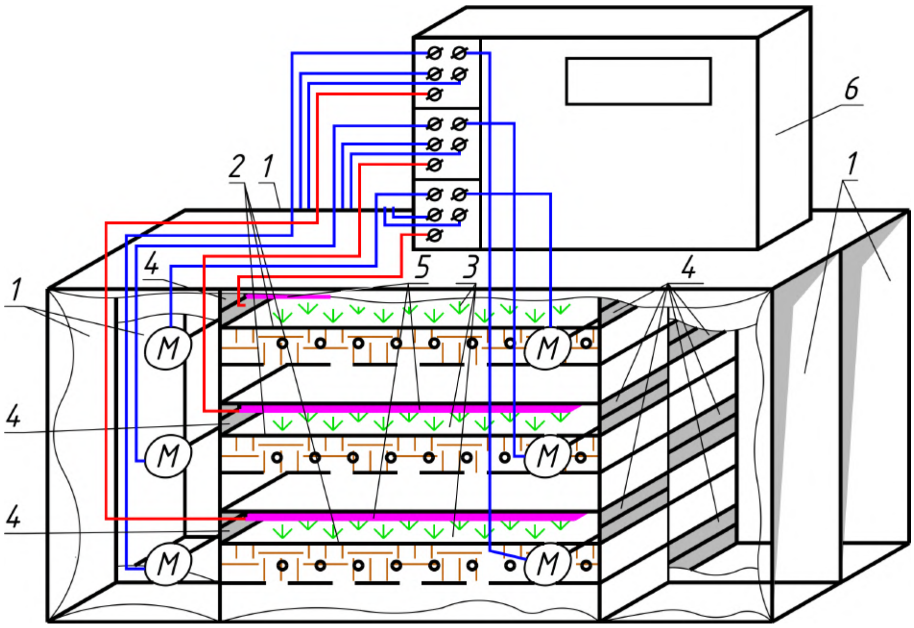

Figure 2. Phytofilter: 1 – duct; 2 – planting tray with irrigation and drainage; 3 – space with plants to pass inlet or outlet air depending on the current gas exchange; 4 – motored valve; 5 – illumination (we recommend growing LED phytolamps); 6 – controller of illumination and valves

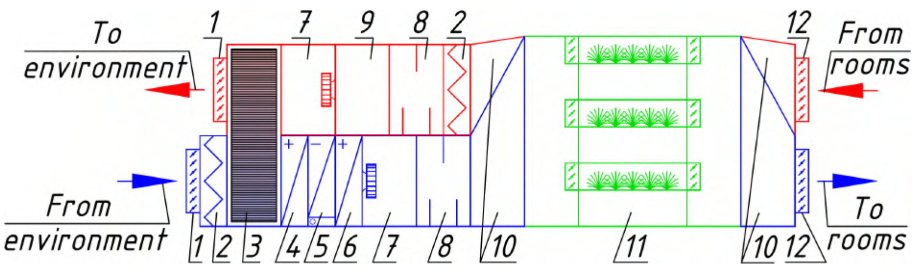

Figure 3. Installation of phytofilter: 1-9 – inlet-exhaust air handling unit; 1 – thermal-insulated valve; 2 – filter; 3 – heat recovery unit (in this scheme – rotor regenerator); 4 – heater; 5 – cooler with condensate diversion; 6 –re-heater; 7 – fan; 8 – sound attenuator; 9 – empty section; 10 – double 3D adapter; 11 – phytofilter; 12 – valve

for air heating in the heating period and re-heating in the cooling period, which almost eliminates additional energy consumption.

We require tiny plants with highly efficient photosynthesis and cleaning for a compact design. The suggested selection is *Chlorophytum comosum*, *Aglaonema Modestum*, *A. pictum*, *A. plumosus*, *A. silver Bay*, *Aloe aristata*, *A.parvula*, *Asparagus plumosus*, *Kalanchoe blossfeldiana*, *Pelargonium tomentosum*, *Philodendron scandens*, *Sansevieria trifasciata* “Hahnii”, *Spathiphillum wallisii*.

If some of the suggested plants grow larger than necessary, trimming can readily fix their crown size. It’s possible to use the secondary materials for substratum, for example, broken bricks or wood after shelling from the russian federation. The main condition is to avoid secondary pollution. For example, particle boards are not suitable.

5. Conclusions

Phytoremediation is a perspective technology for increasing outdoor and indoor air quality. It allows for decreasing VOCs and microbes. But known indoor phytoremediation systems don't take into account plant biorhythms, which causes secondary CO_2 air pollution. We propose a new ventilation phytofilter, which can organise airflows to achieve two goals simultaneously: cleaning and oxygenating inlet air 24/7 and cleaning exhaust air to make a building more environment-friendly, which is very important for densely-built districts.

The continuation of the research is creating and testing experimental models of the phytofilter. Now we are researching gas exchange in plants using a gas-exchange camera in the Laboratory of Heat-Mass Exchange in Green Structures. The results will allow calculation the required biomass. The most throttling factor is the war of the russian federation against Ukraine, which significantly reduce sponsorship possibilities.

Abstract. This study focuses on the development of a multi-stage analysis of building object models (BOM) on a construction site for modeling an "evolutionary" digital twin, by integrating building information modeling (BIM) technology and an artificial intelligence system. The concepts of photo modeling of the construction site using a group of moving cameras were outlined, as well as the possibility of integrating IoT technologies. The dynamic transition of real building structures into intermediate BIM representations of digital twins was investigated, with the prospect of enabling augmented reality technology. An artificial intelligence system combining Convolutional Neural Network (CNN) and Feed Forward Neural Network (FFNN) architectures has been developed as a comprehensive mechanism for the detection, categorization, and evaluation of BIM projects at all stages of their life cycle. The paper addresses the scaling prospects for the development of point cloud and mesh models, as well as the use of big data technology while optimizing the representation of the "evolutionary" BIM project of the digital twin of the construction site. The effectiveness of site conformance detection during the step-by-step construction of a BIM model, which shows consistency and provides a quantitative assessment of the processes occurring on the site, has been determined. The results of this research can be used to improve BIM modeling methods and concepts, in particular towards a multi-stage "evolutionary" representation of the digital twin of the construction site.

1. Introduction

Nowadays, BIM technologies have attained an extraordinary level of integration with many new technologies, such as artificial intelligence, the Internet of Things (IoT), Big Data, and Augmented Reality (AR), which has significantly increased the quality and speed of the entire set of operations and processes related to construction project modeling, implementation, and support. The generation of digital twins of the BOM and the construction site, in general, was an essential branch of the direction.

The purpose of this research is to provide scientific support for the concepts of multi-stage modelling of building site objects utilizing artificial intelligence based on BIM technology. The author's team created a concept that defines the BOM creation process in the BIM system as being separated into an arbitrary number of pieces on a suitable timetable. Such changes enable the formation of a model with distinct evolutionary development and growth dynamics. The implementation of a Structure from Motion (SfM) system, which will allow the creation of digital models from photographs from the construction site and displays a three-dimensional depiction of the state of the BOM in real-time, is critical to the collection of training and learning data. This technology will enable neural networks to categorize not only one representation of a BOM picture, but three reciprocal representations at the same time, namely point clouds, mesh models, and the BOM itself. These will enable the YOLOv5 and FFNN artificial intelligence models to identify faults more precisely during the execution of the BOM on the construction site.

Deng et al conducted a rigorous theoretical investigation of the development of BIM technologies across time. According to the paper [1], BIM technologies have evolved in five stages, as shown below:

Level 1. Static 3D BIM visualization tool;

Level 2. BIM model analyses and simulations;

Level 3. BIM and IoT method integration;

Level 4. BIM and artificial intelligence methods integration;

Level 5. Make a digital twin.

It is vital to highlight that in order to accomplish the fifth level, all preceding levels must be implemented in a single BIM project.

In scientific publications [2–4] the authors consider SfM systems when resolving problems by building three-dimensional models from a point cloud using photometry or videometry. Scientists list a wide variety of uses for SfM systems, such as simulating worker evacuation from a construction site to visualize the site's actual condition, reducing variance between planned and actual conditions, and creating an "as-built" model of an object based on an image of it for reconstruction. Also defined is the ability to interact with images taken by SfM in real-time and by BIM standards. Geometric information is extracted using three-dimensional grid models utilizing tools such as Meshroom (AliceVision 2020), Agisoft Photoscan, or COLMAP.

In the studies [5–7] scientists take intelligent technologies, including SfM, into consideration and find that when scaling projects, they frequently lead to Big Data, which in turn necessitates the use of advanced management, diagnostics, and forecasting from the executors and visualization of this data, in particular, using modern capabilities of The idea of big data analysis is also given a lot of attention since it makes it possible to address several issues linked to the productivity and digitization of different spheres of human activity. As a result, machine learning, intelligent data analysis techniques, and a variety of statistics have all been included in big data analytics.

In papers [8, 9], researchers examine BIM building employing IoT analysis. In addition, the authors determine the considerable importance of high-tech cloud solutions in connecting to the IoT. Given the expansion of BIM technology, it is expedient and important to use IoT, which is defined as a combination of physical and virtual components such as sensors, mechanisms, cloud services, communications, and protocols, to create digital twins of BOM and construction sites. This serves as the foundation for IoT systems.

Sezen et al [10] conduct an experimental study where they investigate precision, recall and mean average precision (mAP) are used as evaluation metrics among YOLOv3, YOLOv4, YOLOv5, and Faster R-CNN algorithms. Thus, based on the results of model training and direct tests, it was concluded that model YOLOv5 is the fastest and most productive when compared to YOLOv4 and others.

Dolhopolov et al [11] provided a practical example of how to employ multi-label classification with FFNN to address issues with a sizable number of input and output classes and the potential to scale into Big Data problems. The design of FFNN is impacted by the duties assigned to the performers, according to the findings of scientific research. To illustrate the parameter space, for instance, training on several parameters is necessary when doing a regression on multiple parameters.

The goal of this research is to provide an analytical foundation for an information system that will allow the concept of multi-stage modeling of building site objects using artificial intelligence based on BIM technology to be confirmed. Achieving this goal may result in the development of a quality standard for working with homogeneous BOMs, which will be decided by the intricate interaction of IoT, Big Data, BIM, YOLOv5, SfM, and FFNN.

2. Materials and method

Considering a complete examination of the scientific works of scientists of various profiles and proving the concept of multi-stage modeling of construction site objects using artificial intelligence based on BIM technology. Figure 1 shows the developed model of an information system that allows you to study a construction object or construction site in real-time and highlight aspects that allow you to model the representation of a construction object in a three-dimensional projection using SfM and IoT cameras. As a result, point clouds, mesh models, and BOMs with varied levels of detail are modeled. In the architecture of YOLOv5, each model of a building object is described as a class, allowing artificial intelligence to identify many photographs based on the stages of execution of the object on the construction site. The categorization data is then sent to the FFNN, which is compared to the standardized data that the project customer expects. As a result, the system's last procedure is to give the user information about the compliance of a certain building object with the standards, which can be determined manually or based on the pre-formed Dataset BOM. The unique feature of this information system's operation is the ability to determine whether the derived models of the architectural item reflect its general trends.

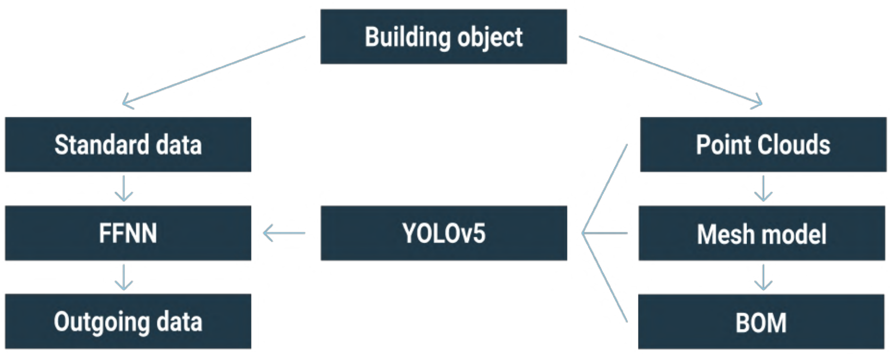

Figure 1. Multi-stage modeling of building site items in an information system model.

The process of obtaining information, known as photo modeling or videometry, is carried out via IoT devices, which can be used in two ways. Figure 2 shows static photo modeling, which is distinguished by the fact that cameras are installed just once and are utilized throughout the whole observation process, and dynamic photo modeling, which may not require the installation of as many cameras and is in motion at specific time intervals.

The advantages of the first method are complete autonomy and reliability of the data collection procedure. However, in the case of a big-scale construction project, a large amount of equipment may be necessary, which is why, in some circumstances, dynamic photo modeling is preferable, especially if building operations are slow.

Thus, within the framework of the study, we have the opportunity to extract information from panoramic photos or photo sequences and model on their basis Point Clouds, Mesh models, and

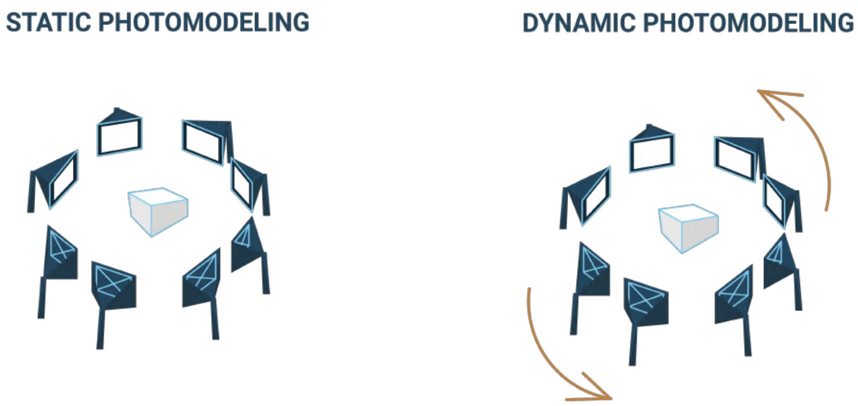

Figure 2. Possibilities for implementing photo modeling of the modeled building object.

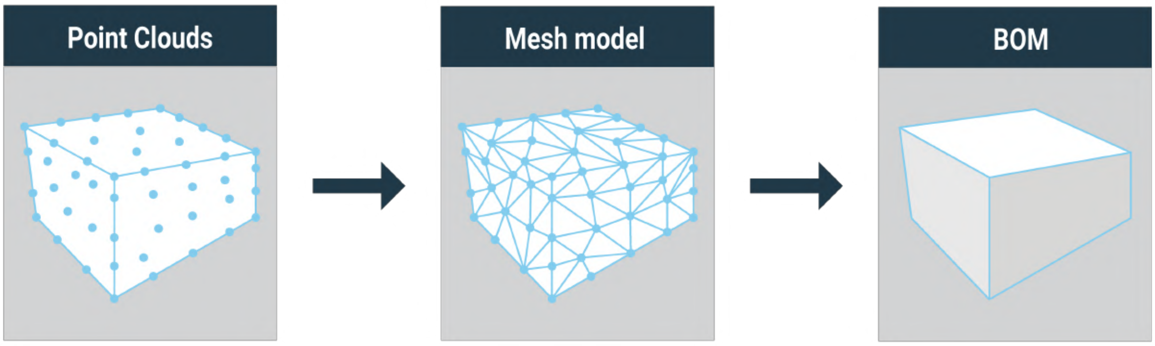

Figure 3. The BOM building process employs photo modeling and SfM.

BOMs of varying degrees of detail based on the project requirements using photo modeling and SfM, which is based on the Agisoft Photoscan software. Geometric forms are replicated with varying degrees of detail during photo modeling (approximately one point for every 5 cm of real size). The higher the image quality, the more detail is captured and the more natural it appears. In practice, however, different sets of input photos are frequently required. Figure 3 shows the BOM construction process utilizing photo modeling and SfM.

Within the scope of the project, 600 visualizations of BOM construction fragments were performed at various time intervals and construction objects, forming the study's learning and training Dataset. Figure 4 shows one of the BOM construction fragments on a real-world example of a building object with serial №5.

A dataset of 600 complete images of the building object was created as part of the study's framework (i.e., 2400 images representing the building object, Point Clouds, BOM, and Mesh Model). The artificial intelligence system recognizes diverse construction sites and their resulting models before determining their resemblance and compliance with the defined standard. Following the development of the models, they were manually tagged for additional training. Given the YOLOv5 model's excellent performance as the fastest and most successful model in the YOLO family, it was chosen for the categorization of building items and their derived models. Experiment results showed that 100 iterations of training took no more than 8 minutes of real-time.

The evaluation metrics chosen were Average Precision – the average accuracy for a given

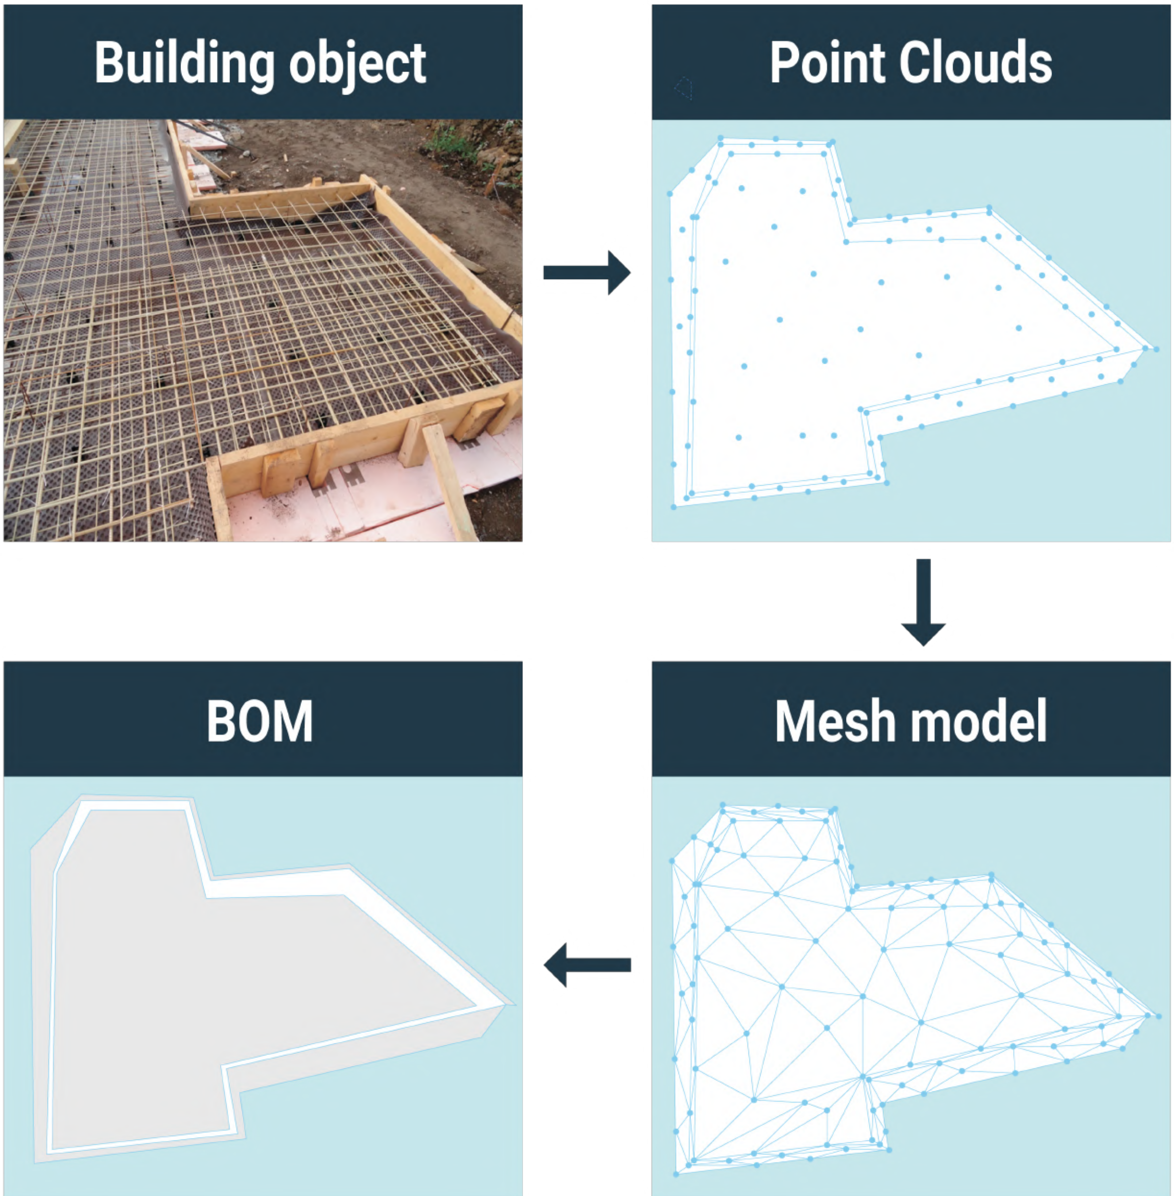

Figure 4. BOM construction using photo modeling and SfM for sample №5.

class, and Mean Average Precision (mAP) – the average accuracy for all classes.

The value of the average precision of the Point Clouds model is determined by equation:

$$AP_{PC} = \frac{\sum_{i=1}^{n} x_i}{n} = \frac{x_1 + x_2 + \cdots + x_n}{n} \tag{1}$$

where AP_{PC} is Average Precision for Point Clouds model; x_i is Average Precision for each iteration of the building object according to the Point Clouds model.

The value of the average precision of the Mesh model is determined by equation:

$$AP_{MM} = \frac{\sum_{i=1}^{n} y_i}{n} = \frac{y_1 + y_2 + \cdots + y_n}{n} \tag{2}$$

where AP_{MM} is Average Precision for Mesh model; y_i is Average Precision for each iteration of the building object according to the Mesh model.

The value of the average precision of the BOM is determined by equation:

$$AP_{BOM} = \frac{\sum_{i=1}^{n} \omega_i}{n} = \frac{\omega_1 + \omega_2 + \cdots + \omega_n}{n} \tag{3}$$

where AP_{BOM} is Average Precision for BOM; ω_i is Average Precision for each iteration of the building object according to the BOM.

The value of the average precision of the class is determined by equation:

$$AP = \frac{AP_{PC} + AP_{MM} + AP_{BOM}}{3} \tag{4}$$

where AP is general Average Precision of the class; AP_{PC} is Average Precision for Point Clouds model; AP_{MM} is Average Precision for Mesh model; AP_{BOM} is Average Precision for BOM.

The value of the mean average precision (mAP) is determined by equation:

$$mAP = \frac{\sum_{j=1}^{k} AP_i}{k} \tag{5}$$

where AP_i is Average Precision of i class; mAP is mean Average Precision; k is number of defined classes to recognize.

Figure 5 shows the visualization of mathematical processes depicted in (1), (2), (3), (4), and (5) during YOLOv5 work on creating object classification.

The following libraries and software were used in the study: Python 3.8, Numpy, Keras, Tensorflow, Pytorch, json, pandas, CUDA 11.1, and OpenCV 3.2.0.

The YOLOv5 model is trained in the ratio of 80% of training images, and 20% of test images. Images were separated according to the stages of development of simple building things. Table 1 shows the training parameters for the YOLOv5 model.

Comparison according to the FFNN model should be performed when certain standards are defined. The artificial limits that the standard must take into account are shown in table 2.

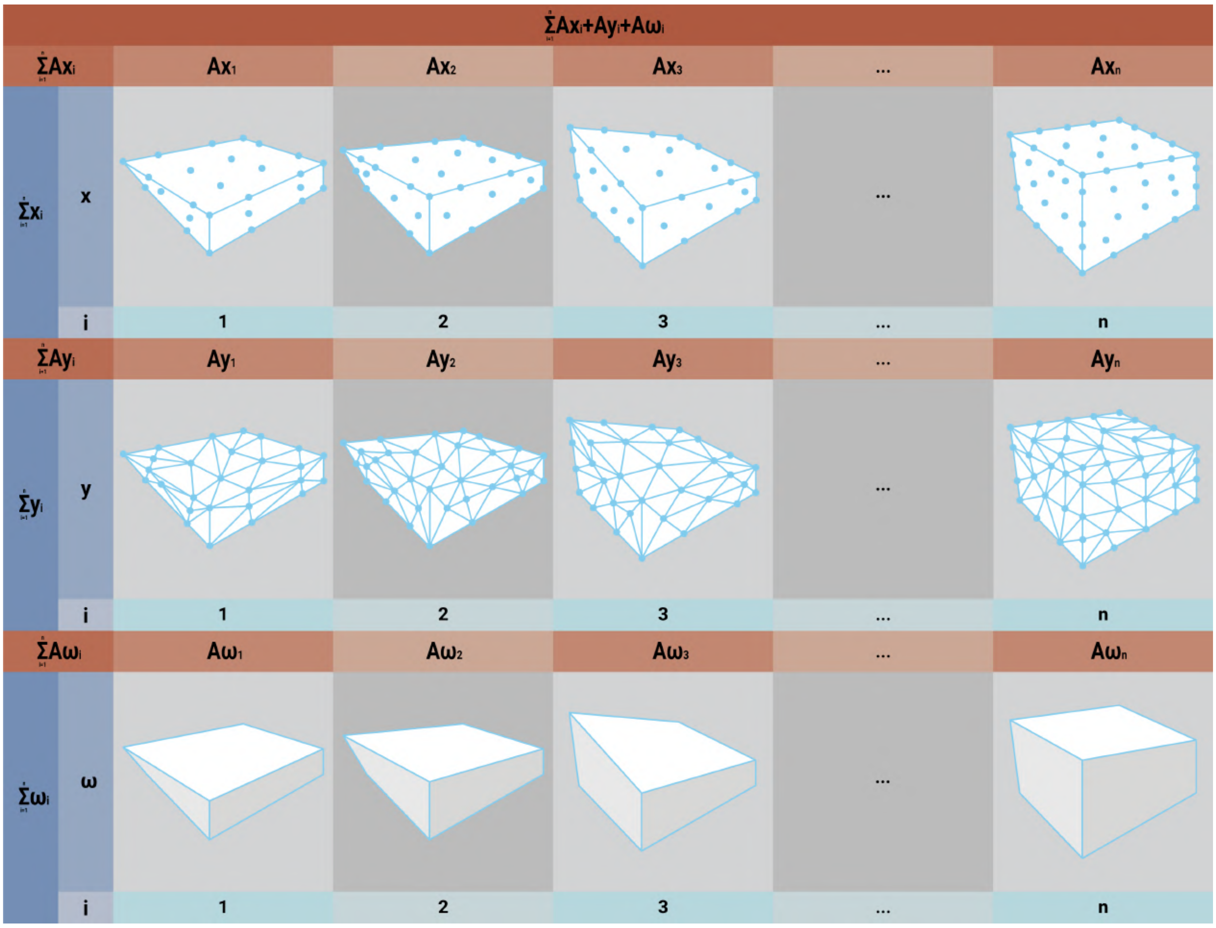

Figure 5. Visualization of mathematical processes about the derivatives of the building object during their classification.

3. Results

Metrics were computed for all classes defined in the Dataset. The maximum Average Precision for the general classification was found for specimen №5 and was 0.88. In general, the YOLOv5 model produced correct classification results for the stated classes and had no discrepancies. However, because some building objects were more difficult to distinguish, the mAP of the YOLOv5 model is 0.73. Figure 6 shows an example of the findings of Instance №5. BO5, BOPC5, BOM5, and BOMM5 are building object, building object (Point Cloud model), building object model (BOM), and building object (Mesh model) in this example, respectively.

Table 3 shows the generalized YOLOv5 classification results by building objects. The indicators range from 0 to 1 and are pre-normalized.

Table 4 shows how the FFNN model works regarding the standards given by the customer based on the building objects. The indicators range from 0 to 1 and are pre-normalized. As a result, the acquired values demonstrate the conformity of classified architectural objects and their derivative models to the required requirements.

4. Conclusion

Thus, the concept of multi-stage modeling of building site objects utilizing artificial intelligence based on BIM technology was proved to be feasible. The classification by time intervals was handled by the information system. The YOLOv5 model displayed an incredibly quick

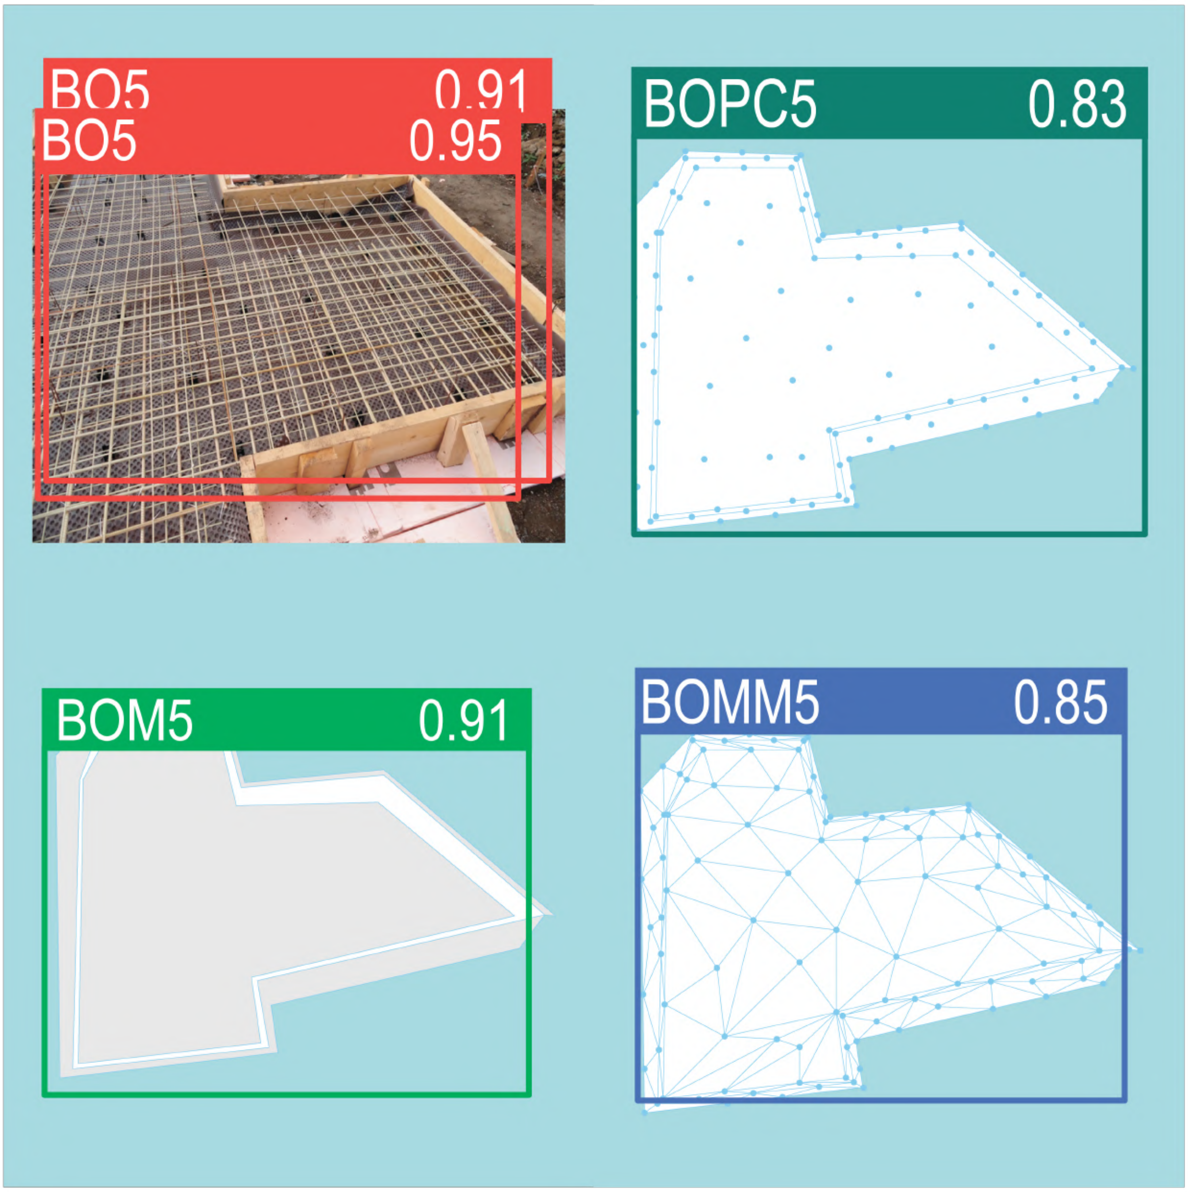

Figure 6. BOM construction is based on photo modeling and SfM classification results based on building objects. The indicators are pro-normalized and range from 0 to 1.

learning process (92 minutes for 500 iterations) as well as a relatively serious mAP of 0.73. Simultaneously, the YOLOv5 model performed classification by the building object's class as well as by its derivative models Point Cloud, Mensh model, and BOM, where it also displayed the related findings. The possibility of establishing quality standards with the help of the FFNN model, which was performed for general indicators by class, was also evaluated, but it can be realized for each stage of the building object's development individually. As a result, the comparison of models and standards based on example No5 revealed a high degree of conformity, ranging from 0.92 to 1.00. The information system model was accurate. Simultaneously, two choices for setting up the building site for photo modeling, static and dynamic, were provided.

The research has implications for the implementation of novel Augmented Reality technologies

Abstract. The groundwater is less susceptible to anthropogenic influence and the water quality of these sources is more stable. At the same time, the groundwater often has an increasing iron concentration. Despite the sufficient availability of proven methods for iron removal from water, it becomes necessary to search for more resource and energy saving technologies which is due to the constant rise in the cost of resources for the construction and operation of water treatment plants. The aeration methods for the iron removal from groundwater are often used, as cheaper ones. The polystyrene foam filters with upflow filtration are of particular interest, as the most reliable in operation among the developed types of filters with floating medium. A further reduction the cost of water is possible by using granules of foam polystyrene obtained by a production method, which ensures an increased grain size in comparison with the traditional method of their obtaining. The positive experience in such filters implementation allowed to recommend the placement of iron removal equipment in the existing water towers.

1. Introduction

The availability of sufficient water amount of adequate quality is one of the main factors of safe living conditions and sustainable development of the state [1, 2]. However, human activity negatively affects the environment, including water resources, which leads to their significant pollution and exhaustion [3–5].

Thus, according to prediction, a half of the world's population will experience water shortages in the near future [6]. The preference is given to groundwater (artesian, springs) underflow when choosing a source of water supply [7, 8].

Groundwater is the main source of drinking water in many countries [9–11]. As a rule, a significant proportion of protected groundwater sources have elevated concentrations of iron, less often hydrogen sulphide, ammonium, manganese, hardness salts, mineralization and other contaminants [12, 13].

Iron content is associated with regional, climatic, landscape and hydrological features. It is known that an increased concentration of iron in water gives it a brownish colour, an unpleasant metallic taste, and causes overgrowth of water supply networks and fixtures [14, 15].

Iron in natural waters can be in the form of ferrous and ferric ions [16, 17], colloids of inorganic and organic origin, which has a significant impact on the choice of method of iron removal.

According to [6] methods of iron removal from water are divided into reagentless, reagent, ion-exchange, membrane and biochemical. At the same time in [18] it is proposed to divide them into four groups: traditional strategies, biological strategies, strategies based on membrane technology and strategies based on nanotechnology.

The preference is given to reagentless (aeration) methods for the iron removal from water because they are relatively simple to operate and easily automated [14, 19]. The most widely used aeration methods include contact iron removal, in which water is fed directly into the granular medium after aeration [6]. In this case the medium grains can have a larger size than in deep aeration. In addition to quartz sand, the other natural and artificial materials are used as a filter granular medium. The type of filtration medium, parameters of its grains and layer height have a significant impact on the efficiency of water treatment, size of filtration units and their productivity. The polystyrene foam is one of the economically suitable medium [6, 20].

The work is devoted to the development of resource and energy-saving schemes of contact iron removal from groundwater at polystyrene foam filters with upflow filtration.

2. Materials and methods

Foam polystyrene filters with upflow filtration have been investigated for a long time in the laboratory of the department of water supply, drainage and drilling at the National University of Water and Environmental Engineering [6, 20].

The plant for studying the iron removal from water consisted of a filtering column, a filtration rate regulator, a piezometer shield and a unit for dosing the iron solution. The filtering column was made of a transparent pipe 150 mm in diameter and 2000 mm in height. A cone was fixed below to it with a branch pipe for connection of aerated water and a washout pipe. A tank of 500 mm in diameter was connected above. It was possible to visually observe the processes occurring in the sublattice space thanks to such construction of the plant. Four branch pipes for the piezometers connection and five samplers were arrange along the height of the filtration column d. The amount of water sampled by the samplers did not exceed 5% of the flow rate passing through the filtration column. The head losses in the filtration column was monitored with the help of the piezometer shield.

The construction features of filters, water treatment efficiency, hydraulic laws of processes in the medium for different operating conditions were studied. The impact of granulometric composition of the medium, layer height, filtration rate, initial water quality parameters (iron concentration, pH, alkalinity, etc.) on these processes was studied. Special attention was paid to investigation of the medium regeneration by different methods. Extensive pilot and industrial production studies were conducted in the water supply systems of a number of settlements of the north-western regions of Ukraine at the introduced plants for iron removal from water with foam polystyrene filters of productivity from 2 to 900 m^3/day.

The polystyrene foam medium can be obtained in the production conditions (plants of producing the polystyrene pellets) and directly at the place of use. As a rule, the polystyrene is foamed by steam in the first case and by water in the second case. The medium amount in the first case is larger and its density and cost is lower. It is advisable to use gravity polystyrene foam filters with increased granule size at the iron removal from water for medium and large consumers (figure 1). The use of industrially manufactured polystyrene foam pellets allows reducing the cost of medium purchase by 4.5 times.

3. Results and discussion

Foam polystyrene filters with upflow filtration can be used in the reagent schemes of water clarification and decolorization, in the schemes of iron removal from water, for water pretreatment.

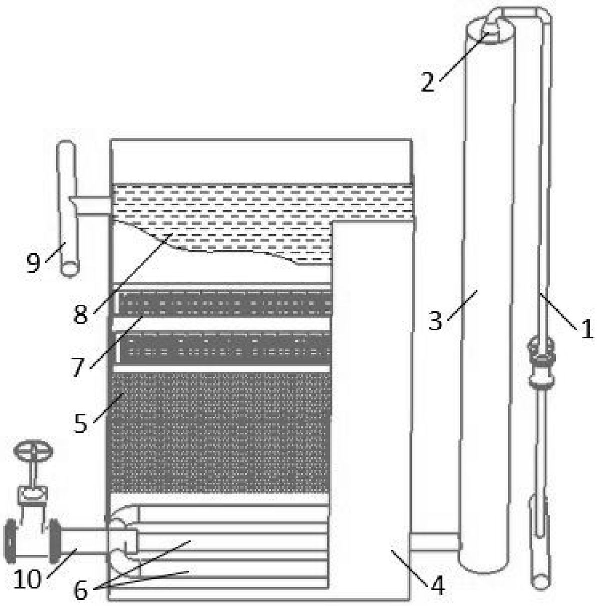

Figure 1. Iron removal from water at the gravity polystyrene foam filters with upward filtration: 1 – the groundwater supply pipeline; 2 – the aerator; 3 – the air separator; 4 – the filter body; 5 – the polystyrene foam medium of industrial production; 6 – the bottom drainage and distribution system; 7 – the holding grid; 8 – the above-filter volume of water; 9 – the pipeline for filtrate removal; 10 – the washout pipeline.

It is recommended to use aeration followed by filtration aimed at removing water treatment from iron ions. It is known that a catalytic film of iron oxides should form on the surface of the medium in order to obtain the necessary effect of iron removal from water, which is not washed off after the filters washout. The catalytic film of iron oxides on the surface of the medium intensifies the adsorption of ferrous iron and its oxidation. Thus, there is no direct contact of the treated water with the surface of the floating medium (polystyrene foam). The ordinary foam polystyrene filters are used at low concentrations of iron ions in the source water and at significant concentrations of iron ions with a growing layer of suspended sediment and foam polystyrene medium. The construction of such filters provides for a sediment layer in the sub-filter space, where the main iron extraction takes place and the final one is directly in the foam polystyrene medium. The sediment layer increases over time, increasing the efficiency of water treatment in it. A part of the sediment is discharged with the washout water. The use of expanded polystyrene filters with a growing sediment layer with each washout of the medium makes it possible to significantly reduce the building area of the wastewater treatment plant. At the same time, the total height of the filtration room will be slightly higher.

We propose the concentration of iron in water after passing the growing layer of suspended sediment $[Fe_l]$ (mg/L) to determine by the equation

$$[Fe_l] = [Fe_0] \exp\left(-\frac{K_1 H_1}{V}\right), \tag{1}$$

where $[Fe_0]$ (mg/L) is the concentration of iron in source water; V (m/h) is the filtration rate; H_1 (m) is the height of the suspended sediment layer; K_1 (1/h) is the coefficient, taking into account the physicochemical parameters of water and contact medium.

The value of the coefficient K_1 was obtained experimentally and is 0.7-2.5 1/h. The studies were conduct at a water temperature of 5-15 $^\circ C$ for the purpose of determining H_1, the concentration of iron in the source water 15-30 mg/L and the rate of upflow of 2.5-4.0 m/h. The following empirical dependence H_1 (cm) was obtained based on these studies

$$H_1 = H_0 + 0.0004V^4[Fe_0]^{1.8}t, \tag{2}$$

where H_0 (cm) is the initial height of sediment layer; t (h) is the duration of water treatment in the growing layer of suspended sediment.

To check the adequacy of the last equation in figure 2 the dependences of the growth of the suspended layer of deposit obtained experimentally were built with points and by straight lines were based on equation (2). It can be seen from figure 2, that the growth rate of the sediment layer calculated by the equation (2) agrees well enough with the data obtained in the process of research, the error does not exceed 15%.

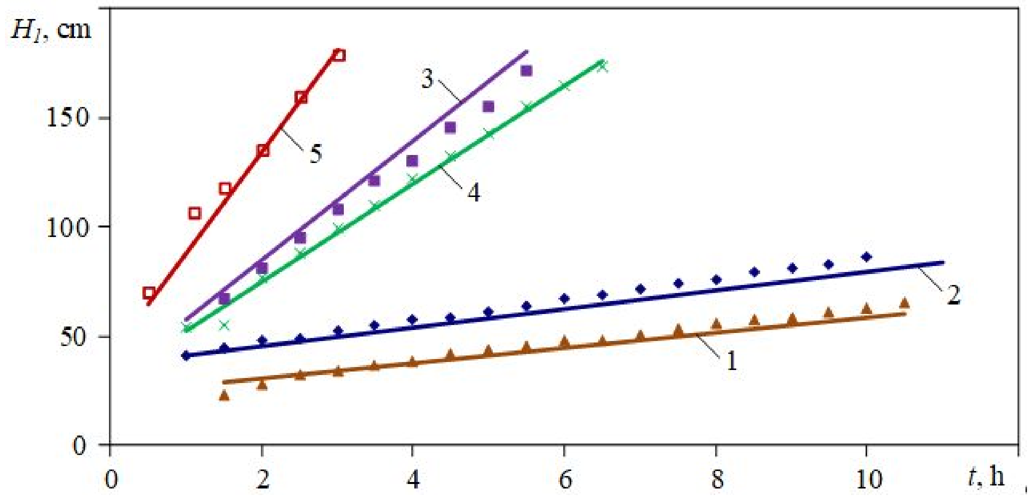

Figure 2. Growth of the suspended sediment over time: 1 – $V = 2.5$ m/h, $[Fe_0] = 20$ mg/L; 2 – $V = 3.0$ m/h, $[Fe_0] = 15$ mg/L; 3 – $V = 3.5$ m/h, $[Fe_0] = 25$ mg/L; 4 – $V = 4.0$ m/h, $[Fe_0] = 20$ mg/L; 5 – $V = 4.0$ m/h, $[Fe_0] = 30$ mg/L.

The peculiarity of the foam polystyrene filters operation with the growing sediment layer is a gradual reduction of iron concentration in the water entering the polystyrene foam medium. We propose the concentration of iron in the filtrate $[Fe_f]$ (mg/L) to determine by the equation

$$[Fe_f] = [Fe_l] \exp\left(-\frac{K_2 L}{V}\right), \tag{3}$$

where L (m) is the thickness of filtration medium layer; K_2 (1/h) is a coefficient considering the impact of catalytic properties of the filtration medium to the efficiency of impurities detention from water.

Coefficient value K_2 is obtained experimentally and is 15-20 1/h.

The concentration of iron in the filtrate during the iron removal from water at polystyrene foam filters with the growing layer of suspended sediment is determined by substituting equations (1) and (2) into equation (3).

The increased sub-filter space is the feature of the foam polystyrene filter with a growing layer of deposit. The height of the sub-filter space H_u (m) to ensure the required initial height of the growing layer of suspended sediment after washout, is

$$H_u = 0.06it_b + h_0, \tag{4}$$

where 0.06 is the transfer coefficient; i (L/(s·m^2)) is the washout intensity; t_b (min) is the washout time; h_0 (m) is the initial height of the suspended sediment layer which depends on the quality of initial water and the upflow rate.

The height of sub-filter space increases with increasing duration and the washout intensity. The washout intensity and duration of polystyrene foam depends on its height and granulometric composition. At the same time, a longer duration and intensity of washout is necessary with an increase in the height and diameter of the grains of the medium. Therefore, it is necessary to accept fine-grained medium to reduce the height of the sub-filter space.

Table 1 shows the results of four gravity filters with polystyrene foam medium obtained in production conditions. The total capacity of the filters was up to 1000 m^3/day. The filtration was conducted by upflow through the polystyrene foam medium with the equivalent grain diameter of 2.8 mm. The filtration rate was accepted as 7 m/h and the medium layer height was 1.0 m based on the results of laboratory tests. The washout of polystyrene medium was carried out by treated water from the combined above-filter space of filters by opening the gate valve on the washout pipeline. Filters are taken for washout alternately once a day with a calculated washout intensity of 18 L/(s·m^2) and a duration of 3 min.

Table 1. Results of the iron removal from water.

Time from the beginning of the filters operation, months	Concentration of iron in the filtrate, mg/L				
	Source water	1 filter	2 filter	3 filter	4 filter
2	1.07	<0.05	<0.05	<0.05	<0.05
3	0.83	<0.05	<0.05	<0.05	<0.05
4	2.88	0.07	0.10	0.10	0.10
5	0.97	0.05	0.06	0.05	0.06
6	1.37	<0.05	<0.05	0.10	<0.05

The semi-annual studies showed satisfactory quality of the filtrate by the concentration of total iron, which did not exceed 0.1 mg/L.

The results of long-term laboratory and industrial studies on the implemented water treatment plants with gravity polystyrene foam filters showed their efficiency, reliability and ease of service [6, 20]. This experience allowed us to recommend the placement of the iron removal equipment in the existing steel water towers and the tower of water iron removal plants for small consumers (rural water supply systems) (figure 3). It allows to avoid the construction of filtering plants and clean water reservoirs, the construction of network pumps and filters body, which significantly reduces building costs in comparison with the previous scheme. We have proposed and implemented a combined medium consisting of small granules of polystyrene foamed with water and large granules foamed with steam to ensure the required efficiency of the iron removal from water and to reduce the cost of the medium. Tower iron removal plants operate in the discrete mode depending on the volume of the tower tank and the mode of water consumption.

Granular filters, including polystyrene foam filters, need periodic regeneration of the medium layer (washout). Reducing the volume of washout reduces the harm to the environment, reduces the size of plants for the water treatment, energy costs for its pumping and the cost of water. The water from the above-filter space is used for the polystyrene foam filters washout. Therefore, the reduction of washout volume will also reduce the total height of the filter. We have tested the impulse washout of polystyrene foam medium, which allows to save 15-40% of washout water in comparison with the continuous water washout.

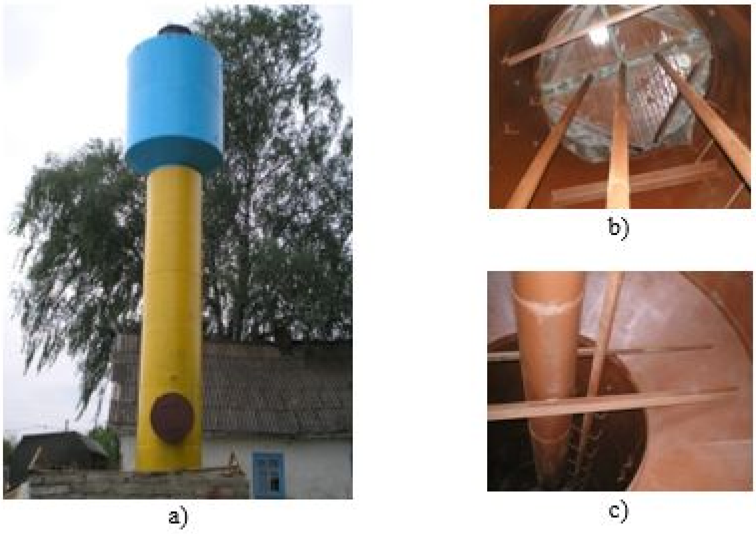

Figure 3. Reconstruction of metal water tower using the polystyrene foam filter: a) the general view of the tower-column; b) the holding grid, pipelines: the inlet water supply (left), the aerated water (centre), the filtrate intake (right); c) the air separator (left) and the inlet water supply pipeline (right).

4. Conclusions

Foam polystyrene filters can be used in schemes for iron removal from water. At a low concentration of iron ions the polystyrene foam filter is used in the source water without a contact mass at the bottom of the filter, and at a significant concentration of iron ions is used with a growing layer of deposit and the polystyrene foam medium. The implementation of contact water iron removal schemes with foam polystyrene filters with upflow filtration allows to reduce building and operation costs during reconstruction of existing and building new water iron removal plants. In addition, the use of tower water iron removal plants in existing rural water supply systems significantly reduces the assembling time. Ease of maintenance of polystyrene filters with upflow filtration makes them competitive in the absence of highly qualified service personnel. It is reasonable to apply mathematical modelling as one of the directions of future studies for substantiation of rational constructive and technological parameters of foam polystyrene filters operation and service life of the medium.

E-mail: shevtsova.gv@knuba.edu.ua

Abstract. The article concerns of the comparative study of traditional settlements historic experience of "non-detached" preservation. "Non-detached" there is understood like a way to preserve the whole settlement on its original place, with its local traditions, community system, crafts and customs, and in the harmony with natural environment. The cases of the study are mountain Shirakawa village Ogimachi in Japan and Kryvorivnia village in Ukraine. The both settlements are generally showing very similar historical background of geographically isolated life in the harmony with high mountain nature that leads to the shaping of original local architecture style, cultural traditions and community features. Similarly, the initiative of revitalization in the both cases emitting from local communities. Nevertheless, the history of preservation and revitalization efforts of the two cases is quite different. While in Shirakawa village Ogimachi local community took revitalization efforts starting from the middle of 20th century, Kryvorivnia village was engaged in the process starting from the middle of 19th century just with some interruption due to the soviet times. Currently the both settlements achieved good results in their revitalization and local traditions preservation activity also keeping harmony with environment. Shirakawa village Ogimachi is mostly orientated on inner community life that is almost not intersected with flourishing local tourism. Contrary, Kryvorivnia allows tourists to participate freely in local community life, rituals and festivals. Thus each of the two cases examined finally found its original way of historical settlement culture sustainable preservation and revitalization.

1. Introduction

The preservation of traditional settlements in "non-detached" way is an interesting and quite rare experience that could be observed mainly in the territories geographically isolated that lead to the phenomenon of specific local "time delay". It some cases such traditional settlements deny the common way of transferring their old buildings to the "open air rural museums" instead choosing the way of "non-detached" settlement preserving as a core of local architecture, culture and traditional way of living. The current circumstances of world globalization any case have to be took in the consideration there leaving the village community to make a choice between their identity dissolving in the case of fully opening to the world or cultural stagnation in the case of fully closing from it. The original strategies of creative sustainable development and revitalization can help the situation allowing the local communities to find a "middle way" of balancing between these two crisis points. It is due to emphasize that the common receipt for such activities is not exist. Every traditional settlement is looking for its unique way to achieve the balance between the traditional and modern life, cultural stagnation and globalization dissolving often designating the settlement as UNESCO Cultural Heritage [1, 2].

Here is analyzed and compared the unique revitalization experience of Shirakawa village Ogimachi in Gifu prefecture, Japan (UNESCO World Heritage) and Kryvorivnia Carpathian village in Ivano-Frankivsk district, Ukraine. The research was fulfilled basing of personal author field research of the both cases. The research of Shirakawa village Ogimachi case was supported by Grant of Hakuho Foundation Japanese Research Fellowship program 13th (2018-2019). The main methods of the research were "in situ" observation, fixation and interviews.

2. Shirakawa village Ogimachi case

Shirakawa village Ogimachi is one of a group of very interesting deep mountain traditional settlements historically formed on the border of Gifu and Toyama Prefectures. Shirakawa-go is located in a narrow valley of Shogawa river (figure 1).

Figure 1. The picturesque landscapes of Shirakawa village Ogimachi.

Up to the beginning of 20th century this geographically isolated area was really difficult to access. Due to this, here was formed a cluster of settlements with original architectural Gassho-style rural houses and specific social culture [3, 4].

2.1. Historical overview of Shirakawa Ogimachi settlement

Local recordings suppose that the settlement existed here at least from 11th century At the beginning of 21th century the population of Shirakawa village Ogimachi consisted for about 600 people. There for about 60 Gassho-style farmhouses mostly built from early 19th century till early 20th century [4], two Buddhist temples and a Shinto shrine.

The large Gassho-style rural houses of the region are unique in Japan. The name "Gassho" is coming from the image of their high triangle thatched-roofs that are similar with two hands jointed for a pray. The houses are usually face to the north and sous to minimize wind force according to the predominant wind direction of the region (figure 2).

The construction of the houses is extremely strong and spacious allowing to bear local winds and high weight of the snow as well as sheltering big local families [5, 6]. Layout and compositional structure of the houses is perfectly adapted to the local craftsmanship and the way of life. Namely, due to the luck of agriculture grounds the main jobs of the villagers historically was silkworm farming as well as Japanese paper (washi) and nitre for gunpowder manufacture. Thus the houses have wide working spaces in a ground floor as well as multileveled roofing spaces used for silkworm nests and their food (mulberry tree leaves) storage. These spaces due to the original roof construction are properly ventilated and disinfected with open

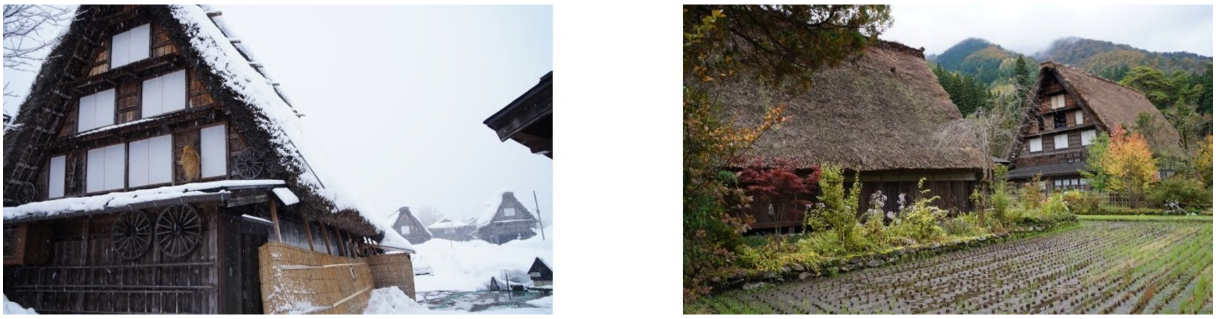

Figure 2. Gassho-style rural houses.

domestic fireplace smoke freely penetrating all roofing joints and creating perfect environment for silkworms breeding.

It have to be noted that from the beginning of 20th century the quantity of Gassho-style houses of the area significantly diminished. As for 1924 there were for about 300 such buildings in the region while by 1961 they were already only 190 [4]. This situation arose due to the nearby construction of hydroelectric power plant on Shogawa river at the beginning of 1940th that led to waterlogging and abandoning of several small villages of the area. Some houses also were lost by fires or reselling [4,6]. Finally facing with this problem the residents of Gassho-style dwellings of Shirakawa village Ogimachi started a movement to protect the houses of the settlement. They concealed the three principles of "Do not sell", "Do not rent", and "Do not destroy" in 1971 establishing the "Association to Protect the Natural Environment of Shirakawa-go, Ogimachi Village" starting in the village different preservation activities. These efforts lead to further selection of the area as a district for the protection of nationally important traditional buildings in 1976 [4].

Finally there shaped very interesting form of traditional rural settlement preserving directly at the place, without usually implemented in such cases museification or "open air rural museum" creation. The habitants of the village are living at theirs houses and at the same time serving as the caretakers for them.

In 1995, Shirakawa village Ogimachi together with neighboring settlements were registered as the UNESCO World Heritage Site as the "Historic Villages of Shirakawa-go and Gokayama" by following criterion [5]:

Criterion (iv): The Historic Villages of Shirakawa-go and Gokayama are outstanding examples of traditional human settlements that are perfectly adapted to their environment and their social and economic raison d'être.

Criterion (v): It is of considerable significance that the social structure of these villages, of which their layouts are the material manifestation, has survived despite the drastic economic changes in Japan since 1950. As a result they preserve both the spiritual and the material evidence of their long history.

UNESCO World Heritage site is consisting of three locations as Shirakawa village Ogimachi in Gifu Prefecture and neighbor villages Ainokura and Suganuma in Toyama Prefecture together forming 68 hectares of preserving area surrounded with buffer zones [5].

2.2. Modern situation of Shirakawa village Ogimachi preservation and revitalization, community and touristic activities

The management and daily preservation activity of Gassho-style rural houses is the responsibility of the owners. More complicate restoration works are held by professionals. Special attention is given to the use of traditional materials [4, 5, 7].

The thatched-roofs of the local houses require the replacement every 20-30 years. Nowdays it is extremely valuable proses (for about more than 10 million yen, or approximately 75000 dollars costs only to replace one side of the roof) must be done by villagers themselves [4]. For this situation there exist traditional local community called yui, that accumulate the money from all households to allow roof replacements of 2-3 houses a year. It takes for about 200 or even more workers and up to 100 of them could climb on the roof at once. One side of the roof replacing usually takes 2 days of the work. The work is divided among all yui community participants depending of their age, sex and qualification. So, while young men are directly engaged in the process on the roof, senior people supervise the work, teenagers and women are preparing grass bundles on the ground or serve the meals to other participants. After the work is finished, the owners of the house prepare a feast called naorai for all who was engaged in the process. Old village records proving that the tradition of yui existed there at least from the end of 18th century [4]. So it can be cleared that traditional dwelling maintaining techniques of Shirakawa Ogimachi settlement are carefully transferred to the new generation (figure 3).

Figure 3. The roof replacement in Shirakawa village Ogimachi.

Accustomed to live in tight close community from the ancient times, the habitants of Shirakawa village Ogimachi are still preserve strong community relationship not only in the field of yui roof replacement activity but also in the traditions of daily social life as well as annual festivals, weddings, funerals and so.

Traditional manufacture of the settlement (silk-worms farming, paper and gun-powder production) is abandoned now. Instead, almost all habitants are engaged in tourism activities holding in their Gassho-style buildings architectural and folklore museums, cafes, souvenir shops or guesthouses They are still preserving natural way of life in accordance with the nature including local agriculture and cuisine based on self-cultivated cereals and vegetables, forest plants and mushrooms. The old settlement traditions are studied in local schools that itself also is a very interesting example of tradition preservation activity.

This extremely picturesque place quickly gained the attention of domestic and foreign tourists, but from 2008 when a new Tokai-Hokuriku Expressway was constructed nearby making smooth access to the area, the touristic overgrowth of the settlement became a problem. Most of the tourist are visiting there by guided buses or private cars for a day returning trip and thus not are so useful for local economic. Recently due to coronavirus disease the situation changed a little but with world recovering from the epidemic this problem intends to return.

3. Kryvorivnia case

Kryvorivnia village is located in the deep forestland Carpathian mountains of Ivano-Frankivsk district at the valley of Black Cheremosh river. This territory is historical place of Hutsul Ukrainian ethnic subgroup habitation preserving till now their original wooden building technics, crafts, traditions and local dialect. The village has typical for the area dissolved urban structure of small and sometimes quite separated with the mountain landscape clusters of rural houses.

3.1. The history of Kryvorivnia settlement

Kryvorivnia village is known from the historical records from 18th century but the real age of the settlement could be much more ancient. From the middle of 19th century and so on, Kryvorivnia became popular as a natural resort and finally get attention of the famous cultural personalities often being visited by Ukrainian writes, historians and artists of the time as Ivan Franko, Lesya Ukrainka, Mykhailo Hrushevsky and others [7]. In 1910-1911 Mykhailo Kotsiubynsky who lived there for a while, wrote his famous based on the local Hutsul people legends and traditions novel "Shadows of Forgotten Ancestors" ("Wild Horses of Fire"). Later, in 1964, a famous Sergei Parajanov filmed this novel at the same place at Kryvorivnia [8].

During the dark times of the Second World War and further soviet occupation the cultural life of Kryvorivnia village significantly declined. Until the end of 20th century it remained just one of the calm and lovely sightseeing but not outstanding villages of Ukrainian Carpathians.

3.2. Kryvorivnia village tradition preservation, modern revitalization activity and community life

New period of Kryvorivnia village culture flourishing started at 1995 with a young priest Ivan Rybaruk obtaining parish at local wooden Virgin Mari's Nativity church. The cultural and revitalization efforts of the new priest were willingly supported by local community that quickly started to restore old traditions, religious and community life and indigenous folk festivals of Kryvorivnia. The most notable of such festivals are the cycle of winter religious celebrations of Orthodox Christmas, the same as spring Easter festival and summer "Sheeps sending to poloninas" festival attracting many domestic and foreign tourists and guests.

There are still flourishing the tradition of so called "kolyadka" an ancient folklore Christmas songs the same as local musical bands performing with violins and "trembitas" – extremely long Hutsul trumpets fabricated from the wood of the trees striked by the lightening. At the day of Baptism that is celebrated there at 19th of January, local community and the guests praying on the bank of Black Cheremosh River near erected in the water big decorated Cross made of the river ice. "Sheeps sending to poloninas" festival took place in Kryvorivnia in June. In this day the villagers sanding their sheeps to the upper mountain pastures (so called poloninas) for all of the summer (figure 4).

A very special feature of Kryvorivnia culture is the tolerance to the other religions, nationalities and ways of living. Significant Orthodox services are sometimes held there together with Catholic and Greek Catholic priests. The people of any other religion also allowed to

Figure 4. Christmas and Baptism annual festivals in Kryvorivnia.

Figure 5. Maria's Nativity wooden Church of Kryvorivnia: metal leafs covered exterior, the original exterior after the restoration at the end at 2010th, interior.

come and pray in the local Maria's Nativity Church that is the center of community life and revitalization activity (figure 5).

This wooden church is supposed to be built in nearby place in 17th century and then relocated to Kryvorivnia grounds in 1719. It is a good example of local Hutsul architecture style. The wooden log church has cross-shape layout and one central opened to the interior and lightened with windows massive octagonal dome-tower. In the soviet times it was registered as National Cultural Property, but as it was then usual, nobody of the officials cared about the situation on the place. As a result, by 1980th the top of the church decayed and the dome-tower and the walls were covered with metal leafs as a recent cheap but harmful for the wooden structure repairing method. At late 2010th, due to community efforts, local carpenters repaired Maria Nativity church recovering its original exterior covering the walls and tower with chopped wooden planks as it was there traditionally accustomed for rain penetrating preventing.

A huge amount of 200-100 years old rural dwellings are still in use in Kryvorivnia, but in this case we can speak not only about old architecture traditional maintenance skill preserving. It is notable that local building carpenters are still preserving and passing to the new generation their skill to build new traditional rural houses, chapels and churches. Building customs and dwelling evil defence pre-Christian traditions also are still in use.

Other traditional crafts, manufacturing and arts such as agriculture skills, sheep breeding, cheese making, carpets making, wood curving, egg painting (pysanka art), and so also are flourishing. In this case it is quite natural that Kryvorivnia obtained a great popularization as a place of mountain green-tourism, sightseeing, hiking and skiing, mostly attracting single travellers, small groups of friends and families who can easily settle in the villagers dwellings or small house-hotels closely communicating with local habitants and fully participating in their life activities.

There is also significant museum activity that permanently has a tendency to increase. On the moment at Kryvorivnia functioning 7 museums of different types. Such as of literature and art celebrities memorizing museums, ethnographic and historic museums, the museum of local dwelling of 19th century "Hrajda" – Hutsul type rural house with inner yard operating by the family of its owners, and "Didova apteka" ("My grand-father's pharmacy") museum created by local Zelenchuk family for the memory of their grand-father, famous local herb healer [9]. Recently there opened also a museum of repressed by soviets local talented female artist, ethnographer and writer Paraska Plytka-Horytsvit (1927–1998) whose significant heritage is now carefully classified and popularized by the local community [10].

At recent 20 years Kryvorivnia also fully reobtained its historic significance as an "artistic hub" of Carpathians often being visited by writers, artists, actors, photographers, filmmakers and other representatives of culture. In this meaning, Kryvorivnia village could fully reobtain its historic function as artistic hub and "cultural capital" of the Carpathians.

4. Comparing the cases

The two cases of traditional settlement “non-detached” preservation and revitalization examined there have very similar initial geographic circumstances both being located in the deep mountain forest regions historically hard to assess and due to this almost fully preserving their original building skills, customs, way of living and social relationship. The both are steel deeply integrated to natural surroundings. Their revitalization activity is the result of local community efforts and the way of this activity is mostly inspired by local habitants decisions sowing the diversity of original revitalization methods.

In Kryvorivnia community we can observe stronger religious component than in Shirakawa Ogimachi case. Due to the personality of local priest, the religious community of Kryvorivnia consolidated around ancient wooden church finally becoming the driving force of local preservation, revitalization and cultural activity. At the same time, in Shirakawa Ogimachi case can be observed stronger cooperation of the local community with prefectural authorities and central government significantly helping in old Gassho-style houses and surrounding territory preservation process and integrating the efforts of the community with Japanese law and UNESCO World Heritage programs.

At figure 6 it is shown the difference between functional abilities of these traditional settlements and the situation with their different traditional activity components preserving. Summarizing the results of figure 6, we can state that functional diversity of Kryvorivnia settlement case is richer and having longer traditions of conscious local cultural activity than Shirakawa Ogimachi case. The approach to traditional building skills preservation also is different. Shirakawa Ogimachi is preserving bigger than Kryvorivnia amount of originally shaped ancient rural houses. While the local artisans of Shirakawa Ogimachi are concentrating their building skills mostly on the maintenance of the Gassho-style houses, living big reparation works to the restoration specialists, Kryvorivnia’s artisans are able to repair, and even rebuild local architecture in the traditional way. There is also still flourishing the tradition of ancient building methods transferring to the next generations. Kryvorivnia building carpenters are not only erecting new diverse rural structures of traditional techniques on the territory of the settlement but also spreading their skills to the wide neighboring area.

The approach to touristic activity organization at Shirakawa Ogimachi and Kryvorivnia also are basically different. While Shirakawa Ogimachi community rather considering the tourists as a passive spectators allowed to observe local life, in Kryvorivnia the tourists and guests fell themselves fully involved in the process of local life including participation in religious services, festivals preparing activity, crafts and local cuisine dishes fabrication and so (figure 7).

The reasons of such difference are probably nestling in the history and culture of the both settlements as well as in the different mentality of their habitants. In Japanese history rural settlements were practically closed social systems with strong local community consolidation not allowing to the strangers to enter in or to the members of communities to go out. While the Ukrainian Carpathian settlements historically had quite open social structure where people settled around separately in small family groups with free coming in and out and consolidating only in the case of practical or defense needs (figure 8).

In general it can be stated that Kryvorivnia traditional settlement is much more that Shirakawa village Ogimachi integrated in the modern world and directed rather to the future development in the harmony with their traditions and surroundings than to stagnation like an artificially limited reserve of traditional life style.

5. Conclusions

The main problem for historical settlement with traditional way of living now is to consider the appropriate proportion between local traditions stagnation and modern life integration. At the cases examined it can be seen that for each historical settlement this question can

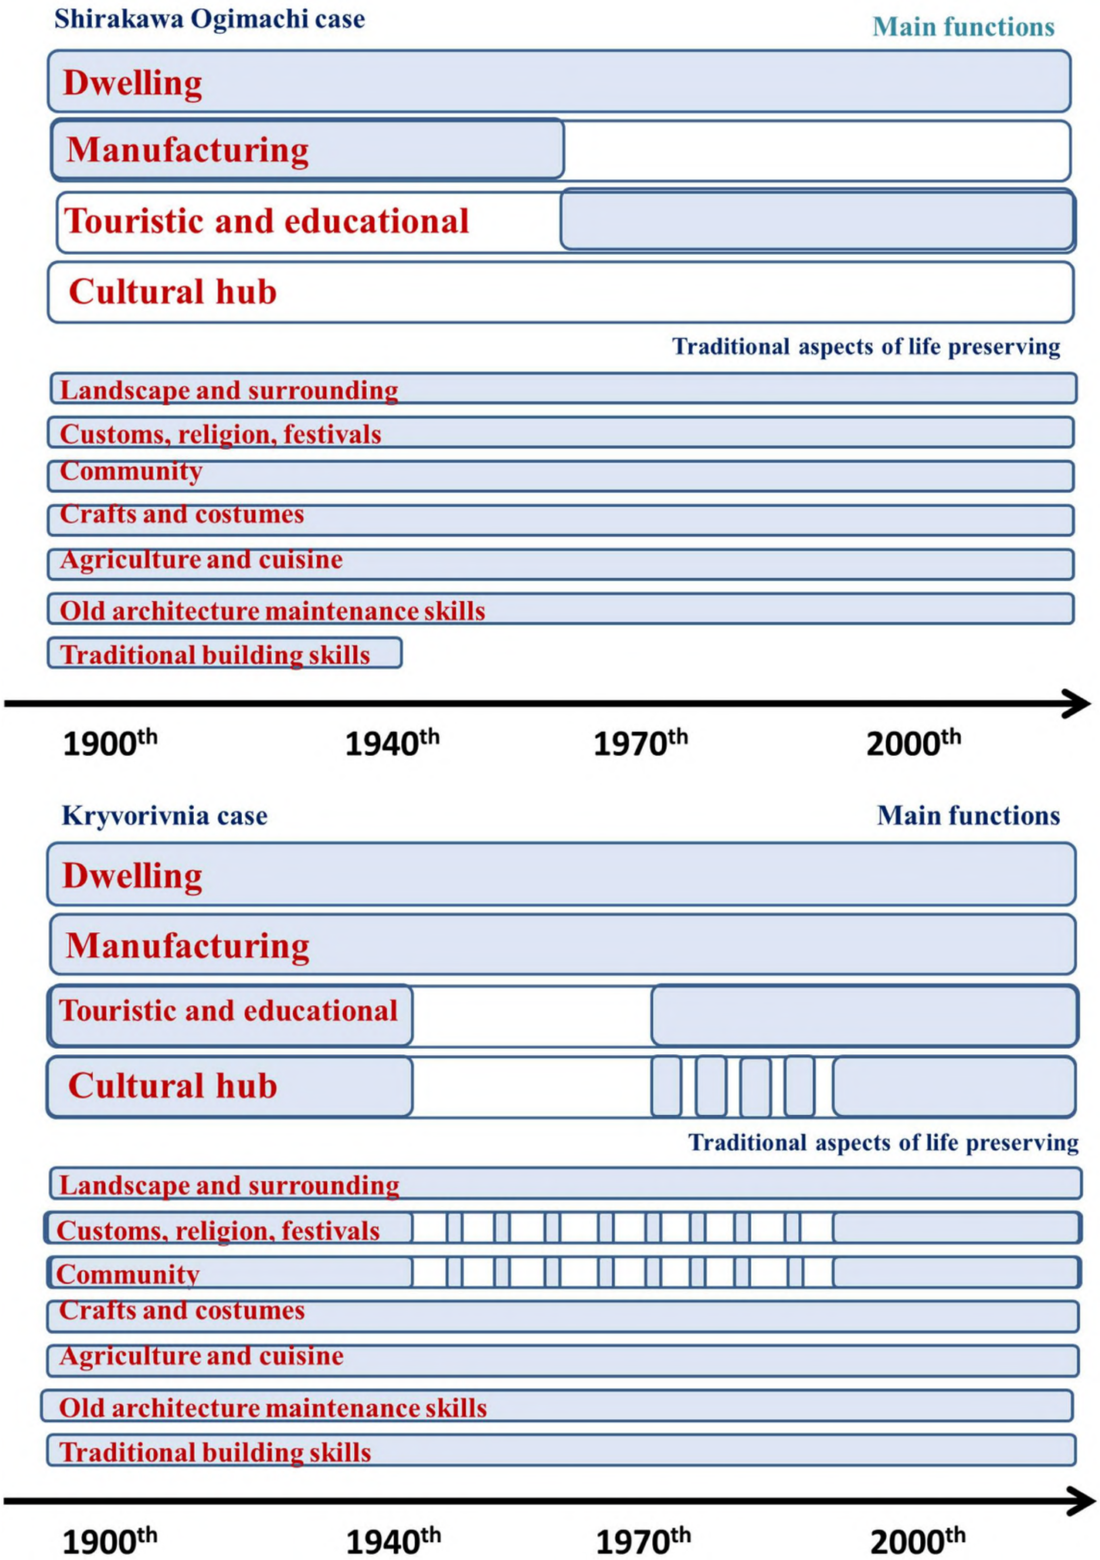

Figure 6. Shirakawa Ogimachi and Kryvorivnia cases functional abilities and traditional activity components preserving (by author).

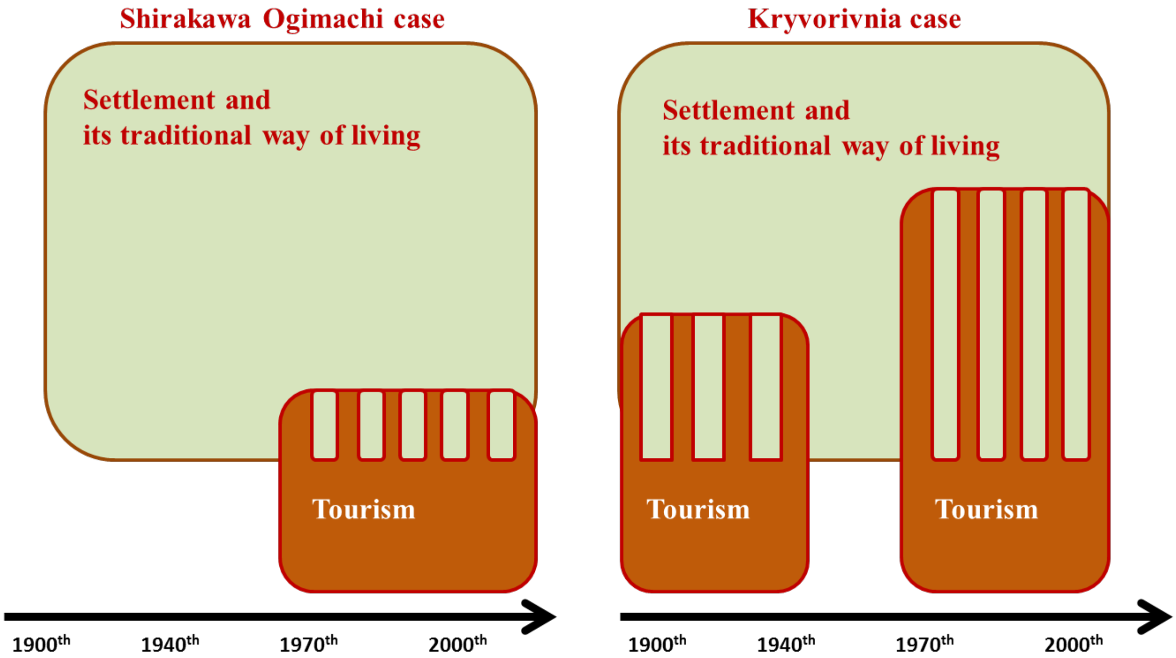

Figure 7. Local life and touristic activity interaction at Shirakawa Ogimachi and Kryvorivnia cases.

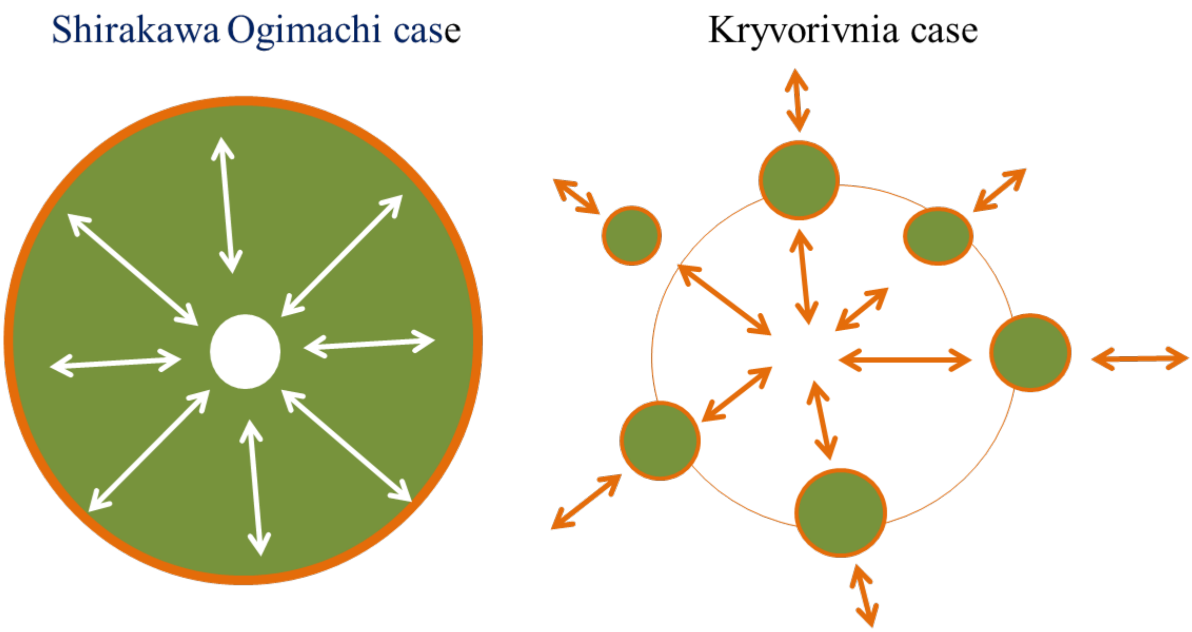

Figure 8. Traditional settlement structure of Shirakawa Ogimachi and Kryvorivnia.

have deferent answers. The “non-detached” preservation of the settlement is possible now only in coexistence with surrounding nature that shape both possibility and necessity to practice continually traditional way of living, customs, building technics, crafts, agriculture and social relationship. From the one hand, the complete stagnation of the local traditions and the way of living in the ancient "status quo" usually leads to the settlement life conservation or museification existing separately from the real word. From the other hand, the excessive openness to the word could lead to the settlement identity dissolving. The decision of desirable proportion between this two crisis points are usually made by local communities and generally reflecting deep national mentality and historical background of the settlement. The same could be applicable also for the question of touristic activities separating or engaging on the local community life of the settlement. Revitalization methods of historical settlements with traditional way of life often are the original products that can lead the local communities to unique domestic heritage preservation and revitalization methods and sustainable development strategies creating.

Abstract. The war in Ukraine has led to large-scale destruction. The scale and nature of changes in the urban planning parameters of the Luhansk region under the influence of hostilities and the restoration of urbanized territories are studied. The purpose of the study is to determine the models and principles for the restoration of urban areas affected by hostilities. Theoretical and empirical methods of system and statistical analysis, analytical comparisons, urban planning analysis were used for the study. The paper considers the quantitative and qualitative nature of the impact of destruction and the socio-demographic and economic consequences caused by them on the change in the urban planning parameters of the Luhansk region. The information base consists of literary and archival sources, cartographic materials. The analysis of urban planning tasks for the restoration of urbanized territories destroyed as a result of hostilities is carried out. It is established that the war changed certain functions of the region. The task arises to determine how the change in functions affects the transformation of the territorial typology of the use of territories. The region is at the beginning of the phase transformation of the urban form. A methodology for assessing and making urban planning decisions is proposed. The urban planning tasks and directions for the restoration of the urbanized territories of the Lugansk region, destroyed as a result of hostilities, are analyzed. From the intermediate conclusions, it is advisable to single out that the region has significantly changed its functions. The military and special nature of the use of the territories will be a priority. So, the planning frame of the territory should undergo changes. It is necessary to revise and update general layouts, regional development schemes aimed at the advanced development of programs and projects that primarily ensure the structural growth of territories. The region will experience a labor shortage. So, recovery programs will face a shortage of builders. It is advisable to create and strengthen the departments of the chief architect of the city, expand the staff, to develop current and future tasks for the development of cities.

1. Problem statement

The hybrid intervention of Russia in early 2014 led to an armed conflict known as the ATO/JFO [1, 2]. On February 24, 2022, an open war began. In combat operations, all types of weapons and combat arms are used. Appropriate are the scale and consequences of the destruction. The use of heavy weapons, aircraft, missile strikes in highly urbanized areas for many months leads to large-scale destruction of populated areas to the state of 'scorched earth'. The war is not over yet.

‘Wars begin when you will, but they do not end when you please’ – Niccolo Machiavelli

We also do not set ourselves the task of guessing the date of the end of the war. The fundamental point is the fact that after the end of the war, restoration begins, aimed at eliminating the consequences of hostilities, restoring populated areas, territories abd urban planning systems. Unfortunately, there is every reason to assert that the scale and nature of the destruction of individual urbanized territories is so significant that questions arise as to what and how will have to be restored? The destruction of an individual house is not a problem of its restoration. The destruction of 70% of the housing stock, engineering systems for the city, road and transport infrastructure, raises the question – in what sequence, in what volumes is it necessary to restore the city? There arise the tasks of assessing and determining the scope of work, the order of renewal, the forecasted terms of restoration, sources of financing, the availability of labor resources and the urban development base. And all this in a region that was in decline even before the hostilities. In fact, the question arises of developing a regional program for the development of the territory (region), in parallel with the development of general layouts for the development of settlements for the post-war period. For a detailed analysis of the situation, the development of rational urban planning solutions, it is necessary to solve a number of scientific problems:

- to give a quantitative and qualitative description of the extent of destruction;
- develop a methodology for assessing the impact of the nature of destruction on the state of objects and the possibility of their restoration;
- develop a classification of urban objects and systems according to certain typological features; propose principles and models for the restoration of disturbed urban areas aimed at their sustainable development.

A comprehensive analysis will make it possible to develop options for the long-term and advanced development of the Sievierodonetsk-Lysychansk agglomeration, the functional and planning structure of the settlement.

2. Purpose, idea and research methodology

2.1. The goal of the research

Study of the impact of the scale and nature of destruction as a result of hostilities in the Lugansk region on the possibility of restoring urbanized territories. Determination of models and principles for the restoration of urbanized territories destroyed as a result of hostilities.

2.2. The idea

The armed conflict in eastern Ukraine continued in the worst possible way. Various possible scenarios were predicted, but a full-scale military invasion was considered the most frightening, and therefore hypothetically less likely [3–5]. The totality of internal and external factors, the unpredictability of the modus operandi of the Russian leadership led to the fact that a large-scale war is taking place on the territory of Ukraine, in the east of Europe, with a scale of destruction that the continent has not known since WW2. The use of heavy weapons leads not only to the destruction of individual objects, but also to the destruction of territories. Individual settlements were wiped off the face of the earth. This turns the consequences of the war into a systemic problem that will take years to resolve. The hostilities resulted in the evacuation of the population, the cessation of economic activity, and the paralysis of the housing and utilities sector. It becomes obvious that in the event of the end of the war, complex methodological tasks will arise, covering the priority of restoration, the list of objects subject to and not subject to restoration, approximate time for the implementation of programs and plans for restoration, the definition of the town-planning base for the development of territories, and many other issues. The tasks of updating the general layouts of settlements will become relevant. Regional development programs will have to be radically revised. The new functions of the regional typology are becoming a reality and require taking into account the tasks of improving the territorial planning organization of the Luhansk region and urban development.

2.3. Methodology

Theoretical and empirical methods of systemic and statistical analysis, analytical comparisons, urban planning analysis were used for the study. The paper considers the quantitative and qualitative nature of the impact of destruction and the socio-demographic and economic consequences caused by them, the change in the urban planning parameters of the Luhansk region. The information base consists of literary and archival sources, cartographic materials.

3. Results

An analysis of the scale of destruction indicates a potential change in individual functions and forms of the region. The evolutionary gradual nature of urban transformations has been replaced by an abrupt transition to a new quality. The transformations are in the nature of phase shifts. Post-war restoration will lead to changes in the planning framework of the territory. Recovery tasks are defined, which should take into account changes in the nature of the region's functions. The basic principle is to update and revise general layouts for populated areas and regional development schemes. Anticipatory reconstruction is the priority model of reconstructive restoration. It is advisable to create vertically integrated departments of architecture and urban planning of cities and the regional administration. A classification of construction and infrastructure facilities according to typological features is proposed in order to form post-war reconstruction programs. It is expedient to give priority in restoration to urbanized cells with the maximum development potential.

It is still impossible to make a comprehensive assessment of the consequences of the war. The war is not over yet, the scale of losses and destruction cannot be correctly calculated. Secondly, there is hardly a methodology that allows modeling the volume of losses in a single indicator. Officials give a variety of information, which ultimately allows us to draw conclusions - the scale of destruction is colossal.

"Since Russia's full-scale invasion of Ukraine, the invaders have completely destroyed six cities. This was announced by Deputy Head of the Office of the President of Ukraine Kyrylo Tymoshenko in a video message to the participants of the forum 'Revival of Ukraine –- Revival of Communities' The Donetsk and Lugansk regions suffered the most. There, some cities were destroyed very badly. These include Mariupol, Volnovakha, Rubizhne, Popasna, Liman and Sievierodonetsk. *'According to our preliminary estimates, more than 350,000 objects and millions of square meters of residential, educational, medical, and sports infrastructure have been destroyed in the country, thousands of kilometers of roads and railways, airports, ports, and much more have been damaged. Some of these facilities can be restored, some have been destroyed to the ground'* – Tymoshenko said. The number of damaged and destroyed housing in Ukraine is close to 35 million square meters. Even with a relatively calm economic and social situation, it may take a long time to restore it." [6]

"In Sievierodonetsk, Luhansk region, 90% of residential buildings were damaged as a result of hostilities. This was announced by the head of the regional military administration Sergei Gaidai *'... 70% of the houses destroyed by the Russians are not being restored. In addition, the critical infrastructure of the city is completely destroyed ...'* In addition, the so-called 'LPR' stated that they were not going to restore Popasna: the city was completely destroyed." [7]

It is appropriate to point out that a city is not an arithmetical aggregate of residential buildings. Definitions and criteria of cities in the scientific community differ. What is common is a certain number of the population, mainly engaged in non-agricultural activities, the compactness of the settlement, anthropogenic transformation of the territory. The main functional zones of the city include rural, industrial, landscape and recreational. The defining characteristic of a city is the list of functions and services it provides. Functions of the city are the main types of activities performed by its residents. The main groups of functions are distinguished – city-forming (specialized, exogenous), which determine the economic base of the city. These production functions are industrial production, construction, transport, higher education institutions, tourism and sanatoriums. City services (endogenous) are functions of the city, performed exclusively in relation to its population [8].

Figures 1 and 2 show a panorama and a bird's-eye view of the Popasna district. Figure 3 shows, what the village of Novotoshkivka turned into. The first question that arises is what functions and services inherent in the city are possible? How to estimate the scale of destruction? How should the program for reproduction of these settlements look like?

Figure 1. Panorama of the city of Popasna (population 19,199 people on January 1, 2022) of the Luhansk region [9].

Traditionally, war losses are calculated in monetary terms. But it is possible to argue that any estimates are not final, money has its value, which is determined by the discount rate, and the value of money (as a category) changes over time. Inflationary processes, an integral part of the economy, also contribute their share and are not subject to correction. That is, we can only talk about forecast indicators and program targeting – therefore, any sums of losses are indicative and fix concrete facts for a certain period of time.

Methodologically, these circumstances are taken into account in various methods of real estate valuation, when, depending on the conditions, the object, and the impact factors, the cost method, income method, and comparative method are used [12].

The basis for the financial assessment is the cadastre (registry) of objects that have been destroyed and need to be restored. And in this case, the problem has no methodological support. An attempt to apply an inductive approach (methods of induction and deduction) forces us to develop certain classifications according to certain criteria (features). For example:

Figure 2. Photo of the destruction of a residential building in the city of Popasna, Luhansk region [10].

completely destroyed; partially destroyed; (not) suitable for restoration. But this method gives errors in assessing systems, territorial entities. It is also problematic to determine the degree of destruction of an object and assign it to a certain category. The method of expert assessment seems to be the most adequate, when a qualitative (determining) conclusion is made on the basis of an integral assessment of the amount of identified defects. The list of defects is determined by the methodology, the presence and significance – by experts, the degree of influence of defects on the general condition – by a qualimetric assessment.

It is important to evaluate the final resource of the restoration object and its residual value, since these parameters influence the decision on the feasibility of restoration or replacement. This is also a difficult methodological task, given the fact that there is no real experience of restoring objects destroyed as a result of hostilities in Ukraine. The residual value should also reflect the usefulness of the object – the ability to provide a certain function of urban planning activities.

The primary classification of objects holding destruction as a result of hostilities according to typological features may include:

- Individual residential houses;
- Multistorey residential buildings;
- Educational institutions and youth education – kindergartens, schools, colleges, universities;
- Cultural institutions – palaces of culture, theater buildings;
- Administrative buildings of cities and towns;

Figure 3. Novotoshkivske village (population 2,119 people on January 1, 2022), Luhansk region [11].

- Complexes of public utilities and engineering structures to ensure the functioning of cities;
- Structures and complexes of public transport enterprises;
- Transport facilities – railway stations, airports;
- Industrial companies;
- Objects and structures of engineering networks for gas and electricity supply, drainage and sewerage, water and heat supply;
- Elements of road infrastructure;
- Parks, squares, recreation areas, landscape areas.

The above classification makes it possible to group objects according to the characteristics of the size of the territories and according to the principle of the priority of fixing the land plot (priority of the territory).

An individual residential building can be relatively easily assessed in terms of the nature of defects or the degree of destruction, the possibility of repair, and the cost of repair. But if this building is located on a plot of manor development, in which engineering communications are destroyed? The cost and laboriousness of laying or repairing engineering networks of electricity, gas supply, water supply can be several times higher than the cost of restoring a house. That is, the problem of a separate house should be considered within the framework of the task of restoring a certain area of the manor development. The second part of the problem is legal in nature – what to do if the owner or legal representative of the owner of the house is absent? How to resolve issues with the house and land? What parameters or factors are more decisive – the attractiveness of the territory or the degree of preservation of houses? Similar questions arise for apartment buildings, despite the fact that there will be even more uncertain positions for objects of this class.

The classical theory of town planning development is based on the evolutionary, gradual nature of transformations with the aim of improving the town planning situation [13, 14]. In our case, unfortunately, we have changes that are sudden, external in nature, partially catastrophic, partially leading to changes in the urban or regional situation radically [5]. Figures 4 and 5 show only a small part of the destroyed city of Popasna (the history of Popasna as a settlement begins in the middle of the 19th century). The city's economy was mainly focused on railway transport and the coal industry. A railway-car repair works, a locomotive bay and wagon depot, and an elevator operated in the city. The population of the city was up to 20,000 people.

Figure 4. Satellite image of the damaged locomotive bay and wagon depot in the city of Popasna, Luhansk region [15].

A recursion is fixed when the usage form changes as a result of a war. The impact of the war determines the changes in the function of the use of the territory. Change of function — if it is irreversible, determines the change in form during the period of post-war reconstruction. For example, to what extent the coal-mining part of the economy of individual cities will remain. Lisichansk is known to be the birthplace of coal-mining Donbass. Will it be economically feasible to keep the coal mines of Lisichansk?

If we draw an analogy with the Chernobyl disaster, there has also been a catastrophic change in the regional situation. For obvious reasons, part of the territory was withdrawn from usage, the residence and attendance of people in the Chernobyl Exclusion Zone was limited. However, this zone is under control, a number of programs have been developed aimed at stabilizing the general situation, special activities, construction, various types of research and control are

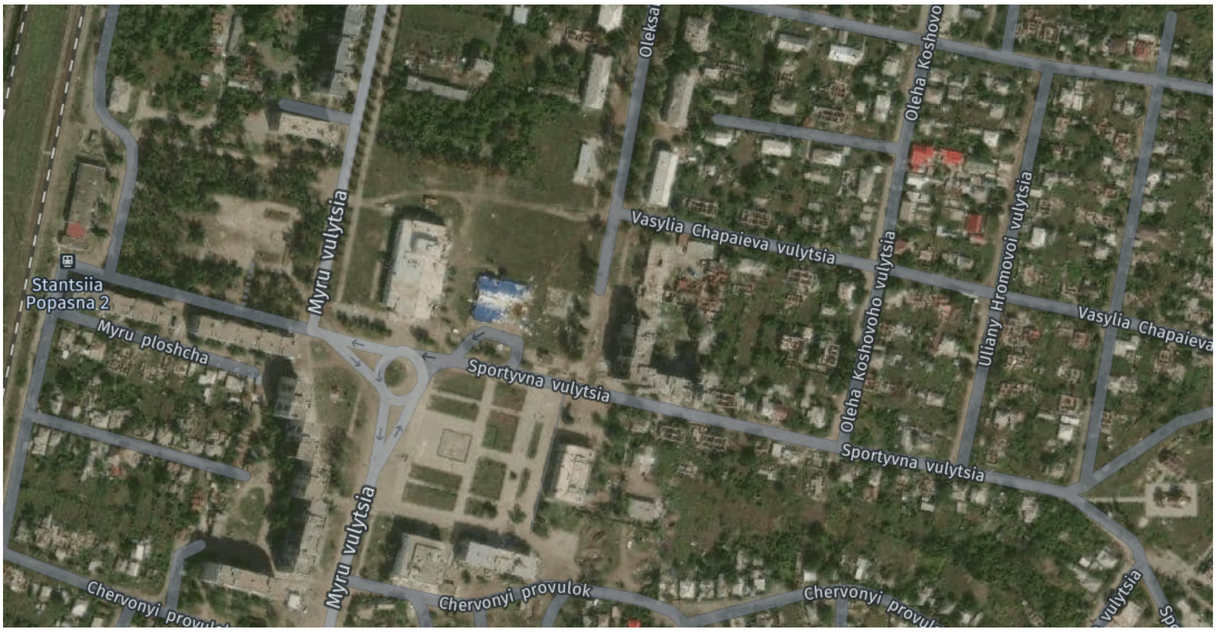

Figure 5. Satellite image of a part of the destroyed district of the city of Popasna, Luhansk region [15].

being carried out. But this exclusion zone is unprofitable, it generates losses. There is a balance between minimizing the harmful effects and the cost of maintaining the zone. After the liberation of the occupied territories, they must be returned to normal economic activity, profitable and generally useful. In this case, the problem arises of determining the balance between the costs of restoring territories destroyed as a result of hostilities and their further efficiency of use.

The situation in the temporarily occupied territories remains difficult, so far it is impossible to talk about fixing the general state of damage losses. Natural and climatic factors are a significant factor in changes and the winter period will make its own adjustments. In the context of the liberation of the territories, spring will give a rough idea of the scale and inevitability of the destruction of the housing stock. Damaged roofs of buildings and lack of heating will lead to soaking of the walls. Freeze and frost retreat cycles can reduce the bearing capacity of structures. Two seasons in a row will make the buildings uninhabitable.

Spring will give an idea of the influence of such factors as the level of urbanization, the scale of destruction (in percent), the availability of labor resources and the active share of the population on the preservation and development of the territory of the so-called Rubizhne-Sievierodonetsk-Lysichansk triangle.

A separate scientific task is to assess the impact of migration processes on the directions of the functional development of the territory [16]. Migration had a multi-vector character. Most of the citizens moved to Ukraine. Some of them turned out to be refugees in European countries. Some part went to Russia. Part of the population remained. Among them – most of the economically inactive population – pensioners. The percentage of the active part of the population has decreased – but now it is difficult to estimate its number, despite the fact that migration processes continue. Employable people are looking for an opportunity to leave for regions with higher salaries. This trend has been fixed in the Donbass for a long time [4, 17–19]. The war gave the character of a catastrophe. Since there are no socio-economic prerequisites for mass incentives for the return of able-bodied people, this trend is becoming irreversible. It can be argued that the period of intensive colonial development of Donbass has expired. The region cannot offer attractive working conditions and becomes a donor of labor resources. As already noted in previous studies [20], the region stagnates, the nature and directions of development of the territory are determined by the functional processes taking place on it. Apparently, it should be noted that the trends have not been finally determined, but the general direction is currently negative.

The cities of Luhansk region can be classified as industrial cities without a notable historical heritage. These cities have different planning structures and their own unique compositional construction. The consequences of destruction lead to the fact that the basic urban planning principles require adjustment. Changing the functions and form of territories is the task of restoration. At the initial stage, it is difficult to determine the dominant part. [21] Comprehensive reconstruction of destroyed cities is based on the principles of protection and safety; accessibility; autonomy; adaptability; attractiveness; environmental friendliness and restoration of the environment.

- *Principle of protection and safety.* The urban form should protect residents from various types of danger. For border regions, there is an existential threat of a resumption of war, and this factor must be taken into account.
- *Principle of accessibility.* For border regions, accessibility should be a basic direction towards the so-called center. The traditional concept includes both limitations and a combination with the principle of safety, including the ability to move quickly.
- *Principle of autonomy.* Creating resilient management systems. A sufficient level of infrastructure and resource provision is necessary for functioning and sustainable development.
- *Principle of adaptability.* The spatial and architectural-planning organization of the city should have a complex structure but be adaptable, flexible, and able to quickly respond to possible changes, corrections, and new trends.
- *Principle of flexibility.* The urban development management system should be more flexible. Feedback on problems and response time should be accelerated.
- *Principle of attractiveness.* The set of factors and conditions that will contribute to the return and attraction of people, enterprises, and capital.
- *Principle of ecological sustainability.* The restoration of the environment should be an active process.

The process of restoring liberated cities will have its atypical differences. Obviously, the beginning of everything will be the restoration of the management system in conditions of a state of emergency. Not all norms of civilian legislation will work. The primary actions will concern individual objects critical for the functioning of the liberated cities. The restoration process will be divided into three stages (directions) – object reconstruction, functional reconstruction, and urban (territorial) reconstruction. It will be difficult to determine the predominant direction at the initial stage. Different methods and types of work are developed for each stage. Work can be performed simultaneously or sequentially depending on the condition and characteristics of each group of buildings that form the restoration area, as well as the goals and financing of the reconstruction.

Based on a comparative study of buildings and structures within a residential block and determining new requirements for them, the tasks of reconstruction and measures of reconstructive intervention are identified [21]. The measures of reconstructive intervention depend on the level of suitability of individual buildings for normal operation; the degree of preservation of planning and volumetric spatial qualities of the site (scale of destruction); architectural-planning and structural qualities of individual buildings; the ability of buildings to meet urgent social needs, that is, whether they need to be given a new function.

Object reconstruction of buildings aims to restore their functional properties and primary housing qualities. The principles of object reconstruction include:

- Preservation of the primary architectural and planning solution of the building in the existing development (reconstruction involves partial restorative repair, capital repair, or modern conversion);
- Dominance of the overall reconstruction concept of the quarter in selecting project solutions for restoring the building.

Functional reconstruction of buildings and structures within a block aims to find the optimal modern functional use, taking into account the real condition of the block. Determining the optimal functional solution for a civil building is based on comparing the primary function of the building, its current state, and the possibility of transforming it to meet modern needs. The project solution may involve restoring the primary function, developing the primary function, or forming a new function for the object. Restoring the primary function is achieved through repairing and reconstructing the building using various methods. Alternatively, complete reconstruction of a ruined building is possible. Developing the primary function is achieved through reconstruction of the building using full reconstruction or partial modernization methods. Forming a new function (adaptation) is recommended during reconstruction of the building using partial or full modernization methods, primarily as part of a detailed planning project for a group of buildings. When choosing new functions for a historical building, it is essential to adhere to principles such as maximum similarity between the new and existing functions, and preserving the correspondence or proximity of the selected function to the previous purpose of the object.

The main principle of functional reconstruction of blocks with a complete or partial list of service objects may be the preservation and orientation towards multifunctionality. Choosing the correct functions for the block and its individual buildings, in combination with optimal means of reconstruction, may be the only way to ensure survival and development of the entire planning element as a whole.

Urban/territorial reconstruction includes the reconstruction of the spatial territorial structure as the basis for preserving and developing the main functions of the city. The reconstruction of the spatial structure aims to organize and adapt it to post-war realities. The principles of urban reconstruction include:

- maximum preservation of the existing spatial structure, which requires minimum investment in territorial transformation;
- addition and expansion of the spatial structure with new elements, taking into account the current state and post-war realities.

At this stage, the hierarchy of compositional structural elements of the level-agglomeration-urban planning unit is determined. Prospective territorial hubs are formed that provide for the development of the main functions of the city, and areas for deferred reproduction are reserved.

The research [22–24] identifies three models (forms) of reconstructive activity:

- The “restorative” reconstruction model;
- The “supportive” or “accompanying” reconstruction model;
- The “proactive” or “anticipatory” reconstruction model.

The proactive reconstruction model has a high level of stimulation for future activity, is designed for implementation over a period of 5-7 years, and results in a reconstruction concept or target program. The supportive reconstruction model has a medium level of stimulation for future activity, is designed for implementation within 5 years, and provides for the development of a reconstruction project (program). The restorative reconstruction model has a low level of stimulation activity, operates within a timeframe of 0.5-1 year, and involves the development and implementation of a reconstruction project for an object [22]. At the initial stage, situational response will be implemented for emergency restoration of urban objects and functions. This will be followed by a period of implementation of programs and projects for supportive and proactive reconstruction. Within 2-3 years, an adequate target program for the reconstructive development of urbanized territories should be developed. Object-oriented response and current development should be subordinate to the programmatic goals of the proactive reconstruction model. The figure 6 contains a scheme of methodical interaction of models of reconstructive activity. Situational response, which leads to systemic error, promotes the accumulation of problems and contradictions, ultimately resulting in the degradation of territories and regional crisis state, is a negative alternative.

There is a task to correctly assess and determine trends, which will allow determining the direction of changes. The situational analysis will allow to determine the tasks transformed in order to ensure the sustainable development of the region in the new conditions created by the post-war situation. After the occupation, it is necessary to develop a program of regional restoration/renewal covering the territory of the regions, town-planning formations (cities and settlements), infrastructure objects, objects and infrastructure systems of urban and group settlements. [25–28]

It is not possible to develop a separate city with leading indicators on the destroyed territory. The concentration of finances in a separate city (populated area) will not have a great effect in terms of improving the quality of life in the region. Likewise, spreading a thin layer of funding over the territory will not ensure its sustainable development. It is necessary to determine growth points, directions of advanced development and support a function that can provide a high level of benefit.

Orientation tasks and prerequisites that must be analyzed and solved at the first stage are quite numerous.

Administrative and territorial reform of the region (for example, what city will be the regional center or fulfill most of its functions) [29].

Will individual cities retain their status? For example, Hirske, Popasna, individual villages – completely destroyed, Rubizhne-Sievierodonetsk-Lysychansk agglomeration – perhaps more expedient as a single administrative entity? On the formation of military-civilian administrations of districts – former cities forming an agglomeration? Problems of the functioning of city councils and city executive committees of cities. Problems important for the normal functioning of cities have not been resolved for years: the political situation on the ground is far from normal, which means that important decisions should not be made at the level of local government.

Define zones that will have special border region conditions. As noted, the region from the internal, transboundary has become a border region [5, 20]. The state, the Ministry of Defense, the Armed Forces of Ukraine are likely to have priorities in the use of parts of the territory.

It is also necessary to determine the configuration – the supporting frame of communication routes, taking into account new realities. If there is a special regime zone, are the roads needed (P07 Chertkovo, T1 302 Tanyushevka, P22 Chervona Talivka, M04 Izvarine, E20 Dolzhansky)? Subject to the strict requirements of the visa regime, foreign citizens will have to travel on other routes. Certainly, undergo changes in the category of roads that have the direction of the road along the border, and unite the major cities of the regions.

This will determine (possibly) additional engineering structures, tasks for the restoration and reconstruction of existing bridges, flyovers, airfields, etc.

As an example, the Siverskyi Donets River on the border with Russia flows along the border line for a considerable distance – from the settlement of Novokievka/Makarov yar to the settlement Popovka. The river should be provided with means of control, protective structures.

It is possible that it will be necessary to regulate the flow of the Siverskyi Donets and create

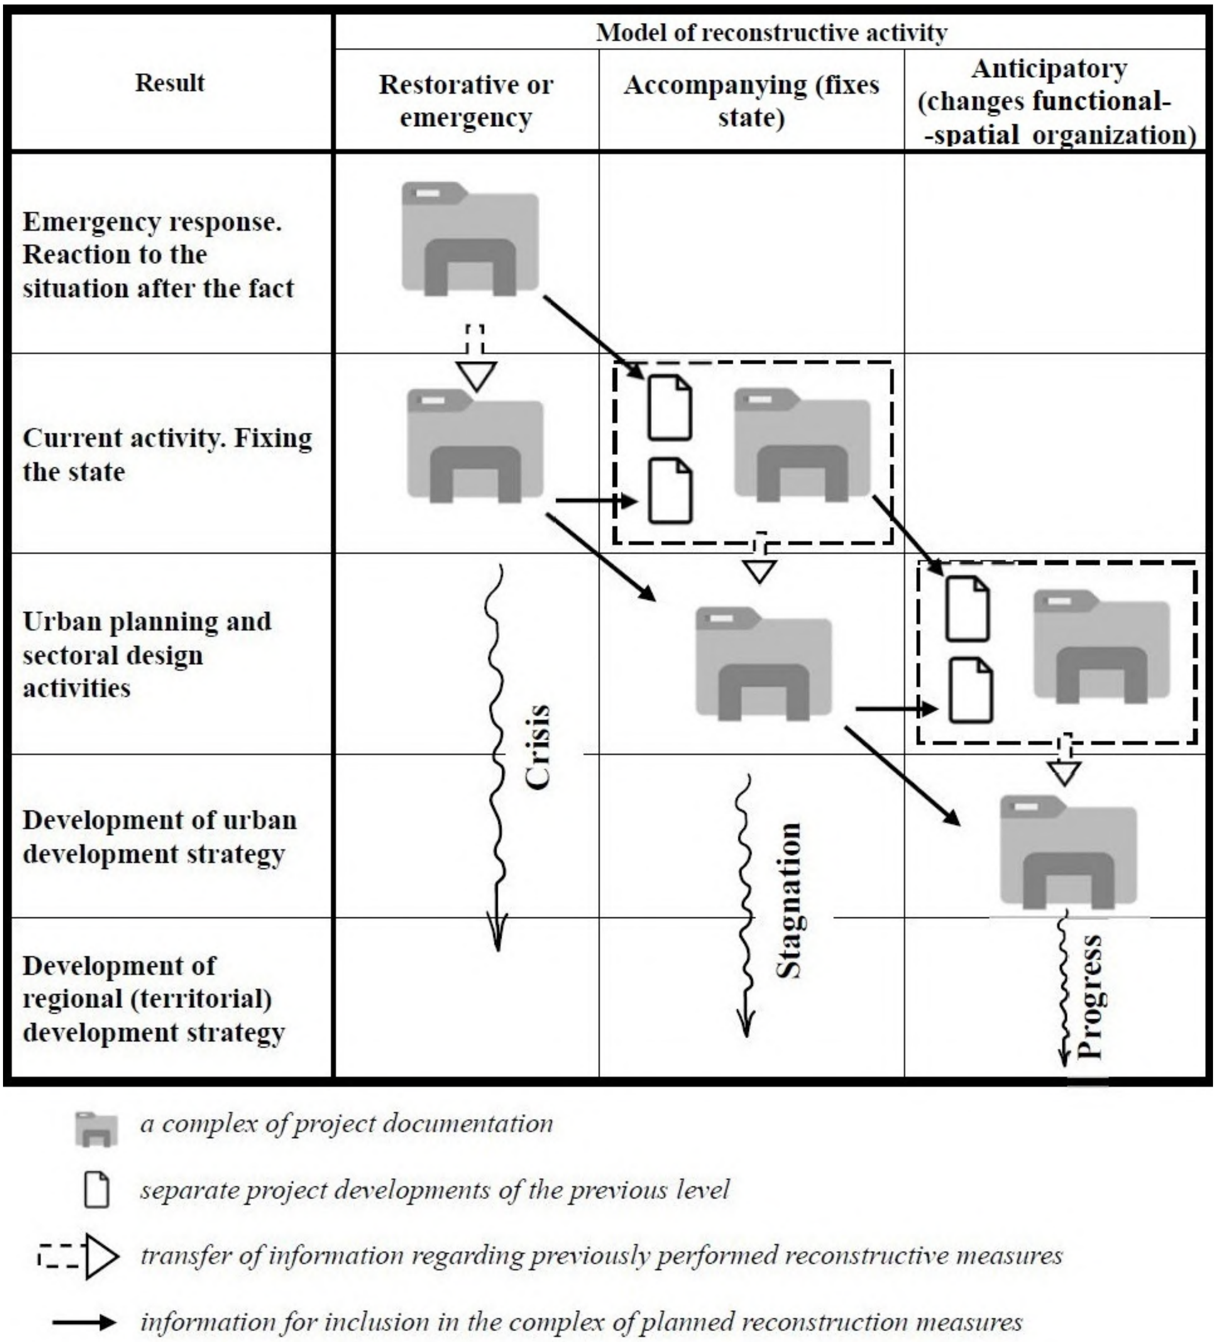

Figure 6. Scheme of methodical interaction of models of reconstructive activity.

additional water management complexes.

There is a need for a cadastre of enterprises and institutions that will operate in the region and be subordinate to the central executive authorities (correctional colonies, detention centers, military camps, training grounds).

Perhaps there will be zones and territories with limited use, which will need to be determined, for example — mined.

Determine the objects that should be financed by the state and include them in programs and general layouts for urban development.

It is necessary to determine the objects in which there is a need to ensure the sustainable development of cities and the region — schools, kindergartens, sports facilities, hospitals, clinics, homes for the elderly, administrative buildings. For example, in the city of Lysychansk, almost all administrative buildings were destroyed. And if the functions are listed, then the basic list contains the buildings of the city hall, the national police, the prosecutor's office, the court, the security service, the ambulance station, and the fire station.

Depending on the results of the administrative-territorial reform, it is expedient to determine the placement of universities, colleges, and student residence buildings. In the territories occupied since 2014, a large number of educational institutions remain, the property of which consists of buildings, structures, and land plots. Part of the displaced institutions of higher education were reorganized by merger. The Ministry of Education of Ukraine acts as the manager of the property. The owner is the State Property Fund of Ukraine. Leaving the region without education means leaving the region of the future. Thus, the location of the leading educational institutions in the region should be determined.

It is necessary to determine objects of a commercial nature, their legal status, conditions for further functioning. In the region, there are several large enterprises that require balanced legal decisions – coal mines, private and state, Lysychansk oil refinery plant, 'Zarya' chemical plant, Rubizhne cardboard mill, Sievierodonetsk chemical plant 'Azot' and others. One should hardly care about the development of the network of gas stations. Large networks of this segment will solve this problem at the level of commercial attractiveness. It is quite obvious that the network management wants to know the plans for the development of the road network in order to coordinate their projects.

4. Conclusions

The cities of Luhansk region are predominantly known for their industrial character and lack a significant historical heritage. The destruction caused by past conflicts has necessitated adjustments to the fundamental urban planning principles. The process of restoring these cities involves determining the dominant aspects and implementing comprehensive reconstruction based on the principles of protection, safety, accessibility, autonomy, adaptability, attractiveness, and environmental friendliness.

Given the military and special nature of certain territories, prioritizing their planning framework is essential. Cross-border cooperation has shifted towards establishing clear borders and protective exclusion zones. The delimitation and demarcation of borders have been gradual, and stricter border control measures are now in place.

The restoration of liberated territories requires a thorough review and update of general layouts and regional development schemes to focus on advanced programs and projects that facilitate the structural growth of the regions. The model of anticipatory reconstructive activity takes precedence in this regard.

To support the development of cities, it is crucial to establish and strengthen departments responsible for urban development tasks, such as the Chief Architect's office, with an expanded staff of specialists.

We propose the establishment of a Regional Civil-Military Administration department dedicated to urban and territorial development, staffed with qualified experts.

Urbanized areas with normal population density tend to be more successful and competitive in their development.

Investing in education and job creation should be prioritized over general improvements to the territory. This focus will play a crucial role in the region's growth.

Considering the anticipated population migration, the region is likely to experience a shortage of labor during recovery programs, particularly in the construction industry.

It is essential to allocate a portion of the territory for environmental purposes and landscape reproduction, such as preserving forests and riverine areas.

The preservation of ecologically significant areas should be a priority to maintain the region's environmental balance.

In summary, the restoration of the cities in the Luhansk region demands a careful reevaluation of urban planning principles, cross-border cooperation, and investments in education and job opportunities. Prioritizing environmental preservation and sustainable development will contribute to the region's long-term success and growth.

Abstract. The purpose of the study is to determine the state of transformational conversions in Ukraine on the way to achieving the goals of sustainable development, in particular, the condition of the development of cities and communities. With this goal, an analysis of Ukraine's position according to indicators of sustainable development in dynamics was carried out. It has been established that Ukraine is committed to the values and goals of sustainable development. An assessment of measures regarding the adaptation of sustainable development goals in Ukraine was conducted. It has been found out, that Ukraine has made progress in achieving twelve of the 17 goals that determine the country's sustainable development in the economic, social, and environmental spheres, including SDG 11 "Sustainable cities and communities". The state and amounts of financing of the "Stable cities and communities" goal were analyzed, and the disadvantages of the Ukrainian system of state strategic planning and budgeting were identified. Proposals regarding the innovative nature of economic development in the context of sustainable development of cities and communities have been researched and substantiated. Approaches to the management and development of cities and communities are proposed, which should be based on inclusiveness, safety, and sustainability principles.

1. Introduction

In the modern activity of mankind, issues related to various aspects of cities sustainable development are considered key factors in the development of the modern economy. The sustainable development of spatial systems, as a form of organization and ensuring a high quality of human life, gave impetus to changing approaches and strategies in the development of states, regions, cities, and territorial communities. The principles proposed by the international and European community, outlined in the Leipzig Charter "European Cities on the Path to Sustainable Development", the Strategy for Smart, Sustainable and Inclusive Growth "Europe 2020" and the UN Global Sustainable Development Goals are an illustration of approaches to sustainable development at the micro-, meso-, macro- and mega-levels. The conceptual principles of managing the sustainable development of the city are based on the guiding principles and regulations of the European Union, namely: the Charter of the Congress of Local and Regional Authorities of Europe (Strasbourg, 1957), the European Charter of Regional Spatial Planning (Torremolin Charter, 1983), the European Charter of local self-government (Strasbourg, 1985), the Gothenburg Strategy for the Sustainable Development of Europe (Gothenburg, 2001), the Leipzig Charter for the Sustainable Development of the City (Leipzig, 2007), the Europe 2020 Strategy "A strategy for smart, sustainable and inclusive growth" (Brussels, 2010).

The sustainable development of cities makes them viable, able to adapt, mitigate adverse consequences, and stimulate positive socio-economic and environmental changes. Sustainable development covers all aspects of the healthy development of the city and should provide solutions to financial, economic, social, and environmental problems.

2. Research methods

The research methodology is based on a literature review, survey, and qualitative case study.The authors analyzed scientific publications from the scientometric database for the period 2014-2020 regarding the reflection in them of aspects of sustainable development of territorial communities and cities. This made it possible to identify specific features of development in Ukraine. For an in-depth analysis, the authors used a case study. The work uses methods of generalization and comparison to determine the level of sustainable development goals in Ukraine and other countries of the world.

The purpose of the study is to determine the state of SDG 11 in the realities of Ukraine and compare it with other sustainable development goals and determine the place of Ukraine in indicators of sustainable development.

3. Research results

At the end of the 20th century, the principles of sustainable development were approved by the world community at the UN Conference on Environment and Development in Rio de Janeiro (1992) and finalized in the UN report "On Human Development" in 1994 into a universal concept of sustainable development. The essence of the concept of sustainable development in its modern understanding is the balance of social development in social, ecological, and economic aspects. Sustainable development is the development that satisfies all spheres of society's life without harming the opportunities of future generations [1]. Historically, Ukraine's path to sustainable development began at the same conference in Rio de Janeiro, when the Rio de Janeiro Declaration and Agenda for the Program of Action in the 21st Century were signed. Subsequently, Ukraine confirmed its desire to follow this path and, as a result, in 1997, the National Commission for Sustainable Development was created under the Cabinet of Ministers of Ukraine.

In 2015, in New York, as part of the agenda of the summit "Transforming our world: an agenda in the field of sustainable development until 2030", the UN General Assembly approved 17 sustainable development goals aimed at fighting poverty, protecting the planet and improving the lives and prospects of everyone, around the world and called on countries, the public sector and business to unite for their implementation. Goal number 11 is the sustainable development of cities and communities [2].

Since 2015, several reforms have been launched in Ukraine (figure 1) aimed at implementing socioeconomic transformations and strengthening the democratic system. The Sustainable Development Goals (SDG) are integrated into a public policy based on "leaving no one behind". The result of the inclusive SDG adaptation process for Ukraine, taking into account the specifics of national development, was the SDG system, which consists of 86 tasks with 183 indicators for monitoring. The government established an Interdepartmental Working Group on SDG issues to coordinate work on achieving the goals. For now, the responsibility of the ministries for SDG tasks has been established, the President of Ukraine has adopted a Decree that attaches the Goals as a reference point for the development of program and forecast documents, and an SDG monitoring system has been developed. In 2019, an analysis of the degree of SDG incorporation (at the level of SDG tasks) was carried out. In total, 17 goals and 86 national tasks of the SDG are incorporated into 162 regulatory and legal acts of the Government, 1,394 goals, and 4,296 measures established in these acts are aimed at the implementation of goals and tasks. But, despite a significant number of state strategic documents and a large volume of tasks and measures, not all tasks of the 17 goals are taken into account [3–5].

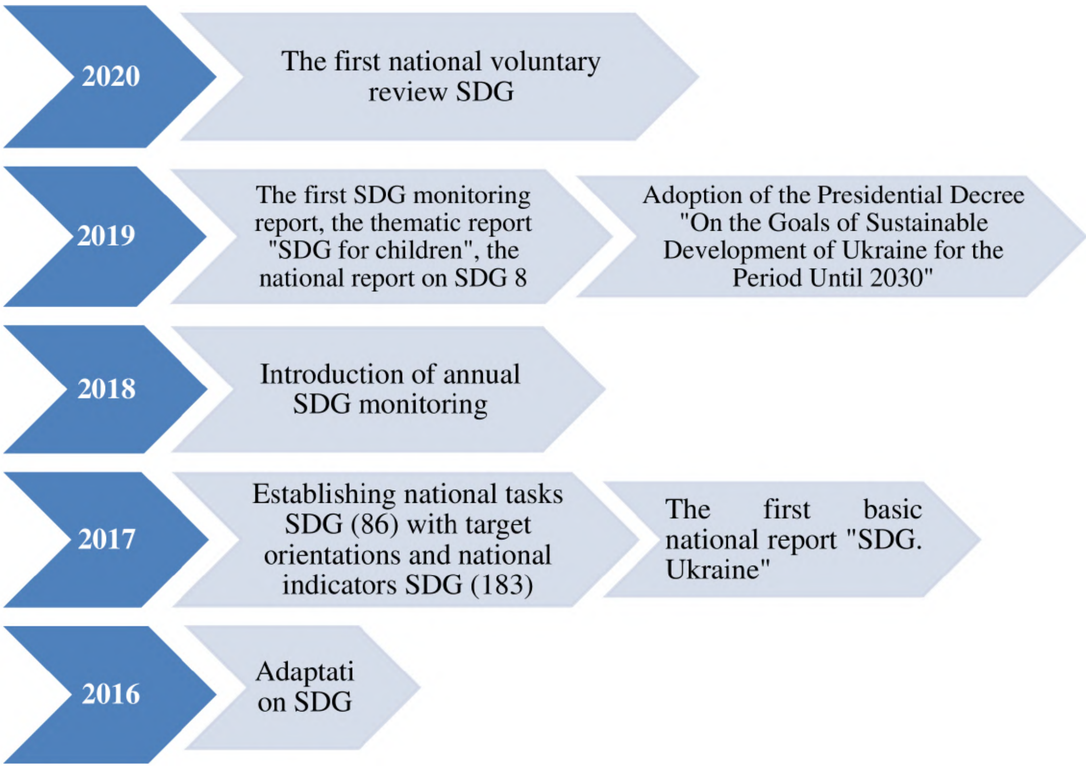

Figure 1. Statistics of actions related to the adaptation of sustainable development goals in Ukraine (based on [3–5]).

In 2021, according to the Sustainable Development Goals Index (SDG 2022) (figure 2), Ukraine took 37th place out of 163 countries, ahead of Australia (38th place), Lithuania (39th) and the USA (41st). Finland, Denmark and Sweden occupy the first places in the ranking of the SDG 2022 index, and the Central African Republic and South Sudan are the last [6].

Studies show that in 2021, progress is being made in Ukraine in achieving twelve of the 17 goals that determine the sustainable development of the country in the economic, social, and environmental spheres, including SDG 11 “Sustainable cities and communities” (figure 3). Ukraine has made the most progress in achieving the goal of “universal elimination of poverty in all its forms”. At the same time, Ukraine did not deteriorate its position in any of the basic objectives. However, the analysis of state strategic documents points to the disadvantages of the Ukrainian system of state strategic planning and budgeting. Thus, a large number of strategic and programmatic documents for 17 targeted areas of development leads to unclear coordination of efforts to achieve goals and perform tasks, forms a discrete rather than a systematic approach to policy formation, scatters financial, material, and human resources prevent the ability to concentrate on the efficient use of resources to achieve a certain result. The consequence of the lack of systematic work is, among other things, underfunding of important tasks and measures, low degree of their implementation, duplication of functions, tasks, and measures between executive authorities, and low responsibility for failure in the achievement of results.

In general, in the world ranking of indicators of sustainable development, Ukraine occupies not the worst, but also not the best positions. Thus, in 2020, according to the international analytical organization Legatum Institute, Ukraine took 92nd place in the ranking of the well-being of countries, which is 4 positions higher than in 2019 (figure 4). At the same time, among all the countries of Eastern Europe, Ukraine ranks last in the rating. The reason for this is

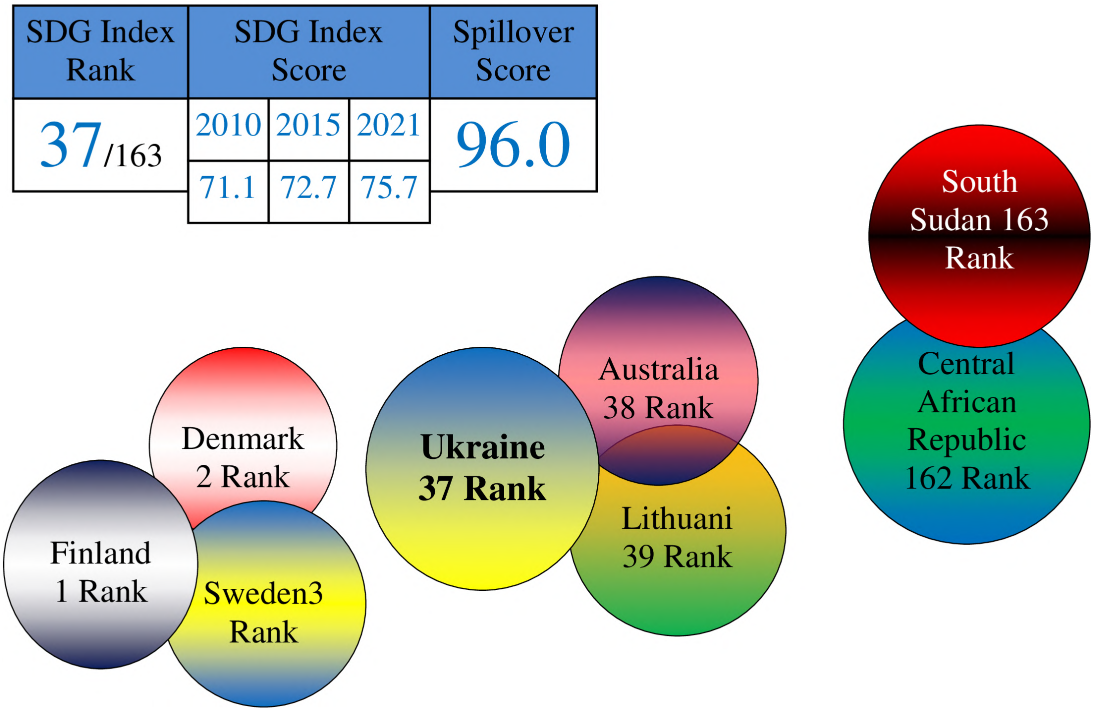

Figure 2. Ranking and score of Ukraine according to the SDG 2022 index (based on [6, 7]),

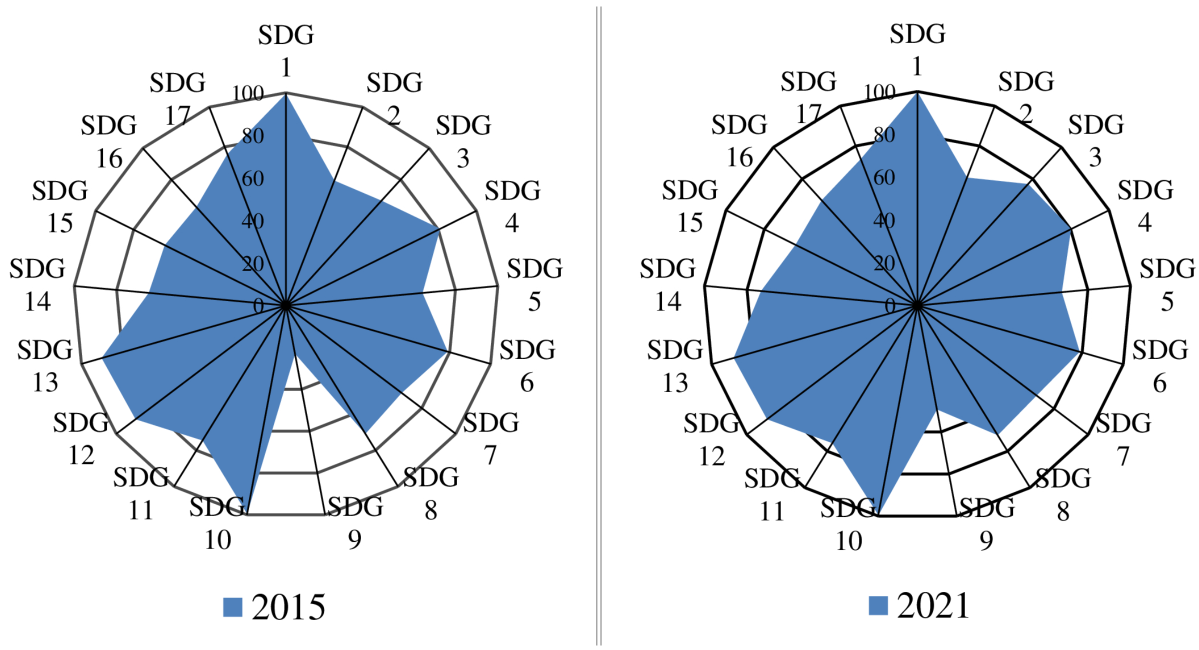

Figure 3. The average value of achieving the goals of sustainable development in Ukraine (based on [7]).

the war in the East of Ukraine, which has been going on since 2014, which significantly lowers Ukraine's security rating (to 144th place out of 167). In addition, there are problems in the sphere of freedom of assembly and association in Ukraine, and indicators of religious tolerance in Ukraine have increased in recent years. The first places in the Legatum Institute rating are occupied by Denmark, Norway, and Switzerland. The last two are the Central African Republic and South Sudan [8].

Ukraine belongs to the developing countries, and according to the results highlighted in the latest report on the Inclusive Development Index in 2018, it ranked 49th among 74 developing countries. Lithuania, Hungary, Azerbaijan, Latvia, and Poland are 5 developing countries that are leading in terms of inclusiveness of economic growth. Norway, Iceland, Luxembourg, Switzerland, and Denmark are among the top five countries developed by the level of inclusiveness of economic growth. Ukraine's development trends indicate that the inclusiveness of its economic development decreased by 6,8 percent from 2014-2018. In particular, the distribution of wealth in Ukraine is one of the most uneven among all developing countries. At the same time, the level of income inequality and the level of poverty in Ukraine is low: the middle class, in the opinion of WEF experts, remains numerous, health care and support for the unemployed are at a sufficient level, and the education system contributes well to inclusive growth. However, constant wars in the east of the country contribute to regression, as they disproportionately affect the poorest strata of the population, prompting talented people to leave the country in search of opportunities for self-realization. The priorities are to increase the level of professional education, reduce the administrative burden on the creation of new enterprises, expand the financing of entrepreneurs and increase attention to the fight against corruption [9–11].

According to the current Environmental Performance Index (EPI), in 2022 Ukraine ranked 52nd among 180 countries in the world, and Ukraine has advantages in rational nitrogen management [12]. For reference, in 2020 and 2018, Ukraine ranked 60th and 109th, accordingly [10], and in 2016, it ranked 44th in almost all indicators, including water quality and air cleanliness.

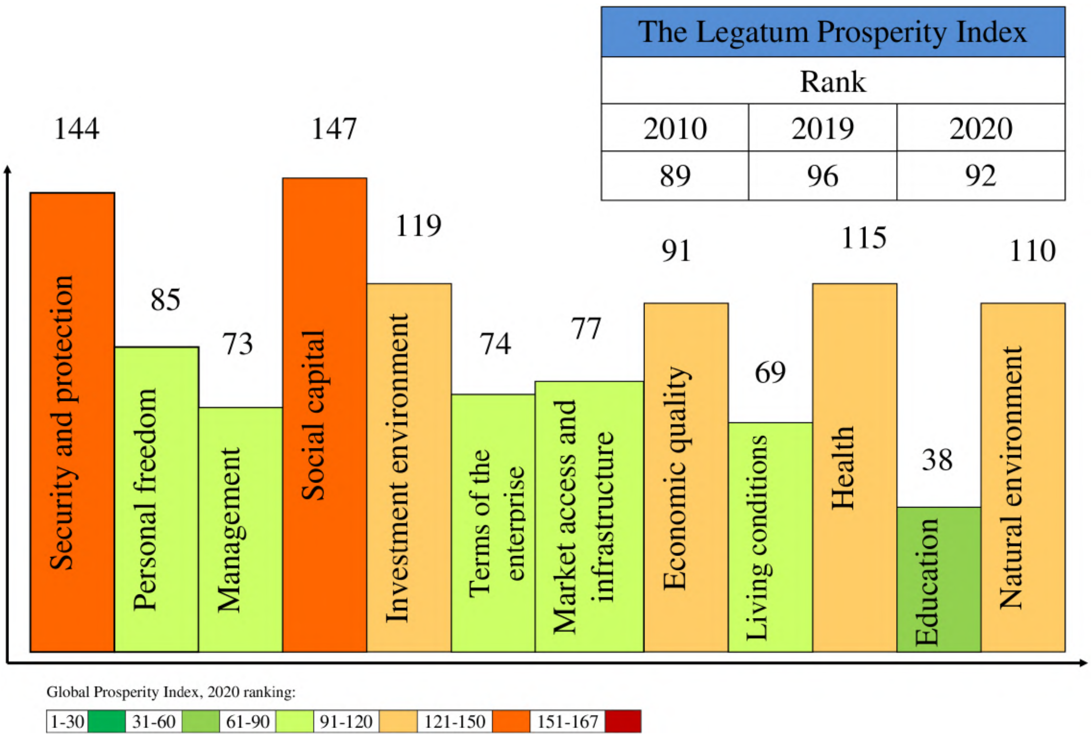

Figure 4. Ranking of Ukraine according to the Legatum Prosperity Index (based on [8]).

The current situation in the economy of Ukraine is characterized by not very high innovation activity, which is primarily related to the lack of own funds for enterprises and limited budget funding. Thus, according to the Global Innovation Index 2022 global innovation rating, Ukraine took 57th place out of 132 economies, holding the 4th position among 36 countries of the lower-middle income economic group, and is 34th among 39 European economies. Compared to previous years, Ukraine slightly worsened its results (for comparison, in 2021 – 49th, in 2020 – 45th, in 2019 – 47th, and 2018 – 43rd place, accordingly). Switzerland is recognized as the most innovative country, immediately after is USA, Sweden, Great Britain, and the Netherlands. It is also noted that China approached the TOP-10 innovative economies of the world (11th place), while Turkey and India entered the TOP-40 for the first time [13, 14].

As already mentioned above, of the seventeen sustainable development goals approved by the UN General Assembly in 2015 within the framework of the agenda of the summit "Transforming our world: agenda in the sphere of sustainable development until 2030", goal number 11 is the sustainable development of cities and communities.

The tasks of sustainable development of cities and communities include ensuring by 2030: access to sufficiently safe and inexpensive housing, safe, inexpensive, and environmentally sustainable transport systems, open for all and ecologically sustainable urbanization, preservation of world cultural and natural heritage, reduction of damage from natural disasters, reducing the negative environmental impact of cities, ensuring access to safe and open to all green zones and public places, improving the quality of national and regional development planning, implementing a comprehensive management approach in cities and settlements, assisting the least developed countries in the construction of sustainable and durable buildings.

Cities are the dominant form of socioeconomic organization and engines of the economic growth of any country. Among the variety of modern urban concepts, sustainable development has the longest history and the widest recognition in the world, but recently the Smart City concept has become increasingly popular. Smart sustainable cities become "innovative cities that use informational and communication technologies and other means to improve the quality of life, the efficiency of cities work and services, and competitiveness, while ensuring accordance of the needs of current and future generations in terms of economic, social, environmental, and also cultural aspects [15].

Rapid urbanization leads to ineffective allocation and application of resources, overtime increasing the burden on the environment. Enterprises that work in cities and contribute to overall economic prosperity have the opportunity to support infrastructure development by participating in the elaborateness of strategies for the development of cities and communities, using their capabilities and knowledge to identify innovative and economically effective solutions to complex, interdisciplinary issues of urban sustainability.

Realizing their responsibility, communities, and cities all over the world are increasingly paying attention to issues of sustainable development, and Ukraine is also trying to keep pace with global trends. As of January 1, 2022, Ukraine has accrued 461 cities (including 2 cities with special status). The urban population in Ukraine, as of January 1, 2022, is 28 million and 693 thousand people, which is 69.7 percent [16].

Studies show that, despite Ukraine's clear movement towards achieving the goals of sustainable development, funding for SDG 11, although high at the current stage, but still not sufficient from the side of Ukraine, as well as international institutions. The main source of funding for regional development is several subventions from the state and local budgets. One of the tasks of Goal 11 is to increase housing affordability: this goal is financed from local and state budgets. To the objectives of SDG 11, local authorities are developing regional development strategies, although some communities have not yet completed this task. Such programs are developed by the communities themselves and at the expense of international technical assistance (ITA) projects. The level of housing and communal services financing remains low. In addition, neither state nor local budgets allocate appropriate funds for financing ecologically sustainable development. Also, it can be noted that most of the projects implemented in the public sector aimed at the realization of SDG 11 do not find support from international financial institutions (IFI). In the structure of bank loans granted in 2021, which can be conditionally divided into sustainable development goals, only 8 percent was issued for the development of SDG 11.

The assessment of the financing of sustainable development goal 11 "Sustainable cities and communities" for the period 2017-2020 shows that these are investments by state-owned enterprises in construction, restaurants, and hotels. In particular, these are investments in state project institutions, housing and communal enterprises of central state authorities, etc. Private investment financing of SDG 11, which includes investment in urban development (primarily investment in operations with real estate, hotels, and restaurants and 50 percent of investment in construction), can be assessed as high, (figure 5).

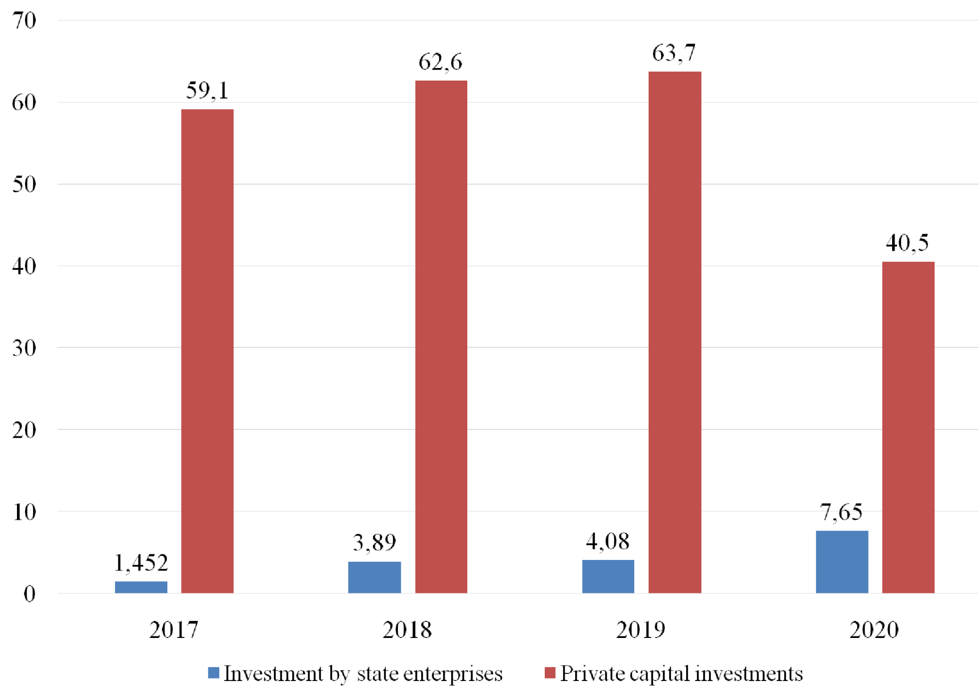

Figure 5. Financial investments in SDG 11 in Ukraine within the framework of the state and private sector, million UAH (based on [17]).

International technical assistance (ITA) is one of the important mechanisms for financing sustainable development in Ukraine. Ukraine, as a developing country, has been receiving ITA since 1992 and quite actively uses this financial instrument in almost all sectors of the economy. ITA projects also paid significant attention to SDG 11 "Sustainable Cities and Communities". 326 million dollars were allocated for SDG 11 to implement 119 projects in such sectors as "Regional development", "Culture and historical heritage", "Development of youth and sports", "Decentralization and promotion of regional development" and partially in the sector "Development of social infrastructure and services". In particular, these projects are aimed at supporting the natural reserve fund of Ukraine, helping local self-government bodies improve the management of resources and services by community priorities, increasing the role of cultural heritage sites as tourist destinations, improving the effectiveness of work with youth and the quality of youth policy at the local and national levels. The main projects in 2016-2020 within the framework of SDG 11 were the US projects "Decentralization that ensures better results and efficiency" (DOBRE), "Ukrainian national identity through youth" and the EU project "U-LEAD with Europe: Ukraine – expanding opportunities on places, accountability, and the Development Program".

The sustainable development of cities and communities in Ukraine is also ensured by special programs of the Ministry of Development of Communities and Territories, including SFRD. Community development budgets are also important. Priorities of regional development and tasks related to their implementation are determined by the State Strategy of Regional Development for the period until 2027. To fulfill this, appropriate regional strategies have been accepted. At the same time, some communities in Ukraine still have not developed and approved development strategies. The importance of the strategies lies in the fact that they allow enterprises to understand the local government's policy regarding the development of the relevant community and to estimate the amount of funding for the implementation of the planned changes.

Different proposals and approaches to local development strategies suggested by different projects complicate the implementation of strategic planning at the community level. One of the tasks of this goal is to ensure housing affordability. Several state programs are aimed at this. These programs are implemented by state institutions, whose source of statutory and operating capital formation is the state budget. Among them are programmed to reduce the cost of mortgages and housing rent for representatives of certain professions, which are implemented by the State Fund for the Assistance of Youth Housing Construction and the Entrepreneurship Development Fund (7 percent affordable mortgage).

However, today in Ukraine, as a result of the full-scale war, the situation in the direction of achieving the goals of sustainable development, in particular sustainability and cities, has significantly worsened, Mariupol, Volnovakha, Rubizhne, Popasna, Liman, and Severodonetsk were completely destroyed. The situation in the occupied communities of the Kherson region is very difficult. Some communities of the Mykolaiv region and Zaporizhzhia suffered significant destruction. In Kharkiv, part of the Northern Saltivka micro-district was also destroyed. Due to Russia's war against Ukraine, millions of citizens lost their homes. According to preliminary calculations by the Ministry of Community and Territorial Development, more than 2.4 million Ukrainians live in destroyed or significantly damaged dwellings. This is a preliminary figure because, in the conditions of martial law and temporary occupation of some regions, it is impossible to accurately calculate the number of uninhabitable housing. According to the data given by the regional military administrations, from February 24 to October 18, 2022, almost 160,000 damaged or destroyed objects were recorded in the territories available for counting. 60 percent of them have a degree of destruction of more than 50 percent. Among the damaged real estate objects, residential premises predominate – more than 142,000. Of them, more than 54,000 are with a degree of destruction up to 50 percent, and 88,000 are 50-100 percent [18].

As of June 2022, the cost of direct damage has reached more than 97 billion US dollars, and as of February 2023, losses are estimated at 135 billion US dollars. Most affected were residential buildings (40 percent of total damage in 2022 and 38 percent in 2023), transportation (31 and 26 percent, respectively), energy (3 and 8 percent, respectively), and trade and industry (10 and 8 percent, respectively). Donetsk, Kharkiv, Luhansk, Zaporizhzhya, Kyiv, and Kherson regions are the most affected (figure 6). Disruptions to economic flows and production, as well as additional war-related costs, are collectively estimated as losses of US dollars 252 billion as of June 2022 and US dollars 290 billion as of February 2023 [19, 20].

In the first quarter of 2022, Ukraine's gross domestic product (GDP) contracted by 15.1 percent year-on-year, and the poverty rate is expected to increase from 2 percent to 21 percent (based on a poverty line of US dollars 5.5 per person per day). The cost of the need for reconstruction and restoration, as of June 1, 2022, is estimated at more than 349 billion US dollars, which exceeds the GDP of Ukraine in 2021 by more than 1.6 times [19]. As of April 2023, according to the updated data of the damage assessment and recovery needs (RDNA2),

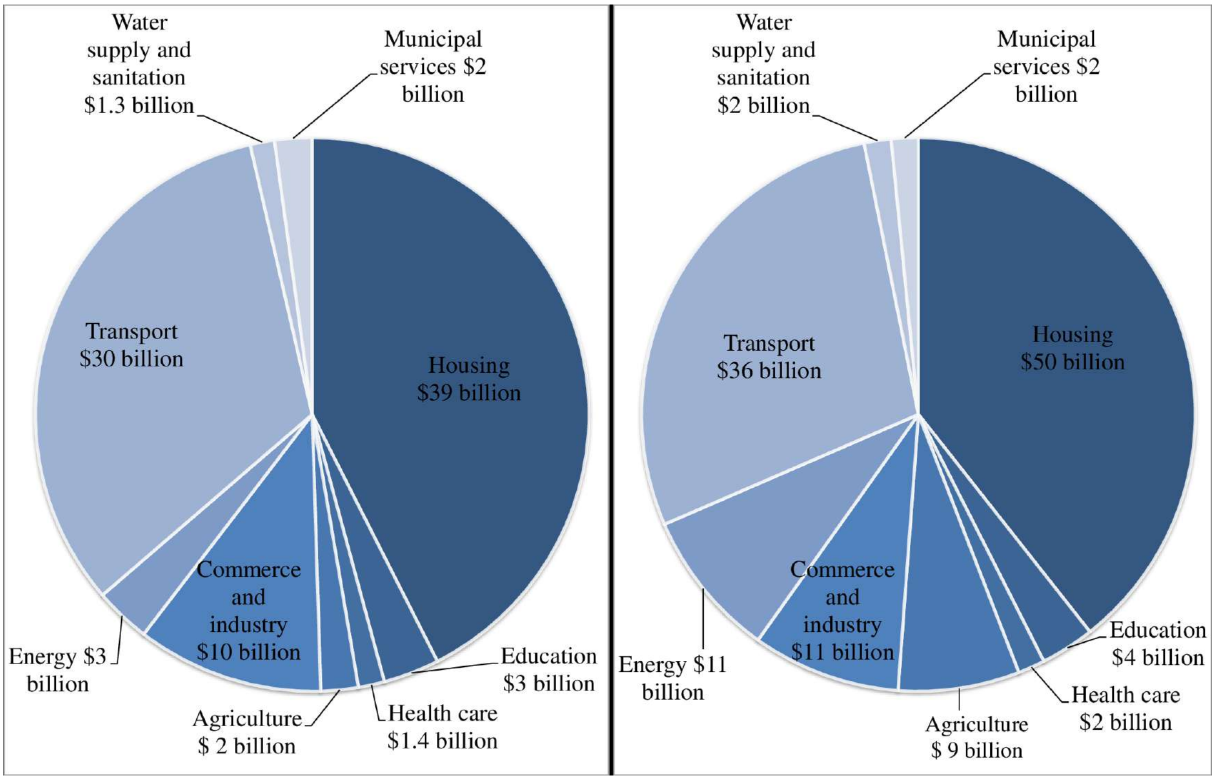

Figure 6. The total amount of damage caused to the cities and territories of Ukraine as a result of the full-scale war (based on [19, 20]).

the needs of our state for reconstruction have increased to 411 billion dollars (this is 2.6 times more than the projected GDP of the country in 2022) [21].

As shown in figure 7 according to the calculations made in 2022, extremely large losses and needs of financial resources are needed to restore the infrastructure of cities, in particular, the transport sector (21 percent), housing (20 percent), energy (3 percent), the sector of social protection and means of livelihood (6 percent), liquidation of explosive objects (9 percent), etc. [19]. However, the 2023 figures indicate that the level of destruction is steadily increasing and, according to the assessment, the greatest recovery needs are in the transport sector (22 percent), housing (17 percent), energy (11 percent), social protection, and livelihoods (10 percent). The greatest increase in the level of destruction is noted in the energy sector (increased more than fivefold compared to June 2022) [20, 21].

In 2022, Ukraine's GDP fell by 29.2 percent, 13.5 million people were displaced in Ukraine and Europe, millions lost their homes, and 7.1 million people were below the poverty line as poverty rose from 5.5 to 24.1 percent, setting the country back 15 years. In general, the achievement of many Sustainable Development Goals (SDGs) as a result of military actions is extremely difficult to sustain and achieve shortly, especially those related to poverty, health, education, energy, industry, peace, and justice, sustainable development of cities and communities. After the end of the war, all cities, including the infrastructure, will need to be rebuilt, but it must be rebuilt based on the principles of sustainable development. That is, it will be necessary to make important decisions and take important steps so that cities in the future become modern, innovative, inclusive, low-carbon, resistant to disasters and climate change, and meet the standards of the European Union. Despite the huge total amount of funding, the experience of other countries shows that reconstruction takes many years and a phased approach is critical.

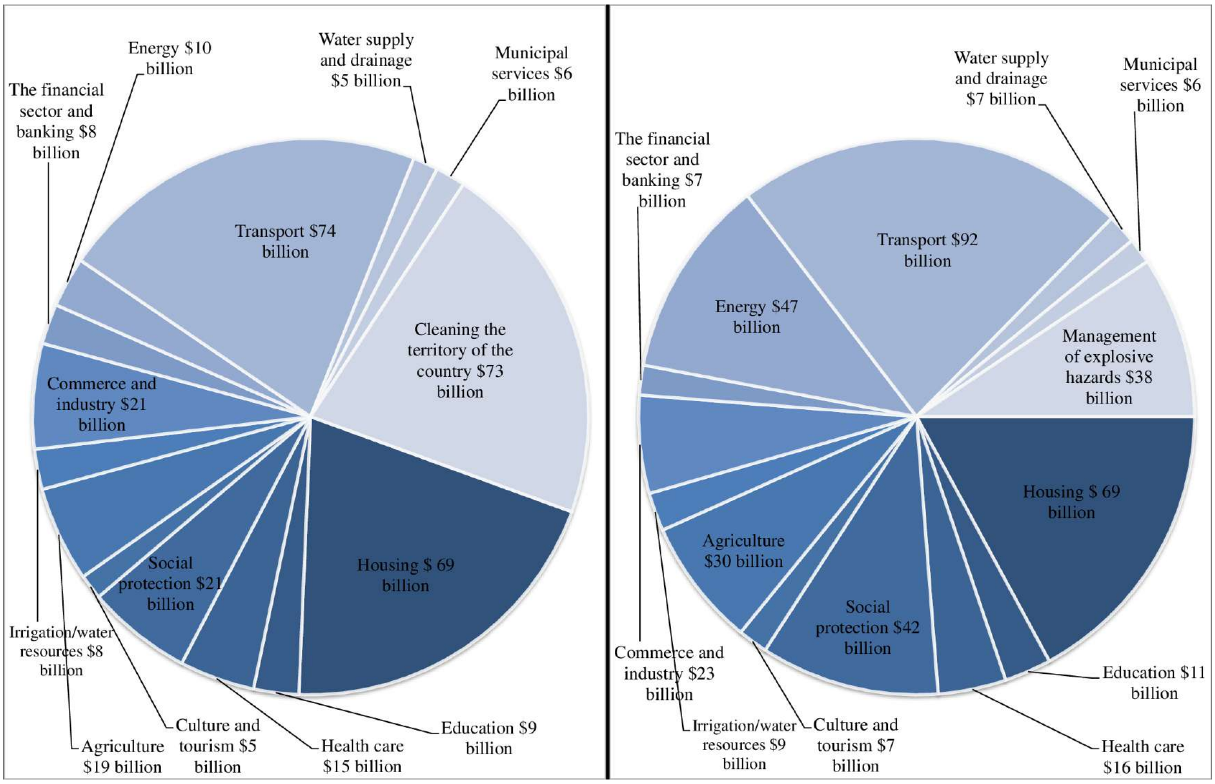

Figure 7. The total volume of needs for the reconstruction and restoration of cities and territories of Ukraine as a result of a full-scale war (based on [19–21]).

At the same time, it should be understood that the implementation of sustainable practices in cities and communities is not just a process that can be implemented in a month or a year. This requires additional investments, also the approval and realization of the State Regional Development Strategy, ensuring appropriate coordination of the process of implementation of regional development strategies in all regions based on smart specialization, strengthening the connection between strategic, spatial, and budget planning, reducing the negative impact of polluting substances on the environment, including the environment of cities, through the use of innovative technologies, etc., which will contribute to the transformation of large cities into rational and sustainable communities, the residents of which will be able to enjoy such advantages as reducing energy costs, improving the quality of services, reducing the amount of waste, creating a more favorable urban environment, creating opportunities for economic activity and development.

The recovery and reconstruction plan after hostilities in Ukraine should also be based on the following principles.

- *Inclusivity and equality.* Recovery and reconstruction must be closely linked to efforts to strengthen social inclusion and gender equality. That is, it is necessary to act according to the principle of "sustainable cities for people and created by people". Inclusivity starts with transparency and public participation. People must understand the consequences of local government decisions on community development and participate in their development.
- *Sustainability and reconstruction are based on the "build back better" principle.* The main part of Ukraine's infrastructure was built during the Soviet era and, at the same time, was constantly worn out due to insufficient funding. Today, the country's infrastructure

needs restoration in war-affected territories and radical modernization in territories where military operations did not take place. Rehabilitation and modernization must be carried out by climate change and sustainable development goals. For example, the road network suffers from a chronic lack of maintenance and repair, as well as needs major repairs, and more than half of the water supply networks are in critical condition. Social infrastructure is also not in the best condition, in particular schools, kindergartens and basic healthcare facilities are outdated and in need of reconstruction and modernization, as well as increased energy efficiency and increased resilience to climate change. Ukrainian industry and the energy sector will also need to adapt to best practices and standards that provide for higher efficiency and greater sustainability. For cities to be sustainable, urban infrastructure must be sustainable. According to the United Nations Environment Program (UNEP), sustainable infrastructure systems are "planned, designed, constructed, operated and decommissioned in such a way as to ensure the economic, financial, social, environmental (including resilience to climate change) and institutional sustainability of the entire infrastructure life cycle". This infrastructure can be nature-based, conventionally built, or combine elements of both to form a hybrid infrastructure. Building with nature, not against it, has direct benefits for cities. The term natural infrastructure (NBI) includes areas or systems that use nature to provide infrastructure services to people, the economy, and the environment. Examples of NBI include natural ecosystems such as forests, mangroves, wetlands, and grasslands. But NBI can also include engineered or "grey" structures that include natural solutions such as rain gardens and green roofs [22].

- *Local solutions and local development.* Restoration, revitalization, and modernization must be designed and implemented in such a way as to support the local economy. Any structure or process related to recovery and revitalization must utilize the economic and human capital of the country. Modernization of social infrastructure, housing stock, and transport infrastructure must be carried out based on the development and needs of the local community, business, and industry.
- *Focusing on community needs.* Community-based development, with the active involvement of citizens, is a key component in building a sense of ownership and ensuring the sustainability of recovery and revitalization. Innovative approaches are essential to ensure the participation of the entire local community in restoration and revitalization. Community needs cannot be identified through a top-down approach, and any such attempt can only lead to investments that are not linked to real needs on the ground and are unlikely to deliver sustainable results.

4. Conclusions

Based on the conducted research, it was established that since 2015, several reforms aimed at achieving the goals of sustainable development have been introduced and started in Ukraine, which is integrated into the state policy based on "leaving no one behind". However, despite the great number of efforts and the development of normative documents, not all tasks of the sustainable development goals are taken into account and fulfilled.

From year to year, progress is constantly observed in Ukraine in achieving the goals of sustainable development, including SDG 11 "Sustainable cities and communities". In the world ranking of indicators of sustainable development, Ukraine is not a leader, but it is not lagging either. Despite the efforts and significant work carried out by Ukraine in the direction of achieving the goals of sustainable development, the financing of SDG 11, although it is observed, and it can be said that its level is high, however, it is not sufficient from the side of Ukraine, as well as international institutions. Today and in the future, the model of inclusive growth in Ukraine should be based on the European experience and guided by the principles of intellectual, sustainable, and comprehensive development. If we turn to history, then Stefan Füle's remark at the meeting of the Ukraine-EU Parliamentary Cooperation Committee in Brussels on March 22-23, 2010, that Ukraine now needs "concrete reforms, not just encouraging words", is still relevant today.

What is necessary today is a better understanding of the importance of achieving the SDG both at the central and local levels, as well as improving the skills of civil servants and deputies at all levels, which requires the development and conduction of training on relevant topics, including the methodology of financial development assessment and operational comprehensive assessment, to the program of advanced training courses for civil servants. In particular, special programs on issues of sustainable development and achieving the SDG, analysis of poverty and social impact should be introduced. The SDG cannot be achieved without the active role of national business. The development of corporate social responsibility of business in such conditions is extremely important.

The post-war reconstruction of Ukraine and its further development should cover as much as possible the management organization of sustainable territorial development for the short, medium, and long-term perspective at the state, regional, and local levels. In the process of defining the SDG, relevant tasks, and indicators for a long-term perspective, it is necessary to take into account global development guidelines, principles of sustainable development, and public opinion regarding the vision of future development. World experience shows that social progress largely depends on maintaining a balance between the goals of supporting the economic growth of territories, business competitiveness, ensuring environmental safety, and reducing social inequality. Organizations, without exception, in their daily work have to take into account the goals and principles of the SDG, as external general settings, landmarks, and beacons that determine only the direction, what to strive for, and what to be for this.

Ensuring a sustainable future for Ukraine is possible through the development and implementation at the national level of the strategic and target foundations of state regulation of the country's sustainable development. Accordingly, the research on conceptual approaches to ensuring sustainable development in Ukraine, the definition of modern vectors of sustainable development of territorial communities in the conditions of post-war reconstruction acquires particular relevance.

Restoration of critical infrastructure, ensuring the energy security of the country (SDG 7, 9, 11). The planning of the restoration of the territories of Ukraine must be effective, in terms of the restoration of the life activities of cities, rural territories, and their communities, the authorities are endowed with the appropriate powers. Government representatives must make high-quality, effective, long-term systemic decisions. The best international experience of rebuilding cities after large-scale destruction shows that only an integrated approach based on the principles of sustainable development can restore the well-being of the population and social and cultural life. Stable and sustainable development of cities and regions is based on the principles of sustainable development: development of sustainable mobility, and ensuring the inclusiveness of public spaces.

Abstract. Tourism development in Ukraine has improved in terms of tourist flows, both as a diversification of tourism demand and tourism products in the last decades. Cultural tourism is a promising direction of tourist activity and occupies a leading position in the modern global tourist management system. The object of research is cultural tourism within the tourist destination of the Ivano-Frankivsk region. Regarding this, the authors revisit the phenomenon of cultural tourism in the country, in order to identify cultural tourism potential through cultural consumption among tourists, applying a special tourism survey. The purpose of this research is to identify the main problems of the development of cultural tourism in the Carpathian region from the point of view of demand and supply of cultural tourism programs based on the results of a comprehensive sociological study on the evaluation of tourist objects and the possibility of their inclusion in the cross-border tourist product “Carpathian Cultural Route”. The results of the survey demonstrated responses from 264 consumers of cultural tourism, which is 2,5% of the number of tourists (general population), and 140 respondents – employees of cultural institutions (objects of cultural tourism), the calculated sample of which was 28% of providers of cultural tourism services. The estimated sample was 28% of cultural tourism service providers. Among the positive aspects of the visit, tourists noted the price policy of institutions acceptable to them, the high level of authenticity and historical and cultural value of objects, the appropriate quality of service, and emotional comfort when visiting cultural and historical objects. According to consumers, the main problems of the development of cultural tourism are the low level of infrastructure support of objects and tourist destinations in general, the limited range of additional services, and limited information about the object. The authors emphasize the importance of developing culturally coherent policies to increase the competitiveness of tourist destinations. The most significant problems of the development of cultural tourism from the point of view of employees of tourist objects of cultural tourism are low level of infrastructure development of cultural tourist objects and tourist destinations in general, insufficient financing of institutions, low level of monetization of objects, low level of tourist and cultural activities in a tourist destination, insufficient advertising of the tourist object, imperfection of state tools for regulating tourist activity within cultural objects, low qualification of employees. Scientific developments on this topic will foster the application of innovative approaches towards the differentiation of cultural tourism objects, which, as a consequence, will help to target potential consumers and improve cultural tourism programs.

1. Introduction

Experts of the World Tourism Organization have identified the five most promising types of tourism in the 21st century, among which cultural tourism occupies an important place. Recently, the UNWTO confirmed [1] that cultural tourism is the main element of international tourism consumption, accounting for more than 39% of tourism incomes.

Cultural tourism research is developing rapidly, particularly in areas such as cultural consumption, cultural motives, heritage conservation, the economics of cultural tourism, anthropology, and relations with the creative economy. Major research trends include a shift from tangible to intangible heritage as a tourism resource, greater attention to indigenous and other minority groups, and a geographic expansion of cultural tourism research [2]. In the allocation of cultural tourism as a specific sector in the tourism system, a combination of the characteristics of tourist demand in cultural tourism is considered, which consists in acquiring new experiences and impressions to ensure cultural needs and the characteristics of offers – special tourist resources that are involved in the process of satisfying demand in the field of cultural tourism [3].

Cultural is recognized as one of the main resources used to counteract seasonality in tourist destinations, being by its very nature non-seasonal. Promoting cultural tourism is just one component for effectively counteracting seasonality [4]. Research on the demand for cultural tourism, as a rule, shows the differentiation of the market. The study of the demand for cultural tourism, as a rule, indicates the differentiation of the market. Thus, the authors substantiate the importance of studying the demand for cultural tourism on the example of a number of Asian countries. Location-based social media data provides information on the observed behavior of tourists, which is considered more progressive than traditional surveys that collect spoken responses from tourists. Scientists also classify cultural tourism attractions on the basis of tourists' preferences revealed by their travel trajectories [5].

The theoretical and methodological aspects of the development of tourism are highlighted [6], the thesis that cultural tourism is a means of forming national identity, that is, it fulfills an important humanitarian and state-building mission, is a means of education and enlightenment, is substantiated. Community Cultural Development methods can enhance community capacity and the sustainability of tourism by increasing residents' effective participation in decision-making, encouraging locals' partnership in, and ownership of, tourism projects, and providing space for negotiating the tourist gaze in guest-host relationships [7]. Also, World cultural heritage is of great significance in promoting the sustainable development of cities, and history culture is very important to achieve the goal of sustainable development [8]. Regional studies of cultural tourism relate to the resource base, the search for potentially attractive tourist locations that have cultural value and will contribute to the creation of a positive image of the tourist destination, directions for future actions, ideas, and projects that will help realize the strategic vision of the development of cultural tourism [9–12]. The scientific developments of Ukrainian scientists in the field of cultural tourism relate mainly to the methodologies of the organization of cultural tourism and the justification of the development of cultural tourism at the regional level. Modern trends in the development of cultural tourism in Ukraine were analyzed using the example of Lviv and Kamianets-Podilski as the most popular tourist destination in Ukraine [13]. However, the scientific publications do not cover issues related to the analysis of the problems of the development of cultural tourism in Ukraine through the prism of demand and supply in the market of tourist services.

The *purpose* of the research is to outline the main problems of the development of cultural tourism in the Carpathian region from the point of view of demand and supply of cultural tourism programs based on the results of comprehensive sociological research on the evaluation of tourist objects and the possibility of their inclusion in the cross-border tourist product "Carpathian Cultural Route".

The *task* of the research is to analyze the results of the research on the demand for cultural tourism through surveys of tourists who visit cultural tourism objects and tourist objects of cultural tourism (tourist offer of cultural tourism) by surveying the management staff of institutions regarding the problems of the development of tourist objects of cultural tourism.

The *subject* of research is the development of cultural tourism through the prism of the analysis of demand and supply in the market of cultural tourism in the Ivano-Frankivsk region.

The *object* of research is cultural tourism within the tourist destination of the Ivano-Frankivsk region. The scientific novelty of the research consists in substantiating the problems and prospects of the development of cultural tourism based on the analysis of the results of consumer research on cultural tourism service providers on the example of the development of cultural tourism in the Ivano-Frankivsk region.

2. Materials and methods

Cultural tourism deals with the main components of natural and cultural heritage. These are special cultural landscapes, and architectural monuments, and museums of various types, and historical cities and settlements, and archaeological excavations, and crafts, and holidays, and also national cuisine.

National cultures are a powerful motivator of tourism. The Ukrainian Cultural Foundation considers cultural tourism as a powerful tool not only for spreading information about the country's cultural heritage, preserving it to maintain a high level of attractiveness, but also as a good tool for its monetization and increasing its role in the socio-economic development of communities [14]. Scientists confirm that cultural tourism should be considered as a powerful factor in the development of countries and regions. For example, the cultural and tourism policies of 101 countries of the world were analyzed countries and found that countries that significantly support cultural heritage have more significant success in tourism, especially inbound tourism [15]. The interaction of tourism and cultural heritage can become a factor in increasing the competitiveness of countries in the tourism market. Scientists offer a cultural explanation of the competitiveness of travel and tourism of countries by studying the relationship between the competitiveness of tourist destinations and interest in the national culture of the countries of tourist arrivals [16]. Direct correlations were revealed by analyzing data from 73 countries. The authors emphasize the importance of developing culturally coherent policies to increase the competitiveness of tourist destinations [17]. The introduction of innovations in the field of cultural tourism is also an urgent scientific problem. Heritage tourism destinations are facing the challenge of realizing innovative development based on cultural inheritance conservation [18]. Specifically, the article analyzes the effect of two contingent environmental factors, namely competitive intensity and technological dynamism, on the relationship between innovation capability and pioneering orientation in hospitality and tourism firms. The results show that innovation capability is a key antecedent of pioneering orientation in hospitality and tourism firms [19]. Technologies that require visitors' active participation afford opportunities for verbal and physical interactions with other visitors. By contrast, passive technologies, providing recreational and artistic content to visitors without them having to interact with the technology, tend to preclude social interactions [20].

The original, preserved authentic material and immaterial culture of certain ethnographic regions, for example, Hutsulshchyna, Pokuttya, Boykivshchyna became a magnet for many visitors from Ukraine and foreign tourists. However, the number of tourist arrivals, in accordance with the available cultural tourism attractions, can be much higher, because cultural and educational is the main motivation for visits to the Ivano-Frankivsk region [21]. Different types of tourism are developing in the region, and accordingly, a network of enterprises serving the tourism sphere [22]. But it is necessary to take into account that the development of tourist activity should be regulated taking into account the prevention of overtourism and damage to the environment. The result of uncontrolled infrastructure development, the growth of mass unregulated visits to famous cultural and natural complexes can have a negative impact on destinations, as well as on the local socio-cultural environment [23–25]. To identify problems and ways to improve cultural tourism, the opinion of providers of cultural tourism services (cultural institutions) and consumers of these tourist services is important, which is the basis for developing development strategies and conducting an active promotional policy of cultural objects. For this purpose, a comprehensive study was conducted, part of which was a survey of tourism entities that provide cultural tourism services and visitors to cultural tourism objects.

Questionnaire survey (questionnaire) is the most popular method of quantitative sociological research. Questionnaire surveys for sociological marketing research are most in demand today. You can get information with the help of a survey, which is not always reflected in documentary sources or available for observation. Therefore, a field survey was chosen as the main research method. This approach refers to a methodological procedure that collects data from a selected group of respondents in the areas where the respondents are currently located, namely at the workplace and during customer visits to the objects. In this way, responses were received from consumers and providers of cultural tourism services. This method is effective in cases where the source of information is directly the participant-carrier of information (in our case, the management of institutions and visitors of objects). This method is still the only one available in this case due to the lack of other systematic statistical data of this kind, despite the criticism [26].

A sample of 2,5% of respondents from the general population is sufficient to obtain representative information. The volume of the general population is determined by the authors according to the number of cultural institutions in the research region and is about 500 institutions, which include, in addition to cultural and historical objects with protection status (including local ones) and other institutions, for example, private tourist attractions and museums, that is, institutions that actually provide cultural tourism services. From the compiled database of establishments, those that are most popular and those located along and near the cross-border highways Lviv-Rohatyn-Ivano-Frankivsk-Yaremche-Rakhiv-Solotvyno and Lviv-Halych-Ivano-Frankivsk-Kolomiya-Kosiv-Verkhovyna. Questionnaires were offered to 154 respondents-cultural institutions, information was received from 140 objects. The calculated sample was 28%, which allows us to assert the representativeness of the survey within the studied region.

Two hundred and sixty-four people took part in the questionnaire. The sample for which the study was conducted included persons representing the adult population (over 18 years old) by gender, age, and education.

This number of respondents was 2,5% of the number of tourists (general population) who were served by travel agents and tour operators in the Ivano-Frankivsk region in 2020 [27]. The respondents filled out the questionnaire immediately on the spot, which guaranteed their complete return and, in addition, the researcher was able to be present when filling out the questionnaires, helping the respondents by clarifying certain questions.

Questionnaires with a small number of questions to the respondents were formed in order to get answers more guaranteed. These are structured questions about the main characteristics of the institution, its activities, outlined problems and prospects for their development. Sample field surveys were conducted during the "low" tourist season – September – November – 2021 in the objects of visits – tourist objects of cultural tourism and visitors of these institutions.

3. Results

The survey of consumers of cultural tourism services showed a number of positive and negative impressions made on them by tourist objects of cultural tourism, features of tourist services in them and within tourist destinations. Tourists noted the acceptable for them price policy of institutions among the positive aspects of the visit. 53,8% of tourists indicated a high rating of "excellent", 31,8% – "good", 8% – "satisfactorily", and 5,3% of respondents didn't answer the question (figure 1).

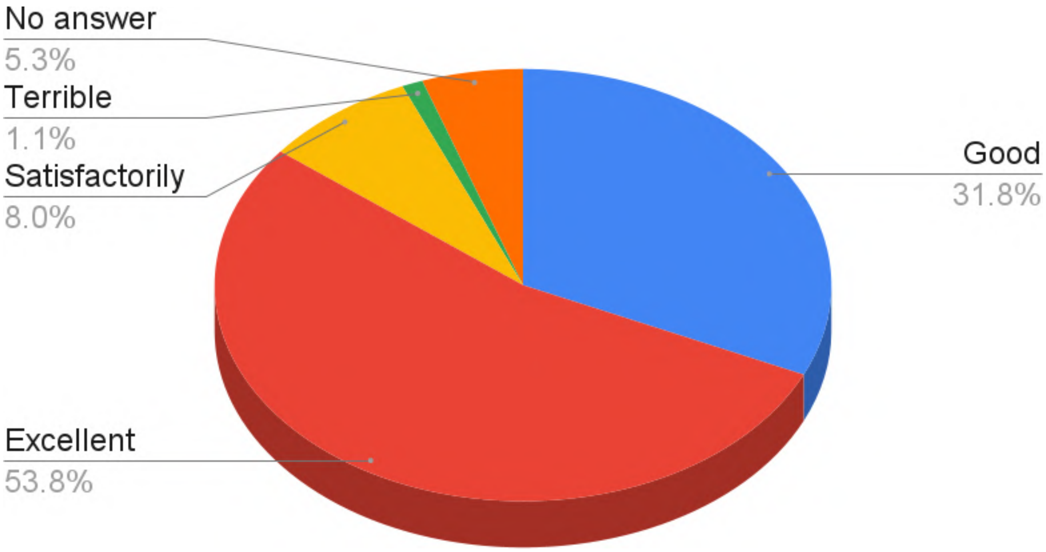

Figure 1. Distribution of respondents' answers regarding price policy when visiting cultural and historical objects.

62,9% of respondents gave the answer "excellent" regarding the assessment of the authenticity (uniqueness) of cultural and historical objects, 25,8% – "good", 7,6% – "satisfactorily", 1,1% – "badly", 2,6% – no answer (figure 2).

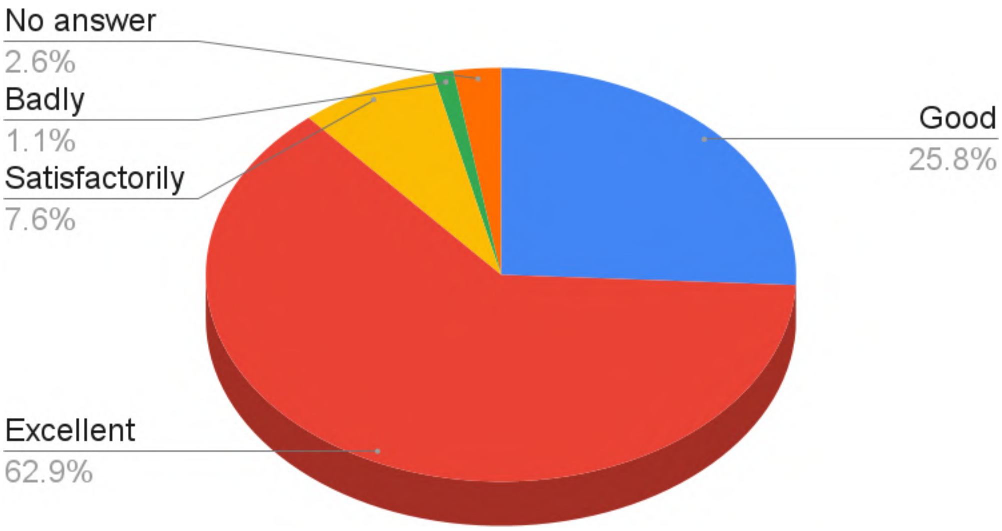

Figure 2. Assessment of the authenticity of cultural and historical objects.

According to the state of preservation of tourist objects as a cultural and historical value, 65,2% of surveyed tourists rated it as "excellent", 23,5% – "good", 8,3% – "satisfactorily", 2,2% – didn't indicate the answer to the question and less than 1% – "badly" (figure 3).

The quality of service when visiting cultural and historical sites in Ivano-Frankivsk and Transcarpathian regions was assessed as "excellent" by 59,8% of respondents, "good" by 25,8%

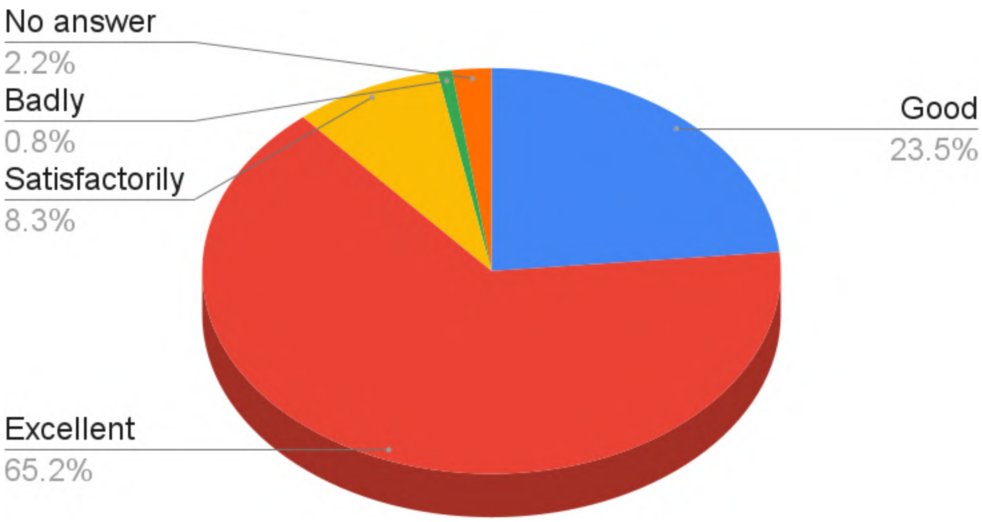

Figure 3. Assessment of the cultural and historical value of tourist objects.

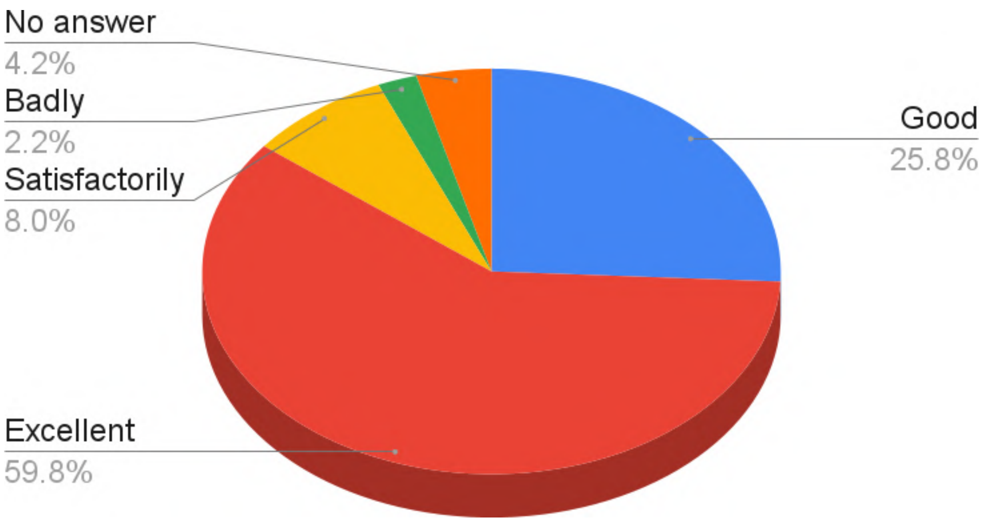

Figure 4. Assessment of the quality of service when visiting cultural and historical objects.

of tourists, 8% – "satisfactorily", 2.2% – "badly", 4,2% of visitors did not indicate the answer to the question (figure 4).

The largest number of tourists (70,1%) scored "excellent", 18,6% – "good", and 7,6% – "satisfactorily" according to the parameter "Emotional comfort". This indicates a positive general impression when visiting tourist locations in the Carpathian region (figure 5).

Most of the tourists (37,9%) rated the recreation infrastructure of the territory, where cultural and historical objects are located, as excellent, 34,1% – "good", 18,9% – "satisfactorily", 4,2% – no answer, the remaining 4,9% of visitors were dissatisfied with the arrangement of the rest area near tourist locations (figure 6).

Respondents quite positively assessed the availability of information when visiting cultural and historical objects: 35.2% of respondents rated it as "excellent", 29.2% – "good", 24.2% – "satisfactorily", 5.7% – provided no answers, 5.7% – of surveyed tourists were dissatisfied with information accessibility to tourist facilities (figure 7).

Territorial accessibility when visiting cultural and historical objects was rated as "excellent"

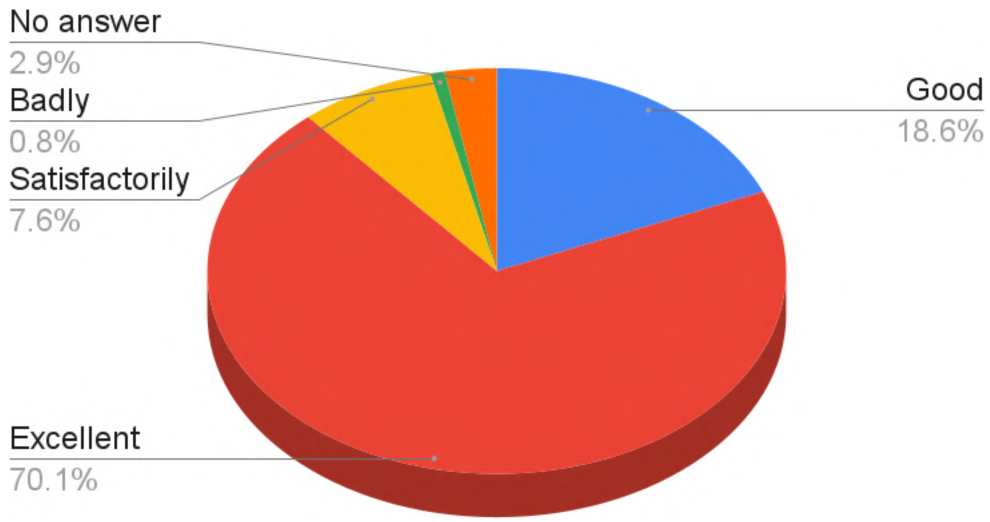

Figure 5. Assessment of emotional comfort when visiting cultural and historical objects.

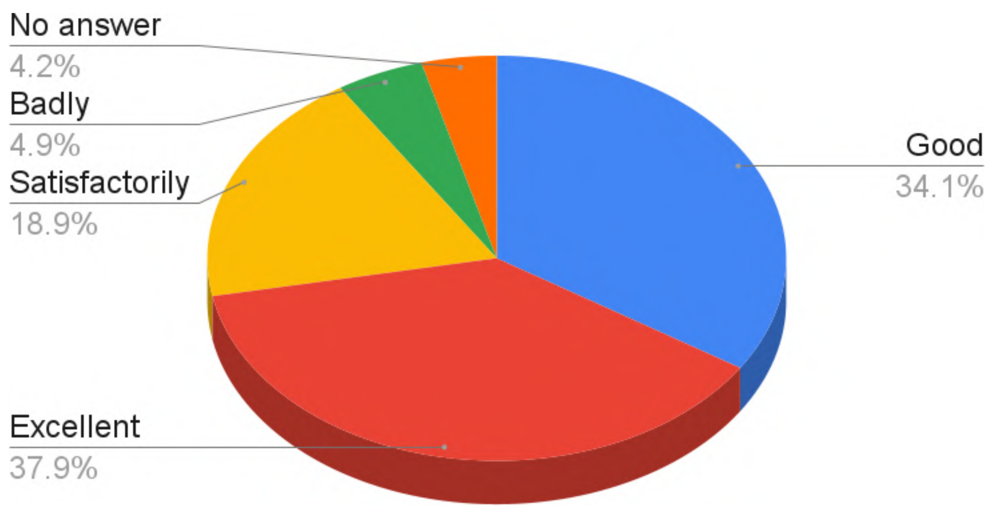

Figure 6. Assessment of the recreational infrastructure of the territory where cultural and historical objects are located.

by 50,8% of tourists from the total sample of all respondents, "good" – 30,7%, "satisfactory" – 14%, "badly" – 1,1%, 3,4% of respondents did not indicate the answer to the question (figure 8).

47,3% of respondents rated the attractiveness of cultural and historical objects of Ivano-Frankivsk and Transcarpathian regions as "excellent", 37,9% – "good", 9,5% – "satisfactorily", 0,8% – "badly" and 4,5% of tourists did not answer the question (figure 9).

Natural objects (mountains, waterfalls), the historical value of cultural heritage objects, and architectural monuments of the research area made the most positive impression on visitors (figure 10).

Tourists faced a number of problems when visiting cultural and historical objects of the Carpathian region, among which the most significant are:

1. **Low level of infrastructural support of objects and tourist destinations in general.** The majority of respondents (15%) indicated that a significant drawback is the poor condition of the roads, which makes it difficult for vehicles to move. The surveyed

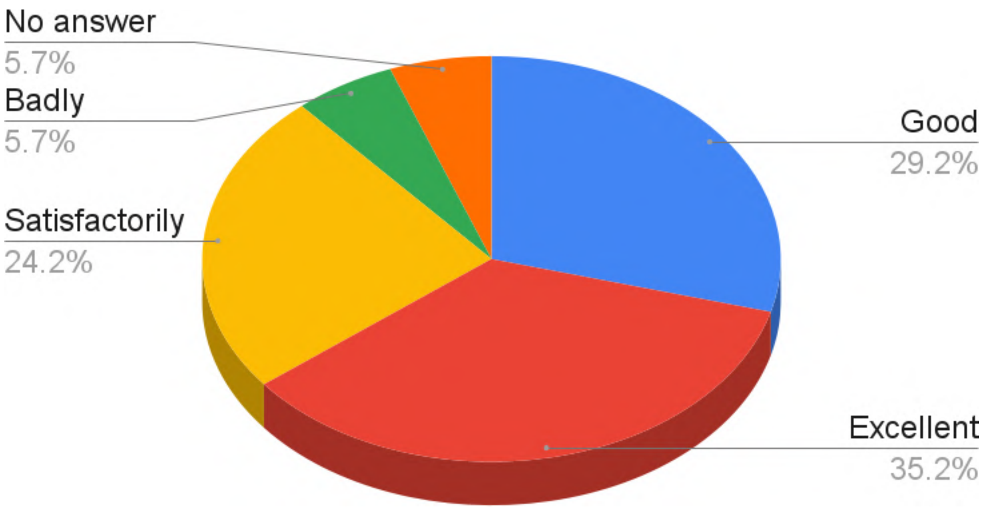

Figure 7. Assessment of information availability when visiting cultural and historical objects.

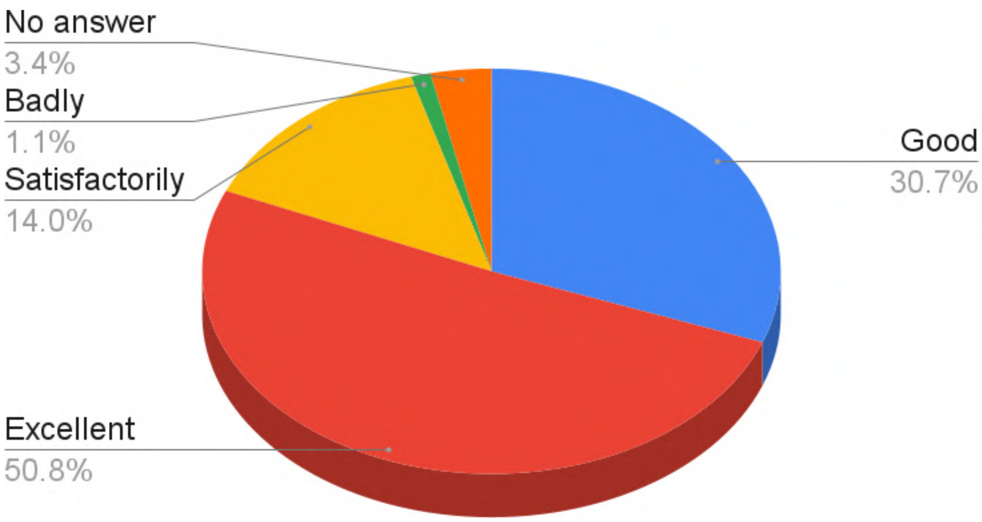

Figure 8. Assessment of territorial accessibility when visiting cultural and historical objects.

tourists noted those services determined by the development of infrastructure and the lack of which causes the greatest discomfort, among them: limited access to the Internet (9,5%), lack of food establishments (8,5%), insufficiently developed transport connections (10,9%), littered territory (6,3%), inaccessible mobile communication (5,1%). The discrepancy between the price and the quality of services (3,2%), unfriendly service staff (1,7%) and the danger of some historical objects (ruins) (1%) was also noted (figure 11).

2. **Limited range of additional services.** A significant part of the surveyed tourists (13,8%) indicated the limited range of services at the object, 11,7% – the absence of cultural and entertainment institutions.
3. **Limited information about the object.** 13.3% of respondents indicated limited information about the object, despite the rather high level of information availability on the cultural object. Almost a quarter of respondents (24.3%) received information about interesting tourist locations from acquaintances, 12.8% – obtained information from social networks, 10.3% – a previous visit, 8.5% – information provided to tourists in travel agencies

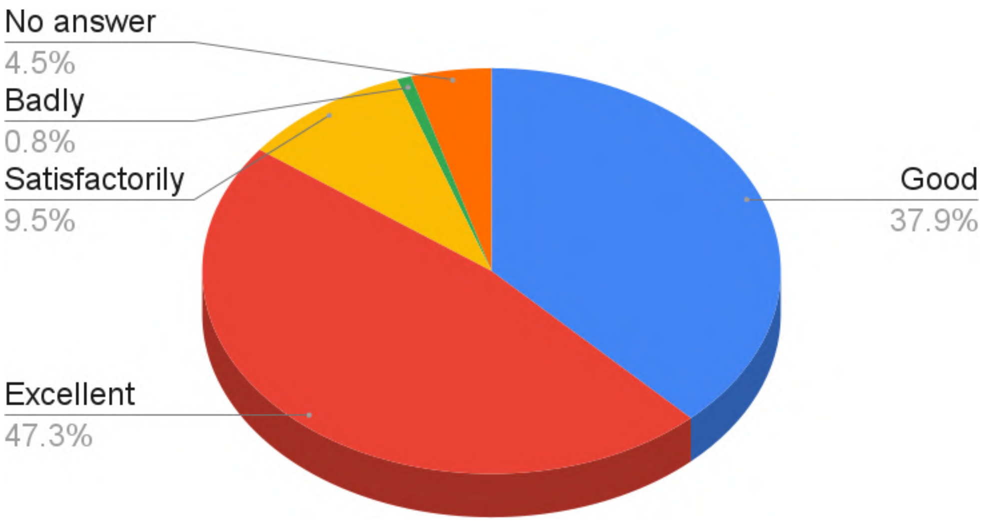

Figure 9. Assessment of the attractiveness of cultural and historical objects.

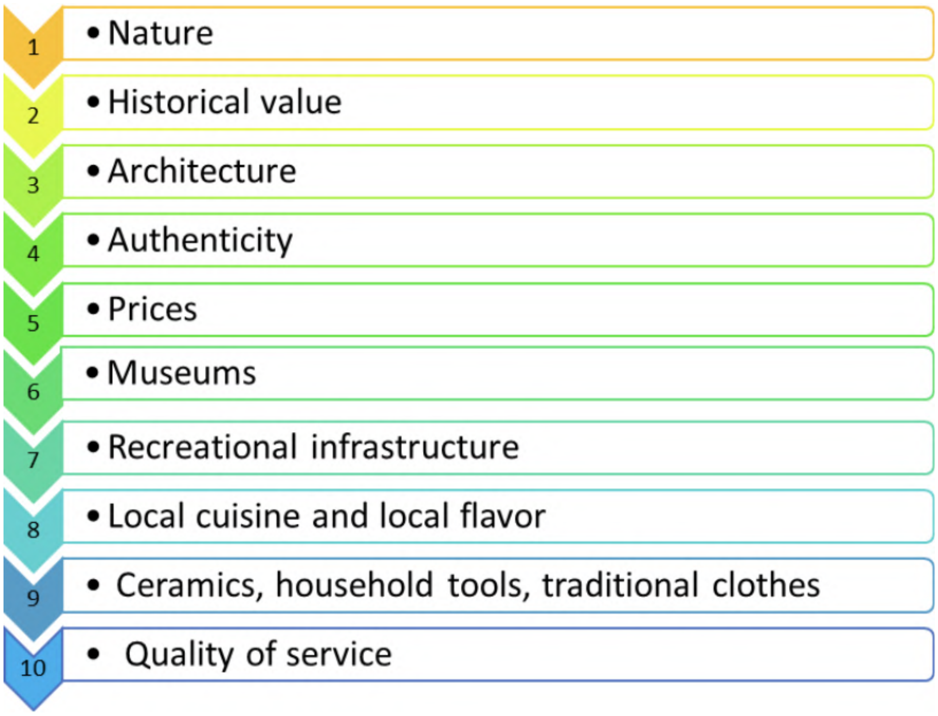

Figure 10. Top 10 answers of the respondents to the question "What did you like most about the object of the visit?"

, 5.2% – other (banners, YouTube), 2.7% of respondents use books, guidebooks, magazines, booklets to obtain information about recreation opportunities, 2.4% – tourist information centers, 2.4% – mass media and 0.6% – exhibitions and fairs.

Only 27% of the respondents from the total sample of those interviewed left comments and expressed suggestions for improving the attendance of cultural and historical objects in the research territory during the sociological research. This is very valuable information that can be used in the work of cultural objects to improve their activities. Although the suggestions were

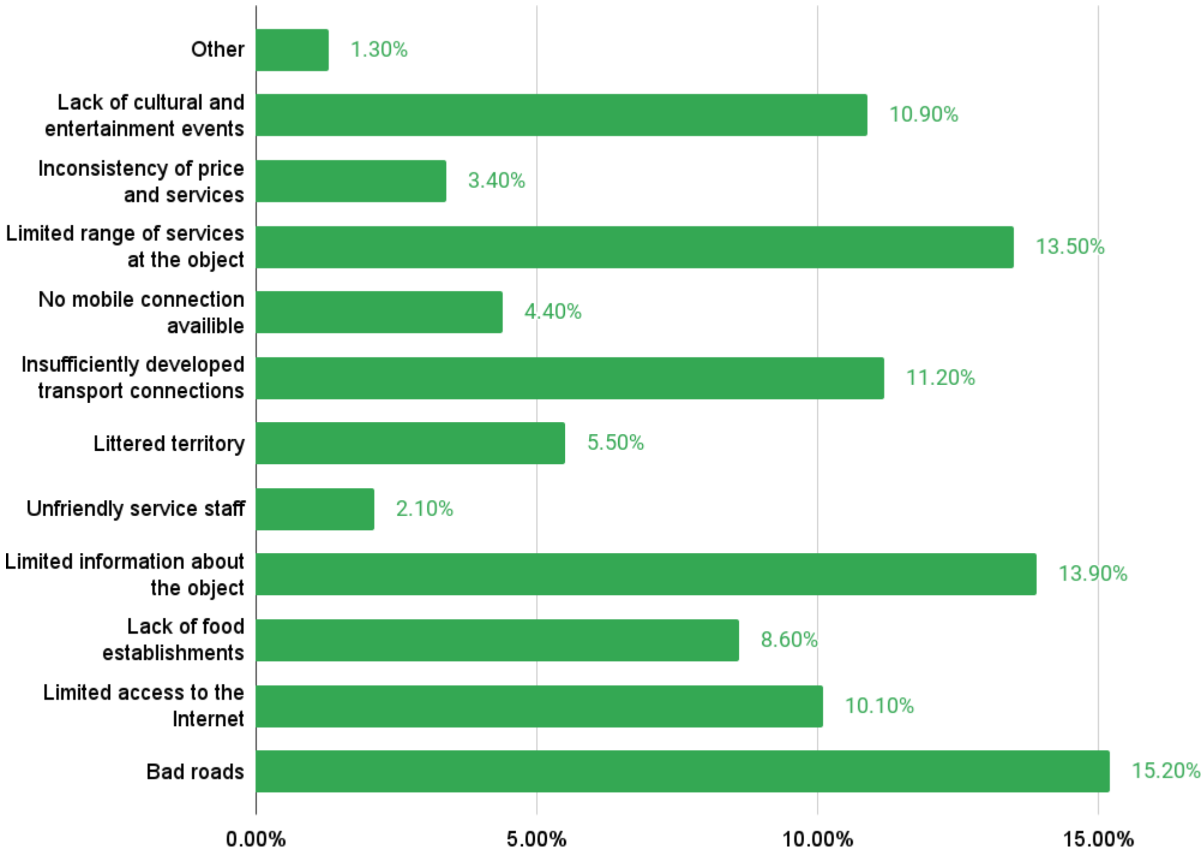

Figure 11. Distribution of respondents' answers to the question "What problems did you encounter when visiting a cultural and historical object?"

expressed by a small number of respondents, we can say that the advice was given by consumers who have experience in tourist trips, who support the development of culture and tourism and can formulate their vision of problems and ways to solve them. Respondents noted the following directions for improving recreation: improving infrastructure (22,2%) and beautification of the territory (18,5%), attracting sponsors for the restoration of cultural heritage (11,1%), restoration of cultural and historical objects (11,1%), information provision (7,4%), public toilets (3,7%), cultural and entertainment events (3,7%) (figure 12).

During the survey of employees of cultural tourism facilities, a number of problems were outlined, which the respondents noted as barriers to the development of tourism activities. Among the institutions most mentioned by employees are:

1. **Low level of infrastructure development of the cultural tourist object and the tourist destination in general.** The level of development of tourist infrastructure, which is the basis of tourist activity, was assessed by 63,2% of respondents as underdeveloped and indicated this factor as a significant barrier in the development of a tourist cultural object. A detailed analysis of the infrastructure will be provided in our next publications.
2. **Insufficient financing of institutions.** 59,6% of respondents pointed to the insufficient amount of finance for the development of tourist objects. More than 78,6% of respondents indicated the need for two or more sources of financing. 75,9% of respondents noted that their own funds earned in the process of tourist activity are a source of income. Respondents also see a solution to the problem of underfunding in participation in grant programs (14,8%).

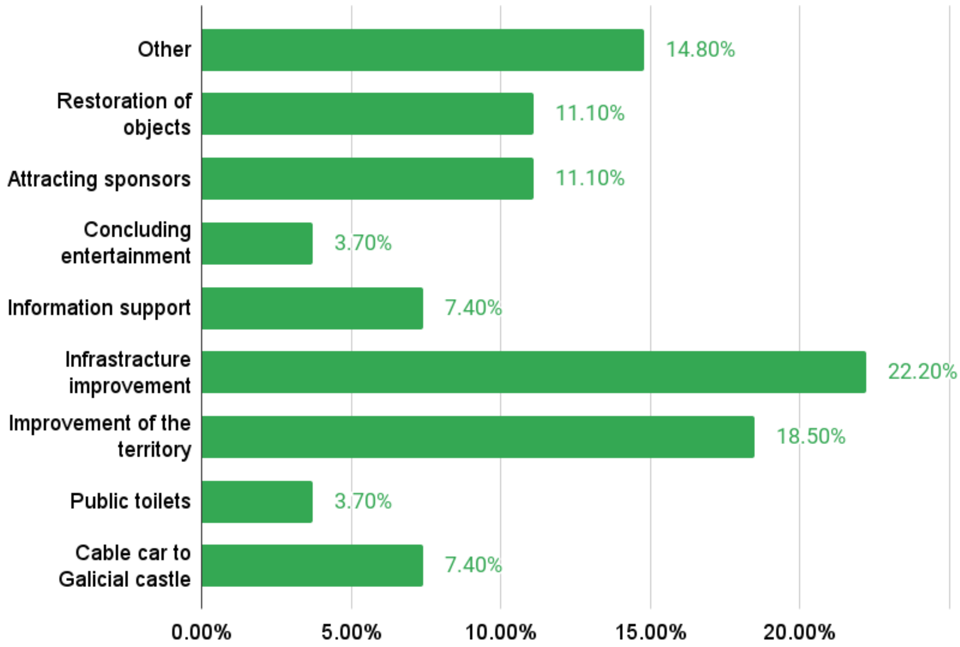

Figure 12. Distribution of respondents' answers regarding improvement of recreation in Ivano-Frankivsk and Transcarpathian regions.

On the other hand, the survey of consumers showed that they are ready to spend additional funds within the framework of visiting cultural objects. Almost a quarter of respondents (24.7%) are ready to spend additional money on souvenirs, 18.5% of respondents – on entrance tickets to museums, 12.6% of respondents – on organized excursions, 9.5% – on festivals, 7.2% – master classes, 7% – entertainment events. Only 2% to 5% of tourists spend additional money on concerts, performances, shopping, SPA and donations in churches (figure 13).

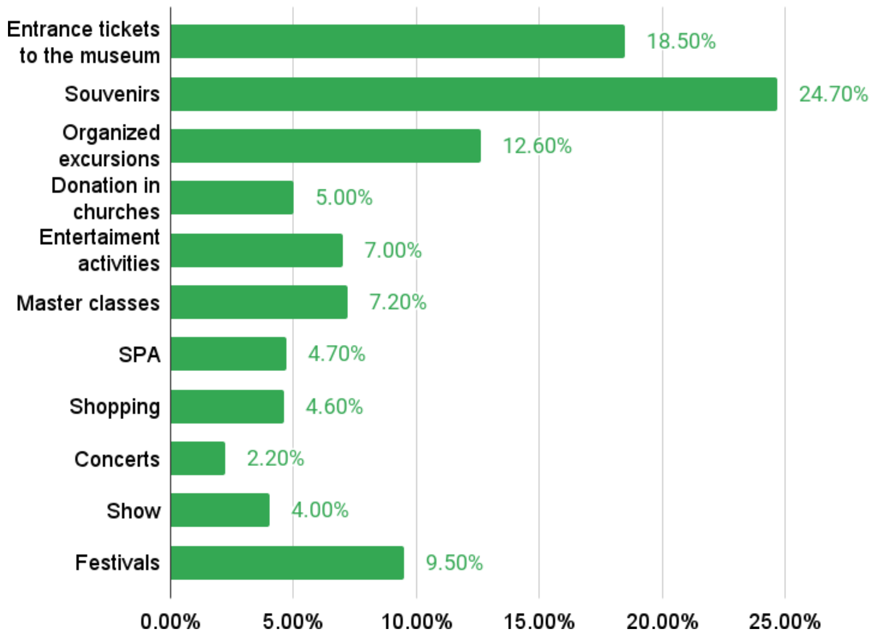

Figure 13. Potential expenses of tourists at cultural tourism objects.

3. **Low level of monetization of objects.** The problems of financing the activities of the objects and the low level of their monetization are related to each other. The low price for visiting the objects (free visiting in 52,2% of the objects), and the lack of excursion programs (17,6% of respondents) prevent the development of the object as a tourist attraction. 52,2% of respondents also agree with the thesis about the insufficient number of attractions within the objects, which makes it impossible to diversify tourist services and increase income.
4. **Low level of tourist and cultural activities in the tourist destination.** 50,7% of respondents – tourist objects point to the insufficient number of cultural events that are held in tourist destinations, three quarters – to the readiness to join these events. Public-private partnerships in this area, combining the efforts of cultural and tourism institutions can be the key to revitalizing both tourism and culture. 84.6% of respondents are ready to take part in the developed tourist programs for the activation of tourist activities at cultural tourism objects (figure 14).

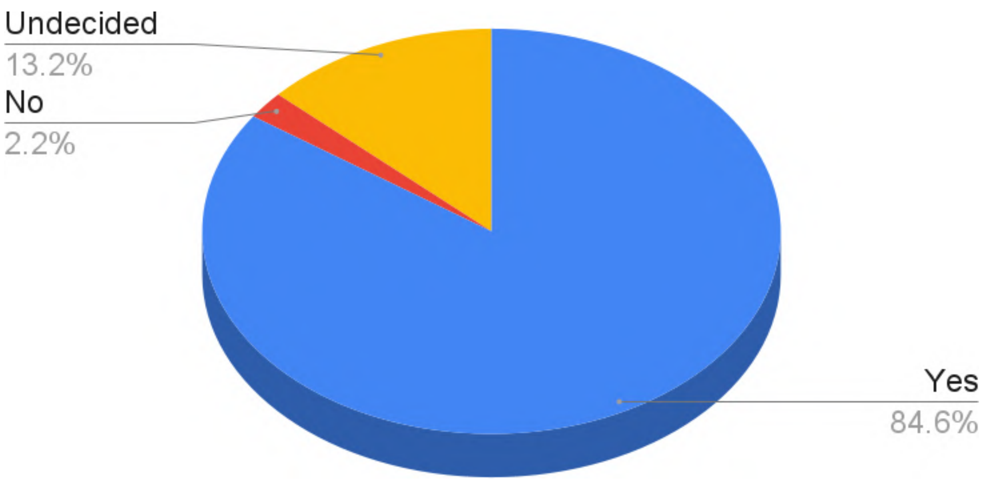

Figure 14. Readiness of respondents to participate in tourist programs.

5. **Insufficient advertising of the tourist object.** 26,5% of respondents agree with the thesis about insufficient advertising of the cultural object.
6. **Imperfect state tools for regulating tourist activity within cultural objects.** Imperfect legislation and high tax pressure in this field were indicated by 16,1% and 11% of respondents, respectively, as a problem in the development of tourism. This answer was mainly given by private craft traditional productions, private museums, and museums that do not belong to the Ministry of Culture of Ukraine.
7. **Low qualification of employees.** 8,8% and 8,1% of respondents indicated the low qualification of employees and the low quality of services as a barrier to the development of tourist objects. However, the respondents, in general, are open to gaining new experience and knowledge about tourist activities at the objects of historical and cultural heritage: 73,5% of respondents are ready to participate in training within the framework of projects of this direction, 11,8% did not answer this question, 13,2% of respondents were undecided on this issue, 1,5% of respondents answered this question negatively (figure 15).

In general, 72% of respondents clearly outlined the ways to solve the problems of the development of cultural objects as tourists. However, 28% of respondents did not formulate their own problems, which became barriers to development and obviously do not work on their solution (figure 16).

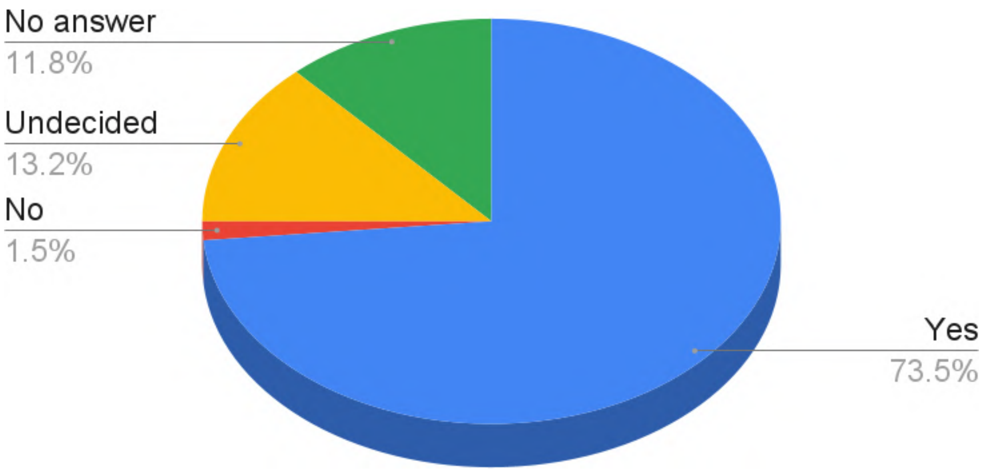

Figure 15. Readiness of respondents to participate in training as part of projects.

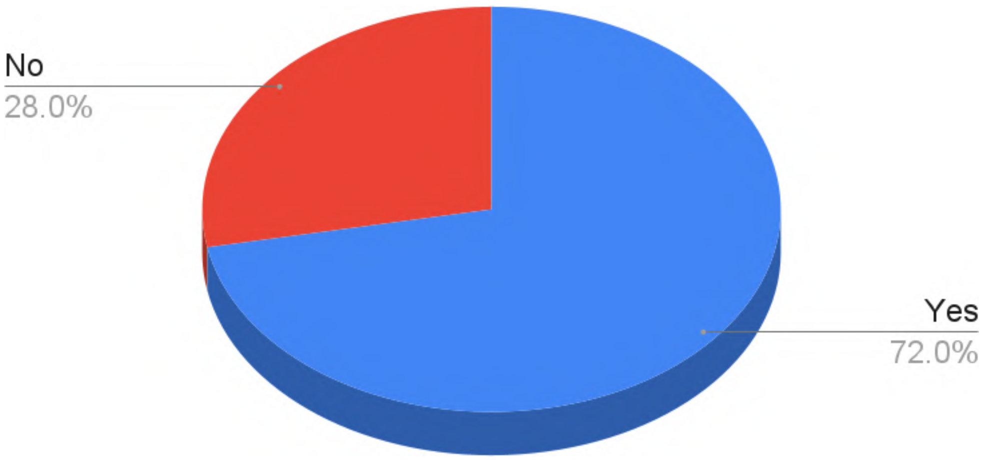

Figure 16. Distribution of respondents' answers regarding the question "Are you aware of ways to solve your problems in the development of tourist objects?"

4. Conclusions

Ukraine is attracting increased interest in the world. Our country has become a symbol of courage and stability. Ukraine was considered "terra incognita" in past years from a tourist point of view, so experts predict an increase in tourist visits after the war. The analysis of literary sources on cultural tourism revealed a certain lack of coverage of the problems of the development of cultural tourism from the point of view of the consumer and the service provider. Studying the problems of cultural tourism development through the prism of supply and demand is the most informative and reliable way, according to the authors, which allows taking into account the opinions of producers and consumers of cultural tourism services.

From the point of view of applying a group of research methods, according to the authors of the article, obtaining voluntary information from persons who are involved in the work of a tourist object of cultural tourism is the most accurate, as it includes an expert assessment of persons who have certain qualifications, experience and are constantly present on the object. Obtaining information from tourists visiting cultural objects allows you to reach the consumers of cultural tourism, that is, its target audience. Elaboration of the results of the survey of consumers and providers of cultural tourism services made it possible to identify the problems that were noted by two groups of respondents. Among the most relevant are the unsatisfactory state of roads and tourist infrastructure in general, the low level of dissemination of information about cultural tourism objects, the lack of additional services at the cultural tourism object, etc. The research of a wide range of problems of demand and supply in cultural tourism will allow for the improvement of cultural tourism programs, identify its target audience, offer ways to improve the resource potential of cultural tourism, etc. The scientific developments of this subject should contribute to the application of innovative approaches to the differentiation of cultural tourism attractions, which helps to orientate potential tourists.

Abstract. This article raises the question of the role of non-formal and hybrid education as a form of personal and social sustainability in the war-time adversity. The authors attempt to estimate the role of the eco-facilitation course as one of the original Ukrainian approaches to psychological assistance. The course was provided to different categories of students (displaced and relocated within Ukrainian borders or with a refugee status in Europe and USA). It was found that experimental training by the method of ecofacilitative teaching contributes to individual and social sustainability in terms of rhythmic development (thesis-antithesis-synthesis). In particular, the changes in pedagogy reflect the logic of their non-directive teaching (ecofacilitation). Ecofacilitation is an educational course aimed at developing skills for sustainable self-development or personal stabilization in conditions of instability and chaos, which closely corresponds to the living conditions of an individual during wartime.

1. Introduction

The psycho-emotional state of people during the war in Ukraine, in situations of high and prolonged uncertainty, is characterized by a significant degree of dynamism, variability, the so-called "psychological swing" when the resource, conscious and active condition is abruptly replaced by exhaustion, loss of meanings and guidelines. In this regard, the search for effective individual and group forms of a non-clinical, psychological and pedagogical nature is actualized. These forms could be viewed as such that ecologically, consistently and rapidly contribute to the stabilization of the personality at various stages of its development in adversity. Such flexible, often hybrid forms and technologies have a high, in a sense, universal stabilization potential empowered by psychological and pedagogical mechanisms of ensuring a sustainable future. The formation of an ecological attitude towards the environment is carried out through pedagogical and psychological influence on an individual. In the context of our research, these two disciplines are combined under the concept of social therapy as a condition for the formation of an adequate attitude towards the environment.

2. Psychological markers of the war in Ukraine. Pedagogical research to psychological sustainability: literature review

A number of studies reflect the negative experiences of the considerable part of the population, which are determined by a radical change in a lifestyle – forced immigration, displacement to other regions, loss of loved ones [1–3], a significant reduction in social programs including medicine, the need to overcome migration stress, such as unemployment, poverty, food insecurity, social exclusion and housing difficulties, etc. [4–6].

Another group of studies shows that along with, or as a result of, a radical change in socio-psychological conditions, the population of Ukraine, for the first time within decades, encountered a number of positive phenomena – such as cohesion [7] activation of hidden psychological and social mechanisms of self-regulation [8]; even a certain level of well-being, including psychological, physical, social [9]; various determinants of resilience, both individual and collective [10].

In studies devoted to the problems of sustainable development or spontaneous system's stabilization in critical periods (COVID-19), the authors come to conclusions (a) about the emergence of spontaneous and rhythmic personality stabilization such as "thesis-antithesis-synthesis" (immunity/or protective socio-psychological regulation can manifest itself in terms maintaining a certain rhythm of development, accompanied by signs of spontaneous resistance, well-being and tolerance to uncertainty) [11,12]; (b) that not only in the context of the pandemic, but also at various stages of military aggression, the Ukrainian education ecosystem showed informal aspects of self-organization, which contributed to stabilization not only at the individual but also at the level of group development [13]. The process of socio-psychological regulation at the individual and social can manifest itself by maintaining a certain rhythm of development, a certain level of well-being and tolerance to uncertainty. Factors contributing to the preservation of a certain level of resilience and well-being include an increase in psychological volunteering, and a critical approach to history, social events and communal dialogue [14].

To one of the forms of stabilization we include a certain pedagogical interaction with students in universities within non-formal education programs. For example, formal training at the University of Educational Management (Ukraine) during the first active phase of the war was delivered as a so-called "live psychological laboratory". It was complemented by innovative forms of training: daily streaming counseling classes, elements of SALT – system of accelerated learning and teaching, Accelerated Learning (AL) and Intensive Learning (IL) [15, 16], weekly support group to help students in their daily activities, supervision certified course of eco-centered facilitation; International discussion club PsyDetox). This approach made it possible to achieve good academic results, it contributed to the assimilation of not only the curriculum but help stabilize the psychological condition of students and teachers during the war adversity [13]. This provides a certain ground to assume that the spontaneous tendency of any even formal system to stabilize itself in critical situations can be related to a form social therapy.

3. Experimental research on the development of psychological sustainability: a rationale

To this form of a social psychotherapy, we include ecofacilitative training of psychologists which is antithetical to the existing system of traditional directive teaching. The main differences between eco-facilitative education and traditional education are: short-term vs long term teaching exposure, personal orientation vs program or curriculum orientated process, tolerance for ambiguity vs intolerance for ambiguity. Experimental social therapy pedagogy is also hybrid, facilitates individual educational and teaching trajectories of the student and the teacher.

This form was implemented at the time of experimental distance learning called "The Intensive Course of Eco-Centered Facilitation" (ICEF-course). ICEF-course is focused on achieving the following educational outcomes: appropriation of eco-centered facilitation theoretical background; introduction into a non-deficiency principal of post-traumatic growth and development; acquisition of non-directive guidance of group dynamics in uncertainty and semantic chaos; development of eco-facilitative counselling skills as well as the skills for professional deliberative practice, assessment of the psychologist's competence.

The intensive character of the pedagogical course was ensured by its multi-factor determination: the personal interest of students, the demonstration of live eco-facilitative (psychological) sessions with real clients and professional assistance, implementation of individual educational trajectories, combination of mandatory and optional components of the course. A special focus of the course is the therapeutic effect for students in the conditions of the war adversity and forced emigration.

The course program is designed for 72 academic hours over two months (classes 2 days a week) and includes three main modules: live Eco-facilitative counselling sessions, their analysis held by P. V. Lushyn; methodological rationale for ecofacilitative counselling and practice; Eco-facilitative internship: gaining the experience of a client, a counselor, a supervisor. The course program covers the following topics: psychological and social conditions of the personality change process; principal features of the personality change process; psychology of self-development and self-organization of personality; theoretical, methodological, and empirical analysis of scientific research on personality change process; ecofacilitation and the principle of ecology; ecosystem in the personality change process; psychological guidance of post-traumatic development; practice of ecofacilitation in the conditions of the modern world. Autonomous student's work included: deliberative practice, recording eco-facilitative sessions, writing reflective essays. Optional: participation in the work of PsyDetox International Discussion Club and supervisional group sessions. The learning process involves minimal regulation in terms of its intensity and evaluation of the results of each participant. It is focused on toleration of uncertainty, creating conditions for the manifestation of one's own educational motivation, the possibilities of designing and implementing an individual learning trajectory and psychological stabilization in terms of development.

The research goal is to study the socio-therapeutic potential of ecofacilitative pedagogy as an important factor for social and individual stabilization (by means of preparation of future professionals) in wartime adversity in Ukraine.

4. Methodology

Indicators of psychological stabilization in terms of changes during experimental training are studied by means of content analysis of the reflective essays, current and final written reviews of students. These indicators are semantically represented as psychological emergent, shifts in emotional (sensations, feelings, interest, interest, insight, catharsis), cognitive (comprehension, understanding, cognition), behavioral (attitudes, actions, experience, skills), value (meanings, worldview) spheres. Content analysis allows to determine the psychological state, identify attitudes, interests, intentions, values, belief systems, "models of the world", focuses of attention of the authors of the texts and is characterized by objectivity of conclusions, rigor of the procedure. It consists in the choice of semantic units of the analysis, a quantification of the text (similar to the standard methods of classification by selected groups) with the subsequent interpretation of the results. Semantic units or units of the analysis could be the concepts, simple sentences or judgments, topics which are expressed in whole semantic paragraphs, parts of texts, events, etc. The units of the account can be estimated by the frequency of mention in texts or the physical length of the texts, the area of the text is filled with semantic units, the number of lines, paragraphs, signs of the text, etc. [17–19].

In this paper, the content analysis included: a) the definition of a universal category that answers the most generalized question of content analysis – indicators of psychological stabilization of the individual in terms of change and development; b) formulation of the basic judgment (statement) "Studying at the ICEF-course contributes to the psychological stabilization of the individual in terms of development"; c) decomposition of complex sentences into simple ones with the transformation of adjective and participle turns into separate simple sentences; d) identifying and counting all semantic units of analysis of simple sentences that fall under the basic judgment and represent a complete thought. The selection of analytical units in the texts was carried out by two experts, the results were compared and subsequently analyzed.

As factors of stabilization in terms of personal change and development are considered: age, professional and previous educational experience, activity and experience of psychological assistance acquired during the course. Professional experience reflects the professional status of the subject either as a practicing psychologist, or as a student – a future psychologist, or as a representative of other professional groups. Previous educational experience is an indicator that combines the presence of basic psychological education and specialization in different modalities of psychological assistance (absent, polymodal, monomodal); level (number of hours) of specialization in "Ecofacilitation" modality (initial, intermediate, advanced), as well as membership in the public association of psychologists (Ukrainian Association of Environmental Psychological Assistance). Indicators of academic activity, motivation and success are studied according to the following markers: the intensity of attendance at the main and optional events of the course, internship in the course – the experience gained by the client, consultant and supervisor, as well as the results and scope of deliberative practice (independent work on recording consultations).

The participants of the study were students of the ICEF-course ($N = 51$), the average age 32 ± 5.3 years, men 11.8 %, women 88.2%. Among them are those who study Psychology at the university 13.7 %, psychologists of organizations and self-employed psychologists 29.4 %, workers in other fields (economic, legal, IT, military, artistic) 34 % and temporarily unemployed 22.9 %. Outside of Ukraine 39.2 %. The sample is not homogeneous, randomized, everyone could take part in the course. Statistical processing includes descriptives, frequency, cluster analysis, Kruskal-Wallis Test and carried out using the SPSS statistical package.

5. Results and discussions

An example of semantic units of text analysis, which are indicators of stabilization in terms of change and development, are judgments that testify to the dynamics at different levels: emotional – "There are many insights that I will analyze later", "This work inspired me so much", "Difficult situations in me can be viewed as opportunities I never thought before"; cognitive – "It became aware that I know what I want", "I saw order and began to trust myself", "I found another cycle in my life – 8 months", "I realized my main mistake"; behavioral – "Previous time I failed, now I will succeed, will pass through it calmly", "Now with new powers and new strengths I will move further", "And after the second Sunday at night I felt the strength and inspiration to answer her"; value-semantic – "New meanings are being born for the future life", "I strongly pushed my interpretation of children", "Now I have received avoidant experiences and cooperation with the invisible", "This course has become useful for me not only in professional growth, but also in personal growth". The total number of selected judgments is 2777. The analytical units allocated from them are 441 (100 %), including: emotional nature – 147 (33.3 %), cognitive-rational – 109 (24.8 %), behavioral – 129 (29.2 %), semantic – 56 (12.7 %).

Clustering of variables made it possible to distinguish four groups of participants in which the parameters under study are manifested differently (table 1).

In different groups according to the studied parameters, statistically significant differences or differences at the level of trends were identified. The indication of the features of the manifestation of psychological stabilization of the individual and professional, educational experience, educational activity of participants in the context of different typological groups is presented (figure 1).

On the basis of the results, we obtained a typology of development and stabilization of the personality in the conditions of intensive training.

Type 1 – "professionals" (23.5 %), who active in learning and stable in development. By age, it is probably the oldest group of people with significant professional psychological experience, good educational experience and specialization in an eco-facilitative approach. They always attend

Table 1. Manifestation of the studied parameters in typological groups.

Researched parameters	Type 1	Type 2	Type 3	Type 4	Sig.
Age	29.0	25.2	20.8	30.1	0.089
Professional psychological experience	30.3	24.8	26.7	21.9	0.153
Previous educational experience	31.6	24.8	16.8	32.3	0.045
Main activity	33.3	23.3	36.0	9.5	0.000
Optional activity	32.7	29.4	28.1	4.5	0.000
Practicing on the course	44.5	15.5	31.8	18.6	0.000
Deliberative practice	31.5	16.5	44.9	19.2	0.000
Indicators of stabilization	27.3	23.0	39.6	14.9	0.003

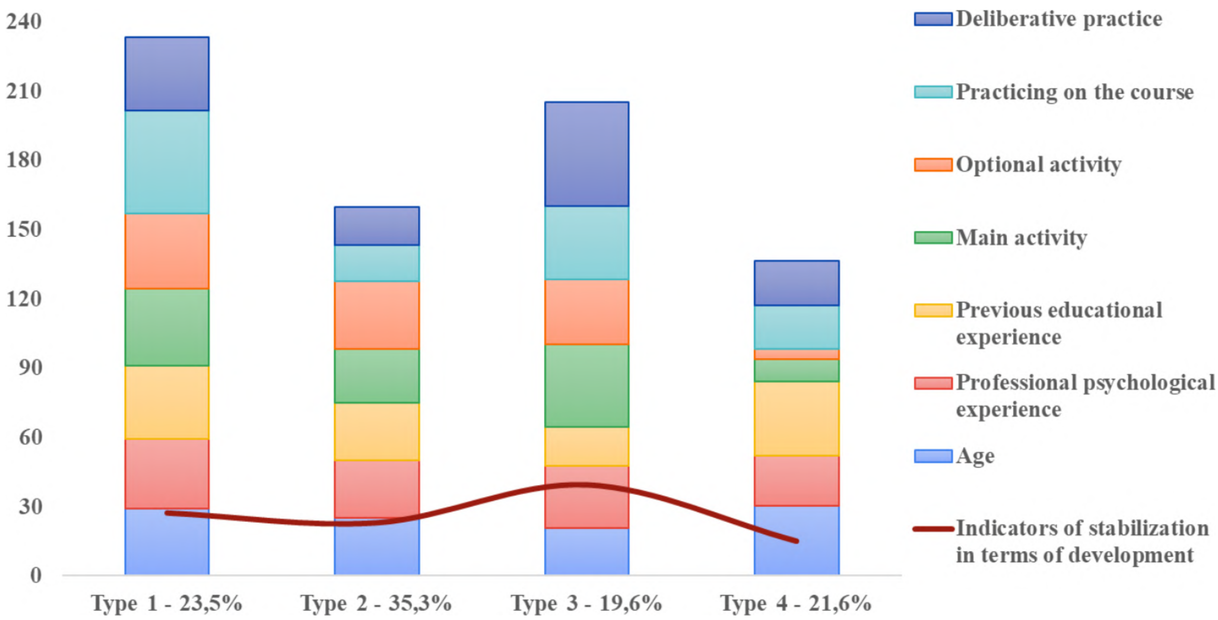

Figure 1. Psychological development of personality in different typological groups.

the sessions in the main and optional classes of the course, are motivated and actively practice during classes, are interested and gain the experience of a client, counselor, supervisor. Although they their weakest spot is not making use the opportunities of the deliberate practice to the fullest. Therefore, in this aspect their zone of professional development is not significant So, their key features are a convincing educational and professional psychological background; they have the highest activity in all components of the course program, with the exception of deliberative practice. The students of the group are stable in terms of psychological dynamics – emotional, cognitive, behavioral; value reactions and changes. In this type, the highest educational activity is manifested on the "wave" of the stable personal and psychological development.

Type 2 "those who are interested – interesants" (35.3 %) – actively observing, although refraining from active practice, they demonstrate moderate, evolutionary development. These participants are the most distant from professional psychological activities, but at the same time they are quite knowledgeable and have a moderate level of specialization in the eco-facilitative approach. They are involved in the optional activities of the course as much as possible. Not too active in main classes, and obtaining the experience of the client, a counseling and supervising. Their personal and psychological development is associated with psychological changes of an evolutionary nature.

Type 3 "beginners" (19.6 %) are persistent in learning, mastering eco-facilitation, very dynamic in their personal development. These are the youngest participants in age, close to professional psychological activity, since among them there is a significant proportion of applicants for psychological education, but now they have minimal experience and initial specialization in the eco-facilitative approach. They are characterized by maximum inclusion in the main classes of the course and somewhat lower in electives. Gaining client's experience and moderate, rather, "cautious" practice in the classroom as counselors and supervisors, they actively complement their own deliberative practice. Against the background of such a motivated attitude towards learning, the psychosemantic markers of their psychological dynamics look the most expressive and convincing.

Type 4 "observers" advanced and beginners (21.6 %). They support their psychological balance. Among them are both professional psychologists and representatives of other professions. There are those who have maximum learning experience, specialization in the eco-facilitative approach and are members of the community of eco-facilitators. There are others amongst them who are just beginning their acquaintance with psychology and the ecofacilitative approach. But all of them are united by the fact that they are not very active in the learning process, they mainly participate in the basic training sessions that provide an opportunity to observe and discuss "live psychological case". They are not active in practicing during classes, independent work, logging. In terms of personal and psychological, their dynamics is minimal. Regarding this type, the question arises – what is the meaning of learning for them? The answer may be that passive observation, being in an ecological educational context, and therapeutic space allows the most knowledgeable and ignorant of psychology, to find and maintain their own psychological balance in the eco-therapeutic educational format.

6. Conclusion

The results obtained allow us to formulate the following conclusions. First, the hypothesis is confirmed that the experimental educational and therapeutic format of accelerated preparation of future processionals, psychologist in particular, in the context of non-formal education. This form of education can be attributed to social therapy, which creates conditions for the implementation of various strategies for the personal growth and development of students.

Secondly, age, professional psychological experience may influence the dynamics of psychological stabilization. Most convincing factors are the educational experience of psychological specialization, staying in the educational and therapeutic environment and the possibility of performing various types of educational activities within the existing intrinsic motives and developmental trajectories.

Thirdly, the strategies of learning and psychological stabilization in terms of development and change are manifested nonlinearly and are represented by dynamically changing types of "observer", "actively interested","persistent student", "professional". These types reflect some trends in a wide range of unique strategies for personality stabilization and development – from passive observation to active practice with oneself and others at different stages of the professional and life pathways.

Fourthly, staying in a developing educational and psychological environment constitutes the antithesis for exposure to the military environment which opens up a certain prospect for psychological well-being, resilience of an individual, and therefore of society.

Abstract. The impact of high dams with large reservoirs with long-term regulation is covered in the scientific literature quite widely. The information and recommendations on the use of low-head dam for the creation of the low backwater are not enough. Large dams reduce the mean annual flow downstream, the magnitude and frequency of floods, lead to the accumulation of suspended solids, nutrients compounds (nitrogen, potassium, phosphorus), which, together with increasing temperature leads to the "blooming" phenomenon of the reservoir and the overgrowth, create barrier for sediments transferring and fish. The main reason of the deterioration of the water quality is the water retention time in the formed reservoir and anthropogenic pollution, although the literature rarely provides quantitative data of the water retention time for the evaluated reservoir. The environment risks assessment of the impact of the reservoir should include the calculation of the water retention time, the presence of pollutants in the river, which may indicate future negative effects. The hydrological regime of the river after the backwater creation should correspond to the natural flow with the floods passage by the entire width of the river bed, which will significantly improve flood management, sediments transport and washing the river bed. The significant risk is the shallowing of the river downstream, the amount of water discharged into the downstream should be at least 75% of the river flow. Releasing the flow to the downstream with an overflow or through fish passage structures allows to enrich the water with oxygen. In order to preserve biodiversity, it is necessary to create or leave islands and shallow water areas for the needs of waterfowl. To ensure an environmentally friendly regime operation of the low-head dam the crest of the spillway structure should be at the bottom level along the entire cross section. The low-head dam should be provided with automatic control system and communication with the hydrometric station for a quick response to the flow changes in the river.

1. Introduction

In recent decades, more and more attention has been paid to the impact of artificial hydraulic structures on the river environment and the minimization of risks. Considerable attention is paid to water replenishment of floodplain [1,2]. The problem of disconnection between the floodplain and the river takes plays as a result of the flood control dykes' construction in the urbanized areas, and the water replenishment problem of the floodplain and oxbow lakes is possible to solve by the river flow management and artificial structures. The article [3] analyses the prospects of watering the old river bed and the oxbow lake in the urbanized area, which is protected from floods by earth dykes. It is not possible to restore the connection between the floodplain and the river by destroying dykes on the urbanized areas. The old river bed is completely dry and the oxbow lake is silted and overgrowth because of the absence of the connection between the river and the floodplain in the summer. The analysis of the hydrological regime of the river and various replenishment scenarios showed that it is necessary to create backwater in order to water replenish the old river bed and increase the volume of the oxbow lake.

The large dam construction experience and the analysis of their operation indicates their significant impact on the hydrological regime of the river and the floodplain. High dams primarily affect the hydrological regime of rivers: decrease the mean annual flow downstream especially in the dry season, and decrease the magnitude and frequency of floods [4].

The large dams change the chemical parameters of water quality. Kamidis et al [5], Fantin-Cruz et al [6] indicate the significant decrease in suspended solids due to sedimentation in the reservoir, nitrogen concentration due to denitrification, decrease in phosphorus concentration in the water downstream and anaerobic conditions in the lower layers of the reservoir. Deep reservoirs are characterized by temperature stratification and the temperature increase in the summer due to long retention time. In the article [7] is indicated that large reservoirs in highly urbanized watersheds can improve the water quality downstream reducing the turbidity and concentrations of pollutants due to storage in reservoir. Shallow water reservoirs with the long water retention time accumulate nutrients (phosphorus, nitrogen), which, together with the warming of the water in the summer, leads to the water “blooming” which leads to decrease the oxygen in the water, and phytoplankton transporting into downstream [8]. The water quality and temperature changing, nutrients and sediments storage are associated with long water retention time in large reservoirs, high dams also cause disconnect habitat along the river [9], decrease in flood flow, and as a result limit floodplain replenishment.

The researches of low-head dam are paid less attention. The study of five small reservoirs with storage capacity of 0.14–0.64 hm^3 in the Nerbioi-Ibaizabal watershed showed that the lack of ecological flow in the summer negatively affects the density, richness and diversity of macroinvertebrates in the areas below the dam [10]. Ignatius and Rasmussen [11] note the increase in temperature, the decrease in the concentration of nitrates and phosphates, and the dissolved oxygen increase in the water downstream when water overflow the crest of the dam. In the article [12] is noted that the impact of low-head dams depends on the composition of sediments, the length of the reservoir and the construction of the dam, which can retain sediments or allow them to be transported downstream.

At the same time, studies of the impact of dams built by beavers [13, 14] also indicate the water speed decrease in the reservoir, fine sediment storage, the temperature increase, the dissolved oxygen decrease, the increase in the dissolved organic carbon and ammonium transport downstream, the decrease suspended solids and nitrates transport downstream. That changes lead to the complication of existence and as the result increase of biodiversity.

One of the important factors affecting the formation of the regime of dissolved and suspended substances, biogenic elements in water and bottom sediments, the conditions of life of aquatic organisms, their populations and groups is the water retention time, which shows the time that water or any dissolved substance remains in the reservoir. The water exchange is formed due to the water inflow from the catchment area and its outflow from the reservoir, contributing to the intensive passage of chemical and biological processes. According to Oksiyuk et al [15], the water retention time should not exceed 7–9 days for the optimal development of phytoplankton and reducing the probability of water ”blooming”. The optimal functioning of the hydrobionts is ensured if water retention time is rates to 4–6 days. The zoobenthic microorganisms change to the less valuable pelophilic species if the reservoir water retention time ranged from 5 to 11 days. In reservoirs with long water retention time more than 15–20 days, the accumulation of organic substances and biogenic substances can be observed, which leads to oxygen deficiency and “flowering” of water [6].

The reason for the overgrowth of water bodies with higher aquatic vegetation is the high biogenic substances concentration (nitrogen, potassium, phosphorus) and the low water depth. Nowak and Lawniczak-Malińska [16] showed that reeds can grow in the large amplitude of lake depth, but its optimal growth is observed in the range from 0 to 1.6 m, while the roots reach the maximum depth of 1.7 m. At the same time, less overgrown water bodies are characterized by the depth of more than 2.5 m with the low nitrogen and potassium concentrations [17].

The aquatic ecosystem sustainability is also affected by the amount of water discharged downstream. Many authors confirm the need to ensure the natural regime of the ecological flow: variability, magnitude, frequency, duration, timing and rate of change, which should be from 75% to 100% of the river flow [9,18,19]. Waligórski and Janicka [8], Ignatius and Rasmussen [11] emphasize the importance of water overflow downstream, which create additional water aeration downstream.

The anthropogenically altered water environment requires the assessment of many factors that may negatively affect the environment in the urbanized areas. Urban river demande integrated water resources management even for environmental improvement projects. Relevance of the topic: floodplain water replenishment aimed to improve the urbanized environment requires intervention in the hydrological regime of the river bed, which requires a comprehensive assessment and development of hydrological regime means of minimizing the environment risks.

The aim of the work is to assess the main parameters that undergo changes during the backwater creation and to develop an environmentally friendly hydrological regime operation of the low-head dam to minimize the environment impacts.

2. Materials and methods

2.1. Study area

The natural flow of the Uzh River in the central part of the city is characterized by significant irregularity and frequent floods. The most catastrophic floods occur in the cold period of the year, there are low water levels with periodic rain floods in the summer. The floodplain of the Uzh River is limited by flood protection dyke in the central part of the city. It is necessary to create the backwater near the area of Bozdos Park in the central part of the city to water replenishment of the floodplain lake and old river bed.

To replenish the old riverbed, it is planned to install the flap gates at the entrance to the old riverbed and at the end to create the required depth of up to 2.0 m. Water replenishment of the floodplain lake is carried out through the tubular spillway. To provide water exchange in the lake, it is connected to the old riverbed by tubular spillway. The backwater on the Uzh River is planned to be created by two flap gates to minimize main riverbed narrowing. The small reservoir is formed as the result of the backwater with the height of approximately 2.5 m (figure 1). The fish passage is provided for free fish movement. The backwater creation for water replenishment is necessary during the dry season. Since there is the spawning period from March 25 to May 15 which prohibit the activities that may affect fish spawning in the Transcarpathian region, it is actually possible to start to create backwater after the May 16th.

2.2. Study methods

The seven cross-sections were analysed to establish the hydrological regime of the river in the area of the future reservoir, which located at the distance of 250 m, the first at the flap gates cross-section and the seventh at the top of the reservoir. The curves of the $h = f(Q)$ were calculated for each cross-section on the base of the curve for Uzhhorod hydrologic station and the water levels were calculated in the natural riverbed for typical years of the stable summer-autumn low flow of the 95%, 75% and 50% probability. The function of the average velocities and river flow in the cross-sections were determined.

Figure 1. Study area: 1 – flap gates; 2 – back water; 3 – pipes for water replenishment; 4 – floodplain lake; 5 – old river bed; 6 – spillway for old river bed replenishment.

The simulation of the backwater creation and water level fluctuations in the formed reservoir including the water replenishment of the floodplain lake and old riverbed was carried out by the water balance method according to the equation:

$$\Delta W = W_{inf} + Pf - E_0 f - W_{out} - RI_{lake} - RI_{orb} - SI, \tag{1}$$

where ΔW – change in storage, m^3; W_{inf} – inflow volume, m^3; P – precipitation, m; f – reservoir area, m^2; E_0 – evaporation from the water surface in the ice-free period, m; W_{out} – volume of the ecological flow downstream, m^3; RI_{lake} – volume of the flow into the floodplain lake, m^3; RI_{orb} – volume of the flow into the old riverbed, m^3; SI – seepage outflow from river, m^3.

Meteorological data (temperature, wind speed, precipitation) for the specified years are taken from the data of the Uzhhorod climate station. The riverbed is the lowest points for the groundwater discharge in the area from the backwater beginning to the territory of the Bozdos Park. The water rising will cause temporary soil wetting losses in the aeration zone, but compared to permanent seepage into the Bozdos Park area, these losses can be neglected. Bozdos Park is located in the middle of the river loop, and the ground flow in the middle loop has the direction from upstream side of the dam to the downstream of the river loop. These seepage losses were calculated according to equation (4) of the article [3] as the seepage losses from the river with backwater to the river downstream. The methodology for determining precipitation, evaporation from the water surface as components of the water balance is described in work [3].

The length of the backwater in the Uzh River is calculated according to the equation:

$$L = k\frac{H}{i}, \tag{2}$$

where L – length of the backwater, m; k – coefficient for mountain rivers is 1.2; H – hydraulic head, m; i – hydraulic gradient of the river.

The hydraulic retention time calculated as relation between reservoir volume and mean river inflow during the period of back water formation by equation [20]:

$$HR = \frac{V}{Q_{mean}} 86400, \tag{3}$$

where HR – hydraulic retention time, day; V – reservoir volume obtained from the curve of water levels and volumes, m^3; Q_{mean} – mean river inflow during the period of backwater formation, m^3/s; 86400 – coefficient to covert seconds into day.

To regulate the water flow in the river, the flap gates were chosen, which allow in horizontal position to pass sediments without creating barrier during the flood. The lifting of the flap gates to create backwater begins with flow increasing in the river after May 15th (136 calendar day). The ecological flow to the downstream is at least 75% of the flow entering the reservoir. At the same time, the floodplain lake and the old riverbed are being filled, which is possible due to the spring flood period. To maintain the water retention time at the range of 4-6 days in the old riverbed and the floodplain lake, the optimal water supply to the old riverbed is 0.5 m^3/s, to the lake is 0.3 m^3/s. The simulation carried out for two scenarios of the reservoir operation in the interaction of Uzh River – floodplain lake – old riverbed: maintenance of the constant maximum water level of the backwater (scenario 1); using the flow accumulated in the reservoir to increase the ecological flow up to 75% to the downstream (scenario 2).

3. Results and discussion

The environmental impact of the dam on the hydrological, biological, geomorphological parameters of the reservoir and water quality can be summarized using the diagram (figure 2). At the same time, the hydrotechnical structures for water replenishment of the floodplain is not the permanent backwater like the ordinary dam. The backwater is temporarily formed by the flap gate after the end of spawning (after the May, 15) and is maintained until the end of October (before autumn floods). The ordinary dam creates the physical barrier for the fish movement. The fish passage is necessary to move cross the dam.

The main impact on the river is the creation of the backwater for the certain water volume accumulation, which create due to the reduction of water discharge to the downstream. The impact of the low-head dam with small reservoir volume on flood flow and flood levels is insignificant, and the risk can be minimized due to the gates design. The evaporation from water surface increase, but this loss is appreciable for big water surface and shallow reservoir. The water level increase due to the backwater increases the groundwater table in the hyporheic zone, which also leads to river flow loss. But at the same time, the recharge of groundwater can have both the negative (increasing ground water table) and the positive is the water replenishment to maintain the biodiversity of the floodplain during the dry season. Water level fluctuation could cause groundwater changes and lowering the soils bearing capacity and as a result banks instability and foundations subsidence on the urban area.

The water speed decreases in the reservoir, which leads to the sedimentation of suspended solids, pollutants, nutrients and the deposition of bottom sediments. The creation of non-flowing conditions in the presence of significant nutrients concentrations can lead to the overgrowth of the reservoir and, to its “blooming” under the condition of rising temperatures. The rapid development of algae leads to the decrease of the oxygen concentration in water and as a result the fish death. The pollutants and nutrients accumulation are directly related to the water retention time in the reservoir, and as shown by Oksiyuk et al [15], the water retention time in the range of 4-6 days provides optimal conditions for the biodiversity. It is possible to ensure short water retention time only by minimizing losses from the reservoir and regular ecological flow to the downstream, which should replicate the natural hydrological regime of the river.

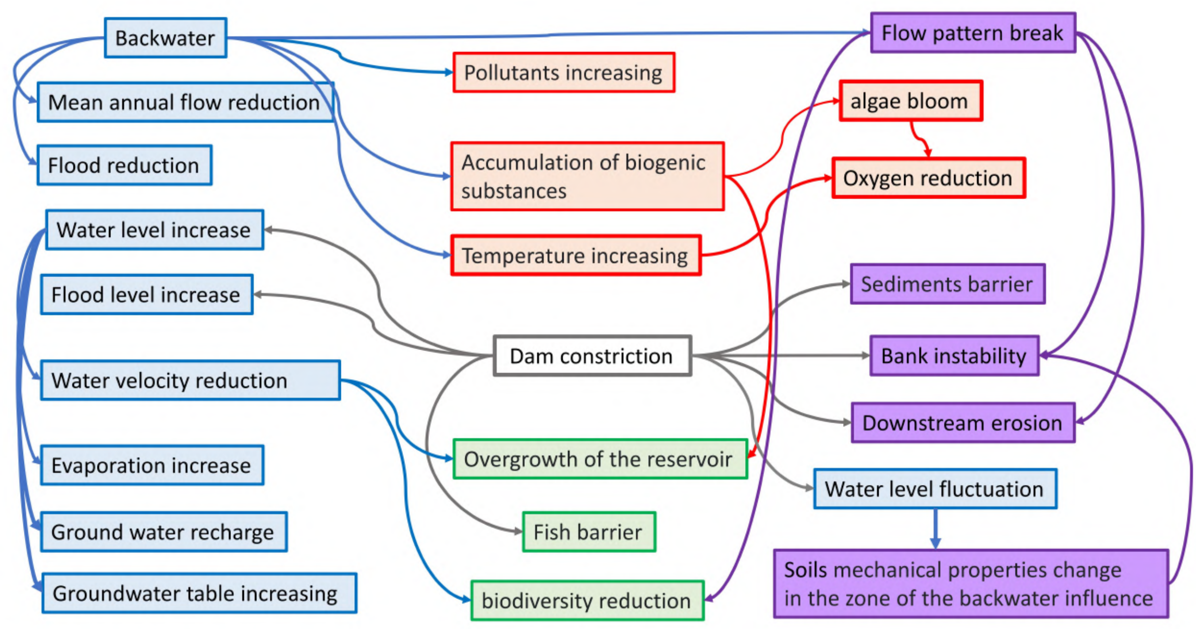

Figure 2. Environmental risks of the reservoir creating on the river: blue – hydrological and hydraulic; red – water quality; green – biological; violet – geomorphological.

Sediment transport occurs mostly during the floods, therefore, to ensure the transport of sediments, it is necessary to ensure the free passage of flood discharges across the full width of the riverbed. Since the water replenishment of the floodplain should be carried out during the dry season, there is no need to create backwater in the period from November to May. So, the main floods will pass through the full cross section of the river, which will ensure the sediments transportation and washing of the riverbed. On the example of the Uzh river, the highest floods occur in March in the year of 95% probability; in March and April in the mean year; in January, February and March for the year of 75% probability. During these periods, backwater is not created and nothing prevents the sediments movement. The flap gate is completely going down when the flow exceeds 103.8 m^3/s, which allows sediment to pass through the gate sections and ensures periodic washing out of the reservoir.

Ensuring the intensity of water exchange, which is formed due to inflow into the reservoir, has the greatest impact on water quality and reservoir overgrowth. Preservation of the shallow water part on the islands formed by sediments will preserve the biodiversity of wetland birds of the Uzh River. The reservoir volume without bottom clearing and preservation of the sediments side as shallow water for coastal fauna is 319,680 m^3, the water retention time of the reservoir on the Uzh River is 0.44 days for the year of 95% and 0.3 days for the mean year and the year of the 75%, which can be considered sufficiently intensive and favourable for the biodiversity. The water retention time is 6.3 days for floodplain lake, and one is 1.5 days in the old riverbed, which is also quite favourable intensity.

The simulation showed that ensuring the short water retention time in the floodplain lake and the old riverbed while maintaining the constant maximum water level in the Uzh river at the level of 110.2 m leads to the reduction of the ecological flow to the downstream (red line on the figure 3, figure 4 and figure 5) by 40% of the inflow for the very dry year of the 95% and the year of 75% probability, which is associated with long-term low flows in the summer period. If ecological flow is supported at the level of 75% of the inflow (black line on the figure 3, figure 4 and figure 5), it is possible to use the accumulated during the rain floods water in the reservoir, that will decrease the water level in the reservoir (blue line on the figure 3, figure 4 and figure 5) due to losses on evaporation, filtration and discharges into the floodplain lake and old riverbed. For some summer days with low water flows, it will be necessary to close the gates and stop the fresh water supply to the old riverbed (green line on the figure 3), which will not significantly affect the water quality in the old riverbed due to the short water retention time, but the water level will slightly decrease.

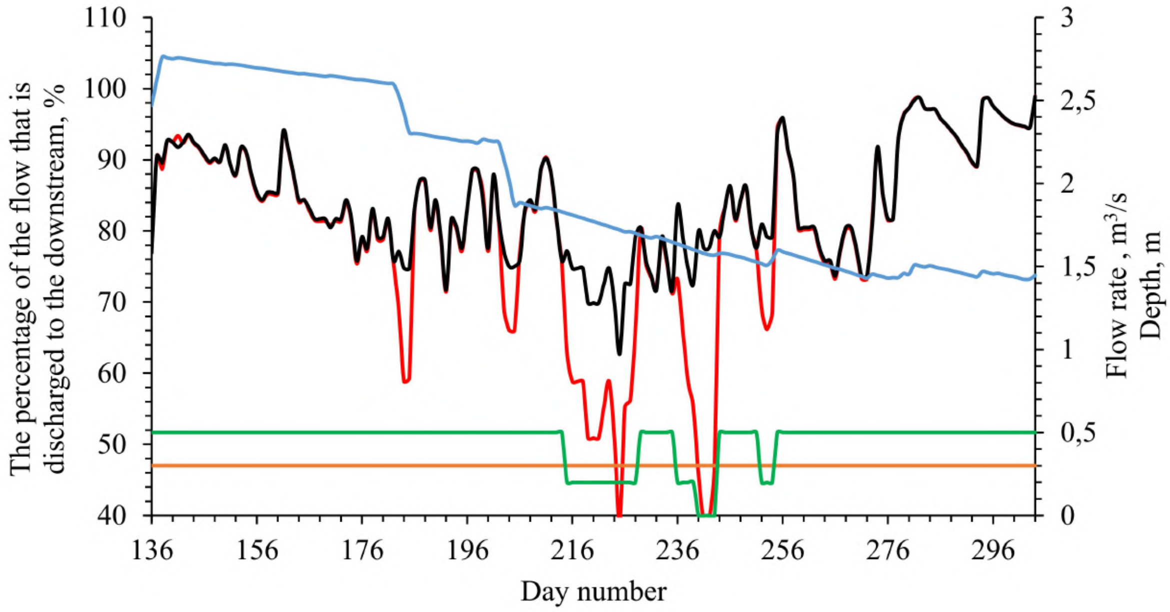

Figure 3. Simulation of the hydrological regime of the Uzh River under backwater conditions during very dry year of the 95% probability: red line – the percentage of the flow (ecological flow) that is discharged to the downstream (scenario 1); black – ecological flow to the downstream that is higher than 75% of the inflow (scenario 2); green – water supply to the old riverbed; orange – water supply to the floodplain lake; blue – the water level in the reservoir on the Uzh River (scenario 2).

The constant water level in the reservoir makes it easy to realize in practice the uniform water supply into the floodplain the dry season. The use of the second scenario with water level fluctuation in the reservoir makes it difficult to regulate the flow into the lake and the old riverbed, and will require complex automation and manoeuvring by the gates at the entrance to the old river and the lake, otherwise the water supply into the lake and old riverbed will be decrease due to head decrease.

4. Conclusions

The general requirements for creating the hydrologically friendly river regime in urbanized areas:

- the water retention time in the range of 4-6 days to avoid future environmental risks;
- the depth of the reservoir should be more the 2.0m with shallow areas;
- the hydrological regime of the river should be corresponded to the natural with ecological flow at least 75% of the inflow of the river;
- the crest of spillway structure should be designed on the bottom level along the entire cross section to provide sediments transporting and decrease flood risk;

- automatic control system and communication with the hydrometric station should be installed for a quick response to the flow changes in the river.

