Abstract. This paper presents the preface of the proceedings for the 4th International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters (ICSF 2023), a multidisciplinary event that explores the challenges and opportunities of sustainability in various domains. The preface outlines the conference's objectives, themes, workshops, and topics, as well as its contribution to advancing sustainable development and global dialogue. It also acknowledges the efforts and inputs of various stakeholders who have made the conference possible, especially in light of the pandemic situation. Furthermore, it thanks IOP Publishing for its support and flexibility in facilitating open access publishing. The paper concludes by looking forward to future editions of ICSF and the ongoing quest for a more sustainable and interconnected world. The paper invites readers to delve into the rich and diverse content that shapes this influential conference.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 011001 doi:10.1088/1755-1315/1254/1/011001

1. Introduction

Welcome to the **International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters** (**ICSF**) proceedings. This conference serves as a cornerstone for global discourse on sustainable development, providing a peer-reviewed international platform where researchers, scientists, engineers, and practitioners converge to share their latest research findings, innovative ideas, and practical applications. As we delve into these proceedings, we embark on a journey across diverse disciplines, united by a common goal of advancing sustainable practices.

Figure 1 showcases the emblem of ICSF 2023, a symbol of our collective commitment to fostering sustainable futures.

Figure 1. The emblem of ICSF 2023.

Since its inauguration in 2020, ICSF has cultivated a space that encompasses the entire spectrum of sustainable development. With a focus on the intricate intersections of sustainability, environment, and technology, ICSF explores their far-reaching implications for corporations, governments, educational institutions, regions, and societies, both in the present and the future [1–4].

ICSF 2023 stands as a two-tiered platform, comprising pre-conference workshops and the main conference, ensuring an enriched experience for all participants.

The subsequent sections delve into the diverse workshops that comprised ICSF 2023:

The *Sustainable Development of Mining Science and Industry Workshop* (SusDevMiningScI'2023) stands as a peer-reviewed international forum dedicated to exploring cutting-edge scientific and technological achievements in mine safety, geological research, and the preservation of mineral resources. With a focus on topics spanning mining subsurface exploration, mining systematology, and geotechnical engineering, this workshop underlines our commitment to sustainable practices. Dr. Serhii Chukharev leads the program committee, guiding these vital discussions.

Workshop URL: `https://sites.google.com/knu.edu.ua/nigri-ecochemsd-ws2023/`.

1.1. Geography for Sustainable Development (GSD-2023)

Geography for Sustainable Development (GSD-2023) serves as a peer-reviewed international workshop, offering a platform for researchers deeply engaged with the challenges of sustainable development within the geographical context. Covering an array of topics, including biogeochemical cycles, climate, natural resources, and more, this workshop is a testament to the expansive scope of geography's role in shaping sustainable futures. Dr. Olga Bondarenko guides these explorations through her leadership.

Workshop URL: `https://bondarenkoolga9.wixsite.com/gsd-2023`.

1.2. Ecochemistry for Sustainable Development (EcoChemSD-WS'2023)

The *Ecochemistry for Sustainable Development Workshop* (EcoChemSD-WS'2023) operates as a peer-reviewed international gathering, nested within the 4th International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters (ICSF). This workshop engages with the multidimensional aspects of environmental chemistry, ecochemistry, and their resonance within fields such as geochemistry, agroecology, and green chemistry. Dr. Pavlo Nechypurenko spearheads these discussions, forging pathways towards sustainable chemical practices.

Workshop URL: `https://sites.google.com/view/ecochemsd-ws2023`.

1.3. Biodiversity and Ecosystems Sustainability (BiodES-2023)

Biodiversity and Ecosystems Sustainability (BiodES-2023) stands as a peer-reviewed international workshop, lending its focus to the critical task of conserving biodiversity and fostering ecosystem sustainability. Rooted in applied science and education, this workshop offers a vital foundation for addressing global challenges and nurturing sustainable futures. Dr. Viacheslav Osadchyi leads the charge in exploring the intersection of environmental, technological, and biological aspects in this context.

Workshop URL: `http://biodes.mdpu.org.ua/`.

1.4. Water Management and Environmental Engineering (WaterManEnvE-2023)

The *Water Management and Environmental Engineering Workshop* (WaterManEnvE-2023) stands as a peer-reviewed international platform, encapsulating contributions that span the breadth of water management, environmental engineering, and educational technologies. With a focus on topics including water resources, irrigation, hydraulic engineering, and more, this workshop navigates the complexities of managing our most precious resource sustainably. Dr. Serhii Klimov provides direction for these explorations.

Workshop URL: `https://sites.google.com/nuwm.edu.ua/watermanenve-ws2023/`.

1.5. Innovative Approaches for Solving Environmental Issues (IASEI-2023)

Innovative Approaches for Solving Environmental Issues (IASEI-2023) converges as a peer-reviewed international workshop, focusing on advancing environmental science research. Covering topics ranging from environmental protection to nuclear safety and technological solutions, this workshop embodies the spirit of pioneering solutions for pressing environmental challenges. Dr. Andrii Iatsyshyn leads the charge in cultivating innovative discussions.

Workshop URL: `https://www.igns.gov.ua/en/iasei-ws-2023/`.

1.6. Sustainable Energy Workshop (SEnW-2023)

Sustainable Energy Workshop (SEnW-2023) embarks on an exploration of innovative solutions in energy systems. Covering a diverse array of topics including solar and wind energy, energy policy, climate change, and more, this workshop underlines the essential role of sustainable energy in shaping our future. Guided by Dr. Volodymyr Artemchuk, this workshop paves the way for sustainable energy practices.

Workshop URL: `https://ipme.kiev.ua/en/SEnW-2023/`.

1.7. Conference sessions

The conference unfolded through a series of sessions, each shedding light on different facets of sustainable development. These sessions encompassed topics ranging from sustainable materials and technologies to socio-economic development, energy systems, and beyond. These sessions, as detailed below, comprised the backbone of ICSF 2023:

Session 1. Sustainable Materials and Technologies (May 23, 2023)
Session 2. BiodES-2023 – Biodiversity and Ecosystems Sustainability. Sustainability, Biodiversity and Conservation (May 23, 2023)
Session 3. SEnW-2023 – Sustainable Energy Workshop. Sustainable Energy. Infrastructure and Sustainability (May 23, 2023)
Session 4. SusDevMiningScI'2023 – Sustainable Development of Mining Science and Industry. Geotechnical and Geoenvironmental Engineering. Sustainable Mining (May 23, 2023)
Session 5. Sustainable Building and Architecture. Sustainable Cities and Society (May 24, 2023)
Session 6. WaterManEnvE-2023 – Water Management and Environmental Engineering. Environmental Engineering, Sustainability, and Green Technology (May 24, 2023)
Session 7. EcoChemSD-2023 – Ecochemistry for Sustainable Development. Sustainable Use of Natural Resources (May 24, 2023)
Session 8. IASEI-2023 – Innovative Approaches for Solving Environmental Issues. Environmental Pollution and Sustainable Development. Environmental Risk Assessment and Sustainable Development. Sustainable Environment and Environmental Management (May 24, 2023)
Session 9. Sustainable Socioeconomic Development. Governance, Legislation and Policy for Sustainability (May 25, 2023)
Session 10. GSD-2023 – Geography for Sustainable Development. Agroecology and Sustainable Food Systems. Geography and Sustainability. Sustainable Transport (May 26, 2023)

This volume is a repository of the scholarly contributions presented at ICSF 2023. With meticulous reviews conducted by a minimum of three program committee members, the selected papers embody the spirit of rigorous exploration and discovery.

Authors were invited to submit full research papers including surveys, tutorials, perspective/colloquia articles in conference topics of interest (`https://www.morressier.com/call-for-papers/62c564c8178bca0013ca7d13`). There were 243 submissions received. Each submission was reviewed by at least 3 program committee members. The committee decided to accept 147 papers.

The unfolding events of the ongoing Russian invasion of Ukraine necessitated a hybrid conference format. By embracing both in-person and online modes, ICSF 2023 extended its reach across borders, allowing more than 200 participants from 18 countries to participate through platforms such as Zoom and Google Meet.

The presentation slots were defined as follows:

- invites talks (25 min): 15 min presentation, 10 min question answering and discussion,

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 011001 doi:10.1088/1755-1315/1254/1/011001

- other talks (15 min): 10 min presentation and 5 minutes question answering and discussion.

The full ICSF 2023 program is available at the https://icsf.ccjournals.eu/2023/ where details of the sessions, usually headed by one or more invited presentations. Video records of talks are available at the *Not So Easy Science* YouTube channel (https://www.youtube.com/channel/UCH3gego79m-ofCiNEgEzMuA).

2. ICSF 2023 program committee

- *Leon A. Abdillah*, Universitas Bina Darma, Indonesia [5]
- *Khairulla Aben*, KAZ Minerals, Kazakhstan [6]
- *George Abuselidze*, Batumi Shota Rustaveli State University, Georgia [7]
- *Rajendran Sobha Ajin*, Kerala State Disaster Management Authority, India [8]
- *Oksana Alpatova*, Zhytomyr Polytechnic State University, Ukraine [9]
- *Jamil Abedalrahim Jamil Alsayaydeh*, Universiti Teknikal Malaysia Melaka, Malaysia [10]
- *Volodymyr Artemchuk*, G. E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine, Ukraine [11]
- *Vitalina Babenko*, V. N. Karazin Kharkiv National University, Ukraine [12]
- *Jozef Bendík*, Slovak University of Technology in Bratislava, Slovakia [13]
- *Tetiana Bilan*, State Scientific and Technical Center for Nuclear & Radiation Safety, Ukraine [14]
- *Ihor Blinov*, Institute of Electrodynamics of the National Academy of Sciences of Ukraine, Ukraine [15]
- *Valery Bliznyuk*, Clemson University, United States [16]
- *Olha Bondarenko*, Kryvyi Rih State Pedagogical University, Ukraine [17]
- *Nataliia Bordiug*, Zhytomyr Polytechnic State University, Ukraine [18]
- *Orkhontuul Borya*, Mongolian University of Science and Technology, Mongolia [19]
- *Liudmyla Burman*, Kryvyi Rih State Pedagogical University, Ukraine [20]
- *Matej Cenky*, Slovak University of Technology in Bratislava, Slovakia [21]
- *Serhii Chukharev*, National University of Water and Environmental Engineering, Ukraine [22]
- *Hanna Danylchuk*, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine [23]
- *Iryna Davydova*, Zhytomyr Polytechnic State University, Ukraine [24]
- *Kremena Dedelyanova*, Scientific and technical union of mining, geology and metallurgy in Bulgaria, Bulgaria [25]
- *Elena Degtyarenko*, National University of Life and Environmental Sciences of Ukraine, Ukraine [26]
- *Natalya Demchenko*, Institute of Marine Biology of the NAS of Ukraine, Ukraine [27]
- *Viktor Demchenko*, Institute of Marine Biology of the NAS of Ukraine, Ukraine [28]
- *Viktor Denysenko*, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine [29]
- *Nataliia Dereviahina*, Dnipro University of Technology, Ukraine [30]
- *Tetiana Derkach*, Kyiv National University of Technologies and Design, Ukraine [31]
- *Viktoriia Dmytrenko*, National University ”Yuri Kondratyuk Poltava Polytechnic”, Ukraine [32]
- *Iryna Dubovkina*, Institute of Engineering Thermophysics of NAS of Ukraine, Ukraine [33]

- *Alina Dychko*, National Technical University of Ukraine ”Igor Sikorsky Kyiv Polytechnic Institute”, Ukraine [34]
- *Mykhailo Filatiev*, Volodymyr Dahl East Ukrainian National University, Ukraine [35]
- *Branko Gluščević*, University of Belgrade, Serbia [36]
- *Volodymyr Grinchenko*, Anatolii Pidhornyi Institute of Mechanical Engineering Problems of the NAS of Ukraine, Ukraine [37]
- *Olena Hanchuk*, Kryvyi Rih State Pedagogical University, Ukraine [38]
- *Olena Herasymchuk*, Zhytomyr Polytechnic State University, Ukraine [39]
- *Serhii Honchar*, G. E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine, Ukraine [40]
- *Teodora Vassileva Hristova*, University of mining and geology “St. Ivan Rilski”, Bulgaria [41]
- *Pavlo Hryhoruk*, Khmelnytskyi National University, Ukraine [42]
- *Andrii Iatsyshyn*, Institute of Environmental Geochemistry of the NAS of Ukraine, Ukraine [43]
- *Anna Iatsyshyn*, State Scientific Organization “Ukrainian Institute of Scientific Technical and Expertise and Information”, Ukraine [44]
- *Nataliia Ivanenko*, Institute of General Energy of the NAS of Ukraine, Ukraine [45]
- *Mykola Kharytonov*, Dnipro State Agrarian and Economic University, Ukraine [46]
- *Serhii Klimov*, National University of Water and Environmental Engineering, Ukraine [47]
- *Oleksandr G. Kolgatin*, Simon Kuznets Kharkiv National University of Economics, Ukraine [48]
- *Elena Komarova*, Foxford [49]
- *Valerii Korniyenko*, National University of Water and Environmental Engineering, Ukraine [50]
- *Valeriia Kovach*, State Institution “The Institute of Environmental Geochemistry of National Academy of Sciences of Ukraine”, Ukraine [51]
- *Liudmyla Kovalchuk*, National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”, Ukraine [52]
- *Oksana Kovtun*, University of Educational Management [53]
- *Vladislav Kuchanskiy*, The Institute of Electrodynamics NASU, Ukraine [54]
- *Anton Kudin*, National Bank of Ukraine, Ukraine [55]
- *Andrey Kupin*, Kryvyi Rih National University, Ukraine [56]
- *Olena Kuzminska*, National University of Life and Environmental Sciences of Ukraine, Ukraine [57]
- *Khavalbolot Kyelgyenbai*, Mongolian University of Science and Technology, Mongolia [58]
- *Evgeniy Lavrov*, Sumy State University, Ukraine [59]
- *Maria Lazăr*, University of Petrosani, Romania [60]
- *Nadiia Lobanchykova*, Zhytomyr Polytechnic State University, Ukraine [61]
- *Oksana Lunova*, State Ecological Academy of Post-Graduate Education and Management, Ukraine [62]
- *Nataliia Maksyshko*, Zaporizhzhia National University, Ukraine [63]
- *Svitlana Malchenko*, Kryvyi Rih State Pedagogical University, Ukraine [64]

- *Juliya Malogulko*, Vinnytsia National Technical University, Ukraine [65]
- *Anatolii Matsui*, Central Ukrainian National Technical University, Ukraine [66]
- *Ahmed Salah Eddine Meddour*, University of Science and Technology Houari Boumediene, Algeria [67]
- *Oleksii Merkulov*, Iron and Steel Institute of Z.I. Nekrasov of NAS of Ukraine, Ukraine [68]
- *Ivan Mytiai*, National University of Life and Environmental Sciences of Ukraine, Ukraine [69]
- *Roland Iosif Moraru*, University of Petrosani, Romania [70]
- *Victor Mutambo*, University of Zambia, Zambia [71]
- *Oleksii Mykhailenko*, Kryvyi Rih National University, Ukraine [72]
- *Tetiana Nazarenko*, Institute of Pedagogy of the National Academy of Educational Sciences of Ukraine, Ukraine [73]
- *Victor Nazimko*, Institute for Physics of Mining Processes NAS Ukraine, Ukraine [74]
- *Pavlo Nechypurenko*, Kryvyi Rih State Pedagogical University, Ukraine [75]
- *Roman Oliynykov*, V.N. Karazin Kharkiv National University, Ukraine [76]
- *Kateryna Osadcha*, Bogdan Khmelnitsky Melitopol State Pedagogical University, Ukraine [77]
- *Viacheslav Osadchyi*, Borys Grinchenko Kyiv University, Ukraine [78]
- *Olena Pakhomova*, Oles Honchar Dnipro National University, Ukraine [79]
- *Marinela Ivanova Panayotova*, University of Mining and Geology “St. Ivan Rilski”, Bulgaria [80]
- *Natalia Panteleeva*, Kryvyi Rih State Pedagogical University, Ukraine [81]
- *Andrii Peremetchyk*, Kryvyi Rih National University, Ukraine [82]
- *Mykhailo Petlovanyi*, Dnipro University of Technology, Ukraine [83]
- *Oleksandr Popov*, Institute of Environmental Geochemistry of the NAS of Ukraine, Ukraine [84]
- *Vasyl Porokhnya*, Classic Private University, Ukraine [85]
- *Oleg Pursky*, Kyiv National University of Trade and Economics, Ukraine [86]
- *Olena Remezova*, Institute of Geological Sciences of the National Academy of Sciences of Ukraine [87]
- *Ivan Sakhno*, Donetsk National Technical University, Ukraine [88]
- *Serhiy Sakhno*, Kryvyi Rih National University, Ukraine [89]
- *Myroslav Sanytsky*, Lviv Polytechnic National University, Ukraine [90]
- *Tetiana Selivanova*, Kryvyi Rih State Pedagogical University, Ukraine [91]
- *Serhiy Semerikov*, Kryvyi Rih State Pedagogical University, Ukraine [92]
- *Volodymyr Shamrai*, Zhytomyr Polytechnic State University, Ukraine [93]
- *Yevhenii Shapovalov*, National Center ”Junior Academy of Science of Ukraine”, Ukraine [94]
- *Vadym Shchokin*, Kryvyi Rih National University, Ukraine [95]
- *Vadym Shkarupylo*, National University of Life and Environmental Sciences of Ukraine [96]
- *Paweł Sikora*, West Pomeranian University of Technology, Szczecin, Poland [97]
- *Sergii Skurativskyi*, Institute of Geophysics National Academy of Sciences of Ukraine, Ukraine [98]
- *Wiktoria Sobczyk*, AGH University of Science & Technology, Poland [99]

- *Viktor Sopov*, Kharkiv National University of Civil Engineering and Architecture, Ukraine [100]
- *Valentyna Stanytsina*, Institute of general energy of NAS of Ukraine, Ukraine [101]
- *Viktoriia Stoliarenko*, Kryvyi Rih State Pedagogical University, Ukraine [102]
- *Andrii Striuk*, Kryvyi Rih National University, Ukraine [103]
- *Radomir Timchenko*, Kryvyi Rih National University, Ukraine [104]
- *Mihaela Toderaș*, University of Petrosani, Romania [105]
- *Krzysztof Marian Tomiczek*, Silesian University of Technology, Poland [106]
- *Vitalii Tron*, Kryvyi Rih National University, Ukraine [107]
- *Illia Tsyhanenko-Dziubenko*, Zhytomyr Polytechnic State University, Ukraine [108]
- *Tetiana Vakaliuk*, Zhytomyr Polytechnic State University, Ukraine [109]
- *Iryna Varfolomyeyeva*, Kryvyi Rih State Pedagogical University, Ukraine [110]
- *Kateryna Vlasenko*, National University of Kyiv-Mohyla Academy, Ukraine [111]
- *Yuriy Vynnykov*, National University "Yuri Kondratyuk Poltava Polytechnic", Ukraine [112]
- *Petro Vyshnivskyi*, National University of Life and Environmental Sciences of Ukraine, Ukraine [113]
- *Teodoziia Yatsyshyn*, Ivano-Frankivsk National Technical University of Oil and Gas, Ukraine [114]
- *Yuliia Yechkalo*, Kryvyi Rih National University, Ukraine [115]
- *Stefan Zaichenko*, National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute", Ukraine [116]
- *Nataliia Zachosova*, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine [117]
- *Ievgen Zaitsev*, The Institute of Electrodynamics of the National Academy of Sciences of Ukraine [118]
- *Artur Zaporozhets*, Institute of of General Energy of NAS of Ukraine, Ukraine [119]
- *Olexander Zhukov*, Bogdan Khmelnitsky Melitopol State Pedagogical University, Ukraine [120]
- *Oleksandr Zgurovets*, Institute of General Energy of NAS of Ukraine, Ukraine [121]
- *Iryna Zinovieva*, Kyiv National Economic University named after Vadym Hetman, Ukraine [122]
- *Valerij Zvaritch*, Institute of Electrodynamics of the National Academy of Sciences of Ukraine, Ukraine [123]

3. ICSF 2023 organizers

The 4th edition of the International Conference on Cognitive and Natural Sciences (ICSF) was meticulously coordinated by the Academy of Cognitive and Natural Sciences (ACNS), a non-governmental organization dedicated to nurturing the growth of researchers' expertise in the cognitive and natural sciences arena. ACNS's mission encompasses enhancing research, safeguarding rights and liberties, and catering to professional, scientific, social, and various other interests.

ACNS is engaged in a spectrum of activities, including:

- Spearheading research initiatives within the cognitive and natural sciences domain and fostering collaborative ties among researchers [124, 125].

- Orchestrating conferences, workshops, training sessions, internships, and other platforms for the exchange and dissemination of knowledge in the realm of cognitive and natural sciences [126, 127].
- Publishing scientific journals, conference proceedings, collections of scholarly works, and related materials (`https://acnsci.org/cms/journals/`).

Among ACNS's prominent publications is the Diamond Open Access journal titled *Educational Technology Quarterly* (ETQ) [128], a peer-reviewed journal delving into the ways digital technology can enrich the field of education. Notably, ETQ covers a broad range of topics aligned with the Sustainable Development Goals (SDGs), with the exception of Goal 4 – Quality Education.

Here are select topics from *Educational Technology Quarterly* (ETQ) categorized by SDG goals:

SDG 3 (Good Health and Well-being)
- Addressing continuing education during the pandemic and preparing children for STEAM education, aligning with health and education goals [129].
- Examining the well-being of employees during remote work and the impact of stress on their mental health [130].
- Exploring the use of cloud technologies in education during the COVID-19 pandemic, potentially enhancing education and well-being [131].
- Enhancing physical education teachers' competency in health preservation, contributing to improved well-being [132].
- Investigating the use of virtual reality in education to improve student health and learning outcomes [133].

SDG 8 (Decent Work and Economic Growth)
- Aligning educational programs with real-life job requirements to ensure quality education and employability [134].
- Enhancing education and career guidance through innovative digital solutions [135].

SDG 9 (Industry, Innovation, and Infrastructure)
- Improving infrastructure and technological innovation in education [136].
- Enhancing education quality and integrating digital tools, aligning with education and technological innovation goals [137].
- Elevating the quality of education and enhancing technology infrastructure for software engineering education [138].
- Elevating the quality of physics education (STEM) through blended teaching methods and technology integration [139].
- Developing academic cloud infrastructure and integrating innovative technology platforms to improve education quality [140].
- Enriching the learning environment through digital transformation and innovative technologies [141, 142].
- Enhancing the quality of distance education through expert examination and training programs for course developers [143].
- Leveraging innovative technologies like augmented reality to enhance language education [144].
- Analyzing the impact of digital disruption on education and business continuity, aligning with improving education quality and technological innovation [145].
- Utilizing online courses to enhance programming education and promote innovation in education [146].

- Creating an educational encyclopedia to disseminate verified knowledge, promoting education quality and innovation [147].
- Enhancing education quality and innovation through virtual labs [148].
- Integrating STEM education and technology, aligning with educational quality and innovation goals [149].

SDG 15 (Life on Land): Utilizing plant recognition systems to support environmental awareness and conservation efforts [150].

SDG 16 (Peace, Justice, and Strong Institutions): Monitoring and countering negative psychological influences, which might promote peace and well-being [151].

4. Proceedings structure

4.1. Advancements in materials science and engineering for sustainable development

This proceedings section delves into the realm of materials science and engineering, unveiling a tapestry of innovative research endeavors aimed at fostering sustainable development. The featured studies collectively showcase the intricate relationship between material composition, quality, and their impact on various industrial processes and applications [152]. From investigating the role of lime content in iron ore sintering [153] to the sustainable performance of alkali-activated cement concrete with exceptional freeze-thaw resistance [154], the range of topics traverses the spectrum of material behavior and application.

The section delves into the realm of alternative materials, exploring sustainable modified pozzolanic supplementary cementitious materials harnessed from natural zeolite, fly ash, and silica fume [155]. Furthermore, it presents a meticulous balance between theoretical and practical aspects, with research on the stress-strain state of compressed concrete-filled steel tube elements [156] and the influence of deformation degree on grain sizes in metal alloys during cold rolling of sheets [157].

Innovation takes center stage with studies on robust methods for controlling casting processes and casting quality [158], as well as the technology behind forming wear-resistant thermite alloy layers through high-temperature synthesis [159]. The intersection of material science and medical applications is also explored, as evidenced by the design and research of biologically active polymeric hydrogel transdermal materials modified by humic acid [160].

Electromagnetic radiation protection finds a place in this collection, focusing on ceramic-inorganic polymer composites that harmonize mechanical properties with efficient electromagnetic shielding [161]. The section also touches upon the evolving energy landscape, offering insights into enhancing the discovery and storage of natural gas deposits [162], including improvements in drilling mud and terrestrial storage-shelter facilities [163].

In essence, this proceedings section encapsulates the pioneering strides made within materials science and engineering, underscoring their pivotal role in realizing sustainable development goals across a diverse range of sectors and applications. The studies presented here illuminate the path toward a more resilient and resource-efficient future.

4.2. Ecological dynamics and biodiversity assessment in changing environments

This section of the proceedings unveils a diverse array of studies centered around the intricate interplay between ecological dynamics and biodiversity assessment within evolving environments. The talks featured here encapsulate the multifaceted nature of environmental changes and their profound impact on various facets of ecosystems.

Exploring the ecomorphic aspect of soil macrofauna community transformation under recreational impact [164], the section kicks off by delving into the intricate relationships between human activities and the delicate balance of terrestrial ecosystems. Moving forward, biocenotic influence takes the spotlight as researchers investigate the role of the great cormorant in shaping the Azov-Black Sea region's biodiversity [165].

The section transcends traditional boundaries by addressing the accumulation of endocrine-disrupting compounds in aquatic organisms, offering insights into the potential ecological and hygienic implications of pollutant accumulation in Procambarus Virginalis tissue from the Dnipro River [166]. Biodiversity assessment within the Danube region emerges as a pivotal tool for the development of protected areas [167], showcasing the critical role of scientific research in conservation planning.

Evaluating the impact of environmental stressors, researchers explore seeds' similarity between cultural and natural flora in southern Ukraine under chloride load [168]. Furthermore, the section highlights the importance of information provision for monitoring sustainable development [169], emphasizing the synergy between ecological research and effective management strategies.

Intricacies of marine ecosystems come to the fore as a system of environmentally important decision-making is delineated for the sustainable use of marine estuaries in the face of anthropogenic and climatic changes [170]. Chromosomal studies in Pelophylax ridibundus across different populations unveil insights into the genetic makeup of amphibian populations in southern Ukraine [171].

Expanding the horizon, researchers probe the impact of mini-hydropower on water chemistry and phytoplankton in Ukrainian reservoirs [172], offering a glimpse into the intersection of renewable energy and ecosystem dynamics. The section culminates in an analytical examination of wind farm impact on bats, using activity indices and species diversity to decipher the intricate relationship between wind energy and bat populations [173].

Through temporal dynamics of steppe plant communities [174] and differential ecomorphic analysis of urban park vegetation [175], this proceedings section encapsulates the nuanced exploration of ecological shifts and biodiversity assessments in a dynamically changing world. The contributions within this section collectively illuminate the multidimensional nature of environmental challenges and the intricate pathways towards sustainable solutions.

4.3. Innovations in energy systems and sustainable technologies

This section of the proceedings brings together a diverse array of presentations that collectively epitomize the cutting-edge innovations and research breakthroughs in energy systems and sustainable technologies. The talks featured in this section traverse the intricate landscapes of energy generation, consumption, storage, and efficiency, shedding light on the profound advancements shaping the future of the energy sector.

The journey commences with explorations into the application of on-board energy storage in electric locomotives for quarry railway transport [176], unveiling novel strategies to enhance energy efficiency in industrial transportation. Shifting focus to economic potential, researchers delve into the realm of anaerobic fermentation and green ammonia production [177], envisioning a pathway to leverage sustainable energy sources for the European energy market.

Monitoring and diagnostic systems for hydro units, coupled with smart grid technology, occupy the spotlight as researchers navigate the complexities of maintaining optimal technical conditions [178]. Electricity consumption simulation using advanced modeling techniques illuminates the intricate patterns that govern energy demand [179].

Addressing environmental challenges, atmospheric dispersion modeling under high uncertainty conditions provides critical insights into managing potential hazards [180]. Short-term electricity imbalance forecasting utilizing artificial neural networks underscores the synergy between cutting-edge computational methods and energy grid stability [181].