Abstract. The article examines water regulation on drained lands by innovative modular drainage systems with multi-level connection of regulating drains, diagrams of their design parameters are given. The main goal of the article is to demonstrate the results of analytical studies of water regulation by drainage modules under the condition of laying drains at different depths are given. The equations derived in this article allow you to use them to calculate the distance between regulating drains of different installation depths, perfect in terms of the degree and nature of the opening of the aquifer during infiltration water supply within drainage modules. Variants of the application of methods for calculating the parameters of regulatory drainage modules are proposed, which allow predicting groundwater level regimes, establishing watershed lines between perfect shallow-deep drains.

1. Introduction

Most of the drainage systems operated in Ukraine were built more than 30 years ago. On many of them, the drainage does not work as necessary, and therefore the optimal water regime is not observed. This is due to the physical wear and tear of the elements of the drainage system or violation of the rules of operation of the drainage system or a change in the direction of agricultural use of the drained lands themselves. Another possible reason is the low quality of construction [1, 2]. Therefore, for the successful use of territories with constructed but defective drainage, it is often necessary to carry out restoration works, which will ensure the optimal water regime of the soil, and, accordingly, agricultural production at the required level. However, approaches to design have changed, new, in certain cases, more effective designs of drainage systems have appeared. Climate change must also be taken into account. So, the current state of water management systems in the humid zone requires new effective approaches to both construction and reconstruction [1–4], as well as to the design of regulatory drainage networks [5].

In order to effectively regulate the water regime of the soil, we have proposed new innovative designs of closed regulatory drainage networks, which include drainage modules from periodically repeated drains with different laying depths (figure 1).

Conducted experimental studies show that regulatory networks, which include drainage modules, have a greater hydrological effect than their counterparts and allow to unload the upper layers of the soil from excess infiltration water in a faster time, which is especially important

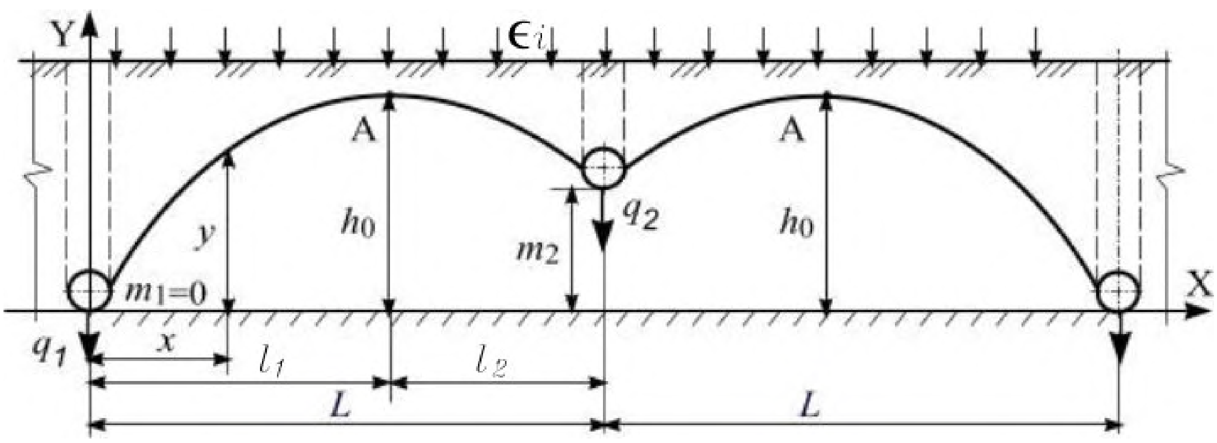

Figure 1. Scheme for calculating groundwater levels between shallow and deep drains during infiltration feeding (the deep drain is located on the waterproof layer, the shallow one is above the waterproof layer), the A-point of the water separation between shallow and deep drains.

during critical periods of the operation of drainage networks (the period of spring floods and the period of summer torrential rains).

Equally important for regulating the water regime of the soil is the calculation of the parameters of the adopted drainage schemes.

2. Materials and methods

If the drainage network is reinforced with additional drains, then in this connection Oleynyk [6,7] proposes a method of filtration calculation of drainage for irrigation arrays. Approximate calculations of such drainage are based on the method of filtration resistances [6]. In the case of imperfect drains by the degree of opening of the aquifer (the drains are above the waterproof layer) and imperfect drains by the nature of the opening of the aquifer (the drains are protected by filtering material), a linear equation is used to predict and calculate the position of groundwater levels when constructing the technique of filtration resistances in any intersection of the filtration flow.

3. Results and discussion

We will calculate the parameters of the regulating drainage module during infiltration water supply of perfect drains of shallow and deep laying (shallow laying drain – perfect according to the degree and nature of the opening of the aquifer, deep – perfect according to the nature of the opening of the aquifer).

Consider the steady, uniform movement of the filtration flow of water in the directions of the deep and shallow drains (from point A, figure 1) of the regulating drainage module in homogeneous soil.

The calculation of the mode groundwater level (for the circuit in figure 1) can be performed on the basis of the Boussinesq's equation, which includes partial derivatives

$$k_f \frac{\partial}{\partial x}\left(h\frac{\partial h}{\partial x}\right) + \varepsilon_i = 0, \tag{1}$$

where ε_i – vertical infiltration of water, k_f – soil filtration coefficient. Since $h = h(x)$, the equation (1) includes ordinary derivatives and will be written in the form

$$k_f \frac{\mathrm{d}}{\mathrm{d}x}\left(h\frac{\mathrm{d}h}{\mathrm{d}x}\right) + \varepsilon_i = 0. \tag{2}$$

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012083 doi:10.1088/1755-1315/1254/1/012083

Dividing the variables of equation (2), we find

$$d\left(h\frac{\mathrm{d}h}{\mathrm{d}x}\right) = -\frac{\varepsilon_i}{k_f}\mathrm{d}x, \tag{3}$$

and after integration we get

$$h\frac{\mathrm{d}h}{\mathrm{d}x} = -\frac{\varepsilon_i}{k_f}x + C_1; \tag{4}$$

$$h^2 = -\frac{\varepsilon_i}{k_f}x^2 + 2C_1 \cdot x + 2C_2; \tag{5}$$

In the case of water infiltration, when $\varepsilon_i > 0$, we obtained equation (5) – the equation of an ellipse.

Let's determine the constants C_1 and C_2 separately for a deep drain arranged on a water-resistant layer and a shallow hanging drain imperfect in degree and perfect in nature of the opening of the aquifer.

Since when $x = 0, h = 0$ and when $x = l_1, h = h_0$, then from equation (5) we find

$$C_2 = 0; h_0^2 = -\frac{\varepsilon_i}{k_f}l_1^2 + 2C_1 \cdot l_1 + 2C_2. \tag{6}$$

where

$$C_1 = \frac{1}{2l_1}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right). \tag{7}$$

Substituting the values of the constants C_1 and C_2 into the equation (5), we get

$$h_0^2 = -\frac{\varepsilon_i}{k_f}x^2 + \frac{1}{l_1}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right)x. \tag{8}$$

After simple transformations in accordance with (figure 1), we make sure that equation (8) defines an ellipse centered on the axis $0x$ at the point x

$$\frac{h_0^2}{\frac{1}{4}\frac{k_f}{\varepsilon_i l_1^2}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right)^2} + \frac{\left[x - \frac{1}{2}\frac{k_f}{\varepsilon_i \cdot l_1}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right)\right]^2}{\frac{1}{4}\left[\frac{k_f}{\varepsilon_i l_1}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right)\right]^2} = 1. \tag{9}$$

So,

$$x = \frac{1}{2}\frac{k_f}{\varepsilon_i l_1}\left(h_0^2 + \frac{\varepsilon_i}{k_f}l_1^2\right)^2 = \frac{1}{2}\left(l_1 + \frac{k_f h_0^2}{\varepsilon_i l_1}\right), \tag{10}$$

where x is the abscissa of the point of the largest h_0 value for a deep drain.

Assuming in equation (10) that $x = l_1$, we find $2l_1 = l_1 + \frac{k_f}{\varepsilon_i}\frac{h_0^2}{l_1}$, where

$$l_1 = h_0\sqrt{\frac{k_f}{\varepsilon_i}}. \tag{11}$$

For an imperfect shallow drain when $x = l_1, h = h_0 - m_2$, and when $x = l_1 + l_2, h = m_2$, then from equation (4) we find

$$(h_0 - m_2)^2 = -\frac{\varepsilon_i}{k_f}l_1^2 + 2C_1 l_2 + 2C_2; \tag{12}$$

$$m_2^2 = -\frac{\varepsilon_i}{k_f}(l_1 + l_2)^2 + 2C_1(l_1 + l_2) + 2C_2. \tag{13}$$

where

$$m_2^2 - (h_0 - m_2)^2 = -\frac{\varepsilon_i}{k_f}(l_1 + l_2)^2 + \frac{\varepsilon_i}{k_f} l_1^2 + 2C_1 l_2; \tag{14}$$

$$2C_1 = \frac{1}{l_2}\left[\left(2h_0 m_2 - h_0^2\right) + \frac{\varepsilon_i}{k_f}\left(2l_1 l_2 + l_2^2\right)\right]; \tag{15}$$

$$2C_2 = (h_0 - m_2)^2 + \frac{\varepsilon_i}{k_f} l_1^2 - \frac{l_1}{l_2}\left[\left(2h_0 m_2 - h_0^2\right) + \frac{\varepsilon_i}{k_f}\left(2l_1 l_2 + l_2^2\right)\right]; \tag{16}$$

Substituting the determined values of the constants into the equation (17), we obtain

$$\begin{gathered}\tfrac{k_f}{\varepsilon} h^2 + \left\{x - \left[\left(h_0 m_2 - \tfrac{1}{2}h_0^2\right)\tfrac{k_f}{\varepsilon l_2} + \left(l_1 + \tfrac{1}{2}l_2\right)\right]\right\}^2 = \\ = \frac{k_f m_2^2}{2\varepsilon_i} + \frac{1}{2}l_2^2 + \frac{k_f}{2\varepsilon_i}\left(h_0 - m_2\right)^2 + \frac{h_0^2}{4}\left[\left(2m_2 - h_0\right)\frac{k_f}{\varepsilon_i l_2}\right]^2;\end{gathered} \tag{17}$$

$$A^2 = \frac{k_f m_2^2}{2\varepsilon_i} + \frac{1}{2}l_2^2 + \frac{k_f}{2\varepsilon_i}\left(h_0 - m_2\right)^2 + \frac{h_0^2}{4}\left[\left(2m_2 - h_0\right)\frac{k_f}{\varepsilon_i l_2}\right]^2. \tag{18}$$

The equation (18) is the equation of an ellipse.

$$\frac{h^2}{A^2 \frac{\varepsilon_i}{k_f}} + \frac{\left\{x - \left[\left(h_0 m_2 - \tfrac{1}{2}h_0^2\right)\tfrac{k_f}{\varepsilon l_2} + \left(l_1 + \tfrac{1}{2}l_2\right)\right]\right\}^2}{A^2} = 1 \tag{19}$$

The abscissa x is the point of the largest h_0 value for a shallow drain

$$x = \frac{\frac{k_f}{\varepsilon_i}\left(h_0 - m_2\right)^2 - \left(2h_0 m_2 - h_0^2\right)\frac{k_f}{\varepsilon_i}\frac{l_1}{l_2} - \left(l_1^2 + l_1 l_2\right)}{\frac{k_f}{\varepsilon_i l_1} h_0^2 - (l_1 + l_2) + h_0\left(\frac{h_0 k_f}{l_2\varepsilon_i - 2m_2}\right)}, \tag{20}$$

$$h_0 = A\sqrt{\frac{\varepsilon_i}{k_f}}. \tag{21}$$

Taking into account the value of A, we get

$$h_0^2 \frac{k_f}{\varepsilon_i} = \frac{k_f m_2^2}{2\varepsilon_i} + \frac{1}{2}l_2^2 + \frac{k_f}{2\varepsilon_i}\left(h_0 - m_2\right) + \frac{h_0^2}{4}\left[\left(2m_2 - h_0\right)\frac{k_f}{\varepsilon_i l_2}\right]^2, \tag{22}$$

where

$$l_2^2 - \frac{h_0^2}{2}\left[\left(h_0 - 2m_2\right)\frac{k_f}{\varepsilon_i}\right]^2 \cdot \frac{1}{l_2^2} + \frac{k_f}{\varepsilon_i}\left[m_2 + \left(h_0 - m_2\right)^2 - 2h_0^2\right] = 0; \tag{23}$$

or

$$l_2^4 - \frac{k_f}{\varepsilon_i}\left[h_0^2 + 2m_2\left(h_0 - m_2\right)\right] l_2^2 - \frac{h_0^2}{2}\left[\left(h_0 - 2m_2\right)\frac{k_f}{\varepsilon_i}\right]^2 = 0. \tag{24}$$

After solving the biquadratic equation (23), we get

$$l_2 = \left\{\frac{1}{2}\frac{k_f}{\varepsilon_i}\left[h_0^2 + 2m_2 h\right] \pm \sqrt{\frac{k_f^2}{4\varepsilon_i^2}\left[h_0^2 + 2m_2\left(hy_0 - m_2\right)\right]^2 + \frac{h_0^2}{2}\left[\left(h_0 - 2m_2\right)\frac{k_f}{\varepsilon_i}\right]^2}\right\}^{\frac{1}{2}}. \tag{25}$$

Then the total distance (figure 1) between the drains of shallow and deep laying $L = l_1 + l_2$.

If in (25) in the root expression $\frac{h_0^2}{2}\left[(h_0 - 2m_2)\frac{k_f}{\varepsilon_i}\right]^2$, and $h_0 = 2t_2$, then $l_2 = 0$ (if there is a sign before the root (–) and if we take a sign before the root (+)), then

$$l_2 = \sqrt{\frac{k_f}{\varepsilon_i}\left[h_0^2 + 2m_2\left(h_0 - m_2\right)\right]}. \tag{26}$$

The total distance (figure 1) between the drains of shallow and deep laying L

$$L = l_1 + l_2 = h_0\sqrt{\frac{k_f}{\varepsilon_i}} + \sqrt{\frac{k_f}{\varepsilon_i}\left[h_0^2 + 2m_2\left(h_0 - m_2\right)\right]}. \tag{27}$$

The largest value of $h = h_0$ (figure 1) can be determined

$$h_0 = \frac{1}{2}\sqrt{\frac{\varepsilon_i}{k_f}} + \left(\frac{k_f}{\varepsilon_i}\frac{m_2^2}{L} + L\right) \tag{28}$$

at the point with the abscissa $x = \frac{1}{2}\left(\frac{k_f}{\varepsilon_i}\frac{m_2^2}{L} + L\right)$.

The value of the ordinate $h(x)$ at an arbitrary value x can be determined using (28).

$$h(x) = \sqrt{\left(\frac{m_2^2}{L} + \frac{\varepsilon_i}{k_f}L\right)x - \frac{\varepsilon_i}{k_f}x^2}. \tag{29}$$

The resulting equations (13), (27) were studied for the possibility of using them to calculate the distance L between perfect regulating drains of shallow-deep laying according to the degree and nature of the opening of the aquifer during infiltration water supply. Equations (13), (27) and (29) include rather relative, interdependent values of l_1, l_2 and h_0.

Analyzing the equation (29), it can be argued that it has an advantage over (8) because it includes only two given values – the distance between the drains L and the hanging height m_2 of an imperfect drain of shallow laying above the waterproof layer.

Thus, the given methods of calculating the parameters of regulating drainage modules operating in the mode of intensive reduction of groundwater level during infiltration water supply in the case of established groundwater filtration allow to predict groundwater level regimes and calculate the distances between drains of shallow-deep laying perfect in terms of the degree and character of the opening of the aquifer.

4. Conclusions

- According to the results of theoretical and experimental research, generally accepted methods and mathematical models describing the movement of water in the soil have been improved.
- Calculations of the parameters of the drainage modules make it possible to predict the groundwater level regimes between perfect and imperfect (material) drains of shallow-deep laying, as well as to obtain the position of the groundwater level in dynamics and in the time during which the groundwater level decrease from the surface of the earth to a depth equal to the drainage rate.
- The methods obtained theoretically and experimentally should be used to calculate the distances between perfect and imperfect (material) drains of shallow and deep laying according to the degree and nature of the opening of the aquifer during infiltration water supply.

Abstract. The modern approach to the implementation of water management activities is based on a quantitative assessment of the quality of water resources, which includes a certain set of indicators to reflect the needs of users in the composition and properties of water, to assess their condition, etc. Ecological assessment is a preliminary stage and a condition for ecological standardization of surface water quality. To analyze the compliance of water quality with ecological standards, the obtained results are compared with the values of ecological standards for the corresponding water body. The study carried out a quantitative assessment of water quality in the Vidsichne reservoir, near Zhytomyr (Ukraine). This assessment is based on the introduction of risk weighting factors from certain types of pollutants to the calculation formula of the integral indicator. Monitoring studies on hydrochemical indicators in the reservoir showed an increase in manganese content to 0.40 mg/dm^3. To calculate the integral indicator of water quality, manganese and the related level of oxygen dissolved in water, biological oxygen consumption (BOC) were selected. It was established that the water in the reservoir belongs to the fourth quality class, that is, it is polluted. A model map of manganese concentration was built and the ecological coefficient of water quality was calculated, which indicates a 5-fold excess of ecological standards. The use of a graphic method of comprehensive assessment of the state of water in any reservoir is substantiated. The increase in manganese content is due to the seasonal increase in air temperature. The constructed mathematical model of the dependence of manganese content on temperature makes it possible to predict the state of the water body depending on climatic conditions and indicates an increase in the value of this indicator from 12°C and above. Quantitative assessment of water quality in the reservoir based on the sum of ecological indicators reflects the needs of users in the composition and properties of water and makes it possible to assess their condition.

1. Introduction

Pollution of water bodies is one of the components of the global environmental problem, which is getting bigger every year. Many changes that occur in the chemical composition of water in rivers are caused by climatic changes. The available numerous methods and techniques are directly or indirectly based on the transformation of quantitative indicators into qualitative indices of the ecological state. According to the analysis of numerous studies, the objective assessment of the ecological state of water bodies is based on the combined use of hydrochemical and hydrobiological data [1–3]. As part of the standard approach, the indicators determined at individual points of the water body are compared with the normative values of the corresponding indicators [4–6]. However, recently, an alternative method of water quality assessment, which uses biotesting, has become widespread [7].

Over the past few years, there has been increasing concern about the decline in the quality and availability of drinking water. This decline in water quality is mostly due to anthropogenic practices such as agriculture, industry, domestic and municipal waste. In order to minimize the recorded impact on water bodies, it is extremely important to understand the overall composition, structure and dynamics of these ecosystems, which allows the implementation of measures (example, more specific procedures, public information and monitoring programs) to ensure the protection of water resources and ensure water quality [8, 9].

Water supplied to the city of Zhytomyr centrally from the city water supply is taken from the Teteriv River in the area of the Vidsichne water intake. Water in the reservoir is characterized by unstable quality, especially during the spring flood and summer months. Water quality during these periods deteriorates, according to the level of phytoplankton, manganese and other indicators.

In previous years, illegal sand mining was carried out near the reservoir, which increased the amount of silt in the reservoir and, accordingly, the accumulation of manganese compounds in the reservoir. Natural processes, such as rock erosion, climatic conditions affect the composition of soil and water in the reservoir area. This leads to a change in the chemical composition of water and affects the development of the reservoir ecosystem [10].

According to the Water Framework Directive 2000/60/EC (WFD), the ecological status of a water body is based on specific physical, chemical, biological and hydromorphological parameters. Especially for highly altered water bodies, the parameters are determined according to the type of reservoir [6].

The purpose of the study was to establish and substantiate the quality of water in the Vidsichne reservoir, near Zhytomyr, using a comprehensive assessment based on the introduction of weighted risk factors from certain types of pollutants to the calculation formula of the integral indicator. The selected pollutant was manganese and the associated level of oxygen dissolved in water, biological oxygen consumption (BOC).

2. Research methods and tools

Three methods were used to quantitatively assess water quality in the Vidsichne reservoir [11,12]. This is the determination of the modified *water pollution index, the ecological coefficient of water quality graphically and the level of the quality of a water object* based on a three-level classification by characteristics. The research used a method of assessing water quality based on the water pollution index, which is common in practice.

The definition of the *water pollution index* is based on indicators of the chemical composition of water, which makes it possible to use information from surface water monitoring. The calculation was based on the following ingredients: manganese, BOC, oxygen dissolved in water. These indicators were chosen because they are mandatory for surface water calculations. According to the methodology, the average arithmetic value was calculated for each indicator, which was compared with their maximum permissible concentrations for each indicator. The water pollution index (WPI) was calculated according to the formula:

$$WPI = \frac{1}{n} \sum_{i} \frac{C_i}{MPC_i}, \tag{1}$$

where C_i is the average concentration of one of the n indicators of water quality, mg/dm^3; MPC$_i$ is the maximum permissible concentration of one of the n indicators of water quality, mg/dm^3; n is the number of indicators [11].

The *ecological coefficient of water quality* in the reservoir was determined according to the standard method with the construction of a map model in the form of a circular diagram with radii scales [12]. The value of division is the MPC of the indicator, and each axis corresponds to the year of observation of this indicator. After constructing the diagram, the ecological coefficient of water (K_e) quality is determined according to the formula:

$$K_e = \frac{F_{fact}}{F_{optim}}, \tag{2}$$

where F_{fact} is the area of the diagram limited by the actual values of the hydrochemical characteristics; F_{optim} is the area of the diagram, limited by the optimal (normative) values, which is found according to the formula:

$$F_{optim} = \pi r^2, \tag{3}$$

where r is the radius of the circle, which is limited by optimal (normative) values.

The third *technique relates to establishing the level of water quality* of the water object Vidsichne. For this purpose, a three-level classification was carried out: 1) according to the signs of recurrence of pollution cases; 2) multiples of exceeding standards; 3) creation of general evaluation scores.

The first degree of classification is based on the determination of the level of pollution resistance. As a measure of the persistence of pollution, the value of recurrence of cases of exceeding the MPC (H), which is common in hydrochemical practice, was used, which was found according to the formula:

$$H = \frac{N_{MPC}}{n}, \tag{4}$$

where H is the frequency of cases of exceeding the MPC of the ingredient; N_{MPC} stands for the number of analysis results in which the content of the ingredient exceeds its maximum permissible concentration; n is the total number of analysis results for the ingredient.

After conducting an analysis of contamination based on repeatability, the following characteristics were identified as qualitatively different:

- pollution can be observed in individual samples, that is, it can be single;
- pollution may be unstable;
- pollution may not be dominant, but obviously persistent;
- pollution can be dominant, i.e. characteristic.

Qualitative expressions of selected characteristics of water pollution were awarded quantitative expressions in points (table 1).

Table 1. Water classification of water bodies according to the signs of recurrence of pollution cases.

Frequency, %	Characteristics of water pollution of water bodies based on recurrence	Partial evaluation points expressed conditionally	Partial evaluation points absolute values
[0;10]	single	a	1
[10;30]	unstable	b	2
[30;50]	stable	c	3
[50;100]	characteristic	d	4

The second level of classification is based on establishing the level of pollution, the measure of which is the indicator F of the multiplicity of exceeding the MPC:

$$F = \frac{C}{C_{MPC}}, \tag{5}$$

where, F is the frequency of exceeding the MPC for the ingredient; C is the concentration of the ingredient in the water of the water body, mg/dm^3; C_{MPC} is the maximum permissible concentration of the ingredient, mg/dm^3.

According to the analysis of water pollution of water bodies, four qualitatively different degrees of pollution level were separated according to the frequency of exceeding standards by a separate pollutant: 1) low; 2) average; 3) tall; 4) very high. Qualitative expressions of the selected characteristics were assigned quantitative expressions of gradations in points (table 2).

When combining the first and second stages of water classification for each of the considered ingredients, generalized estimates of water quality are obtained for a certain period of time (table 3). Generalized characteristics are assigned generalized evaluation points S, obtained as a summary of individual characteristics, as an example, table 3 [11].

Informational materials of the State Agency of Water Resources and the State Department of Environmental Protection in the Zhytomyr region served as the initial data for the calculation of environmental indicators and the construction of models. The data of hydrochemical observations of the laboratory of the city water supply were used as the initial information

Table 2. Water classification of watercourses according to the level of pollution.

Multiplicity of exceeding standards	Characteristics of the pollution level	Partial evaluation points expressed conditionally	Partial evaluation points absolute values
[0;2]	low	a_1	1
[2;10]	average	b_2	2
[10;50]	high	c_3	3
[50;100]	very tall	d_4	4

Table 3. Variations in the water quality of watercourses are possible depending on individual ingredients and pollution indicators.

Comprehensive characteristics of the state of water pollution of the watercourse	Characteristics of the water quality of the watercourse	Partial evaluation points expressed conditionally	Partial evaluation points absolute values
Low-level single pollution	slightly polluted	$a \cdot a_1$	1
Single contamination of medium level	polluted	$a \cdot b_1$	2
High-level single contamination	dirty	$a \cdot c_1$	3
Single pollution of a very high level	dirty	$a \cdot d_1$	4
Unstable low-level pollution	polluted	$b \cdot a_1$	2
Unstable pollution of medium level	dirty	$b \cdot b_1$	4
Unstable pollution of a high level	very dirty	$b \cdot c_1$	6
...	...	...	...

for the study of the qualitative condition of the Vidsichne reservoir, namely, the indicators of manganese, BOC and the content of dissolved oxygen in the water.

3. Results and discussions

Water supplied to consumers in the city of Zhytomyr is taken from the Teteriv River in the area of the Vidsichne reservoir, which is located at a distance of about 8 km from the city (figure 1). A certain supply of water accumulates in the reservoir with very little water exchange, which is due to a geographical position and climatic conditions: firstly, insignificant precipitation, and secondly, long-term hot weather in the summer during the last three years. In addition, due to the incorrect operation of dredgers in Vidsichne, the current moved to the opposite bank. A stagnant zone has formed near the water intake, where silt accumulates. This is an environmental problem that needs a separate solution. Water from streams flowing out of swamps enters the reservoir and contains an increased chemical content of metal ions (for example, iron). Sewage pollution of settlements upstream of the reservoir is observed.

Figure 1. Map of the location of the Vidsichne reservoir.

The specified reasons in the conditions of regulation of the Teteriv River led to a sharp deterioration in the quality of water in the Vidsichne water intake. If during the design period of the city's water supply facilities, the quality of water in the Teteriv River met the requirements for the first class of surface water supply sources by all indicators, but at the present time, due to a number of ingredients, such compliance no longer exists. The analysis of hydrochemical and hydrobiological indicators presented by the chemical laboratory of the city water supply showed that the level of phytoplankton (blue-green algae) and zooplankton in the river water has increased dramatically in recent years. The accumulation of a significant amount of organic nutrients also causes a persistently elevated level of microbiological indicators in the summer-autumn period in comparison with previous years. Such a physical indicator as turbidity increased to an average monthly level of 11.7 mg/dm^3 and a maximum of 14.9 mg/dm^3

during 2020. In addition, prolonged hot weather in the summer period in recent years led to a significant decrease in the content of dissolved oxygen and an increase in carbon dioxide.

As a result of the long-term increase in water temperature in the Vidsichne reservoir, the death of blue-green algae begins, which leads to the deterioration of water quality, and the content of manganese, which reaches 0.40 mg/dm^3, increases. Therefore, according to the Water Framework Directive 2000/60/EC (WFD), the ecological status of a specific water body is assessed by both comprehensive and specific indicators. Such a characteristic indicator for the Vidsichne reservoir is the concentration of manganese ions [6].

Manganese belongs to microelements that significantly affect the metabolic processes in the body of plants and animals. It is one of the main elements necessary for water oxidation in the processes of photosynthesis and carbon utilization in carbo-oxidation reactions around green algae. In aquatic ecosystems, manganese in concentrations exceeding the maximum permissible level becomes biologically dangerous and can be considered as a toxicant. The main factors that increase the manganese content in water are temperature and hydrobiological indicators, that is, the amount of phytoplankton.

The research used the results of chemical analyses of water quality indicators in the reservoir, which were carried out during 2019–2021. To calculate the water pollution index by formula (1), indicators related to the biological oxygen consumption (total), dissolved oxygen, and manganese were used (table 4).

Table 4. The results of the calculation of water pollution indices for the Vidsichne reservoir.

Indicator	C/MPC, ratio for O_2 norm/C in 2019	C/MPC, ratio for O_2 norm/C in 2020	C/MPC, ratio for O_2 norm/C in 2021
BOC$_{full}$	1.650	1.636	1.770
Dissolved oxygen	0.666	0.595	0.617
Manganese	8.000	6.200	8.000
The sum of ratios	10.316	8.428	10.387
Water pollution index	3.46	2.81	3.46
Water quality class	IV	IV	IV

The table 4 shows that for all three years of water research in the Vidsichne reservoir, the pollution index is within 2.80-3.50, which corresponds to the fourth quality class. This means that the water is polluted and under significant anthropogenic influence, the level of which is close to the limit of sustainability of ecosystems. The dynamics of changes in the presented indicators over the years (figure 2) shows a consistently high concentration of manganese in the reservoir.

With a further increase in the concentration of manganese in the water, the ecosystem may lose its balance.

To establish the ecological coefficient of water quality in the reservoir, a model-map with scales-radii for the manganese ingredient was built. The value of dividing such a diagram is the maximum allowable concentration of manganese in drinking water, which is 0.05 mg/dm^3 and the number of axes corresponds to the average annual value of the indicator in 2019, 2020, and 2021 years of the study, respectively ($\bar{C}_{Mn,2019}$, $\bar{C}_{Mn,2020}$, $\bar{C}_{Mn,2021}$). For each indicator, according to the methods described above, average annual arithmetic values were calculated (table 5).

The central shaded circle with a radius corresponding to the MPC value is the ecological optimum. All values of average annual concentrations of manganese that fall into this area correspond to standards for drinking water. The other shaded area is the actual

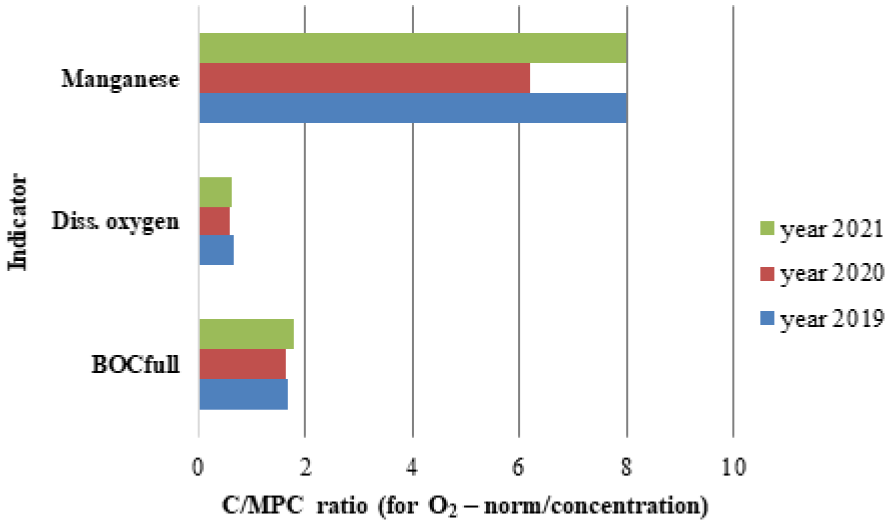

Figure 2. Dynamics of changes in the investigated water quality indicators in 2019-2021.

Table 5. Average annual arithmetic values of the investigated indicators.

Indicator	Average annual values of indicators in 2019	Average annual values of indicators in 2020	Average annual values of indicators in 2021	MPC, mg/dm^3
BOC_{full}, mg O_2/dm^3	4.95	4.91	5.31	3.00
Dissolved oxygen, mg/dm^3	9.01	10.08	9.73	6.00
Manganese, mg/dm^3	0.40	0.31	0.40	0.05

manganese concentration values. Since the indicators are outside the circle, this indicates water contamination with manganese and non-compliance of water quality with regulatory requirements.

Figure 3 presents a model map of manganese for the water of the Vidsichne reservoir. According to the methodology, to calculate the environmental factor of water quality, the following were calculated: F_{fact} – the area of the diagram, limited by the actual values of average annual manganese concentrations, and F_{optim} – the area of the diagram, limited by the optimal value of manganese concentration in water (formula 3). Plotting the actual change in hydrochemical characteristics on the diagram shows the state of the river water, which can be used to consider possible sources of pollution, and the ratio of the area occupied by the diagram of actual pollution to the area occupied by the optimal values of the standardized indicators gives ecological coefficient of water (K_e, formula 2). The values of the first class of ecological classification of the quality of surface water are taken as the optimum. Water quality class: I – very clean – < 0.3:

$$F_{optim} = \pi \cdot 0.3^2 = 0.28.$$

The area of the figure occupied by the diagram of actual contamination, which is the area of the formed triangle, is $F_{fact} = 1.52$. Thus, according to (2), the ecological coefficient of water quality is equal to 5.4. This indicates that manganese contamination of water exceeds regulatory requirements by 5.4 times:

$$K_e = \frac{1.52}{0.28} = 5.4.$$

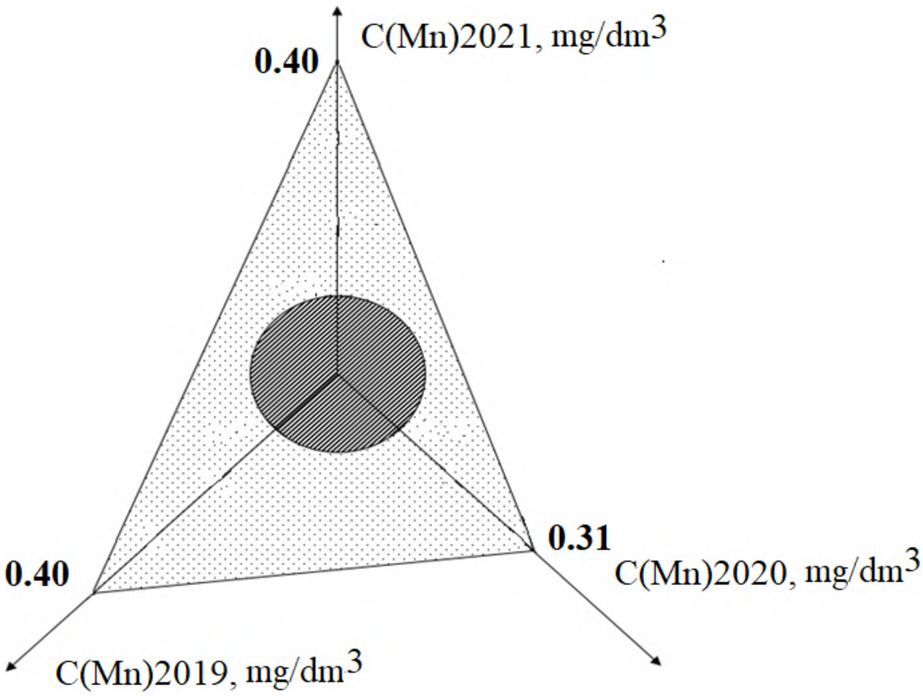

Figure 3. Model map for calculating the ecological coefficient of water quality.

The level of water quality was established according to the method described above for manganese, as the most influential ingredient on the quality of surface water in the reservoir. The calculated value of repeatability of cases of exceeding the MPC is 83% compared to the total number of results (formula 4). This indicates that manganese contamination is dominant, that is, it is characteristic, as the repeatability value is in the range of 50–100%. Such pollution corresponds to the following partial evaluation points (table 3): 1) conditionally expressed – d; 2) absolute values – 4 points.

The second level of classification is based on the establishment of the indicator of the frequency of exceeding the MPC for manganese, as the ratio of the average value of the concentration of manganese over three years to its maximum permissible concentration (formula 5). Calculations showed that the value of the multiplicity of exceeding standards is within 2-10, which corresponds to the average level of pollution, the qualitative expression of which is the following partial evaluation points: conditionally expressed – b_1; absolute values – 2 points. When combining the first and second stages of water classification, we get that the characteristic pollution of the average level is evaluated by generalized points: conventionally expressed – $d \cdot b_1$; absolute values – 8 points. And this means that the water in the Vidsichne water intake is highly polluted with manganese (table 3).

All three considered methods of studying the quality of drinking water make it possible to establish the compliance of water with current regulatory standards. They can be used to establish the ecological character of drinking water by any ingredient [12].

Recently, in the conditions of global climate changes, high temperature indicators, there is a constant increase in the manganese content in the reservoir due to a decrease in the dissolved oxygen content. Further studies showed a direct dependence of this indicator on water temperature (figure 4). Using the method of least squares, we obtained the dependence of Mn concentration (y, C(Mn), mg/dm^3) on temperature (x, °C) in the form of an approximation: $y = ax^3 + bx^2 + cx + d$, where $a = 2.65 \cdot 10^{-4}$ mg/dm^3 °C^3, $b = -6.472 \cdot 10^{-3}$ mg/dm^3 °C^3, $c = 4.461 \cdot 10^{-2}$ mg/dm^3 °C^3, $d = 1.17 \cdot 10^{-1}$ mg/dm^3 °C^3 (figure 4).

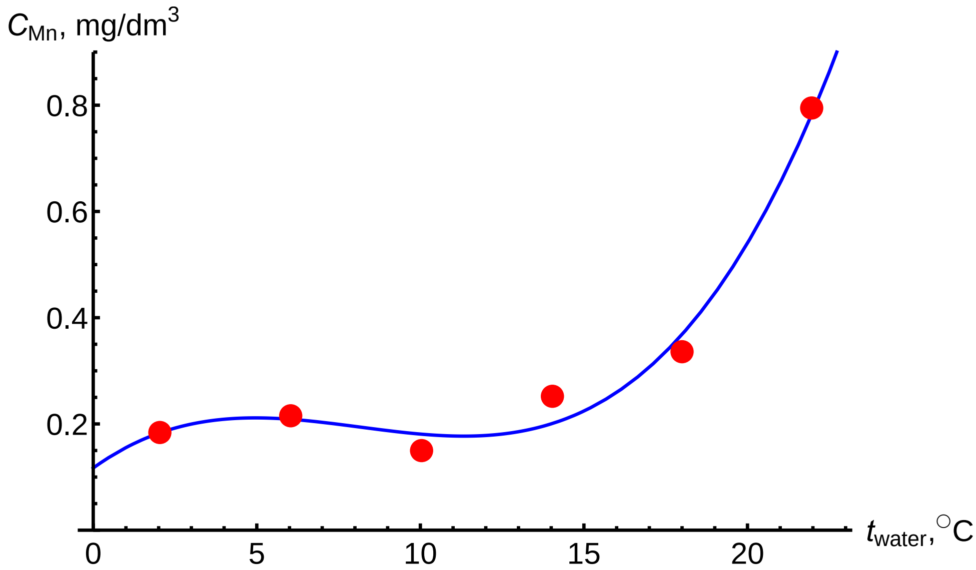

Figure 4. Dependence of manganese content on water temperature

The R^2 approximation reliability value is 0.9831. The assessment was carried out using the Excel program.

The built mathematical model indicates a significant increase in manganese content at temperatures from 14°C to 22°C and higher. At elevated temperatures, the concentration of manganese in water reaches values that are 15 times higher than the standard values.

4. Conclusions

The developed procedure for assessing water quality in natural waters allows us to conclude that the water of the Vidsichne reservoir is characterized by unstable quality. According to the content of manganese, the water belongs to the fourth quality class, that is, it is polluted.

It is reasonable to carry out a quantitative assessment of surface quality based on the following indicators: water pollution index, ecological pollution coefficient and water quality level. The graphical method of comprehensive assessment of the state of water is the basis for calculating the ecological coefficient in any reservoir.

The constructed model-map of manganese concentration for the Vidsichne reservoir indicates water pollution, and the environmental quality coefficient – a 5-fold excess of environmental standards. Mathematical processing of the results of chemical analysis of manganese concentrations during the year showed that the manganese content in water increases with increasing air temperature.

Abstract. The research of the Ukraine's place in global trends of sustainable development from the position of digital economy is presented. An economic essence of digital economy and its significance for Ukraine is studied. Its main components are defined. The relationship between the digitalization of the economy and the level of sustainable economic development is substantiated. Considering the fact that the development of the digital economy is characterized by a large number of indicators at the global level, the Global Connectivity Index is chosen to analyze the relationship with the SDGs achievement. The hypothesis about the dependence of SDGs achieving on the possibilities of the digital economy is confirmed with the help of mathematical modeling using correlation-regression analysis. The analysis of the relationship between Global Connectivity Index and SDGs Index is conducted. The level of influence of GCI component groups (broadband, cloud, AI, IoT) on the levels of SDGs is determined. Based on the analysis two components of the GCI index – the Internet of Things and the state of the broadband Internet, which have a significant impact on the level of SDGs achievement, are identified by the authors. It was found that two other components – the development of artificial intelligence and cloud technologies have a moderate impact on SDGs achievement. The global map of the digital technologies development level in compliance with the SDGs achievement is presented. Visualization on the map makes it possible to group countries with a high level of digitalization and achieving the SDGs on the one hand, and a high level of digitalization and relatively low indicators of sustainable development on the other hand, and vice versa. The analysis of Ukraine's place on this world map is performed. The role of digital transformation in achieving of the defined SDGs is identified.

1. Introduction

Ukraine is one of the largest European countries in terms of territory and population being at the same time quite poor from a financial point of view. Unlike other countries in the world it is rather slow in carrying out key reforms, in particular tax, land and labor market reform, etc. Until now, the period of transformation to a market economy has not been properly completed, and acceptable conditions for attracting investments and conducting business have not been created. Since 1991 the state's population has decreased by more than 10 million people. The main factors of the demographic crisis which we can now observe are, first of all, war with Russian invaders and martial law, the excess of mortality over the birth rate and population migration from Ukraine. These reasons as well as weak economic and social development, the inability to ensure a high standard of living led to the fact that many Ukrainians decided to leave the country. Labor migration causes losses to the Ukrainian's economy.

But simultaneously Ukraine is characterized by high growth rates of the IT sector – 20-35 % annually. The developed IT industry is quite an considerable factor in the growth of technological efficiency of the Ukrainian's economy. This industry is export-oriented (more than half is exported to the USA). Computer services account for almost 25 % of all services exports of Ukraine. The export share of IT in the total structure of exports is almost 7 % and it shows annual growth. The growing demand for digital technologies, cloud data storage, and cyber security can become a powerful driver of the further growth of the domestic IT sector. It is necessary to underline that many residents of the country who emigrated continue to work for Ukraine while working abroad online. The full-scale military aggression of the Russian invaders did not slow down the pace of transformation of Ukraine's digital environment. Over past 20 years the digital economy development is supposed to be one of the predominant factors that have influenced a significant increase in labor productivity in the global economy and also contributed to improved access to quality public and social services.

Ukraine invests only 0.5 % of GDP in R&D centers. This is three times less than the indicators of Poland and five times inferior to the indicators of Hungary. The low level of investment in innovative developments creates a more than 3-fold gap in labor productivity with neighboring EU member states [1]. A significant barrier to the digital economy development of Ukraine is digital divide, which includes such components as: technological, competence, economic, financial, and physical. It makes it impossible to realize the rights and responsibilities of citizens by limiting access to technologies, competences, means of digital production and interaction. In the conditions of the digital economy there is an opportunity to form and develop skills in the usage of digital technologies, their individual aspects, phenomena and processes as well as the use of relevant tools to substantiate optimal decisions, including solving complex economic tasks.

In the conditions of the digital economy the structure of business is changing in the form of its management, the cooperation with other counterparties is being established in other ways. As aptly noted by TechCrunch, the Uber company, although it is the largest, does not own any vehicles. The Facebook network does not directly create its own content. Alibaba, as the most powerful platform for sales, does not have its own products that can be sold. This indicates that something really interesting is now happening [2]. Digitization of life activities as a necessary technical condition of the contemporary global economy is the main tool that ensures its development. In the process of transition to sustainable development the task of mandatory consideration of the environmental factor necessarily arises. To properly ensure the sustainable development of society, the ecology of the environment should not be disturbed, the natural basis for the reproduction of human life should be preserved. Nowadays the main goal of sustainable development ensuring is dynamic socio-economic growth and the preservation of the environment, rational usage of the existing potential of natural resources to meet the needs of the present and future generations as well as development of an effective economic system etc. Sustainable development requires the presence of several vectors, including nature, production and society. It targets business to operate without harming the environment with effective financial indicators at the same time [3].

A total of 17 positions are allocated to the goals of sustainable development (SDGs). Undoubtedly, the role of digital transformation in Ukraine in SDGs achievement is significant. It will be investigated in this work. However, it should be noted that, in turn, the implementation of some of the SDGs will also contribute to the improvement of a current level of the digital economy of Ukraine.

2. Literature review

Under the conditions of the globalization next wave priority is given to the progressive digital economy in the development of the country. Its key factor is information, knowledge and ways of accessing them. Being a virtual environment the digital economy is able to complement the existing reality of today. Of course, it has a lot in common with the traditional economy. It is often difficult to draw boundaries between them. There is still no single definition of it agreed upon by the international community. In the vast majority of foreign sources, the emphasis is on the description of technologies and methods of interaction between economic agents when somebody is interpreting the digital economy. At the same time, specific types of technologies are often noted and certain forms of changes in economic processes are indicated. Sometimes the actual definition of the digital economy is replaced by a list of directions of its influence on economy or social sphere. It is worth noting that there is still no single concept of building a digital economy in Ukraine.

The concept of the digital economy in modern economic realities and the description of its boundaries will make it possible to create a multifunctional system of statistical measurements for its continuous monitoring of the digital economy, substantiation and evaluation of the digitalization policy. The term of digital economy first appeared in in the second half of the nineties of the twentieth century. In these years works of Tapscott [4] and Negroponte [5] were published. This term became widespread, the concepts of Web, Network, New and Internet economy. This term acquired a specific meaning. Digital economy began to develop in the late 1950s, and since the 1960s, digital innovation has been actively spreading around the world. The next (second) stage of digitalization is associated with the worldwide spread of mobile communications and the Internet which is characteristic of the mid-90s of the 20th century. In definitions of the digital economy by Tapscott the emphasis is placed on the Internet as its main component [4].

Supporting this position, we note that the main resource of knowledge in the period of the digital economy is information, if it has the characteristics of accuracy, reliability, timeliness. It is obtained precisely with the use of the Internet. The virtual network of the Internet traditionally serves as the basic platform for the digital economy progress. In recent years significant changes took place in human life. Thanks to the use of smart things, technology of blockchain, industrial Internet of things, the production process and forms and management models have also changed. Now the digital economy, based on digitization and its own specifics makes it possible to overcome spatial and sectoral limitations. It is impossible without financial technologies (FinTech), the Internet of Things (IoT), e-commerce, digital marketing (Digital Marketing) and principles of e-business management.The development of intelligent systems connected to the Internet of Things can create unique opportunities to strategically address challenges related to the UN Sustainable Development Goals to ensure a just, environmentally sustainable and healthy society [6].

The next stage of digitization that we are currently observing is connected with the proliferation of digital currencies. Various digital currencies (bitcoins and others) have already confidently won their place on the global financial market, their quantity (as well as the scale of operations with them) is increasing. This led to the formation of a new currency component of the financial world architecture that meets the requirements of the times. They have been in use since 2009 and in 10 years have proven their demand and importance. The classic understanding of the digital economy is that it is an activity the production key means in which are digital data and the mechanism of their usage. This makes it possible to significantly strengthen the efficiency or productivity of various economic activities. The economy, which involves the usage of digital technologies or services, is also called digital. In the interpretation of the essence of the digital economy by the Australian government, attention is drawn to the fact that it is a global network of activities, in particular economic and social, which is provided thanks to communication and information technologies.

The digital economy necessarily uses devices that we deal with every day, for example, phones and laptops. It allows you to quickly find the best place for rest or entertainment, quickly receive important information from a friend, etc. When paying for goods, you can use credit cards. Its mechanisms are also may be used during treatment. Companies that conduct business using elements of the digital economy are able to improve cooperation with contractors, buyers or suppliers. Digital economy is supposed to be a key driving force provoking economic growth. Bahl claims that this has profound consequences for doing business in the regions [7]. The definition of the digital economy provided by Bukht and Heeks is vague, somewhat blurred. We accept that it is based on digital services or goods, but we do not agree that it is part of the economic result [8]. Kolyadenko examines the digital economy as such, which is based on the manufacture of electronic services, goods and the spreading of them using e-commerce (computer networks) [9]. Veretiuk and Pilinskyi draws attention to the fact that the computer platform serves as a means to which the digital economy transforms all information knowledge as well as resources [10].

The digital economy is considered to be basis of the Industrial Revolution (Fourth) while the change in the general technology is clearly visible and there are signs of a change in the techno-economic paradigm. The modern phase of the industrial revolution is connected with the progress of Internet communication technologies, which have significantly changed the technology of business processes and received the name "digitalization". Summarizing existing definitions of digital economy, it should be noted that in most the component approach of definitions prevails.

Mesenburg distinguish such three component parts of digital economy: auxiliary infrastructure; e-business (conducting business activities through network); e-commerce (distribution of goods, products and services using the Internet) [11]. Therefore, the most successful, to out mind, is the following definition: digital economy is an dynamical innovative economy which is based on the innovations and information implementation as well as communication technologies in various types of economic activities and spheres of society life, which in turn makes it possible to increase the effectiveness, strength and competitiveness of various companies and the standard of population living in general. Digital transformation fundamentally converts areas and business processes based on the Internet and innovative digital technologies, that is, it is not limited to the implementation of information technologies. The digital economy is capable to significantly change existing business processes [12]. The modern Industry 5.0 system puts a human-centered approach at the center of the production process and uses innovative technical advances to ensure sustainable and sustainable intelligent production [13].

The digital economy is a driver for development and accelerating worldwide economic progress, increasing the level of labor productivity, creating new markets and types of economic activity. This is confirmed by the cooperation between the G20 countries, which are actively involved in the development of the digital economy. The digital economy definitely creates opportunities for sustainable and inclusive growth [14]. Those countries and associations that plan, gradually and systematically build the foundations of leadership and actively join the mechanisms of the digital economy achieve accelerated economic development at a faster rate. The progress of digital economy in general involves a significant transformation of labor market, which is characterized by complexity. This process is taking place gradually, because an increasing number of traditional sectors of the economy involve elements of the digital economy in activities conducting. It is worth emphasizing that the consept of "digital shadow economy" is also wide spread in the world. For example such its components are researched by scientists, as determinants of consumers' illegal behaviour online [15].

It has been established by Gasparėnienė et al that the digital shadow economy is an illegal operation in the Internet used to generate illicit cash flows for suppliers of goods/services or buyers. It allows to avoid officially declared income, because it can be not calculated and not accounted [16]. Research by these authors is a substantial contribution to the theory evolution of digital economy in general. It shoud be also pointed out that digital economy is a priority component of an innovative economy. As Pavelko et al note, formation of innovative economics should be aimed at reduction the cost of production, developing high-quality products, advance of human life and elevation it to a qualitatively brand new level [17]. The new products at the same time involve various innovative digital technologies types and forms.

The digital economy has a specific feature. It is related to the on-demand economy, that is, when using it, there is no sale of services, goods and access to them specifically at that moment when they are required. Receiving orders are placed online, and their fulfillment – offline. The advantages of the on-demand economy are the next: high velocity of obtaining the required services or goods; a decrease in their value for the end user due to a reducing in the number of intermediaries on this path; simplifying the exit of goods and services suppliers to users. Digital economy for its successful formation needs effectively functioning of three components: regulatory and legal framework that would contribute competition and entering the market for enterprises, allowed companies to fully use digital technologies; skills which are required by employees for use possibilities of digital technologies; effective establishments which use the Internet in order to increase rights and enlarge opportunities of citizens. It should be noted that in current conditions of the digital economy development digital skills as well as innovations and competitive advantages are key to achieving individual success [6, 18–21]. From the macro level point of view we speak about the level of society digitalization and smart cities [22, 23]. The digital economy acts not only as an effective foundation for the progress of public administration system, sphere of society, business, economy, the but also contributes to the achievement of a whole sustainable development, which will be confirmed in this article.

According to UNESCO sustainable development is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." Corejova and Chinoracky [24], Laitsou et al [25] agree that the digital economy can be seen as a tool for expanding economic growth which, in turn, is part of the concept of sustainable development. Many researchers point to a positive connection between the development of the digital economy and sustainable development. Frey noted that the development of the digital economy can provide a sustainable development stimulus for economic growth [26]. Skliarov and Prokopov note that the development of the digital economy will transform the traditional economy from a resource-consuming economy to a resource-creating economy [27]. The intensive development of the digital economy not only provides spatial growth momentum for the region, but also helps to promote the economic growth of neighboring regions and ultimately forms regional coordination and sustainable development [28]. The role of infrastructure is undeniable in the growth process of any economy, as it helps to diversify production, expand trade, overcome the pressure of demographic and environmental problems and ultimately improve the quality of human life [29].

International analytical agencies also pay great attention to the relationship between digital technologies and sustainable development. Huawei's report "Accelerating SDGs through ICT" shows that SDG 4 (Quality education), SDG 3 (Good health and well-being) and SDG 9 (Industry, innovation and infrastructure) with 73 %, 71 % and 65 % respectively have the highest the level of interconnection with the development of digital technologies. The report also emphasizes that even small technological improvements can lead to better achievement of the aforementioned SDGs [30]. However, digital transformation also increases inequality and undermines social cohesion, given the gap between countries with access to the Internet (over 80 % of the population in developed countries) compared to developing countries (45 %) [31]. For developing countries that are lagging behind the most, SDG 1 on poverty reduction and SDG 5 on gender equality are most relevant. In the future, the digital economy is potentially the largest and most important opportunity for dynamic change in sustainable development worldwide [32–35]. In addition, digitalization is seen as a key driver of transformative environmental change and innovation in the next decade [36].

Countries are innovating and transforming practice by adopting and adapting the DPG. Such DPGs as digital payment solutions, data transfer protocols or digital health services can be included to improve the delivery of public services in a safe, reliable and inclusive way. Properly assembled, DPGs can create a digital public infrastructure that is powerful enough to ensure societal impact for current and future generations [37]. Zhuge et al conclude that new enterprises can deepen their competitive advantages by improving their digital capabilities, which leads to improved performance in terms of environmental, economic and social benefits and promotes sustainability. Green knowledge creation acts as a mediator between digital capabilities and sustainable development [38]. Understanding the relationship between the SDGs and digitalization allows for the development and coordination of national digital economy policies and programs that contribute to better sustainable development [39].

Imran et al [40] show that the digital economy does not always have a positive effect on sustainable development. Thus, 4G coverage and mobile broadband have been found to be positive in terms of impact on SDGs. Total Fixed Broadband Coverage and Fixed VHCN are significant but have a negative impact on SDGs. ICT professionals and ICT graduates were significant variables that negatively affect the SDGs. Use of Internet services has the largest number of subdimensions, five of which are significant. These are: news, social networks, online courses, banking and shopping. The first two have a positive effect on SDGs, and the last three have a negative effect [40]. While synergies between digitization and sustainable development are generated in aspects related to economic and social sustainability, trade-offs arise in areas related to environmental protection, such as climate change, depletion of natural resources and waste generation due to their negative connection with existing models of economic development [41]. Also, digitalization may contradict a just transition to sustainability if the digital regime is not reoriented towards inclusive practices, democratic governance and environmental regulation [42].

The paper's hypothesis is that the development vectors of global digital economy are closely correlated with the sustainable development goals. Taking into account the fact that the SDGs achievement is related to the level of digital transformation, we will perform an analysis of the relationship of individual indicators at the global level. We will also investigate the role of Ukraine's digital transformation in SDGs achievement.

3. Material and methods

The main evaluation systems of digital development indices include the European Union (EU) Digital Economy and Society Index, the Organization for Economic Co-operation and Development (OECD) digital economy indicator system, the World Economic Forum (WEF) Network Readiness Index (NRI), the Digital Evolution Index (DEI); Digital Adoption Index (DAI); ICT Development Index (IDI); Global Innovation Index (GII); economy digitization index (Boston Consulting Group – e-Intensity); the world digital competitiveness index (IMD World Digital Competitiveness Index – WDCI). A commonly used tool is the Digital Economy and Society Index (DESI).

Given that digital technologies and global connectivity are comprehensive and deep, the Global Connectivity Report is published annually, which provides a detailed analysis of global digital connectivity and its mechanisms. The Global Connection Report 2022 provides analytical data on digital development of society by countries, regions, categories of population, gender, etc. [43]. The global connection index (GCI) can be considered as an indicator of the digital economy development. GCI provides an opportunity to analyze a wide range of ICT infrastructure. The index was calculated for the first time in 2014. 79 countries are involved in the calculation, each of which calculates 40 indicators of development of digital technologies, the impact of information systems development on economic growth. The 40 indicators can be analyzed both vertically (Supply, Demand, Experience, Potential) and horizontally (Broadband, Cloud, IoT and AI) [44].

The UN Sustainable Development Agenda for the period up to 2030 envisages 17 SDGs in the global system. They aim to solve fundamental problems such as ending poverty and hunger, protecting the planet and ensuring peace. The SDGs are also aimed at other priorities, in particular the prevention of climate change, economic inequality, the development of innovations, sustainable consumption, peace and justice [45]. Through the definition of the SDGs Index, for each country, a total score characterizing the level of SDGs achievement, is determined. The maximum score – 100 points – corresponds to the achievement of all SDGs [46]. Given the fact that achieving of the SDGs is largely related to the level of digital transformation, it is advisable to analyse the relationship between these indexes at the global level and to determine which of The Four Technology Enablers have an impact on SDGs achieving. The values of the indices for each country, which are the basis for analysis of the relationship, are given in the table 1.

Table 1: GCI and SDG Index indicators (2020), based on [44, 45].

Country	GCI Total	GCI Broadband	GCI Cloud	GCI AI	GCI IoT	SDG
Algeria	32	44	24	21	24	70.9
Argentina	45	56	59	30	33	72.8
Australia	72	98	54	39	57	75.6
Austria	66	78	39	39	69	82.1
Belarus	46	64	33	21	30	78.8
Belgiu	66	83	54	42	51	82.2
Brazil	47	59	42	27	30	71.3
Bulgaria	52	65	36	24	27	73.8
Canada	70	95	54	39	48	79.2
Chile	55	68	51	30	45	77.1
China	62	84	66	48	42	72.1
Colombia	42	41	42	30	33	70.6
Croatia	51	63	36	24	39	80.4
Czech Republic	57	72	39	30	42	81.4
Denmark	77	90	57	48	78	84.9
Ecuador	38	42	30	30	33	72.5
Egypt	36	41	30	24	31	68.6
Estonia	61	78	36	33	45	81.6
Finland	76	89	63	42	75	85.9
France	70	89	54	45	57	81.7

The hypothesis that the achievement of the SDGs depends on the capabilities of the digital economy can be confirmed using mathematical modeling, that is, its expression through a regression equation. Regression analysis will make it possible to draw reasoned conclusions about the relationship of the studied quantities, which are based and supported by specific mathematical calculations. In the case of the relationship between GCI indices and SDGs it is advisable to analyze the degree and nature of the influence of each of the groups of GCI components (broadband, cloud, AI, IoT) on the level of SDGs as well as to conduct such an analysis in the form of a multivariate correlation analysis, which evaluates the strength of the relationship between the studied variables

Using a multiple regression analysis it is possible to select a multivariate statistical model and to describe the form of the relationship between the factors. A multivariable linear regression model with m independent (factor) variables will look like this:

$$Y_t = a_0 \cdot x_{i0} + a_1 \cdot x_{i_1} + a_2 \cdot x_{i_2} + a_3 \cdot x_{i_3} + \sum i \quad (1)$$

where x_{ij} are the factor variables – broadband, cloud, AI, IoT; i – number according to the order of the object in the population being studied, $i = 1, 2, \ldots, n$; $\sum i$ – a random error that has a mathematical expectation of 0 and a variance q_2; x_{i0} – dummy variable equal to 1 in all observations.

In this model the parameters a_{ij} to be estimated are unknown.

Regression statistics calculated from the original data are shown in table 2.

Table 2. Regression statistics

Multiple R	0.765531723
R Square	0.586038819
Adjusted R Square	0.554195652
Standard Error	3.180923684
Observations	57

As can be seen from the above data there is a close relationship between the SDGs and the GCI. The correlation coefficient of 0.7655 between the specified arrays of data indicates a close direct connection between the global level of sustainable development and digital transformation.

Correlation coefficients of individual components of GCI with SDG are given in table 3.

Table 3. Correlation coefficients

	Broadband	Cloud	AI	IoT
SDG	0.611104	0.312098	0.503799	0.699281

The results of analysis of variance are shown in tables 4, 5.

Table 4. Analysis of variance (part 1).

	df	SS	MS	F	Significance F
Regression	4	744.863359	186.2158	18.40391	1.78425E-09
Residual	52	526.1503253	10.11828		
Total	56	1271.013684			

Table 5. Analysis of variance (part 2)

	Coefficients	Standard Error	t Stat	P-value	Lower 0.95	Upper 0.95
Intercept	66.8172	1.9061	35.0548	0.0000	62.9924	70.6420
Broadband	0.0839	0.0403	2.0798	0.0425	0.0030	0.1648
Cloud	-0.1695	0.0548	-3.0914	0.0032	-0.2796	-0.0595
AI	0.0825	0.0913	0.9031	0.3706	-0.1008	0.2657
IoT	0.1921	0.0512	3.7524	0.0004	0.0894	0.2948

The estimation of the parameters based on the results of the correlation-regression analysis indicates the adequacy of the obtained model. The analysis of correlation coefficients makes it possible to determine the degree of influence of digitalization factors on SDGs achieving.

We can see that the highest level of influence (coefficient 0.699) has the level of development of the Internet of Things. This situation can be explained by the fact that the spread of such achievements of the digital economy as sensors hat transmit information to databases for managing people's habitat, strengthening the interconnection between various devices that accelerate management processes, make it possible to solve environmental problems quickly, control the state of air and water, expand the possibilities of agriculture to overcome the problems of poverty, etc. The state of broadband Internet also has an important role (correlation coefficient 0.611) for the achievement of the SDGs. As the basis for the development of digital technologies the collection and transmission of information, this component directly affects the development and achievements of industry, health care, education, energy conservation, city management, etc. The development of artificial intelligence has a moderate relationship with the SDGs. We explain this by the fact that the latest achievements of artificial intelligence may not become widely distributed in a short period of time and therefore may have a certain time lag. As for cloud technologies we do not observe a significant relationship with the resulting indicator, which can be explained by the fact that cloud technologies are only a tool for storing and accessing information.

The global map of the level of digitalization in accordance with the achievement of the goals of sustainable development looks like this (figure 1).

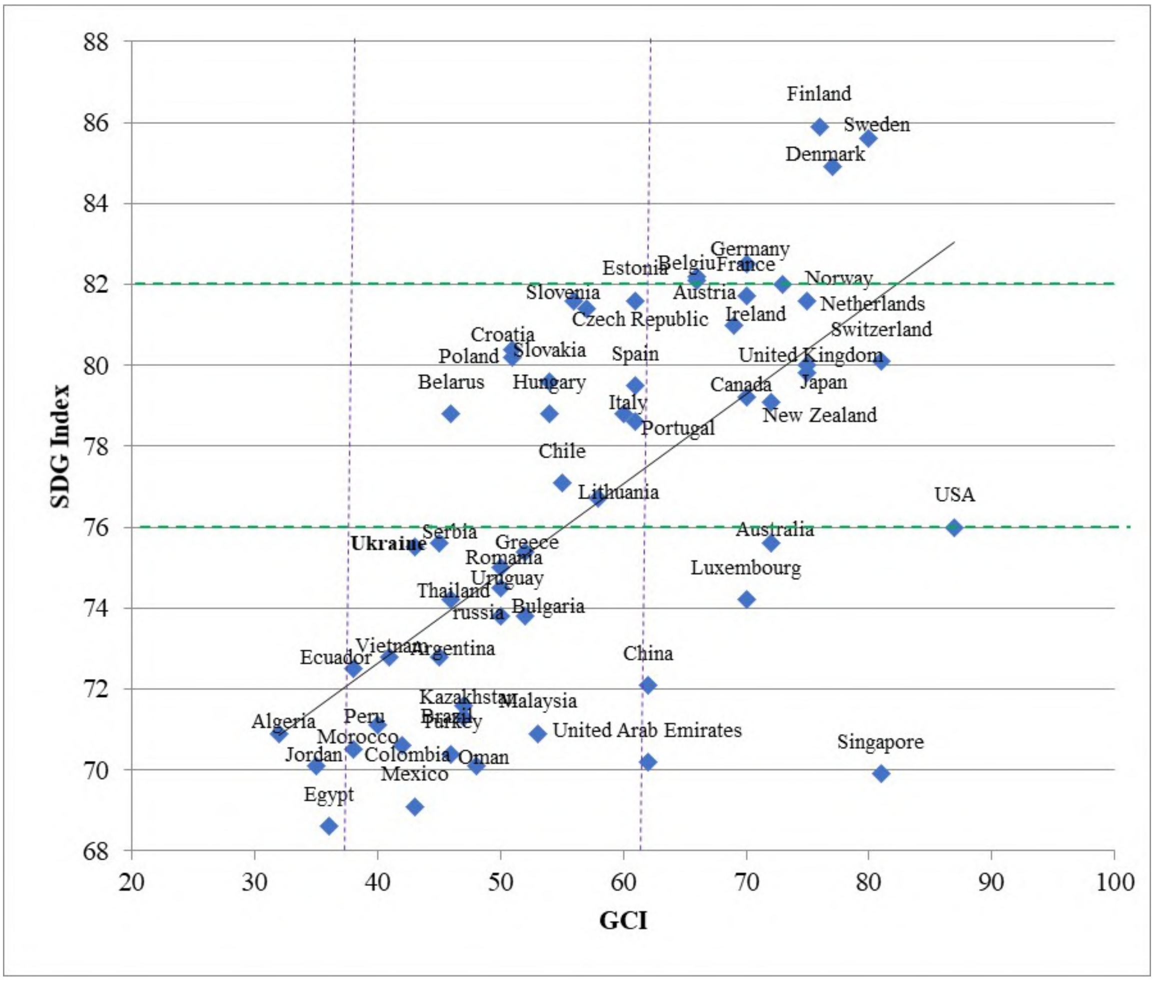

Figure 1. Global Connectivity Index and Sustainable Development Goals Index (2021).

According to figure 1 it is possible to clearly trace the three leading countries in terms of the level of digital transformation and the achievement of sustainable development goals – Finland, Sweden, and Denmark, which have the highest SDGs Indicator level and one of the highest indicators of digitalization. The group of countries with a high rating of the development of the digital economy and a sufficient level of indicators of sustainable development include mostly developed European countries (Germany, France, Norway, Austria, Netherlands, Switzerland, United Kingdom), as well as Canada, Japan, and New Zealand. A number of countries with a relatively lower rate of achievement of sustainable development goals (USA, Australia, Luxembourg, Singapore) demonstrate, however, a high level of development of digital technologies. Ukraine, with a Global Connectivity Index of 43 and a Sustainable Development Goals Index of 75.5, is in the group of countries with an average level of digital technology development and a below-average level of achievement of SDGs. However, the dynamics of Ukraine's indicators are positive both by one and by another indicator. And in terms of the level of digitalization Ukraine confidently holds the first positions in the context of the speed of progress. So, taking into account the fact that the SDGs are closely correlated with the development vectors of the global digital economy we will determine the key trends and prospects of digital transformation in Ukraine in accordance with the 17 SDGs (table 6).

Table 6: The role of digital transformation of Ukraine in achievement of the SDGs.

SDG	The impact of digital transformation
1. No poverty	Digitalization provides opportunities for the least protected sections of the population to have access to social programs through online platforms, crowdfunding, mobile applications
2. Zero hunger	Digital transformation makes it possible to improve the efficiency of agricultural production on the basis of precision agriculture, allows to ensure the openness and stability of the agricultural market
3. Good health and well-being	Digital medicine enables online interaction between patients, healthcare professionals and institutions using digital technologies through the creation of a national electronic system
4. Quality education	The digital vortex brings digital skills (competencies) to the first positions among all the skills of citizens. Learning is changing from a "know-it-all" principle to a "knowing how to learn throughout life and become self-fulfilled and competitive". Digital technologies provide much wider access to knowledge, and also contribute to the emergence of new professions
5. Gender equality	Digital transformation in Ukraine allows men and women to have equal access to information resources, and to perform various types of work that reduce the level of differentiation between men and women
6. Clean water and sanitation	The use of sensors in the Internet of Things as well as their system analysis by means of Big Data allows monitoring the state of water and its use
7. Affordable and clean energy	The analysis of Big Data obtained through a network of digital tools makes it possible to develop projects for the use of renewable energy sources, to modernize the existing energy complex with the aim of efficient use of energy resources

Continuation of table 6

SDG	The impact of digital transformation
8. Decent work and economic growth	The systemic development of "open data" is an important factor in economic growth and can affect the growth of the EU economy by 0.5–1 % [47]. If there are risks of unemployment in certain professions, the digital transformation creates new types of economic activity that give every person the opportunity to realize himself.
9. Industry, innovation and infrastructure	Innovative development through digitization is ensured by large-scale initiatives to integrate the best international ICT practices into industrial sectors. As a result, the formation of joint groups that will unite specialists of digital technologies and industry in order to develop and implement integrated products and services is predicted. This will significantly contribute to the innovative development of the industry, will allow to reduce costs and significantly increase the added value due to the use of improved digital infrastructure.
10. Reduced inequalities	The access of various strata of the population and social groups to digital technologies, in particular mobile applications, electronic platforms, remote communication, makes it possible to realize personal interests of a person, to work remotely, which reduces social inequality
11. Sustainable cities and communities	Smart City complexes, built on the basis of the interaction of IoT, Big Data Analysis, electronic platforms and other digital technologies, make it possible to make cities safer, more comfortable for residents through monitoring the quality of city air, water, traffic flow management, social services, etc.
12. Responsible consumption and production	Achieving this goal of sustainable development is largely facilitated by the development of the sharing economy, which includes shared living (coliving), shared use of cars (carsharing), offices (coworking), gadgets, clothes and even food (foodsharing). Part of this digital trend includes cloud technologies
13. Climate action	The means of the Internet of Things make it possible to monitor air quality, emissions of harmful substances, use of electricity, and take appropriate operational measures to combat climate change.
14. Life below water	The use of digital technologies allows more efficient use of marine resources for sustainable development, in particular through satellite images, analysis of large arrays of data obtained through sensors
15. Life on land	Digital control of soil quality, biodiversity, use of natural resources, promotes their sustainable use
16. Peace, justice and SI	Expanding citizens' access to digital state services, platforms, development of open data contributes to the achievement of this goal
17. Partnerships for the goals	A global partnership enabled by digitalization is bringing countries and continents together to achieve the Sustainable Development Goals. An example is Ukraine's assignment to the "Digital Europe" program, which provides financing for digitization projects

The digital agenda of Ukraine "Ukraine 2030s – a country with a developed digital economy" [48] defines the key strategic, operational directions of digital transformation, development scenarios, a list of digitalization initiatives and projects as well as ways of managing challenges associated with the specified processes.

So, the digital transformation of Ukraine, which is focused on such key digital trends as: data, which is becoming the main factor of competitiveness; development of the Internet of Things; digital transformations of economic sectors; sharing economy; virtualization of IT systems of the physical infrastructure; Artificial Intelligence; digital platforms, rapidly bringing Ukraine closer to achieving the SDGs. The full-scale military aggression of the Russian Federation not only did not slow down the pace of digital transformation of Ukraine, but also contributed to the development of all these processes with the aim of bringing Ukraine closer to victory.

In particular, it should be mentioned that the functionality and number of users of the state digital application and "Diia" portal for citizens to receive public services online has significantly expanded. The application "eEnemy" has found its usage for the identification of Russian troops on the territory of Ukraine. Another important achievement of Ukraine is that the application for electronic registration of damaged property became in demand, the idea of a digital mortgage "eOselya" became revolutionary. Thus, the volume of educational programs for the development of digital education has expanded considerably as well as the number of regional informatization programs has increased.

4. Conclusions

Consequently, the development of the digital economy at the global level and at the level of national economies significantly contributes to the SDGs achievement. It is evidenced by the results of the conducted research. According to the authors' calculations there is a close relationship between the SDG Index and the GCI.

Based on the analysis the authors identified two components of the GCI index – the Internet of Things and the state of the broadband Internet, which have a significant impact on the level of SDGs achievement. This is due to the fact that the use of elements of the Internet of Things, interconnected by digital technologies of devices and sensors, which allows the transfer and exchange of data between the physical world and computer systems in automatic mode, makes it possible to solve economic, environmental, and social problems quickly and promote sustainable development. The explanation of the close connection between broadband and the level of sustainable development is also quite simple, since the speed of accumulation and exchange of information, the use of elements of artificial intelligence and other achievements of the digital economy directly depends on its quality and coverage density. This, in turn, contributes to sustainable economic development.

The development of artificial intelligence and cloud technologies have a moderate impact on SDGs achievement. The authors explain this result by the time gap between the latest achievements of AI and their widespread introduction into social processes that would have an impact on sustainable development, simultaneously cloud technologies are only a tool for storing and accessing information.

The analysis of Ukraine's place on the world map of the digital economy development and the level of SDGs achievement leads to the conclusion that Ukraine with a Global Connectivity Index of 43 and a Sustainable Development Goals Index of 75.5 is in the group of countries with an average level of digital development technologies and below the average level of SDGs achievement. At the same time a positive dynamic is observed for both indicators.

The authors identified the key trends and prospects of Ukraine's digital transformation in accordance with the 17 SDGs and the Digital Agenda of Ukraine "Ukraine 2030E – a country with a developed digital economy". The implementation of the above prospects will make it possible to move steadily towards achieving the SDGs even during martial law.

Abstract. A research of the causes and consequences of bulking of activated sludge was conducted at existing biological wastewater treatment plants (municipal and local at an industrial enterprise). The filamentous bacterium that was caused the bulking of the activated sludge in the studied treatment plants was identified as Type 021N. It was established that the studied filamentous bulking causes a significant deterioration of the technological characteristics of activated sludge flocs and it is accompanied by suppression of the nitrification process. To suppress the bulking of activated sludge two methods of suppressing the inflow of hydrogen sulfide into biological treatment plants were successfully used: blowing from wastewater at municipal treatment plants and inhibiting its formation at local treatment plants in the settling and laminar flow zones.

1. Introduction

The ability of activated sludge to form strong, rapidly easy settling flocs is one of its main properties, which is used to organize the process of biological wastewater treatment in the system of aeration tank–secondary clarifier. The formation of flocs is due to the presence in the microbiocenosis of active sludge bacteria, which secrete biopolymers-flocculants. In this way, they aggregate and spontaneously separate from the treated liquid. Bulking of activated sludge is a violation of the process of separation of activated sludge from purified wastewater. This is due to the intensive development of filamentous microorganisms, which causes the losses of sludge its ability to sedimentation [1–5]. The development of such type of activated sludge leads to a decrease in the volume of excess sludge water, a deterioration in the density and water yield of the sludge, an increase in the content of suspended substances in purified water, removal of sludge particles together with purified water, and a decrease in the concentration of activated sludge in the recirculation flow until it is completely removed from the system [6–8]. Thus, bulking of activated sludge could be causing serious operational problems and increasing wastewater treatment costs.

The problem of preventing and suppressing the bulking of activated sludge is given a lot of attention by specialists, technological and microbiological studies are involved, including molecular biological studies of the mechanisms underlying filamentous bulking (the role of extracellular polymeric substances regulated by quorum sensing) [9–12]. There are four known hypotheses explaining filamentary bulking of activated sludge: the hypothesis of selection by reserve substances, the hypothesis of diffusional selection, the kinetic hypothesis, and the hypothesis of metabolic selection [8, 13].

The microflora of activated sludge is represented by unicellular bacteria, filamentous bacteria, actinomycetes, fungi, algae. Microbial cells in activated sludge can be represented in two forms: free-floating individual cells and aggregates of individual cells (flocs, biofilm), which enable individual bacterial cells to remain in the recirculation streams. The filament growth is the perfect combination of these two growth forms. In fact, filaments (trichomes) are chains of individual cells, which are characterized by almost the same mass exchange as individual cells, and the ability to stay in structures is close to flocs or immobilized biomass [1, 3, 6, 13, 14].

The peculiarities of the development of most filamentous microorganisms make it impossible to use the classical microbiological technique of species identification, which is based on obtaining first accumulating and then isolating pure cultures. There are more than 30 different types of microorganisms, mainly bacteria, that cause one or another degree of bulking of activated sludge [13,15]. Most filamentous bacteria that cause bulking do not have strict systematic names (they are not identified by indicators required by general microbiology), but have a number, because their characteristics are still poorly studied. There are 30 species of filamentous bulking-causing bacteria, about 10 species of this bacteria are caused of operational problems in biological treatment plants. The most complete and popular classification of filamentous organisms of activated sludge is proposed in [15]. Classification keys and characteristics of filamentous bacteria that cause sludge bulking are based on microscopic examination of filamentous organisms. In activated sludge, with the help of these keys, 21 species of different filamentous organisms can be identified. The classification is technological rather than microbiological, since for a number of bulking-causing microorganisms, their species affiliation has not been established. However, their main morphological features have been noted, allowing to assign them to one or another type. D. Eikelboom also notes a number of technological parameters that contribute to the development of a specific causative agent of filamentous bulking.

Activated sludge with ideal sedimentation capacity (sludge volume index 80-120 cm^3/g) always contains a certain number of filamentous microorganisms. At the same time, filamentous forms play a significant role in the creation of strong and large (100-2000 μm) flocs of activated sludge [13]. Filamentous microorganisms can affect the sedimentation characteristics of activated sludge in three ways [15]:

- Filamentous microorganisms protrude from the flocs and prevent them from being tightly connected. The structure of the flocs is not disturbed;
- The appearance of flocs with an open structure of agglomerates, which sedimentation relatively slowly and are poorly compacted. Some filamentous bacteria are formed balls of filaments.
- Filamentous microorganisms that cause the floating of activated sludge, which leads to the appearance of layers of foam.

Along with the size of the population of filamentous microorganisms, their shape and length also affect the sedimentation characteristics of activated sludge. The size of population and morphology of filamentous microorganisms are important for sludge sedimentation. But no less important factors determining the settling velocity of the flocs are their physicochemical properties [13, 16]:

- The shape of the floc. “Round” flocs settle better than flocs with an irregularly shaped flocs;
- The size of the floc;

- The structure of the floc. Compact flocs settle faster than open clusters;
- The ash content;
- The degree of bonded water by the floc (zooglyic bulking of sludge);
- The surface charge on the floc.

Some compounds in wastewater can stimulate the growth of certain filamentous bacteria because these compounds are not used by most other microorganisms (lack of competition). The most typical example of such compounds is sulfide (H_2S). Reduced sulfur compounds stimulate the development of such filamentous bacteria as Thiothrix, Type 021 N, Beggiatoa and Type 0914 [15, 17–19].

In order to overcome filamentous microorganisms, certain methods have been developed. These methods suppress or the symptoms or the cause of bulking [13, 15–18, 20]:

- Chlorination;
- Addition of hydrogen peroxide;
- Ultrasonic treatment of sludge;
- Addition of flocculants, calcium compounds, iron and aluminum salts;
- Regulation loads on sludge;
- Increasing aerobic capacity in regenerators;
- Immobilization of sludge;
- Mutagenic effects.

The purpose of the work is identification of filamentous bacteria that caused the bulking of activated sludge during the treatment of municipal wastewater and local treatment of industrial wastewater, determination of the consequences of bulking of activated sludge for the efficiency of wastewater treatment from nitrogen compounds, and the development of technological measures to suppress and prevent bulking.

2. Objects and research methods

The object of the study was the bulking activated sludge of two sewage treatment plants: municipal (object 1) and local (object 2) for the treatment of industrial wastewater of a milk processing enterprise.

Identification of filamentous microorganisms was carried out according to Eikelboom's method, which is based on the determination of the following characteristics: mobility, branching, shape of filaments, attached growth, diameter of cells, presence of transverse walls between cells, shape of cells, presence of capsules, presence of various granules [15]. Microscopy of preparations, study of activated sludge microorganisms and identification of filamentous bacteria were carried out according to [15, 21]. In the table 1 also shows methods of researching the technological characteristics of activated sludge flocs [15], which affect its sedimentation properties.

The sludge volume index and hydrochemical indicators of wastewater were determined according to the methodology recommended by the professional literature [21]. Filament index – according to the recommendations of Eikelboom [15].

3. Results and discussion

Microscopic research of bulking activated sludge samples were carried out at object 1. The research showed that the formed activated sludge flocs (generally small, weak, irregularly shaped, open structure) were almost absent. It was also noted the presence of continuous strong strands and plexuses of filamentous bacteria (the filament index reached maximum values), caused by a high concentration of filamentous bacteria of one species. When the sludge volume index

Filament index	5	4-5

exceeded 1000 cm^3/g, filamentous bulking-causing bacteria were found in sludge samples from the regenerator, which were studded with sulfur crystals. A sulfur test with these filamentous bacteria was also positive. Data on the determination of the characteristics of filamentous bacteria, necessary for their identification, are presented in 3. On the basis of these characteristics (table 2) and Eikelboom's identification keys, filamentous bacteria were identified as Type 021 N.

Since Type 021 N bacteria belong to sulfur bacteria, the presence of hydrogen sulfide (sulfides) in the incoming wastewater was considered as the main factor initiating their development. This assumption was confirmed by the data of monitoring these parameters for 1 year (figure 1). Therefore, an increase in the content of sulfides in wastewater ($\geqslant$ 1 mg/dm^3) entering the treatment plant positively correlates with an increase in the sludge volume index, i.e. development activity of filamentous bacteria Type 021N. It should be noted that hydrogen

sulfide in the incoming wastewater consistently exceeds the permissible content (1 mg/dm^3). The constantly high content of hydrogen sulfide in the wastewater entering the treatment plant is confirmed by the deposits of sulfur (a product of the oxidation of hydrogen sulfide by oxygen) on the walls of the channels for supplying water to the aeration tanks (before grates, after sand traps, in secondary clarifiers). Hydrogen sulfide enters to the wastewater in two ways: in the initial composition of industrial and domestic wastewater and through the formation as a result of microbiological sulfate reduction in treatment plants.

Therefore, a decrease of the sulfates concentration in wastewater during treatment at treatment plants attracts attention – by an average of 25% causing a big interest. This indicates that the wastewater during treatment at the treatment plant passes through areas where sulfate reduction occurs, forming hydrogen sulfide, as well as its partial oxidation to elemental sulfur. Sulfur precipitated not only on the walls of structures, but also on activated sludge, as evidenced by its whitish color during bulking, very rapid decay and chemical analysis data.

The formation of hydrogen sulfide in wastewater by sulfate reduction during transportation of wastewater by networks or during sedimentation in biological treatment plants (including secondary clarifiers) is facilitated by a number of parameters: low redox potential, low water stability (high content of organic substances in the absence of nitrites and nitrates), the presence of specific organic substrates. The presence of hydrogen sulfide, which leads to the active development of Type 021 N and an increase of the sludge volume index, can inhibit the activity of nitrifying bacteria in activated sludge in biological wastewater treatment and the formation of nitrates. The conducted studies confirmed this assumption (figure 2). As can be seen, the lower the sludge index, the higher the content of nitrates – nitrification products in the treated

wastewater.

Theoretically, an effective method for suppressing the development of sulfur filamentous bacteria Type 021N is the removal of hydrogen sulfide, a specific substrate for their development, from wastewater. Such removal can be carried out chemically during the precipitation of sulfides and by blowing off and oxidizing hydrogen sulfide with air as well. Since the concentration of hydrogen sulfide in the wastewater at object 1 after sand traps and primary clarifiers slightly increased, it is more expedient to place the operation of stripping and oxidizing hydrogen sulfide in wastewater with air directly in front of the aeration tank. This solution was implemented in the form of a pre-aerator, in which the wastewater was subjected to intensive aeration for 10 minutes. The concentration of hydrogen sulfide in wastewater entering the line of aeration tanks decreased to 0.4-0.6 mg/dm^3. This turned out to be sufficient so that, despite the high water temperature (23 °C), the sludge volume index in the entire system of wastewater treatment plants decreased from 280 to 150 cm^3/g in 2 days.

Object 2 is the local biological treatment plant (SBR reactor) of a milk processing enterprise. Sulfur compounds and thermals are typical of dairy wastewater, since sulfur is found in milk protein and in the free amino acids formed during the hydrolysis of milk protein. In addition, lactic acid is an optimal organic substrate for microbiological sulphate reduction generating hydrogen sulfide. The presence of these two factors creates an increased risk of sludge bulking at the treatment plants of milk processing enterprises, which is also noted in the statistics of activated sludge bulking made by Eikelboom [15]. In the provided samples of activated sludge from object 2, a deep violation of the technological properties of activated sludge was noted: a weakening of the compactness of flocs, its structure and shape, an increase in the sludge volume index. But the most important thing in activated sludge was found to be a mass development of filamentous bacteria (filamentous index 4-5), which, upon detailed examination, were identified as Type 021N [1, 2].

To restore the sedimentation properties of activated sludge, measures were taken to eliminate the stagnation zones of wastewater, in which sulfate reduction processes most likely developed. The measures taken to thoroughly clean the wells and the capacity of the sewage pumping station led to positive results. After 15 days, the microbiological characteristics of the sludge, the technological parameters of activated sludge flocs have changed for the better. The activated sludge filament index decreased from 5 to 3, the activated sludge flocs quality (size, shape, strength, structure) improved significantly. Thus, the removal of hydrogen sulfide from the activated sludge treatment medium is an effective intervention for suppressing the development of Type 021N filamentous bacteria and the activated sludge bulking caused by them.

4. Conclusion

Experimental research at existing sewage treatment plants in which bulking of activated sludge took place were aimed at identifying the filamentous bacteria that cause bulking and the reasons for their massive development, determining the impact of this process on the efficiency of wastewater treatment, and approving measures to suppress this process and further prevent it.

Experimental research with the help of tests recommended by Eikelbub and the identification keys developed by him allowed to identify the filamentous bacterium that caused the bulking of activated sludge in the studied municipal and local industrial treatment plants as Type 021N.

Experimental studies established a negative effect of bulking of activated sludge on the activity of nitrification in the structure, which caused a decrease in the formation of nitrates.

To suppress the bulking of activated sludge, two methods of suppressing the inflow of hydrogen sulfide into biological treatment plants were tested: blowing hydrogen sulfide from wastewater at municipal treatment plants and inhibiting its formation at local treatment plants in the precipitation and laminar flow zones. The implemented measures gave a positive result: the sludge volume index decreased to normative values, the technological properties of activated sludge flocs were restored, and the concentration of filamentous bacteria Type 021N decreased to the required minimum.

Abstract. Climatic changes, physical and moral deterioration of the main funds of land reclamation systems in Ukraine prompt a change in conceptual approaches and reform of the water management system for efficient use of irrigated lands. One of the components of the agricultural hydrotechnical reclamation development is the provision of an appropriate level of ecological and reclamation status of irrigated lands and territories adjacent to irrigation systems (first of all, an open network of canals). The purpose of these studies is to assess the modern technical and hydrogeological-ameliorative state of the Kilchen irrigation system (total area of 35.3 thousand hectares) for a long period of operation of more than 50 years. The main research methods were field diagnostic surveys of the technical conditions of the main structures and elements of the irrigation system (open channels in the earthen channel). The trends of changes in climatic conditions of the territory over the last decade are analyzed. Analytical processing of the stock materials data and field observations of changes in the groundwater level, its chemical composition and mineralization in 24 observation wells along the main channel was carried out. The main chemical composition of groundwater in the research area is characterized as sulfate and sodium-calcium with total mineralization in individual areas from 0.6-0.9 to 1.7-3.5 g/l. According to the known methods of R.O. Bayer and V.A. Kovda calculations of the predicted change in the level and critical depth of groundwater have been performed. The established terms of change vary between 9-11 years, provided that irrigation is intensified and the irrigation system is fully operational. Based on the forecasting results, groundwater mineralization is expected to decrease from 3.5 g/l to 2.27 g/l between 2021 and 2029. It was determined that the level of groundwater above the calculated critical levels in different years occupies from 30.7 to 51.0% of the territory in the area of operation of the Kilchen irrigation system. The reclamation state of part of the irrigated lands in 2021 with a total area of more than 13.000 ha was distributed according to the following criteria: 12.000 ha – favorable, 1.200 ha – satisfactory, about 50 ha – unsatisfactory due to the manifestation of soil salinization processes. As of 2021, of the soils on an area of about 10.000 hectares that were studied, almost 8.500 hectares of soils are non-saline, more than 1.200 hectares are slightly saline, and about 50 hectares are moderately saline. For comparison, in 2003, all soils on the same area were non-saline, which indicates the deterioration of the ecological and melioratic state of the territory and the decrease in the quality of irrigation water.

1. Relevance

One of the most important issues of Ukraine's national security during the war is ensuring food security [1]. Nowadays, the agrarian sector of the economy has the most dynamic development and provides a significant share of currency inflows to Ukraine. With rapid changes in climatic conditions and a shortage of soil moisture, obtaining consistently high yields of agricultural crops, regardless of weather conditions, is ensured by irrigation. Almost all irrigation systems in Ukraine were built in the 60s and 70s of the last century. The terms of their technical operation have exceeded (or are approaching) the project indicators. Among the main factors that negatively affect the operation of hydromelioration systems, the following are distinguished: inadequate state funding, which does not provide the opportunity to carry out current and capital repairs in a high-quality and timely manner; physical wear and tear of fixed assets; significant non-productive losses of water from the irrigation network, causing flooding or inundation of adjacent territories, soil salinization, etc.; the high cost of irrigation water and the use of low-quality water resources [2].

The consequence of long-term operation of hydromelioration systems at an unsatisfactory and insufficient level of technical operation is the deterioration of the ecological and meliorational state of the territories adjacent to these systems. This problem requires the development of appropriate technical and technological solutions for the further development of irrigation reclamation in Ukraine [3]. It should be noted that the priority areas of development indicated in the "Strategy of Irrigation and Drainage in Ukraine for the period until 2030" approved by the order of the Cabinet of Ministers of Ukraine No.688 dated August 14, 2019 are:

- conducting a detailed audit of the use of reclaimed land and inventory of land reclamation systems;
- implementation of institutional reforms of shade resource management and land reclamation;
- creation of the umbrella organization for effective management and reliable operation of reclamation systems;
- implementation of investment and infrastructure projects for the restoration and development of land reclamation in Ukraine.

At the same time, in order to realize the set goals, it is necessary to carry out a thorough assessment of the current state of both the technical resources of the country's reclamation complex as a whole, and the ecological and reclamation state of the territories adjacent to the irrigated systems in particular [4]. In domestic and international practice, the importance of systematic long-term data collection on the level of groundwater on irrigated lands is noted [5]. Such data are critical to research and solve many of the complex environmental problems of adjacent irrigated areas that irrigated agriculture commonly faces. Foreign researchers pay great attention to the periodicity of observing the ecological and meliorational state of irrigated lands [6] and establishing the impact of irrigation systems on the state of the surrounding natural environment [7].

At responsible facilities, hydrographs are most often used, which record data continuously, since periodic monitoring may not reflect short-term loads in the form of extreme fluctuations in water levels in hydraulic reactions. The disadvantage of constant monitoring is the need for large capital investments. However, it does not always provide an opportunity to see a global change in the trend of the groundwater level. Most often, observations are analyzed every 5-10 years.

Recently, the ecological and reclamation state of irrigated lands is affected not only by their technical condition, but also by changes in climatic indicators. The global trend of increasing air temperature during the growing season and decreasing the amount of productive precipitation leads to a greater manifestation of the salinization and salting processes of irrigated soils [8]. Climate change leads to a decrease in productive moisture in the soil and a decrease in the level of groundwater due to the lack of seasonal replenishment. Due to the lack of productive precipitation, some European countries, in particular France, state an active reduction of the aquifer and a decrease in the level of groundwater. According to the regulations in Ukraine, irrigation systems monitor the condition of irrigated and adjacent lands according to hydrogeological indicators; monitor indicators of the soils and groundwater chemical composition, the technical condition of the reclamation system, flooding of nearby settlements within the area of the reclamation system operation etc. [9].

Such monitoring of reclaimed land is carried out with the aim of ensuring rational use of land and water resources, identifying the causes of their unsatisfactory state, quality and pollution, timely implementation of reclamation measures to prevent soil degradation and harmful effects of water, reproduction of soil fertility, protection of water and land from pollution, timely performance of repair and restoration works (reconstruction) [10].

State programs are relevant and necessary to ensure the collection of data for ecological and remedial monitoring and the future forecast of the negative consequences of the impact on the environment. These programs make it possible to efficiently use the network of observation wells and monitor the water level in them at the local, regional, and state levels. Monitoring the level of groundwater on irrigated areas is an important task in the organization and implementation of ecological and remedial monitoring. Thus, the purpose of this work is to assess the hydrogeological and reclamation state of the territory in the zone of the Kilchen irrigation system influence at the current stage of exploitation.

2. Research methods

Field diagnostic surveys of the technical condition of the irrigation system's main structures and elements (open channels in the earthen channel) were carried out. Analytical processing of data from stock materials and field observations of changes in the level of groundwater and its quality in observation wells was performed. The calculation of the forecast change in the level of the groundwater critical depth was carried out using various methods (according to the methods of R. O. Bayer and V. A. Kovda). QGIS, AutoCAD, and Microsoft Excel software packages were used during the processing of the material.

3. Results and discussion

The Kilchen (formerly Frunzen) irrigation system is located on the territory of the Dnipropetrovsk region. The irrigation system was built in two phases: the first was put into operation in 1970, and the second in 1975. The total area of the irrigation area is 35.3 thousand hectares (20.1 thousand hectares and 15.2 thousand hectares, respectively). The source of power for the Kilchen irrigation system is the Dnipro Reservoir on the Samara River, from which water flows through a 4.25 km long canal by gravity to the main pumping station No. 1 (MPS-1) and is fed into the main canal of the first line (26.8 km long). The channel of the underwater channel is earthen, and the channel itself is designed for the passage of water up to 20 m^3/s.

Main and distribution canals (total length 47 km) of the Kilchen irrigation system are built with an anti-filtration coating mainly from reinforced concrete slabs laid on polyethylene film, as well as in open reinforced concrete trays (5.2 km long).

The drainage network was built on an area of 24.6 thousand hectares, which makes it possible to maintain an optimal water-salt regime in the irrigated and adjacent territories. A cut-off horizontal drainage (3.6 km long) was created along the main canal of the first stage, and forest strips were planted along the borders of the fields. The first stage of the Kilchen irrigation array is located on the left bank of the Dnipro River within the Dnipro and Tsarychan districts of the Dnipropetrovsk region (figure 1).

The irrigation array is located mainly on the second floodplain terrace of the Dnipro and partially on the watershed plateau of the Kilchen and Chaplinka rivers. The surface is flat, dissected by a truss-beam network. Soils are not saline. The soil cover consists mainly of ordinary low- and medium-humus rich chernozems. Hydrogeological conditions are marked by the presence of an aquifer in anthropogenic sediments at a depth of 2-15 m, on the watershed

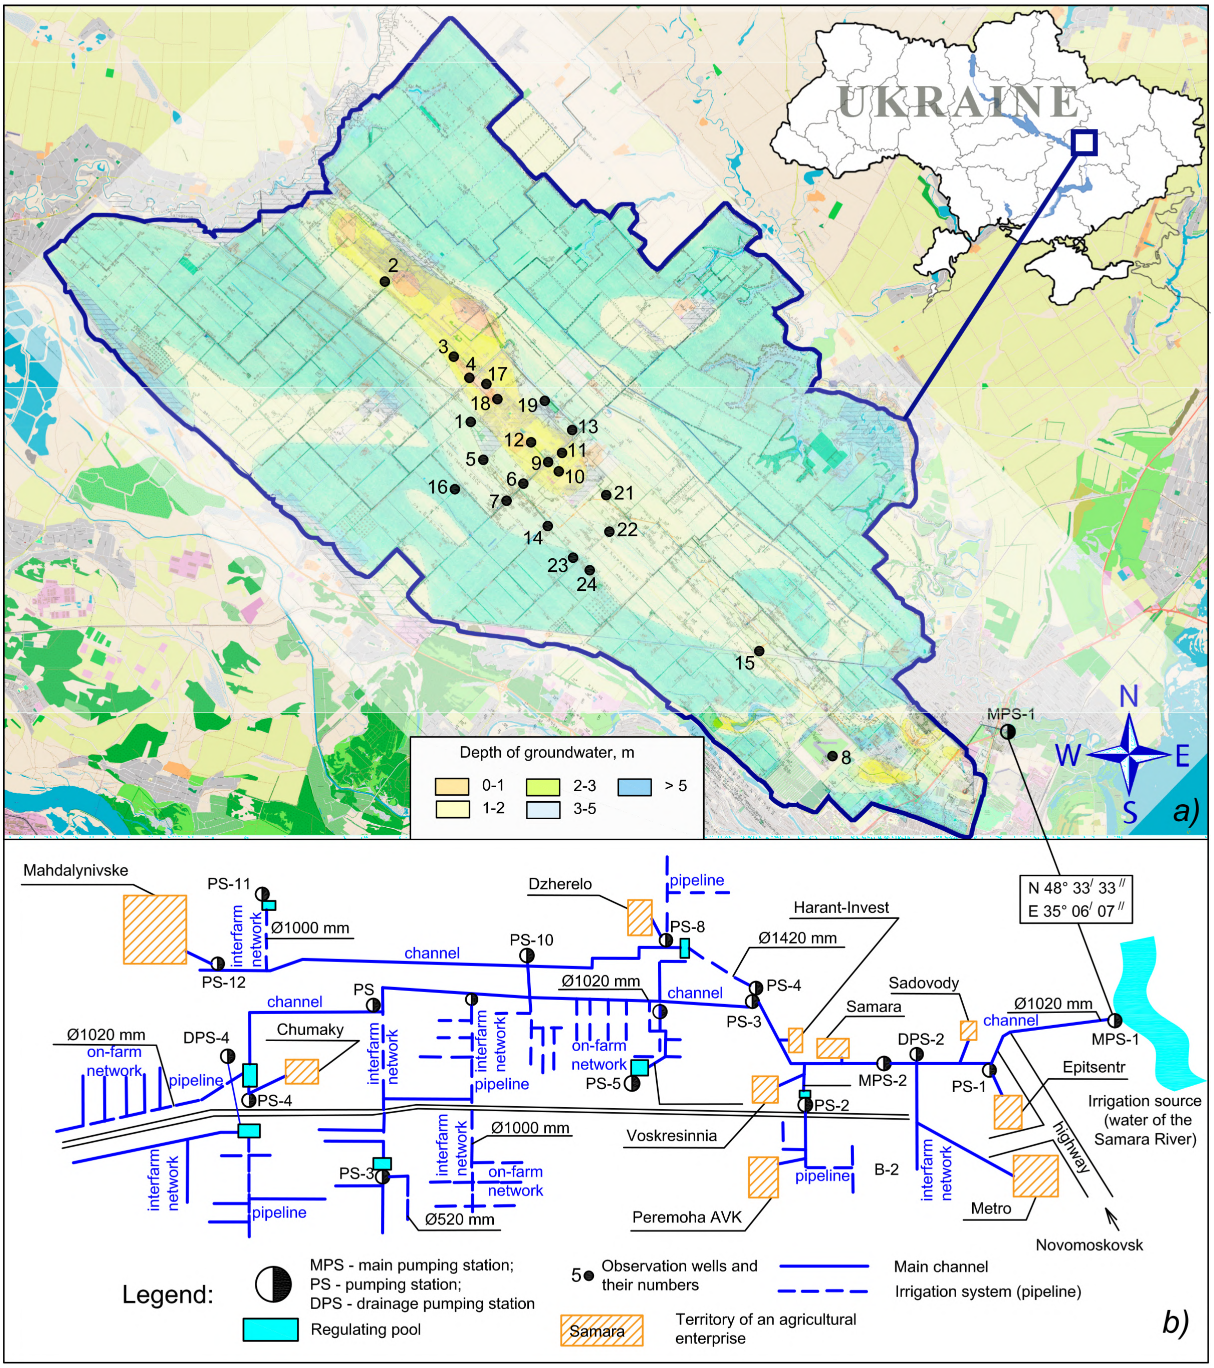

Figure 1. Overview diagram of the Kilchen irrigation system: a) – an area within the region with specific levels of groundwater; b) – a diagram indicating the positions of channels and pumping stations.

plateau – up to 45 m. The chemical composition of groundwater is sulfate and sodium-calcium with mineralization from 0.6-0.9 to 1.7-3.5 g/l.

The northern border of the irrigation system runs along the main channel and along the village of Ulyanivka to the Chaplinka River, and the western part of the massif is limited to the village of Petrikyvka. The southern border runs along the Dnipro-Poltava highway, and the eastern border along the Dnipro-Novomoskovsk highway. The total length of the irrigated massif is 35 km with a width of 7-9 km.

(b)

Figure 2. Anti-filtration lining of the main channel with reinforced concrete slabs: (*a*) – at the construction stage in 1965 (archival photo); (*b*) – unsatisfactory technical condition and damage at the current level of operation (author's photo).

The natural boundaries of the irrigation array are: in the north – the slopes of the watershed plateau, in the south – the ledge of the first floodplain terrace of the Dnipro River, in the east – the Kilchen River and in the west – the Chaplinka River. Next to the irrigation network, there are 53 agricultural enterprises with a total area of about 13.331 hectares, including 1.790 hectares of irrigated land. Agricultural enterprises specialize in the production of grain and vegetable and meat and dairy products.

As of April 1, 2021, the irrigated area under the control of the Kilchen irrigation system in the Dnipro district is 96,601 hectares, including 1,549 hectares of actually irrigated land.

According to the results, own field diagnostic surveys of the main channel testify to its unsatisfactory technical condition at the current level of operation (figure 2). In particular, the damage to the anti-filtration coating of the canal, the development of shrubby vegetation, and the destruction of individual water supply and water permeable elements of the structure are noted.

The effectiveness of irrigation hydrotechnical reclamations and the quality of surface and groundwater are impacted by rapid changes in climate. The climatic conditions in 2010 and 2018 showed an increase in air temperature by 1.97 °C and 0.84 °C compared to the long-term average temperature of 9.2 °C (table 1). However, in 2021, the average annual air temperature was almost similar to the long-term values. In 2010, the amount of precipitation was 13.3 mm higher than the long-term average value of 429 mm, while in 2018 and 2021, the precipitation levels exceeded the long-term average by 255.7 mm and 252 mm, respectively. Data on meteorological observations from previous years were obtained from open sources on the internet and archives of the Dnipropetrovsk Hydrogeological and Reclamation Expedition.

The assessment of the hydrogeological and reclamation state of irrigated lands was carried out based on the analysis of the groundwater level depth during the vegetation and irrigation period of the corresponding year. On the area of the irrigation array, the regime network consists of 255 observation wells.

In 2021, the distribution of controlled areas according to the depth of groundwater levels of 2-3 m on the irrigation array was 302 hectares, with a level of 3-5 m – more than 4 thousand hectares, and with a level of more than 5 m – about 9 thousand hectares. The level of groundwater in some observation wells by years of research is shown in figure 3.

Table 1. Dynamics of changes in climatic indicators at the object of research.

Month	Average air temperature, °C			Precipitation, mm

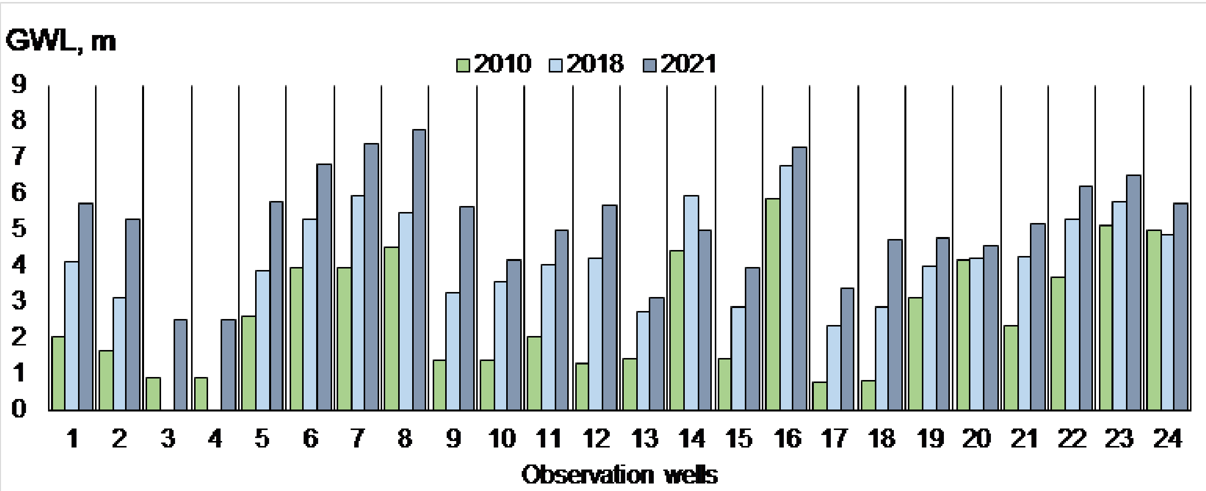

Figure 3. Groundwater level (GWL) in the area of operation of the Kilchen irrigation system main canal (average annual data).

In order to assess the hydrogeological and meliorational state of the sites in relation to the depth of the subsoil, it is necessary to determine their critical depth of the subsoil. The critical depth of the groundwater level is determined by two methods: according to the R. O. Bayer's method – determined by mineralization and the type of the groundwater chemical composition [11]; according to the V. A. Kovda's method [12] – calculated using the formula:

$$H_{kr} = 170 + 8 \cdot t\,(cm)\,, \tag{1}$$

where t – is the average annual air temperature.

According to the R. O. Bayer's method, with a sulfate type of soil and mineralization of groundwater up to 3 g/l, the maximum value of the groundwater critical level occurrence is 1.5 m.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012087 doi:10.1088/1755-1315/1254/1/012087

The average annual air temperature for the Dnipro region is 9.2 °C, therefore according to the formula of V. A. Kovda, the maximum value of the critical level of groundwater is: $H_{kr} = 170 + 8 \cdot 9.2 = 2.4\,(\mathrm{m})$.

In 2010, with the lowest amount of precipitation and the highest average air temperature according to average annual indicators, an unsatisfactory hydrogeological and reclamation condition was observed in the territory of the irrigation system. The level of groundwater above the critical level (2.4 m) occupied 51% of the territory around operation of the Kilchen irrigation system, of which 30.7% exceeded the critical depth of the groundwater level above 1.5 m. The rise in the level of groundwater led to flooding of the territories of the Ulyanivka village and the Chumaki village and the rise of the water level in Lake "Ozerishche", which caused the basements of buildings in these settlements to be filled with water. There was a pull-up of salts from mineralized groundwater in these territories, which prompted the processes of salinization and salinization.

Areas with an unsatisfactory hydrogeological-ameliorative state of irrigated lands include areas with a depth of GWL above the critical level for their mineralization of more than 1 g/l, and areas with an average degree of salinity or an average degree of soil salinity.

Areas with a satisfactory hydrogeological and meliorational condition of irrigated lands include areas with a depth of GWL from critical to 5 m with mineralization of more than 1 g/l, and areas with a weak degree of salinity or a weak degree of soil salinity.

Areas with a good hydrogeological and meliorational condition of the land include areas with a depth of groundwater level above the critical level with good natural or artificial drainage and fresh water, as well as areas with non-saline and non-saline lands.

In 2010, 42% of the territory was in an unsatisfactory reclamation state due to the high level of groundwater (above 1.5 m) and the establishment of an average degree of salinity on an area of 52 hectares, while in 2018 and 2021, the ecological and reclamation state changed significantly towards improvement. Climatic indicators during this period were characterized by a slight increase in the average annual air temperature and a significant increase in the amount of precipitation – by 58-60% of the average long-term values. The specified amount of precipitation was extremely unevenly distributed throughout the year and was showery in nature. Despite the increased amount of atmospheric precipitation at that time, the stabilization of GWL was noted due to their redistribution over the surface by horizontal spreading and weathering.

In 2018 and 2021, a decrease in the groundwater level was observed in all observation wells. The terrain in the area of observation well 18 is of concern. The rate of groundwater level rise per year is 0.3 m. It was necessary to calculate the time of groundwater rise to the critical level. If such a trend is maintained, the time for the groundwater level to rise to critical values is determined by the formula:

$$t = \frac{Hp - Hkr}{\triangle h}, \tag{2}$$

where H_p – groundwater level before irrigation; H_{kr} – critical depth of the groundwater level, m; $\triangle h$ – the amount of groundwater level rise per year, m.

The time for groundwater to rise from the level of 5 m according to formula (2) to the critical level of 1.5 m is 11 years and 7 months, and the rise to the level of 2.4 m is 8 years and 8 months (figure 4).

Predicting the mineralization level of groundwater when it reaches the critical depth is achievable by determining the average mineralization of the water layer upon reaching a certain level of groundwater [13]. This calculation depends on the infiltration of irrigation water and atmospheric precipitation as per the formula

$$C = \frac{C_0 \cdot h_0 + C_n \cdot h_n}{h}, \mathrm{g/l} \tag{3}$$

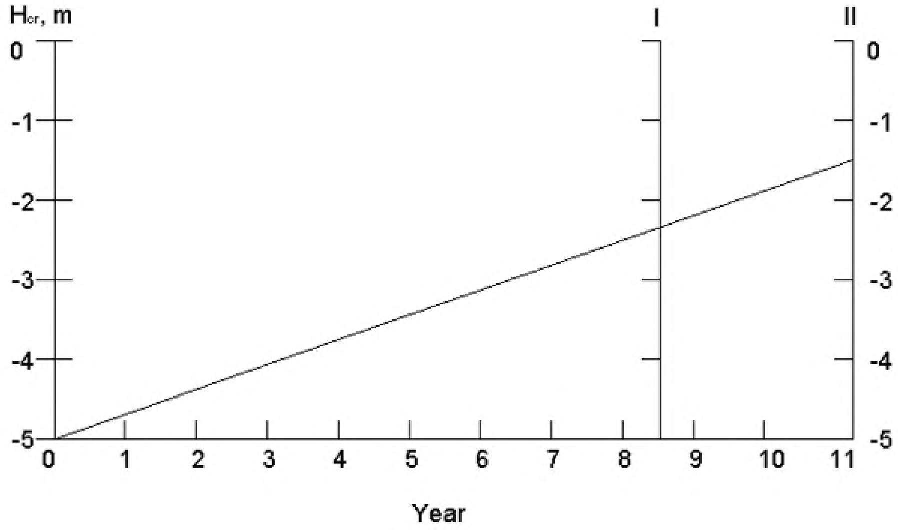

Figure 4. The time prediction of reaching the critical level of groundwater at observation well 14.

where C – average mineralization of the groundwater layer, g/l; C_0 – mineralization of the water infiltration layer, g/l; h_0 – layer of the infiltration water, m; C_n – mineralization of the solution in the pores squeezed out of the aeration zone, g/l; h_n – a layer of natural moisture squeezed out of the aeration zone, m; h – the height of the groundwater level rise during the t period, m.

The mineralization of the water infiltration layer is determined by the formula

$$C = \frac{N_{precp} \cdot M_{precp} + N_{irr} \cdot M_{irr}}{N_{precp} + Nirr}, \text{g/l} \tag{4}$$

where N_{precp} – the total rate of atmospheric precipitation for the t period, m^3/ha; M_{precp} – mineralization of precipitation, g/l; N_{irr} – total irrigation rate for t period, m^3/ha; M_{irr} – mineralization of irrigation water, g/l.

The mineralization of the solution in the pores, squeezed out of the aeration zone, is determined as follows

$$C_n = \frac{C_a \cdot 1000}{W \cdot Wg}, \text{g/l} \tag{5}$$

where C_a – the average content of salts in the soils of the aeration zone, %; 1000 – conversion factor; W – relative humidity of the soil, %; W_g – hygroscopic soil moisture, %.

The typical water mineralization for the Kilchen irrigation system is 2.31 g/l. In 2021, based on climatic indicators, the total atmospheric precipitation rate was 6810 m^3/ha with a mineralization level of 0.02 g/l. "Agro-Kompaniya" LLC requires a total irrigation rate of 13,650 m^3/ha, resulting in a mineralization of the infiltration layer of water at 1.55 g/l. The relative humidity of the soil for Agro-Company LLC ranges between 24-26 %, with hygroscopic humidity at 5 % and an average salt content of 0.24 %, leading to a mineralization of the solution in the pores squeezed out of the aeration zone at 2 g/l. The predicted mineralization for a 2.1 m layer of infiltration water and a 1.1 m layer of natural moisture squeezed out of the aeration zone at a groundwater level rise of 2.4 m is 2.27 g/l. As a result, the mineralization of groundwater is expected to decrease from 3.5 g/l to 2.27 g/l between 2021 to 2029.

The meliorative state of irrigated lands in 2021 with a total area of more than 13,000 hectares is divided according to the relevant criteria into 12.000 hectares – favorable, 1.200 hectares – satisfactory, about 50 hectares – unsatisfactory due to the manifestation of salinization processes.

As of spring 2021, out of the 9.683 ha of soils studied, 8.409 ha are non-saline, 1.236 ha are slightly saline, and 38 ha are moderately saline, while all soils were non-saline in the same area in 2003.

The following studies of the ecological and reclamation state of the Kielce irrigation system in 2021 showed the processes of the groundwater level stabilization and the absence of a systematic rise of it to a critical level compared to what was observed in 2010. It is necessary to pay attention to the territory with an underground water level of 2-3 m (302 hectares of area) and land in LLC "Agro-Kompaniya", where no general tendency to decrease the underground water level was observed.

4. Conclusions

In order to improve the ecological and remedial the soils condition of the Kilchen irrigation system, it is proposed to carry out systematic control of the groundwater level. Increased attention should be paid to monitoring the observation well 14, which is located on the lands of Agro-Company LLC. On irrigated areas, it is necessary to control the irrigation regime of agricultural crops in accordance with the groundwater level in those places where it reaches the level of 2-3 m, and to maintain the humidity of the soil arable layer at the level of 80-85% the lowest moisture content of the soil. It is recommended to carry out chemical reclamation measures on saline areas by applying phosphogypsum at the rate of 3 t/ha under plowing in the fall once every 3 years.

It is worth noting that over the last decade, the groundwater level in the area of operation of the Kilchen irrigation system has decreased significantly. The main reasons for this are a change in climatic conditions with a tendency towards dryness, as well as a decrease in water consumption. Nowadays, several times less water resources are pumped through the main channel than is provided by its design indicators.

The calculated critical depth of the groundwater level according to the method of R. O. Bayer is 1.5 m, and according to V. A. Kovda – 2.4 m. The estimated time to reach the critical level of groundwater is about 9-11 years. Taking into account the constant decrease in water consumption volumes, this indicator can be significantly reduced for a period of more than 20 years. The main chemical composition of groundwater is characterized as sulfate and sodium-calcium with total mineralization in some areas from 0.6-0.9 to 1.7-3.5 g/l. Based on the forecasting results, groundwater mineralization is expected to decrease from 3.5 g/l to 2.27 g/l between 2021 and 2029.

Abstract. Biomass gasification is one of the effective methods of obtaining electrical and thermal energy. Thermal gasification is a simple and effective method for most lignocellulosic waste. The generation of combustible gases under such conditions has significant prospects both in the national economy and in a number of chemical-technological processes. The high-ash carbon residue remaining after thermolysis has shown its effectiveness as one of the important components of organo-mineral fertilizers. The results of field research in 2018-2019 with Moskito corn hybrid (*Zea mays L.*) and Mulan winter wheat F2 hybrid (*Triticum aestivum L.*) on dark-gray podzolic soil confirmed the high agrochemical efficiency of our proposed fertilizers. The introduction of Moskito corn hybrid organo-mineral fertilizer into the nutrition system improved the structural indicators of the harvest: in the experiment, the 1000 grains weight increased by 14.7%, the mass of grain from one cob – by 20% compared to the control. Balanced nutrition of experimental plants Mulan winter wheat F2 hybrid in the variant with the use of BG-II when sowing at a dose of 1t/ha and favourable weather conditions led to an increase in grain quality (protein content) to the 2nd class – 13.0% against the 3rd grade in control (12.2%).

1. Introduction

The constant increase in the price of energy resources and the annual decrease in their reserves prompts the scientific community to search for and develop alternative energy sources [1–3]. Today, technology using biomass as a renewable source is gaining significant development. The generation of combustible gases from organic waste has significant prospects both in the national economy and in some chemical-technological processes [4–12]. Thus, the existing situation in Ukraine for the development and implementation of the concept of sustainable development implies not only the inextricable connection of its economic, ecological and social components but also their balance.

Agricultural waste, which in most cases is not used, creates a number of environmental problems or simply rots. It is clear that only the implementation of radical steps could significantly change the situation. One of these steps should be deep processing of accumulated waste, aimed not only at reducing its volume but also at maximizing the energy and resource potential of such waste. Gasification of biomass is one of the effective methods of obtaining electrical and thermal energy [4–12]. The attractiveness of using vegetable raw materials is the absence of sulfur-containing compounds, and as a result of high-temperature thermal decomposition, it is possible to obtain combustible gas, which does not produce dangerous oxides in the environment when burned. Thermal gasification is a simple and effective method for most cellulose- and lignin-containing biomass waste. Reviews of research, demonstration and commercial biomass gasification plants that exist in the world are given in works [13–17]. A byproduct of gasification is an ash residue [18–20]. The processing of waste generated by society is one of the indicators of its sustainability [21, 22]. Therefore, in most of the developed countries utilisation and wastes disposal have become a priority in the economic sectors. In today's high-tech economy, innovative products that are made from waste from industrial processing of lignocellulosic biomass are becoming more and more important [20–22]. Such innovations should become the basis of ensuring advanced positions in the production of organic-mineral fertilizers field, and fodder, which are aimed at technological and organizational modernization and competitiveness. At the current level of development of science and technology, it is optimal to use secondary raw materials. In addition, 800-900 thousand tons of limestone and granulated organic-mineral fertilizers and other products can be produced annually from unused processing waste [20, 23].

Nowadays, as a result of high prices for fertilizers, agrochemical science specialists face the problem of determining the most economically and agrochemically effective system of improvement (types of fertilizers, methods and rates of application). It should be noted that the large grounds in the country have a low supply of available phosphorus. At the same time, the main problem in agriculture remains the increase in the production of high-quality food and fodder grain [24, 25]. In corn and wheat, due to a lack of phosphorus, there is a free delay in development, the ripening period comes later, and there is a risk of under-ripening, given the rather short growing season [26]. Phosphorus is absorbed by corn approximately evenly for a long time until the harvest is reached. It is phosphorus fertilizers that stimulate the development of the root system, laying reproductive organs, contribute to the rapid formation of cobs and contribute to the achievement of the harvest. The lack of available phosphorus in plant nutrition inhibits the growth and development of flowers and grains in corn cobs. Corn has an increased need for potassium, as do other carbohydrate-rich crops [27]. It is necessary for the formation of cobs and the accumulation of starch and sugar. In addition, corn is quite sensitive to the organic fertilizers application and requires a high rate of mineral components in the fertilization system.

Taking into account modern trends, the growth of phosphorus needs in agricultural production and the lack of an opportunity to satisfy them at the expense of mineral raw materials of domestic phosphate reserves, the method of utilization of ash from the sediments of the aeration station into a valuable organic-mineral fertilizer is quite justified. XRF analysis of ash obtained during the gasification of municipal sludge showed a sufficiently high P_2O_5 content at the level of 16.4%, for comparison, superphosphate contains 19-21% P_2O_5 [28]. Ash, which is formed in this way, has the following main components: silicon dioxide, phosphates of iron, calcium, magnesium, silicates of aluminium, potassium, iron, and others. In addition, ash contains biogenic meso- and microelements (sulfur, boron, manganese, zinc, molybdenum, and others), as well as compounds in the form of main phosphates and silicates [28]. The existing reagent methods, which ensure the transformation of heavy metals into a stationary state, mostly have a temporary effect or are quite expensive. The use of products of humic nature is an effective means for their detoxification.

Thus, the aim of our work was the production of high-energy gas by gasification of lignocellulosic waste and the creation of organo-mineral fertilizers based on the ash of processed plant waste and sediments of the aeration station, the humic component and the study of their influence on the yield and quality of winter wheat and corn grains. The development of the formulation of such composite ecologically safe fertilizers of prolonged action, and their use in agricultural production will allow increasing not only the supply of phosphorus and potassium to wheat plants, but also the drought, frost, and winter resistance of the culture. All this will contribute to the improvement of the economic and ecological indicators of crop production – a reduction in the cost of wheat grain due to an increase in the yield and quality of the grain, a reduction in the costs of phosphorus and nitrogen fertilizers at a negligible cost and the cost norms of new organo-mineral fertilizers of prolonged action.

2.1. Gasification of lignocellulose biomass

Lignocellulosic biomass gasification was carried out at the installation [29] in two modes: under conditions of incomplete oxidation of raw materials with the formation of combustible gases, air containing 21% oxygen and 78% nitrogen is used as an oxidizer, and in an inert atmosphere (argon).

2.2. Characterisation of raw materials and obtaining products

All chemical analysis was carried out twice allowing to calculate the mean values and standard deviations, which do not exceed 5%. The inorganic components were determined using Expert 3L XRF (INAM, Ukraine). The sample was analysed three times. The calorific value of the samples was investigated on an IKA C200 (Germany) calorimeter according to a standardized method, by burning the sample in an oxygen atmosphere in a calorimeter bomb. The results were determined in automatic mode on the installed software. The qualitative and quantitative composition of the formed gases and liquid products was determined by the gas chromatography method. Gas chromatographic analysis of inorganic gases (hydrogen, carbon mono- and dioxide) and methane was carried out on a chromatograph Chrom-5 (Czech Republic) with a detector for measuring the thermal conductivity of gases. For the analysis of light gases, stainless steel 1.5 m long and 3 mm internal diameter, filled with a sorbent: activated charcoal of the SKT brand with a fraction of 0.25–0.50 mm, impregnated with a 10% $NiSO_4$ solution. The carrier gas is argon, the flow rate of which was 20 ml/min. The temperature of the columns thermostat and the detector is 100 °C, the evaporator temperature – 120 °C, and the detector current – 40 mA.

Hydrogen analysis was carried out on a glass chromatographic column with a length of 1.5 m and an internal diameter of 3 mm, filled with pre-fired CaA zeolite with a fraction of 0.25–0.50 mm. The carrier gas is argon, the flow rate of which was 30 ml/min. Analysis temperature – 60 °C, evaporator temperature – 120 °C, detector current – 80 mA. The gas sample was introduced into the chromatographic column through a calibrated loop using a dosing tap. The sample volume was 0.37 ml. Analysis of organic reaction products was carried out on a chromatograph "Agilent Technologies 7890A" (Agilent, USA) which was equipped with a flame ionization detector and using a DB-624 UI quartz capillary column with a length of 60 m and an internal diameter of 0.32 mm in a combined temperature regime (isothermal – 10 minutes at 40 °C, then programming the temperature from 40 to 250 °C at a speed of 5 degrees/min. Samples were introduced into the column with a microsyringe with a capacity of 1.0 mcl. Processing of the analysis results was carried out according to the areas of chromatographic peaks by the method of internal normalization using calibration coefficients.

2.3. Field experiments of organo-mineral fertilizers

To carry out scientific research work on determining the efficiency of using organo-mineral fertilizers based on the ash of plant waste and sediments of the aeration station in feeding Moskito corn hybrid (*Zea mays L.*) and Mulan winter wheat F2 hybrid (*Triticum aestivum L*) the following were used:

- ash from the Bortnychi wastewater treatment plant sludge with contents: P_2O_5 – 16.4 %, CaO – 6 %, Al_2O_3 – 10%, SiO_2 – 56 %, less than 1% – oxides Cu, Fe, Zn, Ti, S, Mn and Ni;
- rice husk ash with amorphous SiO_2 content – 97.8 % and close to 1 % K_2O and CaO;
- sunflower husk ash with K_2O content – 58%;
- urea;
- humic component – potassium lignohumate grade A, TU 2431-007-31054001-99 – a mixture of potassium salts of humic and fulvic acids, macro- and microelements (S, Ca, Si and others) has the properties of an adaptogen, immunomodulator, adhesive.

Field experiments was carried out in the experimental field in the Horodyzhe village t of Boryspil district of Kyiv region on dark gray podzolic light loam soil with average content of mobile compounds of basic macronutrients.

The first experiments with Moskito corn hybrid (*Zea mays L.*) were performed on four repetitions. The area of the sown area was 1300 m^2, the accounting area was 1200 m^2. Placement of options – systematic. Seed sowing rate – 80 thousand similar corn's seeds per ha. The predecessor in the experiment was corn. Agrotechnics is typical for the Forest-Steppe zone of the Left Bank and adapted to farm conditions. The scheme of the experiment with Moskito corn hybrid (*Zea mays L.*) provides the following doses of mineral fertilizers: before sowing was applied OMF-I at a dose of 0.5 t per ha on the background of nitroammophos fertilizer 32:32:32 (200 kg/ha) before sowing, liquid complex fertilizers (ammonium polyphosphate (APP)) ($N_{16}P_{55}$) at a dose of 150 kg/ha, urea ammonium nitrate (UAN-32) N_{96} (300 kg/ha) and timely nitrogen fertilization with ammonium sulfate (100 kg/ha) N_{21}, in certain phases of the growing season. Control – background ($N_{165}P_{87}K_{32}$), without the introduction of organic-mineral fertilizer. The main agrotechnical measure for the intensification of plant growth and development, strengthening the absorptive function of the root system, was the application of organo-mineral fertilizer at a dose of 0.5 t/ha according to the experiment scheme:

1. Background (control) – $N_{165}P_{87}K_{32}$;
2. Background + OMF-I – 0.5 t/ha.

Direct sowing of corn seeds was carried out with a Super Walter W1770 seeder. According to climatic conditions, the growing season of 2018 year was marked by variability and contrast of the first and second half of the corn growing season. The first half was characterized by waterlogging, and the second – high temperatures and heat (temperature 25-30 ^oC and above). Due to the sufficient moisture content in the soil, the corn plants grew well and developed to a state of milk-wax ripeness, in which the harvest was recorded and plant samples were taken according to the standard method – GOST-27262.

The second experiment was performed on four repetitions. The area of the sown area was 2.0 ha, the accounting area was 1.6 ha. Placement of options – systematic. The predecessor in the experiment was sunflower. According to the experiment scheme, the fertilizer application was carried out on September 25, and the sowing – was on September 28. The rate of sowing is 250 kg/ha, and the rate of new BG-II organic-mineral fertilizers application is 0.6 and 1.0 t/ha. Agrotechnics is typical for the Forest-Steppe zone of the Left Bank and adapted to farm conditions.

1. Background (control) – $N_{165}P_{87}K_{32}$.
2. Background + BG-II – 0.6 t/ha.
3. Background + BG-II – 1.0 t/ha.

The fertilization system of Mulan winter wheat F2 hybrid (*Triticum aestivum L*) provided for the introduction of 200 kg of 13:13:29 fertilizer mixes under the main tillage and 200 kg of urea-ammonia mixture after the restoration of spring vegetation in the control.

Harvesting and accounting were performed manually from each plot by the weight method according to the Dospekhov's method [30] in the phase of full grain maturity. Corn and winter wheat grain moisture and their structural analysis was carried out in cob samples (50 pcs.) and sheaves (50 pcs.), which were taken during harvesting separately at each accounting plot. Crop grain yield was calculated at a moisture content of 14%.

Plant sample selection and preparation were performed according to standard methods [31]. The content of nitrogen and phosphorus after wet ashing in dry Moskito corn hybrid (*Zea mays L.*) and Mulan winter wheat F2 hybrid (*Triticum aestivum L*) samples were determined by the method of Ginsburg with the following determination: nitrogen – photometric method using Nessler's reagent, phosphorus – photometrically by the method of Denizhe in modification of Levitsky. The inorganic components of plant sample ash were determined using Expert 3L XRF (INAM, Ukraine).

Determining the structure of the corn and winter wheat harvest was carried out by the Maysuryan method The corn and winter wheat harvest structure was carried out by the Maisuryan method, and the dry matter content of the grain was determined by the thermogravimetric method (GOST 13586.5-93), 1000 grains weight (GOST 10842-89), determination of hectolitre weight (GOST 10840-64). Determination of grain quality was performed by infrared spectroscopy Infratec 1241 (DSTU 4525:2006 and DSTU 4117-2007).

3. Results and discussion

The raw material that enters the high-temperature zone under the action of the oxidant – air decomposes and turns into gas and ash components, which in turn are carried out of the heat treatment zone into the cooling and separation zone in the separator. Ash was separated from the gas in the separator, which after passing through the cleaning line, was burned on a burner. After a certain period of time, gas was sampled for analysis. The results are shown in table 2.

From the obtained results it can be seen (table 2) that the main combustible component after gasification in the air environment is carbon monoxide, of which at least 20% is generated, the amount of hydrogen does not exceed 10%, methane 5%, C_2-C_6 hydrocarbons 2%. In turn, such

Table 2. Analysis of the generated gas.

Gas component	Content in the gas phase (%mass.)					
	rice husk		switchgrass		pine sawdust	
	air	Ar	air	Ar	air	Ar
H_2	8.90	33.45	8.55	34.47	7.55	32.54
N_2	51.45	5.02	52.24	4.63	51.00	4.26
CO	20.33	32.30	20.70	31.84	23.30	33.04
Hydrocarbons C_2-C_6	2.15	1.02	1.92	0.92	2.45	0.95
CO_2	11.14	20.08	11.53	20.46	9.70	21.23
H_2O	1.75	1.40	1.36	1.25	1.50	1.30

gas contains a non-combustible part, which consists of nitrogen – at least 50%, which is due to the nature of the oxidizer and carbon dioxide, which is about 10% in the gas. The energy characteristic of such gas is in the range of 5400-6500 kJ/m^3. At the same time, the gas produced during the process in an argon environment has a calorific value of 10,000 kJ/m^3, which does not contradict and corresponds to literature data [32]. Such gases can be used as a substitute for natural gas, with a much lower calorific value, or in electricity generating plants.

The carbon residue left after the process is a valuable raw material. Such a product from switchgrass and pine sawdust is a low-ash substance (table 3), which is important for metallurgy, where coke is used as a reducing agent. In turn, it is undesirable to obtain coke from rice husk for direct use as fuel due to the high ash content (table 3). But such material is a direct raw material for synthesising such materials as silicon carbide due to the high content of amorphous silicon dioxide – 95-96% [33], and using the previously described ecologically safe waste-free technology and highly pure biogenic silicon dioxide [34].

Table 3. Characteristics of carbon material from biomass.

Raw materials	Higher heat of combustion (J/g)	Ashiness (%)
Rice husk	18078	37.0-39.0
Pine sawdust	19055	2.0-3.0
Switchgrass	19689	6.0-8.0

In addition, such a high-ash carbon residue showed its effectiveness when using it in the production of organo-mineral fertilizers. In order to solve the optimization of phosphorus nutrition of corn on dark grey podzolized soil, OMF-II was applied to the fertilization system in a post-sowing application at a dose of 0.5 t/ha. Our structural analysis shows that all the structure elements participate in crop formation and change depending on the level of nitrogen, phosphorus, potassium, microelements and weather conditions during the growing season of the corn plants. Cob and grain sizes are important elements of crop structure that directly affect the corn plants' productivity. As evidenced by the structural analysis data (table 4), the absence of OMF in the fertilization system affected the reduction of such important indicators as the grain yield of one plant and the 1000 grains weight, which have a significant impact on the yield.

Cob diameter under the influence of fertilizer variants in the experiment increased by 12%. The largest cobs of the plant were formed with the application of 0.5 t/ha OMF-II – 20.1 cm. Quantitative analysis of such cob indicators as the number of rows and grains per row shows a significant increase in these indicators relative to control. The content of grains per row increased

Table 4. Elements of the yield structure and productivity of Moskito corn hybrid, 2018.

Treatment	Cob diameter (cm)	Cob length (cm)	Cob weight (g)	Number of rows (pcs)	The number of grains per row (pcs)	The number of grains per cob (pcs)	1000 grains weight (g)
$N_{165}P_{87}K_{32}$ – background	4.5±0.03	18.2±0.6	206±10.6	13,9±0,41	39.6±1.6	534±22.9	278±11.9
Background + OMF -II (0.5 t/ha)	4.9±0.03	20.1±0.6	219±10.5	14.3±0.43	45.0±1.6	639±30.1	319±15.3

by 13% with the introduction of OMF-II.

One of the important indicators of crop structure, which is the most prerequisite for increasing yields is grains weight, which is formed on the cob. The largest weight of grain in the cob was established – when applying OMF at a dose of 0.5 t/ha – 643g (+20%) compared to control. The 1000 grains weight, as an indicator of the grain size formed on the cobs, was the highest – 319 g in the variant where OMF was applied at a dose of 0.5 t/ha and exceeded the control indicator by 14.7%.

Corn feeding conditions for grain, soil and climatic conditions during the growing season and the method of soil cultivation largely determine the amount of its harvest. Establishing the difference between the corns yield under mineral and organo-mineral fertilization systems with the application of our fertilizers was aimed of our research. This is evidenced by the results of the study of the effect of OMF and mineral fertilizers on productivity in our experiment with corn (table 5). In our investigation, humic acids, biophilic silicon, and sulfur in the composition of OMF contribute to the mobilization of poorly soluble phosphates of fertilizers and soil and the improvement of phosphorus nutrition of corn plants. With the use of such fertilizers (OMF-II), plants formed a more powerful root system with improved morphological indicators and an increased absorption surface. The experimental plant's roots weight exceeded the control samples by 28%. Such changes in the indicators of the root system led to a significant increase in the roots volume and the rhizosphere cell of the soil, where numerous chemical and biological transformations, sorption, desorption, and absorption take place. In addition, this indicates the absence of toxic effects of macro- and microelements, which contain the studied OMF-II. Namely, the imbalance of elements in the nutrition system leads to extremely negative consequences – a decrease in the productivity of crops and a deterioration of quality indicators.

Table 5. Yield and quality of Moskito corn hybrid, 2018

Treatment	Crop yields (t/ha)					Yield increase		Content (%)		
	replication				Average					
	1	2	3	4		t	%	starch	fat	albumen
$N_{165}P_{87}K_{32}$ – background	10.8	10.5	9.9	11.2	10.6	–	–	73.3	3.3	7.0
Background + OMF -II (0.5 t/ha)	12.9	13.5	12.2	13.7	13.0	2.4	22.6	73.2	3.5	7.8
HIP_{05}	0.53	0.64	0.79	0.75	0.77					

The data from determining the grain productivity of one plant were positively correlated with the obtained grain yield on the corresponding experimental plots. The yield increase (2.4 t/ha) compared to the control by 22.6% with the additional application of nutrients to the soil in the form of OMF-II according to the economic background N165P87K32 (table 5). This indicator significantly exceeds the average statistical yield of this crop in Ukraine (6.4-7.0 t/ha) due to the increase in the gross content of the main nutrients and their availability in the soil of the experimental site. It is known that the corns yield is formed due to precipitation, solar radiation and air temperature. Therefore, in our opinion, very favourable climatic conditions in July-August had a significant impact on the increase in yield in the reporting year. During this period, more than 155 mm of precipitation fell compared to the same months in 2017, which contributed to the optimization of mineral nutrition, growth and development of corn plants in a critical period regarding moisture. The high yield of the Moskito hybrid with the application of our OMF is probably due to the intensive supply of photoassimilants to the grains. The conducted analysis of the grain of the corn of Moskito confirms that it was suitable for food, fodder, technical needs and export. The increase in productivity with the OMF use strengthens the "effect of growth dilution". The 1000 grains mass, and therefore the grains size, increased significantly, while the rate of accumulation of proteins and fats did not change significantly. The introduction of OMF 0.5 t/ha into the corn fertilization system contributed to the formation of grain with better protein content – 7.8% compared to the control – 7.0%, where only mineral fertilizers were applied. The fertilization system did not affect the starch content in the grain (table 5). This indicator remained at the level of 73%.

Among grain crops, corn has the highest uptake and assimilation coefficient of macro- and microelements from the soil. For the formation of one grain ton and the corresponding number of vegetative organs, it takes from the 1 ha soil, kg/ha: N – 20-30, P_2O_5 – 8-10, K_2O – 15-17, as well as a lot of calcium, magnesium (Mg) – 6-10, sulfur (S) – 4-5, manganese (Mn) – 0.15, zinc (Zn) – 0.05-0.1, boron (B) – 0.01-0.02, molybdenum (Mo) – 0.01, iron (Fe) – 0.2 and other trace elements. Traditionally, this culture is considered an "indicator" of the content of trace elements in the soil. Corn is sensitive to their use, especially zinc (Zn), manganese (Mn), copper (Cu) and boron (B), the lack of which slows down plant growth and development and reduces crop productivity [35, 36]. As evidenced by the data of the elemental analysis of the ash of the plant samples of the Moskito hybrid corn (table 6), the grain did not contain such dangerous elements as cadmium, lead, or copper.

Taking into account the importance of wheat as a leading crop in Ukraine's agriculture and negative forecasts regarding global climate changes, the development of environmentally safe and effective prolonged action organo-mineral fertilizer, which would ensure the improvement of mineral nutrition of plants and increase their drought and frost resistance, is important and relevant. The winter wheat yield is directly dependent on the quantitative expression of each structural element. Its value is an integral indicator of productivity by phases of plant growth and development. Our structural analysis shows that all structure elements participate in the crop formation and change depending on the level of phosphorus supply to the plants and weather conditions. The size of the ear and its filling with grain are important elements of the crop structure that directly affect plant productivity. As shown by the data (table 7), with the additional application of nutrients in the form of BG-II fertilizers, there was a significant increase in the indicator – the grains number per ear by 85% in the version where 0.6 t/ha was applied in the background and by 74% – in variant with the application rate of 1.0 t/ha. The results of our research indicate a significant increase (up to 72%) in the Mulan winter wheat plants' productive tilling compared to the control with the application of BG fertilizers at a dose of 1.0 t/ha and by 56% at – 0.6 t/ha. It was characteristic of the Mulan variety that the mass of grains both from the main ear and the side shoots did not depend on the fertilization options. Therefore, the following indicators influenced the overall productivity of plants: synchronous

development of the main and side stems, high productive tilling, and ears graininess.

The results of a field experiment with Mulan winter wheat F2 hybrid (*Triticum aestivum L.*) (table 8) show that the harvest yield of the experimental wheat plants depended on the fertilization options, the weather conditions occurred during the phase of the emergence of the plants into the tube, milk ripeness and as well as on the grain size of the ear, the number of productive stems on the plant. Our BG-II introduction into the fertilization system and favourable weather conditions ensured the improvement of experimental plants' nitrogen-phosphorus nutrition. It allowed obtaining an additional harvest of winter wheat grain of 2.5 t/ha using BG-II fertilizer at a dose of 0.6 t/ha and – 1.5 t/ha for the use of 1 t/ha BG-II (table 8).

The main task of rational fertilization system is to achieve a positive balance of nutrients. Recently, in connection with the decrease in the use of organic and mineral fertilizers in many farms of Ukraine, the balance of the main nutrients has become negative, which caused a decrease in soil fertility. Therefore, knowledge of the ways of nutrients loss and their supply is very important for the optimal fertilizer application systems development. Obtaining an increase in

Table 8. Yield and quality of Mulan winter wheat F2 hybrid (*Triticum aestivum L.*), 2019.

Treatment	Crop yields (t/ha) replication					Yield increase		Content (%)
	1	2	3	4	Average	t	%	albumen
Control	5.3	5.6	5.4	5.3	5.4	–	–	12.2
Background + BG-II (0.6 t/ha)	7.4	7.9	7.6	7.9	7.9	2.5	46	12.8
Background + BG-II (1 t/ha)	7.0	7.3	6.6	6.7	6.9	1.5	28	13.0
HIP_{05}	0.26	0.32	0.30	0.31	0.30			

yield is associated with additional nitrogen and phosphorus absorption by experimental plants of Mulan winter wheat F2 hybrid (*Triticum aestivum L.*) with the application of BG-II fertilizers. As a result of the conducted research, a high positive correlation (r=0.9) was established between the grain productivity of one plant, grain size of the ear, productive tilling and grain yield. The quality of winter wheat grain largely depends on varietal and genetic characteristics, soil and climatic conditions, as well as on the basic nutrients supply. However, the fertilizers application is one of the most effective means that causes changes in the chemical composition of plants and increases the grain quality. There are conflicting data on the effect of an increased phosphorus nutrition's level on protein content and grain technological quality. Some authors point to the positive effect of phosphorus nutrition on grain quality, which is that excess nitrogen delays protein synthesis and encourages the accumulation of ammonia and nitrate nitrogen, which is harmful to plants, and phosphorus prevents this unwanted process. As shown in table 8, under favorable weather conditions, balanced nutrition with the introduction of our fertilizers (BG-II), the protein content increased by 6.6%. In the control, the experimental grain contained 12.2% protein (3rd grade, filler), then with the introduction of BG-II at a dose of 1t/ha, this indicator improved to 13.0% (2nd grade).

The elemental analysis (table 9) of the Mulan winter wheat F2 hybrid (*Triticum aestivum L.*) plant samples ash allows us to state that when BG-II was added to its fertilization system, the grain did not contain such dangerous elements as cadmium, lead, copper, and others.

The presence of calcium in the composition of our organo-mineral fertilizers is a source of replenishment of the soil, affects the fixation of organic substances in it, which provides favorable conditions for the formation of soil optimal physical properties. The organic carbon contained in such fertilizers ensures a positive balance of humus in the soil. Such fertilizers can

be used as an effective ameliorant, especially for acidic (podzolic) soils because they have a slightly alkaline reaction. In addition, it should be added that the introduction of such organo-mineral fertilizers in increased doses can significantly change the nitrogen balance in the soil from non-hydrolyzed forms to mineral and easily accessible to plants, improve phosphorus-potassium nutrition (increase the content of mobile compounds of phosphorus and potassium in the soil), increase the content of clay-mineral particles in the upper genetic layer, which will probably lead to soil cultivation due to the high content of sulfates and calcium carbonates in the composition of organo-mineral fertilizers.

4. Conclusion

High-temperature thermolysis of lignocellulosic waste was carried out with the production of combustible gases at a laboratory facility. It was established that under the conditions of thermolysis, a gas with a calorific value of 5400-6500 J/m^3 is formed in the air, and under inert conditions – 10,000-12,000 J/m^3, and a carbon residue with a calorific value of 18,000-20,000 J/m^3. It's shown that high-ash carbon after the process can be a precursor in the production of silicon oxides and carbides, as well as be one of the important components of organo-mineral fertilizers. With the help of the proposed disposal of wastewater treatment plant sludge ash and plant waste into agrochemically effective fertilizer, we can solve such problems as reducing the volume of accumulated sediment at aeration stations, while involving a valuable source of calcium, phosphorus and some biogenic trace elements in the composition of such necessary products for modern agricultural production. The growing shortage of food, which is associated with the increase in the population and the depletion of agricultural land, the predicted ecological crisis, the expected global warming, as well as the high requirements (standards) that are currently being set for agricultural products, make it urgent to solve the issue of introducing new, environmentally safe, natural organo-mineral fertilizers.

Abstract. TThe paper substantiates the feasibility of creating an adsorption technology with controlled activation of the adsorbent for the removal of sulfur dioxide, nitrogen oxides, and carbon from the flue gases of coal-fired power plants. In laboratory conditions, the effect of mechanical activation on the adsorption capacity of ash was studied. It is shown that the controlled mechanical activation is able to increase the adsorption capacity of ash relative to sulfur dioxide by 2.7 times, to nitrogen oxides by 2.1 times, to carbon monoxide by 5 times or more.

1. Introduction

The National Report on the State of the Environment in Ukraine in 2020 [1], shows that 3.8 tons of pollutants were present per square kilometer of the country's territory. The main chemical components entering the atmospheric air from stationary sources are substances in the form of suspended solid particles – 248.9 thousand tons (11.1% of the total volume of pollutants), dioxide and other sulfur compounds – 782.1 thousand tons (34.9%), methane – 429.1 thousand tons (19.1%), nitrogen oxide – 3.4 thousand tons (0.15%), carbon monoxide – 707.3 thousand tons (31.5%). Almost 37.9 % of pollution from stationary sources comes from the energy sector, mainly thermal power plants. In Ukraine, flue gases from coal-fired power plants, boilers, and heaters are released into the environment without treatment. The problem of atmospheric air pollution in Ukraine with toxicants remains relevant.

Independent researchers [2] also confirm the significant damage that flue gases from coal-fired power plants cause to the environment. According to this report, Ukraine is one of the leaders in Europe in terms of atmospheric air pollution with sulfur and nitrogen emissions emitted together with the flue gases of coal-fired power plants. Among the thirty coal-fired power plants in Europe that pollute SO_2 the most, 12 belong to Ukraine. Ukraine ranks second in Europe in air pollution with nitrogen oxides. Ukraine produces 34% of its electricity consumption from 20 coal-fired power plants built before 1976, none of which have desulfurization equipment. Therefore, the task of cleaning flue gases of coal-fired power plants from sulfur, nitrogen and carbon oxides is extremely relevant in the European context.

There are a lot of various studies aimed at improving coal combustion processes and implementing technological processes that reduce emissions of sulfur oxides, nitrogen, and carbon. Zaporozhets et al [3] provides statistical studies of emissions into the atmosphere by stationary and mobile sources of pollution in Ukraine for 1990–2018. It also indicates the need to reduce emissions of toxicants into the atmosphere. This can be achieved through the introduction of new technological processes at coal-fired power plants.

Chernyavsky et al [4] summarizes the experience of burning coal mixtures at three power plants of Ukraine. The issues of production, grinding, burning of mixtures and ecological aspects of their use are considered. Popov et al [5] shows that burning coal leads to the accumulation of ash and slag waste. Although they are environmental pollutants, under the right conditions these wastes can become a sorbent and be used in technologies for the adsorption of sulfur oxides, nitrogen and carbon from flue gases. Moreover, flue gases are formed in the same combustion processes where these solid ash and slag wastes are formed.

Volchyn et al [6] established an analytical relationship between SO_2 emissions in flue gas at coal-fired thermal power plants and the ash content of Ukrainian thermal coal. Thus, the research data indirectly indicate the possibility of controlling the sulfur oxide content due to technological processes aimed at ash activation. Schmauss and Keppler [7] show that sulfur dioxide is actively adsorbed by volcanic ash, so it can be concluded that ash from burning coal will similarly adsorb SO_2. Walawska et al [8] proves that the mechanical activation of solid particles significantly improves their characteristics as adsorbents for SO_2. Wu et al [9] proves that different modes of mechanical activation of coal slag significantly change its physicochemical characteristics and adsorption capacity. That is, mechanical activation of coal ash is potentially able to improve the adsorption of sulfur dioxide and other toxicants from flue gases. Shukor et al [10] studied the adsorption of sulfur dioxide by carbon. Carbon is also contained in ash as a product of incomplete combustion of coal, so the adsorption characteristics of coal ash may partially depend on its carbon content. Articles [11, 12] show that carbon can also actively adsorb nitrogen oxides.

The analysis of the literature showed that when burning coal at TPPs, solid wastes are formed – ash and slag, and gaseous wastes – oxides of sulfur, nitrogen, and carbon. At the same time, it is possible to create such a technological process, when the solid emission – ash, will be mechanically activated and will adsorb oxides of sulfur, nitrogen, and carbon. Such a technology, provided it is created, has a real perspective for implementation at coal-fired thermal power plants of Ukraine and Europe. The idea of creating such a technology emerged as a result of own research [13] of various chemical processes, when mechanical and chemical activation of the catalyst significantly accelerated chemical transformations. Adsorption is one of the stages of catalysis, so mechanical activation of MA can affect adsorption as a separate process. Studies of processes using coal as a raw material [14, 15] have shown that coal can be mechanically activated. This formed the basis of this work, where ash from coal combustion was activated under controlled conditions. This increased its sorption capacity relative to sulfur dioxide, nitrogen oxides, and carbon monoxide. Research results can become the basis of technology for removing toxicants from flue gases of coal-fired power plants.

2. Laboratory equipment and methodology of the experiment

The laboratory unit for researching the process of adsorption from flue gases under the conditions of mechanical activation is presented in figure 1.

Adsorption of nitrogen oxides, sulfur oxide (IV), and carbon monoxide was studied. Ash from burning coal and zeolites of various types were used as a sorbents. Before the start of the experiment, the V-1 tank is filled with a mixture of air, sulfur oxide (IV), nitrogen, and carbon, which is an analogue of flue gases produced during the burning of coal at power plants in different modes. The obtained gas mixture enters Ads adsorber from above. The adsorber is filled with sorbent and dispersing material.

The temperature in the adsorber is maintained by an electric heater H, measured by a

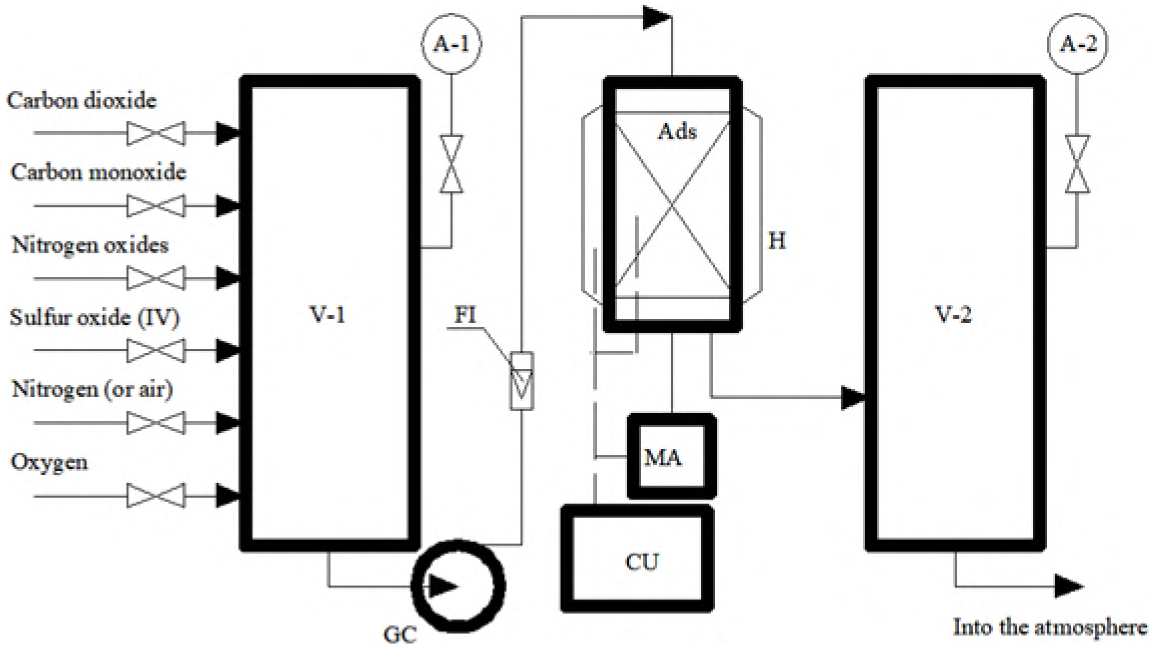

Figure 1. Laboratory unit for studying the process of adsorption of substances from flue gases using mechanical activation. CU – control unit; V-1 – container with a gas mixture; A-1-2 – gas mixture analysis points; H – electric heater; Ads – reactor-adsorber; MA – vibrating device; GC – compressor; V-2 – receiver of adsorbed gases; FI – rotameter.

thermocouple. The activation of raw materials in the adsorber is carried out by forced mechanical oscillations with the help of an vibrating device MA. The temperature in the reaction zone and the intensity of activation are set and maintained by the control unit CU. When the adsorber moves with a certain frequency and amplitude, a vibro-thinned layer of dispersing particles is created and mechanochemical activation of the sorbent surface by them. A metal felt filter is located at the outlet of the adsorber, which prevents the removal of sorbent particles from the adsorption volume. Gases from the adsorber enter the V-2 receiver. Pumping of the gas mixture from V-1 to V-2 is carried out by the compressor GC. The unit has two sampling points of the gas mixture for analysis: the initial mixture and the final products. The content of oxides of nitrogen, sulfur and carbon is determined by a portable gas analyser OKSY-5M-5H with an error of ±5 ppm.

The volume of the laboratory adsorber is 8 cm^3, the capacity for gases is 50 liters. At a gas supply rate of 5-25 l/h, the duration of the experiment is 2-8 hours. Variable parameters during the experimental work were: temperature, flow rate of the gas mixture, concentration of gases in the mixture, vibration frequency of the vibrating device.

3. Research procedure

The AnC theory allows predicting intensification by mechanical activation of not only chemical transformations, but also other stages of the catalytic process, for example, the adsorption stage. Thus, it is possible to distinguish a separate direction of research – mass exchange processes. The degree of sorption and sorption capacity are highly dependent on temperature, intensity of activation, type of sorbent. The dependence of sorption efficiency and sorption capacity passes through maxima and is very similar to the dependence of the degree of transformation and the speed of chemical reactions on the frequency of mechanochemical activation in processes that take place using aerosol nanocatalysis technology. This indicates that sorbent activation is very similar in nature to catalyst activation. figure 2 shows the effect of mechanical on the sorption capacity of the sorbent – coal ash – relative to sulfur oxide (IV).

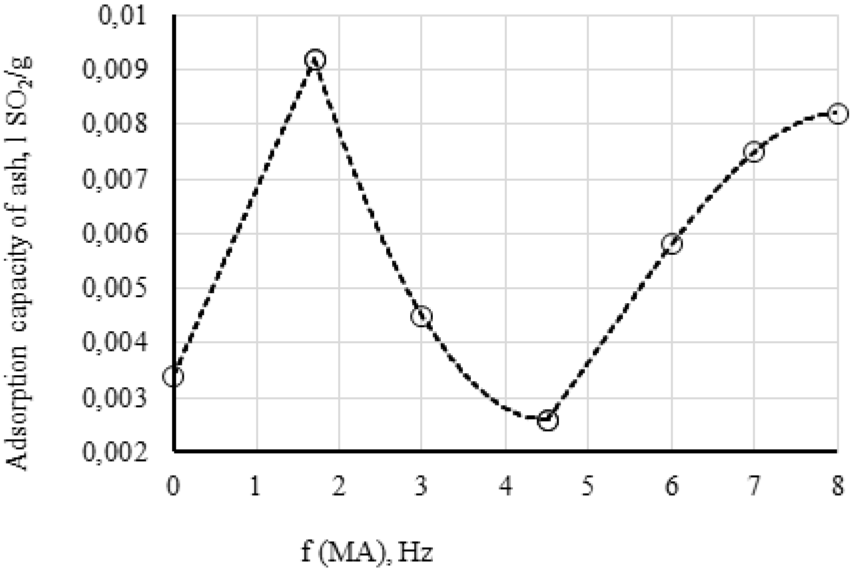

Figure 2. The effect of MXA on the adsorption capacity of ash in relation to SO_2 at 473K.

The presence of a maximum of the adsorption capacity at an MA intensity of 1.7 Hz and a tendency to a second maximum at an MA slightly higher than 8.0 Hz is observed. The dependence is described by equations (1).

The capacity achieved with the help of MA adsorption is such that it provides effective purification from sulfur oxides of flue gases from the burning of energy grades of coal with an ash content of 30%.

$$\begin{gathered}\theta = 0.0034f + 0.0034,\ \text{(0-1.7 Hz)};\\ \theta = 0.0008f^2 - 0.0076f + 0.0196,\ \text{(1.7-4.5 Hz)};\\ \theta = -10^{-5}f^3 + 0.0015f^2 - 0.0054f + 0.006,\ \text{(4.5-8.0 Hz)};\end{gathered} \tag{1}$$

The use of MA is able to increase the adsorption capacity of ash by 2.7 times at a temperature of 423K, i.e. it allows to organize an industrial technology for removing sulfur oxides without cooling flue gases, which will significantly reduce energy costs on the scale of an industrial process. The use of ash from the burning of the same coal as a sorbent will allow reducing material costs on the scale of the industrial process. The process is able to provide 100% removal of SO_2 when its content in flue gases is up to 650 ppm (a typical amount for flue gases from burning low-quality thermal coal with an excess of 1.25 air) at an adsorbent concentration of 60 g/m^3 of flue gases.

In figure 3 shows the effect of MA on the adsorption capacity of the same ash in relation to nitrogen oxides. The values are in the same range as for SO_2.

The use of MA is able to increase the sorption capacity of ash in relation to nitrogen oxides by 2.1 times at a temperature of 423K and ensure 100% removal of NO_x from flue gases from the burning of thermal coal at a concentration of sorbent (ash) at the level of 20 g/m^3 of flue gases, which corresponds to the technological mode of combustion at industrial plants. This cleaning technology does not even require an additional amount of adsorbent.

The presence of a maximum of the adsorption capacity at an intensity of MA near 3.0 Hz and a tendency to a second maximum at an MA above 8.0 Hz is observed. The dependence is

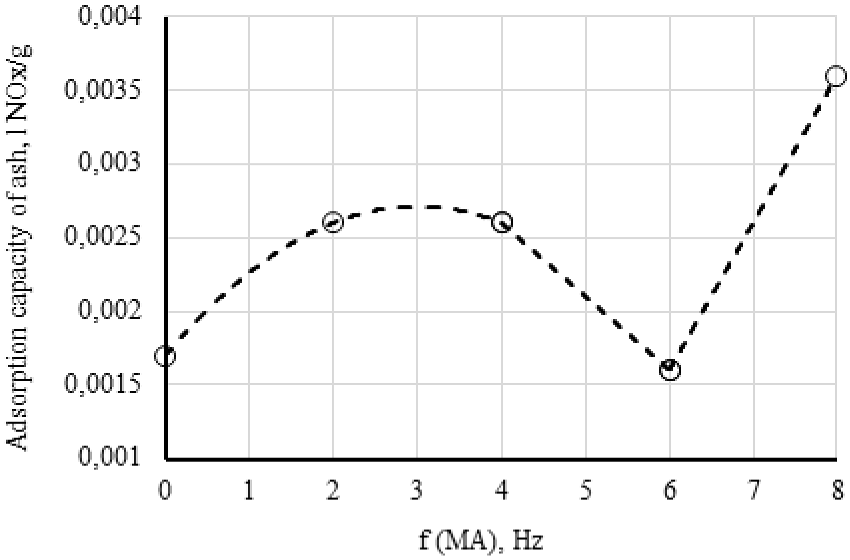

Figure 3. The influence of MA on the adsorption capacity of ash in relation to NO_x at 473 K.

described by equations (3). The capacity achieved with the help of MA adsorption is such that it provides effective cleaning of flue gases from the combustion of energy grades of coal with an ash content of 30% and a NO_x content of up to 250 ppm from nitrogen oxides.

$$\begin{gathered} \theta = -0.0001x^2 + 0.0007x + 0.0017, \text{ (0-4.0 Hz)}; \\ \theta = -0.0005x + 0.0046, \text{ (4.0-6.0 Hz)}; \\ \theta = 0.001x - 0.0044, \text{ (6.0-8.0 Hz)}; \end{gathered} \tag{2}$$

In some modes of coal burning at thermal power plants, carbon monoxide formation is possible, so it is advisable to study the ability of ash to adsorb it as well. In figure 4 shows the influence of MA on the adsorption capacity of ash in relation to CO, and the change in adsorption capacity from MA is described by equations (3), (4).

$$\theta = 0.0019f, \text{ (0-1.2 Hz)}; \tag{3}$$

$$\theta = -0.0004f^3 + 0.0038f^2 - 0.0112f + 0.011, \text{ (1.2-4.0 Hz)}; \tag{4}$$

For carbon monoxide, the influence of MA is particularly noticeable. In the absence of MA, it was not adsorbed at all under the experimental conditions. The use of MA at the level of 1.2 Hz made it possible to increase the adsorption capacity of carbon monoxide by more than 5 times in comparison with other modes of MA.

4. Conclusions

The development of technological processes capable of removing oxides of sulfur, nitrogen, and carbon from flue gases of coal-fired power plants is an urgent scientific and practical task. Adsorption processes using ash from the burning of the same coal as an adsorbent are promising.

The use of controlled mechanical activation can significantly affect the adsorption capacity of ash relative to oxides of sulfur, nitrogen, and carbon.

It is shown that the controlled mechanical activation is able to increase the adsorption capacity of ash relative to sulfur dioxide by 2.7 times, to nitrogen oxides by 2.1 times, to carbon monoxide by 5 times or more.

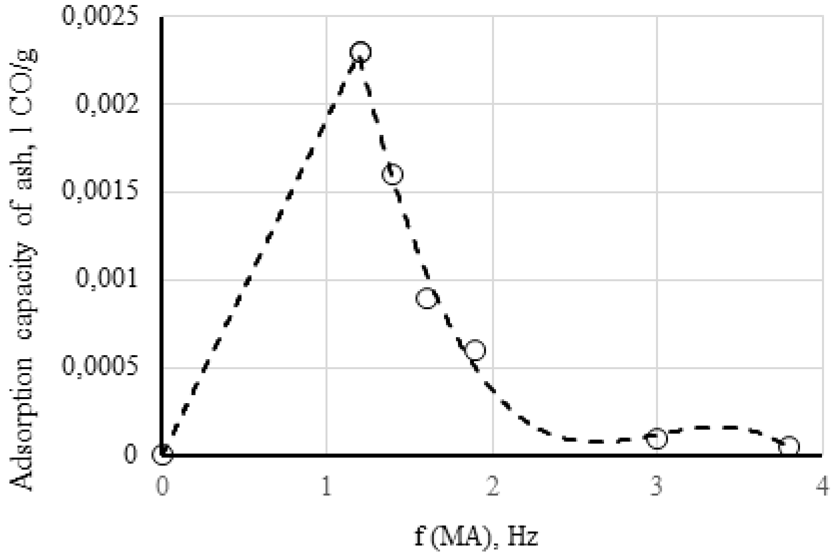

Figure 4. The influence of MA on the adsorption capacity of ash in relation to CO at 473 K.

A mathematical description of the influence of MA intensity on the adsorption capacity of ash relative to oxides of sulfur, nitrogen, and carbon is provided. This makes it possible to optimize the MA regime to achieve the most effective adsorption capacity of ash.

The research results can form the basis for the creation of industrial technology designed for the purification of flue gases of coal-fired power plants from sulfur dioxide, nitrogen oxides and carbon monoxide. But for this, it is still necessary to study the desorption stage and to propose ways of chemical binding of concentrated oxides of sulfur, nitrogen, and carbon into non-toxic products.

Abstract. The paper considers one of the important problems of water use – determination of the humidification conditions of the territory for the hydromelioration needs. The methodical approach to determining the probability of exceeding natural moisture by a group of criteria is highlighted. Nowadays there is no single, reliable and simple method for determining this indicator. Assessing climatic conditions, considering their impact on crop productivity, it is necessary to take into account hydrometeorological factors that have a decisive influence on the development of crops and, accordingly, determine their yield. These include, first of all, precipitation, moisture reserves in the soil, evapotranspiration and other complex indicators that allow to take into account the distribution of meteorological factors during the growing season of the crop and their possible negative impact on the development of the plant, because each crop requires a certain optimal regime of soil temperature and moisture at different stages of its development. The article presents the solution of the set tasks on the example of winter wheat crops according to the data of the Dnipro meteorological station (airport).

1. Introduction

The determining factor in the development of agricultural production in the Steppe of Ukraine is natural resources, which are characterized by bioclimatic potential, soil fertility and water regime. According to FAO estimates, Ukraine has the potential for a significant (up to 3 or more times) increase in agricultural production and exports, provided that the available natural resources are used more efficiently. Insufficient level of their use is limited by a number of factors, the main of which is the natural moisture supply deficit on more than 2/3 of the territory of Ukraine.

Thus, significant variability of moisture conditions in Ukraine is the main limiting factor that limits not only the level of crop productivity, but also the use of natural and anthropogenic potential of agriculture.

Many years of agricultural experience and scientific researches show that it is possible to prevent and mitigate the negative effects of climate changing on agricultural production only with the help of irrigated land reclamation [1].

Despite thousands of years of mankind experience in irrigated agriculture, the issue of vegetative irrigation of crops has not been studied enough. The key point here is the methodology for determining the availability of natural moisture in the territory. The correct choice of the year-model in the development of the irrigation regime will prevent serious miscalculations in the design of irrigation systems, waterlogging, flooding and flooding of irrigated lands, which will inevitably lead to secondary salinization and anthropogenic soil pollution and soil degradation in irrigated areas of Ukraine.

The aim is to develop scientific approaches to environmentally safe water use aimed at preventing the growth of anthropogenic impact on the environment, ensuring environmentally safe living conditions for the population and economic activity and protection of water resources from pollution and depletion, rational use of water resources, ensuring sustainable functioning of ecosystems in the river basins of Ukraine, prevention of harmful effects of water and elimination of its consequences.

2. Literature review

The analysis of scientific and normative materials in the field of hydromelioration shows insufficient reliability of existing methods for calculating the availability of natural moisture in the territory, which are used to improve the methods of water use rationing and assessment of the complex impact of hydrometeorological factors and irrigation regimes on crop yields and the ecological condition of reclaimed lands.

It is customary to assess the natural water availability of the territory based on the amount of precipitation during the growing season, climatic indicators, crop water deficit and actual moisture content of the calculated soil layer.

The sum of precipitation is mainly used in agroclimatology to assess the moisture conditions, which is calculated as a cumulative total and graphically represented in the form of integral curves.

Lebedev studied in detail the methods of constructing the curves of availability of various climatic factors and developed a methodology for constructing nomograms of availability of precipitation amounts [2]. Any probabilistic characteristic of climate is given on the basis of analysis of a representative series of observations. The types of curves proposed by Lebedev have great stability in space, which allows them to be used for a large area, including those that do not have a representative series of observations.

Such nomograms are constructed for different territories and they can be used to estimate the availability of natural moisture in the territory. As an example, figure 1 shows such a nomogram for the South of Ukraine [3].

Assessment of the moisture availability in the territory only by the amount of precipitation is insufficient and not always objective, since each year has a specific intra-annual distribution of precipitation uncharacteristic of others. A year with long dry periods and one or two large rains can be equated to a year in which rains fell evenly throughout the growing season, although the humidity of the territory in such conditions will be different. Therefore, to exclude the peculiarities of individual years, it is advisable to consider the frequency of precipitation or take not one, but several years that are closest to the calculated availability and average their meteorological data.

The disadvantage of this method is that not only precipitation affects the humidity of the territory, but also other agrometeorological factors that are not taken into account here.

Therefore, for a more correct and objective determination of the availability of the territory's humidity, various climatic indicators are used, taking into account not only the income (precipitation) component of the water balance of the territory, but also the costs, that is, the so-called meteorological complexes. An example of the application of such systems is the methodology for selecting a year of a given availability by a complex climatic indicator (CCI),

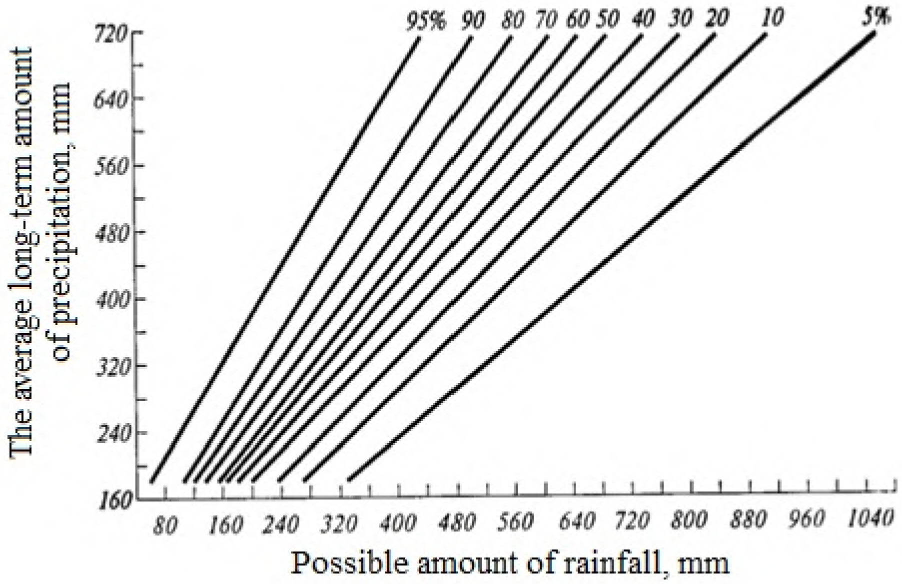

Figure 1. Graph for calculating the amount of precipitation of different availability per year (according to A. M. Lebedev) [3].

which was developed for zones of sufficient and unstable moisture in Ukraine. It is based on the availability integral indicator of CIP_j vegetation values of meteorological factors and meteorological complexes built on their basis [4–6].

The latter is determined by the formula

$$CIP_j = 1 - \frac{\sum\limits_{i=1}^{l} m_{ij}}{l \cdot n_j}, \tag{1}$$

where $\sum\limits_{i=1}^{l} m_{ij}$ – is the sum of places occupied by meteorological factors and complexes of the set $\{i\}$, $i = \overline{1, l}$ is the sum of places occupied by meteorological factors and complexes of the set, in the statistical sequences of their vegetation values for the years of observations reduced to a comparative form $\{j\}$, $j = \overline{1, n_j}$.

The value of the indicator CIP_j defined by (1), vary within $\{0;\ 1\}$ almost never reaching the limit values, which confirms the really complex and ambiguous nature of climate-forming components [6].

The choice of the year of a given availability by crop water consumption deficits by the real year method is carried out by a retrospective series of years, taking into account the composition of crops. According to this series of observations, crop water deficits are determined and their availability is calculated by the statistical method [7].

Water consumption deficits are calculated using total evaporation, which is determined by meteorological factors and biological characteristics of crops. The most widespread in Ukraine are the bioclimatic method [8, 9]; improved bioclimatic method [10]; biophysical method [11].

For a long time, the Penman [12] and Blaney-Criddle [13] methods were widespread in the world. Taking into account some inaccuracy of these methods in 1990, the FAO Council of Experts recommended to approve the combined Penman-Monteith method as a standard for calculating the reference evapotranspiration (ET_0). The method provides for the determination of ET_0 of a hypothetical crop with a height of 0.12 m, a surface resistance of $70\,\text{cm}^{-1}$ and an albedo of 0.23, similar to lawn grass of the same height in the phase of active vegetation and sufficiently moistened. The Penman-Monteith equation is derived from the soil surface energy balance equation, and the dependence of ET_C on ET_0 reflects the crop coefficient K_C, which characterizes the differences between a typical agricultural crop and a reference lawn grass [14–18]. Numerous researchers have analyzed different calculation methods in different regions. As a result, the Penman-Monteith method was adopted worldwide as a standard method for determining evapotranspiration (ET_0). ET from the plant surface under non-standard conditions is given by the stress coefficient (K_S) or modification of the culture coefficient.

Probably the most objective criterion for determining the availability of natural moisture in the territory is the actual moisture reserves in the calculated soil layer. In the presence of a representative series of data on moisture reserves, their availability is also determined by generally accepted statistical methods.

Nowadays, more than 20 methods of soil moisture measurement have been developed. But all of them have certain disadvantages that limit their use – significant time discreteness and uncertain representativeness when transferring their values to other fields or arrays; some of them have low efficiency.

These shortcomings are absent in the calculation methods for determining the content of moisture reserves in the soil. They usually involve the calculation of indirect indicators of moisture content based on previous weather conditions. In some methods, a simplified water balance equation is used, considering the initial soil moisture reserves measured by instrumental methods. It should be noted that errors of instrumental measurements and calculation errors of water balance components significantly reduce the accuracy of these methods. The method of determining daily soil moisture reserves developed at the Dnipro State Agrarian and Economic University is devoid of these shortcomings [19]. Therefore, in our research, we will use this method in assessing the natural availability of the territory by soil moisture reserves.

3. Research methodology

Time series depending on the nature of the time parameter are divided into interval and momentary. When assessing the availability of natural moisture in the territory, we deal with interval series in which the value of the indicator is calculated for certain periods of time. These series correspond to flow variables. It should be noted that a series whose levels are the result of an integral series, starting from a certain defined level, is considered momentary.

In our research, we will assess the moisture availability of the territory by the amount of precipitation, complex climatic indicator, water consumption deficit and moisture reserves. All these criteria for assessing the natural moisture availability of the territory will be determined for the growing and/or critical periods of crop development.

The initial data will be meteorological data on average, maximum and minimum air temperature (^0C); atmospheric pressure at sea level (hPa); average relative humidity (%); daily precipitation (mm), air humidity deficit and average wind speed (km/h). This paper presents studies based on data from the Dnipro meteorological station (airport) for winter wheat. Meteorological data were taken from [20].

The amount of precipitation to assess the moisture conditions is calculated by accumulating their daily values for the corresponding period.

The complex climate indicator is calculated according to the recommendations set out in [4–6].

It is difficult to determine evapotranspiration in the field accurately, so it is usually calculated using empirical and semi-empirical equations. Some of them can be applied only in specific climatic conditions and cannot be used for other conditions and territories. Given that the Penman-Monteyn method is considered to be the standard method in the world, we will use it in our research.

Numerous computer programs have been created to determine ET_0 by the Penman-Monteith method. The Food and Agriculture Organization of the United Nations (FAO) recommends using the CROPWAT 8.0 program. However, the existing databases of this program (CLIMWAT, FAOCLIM) should be checked for compliance with real data and missing climatic parameters in certain periods of time. In addition, they contain only average monthly data, and there is no data on meteorological factors, soil and agroclimatic conditions and genotypic characteristics of crops grown in Ukraine. Therefore, the use of this program for the study area is impossible.

Considering the above-mentioned findings, it is advisable to use meteorological data measured at the meteorological station in the studies of natural moisture availability of the territory. Since the reference evapotranspiration (ET_0) is an indicator of climate impact, it is advisable to adopt it as a criterion for assessing the moisture availability of crops.

To calculate evapotranspiration (ET_0) we use the ET_0 Calculator Version 3.2 [21].

The choice of the year of a given availability is usually made on the basis of a retrospective series of years by ranking and determining the value of the exceedance probability. The disadvantage of this method is that the same number of years is attributed to each group of years by moisture conditions, and this is not true. After all, any series of observations contains a different number of years by moisture conditions. This drawback can be overcome by using methods based on artificial neural networks.

The analysis of the obtained results will be carried out by mathematical-statistical and cluster methods. The cluster method is used to solve the problem of classification of data obtained as a result of calculations. In addition, cluster analysis, unlike most mathematical and statistical methods, allows the distribution not by one parameter, but by several, and allows us to consider a set of input data of almost arbitrary nature.

The number of clusters is usually taken from 4 to 9 – 2-3 clusters are uninformative, and more than ten clusters are difficult to process. Therefore, in our studies, we take five clusters, each of which characterizes the moisture conditions of the year by the probability of exceeding (availability p, %): 0-20% – very wet, 20-40% – wet, 40-60% – average, 60-80% – dry, 80-100% – very dry.

Statistical multivariate cluster analysis of moisture availability of the study area will be conducted using Kohonen networks. The advantage of the network is that it is able to function in the face of interference, because the number of classes is fixed, the weights are modified slowly, and the adjustment of weights ends after training. It should be remembered that Kohonen maps offer only hypotheses about the cluster structure of the data. Therefore, for each cluster, its meaningful interpretation will be carried out using mathematical and statistical methods.

The distance to the center of the cluster is used as a criterion for the correspondence of a certain year to the humidity conditions of the territory. In this aspect, the scale becomes crucial in cluster analysis, because due to the heterogeneity of the features measurement units it becomes impossible to correctly calculate the distances between points. This problem is solved by preliminary standardization of variables.

To process the obtained calculations, the computer programs Mathcad and Deductor Studio were used [22].

4. Results and discussion

The table 1 shows the data on the calculation of the probability of exceedance separately for each of the adopted criteria using the mathematical and statistical method. To do this, the retrospective series were ranked separately for each criterion, and then the security of each member of the ranked series was calculated.

The analysis of table 1 shows that when choosing a year of a certain availability according to different criteria, the calculated real years, which characterize the moisture conditions of the

Table 1. Provision of the year by natural moisture of winter wheat crops.

Year	BCC	Year	ETo, mm/day	Year	P, mm	Year	W_{100}, mm	p, %	Humidification conditions
2021	0.938	2002	180.7	2014	286	2021	269.5	4.17	very wet

2022	0.329	2005	222.2	2022	106	2018	233.1	62.50	medium dry
2019	0.292	2009	224.5	2019	103	2009	232.5	66.67	(p = 60-80 %)
2003	0.248	2011	227.1	2018	99	2019	229.2	70.83	–
2002	0.180	2010	228.8	2007	94	2022	226.6	75.00	–
2007	0.180	2019	234.2	2012	92	2003	220.2	79.17	–
2009	0.174	2007	237.8	2003	87	2013	217.4	83.33	dry
2012	0.149	2018	239.2	2009	72	2012	209.2	87.50	(p=80-100 %)
2018	0.118	2013	249.1	2002	65	2020	207.8	91.67	–
2013	0.112	2012	252.3	2013	55	2007	191.6	95.83	–

year by the probability of exceeding, do not coincide.

Thus, there is no clear answer as to which of the years should be taken as a model year. Therefore, in order to minimize internal differences between the evaluation criteria in each of the 5 groups that characterize the moisture conditions of the year by the probability of exceeding (provision p, %) and at the same time maximize the differences between the groups, we will use the cluster analysis method for the data presented in table 1.

The table 2 shows the main result of the cluster analysis in the form of a cluster number and a list of years belonging to each cluster. As additional information, the table contains the distance from the object to the center of the cluster. It will help to understand which of the years most closely corresponds to the moisture conditions.

The analysis of table 2 shows that the number of years in the clusters is different. Therefore, the determination of the probability of exceedance (p, %) by the conventional ranking is illegal.

Thus, the assessment of moisture conditions of the year can be carried out not by the quantitative criterion, but by the qualitative one. Since during the cluster analysis the entire retrospective series was divided into 5 clusters, the probability of exceeding (p, %) of each cluster can be estimated as the average of the established limits.

To visualize the data in table 2, we use Kohonen maps (Self-Organizing Map, SOM) (figure 2). The principle of building Kohonen maps is that in the process of training the model, neurons on the Kohonen map compete with each other for the right to best match the input data. This principle of competition and matching allows you to create a map that reflects the data structure of the original space in a lower-dimensional space. This facilitates further data analysis

Table 2. Distribution of years by moisture conditions into clusters.

Year	Cluster number	Distance to the cluster center	Humidification conditions
2001	0	0.2605	very wet
2004	0	0.2571	(p = 0-20%)
2014	0	0.2356	-
2016	0	0.2297	-
2021	0	0.2773	-
2000	1	0.1991	moist
2006	1	0.1974	(p=21-40%)
2008	1	0.0773	-
2015	1	0.0773	-
2017	1	0.1539	-
2007	2	0.3663	average
2009	2	0.2313	(p=41-60%)
2012	2	0.2677	-
2013	2	0.2375	-
2013	2	0.1960	-
2019	2	0.1927	-
2002	3	0.4593	medium dry
2003	3	0.1237	(p=61-80 %)
2020	3	0.2255	-
2022	3	0.0624	-
2005	4	0.0500	dry
2010	4	0.1147	(p=81-100%)
2011	4	0.1494	−

and visualization. The process of building a Kohonen map can be reduced to the following main stages: initialization; model training; successive iterations; end of training and mapping itself.

To evaluate the accuracy of Kohonen mapping, the mapping error is used as a metric. It occurs when SOM is trained on a large data set. This error measures the distance between the values obtained by SOM and the actual data values. Kohonen maps are considered to be highly accurate if this error does not exceed 0.1. In our research, we used the Deductor 5.3 analytical platform to build the Kohonen map and found an error of 0.01.

The analysis of figure 2 shows that the size of the clusters is different and the years are not evenly spaced. The cluster size is defined by its radius or standard deviation of the year for a particular cluster. A year belongs to a cluster if the distance from the location of the year in the cluster to the center of the cluster is less than its radius. In cases where this condition is met for two or more clusters, the year is controversial, that is, according to some of the selected criteria it can be attributed to several clusters. Therefore, in order to eliminate such ambiguities, the final choice of the year characterizing the established moisture conditions is made by the distance to the cluster center.

Consequently, the year with the minimum distance to the cluster cent is taken as the model year. In the calculations presented in this paper, we assume that for winter wheat a very wet year is 2016, a wet year is 2008, an average year is 2019, an average dry year is 2003, and a dry year is 2005.

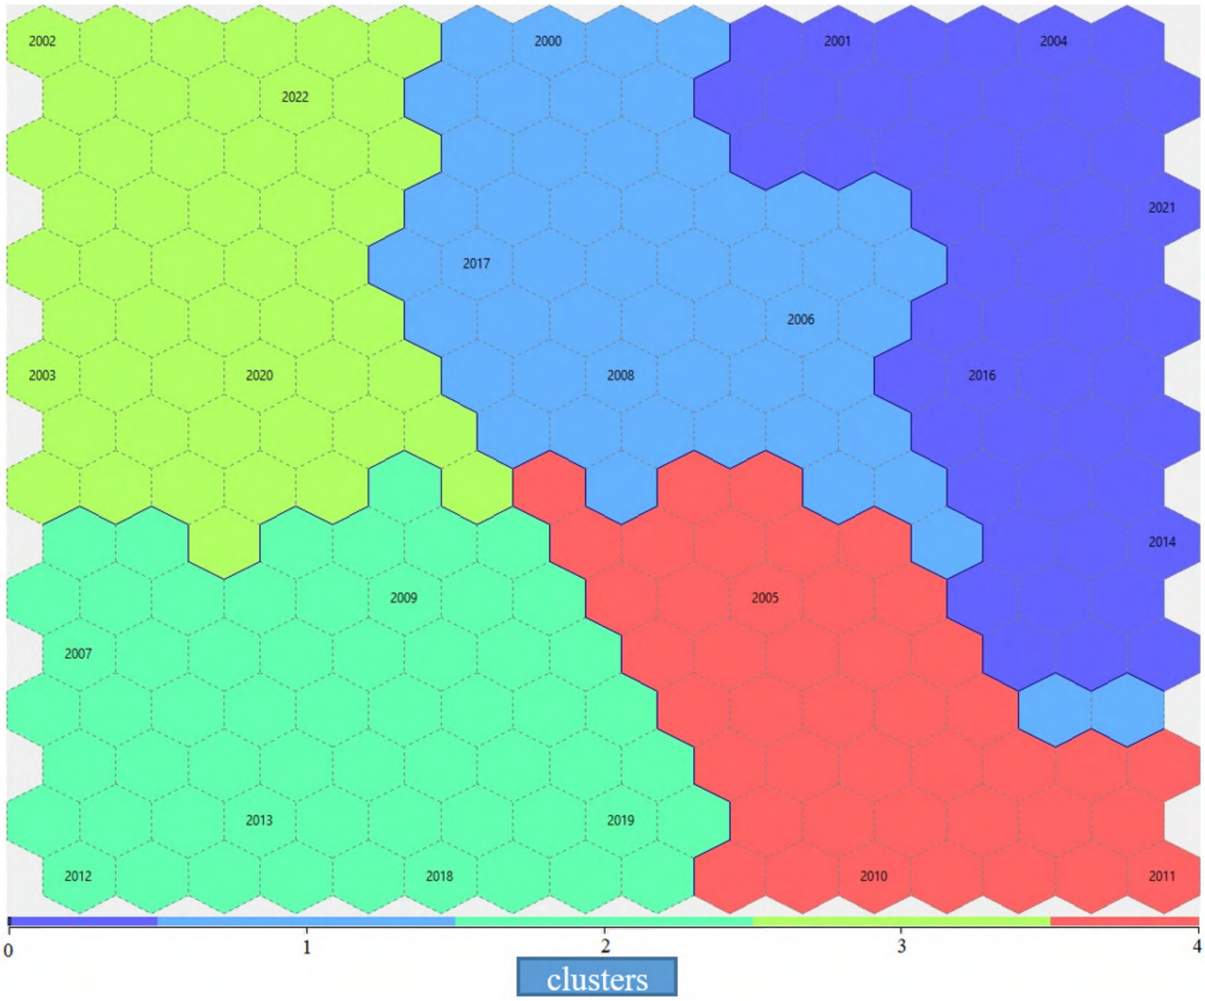

Figure 2. Distribution of years in clusters.

5. Conclusions

The data shown in table 1, table 2 and figure 2 indicate that when assessing the natural conditions of the territory based on hydrometeorological data, the cluster analysis method has significant advantages over the statistical one, as it gives a clear answer to which of the available retrospective years most accurately characterizes the moisture conditions of the territory. This is due to the consideration of several criteria. Assessment of natural moisture availability of the territory by several criteria allows to characterize the dynamics and intensity of changes in hydromelioration factors during the growing season of crops.

In the context of global climate change, the problem of availability and use of water resources is exacerbated, and the use of the proposed methodology for determining the moisture availability of the territory makes it possible to more accurately determine the need for water during hydro-amelioration measures. That is why it is advisable to choose the calculation year according to several criteria using the cluster analysis method.

Abstract. The article considers the pre-war conditions main components of the Southern Bug mouth ecosystem. The results of sediments samples study have shown transformation of lagoonal accumulation, appearance of reducing condition spots in sediments, presence of exceeding MAP for lead. An estuarine water analysis given an idea about hydrochemical features mouth section of river, namely: high concentration of suspended solids – on an average 11,4 mg/dm^3; increasable concentration BOD$_5$ – an indicator of easily oxidized organic substances content; periodic significant exceeding MAC of ammonium and nitrite nitrogen. Hydrobiological changes primarily concern a decrease in primary productivity due to a decline in phytoplankton biodiversity; there was also a reduction of zooplankton. The current state of the Southern Bug River mouth ecosystem is formed predominantly under the periodic dredging of shipping channels followed by the formation silt dumps. The post-war revitalization of the Southern Bug estuary ecosystem should include measures to mitigate the negative effects of anthropogenic activity especially the consequences of hydraulic engineering works.

1. Introduction

The Southern Bug is one of the largest rivers of Ukraine, which constantly experiences significant anthropogenic pressure due to the high regulation of the river, large-scale ploughing of coastal areas, dense settlement load. At the same time, the Southern Bug plays a very essential economic and social role in the functioning of the Black Sea region of Ukraine – it is a transport artery, a source of drinking water and food, a place of recreation, etc. If you look at this range of ecosystem services, especially in the context of global climate change, it is impossible to overestimate the importance of the Southern Bug River in the socio-economic development of the southern part of Ukraine [1]. However, now, since the beginning Russia's full-fledged military aggression, the territory the Southern Bug River mouth is under catastrophic influence due to bombing and shelling.

The current state of the Southern Bug mouth ecosystem is formed under the influence of the multi-purpose usage of the river; one of the most powerful factors affecting the estuary part of the river is shipping and the associated periodic dredging of shipping channels. The Bug-Dnipro-estuary Canal (BDEC) serves as the entrance for the ships to Mykolaiv Port and a number of ports in the estuary. In addition, the lower part of the Southern Bug is intensively used for economic purposes: hydrotechnical (water intakes, discharges), fisheries, irrigation, etc. [2]. Periodic hydrotechnical dredging measures have a significant impact on the functional capacity of the river ecosystem and its biota.

The key goal of the presented research was to characterize the pre-war state of the Southern Bug River mouth ecosystem using a wide range of indicators, including lithological, hydrochemical and hydrobiological ones.

In order to achieve the above goal, expeditionary research of the Southern Bug River mouth, laboratory and desktop processing of the results was carried out. Moreover, comparative assessment of the obtained results with the results of own previous research and literature data was fulfilled; the features of the obtained indicators in the context of anthropogenic activity are characterized and possible ways of mitigating environmental problems are considered.

2. Materials and methods

The presented materials are based on the research data of the Southern Bug lower part in the spring and summer of 2021, analysis of research data of 2012 and analysis of literature. The research area is the Southern Bug River mouth, which is part of the Dnieper-Bug estuary (figure 1).

Figure 1. The research area.

The study of modern sediments of the lower part of the Southern Bug River has been carried out. The sampling points were located along profiles that crossed an investigation object. We researched samples from two profiles: first – near the port Olvia, second – across the Southern Bug (between villages Parutyne – Lymany).

The Southern Bug River research area was conducted at the lower reaches, below the Mykolaiv city; 18 samples of sediment and 27 samples of water were selected. Samples of sediments were taken with the special cylindrical equipment. The thickness of the sediment layer selected for analysis was 0.1–0.25 m. After drying, the selected samples were subjected to averaging at the points of selection.

The sediment samples analysis included the description of sediments, determination of their granulometric composition and density; definition of physical and chemical indicators: pH, Eh, electrical conductivity. The chemical composition study of the samples consisted in the pollutant elements determination, the water-soluble salts content and iron oxides.

The water samples analysis included the determination of the chemical indicators, namely: pH, total salts, dissolved oxygen, suspended substances, chlorides, sulphates, biological oxygen consumption (BOD_5), the content of ammonium, nitrite, nitrate and total phosphorus. All indicators in the water were determined by standard methods.

Hydrobiological studies consisted in general assessments of phytoplankton and phytobenthos, zooplankton and zoobenthos, and characterization of higher aquatic vegetation involved. The samples of phytoplankton were taken and processed through standard hydrobiological procedures [3,4]. Both qualitative and quantitative characteristics of phytoplankton in performing ecological analysis were used.

3. Results

The modern sediments of the mouth Southern Bug River mouth represent mainly silt. Sands develop in some places in the form of narrow coastal strips, as well as on beaches and capes. Shell rocks occur in the form of small spots on beaches and spits that cannot be mapped.

Due to the solid runoff from the Southern Bug River, estuarine deposits are covered with a thin layer of modern sediments in the Dnieper-Bug estuary, in the Bug part area of the shipping channel and the water areas of the ports. The role of solid runoff from the Southern Bug River and the Inhul River is small in the formation of depth topography and silting of the shipping channels of the Dnieper-Bug estuary. The origin of sandy coastal strips and spits does not depend so much on the flow of rivers, with the erosion of the shores composed of fine sand. The maximum discharge of suspended sediments is observed at the rise of the spring flood, the minimum – during the winter low tide.

Extracted sediment, which is picked up due to permanent dredging works in the Southern Bug River mouth is transported to local soil dumps, where it forms continuous silt deposits. Sediments of the Southern Bug mouth, at the present stage, along the route of the Bug-Dnieper-estuary Canal (BDEC) are represented by: sandy silts with inclusions of fine sand, loamy silts, flowing clay silts [5].

The results of the sediments granulometric composition of the Southern Bug River mouth testify to the transformation of lagoonal sediment accumulation (table 1, figure 2). The data obtained from the Parutyne – Lymany profile shows a predominance of psammite. While the material taken upstream (in the area of the port of Olvia) has a siltstone-psammite composition of the samples near the shore and a pelitic composition in the central part of the river, in the direction of the Bug-Dnieper-estuary Canal.

The data listed in Table 1 shows a significant variation in grain size and at the same time make it possible to identify a tendency to the increase of pelitic fraction in sediments. Areas along the shipping channel have sediments represented mainly by pelity. Finely dispersed material is constantly stirred by ships and dispersed over a long distance. In addition, shipping channel sections contain a large amount of industrial waste.

Technogenic sediments are widely developed in the studied area. Moreover, they are most widespread in the coastal part of the land and much smaller in open water areas. In the water area, the Southern Bug mouth man-made formations were discovered by a number of drilling wells in the form of different area spots, mostly not far from the ports. In the water area of the estuary, the fields of technogenic sediments occur near landfills of raised soil from the estuary depth during passage, deepening and periodic cleaning of shipping channels, capital dredging and during other dredging works [5].

Bottom soil, during research in 2021, was characterized by thick creamy consistency of almost black colour in the area of the port of Olvia with a noticeable smell of hydrogen sulphide in two plots. In the area of the Parutyne – Lymany profile, the sediments were brown with black

interspersed and had a weak marine smell.

According to the research results, the density of the sediment in the Parutyne – Lymany profile varied from 2.23 to 2.47 g/cm^3; the density of the port Olvia profile sediment was lower and ranged from 1.52 to 1.69 g/cm^3. Density indicators of sediment samples correlate strongly with its particle size composition.

Chemical analysis of sediment samples made it possible to obtain the following data on chemical elements-pollutants (table 2). Research results show that with the exception of one sample, the content of elements-pollutants in all profile‘s samples did not exceed the MAC for soils.

Table 2. Chemical analysis of sediment samples in the profile port Olvia.

Cu	mg/kg	16.5	26.5	35.1	24.5	34.3	25.0

The values of physical and chemical parameters of the current sediments of the studied profiles are shown in table 4.

Table 4. Physical and chemical parameters of the sediments.

Sampling locations	Concentration of water-soluble salts, % in 100 g of dry sample	pH (Units)	EC (mkSm/cm)	Eh (mV)	k (Fe_2O_3/FeO)
Parutyne – Lymany profile	0.157	7.14 – 7.62	0.45	+85.0 – +175.0	1.77 [6]
Port Olvia profile	0.875	6.45 – 6.95	1.95	-105.0 – +105.0	0.90

It should be noted that the content of water-soluble salts in the sediments depends on their sorption capacity, which, in turn, depends on the grain composition of the sediments. Accordingly, finely dispersed sediment (especially in dumping areas) has a greater sorption capacity and is more saline. However, of course, water salinity determines the content of water-soluble salts in the sediments. The salinity of the water at the Southern Bug mouth is on average 2.3–3.5‰, the maximum being 10–11‰. During the period of spring observations, water salinity in the area Parutyne – Lymany profile was 3.5‰, and the port Olvia profile was 3.1‰.

Mixing of two different waters: fresh river water and salty seawaters play a special role in the formation of the hydrochemical regime of the Dnieper-Bug estuary water. Fresh river water and salty seawaters determine the special chemical composition of the water of the Southern Bug mouth. However, the main source of biogenic substances entering the river is river runoff, hydrobionts, sediments and wastewater.

The indicator of the acid-base state (pH) of the water in the Southern Bug mouth is quite variable and ranges from 6.9 to 8.9 units, depending on the growing season. Most hydrobionts can usually tolerate a pH range of 5 to 9. Nevertheless, the change in pH to the alkaline side, which is observed during the "water bloom", can lead to an increase in free ammonia in the water, into which ammonium ions pass because of the increase in pH. Both ammonium ions and ammonia can be present in water within pH 8–9.

An important factor influencing the process of forming a chemogenic and biogenic complex of bottom sediments is the saturation of the water object with oxygen. Bottom sediments of natural water flow relate to the balanced aerobic-anaerobic system type. However, there are the shifts of aerobic-anaerobic balance toward anaerobic, which, in its turn, leads to the formation of another chemogenic complex and partial or total destruction of conventional ecotypes. One of the indicators of aerobic-anaerobic shift in balance toward reduction can be displacement of the ratio in the bottom sediments of iron oxides, namely the predominance of FeO over Fe_2O_3. In a number of works [6–8], the dynamics of accumulation and distribution features of a number of metals, including iron oxides, in river sediments have been analysed. The authors note that with the increase in the volume of organic matter runoff, whose rate of biodegradation does not keep up with the rate of its arrival, the development of anaerobic conditions is possible, which is reflected in the ratio of metal oxides.

Determining the ratio k (Fe_2O_3/FeO) shows fluctuations in river redox conditions. In the bottom layer of Parutyne – Lymany profile k (Fe_2O_3/FeO)>1, therefore the oxidation-reduction conditions can be defined as transient with a non-constant aerobic-anaerobic balance or oxidative. While in the Port Olvia profile in the bottom layer k (Fe_2O_3/FeO)<1 on average, indicating the formation reducing conditions.

Thus, the study has shown that there is recently been a general tendency to silting rivers, especially in their lower reaches. This leads to a shift in the natural aerobic-anaerobic balance to the reducing side, which negatively affects the hydroecosystem in general. An indicator of this process can be the ratio of iron oxides (k Fe_2O_3/FeO) and the value <1 [6].

The average concentration of dissolved oxygen in water during the research period was at the level of 5.1 mg O_2/dm^3. However, the values of this indicator differed significantly: in the surface water – in the range of 6.5 – 8.0 mg O_2/dm^3 and in the bottom layer – 0–3.5 mg O_2/dm^3. In the profile Parutyne – Lymany, the oxygen content was higher than in the profile of the port of Olvia. At two sites in the port Olvia profile, oxygen in the bottom layer of water was not determined, and Eh of the sediment had negative values.

Relating our data to the information provided by the Laboratory of Analytical Control of the State Administration of Ecological Resources in Vinnytsia Oblast, we can note that the data are comparable. So, the water quality in the Southern Bug River in 2003–2008, was characterized with the satisfactory oxygen regime (the content of dissolved oxygen was within the range of 7.1 to 10.8 mg O_2/dm^3 [2]; water hardness average being 3.6–8.0 mg-eq/dm^3.

The concentration of total phosphorus, according to our research, in the water area of the port

Olvia profile varied in the range of 1.4–3.2 mg/dm^3; ammonium nitrogen – 0.1–0.25 mg/dm^3; nitrate concentration was determined within the range of 11.0–14.3 mg/dm^3; the nitrite content being 0.005–0.04 mg/dm^3.

The degree of surface waters pollution in Ukraine is regulated by the established maximum allowable concentrations (MAC). Most of the standards were approved during the Soviet era, and have since then expired. However, new standards have not yet been adopted in Ukraine, so State sanitary rules 4630-88 dated 04.07.1988 are used for comparisons. According to the state sanitary rules, the presented indicators of nitrogen content do not exceed the norms.

The turbidity and colour of the water depend on many factors and fluctuate significantly in the estuary of the Southern Bug throughout the year. The main natural factors of water turbidity are the amount of solid runoff and the mass of phytoplankton (especially the development of microalgae in the summer months). However, significant turbidity in certain areas is caused by anthropogenic factors: dredging, shipping and dumping. Thus, the concentration of suspended particles in the port Olvia profile water that we measured, ranged from 7.6 to 12.6 mg/dm^3 (under the conditions of the MAC of 0.75 mg/dm^3). According to [5], during the operation of a dredger, the water turbidity can reach 70 mg/dm^3 and spread in the radius of 50 to 150 m, depending on the speed of the current. Undoubtedly, the decrease in water transparency is reflected at all levels of the trophic chain of the hydroecosystem.

Determination of biological oxygen demand (BOD_5) – is an indicator that characterizes the content of easily oxidized organic substances pollutants, contained in water – confirmed the differences between the profiles. If in the area port Olvia profile this indicator did not exceed the MAC and fluctuated in the range of 2.3–3.1 mg O_2/dm^3, then in the area of Parutyne – Lymany profile the values of this indicator were on average twice higher – 4.7–8.2 mg O_2/dm^3, which in some places exceeds the MAC by one and a half times. Comparison of this indicator with [2] resulted in same data. So, pollution with organic compounds observed (biological oxygen demand (BOD_5) fluctuated within the range of 2.11–5.4 mg O_2/dm^3.

The concentration of sulphates in the water slightly exceeded the MAC in the port Olvia profile. Thus, we determined sulphate concentrations within the range of 502.5 – 532.5 mg/dm^3. In the area of the Parutino-Lymany profile, on the contrary, the concentration of sulphates was lower, it did not exceed the MAC, and amounted to 315.0 – 340.5 mg/dm^3. The chloride content was high and was determined at the level of 3047.0 – 3244.0 mg/dm^3. This is definitely higher than the MAC, however, the chloride concentration is mainly determined by the inflow of seawater.

In general, the hydrochemical parameters of the Southern Bug mouth water in the studied period did not differ from the average long-term values. The most threatening situation is with significant turbidity of the water and extremely low oxygen concentration in some places.

A key goal presented in aquatic biology studies is to introduce data characterizing the status of the aquatic environment with a broad range of measurable indicators including in-stream habitat, phytoplankton, zooplankton, macroinvertebrate and macrophyte assemblages.

The area of the Southern Bug mouth is a transition zone – the continuum between freshwaters and coastal marine waters. According to the EU Water Framework Directive (The Directive 2000/60/EC) are defined as "bodies of surface water in the vicinity of river mouths which are partially saline in character as a result of their proximity to coastal waters but which are substantially influenced by freshwater flows". The salinity is a major, if not the most important, natural factor structuring the algal communities and explaining their variability within these ecosystems [9–11]. Furthermore, transitional waters have intrinsically higher productivity in comparison to open seawaters. This may be attributed to the fact that such zones are deemed to be naturally stressed systems as they work as basins for runoff from their catchments and impact of saline waters from the sea [12]. Thus, in the water area of the Southern Bug low reaches (below the city of Mykolaiv), a transitional community is formed, consisting of freshwater and marine species that are on the edge of their ecological ranges.

The phytoplankton community composition of the Southern Bug estuary system fluctuates from 50 to 60 species in the context of average long-term indicators (over the past 15 years), which are represented mainly by cyanobacteria, diatoms and green algae [13, 14]. Diatoms (*Chromista, Bacallariophyta*) have a wide range of interesting morphological and physiological features and are the main component of marine and freshwater ecosystems [15]. The majority of centric diatoms genera are discovered in strictly marine waters but in freshwater environments, this group is present with much less diversity [16].

The transitional zone of the Mykolaiv area with its changing salinities is offering conditions for the existence of 24 centric diatom taxa representing 11 genera. Species-indicators of eutrophication in the coastal zone of the Black Sea waters, which enter the estuary and then move upstream of the South Bug River, have been identified [17]. Thus, the following taxa are resistant to pollution by organic substances: *Aulacoseira subarctica, Cyclotella atomus, C. choctawhatcheeana, Cyclostephanos dubius, Melosira varians, Skeletonema subsalsum, Stephanodiscus hantzschii, S. Minutulus.*

Only taxa with high euryhalinity tolerance are able to move upstream and adapt to eutrophic freshwaters. The study [17] shows that salinity is one of the most significant factors for the species composition of diatoms. The appearance of three alien marine species (*Actinocyclus normanii, Skeletonema subsalsum, Thalassiosira incerta*) in the lower part of the Southern Bug might be considered as the immigration of marine species into this area due to change in salinity. Therefore, the monitoring of these species is important for biodiversity conservation.

At present, freshwater and euryhaline species prevail – up to 59%. The number of halophilic representatives of phytoplankton varies from season to season (which is associated with the upward of seawaters). The optimal water salinity for phytoplankton is 0.4–5.2 ‰.

In spring, cyanobacteria, diatoms and dinophytes predominate in phytoplankton. However, the biomass of phytoplankton in spring is low, up to 1.5 g/m^3. In summer, biomass of phytoplankton increase. Cyanobacteria play the dominant role in the formation of summer phytoplankton biomass. Many representatives of diatoms, dinophytes, and golden algae, contained in the phytoplankton of the study area are of little value in terms of nutrition. Their share in the formation of the total biomass of phytoplankton is 75%. During the vegetation period, the number of phytoplankton varies within the range of 600 – 261530 cells/m^3, and the biomass – within the range from 1.45 to 21.04 g/m^3. The smallest phytoplankton biomass is observed in dumping areas (storage of sediment after dredging). In the areas adjacent to the port under partially anaerobic conditions, the phytoplankton biomass is minimal.

The qualitative structure of cyanobacteria has not changed significantly in recent years, which indicates the stability of the hydrobiological situation. The dominant species are: *Aphanizomenon flos-aquae, Microcystis aeruginosa, Oscillatoria agardhii, Anabaena spiroides.* Among diatoms *Diatoma elongatum, Melosira granulata* and *Nitzchia tenuirostris* are most frequently registered. A group of protococcus dominated by *Scendesmus quadricauda* forms the basis of green algae. Vegetation of other groups of algae (euglenoid, dinophytic, golden, yellow-green) is determined at a much lower level. The dominant species are: *Euglena viridis, Cerratium hirundinella, Synura uvella.*

As a result of the intensive hydrotechnical construction of the previous century, the conditions for the existence of hydrobionts along the entire length of the Southern Bug River have changed significantly, which was inevitably reflected in the Bug estuary ecosystem. The researched area of the river is constantly under severe stress due to anthropogenic influence, the most important factor among which is water turbidity, which limits the photosynthetic activity of algae. These waters can be considered among the most affected and endangered ecosystems. Considering that, it is difficult to exclude these impacts on the species diversity of spatial and ecological gradual boundaries between the systems; nevertheless, salinity is believed to be a prevailing stressor [18, 19].

Studies of microphytobenthos have carried out upstream the city of Mykolaiv [20] show a much larger number and a greater variety of algae. Thus, data on the identification of 121 species of algae, which belong to 61 genera, 34 families, 20 orders, 6 classes and 5 divisions, are given. By the number of species, diatoms prevail (86 species or 71.07%), a much smaller number of representatives fall into the rest of the divisions. Thus, there are 20 species of green algae (16.52%), 9 species of cyanobacteria (7.43%), 3 species of euglena and chara (2.47% respectively).

The species diversity of zooplankton has almost halved over the past 30 years. At the end of the 1990-s 72 taxa were identified in zooplankton, while in the last 5 years only 36 species were identified in the water area of the Southern Bug mouth area. Wheel animalcules (*Rotifera*), copepods (*Copepoda*) and water fleas (*Cladocera*) form the main part of the zooplankton biomass. Freshwater and euryhaline forms dominate [13, 14, 21].

The number of zooplankton (average annual) does not exceed 18 th. specimens/m^3 and the biomass does not exceed 1.5 g/m^3. Among the representatives of zooplankton 40% are wheel animalcules. In spring, water fleas (up to 70%) represent the main biomass of zooplankton. The basis of the biomass of rotifers was formed by *Asplanchna priodonta*. However, the numbers were formed by smaller forms of *Filinia longiseta, Brachionus angularis, Keratella quadrata*.

The fauna of the depth (zoobenthos) and periphyton is more diverse and rich than the aquatic fauna. At the mouth of the Southern Bug River (study area), water exchange is slowed down and salinity is increased. Oligochaetes, polychaetes, gammarids and chironomids dominate in the silt and sandy-silt bottom areas. The biomass of summer zoobenthos of silted sands is up to 26 g/m^3. Among polychaetes *Hypaniola kowalewskii* and *Nereis diversicolor* dominate. Among gammarids *Pontogammarus robustoides* and *Dikerogammarus haemobaphus* are identified.

In some places, there are still small colonies of mollusks *Dreissena bugensis*, and along the spits (including the Northern Spit) there are mollusks *Cerastoderma edule*. Taxonomic diversity, abundance and biomass of zoobenthos of the Bug estuary are not the same in different areas. At great depths with increased salinity, low oxygen concentration and the presence (in some places) of hydrogen sulfide, the zoobenthos is taxonomically poor. Oligochaetes (24%), polychaetes (15%), molluscs (18%), and sometimes chironomids prevail in such areas not forming mass settlements.

Studies of higher aquatic plant in the mouth area of the Southern Bug River showed a depleted species composition of floristic communities [22], which form two plant complexes – coastal (helophytes) and aquatic (free-floating). The helophytes community, which is formed by border strips of different lengths and massiveness along the coastline, is represented mainly by reeds (*Phragmites australis*), in some places there are cattails (*Typha latifolia, Typha angustifolia*), sedges (*Carex acuta, C. raparia, C. gracilis*).

Mainly representatives of the genus *Potamogeton* qualify as aquatic vegetation, which forms "spots" of hydatophytes and floating pleistophytes in the water area, namely: *P. crispus, P. lucens, P. pillsum, P. natans, P. perfoliatus*. In addition, *Myriophyllum spicatum, Ceratophyllum demersum* are found in the water area.

4. Discussion

The specificity of the processes that take place in the Southern Bug River mouth is caused by the constant interaction of different physical and chemical properties of river and seawaters masses. The upward-downward fluctuations of water levels are a characteristic feature of the hydrological regime of the Bug estuary system. Getting through the flume of the navigable canal to the Bug estuary seawater stagnates due to very slow water exchange at the bottom. Seawater moves in the south winds and it is a constant source of increasing salinity at the mouth of the river, which fluctuates between 2–3.5‰ for most of the year.

Another feature of the Southern Bug mouth water is its considerable turbidity. Anthropogenic activity is the main cause of high concentration of suspended particles in the water. It is provoked by permanent dredging works in the Southern Bug River mouth and transporting material to local soil dumps. In 2021, the average content of suspended solids in water in the profiles below the city of Mykolaiv were 11.4 ± 0.5 mg/dm^3.

Current sediments of the Southern Bug mouth reflect to transformation of lagoonal sediment accumulation. The role of sediment runoff from the Southern Bug River and the Inhul River in the formation of the bottom relief and siltation is insignificant. The current sediment of the Southern Bug mouth is mainly represented by pelity.

The content of pollutant elements in the sediment samples mostly does not exceed the MAC, except for lead in one sample. However, in our opinion, the presence of reducing conditions in river's bottom layers fixed some samples is much more important is a great concern.

Permanent turbidity of water leads to a decrease in the photosynthetic activity of phytoplankton, which in turn is reflected in reduced primary production. Other hydrochemical indicators, that periodically have increasable concentration in the Southern Bug mouth water, include: BOD_5, which is characterized by periodic, sometimes significant, exceeding of MAC, ammonium and nitrite nitrogen.

Very often, transitional water is a place with increased biodiversity as the estuarine community consists of both freshwater and marine species. The Southern Bug mouth waters are considered to be among the most affected and endangered ecosystems. According to the literature review, decrease in primary productivity led to decrease in zooplankton almost by half. The composition of phytoplankton is dominated by representatives of diatoms, dinoflagellates and golden algae, which are of little value in terms of food, whose specific weight in the formation of the total biomass of phytoplankton is up to 75%.

Analysing all of the above, it should be noted that the post-war revitalization of the Southern Bug estuary ecosystem should include measures to mitigate the negative effects of anthropogenic activity, especially the consequences of hydraulic engineering works.

5. Consequences

The presented comprehensive research can be considered as the current pre-war state of the Southern Bug mouth ecosystem. The results of the conducted research are: assessment of the sediments features of the researched river section, assessed water conditions and characteristic of the groups of hydrobionts.

Appearance of reducing condition spots in sediments, increased turbidity, change of hydrochemical conditions, reducing of some fodder species (plankton and benthos) – these are short list of current anthropogenic transformation of Southern Bug mouth ecosystem.

The first and urgent measures to revitalize the mouth of the Southern Bug should be actions to eliminate and mitigate the consequences of hostilities. Further revitalization measures should be aimed at preserving biodiversity, which is possible under the conditions of maintaining the normal state of water and sediments in the Southern Bug, especially in the transitional estuarine zone.

Abstract. The article presents the results of research into the process of transferring electrical energy from solar panels through a hybrid solar inverter to a three-phase electrical network. An automatic regulation system is presented, which provides power regulation and operation in the mode of maximum power selection from solar panels. The results of the study of the energy efficiency of the system, the parameters of electromagnetic compatibility and the emission of higher harmonic currents are presented.

1. Introduction

The generation and consumption of electricity in the world is constantly growing. At the same time, the generation of electricity from alternative energy sources, including solar photovoltaic panels (PV), is also growing rapidly [1, 2].

In 2020 total electrical power generation of all solar panels was about 760 GWh, what is approximately 3% of the world's total electricity. At the same time, the total amount of solar energy that the Earth receives from the sun per year is $174{\cdot}10^{14}$ PWh, which indicates significant reserves of the possibility of solar generation [3, 4].

The conversion of sunlight into electric current with the help of the photoelectric effect, which occurs in solar photovoltaic cells. The first solar photovoltaic cell was invented by the American scientist Charles Fritts back in the 1880. The first industrially produced solar cell was developed in 1931 by the German engineer Bruto Lange. However, the efficiency of such a solar element was approximately 1%. Since then, the parameters of solar panels have been constantly improving.

Monocrystalline solar panels, polycrystalline solar panels and thin-film solar cells are widely used today. The most important parameters of solar panels are their efficiency and cost. Polycrystalline solar panels have an efficiency of 15.5-18%, and monocrystalline solar panels have an efficiency of 18.5 to 23.5%. However, monocrystalline solar panels have a higher cost, which is due to the fact that monocrystalline panels use monocrystalline silicon with a very high degree of purification above 99.99% [5, 6].

Today, some experimental samples of solar panels have an efficiency above 47%. In 2013, Sharp created a three-layer 4×4 mm indium-gallium-arsenide photocell with an efficiency of 44.4%. Another way to increase the efficiency of solar panels is the use of additional lenses.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012092 doi:10.1088/1755-1315/1254/1/012092

Thus, a group of specialists from the Institute of Solar Energy Systems of the Fraunhofer Society, the companies Soitec, CEA-Leti and the Berlin Helmholtz Center created solar panels using a Fresnel lens, a photocell with an efficiency of 44.7%.

In 2014, the Fraunhofer Institute for Solar Energy Systems created solar cells in which, thanks to a lens focusing light on a very small photocell, the efficiency is 45%. Therefore, the prices of such solar cells are an order of magnitude higher. A promising direction is the creation of nanoantenna-based photocells that work on the direct rectification of currents induced in the antenna of small sizes (about 200-300 nm) by light (that is, electromagnetic radiation of a frequency of about 500 THz). Nanoantennas do not require expensive raw materials for production and have a potential efficiency of up to 85%. But this technology is not yet ready for serial production [7, 8].

The purpose of the study is to obtain scientific results of the process of transferring electrical energy from solar panels through a hybrid solar inverter to a three-phase electrical network. To achieve the purpose, the following objectives were set:

- to develop a simulation model of a system for generating electricity from solar panels to a general industrial network using a solar inverter;
- investigate transients in the electrical network and solar panel when starting the converter.

2. Results and discussion

One of the most important characteristics of solar panels is its current-voltage characteristic, the shape of which depends on the level of solar radiation and temperature. For an example, consider the volt-ampere characteristics of the Era-370W-24V-Mono solar panel (figure 1).

At the same time, the current-voltage characteristics of the solar panel largely depend on the temperature of the panel, while an increase in temperature reduces the generated power (figure 2). Based on figure 2, it can be seen that when the solar panels are heated, the voltage and current, and therefore the power generated by the solar power, decreases. So, it makes sense to cool the solar panels. Thus, lowering the temperature of a heated solar panel from 75 °C to –25 °C will increases the maximum generated power by approximately 35%.

When the current consumed by the solar panel changes, the voltage of the solar panel changes, and thus the power generated by the solar panel changes. At the same time, the dependence of

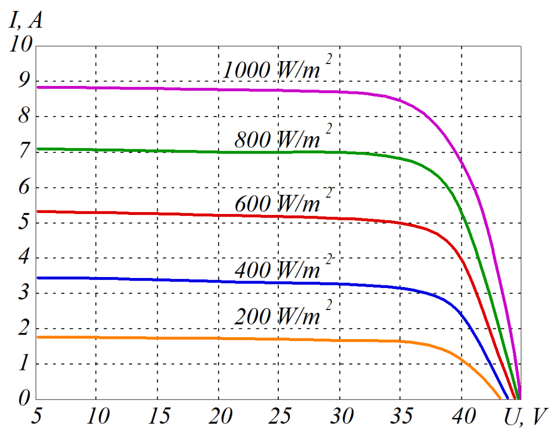

Figure 1. Current-voltage characteristics of solar panel Era-370W-24V-Mono at different levels of solar radiation (with ambient temperature of 25 °C).

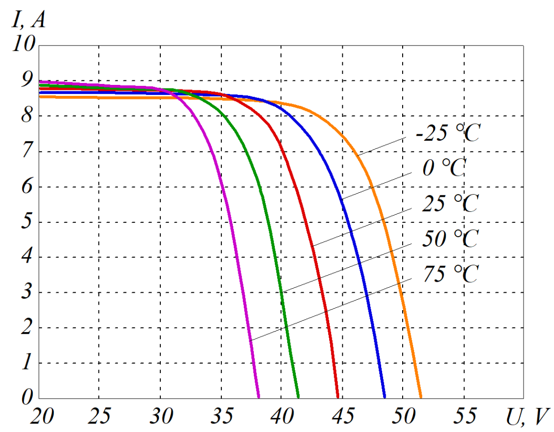

Figure 2. Current-voltage characteristics of solar panel Era-370W-24V at different temperatures (at a sun radiation intensity of 1000 W/m^2).

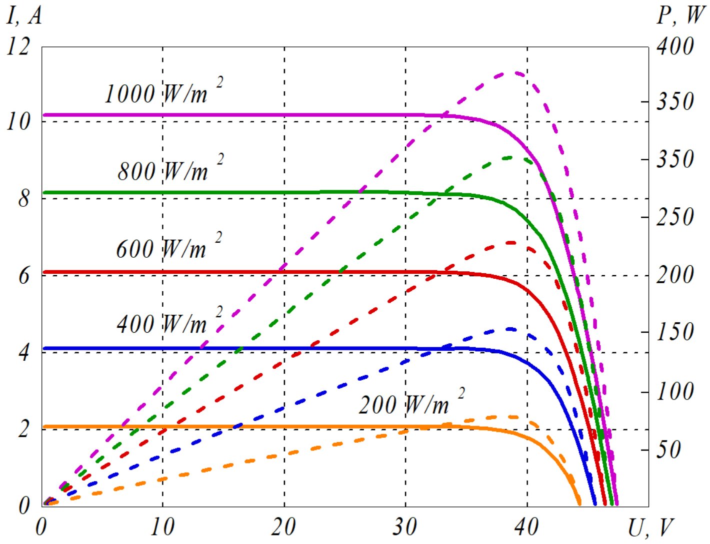

Figure 3. Dependence of the maximum power of the solar panel as a function of the consumed current and the level of solar radiation.

the power of the solar panel on the consumed current is shown in (figure 3). It can be seen that the solar panel has a point of generation of maximum power, which is determined by a certain amount of current consumed by the solar panel. Thus, by adjusting the amount of current consumed by the solar panel, it is possible to enter the maximum power generation mode. This algorithm is called MPPT – maximum power point tracking [9, 10]. Most traditional MPPT algorithms are based on the concept of tilt tracking. One of the typical tilt tracking methods is the algorithm Perturb and Observe (P&O). The disadvantage of this method is the loss of generated power during the search for the point of maximum power generation, which can last for a considerable time.

Determining the maximum power generation point can also be done by exact calculation by polynomial approximation of the solar panel current-voltage characteristics and using solar radiation and temperature sensors [11, 12].

Polynomial approximation of the current-voltage characteristics of the Era-370W-24V-Mono

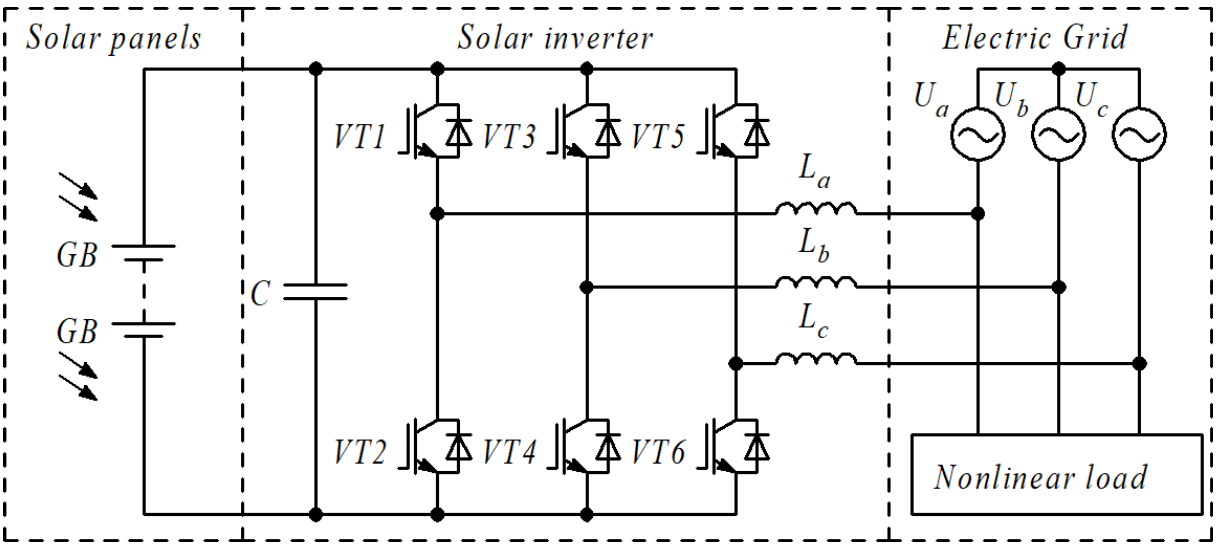

Figure 4. Power generation system “solar panels – solar inverter – electric grid”.

sleeper panel at different levels of sony radiation:

- at a sun radiation intensity of 1000 W/m^2:

$$i_{pv_{1000}}(u) = -44500u^5 + 31375u^4 - 7716u^3 + 764.46u^2 - 24.9u + 18.2; \quad (1)$$

- at a sun radiation intensity of 800 W/m^2:

$$i_{pv_{800}}(u) = -46402u^5 + 33583u^4 - 8494u^3 + 866.8u^2 - 29.1u + 14.7; \quad (2)$$

- at a sun radiation intensity of 600 W/m^2:

$$i_{pv_{600}}(u) = -1980888u^6 + 176912u^5 - 60166u^4 + 9587u^3 - 698.9u^2 + 18u + 11; \quad (3)$$

- at a sun radiation intensity of 400 W/m^2:

$$i_{pv_{400}}(u) = -209032u^6 + 189327u^5 - 64729u^4 + 10272u^3 - 739.4u^2 + 18.68u + 7.097. \quad (4)$$

The obtained polynomials make it possible to analytically determine the generation point of the maximum power of the solar panel as a function of the current consumed by the hybrid inverter. Thus, by regulation the the solar panel current, it is possible to obtain the maximum power that is functionally realized by the semiconductor converter that takes power from the solar panel.

Converters, called solar inverters or hybrid inverters, perform the functions of selecting electrical energy from solar panels, operating in the maximum power generation mode, and ensuring the transmission of electrical energy to the general industrial electrical network (figure 4) [13, 14].

The standards EN 50549-1, EN 50549-2 define the requirements for generating plants to be connected in parallel with distribution networks [15, 16].

A solar inverter, when generation electrical energy to the electrical network, can work both in the voltage-source mode and in the current-source mode. When operating in current-source mode, the solar inverter must operate in a mode similar to the operation of a power active filter with forced formation of a given shape and phase of the current. At the same time, the generation mode in the current source mode has significant advantages, namely: the possibility of operation in the power factor mode close to unity; peration in reactive power compensation mode; operation in the mode of compensation of higher current harmonics caused by non-linear and impulse load of the electrical network. At the same time, the low level of higher harmonics of currents in the electric network causes a decrease in additional power losses in it.

At the same time, for operation in the power active filter mode, a necessary condition for stable operation is the need to maintain the voltage on the solar panels higher than the amplitude value of the linear voltage of the electrical network [17, 18].

To maintain this condition, it is necessary to connect a fairly significant number of solar panels to a solar inverter. When the voltage generated by the solar panels is lower than the amplitude value of the line voltage of the network, then it is necessary to use additional step-up DC–DC converters between the solar panels and the solar inverter [19, 20]. Also, DC–DC converters can be used, providing galvanic isolation between the input and output of the converter. These converters: flyback converter; forward converter; half-bridge push-pull converter junction; full bridge DC–DC converter.

In addition to the function of increasing the voltage from solar panels, DC–DC converters also provide the function of extracting electricity from the solar battery to chemical energy storage devices, such as acid, alkaline or lithium-ion batteries, implemented by semiconductor converters. To implement the function of maximum power selection from the solar panel in

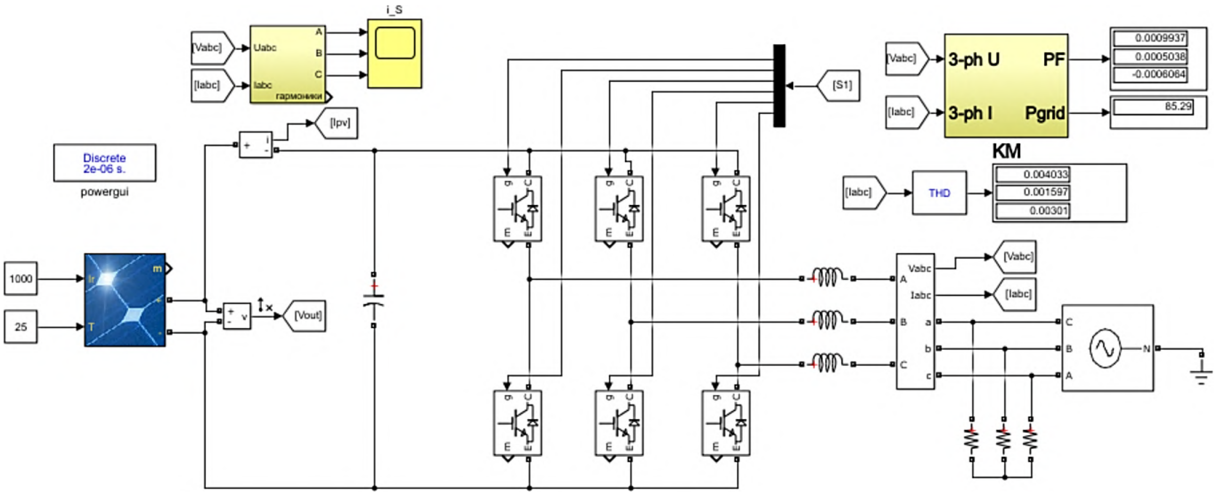

Figure 5. Matlab model of the system “solar panels – solar inverter – electric network”.

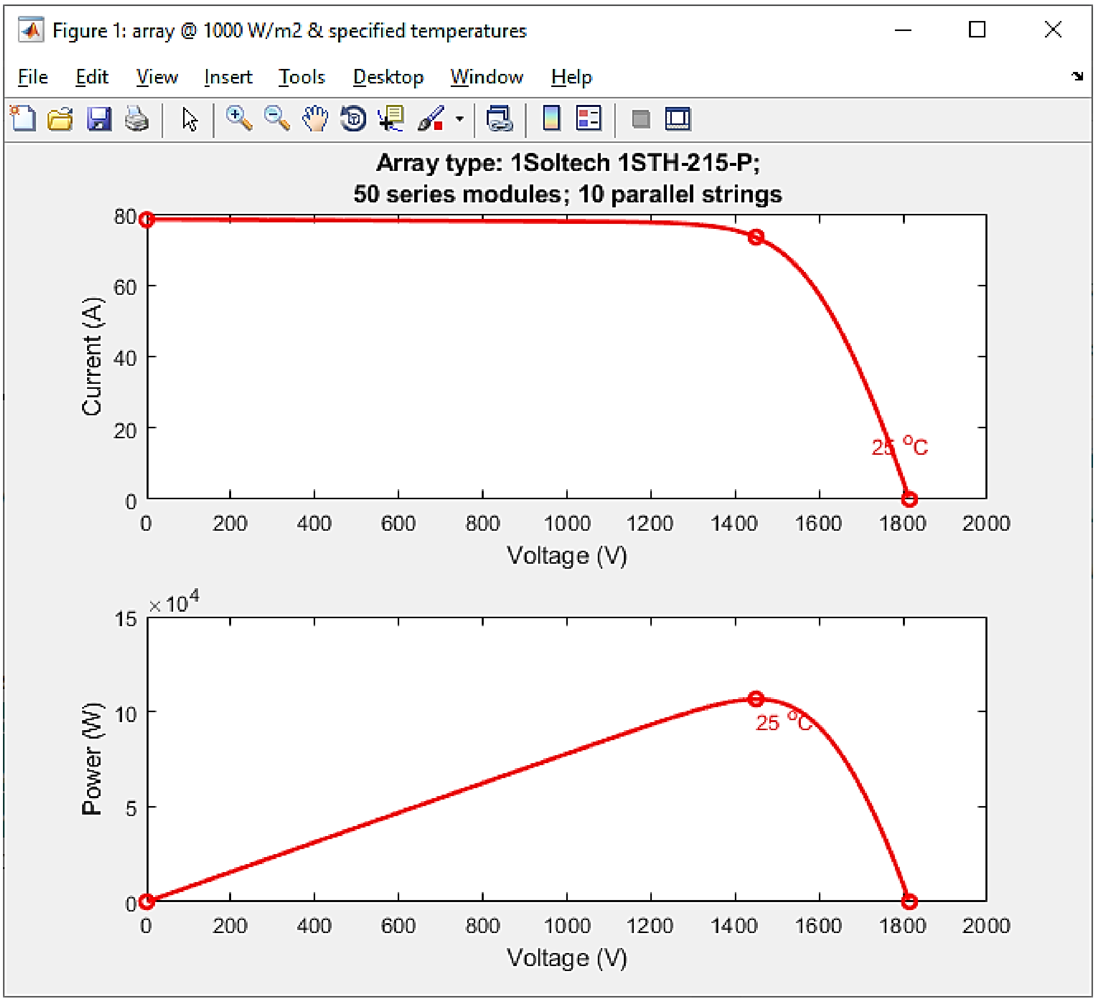

Figure 6. Current-voltage characteristic and power-voltage characteristic.

the DC–DC converter, it is necessary to ensure the implementation of the input current value adjustment for maximum power selection from the solar panel [21, 22].

To determine the parameters of the intensity of the power of electrical energy, which is generated in the sleep panel through the sleep panel, as well as the implementation of the selection of the maximum tension in the sleep panels, a computer simulation model has been developed, which is shown in figure 5.

In the model, the block of solar panels consists of 500 solar panels of the Soltech 1STH-215P type (10 parallel solar panels, 50 serial solar panels in each branch). The maximum current generated by the block of solar panels is 73.5 A. The maximum power generated by the block of solar panels is 1450 V. The maximum power of a block of 500 solar panels is 106.57 kW (at a solar radiation level of 1000 W/m^2 and at a temperature of 25 °C).

The main parameters of the Matlab model of the power active filter are given in table 1.

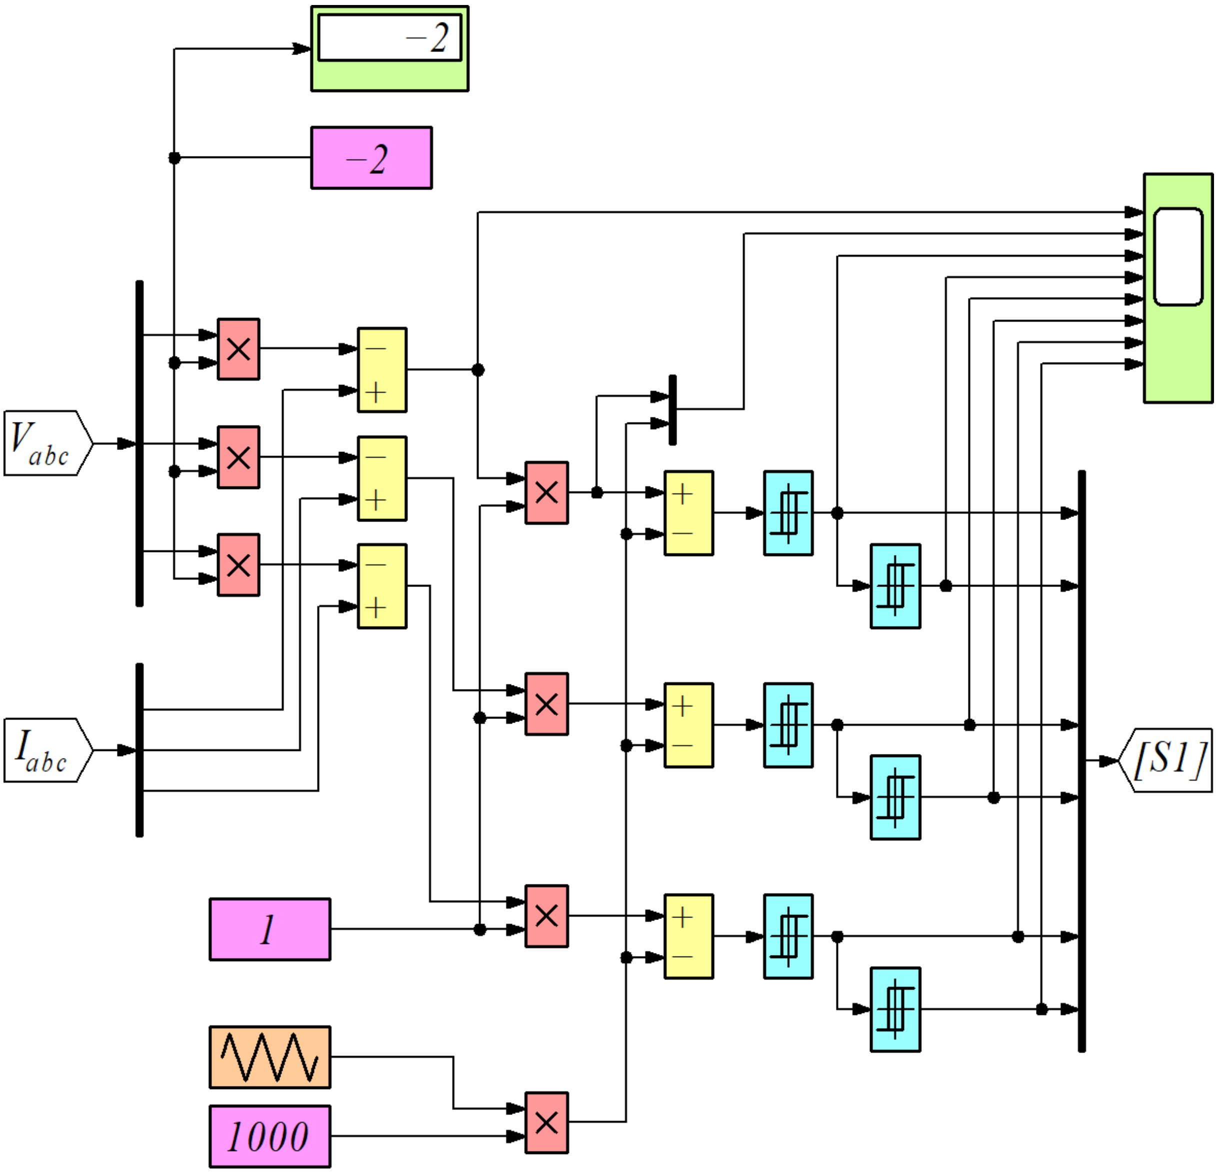

Figure 7. Structure of the hybrid inverter control system.

Table 1. Main parameters of Matlab model.

Parameter	Value
Network voltage, V	220/380
Network load active resistance, Ohm	5
Network inductance, mH	0.1
Inductance of the inductor of the hybrid filter, mH	0.6
Hybrid inverter capacitor capacity, mF	2
PWM frequency, kHz	1-10

Current-voltage characteristic of a set of 500 solar panels simulated in Matlab model is shown in figure 6.

The control system of the hybrid inverter is implemented on the basis of the control system of the power active filter with PWM control with an adjustable modulation frequency from 1 kHz to 10 kHz. The structure of the control system implemented in the model is shown in figure 7.

The implementation of the maximum power selection in the hybrid inverter is implemented by controlling the phase current of the solar inverter by setting the modulation coefficient.

Transient processes of current, voltage and power of solar panels at the start of the solar inverter are shown in figure 8. As can be seen from figure 8, the voltage of the block of solar panels increases from zero during startup.

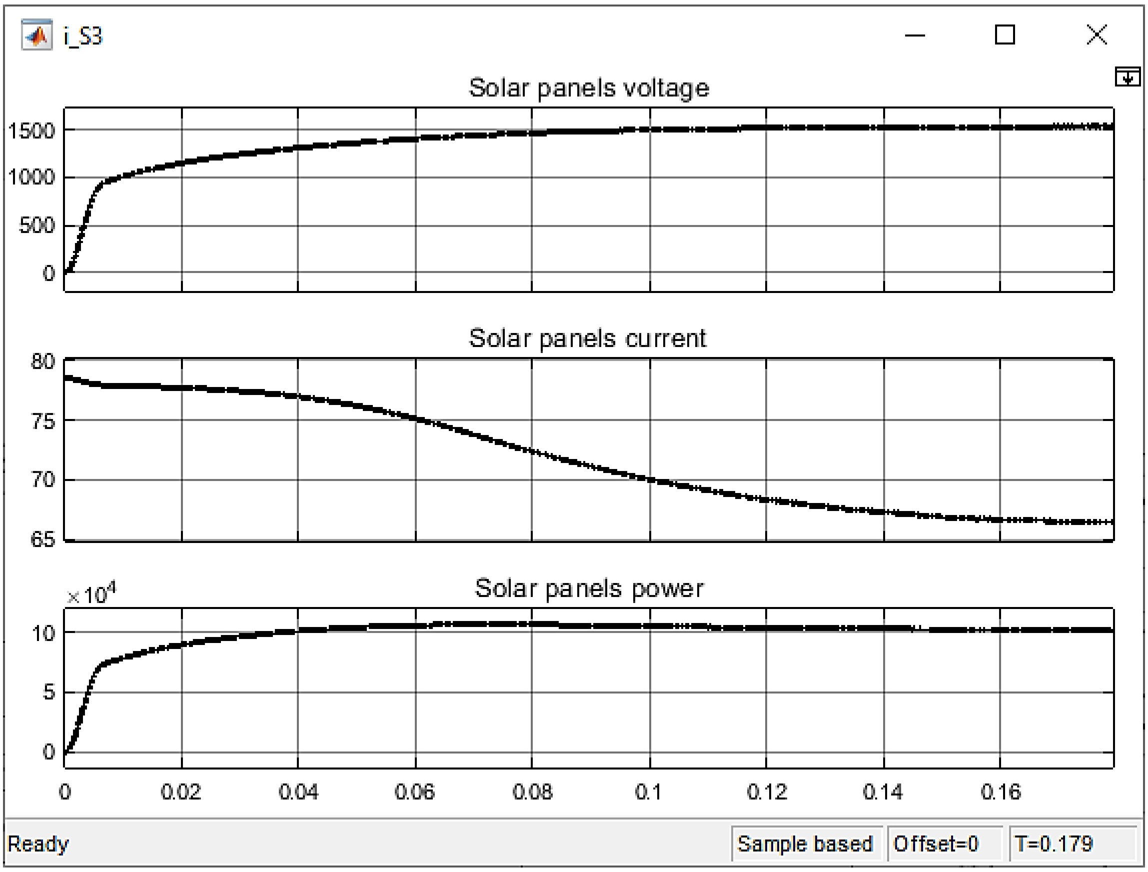

Figure 8. Voltage, current and power of a solar panel delivered by a hybrid inverter.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012092 doi:10.1088/1755-1315/1254/1/012092

As is known, the condition for the implementation of the power factor correction mode and the formation of the sinusoidal form of the generated current is that the voltage in the direct current link of the solar inverter is higher than the amplitude value of the line voltage of the network, into which the energy from the solar panels will be transferred. Therefore, to improve the start-up mode of the solar inverter, it is advisable to perform the start-up with a precharged capacitor of the inverter to the level of a larger amplitude value of the line voltage of the network (figure 9).

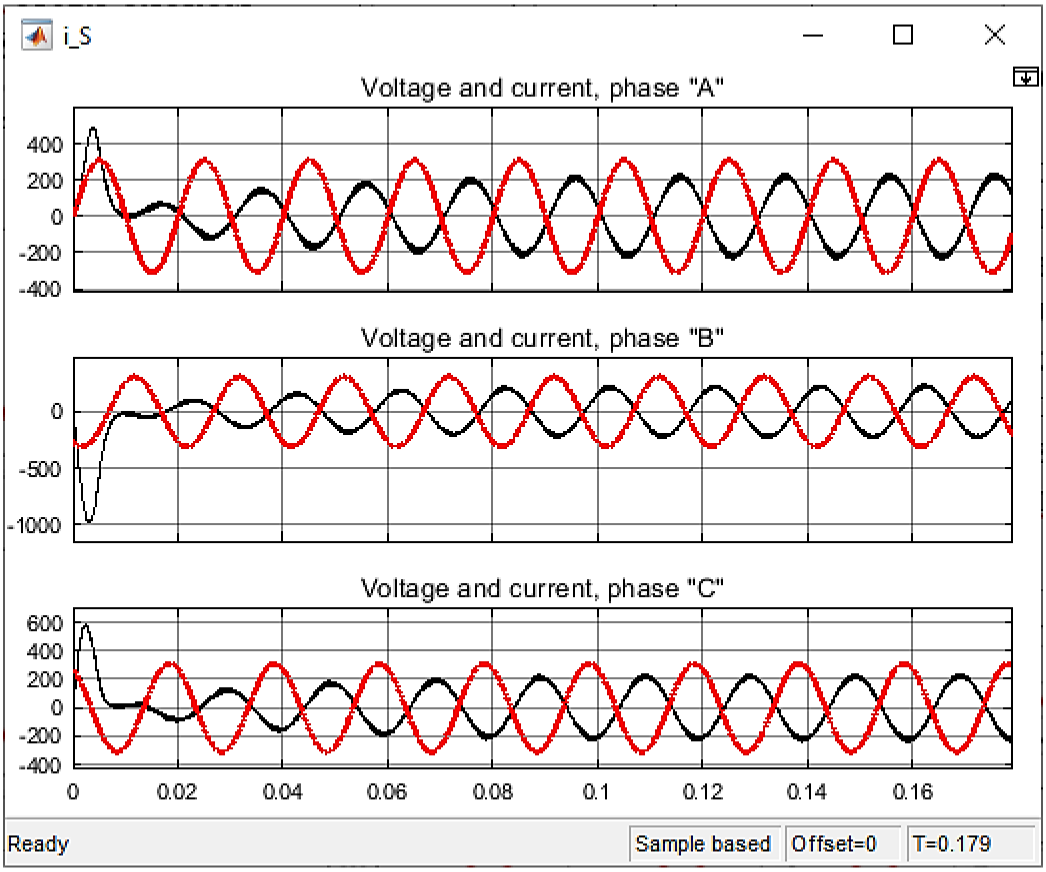

Figure 9. The transition process of transferring electrical energy from the hybrid inverter.

The power factor in the mode of generating electricity to the electric grid is 0.991. The results of the harmonic analysis of the form of the current generated from the solar inverter to the electric grid are shown in figure 10.

As can be seen from figure 10, the current generated from the solar inverter to the electrical network has a harmonic distortion coefficient equal to 3.63%, and the amplitude value of all harmonics in the spectrum does not exceed 2.4%, which meets the requirements of international standards.

To calculate the efficiency of the hybrid inverter, the characteristics of the IGBT module CM1200DC-34S, Mitsubishi with a nominal current of 1200 A and a nominal voltage of 1700 V were taken. The characteristics for which the calculation was given and which determine power losses are shown in figure 11.

The results of polynomial approximation of the energy characteristics of power transistors at a temperature of 25 °C are given in the following expressions.

When using the developed algorithm, power losses were determined, as well as the quality of

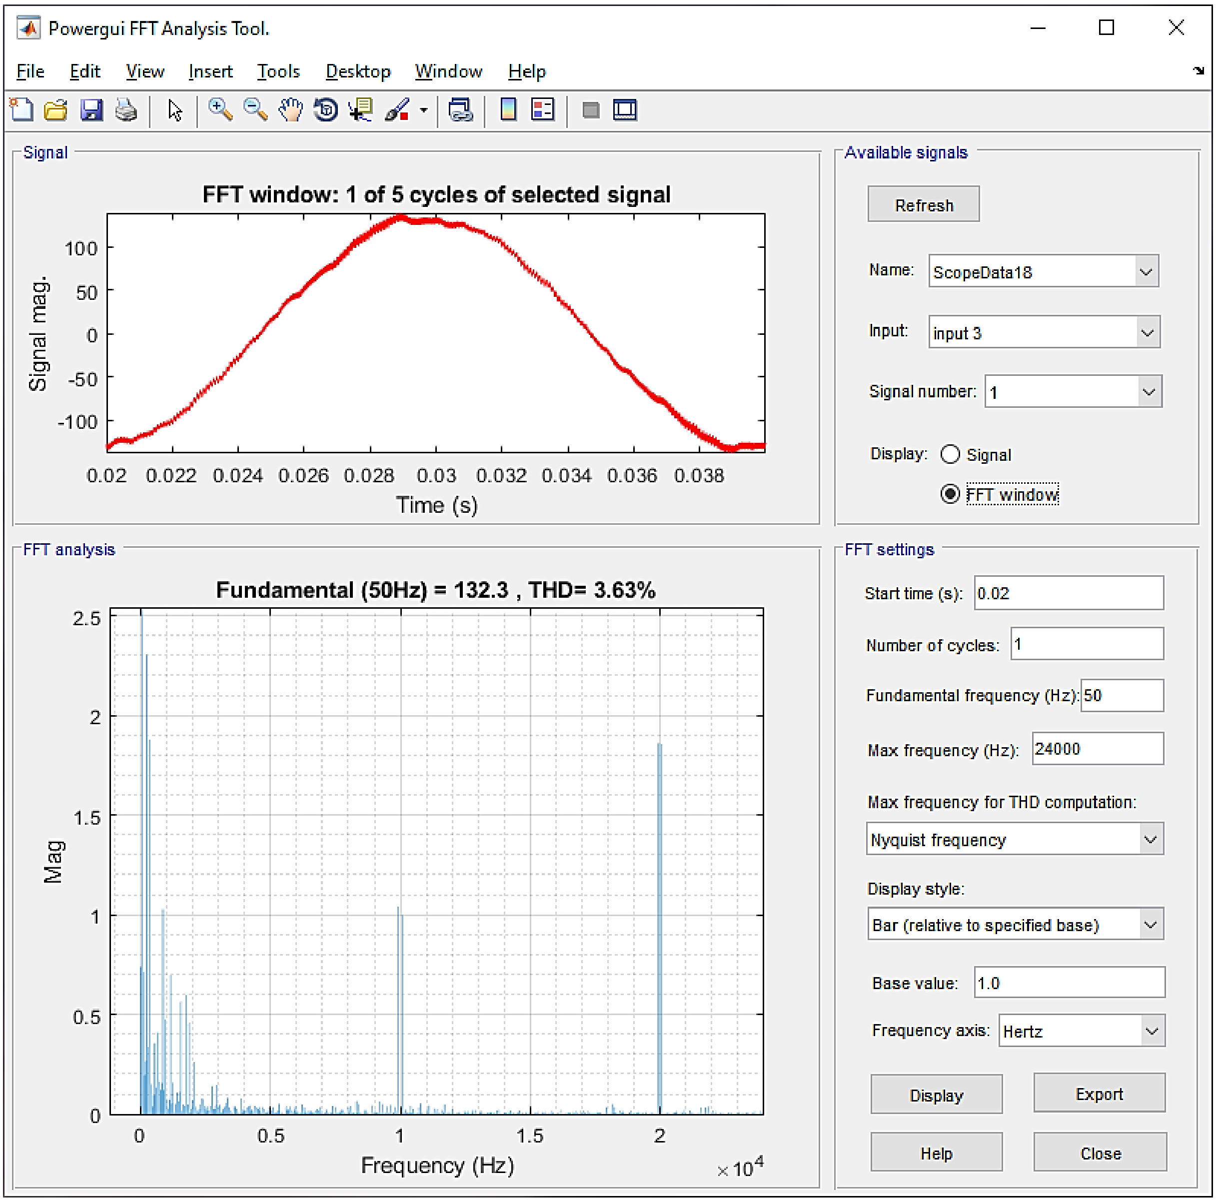

Figure 10. Harmonic analysis of the shape of the current generated from the solar inverter.

the realized current when setting different modulation frequencies.

$$U_{ce}(I_c) = -0.162I^4 + 0.942I^3 - 2.009I^2 + 2.746I + 0.57; \tag{5}$$

$$U_{fw}(I_f) = -0.185I^4 + 1.054I^3 - 2.171I^2 + 2.735I + 0.68; \tag{6}$$

$$E_{on}(I_c) = 0.2406I^2 - 0.006I + 0.0496; \tag{7}$$

$$E_{off}(I_c) = 0.0587I^2 + 0.1842I + 0.0547; \tag{8}$$

$$E_{rec}(I_f) = 0.0054I^5 - 0.0368I^4 + 0.1002I^3 - 0.1601I^2 + 0.2309I + 0.0227. \tag{9}$$

The calculation carried out during modeling determined the dependence of the amount of power loss in one power switch of the inverter as a function of the PWM frequency in figure 12.

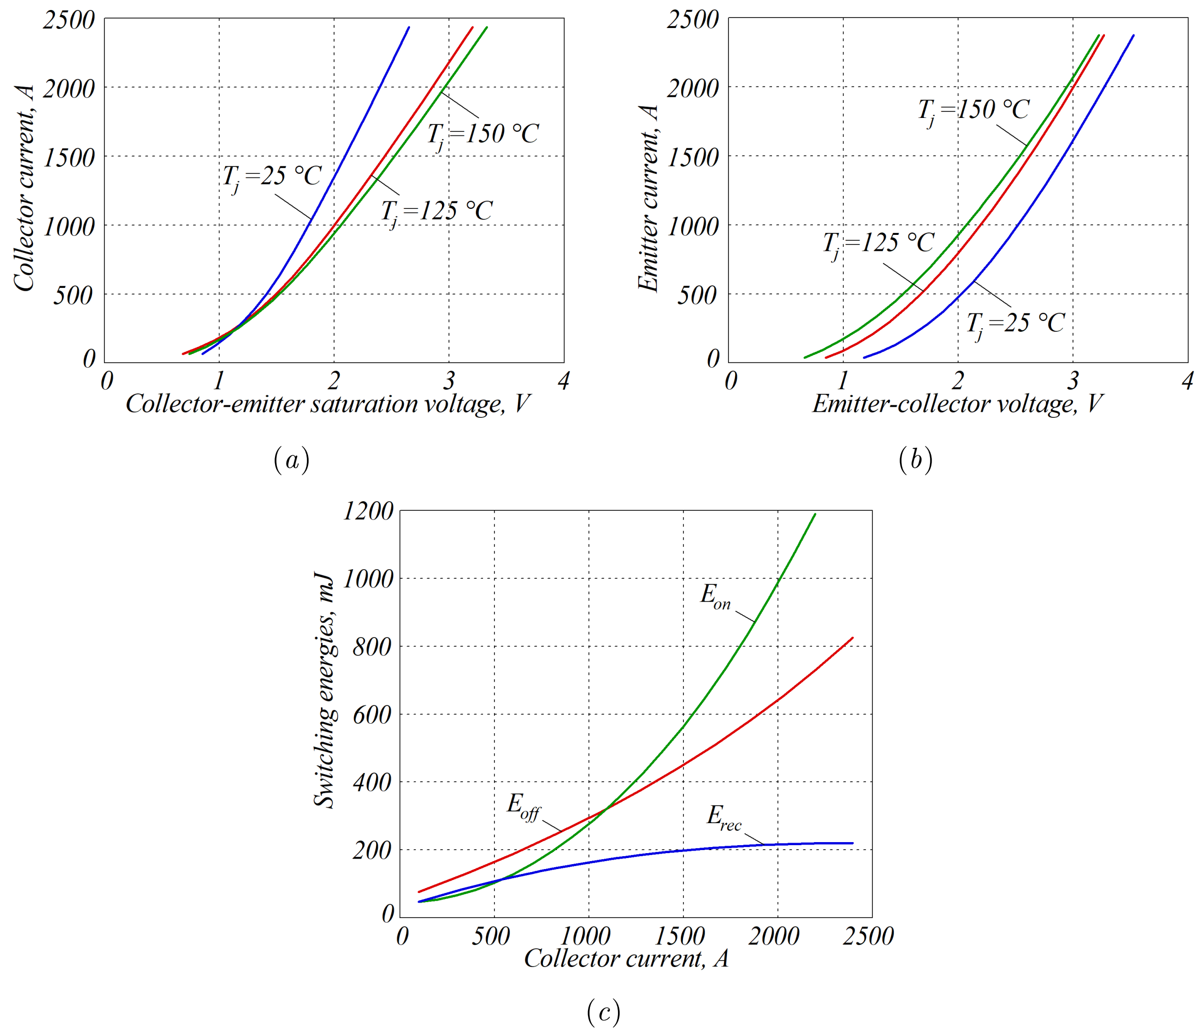

Figure 11. Energy characteristics of the CM1200DC-34S module: (a) volt-ampere characteristic of the transistor; (b) volt-ampere characteristic of the reverse diode; (c) dependences of the switch-on energy, switch-off energy and reverse diode recovery energy from the commutated current.

Dependence of power losses in the CM1200DC-34S power transistor on the PWM frequency at a DC link voltage of 1500 V and a current amplitude of 223 A (maximum power point of solar panels).

Thus, the efficiency of the hybrid inverter when transferring electricity from the solar panels to the electrical network was from 98.4% at a PWM frequency of 1 kHz to 92.7% at a PWM frequency of 6 kHz.

3. Conclusions

The article shows that the generated power from solar panels has a maximum point, which depends on the amount of current consumed from the solar panel. The circuit solutions of semiconductor converters are determined, which provide the maximum power extraction modes from solar panels and the transmission of electricity to general industrial electrical networks with high quality parameters.

The developed computer simulation model of a system for generating electricity from solar

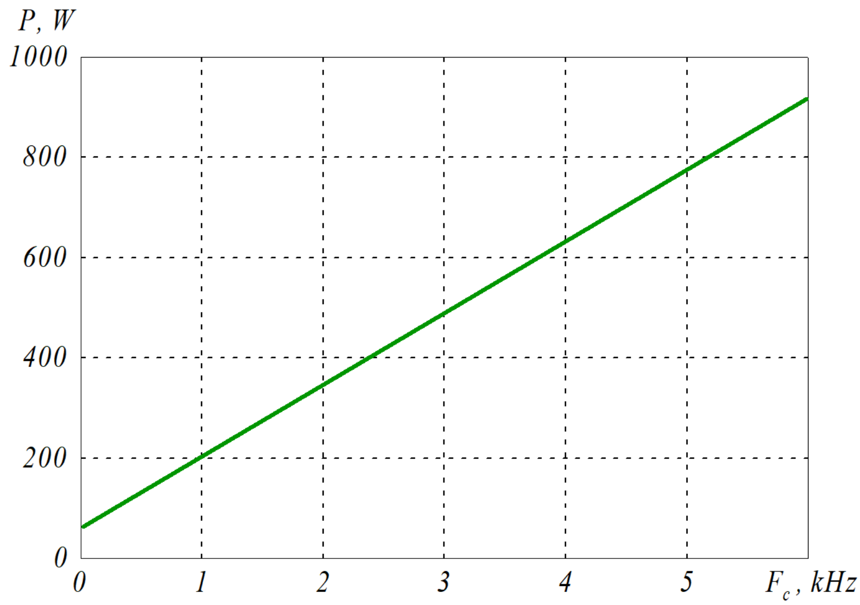

Figure 12. Dependence of power losses in the CM1200DC-34S power transistor.

panels of Soltech 1STH-215P types to a general industrial network using a solar inverter with a PWM control system, which makes it possible to transfer electrical energy with a power factor close to unity (0.98) with a low level of higher harmonics (total harmonic distortion 3.36%).

The model also explores the transients in the electrical network and the solar panel when starting the converter. Recommendations are given for starting a solar inverter with a pre-charged capacitor, which will improve the quality of the current in the start mode.

Abstract. European grayling is a perspective object of a recreational fishing. In addition, the presence of this species in sufficient quantities in rivers has a positive influence on the formation of the recreational attractiveness of mountain regions, where tourism is one of the main sources of local communities existence. However, grayling stocks in the watercourses of Ukraine are significantly depleted nowadays, and populations are in a condition of lack, what has led to the inclusion of this species into the Red Book of Ukraine. Working out of biotechnologies of artificial reproduction of rare fish species in aquaculture conditions for the further reintroduction of the resulting offspring into natural water bodies takes an important place in the system of environmental protection measures to preserve biodiversity. After all, the reintroduction into nature of artificially obtained fish fry is one of the effective ways to restore the optimal number and structure of rare fish species natural populations, and this, in turn, will allow in the future to restore the limited exploitation of the stock of these fish species. One of the critical artificial fish reproduction technology links is the transfer of larvae to external nutrition. Namely on this stage the highest mortality rates are observed. The usage of live feeds as a starter fodder can significantly improve the situation. Forage organisms, in addition to having high nutritional value, can serve as delivering tools of various targeted products, including probiotics, to a fish larvae organism. The assessment of the usage of probiotic strain *Lactobacillus casei* IMV B-7280 feasibility is carried, and also the possibility of usage the culture *Daphnia magna* Straus, 1820 grown in the presence of trehalose lipids, within the technology of early feeding of the European grayling *Thymallus thymallus* (Linnaeus, 1758). It was shown that the larvae of the European grayling, which received investigated probiotic microorganisms strain, had 15% bigger weight on the final stages of feeding than the larvae of the control group. Introduction to the diet of grown-up grayling larvae of the culture *Daphnia magna*, previously received of common cultivation with microalgae *Desmodesmus armatus* (Chodat) E.H.Hegewald 2000 with addition of trehalose lipids, contributed to the reduction of larval mortality and the acceleration of their growth rate. Further improvement of proposed approaches of growing grayling fish planting material can be extrapolated to other fish species and in the future may be applicable in the process of growing rare fish species in conditions of farm aquaculture fish farms, what will allow them to be involved into environmental protection activities by placing appropriate orders. This, in its turn, will contribute to the stable development of communities in rural areas.

1. Introduction

The development of methods and practical measures for gene pool preservation and population size restoration of rare and vulnerable aboriginal fish species requires the implementation of integrated research, among which the work out of reproduction biotechnologies of such species in the conditions of aquaculture, takes prominent place. European grayling, in addition to having high food and taste qualities, is a promising object of recreational fishing. Due to this fact, the presence of this species in sufficient quantity in rivers has a positive influence on the formation of recreational attractiveness of mountain regions, where one of the main sources of existence of local communities is tourism. However, nowadays grayling stocks in the watercourses of Ukraine are currently significantly depleted, and populations are in a condition of lack, what has led to the inclusion of this species into the Red Book of Ukraine. Restoring the optimal number and structure of natural populations is one of the main prerequisites for removing the species from the protection lists, including from the Red Book of Ukraine, and will allow limited exploitation of fish stocks in the future.

Usage of aquacultural methods of supporting the quantity of rare and endangered fish has found an application in the countries of the European Union. Thus, due to the artificial fish reproduction and the growing of resulting offspring to a viable condition for further stocking in the Baltic countries, it became possible not only to restore the normal population size of brown trout, and also to implement licensed fishing for amateur fishermen. There is the same situation with the population of Danube salmon in Slovakia.

The development of correction technologies of live feeds nutrient composition in order to improve their nutritional value will allow to increase the young fish survival on early stages of development and thereby to reduce the cost of receiving fish planting material works. Improved and developed technologies and approaches of receiving and growing rare fish species planting material to a viable condition, including the European grayling, in future will find an application in the process of growing these species in conditions of aquaculture fish farms, what will allow in the future find application in the process of growing these species in the conditions of farm aquaculture fish farms, which will allow them to be involved into environmental protection activities by placing appropriate orders. This, in its turn, will contribute to the stable development of communities in rural areas.

Usage of probiotics in aquaculture as treatment-and-prophylactic means of dysbiosis correction is an efficient method of compensation of negative effect of strenuous conditions of fish keeping within industrial aquaculture. In addition to increasing various fish diseases resistance, probiotics are able to synthesize a number of extracellular enzymes, what increases the bioavailability of forages and ensures decreasing in its costs, what contributes to the intensification of fish growing processes [1]. Usage of probiotics also positively influences on stabilization of digestive tract functions and improving its enzymatic activities, normalizing of mucus formation on the fish body surface and improving of the gill apparatus [2]. Probiotic microorganisms contribute to enhancing of phagocytic, lysozyme, complement acrivities, and also expression of various cytokines in fishes [3].

Among the great variety of probiotic microorganisms, representatives of the genus *Lactobacillus* cause a substantial interest for aquaculture. It is based on the fact that there were not found any species of *Lactobacillus*, which could be pathogenic or conditionally pathogenic to aquatic organisms [4]. Due to a number of adaptive capabilities, namely a high level of adhesion, synthesis of organic acids and hydrogen peroxide, resistance to adverse conditions of digestive tract, they are able to colonize digestive tract of hydrobionts successfully and resist pathogenic microflora [5].

One of the main technological problems of the use of probiotic preparations is related to ensuring targeted delivery of the appropriate bacteria to fish organism. Probiotics introduction directly into water leads to its dispersion in a significant volume of the environment, its introduction into granular forages is also problematic - in the process of extrusion, which is used in the production process of most types of modern production forages, the viability of microorganisms can significantly decrease. Live feed can serve as a reliable vector for targeted delivery of probiotics into fish organism [6]. Traditionally in aquaculture brine shrimp nauplia are used as a live feed, which are of the right sizes for feeding early larvae of the vast majority of fish species [7]. On the later stages of fish development, it is more expedient to use larger feed organisms, in particular various species of Cladoceran [8]. It makes improving the increasing technologies for a biomass of live feeds an urgent issue, namely searching for inexpensive alternative environments, a possibility of nutrient correction, and most important – the acceleration of cultivation rates. The usage of biosurfactants allows to improve absorption of nutrient substrates by forage organisms, in particular by daphnias, what ensures the growth rate of their biomass acceleration. Within the biotechnology of receiving biosurfactants the main method is a microbial synthesis. In particular, in such way trehalose lipids can be received. At the same time, it is important to understand whether the appropriate preparations will not have a negative impact on fish, which is fed with live feeds grown with the usage of biosurfactants.

The usage of live feeds and probiotics helps to increase the viability of young fish. This is especially relevant in production of fish planting material intended for introduction into nature. After all, the living conditions change during fish transfer from comfortable aquaculture conditions to natural water reservoirs is often the cause of large losses. Receiving of fry with high viability is especially relevant within carrying out work on a rare fish species reproduction.

Taking into account the above, the aim of the work was to assess the feasibility of probiotic strain *Lactobacillus casei* IMV B-7280 usage and also, the opportunity of usage the culture Daphnia magna grown in the presence of trehalose lipids, within the technology of early feeding of the European grayling *Thymallus thymallus* (Linnaeus, 1758).

2. Materials and methods

Experimental growing of European grayling larvae took place in 2021 on the State Enterprise "Trout hatchery "Lopushno" basis, which belongs to the department of the State agency of land reclamation and fisheries of Ukraine. Incubation of caviar and growing of fish planting material was carried out according to generally accepted recommendations for grayling [9]. Larvae were reared in 20×40 cm trays with a water volume of 18 liters. During all the time of experimental growing the quality of water was controlled with Combo Water Testing Meter AZ-86031.

In both control and experimental groups, the initial number of larvae in trays was 500 individuals. Experimental feeding of larvae was started on the ninth day after hatching from eggs. Introduction of forage was carried out every hour from 8:00 a.m. to 7:00 p.m., alternating with starter dry forage Biomar and live feeds. As starter live feeds nauplia artemia was used, namely *Artemia* spp.

On the first stage of experiment with a duration of 13 days grayling larvae received corresponding dry forage Biomar and intact nauplia artemia, and larvae of experimental group – dry forage and nauplia artemia enriched by probiotic microorganisms culture *Lactobacillus casei* IMV B-7280.

The cultivation of artemia was carried out with common aquacultural method [10] . After the procedure of cleaning cyst sash and cysts which did not hatch, nauplia artemia were transferred to a fresh environment with the appropriate salinity, where lyophilized cultures of probiotic microorganisms with a concentration of 5×10^{11} CFU/l were introduced. The bioencapsulation procedure lasted for 12 hours with constant aeration and lighting.

On the second stage of experiment with a duration of 7 days was investigated the expediency of live feeds usage within the technology of feeding grown grayling larvae. From individuals, which previously got the standard ration without probiotics, the control group of grayling larvae was created and they were fed with the dry forage Biomar, and also research group in which fish got live feeds besides the dry forage, namely *Daphnia magna* Straus, 1820. Feeding was carried out every hour and half during daylight hours. The initial number of grayling larvae is 200 individuals in each tray. In order to increase the nutritional value of forage organisms, daphnia was cultivated together with the green microalgae *Desmodesmus armatus* (Chodat) E.H.Hegewald 2000 [11]. Acceleration of the growth rate of biomass was provided by the addition of trehalose lipids preparation, which was received from the culture fluid of *Rhodococcus erythropolis*.

All researches were performed in triplicate. Effects of dietary treatment were analyzed by a one-way analysis of variance (ANOVA), followed by Tukey's or Student's post hoc test to determine significant differences. Previous to statistical analysis, data were transformed with natural logarithm if identified as non-homogenous (Levene's test) to meet the assumptions for statistical methods. Mean values were considered significantly different at $p \leq 0.05$. Statistical analysis was computed using MS Excel software and STATISTICA 6.0 application package.

3. Ethical considerations

The research conducted in this study adhered to a comprehensive set of ethical principles and guidelines in compliance with both national regulations in Ukraine and institutional policies. Below are the specific ethical considerations and procedures that were followed throughout the experiment:

3.1. National and institutional compliance

1. All aspects of this research were conducted in strict accordance with the principles outlined in the European Convention on the Protection of Vertebrate Animals Used for Research and Other Scientific Purposes. This convention outlines the ethical treatment of animals in scientific research and serves as a fundamental guideline for our ethical approach.
2. We also adhered to the relevant national legislation, specifically the Law of Ukraine "On the Protection of Animals from Cruelty". This law governs the ethical treatment and welfare of animals used in research within the jurisdiction of Ukraine.

3.2. Animal welfare and care

1. Throughout the entire duration of the experiment, we maintained a rigorous standard of constant care for the animals involved. This included regular monitoring of their health and well-being, with immediate action taken to address any signs of distress or discomfort.
2. Special attention was given to ensuring that the animals did not experience any unnecessary pain, suffering, or anxiety. Procedures and handling techniques were designed to minimize stress and discomfort.
3. In cases where it was necessary to euthanize animals, we employed humane methods that were consistent with internationally accepted practices to minimize suffering.
4. To minimize the impact on the animal population, we carefully selected the smallest necessary number of animals required to achieve the research objectives effectively.

3.3. Personnel qualifications

All individuals involved in conducting the experiments and caring for the animals possessed appropriate educational and professional training. This ensured that the highest standards of animal welfare and ethical conduct were upheld throughout the study.

4. Results and discussion

At the the Trout hatchery "Lopushno" the experience of artificial reproduction of aboriginal salmon fish is accumulated, including European grayling what is highlighted in a number of scientific publications [12, 13]. Further researches are aimed at improving proven technologies. Special attention is paid to the problem of young fish mortality reducing and accelerating its growth rates.

On this farm, the incubation of grayling caviar is carried out in horizontal tray apparatuses for salmon fish. Due to the lack of an opportunity to heat the water, the duration of incubation of eggs and hatching periods at the enterprise depend on weather conditions and may significantly differ in different years. An average embryogenesis of grayling lasts 22-24 days [13]. In 2021 the interval between the beginning and the end of embryos hatching from caviar took 11 days. Larvae transition to exogenous nutrition began on the sixth day after hatching, and after 9 days 100% of survived larvae switched to external nutrition, what correspond with the data of other authors [13]. Accordingly, that is why namely on the 9th day after the embryos hatching completion, experimental grayling larvae feeding was started, and was carried out in two stages.

During the experiment, the water temperature in the trays increased by approximately 2 °C, while the concentration of oxygen dissolved in the water, changed insignificantly (figure 1). In general, the quality of water corresponded to the norm [9].

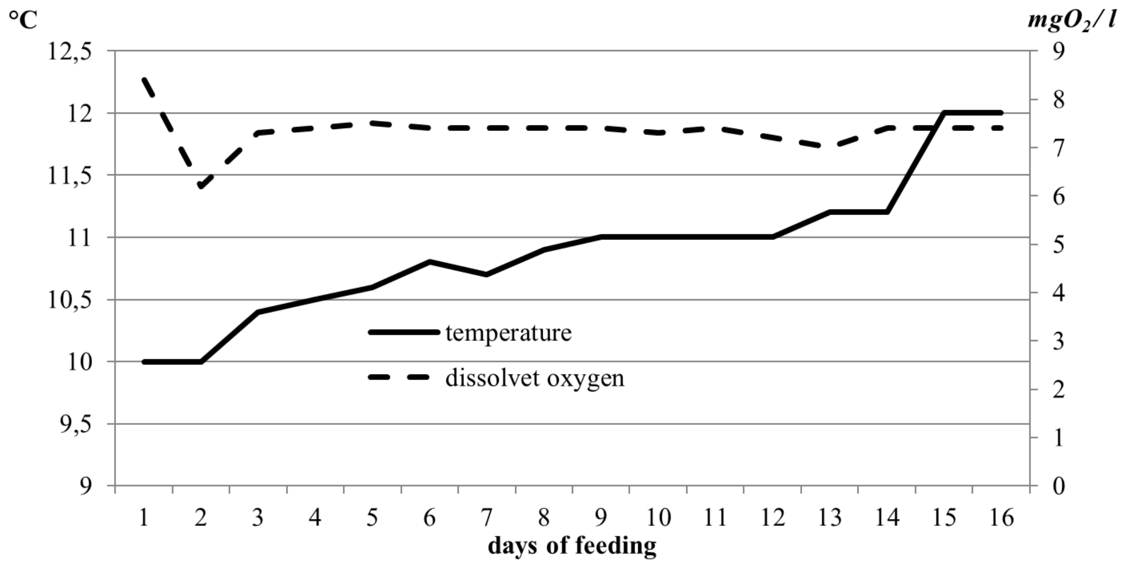

Figure 1. Dynamics of water temperature and concentration of oxygen dissolved in water during experimental European grayling larvae feeding.

Research results showed that grayling larvae, which received encapsulated into artemia lactobacilli, were characterized by a higher growth rate at all stages.

Thus, with the same average initial body weight of 0.02 g, after thirteen days, individuals of the research group were 15% heavier than larvae from the control group (figure 2). It is known that probiotic microorganisms are able to product extracellular digestive enzymes, including protease [2]. As a result, nutrients are engulfed and absorbed more efficiently during a simultaneous use with probiotics, and forages, enriched with them, have a higher nutritional value.

Besides, it is known that *L. casei* has the ability to produce a specific bacteriocin-caseicin, which has an expressive bacteriostatic and weak bactericidal action. Caseicin can be producted extracellularly as well as inside a cell in a ratio of 50 : 1 [14]. It can be assumed that this bacteriocin contributes to the increased elimination of pathogenic and conditionally pathogenic microorganisms in nauplia artemia, which are received from cysts collected of natural conditions. It allows to protect young fish to some extent from pathogens which may be transmitted with

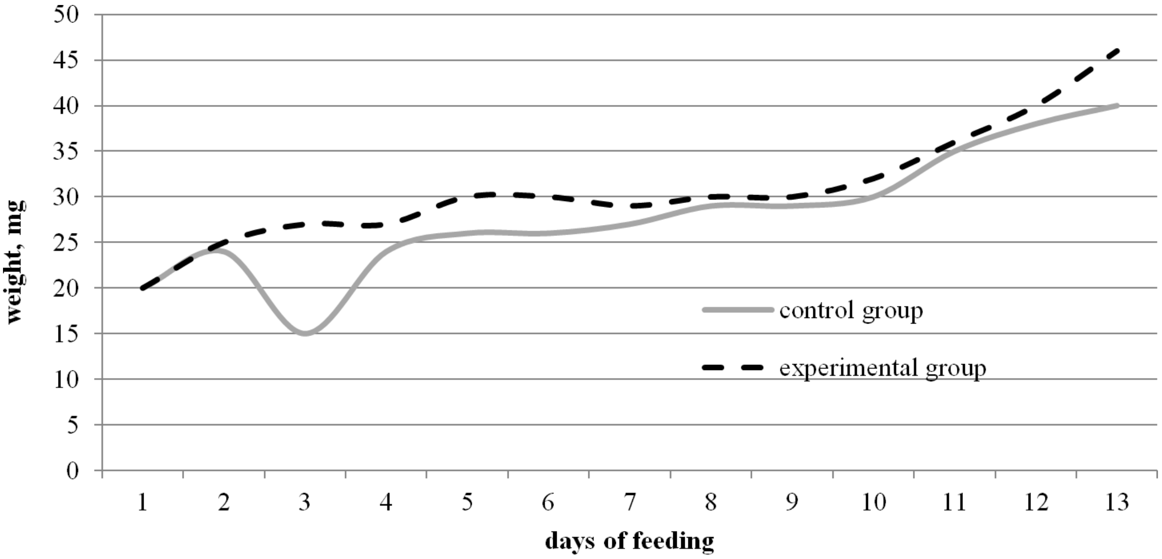

Figure 2. Dynamics of body weight accumulation of European grayling larvae during feeding with artemia, non-encapsulated and encapsulated with lactobacilli.

live feeds.

The positive effect of using live feeds lies in the fact that they have the necessary set of nutrients for fish, as well as contain their own hydrolytic enzymes which improve the functional activity of fish larvae digestive tract, increase the level of feeds conversion and their digestibility. All of this contributes to the growth intensification processes of young fish.

The introduction of *D. magna* to ration of European grayling youth contributed to the faster accumulation of fish body weight. Thus, the average daily gain of individuals of the control group amounted 3.1 g, and the larvae of the research group – 4.3 g, what is 36% more (figure 3).

Producers of a large quantity of essential micronutrients for fish are microalgae [15, 16].

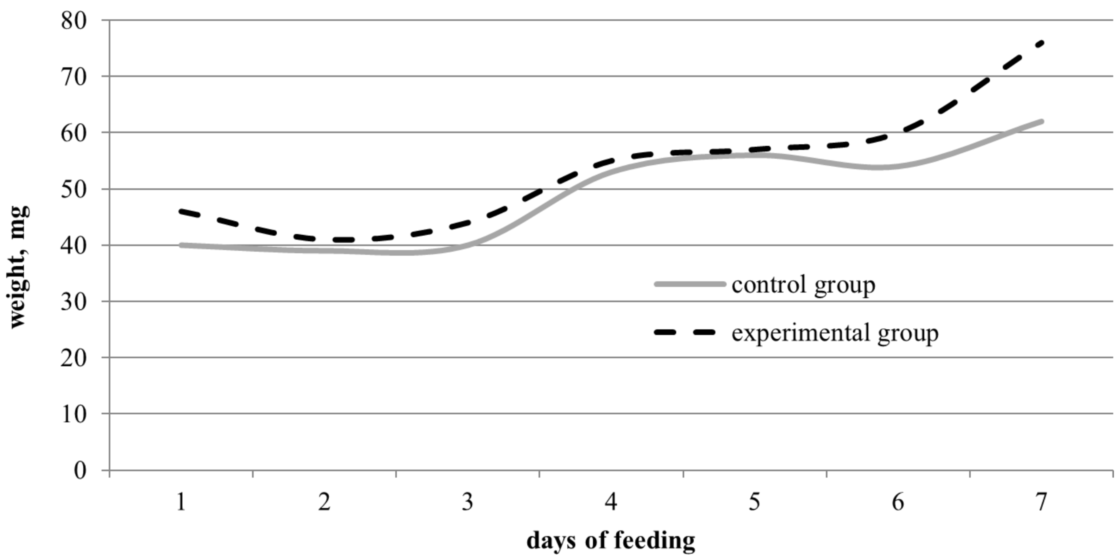

Figure 3. Dynamics of body weight accumulation of growing European grayling larvae under conditions of adding live feed to the diet.

However, due to the existing cell wall, algae are often poorly digested by fish. In return, phytomass is partially digested in a digestive tract of zooplankton, what makes it bioavailable to a fish organism [11]. According to this, combined cultivation of microalgae with feed zooplankton allows to receive live feeds with improved nutritional value.

According to this, one of the problems of receiving a sufficient amount of live feeds for young fish feeding is the rapid increase of its biomass. This can be achieved with the help of biosurfactants usage. Among the wide variety of biological surface-active substances, trehalose lipids are perspective for use – it is the one of glycolipids groups, in which the carbohydrate component is represented by trehalose. Trehalose is a disaccharide in which 2 residues of D-glucose are connected by an α, α-glycosidic bond. Trehalose dissolves well in water and alcohols. According to this, its compounds with fat acids and other lipid nature substances have amphipathic properties, i.e., they dissolve in water and as well as non-polar solvents. It allows nutrients in a digestive tract to form micelles and to transform hydrophobic compounds into a soluble condition [17]. The ability to form micelles, on the one hand, ensures emulsification of fats, what speeds up their digestion, and on the other hand, facilitates the transportation through biological membranes, thereby improving an absorption in intestines.

Previous researches have pointed out that the introduction of biosurfactants speeds up the growth rate of forage zooplankton cultures and also reduces the effective concentration of biocides [18].

Trehalose lipids are synthesized in significant quantities by *Rhodococcus erythropolis* and are accumulated in a culture liquid. The question remains whether the rests of biosurfactants or their derivatives will have a negative effect on young fish. Previous researches have pointed out that the introduction of growing grayling larvae of live feeds biomass, grown by co-cultivation with green algae in presence of trehalose lipids, intensifies the growth rate of fish larvae mass, as well as contributes to increasing of survival rate of fish of the research group in comparison with the control group of individuals (figure 4).

5. Conclusions

Feeding of European grayling larvae during the period of its transition to external nutrition with nauplia artemia, enriched with lactobacilli *Lactobacillus casei* IMV B-7280 ensures acceleration of growth processes.

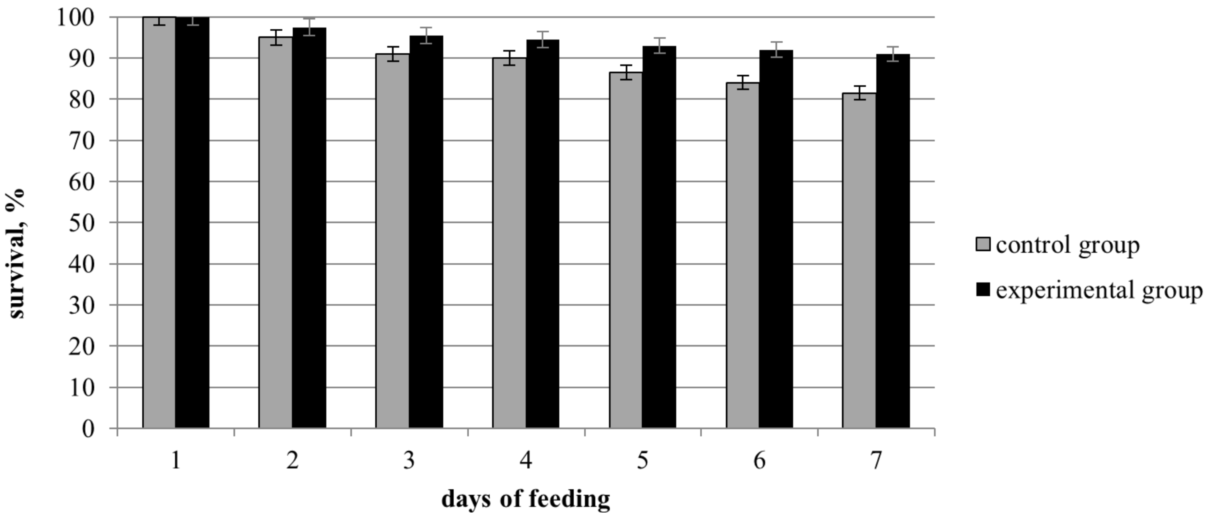

Figure 4. Dynamics of European grayling larvae survival under conditions of live feeds of adding live feed to the diet.

Introduction of *Daphnia magna* culture, previously received of co-cultivation with microalgae *Desmodesmus armatus* with addition of trehalose lipids, into a growing grayling larvae ration, contributes to reducing the mortality of young fish and accelerating its growth rate.

The usage of lactic acid probiotic microorganisms *Lactobacillus casei* IMV B-7280 for incapsulation in artemia nauplia, and also the procedure of co-cultivation live feeds with microalgae in in the presence of biosurfactants, may be appropriate for young fish feeding, but the effectiveness of these procedures has to be investigated for each specific species separately.

Abstract. Heap leaching technology is increasingly being used to extract metals from poor ores, especially in the gold mining industry and is characterized by low capital costs compared to other methods. The purpose of this work is to develop modes and indicators of heap leaching of gold from the destructured oxidized ore of the Belsu deposit, Kazakhstan. The material composition of the ore has been studied, studies of percolation and pelletizing modes have been carried out. For the first time, studies on heap leaching for oxidized ore of the Belsu deposit (Kazakhstan) were conducted. It has been established that gold is well extracted by heap leaching from ore crushed to -25 mm and -12 mm after preliminary pelletizing. The degree of dissolution of gold from ore with a size of -25 mm and -12 mm has similar values – 74.41% and 76.57%, respectively. The leaching tails contain 0.478 g/t and 0.440 g/t gold. The consumption of sodium cyanide did not exceed 0.47 kg/t. The expected extraction of gold into the Dore alloy will be 66.60-68.53% with an initial gold content of 1.87-1.88 g/t in the ore. According to the developed technology, an industrial plant for heap leaching of gold from oxidized ore of the Belsu deposit was built.

1. Introduction

Heap leaching technology is increasingly being used to extract metals from poor ores, especially in the gold mining industry and is characterized by low capital costs compared to other methods. For many decades, the demand for heap leaching has been growing due to its environmental advantages [1–5]. The long-term practice of foreign plants using this technology confirms their high technical and economic efficiency [4–10].

However, a big problem is the destructured and clay ores, which reduce the seepage of the gold-dissolving solution, which leads to decrease of gold extraction [11–15]. Based on the extensive experience of heap leaching operations, agglomeration of crushed ore can be successfully considered and used as a pretreatment of ore that contains a significant amount of fines and clay minerals [14–21].

The purpose of this work is to develop modes and indicators of heap leaching of gold from the destructured oxidized ore of the Belsu deposit, Kazakhstan with recommendations for use on an industrial scale.

2. Experiment

2.1. Materials

The gold-bearing ore of the Belsu deposit in the Abay district, Abay region, Republic of Kazakhstan was studied (figure 1). The technological sample is represented by two types of ores in terms of physical structure: destructured weathering crust (sometimes clumped together) and strong quartz-containing pieces of ore, the number of which is much smaller by weight.

Figure 1. General view of the ore deposit.

2.2. Methods

According to the results of assay analysis, the average gold content in the ore is 1.88 g/t. The chemical composition of the ore is shown in table 1.

The industrial value in the sample is gold. Other metals are contained in insignificant quantities and are out of interest for industrial production. Arsenic is practically absent, and the antimony content was 0.082%. The sample belongs to a poor sulfide type of ore (Sulfide < 1%). According to the degree of oxidation, the sample is assigned to the oxidized zone. The results of wet sieve analyses of a crushed sample with a size of -25 mm and -12 mm are shown in figures 2-4.

The visual determination of a large amount of destructured ore in the sample was confirmed by the results of the sieve analysis. According to the physical condition, the initial ore sample (and even more crushed ore) is highly destructured. The amount of fine grade (-2.5 mm) in the crushed sample of -25 mm and -12 mm was 82-83%. This will create serious problems for leaching solutions to seep through the ore stack during heap leaching.

Table 1. Chemical composition of gold-bearing ore of Belsu deposit.

Components	Content, %	Components	Content, %
Copper	0.037	Potassium oxide	1.37
Nickel	0.003	Silicon oxide	57.42
Cobalt	0.013	Aluminum oxide	16.40
Zinc	0.041	Arsenic	0.02
Lead	0.042	Antimony	0.082
Iron	5.66	Total sulfur	0.43
Calcium oxide	1.75	Sulphate sulfur	0.40
Magnesium Oxide	1.10	Sulfide sulfur	0.03
Sodium oxide	0.59	Degree of sulfur oxidation	93.02

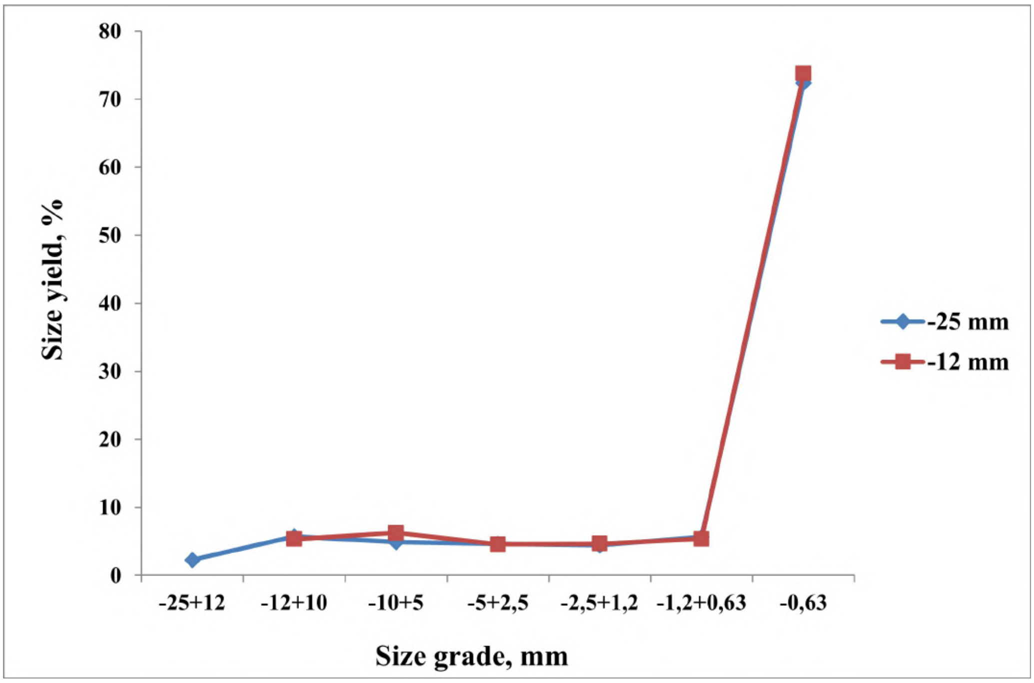

Figure 2. Granulometric characteristics of crushed ore.

2.2.1. Laboratory tests of cyanide leaching of gold. To evaluate the type of the gold in the ore, standard bottle tests were carried out on crushed ore with a grain size of 90% of the -0.071 mm class. To assess the change in the degree of dissolution of gold with an increase in the size of the ore, an additional bottle test is carried out on crushed ore with a size of -2.5 mm.

Laboratory studies on cyanide leaching were carried out in a bottle agitator with a rotation speed of 30 rpm. The modes of leaching were as follows: the mass of ore samples for each experiment was 300 g, the ratio Solid:Liquid = 1:2, pH 10-11, the concentration of sodium cyanide was 0.100%, the duration of leaching was 24 hours. During the leaching process, the concentration of sodium cyanide and the pH of the solution were monitored, reagents were added if necessary.

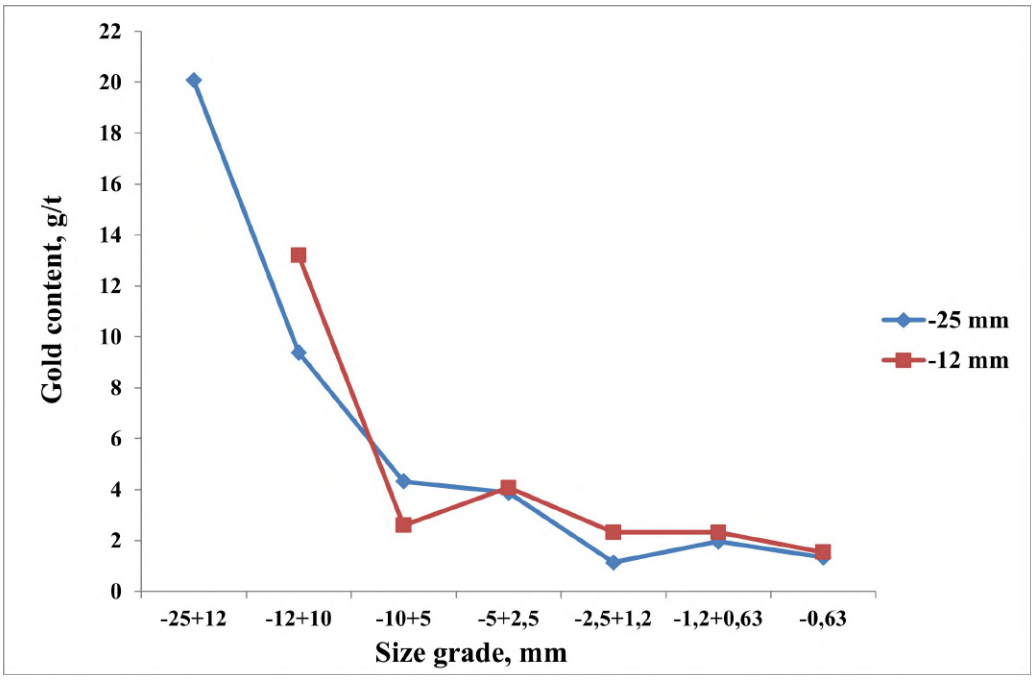

Figure 3. Change in gold content for ore of various sizes by class.

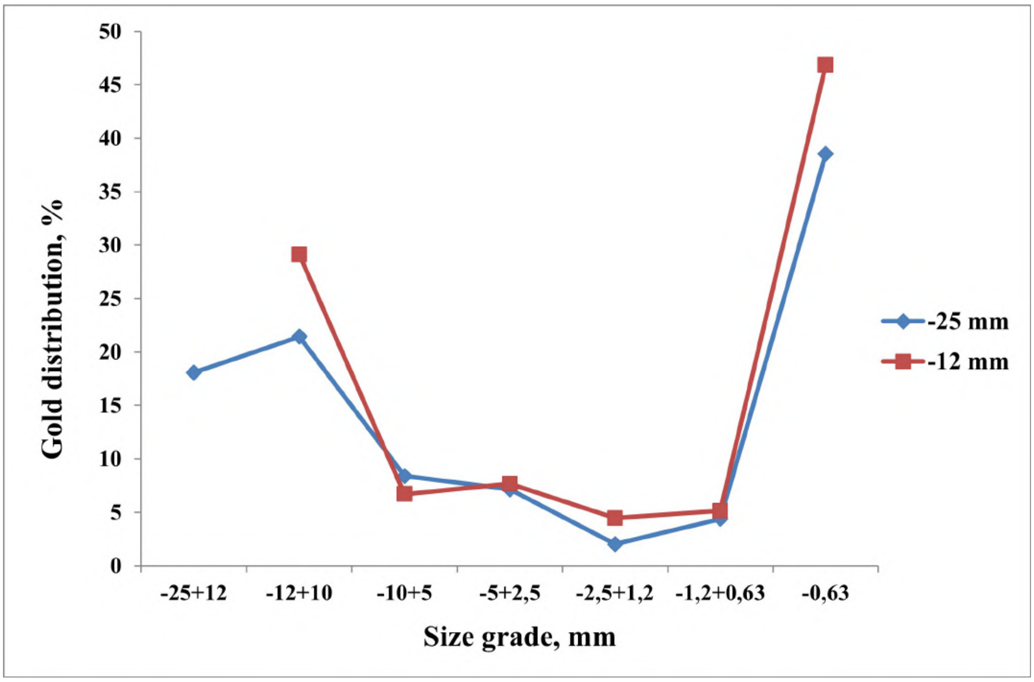

Figure 4. Distribution of gold for ore of various sizes by class.

2.2.2. Determination of percolation characteristics of the initial non-pelletized ore. In world practice, when the ore size is less than 12 mm, as a rule, preliminary pelletizing of the ore with cement is carried out before stacking it. Pelletizing is carried out in agglomerating devices of various types. All this requires certain material costs and increases the cost of gold production [6,14,15,19]. In this regard, the possibility of using non-pelletized raw materials was tested by determining its percolation properties.

To test the possibility of using non-pelletized ore for heap leaching, percolation tests of ore samples with a size of -25 and -12 mm, i.e. the size that will be used during column tests, were carried out.

Percolation tests were carried out in a column with a diameter of 97 mm and a height of 515 mm. The column was filled with 5.0 kg of ore, its compaction was performed by shaking, water was poured from the bottom up, the degree of shrinkage of the ore was determined after soaking, after holding for 2 hours and additional shaking, the maximum percolation rate of water through the ore layer was determined.

2.2.3. Research on the technology of heap leaching of gold. Studies on the technology of heap leaching of gold were carried out in columns. Heap leaching of gold in columns was carried out in a closed cycle: leaching of gold from ore with alkaline cyanide solutions; sorption of dissolved gold with a sorbent; return of the solution to leaching after adjusting the concentration of sodium cyanide and pH.

Anion exchange resin AM-2B was used as a sorbent for the extraction of dissolved gold from productive solutions. The choice of ion exchange resin as a sorbent is due to the presence of a large number of fine sludge particles in the ore of the Belsu deposit. When using activated carbon, thin sludge particles will have a negative effect on resin, reducing its sorption activity.

The installation for conducting column tests included 2 columns for leaching gold from ore:

- for ore size -25 mm: the diameter of the leaching column is 260 mm; the height of the column is 2420 mm; the height of the ore layer in the column is 2420 mm. The mass of ore in the column by dry weight is 136.97 kg.
- for ore size -12 mm: the diameter of the leaching column is 253 mm; the height of the column is 2410 mm; the height of the ore layer in the column is 2410 mm. The mass of ore in the column by dry weight is 137.46 kg.

Solutions of 0.05% (0.5 g/l) sodium cyanide were used as a leaching solution, the pH was maintained in the range of 10.5-11.0 due to the addition of sodium hydroxide.

3. Results and discussion

The results of bottle tests of cyanide leaching of gold are presented in table 2.

Table 2. Results of bottle tests of cyanide leaching of gold from samples of various sizes.

Name of parameters	-2.5 mm		90 % -0.071 mm	
	1	2	1	2
Au content in the liquid phase of the pulp, mg/l	0.77	0.79	0.95	1.04
Au content in the solid phase of tails, g/t	0.28	0.28	0.10	0.12
Estimated Au content in ore, g/t	1.82	1.86	2.00	2.20
Degree of dissolution Au, %	84.62	84.95	95.00	94.55

The results of bottle tests of cyanide leaching of gold from crushed ore (90% -0.071 mm) confirmed that the gold in the ore is mainly in free form, the degree of dissolution of gold from the crushed sample reached 94.5-95%.

From a crushed sample with a size of -2.5 mm, 84.62–84.94% (average 84.79%) of gold is dissolved, i.e. it decreases by 10%, but this decrease is not drastic and assumes fairly good indicators for heap leaching.

The consumption of sodium cyanide for interaction with minerals was 0.84-1.80 kg/t.

The results of percolation tests of crushed ore are shown in table 3.

Table 3. Results of tests on percolation of crushed ore.

Name of indicators	-25	-12
Degree of shrinkage of the ore after soaking, %	0.42	0.63
Degree of shrinkage of the ore after soaking and shaking with water, %	0.84	1.25
Percolation rate of water through the ore layer, m/h	0.01	0.01

The degree of shrinkage of the ore after soaking and shaking with water for both sizes met the requirements of the guidelines (no more than 10%), and the percolation rate of water through the ore layer is many times lower than the regulated one (at least 10 m/h). Ore without preliminary pelletizing is not suitable for heap leaching.

Pelletizing modes have been developed to conduct the heap leaching process. Portland cement of the M-400 D20 GOST 10178-85 grade was used as a binder for pelletizing ore. The results of tests to determine the optimal consumption of Portland cement are shown in tables 4, 4.

Table 4. Determination of optimum Portland cement consumption for pelletising -25 mm crushed ore.

Added Portland cement during granulation, kg/t	10	18	22
Added water during pelletizing, l/t	176.0	190.7	181.9
Ore moisture after pelletizing, %	16.71	17.59	16.94
Percolation rate of water through a layer of granular ore, m/h	46.42	60.93	60.93
Degree of destruction of granules after percolation test, %	28	5	3

Table 5. Determination of optimum Portland cement consumption for pelletising -12 mm crushed ore.

Added Portland cement during granulation, kg/t	10	18	22
Added water during pelletizing, l/t	184.8	196.5	205.3
Ore moisture after pelletizing, %	17.31	17.98	18.49
Percolation rate of water through a layer of granular ore, m/h	17.41	60.93	60.93
Degree of destruction of granules after percolation test, %	30	5	3

All regulatory parameters of percolation for ore with a grain size of -25 mm and -12 mm are satisfied by the following modes: portland cement consumption of 18 kg/t; water consumption of 190.7 l/t (for a grain size of -25 mm) and 196.5 l/t (for a grain size of -12 mm); humidity of granules is about 18%.

Two column tests were carried out, with preliminary pelletizing of ore with a consumption of Portland cement of 18 kg/t. Figure 5 shows the obtained granules.

The results of studies on heap leaching of gold from pelletized ore are presented in figures 6-8.

To dissolve gold, 31 leaching cycles were required for ore with a grain size of -25 mm and 32 cycles for ore with a grain size of -12 mm. The total amount of productive solution to achieve complete leaching was 2.192-2.296 m^3/t.

-25 mm

-12 mm

Figure 5. Pelletized ore -25 mm and -12 mm

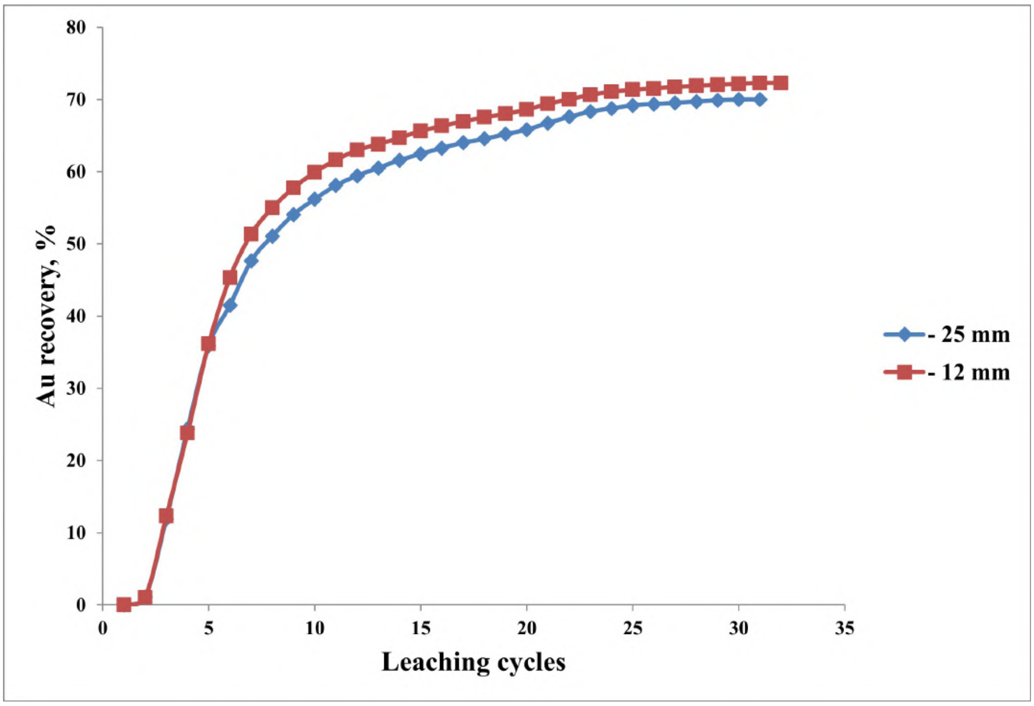

Figure 6. Dependence of gold extraction on the duration of leaching.

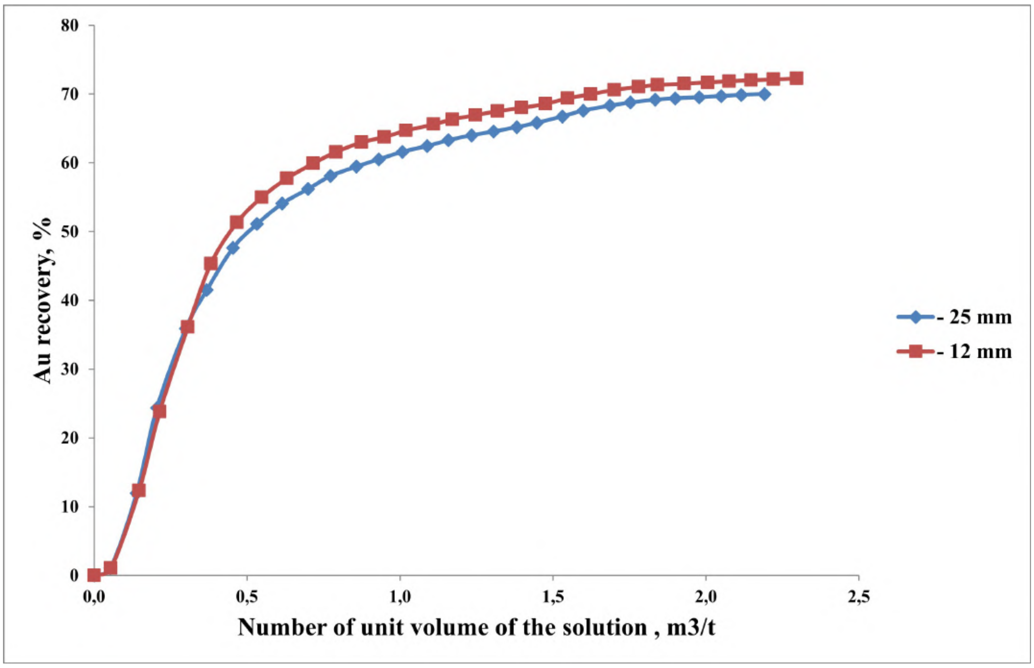

Figure 7. Dependence of gold extraction on the amount of solution passed.

The consumption of sodium cyanide did not exceed 0.47 kg/t, the consumption of sodium hydroxide was 0.150-0.147 kg/t. The gold content in the leaching tailings is 0.478 g/t and 0.440 g/t. Based on the data obtained, the gold balance was calculated during heap leaching of gold from the ore of the Belsu deposit (table 6).

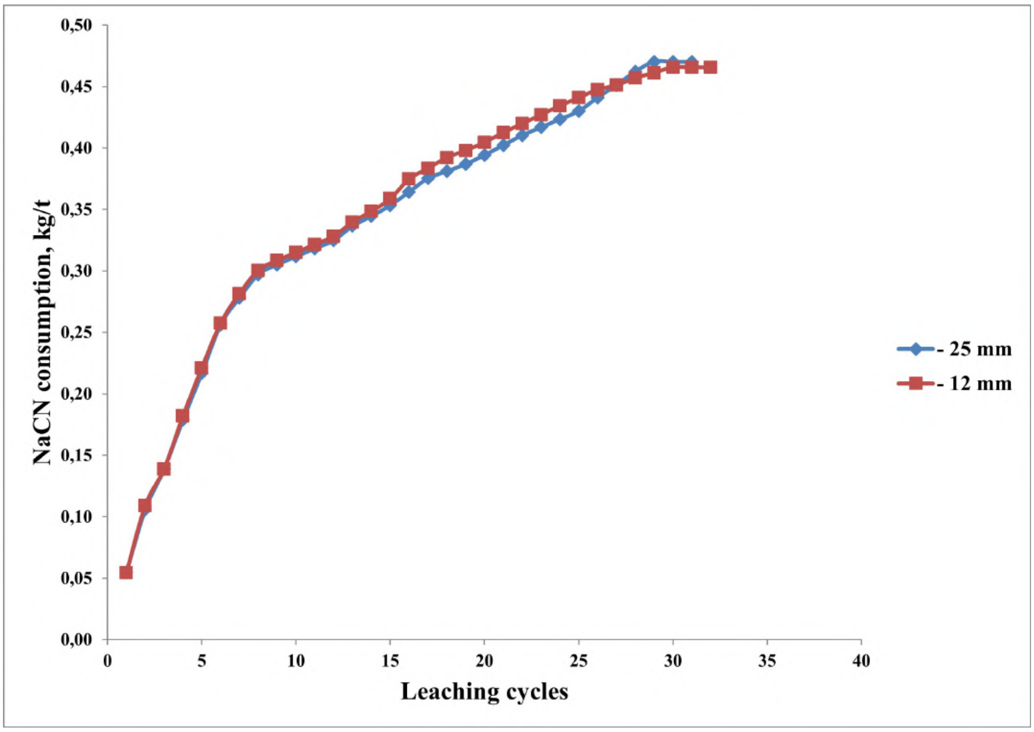

Figure 8. Sodium cyanide consumption during leaching

Table 6. Gold balance during column tests on heap leaching of gold.

Name of indicators	-25	-12
Gold extracted by ion-exchange resin, g/t of ore	1.381	1.429
Gold extracted by ion-exchange resin, %	74.02	76.09
Gold extracted at the water washing operations, g/t of ore	0.003	0.005
Gold brought with the analyzed solutions, g/t of ore	0.004	0.004
Gold content in column leaching tailings, g/t	0.478	0.440
Calculated gold content in the initial ore, g/t	1.866	1.878
Degree of gold dissolution from ore by balance, %	74.41	76.57
Expected gold extraction into commercial product – Doré bars, %	66.60	68.53

From ore, gold is satisfactorily dissolved during heap leaching. According to the balance, the degree of dissolution of gold from ore was 74.41-76.57%.

The obtained high technological indicators of column tests indicate that the oxidized ore of the Belsu site can be efficiently processed by heap leaching with preliminary pelletizing with cement.

According to the research results, technological regulations have been developed and an industrial plant for heap leaching of gold from the ore of the Belsu deposit has been built.

4. Economic of production

The total investment in the organization of the production site at the Belsu field amounted to 8 million US dollars. At the market price of gold of 1800 US dollars per 1 troy ounce, the total revenue will be 147.7 million US dollars. All in-sustaining costs 1042 US dollars per troy ounce of gold. The project implementation period with an annual output of 500 thousand tons of ore will be 6 years. The net present value for the period of the project implementation at a discount rate of 15% will amount to 24.8 million US dollars. The investment return period is 1 year.

5. Conclusions

The gold-bearing ore of the Belsu deposit is extremely destructured. The amount of class -2.5 mm limiting percolation during heap leaching was 82-83%. Processing of ore of such granulometric composition by heap leaching technology is impossible.

We have developed ore processing modes of the Belsu deposit with preliminary pelletizing. Cement consumption was 18 kg per 1 ton of ore. The degree of dissolution of gold from ore with a size of -25 mm and -12 mm has similar values – 74.41% and 76.57%, respectively. The leaching tails contain 0.478 g/t and 0.440 g/t gold, respectively. The consumption of sodium cyanide did not exceed 0.47 kg/t. The consumption of sodium hydroxide was 0.150-0.147 kg/t during gold leaching. The volume of passed solutions for complete leaching of gold was 2.192-2.296 m^3/t of ore, which characterizes a fairly good kinetics of gold dissolution. The expected extraction of gold into the Dore alloy during processing of the ore of the upper oxidized zone under industrial conditions will be 66.60-68.53% with an initial gold content of 1.87-1.88 g/t in the ore.

For industrial conditions of heap leaching, it is recommended to use the ore of the Belsu deposit with a size of -25 mm with its preliminary pelletizing with cement. The developed technology made it possible to efficiently process this ore and obtain gold in the form of marketable products – the Dore alloy. The economic calculation confirmed the effectiveness of the developed technology, the technology has been introduced into industrial production.

Acknowledgments

The team of authors is also very grateful to the colleagues who participated in the organization of experiments.

Abstract. Land use planning of territorial communities is an important component of creating rational sustainable land use. The key task of planning is to find a balance between the economic and ecological components of land use. The most effective agricultural land on the territory of communities is arable land. Advanced modern software and the remote zoning data amount of land make it possible to conduct a complete analysis of land resources condition. To evaluate project decisions, plan indicators and determine land use trends, it is necessary to use integrated indicators that comprehensively describe spatial characteristics. On the basis of complex numbers, it is offered to use an indicator that consists of the territory assessment arableness and the area of land massifs to the perimeter ratio. For the assessment, a "reference" project is used, which was created taking into account the developed recommendations. The integration of the indicator makes it possible to indirectly evaluate the ecological and economic component of agricultural activity. The use of complex numbers makes it possible to expand the use of analysis tools and the capabilities of computing technology.

1. Spatial development planning in Ukraine

The land reform began in 1990 and was a continuation of the constant search for rational use of land from the previous period. As a result of these searches, the use of land resources is currently planned at the level of territorial communities. The main technical planning document is the Comprehensive Spatial Development Plan. Also, the calculation of the normative monetary valuation of land, which affects the amount of rent and the calculation of land tax, will be carried out in the future on the territory of territorial communities. There are projects that will use the territorial community as a unit for conducting land management works (inventory of land and natural resources) during the planning of territorial communities' spatial development. Indicators of land resources use should be objective and include as many indexers as possible related to the spatial characteristics of the territory [1]. Unfortunately, modern indicators are mainly focused on the land ratio. The indicators need some improvement based on the characteristics of the territory organization. When planning the use of land resources, there are many project options, and which option to apply depends on the calculated indicators, which should comprehensively characterize economic activity.

The use of land resources, as the main spatial basis and means of production, depends on the planning and design efficiency. Planning is based on evaluations of project decisions, which in turn depend on criteria [2]. Currently, such indicators of land resources use as arable land, agricultural development, the coefficient of anthropogenic load, the coefficient of territory ecological stability are very popular. But the use of these indicators has both positive and negative impacts. The positives include the fact that these indicators are intuitive and can be easily compared. The negatives include the fact that all indicators do not take into account the spatial placement of objects, but only fix their ratio [3]. It should be noted that indicators (indices) that characterize the spatial relationship of land exist and include: the index of the standard deviation of the counter size, the shape index, the index of the average distance between contours, the fragmentation index, etc. But all these indices are more related to the study of landscapes and to a lesser extent to agricultural activities. They also have their positive and negative sides of application. The positives include the fact that they are very closely correlated with each other. The negatives include the fact that these indicators separately are not very informative.

Indices of spatial development are evolved for many programs in different countries of the world: Poland, Spain, Taiwan, Norway, etc. Sowińska-Świerkosz and Soszyński [4] conducted a review of the relevant literature (102 articles), which allowed to choose the most similar indices of the rural areas study: an index that covers rural areas with a high risk of urbanization, an indicator of the rural areas viability, and an index of the land strategic location. Metrics used to analyze the spatial aspects of rural urbanization and those related to sustainability proved to be the most effective. The study [5] developed the Index of Prognosis Rural Landscape Preferences (IPRLP), which consists of nine variables relating to the presence or percentage of various landscape attributes. Nogués et al [6] investigated the possibility of using stability indicators to determine and measure the quantitative and qualitative spatial stability of territories. The essence of the study was to combine social, economic, environmental and spatial indicators into a single local index using robust principal component analysis and a multi-criteria decision-making method. Chang et al [7] applied the two-dimensional local indicator of spatial autocorrelation (BiLISA) to determine the spatial distribution of synergies and trade-offs between different co-benefits. The research paper [8] defines planning tools for the protection of arable land. Factors and prerequisites of spatial planning indicators are analyzed. Barneveld et al [9] evaluated the use of the connectivity index to evaluate anti-erosion measures.

2. Application of spatial development complex indicators

Economic activity is a complex ecological and economic process, and therefore we suppose it appropriate to consider the use of more complex indicators. The indicators, indices and coefficients listed above are displayed as real numbers. Although mathematical sciences, computer technology has taken a big step forward and researchers for spatial planning have the opportunity to use mathematical objects more complex than real numbers. For example, complex numbers that can more deeply describe various factors of planning or designing the land resources use. It can be determined that scientists divide ecological, economic and social aspects of agricultural activity, as well as their ecological-economic, socio-economic, etc. integrations. To reflect such project evaluation criteria, an indicator can be used that will simultaneously take into account environmental and economic factors. It is rather difficult to directly compare environmental and economic indicators.

As a rule, ecological indicators are converted into economic indicators by calculating the amount of funds necessary to prevent the manifestation of negative natural and anthropogenic phenomena. It should be noted that economic indicators have a limited scope, because there are such phenomena as inflation, currency devaluation, etc. This forces the use of discounting methods. Also, economic processes are affected by changes in market conditions and other factors that limit long-term forecasts and the use of economic indicators that were taken into account due to environmental ones. Therefore, we suggest using the ratio of arable land to the entire area as an ecological indicator. Arable land is intensively used, while the natural environment is deteriorating [10]. Ecologically stabilizing lands have a positive effect on arable land: water bodies, natural fodder lands, forested areas.

As a technical indicator that affects economic costs, usage the ratio of the area of arable land contours to the perimeter. This indicator takes into account the spatial location of agricultural production various objects. We suggest making calculations in complex numbers, which will make it possible to combine various aspects of economic activity. The number $a + bi$, where a and b are any real numbers, i is an imaginary unit, is called a complex number (a is the real part, bi is the imaginary part of the complex number, and b is the coefficient of the imaginary part). The real part will take into account territory, and the coefficient for the imaginary part will calculate the spatial indicator, which is the sum of the area to the perimeter ratios. Thus, our indicators will take into account both the ecological part and spatial characteristics.

Spatial indicators of forecasting the use of land resources are in the fact that there are dependencies on the shape of fields and working areas and various economic effects [11]. The economic efficiency of economic activity depends on various costs, one of which is the fuel and oil cost and agricultural machinery depreciation. This is due to those idle runs and turns of agricultural machinery. That is, the shape of the field affects the amount of expenses. In turn, costs are part of the economic component. Indicators of the intensively used land and ecologically stabilizing land ratio do not take into account economic effects. With the same land ratio, the ecological effect can be different. Different configurations of fields and working areas can create more protected areas from negative natural and anthropogenic phenomena. In figure 1, we see 3 schematic views of the arable land configuration with ecologically stabilizing lands. Yellow color shows conditionally arable land, green shows ecologically stabilizing land, purple shows positive impact on arable land. By positive influence we mean anti-erosion protection, creation of microclimatic conditions for the growth of agricultural crops, etc. All three schematic options have the same land ratio. Plowability is 50%. Regarding the ease of working areas use, option A is better, option B is somewhat worse. Option C is not suitable for the use of powerful agricultural machinery at all. Regarding the impact on arable land, option C provides the best impact due to the mosaic structure of the territory. Option A has the minimum influence area.

On the one hand, the high contour and fragmentation of the territory creates biological diversity, provides greater protection against wind and water erosion, and provides a stronger interaction between ecologically stabilizing lands and intensively used lands. On the other hand, high contouring worsens the use of agricultural machinery due to idle turns, increases the costs of fuel and oil and work time (increase in wage costs), amortization, wear and tear of agricultural machinery, etc [12]. Thus, we need to find a balance between the economic and ecological components of land resources use. When designing, as a rule, several options are formed according to different rules, which in turn arise due to the fact that there are no universal ideal management conditions. There are always many factors and many options to consider. At the final stage of planning, these projects are evaluated and the best one is selected. If we use only the land ratio indicator, there is no economic evaluation of the project. If we use only economic indicators, there will be no information on environmental safety. Therefore, our offered indicator based on complex numbers will at least indirectly contain both components. This will make it possible to more objectively and qualitatively find the best option for spatial planning of land resources [13]. Land use is central to addressing food security, including biodiversity conservation, climate change, sustainability issues, sustainable energy, achieving social justice, and poverty alleviation.

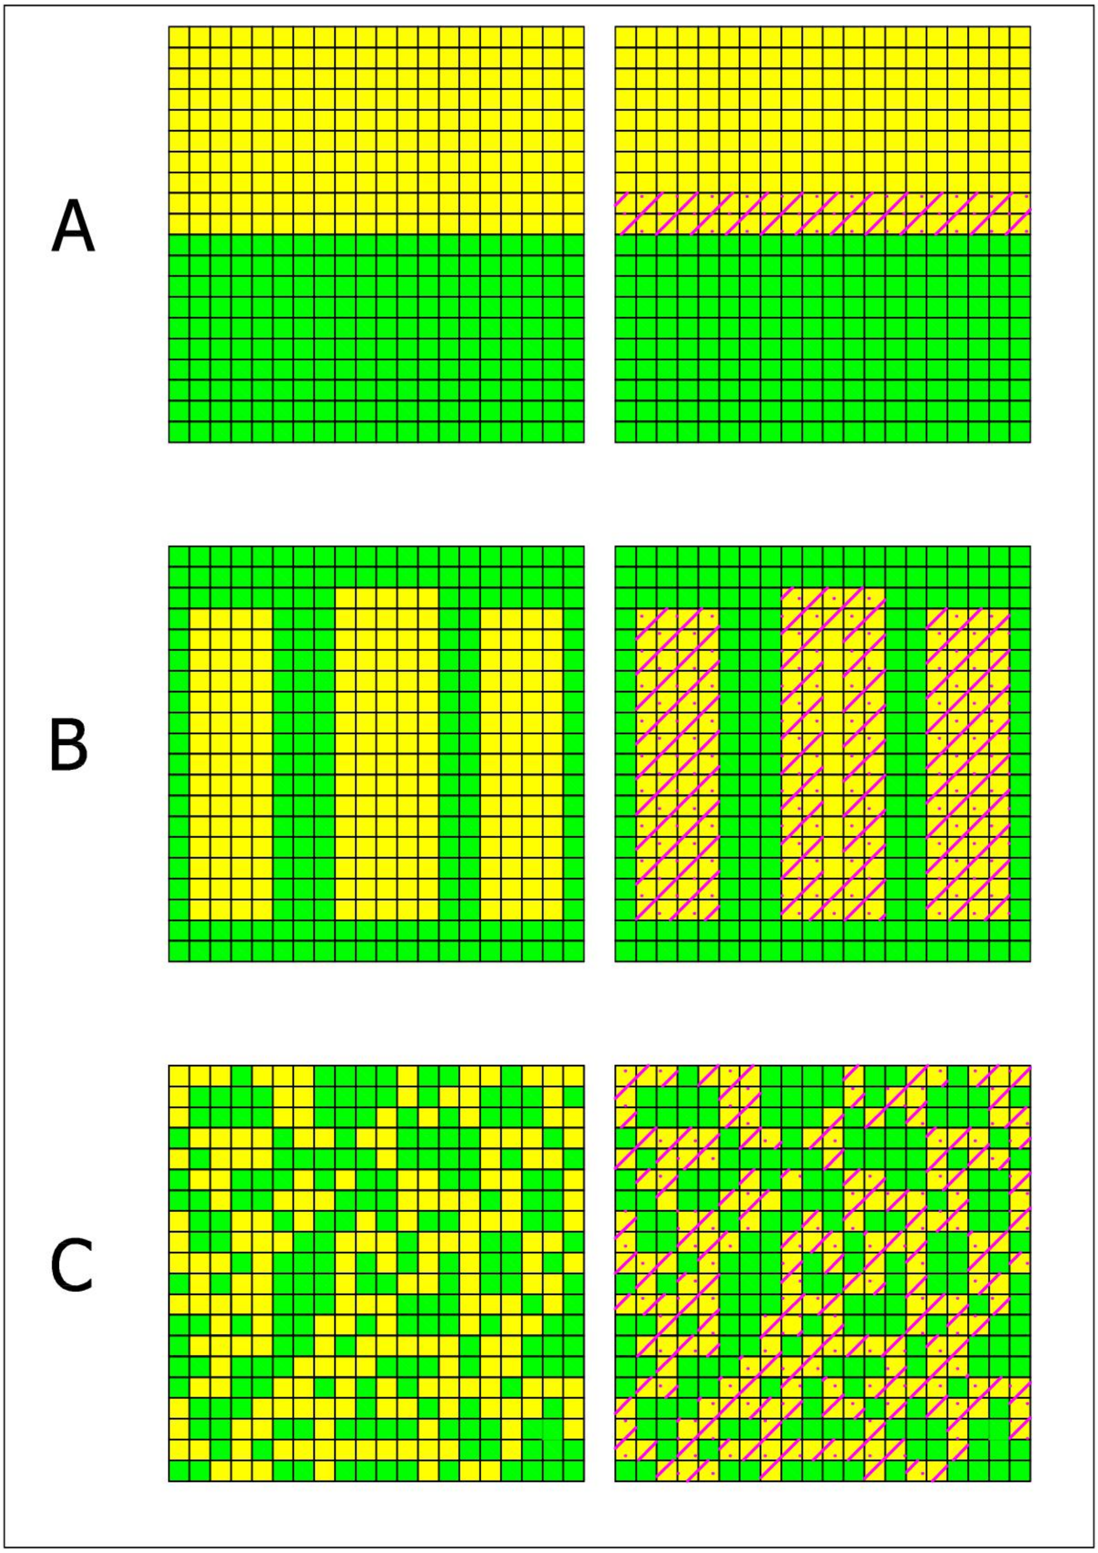

Figure 1. Options of spatial development comprehensive assessment.

To calculate the "reference" complex indicator, the 2013 recommendations of the Derzhkomzem (State Committee of Ukraine on Land Resources) were used regarding the ecological and economic substantiation of land management and the introduction of crop rotation. These recommendations suggest that the shape of the field be rectangular or trapezoidal, have parallel sides, an aspect ratio of 1 to 5, and be located, if possible, from north to south with long sides. The area of the field should be up to 400 hectares. Field protection forest strips should be located along the boundaries of the working plots, entrances to each land plot should be provided. Field protection forest strips should be located at an angle of 90 degrees in relation to harmful winds (with a deviation of up to 30 degrees).

With the help of the software, a "reference" project was designed and the sum of perimeter and area ratio was determined. The considered perfect conditions do not take into account the relief, variegation of the ground cover, etc. For the calculation, we used an area of 1000 hectares with a plowing rate of 50%. In scientific sources, researchers have come to a consensus that the rate of plowing is too high for Ukraine and should be reduced. But there is no agreed exact data on the size of the plowability indicator.

Next, using our example, we calculate how much the complex number of the "reference" project differs from the corresponding options. We make a general conclusion, which option is the best. For option A, the comprehensive assessment was $0.5 + 0.005i$, for B – $0.5 + 0.007i$, for C – $0.5 + 0.092i$, for the "reference" project – $0.5 + 0.008i$. Next, we find the distance between the points – the length of the corresponding vector. Consequently, we can say that the closest to the standard and recommended option is B.

3. Difficulties and issues that need to be refined regarding complex indicators

Using complex numbers, as opposed to real numbers, makes comparisons difficult. We can compare only the real and imaginary parts. To avoid this problem, we suggest developing a "reference" assessment object. That is, a project that will take into account all existing recommendations from the ecological and economic side. When evaluating project options or different projects for the offered indicator, we will compare them with the evaluation of the "reference" object – how far is our indicator from this point.

The offered complex indicator proposed can be used in two directions. The first, when you need to compare different project options of the same territory. The second, when you need to compare (evaluate) different territories. After conducting a spatial and statistical analysis, it is possible to develop "benchmarks" for various natural and agricultural areas. The lands on the territory of Ukraine are located in several natural climatic zones, which are divided into natural and agricultural areas, which differ from each other in relief, natural and climatic conditions, as well as contour and fragmentation. It is precisely because of such significant differences between natural and agricultural areas that it is not desirable to use the same "standard" for comparison. In the calculation of these indicators, with which the existing farms or project options will be compared in the future, it is planned to apply the terrain characteristics. If previously it was difficult to calculate such indicators due to the lack of necessary data and the difficulty of calculation, now using modern geographic information systems and appropriate software (QGIS, ArcGIS, Digitals) it is possible to quickly calculate the above spatial indicators.

A certain obstacle to the calculation and implementation of the above indicators is the lack of information on the characteristics of the communities' territory. Territorial communities have appeared recently and there is no generalized up-to-date and verified information on spatial resources. Information on land resources in full is not yet available. In the direction of overcoming the obstacle, very significant steps are being taken, for example, the use of an information portal, which is constantly filled with information on the land resources use. It should be noted that for a full-scale assessment of the entire territory of Ukraine or even within the boundaries of the natural-agricultural region, there is still not enough information. There is

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012095 doi:10.1088/1755-1315/1254/1/012095

a certain positive trend thanks to services (sites) that provide free satellite images of the earth's surface. With the help of GIS programs, you can find information about the physical properties of land plots.

Another obstacle to the use and calculation of complex indicators is the lack of a form of statistical reporting related to the use of land resources. According to the old form, there is data up to 2016. The new form has not been implemented and is at the stage of development, and therefore there is a certain "information vacuum regarding the use of land resources".

Therefore, a promising application of the offered indicator is the monitoring of changes related to the progress and impact of the land reform. For example, after analyzing satellite images of the Earth's surface taken in 2000 and images of 2021, we see that there are two trends. The first trend is an increase in contour and fragmentation without changes in the structure of the land. This is due to the increase in the number of land users and business entities. The second trend is a change in the structure of land, by involving intensive cultivation of fodder land. Both the first and second trends can be calculated and analyzed using the offered indicator. This will make it possible to conduct at least a partial and intermediate assessment of land reform effectiveness. Land relations is a complex multifaceted system and it is difficult to characterize it with one indicator. But there is an opportunity to note trends and evaluate prospects. When spatial planning of the communities' territory, design and planning solutions of larger territorial units (districts, regions of the country) must be taken into account.

The use of complex indicators in land management should help to identify patterns that were not the focus of scientists' attention before. In the future, it is planned to improve the real part of the indicator (the ratio of arable land to the total area). Various multidimensional statistical searches, finding the correlation dependence of environmental effects and economic gains on the value of the above-mentioned indicator will help to do this. But it should be noted that economic calculations are also characterized by a lack of information. There are two levels of problems with statistical data: practical and methodical. The practical one is that costs directly related to production are a trade secret. The methodological level is that the final result of agricultural activity is influenced not only by the production component, but also by others, such as marketing. It is difficult to investigate the direct influence of land, contour, and fragmentation ratio on the economic component of economic activity.

4. Conclusions

The offered evaluation of design and planning solutions index will make it possible to evaluate both the ratio of lands and their spatial placement in an integrated manner. The use of complex numbers will make it possible to implement new analysis approaches in land management to find regularities in the influence of spatial placement on the economic activity results. For territorial communities in Ukraine, an important success factor is the use of arable land, as the most effective agricultural land. Finding a balance between economic benefit and ecological stability is a key task of the territory spatial planning.

The offered approach application requires a significant amount of relevant information. Unfortunately, there are certain obstacles regarding access to the characteristics of the land resources use. Modern software and land remote sensing data allow highly complex analyses. The indicators mentioned above must be tested and improved. Including relief characteristics in complex indicators will provide even more accurate spatial analysis data.

Prospective areas of use of the proposed indicator are the determination of average statistical characteristics of the spatial indicators of the most productive lands. On their basis – determination of optimization parameters, ways of reducing economic costs, achieving ecological balance. First, it is possible to determine the most successful (effective) design and planning solutions. Secondly, there is an opportunity to analyze trends and trends in the development of land relations, to draw conclusions about problems and proposals to overcome them. Territorial communities receive a new decision-making and assessment tool that will allow more efficient use of available land resources. Land management should fully use modern computer technologies, GIS, and mathematical methods. Only multilateral methods of evaluating planning and project decisions will ensure effective spatial development of territorial communities and the country as a whole.

Abstract. The biomass of forest wood residues (waste) in the Ukrainian Carpathians is now an important resource for ensuring energy security under martial law and the formation of strategic directions for energy independence from imported fossil energy resources and the development of a green economy. As a result of the study, the indicators of the total potential of wood biomass of forest wood residues in the forests of the Ukrainian Carpathians were established both in volumetric units and primary energy units. These indicators are differentiated by territorial administrative units of the region and predominant forest stands. The information basis for the assessment of these indicators was the research data on biometric assessment of trees collected in temporary trial plots, as well as mathematical dependencies of conversion factors of biomass components. The study found that the environmentally safe annual potential of the studied resource is about 800 thousand m^3, or 7.7 PJ, which can be additionally involved in the process of generating heat or other types of energy. The results of the study of forest residues biomass potential are an informational component for the formation of a regional program for the development of forest bioenergy in the Carpathian region of Ukraine.

1. Introduction

Use of wood biomass from forest waste is currently not only one of the areas of renewable energy development and a component of green economy mechanisms, but also an important social area for ensuring energy security of Ukraine's population under martial law. An intensive development of the national renewable energy sector is linked, among other things, to the destruction of a significant number of energy infrastructure facilities during missile strikes on the territory of Ukraine. It also stimulates implementation of low-carbon production approaches, as envisaged by the Low-Carbon Development Strategy of Ukraine, and facilitates positive environmental impact in urbanized conditions.

An imbalance of the current paradigm of mankind's energy supply, based on the dominance of fossil fuel energy, is also noted in the Energy Report [1] by World Wildlife Fund (WWF) in cooperation with ECOFYS energy consulting agency. Due to the progressive global decline in reserves of non-renewable natural energy resources (gas, oil, coal) and the urgent need to reduce harmful emissions, the challenge of using alternative fuels has become particularly relevant [2]. Wood biomass from forest waste in forests of Ukrainian Carpathians, one of the most forested regions of the country, serves as an important renewable energy resource for the region's green economy and is an integral part of the national energy sector in the context of energy dependence on fossil energy resources.

The forests in Ukrainian Carpathians, accounting for over a third of Ukraine's wood biomass reserves, remain an important environmental and social factor in development of local communities in mountainous areas. This necessitates the application of environmentally sound approaches to use of forest resources, ensuring a balance between economic, social and environmental components of the regional mountain forest management system.

While focusing on resource potential of forest wood biomass, researchers often do not consider the environmental component of forest stands' functioning, omit the important role of forest residues in logged areas in forming stocks of mineral nutrients as a result of biodegradation [3,4].

Uncontrolled use of wood biomass for energy purposes may have negative consequences for forest plant communities. For example, according to the published research [5], an increase in volume of wood biomass harvesting in Swedish forests may have negative consequences for the environment, forest soil fertility, and conservation of forest biodiversity. Excessive use of logging residues may also have a negative impact on mammal populations [6] and the ability of forest plant communities to provide ecosystem services [7].

The use of wood biomass is characterized by different ways of converting it into heat, electricity, and other types of energy. At the same time, researchers from Latvia [8] prove the inefficiency of using wood biomass for electricity production and conclude that the transition to renewable energy without radical changes in the existing economic system in the country will further exacerbate the environmental problems of bioenergy. When using forest residues for biofuel production, it is also necessary to consider their qualimetric features. A high percentage of bark in forest residues causes the formation of a significant amount of ash in the course of their combustion, which requires an increase in cost of fuel boilers maintenance [9].

The prospects for use of logging residues for energy production were also noted by Spanish and Italian researchers [10], who concluded that use of forest residues from natural forests is more environmentally friendly than wood biomass obtained from energy plantations. Energy from wood biomass can serve as an indicator of energy sustainability in the face of current challenges (extreme weather events, climate change, environmental pollution, loss of biodiversity) [11].

In the process of assessing potential opportunities for involving wood biomass in the energy sector, the long-term planning process is important, given the environmental acceptability, economic feasibility and reliability of resource formation [12]. This approach allows to involve the maximum number of stakeholders for the effective implementation of renewable energy technologies. Given that use of wood biomass as an energy resource ensures the development of low-carbon production, its sustainable use serves as a tool for mitigating global climate change. Thus, according to research by scientists from Thailand [13], if wood biomass is used for bioenergy production in Southeast Asia instead of burning coal, diesel or natural gas, the total emission reduction could be 229.9, 215.4 or 207.9 Tg CO_2 per annuum.

Accumulation of wood biomass in the form of dead wood in forests with a significant anthropogenic load can contribute to an increase in fire hazard due to build-up of forest combustible materials stocks [14, 15]. Therefore, a portion of dead wood can be used as an energy resource without compromising biodiversity conservation.

Thus, based on the analysis of the literature, it can be concluded that forest biomass, including forest residues, remains on the agenda of global scientific community as a strategic renewable energy resource. At the same time, its use should be carried out in compliance with the conceptual framework of sustainable development.

The *purpose* of this research is to assess the potential of biomass of forest residues in forests of Ukrainian Carpathians as an important part of renewable energy resource and a component of regional green economy development.

2. Materials and methods

The research is focused on forest stands in Ukrainian Carpathians, which according to the information from the stand level database run by Industrial Association "Ukrderzhlisproekt" (Ukrainian Industrial Association for Forest Management Planning), cover an area of 2012.3 thousand hectares and feature growing stock of 577.5 million m^3 within four administrative regions (table 1). Spruce, beech, and fir stands predominate in the research region, accounting for about 70 % of forested area. Almost a half of these stands are mid-aged ones.

Table 1. Quantitative characteristics of forest plots in the research region.

Administrative region	Quantity of forest plots, pcs.	Area, thou. ha	Growing stock, Mio. m^3
Zakarpattia	111841	641.9	210.9
Ivano-Frankivsk	132695	531.0	150.4
Lviv	180302	606.6	151.4
Chernivtsi	55463	232.8	64.8
Total	480301	2012.3	577.5

To carry out the research of weight characteristics of biomass components, we used experimental data collected on temporary sample plots using a unified methodology [16]. The total amount of experimental data used for the purposes of our research is 662 model trees, 513 experimental sections of tree trunks and 246 samples of crown branches (table 2).

Table 2. Quantitative characteristics of forest plots in the research region.

Tree species	Quantity, pcs			
	sample trees	sample sections		
		total	including	
			trunk	crown branches
Norway spruce	279	249	150	99
Silver fir	200	342	243	99
European beech	183	168	120	48
Total	662	759	513	246

The research uses the statement that forest wood residues (waste) are primarily represented by wood raw materials harvested in the process of thinning (lighting, clearing and partially first commercial thinning) in the form of whole trees, as well as logging waste, logging residues (parts of trunks, branches, treetops, etc.), stumps and roots that are formed after final cuts, sanitary cuts and other forest tending and care measures.

To establish the total biomass stocks of crown branches, which form the bulk of forest wood residues volume in the forests of Ukrainian Carpathians, we used mathematical dependencies of biomass expansion factors tested for the territory of the research region [17]. To estimate the energy potential of wood biomass of forest residues, we used a dependence that reflects the sum of its structural components and has the following form:

$$PFWW^{tot}_{a,j} = PFP_{a,j} + PFW_{a,j} + PSRA_{a,j}, \tag{1}$$

where $PFWW_a, j$ – total energy potential of forest wood waste in year a over a territory j, m^3; $PFP_t a, j$ – potential of forest products harvested at thinning in young stands (lighting, clearing) in year a over a territory j, m^3; PFW_a, j – potential of forest waste (parts of trunks, branches, treetops, etc.) in year a over a territory j, m^3; $PSRS_a, j$ – potential of stem residues and stumps in year a over a territory j, m^3.

3. Results and discussion

Using information on biometric characteristics of forest stands obtained within the framework of the current State Forest Account and the proposed modeling tools [18], it was found that the total biomass of crown branches in forests of Ukrainian Carpathians exceeds 50.0 million tons of dry matter (table 3). Nearly 45 % of the biomass is accumulated in stands of Zakarpattia region, where its density is 3.8 kg $\cdot$ (m^2)$^{-1}$. This region is dominated by European beech stands (more than 60 % of forested area), which form a much larger crown compared to coniferous tree species. In general, in forests of Ukrainian Carpathians, the share of branches biomass of European beech is 58.2 %.

Table 3. Biomass of crown branches in forests of Ukrainian Carpathians.

Administrative region	Biomass of crown branches, million ton						Mean, kg $\cdot$ (m^2)$^{-1}$
	total	by tree species: Norway spruce	Silver fir	European beech	other species		
Zakarpattia	24.5	2,7	0.2	19.6	2.0		3.82
Ivano-Frankivsk	12.0	4.4	0.6	4.9	2.1		2.25
Lviv	12.5	1.4	1.0	4.8	5.4		2.06
Chernivtsi	5.8	1.2	0.6	2.6	1.4		2.47
Total	54.8	9.7	2.4	31.9	10.8		2.72

Every year, more than 2.5 million m^3 of wood is harvested in the research region. As a result, a significant amount of forest wood residues is formed. They can serve as a significant source of energy resource that must be used in compliance with an ecologically balanced approach to nutrients cycling in forest plant communities while ensuring low fire hazard.

To assess the potential of wood biomass in forest residues in units of primary energy (Joules), quantitative values of energy content per unit volume (table 4) were established based on density of biomass components [18]. The energy value of biomass was determined based on data by Shvidenko et al [17]. In terms of energy value, 1 m^3 of wood over bark of European beech branches is equivalent to 310 m^3 of natural gas. In the research region, beech biomass has the highest consumer demand as an energy resource for heat production during the heating season.

A 110-120 years aged beech stand features the proportion of crown branches of about 20-25 % of its total stem stock. For spruce and fir, this figure is about 10-15 %. Currently, more than 80 % of logging residues remain on site after logging, some of them can be used for heat production without harming the environment.

The research resulted in an assessment of environmentally safe potential of wood biomass from forest wood residues. This type of energy potential accounts for requirements related to

Table 4. Energy value of tree biomass components (crown branches).

Tree species	Energy value of dry matter of live biomass components of crowns, GJ $\cdot$ $(m^3)^{-1}$		
	wood	bark	wood over bark
Norway spruce	9.959	7.653	9.351
Silver fir	9.476	8.511	9.083
European beech	10.156	8.547	9.852

biological cycling of nutrients, biodiversity conservation, and compliance with environmental requirements for use of forest wood waste. It also takes into account orographic features of mountain forests. In total, more than 800 thousand m^3 (table 5) of forest residues can be additionally used as a renewable energy resource annually.

Table 5. Biomass potential of forest residues in forests of Ukrainian Carpathians.

Administrative region	Biomass of forest wood residues, thou. m^3				
	total	by tree species			
		Norway spruce	Silver fir	European beech	other species
Zakarpattia	239.7	26.6	2.0	191.3	19.8
Ivano-Frankivsk	171.8	63.2	8.1	70.8	29.7
Lviv	206.2	22.7	16.1	78.9	88.6
Chernivtsi	182.7	37.1	19.3	83.3	43.1
Total	800.4	149.5	45.5	424.3	181.1

The energy value of the studied biomass potential of forest residues in forests of Ukrainian Carpathians is almost 7.7 PJ (table 6), which is roughly equivalent to more than 240 million m^3 of natural gas.

Table 6. Energy potential of forest wood residues biomass in the forests of the region.

Administrative region	Energy potential of forest wood residues biomass, TJ				
	total	by tree species			
		Norway spruce	Silver fir	European beech	other species
Zakarpattia	2338.1	248.7	18,4	1884.7	186.3
Ivano-Frankivsk	1641.9	590.5	73.8	697.8	279.7
Lviv	1969.5	211.8	146.0	777.3	834.3
Chernivtsi	1748.0	346.7	174.9	820.5	405.9
Total	7697.4	1397.8	413.1	4180.3	1706.3

At the same time, the main problem of utilizing the assessed energy potential is the logistics of this resource to the end user. At present, one of the problems hindering the introduction of new technologies for energy use of wood in the Carpathian region of Ukraine is the lack of a developed network of high-quality forest roads. Here, 10 to 20 % of forest areas covered with forest vegetation remain technically inaccessible. An important precondition for efficient production of solid biofuels is creation of a closed technological cycle of wood processing, starting with logging and ending with processing of waste into pellets or other types of biofuels. The production process should start at a forest plot and a forest road. It should include all logistics and other stages that would guarantee high economic efficiency, low production costs and, ultimately, high price competitiveness compared to traditional energy resources. The system of financial and economic incentives for development of forest bioenergy in the region also needs to be optimized. Due to the lack of financial incentives for implementation of bioenergy projects from the state and local governments in the region, most of them are implemented with the support of foreign funds and programs.

4. Conclusions

The research results present quantitative values of biomass potential of forest wood residues in forests of Ukrainian Carpathians, which will serve as an information basis for formation of a strategy for development of regional forest bioenergy and green economy. In general, the total biomass of crown branches, as the main component of forest wood residues, is more than 50.0 million tons of dry matter. Almost half of this volume is accumulated in the stands of Zakarpattia region. The energy value of the biomass resource varies from 9.083 GJ $\cdot$ $(m^3)^{-1}$ for Silver fir stands to 9.852 GJ $\cdot$ $(m^3)^{-1}$ for European beech stands. In terms of energy value, 1 m^3 of wood over bark of European beech branches is equivalent to approximately 310 m^3 of natural gas. Currently, more than 80 % of logging residues are left for biodegradation at logging sites. According to the results of our research, more than 800 thousand m^3 of forest wood residues can be additionally used as a renewable energy resource without harming the environment and functioning of forest plant communities in the region. In energy terms, this is almost 7.7 PJ, or approximately more than 240 million m^3 of natural gas. At the same time, to facilitate the efficient use of this resource, it is necessary to ensure compliance with the basic principles of sustainable development of the mountainous region, balancing its economic, environmental and social aspects. State regulation, regulatory support, financial and economic incentives for development of forest bioenergy are necessary in the region. Also, development of wood biomass processing technologies as well as development of regulatory and information tools for assessing and monitoring energy potential of forest biomass are of crucial importance. Implementation of the above framework recommendations will facilitate implementation of positive systematic changes in the renewable energy sector, enable accounting for energy needs of the society and uphold energy security principles during martial law.

Abstract. The cadastral information about the lakes of the nature reserve fund (NRF) should be based on landscape-geographic principles using modern geo-information systems.Within the research, based on the instrumental field research and the use of software packages ArcGIS Desktop and ReefMaster Software, a bathymetric map of Lake Serednie (Nobel National Natural Park, Ukraine) and other spatial models were developed. The main hydrological and morphometric parameters of the lake basin were calculated, a landscape map of the natural aquatic complex was created and its landscape metric analysis was carried out at the level of aquatic tracts and facies. The research revealed changes in the level regime and shoreline of the lake caused by the long dry periods of 2016-2021 and life activity of beavers. The created integrated cadastral landscape model of the lake with limnology parameters should serve as a basis for the recreational nature use, monitoring and geo-ecological certification of the reservoirs of the NRF.

1. Introduction

According to Article 56 of the Law of Ukraine "On the Nature Reserve Fund of Ukraine", the state cadastre of the territories and objects of the nature reserve fund (NRF) is a system of necessary and reliable information about the natural, scientific, legal and other characteristics of the territories of the objects included to the NRF [1]. In Ukraine, the natural reserve fund is safeguarded as a national asset and subject to a distinct set of rules for its protection, reproduction, and usage. Furthermore, Ukraine regards this fund as a crucial component of the global network of special-protected natural territories and objects. The corresponding cadastral system should incorporate current geospatial data, metadata, and various online sources, including publications, that comply with the terms of the Spatial Data Infrastructure [2]. In 2021, the Ministry of Environmental Protection and Natural Resources of Ukraine presented an electronic cadastre of territories and objects of the NRF. The information layer "Nature Reserve Fund" appeared on the Public Cadastral Map, which at that time contained information on 8,633 NRF objects, or 88 percent of the area of the NRF of Ukraine [3].

Lake reservoirs occupy a prominent place in the structure of the NRF objects of Ukraine. They are part of nature reserves, national nature parks, regional landscape parks, landscape reserves, hydrological natural monuments, protected tracts, etc. Unfortunately, there is rather limited information about lakes of the NRF and, it should be noted, such situation is not unique [4]. On the Public Cadastral Map, lake objects of the NRF and other water bodies are shown as separate entities with provided information about the area, ownership, etc. Undoubtedly, information on some parameters of land use and landscape components can be added in other layers.

Today, one of the important tasks of protected nature resource management is the creation of an information database about local NRF objects, including lakes, which should later appear on the Internet portals of the institutions of the nature reserve fund. The cadastral information should serve as a basis for recreational nature use, monitoring observations, geo-ecological certification of water bodies [5]. In 2015, Svidzynska et al updated the issue of developing an open cadastre of protected areas of Ukraine [6], which support geo-ecological approaches in the organization of nature reserves.

Among the other studies, which are similar in subject matter, it is worth highlighting the work on the anthropogenic loads on surface water status in Lithuania [7]. A model of geographic management of a nature reserve [8] was developed within the framework of the "Electronic Turkey" project.

Some studies were devoted to the validation of remote sensing indices for water monitoring using Sentinel-2 [9, 10], which can be applied to the cadastre development of lake systems of protected areas. Although successfully tested the methods of capturing littoral zones (up to 1.6 m under clear water conditions) using a UAV complex with a LIDAR scanner on board [11]. The use of the proposed technology greatly facilitates the collection of data for cadastral landscape modeling of lakes, since the shallow zone with higher aquatic vegetation is the most inconvenient for measurements.

For a long time, we have been conducting landscape and limnology studies within the boundaries of Polissia region of Ukraine with the aim of developing cadastral and landscape models of lakes [12, 13], primarily in the territory of the NRF.

2. Materials and methodology

The model protected nature area of this research is Nobel National Natural Park (NNP) in Ukraine, which is located within the physiographic region of Volyn Polissia. The landscapes of the park are characterized by an extensive hydrographic network, swampy wetland complexes, sand dunes and green massifs of forests with areas of cranberries, blueberries, lingonberries, etc. The park includes 12 lakes (Nobel, Omyt, Nihovyshche, Zasvitske, Postvitske, Zadovzhe, Ostrivske, Velyke, Serednie, Khoromne, Lypenske, Liubynske).

The lakes play a significant role in the hydrological functioning of the landscape, the accumulation of fresh water and organic-mineral resources represented by sapropel. Among the most important functions – serving as habitats for waterfowl and numerous migratory bird species. The lakes of Nobel NNP have significant recreational and tourist potential. Among the lakes of the park, a group of Ostrivski lakes stands out. This group includes a picturesque Lake Serednie, which was formed in the Nyzhnostyrskyi physical-geographical district of Volyn Polissia (figure 1).

The development of the cadastral landscape model of Lake Serednie (North 51.72392176915384, East 25.834182861365576) included field instrumental research, in particular, high-precision echo sounding of the reservoir, research into the composition and thickness of lake sediments, the study of the species diversity of above-water and underwater plant communities, and determination of the temperature regime in the summer. The hydrometric work was carried out in May 2021 using a Humminbird 597ci HD sounder mounted on the transom of a rubber boat. The water level during the measurements was recorded using a Leica GNSS/RTK receiver. SRTM v.3 radar survey data were processed in the ArcGIS Desktop software complex to set the boundaries and configuration of the catchment area. Probing of the bottom sediments of the lake was carried

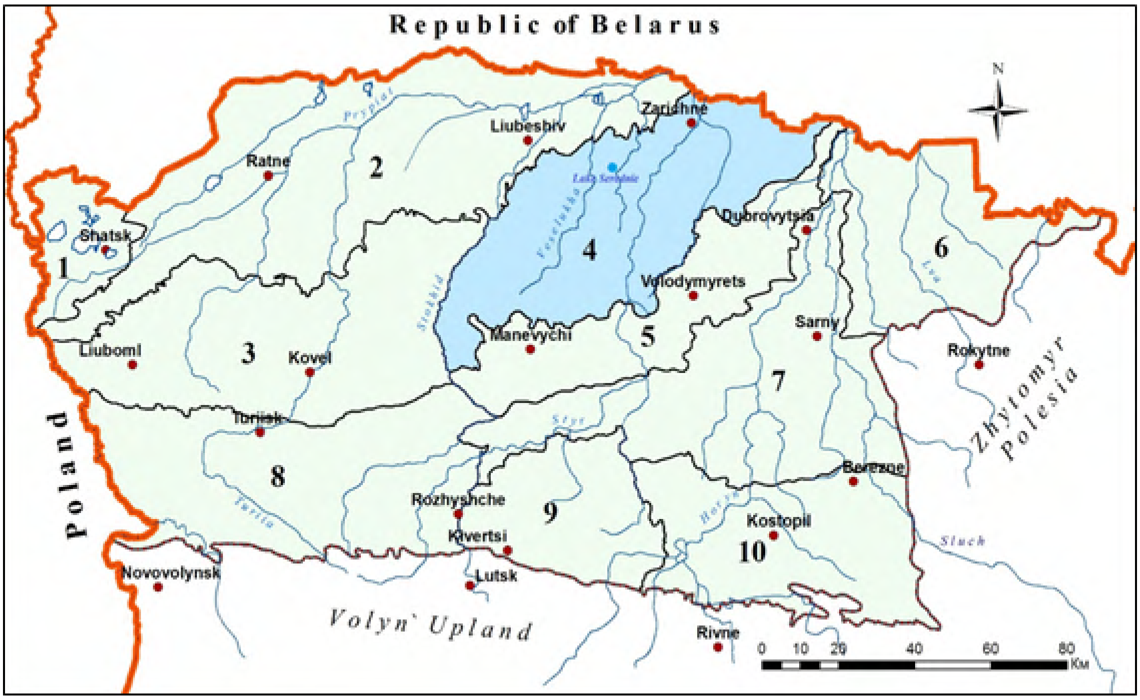

Figure 1. Localization of the Lake Serednie basin on the scheme of physical and geographical zoning of Volyn Polissia. *Physiographic regions:* 1 – Shatsk, 2 – Upper-Prypiat, 3 – Liuboml-Kovel, 4 – Nyzhnostyrskyi, 5 – Manevychi-Volodymyrets, 6 – Lva-Horyn, 7 – Kolky-Sarny, 8 – Turiisk-Rozhyshche, 9 – Kivertsi-Tsuman, 10 – Kostopil-Berezne.

out from the ice in winter with a spoon-type geological drill.

The next stage was the processing of field materials, development of a bathymetric map and landscape mapping of Lake Serednie. The cartographic models were developed using ArcGIS Desktop and ReefMaster Software. From the landscape point of view, we consider the lake to be a natural aquatic complex (NAC) of the rank of a complex tract. The landscape map of the NAC of the lake was developed based on the materials of the bathymetric survey, taking into account the micro-relief of the lake basin, the composition and thickness of sapropel deposits, the species diversity of the plant communities of the reservoir and thermal features.

The research methodology was based on the studies on the field geographical research [14], underwater landscape science [15], limnology [16], bathymetry and GIS mapping [17,18], as well as many years of experience in constructive landscape modeling of lake-basin systems in Polissia region of Ukraine.

The purpose of the research is to develop a cadastral landscape model of Lake Serednie (Nobel NNP) for the needs of protected and recreational nature resource management.

3. Results and discussion

The basin of Lake Serednie was formed in the following landscape areas: 1) high areas between rivers on water-glacial sands with close deposits of chalk marls; 2) inter-fluvial marshy plains on fluvial-glacial and ancient alluvial deposits. The Pleistocene glaciation, as well as postglacial processes, had a significant impact on the formation and development of the landscapes of the basin system of Lake Serednie and Nobel NNP as a whole. The activity of water flows, aeolian processes and excessive moistening subsequently affected the morphological structure of the landscapes of Nobel NNP and lake-basin systems (LBS).

The field research in the lake basin and its adjacent territories revealed dominant morphological units of the landscape of a lower rank, in particular, tracts (or geotopes):

1) Hills and dunes with gentle (6-10°) slopes, covered with lichen-shrub pine forests on hidden podzolic, sometimes crushed stone, sandy soils.
2) Elevated areas between rivers, complicated by karst funnels, covered with lichen-bilberry-green moss pine and birch-pine forests on slightly podzolic, sometimes clayey, sandy soils.
3) Undulating areas between rivers covered with sedge-bilberry-green moss and various grass-green moss oak-pine and birch-oak-pine forests on sod-weak podzolic clayey sandy and loamy soils, sometimes meliorated.
4) Local closed mounded depressions covered with various grass-cereal-green moss and sedge-juncus -green moss alder-birch-pine sparse forests on sod gumbo sandy and sandy loamy soils.
5) The lakeside narrow depressions, which are filled with water during floods, covered with reed-sedge-herbaceous and shrubby-sedge-reed alder and willow small forests on meadow layered gumbo sandy and sandy loamy soils.
6) Lake depressions of irregular shape formed on sapropel deposits.

The catchment area of Lake Serednie is not big and makes 54.3 hectares. It is elongated in a sub-latitudinal plan from the northwest to the southeast in accordance with the configuration of the lake.

Based on the results of echo sounding data processing, we built a bathymetric map of Lake Serednie (figure 2).

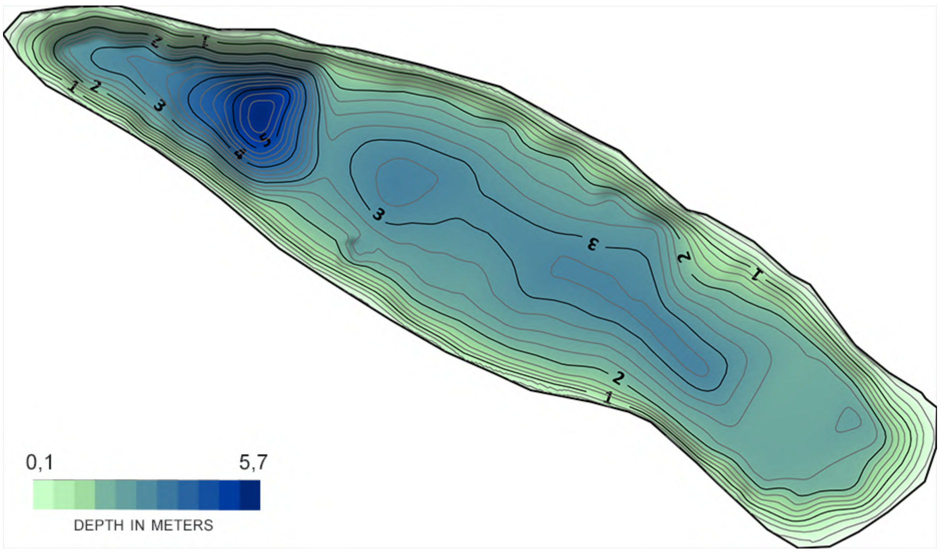

Figure 2. Bathymetric map of the Lake Serednie.

Isobaths are drawn at intervals of 0.25 m. Up to 2.0 m, the depth increases gradually, and from 2.0 m, the isobaths have some differences. In the northwestern part, a funnel-shaped depression with a maximum depth of 5.67 m was found from 4.0 m and deeper. The central part of the bed of the lake basin has a depression of elongated shape of more than 3.0 m. The average depth of the reservoir is 2.4 m. The area of the lake is 0.19 km^2. The length of the reservoir is 1.002 km, the maximum width is 0.262 km, and the average is 0.190 km. The coastline has a length of 2.257 km. The northwestern part of the coastline and lakeside terrace is undergoing

** The average annual runoff module is 4.0 $dm^3/s{\cdot}km^2$.

transformations due to the life activity of beavers (numerous burrows leading from the shore into the lake, fallen trees). The volume of the lake water is 435.2 thousand m^3. Other morphometric and hydrological parameters of the lake are given in table 1.

The developed three-dimensional model of Lake Serednie is an additional element of the visualization of the lake basin micro-relief (figure 3a).

It clearly shows a depression in the cone-shaped northwestern part of the basin bed. The aforementioned funnel-shaped depression is very well shown on the longitudinal profile of the underwater topography of the lake (figure 3b). The slopes of the lake basin from the water surface are steep (10-15°) up to 2.0 m, very steep (15-20°) up to 3.0 m, and steep (more than 20°) from 3.0 m and deeper. The differentiation of the relief of the basin by the steepness of the slopes is important in the further development of the legend of the landscape map, in particular, the determination of the processes of accumulation or transit of mineral particles and dead remains of aquatic organisms.

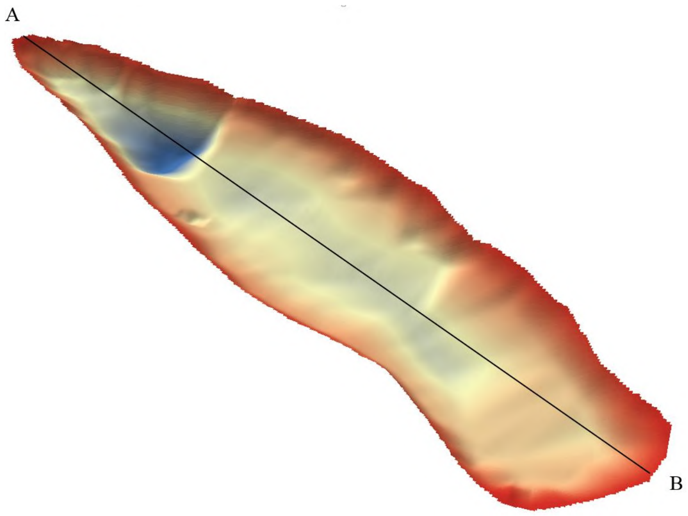
The relief of the lake basin affects the distribution of areas and volumes of water masses of the lake (figure 4).

The area of the littoral zone of the reservoir with a depth of up to 3.0 m is the largest and is 15.35 hectares (78.8 %), it accumulates 413.3 thousand m^3 of water masses (94.95 %). 21.20 % of the area of the lake with 20.9 thousand m^3 of water is at a depth of more than 3.0 m.

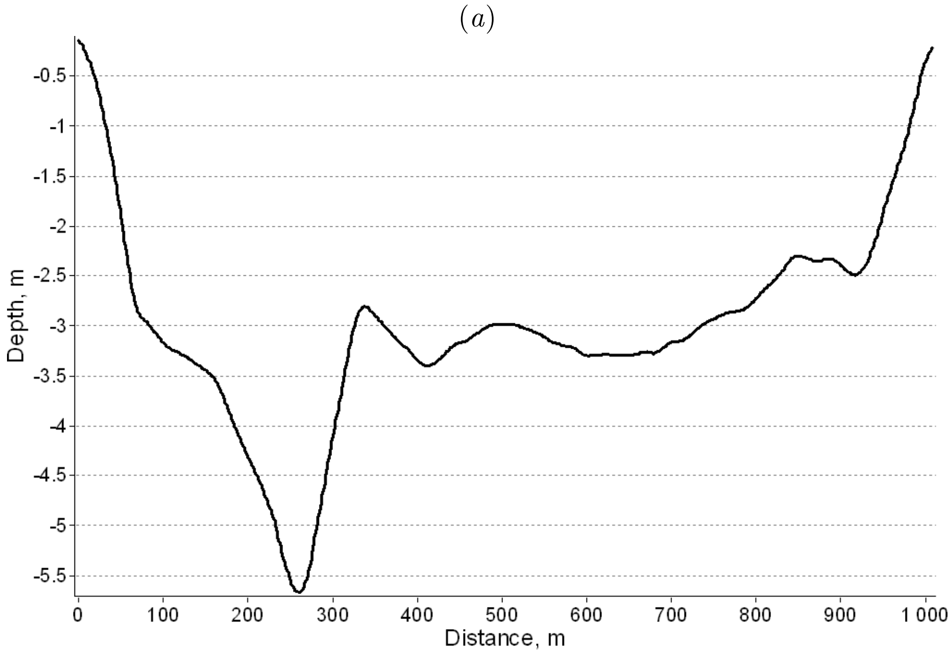
Based on the results of bathymetric surveying, landscape field research and computer processing of materials, a digital landscape map of Lake Serednie was developed (figure 5).

Typical landscape elements shown in figure 5:

I. *Littoral aqua subtract on sandy-muddy, peat-swamp sediments and sapropel underlain by alluvial sands with species diversity of surface and underwater plant communities.*
   Aquafacies:
   1.1. Littoral, accumulative peat-swamp and sandy-muddy of low-thickness (up to 0.5 m) Carex-Typha-Phragmites associations, with a homogeneous temperature regime in summer.
   1.2. Littoral, accumulative swamps and peat-swamps of low-thickness (up to 1.5 m) sparse



(a)



(b)

higher aquatic plants, with a homogeneous temperature regime in summer.

1.3. Littoral, abrasion-accumulative sandy-muddy of low-thickness (0.5-1.0 m) sparse Potamogeton associations, with homogeneous temperature regime in summer, complicated by fallen trees and beaver activity.

1.4. Littoral, abrasion-accumulative muddy-sandy and sandy of low-thickness (0.5-1.0 m), with impoverished underwater vegetation and a homogeneous temperature regime in summer.

1.5. Littoral, accumulative-transit algal-carbonate-sapropel of low-thickness (1.0-2.50 m) filamentous-chara algae associations, with a homogeneous temperature regime in summer.

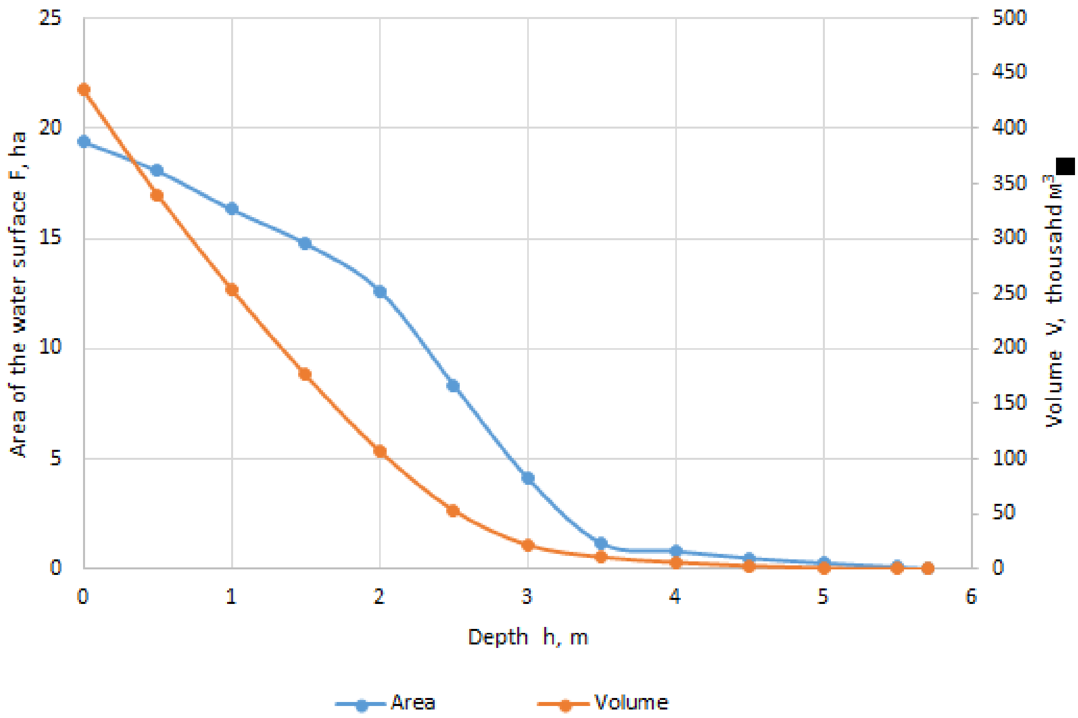

Figure 4. Morphometric curves of areas and volumes of water of the Lake Serednie.

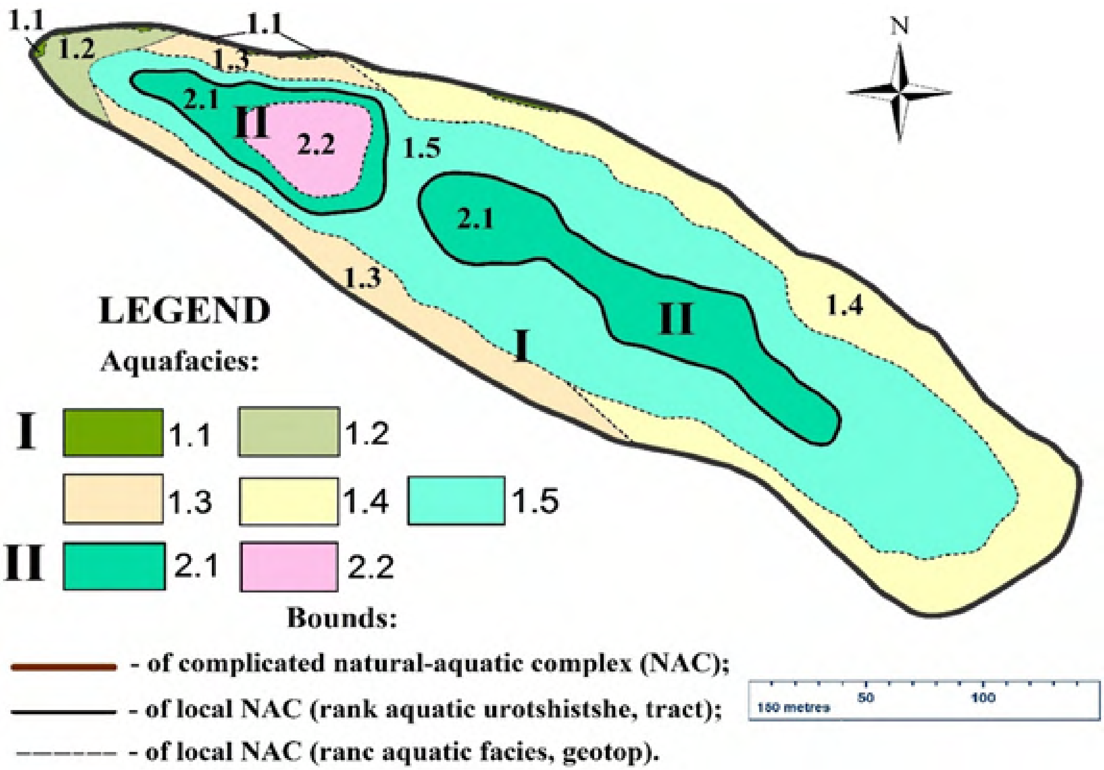

Figure 5. Landscape structure of the natural-aqual complex of Lake Serednie.

II. *Sublittoral-profundal aqua subtract on clay-limestone and organic-limestone sapropel underlain by carbonate loams, with impoverished species diversity of underwater vegetation.* Aquafacies:
   2.1. Sublittoral, accumulative and transit-accumulative clay-limestone-sapropel of medium-thickness (2.5-3.0 m) free-floating algae, with a heterogeneous temperature regime in summer.
   2.2. Profundal, accumulative funnel-shaped depressions organic-limestone-sapropel of medium-thickness (3.0-3.5 m) single floating algae, with a slight temperature amplitude in summer.

Two types of aquafacies were identified in the sublittoral-profundal aqua subtract with depths of more than 3.0 m. In total, there are 13 landscape contours in the NAC; the average area of a landscape contour is 1.5 hectares. Other landscape metric characteristics of Lake Serednie NAC are given in table 2.

Table 2. The complexity of the natural-aqual complex territorial structure of the Lake Serednie.

NAC type		Area of NAC type, ha		% of the type area	
Subtract	Aquafacies	Subtract	Aquafacies	Subtract	Aquafacies
I.		15.35		78.80	
	1.1		0.14		0.71
	1.2		0.42		2.16
	1.3		1.88		9.65
	1.4		4.40		22.59
	1.5		8.51		43.69
II.		4.13		21.20	
	2.1		3.35		17.20
	2.2		0.78		4.0
Totally		19.48	19.48	100.0	100.0

The research identified two aqua subtracts and seven types of aquafacies in the lake NAC. The littoral aqua subtract with depths mainly up to 3.0 m occupies more than 78.0 % of the NAC area and includes five types of aquafacies. The differentiation of aquafacies was carried out taking into account the micro-relief of the lake, the composition and thickness of bottom sediments, the characteristics of aquatic plant communities and the temperature regime in the summer season.

4. Conclusion

The research established that during the summer seasons of 2016-2021, the water level in the lake changed a lot. The retreat of the water cut from the shoreline of the lake was 5.0-6.5 m in the southeastern part of the reservoir. The shoreline of the lake undergoes noticeable changes due to the life activity of beavers, especially the littoral aquafacies with index 1.3. In our opinion, the activity of beavers affected the impoverished state of surface and underwater plant communities. The railway embankment is a limiting factor in the inflow of surface water from the catchment area in the northwestern sector.

The developed series of cartographic models:

1. Reflects the current geoecological state of Lake Serednie and is important in evaluating the geoecological parameters of the whole lake landscape system and its individual elements, and in revealing its functional features.
2. Acts as an information and analytical basis for planning measures to optimize nature use and protect water resources from pollution and quality impairment. The spatial models and typological structure of the land areas within the lake basin and the aquatic complex are especially important in this respect.

The bathymetric maps, the calculated main hydrological parameters of the lake, and the developed aquatic complex model should become the basis of the landscape and cadastral passport of Lake Serednie for the needs of protected and recreational nature resource management.

The benchmark landscape and limnology characteristics of the entire lake basin should become the starting point of further monitoring observations.

In the conditions of climate change and its regional components, the demand for such research will only grow.

Abstract. This paper is aimed at a comparison of Ukrainian and international resource classification systems' fundamental features. As a result, the most common and different features were outlined. The importance of accounting for the social and environmental viability of projects is determined. This study highlights the significance of the harmonization of domestic classification with international standards.

1. Introduction

All known international standards for the assessment of reserves and resources, as well as domestic regulatory documents, contain object classifications according to important geological and industrial features. These systematizations don‘t appear by chance, and as a rule, reflect the traditions and stages of exploration and evaluation of mineral deposits in a particular region.

The classification of mineral reserves and resources of the State Subsoil Fund establishes the principles for calculating, geological and economic assessment and state accounting of mineral reserves that are common for the State Subsoil Fund of Ukraine according to the level of their industrial significance and the degree of geological and feasibility study, the conditions that determine the readiness of explored mineral deposits for industrial development, as well as the basic principles for quantifying mineral resources [1]. The practice of using this classification systematizes mineral reserves and resources according to certain levels of industrial significance and the degree of technical, economic, and geological study. This classification contains distributable classes that are identified using an international three-order numeric code. Today our classification is harmonized with the United Nations Framework Classification for Resources (UNFC) 2009 version despite the fact that there is already an updated version of 2019 [2].

The relevance of this study is related to the integration of domestic subsoil use into European industries, as well as into the global systems for investing in mining facilities. Thus, the domestic mineral resource base takes into account many minerals from the list of critical and strategic ones for such countries as the United States of America, Canada, Japan, Australia, and the European Union. Understanding the availability and maturity of our deposits will accelerate their investment and development. Understanding the requirements of international standards for the exploration of deposits will allow us to study quickly and efficiently own objects and select interesting foreign objects.

The analysis of classification systems allows us to determine directions for further changes and harmonization of the national evaluation system. Until recently, social and environmental factors were rarely taken into account when classifying mineral reserves and resources. Their importance has grown significantly over the past few years. Many projects have been delayed or canceled because they did not meet social or environmental expectations, even if they met all other requirements of quantity, quality, and profitability. The various factors involved in the classification of resources do not exist in isolation but operate in a complex manner. In particular, specific issues of property rights and use of the resource, licensing conditions, and other legal issues, which as a result also create economic conditions, can be affected by social and environmental risks. The delay caused by the resolution of these issues in connection with socio-environmental problems can have a significant impact on the economics of projects and even make them economically unprofitable [3].

2. Results

Until recently, social and environmental factors have rarely been considered in the classification of natural resources. Their importance has grown considerably in the last few years. Many projects have been delayed or canceled because they failed to meet social or environmental expectations, even though they met all other requirements. The various factors involved in resource classification do not exist in isolation, and the distinction between them is rarely black and white. The related issues of ownership, contract terms, legal, regulatory issues, and in some cases, financial conditions may be affected by social and environmental issues. A delay due to the resolution of these as a result of socio-environmental issues can have a significant impact on the economics of projects, even making them no longer economically viable.

Socio-environmental issues, typically described as a requirement for “social license” or “social license to operate” (SLO), have attracted a significant amount of interest and attention in recent years. A project cannot proceed unless the important social and environmental contingencies are resolved, typically described as obtaining an SLO. UNFC is a tool for effective management of national resource endowments needed for realizing the Sustainable Development Goals (SDGs). UNFC applies to energy and mineral resources; injection projects for the geological storage of CO_2; and anthropogenic resources such as secondary resources recycled from residues and wastes. UNFC aims to provide necessary specifications and guidelines for optimizing the management and development of resources, with positive impacts on society, the environment, local economies, and employment [3].

In 2022, the problems and risks of social licenses have become especially acute, which is especially noted by the forecasts of global audit companies. Table 1 lists the Top 10 business risks and opportunities for mining and metals. The risks of social licenses appeared in the lists of top risks in 2015, but until 2022 they did not rise above 5th place.

With Ernst and Young’s (EY) data released at the end of 2022 [4], environmental, social, and corporate governance (ESG) remains a top risk and challenge for mining and metals companies in 2023. This issue is now widely included in corporate strategies due to its impact on almost all aspects of operations – productivity, logistics, economics and finance, sales markets, etc. Some of the biggest areas of ESG improvement are not new – ensuring diversity, equity, and inclusion still remain challenges, and mine closures and rehabilitation require longer-term, more strategic planning [4].

However, every year the demands on mining enterprises are becoming stricter and today, water resources management and biodiversity are fast becoming urgent priorities in the face of climate change. Stakeholders expect from companies a better assessment of risks and opportunities to minimize them with the help of transparent studies and guarantees for their

results. Stricter reporting will be critical if companies are to meet growing stakeholder expectations and avoid accusations of greenwashing. A bonus for companies that meet these requirements is significant competitive advantages — from access to capital and resources to obtaining a license to conduct activities and attracting highly qualified personnel [4].

Among the most significant for the extractive industry in the list of social and environmental factors were the following (in descending order): water resource management problems, compliance with the processes of decarbonization of production, reduction of the negative impact on climate change, environmental friendliness of production and volumes of emissions that are directly or indirectly related to enterprises, etc.

Classifications of mineral reserves and resources always reflect the most important features of mineral projects that determine their effectiveness. From the beginning, these were basic geological and mining technical characteristics, then economic and environmental factors. Now such a sign is environmental, social, and governance, which directly affect the possibility of project implementation. Next, we analyze existing system classifications to determine the direct and indirect ways in which these systems account for these ESG factors.

The development of international reporting standards for the assessment of mineral resources began at the end of the 20th century as a result of globalization processes in the extractive industry (figure 1). The largest mining companies are developing international projects and diversifying the regional risks of the mining business. This necessitated the development of integrated assessment systems that create unified and understandable tools for assessing mineral reserves and resources, regardless of the location of the assessment object itself.

This study analyzes and compares the classification features of various systems: Ukrainian classification [1], UNFC [2], The Petroleum Resources Management System (PRMS) [5], The Committee for Mineral Reserves International Reporting Standards (CRIRSCO) [6] in order

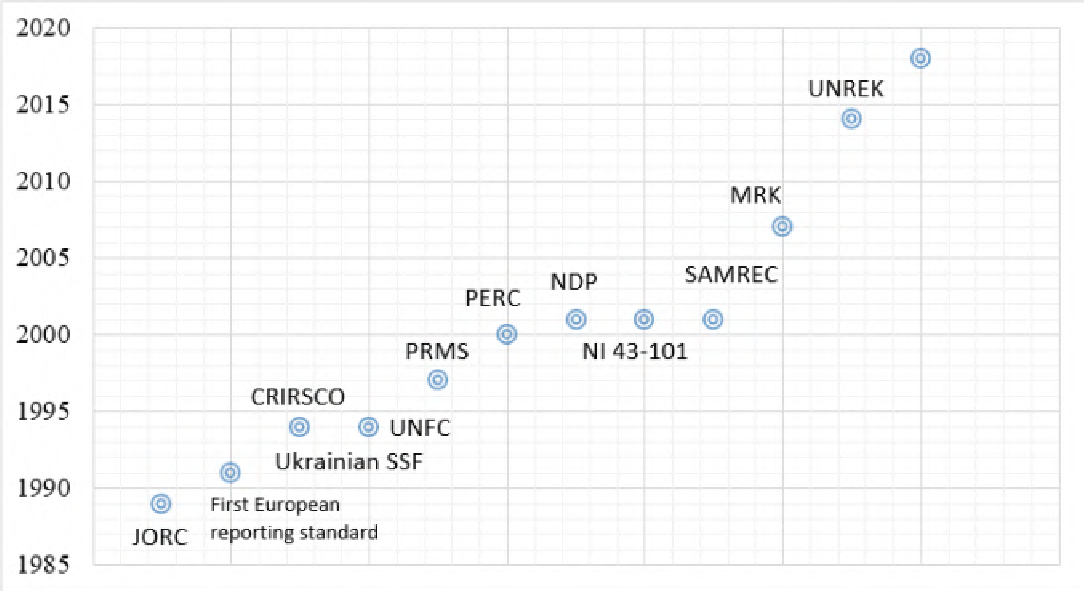

Figure 1. Development of international and national standards for mineral assessment in the period 1990-2020.

to establish features that allow determining the social and environmental risks of subsoil use projects.

In the mining projects valuation, environmental and social risks, as well as ESG in general, are often used in the context of investment attractiveness, although stakeholders include not only the investment environment, but also customers, suppliers, company personnel, local populations, and governments, who are increasingly interested in safe (in all senses), and stable development of organizations and companies on their territory. The presence of these direct features in the classification systems indicates the orientation of the assessment standards to the comprehensive assessment of projects as such meeting the goals of sustainable development.

Below are comparisons of the basic parameters of classification systems (table 2): CRIRSCO (by International reporting template for the public reporting of exploration targets, exploration results, mineral resources, and mineral reserves [6], PRMS Petroleum resources management system update 2018 [5], The Norwegian Petroleum Directorate's resource classification system (NPD) 2016 [7] Ukrainian Classifications of reserves and resources for minerals of the State Subsoil Fund (SSF) [1]. The features of classifications are given in the order in which they are considered in the system.

From the given comparison, it is fixed that the social and ecological viability of subsurface and natural resources projects is used as a direct feature only in the UNFC. In 1997, the UNFC was developed for solid minerals and conventional energy resources with the aim of becoming an ideal tool for comparing different regional and national standards. Currently, this classification has been expanded to include other types of resources. Today, the UNFC covers energy resources, including oil and gas; renewable energy projects; atomic energy resources; solid minerals; CO_2 storage projects; underground water; and anthropogenic resources, such as secondary resources recycled from production residues and wastes. An important feature is the systematization of information not only for geological and mining enterprises but also for all interested parties. Such parties are defined as international and regional organizations in the field of international research of mineral resources and energy (to facilitate the formulation of a consistent and visionary strategy of actions), national and local governments (for the sustainable

management of national resources), companies and industrial enterprises (for the development of production and technologies, project management and financing), financial organizations and funds (for project management and financing) [2, 3]. Thus, the UNFC itself is a tool for the effective management of national resources necessary for the realization of sustainable development goals, which enables all interested parties to find a common understanding of the development of resources and territories, as well as to compare projects in different types of resources and subsoil use. The development of the basic characteristics of the classification of reserves and resources in the UNFC from 1997 to 2020 is shown in the following table 3.

Table 3. Development of Principal elements of the UNFC.

	Year

Other standards and classification systems have evolved in accordance with the more practical and rational objectives of providing reliable valuations for investors of all levels. The CRIRSCO standard notes that the extractive industry today is a global international business whose financial and operational success depends on the trust and confidence of investors [6]. Unlike many other industries, geology and mining deal with mineral resources that are exhaustible and non-renewable. The main emphasis on the risks of mining projects in these standards is made on geological risks, which depend on the reliability of information about objects from the beginning of the geological study to the end of mining. Subsoil users are encouraged to effectively and transparently assess the risks associated with investments to ensure the high level of confidence necessary to sustain their activities [6]. ESG criteria are taken into account as part of modifying factors that determine the possibility of converting mineral resources into reserves that are designed and have individual technical, technological, and organizational solutions for implementation, which forms their economic and environmental assessment in the relevant legal and regulatory conditions. In the hydrocarbon resource assessment standards 2018, the social and environmental component is also indirectly taken into account in the project success criteria ("chance" for commercial implementation) and uncertainty parameters.

3. Conclusions

The paper presents a comparison of classification features in the exploration and evaluation of mineral resources in domestic and international practice. This study analyzes and compares the classification features of various systems: The Ukrainian Classifications of reserves and resources for minerals of the State Subsoil Fund, The United Nations Framework Classification for Resources, The Petroleum Resources Management System, The Norwegian Petroleum Directorate's resource classification system, the Classification of the Committee for Mineral Reserves International Reporting Standards.

As a result, the most common feature of classifications is the level of geological study. This feature makes it possible to distinguish 4 groups of geological knowledge. Features of economic viability and status of the project, as a rule, are used in international practice. Important criteria, which are now reflected only in the UNFC, are the social and environmental viability of projects. This determines the importance of accounting for ESG in our valuation and resource accounting systems.

In recent years, social and environmental risks have become basic for the implementation of mining projects. Their growth can lead to the postponement of projects in time or the complete cancellation of decisions made because they did not meet social or environmental expectations, even if they met the requirements of quantity, quality, and profitability. Such changes must be reflected in classification systems for reserves and resources assessment that are used by all stakeholders to make management and investment decisions. Today, the social and ecological viability of subsurface and environmental projects is used as a direct feature only in the UNFC, and its inclusion took place in 2009 in the part of social factors, and in 2019 – in the part of environmental factors. This shows that the UNFC is a tool for the effective management of national resources, necessary for the realization of the goals of sustainable development, which enables all interested parties to find a common understanding of the development of resources and territories, as well as to compare projects in different types of resources and subsoil use.

In other international standards, as well as in the domestic classification of the State Subsoil Fund, the ESG criterion is taken into account indirectly, which is one of the key areas of development of these mineral resource evaluation systems. Such development can take place in two directions: 1) inclusion of social and ecological criteria of the direction as basic features, while this is possible both in the form of complex parameters and individual classes/subclasses; 2) use and improvement of existing methods of resource valuation, taking into account the environmental and social risks of the implementation of mining projects.

Abstract. The modern achievements in the construction of small flying machines cause the active development of remote monitoring, in particular geophysical airborne gamma-ray spectrometer surveying. Such observations are important, since large amounts of man-made radioactive materials get into the environment, especially during accidents like at the Chornobyl or Fukushima nuclear plants. On the other hand, the natural distribution of radioactive sources is inhomogeneous and can provide us with useful information about the soil structure. One of the problems appearing at the handle of information collected with unmanned aerial vehicles concerns the correction of readings to identify the peculiarities of gamma-ray fields. To perform this, the analytical method based on the solution of the inverse problem formulated in terms of integral relation is used. In this research, to reconstruct the surface distribution of the gamma-ray field, the Tikhonov and Landweber techniques are applied. It is shown that these algorithms allow one to distinguish radioactive hot-spots located closely.

1. Introduction

To support the sustainable development of economies and human societies, the effective implementation of innovative technologies, methods of rational nature management, and safety components should be realized. To a large extent, this applies to handling the radioactive materials which can provide significant benefits and at the same time can cause substantial damage. To organize the effective control of radioactive materials accompanied by ensuring radiation safety, the novel achievements in the fields of remote sensing and information technologies [1–4] can be useful. There are many different means for gathering and processing information on observed objects including satellites, manned aviation, ground observation, and etc. [5]. Among them, the small flying machines or so-called unmanned aerial vehicles (UAVs) should be noted, the use of which has developed rapidly due to their advantages [1,6–9] including the possibility to reveal the size-limited gamma-ray anomalies [10].

Nevertheless, the collected data undergo the influence of different effects, i.e. UAV velocity and high, detector's properties, attenuation, natural radiation, and require further processing and corrections. To improve the quality of UAV measurements, it is utilized the approach [11–15] which is based on the use of a solution of inverse problem. This problem involves a multiple integral relation, approximation of which, in turn, causes well-known problems. However, the main obstacle relates to the construction of a solution to the inverse problem, since we deal with an ill-posed problem that produces strong instability, oversmoothing effects, and etc. To overcome this difficulty, many techniques have been developed including the Tikhonov and Landweber algorithms, which we used in these studies.

2. Research aim and objectives

In this research, we consider the adaptation of algorithms for the inverse problem which arises during the remote monitoring of distributed radioactive (namely gamma-ray) fields. In particular, restoration of the gamma field, distributed over the ground surface, and identification of its peculiarities (local intensities) are performed.

3. Statement of the problem

As known from numerous experiments [15–17], the readings of airborne detector require some corrections. One of the possible ways to do this is the inversion of airborne data using the algorithm of the proper inverse problem. The mathematical statement of this problem involves the integral relation describing the attenuation of the gamma radiation with distance from the ground surface, the distribution of radioelement sources in the ground, and the detector's properties. The UAV velocity also should be taken into account.

Thus, consider the simplified scheme (figure 1(a)) of remote sensing, continuing our studies presented in [6]. A small flying machine is equipped with a detector providing us the counting of gammas emitted from the ground surface. UAV moves along the axis Ox with the velocity v. It is marked by the point D with the coordinates (x^d, y^d) and the altitude h^d in figure 1(a).

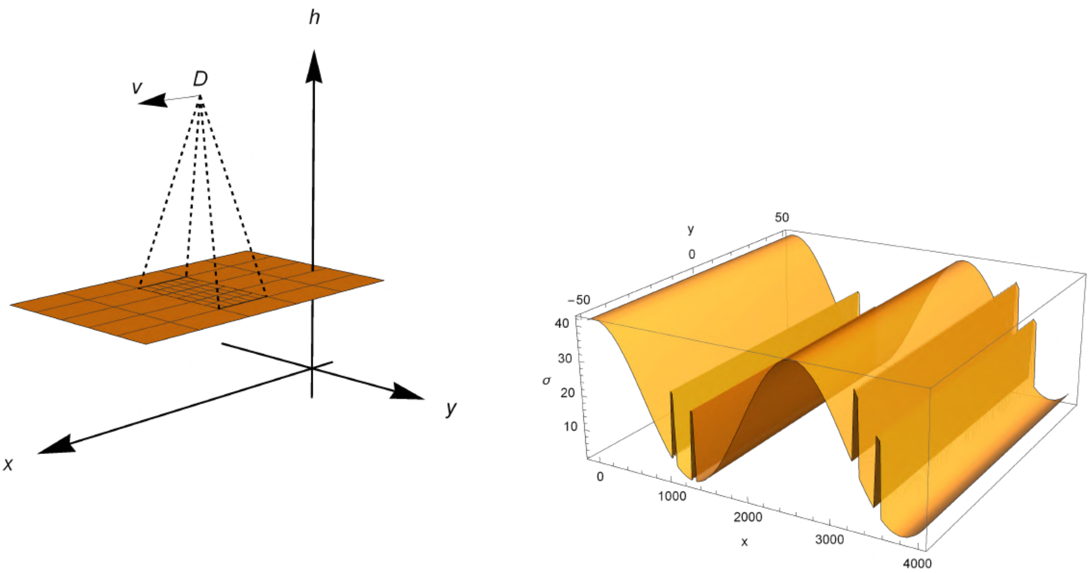
Let us assume that the detector's eyeshot is formed by the collimator with a rectangular cross-section and the aperture 2θ rad. Then the view window appearing on the ground surface is almost rectangular. The size of this window depends on the detector's altitude h^d and θ. The elementary geometric reasoning leads us to the simple relation for the window side $2\Delta x = 2\Delta y = 2(h^d - h)\tan\theta$, where $h(x, y)$ stands for the relief altitude. Dealing, for instance, with the detector with $\theta = \pi/3$ rad located at a height of 55 m above the ground surface, the view window size is $2\Delta x = 190$ m.

During a flight, the detector collects gammas and fixes the number of gamma quants $W(t_i)$ at discrete moments of time t_i, $i = 1, 2, \dots, N$. For the sake of simplicity we will assume that all time intervals $[t_{i-1}; t_i]$ are of the same length and, therefore, the detector's exposure time is $t_i - t_{i-1} = \tau = const$. Thus, if we fixed $\tau = 1$ s and $v = 27$ m/s (about 100 km/h), then UAV flying $L = 4000$ m provides us with $L/(\tau v) \approx 140 \equiv N$ values of W.

Thus, in general, to evaluate the number of trapped gamma rays at a time moment t_i, it can be used the following integral [3, 11–13, 15, 16] equation

$$\Lambda \int\limits_{t_{i-1}}^{t_i} dt \int\limits_{\Omega} \sigma(X)\, \Phi\left(X^d, X\right) d\Omega = W(t_i), \qquad i = 1, \dots, N, \tag{1}$$

where σ is the density of gamma sources; $X^d = (x^d, y^d) \in R^2$ is the detector's position and



(a) (b)

Figure 1. The simplified scheme of remote sensing (a) and the surface of the function $\sigma(x, y)$ – the density of gamma sources (b).

$X = (x, y) \in R^2$ is a point in the domain Ω representing a radioactive material; Λ is the scaling factor depending on the geometric and physical properties of detector.

The quantity

$$\Phi = \phi\left(X^d, X\right) \frac{e^{-r\mu}}{4\pi r^2},$$

where μ is the coefficient of attenuation in air; the function $\phi = (h^d - h)/r$ coincides with the cosine of angle between the vertical and the direction from the detector to the point X; $r = \sqrt{(h^d - h)^2 + (x^d - x)^2 + (y^d - y)^2}$ is the distance between detector and the point X lying on the surface.

Thus, the problem arises: to restore the surface distribution $\sigma(x, y)$, when the data W are given. This is a well-known *inverse* problem.

4. Construction of the algorithms for the inverse problem

Before solving the inverse problem, we prepare the test data W for checking the quality of the algorithm's work. In fact, evaluating the quantities $W(t_i)$, the *forward* problem is solved. Thus, we specify the function of radioactive sources density

$$\begin{aligned}\sigma(x, y) =& 20\left(\cos\left[\frac{x}{400}\right] + 1.1\right) + 20\,UnitBox\left[\frac{x - 3500}{50}\right] + 20UnitBox\left[\frac{x - 3250}{50}\right] + \\ &+ 20UnitBox\left[\frac{x - 1000}{50}\right] + 20UnitBox\left[\frac{x - 1250}{50}\right],\end{aligned} \tag{2}$$

where $UnitBox[z]$ stands for the in-built *Mathematica* package function, equal to 1 for $|z| \leq 1/2$ and 0 otherwise.

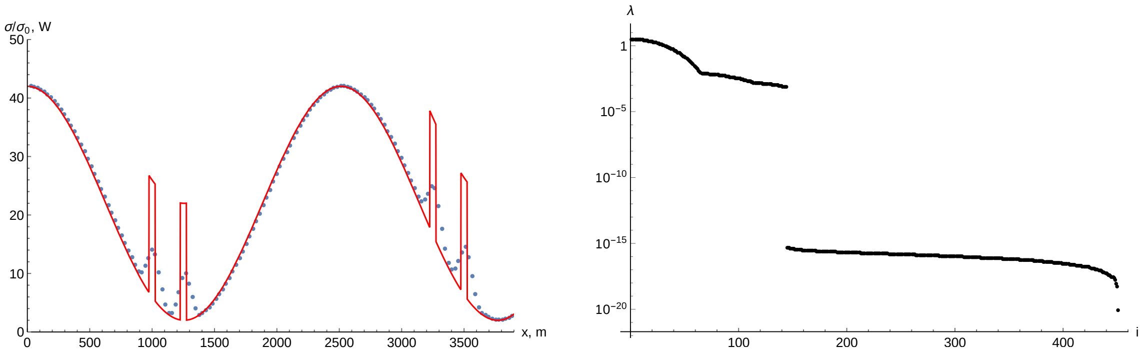
Using the function $UnitBox[z]$, we model the localized sources of high radioactivity. In other words, four peaks on the density function σ can represent, for instance, trenches containing radioactive waste. Actually, in this research, the function (2) doesn't depend on y and its graph is depicted in figure 1(b). The model (1) also requires the parameter $\mu = 0.001$ 1/m; relief profile $h(x, y) = 20$ m; UAV altitude $h = 75$ m. Although we can incorporate in relation (1) the UAV specified velocity v_i at each interval $[t_{i-1}, t_i]$, but in this research we neglect small deviations of UAV velocity and it is assumed that the UAV moves all flight time with the mean constant velocity $v = const$. Since the UAV's movement is performed along the axis Ox, its coordinate $y^d = 0$.

Then, substituting the new variable $u = vt$ and other parameters and functions into relation (1), we get

$$W_i = \frac{\Lambda}{v} \int\limits_{(i-1)\tau v}^{i\tau v} du \int\limits_{i\tau v-\Delta x}^{i\tau v+\Delta x} dx \int\limits_{-\Delta y}^{\Delta y} dy\, \sigma(x, y) \frac{(h^d - h)}{4\pi r^3} e^{-r\mu}, \qquad i = 1, \ldots, N, \tag{3}$$

where $t_i = \tau i$, $r = \sqrt{(h^d - h)^2 + (x^d - x)^2 + (y^d - y)^2}$. In *Mathematica* package, the relation (3) is evaluated by means of the function *NIntegrate[]*.

For convenience, we take $\Lambda = \sigma(0, 0)/W_1$, in order to normalize data and to compare with the parent distribution σ. Figure 2(a) represents the comparison of the exact graph of the density function σ and data W.



(a) (b)

Figure 2. The comparison of the profile of the function (2) and data W evaluated by the formula (3).

Now, to develop the algorithm for the inverse problem solution, we discretize the integral relation (3) using the rectangle method:

$$\int\limits_a^b f(x)dx = \Delta_0 \sum_{k=1}^{n} f\left(a + \frac{2k-1}{2}\Delta_0\right), \qquad \Delta_0 = \frac{b-a}{n}. \tag{4}$$

Applying formula (4), the approximation of integral (3) can be cast in the following form

$$\begin{aligned} &W_i = \frac{\delta_x \delta_d \delta_y}{v} \sum_{k=1}^{N_2} \sum_{j=1}^{N_1} \sigma(x) \sum_{\ell=1}^{N_y} \Phi\left(x, y, x^d, y^d\right); \\ &x = (i-1)\tau v + \frac{2j-1}{2}\delta_d + \frac{2k-1}{2}\delta_x - \Delta x; \qquad y = -\Delta y + \frac{2\ell-1}{2}\delta_y; \\ &x^d = (i-1)\tau v + \frac{2j-1}{2}\delta_d; \qquad y^d = 0, \end{aligned} \tag{5}$$

where $\delta_x = 2\Delta x/N_2$, $\delta_d = \tau v/N_1$, and $\delta_y = 2\Delta y/N_y$.

Before using relation (5), we transform the argument x of σ in such a way that it will be multiple of the spatial step δ_x. Thus, let us assume that $\tau v = q\delta_x$, $\delta_d = p\delta_x$, $\Delta x = \varepsilon\delta_x$, where q, p, ε are natural numbers. Assuming that $q = [\tau v/\delta_x] \equiv N_1$, $r = 1$, $\varepsilon = [\Delta x/\delta_x] \equiv N_2/2$, where the function $[\cdot]$ returns an integer part of its argument.

Next,

$$x = (i-1)\tau v + \frac{2j-1}{2}\delta_d + \frac{2k-1}{2}\delta_x - \Delta x = \frac{\delta_x}{2}\left[2(i-1)q + (2j-1)p + (2k-1) - 2\varepsilon\right].$$

Since $i, q, j, p, k, \varepsilon$ are natural numbers, then the set of unknown values $\sigma(x)$ is defined for the multiple values δ_x.

Then, putting $\sigma(\frac{\delta_x}{2}\left[2(i-1)q + (2j-1)p + (2k-1) - 2\varepsilon\right]) = \sigma_f$, where $f = 2(i-1)q + (2j-1)p + (2k-1) - 2\nu$ are natural, the relations (5) can be presented in the form

$$W_i = \frac{\delta_x\delta_d\delta_y}{v}\sum_{k=1}^{N_2}\sum_{j=1}^{N_1}\sigma_f\sum_{\ell=1}^{N_y}\Phi_{i,k,j,\ell}, \tag{6}$$

which is the linear system of algebraic equations with respect to σ_f.

This system can be written in the matrix form

$$w = Kg, \tag{7}$$

where $w = (W_1, \ldots, W_N)^\top$, $g = (\sigma_{2-2\varepsilon}, \sigma_{4-2\varepsilon}, \ldots \sigma_{2(Nq+\varepsilon-1)})^\top$.

For instance, if we fix $\delta_x = 9$ m, then $q = 3$, $\varepsilon = 10$, $\tau = 1$ s, $v = 27$ m/s, $N = 144$, then structure of the system (6) can be understood from the first two equations

$$\begin{aligned} W_1 &= K_{1,1}\sigma_{-18} + K_{1,2}\sigma_{-16} + K_{1,3}\sigma_{-14} + K_{1,4}\sigma_{-12} + K_{1,5}\sigma_{-10} + \cdots + K_{1,22}\sigma_{24}, \\ W_2 &= K_{2,4}\sigma_{-12} + K_{2,5}\sigma_{-10} + \cdots + K_{2,25}\sigma_{30}. \end{aligned}$$

We see that the system is the set of *coupled* equations. The matrix K is multi-diagonal and not square, in general. This means that the system does not possess the unique solution and as a rule it is ill-conditioning. To obtain the proper solution in this case, the regularized algorithms are used. In this research, we apply the Tikhonov and Landweber algorithms [18].

4.1. Tikhonov method

Let us recall shortly that the Tikhonov regularization technique is based on the singular value decomposition (SVD) procedure applied to the matrix K and elimination of singular elements from the system's solution which produce the solution's instability. As shown in [18], using the SVD presentation of the $m \times n$ real-valued matrix K in the form $K = U\Sigma V^\top$, where U and V are the $m\times m$ and $n\times n$ unitary matrices respectively, $\Sigma = diag(\lambda_i)$ is the $m\times n$ diagonal matrix with diagonal nonnegative entries λ_i called singular values of K. Then the solution of system (7) can be cast in the matrix form $g = V \cdot diag(\lambda_i^{-1}) \cdot U^\top \cdot w$. To get rid of small singular values of the matrix $diag(\lambda_i^{-1})$, the Tikhonov filter function transforming the small singular values is used. Thus, instead of exact system's solution we have

$$g \approx g_\alpha = V \cdot diag((\lambda_i^2 + \alpha)^{-1}) \cdot U^\top \cdot w.$$

Using the identity $K^\top K + \alpha I = V \cdot (\lambda_i^2 + \alpha) \cdot V^\top$, where I is the unit matrix, the preceding relation reads as follows

$$g_\alpha = (K^\top K + \alpha I)^{-1} K^\top \cdot w, \tag{8}$$

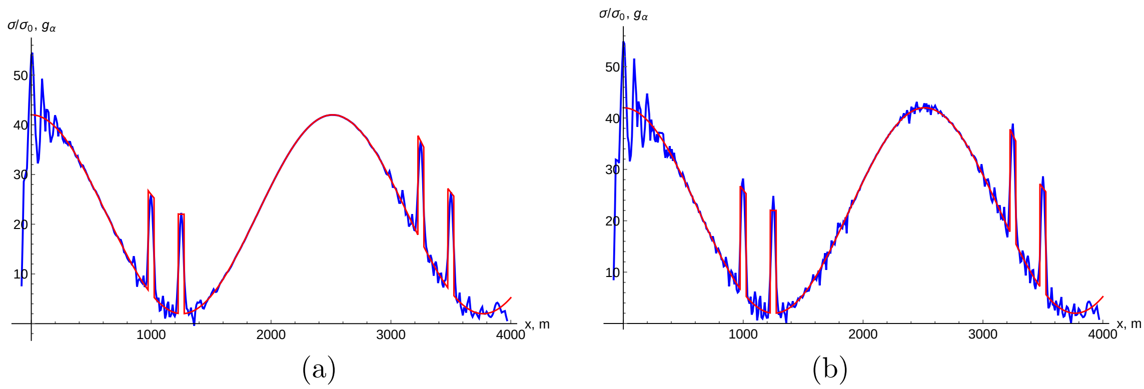


Figure 3. The comparison of the profile of the function (2) and the restored data g_α evaluated by formula (8). Here $\alpha = 10^{-3}$ (a) and $\alpha = 0.5 \cdot 10^{-8}$ (b).

where α is a regularization parameter.

Thus, at first consider the properties of matrix K used in this research. Instead of direct evaluation of K's singular values, it is simpler to evaluate eigenvalues of $K^\top K$ using the in-built *Mathematica* function *Eigenvalues*[]. The resulting distribution of eigenvalues λ_i^2 is presented in figure 2(a) (here the semilogarithmic plot is used) and shows the presence of small singular values for large i. Finally, putting $\alpha = 10^{-3}$, the solution (8) is evaluated and after rearranging $((-20+2j)hx/2; (g_\alpha)_j)$, $j = 1, \ldots, N$ the figure 3(a) is plotted. When α decreases up to $0.5 \cdot 10^{-8}$, the solution (8) is depicted in figure 3(b) and the growth of spurious fluctuations is observed. It means that α is too small.

In these studies we also are interested in the solution when the components of system (7) are desturbed by noise modeled with the random normally distributed numbers ξ. Thus, we consider the system (7) in the form $w = (K+\xi)g$, where $\xi \sim Norm(0, b)$. If we take the standard deviation $b = 5 \cdot 10^{-4}$, the *Mathematica* function *RandomVariate[NormalDistribution*[0, *b*], *Nq*] generates Nq random numbers. The random data histogram is depicted in figure 4(b) and tells us about a good approximation of normal distribution. As expected, the corresponding solution of inverse problem plotted in figure 4(a) shows more irregularity in comparison with the non-noised solution from figure 3. When $b = 0.001$ and random numbers undergo a greater deviations from their mean value (figure 4(d)), the solution (8) drawn in figure 4(c) becomes even greater irregularity, so that doublet structures become faintly visible against the background of fluctuations. The similar solution's behaviour is observed, when noise is added to the vector w in system (7) but at the smaller values of b.

4.2. Landweber method

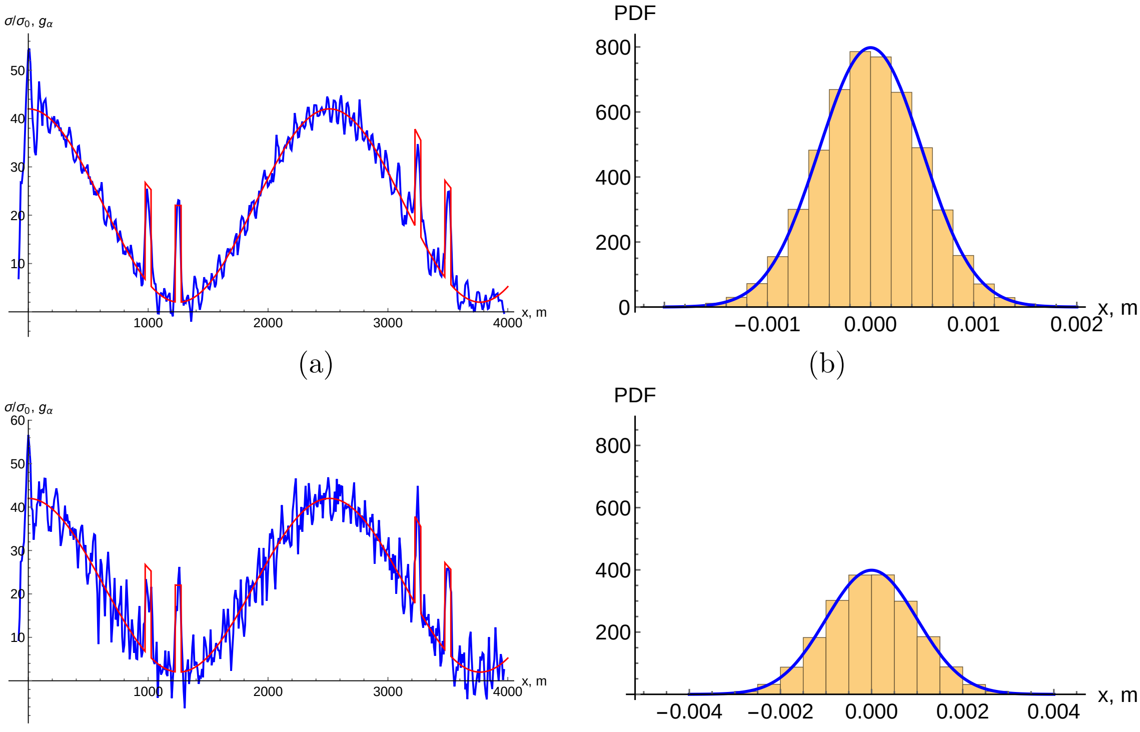
This technique belongs to the iterative regularization methods and is written in the form of iterative procedure [18]

$$(g_\alpha)_{\nu+1} = (g_\alpha)_\nu - \eta \cdot \operatorname{grad} J((g_\alpha)_\nu), \qquad \nu = 0, 1, \ldots, \tag{9}$$

where $J = \|K \cdot g - w\|^2/2$, $\operatorname{grad} J = K^\top \cdot (K \cdot g - w)$, η is a scalar controlling the speed of iteration convergence.

As shown in [18], the procedure (9) can be reduced to the matrix representation

$$(g_\alpha)_\nu = \eta \sum_{j=0}^{\nu-1} \left(I - \eta K^\top K\right)^j K^\top \cdot w. \tag{10}$$

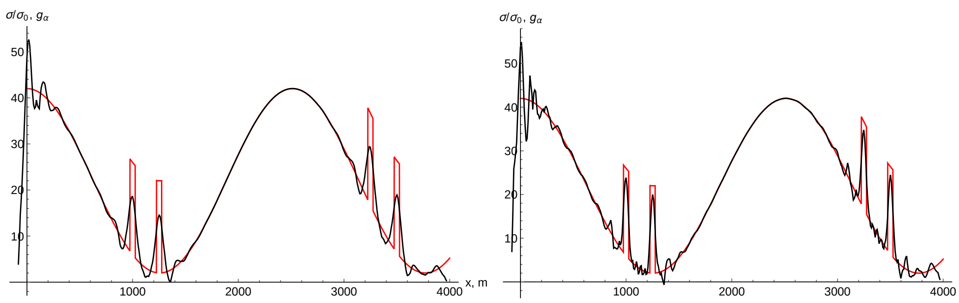


(a) (b) (c) (d)

Figure 4. Tikhonov method. Inverse problem solution (8) when noise is added. Here the standard deviations are $b = 5 \cdot 10^{-4}$ (b) and $b = 0.001$ (d).

Let us first fix not large iteration number $\nu = 50$. Then the corresponding solution (10) is shown in figure 5(a) and represents a good discrimination of the doublet pairs.

When the number of iterations are sufficiently large, i.e. $\nu = 500$, the solution (9) is plotted in figure 5(b). We see that the difference between exact solution and its approximation becomes smaller. It should be noted that the development spurious oscillations at the left edge of the interval, whereas the solution at the right edge behaves well. The reason for this instability requires additional studies, although this effect does not influence the hot-spot detection.



(a) (b)

Figure 5. The Landweber algorithm. The profiles of g_ν defined by (10) evaluated at $\nu = 50$ (a) and $\nu = 500$ (b). Here $\eta = 0.4$.

5. Concluding remarks

Thus, the research outlined above dealt with the mathematical issues devoted to the remote sensing areas contaminated by the highly radioactive materials. Nowadays the use of UAVs for remote sensing grows rapidly, therefore, support and assistance of UAV technology are extremely important. To do this, modern software and numerical methods are utilized. In particular, the software *Mathematica* package offers the tools for constructing the solutions of forward and inverse integral problems in a simple way.

Using this package, we adopted the Tikhonov and Landeweber algorithms for the inverse problem and applied them to the test problem which takes into account the surface density distribution of gamma sources with doublet structures, while other quantities were chosen as simply as possible. It turned out that the algorithms for the inverse problem reconstruct the close doublet structures quite well, remaining them separated.

Presented studies can be used for organizing the monitoring of the territories with man-made radioactive waste, for instance affected by accidents at nuclear NPPs [14]. As is well known [6], the territory of the Chornobyl Exclusion Zone contains huge amounts of spent nuclear fuel, radioactive waste, and its temporary localization. These storage facilities consist of complex “Vector”, radioactive waste disposal points “Buryakivka”, “Pidlisnyi”, “ChNPP Stage III”, nine temporary radioactive waste confinement sites with a total area about 10 hectares and include nearsurface disposal facility, trenches, and mound storages. In order to distinguish the contours of lost trenches, the use of presented findings is promising.

The results obtained can be interesting for the experts in the fields of remote sensing of radiation, homeland security, ecology, nuclear medicine, and etc.

Abstract. The nature and properties of neutron radiation impose specific requirements on the creation and operation of such materials. The presence of accompanying and induced radiation, weather conditions, as well as the peculiarities of the location of functional layers require a hierarchical approach to the development of such neutron-absorbing materials. It was shown that the conceptual scheme of creating Gd-containing protective materials consists in taking into account all factors of their operation. In particular, it is shown that the presence of neutron-absorbing components is a necessary but not sufficient condition for their successful application in environmental conditions. In this work, Gd-containing chitosan films were prepared as an example of the proposed conceptual scheme for the creation of environmentally friendly neutron-absorbing nanocomposites. The prepared Gd films were characterized and their neutron permeability was estimated. The approach presented in this work contributes to the development of sustainable and responsible production practices, supporting SDGs 9 and 12.

1. Introduction

The need for protection against neutron radiation is due to the increasing level of radiation load. The growing level of radiation danger is associated with the rapid progress of science and technology and the expansion of the spectrum of the use of radiation technologies in the industry. Examples of such applications are non-destructive testing systems (cargo and car scanners), high-energy particle detectors (CERN), creation of new radiation sources (subcritical assembly "Neutron Source", Kharkiv, Ukraine) and compact nuclear power plants.

The need for protection against neutron radiation is also urgent in space, where protection against cosmic radiation (high-energy heavy particles) [1] during travel and equipment operation is important. The main task of neutron-absorbing materials is to cut off the neutron part of the spectrum during the collision with high-energy particles, which reduces the radiation load.

2. Analysis of research and publications

Nowadays, nuclear technologies are widely used all over the world, in particular for environmental protection [2], scientific research [3, 4], medical imaging and therapy [5], neutrons in the field of nuclear energy [6], agriculture [7], etc. Neutron radiation is one of the most dangerous types of radiation and poses a real danger to radiation workers and the public. Its impact on biological tissue leads to ionization of the material and, as a result, significant changes in the functionality of the cell or loss of the ability to recover. Other chemical elements can also be formed, including radionuclides that create induced radioactivity in the body. This problem is also relevant for nuclear installations because, to neutron irradiation, the equipment becomes radioactive and is unusable.

To solve the problem of exposure to neutron radiation, it is necessary to limit the duration of exposure, maximize the distance from the radiation source, and use shielding material [8]. Over the past few years, several studies have been conducted on various protective materials against the dangers of ionizing radiation [9]. According to scientific studies, shielding materials usually consist of a matrix and a filler. Frequency the matrices used are hydrogen-enriched polymers, cement and glass [10–13]. Examples of elements and their compounds that can be used as fillers for neutron shielding are boron, cadmium, and selenium [14–16]. However, the price of these fillers is relatively high. Concrete is not optimal because it is heavy, cracks easily, and is prone to voids. Glass has a limited range of potential as a protective material [10]. Hydrogen-enriched polymers are widely used as matrix materials for nuclear shields due to their lightweight, good manufacturability, and strong ability to slow down neutrons [13, 17]. However, cost-effective composite shields with hydrogen-rich polymer matrices should be further investigated as shielding materials against the dangers of neutron radiation [8].

It is worth noting that epoxy resin is often used as a matrix in radiation shielding materials due to its high hydrogen content, excellent processability, strong radiation resistance, and suitability for adding a lot of inexpensive shielding fillers [13, 17]. The paper [13] presents the use of some secondary metallurgical resources and epoxy resin for the preparation of composites for various types of radiation. However, the shielding mechanism in these multiphase composites was never been elucidated.

Natural isotopes of Gd have a high ability to capture neutrons. Two of the seven stable isotopes ^{155}Gd and ^{157}Gd have very high neutron capture cross sections (55,000 and 255,000 barn, respectively). ^{155}Gd has the highest neutron capture cross section among all stable elements of the periodic table. The neutron capture cross section of ^{155}Gd is 65 times higher than that of the widely known ^{10}B [18, 19]. In figure 1 shows the cross-section of neutron capture by boron and gadolinium isotopes depending on the neutron energy. When a neutron is absorbed in the Gd nucleus, complex transformations occur, as a result of which γ-quants are generated, which displace electrons from the inner levels. This leads to the emission of internal conversion electrons, Auger–Koster–Kronig electrons, as well as photons and γ-quants. Computer modeling of the Gd neutron capture reaction predicts the output of 1.83 γ-photons, 0.84 γ-quant, and 0.69 internal conversion electrons [20].

The latest achievements in the development of nano- and micro-composite materials for the protection of workers and equipment from neutron irradiation are covered in the book [22]. In particular, the use of powder fillers as neutron absorbers is considered. In particular, it has been shown that the use of samarium (Sm) and Gd as fillers is effective in terms of the intensity of their interaction with neutrons [23], but at high concentrations it can cause the release of a significant amount of secondary gamma radiation. In this case, additional measures should be taken to protect against gamma radiation. As an optimal solution, the use of mixed boron-

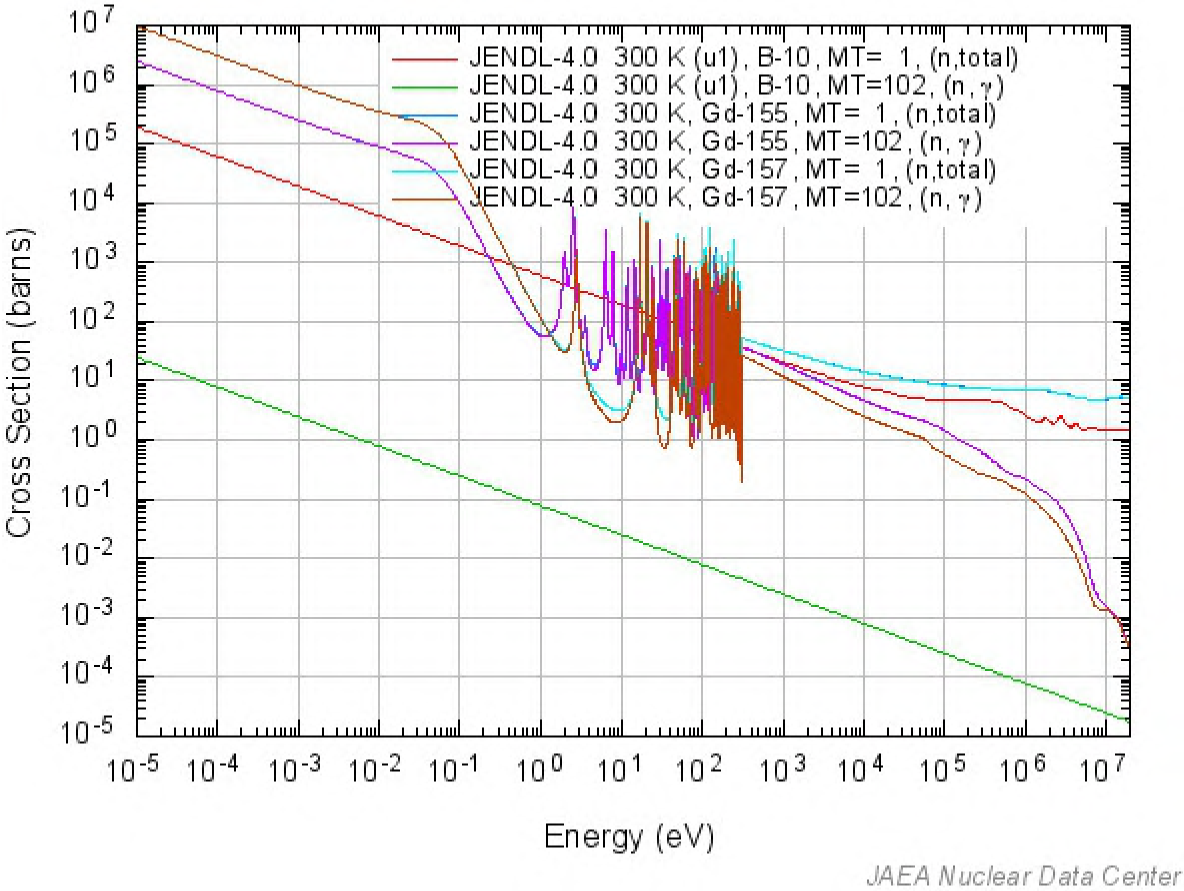

Figure 1. Section of neutron capture by ^{155}Gd, ^{157}Gd and ^{10}B isotopes [21].

gadolinium-containing fillers is proposed, which makes it possible to achieve optimal absorption of neutrons for different energy spectra and, accordingly, the release of an "optimized" amount of secondary radiation.

It is known from other literary sources that wood is a good adsorber of ionizing radiation [24]. In this regard, *it can be assumed that the use of wood in combination with Gd-containing materials is promising, since wood has good absorbing properties relative to secondary gamma radiation and, in addition, good structural properties.*

The use of thermoplastic composite materials for protection against neutrons in outer space is covered in [25]. Also, to protect workers and equipment from neutron radiation, it was proposed to use thermoset polymers filled with inorganic fillers. Methods of their production, properties and neutron shielding characteristics were analyzed [26].

The goal of this scientific article is to develop a conceptual scheme for the creation of environmentally friendly Gd-containing neutron-absorbing nanocomposites, and to validate this scheme through the preparation and characterization of Gd-containing chitosan films as a potential neutron shielding material.

This work, we believe, is contributing to sustainable development goals 9 (industry and innovation) since it offers an innovative approach for neutron shielding and 12 (responsible production) due to the possibility to develop environmentally friendly neutron-shielding materials.

3. Results and discussion

Neutron-shielding composite materials act as part of certain objects as components of protective structures. In particular, neutron-shielding composites can act as components of coatings, insulating, protective and structural materials, etc., to fulfill their functions. Accordingly, during the operation of materials containing neutron shielding composites, it is important to take into account the influence of various factors on them, including the environment [27]. Among the factors that can have a direct (negative) impact, it is worth highlighting:

- weather conditions;
- accompanying radiation (gamma radiation, beta particles);
- induced radiation (caused by the interaction of neutrons with matter);
- the factor of material properties change due to aging and mechanical stress, etc.;
- others.

In this context, the use of Gd-containing composites as part of protective materials seems most likely in two scenarios: indoor and in the open air.

Obviously, the use of neutron shields outdoors includes a set of parameters that are suitable for the indoor applications, plus a protective coating against weather conditions (humidity, solar radiation, temperature, etc.).

The basics of technologies and materials that are suitable for protection against weather conditions are well studied and worked out, so their detailed coverage here is unnecessary.

In particular, in figure 2, a four-component scheme is proposed, which consists of a protective coating (layer 1), an intermediate layer 2, a neutron protective layer 3, and a structural or main layer 4. An example of the arrangement of protective layers is shown in figure 2 below.

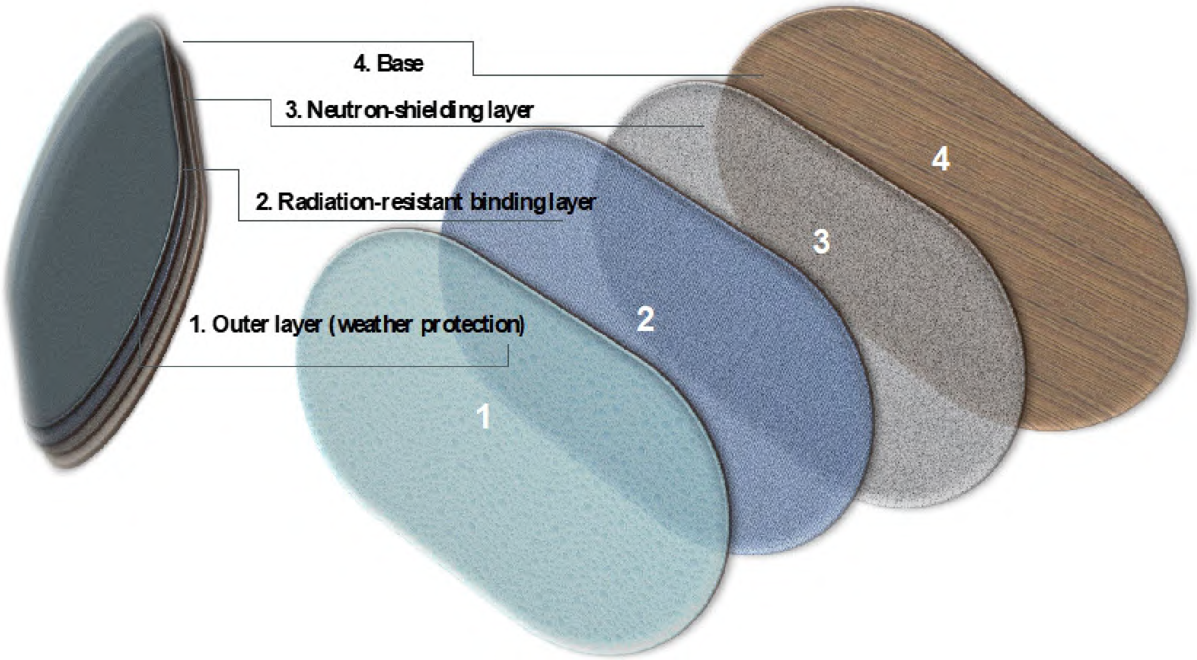

Figure 2. An example of proposed scheme of the arrangement of protective layers for a neutron-shielding composite material.

In addition to weather conditions, the impact of accompanying radiation is important, the presence of which should be expected at facilities with increased nuclear danger. It is important that the protection against accompanying radiation is at the front of the composite, for example as a protective paint, coating, varnish, etc. The radiation-resistant coating is applied to the base, which should ensure its reliable fixation and, accordingly, resistance to weather conditions. The basics of such technologies are well studied and worked out, so there is no need to cover them in detail in this project.

The base can be any material that meets the technical requirements, such as wood. Wood has good structural properties and is a sufficiently effective material for protection against gamma radiation.

The next layer can be directly Gd-containing neutron-absorbing composite material. The neutron protective layer should be located closest to the front of interaction with potential radiation sources. The work resource must exceed the maximum one-time load by several times. The thickness of the layer and the amount of neutron-shielding composite in it may vary depending on the specific purpose.

Taking into account the accompanying factors present during the operation of such composites in real conditions, it is also important to take into account other components of the interaction of neutrons with matter. It is worth noting that it is important to provide the neutron-absorbing composite material with a radiation-resistant shell several microns thick, made of a material that prevents the propagation of secondary electrons and neutralizes free radicals. It is worth noting that the formation of secondary electrons due to the interaction of neutrons with boron and gadolinium can cause the breaking of chemical bonds on a micrometer scale, and that is why it is important to “neutralize” such secondary electrons. Examples of such electron- and radical-absorbing materials can be cross-linked polymer hydrogels (for example, based on lignin) and surface-modified inorganic oxides (silica, magnetite, titanium oxide, etc.). The effective mileage (thickness of the substance layer that stops almost all particles) is given in table 1.

Table 1. Thickness of the layer of substance that stops most of $\beta-$particles.

Substance	**Electron energy, MeV**			
	0.05	**0.5**	**5**	**50**
	mean free path, cm			
Air	4.1	160	2000	17000
Water	$4.7 \cdot 10^{-3}$	0.19	2.6	19
Aluminum	$2 \cdot 10^{-3}$	0.056	0.95	4.3
Lead	$5 \cdot 10^{-4}$	0.02	0.3	1.25

The features of the structure of layer 3 and its interaction with neutron radiation are shown in the figure 3.

Beta particles (electrons and positrons) interact with electrons and nuclei in matter to a complete stop. The distance of beta particles depends on their energy.

When considering the use of neutron-shielding composite materials in protective structures, it is important to take into account various factors that can negatively impact the materials, such as weather conditions and accompanying radiation.

In this study, as chitosan films with and without Gd were prepared by a solution casting method. The films were cast from a chitosan solution containing the appropriate concentration of Gd salt, and then dried to obtain a thin film. The resulting films were characterized using scanning electron microscopy and their stability to electron beam was evaluated at the first stage.

The SEM micrograph in figure 4 shows the cross-sections of the chitosan film with and without the Gd, as a model of the Gd-containing neutron-absorbing composite material. The thickness of the film with Gd-containing composite material is 15 micrometers, while the thickness of the

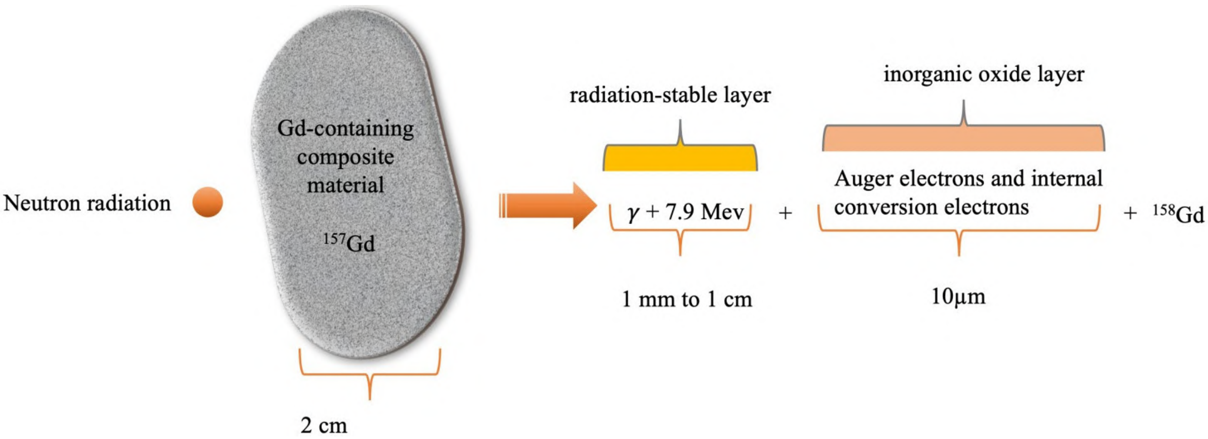

Figure 3. Radiation factors to be taken into account when developing a neutron shielding shell.

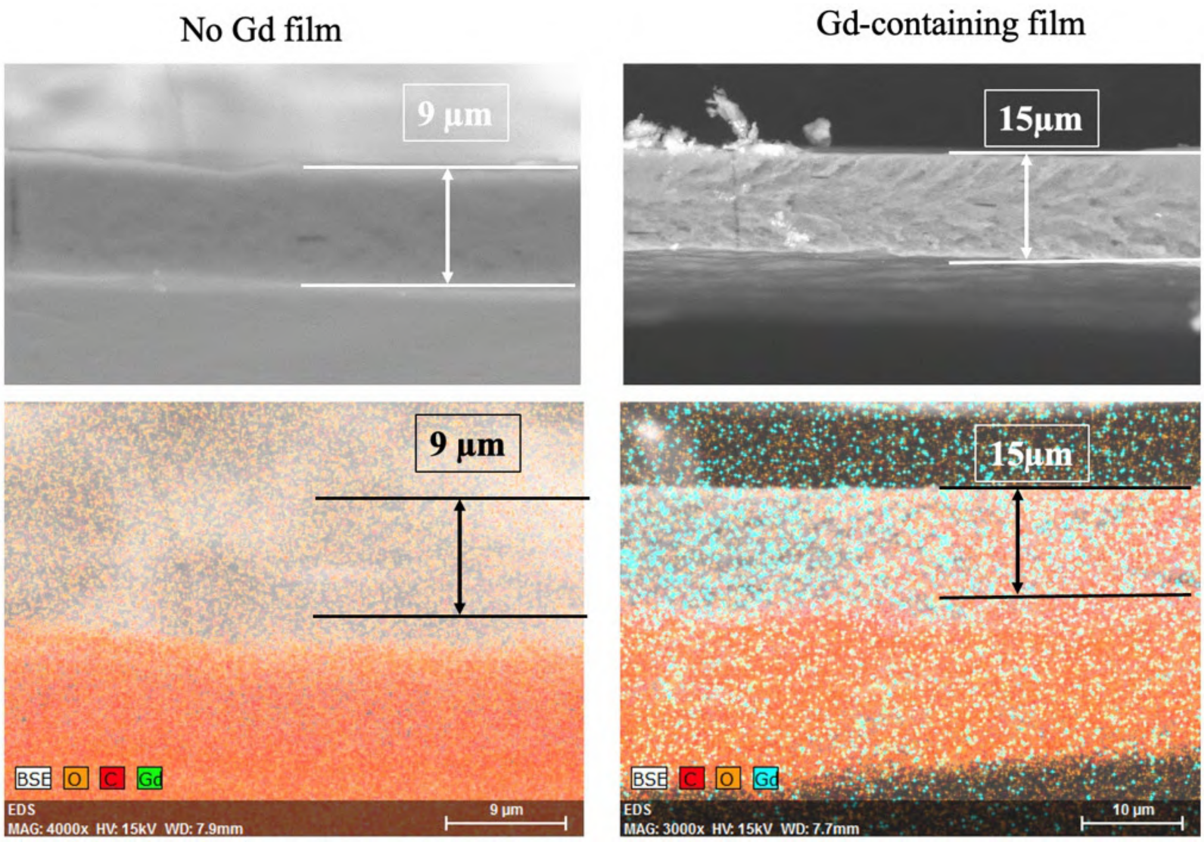

Figure 4. SEM micrograph of cross-sections of chitosan film with and without Gd-containing neutron-absorbing composite material.

film without Gd is only 9 micrometers. The element analysis (EDS) confirms the presence of Gd inside the film.

The results of this study suggest that chitosan, a natural polymer, can be used as a base material for the development of Gd-containing neutron shielding composites. The addition of Gd to the chitosan film increases its thickness and neutron shielding properties, making it a promising material for further development and application in neutron shielding.

The micrographs reveal the non-stability of the "just" chitosan film when exposed to the electron beam, as evident from the irregularities and deformations observed in the image (figure 5). In contrast, the Gd-containing chitosan film exhibits a more stable morphology under the same conditions, highlighting the potential of Gd as a stabilizing agent for natural polymer-based neutron shielding composites.

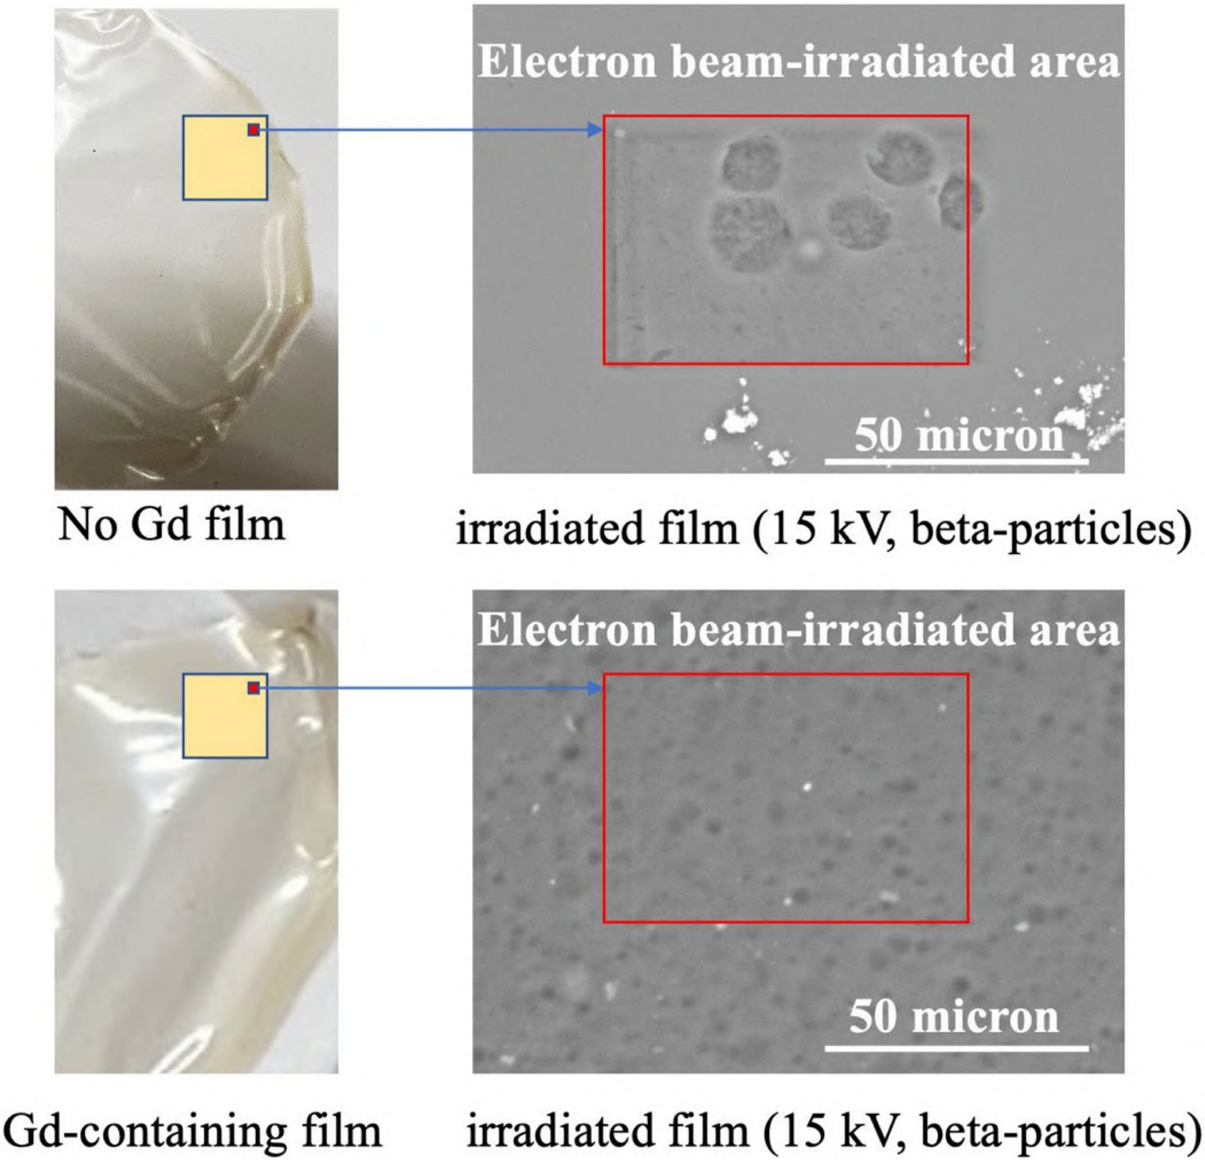

Figure 5. SEM micrographs of the cross-section of the chitosan film with and without Gd under electron beam.

The table 2 below compares the thickness, Gd content, and neutron shielding efficiency of the samples. The control sample (Chitosan) has a thickness of 9 μm and no Gd content. The Chitosan-Gd samples have a thickness of 15 μm and varying Gd content ranging from 3 wt% to 8 wt%. The neutron shielding efficiency of the samples is also provided, with the Chitosan-Gd samples showing increasing efficiency with increasing Gd content. This table helps to provide a concise overview of the properties of the different samples and facilitates easy comparison between them. This table helps to provide a concise overview of the properties of the different samples and facilitates easy comparison between them. The values for neutron permeability vere calculated according to [28] and are in good agreement with the data obtained in [29].

Table 2. Thickness comparison, Gd content, and neutron shielding efficiency of the samples.

Sampler	Thickness, (μm)	Gd content, (wt%)	Thermal neutron permeability, %
Control(Chitosan)	9	0	100
Chitosan-Gd	15	3	18.7
Chitosan-Gd	18	5	11.2
Chitosan-Gd	21	7	8
Chitosan-Gd	24	8	7

Further studies can be conducted to optimize the concentration of Gd within the film and to explore the feasibility of scaling up the production of such composites for practical use. It should be noted that the work described in this research paper represents only the beginning of the development and preliminary testing of the Gd-containing neutron shielding composites based on natural polymers such as chitosan and cellulose. Further research and testing are needed to optimize the composition and manufacturing process of these composites and to evaluate their performance under various environmental conditions and neutron radiation sources.

4. Conclusions

The nature and properties of neutron radiation impose specific requirements on the creation and operation of such materials. In particular, it is shown that the presence of neutron-absorbing components is a necessary but not sufficient condition for their successful application in environmental conditions. The presence of accompanying and induced radiation, weather conditions, as well as the peculiarities of the location of functional layers require a hierarchical approach to the development of such neutron-absorbing materials. As a result of literary data analysis, such an approach was proposed. It was shown that the principle scheme of creating Gd-containing protective materials consists in taking into account all factors of their operation. The approach, developed in this work is contributing to sustainable development goals 9 (industry and innovation) due to offering a more advanced and innovative approach for neutron shielding. Also, the development of environmentally friendly neutron-shielding materials contributes to SDG 12 (responsible production) due to decreased risk of the contamination of nature by toxic materials. The current study provides valuable insights into the potential of using chitosan as a matrix for Gd-containing composites and demonstrates the successful incorporation of Gd into the chitosan film as shown in the SEM images and EDS analysis. However, more extensive testing and evaluation of the material properties and performance are necessary to determine the feasibility and practical applications of these composites in real-world scenarios.

Abstract. The paper presents a comprehensive analysis of potential scenarios for Shelter Object transformation into an environmentally safe system after the commissioning of the New Safe Confinement. The analysis of scenarios is based on the developed factor-criteria model, which includes two groups of indicators in the scenario assessment: groups of factors and sets of criteria for each factor. The assessment of a separate scenario is carried out using the global value indicator. The global value of the scenario is determined taking into account the criterion content of all assessment factors. Characteristics of groups of factors and their criteria were determined by means of peer review. The assessment of the global values of scenarios allowed us to rank them. Based on the analysis, the most reasonable and realistic strategy for the phased removal/transfer to a controlled state of fuel-containing materials was proposed. The strategy also includes processes for further management of these materials and associated radioactive waste. As well as "Shelter" Object transformation processes in the process of its transformation into an environmentally safe system and determination of its final state. Based on the results of the comparative analysis of scenarios, it was found that the scenario that provides for the removal of known accumulations of fuel-containing materials during the life cycle of the New Safe Confinement is optimal if the activities on the phased retrieval of fuel-containing materials are properly financed.

1. Introduction

Despite the completion of construction and commissioning of the New Safe Confinement (NSC), the accumulation of fuel-containing materials (FCM) formed as a result of the beyond-design basis accident at Unit 4 remains the main source of hazard of the "Shelter" Object (SO). Moreover, the potential danger of FCM may increase over time due to the spontaneous destruction of the surface of paw-shaped FCM with the formation of highly active dust. The formation of such dust in the "Shelter" Object is a radio-ecological hazard not only of a local but also of a global nature since the NSC is not a hermetic structure. The problem of FCM degradation and methods of their evaluation and subsequent removal is extremely important not only for the SO but also for other facilities with similar conditions, such as the decommissioning of damaged reactors of the Fukushima Daiichi NPP [1]. Therefore, it is extremely important to remove or transfer to a controlled state FCM before the process of their destruction can acquire a large-scale character.

Resolution of the Presidium of the National Academy of Sciences of Ukraine No. 141 dated 16.05.2018 [2] states that scientific research on the transformation of the "Shelter" Object into an environmentally safe system is one of the priority areas of fundamental and applied research of specialized institutions of the National Academy of Sciences of Ukraine.

In work [3], the main directions of such research were determined and the following works were carried out:

- definition and analysis of factors affecting the choice of scenarios for the transformation of the "Shelter" Object;
- assessment of the risks of adverse effects on the environment of each of the FCM accumulations both during the life cycle of the NSC and after its decommissioning;
- analysis of possible options for the transformation of the "Shelter" Object;
- determination and substantiation of criteria for the final state of the "Shelter" Object;
- development of scenarios for the step-by-step transformation of the "Shelter" Object.

The ultimate goal of ensuring the nuclear and radiation safety of the "Shelter" Object – New Safe Containment" system (SO-NSC) should be the removal of all FCMs, and the organization of their safe storage and/or processing. An approach that considers the technological space of SO as a system of interconnected zones of FCM extraction, which are significantly different from each other, is promising. At the same time, for each extraction zone, one should consider individual technological approaches or scenarios for the extraction of FCM and handling of associated RAW.

At present [4], seven specific zones of FCM extraction in the future, using different technologies, are considered (figure 1):

- 1st zone – the central hall (CH), premises above the 18,000 mark, including the southern holding pool;
- 2nd zone – reactor shaft, sub-apparatus room (app. 305/2), etc. at marks from 9,000 to 18,000;
- 3rd zone – below the 9,000 mark: service corridor at the marks from minus 0.650 to 8.000, steam distribution corridor (SDC) (approx. 210/5, 210/6, 210/7), pressure-suppression pool (PSP):
  - second floor – PSP-2 (app. 012/13, 012/14, 012/15, 012/16);
  - first floor – PSP-1 (app. 012/5, 012/6, 012/7, 012/8);
- 4th zone – part of the hall within the SO;
- 5th zone – the space behind the pioneer walls;
- 6th zone – rubble under the cascade wall;
- 7th zone – local zone of the SO.

It is also necessary to take into account the guaranteed service life of the NSC, which is only 100 years, and the half-life periods of the nuclear materials contained in it are many orders of magnitude longer, and therefore their danger to the environment will remain for more than one millennium. This indicates that the problem of further transformation of the "Shelter" Object into an environmentally safe system (ESS) remains relevant even after the commissioning of the NSC and requires special scientific research.

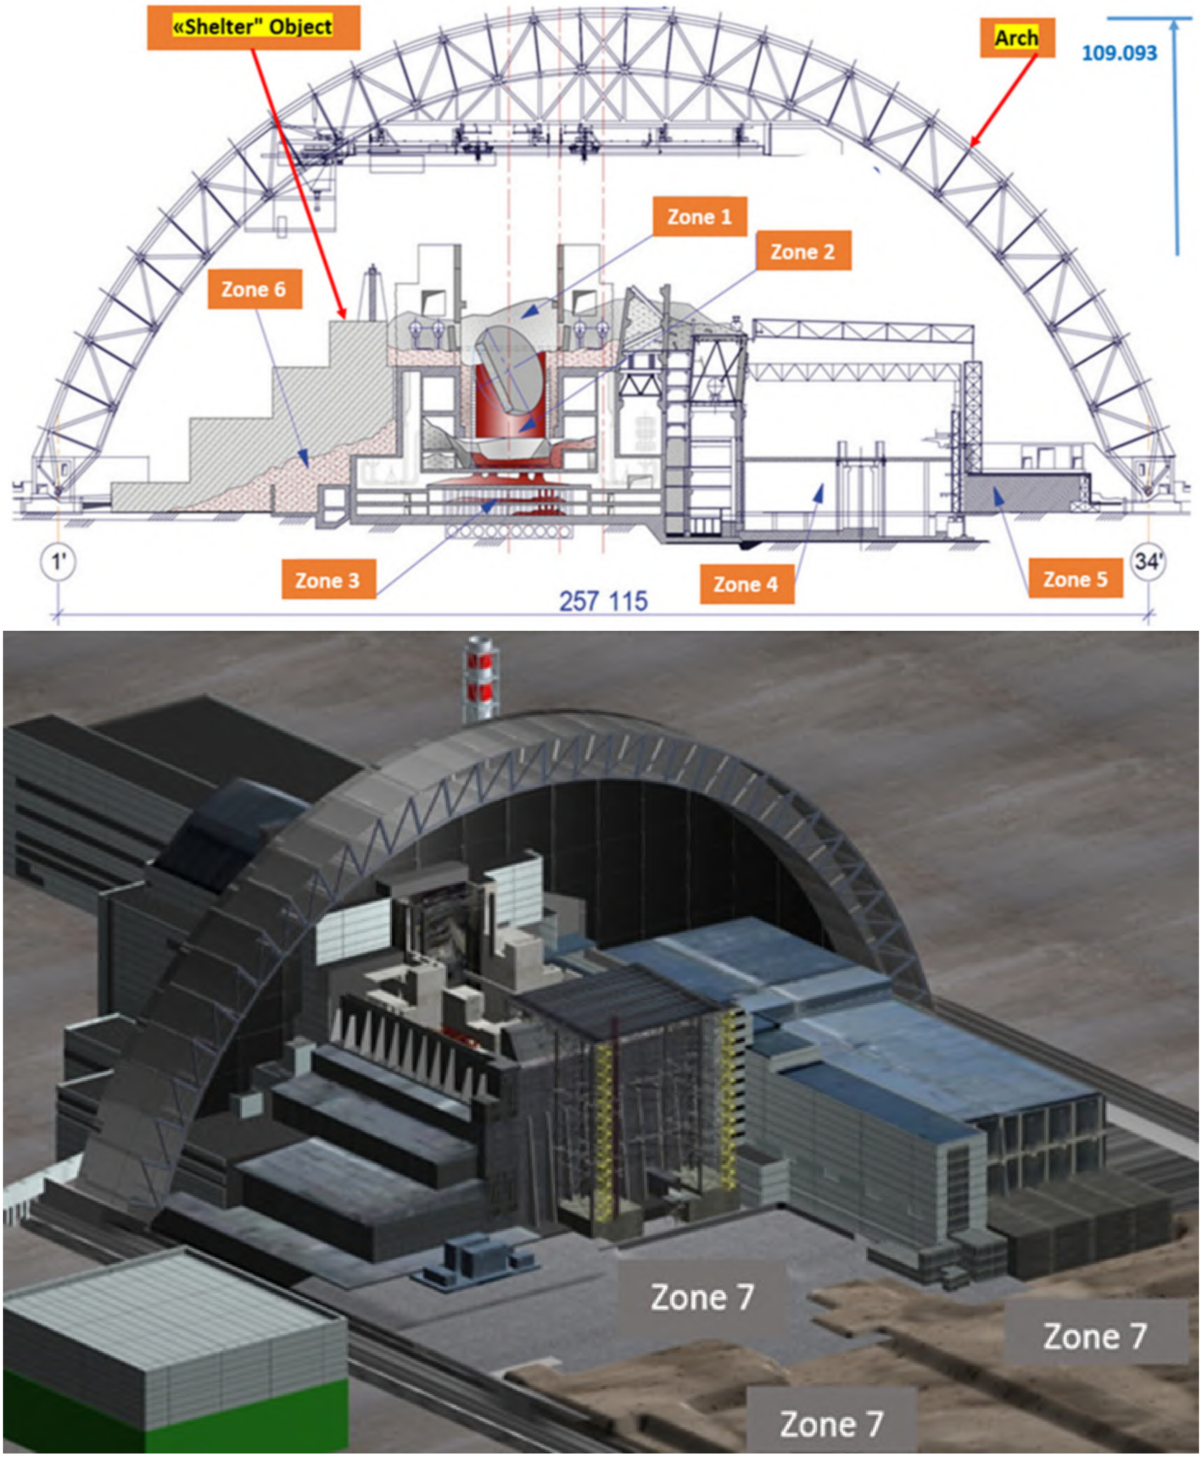

Figure 1. FCM extraction zones. Zone 1 – upper marks of the SO (Central Hall and other rooms are above the mark 18,000); Zone 2 – intermediate grades of SO (utility room, other rooms on the marks from 9,000 to 18,000); Zone 3 – lower marks of SO (premises below the mark 9,000); Zone 4 – part of the Machinery Hall within the SO; Zone 5 – the space behind the Pioneer walls; Zone 6 – rubble under the cascading wall; Zone 7 – local zone of the SO.

Thus, as of 2022, the following scenarios for the transformation of the “Shelter” Object into an environmentally safe system [5] have been determined, presented in table 1.

Table 1. Potential scenarios for the implementation of the strategy “staged removal of FCM”.

No	Withdrawal during the life cycle of the NSC	Deferred withdrawal after decommissioning of the NSC	Burial on site
1	Zones 1-6	Zone 7	–
2	Zones 1, 2, 3, 4, 6	Zones 5, 7	–
3	Zones 1, 2, 3, 4, 6	Zone 5	Zone 7
4	Zones 1, 2, 3 (SDC), 4, 6	Zones 3 (PSP), 5	Zone 7
5	Zones 1, 2, 3 (SDC), 4	Zones 3 (PSP), 5, 6	Zone 7
6	Zones 1, 2, 3 (SDC)	Zones 3 (PSP), 4, 5, 6	Zone 7
7	Zones 1, 2, 3 (SDC)	Zones 3 (PSP), 5, 6	Zones 4, 7
8	Zones 1, 2, 3 (SDC)	Zones 3 (PSP), 6	Zones 4, 5, 7
9	Zones 1, 2	Zone 3	Zones 4, 5, 6, 7
10	Zones 1, 2	Zone 3 (SDC)	Zones 3 (PSP), 4, 5, 6, 7

The object of the study is the SO-NSC system. The research object is a complex system in which its technical, technological, security, financial, infrastructural, and other parameters are connected. Therefore, the main method of his research is a systematic analysis of factors affecting the solution of the problems of transforming the “Shelter” Object into an environmentally safe system.

The subject of the research is a comprehensive analysis of the scenarios of transformation of the “Shelter” Object into an environmentally safe system. The complexity of the analysis processes is ensured by taking into account all the parametric and non-parametric component characteristics of the scenarios, as well as their internal technical, economic, safety, technological, etc. structure.

In work [6], a methodology for detailed assessment of nuclear power systems (NPS) was developed, including key assessment areas: economy, infrastructure, waste management, proliferation, resistance to proliferation, environment, etc. Comprehensive decision-making support is necessary for the comparative evaluation of alternative options and the selection of the most promising solution. But estimates according to the INPRO methodology [7] require sufficiently detailed design information for NPS components. For the SO-NSC system, such information is at the stage of development. The most adequate use of the multi-criteria optimization technique for the comparative evaluation of the scenarios of the transformation of the “Shelter” Object into an environmentally safe system is the work [8], using which it was decided to apply the expert evaluation of the criteria that characterize the scenarios.

The main tasks of the research presented in the work are:

- complex analysis of scenarios based on the grouping of factors and the determination of criteria relevant to them;
- the creation of a comprehensive evaluation model based on the global value of the scenario;
- practical use of the scenario evaluation model based on collegial expert evaluation of factors and criteria for the studied scenarios.

The article aims to rank the scenarios by their global (complex) value. A comprehensive analysis of the scenarios of step-by-step extraction of FCM after the commissioning of the NSC is being carried out for the first time.

2. Model of complex analysis of scenarios of transformation of the "Shelter" Object

2.1. Formation of a data array for complex analysis of scenarios

According to the recommendations of the IAEA [9–12], the decision-making criteria include:

- radiation protection criteria, which are:
  - implementation of anti-radiation protection of personnel, the population, and the environment in accordance with the requirements of the Laws, norms, and rules in force in Ukraine;
  - implementation of anti-radiation protection of personnel in accordance with the ALARA principle [13];
  - assessment of radiation consequences for personnel, which takes into account exposure caused both by activities during the implementation of the main task and by being in the exclusion zone;
  - assessment of radiation consequences of potential accidents for personnel, population, and environment;
- criteria for handling RAW;
- general technical criteria, which are:
  - creation of deep echelon defense;
  - quality assurance;
  - exchange of experience;
  - consideration of the human factor;
  - application of proven engineering and technical practice.

For the practical application and implementation of the environmental safety analysis of work execution options in the implementation of scenarios of phased removal of FCM, the criteria given in table 2 are defined.

The comparative analysis of the proposed scenarios for the phased removal of FCM is performed based on expert evaluations of the values of an array of criteria, which reflect various aspects of the condition of the "Shelter" Object and the specifics of its transformation into an environmentally safe system. The key goal in determining expert evaluations is the indicator of "achieving a given level of environmental safety". A nine-point scale is proposed for expert evaluation of criteria [14].

All the specified criteria are evaluated non-parametrically by a group of experts (in points), collegially, with the definition of a jointly agreed point evaluation of the criteria for each scenario.

2.2. Formalization of the model of the comparative analysis of scenarios of the conversion of SO

The array of criteria presented in table 2 can be grouped by factorial features, namely:

- factor 1 – security components of scenarios:
  - risks of changes in properties (degradation) of FCM over time R_D, %;
  - risks of destruction of protective barriers around FCM accumulations over time R_{DPB}, %;
  - radiological risks R_{Rad}, person/year;
  - project implementation time (scenario) T, years;
- factor 2 – financial components of the scenarios:
  - costs for creating protective barriers for containment and isolation of FCM after decommissioning NSC OE_{CPB}, thousand UAH;

Table 2. Criteria for the comparative analysis of scenarios of phased extraction of FCM.

No	The name of the criterion	Marking
1	Operating costs for ensuring the current security of the "Shelter" Object, thousand UAH.	OE_{ECS}
2	Costs for the creation of protective barriers for containment and isolation of FCM after decommissioning of the NSC, thousand UAH.	OE_{CPB}
3	Costs for the creation of additional infrastructure for the extraction and further handling of FCM and other RAW after the decommissioning of the NSC, thousand UAH.	OE_{CAI}
4	The degree of use of the infrastructure of the NSC for the extraction and further handling of FCM and other RAW, %	L_{UI}
5	Risks of unpreparedness of warehouses for intermediate storage of recovered FCM, %	R_{UISF}
6	Risks of the unpreparedness of the geological repository for the final disposal of FCM, %	R_{UGR}
7	Radiological risks, people/year	R_{Rad}
8	Risks of changes in properties (degradation) of FCM over time, %	R_D
9	Risks of underfunding of works on the phased removal of FCM and their subsequent handling, thousand UAH/year	R_{UFW}
10	Risks of the destruction of protective barriers around FCM accumulations over time, %	R_{DPB}
11	Project implementation time (scenario), years	T

  – costs for the creation of additional infrastructure for the removal and further handling of FCM and other RAW after the decommissioning of the NSC OE_{CAI}, thousand UAH;
  – operational costs for ensuring the current security of the OE_{ECS} "Shelter" Object, thousand UAH;
  – risks of underfunding of works on the phased removal of FCM and their further handling by R_{UFW}, thousand UAH / year;
- factor 3 – infrastructural components of the scenarios:
  – the degree of use of the infrastructure of the NSC for the extraction and further handling of FCM and other RAW, L_{UI}, %;
  – risks of non-readiness of storage facilities for intermediate storage of recovered FCM R_{UISF}, %;
  – risks of unpreparedness of the geological repository for the final disposal of the FCM R_{UGR}, %;

By analogy with [15], we will introduce the concept of "scenario values" SF_i, (significance function). For practical use in accordance with the purpose and objectives of the research, this indicator is identically equal to the predicted level of environmental safety in the implementation of the i-th scenario with the corresponding groups of factors Φ_i and their constituent criteria:

$$\begin{Bmatrix} SF_1 \\ ... \\ SF_p \end{Bmatrix} \equiv \begin{pmatrix} \Phi_1 \begin{Bmatrix} R_{D,1} & R_{DPB,1} & R_{Rad,1} & T_1 \\ ... & ... & ... & ... \\ R_{D,p} & R_{DPB,p} & R_{Rad,p} & T_p \end{Bmatrix} \\ \Phi_2 \begin{Bmatrix} OE_{ECS,1} & OE_{CPB,1} & OE_{CAI,1} & R_{UFW,1} \\ ... & ... & ... & ... \\ OE_{ECS,p} & OE_{CPB,p} & OE_{CAI,p} & R_{UFW,p} \end{Bmatrix} \\ \Phi_3 \begin{Bmatrix} L_{UI,1} & R_{UISF,1} & R_{UGR,1} \\ ... & ... & ... \\ L_{UI,p} & R_{UISF,p} & R_{UGR,p} \end{Bmatrix} \end{pmatrix} \quad (1)$$

where:

- $\Phi_1 \begin{Bmatrix} R_{D,1} & R_{DPB,1} & R_{Rad,1} & T_1 \\ ... & ... & ... & ... \\ R_{D,p} & R_{DPB,p} & R_{Rad,p} & T_p \end{Bmatrix}$ – safety factor of scenarios with its own criteria;
- $\Phi_2 \begin{Bmatrix} OE_{ECS,1} & OE_{CPB,1} & OE_{CAI,1} & R_{UFW,1} \\ ... & ... & ... & ... \\ OE_{ECS,p} & OE_{CPB,p} & OE_{CAI,p} & R_{UFW,p} \end{Bmatrix}$ – the financial factor of the scenarios with its criteria;
- $\Phi_3 \begin{Bmatrix} L_{UI,1} & R_{UISF,1} & R_{UGR,1} \\ ... & ... & ... \\ L_{UI,p} & R_{UISF,p} & R_{UGR,p} \end{Bmatrix}$ – the infrastructural factor of the scenarios with its criteria.

Thus, the initial conditions for using the scenario evaluation method based on collective expert evaluations are a set of factors Φ_1, Φ_2 and Φ_3 with groups of criteria defined for them.

Then a separate i-th scenario will be represented by a complex or integral value criterion W_i, which is determined based on the weight of factors and criteria that form them. This will allow you to rank the scenarios according to their relative value:

$$W^* > ... > W^0 \quad (2)$$

where $W_i^* = \text{argmax}(W_i), W_i^0 = \text{argmin}(W_i)$.

2.3. Algorithm for determining complex values of scenarios based on group expert evaluation

Determining the complex values of scenarios based on group expert evaluation is a step-by-step process.

At stage 1, arrays of scenario evaluation criteria are formed

$$\begin{gathered} Sc_i = (OE_{ECS(i)}, OE_{CPB(i)}, OE_{CAI(i)}, L_{UI(i)}, \\ R_{UISF(i)}, R_{UGR(i)}, R_{Rad(i)}, R_{D(i)}, R_{UFW(i)}, R_{DPB(i)}, T_i) \end{gathered} \quad (3)$$

where: i is a separate scenario, $i = \overline{1,p}$, p is the number of scenarios.

As a result, we get an array of criteria with a definition of their characteristics.

At stage 2, criteria are grouped by qualitatively homogeneous factors Φ_j.

The result is the formation of three groups of factors for p scenarios with their own criteria (1): Φ_1 – security, Φ_2 – financial, Φ_3 – infrastructural.

Sc_1	...	Sc_i	...	Sc_p
Φ_{11}	...	Φ_{i1}	...	Φ_{p1}
Φ_{12}	...	Φ_{i2}	...	Φ_{p2}
Φ_{13}	...	Φ_{i3}	...	Φ_{p3}

At stage 3, a group expert evaluation of factors and criteria within the factors is carried out according to point evaluations according to the proposed scale.

The result is the formation of point scores expert assessment matrices for factors and their criteria for p scenarios:

Scenario 1		...	Scenario i		...	Scenario p	
factors (points)	criteria (points)	...	factors (points)	criteria (points)	...	factors (points)	criteria (points)
Φ_{11}	$R_{D(1)}$, $R_{DPB(1)}$, $R_{Rad(1)}$, T_1	...	Φ_{i1}	$R_{D(i)}$, $R_{DPB(i)}$, $R_{Rad(i)}$, T_i	...	Φ_{p1}	$R_{D(p)}$, $R_{DPB(p)}$, $R_{Rad(p)}$, T_p
Φ_{12}	$OE_{ECS(1)}$, $OE_{DPB(1)}$, $OE_{CAI(1)}$, $R_{UFW(1)}$	...	Φ_{i2}	$OE_{ECS(i)}$, $OE_{DPB(i)}$, $OE_{CAI(i)}$, $R_{UFW(i)}$	...	Φ_{p2}	$OE_{ECS(p)}$, $OE_{DPB(p)}$, $OE_{CAI(p)}$, $R_{UFW(p)}$
Φ_{13}	$L_{UI(1)}$, $R_{UISF(1)}$, $R_{UGR(1)}$	...	Φ_{i3}	$L_{UI(i)}$, $R_{UISF(i)}$, $R_{UGR(i)}$	...	Φ_{p3}	$L_{UI(p)}$, $R_{UISF(p)}$, $R_{UGR(p)}$

At stage 4, the matrix of advantages for factors is formed based on the factor scores:

$$A^{\Phi} = (a_{i,j}^{\Phi}) \tag{4}$$

where: $a_{i,j}^{\Phi}$ – advantage of the i-th factor over the j-th. For the i-th scenario, the benefits matrix looks like this:

$$A_i^{\Phi} = \begin{pmatrix} 1 & \Phi_{i1}/\Phi_{i2} & \Phi_{i1}/\Phi_{i3} \\ \Phi_{i2}/\Phi_{i1} & 1 & \Phi_{i2}/\Phi_{i3} \\ \Phi_{i3}/\Phi_{i1} & \Phi_{i3}/\Phi_{i2} & 1 \end{pmatrix} \tag{5}$$

The result is an estimate of the weight of the factors for the i-th scenario according to the formulas:

$$\Omega_i^{\Phi 1} = \frac{\sqrt[3]{1 \cdot (\frac{\Phi_{i1}}{\Phi_{i2}}) \cdot (\frac{\Phi_{i1}}{\Phi_{i3}})}}{\sqrt[3]{1 \cdot (\frac{\Phi_{i1}}{\Phi_{i2}}) \cdot (\frac{\Phi_{i1}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i2}}{\Phi_{i1}}) \cdot 1 \cdot (\frac{\Phi_{i2}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i3}}{\Phi_{i1}}) \cdot (\frac{\Phi_{i3}}{\Phi_{i2}}) \cdot 1}} \tag{6}$$

$$\Omega_i^{\Phi 2} = \frac{\sqrt[3]{(\frac{\Phi_{i2}}{\Phi_{i1}}) \cdot 1 \cdot (\frac{\Phi_{i2}}{\Phi_{i3}})}}{\sqrt[3]{1 \cdot (\frac{\Phi_{i1}}{\Phi_{i2}}) \cdot (\frac{\Phi_{i1}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i2}}{\Phi_{i1}}) \cdot 1 \cdot (\frac{\Phi_{i2}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i3}}{\Phi_{i1}}) \cdot (\frac{\Phi_{i3}}{\Phi_{i2}}) \cdot 1}} \tag{7}$$

$$\Omega_i^{\Phi 3} = \frac{\sqrt[3]{(\frac{\Phi_{i3}}{\Phi_{i1}}) \cdot (\frac{\Phi_{i3}}{\Phi_{i2}}) \cdot 1}}{\sqrt[3]{1 \cdot (\frac{\Phi_{i1}}{\Phi_{i2}}) \cdot (\frac{\Phi_{i1}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i2}}{\Phi_{i1}}) \cdot 1 \cdot (\frac{\Phi_{i2}}{\Phi_{i3}})} + \sqrt[3]{(\frac{\Phi_{i3}}{\Phi_{i1}}) \cdot (\frac{\Phi_{i3}}{\Phi_{i2}}) \cdot 1}} \tag{8}$$

At stage 5, a preference matrix is formed for criteria based on point scores:

$$A^{KP} = (a_{i,j}^{KP}) \tag{9}$$

where: $a_{i,j}^{KP}$ – advantage of the i-th criterion over the j-th. For the i-th scenario, the benefits matrix looks like this:

- for the array of criteria grouped in "Factor 1 – security components of scenarios"

$$A_i^{KP}(\Phi_1) = \begin{pmatrix} 1 & R_{D(i)}/R_{DBP(i)} & R_{D(i)}/R_{Rad(i)} & R_{D(i)}/T_{(i)} \\ R_{DBP(i)}/R_{D(i)} & 1 & R_{DBP(i)}/R_{Rad(i)} & R_{DBP(i)}/T_(i) \\ R_{Rad(i)}/R_{D(i)} & R_{Rad(i)}/R_{DBP(i)} & 1 & R_{Rad(i)}/T_(i) \\ T_{(i)}/R_{D(i)} & T_{(i)}/R_{DBP(i)} & T_(i)/R_{Rad(i)} & 1 \end{pmatrix} \quad (10)$$

- for the array of criteria grouped in "Factor 2 – financial criteria of scenarios"

$$A_i^{KP}(\Phi_2) = \begin{pmatrix} 1 & OE_{ECS(i)}/OE_{CPB(i)} & OE_{ECS(i)}/OE_{CAI(i)} & OE_{ECS(i)}/R_{UFW(i)} \\ OE_{CPB(i)}/OE_{ECS(i)} & 1 & OE_{CPB(i)}/OE_{CAI(i)} & OE_{CPB(i)}/R_{UFW(i)} \\ OE_{CAI(i)}/OE_{ECS(i)} & OE_{CAI(i)}/OE_{CPB(i)} & 1 & OE_{CAI(i)}/R_{UFW(i)} \\ R_{UFW(i)}/OE_{ECS(i)} & R_{UFW(i)}/OE_{CPB(i)} & R_{UFW(i)}/OE_{CAI(i)} & 1 \end{pmatrix} \quad (11)$$

- for the array of criteria grouped in "Factor 3 – infrastructural criteria of scenarios"

$$A_i^{KP}(\Phi_3) = \begin{pmatrix} 1 & L_{UI(i)}/R_{UISF(i)} & L_{UI(i)}/R_{UGR(i)} \\ R_{UISF(i)}/L_{UI(i)} & 1 & R_{UISF(i)}/R_{UGR(i)} \\ R_{UISF(i)}/L_{UI(i)} & R_{UGR(i)}/R_{UISF(i)} & 1 \end{pmatrix} \quad (12)$$

The result is an assessment of the weight of the criteria for the relevant factors for the i-th scenario as a ratio of the geometric mean from a separate row of the matrices (9), (10), (11) to the sum of the geometric means of all rows of the matrices:

$$W_i^{\Phi 1,2,3} = \frac{\sqrt[m]{a_{ij} \cdot \ldots \cdot a_{im}}}{\sum \sqrt[m]{a_{ij} \cdot \ldots \cdot a_{im}}} \quad (13)$$

where: m – the number of criteria in the corresponding factor.

For the specified factors, we will obtain the vectors of the relative values of the criteria:

$$W_i^{\Phi 1} = \begin{pmatrix} W_{R_{D(i)}} \\ W_{R_{DPB(i)}} \\ W_{R_{Rad(i)}} \\ W_{T_{(i)}} \end{pmatrix}, W_i^{\Phi 2} = \begin{pmatrix} W_{OE_{ECS(i)}} \\ W_{OE_{CPB(i)}} \\ W_{OE_{CAI(i)}} \\ W_{R_{UFW(i)}} \end{pmatrix}, W_i^{\Phi 3} = \begin{pmatrix} W_{L_{UI(i)}} \\ W_{R_{UISF(i)}} \\ W_{R_{UGR(i)}} \end{pmatrix} \quad (14)$$

At stage 6, a vector of complex indicators $W(\Omega, \omega)$ is formed, containing evaluations of the criteria that form them $\omega_1^i, , \omega_k^i$ and groups of factors based on determining their weights $\{\Omega^1, , \Omega^m\}$:

$$W = [\langle(\omega_1^1, ..., \omega_k^1), \Omega^1\rangle; \langle(\omega_1^2, ..., \omega_l^1)\Omega^2\rangle; ...; \langle(\omega_1^m, ..., \omega_z^m)\Omega^j\rangle] \quad (15)$$

where: k, l, z – the number of criteria that form the relevant factor.

The result is the determination of the complex indicators of the weight (values) of the scenarios $W = \langle\omega, \Omega\rangle$ taking into account the determination of the weight of the relevant criteria ω based on the weight of the structural factors Ω. It is performed using a geometric weighted multiplicative convolution of the form:

$$W_{(Sc_j)} = \sqrt[m]{\Pi_{i=1}^m [(\omega_i^j)^{\Omega^j}]_{(Sc_j)}}, j = \overline{1, n} \quad (16)$$

where: $S_{Cj} \in S_c$ – the array of scripts; ω_i^j – weights of the criteria that form the factors of the corresponding scenarios; Ω^j – factor weights for scenarios.

For expression (15), we obtain the vectors of the relative values of the scenarios defined by (16):

$$W = \begin{pmatrix} W_{Sc(1)} \\ \ldots \\ W_{Sc(i)} \\ \ldots \\ W_{Sc(p)} \end{pmatrix} \tag{17}$$

Scenarios are ranked by the value of their complex value according to (2):

$$W^* > \ldots > W^0$$

where: $W_i^* = \text{argmax}(W_i), W_i^0 = \text{argmin}(W_i)$.

3. Practical implementation of a comparative analysis of scenarios for the transformation of the "Shelter" Object into an environmentally safe system

According to clause 1 of the article, the comparative analysis of scenarios will be carried out on the basis of factorial-criterion group expert evaluation (EE). A working group of experts was created to perform the work according to the EE method, which meets the requirements of qualification and competence, which will ensure the reliability of the implementation of the EE. In the work of the group of experts on scenario evaluation, collective expert evaluations are applied. The input conditions for EE scenarios are:

- number of scenarios – 10;
- all expert assessments for all stages of practical use of the model are carried out on a nine-point scale (from 1 to 9 points).

Each factor or criterion within the scenario is assigned a collegial assessment in points, which can be equivalent for different indicators and different scenarios. The process of collegial point expert evaluation is carried out in two stages:

- stage 1 – scoring of three groups of FACTORS for ten scenarios;
- stage 2 – scoring of the CRITERIA, which are included in the relevant groups of factors, for ten scenarios.

Based on the results of expert scoring for ten scenarios, the relative complex values of the scenarios are determined according to the proposed model. Based on the determined relative complex values of the scenarios, the scenarios are ranked according to their relative complex value.

At the **first stage** of the model implementation, a group expert evaluation of defined groups of scenario factors was carried out. The results of a collegial group expert survey and evaluation of factor weights for the scenarios calculated according to formulas (6), (7) and (8) are given in table 3.

At the **second stage** of the model implementation, a group expert evaluation of the criteria for the relevant groups of scenario factors was performed. The results of the collegial group expert survey are given in tables 4-6.

The determination of the complex indicators of the values of the scenarios taking into account the determination of the weight of the relevant criteria based on the weight of the structural factors of the type (15) was carried out according to the formula (16).

The results of the comprehensive assessment of the scenarios can be provided either in the form of a vector or in a tabular format. T7 presents the results of calculations in tabular format.

Table 3. Results of group expert assessment of scenario factors.

Scenario	Scenario factors (in points from 1 to 9)			Factor weights for scenarios		
	$\Phi 1$	$\Phi 2$	$\Phi 3$	$\Omega(\Phi 1)$	$\Omega(\Phi 2)$	$\Omega(\Phi 3)$
Scenario 1	9	7	9	0.360	0.280	0.360
Scenario 2	9	7	8	0.375	0.292	0.333
Scenario 3	8	6	8	0.364	0.273	0.364
Scenario 4	8	6	8	0.364	0.273	0.364
Scenario 5	7	6	7	0.350	0.300	0.350
Scenario 6	7	5	7	0.368	0.263	0.368
Scenario 7	6	5	6	0.353	0.294	0.353
Scenario 8	5	6	6	0.294	0.353	0.353
Scenario 9	4	7	5	0.250	0.438	0.313
Scenario 10	4	7	5	0.250	0.438	0.313

Table 4. Group expert evaluation of criteria for groups of scenario factors (safety factor).

Safety factors (in points from 1 to 9)					Scenario criteria values			
Scenario	R_D	R_{DPB}	R_{Rad}	T	$\omega(R_D)$	$\omega(R_{DPB})$	$\omega(R_{Rad})$	$\omega(T)$
Scenario 1	9	9	8	9	0.257	0.257	0.229	0.257
Scenario 2	9	9	8	7	0.273	0.273	0.242	0.212
Scenario 3	8	8	8	8	0.250	0.250	0.250	0.250
Scenario 4	7	8	7	7	0.241	0.276	0.241	0.241
Scenario 5	6	8	7	6	0.222	0.296	0.259	0.222
Scenario 6	6	8	7	5	0.231	0.308	0.269	0.192
Scenario 7	6	8	6	7	0.222	0.296	0.222	0.259
Scenario 8	6	8	6	8	0.214	0.286	0.214	0.286
Scenario 9	5	8	5	9	0.185	0.296	0.185	0.333
Scenario 10	5	7	5	9	0.192	0.269	0.192	0.346

The vector of complex relative values of the scenarios defined by (16):

$$W = \begin{pmatrix} W_{Sc(1)} = 0.6642 \\ W_{Sc(2)} = 0.6212 \\ W_{Sc(3)} = 0.6369 \\ W_{Sc(4)} = 0.6382 \\ W_{Sc(5)} = 0.6429 \\ W_{Sc(6)} = 0.6453 \\ W_{Sc(7)} = 0.6461 \\ W_{Sc(8)} = 0.6449 \\ W_{Sc(9)} = 0.6333 \\ W_{Sc(10)} = 0.6328 \end{pmatrix} \tag{18}$$

The results of the ranking of the scenarios by the value of the complex value:

$W_i^* = \text{argmax}(W_i) = 0.6642 - \text{scenario 1}$

$W_i^{-1} = 0.6461 - \text{scenario 7}$

Table 5. Group expert evaluation of criteria for groups of scenario factors (financial factor).

Scenario 3	0.636855
Scenario 4	0.638161
Scenario 5	0.642854
Scenario 6	0.645337
Scenario 7	0.646057
Scenario 8	0.644912
Scenario 9	0.633337
Scenario 10	0.632818

$$\begin{gathered}
W_i^{-2} = 0.6453 - \text{scenario } 6 \\
W_i^{-3} = 0.6449 - \text{scenario } 8 \\
W_i^{-4} = 0.6429 - \text{scenario } 5 \\
W_i^{-5} = 0.6382 - \text{scenario } 4 \\
W_i^{-6} = 0.6369 - \text{scenario } 3 \\
W_i^{-7} = 0.6333 - \text{scenario } 9 \\
W_i^{-8} = 0.6328 - \text{scenario } 10 \\
W_i^{0} = \operatorname{argmin}(W_i) = 0.6212 - \text{scenario } 2
\end{gathered}$$

4. Conclusions

Thus, on the basis of the conducted research, the following conclusions can be drawn:

- collegial expert assessments conducted for factors and their criteria are competent and consistent;
- calculated based on EE weights of the factors $\Omega_i^{\Phi j}$ for the considered scenarios and the weights of the criteria ω_i^j for the corresponding Ω^j factors for the scenarios based on the comparison matrices are reliable and significant which is confirmed by the calculated consistency indices that do not exceed 10%;
- the vector of relative complex values of scenarios (15) is the basis for making managerial decisions;
- according to the $\operatorname{argmax}(W_i)$ principle the best scenario is "scenario 1" – the base scenario. The value of the relative complex value is $W_i^* = \operatorname{argmax}(W_i) = 0.6642$;
- the worst scenario according to the $\operatorname{argmin}(W_i)$ principle is "scenario 2". The value of the relative complex value of which is the minimum among the estimates and is $W_i^0 = \operatorname{argmin}(W_i) = 0.6212$;
- a series of scenario evaluations ranked by relative complex value:

$$\begin{cases} W_i^* = W_1 > W_7 > W_6 > W_8 > W_5 > W_4 > W_3 > W_9 > W_i^0 = W_10 \\ 0.6642 > 0.6461 > 0.6453 > 0.6449 > 0.6429 > 0.6382 > 0.6369 > 0.6333 > 0.6328 > 0.621 \end{cases}$$

Therefore, with proper financing of the step-by-step extraction of FCM, the priority is the basic scenario – Scenario 1, which provides for the removal of all FCM accumulations (except FCM localized in man-made soil under NSC structures) during the life cycle of NSC. When implementing such a scenario, the NSC infrastructure is used to the maximum, the costs of creating protective barriers to contain and isolate FCM are reduced, as well as the costs of creating additional infrastructure for the extraction and further handling of FCM and other RAW after decommissioning of the NSC.

Since the values of the values of the relative complex value of all scenarios do not differ significantly, under certain circumstances (mostly due to the financial component) other scenarios, which provide for the delayed removal of individual accumulations of FCM, may become better.

Abstract. The data on pH changes and corresponding equilibrium shifts of the carbonate system of process and return waters of the circulating cooling system (RCS) of the Rivne NPP during water treatment were analysed. In the additional cooling water previously clarified by liming, there is no dissolved carbon dioxide and no residual free alkalinity. The effects that occur during heating, cooling, and aeration in the RCS cause a shift in the equilibrium of the carbonate cooling water system with a decrease or increase in the content of carbon dioxide, bicarbonate, and carbonate ions, and pH level. The influence of the shift of the carbonate system and the changes in pH level during the discharge of return water from the Rivne NPP into a natural water body (Styr River) was analysed.

1. Introduction

The water is an essential component for the operation of nuclear power plants (NPPs), as it is needed for cooling in the processes of the steam-water cycle [1]. However, wastewater discharges into natural reservoirs can lead to changes in the chemical equilibrium of their components, which is a potential technogenic hazard and requires constant monitoring in the operation of nuclear power plants [2, 3]. Carbon dioxide, bicarbonate and carbonate ions are important parameters for monitoring the water-chemical regime of the NPP cooling system.

These are the main components of the carbonate buffer system of natural waters providing the ability to neutralize acids and determine the alkalinity of water. That is why, in water treatment technologies of the circulating cooling system (RCS) of nuclear power plants, the components of the carbonate system shall meet a number of environmental standards [2], which is also essential in a view of the sustainable development of the entire energy sector [4].

1.1. Literature review

We know that in natural waters, the ratio of carbon dioxide, bicarbonate, and carbonate ions is a forming factor in the pH level of the aquatic environment. Each of the components of the carbonate system of water exists in a certain pH range. If any of these forms is in a given amount, this determines a certain pH value of water, which in turn determines the presence of co-existing forms of carbonates. Dissolved carbon dioxide interacts with water and forms bicarbonate and carbonate ions, and an increase in the water pH level, as an important component of the carbonate equilibrium, leads to a shift in the carbonate equilibrium towards the formation of calcium carbonate [5–7]. When studying river carbonate systems, it was found that in waters with higher alkalinity, atmospheric equilibrium occurs more slowly, since part of the carbon dioxide entering the river stream passes into bicarbonate ions [8]. The result of this direct buffering is a constant preservation of pH, alkalinity index, and an increase in dissolved inorganic carbon index. In addition, the components of the carbonate water system are influenced by the hydrobiological processes. In particular, during the active vegetation season of the planktonic organisms, due to the consumption of carbon dioxide during the aquatic plants' photosynthesis, the carbon dioxide is assimilated with the formation of bicarbonate ions, which is manifested in the increase in water pH levels [9].

In the technological cycles of water cooling systems, the pH value of the water is also influenced by such factors as water temperature, water movement speed, time spent in the system, the intensity of aeration and evaporation of water, as well as the addition of chemical reagents and metallurgy of the system components [10, 11].

For example, in a model study of carbon dioxide release and changes in the carbonate system when heated without aeration, with the formation of calcium carbonate scale, the conditions of multi-stage RCS evaporation were reproduced. It was found that when evaporating without aeration, the pH shifts to higher values and significantly affects the concentration of bicarbonate and carbonate ions in cooling water [12]. The effect of concentration of soluble salts and precipitation of calcium carbonate in return waters was also observed when the cooling water was repeatedly heated in the turbine condenser, which indicated a shift in the equilibrium of the RCS carbonate system [13]. It is also proved that the other chemical components present in industrial cooling systems, after discharges into natural water bodies, make the chemical composition of surface waters more complex and can change their pH value [14]. An important element of safety is scientific studies and engineering achievements aimed at improving design solutions and increasing the reliability of NPP systems and components. The essential service RCS NPP whose reliability, safety, performance of functions and efficiency are influenced by the established water chemistry [15].

1.2. Relevance and goals of research

It is obvious that when operating cooling systems of nuclear power plants, in each specific case it is important to monitor the water-chemical regime of both the RCS itself and the natural water bodies to which their discharge waters fall. This will improve the understanding of the conditions to protect the natural surface waters, and therefore contribute to the environmental safety of the operation of nuclear power plants.

That is why the goal of our research was to analyze the formation of the carbonate system of the Rivne NPP and its influence on changes in the pH levels of the surface waters of the Styr River in order to optimize the use of chemical reagents in water treatment technology minimizing the ecological impact of discharged water on surface waters and improving the effectiveness of the water and chemical regime RCS.

2. Object and methods of research

The carbonate system of process and return water of the Rivne NPP was the object of this study. Water treatment of RCS cooling water is carried out by liming with bicarbonate regime dosage, followed by stabilization treatment with sulphuric acid. The water balance of the RCS of the Rivne NPP is given in (figure 1). Note that in accordance with the national standards of Ukraine requirements regarding the composition and properties of drinking water objects usage,

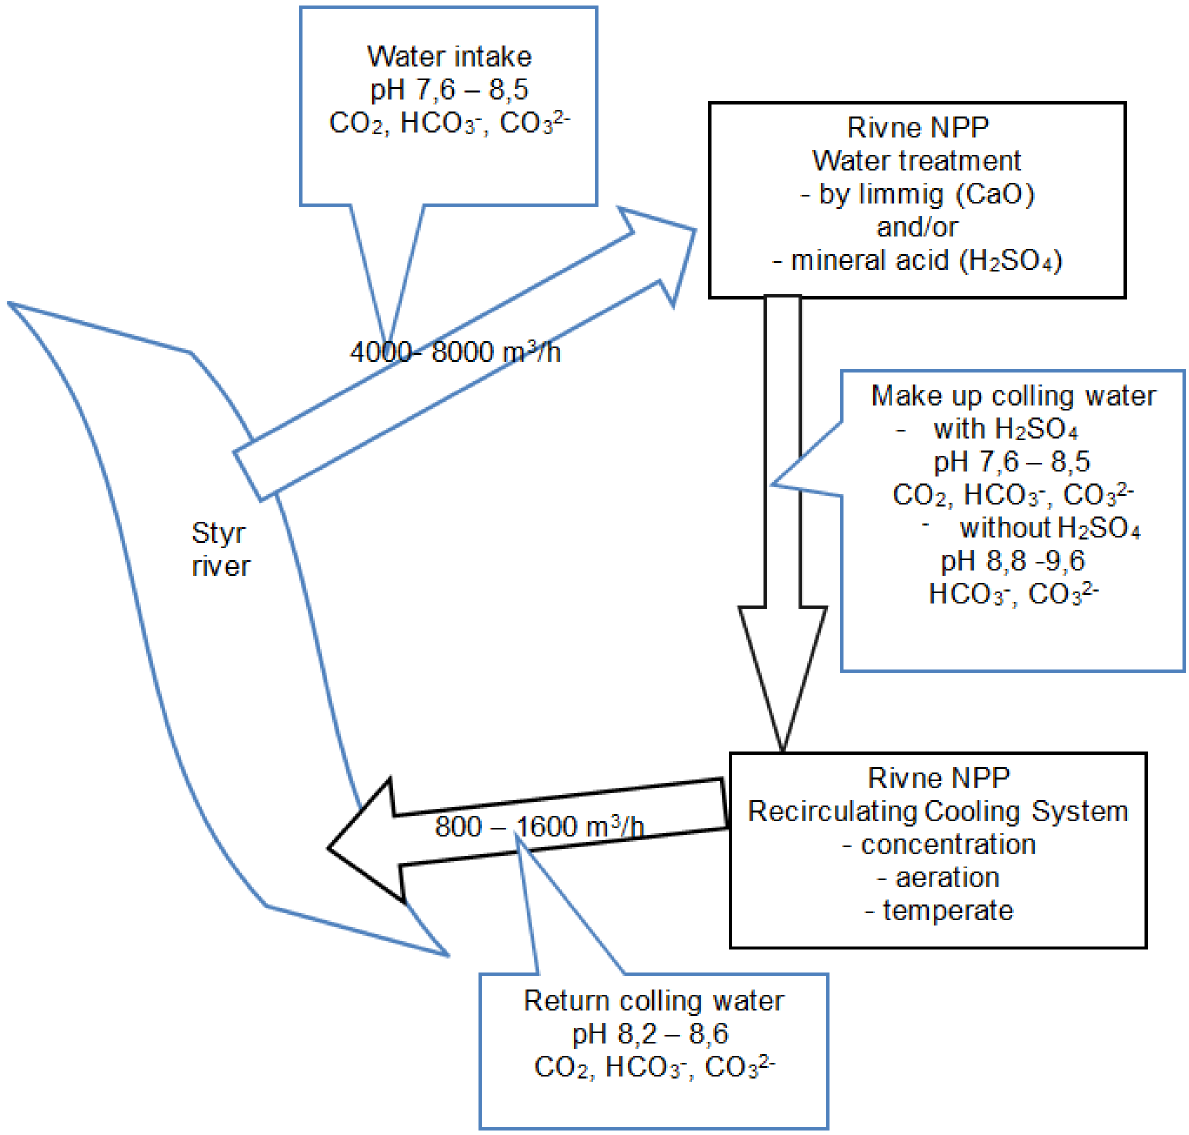

Figure 1. Cooling water balance of the Rivne NPP RCS.

the water of recreation areas reservoirs, as well as the water of fisheries reservoirs should not exceed the values of 6.5-8.5 for pH levels.

The pH was measured with the “I-160” ionometer according to the standard method [16]. The analysis of the chemical control data of RCS was carried out in accordance with the reports on the assessment of the impact of non-radiation factors of the Rivne NPP [17].

3. Results

The dynamics of changes in the pH levels of technological waters of the Rivne NPP and the water of the Styr River are shown in the table 1 and at figure 2, figure 3, respectively. The data shown in the table indicate that the pH level of Styr River meets the requirements of national standards of Ukraine and this is determined by the content of bicarbonate ions.

During water treatment by liming, the pH level increases to 9.4-9.8 units, there is a shift in the carbonate equilibrium with the formation of carbonate ions and precipitation of calcium

Table 1. Descriptive statistics of the results distribution of average annual pH measurements in the process water of the Rivne NPP and the water of the Styr River during water treatment with constant and factorial dose H_2SO_4.

carbonate, the overall hardness is significantly reduced compared to incoming water, and the free alkalinity is formed. During stabilization treatment with sulphuric acid, the alkalinity is neutralized to form bicarbonates. The need for stabilization treatment with sulphuric acid is determined by the quality indicators of RCS cooling water.

Within the work of Rivne NPP RCS, during the period of our research, there were periods of recharge with additional water, neutralized or not neutralized with the sulphuric acid. When feeding with water neutralized with sulphuric acid, an increase in pH level was observed in the RCS cooling water, and the non-neutralized one has a decrease in pH level, which in both cases is due to the accumulation of bicarbonate ions (figure 2, figure 3). Regardless of the method of stabilization treatment, the stabilization of the pH values of RCS cooling water is observed in the range of 8.3-8.7. In all cases, the variation coefficients of the pH change ranges were less than 10%, which indicates their low variability and, consequently, relative constancy of the values.

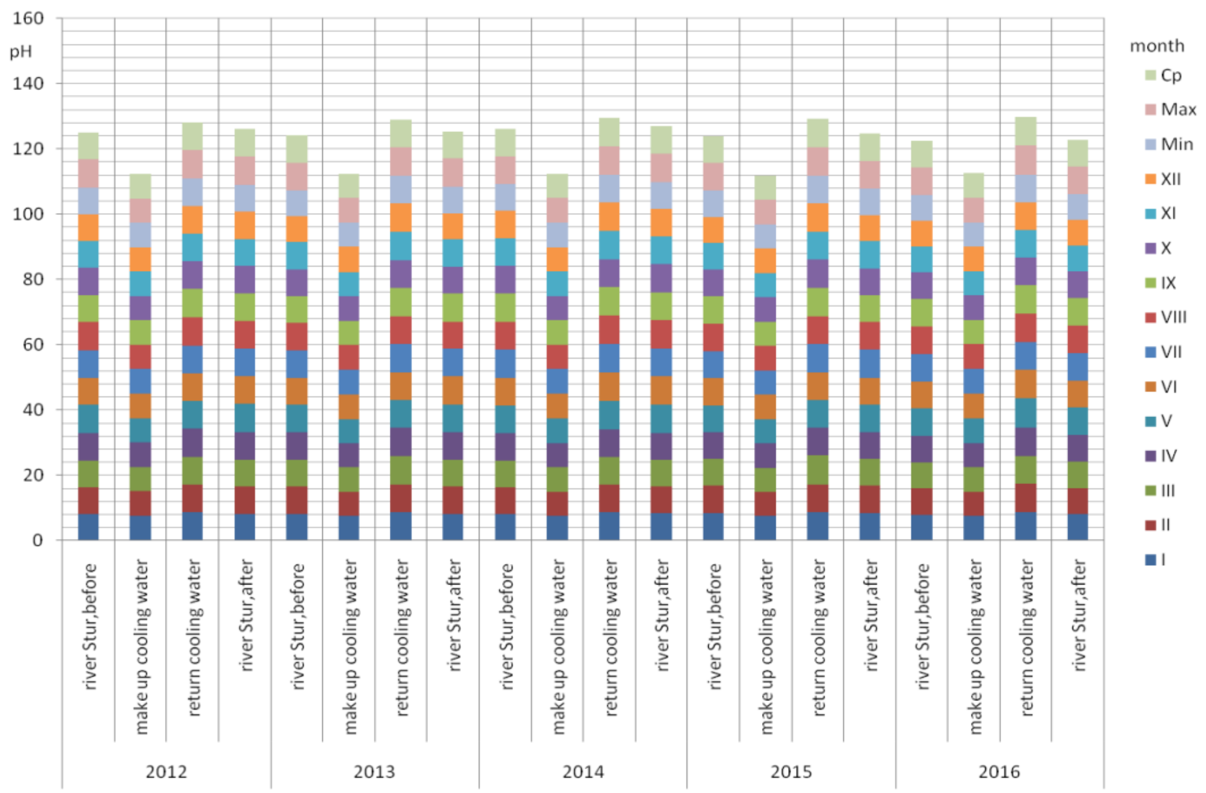

Figure 2. Change of pH in the process water of the Rivne NPP and the water of the Styr River for 2012 – 2016 (diagram with accumulation).

The discharge of return water with a pH level of 8.3-8.7 of the Rivne NPP does not affect the pH values of water in Styr River and compliance with the requirements of national standards of Ukraine (figure 2, figure 3). The data of pH control of the Styr River given in the figure show that the indicator is subject to seasonal fluctuations throughout the year. Thus, in winter, the pH level decreases to 7.5-8.0 units, and in summer it increases up to 7.8-8.5 units.

4. Discussion

When operating RCS, it is important to ensure the water-chemical regime (WCR), in order to prevent the formation of scale, corrosion, and biological interference [2]. According to the results

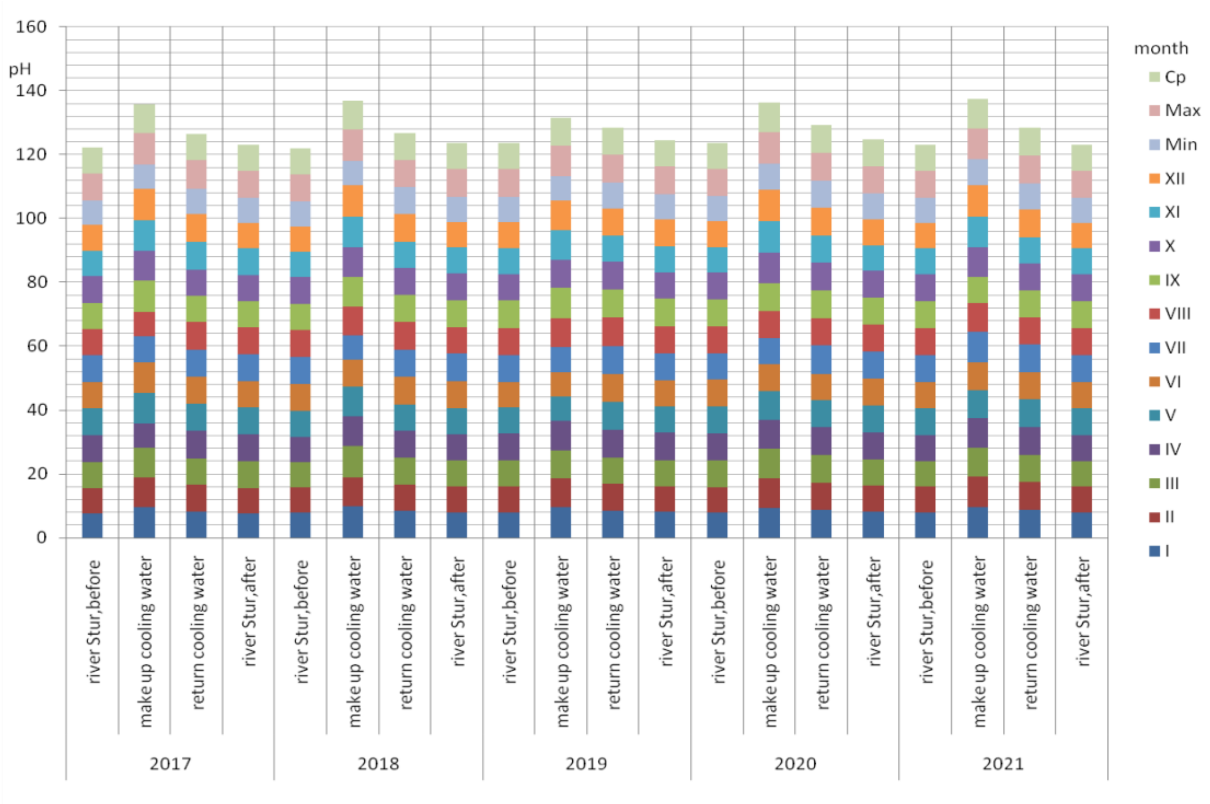

Figure 3. Change of pH in the process water of the Rivne NPP and the water of the Styr River for 2017 – 2021 (diagram with accumulation).

of our research, it was found out that in the technological cycle of the RCS of the Rivne NPP, additional cooling water is completely devoid of carbon dioxide during the pre-liming, and the formation of carbon dioxide occurs when neutralized with sulphuric acid and when heated in heat exchangers by consumers with the release of calcium carbonate sediment. In the cooling tower, when cooling and aeration of cooling water with pH level 9.6 ± 0.2, without pre-stabilization treatment with sulphuric acid, occurs carbon dioxide absorption from the air can be observed to establish the equilibrium of the carbonate system by neutralizing the residual free alkalinity of the pre-limed water, which confirms the control data of cooling and additional water figure 3.