The proceedings then delve into a SWOT analysis of electric transport [182], unveiling opportunities for vehicle-to-grid (V2G) integration and its potential impact on power system sustainability. The crucial intersection of education and sustainability takes center stage as researchers delve into the role of high-quality education in fostering resilience in the face of energy challenges [183].

In the context of renewable energy development, investigations into the capabilities of Ukrainian higher educational establishments to meet personnel demands underscore the importance of knowledge dissemination [184]. The section progresses with research focused on components for heat storage materials, embracing energy storage as a cornerstone of sustainable systems [185].

From computational challenges [186–193] to real-world implementation [194–197], this proceedings section encapsulates the evolving landscape of energy systems and sustainable technologies. The presentations within this section collectively illuminate the innovative spirit driving the transition toward cleaner, more efficient, and resilient energy solutions [198].

4.4. Advancements in mining and minerals engineering

This section of the proceedings provides an insightful journey through the domain of mining and minerals engineering, where an array of research endeavors converges to advance innovation, efficiency, and sustainability within the industry. The talks featured herein encompass a diverse spectrum of subjects, ranging from pioneering technologies for mining operations to strategies optimizing resource utilization and elevating worker safety.

- *Exploring mining operations.* The section commences with an exploration of advanced control strategies applied to multi-pump systems in underground mines. This research showcases the integration of fuzzy inference systems for controlling power consumption [199]. A subsequent dive into the dynamic interplay between solid particles and hydraulic classifiers enriches our comprehension of material flow behavior [200].
- *Innovations in mining technology.* Advancements in mining technology take center stage, introducing innovative approaches to equipment combinations within longwall mining. These adaptations exemplify the industry's resourceful response to geological challenges [201]. Concurrently, the utilization of vibratory jaw crushers with inclined crushing chambers symbolizes the pursuit of processing efficiency for brittle materials [202].
- *Balancing economics and sustainability.* The conference also delves into economic dimensions, investigating the intricate nexus between open pit productivity and wider economic indicators of mining development [203, 204]. Furthermore, a meticulous study of hydroerosion process parameters provides pivotal insights for sustainable mining practices [205].
- *Resource optimization and development.* Optimization emerges as a central theme, from determining drilling parameters to enhance resource extraction efficiency [206]. Meanwhile, the proceedings encompass sustainable development initiatives, such as cluster creation and risk management strategies that enhance worker safety [207].
- *Maximizing efficiency in mining processes.* In-depth insights into the operation of percussion downhole drilling machines reflect the industry's commitment to process optimization [208], yielding pathways to enhanced productivity. Investigating the component composition of processed forming mixtures underscores the need for resource reuse through mineralogical analysis and reuse recommendations [209].
- *Strategic approaches to sustainability.* Sustainability takes a prominent role through discussions on sustainable development approaches via mining cluster creation [210], highlighting collaborative clusters as drivers of regional growth while adhering to sustainability principles. A study centered on clusterization of dissipative structures enhances our understanding of complex systems' behavior [211].
- *Predictive models for safer mining.* Numerical simulation of surface subsidence during coal seam excavation advances predictive modeling [212], enhancing safety in underground

mining operations [213]. The symposium's focus also extends to the dynamic interplay between thin-walled reinforced concrete shells and foundation soil, emphasizing structural integrity and longevity [214].

- *Resource management and analysis.* The proceedings spotlight technological solutions for efficient resource management through investigations into automatic control devices for oil quantity and quality in reservoirs [215, 216]. Integrated research into stress-strain state anomalies offers insights into subsurface behavior, guiding strategies for safer and sustainable mining practices [217].
- *Understanding raw materials.* The multifaceted nature of resource extraction is explored through inquiries into the influence of natural mineral impurities and moisture on hazardous coal seam properties [218]. Understanding raw material characteristics emerges as a cornerstone for safe and sustainable mining practices.
- *Efficiency in ore extraction.* Enhancements in caved ore drawing techniques from ore deposit footwalls exemplify the industry's commitment to economic and environmental advancement [219], contributing to more efficient ore extraction.
- *Precision in mining operations.* Identification of resistance torque in drill rod rotation underscores precision and safety in mining operations, emphasizing the importance of machinery dynamics [220].
- *Strategic resource management.* Geometrization of Kryvbas iron ore deposits leverages technology and geological analysis to inform resource management [221], illuminating the spatial dimensions of mineral deposits.
- *Enhancing mineral processing.* Refining beneficiation techniques takes center stage through parameters evaluation in the process of solid-phase pulp sedimentation [222], contributing to resource efficiency and waste reduction in mineral processing.
- *Analytical advancements.* Recognition of mineralogical and technological varieties through ultrasound backscatter spectrograms signifies progress in analytical methods, aligning with the industry's pursuit of precise and sustainable resource characterization [223].
- *Predictive models for safer operations.* The section culminates with a spotlight on resource utilization, as researchers present innovative approaches for repurposing mining waste and acid mine drainage into valuable nanoparticles [224]. Additionally, the symposium delves into the influence of mineral content and moisture on coal seam behavior, unveiling the intricate facets that underlie hazardous properties [225].

In essence, this proceedings section underscores the pivotal role of engineering and scientific advancements in shaping the future of mining and minerals engineering. Collectively, the presentations reflect the industry's unwavering pursuit of technological progress and sustainable practices, resulting in a comprehensive exploration of mining's evolving landscape.

4.5. Innovations in architecture, urban planning, and sustainability

Within the bounds of this proceedings section, a tapestry of innovative concepts and solutions in architecture, urban planning, and sustainability unfurls. The diverse array of talks curated in this section showcases the dynamic evolution of design and planning practices, rooted in both tradition and cutting-edge technology.

The exploration begins with a study on the determination of bearing capacity in biaxially bended beams, an endeavor central to structural design [226]. Bridging the gap between the built environment and nature, a biotechnical approach to enhance indoor and outdoor air quality captures the essence of sustainability in architecture [227].

The integration of information systems takes center stage as a multi-stage analysis of object models on construction sites is presented [228]. This discourse transcends conventional boundaries, reflecting the synergistic blend of technology and construction practices.

Groundwater treatment using polystyrene foam filters exemplifies the innovative application of materials in environmental engineering [229]. This approach showcases the ingenious ways in which modern materials can contribute to ecological solutions.

History and culture intertwine as traditional settlements are explored for lessons in preservation. Comparative studies of Shirakawa village in Japan and Kryvorivnia village in Ukraine delve into strategies for preserving heritage while maintaining functionality [230].

In post-conflict landscapes [231], the principles of urban restoration are examined, offering insights into the intricate balance of reconstructing urban spaces that are both functional and reflective of the community's needs [232].

The section concludes with an insightful overview of transformational processes in sustainable urban development, specifically in the context of Ukraine [233]. Perspectives on cultural tourism's development in the Carpathian region lend depth to the discourse [234], reflecting the intersection of cultural heritage and economic growth.

As a blend of innovative thinking, traditional wisdom, and contemporary technological advancements, this section encapsulates the essence of architecture, urban planning, and sustainability. The talks therein serve as a testament to the multifaceted nature of these disciplines and their profound impact on shaping the present and future of our built environment.

4.6. Advances in hydrology, water management, and environmental engineering

This section of the proceedings unearths a diverse range of talks, each a vital piece in the mosaic of hydrology, water management, and environmental engineering [235]. The common thread woven through these discussions is a shared commitment to preserving, managing, and optimizing one of our planet's most precious resources – water.

The journey commences with the exploration of the hydrological regime of the Uzh River under the complex interplay of backwater conditions [236]. In striving to mitigate risks in urban environments, this study probes the intricate dynamics of river systems and their interaction with urban landscapes.

Advancements in technology are showcased in the realm of water regulation and drainage. The evolution of modular systems within the humid zone's landscapes underscores the innovative potential to manage and control water flow in dynamic environments [237].

The quantitative assessment of water quality in the "Vidsichne" reservoir serves as a cornerstone of environmental stewardship. By delving into the intricate chemistry and biology of water bodies, this research [238] lays the foundation for informed decision-making in water resource management.

In the context of the digital age, a forward-looking perspective emerges. The role of Ukraine in the global trends of sustainable development is critically analyzed within the framework of the digital economy [239], reflecting the intricate interplay between technology and sustainability.

The biological treatment of wastewater is dissected as the phenomenon of bulking in activated sludge systems is scrutinized. Through this lens, the symbiotic relationship between microbiology and environmental engineering comes to light [240], with implications for sustainable wastewater treatment.

The section delves into the hydrogeological and ameliorative state of the Kilchen irrigation system territory, a testament to the multidisciplinary nature of environmental engineering. This study [241] echoes the broader imperative of harmonizing human activities with the natural environment.

From biomass to gases, sustainable processing takes center stage as the extraction of pollutants from flue gases through mechanical activation is investigated [242]. This speaks to the confluence of chemical engineering, environmental science, and sustainability goals.

Rounding out the section is a methodological exploration, a blueprint for determining the availability of natural moistening for land reclamation needs. This research [243] underscores the intricate nexus of climate, hydrology, and land management.

In essence, this section reflects the interdisciplinary nature of hydrology, water management, and environmental engineering. It underscores the relentless pursuit of sustainable solutions in an ever-changing world, where the preservation of water resources and the environment stand as pivotal endeavors.

4.7. Ecology, renewable energy, and resource management

Within the tapestry of these proceedings lies a section dedicated to exploring the delicate balance between ecology, renewable energy, and resource management. The talks within this segment delve into the intricate dance between humanity and its environment, seeking sustainable harmony.

The Southern Bug River mouth ecosystem is unveiled in all its complexity, offering a snapshot of its current state [244]. Through meticulous study, the intricate web of interactions that sustains this ecosystem comes into focus, revealing insights into the challenges and opportunities for conservation and restoration.

Shifting gears, the energy dynamics of solar panels and inverters intertwine with the broader electric network. This study [245] scrutinizes the marriage of renewable energy and grid infrastructure, offering glimpses into the optimization and challenges of harnessing sunlight to power our lives.

In the world of fisheries, probiotic microorganisms find a place in the production technology of European grayling fish stock [246]. The intersection of biology and aquaculture is explored, illustrating how microorganisms can contribute to the well-being of aquatic ecosystems and sustainable fish farming.

Heap leaching emerges as a technique for extracting gold from oxidized ore, with the Belsu deposit as its backdrop [247]. This method, rooted in chemical engineering, showcases how modern technologies can unlock the value of mineral resources while minimizing environmental impact.

A focus on spatial development drives a quest to enhance indicators that illuminate the transformation of territories. Through thoughtful analysis, this research [248] offers insights into urban planning, land use, and the intricate relationships that shape the built environment.

In the heart of the Ukrainian Carpathians, the potential of biomass from forest residues takes center stage [249]. This exploration of regional green economy emphasizes the symbiotic relationship between sustainable forestry practices, economic growth, and environmental stewardship.

The section also delves into cadastral and landscape modeling of lakes, casting light on the role of proper resource management in sustaining natural beauty and recreational opportunities [250]. This approach demonstrates the synergy between ecological conservation and human enjoyment.

Lastly, the interplay between social and environmental features becomes apparent through an examination of minerals resources classification systems [251]. Intrinsic connections are forged between societal needs, resource extraction, and environmental protection, reflecting the complexity of resource management.

This section encapsulates the intricate tapestry of humanity's relationship with its surroundings. It shines a light on the sustainable pathways forward, where ecology, renewable energy, and resource management converge to shape a harmonious future.

4.8. Environmental science and sustainability

The section consists of 21 talks that address various environmental issues and solutions in the context of war and energy. The talks are grouped into four sub-sections: radiation pollution, energy production, environmental risk assessment, and ecological diversity.

The first sub-section focuses on radiation pollution caused by war and nuclear power plants. The talks in this sub-section present mathematical tools for restoring the surface distribution of radiation pollution based on remote measurement data [252, 253], a conceptual scheme for creating environmentally friendly Gd-containing neutron-absorbing nanocomposites [254], a factor-criterion model for selecting the optimal option for transforming the "Shelter" object into an environmentally safe system [255], and the formation of the carbonate system of circulating cooling water of the Rivne NPP and its influence on the surface waters pH levels of the Styr River [256]. These talks provide novel approaches and techniques for reducing the radiation exposure and contamination of humans and the environment.

The second sub-section focuses on energy production from various sources, such as nuclear, biogas, and nanocomposites. The talks in this sub-section present a neural network model of investment process of biogas production [257], perspectives of nuclear energy development in Ukraine on the global trends basis [258], and development of recommendations for improving the radiation monitoring system of Ukraine. These talks explore the feasibility, benefits, and challenges of different energy options for meeting the growing energy demand and reducing greenhouse gas emissions.

The third sub-section focuses on environmental risk assessment of water bodies [259, 260], soil [261], air [262], and natural ecosystems in the conditions of mineral deposits development, warfare [263], transportation of dangerous substances [264], and fuel and energy complex [265]. The talks in this sub-section present methods and tools for assessing environmental risk using mathematical models, innovative technologies [266], scientific and methodological approaches, decision-making support tools, environmental biomonitoring, satellite imagery [267], etc. These talks aim to identify, quantify, and manage the environmental hazards and impacts of various human activities.

The fourth sub-section focuses on ecological diversity of different organisms in response to environmental stressors, such as electromagnetic pollution, pesticides, urbanization, etc. The talks in this sub-section present studies on the impact of electromagnetic pollution on the phytocenotic diversity of the transcordon region [268], the coherence of the formation of containing and ore containing Precambrian formations Orikhovo-Pavlograd suture zone of the Ukrainian shield [269], ecological adaptations among spruce species along an environmental gradient in urban areas [270], impact of pesticides on the respiration of Planorbarius (superspecies) corneus s. l. allospecies from the Ukrainian river network [271], environmental safety of soil genetic horizons in the impact zone of Lviv city landfill [272], etc. These talks reveal the effects of environmental stressors on the structure, function, and evolution of different biological systems.

The section offers a comprehensive overview of the current state-of-the-art research on environmental challenges and solutions in the context of war and energy. The section also highlights the gaps and directions for future research in this field. The section is relevant and timely for researchers, practitioners, policy makers, and general public who are interested in or concerned about the environmental issues facing Ukraine and other regions.

4.9. Economic and business sustainability

Encompassing a diverse array of talks, this section delves into the intricate interplay between economic practices, business strategies, and sustainable development [273], illuminating pathways toward a sustainable future.

The transformation of Ukraine's national financial system emerges as a pivotal discussion.

Through the lens of sustainability, this exploration [274] unravel novel strategies for integration, aligning economic structures with the principles of environmental and social equilibrium.

The concept of social responsibility takes center stage as its integration within business practices is examined. This inquiry [275] underscores the evolving role of corporations in driving sustainable development, reflecting a growing recognition of the interdependence between business success and societal well-being.

The section delves into the realm of forestry enterprises, dissecting their potential management for sustainable outcomes. By scrutinizing the efficiency of forestry practices, this study [276] offer insights into the conservation of vital natural resources.

The grain industry's investment and operational costs are harmonized through the lens of sustainable development theory. This paper [277] illuminate the complex dance between economic profitability and environmental stewardship within the agricultural domain.

A model-driven exploration into socio-economic systems' sustainable development processes enriches the section. By employing analytical tools, this study [278] unravel the intricate dynamics underpinning societal progress and resilience.

The creation of a favorable environment for organic production emerges as a critical precursor to agricultural sustainability. The study [279] within this section underline how policy instruments can shape agricultural practices to align with ecological and social well-being.

The multi-dimensional nature of Ukraine's sustainable development is meticulously dissected through a structural econometric lens. This study [280] paint a comprehensive picture of the nation's progress, considering its social, economic, and environmental facets.

Addressing the evolving landscape of investment, the assessment of ESG (Environmental, Social, and Governance) competitiveness takes center stage. The study [281] illuminate how enterprises can navigate the shifting expectations of new-generation investors, aligning financial success with sustainable principles.

The post-COVID-19 economic recovery process comes under scrutiny through the lens of Sustainable Development Goals (SDGs). This reseatch [282] navigate the dual challenge of economic rejuvenation while upholding the principles of sustainability.

The section concludes with a focus on the Black Sea Region's role in the global grain trade and the challenges that underpin its development [283]. The economic implications of regional trade dynamics offer insights into the complex balance between trade, sustainability, and economic growth.

As a collective, this section unveils a mosaic of economic and business strategies, each thread intricately woven into the fabric of sustainable development. These studies underscore that economic prosperity can indeed coexist harmoniously with environmental and social well-being.

4.10. Geospatial and technological applications for sustainability

This section delves into the realm of geospatial technology and innovative applications that hold the key to sustainable development in diverse domains. These talks navigate the convergence of technology and sustainability, offering insights into the transformative potential of cutting-edge solutions.

The development of a predictive and search system for amber stands as a testament to the fusion of technology with resource management. By harnessing advanced algorithms, this study [284] seek to optimize the exploration of precious resources while aligning with sustainable practices.

Exploring land use policy implementation at the local level, this section demystifies the conceptual and terminological intricacies. By elucidating the policy landscape, this study [285] contribute to the formulation of strategies that foster sustainable land management practices.

Mining tourism emerges as a catalyst for sustainable development, especially in industrial regions like Kryvyi Rih. This study [286] showcase how the fusion of heritage, industry, and responsible tourism can pave the way for socio-economic progress while preserving local identities.

The integration of remote sensing in assessing military destruction and its aftermath in Ukraine opens new frontiers for data-driven analysis. The study [287] employ technology to unravel the consequences of conflict, spotlighting the interplay between security, resilience, and recovery.

Switching gears, the section delves into the characteristics of BlaBlaCar, a ridesharing giant that exemplifies a sustainable transport solution. This study [288] unravel the potential of the sharing economy to reshape urban mobility and mitigate environmental impacts.

Addressing the rational use of mineral resources and mining waste, this section highlights the symbiotic relationship between industry and environmental sustainability. The study [289] delve into innovative practices that minimize waste while optimizing resource utilization.

Technological innovation takes center stage with investigations into an energy-efficient screw oil press. By reimagining traditional processes, the study [290] underscore how technology can drive efficiency gains with far-reaching ecological implications.

The integration of GIS technologies for geodetic monitoring resonates with this section's overarching theme [291]. This study [292] unveil how geospatial tools offer real-time insights, shaping effective decision-making processes across diverse domains.

Geographical foundations of the sustainable development concept are examined from a paradigmatic level. This study [293] contextualize sustainable development within the fabric of geographic principles, unearthing the interconnectedness of space, environment, and human progress.

Optimized fuel values are scrutinized as a strategy for emission reduction. This study [294] explore the potential of fuel optimization to mitigate environmental impacts, showcasing how technology can revolutionize conventional energy practices.

Engineering analysis of transverse loading dynamics in rail transportation underlines the integration of technology into logistical processes. These studies [295, 296] uncover insights into load-bearing dynamics, with implications for efficient and sustainable transportation.

Energy potential within high-altitude mining transport systems receives attention in this section. These explorations [297] unveil the latent energy resources within mining operations, offering novel strategies for sustainability in challenging environments.

The section culminates in a deep dive into pathophysiological mechanisms, unraveling how technology intersects with health science. These inquiries probe the physiological adaptation of gastric cardia mucosa underlining how scientific understanding can inform sustainable healthcare practices [298].

5. Conclusion

The vision driving ICSF 2023 is to establish a paramount interdisciplinary platform, uniting researchers, practitioners, and educators, to showcase and deliberate upon the latest innovations, emerging trends, concerns, practical challenges, and adopted solutions in the realm of sustainability.

We extend our sincere gratitude to the authors who submitted their papers and to the delegates for their enthusiastic participation and interest in ICSF as a conduit for sharing ideas and innovation. Our heartfelt appreciation also extends to the program committee members, whose unwavering guidance, dedication, and the invaluable contributions of peer reviewers have elevated the quality of the papers. The constructive critiques, improvements, and corrections they provided have significantly enriched the success of this conference. We also recognize the pivotal role of Morressier's developers, whose robust conference management system facilitated every stage of the process, from soliciting papers to coordinating peer reviews and crafting the conference proceedings volume.

A special acknowledgment goes to the session chairs, whose steadfast commitment to shaping the conference and its program has been exceptional. Their role has greatly contributed to the cohesive and productive flow of the conference sessions.

Furthermore, we express our gratitude to IOP Publishing for their generosity in waiving the APC payments for corresponding authors based in Ukraine. This initiative enables authors to publish open access without charge in the prestigious *IOP Conference Series: Earth and Environmental Science* journal (https://iopscience.iop.org/journal/1755-1315). Additionally, the submission extensions offered by IOP Publishing are a testament to their understanding of researchers' challenges and constraints, underscoring their dedication to fostering a supportive academic environment.

As we move forward, we anticipate exceptional presentations and insightful discussions that will expand our professional horizons. We hope that all participants find immense value in this conference and eagerly anticipate the prospect of reconnecting in a more convivial, light-hearted, and harmonious setting at ICSF 2024. The next installment in the series, the 5th International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters, is set to take place in May 2024 in Kryvyi Rih, Ukraine (https://icsf.ccjournals.eu/2024/).

Thank you all for being an integral part of ICSF 2023, and here's to a brighter, more sustainable future that we collectively strive to build.

Investigation of the influence of lime content in the charge and its quality on the sintering process of iron ore raw materials

S G Saveliev and M M Kondratenko

Kryvyi Rih National University, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

E-mail: saveliev_sg@knu.edu.ua

Abstract. Main objectives of the work was to study the influence of degree of roasting of lime contained in the charge on the sintering process and sinter quality, as well as comparing the impact of changes in the mass fraction of active CaO in the charge by varying degrees of burning lime, and by varying the content of lime in the charge. It is shown that the intensifying effect of lime on the sintering process occurs as a result of a decrease in the content of small classes in the charge. When the lime content in the charge is equal to 3 %, an increase in the degree of lime firing from 5 to 96 % led to an increase in the specific productivity of the plant from 0.96 to 1.87 $t/(m^2 \cdot hour)$. The independence of sintering parameters from the content of active CaO in lime with its constant content in the sinter charge and the decisive role of the content of active CaO in the sinter charge with its constant content in lime are confirmed. A new approach to the production of lime for agglomeration processes is proposed: it should have the lowest cost of the active CaO contained in it.

1. Introduction

One of the conditions of the sustainable future is the quality improvement and the increase in production of ferrous metals, the vast majority of which are molten by two-stage scheme "cast iron – steel". Therewith in the worldwide iron making industry, sinter constitutes the major component in the metallic burden of most of the blast furnaces as it has numerous properties which lead to reduced coke rate, increased productivity, better heat transfer and permeability, elimination of raw flux, narrowing of softening and melting zones and better quality of hot metal. The sintering process is greatly influenced by the physico-chemical properties of raw materials used, whose characteristics change from time to time [1].

Lime is an important component of sintering charge. It provides the intensification of sintering and improves the quality of sinter. Therefore, the issue of the efficiency increasing of lime usage in the sintering production demands constant attention from workers and researchers. Thus, in Bhilai Steel Plant, Steel Authority of India Limited, a pilot sintering unit has been established in order to conduct experiments for subsequent application in industrial sinter manufacturing. Studies were taken up to assess the effect of quicklime addition in sinter-mix on sintering process of iron ore fines [1]. The results found have been encouraging with significant increase in productivity.

Efficiency of lime's utilization in iron ore materials' sintering depends on number of factors, the most important of which are the composition of sinter charge, the quality and quantity of used lime. A direct relationship is usually observed between the productivity of sintering machines and the consumption of lime, however, at high consumption of lime, a decrease in the strength of the agglomerate and an increase in the amount of fines in it are noted. In fact, to ensure high productivity of sintering machines and sinter quality, the optimal lime consumption should be determined individually, depending on the component composition of the sinter charge, the properties of charge materials and the features of the processing line for preparing the charge, starting from the averaging warehouse.

The decisive factor that determines the optimal consumption of lime introduced into the sinter batch is the mass fraction of the assimilated charge of lime, that is, slaked and passed the stage of dispersion. The influence of this factor is primarily associated with the technology of moistening the charge and with the design and technological parameters of the used mixing equipment [2].

At the same time, the mass fraction of the lime assimilated by the charge depends on the content of active components in the lime – calcium and magnesium oxides, that is, on the quality of the lime. The required quality of metallurgical sinter is provided by the valid choice of the raw material with optimal chemical and granulometric composition and specific selection of tackle [3]. When choosing a kiln and assigning thermal modes, it is necessary to be guided by the results of control calcinations of lime and analyzes of the batching capacity of lime.

The core indicator of a lime's quality is the content of active CaO, which determines the degree of lime burning. It is acknowledged [4], that lime, which is used in sintering for the intensification of sintering thin iron ore concentrates, must contain not less than 80 % of $CaO + MgO$, and the size of seeds must be $3-0$ mm.

With the aim of achieving required lime size in the conditions of sintering production OJSC "Ural Steel" it has been suggested [5] to upgrade the lime preparation section via closed cycle actualization of lime grinding with an installation of a hammer mill and screening machine (to separate lime into fractions –3 and +3 mm).

The CaO content in lime is sometimes [6] called a purity degree of lime, which was received after the limestone burning. This marker depends not only on the degree of dissociation of Calcium Carbonate but also on the degree of purification of initial limestone.

2. Literature review

The laboratory sinter burnings in Raw Materials Research Center OJSC "Severstal" with the use of lime showed [7] that the dependence of charge pelletization degree on the content of lime in it is extreme. The dependence of the charge sintering rate on the lime content in it also has an extreme nature. The greatest rate of sinter charge which is equal to 16.65 mm/min is obtained by the lime consumption of 28 kg/ton.

In the laboratory and manufacturing conditions the optimal consumption of lime into PJSC "Novolipetsk Metallurgical Plant" (NLMP) sinter charge was determined with consideration of the process of lime hydration and the difference between the amount of water and supreme molecular moisture capacity [2]. It was determined that the exceedance of optimal liming level deteriorates a sinter quality.

The research of the lime mass fraction in JSC "ArcelorMittal Temirtau" sinter charge impact on the process of its pelletization research showed [8] that increasing lime content in charge from 1 to 5 % a percentage of thin fraction in charge 1.6–0 mm which influences negatively on the sintering speed decreases from 18 to 5 %.

Theoretical and technological incentives to use lime in the sinter charge were examined in detail in monographies [9, 10]. The presented results of the impact of lime's quantity in charge correspond to the above-mentioned data.

A significant lime's qualitative characteristic is its reactivity, in other words – rate of hydration that depends on the lime's method of firing and the content of the environment's gaseous state composition. The work [11] demonstrates that industrial furnace calcining largelimestone pellets leads to low reactivity quicklimes both because the calcination temperatureis too high and the CO_2 pressure is too elevated.

To improve a firing thermal behavior on a conveyor it has been suggested [12,13] to use definite proportions of classified lime fractions and solid fuel. In the conditions of PJSC "Metallurgical Plant "Zaporizhstal" the use of improved technology will improve the technical and economic performance of the limestone burning process.

To evaluate the hydration characteristics of the lime, the Constant-temperature Calorimetric Method (CCM) has been used to test four types of lime from the sintering plant, and the granulation and sintering pot test was conducted to validate the results of CCM [14]. It showed that the CCM can precisely test the hydration heat and hydration speed of the lime and avoid the shortage of the tradition ways, and the hydration speed of lime is positively related to granulating effect and sintering productivity. The hydration properties of the four types of lime were remarkably different, the whole hydration heat is positively related with the CaO content of the lime, but the hydration speed is more influenced by the impurities and the microstructure of the lime. In this case, the increasing of the SiO_2 and MgO content can reduce the hydration speed of the lime, and the Al_2O_3 has two way effects. The lime with fine crystal grain size has a large hydration speed.

As can be seen from the above the analysis demonstrates that the lime's impact on a sintering process depends on the charge conditions and the quality of lime, but the reciprocal proportion's impact of this factors have not been examined yet.

3. Problem formulation

Based on the above, in this work were set following tasks:

- to study the impact of the lime burning degree on a sintering process and sinter quality;
- to compare the impact of CaO in charge based on the lime burning degree change and lime content change in charge.

4. Methods

The impact of the lime burning degree on a sintering process and a sinter quality from ArcelorMittal Kryvyi Rih sinterplant's charge was examined in laboratory settings.

The chemical composition of charge components is listed in table 1.

Table 1. The composition of charge materials.

Material	Chemical composition, %								
	Fe_{total}	FeO	SiO_2	CaO	CaO_{act}	MgO	MnO	C	Loss on ignition
Concentrate	65.1	23.5	7.7	0.4	—	0.49	0.20	—	0.94
Agloore	53.3	0.8	11.35	0.46	—	0.37	0.12	—	3.35
Limestone	1.45	0.45	1.7	51.13	—	2.82	No data	—	43.17
Lime I	No data	No data	1.96	59.0	23.6	3.26	No data	—	27.8
Lime II	No data	No data	2.05	61.8	30.9	3.41	No data	—	24.8
Lime III	No data	No data	2.34	70.04	52.8	3.88	No data	—	13.8
Fuel	2.6	0.04	6.89	0.79	—	0.26	0.10	81.36	No data
Manganese ore	4.4	0.15	19.65	6.64	—	1.81	15.9	—	18.69
Return	50.4	9.6	10.5	8.4	—	1.0	1.33	1.64	No data

The quicklime with the grain-size 3-0 mm, which was obtained from limestone burning in an experimental-industrial cyclone furnace was used. The different lime burning degree was obtained by the mode change of furnace.

Mixing and pelletization of charge with the simultaneous moistening up to 7.8 – 8.2 % were proceeded in a drum 0.6×1.0 m in size during 8 min. Pelletized charge was burned in a sintering bowl with an area of 0.132 m^2, in a form of layer of 280 mm in height.

The rarefaction under the grate of the sintering bowl in a sintering process was maintained permanent and equal to 11.28 kPa (∼ 1150 mm water column). The preparation conditions of the sinter charge and the mode of its sintering during the research were the same. Each experiment, which included assembling, preparing and sintering the sinter charge, was repeated 3-5 times.

In order to compare the impact of the active CaO content in lime, at a constant flow rate in the charge, sintering was performed with the same types of lime, setting them in the charge in the same amount – 3 % of the charge‘s weight. In this set of sintering, the content of active CaO in sinter charges was 0.71; 0.93 and 1.58 %, respectively.

To test the assumption of the determining impact on the sinter process of the amount of active CaO which is being added by lime into the charge, regardless of the lime burning degree, sintering was performed at a constant content of active CaO in the sinter charge, which was equal to 1.26 %. Herewith was used a lime with a degree of firing of 40, 50, 75 and 96 %, the content of which in the sinter charge in each case was 5.3; 4.1; 2.4 and 1.6 %, respectively.

5. Analysis

The main results of sintering with lime content in the sinter charge of 3 % at different burning degrees are shown in figures 1 - 5.

The intensifying effect of lime on the sintering process is associated, first of all, with a decrease in the gas-dynamic resistance of the pelletized charge layer due to a decrease in the content of small classes (figure 1) and an increase in the strength of individual pellets.

This is due to the viscous properties of lime, hydration hardening of which is carried out according to the scheme of dissolution – colloidization – crystallization. When the content of lime in the sinter charge of 3 % increase in the degree of firing of lime from 5 to 96 %

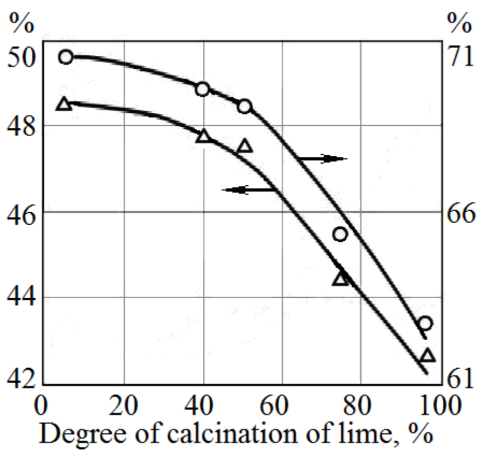

Figure 1. The influence of the lime burning degree on the indicators of palletization: content of class –3 mm (△) and –5 mm (○) in the pelletized charge, %.

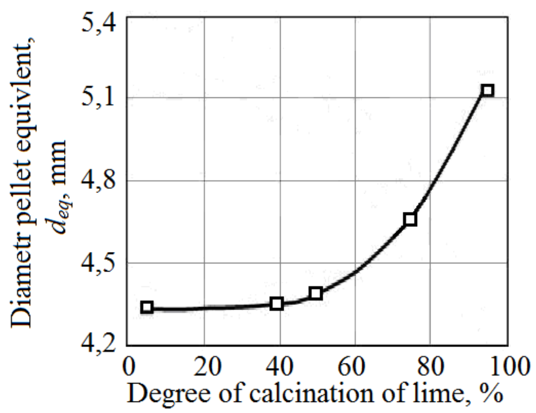

Figure 2. The influence of the lime burning degree on the equivalent diameter of pelletized pellets.

(corresponding to an increase in the content of CaO active in the charge from 0.08 to 2.30 %) led to a decrease in the content of classes 5 - 0 and 3 - 0 mm in the lump charge from 70.7 to 62.7 % and from 48.5 to 42.8 %, respectively. The equivalent diameter of the granules of the pelletized charge, calculated as a weighted average by weight, increased from 4.38 to 5.14 mm (figure 2).

A similar result of the effect of the lime content in the charge on the sintering performance was obtained in [15], in which the positive effect of adding up to 2 % quicklime to the sinter charge on its gas permeability was experimentally established. A further increase in the lime content in the charge no longer improves its pelletizing. The lower value of the maximum allowable lime content in the charge in [15] compared to the conditions in this study is explained by differences in the composition of the ore part of the sinter charge.

The decrease of the sinter charge gas-dynamic resistance leads to an increase in the specific air flow rate on sintering, as a result of what the vertical sintering rate and the specific productivity of the sinter plant continuously increase (figure 3).

The sintering rate during the experiments changed more than twice, and the specific productivity – from 0.96 to 1.87 t/(m^2·hour). That is, for each percent of the lime burning degree increase, the specific productivity of the installation increased by an average of almost 0.96 %. A slightly smaller change in the specific productivity compared to the sintering rate is associated with the influence of variable when using lime of different bulk weight burning degrees of the pelletized charge and the yield of a suitable sinter after sintering.

The yield of the +5 mm class after double dumping of the sinter pie from a height of 2 m while increasing the lime burning degree tends to decrease (figure 4).

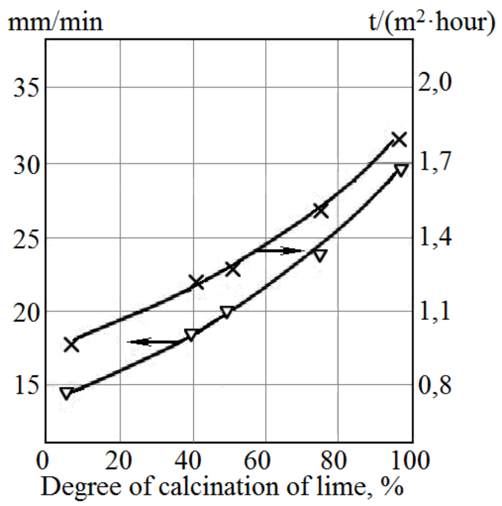

Figure 3. The influence of the lime burning degree on the indicators of sintering: vertical sintering speed (▽), mm/min; specific productivity (×), t/(m^2·hour).

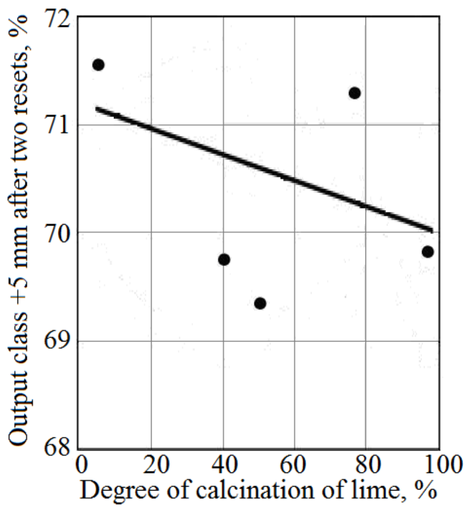

Figure 4. The influence of the lime burning degree on the indicators of the strength of the sinter after two resets.

The dependence of test results of sinter in the drum on the lime burning degree is extreme (figure 5), which is obviously caused by a change with the increase in the degree of calcination of lime, the ratio between the development of processes that have the opposite effect on the strength of the sinter.

Comparison of the results obtained with similar studies of obtaining agglomerate with basicity (CaO/SiO_2) equal to 1.7 under the conditions of PJSC NLMK [2] confirms the extreme nature

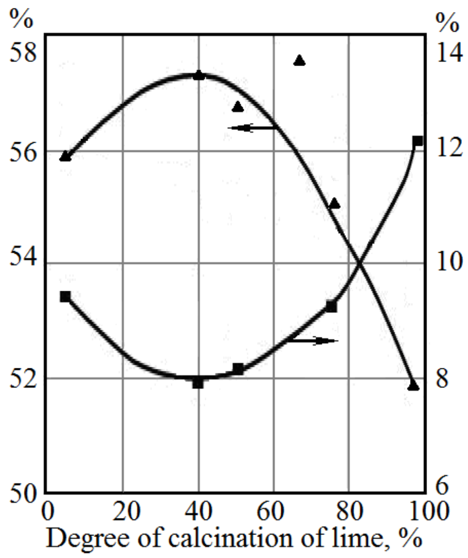

Figure 5. The influence of the lime burning degree on the indicators of the strength of the sinter after the drum test: output class +5.0 mm (▲) and −0.5 mm (■) after the drum, %.

of the dependence of the cold strength of the agglomerate on the mass fraction in the charge of active components of lime (or the content of lime in the charge). The highest strength is obtained when lime is introduced into the charge in an amount of 25 - 30 kg/t of sinter.

Factors that increase the strength of the sinter with increasing the lime burning degree – improving the conditions of mineral formation in the heating zone and improving the conditions of melt formation, reducing the melt viscosity, increasing the sintering temperature due to reduced heat consumption for decomposition of calcium compounds (FeO content in the agglomerate with increasing the lime burning degree increased from 10.0 to 13.1 %) – prevail at the lime burning degree up to about 40 %. The sinter obtained with the use of lime with a burning degree of 35 – 45 % has the best indicators of strength, both on impact and on abrasion. A further increase in the lime burning degree causes a decrease in the sinter test performance in the drum due to the predominant effect on the cooling rate of the sinter, which increases simultaneously with the vertical sintering rate, that is accompanied by an increase in vitreous phases and internal stresses in the sinter structure. Thus, increasing the lime burning degree from 40 to 96 % led to a decrease in the resistance of the sinter to impact from 57.6 to 51.9 % and abrasion from 7.9 to 12.2 %.

It should be borne in mind that another reason for the decrease in the strength of the agglomerate when a certain level of lime consumption in the charge is exceeded may be an insufficient degree of assimilation of the active components by the lime charge. This is due to the emergence of a water deficit in the charge not only for hydration of lime at the stage of preparing the charge for pelletizing, but also for pelletizing the charge [2].

The main results of the experiments confirm the independence of sintering indicators from the content of active CaO in lime at a constant content in the sinter charge (figure 6, figure 7) and the decisive impact of the active CaO content in the sinter at a constant content in lime (figure 7, figure 8).

At the same time, with an increase in the active CaO concentration in the sinter charge in the range of 0.71 - 1.58 %, the sintering rate and specific productivity continuously increase (figure 8), as well as the drum testindicators decrease (figure 9).

This is due to the complex nature of the impact of active CaO in the sinter charge on the strength of the sinter. With the increase of active CaO in the sinter charge simultaneously with the development of processes that increase strength, the development get the processes that reduce it; in particular, the number of vitreous phases and the level of internal stresses in the

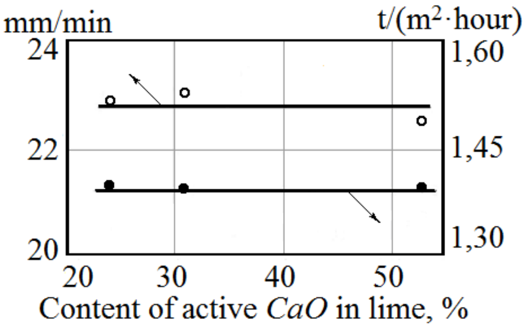

Figure 6. The impact of the active CaO content in lime on the sintering process at a constant content of active CaO in the sinter charge (1.26 %): sintering speed, mm/min (○); specific productivity, t/(m^2·hour) (●).

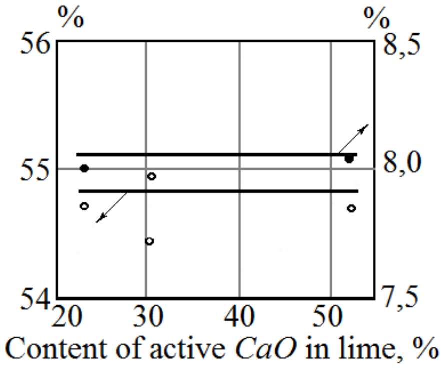

Figure 7. The impact of the active CaO content in lime on the indicators of the strength of the sinter after the drum test at a constant content of active CaO in the sinter charge (1.26 %): output of class +5.0 mm after the drum, % (○); output of class −0.5 mm after the drum, % (●).

structure of the sinter increases as a result of increasing the cooling rate. Obviously, in the studied interval of increasing the active CaO content in the sinter charge at a given composition of the charge, the mode of its preparation and sintering, the processes that reduce the strength of the sinter predominate.

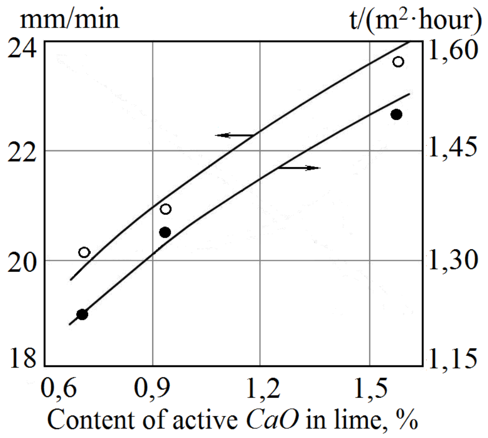

Figure 8. The influence of the content of active CaO in the sinter charge on the sintering process at a constant content of lime in the charge (3.0 %): sintering speed, mm/min (○); specific productivity, t/(m^2·hour) (●).

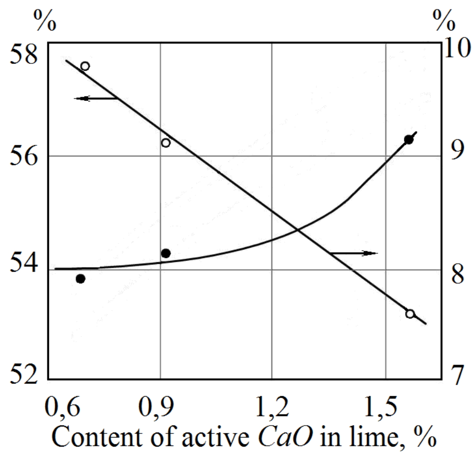

Figure 9. The influence of the content of active CaO in the sinter charge on the strength of the sinter after the drum test at a constant content of lime in the charge (3.0 %); output of class +5.0 mm after the drum, % (○); output of class −0.5 mm after the drum, % (●).

6. Discussion

In the article of Chinese researchers [16], the results of the study are presented, which complement the above-described mechanism of the intensifying effect of quicklime on the sintering process from the position of changing the structure of the sinter. The effect of quick lime on pore characteristics of the high-temperature zone in the iron ore sinter was studied. The equivalent spherical diameter of the pore and its distribution frequency, volume fraction, sphericity, and surface porosity were statistically analyzed. The results indicate that the addition of quick lime increases the permeability of the green bed and shortens the sintering time. With the increase of the addition of quick lime, the porosity of the sinter decreases gradually. 1With the increase of quick lime, the total pore volume and total pore length, the number of pore segments, branching nodes and terminal nodes all decrease.

Comparison of the obtained results with the literature data about the impact of lime content in the sinter charge with a constant burning degree on the sintering process [6, 7] indicates a similar nature of changes occurring in these cases, that is, when the content of active CaO in the charge is changes.

At the same time, from the standpoint of lime on the sintering process the burning degree change can be replaced by a corresponding change in its content in the charge and vice versa.

Since common in both cases is the change in the amount of active CaO by lime which is being added into the sinter charge, this particular indicator (or the amount of $Ca(OH)_2$ in the case of slaked lime) determines the effectiveness of lime under the other equal conditions. It can be noted that with the increasing lime content in the sinter charge, the lime burning degree, which corresponds to the maximum strength of the sinter, will decrease, and with the decreasing lime content – will increase.

7. Conclusions

Studies have shown the high efficiency of using lime as an intensifier of the sintering process. An increase in the amount of active CaO added by lime to the charge from 0.71 to 1.58 % leads to an increase in the specific productivity of the sinter plant from 0.96 to 1.87 t/(m^2·hour). The mechanism of the lime intensifying effect is associated with its positive impact on the process of charge pelletisation (reduction of the proportion of small fractions of 5-0 and 3-0 mm in the pelletised charge), which is accompanied by a decrease in the gas-dynamic resistance of the charge and a corresponding increase in the vertical sintering rate and specific productivity of the sinter plant.

On the basis of the conducted researches it is possible to draw a conclusion that the efficiency of the limestone replacement by lime at sintering is defined by the quantity of active CaO brought by lime in a sinter charge, and in this sense practically does not depend on the lime burning degree or its concentration in charge (with a constant mesh-size distribution of lime, permanent degree of quenching in the process of preparing charge to the sintering, constant lime distribution degree in charge and other equal conditions associated with the use of lime).

A similar pattern occurs when using lime as a binder in the production of pellets. This implies a new approach to the production of lime for pelletizing processes, which should be based on the technical and economic indicators of the unit for the production of lime. It is necessary to produce such lime, which has the lowest cost of active CaO contained in it. This means that it does not make sense to produce lime for pelletizing processes with a high burning degree, because the closer to the maximum possible burning degree, the more heat a single particle of calcium carbonate needs for decomposition. The rational degree of burning is usually 60-70 %.

Given the increase in the relative heat consumption for the decarbonization of $CaCO_3$ with increasing degree of its firing, it should be considered impractical to produce for the process of agglomeration of iron ore materials lime with the highest degree of firing. The optimum degree of lime firing should be about 60–70 %. The validity of this conclusion is confirmed in particular by the fact that in the pelletizing workshop of the Northern Mining and Processing Plant (NorthMPP) laboratory and industrial tests of pellet production using lime as a binder used quicklime, which contained 63 – 67 % $(CaO + MgO)_{act}$ [17].

Abstract. Sodium silicate is used in various industries. Sodium silicate is a basic component in the production of silicate adhesives and paints, silica gel, welding electrodes, corrugated packaging, and geopolymer concretes and cements. All this is currently not produced in the Republic of Kazakhstan. The article discusses the methods of production of sodium silicate and substantiates the possibility of organizing production in the Republic of Kazakhstan. The authors have studied all the available experience in the production of sodium silicate, both now and in the past. At this stage of the research, an analysis was made of the experience in the production of serial and pilot sodium silicate in the USSR in the past and in countries where development has not been suspended at the present time. All possible sources of raw materials of technogenic and natural origin were studied. Business trips and expeditions to natural deposits were carried out and samples of raw materials from various natural and man-made sources were delivered. Studies have been carried out to determine the available volumes of raw materials. Various technologies for melting sodium silicate have been studied, incl. by unconventional schemes, such as smelting in cyclone furnaces. For melting in electric furnaces, various schemes of energy-saving methods for melting sodium silicate were analyzed. Promising ones have been identified. The following types of sodium silicate production were analyzed in the study: traditional smelting (carbonate method), wet method, sodium chloride sublimation method, sulfate method, cullet smelting. The optimal variant has been chosen, which makes it possible to reduce the cost of electricity by several times when introducing a highly efficient innovative technology of electric melting into practice.

1. Introduction

Sodium silicate has found wide application in many industries. It is used as a component of the charge for the production of glass, a filler in the composition of lightweight cement mortars for cementing wells, in the production of heat-resistant and acid-resistant concrete. As for the chemical industry, sodium metasilicate is used in the production of detergents and cleaning agents, household chemicals (Henkel washing powder). It is also widely used in oil production (as a coagulant in the production of regenerating oil) and the textile industry, metallurgy, mechanical engineering. Sodium silicate is used as an inhibitor with a corrosive effect, for disinfection of premises, linen, dishes, plumbing. Interestingly, silicates are one of the components of precious stones (emerald, topaz, aquamarine). They are used as a fire-fighting impregnation for wood (decoration processing), a mixture of sawdust and silicate fills the gap between the walls of safes also to protect against fire [1–3].

Sodium silicate is a basic component in the production of silicate adhesives and paints, silica gel, welding electrodes, corrugated containers, and geopolymer concretes and cements [4, 5]. All this is currently not produced in the Republic of Kazakhstan. As for its use in the production of building materials, the technology is needed by all existing enterprises in the production of small-piece building materials, as well as all enterprises producing reinforced concrete products in regions where there are blast furnace or thermophosphoric slags [6–8].

The technology of production of foam concrete based on geopolymers using sodium silicate is of the greatest interest, since here the strength of foam concrete depends on the strength of the elementary bubble, which, as is known, can be 2-3 or even 4 times stronger than in the case of traditional foam concrete based on Portland cement [9].

It follows from the above that sodium silicate is a widely applicable and necessary component for some industries. Thus, liquid glasses are used as a component of cements – heterogeneous systems, as well as an inorganic adhesive. As a “bundle” or “cured bundle”, water-soluble silicates are used both for the manufacture of composite materials and coatings, and for gluing parts and assemblies of aggregates for various purposes.

In this regard, the authors have studied all available experience in the production of sodium silicate, both now and in the past. At this stage of research, the analysis of the experience of the production of sodium silicate, both serial and pilot-industrial in the USSR in the past and in countries with not suspended development at the present time, was carried out.

Various technologies are classified.

Further, all possible sources of raw materials of both man-made and natural origin were studied. Business trips and expeditions to natural deposits were carried out and samples of raw materials from various natural and man-made sources were delivered. Studies have been conducted to determine the available volumes of raw materials.

Various technologies for melting sodium silicate have been studied, including using unconventional schemes, such as melting in cyclone furnaces. For melting in electric furnaces, various schemes of energy-saving methods for melting sodium silicate were analyzed. Promising ones have been identified.

Polymer concretes made with the use of slag-alkali binders showed increased quality characteristics, such as: strength, frost resistance, heat resistance, durability and impermeability. However, there is a shortage of inexpensive alkaline components on the market of the Republic of Kazakhstan, which would speed up cation exchange processes in the astringent system and increase hydration activity.

In Kazakhstan, there are unlimited natural reserves of sodium sulfate, when melting with lime, soda melt (a mixture of soda and gypsum) is obtained, which is a necessary component of slag-alkaline binders.

Soluble sodium silicate (soluble glass or silicate block) is the most multi-tonnage product of inorganic chemistry and is used in many industries:

1) Geopolymers;
2) Corrugated cardboard, books and other printing products;
3) Welding electrodes (coating);
4) Refractory and acid-resistant concrete;
5) Foam glass;
6) Cement Chipboard;
7) Foam concrete;
8) When arranging waterproofing during construction work;

9) Silica gel (adsorbent);
10) In metallurgy for molding injection mixtures;
11) In mechanical engineering for bundles for briquetting metal chips;
12) Flotation reagents in the enrichment of non-ferrous metals, primarily zinc;
13) Soap and washing powder;
14) In the rubber industry as a raw material for white soot (rubber filler);
15) In the food industry as an emulsifier E550.

The authors are working in the field of reducing energy costs. For this purpose, the technology of reactive power compensation with a magnetic amplifier is proposed, which is key, can be used in hundreds and thousands of companies only in Kazakhstan, where there are significant unit costs for electricity – from mining to street lighting.

2. Materials and methods

Sodium silicate is the most multi-tonnage product of inorganic chemistry. The greatest interest in obtaining sodium silicate with a low cost is shown by manufacturers of geopolymer cements, which require it to produce clinker-free binders. In the production of conventional cement, up to 400 kg of coal is burned for each ton of clinker. At the same time, almost one and a half tons of carbon dioxide are emitted into the atmosphere. In the production of clinker-free cement, granular blast furnace slag is used, of which more than 50 million tons have been accumulated in Temirtau, and the clinker firing process is excluded. However, sodium silicate (aka silicate-block) is also required, when added in an amount of 6-10%, cement of the M800-M1000 brand is obtained! In addition to the construction materials industry, the silicate block is used in a variety of industries (construction, printing, production of corrugated packaging, in the production of adsorbents). Currently, it is not produced in the Republic of Kazakhstan. Usually, a silicate block is obtained by melting quartz sand with soda in bath-type gas furnaces. Such furnaces have a characteristic size of about 40 m and are very expensive due to the use of a large number of refractory materials [10].

The authors are conducting research in the field of possibilities to use an electric direct heating furnace, which provides the same result with dimensions, and, accordingly, the cost is an order of magnitude lower. Considered below are past and present experiences in the production of sodium silicate.

Traditional melting (carbonate method). Currently, most glass industry enterprises in the CIS countries use soda ash and/or mixed with sodium sulfate for melting silicate blocks (figure 1).

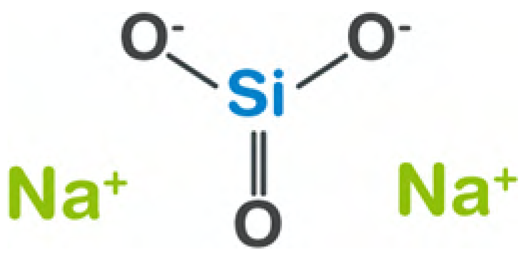

Figure 1. Structure of sodium silicate.

In a mixture with quartz sand, sodium carbonate (soda ash) or potassium carbonate are melted in flared glass furnaces of continuous operation. The reaction proceeds according to the following reaction:

$$n\mathrm{SiO_2} + \mathrm{Na_2CO_3} = \mathrm{Na_2O}\cdot n\mathrm{SiO_2} + \mathrm{CO_2}, \tag{1}$$

$$n\mathrm{SiO_2} + \mathrm{K_2CO_3} = \mathrm{K_2O}\cdot n\mathrm{SiO_2} + \mathrm{CO_2}. \tag{2}$$

This technology, firstly, requires significant capital expenditures for the construction of glass furnaces, so this method is unacceptable for our task. Secondly, the cost of soda ash at the level of 100 thousand tenge per ton with delivery to Karaganda also makes it impossible to fit into the specified cost range, since the amount of soda in the charge is 40%, i.e. the cost of soda alone will amount to 40 thousand tenge per 1 ton of sodium silicate [11].

We took a trip to Lake Tanatar (Altai Krai, Russia) to study the market in order to reduce the cost of soda ash. There is an enterprise for the extraction of natural soda. As will be further shown in paragraph 2 of this study, the use of natural soda from the Altai Krai is impractical.

Wet method. In China, where there are large enterprises for the production of soda ash, a wet method for producing liquid glass by dissolving finely ground quartz sand in a saturated solution of caustic soda is widespread [12].

The large source of amorphous silica available in Karaganda (waste from the production of the "Silicium Kazakhstan" plant) makes this production method very attractive, since the dissolution of amorphous silica occurs much faster and with lower energy costs than quartz sand. The reserves available at the landfill of the enterprise amounted to about 50 thousand tons in 2019. The cost was 3,000 tenge per ton. Part of the amorphous silica was purchased by us and studied at our request by Vladimir Merkulov, professor of the Karaganda State Industrial University for solubility in a 40% caustic soda solution in the laboratory of the Karaganda Industrial Institute. The result of the dissolution reaction was a liquid glass of black color, which is applicable for the production of slag-alkali cement.

However, the cost of caustic soda in the Republic of Kazakhstan at the level of 300 thousand tenge per 1 ton turned out to be unsuitable for any wet method technology due to the high cost.

The method of sublimation of sodium chloride. Of great practical interest are the works carried out in the USSR in the 50 s of the 20 th century on the production of sodium silicate by sublimation of sodium chloride in the presence of water vapor through quartz raw materials [13].

In this case, at temperatures of 600-1000 degrees Celsius, table salt and sodium ions react with quartz glass to produce sodium silicate:

$$\mathrm{NaCl}{+}n\mathrm{SiO_2} + \mathrm{H_2O} = 2\mathrm{HCl} + \mathrm{Na_2O}\cdot n\mathrm{SiO_2}. \tag{3}$$

This method is very attractive for practical implementation due to the low cost [14].

Due to the presence of a high content of unreacted silicon oxide, liquid glass, which is obtained by further dissolution of sodium silicate, contains a large amount of insoluble residue unacceptable by any standards, which, in principle, could be eliminated by conventional filtration, but, apparently, this method has not found practical application for reasons of production safety [15].