When using untreated inlet water to feed RCS, the scale formation calcium carbonate cannot be prevented even at low levels degree of evaporation for cooling water [13]. Therefore, pre-treatment methods are used, which may include physical, physico-chemical and chemical methods of water treatment. Liming is one of the most common technological solutions for water treatment [10]. The dose of lime used for water treatment determines the value of the pH values of the additional cooling water.

According to the results of our research, during the stabilization treatment with constant sulphuric acid (table 1, figure 2), the free alkalinity of pre-limed cooling water with pH 7.5-7.8 values is already neutralized, the absorption of carbon dioxide from the air with neutralization of the residual free alkalinity in the cooling tower does not occur, when cooling in the cooling tower, it is possible to release carbon dioxide formed during the deposition of calcium carbonate by reaction with an increase in the hydrogen pH index, which is due to the concentration of the sample during evaporation and accumulation of bicarbonate ions for cooling water that has been limed and treated with sulphuric acid and does not contain free alkalinity.

The properties of the carbonate system of water during the stabilization treatment with factorial dosage sulphuric acid (table 1, figure 3) depend on the course of two competing reactions that cause the dissolution of carbon dioxide during aeration with the formation of bicarbonate ions, with a decrease in pH level, and, when evaporation in RCS by the decomposition of bicarbonate ions and the formation of carbonate ions, which increases pH level [12]. That is, the initial distribution state of the carbonate system components determined by the initial pH level is the determining factor for shifting the equilibrium of reactions.

We have noticed seasonal fluctuations in the pH value in Styr River. In particular, a decrease in its values in winter and an increase in summer can be explained by seasonal features of the phytoplankton groups development and an increased manifestation of their photosynthetic activity during the warm period [9]. That is, the change in the pH balance of the surface waters of the Styr River during the year is primarily related to the natural factors.

5. Conclusions

In the study of the equilibrium of the carbonate system in the process waters of the RCS of the Rivne NPP and the natural waters of the Styr river, it was found out that the use of stabilization treatment with sulphuric acid in water treatment (solely to ensure environmental standards for the pH value) is impractical.

Results of factorial and constant sulphuric acid dosing have comparable pH values of the cooling water, therefore accumulation of bicarbonate ions and neutralization of carbonate ions from an ecological point of view does not compensate for the artificial introduction of sulphate ions into natural objects for the use of sulphuric acid only to reduce the pH level of water in order to ensure environmental standards. It is advisable to use sulphuric acid only to normalize the water-chemical regime. Taking this fact into account will optimize the RCS water treatment technology of the Rivne NPP with a guarantee of compliance with the environmentally safe water-chemical regime of the discharge water on the Styr river. RCS are widespread project decision for cooling components and systems of power plants, these results of the study can be also applied to any power plant with RCS, where the pre-treatment of cooling water by liming and stabilization treatment with mineral acid is implemented.

Abstract. The paper forms a neural network model of the investment process of biogas production, which allows increasing the efficiency of the management decision-making process on the feasibility of investing in biogas plants. Biogas plants are becoming widespread in the world, although natural climatic conditions are not favorable for biogas production. But modern technological solutions for insulation of bioreactors, their automation and thermal stabilization, allow obtaining biogas in different latitudes. The construction of biogas plants requires significant capital investment. Therefore, these investments require a detailed feasibility study, including consideration of both technical and economic aspects of biogas production. The authors propose to use the mathematical apparatus of shallow neural networks and create a ten-neuron shallow neural mathematical model with the MATLAB mathematical package, which can serve as a tool to support investment decisions in the implementation of the biogas plant project. The proposed model, in contrast to existing approaches, allows us to take into account both quantitative and qualitative factors, which are obtained analytically, expertly and experimentally. In addition, the proposed model allows combining both economic and technical criteria that affect the decision-making process for investing in the process of biogas production. The calculation of investment attractiveness of introduction of biogas utilization unit for the researched enterprise is given. According to the simulation results, it is determined that the investment attractiveness of the introduction of a biogas plant for the given set of input factors indicates the feasibility of implementing a biogas plant.

1. Introduction

In today's world of economics, humanity faces several important issues related to sustainable development, among which the important goals are to increase the production of energy from renewable sources around the world and ecological production. Permanent increase in energy prices causes a constant increase in production costs and reduces profits. One of the ways to ensure energy saving measures is to use biogas as an alternative energy source. This issue is especially relevant for agricultural producers and the food industry, as they regularly receive a significant amount of organic waste, which should be transformed into biogas. The use of biogas as a way to overcome the energy crisis in developing countries is considered [1]. Yu et al [2] analyzed the complex productivity of single-phase and two-phase anaerobic digestion using a hybrid method and determined that the decisive factors are the yield of biogas, electricity consumption and biofertilizers.

The results of research by Nwokolo et al [3] allow us to conclude that the use of biogas plants provides benefits such as reducing greenhouse gas emissions into the environment and improving energy security. In addition, the use of produced biogas leads to a reduction in purchased energy and waste disposal in the biogas plant based on the system of sewage sludge treatment at treatment plants.

In Europe, biogas is produced in a large number of countries, including Poland [4], Finland [5], Germany [6], Hungary [7]. In particular, more than 1,000 biogas plants were built in Germany from 2000 to 2014 [8]. Some questions connected with the state of biofuel in Ukraine are considered by Stanytsina et al [9], Bogoslavska et al [10].

The construction of biogas plants requires significant capital investment. Therefore, these investments require a detailed feasibility study, including consideration of both technical and economic aspects of biogas production. Nurgaliev et al [11] proposed to assess the efficiency of investing in biogas plants by calculating the classic performance indicators of investment projects with and without discounting, given the rapid change in variables.

Taking into account quantitative and qualitative factors, which are obtained analytically, expertly and experimentally, requires a specialized mathematical apparatus. The best mathematical apparatus, in our opinion, is either the theory of fuzzy logic and linguistic variables or the theory of neural networks.

The aim of the work is to form a neural network model of the investment process of biogas production, which allows us to increase the efficiency of the management decision-making process on the feasibility of investing in biogas plants.

Fuzzy logic theory uses a limited information base, within which fuzzy logical equations are formed and the result is calculated [12–15]. Fuzzy logic theory works in a closed information environment, which is limited by knowledge bases. Neural networks are used for processing large data sets, universal approximation and further training of mathematical models. The neural network is a universal approximator, which is an example of artificial intelligence and allows you to support decision-making based on the results of processing large arrays of quantitative and qualitative information. It is proposed to use the mathematical apparatus of shallow neural networks and create a ten-neural shallow neural mathematical model with the MATLAB mathematical package, which can serve as a tool to support investment decisions in the implementation of the biogas plant project.

2. Results and discussion

The production of agricultural products is accompanied by the constant accumulation of organic waste from animal life, crop products, wood processing, etc. Ukraine produces more than 57,000 tons of organic waste annually [16], the vast majority of which simply pollutes the environment. All these wastes require proper and safe disposal, preferably with the simultaneous production of products necessary for agriculture. One of such directions of ecologically safe utilization of organic waste is biogas production. The process of anaerobic fermentation in bioreactors allows you not only to dispose of environmentally hazardous waste, but also to process it into biogas and valuable organic fertilizer.

Biogas plants are becoming widespread in the world, although natural climatic conditions are not favorable for biogas production. But modern technological solutions for insulation of bioreactors, their automation and thermal stabilization, allow us to obtain biogas in different latitudes. A biogas plant is a complex set of interconnected technological elements of the process of utilization of organic waste with their processing into biogas and biofertilizers. The central element of the biogas plant is a bioreactor, that is an insulated tank with a heating element, stirrer, devices for loading the substrate and removing it, gasholder, process control devices. The process of anaerobic fermentation takes place in a bioreactor, but before the raw material enters the reactor, it must go a long way of collection and preparation. First of all, organic waste must be delivered to the site, then crushed and mixed with water, fed at a certain temperature to the reactor. The output of biogas from different types of organic waste is also different (table 1).

The process of anaerobic fermentation is also significantly influenced by the temperature of

Table 1. Biogas yield and methane content when using different types of waste [3].

Output raw materials	Biogas yield per 1 kg of dry matter	Methane content,%
Waste from cattle	200–300	50
Waste from pigs	340–480	60...75
Horse waste with straw	250	56...60
Potato tops	420	60
Maize stalks	420	53
Wheat straw	342	58
Sunflower husk	300	60
Silage	250	84
Fresh grass	360	52
Beet	430	84
Carrot waste	250	60
Wood sawdust	220	51
Solid sewage sludge	570	70
Fecal sediment	250 – 310	60
Household waste and rubbish	600	50

the fermentation regime, thermal stabilization in the volume of the bioreactor, the fineness of raw materials, etc. In addition to complex technical requirements for the implementation of the waste processing process, the investment process of such a decision is subject to significant restrictions on financial, economic and operational requirements.

Biogas can be burned directly, but taking into account the large number of impurities (about 40% CO_2 + other gases 1..3%), it is better to clean it first. From 1 m^3 of biogas with a methane content of 60%, you can get about 2.5 kWh of electricity, or 2.6 kWh of heat.

The process of implementation of the investment decision on the implementation of the disposal plant requires the assessment of many factors of influence, which have both quantitative and qualitative characteristics. Biogas plants require significant capital investment, stable supply of the reactor with heat and electricity, continuous supply of raw materials, maintenance of temperature in the fermentation environment, etc. The decision to implement a biogas plant at the enterprise must be made comprehensively using modern advances in science and technology. In our opinion, in this case, the optimal method of intellectual decision support is the theory of neural networks [17, 18]. This theory allows us to combine into a single mathematical model quantitative and qualitative factors of the technological process of fermentation, as well as financial, economic and operational components of the process of disposal of organic waste as an investment object. The decision to implement a biogas plant must be made taking into account a large number of influencing factors. Significant cost of installations requires careful analysis of all risks and features of the technological process. In addition to the complex technological requirements for the process of anaerobic fermentation related to the quality of raw materials, temperature and humidity of the substrate, there are a number of human factors related to qualifications, motivation and other factors. In general, we propose to determine the degree of feasibility of implementing a biogas plant by the values of investment attractiveness. For this indicator D, we have proposed ranges of values of factors in which it acquires a certain content saturation. If D belongs to the range of values [0...2], then the implementation of the project for the construction of a biogas plant is impractical. In the range [2...4] the investment attractiveness of the construction process biogas plant is below average, in the range (4...6) it is average, in the range (6...8) it is above average; in the range [8...10] it is the maximum investment attractiveness of the process of implementing biogas plant.

The investment attractiveness of the introduction of biogas disposal plant can be considered in the form of the ratio:

$$\mathrm{D} = f(\mathrm{X}, \mathrm{Y}, \mathrm{Z}), \tag{1}$$

where X is a set of financial and economic factors; Y is a set of technical factors; Z is a set of operational factors.

In turn, the above sets of factors can be deployed in the following dependences:

$$\mathrm{X} = f(\mathrm{x}_1, \mathrm{x}_2, \mathrm{x}_3, \mathrm{x}_4, \mathrm{x}_5), \tag{2}$$

$$\mathrm{Y} = f(\mathrm{y}_1, \mathrm{y}_2, \mathrm{y}_3, \mathrm{y}_4), \tag{3}$$

$$\mathrm{Z} = f(\mathrm{z}_1, \mathrm{z}_2, \mathrm{z}_3, \mathrm{z}_4). \tag{4}$$

Detailed characteristics of factors influencing the investment process, their universal set of variations and linguistic terms for evaluation are given in table 2.

Group of financial and economic factors:

- Factor x_1 – linguistic variable (LV) "Qualification level of personnel" characterizes the level of qualification of personnel that will service the biogas plant. Linguistically, we decided to evaluate this factor in terms of "insignificant, medium, high". It is clear that the higher the qualification level of staff is, the more attractive the process of implementing this decision is.
- Factor x_2 – LV "Dependence on external financing entities" characterizes the degree of borrowed capital in total investment capital and the cost of borrowed capital. The higher the share of borrowing is and the higher the cost of such capital is, the less attractive the investment is.
- Factor x_3 – LV "Level of raw material costs" characterizes the level of raw material costs for a biogas plant. Raw materials can be provided free of charge; raw materials utilization can be paid for or they have to be bought. Purchasing raw materials for biogas production is the least advantageous option when considering alternatives.
- Factor x_4 – LV "Level of capital costs" characterizes the amount of capital investment for the construction of a biogas plant in terms of 1 kWh of electricity produced from biogas. According to research results, depending on the type of raw material and temperature regime, this factor may be in the range of 2...10 thousand euros/kWh. It is clear that the higher the level of capital expenditures is, the riskier the investment is.
- The last factor from the financial and economic block is x_5 – LV "Complexity of logistics" characterizes the complexity of delivery of raw materials for the operation of biogas plants and transportation and storage of fermentation products – biogas and biofertilizers to consumers. The volume of processed biomass is slightly different from the input volume of raw materials, and it can be applied to the fields only in spring or autumn. Therefore, the rest of the time the processed biomass must be stored somewhere. Most of the above factors are estimated in conditional points expertly as it is almost impossible to quantify them.

Group of technical factors:

- Factor y_1 – "Type of raw material". Raw materials play an important role in the process of biogas production. The best raw material is sugar pulp or waste, which contains a large proportion of fat. Potato tops, corn stalks, cattle and pig waste are more difficult to decompose in the bioreactor. The "worst" ones are silage and sawdust.

Table 2. Influencing factors as linguistic variables.

Designation and name of the variable	Universal set	Linguistic terms for evaluation
	Financial and economic factors (X)	
x_1 – LV – "Qualification level of personnel"	$U(x_1) = \{1...10\}$ (points)	insignificant, medium, high
x_2 – LV "Dependence on external financing entities"	$U(x_2) = \{0...10\}$ (points)	insignificant, medium, high
x_3 – LV "Level of raw material costs"	$U(x_1) = \{1...10\}$ (points)	low, medium,high
x_4 – LV "Level of capital costs per 1 kWh of electrical energy"	$U(x_4) = \{2...10\}$ (thousand euros)	small, medium, high
x_5 – LV "Complexity of logistics"	$U(x_5) = 1 ... 10$ (points)	low, medium, high
	Technical factors (Y)	
y_1 – LV "Type of raw material"	$U(y_1) = 1...10$ (points)	acceptable, satisfactory, optimal
Y_2 – LV "Crushing of raw materials"	$U(_y2) = 1...10$ (points)	insignificant, medium, high
y_3 – LV "Temperature mode"	$U(y_3) = 20...55$ (degrees, °C)	cryophilic, mesophilic, thermophilic
Y_4 – LV "Thermal stabilization of the fermentation process"	$U(y_4) = 20...3$ (degrees °C)	insufficient, medium, high
	Operational factors (Z)	
Z_1 – LV "Technical complexity of the operational process"	$U(z_1) = 10\ 90$ (percent)	insignificant, medium, high
Z_2 – LV "Level of purification of biogas from impurities"	$U(z_2) = 0\ 99$ (points)	low, medium, high
Z_3 – LV "Level of automation of the production process"	$U(z_3) = 10\ 90$ (percent)	low, medium, high
Z_4 – LV "Degree of reduction of harmful emissions into the environment"	$U(z_4) = 10\ 90$ (percent)	low, medium, high

- Equally important is the crushing of raw materials, which is described visually by experts in the range of {1...10} points – factor y_2. The intensity of the anaerobic fermentation process is directly dependent on the ambient temperature.
- There are three main temperature regimes: "cryophilic" ($T_{opt} = 20°C$); "mesophilic" ($T_{opt} = 3242°C$); "thermophilic" ($T_{opt} = 4851°C$). Factor y_3 – LV "Temperature mode" characterizes the temperature regime in the reactor in the range 20...55°C. The temperature in the environment should be uniform. This is quite difficult to achieve, given the large volumes of the reactor, the presence of stagnant zones under the heating elements, the technological limitations of the mixing speed of the substrate. Thermal stabilization of the fermentation process is estimated by the value of the temperature difference between the hottest and the coldest zone of the reactor volume. It is generally accepted that the temperature difference in the reactor zone should not exceed 3 °C.

Main *operational factors*:

- The technical complexity of the operational process is assessed by experts and is in the range from [10...90]%.
- The level of purification of biogas from impurities is estimated in the range [0... 99]% and is determined by technological calculations.
- The level of automation of the production process and the degree of reduction of harmful emissions into the environment are estimated in the same range.

To develop a mathematical model of intellectual support of decision-making to assess the investment attractiveness of a biogas plant project, there is a need to form a knowledge matrix – concentrated coded information determined by technological calculations, expert evaluations, analytical calculations. The knowledge matrix is a table where the numerical value shows the results of various types of research. The fragment of the knowledge matrix is given in table 3. The sample size for building the model was more than 200 data rows.

Table 3. The fragment of the knowledge matrix.

To build a neural network that would solve the problem with some accuracy, we propose to use a shallow neural network, the block diagram of which is shown in figure 1.

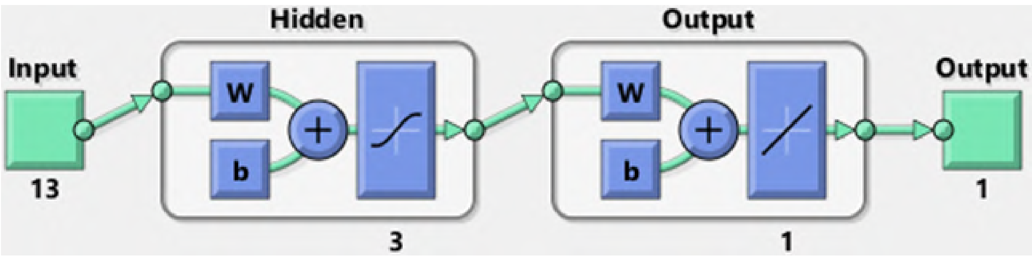

Figure 1. Block diagram of a two-layer neural shallow network.

A two-layer network of direct feed with hidden sigmoid neurons and neurons of linear output can quite successfully solve the problem without excessive accuracy and complexity of calculations (figure 2). This network can also be called a Multilayer Perceptron (MLP) as it is a two-layer neural network with a nonlinear hidden layer that can be used for classification and regression tasks.

The network will be studied according to the Levenberg-Marquardt backpropagation algorithm. The Levenberg-Marquardt algorithm is an optimization method used for adjusting

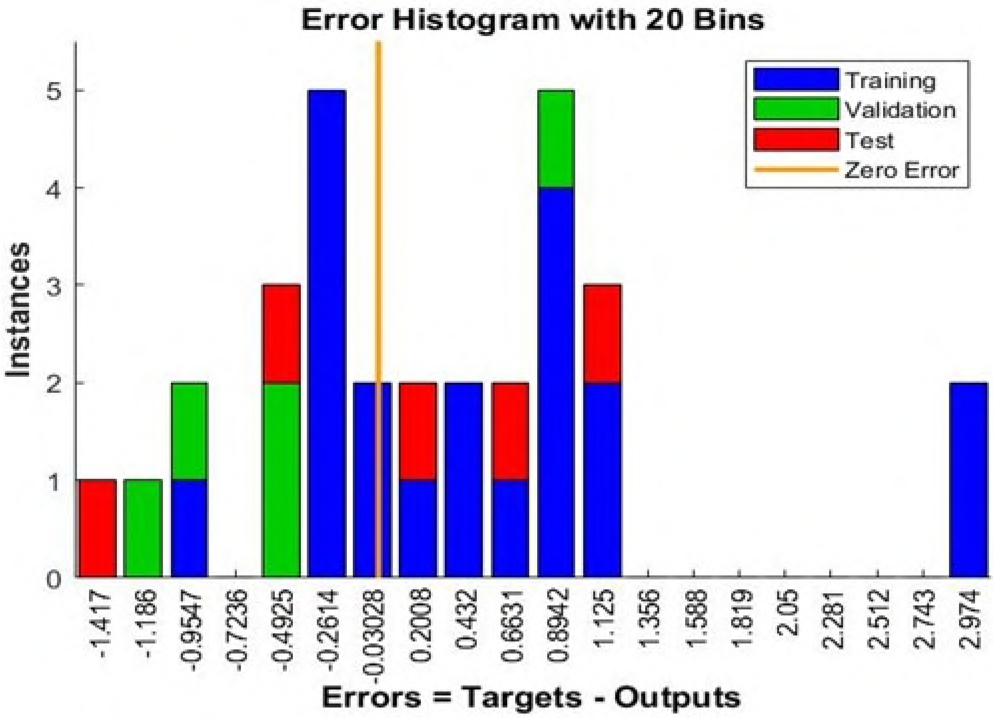

Figure 2. Histogram of errors.

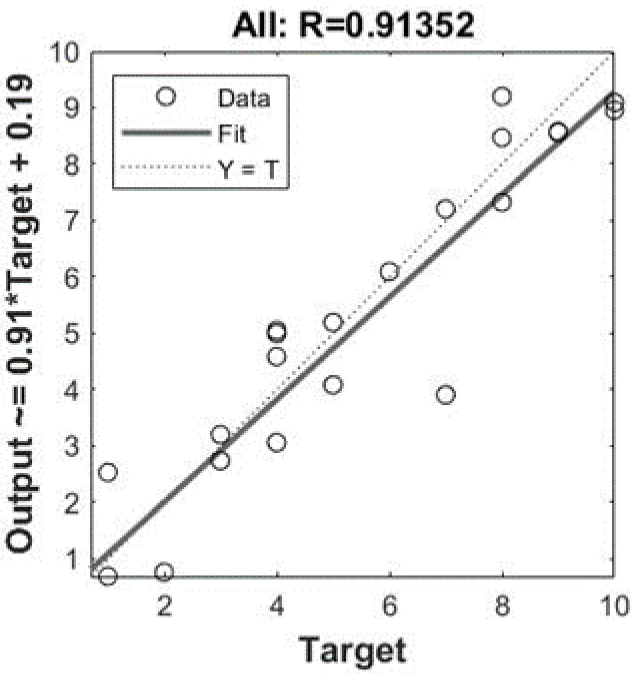

Figure 3. Regression and value of the coefficient of determination.

the weights of a neural network during training. This algorithm is an iterative method based on gradient descent and is designed to solve optimization problems with nonlinear constraints. After loading the data into the MATLAB mathematical package, we performed calculations and determined the calculation errors (figure 3), as well as made a regression graph and determined the coefficient of determination, which in our case was R = 0.91, indicating a high connection density.

For practical use of the proposed model, it is best to create a Simulink model in the MATLAB package. This model has only three blocks: the constant block, where the input values are entered in the form of a vector; the block of the neural network and the visualization block.

In our case – the monitor, where the simulation result is shown as a number (figure 4).

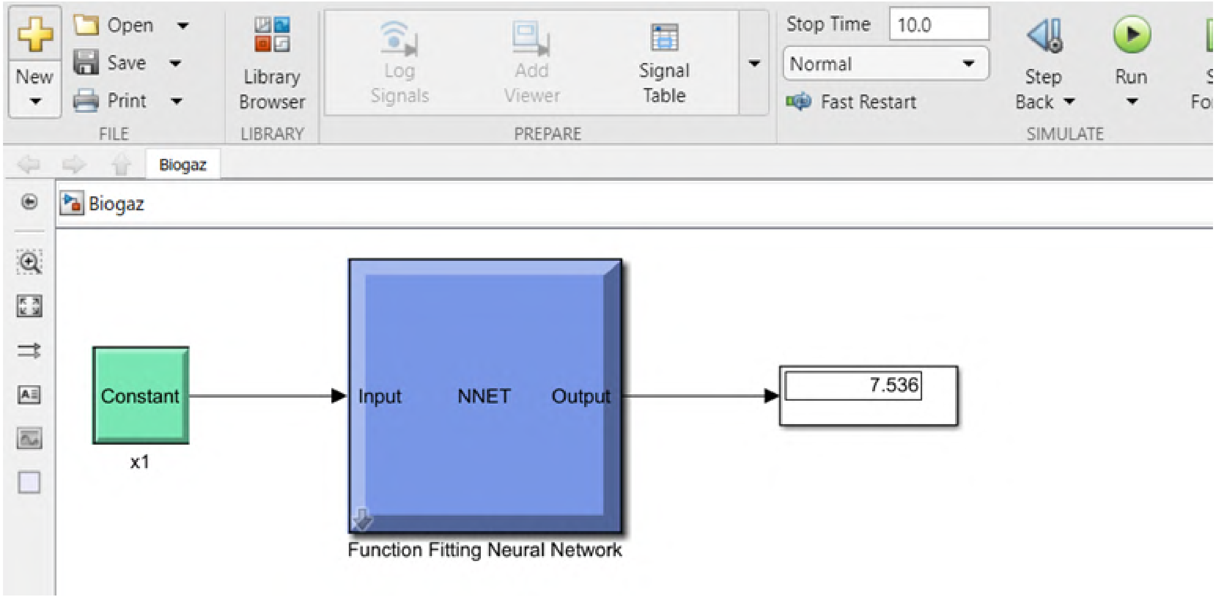

Figure 4. Fragment of the window of the Simulink package of the MATLAB program with the program of neural network modeling.

The decision-making on the feasibility of investing in the construction of a biogas plant is as follows: analytically, expertly or experimentally, the input values are entered into the table. Then their values are loaded into the vector column of the program.

After the calculation, the program displays on the block the value of the investment attractiveness of the introduction of biogas disposal plant (table 4).

According to the simulation results, it is determined that the investment attractiveness of the introduction of a biogas plant with a given set of input factors is D = 7.54, which corresponds to the range "above average", i.e. the plant can be implemented.

3. Conclusions

Thus, the paper proposes a neural network model of the investment process of biogas production.

Taking into account quantitative and qualitative factors, which are obtained analytically, expertly and experimentally, requires a specialized mathematical apparatus. The best mathematical apparatus, in our opinion, is either the theory of fuzzy logic and linguistic variables or the theory of neural networks.

It is proposed to use the mathematical apparatus of shallow neural networks and create a ten-neuron shallow neural mathematical model with the MATLAB mathematical package, which can serve as a tool to support investment decisions in the implementation of the biogas plant project.The proposed model, in contrast to existing approaches, allows us to take into account both quantitative and qualitative factors, which are obtained analytically, expertly and experimentally.

Table 4. Values of input and output variables.

Designation and name of the variable	Universal set	Input values of variables	The value of the output variable D
	Financial and economic factors (X)		
x_1 LV – "Qualification level of personnel"	$U(x_1) = \{1...10\}$ (points)	7	
x_2 – LV "Dependence on external financing entities"	$U(x_2) = \{0...10\}$ (points)	3	
x_3 – LV "Level of raw material costs"	$U(x_1) = \{1...10\}$ (points)	6	
x_4 – LV "Level of capital costs per 1 kWh of electrical energy"	$U(x_4) = \{2...10\}$ (thousand euros)	5	
x_5 – LV "Complexity of logistics"	$U(x_5) = 1 \ldots 10$ (points)	3	
	Technical factors (Y)		
y_1 – LV "Type of raw material"	$U(y_1) = 1...10$ (points)	8	
Y_2 – LV "Crushing of raw materials"	$U(_y2) = 1...10$ (points)	3	D=7.54
y_3 – LV "Temperature mode"	$U(y_3) = 20...55$ (degrees, °C)	50	
Y_4 – LV "Thermal stabilization of the fermentation process"	$U(y_4) = 20...3$ (degrees °C)	8	
	Operational factors (Z)		
Z_1 – LV "Technical complexity of the operational process"	$U(z_1) = 10\ 90$ (percent)	20	
Z_2 – LV "Level of purification of biogas from impurities"	$U(z_2) = 0\ 99$ (points)	60	
Z_3 – LV "Level of automation of the production process"	$U(z_3) = 10\ 90$ (percent)	50	
Z_4 – LV "Degree of reduction of harmful emissions into the environment"	$U(z_4) = 10\ 90$ (percent)	70	

In addition, the proposed model allows us to combine both economic and technical criteria that affect the decision-making process for investing in the process of biogas production. The calculation of investment attractiveness of introduction of biogas utilization unit for the researched enterprise is given.

According to the simulation results, it is determined that the investment attractiveness of the introduction of a biogas plant for the given set of input factors indicates the feasibility of implementing a biogas plant.

Abstract. A brief analysis of the mining industry impact on the environment is provided. It is proposed to assess the ecological situation of water bodies on the territory of Iron Ore Dressing Works (GOK) according to the magnitude of ecological risk (e.g. Iron Ore Dressing Works (Northern GOK)). Calculations of ecological risk values based on the content of microcomponents in the water were carried out for man-made (tailings storage) and natural water bodies (the Saksahan river, a pond in the Nedayvoda stream). It was concluded that over time (from 2014 to 2020) the ecological risk of most water bodies is increasing from 0.17 in the Saksahan river to -2.53 in tailings storage. The complex ecological situation on the territory of the Northern GOK proves the need to implement more effective environmental protection measures in order to achieve the criteria of sustainable development.

1. Introduction

The growth of humanity's needs set the global task of providing food with the necessary caloric content and composition, water of an acceptable quantity and quality, territory that provides many aspects of human activity, energy that does not cause global geo-ecological crises, and products of industrial activity that do not lead to an unacceptable level of environmental pollution. These needs are steadily growing, moving the ecosphere from a crisis, but still stable state to an unstable one and with further development of instability – to a global catastrophe.

The mining activity of the regions significantly affects their sustainable development. It can be a source of employment for local residents, a source of state income, an engine of economic growth and development of remote areas. However, significant environmental impacts and inequitable distribution of economic benefits can exacerbate instability and cause conflict.

Each problem of the mining industry is local, but the fundamental issues of mining in the relevant format are international in nature.

Sustainable mining is a theoretical and highly unlikely goal to achieve. Metals and minerals are non-renewable resources, and their use can only be sustainable if consumption declines, and the rate of decline is going to be greater than the rate of depletion. From a practical perspective, achieving sustainability in the mining industry is a distant prospect, but many mining companies and industry associations are moving towards more economically, environmentally and socially responsible business practices.

Mining invariably benefits people and harms the environment. At the stages of their extraction and processing, numerous environmental problems arise.

First of all, during the extraction and processing of minerals, a large geological cycle is disrupted, in which various systems are involved. As a result, there is a great impact on the ecology of the mining region, and such an impact has negative consequences.

Impact of mining on the lithosphere [1]

1. The development of deposits of dense rocks is accompanied by significant extraction of forested and agricultural lands. Mining leads to significant changes in the landscape: the creation of anthropogenic forms of meso-relief – quarries, dumps.
2. Possible activation of geological processes (karst, landslides, scree, subsidence and displacement of rocks). During underground mining, subsidence pits and sinkholes are formed.
3. Mechanical disturbance of soils and their chemical pollution.

Impact of mining on the atmosphere [1, 2]:
As a result of the processes of primary processing of mined ores, large volumes of mine methane, sulfur, and carbon are emitted into the air. In addition, a large amount of dust enters the air during mining. When 1,000 tons of explosives are used, about 40 million m^3 of atmospheric air is polluted, exceeding the limit of permissible concentrations tenfold, and its spread is possible over 15 km. As a result of mass explosions in quarries, from 0.027 to 0.170 kg of dust is formed per 1 m^3 of rock.

Every day, up to two kilograms of dust falls on the territory adjacent to the quarries, as a result, the soil remains buried under a half-meter layer for many years, and often forever, and, accordingly, loses its fertility.

It should also be noted the negative impact and composition of explosives used in open pit development. Harmful gases produced as a result of the explosion are released into the air for 10–15 hours [2].

Impact of mining on the hydrosphere
The development of mineral deposits by an open method causes not only the degradation of the earth's surface in the area of mining operations, but also a sharp change in hydrological and hydrogeological conditions, which lead to a change in the quality of surface and underground waters [1]. As a result of the extraction of natural raw materials, reservoirs and underground waters are depleted, swamps are drained.

Surface waters suffer from pollution as a result of mineral extraction and processing. As in the atmosphere, a large amount of salts, metals, toxic substances, and wastes get into the water. As a result, microorganisms living in water bodies and fish die. If people use polluted water for their economic needs and for food, it leads to deterioration of the health of the population.

2. Methods

Assessment of the ecological situation of a certain region or the entire country is an urgent task today [3]. Environmental risk has an important place in the environmental assessment of the current or projected situation. Environmental risk – at all levels: from local to global – assessment of the likelihood of negative changes in the environment caused by anthropogenic or other influences. It is important to note that any economic activity always has an environmental risk.

There are four main directions in risk assessment: engineering, modeling, expert and social. In the modeling direction, mathematical models of processes that lead to undesirable consequences for humans and the environment when using harmful chemicals and compounds are developed.

The theory of probability and the means of mathematical statistics are used for the quantitative analysis of environmental risk. A peculiarity of the assessment of environmental risks is their dynamism, that is, there is a need to monitor the state of the environment as a whole and its individual components.

For water bodies, ecological risk is the probability of undesirable consequences in water ecosystems and their components as a result of anthropogenic and natural factors, including a decrease in water quality. Several methods of ecological risk assessment have been developed and used both for individual regions and river basins, as well as for certain sections of rivers subject to anthropogenic pressure.

This study used the method of environmental risk assessment [4] according to the formulas:

$$Risk = -\ln(P), \tag{1}$$

where:

$$P = \frac{\sum_i n_i}{N}, \tag{2}$$

where:

$$\sum_i n_i = \sum_i \frac{C_i}{TLV}, \tag{3}$$

where C_i is the concentration of the different pollutant (DP) that exceeds the threshold limit value (TLV) [5]; N is the total number of DP analyzed (content greater than TLV and less).

3. Results

The results of hydrochemical observations on the territory of the Northern GOK (Kryvyi Rih), which were conducted by the State Enterprise "Ukrchormetgeology", were used to assess the environmental risk.

The water objects of the natural-technogenic complex of Northern GOK include the tailings storage facility and the section of the Saksahan river, ponds and man-made water objects (figure 1).

The Northern GOK tailings pond has been in operation since 1963. The main dam of the Northern GOK tailings pond is located at a distance of 2.5 km from the mouth of the Petrykov creek, which flows into the Saksahan River. Also, in Petrykov creek along the outer contour of the right-bank enclosing dam, tailings, two emergency tanks were created: the first – in the western part and the second – in the northern part of the tailings. The area of the tailings pond is 1295 ha (of which the tailings pond itself is 980.0 ha, the circulating water pond is 315.0 ha). The length of the tailings pond is 17.3 km (tailings pond – 11.0 km, circulating water pond – 6.3 km). The contour of the tailings pond is closed by a 1.2 km long dividing dam, which separates the circulating water supply pond from the tailings pond itself. In addition to sludge pulp, quarry water (2.5 million m^3 / year), mineralization mine water (5.5 million m^3 / year), wastewater from treatment plants (36.15 thousand m^3 / year), and precipitation are discharged into the tailings pond, and surface filtration waters that were made from drainage systems built around the storage [6].

Preliminary studies have established that a persistent geochemical and hydrochemical anomalies has formed on the territory of the Northern GOK.

The center of the anomalies is a tailings, which pond's water has an elevated content of microcomponents: lead, cadmium, vanadium, bromine [6]. The content of some microcomponents also has an increased in the water of the river Saksahan and in the water of the pond Nedayvoda.

The results of the ecological risk calculations of water bodies on the territory of the Northern GOK are presented in figure 2.

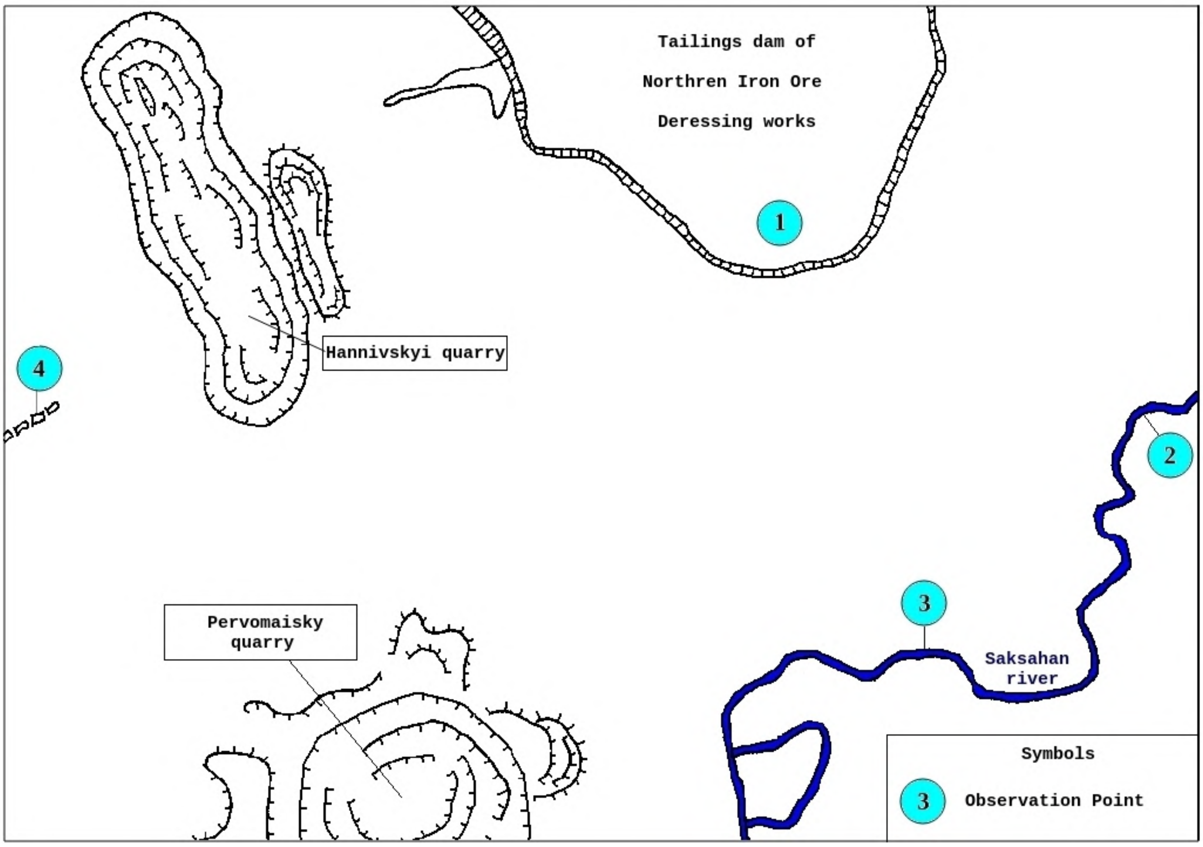

Figure 1. Map of Northern Iron Ore Dressing Works in Kryvbas with observation points for chemical composition of water (downstream) № 1 – Tailings dam NorthernIron Ore Dressing Works; № 2 – the first water meter post, the Saksahan River; № 3 – the second water meter post, the Saksahan River; № 4 – pond in the beam Nedaivoda.

According to the results of the calculations, it can be concluded that in general the ecological situation in the water bodies of the Northern GOK is deteriorating. The greatest concern is the too high content of bromine, both in the water of the tailings pond and in the water of water bodies. Let me remind you that bromine belongs to the second class of danger [5]. Bromine is a chemical element that is energetically accumulated by plants, animals in landscapes [7]. An excess of bromine in the human body leads to a decrease in the concentration of iodine in the hormones of the thyroid gland (hyperthyroidism), and also contributes to the rapid release of chloride ions by the kidneys.

The main symptoms of excess bromine are: memory impairment, insomnia, skin rashes, indigestion, bronchitis, rhinitis, as well as possible neurological disorders. Since this trace element is considered a very poisonous substance, the ingestion of a large amount of it into the human body causes serious consequences, even fatal. [8]

As mentioned earlier [6], the main source of bromine in the tailings pond is mine water. Among the heavy metals, an increased content of lead and vanadium is always noted, which enter the water of the tailings pond and the water of surface water bodies from the enrichment tails.

Among the studied natural and man-made water bodies, the greatest ecological risk is noted in the tailings stogare (-2.53) as of 05/04/2020. It should be noted that over time the ecological risk increases in the tailings stogare and in the pond Nedayvoda. In the Saksahan River, changes

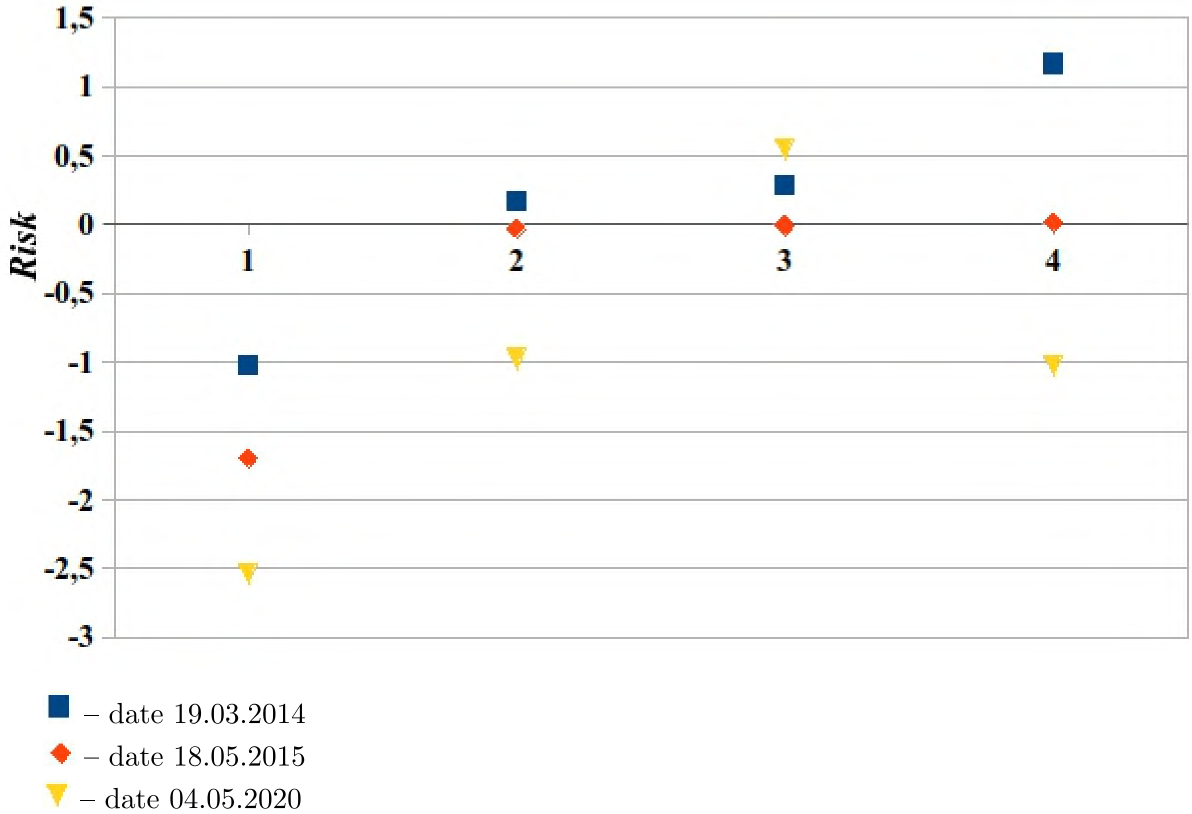

Figure 2. Environmental risk schedule for water bodies on the territory of the Northern GOK by observation points: 1 – Tailings dam Northern Iron Ore Dressing Works; 2 – the first water meter post, the Saksahan River; 3 – the second water meter post, the Saksahan River; 4 – pond in the beam Nedaivoda (2014, 2015, 2020).

in environmental risk values over time do not have a clear dependence. This is due to the fact that the hydrochemical regime of the river is formed under the influence of not only man-made but also natural factors.

It should also be noted that information for assessing the environmental situation in Kryvbas is not publicly available. This is also noted in the report [9, 10] and is a significant drawback of mining and blasting enterprises. Thus, the Metinvest company received zero marks for the Hannivskyi and Pervotravnev quarries, as it did not provide evidence to verify the information or did not provide information at all. Therefore, in order to achieve world standards in the field of mineral extraction according to the criteria of sustainable development, Ukrainian companies still need to pay a lot of attention to the issues of openness of information about nature protection in all main directions: protection and rational use of land, atmosphere, water resources, subsoil, managing of production waste.

4. Conclusions

The mining industry has a significant effect on the ecological state of water bodies, which is confirmed by the calculated value of ecological risk. It was determined that the water of the tailings storage has the greatest environmental risk (-2.53 on 05/04/2020), the Saksagan River (0.17 on 03/19/2014) has the lowest. The magnitude of ecological risk increases over time in almost all water bodies. The proposed method of calculating environmental risk for water bodies

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012104 doi:10.1088/1755-1315/1254/1/012104

can be used to analyze the effectiveness of environmental protection measures and sustainable development of mining areas.

Abstract. An increase in the population and an increase in the negative impact on the environment requires a review of the business organization model. Particular attention is paid to agriculture, which faces the task of solving the food problem on a global scale. At the same time, this industry is one of the leading polluters of the environment. The analysis of statistical data proves the low level of value added that is created in agriculture. The proposed agribusiness ecosystem model allows for a balanced development of agriculture and related industries based on four areas: economic, social, environmental, and innovative. Innovative solutions for all participants in the business ecosystem are based on the transition to a circular economy model using Industry 4.0 tools at all levels of system management: raw material suppliers, agricultural manufacturers, processors, customers, and government.

1. Introduction

A significant increase in the population, industrial and agricultural production, the use of vehicles, and other factors in recent decades have affected the deterioration of the environment, the increase in social and environmental problems, etc. In particular, agriculture is faced with the important task of solving the food problem. According to Agritech Tomorrow [1], population growth and food demand require an increase in crop production of at least 23% to meet the current standard of living.

Traditional production methods and technologies used in this industry cause the aggravation of such global problems of humanity as pollution of the atmosphere and hydrosphere, land degradation, and destruction of biodiversity [2]. Over the last decade, there has been a reduction in the world's forest cover by a third, a significant loss of biodiversity. The rate of growth in the volume of freshwater use exceeds the rate of population growth. There is a high level of soil pollution due to the intensive use of chemical fertilizers and synthetic pesticides. According to experts, about a quarter of global soils have undergone degradation [3]. In addition, agriculture and land use lead to more than 30% of global greenhouse gas emissions that cause climate change [4]. The war in Ukraine has not only socio-economic but also large-scale environmental consequences. Today, there are a number of studies on possible options for the ecological reconstruction of our country [5]. The problem of revising the system of production organization and business processes requires an immediate search for solutions. Since agriculture makes up a significant share of Ukraine's GDP, it is important to introduce innovative methods of organizing production processes in this industry. The European Union has adopted the Green Deal [6], which contains a number of requirements and obligations for manufacturers to comply with the transition to a circular economy model. In contrast to the traditional linear economy, the circular economy involves a closed cycle regarding production, consumption, and recycling, thus reducing the amount of resource consumption, waste, and emissions. Since Ukrainian agricultural enterprises supply a significant part of their products to EU countries, they must comply with the requirements of this agreement and reorient their organizational chains. In turn, this requires the introduction of innovative technologies and management methods to ensure the balanced development of agriculture and related sectors of the national economy.

2. Literature review

The rationale for the need to move from a linear to a circular economy model has been actively considered in the scientific literature in recent years [7–9]. The transition to a circular economy will help keep the value of resources and products at a high level, as well as minimize the production of waste. Government policies of different states based on public-private partnerships to implement the 3R (reduce, reuse, and recycle) model will help improve the efficiency of natural resource use and take a step forward toward achieving sustainable development goals [10].

The need to build supply chains based on the principles of a circular economy is substantiated in [11]. The authors prove that, despite the various external problems that affect the adoption of a particular decision of each company, the inclusion of a transition strategy to a circular economy allows companies to provide environmental advantages in the competition. The relevance of finding ways to solve environmental problems is substantiated in [12, 13], where the authors proposed a number of innovative solutions to solve this problem. At the same time, ensuring a balanced development of society requires taking into account not only environmental factors when building a model for further development [14]. Both when working in the domestic market of the country, and when entering foreign markets, it is necessary to take into account the social factor. In [15], a team of scientists proved the strengthening of social capital and the promotion of responsible research and innovation when a company enters the international level.

The transition to a circular economy, taking into account social indicators, contributes to the formation of the company's reputation and efficiency, and also allows it to enter the so-called circle of charity. At the same time, the existence of a gap between theoretical approaches and practical aspects of the implementation of the circular economy model is noted by scientists in the study []. A conscious choice is needed for all participants in the economic system in the transition to a circular economy, which will ensure their cooperation in a more holistic way. When defining the basic principles of the circular economy, some scientists distinguish between 3R (reduce, reuse, and recycle) [10], 4R (reduce, repair, remanufacture and recycle) [] or 5R (rethink, reduce, reuse, repair, recycle) [16, 17]. The development of innovative technologies allows the introduction of new tools to achieve the principles of a circular economy. In particular, work [18] examines the expected contributions of the introduction of Industry 4.0 tools for the implementation of the circular economy model. For an effective transition to a circular economy model, it is advisable to understand the essence of this process and the interests of all participants: government, suppliers, consumers, international organizations, etc [19].

The purpose of this study is to improve the scientific and methodological foundations for the implementation of the circular economy model based on the ecosystem approach, taking into account the innovative solutions of Industry 4.0.

3. Application of a systematic approach to creating a sectoral economy

Population growth increases the urgency of finding ways to solve the food problem of mankind. Ukraine is one of the key suppliers of agricultural products on the world market. Moreover, in recent decades, there has been a clear trend of reorientation of our state from industrial to agrarian (figure 1).

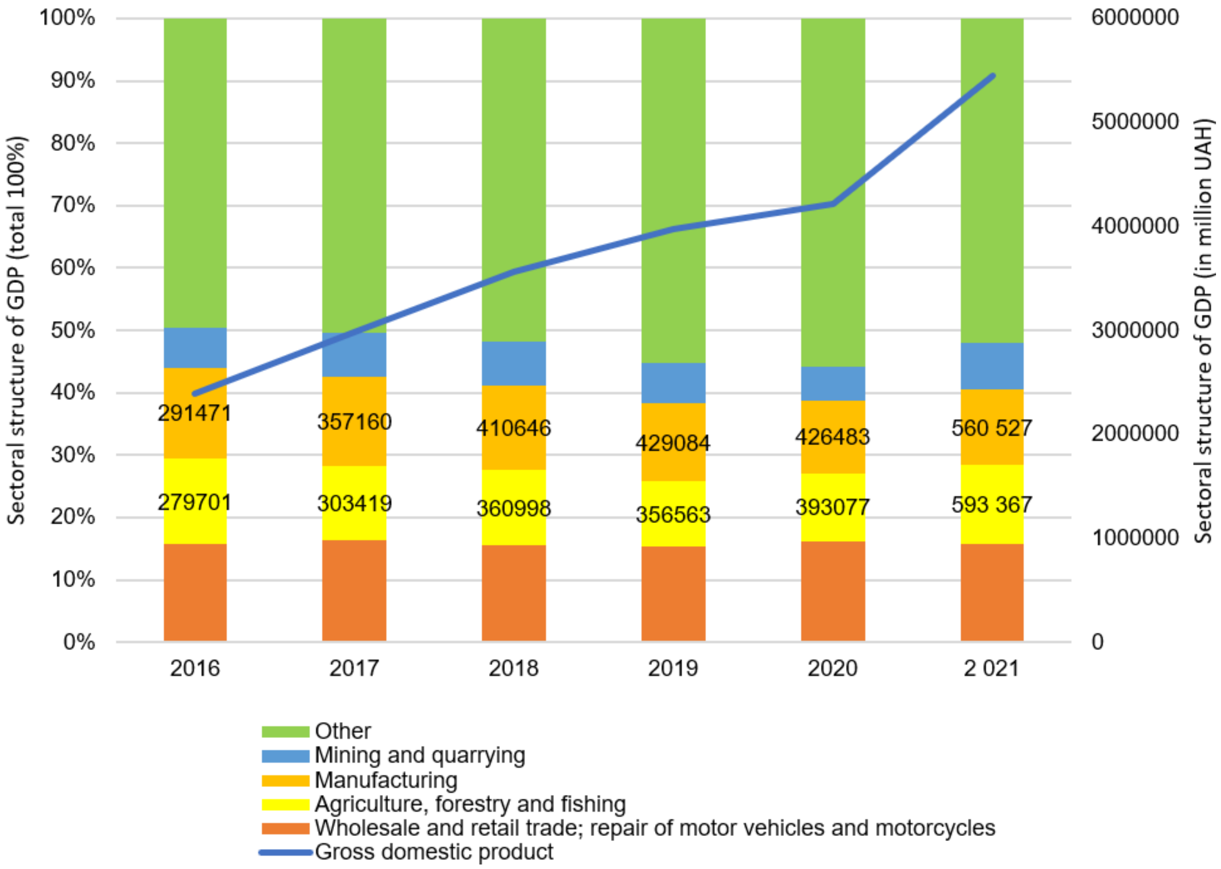

Figure 1. Structure of Ukraine's GDP, 2016 – 2021 (according to [20]).

As seen in figure 1, the share of agriculture is growing and is 10% of GDP in 2021. In turn, the share of the processing industry is gradually declining.

Comparing the share of agriculture in the country's GDP with European countries, this indicator is higher in Ukraine, and it is also higher than the world average (figure 2).

The problem of domestic agriculture is the low value added. For comparison, in European countries, the added value is several times higher (figure 3). In 2019, value added per worker in Ukraine amounted to USD 4,888 against USD 25,476 in European countries.

Value added is determined by the amount of value added at each stage of production, which increases its consumer properties. The added value is determined by the added value of the goods (products), which is formed in the process of procurement, processing, storage, and sale of products at the enterprise [23]. Thus, value added includes labor costs, depreciation, taxes, and profits. The low level of value added in the country indicates a low level of processing of input raw materials (materials), as a rule, is associated with a low level of science intensity of the industry.

In agriculture, value added is created by growing plants or animals. Technologies used in domestic agriculture have a relatively low level of innovation. Leading European countries have a significantly higher level of the added value of agricultural products due to the introduction of an integrated approach, namely: not primary raw materials, but processed products are sold, including for export. Thus, by developing the processing industry within the country, the state

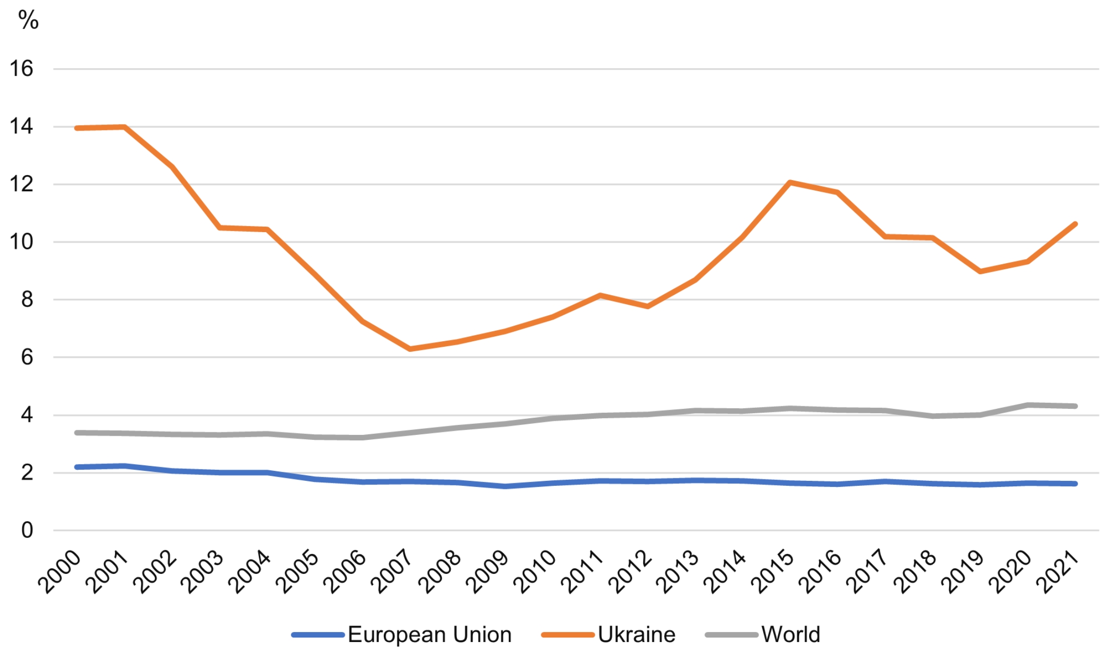

Figure 2. The share of agriculture in the country's GDP, 2000 – 2021 (according to [21]).

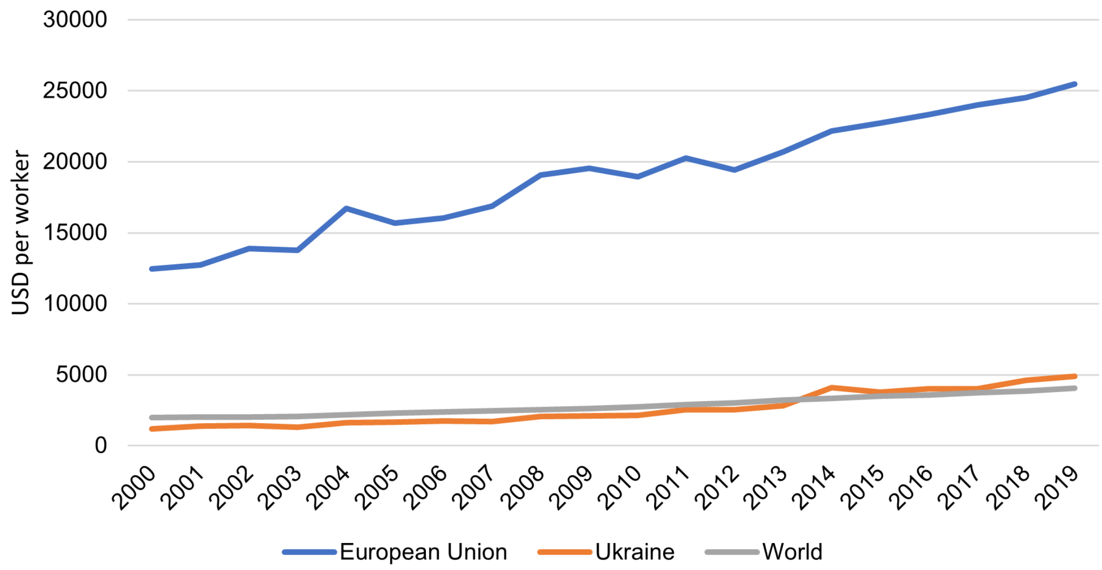

Figure 3. Agriculture, forestry, and fishing, value added per worker (constant 2015 USD) (according to [22]).

simultaneously stimulates the growth of the share of value added of the corresponding products (sector of the economy). To increase the level of the added value of domestic products, we consider it expedient to support the development of processing industries, which will allow us to reorient the country's economy from a supplier of raw materials to foreign markets to a supplier of finished products. This applies not only to agriculture but also to other industries, including metallurgy, which is the main exporter in Ukraine. At the same time, it is necessary to apply a systematic approach to building a sectoral economy. In the conditions of a circular economy, which provides for coordinated supply chains, sectoral relationships should be clearly built, taking into account the purely economic interests of individual economic agents, and taking into account the general economic effect. This approach will simultaneously reduce the country's import dependence since domestic manufacturers will come to replace foreign suppliers of the same household goods. This is especially true at the time of the post-war recovery of the Ukrainian economy.

4. An ecosystem approach for organizing a model of a circular economy on the example of agriculture

A feature of the introduction of the circular economy model in agriculture is not only individual steps to close the circle (processing of consumer waste), but the possibility of involvement in mutual supplies at the stage of production and use. To implement a circular economy in the agricultural sector, it is proposed to use an ecosystem approach. For the first time, the concept of an ecosystem in the economy was introduced by Moore, who proposed considering a company not as a separate economic player in the market, but as an element of a business ecosystem that takes into account several industries [24]. To date, there are various approaches to determining the essence and characteristics of a business ecosystem, taking into account the type of activity, its scale, and management methods. In the course of the study, an ecosystem agribusiness model was developed (figure 4), which includes both direct producers of agricultural products and resource suppliers, consumers, and other economic agents.

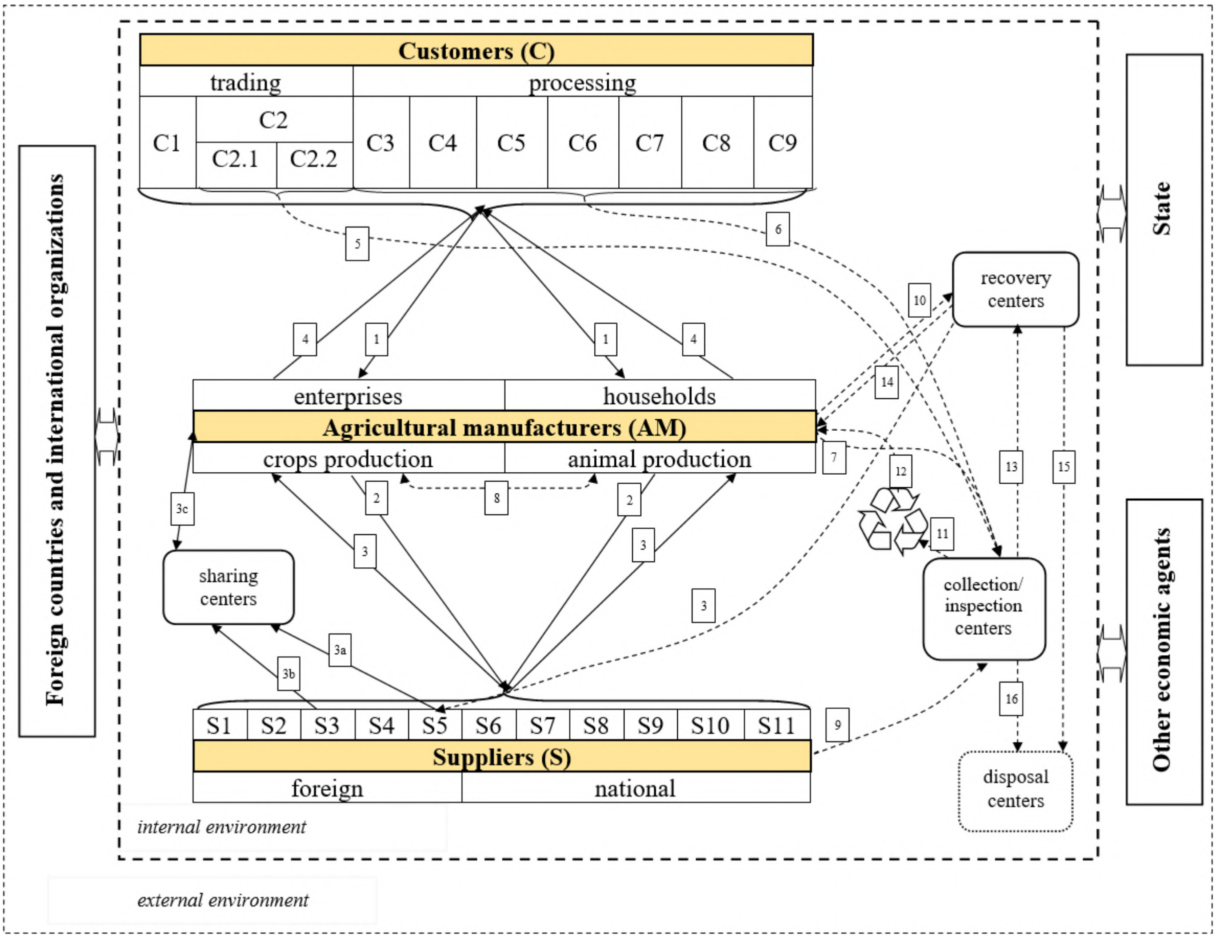

Figure 4. Agribusiness ecosystem model based on the circular economy (based on [25]).

Based on the degree of manageability and influence on the final result, we propose to distinguish between the internal and external environment of the agribusiness ecosystem. The internal environment should include elements that directly interact with each other in the process of creating added value. In particular, the internal environment of the agribusiness ecosystem built on the principles of a circular economy includes the main participants – Customers (C), Agricultural manufacturers (AM), and Suppliers (S), as well as additional, further contributing to the implementation of the circular economy model in the ecosystem – sharing centers, recovery centers, collection/ inspection centers, located centers. Depending on the purpose of the acquisition, Customers (C) are divided into two types – trade and processing. Sales of agricultural products can be carried out on external markets C1 (export) and on the domestic market C2 through intermediaries C2.1 (trade networks, retail trade) and directly to end consumers C2.2. The processing sector is also included among the consumers of agricultural products, namely: manufacturers of food, beverages, tobacco products (C3), manufacturers of textiles, clothing, leather products (C4), wood products, paper, printing (C5), manufacturers of chemicals (C6), pharmaceutical manufacturers (C7), furniture manufacturers (C8), biofuel producers (C9). Agricultural manufacturers (AM), depending on the form of business organization, are divided into legal entities and households, in accordance with the legislation of Ukraine. Farms can also be registered as legal entities or individuals. As a rule, household farms include family farming, producing products for themselves, and the surplus can be sold on the market. Depending on the type of products produced, agriculture is also divided into crop production and animal husbandry. Suppliers (S) of agricultural resources, which can be national or foreign. Depending on the type of resource, suppliers are divided into the following groups: melioration (S1), technologies (S2), land S3), personnel (S4), machinery (S5), fertilizers (S5), plant protection products (S6), breeding (S7), packaging (S8), feed (S9), veterinary drugs (S10). As in any system, there are certain relationships between its elements. As seen in figure 4, customers show demand for agricultural products (arrows 1). After analyzing the demand for products, agricultural producers will determine the demand for the inputs which they need for production (arrows 2). Depending on the cost of the resource, the period of its use, and the use of its financial capabilities, agricultural producers buy them (arrow 3), lease them, or share them. In particular, according to the basics of the circular economy, users can not only buy but also rent or share the necessary non-current assets. For agricultural producers, such assets are machinery, equipment, and land. Sharing centers act as an intermediary between the supplier of these resources and agricultural manufacturers (arrows 3a, 3b, 3c). According to experts, this type of service in agriculture is expected to grow in the coming years (figure 5).

Next, the production process is carried out using the necessary resources, and the products are sold to customers (arrows 4). Depending on the type of agricultural product, the production cycle can last for different times, for example, when growing plants, trees, and animals. The transition to environmentally friendly, organic production using the circular economy model makes it possible to almost completely eliminate waste to be disposed of at all stages. In particular, waste generated at the stage of selling finished products to end consumers, for example, spoiled or expired products (arrow 5) or processors of agricultural raw materials, such as production waste or unused raw materials and related products (arrow 6), fall into collection/inspection centers. Also, waste generated by agricultural producers can be directly redistributed between different producers. Crop waste can be used as animal feed. Also, animal waste can be used as fertilizer for crop production (arrow 8). Some scientists propose to apply the concept of mixed crop and livestock production, that is, a combination of two types of activities within one production unit – crop production and animal husbandry. The use of local feed and manure instead of imported and chemical fertilizers, for example, can help reduce agricultural CO_2 emissions [3]. The rest of the agricultural manufacturers' waste will be transferred to collection/inspection centers for further sorting (arrow 7). Waste generated during the supply

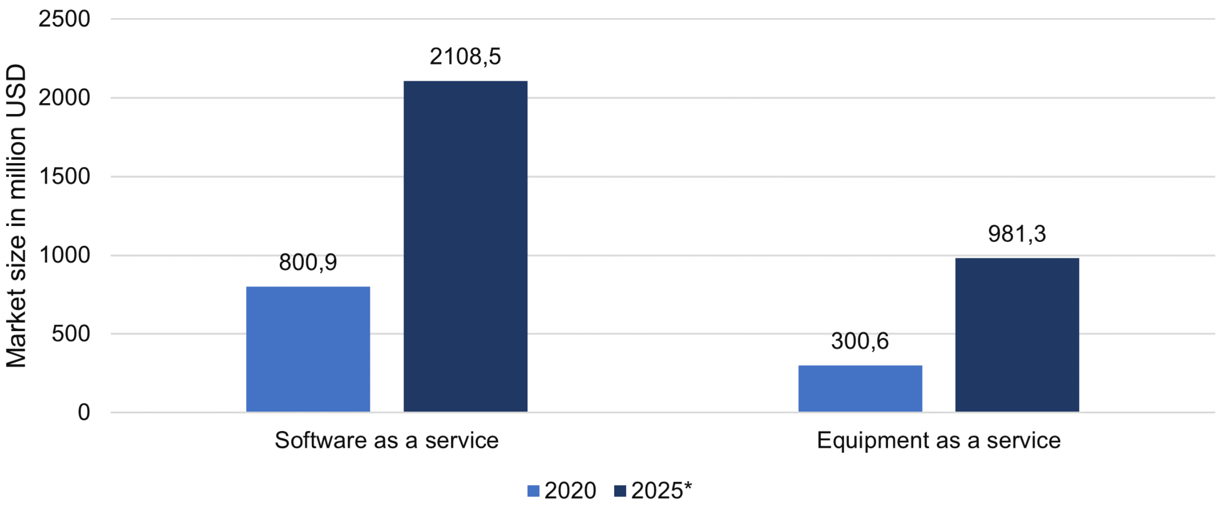

Figure 5. Size of the agriculture technology-as-a-service market in 2020 and 2025, by service type (in million USD) [26].

of resources to agricultural manufacturers (spoiled during transportation and delivery) will also fall into the collection/inspection centers (arrow 9). National suppliers (S) and agricultural processing (C3 – C9) are also mutual suppliers to each other through waste processing. The task of collection/inspection centers is to sort waste with subsequent distribution for processing (arrow 11) and recovery – for equipment and other components of the production process (arrows 10 and 13) with subsequent launch into production (arrows 12 and 14). For example, crop and livestock waste can be used as raw materials for some types of production (in the production of biofuels, textiles, furniture production, etc.). Thus, a much smaller volume is sent to the located centers (arrows 15 and 16).

All elements of the agribusiness ecosystem interact with external actors. The external environment of the agribusiness ecosystem includes state institutions, partners in foreign countries, international organizations and governments of other countries. The state, as a regulatory body, also influences the development of the agribusiness ecosystem (through the development of legal documents, regulations, the provision of permits, etc.). On the other hand, the state can act as a supplier and client through the activities of state enterprises and organizations, that is, acting as a component of the internal environment. In order not to complicate the logical chains of relationships between the participants in the agribusiness ecosystem, figure 4 does not display the settlement flows between them. For effective management of the agribusiness ecosystem, we consider it expedient to use the CATWOE method [27, 28]. This method is one of the tools for solving system management problems. The name of the method comes from the abbreviation: Customers – Actors – Transformation – Worldview – Owners – Environmental constraints, meaning key variables. As part of the agribusiness ecosystem, these components will be:

- Customers – stakeholders related to the product created by the system (customers, customers, end users);
- Actors – stakeholders directly involved in the processes (manufacturers, processors, intermediaries);
- Transformation is a business process that includes the processing process (production of agricultural products, their processing, waste processing processes, repair work, etc.);
- Worldview – a systematic vision of the problem and its potential solution with a preliminary

assessment of the consequences and future prospects (a preliminary assessment of the feasibility of making a decision based on a balanced assessment in four areas: economic, environmental, social, and innovative);

- Owners – stakeholders who are most interested in solving the problem and have the authority to allocate resources for transformation (government bodies, business owners, investors, etc.);
- Environmental constraints – factors or conditions external to the solution of the problem that affects the implementation of the decision (market capacity, legal requirements, international conditions, environmental risk factors, etc.).

By analyzing the impact of each component of the CATWOE analysis, it is possible to maintain optimal conditions for the functioning of the agribusiness ecosystem as a single organism.

5. Innovative tools for balanced business ecosystem development

Circular agriculture was widely practiced in pre-industrial societies. At the same time, due to the industrialization of production, it was gradually pushed aside by the modern model of organizing production processes in this industry, which made it possible to significantly increase its economic efficiency through the widespread use of chemical fertilizers, mechanization, and automation, specialization in growing monocultures, etc. This approach, as we know, has led to negative environmental consequences. Long-term consequences of the negative impact on the environment and humans will be felt for a long time [7].

The development of modern technologies and the application of an ecosystem approach to the organization of business processes in the agricultural sector will ensure decent economic results while maintaining a balanced development. By balanced development, we mean a balance between four components: economic, environmental, social, and innovative. These development vectors should be basic for all participants in the agribusiness ecosystem. According to the concept [29], sustainable development involves taking into account three components: economic, social, and environmental. However, at present, given the rapid development of innovations, in particular, in the era of Industry 4.0, information and communication technologies can significantly optimize business processes, including the agricultural sector [25,30]. Innovations are new and (or) improved competitive technologies, products, or services, as well as organizational and technical solutions [31]. Innovations occur at all stages of interaction between participants in the agribusiness ecosystem: from the stage of supplying resources to the stage of final processing or waste disposal. When taking into account the innovative component, it is important to use a systematic approach, since the agricultural products themselves contain a relatively low degree of innovation, compared with the products of knowledge-intensive sectors of the economy. At the same time, innovative solutions of an individual participant in the business ecosystem will bring a synergistic effect in related industries and at adjacent levels of interaction between participants.

Innovative solutions that will contribute to the effectiveness of the agribusiness ecosystem can occur at three stages: the development (selection) of agricultural products, the production (cultivation) of agricultural products, the consumption and processing of waste, business processes and products of related industries that are part of the agribusiness ecosystem. To improve the performance of the agribusiness ecosystem, we consider it expedient to implement the following measures [1, 3]:

Agricultural manufacturers:

- Mixed farming (mixed farming) – a combination within the same agricultural producer of crop and livestock, which will reduce the amount of waste from each of the individual types of production, as well as mutually provide the necessary resources.

- Shift from mono-crop agriculture to growing a set of interrelated crops, where the cultivation of some creates favourable conditions for others on the same land, which will improve the quality and fertility of the land without the use of chemicals.
- Agroforestry – planting trees in combination with crops or pastures that will help restore biodiversity in agricultural landscapes, increasing soil fertility by increasing the accumulation of organic matter from decaying nature.
- Water recycling and wastewater use – recycling and reuse of irrigation water in agriculture. According to experts, the use of wastewater in agriculture can irrigate an additional 40 million hectares, or 15 percent of all irrigated land [3].
- The use of innovative technologies in crop production – bee vectorization technologies, indoor vertical farming using hydroponics, aeroponics, micro-drip irrigation, laser scarecrows to scare away birds and rodents, the use of minichromosomal technologies without the use of genetically modified products that have allergic and others, etc.) for organic farming.
- Implementation of innovative technologies of Industry 4.0 – precision farming based on Big Data processing, remote sensing, the use of aircraft, robotics, and automation to improve the condition of plants and optimize resources, increase productivity; automated dairy plants, automated cleaning systems, automated feeders, and non-antibiotic treatment of animals with acoustic impulses, as well as the application of robotics, artificial intelligence for animal welfare and agricultural productivity; introduction of real-time kinematic technology (RTK) to reduce soil damage by machinery. Experts estimate that the market value of precision farming will grow from about 7 billion USD in 2021 to 14,5 billion USD by 2027 [32]. The size of the global smart farming market will grow from approximately 12,4 billion USD in 2020 to 34,1 billion USD by 2026 [26].
- Registration on international platforms and promotion of the national manufacturer in the international market.
- Application of modern management methods based on the analysis of world experience and advanced technologies (automation of production and management operations with a combination of agricultural machinery, computer systems, electronics, chemical sensors and data management into a single system in order to improve equipment operation and decision-making, reduce human impact and errors).

Intermediate and end users:

- Transition to responsible consumption of resources, providing for the reduction of food waste, waste sorting, preference for organic products to stimulate and materially support organic production.

Government:

- State support for organic production and the use of new technologies (drip irrigation, precision farming, rainwater harvesting, crop productivity, closed water cycle, green energy, etc.) by providing subsidies, tax incentives, concessional lending, etc.
- Stimulating the development of processing industries operating on domestic raw materials.

Suppliers:

- Development of new varieties and hybrids of plants and animal breeds, strains of microorganisms, brands and modifications of agricultural machinery, technology, chemical and biological preparations (vaccines).
- Development and implementation of new technologies and new types of machinery and equipment.

The innovative smart agriculture approach to agribusiness, which is actively spreading around the world, is based on the use of technologies and solutions of the Internet of Things, which improves operational efficiency, increases yields, and minimizes costs through processing realtime data, their analysis and the use of digital production management systems.

Smart agriculture is introducing a range of programs and digital solutions such as precision farming, variable rate technology, irrigation, and smart greenhouses. Today, precision farming has become the most important innovative agricultural direction in the developed countries of the world. Other promising areas in smart farming include: variable speed technology (VRT), unmanned drones, soil monitoring systems, and precision animal husbandry. The main factors driving the need for the transition from agribusiness to smart agriculture are the current realities of climate change, the need to conserve water and other types of resources, and a focus on improving efficiency through cost optimization [33]. Given the trends, the agricultural sector is the driving force behind the innovative development of the national economy.

6. Conclusions

The application of the proposed concept of agribusiness ecosystem will allow to obtain a synergistic effect in related industries, which, within the framework of this development, will provide the agricultural sector with raw materials, machinery, and other resources. Such an approach will help to increase the level of value added created with the participation of agriculture. Separation of the internal and external environment allows all participants in the business ecosystem to minimize the risks and threats to their own business, reducing the degree of dependence on external influences.

The proposed approach to the formation of a model for a balanced development of a business ecosystem is to take into account four areas of development: economic, environmental, social, and innovative. Taking into account the innovative component of development at all levels of ecosystem management makes it possible to take into account the potential for further development, as well as to balance the interests of all participants. This approach contributes to the optimization of economic results at the system level, while reducing the negative impact on the environment. The innovative technologies of Industry 4.0 reduce economic costs and conquer the consumption of resources, providing the maximum return on them, taking into account the supply chains within the ecosystem.

Abstract. The existing problems of energy, water, and food crises and climate changes determine the need to implement appropriate adaptive measures to improve the ecological and reclamation state of drained mineral soils. For the application of deep loosening of the soil as an adaptive agromelioration measure, a transition from traditional crack loosening of the soil and strip loosening of the soil to improved technologies of continuous layer-by-layer loosening of the soil based on energy-efficient and moisture-regulating principles is proposed. Their comparative evaluation according to the main indicators of overall efficiency was carried out on drained mineral soils of a representative object in the Western Polissia zone of Ukraine. According to the results of the evaluation of various technologies of deep soil loosening, it was determined that the technologies and technical means of continuous deep loosening of the soil have an advantage in all main indicators: agrotechnical, water-physical, energy, technological, ecological, and economic. In particular, the moisture availability of the soil increased by 27 % due to better accumulation of atmospheric precipitation, the yield of cultivated crops also increased by 20-30 %, and the aftereffect period increased to 4 years. This is a cost-effective and investment-friendly adaptive measure to ensure a satisfactory ecological and reclamation state of drained mineral soils (with an investment payback of 1 year). This provides modern principles of adaptive land use in changing climatic conditions and can be an effective alternative to expensive reconstruction and modernization of existing drainage systems.

1. Introduction

The current problems of energy, water, and food crises, as well as climate changes, determine the need to implement appropriate adaptive measures to improve the ecological and reclamation state of drained mineral soils.

In the zone of drainage reclamation, this is possible based on the development of a complex of adaptive, including agro-reclamation, measures. They are aimed at effective regulation of the water regime, regulation and accumulation of moisture in the soil profile and within the system, and improvement of technologies, and means of deep soil loosening according to energy-efficient and resource-saving principles. This will make it possible to effectively accumulate moisture in the soil profile and on the massif to be drained, to increase its moisture supply [1].

2. Analysis of previous studies

The positive aspects of using deep loosening as an effective agromelioration measure on sod-podzolic soils in the Western region of Ukraine have been shown in many studies. At the same time, it was noted the presence of negative agroecological and man-made components of impact on the soil by technical means for its implementation [1].

Some functional advantages of applying deep layer-by-layer loosening on over-moistened mineral soils using strip technology were noted and used by Kozhushko based on the developments of Kravets regarding a trenchless multi-tier soil loosener [2].

Depending on the hydrological, soil, and other conditions, continuous, strip, or crack loosening (cracking) is traditionally considered and used [1].

Traditional deep loosening of drained soils using slit or strip technologies is used only as an auxiliary measure to increase the efficiency of drainage using deep looseners mainly of the riser type. At the same time, only local influence is actually carried out on the active part of the soil massif (the active root layer and the aeration zone of the drained soil) with the formation of vertical filtration channels for the intensification of drainage of surface runoff. This really contributes to the strengthening of the technological effect on drainage, but at the same time, it strengthens the washing water regime in the soil, which over time leads to the impoverishment of the fertile layer and causes a negative ecological effect.

At the same time, the designs of traditional deep looseners actually perform rather coarse loosening, which does not provide the necessary quality of soil structure in accordance with agrotechnical recommendations. They compact the soil of the walls of the incised cracks, require significant energy expenditure during loosening, and have insufficient loosening completeness and the duration of its aftereffect [3].

Therefore, the use of deep loosening as an effective adaptive measure is restrained by the imperfection of existing technologies and means that do not provide the necessary quality and effectiveness of loosening in accordance with modern conditions and requirements.

Research methodology. For a comparative evaluation of the effectiveness of the application of various variants of deep loosening of drained mineral soils on a representative object for the conditions of the Western Polissia of Ukraine, experimental studies were carried out using the main methods of the general theory of the experiment (analytical, experimental and statistical), mathematical modeling and a machining experiment using modern information and computer technologies.

According to the obtained experimental results, predictive calculations were made based on the use of an appropriate complex of forecasting and simulation models, which includes a local climate model, models of the water regime and water regulation technologies of drained lands, a model of the development and formation of the crop of cultivated crops, which are implemented on the basis of a long-term forecast [4].

For an approximate assessment of the ecological sustainability of the researched measures, the degree of consideration of the factors of ecological reliability of their operation and to maintain favorable natural and reclamation and soil regimes within the project term, the calculation of the coefficient of ecological reliability (k_n) of the operation of the reclamation system was carried out based on the set of relevant physical indicators of ecological efficiency (indicators water regime, indicators of salt regime and productivity of drained lands). The ecologically optimal option is considered to be the one for which the coefficient of ecological reliability is in the interval of values $k_n = 0.5...1.0$, in addition, the coefficient of ecological reliability indirectly reflects the ecological and melioration state of drained mineral soils [4].

3. Research results

On the basis of the generalization of existing and our research, we scientifically substantiated the need and possibility through improved energy-efficient and moisture-regulating technologies and technical means of deep loosening to influence the improvement of the technical, technological, and economic efficiency of the use of drained mineral soils.

Deep loosening changes the macrostructure of drained mineral soils and affects the macroaggregate state of soils, their density and porosity, water-physical properties, and, accordingly, the ecological and melioration state of drained mineral soils and the conditions for the development of cultivated crops and productivity (figure 1).

To ensure the implementation of the necessary improvement of deep loosening for modern conditions and requirements, a transition from the traditional widely used crack and strip loosening technologies to continuous layer-by-layer deep loosening of the soil differentiated by depth is proposed. This soil loosening method has been improved according to energy-efficient and moisture-regulating principles, and according to tiered technical means [5].

The improved technology and means of deep continuous loosening make it possible to improve the structure of the soil, which is developed in each horizon, layer by layer. At the same time, it makes it possible to differentiate the value of its loosening by a depth of up to 0.6 m.

Implementation of continuous deep loosening with mechanical reformatting of the macroaggregate and granulometric composition of the soil massif with its layer-by-layer distribution according to agrotechnical recommendations affects the water-physical properties of the soil. It is also decisive for the technological and physical prerequisites for the creation of favorable water-air and natural-ameliorative regimes, and, therefore, the provision of the necessary economic and ecological effects [1].

The formation of a granular and fine-grained structure makes it possible to effectively use the moisture-accumulating potential of the soil. This is done by the formation of a large surface area of soil particles and small gaps between them in the zone above the plow sole, where the root systems of most agricultural crops are potentially located.

The formation of a large- and medium-granular structure to the depth of the drainage makes it possible to quickly remove excess fluid. This excess is removed through the increased gaps between soil particles and simultaneously accumulates in the soil due to the formation of a sufficient surface area of soil particles. The formation of a medium-granular structure in the upper quarter of the upper layer protects the accumulated moisture from excessive evaporation from the surface and weathering.

As a result, a moisture-accumulating structure is obtained in each of the soil layers. This structure is appropriate for the purpose of each layer: with maximum moisture accumulation potential in the upper part of the soil and sufficient water permeability with simultaneous moisture accumulation in the lower part of the soil profile.

The proposed design of the deep loosener for improved loosening is a frame with bearing risers. Soil-loosening working bodies are attached to them in the form of the conjugation of a plowshare with a concave arrow-shaped soil-loosening element of variable curvature. The shape and parameters of the surface of this element determine the necessary deformation, stress, and, therefore, crushing of the soil layer. The general layout of the deep loosener is determined by the spatial distribution of the soil-loosening working bodies in three perpendicular directions (figure 2) [6].

Comparative field production tests of various technologies and means of deep loosening were performed at the facility of the Private Agricultural Enterprise "Myrne" in the Kostopil district of the Rivne region (Ukraine) on an area of 25 hectares [6].

Soil conditions: sod-podzolic clayey sandy soils with a content of physical sand in the arable horizon of 58.3 % (0...20 cm) and in the subsoil layer – 79.8%, with a filtration coefficient of the arable horizon – 0.13... 0.4 m/day, and at a depth of 20 cm or more – 0.13...0.003 m/day.

Depth of laying drainage – 0.8...1.2 m; the distance between the drains is 10...20 m.

The study of the influence of various technologies and deep loosening means on the water-physical properties and agro-melioration state of drained mineral soils was solved by conducting

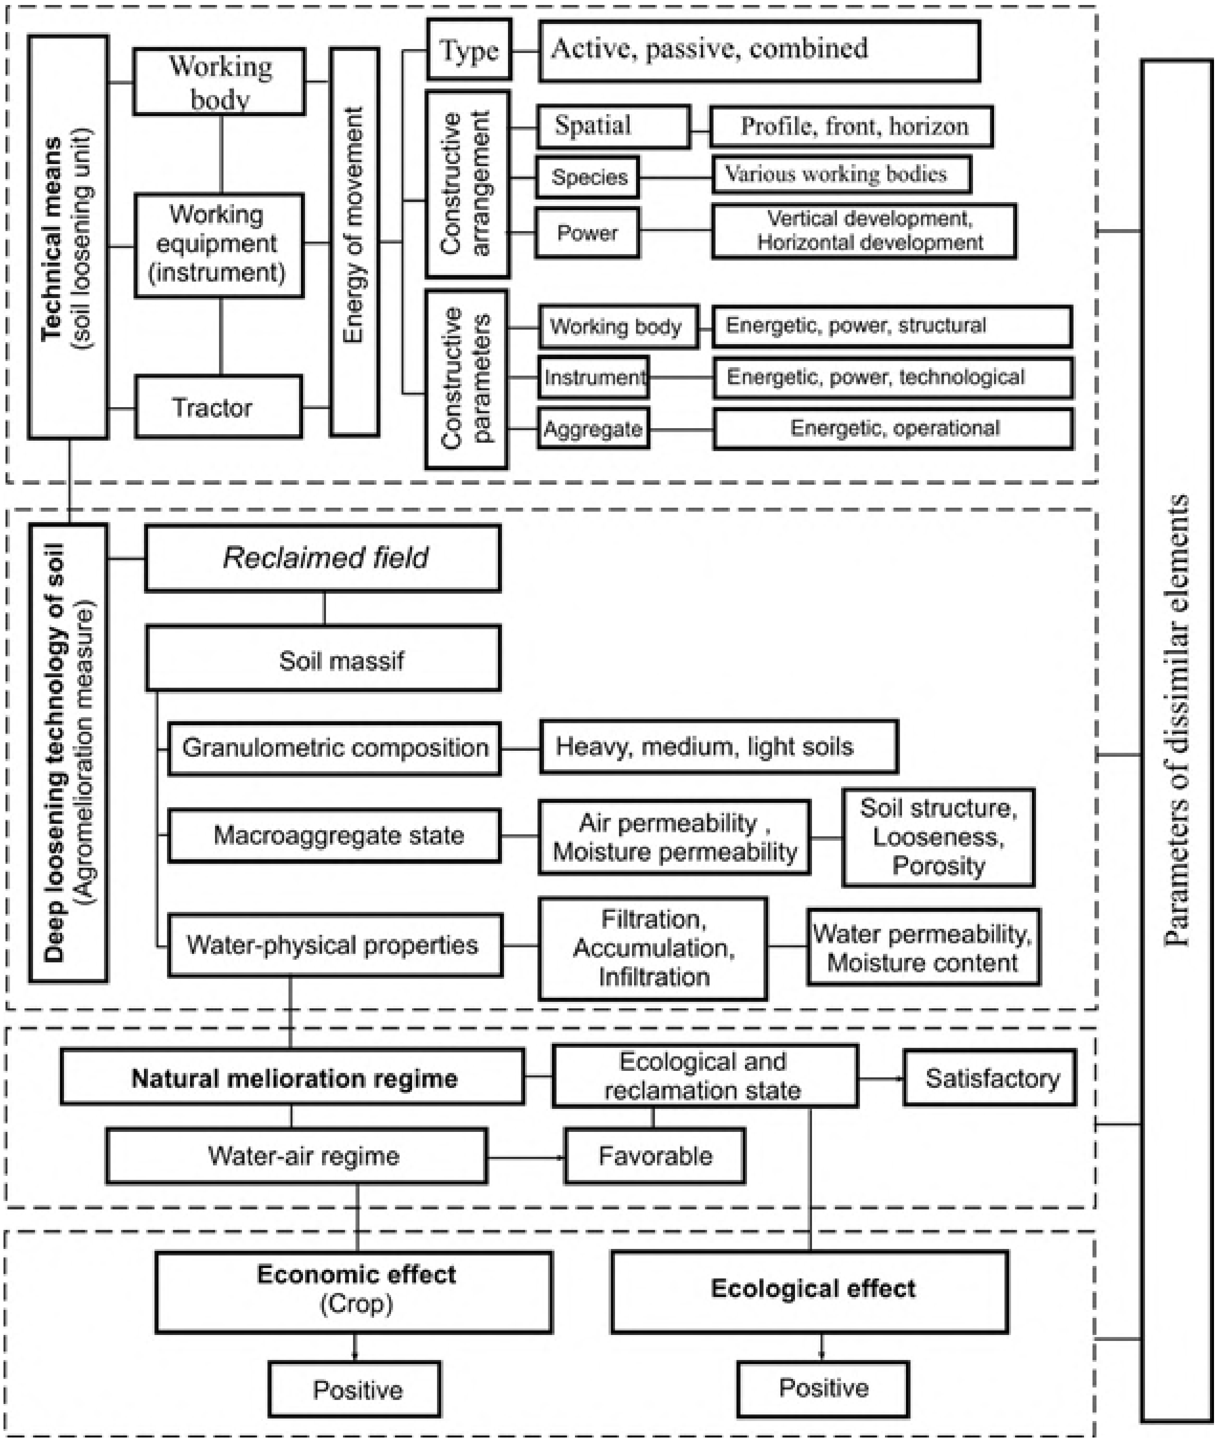

Figure 1. Structural and hierarchical scheme of the necessary principles of improving technologies and technical means of deep loosening of draining mineral soils based on consideration of the interaction between the parameters of heterogeneous elements.

comparative production tests according to the following options: 1 – crevice loosening of the soil; 2 – band loosening of the soil; 3 – improved continuous loosening of the soil; 4 – control option without soil loosening.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012106 doi:10.1088/1755-1315/1254/1/012106

The indicator of the quality of soil loosening was determined in the form of the coefficient of completeness of loosening. It was reduced to the volume of soil on an area of 1 hectare (100×100 m) with a power of 1 m for the objectivity of the assessment by different loosening technologies.

Table 1 presents a generalized comparative characteristic of the values of the main indicators of water-physical properties in the 0.6 m soil layer averaged over time (by the after-effect period) and plane (by the soil profile) and by different types and variants of its loosening.

Table 1. Comparative characteristics of the water-physical properties of the 0.6 m soil layer according to loosening options.

Variants of soil loosening	Soil density[1] γ, t/m^3	Soil cracking[1] A, %	Soil water permeability[1] k_f, t/day
Without soil loosening	1.45	42.2	0.12
Crack soil loosening	1.41 (0.04 t/m^3 /2, 9%)[2]	46.1 (3.9%/9.2%)[2]	0.25 (0.13 t/day /206%)[2]
Strip soil loosening	1.32 (0.13 t/m^3 /8.9%)[2]	47.3 (5.1%/12%)[2]	0.36 (0.24 t/day /296%)[2]
Continuous soil loosening	1.15 (0.30 t/m^3 /21%)[2]	54.9 (12.7%/30%)[2]	0.53 (0.41 t/day /443%)[2]

[1] absolute value, [2] deviation from control

The term of effective technological aftereffect of the considered methods of deep loosening of drained mineral soil was: crevice soil loosening – 1 year; strip soil loosening – 3 years, continuous soil loosening – up to 4 years.

Table 2 presents a generalized comparative characteristic of the averaged values of the main agromelioration indicators of a layer of loosened soil of 0.6 m with a change in the supply of productive moisture and according to the most universal indicator of the productivity of cultivated crops for variants of its loosening.

The best results of deep loosening of mineral soils are achieved when using continuous

Table 2. Comparative characteristics of the main agromelioration indicators of the 0.6 m soil layer according to loosening options.

Variants of soil loosening	Productive moisture reserve [1] Wh, m^3/ha	Productivity of crops according to the coefficient of efficiency [1] PAR, %
Without soil loosening	316	0.80
Crack soil loosening	594 (278 m^3/ha /49.0%)[2]	0.88 (0.08%/10.0%)[2]
Strip soil loosening	655 (339 m^3/ha /51.0%)[2]	0.99 (0.19%/24.0%)[2]
Continuous soil loosening	711 (395 m^3/ha /55.5%)[2]	1.16 (0.36%/45.0%)[2]

[1] absolute value, [2] deviation from control

loosening based on the use of a multi-layer deep loosener. At the same time, the density of the soil in the arable soil layer decreased to 1.1...1.15 t/m^3, and in the sub-arable soil layer – to 1.2...1.3 t/m^3. In addition, the possibility of predicting and obtaining the structure in any horizon of the vertical profile of loosened soil due to the possibility of adjusting the parameters of the working body of the deep loosener was proven. At the same time, unlike other technologies, the optimal structure of loosened soil was achieved: in the arable layer, 55...60% by weight of soil aggregates with a diameter of 10...50 mm; the remaining 40% – by the total weight of aggregates with a diameter of less than 10 mm and greater than 50 mm, and in the sub-arable horizon with a diameter of 20...50 mm – 70...80%, and in total aggregates with a diameter of less than 20 mm and larger than 50 mm – 20 ... 30%.

According to research results, deep loosening also has a positive effect on the temperature regime of the soil, especially the arable horizon, where when the air temperature increases, the maximum temperature in the loosened soil becomes lower than without loosening.

Under the action of deep loosening, the depth of soil freezing decreases by 8...12 cm, and thawing is accelerated by 2-3 days in the spring. This is especially characteristic of the first year after the effect.

Moisture evaporation is related to temperature and water conditions. Deep loosening, breaking the capillary connection in the upper horizons, reduces the intensity of capillary nutrition and, accordingly, reduces its evaporation from the soil surface.

According to [7], deep loosening can be a mechanism that contributes to reducing the evaporation of other greenhouse gases from the soil surface by stimulating their accumulation and absorption deep in the soil mass rather than in the upper soil layer. At the same time, loose soil macroaggregates with a diameter of 2...8 mm are characterized by 51% better-absorbing properties (over a total 20-day period) than soil macroaggregates with a diameter of up to 2 mm.

In addition, the deep loosening carried out accordingly will contribute to the translocation processes of moving soil organic carbon into the depth of the massif, which are one of the methods of its sequestration. The measured rates of carbon sequestration by the soil range from 50 to 1000 kg/ha/year. The global carbon sequestration potential is 0.9...10.3 Pg/year, which can offset from one quarter to one third of the annual increase in atmospheric carbon dioxide, which is 3.3 Pg/year. The cumulative potential of soil carbon sequestration for 25–50 years is 30–60 Pg [8, 9].

Table 3 shows the comparative efficiency of using different variants of deep loosening on drained mineral soils according to the results of field experiments.

The obtained results of the harvest of cultivated crops adequately describe the achieved indicator of the improvement of their growing conditions and ensure their increase on average

Table 3. Comparative effectiveness of deep loosening on drained mineral soils.

	Variants of soil loosening	Year of effect	Cultivated crops	Crop increment	Payback period, years
1	Crack soil loosening	1	sugar beets	13.1 c/ha / 4.5%	1
		2	winter cereals	1.8 c/ha / 6.1%	1
		3	spring cereals	1.4 c/ha / 5.3%	1
2	Strip soil loosening	1	sugar beets	51.6 c/ha / 18.1%	1
		2	winter cereals	4.6 c/ha / 15.9%	1
		3	spring cereals	2.5 c/ha / 9.4%	1
3	Continuous soil loosening	1	sugar beets	93.25 c/ha / 32.3%	1
		2	winter cereals	6.5 c/ha / 22.3%	1
		3	spring cereals	5.1 c/ha / 19.3%	1

according to the options of deep loosening of drained mineral soils: crevice loosening of the soil – 5...10%; strip loosening of the soil – 10...20%; continuous loosening of the soil (improved) – 20...35%.

The results of the analysis show that the method of continuous loosening of the soil provides a greater increase in the yield of cultivated crops than with crackted or strip loosening of the soil. This not only compensates for the cost of its implementation, but also creates a profit.

According to the results of predictive and simulation modeling using the appropriate set of models [4, 10], the effectiveness of the application of improved continuous loosening of the soil during the growing season was determined. This was carried out in combination with various methods of water regulation of drained mineral soils on the example of the studied object (soil – sandy loam, area – 10 ha, cultivated crop – perennial grasses for hay) for the estimated dry growing season under the conditions of heat and moisture supply (p = 70%).

Table 4 shows fragments of the generalized results according to the following options: 1 – preventive sluicing (PS); 2 – preventive sluicing with continuous deep loosening (PS+DL); 3 – preventive sluicing with continuous deep loosening with an aftereffect in 1 year (PS+DL+1 year); 4 – moisture sluicing (MS, subsoil moisturing).

The presented data show that the application of improved continuous loosening of drained mineral soils against the background of preventive sluicing in the estimated dry growing season increases the accumulation of precipitation by more than 90% and increases the moisture availability of the soil according to the $n(IW)$ indicator by 27%. At the same time, the positive effect is partially preserved after 1 year after the action with sufficient environmental reliability.

The efficiency of the technology of water regulation of drained lands (PS + DL) is similar to the moisturizing sluicing (MS, subsoil moistening) according to a set of technological and ecological indicators. At the same time, this method does not require additional costs of irrigation water for moistening the soil massif with lower material costs.

The summarized results of determining the economic efficiency of investments in the reconstruction and modernization of drainage systems using various technologies and means of deep loosening according to the appropriate methods and models [11] are presented in table 5.

The calculations performed to determine the comparative economic efficiency and investment evaluation of various options for deep loosening of drained mineral soils confirm the sufficient feasibility of their use in projects of reconstruction and modernization of drainage systems in the Western Polissia zone of Ukraine.

Thus, all considered technologies of deep loosening of the soil are profitable and economically beneficial. At the same time, the most technologically, economically, and ecologically effective

is the improved continuous deep loosening of the soil.

The technology and means of deep continuous loosening of the soil, which has been improved according to energy-efficient and moisture-regulating principles, make it possible to improve the macrostructure of the active layer of drained mineral soils layer by layer to a sufficient depth. This is done in order to influence their water-physical properties, water, air, heat, and other ecological components of the natural-ameliorative regime of the soil massif, which is positively reflected in the conditions of the development of agricultural crops and their productivity.

4. Conclusion

According to the results of the evaluation of various technologies of deep soil loosening, it was determined that the technologies and technical means of continuous deep loosening of the soil have an advantage in all main indicators: agrotechnical, water-physical, energy, technological, ecological, and economic. In particular, the moisture availability of the soil increased by 27% due to better accumulation of atmospheric precipitation, the yield of cultivated crops also increased by 20-30%, and the aftereffect period increased to 4 years.

This is a cost-effective and investment-friendly adaptive measure to ensure a satisfactory ecological and reclamation state of drained mineral soils (with an investment payback of 1 year). This provides modern principles of adaptive land use in changing climatic conditions and can be an effective alternative to expensive reconstruction and modernization of existing drainage systems.

Abstract. The assessment of the impact of hostilities on the environment remains an important issue for predicting changes resulting from military-technogenic activities and assessing the losses incurred by ecosystems in Ukraine. This article proposes an integrated approach for predicting the possible level of hostilities' impact by utilizing aggregated environmental information on ecosystem composition, indicators of military-technogenic load, organization of trophic networks in relevant biogeographic zones, and biodiversity composition. The concept of environmental safety of hostilities is introduced as a projection into the military technosphere of the ecosystem sustainability concept, where the target function is the conservation of the natural biota of operational zones and areas of hostilities. The article presents a block diagram of the procedure for assessing the state of ecosystems in war zones and proposes a classification of levels of military-technogenic disturbance of natural ecosystems based on the state of edifier sinusia.

1. Introduction

One of the unresolved problems in the field of military ecology is the development of appropriate methods for assessing the damage caused by warfare to natural ecosystems, which is one of the major issues in this field. In Ukraine, an undeclared war with the Russian Federation is ongoing in Polissya and the southeastern industrial regions (Donetsk, Dnipro, Zaporizhzhia, Luhansk, and Mykolaiv). This area is a technologically advanced and industrial region of Ukraine, where pollution of the environment through the conduct of hostilities (HS) and the possible defeat of potentially hazardous objects (PHO) is directly related to the formation of a military-technogenic load (MTL) as a result of the operation and combat use of weapons systems and military equipment at the facilities of industrial-urban agglomerations and on the territory of natural ecosystems.

To conduct a detailed environmental assessment of the impact of HS on natural ecosystems in the practice of forecasting in precision military ecology, it is necessary to determine the relative importance of military-anthropogenic factors influencing the environment, which have qualitative uncertainty, and evaluate the values of the parameters of the natural system, which have quantitative certainty. Today, it is necessary to determine the key factors influencing MTL from HS in natural ecosystems. Unfortunately, the current quantitative uncertainty in predicting the impact of MTL on the components of the ecosystem indicates that our knowledge and information resources are not yet sufficient to predict changes in natural ecosystems under the influence of HS in operational areas.

Recent studies have highlighted the importance of developing appropriate methods for assessing the impact of hostilities on the environment. For instance, studies [1, 2] focused on the environmental impact of military activities in Ukraine and proposed an approach for assessing the ecological status of the areas affected by military operations. Another study [3] evaluated the impact of military activities on the state of natural ecosystems in Ukraine and proposed a system for monitoring the environmental situation in the areas affected by military operations. Furthermore, studies [4, 5] examined the impact of military activities on the environment in Ukraine and proposed a set of measures to reduce the negative impact of military activities on the environment. These studies suggest that developing appropriate methods for assessing the impact of hostilities on the environment is crucial for mitigating the negative effects of military activities on natural ecosystems.

2. Related works

Comparative analysis of several publications on the assessment of anthropogenic changes in various types of ecosystems [1–4] allowed us to formulate the following methodological principles for assessing the MTL from warfare:

1. Differentiated consideration of the reaction of different ecosystems to the same impact of the MTL.
2. In each ecosystem, an artificial change in the environment of the abiotic environmental factors of the military natural-technogenic geosystem (MNTG), which has the greatest indication value, is adopted as criteria for assessing its changes.
3. Integral assessment of the level of MTL on land and ecosystems and in general is carried out in conditional indicators on an appropriate point scale based on an assessment of quantitative data on changes in individual components of ecosystems (for example, due to the ratio of affected and unmodified ecosystem areas).
4. The specificity of military ecosystems determines the development of methodological methods for assessing their ecological state.
5. From the point of view of the possibilities of using empirical data in the study of the system of interaction "military-anthropogenic influence – biota reaction" to predict the state of MNTG, the idea of regulating the effect on biota through its "critical link", which can be a group of species or even one indicator species, seems expedient.

The basis of a comprehensive environmental assessment of the state of natural ecosystems is a joint analysis of biotic and abiotic environment-forming factors that characterize ecosystems in conditions of dynamic military-technogenic load from HS. It is known that a biogeocenosis, ecosystem or biological community that has existed in unchanged form for a long time has a certain intrinsic ability to withstand perturbing natural influences. This ability of the ecological system is often called "resilience" or "stability" by biologists [6].

There is an approach based on trying to link the resilience of a community with some measurable characteristics of it. Among ecologists, it is considered almost an axiom that communities which are more complex in structure and richer in the number of species are more stable [7–10]. As a characteristic of community stability in biology, the information measure of diversity is most often used the Shannon and Simpson indices [11]. However, the direct use of indicators of species diversity as a criterion characterizing the sustainability of ecosystems makes sense only for communities that do not have a quantitative hierarchy. Therefore, in real biogeocenoses that have a pronounced hierarchical structure, the use of diversity indicators to quantify the measure of stability is hardly justified [12].

Recent research has focused on developing comprehensive assessment procedures to evaluate the impact of warfare on natural ecosystems. One such study proposed a methodology for assessing the ecological state of ecosystems in areas affected by military activities using the structural and functional organization of biotic communities [13]. The study emphasized the importance of considering the specific characteristics of different ecosystems and their responses to military-technogenic loads. Another studies proposed a methodological approach for assessing the impact includes both qualitative and quantitative indicators [5,14]. The study [5] highlighted the importance of analyzing changes in vegetation cover at different spatial scales to better understand the impact of military activities on natural ecosystems. The study [15] shows a tool to monitor environmental dynamics and plan military training activities, but its limitation lies in that the obtained values of the indicator vary and are subjective to the experts' knowledge and experience. Thus, further advancing this approach is needed by developing a scientific method to derive the weights of environmental variables.

The peculiarities of the above-mentioned areas of research on the development of a method for assessing losses for the territories of hostilities require the development of comprehensive assessment procedures, for the development of which it is necessary to have reliable environmental information about the components of the ecosystems of the territories of the operational zones of HS.

The purpose of the publication is to develop a comprehensive scientific and methodological approach to assessing losses in natural ecosystems due to the influence of MTL factors during hostilities in Ukraine. Recent research in this area has emphasized the need for a differentiated approach that considers the specific characteristics of different ecosystems and their responses to MTL. This approach should include both qualitative and quantitative indicators and analyze changes in ecosystems at different spatial scales to better understand the impact of military activities on natural ecosystems.

Military Training Areas (MTAs) cover at least 2 percent of the Earth's terrestrial surface. These areas are potentially important for biodiversity conservation. The greatest challenge in managing MTAs is balancing the disturbance associated with military training and environmental values. These challenges are unique as no other nature use is managed for these types of anthropogenic disturbances in a natural setting.

3. Results

It should be noted that almost all the existing approaches to assessing the sustainability of ecosystems have considered this problem in natural ecosystems in relation to natural extreme actions, which for a considerable period of time are familiar to these ecosystems and very rarely are complex. The problem of the stability of ecological systems to the military-technogenic impact of the HS looks completely different. Here dealing, as a rule, with actions that are not peculiar to the natural environment, and are a complex conglomerate of mechanical, physical and chemical factors, combined in different ratios when using certain means of destruction and military equipment on the battlefield.

An equally important circumstance is that when assessing the interaction of natural and MNTG, the stability of the ecosystem has a twofold meaning. On the one hand, the stability of the ecosystem is its property, which characterizes the ability to withstand external military-technogenic loads. But on the other hand, if some ecosystem is resistant to a specific military-technogenic factor, then this factor is safe for this ecosystem. Thus, the concept of environmental safety of hostilities is a projection into the military technosphere of the concept of ecosystem sustainability. Given that the target function in studying the interaction of the military technosphere and the biosphere is the level of preservation of the natural biota of operational zones and areas of HS, then both previously mentioned concepts are tied together through the achievement of these goal, but each of them has its own purpose.

The study of the sustainability of ecosystems should quantify the permissible, according to the conditions of ecosystem conservation, the level of militarytechnogenic load, and the study of causal relationships in the process of its formation should determine the technological ways to achieve a biologically determined threshold for each military-technogenic factor.

An indicator of natural equilibrium is the ability of natural ecosystems to develop with the achievement of reaching the maximum during cyclic succession. Maintaining a HS in an ecosystem changes its abiotic component, which, through the mechanism of homeostasis, influences certain species, usually suppressing them. Therefore, the ecosystem is out of balance and, according to the principle of Le Chatelier-Brown [16], its equilibrium shifts in the direction in which the effect of external action factors and HS weakens. In practice, this means a decrease in the number of species, that is, the degradation of the biocenosis to some new, equilibrium, but lower level. Determining the mechanism of homeostasis in the presence of external action of the HS for all levels of the organization of ecosystems is of great importance for predicting its behaviour at one level or another.

According to the general ideas of classical ecology [17, 18], the stability of ecosystems is associated not only with the very fact of preserving the species' composition but also with the ability to return to the primary equilibrium state after external actions [19]. Thus, with regard to the specifics of the HS, the ecosystem is resistant to MTL as long as its biota retains the ability for self-healing, that is, to return to the path of evolution according to the laws of cyclical succession after the removal of the MTL.

In order to determine the degree of MTL influence factors on the environment and to develop proposals for the decision-maker, a search and development of scientifically based models and indicators for the environmental classification of MTL factors from HS maintenance in operating areas is underway [20, 21]. During the study of the problems of environmental assessment of MTL, a number of issues arise related to the justification of the methodology for its implementation, which is specific to the field of military ecology [22, 23].

Due to the fact that in our time ecosystems are not purely natural, but naturalanthropogenic, it becomes necessary to isolate the factors of MTL in a whole group of other anthropogenic loads associated with industrial and agro-technical activities.

By projecting this condition into the military technosphere, its possible to formulate the concept of environmental safety for the operational zones of HS: hostilities are environmentally safe if the military-technogenic perturbation of the abiotic component of the ecosystem does not exceed the level at which its biota retains the ability to self-healing (that is, to return to the path of evolution according to the laws of cyclical succession after the removal of the MTL).

Thus, the stability of the ecosystem, as the ability to withstand military-technogenic pressure with a limited duration of validity (limited terms of HS), is nothing more than a biologically justified measure of the value of MTL, which, when using various types and systems of weapons and military equipment, makes combat operations environmentally safe.

But earlier it has already been emphasized that any biological restriction can perform regulatory functions in relation to the military technosphere only when it has a quantitative assessment. Therefore, in general, the requirements that must be met by a biologically significant criterion limiting the level of influence of the militarytechnogenic load on the ecosystem is as follows:

- *complexity* – the ability to integrally characterize military-technogenic changes in the natural ecosystem;
- *objectivity* – the possibility of determining on the basis of real natural parameters the state of the natural ecosystem;

- *concreteness* – the presence of the numerical value of the corresponding indicator;
- *purposefulness* – the application of the criterion should ensure the preservation of the natural ecosystem.

For an integral assessment, an ecosystem approach can be applied when there is a whole edifier sinusia or trophic network of vertebrates observed in this territory as an indicator [24, 25].

To form the basic prerequisites for the development of a comprehensive procedure for ecosystem indication of the state of the natural environment of the HS area, will limit ourselves to considering the balance equations of terrestrial ecosystems of military facilities, which are based on the laws of mass and energy storage and describe the mass-energy exchange between the main biotic components of the ecosystem: producers (P), substrates (S) and consumers (Q) (figure 1).

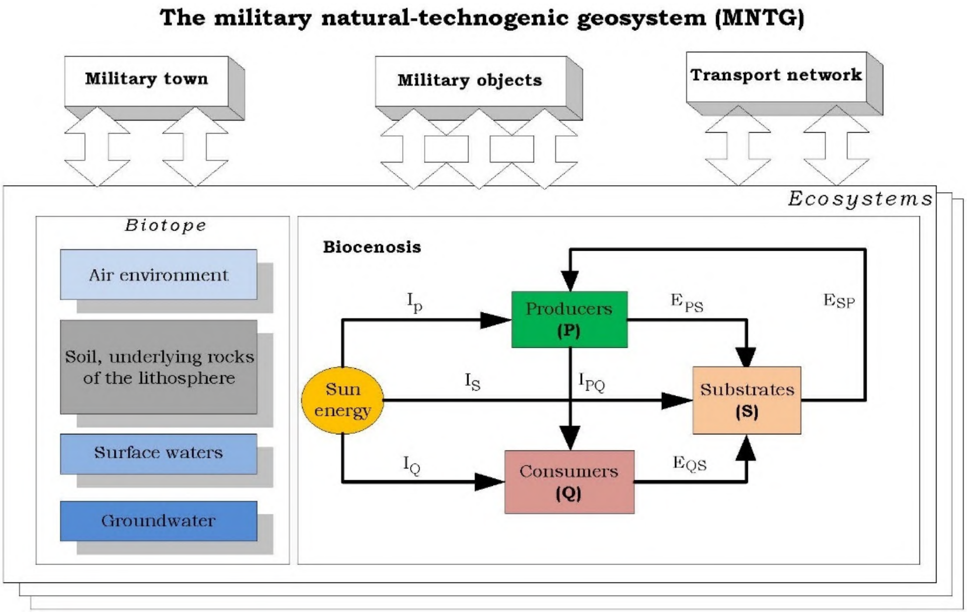

Figure 1. Block diagram of the militarynatural-technogenic geosystem (MNTG).

According to the hierarchical structure of natural geosystems, this scheme identifies the position of MNTG as a subject of study at the landscape and ecosystem levels. By biomass of an ecosystem, means the amount of functioning living matter, expressed in units of mass and related to unit area or volume (it is possible to say that talking about the average density of biomass).

Phyto-mass, zoo-mass, and microorganism mass are distinguished. Producers with biomass $P_i(i = \overline{1,\zeta}), \zeta \in N;\ P^T = (P_1, \ldots, P_\zeta]$ are autotrophic organisms (primarily green plants) capable of creating food from simple inorganic compounds; substrates with biomass S_k $(k = \overline{(1,\xi)}),\ \xi \in N;\ S^T = [S_1, \ldots, S_\xi]$ microorganisms develop; consumers with biomass $Q_j(j = \overline{1,\eta}), \eta \in N; Q^T = (Q_1, \ldots, Q_\eta]$ are heterotrophic organisms (animals (macro-consumers), bacteria and fungi (micro-consumers)) that consume ready-made organic substances but do not break down organic matter into simple mineral components, and feed on producers and other organisms. First-order consumers (those that consume plants) and second, third, etc. order consumers (predators) are distinguished.

The units of measurement of the biomass of the above-mentioned components of ecosystems are:

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012107 doi:10.1088/1755-1315/1254/1/012107

- for producers – phytomass: the weight of autotrophic organisms (green plants) per unit area or volume. For example, 200 kg of grass cover per 1 km^2, 80 kg of leaves per 1 tree, and so on.
- for consumers – zoomass: the number of heterotrophic organisms (individuals, bacteria, and fungi) per unit area. For example, 69 individuals of green lizards per 1 km2, 10 common woodpeckers per 5 km^2, and so on.
- for substrates – the weight of organisms per unit area.

The ecosystem model of the polygon will be described by aggregated coordinates P, Q, S (figure 2). To take into account the impact of HS measures and the restorative (rehabilitation) impact of nature conservation measures in the balance relationships adopted in mathematical ecology to describe the functioning of ecosystems [26–28], will add the functions W and U:

$$\begin{cases} \frac{dP_i}{dt} = \left(L_p^i - D_p^i\right) P_i - \sum\limits_{j=1}^{\eta} a_{ij} Q_j + \sum\limits_{k=1}^{\xi} b_{ik} S_k + \Omega_{p_i} + U_{P_i} + W_{P_i}, i = \overline{1, \zeta}, \zeta \in N \\ \frac{dQ_j}{dt} = \left(L_Q^j - D_Q^j\right) Q_j - \sum\limits_{l=1}^{\eta} d_{jl} Q_l + U_{Q_j} + W_{Q_j}, j = \overline{1, \eta}, \eta \in N \\ \frac{dS_k}{dt} = \sum\limits_{j=1}^{\eta} e_{kj} Q_j - \sum\limits_{i=1}^{\zeta} c_{ki} P_i + U_{S_k} + W_{S_k}, k = \overline{1, \xi}, \xi \in N \end{cases} \quad (1)$$

where:

L_P^i, L_Q^j – coefficients of natural growth of producers and consumers, respectively;

D_P^i, D_Q^j – coefficients of mortality of producers and consumers, respectively;

a_{ij} – the rate of biomass consumption of the producer species (i) by the consumer species (j);

b_{ik} – the rate of conversion of biomass of the substrate species (k) to biomass of the producer species (i);

d_{jl} – the rate of consumption of the consumer species (j) by the consumer species (l);

e_{kj} – reproduction of the substrate species (k) by the consumer species (j);

c_{ki} – the rate of consumption of the substrate species (k) by the producer species (i);

Ω_{P_i} – a function characterizing the transformation of solar energy by the i-th producer species (weather and climatic impact);

$W_{P_i}, W_{Q_j}, W_{S_k}$ – a function characterizing the direct harmful impact of HS on the corresponding components of the ecosystem. Modeled by an impulse impact, which abruptly shifts the system to a new position along the corresponding coordinate;

$U_{P_i}, U_{Q_j}, U_{S_k}$ – a function characterizing the direct restorative (rehabilitation) impact of nature conservation measures on the corresponding components of the ecosystem. It consists of the sum of natural (external migration and succession) and artificial restoration measures.

The coefficients L, D, a, b, c, d, e (indices are omitted) are complex functions of the vector of natural-climatic factors of the polygon $\aleph$, the nature, type, intensity of pollution, internal (related to military activities), background, and externally introduced (from technogenic hazardous objects located outside the polygon) pollutants, i.e., components of the generalized pollution vector Z and the rhythm (chronology) and activity of military activities. The rhythm and activity of military activities are determined by the vector of military activity parameters V.

The generalized pollution vector Z consists of concentrations of pollutants (compounds) present in the given territory. The vector of military activity parameters V includes data on the volume, intensity, duration, and periodicity of military activities.

It is particularly important to emphasize that the impact of pollution occurs slowly and manifests itself after a certain time following the accumulation and "assimilation" of these pollutants by the environment.

Thus, the coefficients of equations (equation (1)) (indexes are omitted) are complex functions of $\aleph, Z, V : L = L(K), D = D(K), a = a(K), b = b(K), c = c(K), d = d(K), e = e(K)$, where $K = \{\rho(\aleph), \Lambda(z), \theta(V)\}$ is a tuple of scalar functions. The form of the functions of natural-climatic factors $\rho(\aleph)$ and their parameters are determined by special observations of climate changes in the region. During the time interval of assessment and forecasting of the state of the ground ecosystems of the military training ground ($T \cong 10$ years), it is assumed that the values of the function $\rho(\aleph)$ are equal to the averaged values over a period of approximately $50 \div 100$ years, since the function of climate parameter changes includes periodic fluctuations with periods that exceed several hundred and a thousand years [29]. It should be emphasized that seasonal weather deviations from the mean value are considered as random parametric disturbances, the characteristics of which can be identified based on multi-year observations and taken into account in the corresponding algorithms.

The pollution function $\Lambda(Z)$ is determined algorithmically. The measurement results of the components of the Z vector are recalculated into a generalized pollution index I (see above).

The function of HS parameters $\theta(V)$ controls the structure of the system of equations (1) and logically coordinates the direct influence of W and the action of pollution Z.

Finally, the dependence of the coefficients in equations (1) on the pollution index takes the form $f(t) = f_0 + f_1 \times exp(f_2 \times I_{(t)})$, where f is replaced accordingly by L, D, a, b, c, d, e with their subscripts, and coefficients f_0, f_1, f_2 are subject to current identification.

In assessment tasks, the pollution index I is calculated for the current time t of observation of the pollution vector Z. In problems of assessing the pollution index I, it is calculated at the current observation time t of the pollution vector Z. In the problem of predicting the pollution index I, it is calculated at a future time t based on the knowledge of the function $\theta_{(V)}$, which is given in the form of a military operation plan.

By linearizing equations (1) near the stable equilibrium point of the polygon mesoecosystem (a mesoecosystem unaffected by human activity), obtain a system of equations in the deviations of the biomass of producers, substrates, and consumers:

$$\dot{X}(t) = A(t)X(t) + \Delta\Omega(t) + \Delta W(t) + \Delta U(t)$$

where:

$X(t)^T = (\Delta P_1, \ldots, \Delta P_\zeta; \Delta Q_1, \ldots, \Delta Q_\eta; \Delta S_1, \ldots, \Delta S_\zeta]$;

$A(t)$ – is a square matrix of size $n \times n (n = \zeta + \eta + \xi)$, n – the number of components in the system), whose elements depend on the time-varying level of pollution caused by HS at the landfill (or external landfill pollution);

$$\Delta\Omega^T(t) = [\Delta\Omega_{P_1}(t), \ldots, \Delta\Omega_{P_\zeta}(t); \underbrace{0, \ldots, 0}_{\eta}; \underbrace{0, \ldots, 0}_{\xi}],\ \Delta W^T(t) = \left[\Delta W_{P_1}, \ldots, \Delta W_{P_\zeta}\right];$$

$$\left(\Delta W_{Q_1}, \ldots, \Delta W_{Q_\eta};\ \Delta W_{S_1}, \ldots, \Delta W_{S_\xi}\right\rfloor\ \Delta U^T(t) =$$
$$= \left(\Delta U_{P_1}, \ldots, \Delta U_{P_\zeta};\ \Delta U_{Q_1}, \ldots, \Delta U_{Q_\eta};\ (\Delta U_{S_1}, \ldots, \Delta U_{S_\xi}\right\rfloor$$

– matrices of size $n \times 1$ composed of deviations of the corresponding components $\Omega_{P_i}, W_{P_i}, U_{P_i}, W_{Q_j}, U_{Q_j}, W_{S_k}, U_{S_k}, i = \overline{1,\zeta}; j = \overline{1,\eta}; k = \overline{1,\xi}$.

Therefore, it is proposed to decompose such an ecosystem into a series of subsystems of homogeneous biocenosis and to aggregate the components of the model to the maximum extent possible (minimizing its dimension) by using corresponding summary indicators (indices) regarding the state of producers, consumers, and substrate. System ecologists determine which specific indicators to use for building the aggregated model systems (equation (1)) based on objective observations [30].

Thus, the entire terrestrial ecosystem of military action is divided into subsystems, for each of which an individual aggregated simulation mathematical model is developed.

Mathematical models (MM) of ecological subsystems are aggregated three-dimensional MMs, which differ in that first-type models are linear (stable), and second-type models are nonlinear (logistic).

At the core of the hierarchy of complex geosystems and their diversity lies a clear and implicit division of two main ways of perceiving information about the environment [30]: biology-ecological, where the hierarchical series is structured according to the scheme: of location and community – ecosystem – biome; ecological and geographical: landscape element – landscape – ecoregion. However, this classification cannot be considered unambiguous. For instance, habitats are often interpreted through abiotic characteristics (environment-forming factors) that determine the conditions for the existence of a species in a specific territory of the HS. However, in relation to animals, vegetation is usually considered as a characteristic of the habitat and a criterion for its selection. As a result, the location becomes comparable in volume to the ecosystem of the HS territory.

If consider one of the blocks or elements of the natural environment in MNTG (figure 2), it is in a quasi-stationary state with internal equilibrium. However, at the border of homogeneous media, there are observed mutually exchange flows of mass transfer that can be activated by ingredients of military origin and military-technogenic energy fields.

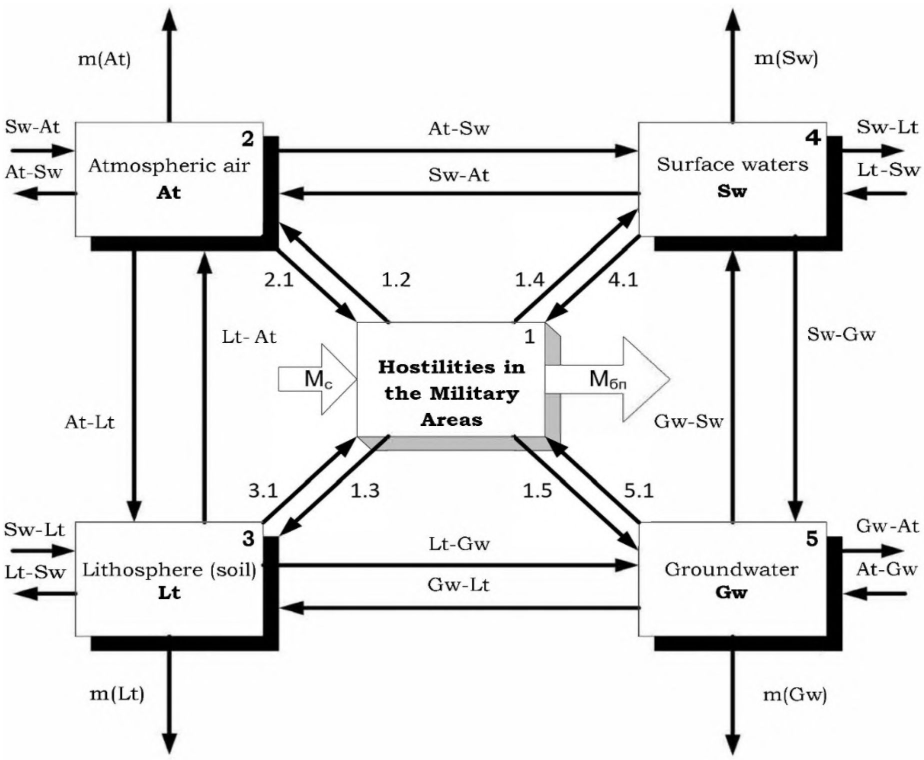

Figure 2. Scheme of interaction of the HS with the components of the environment in the MNTG (for an explanation of the designations, see table 1 [1].

4. Discussion

The general boundaries of MNTG are rather arbitrary, blurred, and determined by the level of natural or altered geochemical background. The flows associated with the "Hostilities in the Military Areas" block are marked with digital indices. The classification of these streams is given in table 1.

The considered scheme of MNTG has a general structural character. In some specific cases, the location of military objects may result in some streams being zero, and the blocks may be transformed or excluded altogether from consideration. The generalized vector index consists of integral pollution indicators according to the corresponding hazard classes $(I_{\Sigma}^{1}, \ I_{\Sigma}^{2}, \ I_{\Sigma}^{3}, \ I_{\Sigma}^{4} \ )$ or integral pollution indicators according to the corresponding components of the abiotic environment of the MNTG $(I_{\Sigma A} \ I_{\Sigma G} \ I_{\Sigma L^p} \ I_{\Sigma L^g})^T$. The impact of pollution occurs sometime after its deposition in the abiotic and biotic components of the MNTG, when the formation of mobile forms in the "soil-plant" system or on the surface of plants begins.

Consider the indicators of MTL, which, by being captured from UAVs and satellite images of remote sensing, make it possible to determine the level of damage to the natural ecosystem's territory caused by HS factors. A classification of the relevant indicators was developed, which

Table 1. Classification of flows between MNTG blocks [1].

Blocks	Combat training	Atmospheric air	Lithosphere	Surface water	Groundwater	Main processes Mass transfer
Hostilities in the MA (1)	–	1.2	–	–	–	Molecular and convective diffusion, filtering, sorption
	–	–	1.3	–	–	
	–	–		1.4		
	–	–	–		1.5	
Atmosphere (2)	2.1	–	–	–	–	For the needs of the HS
	–	–	At-Lt	–	–	Deposition, sorption
	–	–	–	At-Sw	–	Same

is presented in table 2.

Table 2: Characteristics of factors MTL.

Classes of HS territories	Types of disorders in the natural ecosystem	Indicator
	Mechanical impact	
I, II, III	Extraction and replacement of the humus layer with artificial soils during the placement of planar localization fortifications	The ratio of the area of these plots to the area of the disturbed tract
II, III	Drainage ditches	Length, depth, density
I, II, III	Military facilities	Share of paved surface area, height and density of buildings and structures BO
I, II, III	Unpaved roads without hard surface	The width of the carriageway, the prevalence of erosion furrows, thermokarst and other formations
I, II, III	Highways with backup notches	The width of the carriageway, the power of covering the sand and gravel litter, the power and area of the intersection of the recesses
II	Compaction of the upper layers of the soil during the indiscriminate movement of wheeled and tracked military equipment with a change in the species composition of vegetation	Density of traces of the movement of military equipment
II	Channels	Depth, width on the upper eyebrows, water level, flow flow rate
II, III	Deflections	Area, deflection power, groundwater level rise power
II	Pits	Area, depth, water level
II	Dams and dams	Length, height, leakage of leaked moisture, water flow mode
II	Linear communications that impede free movement on the ground	Height, prevalence of erosion
II, III	Shafts formed as a result of the construction of underground utilities	Length, depth, density
III	Soil contamination with metal waste in the form of sleeves and other fragments of shots at the starting positions for firing	Area
III	Contamination of soils in artillery boilers with shrapnel from the explosion of ammunition of various sizes, explosives that did not fully burn, and ammunition that did not explode.	Area, depth.

Continued from table 2

Classes of HS territories	Types of disorders in the natural ecosystem	Indicator
II, III	Electromagnetic pollution from radar and radio communications on military equipment	The intensity of electromagnetic field radiation, the intensity of the electromagnetic field, the oscillation frequency of the waves
	Biotic effects	
I, II, III	Complete destruction of forests due to deforestation	Cutting area, productivity of the destroyed phytocenosis
I, II, III	Cutting deforestation with a change in the direction of land use for the military	Length and width of the cuts, the ratio of the cutting area to the area of the disturbed tract
I, II, III	Depletion (destruction) of animal species populations as a result of their fishing	Species, population size
II, III	Displacement of animal species populations as a result of depletion of food supply	Species, population size
II, III	Depletion (destruction) of hydrobiont populations as a result of violation of the thermic and hydrodynamics of water bodies	Species, population size
III	Depletion (destruction) of animal species populations as a result of ammunition damage	Species, population size

Based on the main provisions of the theory of biocenology, a working hypothesis can be put forward that a necessary and sufficient condition for the self-healing of the biota of the ecosystem in operational zones of HS is the preservation of the viability of the edifier sinusia of its phytocenosis [3, 4].

Several full-scale studies have shown that the degradation of ecosystems is almost irreversible when the population density of edifier group of species (the main forest-forming species in forest ecosystems) decreases by two or more times [3, 26]. The disadvantage of using ecosystem productivity as an indicator characterizing the degree of military-anthropogenic damage to the natural environment is its ambiguity due to its change under the artificial action of various factors. Military-technogenic factors usually lead to degradation of ecosystems and a decrease in their productivity. However, some types of anthropogenic influences can destroy the balance of the natural ecosystem by causing a sharp increase in biological productivity (e.g., the process of eutrophication of reservoirs when mineralized or biologically enriched liquid waste is discharged into them). Therefore, it is advisable not to use the absolute value of the change in productivity or its relation to the basic value of the productivity of the primary (background) ecosystem to assess the degree of impact on the ecosystem.

MTL on the environment makes changes in the mechanism of homeostasis due to the deformation or destruction of feedback, which leads to the gradual replacement of primary ecosystems with less productive ones. Since the existence and functioning of any ecosystems are determined by the leading (edifier) role of a rather limited number of species, mainly plants, military-anthropogenic action on edifiers leads to violations and changes in other components of ecosystems [26, 27, 30]. From the outside, this process is expressed in the reduction and rupture of the ranges of edifier species in primary ecosystems and the transfer of the main role in creating the bioenvironment and drawing up the structure of the biocenosis to other species. Conversely, any violations of ecosystems not associated with the death of edifiers do not lead to a noticeable degradation of the ecosystem or its components. With this approach to assessing the state of the ecosystem, a quantitative change in the population density of autochthonous edifier species could become an indicator of the degree of military-anthropogenic damage to the ecosystem, and the time of action could be attributed to the indicator of its speed. Considering the significant analogy between pyrogenic processes and military-anthropogenic action in the structure and nature of the biota violation, it is possible to classify zones of military-anthropogenic destruction in the zone of HS according to the state of edifier sinusia and give a point assessment of the ecosystem's ability to self-heal (table 3).

Table 3. Classification of levels of military-technogenic disturbance of natural ecosystems.

The value of the criterion, violation on a 5-point scale	The degree of ecosystem disruption	The degree of artificial violation	Share of reduction of types of edifiers	Characteristics of the state of the ecosystem and the possibility of self-healing after the removal of the military-technogenic load
I	Background	Too Small	Up to 10 average 5	Rapid self-healing
II	Weak	Small	11−25 average 18	The oppressed state of most species, the ability to self-healing is fully preserved
W	Moderate	Action on the verge of preserving biota	26−50 average 38	Changing the ratio and role of dominant species in the community. The time of self-healing is very long; the possibilities of self-healing are uncertain
IV	Strong	Destructive action	51−80 average 65.5	Changing the qualitative composition of the self-healing community is impossible. The inevitable emergence of new technogeosystems
V	Very strong	Catastrophic effect	80−100 average 90	The complete destruction of the indigenous community and the removal of land from natural circulation for a long time

Under the military-anthropogenic influence (I and II class), effective and constant monitoring of the density of populations of edifier species is necessary, and work on the reclamation of these territories (especially in class III) should be aimed primarily at restoring the edifier sinusia that formed the basis of the ecosystem before the start of the HS.

5. Conclusion

The biologically justified permissible threshold value of technogenic changes in the phytocenosis edificator sinus of the ecosystem is of paramount importance for determining development paths and selecting database management in the face of inevitable military and technological intrusion into the natural equilibrium ecosystem. Experimentally determined indicators should influence the choice of nature conservation and restoration measures in planning databases, but they do not allow for an integrated characterization of the degree of military-technological disturbance of the ecosystem as a whole.

In this article, a mathematical model (equation (1)) has been developed that:

- adequately reflects the impact of combat operations on biocenoses of educational facilities;
- can be used as a mathematical model of phenomena, the parameters of which, with sufficient experimental data, are identified (calibrated) using identification algorithms with the model;
- after identification (calibration), it can be included in algorithms for complex assessment and prediction of the state of terrestrial ecosystems affected by combat operations.

Of the existing indicators in modern mathematical ecology, productivity indicators are the most suitable for this purpose. For natural equilibrium ecosystems, the productivity of the biocenosis correlates well with its complexity and species composition. Therefore, the suppression or destruction of any species as a result of the impact of combat operations inevitably affects the productivity of the biocenosis, and thus, it can serve as a quantitative assessment of the depth of the military-technogenic impact on the ecosystem.

To assess the corresponding level of changes, the system of indicators presented in table 2 can be used, which is interrelated with the levels of military-technogenic violations (table 3).

With sufficient accuracy for engineering assessments, the primary productivity indicator (biomass produced by producers per unit area per unit time during the growing season) can be used. By applying biology-accepted methods and conducting regular observations using remote sensing satellites or unmanned aerial systems to monitor changes in this indicator over time and space, it is possible to determine both the overall dimensions of military-technogenic impact zones and the dynamics and pace of this process when using various weapons systems and military equipment.

Abstract. The article examines global trends in the development of the nuclear power industry. It includes the following: extending the operating life of nuclear power units; development of atomic energy in the context of the Paris Agreement; development of nuclear-hydrogen energy; synergistic interaction of renewable energy sources and nuclear power plants; introduction of new reactor technologies. The attitude of different countries of the world to atomic energy is described. It is determined that China and India are the leaders in developing nuclear power. It was determined that small modular reactors are considered transformative reactors that will contribute to the further development of atomic energy in the world. The advantages of small modular reactors in comparison with reactors of large capacity are described, and recommendations for selecting small modular reactors for Ukraine are formulated. Installation of small modular reactors at the operational sites of the NPPs of Ukraine can reduce the financial costs of their construction. Therefore, it will contribute to the sustainable development of the nuclear energy industry of Ukraine.

1. Introduction
The complex problem should be solved to ensure the long-term development of humankind. The issue includes the maintenance of energy and economic and environmental security. Therefore, it is necessary to unite world efforts in the search for innovative directions of technological development that ensure a stable and secure future to solve the outlined problems [1]. Currently, the international energy community emphasizes the global revival of nuclear energy and the rapid

development of renewable energy sources. The situation is evidenced by the active construction of new and modernization of existing nuclear power plants (NPP) in many countries [2].

Further digital transformation of society is essential to ensure the sustainable development of humankind. Such change requires an increase in energy consumption due to the need to process ever-increasing volumes of data. At the same time, growth in energy consumption leads to:

1) depletion of energy sources (problem of energy conservation and diversification of energy production types);
2) climate change (the problem of reducing carbon footprint involves transforming the electricity generation sector against the background of reducing the operational resource of existing energy capacities).

Azarov and Zadunaj [1] indicates various international initiatives in the global field of nuclear energy aimed at developing new projects to combine the efforts of many countries in creating innovative nuclear energy technologies. These initiatives are designed to ensure energy security, reduce atomic materials' distribution risks, and solve the problem of radioactive waste. Also, these ideas became the basis of the international project INPRO operating under the International Atomic Energy Agency (IAEA).

Interest in small modular reactors (SMRs) and their applications is growing worldwide. The main driver for SMR development is to meet the need to produce electricity for a broader range of users and applications, replace aging large-capacity reactors, and improve safety. SMRs include new-generation reactors designed to produce electricity up to 300 MW according to the accepted definition of the IAEA. Their components can be manufactured at the factory and transported as modules to the installation site. SMRs can be deployed as a single or multi-module installation. In addition, many SMRs have increased protection properties and safety functions [3].

Hussein [4] emphasized that SMRs are the next stage in developing nuclear reactors and are transformative by many criteria. SMRs are seen as a way to overcome cost overruns and construction delays where sizeable atomic power reactors were supposed to operate. SMRs can play an essential role in addressing climate change by providing a low-carbon source of electricity. They can also help alleviate the problem of nuclear waste disposal by burning spent fuel and nuclear waste.

Examining government documents regarding the regulation of nuclear energy issues in Ukraine for 2018-2019, we see the following:

1) SE "NAEK "Enerhoatom" and Holtec International signed a Memorandum of Understanding on cooperation in the use of SMR-160 in Ukraine. The Memorandum states that it is planned to license SMR-160 technology in Ukraine further to build these reactors at Ukrainian nuclear power plants and to localize production of SMR-160 equipment at Ukrainian enterprises partially;
2) SE "NAEK "Enerhoatom", State Scientific and Technical Center for Nuclear and Radiation Safety and Holtec International signed an agreement on the creation of an international consortium for "introduction of the small modular reactor (SMR) SMR-160 technology in Ukraine" [2, 5].

Therefore, we state that SMR use is also lobbied at the state level in Ukraine.

It was planned to end the operation period of some power units of the NPP of Ukraine between 2030 and 2040. Such power units already had an extended operation period. The fastest choice of the reactor type technology for the construction of replacement and new NPP power units is relevant [6], taking this into account and taking into account the duration of the creation of a nuclear installation.

Four nuclear power plants in Ukraine (15 power units with water-water power reactors) were operating in Ukraine at the beginning of 2022. Their capacity was 13,835 GW. Zaporizhzhya

NPP (6 power units, the largest nuclear power plant in Ukraine) is still under the control of the invaders in the occupied territory for the end of 2022 due to military operations on the part of Ukraine. The construction of SMR on the territory of Ukraine is still updated by the need for a stable electricity supply for the post-war reconstruction of Ukraine and its economy.

2. Literature review

Azarov and Zadunaj [1] analyzed nuclear energy development in the world and the impact of large-scale accidents at nuclear power plants ("Fukushima-1") on it. The need to improve the security of nuclear power plants is emphasized. Innovative technologies of the III-generation reactors are described. It was noted that atomic energy is the most critical component of the world's energy balance, and there is no severe alert.

Analysis of the materials of international organizations (International Project on Innovative Nuclear Reactors, International Atomic Energy Agency, Nuclear Energy Agency, etc.) [7–9] and scientific literature showed that only a few countries in the world started construction of SMRs by the end of 2022. Various concepts and project licensing are still discussed in other countries.

Nosovskyi [10] determined that there currently needs more technical, economic, and scientific justification for the SMR's operation. SMRs are only being developed worldwide, and their operation benefits still need to be confirmed in practice. Furthermore, the analysis showed that SMR technologies used for electricity production are more expensive than power units with a 500-1000 MW capacity.

The report [11] describes the main problems that should be overcome for the large-scale implementation and achievement of economic competitiveness of SMR. An overview of financial and technical aspects, issues of licensing, and legal regulation are presented. Expanding international cooperation in all directions is essential to create a sustainable global SMR market.

Features of SMR modularity and design are described in [4]. The economic advantages of SMRs and flexibility allow them to be used for various purposes. SMRs are considered a means to reduce greenhouse gas emissions. SMR designs incorporate features that were tested and proven in early reactors. They are also relatively safe for the surrounding population.

Azarova and Zadunaj [1] considered existing plans and programs to develop promising "IV generations" reactor technologies. It is necessary to consider several additional factors: principles development for ensuring the acceptability, efficiency, and economic competitiveness of nuclear energy, stability, nuclear and radiation safety, non-propagation, and physical protection.

Currently, SMR concepts can be conditionally divided into five main groups [11]:

1. *Single-module light-water reactors.* Their design uses the proven technology of light-water reactors (LWR) and appropriate types of fuel to create autonomous units suitable for deployment within the concept of distributed generation or capable of replacing small power units operating on fossil fuels;
2. *Multi-module light-water reactors.* They are based on the LWR technology and can be operated as sources of electricity within the framework of the concept of distributed generation or replace medium-sized power units that provide base load;
3. *Mobile/movable reactors.* They are based on LWR technology and allow easily implemented installation movement from one site to another. This category includes reactors of floating power units;
4. *"IV generations" SMRs.* They are based on modern technologies that differ from those used in LWR;
5. *Micromodular reactors.* Their capacity is at most 10 MW. Such reactors can operate in semi-automatic mode, as a rule. Also, they have characteristics that facilitate easily realized transportation compared to larger SMRs; Micro-modular reactors are designed primarily

for off-grid operation in remote areas where they can be competitive with mainstream electricity sources.

Demianiuk [12] defines the characteristics of SMR and the synergy of SMR with renewable energy sources. Progress of SMR projects in the short term and an overview of leading in technical and economic indicators of SMR are described. Finally, a list of priority measures for implementing SMR in Ukraine is outlined.

Classification of SMR projects depending on the novelty of their technical solutions was proposed by Dybach and Plachkov [13]. In addition, a comparative analysis of SMR (SMR-160 Holtec International project) with NPPs operating in Ukraine was made.

Currently, the most developed type is LWR installations with pressurized water among the existing SMR projects. Steam generators are one of the main elements of them. The preferred design is a functional-flow steam generator with functional body movement in tubes with coiled surfaces [14].

Niearonov et al [6] describes the algorithm for choosing reactor technology type based on a comparative evaluation of existing and promising reactors. Adaptation of the KIND-ET toolkit of the IAEA INPRO project on a multi-criteria comparative assessment of nuclear power plants was carried out for the obtained results ranking. Proposals for reactor technology type choice for constructing NPP power units in Ukraine after 2035 are described. Finally, recommendations for optimal reactor technology choices for creating NPPs in Ukraine for 2050 are defined.

The energy of Ukraine, will be endangered unless the country has time to replace NPP power units with new ones within 2040-2050. At the same time, a significant share of the country's human capital will be lost because nuclear energy is a high-tech industry. It requires specialists with a high level of training in various scientific fields. Therefore, developing and implementing programs to transfer nuclear technological knowledge at the state level is essential. The outlined understanding is a vital resource that will determine Ukraine's political and economic realities shortly. Renewal of Ukraine's nuclear power plants is possible in the following directions: construction of SMR and new "large" NPPs [2].

We analyzed the websites of international organizations dealing with nuclear energy issues and scientific literature during working on this research. Functioning of nuclear fuel cycle facilities are considered in publications [1, 2, 4, 15–18], issue of developing mathematical and software tools for assessing the impact t of energy facilities on the environment is considered in works [19–31]. Specifics implementing of alternative and renewable energy sources are described in publications [32–40]. Advanced training of specialists in nuclear energy is discussed in publications [41–44]. The literature review was performed based on open sources and the websites of international organizations [7–9].

Aim is to consider world trends regarding the development of the nuclear power industry and to substantiate the possibilities of building SMR in Ukraine, given their environmental friendliness and safety.

3. Results

We support the opinion of Kilnytskyi [45] that the principles of sustainable development have determined mainly the evolutionary directions of world energy since the beginning of the 21st century. Bet on energy efficiency, energy security, and low-carbon energy with the active construction of renewable energy sources allowed the industry to enter its development's revolutionary and innovative stage. Everything is changed dynamically on the energy map of the planet: the structure of generating capacities, the configuration of energy systems, and the arrangement of national energy markets.

Investments in nuclear energy were stable and promising for a long time. However, the accident at the Japanese NPP "Fukushima 1" (2011) made the world think about security and question the future of atomic energy. Later, talks about global climate change began, and advanced countries took a course on renewable energy. The question arose: will there be a place for nuclear energy in the new "green" world? NPPs do not emit CO_2 and fully fit the carbon bond neutrality policy. At the same time, atomic power plants leave harmful nuclear waste, and the risk of accidents still makes people distrust even high-tech reactors. Therefore, the USA, Germany, Japan, South Korea, and other world powers gradually reduced investments in this industry; the gas crisis occurred in 2021. So, nuclear energy received a chance for revival and a new future [46].

Currently, 440 nuclear reactors are operating in 32 countries. Another 50 are under construction, mainly in Asia. However, the IAEA does not give precise predictions role of nuclear power plants in electricity production worldwide. It depends on whether it will be possible to build new capacities to replace the stations that will be decommissioned. More than half of the active reactors in the world have been operating for more than 30 years. Today, nuclear energy accounts for 10% of global electricity production. According to the low forecast of the IAEA, this share will decrease to 6% by 2050. According to the high estimates, the percentage of nuclear electricity will increase to 12% [47].

Nuclear energy has two advantages over other sources. First, it can provide heat for production processes and cheap and reliable electricity without releasing greenhouse gases. Secondly, nuclear energy currently avoids emissions of 200 million tons of CO_2 annually (equivalent to removing 400 million cars from all world's roads) [48].

Currently, nuclear energy is in trend again. Let's consider how the views of different countries of the world on nuclear energy were changed. Materials for analysis are taken from open sources of information: scientific publications, websites of international organizations, and analytical and reporting materials. Finally, continents and countries grouped the results of the analysis.

3.1. Europe

The **EU** still needs to make a final decision on the status of nuclear energy. There is an ongoing debate regarding including atomic energy in the "green" taxonomy. Taxonomy is a list of environmentally friendly activities. The European Union needs it to show "useful" companies and encourage investors to finance them. Companies with such markers will attract more loans and be supported by the EU authorities. In 2020 scientists from the European Commission recognized nuclear power plants as a safe, low-carbon energy source. But in 2021, the commission refused to include nuclear power plants in the "green" taxonomy due to the problem with nuclear waste disposal. However, the energy crisis in the EU intensified this debate. At the same time, 12 EU countries called the European Commission to recognize nuclear energy as "green" [46].

More than half of **Poland's** energy depends on coal. So, there is also a search for a stable alternative to reduce carbon emissions.

Germany decided to decommission its nuclear power plants after the Fukushima accident. However, seven reactors remain in operation and provide 12% of Germany's electricity. At the same time, renewable energy is successfully developing in the country [47].

Spain has gradually reduced its share of nuclear energy. Seven reactors remain in operation and supply about 20% of electricity. According to government directives, all reactors should be shut down between 2025 and 2035. It is planned to be replaced by stations with renewable energy sources. However, this may affect the timing of the planned shutdowns [47].

France is the informal leader in nuclear energy production in the world. The country's government is most interested in the approval of atomic energy. France operates 56 nuclear reactors. They provide more than 70% of electricity needs. The country is also the world's largest exporter of nuclear power. It also helps build atomic reactors around the globe. At the same time, 12 reactors coming to an end of service life are planned to be turned off.

Along with this, the construction of a new power unit at the Flamanville NPP is underway.

This will be the country's first EPR – a pressurized water nuclear reactor of the third generation with a capacity of 1,650 MW. Construction was delayed for ten years. Flamanville-3 is expected to be launched in 2023 [47, 48].

Slovakia is the country that is building new nuclear power plants in Europe. Four reactors provide half of the country's electricity, and two more are under construction. The situation with two new reactors at the Mohovets NPP demonstrates the general problem of NPP construction. The 2019 opening was delayed due to pressure from neighboring Austria and safety concerns for the power units, which were initially built to Soviet design and modified using "Western" elements [47].

Great Britain ranks tenth in the world for nuclear energy production. "Electricite de France SA (EDF)" began constructing the Hinkley Point C plant in Somerset in 2016. It is expected to be operational in the middle of this decade. Hinkley Point C is expected to supply around 7% of the UK's electricity once connected to the grid. In addition, it is currently underway for the 3,200 MW Sizewell C power station in eastern England. EDF plans to build it in partnership with China General Nuclear Power Group [48].

3.2. North America

Ninety-five reactors are actively operating in the USA, providing 30% of the world's nuclear electricity and remaining its largest producer. NPPs generate about 20% of electricity for the country's needs. From 1978 to 2013, new NPPs were not built. Only in 2012 were permits issued for constructing two new reactors at the Vogtle NPP in Georgia. It happened for the first time in 30 years. New projects began to appear in 2016 when the second power unit of the Watts Bar NPP in Tennessee opened. However, significant delays and rising construction costs led to the closure of two reactors at the V.C. Summer station in 2017 in South Carolina [47]. The development of nuclear power plants in the United States is part of the fight against climate change. The government allocated $1.85 billion to support the nuclear power industry in 2022. This value is 23% more than in 2021. Another $6 billion will be used to extend the service life of the NPP; 2.5 billion will be spent on the construction of experimental reactors [46]. President Biden spoke in favor of nuclear energy and emphasized the expansion of jobs and opportunities that will be created through the development of innovation and investment in the latest small modular reactors [48].

3.3. Asia and the Middle East

China plans to significantly increase the share of nuclear generation in the energy system from 3% to 7.7% in 2035. The country has 49 reactors, and 16 more are under construction. Preference is given to nuclear energy in the country due to excessive air pollution by coal-fired power plants. China is developing and planning to introduce new reactors and increase the number of plants and their capacity. For example, the first SMR may start operating on Hainan Island as early as 2025 [47]. China is ready to build many nuclear power plants on its territory and 30 reactors abroad, competing in this market with France and the USA [46]. In 2021 the President of China was directly present at the foundation laying ceremony of four new nuclear power units in the PRC. Power units 7 and 8 of the Tianwang NPP and 3 and 4 of the Xudapu station will be built using domestic equipment [48].

South Korea announced plans to withdraw from nuclear energy by 2040. As a result, the life of atomic power plants will remain the same, and new facilities will not be built [48].

Japan sees nuclear power as the key to achieving decarbonization goals and reducing greenhouse gas emissions. Therefore, Japan is also considering using nuclear energy by introducing small modular reactors. This is outlined in the country's Green Growth Strategy [48].

The **Indian** government plans to launch nine reactors in three years. The construction of another 12 was approved in 2020. This is the first time a nuclear power plant has been built in the country on such a scale [46]. It is planned to increase the number of nuclear power plants in India within the framework of large-scale infrastructure development programs. Currently, 23 reactors are operating in the country. In addition, 21 new reactors with a total capacity of 15 GW may be installed [48] up to 2031.

The **United Arab Emirates** launched the first Baraka NPP in 2020. It is planned that all four power units of the station, with a total capacity of 5.6 GW, will work already in 2023 and will provide up to 25% of the country's electricity needs [48].

Turkey is building its first Akkuyu nuclear power plant. One of the reasons is a desire to reduce energy dependence. The country imports about 75% of its electricity. The station will have four power units with a total capacity of 4.8 GW. Its first reactor is planned to be launched in 2023 [48].

So, we conclude that China and India became leaders in developing the nuclear energy industry based on the analysis above. Based on the analysis of scientific literature [14, 45, 47, 48], the main problems of the development of nuclear energy in the world are outlined:

- decrease in the competitiveness of nuclear energy and premature shutdown of power units;
- exceeding terms and cost of construction of new NPPs;
- aging of operating power units and need for decommissioning;
- the negative attitude of society against the background of Fukushima and other nuclear accidents;
- the difference in licensing of nuclear reactor projects;
- the need to solve the problem of spent nuclear fuel and radioactive waste;
- the inability of energy markets to attract long-term investments.

We agree with the Lutska [47] that today's security issue remains the most crucial reason for refusing to build new nuclear power plants. It got tougher every time after the accidents at the Chornobyl and Fukushima stations. In 2011 anti-nuclear protests intensified significantly in Europe, where plants are often located near borders with neighboring countries. The next problem is the complex process of nuclear power plant construction. It is often delayed and stopped causing the cost of power units to rise. Also, the issue of handling atomic waste remains relevant. At the same time, some countries see nuclear energy as an opportunity to diversify energy sources, reduce dependence on other energy sources and replace coal-fired power plants [47].

An outline of the world trends in the development of nuclear energy is essential. The research was prepared based on the analysis of various sources [4, 14, 16, 45, 47–50]:

- an extension of the operating periods of nuclear power units;
- development of nuclear energy in the context of the Paris Agreement;
- development of nuclear-hydrogen energy;
- synergistic interaction of renewable energy sources and nuclear power plants;
- introduction of new reactor technologies.

Let's briefly describe the trends outlined above. The critical disadvantage of nuclear energy today is the high capital costs for constructing large atomic power units. Therefore, many countries with operating nuclear power plants are forced to extend the operating periods of their power units. The leading technologies that will ensure the fulfillment of the goals of the Paris Agreement include those with low levels of greenhouse gas emissions. Hydropower, wind, and nuclear power will play an important role. They produce the least amount of greenhouse gas emissions. Every year amount of hydrogen consumption increases. So, the development of hydrogen energy is taking place. Many countries developed their own "Hydrogen Strategy". The world public and scientists predict a significant effect from the operation of hybrid energy systems for the synergistic interaction of renewable energy sources and nuclear power plants. Such hybrid systems will make it possible to generate electricity and provide low-carbon thermal energy for the industry at a price lower than a traditional thermal generation (figure 1).

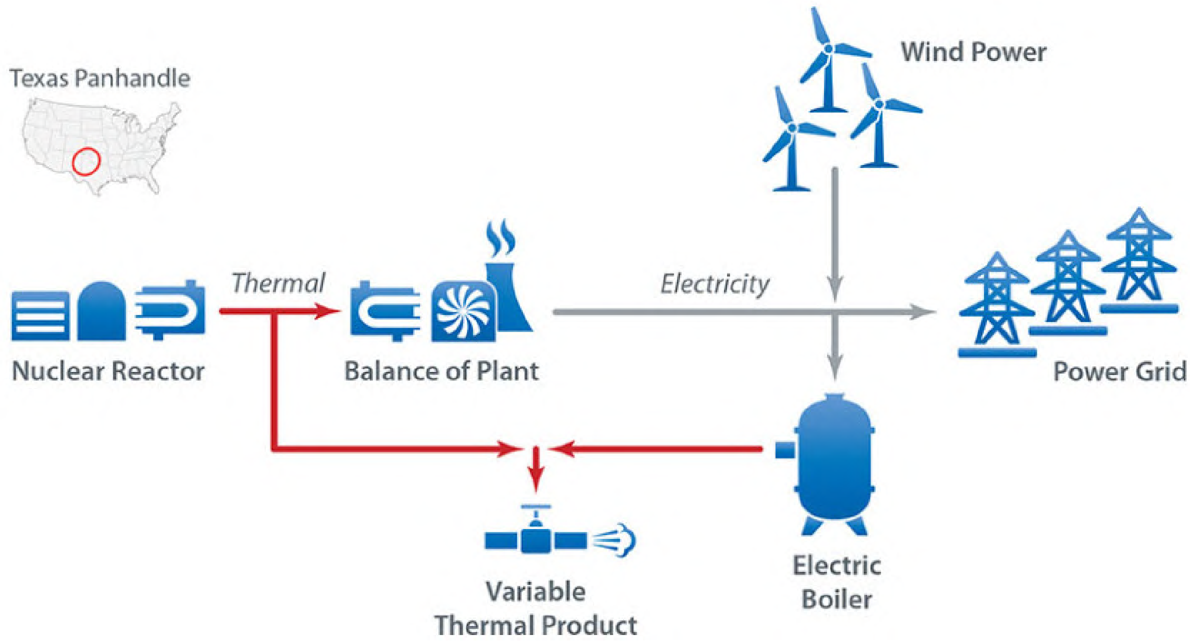

Figure 1. An example nuclear-renewable hybrid energy system configuration [51].

Let's analyze the trend regarding the "introduction of the new reactor technologies" in more detached new reactor technologies caused by the following factors: risk of accident at the nuclear power plant and difficulty of disposal of radioactive waste. The publication [46] indicated that the factors listed above could be leveled by using new reactor technologies. One of the progressive ideas is thorium reactors. Uranium-233 is used for the operation of these systems. The substance is obtained through the irradiation of thorium-232. These reactors are predicted to leave behind less toxic waste. At the same time, there are more thorium reserves in nature than uranium, which is safer to produce. Currently, China decided to build an experimental thorium reactor that will work on an alloy of salts. The reactor will be filled with an alloy of salts. So, it will have a much lower risk of melting or exploding, making the leakage of radioactive components almost impossible. However, thorium is associated with the risk of nuclear propagation. It is hotly debated.

The TerraPower company plans to launch an experimental nuclear reactor in the remote town of Kemmerer (USA). The reactor will be cooled by liquid sodium. There will be no increased pressure in the reactor, So it minimizes the possibility of an explosion. The system will not require external energy sources for cooling. The creators of TerraPower promise to solve the problem of nuclear waste. Now they are stored in concrete containers. Spent fuel from TerraPower will take up two-thirds less space than waste from conventional reactors. Also, the construction of such an object costs much less than usual due to greater use efficiency. This reactor is small in size. It, in turn, reduces capital costs. It produces three times less energy than the average reactor, so it is more profitable to build it [46].

Today, companies and startups worldwide develop new models of nuclear power plants. They should be simpler and cheaper to build, safer, use less fuel, and operate more flexibly. They may influence global trends in the development of atomic energy [47] if the new reactors meet all these criteria.

NPPs with high-power reactors are designed to operate in the base mode. Therefore, it limits the possibilities of using nuclear potential due to the need for daily regulation of loads in the power grid. This drawback can be avoided by switching to SMRs (figure 2). SMRs are cheaper to operate, can be used in shift mode, do not require the construction of powerful underwater power lines, and have higher levels of safety [45].

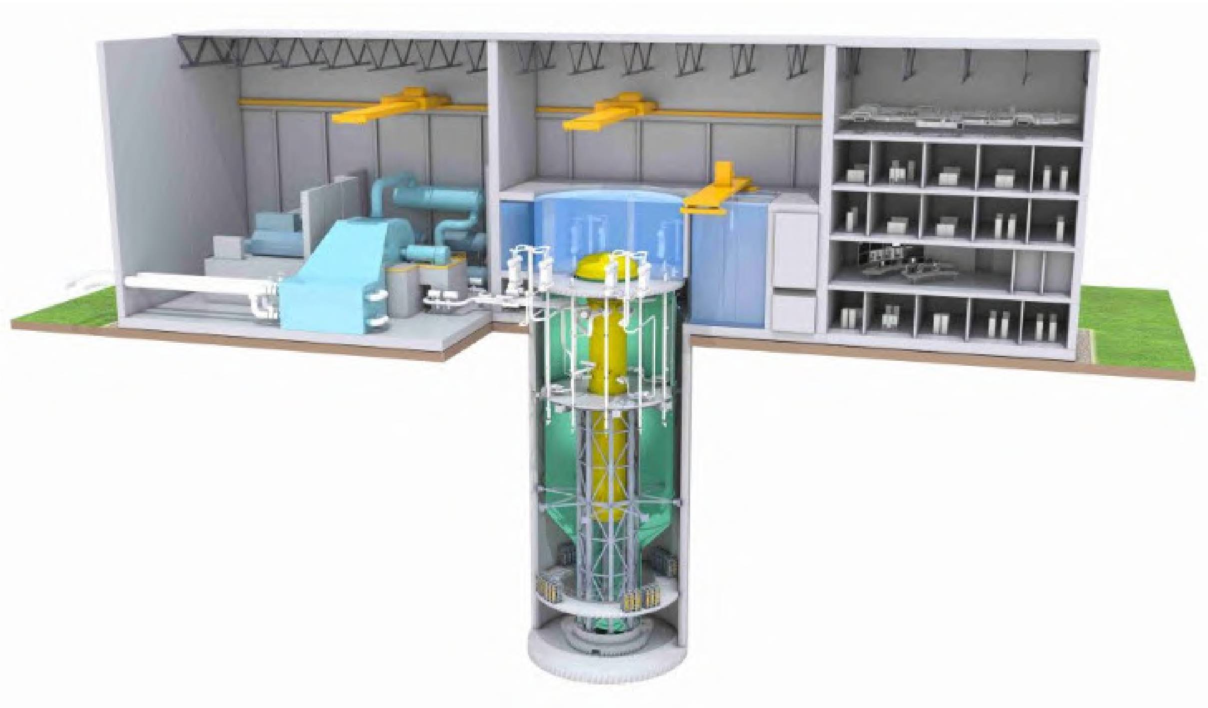

Figure 2. Example of BWRX-300 Small Modular Reactor [52].

Miroshnychenko [46] indicated that SMRs will produce three to four times less energy than conventional ones and will be affordable for underdeveloped countries. In addition, their low cost will make it possible to replace large nuclear power plant reactors that with ending their service life [45].

Dybach and Plachkov described several potential advantages of SMR [13]:

1) higher protection of SMR from undue external influences of natural and artificial nature (possibility of underground placement of the reactor installation). Figure 3 shows this placement of Canada's first SMR;
2) high level of internal self-protection and wide use of passive systems. It allows reviewing (reducing) a set of technological systems necessary for safety, operating in standby mode;
3) modular principle ensures serial production, the possibility of complete factory production of the module and its delivery to the NPP site;
4) operation in power tracking mode (power shift) allows combining SMR with other renewable energy sources.

Figure 3. Example of underground placement of SMR [53].

SMRs can find applications in many areas of nuclear energy use. The steady development of SMRs was revealed as a result of the analysis of the current trends in the development of atomic energy. Currently, the most developed type is LWR installations with pressurized water among the existing SMR projects. Steam generators are one of the main elements of them. The preferred design is a functional-flow steam generator with functional body movement in tubes with coiled surfaces [14].

OECD [11] indicated that worldwide policy-making bodies, enterprises of the nuclear sector, and energy analysts show growing interest in the potential of SMR as a competitive element of low-carbon technologies used in integrated energy systems of the future. In addition, SMRs embody hopes for inherent safety, simplification, and standardization properties. All of this can significantly facilitate and make nuclear power more cost-effective.

SMRs can be placed directly in energy consumption centers. It eliminates the need for external power lines and maintenance in difficult climatic and terrain conditions. Significant reduction in network infrastructure costs allows for increased efficiency and competitiveness of SMR technologies [54].

Gaspar [55] emphasizes that SMRs are smaller and use innovative technologies with many built-in safety features. An important element of their design is minimizing accidents and radioactive emissions. A similar opinion was expressed by Zhou [14]: “SMR possess better safety characteristics and lower amount of radioactive materials (less potential for radioactive release); it is expected that iodine prophylaxis, shelter, evacuation will not be needed to protect public from the SMR".

Considering SMR according to various criteria characterizing their advantages, we will describe the "safety" criteria and its indicators based on [11]:

- reducing the level the severity of emergency modes (a combination of increased levels of simplification and structural integrity is expressed in a smaller number of emergency modes);
- efficiency of passive safety systems (need for active systems decreases, which in the long run simplifies safety assessment, reduces the number of emergency modes, and improves the reactor cooling mode using natural circulation. All this contributes to increasing the time provided for emergency response);
- reduced protective zone outside the site (less need for shielding means and a smaller area of the zone for planning protective measures).

Table 1, table 2 and table 3 compares SMR and high-power reactors according to the criteria "Operational safety," "Infrastructure," and "Personnel resources." This tables was compiled based on publications [6, 12, 54, 55] and open sources.

Ukraine promised to abandon coal burning by 2035. Consequently, the number of thermal power plants will decrease over the years, and domestic energy will gradually lose 30% of its capacity. The decline of thermal power plants will stimulate the development of nuclear power plants and renewable energy facilities. The problem is that 13 out of 15 reactors will become unusable by 2040. Therefore, fourteen power units should be built in the coming decades for the energy transition and replacement of old reactors. Three should be located at the Khmelnytskyi

Table 1. Comparison of SMR and high-power reactors ("Operational safety" criterion).

Indicators	SMR	High-power reactors
Physical safety	Possibility of hidden placement underground, underwater on the territory of military bases, etc. There needs to be more infrastructure, personnel, and length of heating lines.	Risks associated with the extensive infrastructure and territory of the station.
Energy security, infrastructure risks	Integration into the local power system. Flexibility to build up generating capacity. Low distance to the consumers.	Extensive network and consumer life support system risks.
Nuclear and radiation safety	Reduction of the risks and magnitude of caused damage. Absence of "serious accident" consequences.	Probabilistic methods estimate them.
Energy stability	There are no power unit stops due to common causes.	However, the power unit stop occurred due to familiar grounds.
Human factor	We make technical decisions on modularity, quality, and reliability – a minimum number of personnel, a personnel training system, and a department management structure.	The high number of personnel at all stages of the object's life cycle and workshop management structure.

Table 2. Comparison of SMR and high-power reactors ("Infrastructure" criterion).

Indicators	SMR	High-power reactors
Reliable energy supply	Organization of ensuring effective navigation of transit and sea routes, military facilities, etc.	Limited. It is possible with a developed structure of energy networks.
Technical competencies and infrastructure development	Development of competencies within the territory's economy. An educational center, scientific and technological complex, prospective studies of habitats. I am stopping the outflow and employment of the population, particularly the youth.	We were limited by the technology of the power unit (electricity production).
The wide contour of energy conversion and tariff stability	Electricity, heat, fresh water, steam, and hydrogen are modules for the region's infrastructure needs and a reliable life support system.	Limited to electricity production only.
Creation and provision of reliable hybrid energy systems	Ensuring stability, reliability, and quality of the energy carrier, design of hybrid energy systems in local areas, a wide range of capacity changes, and creation and development of industrial nuclear-hydrogen energy.	
Insurance	It is possible for various infrastructure objects.	Not available in its entirety.

NPP, one at the Zaporizhzhya, Rivne, and South Ukrainian NPPs, and eight at new stations. SE "NAEK "Enerhoatom" signed a memorandum with the American company Westinghouse which will participate in constructing five power units worth about 25 billion dollars. Cooperation with Westinghouse SE "NAEK "Enerhoatom" is positive. It is believed that Ukrainian specialists have enough experience to build power units [46].

The first energy cooperatives appeared in Ukraine: several community members united to provide themselves with energy resources. This practice is widespread worldwide, especially in the USA and Germany. In these countries, the total number is calculated in hundreds and thousands, and they unite millions of people. For example, in Germany, 47% of solar energy is produced by citizens and cooperatives. Energy cooperatives are common in Great Britain, Australia, the Netherlands, and Denmark. A Cooperative is also cheaper to administer than a joint-stock company or an investment fund. The primary meaning of energy cooperative for citizens is not to expect mercy from the state or industry monopolies in solving energy supply problems but to develop their energy businesses and earn money independently [45].

The country's energy security and the possibility of further digital transformation of the economy will be endangered if Ukraine does not have time to replace the existing NPP units with new ones during 2040-2050. Also, a significant share of the country's human capital will be lost. Nuclear energy is a high-tech industry and requires specialists with a high level of training in various scientific fields. The "nuclear energy knowledge of Ukrainian specialists" can be classified as a national strategic resource. Therefore, at the state level, it is necessary to develop and implement programs to preserve and transfer nuclear technological knowledge as a resource that will determine Ukraine's political and economic realities shortly [2].

Activities on analyzing prospects for the introduction of SMR technology in Ukraine were also

Table 3. Comparison of SMR and high-power reactors ("Personnel resource" criterion).

Indicators	SMR	High-power reactors
An alternative approach to reloading nuclear fuel	The zone is active for 10-15 years. Filling together with a radioactive installation at notable enterprises. Absence of dose loads on personnel.	Reload every two years. Availability of spent nuclear fuel and radioactive waste infrastructure. Radioactive waste removal. Dose load.
Risks at the decommissioning stage	Large modular dismantling. Reducing the likelihood of exposure to personnel at risk.	Large modular disassembling. They are reducing exposure probability to personnel.
Environmental safety	Local energy system transformation into an ecologically clean system. Significant reduction of emissions (liquid, solid, gaseous) and oxygen combustion. Reduction of environmental consequences.	Placement and assignment restrictions.
Application of waste-free technologies	Development of unavailable resources. Deep processing of minerals, water desalination, waste disposal, etc.	Limitation by purpose.
Social acceptance.	Possibility of visual proof of increased security.	Psychological barriers (after the Chornobyl and Fukushima accidents).

started: working cooperation with potential SMR suppliers (NuScale Power) was established, and work on studying the technical and economic aspects of these reactors is ongoing. In addition, SE "NAEK "Enerhoatom" and "Holtec International" signed a "Memorandum of Understanding" on cooperation in the use of SMR-160 in Ukraine (figure 4).

The work of Demianiuk [12] contains a generalization of SMR safety indicators: frequency of damage to the active zone, the frequency of early/significant release, and the size of the emergency planning zone. In addition, a combination of SMR and renewable energy sources is considered.

Niearonov et al [6] emphasized that using SMR in Ukraine is the most promising direction for developing nuclear energy in Ukraine. At the same time, it is necessary to conduct additional research on determining the optimal ratio of SMR and PWR reactor technologies, considering prospects for deploying renewable energy sources. Priority measures for SMR implementation in Ukraine are described [12]:

1) in-depth strategic analysis of the United Energy System of Ukraine according to international methods (IAEA, OECD);
2) detailing needs of the United Energy System of Ukraine in balancing (maneuvering) capacities and developing technical requirements for SMR;
3) execution of preliminary technical and economic substantiation of SMR construction;
4) development of optimal financial models for the implementation of SMR projects in Ukraine based on public and private partnership.

It is essential to take into account the following aspects [6] during the comparative evaluation of reactor technologies:

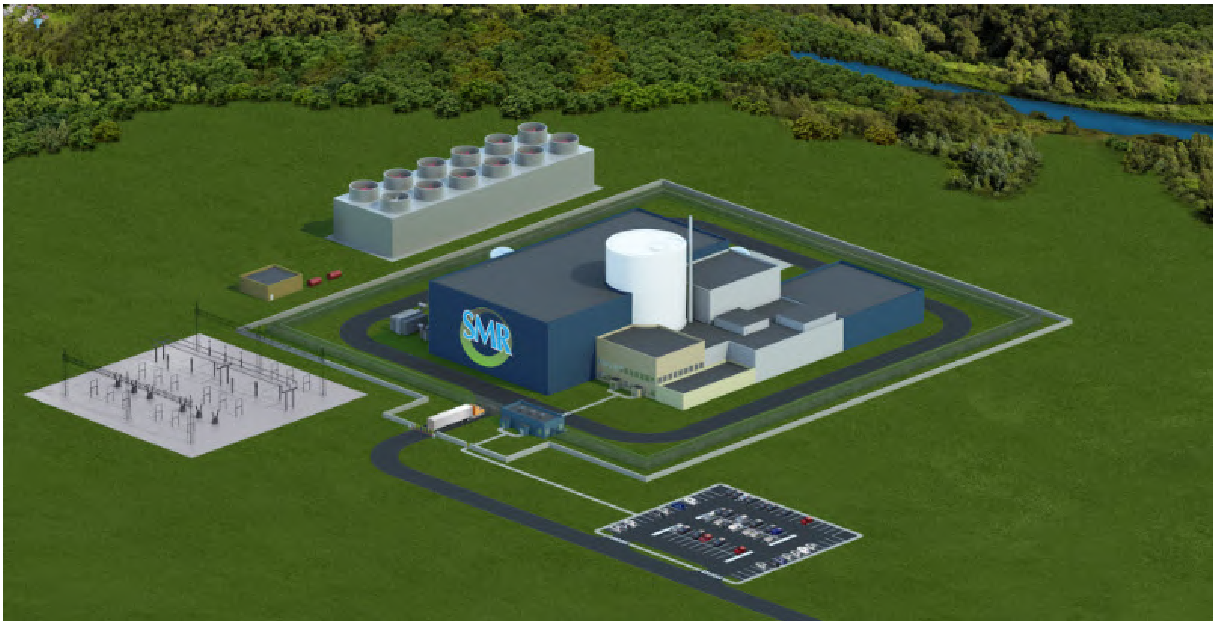

Figure 4. Holtec SMR-160, a 160 MW Electric Nuclear Power Plant [56].

- compliance of reactor technology with international safety standards, criteria of IAEA, WENRA3, EUR4, and comparability with requirements of regulatory documentation of Ukraine on nuclear and radiation safety;
- economy, reliability, the possibility of NPP power units operating in different modes;
- involvement of NPP power units in ensuring conditions of reliable functioning of the unified energy system of Ukraine;
- the possibility of reliable provision of nuclear fuel taking into account own uranium reserves, diversification of suppliers and manufacturers;
- ensuring a non-propagation regime by the legislation and international obligations of Ukraine;
- the possibility of serial construction, further operational support of power units, and production localization of their systems and components.

We agree with the opinion of Vyshnevskyi and Mykytenko [2] that it is impossible to give absolute priority to SMR construction to meet the needs and conditions of functioning of the nuclear energy industry of Ukraine. It is essential to stimulate the entrepreneurial initiative of businesses with the necessary technology and capital. The state's role should remain leading and adequately respond to the existing risks related to the main aspects of private nuclear energy: safe operation of nuclear facilities, countering propagation of atomic weapons, and disposal of nuclear waste.

4. Author contributions

The research results provided in the publication are presented in the aggregate of the joint contribution of individual authors:

- **Oleksandr O. Popov**:
  - Idea and preparation of the draft article.
  - Organization of the authoring team's work and task assignment for article preparation.

- Analysis and synthesis of global trends in nuclear energy development.
- Description of the advantages of small modular reactors (SMR) compared to large reactors.
- Justification of the possibilities of small modular reactors construction in Ukraine considering their environmental friendliness and safety.
- Formulation of article conclusions.

• **Anna V. Iatsyshyn**:
  - Justification of the research relevance and article project preparation.
  - Analysis of scientific publications and websites of international organizations dealing with nuclear energy issues.
  - Analysis of literature sources on the training and qualification improvement of specialists in the energy sector.
  - Identification of important aspects regarding the specialized training of personnel for SMR operation and maintenance.
  - Substantiation of the possibilities of small modular reactors construction in Ukraine considering their environmental friendliness and safety.
  - Formulation of article conclusions.

• **Maryna A. Deineha**:
  - Analysis of literature sources on the operation of nuclear fuel cycle facilities.
  - Examination of how different countries' views on atomic energy have evolved, the results of the analysis are grouped by continents and countries (Poland, Germany, Spain, France, Slovakia, Great Britain, China, South Korea, Japan, Indian, United Arab Emirates, Turkey).

• **Tamara S. Novak**:
  - Analyzed state documents on the regulation of nuclear energy issues in Ukraine.
  - Reviewed how the views of different countries on nuclear energy have evolved. The results of the analysis are grouped by continents and countries.
  - Conducted a comparison of SMRs and large-scale reactors based on the criteria of "operational safety," "infrastructure," and "human resources" using scientific publications and open sources.

• **Dmytro V. Taraduda**:
  - Analyzed materials from international organizations (International Project on Innovative Nuclear Reactors, International Atomic Energy Agency, Nuclear Energy Agency, etc.).
  - Conducted a comparison between SMRs and large-scale reactors based on the criteria of "operational safety," "infrastructure," and "human resources" using scientific publications and open sources.

5. Conclusions

We analyzed scientific publications and websites of international organizations dealing with nuclear energy issues and concluded that nuclear energy is again in trend. Also, the attitude of governments of different countries of the world to atomic energy was considered. It was determined that China and India are the leaders in developing nuclear power.

Global trends regarding the development of the nuclear power industry were considered as a result of the research. They include an extension of the operating life of nuclear power units; the development of atomic energy in the context of the Paris Agreement; the development of nuclear-hydrogen energy; synergistic interaction of renewable energy sources and nuclear power plants; introduction of new reactor technologies.

SMRs are considered transformative reactors that will contribute to the further development of nuclear energy globally. The advantages of SMR compared to high-power reactors include lower time and financial costs for construction and implementation; significant potential for maneuvering energy capacities; higher safety indicators for the environment and personnel; quick response to the needs of the energy market; synergy with renewable energy sources and increasing their efficiency within the framework of a hybrid energy system, etc.

At the same time, SMRs are still under discussion regarding the feasibility of such construction. Only a few countries started their construction. Another vital aspect is the special training of personnel to manage and maintain the SMR.

Military operations on the territory of Ukraine since the beginning of 2022 have confirmed the importance and expediency of the construction of SMR to ensure the energy needs of the state and opportunities for post-war reconstruction and restoration of various sectors of the economy. At the same time, Ukraine's tragic experience with the accident at the Chornobyl NPP requires ensuring environmental safety [57]. Therefore, it uses safe, energy- and resource-saving, low- and zero-waste technologies. Also, preference should be given to light-water (evolutionary) SMR projects. Their technical solutions use the accumulated experience of operation and safety analysis of operational NPPs with VVER. Furthermore, SMRs that can already be installed at the active sites of the NPPs of Ukraine should be chosen. Such actions will contribute to the reduction of financial costs for the construction of SMR and contribute to the sustainable development of the nuclear energy industry of Ukraine.

Therefore, the construction of SMR on the territory of Ukraine will make it possible to reach a new level of development of nuclear energy, ensure a faster transition to the digital economy, and contribute to occupying a key position among countries in the modern atomic energy world space.

Abstract. The effective functioning of the radiation monitoring network is an all-important task for all countries worldwide because the health of personnel working at radiation-hazardous facilities and the population living in the affected areas depend on it. A critical analysis of the functioning of radiation monitoring systems of various countries worldwide (Ukraine, United States of America, France, Sweden, Germany, South Korea, Switzerland, and China) was valid and showed their advantages and disadvantages. Criteria for displaying data on the electronic map about the state of radiation pollution and criteria for reports on the functioning of the radiation monitoring network have been determined. To improve the functioning of the radiation monitoring system of Ukraine, some recommendations for their improvement have been provided.

1. Introduction

Nowadays, many institutions and organizations worldwide use hazardous radiation technologies and sources of ionizing radiation in their activities (about 10 thousand enterprises in Ukraine, as of the end of 2021, were operating). Such objects include nuclear power plants (NPP), research reactors, specialized plants for processing and storing radioactive waste, enterprises extracting and processing uranium ores, and medical facilities using radioisotopes. Oil, gas, coal industry, and heat energy enterprises also participate in the radiation situation formation. During their operation, there is a noticeable redistribution of natural radionuclides (uranium, thorium, decay products, potassium, etc.) in the environment. In addition, fuel for nuclear power plants and spent fuel assemblies are transported through many territories. All these objects are objects of increased danger because emergencies related to their activities can lead to highly complex consequences for the present and future generations due to uncontrolled (accidents) or controlled (terrorist act) release of a significant number of radioactive substances into the environment.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012109 doi:10.1088/1755-1315/1254/1/012109

Therefore, one of the most critical components of the country's national security is the provision of nuclear and radiation safety.

In the territories where radiation-hazardous objects are in Ukraine, either non-automated sampling or stationary automated systems for monitoring the radiation situation are used for radiation monitoring. However, such approaches have some disadvantages: fieldwork is carried out, which poses a threat to humans in conditions of a significant level of radiation in the research territory; not equipment mobility of automatic systems doesn't allow assessment of radiation pollution levels across all studies territory. Furthermore, the non-automated sampling and stationary monitor posts don't allow to spend continuous environmental radiation monitoring in the part of a large square, resulting in information about the radiation situation in the research territory being released with a delay.

One of the main aspects of nuclear and radiation safety is radiation monitoring in the territories where hazardous radiation facilities are located, which various legal acts regulate. From that place, the effective functioning of radiation monitoring networks is an essential task for every country of the health of personnel working at hazardous radiation facilities and the population living in contaminated areas.

The legal acts regulate science publications, and information resources were analyzed in the research of the functionality of radiation monitoring networks. The result of analyzing showed that the problem outlined by us was considered and described in the following directions:

- construction of environmental monitoring networks [1–5];
- development equipment for radiation monitoring networks [6–10];
- development software for analysis and visualization monitoring data [11–14];
- using monitoring data for solving management by the radioactively contaminated territory [15–19].

Therefore, issues of ensuring nuclear and radiation security are looked up worldwide.

The aim is to determine the main advantage and disadvantages of radiation monitoring networks and to provide recommendations for their improvement in Ukraine.

2. Results

Radiation monitoring is an information and technical system of observation, assessment, and forecast of the radiation state of the biosphere. Radiation monitoring is a system of long-term repeated monitoring to assess the state of the radiation situation. Environmental radiation monitoring is a system of regularly monitoring the radiation state of the environment, migration, and accumulation of radionuclides, potentially dangerous phenomena, etc. The primary purpose of monitoring is to provide information to decision-makers.

We will list the main tasks of radiation monitoring [20, 21]:

- observation and control of the state of the territory contaminated with radionuclides, its hazardous parts, and the development of ways to reduce the danger from contamination;
- assessment of the state of objects in the environment according to the parameters that characterize the radioecological situation both in the zone of pollution and outside it;
- identification of trends in changes in the state of radioactive contamination of the environment in connection with the operation of radiation-dangerous objects, as well as during the implementation of radiological protection measures carried out in pollution territories;
- elucidation of possible trends to changes in the state of health of the population living in radionuclides-contaminated areas;
- information provision of the forecast of the radioecological situation in the radionuclides pollution territories and the country in general.

Next, we will analyze the existing monitoring system in Ukraine and compare it with similar systems in other countries. This will allow us to identify shortcomings and determine directions for its improvement.

2.1. Ukraine

To date, non-automated sampling or stationary automated systems for monitoring the radiation situation are used for radiation monitoring in the territories where radiation-hazardous objects are in Ukraine. However, the disadvantage of such approaches and means is, firstly, the need for physical participation of a person in sampling, which creates a significant risk for his health in conditions with a substantial level of radiation in the research territory, and secondly, the lack of mobility of the equipment of automated systems, which does not allow to assess the level of radiation pollution in the entire studied area. They must provide an opportunity to quickly respond to complex radiation environment conditions of limited access to the research object (fire, destruction of the thing, rugged terrain, significant vegetation). Also, non-automated sampling and stationary posts do not allow for continuous environmental radiation monitoring of large areas, for example, such as the Chornobyl Exclusion Zone (CEZ).

Today, radiation monitoring in Ukraine is carried out by various entities – SE "NAEK "Enerhoatom", the State Agency of Ukraine on Exclusion Zone Management (SAUEZM), the State Space Agency, the National Academy of Sciences, and the UkrHydromet Center (UkrHMDs) under the State Service of Ukraine for Emergency Situations (SSUES). However, their systems provide only sectoral observations of the radiation environment.

All received information about radioactivity is open to the public through the Integrated Network of Radiation Monitoring of the Environment (figure 1). You can find out with the help of the map: the radiation level, the location of the measurement point, and who provided the information.

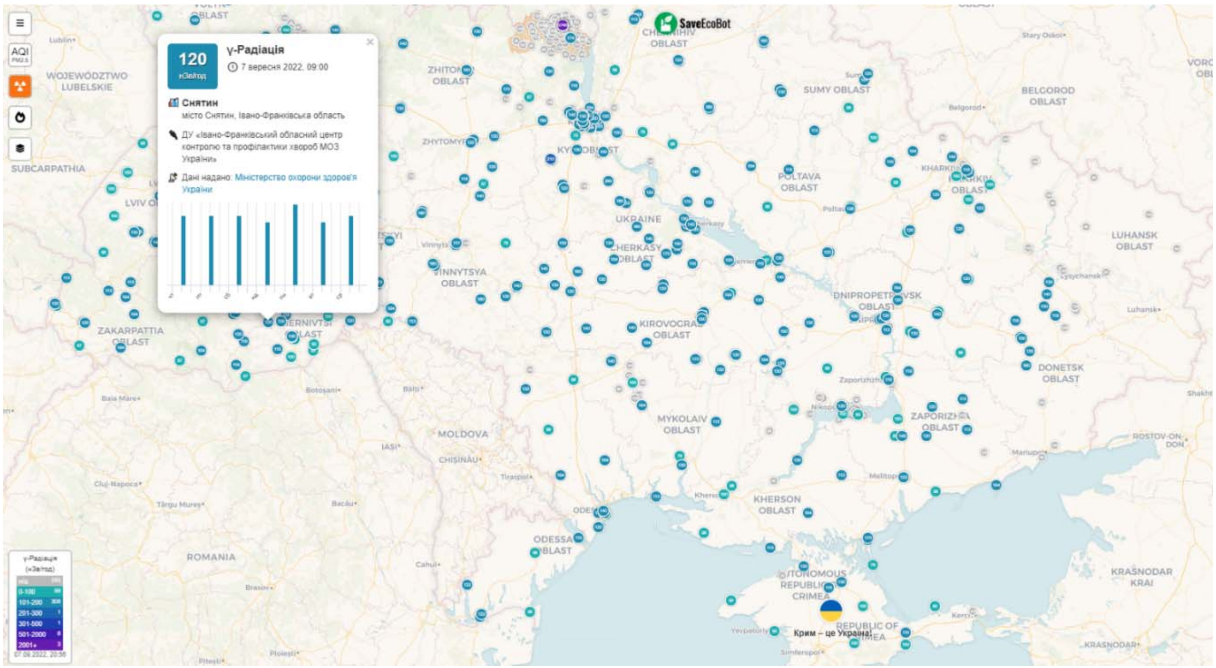

Figure 1. Map of the radiation background in Ukraine [22].

The Ukrainian Hydrometeorological Center of the SES of Ukraine (UkrHMC) monitors radioactive atmospheric pollution through daily measurements of gamma radiation exposure dose, deposition of radioactive particles from the atmosphere, and the content of radioactive aerosols in the air.

The UkrHMC measures radioactive contamination of surface water CS-137 and soil contamination and monitors gamma radiation exposure doses at ten automated points near NPPs. Furthermore, the UkrHMS monitors the concentration of radionuclides, radionuclides in atmospheric precipitation, and the concentration of 'hot' particles in the air within the 30-kilometer zone around the Chornobyl NPP (exclusion zone). In addition, the International Radioecological Laboratory of the Chornobyl Center for Atomic Safety, Radioactive Waste, and Radioecology Slavutych monitors the impact of radiation on biota in the exclusion zone [1].

The SAUEZM implements the state policy in the exclusion zone management, the zone of unconditional (compulsory) resettlement, overcoming the consequences of the Chornobyl disaster. The SAUEZM provides work on determining the radiation status of the exclusion zone, including the industrial site of the Chornobyl NPP, and the area of unconditional (mandatory) resettlement, compliance with radiation safety standards, conducting radioecological monitoring and radiation control in the territories and objects located within them; carry out a general assessment of the radiation situation in the region of zones that have experienced radioactive contamination, environmental radiation monitoring in this territory. At all NPPs, research is conducted on the content of radioactive substances in ecological objects in the areas where the NPP is located in the water of surface reservoirs, the atmospheric air, and the soil of nearby settlements.

2.2. The USA

The nationwide RadNet system was generated to observe environmental radiation pollution levels. System RadNet has tracked radiation levels from testings nuclear weapons and nuclear reactor accidents at Chornobyl NPP (Ukraine) and Fukushima NPP (Japan). During a radiological incident, government officials use RadNet data to help make science-based decisions about protecting the population. Besides, scientists use the RadNet state of radioactive air pollution monitoring data to help estimate the potential radiation dose to humans. Also, use metrological data during the estimated quantity [23].

RadNet has 140 stationary air monitors that run 24 hours a day during the week and collect data near-real-time gamma radiation measurements. Figure 2 shows RadNet static air monitoring locations and precipitation and drinking water sampling locations that reported data in 2020.

Under standard conditions, air monitors RadNet operates continuously, and samples of air, precipitation, and drinking water are analyzed on a planned schedule (table 1) [24]. In addition, during a radiological emergency, the United States Environmental Protection Agency (EPA) can deploy teams to conduct air monitoring and the environment.

Table 1. Sampling frequency of the system RadNet.

Medium	Sampling frequency	Testing frequency
Air filters	Continuous (real-time)	Continuous (real-time)
Precipitation	As rainfall, snow or sleet occurs	Monthly analysis of a composite sample
Drinking water	Quarterly	Quarterly

RadNet system data are available in databases and reports. In addition, EPA publishes analytical and monitoring results after checking to ensure they meet high-quality standards.

Envirofacts RadNet Database includes laboratory analysis results from air monitor filters, precipitation sampling, and drinking water. Also, this database is historical data about sampling

Figure 2. RadNet stationary air monitors [23].

milk. Finally, this database includes the current and historical data needed to estimate long-term environmental radiation trends [26].

As well United States Nuclear Regulatory Commission implements radiation pollution monitoring continuously in states in the USA, such as a sample of bioassay, alpha scans, a physical survey of the disposition of the materials and equipment, sampling or assessment levels to monitor air, surface water, and groundwater, soil, and sediment, equipment, and personnel [6].

2.3. France

On the national level, monitoring the dose equivalent rate is carried out on all territories of France (figure 4) laboratory in the Institut de radioprotection et de sûreté nucléaire (IRSN). The automated detectors represent proportional counters manufactured by BITT Technology (figure 5) [26].

The measurement of the monitors transmitted through a multiprotocol label switching virtual private network (MPLS VPN) or a direct contract between the IRSN and a telecommunications operator, or under the agreement between the IRSN and the Gendarmerie Nationale. The monitoring system ensures receiving of the measurement data in a Microsoft SQL Server database. Each measurement result is automatically compared to a sliding reference average of one week's data. In addition, the measurement automatically checks if it is within the acceptable variation range ±40 nSv/h of this average indicator. Nevertheless, in other cases, size has to be

Figure 3. Filters air radiation monitoring [25].

manually validated by the Téléray remote sensing system [26].

The monitoring system operates in real time. It includes redundancy, a recovery plan, and an agreed service commitment from the network operator. Monitoring of the public radiation dose (passive dosimetry) is carried out using about a hundred dosimeters. However, today monitoring is carried out more and more frequently using radio-photoluminescence (RPL) dosimeters (manufactured by the IRSN's dosimetry laboratory) [6]. The dosimeters are exchanged every three months.

The facility from nuclear fuel processing Orano La Hague has mobile equipment for monitoring discharges and the environment, whether on a routine basis or in other emergencies. Four autonomous trailers are equipped with the following sampling and measurement equipment:

- system for sampling aerosols with continuous alpha/beta measurement;
- probe for continuous measurement of the ambient gamma dose rate;
- mobile sampling equipment allowing samples pf bio-indicators (grass, soil, water).

The measurement data and report are sent in real-time to the correspondent department. Each trailer has an electrical generator and a lighting system.

2.4. Sweden

The Swedish Radiation Safety Authority (SSM) manages two telemetric networks for monitoring external gamma dose rates. A nationwide network consisting of 28 monitoring stations (figure 6) and a network comprised of 30 monitoring stations near nuclear power plants (figure 7) [27].

The monitoring stations operate autonomously and transmit data continuously to the network servers SSM. SSM manages the monitoring stations via special software and ensures supporting

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012109 doi:10.1088/1755-1315/1254/1/012109

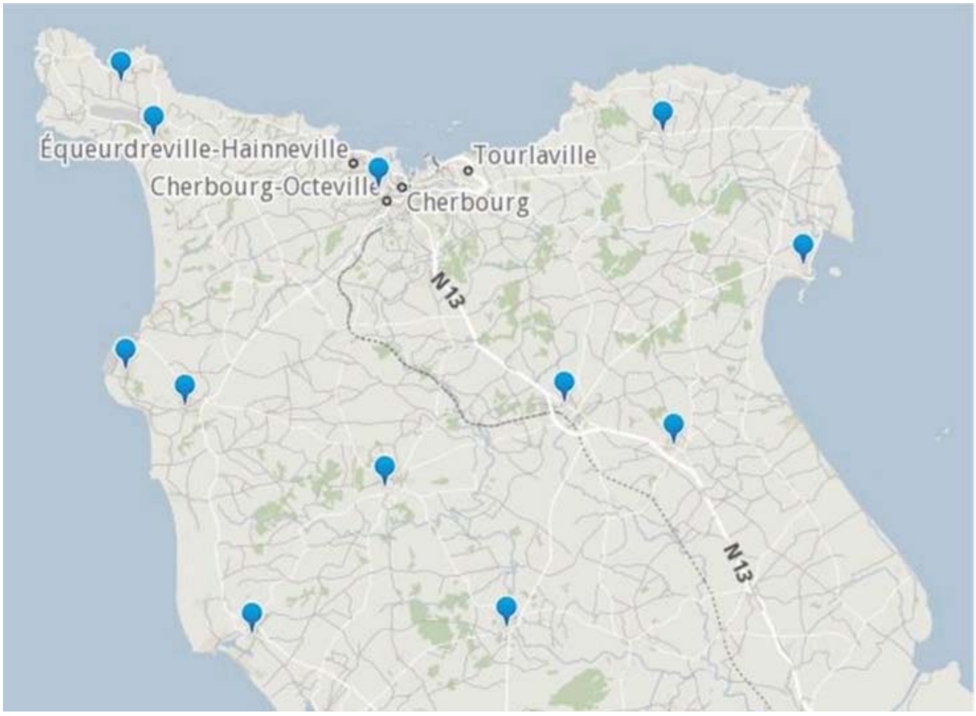

Figure 4. Locations of the IRSN [26].

Figure 5. BITT Technology detectors [26].

operations through collaboration with the administration in the NPP.

The prim y purpose of the nationwide network is to alarm if there is a significant increase above the natural background gamma radiation level and provide an instant overall picture of the radiation situation in Sweden. In addition, the purpose of monitoring networks NPP is to give an early indication of gamma radiation levels and plume direction following a nuclear accident with the release of radioactivity to the environment.

Both networks monitor ambient dose equivalent rate using monitoring probes equipped with

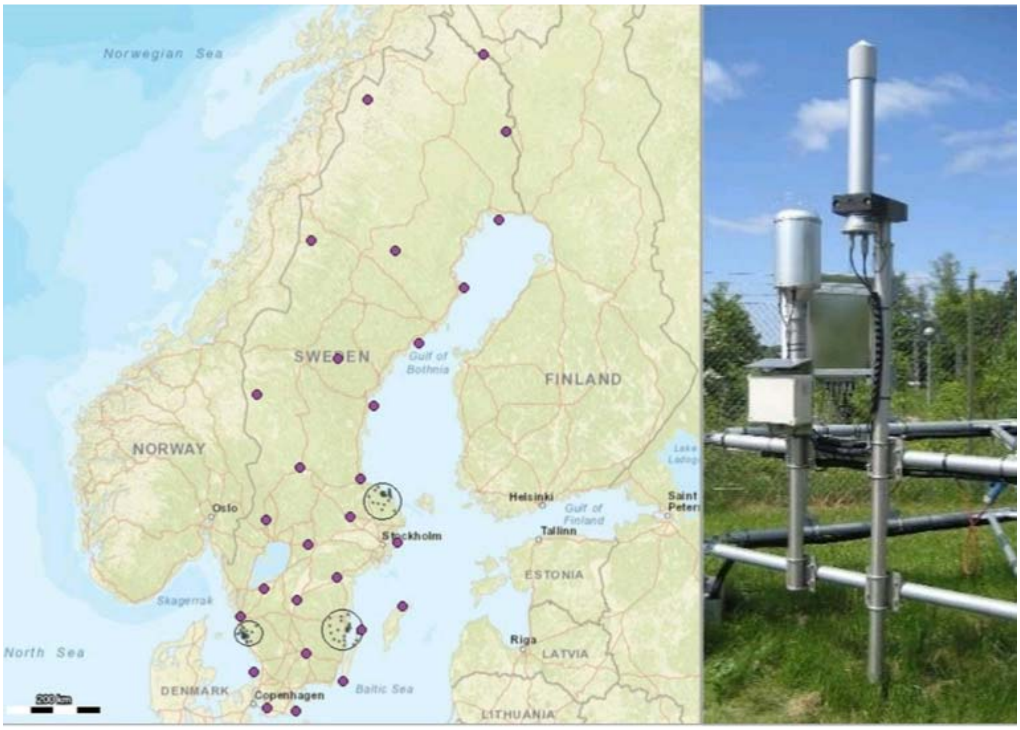

Figure 6. Location of the nationwide network of monitoring stations [27].

Figure 7. Location monitoring stations near NPPC [27].

three compensated Geiger-Muller tubes, enabling a measuring range of 10 nSv/h – 10 Sv/h for every monitoring station.

All monitoring stations use GammaTRACER XL2-3 (Bertin GmbH12, Germany) as a measuring device. The monitoring probes of the nationwide network are mounted on metrological stations, which are managed by Swedish Metrological and Hydrological Institute [28].

2.5. Germany

The German nationwide monitoring network (ADER) includes ∼1800 stationary probes equally distributed over the German territory with a typical distance of 20 km between them (figure 8). Their density is increased in the 25 km emergency planning zone around NPP. These additional probes are installed and operated by complementary networks from federal states. Data are exchanged between das Bundesamt für Strahlenschutz (BfS) and the local government and are carried out on a bilateral agreement. In the emergency regimen, data from all stations can be accessed almost in real-time, enabling the population's information to be efficient and prompt [29].

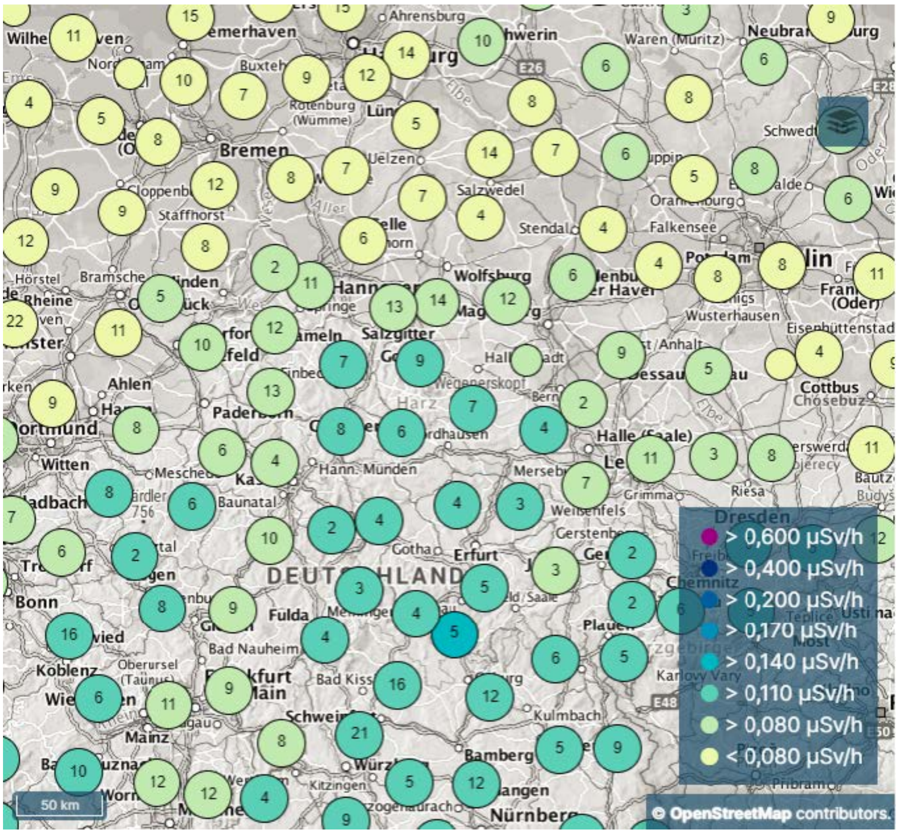

Figure 8. Probes location of radiation monitoring network [30].

The monitoring network is a part of the German "Integrated Measuring and Information System for the Surveillance of Environmental Radioactivity" (IMIS) and German national response plan, which considered the consequences of large-scale radioactive pollution of the environment. Moreover, data was transmitted to the European radiological data exchange platform (EURDEP) to aggregate a complete picture of European persons who accept decisions [31].

Ideally, monitoring stations ADER should be located on extensive flat grassland on undisturbed natural ground. In practice, two rules are used for the selection of new places for the installation of detectors. Firstly, probes must be installed at a height of 1 m on the flat natural ground (grassland) without disturbing buildings at a distance of 20 m. Secondly, considering neighboring stations, necessarily choose aimed at an almost homogeneous coverage of the German territory [31].

2.6. South Korea

The country operates 25 nuclear power reactors, a nuclear research reactor, nuclear fuel fabrication facilities, and radioactive waste disposal facility. Korean Institute of Nuclear Safety (KINS) is the only atomic safety regulatory expert organization that protects the public and the environment from the harmful effects of radiation. KINS, on behalf of the Korean government, conducted radiation monitoring around nuclear facilities and analyzed the relevant samples. Furthermore, local government around nuclear facilities have operated their radiation monitoring system [32].

The received information about radioactivity is open to the public via the Integrated Network of radiation monitoring of the environment (IERNet) (figure 9) [33].

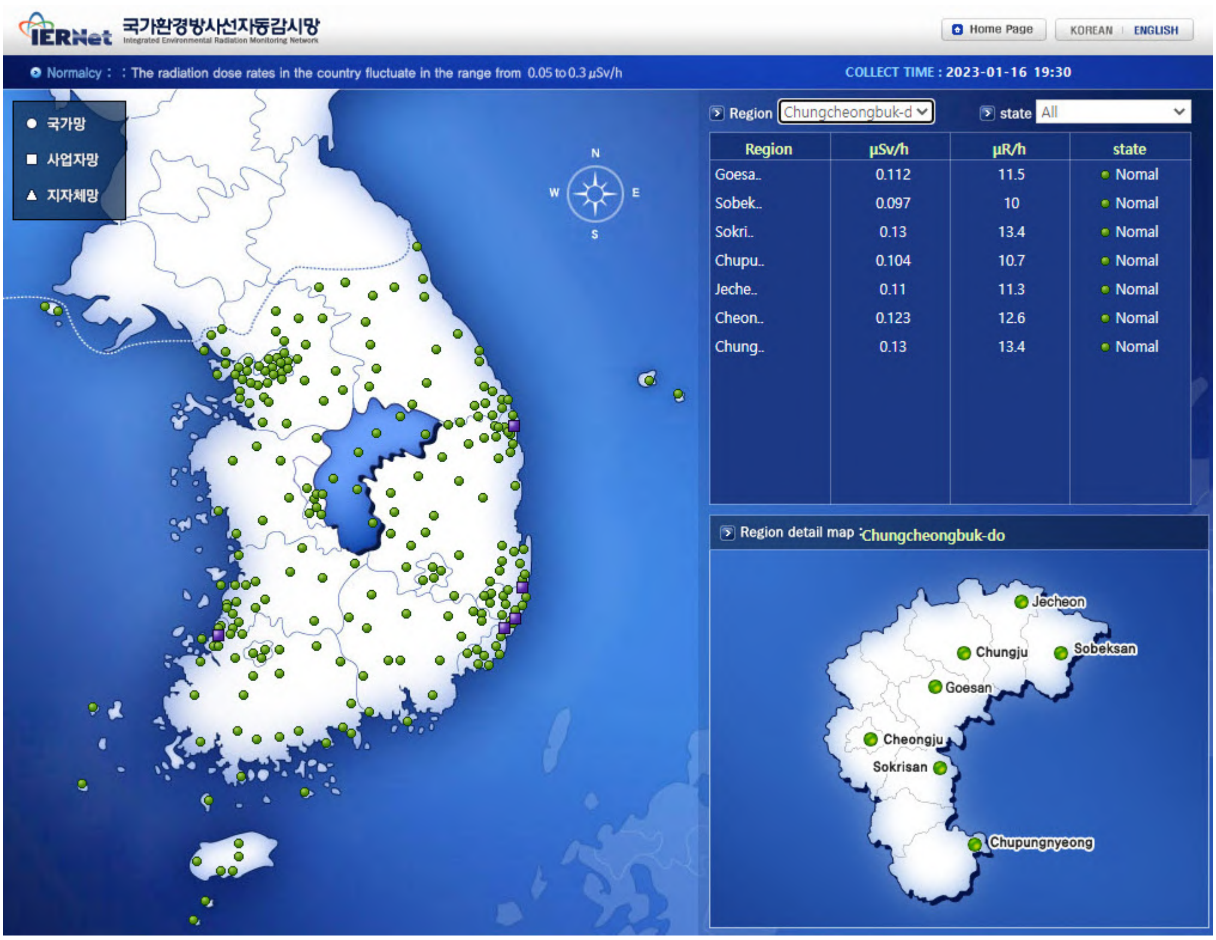

Figure 9. Integrated Network of radiation monitoring of the environment [33].

KINS introduced a mobile monitoring system mounted on vehicles to compensate for the mobility limitations of a fixed monitoring post. Monitoring systems monitor the surrounding areas where nuclear installations are located. That monitoring system can be used to monitor the radioactive plume formed during emergencies of various origins during the operation of these installations. The local government constantly compares the received data for reliability with the results of KINS. All local governments on the territory of which NPPs are located carry out weekly radiation monitoring using a mobile monitoring system. The resulting data are open to the public and are provided as core data for plans for identifying environmental radiation across the nation (SIREN).

2.7. Switzerland

National Emergency Operations Centre (NEOC) has its radioactivity monitoring network – NADAM. It consists of 76 stations, placed on the metrological stations MeteoSwiss in all territory of Switzerland (figure 10), that transmitted the measured values at ten-minute intervals to the NEOC [34].

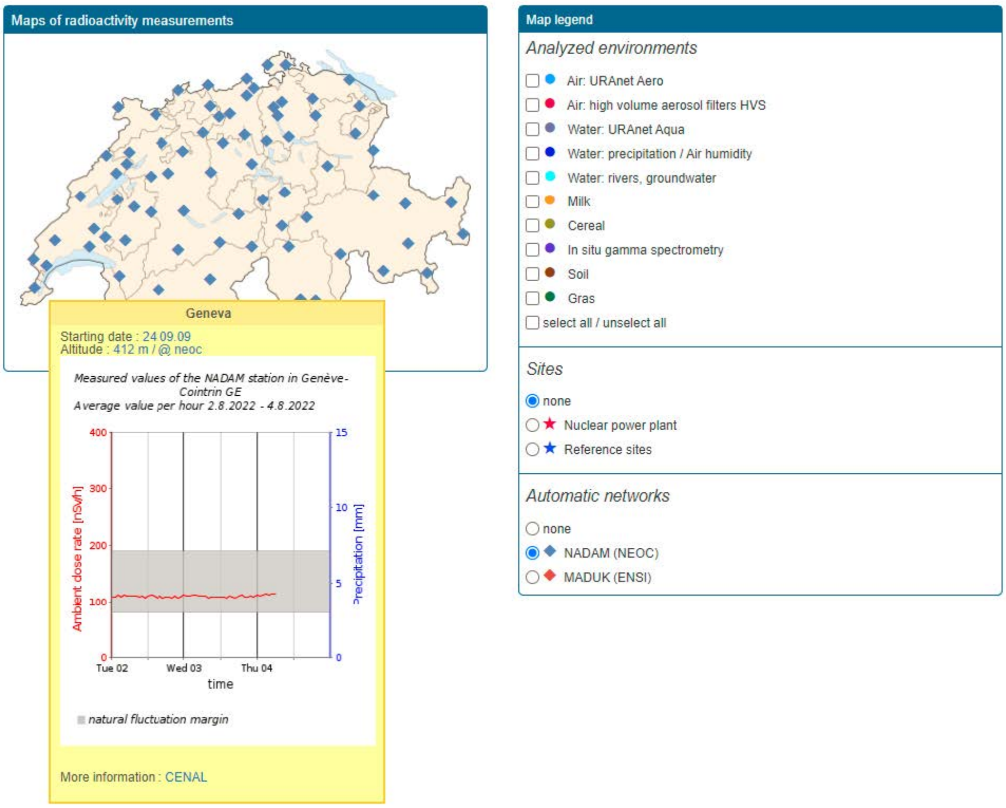

Figure 10. Swiss radiation monitoring system [35].

If the threshold value excessed 1000 nSv/h, an alarm is automatically raised. Depending on locations, the average daily values veer from 80 to 260 nSv/h. This is generally due to differences in the level of natural radiation.

At all stations NADAM, the part of artificial radiation amounts to only a few percent. The fake part mainly comes from the Chornobyl reactor accident in 1986 and the nuclear weapons test in the 1960s. The beginning of rain can lead to a temporary increase in the measurement values due to the natural radioactivity being rinsed from the air. The precipitation intensity and duration of the previous dry period are decisive here. In winter, the snow cover can decrease the part of ground radiation to such an extent that the measured values are below those observed in the long term [34].

2.8. *China*

Mainland China is building and exploiting 56 nuclear power units as of 31 March 2022; 38 are operating units. All data about NPP and environmental radiation monitoring can receive at the website `http://spi.mee.gov.cn:8080/spi` (figure 11).

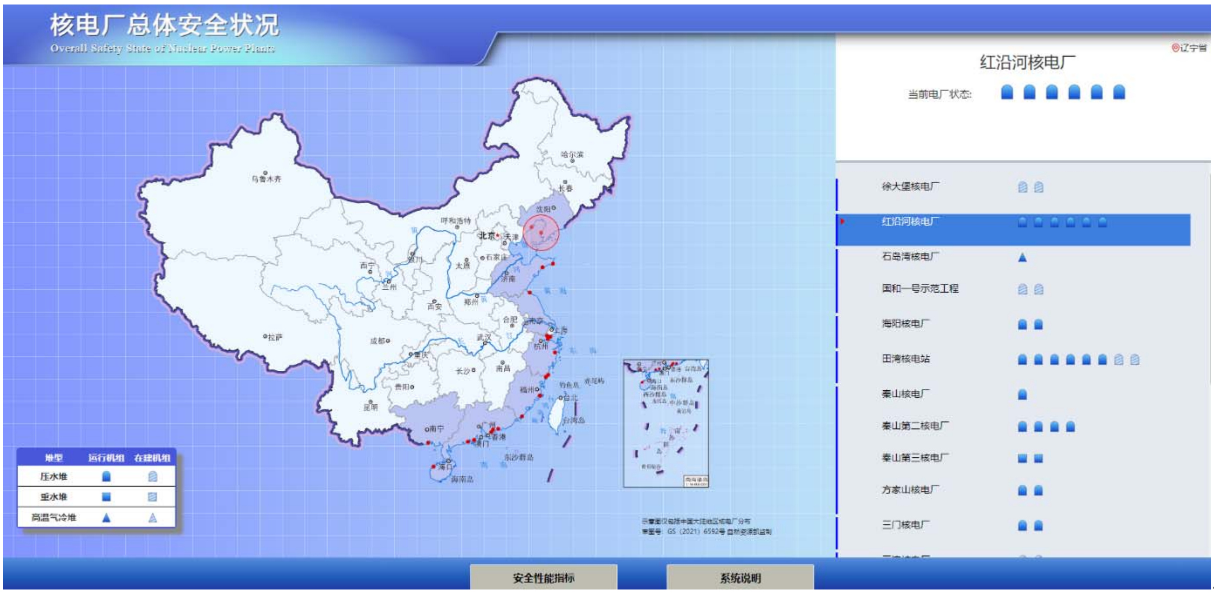

Figure 11. Information about the Chinese NPP location.

3. Discussion

To analyze and compare the nationwide monitoring systems of different countries, the criteria for displaying data on the electronic map about the state of radiation pollution were determined. The authors of the publication attributed to such measures (table 2):

1. Interface in national and English languages.
2. Meteorological data (direction, wind speed, humidity, air temperature, and atmospheric pressure).
3. The speed of updating the display of radiation monitoring data on the map.
4. Number of radiation monitoring networks posts.
5. Coverage density of the radiation monitoring network, m^2.
6. Availability of mobile radiation monitoring stations.
7. Coordinates of locations of stationary posts.
8. Coordinates of locations of radiation-hazardous facilities: NPP, research reactor, specialized plants for the processing and storage of radioactive waste, uranium ore mining and processing enterprises, medical facilities that use radioisotopes.
9. Availability and coordinates of radioactive monitoring stations of water bodies.
10. Availability of these stationary monitoring stations for atmospheric air pollution by chemical substances and dust of various fractions.
11. Ability to export monitoring data for a certain period to a separate file for an independent analysis.

Table 2. Criteria for a report on the functioning of the radiation monitoring networks.

Criteria	Countries							
	The USA	Sweden	France	Germany	South Korea	China	Switzerland	Ukraine
1.	+	+	+	+	+	−	+	+
2.	−	−	−	−	−	−	+	+
3.	daily	daily	daily	daily	daily	daily	daily	daily for most posts
4.	140	58	no data	1800	no data	around 29	76	no data
5.	70243	9111	-	199	-	330931	543	−
6.	Quantity unknown	Quantity unknown	4	Quantity unknown	Quantity unknown	Quantity unknown	Quantity unknown	Quantity unknown
7.	+	+	+	+	+	+	+	+
8.	−	−	−	−	+	+	+	−
9.	+	+	+	+	+	+	+	+
10.	−	−	−	−	−	+	+	+
11.	−	−	−	−	−	−	−	−

Each monitoring network is specific to a particular country, considering all its factors. Each country has information on the coordinates of the locations of stationary posts, and data on radiation pollution is updated daily. Unfortunately, the China map needs an interface in English, which complicates the data analysis process. We want to note that the highest coverage density of the radiation monitoring networks is in Germany; however, in some countries, information on the number of stationary posts was unavailable. As shown in table 2, all the studied countries have mobile radiation monitoring posts, but their number still needs to be determined, except for France. The availability of meteorological data and stationary monitoring stations for atmospheric air pollution by chemical substances and dust of various fractions was available in Sweden, Ukraine, and China. Also, exporting monitoring data for a certain period cannot be exported into a separate file for an independent analysis.

We also analyzed the availability of various reports on the functioning of the radiation monitoring networks of the countries mentioned above, which were found in public access. Accordingly, criteria were developed for the following reports (table 3):

1. Availability of materials in English.
2. Frequency of updating the report on the functioning of the radiation monitoring networks in the country.
3. The year of publication of the last general report on the functioning of the radiation monitoring networks in the country
4. Availability of information about radiation pollution from radiation-hazardous objects.

We want to note that over half of the countries have publicly available outdated reports (from 3-5 years). Notices provided by the International Atomic Energy Agency were public in English, while other pieces were available only in the national language and on other sites. In connection with the military actions in the territory of Ukraine, information about the actual state of operation of the radiation monitoring network is not displayed in open sources on the Internet, including at the NPP.

Table 3. Criteria for a report on the functioning of the radiation monitoring networks.

Criteria	Countries							
	The USA	Sweden	France	Germany	South Korea	China	Switzerland	Ukraine

4. Author contributions

This section describes the contributions of each author to the research presented in this publication.

- *Andrii V. Iatsyshyn*: Idea, justification, and article outline; analysis of literature sources on environmental monitoring networks; analysis of Ukraine's existing monitoring system and identification of monitoring subjects; development of criteria for displaying radiation pollution data on the electronic map; recommendations for increasing the efficiency and information usefulness of Ukraine's radiation monitoring system.
- *Taras G. Ivaschenko*: Analysis of literature sources on using monitoring data to solve environmental safety management problems in radiation-contaminated territories; analysis of the work of the National Emergency Operations Center (NEOC) and weather stations MeteoSwiss (Switzerland) in the field of radiation safety; development of criteria for displaying radiation pollution data on the electronic map; recommendations for increasing the efficiency and information usefulness of Ukraine's radiation monitoring system.
- *Iryna V. Matvieieva*: Analysis of literature sources on the development of software for analysis and visualization of monitoring data; features of operation, construction, and transmission of measured data of the French radiation monitoring system network; features of the process and construction of environmental radiation monitoring networks in China and Hong Kong; development of criteria for displaying radiation pollution data on the electronic map.
- *Julia V. Zakharchenko*: Functions and role of the Swedish Radiation Safety Authority; principles of operation of Sweden's monitoring stations using special software; principle of operation of the German nationwide monitoring network, network density and its construction, transmission of monitoring data; analysis of the availability of various reports on the functioning of radiation monitoring networks of the countries considered in the publication, which were found in public access, and development of criteria for such statements.
- *Anastasiia M. Lahoiko*: Substantiation of the relevance of the research; analysis of literature sources on the development of equipment for radiation monitoring networks; analysis of the national monitoring system RadNet (United States of America), features of its construction and operation of the corresponding equipment; role of the Korea Institute of Nuclear Safety (KINS) in implementing state-level radiation monitoring, the functions and analysis of the Integrated Environmental Radiation Monitoring Network (IERNet); analysis of the availability of various reports on the functioning of radiation monitoring networks of the countries considered in the publication, which were found in public access, and development of criteria for such messages; recommendations for increasing the efficiency and information usefulness of the functioning of Ukraine's radiation monitoring system.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012109 doi:10.1088/1755-1315/1254/1/012109

5. Conclusions

One of the main aspects of nuclear and radiation safety is radiation monitoring in the territories where hazardous radiation facilities are located, which various legal acts regulate. Therefore, the effective functioning of radiation monitoring networks is an essential task for every country of the health of personnel working at hazardous radiation facilities and the population living in contaminated areas.

A critical analysis of the functioning of nationwide monitoring systems of various countries of the world showed that these systems have differences in their organization (density of coverage, technological and scientific support, transmission, processing, and display of data).

The criteria for displaying data on the electronic map about the state of radiation pollution and for reporting on the functioning of nationwide radiation monitoring networks, which showed the advantages and disadvantages of such systems, were defined.

Several recommendations are given for improving Ukraine's radiation monitoring systems for monitoring entities, which will increase their efficiency for information usefulness.

To improve the radiation monitoring systems of Ukraine, the authors suggest the following:

- to improve and optimize the notification system for receiving daily information;
- increase the coverage area of monitoring network posts to obtain more accurate information about radiation pollution;
- increase the number of mobile surveillance posts;
- on the electronic map, which displays the state of radiation pollution, indicate the coordinates of the locations of radiation-hazardous objects (NPP, research reactors, specialized plants for processing and storing radioactive waste, enterprises extracting and processing uranium ores, and medical facilities using radioisotopes);
- make it possible to export monitoring data for a certain period into a separate file for independent analysis;
- implement an interface of maps and reports in English to provide information to the broader masses;
- to update quarterly publicly available reports on the radiation status of the territory of Ukraine, including on the websites of relevant international organizations;
- to prove information on radiation pollution from radiation-hazardous objects.

Abstract. Every year, the world sees an increase in the volume of hazardous goods transported by road. However, emergencies may arise related to the depressurization of containers (tanks, containers, cylinders, etc.) during the transportation of dangerous goods under various circumstances (traffic accidents, natural disasters, acts of terrorism, etc.). Furthermore, it can cause the ingress of hazardous chemicals into the environment and create significant risks for the population of the surrounding areas and habitat. The existing methods for assessing chemical accident consequences need to be revised. Therefore, they are not practical tools for solving problems of prompt response to emergencies associated with accidents while transporting dangerous substances by road transport. Unlike the existing ones, the authors developed new mathematical tools that consider all the main factors. They allow for determining the area of the affected zone, forecasting changes in its scale, and assessing risks to public health due to such emergencies. Comparison of the simulation results with the field measurements data showed high accuracy of the developed mathematical support.

1. Introduction

Hazardous materials are flammable, explosive, poisonous, corrosive, infectious, or radioactive products, for example, gasoline, fuel oil, oil, and chemicals. The most harmful substances are a fundamental part of our daily life and industrial development despite the characteristics of these materials [1].

Approximately 4 billion tons of harmful substances are transported worldwide annually, according to [2]. The demand for hazardous materials in the United States is 3 to 4 billion tons each year. These materials are widely used in manufacturing, agriculture, medicine, and other industrial areas. In China, approximately 95% of hazardous substances are transported from manufacturers to customers by road transport [1]. Between 77.000 and 88.000 million tons of dangerous goods were transported by road within the European Union from 2009 to 2013 [3]. The authors [4] investigated 1932 accidents that occurred worldwide while transporting hazardous substances by road and rail from the beginning of the 20th century to July 2004. They showed that more than half of the accidents occurred on roads.

Danhighwayss traffic accidents are still considered low-probability compared to more frequent and highly unpredictable natural hazards despite the above facts. In addition, this type of accident is classified as an accident with significant consequences which can seriously affect the population and environment.

Analysis of the sources shows that several incidents during the transportation of harmful substances are deficient. Nevertheless, accidents occur, and some of the consequences are very serious. For example, in November 2005, there was an accident in Sinaloa (Mexico) with a truck transporting ammonia.Thirty-nine9 people died as a result of the accident [5]. More than 30 accidents related to the transportation of dangerous substances by road occur annually in China, according to statistics A truck [6]. Truck with liquefied natural gas crashed on the highway in front of the tunnel and overturned in Hunan Province on October 6, 2012. Five people died, and two more were injured, including three firefights, due to the explosion. In 2013, a truck carrying fireworks ahead of Chinese New Year celebrations exploded and destroyed part of an overpass in China's Henan province and killed several people.

It is necessary to consider population density, traffic jams, and road closures while transporting harmful substances in urban areas. City traffic accidents can cause catastrophic human losses due to the high population density. Truck with chlorine collided with another vehicle in a metropolitan area of Nanjing, China, on March 29, 2005. It caused the death of 29 people and the evacuation of more than 10000 people. In October 2020, an 18-wheeler with 5000 gallons of sodium hydrosulfide (an extremely corrosive and toxic substance) overturned downtown Birmingham, England [7] (figure 1). In figure 2 shows a tanker truck accident in New Jersey that spilled 3000 gallons of fuel onto the roadway (February 2019).

Therefore, emergencies may arise related to the depressurization of containers (tanks, containers, cylinders, etc.) during the transportation of dangerous goods under various circumstances (traffic accidents, natural disasters, acts of terrorism, etc.). Furthermore, it can cause the ingress of hazardous chemicals into the environment and create significant risks for the population of the surrounding areas and habitat.

The studies [9,10] consider the risk of dangerous substances transportation as a measure of the probability and severity of damage to the population's health and components of the surrounding natural environment due to potential undesirable events. The risk from transporting harmful substances can be divided into two parts: the probability of an accident and the consequences if it occurs. Reniers et al [11] developed a risk assessment methodology for moving hazardous materials. They divided routes into smaller segments using multi-criteria analysis and assessing the likelihood of accidents involving dangerous vehicles leading to fatalities. The work [12] is aimed at determining the impact of hazardous traffic accidents on people with disabilities. It is done to provide the knowledge base necessary for creating competent disaster preparedness procedures. The article [1] contains a model built to reduce risks of transportation of harmful substances and transportation costs, considering several restrictions. This model was tested on a realistic example of transporting hazardous substances in the densely populated metropolitan

area of Shanghai (China).

Popov et al [13, 14] considered several methods used to assess the situation in the case of accidents related to the spill (emission) of dangerous chemicals from technological containers on road transport. Their shortcomings were identified. It was also established that these methods are not practical decision-making support tools for the prevention and rapid elimination of the consequences of such emergencies. Therefore, developing new mathematical and software tools better than existing analogs in all leading indicators is an urgent and essential scientific problem.

The research aims to develop mathematical tools for assessing the consequences of accidents while transporting dangerous substances by road transport.

2. Development of mathematical means

The developed mathematical means of risk assessment should take into account the realities of the current situation during transporting of chemically hazardous substances (CHS) by road transport, possible types of accidents or partial depressurization, for example, as a result of terrorist acts. We used studies [15–17] to build such tools. Those studies most adequately describe the consequences of forecasting chemical accidents during transportation by road transport of the CHS.

Potential chemical risk in the vicinity of an accident of a mobile chemically hazardous object and the settlement zone near such an object is determined by the formula:

$$\mathrm{R}_x = \sum_{i}^{m} \mathrm{Q}^* \times \mathrm{P}_i \times \mathrm{R}_i, \tag{1}$$

where,

Q^* – case frequency during the year;

P_i – the probability of a person living in the i-th habitat (tables 1, 2);

R_i – conditional probability of injury to a person in the i-th habitat.

Table 1. Average daily distribution of the urban population by place of residence [16].

Time of day, hour	Residential and public buildings	Production buildings	In transport			Outside		
			Cities with a population (million people)					
			0.25... 0.5	0.5... 1.0	More than 1.0	0.25... 0.5	0.5... 1.0	More than 1.0
1...6	0.94	0.06	-	-	-	-	-	-

19...24	0.77	0.14	0.04	0.04	0.06	0.05	0.05	0.03

Currently, the occurrence frequency of dangerous event Q_j^* is calculated by the methods of risk theory or according to statistical data.

The occurrence frequency of dangerous event Q_j^* can be determined using the theory of expert evaluations. Expert assessments of the frequency of technogenic accidents are carried out taking into account their distribution into five levels:

Table 2. Average daily distribution of the rural population by place of residence [16]

Time of day, hour	Field and agricultural production		Residential buildings	
	During the day	At night	During the day	At night
1...6	0.25	0.1	0.75	0.9
6...7	0.6	0.4	0.4	0.6
7...10	0.75	0.75	0.25	0.25
10...13	0.8	0.8	0.2	0.2
13...15	0.85	0.75	0.15	0.25
15...17	0.85	0.5	0.15	0.5
17...19	0.8	0.4	0.2	0.6
19...24	0.5	0.2	0.5	0.8

– frequent failure: > 1 year^{-1};
– probable failure: $1 \ldots 10^{-2}$year^{-1};
– possible failure: $10^{-2} \ldots 10^{-4}$year^{-1};
– rare failure: $10^{-4} \ldots 10^{-6}$ year^{-1};
– almost impossible failure – expected frequency of occurrence $< 10^{-6}$ year^{-1}.

The probability of people being in the i-th environment P_i is determined based on the production activity of personnel. Therefore, calculation of the conditional probability of damage or mathematical expectation of injuries from the negative impact of CHS presents specific difficulties. These difficulties are related to the toxic effect on humans of different types of CHS. It is based on their physical and chemical properties and other exposure times depending on the presence in the zone of possible chemical damage.

The conditional probability of damage in the case of being in the zone of chemical injury is mainly determined by the location of damage, considering the height of the cloud rise. The site is formed due to the spread of the affected cloud to the residential part of the settlement in the braking area and the area of the emergency stop of transport from CHS and can be defined as [15]:

$$R = \frac{\mathrm{S}_B + \mathrm{S}_F}{\mathrm{S}_S}, \tag{2}$$

where,

S_B – area of the threshold chemical damage in the braking zone, km^2;

S_F – area of the threshold chemical damage in the size of the emergency stop of transport with CHS, km^2;

S_S – area of the settlement, km^2.

The area of the threshold chemical damage in the braking zone and the size of the emergency stop is determined by the depth of the threshold damage in these areas.

The area of chemical damage in the braking zone can be calculated by the following formula taking into account the rise of the affected cloud [15]:

$$\mathrm{S}_B = \sum_{i=1}^{n} \mathrm{S}_{B_i} \times \frac{\mathrm{H}_C}{\mathrm{H}_B}, \tag{3}$$

where,

S_B – an area of chemical damage in the i-th braking zone, It is defined as:

$$S_B = \frac{\pi\varphi}{360^\circ}[D_B + (D_{l_i} - D_B) \times k_m]^2 - D_B^2, \tag{4}$$

where,
D_B – distance from the building beginning to the road, m;
D_{l_i} – depth of the threshold lesion at the i-th braking zone, m;
l – is corresponded to the section of the final braking route to the emergency stop, m;
$l = 1$ – is compared to the braking route area when $D_l = D_{B,}$, m;
k_m – coefficient of spread reduction of the affected cloud depending on the building and number of floors of the buildings. It is defined in the paper [15].

The area of chemical damage in the emergency stop zone can be calculated by the formula taking into account the growth of the affected cloud,

$$S_F = \frac{\pi\varphi}{360^\circ}\left[[D_b + (D_{n_i} - D_b) \times k_m]^2 - D_B^2\right] \times \frac{H_C}{H_B}, \tag{5}$$

where,
D_{n_i} – depth of the threshold damage in the emergency stop zone;
φ – spread angle of possible chemical damage. It is determined according to table 3.
H_C – the height of the cloud threshold elevation, m;
H_B – the size of buildings in the settlement, m.

Table 3. Angular dimensions of zones of actual chemical damage

Degree of vertical stability	Inversion	Isometry	Convection
	Steady wind		
φ, degree	11.5	14.5	48.5
	Unsteady wind		
	47	48	69

Thus, determining the threshold depth, lethal chemical damage, and height of their cloud rise are essential in calculating the conditional probability of damage during such events.

The formula determines the length of the spill section before the damaged vehicle stops:

$$L_S = V_D t_{rd} + L_{mn}, \tag{6}$$

where,
V_D – speed of transport at the moment of depressurization, km/h;
t_{rd} – driver reaction time (0.3–1.7 sec);
L – braking distance. It is defined as [16]:

$$L_{mn} = V_D t_b + V_D^2/2\alpha_{max}, \tag{7}$$

where,
t_b – brake system activation time 0.3-0.5 sec;
α_{max} – maximum acceleration (deceleration) of transport, m/s^2, α_{max}=gK_g (g=9.81 m/s^2)
K_g – coefficient of tire adhesion of transport with the road surface. For vehicles in dry weather conditions, K_g≈0.5; during the rain K_g≈0.25.

Assessment of the reliable width of the CHS spill and its height (thickness) of the spill hl in the braking zone has great importance. In addition, the amount of CHS will determine if it spilled in this area, ultimately affecting the depth of chemical damage.

The accepted assumption in the existing methods is that determination of the CHS spill width is equivalent to the spill of petroleum products (1 liter of liquid is spilled on 0.15 m^2 of the road). A statement that h_l=0.05 m is incorrect in emergency braking due to the small amount of spilled CHS with a small depressurization on a relatively long braking distance. Based on this, it is necessary to determine the height of the CHS spill on the underlying surface, taking into account the spill area's width and length and the CHS's density. However, this is different based on the various physical and chemical properties of CHS.

One of the main parameters affecting the depth of the secondary damage cloud as an accident result at the chemically hazardous facility with a CHS spill is the area of the spill, the height of the liquid layer (thickness of the spill film), and degree of infiltration of CHS into the underlying surface. However, determining the actual spill area of CHS is somewhat complicated due to the wide range of CHS. In addition, such substances have different physical properties. So, the liquid layer's thickness may differ and depend on the type of underlying surface [18].

The correction coefficients of the spreading surface $\mathrm{K}_{n.xy}$ and infiltration K_{in} are one of the ways to solve the problem of the influence of the nature of the CHS spill and the degree of its penetration into the underlying surface. Such coefficients were obtained experimentally.

Prompt determination of the spill area plays a crucial role in the decontamination (disinfection) of the territory in the case of an accident with the CHS spill. The spill area of CHS S_{l_xy} can be defined by the formula taking into account the experimentally determined $\mathrm{K}_{n.xy}$:

$$\mathrm{S}_{l\_xy} = \pi\left(3.018\mathrm{V}_y^{0.393}\vartheta_y^{-0.116}\mathrm{t}_l^{0.115}\mathrm{K}_{n.xy}\right)^2, \tag{8}$$

where,

V_y – the volume of spilled CHS of y-the type, m^3;

ϑ_y – kinematic viscosity coefficient CSH of y-the kind, m^2/s;

t_l – fluid spreading time, min.

The height of spilled CHS y-the type on the underlying surface of the x-the type h_{l_xy}(m) can be defined taking into account S_{l_xy} using the formula:

$$\mathrm{h}_{l\_xy} = \frac{\mathrm{m}_y}{\rho_{ly} \cdot \mathrm{S}_{l\_xy}}, \tag{9}$$

where,

m_y – mass of spilled CHS on the underlying surface of a y-th type, kg;

ρ_{ly} – CHS density y-the type, kg/m^3.

The formula determines the evaporation time (striking action) of CHS:

$$\mathrm{T}_{\nu d} = \frac{\mathrm{h}_l \cdot \rho_l}{\mathrm{K}_2\mathrm{K}_4\mathrm{K}_7}, \tag{10}$$

where,

K_2, K_4, K_7 – coefficients according to [15].

The amount of liquid CHS in the braking zone m_b is determined by the formula taking into account the fraction of infiltration during the shedding to stop the damaged transport:

$$\mathrm{m}_b = \int_0^{\mathrm{t}_{nm}} G(t)dt = \mathrm{K}_{in}\left(\mathrm{G}_0 \cdot \mathrm{t}_{nm} - \frac{\rho_{ly} \cdot g \cdot \mu^2 \cdot \mathrm{S}_{ot}^2}{2\mathrm{S}_s} \cdot \mathrm{t}_{nm}^2\right), \tag{11}$$

where,

K_{in} – infiltration coefficient;

G_0 – mass consumption at the initial point in time (kg/s) is determined by the formula [19] for small quantities of depressurization area:

$$G_0 = \mu \cdot \rho_l \cdot S_{ot} \sqrt{2g(h_0 - h_{ot})}, \tag{12}$$

$t_{he} = t_{rd} + L_{nm}/V_b$ – CHS spilling time from the moment of depressurization of the capacity to stopping damaged transport;

V_b – averaged braking rate that is defined as $V_D/2$, m/s;

μ – spilling coefficient 0.6 – 0.8;

S_{ot} – hole area, m^2;

S_s – cross-sectional area;

h_0 – the initial height of the liquid column in the vessel, m;

h_{ot} – hole height, m.

Stop of transport leads to a spill of CHS rest contained in the tank: or until it is over at $h_{ot} = 0$, or partially (at $h_{ot} > 0$), or up to the time of sealing the hole.

The amount of spilled CHS is defined by the formula taking into account the proportion of infiltration m_2 after stopping the damaged transport:

$$m_2 = K_{in} \left(\mu \cdot \rho_l \cdot S_{ot} \sqrt{2g(h_0' - h_{ot})} \cdot t_F - \frac{\rho_l \cdot g \cdot \mu^2 \cdot S_{ot}^2}{2S_s} \cdot t_F^2 \right), \tag{13}$$

where,

t_0 – time of CHS spill after vehicle stops, min;

$h_0{}'$ – the initial height of the liquid column in the tank from the moment of stopping the transport is defined by the formula [20]:

$$h_0' = h_0 - \frac{\mu \cdot S_{ot}}{S_s} \sqrt{2g(h_0 - h_{ot})} \cdot t_{nm} + \frac{g \cdot \mu^2 \cdot S_{ot}^2}{2S_s^2} \cdot t_{nm}^2, \tag{14}$$

Generally, S_S can be calculated as follows [5]

$$S_S = \int_0^{t_{nm}} 2l \sqrt{h_0'(t) \cdot \left[D - h_0'(t) dt\right]}, \tag{15}$$

At short-term spill it can be defined as:

$$S_S = 2l \sqrt{h_0(D - h_0)}, \tag{16}$$

A long-term spill can be defined as:

$$S_S = l \left[\sqrt{h_0(D - h_0)} + \sqrt{h_0'(D - h_0')} \right], \tag{17}$$

where,

$h_0{}'$ – values of the liquid column in the tank for a specific time of the spill, m;

l – tank length, m;

D – tank diameter, m.

The formula defines the time of entire spill through a small hole nm:

$$t_{nm} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \tag{18}$$

The amount of spilled CHS in the emergency stop area with the complete ending (destruction) of the capacity taking into account the fraction of infiltration, is defined as:

$$m_F = K_{in} \cdot (Q_0 - m_b) \tag{19}$$

The following formula calculates the depth of chemical contamination:

$$D_c = min(D_n(D_D); D_{fr}), \tag{20}$$

where

$$D_n = 0,95 \cdot \sqrt[l+b+d]{\frac{m}{0,13(2\pi)^{\frac{3}{2}} \cdot a \cdot c \cdot C_n}} K_B \cdot K_t, \tag{21}$$

For lethal cases

$$D_D = 0,95 \cdot \sqrt[l+b+d]{\frac{m}{0,13(2\pi)^{\frac{3}{2}} \cdot a \cdot c \cdot C_D}} K_B \cdot K_t, \tag{22}$$

where

m – CHS mass taking into account the fraction of infiltration, kg;

C_n, C_D – the value of the threshold and fatal cases for CHS is considered respectively, g/m^3;

K_B, K_t – dependence of depth damage on wind speed and coefficient of exposure to air temperature to the depth;

$a,\ b,\ c,\ d$ – coefficients of the steppe variance models determined according to [5];

The formula defines D_{fr}:

$$D_{fr} = U_n \cdot T_{\nu d}, \tag{23}$$

where

U_n – transfer rate of the cloud front at the given wind speed data and degree of vertical stability of the air, km/h, is determined according to [15];

$T_{\nu d}$ – time of the dramatic action determined by the formula 10.

The height of the lifting cloud for the limited degree of damage, taking into account sheltering of the population in buildings, is determined by the formula:

$$H_n = c \cdot D_n \sqrt{2ln \frac{m \cdot \rho_a (1 - e^{-k_1 \cdot t_{loc}})}{\rho_g \cdot 0,13 \cdot (2\pi)^{\frac{3}{2}} C_n \cdot a \cdot c \cdot D_n^{1+b+d}}}, \tag{24}$$

for lethal cases

$$H_D = c \cdot D_D \sqrt{2ln \frac{m \cdot \rho_a (1 - e^{-k_1 \cdot t_{loc}})}{\rho_g \cdot 0,13 \cdot (2\pi)^{\frac{3}{2}} C_{cm} \cdot a \cdot c \cdot D_D^{1+b+d}}}, \tag{25}$$

where,

p_a,p_g – air and gas density of the appropriate type of CHS respectively, kg/m^3;

t_{loc} – time of localization of the accident;

k_1 – a multiplicity of air exchange in premises of the building, h^{-1};

k_2 – coefficient of the wind speed value;

k_T – ambient air temperature coefficient.

Estimated air temperatures and air exchange requirements in the premises are described in detail in [21].

It should be noted that the disadvantage of the proposed mathematical means is in finding input data. It requires depressurization area to calculate the mass of the spilled CHS by the formula 6.

Calculations were made and compared with full-time measurements to evaluate the accuracy of the proposed mathematical means with the results of other techniques used on the example of an accident occurring in October 2020 at the Birmingham Center (England) [7,22]. Input: there was a tanker depressurization with sodium hydrosulfide, 5000 gallons = 22.73 m^3, the hole was 0.04 m^2 in the bottom, the initial height of the liquid column was 1.5 m, the speed of movement of vehicles was 60 km/h, there was no precipitation inversion, the air temperature was $+15^oC$, the wind speed was one m/s, elimination time was 450 min. Results of calculations of the CHS spilled area on the underlying surface and depth of chemical damage are presented in table 4.

Table 4. Comparison of the calculations results of the CHS spilled area on the underlying surface and the depths of chemical levels defined in various ways.

	Method [23]	Method [24]	Method [25]	Model [15]	Model [16]	Author model	Field measurement
Spill area, m^2	268	280	482	436	323	347	370
δ, %	28	24	30	18	13	6	-
Depth of chemical damage, m	952	985	1476	1347	1130	1158	1246
δ, %	24	21	18	8	9	7	-

The table shows that mathematical models of pollution of the earth's surface and air as a result of the accident during CHS transport by road allow us to determine the necessary parameters of the damage zone with high accuracy. A significant advantage of such models is that, unlike other methods, they take into account: the nature of the underlying surface; the absorption of hazardous chemicals in case of an accident; the parameters of the spill area for various hazardous chemicals.

Subsequently, it is planned to develop a software-modeling complex based on the results obtained. The complex will become an effective tool for supporting management decisions on a prompt response to such situations to ensure a high level of protection of the population and environment, minimize the extent of damage, and ensure the effective elimination of appropriate consequences.

3. Author contributions

The research results presented in this publication are a collective effort of the individual authors:

- **Andrii V. Iatsyshyn** contributed to the conception and design of the study, analyzed the literature, reviewed incidents in Birmingham (October 2020) and New Jersey (February 2019), determined the quantity of chemically hazardous substances in the braking area, and assessed the reliability of the proposed mathematical tools.
- **Liudmyla M. Markina** evaluated the potential chemical risk in the vicinity of the accident and settlement zone, determined the average daily distribution of urban and rural population by place of stay, and assessed the reliability of the proposed mathematical tools.
- **Olha O. Tiutiunyk** determined the main parameters affecting the depth of secondary damage cloud as a result of an accident at a chemically hazardous facility, determined the initial height of liquid column in the tank at the moment of transport stoppage, and assessed the reliability of the proposed mathematical tools.
- **Vadym V. Tiutiunyk** determined the area and extent of chemical damage in the braking area, analyzed the angular dimensions of actual chemical damage zones, and determined the depth of chemical damage and height of striking cloud rise for limiting degree of damage.

- **Elnur Shukurlu** determined the spill area of chemically hazardous substances, determined the height of spill on underlying surface, determined evaporation time (impact effect) of chemically hazardous substances, and determined quantity of spilt chemically dangerous substances in emergency stop area.

4. Conclusions

Every year there is an increase in the transportation of dangerous materials by road worldwide. It is accompanied by emergencies related to the depressurization of containers (tanks, containers, cylinders, etc.) in various circumstances (road accidents, natural cataclysms, terrorist acts, etc.). In such cases, dangerous chemicals can get into the environment and create significant risks to the population of surrounding areas and the environment.

Existing methods of effects evaluating chemical accidents cannot be used to solve the task due to their significant disadvantages (non-considering nature of the underlying surface; CHS absorption; parameters of spilling area of different CHS; use of mathematical apparatus obtained only empirically; use stationary chemically hazardous objects; they do not allow calculate risks of such emergency events for the population health).

New mathematical means of accident assessment were developed to transport hazardous substances in road transport. They, unlike existing ones, take into account the parameters of the car, speed of the driver's reaction, parameters of the depressurization of the tank, nature of the underlying surface, and parameters of construction in the area place of stay. The high accuracy of the proposed mathematical means is confirmed by comparing it with data from field measurements and results of calculations by other techniques.

Further implementation of the developed mathematical support in the form of software will be an effective tool for solving problems of preventive forecasting and prompt response to emergencies related to the entry of such substances into the environment while transporting them by road.

Abstract. On the analysis basis of Ukraine fuel and energy complex priority problems, the key role of the introduction of international standards ISO 14000, ISO 9000 series and HSE policy to create conditions for the prevention of technological effects on environmental components and the formation of prerequisites for a safe environment, both for personnel and for the population of the surrounding territories, are determined. Deterioration of natural resources quality and ecosystems degradation and possible levels of natural environments pollution are used as parameters for environmental risk assessing in the conditions of the fuel and energy complex operation. The concept of environmental risk management in this field is presented. The biomonitoring uses to assess the factors influence of the industry enterprises is proposed. Biomonitoring of the territory around the Burshtyn thermal power plant is carried out, taxonomic characteristics of phytoobjects are given, and the indicative prospects of plants, their diversity and classes of permanence are evaluated. A literature analysis is carried out regarding the convenience, ease of use and phytoindicative suitability of plants under the conditions of the man-made environment complex impact. The highest species representativeness in *Asteraceae* family, represented by 17 species, *Fabaceae* and *Poaceae* – by 5 plant species, is established within the study area. The highest phytoindicative potential of *Cichorium intybus* L. and *Achillea millefolium* L. under the influence of Burshtyn thermal power station is revealed, which indicates the possibility of effective use of these plants as sensitive monitors of the fuel and energy complex enterprises ecological state.

1. Introduction

The facilities of the fuel and energy complex include thermal, hydro and nuclear power plants, the oil and gas and coal industry enterprises, oil and gas pipelines, transformer substations and power transmission lines. Electric power is one of the priority industries of Ukraine, which provides the country's needs in electric energy and exports a significant amount of electricity. Every year there is an increase in the consumption of oil, natural gas and electricity in the world due to constant urbanization and technogenesis. In particular, only in Ukraine for domestic needs by 2030, oil consumption is predicted to increase by 1.5 times, coal – by 2 times, and electricity – by 2.2 times.

Each element of the fuel and energy complex belongs to the category of environmentally hazardous and has a negative impact on the environment, including a direct or indirect impact on the health of personnel. These objects are a source of chemical and physical pollution of local, regional and global levels of air, soil, surface and underground water, the cause of climate change – the greenhouse effect, acid rain, smog, global warming, as well as the reduction of biological diversity. The reasons for the increase in the chemical and physical pollution levels during the activities of oil and gas industry and energy facilities are outdated equipment and technologies for extraction, transportation, processing and use of natural fuel resources. In addition to a number of chemicals toxic to the environment, such as heavy metals, petroleum products, acid oxides, the level of electromagnetic, noise and vibration pollution in the environment increases during the operation of fuel and energy complex facilities. In this respect, power plants and power lines pose a particular danger, the physical pollution from which in most cases significantly exceeds the permissible levels [1–3]. Therefore, establishing an environmental management system based on modern standards ISO 9000, ISO 14000, Health, Safety, Environment policies (HSE) with the use of effective methods of monitoring the ecological state of the environment under the influence of complex pollution from energy and fuel industry facilities is an urgent task ensuring environmental safety of the industry.

2. Literature review and problem statement

The implementation of the ecosystem approach in sectoral policy and improvement of the of integrated environmental management system is one of the tasks of the State Environmental Policy Strategy of Ukraine for the period up to 2030. Thus, one of the principles of this policy is the prevention of emergencies of a natural and man-made environment, which involves the analysis and forecasting of environmental risks, which are based on the results of a strategic environmental assessment, the environmental impact assessment, as well as comprehensive monitoring of the natural environmental state [4–6]. By ratifying the Protocol on Accession to the Treaty on the Energy Community Establishment, Ukraine undertook to implement the regulatory framework of the European Community on energy, environmental protection, competition policy and renewable energy sources [7, 8].

One of the essential steps in gradually achieving compliance with EU technical regulations and standardization and metrology systems was the ratification by Ukraine of the Association Agreement between Ukraine, on the one hand, and the European Union, the European Atomic Energy Community and their member states, on the other hand [4, 9]. According to this Agreement, our country undertakes to adhere to the principles and practices set forth in current EU decisions and regulations. Also, Ukraine undertook the gradual implementation of European standards (EN) as national standards. At the same time, conflicting national standards, in particular the application of interstate standards (GOST/GOST) developed before 1992, are canceled [10].