The group of liquid glasses – alkaline silicate solutions is very extensive. The silicate systems included in this group are classified according to the following criteria.

According to the degree of polymerization (l) of silica – the average number of silicon atoms that form a continuous system of siloxane bonds $\equiv Si - O - Si \equiv$ during polymerization. During the polymerization of silica, its molecular weight (M) increases, and at high degrees of polymerization, an increase in the size (d) of colloidal silica particles occurs. At a certain degree of polymerization (l), colloidal silica appears in alkaline silicate systems both in the form of a sol and in the form of highly dispersed hydrated silica (table 1).

According to the chemical composition, as the alkalinity increases, characterized by the molar ratio $\mathrm{SiO_2/M_2O}$ (the silicate module of the n system), alkaline silicate systems form a series corresponding to the four above forms of silica (table 2).

By monitoring the cation of liquid glasses, potassium, sodium, lithium and silicates of industrial enterprises are monitored. Mixed liquid glasses within four groups have also been synthesized.

Table 1. Degrees of polymerization of silica silicate solutions.

Monomers	$\to$	Lower oligomers	$\to$	Higher oligomers	$\to$	Colloidal silica, sols
$(l = 1)$		$(l = 1 \div 25)$		(polysilicic acids, $M < 10^5$)		$(M > 10^5$ or, $d > 2nm)$

Table 2. Rows with increasing alkalinity of silicate solutions.

High alkaline systems	$\to$	Liquid glasses	$\to$	Polysilicates	$\to$	Sols
$(n < 2)$		$(n = 2 \div 4)$		$(n = 4 \div 25)$		$(n > 2)$

The biggest disadvantage of this method is that, firstly, very toxic hydrochloric acid vapors with high temperature require expensive hardware for their cooling and dissolution in water, and secondly, the production of hydrochloric acid requires licensing [13].

Sulfate method. There are quite large deposits of sodium sulfate in Kazakhstan, which are currently not in demand by anyone.

The sulfate method for producing soluble glass is based on the interaction at high temperatures (1300-1500°C) of sodium sulfate with silica in the presence of a reducing agent (most often charcoal) [14].

In general, the process of formation of sodium silicate can be expressed by the equation:

$$4Na_2SO_4 + 2C + 4SiO_2 = 4Na_2SiO_3 + 4SO_2 + 2CO_2. \tag{4}$$

The reaction between Na_2SO_4 and silica, even with a significant increase in temperature, proceeds slowly and quantitative completion of it is almost impossible.

In order to accelerate the reaction, it is necessary to add a reducing agent to the charge to convert Na_2SO_4 to Na_2SO_3, which reacts with silica.

The reducing agent can be various organic substances containing carbon: sawdust, charcoal, resins, coal pitch, etc. Sawdust and charcoal are low-ash. This allows them to be widely used in the production of soluble glass.

The reducing agent, burning inside the melt, attaches oxygen contained in Na_2SO_4, as a result of which the latter passes into sodium sulfite Na_2SO_3.

Coal is added to the charge in an amount of 3-7% by weight. The amount of reducing agent introduced into the charge significantly affects the properties of the resulting soluble silicate.

With an insufficient amount of reducing agent, Na_2SO_4 remains in the melt, which does not mix with sodium disilicate and silica, which is in excess against the formula Na_2SiO_3 and $Na_2Si_2O_5$, and causes the alloy to delaminate.

With an excess of carbon in the melt, sodium sulfide Na_2S is obtained, which forms iron sulfide FeS when interacting with iron oxides, staining the soluble glass in dark colors [16].

Since, for cost reasons, this method, subject to obtaining a license for subsurface use, turns out to be the most attractive, we have studied this method more closely with the involvement of OOO "Research Institute Stromcomposite" Krasnoyarsk, Russia.

The sulfate method proposed by Krasnoyarsk NIIstromproekt, as well as the method of salt distillation described above, allows to obtain a silicate block with a low cost due to the use of a number of heat-saving aggregates [17].

Thus, it is the sulfate method with the condition of using energy-saving solutions that could become the way that would ensure the cost of the silicate block at a given level, but it has a number of significant drawbacks:

- Formation of sulfur dioxide, which requires neutralization and, accordingly, additional capital costs [11];

- As well as in the carbonate method, this one provides for the construction of an expensive glass furnace; which, in the absence of natural gas (Karaganda), also requires additional capital costs for the production of generator gas from coal.

Melting of cullet. The difference between construction or bottle glass and silicate blocks is only that the amount of soda in the raw charge in the latter case is 15% more [18].

Currently, cullet in the Republic of Kazakhstan is formed not only in window shops, but also in numerous service stations for the replacement of automobile windows. The currently unclaimed secondary glass container market is added to this volume.

In Karaganda, the service for collecting glass from window shops with delivery to the intended place of consumption is 3,000 tenge per ton. Here it is required to add 15% soda ash or sodium sulfate, i.e. the cost of raw materials in this case will be no more than 18,000 tenge per 1 ton. Processing processes (crushing and sorting), wage costs and other overhead costs will amount to about 3,000 tenge per ton. Thus, excluding energy costs, the total cost will be 21,000 tenge per 1 ton of silicate blocks. Such preliminary calculations make the processing of cullet along with sodium sulfate one of the likely ways to solve the engineering and economic task.

Study of potential sources of raw materials. Sodium silicate, produced in the form of a silicate block by Russian enterprises, is currently imported to the Republic of Kazakhstan, where it is dissolved in water and further used at enterprises of the construction, corrugated cardboard and, mainly, metallurgical industry. The most tonnage direction for the sale of sodium silicate could be the sector of production of polymer cements and concretes. The main problem in the production of annealed, clinker-free binders obtained from the waste of steelmaking enterprises (granulated blast furnace slag) is the lack of inexpensive primary or secondary alkaline materials on the market that can not only activate such binders, but also match the low price of traditional Portland cement [19].

Melting a sodium silicate block requires silicon dioxide and a suitable source of sodium.

Silicate raw materials can be man-made sources, such as cullet and microsilicon, as well as natural quartz sand [20].

Natural inexpensive sources of raw materials can be natural soda and sodium sulfate. Unfortunately, there are no technogenic alkaline sources in Kazakhstan in practically applicable volumes.

The experience of the silicate-block workshop in the Soviet period, which worked in Balkhash on the territory of the copper smelter, showed that the use of sodosulfate waste from the Pavlodar aluminum plant allowed to obtain high-quality silicate-block with a very low cost. However, along the way, an unacceptably high level of sulfur dioxide emissions was formed, which seemed insignificant “under the cover” of the main production of the combine, which also emits a huge amount of sulfur dioxide. The sodosulfate mixture is an excellent and cheap raw material for melting silicate blocks (if the furnaces are equipped with equipment for neutralizing sulfur dioxide), but the Pavlodar aluminum plant has changed the technology and does not currently ship the sodosulfate mixture.

Another inexpensive source, besides the soda-sulfate mixture, could be a deposit of natural soda. As it is known in the USA, it is due to the use of natural garden raw materials that the bulk of silicate blocks is produced.

Natural, and therefore inexpensive, soda raw materials in Kazakhstan in the explored deposits are available in negligible quantities. For example, a deposit with reserves of less than 500 tons is known in the Almaty region.

In the Altai Krai, water from Lake Tanatar with a soda content of about 5% is pumped into sedimentary basins, in which, when the temperature drops, soda precipitates, and the water drains back into the lake. There is no soda drying at the enterprise. Therefore, in addition to the natural humidity of 17%, each soda molecule contains 10 more molecules of chemically bound water.

Moreover, production was suspended after a single buyer from Stepnogorsk stopped acquiring it, after which the Altai Soda company went bankrupt. Currently, it is not possible to purchase soda from this source. It should be noted that even before the bankruptcy, the price at the level of 60 USD per 1 ton at the Kulunda station was unacceptable due to the high-water content (both chemically bound and free moisture). It turned out that 60-70% of water had to be transported, not soda. Thus, this source of raw materials for use in the production of slag-alkali cement was also unacceptable.

As a result, we came to the conclusion that cullet is currently the most suitable as the main source of raw materials, which is not only a source of silicate, but also sodium raw materials.

During the study, we found that the waste landfill of the city of Karaganda is ready to supply 200 tons of cullet every month. And together with the city of Astana and other cities of Central Kazakhstan, the total volume of available cullet is estimated at around 1000 tons per month. Other sources are workshops for the production of windows and replacement of car windows. The films inside the triplex are a harmful impurity, they are coked during melting, giving a dark color, but for a silicate block that will be used in the production of slag-alkaline cement, this is permissible.

3. Results and discussion

The main elements of modern furnaces that allow saving energy are various heat exchangers that usefully use secondary heat. In glass furnaces, fuel gases can be used to warm up incoming raw materials.

In the technological scheme proposed by OOO "Research Institute Stromcomposite" Krasnoyarsk, Russia, fuel gases are also used to produce charcoal used in the sulfate method: Sodium sulfate Na_2SO_4 (0.91 t/h), burnt molding earth (1.46 t/h) and charcoal (0.56 t/h) are fed into the melting furnace.

The components are pre-crushed and homogenized in a rod mixer.

Melting is carried out due to the combustion products of the generator gas coming from the gas generator, in which the working medium is charcoal. With an average coal consumption of 0.42 t/h in the gas generator, 2800 kg/h (2240 nm^3/h) of gengas is formed. The combustion of this amount of gengas with the supply of 2700 kg/h (2100 nm^3/h) of blast air into the combustion chamber produces 5500 kg/h of combustion products with a temperature of approximately 1550°C and a heat content of 2.9 Gcal/h.

At the outlet of the melting furnace, the temperature of the combustion products decreases to 9000°C with a residual heat content of about 1.5 Gcal/h. The total mass of the combustion products reaches approximately 6100 kg/h due to the addition of the products of the silicate block formation reaction: CO and SO_2. The amount of the first is approximately 0.18 t/h, the second is 0.42 t/h.

The combustion products are subjected to oxidative afterburning, for which 600 kg/h (465 nm^3/h) air is supplied to the afterburning chamber. As a result of afterburning, the amount of combustion products increases to 6700 kg/h, its heat content increases to 1.9 Gcal/h, and the temperature increases to 1000°C.

These combustion products are sent to retorts for dry distillation of wood waste. The retort capacity is 1 t/h of charcoal. If the initial moisture content of wood waste is 40%, then the required amount of wood waste is 5.5 t/h.

As a result of dry distillation, the heat content of combustion products drawn through the wood layer increases due to exothermic reactions of wood decay by 0.8 Gcal, however, approximately 0.3 Gcal/h is lost to the environment, and, with the charcoal leaving the retort [21].

Thus, the total heat content of combustion products at the outlet of the retort reaches 2.4 Gcal/h, and their mass increases to 11200 kg/h due to the addition of 4.5 t/h of volatile decay products. The temperature of the combustion products at the outlet of the retort will be approximately 650°C.

Volatile wood decay products contain: CO, acids, alcohols, ketones, light hydrocarbons, resin vapors, free hydrogen, therefore they must be subjected to afterburning. In 4.5 t/h of volatile, combustible compounds 1200 kg, the rest is physical and pyrogenetic water, CO_2, N. With an average calorific value of a mixture of combustible compounds 4500 kcal/kg, afterburning of volatile compounds taking into account losses allows you to get an additional 5.4 Gcal/h. For afterburning, blowing air is used in an amount of 2500 kg/h.

Thus, 13700 kg/h of combustion products with a heat content of 7.8 Gcal/h come out of the afterburning chamber.

The combustion products are sent to the heat recovery boiler G 400-PE-1 for the production of 10 t/h of steam with parameters: $T_p = 260$°C, R_p=14 atm.

Of the 10 t/h of steam, 3.7 t/h is spent on the production of electrical energy in the block electric turbine generators TGV-500M, the remainder is used for technological needs.

The process of hardening of liquid glass is accompanied by the manifestation of adhesion properties to the quartz sand filler and is carried out with natural (in air) or artificial (heating, blowing warm air) drying of the mixture. In contrast to the manufacture of casting molds, in this process it is necessary to avoid the destruction of the liquid glass base in order not to further reduce its solubility in water.

In addition, to achieve high strength, first of all, it is necessary to achieve the most dense packing of sand grains, which, in addition to molding pressure, requires a certain grain size distribution and optimal viscosity of liquid glass. In this case, the dependence of strength on the glass content in the system passes through a sharp maximum. This dependence is shown in figure 2.

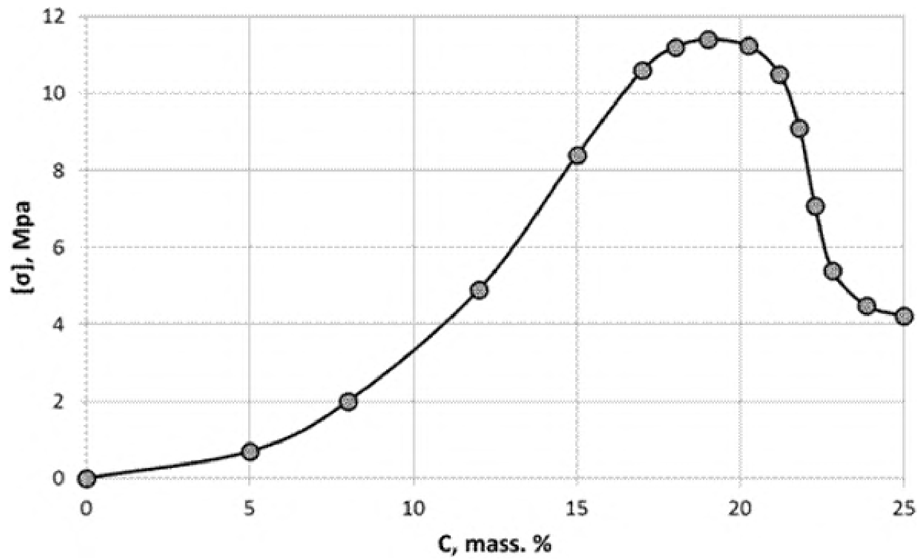

Figure 2. Dependence of the tensile strength on the content of liquid glass.

After the recovery boiler, the combustion products are neutralized in a "wet" scrubber [22].

The high cost of glass-melting furnaces of the bath type, which are used in glass factories with a capacity of 40-60 tons per day, is estimated at 2-3 million US dollars. This goes beyond the boundary conditions. Sodium silicate is a key source of reactive silica, which is in high demand in many industries including detergents, rubber, food and beverages, and paper and pulp. The global sodium silicate market was valued at USD 6.3 billion in 2018, growing at a CAGR of 3.2% during the forecast period 2020-2026 figure 3.

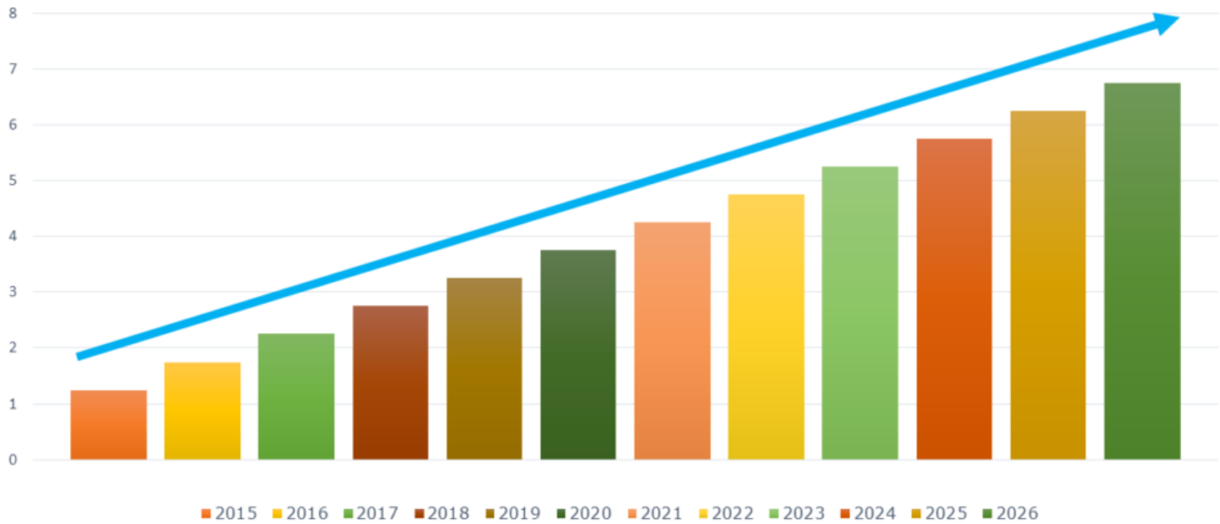

Figure 3. Global market forecast according to [23].

The growing demand for other derivatives such as silica gels and silica sols in applications including paints and coatings, plastics and inks is expected to have a positive impact on market growth during the forecast period. Another promising melting method would be glass melting in a cyclone furnace [18].

Scientists of the Academy of Sciences of the Kazakh SSR were seriously engaged in this topic in the 70s of the 20th centuries and were among the world leaders. Such an experimental furnace was even used for melting copper raw materials at the Balkhash copper Smelting plant.

Cyclone furnaces consume 1.5-1.6 times less fuel than rotary furnaces, and have a cost 10-20 times less in terms of capital costs for their construction [10].

It turned out that cyclone furnaces are currently used to produce mineral and glass wool in Germany.

The main disadvantage of melting raw materials in a cyclone is the huge volume of fuel gases that require purification. The fact is that in cyclone furnaces, the charge in a pulverized state with speeds of several hundred km/h is blown into the cyclone together with fuel gases. Some of the raw materials are melted, but some come out of the cyclone, which leads to a loss of raw materials up to 15%. At the same time, there is a technical problem of cooling the flow of the outgoing gas and its purification from solid impurities. Such a task is quite feasible, but in the given parameters of the task it will require the construction of a battery of heat-resistant cyclones, the cost of which is higher than the cost of the furnace itself.

Therefore, our research should be in the field of energy saving of electric direct-heated glass furnaces. The design of such furnaces is simple, requires little space and capital costs. The only drawback of such furnaces is the high-power consumption – 1000 kw-hours of electricity is required for 1 ton of silicate blocks, which at current prices is 16,000 tenge per ton of silicate blocks.

As part of the task, it is required to reduce the electricity consumption to 7000-8000 tenge per ton of silicate blocks. In the course of the conducted scientific and technical search, it turned out that currently there are technologies that can reduce consumption costs by 2 or even more times.

The main component is an electric direct heating furnace. The efficiency of such furnaces is many times higher than the efficiency of gas furnaces, since in our case the heat flow is carried out from below (bottom electrodes), and not from above, as in the case of coal or gas furnaces, where the torch heats the mass from above, which is why it is necessary to build an expensive vault. But in our case, the electric furnace is additionally equipped with a reactive energy compensation unit with a magnetic amplifier, as a result of which electricity is saved at least 2 times.

The authors are engaged in the introduction into practice of a highly efficient resource-saving process for the production of sodium silicate from cullet with the use of innovative electric melting technology, which allows a multiple reduction in energy costs and the use of energy-saving technology for obtaining an aqueous solution of sodium silicate using a highly efficient apparatus protected by a patent.

The introduction of the proposed technology will allow not only to start a solution for import substitution, but also to indicate a technical solution for involving tens of millions of tons of Temirtau and Taraz slag into economic turnover, which will reduce carbon dioxide emissions by reducing the production of Portland cement, which currently produces carbon dioxide in rotating coal furnaces almost more than cement itself.

In addition, it is planned to obtain sodium silicate not from quartz raw materials and soda, but from secondary glass and soda, since there is already a high amount of sodium oxide required in the cullet. Another difference of the proposed technology is the use for electric melting of a furnace equipped with a reactive power compensation unit with a magnetic amplifier, which will make it possible to reduce the specific amount of electricity by at least 2 times.

The second technical difference is the technology of dissolution of sodium silicate. Traditionally, sodium silicate is dissolved in water in autoclaves at high vapor pressure, which is too energy-consuming. In our case, the silicate block is crushed and dissolved in water at a temperature of 95-98 degrees Celsius at normal pressure. At the same time, an energy-efficient device is used, protected by patent No.2397 with the authorship of one of the team members – T. S. Dauletbakov [24].

The traditional technology of melting sodium silicate involves melting quartz sand and soda in bathroom furnaces. This technology, firstly, requires high capital investments for the construction of a bathroom furnace, and secondly, requires the presence of a source of natural gas or where there is none, as in our case, a gas generator set for the production of generator gas from coal, which also increases the cost of the project [11].

The technology of dissolving quartz sand in caustic soda solution is also known, which sharply increases the cost of products due to the high cost of NaOH (caustic soda). The technology of obtaining sodium silicate from cullet with the addition of 8-15% soda ash (Na_2CO_3) is also used with melting in bathroom furnaces and is the closest to this project.

We propose the production of sodium silicate from cullet with soda and / or sodium sulfate, but, characterized in that:

- Melting is carried out not in an expensive bath-type gas furnace, but in a compact electric furnace of direct heating;
- The electric furnace is equipped with a reactive power compensation unit with a magnetic amplifier, which gives a multiple reduction in electricity consumption of at least 2 times;
- The components of the charge are mechanically activated in a roller mill before melting.

This leads to a partial reaction of the formation of sodium silicate already in the mill and further to a multiple reduction in energy costs during melting in the furnace at least 1.5 times more.

At the stage of dissolution of the silicate block in water, an autoclave-free technology is provided, in which the finely ground silicate block is dissolved in water at normal pressure, which reduces energy consumption compared to the traditional technology of dissolution in superheated steam at high pressures.

The cost of water vaporization is 2260 kJ/kg, so the specific heat required for heating water from 0 to 98 degrees Celsius is only $4.1 \times 98 = 401$ kJ/kg.

That is, the amount of energy required for water vaporization, taking into account that the steam still needs to be heated to 150 degrees with traditional technology compared to the proposed 6 times more.

The main problem in the production of sodium silicate is high capital intensity and high energy intensity.

The authors are working in the field of reducing energy costs. For this purpose, the technology of reactive power compensation with a magnetic amplifier is proposed, which is key, can be used in hundreds and thousands of companies only in Kazakhstan, where there are significant unit costs for electricity – from mining to street lighting.

In a broad sense, reactive power compensation technology with a magnetic amplifier can be used not only for melting sodium silicates, but also in metallurgical furnaces, mining farms, electrolysis workshops, and municipal lighting. The technology of reactive power compensation with a magnetic amplifier is currently tested and used in Turanga LLP (Almaty) in industrial conditions at a wood thermating plant with a capacity of 150 kW. It is planned to apply the same technology in the melting of sodium silicate in an electric furnace with a capacity of 1MW.

4. Conclusions

The most likely to be used under the conditions of the task is the processing of natural sodium sulfate. However, in terms of availability, this type of raw material, despite its widespread distribution in Kazakhstan, is not suitable for solving this problem, since no one has the rights to extract it.

Therefore, the processing of recycled glass, now unclaimed by the domestic industry, can be a source of raw materials for the production of silicate blocks with a given cost at the level of 28-30 thousand tenge per ton.

The engineering and technical embodiment of melting can be cyclone melting, provided that the issue of waste gas purification is resolved, as well as melting in electric furnaces, provided that energy savings are ensured.

Sodium silicate, produced in the form of a silicate block by Russian enterprises, is currently imported to the Republic of Kazakhstan, where it is dissolved in water and further used at enterprises of the construction, corrugated cardboard and, mainly, metallurgical industry.

The most tonnage direction for the sale of sodium silicate could be the sector of production of polymer cements and concretes. The main problem in the production of non-roasting, non-clinker binders obtained on the basis of waste from steelmaking enterprises (granulated blast furnace slag) is the lack of inexpensive primary or secondary alkaline materials on the market that can not only activate such binders, but also match the low price of traditional Portland cement.

Thus, the introduction of the proposed technology will allow not only to start a solution for import substitution, but also to indicate a technical solution for involving tens of millions of tons of Temirtau and Taraz slag into economic turnover, which will reduce carbon dioxide emissions by reducing the production of Portland cement, which currently produces almost more carbon dioxide in rotating coal furnaces, than the cement itself.

In addition, the project provides for the production of sodium silicate not from quartz raw materials and soda, but from secondary glass and soda, since there is already a high amount of required sodium oxide in the cullet.

Another difference between the project and the traditional ones is the use of an electric furnace equipped with a reactive power compensation unit with a magnetic amplifier, which will make it possible to reduce the specific amount of electricity by at least 2 times.

The second technical difference is the technology of dissolution of sodium silicate. Traditionally, sodium silicate is dissolved in water in autoclaves at high vapor pressure, which is too energy-consuming. In our case, the silicate block is crushed and dissolved in water at a temperature of 95-98 degrees Celsius at normal pressure. At the same time, an energy-efficient device is used, protected by patent No. 2397 with the authorship of one of the team members – T. S. Dauletbakov.

But the most important consequence of the project is the practical expansion of reactive power compensation technology with a magnetic amplifier, which in the future can be used in all power grids with a significant reduction in energy consumption and ultimately significantly affect the decarbonization of the industry of the Republic of Kazakhstan.

Abstract. The application of blast furnace cements with minor clinker constituent is an actual task due to their conformity with modern tendencies of sustainable development. The alkali metal compounds were proposed to increase activity of CEM III/C. The aim of the research was to investigate the effects of technological factors on porous structure of alkali-activated blast furnace cement concrete (further, AABFC concrete) to ensure its sustainable performance by criterium of freeze-thaw resistance in NaCl solution. The effects of fresh concrete consistency, aggregate state of alkaline component and curing conditions on sustainability of AABFC concrete were investigated. Increasing of fresh concrete consistency from class S1 up to class S4 due to chemical plasticization as well as application of alkaline component in dry form, in contrast to liquid form, ensures negative changes in porous structure of AABFC concrete. These changes cause decreasing of freeze-thaw resistance from mark F500 down to F200. It was revealed that hardening of plasticized AABFC concrete under normal conditions ($t = 20 \pm 2\ ^\circ$ C, $RH = 95 \pm 5\%$), compared with hardening in water or under steam curing ($t = 85 \pm 5\ ^\circ$ C), ensures more effective porous structure which causes maintained freeze-thaw resistance of F300 in contrast to F200 and F250 agreeable.

1. Introduction

To decrease the content of clinker constituent in cements due to use of ground granulated blast furnace slag (further, GGBFS) [1], fly ash [2], limestone [3], natural zeolites [4], biochar (the carbon negative product of pyrolysis) [5], etc. is an effective way to meet the requirements of sustainable development. Besides of ecological aspect (effective consumption of raw recourses, reduction of CO_2 emission), such replacement causes diminution of prime and logistics costs, as well as provides the means to use local raw materials [6, 7]. However, these cements suffer from slow hydration kinetics, resulting in less early strength gain, which is main drawback in construction applications.

The most known ways to activate hydraulic properties of the cements containing GGBFS is to apply calcium [8] and sulfate activators [9]. It is also known that low alkaline [10], nearly neutral salts [11] as well as Na (K) salts of strong acids [12] can be used as activators as well. However, insufficient strength of blast furnace cements in accordance with [13] and the possibility to increase only early strength are disadvantages of these means [14, 15]. It was shown, that the application of oxides [16] or salts of alkaline metals (sodium aluminate [17], sodium carbonate and silicate [18]), which provide an high alkaline reaction in water, can be a solution to increase the efficiency of blast furnace cements with minor clinker constituent without decrease of strength. Thus, blast furnace cements activated by alkali metal compounds are in compliance with mandatory requirements [19].

The alkali-activated blast furnace cements (further, AABFC), obtained due to mentioned activation, are the most perspective ones to ensure advanced service life of concrete structures. To ensure the durability of constructions is one more current world tendency of sustainable development of mankind. This fact can be confirmed by numerous scientific researches concerning durability of structures which are exposed to different aggressive effects, i.e. atmospheric [20], freeze-thaw cycles [21], alkali of aggregate [22], seawater [23], high temperatures [24], fire [25,26], etc. Proposed recommendations to ensure durability of structures while use of recycled concrete [27–29].

In general cases, alkali-activated blast furnace cement concretes are characterized by advanced performances in aggressive environments such as corrosion resistance [30], sulfate resistance [31] and freeze-thaw resistance [32], including salt scaling resistance [33], in comparison with analogues based on traditional clinker cements.