Thus, the enterprises policy should be based on the principle of preventing the occurrence of dangerous ecological consequences for the environment, personnel and the population of the surrounding territories, while one of the main tools is the monitoring and assessment of the existing environmental state.

There are a number of conceptual approaches for an environmentally safe production process, which are used at the facilities of the fuel and energy complex [8, 11].

The specified principles require appropriate tools that will allow making environmentally safe management decisions at the early stages of designing the planned activity. The task of obtaining a group quantitative expert assessment taking into account the coefficients of the estimated indicators relative importance of the planned activity impact on the environment is currently solved by the criterion-expert weighting methods, which form the basis of the information support of life cycle assessment (LCA) methodology, which is widely used in the environmental design practice in Western Europe and America countries [4]. The theoretical foundations of this approach are approved in international standards of the ISO 14040-14049 series "Life cycle analysis methodology" [8].

An important tool for managing environmental safety, preventing health impacts and creating a safe production environment is the policy "Health, Safety, Environment (HSE)" – these are separate issues, each with its own technology, but they are often combined into the same functional groups in fuel and energy companies. The main principles of this policy at fuel and energy facilities are [4, 12]:

- to aim at creating a safe, encouraging working environment;
- to warn about danger and take measures to prevent it;
- to provide education and training in order to ensure compliance with laws and regulations related to occupational H&S and to maintain and develop H&S workplaces and management systems;
- to lead efforts to address environmental issues on a global scale and for local communities by recognizing environmental measures as a pressing issue towards the creation of green and sustainable energy systems.

The creation of a favorable production environment from the point of environmental protection view and safe working conditions is based on the environmental components monitoring and their changes under the influence of man-made factors. Among the environmental monitoring methods biological monitoring deserves attention, and in particular, one of the most promising methods is phytomonitoring – the use of plant organisms that exist in a certain territory as a population and respond to ecological changes in the environment with a number of appropriate reactions [13]. Plant organisms are widely known for their phytoremedial and phytoindicative properties, and their ability to exhibit wide ecological plasticity in accordance with the genetically programmed capabilities of the reaction norm [14, 15]. A large number of publications are devoted to the study of indicative parameters of the vital state of plants in conditions of anthropogenic pollution [16–18].

However, there are relatively few works dealing with the role of herbaceous phytocenoses as objects of biological monitoring of the territories around the enterprises of the fuel and energy complex.

3. Objectives and methods

During the activity of the fuel and energy complex enterprises, in addition to the toxic substances influence, there is the electromagnetic, noise and vibration pollution influence, which creates conditions for disturbing the balance in natural systems and the human body. Creating conditions for its prevention and researching possible consequences on the environment is an urgent scientific task. The main tasks of this article are:

- to establish the environmental policy principles of the fuel and energy complex, which should create conditions for preventing the consequences of its influence;
- to propose the concept of environmental risk management for the fuel and energy complex objects;
- to analyze literature data on the possible of chemical and physical pollution impact of fuel and energy complex objects on the vital plants state, as well as on animal biodiversity and human health;
- to conduct a taxonomic and biomorphic plants characterization under the pollution conditions from the Burshtyn thermal power station;

- to evaluate the types of vegetation cover diversity, its vital state, distribution in the territory around one of the largest industrial enterprises of the fuel and energy complex of Ukraine – the Burshtyn thermal power plant;
- to identify the most promising plants-indicators of the territories ecological state around the Burshtyn Thermal Power Station with the aim of introducing them into the system of ecological monitoring of territories located near powerful energy facilities.

In the course of environmental management research, the analysis, deduction and system-structural methods are used. Detection of environmental impacts of the fuel and energy complex is based on the life cycle assessment method. The establishment of monitoring plots in the territory around the Burshtyn power station is carried out according to the author's methodology [19]. The establishment of life forms is based on biomorphological classification, the species composition of the phytocenoses of the experimental area is recorded using the Plant Snap mobile program, the phytocenotic diversity, the permanence class of each species is established according to the generally accepted methodology [19].

4. Research results

4.1. Environmental risk management of the fuel and energy complex facilities

The current priorities of the world community demand comprehensive control and reduction of environmental pollution. Effective management of environmental safety requires constant monitoring to identify the "weaknesses" of the existing management system.

At this stage, the system of environmental management in Ukraine is at the stage of formation, this also applies to the fuel and energy industry. The lack of an effective environmental policy of the fuel and energy complex of Ukraine in previous decades caused the accumulation of problems, the solution of which requires the regulatory documents appropriate base creation and a scheme for their implementation. At this stage, the pollution created by the fuel and energy complex increases the level of environmental and social risk in the spatial context.

According to the data of the Department of Labor Protection, Environmental and Industrial Policy of Naftogaz of Ukraine, intensive work is currently underway in the direction of integration into the European Energy Community. Among the important tasks is the implementation of EU Directives, international and European standards, including environmental protection management issues. The specified activity will minimize environmental risks during production activities and increase the level of environmental safety. Such positive trends will provide an opportunity to improve the company's international image and increase investment attraction. In 2018, the company received ISO 14001:2015, OHSAS 18001:2010 and ISO 50001 certificates from the authoritative international certification body TÜV SÜD Management Service GmbH, and in 2017, it passed a third-party surveillance audit for compliance with ISO 9001:2015 requirements. At present, Naftogaz has implemented the "VISION ZERO" vision – the HSE (Health, Safety and Environment) vision, according to which injuries, deaths, accidents and other negative consequences from operational activities are unacceptable [20, 21]. The spheres of influence considered within the framework of the HSE policy are of primary importance for the fuel and energy industry, and compliance with the guiding principles of safety and environmental protection is mandatory and dictated by the internal policy of most corporations. The implementation of the HSE policy makes it possible to define the principles by which operations are carried out and risks are controlled throughout the industrial cycle. Figure 1 shows the process of risk assessment and management in the HSE system.

The basis for building an environmental management system in the fuel and energy sector is the ISO 14000 series international standards and the corresponding national standards [8].

The trends of the modern environmental policy of the fuel and energy complex of Ukraine allow us to conclude that specialized companies strive to improve the environmental management

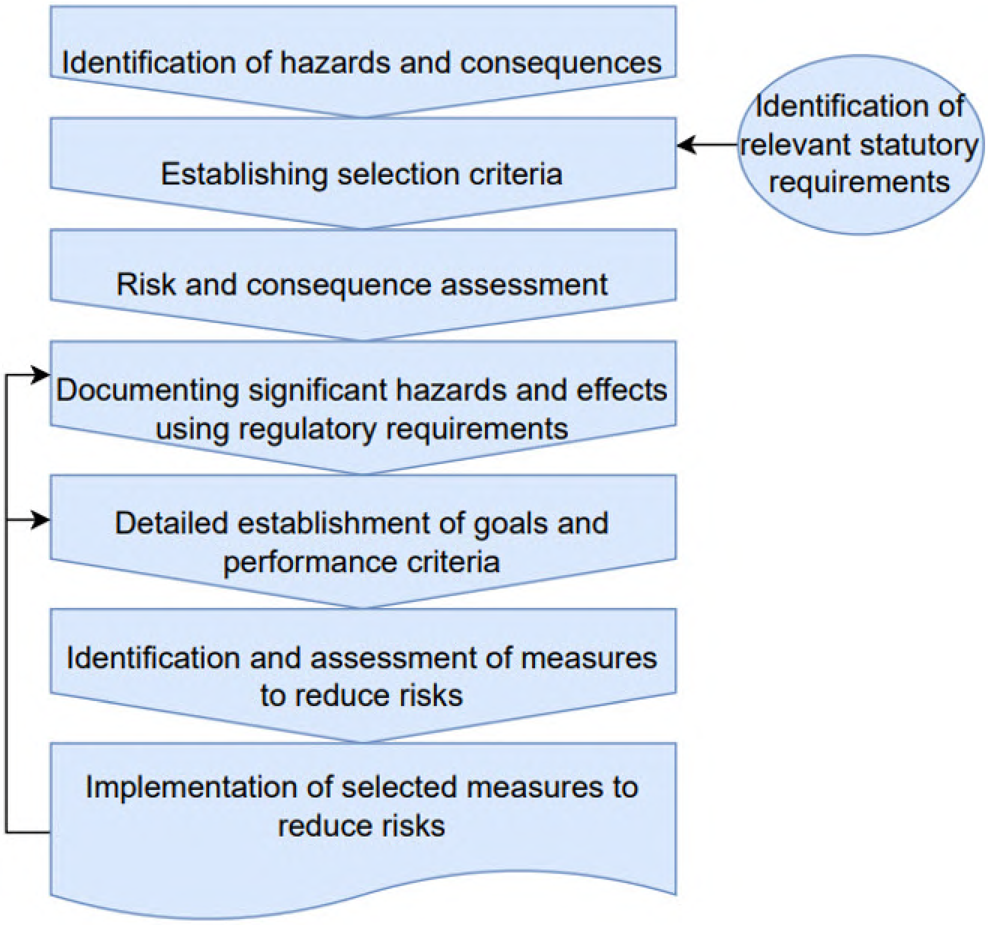

Figure 1. Risk assessment and management process [20].

system in order to meet the requirements of the EU and strengthen their stable positions on the European market. Solving the tasks is based on the comprehensive implementation of the environmental management system, the basis of which is laid in the international quality standards of the ISO 14000 series [7]. The ISO 9000 series international standards provide ideas for a systematic approach to management, decision-making based on factual material, and continuous improvement of the organization as a whole [10]. The specified principles require appropriate tools that will allow making ecologically safe management decisions at the early stages of man-made activities designing. Therefore, there is a need to use effective tools for assessing and monitoring the existing impacts consequences on the environment for the possibility of improving the eco-efficiency indicators of fuel and energy enterprises.

There are a number of methods for determining the environmental safety level based on environmental risk assessment [22, 23].

This approach is considered one of the promising tools for making managerial decisions. Along with the environmental safety assessment of naturall components, it is appropriate to assess the level of environmental safety based on biomonitoring.

One of the environmental risk definitions is the probability of adverse consequences for the environment, any changes in natural objects and factors, occurrence of extraordinary events in a certain period of time, expressed by quantitative parameters. Such parameters can be the following values:

- possible natural indicators of damage, that is, the number of victims and destroyed objects, the amount of the lost harvest;
- the possible dimensions of the quality deterioration of natural resources, degradation of ecosystems;
- the possible level of natural environments pollution.

Environmental risk assessment, which is predictive in nature, is carried out by three main methods:

- the method of analogy, i.e. comparison with other similar objects, and the comparison is made according to the same parameters;
- according to statistical data based on similar phenomena that have already happened;
- in a theoretical way, that is maintained by mathematical modeling.

In order to determine the optimal method of environmental risk assessment, it is necessary to take into account the origin of negative impact factors (phenomena), processes in the ecological system that suffered damage, the final state of the ecosystem (consequences of the negative factor of the environment and public health components). Depending on the level, there are features of environmental risk analysis (table 1).

The above indicates the need for an integrated approach to ecological and economic risk assessment at the cross-border level. The risk assessment methodology in the spatial context should be based on the compliance of its principles with European directives and be oriented

Table 1. Peculiarities of environmental risk analysis at the micro and macro levels [24].

	Micro level	**Macro level**
Aim	Assessment of direct damage from man-made phenomena.	Consequences determination of environmental damage for the natural territorial complex components.
Model of the analyzed system	Deterministic matching functions.	The function of probabilistic characteristics.
General appearance of the model	*Risk=M(x)*, where *M(x)* – mathematical expectation of a negative phenomenon.	$Risk = P(x) \cdot M(x)$, where *P(x)* – the probability of a negative impact on the natural-territorial complex components.
Quantitative analysis	$Risk = \frac{1}{CL_{50}} \sum_{i=1}^{n} \frac{C_i}{MPC_i}$, where CL_{50} – the lethal concentration of the toxicant in the waste as a criterion of toxicity, C_i – the content of toxic substances in the components of the environment, MPC – maximum permissible concentration.	$Risk = -P_i \cdot \ln(P_i)$, where P_i – the probability of a negative impact on the i-th component of the environment: $P_i = \frac{1}{\sqrt{2\pi} \cdot \sigma_{min} \cdot K} \cdot \exp\left[-\frac{x}{2 \cdot \sigma_{min}^2}\right]$, where K – hazard class value, σ_{min} – normalized indicator.

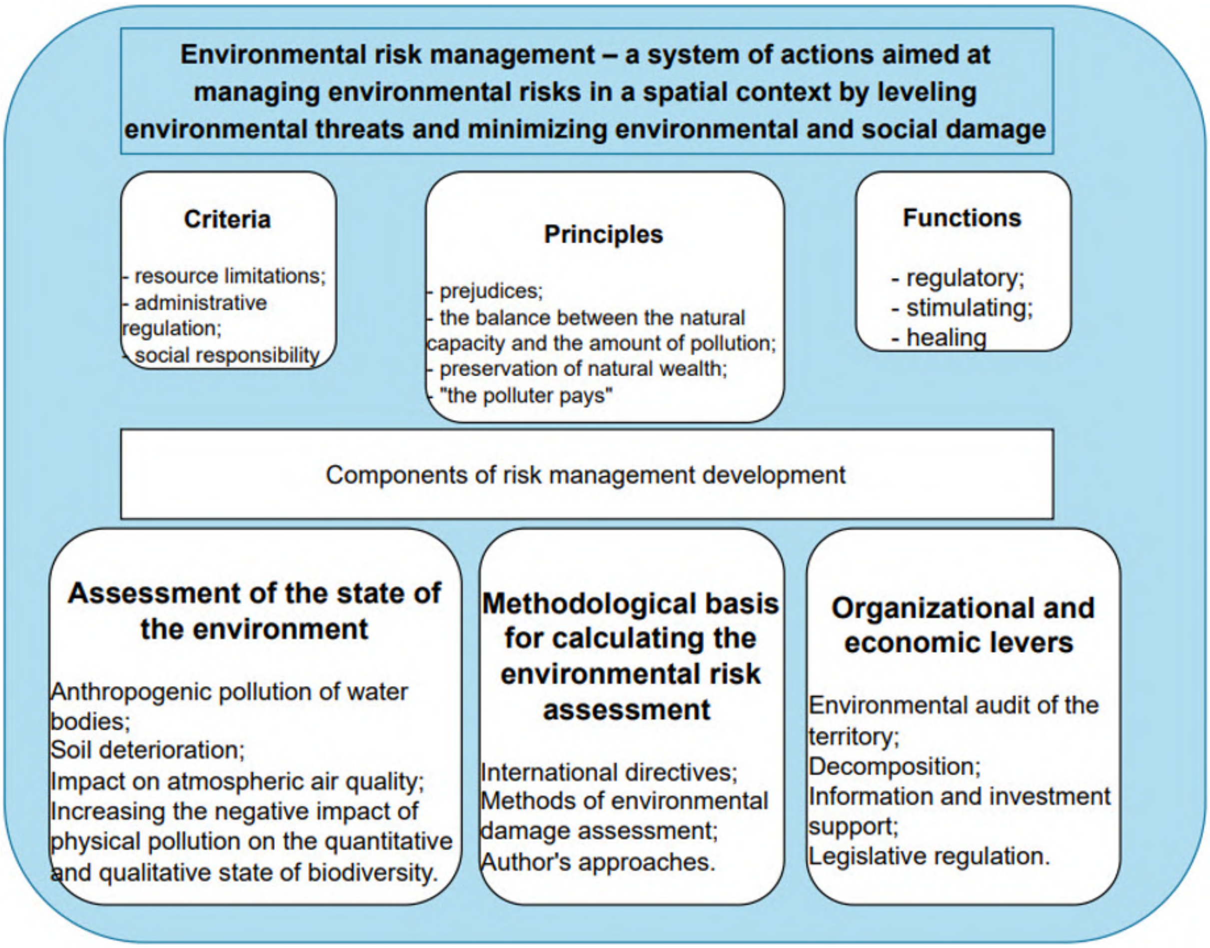

Figure 2. Risk management of fuel and energy complex facilities.

towards the transformation of national environmental protection legislation. In figure 2 presents the proposed concept of risk management of the fuel and energy complex [25].

An important role in the risk management implementation belongs to the choice of implementation methods of the stages indicated in figure 2. In this work, attention is paid to the environment quality assessment under the influence of complex chemical and physical pollution from the Burshtyn thermal power station on the vital state of plant communities. The diversity types, constancy and bioindicative potential of plants that exist under the influence of an industrial enterprise are analyzed.

4.2. Biomonitoring in conditions of complex environmental pollution by the fuel and energy enterprises

The research was carried out under the influence of the Burshtyn thermal power station, located in the Ivano-Frankivsk region at the intersection of power lines connecting Ukraine with Hungary, Romania and Slovakia.

Within a radius of up to 1 km from the source of pollution, seven monitoring sites with an area of 25 m^2 have been laid. The species composition of phytocenoses, abundance, family membership and life forms are analyzed within each site. A biomorphological analysis of the flora is carried out by assigning each type of plant to a specific biomorph and expressing the number of species of each biomorph in percentages. A taxonomic characterization of plants is carried out at each monitoring site and the phytocoenotic diversity of plants is calculated. Phytocoenotic diversity is determined as a percentage, taking as 100% the diversity of plants in the monitoring area with the largest number of plant species. Accordingly, phytocoenotic diversity is calculated in all other points, having the total species number of plants of these points.

To identify dominant and diagnostic species in the monitoring system, plant lists are compiled and the number of monitoring points where each plant species is present is analyzed. If the species is present in all monitoring points, its persistence coefficient is taken as 100%, if in some of the points, then the persistence coefficient is calculated proportionally. For example, if 25 points are entered in the table, and the species is present in 10 points, then the coefficient of constancy is equal to: $C = 10 \cdot 100/25 = 40\%$, if in 5 descriptions – 20%, etc.

All types of plants are divided into three groups depending on the constancy coefficient value. With values of the coefficient constancy over 60%, the species belong to the group of high constancy; with values of the coefficient constancy 20-60% – medium stability; with values of the coefficient constancy less than 20% – low constancy. The constancy class of each species is determined according to the scheme:

I class – less than 20%;
II class – 21-40%;
III class – 41-60%;
IV class – 61-80%;
V class – 81-100%.

The main environmental pollutants entering the atmosphere as a result of the power plant operation include acid oxides, which cause acid rain and cause tissue necrosis in plants and their subsequent death. In addition, a change in the natural value of pH in soil ecosystems inhibits the growth and development of plant seeds and causes the death of invertebrates [26,27]. Heavy metals present in industrial Burshtyn thermal power station emissions led to the biosynthetic processes blocking in plant tissues, inhibit cell division, photosynthesis and cause premature aging of plants.

According to the literature, low-frequency electromagnetic radiation leads to a decrease in the biomass of earthworms, blocking the mitochondrial activity, gene expression disruption and lipid and protein metabolism changes in Caenorhabditis elegans [28, 29]. Electromagnetic radiation causes changes at the level of informational relations between individuals in insect populations, disrupts physiological indicators, metabolism, growth and development, and leads to the appearance of mutations. Electromagnetic influence manifests itself in the disruption of intraspecific communications in birds, fish and reptiles [23, 30–32].

The consequences of short-term exposure to electromagnetic radiation on the human body include headache, general weakness, increased fatigue, sleep disturbances, irritability, and slowing of motor and speech reactions [33]. Long-term electromagnetic influence leads to a decrease in pulse frequency, a decrease in blood pressure, changes in blood composition, intensification of cell proliferation, reduced work capacity, changes in the activity of the internal secretion glands, circulatory, digestive, cardiovascular and nervous systems disorders, hair loss, fragility nails, skin diseases [31, 34]. It is known that electromagnetic radiation inhibits the growth and development processes of plants, causes changes in the shape and size of flowers, leaves, stems, the appearance of extra petals, and a decrease in plants dry weight [26,27,35]. The phytocoenotic diversity of the territory is an indicator of the ecological system environmental state, therefore, the study of the plant community's species composition makes it possible to identify the most promising species in terms of phytoindication [36, 37].

Under the influence of Burshtyn thermal power station 45 species of herbaceous plants and 1 tree species belonging to 18 families are recorded in the monitoring areas (table 2). The dominant family is Asteraceae represented by 17 species, *Fabaceae* and *Poaceae* – by 5 species each. The family *Hypericaceae* is represented by three species of plants, *Rosaceae*, *Plantaginaceae* and *Apiaceae* – by two species, the rest of the families in the monitoring areas have one representative of the plant species each.

Table 2. Species diversity of phytocenoses at monitoring points of the complex impact of the Burshtyn thermal power station.

In the conditions of the monitoring sites, a relatively uniform diversity of plant cover is noted with the lowest phytocenotic diversity – 63% (table 3). The number of plant species varies between 10-16, the number of families – between 5-9.

Phytocoenotic diversity under Burshtyn thermal power station influence is represented by all classes of constancy (table 4).

The V class of permanence includes two species of *Achillea millefolium* L. and *Cichorium intybus* L., which are expedient to use in phytomonitoring of complex pollution areas from the fuel and energy complex facilities (figure 3, figure 4).

Table 3. Taxonomic characteristics of phytocenoses at monitoring points of the Burshtyn thermal power station complex impact.

Monitoring site	Number of plant families	Number of species	Phytocoenotic diversity, %

Figure 3. *Achillea millefolium* L. under Burshtyn thermal power station influence.

Figure 4. *Cichorium intybus* L. under Burshtyn thermal power station influence.

The species *Artemisia vulgaris* L., *Lotus corniculatus* L., *Daucus carota* L. have medium bioindicative potential, and the species *Medicago sativa* L., *Trifolium pratense* L., *Centaurea jacea* L., *Erigeron annuus* (L.) Desf., *Arctium tomentosum* Mill., *Hypericum perforatum* L. have a low monitoring capacity. Half of the species belong to the I class of permanence, so they cannot be used for bioindicative purposes.

5. Discussion

The implementation of the ISO 14000, ISO 9000 series standards and the introduction of the HSE policy at the enterprises of the fuel and energy complex involves the constant improvement of processes and technologies to reduce the impact on the environment and prevent the occurrence of man-made impacts on the environment. In this aspect, an extremely important role is played by improving the qualifications of personnel regarding safe work within specialized enterprises.

Among the 45 species of herbaceous plants *Achillea millefolium* L. and *Cichorium intybus* L. have the highest representativeness on the monitoring sites, which indicates their phytoindicative potential and the possibility of being used as ecological state biological monitors of the territories around industrial and energy enterprises. In the absence of the specified species in the experimental area *Artemisia vulgaris* L., *Lotus corniculatus* L., *Daucus carota* L. can also be used for phytoindication. The remaining species around the Burshtyn power station are characterized by low prevalence and are not appropriate as phytoindicators of the specified industrial facility ecological state.

6. Conclusions

1. The concept of environmental risk management in this field is presented. Among the environmental risk assessment parameters in the conditions of the fuel and energy complex, the deterioration of the natural resources quality and the ecosystems degradation and the pollution possible levels of natural environments are highlighted.
2. It is proposed to use biomonitoring to assess the factors influence of this complex enterprises on the environment components. The bioindicative potential of *Achillea millefolium* L. and *Cichorium intybus* L. under the influence of pollution from the Burshtyn thermal power station is established. It is proposed to use species as biological monitors of the territories ecological state affected by the fuel and energy complex enterprises.
3. It was established that only 10% of all phytocenoses types that exist under the influence of

the industrial enterprise show high resistance to pollution under the operation conditions of the Burshtyn thermal power station. The significant diversity of plant species in the area of the enterprise influence indicates the natural potential of this ecosystem vegetation for self-preservation, however, the small representativeness of plant species indicates a significantly weakened reproductive potential in stressful existence conditions. In general, in unfavorable growth conditions, plants direct their energy resources to self-maintenance, and the processes of self-reproduction in these conditions of existence are suppressed.

Abstract. The general aim of this research is to analyze spatial-temporal changes of air quality, which are the consequences of the military invasion of the Russian on the territory of Ukraine based on open remote sensing data, geoinformation and cloud technologies. The density of NO_2, SO_2, CO and HCHO as well as the density of O_3 and the absorbing aerosol index (AAI) extracted from the Sentinel-5P satellite using Google Earth Engine (GEE) showed reduced emission of primary air pollutants and a high level of atmospheric restoration compared to 2021, the year before the war. At the same time values of the AAI increased significantly, indicating the presence of smoke and dust in the air. Obtained results showed one more aspect of the drastic effect of the war on the economic and social processes and environmental conditions. The consequences of this ecological effect can have a long-term negative impact on the health of populations.

1. Introduction

The full-scale war unleashed by Russia on Ukraine's territory caused irreparable loss of population, damage to the infrastructure and destruction of the economy, but also caused a significant deterioration of the environment and the formation of significant ecological problems. Thus, as preliminary estimated [1], 900 protected natural territories of Ukraine have been affected and more than 1.2 million hectares (30% of all protected areas of Ukraine) suffer from the effects of the war. As a result of shelling, uncontrolled forest fires occur, and the amount of waste has increased catastrophically. As a result of damage to the water supply infrastructure, 1.4 million people in Ukraine currently have no access to safe water.

The state of atmospheric air is an important indicator of the ecological situation [2]. The direct and indirect impact of active military operations through the bombing and burning of forests and industrial and energetic objects causes the formation of large volumes of pollutants in the atmospheric air. According to the data of the Ministry of Environmental Protection and Natural Resources, as of January 11, 2022, estimated losses due to air pollution amounted to UAH 1,000 billion [3]. It is obvious that for a general analysis and assessment of the impact of military operations on air quality, it is necessary to use background monitoring data to display an entire perspective of air quality changes during the war. The solution to this problem is complicated by the difficult or completely closed access to environmental data due to security issues or the lack of funding for systematic monitoring.

The *purpose* of this study is to assess the change in the volume of the main atmospheric air pollutants over the territory of Ukraine compared to the pre-war period using open data of

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012112 doi:10.1088/1755-1315/1254/1/012112

remote monitoring and geoinformation and cloud technologies.

2. Data and methodology

Global monitoring results with a spatial resolution near 1 km^2 which were obtained with the Sentinel-5P TROPOMI satellite instruments during 2021 and 2022 were used as input data for the study. The overall results of the previous studies [4, 5, 6] confirmed the capability of Sentinel-5P data to be used in monitoring the air quality.

The offline (OFFL) versions of air quality datasets of TROPOMI products, including the density of nitrogen dioxide NO_2, sulfur dioxide SO_2, ozone O_3, formaldehyde HCHO, carbon monoxide CO in the unit of mol/m^2 and unitless aerosol absorbing index (AAI), which represent pollution by the absorbing aerosols were used in this study. The general characteristics and sources of the input data are shown in the table 1.

Table 1. List of datasets used in the study.

Variables	Observation period	Earth Engine Snippet
NO_2	2021-2022	COPERNICUS/S5P/OFFL/L3-NO2
SO_2	2021-2022 (data are N/A in Jan and Dec)	COPERNICUS/S5P/OFFL/L3-SO2
CO	2021-2022	COPERNICUS/S5P/OFFL/L3-CO
HCHO	2021-2022	COPERNICUS/S5P/OFFL/L3-HCHO
O_3	2021-2022	COPERNICUS/S5P/OFFL/L3-O3
AAI	2021-2022	COPERNICUS/S5P/OFFL/L3-AER-AI

Google Earth Engine, a cloud computing platform, which is a modern powerful open tool for solving environmental monitoring problems, was used as an environment for data preparation and analysis [7, 8, 9]. This platform has been successfully used in various scale research [10, 11, 12, 13, 14] to analyze changes in atmospheric air quality during the lockdown due to the COVID pandemic in 2020-2021.

Additionally, for the territory of Ukraine it was investigated the changes in NO_2, CO, O_3, SO_2, and $PM_2.5$ atmospheric pollution during the first months of the full-scale war, compared to the similar periods of 2019, 2020 and 2021 [15]. The aforementioned study found a high correlation between NO_2 and $PM_2.5$ with the intensity of hostilities, an increase in CO and O_3 levels, and a significant decrease in SO_2 concentrations as the war intensified.

Therefore, taking into account previous research experience, Google Earth Engine is chosen as the optimal tool for working with large-scale observational data.

Visualization of the obtained analysis results were carried out using QGIS 3.22.14 "Białowieża".

This study included the following stages:

- downloading observed data;
- filtering and clipping data for the research area (the whole Ukraine);
- calculation and mapping of generalized monitoring results (average annual values) for 2021 and 2022;
- calculation of average monthly values of air pollutants for 2021 and 2022;
- construction of time series;
- Loading and saving spatio-temporal data for further research.

3. Results and discussions

The spatial distribution of the air pollutants is shown in figure 1.

The obtained results showed a decrease in the average annual density value for NO_2 (1.99%), CO (11.72%), HCHO (1.54%), and SO_2 (32.77%) in 2022 compared to 2021.For the average annual value of O_3 density, an increase of 1.55% is observed (figure 2).

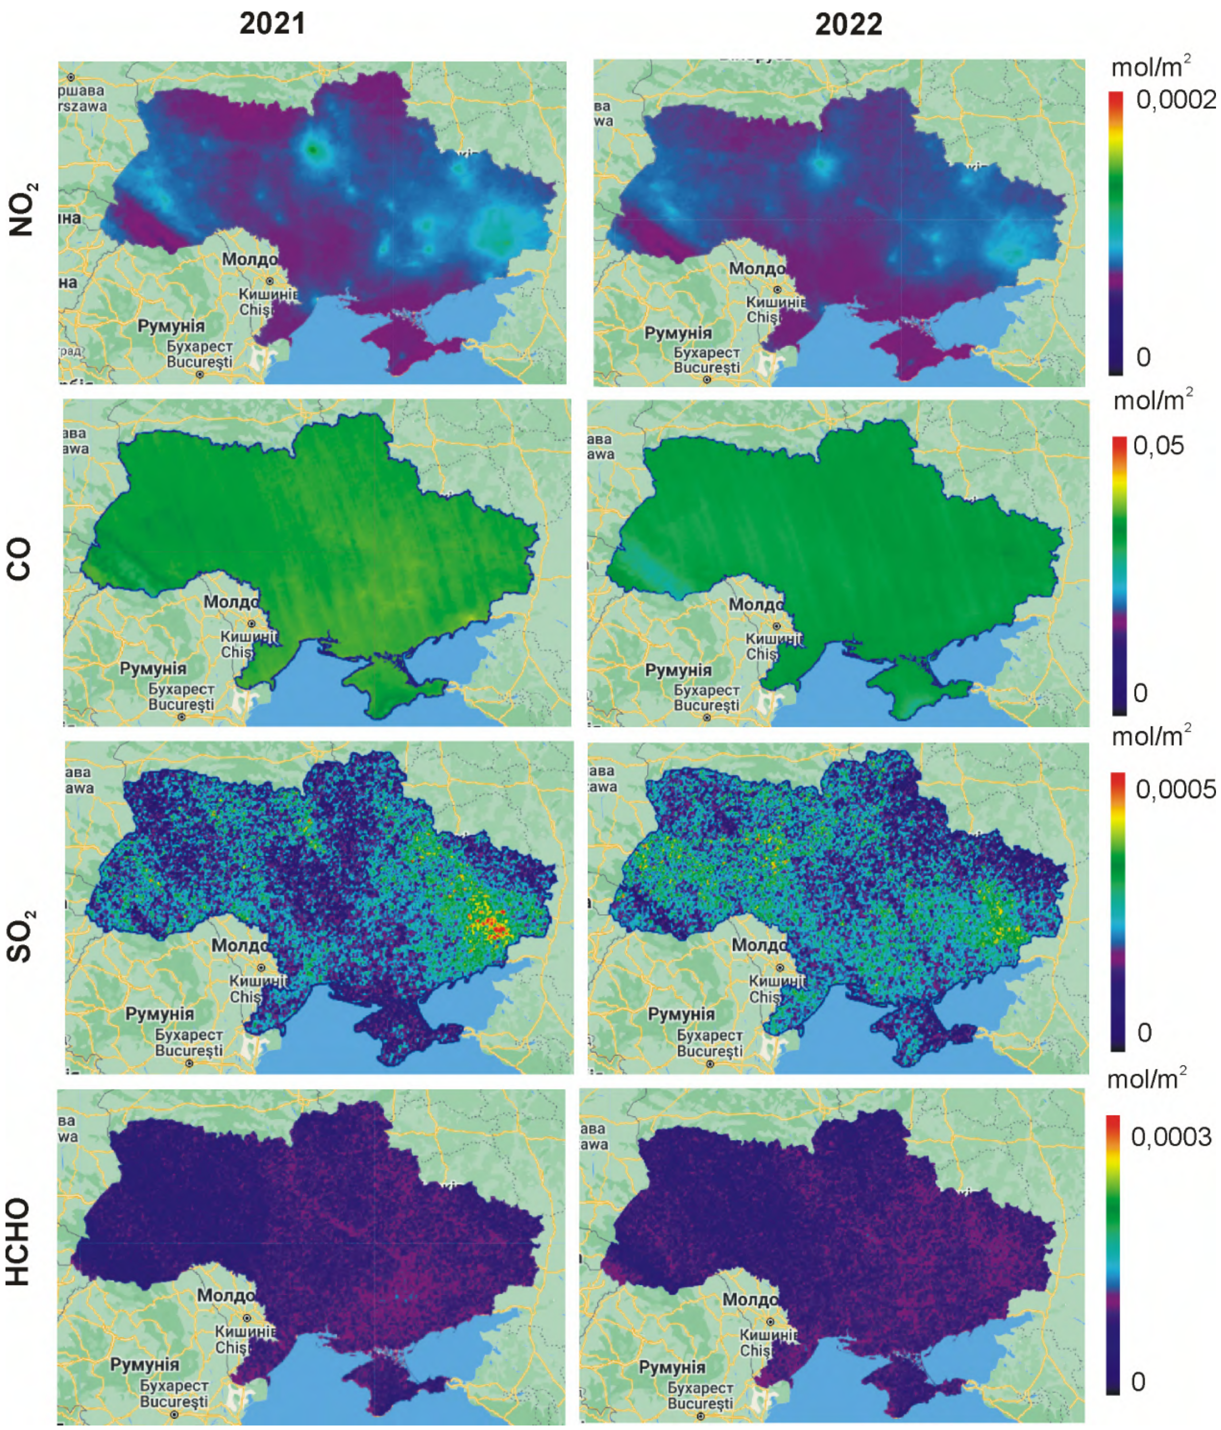

Figure 1. Spatial distribution of air pollutants over Ukraine in 2021 and 2022.

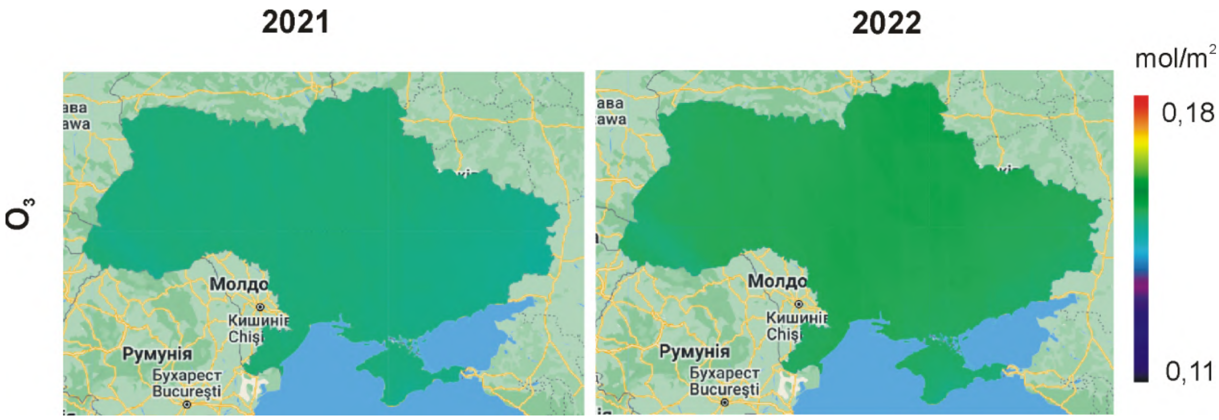

Figure 2. Spatial distribution of O_3 density over Ukraine in 2021 and 2022.

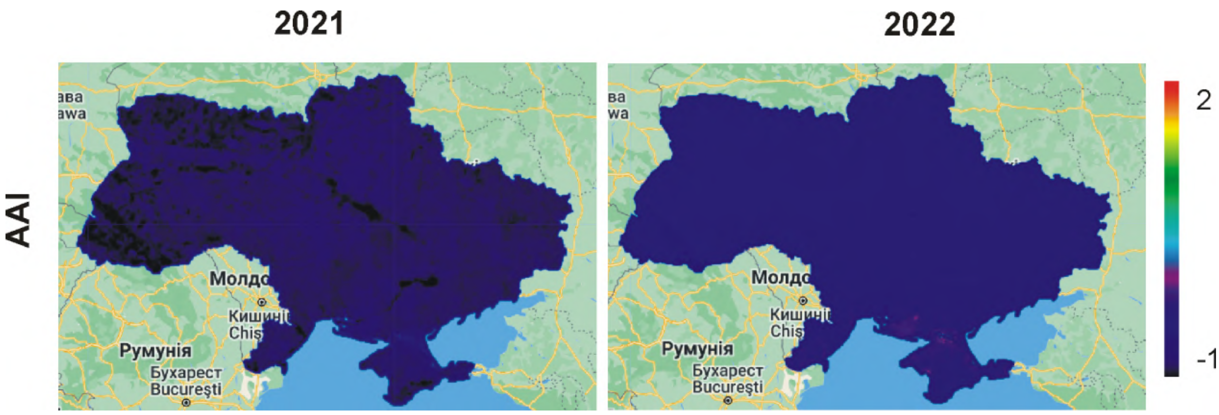

Figure 3. Spatial distribution of AAI values over Ukraine in 2021 and 2022.

The average annual value of AAI in 2022 also increased by 55.84% compared to 2021 (figure 3), which is evidence of a huge concentration of aerosols, smoke and dust in the atmosphere, resulting from explosions and fires.

Average monthly values were calculated separately for 2021 and 2022 using JavaScript language tools in Google Earth Engine to evaluate and compare the temporal dynamics of the considered variables. The created time series of the seasonal dynamics of the air quality are presented in figure 4. It is obvious that with a general tendency to decrease the amount of the considered pollutants, the seasonal patterns of its variability were preserved during 2022.

Evidently, the decrease in emissions of pollutants into the atmosphere, and therefore their content in the air, is connected with the shutdown of enterprises and is a reflection of the negative impact of military aggression on the Ukrainian economy. It should also be realized that pollution has become more dispersed in space. Emissions of specific substances occur as a result of explosions, which settle in soils, surface waters, migrate into bottom sediments and groundwater[16, 17, 18]. Thus, a necessary step will be to conduct a diagnostic assessment and analysis of the specific pollutants content (in particular, heavy metals, carcinogens, etc.) with the involvement of the developed investigated methods of individual environmental components [19, 20, 21, 22].

Figure 4. Monthly average density of pollutants, O_3 and AAI over Ukraine (2021-2022).

4. Conclusions

The study of changes in the values of NO_2, CO, O_3, SO_2, HCHO density in atmospheric air and the absorbing aerosol index (AAI) as a result of military operations for the territory of Ukraine were conducted using the Google Earth Engine cloud geoinformation platform and remote sensing data of the Sentinel-5P TROPOMI.

The study of the distribution of pollutants showed declining annual mean values of NO_2, CO, SO_2, and HCHO in 2022 compared to the 2022 year. In contrast, overall higher O_3 was observed. The AAI increasing significantly.

The obtained results are a clear indication of the armed conflict's impact on air quality, the health of the population and the environment in general. They are important for conducting audits and designing an environmental monitoring system for assessing losses due to military aggression and post-war environmental restoration.

Abstract. This paper presents the results of detailed geological and structural surveys within the Orikhovo-Pavlograd suture zone of the Ukrainian shield. In the northern part of the Orikhovo-Pavlograd suture zone of the Ukrainian shield, dislocation structures of several generations are identified, which differ from each other in spatial placement and R-T values of material filling. The structures of the first five generations are formed by mineral parageneses from granulite to green shale facies of metamorphism; their age is connected to the time range of 3.6–1.8 billion years. Later dislocation structures are postmetamorphic. At the micro-meso levels of the organization, the selected structures are represented by striation, shale, linearity, cleft, cracks, etc.; at the macro level, they are represented by viscous and brittle faults. Systematized data on the structural and material organization of U-, Th-containing Pivnichno Tersyansk folded shape according to the principle of hierarchy of geological structures. It is shown that this U-, Th-perspective object is a highly ordered propulsion structure. That is, its formation was provoked by Paleoproterozoic displacements and occurred synchronously with the formation of containing geological bodies by turning up existing Precambrian formations with the creation of new structural and material parageneses. An idealized model of forming a single U-, Th-perspective structure is created, this will contribute to the search for uranium-thorium mineralization and the expansion of the mineral resource base of nuclear energy in Ukraine.

1. Introduction

The Orikhovo-Pavlograd suture zone crosses the Ukrainian shield (US) in a submeridional direction and traces beyond its borders. It has a deep structure in the form of a package of tectonic plates of subvertic fall. Within the US, this suture zone can be traced at a distance of up to 200 km with a width of 40 to 4 km and separates the Serednioprydniprovsky and Pryazovsky Megablocks of the US. The Orikhovo-Pavlograd suture zone differs from adjacent

Megablocks in the nature of the manifestation of the Moho interface surface – within the zone it is fixed in the depth range of 42-46 – 53 km, in Megablocks – at the level of $\sim$ 40 km [1]. But the zone is most clearly distinguished relative to Megablocks as a deep linear zone of increased electrical conductivity [1].

According to [2], the depth of the sole of the "Granite" layer of the Earth's crust within the studied part of the gorge is $\sim$ 10-15 km.

The depth of the sole of the transition layer for the Orikhovo-Pavlograd zone is 25-30 km; the depth of the erosion section is determined at 17-20 km [2].

The zone is filled with an association of crystalline rocks, generally similar to such adjacent Megablocks, at the same time, it is characterized by characteristic (suture) structural and material features [1, 3, 4]. The following age figures are known for geological bodies of the zone: 3.6, 3.2, 3.0, 2.8, 2.0, 1.9 billion years [1,3,5–8].

The Orikhovo-Pavlograd zone is identified [1] with the zone of collision of the Pryazovsky and Prydniprovsky microcontinents at the archaea Proterozoic boundary and is interpreted, together with the adjacent edge parts of Megablocks, as regions of permanent stretching-compression of the crust. In other words, these are areas of more intensive processing of the epiarchean foundation, compared to the central parts of Megablocks.

The western border of the zone is considered to be the Orikhovo-Pavlograd deep fault, which runs far beyond the US (to the Kursk magnetic anomaly area), because it is clearly expressed in physical fields. According to deep seismic sounding data, a ledge of the Moho section with an amplitude of 8 km is recorded in the fault zone (at Chapter 44-46 km). Gabbro-peridotites of the Novopavlivsky section and the Malotersnyansky alkaline massif are associated with this fault. The Orikhovo-Pavlograd fault has an inclined-stepped displacement surface, which is formed from structures of higher orders with an easterly fall. The angles of incidence vary from 70-80° in the near-surface part of the foundation to 40° in the upper mantle. The eastern boundary of the zone is considered to be the West-Azov (Azov-Pavlograd) fault, it is also well expressed in physical fields and is fixed by the gravitational step. The fall of the fault offset in the upper parts of the crust (0-3 km) is subvertic, and with depth it becomes more inclined with a fall to the West [1].

According to Gintov [9], the kinematics of the Pavlograd fault zone is determined as follows: the zone was formed as a right horizontal shift ($\sigma_1 - 20/0, \sigma_3 - 290/0, \sigma_2 - \perp$) and activated as a left Skido-zdvig ($\sigma_1 - 275/30, \sigma_3 - 35/50, \sigma_2 - 155/45$). The age of this fault zone is considered by Gintov as neoarchean, since it intersects and deforms by the Devladovsky fault zone; according to the latter, neoarchean hyperbasites took root in the Earth's crust.

According to Kruglov et al [4], The Orikhovo-Pavlograd zone, like other suture zones of the gorge, differ sharply in formation content, but usually only in dislocation intensity and other features from one of the adjacent Megablocks, while at the same time they have many common features with the other. That is, according to the authors [4], suture zones are not peer-to-peer with Megablocks and independent structural-formation zones. In particular, the Orikhovo-Pavlograd zone (synclinor zone) occupies the westernmost part of the Priazovsky megablock and borders the West Priazovsky anticlinor zone along the Korsatsky and Pavlograd deep faults.

Within the Orikhovo-Pavlograd suture zone, known uranium (thorium-uranium) mineralization is represented by a small number of ore occurrences of uranium (thorium-uranium) hydrothermal in mineralized zones of crushing of crystalline rocks of the ore formation. It mainly tends to its western parts within the Orikhovo-Pavlograd deep fault, these are the Pivnichno Tersyansk, Vasynivsky, Novopavlivsky ore occurrences, etc. [8].

2. Results and discussion

The authors of the article carried out detailed geological and structural works in the northern part of the Orekhovo-Pavlograd seam zone (River Vovcha Basin , next to the village Vasylkivka),

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012113 doi:10.1088/1755-1315/1254/1/012113

where feldspar quartzites, Garnet-biotite gneisses, tonalites–tonalito-gneisses, and granitoids were studied in quarries. It is established that deformation formations of 7 generations are manifested in all the studied rock varieties. These are banding, slitting structures, shale formation, several generations of mineral linearity, and brittle cracks. The actual material on the placement of metamorphogenic structures was processed using the StereoNett 2.46 program; the Pivnichno Tersyan folded shape was also characterized in accordance with the principle of hierarchy of geological structures.

Generation structures-1 expressed as relict lenticular subtiles among later dissection planes. Such bodies of various sizes – from several *see* up to the first meters; the ratio of their long axis to the short one (**a: C**) reaches 7. Axis **a** obliquely submerged in azimuth 330-0 (1 in figure 1).

For quartzites, these are close to massive bodies of essentially quartzite composition, which are distinguished by shades of colors ranging from dark gray to light gray, almost white (L_1 in

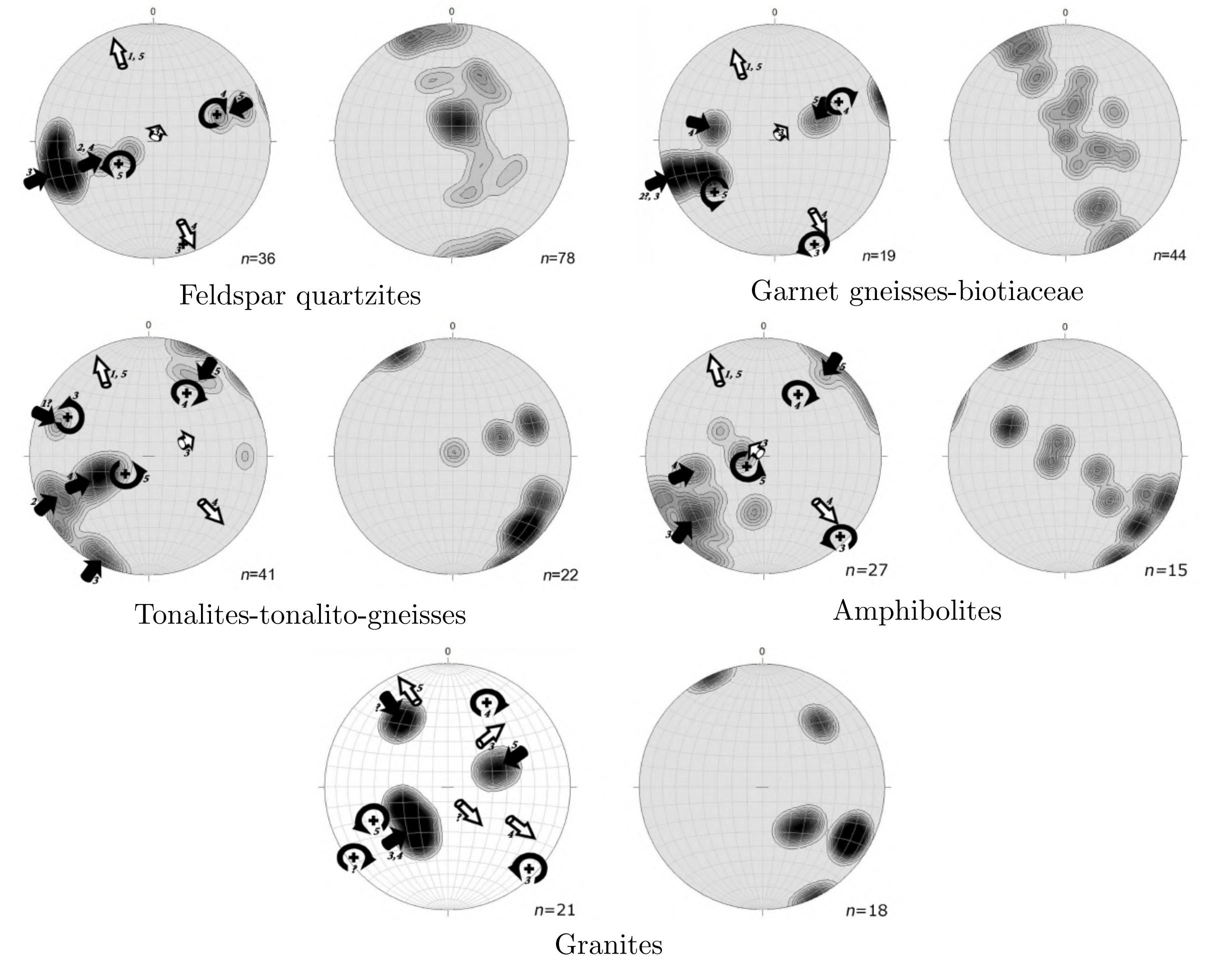

Figure 1. Stereograms of the poles of the planes of striation and shale formation and immersion of linearity along mineral aggregates and folded axes for conducting petrotypes of the Orikhovo-Pavlograd suture zone. Projection on the lower hemisphere. Gradation of isolines: 1-2-3-4-5-6-7-8-9-10-11-12-13-14-15. Arrows – directions of action of tectonic stresses (for simplification shown by one Arrow): Black straight lines – compression, white lines – stretching; rounded lines – rotation, crosses – their axes. The numbers next to it are the stage index. n – number of measurements.

figure 2).

For geological bodies of Garnet-biotite gneisses, relict formations are poorly diagnosed by shadow linearity in the separation planes, which is expressed as the division of rock into dark and light gray fractions (L_1 in figure 3). In tonalites–tonalites-gneisses, the structures of this generation are represented by elongated massive bodies of the tonalite composition (figure 4 marked – t), enderbites, and amphibolites.

Generation structures-2 they are most clearly expressed in tonalito-gneisses and are represented by striation, which is due to variations in the mineral composition. Banding has a dip azimuth of planes of ~ 70, < 80-90. The thickness of the strips does not exceed 1 cm (2 in figure 1 A and Y_2 in figure 4).

In Feldspar quartzites, the structures of this generation include one of the shale formations formed by rock-forming minerals and their lenticular aggregates (figure 2); it has elements of occurrence similar to banding in tonalito-gneiss. The structures of this generation also include linearity, which sinks at angles of $\sim 45°$ in both quartzites and biotite gneisses (L_2? in figure 2, figure 3).

Generation structures-3 it is represented by striation and shale with steeply falling mineral linearity. The banding of this generation is most clearly distinguished in geological bodies of the composition of tonalites–tonalites-gneisses and Garnet-biotite gneisses. In tonalito-gneiss, these are Lenses strips with capacities of several cm (3 in figure 1, Y_3 in figure 4) granite composition, which are secant to the structural elements of previous generations in several degrees. In garnet-biotite gneisses, these are leuco- and melanostripes. The first of them are quartz-feldspar composition, the second correspond to gneiss proper (figure 3). The shale content of this generation is well expressed in Feldspar quartzites; it is formed by rock-forming minerals and their aggregates (figure 2).

Mineral linearity of Generation-3 in tonalito-gneisses is weakly expressed; it is most clearly distinguished in geological bodies of the composition of Feldspar quartzites by elongated aggregates formed by feldspar, biotite and garnet; in bodies of the composition of Garnet-biotite gneisses, linearity is relatively moderately expressed by elongated aggregates of biotite and Garnet (3 in figure 1; L_3 in figure 2, figure 3). The size of such units is from several to 8 mm, **a: c** – 5-7, their placement reproduces subvertic chains several tens of centimeters long.

Generation structures-4 for all the studied breed varieties, they are represented by separation. They are expressed by a shale matrix (actually dissociation zones), which contains lenticular bodies subordinate to it with a relatively massive structure. The separation planes are formed by single-system placement of flat grains and aggregates of rock-forming minerals. Dip azimuth of planes shale/slotting planes ~ 70 at angles of about 40. For quartzites, the dissection structures are expressed as alternating shale feldspar quartzites and close to massive quartzites (figure 2). For Garnet-biotite gneisses, the dissection structures are represented by separate gneiss dissection zones that distinguish the striped gneisses themselves. The capacities of such zones are the first *see*, the distance between them reaches several tens of centimeters – the first meters. For tonalites–tonalites-gneisses, the shale Matrix corresponds to gneisses of the tonalite composition (tonalite-gneisses). Packages of shale tonalito-gneiss reach capacities from several meters to several tens of meters (figure 4). Such packages contain lenticular bodies of the composition of tonalites and enderbites and striped tonalites, as well as folded-lenticular bodies of the composition of amphibolites with dimensions of tens *see* – first meters.

In the shale planes, there is a mineral linearity that sinks obliquely to the Southeast (4 in figure 1). In Feldspar quartzites, this linearity is formed by Muscovite aggregates; in garnet-biotite gneisses-Muscovite and biotite (L_4 in figure 2, figure 3); in tonalites – tonalites-gneisses, linearity is represented by hinges of folded bodies of amphibolites and elongated spindle-shaped aggregates of quartzite composition. The dimensions of the latter along the long axis reach 20 cm, **a: C** exceeds 10 (figure 5).

varieties of breeds. These are fragile cracks, narrow (with several capacities mm – the first ones *see*) zones of crushing, cataclysm and milonitization of rocks. Within such formations, no dynamometamorphic changes in rocks are recorded, so they are not displayed on stereograms, but they are visible in figure 2, 4. The elements of occurrence of structures of this generation are as follows: dip azimuth of planes $\sim$ 0, $<$ 45, 80; dip azimuth of planes $\sim$ 190, $<$ 0 – 45; dip azimuth of planes 270, $<$ up to 40; dip azimuth of planes $\sim$ 70, $<$ 80-90. The latter planes contain beard and linearity in sliding strokes. The first of them sinks obliquely, the second up

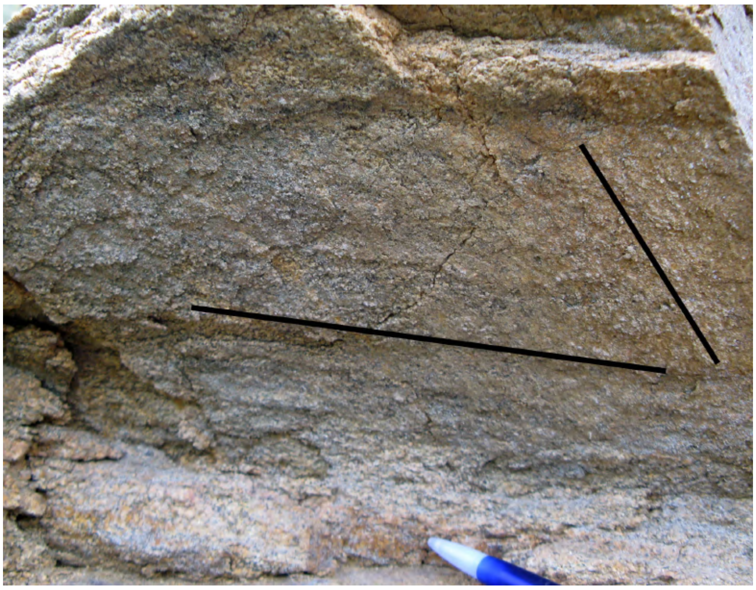

Figure 6. Two generations ($L_{6,7}$) linearities (underlined by lines) in the submeridional planes of the separation of tonalito-gneiss, represented by striations, and sliding strokes. Western exposure

to 45 in the southern points (figure 6).

Geological bodies of granites and amphibolites also have a hybrid structure similar to that of tonalito-gneisses and garnet-biotite gneisses (figure 1, figure 7). The amphibolites are found as very dispersed lenticular-house bodies of various sizes among the shale matrix of the tonalito-gneiss composition (figure 4). We have not recorded geological bodies of granite composition in the form of single manes and their immediate boundaries with formations of a different composition. But these "manes" of granite composition in the transverse (up to the leading shale) cross-section have an inhomogeneous, striped-folded internal structure (figure 7). The latter is expressed by lenticular subtiles with internal drawing folds and resistances that reproduce the right-wing structural pattern. The base of this pattern is formed by white granites, the contours of lenses, folds and feather are formed by red ones. At the same time, the ribbon-like bodies of red granites are not injections, the boundaries between them and white granites are gradual, and the shale of white granites is subordinated to the structural pattern formed by the striation of red granites.

The latter is often divided into quartz and feldspar fractions, and the cores of folded forms contain sickle-shaped clusters of dark-colored minerals.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012113 doi:10.1088/1755-1315/1254/1/012113

All this indicates that the formation of both types of granites occurred simultaneously due to synshifts structural and material transformations.

From time to time, fairly dispersed shale planes can be traced within the granitoids, falling to the northeast and west – southwest. That is, shale is similar to that of generations 4 and 5 in other types of rock bodies. Therefore, it can be assumed that folding with material transformations in granitoids occurred at the third stage of structural-material transformations of the studied part of the suture zone.

Thus, in all rock varieties of geological bodies within the part of the studied zone, the same structural and material paragenesis was manifested. They are the same in terms of spatial position, the number of generations of structural elements, and R-T implementation conditions. Consequently, all the studied rock varieties of the Orikhovo-Pavlograd zone were formed similarly and gradually, structural and material transformations in their volumes occurred cooperatively/simultaneously, in several stages under significantly shifted tectonic conditions against the background of regressive changes in the R-T parameters of the medium. Moreover, such transformations took place together in the entire volume of the suture zone fragment under study – from the micro - to macro-level of its petro-structural organization. The latter is evidenced by the self-similarity of structural forms at all levels of subordination for all geological bodies studied. That is, the studied volume of crystalline rocks is the only dislocation system that was formed during at least five stages of structural and material transformations of the crystal base.

The formation of the studied dislocation structures occurs in a shift environment [9–11], that is, their shape and placement are subordinated to the directions of action of tectonic stresses. At the micro level, these structures are formed using diffusion, filtration and other mechanisms of substance movement. Accordingly, their material filling reflects the conditions of formation of the studied structures. According to [5–7], the degree of metamorphism of the substance of dislocation formations reached granulite and amphibolite facies. Therefore, with age ranges 3.6; 3.4-3.3; 2.8-2.7, 2.0 billion years [5–7] and 1.9 [8] billion years we associate the formation of the metamorphogenic dislocation structures described above. According to Goryainov et al [12], we link the structures of generation-3 to the timestamp $\sim$ 2.8 billion years ago, generation-4 $\sim$ 2.0, generation-5 $\sim$ 1.9-8 billion years ago.

Pivnichno Tersyansk folded form of the Orikhovo-Pavlograd suture zone as its around shift component

Under tectonically active conditions, which are recorded in variations in the spatial position and P-T values of the creation of the studied structures, the ore substance could not be unused to the above-described transformations of the Precambrian Foundation. And ore bodies within the suture zone could be created only under tectonic conditions, under which both the containing rocks and the entire part of the foundation under study were formed. This is evidenced, for example, by the data systematized for *Pivnichno Tersyansk folded shape*, based on the materials of works [1, 8]. They are listed below in paragraphs 1-5, starting from the macro level of the petro-structural organization of the object (point 1), ending with the micro level (point 5). For such systematization, the Pivnichno Tersyansk folded form was chosen because it was relatively well studied by previous researchers due to the fact that this structure contains a deposit of ferruginous quartzites, ore occurrences of uranium and thorium, and manifestations of other mines [1, 8]. In addition to the above, the Pivnichno Tersyansk folded form is composed of rock associations similar to those that we studied within the Vasylkivska site.

1. The Pivnichno Tersyansk folded form at the macro level is expressed by two components-linear (plate – shaped) and sub-ring-shaped. The elements of the first of them are subordinated to the following elements of the Orikhovo-Pavlograd suture zone as a whole

(figure 8). Namely, the linear component has an dip azimuth to the southeast at an angle (<) of 80-85° with an extension of up to 2 km and a power of ∼ 0.5 km [1, 13]. It is traced to a depth of ∼ 0.5 km. The sub-ring component (brachisincline according to [13]) reaches a diameter of 1.0 km. Its axis has a near – latitude direction, the fall of the wings in the southern part of the brachisincline is close to vertical, in the northern part-a fall to the south at < 50-60° [13].

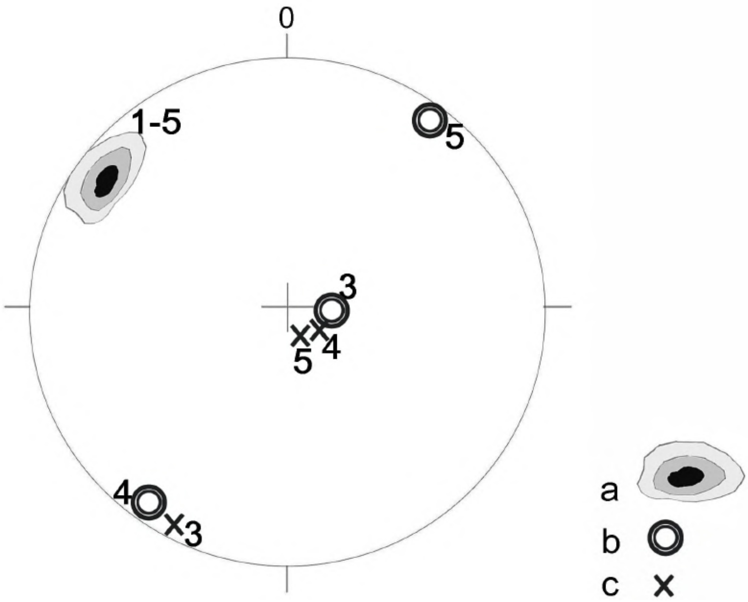

Figure 8. Schematized diagram of the placement of planar and linear structural elements for the Pivnichno Tersyansk folded shape, according to data from [1, 13] in the projection on the lower hemisphere. a – the pole of a linear (plate – like) macro-component; b-metamorphogenic linearity (tensile axes), respectively, of the above (in figure 1) data; c – projections of rotation axes. Digits – numbers of structure generations.

If we start from the fact that the linear and sub-ring components of the Pivnichno Tersyansk folded form were formed interrelated, in several stages (as well as the contained geological bodies of figure 1-figure 7), then the linear component is the zone of secondary striation and separation of stages 3-4; its pole is the point of application of tectonic compression forces. The placement of the rotation axes of generations-4 and 5, however, is close to vertical (even if the tension axes are placed sub-wide, according to the placement of the axis of the sub-ring component). That is, it follows from these data that the sub-ring component of the Pivnichno Tersyansk folded shape was formed due to the propulsion rotation of metamorphogenic strata. Accordingly, in this component, relative to the linear one, petro-structure formation occurred at lower R-T indicators of the medium. The elongated tail of the sub-ring component indicates a left-hand rotation, which we associate with the fifth stage of structural and material transformations of the studied part of the foundation; this is about 1.9-8 billion years ago. In the tail section, as a marker of relative compaction, there is a granite massif. The model of formation of such structures is recorded in natural models of structure formation (figure 7).

2. At the meso-level, both components, linear and sub-ring, of the Pivnichno Tersyansk folded shape are formed by consistent stratal-lenticular geological bodies with elements of occurrence that are similar to those for macro-composite ones. Mesotil capacities range

from a few meters to 70 m with a horizontal length of tens of meters to several kilometers. That is their **a: c** (the ratio of the long axis to the short axis) reaches 10.

Material, within the linear macro-component, geological bodies of the meso-level are represented by amphibolites, modified to varying degrees by ultramafic rocks, chloritized amphibol-magnetite quartzites and quartz-magnetite shales. Within the sub – ring component-biotite, biotite-garnet, biotite-silymanite gneisses, feldspar and glandular quartzites.

According to the studies [10,14], as well as ours, which are given above, the formation of the above-described structure of the Tersyansk folded shape is possible due to the involvement of the primary crystal base in repeated deformations of shear-stretching and scrolling of its individual fragments. That is, it is a secondary stratification – tectonostratification of the geological environment **a: c** it is an expression of the degrees of elongation of geological bodies under such deformations; the degree of metamorphism is an indicator of the P – T conditions of the dislocation process. In this case, in the linear macro-component of the Tersyansk folded form relative to the sub-ring form, the degree of metamorphism is higher, which is one of the confirmations of increased strain pressures within the linear component at the time of formation of the Tersyansk form as a whole.

3. Geological bodies of the meso-level, both in linear and sub-ring components Tersyansk folded shape, striped and slate [1, 13]. The striping is caused by changes in the mineral composition and dimensions of mineral grains; the capacities of pronounced banding in this way range from a few millimeters to several centimeters. Shale formation is caused by the single-system placement of flat minerals and their aggregates.

   As shown above, we have identified several generations of striation, shale, and mineral linearity. All of them are more or less manifested in all varieties of breeds. But the most intense is the shale formation and linearity of generation-4, which actually creates a mutual agreement of all geological bodies.

   Striation and shale formation and their coherence are expressions of the shear/stretch process at the micro level. At this level it is realized due to syndeformational recrystallization in the direction of relatively reduced strain pressures [15, 16].

4. Accordingly, [8] uranium-thorium mineralization within the Orichovo-Pavlograd suture zone is localized in layers of schistose and mylonitized chlorite-mica quartzites among micaceous quartzites of the Vovchansk Formation. According to our data, such “layers” in quartzites are the result of at least the fourth stage of structural and material transformations of the studied zone fragment.

5. In the mineral composition of the studied geological bodies, there are mineral parageneses from the granulite to green-shale degree of metamorphism [1, 7, 13]. Within the Vasylkivska site, depending on the degree of separation, the chemical composition of minerals changes [7].

   According to isotope studies [5–8], for tonalites and biotite gneisses, the age figures in 3.6; 3.4-3.3; 2.8-2.7, 2.0 for quartzites 2.8-2.7, 2.0 and for rare earth mineralization 1.9 billion years.

So, from all the above data, it follows that all the structural, material and age attributes of the northern part of the Orikhovo-Pavlograd suture zone are highly consistent. This is a consequence of tectonic-metamorphogenic transformations of this fragment of the crystalline basement in several stages. The transformations of the Fourth of the selected stages, which we link to the timestamp of 2.0 billion years ago, were most intensively implemented.

3. Conclusions

The Orikhovo-Pavlograd suture zone is a complex dislocation formation, because it was formed in several stages of tectonic-metamorphogenic transformations of the crystal base. The first five of them appeared under P-T conditions from granulite to greenschist facies of metamorphism, the next ones – at low temperatures. Despite the multi-stage and multidirectional deformation processes within the zone, its structure is dominated by submeridional anisotropy. This is due to the submeridional linearization of heterogeneous and multi-age Geological objects in the same direction [10]. Such a structure as a whole can be defined as a subvertic secondary monoclinal, reinforced with melange.

The Pivnichno Tersyansk folded form is a highly coordinated dislocation structure that was formed under significantly shifted tectonic conditions. It takes the position of a motor roll structure, which was finally created at the 4th and 5th stages of structural and material transformations of the Precambrian basis. This is about 2.0 and 1.9 billion years ago. We have attempted to restore such transformations in the form of a step-by-step model of the evolution of the structural-material pattern of the studied crystal base fragment (figure 9). Based on similar data on the structural and material organization of megablocks adjacent to the Orikhovo-Pavlograd zone [17], we form the basis of the scheme in figure 9 the vision that the Precambrian basis, within the limits of these components, at the initial stages of their formation (I – III in figure 9) had a single structural plan (the same both within the suture zone and within adjacent Megablocks). At the final stages (IV-V in figure 9) development within the suture zone was dominated by significantly shifted geological and dynamic conditions (relative to adjacent megablocks).

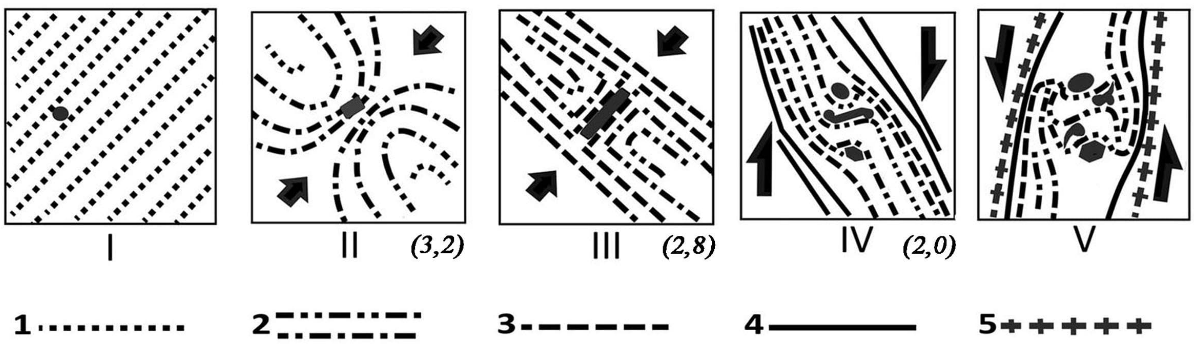

Figure 9. Schematized step by step (I-V) model of formation of the structural and material pattern of the studied part of the Orikhovo-Pavlograd suture zone. Arrows – restored directions of application of tectonic forces (in modern coordinates). 1 – 5-generation of planar structures to the appropriate stages of development of the structural plan. Gray bodies (rectangles, ovals, and irregular ones) are ore formations. 3.2, 2.,8, 2,0 – isotopic age according to their predecessors.

An idealized model of the formation of a single U-, Th- promising structure has been created, which will contribute to a more targeted search for uranium-thorium mineralization and expand the mineral resource base of the nuclear power industry in Ukraine according to the final result.

Abstract. Knowledge about current state of the trees in urban areas may be important for foresting and green planting of city landscapes and for improving environmental quality in these areas. The object of this study were to screen a range of morphometric, physiological and biochemical parameters among species of the genus spruce (*Picea* A. Dietr.) in urban areas of Kryvyi Rih City and to assess the ecological adaptations among species of the genus spruce (*Picea* A. Dietr.) along an environmental gradient in urban areas of Kryvyi Rih City. During 2017-2021, the 7 research plots in Kryvyi Rih City urban areas along an environmental gradient (low, moderate and high levels of the environmental impact) and 1 research plot in the background area (control) were established. The 30–40-year-old trees of indigenous spruce species (Norway spruce (*Picea abies* (L.) Karst.)) and non-native spruce species (Colorado blue spruce (*Picea pungens var. 'Glauca'*)) were investigated. The morphometric characteristics of trees, vitality of trees and chlorophyll *a*, chlorophyll *b* content in needles were studied. The results showed that in background area the tree height (14.5-15.1 m and 11.7-12.5 m for Norway spruce and Colorado blue spruce), diameter at breast height (25.3-28.1 cm and 24.6-27.2 for Norway spruce and Colorado blue spruce), chlorophyll *a* content (0.75-1.04 mg/g of wet weight and 0.96-1.24 mg/g of wet weight for Norway spruce and Colorado blue spruce) and chlorophyll *b* content (0.33-0.41 mg/g of wet weight and 0.42-0.50 mg/g of wet weight for Norway spruce and Colorado blue spruce) were typical of mature 30–40-year-old spruce trees. In Kryvyi Rih City urban areas the ecological stress along an environmental gradient decreased the values of growth, vitalyty and photosynthetic activity of the trees by 15-50%. Colorado blue spruce trees (non-native species) exhibit greater ecological tolerance and ecological adaptations than Norway spruce trees (indigenous species). Colorado blue spruce is less sensitive to environmental impact and have a better ecological adaptive balance of pigment content than Norway spruce. Our results confirm that from a sustainable development of the urbane areas perspective it is necessary to using the Colorado blue spruce for greene planting.

1. Introduction

Today, the state of the environment in industrial cities is very critical, causes concern and requires practical measures to improve it [1–5]. The trees play an important role in improving the quality of the urban areas. Landscaping of these areas with woody plant species is an important practical measure for the implementation of sustainable development in current cities [5–9]. Among the assortment of plants, preference is given to those with high phytoncide properties [6, 10, 11]. In particular, such plants are conifers, which clean the air of harmful substances all year round, absorbing almost all types of chemical compounds entering the atmosphere with emissions from industry, energy, motor vehicles [12–15]. However, improving environmental conditions, coniferous plants themselves suffer from the negative effects of air pollutants, which leads to changes in their biological parameters, biochemical characteristics and, in general, to a decrease in their viability [6, 11, 16]. Due to this speed of reaction to pollutants substances, plants of conifers are used as environmental indicators [5, 6, 10, 13].

In Kryvyi Rih, one of the largest industrial cities of Ukraine, the level of atmospheric air pollution significantly exceeds the limits [10, 17]. Emissions from industrial enterprises and intensive traffic lead to the formation of harmful substances in the air, among which are noted: nitrogen oxides, sulfur dioxide, carbon monoxide, etc. [13–15]. The negative impact of pollution is enhanced by adverse natural and climatic conditions, which in the steppe zone are exacerbated due to climate change, which causes global warming [17,18]. It is difficult for introduced conifers to adapt to the urbotechnogenic environment of a large industrial steppe city.

Among the widespread assortment coniferous plants of Kryvyi Rih excrete out trees of spruce species, which grow all over the city in different types of plantings. In addition, they are characterized by high phytoncide activity, year-round decorativeness, attractive color of the needles [5, 6, 11]. Considering on it, the objectives of the study were (1) to screen a range of morphometric, physiological and biochemical parameters among spruce species in urban areas of Kryvyi Rih City, (2) to assess the ecological adaptations among spruce species along an environmental gradient in urban areas of Kryvyi Rih City.

2. Material and methods

2.1. The study area

The urbane areas of Kryvyi Rih City (central part of Ukraine) was chosen for the present study. It is situated between 47°53'54" and 48°8'52" north latitude and 33°19'52" and 33°33'38" west longitude. The climate of this area is characterized by short springs, hot and dry summers and cold winters with little snowy. The monthly mean air temperature ranged from -5.1°C (in January) to 22.2°C (in July). The mean annual precipitation was from 400 to 450 mm [2, 3, 16]. Kryvyi Rih is one of the largest industrial city in Europe, specializing in iron ore mining and production of iron ore concentrate, iron ore agglomerate, iron ore pellets, cast iron smelting and steel smelting. In this city the industrial activity (mining, processing and smelting operations) generate a lot of pollutants (dust, carbon / sulphur / nitrogen oxides, heavy metals) that is released into the atmosphere. The annual emissions air pollutants range from 400 000 to 700 000 tons per year [2, 17].

2.2. Research design, data collection and sampling

In our study the 30–40-year-old trees of indigenous spruce species (Norway spruce (*Picea* (L.) Karst.)) and non-native spruce species (Colorado blue spruce (*Picea pungens var. 'Glauca'*) were investigated. A systematic random sampling design was used for selection of sampling sites. The study area was divided into two locations as control area and environmental imputed area. The territory of Kryvyi Rih Botanical Garden arboretum was used as a control (sampling site 1). The environmental imputed area was divided into sub-locations as (i) low environmental impact (sampling sites 2, 3), (ii) moderate environmental impact (sampling sites 4, 5, 6) and high environmental impact (sampling sites 7, 8). All research points were located at three Kryvyi Rih City Districts such as Ternivskyi, Pokrovskyi and Metalurhiinyi. The spatial distribution of the sampling sites is shown in figure 1. Field data were collected through direct enumeration and measurement of 30-40 trees in every sampling site [19]. In each site, the tress were recorded and: (i) their diameter at 1.3 m above ground (in two perpendicular directions by a caliper); (ii) their height (by a hypsometer), (iii) the crown height and diameter (in two directions: east-west, south-north) were measured and (iv) their vital state was assessed (by Yarmishko [20]). In each site the 10 dominated trees were randomly selected. From each trees five samples of the two-year needles were sampled. After sampling, needles were combined to give one composite sample per site. The samples were stored in plastic bags in a freezer (–4 °C) before analysis [21].

2.3. Analytical methods

The concentrations of chlorophyll *a* and chlorophyll *b* in two-year needles were determined spectrophotometrically using a SF–2000 instrument according to follow methodical [22]. Approximately 0.1 g crushed needles samples were soaked in 2 mL dimethyl-sulfoxide and incubated in water bath at 67°C for three hours. The absorbance of samples was measured at 665 nm (chlorophyll *a*) and 649 nm (chlorophyll *b*).

Content of chlorophylls and carotenoids was calculated using the following equations by Wellburn [23]:

$$\mathrm{Cchl}\ a = 12.19 \times \mathrm{A}\ 665 - 3.45 \times \mathrm{A}\ 649 \tag{1}$$

$$\mathrm{Cchl}\ b = 21.99 \times \mathrm{A}\ 649 - 5.32 \times \mathrm{A}\ 665 \tag{2}$$

where A is the absorbance; Cchl *a* is concentration of chlorophyll *a*, mg/mL; Cchl *b* – is concentration of chlorophyll *b*, mg/mL.

Pigment concentration was expressed as mg per g of raw weight using the following equation by Wellburn [23]:

$$\mathrm{PC} = (\mathrm{C} \times \mathrm{V})/(\mathrm{H} \times 1000) \tag{3}$$

where: PC – content of pigments in needles, mg/g of raw weight; C – pigment content in extract, mg/mL; V – volume of extract, mL; H – weight of needles, g.

All determination was done in four replicates for each species.

2.4. Statistical analysis

The results were statistically analysed using a descriptive statistics. The differences between mean values from environmental imputed area and control were tested by a Student's t-test for independent variables at 5% probability level ($p < 0.05$) [24, 25]. Statistical analysis was performed using Microsoft Office Excel 2003.

3. Results and discussion

The territory of Kryvyi Rih Botanical Garden arboretum is characterized by environmentally friendly conditions for spruce species. That is why in control plot, the basic morphometric characteristics included tree height (14.8±0.14 m and 12.1±0.22 m for Norway spruce and Colorado blue spruce, respectively) and diameter at breast height (26.7±0.71 cm and 25.9±0.65 for Norway spruce and Colorado blue spruce, respectively) were typical of mature spruce 30–40-year-old trees and comparable to those reported by many authors [26, 27]. It should also be noted that in the control plot, the vitality of spruce trees was assessed as "healthy": 93.3% and 95.7% for Norway spruce and Colorado blue spruce, respectively (table 1).

According to obtained results, in control site the tree height of spruce species were more and the diameter at breast height of spruce species were large than morphometric characteristics of same age spruce trees from environmental impact areas (table 1). Thus, in low environmental impact area the mean of tree height of Colorado blue spruce was statistical significance lower than the bouground value (by 11.5%). In moderate environmental impact area the means of tree height were lower than control (by 18.2% and 19.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In this area the means of diameter at breast height were statistical significance lower than mean values from bouground area (by 16.3% and 8.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In high environmental

M – Mean; SD – Standard Deviation. Asterisks indicate that the difference between control and research plots are statistically significant, $p \leq 0.05$.

impact area the means of tree height were lower than the bouground value (by 30.1% and 28.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In this area the means of diameter at breast height were statistical significance lower than control (by 21.6% and 14.9% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)).

According to obtained results, in control site the tree height of spruce species were more and the diameter at breast height of spruce species were large than morphometric characteristics of same age spruce trees from environmental impact areas (table 1). Thus, in low environmental impact area the mean of tree height of Colorado blue spruce was statistical significance lower than the bouground value (by 11.5%). In moderate environmental impact area the means of tree height were lower than control (by 18.2% and 19.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In this area the means of diameter at breast height were statistical significance lower than mean values from bouground area (by 16.3% and 8.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In high environmental impact area the means of tree height were lower than the bouground value (by 30.1% and 28.1% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)). In this area the means of diameter at breast height were statistical significance lower than control (by 21.6% and 14.9% for Norway spruce and Colorado blue spruce, respectively ($p < 0.05$)).

As demonstrated in table 1, in all environmental impact areas the vitality values of the all spruce species were statistical significance lower than control levels. The vitality values in Norway spruce trees were significantly lower in low environmental impact area by 15-16% ($p < 0.05$), in moderate environmental impact area by 17-18% ($p < 0.05$) and in high environmental impact area by 50-51% ($p < 0.05$). Colorado blue spruce alsow showed differences in vitality values but showed a more smaller amplitude. The means of tree vitality was statistical significance lower than the control value by 9.9%, 23.2% and 40.0% in low, moderate and high environmental impact areas, respectively ($p < 0.05$).

The needles chlorophyll concentration is an important parameter that is regularly measured as an indicator of plant metabolism, plant stress and of plant's current state in urban areas [11, 28–31]. It has been found that maximum contents of chlorophyll *a* in needles of spruce species were in May in control site: 1.04 mg/g of wet weight and 1.24 mg/g of wet weight for Norway spruce and Colorado blue spruce, respectively (figure 2). These values were statistical significance higher than concentration of this pigment in environmental impact areas by 16.3% – 20.6% ($p < 0.05$). The results of our study concur with the findings of previous researches.

The data of many authors in different countries indicated a higher concentrations of chlorophyll a in needles of spruce species in May [6, 32]. This is due to sufficient rainfall and optimal air temperature for the plant development, increasing during the next months.

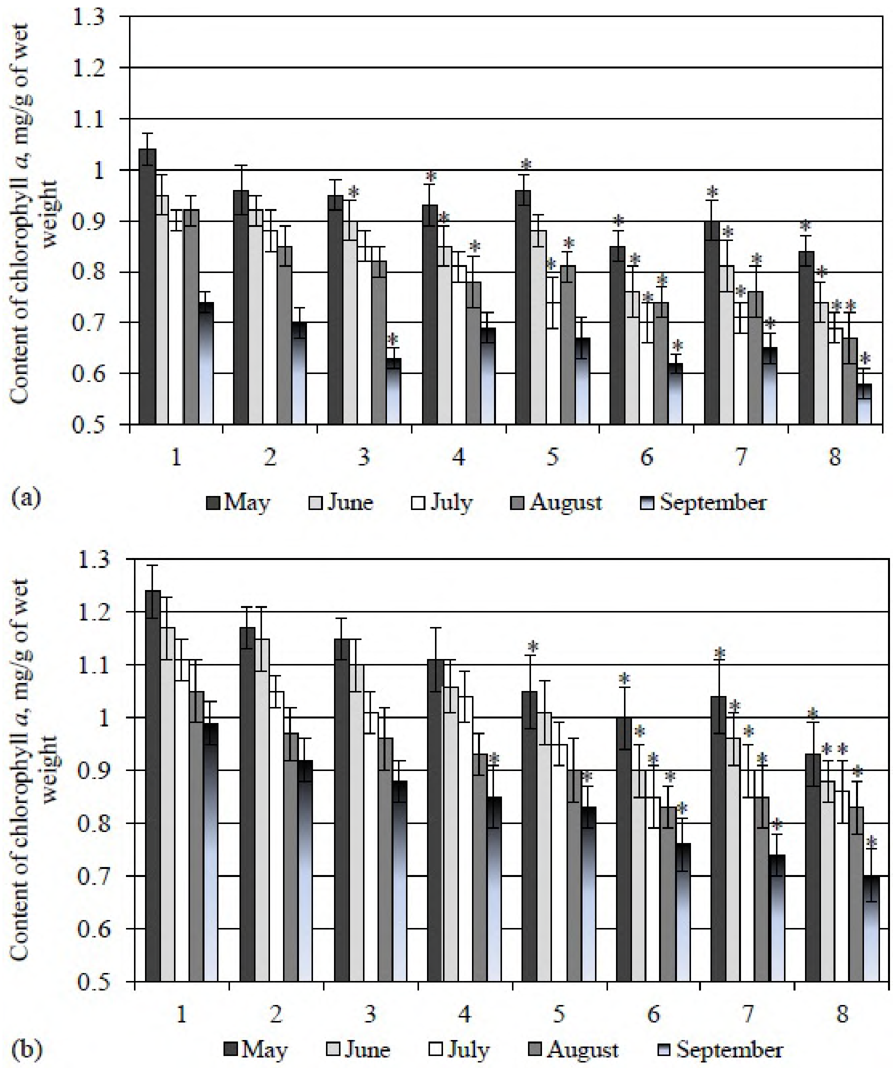

Figure 2. Content of chlorophyll a in needles of spruce species along an environmental gradient in Kryvyi Rih City urban areas, mg/g of wet weight, $n = 5$ (A – Norway spruce (Picea abies), B – Colorado blue spruce (Picea pungens var. 'Glauca'). 1 – control site, 2-8 – environmental impact sites. Asterisks indicate that the difference between control and research sites are statistically significant, $p \leq 0.05$).

The lowest chlorophyll a content in needles of spruce species were found in September in high environmental impact area: 0.58 mg/g of wet weight and 0.70 mg/g of wet weight for Norway spruce and Colorado blue spruce, respectively. These values were lower than control by 21.6% and 29.3% ($p < 0.05$). For both species, we observed a general tendency to reduce this pigment concentration during summer and autumn, especially in September, as this period was characterized by low rainfall and air drought. In the course of five-month studies, was found a significant decline in the chlorophyll a content in needles of spruce species along an environmental gradient. But in all environmental impact areas the content of this pigment in the needles of Colorado blue spruce was a relative stability and higher than in the needles of Norway spruce. We hypothesize that Norway spruce is more sensitive to environmental impact than Colorado blue spruce.

The result of our investigation clearly indicated that minimal contents of chlorophyll b in needles were found in September in high environmental impact area (near cast iron smelting and steel smelting plants). At this site concentration of chlorophyll b was 0.29 mg/g of wet weight in needles of Norway spruce and was and 0.33 mg/g of wet weight in needles of Colorado blue spruce. These values were lower than control by 14.7% and 21.4%, respectively ($p < 0.05$).

During five months of our investigations, there was a significant decrease in the value of chlorophyll b concentration in the needles of both spruce species along an environmental gradient in Kryvyi Rih City urban areas. We imply that this phenomenon is determined by distance from urban roads, from ore mining and processing enterprises and from metallurgical combine.

It is known from earlier publications that environmental pollution decreased the content of chlorophyll b in needles more than the content of chlorophyll a in needles [11,32]. It may reduce the activity of the photosynthetic apparatus and disrupt the plants metabolism. However, other researchers reported that chlorophyll a was to be less stable than chlorophyll b in the pigment complex of conifers in urban areas [33, 34]. In our research, the second variant of the dynamic changes in pigment complex of needles was confirmed: along an environmental gradient in Kryvyi Rih City urban areas more significantly decreases the content of chlorophyll a than content of chlorophyll b.

Still remain controversial the data about of the photosynthetic apparatus stability in coniferous plants under environmental effects. Some authors [35] were noted that Norway spruce and Colorado blue spruce had the same inhibition effects of the pigment complex functioning under the stress influence of the air pollution. But according to results of the our research Colorado blue spruce had a better adaptive balance of pigment content than Norway spruce.

Many authors [6,10,11,32,36,37] reported that the morphometric characteristics, vitality and intra-annual dynamics of chlorophyll content in needles of spruce species determined by climatic conditions and environmental impact level. According to our results, the maximum decrease of values of morphometric characteristics, vitality and chlorophyll content were wound in the southern part of the Kryvyi Rih City near largest in Ukraine processing, cast iron smelting and steel smelting enterprise. Finally, our results are agree with several numerous studies and key sciences publications. The obtained results of this study help to provide important information on understanding how trees of spruce species can affecting on urban ecology and urban sustainable development by temperature reduction, by reduce heat stress, by carbon storage and by promoting biodiversity. Besides, they may serve as reference levels for future studies in other urban areas at similar sites all over the world.

As in previous case, the maximum contents of chlorophyll b in needles of spruce species were in May in control site: 0.41 mg/g of wet weight and 0.50 mg/g of wet weight for Norway spruce and Colorado blue spruce, respectively (figure 3). These values were statistical significance higher than concentration of this pigment in environmental impact areas by 9.8% – 18.0% ($p < 0.05$).

4. Conclusions

In the present study, the large range of morphometric characteristics, vitality and of chlorophyll content in needles of Norway spruce and Colorado blue spruce were observed. In control plot, the tree height, diameter at breast height, chlorophyll a content and chlorophyll b content were typical of mature spruce 30–40-year-old trees. Based on the obtained results, it can be concluded that spruce species is affected by environmental impact. In Kryvyi Rih City urban areas the ecological stress along an environmental gradient decreased the values of growth, vitalyty and photosynthetic activity of the trees by 15-50%. Our study demonstrated that Colorado blue

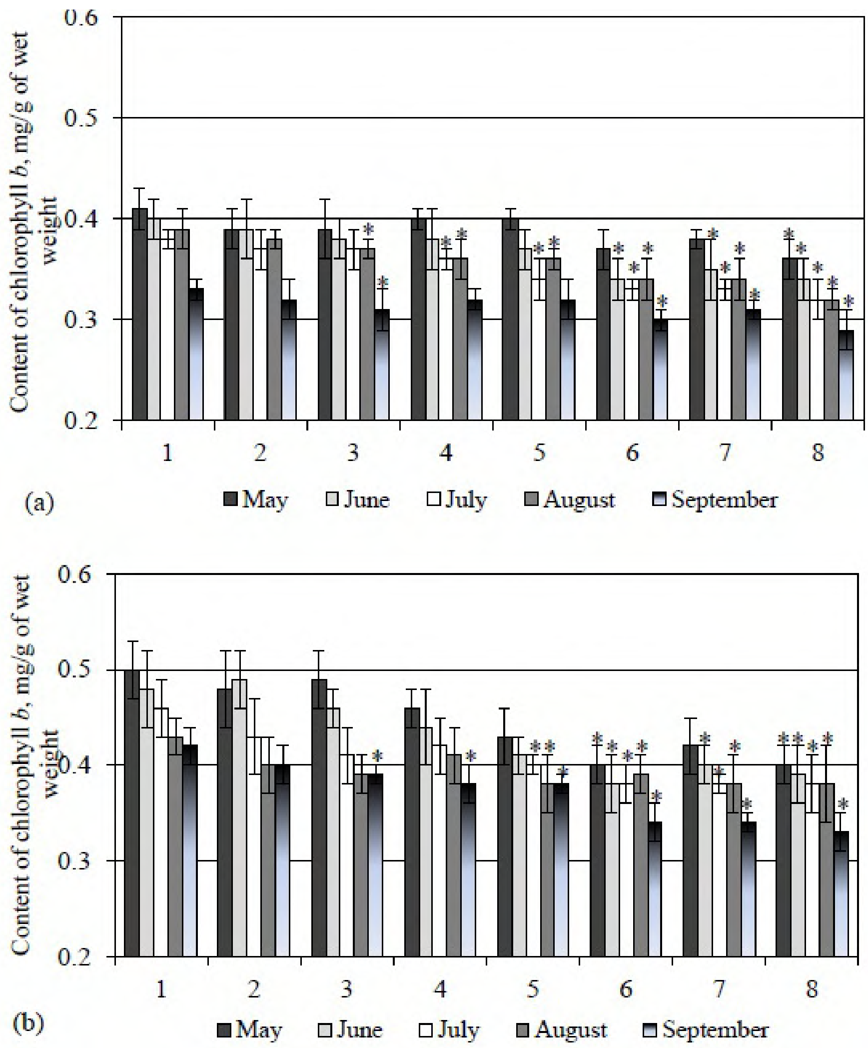

Figure 3. Content of chlorophyll b in needles of spruce species along an environmental gradient in Kryvyi Rih City urban areas, mg/g of wet weight, $n = 5$ (A – Norway spruce (Picea abies), B – Colorado blue spruce (Picea pungens var. 'Glauca'). 1 – control site, 2-8 – environmental impact sites. Asterisks indicate that the difference between control and research sites are statistically significant, $p \leq 0.05$).

spruce trees exhibit greater ecological tolerance and ecological adaptations than Norway spruce trees. Colorado blue spruce is less sensitive to environmental impact and have a better adaptive balance of pigment content than Norway spruce. Our results confirm that from a sustainable development of the urbane areas perspective it is necessary to using the Colorado blue spruce for green planting.

Abstract. The Donbas is a region dominated by heavy industry, particularly coal mining, chemical processing sites and metallurgy. Intensive mining and steel smelting led to substantial environmental damage before the armed conflict. The fighting in eastern Ukraine has exacerbated an already fragile ecological situation, introducing a range of new risks – of stray munitions hitting extensive chemical and industrial facilities or interconnected mines being flooded and poisoning the water throughout the region. Besides, one of the main hazards is flooding territories associated with closing coal mines. Assessment impacts of uncontrolled mine flooding and towns and villages and associated hazardous processes of surface and groundwater contamination, surface subsidence and dangerous deformations of residential and industrial buildings and other facilities carried out the remote sensing and geological data.

1. Introduction

Nowadays, the negative anthropogenic impact on the environment is felt especially acutely and has acquired a global character. This is because the effect on nature was previously insignificant, but now it predominates, and new factors constantly appear. Damage caused to natural components leads to negative consequences and reflects the reverse reaction of this impact (adverse for society). Such dangerous environmental changes (primarily of anthropogenic nature) spreads over several hundred thousand square kilometres of the territory of Ukraine.

Recently, the environmental situation in the Donbas has been sharply aggravation caused by the decommissioning of mines and their transition to a new ecological state. We should note that the environmental situation in the Donetsk and Luhansk regions has significantly worsened in recent years and became the theatre of military conflict with active hostilities in 2014-2023 and was partially under the power of the occupation forces, acquiring signs of an ecological disaster. There are 220 coal mines on the territory of the Donetsk coal basin, 97 of which are in operation, 14 are in drainage mode, 39 are in the process of flooding, and 70 are at the liquidation stage. In addition, a total of 2 mines were deregistered due to the completion of liquidation works [1].

Stopping the operation of drainage and ventilation equipment causes the accumulation of water and methane in the mines. The rise in the level of underground water significantly increases the impact of negative artificial factors and leads to the following: flooding of significant areas of pollution of underground and surface sources of drinking water, rivers and reservoirs; a critical reduction in the strength and bearing capacity of mining rocks and soils within the limits of the influence of mining; expansion of subsidence zones of the massif with the possibility of violations of surface structures; increasing seismic hazard; the formation of unpredicted explosive areas due to changes in methane migration routes. Critical conditions have been created for solving the mentioned problems in almost the entire region of Donbas.

The actual rates of filling mines with water are much higher than expected, which were calculated based on natural filtration coefficients of the mining massif and other multiparametric factors [2]. Hence, the need for more accurate data on the environment's basic parameters and unforeseen problems arise after the closure of mines. In addition, the situation is complicated by the need for more reliable data on hydrogeological connections between mines.

The remote sensing technique's efficiency, cost-effectiveness and productivity make it reasonable to use them in solving complex geological hydrogeological, geophysical and environmental problems related to regional geo-ecological security. In this study, ecological issues associated with the flooding of mine waters due to the closure of coal mines are solved (in the example of the territory of the Main Anticline of Donbas).

2. Analysis of the state of the study of the existing native experience regarding the threats of flooding associated with the closure of coal mines

Numerous works by Ukrainian scientists give environmental monitoring and coverage of the consequences of the closure of mines. As evidenced by studies of Rudko and Yakovlev [3, 4], Dovgiy et al [5, 6], Dovgyi and Korzhnev [7], Shybetskyi et al [8], Panova et al [9], Goshovskyi and Zurian [10], Trofymchuk et al [11, 12], Anpilova et al [13], Dolin et al [14], Lyuta and Sanina [15]. During the full-scale development of the mining area, the geological environment becomes the primary "depot" of the majority of man-made emissions and mechanical, physical and chemical effects on the components of the environment (ground atmosphere and surface hydrosphere, soils, the upper zone of the lithosphere, etc.).

The wet method of closing mines is most often used today in Ukraine – the damp process conserves 90 percents of mines. However, many environmental problems have arisen due to its use since the man-made load on the geological environment; the hydrosphere increases significantly when the mining works are flooded. In addition, large areas of coal-bearing rocks opened by mining and a sharp increase in their permeability due to the man-made fracturing of rocks led to the active influence of mines on the hydrogeological conditions of the surrounding territories [16].

The consequences of mine liquidation have yet to be thoroughly studied, so it isn't easy to choose the final, most rational method of mine liquidation from the point of view of ecology and economic market relations. Nevertheless, the processes of man-made influence must be monitored and analyzed in detail to ensure the minimum negative impact of liquidated mines on the environment. Therefore, it is necessary to carry out routine monitoring observations using ecological methods and the application of remote sensing data. This makes it possible to carry out work in the monitoring mode, to investigate two typical signs of the flooding process – subsidence of the surface and an increase in the area of soil moistening and the release of underground water to the surface. Unfortunately, such studies are still rare in Ukraine. In particular, modelling the potential development of flooding was carried out, taking into account the zones of propagation of large-amplitude movements, which are given by Ulytsky and Boyko [17]. Therefore, the methods of representation of the remote sensing data and the results of the processing are tools for anticipatory forecasting of changes in the hydrogeological situation within the territories of the distribution of mines flooded and liquidated.

3. Geological structure of the region of the Main Anticline of Donbass

The main anticline is located in the axial part of the Donbas and is the most significant linear fold of the Donetsk Basin. The anticline is confined to the longitudinal Central-Donetsk deep-seated fault, common to Donbas and the Dnipro-Donetsk depression (figures 1 and 2).

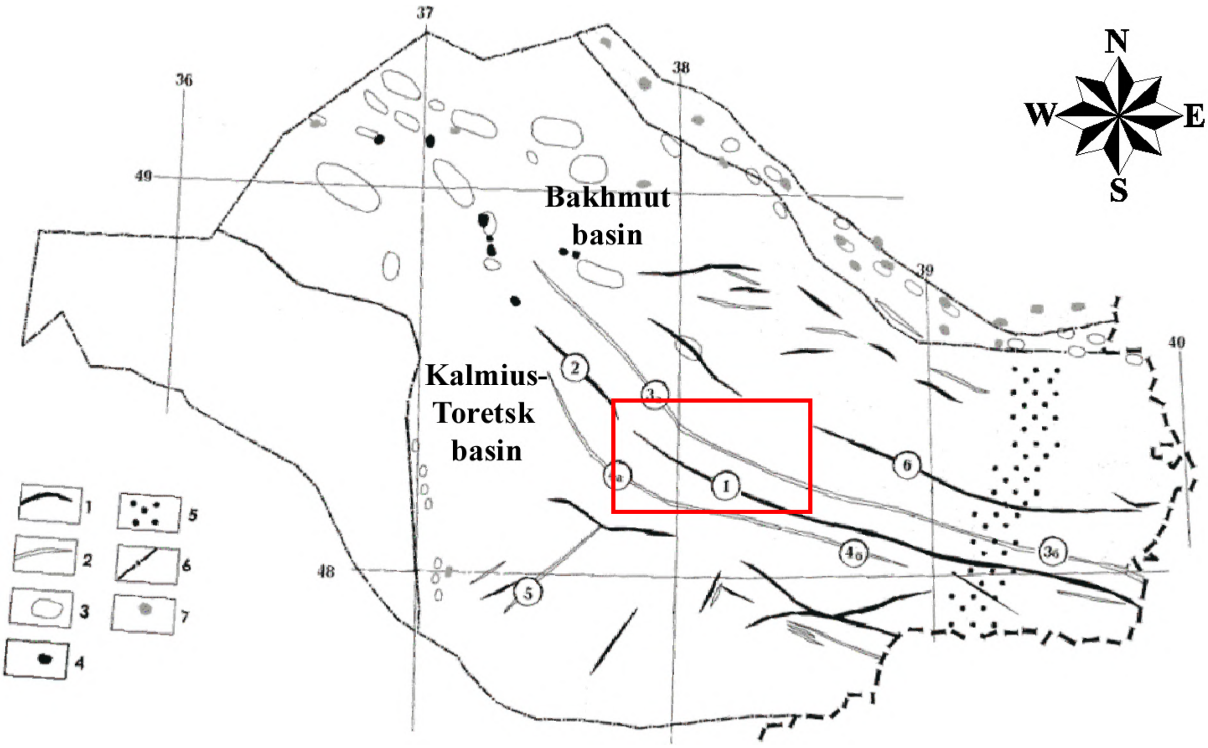

Figure 1. Scheme of plicative structures of Donbas according to [18]. Legend: 1 – anticlines (1 – Main, 2 – Druzhkivsko-Kostiantynivska, 6 – Northern), 2 – synclines (3 – Main: 3a – Bokovo-Khrustalska, 3b – Dovzhanska-Sadkinska, 4 – South: 4a – Chistyakovo-Snizhnyanska, 4b – Shakhtynsko-Nesvitaevska, 5 – Vovchanska), 3 – brachyanticlines, 4 – salt stem, 5 – Stepanov shaft (transverse Rovenkiv uplift), 6 – borders of the region, 7 – gas deposits. The red rectangle is the research region.

The main anticline is a linear fold that extends in a straight line along the azimuth of approximately SW 3000 and dips undulipodia to the northwest at an angle of 3-50. Anticlinal folds of the second order are established within its boundaries. The formation of ore bodies, including the Mykytivske mercury deposited, is connected with these structures.

Rocks that make up the fold flanks lie symmetrically with steep dips (50-700). The axial plane of the anticline is vertical or dips steeply to the northeast. Immovables complicate the structure of the Main anticline.

The oldest rocks are exposed in the axial part of the anticline and belong to the Serpukhovian stage of the Lower Carboniferous (geological suite C51), about 400 m thick. The sediments are represented mainly by shale and are characterized by extremely low carbon content.

Deposits of the middle part of the coal system are the most widely distributed in the research region. They are divided into seven suites belonging to the Bashkirian and Moscovian Stages. According to the lithological composition of the rocks, they are typical for the Donetsk basin. This alternation of marine and continental deposits, clay and sandy shales, sandstones and subordinate layers of limestone and coal. The thickness of the Middle Carboniferous deposits increases from 2525 m in the northwest to 4885 m in the southeast.

The middle section is the main coal-bearing part of the Donetsk Carboniferous and has about 66 coal seams, a large amount of which reaches the working thickness.

The lower layers of the Middle Carboniferous rocks consistently cover the sediments of the upper part of the coal system. They are represented by a rhythmic layering of sand-clay rocks,

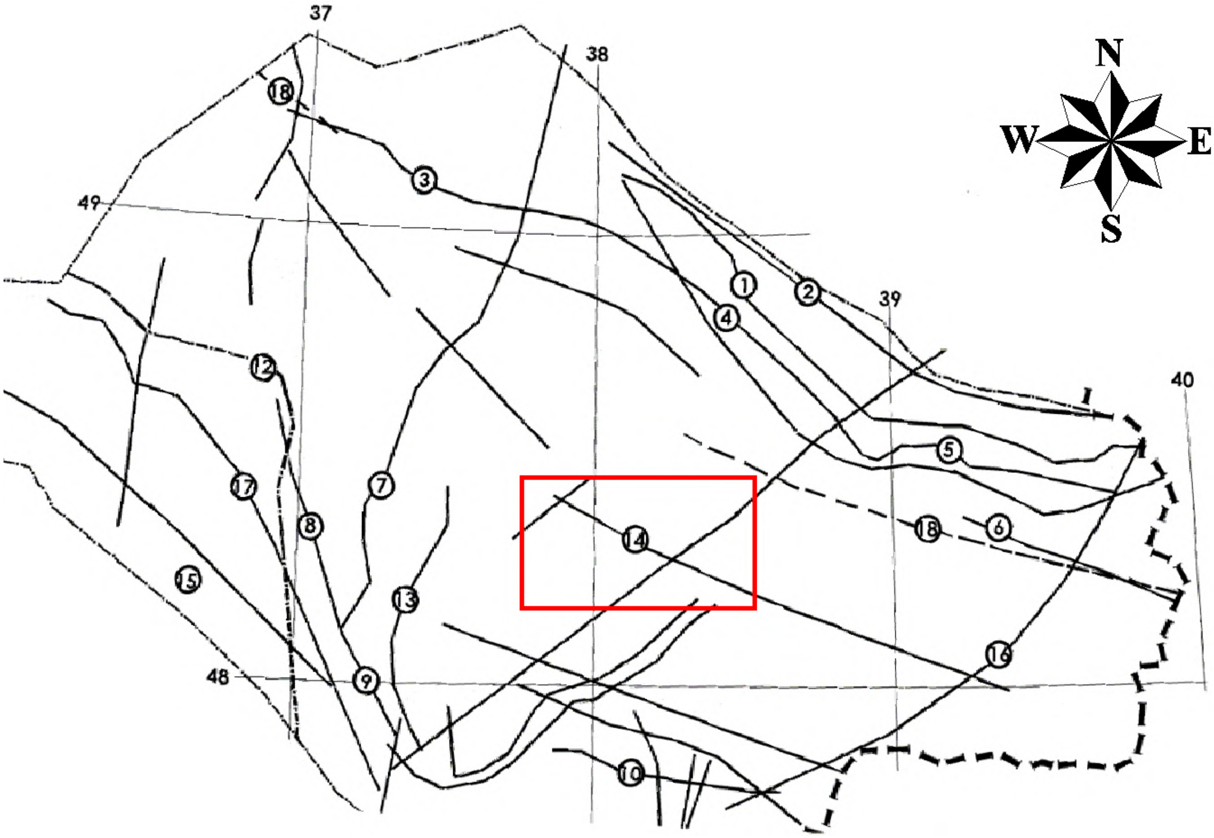

Figure 2. Figure 2 – Main faults of Donbas according to [18]. Legend: 1 – North Donetsk thrust, 2 – Krasnoretsky thrust, 3 – Sviatohirsky thrust, 4 – Maryiv thrust, 5 – Almaznyy thrust, 6 – Krasnodon thrust, 7 – Central thrust, 8 – Kotlyn thrust, 9 – Yalinsky thrust, 10 – Kuteinikovsky skid, 11 – Southern Donbas fault, 12 – Central-Priazov fault, 13 – Selydiv thrust, 14 – Main anticline fault, 15 – Southern Donbas fault, 16 – Yelanchyk-Rovenkiv fault, 17 – Kryvorizko-Pavlivskii fault, 18 – the presumed northeastern marginal fault of the Riphean graben. The red rectangle is the research region.

limestones and coal. However, the frequency and amplitude of oscillations are significantly reduced compared to the underlying layers of rocks, and the section becomes more uniform. Deposits are widely distributed to the southwest and northeast of the axis of the Main anticline within the synclines.

Sediments of the Mesozoic-Cainozoic age are spread outside the Main anticline on the territory of adjacent syncline structures.

The territory where the Main anticline is located belongs to the open Donbas, rising at an average rate of 2.5-3.8 mm/year.

According to the data of deep seismic sounding (DSS), a rigid plate of the Precambrian folded basement is reliably fixed under the open Donbas. Thus, the area has a two-tiered structure typical for a platform with imitation of basement faults in the form of tense anticlinal folds and rigid blocks – in the state of fields of relatively calm deposits of Paleozoic rocks with sustained thickness and stable composition. The change in the structure, composition and metamorphism of rocks does not occur gradually or imperceptibly but rather abruptly within areas that are sufficiently narrow and strictly fixed for the entire section. The formed fault-block structure of the territory significantly impacted the development of a wide variety of processes – geodynamic, seismic, filtration, ore and gas formation [19–21].

The formation of the Main anticline and the surrounding area, according to Gintov et al [22], took place in 10 stages [23]. First, we established that the direction of the tension axis was longitudinal relative to the anticline, and the sub-vertical orientation of the compression axis characterized the Kimmerian stress field. The voltage field has a pulsating character. At the same time, there was a change in the indexing of the tension axis with the intermediate axis of the stress field. The reset character of the deformations in stretching conditions along one axis prevailed [23, 24].

Within the Main anticline, the coal-bearing of the southern flank of the anticline is higher than that of the northern flank. Consequently, coking grades of coal have been developed in most of the regions of the district. The degree of coalification in the section increases from the upper to lower horizons. It is represented most clearly on the northern flank and less on the southern side.

The water-bearing capacity of coal deposits is generally low. Inflows into mining operations for individual coal seams are at most 100 m^3/hour. With depth, the fracturing and water-bearing capacity of coal deposits decreases significantly. At a depth of 400-500 m and more, the deposits of the coal system are practically waterless, except for regions of local irrigation within the zones of tectonic disturbances.

The main aquifers are adapted to limestones and sandstones of the coal system and, within the weathering zones, water-bearing and fractured shales. Limestones are the most fractured rocks. Sources with a flow rate of up to 11.0 l/sec are adapted to their exits to the daylight surface. The flow rates of springs fed by sandstone waters are usually one l/sec. But the total costs for sandstone springs are generally much higher than for limestone springs because sandstones are much thicker than limestone.

Among the many numerous tectonic disturbances in the area, especially discharges, are characterized by increased water capacity.

Thrusts, as a rule, could be better watered. Water inflows from tectonic zones quickly decrease over time, and after a few months, they stop altogether. Coal aquifers are mainly fed by atmospheric precipitation, which causes significant fluctuations in inflows to mines by two or more times throughout the year. In addition, a hydrographic network and numerous mining operations drain coal aquifers. The waters of coal deposits, regardless of water-bearing rocks (limestones or sandstones), are characterized by high mineralization and hardness and therefore are usually unsuitable for drinking and technical water supply. Mine waters have an even worse quality characteristic – the content of dry residue in the water reaches 5000 mg/l and more, and the hardness is more than 100 nem. degree. Despite the poor quality of water from coal deposits, the water is partially used for drinking and technical water supply, and in agriculture, it is used for watering livestock.

4. Formation of the fractographic base, selection of the necessary satellite images

The database of input materials was formed using the Remote Sensing Software Erdas Imagine, which allowed them to be analyzed and compared. As a coordinate system, a rectangular coordinate system was chosen – UTM / WGS 84 / zone 37. The choice of this coordinate system is due to the zone in which the research area is located (zone 37), and the selection of the UTM / WGS 84 system is because the data of remote sensing of the Earth have precisely this coordinate system. Geometric correction of the input data was carried out in the space image processing program Erdas Imagine using the Geometric Correction module.

The study used a digital terrain model from the Shuttle satellite to the study area. Also, we took satellite images from the Landsat 8 satellite on October 9, 2020, for the study area (figure 3).

Using the Erdas Imagine software, we made a mosaic of topographic maps with a spatial

Figure 3. Fragment of the image from the Landsat 8 satellite on October 09, 2020, a combination of channels 7 (SWIR2) – 5 (NIR) – 4 (RED), the spatial resolution of 30 m. In addition, topographic maps on a scale of 1: 100,000 were used for the territory of the nomenclature study (M37 – 124, 125, 126, 136, 137, 138).

resolution of 17 m. A mosaic of geological maps on a scale of 1: 200,000 was made for the study area (figure 4).

5. Results of the assessment of the possibility of establishing flooding of territories based on remote sensing data

Mainly we gave attention to the problem of flooding the territory of Donbas to establish the depth of underground water, the places of its exit to the surface, the flow rate and composition of water, the impact on the environment, etc. But we needed more than the available information for a reliable mapping of the areas of flooding of the daylight surface, which was crucial in solving the issues of the ecology of the surrounding territory. All the more so, since we did not carry out the work in the monitoring mode, all the researchers pointed out the need for such work. The interferometry method based on remote sensing data helped to partly solve this issue [17]. These materials made it possible to establish the area of flooding of the daytime surface based on the assessment of the subsidence of the Earth's surface, which accompanies the flooding process. Using space images allows for monitoring the development of the flooding process over time. But the proposed approach does not record the presence of water on the surface or does not allow the estimation of soil moisture. The presence of water or increased soil moisture directly reflects the development of the process of flooding the territory.

One effective method of determining the daytime surface's humidity based on remote sensing data is using various water indices. Water indices are designed to assess the presence of moisture in vegetation or open ground. The presence of moisture in vegetation directly indicates its condition: a high moisture level characterizes healthy vegetation characterized by good growth. The humidity of the open ground is directly relevant to our research, while the moisture of the

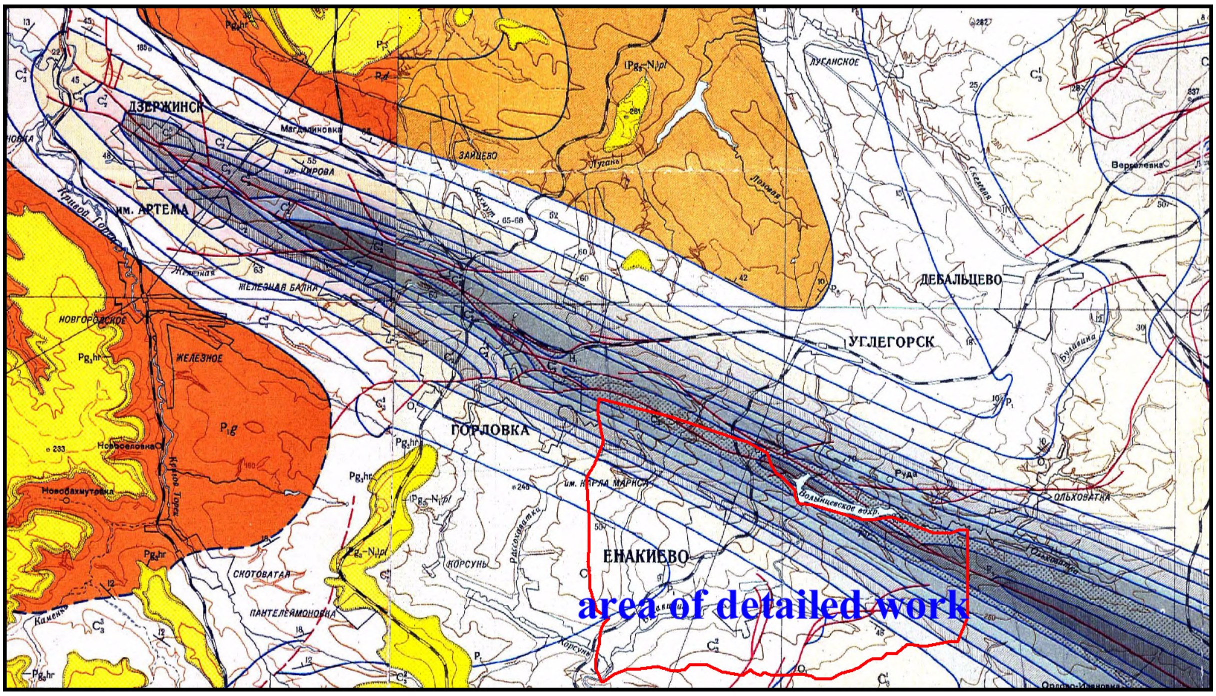

Figure 4. Fragment of a mosaic of geological maps of scale 1: 200,000 nomenclatures (M37 – 32, 33 [19, 20]) for the study area, the spatial resolution of 10 m.

vegetation cover is an indirect indicator of soil moisture. Therefore, we hope the soil moisture indicator will be more informative than the vegetation cover moisture [25, 26].

To calculate humidity indices, values of spectral brightness in the near, medium and infrared ranges are most often used – in the ranges where the radiation is most intensively absorbed by water. These ranges are most sensitive to moisture in vegetation and ground cover. In this study, the five most widely used humidity indices were used: DSWI (Disease water stress index) [27]; NDII (Normalized Difference Infrared Index) [28]; SR-SWIR (Simple Ratio SWIR) [29]; RDI (Ratio Drought Index) [30, 31]; NWI (Normalized Water Index) [32]. The calculation of these indices was carried out using materials from the Landsat-8 satellite.

To assess the possibilities of using the indicated moisture indices for the study of flooding of the territory of Donbas, a mapping scheme (figure 5) of the potential development of subsurface flooding, which accompanies the flooding of mines, taking into account the propagation zones of large-amplitude movements and numerical modelling of geofiltration, was used [17].

According to the data of the mapping scheme, we selected two areas with depths of underground water levels of 0-3 m (flooded "wet" regions) and more than 10 m from the daytime surface ("dry" regions). The values of the five specified humidity indices were calculated for these areas. Separately, the values of the moisture indices were calculated within the areas of "wet" and "dry" areas covered with woody vegetation and open grounds. The comparison of two distributions of values was carried out using the λ criterion (Kolmogorov-Smirnov) [33].

The maximum values of the λ criterion (table 1) were calculated for dry and flooded areas, and we made the ranking of humidity indices.

The analysis of the obtained results proved that statistically, all the areas that were compared using all five moisture indices differ with reliability higher than 0.99. This allows us to state that we can use multiple satellite imagery to establish flooded areas covered with woody vegetation and open ground. The values of the lambda criterion for multiple and areas with open ground

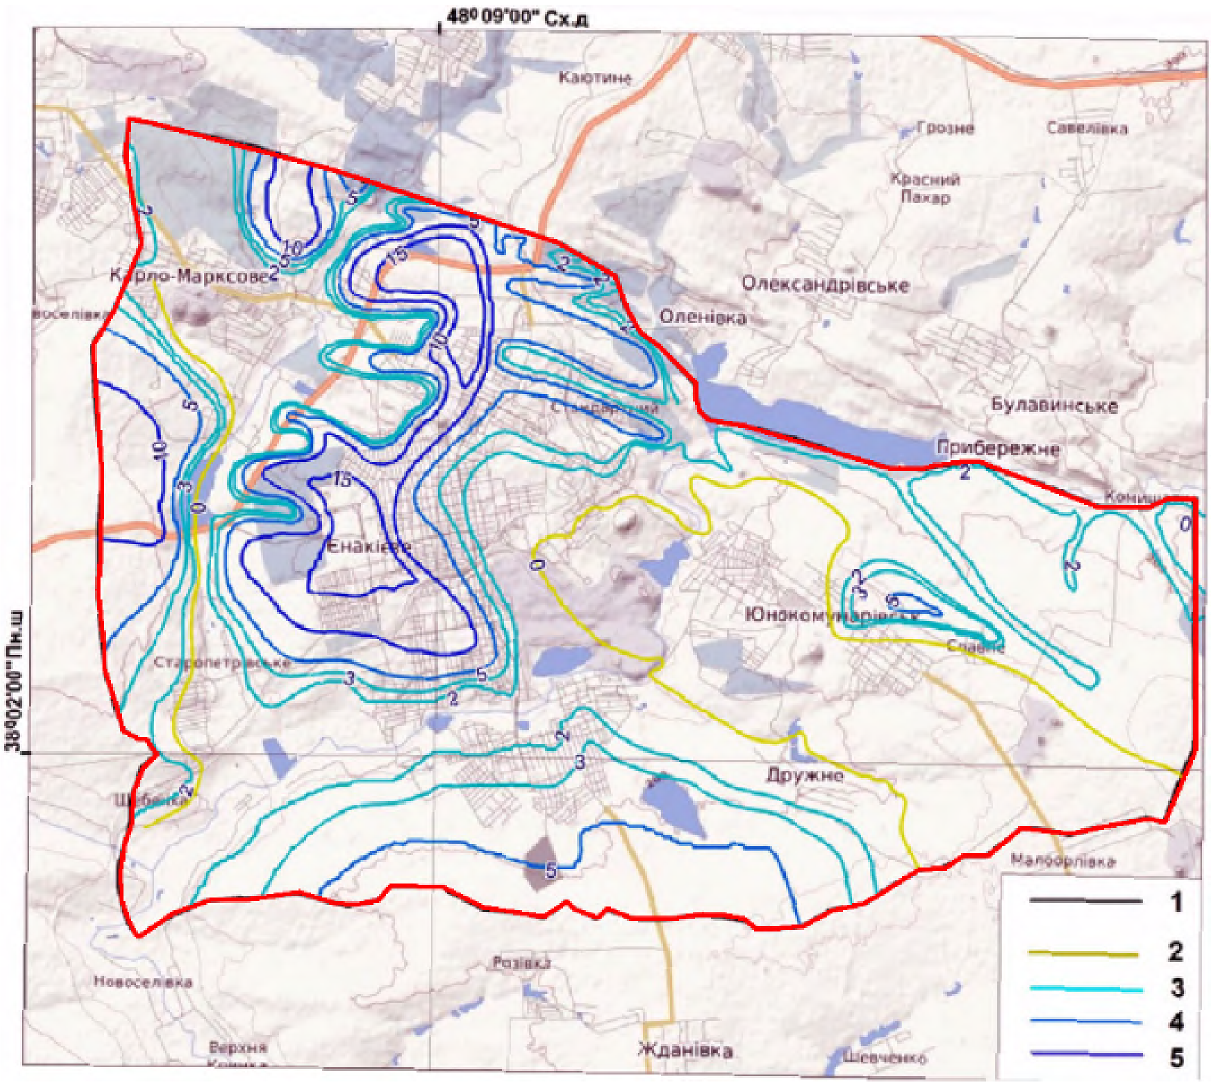

Figure 5. Map-scheme of predicted depths of underground water levels, obtained on the basis of numerical modeling of geofiltration according to [17]. Legend: 1 – catchment area and geofiltration model area; 2–5 – depth of underground water levels, m: 2 – about 0 m; 3 – 1–3 m; 4 – 5–10 m; 5 – more than 10 m.

Table 1. Maximum values of the λ criterion on dry and flooded areas covered with woody vegetation and areas with open ground at different moisture indices.

Area covered with woody vegetation		Areas with open ground	
SW-SWIR	12.3	SW-SWIR	22.1
NWI	5.7	DSWI	21.6
NDII	3.9	NDII	20.9
RDI	3.8	DI	20.9
DSWI	2.4	NWI	9.2

differ significantly from each other (table 1). Areas with dry and flooded soils disagree much more strongly than woody vegetation in arid and flooded areas.

The SR-SWIR index will be the most informative among the five studied moisture indices for areas covered with woody vegetation and open ground. The informativeness of other indexes for the territory covered with woody vegetation will be of the same order, much less than the value of the SR-SWIR index. In the region with open ground, all indices are characterized by relative values of informativeness, and only the NWI index is characterized by significantly lower informativeness.

6. Conclusion

Assessing flooding of the territory, we proposed to use known humidity indices, which are established based on multiple satellite imagery. The analysis of the possibilities of using five moisture indices – DSWI, NDII, SR-SWIR, RDI, and NWI proved that we could use all of them to assess the flooding of territories. Comparing the distributions of the values of the specified indices within dry areas where the depth of groundwater is more profound than 10 m and flooded areas where the depth of groundwater is 0-3 m was performed using the well-known statistical λ criterion (Kolmogorov-Smirnov). As a result of the comparison, it was established that all five water indices could be used to select flooded areas. The ranking of humidification indices according to their capabilities, which was based on the analysis of the values of the λ criterion, showed that the SR-SWIR index is characterized by the most significant capabilities, both for areas covered with woody vegetation and for areas with open ground.

Therefore, the possibility of using multi-zone space images to assess the flooding of the territory of Donbas due to the mass closure of coal mines through the so-called "wet conservation" has been established.

Abstract. We studied the impact of different concentrations in water environment of the pesticides widely used in Ukraine (insecticide "Actor", fungicide "Scooter", and herbicide "Titus-C") on the features of pulmonary and surface respiration of *Planorbarius* (superspecies) *corneus* s. l. vicaristic genetic allospecies ("western" and "eastern"). Pesticides get into the mollusc organisms percutaneously through the covers of their body during their respiration and, in much less amounts, with the food. Both the allospecies are characterized by bimodal respiration mode. It was established that the used pesticides in the concentration range 10-50 mg/L caused the rapid development of pathological process (intoxication). The lethality of experimental animals occurred due to the asphyxia and heart paralysis, caused by the intensive mucus production and destruction of the respiratory epithelium: first in body covers, later – in lungs. "Eastern" allospecies appeared to be more sensitive and less durable for all used pesticides, so it tends more to regress under the high contamination of water environment by these toxicants.

1. Introduction

Pesticides now belong to the most widespread among artificially synthesized stable organic toxicants in Ukrainian river network. Many years of sometimes uncontrolled their use in agriculture in the last decade caused the contamination of surface waters and deterioration of their nature ecological balance [1]. They get into the water ecosystems due to the flow of melted, rain and ground waters from the treated soils and due to blowing by wind during cultivation of lands near water bodies. Because of the cumulative features, these toxicants are accumulated and circulate in the tissues and organs of almost all the hydrobionts, and involve into the trophic chains of water bodies, increasing their concentration in times [2].

The toxical impact of pesticides on the water animals largely depends on their ability to be consumed (bio-availability), to accumulate in organisms (bio-concentration) and in trophic chains (bio-magnification), their dose power and stability in the environment [3]. The harmful action of these toxicants on the hydrosphere consists of the change of physico-chemical properties of water environment – changing its oxygen mode, decrease of phyto-/zooplankton amount, direct harmful action on ichthyofauna, gradual loss of turgor and death of higher aquatic plants [4–7].

Pesticides used for intensification of agriculture production are divided in three main groups: herbicides to fight the higher plants, insecticides for insect defense, fungicide against the fungal pathogens. Insecticide are the most acute toxic among all and lead to the decrease of water animal growth causing various metabolic and reproductive deteriorations [8, 9]. Fungicides are accumulated in water environment and in hydrobionts' food chain objects causing their intoxication and death. Herbicides worsen the water quality (bad taste and smell) decreasing the oxygen level, food supply and bioproductivity of hydrobionts [10].

Under improper use of pesticides, the danger arises for existence of the main water ecosystems, ecological links between water organisms are disturbed, their biodiversity is lost. To reveal the consequences of these toxins' impact on the water bodies and their inhabitants, more and more often the experimental method of bio-testing is used in water toxicology. This procedure consists of identification of toxicity of chemical compounds for hydrobionts by the quantitative changes of their vital functions. As test-objects one could use the animals highly-sensitive to the action of these compounds and able to accumulate them in organisms. The vicaristic genetic allospecies of *Planorbarius* (superspecies) *corneus* sensu lato, widespread in Ukrainian river network, belong to such animals. Until now, there were no data on functioning of their respiration system under the impact of the most widespread pesticides.

The aim of present study was to identify the features of impact of three different widespread in Ukraine pesticide groups (insecticides, fungicide, herbicide) in different concentrations on the indexes of pulmonary and surface (diffusive) respirations in "western" and "eastern" *P. corneus* s. l. allospecies, and to estimate the availability of these molluscs to be used as bio-indicators for monitoring the state of surface waters under their pollution of used toxicants.

2. Material and methods

2.1. Collection of molluscs

We collected a total of 1358 individuals of P. *corneus* s. l. in July-August of 2021. Among them, 679 individuals were from the "western" allospecies, collected at the Hnyla river (Horodnytsia village, Ternopil region, $49°24'38.5''N$ $26°01'05.2''E$), and 679 individuals were from the "eastern" allospecies, collected at Psel river (Sumy, Sumy region, $50°54'26.5''N$ $34°48'18.1''E$). The allospecies were identified based on their conchiological traits.

2.2. Acclimatization and care of molluscs

Upon collection, the molluscs were transported to the laboratory and subjected to a 15-day acclimatization period. During this time, they were housed in 10 L tanks at a density of 4 individuals per liter of water. The water temperature was maintained at $20 - 22°C$, with a pH range of 7.5-8.6 and oxygen levels of 7.5-8.6 mg/L. The molluscs were provided with daily environmental changes and were fed a diet consisting of *Cladophora sp., Miriophyllum spicatum* L., and *Alisma plantago-aquatica* L. mixture collected from the collection sites.

2.3. Experimental procedures and toxicants

We conducted both pilot and main experiments following standard methods. As toxicants, we used the insecticide "Actor" and fungicide "Scooted" (from "Simeinyi Sad" Ltd, Ukraine), as well as the herbicide "Titus-C" (from "Dunlop" Ltd, Ukraine) at concentrations of 10, 20, 30, 40, and 50 mg/L. These solutions were prepared using two-days aged tap water from the Zhytomyr water supply. The exposure period was 7 days.

2.4. Monitoring behavioral and physiological reactions

To assess the effects of the pollutants, we monitored the behavioral and physiological reactions of the molluscs [11]. The number of "inspirations" was determined by counting the emergences of each individual from the water surface tension film to which they were attached using their pneumostome, a process accompanied by a clear clapping sound. This behavior signified the initiation of "inspiration", where atmospheric air was drawn through the pneumostome into the respiration syphon and then into the mollusc's pulmonary cavity.

2.5. Surface respiration assessment

Surface respiration intensity was estimated by measuring the survival duration of experimental molluscs that were deprived of pulmonary respiration. These molluscs were placed at the bottom of an aquarium in small, water-permeable boxes made from densely and finely perforated plastic sheathing, with weights attached to the bottom. We analyzed the obtained results using basic variation statistical methods.

Table 1. The impact of pesticides in different concentrations (mg/L) on indexes of lung respiration of P. *corneus* s. l. allospecies. "Western" allospecies.

Pesticide	Concentraion, mg/L	n	Daily number of inspirations $M \pm m$	Interval between inspirations, min $M \pm m$	Duration of inspiration, min $M \pm m$	Volume of inspiration, number of bubbles $M \pm m$

2.6. Ethical compliance

Throughout the experiments, we strictly adhered to ethical norms and principles governing research involving living organisms, in full compliance with the current laws of Ukraine. As part of our ethical commitment, we emphasize the following:

1 *Invertebrate research*: the experimental molluscs in our study belong to the category of invertebrates, and we ensured that ethical considerations for their welfare were upheld.

2 *Compliance with Ukrainian laws*: we affirm that our research is fully compliant with the prevailing laws and regulations of Ukraine, including those governing the ethical treatment of research subjects.

3 *Ethical review*: this research received approval from the Human or Animal Ethics Committee at Zhytomyr Ivan Franko State University. The committee reviewed and approved the ethical aspects of our study to ensure the humane treatment of the experimental subjects.

3. Results and discussion

Pesticides can get into the molluscs' organisms percutaneously through their body covers of during respiration and in much less amounts from their food. Allospecies of P. *corneus* s. l. possess the bimodal respiration mode. The lungs are the adaptive acquisition in these molluscs for the new environment, where they found themselves in ancient times due to their forced transition from water to land environment, acquiring the ability to breathe by atmospheric air. The pulmonary respiration is performed by them via the periodical emergences under the water surface tension film to take the air through pneumostome. The surface respiration is established due to the diffusive income of water-solved oxygen in the molluscs' blood through their epithelial body covers and adaptive gill of quite large area. It is known, that efficiency of oxygen supply is almost equal for both modes: 0.025 and 0.03 O_2 (mg)/L (per 1 g of fresh mass, respectively).

We established that pesticides in the concentration range from 10 to 50 mg/L caused the rapid development of pathological process in ramshorn allospecies. Under the 10 mg/L concentration, obtained indexes of both pulmonary and surface respirations were close to those found in control group (tables 1-4), which corresponds with a latent phase of intoxication.

Under the concentrations of mentioned pesticides of 20-30 mg/L, the indexes of both respiration modes demonstrated the development of adaptive process in form of stimulation of all studied indexes in studied allospecies, which increased with increasing of used toxicant's concentration. This corresponds with the next phase of pathological process – stimulation. Studied molluscs showed the increase of daily number of "inspirations" and of their duration

	10	19	43.04±2.71
	20	18	45.69±3.28
	30	19	49.03±3.63*
	40	17	20.48±2.49**
	50	19	19.02±3.10**

Note: n – number of individuals studied; MPC – maximum permissible concentration of ions in the water; $M \pm SE$ – mean value of index and its standard error; * – statistically significant differences ($p \leq 0.05$); ** – highly significant differences ($p \leq 0.001$).

by 1.1 times, intervals between them by 1.1-1.3 times, and "inspiration" volume by 1.3 times ($p \leq 0.05$–0.001). We registered also the increase of the surface respiration indexes (estimated by the survival rate without pulmonary respiration) by 1.1 times ($p \leq 0.05$).

However, under the impact of higher toxicants' concentrations (40 and 50 mg/L), the level of mentioned way of defense appeared to be insufficient to successfully defeat the harmful action of toxic agent. Due to that, the experimental molluscs rapidly developed the depressive phase of intoxication process, which was caused by structural and functional damages of both their lung and cover epitheliums; it was quickly replaced by sub-lethal and lethal phases. Comparing to the control group, experimental P. *corneus* allospecies demonstrated the decrease of daily "inspiration" number by 1.2-1.3 times, interval between them by 1.6 times, "inspiration" duration by 1.3-1.4 times, and "inspiration" volume by 1.6 times ($p \leq 0.05$–0.001). Noteworthy, the survival of the studied allospecies without ability to perform the pulmonary respiration decreased by 2.1 times ($p \leq 0.001$).

Changes in both respiration modes in studied molluscs were followed with manifestations of fast ethological and physiological responses-reactions to the toxic environment impact. Avoiding of toxic environment is one of the first fast behavioral defensive reactions, which such molluscs possess. It is caused by the presence in P. *corneus* s. l. allospecies the neural connection between their organs receipting the chemical stimuli (osphradia) and the muscles responsible for movement in space as a result of stimulus obtained. This reaction, however, was observed during long time only under the low (10 and 20 mg/L) and moderate (30 mg/L) concentrations of used pesticides, and quite quickly fully slowed down under the high (40 and 50 mg/L) concentrations.

The lethality of experimental molluscs occurred due to the asphyxia and heart paralysis, caused by the intensive mucus production and destruction of the respiratory epithelium: first in body covers, later – in lungs. In both studied allospecies the fast and powerful watering of epithelium cells caused first the rapid growth of cell elements volume due to edema, which, although, strongly crimpled and destroy soon, and finally were exfoliated. The abruption of their leftovers was sometimes followed with disruption of underlying tissues and bleeding, less often with powerful bleeding. Similar deteriorations usually occurred earlier and manifested brighter in “eastern” allospecies individuals. That may be considered as the consequence of this allospecies range being spread on the territories with higher climate drought comparing to those inhabited by “western” allospecies.

4. Conclusions

The indexes of pulmonary and surface diffusive respirations in P. *corneus* s. l. allospecies showed their clear dependence on the environmental pesticide concentration. Toxic-resistance of “eastern” allospecies to the used toxicants appeared lower than in “western” allospecies. That’s why the first appeared more sensitive and less endurance to the impact of used toxic agent.

Allospecies of ramshorn can be recommended for use in the system of ecological monitoring as indicator species. As the aim functions, the indexes of pulmonary and surface respirations should be considered.

Abstract. Landfills cause significant technogenic pressure on the environment, being the center of depositing large volumes of hazardous materials in a relatively small area. Interacting with each other they form hazardous substances and compounds. In this study, we describe three genetic soil horizons that are within the impact zone of the landfill of a city of millions of people. It was established that the distribution of mobile forms of heavy metals according to the profile of the studied soils tended to gradual decrease with depth. When describing the genetic horizons of three profiles located in the impact zone of the landfill, it was established that the content of heavy metals in them does not exceed the MPC, except for Pb. The soil at the foot of the landfill turned out to be the most contaminated with heavy metals (profile No. 3). The activity of micromycetes in this soil was the lowest here. In general, all soils in the impact area of the landfill are impoverished in micromycete distribution. The taxonomic composition of mycelial fungi and the identified species' ecological and biological characteristics indicate significant ecosystem pollution by household waste.

1. Introduction

The edaphotope has a significant influence on the development of phytocenoses. Depending on its physicochemical, mechanical, and acidic properties, vegetation in landfills develops in different ways. In the impact zone of technogenic landscapes, there is an increased radiation background and increased activity of radionuclides in edaphotops. Numerous studies of edaphotopes of technogenic landscapes are being conducted in Ukraine. According to Uzbek and Halahan, in the technogenic landscapes, the edaphotope is a man-made, spatially limited bioinert system that is in constant development under the influence of soil formation factors [1]. In work [2], the contribution of the moss cover *Campylopus introflexus* (Hedw.) Brid. in the restoration of technogenic substrates due to the improvement of their edaphotopic properties is defined.

A carbon source of 4–6 g/L at pH 5–8 was found to enhance the heavy metal bioremediation potential of *Pseudomonas aeruginosa, Enterobacter cloacae, and Klebsiella edwardsii* isolated in a landfill in Lagos, Nigeria. The role of native bacteria in the remediation process can be optimized and used to standardize on-site bioremediation as well as establish biodegradation protocols. Great benefits can be provided by effective remediation of contaminated soils by improving soil condition and yield [3].

Soil microscopic fungi are very sensitive to changes in soil characteristics, so they can serve as indicators of its condition [4]. Micromycetes are not only an integral component of terrestrial and aquatic biocenoses, which control a wide range of biosphere functions, but also the main group of microorganisms responsible for both the synthesis and destruction of humic substances in the soil. Technogenic impact on the environment, as well as the rapid development of nanotechnology, make the problem of studying the interaction of micromycetes with organic matter of natural origin urgent.

The main feature of micromycetes is that they dominate soil microbiota. They represent the most specific group of microorganisms that participate in the mineralization of organic plant and animal residues and the formation of humus. The rate of decomposition of organic substances is determined by such factors as the chemical composition of the substrate, the efficiency of providing nitrogen to microorganisms, the composition of the microbial environment, and environmental conditions. Fungi under aerobic conditions are capable of decomposing even complex polymer compounds, for example, lignin, unlike other microorganisms, which are more conducive to the mineralization of low molecular weight organic compounds. Some soil fungi are able to decompose humus and use it as the only source of nitrogen and (or) carbon. At the same time, micromycetes participate not only in the process of destruction but also in formation of humic substances [5].

It has been established that the contribution of fungal bioaugmentation to the decontamination of soil has been clearly observed, and therefore mixed fungal organisms may serve as future bioremediation agents for contaminated areas [6]. It has also been proven that the synthesized rhamnolipids can significantly increase the activity of soil enzymes to facilitate the digestion and transformation of heavy metals from the soil to the aerial part of ryegrass [7].

The study of the enzymatic activity of the soils of technogenic territories of the Nemyriv sulfur deposit is shown in the paper [8]. It was established that the low activity of oxidoreductases and urease in the soils of the former development of sulfur deposits is a consequence of significant inhibition of the activity of soil microflora – the main producer of enzymes – by technogenic factors. The formation of a phytoremedial cover on the surface of devastated landscapes of coal mining is given in the article [9]. The role of plant cover in the restoration of disturbed lands has been established.

It should be noted that the conditions of local growth on the landfills' surfaces negatively affect the growth and development of vegetation. Among the analyzed metals, iron reached the highest values in samples of *Tanacetum vulgare L.*, namely, stems (103.4–6564.6 mg/kg of dry matter), roots (6563.6–33,036.6 mg/kg of dry matter), leaves (535.1–11.275 mg/kg of dry matter), and soil (12.389–39.381.9 mg/kg of dry matter). Cd, as well as Cr, Ni, and Zn, accumulate mainly in the leaves, while Co, Cu, Fe, Hg, Mn, and Pb accumulate mainly in the roots of *T. vulgare* [10]. However, grass species that are tolerant to the high content of heavy metals in red mud dumps were investigated [11]. Namely, based on the metal resistance index, 51.4, 10.8 and 37.8% of grass species showed sensitive, moderate, and high metal resistance – *Brachiaria mutica, Cynodon dactylon, Dactyloctenium aegyptium, Digitaria ischaemum, Digitaria longiflora, Eragrostis cynosuroides, Launaea asplenifolia, Parthenium hysterophorus, Sporobolus diander, Stylosanthes scabra.* The research suggests a potential pathway for phytomanagement of abandoned red mud landfills through remediation using dominant metal-tolerant plant species [11].

The fact that landfills are polluting objects has been described by many scientists in their works. The impact of landfills on the human body is constantly being studied. Scientists have found that solid waste from a modern city contains more than 100 items of extremely toxic substances, including dyes, pesticides, solvents, medicines, used motor oils, phytochemicals, etc. Thermometers, fluorescent lamps, and various appliances contain mercury, an extremely dangerous substance because it is a volatile metal that can evaporate at low temperatures and, when exposed to microorganisms in landfills, turns into methylmercury, which can cause massive poisoning if ingested through water and food.

One of the world's largest landfills is the Lviv Municipal Solid Waste Landfill, which was included in the list of the 100 Greatest Environmental Disasters of Ukraine. Due to violations of the landfill's operating requirements, it has turned into a spontaneous landfill. The landfill is 3 km from the northern border of Lviv, near the village of Velyki Hrybovychi. It has been operating since 1957. Over the years, it has accumulated over 50 million cubic meters of waste. Until 1990, not only municipal solid waste, but also toxic industrial waste was stored within its boundaries. According to rough estimates, the amount of waste reached 2 million tons. In addition to garbage, more than 200 thousand tons of acidic tar, waste from the Lviv Oil Refinery, which is no longer in operation, has accumulated at the landfill. The thickness of the garbage layer in the southeastern part of the landfill reaches 50 meters, while in the northwestern part, it varies from 1-3 to 10 meters. Its total area is 33.6 hectares.

Thus, the investigation of edaphotopes of technogenic landscapes, including landfills, is relevant from the point of view of reducing their harmful effects and returning land to national economic use.

2. Materials and methods

Physico-chemical investigation of edaphotopes of soil horizons within the impact zone of the Lviv city landfill were carried out according to the state standards of Ukraine [12–14].

The surveys were conducted in July 2020, before the start of the reclamation of the Lviv landfill.

The content of mobile forms of heavy metals in edaphotops was determined: mobile forms of copper, zinc, cobalt were determined by the Rinkis method, lead, cadmium – by the atomic absorption method. They were also guided by the state standards [15].

Determination of the quantitative and qualitative composition of micromycetes of technogenic edaphotopes of landfills was carried out by sowing soil suspension from decimal dilutions on wort-agar and Chapek's agar medium. Cultivation of the studied samples was carried out at +26. . . +28 °C. Isolated cultures were studied with a microscope "MBI-6" according to the method adopted in mycological studies [16]. The study of isolated micromycetes was carried out according to the generally accepted definition [5].

3. Results and discussion

For investigation of the influence of landfills' hazardous factors on the formation of the soil profile, the soil profile cuts were made, from which mixed soil samples were selected according to genetic horizons. Mycological and agrochemical analyzes were carried out, as well as analyzes for the content of nutritious minerals, heavy metals, and toxic elements (figure 1).

It should be noted that in the impact zone of the Lviv city landfill, we have carried out ecological monitoring of the hazardous substances distribution in edaphotopes as a result of the spillage of acid tar storage facilities, two lakes of which are stored on the southern side of the top. It has been established that hazardous substances expand to a distance of 1,500 m from the foot of the landfill.

3.1. Genetic soil horizon No. 1

The peatland (profile No. 1) is located within a radius of 2 km east of the foot of the landfill. The land belongs to the Dublyany City Council of the Lviv District (Lviv Region). In terms of peat reserves, this deposit was one of the largest in the world. After the Second World War, the local population made peat briquettes by hand to heat houses. As a result, the peatland lost a significant part of its capacity. At the moment, agricultural products are grown on peatlands, which is prohibited due to the deposition of polluting substances in peat, including leachates from landfills. The danger of landfill leachates is described in scientific works [17–19]. Malovanyy et al [20] presents a rational scheme of the biological conveyor of an open-type installation for cleaning landfill leachate. Laboratory studies were conducted to determine the efficiency of using nozzles for the immobilization of microbiocenosis in aerated lagoons, which are used to clean landfill leachate. The interest in studying the physical and chemical properties of peat, which is

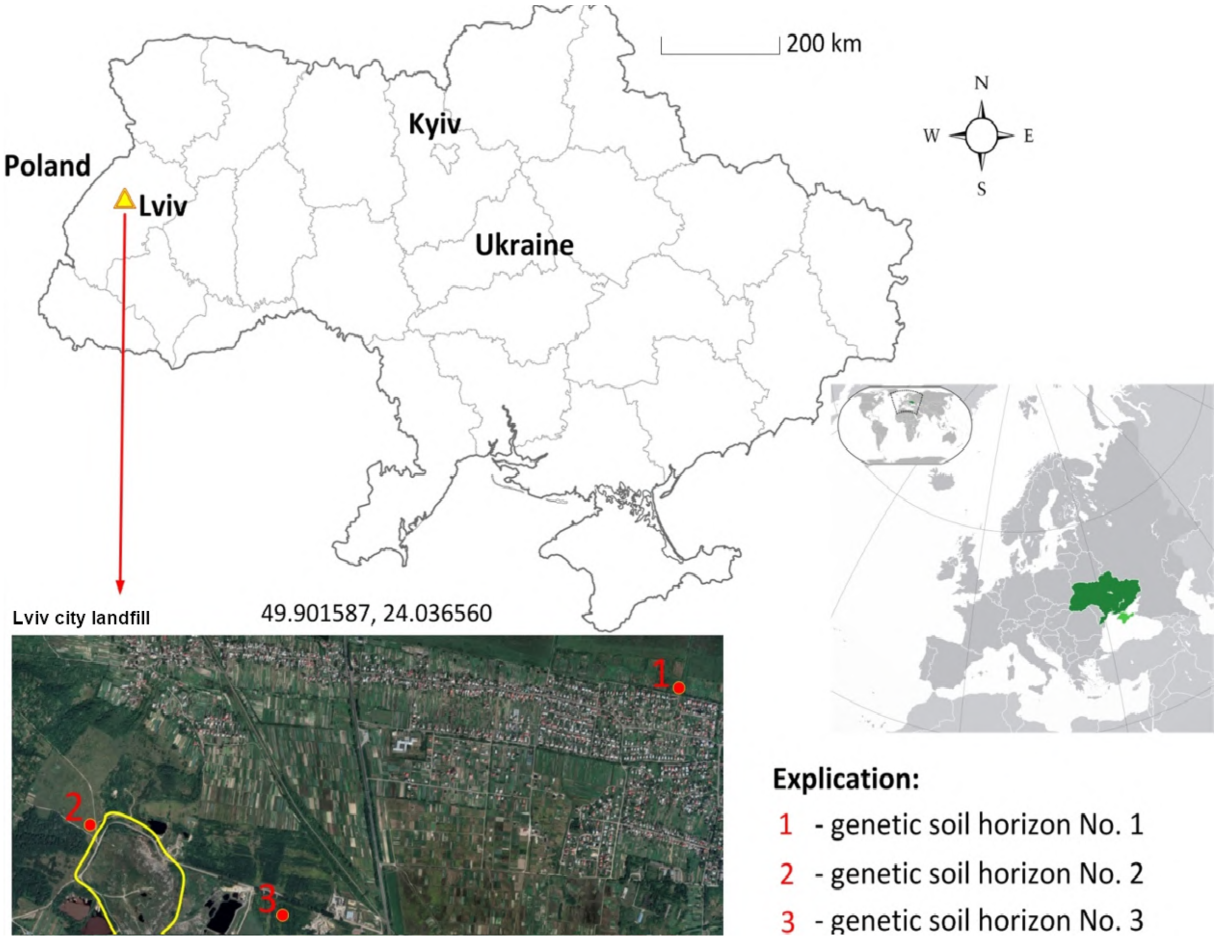

Figure 1. Location of objects of research in the impact zone of the Lviv municipal landfill.

located in the zone of influence of landfills, is caused by the fact that it is the main component of the landscape, in which various biogeochemical and migration processes occur, being a natural sorbent of various chemicals and an indicator of the degree of the natural ecosystem destruction.

When describing the deep peatland, it was found that the content of heavy metals in the surface layer T1 significantly exceeds the indicators in the genetic horizon T2 (figure 2, figure 3).

In view of the above-mentioned data, it can be stated that the content of cobalt in peatlands does not exceed the MPC, which is 5 mg/kg. The mercury content is 250 times lower than the MPC, which is 2 mg/kg. The cadmium content is twice as low as the permissible standard of 0.7 mg/kg. In general, the presence of this toxicant in the soil section with a concentration of 0.5 MPC is a negative phenomenon. The source of cadmium in landfills is waste containing varnishes and paints, fluorescent lamps, batteries, etc. Cadmium sulfide is the basis of yellow paints used in vehicle painting, textile production, and soap making. Cadmium selenide is used as a red dye. Cadmium is also used in semiconductor materials, cryogenic technology, lead-cadmium and mercury-cadmium elements of reserve batteries, and anti-corrosion metal coatings.

The distribution of the content of mobile forms of heavy metals according to the profile of the studied soils is demonstrated by their gradual decrease with depth.

The physical and chemical composition analysis of section No. 1 showed that the peatland has a significant supply of nitrogen (56.05 mg/100 g) and potassium (58.5 mg/100 g) nutrients

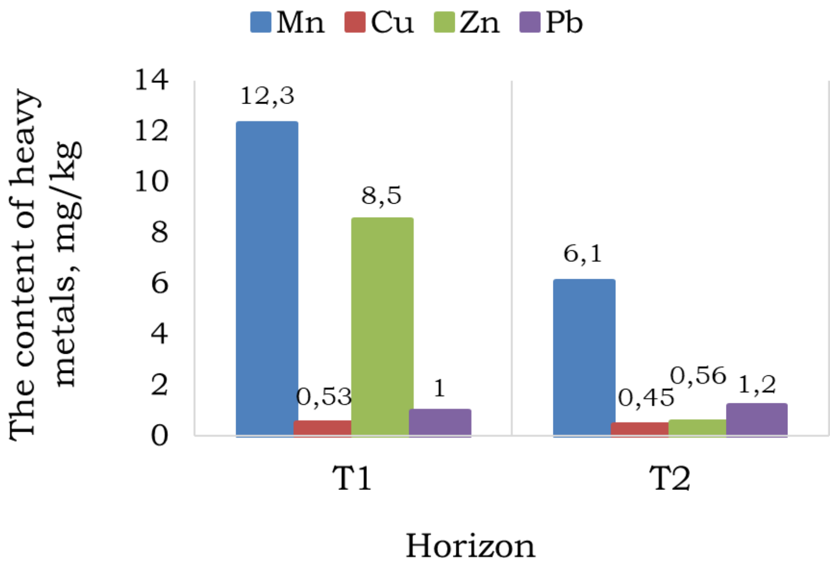

Figure 2. The content of manganese, copper, zinc, and lead in the studied horizons of section 1.

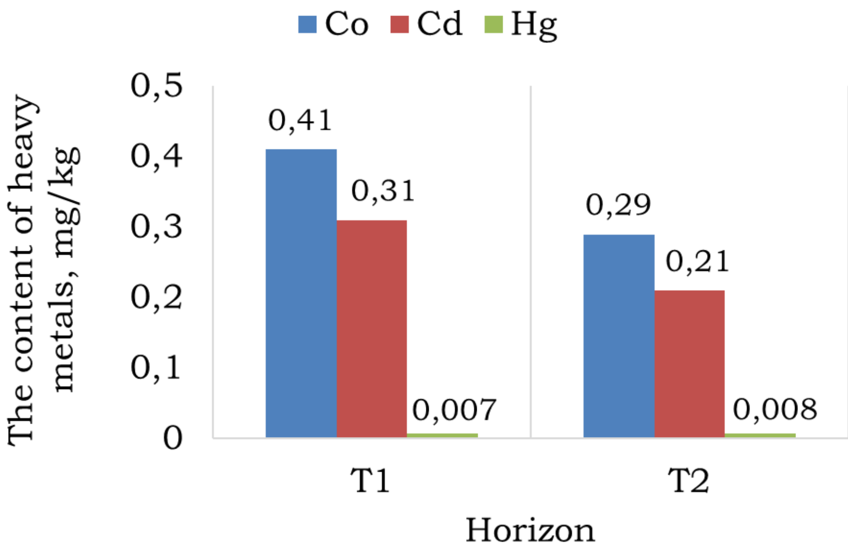

Figure 3. Content of cobalt, cadmium and mercury in the studied horizons of section 1.

and a low content of humus (2.06%) and nitrogen fertilizers (0.84 mg/100 g). In terms of humus, the peatland is considered like weakly humus.

When adding peat to the soil, it is necessary to improve agrophysical properties, since peat is depleted in nutrients. Effective use of peat for the development of agricultural crops is possible when fertilizers are applied to it.

The analysis of the micromycete activity of landfills showed that the families *Mucoraceae, Moniliaceae*, and *Tuberculariaceae* are widespread in the T1 horizon of the peatland. The total number of micromycetes was determined by sowing on Chapek's acidified nutrient medium (the number of colony-forming units – CFU in g of soil). This indicator turned out to be quite low compared to the background values. In general, all soils are characterized as very poor in the degree of micromycetes distribution.

10 species of micromycetes were found in soil profile No. 1. Among them are representatives

of the following families: *Mucoraceae* – 1 pc.; *Moniliaceae* – 5 pcs.; *Tuberculariaceae* – 4 pcs.

It should be noted that the presence of micromycetes of the genus *Fusarium* in the edaphotope indicates a significant content of mineral substances and a low content of heavy metals. This genus of micromycetes was discovered by researchers in landfill leachate during the study of a biosorption multilayer filter. Micromycetes of the genus *Fusarium*, along with bacteria, took an active part in the formation of the filter biofilm.

The analysis of peatland micromycetes by growth rate showed that slow-growing micromycetes have the largest share – 70%, respectively, fast-growing – 30%. Undoubtedly, such an indicator of the growth rate of mushrooms is negative, as it causes inhibition of the development of successional processes. The distribution by color showed that dark-colored micromycetes of the *Moniliaceae* family predominate and are characterized as toxic (80%), the share of light-colored ones is 10%, unclassified – 10%.

3.2. Genetic soil horizon No. 2

When describing soil profile No. 2, it was found that the soil is sod, shallow, light loamy, and glazed. The profile is made on the western side of the Lviv landfill at a distance of 20 m from the road that leads to the village Zbyranka. The soil-forming and underlying rock is loess loam. Genetic horizons H(gl) and P(h)(gl) were revealed.

It was established that the mobile forms of such heavy metals as Mn, Cu, Zn, and Pb do not exceed the maximum permissible concentration (MPC) and accumulate in the upper horizon. Exceeding the MPC is observed only for lead (2 mg/kg) in the H(gl) horizon. At a depth of 30 cm or more, the concentration of these elements decreases 10 times (figure 4).

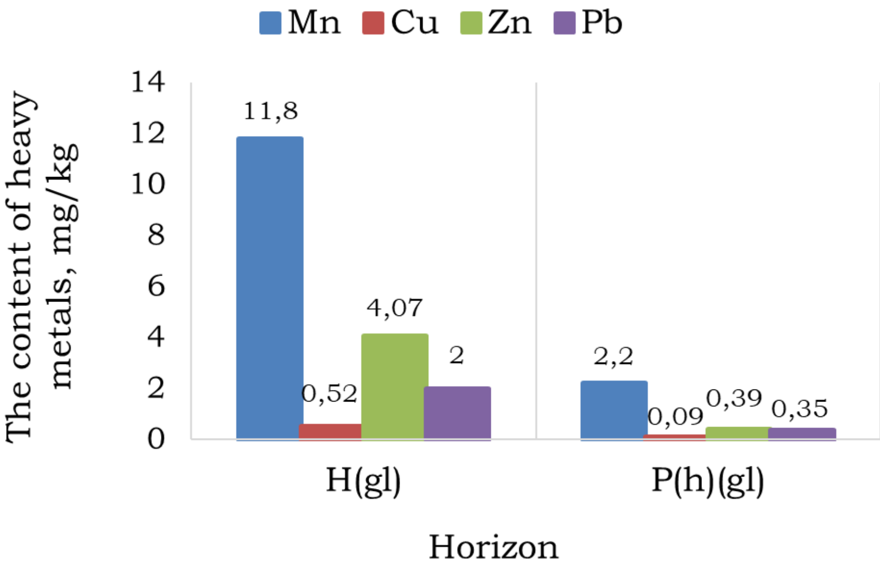

Figure 4. The content of manganese, copper, zinc, and lead in the studied horizons of profile 2.

Mobile forms of pollutants such as Co, Cd, and Hg accumulate, mostly, in the P(h)(gl) horizon of profile No. 2, but their content does not exceed the MPC (figure 5).

The mineral composition of the genetic horizons of soil profile No. 2 has quite high indicators, with the exception of humus, with content of 1.53-1.7%. According to this indicator, the soil belongs to low-humus, which is a disadvantage for the development of vegetation in the impact zone of the landfill. The content of NO_3 in the horizon is 20.6-30.5 mg/100 g of soil, P_2O_5 – 9.92-11.51 mg/100 g of soil, K_2O – 55.8-56 mg/100 g of soil (figure 6).

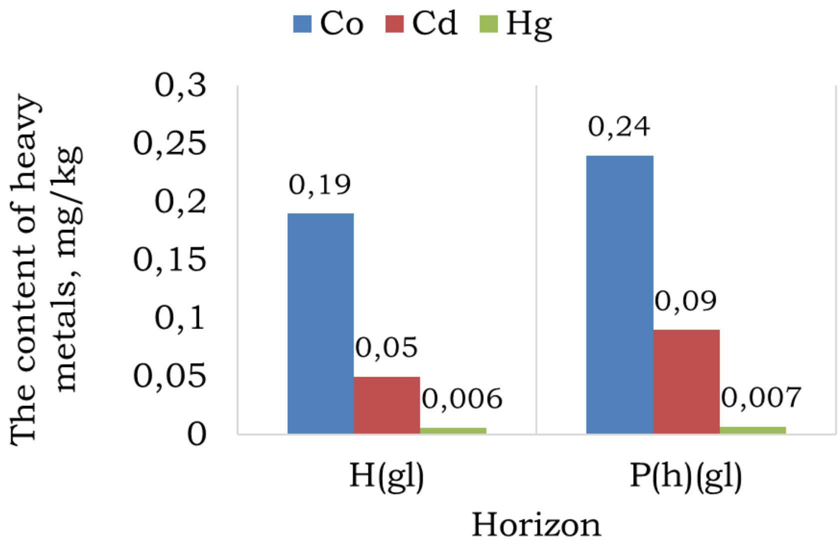

Figure 5. Content of cobalt, cadmium, and mercury in the studied horizons of profile 2.

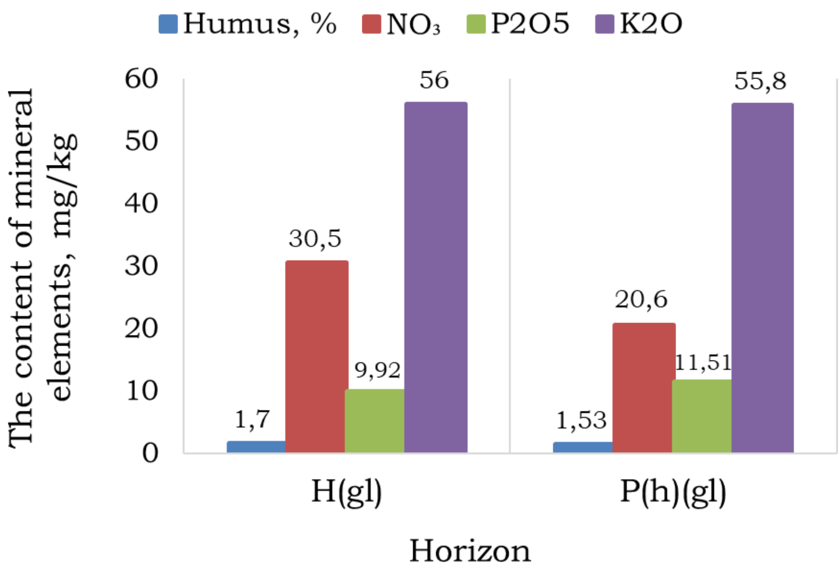

Figure 6. The content of mineral elements in the horizons of profile 2.

Thus, the soil located on the western side of the landfill did not tend to accumulate heavy metals, the concentration of which would exceed the MPC. However, the humus content in these soils is low, worsening the conditions for the syngenetic stages of succession.

The species composition of the micromycetes of the genetic horizons of the profile differs. Micromycetes of the *Mucoraceae, Moniliaceae* families develop in the H(gl) horizon. The P(h)(gl) horizon is inhabited by *Moniliaceae, Tuberculariaceae,* and *Dematiaceae.*

The life activity of the micromycete *Rhizopus stolonifer* (bread mold) in the upper horizon of the profile indicates their active participation in the syngenesis and decomposition of litter and leaf litter. These micromycetes develop on bread, fruits, and vegetables. It is well-known that microscopic fungi *Rhizopus stolonifer* can cause an allergic condition in humans. Micromycetes of the genus *Aspergillus* acquired the greatest development in this soil. These microfungi are involved in the transformation of organic matter and plant residues. In general, the micromycete species composition of the profile is extremely depleted, and the abundance of the species composition is low.

One of the most opportunistic and toxin-producing micromycetes is *Aspergillus fumigatus* Fries.var.sclerotiorum, discovered by us in this soil profile. This micromycete can cause mycosis and mycotoxicosis in living organisms (humans, animals). On figure 7 is shown a micromycete under a microscope.

Analysis of micromycetes by color and growth rate showed that dark-colored (78%) and slow-growing (89%) micromycetes develop within this genetic horizon. The rates of slow growth are even higher than for the peatland, indicating the detrimental effect of the hazardous factors of the landfill on micromycetes, including heavy metals and radionuclides. The share of fast-growing micromycetes is 11%, light-colored – 11%, and unclassified – 11%.

3.3. Genetic soil horizon No. 3

The studies of turf soil (profile No. 3), formed in conditions of moistening of the territory, showed that it has slightly different physical and chemical parameters. The name of the soil (with mechanical composition) is the field: sod, deep, clay, medium loam (light).

It was formed on diluvial sediments. The cut is laid 100 m east of the foot of the landfill and

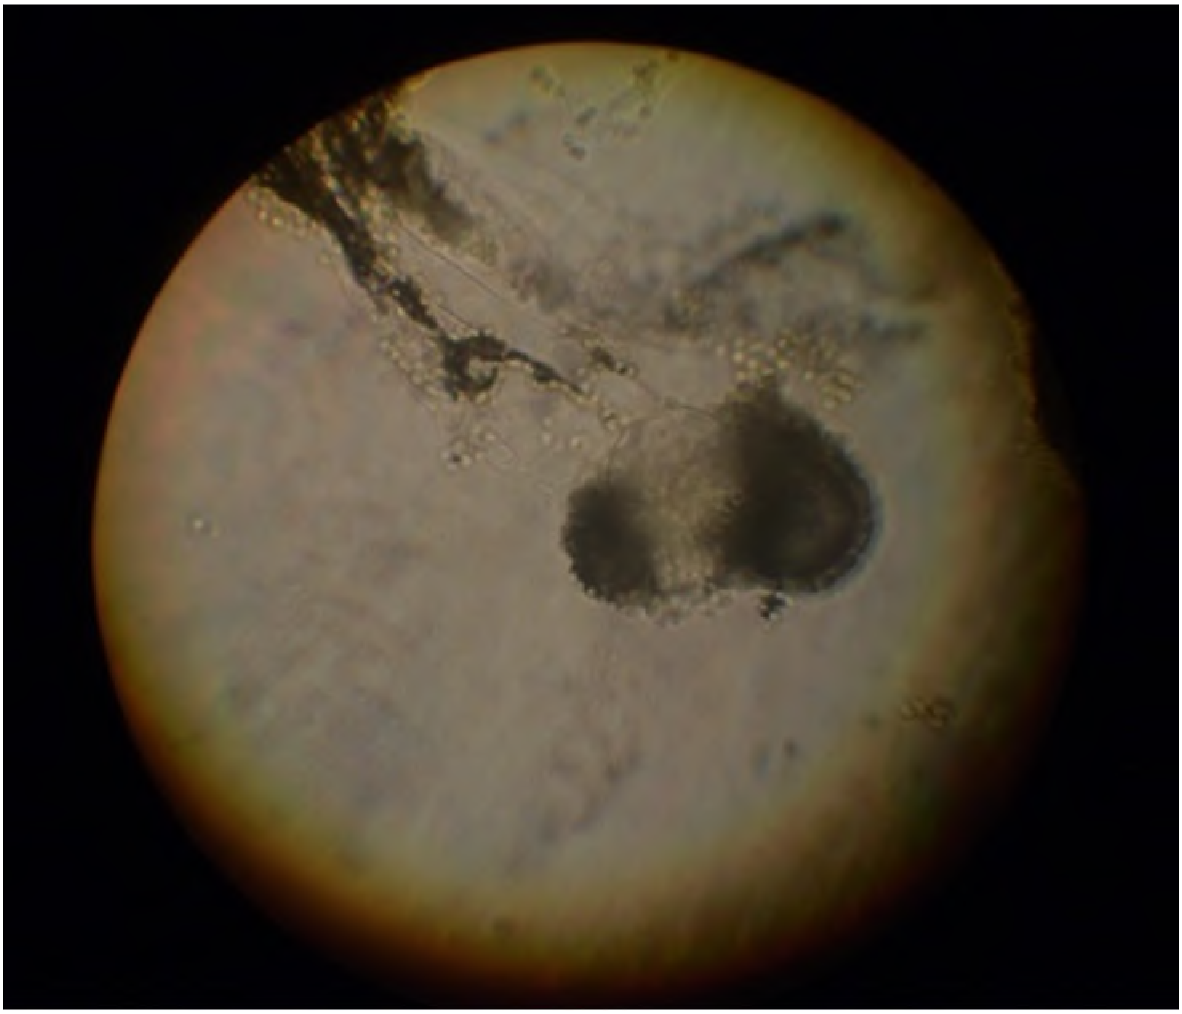

Figure 7. *Aspergillus fumigatus* Fries.var.sclerotiorum.

70 m perpendicular to the road that leads to it. Such genetic horizons as H(o), H, H(p)(gl), P(h)(gl) were identified.

The content of mobile forms of Mn and Cu increases with depth (from 29.4 mg/kg to 39.7 for Mn and from 0.57 mg/kg to 0.93 mg/kg for Cu), however, they do not exceed the MPC. The content of Zn in genetic horizons is 1.6-3.9 mg/kg and also does not exceed the MPC. The content of Pb in the genetic horizons exceeds the MPC by 1.5 times and the concentration increases with depth starting from the level of 23 cm (figure 8).

Concentrations of mobile forms of Co, Cd, and Hg increase with depth but do not exceed the MPC. The accumulation of heavy metals in the genetic horizon P(h)(gl) indicates their leaching to the parent rock (figure 9).

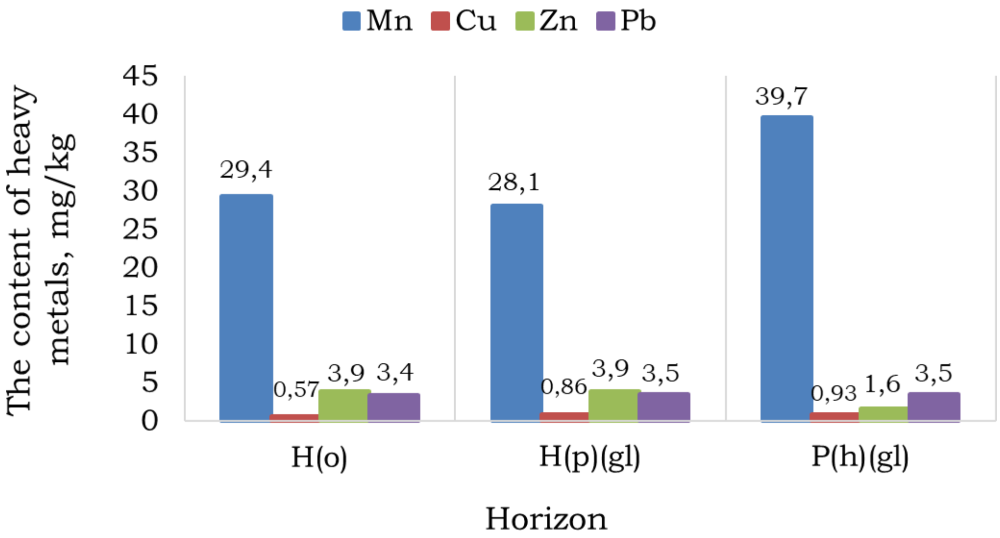

Figure 8. The content of manganese, copper, zinc, and lead in the investigated horizons of profile 3.

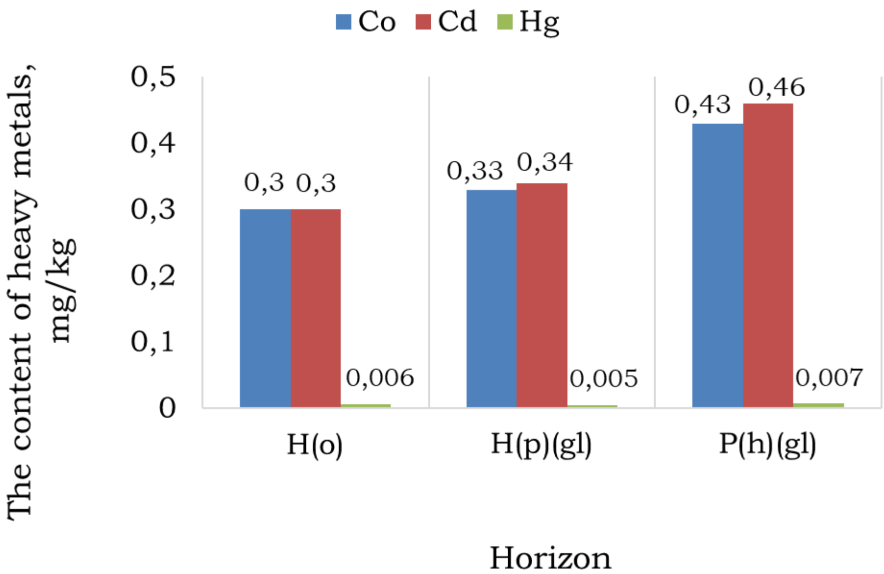

Figure 9. The content of cobalt, cadmium, and mercury in the studied horizons of profile 3.

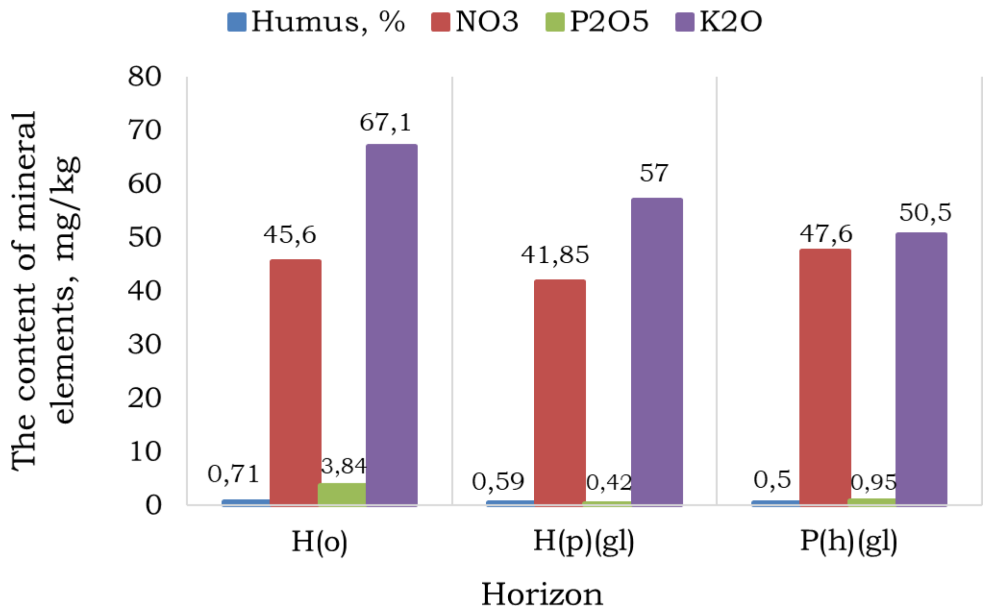

Figure 10. The content of mineral elements in the studied horizons of profile 3.

The humus content in the horizons decreases with depth and is only 0.5-0.71%. There is also a low content of P_2O_5 – 0.95-3.84 mg/100 g of soil and a decrease in concentration with depth. The concentrations of NO_3 and K_2O in the horizons are relatively high ranging from 41.85 to 47.4 mg/100 g of soil for the former, and from 50.5 to 67.1 mg/100 g of soil for the latter (figure 10).

Data on the content of heavy metals and the mineral composition of soil profile No. 3 make it possible to assert the negative impact of landfills on the adjacent territories and the environment. The concentrating of toxic elements with depth indicates their leaching to lower horizons and parent rock, which causes long-term technogenic pressing in the impact zone of landfills.

The species composition of micromycetes in section No. 3 is extremely depleted. A total of 10 species belonging to 3 families of the class *Hyphomycetes (Deuteromycetes)* were found.

The above data indicate the biological activity of micromycetes only in the upper layer of the horizon. Species *(Moniliaceae)* that carry out transformation reactions of complex organic compounds (solid and liquid paraffins, alcohols, diesel fuel, steroids) became the most widespread here. With depth (23-43 cm), the species composition and number of colonies decrease sharply, which indicates the contamination of the edaphotope with heavy metals, in the particular lead. At a depth of 43 cm and below, the vital activity of only one species is observed – *Mycelia st. dark*.

Analysis of micromycetes by color and growth rate of soil profile No. 3 showed that within this genetic horizon, dark-colored micromycetes develop the most (60%), light-colored micromycetes – 30%, unclassified – 10%. According to growth classification, only slowly growing micromycetes (100%) develop. The absence of any type of fast-growing micromycetes indicates strong pollution of the horizon with dangerous substances and compounds.

4. Conclusions

The conducted research and the results of analytical work in the laboratory showed that in the areas adjacent to the Lviv city landfill, mostly wet soils are common. The reason for their formation is insufficient drainage of the territory, which causes waterlogging in the area. Turf soils and peatlands were found.

When describing the genetic horizons of three profiles that are in the impact zone of the landfill, it was established that the content of heavy metals does not exceed the MPC, except for lead. The soil at the foot of the landfill turned out to be the most contaminated with heavy metals (profile No. 3). Also, the lowest activity of micromycetes was found in this soil.

The families *Mucoraceae, Moniliaceae,* and *Tuberculariaceae* are widespread in the T1 horizon of the peatland (profile No. 1). The presence of micromycetes of the genus *Fusarium* in the horizon proves a significant content of mineral substances and a low content of heavy metals. The species composition of the micromycetes of the genetic horizons of profile No. 2 is significantly different. Micromycetes of the *Mucoraceae*, and *Moniliaceae* families develop in the H(gl) horizon. The P(h)(gl) horizon is inhabited by *Moniliaceae, Tuberculariaceae,* and *Dematiaceae*. The species composition of micromycetes in profile No. 3 is extremely depleted. A total of 10 species belonging to 3 families of the class *Hyphomycetes (Deuteromycetes)* were found. With depth (23-43 cm), the species composition and number of colonies decrease sharply, which indicates the contamination of the edaphotope with heavy metals, in the particular lead. At a depth of 43 cm and below, the vital activity of only one species is observed – *Mycelia st. dark*.

It was found that the mobile forms of such heavy metals as Mn, Cu, Zn, Pb do not exceed the maximum permissible concentrations (MPC) and accumulate in the upper horizon No. 2. Exceedance of the MPC is observed only for lead (2 mg/kg) in the H(gl) horizon.

All soils in the area affected by the landfill are characterized as very poor in micromycete distribution. The taxonomic composition of mycelial fungi and the ecological and biological characteristics of the identified species indicate significant pollution of the ecosystem by household waste.

Abstract. The assessment of the transformation level in the Buniv River basin (Ukraine) transformation was performed. Substantiates the need to improve the monitoring system within the river basin, as the main tool for assessing and predicting changes in the aquatic ecosystem and managing the processes of its anthropogenic. The research methods included on-site investigations, laboratory and analytical studies, data processing using GIS technologies. A topographic survey of the Buniv River's floodplain within the village of Rokytne town was performed. The on-site investigations included field surveys and water sampling at 4 control sites on the Buniv River for 13 quality indicators. The analysis of the obtained cartographic models indicates a significant anthropogenic transformation of the natural landscapes. A significant part of the watercourses of the Buniv River basin was once directed and transformed into main canals of the meliorative systems. This causes the formation more dangerous flood flow.

1. Introduction

The current national environmental policy of Ukraine in the field of water management is aimed at the Implementation of the Water Framework Directive 2000/60/EC (EFWD) [1] on ensuring sustainable resource management, meaning the European Model of Water Resources Management. The EFWD aims to protect and improve the state of water resources and promote their sustainable and balanced usage. It sets out the basic provisions for EU countries to achieve good surface, ground, transitional and coastal waters within each river basin. In order to implement the EU's directives on river basin protection, the Verkhovna Rada of Ukraine preserved the integrated approach to water resources management based on the basin principle at the legislative level. For this, they adopted in 2016 under No. 1641 – VIII the Law of Ukraine "On the modification of some legislative acts concerning the introduction of integrated approaches in the water resources management by the basin principle"; on 26.10.2017 under No. 25 the Order of the Ministry of Environment "On the allocation of sub-basins and water management areas within the established areas of river basins"; on September 19, 2018, under No. 758 the Resolution of the Cabinet of Ministers of Ukraine "On approval of the procedure for state water monitoring," etc.

The above-mentioned law and bylaws are aimed at implementing a system of integrated water resources management based on the basin principle by:

- Developing and adjusting the river basin management plans
- Developing the water management balance sheet;
- Determining the hydroecological state of the surface waters.
- Determining the powers of the central and local authorities, local self-government bodies in the implementation of water protection measures, etc.

In addition to this, the relevant State Agency for Water Resources of Ukraine is committed to developing the river basin management plans for 9 river basin districts. As of today, the water massifs and the typology of the general hydrographic network of Ukraine have been identified; the diagnostic and operational monitoring of the transformed surface water massifs has been carried out, and the reference conditions of the river basins have been established.

Also, in 2021, plans were made to complete the works on creating classifications of the ecological state of water bodies, establishing their ecological and chemical states, as well as determining ecological purposes for these water bodies.

Volyn Polissia is transboundary region. At the same time, Ukraine has committed itself to implement the Convention on the Protection and Use of Transboundary Watercourses and International Lakes (Convention on Transboundary Waters) [2]. The main purpose of this Convention is to approve the measures to protect and ensure the quantity, quality and sustainable usage of both surface and underground transboundary water resources at the local, national and cross-border levels. Within the Convention, the industry institutions should apply an integrated basin approach based on the understanding that water resources are an integral part of the ecosystem and play a crucial role in the socio-ecological and economic development of territories.

The Convention requires the states to fulfill certain obligations: to control and reduce the negative transboundary impacts on the hydroecosystems and river basin territories at the different levels; to apply an ecosystem approach in the field of common water resources management in compliance with the principles of “polluter pays”, “cautiousness”; the conservation and the restoration of ecosystems; to implement environmental impact assessments; to set common goals to achieve a “good state” of water quality, monitoring the state of transboundary rivers; to minimize man-made risks, etc.

Therefore, today, in our opinion, it is extremely important to develop and implement a joint program for monitoring rivers and to apply a common tested and approved methodology for effective integrated water resource management of the transformed rivers. This includes the assessment of the ecological state of river basins using GIS technologies; determining the environmental goals to achieve a “good state” of water quality; developing compensatory water protection measures; developing the design and estimate documentation if necessary; the organizational tools for attracting water users, all interested parties, state authorities, and local self-government bodies, etc. Along with these important and topical issues is the need to ensure the flood safety of riverine territories of the Polissia zone, as well as adapting to climate changes.

This is exactly the problem that arose in the basins of small rivers in the border areas of Volyn Polissia after the flood on May 17, 2018. Then, as a result of great precipitation, there was a rapid rise in water levels, which led to the flooding of residential buildings, including the threat of the destruction of the pressure front structures at the recreational reservoir in the Rokytne town (Rokytne), Rivne region [3]. The heavy rain on May 16, 2018, which lasted about 10 hours, led to the flooding of 378 households located on the border territories of the Sarny district in the Rivne region, as well as the different infrastructure facilities. The most affected locations were those belonging to the basin of the Buniv River (a tributary of the Lva River).

Therefore, today it is important to use methodological approaches to protect, preserve and restore the surface waters of the Buniv River basin, which is the goal of our work.

This research is devoted to developing the methodology elements for managing transformed basins of the small rivers at the border part of Volyn Polissia, substantiating technological solutions for the restoration and protection of the surface waters, which were tested on the example of the Buniv River basin.

In order to achieve the set **goal**, the following **tasks** were performed: on-site investigations and instrumental studies of the Buniv River basin were carried out; the ecological stability of the landscape and hydrological and morphological features of the river were assessed; the quality of the river's surface water and bottom deposits were assessed; management solutions were developed to achieve a "good state" of surface water quality according to the requirements of the EU WFD, as well as to protect the territory from floodwaters.

This report is a study on the changes in the ecological state of the Buniv River basin. The indicators that characterize the quality of river surface water and the compensatory organizational and technical solutions for restoring the aquatic ecosystem are the subject of the study.

2. Brief literature review

The Volyn Polissia waterways, especially the small rivers, are exposed to significant anthropogenic pressure [4–7]. The quality of the surface water does not meet the requirements of the EU Water Framework Directive, and their current state is assessed as critical [8]. In the border areas of Volyn Polissia, small rivers with their swampy catchment area and preserved forest vegetation form the water content, hydrochemical regime, hydroecological state and water quality of the basins of medium and large tributaries of the Prypiat. Unfortunately, the majority of rivers have been diverted, become shallow, and are affected by the pollution from diffuse and point wastewaters from industrial enterprises, agricultural production, utilities, etc.

A significant role in the destruction of the ecological situation in these river basins is played by non-compliance with the requirements of water legislation (Water Code of Ukraine) [9], deforestation, the "chemization" of agriculture, creating and functioning a cascade of ponds and reservoirs, violating the rules of operation in water bodies, violating the mechanisms of hydraulic structures (cross regulators) that do not provide water passage during floods and inundations, the intensive use of water resources, the discharge of significant volumes of polluted water, etc. Such a powerful transformation of the territories [6] and water areas of river basins at the border territories in terms of the scale of manifestations and the impact intensity makes it necessary to find ways to optimize resource management, develop compensatory water protection measures (technological road map) and integrate water resources management in these transformed river basins of the border territories [4, 5].

Further delay in resolving this problem will lead to a decrease in the assimilation capacity of hydroecosystems of the Volyn Polissia river basins [10], and deterioration in the ecological situation of the main border artery, meaning the Pripyat River. For Ukraine and Belarus, resolving the above problems is extremely important, especially for the residents and water users living in the border areas that use surface water for various economic purposes.

3. Methods of factual analysis. Research area

The research methods included on-site investigations, laboratory and analytical studies, data processing using GIS technologies. A topographic survey of the Buniv River's floodplain within the village of Rokytne was performed. The on-site investigations included field surveys and water sampling at 4 control sites on the Buniv River for 13 quality indicators. A full-scale survey of individual sections of the river catchment area was carried out using an unmanned aerial vehicle. The chemical and analytical quality control of the Buniv River's surface waters was carried out according to regulatory requirements in the certified laboratory of water quality at the National University of Water and Environmental Engineering in Rivne city. The instrumental studies (dissolved oxygen content, oxygen saturation temperature, pH, ox-redox potential) were determined at the sampling site using certified mobile devices, the EZODO 7031 and Adva AD 11.

The procedure for sampling water at the Buniv River for hydrochemical analysis was carried out according to the relevant state standards:

- GOST 17.1.5.05 – 85 General requirements for sampling surface and sea waters, ice and atmospheric precipitation // State Committee of the USSR on standards;
- DSTU ISO 5667-1: 2003 – Water quality. Sampling. Part 1. Instructions on the draft programs for sampling // Order No. 102 of the State Consumer Standard Service of June 11, 2003;
- DSTU ISO 5667-6: 2009 Water quality. Sampling. Part 6. Guidelines for sampling from rivers and streams (ISO 5667-6: 2005, IDT);
- Methodological guidelines "Sanitary and virological control of water objects" under article 40 of the Law of Ukraine "On ensuring sanitary and epidemiological welfare of the population" // Order of the Ministry of Health Care of Ukraine No. 284 of 30.05.2007.

Water sampling for analysis was carried out under conditions for the river's lowest water content (during the summer low water period) at daylight hours. The sampling control points (research area located on N 51.280588, E 27.218915) assumed representativeness according to the level of anthropogenic load: 1-st section of the Buniv River, 50 m below the railway bridge (point PK-21); 2-nd section – Buniv River, 250 m below the railway bridge (point PK 18); 3-rd section – Buniv River, reservoir (PK10); 4-th section – Buniv River, the reservoir (PK3) (figure 1).

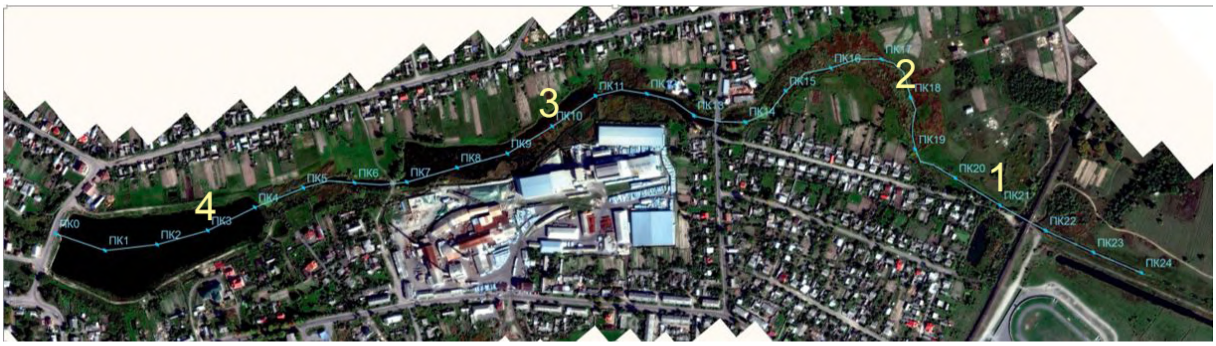

Figure 1. The sampling control points location (*marked in yellow*) and diagram of the survey route (*from PK0 to PK24*).

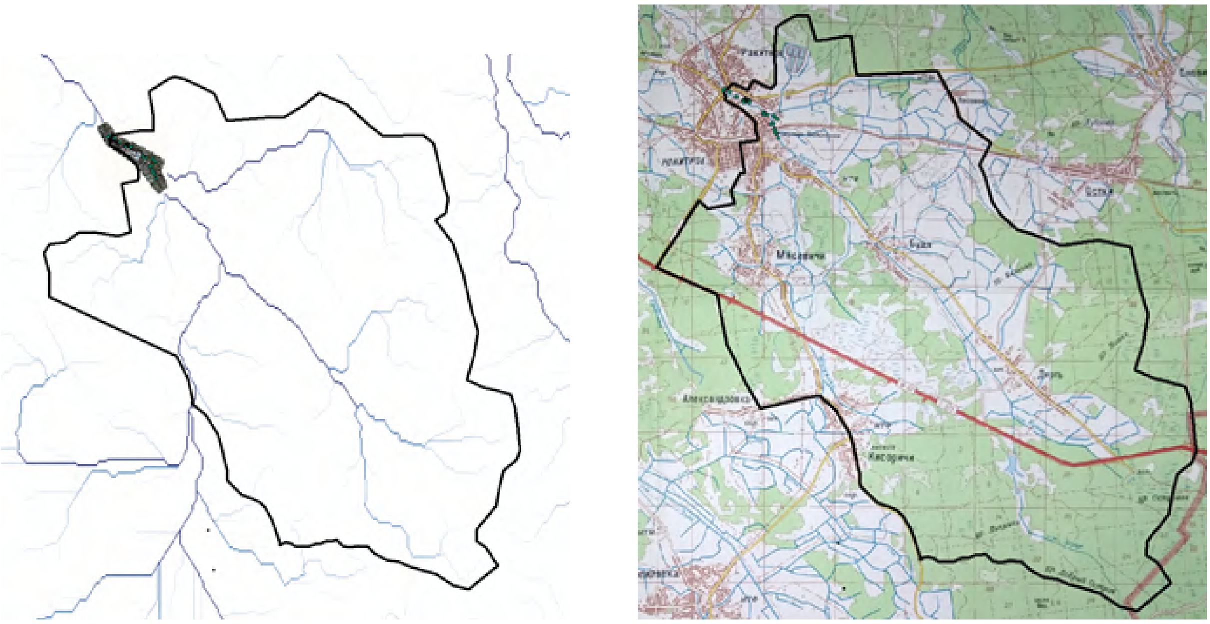
The assessment of the Buniv River basin's surface water quality was carried out in accordance with the method of "Comprehensive Expert Assessment of River Basin Ecosystems" (IE) [11].

Sampling bottom deposits was carried out under the standards (DSTU ISO 5667-12-2001 Water quality. Sampling. Part 12. Guidelines for sampling bottom deposits [ISO 5667-12:1995, IDT]) on a 50 x 50-meter grid with a clamshell and capture area of 0.1 m^2. Immediately after lifting the samples of bottom deposits, their field description was carried out. The mixed samples were used for further laboratory study and clarification with a lithological study of the bottom deposit composition. A total of 3 samples of bottom deposits in the Buniv River and 2 samples in the reservoirs were collected. For calculating the total pollution index we used the methods in force in Ukraine.

3.1. Description of the research area

The Buniv River basin is a typical small river of the border territory, located within the Sarny district of the Rivne region, a right tributary of the Lva river tributary (Pripyat river basin, 16-th ecoregion). The length of the river is 23 km, the slope of the river is 1.1 m/km. It is formed from many unnamed streams and reservoirs. The river has two main tributaries. An assessment of the Buniv River basin's territory was carried out based on remote sensing data (Sentinel 2, SRTM) and topographic maps (figure 2). As we can see, the catchment area obtained using DEM processing is not relevant to the actual real situation in south-western part (near villages Kysorychi and Masevychi). There, the network of drainage channels and regulation constructions has altered the conditions of flow accumulation. It's a good illustration of the necessity of using topographic maps for hydrological research within Volyn Polissia where similar constructions is widely spread.



(*a*) (*b*)

Figure 2. Setting catchment boundaries according to satellite data (*a*) and topographic map (*b*).

The analysis of the obtained cartographic models indicates a significant anthropogenic transformation of the natural landscapes. A significant part of the watercourses of the Buniv River basin was once directed and transformed into main canals of the meliorative systems (figure 3). As a result, the profile of the riverbed and its tortuosity have changed. The direction of the river's hydrographic network led to an increase in the slopes, carrying capacity, and speed of the flood wave.

Also, engineering surveys and a full-scale survey of the basin territory indicate that currently there is an increase in anthropogenic load on the river basin due to the overregulation of river flow, floodplain development, changes in morphological parameters, flooding of the territory, and so on. In our opinion, the changes in the structure and the water body's functioning parameters are a consequence of the manifestation of transformation and degradation processes that develop under the influence of natural and anthropogenic factors.

Today, the economic development of the catchment area is quite high. A significant percentage of the territory is located in residential areas; the floodplain of the river is disturbed and built

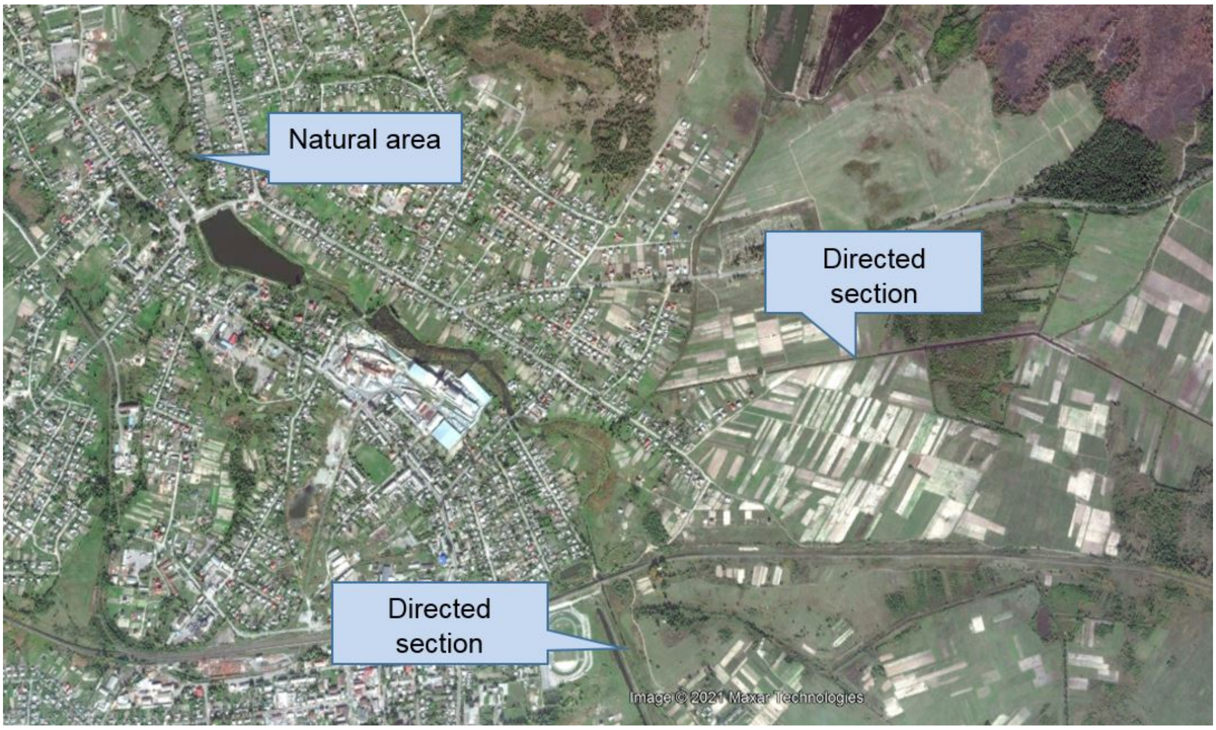


Figure 3. Typical natural and directed sections of the Buniv River hydrographic network (image source: Google Earth Pro).

up. Uncontrolled and untreated surface runoff flows from the residential areas to the Buniv River and, accordingly, to the reservoirs in Rokytne. Most often, these are formed after heavy rains or during the melting of snow cover. A significant part of the households at Rokytne are located in the floodplain of the river, in the zone of possible territory flooding during floods and inundations.

In general, the Buniv River basin chosen for the study is typical for the border part of Volyn Polissia. Its main features include a significant transformation of the natural hydrographic network into a system of ameliorative channels by straightening riverbeds; the presence of water-regulating structures that are not always in good condition; the significant drainage of wetlands; the insufficient carrying capacity of some bridge crossings; the active use of floodplains for residential development and economic activities; the insufficient density of the monitoring system for registering extreme precipitation in the small river basins.

These factors pose a danger to aquatic ecosystems, the population and engineering infrastructure of the border areas.

4. Results and discission

4.1. Hydrological and morphological assessment of the river

For evaluating the valley and riverbed transformation, and undertaking management decisions on the flood safety of territory planning, we performed a topographic survey of the Buniv riverbed and valley within the most affected part of Rokytne.

The analysis of the constructed longitudinal profile along the river axis (the diagram is shown in figure 1) allowed dividing the study into five sections, differing in their carrying capacity and passing conditions of the flood wave.

1. The section near the railway bridge (from PK 24 to PK 19) has a length of 500 m. The

average slope is 0.022%, rectilinear; it has ridge formations of bottom deposits with a length of 14..16 m. and a height of 0.3..0.4 m. This situation is typical for the Buniv River almost along its entire length. As a result, the first section has the appearance of the non-typical flat Polissia river (figure 2), and represents the principal channel. These transformations contribute to a shorter duration of water standing on the floodplain, but the floods become more pronounced with higher maximum costs. Thus, this section is estimated at a comparably high carrying and transport capacity, which intensely transfers water to the next section.

2. The next section further downstream (from PK 19 to PK 16+75), with a length of 300 m, is characterized by a conditionally undisturbed current; it has a formed meander, as a result of which the channel slope decreases by 30%, having an average slope of 0.013%. A decrease in the river's slope leads to a decrease in the flow rate, the ability to carry deposits, and, accordingly, an increase in water levels at the maximum flow rates.
3. Further, the riverbed (the section from PK16+75 to PK12.0 with a length of 475m) is under the influence of a bridge crossing. From the upper part, from PK16+75 to the bridge, the channel is positioned, due to the support of the stream by the river crossing. The water level on the site is close to the horizontal level and has a slope of 0.003%. A sharp drop in speed causes sediment deposits in this area during the decline of floods and inundations. In the future, shallow water will form on this site, additionally overgrown with higher aquatic vegetation. Further floods begin at higher bottom levels and, accordingly, at higher water levels. Below the bridge, there is an increase in the slope to 0.067%, a significant acceleration of the flow causing bottom erosion. This is due to the high rates of compressed flow coming out of the bridge opening.
4. The next section (from PK16+75 to PK 6+75) with a length of 1000 m is the surface of the enterprise's reservoir and has a zero hydraulic slope. For a long time, the reservoir was not operated according to the design modes. Instead of the normal headwater level mark at 171.25, which is provided for in the project, the mark of 170.70 m is kept. This is due to developments at the territory previously allocated for the reservoir. Due to the decreased depth, the reservoir is a shallow water area with developed higher aquatic vegetation. From the point of view of flood safety, the section is characterized by low carrying capacity due to the significant overgrowth of the riverbed with aquatic vegetation and almost zero hydraulic slope. In addition, it determines the operation of the stage opening on the PK 13+30 in the flooded spillway mode, which approximately by 10..15% reduces its carrying capacity.
5. The section of the next reservoir also has a zero hydraulic slope. In addition to the functionality of the culverts, the reservoir is in a good condition. The lack of proper regulation of water discharge affected the scale of flooding in Rokytne during the flood on 17.05.2019, figure 4 shows the impact of existing engineering infrastructure on the formation of flood zones. As can be seen, there is an excessive compression of the river flow, which causes the flooding of the river valley.

We have calculated the maximum flow rate through the opening of the road bridge on 8 Bereznia Street in Rokytne. (indicated by the arrow in figure 5) for the flood conditions on May 17, 2019, as for a spillway with a wide threshold of 26.6 m^3/s. This corresponds to a provision of 3%, that is, 1 time in 30 years; these floods can occur in the summer.

4.2. Proposed solutions
Operation of culverts

The lack of water level regulation at culverts during the May 17-19, 2019 flood caused a short-term overflow of water through the earthen dam. It has been established that the erosion of an earthen dam during the floods leads to a breakthrough and the formation of a wave with a

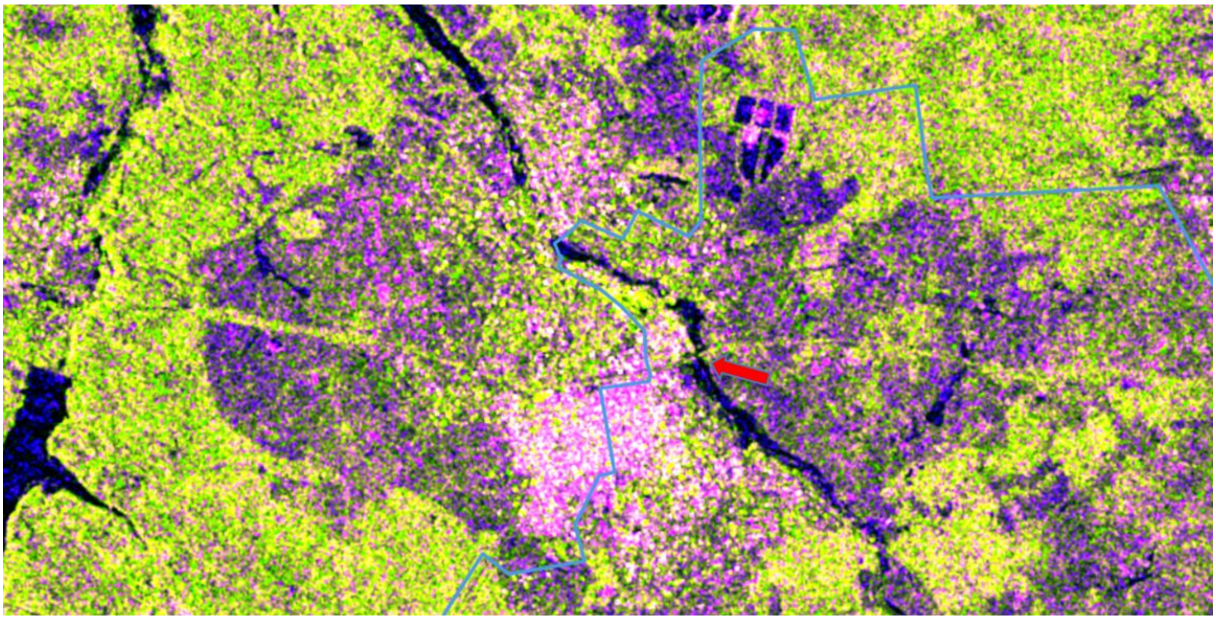

Figure 4. Fragment of the basin of Buniv River during the flooding on May 17, 2019 (model obtained using EOS Land Viewer).

great destructive force. This was prevented by the retention of a certain amount of water by the technical reservoir of the glass factory, as well as flooding of the floodplain above the automobile bridge.

In addition, the backup of water from this reservoir reduced the carrying capacity of the objects located upstream, which certainly contributed to a long stay of high water levels in the flooded areas.

Thus, a necessary condition for flood management is the development and implementation of a reservoir management plan depending on the meteorological situation in the river basin.

Technical capabilities of flood runoff redistribution

The technical capabilities for delaying this volume at the Buniv River's catchment area above Rokytne will allow floods in the banks of the river to pass through the village. However, the possible regulation of runoff should still include the release of water into the floodplain, as this is an important component of maintaining the ecosystem and the river water quality.

It should be noted that it is unlikely to find such opportunities without allocating land plots for polders or reservoirs. We estimated the flood volume to be 3.45 million m^3. In order to retain this amount of water within the Buniv River's tributaries, it needs to have a total length of about 700 km. The river basin does not have such a developed hydrographic network. This approach also requires a significant number of regulatory structures at individual channels.

A technically possible method is to transfer part of the flood runoff (figure 5) from the Buniv River to the Lva River (above the villages of Masevychi, Buda) and the Berest River (in front of Rokytne and near Lisove village).

To do this, it is necessary to arrange either appropriate cross regulators, or lay pipeline structures that have a carrying capacity at a safe level for Rokytne's flow rates, whose value shall be determined by calculation. The economic feasibility of this type of construction should be justified by the agricultural, flood control and other needs and costs for their maintenance.

According to DSTU 7369:2013, the bottom deposits of the Buniv River belong to Group 1 of

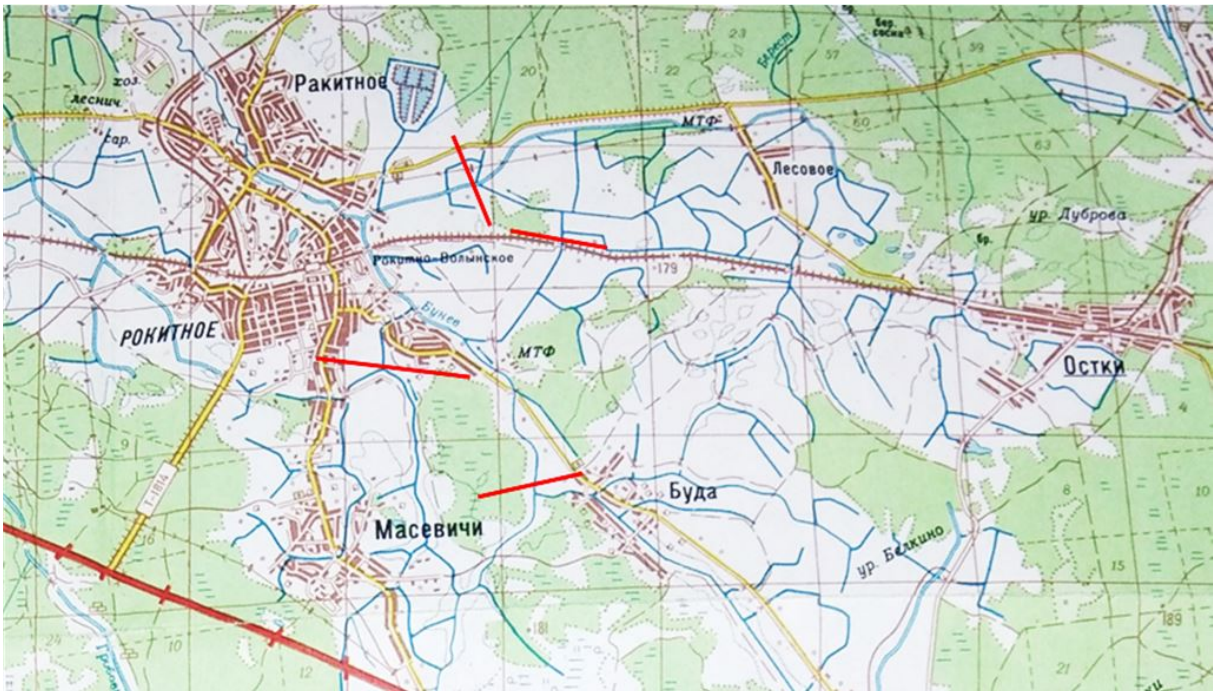

Figure 5. Creating a possible redistribution of flood runoff.

the group's classification for the permissible values of heavy metals in the deposits. Regarding the maximum permissible concentrations (MPC) of chemical elements in the soil, an excess content in the bottom deposits of the Buniv River was observed only for Co, averaging 1.6 times at the cross-section, and Cd averaging 2.3 times at the cross-section. High levels of heavy metals in water or other media have a toxic effect, and the accumulation of such elements in the tissues of hydrobionts causes a violation of biochemical processes and physiological functions.

4.3. Limnological surveys

The analysis results of the chemical element content in the bottom deposits of the studied section (table 1) indicate the presence of all six studied elements.

Table 1. Chemical composition of the bottom deposits of the Buniv reservoir.

Cross-section No.	Indicators						
	Cs137, Ci/km^2	Cu	Zn	Mn (mg/kg)	Co	Cd	Pb
1	0.017	2.25	17.4	234.8	6.1	1.3	13.0
2	0.016	2.21	4.00	237.4	5.7	1.4	15.1
3	0.018	2.86	4.25	251.6	5.9	1.3	14.8
4	0.003	2.18	5.10	197.2	5.3	1.7	14.6

The source of anthropogenic entry of heavy metals into water bodies is primarily associated with road transport and wastewater, including natural causes such as the decomposition of dead hydrobionts.

4.4. Hydrochemical assessment of the Buniv River's surface water quality

The surface water quality of the river was assessed using the main hydrochemical indicators, which are crucial in the formation of the surface water quality of Volyn Polissia's typical rivers. The summary results of the Buniv River surface water quality assessment, namely, the actual concentrations of biogenic substances, the multiplicity of exceeding environmental standards and the degree of surface water pollution are presented in table 2.

Ammonium and nitrogen ammonium. The concentration of ammonium in water bodies for domestic use should not exceed 2 mg N/dm^3 by nitrogen. MPC$_{fishfarm}$ of ammonium salt is 0.5 mg N/dm^3 (by nitrogen) (this limiting indicator of harmfulness is toxicological). According to European standards, the concentration of ammonium in recreational reservoirs should not exceed 0.1 mg NH_4/dm^3.

The presence of ammonium ions is mainly associated with the processes of biochemical degradation of the protein substances, deamination of amino acids, and decomposition of urea under the urease action. The content of ammonium ions in natural waters varies from 12 to 205 mg N/dm^3 in terms of nitrogen. During the transition from oligotrophic to meso – and eutrophic reservoirs, both the absolute concentration of ammonium ions and their share in the total balance of bound nitrogen increase.

The presence of ammonium in concentrations near 1 mg/dm^3 reduces the ability of fish hemoglobin to bind oxygen. The signs of intoxication are disturbances, convulsions, the fish throws itself on the water and jumps to the surface. The mechanism of toxic action is a violation of the central nervous system, damaging the gill epithelium, hemolysis (rupture) of the red blood cells. The toxicity of ammonium increases with increasing pH medium. The increased concentration of ammonium ions can be used as an indicator that reflects the deterioration of the sanitary condition of a water body, the process of contamination of the surface and underground waters, primarily by domestic and agricultural effluents.

Nitrites and nitrite nitrogen. For nitrites, the MPC$_{household}$ is set at 3.3 mg/dm^3 as an ion of NO_2^- or 1 mg/dm^3 in terms of nitrogen. The MPC$_{fishfarm}$ is 0.08 mg/dm^3 as an ion of N_2^- or 0.02 mg/dm^3 in terms of nitrogen. According to European standards, the concentration of nitrites in recreational reservoirs should not exceed 0.03 mgN_2^-/dm^3.

Nitrites are dissolved in surface waters. The acidic waters may contain small concentrations of nitric acid (HNO_2^-) (not dissociated into ions). The increased content of nitrites in the Buniv River indicates an increase in the decomposition of organic substances under conditions of slower oxidation of NO_2^- into NO_3-, which indicates the contamination of the water body.

Nitrates and nitrate nitrogen. The MPC$_{household}$ for nitrates is 45 mg/dm^3, or 10.0 mg/dm^3 (for nitrogen) and the MPC$_{fishfarm}$ is 40 mg/dm^3 (by NO_3-) or 9.1 mg/dm^3 (by nitrogen). According to European standards, the concentration of nitrates in recreational reservoirs should not exceed 5.0 mg NO_2^-/dm^3. The presence of ammonium nitrate in concentrations of up to 2 mg/dm^3 does not cause a violation of biochemical processes in a reservoir; the maximum concentration of this substance, which does not affect the sanitary regime of the reservoir, is 10 mg/dm^3. The harmful concentrations of nitrogen compounds (primarily ammonium) for various fish species are on the order of hundreds of milligrams per 1 dm^3 of water.

Phosphates. The MPC$_{household}$ for phosphates is 3.5 mg $PO_4{}^{2-}$/dm^3, the MPC$_{fishfarm}$ is 0.05 mg $PO_4{}^{2-}$/dm^3.

According to European standards, the concentration of phosphates in recreational reservoirs should not exceed 0.2 mg of $PO_4{}^{2-}$/dm^3. The excessive phosphorus compounds from various sources such as mineral fertilizers, untreated domestic wastewater, and industrial waste are being carried by surface runoff from fields into the river. This inflow causes significant growth in the water body's plant biomass. As the concentration of phosphorus in the water increases, it changes the trophic status of the reservoir, leading to a restructuring of the entire water community. This restructuring results in the prevalence of putrefactive processes, leading to

Table 2. The Buniv River's surface water quality assessment.

Control point	Actual content, mg/dm^3	Multiplicity of exceeding			Water quality category	Contamination level
		fish farm norms	household norms	Directive 76/160/EC		
			by nitrites content			
1	0.490	8.4	0.2	–	4.8	Dirty – very dirty

			by nitrite nitrogen content			
1	0.180	10.0	0.2	6.7	7.0	Very dirty
2	0.014	0.7	0.0	0.5	4.7	Moderately polluted
3	0.076	3.8	0.1	2.5	6.5	Dirty- very dirty
4	0.059	3.0	0.1	2.0	6.2	Dirty
			by nitrates content			
1	1.800	0.1	0.0	–	–	Slightly polluted
2	3.200	0.1	0.1	–	–	Polluted
3	6.200	0.1	0.1	–	–	Dirty
4	5.700	0.2	0.1	–	–	Very dirty
			by nitrate nitrogen content			
1	0.630	0.1	0.1	0.1	4.1	Slightly polluted
2	0.310	0.0	0.0	0.0	1.2	Very clean
3	1.440	0.1	0.1	0.3	6.4	Dirty
4	1.390	0.2	0.1	0.3	6.2	Very dirty
			by phosphate content			
1	1.100	7.1	0.3	5.4	7.0	Very dirty
2	0.710	4.0	0.2	3.0	7.0	Very dirty
3	0.820	5.8	0.2	4.4	7.0	Very dirty
4	0.900	6.7	0.3	5.0	7.0	Very dirty

an increase in turbidity, salinity, and bacterial concentration. One of the components of the eutrophication process is the proliferation of cyanobacteria, also known as blue and green algae. Several of these algae produce toxins that fall under the category of phosphorus and sulfur-containing organic compounds, which can be neuro-paralytic. The toxins produced by these algae can result in various health issues such as skin disorders and gastrointestinal ailments. In severe cases, paralysis may even occur when a substantial amount of algae enters the body.

Biochemical oxygen consumption. The $MPC_{household}$ of BOD5 is 3.0 mg/dm^3; for $MPC_{fishfarm}$ it is 2.0 mg/dm^3. According to European standards, the BOD5 indicator is not normalized in recreational reservoirs. BOD5 identification in the surface waters is used to assess the content of biochemically oxidized organic substances, the living conditions of hydrobionts, and as an integral indicator of water pollution.

Dissolved oxygen. The $MPC_{household}$ for the content of oxygen dissolved in water is >4.0 mgO_2/dm^3; for $MPC_{fishfarm}$ it is >6.0 mgO_2/dm^3. According to European standards, the content of oxygen dissolved in water in recreational reservoirs is not normalized. The content of oxygen dissolved in water reflects the intensity of the processes in the hydrobiochemical systems. The oxygen identification in the surface waters is included in the observation programs to assess the living conditions of hydrobionts, including fish, as well as indirect features of surface water quality assessment and wastewater treatment management. The content of dissolved oxygen is necessary for aerobic respiration and is an indicator of biological activity (i.e. photosynthesis) in the reservoir.

4.5. Managing a transformed river basin

The assessment of the transformation level in the Buniv River basin makes it necessary to improve the monitoring system within the river basin, as the main tool for assessing and predicting changes in the aquatic ecosystem and managing the processes of its anthropogenic transformation. Water quality monitoring can be effectively supported through the use of satellite technology [12, 13].

The basic model of monitoring the condition of the Buniv River and its objectives can be presented in the form of a diagram given in figure 6.

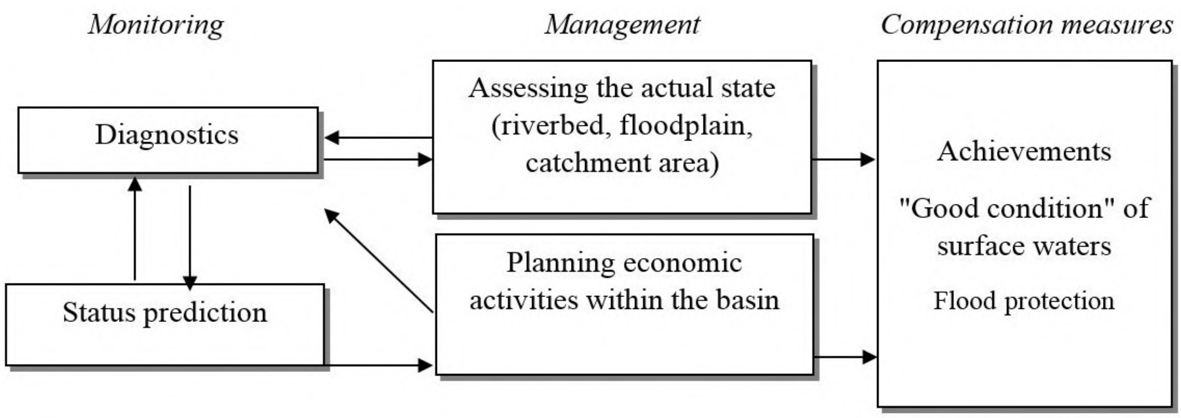

Figure 6. Flowchart for surface water quality monitoring and management.

Public environmental monitoring, if implemented, could be a valuable supplement to the existing system of monitoring water bodies. This will increase the availability of environmental information for all stakeholders, quickly obtain the necessary data in the event of an emergency accident, as well as current, regular monitoring of the impact of water users on the ecological state of the rivers. Local public organizations in the framework of public monitoring should perform the following functions: monitoring objects that are not included in state monitoring programs; implementing environmental control and notification of accidents and emergencies; developing environmental education and awareness; evaluating the environmental impact of projects for planned activities within river basins, etc.

For the effective management of border area basins, including the Lva River, it is necessary to create a Basin Council, which will include the representatives of Sarny District Administration, the Rivne Regional Office of Water Resources, the State Environmental Inspectorate in Rivne region, scientists, public activists and water users of the river basin. The main task of Basin Councils will be to develop, coordinate and approve the River Basin Management Plans. An important issue in the Council's activities is monitoring the implementation of the planned water protection measures within the river basin.

5. Conclusions

For the effective management of water resources in border areas, it is necessary to develop and implement water protection measures that are defined in the river basin management plans and develop and implement a joint program for public monitoring of the cross-border rivers.

The increase in the social and economic risks in the study area and the material losses associated with flooding the households in the floodplain of the Buniv River are caused by anthropogenic factors, namely, the development of the river floodplain, the violation of the requirements of the Water Code of Ukraine and ignoring the danger from natural flood and overflow phenomena.

It is possible to reduce the threat of territorial flooding and ensure the flood safety of the river cross-border territories of the Polissia zone by applying organizational and economic measures and implementing the following compensatory hydraulic measures:

- A periodic clearing of the riverbed section adjacent to the bridge from the deposits coming from the upper sections. This will help to increase the slope on the site, reduce the hydraulic resistance of the bottom turbulence and reduce the likelihood of spillway operation in semi-pressure and pressure modes;
- Reducing the resistance of water flow at culverts and reservoirs, creating flood corridors.

Reservoirs require developing regulatory rules that provide for the level of water response depending on the current meteorological situation. Thus, if the amount of precipitation in three days reaches 20 mm, then it is already advisable to clear the river valley, prepare households for high water levels and work with both reservoirs in order to overcome flooding.

The most effective approach to prevent flooding of large areas of Rokytne is to prevent the inflow of significant water consumption within the city limits. To do this, one should: arrange structures above the village that will allow the transfer of runoff through a network of channels.

The surface water quality assessment shows that the overall ecological state of the surface waters of the studied aquatic ecosystem is assessed as unsatisfactory. The block of tropho-saprobiological indicators is dominant and determines the water quality. At the same time, its deviation from the environmental standards is primarily caused by the biogenic elements of the nitrogen group (ammonium, nitrite and nitrate nitrogen) and phosphates.

In the upper and middle part of the river basin, it is necessary to carry out organizational and economic measures to reduce the inflow of pollutants with diffuse runoff, as well as hydraulic works to clear the riverbed and the riverbank stabilization. Also, in the middle section of the river, it is necessary to clean the surface waters of the river from the excess regional content, nitrite nitrogen, phosphates; we propose equipping a bioplateau according to the type of surface flow and an aeration treatment corridor.

Abstract. The article analyzes modern scientific approaches to sustainable finance and features of the transition of national financial systems, markets, financial flows in the direction from unsustainable to innovative sustainable technologies. The latest practice of implementing investment and financial activities in accordance with the goals of sustainable development is systematized. In the context of building a system of sustainable finance in Ukraine, the parity of two vectors of its functioning should be taken into account: ensuring both the sustainability of the financial sector itself and the sustainable functioning of the economy as a whole. That is, the development of the national system of sustainable finance in Ukraine is based on the generally recognized world practice in the field of sustainable finance and the decisions of the United Nations Organization, which relate to the financial aspects of sustainable development. In the context of this transformational process, Ukraine joined the Paris Agreement and received the Second Nationally Determined Contribution, which is a concept of state development to achieve ecologically and economically expedient transformations in all sectors of the economy. Financing of the Second Nationally Determined Contribution by 2030 should include a combination of domestic budget allocations, the private sector (domestic and foreign), bilateral and multilateral financial mechanisms, and international assistance. The article focuses on the need to understand the concepts and tools for ensuring financial stability, to determine the differentiated characteristics of the main directions of the transformation of the financial system and typologies of its transition. The authors single out the basic characteristics of transitions to sustainability and innovation processes: rethinking the achievement of new economic, environmental and social goals; time limit; creation of new socially inclusive, fair, ecologically sustainable economic systems; rejuvenation of the economic system through constant innovation; ensuring support for the financial orientation of transitions to sustainable development, which require integration and coordination of financial flows.

1. The problem

Since the Rio 2012 Summit, the issue of financing the needs of sustainable development has come to the forefront of the activities of the global establishment, academics and the business community. It is becoming increasingly clear that only with the establishment of a financial system that is sustainable and at the same time capable of providing financing for sustainable development can the complex of problems related to sustainable development of the state be effectively addressed. Over the past 20 years, the concept of sustainable finance has emerged and gradually become more widespread under the auspices of the United Nations Environment Program's Finance Initiative. It has accumulated a new financial paradigm of taking into account social, environmental and governance factors (the so-called ESG criteria) of sustainable development in financial activities, as well as the principles of responsible financial behavior. To date, the world has gained considerable experience in organizing sustainable financial activities in various industries and areas. However, in Ukraine, very little attention has been paid to the concept of sustainable finance, as well as to the theoretical, methodological and practical aspects of organizing sustainable financial activities to achieve the goals of climate stability and sustainable development. Therefore, the tasks of substantiating the theory and methodology of applying sustainable finance practices in Ukraine and adapting existing concepts of financial sustainability to the conditions of our country are very relevant.

The purpose of the publication is to characterize the possibilities of organizing a sustainable financial system in Ukraine to achieve the goals of climate stability, financing sustainable development and ensuring sustainable management in the country based on the implementation of the best international recommendations and practices in the field of sustainable finance.

2. State of finance in sustainability transitions research

The transition of the globalized economy and the world financial system to sustainable development requires a fundamental transformation of national financial systems, markets, financial flows in the direction from unstable to innovative sustainable technologies, the latest practice of implementing investment and financial activities in accordance with the goals of sustainable development. This applies both to the energy transition, where new low-carbon technologies are more capital-intensive and environmentally friendly, and to other areas of the economy, for example, the transition to sustainable urbanization, circular economy, green energy, etc.

It is undeniable that the transition to sustainability also concerns the financial sphere, which provides society with the necessary resources, and the economy with mechanisms and tools for financing changes. It should be noted that the specifics of the functioning of the financial system and its role in the transformation to sustainability have been studied by foreign and domestic scientists. Such interest in the scientific community is explained by the fact that financial capital is an interchangeable resource that is instantly directed to new technologies through free capital markets according to neoclassical economic models. Another feature of financial capital is that it has a wide variety of forms and structures, is often distributed through financial intermediaries and other actors whose activities are based on existing institutions and infrastructure [1].

Also, the "green" essence of sustainable finance is reflected in the distribution of idle social capital between different economic sectors, such as renewable energy, green cities and buildings, climate crises, corporate governance and environmental protection.

Having analyzed scientific publications related to the actualization and conceptualization of the transition of finance and financial systems to sustainability, it is possible to single out the following main directions of their research.

The first concerns research on the connection between financial crises and the transition to the concept of sustainability, as well as the direct development of conceptual approaches to ensure the development of sustainable finance. In particular, Geels [2] analyzes the crisis of 2008-2009, where attention is focused on its potential for the transformation of global economic systems, the possibility of initiating such a transition, and the analysis of state policies for responding to crisis phenomena.

The research by Quatrini [3] is devoted to the impact of the global pandemic crisis of COVID-19 on the transition to a sustainable future and sustainable investments, it is proposed to use decision support tools (DST) for ensuring sustainable development that contribute to investment decisions – ranking, sustainability ratings, standards, strategies, etc. The author comes to the conclusion that in order to effectively make an investment decision, it is necessary to change the existing practice of assessing sustainability, using new technologies and tools (artificial intelligence for checking the forecasting results, the rating model Impact ÆSSURANCE).

As mentioned above, publications related to the development of the conceptual foundations of the development of sustainable finance, the identification of connections between sustainability and, for example, "green" finance, should be included in this group of developments. This problem is highlighted by Wang et al [4], in which the authors emphasize that in order to achieve the goals of sustainable development, all sectors of society need to invest approximately 5 to 7 trillion US dollars annually, and the Paris Agreement provides for long-term financing with cost-benefit calculations, and within a certain period time and significant global investments.

Urban and Wójcik [5] offers a conceptual approach to sustainable finance as a multi-level socio-technical system in which the financial sector functions in a socio-technical landscape. The landscape is seen as a superstructure that includes various social groups and institutions governed by intersubjective norms that result from the process of globalization and capitalization of markets. In turn, as the authors note, capitalism and globalization, which are the main components of the modern financial regime, have a negative impact on both the regime and the trajectory of niche innovations. All this slows down the transition of the financial system to the conditions of sustainability.

Second, a number of scholars consider the availability of financial capital as an investment, energy, climate and environmental issue: for example, how new climate technologies and sustainable finance enable green growth, and using a cross-supplemented ARDL model found that climate technologies, access financial institutions to green investments and the circulation of green bonds (financial market efficiency) significantly reduce carbon emissions [6].

Furthermore, Ronaldo and Suryanto [7] prove that green investment (the indicators of which are waste management, investment in green enterprises and processing, ecological production) is of vital importance for achieving the goals of sustainable development of rural areas from the point of view of ecological and economic sustainability due to the implementation of "green" technologies, which in turn will lead to the development of "green" micro-entrepreneurship and improve the population's vital indicators.

In the framework of this direction, sufficient attention of scientists is devoted to the problems of sustainable financing and the development of the state policy of the transition to "green" energy. Besides, in the article [8], the impact of green financing and renewable energy sources (solar energy, bioenergy, hydropower and wind energy) on the sustainable development of China was investigated. Zhou and Li indicate that there is a significant need for an effective public policy regarding the widespread use of renewable energy to reduce environmental degradation and improve public health at a high level of economic activity.

Li et al [9] updated and modeled the connections between "green" financing, volatility and geopolitical risks regarding investments in renewable energy sources. The results of the study showed that green finance (in the form of green bonds) and green regulations, such as environmental taxes, play a significant and positive role in encouraging investment in renewable energy sources. Nevertheless, oil price volatility and geopolitical risk have a negative impact on the structure of investments in clean energy sources.

Thirdly, individual institutional components of the financial system are investigated, the prospects for their changes and the expansion of the range of financial instruments ensuring the transition of the financial market to sustainability are determined.

Since 2009, when the World Bank issued the first green-labeled bond for a group of Swedish pension funds, the market for fixed investment products has significantly evolved, expanded and diversified through the introduction of new structured finance instruments. In addition to green bonds, the market now offers blue bonds, social bonds, sustainable development bonds, disaster bonds.

Today, individual assets of direct investment funds, investment funds, exchange funds and those created on the basis of public-private partnerships, mixed financing instruments (multi-level investments) and risk-sharing instruments (guarantees, weather insurance, first loss capital), other instruments raising public and/or private sector capital for specific purposes, often related to achieving sustainability or other environmental or social commitments [3].

The transformation of the financial system into a sustainable one requires taking into account the prerequisites of the concept of sustainability in the activities of financial institutions, including banks. In the study [10], a benchmark assessment of the sustainability practices of 37 largest banks by total assets, located in Europe, America, Asia, Africa and the Asia-Pacific region, was carried out. The author found that the percentage of banks that adapted their management structure and implemented measures that contribute to increasing the level of sustainable development culture increased by 25% compared to 2020 and reached 74%. Banks have implemented the following measures: sustainability training programs (84% of assessed banks), sustainability policies (81%) and board statements on sustainability commitments (84%). However, it should be noted that the degree of consideration of non-financial factors varies depending on financial institutions. Usually, such actions are carried out by large international banks, for example, Societe Generale, Hongkong and Shanghai Banking Corporation-HSBC, Credit Agricole, Triodos).

Fourthly, part of the publications is focused on the issues of the systemic nature of sustainable finance (systemic approach) and the transformation of the financial system to the conditions of sustainability. Thomas and Mantri [11] considered finance as a complex adaptive system of systems (CASOS), which complicates its design for sustainable development using traditional approaches. The work proves that the problem of sustainability is multi-scale / multi-model, which is inherently adaptive and requires that adaptive agents evolve together with the corresponding cohort system. The authors propose an axiomatic approach to the design of sustainable finance that takes into account the vision of sustainable development as meeting the needs of the present without compromising the ability of future generations to meet their own needs.

Naidoo [12] conducted a thorough study of a new approach to overcoming the polarity of the financial system by interpreting the characteristics of the process of its transition to sustainability from the point of view of meeting certain requirements. According to the Naidoo, there are five initial requirements – changes in the direction of development, temporal dynamics, the influence of coexisting systems, a conflicting social context and contextual experimentation. That is, the article offers initial parameters that inform about the reaction of financial systems to the requirements of the transition to sustainability and make it possible to evaluate it.

Thus, the financial system is able to provide radical and transformational changes to sustainability in the economy, large-scale investments in infrastructure, despite the challenges of the crisis. In addition, the challenge of the gradual transition to sustainable finance lies within an interconnected global financial system that is struggling to keep pace with the digital economy and ensure resilience to new risks. Therefore, the above-mentioned global contexts, challenges and the need to understand the possibility of gradual transformation of the national financial system to sustainability determine the relevance of this study.

3. The basic institutional foundation of the formation of the national system of sustainable finance in Ukraine

When considering the formation of the national system of sustainable finance in Ukraine, first of all, it is necessary to pay attention to the main positions of the national model of sustainable management, which is aimed at ensuring socio-ecological and economic growth due to the inclusion of natural, physical and human capital in economic circulation (input effects), ensuring the corresponding structural changes in the economy, primarily in the "green" direction, taking into account the climatic requirements of sustainability (efficiency effect); the need to make powerful investments in the reconstruction and modernization of infrastructure, including both its industrial, social and environmental components (stimulus effects) and stimulation of relevant innovative activity, primarily in the field of development of environmentally friendly and climate-neutral technologies (innovation effects).

It is obvious that according to the above positions, building a system of sustainable finance in Ukraine must first of all take into account the parity of two vectors of such a system, that is, ensuring both the sustainability of the financial sector itself and the sustainable functioning of the economy as a whole. Thus, by building responsible financial behavior and purposeful financing of sustainable development measures, taking into account environmental, social and economic priorities, it is necessary to ensure the implementation of such processes as:

- firstly: the inclusion of natural, production, financial, human and other resources in economic circulation with the help of specific financial instruments – "green" instruments of the stock market, loans, insurance policies, etc.;
- secondly: sustainable financing of the "green" transition with the aim of minimizing climate change and reducing the economic burden on the environment as a whole;
- thirdly: the formation of powerful investment resources for the stabilization of the economy and the implementation of the investment policy of sustainable development,
- fourth: creation of a system of financial support for innovations aimed at greening the economy, "green" technological structural changes, minimizing the impact on the climate, taking into account the most modern trends in the implementation of the financial policy of sustainable development of the UN and the leading countries of the world.

Taking into account the above, the development of the national system of sustainable finance in Ukraine should be based on the universally recognized practice in the field of sustainable finance and the decisions of the United Nations Organization, which relate to the financial aspects of sustainable development. Thus, at the 75th General Assembly of the United Nations (UN) in September 2020, it was emphasized that the last decade has become the hottest in the history of mankind, the concentration of greenhouse gases continues to grow, so humanity must urgently change course, there are less than ten left years, and therefore already in the next decade, that is, by 2030, it is necessary to ensure appropriate changes in the management of the economy and finances in order to minimize further negative impacts on the natural environment and to allocate appropriate financial resources for this [13].

Today, it is recognized that climate and environmental challenges require a change in the financial policy of governments and individual financial institutions in the direction of organizing sustainable financial activities and forming an effective system of sustainable finance at the level of countries and the world. Today, climate and environmental challenges are recognized by the European Central Bank (ECB) as two main risk factors. According to the estimates of the Bank for International Settlements (BIS), they are one of the sources of systemic financial risks and may become the cause of the next global financial crisis [14]. The UN Framework Convention on Climate Change (1992), the UN Agenda for Sustainable Development until 2030, and the 2015 Paris Agreement on Climate Change are the main documents that countries should be guided by to confront climate challenges and achieve a sustainable future.

The specified documents, in particular, state that one of the three ways to combat climate threats in the context of sustainable development is to ensure the consistency of financial flows with the direction of low-carbon and climate change-resistant development of various-scale territorial entities (regions, countries, global economy, etc.).

According to these documents, starting from January 1, 2021, each country chooses its goals for reducing and/or limiting greenhouse gas emissions. Such goals are characterized as Nationally Determined Contributions (NDCs). The main goal of the Paris Agreement includes the following three sub-goals:

sub-goal (a): keep the increase in global average temperature well below +2 °C above pre-industrial levels and focus efforts on limiting temperature increase to +1.5 °C above pre-industrial levels, as this will significantly reduce the risks and impacts of climate change;

sub-goal (b): increasing the ability to adapt to the negative impacts of climate change, supporting climate change mitigation, development with low greenhouse gas emissions in a way that does not threaten food production;

sub-goal (c): harmonization of financial flows with the path of development, with countermeasures against climate change and with low emissions of greenhouse gases [15] (figure 1).

The main differences between the Paris Agreement and the Kyoto Protocol are as follows:

- First: changing the nature of the emissions reduction target from an “obligation” to a “contribution”. If the Kyoto Protocol provided for a legally fixed amount of greenhouse gas emissions for countries, which was not to be exceeded, the Paris Agreement gives each country the right to determine its contribution to the reduction of greenhouse gas emissions, taking into account national circumstances.
- Second: inclusion of all countries of the world with approved plans to reduce greenhouse gas emissions in the form of nationally determined contributions. The Kyoto Protocol provided quantitative commitments to reduce greenhouse gas emissions only from developed countries (Annex B to the Kyoto Protocol). Instead, the Paris Agreement consolidates contributions from countries that are Parties to the Paris Agreement.
- Third: introducing a bottom-up approach instead of a top-down approach, enabling all participants, not only at national, but also at local/local or even corporate levels, to contribute regarding the reduction of greenhouse gas emissions.

The participation of each individual country in achieving the global goal is determined by it individually and is called “Nationally Determined Contribution” (NDC). The Agreement requires that such contribution be “ambitious” and established “with a view to achieving the objective of the Agreement”. The country reports on participation and it is reviewed every 5 years.

Thus, participation in the Paris Agreement is largely voluntary and thus requires the development of appropriate frameworks and formats for sustainable financial behavior based on voluntary responsibility. The country’s participation is registered in the secretariat of the Framework Convention. Each subsequent participation parameter should be more ambitious than the previous one. Countries can cooperate and combine their nationally defined parameters of participation.

During the UN Climate Conference in 2015, the participating countries set their own obligations – the “Intended Nationally Determined Contribution” (Intended Nationally Determined Contribution), which will serve as the initial nationally determined contribution, if the country does not provide another in accordance with the procedure established by the

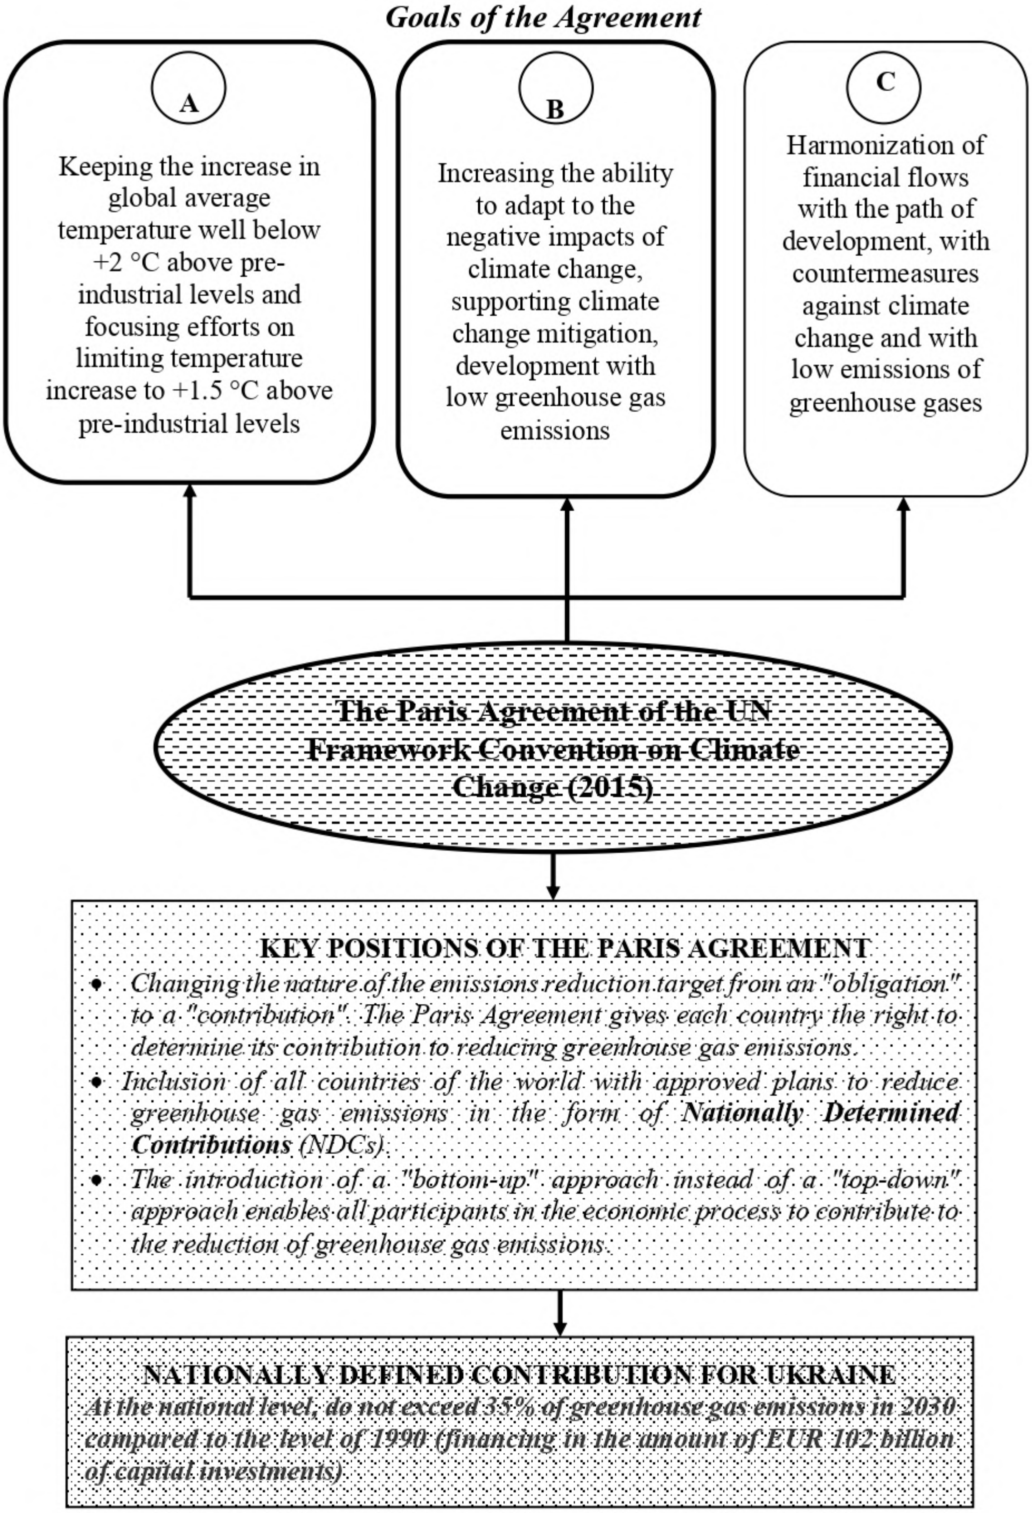

Figure 1. Formation of the nationally defined contribution of Ukraine to the Paris Agreement of the UN Framework Convention on Climate Change (based on [15, 16]).

Agreement. The level of each country's nationally determined contribution is determined by a voluntarily binding, but not mandatory, target.

At the end of July 2021, the government of Ukraine approved the updated national determined contribution of Ukraine to the Paris Agreement, according to which the current climate goal of Ukraine is to reduce greenhouse gas emissions to the level of 35% compared to 1990 by 2030 [17]. Among the main measures to achieve such an indicator in the next 10 years, it is necessary to implement and, accordingly, finance a number of economic tasks, which include: modernization of energy and industrial enterprises; development of renewable energy sources; energy efficiency measures in all sectors of the economy; thermal modernization of buildings; increasing the share of organic agriculture and resource-saving agricultural practices; electrification and renewal of transport; introduction of waste management hierarchy; increase in forest cover and reform of forest fund management [16].

It is noted that strategic goals for decarbonization and a consistent approach to their achievement are a logical continuation of Ukraine's European integration course.

4. Problems of financing the nationally determined contribution of Ukraine to the Paris Agreement

In order to achieve the declared goals of the transition to a low-carbon and resource-efficient economy and to ensure its sustainability, a clear state policy of sustainable financing is necessary, which involves not only a deep understanding of the content of environmental and social risks, but also the existence of an effective system for managing such risks. By financing relevant programs and projects, banks and other financial institutions play a key role in the decarbonization of the economy and the development of its resource efficiency.

In the context of the development of sustainable financing, Regulation 2020/852 of the European Union on the creation of foundations for the promotion of sustainable investment establishes six environmental goals of sustainable economic activity, namely mitigation of the consequences of climate change; adaptation to climate change; sustainable use and protection of water and marine resources; transition to a circular (closed loop) economy; pollution prevention and control; protection and restoration of biodiversity and ecosystems [18]. At the same time, the second (updated) nationally determined contribution of Ukraine to the Paris Agreement is the main document that will determine the goals set for achieving climate neutrality and the financial resources necessary for this. This document represents the concept of state development to achieve ecologically and economically expedient transformations in all sectors of the economy: energy, industry, transport, buildings, agriculture and forestry, waste management, etc.

Ukraine is a participant in key international agreements aimed at solving problems caused by environmental/climatic challenges. In accordance with the Paris Agreement of 2015, our state undertook to ensure that by 2030, the amount of greenhouse gas emissions produced by all sectors of the economy would not exceed 35% of the 1990 level. Achieving these goals requires strong financial support.

Thus, in March 2021, the Cabinet of Ministers of Ukraine approved the National Economic Strategy for the period until 2030 [19], according to which the country plans to achieve climate neutrality no later than 2060. According to experts, for the transition of Ukraine to a climate-neutral economy, it is necessary to attract about 102 billion euros of capital investments by 2030, that is, about 10 billion euros of annual financing [16]. The estimated investment plan is presented in table 1.

Financing of the Second (updated) Nationally Determined Contribution by 2030 should include a combination of domestic budget allocations, private sector (domestic and foreign), bilateral and multilateral financial mechanisms and development assistance. According to the experience of developed countries, the majority of resources should come from private investors, who are usually better at managing the risks associated with the construction and operation of

Table 1. Investments necessary to achieve the goal of the Second (updated) nationally determined contribution in 2021-2030 (project) [20].

Sector of the economic system	Capital investments, billion euros
In total	102
1+2. Energy + Industrial processes (without consumer spending)	93
Agriculture	2
Production of energy and heat	26
Industry	37
Buildings (excluding consumer spending)	16
Heating	16
Including thermal modernization of buildings	13
Extraction and transportation of energy resources	8
Transport (excluding consumer spending)	3
Private cars	3
3. Agriculture	2.3
4. Land use sector, changes in land use and forestry	3
5. Waste	2

facilities.

Thus, the role of the public sector will rather focus on providing the necessary regulatory tools, financial incentives and information that will facilitate the attraction of investment from the private sector. Both state and local budgets will play an important role in increasing capital investment in the various sectors of the economy represented in the Contribution. According to experts, financing from the private sector will provide approximately two-thirds of financing for the development of low-carbon infrastructure, and public sector resources will cover the rest through low-interest loans from state development banks or through special support programs [16].

Forecast calculations presented in the Project of analytical review of the updated nationally determined contribution of Ukraine to the Paris Agreement [16] lay the basis for the formation of a further algorithm of actions to ensure sustainable financing of the obligations of our state in accordance with the Paris Agreement.

Starting from August 27, 2022, the Ministry of Environment, together with the Ministry of Finance, the Ministry of Energy, the Ministry of Agrarian Policy, the Ministry of Infrastructure, the Ministry of Economy, the Ministry of Regions and the Government Office for the Coordination of European and Euro-Atlantic Integration have started the process of forming a road map of key transformations and measures to implement the updated nationally determined contribution to the Paris Agreement [21]. The operational plan of measures for the implementation of the updated nationally determined contribution to the Paris Agreement is being developed in order to strengthen internal coordination and monitoring of the implementation of climate goals, as well as to expand cooperation with international financial organizations and partners.

First, the plan should be broadly aggregated across all sectors represented in the updated Nationally Determined Contribution to the Paris Agreement and EBRD modeling results. Then, on the basis of these measures, the priority key transformations that the country must implement by 2030 will be formed, and the financial resources necessary for this will be identified. The document proposes, at the national level, not to exceed 35% of greenhouse gas emissions in 2030 compared to the level of 1990, or, in other words, to reduce greenhouse gas emissions by 65% in 2030 compared to 1990 [21]. The most important goal of developing such strategic documents for the development of climate finance in Ukraine is to ensure the effective use of public funds and the mobilization of private financial investments.

As an institutional basis for the formation of climate finance in Ukraine as a component of sustainable finance, national and territorial financial funds of the appropriate direction, budgetary institutions of the public financial sector and financial institutions of development can act. Ukraine can attract existing or create new state funds, for example a special state fund (Climate Fund, Green Transition Fund or Green Economy Fund).

In this way, it will be possible to finance climate projects both centrally and from various sources, as well as to facilitate their coordination and support transformations in selected sectors with the help of special programs. Examples of such institutions include the Modernization Fund operating at the EU level, and the National Fund for Environmental Protection and Water Resources Management operating in Poland. These funds are separate legal financial institutions that provide financing in accordance with accepted programs and criteria based on various support mechanisms – covering a portion of the loan, providing co-financing, grant programs, etc.

As financial institutions of the public sector, which are relevant to the climate component of sustainable finance, it is possible to consider, first of all, the state and local budgets, as well as the funds of various public organizations and associations. In particular, the State and local budgets should play an important stimulating role in increasing capital investments in various sectors of the economy. The main task is to create a favorable investment climate for the implementation of the “green” energy transition, to encourage business and private investors to invest in environmentally friendly technologies and infrastructure. One solution could be the extension of tax incentives to encourage green investments, for example, exemption from payment of sales VAT and excise tax on electric vehicles [22].

Development Financial Institutions (DFIs) will also play a major role in climate change financing and the formation of a national system of sustainable finance. Curently, there are many significant contributors to the financing of climate projects in Ukraine, including: Clean Technology Fund (CTF) of the World Bank; Global Environmental Fund (GEF), which operates in Ukraine through UNDP; UNEP and UNIDO; The Finland-Ukraine Trust Fund, established by NEFKO, and the Eastern European Partnership for Energy Efficiency and the Environment (E5P), established by the European Commission for the purposes of Ukraine. DFIs in the last decade have become an important source of sustainable investment in Ukraine, which ranks 4th in the world as a recipient of climate finance from such bilateral and multilateral sources.