It is well known that the durability of concrete structures cannot be evaluated using only one performance. The most important properties of concrete for a specified case are used for evaluation of durability depending on destination and environment [34]. Resistance of concrete to freeze-thaw cycles and sodium chloride scaling is one of the criteria. The mentioned environment can be classified as exposure class XF4 (road and bridge decks exposed to deicer agent, splash zones of marine structures, etc.) according to [35]. It is well known that NaCl is the most demanded salt among deicers [34, 36, 37] as well as the predominant one in seawater [38, 39]. The above results have been defined the choice of sodium chloride as corrosion environment to evaluate the durability of concrete to freeze-thaw resistance.

Increased freeze-thaw resistance of AABFC concrete in NaCl solution is caused by several factors, including features of hydrated phases. It is known, that interaction of sodium chloride with hydration products of Portland cement ensures destruction of concrete. Particularly, decreasing of $Ca(OH)_2$ in hydration products in consequence of leaching as well as exchange reaction with sodium chloride NaCl with formation of $CaCl_2$ leads to decreasing of basicity of highly-calcium hydrosilicates (the main hydration products of portland cement) [34, 40]. Besides, participation of sodium chloride in hydration processes of portland cement ensures transformation of monosulfate $3CaO \cdot Al_2O_3 \cdot CaSO_4 \cdot 10H_2O$ to Friedel's salt $3CaO \cdot Al_2O_3 \cdot CaCl_2 \cdot 10H_2O$ (AFm-phase) as well as to secondary ettringite $3CaO \cdot Al_2O_3 \cdot 3CaSO_4 \cdot 32H_2O$ (AFt-phase) [41,42]. Formation of secondary ettringite can cause destruction of concrete due to crystallization pressure on porous sides while volume increases. Advanced freeze-thaw resistance of AABFC concrete in solution of NaCl is caused by the absence of portlandite in hydration products [43] as well as by the absence of ettringite or due to changes in its morphology in highly-alkaline hydration medium from filamentous, needle to prismatic as well as plate shape [44].

Solution of NaCl can also provide steel reinforcement corrosion in constructions in consequence of transport of aggressive Cl^- ions in concrete [45]. AABFC concrete is characterized by increased protective properties to steel reinforcement due to high content of gel-like hydrosilicates and formation of alkaline hydroaluminosilicates (analogues of natural zeolites), which can bind Cl^- ions [43, 46, 47]. The enhancement of steel reinforcement protection in AABFC concretes, obtained from high consistency mixes, was proposed [12,18,23].

Increased freeze-thaw resistance of AABFC concrete compared with portland cement concrete is caused also by influence of alkaline component on decreasing of freezing temperature of solution in porous space [43]. It is well-known, that increasing of water volume while formation of ice by 8. . . 9 % ensures pressure on sides of pores and causes destruction of concrete [34]. However, freezing of liquid in pores occurs at temperatures below 0 $^\circ$ C because of solution in pores of stone is not pure water and contains soluble substances (alkalis, oxides and hydroxides of alkaline-earth metals, sulfates, etc.) [48]. Increased content of compounds of alkaline metals in porous solution causes increased freeze-thaw resistance of AABFC concrete compared with portland cement [43, 49].

The peculiarities of porous structure cause advanced freeze-thaw resistance of AABFC concrete. In common case, the porous structure of cement stone is presented by gel (1.5. . . 10.0 nm), capillary (0.01. . . 1.00 nm) and closed (10. . . 500 μm) pores [50]. At that, freeze-thaw resistance and accordingly durability of concrete are caused mainly by capillary porosity in contrast to strength of concrete, which depends on total porosity [34]. Capillary effect, which is caused by dependence of freeze point from the size of pores, causes the influence of porous structure on freeze-thaw resistance of concrete. Water firstly freezes in capillary pores whereas one remains in liquid form in smaller gel pores while freezing. Thermodynamic unbalanced state causes motion force for removal of water from smaller to larger pores and occurs because of the pressure under water is higher than under ice [34]. Increased gel phase while decreased volume of capillary pores compared with Portland cement [43] causes advanced freeze-thaw resistance of AABFC concrete.

Porous structure of AABFC concrete in one's turn is caused by technological factors such as consistency of fresh concrete, form (state) of alkaline component, curing conditions, etc. The modern requirements to consistency fresh concretes are governed by practice [51–55]. Consistency of fresh concrete is regulated by surfactants. Principles for choice of surfactants as the bases of complex admixtures were proposed [56, 57]. Effectiveness of complex admixture "polyorganohydrosiloxane – sodium lignosufonate – polyethylene glycol" for AABFC concrete was determined while providing both electrostatic and steric mechanism of plasticization [56]. However, increasing of consistency causes negative changes in concrete structure, which lead to increasing of porosity and consequently less freeze-thaw resistance.

The features of AABFC technology, which are caused by different aggregative state of alkaline components and chemical admixtures (dry form or liquid form), provide various intensity in formation of hydrosilicate gel and, consequently, different performances of AABFC concrete [43]. Thus, the aim of this research was to investigate the effects of technological factors on porous structure of AABFC concrete to provide its high freeze-thaw resistance in solution of sodium chloride as criterium of sustainable performance.

2. Raw materials and testing techniques

The main constituents of the blast furnace cement (CEM III/C, in accordance with EN 197-1:2011) were presented by:

- ground-granulated blast furnace slag (further, GGBFS) (% by mass: CaO – 47.30, SiO_2 – 39.00, Al_2O_3 – 5.90, Fe_2O_3 – 0.30, MgO – 5.82, SO_3 – 1.50, TiO_2– 0.31), basicity modulus= 1.11, content of glass phase= 84.0 %, specific surface= 450 m^2/kg (by Blaine);
- Portland cement CEM I 42,5 R (% by mass: CaO – 64.13, SiO_2 – 25.14, Al_2O_3 – 5.17, Fe_2O_3 – 4.12, MgO – 0.88, SO_3 – 1.27, $K_2O + Na_2O$ – 0.99).

The blast furnace cement was composed, % by mass: GGBFS – 95, Portland cement – 5.

The alkaline component (33 mass % Na_2CO_3 + 67 mass % $Na_2O \cdot SiO_2 \cdot 5H_2O$) was introduced into a concrete mixer in dry form (powder) or in liquid form (water solution, 1180 kg/m^3) in such a way that its content in the concrete (as Na_2O-equivalent) would be equivalent. The contents of alkali metal compounds (alkaline activators) were taken over 100 % of the aluminosilicate components in accordance with [19].

A river silica sand (fineness modulus 1.8) was used. A granite gravel with grain sizes between 5. . . 10 mm (fr. 5/10) and 10. . . 20 mm (fr.10/20) was used as coarse aggregate.

Reference composition of concrete was used according to [58], while application of alkaline component in dry form or in liquid form, kg/m^3: AABFC – 350, silica sand – 740, granite gravel – 330 (fr.5/10) and 780 (fr.10/20).

AABFC concrete was modified by complex admixture (CPA) with the main plasticizing effect. CPA was presented by the components:

- sodium lignosulfonate (further, LST) in accordance with CAS 8061-51-6 (pH $\geqslant$ 8.5);
- waterproofing agent based on ethyl hydro-siloxane polymer (further, WA) in accordance with CAS 63148-57-2.
- surfactant based on polyether (polyethylene glycol "PEG-400", JSC "Barva" in accordance with CAS 25322-68-3.

WA was used to intensify grinding and to prevent sorption of water from air and to retain the properties of AABFC. Contents of CPA components, % by mass of AABFC, were: LST – 1.00, WA – 0.06, polyethylene glycol – 0.50.

The AABFC components and a half of aggregates together with LST and mixing liquid (water or solution of the alkaline component) were properly mixed in mixer for 1 min, then the remaining part of aggregates was added and mixed together for the next 2 min.

Consistency (workability) was determined by cone slump according to the national standard of Ukraine [59].

The prepared concrete mixtures were placed into moulds and compacted under vibration at a vibrating table, then covered with a plastic film and placed into a chamber for hardening under normal conditions (t = 18±2 ° C and RH = 95±5 %), where it was stored for 2 days until demoulding. A part of the specimens after taken from the moulds was placed for further hardening in water, the other part was left for hardening under normal conditions, and some specimens were steam cured at t = 85±5 ° C.

Water absorption and porosity of the AABFC concrete were tested in accordance to national standard of Ukraine [60]. The concrete cubes (100 mm) after 28 days of hardening were dried up to a constant weight at t = 105±10 ° C. Then, the specimens were saturated with water until a constant weight would be obtained at t= 20±2 ° C. The values of porosity were calculated from the values of average density and water absorption.

Freeze-thaw resistance of AABFC concrete (figure 1) was studied according to the third test method prescribed by the national standard of Ukraine [61]. According to this accelerated method, the concrete cubes (100 mm) were saturated with a 5 % solution of NaCl at t= 18±2 ° C and after that were subjected to freezing at t = -50 ° C. Thawing was done in a 5 % solution of NaCl. A class of concrete in freeze-thaw resistance was designated as a number of alternate freezing and thawing at which a mean compressive strength decreased by no more than 5 %. The freeze-thaw resistance of concrete was assessed by the correspondence between permissible number of freezing-thawing cycles by the mentioned method and by the first (basic) method prescribed in mentioned standard.

3. Results and discussions

The effects of fresh concrete consistency, aggregate state of alkaline component and curing conditions as technological factors on porous structure of AABFC concrete were investigated to ensure its sustainability.

3.1. Effects of fresh concrete consistency and aggregate state of alkaline component

The porous structure and corresponding values of freeze-thaw resistance of AABFC concrete were compared. AABFC concrete was obtained with different consistency (table 1, figure 2, figure 3, figure 4): class S1 (reference) and class S4 (plasticized by CPA). It was revealed, that consistency of fresh concrete is important factor of porous structure. Thus, increasing of

Figure 1. A freezing chamber for testing freeze-thaw resistance.

Table 1. The porous structure and freeze-thaw resistance of alkali-activated blast furnace cement concrete versus form of alkaline component and consistency.

Strength class of concrete	W/C (S/C)	Consis-tency, cm	Water absorption Wm, %	Changes in mass, %	Changes in strength, %	Freeze-thaw resistance
			Dry form of alkaline component			
B35	0.36	18	3.39	+1.05	-9.0	F200
B40	0.34	2	3.12	+0.8	+0.5	F400
			Liquid form of alkaline component			
B35	0.34	20	3.70	+0.04	-1.0	F300
B40	0.32	3	2.88	+0.19	-5.7	F500

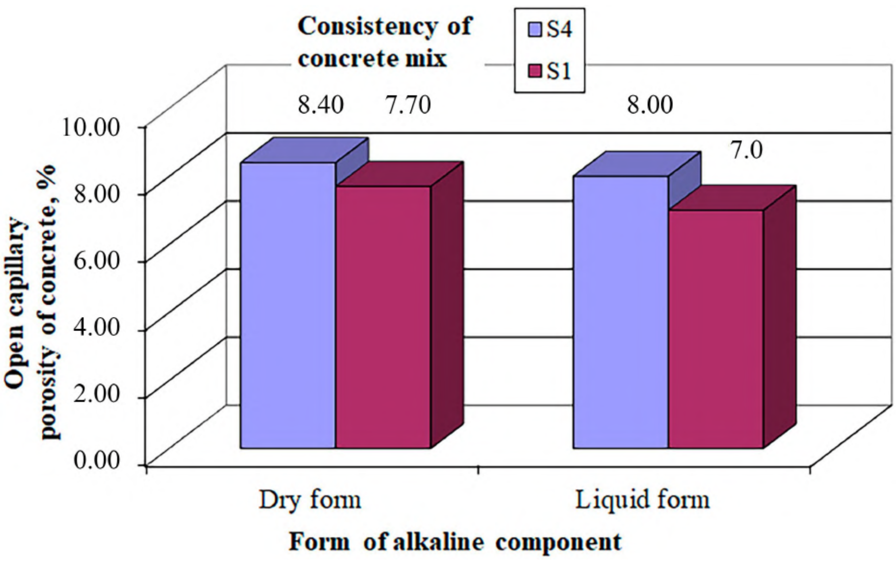
Note. The specimens hardened in water

consistency from class S1 up to class S4 while application of alkaline component in dry form ensured deterioration of porous structure, i.e. increasing of volume of open capillary pores by 9.1 % (figure 2a) and decreasing volume of conditionally closed pores by 41.2 % (figure 2b). Less volume of conditionally closed pores determined formation of minor dense and more permeable structure, which caused deterioration of physical and mechanical properties of AABFC concrete, including freeze-thaw resistance decrease from mark F400 down to mark F200 (figure 3a). Application of alkaline component in liquid form provided the similar dependence. Changes in consistency from class S1 up to class S4 ensured increasing volume of open capillary pores by 14.3 % (figure 2a) and corresponding decreasing of conditionally closed pores by 20.7 % (figure 2b), that was factor of reduction of freeze-thaw resistance from mark F500 down to mark F300 (figure 3b).

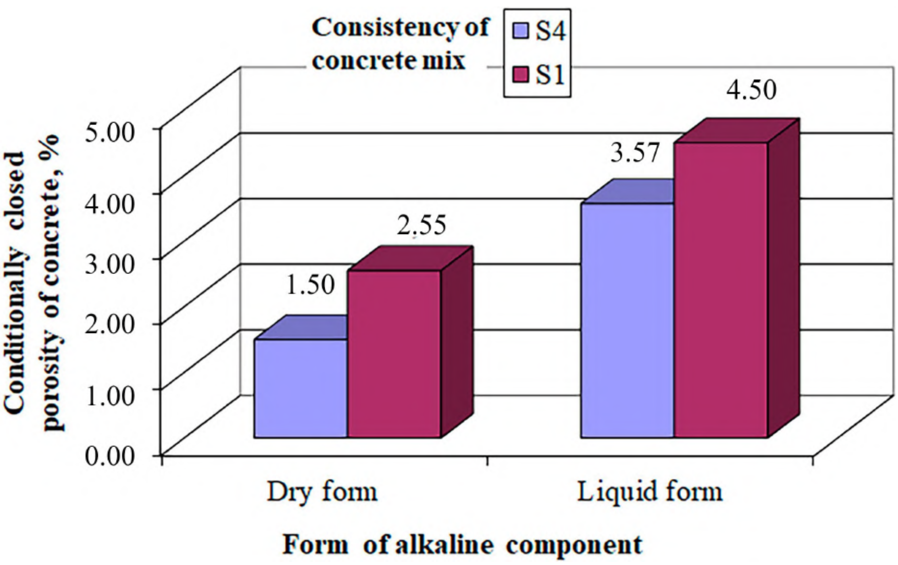
Specified changes in porous structure and freeze-thaw resistance of AABFC concrete was caused by increasing values of water/cement ratio (W/C) from 0.34 up to 0.36 or solution/cement ratio (S/C) from 0.32 up to 0.34 while application of alkaline component in dry form or liquid form agreeably. Less freeze-thaw resistance of AABFC concrete was also caused by increased air-entraining due to CPA. That is explained by decreasing of surface tension between water and air [62].

Thus, increasing consistency caused negative effect on freeze-thaw resistance of AABFC concrete that is in dissonance with the modern requirements to high consistency of fresh concrete.

Application of alkaline component in dry form, in contrast to liquid form, ensured higher volume of open capillary pores by 5.0 % and 10.0 % at consistency classes S1 and S4 agreeably.



(*a*)



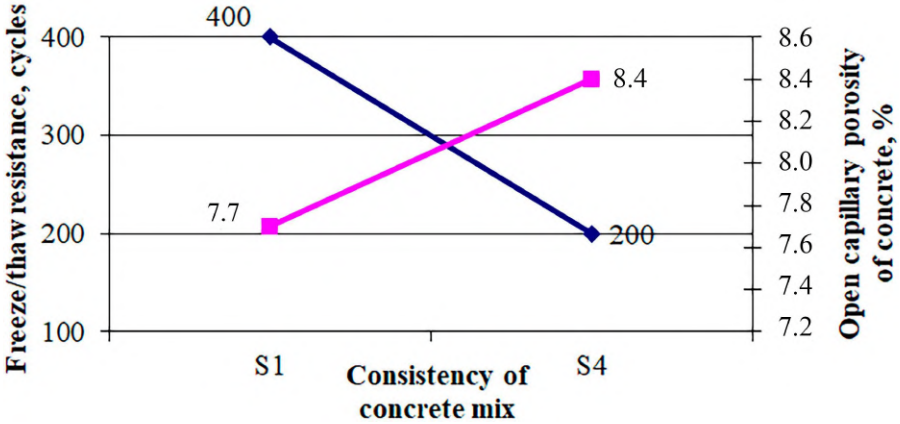
(*b*)

Figure 2. The influence of consistency and form of alkaline component on the volumes of open capillary pores (*a*) and conditionally closed pores (*b*) of alkali-activated blast furnace cement concrete.

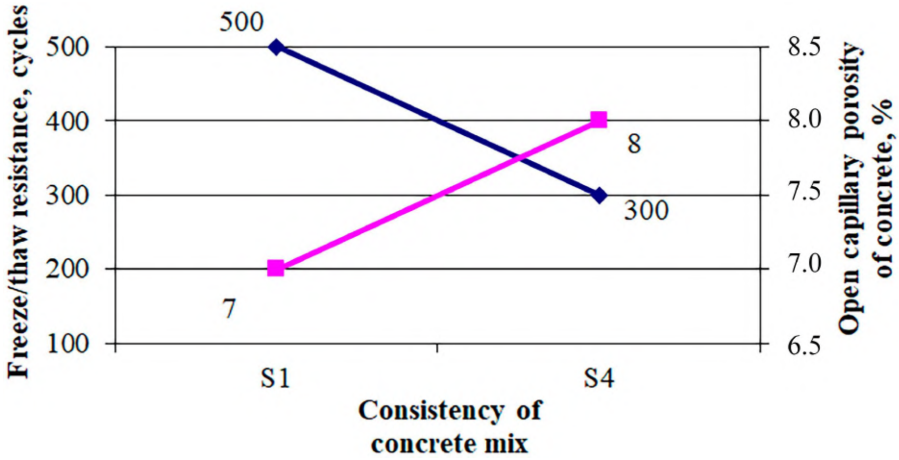
Lack in filling intensity of porous space by hydrosilicate gel caused this phenomenon (figure 2a).

Decreasing volume of conditionally closed pores by 58.0 % and 43.3 % consequently occurred (figure 2b). Specified changes in porous structure ensured decreasing tendency in freeze-thaw resistance of AABFC concrete from F500 down to F400 (figure 4a) as well as from F300 down to F200 (figure 4b).

Obtained regularities confirm expediency of alkaline component exactly in the liquid form, that is on contrary to modern requirements concerning production of AABFC's namely under "all-in-one" technology.



(*a*)



(*b*)

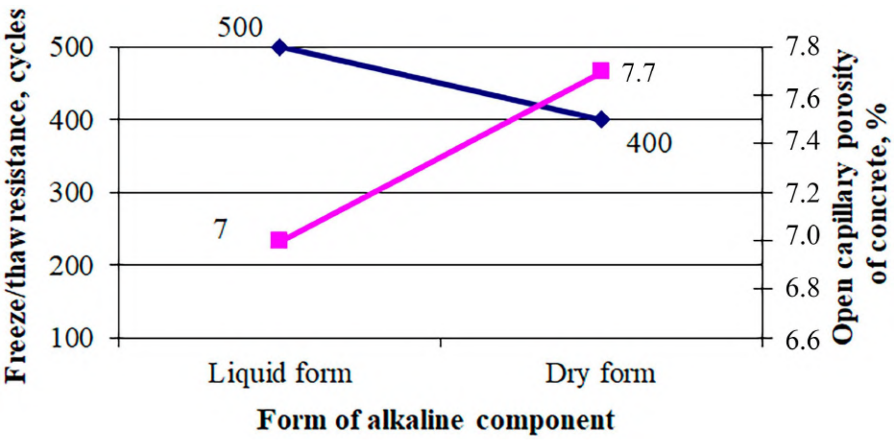
Figure 3. Open capillary porosity and freeze-thaw resistance of alkali-activated blast furnace cement concrete vs. form of alkaline component: dry form (*a*), liquid from (*b*).

3.2. Effect of curing conditions
Normal curing conditions of AABFC concrete was more advisable if compared with curing in water or under steam curing in the view of formation of effective porous structure (table 2).

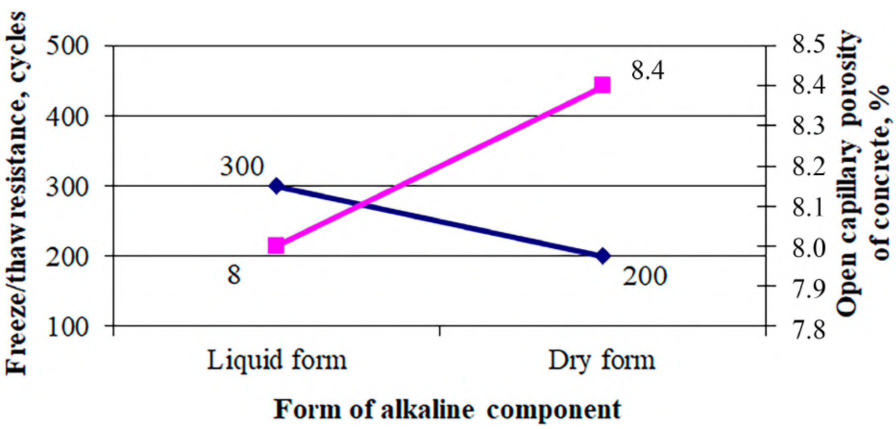
Porous structure of plasticized AABFC concrete, at consistency of class S4 and after hardening during 28 d under normal conditions, was characterized by decreased volume of open capillary pores by 5.0 % and 1.3 % as well as by increased volume of conditionally closed pores by 35.7 % and 20.0 % compared with analogues under water or steam curing (figure 5). Specified changes in porous structure contributed to formation of AABFC concrete with more dense and impermeable structure, which is able for self-healing. This phenomenon provided advanced freeze-thaw resistance mark F300 in contrast to marks F200 and F250 of analogues (figure 6).

Thus, effective technological decisions to ensure advanced freeze-thaw resistance of AASC concrete in solution of sodium chloride as criterium of its sustainability were determined.

4. Conclusion
1. The activization of blast furnace cement by alkali metal compounds although taking into account the influence of technological factors on porous structure of concrete can provide



(a)



(b)

Figure 4. Open capillary porosity and freeze-thaw resistance of the alkali-activated blast furnace cement concrete vs. consistency: class S1 (a), class S4 (b).

Table 2. The porous structure and freeze-thaw resistance of alkali-activated blast furnace cement concrete versus curing conditions.

Curing conditions	Strength class of concrete	W/C	Consis-tency, cm	Water absorption Wm, %	Changes in mass, %	Changes in strength, %	Freeze-thaw resistance
			Dry form of alkaline component				
Water	B35	0.36	18	4.0	-0.12	-1.68	F200
Steam curing	B35	0.36	19	4.2	+0.16	+1.85	F250
Normal conditions	B35	0.36	19	4.1	+0.12	+4.608	F300

its sustainable performance by criterium of advanced freeze-thaw resistance in solution of sodium chloride. Fresh concrete consistency, aggregate state of alkaline component and

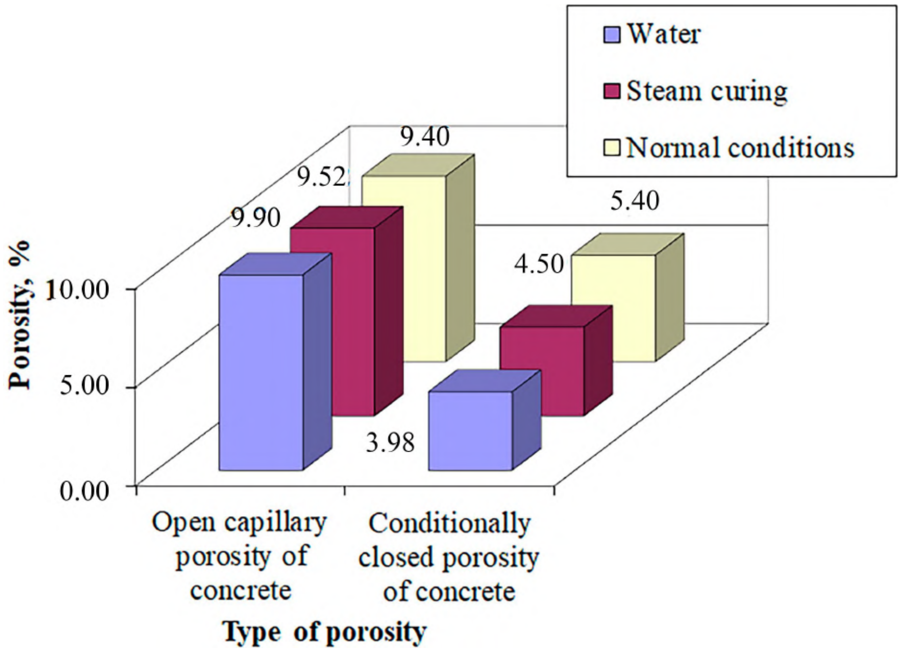


Figure 5. Porous structure of alkali-activated blast furnace cement concrete vs. curing conditions.

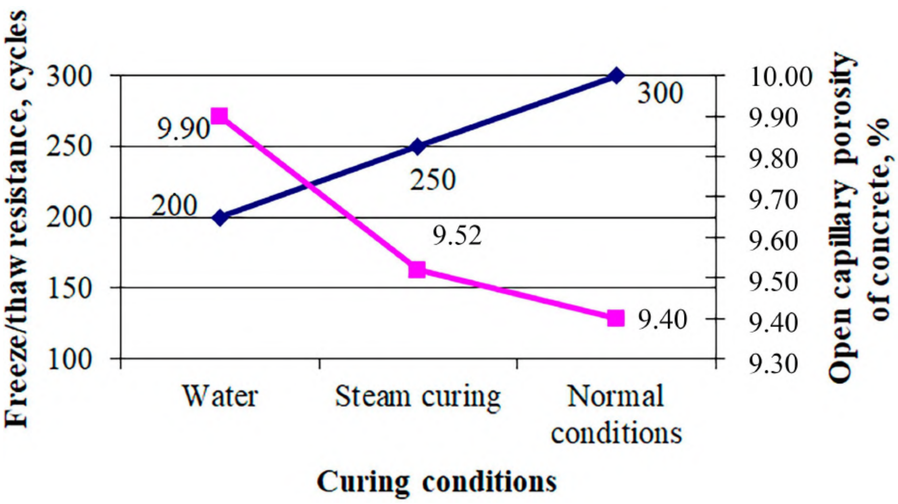

Figure 6. The volume of open capillary pores and freeze-thaw resistance of alkali-activated blast furnace cement concrete vs. curing conditions.

curing conditions are considered as appropriate technological factors to handle the structure of alkali-activated blast furnace cement concrete under the exposure class XF4.

2. It was shown, that increasing of fresh concrete consistency from class S1 up to class S4 by means of chemical modification as well as application of alkaline component in dry form caused less freeze-thaw resistance of alkali-activated blast furnace cement concrete in solution of NaCl as a result of negative changes in porous structure. Thus, application of complex admixture “polyorganosiloxane – sodium lignosulfonate – polyethylene glycol” while use of alkaline component in dry form ensured increasing open capillary porosity by

20 % and decreasing of conditionally closed porosity by 67 % that was accompanied by diminution of freeze-thaw resistance the concrete by 60 %.

3. It was revealed, that negative effect of plasticization can be compensated while dry form of alkaline component and sustainable performance of alkali-activated blast furnace cement concrete can be ensured due to hardening under appropriate temperature-humidity conditions. In that way, freeze-thaw resistance of the plasticized concrete while hardening in normal conditions, in contrast to hardening in water or under steam curing, increased up to 1.3…1.5 times in consequence of reduced open capillary porosity by 5.0 % and increased volume of conditionally closed pores by 36.0 %.

E-mail: msanytsky@ukr.net

Abstract. The present study examined the effectiveness of pozzolanic supplementary cementitious materials (P-SCMs), such as fly ash (FA), super fine zeolite (SFZ) and silica fume (SF), in reducing the energy intensity and CO_2 emissions of concrete based on ordinary Portland cement. Optimization of the composition of the P-SCMs was carried out by the simplex-lattice Scheffe method according to the criterion of pozzolanic activity. The type and level of P-SCM replacement was analyzed to improve cement paste properties and target CO_2 reduction in concretes. It is shown that the combination of pozzolanic materials of different origin and granulometric composition helps to improve the quality of bended cements and speed up the concrete production process. Blends of pozzolanic P-SCMs results in environmentally friendly concrete with a significant positive impact on the environment. This can be considered the main initiative of sustainability of concrete production.

1. Introduction

An important problem according to the priority areas of the European Green Deal is ensuring carbon neutrality, introducing innovations, modernization and greening of industry. According to the low-carbon development strategy presented by the European Cement Association (CEMBUREAU), it is necessary to reduce carbon dioxide emissions at every stage of the production and technological chain – from the production of clinker, cement and concrete to construction. Already by 2030, it is planned to reduce CO_2 emissions during the production of cement by 30%, and at the stage of concrete production and construction – by 40% [1–5].

Solving the problem of energy efficiency and reducing CO_2 emissions in building production is largely determined by the search for technological and ecological ways to replace a part of Portland cement clinker with supplementary cementitious materials (SCMs). Due to the rational selection of SCMs in the production of low-carbon cements, technical, ecological and economic benefits are achieved [6–8]. Another way is to add SCMs directly to the concrete mixture instead of a part of Portland cement, which helps to reduce the cost of concrete, increase its strength in subsequent periods of hardening, and increase durability. In this case, replacing each kilogram of clinker in concrete with supplementary cementitious materials allows reducing CO_2 emissions by 0.6–1.0 kg [9–12].

One of the main non-clinker constituent, which has been used in cement production for many years, is granulated blast furnace slag (GBFS) [13, 14]. At the same time, rapidly growing consumption of Portland cement as well as low availability of ground granulated blast furnace slag (widely used as SCM) serious steps should be taken to find alternative solution for cement industry. Therefore, there is a growing interest in the use of a by-product of thermal power plants – fly ash. This product is an amorphous vitreous pozzolanic material and, when mixed with cement, significantly affects the strength development of the cementitious composites. Fly ash increases the durability and strength of concrete at a later age, but at the same time reduces the early strength of concrete. It also reduces the amount of water-reducing admixtures required to obtain the same consistency [15–17]. However, the availability of fly ash is also limited in some parts of Europe. Therefore, it is recommended to add other types of pozzolans to the composition of so-called "green" cements together with fly ash. At the same time, with an increased amount of pozzolans, they significantly affect the strength of concrete. Silica fume significantly increases the strength and durability of concrete, but it has a high water demand, so it requires the use of an increased amount of water-reducing admixtures [18, 19].

Significant resources in the European region of natural pozzolans – zeolite tuffs – make it possible to solve the problem of regional application of SCMs [20–22]. High-silica zeolite tuffs (the main mineral is clinoptilolite $(\mathrm{Na, K})_6[\mathrm{Al_6Si_{30}O_{72}}]24\mathrm{H_2O}$) have unique characteristics, such as a high specific surface area and the ability to exchange cations. The introduction of natural zeolites allows binding excess alkalis $(\mathrm{Na^+, K^+})$ into insoluble hydroaluminosilicates as part of inorganic complexes.

The pozzolanic activity of SCMs, which is evaluated by their reactivity, mainly depends on three parameters – the nature of the activity (hydraulic, pozzolanic), the chemical composition of SCMs and their dispersion, while SCMs particles smaller than 10 micrometers are reactive [23–25]. The effectiveness of the increased dispersion of artificial and natural pozzolans is confirmed by the development of ultrafinely dispersed supplementary cementitiouse materials that belong to superpozzolans and provide accelerated binding of calcium hydroxide – a product of the hydrolysis of the alite phase of Portland cement clinker [26, 27]. Such interaction of superpozzolana with products of hydration of Portland cement clinker leads to a decrease in porosity, which helps to increase the strength, corrosion resistance of concrete and determines its durability. However, a high content of finely dispersed SCMs causes an increase in the water consumption of concrete, which leads to a loss of early strength [28–30].

The physical approach opens significant prospects for improving the technical properties of building composites. It consists in not changing the chemical and mineralogical composition of Portland cement clinker, but reducing the water-binder ratio (W/B) of multicomponent cementitious systems and increasing the packing density of binder grains in the cement paste with the help of highly effective superplasticizers, especially of the polycarboxylate type [31, 32].

The creation of modified concretes using multi-component SCMs involves the optimization of their compositions due to the intensification of pozzolanic reactions in the concrete cementitious matrix. The effectiveness of such an idea lies in the maximum disclosure of the synergistic role of highly dispersed pozzolans in the composition of low-carbon cementitious systems, which will ensure a directed effect on the processes of regulating the properties of modified concrete and mortars. The assessment of the indicator of the impact of multi-component SCMs on the environment allows to determine their suitability for the production of low-carbon concrete. In advanced EU countries, $\mathrm{CO_2}$ emissions are reduced to 83.4 kg of $\mathrm{CO_2}$ per 1 ton of concrete. One of the main directions of reducing the $\mathrm{E_{CO_2}}$ indicator is the replacement of a part of Portland cement CEM I type in concrete with multicomponent mineral additives, which is a relevant approach to achieve sustainability in construction industry [33–35].

In recent years, significant attention of researchers and manufacturers has been attracted by alkali-activated binders, which provide significant potential for the development of promising technologies [36–38]. Alkali-activated cementitious materials are characterized by accelerated hardening and are at the epicenter of a new and necessary transition from modern Portland cement to eco-cements of the future. In particular, this technology may soon reach such a stage of development that it will serve as a link for the development of clinker-free alternative binders [39–42].

The purpose of the work is the rational design of the granulometric and material composition of combined pozzolanic SCMs, which, when combined with admixtures of superplasticizing action, create the possibility of obtaining eco-efficient modified blends with specified quality indicators and a reduction in CO_2 intensity per product unit.

2. Raw materials and testing techniques

The Portland cement CEM I 42.5 R JSC "Ivano-Frankivskcement" (Ukraine) was used in experiments. The contents of the main clinker phases, mass.%: C_3S – 61.95; C_2S – 12.31; C_3A – 7.0; C_4AF – 11.75.

Pozzolanic supplementary cementitious materials (P-SCMs) were used for the study:

- natural zeolite with 69.8 mass.% SiO_2 provided from Sokyrnytsky quarry. Super fine zeolite (SFZ) was obtained by grinding natural zeolite to a specific surface area greater than SSA=11000 cm^2/g;
- fly ash (FA) with 57.8 mass.% SiO_2 and 24.2 mass.% Al_2O_3 from Burshtyn TPP, SSA=4100 cm^2/g;
- silica fume (SF) Elkem Microsilica Grade 940-U with 94.7 mass.% SiO_2, SSA=18 000 cm^2/g.

Superplasticizer type polycarboxylate ethers (PCE) was used in this study. Lignosulfonate (LS) was used for comparison.

The chemical composition of fly ash and zeolite was determined using an ARL 9800 XP X-ray spectrometer (Thermo Electron SA, Switzerland). The specific surface of Portland cement and SCMs was determined on Blaine's device. Determination of the strength of blends was carried out in accordance with DSTU B EN 196–1:2015, bleeding in accordance with DSTU B EN 196–3:2015, DSTU B EN 196–6:2015. Pozzolanic activity was determined according to EN 450-1:2009, ASTM C593-06 [43]. According to the methodology based on Italian method, the strength indicators should be $R_f \geq 0.5$ MPa. and $R_c \geq 2.5$ MPa.

The optimization of the composition of pozzolanic supplementary cementitious materials (P-SCMs) was carried out by the simplex-lattice Scheffe method according to the criterion of pozzolanic activity according to EN 450-1:2009. The optimal ratio between P-SCMs components was determined using a simplex-lattice Scheffe "blend-properties" plan to ensure an even spread of experimental points in the factor space. The Gibbs concentration triangle was used in the analysis of the experimental plan. The criterion of pozzolanic activity of P-SCMs according to EN 450-1:2009 was used as the target function. The criteria for the effectiveness of the modifiers (plasticizing and water-reducing effects) were determined according to DSTU B V.2.7-69.

3. Results and discussions

Highly dispersed SCMs such as super fine zeolite and microsilica are characterized by increased water demand – 42.5 and 55.0 %, while having low bleeding (3.0 and 1.0 %, respectively). Fly ash has a lower dispersion compared to other pozzolanic materials. Fly ash is characterized by particles of the correct spherical shape, which provide a plasticizing effect due to the "roller bearing effect". Therefore, its water demand is reduced (27.0 %), but it is characterized by significant bleeding (34 %).

According to EN 450-1:2009, the strength activity index (SAI) after 28 days should be more than 75%, and after 90 days – more than 85%. As can be seen from the figure 1, super fine zeolite and silica fume reach the corresponding indicator of Psai $\geq$ 75% already after 2 days of hardening. The SAI of fly ash meets the requirements of EN 450-1:2009, but is significantly lower compared to super fine zeolite and silica fume.

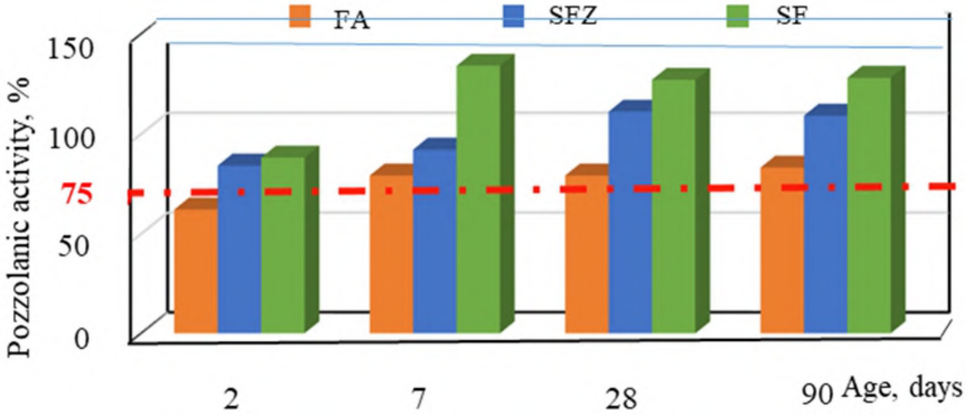

Figure 1. Pozzolanic activity of SCMs according to EN 450-1:2009.

According to ASTM C593-06, the mortar strength for super fine zeolite is 5.2 MPa (requirement $R_c \geq 4.15$ MPa), while for fly ash it is 4.5 MPa. According to the methodology based on Italian method [26], the strength indicators of lime-pozzolan paste in the ratio lime:pozzolan=1:3, for microsilica and super fine zeolite after 28 days of hardening reach 4.6/9.5 MPa and 3.2/7.9 MPa, respectively, and for fly ash – 0.6/1.8 MPa.

The optimal compositions of complex pozzolanic supplementary cementitious materials blends FA – SFZ – SF are determined by the indicator of Strength Activity Index (SAI). The combined effect of components on the pozzolanic activity of P-SCMs after 28 and 90 days of curing was investigated using the Scheffe simplex-lattice plan "blends-property" method. For the three-component mixture "SFZ (X1) : FA (X2) : SF (X3)" each point of the triangular diagram corresponds to one P-SCM ratio. The regression equation, taking into account the significance of the pozzolanic activity coefficients of the P-SCMs blends after 28 and 90 days, is as follows:

$$\mathrm{Psai}_{28} = 84.3456 \cdot X1 + 60.2381 \cdot X2 + 88.7843 \cdot X3 - 20.349 \cdot X1 \cdot X2 - 78.8945 \cdot X1 \cdot X3 - \\ -67.9326 \cdot X2 \cdot X3 + 27.6734 \cdot X1 \cdot X2 \cdot X3.$$

$$\mathrm{Psai}_{90} = 111.4523 \cdot X1 + 76.3598 \cdot X2 + 127.9043 \cdot X3 - 40.641 \cdot X1 \cdot X2 - \\ -88.8047 \cdot X1 \cdot X3 - 35.9429 \cdot X2 \cdot X3 + 8.6034 \cdot X1 \cdot X2 \cdot X3.$$

The analysis of the response function surfaces (figure 2) allows to establish that for the two-component P-SCMs-2, the optimal values of the pozzolanic activity indicators are achieved at the ratio FA : SFZ = 0.46 : 0.54, which after 28 and 90 days are respectively $\mathrm{Psai}_{28} = 94$ % and $\mathrm{Psai}_{90} = 126$ %. At the same time, for the ternary mixture P-SCMs-3, the maximum SAI values are achieved at the ratio FA : SZF : SF = 0.35 : 0.40 : 0.25, with $\mathrm{Psai}_{28} = 99$ % and $\mathrm{Psai}_{90} = 134$ %. When the content of fly ash increases over 60 mass.% in the FA – SFZ – SF pozzolan blends, a decrease in the pozzolanic activity of the combined SCMs is observed. Therefore, the combination of highly active pozzolans (SFZ and SF) with fly ash, which has a plasticizing effect, allows to obtain a three-component pozzolan additive P-SCMs-3, which provides optimal workability and strength of binder.

Studies of the effects of the three-component complex pozzolanic additive P-SCM-3 on the physical and mechanical properties of binders have established that with an increase in the content of P-SCM-3 from 25 to 75 mass.% in the composition of blends, there is an increase in the specific surface from 5900 to 7700 cm^2/g, an increase in water demand by 5.0 %, an extension of the hardening period and a decrease in the bleeding coefficient from 14.4 to 6.8 %. Early strength of blends with a content of 25 mass.% of P-SCM-3 is reduced by only 13 % compared

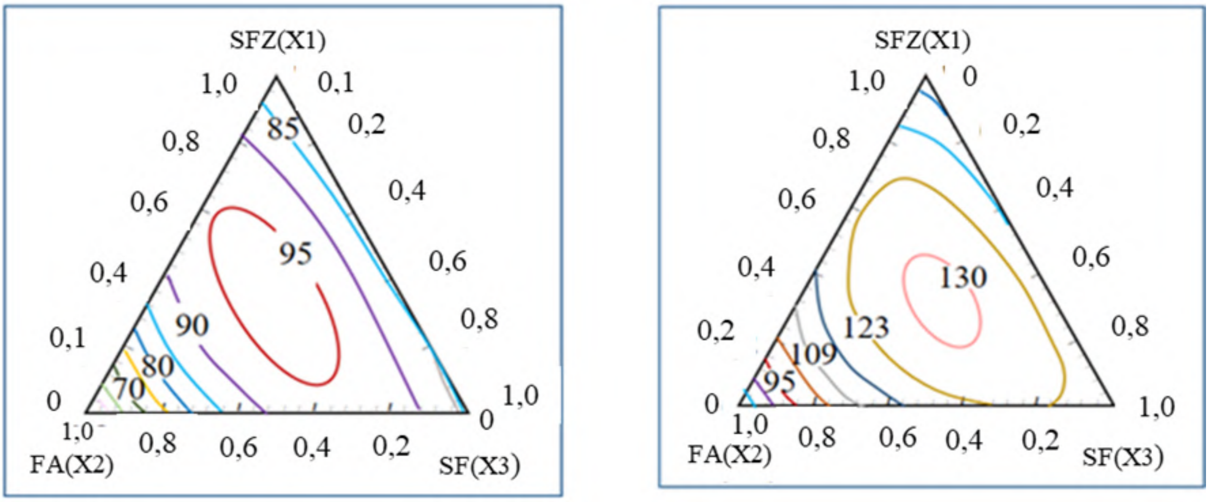

Figure 2. Isolines of effects of the composition of P-SCMs "SFZ – FA – SF" on pozzolanic activity after 28 days (a) and 90 days (b).

to CEM I. With the content of the combined pozzolanic additive P-SCM-3 increases, the early strength decreases proportionally. With a content of 50 mass.% P-SCM-3 in the composition of the blend after 28 days of hardening, the difference in strength is 13 %, that is, due to pozzolanic reactions, a certain increase in strength is achieved. To obtain pozzolanic blends of strength classes 32.5 and 42.5, the effective range of replacing Portland cement CEM I with a combined pozzolanic SCMs is 25...50 mass.%.

Significant reserves of improving the physical and mechanical properties of pozzolanic blends are achieved due to the use of LS and PCE plasticizing admixtures. As can be seen from the table 1, when introducing 1.0 mass.% PCE to blend of 50 mass.% CEM I 42.5R + 50 mass.% P-SCM-3, the flow ability of a standard cone (W/C=0.50) increases from 144 to 290 mm, and when 0.8 mass.% LS is introduced, it increases to 225 mm. For the LS-modified blend, the water-reducing effect is Δ W/C = 14 %, and when modified with 1.0 mass.% PCE – Δ W/C = 22 %. At the same time, the blend modified by PCE is characterized by higher compressive strength (R_{c2} = 20.6 MPa and R_{c28} = 54.4 MPa).

Table 1. Influence of modifiers on the physical and mechanical properties of the blend of 50 mass.% CEM I + 50 mass.% P-SCM-3.

The amount of modifier, %	W/C	Flow, mm	R_{c2}, MPa	R_{c7}, MPa	R_{c28}, MPa
–	0.50	144	11.9	32.5	40.7
		PCE			
1.0	0.50	290	11.9	33.5	38.7
1.0	0.39	145	20.6	38.8	54.4
		LS			
1.0	0.50	225	12.8	24.1	37.3
1.0	0.43	141	18.3	35.6	48.1

By mixing CEM I 42.5R and 50 mass.% P-SCM-3 low-carbon pozzolanic cement type CEM IV (SSA=6850 cm^2/g) was obtained. When tested according to DSTU B EN 196-1:2015, the compressive strength after 2 and 28 days is 15.0 and 44.8 MPa, which corresponds to CEM IV/B 42.5. For this pozzolanic cement, the water demand is 31.5%, the bleeding is 9.1%. Thus, optimization of the granulometric and substance composition of blends allows to obtain low-carbon blended cements of strength class 42.5. Using the method of differential calorimetry, it was established that for this pozzolanic cement the heat of hydration after 24 h decreases by 1.55 times compared to CEM I 42.5 R and is 149 J/g, that is, according to DSTU B EN 197-1:2015, this pozzolanic cement refers to CEM IV/B 42.5– LH.

Carbon dioxide emissions of cement and concrete are significantly reduced with the combined use of FA, SFZ and SF. For blended pozzolanic cements (clinker factor – 0.50) CO_2 emissions are reduced to 456 kg/t, which is 45% less compared to Portland cement CEM I 42.5 R. At the same time, the total energy costs for grinding pozzolana cement (32 kW·h/t) are 40% smaller compared to CEM I. When using complex pozzolanic supplementary cementitious materials, optimization of the properties of binder is ensured: workability, standard and early strength, durability, cost, impact on the environment.

4. Conclusion

Modified multicomponent pozzolanic supplementary cementitious materials (P-SCMs) containing fly ash, super fine zeolite, silica fume, in combination with superplasticizer admixtures, can be effectively used to improve both fresh and hardened properties of concrete. Fly ash is commonly used with silica fume in concrete production to compensate for the slow strength development of fly ash at early ages. The use of super fine zeolite instead of silica fume or its part opens up new opportunities for improving the technological and technical properties of concrete.Technologically optimized blends based on combined pozzolanic SCMs become a rational solution to the problem of improving the energy efficiency of building production. Sustainability assumes that the combination of SCMs with pozzolanic action of different dispersions, based on fly ash, super fine zeolite and silica fume, ensures reduction of CO_2 emissions and cost of concrete production.

Abstract. Modern building structures must meet the requirements of efficiency and resource-saving. The main direction for implementing these requirements is to reduce the consumption of steel (14–16%) and save cement (10–12%). These tasks can be solved through the rational combination of concrete and steel when they work together and the use of high-strength materials. One embodiment of this task is the use of Concrete Filled Steel Tube (CFST) structures. The purpose of this study is to identify the possibility of using the Drucker-Prager model by comparing the results of test studies on short compressed Concrete Filled Steel Tube (CFST) elements with different strength and deformation characteristics of the concrete core to the results from finite element analysis (FEA) modelling of corresponding CFST elements. Additionally, the behaviour of a steel pipe without a concrete core was investigated. The results show that the FEA method used in this work is sufficiently accurate for studying the behaviours of short CFST elements. The modelling technique adopted in the study made it possible to consider the redistribution of stresses in the concrete and pipe dynamically. The stress distribution patterns inside the concrete during both linear and non-linear deformations of CFST elements, as well as the characteristics of the interaction between the concrete and pipe in the contact zone, have been revealed.

1. The problem formulation and its relationship with scientific and practical tasks

The construction of modern buildings and structures requires the use of compressed elements with a high bearing capacity. One of the solutions to this problem is the use of Concrete Filled Steel Tube (CFST) elements. However, the wide distribution of this type of structural element is their significant metal consumption. In compressed CFST elements, the load is taken by both the pipe shell and the concrete core [1, 2]. Increasing the bearing capacity of the core helps to reduce steel consumption while maintaining the bearing capacity of the CFST element [3]. In the limiting state, CFST does not collapse in the conventional sense. Because the destroyed concrete reinforced by the shell is included in the joint work. That is, the combination of one structural element of several components from different structural materials leads to the formation of a special state of interaction between them. Therefore, the use of a rationally selected core will lead to a significant reduction in the need for metal and cost savings during the construction of the structure. Thus, the study of the behaviour of solid section elements compressed by CFST will allow choosing of the most effective design solutions for such structures. Modern FEA methods for simulating the behaviour of structures allow you to get significant savings in time and resources when checking the correctness of the design decisions made. However, to ensure the similarity of mathematical and physical models, it is necessary to use modern models of the behaviour of materials, in particular, concrete.

2. Research and publications analysis

At present, buildings and structures designed and built using CFST are represented almost all over the world. At the moment, the robot TB under static loading has been widely studied. In work [4] stress-strain state CFST was estimated using the complex variable apparatus. The resulting solution is exactly within the boundaries of the formulated prerequisites. The key of which is the continuous joint work of individual components (pipe and concrete core) at all stages of loading until the limit state is reached. An analysis of the comparison results revealed that satisfactory agreement between theoretical and experimental studies was only for samples with a core of ordinary heavy concrete of low and medium ranges of strength classes. Thus, this approach limits the possibility of extending the obtained solution to CFST elements with other component materials, for example, high-strength concretes. In addition, the results obtained cannot be extended to other design solutions other than a solid two-component CFST element. For example, elements with voids in a concrete core, reinforced cores, etc. In the work [5] the method of estimating the stress-strain state based on the mechanical model of a composite body is considered. This approach makes it possible to take into account the loss of contact interaction between individual CFST components. This adequately describes the operation of a CFST element with a wide range of physical and mechanical characteristics of the components. In addition, the general methodological approach allows us to consider any design solutions for the CFST element, for example, to take into account additional bar reinforcement, etc. But a significant drawback is the laborious process of forming a system of resolving equations for the skin of such design solutions. At the same time, the issue of ambiguity in the conduct of calculations for such structures hinders the wider introduction of this kind of combination of steel and concrete, including taking into account the strengthening of their cores. The aim of the research was to formulate the prerequisites for performing an analytical calculation of compressed CFST elements with a high-strength core, as well as to evaluate the effectiveness of structural CFST elements with hardened cores compared to steel elements.

Due to many advantages that draw attention to the presented designs [6, 7], previous studies were aimed at clarifying the mechanism of development of the stress-strain state of CFST elements with a hardened core for a more reliable and specific assessment of their characteristics [8–15].

Previous CFST studies using FEA [16–22] have shown that it is possible to accurately model the behaviour of this type of structural element. However, most of the considered models worked only at the stage of linear deformations of the concrete core. The study of the nonlinear behaviour of concrete was hampered by the lack of software implementation of nonlinear models of concrete behaviour, such as the Drucker-Prager model.

3. Formulation of the problem

Combining the geometric parameters and mechanical properties of the materials of the CFST components provides a variety of design options. Each of them has its own advantages and disadvantages. This creates uncertainty in the final decision. The choice can be made only by having an idea about the work under a load of a particular design solution. The developed methods for designing CFST structures, which are based on exact mathematical solutions, are cumbersome and limited in application. For adequate modelling of the stress-strain state of complex structural elements, it is not enough to imagine a model in which individual elements have excellent mechanical characteristics. The transition between different stress-strain state CFST structures throughout their life cycle is caused by a change in the magnitude and direction of external force factors. Therefore, the search for an adequate mechanism for assessing the stress-strain state of CFST structures is relevant.

The purpose of this study is to identify the possibility of using the Drucker-Prager model by comparing the results of test studies of short CFST elements with different strength and deformation characteristics of the concrete core with the results of FEA modelling of the corresponding CFST elements.

4. Statement of material and results

4.1. Methodology for conducting test studies

The purpose of this study is to identify the possibility of using the Drucker-Prager model by comparing the results of test studies of short CFST elements with different strength and deformation characteristics of the concrete core with the results of FEA modelling of the corresponding CFST elements.

Samples were tested after 28 days of natural hardening. Samples were tested in a GSM-250 press. The samples were loaded through the hinges along the longitudinal physical axis, the position of which was established by the trial loading method. The loading steps were 0.1 of the expected breaking force at the beginning of the test and 0.05 before reaching the ultimate limit state.

Longitudinal deformations during the testing of samples were measured using dial gauges with a division value of 0.01 mm. Simultaneously, the deformations in the compressed elements were measured using electric strain gauges. The AID-2M device was used to take the indicators. Each electric strain gauge was connected to an AID-1 measuring device, through which deformations were recorded.

The mechanical characteristics of the metal were determined by testing empty pipes for compression. Tensile strength was determined on standard samples-strips cut from the walls of pipes. The test results are given in table 1. The characteristics of concrete were determined

Table 1. Physical and mechanical characteristics of steel pipes.

Sample Series	Pipe diameter and wall thickness D_{xt}, mm	Compressive strength, MPa	
		R_y	R_u
P	163.0×5.5	317	475

by testing concrete prisms. The longitudinal and transverse deformations were measured with the help of electric strain gauges. Longitudinal strains were also measured with dial gauges. According to the results of the test, graphs of the dependence of deformations on stress $\sigma - \epsilon$ were plotted, the prismatic strength was determined, and Young's modulus and Poisson's ratio of concrete were calculated. The cubic strength of concrete was determined by testing cubes with an edge of 150 mm. The deformation - strength characteristics of concrete are given in table 2.

Table 2. Deformation - strength properties of concrete.

Sample Series	$f_{ck,cube}$, MPa	$f_{ck,prism}$, MPa	$E_b \times 10^{-4}$, MPa	ν
CFST 1	26.8	18.8	1.98	1.98
CFST 2	82.3	64.2	2.20	0.14
CFST 3	98.7	80.0	2.40	0.13

4.2. Modelling method adopted in the work
The modelling of the operation of CFST elements was carried out considering the nonlinear function of the components. The calculation was carried out considering large deformations. By the task, the CFST elements have a symmetrical tubular section and a central load case, to reduce the size of the model and reduce computational costs, the analysis was carried out considering the modelling of cyclic symmetry. In this case, the behaviour of one symmetrical sector (1/4 of the tubular component) was calculated, and the results obtained were used to build the response behaviour of the full component (as a post-processing step).

The simulation was carried out using the non-commercial software ANSYS Student by the finite element method in the Workbench environment. The non-linear calculation of CFST elements was carried out considering the concrete work model – Drucker-Prager and taking into account the multilinear isotropic hardening of steel. The joint work of the steel pipe and the concrete core in the model was provided by frictional contact. Following studies [18], the friction coefficient was taken equal to 0.5 in the simulation. [23].

Three models of CFST elements were analysed, which had the same external diameter of 119 mm but differed in the strength of the concrete core. In addition, the behaviour of a steel pipe without a concrete core was investigated.

4.3. Features of concrete modelling
The Drucker-Prager model was used to simulate the behaviour of concrete, which describes the nonlinear behaviour of concrete and is based on the theory of plastic flows. The calculation of the parameters of the Drucker-Prager model was carried out according to the methods proposed in the works [24–29]. The validity of the accepted parameters was tested in the work [30].

The parameters given in table 3 were used in the calculations of the behaviour of concrete.

4.4. Features of steel modelling
Considering large plastic deformations, the steel pipe material model was developed considering multilinear isotropic hardening. Non-linear steel curves are found in Figure 1, and steel structural information data are presented in table 4.

4.5. CFST FEA model
When preparing the mathematical model, the parametric design was applied, which allows changing the model when its geometry changes. CAD models were created in SpaceClaim. Models were transferred to ANSYS Workbench via a direct interface.

The contact between the concrete core and the steel pipe was assumed in the calculations as Frictional, with a friction coefficient of 0.5. The connection between the base plates and the pipe was set as Bonded and between the base plates and the pipe was Frictionless.

All elements were modelled using SOLID186 hex elements. The SOLID186 element is defined by 20 nodes having three degrees of freedom per node. The element maintains ductility, hyperelasticity, creep, large deflections, and large stresses. The size of the concrete element

was taken equal to 15.2 mm, for the pipe - 5.5 mm. The size of the elements of the base plates was assumed to be 32 mm (figure 2).