In total, the EBRD and the EIB mobilized over 13 billion euros in loans and 2 billion euros in grants during 2014-2019, with the aim of helping Ukraine stabilize the economy and implement comprehensive economic reforms. The EIB mobilized €4.6 billion in loans to support infrastructure development and reforms in the transport, energy, agriculture, education and municipal sectors. EBRD investments in the amount of 4 billion euros were also attracted to promote the development and reform of the banking sector, agribusiness, transport and small business. In addition, the EU’s annual program of actions to support Ukraine is financed from the general budget of the EU.

Thus, in 2020, Ukraine attracted 165 million euros for several budget areas (agriculture and development of small farms; technical cooperation; civil society; climate actions) [16]. It is expected that the DFI will continue to play the role of a catalyst for attracting sustainable investment in Ukraine. According to the calculations of experts, if a third of the future financial aid to Ukraine from the EU in the period 2021-2030 is directed to projects to prevent climate change, about 10 billion euros can be attracted for Ukraine, which is equivalent to 1 billion euros per year, which, according to our according to estimates, it will cover at least 10% of the investments in our country estimated for climate goals.

The United Nations Development Program (UNDP) is also a powerful institution supporting the development of sustainable financing at the international level [23]. On January 24, 2022, in Kyiv, the National Bank of Ukraine and the United Nations Development Program (UNDP) in Ukraine signed a memorandum of cooperation (hereinafter referred to as the memorandum) in the field of development of sustainable financing standards and the application of environmental, social and management approaches (Environmental, Social and Governance – ESG) in the financial sector. According to this document, the parties will implement joint measures to ensure more sustainable, inclusive and "green" economic development with the aim of increasing the resilience of the financial system of Ukraine to environmental, social and managerial risks [24].

UNDP supported Ukraine's desire to create the necessary foundations for the development of sustainable financing in the country, taking into account the fact that the development of the "green" economy and "green" finance have become key areas of support for the authorities of Ukraine for UNDP. Thanks to the strategic partnership of UNDP and the National Bank of Ukraine, complex regulatory and institutional frameworks will be developed by 2025 to support sustainable financing in Ukraine in accordance with the previously proposed NBU Policy and Roadmap for the Development of Sustainable Financing in Ukraine. According to the statements of the leadership of the UNDP representative office in Ukraine, this organization is ready to further strengthen the potential of the National Bank to implement the Policy on the Development of Sustainable Financing for the period until 2025 and support the strengthening of the country's economy for the benefit of the Ukrainian people.

In turn, the National Bank of Ukraine undertook to actively work in the direction of promoting sustainable financing in accordance with the global concept of sustainable development and the European integration vector of Ukraine's foreign and domestic policy. According to the signed memorandum, experts of the National Bank will receive qualified advisory assistance from UNDP during the period of implementation of the Roadmap regarding the development of standards regarding the disclosure of information about environmental, social and management risks by financial non-banking institutions. First of all, it is important to hold online meetings dedicated to the review of international standards and practice on this topic. The parties will also cooperate with the aim of organizing corporate governance related to the introduction of ESG principles, developing sustainable financing standards and improving the management of environmental and social risks in banking and non-banking financial institutions.

Cooperation between UNDP and the National Bank will contribute to the implementation of the Agenda for the period until 2030 in Ukraine, strengthening the efficiency and involvement of the financial sector in the sustainable development of Ukraine with the help of non-regulatory mechanisms, as well as supporting an active dialogue between the public and private financial sectors regarding the financing of the Sustainable Development Goals with in order to better align policies, strategies and investment flows.

Despite the large-scale war in Ukraine, the country's government continues to implement planned measures to achieve the Sustainable Development Goals (SDGs). Thus, after a meeting with state institutions and development partners regarding progress in achieving the SDGs, the Secretariat of the Cabinet of Ministers of Ukraine announced its intention to conduct and submit a Voluntary National Review (hereinafter referred to as the Review) in 2023. The Review is a process by which countries assess and present national progress towards the 2030 Agenda for Sustainable Development and its 17 SDGs and 169 goals. All 191 UN Member States have agreed to achieve the SDGs by 2030, and countries are also expected to conduct at least two Reviews during the SDG implementation period.

The Voluntary National Survey in Ukraine for 2021 showed a decrease in the poverty rate from 58.3% in 2015 to 43.2% in 2018. However, these positive trends are quickly changing: early UNDP forecasts showed that up to 90% of Ukraine's population could face poverty and vulnerability to poverty if the war continues for another year [25].

Thus, the government of Ukraine and financial institutions are gradually implementing measures that will contribute to the further transition of the national financial system to sustainability, taking into account the country's losses from the destruction of energy, transport and urban infrastructure, the need to restore business in the post-war period.

5. Understanding the conceptualization of the transition to sustainable finance

For the development of state strategies and programs for the transition of the national financial system to sustainability, the necessary basis is a scientific conceptual understanding and justification of this process. In modern science investigating the transition to the sustainability of the world financial system, attention is focused on: differentiated characteristics of the main directions of transformation (taxonomy of sustainable development projects, disclosure of information on non-financial risks by non-financial institutions, standardization of requirements for instruments for mobilizing financial resources, disclosure and consideration of information on non-financial risks by financial institutions, formation (development) of the infrastructure of sustainable finance); determination of typologies of such transitions and their features [26]. Despite the heterogeneity of transient processes, certain main characteristics can be singled out, which provide the basis for conceptual understanding of this process.

In particular, transition processes are non-linear and destructive, aimed at achieving a new stable economic state of the system. In addition, multi-level and conflicting interactions are typical for transitional processes that lead to evolutionary (structural) shifts and the emergence of a new (innovative) type of systems and processes [27], when such systems demonstrate the possibility of variations and alternatives for choosing ways to achieve a new steady state.

The scientific basis of sustainable finance is the classification of the characteristics of transitional processes and practical consequences of the Paris Climate Agreement and the SDGs proposed in [12], which is illustrated in table 2. This interpretation is the result of the generalization of modern scientific developments at the initial stage of research, which will be further developed when it will be possible to implement conceptual and empirical conclusions obtained as a result of research on transitions to sustainable development.

According to the given conceptual approach, the characteristics of transitions to sustainability and innovation processes are distinguished, which are the result of technological revolutions and profound changes that will lead to the modernization and rejuvenation of the economic system, the impact of which goes beyond the boundaries of the created new industries or technologies. Thus, technological revolutions are a specific form of transition to sustainability, but at the same time it is necessary to take into account the following special characteristics of such a process. First, transitions to sustainability lead to a strategic rethinking of the achievement of new economic, environmental and social goals associated with existential threats and risks.

Second, such transitions are inherently time-bound processes that require acceleration to achieve certain results of transformative impact on the environment, society, and economy by 2030, while technological revolutions do not have specific time limits.

Third, sustainable financial systems generate impacts at the environmental and social levels, creating new socially inclusive, equitable, environmentally sustainable economic systems while simultaneously destabilizing old ecologically unstable and socially unequal ones. At the same time, technological revolutions may not reflect the social quality of innovations.

Fourth, sustainability transition processes aim at rejuvenating the entire economic system as a primary goal, paying more attention to system-level impacts that can be achieved through different types of innovation; while technological revolutions focus on innovation, and system-level impacts are positioned as an indirect consequence of their diffusion.

Fifth, the Paris Agreement and the SDGs support the financial orientation of transitions to sustainable development, which require integration and coherence of financial flows, while the

Table 2. Characteristics for informing the demand on the financial system [12].

Characteristics	Indicative demands placed on the financial system
Directional changes	The intermediaries, markets and infrastructure of the financial system consistently directs itself toward achieving a new sustainable economic system.
Temporal dynamics	The financial system responds across short, medium and longer-term timeframes to address the systemic needs of transition processes.
Co-existent system impact	The financial system generates environmental and social system-level impacts, by creating new socially inclusive, environmentally sustainable economic systems and simultaneously destabilising old environmentally unsustainable, socially unequal economic systems.
Contested social context	The financial system engages with a broad base of stakeholders in developing its response to support the transition process.
Contextual experimentation	The financial system experiments and applies adaptive approaches to address the contextual needs of sustainability transition processes.

financing of technological revolutions does not provide for such prerequisites.

Moreover, at the initial stage of development and unification is the terminological apparatus regarding such definitions as, for example, “green finance” (different interpretations of such institutions as the United Nations Economic and Social Commission for Asia and the Pacific, OECD, World Bank), definitions of individual financial segments and instruments, such as banking, bonds or institutional investments (China Banking Regulatory Commission, Global Sustainable Investment Alliance, International Development Finance Club), approaches to distinguish industries and technological sectors that primarily require sustainable investments [28].

6. Proposals for the Roadmap for the development of sustainable finance in Ukraine in 7 main areas of work

Taking into account European approaches to strategizing the development of the sustainable finance system and within the framework of the commitments undertaken when joining the global Sustainable Banking Network, in November 2021, the National Bank of Ukraine presented a comprehensive vision of building and future development of the sustainable financial sector in Ukraine – the NBU Policy on Sustainable Finance Development until 2025 as a separate document that is strategic for the formation of a sustainable finance system in our country. Overall, the NBU Policy on Sustainable Finance Development until 2025 is a comprehensive document that will help financial market participants to take into account the NBU’s holistic vision in their plans for the coming years and prepare in advance for the discussion and implementation of future regulatory changes.

The Policy on the Development of Sustainable Finance in Ukraine until 2025 proposes a Roadmap for the Development of Sustainable Finance in Ukraine until 2025, which aims to determine the actions of the National Bank of Ukraine to create a reliable, predictable and stable regulatory framework for the development of sustainable finance in the country, indicating specific time frames and taking into account the need to ensure consistency and adaptation of the banking system and non-bank financial institutions to changes [20].

The Roadmap for the Development of Sustainable Finance in Ukraine is detailed in the following 7 main areas of work. Our proposals to this Roadmap are summarized as follows.

With regard to the first area – improving corporate governance in banks and non-bank financial institutions (NBFIs) with regard to ESG factors, it is necessary to clearly define and detail the concept and structure of ESG factors in accordance with each of the sectors of financial activity, as well as to clearly define and implement the concepts of “sustainable finance”, “climate finance”, “green finance”, “low-carbon finance” in the legislation, taking into account national specifics.

In the second area – the development of ESG disclosure standards – the proposals relate to the formation of a complete, comprehensive and understandable list of financial services in the context of various types of activities in such a way as to exclude double or vague interpretation of terms and thus ensure, on the one hand, the protection of the financial sector from greenwashing, and on the other hand, the effective financing of green projects.

In the third area of developing requirements for banks and NFIs to manage environmental and social risks, it is necessary to adopt a new Law of Ukraine “On Environmental Insurance” and create a sovereign wealth fund in Ukraine, which will become a factor in stabilizing the banking system of Ukraine, including taking into account the impact of ESG-related risks.

In the fourth area – establishing criteria for evaluating and selecting projects for financing, taking into account their role in sustainable development, it is necessary to develop clear regulations for full and clear criteria for evaluating and selecting projects for financing with the participation of stakeholders from public administration, business, and society.

In the fifth area, which is the formation of a sustainable finance system in terms of ensuring that financial institutions disclose information on how sustainable their activities are, the proposals relate to the organization of a review and implementation of best international standards and practices in this area in the Corporate Governance Code of these institutions.

In the sixth area, the integration of climate aspects into the financial stability system, it is necessary to improve the national system of statistical indicators to assess the impact of climate aspects on financial stability and to supplement the Roadmap with a paragraph on attracting external international financial assistance for the use of prudential instruments for sustainable development.

In the seventh area, which concerns the organization of work and implementation of measures to raise the level of financial awareness of economic entities in the development of sustainable finance in Ukraine, it is necessary to organize a National Sustainable Finance Platform, as recommended by UNDP, in order to create an active space for communication and interaction between stakeholders to develop effective management solutions in the field of sustainable finance, provide advice on harmonizing the technical criteria of the EU and Ukrainian taxonomies and updating them. Ukraine also needs to develop specific practices for implementing sustainable finance policies in the national economic system.

In order to create a national sustainable financial system in Ukraine, it is necessary to give impetus to three powerful processes that are increasingly gaining momentum in the global economy.

The first of these is an inclusive process – the capitalization of natural resources and the inclusion of natural capital in financial valuations.

The second is the formation of a system of sustainable financial relations in various areas of financial activity – investment, banking, insurance, and stock markets.

The third process is the dissemination of innovative approaches of “good governance” and “new public management” to the organization of management of economic systems through platforms, which are focused on decentralization, consensus, participation and responsibility.

These are the areas in which stakeholders should focus their efforts in the process of implementing measures to organize a sustainable financing system in our country.

7. Conclusion

The development of the national system of sustainable finance in Ukraine should be based on universally recognized global practice in the field of sustainable finance and the decisions of the United Nations Organization, which relate to the financial aspects of sustainable development. The main documents that the government of Ukraine should be guided by in order to face climate challenges and achieve a sustainable future are the UN Framework Convention on Climate Change, the UN Agenda for Sustainable Development until 2030 and the Paris Agreement on Climate Change, according to the decisions of which the participation of each individual country in achievement of the global goal is determined by it individually and is called "nationally determined contribution".

In the context of the development of sustainable financing in Ukraine, the Regulation of the European Union 2020/852 on creating the foundations for promoting sustainable investment enshrines the six proposed UN environmental goals for sustainable economic activity, and the main document that defines the goals for achieving climate neutrality and the necessary financial resources is the Second (updated) the nationally defined contribution of Ukraine to the Paris Agreement, which represents the concept of state development to achieve ecologically and economically feasible transformations in all sectors of the economy: energy, industry, transport, construction, agriculture and forestry, waste management, etc.

Financing of the Second (updated) nationally determined contribution until 2030 should include a combination of domestic budget allocations, the private sector (domestic and foreign), bilateral and multilateral financial mechanisms and development assistance, while, according to the experience of developed countries, the majority of resources will come from private investors, and the role of the public sector will focus on providing the necessary regulatory tools, government guarantees, financial incentives and information that will facilitate investment from the private sector.

Starting from August 27, 2022, the Ministry of Environment, together with the Ministry of Finance, the Ministry of Energy, the Ministry of Agrarian Policy, the Ministry of Infrastructure, the Ministry of Economy, the Ministry of Regions and the Government Office for the Coordination of European and Euro-Atlantic Integration began the process of forming a road map of key transformations and measures for the implementation of the nationally determined contribution to the Paris Agreement, including the financial sector. in order to strengthen internal coordination and monitoring of the implementation of climate goals, as well as to expand cooperation with international financial organizations and partners, which requires a corresponding revision and modernization of the Roadmap for the development of sustainable financing in Ukraine, proposed by the National Bank of Ukraine, primarily in terms of the specification of measures for the development of legislation on environmental insurance, asset securitization mechanisms, application of prudential tools for sustainable development, etc.

The institutional basis for the formation of climate finance in Ukraine as a component of sustainable finance is at the stage of formation, and its main structural elements can be newly created national and territorial financial funds of the appropriate direction, budgetary institutions of the public financial sector and financial institutions of development, for example, a special state fund – the Climate Fund, the Green Transition Fund or the Green Economy Fund, etc., primarily for effective financing of the process of achieving Ukraine's Nationally Determined Contribution to the Paris Agreement.

Development finance institutions (DFIs) are significant contributors to the financing of climate projects in Ukraine, which ranks 4th in the world as a recipient of climate finance from such bilateral and multilateral sources, and climate change prevention projects in 2022-2030 for Ukraine may be at least about 10 billion euros of EU aid funds have been attracted, which is equivalent to 1 billion euros per year, and this, according to our estimates, will cover at least 10% of the funds calculated for climate goals.

Furthermore, in order to ensure the transition of Ukraine to sustainable finance, a necessary condition is the development of concepts and tools, the definition of differentiated characteristics of the main directions of transformation and typologies. Therefore, the research of connections between the characteristics of the processes of transition to sustainability and the requirements for the financial system is an urgent task of further scientific research.

Abstract. The paper focuses on the fundamental components of socially responsible business and their accounting in terms of dividing it into determinants that is justified by the emergence of corporate social reporting, the expansion of the boundaries of traditional accounting concerning the introduction of indicators related to social costs, environmental and atypical aspects. The aim of the research is to comprehensively analyze all components of the social accounting system, identify the peculiarities of socially responsible business in the context of sustainable development, and develop recommendations for the formation of methodological and organizational components of presenting relevant information in the reporting of enterprises. We have found that the modern system of social accounting reveals the facts of economic activities concerning the accounting of social costs, economic and environmental measures to make effective management decisions in terms of the impact of the enterprise activities on society, adapted to the requirements of the external and internal environment. An overview of scientific views on the essence of accounting for social reporting is considered using the methods of analysis, synthesis, comparison, grouping and generalization. The author's opinion of the social accounting system involving the following main determinants as accounting for social responsibility of business, formation of accounting information in terms of sustainable development, environmental consequences of activity, accounting for atypical social components, accounting for reputational capital, is considered. We have substantiated that further implementation of social accounting and preparation of annual reports based on the proposed elements, can help in the formation of corporate and social responsibility of the company, expanding the range of interested parties: partners, customers and investors, i.e., magnetizing in the form of reputational capital.

1. Introduction

In the last two decades, the issue of studying corporate social responsibility of business, reporting, social accounting, and auditing, both at the national and international levels, has become relevant in scientific circles. The basis for the changes is trends in the global economy leading to increased competition between countries for limited natural, socio-economic, and financial resources. The problem of accounting for the social responsibility of business in conditions of limitation of socio-economic and natural resources is designed to balance the economic, social, and ecological aspects of development. The concept of sustainable development is inextricably linked with the concept of social responsibility of business. The implementation of the principles of social responsibility in the practice of enterprise activity determines the need to account for such activity as the basis of the sustainable development of the enterprise. Therefore, there is a growing interest in finding new methods and, accordingly, the newest objects of accounting for socially responsible activities. The problems include the implementation of the ideas of social justice, corporate responsibility and sustainable development based on the theory of "interested persons". At the same time, the sphere of business is maximally integrated into the social and political environment, and the level of correlation of the state of individual systems and their elements as factors of development reaches maximum values. Under such conditions, there is a change in the purpose and functions of individual elements of the management process within the enterprise, including in the field of socially responsible activity and its accounting.

The issue of accounting for socially responsible activity in modern conditions and the purpose of certain types of it, is constantly raised in the socio-economic literature. Deegan defines social accounting as a direction in accounting that shows the degree of impact of company's activities on the environment [1], and Killian and O'Regan describes the accounting of socially responsible activities as a process that helps form the reporting of enterprises, which provides solutions to their social and environmental tasks [2]. Yang et al, substantiates that the goal of socially oriented accounting is the creation of an information system that allows comparing the results of economic activity with the social needs of society [3].

It should be noted that we share the position of Owen and Swift, who note that social accounting and reporting are an integral element of corporate reporting in a democratic society [4]. According to scientists, it is this type of reporting that allows businesses to develop a level of social and environmental responsibility that, in its turn, will allow the sustainable development of the entire society to be achieved. In the article, we tried to expand the boundaries of the research and modernize the vision of these authors concerning the main components of modern social accounting in conditions of sustainable development.

The aim of the research is to comprehensively analyze all components of the social accounting system, identify the peculiarities of socially responsible business in the context of sustainable development, and develop recommendations for the formation of methodological and organizational components of presenting relevant information in the reporting of enterprises.

A peculiar approach to justifying the need to create an account system of social accounting is presented by Cooper et al [5]. The purpose of the accounts, according to the authors, is to stimulate ideological and socially oriented activities, popularization of ecological ideas. From this point of view, social accounting is a tool for creating prerequisites for social justice in society. As a result of the research, the working hypothesis has been substantiated, which states that social accounting is an integral component of sustainable development of a modern enterprise. This was achieved through the application of a complex of specialized research methods, including mathematical and economic analysis. Such substantiation made it possible to formulate the basic components of reporting on social accounting and social costs of business, particularly in terms of disclosing information not only about internal corporate social responsibility but also external projects. Therefore, representatives of businesses should disclose in their reporting information about investments in sustainable development of society, such as educational projects, infrastructure, support for startups and innovations, territorial communities, eco-projects, and social partnerships. All the achievements outlined have formed the scientific novelty of the conducted research.

The issues of the characteristics of socially responsible business are considered in related studies [6–12] and recommendations in the field of social accounting [13, 14]. Baret and Helfrich [15] distinguish the concepts of tax, environmental, strategic, adaptive, actuarial, innovative, network, social accounting, and others. The analysis of the works of domestic and foreign scientists indicates insufficient theoretical development of the main provisions and components of socially significant activity and the lack of a unified point of view concerning the categorical apparatus and tasks of social accounting, social responsibility that determines the need for further research in this area. Therefore, our research is aimed at shifting certain emphasis of scientific interest to the accounting of socially significant processes and human value components.

The purpose of the article is to assess the costs of social direction and develop recommendations for the formation of methodological and organizational approaches to the preparation of corporate social reporting in modern business conditions.

To achieve the goal we should solve a complex of interrelated, consecutive tasks defining the objects of accounting for social responsibility of business, social accounting and their essence, elemental composition, and the components of modern social accounting, reviewing the indicators of the development of socially responsible business in the context of the progress of relevant costs.

2. Materials and methods

Recommendations and reporting standards being the main principles of social accounting, auditing and reporting are used in the work based on the study of international experience and analysis of modern practices [16–19]:

- The Social Reporting Standard of companies developed by the Institute of Social and Ethical Accountability AA1000 AS, based on the Triple Bottom-Line reporting method of John Elkington;
- SA 8000 "Corporate Social Responsibility" defining the requirements for social protection of employees, and aiming at respecting human rights and improving the working conditions of employees by companies;
- The international standard ISO 26000:2010 "Guidance on social responsibility" presenting recommendations on the principles of social responsibility, the main topics and issues related to social responsibility;
- GRI (The Global Reporting Initiative), an international reporting standard for voluntary application by organizations reporting on sustainable development. The Recommendations propose a list of specific indicators for reporting on social, environmental, and economic activities of the enterprise.

There are legal requirements for social accounting, auditing and reporting in some countries (e.g., Bilan Social in France). The Financial Times, together with the London Stock Exchange, publishes the FTSE4Good index, which assesses the performance of companies in the field of social responsibility and promotes investment in these companies.

According to different sources, accounting for elements of socially oriented components of business, social (non-financial) accounting has different interpretations: non-financial reports, reports on sustainable development, reports on corporate social responsibility, environmental accounting. Today, more than 400 companies prepare annual reports based on the results of social accounting and auditing, which cover issues of sustainable development and corporate social responsibility ("Triple bottom reports"), but the reports differ significantly in format, style, and assessment methodology (even in the same industry) [20].

Thus, non-financial (social) reports include reports of companies that contain not only economic, but also social and environmental indicators, which characterize the level of achieving the goals of economic sustainability, social well-being, and environmental stability of society by enterprises.

General scientific and specific research methods were used while studying the components of the accounting system of socially responsible activity, namely: comparison, analysis and synthesis when considering theoretical approaches to social accounting, analogy and abstraction in the process of systematizing research elements, specification and extrapolation when developing recommendations for approbation of theoretical assets in practical activities, establishment of specifics of implementation of corporate social responsibility programs against the background of assessment of the dynamics of indicative indicators of the development of socially responsible business.

To substantiate the working hypothesis of the article, which is formulated later on, the authors applied a complex of mathematical and economic analysis methods, which were systematized based on the approach of Vlastelica et al [21]. In the mentioned research, the authors identified the influence of individual elements of corporate social responsibility on the overall reputation of the enterprise using expert and respondent assessments. We adapted and supplemented this methodology for the needs of our own research. As a result, the authors formed a set of indicators for the effectiveness of business social expenditures, methods of their comparison, and ensured comparability, which allowed analyzing the impact of business social responsibility on achieving its sustainable development goals.

3. Research findings

Approaches to the definition of “socially responsible business” provide for achieving the overall goal of the enterprise’s activity in the form of maximum contribution to sustainable development. The social responsibility of business is a contract between a businessman and the society in which he operates. There is no single approach to the definition of a socially responsible business (“corporate social responsibility”), so we have formed different visions of the interpretation of its content (table 1).

Table 1. Definition of “social responsibility of business” [18, 22–24].

Source (author)	Definitions
ISO 26000:2010 ”Guidance on social responsibility” [18]	Social responsibility is the responsibility of an organization for the impact of its decisions and activities on society and the environment through transparent and ethical behavior that promotes sustainable development, taking into account the health and well-being of society; takes into account the expectations of stakeholders and complies with applicable law; is consistent with international standards of conduct and integrated into the activities of the entire organization
World business council for sustainable development [22]	Corporate social responsibility of business is a permanent commitment of business to promote sustainable economic development, in symbiosis with workers, their families, local communities and society as a whole to improve their quality of life
Green Book of the European Union [23]	Social responsibility of business – integration of social and environmental aspects into the daily commercial activities of enterprises and their interaction with stakeholders on a voluntary basis
G. Bowen [24]	Social responsibility of business is the implementation of such policies, making such decisions, or following such a line of behavior that would be desirable from the point of view of the goals and values of society

The active social position of the company is related to the social responsibility of business (SRB), which is usually understood as the responsible attitude of the company to its product or service, to consumers, employees, and partners, and constant interaction in dialogue with society, and participation in solving the most acute social problems.

We have generalized the interpretation of the definition "social responsibility of business", which we understand as the activities of a business entity aimed at satisfying the interests of all "stakeholders" in order to achieve the most favourable economic, environmental and social results, that is the main components of sustainable development. That's why, We consider that to ensure the sustainable development of society, the social responsibility of business is no less important than the development of economic infrastructure, political stability, or innovative development projects. Social responsibility and sustainable development are interrelated concepts that help businesses become more environmentally and socially responsible while ensuring their long-term profitability.

Therefore, it is important to implement the concept of socially responsible behavior in enterprises that strive for their own sustainable development. Consequently, such activity, as a new component of business, requires its own accounting to meet the information needs of stakeholders. That is why it is necessary to introduce the accounting of corporate social responsibility into domestic practice. Its purpose is to preserve values, determine the results of socially responsible activities, and satisfy all stakeholders.

SRB is widespread among European countries. In some countries (Denmark, France, Finland, Sweden), it is integrated into public policy, in others (Greece, Ireland, the Netherlands, Slovenia), socially responsible practices are exclusively the prerogative of companies.

Recently, the idea of corporate social responsibility (CSR is a free choice of the company regarding the obligations to improve the welfare of society by implementing appropriate approaches to doing business and allocating corporate resources [25]) has become widespread within the framework of international initiative of the Global Compact, the purpose of which is the implementation of general principles of social equality and environmental preservation, and the creation of conditions for business cooperation with trade unions and non-governmental organizations. Thus, private businesses, joining the agreement in cooperation with other social partners, will be able to contribute to the realization of the idea of forming a stable and open global economy.

In the European Union, the role of CSR is to support the sustainable development of companies that leads to the improvement of the situation on the labour market, as well as the quality of products and services provided by companies.

Therefore, it is important to implement the concept of socially responsible activities at enterprises. Accordingly, these activities require accounting. In Ukraine, insufficient attention is paid to socially responsible activities (SRB, CSR). We believe it is necessary to introduce social accounting into domestic practice for information support of socially responsible activities of domestic business entities.

The purpose of accounting for socially responsible activities is to preserve values, to determine the results of socially responsible activities, and to satisfy all stakeholders. The social function of entrepreneurship (usually in practice, the categories of "social responsibility of business", and "corporate social responsibility") are evaluated with the help of a social audit.

3.1. Substantiation of social accounting essence and its components

Modern forms of global accounting business communication in terms of sustainable development are aimed at establishing promising relations and stabilizing the economic environment. Social accounting is a process of forming systematic, relevant information that characterizes socially responsible activities of a business entity and directed at making social decisions within the concept of sustainable development of the enterprise.

Recently, companies have been trying to pay attention to the implementation of programs and projects of social orientation, such as support for environmental protection, health, healthy lifestyle, creation of favourable working conditions, prospects for career development of staff, charity, etc. It means that the formation of public accounting information – financial reports –

must take place from the standpoint of sustainable development.

The combination of three main components of society's life: economic, social, and environmental, is embodied in the concept of sustainable development. This is a concept that describes the relationship between the social and environmental impacts of a company's economic activities on certain interest groups and on society, and is an important element of corporate social responsibility. It is this approach that will serve as a tool to ensure balance in the presentation of accounting information on social responsibility of business, certain social aspects, environmental factors of development and prospects of the enterprise.

Thus, social accounting covers: 1) accounting of corporate social responsibility; 2) accounting of sustainable development indicators; 3) environmental consequences of economic activities (accounting of social costs, the main part of which is related to the environment); 4) accounting of atypical social components (some accounting elements); 5) reputation capital (figure 1).

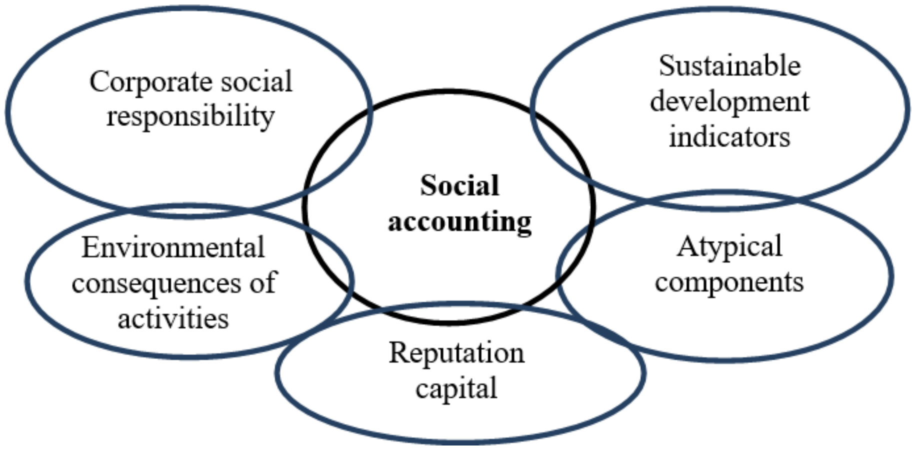

Figure 1. Components of the social accounting system.

According to its functional purpose, the social accounting system should be considered in the context of accounting subsystems (determinants) that characterize the state and use of labour resources. In terms of this approach, social accounting may be considered as a direction in accounting, which expands the boundaries of traditional accounting, reveals the facts of economic activity in accounting for social costs, economic and environmental measures in order to make effective management decisions on the impact of the enterprise on society, adapted to the requirements of the external and internal environment.

Thus, modern social accounting should combine the elements of accounting for social responsibility of business, environmental impacts of activities and relevant targeted measures, as well as the formation of accounting information in the context of sustainable development. In the practice of applying international non-financial reporting standards, such reports are called "Triple Bottom Line Reports". Each of these elements is aimed at highlighting the essence of various aspects of accounting, and accordingly has a different accounting essence.

3.2. The essence of corporate social responsibility accounting

Accounting for corporate social responsibility should reliably reflect the information on operations that affect the life of society and involve measures of green production, innovation of production technology and products; implementation of social programs and activities for both employees and society. Corporate social responsibility emerged as a response to the constant expectation of a more adequate and active role of business in society [21] and is directed not only external – to society and the business environment, but to its own staff. Research of practical activities by 469 American companies revealed a positive correlation between corporate responsibility of business and profitability of assets, sales growth, and proved that enterprises that consider the interests of all social groups grow on average four times more intensively than those that consider only the interests of shareholders [26].

Accounting information should reveal the costs of the enterprise to ensure the needs of its own employees, their motivation and improvement of external environment: the impact of business on the environment, health and education of the population, the state of renewable and non-renewable resources. It is also important to show the effectiveness of such expenditures, i.e., the ratio of their amount to the expected positive consequences in potential monetary terms, if they can be determined. It is the information as part of the company's annual reporting that will allow to present the business as a conscious, mature, and promising enterprise. To accept responsibility for the impact on society means, above all, that the company should report on its actions and keep records of them. Therefore, a conceptual approach that describes the relationship between social and environmental impacts on the company's economic activities and on certain interest groups is an important element of social responsibility.

Thus, the essence of corporate social responsibility accounting can be presented as a process of collecting, processing, summarizing and presenting accounting information on the costs of socially responsible activities and their potential or actual effectiveness.

3.3. Specific features of accounting for sustainable development

The concept of sustainable development is based on the thesis that the company's responsibility extends to all stakeholders. It is the stakeholder theory that is the basis of modern social accounting that significantly expands the scope of traditional accounting by introducing non-financial indicators that create new opportunities for the implementation of management control tools – Balanced Scorecard, Accountability Scorecard, Performance Pyramid, and other models.

Within this concept, a stakeholder is anyone who is directly or indirectly affected by the company's activities. This concept provides for the optimal use of limited resources and the use of environmentally friendly natural energy and material-saving technologies, including the extraction and processing of raw materials, the creation of environmentally acceptable products, minimization, recycling, and disposal of waste. From an environmental point of view, sustainable development should ensure the integrity of biological and physical natural systems.

Accounting for sustainable development is the most comprehensive element of accounting systems, but at the same time, in our opinion, it becomes a subsystem of social accounting. Sustainable development combines such aspects as environmental, social environment, microclimate of the enterprise, transformation of the company's goals, change of management priorities, etc. Accordingly, the management services of the enterprise should set themselves the task of analyzing the efficiency of current and future costs of the enterprise, assessing the impact of social and environmental measures. It is this approach of accounting for sustainable development that provides for the expansion of the subject of accounting from the presentation of exclusively retrospective information on economic activity (as provided by financial accounting) by including elements of analysis and risk management in accounting processes.

Thus, the essence of accounting for sustainable development may be presented as a process of processing and presenting accounting information in the part of implementation and evaluation of the effectiveness of current and future costs of the enterprise, the impact of social and environmental measures on the strategic goals of the enterprise.

3.4. Accounting for environmental consequences of economic activity

In the present conditions of technology development and the state of the planet, environmental accounting is distinguished as an independent subsystem. Within the scope of corporate social responsibility accounting, the level of disclosure of information on the environmental friendliness of business is insufficient. The enterprise, which claims to form a positive image in the society and cooperation with prospective partners, discloses information on the current state of environmental measures, their positive effects, environmental fees and means of overcoming the consequences of previous year activities in its annual report. Accordingly, the system of accounting data formation goes beyond the calculation and systematization of internal information. Instead, there is an active mutual integration of accounting data and methods of economic analysis, mathematical modeling, and forecasting.

On the other hand, the issue of environmental protection is a vital part of modern entrepreneurship. The phenomenon of Greta Thunberg is primarily due to the relevance and importance of the issues she raised [27]. At the same time, all skeptics are trying to calculate, i.e., to consider, positive and negative economic consequences of each of her steps. However, in our opinion, the main emphasis should still be on considering the environmental friendliness of your own business, not environmental organizations. Therefore, environmental accounting at the present stage is no longer a curiosity, but a necessary element of an effective accounting and analytical system. In the most general terms, social accounting provides information on personnel, products, and services, and focuses on the prevention or reduction of environmental pollution.

Thus, the essence of environmental accounting may be presented as the process of collecting, processing, summarizing, and presenting accounting information on the costs of retrospective and prospective environmental protection measures and their potential or actual effectiveness.

3.5. Atypical components of social accounting

Social accounting studies, controls and generalizes the processes related to the reproduction of material and social relations at the enterprise, in society. However, some aspects remain outside the analysis of socio-economic activity of the enterprise, as they are not subject to accounting data. We have called such components of social accounting atypical, i.e., those that do not comply with statistical expectations concerning social accounting or significantly deviate from it, but are those cases that characterize social stability and contribute to the effective operation of the enterprise and society as a whole, e.g., the structure of revenues by types of audit services, indicators of income inequality, charity, access to social investments, the presence of cases of social exclusion, inclusion of employees with disabilities, trade unions, gender equality, implementation of ethnic norms and values, etc.

Another positive example of the need to account atypical components can be the data of a survey of German companies on the positive correlation between investments in personnel development and the value of the company's shares. Accordingly, 87 percent of European companies' employees feel committed to socially responsible enterprises [28], and 33 percent of Europeans say that most of the economically active population would agree to work in a socially responsible company even if their salary is lower [29].

Accounting for atypical social components of the business entities' development is human-oriented and aimed at preserving the stability of social and cultural systems, in particular, at reducing the number of destructive conflicts between people, ensuring a healthy social and psychological climate in society, etc. An important aspect of this approach is the equitable distribution of goods and services.

3.6. Reputation capital as the result of social accounting and its formation in reporting

Non-financial accounting methods focus on the collection and registration of accounting data, their generalization and presentation in financial statements. As a result, an array of analytical information forms that serves as the basis for socio-economic analysis. While analyzing, the current efficiency of the incurred costs is calculated in terms of protecting the interests of own employees, conducting environmental measures, modernization of production technology and products, logistics systems, etc.

A feature of the accounting process of social accounting is the transformation of carriers of accounting nomenclatures. At the initial stage of social accounting, in addition to primary, purely accounting, documents, an important component of accounting nomenclatures are orders and economic justifications of the costs that will incur. At the stage of current accounting, there is a need to introduce own accounts for analytical accounting of non-production social and environmental costs. In addition, the company should provide a reasonable methodology for the distribution of such costs (as general production costs) depending on their materiality in terms of each individual type of product or service. At the stage of summarizing accounting, social accounting information is presented in annual reporting. The disclosure of such information in the numerical tables (forms) of the financial statements is incorrect. However, in the annual financial statements, it is possible to disclose all the necessary information in tabular forms, as well as in graphical and textual ones. It is at this stage of the accounting process that the goals and effectiveness of those measures that have become the objects of social accounting, are presented.

Presentation of such information in the annual reporting allows presenting socio-environmental risks and consequences of activities, justifying the necessity and effectiveness of the measures taken, etc. Reporting, formed by the triple bottom line method and containing social accounting information allows the company to form its own positive image in the business environment. Presentation of the company's social and environmental awareness in the annual reporting allows directing the users' opinion in the necessary direction for stakeholders. In our opinion, the positive image of the company can monetize in the form of reputational capital (goodwill) over time. That is, social accounting is not only a comprehensive method of processing accounting information, but also an effective management tool, especially value-oriented. Reputation capital is created by the enterprise from many details: product reliability and stability of payments, level of service offered to customers, investment attractiveness of business, employee satisfaction, environmental awareness, etc. Such capital can be seen as a value expression of the company's image in different markets and for different purposes. Accordingly, it can be valued also differently.

Thus, the process of quantitative assessment of reputation capital can be presented in the company's reporting in the context of social accounting: on the one hand, the result of realized social and environmental costs, and on the other hand, as their main goal, which is achieved in the form of economic efficiency.

3.7. Overview of success indicators of socially responsible business

In some studies on corporate social responsibility and social accounting as a fundamental component of sustainable development, the thesis that this is the prerogative of predominantly large businesses is directly or indirectly encountered. That is, large companies, as a maximum contribution to sustainable development, implement environmental activities (reduce environmental pollution, minimize and utilize waste, use natural resources rationally, implement programs for the health protection and strengthening of employees), educational projects, invest funds in the development of territorial communities and infrastructure of the region, create favorable conditions for personal development of personnel and improving their social security. In the conditions of the world COVID-19 pandemic, this thesis was partly refuted by reality, as even small companies invested funds in the safety of the environment and creating a barrier-free distance space for effective work in the context of sustainable development. However, the scale of costs of social responsibility and accounting mechanisms for their presentation for large consortia and holdings are integrated into the domestic business environment mainly from world experience.

A large-scale study in the American market confirmed the existence of a close direct link between the profitability of assets, sales, and their social activity, especially in terms of sustainable development. The performance of 300 corporations that have publicly stated the importance of ethics codes in their activities is two to three times higher than those companies, which have not done it. Enterprises that consider the interests of all community groups grow on average four times faster than those that consider only the interests of shareholders [26].

As experts in economics and business, Vlastelica et al [21] identified a successful set of indicators for evaluating the development and performance of social expenditures by businesses. In order to establish the characteristics of implementing corporate social responsibility programs by large businesses that contribute to sustainable economic development, we will supplement this set of indicators with measures of the number of employees in the enterprise, the total amount of expenditure on social projects, and the attractiveness of the business to employees, which we will use in our further calculations.

To determine the objects of research for evaluating the indicators of business development and its social responsibility in the context of sustainable development, we will use the data of Forbes analysts, who regularly compile rankings of the largest companies based on various criteria and parameters based on consolidated reporting [30], including Forbes' ranking of the best employers, which shows companies that best balance work and life for employees [31], and the DSNews ranking, which presents companies that carry out the best corporate social responsibility programs in Ukraine [32]. The comparison of the participants of these ratings shows that seven of them are present in all three ratings: Kyivstar, Sandora LLC (PepsiCoUkraine), MHP, Farmak, Metinvest, CarlsbergUkraine, AB InBevEfesUkraine.

The scale of business and peculiarities of their reporting unite all these enterprises, which also includes coverage of sustainability issues. These enterprises use international financial reporting standards, and present annual reports as part of not only financial reporting, but also reports on sustainable development and social responsibility reports [33–39]. The relevant business entities implement socially significant projects that do not bring them profit in the classical sense, but form the potential for the development of business environment and a positive business image, i.e., the prerequisites for the formation of reputation capital. In such reports, the main source of information on social responsibility today is the description of the relevant projects and the assessment of the total costs for their implementation (social responsibility costs).

The selected companies for analysis have access to the international market and are successful in terms of conducting business within the framework of sustainable development. The dataset for further analysis within these companies is provided in the Appendix to this article. The obtained time series based on comparing the growth rates of key business development indicators using the selected and previously adapted methodology [21] are grouped in figure 2.

Thus, as graphs show, the amount of social expenditures is not directly dependent on the profitability of the analyzed enterprises. Such projects are mostly permanent, and therefore, are implemented by businesses even in conditions of unprofitability. At the same time, the volume of social expenditures is growing at a rate similar to the growth of the business value itself, i.e., the scaling effect is working. Accordingly, we can say that the business social responsibility and the social accounting and reporting system formation should not be recognized as neither the cause nor the consequence of the enterprise development, but in modern realities, it is definitely an integral part of it.

The analyzed indicators may exhibit significant variability across different business sectors. However, their impact on the results of this study has been mitigated by using growth rate indicators, and for larger datasets, classic normalization methods with automated computational systems can be applied.

Socially responsible business forms its own positive business image, which is transformed into reputation capital. Due to this, the investment value of its securities increases, and therefore,

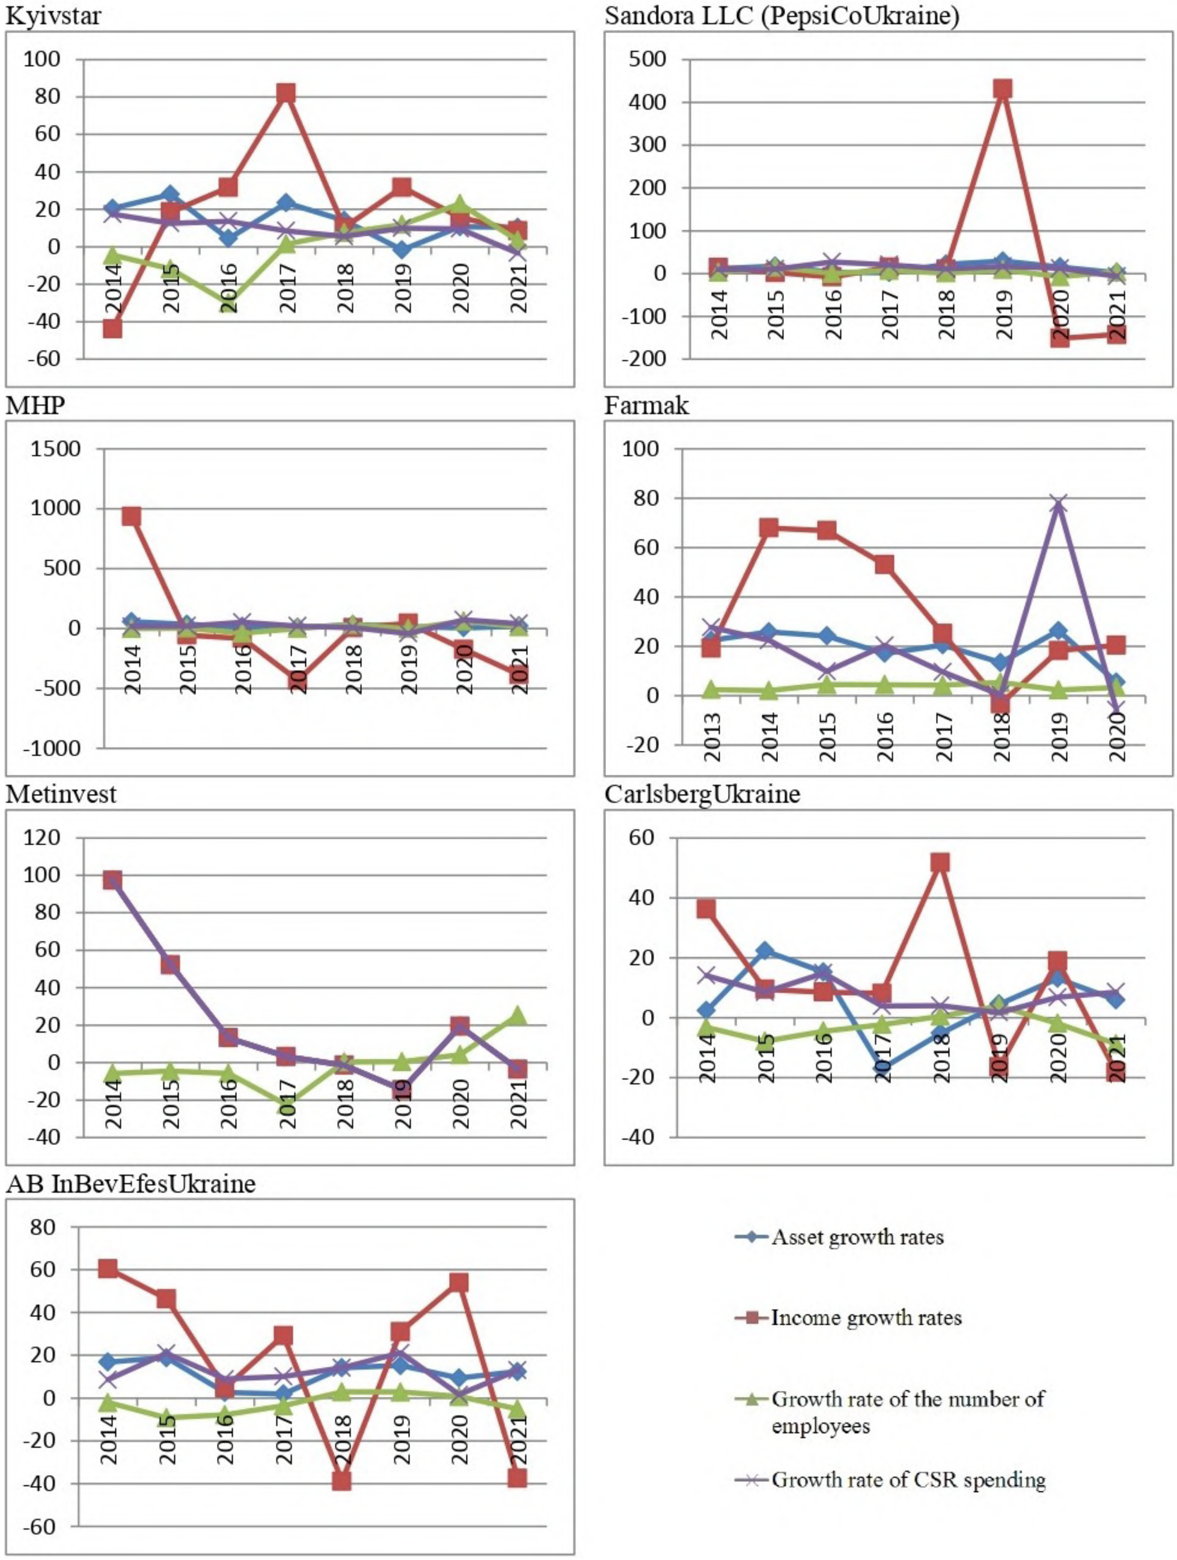

Figure 2. Dynamics of indicative indicators of business development and its social responsibility.

the reputation is monetized. A good example of the opposite effect can be the quotes of SpaceX, Tesla Inc and Twitter shares against the deterioration of their owner's image due to statements about the war in Ukraine, the increase in fees for the use of Starlink technologies in Ukraine and Poland, as well as a sharp deterioration in working conditions and social security of their own employees [40] (figure 3).

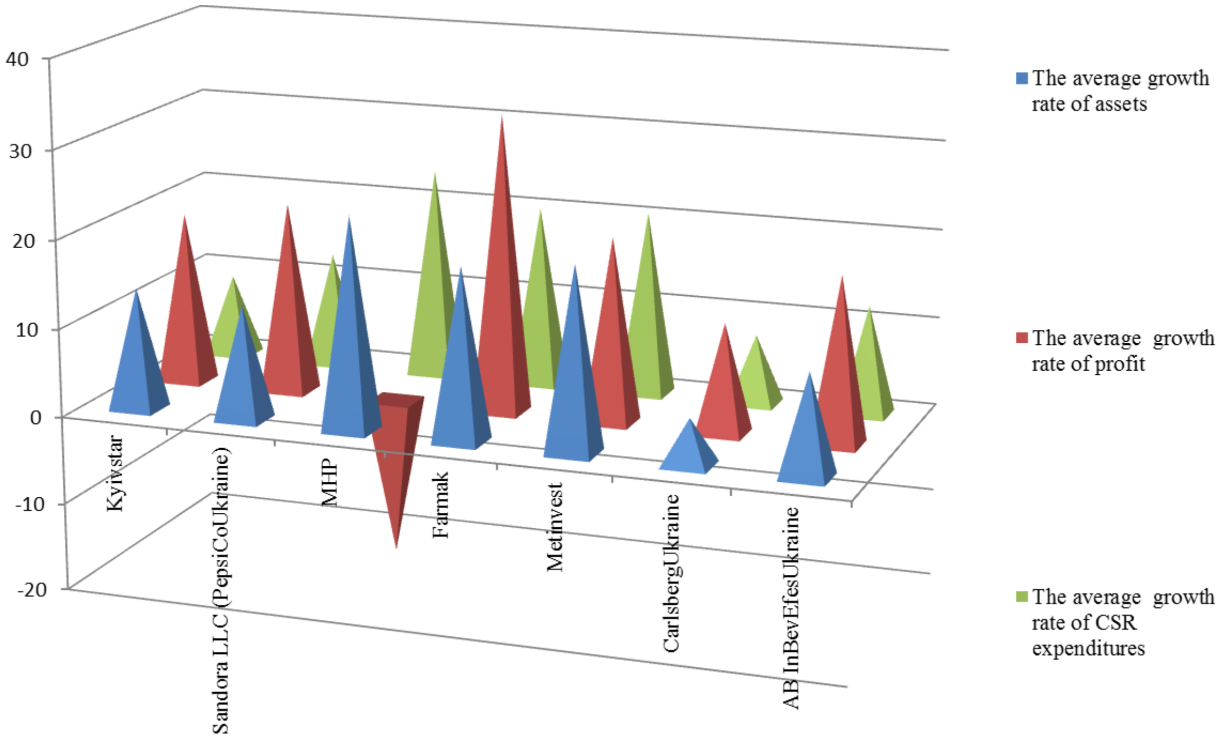

Figure 3. Comparison of average dynamics of key indicators of socially responsible business in the context of sustainable development.

Thus, as a result of the analysis, it has been proven that the actual amounts of corporate social responsibility expenditures from the perspective of sustainable development do not depend on profitability, but rather correspond to the scale of activities of the analyzed enterprises, since the average growth coefficient for a series of asset dynamics and the average growth coefficient for a series of social responsibility expenses dynamics for all analyzed enterprises are either identical or very close in value. In the future, the proposed working hypothesis can be empirically tested on a larger scale based on the methodology already presented.

So, reports on corporate social responsibility should be aimed at disclosing information about expenses made towards the relevant areas of expenditure. Such expenses should be perceived as investments in sustainable development of the external business environment, which over time convert into the company's own reputational capital and shape real growth in the value of the enterprise not just as a collection of assets, but as a value system. Accordingly, the organizational component should provide for the systematization of the information basis of such reporting: a list of social responsibility projects and the actual amount of expenses incurred for their implementation. The methodological component should include the formation of a unique approach to presenting this information by disclosing it according to socially significant directions: educational projects, infrastructure, support for startups and innovation, territorial communities, eco-projects, and social partnerships, among others. All analyzed enterprises already finance similar initiatives to some extent, but present information about them in the form of brief summary tables or concise presentations. In our opinion, disclosure and detailing of information on social expenses according to the specified directions (in the form of typical accounting tables with indicators of economic elements of the incurred expenses) will allow for creating preconditions for evaluating their effectiveness in the future. Moreover, disclosure of the actual components of incurred expenses will allow for evaluating the reality and scale of social responsibility projects of each economic entity. Thus, an educational project can be both a school trip to a production facility and the organization of a summer school with professional tutors. At the same time, the effectiveness and costs of these educational projects will be radically different, which should be illustrated by reports on social accounting.

4. Conclusion

We consider business social responsibility as the activities of a business entity aimed at satisfying the interests of all stakeholders in order to achieve the most positive economic, environmental and social results. Accounting of socially responsible activities may be considered as a direction in accounting, which expands the boundaries of traditional accounting, concerns many aspects and facts of economic activities: economic and environmental measures, implementation of social programs, building relationships with stakeholders, creating proper working conditions, implementation of ethnic norms and values in order to make effective management decisions on the impact of the enterprise on society, adapted to the requirements of the external and internal environment. Arguably, in order to ensure socially responsible activities of business entities, it is necessary to introduce social accounting into business practice. The study argues that in order to ensure the socially responsible activity of business entities, it is necessary to introduce social accounting into business practice. It has been proven that the modern system of social accounting contains the following main structural determinants: accounting of corporate social responsibility, accounting of environmental consequences of economic activity, accounting of sustainable development, atypical components of social accounting, reputation capital. These components are tangential, prolong each other, but have different essence. The social accounting system is implemented by combining methods of non-financial accounting, economic analysis and economic and mathematical modeling. In modern conditions, social accounting becomes an effective tool for enterprise management. Annual reports prepared using social accounting approaches present the company as a conscious, business-mature, and promising partner. Presentation of social accounting information in the annual reporting allows to present the effectiveness and prospects of the company's social and environmental measures and to promote the formation of reputation capital as monetization of the company's positive image in the growth of its total value and investment attractiveness in the market.

During the analysis of the criteria that describe the features of the implementation of social responsibility projects and their accounting process, we established that the amount of actual CSR expenditures does not directly depend on the profitable activity of the enterprise. However, it corresponds to its scale, because the average growth rates for a number of assets dynamics and social responsibility expenditures within the studied enterprises are either identical or quite close in value. The results of the analysis confirm the need for social accounting and the formation of reports on social expenses (which currently exist partially in the form of corporate social responsibility reporting), which in turn convert into economic benefits in the form of reputation capital. In other words, business investments in sustainable development of the external environment today will create conditions for their own sustainable development tomorrow and contribute to the growth of the value and worth of such businesses. As an expert in economics and business, I believe that this demonstrates the importance of considering social and environmental factors in business decision-making for long-term success.

Abstract. The paper is devoted to the problems of ensuring the efficiency of forestry enterprises' potential management. It was determined that forest plays a crucial role in ensuring people's living conditions, i.e., providing food, fuelwood, medicines, income, and employment, etc. Due to crisis tendencies in the forestry sector which were exacerbated by the full-scale war on the territory of Ukraine, the necessity of improvement of forestry enterprises' potential management is beyond doubt. The main problems of the forestry sector of Ukraine were outlined. It was determined that the ways of improving the forestry enterprises' potential management should be considered at national and individual enterprises levels. The peculiarities of the forestry sector reform and its planned outcomes were analyzed. It was proposed to supplement the measures of macroeconomic direction by enhancing the forest certification and implementing a participatory approach in management. Based on correlation and regression analysis, the main directions of measures for individual enterprises were defined. Such directions include reducing the duration of the operating cycle, increasing labour productivity, and increasing the rate of net income growth. The measures within each direction were proposed.

1. Introduction

The quantity and quality of resources available for the formation of living conditions determine humanity's existence. Forest resources are vital for human beings due to their role in society. Forests provide healthy food, fuelwood, medicines, income, and employment for people [1]. Forests are also a source of renewable materials in the case of rational resource use policy [2]. Forests are also important from the climate changes standpoint. According to World Economic Forum, deforestation is the factor that endangers climate on our planet, forming negative impact on natural environment and livelihoods, and almost 1.6 billion people depend on forest ecosystems for food, water, wood and employment [3]. During the last decades, due to inappropriate and irrational use of forest resources, deforestation and forest degradation have aggravated worldwide. This causes damage to both the natural environment and human living conditions, resulting in a wide range of issues related to environmental depletion. Thus, efficient policy in the sphere of forest management gains a crucial role in ensuring the well-being of society as a whole. We believe that such an efficient policy should be implemented at national and regional levels and at the level of individual enterprises, especially forestry enterprises.

It should be mentioned that the efficient use and reproduction of forest benefits achieving the sustainable development goals, which are the key guidelines for the development of humanity. In particular, the following goals are under the impact of forest conditions: SDG 2 "Zero hunger", SDG 3 "Good heath and well-being", SDG 6 "Clean water and sanitation", SDG 12 "Responsible consumption and production", SDG 13 "Climate action", SDG 15 "Life on land" [4]. Forest ecosystems are an essential prerequisite of society's sustainability model as they provide water conservation, wind and soil control, carbon sequestration, and biodiversity [5]. Thus, we can conclude that efficient forest management mechanisms are of particular importance in ensuring the sustainable development of individual countries and the world as a whole.

Efficient forest management is urgent for Ukraine, as the forest cover level has reduced significantly over the past century. The forest cover level in Ukraine is estimated at 15.9 %, while the optimal level is calculated as 20 % [6]. A lower-than-optimal level of forest cover determines the presence of problems related to the depletion of the natural environment, soil erosion, and decreased resource availability. It creates a threat to ensuring the sustainable development of the country. Thus, the development of effective mechanisms of forest use is an essential and urgent task, which is intensified due to the destructive consequences of hostilities on the territory of Ukraine. Considering the above, efficient forest management mechanisms should be implemented both at the national level and the level of individual enterprises. Therefore, we consider it necessary in this context to analyze the key factors of impact on the activities of forest-user enterprises and to propose directions for improving the management of the potential of forestry enterprises. This determines our study's relevance and identifies the key tasks to be implemented within the framework of the study.

2. Literature review

Forest resources are among the most crucial for people's existence, alongside water and soil resources. During the last decades, the processes of deforestation due to human activity, forest fires and increasing population have intensified significantly, causing such adverse effects as climate changes, extinction of plants and animal species, and total forest resources degradation. These reasons define the necessity for a balanced approach to forest management formation. Effective forest management is also one of the constituents of sustainable development, the key goals of which were defined by the UN General Assembly. The relevance, expedience and cruciality of the issues related to effective forest management system formation have shaped considerable scientific interest in the relevant sphere. This has been especially noticeable during the last decade, which is explained by the aggravation of many crises associated with rational forest use.

Forest ecosystems are crucial for sustainable development [5]. Zheng et al define that forests provide ecological, economic, and social benefits. The research is based on the idea of finding an appropriate management system in order to balance all of the aspects mentioned above. The authors use the Analytic Hierarchy Process method to define a model of indicators for forest management. The measures for effective forest management are also proposed in the paper [5].

Another research dedicated to the peculiarities of forest management was held by Knoke et al [7]. The authors emphasize the necessity of providing forest resilience under climate change conditions. The stability issue is quite essential for the forest case, as production time in forestry extends for long periods, which causes the vulnerability of forest ecosystems. The authors also define a relation between forest losses and economic losses, considering the role of forests in the country's economic development. Two silvicultural management systems are analyzed in the research, i.e. continuous cover forestry and clear fell forestry [7]. The research by Malindzakova et al [8] reflects forest management peculiarities and main directions. The system of indexes is used for the economic evaluation of forest management [8]. Mishenina and Dvorak [9] state that one of the ways to improve forest management from a national perspective is the implementation of a public-private partnership mechanism. According to the authors, public-private partnership contributes to sustainable development, decentralization, liberalization, and capitalization of natural resources. The characteristic features and advantages of the public-private partnership are also considered in the research [9].

Pietarinen et al [2] investigate the relationship between forestry and sustainable development in Finland. Scientists note that not all dimensions of sustainability have the same weight in the policy of forest use; the economic aspect dominates. Considering that Finland aims to be one of the key players in the bioeconomy based on forest use, the authors emphasize the need to strengthen ecological and social aspects in forming forest policy [2].

The participatory approach benefits the formation of an effective and efficient forest management system. It promotes decentralization in the corresponding sphere [1]. As Tessema and Nayak [1] state, participatory forest management contributes to sustainable management and forest ecosystems conservation, which is a vital issue for ensuring the stable development of society as a whole. The research deals with major aspects of the interaction of local communities with forest ecosystems in Ethiopia. Community forest enterprises are one of the manifestations of the participatory approach in forest management [1]. According to Piabuo et al [10], the role of community forest enterprises is similar to social enterprises, as they meet economic, social, and environmental challenges. The research is based on the Cameroon community forests enterprises and is aimed at their analysis, classification and activity study considering economic, social and governance dimensions [10].

An integrated approach reflecting a combination of participatory approach and forest certification is demonstrated by Degnet et al [11]. Using the example of forestry enterprises in Mozambique, the authors consider how the implementation of forest certification affects the well-being of communities living in the area adjacent to the forest [11].

Forest certification is another issue which has gained special scientific interest due to its relevance. Thus, Malek and Abdul Rahim [12] surveyed the publications dedicated to the forest certification aspect. The thematic analysis of forest certification literature dating from 2017 to 2021 was held. According to scientists, forest certification is important for achieving the sustainable development goals. The research provides a comprehensive analysis of the main trends in the forest certification literature of recent years and uses the results of the analysis to define gaps in the knowledge in the respective sphere [12]. Zubizarreta et al [13] analyze the certification processes in Spain regarding forests. The authors believe that the forest certification is a driver for forest management systems to be more environmentally and socially responsible. The paper defines the main motives for certification, based on a survey of 124 certified companies in Spain. Key mechanisms for certification promotion in Spain are also defined in the research [13].

Forest certification with a relationship to forest degradation in Sweden is reviewed in the research of Villabolos et al [14]. Two main certification schemes and their effects are considered in the article. The process and mechanisms of certification itself and maintaining the certificate are also defined in the paper. The authors investigate the impact of certification implementation on three indicators: environmentally important areas preserved during felling, the number of trees and high stumps left after felling, and the area set aside for conservation purposes [14].

Shvets et al [15] provide an analysis of the financial and economic activity at the example of forestry enterprises in the Zhytomyr region. The scientists have defined that the main challenges faced by the enterprises are those related to a decrease in demand, export issues, expenses increase, and inefficient human resources use. The authors' opinion on ways of solving relevant issues is provided [15]. Furdychko et al [16] directs its scientific efforts to solve the problems of balanced forestry land use. The work examines the dynamics of changes in the volume of forest resources based on a comparison of data for Ukraine and Poland, analyzes the impact of individual factors on the balanced use of forestry land based on the results of the production and economic activities of state forestry enterprises [16]. Tsehelnyk [17] provides a detailed analysis of the trends and conditions of the Ukrainian forestry industry and necessitates institutional changes in forest management mechanisms. Diadchenko and Saharnatska [18] consider forest enterprises management from a financial stability standpoint. The authors highlight the economic, social, and environmental components of the financial stability management model, as well as propose measures to increase the level of the corresponding indicator [18].

Summarizing the above, we should note that most scientific works are devoted to the determination of national-level levers of forest management, while the level of individual enterprises remains insufficiently covered, which determines the relevance of this study.

3. Objective of the research

The research aims to define ways to improve forestry enterprises' potential management based on internal factors which impact the respective enterprises functioning. The defined purpose involves solving the following tasks: to identify the role of the forest enterprises in the economy of Ukraine; to determine the consequences of the full-scale war on the territory of Ukraine; to consider ways of improvement of forestry enterprises' potential management at the national level; to detect key internal factors of impact on the functioning of the forestry enterprises; to propose measures for improvement of potential management at the level of individual enterprises.

4. Methodology

The methodological foundation of the research is a system method which allows to consider forest enterprises' potential management at both national level and level of individual enterprises. The set tasks involved the use of the following methods: monographic – to study and examine available publications on forest management; correlation and regression analysis – to identify key factors of impact on the formation of net profit of forestry enterprises; analysis and synthesis – to identify the key trends of forestry enterprises functioning; generalization – for formulating research conclusions; the deduction method – to propose and substantiate key measures for improvement of forestry enterprises potential management; graphical and tabular – to visualize the obtained research results.

5. Results of the research

Forestry is one of the essential segments in the economy of Ukraine. The sustainable development of forestry is based on the combination of ecological, economic and social functions of forests. Ukraine is a part of the world society that strives for the sustainable development of forestry. Forestry enterprises are obliged to conduct their activities based on sustainable development.

Balanced management of forestry combines a set of measures for the use, reproduction, formation, and protection of forests. The sustainable development of forestry is ensured under rational resource use, responsible consumption and reproduction. The economic activity of forestry enterprises to ensure sustainable development must be stable and efficient, that is, profitable. The enterprise's financial results depend on the sales volume of products and services.

The conditions for afforestation in Ukraine are heterogeneous, so forests are spread unevenly across the country's territory. The forest coverage of Ukraine is 15.9 %. Despite the relatively small area of forests, Ukraine ranks 9th in Europe in forest area and 7th in wood reserves.

Forestry in Ukraine, according to the "Classifier of types of economic activity", includes four groups: forestry and other activities in forestry (group 02.1), logging (02.2), collection of wild non-wood products (02.3) and provision of auxiliary services in forestry (02.4). Forest enterprises also provide services in several other essential industries: hunting, primary wood processing, food industry, etc.

According to the Land and Forest Codes, forests of Ukraine can be in state, communal, and private ownership. The vast majority of forests are in state ownership. About 1.3 million hectares (13 %) of forestry land plots in permanent use by municipal enterprises subordinated to local self-government bodies attribute to communal ownership.

Table 1. Main financial results of forestry enterprises of Ukraine

Indicator	Years			Deviation			
				2020 to 2019		2021 to 2020	
	2019	2020	2021	+/-	%	+/-	%
Funding from the general fund under budget programs, UAH billion	0.29	0.31	0.34	0.02	6.90	0.03	9.68
Net income from selling products (goods, works, services), UAH billion	15.20	14.46	22.80	-0.74	-4.87	8.34	57.68
Net profit, UAH billion	0.29	0.19	1.02	-0.10	-34.48	0.83	436.84
Profitability of activity, %	1.90	1.0	4.40	-0.90	-	3.4	-
Taxes paid, UAH billion	4.90	4.88	7.32	-0.02	-0.41	2.44	50.00

According to the information of the State Agency of Forest Resources of Ukraine [19–21], table 1 summarises the main financial results of forestry enterprises of Ukraine.

The generalised results of the activity of forestry enterprises of Ukraine [19–21] indicate the ambiguous financial performance of the industry. Over the past three years, there has been, in general, an increase in the net income from the sale of products (goods, works, and services), the net profit of enterprises, and the received amounts of budget financing.

However, financing from the general fund during 2019-2021 under budget programs was approximately 20 % of the need for budget financing. The tax burden has a significant impact on the financial condition of enterprises. On average, the percentage of paid taxes and duties on net income is 39 %. The most significant amount of taxes and fees to the budgets of all levels was paid by enterprises of the regional governments: Zhytomyr Oblast – UAH 873 million, Rivne Oblast – UAH 685 million, Chernihiv Oblast – UAH 553 million, Kyiv Oblast – UAH 534 million, Sumy Oblast – UAH 488 million, and Volyn Oblast – UAH 452 million.

According to Tsehelnyk [17], the main problems of forestry enterprises' potential management include the following:

- absence of a balanced strategy of development and management in the forestry sector;
- inaccurate distribution of management functions, which in some cases leads to duplication of functions or loss of their performance;
- financing disbalances;
- lack of effective mechanisms for stimulating the introduction of nature-preserving technologies;
- lack of a transparent mechanism for the timber sale, illegal felling and circulation of illegally harvested wood;
- the unsatisfactory state of ensuring the use of forests by local communities for recreational purposes.

The extremely important role of forests in terms of ecological, economic, and social sustainability of Ukraine determines the necessity to provide balanced resource-use mechanisms. It is necessary to balance the objectives of forest conservation, their ability to provide ecosystem services, the economic need for deforestation and the right of communities to profit from the exploitation of forests [16].

It should be noted that the activity of forestry enterprises is currently characterized by the presence of crisis tendencies, which are aggravated by the influence of a full-scale war.

The full-scale war in Ukraine affected the population, the economy, and the environment, including forests. Based on the materials of the EU4USociety project [22], the main problematic issues and prospects for developing forestry enterprises in Ukraine, particularly in war conditions, are summarised.

The main problem areas in war conditions:

1. *The difficulty of demining de-occupied territories.* Lands where active hostilities were fought, strewn with ammunition. Russia's active military operations complicate the speed of demining. Analysts emphasize that the cities and infrastructure will be demined first – it will take about ten years for the forests to be.
   According to WWF-Ukraine and the Regional Eastern Fire Monitoring Center [23], more than fifty different types of explosive munitions can be found in the forests of Ukraine that have fallen into the zone of military operations. Conventionally, the territory of the combat zone can be divided into the following types:
   (a) territories where active ground combat operations were conducted;
   (b) territories subjected to air bombardment and shelling from long-range ground units;
   (c) territories of deployment of military units;
   (d) territories that were mined to provide resistance to enemy troops.
   There is particularly little information on forest demining as of today, as surveys and demining were carried out locally, in small areas, primarily forest roads.
   According to the Institute for the Study of War [23], the areas of Polissia forests that were in the zone of military operations are as follows: Zhytomyr Oblast (127,789.8 ha), Kyiv Oblast (165,307.7 ha), Chornobyl Exclusion Zone (148,711.1 ha) Chernihiv Oblast (423499.0 ha), Sumy Oblast (287861.9 ha).
   A total of 114 state forestry enterprises, 20 agricultural enterprises, 14 municipal enterprises and 12 other forest users and owners were affected by military operations among enterprises and organisations whose activities are connected with forest. The most significant number of forests that have fallen into the zone of military operations is in the Chernihiv Oblast.
2. *Firefighting policy.* According to specialists, pristine pine forests are the most dangerous in the ignition. The map of hostilities shows that such forests are in the east of Ukraine, Polissia. Fires not only cause a loss of forest cover but also are a potential danger to the lives of residents. A possible scenario for territories with active hostilities is conservation with an analogue to the exclusion zone.
   WWF-Ukraine and the Regional East European Fire Monitoring Center [23] summarised that since the beginning of the war in Ukraine, fires have covered a total area of 2.4 million hectares, of which 1.5 million hectares (64 %) are in the territories with military operations and occupied territories: forests – 320 thousand hectares (13.1 %), agricultural land – 1340 thousand hectares (55.1 %), built-up areas – 129 thousand hectares (5.3 %), other natural landscapes – 645 thousand hectares (26.5 %). The location of nature conservation areas affected by fires (Emerald Network) is 425,000 hectares, of which 292,000 hectares (69 %) are in the territories with military operations and occupied territories.
3. *Economic restrictions.* Today, the rules for the implementation of forestry activities, in particular in the field of phytosanitary legality, are in force. During the war in Ukraine, the volume of illegally harvested wood remains consistently high, and such products will not be able to enter the EU market.
4. *Unsubstantiated and inappropriate closure of public access to some registers*: open register of logging tickets, including maps of quarter-separation division; public cadastral map; a layer with the boundaries of forests and objects of the nature reserve fund on the Ecosystem portal; a single registry for environmental impact assessment – materials for cases of deforestation, a single inspection portal.
5. *Improper ban on visiting forests where there were no hostilities.*

The above determines the need to define the priority directions for improving the management of the potential of forestry enterprises.

We believe that it is expedient to implement improvements both at the national level and at the level of individual enterprises. It is worth noting that certain changes are already taking place at the national level, considering the forest reform.

By the Resolution of the Cabinet of Ministers of Ukraine, "Some issues of reforming the management of the forest sector" [24], the state-specialised economic enterprise "Forests of Ukraine" was founded. Thus, there was a merger of specialised state forestry enterprises belonging to the sphere of management of the State Forestry Agency. The newly created enterprise "Forests of Ukraine" will be a joint-stock company. 100 % of the shares of this joint-stock company belong to the state.

The main advantages of creating a state enterprise "Forests of Ukraine" are as follows [25]:

- elimination of financial imbalances (equalisation of wages, increase of investment attractiveness of stagnant enterprises);
- management of forestry by EU standards and practices, resolution of the conflict of distribution of functions in the forestry sector (controlling - managing);
- increasing the investment attractiveness of the industry (credit resources, EU grants for the implementation of innovation and investment projects);
- detinization of the timber market, overcoming corruption, reducing illegal logging;
- use of modern information technologies for forest management;
- ensuring sustainable/efficient development of forestry.

We will present the consequences of implementing this reform through specific manifestations of the potential of forestry enterprises:

1. *Ecological potential.* The reform will allow for increasing the level of forest cover, mainly through implementing the President's Program "Green Country" and expanding the area of Ukraine's forests by 1 million hectares. Increasing forest cover will contribute to the achievement of UN Sustainable Development Goal 13 "Climate Action", and the EU Green Course Program to build a climate-neutral Europe by 2050. As a result, it will be possible to use forests tirelessly, that is, to optimize the use of wood and increase its in-depth processing.
2. *Production potential.* The creation of a single enterprise for the organization of cultivation, maintenance, and harvesting of forests will form the prerequisites for facilitating and expanding access to quality raw materials for Ukrainian wood processing enterprises.
   Simplifying the access of wood processing enterprises to forest raw materials will contribute to optimizing the use of wood and increasing its in-depth processing. This will make it possible to increase the added value created in the industry with smaller volumes of roundwood consumption.
3. *Labour potential.* Over the past 30 years, 60,000 workers have left the industry (62 % of the total workforce). Many enterprises need help to ensure stable functioning and employee confidence in the future, leading to layoffs. "Forests of Ukraine" will be able to provide the redistribution of labour resources, offering qualified workers positions throughout Ukraine with social security.
4. *Property potential.* The reform will create conditions for the renewal of fixed assets, the material and technical base, and the purchase of modern equipment, cars, and firefighting equipment for the protection and protection of forests. It will also create conditions for the restoration of forests and the increase of forest cover.

5. *Management potential.* The structure of "Forests of Ukraine" provides for the optimization of management personnel, which will free up funds for the payment of highly qualified forestry specialists in various production areas.
6. *Information potential.* Further digitalization of forestry enterprises' production processes will attract highly qualified specialists to production.

The Decree of the Cabinet of Ministers of Ukraine approved Ukraine's State Forest Management Strategy until 2035 [26]. According to the Strategy, the primary goal of a forestry enterprise is to build a transparent and effective enterprise management system for obtaining profit from economic activity. But the achievement of the goal must necessarily be accompanied by the preservation and increase of the country's natural resources and the sustainable development of forestry.

The main tasks of the forestry enterprise should be [26]:

- management of state property of permanent forest users, renewal of fixed assets and material and technical base of forestry enterprises, provision of enterprises with modern equipment for afforestation, and protection of forests, which are priority goals, with the aim of obtaining income for its owner – state;
- organization of forest management, safety, security, rational use and reproduction of forests;
- equalization of financial imbalances, increase of revenues to budgets of all levels;
- implementation of measures to preserve biodiversity in forests;
- conducting recreational activities;
- popularization among the population of the importance of conservation and rational use of forests;
- involvement of the public in the matter of forest reproduction and protection;
- ensuring equal opportunities, conditions and pay for women and men and actively encouraging women to participate at all employment levels.

While we believe that the mentioned reform will benefit the improvement of forestry enterprises management, there is still room for further progress on the national level. One of the ways of improvement is to intensify forest certification processes. According to Malek and Abdul Rahim [12], forest certification is the process of assessing the compliance of forest management with defined standards, which is carried out by independent certification organizations [12]. Such standards usually include economic, ecological, and social [13]. This process is voluntary, but it contributes to increasing the efficiency of forest resources management and positioning enterprises in ecologically sensitive markets. The two dominating in the world schemes of certification are the Programme for the Endorsement of Forest Certification Schemes (PEFC) and the Forest Stewardship Council (FSC) [12, 13].

The role of forest certification is essential due to the following facts:

- forest certification promotes environmental sustainability;
- acts as a tool for ecosystem services;
- influences the image of forest enterprises [12];
- promotes price premiums and improved market access [14].

Although there are studies that state that forest certification has limited effects [14], we believe it is an important tool for improving the forestry enterprises' potential management with a sustainability perspective.

It should be mentioned that the appropriate processes in Ukraine started in 2001, and as of December 21, 2022, more than 4 mln ha are FM-certified (forest management) by FSC (about 42 % of the total area of the forest) [27].

Zubizarreta et al suggest that forest certification can be promoted with the use of 5 mechanisms, 3 of which are external (market, signalling, and legal mechanisms), 2 are internal (learning and moral mechanisms) [13]. Thus, the mentioned mechanisms accompanied by balanced state policy in the sphere of forest certification will contribute to strengthening the respective processes, which in its turn will benefit both the sustainable development of the country and efficient forestry enterprises' potential management.

Another important way of increasing forestry enterprises' functioning efficiency is implementing the participatory approach, which involves local communities in forest management processes. In general, participatory forest management envisages engaging the local community to achieve sustainable forest management objectives [1]. We believe that the following measures can assist in involving local communities in achieving sustainable forest management:

- increasing the level of awareness of the local communities about the peculiarities of forest management based on sustainability and minimization of negative anthropogenic impact;
- popularization of a responsible and protective attitude to forest resources;
- involvement of local communities in environmental protection activities and environmental actions;
- implementation of a system of grant support for local initiatives aimed at forest conservation and rational forest use.

The participatory approach can be implemented in different forms, such as decentralized forest management, participatory forest management, joint forest management and community-based forest management [11]. The participatory approach is also promoted by forest certification [11].

One of the ways of participatory approach implementation is creating community forest enterprises, which will be able to meet economic, social and environmental challenges [10]. Such form of economic entities in the forestry sector will promote decentralization processes, but it also has disadvantages due to disbalances in the forestry sector of Ukraine. Thus, in our opinion, this direction of reform is currently not relevant enough in the conditions of Ukraine.

According to Mishenina and Dvorak [9], a participatory approach can be implemented through the public-private partnership mechanism. The authors state that the public-private partnership (PPP) mechanism is a perspective tool for economic and ecological policy implementation in the forestry sector under conditions of state and communal ownership of forests [9]. Considering the fact that 73 % of Ukrainian forests are in state ownership and 13 % are in communal ownership [6], implementation of PPP programs and mechanisms could benefit the effective functioning of the forestry enterprises and forest management as a whole.

PPP programs can contribute to efficient forest management in the following ways [9]:

- providing co-financing of projects, i.e. attracting investments to the forestry sector;
- distribution of risks between partners;
- distribution of responsibility between partners.

It should be mentioned that there is a variety of forms of PPP, which expands the possibilities of using this tool in various situations. Mishenina and Dvorak define that the agreements between forestry and recreational forest protection subcomplexes should be considered [9]. Another issue that can be solved within PPP programs, in our opinion, is the proper implementation of the forest silvicultural system. Scientists define that a continuous cover forestry system is the one that benefits both ecological and economic aspects of forest management [7]. Such a system envisages that the next generation of trees is established before the final crop trees have reached the optimal rotation period [7]; this promotes the balanced forest use mechanisms and contributes to the sustainable development of the country as a whole.

To conclude the main aspects related to the rational level of forest management, we believe it is important to identify key issues of the respective sphere. According to Pietarinen et al the dominant issues are: ecological modernization, civic environmentalism, and green governmentality [2].

In order to determine the ways of forestry enterprises' potential management improvement at the level of individual enterprises, it is necessary to conduct an appropriate analysis. To define priority measures for the improvement of forestry enterprises management, we find it expedient to identify key factors of impact on the basis of correlation and regression analysis. Net profit of the forestry enterprises was chosen as a dependent variable (Y), as the respective indicator is an absolute measure of business entities' performance. We believe that such choice of the dependent variable is due to its particular importance from the enterprise development perspectives standpoint. It is the net profit which reflects the internal capabilities of the enterprise to provide necessary funding for the development initiatives. Thus, we consider it expedient to analyze the impact of individual factors on the formation of the net profit. As the independent variables the following indicators were chosen:

X_1 – fixed assets to current assets ratio;
X_2 – fixed assets turnover;
X_3 – current assets turnover;
X_4 – ratio between receivables and payables;
X_5 – operating cycle duration, days;
X_6 – labour productivity, ths. UAH / person;
X_7 – net revenue growth rate;
X_8 – material capacity;
X_9 – sales profitability;
X_{10} – current ratio;
X_{11} – cash ratio;
X_{12} – financial leverage.

The choice of the mentioned above indicators is defined by the fact that they represent, in our opinion, key aspects of resource provision and the financial condition of the forestry enterprise. Another factor that impacts the selection of the mentioned criteria is the availability of the data. All necessary data for calculating the relevant indicators are contained in the official financial statements of enterprises. So, we can conclude that the choice of the independent variables meets the following requirements:

- the indicators in complex reflect the main directions of the resource provision of the forestry enterprises (e.g. technical, material, human resources);
- the main complements of the financial state such as stability, profitability, and economic activity are characterized within the chosen indicators;
- the data for calculating and analysis of the mentioned above indicators are available in the financial statements of the enterprises.

In the next step, we will form the observation base for correlation and regression analysis. As the research objects, 10 forestry enterprises of the Polissia region were chosen. Within the framework of this research, the following oblasts belong to the Polissia region: Volyn (SE "Horodotske forestry", SE "Manevytske forestry"), Rivne (SE "Bereznivske forestry", SE "Sarnenske forestry"), Zhytomyr (SE "Bilokorovytske forestry", SE "Korostenske forestry"), Kyiv (SE "Bohuslavske forestry", SE "Teterivske forestry"), and Chernihiv (SE "Horodnianske forestry", SE "Chernihivske forestry"). The observation period is 2019-2021. Such observation period is determined due to the fact that financial statements of the enterprises for 2022 were not formed and publicized at the time of the research. At the same time, the selected period covers 2019 (the pre-crisis period due to the COVID-19 pandemic), 2020 (the crisis period), and 2021 (the period of overcoming the consequences of the crisis). Thus, the total number of observations is 30, which ensures the representativeness of the raw data for correlation and regression analysis.

The initial data for the analysis are presented in table 2.

According to the calculated data, we can note some common trends in the development of forestry enterprises:

- during 2019-2020, in the activity of the vast majority of the analyzed enterprises, a reduction in activity volume is observed, while in 2021, there is a substantial increase;
- high degree of production costs capacity of the enterprises' activity;
- a sufficient level of liquidity;
- current assets mostly dominate the structure of assets.

It should be mentioned that a high level of cost capacity is considered by scientists as one of the most crucial factors influencing the forestry enterprises functioning [15].

The next step is to analyze the factors from the interrelationship point of view, as well as to perform a multicollinearity test. The results of the correlation analysis are presented in the matrix of pair correlations (table 3).

According to the data presented in table 3, we must note that there is a relationship of varying degrees between the dependent and independent variables. The strongest (highest) level of influence on the formation of the net profit indicator (Y) is determined by factor X_6 (labour productivity). Independent variables X_5 (the operating cycle duration) and X_7 (net revenue growth rate) are also marked by a substantial degree of connection. It is worth noting that according to the multicollinearity test, there is a substantial degree of connection between X_6 and X_7 factors, but we believe it is appropriate to leave both factors for further consideration.

The equation formed by the results of regression analysis is the following:

$$Y = -6359.68 - 82.07X_5 + 12.74X_6 + 4938.27X_7, \tag{1}$$

where Y – net profit, ths. UAH, X_5 – the operating cycle duration, days, X_6 – labour productivity, ths. UAH / person, X_7 – net revenue growth rate, coefficient.

According to the regression equation parameters, the determination coefficient $R^2 = 0.7$; that is, 70 % of the variance of the values of the dependent variable (net profit) is explained by the obtained equation. It should be mentioned that the relatively low level of determination coefficient is due to the fact that net profit formation, in addition to the internal factors analyzed in the model, is influenced by a significant number of external factors, for example, the exchange rate volatility, the balance of the foreign trade balance, the international policy of the government, the level of inflation, etc. Thus, we believe that for the purposes of the current research aimed at improvement of forestry enterprises internal management, the value of the determination coefficient is sufficient. According to the results of the F-test (Fisher's test), the constructed model is considered adequate for the sample data because $F_{fact}(20.17) > F_{crit}(3.35)$ (with a probability of error of 0.05).

Thus, as a result of the built model, we can highlight key directions for increasing the efficiency of the functioning of forestry enterprises in terms of the formation of net profit:

- reducing the duration of the operating cycle;
- increasing the level of labour productivity;
- ensuring the growth of net revenue at progressive rates.

The basic activities within forest management include the following: technological activities, quality activities, transport activities, storage, and delay [8]. That means that the mentioned

above directions should be implemented within each and every basic activity to achieve the proper result and to increase the efficiency of forestry enterprises' functioning.

The next step of our study is to identify key measures of forestry enterprises' potential management improvement according to the defined impact factors.

1. *Reduction of the duration of the operating cycle.*

The duration of the enterprise's operating cycle is an indicator of the rhythm of all business processes of the forestry enterprise, which is ensured by the action of internal and external environmental factors. According to the National Accounting Regulation (Standard) 1 "General Financial Reporting Requirements" [28], the operating cycle is interpreted as the time interval between the acquisition of stocks for the implementation of activities and the receipt of funds (cash equivalents) from the sale of products or goods and services produced from them.

The shortening of forestry enterprise operating cycle can be achieved through the reduction of the terms of turnover of assets, particularly in the part of stocks and receivables. Shortening the operating cycle leads to more stable financing of the company's current activities. Sufficient financing creates conditions for the uninterrupted supply of materials to the production process, which means the optimization of the duration of the production process and the sale of products based on high quality and the use of existing competitive advantages on the market. In turn, selling products should be accompanied by a rational policy of managing the company's receivables.

Forestry enterprises can achieve a decrease in turnover time of current assets under the following conditions:

- implementation of economically justified stock norms;
- compliance with the principle of optimal price-quality ratio when forming stocks;
- improvement of logistics management and improvement of the sales policy of enterprises;
- intensive reproduction of the elements of the property potential of the enterprise;
- active introduction of aspects of the circular economy on the ground in forestry;
- 100 % implementation of certification of forestry enterprises;
- study of the product structure and increase in the specific weight of products of high demand;

- effective management of receivables (control over the occurrence and state of receivables at each stage of the implementation of management decisions; control of settlements with debtors for deferred and overdue debts);
- building a rational system of interaction with banks regarding the attraction of funds and the implementation of settlements, and the implementation of optimal credit policy;
- constant monitoring and improvement of the company's settlement system.

The strategic management of the operating cycle requires a separate study. In forestry, the operating cycle includes economic operations for reproducing and harvesting forest resources. Growing such assets exceeds one operating cycle and is 50-70 years.

2. *Increasing labour productivity.*

Savings in the consumption of current assets helps to improve the use of production facilities and increase labour productivity. Scientific, technical, organizational, structural and socio-economic changes are classical factors of labour productivity improvement. Personnel turnover and the problem of HR policy of forestry enterprises require balanced management steps to increase labour productivity. The war in Ukraine complicates the situation.

So, forestry enterprises can take following steps in this sphere:

- make structural changes in production;
- improve the material and technical level of activity and production;
- improve management, organization of production and labour (improvement of the structure and rational distribution of management functions, social protection of employees, increase of the wage fund);
- increase in production and sales volumes (management and structural reform of forestry enterprises along with a relative reduction of employees);
- diversifying forestry enterprises' activities (expanding areas of activity and searching for new types of activities).

3. *Ensuring the growth of net income at progressive rates.*

The proposals summarized by us from the point of view of shortening the operating cycle and increasing labour productivity in the complex may be effective for the growth of the net income of forestry enterprises. This indicator is a marker of the financial and economic condition of the forestry enterprise. Also, the indicator reflects the level of economic security of the enterprise. Diversification of the activities of forestry enterprises is one of the ways of achieving the growth of net income at a faster pace. One of the options for diversification is the cultivation of energy crops on forestry lands that cannot be used for other needs and the subsequent production of products from the corresponding crops [18]. This measure will contribute not only to the better use of forest resources but also will generate an additional flow of income for the enterprise.

Another important issue to be addressed for the efficient functioning of forestry enterprises is their adaptation to the conditions of the external environment. As we mentioned earlier, the process of functioning of forestry enterprises and the process of their net profit formation, in particular, are being influenced by a large variety of external factors. Thus, it is essential to form the mechanism of enterprise interaction with the environment. Such a mechanism will benefit not only to efficient functioning of the forestry enterprises, but also to reducing the negative anthropogenic influence on the environment [29].

6. Conclusions

As the result of the conducted research, we can conclude the following.

1. Forest is an extremely important resource that not only ensures the livelihood of mankind but is also a source of renewable resources under conditions of balanced environmental management. Forest ecosystems create conditions for people's lives, thus forming a critically important foundation for ensuring the sustainable development of any country. The forests of Ukraine cover 15.9 % of the territory, providing economic, ecological and social functions. Efficient functioning of the forestry enterprises contributes to the sustainable development of the country due to the performed functions.
2. Negative trends have been observed in recent years related to deforestation, forest degradation, and a decrease in the efficiency of forestry enterprises functioning. The existing crisis trends in the forestry sector have significantly deepened as a result of the full-scale war on the territory of Ukraine, which necessitates the implementation of measures to improve the management of the potential of forestry enterprises. The main problematic issues related to the consequences of the full-scale war are the following: the difficulty of demining de-occupied territories; forest fires, economic restrictions, inappropriate closure of public access to some registers, improper ban on visiting forests where there were no hostilities. These and other threats to the efficient functioning of the forestry enterprises define the necessity of improvement of the existing enterprise management mechanism in the relevant sector of economic activity.
3. Considering the complexity of the problems related to effective forest management, we are convinced that measures to increase the efficiency of the use of the forestry enterprises' potential should cover both the national level and the level of individual economic entities. It is worth noting that at the national level, there are already changes related to forestry sector reform. In particular, the creation of the state enterprise "Forests of Ukraine" will contribute to a balanced approach in the field of forest management. At the same time, we believe that it is possible to expand the priority directions of state policy in the specified area with the measures related to enhancing certification processes, as well as implementing a participatory approach in forest management.
4. To determine the measures that should be implemented to improve the enterprise potential management system at the level of individual enterprises, the method of correlation and regression analysis was used. The observation base was formed by data for 2019-2021 on 10 forestry enterprises in the Polissia region. The net profit was chosen as a dependent variable as it is the indicator which reflects the economic result of the enterprise functioning. The conducted analysis made it possible to detect that the key internal factors of influence on the net profit, thus, on the efficiency of the enterprise, are as follows: the operating cycle duration, labour productivity, net revenue growth rate.
5. Based on the analysis, it was found that priority measures should include reducing the duration of the operating cycle, increasing labour productivity, and ensuring high rates of net income growth. Key measures within each of the considered directions are proposed. Considering the caveats on the model of the dependence of net profit on internal factors, it was determined that an important direction of increasing the efficiency of management of the forestry enterprises' potential is also ensuring the mechanism of interaction with the environment.
6. The prospects for further research lie in the definition of strategic measures in the identified areas (in particular, regarding the management of the duration of the operating cycle), as well as in the study of the influence of external factors on the activities of forestry enterprises.

Abstract. Approaches to harmonization of methods for determining the optimal level of investment in the renewal of the fleet of combine harvesters and current expenses of agricultural enterprises under conditions of implementation of sustainable development goals in the activities of economic entities are investigated. It is established that the implementation of the concept of sustainable development for the domestic agricultural sector intensifies the processes in it, brings to the fore the problems of ensuring food security of the State, increasing the production of safe products while preserving landscapes and minimizing anthropogenic pressure. At the same time, the seizure of part of the territory, mining of the liberated and adjacent to the combat zone areas raises the issue of rational use of land resources. Under such conditions, only further introduction of innovations aimed at increasing yields and the use of intensive technologies is the most important vector for the development of domestic agriculture. This places strict requirements on the technical condition of its resource potential. Unfortunately, the unsatisfactory technical condition of the grain harvesting machinery fleet and its destruction as a result of hostilities exacerbate the problem of technical support for grain production, in particular for harvesting. Under such conditions, an important task is to develop methodological techniques for determining the optimal, harmonized values of investments in the reproduction of resource potential and operating costs. The tested methodological approach allows determining the optimal level of investment in the renovation of the combine harvester fleet, taking into account the peculiarities of wheat production organization, grain price conditions, material resources, harvesting equipment, and financial factors. The calculations showed that it is economically inexpedient to invest in the renewal of the combine harvester fleet using the most common combine harvester models if one unit has less than 600 hectares of wheat crops. A positive feature of the tested approach is the ability to minimize unproductive costs by taking into account technological and market factors in determining the optimal level of costs. Instead, the introduction of innovations leads to a change in the form of the production function, which should affect the dynamics of the marginal efficiency of investments, and therefore it is promising to expand approaches to modeling and take into account the role of innovations in finding the optimal level of current costs and investments.

1. Introduction

The functioning of the agrarian sector on the basis of sustainable development implies that it provides three interrelated functions: economic (providing income to agricultural producers), social (ensuring food security, providing productive employment, improving the quality of life) and environmental (maintaining biodiversity, preserving the integrity of the agricultural landscape, soil fertility, clean air and water resources) [1]. Understanding the role of the agricultural sector, in particular the grain industry, through the prism of the Sustainable Development Goals [2] allows us to consider the latter as a guarantor of the country's economic and food security. Ensuring the sustainability of agricultural production and the realization of its social function determines the increase in grain production, which places strict requirements on the fleet of combine harvesters. Problems in this area have been repeatedly discussed during discussions on the prospects for the development of the agricultural sector. In particular, it is worth mentioning the 2.5-fold reduction in the fleet of combine harvesters of Ukrainian agricultural enterprises during 2000-2020, which led to a permanent increase in the amount of operating hours per unit. As a result, the workload per combine harvester reached almost 200 hectares at the end of 2020, while in Germany and France in 2016-2020 it did not exceed 60-70 hectares of wheat crops.

The problem can be solved by simultaneously increasing investments in the renovation of the grain harvester fleet and obtaining harvesting equipment on a land-list basis. The drop of more than 30% in gross domestic product significantly limits the investment opportunities of agricultural companies and significantly increases the cost of borrowed resources. Under such conditions, it is particularly important to justify approaches to determining the optimal level of capital expenditures and their harmonization with the level of current costs caused by the technological process.

Sustainable development is a basic concept for business and policy development that reflects the understanding that progress is impossible without addressing pressing environmental issues such as ecosystem degradation and climate change. This implies that society can only develop on the basis of meeting the needs of the present while protecting the livelihoods of present and future generations [3]. Since the laws of nature and social development are unchanging and immutable [4], the solution is for society to respect the limits of "safe workspace" [5, 6] and limit environmental damage [7]. Although "sustainability is a pluralistic concept" [8], in a broad sense it focuses on simultaneously ensuring economic growth, societal prosperity, and environmental protection [9]. In this sense, the concept of sustainable development integrates economic, social, and environmental concerns and offers a new way of thinking that recognizes the world as interconnected between nature, society, and the economy [10].

It should be noted that population growth and changes in the structure and volume of consumption cause an increase in anthropogenic pressure [11]. Sustainable land use can reduce the negative impact of these stressors. The Sustainable Development Goals (SDGs) were formulated in 2015 to meet the demands of the present, and they enshrine the commitment of developed countries to end poverty and hunger by 2030. However, climate change poses a challenge to achieving these goals, as slow processes of environmental change, increased climate variability, and extreme weather events negatively affect agricultural productivity [2]. That is why innovation strategies, in particular agricultural innovation systems (AIS), are key examples of potential ways to improve the economic, environmental and social performance of the agricultural sector. Not only because agriculture contributes about 30% of the world's gross domestic product and has a high return on investment [12], but also because of the long-term positive impact of agricultural research and development (R&D) on productivity growth, and because new technological solutions contribute to the sustainable use of natural resources. Nevertheless, agriculture receives about 5% of R&D investments [13].

In turn, an important economic problem in economics and econometrics research is the substantiation of approaches to determining the economic and environmental optimum of operating (technological) and capital costs in the context of rapid implementation of R&D results. A significant contribution in this area has been made by scientists who have studied the use of production functions. In particular, we note the works devoted to the identification of production functions [14–19]. Secondly, studies on industrial organization [20], trade [21–24] and international economics [25], which aim to measure productivity [26], returns to scale, and more recently, prices [16, 27, 28] using production functions. Third, a significant contribution has been made in works that focus on the development of methods for estimating multi-product production functions [29–33]. And fourth, a whole area of macroeconomic literature, starting with [34], is devoted to the issues of uncertainty in product prices. The approaches of these authors are based on the assumption of the form of the production function, which allows its identification [35].

Investment is a continuous, systematic activity that focuses on the entire organization, including its forms and methods [36]. Investing in innovation determines the ability of an agricultural enterprise to maintain competitive advantage and better respond to rapid market and economic changes [37–40]. This process is based on the use of tools and measures that are important for the transition of society and the economy to sustainable development [41, 42]. Recognition of agricultural innovation as a driving force for addressing environmental issues and social inequalities has led to the emergence of sustainable entrepreneurship in the agricultural sector [43]. Sustainable entrepreneurship encompasses business entities that can achieve profitability by exploiting environmental market gaps [44]. They address social and environmental challenges through a business approach based on human values and go a step further to mitigate the impact of economic crises while promoting economic growth and social equity [45, 46].

However, today's challenges, in particular the complexity and, in some aspects, the impossibility of predicting the development of economic processes, make it important to study approaches to determining the optimal level of investment and their harmonization with the level of current costs of agricultural enterprises.

2. Results and discussion

The functioning of the agrarian sector on the basis of sustainable development, the realization of its economic and social function, overcoming the challenges caused by the actions of the aggressor, leads to a reorientation of approaches to modeling technological processes to effective principles, maximizing production and profit. In view of this, nonlinear production functions that maximize the output or added value were chosen as the methodological basis for modeling the cost optimum. In turn, there is a need to harmonize approaches to determining the optimal amount of operating costs that maximizes output with the amount of investment to restore the resource potential damaged as a result of hostilities. The harmonization of economic processes is usually interpreted as their mutual coordination, systematization, unification, coordination, streamlining, and compliance. Harmonization of economic processes helps to balance the functioning of a business entity. Its systemic vision switches to the coordination of the formation and use of its resource potential, investment and operating costs. Thus, the methodological basis of our study is a system of models that allows harmonizing the ratio of operating expenses and capital investments.

The first step towards solving the problem was to determine, based on the statistical processing of the 2020 reports of Ukrainian agricultural enterprises, the equation of dependence of wheat yield on variable costs per hectare of harvested area:

$$f_1(x) = -0.180x^2 + 6.425x, \tag{1}$$

where $f_1(x)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand.

The dependence has a high level of statistical reliability, as evidenced by the value of the coefficient of determination (R^2), which for function (1) is 0.9106, as well as the excess of the calculated value of the Fisher coefficient ($F_p = 28.0$) over its tabular value ($F_{tab} = 0.116$). At the same time, based on the values of the Student's t coefficient, the coefficients for the linear and quadratic terms of the formula (1) were also highly reliable. In particular, with the tabular value of this coefficient from -1.72 to 1.72, its actual values with the specified members were equal to 3.2 and 6.17, respectively.

The relevance of the application of function (1) for planning calculations ensures compliance with the optimal wheat harvesting terms, which in the case of single-phase (direct) harvesting should not exceed 6-10 days after the wheat reaches full maturity. At the same time, an analysis of the conditions and timing of early grain harvesting in 2016-2020 shows that due to the insufficient quantity and unsatisfactory technical condition of most of the grain-harvesting equipment, its duration was from 32 to 55 days [47]. At the same time, the extension of the duration of the harvesting campaign beyond a ten-day period caused a daily decrease in productivity by 1% [48], as a result of which more than 10% of the potential harvest, i.e. 6-6.5 million tons of grain, was lost.

Considering this circumstance, the question arose – is it possible, by slightly reducing the expected level of yield and the planned level of costs, to minimize crop losses and maximize the financial result, and how to implement such an approach in the production function (1). To solve it, a component was introduced to equation (1), which allows to adjust the expected potential yield by the amount of potential losses, proportional to the duration of the harvesting campaign (d). Taking this into account, the modified form of function (1) is as follows:

$$\begin{aligned} f_2(x,d) &= (-0.180x^2 + 6.425x) - 0.01(d-10)\cdot(-0.180x^2+6.425x) = \\ &= (1.1-0.01d)\cdot(-0.180x^2+6.425x), \end{aligned} \tag{2}$$

where $f_2(x,d)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand; d – duration of the collection campaign, days.

In the future, functions (1) and (2) were combined into a system that allows you to determine the expected yield in the event that the harvesting campaign ends in the optimal agrotechnical period or in the event that it is extended beyond a ten-day period:

$$f_3(x,d) = \begin{cases} (-0,180x^2 + 6,425x) \text{ if } d \leq 10 \\ (1,1–0,01d)\cdot(-0,180x^2+6,425x) \text{ if } d \geq 10, \end{cases} \tag{3}$$

where $f_3(x,d)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand; d – duration of the collection campaign, days.

The inclusion of the variable d in function (2) necessitated the formalization of approaches to calculating the latter. It is logical to calculate it through the ratio of the expected gross harvest and the total productivity of the combine harvester fleet of the agricultural enterprise. In turn, the expected gross yield is the product of the sown area and the planned yield. The latter, for modeling purposes, can be determined using function (1). In the meantime, the total productivity of the farm's combine harvester fleet is determined by their number, hourly productivity, and shift duration. At the same time, to take into account the production conditions and the technical condition of combine harvesters, it is advisable to introduce a shift time efficiency factor:

$$d(pl,x,k) = \frac{pl\cdot f_1(x)}{k\cdot W_{hour}\cdot T_{zm}\cdot K_{vrch}}, \tag{4}$$

where pl – is the area from which wheat was harvested, ha; $f_1(x)$ – expected yield of wheat, tons/ha; W_{hour} – hourly productivity of the grain harvester, centner per hour; T_{zm} – shift duration, hours (according to [49–51] the recommended value is 12.0 hours); K_{vrch} – coefficient of use of the working time of the shift (according to [49–51] the recommended value is 0.7);k – is the number of grain harvesting units, units.

Taking into account the purely individual nature of the formation of the size of wheat sowing areas and the fleet of combine harvesters for each agricultural enterprise, their ratio in formula (4) was replaced by the planned area of wheat threshing by one combine harvester (N):

$$d(x, N) = \frac{N \cdot f_1(x)}{W_{hour} \cdot T_{zm} \cdot K_{vrch}}, \tag{5}$$

where N – is the planned area of wheat threshing by one combine harvester, ha.

After that, based on the analysis of statistical reports, it was determined that domestic grain producers mainly have units with an engine power of 330-335 hp. The analysis of the market of grain harvesting equipment shows that the closest to the indicated capacity are the sixth class combines widely represented on it – *New Holland CR7.90*, *John Deere S670*, *John Deere S770*, *CASE IH 7140*, *CASE IH 7240*, *Gleaner S97*, *Claas Lexion 740*, *Massey Ferguson 9540*, *Massey Ferguson 9545* [52]. With this in mind, based on the analysis of the offer of aggregates from this list on the Tractorhouse.com website [53], the model with the largest number of lots – *John Deere S670*, which has a nominal engine power of 317 hp – was chosen as the base model with hourly productivity of 111.27 centner per hour.

Further, by substituting into function (5) the actual and recommended values of the hourly productivity of the John Deere S670 combine (111.27 t/ha), the duration of the shift (12 hours), the coefficient of utilization of the working time of the shift (0.7), an analytical expression was formed functions of the dependence of the duration of the harvesting campaign on the planned threshing area with one unit and variable costs per crop unit:

$$d(x, N) = \frac{N}{937.67} \cdot (-0.180x^2 + 6.425x), \tag{6}$$

where x – variable production costs per 1 ha of harvested wheat area, UAH thousand; N – is the planned area of wheat threshing by one combine harvester, ha.

Later, the variable d in the second equation of system (3) was replaced by the right-hand side of expression (6):

$$f_3(x, d) = \begin{cases} (-0.180x^2 + 6.425x) \text{ if } d \leq 10 \\ \left[(1.1 - 0.01\frac{N}{937.67}(-0.180x^2 + 6.425x)\right](-0.180x^2 + 6.425x) \text{ if } d \geq 10 \end{cases}, \tag{7}$$

where, $f_3(x)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand; d – duration of the collection campaign, days; N – is the planned area of wheat threshing by one combine harvester, h.

A graphic illustration of the dependence of wheat productivity on variable costs at different harvesting areas indicates a reduction in non-productive losses in the case of a reduction in the load on the grain harvester and an increase in the technological efficiency of grain production (figure 1).

The next step was the modeling of the impact on the economic efficiency of grain production of the intensity and load on grain-harvesting equipment during wheat threshing. For this reason, the system of equations (7) was transformed. In particular, based on the assumption of one hundred percent marketability of grain production, in order to determine the expected volume of marketable products, the equations were multiplied by the average price of wheat grain sold by agricultural enterprises of Ukraine in 2020, which, according to the official website of the State Statistics Service, was 386.75 UAH/ha. Taking into account the measurement of variable costs per crop unit in the system of equations (7) in thousand UAH, the price of 1 t of wheat grain was converted into the unit of the same name.

After that, to determine the expected profit, the right-hand side of the equations was reduced by the value of variable costs x and the average value of fixed costs in the production of wheat

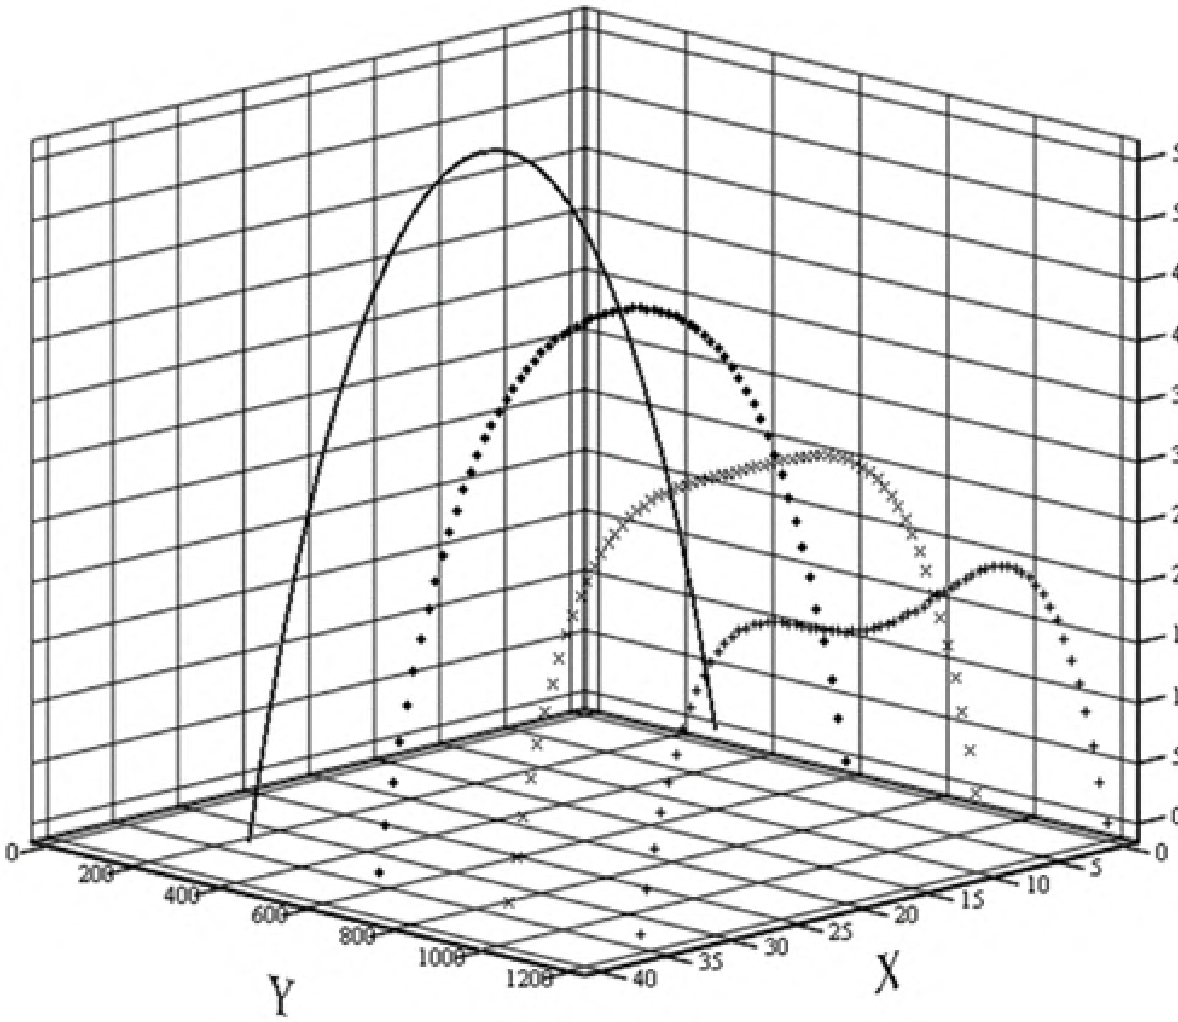

Figure 1. Impact on wheat yield of production intensity and conditions of use of harvesting equipment by agricultural enterprises of Ukraine in 2020 (according to the official website of the State Statistics Service of Ukraine `http://www.ukrstat.gov.ua/`). Graph of dependence of yield (centner per ha) on variable production costs per 1 ha of crops (UAH thousand) at $+++$ – annual load on a grain harvester of 1200 hectares; $\times\times\times$ – annual load on a grain harvester of 900 hectares; $***$ – annual load on a grain harvester of 600 hectares; —— – annual load on a combine harvester of 300 hectares; X – variable production costs per 1 ha of area, UAH thousand; Y – annual load on the grain harvester, ha.

grain, which, according to the analysis of the reporting on the costs of agricultural enterprises of Ukraine for 2020, amounted to 2,711 thousand UAH/ha.

$$f_6(x,d) = \begin{cases} (-0.180x^2 + 6.425x) - x - 2.711 \text{ if } d \leq 10 \\ \left[(1.1 - 0.01 \cdot \frac{N}{937.67}(-0.180x^2 + 6.425x)\right] \cdot (-0.180x^2 + 6.425x) \text{ if } d \geq 10 \end{cases}, \quad (8)$$

where $f_6(x,d)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand; d – duration of the collection campaign, days; N – is the planned area of wheat threshing by one combine harvester, h.

Graphical interpretation of the behavior of function (8) indicates a decrease in the maximum profit, as well as the optimum cost, which guarantees its achievement in case of an excessive increase in the load on the grain harvester (figure 2).

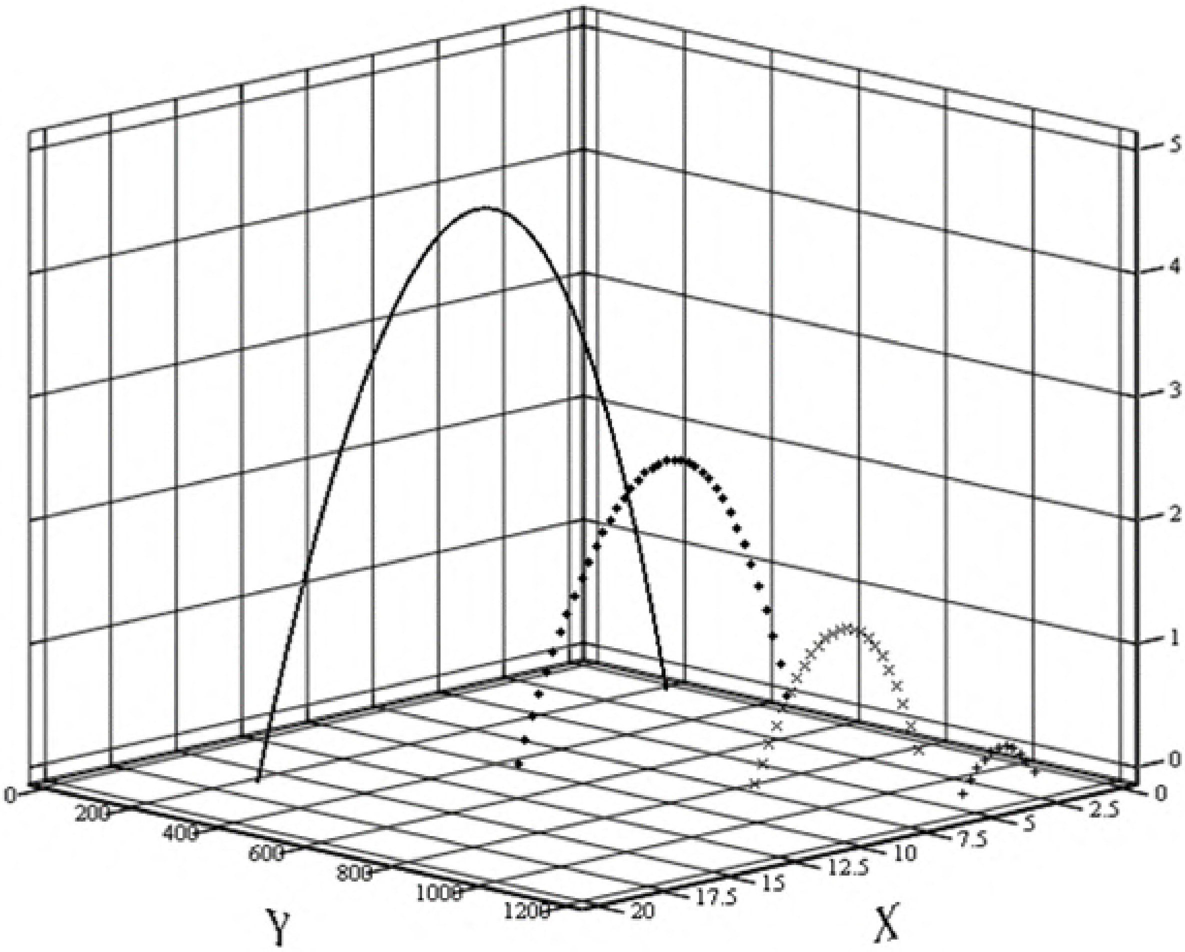

Figure 2. Impact on the economic efficiency of wheat production of production intensity and conditions of use of available harvesting equipment by agricultural enterprises of Ukraine in 2020 (according to the official website of the State Statistics Service of Ukraine `http://www.ukrstat.gov.ua/`). Dependence of profit (thousand hryvnias per ha) on production costs per 1 ha of crops (*UHA thousand*) at + + + – annual load on a grain harvester of 1200 hectares; × × × – annual load on a grain harvester of 900 hectares; ∗ ∗ ∗ – annual load on a grain harvester of 600 hectares; —— – annual load on a combine harvester of 300 hectares; X – variable production costs per 1 ha of area, UAH thousand; Y – annual load on the grain harvester, ha.

So, under the conditions when each harvester of an agricultural enterprise accounts for 300 hectares of wheat crops, the maximum profit of 4.2 thousand UAH/ha is guaranteed by technology with variable costs of 9.0 thousand UAH/ha. Instead, the choice of this technology at a load of 1,200 ha leads to a loss of -2.7 thousand UAH/ha. Under such a load, the technology with variable production costs of 3.9 thousand UAH/ha is optimal, for which the financial result will be equal to +0.4 thousand UAH/ha.

Therefore, under the conditions of threshing 1200 hectares of wheat with each combine harvester, it would be more expedient for the farm to use the technology with variable costs per crop unit almost six times lower compared to the technology that allows to achieve maximum productivity. It is clear that the rejection of industrial technologies reduces the efficiency of using the resource potential of agricultural formations, and therefore it is logical to increase investments in the technical base of harvesting operations. But taking into account the effect of agrobiological factors, the payback of such investments has a declining character. Therefore, when determining the optimal amount of capital and current costs, model (8) was transformed by including the increase in depreciation deductions and other fixed costs due to capital investment.

So, to calculate the increase in depreciation deductions, the average costs for the purchase of a combine harvester in the reporting year – UAH 4,845.4 thousand were evenly distributed over the 12 years recommended by the John Deere company as a guideline for the productive use of this brand of combine harvester. The obtained value – UAH 403.8 thousand should be distributed to the entire fleet of combines and the planned load during wheat harvesting. For example, in the case of doubling the fleet of combines, the average increase for each combine will be 50% of UAH 403.8 thousand, similarly, in the case of a fourfold increase in the fleet, the share of purchased will reach three quarters, and therefore each combine will account for 75% of 403.8 UAH.

Taking this into account, the formula for calculating the increase in depreciation deductions looks like this:

$$A = \frac{403.8 \cdot n}{N}, \tag{9}$$

where n – is the share of newly purchased grain harvesters in their total number; N – annual load on the grain harvester, ha.

In addition, a potential increase in fixed costs was formalized under the conditions of payment of interest for the use of a loan taken out to cover the costs of purchasing a combine harvester. Thus, according to the statistical data of the official website of the National Bank of Ukraine, in 2020, agricultural commodity producers attracted long-term loans for the purchase of equipment at an average rate of 16%. Thus, under the conditions of linear accrual of interest payments, the annual cost of paying interest (I) will be equal to:

$$A = \frac{775.3 \cdot n}{N}, \tag{10}$$

where n – is the share of newly purchased grain harvesters in their total number; N – annual load on the grain harvester, ha.

So, taking into account the potential increase in fixed costs, the system of equations for determining the expected profit looks like this:

$$f_7(x,d) = \begin{cases} (-0.180x^2 + 6.425x) - x - 2.711 \text{ if } d \leq 10 \\ \left[(1.1 - 0.01 \cdot \dfrac{N}{937.67} \cdot (-0.180x^2 + 6.425x)\right] \cdot \\ \cdot(-0.180x^2 + 6.425x) - \dfrac{(403.8 + 775.3) \cdot n}{N} \text{ if } d \geq 10 \end{cases}, \tag{11}$$

where $f_7(x,d)$ – is the expected yield of wheat, tons/ha; x – variable production costs per 1 ha of harvested wheat area, UAH thousand; d – duration of the collection campaign, days; N – is the planned area of wheat threshing by one combine harvester, h.

Graphical interpretation of the behavior of function (11) shows the non-linearity of changes in the payback of investments (figure 3).

In particular, the reduction of the load from 1,200 ha to 900 ha, due to the expansion of the collection equipment park, leads to an increase in fixed costs by 0.3 thousand UAH/ha. As

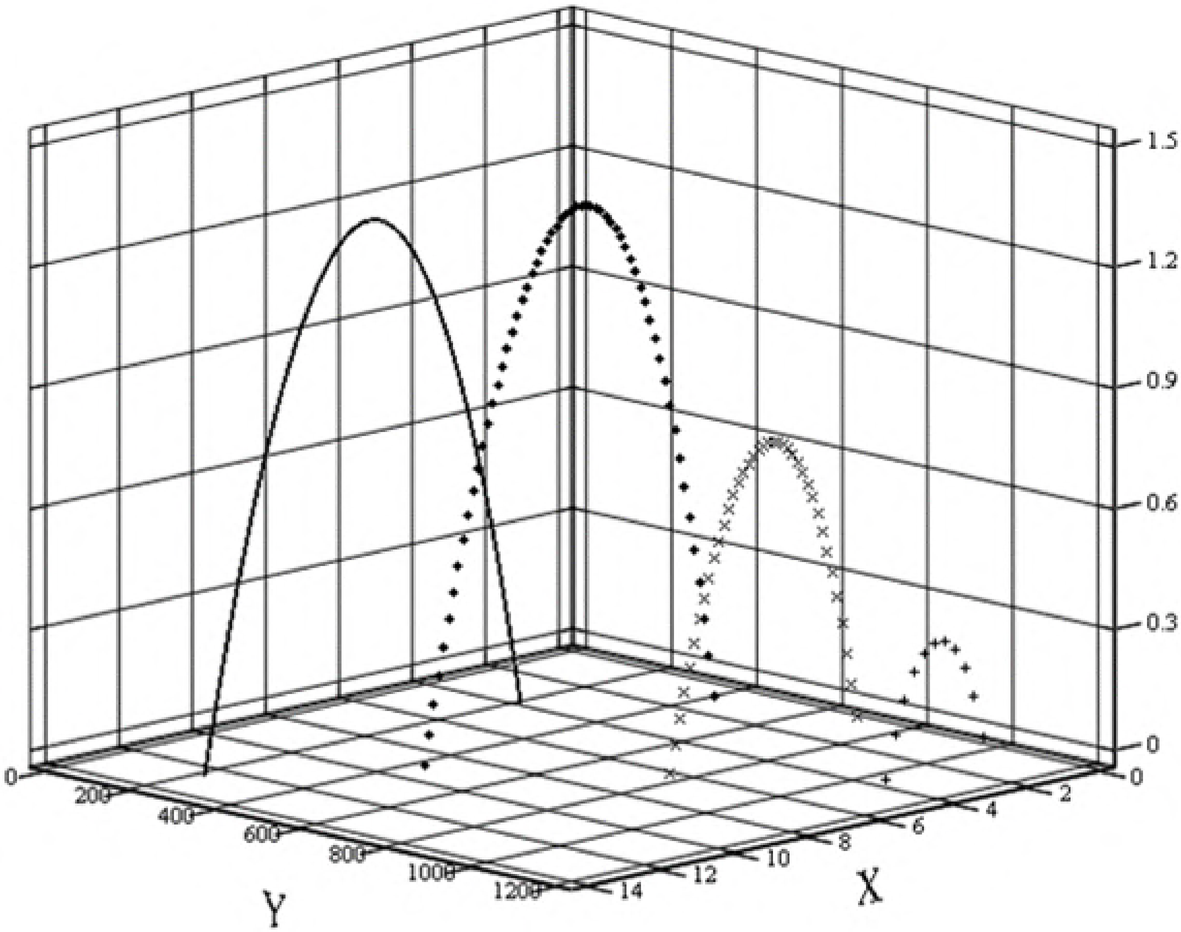

Figure 3. Impact on the economic efficiency of wheat production of production intensity and conditions of use of existing and newly acquired harvesting equipment by agricultural enterprises of Ukraine in 2020 (according to the official website of the State Statistics Service of Ukraine `http://www.ukrstat.gov.ua/`). Graph of dependence of yield (centner per ha) on variable production costs per 1 ha of crops (UAH thousand) at $+++$ – annual load on a grain harvester of 1200 hectares; $\times\times\times$ – annual load on a grain harvester of 900 hectares; $***$ – annual load on a grain harvester of 600 hectares; —— – annual load on a combine harvester of 300 hectares; X – variable production costs per 1 ha of area, UAH thousand; Y – annual load on the grain harvester, ha.

a result, it becomes possible to switch to technology with variable costs of UAH 5,000 with a simultaneous increase in the production intensity indicator by 1,100 UAH/ha (t1). At the same time, the consequence of reducing the duration of the harvesting company and reducing non-productive costs is an increase in productivity to UAH 23.1 thousand, which, with one hundred percent marketability of production, is equivalent to an increase in revenue by 1.9 thousand UAH /ha ($23.1 - 18.3 \times 0.3868$). As a result, the profit of the agricultural enterprise increases by 0.4 thousand UAH/ha. Similarly, under the conditions of reducing the load from 1,200 to 600 ha, the expected profit increase will reach 1,000 UAH/ha. At the same time, under the conditions of reducing the load from 1,200 to 300 hectares, the financial result will increase by only UAH 0.9 thousand, which indicates a decrease in the marginal efficiency of costs.

Thus, in the case of an increase in the park, which allows to reduce the load from 900 to 600

Table 1. The influence of the load on the John Deere S670 combine harvester on the optimal intensity and efficiency of wheat grain production by agricultural enterprises in 2020 (according to the official website of the State Statistics Service of Ukraine `http://www.ukrstat.gov.ua/`).

Indicators	Load on combine harvester, ha			
	300	600	900	1200
Optimum expenses, thousand hryvnias/ha				
plenteous	17.8	17.8	17.8	17.8
profitable	9.0	6.7	5.0	3.9
Productivity (c/ha) with costs at the level				
crop optimum	52.5	42.0	31.4	20.9
profitable optimum	41.7	30.6	23.1	18.3
Financial result (thousand hryvnias/ha) with costs at the level of the harvest optimum, under the conditions of use				
using exclusively available grain harvesters	0.4	-4.5	-8.5	-12.6
investments in the renewal of the fleet of grain harvesters	-1.4	-5.4	-9.5	-12.6
Financial result (thousand hryvnias/ha) with expenses at the level of the profitable optimum, under the conditions of use				
using exclusively available grain harvesters	4.2	2.3	1.1	0.4
investments in the renewal of the fleet of grain harvesters	1.3	1.4	0.8	0.4
Average fixed costs, thousand UAH/ha	2.7	2.7	2.7	2.7
Investments are included in the current year's fixed costs	2.9	1.0	0.3	-
including including depreciation	1.0	0.3	0.1	-
interest expense	1.9	0.6	0.2	-

ha, the increase in fixed costs is 0.7 thousand UAH/ha, the optimal level of variable costs is 1.7 thousand UAH/ha, marketable products – 2.9 thousand UAH/ha $(30.6 - 23.1 \times 0.3868)$. As a result, the marginal return on costs will be equal to +20.8% $((2.9-(0.7+1.7))/(0.7+1.7)\times 100)$. On the other hand, in the event of a decrease in the load from 600 to 300 ha, fixed and variable costs, as well as marketable products, increase by 2.3, 1.9 and 2.9 thousand UAH/ha, respectively, and the marginal loss of costs is -30.9% . Therefore, under unchanged conditions (production technology, product price situation, production resources, agricultural machinery, interest rates, etc.), the mark of 600 hectares of wheat crops per John Deere S670 combine harvester is the economic limit of the feasibility of investments in the renovation of the combine harvester park of domestic agricultural enterprises by purchasing similar or similar units.

3. Conclusions and prospects for further research

The implementation of sustainable development goals for Ukraine determines the intensification of processes in the domestic agricultural sector, brings to the fore the problems of ensuring food security of the state, increasing the production of safe products while preserving landscapes and minimizing anthropogenic pressure. In turn, the seizure of part of the territory, contamination of the liberated and adjacent territories with explosive objects further actualize the problem of rational use of land resources. Under such conditions, only further introduction of innovations aimed at increasing yields and the use of intensive technologies is perhaps the only possible way to develop domestic agriculture. The latter places strict requirements on the technical condition of its resource potential. Unfortunately, the unsatisfactory technical condition of the grain harvesting machinery fleet and its destruction as a result of hostilities exacerbate the problem of technical support for grain production, in particular for harvesting. Under such conditions, an important task is to develop methodological techniques for determining the optimal, harmonized values of investments in the reproduction of resource potential and operating costs.

The tested methodological approach allows determining the optimal level of investment in the renovation of the combine harvester fleet, taking into account the peculiarities of wheat production organization, grain price conditions, material resources, harvesting equipment, and financial factors. The calculations showed that it is economically inexpedient to invest in the renewal of the combine harvester fleet with John Deere S670 or similar combine harvesters if one unit has less than 600 hectares of wheat crops. A positive feature of the tested approach is the ability to minimize unproductive costs by taking into account technological and market factors in determining the optimal level of costs. Instead, the introduction of innovations leads to a change in the form of the production function, which should affect the dynamics of the marginal efficiency of investments, and therefore it is promising to expand approaches to modeling and take into account the role of innovations in finding the optimal level of current costs and investments.

Abstract. The triune concept of sustainable development takes into account environmental, social and economic issues in general. At the same time, the solution of the problems of resource conservation and socio-economic development do not contradict each other, but contribute to mutual reinforcement. The purpose of this study is to build, describe, test and analyze economic and mathematical models of the processes of self-organization of the socio-economic system within the framework of the concept of sustainable development. The considered models take into account both quantitative and qualitative characteristics. The research methodology is based on the assumption that the system under consideration is dynamic. The study makes it possible to evaluate the process of sustainable development of the socio-economic system in terms of the formation and influence of its characteristics on the overall result. Various options for formalizing the level of motivation of economic activity are described and analyzed, one of which is based on the economic interpretation of the Weber-Fechner psychophysiological law. The assumption of the continuous development of innovative technologies made it possible to reveal the existence of a "fatigue point", the onset of which indicates the possibility of increasing the growth rate of production activities due to its technological transformation.

1. Introduction

Human development in recent decades is often characterized by growth adverse impact on the external environment. Factors in this are also wars, political and socio-economic instability. People's actions have a negative impact on the environment. This threatens the survival of the Earth and future generations. This necessitates changes aimed at more rational and effective management of resources, which will reduce pressure and negative impact on the environment.

As a result, it became necessary to develop strategies for the development of mankind that would prevent the deterioration of the quality of the environment, eliminate the consequences of such deterioration, and contribute to the formation of conditions for providing resources for the current and future generations [1].

Such a viable behavior, to ensure the long-term exploitation of resources, without putting a threat to future generations, is considered within the framework of the concept of sustainable development [2].

The most progressive concept is the triune concept of sustainable development: environmental, social and economic issues are considered as a whole, and the goals of resource conservation and socio-economic development contribute to mutual reinforcement [3].

This understanding of sustainable development implies a balance between the three components of sustainability [2]:

- environmental sustainability, which is aimed at maintaining the quality of the environment necessary for the implementation of economic activities and ensuring the quality of life of people;
- social sustainability that seeks to ensure human rights and equality, the preservation of cultural identity, respect for cultural diversity, race and religion;
- economic sustainability needed to maintain natural, social and human capital to ensure living standards.

Only such an interpretation of sustainable development makes it possible to form the conditions for achieving a high standard of living, a developed economy and conservation of resources.

This approach is consistent with the definition of Brundtland [4], who defined sustainable development as the process of meeting the needs of the subject in the current cycle without harming the ability to meet the needs in the next cycle.

This concept assumes that the effective solution of environmental problems should be accompanied by the development of environmental awareness in the performance of economic entities of their main functions, the use of appropriate forms of economic behavior [1].

Thus, it is relevant to study the forms of economic behavior in the context of sustainable development and develop methods for quantitative and qualitative assessment of the results of their use.

At the same time, the current stage of development of the concept of sustainable development is characterized by the transfer of the problem from the global and macroeconomic levels to the microeconomic level, the subjects of which are actively involved in causing harm to the environment and become subjects of its elimination [5].

With this approach, the sustainability of an individual microeconomic entity becomes not just a concept, but also an object of sustainable development, which forms the features of modeling, design, organization and management [6].

Thus, in the article [7], the problems of decision-making in the management systems for sustainable development of complex technological and socio-economic objects are studied, the limitations of traditional expert systems are shown.

The study [8] developed a methodological approach for conducting a comprehensive assessment of the socio-economic parameters of sustainable development. To obtain justified results, the work uses such modeling methods as a fuzzy logical model, the Saaty hierarchy method, the Mamdani algorithm, quantitative and qualitative methods of comparison.

In the article [9], the logistics system of enterprise management is presented in the form of an optimization model that combines economic and environmental factors. This model allows you to evaluate and take into account the impact on the environment.

Article [10] is devoted to the study of a dynamic model for the optimal use of water resources with taking into account the interests of regional counterparties of the two hierarchy levels. The problem is solved by simulation methods.

At the same time, the management of sustainable development processes often provides for such a type as organization by structures of the upper hierarchical level [8, 10–12].

The purpose of the study is to substantiate the strategies of economic behavior of socio-economic entities within the framework of the concept of sustainable development. To achieve this goal, it is necessary to complete the following tasks: within the framework of existing methods of economic and mathematical modeling, describe an adaptive process model that takes into account the self-organizational and reflexive features of a socio-economic subject;

conduct model experiments to identify cause-and-effect relationships between the motives for the formation of economic behavior and results.

2. Results

It should be agreed that in socio-economic systems, the main system-forming element of models is meaningful or semantic approaches, and more complete models are built on target settings, which are based on value orientations, which are the main, fundamental basis for choosing system management models [13]. Most of these systems are dynamic.

The two fundamental elements of the concept of sustainable development are development and sustainability. At the same time, classical economic theory considers development within the framework of economic growth [2].

In the study [14], an isomorphic connection between the concept of "dynamic system" and "autonomous system of ordinary differential equations" is established. The main mathematical apparatus in this case is the qualitative theory of differential equations [15], and the model is formalized by a system of autonomous differential equations

$$\frac{\mathrm{dx}_i}{\mathrm{dt}}=\mathrm{F}_i\left(\mathrm{x}_1,\mathrm{x}_2,..,\mathrm{x}_n\right),(i=1,2,..,n), \tag{1}$$

where x_i is some quantitative characteristic of the socio-economic agent, which takes part in the process, which corresponds to the coordinate of the vector in the n-dimensional economic space.

The approach to building a possible full-factor model of the process of sustainable development consists in the balanced consideration of economic, social and environmental factors, among which the following are distinguished: individual; intrasystemic; external. At the same time, the external influence can be characterized by a known function or have a random nature.

In this case, system (1) takes the form

$$\frac{\mathrm{dx}_i}{\mathrm{dt}}=\mathrm{F}_i\left(\mathrm{x}_1,\mathrm{x}_2,..,\mathrm{x}_n,t\right),(i=1,2,..,n) \tag{2}$$

and is classified as a system of ordinary differential equations.

The two fundamental elements of the concept of sustainable development are development and sustainability. At the same time, classical economic theory considers development within the framework of economic growth [2].

If one characteristic is taken as an indicator of the level of development, then in equations (1), (2) $n = 1$. In this case, the development model (growth, increase, accumulation) can be represented in the form

$$\frac{\mathrm{dx}}{\mathrm{dt}}=k\mathrm{x}, \tag{3}$$

where k is a coefficient that characterizes the growth rate.

Equation (3) corresponds to the Malthusian or exponential law of population growth [16]. A particular solution to equation (3) is described by the function

$$\mathrm{x}\left(t\right)=x_0\exp\left(kt\right), \tag{4}$$

where x_0 is the value of the indicator under study at the initial time $t = 0$.

It is obvious that function (4) will correspond to development only when it increases. This is ensured by the condition $k > 0$, the fulfillment of which is accompanied by the theoretical possibility of an infinite increase in the indicator studied in the model

$$\lim_{t\to\infty,k>0} x_0\exp\left(kt\right)=\infty. \tag{5}$$

In this case, the management of the development process in the context of the concept of sustainable development can be accompanied by an organizational impact on the system, which is displayed in equation (3) by the transition $k = k(t)$. That is

$$\frac{\mathrm{dx}}{\mathrm{dt}}=k\left(t\right)\mathrm{x}. \tag{6}$$

It should be noted that some studies suggest modifications to model (3) [17, 18], which allow correcting the dynamics of unlimited growth as a consequence of a lack of resources [19]. At the same time, the limited resources are displayed in such models only indirectly, and the social and environmental components of the concept of sustainable development are absent.

Unlike classical and neoclassical economics, institutional economics provides for bounded rationality [20]. For institutional economics, a characteristic type of management is self-organization [21] and a synergistic approach to management [22]. Equilibrium in this case becomes the main goal of the functioning of the economic entity, which is consistent with the concept of sustainable development.

This principle corresponds to the form of the function $k(t)$ in equation (6)

$$k\left(t\right)=k_{max}\left(1-\frac{\mathrm{x}}{\mathrm{x_{Lim}}}\right), \tag{7}$$

where k_{max} is a constant positive coefficient characterizing the maximum value of the growth rate; x_{Lim} is the value of the indicator under study, limiting its increase.

In this case, equation (6) is transformed to the form

$$\frac{\mathrm{dx}}{\mathrm{dt}}=k_{max}\mathrm{x}\left(1-\frac{\mathrm{x}}{\mathrm{x_{Lim}}}\right), \tag{8}$$

which is a logistic (Verhulst-Pearl) model [23].

The essence of the presented equation is that changes in the system depend on factors that contribute to its development (growth) and factors that inhibit (limit) this development (growth). This means that within the system there is a certain regulatory mechanism that ensures the process of sustainable development at the level of self-organization.

The different influence of individual factors on the overall result is more clearly displayed if equation (8) is converted to the form

$$\frac{\mathrm{dx}}{\mathrm{dt}}=k_{max}\mathrm{x}-\frac{k_{max}}{\mathrm{x_{Lim}}}\mathrm{x}^2. \tag{9}$$

The Verhulst-Pearl equation (8) is quite universal and can be used to describe various dynamic processes [10, 23–26].

Thus, in population models, as the x_{Lim} value, which limits growth, an objective indicator of the capacity of the ecological environment is considered [23, 24], and in models of production processes, in addition to environmental restrictions [10], the consumption potential in the market can be assessed [25].

At the same time, the concept of sustainable development of such socio-economic entities as households also implies a self-organizational type of management of their economic behavior. In this case, a unitary strategy of economic behavior may be characterized by the desire to achieve a level of opportunity x_{Lim} (income) that allows them to satisfy economic needs that correspond to their social and cultural level [26]. This approach to modeling rational economic behavior is consistent with the theory of Gossen [27], according to which rationality is determined by the desire to increase satisfaction (reduce dissatisfaction).

It should be noted that under the initial conditions $x(t_0) = x_0$, a particular solution to equation (8) will be the logistic function

$$x(t) = x_{Lim} \frac{x_0 \exp(k_{max} t)}{x_{Lim} + x_0 (\exp(k_{max} t) - 1)}, \tag{10}$$

for which

$$\lim_{t \to \infty} x(t) = x_{Lim}. \tag{11}$$

Thus, the dynamics of the results of production activities for given model values of parameters and initial conditions is shown in figure 1.

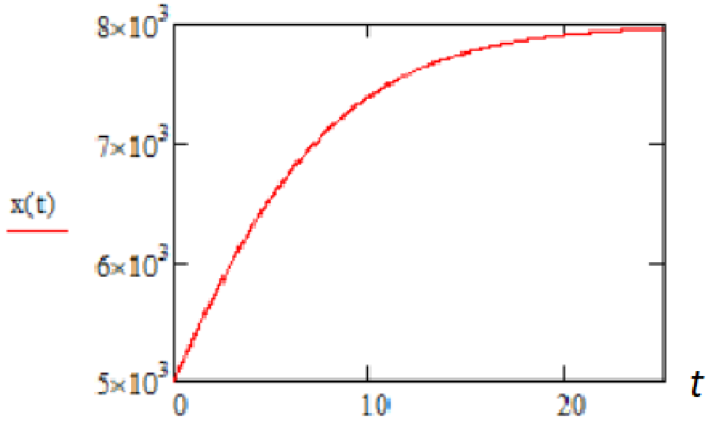

Figure 1. Graph of function (10) at $k_{max} = 0.2$ (productivity growth coefficient); $x_{Lim} = 8000$ pcs (maximum permissible productivity in terms of environmental safety); $x_0 = 5000$ pcs (productivity at the initial moment of time).

By controlling the parameters of the model, one can contribute to the formation of conditions for sustainable development.

A more general case is when the limiting parameter x_{Lim} changes with time, that is, $x_{Lim} = x_{Lim}(t)$. This situation may be a consequence of the development of technologies that allow gradually increasing the effectiveness of economic activity without increasing environmental damage and without increasing the ecological footprint. [28, 29]. We will use the assumption that there is a direct relationship between the innovative level of technology and the level of production acceptable from the point of view of environmental safety.

With the same increase in each period of time, a constant growth rate is observed, and the function itself $x_{Lim} = x_{Lim}(t)$ has the form

$$x_{Lim}(t) = x^0_{Lim} (1 + a_1 t), \tag{12}$$

where x^0_{Lim} is the initial value of x_{Lim}; a_1 is the percentage of growth per unit of time.

If development occurs at a constant rate, but relative to the level reached in the previous time interval, then the function has the form

$$x_{Lim}(t) = x^0_{Lim} (1 + a_2)^t, \tag{13}$$

where a_2 is the percentage of growth per unit of time.

It should be noted that formulas (12), (13) imply discrete time. At the same time, function (13) more correctly reflects the process of sequential development.

Passing to the continuous growth form, function (13) is transformed to the form

$$x_{Lim}(t) = x^0_{Lim} \exp(a_2 t). \tag{14}$$

Using function (14) we transform equation (8)

$$\frac{\mathrm{dx}}{\mathrm{dt}} = k_{max}\mathrm{x}\left(1 - \frac{\mathrm{x}}{x^0_{Lim}\exp(a_2 t)}\right). \tag{15}$$

The general solution of equation (15) has the form

$$x(t) = \frac{x^0_{Lim} x_0 (k_{max} - a_2)}{k_{max}\exp((k_{max} - a_2)t) + x_0}\exp(k_{max} t). \tag{16}$$

The joint dynamics of the results of production activity (16) and function (14) for given model values of parameters and initial conditions is shown in figure 2.

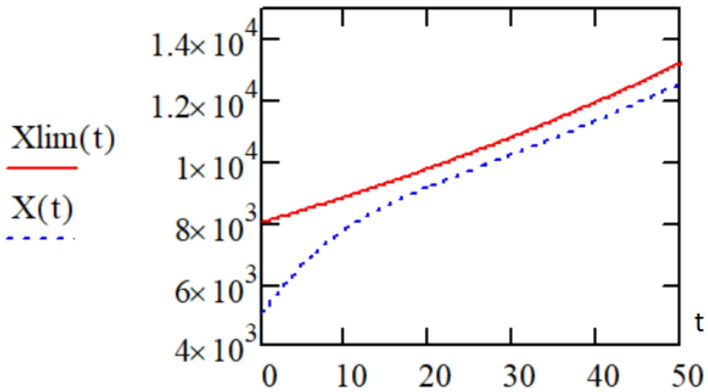

Figure 2. Graphs of functions (14), (16) at $k_{max} = 0,2$ (productivity growth rate); $x^0_{Lim} = 800$ pcs (initial value of maximum allowable capacity); $x_0 = 5000$ pcs (performance at the initial moment of time); $a_2 = 0.01$.

Functions (14), (16) have the equality

$$\lim_{t\to\infty} x(t) = \lim_{t\to\infty} x_{Lim}(t). \tag{17}$$

That is, an increase in the allowable production threshold is accompanied by a corresponding increase in production (figure 2). At the same time, at each moment of time there is some lag, which can be estimated by the function

$$F(t) = x_{Lim}(t) - x(t) = x^0_{Lim}\exp(a_2 t) - \frac{x^0_{Lim} x_0 (k_{max} - a_2)}{k_{max}\exp((k_{max} - a_2)t) + x_0}\exp(k_{max} t). \tag{18}$$

This function characterizes at each moment of time the value of the deviation of the real results of economic activity $x(t)$ from the possible ones $x_{Lim}(t)$. It is not difficult to show that function (18) has an extremum, namely, a minimum. The visualization of this fact is shown in figure 3.

We propose to call the minimum point of function (18) the "fatigue point", which is characterized by the fact that at this point in time the growth of economic activity in a given mode ceases to have a critical impact on its potential development. This can be explained by the

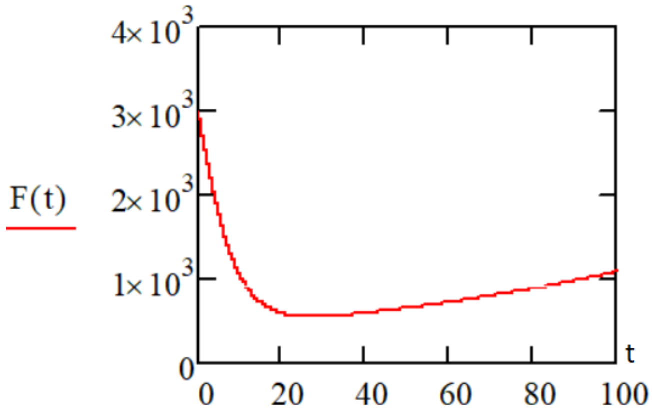

Figure 3. Graphs of functions (8) at $k_{max} = 0,2$ (productivity growth rate); $x^0_{Lim} = 800$ pcs (initial value of maximum allowable capacity); $x_0 = 5000$ pcs (performance at the initial moment of time); $a_2 = 0.01$.

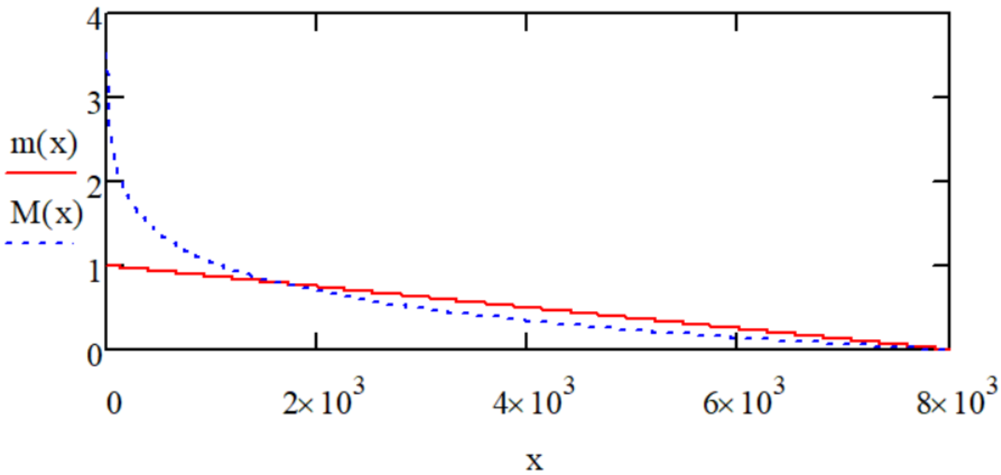

Figure 4. Change in motivation (19) and (20) with $x_{Lim} = 8000$ pcs, $r = 0.5$.

fact that in the situation under study, innovative development concerns only the environmental (resource) component, while the production component remains constant $k_{max} = Const$. This makes it possible to determine the point in time when it becomes possible to increase the growth rate of production activities due to its technological transformation.

Speaking about the self-organization of the processes of sustainable development of socio-economic systems, it should be noted that consciously or subconsciously their motivators may depend on individual or unitary social, cognitive and emotional factors [30].

The level of motivation for the development of the system under the existing constraints x_{Lim} in model (8) is represented by the function

$$m(x) = \left(1 - \frac{x}{x_{Lim}}\right). \tag{19}$$

At the same time, psychological and social factors can influence the assessment of objective quantitative indicators and subjective qualitative indicators. This allows us to give an economic interpretation of the Weber-Fechner psychophysiological law [31] and quantify motivation by the function

$$M\left(x\right)=r\ln\left(\frac{\mathrm{x_{Lim}}}{\mathrm{x}}\right), \tag{20}$$

where r is the scale factor.

Analysis of changes in functions (19), (20) (figure 4) displays their distinctive features.

First, $m(N) \in [0;1]$, and $M(N) \in (0;+\infty)$. Secondly, with a sufficiently large deviation of the values of the indicator of the level of economic activity from the boundary value x_{Lim}, the non-linear motivation function $M(x)$ significantly exceeds the values of $m(x)$, and with small deviations it can become smaller. This fact can be explained by the existence of features of a particular socio-economic system, which, in a critical situation, stimulate the search for additional opportunities to realize the existing potential. Such features are displayed by the scale factor r.

Taking into account the content and form of function (20), equation (8) can be modified

$$\frac{\mathrm{dx}}{\mathrm{dt}}=k_{max}\mathrm{x}r\ln\left(\frac{\mathrm{x_{Lim}}}{\mathrm{x}}\right). \tag{21}$$

The general solution of equation (21) has the form

$$x\left(t\right)=x_{Lim}\exp\left(-ln\left(\frac{\mathrm{x_{Lim}}}{\mathrm{x}}\right)\exp(-k_{max}rt)\right). \tag{22}$$

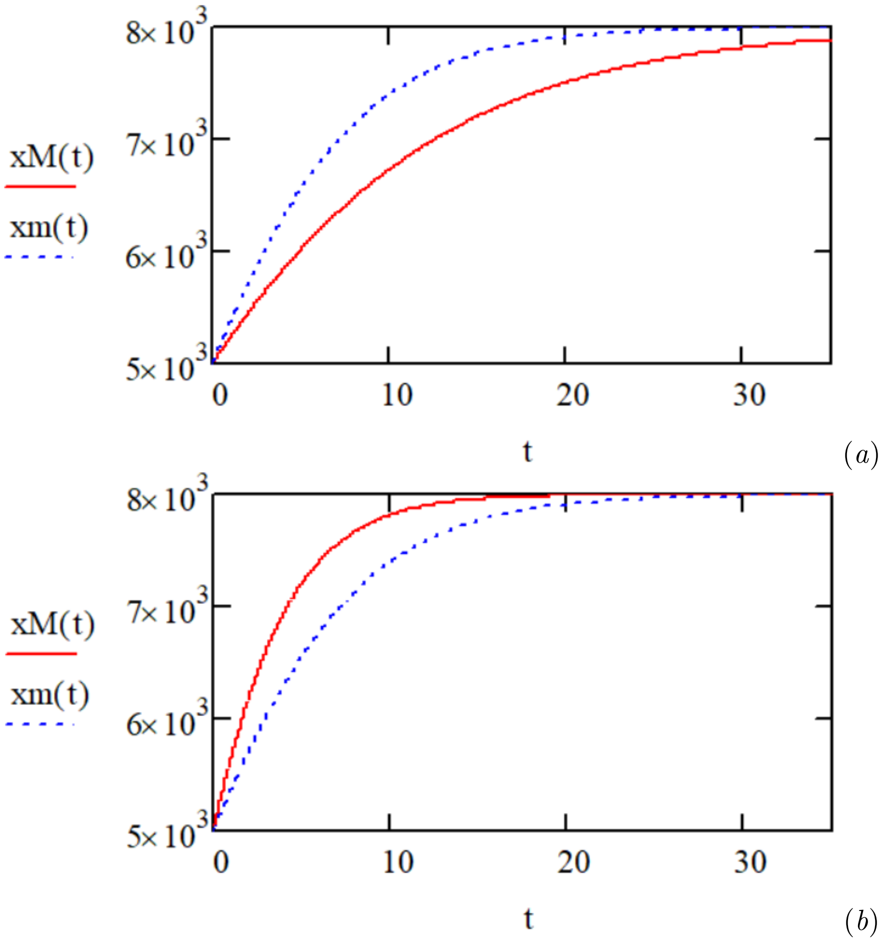

Figure 5. Comparative dynamics of function (10) – $xm(t)$ and function (22) – $xM(t)$ at $x_{Lim} = 8000$ pcs, $x_0 = 5000$ pcs, $k = 0.2$: at $r = 0.5$ (a); at $r = 1.5$ (b).

Let's compare functions (10) and (22) (figure 5).

Obviously, depending on the individual characteristics of the socio-economic system, which are displayed in the model (21) by the scale factor r, the process of sustainable development can proceed less (figure 5a) or more (figure 5b) intensively.

It should also be noted that the use of the previously considered option $x_{Lim} = x_{Lim}(t)$ (14) in model (21) also makes it possible to identify the "fatigue point". The results obtained can be explained by the presence of institutional features of socio-economic systems.

3. Conclusions

1. The proposed methodology for modeling the processes of sustainable development of socio-economic systems is based on a combination of neoclassical and institutional approaches and is characterized by limited rationality, which implies the achievement (maintenance) of an equilibrium state of the socio-economic system.
2. The motivational and stimulating factor in the formation of sustainable development processes is the desire to achieve (maintain) a possible (satisfactory) level of development. Under such conditions, the quantitative assessment of motivation is defined as the magnitude of the deviation between the possible (satisfactory) level and the real one.
3. To take into account socio-economic features, an economic interpretation of the Weber-Fechner psychophysiological law was proposed, which made it possible to formalize motivation in a logarithmic form, which, unlike a linear one, allows taking into account individual (group) features of the socio-economic system under study.
4. An analysis of the constructed models made it possible to identify the presence of a "fatigue point", that is, the moment in time when the growth of economic activity in a given mode ceases to have a critical impact on its potential development. This moment testifies to the possibility (necessity) of increasing the growth rate of production activity due to its technological transformation.
5. The constructed models can be attributed to simulation. They make it possible to study transitional processes within the framework of the concept of sustainable development.
6. According to the authors, the development of a methodology for determining the scale factor will allow taking into account the individual features of the economic behavior of the modeling object.

Abstract. The significance of protection of environmental components (soil, water, air, biodiversity, landscape) in global aspect directs the development towards sustainable agriculture, and organic production in particular. Organic production as a way of achieving sustainable growth is determined in the three main aspects of sustainable development: economic, social and ecologic sustainability. The conducted in the article analysis of statistical data on the development of domestic market of organic agricultural products shows that organic production in Ukraine is developing at a fast pace and stays one of the priorities for the further development of agro-industrial complex. At the same time, difficult current conditions of functioning of domestic organic enterprises can influence negatively the further development of this sphere, that will result in decrease of organic products export and will have negative impact on food security of other countries. Considering the mentioned, the purpose of the article is the substantiation of tools and measures which will ensure the formation of favorable environment for conducting organic production in the war and post-war periods. With the aim of systematization of the tools for the formation of "favorable environment" for the development of organic agricultural production their study is conducted with further grouping into regulatory and legal, political, stimulating and compensatory, fiscal and restrictive, financial and investment, infrastructural, informational, social and cultural, marketing, and digital. In the course of further research, within each group of tools a specific list of measures that must be implemented to simulate the development of organic agriculture and the circle of subjects responsible for their implementation were determined. It was proven that the formation and implementation of the defined tools and measures should take place at the international, national, regional, and local levels. The content characteristics of each group of tools, which are highlighted in the article, are important guidelines for the formation of effective state social and economic policy and international cooperation development in the conditions of aggravation of influence of global challenges and provide the certain opportunity for definition of ways of their improvement.

1. Introduction

Within the framework of sustainable development concept, the scientific and expert environment offer to implement the set of balanced goals and strategies of regional, national, and industrial development, aimed at solving modern ecological, economic, and social challenges, that acutely faced humanity [1]. Today, the issue of environmentalization of world countries' economies as well as of Ukraine's economy is especially relevant. In our country the processes of environmental pollution as a result of military operations take place in many regions of the country, and the natural environment changed by man does not always have a positive effect on society.

The importance of this problem, among other things, is related to the growth of the world population and the need to solve threats to food security, as well as to the climate changes. One of the ways of solving the mentioned problems is the implementation of environmentally safe ways of agricultural production, namely organic production [1]. It is organic agriculture that provides an opportunity to agree and harmonize environmental, economic, and social goals in the agricultural sector of the Ukrainian economy [2].

Organic production as a way of achieving sustainable growth is determined in the three main aspects of sustainable development: economic sustainability – increasing competitiveness, strong market orientation and increased incomes; social sustainability – bigger responsibility towards consumers' demands, improving food quality and safety; regional development; ecologic sustainability – unified framework, effective implementation and control, standards of protection of environment and health [3].

The essence of the concept of "organic production" is revealed in a number of regulatory documents. According to the law of Ukraine "On the main principles and requirements towards organic production, circulation and labelling of organic products", organic production defined as the certified activity that involves production of agricultural products (covering all stages of technological process, namely primary production (including harvesting), preparation, handling, mixing and procedures related to it, filling, packing, processing, recovery and other alterations to the state of the products), performed in compliance with legal requirements in the sphere of organic production, circulation and labelling of organic products [4].

EU Commission Regulation 2018/848 defined organic production as an overall system of farm management and food production that combines best environmental and climate action practices, a high level of biodiversity, the preservation of natural resources and the application of high animal welfare standards and high production standards in line with the demand of a growing number of consumers for products produced using natural substances and processes [5].

Thus, the requirement for organic agriculture include not only compliance with environmental standards of product purity, but also of the environment. It ensures the balanced state of ecological system, which is the basis for sustainable development of economic and social sphere.

World experience proves that the introduction of environmentally friendly technologies in the production of agricultural products allows to increase the level of their profitability and competitiveness, reduce the production costs of enterprises, create a basis for environmentally safe development of the economy, additional jobs in rural areas and new prospects for small and medium-sized farms, to raise the standard of living and health of the population, to switch to a scientifically substantiated system of land use, etc.

Furthermore, organic production is considered in two aspects of protection: environmental protection by using management practices that do not have adverse effects on environment, and the health of consumers – by the provision of organic products [6].

The development of various laws, regulations, programs, and concepts is a significant confirmation of the acuteness of the raised problem regarding the need to activate environmentally oriented entrepreneurship for the purpose of sustainable development of agriculture. On March 3, 2021 the Cabinet of Ministers of Ukraine approved "The National Economic Strategy until 2030", which officially sets the goal for % of land under organic production. According to the strategy, it is planned that the percentage of lands with organic status should be at least 3 % (now, this figure is 1 %) of the total area of agricultural lands in Ukraine, which is approximately 1.3 million hectares [7]. The European Union intends to increase the organic farming area up to 25 % by 2030 (now, this figure is 8 %). Simultaneously, at least 10 % of agricultural land should be converted into "living areas" with a high biological diversity [8].

Thus, the expediency of implementation and spread of organic production in the world as well as in Ukraine is beyond any doubt. At the same time, in order to promote the development of domestic organic agriculture, it is necessary to create a favorable environment through the justification and implementation of appropriate tools, taking into account the effect of martial law on the territory of our country.

2. Literature review

The scientific and applied problems of the development of organic agriculture were constantly in the field of view of many Ukrainian and foreign scientists. Thus, Shkuratov et al [2] dedicate their work to the study of theoretical and methodical foundations of ecological and economic prerequisites of organic agriculture development. The authors propose the ways of increasing the efficiency of production of organic agricultural products and substantiate the directions of formation of a system of ecological and economic imperatives of the development of organic agriculture, which should become a guideline for the state government and local self-government during the design of the organic farming development program.

Shulyak [9] defines the following tool of regulating and activating of ecologically oriented entrepreneurship on rural territories: coercive-restrictive, stimulating and compensatory, financial, informational, social and psychological, market (marketing). In the opinion of the author, the configuration of the outlined measures, focused on a three-level system of formation and implementation (national, regional, local levels), will enable the coordination of environmental and economic interests of business entities.

Hranovska [10] substantiates the necessity of formation of the mechanism of stimulating of organic production by agricultural enterprises on the basis of implementation of following tools: subsidial (preferential crediting, preferential taxation, budget payments, compensations, subsidies, price premiums, co-financing of scientific and research developments); infrastructural (creation of production and sales chains, development of rural territories, formation of laboratories and quality assessment centers, conduction of marketing research, activation of various economic agricultural formations); informational (establishment of information centers, public organizations, development of agricultural parks, eco-villages and ethnic centers); legal (certification, insurance, legal aid, activation of development and implementation of state programs for development and stimulating organic production).

The study of Hou et al [11] is one of the few studies that comprehensively examines the impact of macro-level factors on organic production in the U.S. Specifically, this research looks at the determinants including macroeconomic factors, policy factors, demographic factors, and agricultural input factors that cover many aspects of organic farming. The multivariate analytical framework with multiple year data enables this study to examine whether a series of factors can effectively promote organic farming and by how much. This study provides evidence using state-level observations and a robust econometric method to further support the findings of relevant literature.

It should also be mentioned that a significant amount of research is devoted to the issues of state regulation of development of organic production in Ukraine. Thus, Hvozd [12] provides a scheme of organizational and economic mechanism of state regulation of the organic agricultural production market in Ukraine. The author also substantiates its legal (Laws and Resolutions of the Verkhovna Rada of Ukraine, Resolutions of the Cabinet of Ministers of Ukraine, normative acts and state standards of organic production, Private organic standards), normative (institutions, regulations, methodical recommendations), economic (crediting, material and technical support, budget policy, taxation, pricing, agricultural insurance), administrative (antimonopoly policy, standardization, quotas, production certification, environmental control, licensing), institutional support (state authorities, international organizations, associations of enterprises, organizations for the protection of consumer rights, regional bodies of influence on the vector of development of the food sector).

At the same time the relevance of the research in the sphere of organic production development as of an important constituent of sustainable development of rural territories and of a strategically important direction of agricultural business in Ukraine objectively indicates the need for a thorough study of its individual aspects, in particular, regarding the theoretical vision of tools for creating a favorable environment for its management in the war and post-war periods.

3. Objective of the research

The purpose of the research is the substantiation of conceptual foundations of formation of a favorable environment for the development of organic agriculture in Ukraine considering current conditions of martial law. The set purpose involves solving the following tasks: study of the trends of organic production sphere development; identification of tools which have a decisive influence on the formation of a favorable environment for the development of organic production; substantiation of specific measures within individual tools and definition of the subjects responsible for their implementation.

4. Results

Today, organic production is developing in almost all countries of the world and is promising for further development in Ukraine as well. Constantly growing consumer demands for organic products, as well as the global trends towards sustainable farming, allow Ukraine to be the active participant in the world organic market. The organization of the effective output of organic products in the management system of the agrarian nature remains relevant and is considered as one of the major ways of the agricultural production ecologization [13].

According to the latest operational monitoring data which the Ministry of Agrarian Policy and Food of Ukraine (MAPF) collected from certification bodies that certified organic production and circulation of organic products in Ukraine (EU Regulation and NOP) as of the end of 2021, the total area of organic and inconversion agricultural lands in Ukraine was 422,299 hectares (including organic agricultural area 370,110 hectares). Organic agricultural land remains 1 % of the total agricultural area in the country. The number of organic operators in 2021 was 528, with 418 agricultural producers among them [14]. These operators include producers, processing companies, importers, and exporters of organic products (figure 1).

Over the past four years, the number of organic operators has been on a downward trend (table 1). In particular, in 2021, compared to 2020, their number decreased by 21 units (or by 3.8 %).

The data show that during 2016-2020 the area of agricultural lands with organic status has increased more than 2 times (by 104.3 %). But in 2021 the decrease of the land area by 9.9 % (26054 ha) is observed comparing to the previous year.

Unfortunately, it is expected that the area of organic lands will shrink in 2022 as a significant part is occupied in the southern regions of the country. Since the beginning of the full-scale war, about 120,000 hectares of certified organic land were lost, especially in Kherson and Zaporizhzhia oblasts [14].

As for the Ukraine's organic domestic market it has been growing slowly but steadily, despite different challenging economic circumstances. A total of 9,780 tons of organic products (which is 11.4 % more than in 2020) at a value of UAH 900 million are estimated to have been sold on the domestic market in 2021, equivalent to 33 million USD at the National Bank of Ukraine exchange rate as of December 31, 2021.

Even though Ukrainians consume much less organic products (less than 1 euro per capita) than residents of EU countries and Switzerland, the interest in more natural and healthy foods has been growing [14].

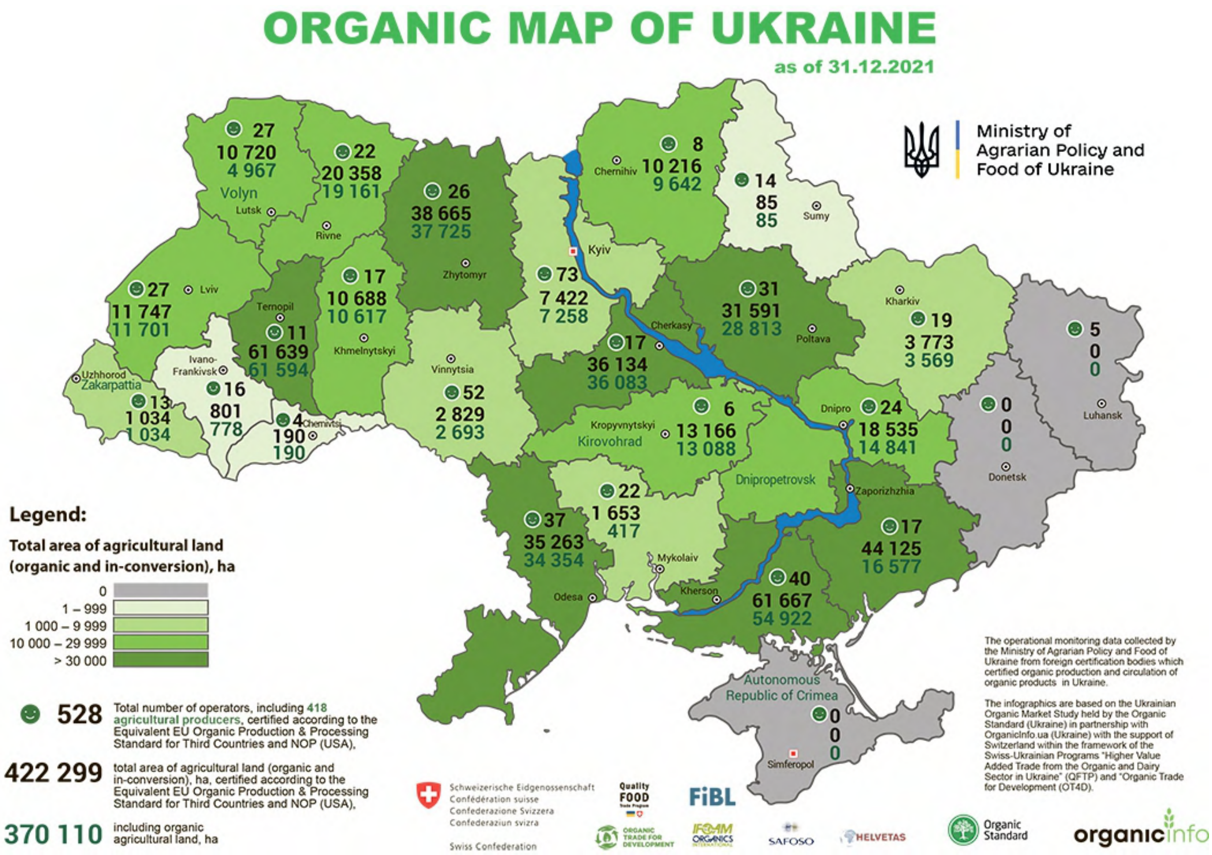

Figure 1. Organic map of Ukraine, as of December 31, 2021 [15].

Table 1. Organic production in Ukraine for 2016-2021 [16].

Indicator	Years					Deviation, %	
	2017	2018	2019	2020	2021	2021 to 2017	2021 to 2020
Number of organic operators:							
total number of operators	504	635	617	549	528	4.76	-3.83
including agriculture producers	304	501	470	419	418	37.50	-0.24
Area of agricultural land, hectares:							
total area of agricultural land (organic and in-conversion)	289000	309100	467980	462225	422299	46.12	-8.64
organic agricultural land	201000	233500	384529	410583	370110	84.13	-9.86
Sales of Ukrainian organic products, million USD:							
domestic market, million USD	-	21	24	26	33	57.14*	26.92
tons	-	6700	7350	8778	9780	45.97*	11.41

tons	254000	390000	469000	332000	261000	2.76	-21.39

* Deviation 2021 to 2018, %

In recent years, Ukraine has consolidated its position as a world leader in the supply of organic products to the EU as well as an important player for other international organic markets and has taken an important place in ensuring a sustainable food system and food security in the world [14]. Thus, in 2021 Ukraine exported about 261,000 tons of organic products worth USD

222 million to over 30 counties, 82 % of which were exported to the EU [15].

At the same time in 2021 Ukraine slightly reduced the export volumes to the EU (189,239 tons in 2021 compared to 217,210 tons in 2020), but it still remained among TOP 5 organic suppliers to the EU. The total share of Ukrainian organic imports was 6.6 % in 2021.

As for the imports from Ukraine, it ranked No 1 by organic import volumes of cereals (other than wheat and rice), and was among TOP 3 suppliers of oilcakes, oilseeds and soybeans. In addition, Ukraine moved up into the second place by organic import volumes of fruit (fresh or dried fruit and berries, excluding citrus and tropical fruit).

The full-scale war that Russia started against Ukraine in 2022 caused colossal losses to the organic sector, however, it did not prevent Ukraine from maintaining its leadership position in the export of organic products. Thus, despite the temporary occupation of one-third of the organic land, hostilities, and problems with logistics, during the 8 months of 2022, Ukraine exported 24 % more organic products compared to the same period in 2021 [14].

Today the development of organic market in Ukraine is one of the priority directions of the agriculture development. Statistical data evidences that our country has reached certain results in the development of its own organic production, possessing favorable conditions for organic agriculture, including the size of the country, geographical location, proximity to potential export markets, large area with fertile soils.

At the same time, since the beginning of Russia's full-scale invasion of Ukraine on February 24, the Ukrainian organic sector, and the entire agrarian industry, has been suffering from Russian aggression. Problems include occupied land; mined fields; destroyed farms, warehouses, and infrastructure; lack of fuel and vehicles; and domestic demand that has nosedived. After the Northern regions and some districts in the Southern regions were liberated, organic operators started to resume their activities there, and some of them relocated their businesses to other regions. Organic producers in other regions did not stop their activities or stopped for a very short time.

Organic production as a sector having a great potential for making significant contributions to sustainable development (and thus put as a priority in a number different levels, especially by the European Union and international community) leads to various positive influences on environment, society and economy [17].

Considering the above, the urgent issue is the creation of a "favorable environment" for functioning of organic production with the purpose of formation of an effective strategy for its development in the conditions of martial law, aimed at the production of environmentally safe products, increasing the competitiveness of agricultural entities in the internal and foreign markets.

In accordance with the Protocol on Sustainable Development of Agriculture and Rural Areas to the Framework Convention on the Protection and Sustainable Development of the Carpathians, "favorable environment" is a complex of interrelated conditions, such as: legal, organizational, fiscal, informational, political, and cultural which contribute to sustainable and efficient use of participants' opportunities in development processes. In this document it is also defined that "sustainable agricultural and rural development" is a management and conservation of the base of natural resources, as well as orientation of technological and institutional changes in order to ensure the achievement and constant satisfaction of human needs of the present and future generations [18].

Shkuratov et al [2] have provided the systematization of the factors of impact on the development of organic agricultural products, which is based on their division into four main functional groups according to the following characteristics: organizational and legal, financial and economic, technological, and social and psychological, and provides the opportunity to improve and form efficient measures of the development and implementation of the organic agricultural products system taking into account the sphere of influence of such factors.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012124 doi:10.1088/1755-1315/1254/1/012124

In general, the conducted literature review shows that scientists have not formed a single approach to the systematization of tools that must be used to create a favorable environment for the development of organic agriculture.

Taking into account the existing views of scientists and the current complex conditions of the functioning of organic enterprises, we consider it necessary to highlight the following tools that have a decisive influence on the formation of a favorable environment for the development of organic agriculture in Ukraine (table 2).

Table 2: The tools which affect the formation of a "favorable environment" for organic agriculture development.

Tools	Measures	Responsible subjects
Regulatory and legal	Further development of the legislative and regulatory framework of regulation of relations in the sphere of production, circulation, certification, and labeling of organic agriculture products. Further harmonization of Ukrainian legislative framework with the requirements of European legislation. Activation, development, and implementation of state and regional programs for development and stimulation of the organic production.	State
Political	Development of international cooperation, including international trade; further cooperation with projects of international technical aid in the sphere of organic production.	State, international partners
Stimulating and compensatory	Provision of financial assistance in the form of targeted subsidies and grants, preferential taxation, preferential crediting, special insurance regime, financing (at least partial) of socially important organic projects and programs, full or partial repayment of the cost of certification services, co-financing of scientific R&D.	State, financial and credit institutions
Fiscal and restrictive	Introduction of environmental payments, licensing, financial sanctions for violations of environmental regulations, taxes, fees, fines, etc.	State
Financial and investment	Formation of the specialized investment funds, environmental banks and programs; development of environmental insurance.	State, international partners, investors (internal and external), economic entities
Infrastructural	Creation of production and sales chains, development of rural territories, formation of laboratories and quality assessment centers, activation of various economic agricultural formations, creation of an extensive system of certification bodies.	State, international partners, non-governmental organizations, economic entities

Continued on next page

Table 2 – continued from previous page

Tools	Measures	Responsible subjects
Informational	Providing free access for economic entities to the regulatory base in the sphere of organic production and products circulation, formation of local environmental information and consulting centers; establishment of public organizations, environmental consulting, information dissemination among the consumers and operators and creation of a system of cooperation between them on the entire production chain – from the economic entity to the consumer.	State, international partners, non-governmental organizations, economic entities
Social and cultural	Formation of the environmentally and socially oriented corporate culture and responsibility, environmental ethics and consciousness of the entrepreneur and of the society as a whole; activation of environmental education; orientation on production and consuming of natural products.	Economic entities, non-governmental organizations, state (institutions of education, culture, upbringing, health)
Marketing	Popularization of organic production based on the organization of various events (exhibitions, fairs, conferences, etc.) to promote organic agriculture in the internal and foreign markets. Formation of the organic products market; development of ecological marketing; creation of ecological brands.	State, economic entities, non-governmental organizations, international partners
Digital	Saturation of agricultural business with such modern digital technologies as the Internet of Things, artificial intelligence, the use of big data (Big Data), robotization of production and management processes.	State, international partners, investors, economic entities

Legal regulation consists in the development and adoption of laws, regulations, resolutions, requirements, and standards that establish legal, economic, social, and environmental rules for the cultivation, production, processing, certification, transportation, storage and sale of organic products. It is also responsible for fair competition on the market of organic products.

During last years government together with public organizations and international projects has been working on the improvement of legislative and regulatory framework. In particular, a set of legal documents was adopted, as well as amendments to the current legislative acts that regulate the sphere of certification and labeling of organic products in Ukraine were made [19]. A significant landmark for Ukrainian organic legislation occurred in 2021, when amendments to the Law of Ukraine No 2496-VIII "On the main principles and requirements towards organic production, circulation and labelling of organic products" came into force. Together with the Law, adopted on July 10, 2018, this is the legal foundation of organic production, circulation, and labelling of organic products in Ukraine [14]. Earlier manufacturers certified their production according to the legislation of other countries, mainly the EU. Now Ukraine will have its own certification system in accordance with national legislation. Such changes contribute to the development and transparency of the domestic organic sector and to the improvement of

Ukraine's image in the world trade arena. At the same time, one of the urgent tasks is the further harmonization of Ukraine's legislation on the organic products manufacturing with the world certification systems. The compatibility of such systems will make it possible to expand the external market of organic products [19].

Besides it, considering European orientation of Ukraine and difficult conditions of functioning of domestic organic producers, there is an urgent need to develop and adopt national and regional programs for the development of organic production in Ukraine, as an environmentally, socially, and economically expedient direction of production activity.

The implementation of political instruments is manifested in the fact that the development of the Ukrainian organic sector has been also supported by different countries within international programs/projects of technical support. Representatives of these projects take an active part in the development of a legal framework that will effectively regulate the process of organic production. The largest of such projects are Project "German-Ukrainian Cooperation in Organic Agriculture" (COA) – Phase II, implemented by AFC Consultants International / IAK Agrar Consulting GmbH and funded by the German Federal Ministry of Food and Agriculture (BMEL); Swiss-Ukrainian Program "Higher Value Added Trade from the Organic and Dairy Sector in Ukraine" (QFTP) implemented by the Research Institute of Organic Agriculture (FiBL) in partnership with SAFOSO AG and supported by Switzerland; Swiss-Ukrainian Program "Organic Trade 4 Development in Eastern Europe" (OT4D) supported by the Swiss State Secretariat of Economic Affairs (SECO) implemented by the IFOAM – Organics International in consortium with HELVETAS Swiss Intercooperation and Research Institute of Organic Agriculture (FiBL) and supported by Switzerland and other [14]. It should be noted that thanks to the Swiss support Ukraine has managed to establish a committed organic stakeholder network with its own Organic Standard control body, Ukrainian organic web portal OrganicInfo, organic national policy dialogue, and agreed on the joint vision for Ukrainian organic sector development through Organic Initiative.

Under terms of martial law, the government attention should be concentrated on the creation of the conditions for international trade implementation, particularly, on finding export opportunities, new logistic solutions for supplying Ukrainian organic products to other countries, expanding sales markets. Solving these problems is possible due to system and effective cooperation of Ukrainian government and international partners. Efforts in the political arena should be directed to this. Despite the full-scale war and threats for the country Ukraine proceeds to contribute largely to the world's food safety. In particular, the sowing campaign of 2022 was carried out, alternative logistics routes were developed for the supply of Ukrainian agricultural products abroad. Considering the above, with the help of political instruments it is necessary to create conditions for the export of Ukrainian organic products through lobbying at the political level and promotion on the international arena, as well as solving the urgent needs of exporters of organic products.

With the help of stimulating and compensatory, and fiscal and restricting tools the state motivates manufacturers to production of organic agricultural products and establishes certain sanctions for violators of environmental norms in general and organic production requirements in particular with the aim of ensuring the presence of high-quality organic products on the market.

A system of grants, dotations, provision of land plots at a discounted price, etc. can be material incentives for manufacturers of organic products. Considering the complex economic conditions of functioning, implementation of these tools is one of the main stimulating factors, which contributes to the decision to switch to organic production.

It should be mentioned that currently the work in this direction continues. Thus, Organic Initiative launched the grant program "Support for the Organic Sector in Ukraine". The grant program's purpose is to support organic producers to overcome the current situation and preserve and strengthen the organic sector's capacity in the mid- and long-term. According to the results of the grant program's (two phases), about 120 organic market operators received support for a total amount of about 350,000 USD to cover costs for organic certification, purchasing organic food products from organic producers (with further distribution among IDPs, vulnerable populations, etc.), purchasing inputs, further development of the marketing activities at the domestic market, purchasing equipment, etc. A significant proportion of this support was provided by OT4D and QFTP programs [14]. Within the fundraising campaign of the Future Foundation for Agriculture "Support for Emergency Aid Ukraine Organic Farming" 170 enterprises were supported, among them organic producers and organizations of the organic sector in total 560,000 Euro [20].

Implementation of the appropriate mechanisms for realization of functioning of the defined stimulating and compensatory tools for market operators should provide the access of organic products manufacturers to additional and released financial resources, at the expense of which they will be able to repay the received loans on time, to implement into production innovative technologies, aimed at increasing the ecological characteristics of the products and decreasing the environment pollution, to start timely the process of product certification according to organic standards, and in the future to reduce gradually the cost of products for the final consumer. All this will have a positive impact on the formation of investment attractiveness of the organic production enterprises, as well as will promote activation of their activity [21].

At the same time, in case of violation by producers of organic products of ecological requirements, penalties should be applied to them in the form of additional payments for environmental pollution, fees for non-compliance with cultivation technologies, fines for low-quality food products, deprivation of certification with the obligation to return funds for their certification, other financial sanctions. The set of fiscal and restrictive tools of state policy should be preventive in nature and should be aimed at ensuring compliance with production technology at all its stages by organic enterprises, in order to provide the production of high-quality and environmentally safe products.

Financial and investment tools should be singled out in a separate group, the implementation of which consists in the formation of specialized investment funds, environmental banks and programs; development of environmental insurance. The financial platform for the development of domestic environmentally oriented entrepreneurship is formed by special investment funds (institutional measures designed to direct targeted cash flows (income, profit) for the purposes of environmental protection and improvement), environmental banks and environmental programs. In addition, environmental business insurance (voluntary or state mandatory), i.e. civil liability insurance of business entities for damage caused as a result of economic activity, which causes increased environmental danger, is relevant and effective in modern conditions. Such a financial tool is a powerful method of encouragement and, at the same time, provides a condition for economic stimulation of business entities to function without harming the natural environment, or at least with minimal impact on it [9].

The results of the Organic Ukraine NGO survey of Ukrainian organic businesses, conducted in mid-March 2022, showed that 30 % of Ukrainian organic operators had to suspend their business activities and 70 % required financial support [14]. That is why the issue of activation of financial and investment instruments for the development of organic production is currently acute.

Infrastructural tools for the formation of favorable environment should be aimed at ensuring higher quality and more effective process of implementation of chain "production – distribution – sale", as well as at more efficient marketing policy for the system functioning of the organic agricultural production. Measures that must be implemented within this group of tools include:

- creation of production and sales chains (first of all, the stress must be put on the objective formation of the organic chain and joint responsibility of the "producer – trader – certification body – state authorities" system);

- rural territories development (purposeful change of institutional, economic, ecological, demographic, social, cultural, household, and other most important factors that determine directions and directly affect the growth of the level and quality of life of the rural population and ensure the prevention or overcoming of poverty);
- formation of laboratories and quality assessment centers (formation of modern laboratories to assess the quality and safety of organic products, their analysis for compliance with current standards);
- activation of various economic agricultural formations – participation in programs of development of organic production, communication with organic producers of global markets, etc.;
- creation of an extensive system of certification bodies.

The formation of the necessary conditions for free access for economic entities to the ecological information, regulatory base, environmental passporting, programs of financial support, etc. is provided by informational tools. An important component is the formation of local information and consulting centers, the goals of which should be: shaping the environmental consciousness of citizens, providing environmental consulting, dissemination of the relevant information on the actual state of environment, popularization of the best practices of balanced development, introduction of environmental technologies, organization of different trainings, round tables, educational business seminars for different categories of participants – children and youth, students, educators, representatives of amalgamated territorial communities, employees of local self-government bodies, etc. [9].

Adequate public awareness can ensure support for government decisions that may otherwise be unpopular (for example, decisions to raise prices for natural resources or redirect public resources to improve the environment) [2].

An equally important role in creating a favorable environment for the development of organic agriculture is played by social and cultural tools, namely environmentally and socially oriented corporate culture and responsibility; activation of environmental education, especially in higher educational institutions; environmental ethics and consciousness of the entrepreneur and the whole society. Their implementation should promote increasing the level of professional knowledge, experience, and research in the respective economic sphere through the introduction of appropriate training courses on the theory and practice of organic production in educational institutions of various accreditation levels, the creation of modern research farms and the improvement of training of farmers and controllers. It is also necessary to choose several farms in each region, which would become pilots in the organization of agricultural production.

The popularization of organic production in Ukraine is important for formation of favorable environment of development and promotion of organic agriculture. Such popularization should be made on the basis of implementation of marketing tools and organization of various events: exhibitions, fairs, forums, seminars, conferences, etc.

It should be noted that Ukrainian agrarian sector was very active during all these years and organized a lot of events for promotion of organic agriculture. From year to year, the Ukrainian organic service providers in cooperation with each other, under the patronage of state and regional authorities organize numerous annual events to promote organic agriculture in the domestic market, usually supported by international development partners. Thus, the Organic Ukraine NGO hosted the “Organic Ukraine Regional Forums”, which engaged all 24 Oblast State Administrations to the event organization in 2020 and 2021. For the 5th time, the International Congress Organic Ukraine11 and the 7th Organic Processing and Trade Conference12 were co-organized by Organic Ukraine, Organic Standard and Information Center “Green Dossier” in 2021. The Organic Federation of Ukraine organizes a specialized exhibition “ORGANIC” within the framework of the International Agroindustrial Exhibition “AGRO” which is always accompanied by a special Organic Conference. Organic Products Fair was organized for the 11th time in Kyiv by the Organic Federation of Ukraine.

In these times, it is crucial that the international community knows and sees that Ukraine, its agricultural sector, and the organic sector in particular are operational, have a strong commitment to continue their organic production and trade, and have a positive attitude despite all the wartime difficulties. It is important for the whole country to prove that Ukrainian exporters can fulfil their contract obligations, regardless of various panicked information that is in the media about export disruptions from Ukraine, in order not to lose existing partners and to attract new ones. Therefore, on June 23, the EEPO, Organic Initiative, and other partners with Swiss support (QFTP and OT4D) held the international online event “Organic Export During the War” in order to provide existing and potential partners of Ukrainian exporters from abroad with reliable up-to-date information about the market condition and its capacities [14].

Today’s relevant requirement is the digitalization of business-processes, including those in the sphere of organic production. At the same time, there should be a reduction in the use of manual labour in agricultural production and the saturation of agricultural business with such modern digital technologies as the Internet of Things, artificial intelligence, the use of big data (Big Data), robotization of production and management processes. Innovative digital tools that should be widely used in the sphere of organic production include the following:

- 3D-printing technologies (the use of such innovative tool will allow to upgrade tools for repairing agricultural machinery, to use 3D parts during capital and ongoing repair of equipment);
- blockchain technologies, with the help of which the consumer has the opportunity to access transparent and open information about the origin, production, processing, and transportation of the products he consumes. Such technologies make it possible to control the origin, quality, environmental friendliness of agricultural raw materials and food;
- GNSS – Global Navigation Satellite System, which contributes to increasing the quality of performance of all technological operations in crop production;
- the use of unmanned aerial vehicles and drones helps to carry out quality monitoring of soil condition, the level of quality of performed agricultural operations, and allows to predict the volume and quality of agricultural crops harvest as accurately as possible.

The effects of digitalization of agricultural activities envisage all three approaches of sustainability – economic, ecological and social; they are interdependent and synergic.

Each of the mentioned above groups of tools influences the level of saturation of the market with organic products, restraining or promoting its development.

Formation of the tools and means of influence on the processes of development of environmentally oriented entrepreneurship should be performed on the principles of systematicity, economic expediency, compromise, security, environmental responsibility, monitoring and control. Involving economic, ecological, organizational, regulative, and financial mechanisms and influence levers with the use of different implementation methods will allow to obtain synergetic effect from their implementation.

5. Conclusions

In order to provide the concept of agricultural production sustainable development in Ukraine and in the world at the current stage, while forming a military economy, choosing a strategy for the development of business entities in the post-war period, it is necessary to concentrate not only on obtaining profits, but also on taking care of the preservation of the environment and the social development of society. The organic agricultural production direction is one of the perspective ways of development of agricultural sector of economy, which will allow any country to achieve sustainable social and economic development, and a set of other advantages. Organic production allows to implement the concept of balanced development of the agricultural sphere on the basis of social and economic, natural and resource balance and aims to provide society with safe and high-quality food products, as well as to preserve and improve the state of the environment.

The conducted research shows that Ukrainian organic products are perspective for export to the EU countries and globally. At the same time, compared to global trends, due to the negative impact of a number of subjective reasons, the development of Ukrainian organic agricultural production lags behind significantly, that may form a negative influence on the export potential of the country and on the volumes of organics supplies abroad. Considering this, the development of organic agricultural production requires the creation of a favorable environment for producers and consumers of organic products, aimed at supporting this direction, which will include both direct and indirect stimulation tools.

The scientific novelty of the research consists in the systematic solution of the important scientific problem about the formation and improvement of tools and measures, the complex implementation of which will provide for creation of the favorable environment for development of organic agriculture. The author also defined the circle of responsible persons who should contribute to the implementation of outlined tools and measures.

The research of the tools for the formation of a "favorable environment" for organic agricultural production development is conducted by the author with the aim of their systematization and further grouping into regulatory and legal, political, stimulating and compensatory, fiscal and restrictive, financial and investment, infrastructural, informational, social and cultural, marketing, and digital. During the detailed analysis the necessity to implement these tools in complex was proven. The implementation of the proposed tools will contribute to the development of organic agricultural production, increasing the efficiency of activities of agricultural enterprises and their competitiveness on regional markets, as well as on the external markets, with simultaneous economic growth, social development, and an increase in the level of environmental security of countries. The content characteristics of each group of tools, which are highlighted in the article, are important guidelines for the formation of effective state economic policy in the conditions of aggravation of influence of global challenges and provide the certain opportunity for definition of ways of their improvement.

E-mail: lzomchak@gmail.com

Abstract. The combination of the economic, social and environmental issues of the country-level development in the case of Ukraine requires modernization of the national economic system and permanent deep institutional reforms. These measures should be aimed at forming a diverse, competitive and socially oriented post-industrial economy capable of ensuring sustainable development. To ensure the improvement of the management of Ukraine's sustainable development strategy, structural (simultaneous) model is proposed, based on three endogenous (namely GDP as economic variable, income per household as social variable and the expenses for the environmental protection as environmental variable) and seven exogenous variables. Such an approach makes it possible to investigate the interdependence between variables. Model parameters estimates were calculated with the two-step least squares method. A forecast of the development of the main indicators characterizing the economic, social and environmental components of development at the country level was also estimated. For Ukraine in 2021, according to the forecast based on the structural model, the economic and environmental components will have positive dynamics and rapid growth, while the social component will develop, but more stably and without rapid growth.

1. Introduction

Before the start of the full-scale war in February, Ukraine was making steady progress in achieving 15 of the 17 Sustainable Development Goals (set of 17 Sustainable Development Goals (SDG) according to the "Transforming our world: the 2030 Agenda for Sustainable Development" [1]), and moreover, it achieved the greatest success precisely in reducing poverty. The first Voluntary National Review of progress towards achievement of the Sustainable Development Goals in Ukraine [2] showed that the main achievement is the reduction of poverty for more then 15 percent during 2015-2018.

Now, when the discussions about the recovery of the country and the economy begin, the SDG are used as a reference point to ensure the most effective reconstruction of Ukraine. The war will require a review of development priorities to achieve the SDG. The interpretation of the 16th SDG – "Peace, justice and strong institutions" will change significantly. SDG 1 "Poverty" will now become a key task of social development. SDG 6 "Clean water and sanitation", which covers ensuring the availability and sustainable management of water resources and sanitation, is becoming urgent. Goal 8 "Decent work and economic growth" becomes of primary importance for the return of Ukrainian refugees.

Undoubtedly, radical changes will have to be made to all state programs, because the focus on sustainable development in the "peaceful" version, where the main priorities are overcoming inequality and a green economy, is being revised even in wealthy democracies. The world is feeling the consequences of the energy crisis, including as a result of the sanctions imposed on Russia, and therefore the governments of the countries are not only postponing the green transition, but also resuming coal mining, taking care of the state of the industry.

Since the problems of sustainable development appear from new perspectives, a reasonable explanation of the dependencies between indicators of sustainable development with mathematical methods will help in making management decisions.

The concept of sustainable development has been spreading during the last decades, but the most popular definition was in the Brundtland report [3]. And while its usefulness may still be questioned (e.g. in Beckerman article [4], it is one of the most popular concepts in terms of popularity. Salvia et al [5] investigated trends in sustainable development research in different levels of investigation. Chabay [6] believes that the greatest success in the implementation of the goals of sustainable development can be achieved by applying interdisciplinary complex systems approaches and trans-disciplinary research methods. Schoenmaker and Stegeman [7] think that the biggest problem in the practical implementation of the concept of sustainable development is the balancing of various goals, unlike, for example, economic concepts that consist in maximizing economic indicators. Vavoura and Vavouras [8] investigated COVID-19 impact on sustainable development and record a significant reduction in the social component of sustainable development in European Union, i.e. an actual return to the concept of economic growth, but on the basis of a green deal.

The concept of sustainable development is implemented at different levels: from the union of countries [9] to country [10, 11], region [12, 13], territorial communities [14] and even family business [15] and enterprises [16].

Regarding the investigation of the sustainable development of Ukraine, the researches of both domestic and foreign scientists are also devoted to this problem. In the article [17] the trends in sustainable development of Ukraine comparing to EU counties is described; in [18] it is considered from the position of the European integration of Ukraine as a strategic goal; Kuzior et al [19] study role of the innovative ecosystem of Ukraine and EU in sustainable development and Sokil et al [20] details innovation ecosystem to startups; Semenenko et al [21] investigate changes in sustainable development before and after the war. Also investigations of the sustainable development of Ukraine are devoted to different aeries, such as agriculture [22], transport [23], rural areas [24] and others.

A wide range of mathematical methods and models are used for quantitative analysis and modeling of sustainable development (table 1). The choice of method depends, among other things, on the purpose of the research. In order to reveal the interdependencies between various indicators that characterize the economic, social and environmental aspects of the country's sustainable development, it is advisable to apply structural modeling methods.

2. Structural equations method for sustainable development modelling

A system of simultaneous equations is a statistical model in the form of a set of simultaneous linear equations. They differ from ordinary regression models in that there are two or more dependent variables.

Variables that are explained by the functioning of the system and whose values are determined by the simultaneous interaction of the links in the model are endogenous variables or jointly determined variables.

Variables that help provide explanations for endogenous variables and whose values are determined outside the model are exogenous variables or predetermined variables. Exogenous variables help explain variations in endogenous variables.

Table 1. Methods and models of sustainable development investigation and modelling.

Valaskova et al [41]	regression analysis

Determining from the data sample those variables which are endogenous and which are exogenous belongs to the model developer himself, that is, in essence, it is partially based on the expert method.

A structural simultaneous model is used to describe the structure of relationships between endogenous and exogenous variables. In general, it can be written like this:

$$y_{2t} = b_{21}y_{1t} + b_{23}y_{3t} + ... + b_{2m}y_{mt} + c_{21}x_{1t} + c_{22}x_{2t} + ... + c_{2k}x_{kt} + u_{2t},$$

$$y_{2t} = b_{21}y_{1t} + b_{23}y_{3t} + ... + b_{2m}y_{mt} + c_{21}x_{1t} + c_{22}x_{2t} + ... + c_{2k}x_{kt} + u_{2t}, ...,$$

$$y_{mt} = b_{m1}y_{1t} + b_{m2}y_{2t} + ... + b_{mm-1}y_{m-1t} + c_{m1}x_{1t} + c_{m2}x_{2t} + ... + c_{mk}x_{kt} + u_{mt}.$$

Certain macroeconomic models built with a system of simultaneous equations can be a powerful econometric tool as a result, which will make it possible to investigate complex relationships in various kinds of socio-economic systems, in particular, relationships in ecological-socio-economic systems, in conditions of certain uncertainty, high risks and rapid changes in the economic environment.

Simultaneous models can be both quite detailed and quite compact, so they can be used not only for in-depth analysis considering various scenarios of system development, but also for preliminary diagnosis of the system state or display of the behavior of certain of its components in different situations.

Structural equations are used for sustainable development modeling in the investigations of urbanisation [42], green buildings [43], business environment [44], machine-building enterprises [45] and others.

For modeling sustainable development, simultaneous models can also be considered quite effective, as they make it possible to analyze and forecast the development of environmental, social and economic components both separately and to consider their interrelationships. Also, such modeling makes it possible to assess the overall impact on sustainable development of the changes implemented in each of its components and, if necessary, to change the further strategy.

3. Structural model of sustainable development of Ukraine on three-pillar approach

A simultaneous model of three equations, each of which describes one of the three components of sustainable development (ecological, economic, and social) is proposed for investigation and forecasting the sustainable development of Ukraine.

To describe the economic component, we will use the following variables:

1) Endogenous variable – gross domestic product (million UAH), y_1.
2) Exogenous variables:
   - turnover of retail trade, million UAH, x_1;
   - export of goods, thousands of dollars USA, x_2;
   - inflation, percent, x_3.

To describe the social component:

1) Endogenous variable – disposable income per household, UAH, y_2.
2) Exogenous variables:
   - number of employed population, thousands of people, x_4;
   - average monthly (real) salary per employee, UAH, x_5.

To describe the ecological component:

1) Endogenous variable – expenses for the protection of the natural environment, thousand UAH, y_3.
2) Exogenous variables:
   - volume of emissions of polluting substances into the air by stationary sources, thousand tons, x_6;
   - capital investments for the protection of the natural environment, UAH, x_7.

In general terms, the model looks like this:

$$y_{1t} = f(y_{2t}, y_{3t}, x_{1t}, x_{2t}, x_{3t}, x_{5t}), \tag{1}$$

$$y_{2t} = f(y_{1t}, x_{4t}, x_{5t}), \tag{2}$$

$$y_{3t} = f(y_{1t}, x_{6t}, x_{7t}). \tag{3}$$

The dependence equations will have the following form:

1. Gross domestic product depends on available income per person, costs for environmental protection, retail trade turnover, export of goods, consumer price index, average monthly real wages:

$$y_{1t} = a_{12}y_{2t} + a_{13}y_{3t} + b_{10} + b_{11}x_{1t} + b_{12}x_{2t} + b_{13}x_{3t} + b15x_{5t} + e_{1t}. \tag{4}$$

2. The disposable income per household depends on the gross domestic product, the number of employed people, and the average monthly real wage:

$$y_{2t} = a_{21}y_{1t} + b_{20} + b_{24}x_{4t} + b_{25}x_{5t} + e_{2t}. \tag{5}$$

3. Costs for environmental protection depend on the gross domestic product, the amount of pollutants emitted into the air by stationary sources, capital investments for environmental protection:

$$y_{3t} = a_{31}y_{1t} + b_{30} + b_{36}x_{6t} + b_{37}x_{7t} + e_{3t}. \tag{6}$$

So, the simultaneous model will look like this:

$$y_{1t} = a_{12}y_{2t} + a_{13}y_{3t} + b_{10} + b_{11}x_{1t} + b_{12}x_{2t} + b_{13}x_{3t} + b15x_{5t} + e_{1t}, \tag{7}$$

$$y_{2t} = a_{21}y_{1t} + b_{20} + b_{24}x_{4t} + b_{25}x_{5t} + e_{2t}, \tag{8}$$

$$y_{3t} = a_{31}y_{1t} + b_{30} + b_{36}x_{6t} + b_{37}x_{7t} + e_{3t}. \tag{9}$$

Let's check whether the model is identified, for this we will first write it down in tabular form (table 2).

Table 2. Tabular form of the simultaneous model.

y_1	y_2	y_3	x_1	x_2	x_3	x_4	x_5	x_6	x_7
1	$-a_{12}$	$-a_{13}$	$-b_{11}$	$-b_{12}$	$-b_{13}$	0	$-b_{15}$	0	0
$-a_{21}$	1	0	0	0	0	$-b_{24}$	$-b_{25}$	0	0
$-a_{31}$	1	0	0	0	0	0	0	$-b_{36}$	$-b_{37}$

Let us now check the order condition and rank condition for each equation of the constructed simultaneous model (table 3).

Table 3. Order condition and rank condition.

Equation №	Not included variables	Matrix rank	Included variables-1	Conclusion
1	4	2	2	over identified
2	5	2	2	over identified
3	4	2	2	over identified

Since the order and rank conditions are fulfilled for all equations of the model, we conclude that all of them are over identified, and therefore the model as a whole can be considered as over identified.

Since the equations of the model are over- identified, we cannot use the least-squares method to estimate the parameters, that's is why we used the two- step least-squares method. We will estimate the parameters based on the statistical data of the described variables from 2000 to 2020, which were collected from the website of the State Statistics Service of Ukraine.

4. Simultaneous equations of Ukrainian sustainable development

All the input data about exogenous and endogenous variables are collected from the official web-page of the State Statistics Service of Ukraine [46] for the period 2000-2020 years.

The first step is to construct three regression models of the dependence of each endogenous variable on all exogenous variables.

After the actions taken, we have three models for calculating the theoretical values of endogenous variables, which will be used in the second step as auxiliary variables to obtain estimates of the parameters of simultaneous model:

1) for gross domestic product:

$$y_{1t} = 4554526.41 - 1.55x_{1t} + 14.63x_{2t} - 1098.17x_{3t} + 249.03x_{4t} + 372.47x_{5t} + 86.64x_{6t} - 0.009x_{7t}.$$

2) for disposable income per household:

$$y_{2t} = -1707.95 + 0.001x_{1t} + 0.09x_{2t} + 2.32x_{3t} + 0.07x_{4t} + 0.94x_{5t} + 0.014x_{6t} + 0.00007x_{7t}.$$

3) for environmental protection expenses:

$$y_{3t} = 19684709.17 + 10.89x_{1t} + 45.05x_{2t} - 18399.35x_{3t} - 942.65x_{4t} + 791.26x_{5t} + 431.37x_{6t} + 0.28x_{7t}.$$

The three equations have high coefficients of determination, which indicates that the obtained equations of the simultaneous model perfectly explain the variance of the endogenous variables. For the equation of the economic component, this indicator is 99.58 percent, for the equation of the social component – 99.57 percent, and for the equation of the ecological component – 98.96 percent.

We will also check the statistical significance of model parameter estimates. As mentioned earlier, we will do this using the Student's test with a confidence probability of 90 percent.

Tabular values of the Student's criterion at a probability of 0.1 and 14 degrees of freedom is 1.761, and at 17 degrees of freedom – 1.739.

The obtained empirical values of the Student's test were also calculated as a proportion of the obtained variable parameters and their standard error. The results are described in table 4.

Table 4. Empirical and critical values of Student's criterion.

№	y_1	y_2	y_3	x_1	x_2	x_3	x_4	x_5	x_6	x_7	t_{kr}
1	-2.280	-2.335	3.855	-2.069	2.696	1.773	-	2.999	-	-	1.761
2	3.794	-2.411	-	-	-	-	2.581	2.538	-	-	1.740
3	8.276	-	1.748	-	-	-	-	-	2.643	4.681	1.740

Since the empirical values are greater than the critical values, we can reject the null hypothesis and conclude that all parameters of the obtained simultaneous model of sustainable development of Ukraine are statistically significant. That is, we can use the model to further build a forecast.

In the final form, we have the following simultaneous model of sustainable development of Ukraine:

$$y_{1t} = -792974.45 - 922.97y_{2t} + 0.19y_{3t} - 2.74x_{1t} + 14.97x_{2t} + 4488.29x_{3t} + 1081.49x_{5t},$$

$$y_{2t} = -3422.58 + 0.002y_{1t} + 0.17x_{4t} + 0.44x_{5t},$$

$$y_{3t} = -38700954.51 + 4.56y_{1t} + 820.28x_{6t} + 0.69x_{7t}.$$

5. Forecasting three-pillar approach indicators of sustainable development

Based on the model, we will forecast the dynamics of each selected component of Ukraine's sustainable development. We will use the data for 2021, which is on the website of the State Statistics Office of Ukraine [46], as well as their forecasts of the development of some indicators.

First, let's calculate the theoretical values of all our endogenous variables for 2021. As a result, we have that the GDP is UAH 6433133.192 million; available income per household – UAH 13,518.51, expenses for environmental protection – UAH 2,276,465.42 thousand.

Next, we substitute all these values and get that in 2021 GDP will be UAH 6,433,133.192 million, disposable income per household is UAH 17,381.18,027, and costs for environmental protection are UAH 3,872,110.64 thousand.

Figures 1-3 show the dynamics of our selected endogenous variables from 2000 to 2020, the obtained forecast for 2021, as well as the forecast of the State Administration of Statistics of Ukraine and Forecast.

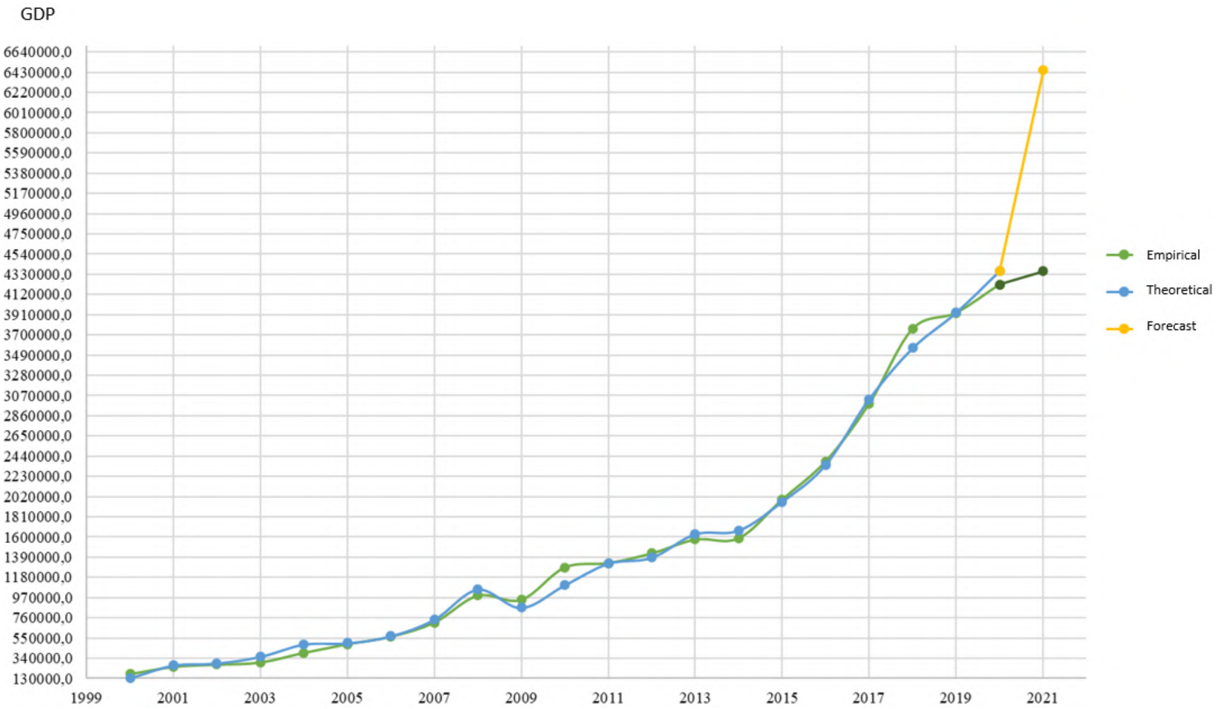

Figure 1. Dynamics and forecast of the gross domestic product.

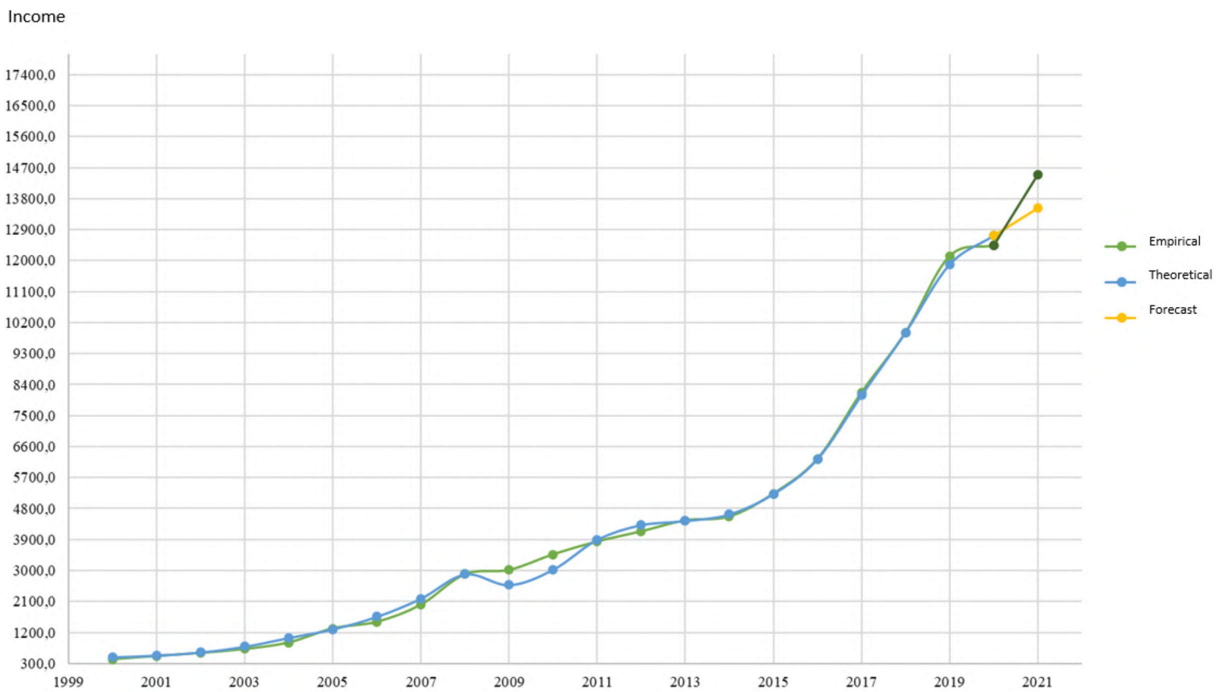

Figure 2. Dynamics and forecast of disposable income per household.

From figures 1-3, it is clear that the forecast for the dynamics of GDP and costs for the protection of the natural environment, which we obtained on the basis of a simultaneous model, significantly exceeds the forecast of the State Statistics Office of Ukraine, but the forecast for

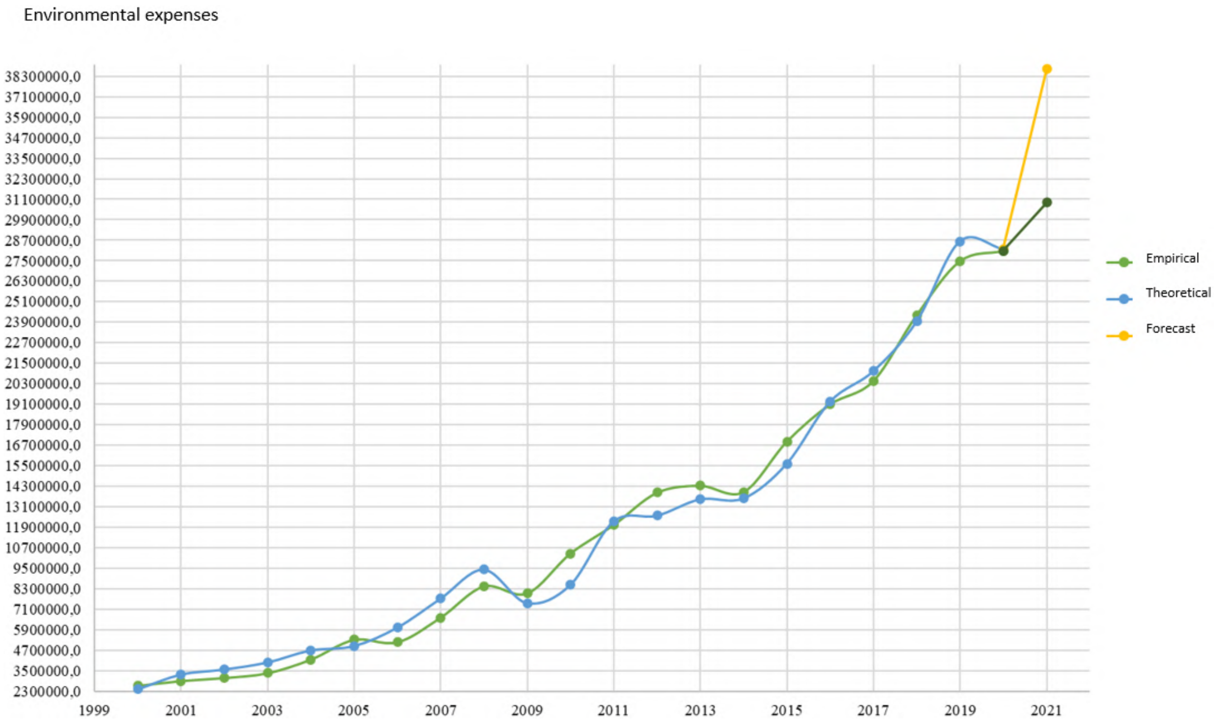

Figure 3. Dynamics and forecast of the expenses for the environment protection.

the change in the dynamics of disposable income per household, on the contrary, shows a less rapid its growth. But in general, both forecasts show a positive development of all indicators.

6. Conclusions

The proposed and implemented structural model of sustainable development of Ukraine based on the three-pillar approach. The economic component of development is represented by GDP as a function of wages, trade turnover, exports and inflation. The social component is described in terms of income per person as a function of GDP, average wages and the number of employed population. Environmental protection costs, which depend on GDP, emissions from stationary sources of pollution, etc., and capital investments in the environment, were used as an ecological characteristic. Since GDP is both the dependent variable in the first equation and the independent variable in the next two equations, the interaction between the three pillars of sustainable development can be explored. In this way, it was found that the growth of household income is not accompanied by the growth of GDP, that is, incomes grow faster than the economy, which is quite unexpected. Simultaneously with the growth of the GDP of Ukraine, the income of households increases, which can be seen from the equation that describes the social component. If we talk about the environmental component, the growth of environmental protection costs is accompanied by GDP growth, and vice versa, GDP growth increases environmental protection costs. Forecasts of three exogenous variables were also obtained, which differs from the official forecasts, but also confirmed the correct selection of variables and the description of the dependencies between them.

Unfortunately, the State Statistics Service has suspended the publication of statistical information for the period of martial law or the state of war, as well as for three months after its termination, and for the occupied territories, even the collection of statistics is not possible. It is obvious that with the beginning of a full-scale invasion, statistical economic, social and environmental indicators have undergone catastrophic changes (which have not yet acquired a clear quantitative dimension) and the assessment of the scale of losses is still ahead. Catastrophic changes took place in various areas, including those that describe the social, economic and ecological components of sustainable development, goals and priorities changed dramatically, so the correctness of forecasts for the following periods will require additional clarification.

The deepest decline of the Ukrainian economy in the entire history of the state took place, household incomes experienced a significant reduction and often large changes in the structure, the environmental consequences of the war also cause significant concern. Obviously, the classical econometric model could not take into account such changes, but it allows to investigate the structure of dependencies between economic, social and environmental indicators and provides tools for its explanation.

We also note that the reconstruction of Ukraine will take place on the basis of the concept of sustainable development and require adequate justification of decisions, and econometric approaches can be used for this purpose.

Abstract. The article substantiates the expediency of modifying the methodology for assessing business competitiveness in the context of accelerated global ESG integration. The authors propose a system of criteria for assessing the competitiveness of enterprises, taking into account the requirements of the EU Taxonomy, Regulation (EU) 2020/852, the CSRD, and stakeholder requests for information support for assessing ESG risks and ESG competitiveness of enterprises. This system of criteria is based on a cognitive approach. Thanks to the use of modeling and information tools, it is based on a lateral understanding of the clarity of the distinction between the criteria and sub-criteria for assessing the ESG competitiveness indicator and its components. The introduction of a system of criteria for assessing the competitiveness of enterprises will ensure obtaining realistic results and making informed decisions to strengthen the competitive advantages of enterprises for a new generation of "conscious investors". The author's own methodology for integral assessment of ESG competitiveness of metallurgical enterprises is proposed. This methodology is based on the synthesis of integral and reference approaches to assessing the homeostasis of competitiveness. It is adapted to the information support of the Management Report prepared in accordance with the GRI (Global Reporting Initiative) and SASB (Sustainability Accounting Standards Board) standards. Its peculiarity is the assessment based on the extended homeostatic plateau of the dynamic system for determining the thresholds of the optimality of the ESG competitiveness indicator of enterprises. This should become the basis for ESG rating and the fundamental basis for determining strategic imperatives for managing the competitiveness of enterprises in the context of global ESG integration.

1. Introduction

The aggravation of the triple planetary crisis due to the shortage of natural resources, environmental pollution and climate change requires a transition to a low-carbon economy. Society's expectations are growing and require preserving the planet's sustainability for future generations. In this context, the integration of sustainability and sustainable development (ESG integration) is recognized as one of the strategic priorities of steel companies. When the question of their competitiveness arises, it is about ESG competitiveness.

Traditionally, the competitiveness of enterprises is assessed through a comparative analysis of integrated competitiveness indicators. It is also possible through a comparative analysis of rating indicators or rating positions. In the context of ESG integration, there is a need to revise approaches to assessing the competitiveness of enterprises, that is, to modify the methodology for its assessment [1, p. 66].

2. Literature review

Usually, the competitiveness of enterprises was assessed by financial and economic indicators [2–6]. However, this is not enough in the context of ESG integration. Investors are increasingly considering the social impact of their investments when choosing an investment object and strive to create added value in their investment portfolio for the benefit of future generations [7]. That is why, according to Segal [8], Datsii et al [9], nowadays attention is increasingly focused on the ESG competitiveness of enterprises.

There are still no uniform criteria for its assessment [8, p. 18]. The number of metrics for its assessment offered by analytical centers, rating companies and stock exchanges is growing steadily every year. The metrics proposed by the Global Sustainable Development Goals, RobecoSAM, the Global Reporting Initiative (GRI), EcoVadis 180+, Bloomberg 700+, ISS 300-500, RobecoSAM 600, Sustainalytics 300+, and companies of the DAX, MDAX, SDAX and TechDAX indices on the Frankfurt Stock Exchange (FWB) are currently used in the world practice, The London Stock Exchange (LSE) (which issued guidelines for ESG reporting in response to requests from investors for whom such information is key to their investment decision-making), the Warsaw Stock Exchange (WSE) (which created the WIG-ESG index, which is followed by the NN TFI fund). In May 2020, the European Central Bank issued guidelines for assessing climate and environmental risks for financial institutions, etc. [8, p. 18].

Of particular note is the methodology for assessing ESG competitiveness based on corporate sustainability indicators. It was introduced in Ukrainian practice in 2019 during the first and only professional rating assessment Sustainable Ukraine (based on the DJSI approach). This was carried out as part of a global international project on ESG rating of CIS countries and enterprises with the strategic support of Standard & Poor's Financial Services LLC, S&P Global (owner of the world's most authoritative SR/ESG rating – Dow Jones Sustainability Raitng/index). The aim of the project was to present to the international investment community a holistic picture of Ukraine's corporate sector in terms of sustainable development and corporate social responsibility [10].

Scientists have their own opinions on this matter. Thus, Datsii et al [9, p. 67] argue that in the world and domestic practice there is no single methodology for scoring (assessing) the ESG direction of business. For the first time, the author's model of scoring trends and regularities of business development is proposed in accordance with ESG-principles, in contrast to traditional trend dynamic models, which identifies and iteratively conceptualizes processes by the set of ESG-indicator components determined using the cocoupling-analysis toolkit (tools for assessing the cocoupling-effect).

There are many examples of metrics for assessing the ESG competitiveness of enterprises. Each of them has advantages and disadvantages. The main disadvantage is that when assessing the ESG competitiveness of enterprises, we believe that the limits of its optimality are ignored. This is usually of the greatest interest to investors and stakeholders in obtaining the expected effects (environmental, social and corporate governance). Any deviation from the defined limits of optimality is accompanied by ESG risks and certain losses. Taking into account the shortcomings of the methods for assessing the ESG competitiveness of enterprises, we consider it appropriate to propose our own methodology for assessing the ESG competitiveness of metallurgical enterprises. This methodology is based on a symbiosis of the integral and benchmark approaches.

3. Calculation methodology

The ESG competitiveness of an enterprise is characterized by a set of numerous indicators. These indicators have been prioritized by each of the components of ESG competitiveness (table 1).

Table 1. A set of indicators for assessing the ESG competitiveness of metallurgical enterprises.

No.	Indicators	Measurement units	Abbreviations
	Partial indicators of the E-component of the ESG indicator		
1	Investments in environmental protection	mln USD	E_1
2	Gross greenhouse gas emissions in CO2 equivalent per 1 ton of steel	t/ton of steel	E_2
3	Total water intake per 1 ton of steel	m^3/ton of steel	E_3
4	Amount of waste recycled	t/ton of steel	E_4
5	Total energy consumption	GJ/ton of steel	E_5
	Partial indicators of the S-component of the ESG indicator		
6	Investments in occupational health and safety	mln USD	S_1
7	Lost time injury frequency rate	without dimension	S_2
8	Investments in healthcare	mln USD	S_3
9	Investments in local communities	mln USD	S_4
10	Payroll level coefficient	without dimension	S_5
	Partial indicators of the G-component of the ESG indicator		
11	Reporting on impact by taxonomy	mln USD	G_1
12	Investment in sustainable development	mln USD	G_2
13	Income	mln USD	G_3
14	Total debt	mln USD	G_4
15	Number of employees (number of jobs created)	persons	G_5

The defined structure includes 15 indicators. The list of indicators may vary depending on the objectives and depth of the study. These 15 indicators are grouped by each of the components E_5, S_5, G_5. To simplify understanding and demonstration, the results of the modeling [11] are presented in the form of a vector:

$$\overline{R} = \{r_1; r_2; \ldots; r_n\}, \quad (1)$$

n – number of indicators.

With this decision, the question of the unidirectionality of the indicators E_j, S_j, G_j. Because among the indicators identified in table 1, some of them should increase (stimulators) and others should decrease (discouragers) to ensure the ESG competitiveness of enterprises. The unidirectionality of the indicators E_j, S_j, G_j can be achieved through normalization, in particular, by applying the combined method [12, p. 74]. This is a modified method of normalization by the "range of variation", which provides:

- for positive direction indicators:

$$r_i = \frac{x_i}{x_{\max}}, \quad (2)$$

- for negative direction indicators:

$$r_i = \frac{k_{\text{norm}} \;--x_i}{k_{\text{norm}}}, \quad k_{\text{norm}} = x_{\max} + 7\%. \quad (3)$$

The main disadvantage of the combined method of normalization is that the standardized indicators that form the information basis for calculating the generalized and integral ones affect the latter with equal force. Their influence is equilibrium. This is not always justified in practice.

This shortcoming can be neutralized by introducing hierarchy coefficients (weighting). This will divide the indicators E_j, S_j, G_j by their significance, strength of influence on the generalized and integral indicator of ESG competitiveness of enterprises. The question arises of determining the weighting coefficients of indicators for each component of the ESG competitiveness of enterprises. This is possible using one of the approaches presented in table 2.

Table 2. Methods for determining the weighting coefficients of each component of the ESG competitiveness indicator of an enterprise [11, p. 46].

The method	Calculation methodology	Advantages
The method of sensitivity theory	$a_i = \dfrac{\lvert u_i \Delta y_i \rvert}{\sum\limits_{i=1}^{n} \lvert u_i \Delta y_i \rvert}$	allows adjusting the weighting coefficients in each period to make them more relevant to the real economy
The method of principal components	$a_i = \dfrac{c_i \lvert d_i \rvert}{\sum c_i \lvert d_i \rvert}$ c_i – contribution of the i-th component to the total variance of the set of indicators; d_i – factor loads	allows to identify only an averaged pattern, but does not provide strict and accurate correspondence in each individual case (period)
Gaming methods	$I_d = \sum\limits_{j=1}^{n} (S_{2j}^{*}) z_{j,t}$ $I_m = \prod\limits_{j=1}^{n} z_{j,t}^{(s_{2j})}$	characterizes the set of weighting coefficients required to form the indicator in additive or multiplicative form

Determination of the indicator of ESG competitiveness of enterprises by the method of integral assessment makes it possible to observe changes in this indicator in the dynamics and to carry out a multicriteria analysis of the competitiveness of enterprises. However, this is not enough to make informed management decisions on maintaining the competitive position of enterprises and improving them in the context of accelerated competition.

For a more realistic assessment of the ESG competitiveness indicator of enterprises and the possibility of forecasting its changes in the medium and long term, we consider it advisable to apply a methodology based on the synthesis of integral and benchmark approaches to assessing business homeostasis. This methodology is adapted to the information support of the Management Report prepared in accordance with the GRI (Global Reporting Initiative) and SASB (Sustainability Accounting Standards Board) standards. It provides for the assessment of the extended homeostatic plateau of the dynamic system for determining the thresholds for the optimality of the ESG competitiveness indicator of enterprises and its components. This can become the basis for ESG rating and the fundamental basis for determining strategic imperatives for managing the competitiveness of enterprises in the context of accelerated global ESG integration. That is why, for each of the components E_j, S_j, G_j of the competitiveness of enterprises, it is necessary to determine the vector of threshold values, namely: lower critical ($x_{\text{low\_k}}$); lower threshold ($x_{\text{low\_lim}}$); lower optimal ($x_{\text{low\_opt}}$); upper optimal ($x_{\text{h\_opt}}$); upper threshold ($x_{\text{h\_lim}}$); upper critical ($x_{\text{h\_k}}$) [13, p. 52].

There is a fairly large number of methods for determining the threshold vector. The most adequate, from our point of view, for this task is the stochastic method of the t-criterion. According to this method, probability density functions should be constructed for given samples of statistical data of competitiveness indicators and statistical characteristics should be calculated: mathematical expectation, standard deviation and coefficient of asymmetry [14, p. 22].

Based on the results of the analysis of statistical data, it was found that the competitiveness indicators assume the hypotheses of normal and exponential distributions. They include formulas for calculating the vector of threshold values [12, p. 70–72], [14, p. 29]:

$$x_{\text{low\_k}} = \mu \;-\; -3 \cdot \sigma, \quad x_{\text{low\_lim}} = \mu \;-\; -t \cdot \sigma, \quad x_{\text{low\_opt}} = \mu \;-\; -\sigma \tag{4}$$

$$x_{\text{h\_opt}} = \mu + \sigma, \quad x_{\text{h\_lim}} = \mu + t \cdot \sigma, \quad x_{\text{h\_k}} = \mu + 3 \cdot \sigma \tag{5}$$

for the exponential law (tail to the right)

$$x_{\text{low\_k}} = \mu \;-\; -\frac{3 \cdot \sigma}{k_{\text{as}}}, \quad x_{\text{low\_lim}} = \mu \;-\; -\frac{\sigma}{k_{\text{as}}}, \quad x_{\text{low\_opt}} = \mu, \tag{6}$$

$$x_{\text{h\_opt}} = \mu + \sigma, \quad x_{\text{h\_lim}} = \mu + t \cdot \sigma, \quad x_{\text{h\_k}} = \mu + 3 \cdot \sigma, \tag{7}$$

for the exponential law (tail to the left)

$$x_{\text{low\_k}} = \mu \;-\; -3 \cdot \sigma, \quad x_{\text{low\_lim}} = \mu \;-\; -t \cdot \sigma, \quad x_{\text{low\_opt}} = \mu \;-\; -\sigma, \tag{8}$$

$$x_{\text{h\_opt}} = \mu, \quad x_{\text{h\_lim}} = \mu + \frac{\sigma}{k_{\text{as}}}, \quad x_{\text{h\_k}} = \mu + \frac{3 \cdot \sigma}{k_{\text{as}}}, \tag{9}$$

t – Student's criterion;
μ – mathematical expectation;
σ – standard deviation;
k_{as} – coefficient of asymmetry.

Establishing thresholds can help build a simulation model of optimal business immunity (homeostasis). To do this, it is necessary to identify:

I – zone of low ESG competitiveness;
II – zone of conditionally acceptable ESG competitiveness (low);
III – zone of optimal ESG competitiveness;
IV – zone of conditionally acceptable ESG competitiveness (high);
V – zone of critical ESG competitiveness.

Under conditions of variability and uncertainty, the limits of optimality of ESG competitiveness and threshold values of the I_E, I_S, I_G indicators may change under the influence of both endogenous and exogenous factors [15, p. 43]. Indicators of immunity (homeostasis) of ESG competitiveness of enterprises are indicators of statics. However, for management decision-making and strategizing, dynamics indicators are currently more important, as they make it possible to observe existing trends and see the future. Therefore, when studying the ESG competitiveness of enterprises, an equally important stage as the previous ones is to assess the vulnerability of ESG competitiveness immunity under the influence of ESG risks and threats.

4. Research results

The authors consider it expedient to do this by rating them according to the scale presented in table 3.

Table 3. Scale for assessing the intensity of threats to the ESG competitiveness of metallurgical enterprises from decarbonization pressure.

Level	Category	Average score values	Characterizing the intensity of ESG risks and threats to the competitiveness of enterprises
A	A1.tr	> 0.80-1.00	Absolutely uncontrolled
	A2.tr	> 0.63-0.80	Insufficiently controlled
B	B1.tr	> 0.37-0.63	Conditionally controlled
	B2.tr	> 0.20-0.37	Sufficiently controlled
C	C.tr	0.00-0.20	Absolutely controlled

The choice of values on the scale of 0.63 and 0.37 is due to the convenience of the calculations: $0.63 \approx 1-(1/e)$, $0.37 \approx 1/e$. The value of $di = 0.37$ usually corresponds to the limit of acceptable values.

In accordance with the defined categories of ESG risks and threats, the correction factor k_r should be determined. It should be used to adjust the limits of optimality of ESG competitiveness and thresholds of the I_E, I_S, I_G indicators.

The frequency of reviewing the limits of optimality of ESG competitiveness and the thresholds of the I_E, I_S, I_G indicators (annual, quarterly) should be specified in the standards for assessing and rating the ESG competitiveness of enterprises.

To confirm the viability of the proposed methodology for assessing the ESG competitiveness of enterprises, we applied it to the assessment of the competitiveness of Arcelor Mittal Group enterprises (table 4).

Table 4. Dynamics of the integrated indicator of ESG competitiveness of metallurgical enterprises in 2010-2021 [16–24].

The existing methodology for forming information support for assessing ESG competitiveness creates a certain limitation in access to information on compliance with ESG principles by enterprises. To model the level of ESG competitiveness of metallurgical enterprises, a set of indicators sufficient for calculations was selected (based on the availability of reliable information sources) (table 5).

Table 5. A set of indicators for assessing the ESG competitiveness of metallurgical enterprises.

No.	Indicators	Measurement units	Abbreviations	Weighting coefficients
	Partial indicators of the E-component of the ESG indicator			
1	Investments in environmental protection	mln USD	E_1	0.307
2	Gross greenhouse gas emissions in CO2 equivalent per 1 ton of steel	t/ton of steel	E_2	0.323
3	Total water intake per 1 ton of steel	m^3/ton of steel	E_3	0.089
4	Amount of waste recycled	t/ton of steel	E_4	0.116
5	Total energy consumption	GJ/ton of steel	E_5	0.165
	Partial indicators of the S-component of the ESG indicator			
6	Investments in occupational health and safety	mln USD	S_1	0.312
7	Lost time injury frequency rate	without dimension	S_2	0.097
8	Investments in healthcare	mln USD	S_3	0.164
9	Investments in local communities	mln USD	S_4	0.151
10	Payroll level coefficient	without dimension	S_5	0.276
	Partial indicators of the G-component of the ESG indicator			
11	EBITDA	mln USD	G_1	0.319
12	Capital investments	mln USD	G_2	0.295
13	Investments in research and development (R&D)	mln USD	G_3	0.154
14	Investment in education	mln USD	G_4	0.133
15	Average hours of training per employee	h./person.	G_5	0.099

To ensure ESG competitiveness, some indicators should increase (stimulators) and others should decrease (disincentives). The unidirectionality of the indicators E_j, S_j, G_j can be achieved through norming. Therefore, indicators r_i $(i = \overline{1,15})$ should be understood as standardized dimensionless values obtained from the values of E_j, S_j, G_j $(j = \overline{1,5})$.

Since the partial indicators of ESG competitiveness of enterprises have different dimensions, to determine the integral indicators of each of the components E-, S- and G-, we will carry out the procedure of normalizing the indicators E_j, S_j, G_j. For a correct comparison, each of the indicators must be normalized (i.e., reduced to the interval from 0 to 1). 0 corresponds to the worst (unacceptable) values of this indicator, and 1 corresponds to the best (optimal) values of this indicator.

To normalize the indicators, it is necessary to determine the minimum and maximum values. Next, we normalize using a formula, the form of which depends on the nature of the indicator: whether it is a stimulator or, conversely, a discourager of the enterprise's ESG competitiveness.

Stimulators of ESG competitiveness of enterprises are indicators that contribute to positive changes in the competitive position of the enterprise. This leads to an increase in the ESG competitiveness indicator. Destimulators are indicators that contribute to negative changes in the ESG competitiveness of an enterprise.

The integral indicators E, S, G will be calculated, taking into account the values of the weighting coefficients, using the following formulas:

$$I_{E,t} = r_{E1t^{0.307}} \cdot r_{E2t^{0.323}} \cdot r_{E3t^{0.089}} \cdot r_{E4t^{0.116}} \cdot r_{E5t^{0.165}} \tag{10}$$

$$I_{S,t} = r_{S1t^{0.312}} \cdot r_{S2t^{0.097}} \cdot r_{S3t^{0.164}} \cdot r_{S4t^{0.151}} \cdot r_{S5t^{0.276}} \tag{11}$$

$$I_{G,t} = r_{G1t^{0.319}} \cdot r_{G2t^{0.295}} \cdot r_{G3t^{0.154}} \cdot r_{G4t^{0.133}} \cdot r_{G5t^{0.099}} \tag{12}$$

We perform convolutions (10)–(12) for the components E-, S-, G-. Next, it is necessary to simultaneously perform integral convolutions for their thresholds with an offset by the asymmetry coefficient in relation to the number of metallurgical enterprises under consideration. We obtain the dynamics of the E-, S-, G- components of the integral ESG competitiveness index vector compared to the integral thresholds. This makes it possible to assess the level of ESG competitiveness by components E-, S-, G.

To fully assess the level of ESG competitiveness of metallurgical enterprises, we consider it necessary to carry out a comprehensive assessment of the level of competitiveness of a metallurgical enterprise by the module of the vector of the integrated competitiveness indicator. To do this, we need to normalize it using the formula:

$$I_{\mathrm{ESG},t} = \frac{\sqrt{I_{E,t^2} + I_{S,t^2} + I_{G,t^2}}}{I_{\mathrm{ESG,max}}} \tag{13}$$

$I_{\mathrm{ESG,max}} = \sqrt{1^2 + 1^2 + 1^2} = 1{,}732$ is the largest possible value of the vector's modulus, given the values of its components in the interval $[0, 1]$.

Similarly, having calculated the threshold values of the integrated ESG competitiveness indicator, it was found that only Metinvest (Ukraine), ArcelorMittal Bremen (Germany) and, starting from 2017, ArcelorMittal Asturias (Gijon) Spain meet the optimal competitiveness limits of metallurgical enterprises during the period under study. This confirms the correctness of the ESG competitiveness indicators calculations presented in table 4.

Within the framework of the proposed simulation model of the limits of optimality of ESG competitiveness of enterprises (figure 1), it is necessary to establish the compliance of each enterprise with the ESG competitiveness zones.

For the defined thresholds (table 6), the following zones of ESG competitiveness are defined for each of the indicators I_E, I_S, I_G:

I – zone of insufficient ESG competitiveness;
II – zone of conditionally low ESG competitiveness;
III – zone of optimal ESG competitiveness;
IV – zone of conditionally high ESG competitiveness;
V – zone of critical ESG competitiveness.

Table 6. Threshold values of the integrated ESG indicator and its components.

	I_E	I_S	I_G	I_{ESG}
$X_{\mathrm{low\_lim}}$	0.270238	0.261238971	0.225934441	0.253193387
$X_{\mathrm{low\_opt}}$	0.416607	0.424581624	0.396628486	0.412773042
$X_{\mathrm{top\_lim}}$	0.663957	0.682757972	0.704862781	0.684063547
$X_{\mathrm{top\_opt}}$	0.832688	0.846100625	0.875556826	0.851636725

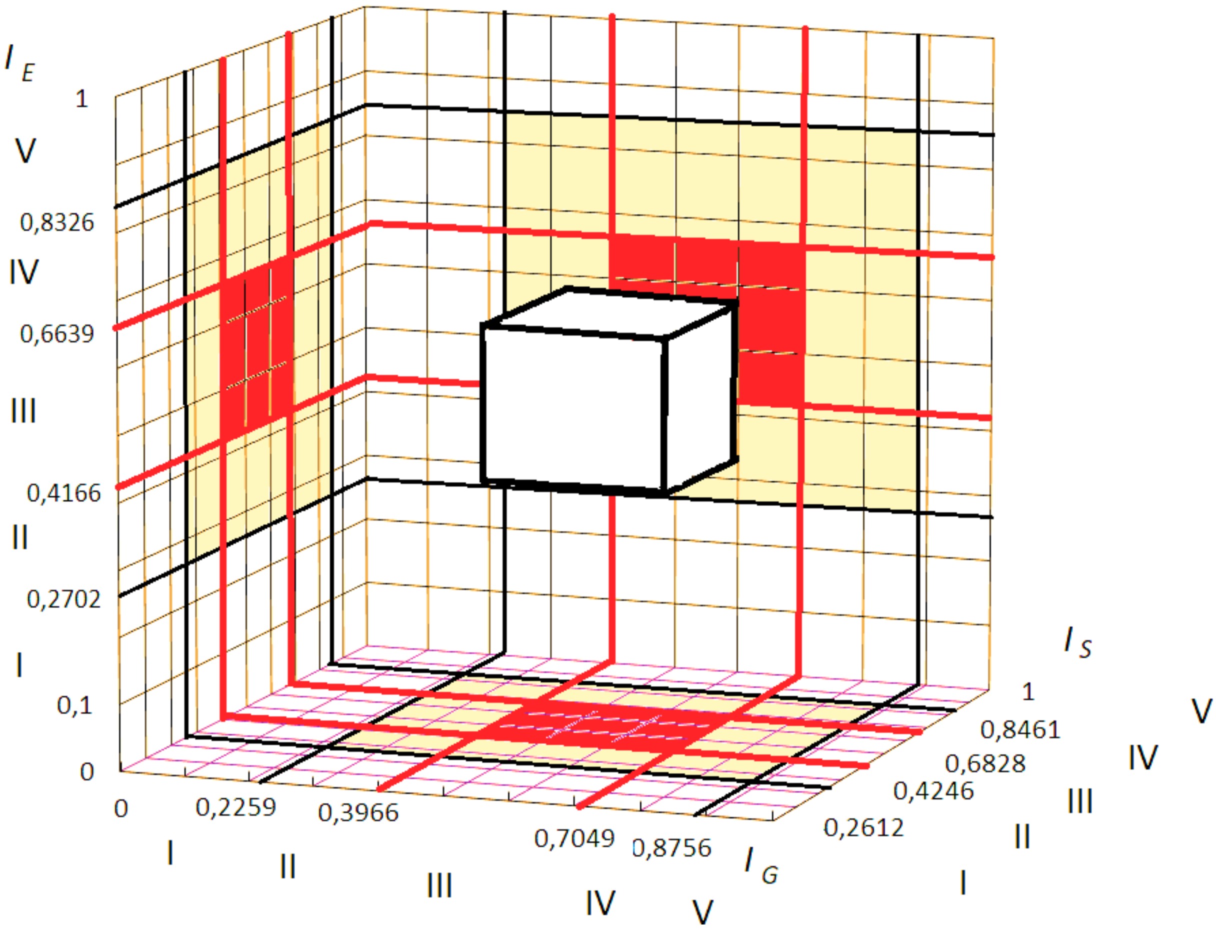

Figure 1. Schematic representation of the threshold zones of the ESG competitiveness indicator of metallurgical enterprises.

Yellow areas correspond to projections of the optimal level of competitiveness. The red areas correspond to the projections of an acceptable level for the integrated ESG competitiveness indicator, I_{ESG}.

Arcelor Mittal Bremen (Germany) and Arcelor Mittal Asturias (Gijon) (Spain) are in the optimal ESG competitiveness zone. This characterizes them as companies with ESG risks that are practically close to zero. Arcelor Mittal Acindar (Argentina), Arcelor Mittal Luxembourg (Luxembourg), and Arcelor Mittal Tubarão (Brazil) are in the zone of conditionally low ESG competitiveness. This confirms that ESG investments can be accompanied by ESG risks.

Only Arcelor Mittal Kryvyi Rih (Ukraine) is in the zone of insufficient (low) ESG competitiveness among the studied metallurgical enterprises. Its ESG investments are the most risky.

The ESG competitiveness of metallurgical enterprises is determined by the amount of invested capital. To assess the forecast of ESG competitiveness, let us find out whether there is a relationship between the ESG competitiveness indicator and total ESG investments. Let's determine the total ESG investments:

$$Q_{E,t} = E_{1,t}, \quad Q_{S,t} = S_{1,t} + S_{3,t} + S_{4,t}, \quad Q_{G,t} = G_{2,t} + G_{3,t} + G_{4,t} \tag{14}$$

It is proposed to use the hyperbolic tangent function for the functional dependence of the integrated ESG competitiveness indicator on total ESG investments. This function has a right

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012126 doi:10.1088/1755-1315/1254/1/012126

asymptote of one. The value of the index is also limited to one. Using correlation and regression analysis [15], the authors propose the following model of nonlinear multivariate regression:

$$I_{\mathrm{ESG},t} = 0.680 \cdot \tanh^{0.158}(\tilde{Q}_{E,t}) \cdot \tanh^{0.123}(\tilde{Q}_{S,t}) \cdot \tanh^{0.205}(\tilde{Q}_{G,t}) \tag{15}$$

$\tanh x = \frac{e^{x} \;--e^{-x}}{e^{x}+e^{-x}}$;
$\tilde{Q}_{E,t} = \frac{Q_{E,t}}{Q_{E\max}}$, $\tilde{Q}_{S,t} = \frac{Q_{S,t}}{Q_{S\max}}$, $\tilde{Q}_{G,t} = \frac{Q_{G,t}}{Q_{G\max}}$ are normalized values;
$Q_{E\max} = 479.348$, $Q_{S\max} = 1237.824$, $Q_{G\max} = 1223.112$.

The coefficients of the multivariate nonlinear regression (15) after initial smoothing and linearization by logarithmization were found by the generalized least squares method in matrix form [8]. The value of the coefficient of determination $R2 = 0.7529$ is quite close to one. There is a relationship between the indicator and the selected factors. The Fisher's test, $F = 67.05 > F\mathrm{crit}(0.95; 4; 66) = 2.51$, showed that with a reliability of 95% (significance level), we can assume that the corresponding R^2 are statistically significant. The proposed mathematical model (15) is adequate to the statistical data. It can be used to diagnose ESG competitiveness.

The regression level surfaces of (15) are shown in figure 2.

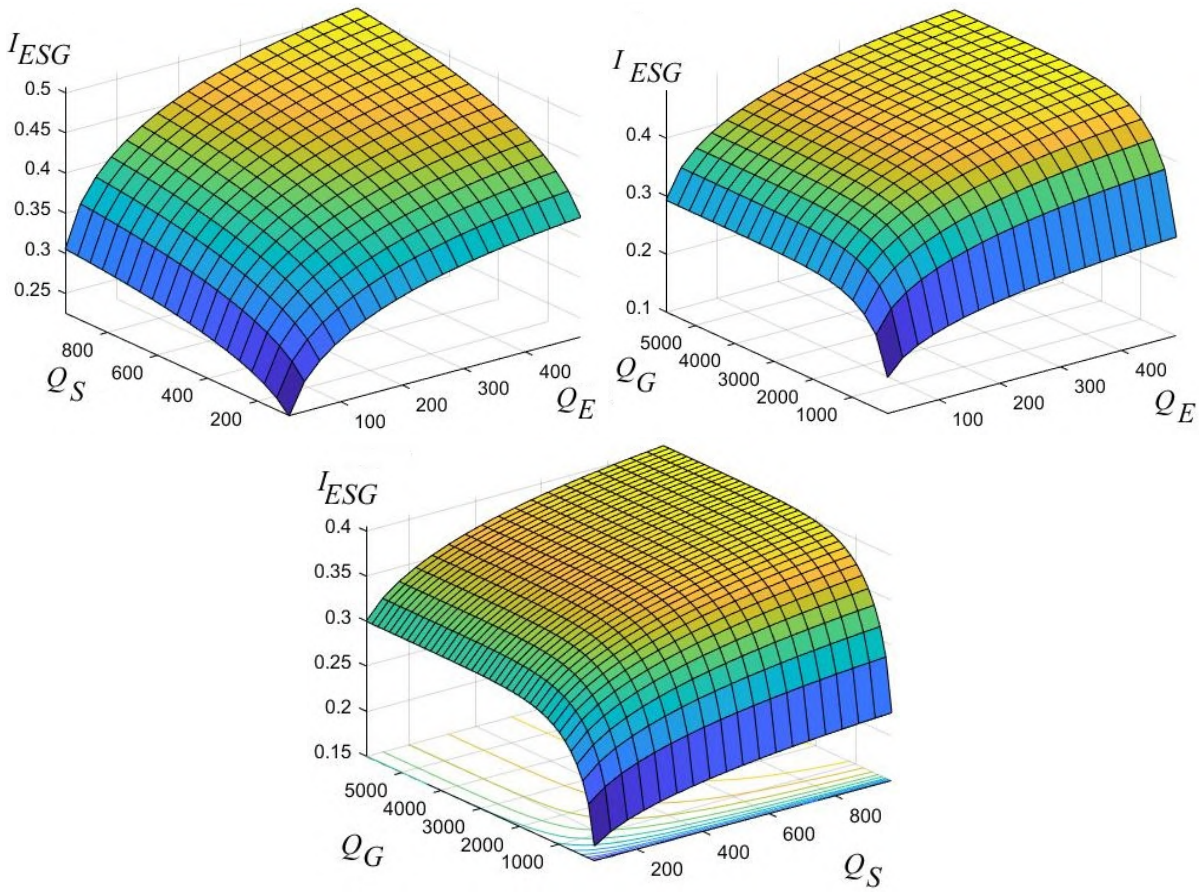

Figure 2. Regression level surfaces of the ESG competitiveness indicator at a fixed value at the level of 2021.

Arcelor Mittal Kryvyi Rih has the lowest level of ESG competitiveness (table 4). We consider the possibility of its improvement if the volume of investments is doubled by 2050 compared to 2021. However, the IESG value does not reach the lower level of the optimality boundary.

According to [13], steel production will remain unchanged in 2050 at the level of 2021, and metallurgical enterprises will need capital investments of 1 thousand USD per ton of steel, i.e. 4,700 million USD.

Table 7. Forecast of the ESG competitiveness indicator of Arcelor Mittal Kryvyi Rih in 2050.

Years	$Q_{E,t}$, mln USD	$Q_{S,t}$, mln USD	$Q_{G,t}$, mln USD	I_{ESG}
Scenario 1 (basic)	50	225	960	0,3539
Scenario 2 (optimistic)	3200	1050	4150	0,4277

Adding this amount to $Q_{G,t}$, then rises above the lower level of the optimality bound I_{ESG}.

It was found that, subject to an increase in ESG investment, Arcelor Mittal Kryvyi Rih will be able to enter the zone of conditionally low ESG competitiveness under the baseline scenario. In the case of the optimistic scenario, the company may get into the zone of optimality.

The threshold values of the limits of optimality of the integrated indicator of ESG competitiveness of metallurgical enterprises and its components E_j, S_j, G_j are determined. This made it possible to form a simulation model of the optimality limits, which should become the fundamental basis for making decisions on ESG investment in metallurgical enterprises.

5. Conclusion

Based on the results of the study, taking into account the requirements of the EU Taxonomy, Regulation (EU) 2020/852, the CSRD, and stakeholder requests for information support for assessing the ESG competitiveness of business, the authors propose a system of criteria for assessing the competitiveness of enterprises. This system is formed according to the cognitive approach, which is based on a lateral understanding of the clarity of the distinction between criteria and sub-criteria for assessing the ESG competitiveness indicator. The implementation of the proposed system in practice will ensure obtaining realistic results, making informed decisions to strengthen the competitive advantages of enterprises in a competitive environment and improving their attractiveness to a new generation of “conscious investors”. The article proposes a methodology for an integrated assessment of the ESG competitiveness of metallurgical enterprises. The methodology is based on the synthesis of integral and reference approaches to assessing the homeostasis of competitiveness. It is adapted to the information support of the Management Report prepared in accordance with the GRI (Global Reporting Initiative) and SASB (Sustainability Accounting Standards Board) standards. Unlike the generally known methods, the methodology provides for the assessment of the extended homeostatic plateau of the dynamic system for determining the thresholds of the optimality of the ESG competitiveness indicator of enterprises and its components. This is the basis of ESG rating and the fundamental basis for determining the strategic imperatives of managing the competitiveness of enterprises in the context of global ESG integration.

Abstract. Assessing the economic development of countries in the context of the tasks defined in the UN 2030 Agenda for Sustainable Development is essential from the point of view of determining progress in achieving the SDGs. It becomes especially relevant in periods of global challenges and disturbances, one of which is the COVID-19 pandemic. The goals of SDG8 and SDG9 contain indicators that are determined mainly by the state of development of the country's economy, so the analysis of trends in their changes is important in the context of identifying trends in economic growth in general, as well as for evaluating progress in achieving these goals. The purpose of the study is to identify the impact of the COVID-19 pandemic on the economic development of countries to achieve sustainable development goals and assess progress trends in the post-pandemic recovery of the economies of Eastern Europe by analyzing quantitative data from official statistical sources. The object of the study is the economic development of Eastern European countries in the conditions of the COVID-19 pandemic. The study period covers the time range from 2017 to 2021 and includes both the pre-pandemic and pandemic periods. Eight countries of Eastern Europe were chosen as research objects. Indicators of official statistics related to SDG8 and SDG9 sub-goals were selected for analysis. The study showed a significant decrease in the values of most indicators, which was caused by the destructive effect of the pandemic. To assess the possible development trajectory, we calculated the estimated value of indicators for 2022 using the Holt-Winters method. The results showed that, despite some progress in 2021, in 2022, the values of the indicators are decreasing. Such estimates correspond to the trends provided by international institutions. We have built a composite indicator to assess the economic development trend comprehensively. The results of the evaluation confirmed the general trend towards a decrease in the level of economic growth in the context of the goals of SDG8 and SDG9 for all the countries of Eastern Europe selected in the study.

1. Introduction

The irrepressible desire to ensure society's economic and technological development was a characteristic feature of the last century. The success of the activity and development of the world's economies was measured mainly by economic indicators, particularly the growth of the gross domestic product. There was a generally accepted opinion in society that this is a sufficient prerequisite for developing well-being and raising the population's standard of living, ensuring the competitiveness of national economies. Achieving appropriate progress was mainly provided due to exploitation and irrational use of natural and resource potential. The results of such irresponsible activity actualized problems of a socio-economic nature, problems caused by the deterioration of the environment, and the loss of value orientations of society. The Sustainable Development Goals (SDGs) [1] were formed to prevent these disturbances and define the strategic perspectives of world development that set global growth priorities until 2030.

Despite some progress in the fight against the spread of COVID-19, due, in particular, to effective restrictive measures, mass vaccination of the population (mandatory in some countries of the world), the permanent nature of the course of the disease causes a further increase in the number of victims of the pandemic. As of early 2023, COVID-19 has been recorded in 231 countries and territories with more than 672 million cases, of which about 6.7 million have been fatal [2]. A sudden spike in cases in Shanghai in May 2022 showed [3] that the pandemic can return to peaks even for countries like China, where stringent anti-epidemic measures are in place as part of the "zero-COVID" strategy, which aims to neutralize any facts disease by strict isolation of all infected. The new increase in morbidity and the continuation of this strategy led to mass protests at the end of November 2022, eventually forcing the Chinese government to abandon this policy.

Such a situation leads to a slowdown in the socio-economic development of the world's countries and, accordingly, causes negative consequences for the prospects of achieving the SDGs. Thus, studying the trend of the economic development of the regions during the COVID-19 pandemic is an urgent problem. The study focuses on the global SDG8 and SDG9, which are most related to economic development, in the context of establishing the dynamics of target indicators, the direction of their change during the pandemic period, and compliance with planned trends. The study is hypothetical and limited to data from 2017 to 2021. The war launched by Russia against Ukraine in 2014, and especially its "hot" phase, which began in 2022, caused an additional negative effect on economic development. However, the lack of necessary statistical data does not allow this impact to be considered in the study. Therefore, all calculated estimates are based exclusively on data, the dynamics of which mainly refer to the pandemic period.

2. Literature review

Given the new global disturbances caused by the COVID-19 pandemic, issues of monitoring economic development remain the focus of international institutions and individual scientists. At the same time, separate countries or territories, as well as global development as a whole, are subject to analysis.

Issues of progress in achieving sustainable development goals are not left out. Report [4] provides a brief overview of global and regional development in achieving the SDGs as of the end of 2021. As can be seen from the charts presented, there is a reduction in the pace of development for specific goals. In particular, this situation is observed for SDG8 in terms of ensuring decent work, which is caused by the growth of unemployment rates. On the other hand, the pandemic gave a significant impetus to the development of remote technologies, which spread after 2019 in trade, service provision, banking, and education, reflected in the relevant component of SDG9. It should be noted that part of the actual data from 2019 to 2021 was not available during the preparation of this report, as the pandemic disrupted the established data collection procedures by the relevant government institutions. Therefore, such data were replaced by simulated data, which gives some of the presented results an estimated character.

Annual reports are prepared by Cambridge University specialists, which reflect the state and dynamics of sustainable development indicators. The report prepared based on the values of sustainable development indicators as of the end of 2021 [5] states that the average value of the global SDG index after 2019 has a downward trend. The slow recovery of poor and vulnerable countries explains this result.

The report also presents statistics for individual territories by territory, as well as data for separate countries and territories. The highest value of the SDG index is for EU countries; the lowest is for Sub-Saharan African countries. However, in this study, there is also a lack of relevant values of some from 2015 or 2016, which makes it impossible to assess the impact of COVID-19 on the dynamics of relevant indicators of the SDGs in individual countries and to conduct a complete comparison of the trajectories of achieving the SDGs.

Considerable attention of researchers is paid to the application of tools of statistical analysis and economic-mathematical modeling to build possible trajectories of sustainable development in the context of the impact of COVID-19 According to the results of a study conducted by the Pardee Center for International Futures at the University of Denver in cooperation with UNDP based on data for 2020 several scenarios of global development were constructed in the context of the long-term effect of the pandemic [6]. Considerable attention in the research is also devoted to the analysis of development trends of countries with a low or average value of the human development index. The main conclusion formed by the authors is that one of the strategies enables such countries to get out of the short-term pandemic crisis and return to the trajectory of sustainable development in the long term.

The use of economic and mathematical models based on expert data to assess progress in achieving the SDGs, particularly SDG9, during the COVID-19 pandemic is presented in the article [7]. However, Fulzele et al mainly consider environmental and energy indicators, focusing on something other than sustainable development's economic aspects. Research [8] aims to use machine learning methods to model possible trajectories of sustainable development from up to 2024. Shuai et al concluded that for most of the SDGs, a significant deviation is expected in the progress of achieving the goals compared to the trajectories that could have taken place in the absence of the pandemic and the preservation of development trends. To return to the basic development trajectories, the authors suggest that the main efforts should be devoted to those sectors of the economy that cause the least negative impact on the environment.

Hryhoruk et al [9] considered the construction of a generalized index for assessing the consequences of COVID-19 on the socio-economic development indicators of Ukraine's regions in the context of sustainable development. As a result, it was established that the pandemic had a more significant impact on economic development than the social component. At the same time, the structure of the location of the regions of Ukraine in the space of built integral indicators of economic and social development remained unchanged. Based on a statistical analysis of indicators, the economic consequences of the COVID-19 pandemic for the Polish economy are considered in the article [10]. Dudzik and Brukwicka conclude that Poland's economy suffered less from the consequences of the pandemic than other Eastern European countries. Identifying patterns of the impact of the COVID-19 pandemic on the SDGs, determining the interrelationship of goals in the context of deviations from the planned development trajectories, and the formation of proposals for the development of business recovery strategies based on the theory of catastrophes is presented in the study by Chang et al [11]. Among the shortcomings of the conducted research, it can be noted that the authors do not associate the obtained results with sustainable development goals.

Without reliable statistical data, studies are often based on survey results or expert assessments. In the article [12], based on the analysis of expert data on the impact of COVID-19 on the SDGs, it was concluded that SDG8 is one of the goals for which the effect had particularly negative consequences. Based on a multifactorial criteria analysis, Elavarasan et al determined the priorities of the components of sustainable development. They proposed comprehensive strategies for building optimal trajectories for achieving the SDGs in the post-pandemic period. According to the authors, this will allow returning to pre-pandemic development trajectories faster. In the article [13], based on the results of processing expert data, the impact of the pandemic on the achievement of SDG8 was investigated using the example of Brazil. Report [14] contains a thorough analysis of the achievement of SDG8 in the context of COVID-19, based on the results of a survey of trade unions around the world. At the same time, the emphasis was placed on evaluating indicators related to sub-goals related to obtaining decent work. The vast majority of respondents confirmed the thesis of a significant deviation in the achievement of SDG8 from the planned trajectory for this sub-goal. The authors identified priorities in developing a strategy to achieve SDG8, among which creating new jobs plays a key role. In the study [15], an analysis of economic growth trends in Eastern European countries and an assessment of the effects of the COVID-19 pandemic were carried out. Sheiko and Storozhenko summarized the forecast assessments provided by international institutions and individual experts regarding the development trajectories of Eastern European countries after 2021 and assessed potential risks and threats. However, this study does not link the obtained results to the achievement of the SDGs.

Article [16] contains the results of evaluating changes in the indicators of individual goals, in particular SDG8, due to the negative manifestation of the COVID-19 pandemic. Based on expert data, a ranking of indicators corresponding to the goals selected for analysis was conducted. It was established that one of the most important indicators is the average annual growth rate of GDP per capita, which characterizes economic recovery. According to Marzouk et al, this ranking of indicators will help identify trends in SDG indicators in light of COVID-19 and contribute to creating sustainable development strategies.

The issue of determining priorities in developing a strategy to overcome the consequences of the pandemic to eliminate instabilities and gaps in the interaction between the components of sustainable development is investigated in studies [17–21]. The authors emphasize that under current conditions, developing a long-term sustainable development strategy goes beyond national development policies. This calls for the integration of the SDGs at both the national and international levels, the identification and prevention of potential risks, and the orientation of national development strategies towards inclusive green growth and the development of digital technologies.

The conducted analysis allows us to state the relevance of researching issues of sustainable development and economic recovery of countries in the post-pandemic period. Considering the variability of the development of the current situation, assessing the impact of the pandemic requires constant revision of the forecast estimates and conclusions regarding the development trends of the countries. Highly appreciating the contribution of scientists and international institutions to the study of the impact of COVID-19 on the achievement of the SDGs and the development of approaches to strategies for the recovery of development, including national economies, in the post-pandemic period, it should be noted that the studies are mainly based on expert data, which contributes a subjectivity in the obtained results. It should also be noted that at the level of European countries, such studies mainly concern EU member states. The purpose of our research is to identify the impact of the COVID-19 pandemic on the economic development of countries to achieve sustainable development goals and evaluate progress trends in the post-pandemic recovery of the economies of Eastern Europe countries by analyzing quantitative data from official statistics. The object of the study is the economic development of Eastern European countries in the conditions of the COVID-19 pandemic. The subject of the study is models and methods of assessing the impact of the COVID-19 pandemic on the country's economic development.

Following the specified goal, the formulated object, and the subject of the research, the research objectives are the analysis of economic development indicators of Eastern European countries in the context of SDG8 and SDG9 in the period from 2017 to 2021, and the identification of the main trends of their change; comprehensive assessment of progress in the recovery of Eastern European countries economic development in the context of SDG8 and SDG9 in the period after 2021.

3. Research methodology

Sustainable development goals are interrelated, so the assessment of progress in achieving them must be comprehensive. This requires the processing of significant amounts of data; therefore, in our study, we will limit ourselves to the analysis of those indicators that are directly related to economic development in the context of the indicators of the goals of SDG8 and SDG9. For the research, we used the toolkit for analyzing the dynamics of indicators – to identify existing trends in their change; forecasting methods – for assessing the trends of changes in indicators for the following periods; integrated assessment technologies – to obtain a comprehensive assessment of the progress of economic development in the post-pandemic period; generalization – for interpreting the obtained results and formulating conclusions in the context of research objectives.

The information base of the research is publications on the research topic, data from a Metadata repository for SDG Indicators [22], a databank of the World Bank [23], the statistical portal of ILO [24], and results of the author's studies.

According to [25], statistical data for SDG8 after 2015 are available for only 60 percent of countries' indicators. For SDG9, this share of data is 70 percent. This makes it difficult to carry out a comprehensive analysis of progress in economic development, in particular, and in the context of the indicators defined in [1] for the goals of SDG8 and SDG9. Therefore, those indicators supported by the necessary statistics were selected for the study.

As objects for evaluating economic development trends, we will choose the countries of Eastern Europe: Bulgaria, Czechia, Hungary, Moldova, Poland, Romania, Slovak Republic, and Ukraine. Most of the countries are members of the EU. According to the World Bank, as of 2021, Ukraine had the status of a country with a Lower middle-income economy; Bulgaria and Moldova had level of Middle-income economies; the rest of the countries belong to the category of countries with High-income industrial economies [26]

We select the period from 2017 to 2021 for the research. The choice of such a period is due to several reasons:

(i) the period from 2017 to 2019 refers to the pre-pandemic period and was used to determine the direction of the impact of COVID-19 on the economic development of countries in 2020;

(ii) the following period is limited to 2021 since, for the vast majority of indicators, there is no data for 2022, which is provided in the section of country statistics by world institutions, in particular, the World Bank, the International Labor Organization, the United Nations Statistics Division.

The active phase of Russian aggression against Ukraine, which began in February 2020, caused new global challenges to the progress of economic development in Ukraine and other Eastern European countries. Hence, their consideration requires a separate study.

We use visual analysis of their values to identify trends in changing indicators. Assessing the predictive values of indicators we execute using the Holt-Winters method [27]. It belongs to the group of adaptive forecasting methods and can be successfully used for a series of dynamics in the absence of a clear trend in changing indicators.

To assess progress in the recovery of the economic development of the countries of Eastern Europe in the context of SDG8 and SDG9 in the period after 2021, we will use the comprehensive index method, which will allow us to comprehensively take into account the change in the values of all partial indicators and reduce them to one measure [9]. This simplifies the interpretation of the obtained result.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012127 doi:10.1088/1755-1315/1254/1/012127

4. Results and discussions

Let's consider the dynamics of indicators that determine the economic development of the countries selected for the study. We have chosen the following indicators: GDP annual growth (percent); Growth Rate of Per Capita GDP at constant 2015 prices in US Dollars (percent); Industry (including construction), value added (annual growth, percent); Exports of goods and services (annual growth, percent); Imports of goods and services (annual growth, percent); Unemployment rate, total (percent); Employment to population ratio, 15+, total (percent).

The first two indicators are among the determining factors in analyzing the country's economic development, as they accumulate all economic activity results. The third indicator characterizes the industry's contribution to economic development and is related to SDG9. The fourth and fifth indicators reflect the foreign economic ties of economic development. The last two are employment indicators, primarily associated with providing decent work as one of the sub-goals of SDG8. For ease of analysis, we will also include the estimated values of indicators for 2022 in the tables together with the initial data. This will simplify our analysis of the expected trend and simplify the calculations of the integral indicator.

The values of GDP change indicators are shown in table 1 and table 2.

The analysis of the presented values shows that in 2020 there was a significant drop in the GDP value, which was reflected in the negative values of the corresponding growth rates. In 2021, GDP growth resumed, but it should be taken into account that such a result was obtained in comparison with the previous year and does not reflect the real change in GDP. The highest growth was observed for Moldova and the Slovak Republic. In general, GDP growth was higher for countries with high-income industrial economies, except Moldova, which belongs to the

Ukraine	2.8	4.0	3.8	-3.1	4.3	3.2

group of countries with middle-income economies. According to the estimates of the values of the indicators for 2022, we note a decrease in the GDP growth rate, which is explained by the higher values of the indicators in 2021 compared to 2020.

The change in the values of the "indicator Industry (including construction), value added" is shown in table 3. Let's draw attention to the fact that for most countries, except Hungary, there was a downward trend in the values of the indicator from 2017 to 2020. in Hungary, such a decrease occurred only in 2020. As in the case of GDP, 2020 turned out to be the most critical year. The reduction or suspension of business activity of many production structures explains this. The year 2021 was characterized by the recovery of businesses in most countries, although the negative trend of the change in the indicator remained for Moldova. Estimated values of the indicator for 2022 also show a tendency to decrease values.

Let's consider the indicators reflecting the volume of foreign trade. This field of activity was also significantly limited due to quarantine restrictions. However, such restrictions gave significant impetus to the development of online trade. Values of indicators are shown in table 4 and table 5.

The analysis of the tables shows that the given indicators in the pre-pandemic period had a changing trend, but in 2020 they also significantly decreased. The most significant export decrease occurred in Bulgaria, the Czech Republic, Moldova, and Romania. For the import indicator, the most significant decrease occurred in the Czech Republic and the Slovak Republic. In 2021, there was a significant increase in the volume of export-import transactions, and the growth rates were the highest during the studied period for all countries except the Czech Republic and Ukraine. For Ukraine, in 2021, the negative trend of decreasing the value of the

Ukraine	9.5	8.8	8.2	9.1	8.9	9.1

export indicator continued, and the rate of decrease was the highest. The year 2022 showed a reduction in the growth rate of indicators, and for Ukraine, the negative trend for the import indicator continued, albeit on a smaller scale.

Analyzing the indicators of unemployment and employment (table 6 and table 7), the following conclusions can be drawn. Regarding unemployment, from 2017 to 2019, there was a gradual decrease in the indicator's value. In 2020, the unemployment rate increased in all countries except Poland and Moldova. In 2021, the trend of unemployment growth continued for all countries except Ukraine. However, the given indicators may not reflect the actual state of the labor market, as they are obtained based on estimates calculated by the ILO [24]. The calculated estimated values of the unemployment rate for 2022 showed that the unemployment rate might remain practically at the previous level. However, the recovery of business activity may be the reason for the decrease in the rate value.

Regarding the employment indicator, from 2017 to 2019, there was also a trend of increasing values for all Eastern European countries. In 2020, the indicator's value decreased for all countries except Romania, and this trend continued in 2021 for all countries except Hungary, Poland, Slovak Republic, and Ukraine. Estimated values for 2022 show an increase in the level of employment, which is consistent with the thesis of the recovery of business activity.

In general, evaluating the trends of indicators, we can conclude that the pandemic really had a negative impact on the economic development of countries, which was reflected in the reduction of their growth rates. The most negative phenomena appeared for the indicators of Moldova, Romania, and Ukraine, and the least – for Poland.

Let's conduct a comprehensive assessment of the level of economic development. For this purpose, we will construct a composite indicator named the comprehensive index of economic

Table 7. Employment to population ratio, 15+, total (percent).

Table 8. Comprehensive index of economic development.

Country	2017	2018	2019	2020	2021	2022
Bulgaria	0.51	0.48	0.53	0.23	0.64	0.58
Czechia	0.64	0.57	0.53	0.23	0.64	0.58
Hungary	0.59	0.59	0.60	0.26	0.68	0.62
Moldova	0.55	0.53	0.51	0.14	0.70	0.61
Poland	0.59	0.62	0.56	0.35	0.70	0.65
Romania	0.66	0.60	0.54	0.25	0.63	0.58
Slovak Republic	0.49	0.57	0.50	0.20	0.59	0.54
Ukraine	0.50	0.45	0.51	0.23	0.45	0.42

development. For the comparability of the results, the values for all countries for each partial indicator will be combined into one sample. We will use the rules given in [9] to normalize partial indicators. At the same time, we take into account that the unemployment rate is a disincentive. Convolution of partial indicators was carried out according to the rule of linear additive convolution. Since we do not have any a priori information about the importance of certain partial indicators, we will choose the same weighting coefficients for their convolution. The results are presented in table 8.

The analysis of the values of the comprehensive indicator allows us to state that in 2022, its lowest values for the entire studied period took place. The most significant drop occurred in Moldova, while the economy of Poland was the most stable. In 2021, an increase in the values of the comprehensive indicator was observed, and the highest values were for Moldova and Poland. The phenomenon of Moldova is explained by the significant growth of individual indicators, which in turn is determined by their low absolute values compared to other Eastern European countries. The assessment of the value of the generalized indicator of economic development for 2022 shows a slight decrease in values, which is consistent with the conclusions made during the analysis of the partial indicators that are components of this generalized indicator.

More accurate estimates of the economic development of the countries of Eastern Europe in 2022 could be obtained, taking into account either the actual values of the indicators, which are currently unavailable, or their expert assessments. Currently, such estimates are available only for GDP indicators.

5. Conclusions

Identifying economic development trends both for the country's economic system as a whole and at the level of its separate regions remains an important task. Such research acquires special significance in periods of global challenges, one of which was the COVID-19 pandemic. Deviation from the trajectory of achieving the stated goals was observed even in the pre-pandemic period, but the COVID-19 pandemic exacerbated the existing problems. It isn't easy to assess all the consequences since this process has not yet ended. In addition, the active phase of Russian aggression created new challenges for sustainable development. However, identifying trends in the change of target indicators in terms of individual SDGs, in particular SDG8 and SDG9, is an urgent task.

The study of the indicators' values from 2017 to 2019 showed that gradual progress in economic development was generally observed despite the lack of clear trends for individual indicators. This allows us to conclude on the gradual improvement and the achievement of the target indicators for SDG8 and SDG9.

The analysis showed that 2020 was the most critical year by all indicators, which led to a significant deviation from the planned trajectory of sustainable development. This finding is consistent with research results provided by other scientists and research institutions. In 2021, the situation began to improve, reflected in the indicator values' growth. Deviations occurred only in individual values for Ukraine and the Slovak Republic. Ukraine had a lower level of development according to the selected indicators, while Poland demonstrated the highest stability of its economy. At the same time, despite the limitations of statistical data, the obtained results showed that for many indicators, the rates of their decline in 2020 for Ukraine were lower than for other Eastern European EU member countries. Estimated values for 2022 showed a decrease in the growing trend of the indicators selected for analysis. This can be explained by the fact that the vast majority of indicators are relative and depend on the previous levels of the corresponding absolute indicators. To comprehensively take into account all indicators, we have built a generalized indicator of economic development. The analysis of its values confirmed the earlier conclusions regarding economic development trends in 2020 and 2022.

Study results can be considered when planning economic development strategies as auxiliary analytical information.

Abstract. The research objective is an analysis of the participation of the Black Sea Basin countries (Ukraine, Russia, Kazakhstan, Bulgaria and Romania) in world grain trade. We started this research before the start of Russia's military actions in Ukraine, and completed it during these actions, so we have a vision of the situation before and after start of war. Subject of research: stability of grain supplies (wheat, corn, barley) from the Black Sea region as a whole and from some of its countries. Results of the research: The research revealed the growing role of the Black Sea region in the pre-war period in the world grain market and identified its key leaders. The share of the Black Sea region in world trade in wheat increased to 34%, barley – to 40,6%, corn – to 25,3% in 2019/2020 marketing year. The calculated coefficients of variation confirmed the decrease in the scattering of grain exports in 2015-2020 vs. 2010-2015, which indicates an increase in stability and reliability of supply in this period. The situation changed radically after the Russian invasion of Ukrainian territories. The maritime logistics corridors of Ukraine that is the one of the key players in this region, were blocked and started working only five months later, but not at full capacity. All these events had its destructive consequences for world trade, in particular, the increase in world prices, disruption of the stability of grain supplies from the Black Sea region and the destruction of established logistics corridors, etc.

1. Introduction

The global problem of the modern world is the prospect of lack of food resources for the ever-growing population of the globe. International organizations (FAO, IFAD, UNICEF, etc.) warn that before the COVID-19 pandemic, 690 million people didn't receive enough food, i.e., 8,9% of the world's population, and the continuation of this trend could lead to an increase in malnutrition up to 840 million tons in 2030 [1]. Thus, the problem of food shortages will only deepen in the near future.

A logical question arises, which countries will be able to provide the growing needs of the world in food? Therefore, the research is devoted to the study of the role of the Black Sea region in world grain trade.

This article is structured as follows. The first section focuses on the relevance of this topic. The second and third sections present a review of the literature and methodological approaches to solving the tasks. The fourth section demonstrates the results of researches, namely analyzes the place and role of the Black Sea region in world grain trade (wheat, corn, barley), assesses the stability of grain supplies from this region as a whole and its individual countries, individual aspects of the impact of the war on world prices were analyzed, a SWOT analysis of Ukraine's competitive positions on the world grain market was carried out. The fifth section summarizes this research and identifies areas for further research.

2. Literature review

With the strengthening of the role of the Black Sea region in world trade in the last 10 years, it was published scientific papers which illuminate the behavior and pricing policy of exporting countries in this region. However, the export policy of individual countries (Ukraine, Russia, etc.) is illuminated more often and its cumulative influence on world trade is analyzed less often.

In particular, Götz et al [2] analyze the negative influence of export restrictions in 2007-2008 on the domestic grain market of exporting countries of Ukraine and Russia and its integration into the world market. However, many changes have taken place since then, with some countries abandoning 'manual' methods of regulation and others abandoning them altogether. In the long term, the regulation of grain exports should be reduced mainly to a system of economic measures, but at the moment, government participation is necessary as a driver in the development of production and logistics infrastructure [3].

One of the conclusions of Svanidze and Götz [4] is the following: unforeseen policy interventions for grain markets further increase the level of grain market uncertainty and, hence, costs of grain trade in Russia. At the same time, the authors consider the increase of spatial market efficiency of grain markets in Russia as the driver of increasing the country's export potential. Together, the conducted study of the state of Russian transport capabilities has revealed the lack of development of the latter, especially railway transport and grain transshipment capabilities in seaports, which prevents an increase in the volume of grain exports to strategic foreign partners [5].

Ukraine doesn't apply strict restrictions and prohibitions, there is a fairly democratic Memorandum of Understanding between the relevant ministry and economic entities – grain exporters and there has never been a 'manual' restriction of exports. One of the main problems in the export of Ukrainian grain is a high share of logistics costs, which reaches 35% of the final cost of production [6].

Some scientists believe that over the last two decades, the Black Sea region developed to be a key global exporting region for corn and wheat [7]. We fully agree with Heigermoser et al, who note that many market participants grapple with insufficient knowledge of factors that drive Black Sea spot prices, while effective futures markets that could facilitate price discovery and risk management are still missing. That's why these factors need more profound study.

Among recent studies, the scientific work of Gafarova et al [8], which examines the price behavior of the main exporters of wheat from the Black Sea region (Ukraine, Russia and Kazakhstan), identifies importing countries in which price discrimination is applied and countries where perfect competition does not allow it. In Goychuk et al [9] were performed tests of market price co-integration (Johansen maximum likelihood test and residual-based tests) as well as threshold error correction techniques were performed for this purpose. The results suggest that Russian wheat prices were co-integrated with EU and U.S. Ukrainian wheat prices were found to be co-integrated with French wheat prices only.

The countries of the Black Sea region have not escaped illicit financial Flows in export operations with agricultural products. The unstable state of the economy of these countries has led to significant financial losses in grain exports [10]. The authors' main contributions are discovered asymmetry of mirror data such as price, trade value and weight of Ukrainian grain.

China has become an increasingly important actor in the Black Sea Region (BSR), and this looks set to continue in the future [11]. According to the author, potential Ukrainian economic growth suggests that Kyiv has the potential to be a key driver in increasing maritime trade and future investment by China in the BSR. In fact, this is exactly what happened before the war

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012128 doi:10.1088/1755-1315/1254/1/012128

in Ukraine. After February 24, 2022, significant transformations took place with the stability of the supply of grain and other agro-food products from this region.

There is a great deal of uncertainty about the impact of the war on food security is recognized by most experts and scientists, including Berkhout et al [12], Glauben et al [13], as it is not even possible to foresee the end date of the war.

However, it is clear that food security in certain regions of the world today is a significant threat [14, 15]. The war in Ukraine is likely to have the greatest impact on regions that depend on imported wheat, particularly from Russia and Ukraine, as a key part of their diets. Even countries that are less dependent on wheat imports from the Black Sea region could face food security issues, as designated by Glauben et al [13].

FAO warns: ‘In the short term, the alternatives to falling exports from Ukraine and Russia seem limited. For example, according to the FAO, wheat and maize harvests in Canada and the US have been disappointing, Argentina is applying export restrictions to combat domestic inflation, and Australia can no longer deliver owing to logistical bottlenecks’ [14].

3. Data and methodology

Time series, arithmetic averages, the method of expert assessments, extrapolations, etc. were used to assess the influence of the Black Sea basin countries on world trade.

The methodological approach involved the calculation of scattering indicators in sales of goods for the selected interval relative to the arithmetic mean sales of this good for the selected period of time to analyze the stability of export deliveries.

$$\sigma = \sqrt{\frac{\sum_{i=1}^{n}(x_i - \tilde{x})^2}{n}}$$

σ – the standard deviation
x_i – the number of sales of good per interval
n – number of intervals
$\tilde{x}$ – arithmetic mean

The arithmetic mean is determined by the formula:

$$\tilde{x} = \frac{1}{n}\sum_{i=1}^{n} x_i = \frac{1}{n}(x_1 + \ldots + x_n)$$

We needed the standard deviation to calculate the coefficients of variation, which more accurately characterize the scattering and reflect the stability of export supplies in the selected time interval.

$$V = \frac{\sigma}{\tilde{x}}$$

V – the coefficients of variation
σ – the standard deviation
$\tilde{x}$ – arithmetic mean

For data extrapolation, the exponential smoothing method was used, which is the most effective when developing medium-term forecasts.

$$U_{t+1} = \alpha \times y_t + (1 - \alpha) \times U_t$$

U_{t+1} – predicted indicator
t – period preceding the forecast
$t + 1$ – forecast period
α – smoothing parameter

y_t – actual indicators for the period preceding the forecast period
U_t – exponentially weighted average for the preceding period predictive

The Delphi method is used to develop the SWOT matrix. The Delphi method relies on experts who are knowledgeable about a certain topic so they can forecast the outcome of future scenarios, predict the likelihood of an event, or reach consensus about a particular topic. For our research, expert opinion was obtained from farmers who are members of the PU 'Agrarian Union of Ukraine'.

The information database of our researches was the data of UN Comtrade [16], The Foreign Agricultural Service (FAS) of United States Department of Agriculture [17], and AgriSupp of the consulting agency UkrAgroConsult [18].

4. Research findings and discussion

4.1. Black Sea region in world grain trade: before war

Research has shown that the key players in world grain trade from the Black Sea region were such countries: Ukraine, Russia, Kazakhstan, Romania and Bulgaria. All these countries (except Kazakhstan) have access to international waterways, its own ports and port elevators, the number of which has been increasing in recent years. Kazakhstan is located within the continent and away from sea routes, so the logistics of this country to the Black Sea and Azov ports runs through the territory of Russia [19].

Over the ten years (2010–2020), grain sales by the above-mentioned countries have increased significantly: wheat – 3,7 times, corn – 6 times, barley – 1,7 times (figure 1).

A growing trend is still evident despite of fluctuations in export volumes. Manufacturers and

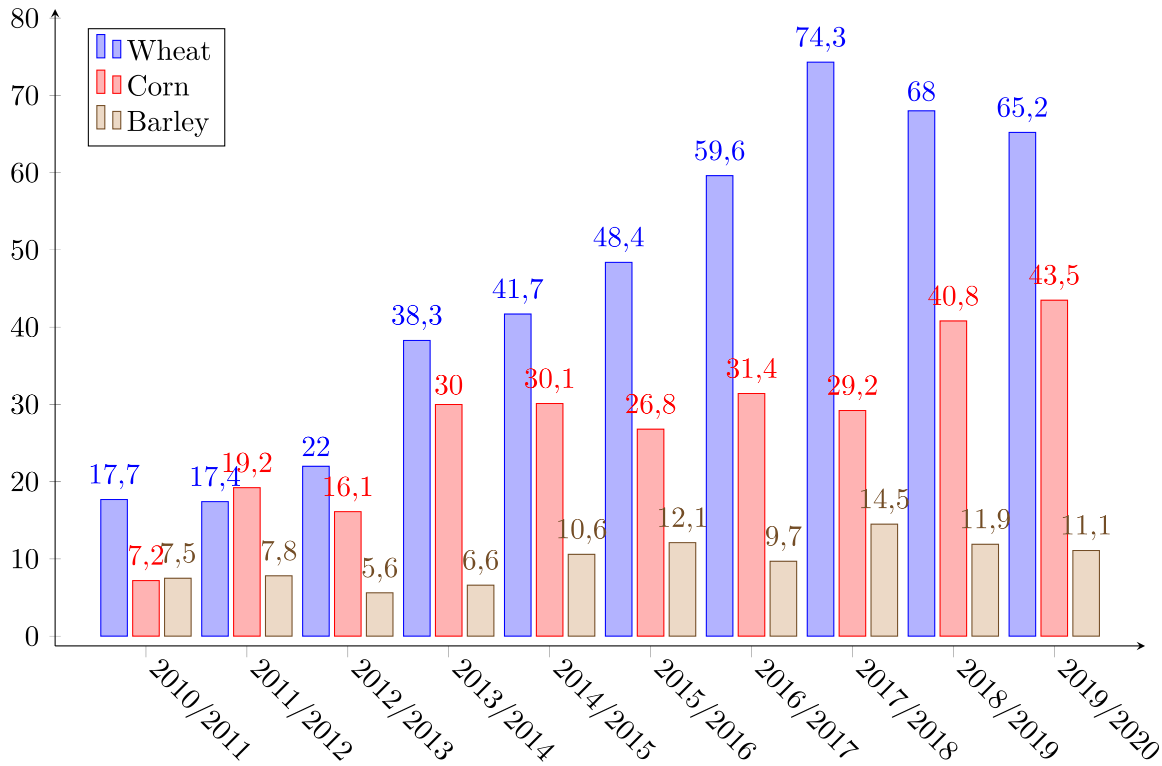

Figure 1. Dynamics of wheat, corn and barley exports by the Black Sea basin countries in the 2010/2011 – 2019/2020 marketing years, million tons.

exporters received more income from the sale of products for export. Governments have also realized the undeniable benefits of receiving dollar-denominated export earnings, so it is now prudent to impose any export restrictions and the situation described by Götz et al [2] is no longer repeated.

Calculations based on AgriSupp [18] and FAS [17] data show that the share of the Black Sea region in world wheat trade increased from 13,2% in the 2010/2011 marketing year (hereinafter – MY) to 34% in 2019/2020 MY, corn – from 7,9% to 25,3%. The share of the Black Sea region in world barley exports, on the contrary, decreased from 47% in 2010/2011 MY to 40% in 2019/2020 MY.

The countries of the Black Sea basin competed with each other, so there are leaders in the export of certain crops. Russia was the leader in wheat exports with a share of 52,1% of the total sales of wheat from the Black Sea region in 2015/2020 – 2019/2020 MY (figure 2).

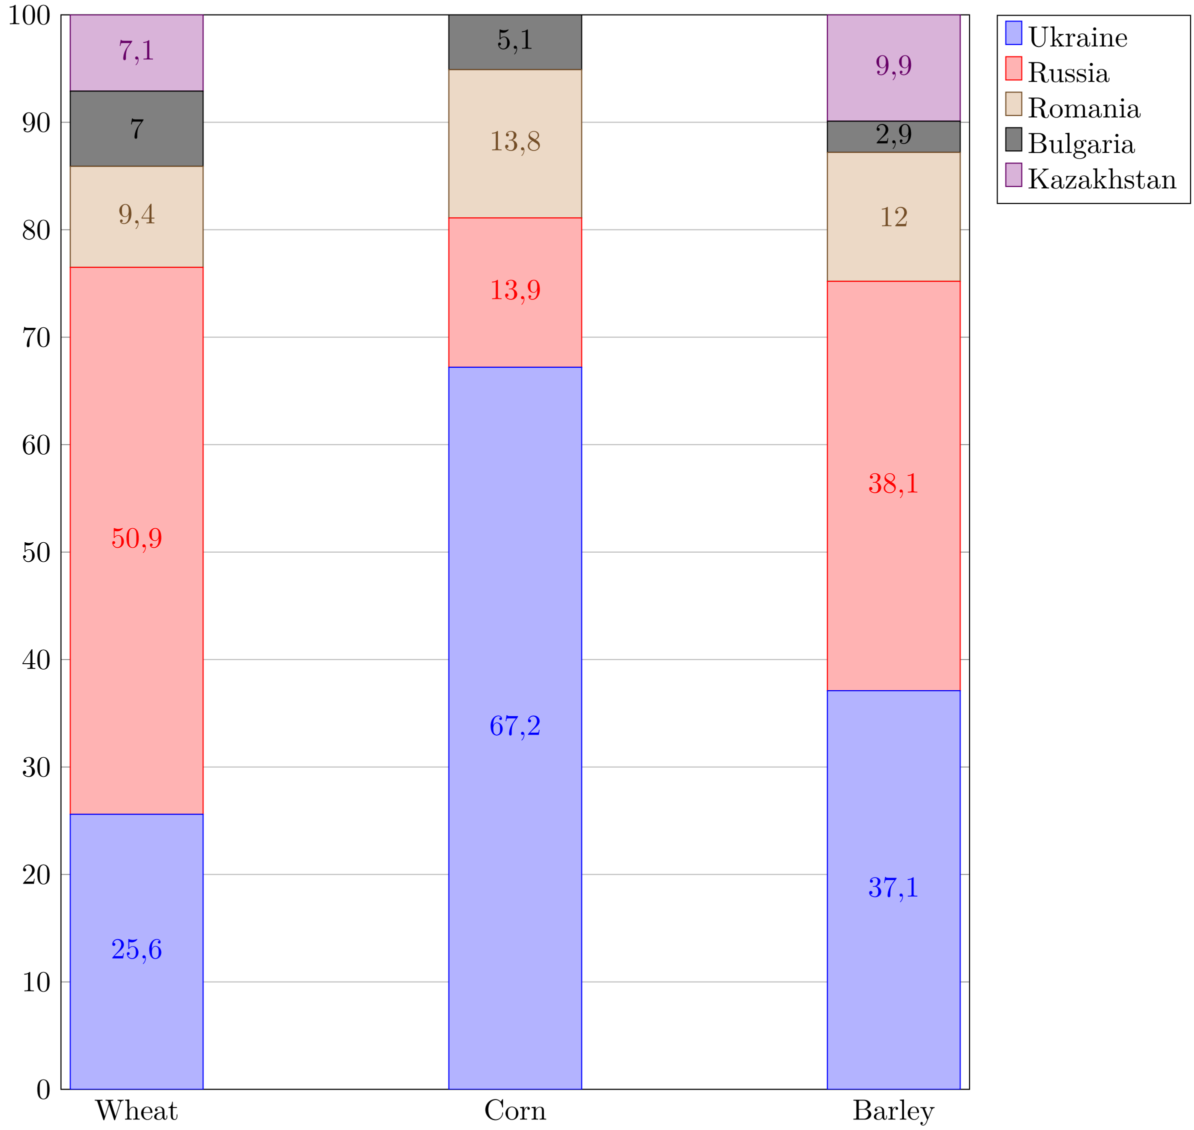

Figure 2. The share of individual countries in the Black Sea region in exports of wheat, corn and barley, on average over the past 5 years (2015/2016 – 2019/2020 MY), %.

Ukraine was the undisputed leader in corn exports, with a share of 67,2%. The share of barley sales in Ukraine and Russia is approximately at the same level – 37% and 38% of the total export of barley from the Black Sea region, respectively.

The issue of stability of supplies from this region is relevant with the strengthening of the role of grain-exporting countries from the Black Sea basin. Naturally, deviations in the time series were quite significant in the period of 10 years (2011–2020) (table 1), because during this period there was a significant increase in supplies of wheat and corn from the Black Sea region to the world market, as well as fluctuations in barley supplies. However, it is important to understand whether the fluctuations of export indicators in recent years are equalizing. Is the Black Sea region able to ensure the achieved high rates of exports? How reliable is the region as a key supplier of grain resources to the world market?

Table 1. Coefficients of variation of grain exports from the Black Sea region and individual leading countries, 2011-2020, %.

Country	Wheat			Corn			Barley

Total	44,8	38,1	13,9	37,8	42,5	19,2	27,4	22,0	13,2
Countries are the leaders in the export of grain in the world									
USA	15,0	14,9	10,3	24,4	29,0	11,1			
EU	25,1	27,9	20,8				28,2	36,8	13,0
Canada	12,5	15,1	6,7				28,2	14,1	26,2
Brazil				35,2	30,1	23,1			
Argentina				34,5	19,6	24,7			
Australia	28,9	14,2	35,7				27,3	15,2	29,7

It should be noted that, the Black Sea countries tried to maintain the image of reliable suppliers of grain on the world market in 2011-2020, learning some lessons of failed ‘manual’ management, which traditionally ended with losses for business and the state budget.

We calculated the coefficients of variation with a breakdown of the time series at intervals of 5 years. Russia showed the largest fluctuations in the export of wheat, corn and barley – 62-69% in the first five-year period (2011-2015), (table 1, figure 3). Grain supplies from other countries of the Black Sea basin are also not stable: the variability of indicators from year to year is significant, on average 30-50%.

The scattering of indicators decreases significantly – by 1,7-2,7 times in the second five-year plan (2016-2020). The highest level of variation in grain exports from the Black Sea region in 2016-2020 remains for corn – 19.2% (table 1, figure 3). The highest deviations in the supply of corn to the world market are shown by Bulgaria – 38,1% and Romania – 33,1%, while Ukraine and Russia have a variation rate of 24,5-24,8%, that shows more stable supplies from these countries.

The rate of variation for wheat from the Black Sea region is quite moderate – an average of 13,9%, with slightly higher rates of variation in Russia, Ukraine and Kazakhstan – 16,0-16,9%.

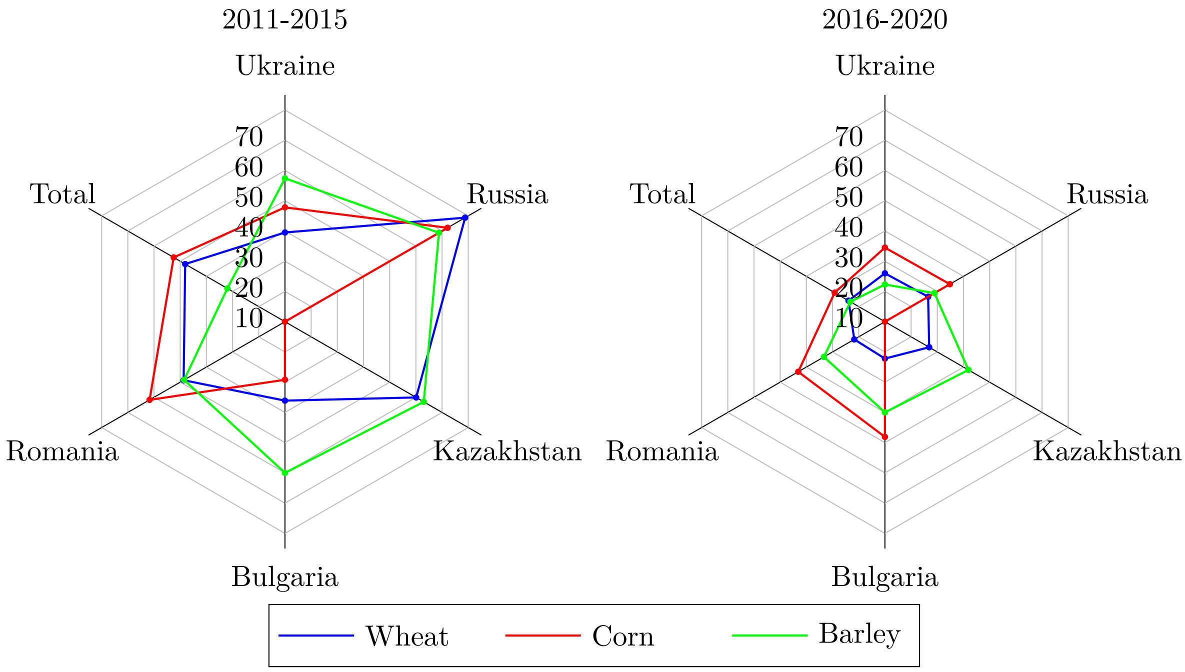

Figure 3. Coefficients of variation of export supplies of grain from the countries of the Black Sea region, 2011-2015, 2016-2020, %.

Kazakhstan and Bulgaria stand out for barley (30,0-31,9%), while Ukraine and Russia had a moderate variation (12,3-18,9%).

The coefficients of variation for the countries that are key exporters of the respective type of grain (wheat, corn, barley) were calculated for comparison. It turned out that the most stable suppliers of wheat to the world market were Canada and USA in 2016-2020, its coefficients of variation are in the range of 6,7-10,2% (table 1). Stable supply of corn is provided by the USA with a coefficient of variation of 11,1%, while Brazil and Argentina have the same variation of export indicators as Ukraine and Russia (23-25%). Ukraine shows the lowest scattering of export indicators for barley – 11,1% and the EU 13,0%, other countries have a significant variation of indicators (> 20%).

The influence on export supplies of various factors should be investigated in more detail to increase the stability of grain supplies from the Black Sea region to world markets, so as gross duties, transitional grain balances, exchange rate fluctuations, export restrictions, imperfect logistics, etc. These issues will be the subject of our further researches in the future.

Thus, the calculations allow us to state that the export activity of the countries of the Black Sea region gained more and more efficiency and stability in the studied period (2011-2020), which indicates the constant development of international relations between the countries that are suppliers and buyers of grain in the Black Sea region.

According to the long-term forecast of the International Grains Council (IGC), world grain trade will grow by 1,3% annually over the next few years. This expansion will be due to increased demand for grain in Asia and Africa because of 1) population growth and increasing popularity of grain and flour products 2) increasing demand for grain crops for feed purposes. Whether these forecasts will come true, taking into account the significant destruction of logistics chains in the Black Sea region, is an open question.

4.2. The impact of the war in Ukraine on trade and world prices
Ukraine held a leading position not only among exporters of the Black Sea region, but also among world exporters before the beginning of the war. Even in the 2021/2022 marketing year, it still managed to take fifth place among wheat exporting countries, third place among barley exporting countries and fourth place among corn exporting countries. The majority of Ukrainian products were exported by sea. The country had almost 3,000 kilometers of sea coast with 18 active ports, including 5 in the occupied Crimea. About 90% of Ukraine's grain export volume passed through sea corridors.

The invasion of Russian troops on the territory of Ukraine led to significant destruction of infrastructure facilities, including logistics chains. The presence of Russian troops in the Black Sea ports of Ukraine paralyzed the export of Ukrainian grain, oil, meal, etc. for five months. The established connections, which were built up over the years, were destroyed, and only starting from August 2022, the so-called 'grain corridor' became to operate that was only partially able to unload grain-filled elevators in Ukraine.

Immediately after the start of Russia's armed attack on Ukraine, agricultural markets around the world were shocked. Commodity prices flew up. In a situation of uncertainty, the demand for products increased, because market participants did not understand what could be expected in the near future. The volatility of wheat prices was higher than for other crops, because it is a food crop that is consumed by the population of the whole world. Futures for American wheat on the CME jumped by 60% compared to the pre-war period (figure 4). Futures prices for US corn also rose, but to a lesser extent – there are by 35%.

We cannot agree with the opinion of the authors Glauben et al [13]: "Currently there is no reason to panic buy or increase export controls on world grain markets in the coming marketing year, as markets appear to be calming".

In November 2022, wheat prices were 32% higher compared to the same period last year,

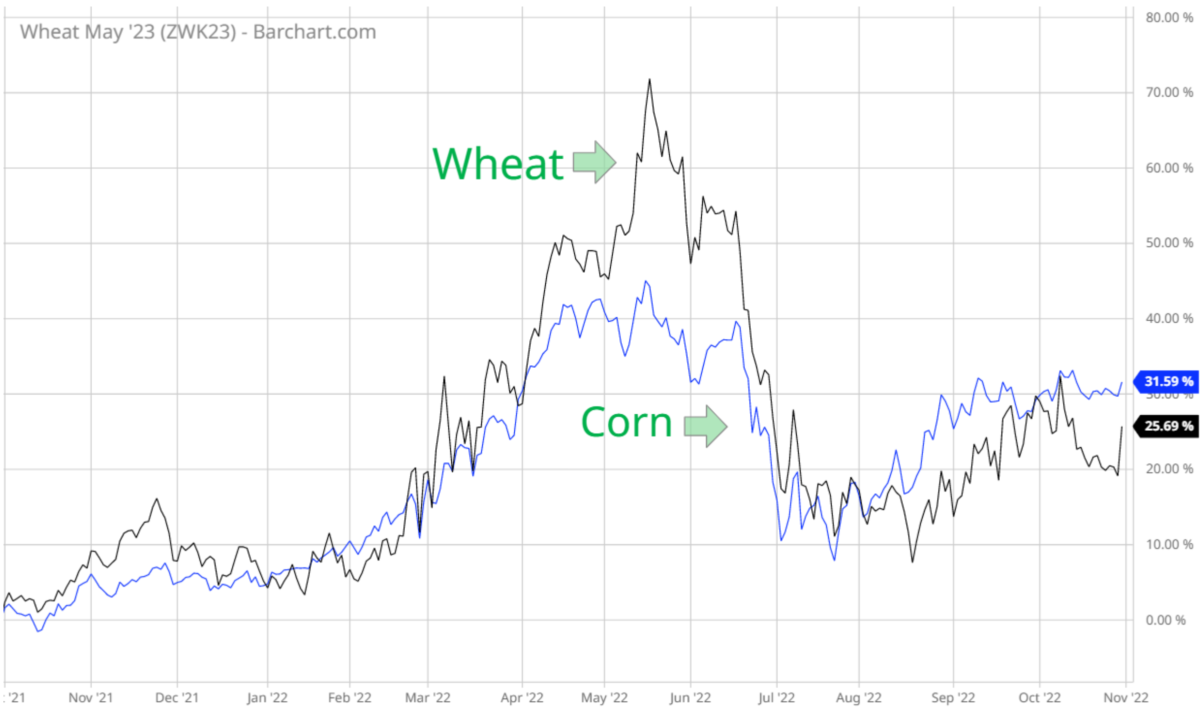

Figure 4. Chicago Board of Trade Wheat and Corn Price Growth Rates, November 2021 – November 2022.

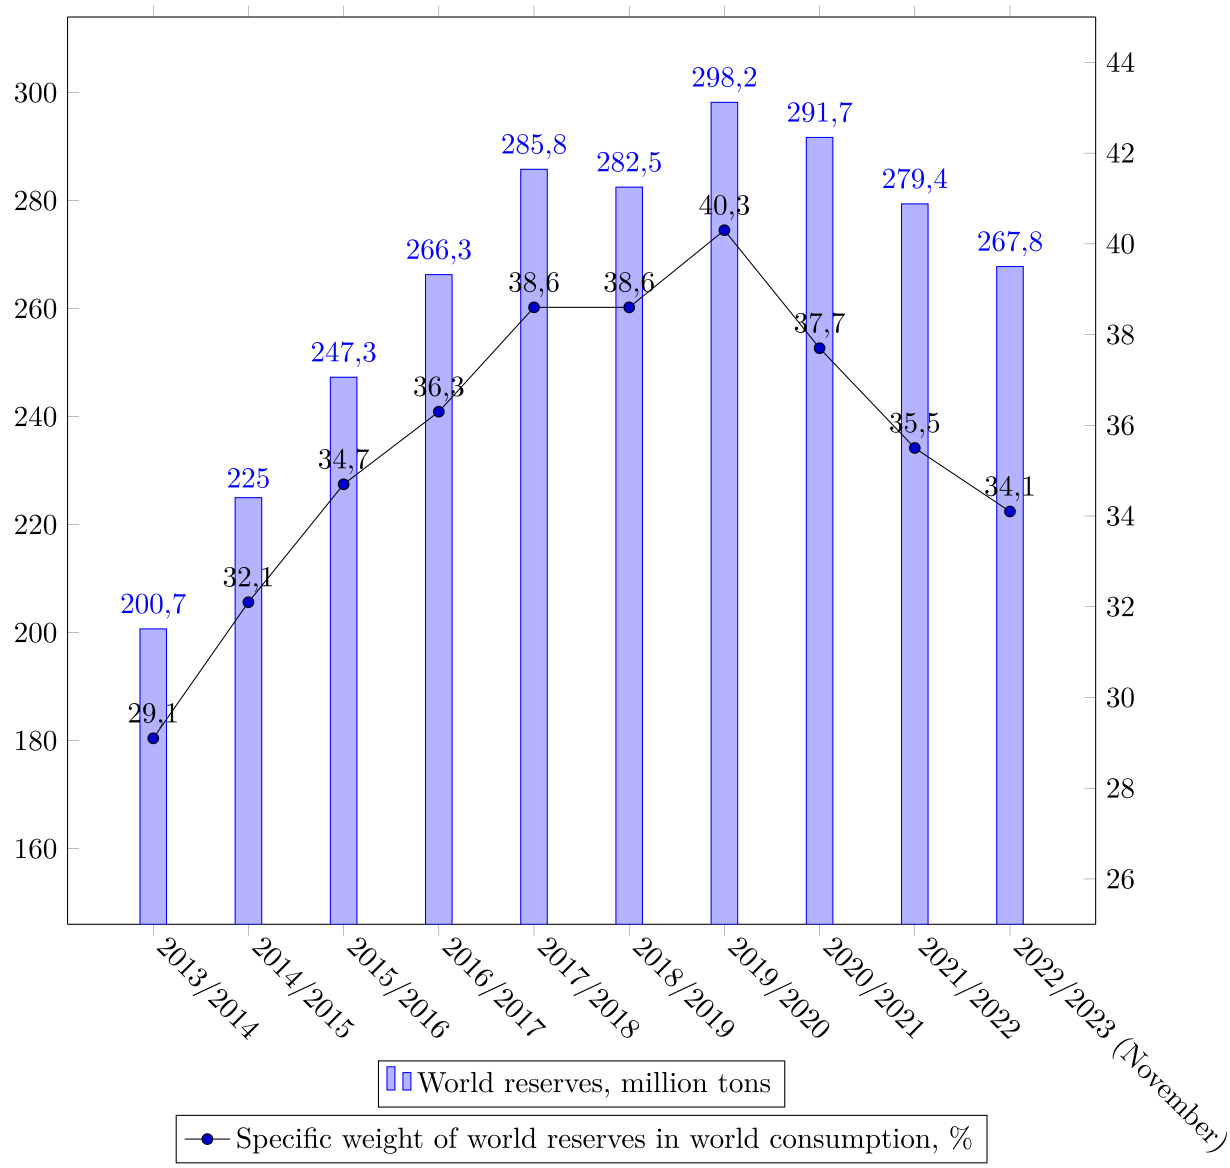

Figure 5. Specific weight of world reserves in world consumption in 2013/2014 – 2022/2023, %.

corn prices were also 26% higher. The world's temporary stocks of wheat are decreasing. Thus, as of November 2022, the indicator of the ratio of temporary stocks of wheat to its consumption calculated by us was 34.1% in the 2022/2023 marketing year (figure 5). Although this is not a critical level, it is the lowest level in the last 8 years [20]. A decrease in global wheat stocks will push prices higher in the future.

The inverse correlation between the level of prices and the level of product reserves was proved as early as the 17th century by the English economist Gregory King, who, using the example of the corn market, calculated the proportions of the correlations: the fall in the harvest and the corresponding increase in prices. In economic science, such a cause-and-effect connection was called the 'King effect' [21]. The reduction of reserves in the current marketing year will lead to another increase in exchange quotations for grain crops [22].

In 2022, Ukraine lost 30% of its wheat crop (−8 million tons), and 17% of its barley crop

(−1,1 million tons). In the fall of 2022, it was possible to sow only 61% of the wheat and 69% of the barley areas. That is, the capacity of the Ukrainian agricultural sector has significantly decreased. It is expected that 42% less Ukrainian wheat will be exported in the 2022/2023 marketing year than in the 2021/2022 marketing year [20]. The loss of grain export volumes from Ukraine will increase world prices in the future. This increase in prices will especially hurt poor countries, which are geographically and economically profitable to buy Ukrainian grain.

Consider the competitiveness of Ukraine in the world grain market under the conditions of Russia's military aggression. For this purpose, a SWOT matrix has been developed, which highlights Ukraine's competitive position on the world grain market (table 2).

Table 2. SWOT analysis of competitive position of Ukraine on the world grain market.

Strengths	**Weaknesses**
• Natural soil fertility, grain traditions • Geographical location, proximity of individual markets • Significant excess of production capacity over domestic needs • Competitive grain prices compared to the prices of other exporting countries • Cheap labor	• Insufficient use of new production technologies, modern equipment, etc. • Unstable legal and regulatory framework, lack of state support for grain producers and exports • Lack of opportunities for small and medium-sized businesses to hedge price risks on the stock exchange • "Bottlenecks" in the logistics of grain cargo • Insufficient quantity of grain of export quality
Opportunities	**Threats**
• Existing potential for growth of grain yields and, accordingly, increase of production (exports) • Interest of China, Africa, the Middle East and other countries in Ukrainian grain and opportunities to expand exports • Expansion of the Export Credit Agency, which has been operating de facto since 2021 • Forceful support of international organizations and some countries in the organization of grain supplies to the world market • Development of alternative logistics routes – transshipment of grain through ports or transportation by rail and road through the western borders	• Military and political instability due to Russia's military actions against Ukraine • The critical environmental situation in the war zone and other regions subject to shelling and bombing. In the post-war period, it will take years to restore disturbed ecosystems, in particular to restore soil fertility. • The activity of the operation of logistics routes in the Black Sea depends on international agreements (it is about the operation of the "grain corridor") • Continuation of the war may lead to further reduction of grain production in Ukraine • Global climate change, which is reducing (moving to the North) the area of favorable agriculture

The SWOT analysis shows that Ukraine has enough strengths and opportunities to expand grain supplies for export. All these opportunities will be realized under the conditions of the most outstanding end to the war and the restoration of normal business activities in the country.

Russia's aggression against Ukraine also threatens global food security [23]. The problem of hunger in the world and the tendency to increase the population on the planet is the reason that should motivate international organizations and individual countries to help Ukraine in restoring its vitality and restoring the stability of export grain supplies to the world market and, accordingly, the sustainability of the development of the Black Sea region.

5. Conclusions and outlook

So, research has shown an increase in the share of the Black Sea region in the supply of grain to the world market before Russia's military invasion of Ukraine. Thus, the countries of the Black Sea basin have provided a third of world wheat exports, a quarter of world exports of corn and 40% of barley on average in 2016-2020. The leaders of this region were Ukraine and Russia. With less experience than traditional players in the international market, the Black Sea countries have shown a fairly steady development of grain export trade in recent years, as evidenced by our calculated coefficients of variation. Thus, comparing the uniformity of grain supply to the world market in 2016-2020, we found that the Black Sea basin provided a higher level of stability of wheat exports than the EU and Australia and the stability of corn supplies from this region at the level of Argentina and Brazil. The most stable suppliers of corn to the world market were the United States, wheat – Canada and the United States, barley – Ukraine. The indicators which were calculated by us confirm the increasing efficiency and sustainability of the development of the Black Sea region in the pre-war period. However, the war started by Russia, destroys the established economic relations between the countries, blocks the arrival of crops from Ukraine, while some countries are in great need of these products.

Because of the complete or partial blockade of Ukrainian ports, the world market did not receive a significant part of the products, which had influence on world prices. With the beginning of the armed aggression, stock exchange quotations for wheat and corn jumped by 60% and 35%, but even after 8 months from the start of the war, they still exceed last year's level, by 32% and 26%, respectively.

Regarding the prospects for the development of export trade from Ukraine: the results of the SWOT analysis confirm the sufficient competitiveness of country. However, a significant number of threats are also present. The best solution to this issue and the elimination of most "threats" is a complete cessation of hostilities and the withdrawal of troops from Ukrainian territories and waters. The restoration of full-fledged business activity of Ukraine, as one of the key players in the world grain market, will allow to restore the sustainable development of world trade and global food security.

Abstract. One of the main domestic and foreign policy principles of Ukraine is the preservation of the environment and its components, which is vital for the human existence, his current and future generations. It was found that the amount of land resources available at our disposal is limited, therefore it requires sustainable management. This calls for recognition of raising awareness importance of the rate at which humans are depleting and destroying land resources. This formed a new paradigm about the role and importance of land management and land use. The purpose of the study is to identify the factors that have the greatest impact on the spread of soil degradation and pollution, and to identify priority environmental measures in the land management system, specifically offers for land conservation, reduced land areas with the use of pesticides and agrochemicals, which would improve the state of agro and ecosystems, would create conditions for the restoration of biodiversity in the agro sphere, would contribute to the prevention of soil degradation and contamination by chemical substances. Implementation of the provided measures is aimed at improving the quality of the natural environment and human living conditions. The indicators dependence of agricultural land use and production intensification factors was revealed through economic and mathematical modeling.

1. Introduction

Land resources are the main component of Ukraine's natural resource potential. Therefore, the concentration of large tracts of land in different types of landowners and land users can become a factor that will cause changes in the nature of use in the country and its regions, affect their social and economic development and the environment condition. The nature of land resources usage affects almost all spheres of social and economic regional development of different levels, in particular territorial communities, the condition and quality of agricultural lands, determines the nature of anthropogenic impact on the environment. By endorsing the Sustainable Development Goals, the global community, including Ukraine, reaffirmed its commitment to sustainable and inclusive economic growth, social inclusion, environmental protection and the development of peaceful, just and inclusive societies through a new global partnership. The result of this work was the national SDG (Sustainable Development Goals) system of the Central Development System, which consists of national development tasks with corresponding indicators [1]. All these goals can still be achieved. As the UN Secretary-General's report states: "The choices we make or don't make today can lead to further destruction or breakthroughs to a greener, better and safer future". [2].

Implementation of sustainable development principles requires the formation of development directions strategic vision based on a new philosophy of thinking and new aspects of political activity. The transition to the principles of sustainable development will require comprehensive structural changes in the management of land resources. That is, the management of land resources is key to achieving the goals of sustainable development, ensuring food security, jobs and income in the long term. In this paradigm, the concept of sustainable management of land resources appeared, which means the use of land resources, including soil, water, animals and plants, for the production of goods to meet changing human needs while simultaneously ensuring the long-term productive potential of these resources and preserving their ecological functions. Increasing investments in sustainable management of land resources can significantly contribute to achieving the Sustainable Development Goals Goal 1 (overcoming poverty in all its manifestations), Goal 2 (overcoming hunger, achieving food security, promoting the balanced development of agriculture), Goal 6 (ensuring accessibility and balanced use water resources), Goal 13 (fighting climate change and its consequences) and Goal 15 (ensuring the protection and restoration of terrestrial ecosystems and promoting their balanced use; implementing balanced forest management; fighting desertification; stopping the process of land degradation and starting their restoration and halting the loss of biodiversity). Thus, ensuring the continued integration of sustainable land management into all state and local programs is a safe investment that ensures better sustainability for all, not only in the country, but in a land-degradation-neutral world.

Effective management of land resources is one of the most important conditions for the development of the state and territorial communities in Ukraine. Over the past decades, almost all issues important for the sustainable development of land relations have been regulated at the legislative level: maintaining a land cadastre, registering rights to real estate, carrying out land management and land valuation [3].

2. Literature review

Problematic aspects of ecological character in the system of land resources management in the sustainable development context, features of rational nature management in the field of agriculture are studied by number of authors [4–10].

Koshkalda et al [5] considered aspects regarding by the need to solve the research and technical problem of providing information support for the assessment of the state of land resource mapping and their management using modern geoinformation technologies, the development and optimization of interconnected algorithms and programs. Used an integrated land cover classification method targeting low-accuracy regions on large-scale maps. Low-accuracy areas can be detected by estimating the accuracy of the data with a moderate resolution spectroradiometer. This method optimizes the entire classification process, including image selection, as well as the classification algorithm and features. An optimal algorithm of classification and features for various regions with low accuracy is proposed, which can be used in the process of regulation and management of land relations.

Tretiak et al [8] claims that today in Ukraine, land (in the form of land use) is not considered at the government level as a terrestrial biologically productive system, which includes soil, vegetation, other biomass, as well as ecological and hydrological processes that occur within this system. According to this the state and quality of land use is not associated with a complex of security threats to human life.

Dombrovska et al [11] considered Remote Earth Sensing, which makes it possible to obtain data on dangerous, hard-to-reach objects and places, and also allows for operational monitoring of large areas of the terrain. The use of modern methods of obtaining data from remote sensing of

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012129 doi:10.1088/1755-1315/1254/1/012129

the earth has significantly expanded the horizons of using such data, their analysis, interpretation and modelling of a wide range of natural processes and human activities. Today, the possibilities of obtaining remote sensing data of the Earth by modern methods, both space and UAV, channel combinations, image visualization indices in combination with geoinformation technologies solve some scientific, practical and economic problems that are already used in industry cadastres.

One of the ecological economy founders, Herman Daly, claims that the human-made economy is “embedded” in the ecological global system. Quality indicators of the environment are determined by the quality of atmospheric air, the quality of agricultural land, the quality of surface water and the quality of biotic resources [12].

Scientific views on the sustainable management system of land resources and soil fertility are actively covered in foreign publications.

Lecarte and Negre [13] provides an overview of the effect of the decline in the number of farms across the EU on the European farming model (EFM), which is built around the notion of multifunctionality and provision of public goods by agriculture. It concludes that in order to foster sustainability and resilience, the EFM and policy tools must embrace the emerging diversity of farmer profiles and stimulate socially desirable adaptive strategies that preserve the multifunctionality of farming.

Rosário et al [14] presents a systematic literature review focused on the use of sociopsychological determinants to understand the adoption of sustainable agriculture innovations, combining conventional bibliometric analysis with the method of vote-count. This method enabled an evaluation of the ability of the determinants considered by the models, as well as respective sociopsychological constructs, to explain the innovation adoption. Our results show a significant growth in the research employing theory and models built on sociopsychological factors to understand the decision-making processes undertaken by farmers in the context of the adoption of sustainable agriculture innovations. The development of statistical models and techniques, such as the structural equation model (SEM), has facilitated the inclusion of a growing set of sociopsychological variables. However, our review highlights that the selection of the sociopsychological constructs used by research to explain farmers’ adoption of sustainability innovations relies mainly on constructs defined for other decisional contexts, such as the adoption of innovations by firms in other sectors.

Anderson et al [15] develops a framework for advancing agroecology in transformations towards more just and sustainable food systems focusing on power, politics and governance. It explores the potential of agroecology as a sustainable and socially just alternative to today’s dominant food regime.

The analysis by Migliorini et al [16] has been partly based on results of a dedicated literature search and partly on grey literature and expert knowledge. After an overview of the history of agroecology, targeted research and education, collective action(political and social), and some agroecological practices in the three countries are presented. These countries share a rather similar use of the term “agroecology”, but they differ regarding(i) the existence/extent of strong civil and social movements; (ii) the type of study/educational programmes, and the relative importance of different scientific disciplines and their evolution; (iii) the development of political support and legal frameworks; and (iv) the elaboration of concepts to rediscover traditional practices and apply new ones, often taken from the organic agriculture sector. Agroecology is an emerging concept for the Mediterranean agricultural sector, with huge potential due to the peculiar socio-cultural, bio-physical, and political-economic features of the region. To boost agroecology in Mediterranean Europe, better networking and engagement of different actors within a coherent institutional framework supporting the transition is strongly needed.

3. Results and discussion

Nowadays, Ukraine's land resources, especially agricultural lands, are subject to significant transformation as a result of human activity. The main factor of transformation is the plowing of soils and their intensive use in agriculture. Lands with fertile soils and geomorphological conditions favorable for agriculture underwent the greatest transformations.

The increase in agricultural development of land resources, which is accompanied by an increase in plowing of land, indicates an increase in the anthropogenic load on a unit of land area, geological imbalance, and the development of soil erosion (figure 1).

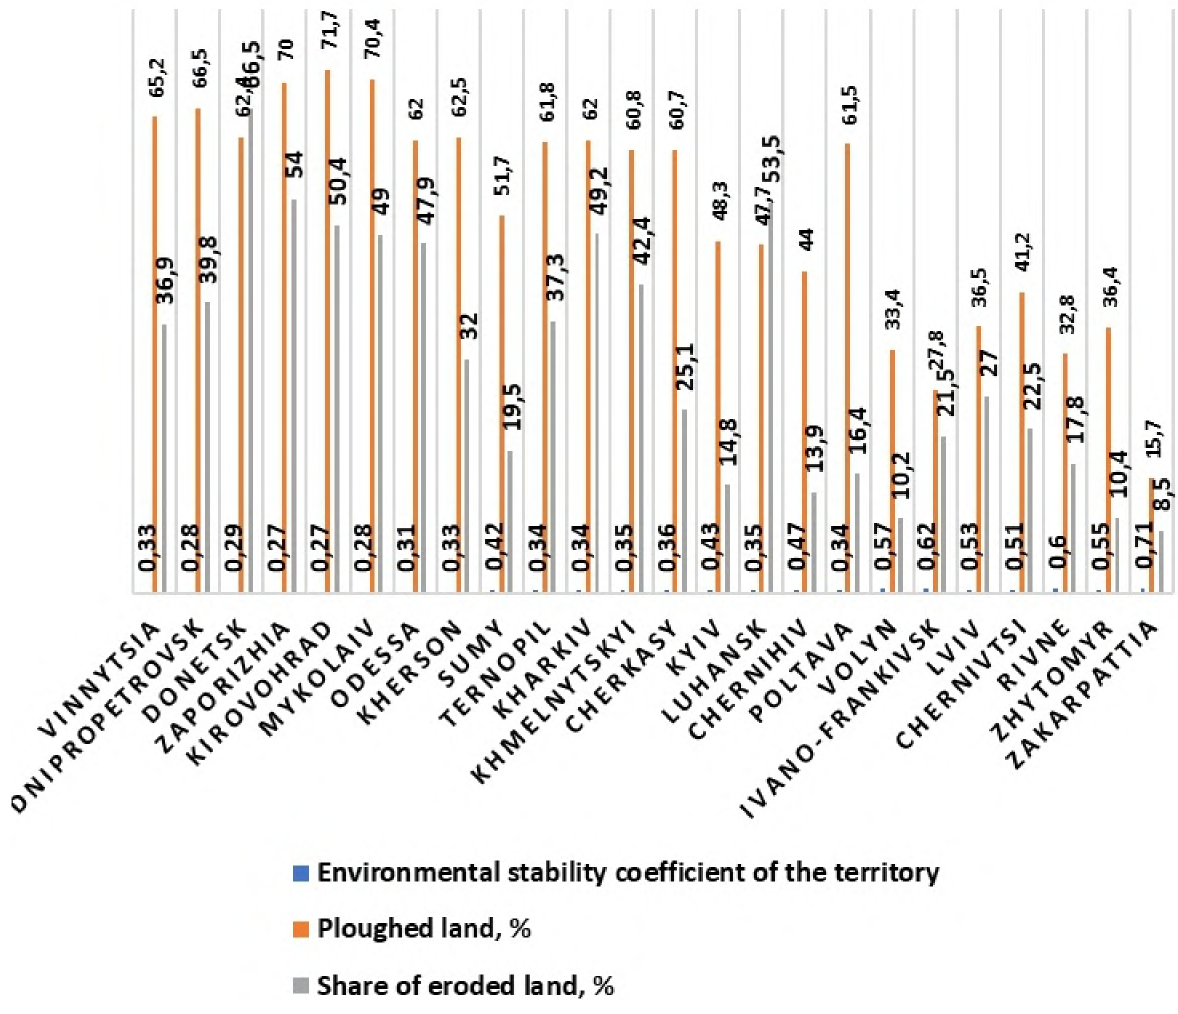

Figure 1. Ecological balance indicators of territorial units of Ukraine.

According to the scientists' methodology of the Land Management Institute of the Ukrainian Academy of Sciences, the coefficient of ecological stability indicates that: less than 0.33 – the territory is ecologically unstable; from 0.34 to 0.50 – refers to steady unstable; from 0.51 to 0.66 – passes into the limits of average stability; if it exceeds 0.66, the territory is ecologically stable. Figure 1 shows that most regions of the country have an ecologically unbalanced and vulnerable territorial structure, which is associated with high plowed land. Only Zakarpattia Oblast has an ecologically balanced territory. There is a direct relationship between land erosion and the degree of ecological stability.

The dependence of agricultural land use indicators and factors of production intensification is most accurately determined by economic and mathematical modeling in the form of a multifactorial regression equation (using the example of agricultural enterprises of the Krasnokut Territorial Community of the Bogodukhiv District of the Kharkiv Region). On the basis of the multivariate regression of the 1st degree, the relationship between the value of gross production (Y) and the area of arable land (X_1), qualitative assessment of arable land (X_2), production costs (X_3), and the cost of fixed and working capital (X_4) was revealed. The dependence obtained as a result of data processing is characterized by the equation:

$$Y = -2828.28 + 0.75X_1 + 59.89X_2 + 0.17X_3 + 0.10X_4$$

To assess the adequacy of the accepted mathematical model, we use Fisher's test.

The values of the equation parameters give reason to note that with an increase in the cost of fixed and working capital and the quality of land, the cost of gross production increases by 0.10 UAH and 59.8 thousand UAH, respectively. An increase in the area of arable land and production costs in farms contributes to an increase in the value of gross products by 0.75 UAH and 0.17 thousand UAH.

There is a fairly close relationship between the effective and factor characteristics (correlation coefficient is 0.8743). The test for significance proves the presence of a non-random dependence, as well as a high level of adequacy of the model construction (the actual F test of $F(3.26) = 8.93$).

Analysis of standardized beta coefficients showed that the cost of fixed production and working capital has the greatest influence on the cost of gross production ($\beta_4 = 0.688$), the next indicator is the arable land area ($\beta_1 = 0.595$), and then production costs ($\beta_3 = 0.326$), point of qualitative assessment of arable land ($\beta_2 = 0.220$).

An important issue today is the improvement of the legal, economic and ecological mechanism for the removal (conservation) of degraded, unproductive and man-made agricultural lands from intensive use. The legal basis for conservation of degraded and unproductive lands are defined by the Land Code of Ukraine [17, articles 171–172] and the Law of Ukraine "On Land Protection" [18, article 51]. The order of land conservation [19] defines the organizational principles of conservation of degraded, unproductive and technogenically polluted lands, reference indicators characterizing soil properties and determining the need for land conservation in natural-agricultural zones. But nowadays, a clear methodology for ensuring its implementation has not been defined. Therefore, it is necessary at the legislative level, with the participation of specialized scientific institutions, to develop a methodology for land conservation.

State and regional programs are adopted for the purpose of conducting soil surveys, protection, rational, ecologically safe use of soils, preservation and reproduction of their fertility. The implementation of state target programs in the field of reproduction, improvement and protection of soil fertility is an integral part of agrarian policy and a decisive factor in ensuring the sustainable development of our country.

Land conservation, regardless of the form of ownership, is carried out according to the working project of land management on land conservation, which defines the types, methods of land conservation, the term of conservation, directions of land use [19].

In order to implement the goals of sustainable development of both the state as a whole and territorial communities (Goal 15 – ensuring the protection and restoration of terrestrial ecosystems and promoting their balanced use; carrying out balanced forest management; combating desertification; ending the process of land degradation, restoring and stopping loss of biodiversity), we developed offers for the conservation of degraded and unproductive lands of the Krasnokut territorial community of the Bogodukhiv district of the Kharkiv region.

Taking into account the indicators that characterize the soil properties and determine the need for land conservation in natural and agricultural zones, it is offered to apply the following directions of conservation:

Erodibility (eroded and deflated). These are lands with moderately and strongly eroded and eroded soils, outcrops of soil-forming and underlying rocks. It is planned to remove from the arable land and further lime and use it for onion pasture lands with standardized livestock grazing or afforestation. Medium and strongly deflated soils are subject to removal from agricultural land by afforestation.

The most disturbed lands with rock outcrops, washed-out and heavily washed soils, these lands should be removed from the arable lands with lime or afforestation. In the Krasnokut community, the area of such lands is 176 hectares (agro-production groups 57d, 57e, 51e, 51g, 51e). Medium-washed soils on complex slopes of more than 3–5° are also subject to transformation into pasture lands, approximately 1560,9 hectares are allocated for pastures, 176.3 hectares for afforestation. On other lands with moderately washed soils, it is advisable to carry out rehabilitation. Conservation-rehabilitation of agricultural lands is planned by allocating them or transferring them to fallows and using them as hayfields and pastures for a period of 10 to 20 years with subsequent return for agricultural use. The area of these lands is 6,824.3 hectares.

Soils of light mechanical composition. These are sandy and clayey-sandy soils. They are permanent centers of deflation. From an economic point of view, the impracticality of their use is due to the inadequacy of costs for maintaining a sufficient level of their fertility, the profit obtained from the harvest. The conservation of these lands is irreversible, that is, they must be removed from the agricultural lands with subsequent afforestation. In the community, this is land on an area of 8.0 hectares (agro-production group 1 a).

Soil salinity. This category of lands is represented by salt marshes, medium and highly saline mainly hydromorphic soils (meadows, swamps), as well as secondary saline soils. Saline soils of natural origin are removed for haying or renaturalized (regeneration) without human intervention. Secondary salinized soils are taken for temporary conservation with subsequent return to the composition of arable lands, if the indicator of the groundwater level is reduced below the critical level and desalination. In the Krasnokut community, this category of land is 133.0 hectares (agro-production groups 141,142', 143', 144', 134'd, 134 e), it is offered to allocate 66.5 hectares for haymaking, and 66.5 hectares to be renaturalized without human intervention.

Salinity. These are medium and highly saline soils. Directions for use are the same as the previous group. These are lands (agro-production groups 165 d, 165 e) on area of 30.0 ha, which should be converted into hay fields.

Waterlogging and swamping. This category includes lands with meadow and sod-podzolic soils, as well as sod-clay, mineral and organic bog soils. These lands must be naturally renaturalized. It practically does not require any expenses, because good watering ensures their quick settlement with natural fauna and flora, adaptation to the surrounding environment. The area of these lands is 266.0 hectares (agro-production groups 176 b, 176 c, 209 c, 209 g, 209 d, 209 e, 209 l, 208 d, 208 e).

Offers for the conservation of degraded and unproductive arable lands by types of degradation and ecologically appropriate directions of their use are given in the table 1.

Removal of degraded and unproductive lands from intensive cultivation will allow: 1) to concentrate investments on more fertile lands and obtain a higher yield of agricultural crops on them; to increase the level of the fodder base development and, on their basis, the livestock industry; 2) to reduce the rate of erosion processes development and further soil degradation; 3) to bring the plowed percentage of the territory of the Krasnokut territorial community of the Bogodukhiv district of the Kharkiv region to 52% (actual ploughed 60.3%).

One of the necessary and determining prerequisites for the development of the land resources management system in the context of sustainable development is the application of the latest technical and technological achievements in the field of protection and reproduction use of land resources. This form of innovative activity in land resources management was reflected, in

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012129 doi:10.1088/1755-1315/1254/1/012129

Table 1. Offers for the conservation of degraded and unproductive arable lands of the Krasnokut territorial community of the Bogodukhiv district of the Kharkiv region.

Degradation types	Area, hectares		Conservation					
	total	%	rehabilitation	conversion				regeneration
				total	hayfield	pasture	forest

particular, in the implementation of the following directions in economic practice: resource-saving technologies in agriculture, the use of remote land sensing data (RSD), GIS technologies, the role of soils in the process of mitigating the consequences of climate change, agroforestry, etc.

Precision agriculture is characterized by the automation of applied methods, in particular, yield registration with continuous monitoring. This management practice is available mainly to large commodity producers of agricultural products, but it is also recommended for small farms. The main obstacles to the wide implementation of precision agriculture are the lack of skills of working with databases and automated decision support systems among business entities [20].

GIS ensures the practical implementation of non-zero risk concept in the land resources management as an ecological and economic system. The concept recognizes the fact that absolute security is insufficient and requires not only the study of factors and sources of increased risk, but also the forecast of the development of events and the assessment of their consequences [21]. By predicting the probability of certain events and the expected amount of profit (losses), investigating alternative solutions, they make the optimal management decision regarding the use of land resources. RSD and GIS data allow solving the following tasks in agriculture, particularly: mapping and inventory of agricultural lands; monitoring and control in crop production; state of crops, evaluation of crop emergence, degree of ripening, damage by pests/diseases; yield forecasting; monitoring and control of pastures and hayfields in animal husbandry; monitoring and control of reduction or loss of soil productivity, degradation, water and wind erosion, salinization, flooding, etc.

In the latest practice of sustainable land resources management, agroforestry is spreading, which allows economic activities to be carried out with the preservation of biodiversity, greening of agriculture and industrial landscapes. Agroforestry reduces the anthropogenic load on natural forests, creates a habitat for native species of plants and animals, and also promotes effective land use in fragmented landscapes [20]. The use of agroforestry methods allows obtaining not only a positive economic effect of increasing the biological productivity and sustainability of agro and forest ecosystems, but also a significant ecological effect.

In order to preserve and reproduce the productivity potential of arable land, the practice of organic and no-till farming are becoming widespread.

Increasing the resilience of agricultural production to climate change, especially in the south of Ukraine, in the areas most affected by drought, requires the expansion of irrigated areas and the restoration of irrigation infrastructure. According to official statistical data, there are 5.48 million hectares of reclaimed land in Ukraine, including 2.17 million hectares of irrigated land and 3.3 million hectares of drained land with appropriate land reclamation infrastructure (reservoirs, main and distribution channels, protective dams, pumping stations, pipelines, pools of daily regulation, collector and drainage network and other hydrotechnical structures and objects). During the last time, about 550,000 hectares of agricultural land were actually irrigated, and bilateral regulation was carried out on the area of about 250,000 hectares. Agricultural producers who use irrigation can increase yields by 30-50%, depending on the crop. The irrigation and drainage infrastructure of the water management and melioration complex was built in the 1960s and 1990s, and today it is in critical condition, especially the intra-farm network. Today, there is no reliable and systematic information about the technical condition of engineering infrastructure objects and the operation of reclamation systems, distribution by owners and water users, location, etc. This makes it difficult to make effective management decisions regarding their use, modernization and restoration. Preliminary calculations and expert assessments indicate that, if the current rate of increase in the deficit of natural moisture supply of the country's arable lands is maintained, by 2050, about 3 million hectares of arable land in the southern regions will be unsuitable for commercial agrarian production of plant products [22]. As a result, and taking into account the tendency of dehydration in the central and northern regions of the country, the gross production of grain (with modern resource supply of agricultural technologies) may decrease by 20-25% or 14-18 million tons.

4. Conclusions

The modern land management system should encourage agricultural enterprises and other interested parties to take decisive action in solving the problems of preserving valuable soil and black soil (chernozem) resources of Ukraine, to economical use and reproduction of their fertile potential. It is necessary to observe legality in the process of land use and land circulation, to promote the involvement of local territorial communities in solving priority problems related to the effective and ecologically safe use of soil resources and the reproduction of their fertile potential, to direct their activities to the improvement of the regulatory and legal framework on the problems of soil conservation, their effective use and reproduction of their fertile potential.

The main ecological directions in the land resources management system should be the following: ensuring the priority of environmental safety requirements in the use of land resources over economic interests; implementation of agrotechnical measures aimed at improving soil fertility and recovery; increasing the share of organic production; strengthening control over illegal plowing of pastures and water protection areas; restoration of forest strips; increase in investments in agriculture; use of modern resource-saving technologies, in particular, resource-saving no-till technology, which allows increasing soil moisture retention, improving water availability, and reducing soil erosion; application of organic fertilizers, in particular, manure, straw, residues of agricultural production; application of remote sensing data and GIS technologies.

In order to ensure sustainable development in the face of climate change and reduce greenhouse gas emissions in Ukraine, it is necessary to start work on the restoration of irrigation systems, form the structures of sown areas with the introduction of resource-efficient technologies for growing drought-resistant varieties and hybrids of agricultural crops.

Abstract. A new (“amber”) branch of the economy is currently developing in Ukraine, which includes the search for, mining and processing of amber. Ukrainian amber is noted for its high quality and is one of the most competitive types of domestic coloured stones on world markets. A significant part of the territory of Ukraine is promising for the discovery of placer deposits of amber, but their industrial development is currently carried out only within the boundaries of “the Pripyat amber-bearing basin” (PAB), which covers the regions of Volyn, Rivne, Zhytomyr, and Kyiv regions. The development of the “amber” industry of Ukraine caused problems of a production, organizational, socio-economic and environmental nature. They significantly influence the socio-economic development of amber mining areas. These are: 1) lack of a national program for the development of the “amber” industry; 2) its insufficient level compared to the real potential; 3) uncontrolled mining of amber; 4) negative impact on the ecology of the natural environment; 5) socio-economic consequences for the population of amber mining areas. “The predictive and search system for amber” (PSSA) allows solving these problems in a complex manner. The PSSA of Ukraine allows systematic research of “the amber-bearing formation” (AF) developed on its territory. PSSA uses scientific ideas about the origin of amber and the main natural factors of its formation, develops methods and a specific research algorithm. The main goal of PSSA is to identify “amber-bearing objects” (AO) in the geological body of the AF, which may contain high concentrations of amber, the so-called “traps”.

1. Introduction

In recent decades, the “amber” branch of the economy has been developing in Ukraine, which integrates the search for, mining and processing of amber. Ukrainian amber, thanks to its high quality, is recognized in the world and represents one of the most competitive types of domestic colored stones on the world market. The territory of Ukraine is promising for the discovery of placer deposits of amber, but their industrial development is currently carried out only within the boundaries of “the Pripyat amber-bearing basin” (PAB), which covers the regions of Volyn, Rivne, Zhytomyr, and Kyiv regions.

In a short time, the development of the “amber” industry of Ukraine caused a number of problems of a production, organizational, socio-economic and environmental nature. They significantly influence the socio-economic development of amber mining areas and at a certain stage were considered from the standpoint of national security of Ukraine [1, 2]. These problems can be presented as: 1) lack of a national program for the development of the "amber" industry; 2) its insufficient level compared to the real potential; 3) uncontrolled mining of amber; 4) negative impact on the ecology of the natural environment; 5) socio-economic consequences for the population of amber mining areas [3, 4]. A comprehensive solution to these problems is provided by "the predictive and search system of amber" (PSSA) [5–7].

2. Metods and materials

The methodology of general systems theory is used in the PSSA. The partial methods used are geological, geomorphological, paleogeographical, paleogeomorphological, laboratory data on amber, and statistical data on the socio-economic status of amber mining areas. The results presented in tables, graphically, on general and thematic maps of various scales, geological and geomorphological sections were further analyzed.

The article is based on the results of the authors' own research, obtained during the implementation of research work on amber in Ukraine, as well as international projects with the Republic of Belarus ("Development of a geological and genetic model of amber-bearing deposits of Ukraine and Belarus" with the financial support of the State Fund for Financial Development of Ukraine and Belarus) and the Republic of Poland ("Amber ways: deposits formation-mining. Scientific-methodical basis, rational use" and "Amber deposits and characteristics" funded by the EU). Stock materials (Geoinform) and geological expeditions of the Ukrainian Geological Company were also used.

3. Results

Lack of a national program for the development of the "amber" industry. The national program for the development of the amber industry in Ukraine is being formed, but its structure and connections of its components are clearly visible – forecasting, searches, development and exploitation of amber deposits, practical use of amber raw materials, regulatory and legal regulation, informational and educational and museum and educational activities. Currently, the amber industry in Ukraine is being developed by various state and private institutions, organizations, and individuals. The stage of spontaneous, chaotic development of the industry has passed and the primary experience of organized work has been acquired by it. To a large extent, this was facilitated by meetings, conferences, symposia on amber topics held in Ukraine and abroad, in which Ukrainian and foreign experts participated. Thanks to them, the content of the national program for the development of the amber industry in Ukraine was determined: active (anticipatory) conducting of forecasting and search for new amber deposits; the creation of state guarantees within the framework of international agreements between interested countries regarding the origin of trade batches of amber; development of quality certification schemes for Ukrainian raw amber and its adaptation to global schemes; establishment of legal and legislative norms of the optimal mode of extraction and sale of amber under the control of the state; in-depth comprehensive study of medicinal properties of amber, succinic acid, processing products and their introduction into medicine; launch of the "Polissya amber" brand and promotion to the international level. International conferences devoted to the topic of amber also made it possible to establish important contacts between scientists of different countries and in the future to carry out mutually beneficial joint interstate projects [8, 9]. This makes it possible to improve national programs for the development of the industry, in particular, to create the PSSA, which, over time, can be integrated into international ones. The PSSA will allow solving the main strategic task of the amber industry – the opening of new deposits of amber raw materials and the expansion of the market for amber products.

A necessary condition for the development of the amber industry in Ukraine is a clear and reliable legal framework. It is prescribed in the articles of the Constitution of Ukraine, Laws of Ukraine and Resolutions of the Cabinet of Ministers (CM) of Ukraine. According to them, the subsoil is an object of the right and property of the Ukrainian people (Constitution of Ukraine, Article 13). It is owned by the Ukrainian people and some of its representatives. On behalf of the Ukrainian people, the rights of the owner are exercised by state authorities and local self-government bodies within the limits set by the Constitution. On behalf of the Ukrainian people, the rights of the owner are exercised by state authorities and local self-government bodies within the limits set by the Constitution. The general procedure for the regulation of relations in the field of the study, extraction and sale of amber raw materials is carried out in accordance with the Codes of Ukraine – On Subsoil, Land, Forestry, Criminal, the Law of Ukraine "On State Regulation of Mining, Production and Use of Precious Metals and Precious Stones and Control of Operations with Them", by-laws adopted for their implementation. By this law, amber is classified as a precious stone of organogenic origin and a mineral of national importance [10–13].

Legal relations in the amber industry at the state level appeared in Ukraine only with the declaration of independence. In 1993, by Resolution (No. 111 dated February 18, 1993), the State Enterprise "Ukrburshtyn" was established for amber mining and processing. At the legislative level, changes were made to the Law of Ukraine "On entrepreneurship" (December 22, 1995), according to which amber mining is allowed only to state enterprises. After 10 years, thanks to the general development trends of our country, the Law of Ukraine (October 18, 2005) removed restrictions on amber mining only by state enterprises. Thus, the legislation in the amber industry determines that the subsoil and what is in it is the property of the Ukrainian people. Protection of the right to them is regulated by legislative acts of Ukraine.

In general, the legislative basis for the development of the amber industry in Ukraine has been created. Currently, only the issues of its normative and legal regulation are being proved. Complaints about the imperfection of the laws here are only partially justified. Laws must be obeyed by everyone – both those to whom it must be done "on duty" and ordinary representatives of society. Problems in the development of the industry began only after openly criminal elements became interested in amber.

At the same time, it should be noted that for the population of mining areas, "amber" is a profound issue. It is history, traditions, life – the opportunity to get an education, build a house, just live. They may not be at the scientific level, but they protect the ecology of their own home. In our opinion, the concept of "mentality" can be used here. Mentality is a combination of inherited (from past generations) and acquired (in current life) elements. The acquisition of the latter is served by the informational and educational and museum and educational directions of the development of the amber industry. Kindergarten, school, college, gymnasium, school, technical school, institute, university, olympics, newspapers, radio, television, Internet, conferences, exhibitions, expositions in salons and museums, specialized amber museums. As can be seen from the list, these areas can be developed systematically on the basis of existing organizational forms.

The insufficient level of development of the amber industry compared to its potential. In Ukraine, a significant database of lithological-facies, paleontological-stratigraphic, structural-tectonic, paleogeographical, geomorphological, paleogeomorphological studies has been accumulated. It gives grounds to predict that Ukraine has perhaps the largest reserves of raw amber in Europe. Currently, industrial amber mining is carried out within the northwestern part and the western slope of the Ukrainian Shield, where the main amber deposits of the PAB are located. However, the northern, northeastern, and southern slopes of the Ukrainian shield and the adjacent areas of the Black Sea and Dnipro-Donetsk depressions (and in the latter, adjacent to the southwestern spurs of the Voronezh anteclise) are considered promising for the discovery of amber raw material deposits. In these territories, in contrast to the PAB, the Paleogene lithological-stratigraphic horizons, which are promising for the discovery of new amber deposits, lie deep.

At the same time, the main resource of raw amber in the explored and currently developed deposits of the PAB is running out. The limitation of the raw material base is the main problem of the development of the amber industry in Ukraine. According to experts, its expansion in the PAB can be achieved by: 1) increasing amber production at known deposits 2) opening new deposits. The first way is limited by the natural and geographical conditions of the territory – all known deposits and manifestations of amber are located among valuable forest and land areas, under swamps; where productive horizons are located at a depth of 5-10 m. The amber in them is extremely dispersed. Outdated search data used by mining enterprises do not allow discovering new large deposits of amber. The second way – the discovery of new industrial deposits of amber is strategic and can determine the development of the amber industry in the coming years. The figure 1 shows fragments of some special maps of the PAB territory, which, in combination with other maps and materials, can be used to search for new types of amber deposits.

The figure 2 and figure 3 shows for the Dubivka area of the Volodymyrets group of deposits: maps: the paleorelief of the formation of promising amber-bearing horizons of the mezhyhirskya and obukhiv switas of the Paleogene (eocene-oligocene); the forecast of placer amber deposits.

Uncontrolled mining of amber. Uncontrolled amber mining causes the greatest damage to the state and the local population. Dangerous due to its predatory lack of control and the annual increase in the volume of shadow mining, it began to flourish in the country from the end of the 80s of the last century. This problem became especially relevant in the mid-1990s, when massive systematic illegal mining of amber covered a huge area of Polissya and prospectors began to use complex mining techniques.

The main reasons for the rapid increase in illegal amber mining are: the growth in demand for amber on the domestic and foreign markets; the possibility of mining with inexpensive, efficient equipment, due to the presence of productive layers close to the surface; the low level of employment of the local population in the districts of Rivne (Rokytniv, Zarichnen, Dubrovytskyi, Volodymyretskyi, Sarnenskyi), Zhytomyr (Olevskyi, Ovrutskyi), Volyn (Ratnivskyi, Manevytskyi, Lyubeshivskyi) regions, where the largest illegal amber mining currently takes place; low level of control of the authorities and law enforcement agencies over the activities of illegals; inadequate responsibility for the committed crime.

Currently, amber extraction by illegal miners is carried out by open (excavator-transport) and underground (motor pump) methods. The mined ore is enriched, washed on sieves. The empty rock is washed away, and the amber remains and is selected. The local population uses motorized pumps, with the help of which rocks are washed out from a depth of up to 10 m. This method belongs to complex underground.

Illegal amber miners mine manually and with the help of motor pumps wherever possible – in the forest, in meadows, in swamps and wetlands, on the banks of rivers and lakes, in exploited or abandoned granite quarries, in dumps, in terricones, within the boundaries of irrigation facilities, protected state facilities, under railway tracks, power line towers, in agricultural lands on all elements of the modern topography of the territory.

The level of qualification of illegal miners is also increasing. In the first years of illegal mining, there were mutilations among inexperienced executors, and frequent deaths of young people during the drilling of shafts in loose and waterlogged sands. Now, every year, an increasing number of qualified workers are involved in shadow production, and not only from among local residents, who unite in teams equipped with hand drills, motor pumps and other tunneling equipment.

Illegal extraction of minerals is classified as a crime, the consequences of which are manifested in the ecological, economic, and social spheres. According to estimates, the development of

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012130 doi:10.1088/1755-1315/1254/1/012130

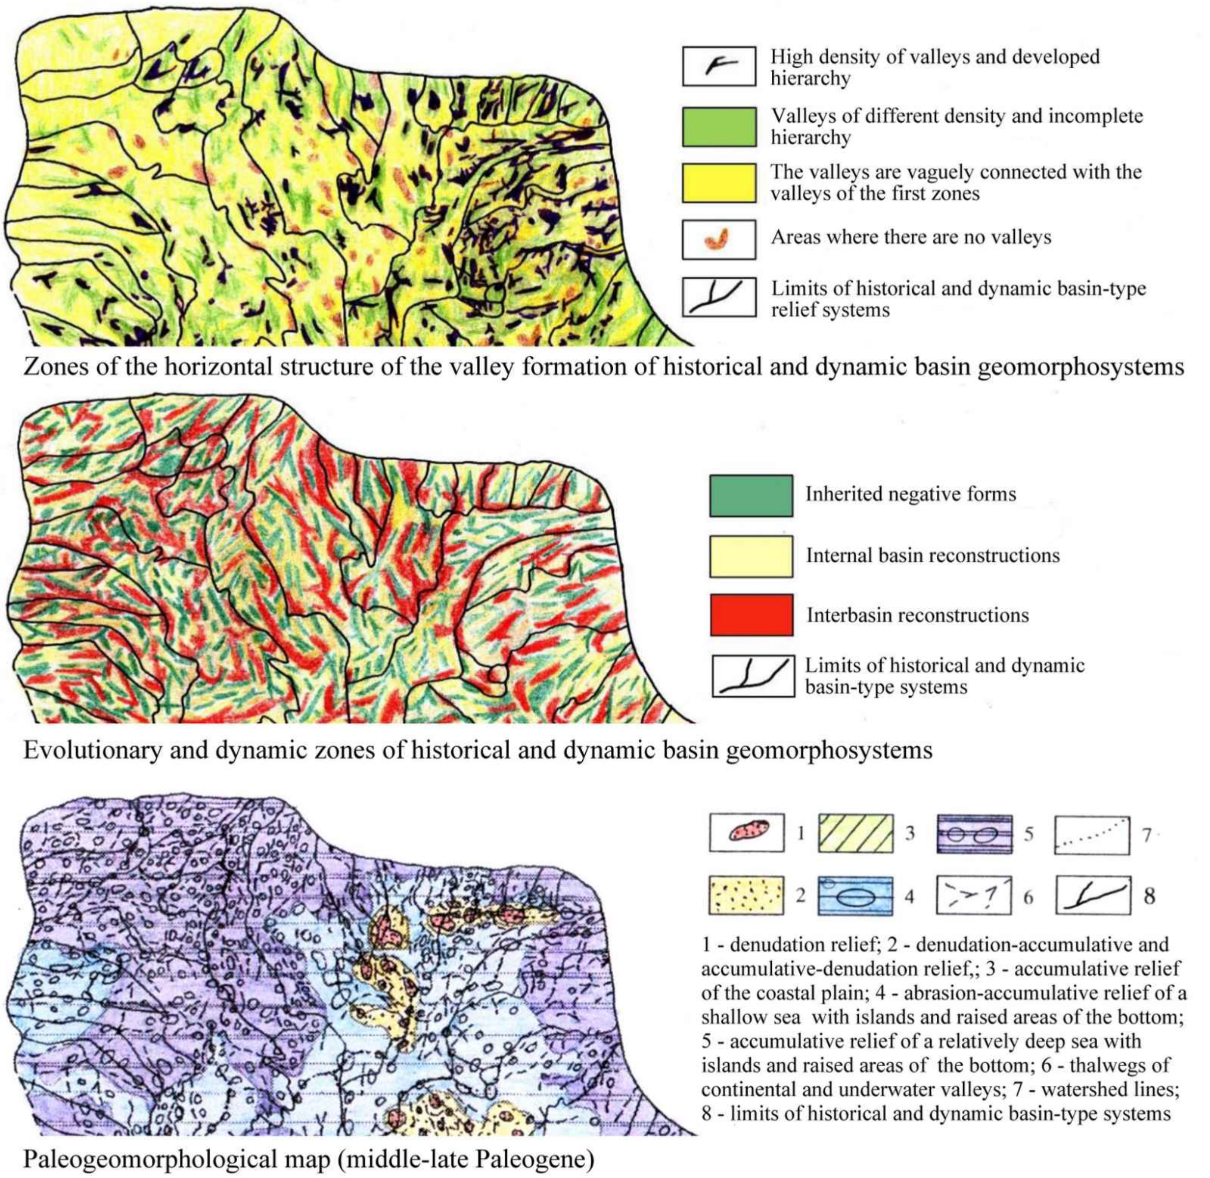

Figure 1. Special maps of the historically-dynamic geomorphosystem territory of the PAB.

amber costs the state UAH 8-10 million per day. According to various estimates, up to 30 tons are exported from the country annually.

To solve this problem, it is necessary to build relations with prospectors. In order to solve the problem of employment, individual prospectors are proposed to be united in prospector artels, for which the possibilities of obtaining permits for simplified subsoil use are opened. But here there is a question regarding the interpretation of the term “seeker”.

In most countries, a prospector is a person who extracts minerals without the use of heavy machinery, exclusively by hand. Therefore, for exploratory mining, it is advisable to transfer small-sized placers that can be developed in an artisanal way. In Polissya, the majority of such placers are located in the Zhytomyr region. It is proposed to introduce the category “local prospector – a citizen of Ukraine”, who is registered and lives in settlements located on amber

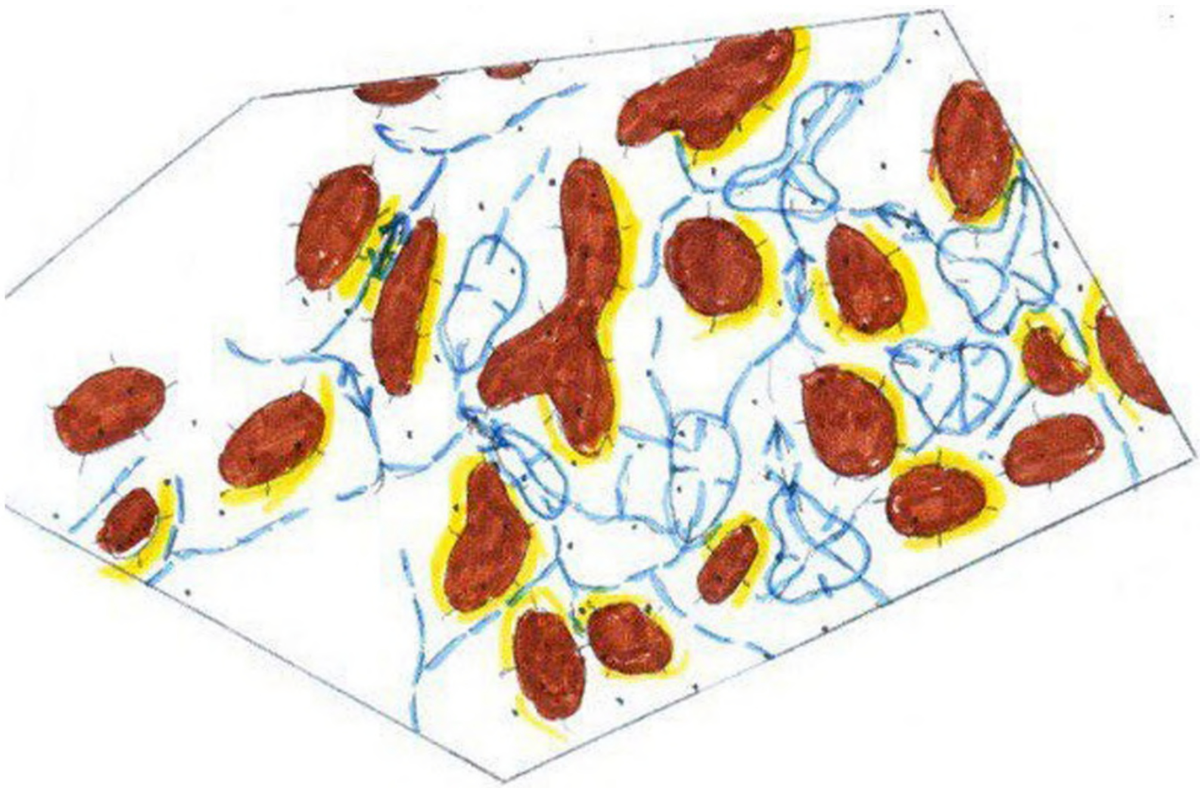

Figure 2. Paleorelief of the formation of promising amber-bearing horizons of the mezhyhirskya and obukhiv switas of the Paleogene (eocene-oligocene) (brown color – denudation relief of islands; yellow color – abrasive-accumulative relief of beaches; shallow sea bottom – thalwegs of underwater valleys, buried areas, directions of movement).

deposits, carries out its extraction and primary sale and compensates for the damage caused to nature as a result of such activities. It is proposed to introduce a special simplified taxation and reporting system for prospectors. In order to solve the issue of sales, it is proposed to create specialized exchanges in mining areas, where it is possible to legally purchase amber raw materials, as well as state points of purchase of mined stone.

The lack of a developed methodology for assessing damages caused by illegal amber mining leads to the state budget not receiving significant funds. The main criteria here are ecology and economy.

Violation of the legislation on subsoil entails responsibility: disciplinary, administrative, civil and criminal.

Negative impact on the ecology of the natural environment. According to the scale of impact on the natural environment of the territory of Polissya, the illegal activity of illegals is equated to the action of spontaneous natural processes. Currently, it is difficult to assess the extent of the damage caused by them. This problem is exacerbated by the fact that uncontrolled amber mining is imposed on the heavily damaged nature of this territory.

Illegal mining (pits-pits, ditches, hand-drilled wells, erosion of the soil with a motor pump) without proper backfilling of the trenches with waste rock disrupts the root system of trees, destroys the shrub and grass undergrowth, and leaves sand mounds and gaping pits filled to the top on the surface of the soil muddy water Problems arise with animals that fall into holes and cannot get out. In the forest, where the diggers have already visited, after a few years all the trees disappear, because the hydrological regime is disturbed by pits and pumps. Unauthorized

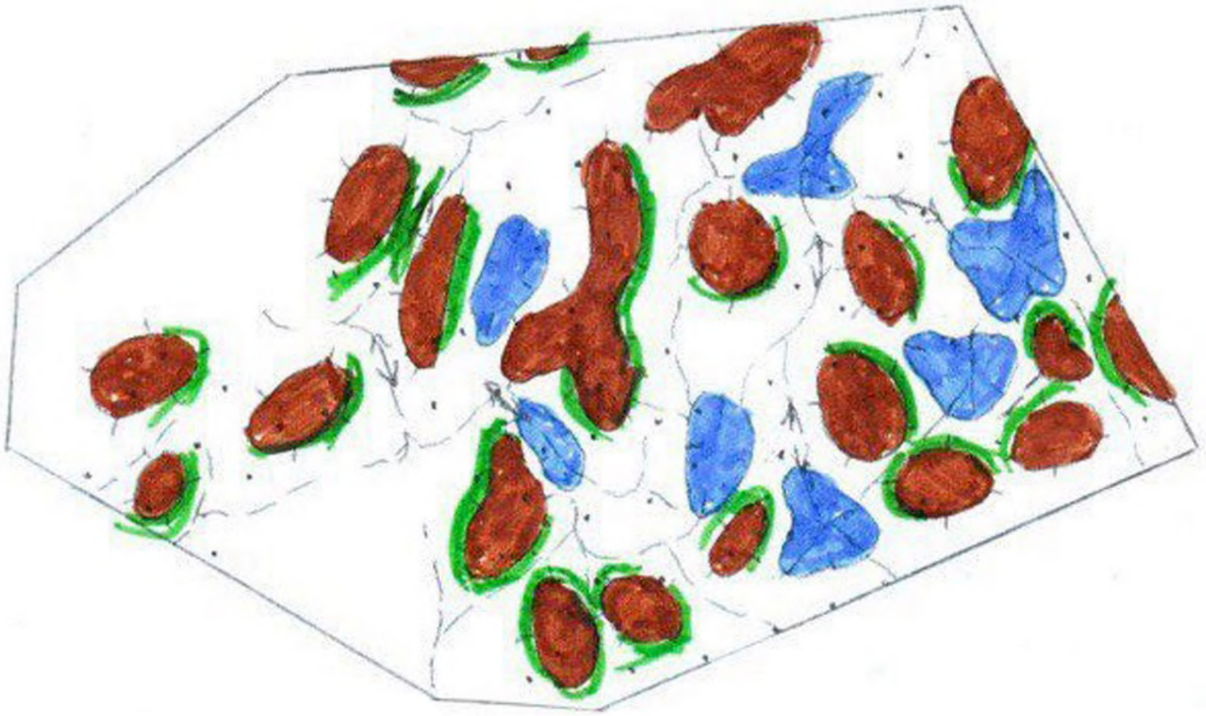

Figure 3. Forecast of placer amber deposits Dubivka area (brown color – low islands – places of wear and tear; green color – bench, beaches – accumulation of large fractions of amber; blue color – buried trap areas – accumulation of large fractions of amber).

mining, which is carried out by hydromechanical methods, devalues productive horizons and deposits lose their industrial value (figure 4).

Very often, amber is mined within the protected natural areas – nature reserves, nature reserves, etc. Violation of the territorial regime makes it impossible for many species of protected animals to exist here.

Illegal mining of amber leads to the destruction of surface (4-5 m) productive horizons. Illegal prospectors choose high-quality and most valuable amber, and the "small stuff" that can be successfully used in many industries remains in the dumps.

Illegal mining of amber in recent years has created another environmental problem – the burning of charcoal. Deliberate arsons are carried out, fallen trees are burned.

Thus, illegal mining of amber affects all components of the natural complex: soils – by removing the fertile layer, disrupting the structure of the soil cover, clogging the land plot, which causes loss of humus, macro- and microelements, destruction of the upper fertile layer, increased wind and water erosion; vegetation – violation of the integrity of the grass cover, illegal destruction of trees, which leads to the violation of the integrity of the grass cover, drying and destruction of trees; animals – by violation of the usual mode of living of animals, the creation of an unusual man-made terrain for them, which leads to the migration of animals to other places, their mutilation, death; water – arbitrary, uncontrolled use of surface and underground water, which leads to a violation of the hydrological regime of the territory, a decrease in the level of groundwater; air – as a result of the burning of fuel and lubricants, the burning of charcoal, the atmosphere is polluted with CO_2, CO, SO_2, NO_2, and hydrocarbons; subsoil – violation of the geological structure of the territory, loss of subsoil, which leads to deformations of the earth's surface, damage to mineral deposits, restriction or complete removal of them from exploitation,

Figure 4. Consequences of illegal amber mining in Zhytomyr region.

impoverishment of subsoil.

Illegal amber mining exacerbated the problem of reclamation of disturbed lands, which is important for the organization of rational amber mining and prevention of the destruction of natural landscapes. This problem should be solved by specialized organizations that have mastered the methodology and have experience in similar work. Reclamation of disturbed lands takes place during 3 stages – preparatory, hydrotechnical, biological. In the preparatory stage, a survey and typification of disturbed lands is carried out and the type of reclamation is chosen. In the hydrotechnical stage, land vacated after mining operations is prepared for their further use. At this stage, the following is carried out: selective removal, storage and preservation of overburden suitable for biological reclamation, including the fertile layer; selective formation of overburden dumps; if necessary, planning and covering the planned surface with a layer of soil; backfilling and planning of deformed surfaces; creation of access roads; drainage and anti-erosion measures. The biological stage of reclamation consists in restoring the fertility of disturbed lands, restoring flora and fauna by agrotechnical and phytoremedial means.

Socio-economic consequences in amber mining areas. Illegal mining of amber within the territory has revealed many shortcomings of modern social life, these are: lack of an effective system of combating illegal mining, use and circulation of amber in Ukraine; the invalidity of some laws regarding the protection of subsoil and the regulatory and legal support of labor activities on the extraction, production and use of amber; low level of environmental education of Ukrainian citizens, primarily young people; social roots of criminal activity (unemployment, etc.).

The results of the work were discussed at scientific and practical conferences in Ukraine and abroad (Poland – Ambermarket, Amberif), scientific seminars at the Polish and Ukrainian

Academies of Sciences.

4. Conclusions

All these problems have a complex nature and cover various aspects of the socio-economic, cultural and political life of the country and can be solved exclusively at the state level. This requires the adoption of a number of state laws and, first of all, the law on preserving the country's national wealth – amber and protecting it from looting. Without the adoption of these laws, the scale of theft will increase, which will lead to the disappearance of the upper productive horizon and the transformation of Polissya into a desert.

The PSSA should solve the mentioned problems of the amber mining areas.

The PSSA of Ukraine allows systematic study and use of AF developed on its territory. The PSSA takes into account scientific ideas about the origin of amber and the main natural factors of its formation, develops methods and a certain research algorithm.

The AF represents a special type of sedimentary geological formations, since their central, formation-forming element (amber) at the beginning of its formation came from the biosphere, and not from the lithosphere (as in most geological formations).

The AF is formed by the processes of tectogenesis, morphogenesis, lithogenesis, oreogenesis of amber, which interact systematically. As a result, tectonic (neotectonic) structures, landforms, deposits, amber deposits are formed. The AF of Ukraine is constantly being studied. In general, its spatio-temporal parameters, structure, trends of transformations of the geological "body" of the AF are understood. Within the boundaries of the PAB, the geological body of the AF is exposed on the surface almost everywhere, intersects with modern (and ancient) "geomorphological formations", which are parts of the historical-dynamic geomorphosystem.

The main goal of the PSSA is to forecast and search for the AOs located in the geological body of the AF. AOs include natural formations or their parts that contain or may contain concentrations of amber. The accumulated experience of amber exploration allows to distinguish stratigraphic, lithological-stratigraphic, lithological, structural-tectonic, paleogeomorphological, geomorphological types of the AOs.

The specific stratigraphic horizons of the Paleogene system (charkiv, mezhihirsky, obukhiv layers) in which primary amber-succinite placers are found belong to the stratigraphic AOs on the territory of Ukraine. This also includes the stratigraphic horizon of the buchac svita of the middle Eocene, the amber-like resins from which, according to many researchers, were the starting point for the formation of the AF of Western and Eastern Europe. AOs of the lithological-stratigraphic type are revealed in the process of detailed study of promising Paleogene horizons. Lithological AOs are "lithological bodies-collectors" that are found in Neogene and Quaternary stratigraphic horizons, in particular cross-cutting "lithological bodies" that cover several stratigraphic horizons. Identification of the structural-tectonic type of AOs requires the use of structural-tectonic models of the tectonosphere for the time of formation of the AF. It will show the tectonic (neotectonic) structures that are dynamically active in the Neogene-Quaternary (neotectonic) time – newly formed or inherited from the morphostructures that formed during the Mesozoic. These structures could influence the processes of lithogenesis and morphogenesis from the time of the accumulation of amber-like resins (middle Eocene), the formation of primary amber-succinite placers (late Eocene-Oligocene), the destruction of primary deposits, redeposition of their derivatives, the emergence of new placer deposits in Neogene and Quaternary horizons. In order to identify paleogeomorphological and geomorphological AOs, it is necessary to have a modern understanding of the "relief" as a "historical-dynamic geomorphosystem" and take into account the peculiarities of its functioning. This approach makes it possible to identify potentially possible relief forms of various stages of the development of the AF on a systematic basis.

The use, as a basic, geomorphosystem factor, allows to search for AOs on a scientific basis, which is important for geoecology and protection of the natural environment in amber mining areas.

It is important to note that the main goal of organized and illegal amber miners today is the search for AOs of stratigraphic and lithological-stratigraphic types. This is influenced by the underground occurrence of AF, which allows the use of available and cheap technologies for the development of amber and does not require the use of relatively expensive scientific developments.

The PSSA of Ukraine contributes to the strategic development of the amber industry in Ukraine, which consists in a comprehensive approach to solving the scientific and practical tasks of finding and developing amber deposits, socio-economic and environmental problems. The concept of the AF creates scientific and methodical conditions for this.

Abstract. Sustainable tourism is fundamentally about preserving and enhancing natural, historical, or cultural heritage, as well as promoting activities related to local identity and history. For mining regions, one of the ways to diversify their economies on a sustainable basis is to develop the tourism sector. The development of niche forms of tourism, which are fully focused on the resources of the industrial area, helps to supplement and diversify the tourist offer in these regions, including industrial tourism and one of its areas - mining tourism. The objective of the study is to reveal the importance of sustainable development for an old industrial region, using Kryvyi Rih as an example, by intensifying tourism activities that would maximize the social, economic, cultural, and environmental benefits of tourism. The research is based on the dialectical method of cognition and a systematic approach. The research was carried out on the basis of parallel use of theoretical (comparative analysis, abstraction, specification and generalization) and empirical methods (expeditionary methods, observations, the method of field visual inspections, content analysis, etc.) As a result of the study, approaches to the concept of "mining tourism" were structured, and the key objects of interest of consumers of this tourist destination were identified. Global trends in the transformation of industrial areas for the needs of mining tourism were analyzed. The information on mining facilities in Kryvyi Rih is systematized and their suitability for the tourism sector is diagnosed. Based on the diagnostics, the use of various mining facilities in thematic tour programs is proposed, which is confirmed by the results of practical tourism activities.

1. Introduction

For a long time there have been discussions in various scientific sources about the interpretation of the term "sustainable development" and its understanding in order to direct the further harmonious development of the triune global system "nature-economy-society". In general, the understanding that further development of society on the planet will be limited by the irrational use of natural conditions and resources led to the emergence of the paradigm of sustainable development in the 1970s. The UN is the leading organization aimed at ensuring of the implementation of the paradigm itself and the achievement of its goals at the global level. The regional and local levels are implemented at the level of individual regions and countries of the world. Since "sustainable development" should ensure the rational use of natural conditions and resources, the attention is usually paid to its ecological essence.

Therefore, in the vast majority of sources sustainable development is defined as the development that enables to meet the needs of current generations and leaves the opportunity for future generations to meet their needs. This is the balanced development of the country and regions, where economic growth, material production and consumption, as well as other types of social activities take place within the limits determined by the ability of ecosystems to recover, absorb pollution and support the livelihoods of current and future generations. The key tasks of sustainable development are determined by the following: restoration and further preservation of natural ecosystems and their ability to self-reproduce in the required volume on the required area; ensuring anticipatory solution of the problem at the same time: economic, social, demographic and spiritual development.

In order to ensure sustainable development and control the indicators of the implementation of the paradigm for a specific time period, the Law on the Strategy of Sustainable Development until 2030 was adopted in Ukraine. The concept is based on the 17 global Sustainable Development Goals adopted at the UN Sustainable Development Summit. In particular, the following important provisions are defined in the strategy: as a result of the dominance of resource- and energy-intensive industries and technologies over many years, the raw material orientation of exports and the excessive concentration of production in industrial regions, such a structure of development management was formed, which is generally inefficient and environmentally dangerous; the level of economic development and welfare of the population does not correspond to the natural, scientific and technical, agrarian and industrial potential of Ukraine and the qualification and educational level of the population, socio-historical and cultural traditions of Ukrainian people; Ukraine has international obligations regarding sustainable development, defined by UN strategic documents; the basis for the implementation of innovative transformations in Ukraine in the direction of sustainable development is the Association Agreement between Ukraine and the European Union, etc. [1].

Tourism is a part of the economic system that has been developing most actively in recent years; even the COVID-19 pandemic, which had a negative impact on international tourism in general, on the other hand stimulated the development of domestic tourism within countries (especially in Ukraine). In this sense, tourism, like any other branch of the economy, performs a dual role: on one hand, it provides income and stimulates the development of individual territories, on the other hand, it brings a significant imbalance to the development of ecosystems (due to seasonal population growth, in particular, the volume of the use of local resources, more household waste is produced, pollution of all components of ecosystems increases, as production volumes of all industries increase).

Thus, it is quite fair to apply the concept of sustainable development to tourism as well. The term “sustainable tourism” is widely known. UNWTO defined sustainable tourism as “tourism that takes full account of its current and future economic, social and environmental impacts, meeting the needs of visitors, industry, the environment and host communities” [2].

According to UNWTO, several conditions must be met for sustainable tourism: rational use of environmental resources and conditions and preservation of natural heritage and biodiversity; tolerant and careful attitude towards authentic host communities; provision of long-term economic development programs taking into account socio-economic benefits for all stakeholders (both tourists and local residents, tourism organizers). UNWTO and UNEP have specified these provisions and defined 12 goals for sustainable tourism.

A rational approach to the use of natural resources is possible when we understand the finitude of these resources (bright examples of post-industrial cities and towns are ghost towns scattered around the world, where life has recently been raging). Over time, the mining areas remain devoid of economic prospects for development and, in fact, are ecologically unpromising and unattractive for development. However, the development of mining tourism using the existing industry (dumps, quarries, mines, reservoirs) and objects of industrial heritage (used quarries and reservoirs in them, abandoned mines and backfills, old mines and tunnels) is an important economic, environmental incentive for the prospective development of mining areas, allows to diversify the economy. In fact, tourism within mining areas is an important tool that, in addition to reducing environmental hazards, can help to preserve heritage and bring the economic revitalization to surrounding areas.

2. Literature review

Mining regions are territories with different spatial coverage, which were formed as a result of the extraction of minerals from the bowels of the earth, thus they are territorially tied to deposits of mineral raw materials or entire basins. Mining regions are formed as a result of close interaction of the processes of human activity with the use of technical means and natural processes inherent in a specific natural zone. As a result of such a complex genesis, mining regions are characterized by a significant imbalance of development; they are characterized by not just the manifestation of natural processes and phenomena, but new ones, which are defined in the literature as accompanying, natural-anthropogenic, anthropogenic, natural-technogenic, post-technogenic processes. According to H. Denysyk and H. Zadorozhnya: "The mining landscape itself is under the influence of exogenous and to some extent endogenous natural processes (modern and neotectonic movements of the earth's crust). The totality of the action of human industrial activity and natural processes generate processes that are layered on the created mining-industrial complex" [3].

A number of works are devoted to the study of the problem of sustainable tourism in industrial and mining regions. Leonard [4] raise the acute issue of creating an economically profitable industrial facility in one of the tourist attractive regions of South Africa (opening of a mining enterprise) or an alternative option of creating a tourist facility (a facility world heritage Mapungubwe, Limpopo), focusing on greater perspective and ensuring sustainable development of the second [4, 5].

The work of Jonsen-Verbeke [6] is of interest and dedicated to the creation of sustainable tourism enterprises based on former industrial and mining areas. It is in this aspect that this study points to the relevance of the scientific search of the authors of this article, since the authors consider the development of mining tourism in the territory of Kryvyi Rih as a promising economic stable way for further development of an industrial city, taking into account all the requirements of sustainable tourism. Herdiansyah et al analyses possible options for the further use of post-industrial areas, one of which is ecological tourism, since it is most aimed at achieving the goals of sustainable development of heavily changed, damaged areas of the ecosystems of mining areas [7].

Ilkovičová and Ilkovič consider the possibilities of combining industrial tourism with educational and ecological ways of creating mining educational trails, entire geoparks in the territories of mineral extraction (for example, in Slovakia, Spiš, Gemer, a well-known area around Banská Štiavnica) [8]. According to the authors, this approach will make it possible to keep the economic development of post-industrial areas stable and restore their ecological potential (with the use of reclamation and revitalization means).

First of all, the studies, focused on the need to preserve industrial, including mining heritage, began to appear in the scientific literature. The issue of including mustard objects in tourist activities began to be raised much later. Accordingly, it can be noted that a number of scientific approaches have been formed regarding the interpretation of the concept of mining tourism and its combination with certain types of tourism.

There is a cohort of scientists who interpret mining tourism exclusively through the lens of heritage. In particular, Różycki and Dryglas note that mining and tourism activity are growing side by side in different regions around the world [9]. Some of the mines are closed after the end of operation. This creates an opportunity for the development of mining tourism [10]. In our opinion, this interpretation somewhat narrows the essence of mining tourism exclusively to its consideration through the prism of heritage. Quite a large number of scientists from different countries of the world use the concept of mining heritage tourism directly in their research, but the study of Cole [11] is considered one of the pioneers, in particular, he considered the transformation of reserve areas of coal mines into objects of industrial heritage in accordance with the goals of sustainable development. We will undertake research into the sustainability of UK mining heritage sites as viable tourism businesses, using the results of the UK Mining Heritage Survey conducted in 2002 [11].

Edwards and Llurdés i Coit examine the importance and perception of mines and quarries in the article "Mines and quarries: Industrial heritage tourism" as foci for industrial heritage tourism and its expansion during the last decades [12].

Jelen considers mining tourism as one of the forms of conservation, interpretation of mining heritage and its transmission to the next generation. At the same time, he emphasizes that "It is also important to find a balance between all the functions of heritage, and not to focus on only some of them for the needs of tourism. Mining heritage may meet the needs of tourism, but it should not be subordinated to these needs and created solely for the purpose of generating income" [13].

Mining tourism can be seen as an important process that helps both to interpret the mining heritage and to serve as a further source of employment and business activity after mining has ended. It is valued as a driving force that may stimulate the economic potential of mining heritage and contribute to its preservation in a form that is able to generate income [14].

In many studies, mining tourism is considered as a component of geotourism. In particular, numerous studies assess the potential of mining sites or regions for the development of geotourism [5, 7, 12, 15–17].

Slovak scientists led by Rybár carried out a significant fundamental work on revealing the structure and features of this tourist destination [18, 19]. Thus, Rybár and Štrba [19] define mining tourism as a form of tourism for both specialists and general public (laics) allowing visitors, via on-site visits of mines, museums, and cultural-historical monuments related to mining activity and life of miners, and ex-site visits of museums with mining expositions, to feel a bond with one of the oldest human activities – raw material extraction, situated and developed mostly in underground over centuries and connecting the visitor with his/her ancestors [20]. In general, analysing the relationship between mining tourism, industrial tourism and geotourism, these scientists come to the conclusion that "mining tourism should be recognized as an equivalent form of tourism, compared to geotourism and industrial tourism".

There is a group of scientists who see mining tourism in the structure of industrial tourism. In particular, Schejbal considers mining tourism a type of industrial tourism that aims to trace the development of mining disciplines and their practical impact on the history of human society [21]. At the same time, the scientist notes that the theoretical basis of mining tourism is the most problematic. The reason is that it is a complex transdisciplinary branch of science that uses earth sciences, related technical disciplines and socio-economic disciplines. Caamaño-Franco and M. Suárez though studying the planning of industrial mining heritage as a tourist attraction, but also consider it in the context of industrial tourism [22].

In recent years, the studies have increasingly used the term "post-mining tourism" [5, 20, 23], which provides for the organization of tourist activities in territories where the active process of mineral extraction has been terminated. Indeed, reimagining post-mining spaces and turning them into tourist spaces has proven to be a successful strategy for mining regions.

Numerous studies devoted to the formation of mining tourism in various geographical locations testify to the importance and relevance of this direction for mining regions. In particular, such locations are Kiruna, Pajala and Jokkmokk in Sweden [24], Las Médulas [22] and Andalusia (Linares, Alquife, Seron and Villanueva del Río y Minas) in Spain [25], Northern

Australia [26], Lota y Coronel territory in Chile [27], Ouro Preto, Chapada Diamantina, Ametista do Sul, Currais Novos and Itu in Brasil [28], Upper Silesia in Poland and Czech-Moravian country in the Czech Republic [6], Nor-Pas-de Calais in northern France [29] and many others. Similar examples of the creation of projects or already implemented ideas of sustainable tourism within mining territories are abundant in various regions of the world.

3. Methodology

The research is based on the dialectical method of cognition and a systematic approach. The research was carried out on the basis of parallel use of theoretical and empirical methods. Theoretical research was carried out using the methods of comparative analysis, abstraction, specification and generalization. The method of content analysis was used in the study of archival documents on the development of mining in Kryvyi Rih basin, various project documentation of operating industrial facilities, international documents on preservation of industrial heritage, and successful foreign examples of successful establishment of mining tourism.

The empirical component of the study included the following stages:

1. **Analysis of the terrain.** In the course of numerous expeditions to the area during the years 2004–2021, photo-fixation was carried out and the remains of industrial heritage objects were studied, which gave grounds for asserting the presence of tourist potential of these objects.
2. **Preparation of recommendations** regarding the preservation of industrial, including mining, heritage and its use in tourism. In the current period, since 2013, the city has adopted a program for development of industrial tourism, in which implementation the authors of the study were actively involved.
3. **Approbation.** Since 2013, the authors of the study have prepared a number of highly specialized excursions on mining topics, as well as complex tours to the city on industrial topics in general. This made it possible to visually assess the impressions of tourists from each visited object, as well as to analyse the objects not only from the standpoint of scientific, in particular, historical and geological value, but also in terms of their tourist attractiveness and safety for tourist activities.
4. **Selection of the most attractive mining objects for tourism.** The development of comprehensive tours of the mining theme in the city of Kryvyi Rih involved the selection of key objects and their prioritization. For this purpose, criteria for the selection of objects were formed, on which basis the most attractive objects for visiting, able to satisfy the aesthetic and cognitive needs of potential tourists, were chosen. For each of the types of mining objects (quarries, dumps, sinkholes, etc.), diagnostics was applied, which included an analysis of the positive and negative aspects for tourist activity. The application of these diagnostics enabled to select the most suitable tour programs for a certain thematic from the entire cohort of available objects.
5. **Offers for mining tourism.** The significance of mining tourism as an important direction of industrial tourism, which development has been supported in the city since 2013 at the municipal level, is substantiated; a mining-themed route has been developed; recommendations have been made on adaptation of mining facilities for visiting and the activation of tourist activities in their environment.

The use of this methodological apparatus is aimed at rethinking the tourist potential of the region in view of the significance of not only the objects that can arouse the interest of tourists, but also the importance of the mining activity of the industrial region itself.

4. Securing informed consent for image utilization

The images featuring individuals in this research were captured by the authors of this study, primarily Volodymyr Kazakov and Viktoriia Patsiuk. Both authors are certified tour guides affiliated with the All-Ukrainian Association of Guides (Civic Union "Ukrainian Tourist Guides Association"), an organization that holds partnerships with esteemed entities such as the World Federation of Tourist Guide Associations and the European Federation of Tourist Guide Associations.

The authors strictly adhere to global standards for personal data protection and respect for individual privacy. Before initiating any tour, explicit consent is obtained from participants for their photographs to be taken. Participants are informed that these images may be utilized for scientific, educational, or promotional purposes. Individuals who prefer not to be photographed are respectfully excluded from the images.

In line with the journal's policy on publishing identifiable individual data (`https://publishingsupport.iopscience.iop.org/ethical-policy-journals/`), we have meticulously followed a robust procedure to secure informed consent from all individuals whose images are featured in this article. This section provides a detailed account of our methodology to ensure full compliance with ethical guidelines and the journal's stipulations regarding image use.

1. *Identification of individuals*: Figures 6 and 8 are identified as containing identifiable human subjects. These individuals represent a diverse group, including research study participants and other relevant persons whose images are included.
2. *Contact and consent*: We proactively reached out to each of the 12 identifiable individuals included in our manuscript. Our communication encompassed a thorough explanation of why their images were being included in this article, addressing any queries or concerns they might have had about the publication.
3. *Documentation*: To ensure transparency and compliance, we meticulously documented all instances of consent obtained. For each individual, we maintained a record of the consent form, which included their explicit agreement for their images to be used in this article.
4. *Awareness of intended publication*: We confirmed with each identifiable individual that they were fully cognizant of the intended publication of their images in this manuscript. We ensured that they understood the context in which their images would be used and the potential for a broad readership.
5. *Ethical considerations*: Throughout this process, we remained committed to adhering to ethical guidelines and regulations governing the use of images in research publications. Our primary objective was to respect the privacy and dignity of all individuals featured in our article.

Additionally, we would like to express our gratitude to Dmytro Antonov for his consent to publish a photograph taken by him.

5. Results

Usually, mining, mining-industrial, post-mining-industrial regions are perceived as territories with an extremely tense ecological situation, severely disturbed landscapes (badlands), as unattractive for life, for development of various types of economic activity and tourism as well. However, using the concept and goals of sustainable development, it is possible to change such a sharply negative perception, due to the active involvement of such regions in various types of industrial tourism. For example, if several new forms of anthropogenic relief were created within a certain natural landscape as a result of mining (for example, a quarry, dump, sump), this leads to the appearance of new types of landscapes, and usually contributes to an increase in the contrast of the environment, and in future, the growth of its attractiveness, the possibility of many options for further development.

Mining regions that combine operating industrial enterprises, objects of industrial heritage, and post-industrial objects within their territory essentially have a whole range of options for prospective sustainable development. One of these options is mining tourism, with means of which it is possible to attract numerous tourists to mining areas.

Having analysed the existing approaches to the interpretation of the concept of mining tourism, we believe this tourist direction does not belong to the structure of geotourism, since in our understanding geotourism is aimed at studying and visiting mainly natural objects. Although, indeed, quite often geotourism and mining tourism have a common object to visit (exposure of mineral deposits, rocks exposed in mines, etc.). At the same time, when the concept of mining or industrial heritage tourism is used, the attention is focused only on heritage objects. A similar situation is with postmining tourism, where the emphasis makes on visiting transformed objects, so these subspecies absolutely exclude the production component. However, the objects of active industry are working mines, functioning mining and beneficiation plants definitely are and can be objects of mining tourism. Therefore, we defend the opinion that mining tourism is an autonomous direction that is a part of the structure of industrial tourism, which combines heritage objects, active industry and regenerated production objects.

As Rybár and Hronček claim, a mining tourist is particularly interested in [18]:

- mining traditions,
- unique machinery,
- modern mining technology,
- illegal visits of underground mines (adrenaline, adventure, illegal collection (robbery)),
- special events in the underground (weddings, concerts, masses, celebrations),
- sports activities (adrenaline sports: rock climbing, motocross, mountain biking, underground collective sports: football, table tennis),
- recreation and wellness (recultivated mining works after surface mining: swimming, sunbathing, walking, in modified spaces of underground mines: health stay rehabilitation (resting, sleeping) in the unique conditions of some types of rocks, jogging, Nordic walking,
- geology, mineralogy, paleontology, collecting, ecology, and biology, unique fauna moreover, flora occurring during and after the mining activity as well as in the recultivated area,
- free time activities utilizing vast spaces (mostly connected to surface mining – tank driving (!), paintball, cross golf),
- other.

Ukraine has a significant potential for development of mining tourism, where work on extraction of various minerals was and is being actively conducted. Kryvyi Rih is a city with the largest range of mining facilities and landscapes. This is due to [30]:

- 8 main and 37 auxiliary iron ore mines here;
- 9 operating quarries, 8 of which are iron ore and 1 is a granite quarry;
- 39 completed quarries;
- 85 dumps;
- 26 failure zones and displacement zones in mine fields of underground mines;
- 15 sludge storage facilities of mines and mining and beneficiation plants;

- 34 speleological objects: 12 open shafts of mines (one lignite and the rest iron ore), 3 shafts (the old mine "Chervonyi Hirnyk", the old mine of Kolachevskyi, the collapsed mine "K-D-1"), 11 tunnels (Kochubeyivskyi, Rakhmanivskyi, Pokrovskyi, etc.), 2 underground workings (at the old Kochubeyivskyi mine), 1 shaft (Northern ventilation mine), 2 downhole shafts of Kozatska mine, 3 gesenks of rising workings (in the ceiling of the shaft of the old Northern ventilation mine and on the sides of the bottom shaft of the mine "K-D-1");

The presence of the listed objects is a powerful resource base for the development of industrial tourism in general and mining tourism in particular. In 2013, the city adopted the Industrial Tourism Development Program for 2013–2015 [31], which was subsequently extended until 2020 and then until 2024 inclusive [32]. After that, active work started to transform an exclusively industrial city into a tourist destination.

However, expeditionary studies of the mining heritage and landscapes of the city took place long before the adoption of the program. Back in 2004, local history work on the study of these objects was initiated by the geographer Volodymyr L. Kazakov, who was joined by his colleagues and students. This made it possible to create a register of mining objects in Kryvyi Rih. With this, the work on development of tourist activities at mining facilities started. One of the directions of this work was a detailed study of mining sites, analysis of their tourist potential and creation of excursion routes. The preparation of these routes and their implementation for both citizens and city guests made it possible to determine the list of the most attractive objects in a practical way that are able to stimulate tourists to come to Kryvyi Rih.

The following were the criteria for selecting objects for their inclusion in the tour programs:

- uniqueness and feature of the object;
- significant morphometric parameters;
- the historical significance of both the phenomenon of industrial heritage and from the point of view of the introduction of innovative technologies at these objects in a certain period of time;
- the possibility of access to the object (convenience of entrances and approaches, the possibility of entering without various agreements with enterprises);
- the object illustrates the processes of natural renaturalization and reclamation;
- the object is a part of the cultural landscape of this region and has an aesthetic appeal.

The existing criteria made it possible to determine the key ones for tourists to visit from the entire list of objects. As experience and communication with tourists show, working quarries and mines arouse the greatest interest among visitors. And if the quarries were visited on a permanent basis, and the open pit of Southern Mining-and-Processing Plant was generally considered the most iconic industrial monument of the city, which is included in the ERIH network [33], then the visits to the mines took place very fragmentarily. Although the Kryvyi Rih mines are the deepest mines in Europe ("Yuvileyna", –1720; "Ternivska", –1620, "Kozatska", –1615), and their headframes are figuratively called "Kryvyi Rih Eiffel Towers" (figure 1). The headframes of some mines have a height of 102–108 metres [34].

Currently, the programs of tours by functioning mining facilities most often include the open pits of JSC "Southern Mining-and-Processing Plant" or Hannivskyi open pit of PJSC "Northern Mining-and-Processing Plant" (figure 2).

Regarding mining complexes, most tourists prefer to go down to the depths of the earth, but it is very difficult to agree on safety issues with enterprises. Visiting surface mining complexes with a climb to the top of pitheads looks more promising in the tourist context. Among the working facilities, the "Yuvileyna" and "Kryvorizka" mines have the best opportunities for this.

The advantages and disadvantages of each of the working objects are presented in the table. Since there is a large number of mining facilities in the city, it was decided to focus on the

Table 1. Analysis of existing suitability for tourism of functioning mining facilities.

Name of the object	Positive features for tourism	Negative features for tourist activity
	Open pits	
Open pit of JSC “Southern Mining-and-Processing Plant”	• availability of 2 equipped covered observation decks; • availability of convenient entrances; • next to one of the observation decks there is a repair shop for truck vehicles, this allows to see the large-sized equipment relatively close; • relative proximity to the administrative centre of the city; • the original shape of the career is heart-shaped; • significant morphometric parameters; • facility of the ERIH network; • the quarry is a part of the structure of the enterprise, which was the first mining and beneficiation enterprise in the territory of the former USSR.	• the need to coordinate a visit to the facility with the management of the enterprise; • lack of toilets; • lack of a point of sale of souvenir products;
Hannivsky open pit of the PJSC “Northern Mining-and-Processing Plant”	• the possibility of free access; • considerable length – 5.8 km;	• located in the remote northern part of the city; • there is no equipped indoor area for visiting; • lack of toilets
	Mines	
“Yuvileyna” Mine	• one of the highest headframe in the city with a height of 108 metres; • most of the lifting is carried out in the elevator; • a wonderful panorama of the northern part of the city;	• the need to coordinate a visit to the facility with the management of the enterprise; • location in the relatively remote northern part of the city
“Kryvorizka” mine	• one of the highest headframe in the city with a height of 102 metres; • ascent is carried out in an elevator; • a wonderful panorama of the central part of the city; • located close to the administrative centre of the city	• the need to coordinate a visit to the facility with the management of the enterprise

Figure 1. The panorama of mining landscapes and mine's dills in Kryvyi Rih (photographed by Volodymyr L. Kazakov from the headframe of the Hihant-Hlyboka mine).

two main facilities, which are the most represented in excursion programs, when analysing the advantages and disadvantages. At the same time, the attention was focused precisely on the existing positive and negative features. The topic of military influence was not raised, as we believe it will be necessary to make a separate study after the end of hostilities.

In addition to the objects of the active mining industry, tour programs in Kryvyi Rih include abandoned mining objects that have formed various man-made landscapes – flooded quarries, dumps, failure zones and other specific objects. These objects are freely accessible for tourists, and some of them could be an excellent springboard for the implementation of various revitalization projects. The advantages and disadvantages of each of these objects are also presented in the table 2.

Some of these objects are shown in the figure 3.

In addition to operating mining facilities and various landscapes, tour programs include auxiliary facilities:

- Open-air museums of mining equipment of PJSC "Northern Mining-and-Processing Plant" (figure 4) and the Mining Department of PJSC "ArcelorMittal Kryviy Rih", where a variety of mining equipment is presented: dump trucks, belt conveyors, magnetic separators, etc. Both of these facilities are included in the ERIH network;
- Museums of labour glory of mining-and-processing plants: Inguletskyi, Southern, Central and Northern ones (figure 5). They reveal the history of the creation and development of

Figure 2. Hannivskyi open pit of PJSC "Northern Mining-and-Processing Plant" (photographed by Volodymyr L. Kazakov).

enterprises, which is reflected in the main documents and photographic materials. You can see reduced samples of the machinery that works at the plants. Some museums have mock-ups of quarries that show installations of the production process. On TV screens, you can see the production process in quarries in real time, including blasting;

- Geological and Mineralogical Museum of Kryvyi Rih National University. This museum has a rich collection of rocks and minerals from around the world. Its entire collection of rocks was included in the State Register of Scientific Objects of National Heritage by a resolution of the Cabinet of Ministers of Ukraine;
- The Training and Course Centre of Kryvyi Rih Iron Ore Plant, which is a unique training ground – a model of the mine workings, located at a 3-metre-depth. Future miners are trained here, and tourists can get to know the essence of mining work, using mining equipment (scraper winch, jackhammer, drill, etc.). Mining horizons are simulated here, where samples of real equipment operated at the enterprise are located, as well as a camera for the temporary stay of miners in case of emergency situations (figure 6);
- 3D video gallery, the object is indirectly related to mining tourism, as it is located in Europe's largest flower clock. And it is here that they show films in 3D format about the history of the city, which is directly related to the formation of the mining industry.

Figure 3. Different types of mining landscapes in Kryvyi Rih (photographed by Volodymyr L. Kazakov (a, b, d) and D. Antonov (c)): a) Karachunivskyi flooded granite quarry; b) the panorama of man-made landscapes from the Burshchytsky dump; c) the failure zone near the Ordzhonikidze mine; d) Kryvyi Rih Grand Canyon.

Table 2: Analysis of existing suitability for tourism of mining landscapes.

Name of the object	**Positive features for tourism**	**Negative features for tourist activity**
	Flooded quarries	
Oktyabrskyi granite quarry	• significant dimensions and depth make it possible to organize various types of water activities: swimming; boating, SUP-boarding, diving; • aesthetically attractive landscapes	• spontaneous recreation; • lack of small infrastructure facilities (toilets, garbage cans, information signs)

Continued on next page

Table 2 – continued from previous page

Name of the object	Positive features for tourism	Negative features for tourist activity
Karachunivskyi granite quarry	• location near one of the largest man-made waterfalls of Ukraine; • significant dimensions and depth make it possible to organize various types of water activities: swimming; boating, SUP-boarding, diving; • aesthetically attractive landscapes	• the presence near the dam of the Karachunivskyi reservoir, which was destroyed during rocket fire; • spontaneous recreation; • lack of small infrastructure facilities (toilets, garbage cans, information signs); • lack of convenient entrances
	Dumps	
Burshchytskyi dump	• a wonderful panoramic view of the city; • a gentle rise; • the possibility of inspecting the objects of the current industry (quarry, dump of PJSC "ArcelorMittal Kryvyi Rih") • location of industrial heritage sites nearby – the remains of the mine No. 5; Belelyubskyi bridge; remnants of the rolling railway of Hdantsivskyi Iron Foundry, etc.; • repeated practice of conducting both daytime and evening excursions to the dump; • significant relative height – about 60 metres; • the object was repeatedly filmed in Ukrainian travel shows	• lack of equipped approach to the object; • the presence of a solid household waste landfill next to the object; • lack of small infrastructure facilities (toilets, garbage cans, information signs)
Petrivskyi dump	• a wonderful panoramic view of the city; • the possibility of inspecting objects of active industry (quarry, dump of the Central Mining-and-Processing Plant) and industrial heritage (Shmakivska mine, built in 1886); • availability of convenient entrances to the facility • an organized celebration of the New Year was held at the object for several years in a row;	• lack of equipped approach to the object; • the ascent is stony and quite steep; • lack of small infrastructure facilities (toilets, garbage cans, information signs)

Continued on next page

Table 2 – continued from previous page

Name of the object	Positive features for tourism	Negative features for tourist activity
	• the locals regularly organize actions to plant trees for the purpose of landfill reclamation	
	Failure zones	
The failure zone near the Kozatska mine	• ccale forms; • nearby is the active two-hole superstructure of the Kozatska mine • the uniqueness of the object; • availability of convenient entrances to the facility; • a significant educational function from the point of view of sustainable development	• located in the remote northern part of the city; • lack of small infrastructure facilities (toilets, garbage cans, information signs);
The failure zone near the Ordzhonikidze mine	• Scale forms; • the uniqueness of the object; • located in the ore field of the oldest operating mine in Kryvyi Rih (Ordzhonikidze mine was founded in 1934 and operates up to this day); • availability of convenient entrances to the facility	• located in the remote northern part of the city; • landslide processes are not fully completed; • lack of small infrastructure facilities (toilets, garbage cans, information signs)
	Specific mining objects	
Kryvyi Rih Grand Canyon	• a unique formation that has no analogues in Ukraine; • a wonderful panoramic view of man-made landscapes; • availability within walking distance of the site of historic mines formed in 1881 – dates of the beginning of iron ore development in the region	• sufficient distance from the administrative centre of the city; • lack of convenient entrances; • lack of toilets
Red lake	• proximity to the administrative centre of the city; • availability of convenient entrances to the facility; • uniqueness; • a significant educational function from the point of view of sustainable development	• lack of toilets

A number of factors influence the direct inclusion of this or that object in the tour program:

- immediate duration of the tour;
- season of the year;

Figure 4. Open-air museum of mining equipment of PJSC "Northern Mining-and-Processing Plant" (photographed by Volodymyr V. Kazakov).

- available weather conditions;
- by which means of transport and where the group is coming from and where it goes next;
- age of tourists;
- specific requests from tourists.

Based on this, a matrix was created for the inclusion of certain mining objects in tour programs (table 3).

The location of these objects within the city of Kryvyi Rih is shown on the map (figure 7).

Monitoring of the websites of domestic tourist operators confirms that since 2016 the offers of tours to Kryvyi Rih have appeared from the following tour operators: "Kraina UA", "Anga Travel", "Ukraine Incognita" (Kyiv), "Visit" (Lviv), "Navigator" Ukraine", "100% Rest" (Kharkiv), "Globe of Ukraine" (Zaporizhya), "Golden Trips" (Dnipro), as well as Odesa tourist hub and tourist centre "Ryba Andriy" (Dnipro), tourist clubs "Bidnyazhka" (Vinnytsya), "Good trip" and "Wild Tour" (Kyiv), tourist companies "Mandrivochka" (Mykolayiv) and "InGreen" (Poltava) and a number of travel agencies from the cities of Kropyvnytskyi, Mykolayiv, Kherson, Kremenchuk, Dnipro, Nikopol, etc., which position themselves exclusively in social networks (figure 8).

6. Conclusions

The development of mining tourism in Kryvyi Rih has all the resource possibilities, but the presence of a powerful resource is not a guarantee of effective tourism. Before this resource is consolidated into a quality tourist product, it must be brought to the proper level. For this, we offer the concept of 3R – reclamation – revitalization – rethinking.

Table 3. Matrix for including mining objects in tour programs.

Reclamation. Its goal is to restore the productivity of areas disturbed by the mining industry and return them to different uses. This involves carrying out a complex of engineering, mining, reclamation, agricultural and forestry works. Restoration of lands disturbed by mining operations is a complex process of landscape regeneration and is carried out in several stages:

- preparatory, on which mining spaces are studied and typified and, due to their specificity, promising opportunities for their economic use are determined;

Figure 5. Museums of labour glory of JSC "Southern Mining-and-Processing Plant" (photographed by Viktoriia S. Patsiuk).

- the stage of mining reclamation is the engineering preparation of the territory for various types of further reclamation, and includes: surface planning; creation of slopes of optimal structure and parameters; regulation of the water regime; various amelioration measures; construction of access roads and other structures;
- the stage of biological reclamation and the transition to the targeted use of mining spaces, aimed at the final restoration of fertility and biological productivity of disturbed lands, the implementation of forests and meadow plantations, the arrangement of the infrastructure of the planned space.

The reclamation of mining spaces and their involvement in the tourism sphere should be adjusted by knowledge about the structure, properties and technology of operation of a specific object and all possible directions of improvement or rational changes in its condition. Therefore, for each landscape, its own development and optimization trend is recommended. Thus, for example, the mining landscapes of the Oktyabrskyi granite quarry and dump, due to long-term self-development and spontaneous recreation, do not require special methods of reclamation, it is enough only to control the volume of water inflows, the ecological quality of the water body and cultivate the spaces, create tourist infrastructure. At the same time, relatively chaotic reclamation is taking place at the landfills of the city, especially at Petrivskyi, by local residents.

Revitalization is a process aimed at the complex transformation of depressed industrial facilities and territories for their functional reformation in order to improve the social living conditions of the population. In Kryvyi Rih in 2019 "Urban hackathon" took place, within which framework the prospects of five industrial facilities of the city were discussed. Four

Figure 6. Lithuanian students during an excursion to the Training and Course Centre of Kryvyi Rih Iron Ore Plant (photographed by Viktoriia S. Patsiuk).

of these mining-related objects are: the “Artem-2” mine, premises and pithead of the mine “Ventylyatsiyna-3”, the premises of the former Lenin Mining Administration, and Burshchytskyi dump.

Expert groups prepared options for the revitalization of these objects. On the site of the former management office of the Lenin mine it is proposed to create a youth centre, on which roof it is planned to create an observatory with a relaxation area. Four floors of the building can be thematic ones, where there will be rooms for work and rest, an art hub, a hostel, a multifunctional centre, a thematic museum with the involvement of moving and interactive elements, exhibition halls, etc. Another option was to create a social centre “InTerny” on the basis of this building. The task of the centre is to help the most affected categories of the population.

On the territory of the mine “Ventylyatsiyna-3” it is proposed to create an active leisure centre “StreetTown”. The buildings offer the following locations: an administrative zone, a food zone, a sanitary zone, an indoor skate park, a trampoline, dance floors. It is also planned to place speleological training locations in the mine shafts and a climbing wall on the wall of one of the buildings. Near the buildings a small parking lot, a skate park, a bicycle area and a fountain with iron fish as a symbol of the iron ore basin are planned to be created [34].

On the territory of Burshchytskyi dump, the creation of a landscape-industrial park “Vidval” is proposed. The peculiarity of this project is the zoning of the territory into several blocks:

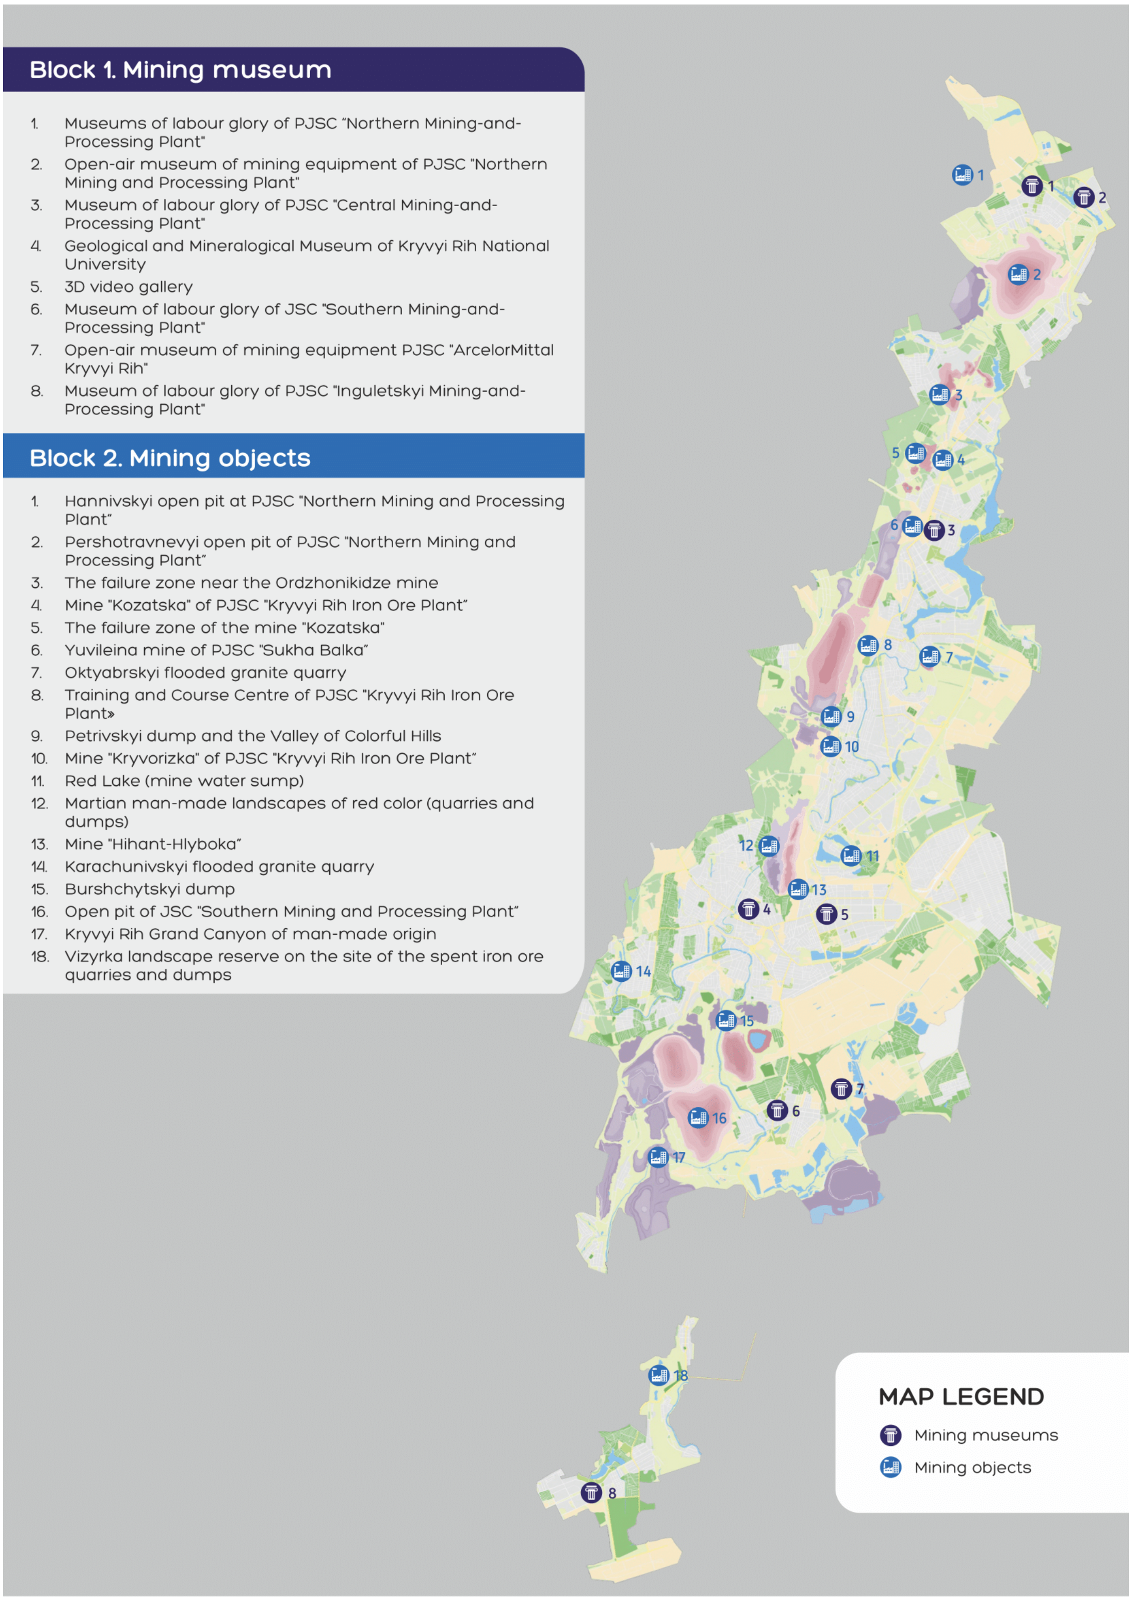

Figure 7. Map of Kryvyi Rih mining sites included in the tour programmes.

Figure 8. A group of tourists on the observation deck of the open pit at JSC "Southern Mining-and-Processing Plant" (photographed by Volodymyr L. Kazakov).

1) sports – since the Ingulets river is nearby, it is planned to equip a zone for riding on water vehicles, as well as to set aside a zone for dirt track and a motorcycle track; 2) recreational – it is planned to lay eco-trails on the slopes of the dump; 3) infrastructural – here it is planned to arrange entrances and parking lots, allocate the territory for a camping site, as well as create a food and picnic area; 4) animated – it is planned to create the inscription "Crooked Horn" on the top of the dump, to organize a park of thematic gabions nearby, and also to conduct a cableway across the Ingulets river to the nearby dump.

The territory of the "Artem-2" mine is the most promising for revitalization. It is proposed to create a multifunctional park of industrial culture (PIK) "Shakhta". The main attraction of the object should be the inclined shaft, which will be used to descend to the mine. On the walls of the shaft it is proposed to create a historical engraving of the development of metallurgy in the city. It is proposed to create a museum of mining equipment in the premises of the mothballed mine. Other premises can be classified as small laboratories and workshops with master classes. In the surrounding area, it is proposed to create an open-air museum of mining equipment, as well as a sports sector with existing playgrounds, courts, a climbing wall, etc. [34].

In addition, in Kryvyi Rih there are also significant prospects for revitalization of the "Higant-Hlyboka" mine pit, which offers a wonderful panorama of the city, the "Pobeda" mine, the flooded Oktyabrskyi and Karachunivskyi granite quarries, as well as Vizyrka landscape reserve, which was created on the basis of 3 exhausted iron ore quarries. On the territory of each of these objects, it is possible to create landscape and industrial park areas, expanding the range of possible areas of recreation and provision of services.

Rethinking. The organization of innovative tourist activities for old industrial regions requires a radical rethinking not only of the resource potential of the territory, but also of methods and approaches to conducting economic (including pure tourist) activities in these regions and realizing the need for total diversification of the economy of these territories not only from the point of view of branching out their production structure, namely due to the growth of the segment of the sphere of services and creative industries.

It is necessary to radically change the perspective of the assessment of mining objects, that is, to perceive the mining heritage not only as an echo of the past, and functioning mining enterprises – not only as a raw material appendage, but to realize that both the heritage and the operating industry have a significant potential for educational and cognitive direction.

It is the revaluation of directions for the use of mining objects and landscapes that is an important factor not only in the development of the tourism potential of mining territories, but also in raising the level of the industrial culture of the population. All this will generally have a significant positive economic, social and humanitarian effect.

Abstract. The article raises the problem of using Earth remote sensing data to collect evidence of damages caused by the military actions of the Russian army in Ukraine. The core data set obtained by deciphering aerial photographs reflects the general current and operational situation in the affected area, reducing the subjectivity and uncertainty of damage characteristics on the ground. Earth remote sensing data visualize visible damage to the environment, which can be recognized and assessed using images of different spectral bands with appropriate resolution. Among the damage caused to the environment as a result of hostilities, according to the Earth remote sensing data, it is possible to study: degradation of land resources, destruction of natural ecosystems by fires, destruction of structures (buildings) and structures. Satellite images with a very high resolution ($\leq$ 1 m) make it possible to quantify the degree of damage to the soil surface due to shell explosions: the amount of metal fragments and chemicals that have entered the soil, damage to the biological cover, etc. Images with a resolution of less than 30 meters in the short-wave infrared (SWIR) range allow to depict the devastating effects of forest and steppe fires caused by military actions. Using two different time frames, one before the fire and one after, will ensure the accuracy, objectivity and reliability of the evidence collected. These very high resolution Earth remote sensing images are used to investigate the destruction of structures (buildings) and constructions. The analysis of satellite images guarantees the diagnosis of the condition of the building in three degrees of destruction: completely destroyed, partially destroyed or not destroyed. In order to ensure the storage, quick search, analysis and visualization of all useful information obtained from the data of Earth remote sensing, it is necessary to use geoinformation systems.The proposed methodology for assessing military destruction is characterized by simplicity, accuracy and versatility, and does not require the use of expensive equipment.

1. Introduction

Constant armed conflicts on the planet throughout the entire existence of mankind lead to catastrophic consequences. So, by the end of 2021, almost 80 million people have lost their homes and been forcibly displaced around the world due to armed conflicts. The full-scale, unprecedented war unleashed by the Russian Federation on the territory of Ukraine since February 24, 2022, in terms of the scale of military operations, human casualties, destruction and material losses, has virtually no analogues since the Second World War. More than 30% of the territory of Ukraine suffered losses from war-related pollution, destruction, bombings, etc. In just half a year of war, the amount of losses from Russia's military aggression, confirmed by the World Bank, amounts to more than 340 billion dollars.

In connection with this, there is an urgent issue of receiving reparations and compensations from the aggressor country for the restoration and reconstruction of Ukraine. The amount and nature of reparations must be determined in accordance with the caused damage. That is why there is a need to measure and confirm war losses.

Such information is collected on the base of the analysis of tens of thousands of public reports from citizens, government, local authorities about loss and damage across the country, as well as on the basis of public sources. However, considering the scale of the damage, it is clear that we need to look for more modern and sophisticated forms of collecting evidence of damages for legal proceedings and lawsuits against the aggressor.

One of the most promising directions in this matter is the use of Earth remote sensing technologies. Aerospace images ensure the independence and persuasiveness of the evidence obtained due to the decryption of the data of ERS. Importantly, this baseline data set reflects the overall actual and operational situation of the damage zone, reducing the subjectivity and uncertainty of damage characterization on the ground.

This is facilitated by access to high-resolution images at various ranges and with a frequency of observation ranging from one to two weeks to daily monitoring.

Currently, in the literature, one can find a sufficient number of examples of the use of ERS methods in areas of armed conflicts in order to study the impact of their consequences on the geographical environment. Conventionally, all these studies can be divided into three areas: legal, applied and methodical.

Legal publications address various aspects of the use of Earth remote sensing data as evidence for legal claims. Most authors [1–3] point to the fact that the value that this unique form of evidence can have is still underutilized compared to its potential. The main problems associated with the use of aerial photographs as evidence in international criminal courts are the limited availability of relevant images, the cognitive bias of external organizations conducting the analysis of ERS as well as the lack of legal certainty in this area (there are no accepted forensic medical standards and methodologies).

As a result, in their works the authors consider various ways to overcome these difficulties, among which the main ones are the following:

- due to the digital and technological nature of satellite evidence, it is especially important to establish its accuracy, objectivity and reliability;
- the development of standardized methods of collecting, storing and interpreting the data of ERS is required;
- for the use of aerial photographs as evidence in courts, it is necessary for judges to be familiar with geospatial data technologies.

Scientific publications of an applied orientation demonstrate the attention of the world public to the monitoring of armed conflicts with the aim of analyzing the observance of human rights, tracking genocides, analyzing the migration of refugees, etc. As an example, we can cite the use of remote sensing data of time series (night lights) to study the development of the crisis and refugee flows after the "Arab Spring" [4]. By means of satellite analysis using Landsat 8 images (2013 and 2015), Sawalhah et al identified the impact of population growth and Syrian refugee settlements on rangeland degradation in Jordan [5].

Obtaining information in near real time provides an opportunity to develop rapid response measures in the provision of assistance and crisis management, as well as early warning systems to minimize civilian casualties in war zones [6].

The impact of armed conflicts on the ecological state of the geographical envelopes of Asia, Africa, and Latin America is considered by Hoffmann et al [2], Ordway [7], Shatnawi et al [8]. Thanks to information obtained from satellite images, researchers studied how military confrontation directly affected the physical environment during the war and the post-war period.

Today, there are examples of the use of ERS data to assess damages from military conflicts by international organizations, such as the United Nations, the World Bank, Amnesty International, etc. [9]. Thus, since 2003, the United Nations Satellite Center (UNOSAT) provides analysis of satellite images during humanitarian emergencies related to natural disasters, complex emergencies and military conflicts. As an example, we can cite the results of damage assessment of buildings in Kherson (Ukraine), based on images received from the WorldView-3 satellite. Analysis of images taken on October 14, 2022 revealed 88 buildings with visible damage. Of these, 4 are destroyed, 69 are substantially damaged, 4 are moderately damaged, and 11 are possibly damaged.

The methodical features of the use of ERS technologies during the monitoring of territories affected by the war were not left out of the attention of scientists. Most of the authors [10–13] note that damage assessment using satellite images is a complex, painstaking process that takes a lot of time and often requires site inspection.

In this regard, more and more researchers pay attention to the use of computer vision to identify different types of damage using aerial imagery. Using the previous stage of machine learning, it becomes possible to effectively apply the automated building damage classifier [12, 14]. As a practical embodiment of this approach, we can give an example of the development of the company "NeuroMarket" (Ukraine), which has created a neural network algorithm that can analyze the degree of damage caused to a building using images from satellites and drones.

Therefore, despite the significant interest in this problem in the scientific literature and world practice in the last 10 years, it should be noted that investigations on the study of environmental damage as a result of military actions are of a purely local, narrowly regional nature.

The objective of this research is to explore the potential application of Earth remote sensing techniques in areas affected by armed conflicts. The study aims to investigate and assess the impact of these conflicts on the geographical environment and the state's economy.

2. Methods

Different time satellite panchromatic and multispectral images with different resolutions have been used in the work (table 1). Image sources are open platforms *FIRMS, EO Browser, Google Earth PRO, USGS Earth Explorer and Maxar Technologies.* It is important that all the sources of the images are official and ensure the independence and persuasiveness of the evidence obtained through the decoding of satellite images. Image processing has been carried out in the open *Quantum GIS* environment.

3. Results and discussion

A full-scale war in Ukraine causes significant damage to the state of nature and the country's economy. According to the estimates of *the KSE Institute*, during just six months of the war, the amount of direct lesion to the economy of Ukraine from the damage and destruction of residential and non-residential buildings and infrastructure (in monetary terms) amounted to \$108.3 billion. Taking into account indirect losses (reduction in GDP, cessation of investments, outflow of labor, additional costs for defense and social support, etc.), this figure ranges from \$564 billion to \$600 billion. Determining all damages, documenting them, and assessing the

Table 1. General indicators of the satellites which images were used in the work and the types of the determined environmental damage.

№	Satellite	Spatial resolution (m)	Spectral bands	Periodicity of removal (day)	Type of environmental damage
1	Terra MODIS	250–1000	36	1–2	Spatio-temporal indicators of fires
2	Landsat 8	15, 30	11	16	Destruction of natural ecosystems by fires
3	Sentinel 2A, 2B	10, 20, 60	13	5	Destruction of natural ecosystems by fires
4	GeoEye	0,46	pan	1	Degradation of land resources and destruction of submitted and constructions
5	WorldView–3	0,31	pan	1	Degradation of land resources and destruction of submitted and constructions

scope for obtaining further reparations and compensations from the aggressor country is a very important task for various government and scientific structures and organizations.

Earth remote sensing data visualize a variety of environmental damage. But at the same time, it should be borne in mind that this is a visual monitoring method and it can be used only to assess those damages that can be visually recognized and evaluated using images of different spectrum ranges and the corresponding spatial resolution.

Thus, of all the environmental damage caused by hostilities, the following can be studied with the help of the data of ERS: degradation of land resources, destruction of natural ecosystems by fires, and destruction of structures (buildings) and constructionls. Let's consider each of these damages separately.

A. Degradation of land resources

One of the most negative and destructive consequences of military operations is the disruption of the soil ecosystem. Millions of exploding projectiles leave behind thousands of square kilometers of excavated Ukrainian land, contaminated with fragments of metal and chemicals.

Satellite images with a very high spatial resolution ($\leq$ 1 m) make it possible to estimate the extent of disturbances in the surface soil layer. Figure 1 shows satellite images of fields in the Donetsk region, taken before and after the intervention of the Russian invaders. In the picture taken after the beginning of the military aggression, we see agricultural fields dotted with hundreds of artillery shells. Funnels of such density almost completely destroy the soil cover and make it unsuitable for use.

Shelling was carried out with the following types of weapons:

- 82 mm — mortars with 82-mm fragmentation and high-explosive fragmentation mines;
- 120 mm — "Grad" installations, field and self-propelled howitzers;
- 152 mm — mortars with 152 mm shells, guns and howitzers;
- 220 mm — rocket salvo fire system "Hurricane".

The size of the recess in the soil corresponds to the caliber of the projectile: 220 mm – the diameter of the funnel is about 7 m, 152 mm – 4–6 m, 120 mm – 2.5–3.5 m, 82 mm – about

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012132 doi:10.1088/1755-1315/1254/1/012132

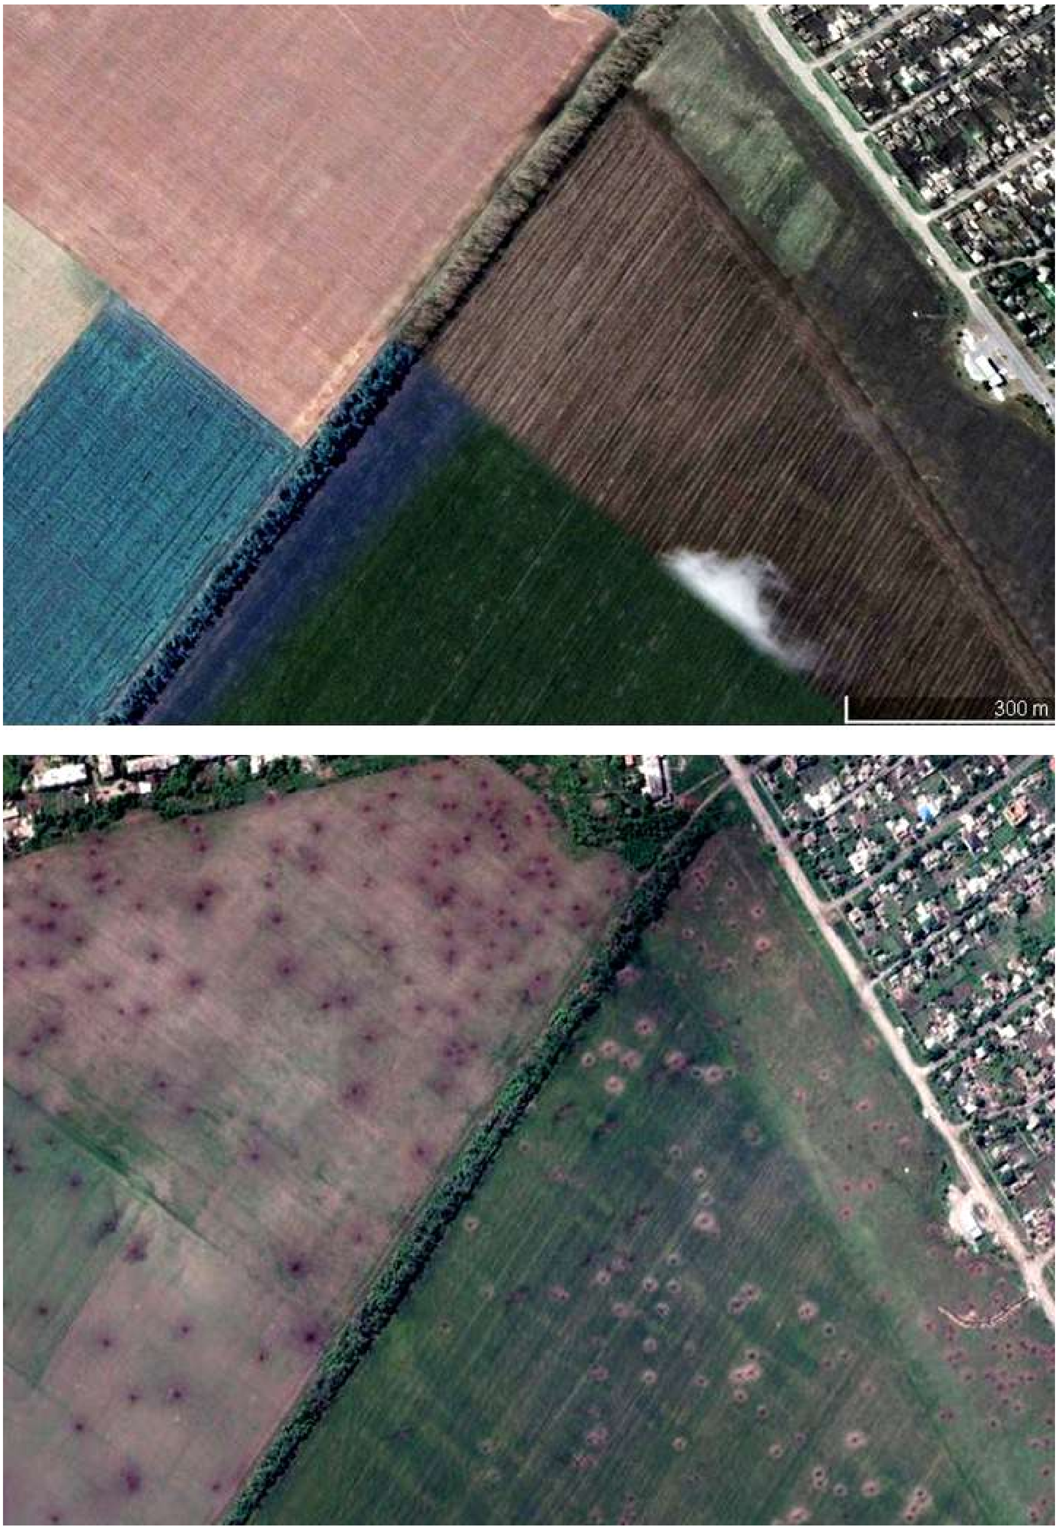

Figure 1. Satellite image of agricultural land near the town of Lyman (Donetsk region). 48.988056. 37.833333. Above – 8.05.21. Below – 26.05.22. [Source: Satellite Image 2022 Maxar Technologies, EPA].

1 m [15]. Using the scale of the picture, you can easily determine not only the number of shelling, but also the caliber of the projectiles.

Figure 2 shows an example of soil ecosystem disturbance calculations. On a plot of agricultural field near the town of Lyman (Donetsk region) with an area of 0.06 square km (200 m x 300 m) there are 71 funnels from explosions. Among them: 6 – from the caliber of 220 mm, 40 – 152 mm, 12 – 120 mm and 13 – 82 mm (table 2).

Artillery projectiles produce fragments weighing 1 gram or more: caliber 82 mm – 1,200–1,550 pieces, 120 mm – 1,600–2,350 pieces, 152 mm – 2,700–3,500 pieces, respectively [16]. Using these data, it is possible to calculate that on a certain section of the field with an area of 0.06 square

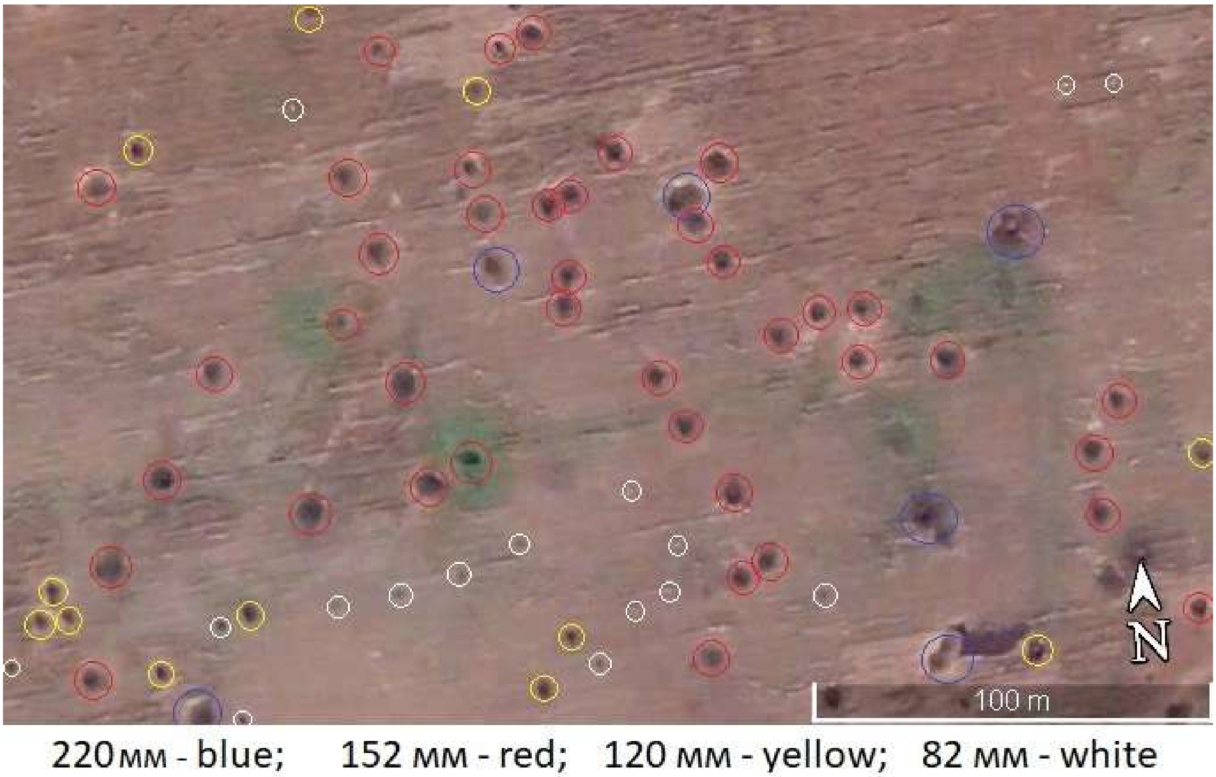

Figure 2. Counting funnels from projectile explosions of various calibers in a field near the settlement of Pisky (Donetsk region). 48.075556. 37.664167. [Source: Satellite Image 2022 Maxar Technologies, EPA].

Table 2. Indicators of soil degradation of the specified territory.

Ammunition caliber, mm	Number of funnels	Number of projectile	Amount of chemical elements, kg				Amount of explosive, kg
			Fe	C	S	Cu	
220	6	23000	570	8.8	9.2	4.4	235
152	40	124000	1500	23	28	10	210
120	12	24000	210	3	4	1.5	25
82	13	18000	38	0.6	0.65	0.25	5
In general	71	189000	2318	35.4	41.85	16.15	475

km, almost two hundred thousand metal fragments with a total weight of about 2.5 tons fell into the soil.

These metal fragments are dangerous. In addition to iron and carbon, they also contain sulfur and copper [15, 16]. Taking into account the number of projectiles and their caliber, it is possible to calculate the total amount of chemicals that have entered the environment in the studied area – this is about 35 kg of carbon, 32 kg of sulfur and 16 kg of copper (table 2).

Chemical elements that have entered the soil are very dispersed. This will contribute to their rapid entry into the soil, and from there into surface water, and in this way they enter the cycle of environmental substances and will be included in trophic chains. So, for example, copper is a heavy metal, individual compounds of which can be quite toxic [17].

In addition, all modern high-explosive and high-explosive fragmentation projectiles release an average of 1.2–1.5 cubic meters of soil per 1 kilogram of explosive [17]. Based on this, as a result of the explosion of 71 shells, the mass of the explosive substance (amotol, hexane) totaled 475 kg. As a result, almost 700 m^3 of soil was uprooted, disrupting its biological cover.

Such destruction of the soil cover together with other negative factors make the territories of rural lands unsuitable for use. It takes hundreds of years to restore land resources from pollution. Even now, in 300 days of the war, according to preliminary estimates by experts, no less than 10 billion dollars will be needed to restore Ukrainian land.

At the same time, it should be taken into account that satellite images can serve as indirect evidence of the negative consequences of shell explosions on the environment.During the detonation of amotol and hexogen, a number of chemical compounds are formed – carbon monoxide, carbon dioxide, nitrogen oxide, nitrogen dioxide, formaldehyde, cyanic acid vapors, nitrogen, as well as a large amount of identified and unidentified toxic organics [17]. It is impossible to calculate even an approximate number of these emissions. Under their influence, surrounding soils, wood, and structures are oxidized.

B. Destruction of natural ecosystems by fires

Monitoring of fire areas is one of the most common areas of practical use of data from ERS So, for example, *NASA* has created *Fire Information for Resource Management System (FIRMS)* scale fires on the Earth's surface. The corresponding site shares near-real time data on active fires from the Moderate Resolution Imaging Spectroradiometer *(MODIS)* aboard the *Aqua and Terra* satellites and the *Visible Infrared Imaging Radiometer Suite (VIIRS)* aboard *S-NPP* and *NOAA 20* (figure 3).

The resolution of Terra MODIS infrared channels is 1 km/pixel. This means that each detected fire cell is displayed as a point in the center of a 1 km × 1 km pixel. It is practically impossible to determine the objects of fires and assess the consequences of fires in images with such a spatial resolution. They can be used only to determine the spatio-temporal indicator of the fire: place and time of occurrence. In addition, with the help of these images, it is possible to record the total number of fires on a daily basis. Thus, most of the fires recorded by the Terra satellite took place in the period from mid-summer to the beginning of autumn 2022 in the territory of forests, forest belts and steppes, mainly in the zone of combat clashes.

For a detailed analysis of fires and their consequences, satellites with a resolution of less than 30 meters should be used (Landsat 8, Sentinel 2A, 2B, etc. – see table 1).

Among all natural ecosystems of Ukraine, forests suffer from hostilities mostly. The massive use of artillery and strike aircraft against military and infrastructure facilities in and near forests causes forest fires, which in dry conditions destroy tens and sometimes hundreds of square kilometers of forest. So, for example, according to the official information of the leadership of Ukraine, almost three million hectares of forests were destroyed during the eight months of the war as a result of shelling by Russian troops on the country's territory.

Mapping the destructive effects of wildfires is most effective in the short-wave infrared (SWIR)

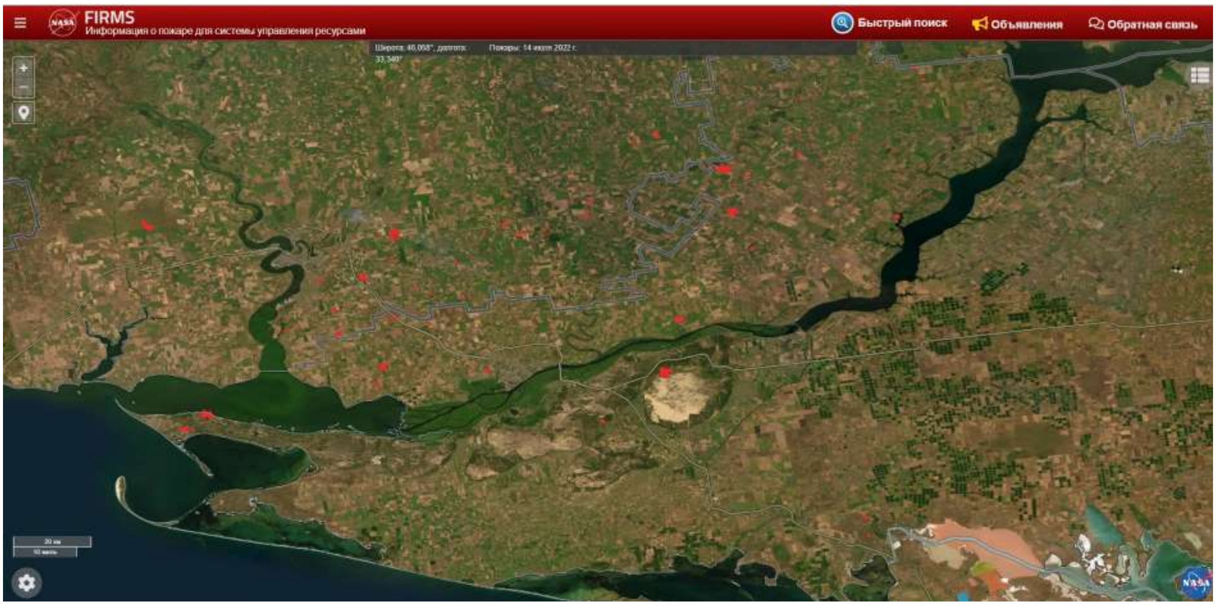

Figure 3. Forest and field fires in the Kherson and Mykolaiv regions. 14.07.22. [Satellite: Terra MODIS. Source: firms.modaps.eosdis.nasa.gov].

Figure 4. Satellite image of the Kinburn Peninsula (Ukraine). 23.07.22. Areas of burnt forests are of brown colour [Satellite: Sentinel-2. SWIR range. Source: EO Browser].

range. For the Sentinel 2A satellite, this is a combination of channels B12, B8A, B04. In this composite, vegetation is shown in shades of green, and recently burned land is shown in brown (figure 4).

For a semi-automated method of calculating the area of fire-destroyed forests, it is possible to process a raster image in the environment of a geographic information system. Figure 5 shows an example of raster classification of a satellite image of the Nedohirsky Forest in the QGIS program with subsequent area determination using the program's functionality.

Figure 5. Satellite images of the Nedogorsky forest (landscape reserve "Inguletsky", Velyka Oleksandrivka, Kherson region). On the left – 21.07.15. Case – 22.05.31. [Satellite: Sentinel-2. SWIR range. Source: EO Browser].

In order to record and calculate the consequences of forest fires, it is necessary to have two pictures taken at different times: one before the fire, the other after (figure 5). In this way, we can ensure the accuracy, objectivity and reliability of the collected evidence. The necessary combination of channels for capturing the analyzed terrain can be obtained using the EO Browser cloud platform. The functionality of the platform allows us to measure the area of destroyed forests with the usage of polygons. In order to record and calculate the consequences of forest fires, it is necessary to have two pictures taken at different times: one before the fire, the other after (figure 6). In this way, we can ensure the accuracy, objectivity and reliability of the collected evidence. The necessary combination of channels for capturing the analyzed terrain can be obtained using the EO Browser cloud platform. The functionality of the platform allows us to measure the area of destroyed forests with the usage of polygons.

Table 3 shows examples of calculations of the territories of damaged forests of Kherson and Mykolaiv regions from shelling by Russian troops using this method. In general, during the period from February 24, 2022 to the moment of the occupation of the right-bank part of Kherson region, several thousand hectares of forest were destroyed only in the territory of these two regions. Detailed monitoring is necessary to obtain more accurate data.

The consequences of agricultural land fires are recorded using a similar method. As a result of Russian shelling in Ukraine, fires were recorded on almost 8,000 km^2 of agricultural land with crops of various farming cultures in just six months of the war. Documentation of the fact of fires is carried out in the presence of public reports from citizens, the government, local authorities, or based on the fixation of the source of ignition from satellite images of low spatial resolution (Terra MODIS). Then images of medium spatial resolution are obtained (Landsat 8, Sentinel 2A, 2B) and the area of the fire is determined in the short-wave infrared range (SWIR) (figure 7).

Table 4 shows examples of calculations of areas with crops in Zaporizhzhia and Kherson regions. It should be noted that forest and steppe fires destroy the fertile soil layer, and along

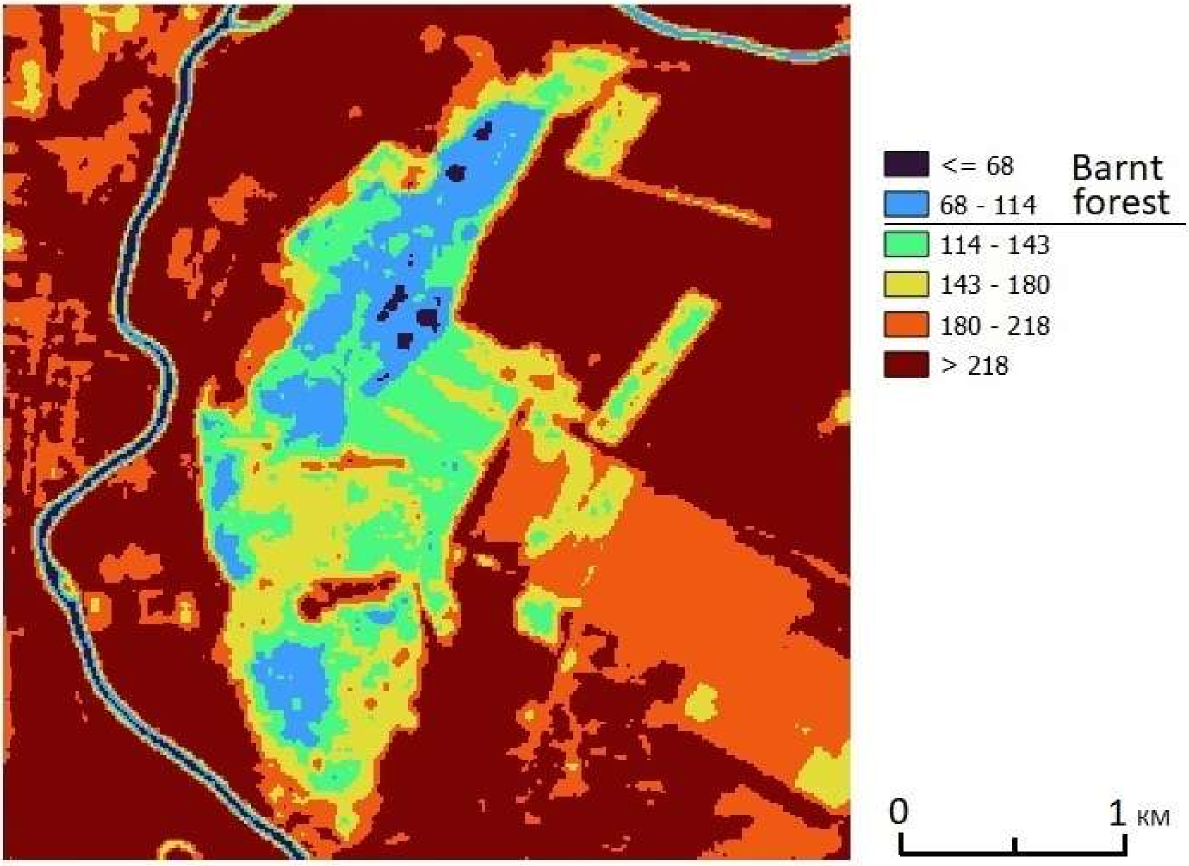

Figure 6. Raster classification of the satellite image of the Nedohirsky Forest in the QGIS program. The area of the burnt forest is marked by blue and black colours.

Table 3. Areas of forests damaged by military operations based on the analysis of satellite images [Satellite: Sentinel-2. SWIR range. Source: EO Browser].

№	Object name	Date of the picture	Burnt field area, km^2
1	Tyuryupynsk forestry (Kherson region)	22-07-15	0.25
2	Heroiske forestry (Kherson region)	22-07-23	0.7
3	Ivanivka forestry (Kherson region)	22-07-23	0.6
4	Nedohirsky forest (Kherson region)	22-05-31	0.4
5	Halytsynove Forestry (Mykolaiv region)	22-08-07	0.015

with it, millions of microorganisms that ensure the natural balance of the environment die. The number of animal and plant populations is also significantly decreasing. Determining the catastrophic consequences of these destructions and estimating the economic losses is possible only by conducting special studies on the area.

C. Destruction of structures (buildings) and constructions

One of the most significant indicators of the destructive actions of the Russian army in Ukraine is the destruction and damage of civilian and military infrastructure. According to official data from Ukrinform, during 300 days of the war, the occupiers destroyed at least 412 industrial

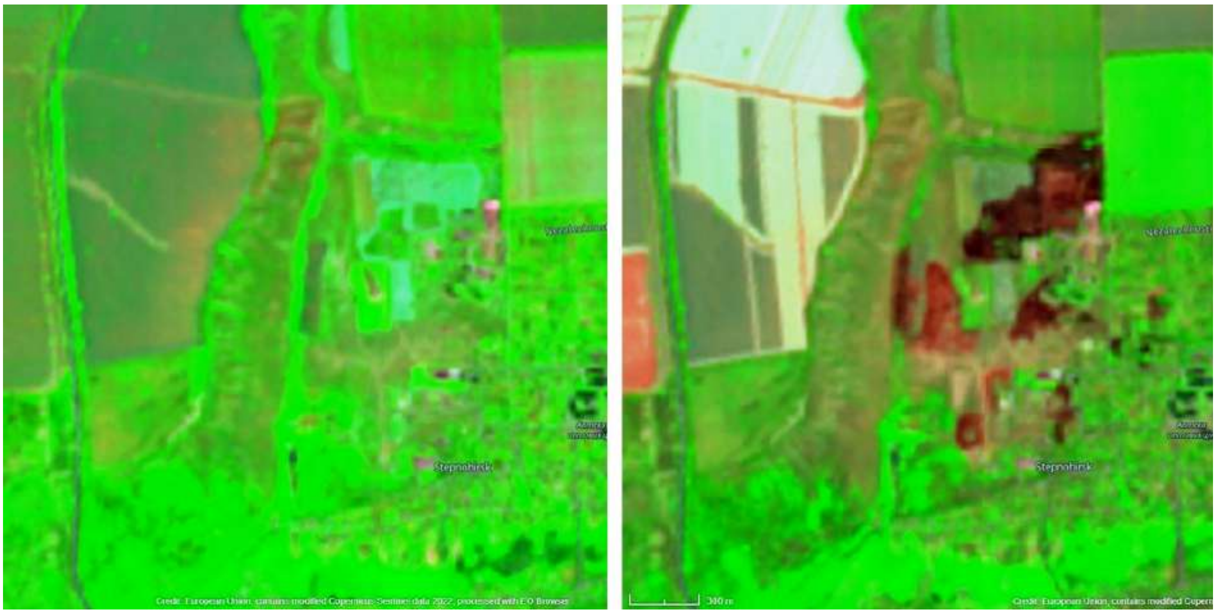

Figure 7. Satellite images of fields near the town of Stepnohirsk (Zaporizhia region). On the left – 22.06.20. On the right – 15.07.22. [Satellite: Sentinel-2. SWIR range. Source: EO Browser].

Table 4. Areas of agricultural crops damaged by fire from military operations according to the results of satellite image analysis [Satellite: Sentinel-2. SWIR range. Source EO Browser].

№	Object name	Date of the picture	Area of burnt crops, km^2
1	The town of Stepnohirsk (Zaporizhia region)	22-07-15	0.7
2	Novooleksiivka vil. (Genichesk district, Kherson region)	22-09-18	0.6
3	Novopokrovka vil. (Genichesk district, Kherson region)	22-09-18	0.5
4	Rozlyv vil. (Kherson Region)	22-08-24	0.12
5	Mala Tokmachka vil. (Zaporizhia region)	22-08-24	5.2

enterprises, more than 15,000 high-rise buildings, 116,000 private houses, almost a thousand medical facilities, 511 administrative buildings, etc. For each of these facts, it is necessary to form an evidentiary base, and considering the volume of work, the ERS becomes important.

To study the destruction of structures (buildings) and constructions, only satellite images with a very high spatial resolution (less than 1 meter – *GeoEye, WorldView-3*) are used. These pictures make it possible to compare the condition of buildings before and after the destruction (figure 8).

Due to the deciphering of the pictures, it is possible to assess the state of destruction of buildings. At the same time, it should be borne in mind that the analysis of satellite images, even with a very high spatial resolution, guarantees the diagnosis of the state of the building in three degrees of destruction: *completely destroyed, partially destroyed or not destroyed.* As an evidence base, such gradation may not be enough. In this case, the obtained data must be supplemented with additional information from verified sources (for example, an examination at the site of destruction), or using images from unmanned aerial vehicles

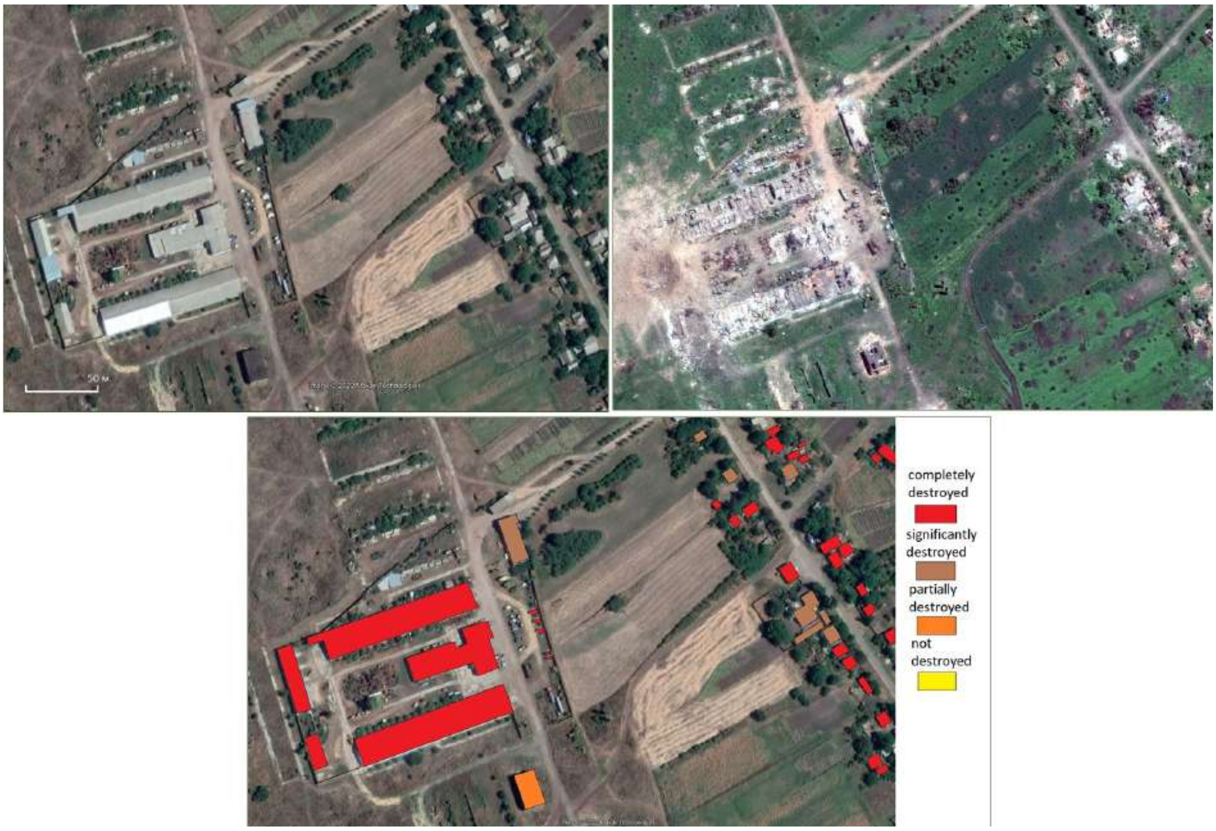

Figure 8. Visualization of buildings damage in the village of Dovgenkove (Kharkiv region) from shelling by Russian troops according to satellite images. Top left – 20.08.22, top right – 22.08.15. The picture below has been processed in the QGIS program [Source: Satellite Image 2022 Maxar Technologies, EPA].

So, for example, the companies SmartFarming and Vkursi Zemli launched the RebuildUA project, the purpose of which is to analyze and document the destruction of the infrastructure of populated areas as a result of Russia's war against Ukraine with the help of drones. The use of drones allows to collect more detailed data about the destruction: to take photos and videos of objects from different angles, from all sides of buildings.

In future, in order to ensure storage, quick search, analysis and visualization of all useful information, it is necessary to digitize it in the GIS environment. With the help of the GIS functionality on the raster image of the satellite photo, destroyed objects are recognized, their types are classified and the level of destruction is determined. Then these objects are digitized, with the creation of separate vector layers with appropriate consideration of their types and level of destruction (figure 8). In this form, the information is analyzed and stored.

Taking into account the amount of destruction in Ukraine, it is clear that recording and assessing the nature of damage as an evidence base requires a significant amount of work with the involvement of state and commercial organizations with experience in the field of practical application of ERS data.

4. Conclusions

1. Aerial photographs are a unique form of evidence of military destruction. The information obtained with their help reflects the general current and operational situation in the

destruction zone, reducing the subjectivity and uncertainty of damage characteristics on the ground.

2. Sources of satellite images are official state or commercial structures which are publicly available. This ensures the independence and persuasiveness of the obtained evidence for trials and lawsuits against the aggressor country.
3. Deciphering the data of remote sensing of the Earth makes it possible to obtain an accurate and complete assessment of environmental damage due to military actions according to the following indicators: degradation of land resources, destruction of natural ecosystems by fires, and destruction of structures (buildings) and constructions.
4. The proposed methodology for assessing military destruction is characterized by simplicity, accuracy and versatility, and does not require the use of expensive equipment.
5. It is possible to increase the effectiveness and evidentiality of the conclusions obtained from the analysis of the ERS data by applying additional surveys at the site of destruction.

Abstract. The article addresses one of the relevant global trends – the sharing economy or participation economy. The authors explore its features and benefits (time and resources saving, rational consumption, use of communication technologies etc.). The publication considers the driving forces, namely peering social networks, real-time technologies, the global economic crisis, environmental issues and a renewed belief in the importance of communities. The authors argue that BlaBlaCar is one of the world leading online ridesharing platforms. The article defines the essence of BlaBlaCar as a new model of shared consumption tracing the history of its inception and development. The authors examine characteristics and peculiarities of BlaBlaCar in terms of a modern information network; reveal the behavioral traits of BlaBlaCar users worldwide and in Ukraine. The article attempts to anticipate the prospects of BlaBlaCar development.

1. Introduction

1.1. The problem statement

Information plays a pivotal role in all spheres of post-industrial society. It is common knowledge that "whoever owns the information owns the world", as it is even more relevant today than in the days of Nathan Rothschild. The swift breakthrough of information technologies and the advance of information production brought about the growing economic importance of the information sector and the advent of new infrastructural elements – information networks. These networks contribute to the evolution of the sharing economy, since people exchange goods and services via them, so the transport is no exception.

The growing demand for transportation causes the creation of new information platforms offering transport services. To function properly transport service platform improve existing logistics systems and introduce a new transport trend – the joint trips in private vehicles arranged via online services for finding fellow travelers now known as ridesharing or carpooling. The term "ridesharing" is coined from two English words "ride" and "sharing" which mean to share a trip, and denotes the phenomenon when a driver or a passenger search for a companion to share a ride in order to travel costs. Carpooling is a shared car trip, agreed upon in advance between a car owner and passengers to save on fuel costs and to reduce the amount of traffic. Unlike hitchhiking, with carpooling, the costs of the trip are shared between the car owner and the passengers. Carpooling used to be practiced only by neighbors and acquaintances, currently with the advent of the Internet and social networks, this phenomenon reached a completely new level.

So, nowadays traditional car transport services are gradually being replaced by car sharing services, which by nature are an example of responsible consumption of resources.

Responsible consumption and production [1, 2], is correspondently the twelfth goal of sustainable development proclaimed by the UN General Assembly in 2015. One of the feasible ways to accomplish this objective is to develop information transport networks, e.g. BlaBlaCar [3], since their advantages in the environment protection are absolutely apparent, because car sharing is incomparable means in reducing humanity's carbon footprint.

The transition to a shared consumption economy is a modern key to sustainable development, which meets the needs of the current generation without threatening the following generations to meet their own needs [4].

1.2. The objective of the article

Within the scope of this publication, we aim to examine the characteristics of BlaBlaCar as one of the world ride-sharing leaders, to consider its advantages and disadvantages, to envision the prospects for its development.

1.3. Theoretical background

There is a growing body of literature that recognizes the importance of the sharing economy, among which are the studies of Lessig [5], Deakin et al [6]. We want to acknowledge the works of Botsman and Rogers [7], Walsh [8], Mazzella [9], Sundararajan [10] on the advantages and pitfalls of the participation economy. Jiang and Tian [11], Barbu et al [12] recognises the critical role played by responsible consumption in the sustainable development. Kim and Jin [13], Mukhopadhyay and Mukhopadhyay [14], Luri Minami et al [15] address the relevant issue of information transport networks. In Ukraine, the phenomenon of sharing is still relatively new and is just beginning to spread [16–21].

However, the researches to date have not yet established how the sharing economy works. Much uncertainty still exists about the advantages of ridesharing compared to traditional transportation services. It is now well determined whether people are ready to share with each other and to what extend exactly. The influence of the quarantine restrictions caused by the global pandemic or the war in Ukraine on carpooling has remained unclear. A number of questions concerning the prospects for the development of information networks are particularly relevant.

The research data in this publication is drawn from three main sources: reports and statistical materials of various companies and their branches, publications and information resources that are freely available and are relevant to the problem of ridesharing or carpooling. As we consider the BlaBlaCar information network as an example of a sharing platform, so data for this study were collected from its official website.

2. Results and discussion

The digitization of modern society encouraged by rapid development of information technologies has led to the emergence of the sharing economy making it a trend modern world. The basis of the sharing economy is the sharing of goods or services, not their ownership. Therefore, it is not the ownership of goods or services that is important nowadays, but timely access to them. Hyper consumption, widespread in the 20th century, was replaced by joint consumption, characteristic of the 21st century [6]. Thus, a new responsible model of consumption and a new approach to any resources use are gradually refined. These models are definitely more appropriate for present-day, as they contribute to the sustainable development of mankind.

Rachel Botsman, a well-known propagandist of the sharing economy, convincing responded a question why humanity should move to a more coherent and responsible consumer culture [22]. In her speech at the TED conference back in 2010, she noted that the majority of people owning a drill use it for only 12-13 minutes of the entire operation time. A car, of about $8,000 average cost, is usually idle for 23 hours a day. Botsman introduced the idea of sharing the equipment or tool by borrowing, lending or leasing them. This constitutes the primary idea of shared consumption economy – instead of possessing, people can share resources, which makes more efficient use of material goods and reduces the costs of their acquisition or production.

Fred Mazzella, a founder of BlaBlaCar, characterized the era of sharing and emphasized that humanity "stands on the threshold of the era of exchange" of goods, knowledge, money, time, skills, content, etc. "The arrival of the sharing age is a logical evolution from the disruptive innovations of the early 2000s, all of which are now allowing individuals to scale their network and gain access to solutions best suited to their needs. But the phenomenal growth and continued popular support of these models is better explained by the virtuous impacts of sharing" [8].

Botsman and Rogers [7] investigate the positive impact of the sharing of goods and services in their research. Moreover, their book *What's Mine Is Yours: Rise of Collaborative Consumption*, substantiates the basic principles and driving forces of the sharing economy [6]. Let us briefly characterize them using the example of ridesharing.

Internet sharing platforms exist all over the world, but they are predominantly developed in European countries such as Belgium, Great Britain, Italy, Spain, the Netherlands, Germany, Poland, France and Sweden. The number of sharing companies and their incomes grow annually, which indicates the growing demand in them among the world's population [2].

Carpooling came into being in the USA and the countries of Western Europe in the 40s of the XX century, and with the advent of the Internet, it received an impetus for development. According to Mordor Intelligence [23], the ride-sharing market will continue to grow rapidly due to the increasing demand for economical and timesaving vehicles and by 2027 it will grow by 18%. The European region presently demonstrates the largest carpooling market, although the Asia-Pacific region shows the signs of even faster growth.

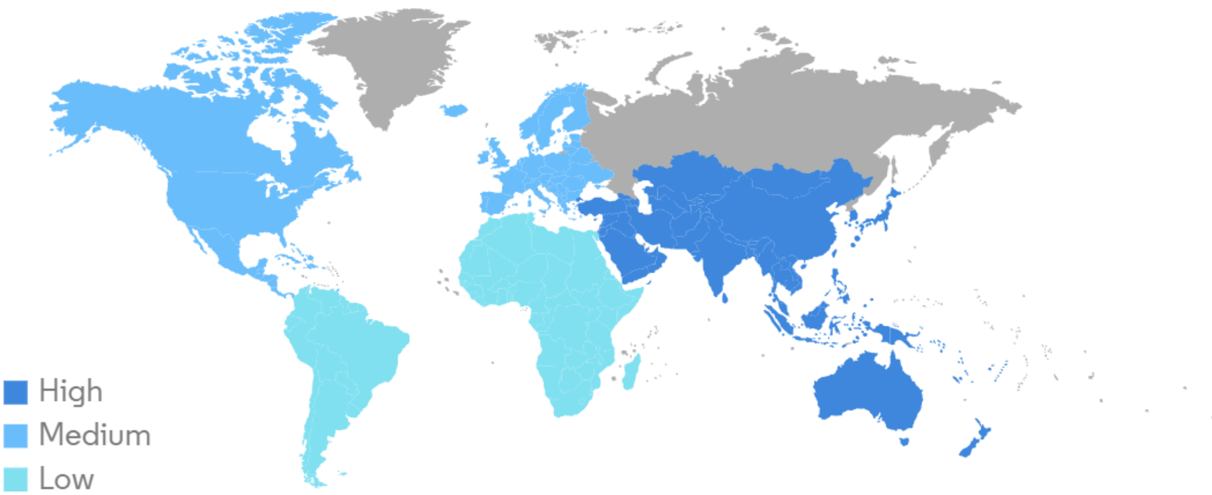

Figure 1. Global Ridesharing Market – Growth Rate by Region (2022 – 2027) [23].

Being the booming market, ridesharing constantly attracts new market players offering transportation services. It is worth mentioning such major players as Via Transportation, Scoop Technologies, Mahindra Logistics Ltd. UCR, Didi Chuxing Technology Co, Zimride, Uber, Nuride, Zipcar, Turo, Getaround, Rides Ridingo, and JayRide.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012133 doi:10.1088/1755-1315/1254/1/012133

Table 1. Basic principles and driving forces of the sharing economy on the example of ridesharing.

Sharing Economy	Ridesharing
Basic principles of functioning and their characteristics	
Profit. In case of use, it brings benefit, in case of idling, it causes lost	Renting a car reduces maintenance costs. Carpooling reduces transportation costs for trip participants. The car owner saves money and resources, fuel, parking fees, maintenance of the vehicle and guarantees to fellow travelers that they will arrive at their destination on time
Saving time and resources (to use, it is not necessarily to own)	Renting a car for a small fee is more profitable than buying it, as modern young people are not usually tied to the place of their residence or work
Rational consumption	Minimizing traffic should effect total fuel consumption, and correspondingly the decrease in harmful emissions and the carbon footprint in the atmosphere
Trust as a basis for sharing	The growth of the carpooling market contributes to an increase in the general level of trust in society
Use of communication technologies	Information platforms providing car transport services contribute to the connection between the car owner and potential passengers
Driving forces of sharing	
Peering social networks and real-time technologies	The quality of communication improves because peering social networks establish a powerful sharing connection between the physical and virtual spheres of life. The economy of shared consumption and its platforms have become the most convenient and cheap means of client information compared to the traditional ones [19]. All mentioned above leads to a reduction in traffic and efficient use of motor vehicles.
World economic crisis	It caused the refusal of people from mindless consumption in favor of responsible consumption; the use of resources and goods, cars particularly, in order to ensure sustainable social development
Environmental issues	The aggravation of environmental issues made the humanity change the approach to their solution from an anthropocentric to an eco-centric. Ridesharing is considered to be one of the means to reduce anthropogenic impact on nature, especially on the atmosphere
Growing trust between people	The basis of ridesharing is the concept of “trust” (client – driver, driver – client).

BlaBlaCar is considered one of the leaders in the shared ride market, and can serve as a vivid example of the sharing economy. BlaBlaCar is a carpooling information network that provides drivers with the opportunity to save on gas expenses and travelers to economize on fares due to shared cost of trip, which turns out to be lower, compared to rail and airline fares. According to the BlaBlaCar regulations, drivers compensate most of the fuel costs allowing passengers to travel cheaper than in public transport.

BlaBlaCar presently supports the intersection of more than 100 million drivers and passengers who share the common goal of traveling cheaply and conveniently. BlaBlaCar as a leader in its field to date offers a variety of route options especially for short distances (less than 150 km).

BlaBlaCar is not only an online platform for a more effective search of traveling companions, but also a cloud data storage. The company has an Internet service that monitors possible trips, warns against fraud and organizes correspondence or calls between a driver and passengers. The international web site of this service is currently functioning in 22 countries worldwide.

We can distinguish three stages of the BlaBlaCar development presented in table 2.

BlaBlaCar is also a powerful information network that takes into account the needs of every person, regardless of age and gender. The information found in the BlaBlaCar network can be grouped into the following categories: rules of use, user characteristics, social impact, environmental efficiency and regional features of user behavior. BlaBlaCar has clear terms of use that allow everyone convenient and safe travel experience:

- registration and profile filling;
- submission of an application to search for fellow travelers or a vehicle.

Registration and profile filling phase suggests different ways of registration possible (via a Facebook account, via e-mail) and entering minimal user information (name, gender and year of birth, preferences, photo). Car owners also need to specify the technical characteristics of their vehicle.

On the phase of submitting an application for travelling companion or finding a car, users can fill out a special form with the place of departure and destination, date and time. After the ride, passengers and drivers leave feedback about the shared ride, which affects trust in the community. There are several criteria for choosing a travel partner or a vehicle, including comfort, price, route, time of a trip, age and experience of the driver and reviews on BlaBlaCar. At the same time, the service is available via mobile applications for iPhone and Android, as well as on the main website on the Internet.

The findings merged from the data analysis can identify the following generalized characteristics of BlaBlaCar users:

- the majority (about 2/3) of BlaBlaCar users are males (62%). We believe that the main reason for the smaller number of female users is the issue of safety, less trust of women in unfamiliar drivers and passengers. To ensure women feel comfortable and safe, BlaBlaCar provides the "Girls Only" option;
- the diversity in age with the predomination (more 1/2 making 43%) of young users (aged 25 to 34), people aged 35 make up 30% of users. This can be explained by the fact that this age group are the most advanced users of social networks, the main consumers of goods and services of the sharing economy;
- BlaBlaCar enables people with special needs to use network services by changing interface settings, zoom and navigation using the keyboard.

We believe an important feature of BlaBlaCar is the positive environment effect due to the reduction of traffic. The report of the French research institute *Le BIPE BRO* [24] on the results of a study, commissioned by the BlaBlaCar company, states that in 2018 BlaBlaCar users, traveling with fellow travelers and sharing fuel costs, reduced CO_2 emissions by approximately 1.6 million tons. The projected saving of CO_2 emissions (in millions of tons) as of 2023 is presented in figure 2. According to the 2018 IPCC report, stabilizing global warming at 1.5°C requires reducing CO_2 emissions by 45% no later than 2030.

Therefore, ridesharing trend and BlaBlaCar particularly can make a huge difference in solving a number of issues and may contribute to the sustainable development of humanity in the near future.

Table 2. Development stages of BlaBlaCar.

Development stages	Stage characteristics
1. The emergence of BlaBlaCar (2006–2010)	The idea to create BlaBlaCar dates back 2004 and belongs to Fred Mazelli, who wanted to go to visit his relatives outside the city, but could not get to them. It occurred to Fred to find a driver who was willing to take him as a passenger on the condition that he shared fuel costs. That shared trip inspired Fred Mazelli to create an information site for finding fellow travelers, and in 2006 Fred Mazzelli purchased the *covoiturage.fr* domain. The co-founders of the project were Fred Nappeson, Nicolas Brusson and Olivier Bonnet. At this stage, the product development strategy was worked out and planned.
2. Development of BlaBlaCar and its entry into the European market of shared trips (2011–2014)	BlaBlaCar enters the European market using different websites (for example, in Spain, the company is called Comuto with the website *comuto.es*). In June 2011, the company expanded its services to the UK and changed the name to BlaBlaCar, as users indicated their level of “talkativeness” from “Bla” (silent), “BlaBla” (moderately talkative) to “BlaBlaBla” (very talkative) when registering on the site. In 2012, BlaBlaCar entered the market of 6 more European countries: Belgium, Italy, Luxembourg, the Netherlands, Poland and Portugal. The Spanish and French sites were renamed to standardize the network. At this stage BlaBlaCar became one of the most expensive startups in Europe thanks to the investments of Insight Venture Partners and Lead Edge Capital.
3. New markets extension, new product offers (2014–2023)	BlaBlaCar came to Turkey in 2014, and India the following year. 2015 was the year BlaBlaCar expanded into Latin America, particularly Mexico and Brazil, with $200 million funding. Since 2019, BlaBlaCar has become part of the BlaBlaCarPro international project, which is a legal bus carrier service. It assists carriers and bus fleet owners to find passengers for nearly 100 million BlaBlaCar users. However, only carriers with legal license to transport passengers can work with this service. In 2018, BlaBlaCar moved beyond carpooling for the first time, announcing the purchase of Ouibus, one of France’s largest bus operators, owned by the state-owned SNCF, which manages the country’s railways. Later on BlaBlaCar, the world’s largest carpooling service for long-distance trips, announces a joint effort with Busfor, the leading service for finding and buying bus tickets in Ukraine and other countries of Central and Eastern Europe. The merger of companies was supposed to contribute to the expansion of BlaBlaCar in the passenger transport market in the region with a population of more than 300 million people. With the onset of the global COVID-19 pandemic, demand for transportation services and platforms dramatically increased as public transportation and intercity transportation were shut down. In this regard, since April 2020, BlaBlaCar has launched a new *BlaBlaHelp app.*, the application helps buy products or medicines in a pharmacy.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012133 doi:10.1088/1755-1315/1254/1/012133

Figure 2. Projected savings of CO_2 emissions [24].

The next stage of our research aims to reveal the behavioral traits of BlaBlaCar users in various regions worldwide. The results of this study show that the behavior of BlaBlaCar users in different countries demonstrate no fundamental divergence. However, it has been established that users from different regions still have some distinctions due to peculiarity of mentality and cultural customs.

The most interesting finding concerns the time and details of the trip planning. For example, the users from the Western, Southern and Northern European countries usually plan shared trip a week or two in advance, and clarify the trip details and check the driver's profile in 2-3 days before the trip takes place. The Central and Eastern Europe users also plan a trip, but usually in 2-3 days, and they clarify the trip details on the day of departure. Moreover, they rarely carry out a detailed check of the driver's profile. However, users from Latin American countries may plan a trip a week in advance, but can often cancel it in 2-3 days; also the driver profile check may not be very detailed.

In the countries of the Asian region, users strictly observe customs and traditions peculiar to oriental culture. Thus, women in India, for example, ride only with a female driver. The gender of the user determines the thoroughness of detail checking in the driver's profile.

BlaBlaCar entered the Ukrainian market in February 2014 due to the takeover of *Podorozhniki*, the Ukrainian startup, whose founder and first regional manager was Oleksiy Lazorenko. In January 2022, because of personnel changes Roman Miroshnichenko took the position of general director of BlaBlaCar in Ukraine.

As of 2023, Ukraine is among the top three countries where BlaBlaCar is developing rapidly. The Ukrainian BlaBlaCar market has currently 8 million users, of which 1 million people use it every month. About one hundred employees work in the Ukrainian office of the company. The analysis of the data taken from the company's official website reveals that 55% of users use the network for vacation trips, 49% for visiting parents or relatives, and 42% for business trips.

Passenger traffic traditionally increases on the eve of holidays. The most popular in 2019 (in terms of the number of seats offered in the cars) proved to be summer destinations in Ukraine, i.e. see resort cities: Berdyansk (Zaporizhia region); Kyrylivka (Zaporizhia region); Iron port (Kherson region); Zatoka (Odesa region); South (Odesa region). Among the most popular winter resort regions were: Bukovel (Ivano-Frankivsk region); Vorokhta (Ivano-Frankivsk Region); Yaremche (Ivano-Frankivsk Region); and Skhidnytsia (Lviv region).

Unfortunately, with the full-scale invasion of Russia into Ukraine, the former popular summer travel destinations are no longer relevant.

The introduction of quarantine restrictions caused by the COVID-2019 pandemic, followed by the Russian-Ukrainian war, effected the development of BlaBlaCar in Ukraine.

In March 2020, BlaBlaCar appealed to its users asking to stop traveling temporarily and urged to use the platform only for exceptional and urgent trips. In accordance with the Government of Ukraine decision to ban passenger transportation, dated March 16, 2020, BlaBlaCar temporarily suspended all bus trips, including on the Busfor platform.

Presently, the government of Ukraine gradually allows restoring long-distance travelling. BlaBlaCar introduced improvements and new features on the platform that are called to assist traveler's necessary safety measures and health precautions. BlaBlaCar reminds every user of safety recommendations the moment he/she post or book a ride, including: not to drive in case of COVID symptoms arise, to wear a medical mask, to keep a safe distance, and not to hold hands.

In April 2020, BlaBlaCar announced the launch of *BlaBlaHelp (iOS, Android)*, a free application that helps buy essentials during the spread of COVID-19 [25]. To date, more than 35,000 users apply *BlaBlaHelp* and the company encourages its users to share the application with those who may need help.

One more company's initiative is the assistance to the Armed Forces of Ukraine by making quick and free of charge trips for the militaries who need to get to their destination.

In the conclusion, we can summarize the salient features of the BlaBlaCar information network:

- BlaBlaCar information network is a part of the sharing economy, which is developing at a fast pace;
- the network provides users with wide possibilities to make trips;
- BlaBlaCar interacts and cooperates with other sharing platforms, expands the car sharing service on the world market;
- the network differs from traditional types of logistics systems;
- some aspects of BlaBlaCar activities are partly non-commercial, international, global and informal;
- BlaBlaCar provides cross-cultural exchange through communication opportunities between users;
- users can travel in any direction and at any time;
- BlaBlaCar site is accessible for users with special needs.

Considering the features listed above, we can distinguish the main advantages and disadvantages of BlaBlaCar.

The main advantages of BlaBlaCar over its competitors, i.e. transport companies, are: a slightly lower price of the trip; free choice of more favorable route and time; individually suitable location of departure and destination; the availability of trip routes that are not provided by the regular carriers; less emission of CO_2 into the atmosphere; and mutual assistance during the COVID-19 pandemic.

We see the main disadvantages of BlaBlaCar as follows:

- many drivers use the BlaBlaCar platform for commercial purposes, although it is against the terms of use of the free platform;
- the lack of reporting documentation, which can create problems with taxation and insurance;
- the issue of income accounting and taxation: the lack of real mechanisms for monitoring the flow of money which causes the transfer of part of the money into the "shadow";

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012133 doi:10.1088/1755-1315/1254/1/012133

- insufficient safety guarantee for passengers and drivers;
- in most countries, BlaBlaCar works only with long-distance transportation, which limits the capabilities of the platform;
- passengers have to tolerate the time and route offered by drivers, which may not always meet their needs;
- the transition from a social platform to a business platform may lead to an increase in service prices and change BlaBlaCar's philosophy.

3. Conclusion

Sharing economy in general and ridesharing in particular grounds in financial benefit, time and resources saving, rational consumption, trust, and communication technologies. Nowadays BlaBlaCar is a new model and a vivid example of the economy of shared and responsible consumption. It is one of the world leading online sharing platforms, which has gone a long path from the idea of finding fellow travelers to mastering the global market of shared trips and offering new products (bus trips, BlaBlaHelp, etc.).

BlaBlaCar has as advantages (traffic minimization, lower trip price, free route and time choice, CO_2 emission reduction), as some disadvantages (insufficient guarantee of passenger and driver safety, lack of reporting documentation, restrictions on intercity transportation).

Thus, BlaBlaCar is a special information network with unique characteristics that distinguish it from other similar networks, and some common features with existing sharing platforms, such as the user communication available. BlaBlaCar is an innovative solution in passenger transportation issue, which has gone through successful testing on the world market and proved competitive with the other companies.

As the prospects of BlaBlaCar development, we can envision the entry of insurance companies into the BlaBlaCar market and implementation of monetization; expansion of the service market and entry to the joint transportation market of Japan, South Korea, Indonesia, Colombia, and Argentina, etc.

Our further scientific research aims at the study of modern trends in the development of the sharing economy in the global economic system.

Abstract. Efficient use and protection of the subsoil is a part of rational nature management in the mineral base of Ukrainian regions and Ukraine as a whole. The components for the rational use of the subsoil include a comprehensive development of mineral deposits, a comprehensive use of mineral raw materials and mining waste, optimization of the structure of mining production and mineral raw materials consumption. The rational use of mineral resources in the modern interpretation of this issue extends to all stages of their development, including the issue of waste disposal. A huge amount of mining waste has been accumulated in administrative regions of Ukraine, and the issue of their disposal has gone beyond just an economic and ecological problem and has acquired a significant socio-demographic significance. Environmental problems have become particularly acute due to the accumulation of toxic waste, among which the most dangerous are heavy metals, petroleum products and acid tars. For the sustainable development of Ukraine, it is necessary not only to develop new reserves of natural raw materials, but also technogenic minerals accumulated in more than 1,600 man-made deposits and objects. The further development of the mineral base requires, at the state level, an urgent solution to problems that hinder the development and ecological rehabilitation on the ground of rational use.

1. Introduction

Hundreds of billions of tons of various types of mineral raw materials: combustible minerals, ores, construction materials, etc., are mined from the subsoil every year. Along the way, in the process of mining, host rocks are also removed and remain at the mining site. Human activity has acquired global dimensions and is commensurate with the geological processes involved in the formation of the planet's landscapes. Long-term exploitation of mineral resources has led to the reduction of their reserves and the depletion of rich or unique deposits. At the same time, the non-restoration and limited reserves are characteristic of the mineral resources, so it is important to find approaches to the effective use of their reserves in order to prevent depletion and excessive losses during extraction. The growing technogenic load and disturbance of the natural environment during the exploration and exploitation of mineral deposits make the issue of overall protection of the geological environment and landscapes an urgent one.

The geoecological approach of the mineral resources study arose mainly on the ground of a need to study the processes accompanying the exploration, extraction and primary processing of minerals [1]. It is caused by the need to monitor, analyze and forecast, aimed at minimizing the negative impact of mining production on the environment, the development of rational schemes for the environmentally safe activities of mining enterprises in the context of optimizing in nature management. The result of the geoecological study of mining areas is the development of measures to improve the quality and conservation of the natural environment and reclamation of mining landscapes. The research is focused on the following issues: protection and rational use of subsoil, surface and groundwater, air environment, reclamation of lands disturbed by mining, disposal of mining waste, ecological and landscape problems of disturbed territories. Due to the global nature of the issue, the purpose of this article is to analyze only the first problem – the rational (efficient) use of mineral resources and mining waste.

The issue of conservation and rational use of subsoil resources has been of particular interest to researchers since the late 1960s and early 1970s, but the majority of publications fall into the 1980s. First and foremost, these are the works of Melnykov [2], Pedan and Mishchenko [3], Rekitar et al [4], and Bent [5]. Among the publications of the last decades, the works of Rudko and Shkitsa [6], Andrievsky [7], Galetsky et al [8], Komov [9], Panov [10], Rudenko et al [11], Mishchenko [12], Syvyi et al [1], Udalov and Kononenko [13], Kilinska and Kostashchuk [14], Rudko et al [15], Hrinov and Khorolskyi [16] should be mentioned. The mentioned works discuss methodological approaches to the rational use of mineral resources. In particular, they develop a conceptual framework, classifications of ways to comprehensively use mineral resources, the main directions of use, classifications of mining and industrial waste and problems of their disposal, the role of comprehensive use of mineral resources in improving the territorial organization of social production, the effectiveness of comprehensive development of mineral resources, and so on. The theoretical and methodological justification of these directions, the development of technological schemes for extracting valuable components at different stages of the mining production process, and finally, the globalization of the problem – i.e., the processing not only of the methodology of rational use of mineral resources, but also of the rational use and protection of subsoil resources in general – are some of the topics discussed in these and many other works that remain relevant today.

2. Results and discussion

Rational use and protection of the subsoil is an integral part of rational nature management within the mining areas. Rational nature management should be understood not merely as the optimization of the processes of intensive use of natural resources and their protection, but also as a system of measures covering the issues of environmental protection and control, reproduction and preservation of these resources, effective use of capital investments in mining enterprises, the distribution of the productive forces of the region [17].

From the general issue of rational nature management in the region, one can single out the rational use of mineral resources. Equally important components of the latter are comprehensive development of mineral deposits, comprehensive use of mineral raw materials and mining waste, optimization of the structure of mining production and mineral raw materials consumption (figure 1).

The maximum satisfaction of society's needs in certain types of raw materials at specified costs and under the condition of compliance with environmental standards can be considered as a criterion for the effective and optimal use of mineral resources. At the same time, factors of an economic, ecological and social nature should be taken into account; in particular, meeting needs for a certain resource, a level of current costs in the production and consumption of the product, economic effect and trends in the development and use of subsoil resources, the implementation of measures to preserve resources for future generations; minimization of harmful effects of

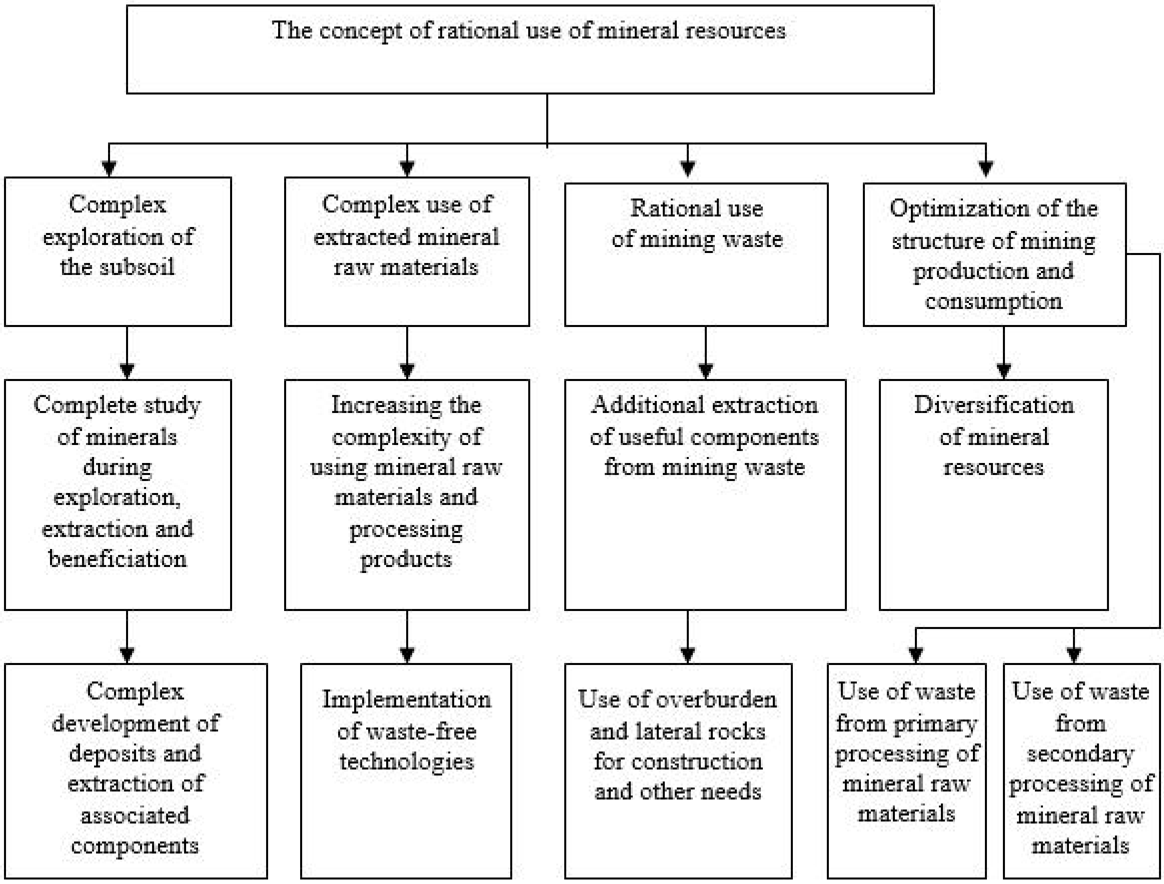

Figure 1. Structure of measures to solve the problem of rational use of mineral resources of the region.

mining on the environment, etc.

Irrational extraction and use of mineral raw materials lead to an increase in costs at all stages of mining production. Losses of minerals during their extraction and primary processing in some cases amount to 40-50%. The growth of mineral losses causes a deterioration in the quality or a decrease in the volume of concentrates produced by mining enterprises due to a decrease in the volume of useful components, a reduction in reserves due to their faster depletion. Mineral raw materials depletion of reserves is one of the main problems of environmental protection. High-waste technologies, non-comprehensive use of mineral raw materials and, as a result, environmental pollution, violation of its dynamic balance are other parts of this problem.

The list of tasks for rational use of mineral resources at various stages of their development and environmental protection issues, which need solving, has a following look (table 1). Rational use of mineral resources covers all stages in their development (search and exploration of deposits, extraction, transportation, primary and secondary processing), including waste disposal. The waste disposal is limited to those groups and types of waste processing, which are direct replacement of certain mineral resources.

The optimal use of mineral resources includes, on the one hand, the most detailed study of deposits at the stage of exploration, pre-exploration and exploitation, the choice of rational schemes for the most complete extraction of useful components during mining enrichment and processing; and, on the other hand, a requirement for a comprehensive use of mineral raw

Table 1. Tasks of rational use of mineral resources and environmental protection.

Stages of development of mineral resources	**Main tasks**		
	Study and complete extraction of mineral resources	**Complex use of mineral resources**	**Environment protection**
Search and exploration of mineral deposits	Rational and effective works on subsoil exploration; complete study of the geological structure; reliability of determination of reserves and quality of minerals; a rational approach to establishing the conditions of mineral raw materials	Research of associated components of raw materials and useful components in overburden, lateral and underlying rocks	Implementation of works without unjustified loss of minerals; prevention of pollution of water horizons; preservation of exploratory mines and wells and their liquidation, if they are not suitable for use and have environmental damage
Extraction of minerals	Selection of rational schemes for exploitation of deposits; reduction of losses in the subsoil; ensuring the maximum completeness of working out the reserves of the deposit	Organization of complex development of the deposit; preservation and accounting of associated components through their selective extraction and storage; utilization of overburden and host rocks	Preventing the negative impact of mining and other types of work on the preservation of mineral reserves; protection of deposits from flooding, pollution and construction; treatment of mine wastewater; air protection in quarries; prevention of oil leakage; rehabilitation of disturbed lands; protection of nature conservation objects
Transportation and processing of mineral resources	Complete extraction of useful (including associated) components from mineral raw materials; reduction of losses during transportation and processing	Economically expedient extraction of associated components from mineral raw materials; use of waste from primary and secondary mineral processing	Use of rational waste storage and preservation schemes with minimal loss of land; use of modern technologies to prevent pollution of the air environment, underground and surface waters, soils, etc

materials (t1). The methods and means of extracting minerals, which are used in modern technologies, do not solve the issue of their complete extraction from the subsoil. The resulting losses sometimes exceed the volume of actual production. Particularly significant losses are recorded in the underground method of development; a quarry method, as a rule, can reduce the loss of raw materials by 3-8%.

The problem of comprehensive use of mineral resources is considered in two aspects: a comprehensive development of deposits and a comprehensive use of raw materials.

A comprehensive development of deposits involves the use of rational, effective methods of extraction of the main and associated useful components in host and overburden rocks. Selective extraction of all industrially valuable components, their storage, and shipment to the consumer, or their accounting, in case of temporary non-use, must be ensured. Most mineral deposits are multiply. Sometimes the content of accompanying components can have a completely independent value, and their economic value may even exceed the cost of the main raw material. Multiple components are an important and permanent feature of mineral resources. Genetic associations of minerals (paragenesis) are well known in petrology, and the need for a comprehensive approach in solving the issues of using mineral raw materials is based on the following: the main component associates with a number of other components. Paragenesis is especially typical for ores of non-ferrous metals. During the comprehensive processing of ore raw materials, in addition to 8-12 profiling chemical elements, additional 62-66 elements can be obtained [15].

The economic effectiveness of the comprehensive use of mineral resources is revealed in various approaches. First of all, the accompanying extraction of valuable components significantly expands the mineral base. This is most important for non-ferrous metallurgy, where the majority of rare elements are contained in ores of basic metals. Sometimes there are much fewer of them in special deposits of rare metals. At the same time, in the process of mineral raw materials comprehensive use, conditions are created for increasing the volume of production with significantly lower capital costs. Many diffuse elements do not have their own minerals at all. Selenium, tellurium, indium, thallium and rhenium are extracted only from non-ferrous metal production waste, which is the only possibility of their production through complex processing of polycomponent ores. Most of the accompanying components are considered valuable, and even incomplete extraction of them from mineral raw materials makes it possible to expand the raw material base of the industry, reduce production waste, increase its economic efficiency and improve the environmental situation.

In addition to the extraction of industrially valuable components from raw materials, its comprehensive use requires the disposal of host and overburden rocks and residual products of enrichment and processing of raw materials. Up to 0.5-0.6 billion tons of rocks and mineral raw materials processing waste are stored annually in surface dumps. The total amount of accumulated mining waste exceeds billions of tons. Up to 1 billion m^3 of mineralized water is pumped out of mines every year [18]. Today, the bulk of such waste cannot be considered as mineral resources, as it cannot be used in industry. On the other hand, their use requires transportation, which is associated with additional costs and makes raw materials uncompetitive. The hundreds of millions of tons of waste accumulated in Ukraine can significantly improve the mineral base of enterprises that extract building stones, raw materials for building ceramics, building sands, and ceramic clays, carbonate raw materials, etc., or drastically reduce the need to open new quarries of building materials.

The waste of primary processing (enrichment) of raw materials is various sand and sand-clay sludge. The volumes of this waste in the regions of Ukraine are measured in hundreds of millions of tons. For example, in Kryvbas area, reserves of sludge from the enrichment of iron ores exceed 1 billion tons. Waste from secondary processing of raw materials is accumulated in significant quantities at enterprises of ferrous metallurgy enterprises (blast furnace slag, ferroalloy slags, iron-containing waste), thermal power industry (ash and slag from burning coal), chemical, petrochemical, coke-chemical industries (phosphogypsum, pyrite cinders, liquid organic and inorganic waste), etc. Often, the content of mining waste in such elements as copper, cobalt, molybdenum, zinc, and others makes them suitable for use in agriculture as agronomic ores.

The density of accumulated waste in Ukraine is 6.5 times higher than in the USA and 3.2 times higher than in the countries of the European Union. Every year, more mining waste accumulates in Ukraine than in 12 EU countries. Donetsk, Dnipropetrovsk, Luhansk, Lviv, and Zaporizhzhia regions should be singled out (table 2). In the densely populated areas of Donbas, Kryvbas, Pre-Dnieper and Pre-Carpathian regions, the level of technogenic load ranges from 2-3 to 10-30 million t/km^2. Table 3 shows the volumes of technogenic waste accumulated within the main mining basins of Ukraine, which account for 79.2% of the total amount of waste [17].

Table 2. Volumes of mining waste in the administrative regions of Ukraine (on the materials of the Ministry of Ecology and Natural Resources of Ukraine).

Administrative units	Dump area, ha	Annual waste volume, million m^3	Volumes of annual waste use million m^3	Volumes of accumulated waste million m^3
AR of Crimea	17.0	0.10	0.05	1.52

Ukrainian enterprises generate up to 100 million tons of toxic waste every year, of which more than 3 million tons belong to I-III hazard classes. The total amount of toxic waste accumulation is 4.4 billion tons. In Ukraine, there is no plant for the processing of toxic industrial waste or landfills for their disposal. The conditions of waste storage and disposal do not meet sanitary and hygienic requirements and are one of the factors of intense pollution of atmospheric air, surface, groundwater and soil. It is also worth mentioning the illegal shipment of 25,000 tons of acid tars into Lviv region; the problem of their disposal has not been resolved by today. In the developed countries of the world, a considerable attention is paid to the issue of effective use of mining waste, and the level of their utilization is 65-80% [8]. In Ukraine, this indicator

Table 3. Volumes of accumulation of industrial waste in the main mining basins of Ukraine [17].

Mining basin	Area of disturbed geosystems, km^2	Volumes of accumulated waste, billion tons	Inflows of mine and quarry waters, billion m^3/year
Donetsk coal (Donbas)	15,000	9.4	788.4
Lviv-Volyn coal	150	0.5	6.2
Dnipro brown coal	38	0.2	–
Kryvyi Rih iron ore (Kryvbas)	170	7.5	–
Pre-Carpathian sulphurous	160	2.6	45.6
Pre-Carpathian saline	24	0.4	2.0
Total	15,542	20.6	–

is estimated to be only 10-12%, there for we have accumulated unused reserves of secondary mineral raw materials.

For the sustainable development of Ukraine, it is necessary not only to develop new reserves of natural raw materials, but also to develop technogenic mineral resources accumulated in more than 1,600 technogenic deposits and objects. Technogenic deposits contain non-ferrous, rare, noble, ferrous metals, rare earth elements, non-ore, construction and energy raw materials, limestone and gypsum meliorants, etc. These components can be removed using the latest technologies. Every year, a technogenic mass accumulates on the earth's surface: 350 million tons of iron, 7.4 million tons of phosphorus, 5.7 million tons of copper, 2.8 million tons of lead, 2.5 million tons of barium, 230 thousand tons of uranium, 190 thousand tons of arsenic, 7.9 thousand tons of mercury [19].

The simplest technological option remains the organization of waste disposal for the production of building materials. A list of construction materials, magnesium and sulfur-containing fertilizers, limestone and gypsum meliorants can be compiled from mineral raw materials waste in Ukraine. It is also possible to additionally obtain coal fuel, ferrous, non-ferrous, rare metals, and fluxes from industrial waste, which is important in conditions of acute shortage of raw materials. The development of technogenic deposits in Ukraine makes it possible to expand the mineral base of the mining industry by 15-20%. Up to 30% of overburden and host rocks removed from the subsoil, as well as waste from their enrichment, can be used for the production of building materials [17].

The problem of effective use of hydro-mineral raw materials is important. It is possible to extract industrial quantities of lithium, boron, germanium, etc. from underground mine waters. For example, the underground waters of Donbas contain from 0.152 to 0.355 mg/dm^3 of bromine, which exceeds the minimum industrial values of bromine by 20-60 times, germanium by 5-8 times, and lithium by 2 times. It is necessary to continue studying the distribution of useful elements and components in mine waters and developing technologies for their extraction [19]. Radioactive waste burial grounds should also be considered as deposits of technogenic raw materials. With a higher level of technological development, they can serve as a source for the extraction and enrichment of radioactive elements.

The main mass of disposed mining waste is used for backfilling spent quarry areas and mine sites, reclamation of disturbed lands. In the backfilling process, not only waste rock is used, but also industrial waste, which can be processed into useful products. However, the technical level of extraction and use of these wastes is insufficient to establish their rational use.

In the main mining regions of Ukraine, there are dozens of technogenic mineral deposits that are preliminarily prepared for processing, which will significantly reduce the cost of their development. According to some estimates, with modern technologies, about 40% of industrial waste can be used to obtain useful raw materials: commercial coal, ore concentrates, cement, building materials, coagulants, chemical meliorants, etc. The Geological Service of Ukraine registered 1,500 industrial waste accumulation sites. Among them, only 13 sites have the status of technogenic deposits (one is being developed), the rest are tentatively classified as potential deposits or technogenic manifestations [12]. According to the amendments to the legislation in the field of waste management, the number of industrial technogenic deposits may reach two or three hundred.

Solving the problem of mining waste as one of the components of the state environmental policy is envisaged by achieving Sustainable Development Goal 12 “Responsible consumption and production”. By 2030, it is planned to reduce the share of landfilled waste to 35.0% of the total volume of generated waste (in 2015, it was 50.0%). At the same time, the number of enterprises where hazardous substances management systems have been implemented should be brought up to 100.0% of the total number of enterprises that use them. Achieving the goal in terms of waste is expected through the use of innovative technologies, which is defined by national task 12.4 “Reduce the volume of waste generation and increase the volume of its processing and reuse based on innovative technologies and production”. The processing of secondary mineral raw materials from mining waste requires significant investments. Solving the problem of attracting foreign investments for the development of the mining industry complicates the Russian-Ukrainian war and the difficult economic situation in Ukraine.

Effective use of technogenic mineral raw materials will ensure [18]: 1) reduction of costs for the search of new and exploration of exploited mineral deposits; 2) preservation of non-renewable mineral raw materials, extension of the life of mining enterprises; 3) production of additional volumes of cheap precious metals, non-metallic and construction materials, etc.; 4) filling of mine and quarry mine sites, planning of post-mining landscapes, carrying out reclamation and revitalization; 5) reduction of anthropogenic load on disturbed territories; 6) release and rational use of land occupied by mining waste storage facilities, elimination of sources of pollution of the natural environment; 7) attraction of investments and improvement of equipment and raw material processing technology.

The use of energy- and resource-saving technologies in the mining sector will improve the environmental situation in Ukraine. The latest technologies are proved to be effective within a short period of time and ensure the maximum output of the final product per unit of raw mineral. The cost of commercial products from mining waste is 5-15 times lower than from ores extracted by traditional methods from natural mineral deposits [20]. Solving the problems of rational use of mineral raw materials is also related to the development and implementation of waste-free technologies. Today, the involvement of man-made waste in production processes is restrained by the low economic capacity of the state.

The accumulation of significant amounts of mining waste in Ukraine is a consequence of the irrational use of certain useful components. Under the condition of comprehensive use of mineral resources, the amount of waste will be reduced by two times. Such comprehensive use allows to increase the amount of obtained industrial raw materials and is of a great economic importance. The reform and development of the mining industry should be based on principles that meet modern economic and environmental requirements.

In recent years, numerous cases of unauthorized use of subsoil and other violations of the legislation in this area have been recorded in Ukraine. Individual enterprises that extract local types of minerals (building stone, sand, loam, sand-gravel mixture, etc.) operate without special permits. There is an illegal development of coal, oil and amber deposits, as well as geological exploration of the subsoil. Geological control over the study and use of mineral resources should be strengthened.

Subsoil protection involves implementation of a set of measures for the complete removal of mineral resources from the subsoil and the maximum possible, economically feasible reduction of losses during their development. Legislation in the field of subsoil protection provides [21]: 1) provision of comprehensive geological study of the subsoil, prevention of unauthorized use of the subsoil; 2) rational extraction and use of reserves of minerals and components; 3) prevention of the negative impact of works related to the use of subsoil, the preservation of mineral reserves, mine sites and operated or mothballed wells, as well as underground structures; 4) protection of mineral deposits from flooding, waterlogging, fires and other factors affecting the quality of minerals and the industrial value of deposits or complicating their development; 5) prevention of unauthorized development of areas of mineral deposits and subsoil pollution during storage of oil, gas and other substances and materials, burial of harmful substances and production waste, discharge of wastewater.

In general, the activities of mining enterprises of Ukraine should be aimed both at the maximum extraction of minerals and the preservation in an undisturbed state of reserves that may become minerals in the future, as well as at bringing areas of land disturbed by mining operations into a condition suitable for further use.