The boundary conditions of the lower support plate were modelled as Fixed Support (figure 3). To improve the convergence of the matrix, the elements were loaded not through the application of a load, but through deformations. Therefore, the boundary conditions of the upper base plate were modelled as Displacement along the Y-axis. The displacement was carried out step by step in equal shares. In total, during 10 steps, the plate was displaced by 30 mm. The CFST behaviour was studied at each loading step.

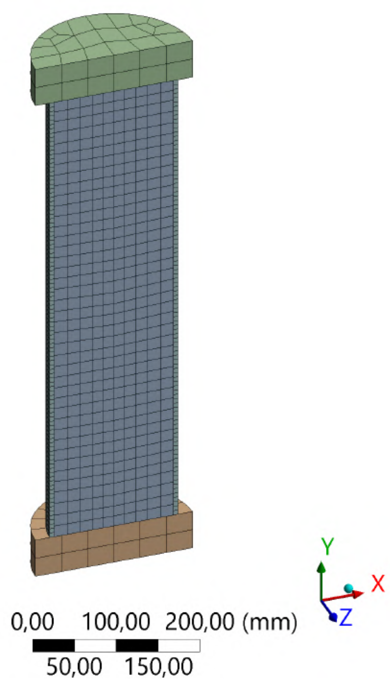

Figure 2. CFST element FEA model.

4.6. Results comparison of simulation and natural experiments

The dependences of deformations of CFST elements on the load were obtained because of test and FEA studies. The results are shown in figure 4 and figure 5. A comparison of the two groups of results shows that the simulation method used in the work is sufficiently accurate to study the behaviour of short CFST. Particularly good correlation is obtained in the region of linear deformations CFST. This allows us to conclude that the proposed method can be used to predict the strength characteristics of CFST elements.

The proposed method also made it possible to "look inside" CFST elements and obtain data that is difficult to obtain as a result of laboratory tests. The stress distribution patterns inside the CFST components at different loading levels are obtained. For example, figure 6 shows the distribution of equivalent stresses for sample CFST-2 at a load of 871 kN. It has been observed that the stresses within the volume of the concrete core are distributed unevenly. The modelling technique utilized in this study enables consideration of the redistribution of stresses within both the concrete core and pipe dynamically. Within the region of linear deformations, the stress distribution of the stress element at the centre of the concrete core and pipe did not

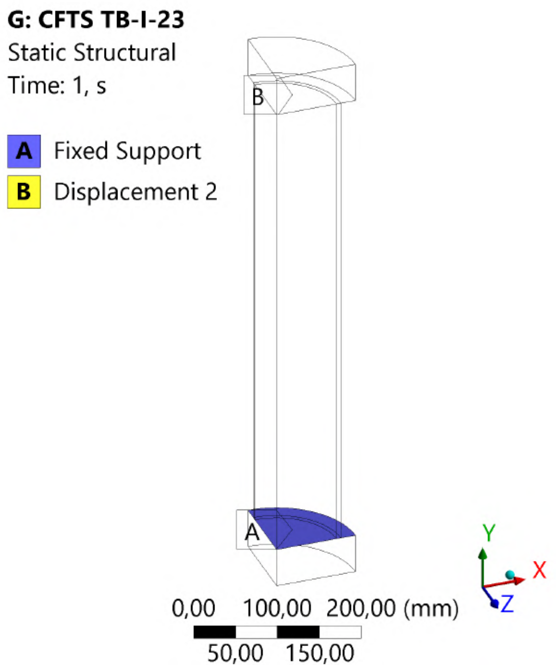

Figure 3. Boundary conditions of CFST element FEA model.

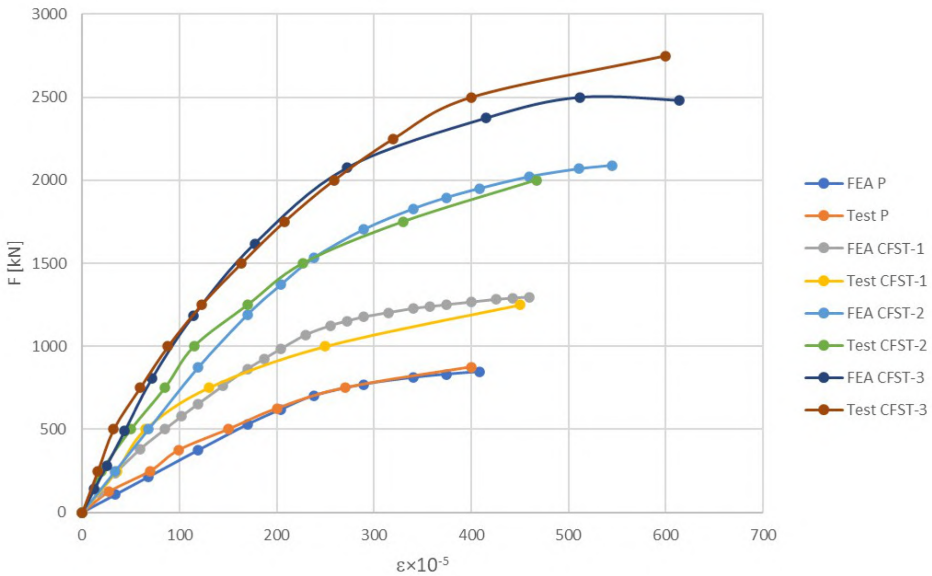

Figure 4. The longitudinal strain of a metal pipe and CFST elements.

differ. However, upon transitioning to the zone of non-linear deformations, the stresses in the longitudinal axis of the concrete core were found to be higher than those in the contact zone with the pipe.

Figure 7 shows the information on the Sliding Distance between the concrete core and the pipe for sample CFST-3 at a load of 2339 kN. Displacement of concrete relative to the pipe was observed in the edge zones adjacent to where the elements were fixed. The maximum

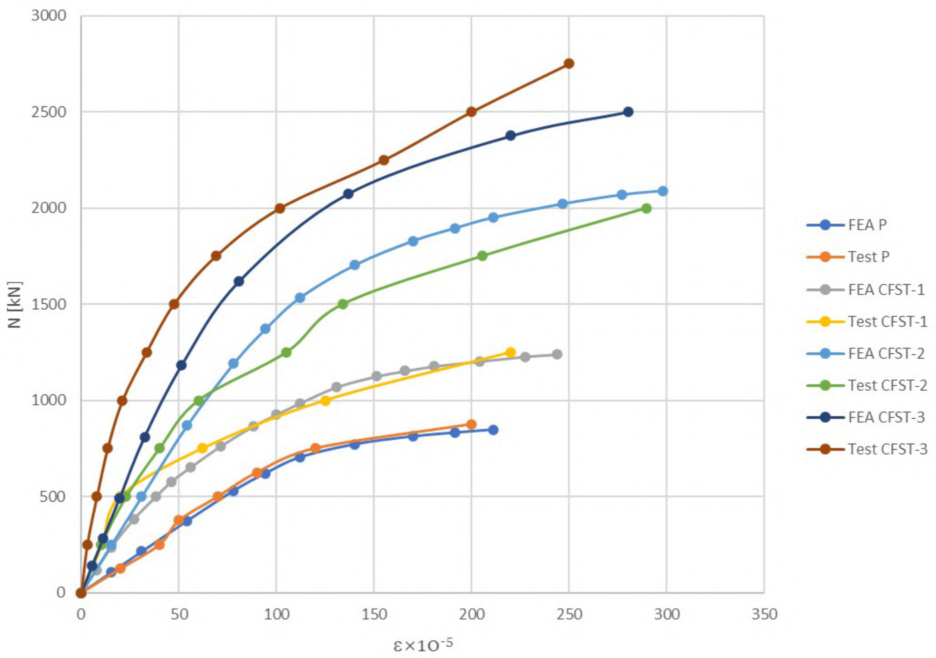

Figure 5. The transverse strain of a metal pipe and CFST elements.

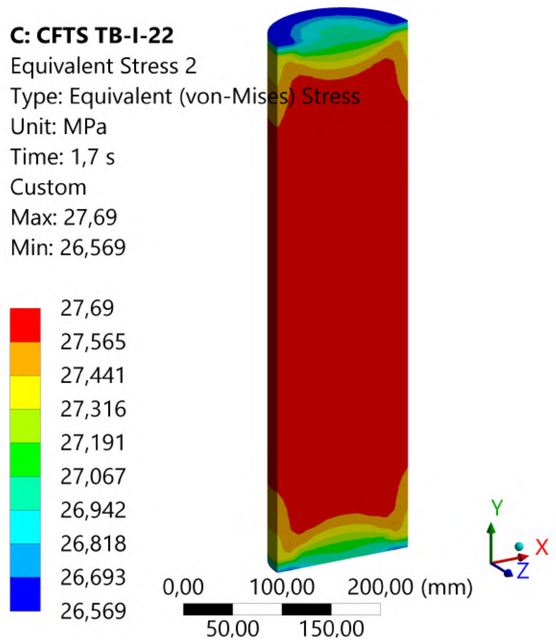

Figure 6. Distribution map of equivalent (von Mises) stress in sample CFST-2 at 871 kN.

displacements were found at a distance of approximately 1/8 of the element length from the fixing planes, where the maximum frictional stresses were also observed. In the central part of the CFST element, no displacement of concrete relative to the pipe was observed. As the transition from linear to non-linear deformations occurred, a gap was observed between the concrete and the pipe, with a value of approximately 0.05-0.06 mm for the middle part of the

CFST element. Before and after this transition, no gap was observed between the concrete and the pipe.

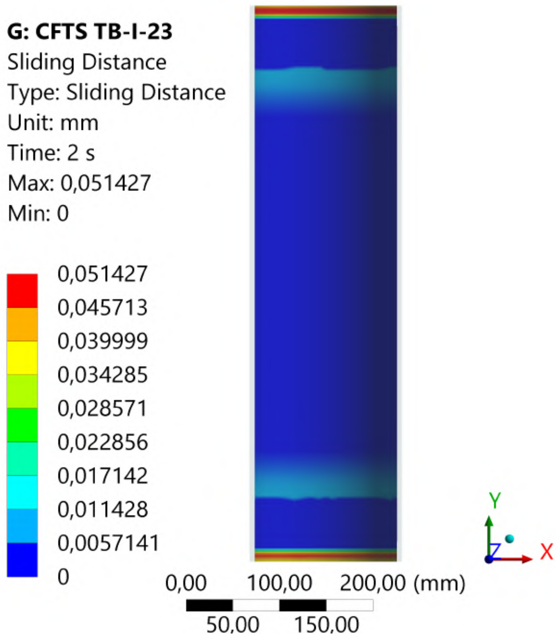

Figure 7. Sliding Distance between concrete core and pipe for sample CFST-3 at 2339 kN.

5. Conclusion

In this work, a comparison of the results of test studies of short CFST elements with different strength and deformation characteristics of the concrete core with the results of FEA modelling of corresponding CFST elements was carried out. This study's conclusions can be summarized as follows:

- The Drucker-Prager model, for which the parameters were calculated based on existing methods and verified for their adequacy, was used to model concrete.
- A model with multilinear isotropic hardening, for which a nonlinear stress-strain curve was set, was used to model steel.
- Parametric design, contact conditions, boundary conditions and step loading were used in the modelling.
- The study showed sufficient accuracy and adequacy of the proposed method for studying the behaviour of short CFST elements.
- The high degree of convergence between modelling and test results provides the possibility of using the Drucker-Prager model to model the behaviour of compressed CFST elements with different characteristics of strength and deformation of the concrete core.
- The application of the FEA method allows for a deeper study of the mechanism of interaction between the concrete core and the steel pipe.
- The proposed method made it possible to reveal the features of stress and displacement distribution in the components of CFST elements, which were detected by modelling and which are difficult to obtain by laboratory studies. In particular, unevenness of stresses in the concrete core, displacement of concrete relative to the pipe in the edge zones and appearance of a gap between concrete and pipe in the transitional regime were observed.

– The features of stress distribution inside the concrete core both in linear and nonlinear deformations of CFST elements, as well as the features of interaction between concrete and pipe in the contact zone, were revealed.

Abstract. The internal structure of metal products was investigated and it was identified that it affects quality and workability of equipment parts. Changes that occur in metal products structure during cold treatment by pressure, which lead to changes in physical and mechanical properties of products, have been analyzed. It was established that grains and borders between them, which determine internal structure of metal products, change their shape and size during cold rolling, depending on percentage reduction value. It is offered to consider grain borders as amorphous layer. Methodology has been developed to study influence of deformation degree during cold rolling to grain size of metal internal structure and intergranular layer volume. Intergranular surface area, its volume and part of surface volume from metal volume were determined. Parameters of internal structure of low-carbon steel were calculated depending on reduction value during cold rolling. According to study results, interconnection between grains size and deformation degree was established; and percentage reduction influence to grain size and borders between them was determined, obtaining a minimum standard grain size with percentage reduction of over 80 %; yield strength and its growth for metal alloy during cold rolling are established, which allows controlling the strength of steel by adjusting the grain size and their junction surface. It is shown that with an increase in deformation degree, yield strength of metal product material increases in hyperbolic dependence, and fraction of amorphous layer and strength properties of low-carbon steel change almost equally in exponential functions. It is revealed that during cold rolling, it is possible to control internal properties of obtained product by adjusting reduction value.

1. Introduction

During the process of mechanisms and machines structures manufacture, requirements for their strength, quality and reliability are constantly increasing. Detail properties are determined by internal structure of metal, which was used for manufacturing. In order to improve metal products quality, it is necessary to find opportunity to control strength of metal and alloys during their manufacture, due to improving internal structure of metal products.

Metals and alloys have certain properties that are divided into physical (specific weight, melting point, heat capacity, electrical conductivity, linear expansion coefficient, magnetic properties); mechanical (strength, hardness, resistance to impact, resistance to fatigue), which determine metals workability; technological (forging property, flowability, weldability, machining by cutting), which determine ability of metals and alloys to undergo different methods of hot and cold processing; chemical (corrosion resistance, high-temperature resistance, high-temperature strength), which determine stability of metals in aggressive environments at normal and high temperatures. All these properties depend on nature of metal and its internal structure, which consists of grains of various sizes. The finer grains in internal structure of metal are, the higher its strength and plastic properties. Therefore, investigation of metal structure change under influence of external factors is a relevant problem, and solution of this problem will enable to manage steel strength during rolling by means of identification of rational treatment modes and will improve metal products quality.

2. Analysis of literature data and problem definition

Within the framework of the program of stable development of metallurgy, the team of scientists of the Department of Metallurgy of Ferrous Metals and Foundry Production of the Kryvyi Rih National University is solving the following important tasks: improving the technology of foundry and rolling production and improving the quality of manufactured products [1, 2].

For correct choice of material for mechanisms structures manufacture with further adding mechanical and other properties that affect reliability and workability of machines, it's necessary to know internal structure of material at micro level. Metals and alloys consist of large number of small crystals of irregular shape – grains and borders between them [3,4]. Borders between grains form inner surface of metal. This surface area is area of intergranular borders in units of volume or mass of metal [5–7]. As it can be seen from sources, inner surface parameters significantly affect mechanical properties of metal products. Mentioned surface is characterized by its value, which depends on grains number and size (diameter), dislocations density, metal porosity and density, disorientation (angles magnitude between grains surfaces) and other parameters, i.e. thickness and volume of surface and fraction volume from total metal volume.

Structural features of crystalline grids of metals and alloys are formed when they crystallize. The faster cooling (crystallization) of melt is carried out, the more and smaller size of equiaxial grains is formed. Distance between the nearest atoms (crystal grid parameter) is less in completely solidified steel comparing to liquid state [6]. During solid steel cooling, grains jointing in it continues due to atoms diffusion, which is accompanied by decrease in intergranular borders. In this case, smaller grains having a larger surface curvature are gradually absorbed by larger grains with less surface curvature. Diffusion process is known of being quite slow. There may also be other behavior of grains and intergranular borders in steel during products deformation: they change shape, collapse, forming new additional surfaces due to grains crushing and formation of new dislocations – vacancies, pores and cracks [4, 6, 7].

During treating metals by pressure, plastic deformation of original material occurs, and it causes changes in its shape and size (figure 1) [2].

During cold rolling hammering harden, grinding and elongation of ferrite grains along the rolling direction occurs. Summarized reduction during cold treatment determines final texture of deformed material. In case of high degree of cold deformation, fine grain is formed. Ability of metals and alloys to plastic deformation is determined by material yield strength, which also depends on its internal structure. Metal alloys yield strength can change with treatment by pressure, which is especially noticeable during metal rolling of cold state. During metals treatment by pressure or during heat treatment, material strength and plasticity change due to change in internal structure – grains are crushed or enlarged, and number of dislocations or vacancies decreases in grains, pores appear and disappear, that means that junction surface between grains changes in metals volume [3, 4]. During cold rolling metal density usually decreases. This is due to the fact that during deformation intergranular cavities and cracks are formed.

Investigation of yield strength and its change under influence of external factors was carried out in works of [8–13].

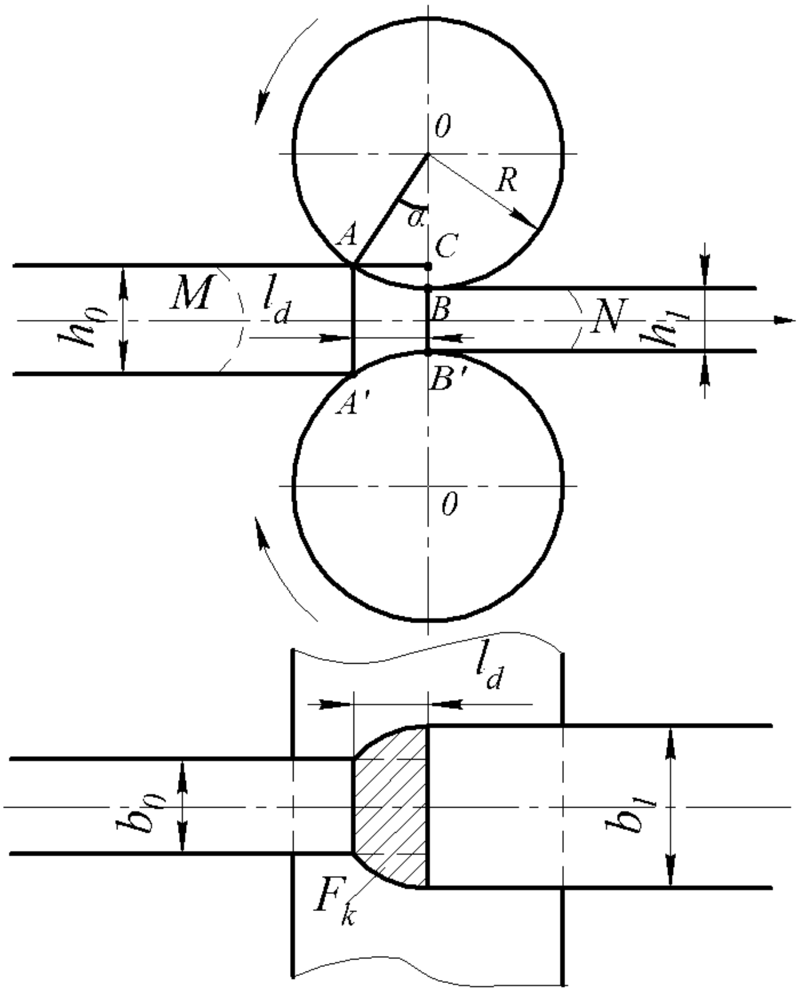

Figure 1. Deformation scheme: $ABB'A'$ is strain zone; h_0 is sheet thickness before rolling; h_1 is sheet thickness after rolling; b_0 is strip width before rolling; b_1 is strip width after rolling; α is capture angle during rolling; h_0, h_1 – initial and final thickness of strip accordingly R is roll radius; F_k is contact area of the sheet with the rolls; l_d is length of the strain zone; M is metal flow before entering the strain zone; N is metal flow when leaving the strain zone.

According to authors, research in this area shall be continued and influence of reduction value during cold rolling on grain size and borders between them shall be considered, which will allow to control strength and plasticity of products by adjusting value of reduction during cold rolling of steel.

3. Purpose and tasks of research

Purpose of work: to analyze influence of deformation degree during cold rolling on grain size and volume of metal internal structure joint surface

In order to reach this goal, following tasks were set: to determine dependencies between metal alloy grains size and borders between them from reduction value during cold rolling; to establish regularities of the impact of the amount of crimp on the grain sizes of the metal alloy, the boundaries between them and the strengthening of the metal.

4. Methodology of research

Low-carbon steel was used in research. The microstructure of cast low-carbon steel (figure 2) was studied and compared with the structure after cold rolling (figure 3), which shows the changes in the shape and size of the grains during pressing.

Using data from list of references [14, 15], geometric characteristics of metal were identified, i.e. intergranular surface area and its volume, and surface volume fraction from metal volume.

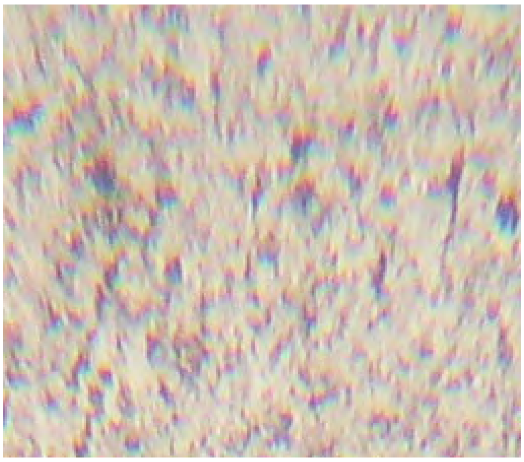

Figure 2. Microstructure of cast low-carbon steel.

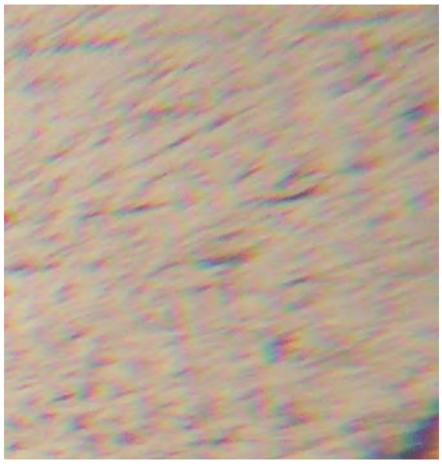

Figure 3. Microstructure of low-carbon steel after rolling.

Intergranular surface volume V_{MZ} was calculated according to formula:

$$V_{MZ} = 3t \cdot d_z^2 n, \tag{1}$$

where d_z – grain size in form of cube, m; n – number of grains, contained in 1 m^3; t – intergranular surface thickness, $t = 0{,}6 \cdot 10^{-3}$ m.

Grain size was calculated according to figure 4 based on standard [15].

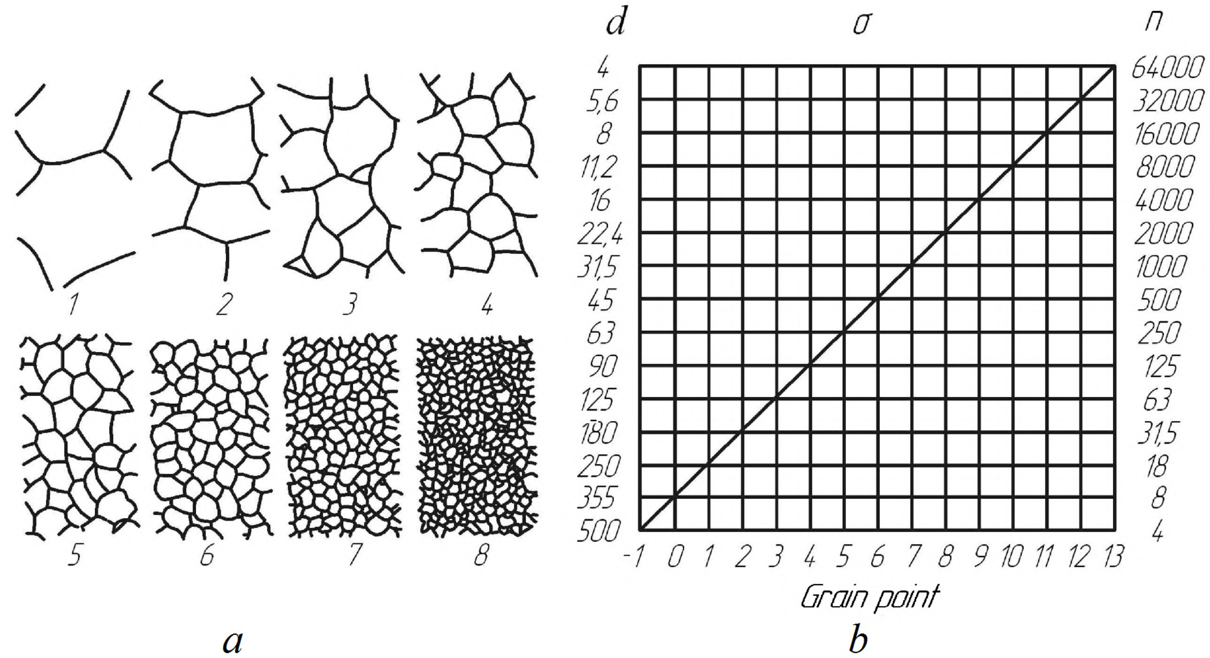

Figure 4. Scale of sizes (a) and nomogram of sizes (b) of grain: 1-8 – points of grains; d – grains size in $m \cdot 10^{-6}$; n – the number of grains per 1 mm^2 [15].

According to Hall-Petch law, yield strength σ_T equals to [16]:

$$\sigma_T = \sigma_0 d + K d_z^{-\frac{1}{2}}, \tag{2}$$

where σ_0 – some stress that is required to slip dislocations (for low-carbon steel $\sigma_0 = 170$ MPa); K – constant that depends on material grade, Hall-Petch coefficient (for calculations $K = 60$ [16]).

Increase of yield strength $\Delta\sigma$ was calculated according to formula: $\Delta\sigma = \sigma_T - \sigma_0$.

Metal yield strength during cold rolling is calculated according to formula:

$$\sigma_T = \sigma_0 + a\varepsilon_\Sigma^n, \tag{3}$$

where a, n – coefficients that take into consideration influence of chemical composition of $a = 33.4$; $n = 0.6$; ε_Σ – summarized deformation degree (in case if rolling is performed in several stages), %.

Deformation degree during study varied from 10 to 80 %.

Deformation degree was determined by the formula [13]:

$$\varepsilon = \frac{\Delta h}{h_0}, \tag{4}$$

where Δh is absolute reduction,

$$\Delta h = h_0 - h_1. \tag{5}$$

Equating formulas (2) and (3), after corresponding transformations, reduction value, which provides specified grain size during cold rolling was determined:

$$\varepsilon = \sqrt[n]{\frac{K/d^{0,5}}{a}} \tag{6}$$

After completing mathematical transformations, we receive dependence of grain size in metal, obtained during rolling, from reduction value:

$$d = \left(\frac{K}{a\varepsilon^n}\right)^2 \tag{7}$$

Offered dependence will enable to adjust grain size changing value of percentage reduction, which determines prospects for controlling steel strength.

5. Results and their explanation

Executed research enabled to identify fraction of intergranular amorphous volume, metal yield strength and its strengthening according to value of reduction during cold rolling. Strengthening value is specified in %. Results of study are presented in table 1.

For more visual observation of changes in amorphous volume fraction, reduction value obtained by formula (3) and metal strengthening value, depending on grain size of internal structure, we draw appropriate graphs (figure 5).

From reference list it is known [17, 18] that fine-grained materials exhibit high plasticity under certain temperature and velocity deformation conditions. Following dependence has been established: the smaller grains size in material is, the more intensive intergranular slipping is developed, and the higher velocity of superplastic deformation and the higher percentage elongation of samples is. These parameters are very important for introduction of technologies that are based on superplasticity effect usage.

Table 1. Parameters of internal structure and properties of steel.