Quantitative indicators of the wealth of Ukraine mineral resources, unfortunately, do not fully reflect the real state of the state's mineral base. Reserves of certain types of minerals, in particular oil and gas, are depleted and imported, the probability of discovering new large deposits is low, and the development of small deposits is unprofitable. Currently, Ukraine mainly has hard-to-reach reserves, the development of which is becoming unprofitable, as well as a large mining industry with worn-out equipment, where the majority of the population is employed.

Ukraine is at the beginning of the stage of subsoil depletion. A high degree of geological study of the territory, the depletion of quality reserves of the main types of mineral raw materials, a low probability of discovering new large and even medium deposits in terms of reserves make it impractical to invest significant funds in prospecting and geological exploration. The technological re-equipment of the mining industry becomes a priority due to the high wear and tear of fixed assets.

Since the 1990s, the mineral base of Ukraine has experienced degradation in all its constituent parts. In particular, the overall production of minerals has fallen, the volume of prospecting and mining exploration decreased to critical values. The consequences of this "collapse" are felt even today. At the same time, a slow rate of decline in production of mining industries in the early 2000s made it possible to increase the share of production in the overall structure of industry by two times compared to 1990 (from 21.2% to 42.6%). During this period, the share of ferrous metallurgy in the overall structure of industry increased by 2.5 times, fuel industry – by 1.8 times, non-ferrous metallurgy – by 2.3 times. Despite this, production of oil with condensate decreased by 1.4 times, gas – by 1.6 times, coal – by 2.0 times, iron ore – by 2.2 times, and manganese ore – by 3.6 times. The main factor in the growth of the share of mining industries is the transition to world prices for mineral raw materials, the preservation of the markets for iron, manganese and titanium ores, facing stones and certain other types of minerals [19].

Subsoil depletion and the formation of an industry structure burdened by heavy industries are accompanied by significant long-term environmental consequences. This is due to saving on environmental costs at the stages of field development that gives a significant economic profit. At the same time, the costs for elimination of the consequences of emergency environmental situations, accidents, and disasters often exceed the profit from mineral raw materials sale.

The biased structure of the economy in the direction of heavy industries and depletion of the mineral base with the accumulation of negative environmental consequences contributed to the development of a deep economic crisis in the Soviet Union in the mid-1980s. Western countries experienced similar crises back in the 1970s, from which they came out by restructuring of their economy with the reduction of heavy industry and the development of knowledge-intensive industries. The economic crisis in most states of the post-Soviet space continues to deepen, and it is exacerbated by a long-lasting and powerful environmental crisis. Ukraine is still in a crisis situation today, despite some signs of stabilization of its economy that was actually achieved as a result of the stabilization of mineral raw materials mining. However, wear and tear of equipment at mining enterprises is very high (up to 70-80%). Due to imperfect technologies of extraction and mineral raw materials processing, unsatisfactory solutions of issues of comprehensive development of deposits, there are up to 70% of explored oil reserves, up to 50% of salts, up to 28% of coal, and up to 25% of metals that remain in the state's subsoil [22].

Ukraine may enter a period of technogenic emergency situations, accidents and catastrophes. Sustainable development of the mining industry can only be ensured by innovative activities. Technical re-equipment of mining enterprises should be carried out to reduce losses of minerals during their extraction and processing; as well as to ensure industrial safety.

The analysis of the mineral base of Ukraine gives reason to include into promising types such non-traditional mineral raw materials for the country as native gold, native copper, rare metals, vein quartz, and various types of precious, manufactured and decorative stones. With certain caveats, this list also includes diamonds, the prospects for opening their deposits have increased. It is predicted that these types of mineral raw materials, after detailed exploration and further exploitation, will lead to the improvement of the state's economic condition, the development of gold and copper ore, rare metal and quartz industries. To expand the prospects for the development of the mineral base, it is necessary to expand the development of such minerals as brown coal, shale gas, development of non-traditional energy sources, in particular gas-methane from coal deposits and gas hydrates.

Ukraine actively participates in the integration processes in the European and world communities. Most industries are related to the functioning of the domestic mineral base. The state's level of development affects the organization of exploration and exploitation of subsoil and the development strategy of its mining industry. Developed countries, even having their own mineral base, are focused on investing into the mining and processing of mineral raw materials in other countries and its import. Developing countries, on the contrary, count on the intensive use of their own mineral deposits for economic development and obtaining profits from the export of raw materials. The current state of the domestic economy is characterized by a significant export orientation of the mineral base and, at the same time, a high level of industry dependence on imported supplies of certain types of minerals, especially oil and gas.

The level of mineral reserves in Ukraine depends on many factors. An example is the situation with stocks of flux raw materials for metallurgical enterprises. Ukraine is provided with dolomite reserves for many years, but providing enterprises with high-quality raw materials is a difficult problem and is possible only by increasing extraction in Southern Donbas, which is currently occupied. An acute situation has developed with flux limestones, the main reserves of which are also concentrated in Donbas. Several large deposits lie at significant depths or occupy arable land, so a proper economic and ecological assessment of their exploitation options is required. Therefore, the prospects for discovering new deposits of high-quality raw materials are limited.

The state is interested in protecting the national producer and promoting the development of export-oriented industries. In Ukraine, industries that secure export growth and, accordingly, are sources for foreign hard currency flow into Ukraine, are material- and energy-intensive and are interconnected with the development and prospects of the mineral base. Today, subsidies are widely used to stimulate exports which causes various forms of dumping. In other cases, we have the export of minerals that have not been converted into a product of intermediate or final consumption. This leads to great losses for the economy of the state, since the prices of raw materials and final production differ by tens or even hundreds of times. This indicates a predatory attitude towards the mining industry and causes depletion of the subsoil without obtaining an economic effect.

In the development strategy of Ukraine, it is important to outline the directions of movement in the field of geological study and use of subsoil: 1) a need to build up reserves of mineral resources, provided that the balance reserves of minerals will be enough for hundreds of years; 2) a need to increase the volume of mineral extraction with significant reserves and complex geological conditions and adverse environmental consequences of the development of deposits; 3) to attract investments in the study of deposits of fuel and energy raw materials, both traditional (oil and gas, brown and hard coal, peat), and unconventional (shale gas, coal-bed methane, gas hydrates of the Black Sea shelf).

3. Conclusions

Analysis of modern approaches to solving the problem of effective mineral raw materials use and mining waste allows us to state the following.

1. Efficient use and protection of the subsoil is a part of rational nature management in the mineral base of Ukrainian regions and Ukraine as a whole. Rational nature management should be understood not only as the optimization of the processes of intensive use of natural resources and their protection, but also as a system of measures covering the protection and control of the state of the environment, the reproduction and preservation of these resources, the effective use of capital investments in mining enterprises, and the placement of productive forces in the region.
2. The components for the rational use of the subsoil include a comprehensive development of mineral deposits, a comprehensive use of mineral raw materials and mining waste, optimization of the structure of mining production and mineral raw materials consumption. The maximum satisfaction of society's needs in certain types of raw materials at specified costs and under the condition of compliance with environmental standards can be considered as a criterion for an effective and optimal use of mineral resources.
3. The rational use of mineral resources in the modern interpretation of this issue extends to all stages of their development, including the issue of waste disposal. Solving the waste problem is limited to covering those groups and types of subsoil resource processing waste that are direct substitutes for certain types of mineral resources. They are grouped under the name of mining waste.
4. A huge amount of mining waste has been accumulated in administrative regions of Ukraine, and the issue of their disposal has gone beyond just an economic and ecological problem and has acquired a significant socio-demographic significance. Mainly, this applies to densely populated areas of Donbas, Kryvbas, Pre-Dnieper and Pre-Carpathian regions, where waste density varies from 2-3 to 10-30 million t/km^2. There are no such similar loads in any country in the world.
5. Environmental problems have become particularly acute due to the accumulation of toxic waste, among which the most dangerous are heavy metals, petroleum products and acid tars. Ukrainian enterprises generate up to 100 million tons of toxic waste every year, of which more than 3 million tons belong to I-III hazard classes. The total volume of toxic waste accumulation is 4.4 billion tons. In Ukraine, there is no plant for the processing of toxic industrial waste or landfills for their disposal, and the conditions for storing and eliminating waste do not meet sanitary and hygienic requirements.
6. For sustainable economic development of Ukraine, it is necessary not only to develop new reserves of natural mineral resources, but also to utilize technogenic, secondary, and unconventional mineral resources, which are accumulated in over 1,600 technogenic deposits and objects. Technogenic deposits of various minerals represent a powerful reserve mineral resource base for the development of the mining industry. They contain non-ferrous, rare, precious, and black metals, as well as rare-earth elements, non-ore, construction and energy

raw materials, mineral fertilizers, limestone and gypsum ameliorants, and so on. The development of technogenic deposits in Ukraine would expand the resource base of mining and metallurgical, coal and mining-chemical industries by 15...20%. Up to 30% of extracted overburden and associated rocks, as well as waste from their beneficiation, can be utilized for the production of various building materials.

7. The comprehensive utilization of mineral resources can only be achieved through the development and implementation of advanced modern technologies in the areas of exploration, extraction, enrichment, and processing of raw materials. In general, solving the problem of rational use of mineral resources, as well as natural resources in general, is related to the development and implementation of waste-free technologies. A geological assessment of waste as technogenic deposits is also necessary (determining the nature of the distribution of useful components in waste masses, studying their technological characteristics, determining the amount of reserves, etc.). Only after carrying out a complex of such assessment works should the issue of ways and methods of waste utilization in specific territories be addressed. Priority should be given to environmental protection measures accompanying current mining-industrial production.
8. Currently, scientific research aimed at addressing such problems as improving existing and developing fundamentally new methods for extracting useful minerals from subsoil and useful components from complex mineral raw materials and mining waste; developing methodologies and technological schemes for studying the distribution of useful components in ores and enclosing rocks at the geological exploration stage; and developing an ecological and economic assessment of complex deposits, among others, remains relevant.
9. The main factors that have influenced the economic development of Ukraine, based on intensive and prolonged use of mineral resources, include: 1) gradual depletion of subsoil; 2) the formation of an economy skewed towards heavy industries; and 3) the accumulation of long-term negative ecological consequences. An economy deformed towards heavy industries requires four to five times more material, capital, energy, mineral, and other resources compared to economies with a balanced industrial structure, where a significant share is comprised of light industry, the service sector, and modern knowledge-intensive production. Depletion of subsoil and the formation of an industrial structure overloaded with heavy industries are accompanied by the accumulation of significant long-term ecological consequences.
10. Further development of Ukraine's mineral and raw material complex requires urgent resolution of state-level problems that significantly hinder the expansion of the mineral and raw material base, its ecological rehabilitation, and rational use. The current system of subsoil use in Ukraine does not meet the requirements of modern market economics, and there are no unified requirements or rules for subsoil use and determination of payments for their use in economic theory. Although Ukraine's mineral and raw material base has sufficient reserves of many types of valuable minerals, some of them are in the stage of depletion, which requires reform of the economic and ecological mechanism for using mineral resources. In strategic terms, it is important for Ukraine to determine the directions of movement in the field of geological exploration and subsoil use.

Abstract. The article presents the investigation of constructive and technological parameters of an energy-efficient screw oil press. It is outlined the principle of operation of an energy-efficient screw oil press. The construction of the oil press is improved by the steam atomizer that is installed in the receiving hopper under the rifled rollers for moisture-thermal treatment with steam, which is completed with the heat exchanger, heating element, expansion tank and hydro group. Also, a steam generator connected to a steam atomizer which is embodied into the receiving hopper. It was analyzed the influence of the optimization criteria (oil yield, energy consumption and press productivity) on the efficiency of the technological process. These optimization criteria depend on the main independent factors: the length of the reception and preparation chamber, the material (sunflower pulp) moisture; the heating temperature, the screw rotation speed, the linear speed of movement of screw shaft turns. The optimal constructive and technological parameters of energy-efficient screw oil press are considered. The energy-efficient screw oil press refers to the equipment of the oil enterprises of small productivity and due to its design, it allows to use a simple technological scheme of oil pressing and to reduce the amount of energy and resources spent on the technological process in the context of use in sustainable food systems.

1. Introduction

At the current stage of economic evolution, in the conditions of the need to transfer the state's economy to an intensive path of development, the most rational use of production potentials is an urgent problem. One of the main tasks of sustainable food systems is the implementation of new technologies for the processing of agricultural products in the conditions of enterprises and farms as well as the production of small-sized, low-energy-consuming equipment for completing technological lines. In Ukraine sunflower is one of the most widespread agricultural crops. This is due primarily to the high profitability of crop cultivation, the possibility of effective sale of both seeds and vegetable oil. There are two methods to get oil from sunflower seeds: pressing and extraction method. However, the costs of producing oil by pressing are 8-10 times lower compared to extraction. All known types of screw presses can be divided into three groups: presses for preliminary and final removal of oil and double-acting presses (both types of removal of vegetable oil is carried out in one machine). The industry of such countries as the USA, Japan, India, China produces many options of oil presses. The geometric parameters of the oil presses, their kinematic and energy indicators are determined by the physical and mechanical properties of oil-containing seeds. Oil-separating presses can be part of oil raw material processing lines, or be independent units. However, according to the principle of action and work process, they are all of the same type. Oil presses that are used in the conditions of farms that process small volumes of sunflower have a number of disadvantages: low yield of oil in one pass, increased time spent on cleaning the press from clogging, which contributes to a significant decrease in the productivity and demands to manually push the oilcake from the hopper into the receiving and preparation chamber during repeated pressing, due to its poor flowability.

Food production is used as an entry point to improving food system sustainability [1]. Furthermore, it is important to provide the conceptual foundations of the mechanism of management of enterprise interaction with environment [2]. Ukrainian sunflower oil is export oriented product and positive trend on the world market will bring benefits for processing enterprises despite on uncertainty of country environment [3]. Various production sources including sunflower oil have the potential for producing improved food and fuel products such as biodiesel production and a renewable solvent phase [4]. Ukraine is one of the world-leading countries in production and export of sunflower oil and integration of the Ukrainian and the EU market is prospective way for economics and further biogas production [5]. The screw presses for different oil crops have almost identical principles of operation, but the technological regimes and constructive peculiarities can be varied [6]. There is some development of modern constructions of oil presses on the basis of analysis of the basic operational concepts for the screw channel and the influence of its parameters on the productivity [7]. It is considered the chemical, chromatography research carried out in the area of assessment of edible oils [8], also it was made a systematic review on effects of plant oil consumption [9]. The rapeseed and sunflower oil are most widespread not only in food technology but also in production of biogas, but there is a need to investigate different operating regimes [10] with use analysis methods to optimize the dimensional parameters and constructional characteristics [11]. The extraction method of processing vegetable oil is usually used in the conditions of big enterprises and there are a lot of issues [12], it is challenging during using high-moisture material [13]. The aspect of optimizing the processing technologies is important for the green manufacturing of oils [14]. It is important to take into account features of oil sunflower seeds and its input parameters [15]. There are a lot of by-products during processing sunflower oil such as press cakes and oil meal, which are high-protein feeds for farm animals [16]. The standardization of biomasses is going to be a key aspect to get good quality biofuels from those residues [17] and the thermal behaviour of these materials need to be studied [18]. With regards to the condition of pre- and post-processing techniques it is suggested to implement the new construction of expellers for oil millers in order to the fatty acid compositions of sunflower oil did not significantly change [19].

The screw presses have some common technical and technological drawbacks. The service condition of an oil screw press was analyzed. It was researched the fracture failure of the bearing rings [20]. Also, there were investigated the major components of the palm oil screw press [21]. The cases of shaft failure indicate common areas of failure that occur around the lower edges of the keyway and shaft shoulders [22]. The effectiveness of screw presses is evaluated for throughput capacity, feed rate, press cake oil content, oil expelling efficiency, percentage un-pressed grits output, percentage sludge output, and specific energy consumption [23]. The driveshaft of screw press is often found to be susceptible to failure, it is important to discover the root cause of this failure and the ways of its prevention [24]. The mechanical oil extraction using a commercial screw press was evaluated in the study [25]. The stress concentration occurred on the keyway of the tooth wheel holder, which finally caused the fracture at this area [26]. It is proposed to assess quality management systems through the values of the set of interconnected processes, to combine the assessments of different processes into one set of data and to estimate this set, which will allow assessing the system with higher objectivity and reliability, particularly in the conditions of enterprises of pressing sunflower oil [27]. The optimal constructive and technological parameters of technological equipment in the processes of agricultural production are considered [28], designing modern processing machines requires a study of the regularities of technological processes, dynamics and conditions of operation [29], but the investigation of constructive and technological parameters of an energy-efficient screw oil press was not the specific subject of research.

The aim of the article is to conduct the investigation of constructive and technological parameters of an energy-efficient screw oil press.

2. Methods

On the basis of the investigation of theoretical provisions of the process of oil separation by pressing sunflower seeds and engineering calculating methods it is proposed the constructive and technological parameters of an energy-efficient screw oil press.

In order to intensify the processing of sunflower seeds, the design of the screw press was improved, the laboratory and experimental studies of the pressing were carried out, the mathematical model on the basis of the main technological parameters has been developed. There was theoretically justified method of calculating the constructive and technological parameters of the screw press, conducted the factor ranking, the insignificant factors were excluded from further consideration.

The research outlined the optimization criteria and selected the coefficients of variation, according to which the optimal design and technological parameters of the energy-efficient screw oil press are presented. In the investigation were used the methods of generalization of theoretical and laboratory experimental studies, mathematical modelling of the process, substantiation of the method of processing experimental data, solution of the optimization problem in determining the constructive and technological parameters of an energy-efficient screw oil press [30].

3. Principle of operation of an energy-efficient screw oil press

The main process of the press method of obtaining oil is squeezing it from the sunflower pulp, which is a loose, porous material. At the beginning of the squeezing, as a result of the convergence of the particles, the oil, which was held on their surfaces, begins to flow through the channels between the particles. Then, with the onset of deformation of the particles, the oil begins to flow through the capillaries that make up the inner part of the particles themselves. From this moment the oil phase is considered continuous. Thus, the squeezing of oil from the sunflower pulp can be considered as the movement of an incompressible fluid in a porous, deformable medium. As the particles of the pressing sunflower pulp come together, the movement of the oil obeys the laws of hydrodynamics. When the oil is pressed deeply under high pressure, the surfaces of the sunflower pulp particles fuse with the encapsulation of the oil in separate areas of the cake. This phenomenon determines the uneven oiliness of the total mass of cake briquettes (shells). The part of the material, from which oil is squeezed out, undergoes elastic and plastic deformations during this process. As a result of the study of the influence of the character of the deformation on the degree of oil squeezing, it was found that the shear stress of the material created during squeezing should be less than the shear stress, which contributes to the emergence of plastic flow. This condition must be observed because in the case of plastic flow, together with the oil, the sunflower pulp will come out through the holes for its draining. At the same time, due to the drop in pressure, oil extraction will deteriorate.

When oil is squeezed out in screw presses, the pressure on the pressed material increases and the oil flows out not only due to the action of external conditions, but also as a result of the resistance of the sunflower pulp itself as it is compacted and the oil is squeezed out. In turn, the resistance of the sunflower pulp in the press depends on its plastic properties. When the sunflower pulp is over-dried, the formation of the cake into a shell stops and the pressed material begins to leave the press in the form of dry, stiff flour or groats with a high oil content. This transition is initially accompanied by an increase in the load on the drive electric motor of the press, and with the cessation of shell formation, its sharp drop. Often at this moment, structurally weak presses fail due to breakage of the most heavily loaded elements or stop under load, forming a pressing due to the failure of safety pins or tripping of protection. When the sunflower pulp is over moistened, the formation of the cake into a shell also stops and the pressed material comes out in the form of a shapeless soft mass. This transition is accompanied by a decrease in the load on the electric drive of the press. Thus, the pressure in the perforated cylinder is mainly depend on the plasticity of the sunflower pulp, the humidity and the temperature of the pressed material. In the process of pressing, the volume of the sunflower pulp is reduced due to the squeezing out of oil, convergence of the inner and outer surfaces of the particles, as well as due to some evaporation of moisture. The time the sunflower pulp stays in the screw press during squeezing depends on the speed of rotation of the screw shaft, the degree of capture of the material by the first turn of screw shaft, the physical and mechanical properties of the material and the degree of wear of the surfaces of the screw turns.

The energy-efficient screw oil press refers to the equipment of the oil and fat industry, namely to small-sized screw presses, which can be used in the enterprises of small productivity. During the development of an improved model, the task of creating a screw press for oil crops was set, in which, after crushing the seed core with rollers, the wet-thermal treatment of the sunflower seed pulp will be carried out using a steam-generating device. It will contribute to the improvement of the intensification of the separation of oil during pressing, and the process of steam heat treatment will not affect the quality of the oil. The energy-efficient screw oil press consists of a bed, a receiving hopper with rifled rollers, a perforated cylinder with slats collected in it, a screw shaft, a steam-generating device, a cone-type adjusting nut and a drive unit. The main attention during the development of the improved design was paid to the implementation of a steam-generating device, which makes it possible to intensify the separation of sunflower oil and thus increase its yield. The use of additional steaming will also contribute to the reduction of frictional forces and resistance of the processing material, which will allow to reduce the operation of the screw shaft and parts of the perforated cylinder and increase the service life of the press. The use of a steam-generating device for moisture-thermal processing makes it possible to increase the productivity of the press when processing oilseeds, reduce the oiliness of the cake, and increase the yield of sunflower oil.

The screw shaft is structurally made of individual screw turns, which differ in pitch and diameter, and intermediate rings, which are mounted on a smooth shaft and fixed against turning with a key. In the receiving hopper, there is a damper, a pair of threaded rollers, which receive a rotational movement from the screw shaft through a V-belt transmission. The main element of the press is the perforated cylinder, which has a welded cylindrical shape. Inside the cylindrical surface there are slats, which are held in place by a tension wedge. The installation of rifled rollers in the receiving hopper turns the sunflower seeds into a pulp, which contributes to the intensification of the oil separation process and the effective use of the perforated cylinder. Figure 1 shows a screw press for separating oil with a steam-generating device for wet-thermal processing; figure 2 shows a section of the receiving hopper with rifled rollers and a steam atomizer, a side view.

The screw press is fixed on the carcass 1. The material is fed into the receiving hopper 5, which is crushed by the rifled rollers 4, and turns into a sunflower pulp. The gap between the rollers is regulated depending on the physical and mechanical properties of the material being pressed. In the hopper, the sunflower pulp is subjected to moisture and thermal treatment with steam, the yield of the oil increases. In addition, the softening of the sunflower pulp will contribute to reducing the wear of the oil press parts. After moisture and thermal treatment, through the loading hole regulated by the valve 11, the material is sent to the middle of the reception and preparation chamber of the perforated cylinder 15, where it is captured by the turns of the screw shaft 13 and moves to the exit from the press. When the screw shaft rotates, the material is

transported into the working space, where oil is gradually squeezed out, which passes through the gaps between the perforated panels 16. Depending on the state of pressing material, the pressure in the working chamber is regulated using the adjustable nut 14. The area between the outer surface of the screw shaft and the inner surface of the perforated cylinder is the working space. Inside the cylindrical surface there are slats, which are held in place by the tension wedge 12. Steam generator 17 consists of: steam atomizer – 6; heat exchanger – 7; tubular electric heater – 8; expansion tank – 9; hydro groups – 10. The press and rollers are driven by the electric motor 2 through the V-belt transmission 3. Thus, the use of a steam-generating device in the design of the screw press will contribute to the intensification of oil separation to increase its yield, and will extend the service life of the structural elements of the machine.

4. Results

Analytical expressions obtained as a result of theoretical studies reflect an idealized technological process. Therefore, the purpose of research was to check the technological reliability, as well as quality indicators of the technological process according to three optimization criteria: maximum oil yield, minimum energy consumption, maximum press productivity. Achieving the set goal was carried out by solving a number of problems, for which: the factors that have the greatest influence on the quality of the technological process and are subject to regulation have been determined; the length of the reception and preparation chamber was increased and a steaming apparatus was installed in the experimental sample of the press; the dependence of oil yield (OY), energy consumption (EC) and press productivity (PP) on the identified variation factors was experimentally investigated. According to the results of optimization and determination of the optimal combination of factors on a sample of the screw press that operated as part of the sunflower seed processing line, the regularities of the technological process of pressing sunflower seeds were revealed.

At the initial stage of the study of any object using the theory of experiment planning, it is necessary, in addition to a thorough study of the literature, to conduct an a priori ranking of factors, which is performed by the method of expert evaluation. The essence of this method is in that the researchers are asked to arrange the factors that affect the progress of the process in the sequence of decreasing influence on the optimization criteria, that is, it is necessary to rank the correspondingly determined ordinal numbers (ranks) 1, 2, 3, $\ldots, k$. Factor ranking must be conducted in order to reduce the volume of experimental work, since insignificant factors can be quickly excluded from further consideration. This facilitates further stages of solving the experimental problem. The process of ranking the experiment is carried out as follows. During the interview, each specialist is asked to fill out a questionnaire, in which the factors, their dimensions and the expected intervals of variation of the factors are indicated. The specialist must assign the place of each factor, as well as supplement the questionnaire with other factors not included in the consideration.

The diagram of factor ranks shown in figure 3. There are chosen the factors: X1 – degree of crushing, mm; X2 – the length of the reception and preparation chamber, m; X3 – the width of the perforated channels, m; X4 – the working area of the perforated chamber, m^2; X5 – material (sunflower pulp) moisture, %; X6 – density of sunflower seeds, kg/m^3; X7 – heating temperature, C^0; X8 – screw rotation speed, s^{-1} ; X9 – linear speed of movement of screw shaft turns, m/s; X10 – level of mass input for pressing, kg/s; X11 – total area of perforated channels, m^2; X12 – the length of the perforated cylinder, m.

Conducted experimental studies showed that with an increase in press productivity, the oil yield ratio decreases, when extracting oil from the cake, oil drains along the entire length of the perforated chamber, it leads to clogging and stopping the press. The established facts allow to conclude that the sunflower seeds in the reception and preparation chamber do not have time to go into the state of pulp, that is, the material is not crushed enough and does not have enough time to heat up. Getting into the main chamber, this mass continues its transition into the sunflower pulp. Therefore, the initial part of the main chamber, almost to the middle, does not

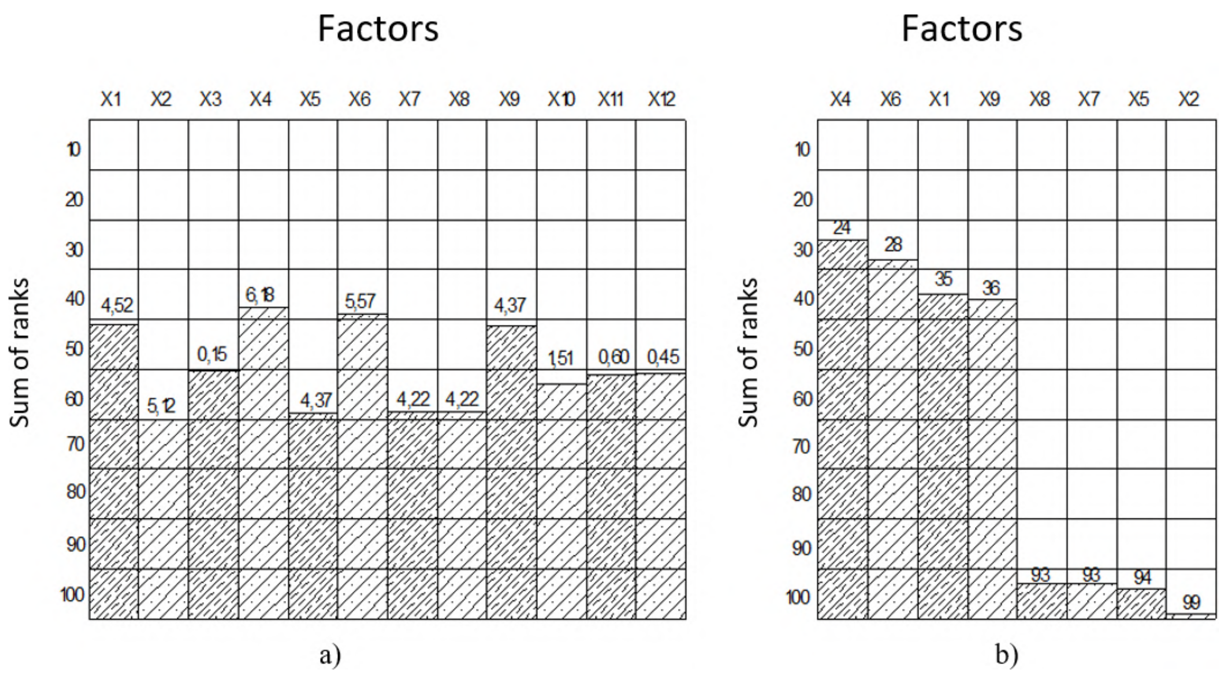

Figure 3. Ranking diagram of factors that affect the quality of work: a) to statistical assessment of the importance of factors; b) after ranking and determining non-significant factors.

work as intended, but performs the functions of a reception and preparation chamber.

In order to increase the efficiency of the process of extracting oil from sunflower seeds with a screw press it was enlarged the length of the reception and preparation chamber, that is, the conditions for obtaining high-quality crushed seeds were ensured. The particle size should be within 0.2-0.8 mm, and the heating temperature should be 80-125 $^{\circ}C$.

Obtained experimental data allowed to make an assumption that doubling the length of the reception and preparation chamber allows a significant increase in the percentage of oil yield.

In accordance with the experimental plan, an assessment of the dependence of technological process indicators, which have the greatest influence, was carried out. The most important indicators are: the length of the reception and preparation chamber, m (X2), the moisture content of the material (sunflower pulp), % (X5), the heating temperature, C^0 (X7), the speed of rotation of the screw shaft, s^{-1} (X8) and the linear speed of movement of the screw shaft turns, m/s (X9), which have the greatest effect on the quality of the screw press. The levels of setting of independent variables (factors) and the range of their variation adopted during the experiments are given in the table 1.

Table 1. Levels and range of variation factors.

Factors	Levels of variation			Interval of variation	Dimension
	-1	0	+1		
X_2	0	0.28	0.56	0.28	m
X_5	3	9	15	6	%
X_7	80	105	130	25	C^0
X_8	0.014	0.025	0.036	0.11	s^{-1}
X_9	0.002	0.04	0.006	0.002	m/s

The repeatability of experiments for each of the optimization criteria is three times. In each line of the plan, the average value of OY (oil yield), EC (energy consumption) and PP (press productivity) was calculated. Two-dimensional intersections of the response surfaces for the considered cases are shown in figure 4, figure 5 and figure 6.

With an increase in the length of the reception and preparation chamber and the humidity of the material (sunflower pulp), an increase in the percentage of oil yield and the productivity of the press is observed (figure 4). The zone of optimal combination of factors is limited by the arcs of the OY, EI and PP curves. The yield of oil will be in the range of 45-50 %; the energy consumption will not exceed 59 kW, and the press productivity will increase to 260 kg/h. For this technological regime, the speed of rotation of the screw shaft is equal to 0.025 s^{-1} , and the linear speed of movement of the turns of the screw shaft is 0.004 m/s.

The analysis of the results of the experiment demonstrates the higher quality of indicators of the technological process when the length of the reception and preparation chamber is 560

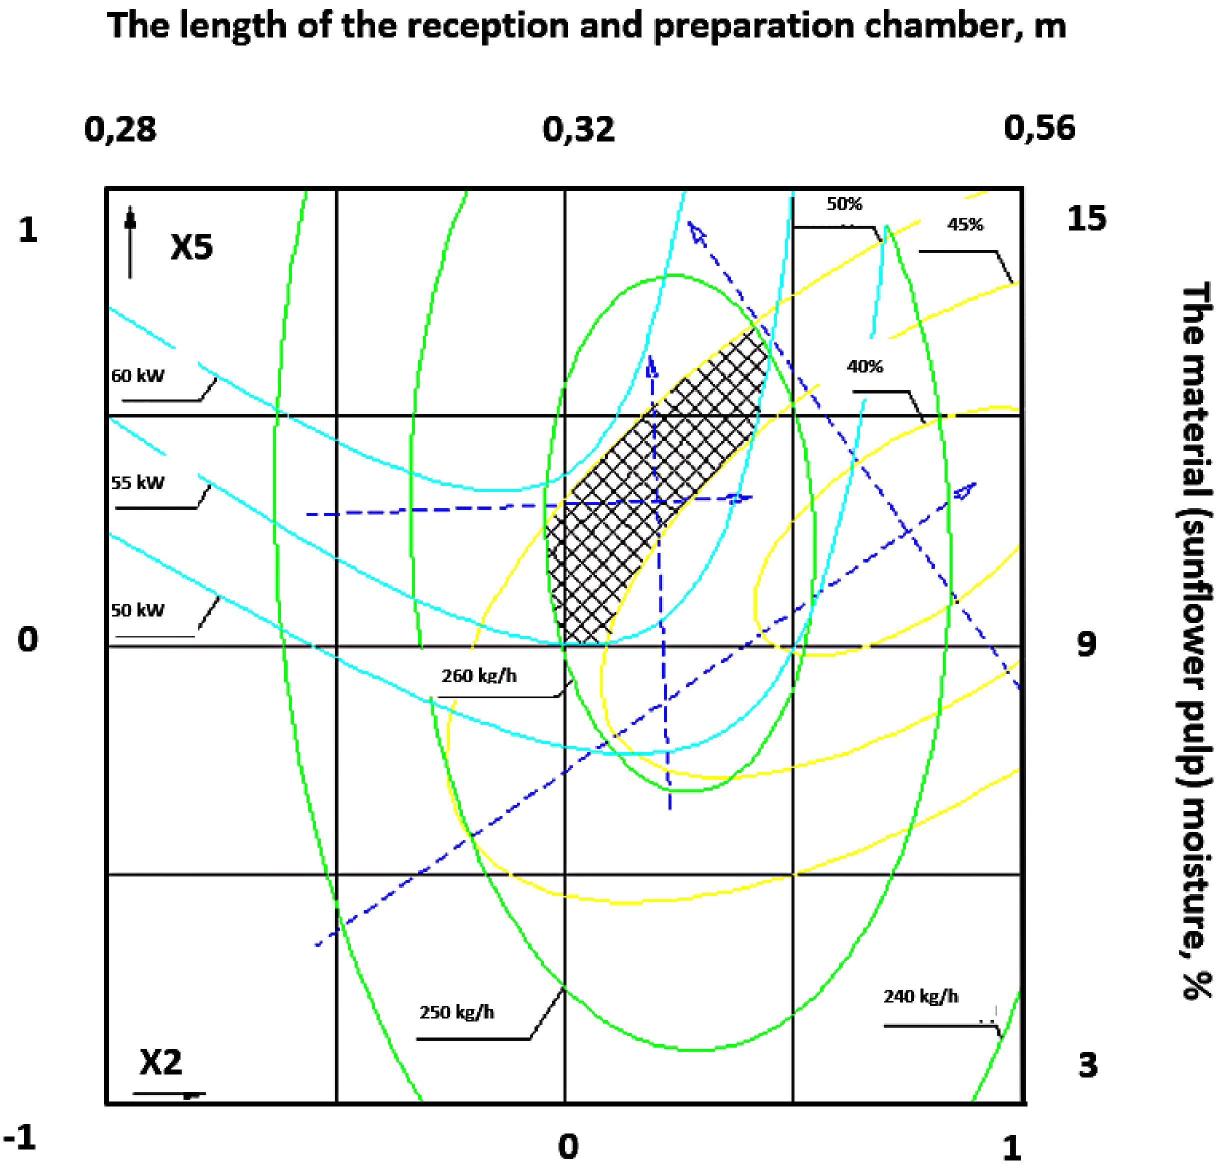

Figure 4. Two-dimensional intersections of response surfaces at X7=+1; X8=0; X9=0.

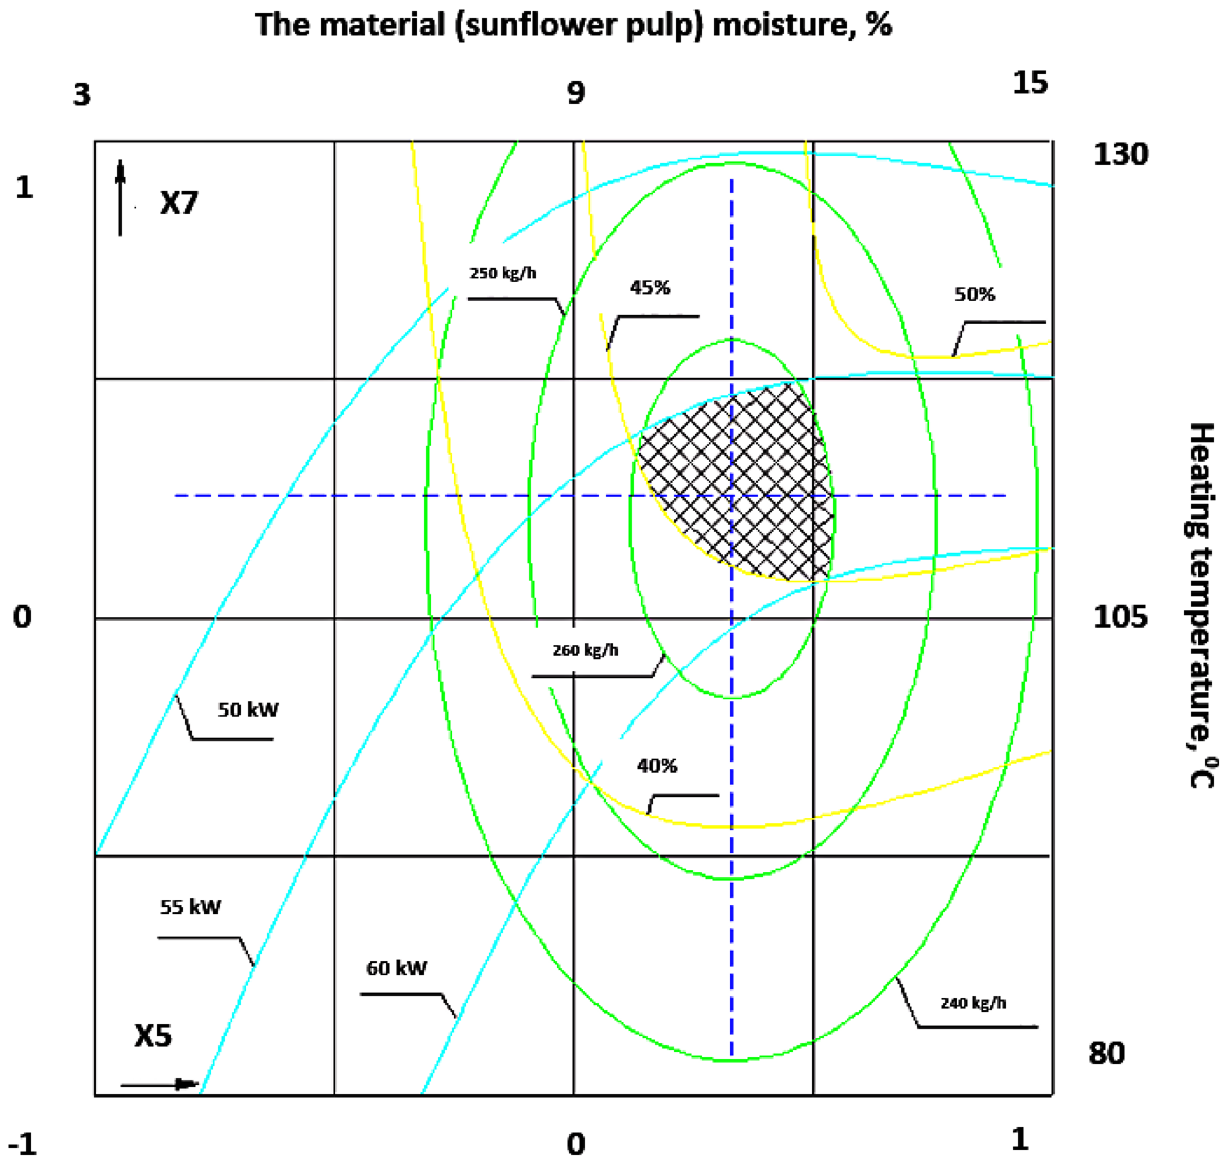

Figure 5. Two-dimensional intersections of response surfaces at X2=+1; X8=0; X9=0.

mm (figure 5). It is possible to achieve an oil yield of up to 50 % with an equipment power of 55-60 kW and a productivity of 260 kg/h. Humidity in the range of 9-15 % promotes better oil separation.

In order to achieve better values of the quality indicators of the technological process, compared to the two previously considered options, it is necessary that the length of the reception and preparation chamber be increased by 280 mm. As a result, it will be obtained more qualitatively crushed mass, and the pressing temperature is in the range of 105 – 130C^0 (figure 6). The selected combination of factors corresponds to the figure limited by the shaded area, the curves OY=50%, EC= 55kW and PP=260kg/h.

5. Discussion

In the context of the discussion of the obtained results it is necessary to point that the study of oil extraction process showed that the remaining oil in the sunflower pulp depends on the

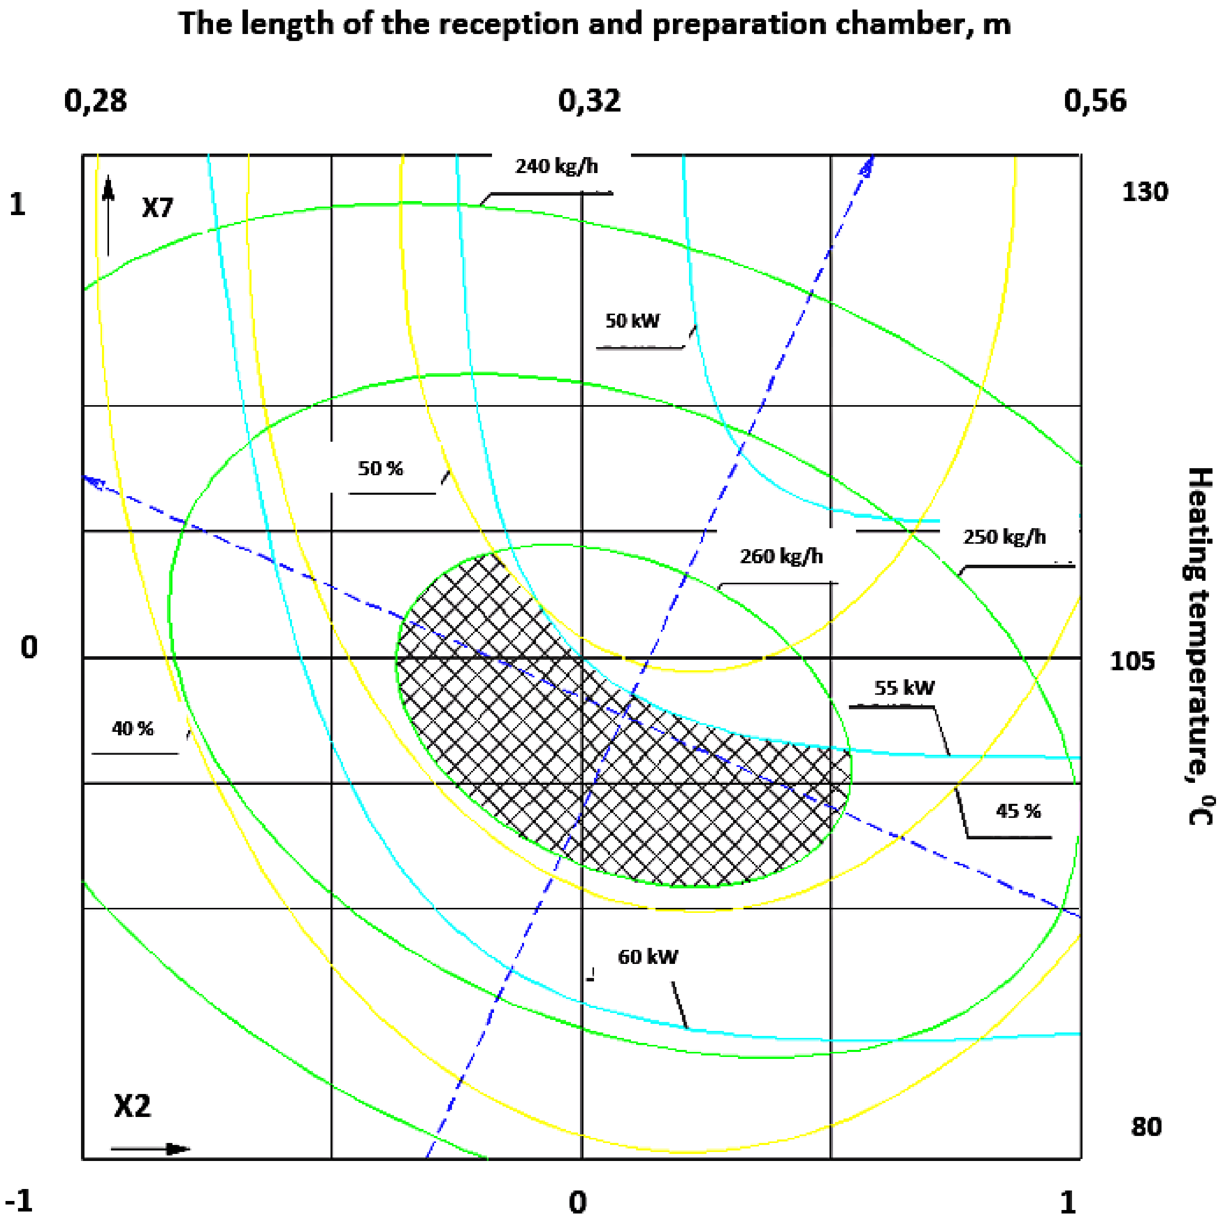

Figure 6. Two-dimensional intersections of response surfaces at X5=+1; X8=0; X9=0.

total and hydrodynamic pressure [31]. On the oil extraction process affect the thickness of the sunflower pulp layer, the permeability of the deforming sunflower pulp layer and its porosity, the viscosity of the oil, the duration of extraction, the degree compaction of the volumetric mass at the beginning and end of pressing and the density of the pressed oil [32]. Presses for extracting oil from vegetable raw materials have a similar principle of operation, but different constructive and technological parameters depending on the crop [33]. As well as the small enterprises or farms need the improvement of technological process indicators through the development of the energy efficient equipment in particular for producing sunflower oil [34].The squeezing of oil in the screw press occurs as a result of the gradual compaction of the sunflower pulp mass due to: reduction of the volume of mass located between turns, as a result of a gradual decrease in the pitch of individual turns and their height [35]. The mechanical effect of these turns on the sunflower pulp occurs during the rotation of the screw shaft [36]. The friction of the pressed material arises on the surface of the turns, the walls of the perforated cylinder and the friction of the particles among themselves [37]. Also, it is important to take into account the resistance of the mechanism that regulates the size of the outlet opening for the cake (cone, diaphragm, ring) [38]. The friction of the pressed material arises on the surface of the turns, the walls of the perforated cylinder and the friction of the particles among themselves [39]. The modernization of the energy-efficient screw oil press, namely the increase of length of the reception and preparation chamber and installation of steaming device can improve the indicators of the factors that determine the quality of oil extraction such as oil yield, energy consumption, press productivity, that was checked experimentally.

6. Conclusion

The technical solutions for pressing oil raw materials in the conditions of farms or small enterprises usually need the improvement of its efficiency. Also, they are not always technological when when it comes to increasing oil yield and equipment productivity. Thus, the urgent task is the production of small-sized, low-energy-consuming equipment for the completion of technological lines for the processing of agricultural products in the conditions of small enterprises in the context of food production sustainability. In order to eliminate these shortcomings, it is proposed to use energy-efficient screw oil press which consist of a carcass, a receiving hopper with rifled rollers, a perforated cylinder, a screw shaft, a steam-generating device, a cone-type adjusting nut and a drive unit.

The special feature of the design of screw oil press is that a steam atomizer is installed in the receiving hopper under the rifled rollers for carrying out moisture-thermal treatment. It is completed with a heat exchanger, a heating element, an expansion tank and a hydraulic group. Additionally, a steam generator connected to a steam atomizer that is implemented into the receiving hopper. The energy consumption of the pressing process is mainly influenced by the independent factors: the length of the reception and preparation chamber, the material (sunflower pulp) moisture; the heating temperature, the screw rotation speed, the linear speed of movement of screw shaft turns. The purpose of research is to check the quality indicators of the technological process according to the following optimization criteria: oil yield, energy consumption, press productivity. On the basis of theoretical and experimental studies, the most profitable constructional and technological parameters of the screw press have been established, namely: the length of the reception and preparation chamber is 560 mm, the moisture content of the pulp is within 9-15 %, and the pressing temperature is 130 $°C$. At the same time, the yield of oil is 45-50 %.

E-mail: elenapomor7@gmail.com, s.kobzan@gmail.com

Abstract. The purpose of the article is to determine the optimal placement of the bomb shelter in the existing urban development. To achieve this goal, the authors used geoinformation systems. The authors set the task of processing topographic and geodetic data and related information. The authors implemented the task employing spatial analysis using existing ArcGis software modules. The use of the geoinformation system in the article makes it possible to significantly increase the speed of information processing than when using traditional methods. The use of the geoinformation system by the authors allows the creation of geodatabases with all the necessary attribute information. The authors researched the example of 522 micro-districts of the Saltivsky residential area of Kharkiv. The intellectual analysis of the existing information was carried out in this work using the geostatistical method for data transformation from a discrete to a continuous representation. In the article, the authors solved the task of determining the location of civil protection facilities using many factors and requirements. Visualization of the dangerous zones of the explosion of building debris during destruction, determination of the optimal route of movement of the population to the bomb shelter, and determination of the time required for this carried out. The obtained results, presented in the form of an algorithm, will make it possible to use the proposed sequence of actions to solve similar problems in the future. The authors developed an algorithm that significantly reduces the time for processing topographic and geodetic data and related information and solves the task of determining the location of civil protection facilities using many factors and requirements.

1. Problem statement

Determining the optimal location of a bomb shelter (object of civil protection of the population) in already formed residential areas is a time-consuming and long-term task. Such research relates to the formation of bomb shelters on a plot of land to protect the civilian population from the shrapnel effect of shells, debris from destroyed buildings, poisonous gases, and radiation.

Over the past 30 years, no one has investigated the problem of determining the optimal location of a bomb shelter. Bomb shelters were actively built during the Second World War and several years after its end. In that period of history, specially built bomb shelters were created and the basements of buildings in large cities were adapted for the protection of the population, and the use of underground subway facilities was planned.

After the collapse of the USSR, bomb shelters were no longer built, on the contrary, bomb shelters were only rebuilt or destroyed. Ukraine got the Soviet infrastructure with the lack of protective structures for the civilian population. Thus, the study of the issue of proper storage and operation of bomb shelters in Ukraine was not conducted.

The study of this topic is very relevant for all Ukrainian cities, as well as, for Kharkiv. Currently, during military operations, the issue of designing and building bomb shelters is relevant due to many rocket and artillery attacks on the civilian population. The research carried out by the authors showed that it is possible to design, build or place a room under a bomb shelter:

- in basements;
- in premises where it was previously planned to place parking spaces;
- at subway stations;
- in rooms on the first floor, protected from the outside by load-bearing walls and with the absence of window and door openings;
- in a new location determined with the help of GIS.

Today, most civil protection facilities are abandoned, in poor condition, or destroyed. In this regard, precisely during active hostilities, a problem arose related to the lack of reliable bomb shelters. In the article, the researchers consider the problem of designing bomb shelters in a new location determined with the help of GIS.

2. Literature review

The design of the optimal location of bomb shelters in residential areas with subsequent operation is subject to clause 16 of part 17 of the Civil Defense Code and clauses 11, 18, 19 [1]. This task is quite complex and requires the analysis of many factors and requirements. The procedure for the creation and maintenance of protective structures of civil defense and their record keeping was approved by the Resolution of the Cabinet of Ministers of Ukraine No. 138 [2].

For example, today, in one of the underground parking lots of the Kharkiv office center, converted into a bomb shelter, residents are hiding from dangerous shelling by Russian soldiers. The rooms of the bomb shelter have heating, ventilation, a storage tank with water, a certain supply of food, and even showers – everything necessary [3]. In the future, the design of new buildings with reinforced underground parking lots, which can be used as a reliable bomb shelter, is being considered. The mayor's office of Kharkiv, which suffered the most during the hostilities, prepared recommendations for developers on the arrangement of "safe rooms" using Israeli experience. A protective room with reinforced walls with a minimum area of 9 m^2 provided within the apartments. A new building should have a separate riser of such rooms, but the arrangement of these safe rooms will significantly increase the cost of the apartment. However, constant rocket and artillery attacks on the cities of Ukraine have shown that for the safety of the civilian population today, it is necessary to build new bomb shelters in populated areas.

Thus, today the government of Ukraine plans to introduce changes to building regulations. There is a need to consider Israel's experience in the planned reconstruction of housing, infrastructure, and bomb shelters. The issue of security is planned to be regulated at the legislative level with prescribed norms and rules [4].

Bomb shelters made of reinforced concrete are of great importance for the protection of people during hostilities. Functional requirements for such structures differ from ordinary residential or commercial structures. Therefore, other approaches are used for the design and construction of bomb shelters. For example, the explosion resistance of such structures should be maximum, especially in the conditions of hostilities, in such countries as Ukraine, Afghanistan, Israel, Syria, and Lebanon. There are developments in the use of ground explosion-proof sheltered cylindrical configurations consisting of vertical and inclined walls with a flat roof made of concrete and steel [5].

It is also necessary to add that the creation of bomb shelters or places to accommodate the population during natural disasters are costly project. The cost of the bomb shelter construction program depends on the population in the risk zone. Such a cost can be equal to the cost of a large military strategic system [6].

For houses that were built earlier, it is necessary to build separate bomb shelters where people can feel safe. The location of such civil protection facilities must be chosen carefully, based on many factors [7]. The issue of finding a city for a future bomb shelter is quite difficult because it is necessary not only to find a free place for construction in an already built-up massif but also to consider psychological and physiological factors of human life [8]. An important feature is that it is necessary to consider the fact that much of the young population either evacuated or is serving in the army, that is, most elderly people remained in the cities.

That is why great importance should be attached to the optimization of evacuation routes for vulnerable population groups when searching for a place to locate a bomb shelter. Also, it is important to develop a road map showing the routes to bomb shelters [9].

Emergency shelters, which provide places for temporary accommodation of the population during natural disasters, play a dual role, they can also be used as bomb shelters. Great attention should be paid to the optimization of location selection. It is necessary to pay attention to the experience of other countries. Special attention should be paid to the optimization of site selection issues using spatiotemporal regularities. Such storage facilities should be designed considering different types of natural disasters [10].

3. Materials and method

Currently, in the city of Kharkiv (Ukraine), as in most modern large cities, there are “sleeping” districts. The peculiarity of these compact places of residence of the population is that almost all the buildings are multi-story and quite close to each other. There are almost no undeveloped areas of the territory. Low-rise buildings (two- and three-story) – kindergartens, schools, and heat distribution stations are unevenly located in the district and in small numbers. To solve the goal set by the authors, namely, to determine the place of the optimal location of the bomb shelter in the already existing urban development, a typical micro district of the Saltivka residential area number 522 was chosen as an example (figure 1).

The peculiarity of this residential massif is the very compact living of people and the fact that the construction was carried out on alluvial soils and sands. The compositions decision of

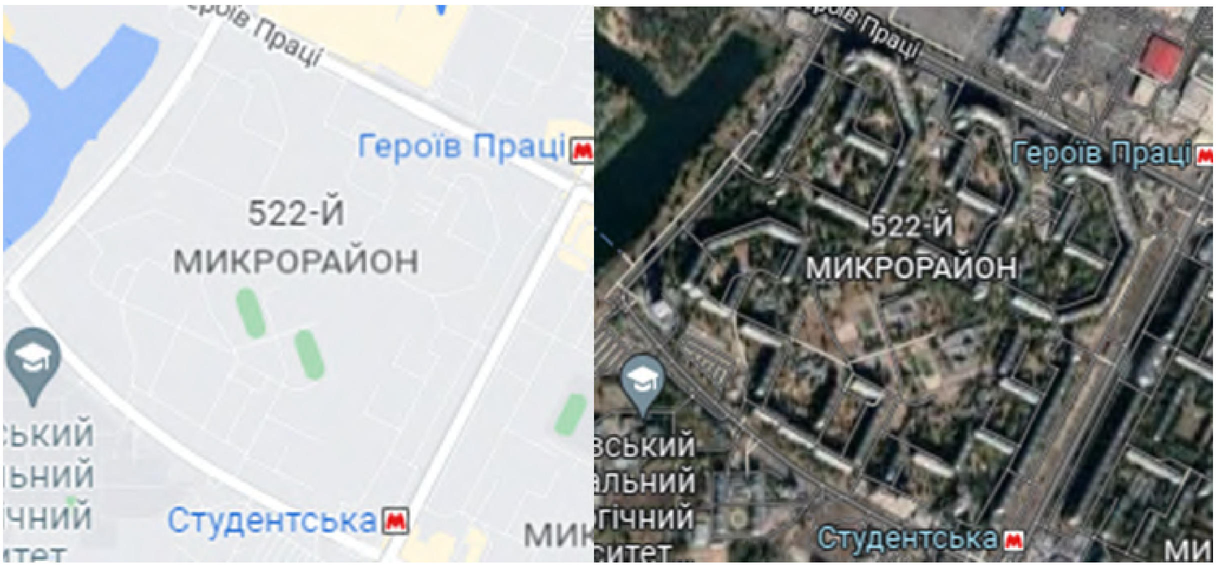

Figure 1. View of the 522nd micro district left – map; on right – is a satellite.

the designers was based on the discovery of plastic groups of rhythmically repeating buildings located along the central pedestrian alley leading to the Zhuravlivsky Hydro-park. The cultural and household services of this consolidated neighborhood were decided according to the principle of "focusing" [11]. Approximately 28,587 people live in the micro-district.

Choosing the location of a bomb shelter in such a densely populated neighborhood requires the processing of large volumes of diverse information and using information technologies designed for modeling spatial data. Modern means of analysis and visualization of territorial placement and modeling based on the use of geoinformation technologies [12, 13].

The main reason for the inclusion of geographic information systems (GIS) in solving the task of designing the placement of a bomb shelter is spatial analysis and decision support based on mathematical and cartographic modeling, visualization, forecasting, and evaluation. The use of

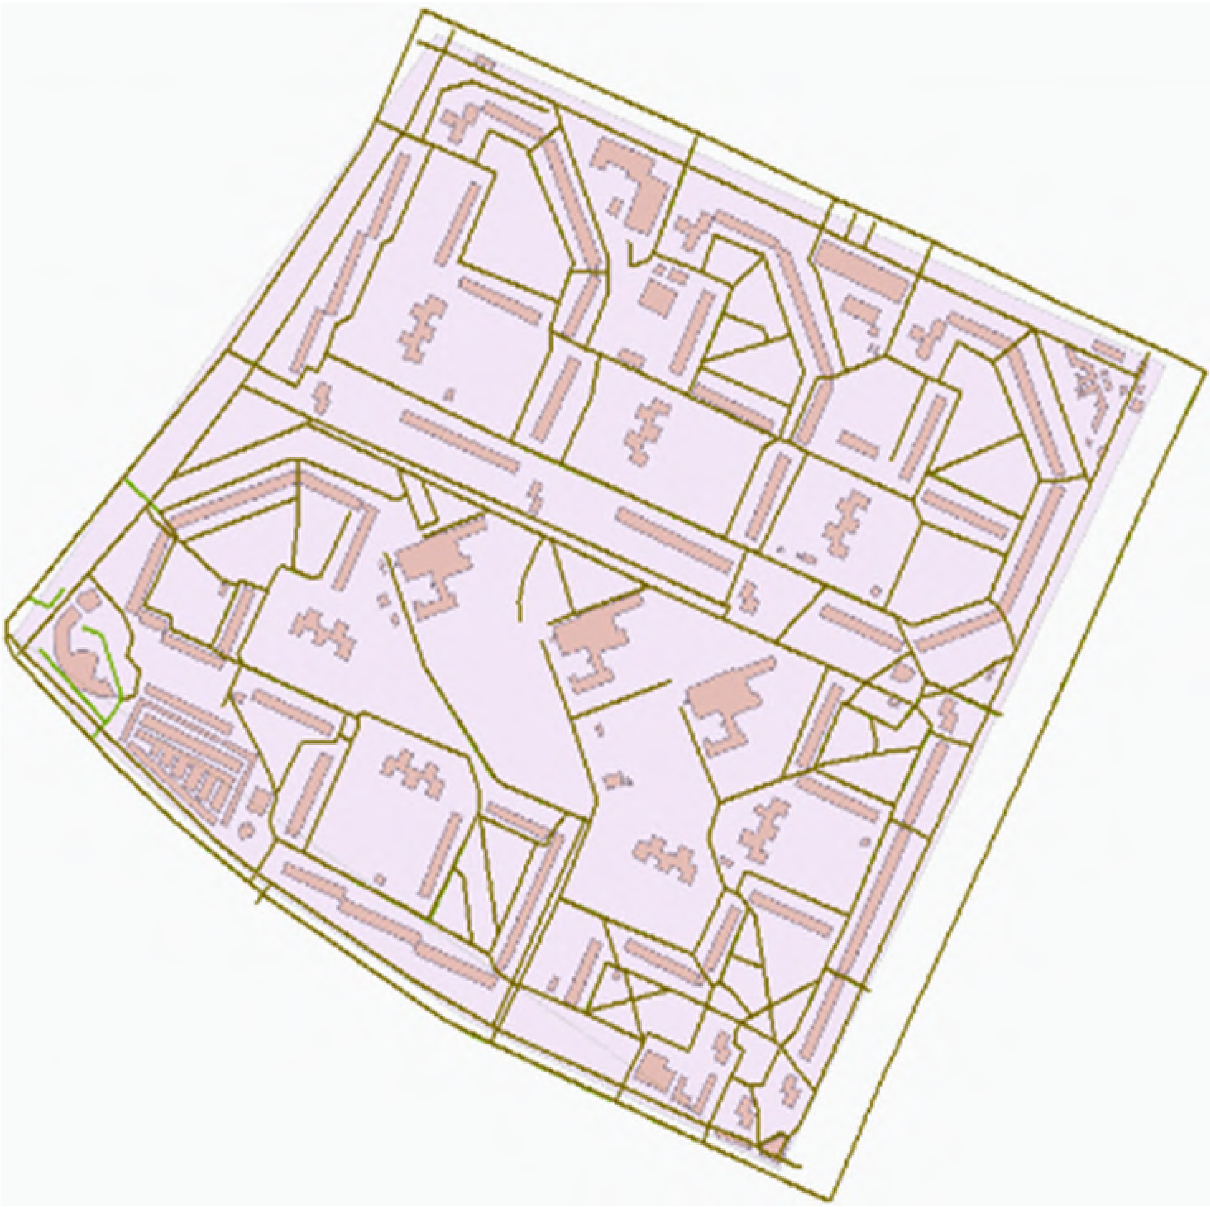

Figure 2. Digital model of the 522nd micro district.

GIS allows you to create a detailed visualization and conduct a qualitative spatial analysis [14,15] of the location of the bomb shelter concerning the territory. The simulation, the results of which are presented in this work, was done using the capabilities of the software product from the American company Esri – ArcGIS.

A personal geodatabase with the necessary layers was created to display the built-up objects of the micro-district. As a result of studying the necessary objects for further analysis, it was decided to use the following layers in the geodatabase:

- Layer Building1 (polygonal) – for displaying buildings.
- Layer Luki1 (point) – for displaying sewer hatches.
- Layer Polygon1 (polygonal) – for displaying the boundaries of the neighborhood.
- Layer Streets ND (dotted) – for displaying walking routes to the bomb shelter.
- Layer Streets1 (linear) – for displaying highways.
- Layer Streets2 (linear) – for displaying footpaths.

For all layers, the USC 2000 zone 7 coordinate system was set. The initial data for vectorization were the materials of the general plan of the Kharkiv. As a result, a digital model of the territory of micro-district 522 of the Saltivsky residential massif was created, considering residential and non-residential buildings (figure 2).

After vectorization, the data was entered into the attribute tables of the corresponding layers. These data will be needed in the future for calculations and analysis of the land plot. An example of a filled attribute table for a point layer of sewer hatches (Luki1) is shown in figure 3.

One of the important characteristics of the 522 micro district is the presence of two metro stations (Heroiv Pratsi and Studentska). During air raids and shelling, they can perform a

protective function for people living nearby. There are also three three-story school buildings in the neighborhood. The peculiarity is that all three schools are located next to each other, and thanks to the presence of stadiums with football fields in two of them, all these schools are at a considerable distance from the adjacent residential development.

To mark on the digital map dangerous zones (on which debris does not fall in the event of a building collapse), it is necessary to calculate the distance of debris falling around the buildings. For this, we will use the following formula:

$$L = (E \cdot 2.9 + 1.5 + 2)/2.9 \tag{1}$$

where

E is the number of floors;

2.9 is the floor height;

1.5 is the height of the semi-basement;

2 is the height of the technical floor.

To determine the height of the only 25-story building in the neighborhood, you need to add 7.2 m, since the technical floor and semi-basement are much higher, unlike the buildings of the old version, which built the entire neighborhood. On the given fragment of the digital map (figure 4) the zones of debris spread around all the houses in the neighborhood are marked.

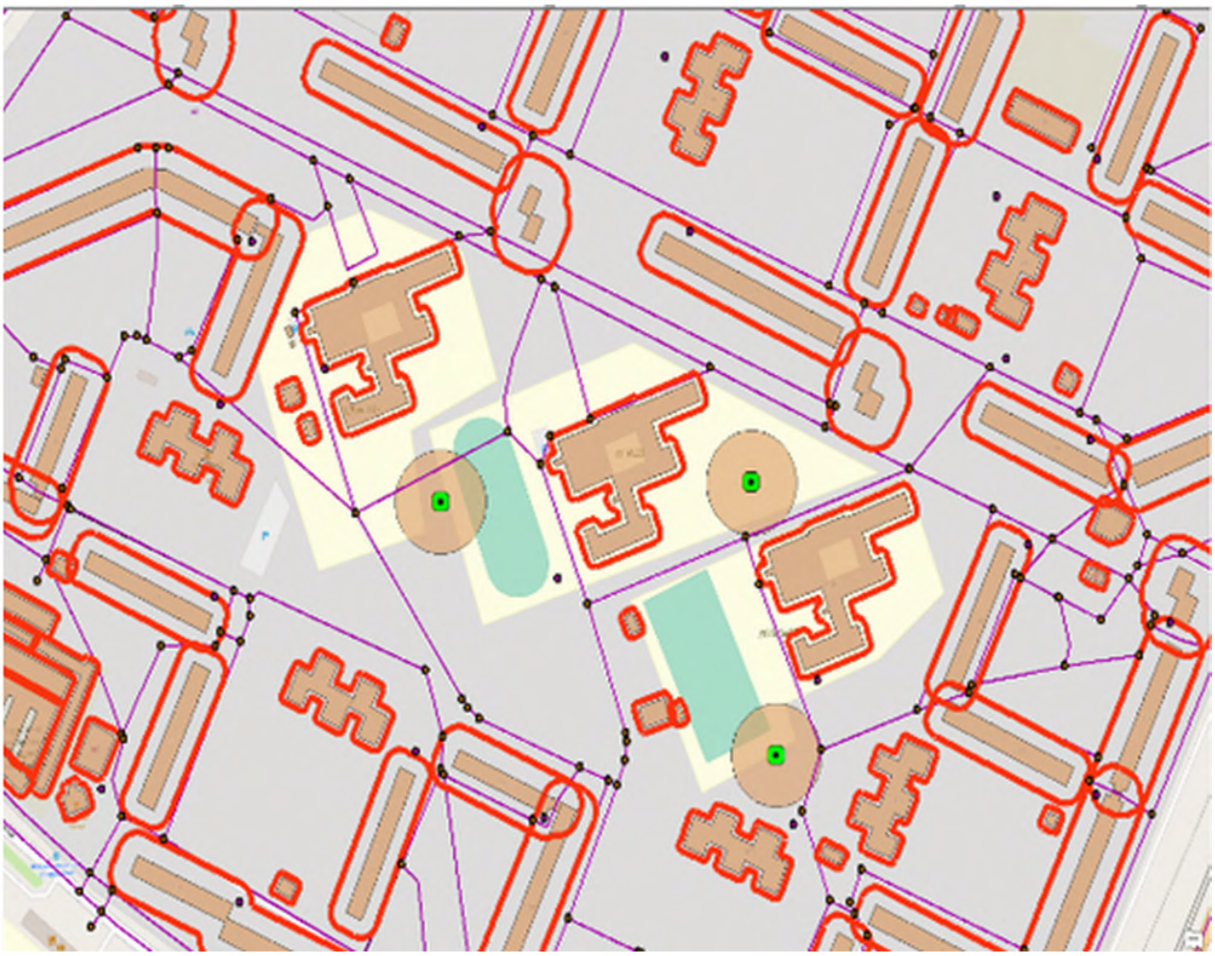

Figure 4. A view of the scattered debris zones around the houses.

From figure 4, from the south, schools are at a safe distance from residential buildings, and if they collapse due to the impact of shells, a large free area remains. Therefore, the authors proposed the creation of bomb shelters on the territory of school sports fields. The location of the bomb shelters themselves are marked on the digital map with dots. Thanks to the calculations carried out in the work, it is proposed to create three warehouses with 2500 places in each.

None of the bomb shelters fall into the area of the explosion of building debris, so the entrance to them not be blocked for the public. Three bomb shelters can accommodate 7,500 people. Approximately 28,587 people live in the micro-district. It means that approximately 30 percent of the population will be to stay in a safe place. The rest of the population can find shelter in the two existing metro stations.

In our opinion, a large civil defense structure should not be built, since, in case of damage to the bomb shelter with high-precision heavy weapons, it will not be possible to move the population to another shelter. In the case of a blockage of the entrance door of the protective structure due to a direct hit, several emergencies exit for evacuation are provided in each structure. And thanks to the fact that the three storage facilities are located next to each other, the civilian population will be able to quickly move to another storage facility. It is more appropriate to build three small bomb shelters, and place sports school grounds and stadiums on top of them. Thus, children are not left without the opportunity to conduct physical education classes in the open air.

To reach the bomb shelter in the event of an alarm, the civilian population needs approximately 15 minutes according to safety standards. Therefore, it is necessary to perform the following calculations for each of the four corners of the neighborhood and determine the time and optimal walking route. The Network Analyst module of the ArcGIS geographic information system was used for this task. The results of the analysis shown in the figure 5. Routes of movement to the bomb shelter from different ends of the 522 micro district and they demonstrate optimal routes from the northeast corner (10 minutes), from the southwest corner (11 minutes),

Figure 5. Routes of movement to the bomb shelter from different ends of the 522nd micro district.

from the southeast corner (4 minutes), from the northwest corner (15 minutes) (figure 5). As you can see, no route exceeds the 15 minutes recommended by regulations.

The received optimal walking routes to bomb shelters must be sent in advance to all residents of the neighborhood using social networks and printed and distributed.

One of the most important stages of determining the optimal place for a bomb shelter in an already existing residential building (figure 6) is the development of a geodatabase, which includes all the necessary factors for choosing the location of a civil defense facility.

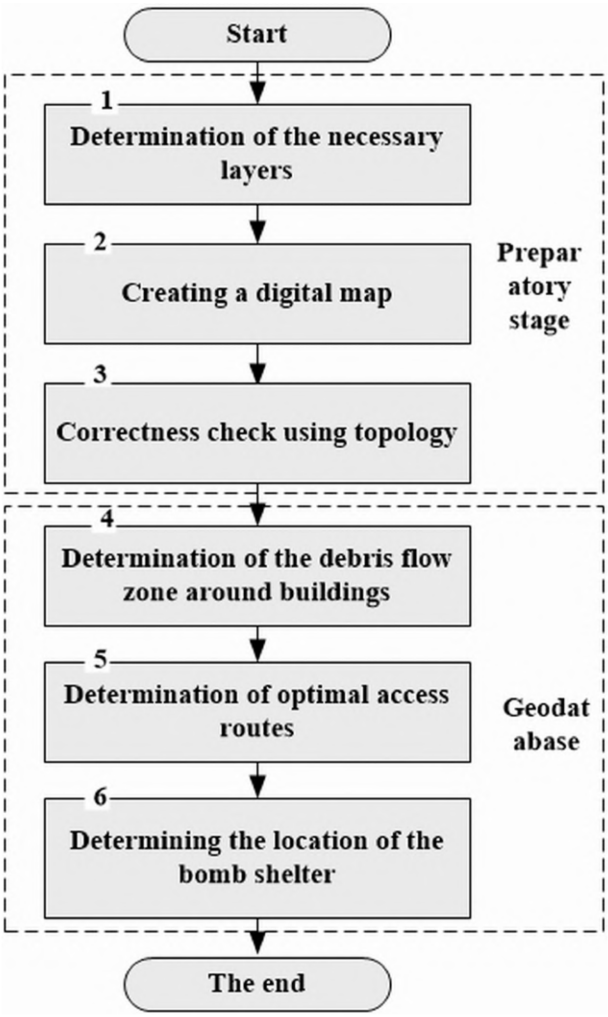

Figure 6. Algorithm for finding the optimal place for the location of the civil protection facility.

4. Results

1. The authors developed a digital geoinformation model of 522nd micro-district of the Saltivska residential area of the city of Kharkiv with the introduction of a significant amount of attribute data.
2. The optimal routes to the designed bomb shelters were calculated using geographic information systems and displayed on digital maps.
3. In the article, calculations are made regarding the distance of debris flying around buildings, and dangerous zones are displayed on a digital map.

4. Reference with the fact that the task of finding a place for the location of a civil protection facility in an already built residential area must be solved not only in Ukraine but also in many other countries of the world. An important feature of the work is that such a design was not foreseen at the stage of development of the master plan of the city's residential area. The authors have developed an algorithm for solving the task of finding a place for the location of a civil protection facility in an already built, crowded residential area.
5. In the research conducted by the authors, the locations of bomb shelters were determined based on the results of the analysis of many factors.

5. Conclusions

Thus, the geospatial modeling used by the authors made it possible to carry out actions to determine the optimal location of the protective structures of the civilian population. The calculations obtained by the authors enable the government and regional authorities to create a civil protection facility for the population in built-up areas.

The application of geoinformation technologies for modeling the optimal placement of bomb shelters in residential areas allowed for considering many factors, such as the spread of debris around buildings, and the optimal route of movement to the bomb shelter. That is, the authors proposed how to solve the task with minimal time expenditure and with the lowest probability of error. With the help of a spatial analysis performed in the ArcGIS geoinformation system, a place was chosen for the construction of a bomb shelter for the civilian population in the 522nd micro district of Kharkiv. A digital geoinformation model of 522 micro districts of the residential area of the city of Kharkiv has been developed.

In the work, with the help of the ArcGIS software package, a geodatabase of this neighborhood was developed, which made it possible to determine the number and location of civil protection facilities. In the future, it is possible to use the proposed sequence of actions to solve similar problems.

In general, the intelligent analysis of geostatic models can be used to process data in any locality thanks to the use of a geostatistical method to transform data from a discrete to a continuous representation.

Abstract. Using GIS technologies, the article analyzes, systematizes, and processes, the data obtained in the process of geodetic monitoring of man-made territories and objects, which will make it possible to analyze the existing state of the object and provide an opportunity to determine critical spatial deviations that can lead to irreversible processes of destruction of buildings and structures. This provides an opportunity to prevent processes that can lead to large-scale disasters, as well as determines the adoption of timely measures to prevent the destruction of structures and predict emergencies.

1. Introduction

On the territory of Ukraine, there are many potentially dangerous objects of the fuel and energy complex, hydraulic structures, industrial facilities, mineral extraction enterprises, and others, of which operational resource is almost exhausted. Therefore, any dangerous phenomena of an endogenous and exogenous nature (earthquakes, landslides, and floods), or man-made factors caused by human activity can lead to large-scale disasters. We must not forget about the energy issue of state security, which is currently gaining great importance. Therefore, a necessary factor in preventing the destruction of objects and predicting deformations of engineering structures is the use of GIS technologies for geodetic monitoring of man-made territories and objects.

2. Methodology

On April 26, 1986, the largest man-made disaster in the history of mankind occurred – the explosion at the Chornobyl nuclear power plant. In a short time – from July to November 1986 – a protective structure was erected over the destroyed fourth power unit of the Chornobyl NPP (a little later it received the unofficial name “Shelter”) to protect the environment from further pollution [1].

Since the “Shelter” facility was built within a short period and under extreme conditions, it does not comply with the rules and regulations for the design, construction, commissioning, and operation of either nuclear installations or radioactive waste management facilities, or regular industrial buildings. Therefore, after its construction, constant engineering, and geodetic monitoring of the state of the entire complex of buildings and structures of the “Shelter” facility became the key task.

The volume of engineering and geodetic observations of the “Shelter” facility includes the regular determination of the height position of the settlement control marks on the foundations and the spatial position of the deformation marks located, respectively, in the plinth (lower tier) and on the upper tiers of the “Shelter” facility (figure 1).

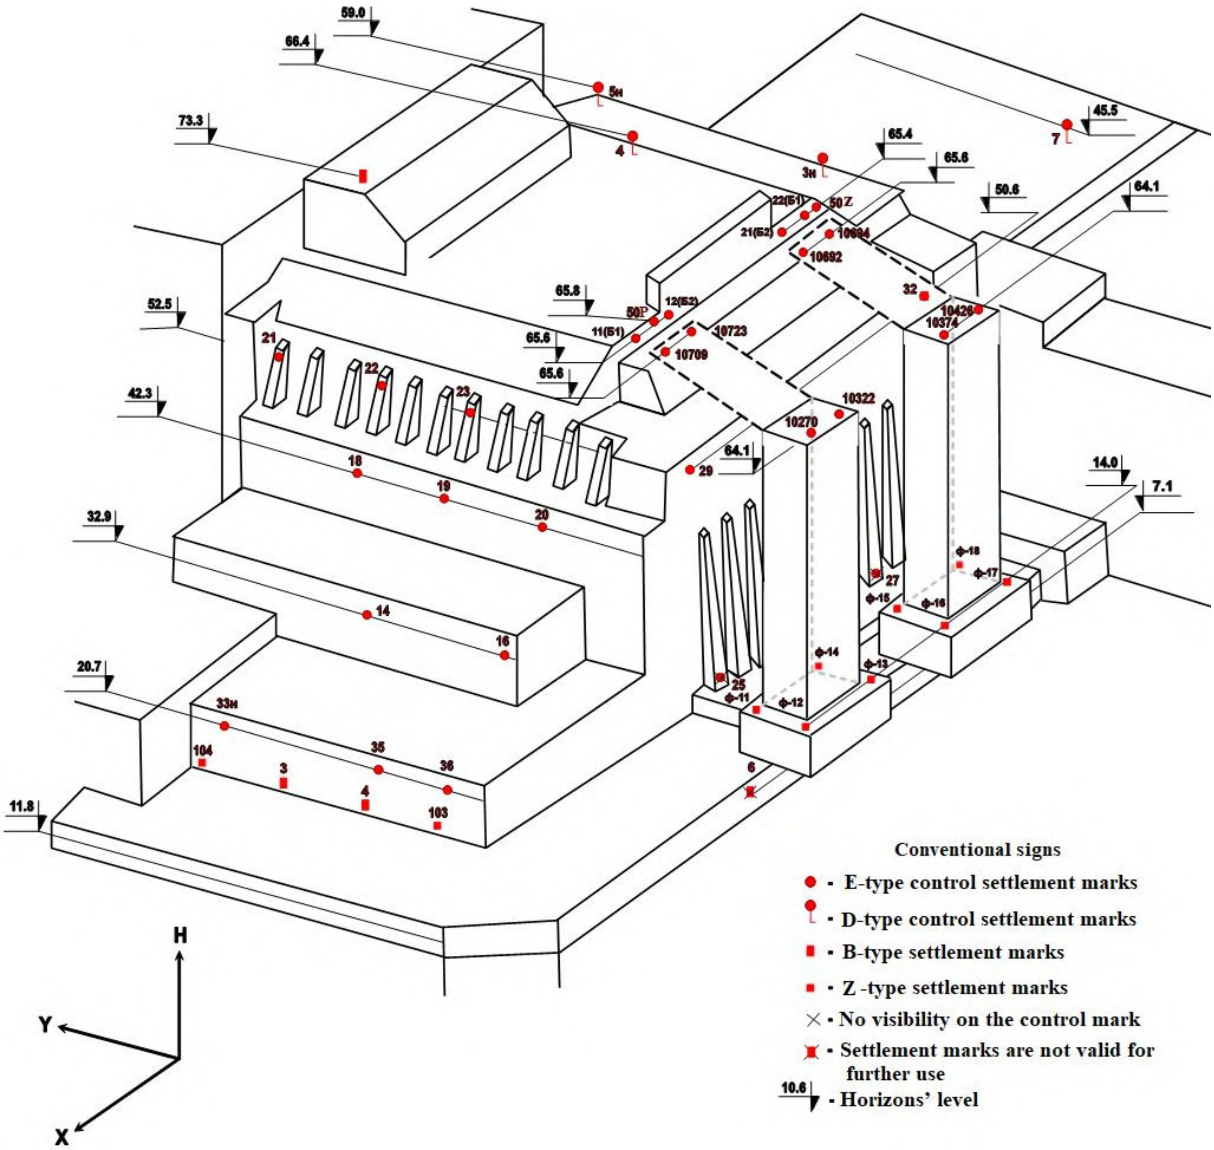

Figure 1. The scheme of the location of control marks at the “Shelter” facility.

The signs installed on the foundations of buildings are placed on the transverse and longitudinal axes of at least four signs around the perimeter. They are installed on the end walls of the “Shelter” facility according to the assembly diagram. In the places of temperature seams on both sides of them, control marks are installed.

When laying sedimentary marks, the conditions of access to them and the possibility of attaching a leveling rail to them should be considered, as a rule, at 0.4–0.8 m from the level of the intersection or the level of the clean floor. Sediment deformation marks should be painted with indelible masking paint, numbered, and tied to the corners of the walls or protrusions according to the scheme [2].

Observations at the points are performed in groups of 4–5 directions to eliminate errors of focus change during one reception of observations due to different distances and errors of closing the horizon. Angular measurements are carried out by high-precision tacheometers [3]. Angles and lines are measured by the method of tunnel triangulation of the 1-T discharge and tunnel trilateration of the 1-T discharge, respectively. The scheme of determining the spatial position of control marks from the points of the plan-altitude network is shown in figures 2 and 3.

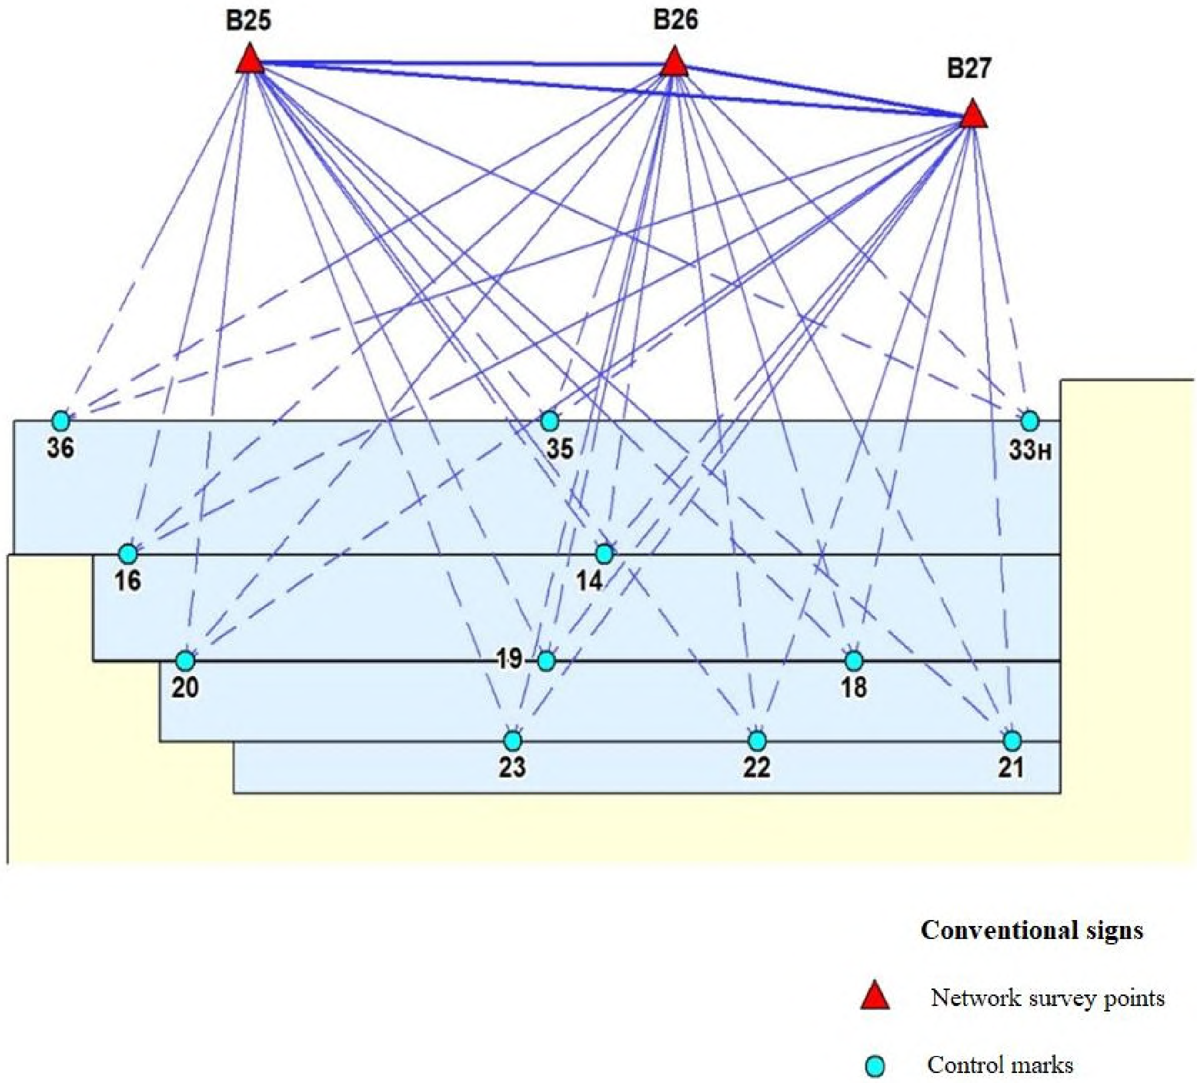

Figure 2. The scheme for determining the spatial position of control marks of the northern cascade wall from the points of the plan-elevation geodetic network at the "Shelter" facility.

Conducting geodetic monitoring by settlement marks requires relevant qualification skills and focus on the process. During the tachymetric survey procedure under the conditions of the increased radiation background, as a rule, two or three surveyors are involved in the work at the same time, which ensures the continuity of the process, since one cycle of observations must be carried out in the same natural and climatic conditions. The obtained survey results are saved on a USB drive in the form of a txt file, which indicates the date of the survey and the object.

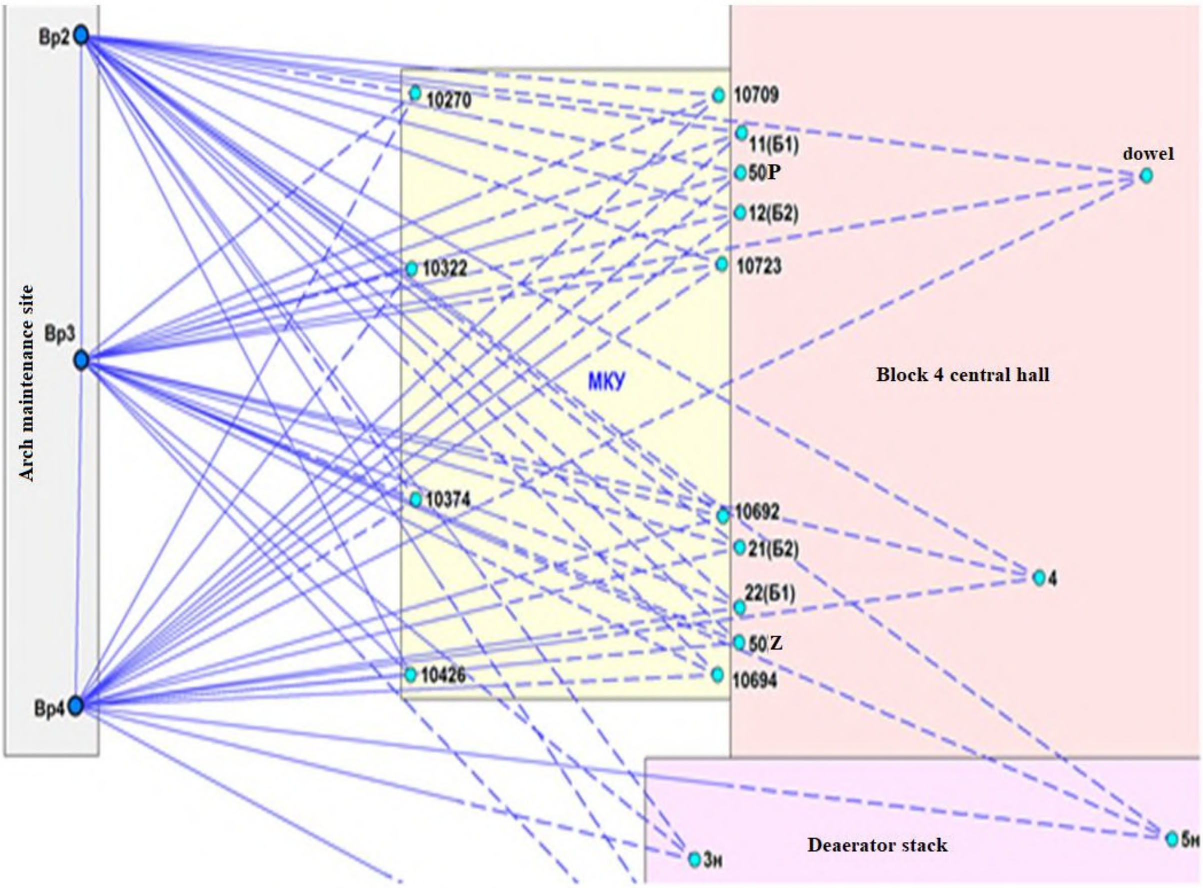

Figure 3. The scheme for determining the coordinates of control marks.

3. Result

Processing of the results is carried out using the CREDO software complex, which allows performing in-camera processing of traditional geodetic measurements and post-processing results of satellite measurements of various accuracy classes in the selected coordinate system with the possibility of considering the geoid model and a complex of reduction corrections. Moreover, various geodetic constructions are performed in the system [4]. The CREDO software product allows importing data from field measurements obtained from electronic tacheometers within accepted formats. After entering the initial data and importing the measurements, the CREDO system automatically recognizes and separates the data by types of measurements and forms the network connections.

The system pre-processes the measurements, calculates, considers the necessary corrections and reductions, and calculates the preliminary coordinates of the points. If necessary, the system allows you to detect, localize and neutralize gross errors in the coordinates and heights of the starting points, linear and angular measurements, and leveling using several methods, including the analysis of the MSE (mean square error) of a unit of weight, automatically in dialog and automatic (tracing) modes by the method of sequential exclusion [5].

The CREDO program analyzes and interprets the results of repeated geodetic measurements during the observation of deformation and sedimentary processes. The program can be used to monitor the condition of buildings and structures, monitor deformation and sedimentary processes, control dangerous areas and solve other local tasks, such as the executive survey of crane tracks, calculation of the deformation of tower-type structures, etc. It is possible to work with graphical data on a plane (2D) and view the deformation surface in a 3D format, both in a static mode and in the dynamics of changes according to the observation cycles [6].

The export of digital models of the terrain, situation, and project solutions made in CREDO systems is implemented in DXF (AutoCAD), MIF / MID (MapInfo), and TXF / SXF (Panorama) format files. At the same time, information about point marks, as well as point, linear, and planar thematic objects is transmitted [7].

After the obtained results of the sediment marks survey, the exported file is uploaded to the CREDO program. As a result, an array of directed vectors to the corresponding points with starting points and names of observation points is obtained (figure 4).

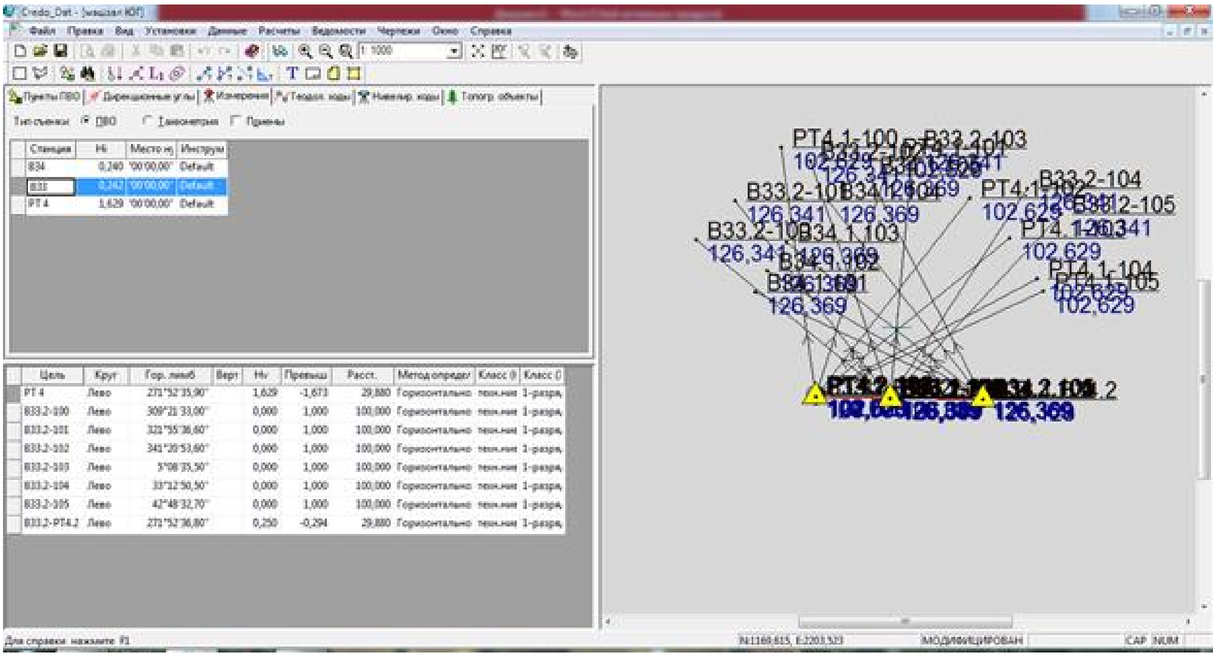

Figure 4. Data processing in the CREDO program.

Next, the file is exported to the AutoCAD software package, where a vector display of the directions of the monitoring points is obtained (figure 5).

Vector directions intersect to form a triangle of measurement error from different survey points (minimum three) under the same observation conditions. At the intersection point of the medians is the center of the observation point (figure 6), where the coordinates of the X and Y point are determined (figure 8). Then the obtained results are entered into the table of observations according to the cycle the geodetic monitoring was carried out.

Since the beginning of the observations, the horizontal movements of 10 control marks of the northern wall of the "Shelter" facility amount to 28 mm on average with the northern direction of the vector. The mark M-18 (figure 8) has the maximum horizontal movements – 34 mm from the beginning of observations.

The average horizontal movements of the control marks (M-16, M-20) of the northwest corner from the beginning of observations are 31 mm with the northern direction of the vector. At the same time, the maximum values of horizontal movements are 33 mm (the M-16 mark).

The average horizontal movements of control marks M-4 and the "Pin" of the roof of the central hall from the beginning of observations is 19 mm with the northern direction of the vector. The maximum values of horizontal movements are 24 mm (for the M-4 mark).

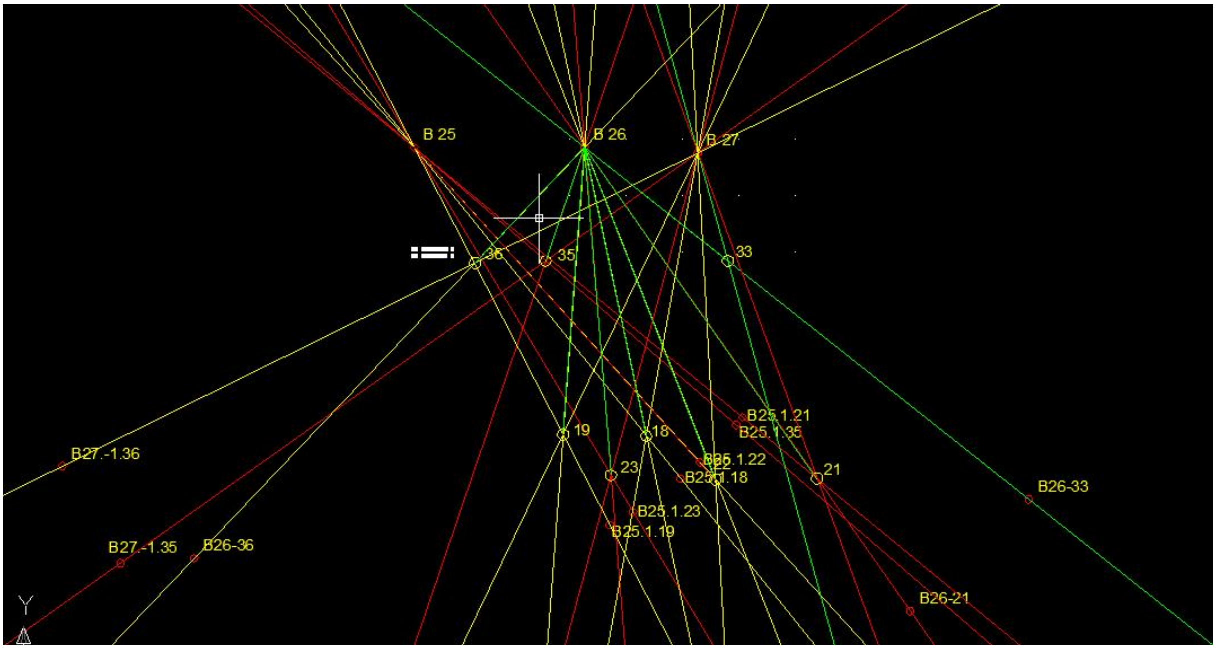

Figure 5. A vector display of directions of monitoring points.

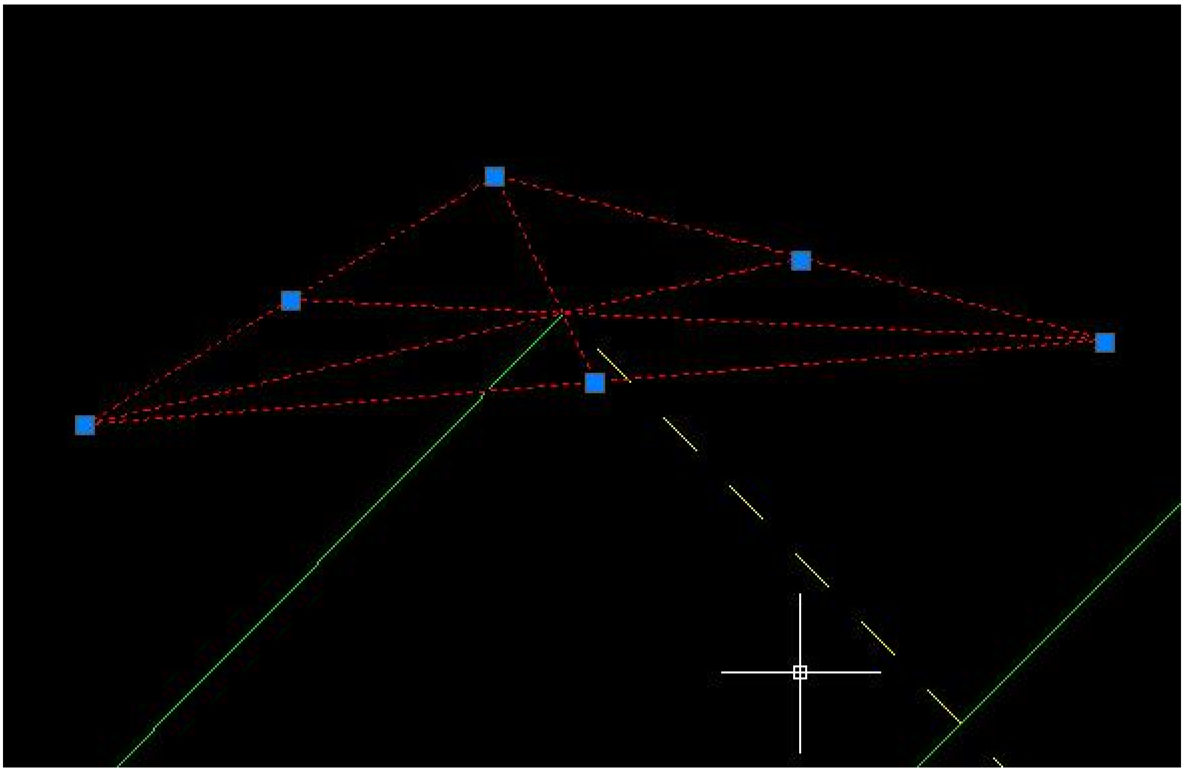

Figure 6. An error triangle, the center of the observation point.

The control marks of the MKU tower along the Z row received average horizontal movements from the beginning of observations – 8 mm with the north-west direction of the vector, and the marks of the P row got respectively 9 mm with the west direction of the vector. The control

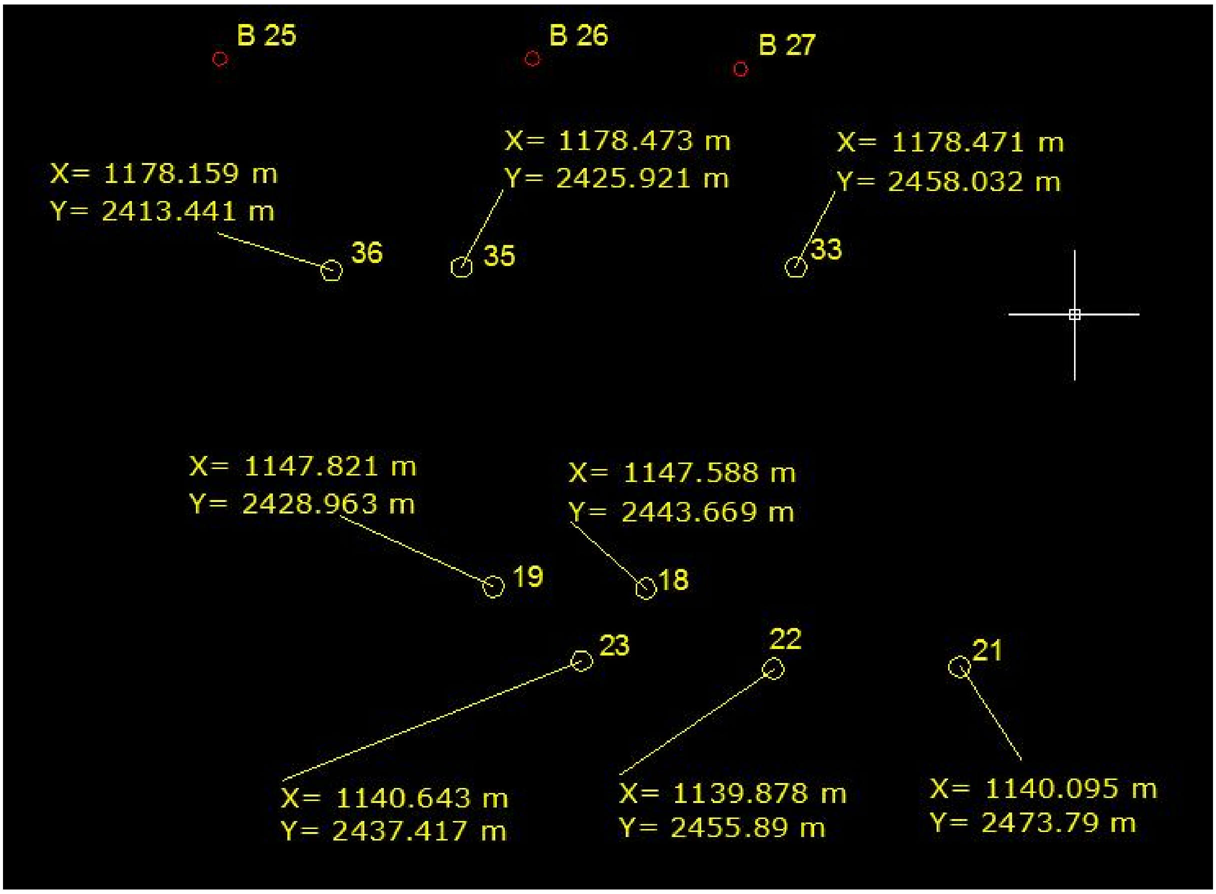

Figure 7. Determined point coordinates.

marks of beams B1 and B2 in rows Z and P received average horizontal movements of 5 mm and 7 mm from the beginning of observations.

Control marks M-50Z and M-50P on the wall axis 50 have received horizontal displacements of 5 mm and 13 mm from the initial observation. The horizontal displacement of the new control marks on the southern wall of the machine hall in row A, from mark M-302 to M-312, during the observation period ranges from 2 mm to 10 mm. The horizontal displacement of the control mark on the western wall of the machine hall on axis 68, mark M-301, has become 6mm since the beginning of the observation.

Analysis of the magnitudes of horizontal and vertical displacements of control marks indicates that the process of deformation is taking place in the object and adjacent buildings and structures.

4. Conclusion

The analysis of the horizontal and vertical movements of the control marks shows that the deformation process of the "Shelter" object and its adjacent buildings and structures continues.

For the analysis of movements of control marks "over a year", operational limits of safe operation are established, since geodetic measurements are equalized between observation same seasons "over a year" with minor fluctuations in measurement temperatures. The obtained results will be used as input data for tracking the dynamics of movements, the stability of building structures and taking timely measures to prevent the destruction of structures, and forecasting emergencies of the "Shelter" facility, as well as its adjacent buildings and structures.

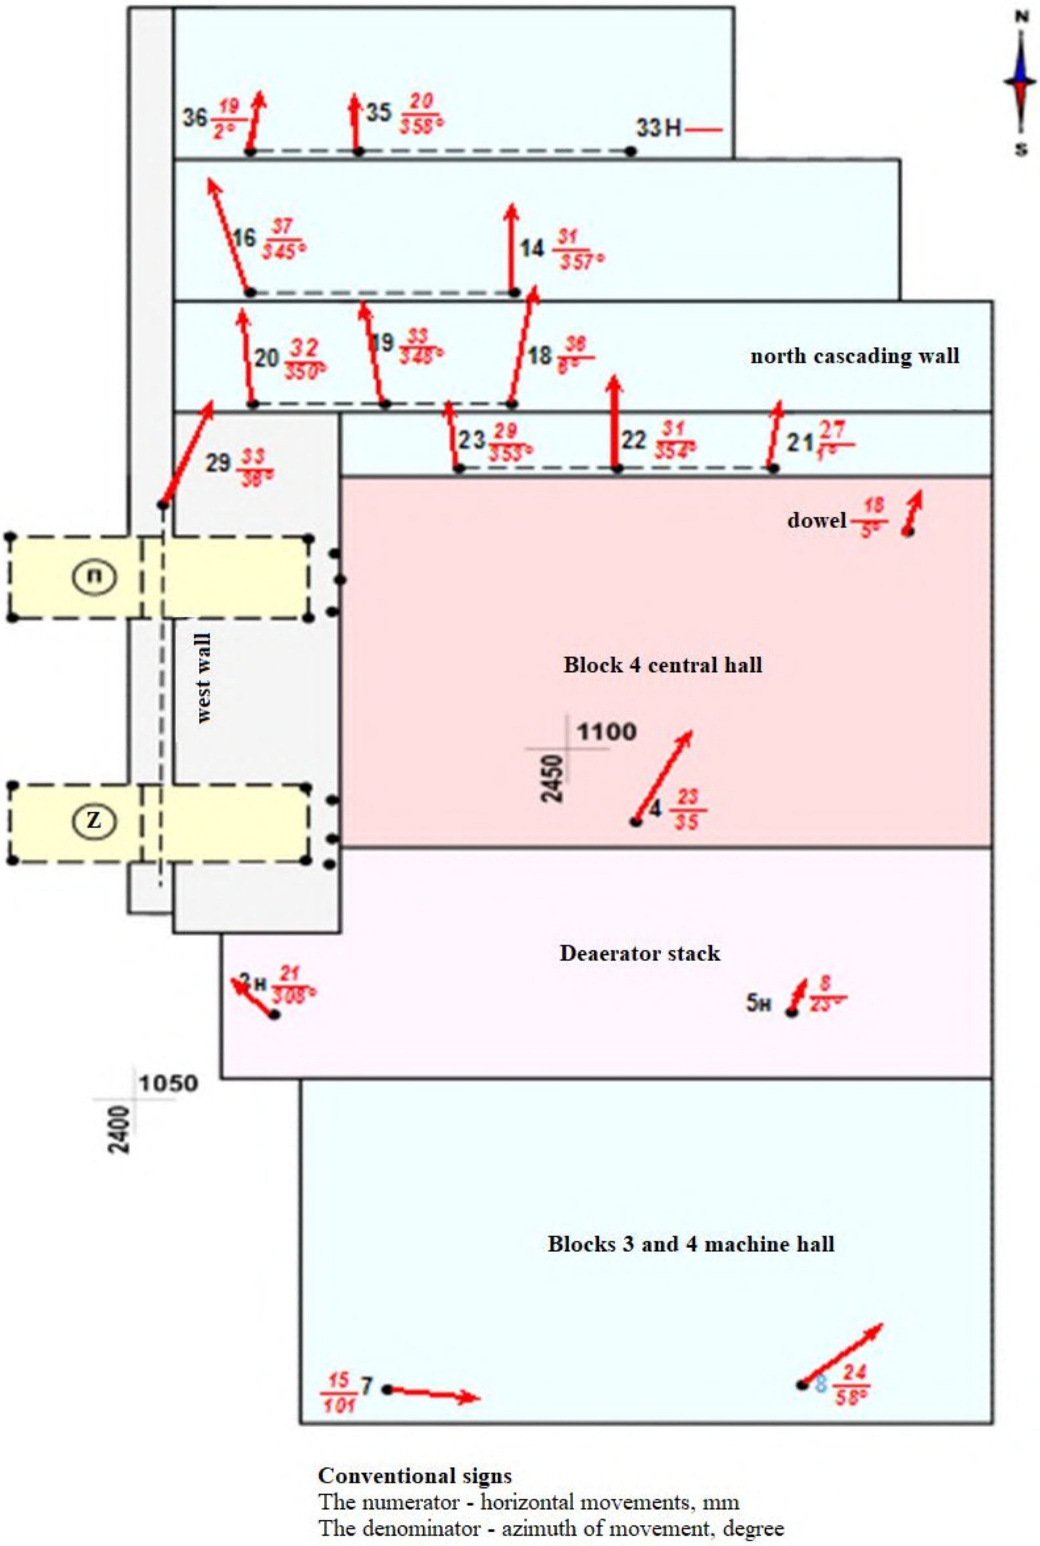

Figure 8. The values of horizontal and vertical movements of control marks of the "Shelter" object.

The values of movements of the control marks of the structures of the northern cascade wall for the annual period, between the seasonal observations of the same name, do not exceed the permissible parameters of movements established by regulatory documents.

The use of GIS technologies allows for fast data processing, reduces the workload on the employee, and makes it impossible to make mistakes during data processing and analysis. With the help of the CREDO software complex, the processing of the results of geodetic surveying of monitoring points reduces the time burden, which allows for a more in-depth analysis of deformation processes, which, in turn, makes it possible to timely identify critical indicators, if any, during data analysis.

Abstract. A constructive solution to the global environmental problem is possible within the framework of the information-space-time paradigm, the main of which is a constant (in terms of the main laws of conservation) amount of information, space and time, and thus deriving equivalent interchangeable units of their measurement. The methodological uncertainty of the very idea of sustainable development prompts the interpretation of this idea precisely taking into account the geographical picture of the world in the context of the informational-spatial-time paradigm.

1. Introduction

During the 30 years of existence of the sustainable development concept (SDC), the global environmental problem, the solution of which it was aimed at, has not been solved, but continues to worsen. Such aggravation forces scientists to revise the methodological guidelines for the development of the subjects of their sciences [1, 2].

Geography has certain advantages compared to other sciences in the correctness of the formulation and subsequent solution of the global environmental problem, on which the complex interrelationships of Nature-Population-Economy are closed [3, 4]. The correct formulation and justification of real ways of solving the global environmental problem is a unique chance for geography to strengthen its fundamental theoretical and methodological positions in the system of sciences and strengthen its applied status [5].

Ukraine's modern progress towards a "post-industrial", "informational", "globalized" society under the banner of the concept of sustainable development, the methodological guidelines of which have not yet been definitively determined, and therefore are rather dubious, forces us to think about the more general principles of human, regional, and national development – development, which determines the social demand for the formation of certain paradigms of scientific research [6, 7].

For a long time, geography has been dominated by the spatial paradigm, which in modern conditions requires further in-depth development and improvement in accordance with the requirements of the time. The scientific community is only beginning to realize the connection between the correct formulation of many global problems, primarily ecological, and the use of geographical space by Man. Most likely, the correct formulation of the ecological problem with the aim of its further solution lies in the optimization of the geographical space – optimization that can be carried out only by researching modern trends in the development of spatial socio-natural systems – Important objects of geographical science.

In fact, the global environmental problem, embodied in the concept of sustainable development, has all the signs of interdisciplinary nature and fundamentally cannot be solved in the realm of only geographical paradigms [8, 9]. The study of the general scientific origins of the global environmental problem allowed the authors to choose an integrative direction for its solution, as well as to consider the typological principles of the formation of spatial socio-natural systems, within which it should be solved as soon as possible.

2. Research methodology and methods

The concept of noosphere genesis, the geographical roots of which are interpreted in the geographical theory of noosphere genesis and in the geographical picture of the world [10], lies in the field of correct formulation of the global ecological problem. The essence of the geographical theory of noosphere genesis lies in a completely different interpretation of the civilizational development of mankind, considered from the standpoint of ecosystemology [11]. The primary spatial unit of noosphere genesis is not a civilization, but a modified human ecosystem, or an agroecosystem, the evolution of which leads to the formation of other noospheric ecosystems – urboecosystems and infraecosystems [10]. In the process of noosphere genesis, a person modifies trophic relations in a natural ecosystem primarily due to a conscious change in its edaphic (spatial) component. This happens due to the formation of "traps" for time, space and information [10]. As a result, an agroecosystem is formed in which spatial relations have changed. But such a change does not make the modified ecosystem of Man less "natural". The synthetic nature of the global environmental problem is manifested in specific relationships, the symbiosis of which ensures its correct formulation. In particular, geography provides awareness of spatial relations, ecology – trophic, history – evolutionary, philosophy – cognitive.

The basis of the author's ideas about the geographical content of the global environmental problem is that when any phenomenon (body, process) develops (moves), it necessarily leaves behind a projection of this movement in a dimension one unit higher than the previous one. Thus, the movement (development) of any material body in the direction of a higher dimension gives this body emergent (qualitatively new) properties. If the above approach is applied to spatial phenomena, when projecting (superimposing) any two-dimensional bodies, one should expect the formation in the "fourth dimension" of some qualitatively new spatial formation. But this statement is valid only for such objects, the proof of the objective existence of which is already feasible and a recognized fact – landscape complexes, ecosystems, agricultural areas, types of land use, types of agricultural territory organization [12].

The ecological (geo-ecological) content of noosphere genesis today is not in doubt among almost anyone, primarily because the spatial boundaries of landscapes and ecosystems have almost been equated [13]. It is from this that the conclusion is drawn that the unifying beginning for the development of socio-natural (noospheric) laws is the territory. At the same time, such a unity does not exclude the formation of their divergent borders in a two-dimensional sense, and, therefore, involves the search for the mechanism of their formation in such a "nature-society" dichotomy, where society is the "Homo Sapiens population" [14].

The general concept of the agroecosystem, or Homo Sapiens ecosystem, was developed in previous works. An agroecosystem is an ecosystem that combines the anthropic and social nature of man [15]. Awareness of the spatial essence of such ecosystems lies within the scope of the subject of geographical sciences and is closest to the content of socio-natural systems. Such a view is also correct because it does not differ from the main position of ecosystemology [11] and gives the right to include a person in biocenotic ecological niches, in which food relations include humanity. However, the role of inanimate (dead according to Vernadskyi) matter in the vital activity of the human population is very special. So, if in other populations this substance does not go beyond the biological limits of the organism, entering it (albeit in transit) as a biochemical component (i.e., included at the organismal level), then the phenomenon of the human population consists in the fact that an inanimate (fossil) substance taken from nature, in its vast majority is deliberately excluded by man from the organismic level and brought to the level of joint consumption by the entire population (figure 1).

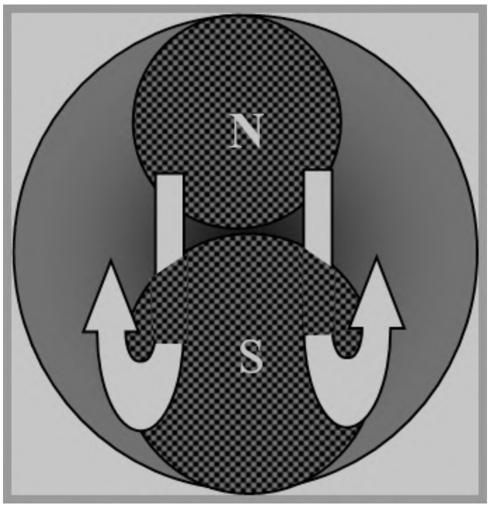

Figure 1. The general direction of the material transformation of the natural environment, which leads to the "compression" of the geographical space (N – nature; S – society).

At the same time, such consumption either does not reach the body, or completely leaves its physiological limits, confirming the purpose of this exchange in only one direction – the extraction of natural inert substance without its return to food chains. It is at this stage that thanks to the technical-cultural-transformative activity of man with the involvement of the inert substance of the biosphere, "materialized information" is formed in the form of "consumer values" [16].

Thus, the transition from the organismic to the population level is conceptually significant in understanding the geoecological essence of the human population. Taking into account the spatio-temporal existence and the total mass of ecological groups of organisms (producers, consumers, reducers) in the biosphere, we concluded that plant species are characterized by a stationary-dispersed type of mediation of geographical space. Animal species and groups (consumers) carry out dynamic and dispersed mediation of geographical space. In contrast to the purely "natural" ones, the human population has a dynamic-continuous type of mediation of geographical space, which is carried out in the direction of its constant "compresion" [17] and fundamental energy-material-informational transformation. At the same time, if in natural geobiocenoses such information exchange is aimed at improving the competitive struggle for the environment (while not going beyond the boundaries of the ecotope), then the human population long ago won this competitive struggle with other species and conducts it within its own population, thereby reaching ecosystem level of organization of living matter. Therefore, the "ecotope" of Homo Sapiens in the classical sense of this term goes beyond the organismic level of the organization of the species and includes the population and even the ecosystem level. Thus, it is more logical to talk about an ecological niche with vaguely defined spatial boundaries. Considering the spatial behavior of Man as the search and subsequent transformation of his ecological niche in the process of noosphere genesis, the spatial dynamics of the Homo Sapiens population was investigated in historical retrospect [18].

3. Research results

As a result of the existing spatial dynamics of Homo Sapiens, the information influence of urboecosystems (hinterlands) on the surrounding space is gradually increasing thanks to the means and tools of the information infrastructure [19], which is where the name "infraecosystems" actually comes from. At the same time, the highest level of information influence, which leads to an increase in planetary entropy, is characteristic of today's so-called "world cities" [20]. This influence is manifested in the diversification and inversion of the geographical space by world cities, studied in previous publications [10, 16]. According to the results of the author's research, the territories that fall into the hinterlands of neighboring "world" or the highest ranked "central" places are forcibly transformed by them into service, or into infrastructure [10]. From this, an important methodological conclusion is drawn, that in W. Chrystaller's theory, central places have always performed not serving, but diversifying functions, redistributing the geographical space to their advantage.

Research in previous publications of the ontological content of the space of time and information made it possible to build a methodological scheme of the interconnection of agro-, urban- and infra-ecosystems (figure 2).

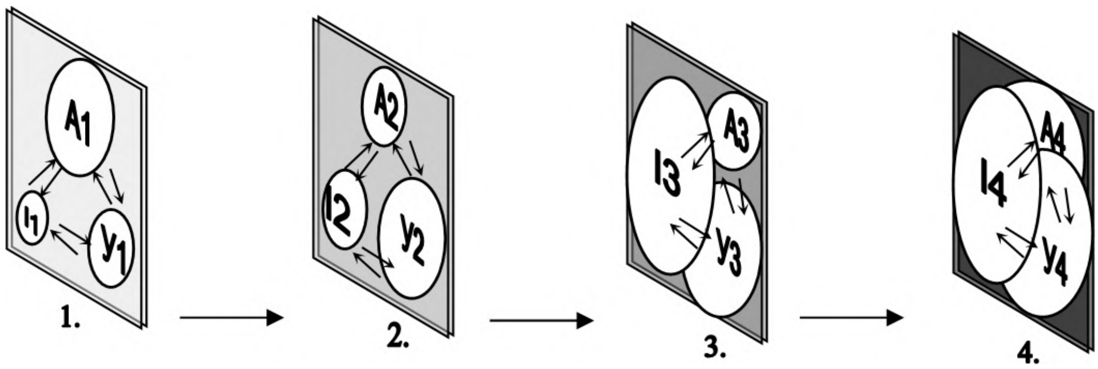

Figure 2. The system of relations in the modified ecosystem of Homo Sapiens and its development over time. Agroecosystems (A) – urban ecosystems, (Y) – infraecosystems (I).

At the early stages of the formation of the modified human ecosystem (agroecosystem), the greatest attention was paid to the actual "food extraction" (figure 2.1). At the same time, information connections between different ecosystems were embodied in the primitive cults of paganism, primarily due to the lack of study of nature and the blind worship of its individual material components. At the same stage, urbo-ecosystems were just beginning to be born (recruitment of the supreme power, priests, and troops into stationary settlements). The degree of compression of the geographical space is the lowest.

At the second stage (figure 2.2) as a result of the Neolithic revolution, which is also called the "axial time" (with the beginning of the process of noosphere genesis), the informational component of this process in the form of the main world religions began to relentlessly and predestinedly form infraecosystems by introducing a spiritual beginning into international spatial relations. Cities (urboecosystems) become the main centers of such informational influence, around which hinterlands are gradually formed, which leads to a gradual "compression" of geographical space.

The third stage – modern – is associated with the acquisition of the highest level of information density by urban ecosystems and the transformation of some of them (world cities) into infraecosystems (figure 2.3). At the same time, global entropy acquires the highest degree, the result of which is the greatest "compression" of geographical space due to the growth of its material filling.

At the fourth stage (figure 2.4), the most developed infraecosystems "pull up" other types of noospheric ecosystems to their level. All three types of ecosystems will grow spatially due to the increase in interdependence, which will lead to the maximum compression of geographical space and the maximum growth of global entropy. According to the author's concept of border conflicts, the next stage of the formation of the modified ecosystem of Man is now beginning – the cosmic one, when cosmoecosystems are already beginning to form [21].

The deepening of general scientific ideas about the role of geographical space as a carrier of physical interactions, gravity, landscape and morphogenesis, the process of interaction between nature and society, modern globalization and post-industrialism, and many other things that are carried out in Nature and perceived by Man, encourage the construction of a proper geographical picture of the world [10].

The existing space-time paradigm of geography – an idea about the participation of the category of time in the development of the geographical process – is developed in a number of works. Just as the classical spatial paradigm (Kant-Ritter-Hettner) was focused on the selection of geocomplexes and geosystems according to their spatial form and territorial structure, the new paradigm is focused on the selection of geographic complexes and systems according to their functioning and vital activity, on the analysis of life cycles of geographic complexes of various types and scales.

For our study, the idea of time as an integral attribute of the process of interaction between nature and society plays a special role, since this process is inextricably linked with the space that life fills as a result of noosphere genesis. In our case, the process of interaction between nature and society (movement) in planetary space-time is considered. It is imagined in the form of its two main components – nature and society. Together, they actively fill the geographical space since the Neolithic, which gradually leads to its compression [10]. Considering the process of noosphere genesis as one that is formed in a certain frame of reference, it is concluded that the compression of geographical space must be compensated by real time. For such compensation, a person creates "time traps" as if putting it off "for later". To a certain extent, humanity has "borrowed" time from nature, by which it is "ahead" of it in the process of its development.

Thus, the main cause of the environmental problem lies in the different rates of development of nature and society. The result of this difference is necessarily "postponed" in geographical space. For a constructive solution to the "global ecological problem", it is necessary to find such areas of space, in which the difference in the speed of nature and society is reflected, and in the future, gradually reducing them, bring them to optimal ratios.

In the future, according to logic, in addition to the real territory, it is necessary to find those "segments" of time that are "borrowed" and that are reflected in space. In order to search for "negative" segments of space, the spatial dynamics of agroecosystems formed on the territory of the Kharkiv region were investigated (figure 3). The study of agroecosystems made it possible to draw a conclusion about the simultaneous existence of two types of borders, the dynamics of which go beyond the limits of two-dimensional understanding. According to modern ideas, such "non-coincidence" leads to an increase in the level of planetary entropy [10], and, therefore, to informational "tension", which, most likely, is the cause of the emergence of not only environmental, but also many other global problems. The above analysis was carried out in the context of the modern space-time paradigm. The absence of an interpretation of the category of information (entropy/negentropy) explains, in the opinion of the author, the impossibility of correctly posing the environmental problem.

It is from this antithesis that the general logic and stage sequence of the development of the new – information-space-time paradigm, reflected in the diagram (figure 4), originates. In this

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012138 doi:10.1088/1755-1315/1254/1/012138

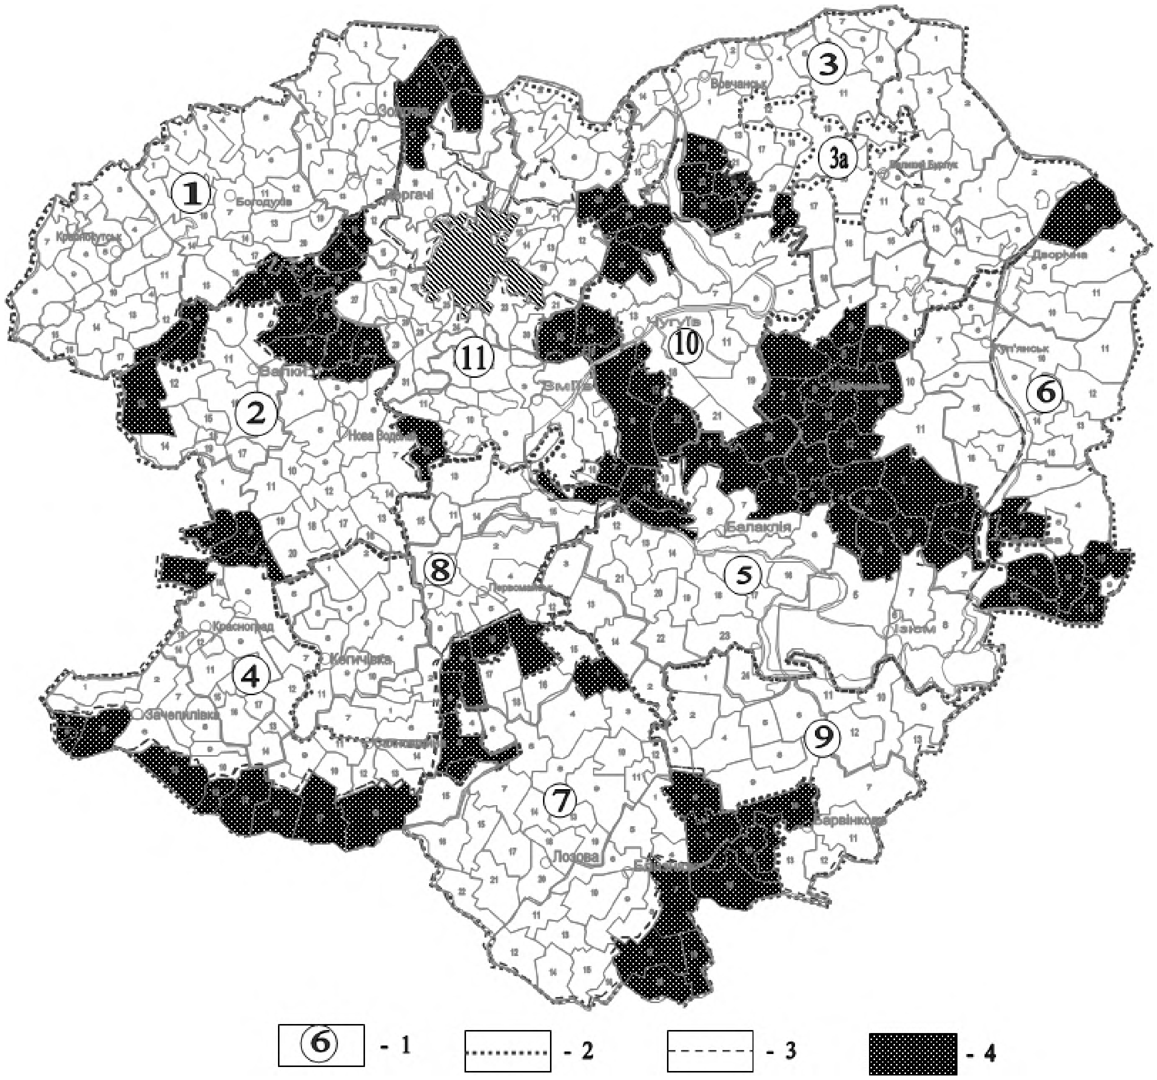

Figure 3. Spatial "mismatch" of agroecosystem boundaries. Explanation of symbols: 1. Numbers of agricultural districts; 2. Boundaries of agricultural districts (economic boundaries of agroecosystems); 3. Boundaries of type of territory organization (natural boundaries of agroecosystems); 4. Areas (segments) of space, on which natural and economic boundaries do not "coincide".

scheme, each of the blocks (stages) that reflect the development of the specified paradigm is a cybernetic system with feedback, where the most contradictory theses that were put forward during the research act as a regulator (R). The horizontal directions of the table reflect the logic of the formation of scientific knowledge from the extraction of empirical facts to the construction of a new theory, and on its basis – a scientific picture of the world. The process of scientific research logically ends with the practical implementation of the results of theoretical research.

At the same time, the main features of the new information-space-time paradigm should be:

1. Genetic unity of space, time and information in the interpretation, description and modeling of geographical process.
2. Equal "participation" of space-time and information in the ontological content of the information-space-time paradigm, which implies the same equal "inclusion" of them by

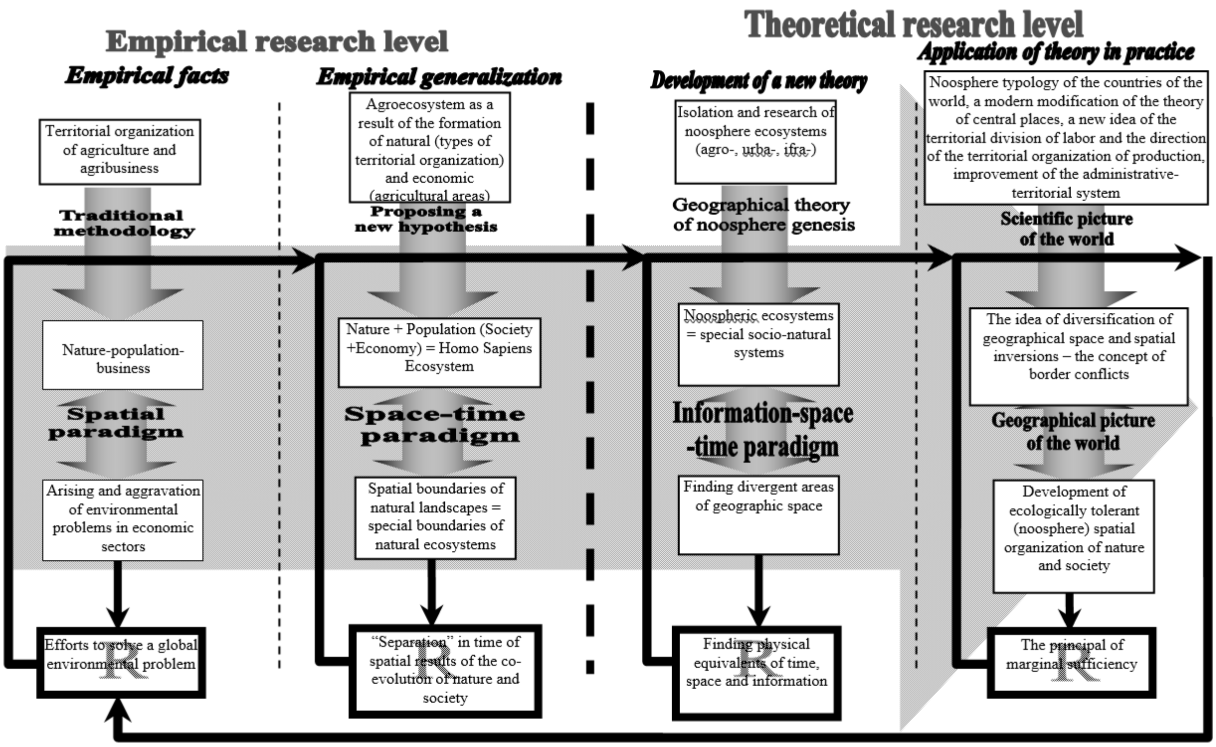

Figure 4. Development of information-space-time paradigm.

geographers and philosophers in the corresponding types of models, classifications and typologies.

3. A constant (in accordance with the main laws of preservation) amount of information, space and time in the areas of development of the geographical process in the entire oecumene.
4. A close cause-and-effect relationship between the qualitative structure of information, time and space and the level of planetary entropy.
5. The presence of invariant information, space and time, consistent with the logic of the process of noosphere genesis.
6. Closeness of the development of ideal models of space use to calculations of world constants.
7. The possibility of deriving equivalent interchangeable units of measurement of space and time information.

Based on the above signs of the new information-space-time paradigm, it is necessary to consider several examples of "deviation" of the development of its information component from the invariant. Thus, in the modified ecosystem of Homo Sapiens, trophic relations are artificially "stuffed" by humans into "time traps" – grain storage in elevators, meat freezing in refrigerators, preservation of vegetables, fruits, meat, milk, production of concentrated products, which almost do not deteriorate over time. "Traps for space" are manifested at the level of agroecosystems in the organization of crop rotations, fodder arable land [22], contour-ameliorative farming systems, and other types of land use, with the help of which Homo Sapiens artificially regulates trophic relations in its own modified ecosystem. Urboecosystems generally lead to asymmetry of geographical space [19].

In our opinion, similar to "traps" for time and space, there are also "traps for information", skillfully "set" by man in the process of noosphere genesis. A very large-scale "trap for information" is the phenomenon of "stretching" by Man of the single gene pool of cultivated plants (N. Vavilov) in the process of noosphere genesis. The difference from time traps at the organismal level is quite significant, since this process vividly embodies the transformation of geographical space through the spatial destructurization of the ecological niche and time, if we consider the desire to breed new high-yielding varieties as "saving time". It is significant that the share of genetically modified food products has been constantly increasing since the beginning of the noosphere genesis process and, according to modern estimates, almost doubles the area of UK [23]. At the same time, there is an increasing decrease in the resistance of the human population to microbiological disturbances [24]. "Traps for information" are manifested in the economy as well. In particular, the very term "shadow economy" comes from hidden (at least from the payment of taxes) commodity and information flows. As for the production of contraband products under the brand name of well-known brands, this is generally an ideal case of "traps for information". Given that such products are much cheaper than the original, the price difference between them can be the monetary equivalent of "stolen" information. Therefore, searches in the geographical space for informational imprints such as the Retheum sphragides can help in understanding the complex structure of planetary space-time. According to our concept, any socio-natural systems carry and leave complex sphragide information, which actually regulates all spatial relations [10].

4. Conclusions

The basis of the modern informational-space-time paradigm of geography is the following basic theoretical propositions, which should help in the formation of the modern geographical picture of the world:

1. During the evolutionary development of humanity on the planet Earth, significant spatial transformations of its surface took place. The modern stage of these transformations is described by complex information processes, which in turn cause the corresponding energy-matter flows. Thus, modern "globalization" of production and social life is carried out under the slogans of the civilizational process, which seems to be able to lead underdeveloped countries to a better fate.
2. At the same time, with the help of a system of repeaters (urboecosystems), there is a spatial redistribution of various resources in favor of developed countries due to the indirect influence on the resource potential of the planet.
3. "Civilization" and anthropocentrism embedded in this term acquires modern forms of spatial chauvinism, which gives reason to automatically assign individual ethnic groups and even entire countries from the standpoint of "civilization" to "civilized" and "uncivilized", "developed" and "underdeveloped". However, the biosphere role of the Australian aborigines, or the "primitive" naturalized societies of South Asia, is much more positive than that of the superpowers. And even further – there is a desire to distinguish between "higher animals" and "lower animals". However, the role of these "lower animals" in maintaining the stability of the biosphere (reducers) is much more positive than the "higher" ones and, above all, the Homo Sapiens species.
4. The so-called "global environmental problem" is the result of spatial incoherence of territorial combinations of different types of relays – infraecosystems, agroecosystems, urban ecosystems; from here, the search for optimal models of the territorial organization of society is quite logically perceived.
5. Higher "informatization" will imply at some stage the oversaturation (compression) of geographical space with various combinations of "retransmitters", which will lead to qualitatively new shifts in the spatial being of humanity. Most likely, such shifts will lead to the identification of two main directions of information density reduction. The first direction is extensive – artificial stretching of the critical limit of compaction due to the development

and implementation of optimization models of geographic space (W. Christaller, W. Isard, B. Rodoman, O. Topchiiev). The second direction is intensive – the gradual formation of artificial ecosystems (cosmoecosystems) in extraterrestrial space.

6. When implementing an extensive (more realistic) way of further development, one should be guided by the principle of marginal sufficiency, according to which the optimization of the geographical space by humans should take place in the direction of rotation of individual groups of elements of the territorial structure and their functions. In particular, the gradual conscious transformation of urboecosystems into agroecosystems and vice versa (A. Chaianov) while preserving the binding function of infraecosystems.
7. The civilization process is a certain period (qualitatively a new stage) of a much longer-term process, which went back to the “axial time” (K. Jaspers) and which is based on the informational processes of the universe, which were embodied in the birth of the biosphere, its further complication, fundamental its transformation by the species Homo Sapiens due to the spatial re-planning of the flows of matter and energy and the subsequent exit beyond the limits of the terrestrial biosphere into the Cosmos.
8. The biosphere-noosphere theory of V. Vernadsky – is the ultimate ideal model of the development of the biosphere, in the event that Humanity becomes “smarter”. Predecessors of V. Vernadsky in the spatial sciences developed models narrower in scope (J. Thunen, A. Weber, W. Christaller). The development of such models relates the mentioned studies to the finding of world constants (absolute zero, acceleration of free fall, speed of light, etc.), but in our case these constants are spatial.
9. The development of ideal models of spatial organization may continue in the search for spatial equivalents of time, energy, and information, based even on the existing laws of conservation. Based on the assumption that the amount of planetary space is constant (invariant), it is possible to search for excess or negative segments of space that arise in the process of noosphere genesis as a result of the formation of “time traps” and “information traps”. Thus, it becomes possible to calculate the corresponding coefficients of “exceeding” the invariant due to going beyond its limits. Most likely, the highest coefficient of space consumption (spatial entropy) will be developed countries that most actively structure it.
10. The system of spirituals and ethical values of humanity should be based on the principles of observing biosphere interests, which requires a deep understanding of one’s place (humanity), and therefore participation in biosphere processes. Instead, humanity should not separate itself within the framework of “globalist”, “post-industrial”, “civilizational” concepts from the process taking place in the biosphere of its evolutionary development. When developing development programs at the national level, it is necessary to take into account global trends in the structuring of geographical space with the subsequent “search” of one’s place in the process. This forces us to look for other perspectives of Ukraine’s “entry” into the “post-industrial” society.

Developing a geographical world picture in the context of the information-space-time paradigm allows for the modification of the main theoretical foundations of modern geography, as well as a new look at the structuring and awareness of the global environmental problem. “Hopelessness” in its solution comes from an incorrect definition of methodological guidelines in the study of the main foundations of the interaction of nature and society, and a derived from this erroneous understanding of the phrase “sustainable development”. The methodological uncertainty of the very idea of sustainable development prompts the interpretation of this idea precisely taking into account the geographical picture of the world in the context of the information-space-time paradigm.

Acknowledgments

The authors are infinitely grateful to the biosphere of our planet for its infinitely long existence, which unquestionably convinces each of us of the true criteria of truly sustainable development, the main of which is the very fact of the existence of life and the extremely complex mechanisms of its support.

Abstract. Aviation is an integral and vital part of modern society. The growth over the last decades has consequences for greenhouse gas emissions and reducing this through efficiency within the same framework is difficult. Precision flight planning is crucial for reliably and optimized real environment aircraft operation. The presented study gives an overview of the status of the legal requirements for flight planning under the current fuel requirements of the European Union Aviation Safety Agency (EASA) and the emerging opportunities for fuel savings. As part of the larger study, planned and actual fuel figures of an international cargo airline were statistically analyzed. The overall analysis showed that there was no significant deviation between planned and consumed fuel. Based on the results, an adjustment of the planned alternative fuel quantity can be considered within the framework of an individual fuel plan. The possible savings potential using the example of Destination Alternate Airport fuel is presented.

1. Introduction

In the 100 or so years since the first powered flight, the aviation industry has experienced rapid growth [1]. Fuel needed to operate thousands of flights worldwide every day is one of the most important cost factors in the airlines' business. According to the International Air Transport Association (IATA) report on the economic performance of the airline industry, global fuel costs were predicted to be \$206 billion in 2019, later estimated to be around \$188 billion in the 2019 end-of-year report. For 2020, the same report predicted fuel costs to fall to \$182 billion, equivalent to 22.1% of average operating costs [2]. Figure 1 shows a corresponding chart by Airbus [3].

Aviation emissions have a climate impact, which came more and more into focus. In 2020 almost every commercially used aircraft still has a propulsion system based on fossil fuels. Emissions from aircraft are greenhouse gases and noise. Fuel costs are therefor not the only driver for reducing the amount of fuel consumed. In recent years, the impact on the environment has become more and more important. The high traffic volume is associated with an enormous demand for aviation fuel and the associated high emissions on the other side. Lee et al. provide an overview of CO_2 and other related emissions and impacts of aviation on the climate [4], likewise Fleming and Ziegler [5] and Filippone [6] – to name just a few examples. Reducing the effects of global warming due to emissions has become a goal. As a result, reducing emissions has become an important issue. The commercial aviation industry has already developed and

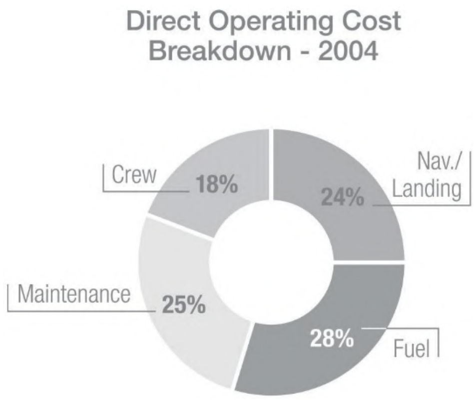

Figure 1. Operating Cost Breakdown.

implemented many techniques to reduce fuel consumption for reasons of economy and efficiency. On the operator side, these are mostly operational improvements, such as reducing the weight of on-board equipment or using a fixed ground power supply instead of the aircraft's auxiliary power unit on the ground. Airlines are searching fuel-efficient routes or flight profiles for most of the time. Measures to reduce noise and pollution are taken by airlines, airports and air navigation service providers in their daily operations [7].

Regulators to reflect the development of emission reduction and fuel saving. ICAO published Doc 10013 – Operational Opportunities to Reduce Fuel Burn and Emissions. It supposes the most effective way to minimize emissions: via the amount of fuel used [8]. For a given route fuel burn depends, if environmental aspects like weather or routing are said to be the same, on the weight of an aircraft. Specific range, flying at given altitude, temperature and speed, depends on aircraft mass. It is the physics of flight, that for an aircraft to fly it must generate lift to overcome its weight. The generation of the required lift and the movement of the airframe through the air create drag. The engines generate the necessary thrust to overcome this drag and enable the movement to generate lift (figure 2). The heavier the aircraft, the higher the fuel consumption. Fuel consumption, for carrying extra weight or extra fuel, is called Fuel Carriage Penalty (FCP). EASA gives a value of about 3 % difference in fuel consumption per kg and flight hour for additional weight [9]. ICAO Doc 10013 gives a value of 2.5 – 4.5 % additional fuel consumption, depending on the characteristics of the aircraft [8]. In addition, fuel savings can be made during climb since the lighter aircraft would reach it's optimal flight level earlier [10]. To minimize fuel burn it is most economical to carry the minimum required fuel for the sector.

New regulations will also be applied in the area of European regulations in 2022. EASA

Figure 2. Elementary forces on an airframe [10].

published Notice of Proposed Amendment (NPA) 2016-06, which follows a performance-based approach by updating the regulatory requirements for fuel planning, selection of aerodromes and in-flight fuel management, thus aims to increase operational efficiency and to have cost and environmental benefits [9]. This proposal to amend the regulations was followed by Opinion 2020-02 and finally by Regulation (EU) 2021/1296, which amends Operating Regulation (EU) 965/2012 in the area of Fuel/energy planning and management, support programmes and psychological assessment of flight crew, as well as testing of psychoactive substances. With the development of Commission Regulation (EU) 2021/1296, changes in ICAO Annex 6 have been transferred to the European regulatory. Fuel-related amendments to Annex 6 of the Convention on International Civil Aviation Organization (ICAO) and new guidance in ICAO document 9976 "Fuel planning manual" are to be incorporated into Regulation (EU) 965/2012 [11]. Various areas of the regulation shift, e. g. CAT.OP.MPA.150 is intentionally left blank and CAT.OP.MPA.151 is deleted [11]. CAT.OP.MPA.180 establishes new fuel/energy plan requirements for aircraft. For the fuel policy, until the adjustment in 2022, the following item was relevant: according to CAT.OP.MPA.150, the operator must establish a fuel policy and purpose of flight planning and in-flight replanning:

...to ensure that every flight carries sufficient fuel for the planned operation and reserves to cover deviations therefrom [12].

The fuel policy is transferred to the so-called Fuel Schemes. The consequences are illustrated below with the use of an example.

2. Methods

Fuel data of an operating airline were examined to explore a statistical background. The airline utilizes Boeing B777-200 aircraft in a freighter version. The operated network contains large airports, together with some local airports. The network destinations result in a mix of short, medium and long-haul flights. Planning and actual consumption were also evaluated. Here, two periods were considered in two steps: a five-year period covering all flights operated and a one-year period for extremely long long-haul flights with high loads.

In order to use the optimization possibilities in the area of fuel planning, which would be possible from 30^{th} October 2022, the corresponding prerequisites must be met. The GM2 to CAT.OP.MPA.180 of Regulation (EU) 965/2012 shows a non-exhaustive list of safety performance indicators (SPI) that can be used to measure safety performance [13]. This served as the reference point for the statistical fuel data evaluation.

In order to illustrate the possible optimisations, using the example of alternate fuel, the legal situation up to 30^{th} October and thereafter is compared below.

CAT.OP.MPA.150 Fuel policy, which will be omitted in the future, requires:

...(c) The operator shall ensure that the pre-flight calculation of usable fuel required for a flight includes: ...

(3) reserve fuel consisting of: ...

(ii) alternate fuel, if a destination alternate aerodrome is required ... [14]

Additional information on compliance with the implementing rules can be found in the Acceptable Means of Compliance (AMC). AMCs are non-binding standards adopted by EASA to illustrate means of determining compliance. Furthermore, there is Guidance Material (GM), as non-binding material for explanation and interpretation. So, in AMC1 CAT.OP.MPA.150 further explanations are given, regarding the content of the fuel policy:

... (4) Alternate fuel, which should:

(i) include:

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012139 doi:10.1088/1755-1315/1254/1/012139

(A) fuel for a missed approach from the applicable DA/H or MDA/H at the destination aerodrome to missed approach altitude, taking into account the complete missed approach procedure;
(B) fuel for climb from missed approach altitude to cruising level/altitude, taking into account the expected departure routing;
(C) fuel for cruise from top of climb to top of descent, taking into account the expected routing;
(D) fuel for descent from top of descent to the point where the approach is initiated, taking into account the expected arrival procedure; and
(E) fuel for executing an approach and landing at the destination alternate aerodrome;... [14]

Figure 3, figure 4 and figure 5 illustrate the possible consequences of the regulatory changes and optimisation options.

Figure 3 shows the missed approach procedure for Runway 26L of the instrument approach for Leipzig Airport (EDDP). In the event of a missed approach, the blue dashed path should be flown, highlighted in green. The corresponding description of the instrument flight procedure

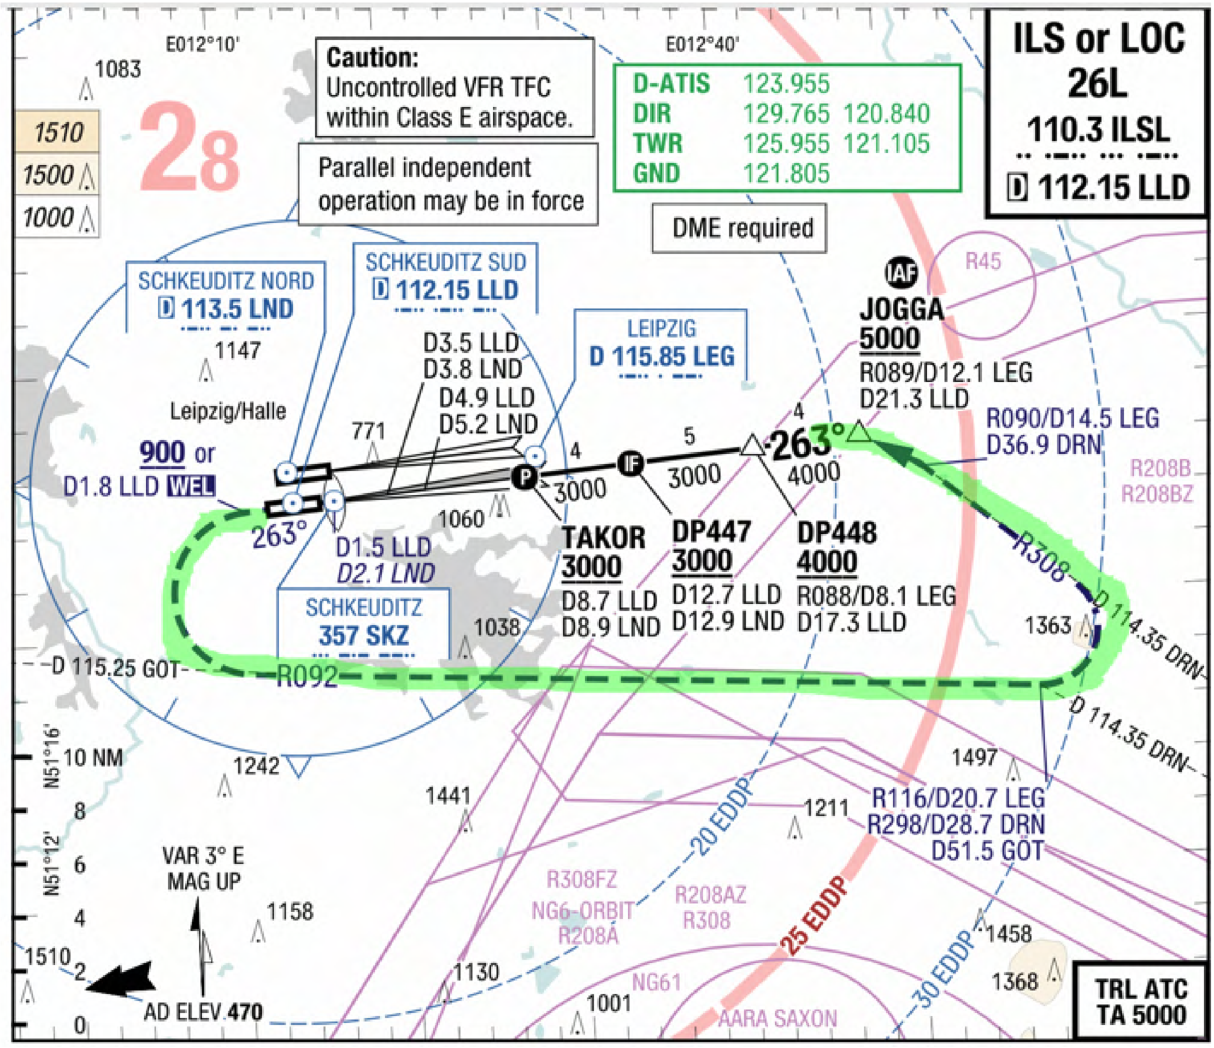

Figure 3. Leipzig Airport Misses Approach Procedure Track [15].

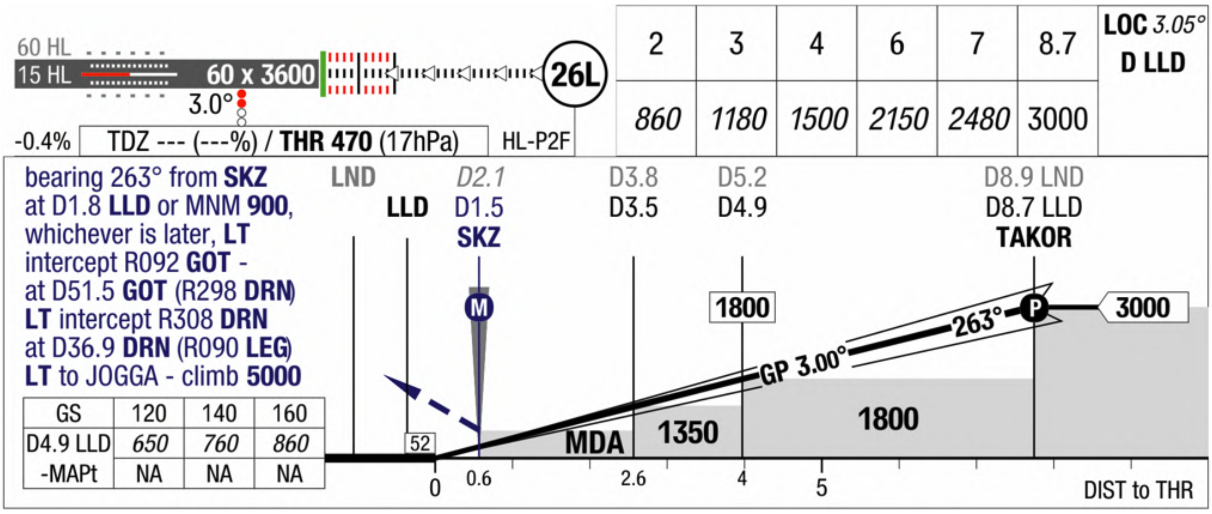

Figure 4. Leipzig Airport Missed Approach Procedure description [15].

can be found in figure 4. As can be seen above, according to the current requirements, the complete missed approach must be taken into account in the planning – here this is approx. 45 – 50 nautical miles, or approx. 12 minutes flying time, to the start of the new approach.

In practice, however, it must be taken into account that, in the event of a missed approach, radar guidance is usually quick and the entire track is not usually flown. In only a few cases does a missed approach occur at all. In the case of a missed approach to the destination alternate airport, this airport may be located in a completely different direction, so that the aircraft would fly directly in this direction after a missed approach.

Figure 5 shows an example of such planning. Here, the approach to Leipzig is planned in a westerly direction. The alternate airport is also in a westerly direction, it is Erfurt (EDDE). Unless a new approach is attempted in Leipzig, the direct route to Erfurt will certainly be chosen

Figure 5. Erfurt as Alternate Airport [16].

without flying the entire missed approach. For these three reasons (infrequent need for a missed approach, often shorter route in the case of a second approach, and a more direct route in the case of a diversion under certain circumstances), a reduction of the fuel required in the planning can be considered. The regulatory basis is presented next.

As mentioned above, the fuel policy will be converted into a fuel scheme. The requirements for this can be found in CAT.OP.MPA.180 Fuel/energy scheme – aeroplanes.

(a) The operator shall establish, implement, and maintain a fuel/energy scheme that:

(1) is appropriate for the type(s) of operation performed;

(2) corresponds to the capability of the operator to support its implementation; and

(3) is either:

(i) a basic fuel/energy scheme, which shall form the basis for a basic fuel/energy scheme with variations and an individual fuel/energy scheme; the basic fuel/energy scheme derives from a large-scale analysis of safety and operational data from previous performance and experience of the industry, applying scientific principles; the basic fuel/energy scheme shall ensure, in this order, a safe, effective, and efficient operation of the aircraft; or

(ii) a basic fuel/energy scheme with variations, which is a basic fuel/energy scheme where the analysis referred to in point (i) is used to establish a variation to the basic fuel/energy scheme that ensures, in this order, a safe, effective, and efficient operation of the aircraft; or

(iii) an individual fuel/energy scheme, which derives from a comparative analysis of the operator's safety and operational data, applying scientific principles; the analysis is used to establish a fuel/energy scheme with a higher or equivalent level of safety to that of the basic fuel/energy scheme that ensures, in this order, a safe, effective, and efficient operation of the aircraft.

In the associated GM1 to CAT.OP.MPA.180 explanations are given on the AMC to be applied. In principle, an operator may choose between three different fuel schemes. The following AMCs apply to the development of each fuel scheme:

(a) Basic fuel scheme: all the AMC that apply to the basic fuel scheme.

(b) Basic fuel scheme with variations: when an operator decides to deviate fully or partly from the basic fuel schemes, the AMC for basic fuel schemes with variations apply to the specific deviation.

(c) Individual fuel scheme: when an operator wishes to apply an individual fuel scheme, the AMC for the individual fuel scheme apply; for the part of the scheme where the operator still follows the basic fuel scheme, the operator should apply the AMC referred to in (a) and (b) [14].

Depending on the chosen level of the scheme, different AMCs, if any, are applied. As previously in CAT.OP.MPA.150, in future in CAT.OP.MPA.181 Fuel/energy scheme – fuel/energy planning and inflight re-planning policy – aeroplanes the requirements for the destination alternate fuel are listed:

(4) destination alternate fuel/energy:

(i) when a flight is operated with at least one destination alternate aerodrome, it shall be the amount of fuel/energy required to fly from the destination aerodrome to the destination alternate aerodrome; or... [14]

However, the supplementary AMC1 to CAT.OP.MPA.181 only refers to the basic fuel scheme for Performance Class A aeroplanes. Performance Class A refers to multi-engine aircraft powered by turbojet or turboprop engines that can carry more than nine passengers or weigh more than

5 700 kilograms. In terms of content, the requirements in point (d) corresponds in principle to AMC1 of CAT.OP.MP.150 (see above). However, if companies choose a basic fuel scheme with variations or an individual fuel scheme, the AMC is not applicable. As a consequence, consideration could be given, for example, to reduce the amount of alternative fuel, e. g. based on statistical experience. This can result in savings, which are presented below.

The examples shown below are based on statistical fuel data from a globally operating cargo airline. Boeing 777 freighter aircraft are used. For the statistical evaluation, various information was provided via the reporting system. Numerous information can be condensed from the reports. Over a period of five years, for which the data were available, the following points were especially found:

- 187 flights, equals 0.59% of 31 315 flights, where planned with no alternate (fuel),
- six flights, out of 39 467 flights, could be identified as have to be diverted, which gives a diversion rate of 0.015%.

This information shows the rare event of landing at the alternate airport and the equally rare legal possibility of planning without an alternate airport (where additional fuel must be planned for 15 minutes of flight time). As shown above, when using a basic fuel scheme with variations or an individual fuel scheme, the AMC1 to CAT.OP.MPA.181 is not necessarily applicable. Airlines could, based on statistical data and a corresponding risk assessment, make a reduction in the planned alternate fuel compared to the current planning/requirement.

In the following it is assumed that a reduction of the alternative fuel by 5 minutes is possible. This corresponds to a value of approx. 700 kg of fuel for a Boeing 777-200 freighter examined. This value can be derived from the final reserve fuel plan – which provides for 30 minutes of flight time at 1500 feet above the airfield. In figure 6 and figure 7 an excerpt from the operational flight plan is presented, in particular the fuel planning and the mass and loading. Figure 6 shows the comparison of fuel planning for a flight from Hong Kong to Leipzig. Since the current approved planning program does not allow a reduction of the alternate fuel, the value of 5 minutes of fuel was included as additional fuel, for comparison. On the left is the original plan, on the right the plan with 5 minutes more fuel.

The values for alternate and final reserve fuel shown in figure 6 do not correspond to those that would result from an actual reduction of the alternate fuel by 5 minutes. The 700 kg / 5 minutes in the right column only affects trip and contingency fuel, but not per legal requirements needed alternate and final reserve fuel. With a real alternate fuel reduction, these values would also be lower and would lead to a more significant reduction in trip and contingency fuel. Therefore, the resulting delta, in this case an additional consumption of 257 kg, is lower than the actual savings would be. This would be possible in the case of alternate fuel reduction. But the trend and thus a rough figure for evaluation is evident. The average additional consumption for this route is 21.34 kg/flight hour, i.e. this would be the savings potential. In the lower part, the corresponding weight information is also listed as a comparison. As can be seen, 700 kg of extra fuel led to a reduction of the maximum possible load from 1 548 kg before to 589 kg after. Here too, a reduction of the alternate fuel would be correspondingly positive. Figure 7 shows the same considerations for the route Hong-Kong to Cincinnati. Here, the difference in fuel, i.e. the savings potential, is 364 kilograms. The average additional consumption for this route is 25.1 kg/flight hour, i.e. this would be the savings potential in this case.

Both examples show the savings opportunities. A single aircraft, with an average flight time of 15 hours, would consume something like 300 kg less fuel per day. Even if these savings seem small, already with a relatively small fleet of only 20 aircraft, the total value is correspondingly high. A conservative projection of 20 kg/flight hour and 15 hours flight time per day with twenty aircraft results in potentially 6 000 kg fuel saving per day. The associated savings in emissions of carbon dioxide are ∼18 900 kg, water ∼7 500 kg and 30 to 150 kg nitrogen oxides per day

– for a fleet of 20 aircraft. These figures are based on the indication that carbon dioxide and water vapor are the most abundant products of jet fuel combustion, with emission indices for CO2 and H2O of 3.15 kg/kg fuel and 1.26 kg/kg fuel burned [17]. These considerations are conservative and do not consider all the other advantages of a lighter aircraft. The values of

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012139 doi:10.1088/1755-1315/1254/1/012139

21 – 25 kg of additional fuel consumption determined above correspond to a fuel penalty factor of approx. 3%. In the further consideration of the savings effects, the savings of the 5-minute fuel weight (here 700 kg for 5 minutes) and the additional consumption added up per flight hour must also be considered as freight delta cumulatively. For the two flights examined above, this results in approx. 1 000 kg difference for freight at take-off.

3. Results

As part of an overarching study, statistical flight data of an airline were analysed over a period of five years. In the first step, information on individual fuel components was examined. In the second step, long flights with high freight volumes were examined in more detail with regard to planning and actual consumption. Analysis of the fuel data has shown that consumption in planning and in practice is at a high and reliable level. As a result of this evaluation, an approach to reducing the alternative fuel consumption is possible. This is based on changes in the underlying operational regulations.

A reduction of fuel has an impact on overall fuel and emission reduction. On this basis, it is recommended that airline operators may evaluate their operational procedures, management- and safety system in preparation of the implementation of a choose a basic fuel scheme with variations or an individual fuel scheme. This allows the planning of lower fuel quantities, reducing emissions.

Evaluation in Piano-x and further reduction of other fuel values possible.

Figure 8 shows almost no difference for an single flight, in the end the results are quit clearly, seen over a year.

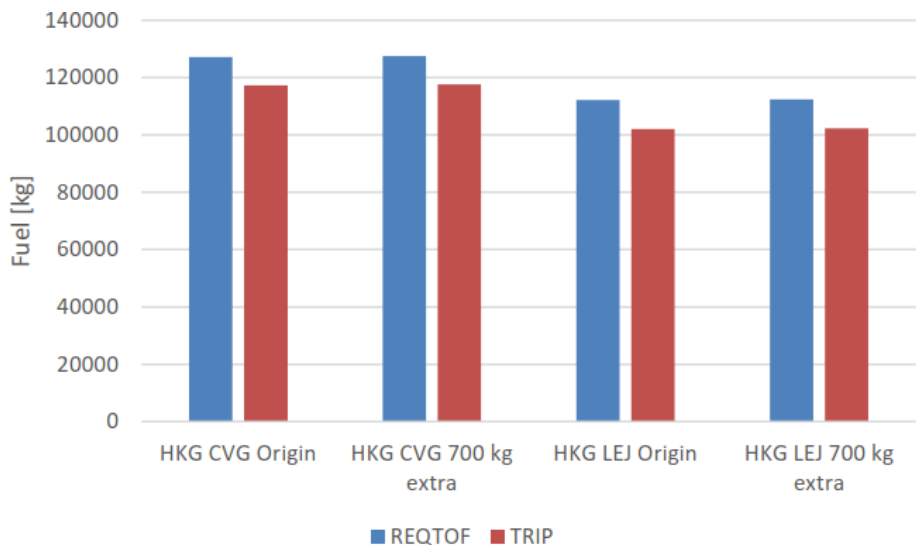

Figure 8. Impact of 5 minutes of fuel.

4. Discussion

The above proposal is the starting point for consideration. Improved risk assessment, calculations based on better data and better decision-making can optimise the amount of additional fuel needed without compromising safety levels. Aviation remains committed to progress towards climate-neutral aviation by 2050 [18]. New concepts are also necessary for this. Further research is needed to identify safety and performance indicators. An in deep evaluation of planning and used alternate fuel figures is recommended. Reducing the fuel components can free up space for additional cargo, which in turn can reduce the total number of flights required. Further considerations should be made here.

Further research is needed to identify performance indicators. The above assessment has focused only on one fuel component. A more in-depth assessment of total fuel numbers is recommended, as well as consideration of other factors such as aircraft system reliability, the influence of weather or airfield processes. Based on these investigations, a risk assessment can be made to further reduce the amount of fuel carried.

Abstract. The article presents the results of the research into the transverse loading of the container during rail transportation. The peculiarity of the container is its walls made of sandwich panels. Such a solution will help to reduce the dynamic loading on the container in operation and, accordingly, improve its strength. Appropriate calculations have been carried out in order to determine the optimum (minimum) sheet thickness, provided that the permissible deflection in operation is ensured. The transverse loading on the container placed on a flat wagon at the side rolling has been investigated. It is found that the acceleration value obtained is almost 5% lower than that acting on the container of a typical design. The strength of the container with sandwich-panel walls is calculated using the finite element method. The results of the calculation show that the maximum stresses are 6% lower than those occurring in the container of a typical design. The research may be of values for those who develop recommendations for designing advanced modular vehicles and improving the efficiency of transportation.

1. Introduction

The efficient performance of the machine-building industry requires development and putting into operation modern structures of vehicles. For a long time railway transport has been the most competitive industry of machine engineering, which accounts for a large proportion of freight transportation [1].

The experience of development of the wagon fleet in the UIC member countries indicates a steady trend in improving the level of traffic safety, which ensures operational reliability and environmental compatibility of vehicles. At the same time, one of the most optimal solutions to achieve these requirements is the introduction of modular vehicles, in particular, containers, into operation.

In addition to a number of advantages of these vehicles in operation compared to others, there are also significant disadvantages associated with insufficient strength of their structures. The reason for it is significant operational loads, including dynamic sign-variable ones affecting the vehicles. These loads affect not only the container, but also the freight inside. Due to the fact that this freight has its own degree of freedom, the container structure can have additional loading. And this loading can damage the container (figure 1 [2]).

This requires additional maintenance costs. Besides, it can also affect the traffic safety and cause ecological damage.

(a) (b)

Figure 1. Damage to containers in operation: (a) design diagram of a flat wagon; (b) deformation and cracks in the cover.

Therefore it is important to research into structural improvements for containers in order to reduce their dynamic loading at operational modes.

Research devoted to the structural improvements in the container is quite relevant, which is confirmed by a large number of publications. For example, in article [3] the authors propose and substantiate the design of a container for fruit and vegetable products. All structural solutions regarding the improvements in the container are confirmed by appropriate strength calculations. The study presents main operational loading diagrams for containers.

Also, the design of a container for transportation of fruit and vegetable products is proposed in [4]. The study presents the results of strength calculation and the operational requirements for the container. At the same time, when designing these container structures, the authors did not propose any solution to improve the strength of container walls.

Special features of designing the ISO container are studied in [5]. The main loading diagrams for the container in operation are analysed, as well as the structural resistance to external loads. However, it should be noted that the improvements proposed in this work do not increase the strength of container walls when containers are transported either by rail or by other transport mode.

To reduce the dynamic loads on vehicles and, thereby, improve their strength characteristics, it is advisable to use sandwich panels in their structures. The use of sandwich panels in the rail vehicle design is substantiated in [6]. The study presents an algorithm for optimizing the bearing structure of a vehicle. The results of the calculations demonstrate that this solution contributes to a 16.36% reduction in the bearing structure if compared to the prototype.

The use of sandwich panels in the vehicle body structure is also substantiated in studies [7,8]. The research was carried out on the example of a rail car. These solutions are implementable in both manufacture and modernization of rail cars. The feasibility of the proposed solutions has been proved by theoretical calculations of the strength for the bearing rail car structure.

A similar solution is proposed in [9]. The author's team focus on improving the reliability of the bearing structure of a vehicle by introducing composite panels. It was proven that the use of such panels could improve the endurance of vehicle bodies.

However, it should be noted that the authors of these studies did not consider the use of sandwich panels for the structure of removable vehicles, in particular, containers.

The review of literature allows us to conclude that the issues of improvements for the container are quite relevant. At the same time, their higher strength by means of sandwich panels in the bearing structures has not yet been thoroughly studies. In this regard, there is a need to conduct research in this area.

The objective of the study is to highlight the results of determining the transverse dynamics and the strength of a container with sandwich panel walls when transported by rail. To achieve the objective the following tasks were set:

- to substantiate the structural solutions to make the container sidewalls of sandwich panels;
- to determine the transverse dynamics of the container;
- to calculate the container strength.

2. The substantiation of the structural solution to make the container sidewalls of sandwich panels

It is proposed to introduce sandwich panels as the components of container sidewalls to ensure their strength. The sandwich panels are composed of two metal sheets with an energy-absorbing material between them (figure 2). Such a solution will improve the strength of the container by reducing its loading.

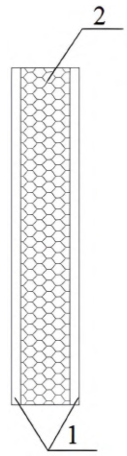

Figure 2. Sandwich-panel construction: 1 – metal sheet, 2 – energy-absorbing material.

Appropriate calculations were carried out to determine the thickness of the cover sheet of the container. The cover sheets for each section were considered as thin-walled slabs with a width of 6.058 m and a height of 2.591 m.

The sheet thickness was determined by the formula [10]:

$$\delta = \sqrt{\frac{P \cdot 96 \cdot (b^2 + \mu \cdot a^2) \cdot a^2 \cdot b^2}{\sigma \cdot \pi^4 \cdot (a^2 + b^2)^2}}, \tag{1}$$

where P – the pressure acting on the sheet area; σ – the allowable stresses of the material of the cover; a – the sheet width; b – the sheet height; μ – Poisson's ratio; π – to constant, which is equaled to 3.14.

On the basis of the calculations it was found that at $[\sigma] = 210$ MPa, $\mu = 0.28$ (steel), the transverse force value $0.6 \cdot P_k \cdot g$, where P_k – the carrying capacity of the container, the value $\delta = 1.6$ mm. Taking this into account, the thickness of the energy-absorbing layer can be taken as 32.8 mm, based on the condition of maintaining the wall size within that of a typical container.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012140 doi:10.1088/1755-1315/1254/1/012140

3. The determination of the transverse dynamics of the container with sandwich panel walls

To substantiate the use of sandwich panels in the sidewalls of the container, mathematical modelling of its dynamic loading was carried out, provided that the container was placed on a flat wagon at side rolling oscillations. The design diagram of the container placed on the flat wagon is shown in figure 3.

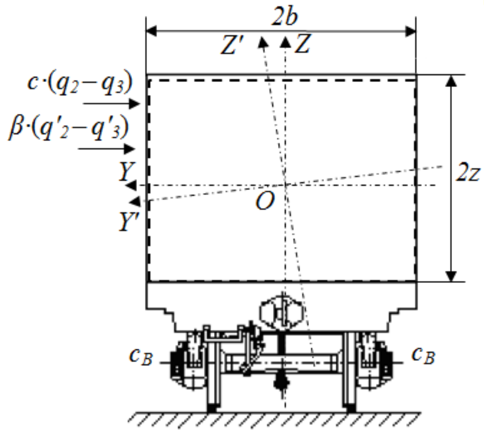

Figure 3. The design diagram of the container placed on the flat wagon.

For this purpose, mathematical model (2) was formed.

$$\begin{cases} I_{FM} \cdot \ddot{q}_1 + c_B \cdot b \cdot (sign(b \cdot q_1)) = F_C; \\ I_C \cdot \ddot{q}_2 - g \cdot (M_k \cdot z^2) \cdot q_2 = F_{FM} + F_f - c \cdot b^2 \cdot (q_2 - q_3) - \beta \cdot b^2 \cdot (\dot{q}_2 - \dot{q}_3); \\ I_f \cdot \ddot{q}_3 = F_C - c \cdot b^2 \cdot (q_2 - q_3) - \beta \cdot b^2 \cdot (\dot{q}_2 - \dot{q}_3), \end{cases} \quad (2)$$

where I_{FM} – the inertia moment of the flat wagon; c_B – the stiffness of the springs of the suspension group of the bogie; b – the half-width of the flat-wagon frame; F_C – the moment of forces occurring between the container and the flat wagon frame; I_C – the inertia moment of the container relative to the longitudinal axis; g – the free fall acceleration; M_k – the mass of the container; z – the half-height of the container; F_{FW} – the moment of forces occurring between the flat wagon and the container; F_f – the moment of forces occurring between the container and the freight; c – the stiffness of the energy-absorbing material; β – the viscous resistance coefficient of the energy-absorbing material; I_f – the inertia moment of the freight; q_1, q_2, q_3 – the generalised coordinates that determine the movement of the flat wagon, container and freight, respectively.

Mathematical model (2) was solved in MathCad at the initial conditions equalling zero [11–13]. The model was reduced to the normal Cauchy form with a subsequent solution according to the Runge-Kutta method [14–16]. On the basis of the calculation it was found that the maximum accelerations to the container were 1.7 m/s^2 (figure 4).

The value of the acceleration obtained was almost 5% lower than that to the container of a typical design. The calculation was made at the stiffness coefficient of the energy-absorbing material 1.5 kN/m and the viscous resistance coefficient 2.0 kN·s/m. These parameters were determined by a sequential selection, provided that the accelerations were within the permissible values.

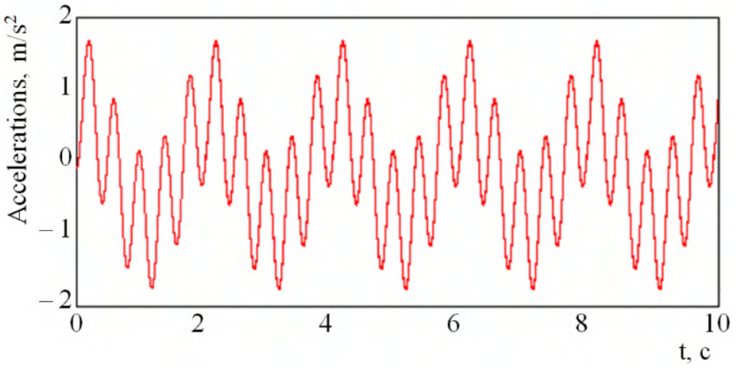

Figure 4. Accelerations to the container.

4. The strength calculation for the container with sandwich-panel walls

The resulting acceleration value was included in the strength calculation of the container. The spatial model of the container was built in SolidWorks (figure 5). It included the structural elements rigidly interacting with each other. The strength calculation was made in SolidWorks Simulation with the finite element method. The Mises criterion was used as the calculation criterion [17, 18].

The viscoelastic connection in the sandwich panels that form the sidewalls was included as the spring-damper connection by means of the software complex options (figure 6).

The design diagram of the container included the following loads (figure 7): vertical static P_v, transverse P_t applied to the sidewall. The transverse loading included the pressure from the freight (grain), as well as the dynamic loading. The dynamic loading was applied from the container slope side.

The pressure from the freight to the container walls was determined with the Coulomb method using Sinelnikov's adjustment:

$$p = \gamma \cdot h \cdot \frac{\cos^2 \cdot (\rho - \alpha)}{[1 + \sqrt{\frac{\sin\rho \cdot \sin(\rho - \alpha)}{\cos\alpha}}]^2 \cdot \cos\alpha}, \tag{3}$$

where γ – the volumetric mass of the freight; h – the container height; ρ – the angle of the internal friction; α – the angle of inclination of the container (taken equal to about 6°).

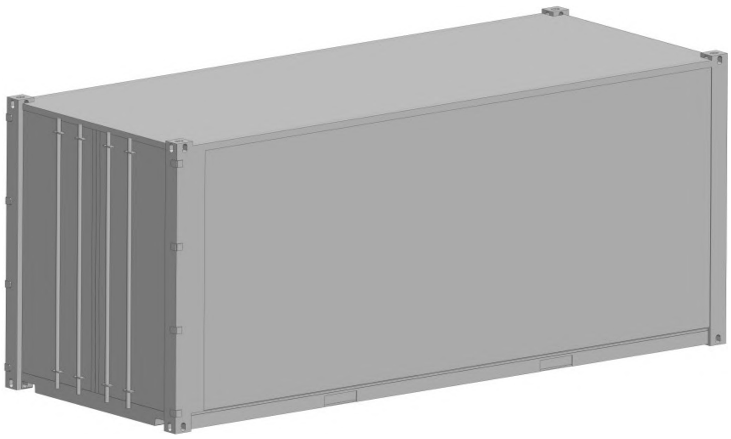

Figure 5. 1CC container with sandwich-panel walls.

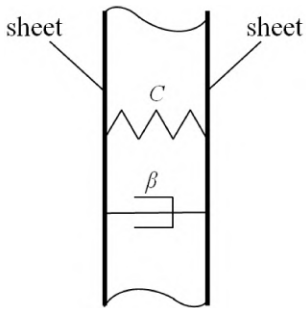

Figure 6. Diagram of viscoelastic bonds in the container walls.

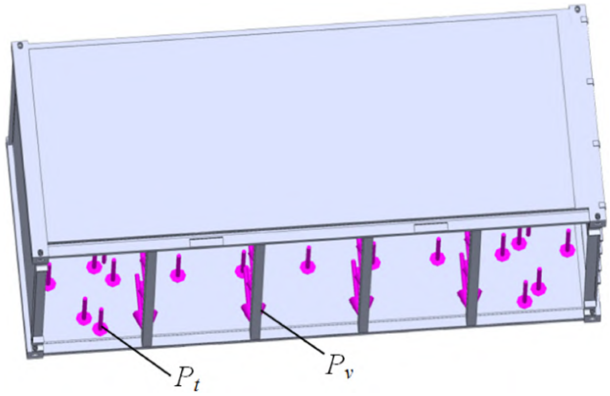

Figure 7. Calculation diagram of the container.

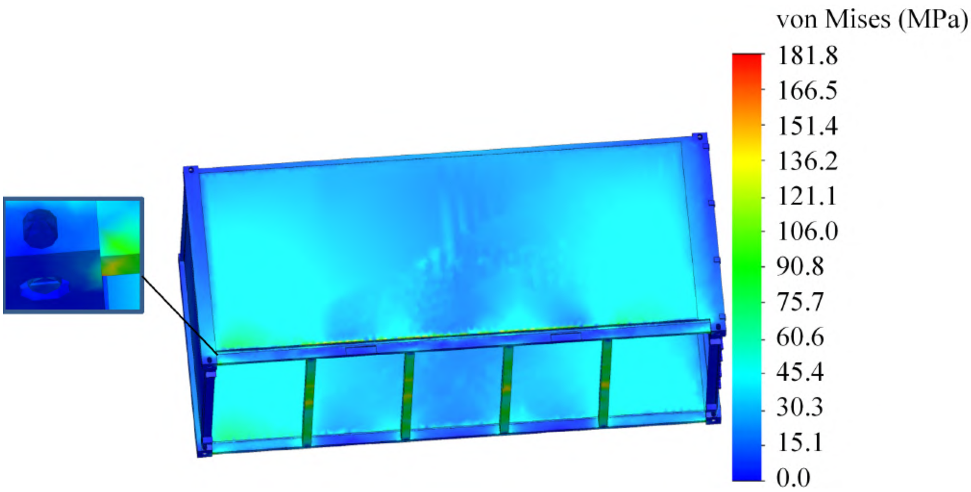

Figure 8. Stress state of the container.

When building the finite-element model of the container, spatial tetrahedrons were used. The model consisted of 373575 nodes and 11119509 elements. The maximum element size was 80 mm and the minimal element size was 16 mm.

The model was secured by fittings. Steel 09C2Cu was used as the structural material [19,20]. The results of the calculation are given in figure 8.

The maximum stresses were recorded in the contact areas between the bottom side rail and the fitting stops; they amounted to about 180 MPa (stress in the external layer). The resulting stresses were 6% lower than those in a typical container design.

The research conducted will be of value for those who develop recommendations for designing advanced structures of modular vehicles and improving the efficiency of transportation.

5. Conclusions

The structural solution to make the container sidewalls of sandwich panels has been substantiated. In this case, the thickness of the sheets that form the sandwich panel should be 1.6 mm, thus ensuring their strength. The thickness of the energy-absorbing layer can be taken as 32.8 mm, while observing the wall size within that of a typical container.

The research deals with determination of the transverse dynamics of the container with sandwich-panel walls. The maximum accelerations on the container are 1.7 m/s^2. The value of the acceleration obtained is almost 5% lower than that acting to the container of a typical design. The calculation is made at the stiffness coefficient of the energy-absorbing material 1.5 kN/m and the viscous resistance coefficient 2.0 kN·s/m).

The research also includes the strength calculation for the container with sandwich-panel walls. The results of the calculation show that the maximum stresses occur in the contact areas between the bottom side rail and the fitting stops; they are equal to about 180 MPa. It should be noted that the resulting stresses are 6% lower than those occurring in a typical container design.

Abstract. The article provides the results of determining the thermal stress state of the composite brake pad of a wagon. The research is made by means of computer simulation with the finite element method using the SolidWorks Simulation options. The design diagram of the pad includes not only the horizontal loads due to its pressing to the rolling surface of the wheel and the friction force, but also the temperature impact taken equal to 400°C. Since the composite material of the pad is fragile, the Mohr–Coulomb criterion is used as a calculation criterion. It has been found that the maximum stresses occur in the upper part of the pad in the contact area between the back plate and the side plate and do not exceed the permissible values. The article presents the results of the calculation of the thermal stress state of the pad with dual wedge-shaped wear. The study includes the actual parameters of the pad wear determined during operational research. The results of the calculation show that the maximum stresses occur in the back plate of the pad and exceed the permissible values by 19.8%. This is explained by the fact that the useful area of the pad decreases, and therefore its loading increases. The research conducted proves the negative impact of dual wedge-shaped wear on the braking efficiency and the strength of the brake pad. This requires development of measures for eliminating this wear.

1. Introduction

The rapid development of the rail industry is accompanied by an increase of the train speed and the axle loading, the need to improve the structures and materials for the rolling stock, an increase in the tare load ratio of rail cars, etc. [1]. In this regard, friction materials used in the railway industry, in particular, for braking systems, should provide a fixed friction coefficient and low wear at various operational (speed, temperature, pressure) and environmental (noise, extreme weather) conditions.

The violation of the operational requirements causes an increased wear of brake pads (figure 1), and therefore, in operation brake shoes can be used for braking. This certainly leads to damage to the rolling surfaces of the wheels and directly affects the train traffic safety.

Therefore, in order to prevent abnormal wears of brake pads, including dual wedge-shaped wear, it is advisable to develop requirements and devices that will ensure the uniform wear of brake pads so that they can serve during the whole repair-to-repair period at depots. This makes it possible to dispose of such brake pads with a minor portion of the working composite mass remaining and save hundreds of thousands of hryvnias for Ukrainian Railways or industrial enterprises with their own freight rolling stock, so that they will purchase brake pads and significantly reduce operational costs.

(a) (b)

Figure 1. Consequences of abnormal wear of composite brake pads: (a) damaged brake shoe with wire instead of the key, used for braking without a pad; (b) part of the damaged pad remaining in the brake shoe.

The issue of traffic safety of freight trains is quite relevant and depends on many factors including the technical condition and the loading of structural components of their brakes. In study [2], for example, the authors analyse stresses and temperatures occurring in the brake pad by applying SolidWorks. They propose an alternative solution to use a composite based on modified alkyl benzene resin to increase the friction coefficient.

Koptovets et al [3] provides the results of testing on freight rolling stock of industrial transport in terms of the efficient braking, as well as structural and dynamic analysis of the brake mechanism. It includes the determination of the type and parameters of the empirical dependence between the friction coefficient of the brake pad on the rolling surface of the wheel and the braking speed, as well as the determination of the kinetic characteristic of the brake for freight rolling stock of industrial transport. However, the authors did not take into account dual wedge-shaped wear of the pads of wagons, which very significantly affects the braking efficiency of industrial transport.

Kiss et al [4] presents a new friction material for brake pads, which affects the service life of the wheels of rolling stock. Particular attention is paid to the problems related to the use of modern brake materials and their influence on thermal and mechanical properties during the transmission of loading to railway wheels when braking.

Muradian et al [5,6] presents the results of operational research into the assessment of factors causing defects of thermal origin on the rolling surface of the wheel pair when interacting with composite brake pads. To prevent such defects, the authors propose using composite pads with metal inserts that will reduce their wear. During the inspection of the brake equipment of the freight train, various malfunctions of the mechanical and pneumatic parts of the brakes were detected; the inspection of the brake pads demonstrated that their wear was wedge-shaped due to touching the upper end against the rolling surface. However, the works do not describe the impact of dual wedge-shaped wear on the strength of brake pads and braking efficiency.

Mazur et al [7] analyse the operational quality indicators of cast-iron and composite brake pads used on various types of rolling stock. The study describes some negative factors of composite pads and explains how they affect the environment and cause damage to rolling surfaces of wheels of rolling stock.

A lot of studies on the use of composite brake pads for rolling stock are dedicated primarily to the issues of traffic safety and environment protection. Therefore, the reduction in operational costs for the railway industry often means that brake pads are considered as a product that is often purchased at the lowest price if it performs satisfactorily. However, this may not imply the lowest operating costs, and the choice of friction material may have a direct impact on the service life of the wheel, the replacement of which is usually much more expensive than that of other car assemblies [8].

Mazur and Sirenko [9] compare the quality indicators and performance characteristics of cast-iron moulded and composite brake pads on the basis of publications overview. They also describe some disadvantages in using composite pads, such as, low thermal conductivity, which causes a thermal impact on the rolling surface of the wheel of rolling stock. This leads to an increase in the maintenance costs for wheel pairs. Another significant disadvantage is the fact that the manufacturing specifications, standards and technical documents do not include the list of components of the rubber mixture and their chemical composition; it contradicts the current legislation of Ukraine and makes it impossible to control these substances. However, the article does not mention the expenses caused by abnormal wear of composite brake pads, which can occur during movement of freight rolling stock when brakes are not applied.

Sharma et al [10] describe various friction braking devices used to reduce the resistance of movement. It is noted that friction brake mechanisms, in which composite brake pads are used, adversely affect the rolling surface of the wheel due to very high temperatures in the pad-wheel friction area, so preference is given to disc brakes.

Some scientists focus on studying disc brakes, calculating the strength of their elements, monitoring their operation, as well as calculating temperature modes for some parts of brake systems used for rolling stock [11, 12]. When friction brakes are applied, thermal energy is generated in the contact area of tribotechnical bodies; this energy is dissipated by forced convection, conduction and radiation from the exposed brake surfaces rotating during the train movement. Day et al [13, 14] state that overheated tribotechnical pairs can cause failures in the brake system, thus it can lead to violation of traffic safety. In this regard, significant theoretical research is being done to reduce the temperature during braking according to movement speeds and brake disc designs.

Other studies [15,16], aimed at introducing modern materials into the design of tribotechnical units, substantiate the effectiveness of their application in modern rolling stock; this makes it possible to increase the speed of movement, the axial load, the efficiency of the brake system, etc. But, at the same time, there are a number of problems associated with abnormal wear of brake pads in wagons that need to be solved. And the problems associated with wear of brake pads and wheels of freight rolling stock actually exist [17]. In this regard, the work related to improvements of the lever transmission elements of wagons to protect the movement of freight trains by increasing the efficiency of their brakes is being carried out.

The analysis of literature allows us to conclude that the issues of dual wedge-shaped wear of composite brake pads used in the brake systems of bogies in Ukraine at present are relevant and require research and development.

The objective of the research was to determine the thermal stress state of the composite brake pad used for a wagon at operational loads. To achieve this objective the following tasks were set:

- to investigate the thermal stress state of the composite brake pad with rated parameters;

- to investigate the thermal stress state of the composite brake pad with dual wedge-shaped wear.

2. The research into the thermal stress state of the composite brake pad with rated parameters

The thermal stress state of the brake pad at operation loading modes was determined using the strength calculation. It was carried out with the finite element methods in SolidWorks Simulation [18].

A composite brake pad 2TP-11 was chosen as the prototype. The main characteristics of the pad are given in table 1.

Table 1. The main characteristics of the brake pad.

Parameter	Measurement unit	Value
Overall dimensions		
– width	mm	80^{+2}_{-1}
– thickness	mm	$65^{+5}_{-1.5}$
Mass		
– for asbestos pad	kg	3.15±0.2
– for asbestos-free pad	kg	3.2±0.25

The spatial model of the pad was built in accordance with its album of drawings in SolidWorks (figure 2). The finite-element model of the pad was built with spatial isoparametic tetrahedrons with four Jacobian points (figure 3). The optimal number of elements of the model was determined by the graphoanalytic method. The mesh was based on the curvature. The number of elements in the mesh was 2829, and nodes – 12219. The maximum element size of the mesh was 15 mm and the minimal element size was 6.2 mm. The number of elements in the circle was 9. The element size gain ratio was 1.6.

The model was fixed by the back plate in the area adjacent to the shoe. The material of the pad was composite with linear elastic orthotropic properties. At the same time, the compressive

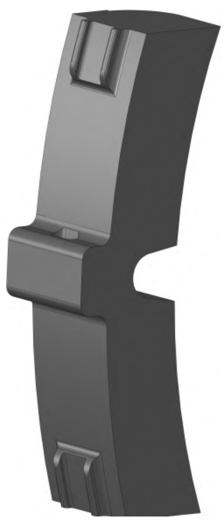

Figure 2. Spatial model of the brake pad.

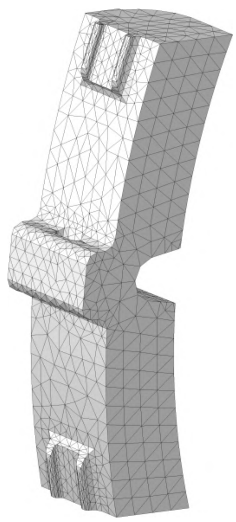

Figure 3. Finite-element model of the brake pad.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012141 doi:10.1088/1755-1315/1254/1/012141

strength of the material was taken equal to 15 MPa, and the tensile strength was taken close to zero.

The design diagram of the pad is shown in figure 4. It included the horizontal load P_H to the working part of the pad, the value of which was taken according to the operational mode of the air distributor: 41.69 – freight mode; 34.34 – medium mode; 17.5 kN – empty mode [19]. Also, the model included the friction force P_{FR} determined by the formula:

$$P_{FR} = P_H \cdot \mu, \tag{1}$$

where μ – the friction coefficient ($\mu = 0.34...0.65$).

The authors took into account the average value of the friction coefficient $\mu = 0.5$.

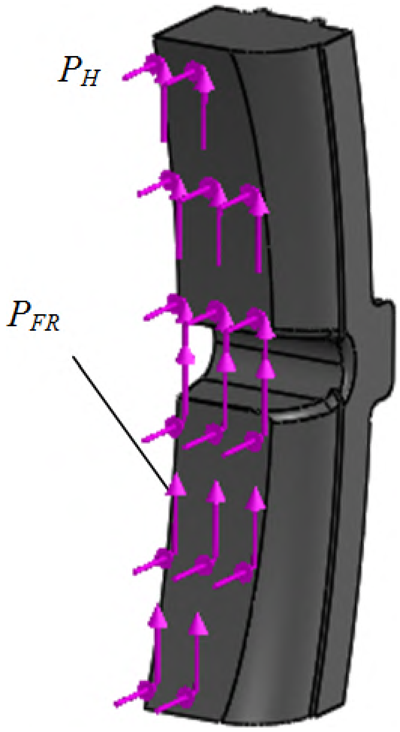

Figure 4. Design diagram of the pad.

It's worth noting that the pad suffered the temperature load during braking. The temperature on the rolling surface of the wheel in operation could be determined using the analytical expression [20]:

$$\Delta\tau_n = \frac{q_T}{\alpha_0} \cdot \left[1 - e^{-\frac{2\cdot\alpha_0}{\sqrt{\pi\cdot\lambda\cdot\gamma\cdot c}}\cdot\sqrt{t}\cdot\left(1-\frac{2}{3}\cdot\frac{t}{t_B}\right)}\right], \tag{2}$$

where q_T – the density of heat flux, kcal/(m^2 · °C); α_0 – the coefficient of heat transfer to the environment; λ – the thermal conductivity coefficient, kcal/(m^2 · °C); γ – the specific weight, kN/m^3); c – the specific heat capacity, kcal/(kgf · °C); t_B – the braking time until a complete stop, s.

The highest temperature during braking on the wheel surface was reached in the middle of this process $t = 0.5 \cdot t_B$:

$$\Delta\tau_{n\max} = \frac{q_T}{\alpha_0} \cdot \left[1 - e^{-0.9433\cdot\frac{\alpha_0}{\sqrt{\pi\cdot\lambda\cdot\gamma\cdot c}}\cdot\sqrt{t_B}}\right]. \tag{3}$$

The temperature on the surface of the wheel when the train stopped was $t = t_B$:

$$\Delta\tau_{nK} = \frac{q_T}{\alpha_0} \cdot \left[1 - e^{-0.667 \cdot \frac{\alpha_0}{\sqrt{\pi \cdot \lambda \cdot \gamma \cdot c}} \cdot \sqrt{t_B}}\right]. \tag{4}$$

The temperature as it was set during braking (at a constant speed):

$$\Delta\tau_{n\infty} = \frac{q_T}{\alpha_0} \cdot \left[1 - e^{-2 \cdot \frac{\alpha_0}{\sqrt{\pi \cdot \lambda \cdot \gamma \cdot c}} \cdot \sqrt{t_B}}\right]. \tag{5}$$

The following input parameters were used in the calculation: $q_T = 25.8$ kcal/(m^2 · °C); $\alpha_0 = 0.03$; $\lambda = 2 \cdot 10^{-4}$ kcal/(m^2 · °C); $\gamma = 2.2 \cdot 10^3$ kN/m^3; $c = 0.28$ kcal/(kgf · °C); $t_B = 120$ s.

By analysing dependencies (2) – (5), can conclude that the temperature on the pad surface was constantly changing by braking time. Therefore, when calculating the strength of the pad, the maximum allowable value of the temperature load P_T was taken into account. This load was applied to the working surface of the pad (figure 5) and was taken equal to 400 °C. The effect of this temperature on the pad material was estimated by introducing a coefficient of thermal expansion of $4.1 \cdot 10^{-6}\ K^{-1}$ for the material.

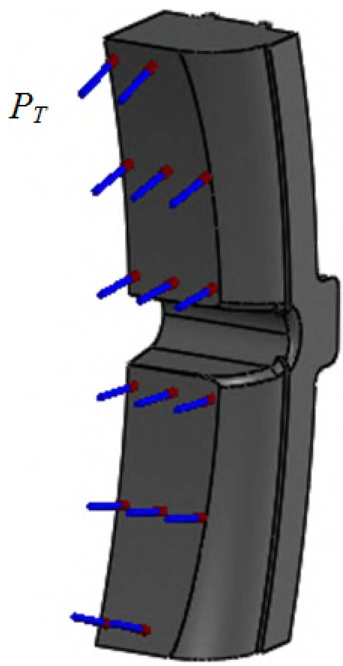

Figure 5. Diagram of the temperature loading applied to the pad.

Since the material mentioned had a small tensile strength and no yield strength, the strength calculation was made according to the Mohr–Coulomb criterion, i.e., the theory of internal friction. It is known that this criterion predicts failures if the simultaneous action of the maximum principle tensile stress and the minimum principle compression stress exceeds the appropriate stress limits [19].

In the case of a uniaxial stress state, the law of strength had the form [21]:

$$\tau \leq (\sigma - U) \cdot tg\varphi + c, \tag{6}$$

where τ and σ – the tangential and normal stresses acting at some point of the base; U – the pressure in the pore liquid; φ – the internal friction angle, c – the specific adhesion.

For the case of the spatial state, the formula took the form:

$$\frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3 + 2 \cdot c \cdot ctg\varphi} \leq \sin\varphi; \tag{7}$$

$$\sigma_1 > \sigma_2 > \sigma_3, \tag{8}$$

where σ_1, σ_2 and σ_3 – the principal stresses.

In accordance with this criterion, failures were predicted in the following cases:

- the principal tensile stresses were greater than zero $\sigma_1 > 0$ and $\sigma_3 > 0$. In this case, the failure criterion was taken into account if the principal stress exceeded the boundary tensile stress, i.e. $\sigma_1 > \sigma$;
- the principal compression stresses were less than zero $\sigma_1 < 0$ and $\sigma_3 < 0$. In this case, the failure criterion was taken into account if the admissible principal stress exceeded the boundary compression stress, i.e. $\sigma_1 > \sigma$;
- the principal tensile stress was $\sigma_1 > 0$, and principal compression stress was $\sigma_3 < 0$. The failure criterion in this case was:

$$\frac{\sigma_1}{\sigma} + \frac{\sigma_3}{\sigma_s} > 1; \tag{9}$$

The results of the calculations are given in figures 6 – 8.

By analysing the results obtained, we can conclude that the maximum stresses occur in the upper part of the pad in the contact area between the back plate and the side plate; they amount to 14.9 MPa and do not exceed the permissible values (15 MPa [22]).

3. The research into the thermal stress state of the composite brake pad with dual wedge-shaped wear

The strength of the brake pad was calculated and its dual wedge-shaped wear was taken into account. The calculation was made for the composite brake pad with dual wedge-shaped wear used for the wagon with a mileage of 63400 km. According to the measurements (figure 9, a), the

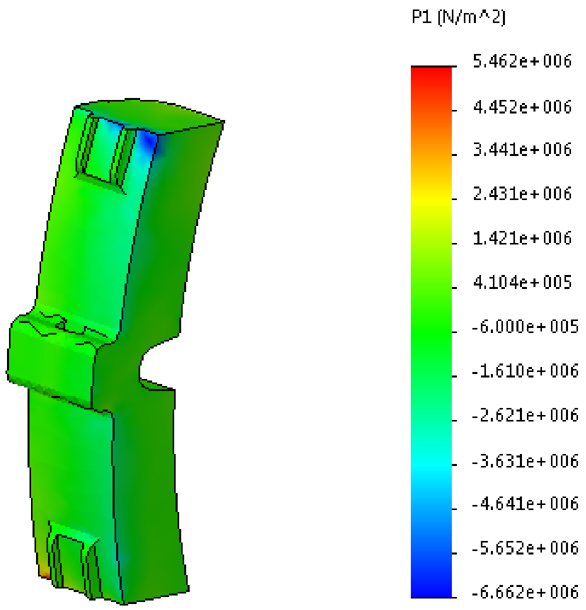

Figure 6. First principal stress in the pad.

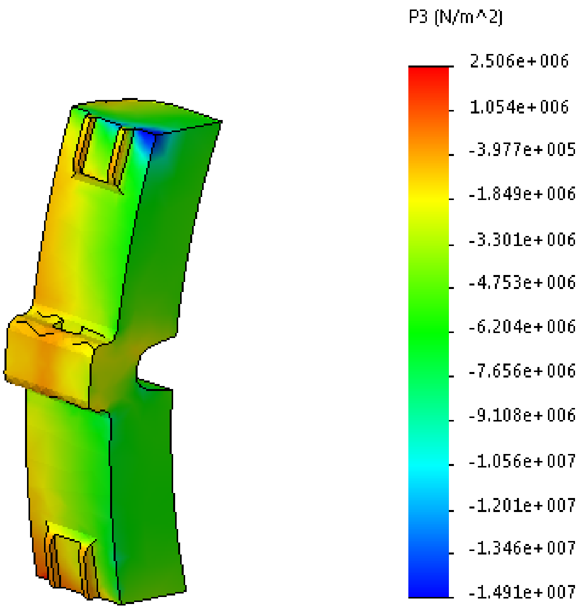

Figure 8. Third principal stress in the pad.

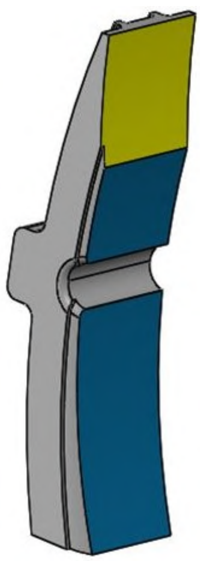
(*a*)



(*b*)

Figure 9. General view of the composite brake pad with dual wedge-shaped wear: (*a*) measurements of the geometric parameters of the pad to determine abnormal wear; (*b*) spatial model.

pad had the following abnormal wear characteristics: thickness at the upper end $\Delta_U = 10$ mm; thickness along the borderline of the plates $\Delta_{BL} = 27$ mm; thickness at the bottom end $\Delta_B = 20$ mm and length of harmful abrasion at the top of the pad $l_H = 85$ mm.

The design diagram of the pad included the loads identical to those shown in figure 10 and figure 11.

The finite-element model of the brake pad with wear consisted of 5429 elements and 24502 nodes (figure 12). The maximum element size of the mesh was 12 mm and the minimal element size was 2.4 mm. The number of elements in the circle was 9. The element size gain ratio was

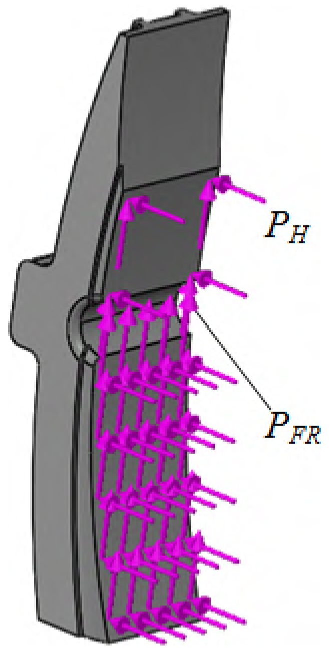


Figure 10. Design diagram of the pad with wear.

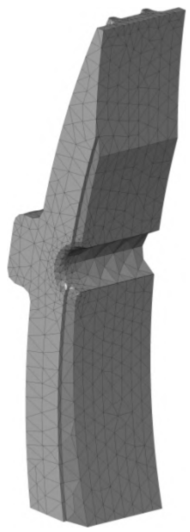

Figure 12. Finite-element model of the brake pad with wear.

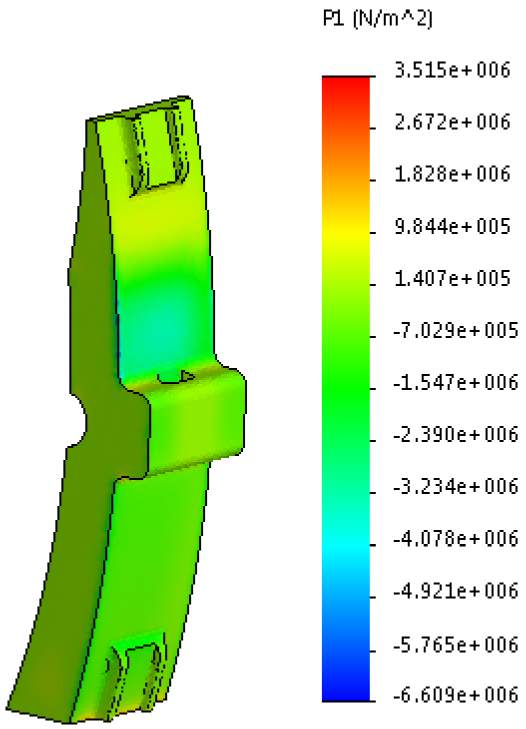

Figure 13. First principal stress in the pad with wears.

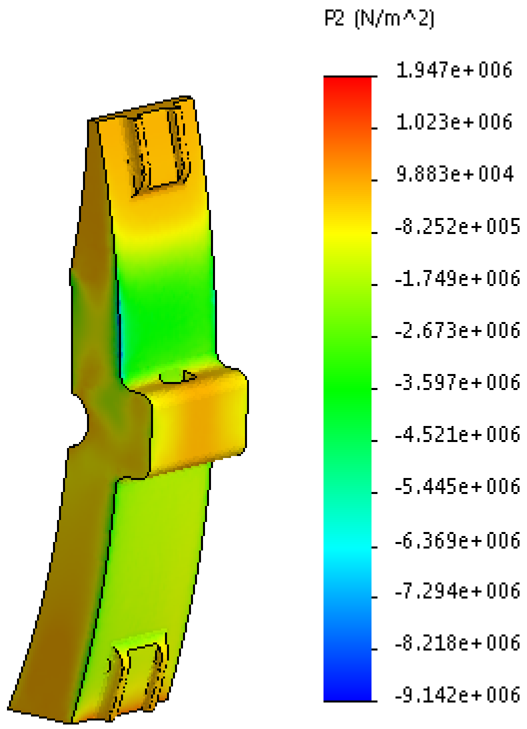

Figure 14. Second principal stress in the pad with wears.

1.6.

The results of the calculations are given in figures 13 – 15. The maximum stresses were recorded in the back plate of the pad and amounted to 18.7 MPa (third principal stress); they exceeded the permissible values by 19.8%.

The distribution of stresses along the upper part of the brake pad is shown in figure 16.

The graph presents the stresses by module. Their numerical values were determined using the probing option in SolidWorks Simulation. From this figure it can be concluded that the maximum stresses occur at a height of 135 – 140 mm from the top of the pad.

4. Conclusions

The research deals with the thermal stress state of the composite brake pad with rated parameters. It has been found that the maximum stresses (third principal stress) occur in the upper part of the pad in the contact area between the back plate and the side plate; they amount to 14.9 MPa and do not exceed the permissible values (15 MPa). The maximum stress distribution in the pad is explained by the fact that the frictional force is taken as upward in the calculation. When pointing it downward, which may be typical for the opposite triangle of the bogie, the dislocation of the stresses is opposite to the resulting loading diagram.

The research includes the thermal stress state of the composite brake pad with dual wedge-shaped wear. The maximum stresses occur in the back plate of the pad and amount to 18.7 MPa (third principal stress); they exceed the permissible values by 19.8%. This is explained by the fact that the useful area of the pad decreases, and, accordingly, its loading increases.

The research conducted proves the negative impact of dual wedge-shaped wear not only on the braking efficiency, but also on the strength of brake pads. This requires the development of measures aimed at eliminating this wear.

Abstract. Review and Justify use of new alternative way of gold ore transportation on high altitude mining operations in Kyrgyzstan in prime purpose of the study. Glaciers of Kyrgyzstan are main source of fresh water supply in Central Asia. Local ecosystem preservation is important part of metal mining in Kyrgyzstan and specific needs of nomads should be taken in the account. Novelty of study is preliminary assessment of mine in Kyrgyzstan for potential gravity energy by loading and dumping point's GPS coordinates are taken on site and review of appropriate technologies for ore transportation in order to reduce carbon emissions. Aerial ropeway specific energy consumption formula and recuperating ropeway system from previous studies are reviewed and used in study. Improvement of existing mine operations by improving transportation practices should be further studied. The design and maintenance of haul roads may allow to reduce diesel fuel consumption by 10% and more. Preliminary potential energy for recuperation by aerial ropeway application in Jerooy and Jamgyr gold mines of Kyrgyzstan are identified. Energy recuperating aerial ropeway system with fuel cells can be strategically long-term preferred solution for mines in Kyrgyzstan located in high altitude.

1. Introduction

About 45% of all glaciers in Central Asia are situated on the territory of Kyrgyzstan. They are the major source of water-supply for rivers, and forecasts of their condition are of particular concern due to the effects of global climate change. Glaciers and snowfields on the mountain tops are of great importance in the regulation for water supply and regulation of natural features of the region. There are 8200 glaciers with total area of 8169, 4 square kilometers within Kyrgyzstan, occupying 4.2% of the country. Water resources of the glaciers of Kyrgyzstan are estimated at 650 km^3 [1].

17 deposits gold deposits are on the state balance nowadays which are: Kumtor, Jerooy, Jamgyr, Makmal, Soltonsary, Terekskoe, Kuru-Tegerek, Taldybulak Levoberezhny, Kurandzhailyau, Terekkan, Terek-Mezhplastovoe, Mironovskoe, Abshyr, Ishtamberdy, Dolpran, Perevalnoe, Chalkuiryuk-Akdzhylga. Officially registered reserves of gold are 1055.256t [2].

As 90% of country territory is located in mountain landscape. Number of gold deposits located above 3000 meters above sea level on visible proximity to glaciers and significant snow walls. Lower hills and valleys are valuable assets for local nomad for cattle and crop farming. Mineral mining in mountain countries like Kyrgyzstan typically has advantages that processing plants can be located bellow mine. This opens opportunity to use potential gravity energy of gold ore are being transported down to processing plant. The main purpose of this paper is to review and evaluate the latest technologies to reduce carbon emission to reduce impact of mining operation to environment.

According to the International Energy Agency mining companies should reduce their carbon emissions by 58% by 2050 compared with 2010 [3]. Meeting this target is going to be the big challenge considering that demand for minerals is growing as the population is growing. The globe is running out high grade deposits and mining low grade ore means task to move more tonnage to longer distances and increase mineral mining at remote locations such us mining in mountains at high altitude.

Nowadays there are solutions for significant reduction of carbon emission while transportation of materials from equipment manufacturers are available. Assessment of running mining operations for emission reduction opportunities must be one of the key elements in this initiative. As transportation costs can take 40-60% of overall mining costs improvement of haul road design and maintenance can reduce consumption diesel fuel and as well. If the rolling resistance is higher than that used during mine planning, the trucks are unable to achieve the expected productivity [4].

There are 4 types of hybrid technology under study by developers: 1. Battery hybrid powertrain; 2. Supercapacitor hybrid powertrain; 3. Hydraulic hybrid powertrain; 4. Compressed-air hybrid powertrain. The power saving of mining hybrid haul truck studied by Chun Jin and others in 2019 [5]. Recycling of lithium batteries are studied by Rahman and Afroz in 2016 [6]. Hydro-Pneumatic Energy Storage System for Hybrid Mining Trucks was studied by Yi and other in 2022 [7]. Niuric and others studied the trolley assist diesel-electric AC trucks in 2009 [8].

Mtu Rolls-Royce engineers' states 220 tonnes payload mining haul truck traveling downhill potentially can recuperate 22% of energy and on loaded downhill application up to 54% of energy can be recuperated. Fuel performance simulation on 220 tonns payload truck shows 29% less green-house gas emission for factory installed hybrid system [9].

The foregoing allows us to conclude that the research for alternative types of transportation of mining material in the development of high-altitude deposits is an actual problem.

The purpose of this research was to find and justify an alternative method of transporting minerals in the high-mountain mines of the Kyrgyz Republic, providing a reduction in energy consumption, a reduction in emissions of harmful gases, and an improvement in the technical and economic indicators of transportation of minerals.

Based on the analysis of existing operations in high-altitude mines, two technological schemes for transporting ore were selected for further study: the use of aerial ropeway and the use of dump trucks with diesel drives.

At the same time, the following main tasks were solved: ensuring cheaper transportation of ore, saving expensive diesel fuel, improving the environmental situation (reducing harmful emissions).

1.1. Related works

Climate change [1] and greenhouse gas emission assessment [10] is vital aspect of further development of energy profile [11] and mineral resource industry of Kyrgyzstan [2]. As transportation of materials is one of the main cost structures of mining operation decarbonization of this process [3] has strategical importance. Improving haul road maintenance and design [4] can be the first action to be considered by miners in their decarbonization plans. Mining trucks widely used in open pit mines have the potential to recover around 30% of potential energy [5] by hybrid trucks technologies. Increasing lithium battery capacity and availability makes feasible use of hybrid and electric trucks in mining industry [12]. Recycling of lithium batteries has great meaning for sustainable resource saving initiative. More than 90% of Cobalt (Co) can be extracted from composition of $CoSO_4$ [6]. Novel energy storage technologies for hybrid trucks is being studied such us the hydro-pneumatic hybrid truck with optimized scheme reduces its fuel consumption and carbon emission by 23.57 kg/day and 72.12 kg/day respectively compare with reverse dragging scheme [7]. For any open pit mines dipper than 150 meters trolley assist diesel-electric mining trucks can be seriously considered [8]. 54% of potential energy can be recuperated on system introduced by Mtu Rolls-Royce [9]. For mine located on mountain terrain conditions aerial rope way can be long term solution. Self-propelled wagons as one of the possible solutions [13] to increase productivity of rope ways can be considered depending on mine's conditions. Recuperation of potential gravity [14] energy can further increase return on investment in aerial rope ways in Kyrgyzstan mines.

1.2. Purpose
Transportation costs may reach 50-70% of overall mining costs. The present work aims to study status of ore transportation from mine sites to processing plans in mines located in Kyrgyzstan at high altitude mountain conditions and possibility to use alternative technologies in order to reduce costs of transportation as well as carbon emission and impact to environment.

To achieve this goal study covers two areas:

1. Review and asses modern alternative technologies for application on mine sites of Kyrgyzstan.
2. Identify potential energy and carbon emission savings while application various transportation technologies.

2. Research methodology
When conducting research, a comprehensive methodology was used, including the analysis of literary sources, the experience of mining operations in high altitude mountains, the study of the terrain of the Jerooy and Jamgyr mines of the Kyrgyz Republic, a technical and economic assessment of the proposed new technological and economic solutions.

The technology of transporting mining material by dump trucks with a diesel drive was adopted as the base for the research. As alternative schemes, the transportation of rock mass by aerial ropeway.

2.1. Methodology and analysis
Aerial ropeway application can be optimal solution for miners in Kyrgyzstan as long terms solution. It can help to reduce impact to glacier ecology and wildlife as well as increase safety for personal. Jerooy and Jamgyr gold mines have significant energy recuperation potential as ore processing plants are located at lower altitude than mine sites.

Table 1 shows the ore loading and dumping point's GPS locations that were taken on site.

Table 1. Ore loading and dumping points of Jerooy and Jamgyr mine sites.

Locations	Title	Jerooy mine data		Jamgyr mine data	
		Coordinates	Altitude	Coordinates	Altitude
Loading point – A	h_1	42°17'32"N 72°45'34"E	3150 m	42°11'13"N 71°32'59"E	3240 m
Dumping point - B	h_2	42°23'34"N 72°43'34"E	2062 m	42°10'32"N 71°31'45"E	2988 m

Table 2 shows potential energy data for related mine sites.

Table 2. Annual potential enegry data of Jerooy and Jamgyr mine sites.

Parameters	Title	Units of measure	Jerooy mine value	Jamgyr mine value
Ore transportation target per year	m	tonnes	1 300 000	150 000
Height of transportation	H	meter	1088	252
Acceleration of gravity	g	meters per second	9,81	9,81
Potential energy	E	Mega Joules	13 875 264	370 818

Potential energy is calculated by formula (1):

$$E = mg(h_1 - h_2). \tag{1}$$

2.2. Calculation methodology of energy consumption of ropeway

Specific energy consumption is the amount of energy consumed by a ropeway for transporting cargo. The specific energy consumption of the ropeway can be calculated by formula (2) [13]. Specific energy consumption for traditional design (with haul rope)

$$e_{HR} = 2\left(1 + k_m + \frac{q_T \lambda}{m_1}\right)(fL + H)\,g, \tag{2}$$

where k_m is the wagon loading coefficient, $k_m = m_0/m_1$; q_T is the distributed load taking into account the weight of rope and wagons; λ is the wagon hanging spacing; m_1 is the total weight of cargo; f is the resistance factor of wagon movement and haul rope; L is the track length in the plan; g is the acceleration of gravity; m_0 is the wagon weight (empty).

Specific energy consuption for ropeway carriyng loaded wagons down the hill can be calculated by formula (3):

$$e_{HR} = 2\left(1 + \frac{m_0}{m_1} + \frac{q_T \lambda}{m_1}\right)(fL + H)\,g. \tag{3}$$

3. Results and discussion

Jerroy and Jamgyr mine operations demonstarate sugnificant potential for energy recuperation. It is importante to evaluate ways to recuperate potential gravity energy and store it.

Figure 1 describes the way recuperative cableway system with fuel cells works [14]. Unit (10) serves for transportation of the load using a skyline (1), mainly for skidding, which uses gravity of the carriage and load to run an electric generator (8) with the help of a winding device (3) and a clutch (5), and voltage from electric generator (8) helps electrolysis of water in fuel cells (10), where oxygen and hydrogen and produced, and consequently they synthesize in fuel cells (10) into water when pulling an carriage up the hill, and at the same time, voltage is produced, and it is transmitted through the switch (13) into an electric motor (9), it runs the winding device (3) using a clutch (6) and it helps to move the carriage down the hill.

The recuperative cableway system with fuel cells can be a practical solution to recuperate energy of cargo traveling down the hill. As Lithium-Ion batteries become widely available at reasonable cost they can can be used as fuel cells in mentioned solution to store recuperated energy. Recycling of Lithium-Ion batteries are very important issue for environment. Recovery of valuable metals from used Lithium-Ion batteries are studied by Wang et al [12].

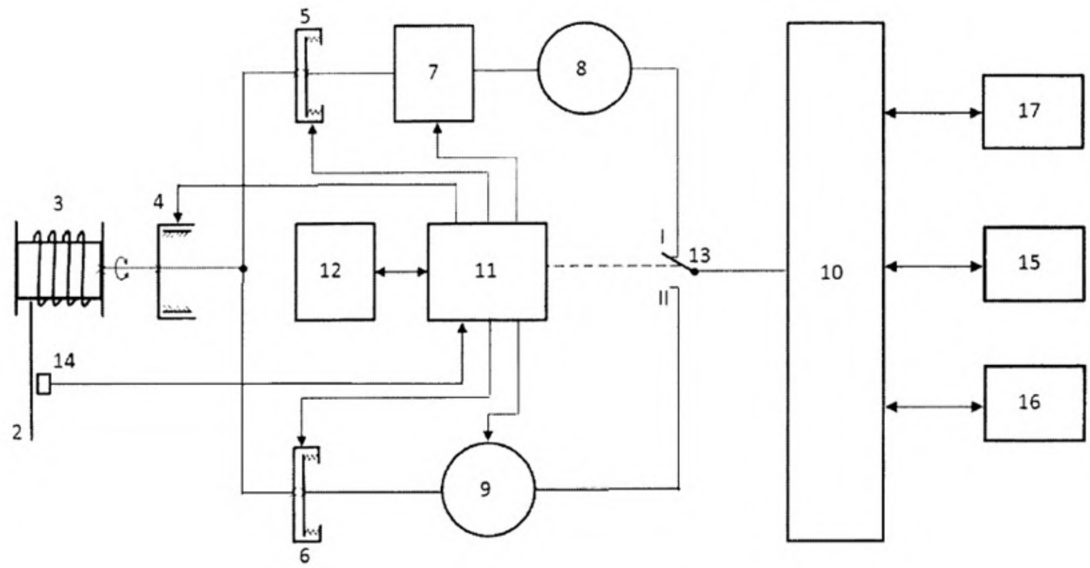

Figure 1. The recuperative cableway system with fuel cells.

The system for transportation of the load, mainly for downhill storage (1), is characterized obtaining energy for the system running from fuel cells (10).

According to claim 1, the system is characterized by the winding device (3) is connected with the electric generator (8) connected with fuel cells using electric conductors in the phase of gravitational approaching.

The system is characterized by that the fuel cell (10) is connected by electric conductors with the electric motor (9), which is connected to the winding device (3) in the phase of moving carriage down the hill.

Results of cycle timing study on site displayed productivity and CO_2 emission estimation because of common way of ore transportation by diesel engine driven truck on one of the gold mines in Kyrgyzstan (table 3).

CO_2 emission calculated by formula (4) [10]:

$$CO_2(t) = \sum VK, \tag{4}$$

where K is the Diesel fuel burn CO_2 emission coefficient CO_2 EF kg CO_2/l – 2.65; V is the Diesel fuel consumption.

Performance of arial ropeway implemented in Cerattepe copper mine in Turkiye described in [15]. Diesel equivalent consumption is estimated as per ration of 0.88 US gallons per 37.95 kWt/hour (table 4).

Specific equivalent fuel consumption of aerial ropeway per one ton at Cerattepe mine in 0.6 liters per ton. Whereas the same parameter for diesel driven dump truck is 2 liters per ton. Thus, CO_2 emission with aerial rope way is 3.3 times lower from fuel consumption point of view. Study does not consist of CO_2 emission and energy consumption for auxiliary processes such as maintenance and repair of equipment and haul road and ropeway.

The mining industry is increasing its electrification processes to meet global demand to reduce carbon emissions. As per International Energy Agency Kyrgyzstan has around 90% of total electricity generation in hydro-based making it one the county with highest shares of renewable electricity in the world. However only about 10% of hydro energy potential has been developed [11].

Table 3. Site performance results of ore transportation by on-high way truck in gold mine in Kyrgyzstan.

Parameters	Units of measure	Value
Payload of truck	tonnes	25
Engine power	kWt	295
Distance	kilometer	35
Average time per trip	hour	2.75
Average fuel consumption per trip	liter	50
Productivity per truck	tonnes per hour	9.09
Fuel consumption	liters per hour	18.18
Average operating time	motor hours	6500
Annual CO_2 emission	kilogram	311968.8
Horizontal length on plan	meters	11749
Vertical fall	meter	-1088
Established power per produced ton	kWt per tons per hour	32.45
Specific fuel consumption	liters per ton per kilometer	2

Table 4. Performance of arial ropeway implemented in Cerattepe copper mine.

Parameters	Units of measure	Value
Productivity	tonnes per hour	60
Motor power	kWt	414
Horizontal length on plan	meters	4471
Vertical fall	meters	-1515
Established power per produced tonn	kWt per tons per hour	6.9
Equivalent of diesel fuel consumption	liter per hour	36.38
Specific equivalent fuel consumption	liter per ton	0.6

4. Conclusions

In this research various drive systems of transportation technologies and their performance in open mine operations located in high altitudes in Kyrgyz Republic.

Main results and conclusions are in following:

1. Analyses of operational performance of aerial ropeway and diesel driven dump trucks shows that aerial ropeway in 3.3 times more energy efficient. Transportation path on aerial ropeway is 3-7 times shorter in compare with haul road for dump trucks operation.
2. Cycle timing study on various mines shows that equivalent diesel fuel consumption of aerial ropeway in high altitude mine conditions can be only 0.6 liters per ton, for transport systems with diesel driven dump truck can reach 2 liters per ton.

Considering amount of renewable energy share in electricity generation of Kyrgyzstan use of aerial ropeways in mining can be significant contribution to environment and local ecosystems.

Acknowledgments
The authors are grateful to the management of Jerooy and Jamgyr mines and Kyrgyz Mining and Metallurgical Institute named after acad. U. Asanaliev for their support and contribution to the study.

Abstract. The model of before- and intrahepatic blockage of the portal system was proposed. Modeling of before-hepatic blockage of the portal system after development of toxic liver dystrophy lead to formation of the liver cirrhosis with stable portal hypertension. Gastritis with signs of hyperplastic and atrophy processes of the mucosa, formation of erosia, inflammatory infiltration of intermediate tissue and rebuilding of the glandulae were the basis of morphological changes of gastric mucosa in rats with experimental before- and intrahepatic portal blockage. Transformation of the cardiac mucosa with expressed polymorphism occured in the patients with the portal liver cirrhosis. Dystrophic and necrobiotic changes typical of hepatic gastropathy with signs of acute or chronic gastritis, formation of inflammatory infiltrates and rebuilding of the cardial mucosa into intestinal type were established microscopically. It is possible to believe that a widening of the veins leads to venous hyperemia and stasis in the portal hypertension. Therefore the morphology of the gastric mucosa was disturbed. It was accompanied bythe indurate changes and cellular destruction with erosia formation. These erosia may be a cause of rupture of the gastric mucosa in strong vomiting in Mallory-Weiss syndrome. This hypothesis needs clinic and experimental study in the future.

1. Introduction

In economically developed countries, cirrhosis of the liver is one of the six main causes of death in patients aged 35 to 60 years. Geographic features of mortality from cirrhosis among men and women are similar [1].

Significant geographic differences in the incidence and mortality of liver cirrhosis are observed in developing and developed regions of the world. This is due to the different level of the economy and the development of medicine [2].

Globally, an estimated 58 million people have chronic hepatitis C virus infection, with about 1.5 million new infections occurring per year [3].

One of the goals of sustainable development in Ukraine is good health and well-being to ensure healthy lifestyles and promote well-being for all, regardless of age. To solve this goal, one of the tasks is to reduce the premature mortality of the population by a quarter, including through the introduction of innovative approaches to the diagnosis of diseases [4].

Therefore the actuality for clinical and experimental researches of etiopathogenetic mechanisms of development and elimination of liver diseases and their complications. The basis of experimental research is working out the methods of the liver cirrhosis modeling, acute and chronic liver insufficiency developed with before, and intrahepatic portal blockage.

The known methods of modeling of before-hepatic blockage of the portal system include the ligation of the portal vein and its intrahepatic branches or to apply cuff on the portal vein decreasing its diameter [5, 6]. The animals die in hours after ligation of the main trunk of the portal vein, and in days (4 – 10) after ligation of its branches. The cirrhotic changes in the liver have no time to appear [6, 7]. It is not possible to apply muff on the portal vein for dosage change of its diameter for small laboratory animals (rats). The portal hypertension developed in such method of modeling in dogs after some months [6]. Opie [8] proposed to model the

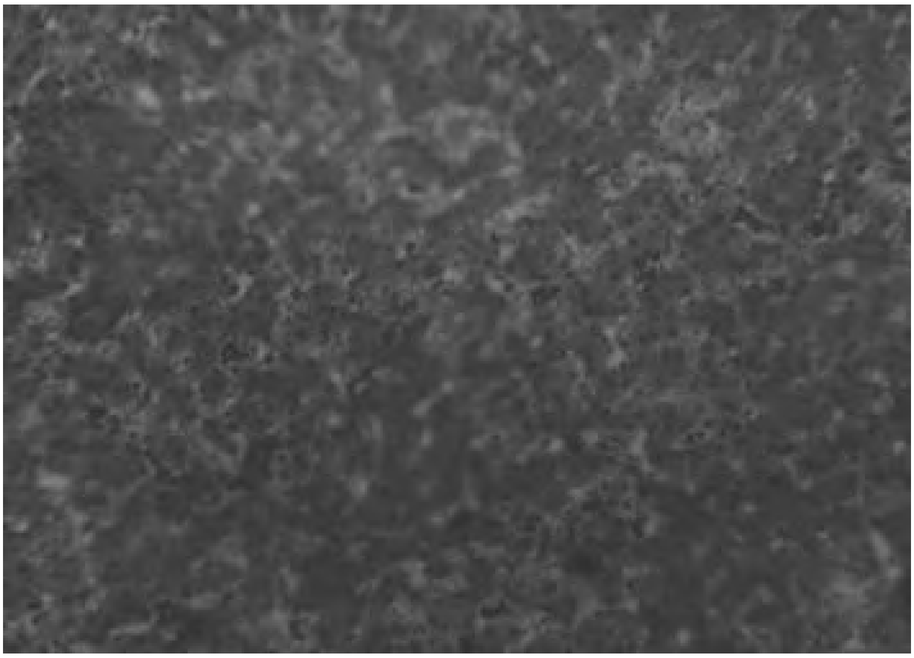

Figure 1. The liver acquired a view of Muscat in the 20^{th} day of experiment.

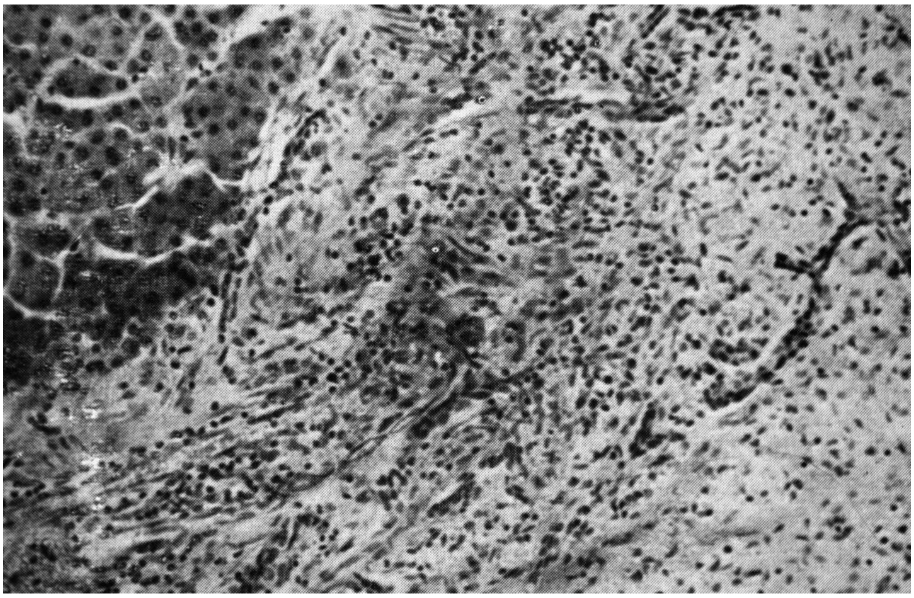

Figure 2. Liver cirrhosis formation in the 30^{th} day of experiment.

intrahepatic portal blockage by injection of chloroform into the jugular vein in a combination of injection of culture of E. coli. The liver cirrhosis developed in 23 days [6, 7].

The famous methods of modeling of before- and intrahepatic blockage of the portal system have low reproduction, it is not possible to do it in small laboratory animals. It has some technical difficulties and low economic effect.

Therefore the purpose of the research includes to elaborate some effective, easy reproductive model of before- and intrahepatic blockage of the portal system. The main purpose of the research was to study pathophysiological mechanisms of adaptation of the mucosa of the gastric cardia to portal hypertension in experiment at rats and in patients.

2. Experimental procedures

The first step of the research was carried out in 20 healthy adult Wistar rats with weights between 240 – 280 gram in period from September to December. Intrahepatic portal blockage was modeled by intraperitoneal injection of Chloroform 0.5 ml/kg two times a week. Before-hepatic portal blockage was modeled by injection of warm (40 – 5°C) Glycerinum 0.1 ml/100 gram from 20^{th} day after the beginning of Chloroform injection. The pressure in the portal vein was measured by surgical polygraphe "Salyut" before and after Glycerinum injection, and also for 20^{th}, 25^{th} and 30^{th} days after the first Chloroform injection. Then the animals were taken out of experiment. The preparations were fixed in 10% Formaline solution on phosphate buffer pH 7.2–7.4 with the temperature +4°C. Histological sections with thickness 10, 15 and 20 mkm were colored by Hematoxilin-eosin, described and photoed by digital photocamera Mustek MDC-3000.

The pressure in the portal vein was measured and analogous histological researches of stomach preparations were done in 5 false operated animals (the control group). A maintenance of the animals including feeding, anaesthesia and euthanasia were carried out according to the rules regimenting the experiments on animals.

The second step of the research was done in 20 preparations of the cardia of the gastric mucosa in patients with the portal liver cirrhosis. The areas of the cardia of the gastric mucosa were taken within 30–45 minutes after patient's death. The preparations were fixed in fresh 10% Formaline solution in phosphate buffer pH 7.2–7.4 at temperature +4°C. Histological sections with thickness 10, 15 and 20 mkm were colored by hematoxilin-eosin, studied under microscope, described and photos made. The statistical analysis of results was done.

The experimental procedures outlined in this section were conducted in strict adherence to a comprehensive set of ethical guidelines, including both international and national regulations. We have provided a more detailed account of the ethical rules and procedures followed during our experiments to ensure transparency and compliance with the ethical standards governing research in Ukraine and internationally.

Our research was conducted in accordance with the regulatory requirements of Ukraine and the norms widely accepted in international research practice. Specifically, we adhered to the following ethical frameworks:

1. We conducted our research in compliance with the principles outlined in the ICH GCP (International Conference on Harmonisation Good Clinical Practice) guidelines, which ensure the ethical conduct of clinical trials and the protection of human subjects' rights and well-being.
2. We followed the principles set forth in the Declaration of Helsinki (2000), which provides guidance on ethical research involving human subjects. This declaration emphasizes the importance of informed consent, confidentiality, and the well-being of research participants.
3. Our research adhered to the provisions of the Council of Europe's Convention on Human Rights and Biomedicine, which addresses the ethical aspects of biomedicine and human

rights, including the protection of personal data.

4. To protect the privacy and identity of individuals participating in our study, we employed encryption identifiers for personal data in accordance with the Convention on the Protection of Personal Data.

All patients who participated in our study provided written informed consent. We ensured that participants were fully informed about the nature and purpose of the research, the procedures involved, potential risks, and their right to withdraw from the study at any time without consequences. Consent forms were used to document their voluntary agreement to participate.

The experiments involving animals were conducted with the utmost respect for ethical considerations. We followed established rules and regulations governing experiments on animals, including:

1. The animals were provided with appropriate nutrition to ensure their well-being throughout the experiment.
2. When necessary, anesthesia was administered to animals to minimize discomfort and pain.
3. Euthanasia procedures were carried out in strict accordance with ethical guidelines to minimize any suffering experienced by the animals.

In addition to the aforementioned international guidelines, our research also adhered to specific institutional policies and ethical review processes at our university and affiliated institutions in Ukraine. These policies encompassed a range of ethical considerations, including patient consent, animal welfare, and the handling of biological samples.

3. Results and discussion

The mean pressure in the portal vein was 58.6 $\pm$6.72 mm H_2O in rats of control group. The mean pressure in the portal vein was 78.8 $\pm$9.43 mm H_2O on the 20^{th} day after the experiment began, 223.4 $\pm$21.71 mm H_2O on the 25^{th} day, 244.0 $\pm$20.56 mm H_2O on the 30^{th} day. The mean pressure in the portal vein was 323 mm H_2O on the 30^{th} day. Weak relationship between an increasing of the portal pressure and the experiment was revealed in the 20^{th} day of experiment. There was strong direct correlation on the 25^{th} and the 30^{th} day of experiment. The coefficient of correlation and its range was 0.512 $\pm$0.43 ($p<0.1$) for study of control data and data of the 20^{th} day experiment, 0.965 $\pm$0.11 ($p<0.001$) for study of control data of the 25^{th} day experiment, 0.981 $\pm$0.17 ($p<0.001$) for study of control data and data of the 30^{th} day experiment. The strong direct correlation between an increasing of the portal pressure and term of experiment was established in comparison data between series of experiment. The coefficient of correlation and its range was 0.953 $\pm$0.28 ($p<0.001$) for study of data of the 20^{th} day and data of the 25^{th} day experiment, 0.961 $\pm$0.27 ($p<0.001$) for study of data of the 20^{th} day and data of the 30^{th} day experiment. The results of the 25^{th} day experiment were correlated with the 30^{th} day experiment (0.615 $\pm$0.45, $p<0.05$).

The changes in the liver parenchyma to be analogous to the toxic liver dystrophy was revealed. The partial necrosis of hepatocytes was discovered, mainly in the center of lobes. There was adipose dystrophy. The relief of the lobes was changed and absent in some parts of the liver. The liver acquired a view of Muscat (figure 1). It may divide some areas of the liver tissue of preserved lobulae in the 20^{th} day of experiment, showed loss of its specific view (figure 2, 3).

In the 30^{th} day of experiment some areas of the liver tissue with necrosis, adiposal distrophy, disintegration of hepatocytes with formation of indefinite blockes appeared (figure 3). Areas of increasing connective tissue were revealed. The cirrhosis began to form.

A view of superficial gastritis was established among the 80% of the rats in the 20^{th} day of experiment before Glycerinum injection. The epithelium loses its high-prismatic shape and stands more plain, the cytoplasm was pellucid. The nuclei pushed to the apical part of cell, were different by size and color. Borders between the cells were indistinct.

In 50% of rats the changes were according to gastritis with disturbance of the glandulae without atrophy. The glandulae and stroma were involved in process in these animals. There was vacuolization of the cytoplasm, necrobiosis of the cells, widening of the glandulae gap. An

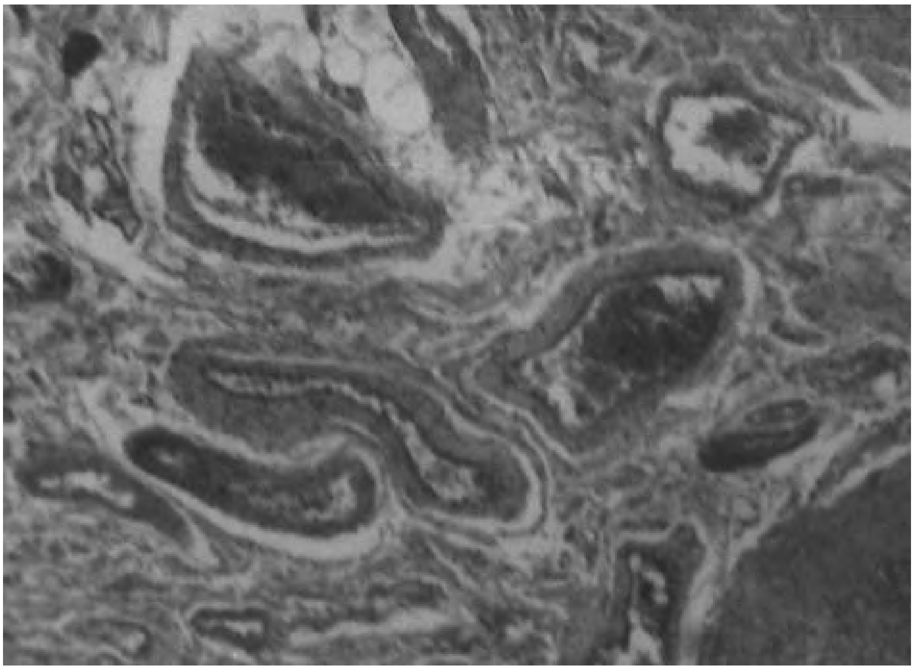

Figure 3. Expressed changes in the gastric mucosa in portal hypertension. 1 – sharply widening vein with stasis and fibrinoid necrosis of the wall. Hematoxilin-eosin. x200.

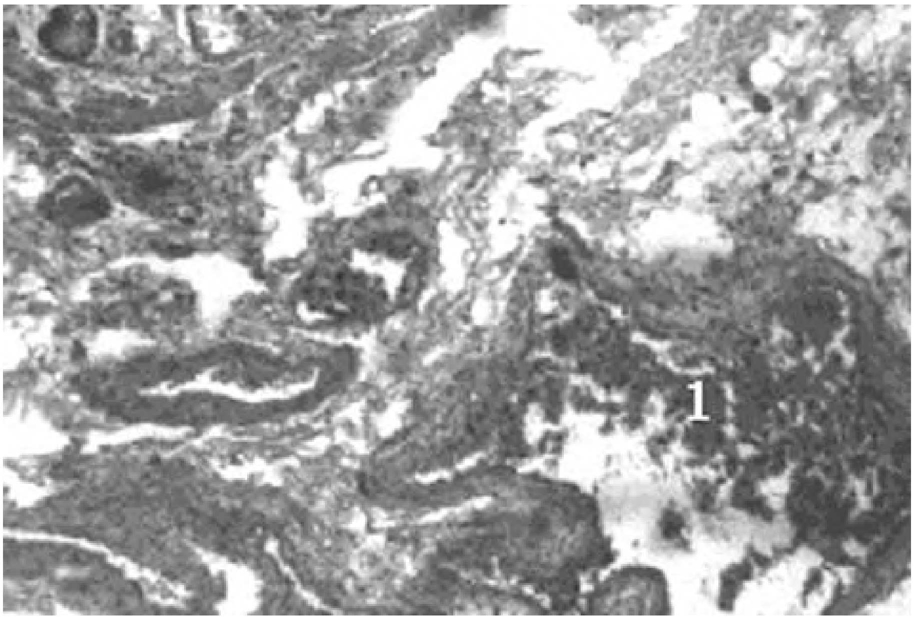

Figure 4. Erosion (arrow) of the gastric mucosa above widening veins (1). Hematoxilin-eosin. x50.

intensive cell infiltration was revealed in terminal parts of the glandulae and intermediate tissue. Basal membrane looked for thickening. Fiberous structures were increased in the stroma.

In 20% of rats changes were analogous to atrophic gastritis and thinning of the mucosa. The glandulae were conserved in small islands among the connective tissue. There were changes in the superficial epithelium and in the epithelium of the glandulae looking for intestinal metaplasia was discovered.

A lot of animals had atrophic gastritis with thinning of the mucosa in the 30^{th} day of experiment. There were multiple erosia of the mucosa in 75% of cases. The submucosal level was widened. The muscular plate of the mucosa had the areas of hypertrophy. The elastic fibers were hyperplastic.

The changes of the vessels in the submucosal level were established. The veins were widened. The epithelium was desquamoused above them. It led to formation of microerosia and erosia. The walls of the veins were thickened. Tunica propria mucosae was oedematic. It had hemorrhages and areas of polymorphic cell infiltration consisting mainly of neutrophills and eosinophills. Thre was proliferation of histiocytes and fibroblasts. Besides there were plasmatic, plump cells and lymphocytes in composition of the infiltrate.

The changes of the glandulae were oppression of formation of the mucus. the gap of the glandulae was widened. There was an increase of fiberous structures in the stroma. The quantity of the glandulae was decreased in any areas.

A death of smooth myocytes and substitution of them by the connective tissue were revealed in areas of the inflammatory infiltrates of the muscular plate in the 30^{th} day of experiment. Sometimes the muscular plate was substituted by fibrous tissue. Hemorrhages into the mucosa and the submucosa were discovered in areas of sclerosis of the tunica muscularis mucosae.

The varices of the gastric submucosal layer and atrophy of the mucosa above them were revealed in 75% all the cases.

The sharply expressed changes of the vessels of gastric cardia were established in the patients of portal hypertension. They manifested by widening, stasis, plasmatic saturation and fibrinoid necrosis of the vessel wall (figure 4).

The desquamation of superficial epithelium was increased above widening veins. It was resulted by formation of microerosion and erosion of different degree (figure 5). Microscopic picture of such type erosion was not typical and depends on stage of the process and the depth of occurrence of the blood vessels. The walls of the vessels were thick as a result of productive vasculitis. There were oedema, hemorrhages and polymorphic cell infiltration in the tunica propria mucosae. A zone of infiltration may be distributed into the submucosal and muscular layers. The neutrophills and eosinophills composed the main part of the infiltrate. There were a lot of lymphocytes, plasmatic and plump cells. A proliferation of histiocytes and fibroblasts was revealed. The lymphocytes and plasmatic cells predominated in small infiltrates (figure 6).

The formation of mucus in the gastric glandulae occured unevenly in zone of inflammatory infiltration. There were cells having significant amount of mucus granules and cells having cytoplasm filled to overflowing of mucus. Some of them lose a connection with the basal membrane and desquamated into the aperture of the glandulae. There was oppression of secret formation in the glandulae epithelium (figure 7).

A combination of dystrophic changes of the glandulae, hyperplastic and atrophic processes in the gastric mucosa with formation of erosia, an inflammatory infiltration of intermediate tissue and changes of the glandulae are the basis of morphological changes of the gastric mucosa in the patients with the portal liver cirrhosis. A cellular composition of the glandulae and a depression of their fumctional activity were connected with dystrophic changes in the gastric mucosa. Borders between the cells were indistinct. Nuclei looked like bubble with hyperchromatosis of the nuclear membrane or piknotic (figure 8).

4. Conclusion

Results of the research allow to constant that it is necessary to create the complex effect for reliable modeling of the liver cirrhosis. Weak expressed portal hypertension during formation of model of the intrahepatic portal blockage was revealed. However such increasing of pressure in the portal vein was not stable. A sharp increasing of the pressure in the portal vein was established after modeling before-hepatic blockage of the portal system. Modeling of before-hepatic blockage of the portal system after development of toxic liver dystrophic lead to formation of the liver cirrhosis with stable portal hypertension. Gastritis with signs of hyperplastic and atrophy processes of the mucosa, formation of erosia, inflammatory infiltration of intermediate tissue and rebuilding of the glandulae were the basis of morphological changes of gastric mucosa in rats with experimental before- and intrahepatic portal blockage.

Transformation of the cardial mucosa with expressed polymorphism occured in the patients with the portal liver cirrhosis. Dystrophic and necrobiotic changes typical for hepatic gastropathy with signs of acute or chronic gastritis, formation of inflammatory infiltrates and rebuilding of the cardiac mucosa into intestinal type were established microscopically. It is possible to believe that a widening of the veins leads to venous hyperemia and stasis in the portal hypertension. Therefore the morphology of the gastric mucosa was disturbed. It was accompanied by the indurate changes and cellular destruction with erosia formation. These erosia may be a cause of rupture of the gastric mucosa in strong vomiting in Mallory-Weiss syndrome. This hypothesis needs clinic and experimental study in the future.