Reduction, %	Grain size, $m \cdot 10^{-6}$	Intergranular surface volume, $(m^3/m^3) \cdot 10^{-3}$	Fraction of intergranular amorphous volume, %	σ_T, MPa	$\Delta\sigma_T$, MPa	Strengthening, %
1.9	355	5.1	0.5	176.8	6.8	4.0
2.6	250	7.2	0.7	178.1	8.1	4.8

66.2	5.6	323.1	32.3	217.4	47.4	28.0
83.5	4	466.6	46.7	234.0	64	37.7

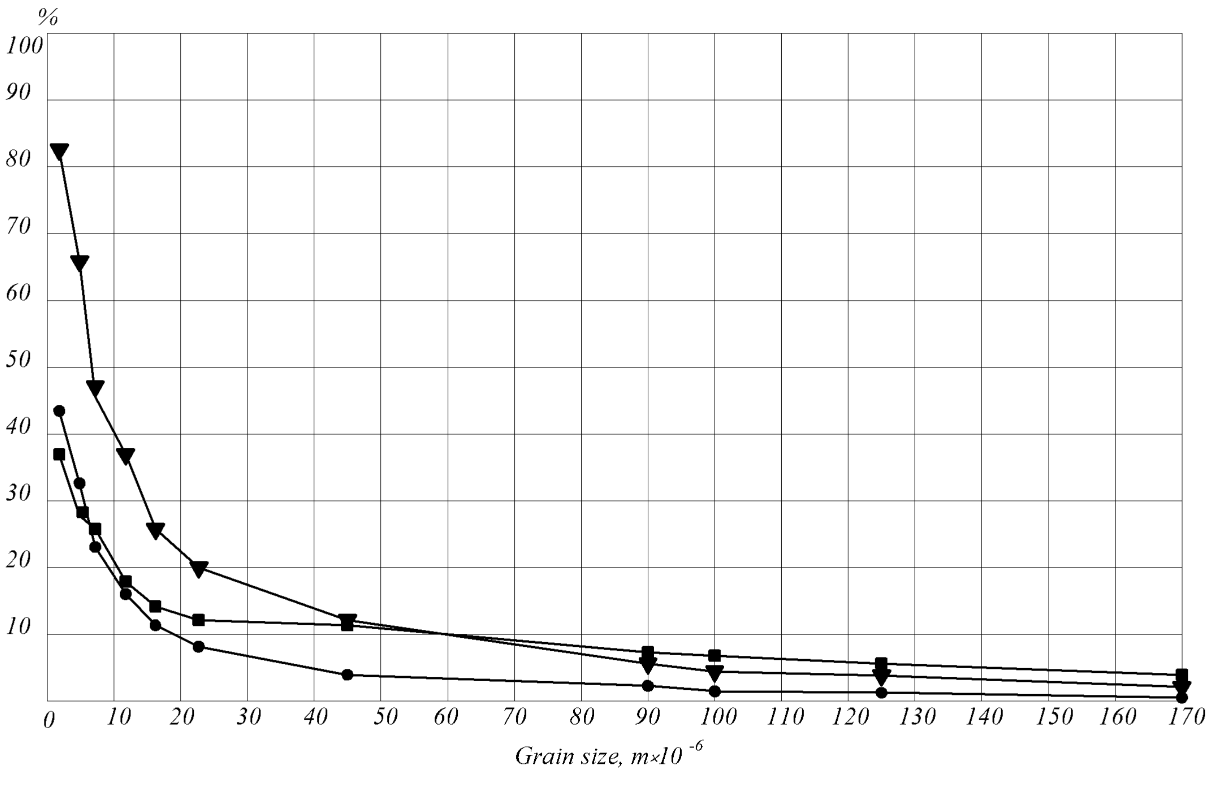

Figure 5. Dependency diagrams of fraction of amorphous volume, strengthening and reduction from grain size: reduction, % (▲); strengthening, % (■); fraction of intergranular amorphous volume, % (●).

During cold rolling, internal properties of treated sheets, i.e. grains size and borders between them, metal yield strength and its changes, can be controlled by reduction value. For this

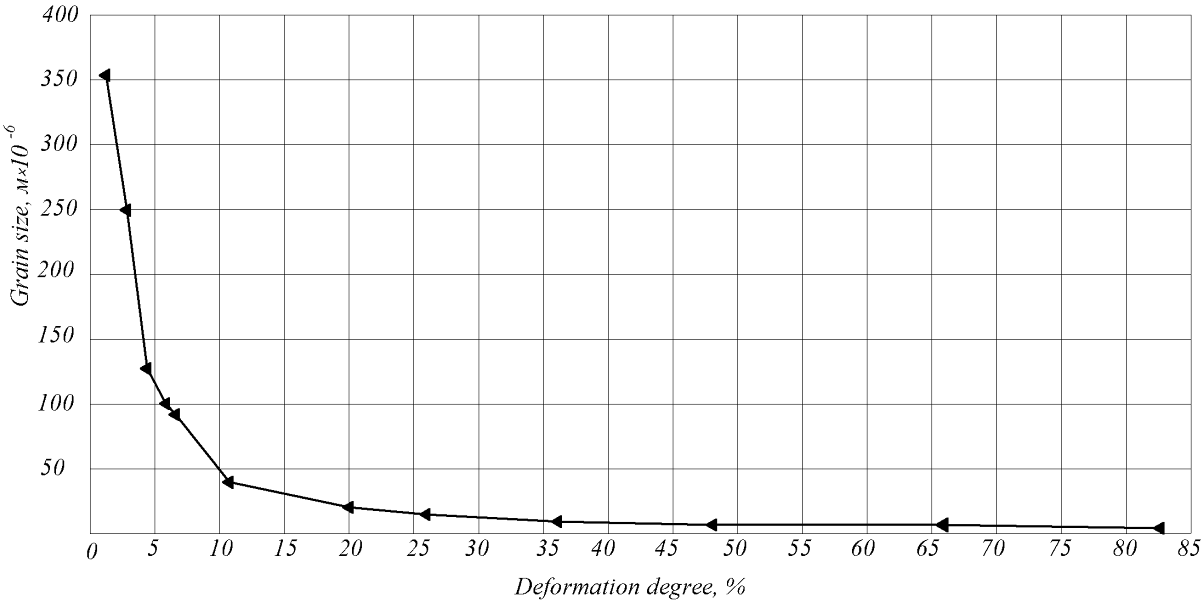

Figure 6. Influence of reduction value on grain size.

purpose, we investigated grain size changes according to formula (7), depending on reduction degree (figure 6).

It shall be noted that grain size decreases with increase in reduction value according to hyperbolic function of n-th order (figure 6). Studies showed that with summarized reduction of more than 80 % during cold rolling, sheets with internal structure having a minimum standard grain size and is characterized with maximum intergranular borders is obtained.

Influence of reduction value to strengthening of metal alloy and fraction of intergranular surface volume is presented in figure 7, where it is clear that these indicators increase almost equally with increased degree of deformation.

Approximation of obtained graphical dependences made it possible to determine that influence of these parameters is performed according to linear function. Studies used least square method, which enabled to obtain following dependencies:

$$line1\varepsilon = 1.8A + 3.7,$$

$$line12\varepsilon = 2.5C - 12.36,$$

where A – fraction of intergranular amorphous volume, %; C – metal strengthening, %.

6. Conclusions

Changes that occur in internal structure of metal products during treatment by pressure were analyzed, it allowed to determine dependencies between metal alloy grains size and borders between them from reduction value during cold rolling.

Regularities of reduction value influence on grains sizes of metal alloy, borders between them and metal strengthening are determined. It is shown that grain size decreases with increase of deformation degree according to hyperbolic function of n-th order, while fraction of intergranular amorphous volume and metal strengthening increase according to linear functions, which enable to control steel strength by adjusting grains size and their joint surface, i.e. changing reduction value.

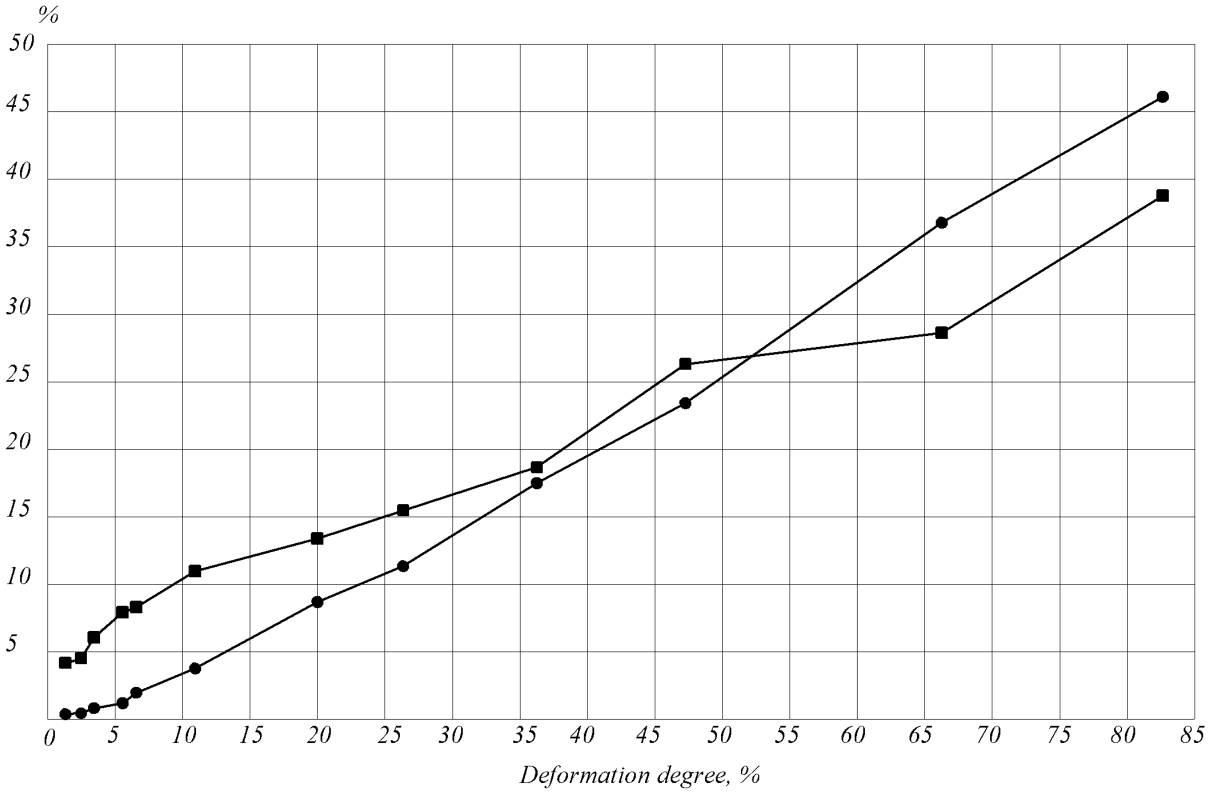

Figure 7. Influence of reduction value on strengthening of metal alloy and fraction of intergranular surface volume: fraction of intergranular amorphous volume, % (●); strengthening, % (■).

Abstract. The paper considers the ways of controlling the processes of producing good-quality castings by using robust methods based on the identification of objects under uncertainty, adaptive control methods, stabilization methods for automatic control systems and their mathematical description. The purpose of the paper is to practically elaborate on the task of creating robust technologies for casting based on the study of the stochastic dispersion models of the casting process parameters and to develop a method for stabilizing the casting processes and a method for stabilizing the quality parameters of the castings. The regular patterns of the stochastic dispersion of the casting process parameters were investigated based on the mechanical performance of the casting alloys, their chemical composition, the physical and mechanical properties of the molding mixtures, the dimensions of the castings, and the features of the casting production process such as pouring temperature, element loss during melting and mold hardness. The results of the conducted investigations have shown that to describe the stochastic dispersion of the casting process parameters, it is appropriate to use the Johnson system of distributions. A method for stabilizing the casting quality parameters was developed. It has been shown that it is more efficient to stabilize the strength and improve the dimensional accuracy of the casting simultaneously. With the existing production process, the dimensional accuracy of the casting corresponds to Grade 11 according to GOST 26645-85. With the increase of the dimensional accuracy grade, the metal content of the casting can be reduced by 16.3% after reaching Grade 10, by 20.4% after reaching Grade 9, and by 24.2% after reaching Grade 8.

1. Introduction

When developing the technological process of manufacturing machine parts, there is a need to set up a quality management system for products, the formation of which depends on various phenomena that significantly affect the products performance [1, 2].

Among the processes that affect the quality of machine parts, an important place is taken by the processes related to the production of good-quality castings, which determine their physical and mechanical and performance properties.

Robust methods based on the identification of objects under uncertainty, adaptive control methods, stabilization methods for automatic control systems, mathematical description of the system can be used for this purpose. Currently, there are, mainly in Japanese industry, some striking examples of the use of the concept of robustness to solve practical quality management problems, where the probability of failure of sophisticated products has been reduced from the rate of 1 to 5 failures per one hundred products to one failure per one million products [3, 4].

2. Analysis of literature sources, purpose and objectives

The parameters of the casting processes and the quality of castings consist of two components, deterministic and stochastic. The deterministic component represents the nominal value of the technology parameters, while the stochastic component accounts for the variability of the casting production processes caused by variations in raw material properties, variance and drift in technology and equipment parameters. Variations in product size, structure and properties are the major challenges in creating a perfectly homogeneous industrial production.

Depending on the specific production conditions, both the deterministic and stochastic components can have a decisive effect on the quality of the casting. Therefore, when solving the problem of casting quality control, both components of the technology parameters must be considered quantitatively. However, the case is somewhat different in practice. The Generation 1 casting technologies used at an early stage of development of the casting technology involved a simplified conceptual model of the technology, whereby controlled process parameters were considered as purely deterministic values [5, 6].

Subsequently, an effective solution to the problem of achieving a high level of quality of industrial products, including cast parts, has proved impossible without any quantitative consideration of the statistical component of the technology parameters. Therefore, the industry in developed countries started to use statistical methods in the field of quality control and quality management in the early 20th century. Up-to-date casting methods developed and improved in the 20th century based on a scientific and technological approach can be identified as Generation II technologies [7].

One of the most important conclusions of the statistical theory of quality management is that in order to solve the problem of creating high-quality industrial products, it is necessary not only to consider but also to manage the degree of stochasticity of technological parameters. Within this approach, the concept of new Generation 3 technologies was developed; these were called robust, and their main feature is resilience to random factors.

The stochasticity factor plays a major role in the formation of the consumer and performance properties of cast parts. A specific feature of the casting technology is that the quality parameters are affected by lots of variables, the number of which, according to experts, is estimated to be 2000 to 3000, while only a small number of them, about a few dozen, can be referred to as controllable variables. As a consequence, there is an inevitably wide variation in the quality parameters of the castings. Therefore, the development and practical use of robust technologies is one of the major scientific and practical challenges in the field of casting technology [8].

The analysis of the situation has shown that the existing pattern of technological research established in the field of casting technology should be supplemented by a fundamentally new stage related to the development of an apparatus, methods and working algorithms to address the issue of stabilizing the parameters of the casting process and the quality of castings.

Improving the quality and competitiveness of industrial products inevitably involves additional costs and an increase in their cost price. To find a rational solution to the problem of improving the quality of castings requires the development of a conceptual and mathematical model of the quality formation process, which considers all costs, risks and losses incurred by the designer, manufacturer and consumer of the products [9].

To date, neither general method nor mathematical and algorithmic apparatus for solving the problem of improving the quality and stabilizing the parameters of castings or cast parts has been developed.

The purpose of the research paper is to practically elaborate on the task of creating robust technologies for casting based on the study of the stochastic dispersion models of the casting

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012007 doi:10.1088/1755-1315/1254/1/012007

process parameters, and to develop a method for stabilizing the casting technology, and a method for stabilizing the quality parameters of the castings.

3. Method

The primary objective in controlling the reliability of a cast part is to determine the function of distributing the load capacity of the casting. Therefore, the first step in addressing the issue of controlling the reliability is to define the general law of load capacity dispersion.

Engineering problems typically use uniform, normal, and exponential distribution laws. These laws can be used to solve training and elementary tasks, but they are totally inappropriate for solving practical tasks related to the management of the quality of castings [10].

The regular patterns of the stochastic dispersion of the casting process parameters were investigated as follows. A hundred empirical functions obtained by statistical sampling in foundries in automotive and tractor, agricultural, and transport mechanical engineering industries were studied [11,12]. The mechanical performance of the casting alloys, their chemical composition, the physical and mechanical properties of the molding mixtures, the dimensions of the castings, and the features of the casting production process such as pouring temperature, element loss during melting and mold hardness were studied as parameters [13, 14].

To examine the possibility of an adequate description of the distribution functions of the casting process parameters, two currently existing versatile Pearson and Johnson systems of distributions were reviewed.

4. Results and discussion

The results of the conducted investigations have shown that to describe the stochastic dispersion of the casting process parameters, it is appropriate to use the Johnson system of distributions. Its advantages can be summarized as follows:

- the system consists of only three types of functions;
- there are relatively simple methods for the approximate calculation of their parameters;
- the scope of the system is universal.

The Johnson system of distributions includes the equation of three curves referred to as S_l, S_b, S_u families in mathematical statistics. The functions of the S_b family describe the distribution of a random variable whose limits are finite and best meet the nature of the dispersion of the casting technology parameters.

A meaningful analysis of the problem of investigating the regular patterns of random fluctuations of the casting processes was conducted as follows. All parameters of the casting processes cannot by their nature take negative and infinitely large values; therefore, they necessarily have an upper and lower limit.

In view of this, it is necessary to impose a requirement on the functions describing the dispersion of the casting parameters, by which the nature of the distribution function used must be consistent with the nature of the parameter being described. It therefore follows that all functions having at least one infinite limit of variation should be discarded to describe the regular patterns of any parameter of the casting processes and systems.

After filtering all known distribution functions through this requirement, the only remnant of these is the Johnson S_b distribution. It alone has two properties at once: meaningful and mathematical adequacy to solve both technological and problems related to the reliability of cast parts. Thus, the Johnson S_b distribution should become the main function when describing the dispersion patterns of the quality parameters of castings and supersede all others, including the normal distribution law.

One of the key components of the problem of improving the quality of castings is the stabilization of the process properties of molding mixtures [15]. The existing approach to addressing this issue based on the data provided by online control of the properties of the molding mixture is ineffective because control over compactability, moisture contact and strength can be carried out no more often than every 30 to 40 minutes, while control over the content of active bentonite, losses during calcination, particle size distribution no more often than once per shift. In this case, deviation from the set parameters of the mixture preparation technology are detected after its application [16, 17].

To stabilize the casting technology in the in-line production of cast parts for agricultural machinery, the following tasks were solved:

- a method was developed, and production and statistical research was conducted to study the parameters of dispersion of the technological properties of molding mixtures;
- mathematical models of the formation process of properties of molding mixtures were built;
- practical recommendations for improving the technological process of production of castings were developed and implemented.

A specific feature of solving the problem of improving the stability of the process and diagnosing the casting defects is the requirement for increased reliability and accuracy of the production information used [18, 19]. For this purpose, a method of issuing data sheets for castings was developed, based on which industrial experiments were conducted in foundries. The point of the method of issuing data sheets for castings was reduced to perform sequentially the following operations.

The following parameters were monitored and recorded in the melting shop: the quantity, size and chemical composition of charge materials, the melting process parameters, the quantity and composition of deoxidizers and fluxes used, the temperature of the metal in the trough and in the ladle, the poring speed and temperature. In addition, samples were taken from each heat in the steel foundry to determine the gas saturation of the metal [20].

The following operations were performed on the molding and pouring conveyor during the mold-making process:

- the numerical indexes in ascending order were stamped on the horizontal surface of the lower half of the mold;
- each mold was sampled for rapid determination of its properties in the shops express laboratory;
- the hardness of the mold surface was determined using a hardness tester at three points on the mold.

After completing the finishing operations the castings, each with an individual numerical index, were presented to the technical control department to be sorted. The information obtained was consolidated in a single table; the increased validity and reliability of the data obtained is due to the individual determination of all process variables for each casting. The data table was used to solve the tasks of stabilizing the technology parameters, determine the causes of casting defects and the degree of influence of individual variables on the quality and extent of casting rejects.

The solution to the problem of improving the stability of the technological properties of molding mixtures under production conditions was implemented as follows. As the object of research, a unified molding mixture used for the production of carbon steel castings was chosen with the following composition: sand – 89 to 92%; refractory clay – 7.5 to 9.5%; fuel oil – 0.8 to 1.0%. The following requirements were set for the mixture: gas permeability of at least 70 GPU, ultimate strength when wet and water content in the ranges of 0.05 to 0.06 MPa and 4.6

to 5.0%, respectively. The results of 120 data obtained at the facility for the determination of the gas generation value of the mixture were processed, and samples for its determination were collected in the workshop at regular intervals for a month.

The data obtained show that the most important technological properties of the molding mixture, which determine the quality of the mold, are extremely unstable. For example, the extreme values of the dispersion range of gas permeability are 50 and 250 GPU, and those of the gas-generation value are 10 and 65 cm^3/g, i.e. the limit values of the dispersion range differ from each other by 5 to 6.5 times.

It therefore follows that in order to solve the problem of dealing with gas-induced casting defects, it is necessary to reduce fluctuations in the gas permeability and gas-generation value of the molding mixture. The solution of this problem is particularly important for steel foundries, in view of the fact that the surface layers of the mold when in contact with the liquid steel are heated to a high temperature of about 1,100 to 1,200 °C [21, 22].

The major factor reducing the quality of steel castings is that these are prone to having gas-induced casting defects such as blowholes, pinholes, gas and shrinkage porosity. Mathematical modeling methods have been used to quantitatively study the conditions for the formation of gas- and shrinkage-induced defects in castings and to develop measures to prevent these defects.

To build mathematical models of the formation of the process properties of the mixture, the regression models were used, and their parameters were determined based on the experimental data. The investigated dependencies, which were generally non-linear, were used to choose control actions [23, 24].

Based on the results of the conducted research, a method for stabilizing the process of the preparation of a molding mixture was developed, which includes the following sequential procedures:

- implementing 100% acceptance control over all raw materials for the preparation of the molding mixture and systematic monitoring of the gas-generation value of the mixture;
- collecting the most reliable input information based on data sheets of molds and castings;
- improving the accuracy of dosing water and fuel oil in the molding mixture, which are the main sources of gas generation in the mold;
- determining the effect of the mixture preparation process parameters on the gas permeability of the molding mixtures and their correction;
- providing a correlation and regression analysis of the dependence of gas permeability of a mixture on its composition and preparation conditions;
- determining the rational limits of gas permeability and gas-generation value for the examined conditions; adjusting the mixture preparation technology.

According to the conducted investigations, it was found that the lower allowable gas permeability limit for a unified molding mixture in a steel foundry was set at 120 GPU, and the gas-generation upper limit value was set at 28 cm^3/g. The accuracy of dosing of the source components in the preparation of clay suspension was improved; the ongoing control over its density was implemented; the accuracy of dosing when introducing fuel oil was improved, and its dosage was corrected, which was set equal to 0.85 ś 0.05% of the batch in the mixer.

A periodic monitoring of the actual clay content in the mixture was implemented, according to which the amount of clay suspension introduced in the mixture can be adjusted. As a result of this work, the stability of the properties of the molding mixture in the steel foundry has been considerably improved. Specifically, the number of cases of gas permeability below 120 GPU was reduced from 23 to 7%; the range of fluctuations of moisture content in the mixture was reduced from 4.1-5.5% to 4.4-5.2%. While the mean gas-generation value and its root mean square deviation in the initial state were 29.2 and 4.2 cm^3/g, respectively, after implementing the stabilization measures, the values decreased to 26.2 and 2.7 cm^3/g, respectively [25].

Implementing the method for stabilizing the process properties of molding mixtures made it possible to improve the quality of castings and reduce rejects with gas-induced defects.

The third task to be solved in this work is to develop a method for stabilizing the quality parameters of the castings. The method for solving this problem is implemented using the following algorithm.

(i) A mathematical model describing the dependence of the quality parameter Y on the independent technological variables x_1, x_2, , x_n, is built, which can be represented as an equation:
$$Y = f(x_1, x_2, ..., x_n). \tag{1}$$
(ii) The mathematical expectation of the studied parameter is determined. If some of the variables x_i or all of them are random, then the parameter Y is also a random variable, its mathematical expectation can be found by the formula:
$$m_y = f(m_{x_1}, m_{x_2}, ..., m_{x_n}), \tag{2}$$
where m_y, m_{x_i} are the expected values of the parameter y and the variable x_i.

(iii) Determined by the numerical and approximate-analytical method of parameter dispersion Y. For the numerical determination of this quantity, the simulation method can be used. The approximate-analytical method is based on the linearization of the function by expanding it in a Taylor series and preserving the first two terms. In this case, the variance of the parameter Y how the function of the variances of the independents is determined by the formula obtained on the basis of the linearization of the dependence (1):
$$D_y = \sum_{i=1}^{n} \left(\frac{\partial Y}{\partial x_i}\right)^2_{m_{x_i}} D_{x_i}. \tag{3}$$
The index of the partial derivative means that its value is determined by $x_i = m_{x_i}$.

(iv) On the basis of processing the results of industrial experiments, the average values and dispersions of the studied technological variables are determined.

(v) According to formula (3), the variance of the studied quality parameter is determined, the mean values found in the previous paragraph are taken as an estimate of the mathematical expectation of the variables.

(vi) The contribution of each variable to the variance of parameter Y is analyzed, recommendations are developed and implemented to reduce the value of the parameter under study.

The described algorithm was used to stabilize the load capacity of the hinge body part cast of steel 45FL of a T-150K tractor. It was found that the cross-sectional area dispersion and the mechanical property dispersion account for 55% and 45%, respectively to the variation of the load capacity; therefore, the degree of dispersion of these two factors should be reduced. The following measures were developed to improve the geometric accuracy of the part:

- reducing the shrinkage variation by reducing the allowable ranges of pouring temperature and carbon content;
- reducing the deformation of the mold when pouring by improving the strength of the molding mixture and its packing density;

- improving the accuracy of production and assembly of the model elements and centering pins;
- minimizing the assembly clearances between the mold and core pins by optimizing the dimensional chains;
- adjusting the dimensions of the core boxes in view of the deformation of the cores during transportation and drying.

By implementing the above technical measures, the dimensional accuracy of the hinge body casting was improved by 2 to 3 classes according to GOST 26645-85 and the coefficient of variation of the bearing cross-section was reduced from 0.0941 to 0.0402.

To determine whether it is possible to reduce the dispersion of the strength of steel 45FL, a mathematical model of its strength was developed as follows:

$$\sigma = 622 + 2871(C - 0.42) + 182(Si - 0.2) + 128(Mn - 0.45), \tag{4}$$

where C, Si, Mn is the percentage of carbon, silicon and manganese in cast steel.

Based on the processing of the results of the chemical analysis of production heats, it has been found that the dispersion of strength is 2,267.4, and 93% of its value is determined by the variation in the carbon content of steel, 5% by the variation in the silicon content, and 2% by the variation in the manganese content. Therefore, to reduce the dispersion of the mechanical properties of cast steel, it is sufficient to reduce the dispersion of its carbon content. The results of experimental heats showed that by improving the accuracy of dosing admixtures and by improving the express control over the carbon content in steel, the range of its variation can be reduced from 0.09 to 0.07%, and the RMS deviation from 0.015 to 0.01-0.012%. This reduction in the RMS variation made it possible to reduce the dispersion of the ultimate strength of steel and lower the strength dispersion from 2,267.4 to 1,154.7. By reducing the carbon content variation, the minimum tensile strength increased from 540 to 581 MPa, i.e. by 7.6%.

A study of the metal content of the hinge body part showed that while maintaining the guaranteed load capacity of this part equal to 31.2 tons by stabilizing the carbon content and increasing the lower strength value, the mass of the part could be reduced by 7.6%. It is more efficient to stabilize the strength and improve the dimensional accuracy of the casting simultaneously. With the existing production process, the dimensional accuracy of the casting corresponds to Grade 11 according to GOST 26645-85. With the increase of the dimensional accuracy grade, the metal content of the castings can be reduced by 16.3% after reaching Grade 10, by 20.4% after reaching Grade 9, and by 24.2% after reaching Grade 8.

5. Conclusions

1. In the production of good-quality parts, an important role is taken by the processes related to the production of castings, which determine their physical and mechanical and performance properties.
2. Robust methods based on the identification of objects under uncertainty, adaptive control methods, stabilization methods for automatic control systems and mathematical description of the studied processes are promising to manage the quality of castings.
3. The analysis of the situation has shown that the existing pattern of technological research established in the field of casting technology should be supplemented by a fundamentally new stage related to the development of an apparatus, methods and working algorithms to address the issue of stabilizing the parameters of the casting process and the quality of castings.
4. Based on production and statistical research, the regular patterns of the dispersion of the casting process parameters and the quality of castings were studied. It has been shown

that the Johnson Sb distribution is the most appropriate in terms of the meaningfulness and accuracy of describing the variation in the characteristics of technological processes and parameters of castings and cast parts. The obtained results can be used to improve the efficiency of problem solving in the casting quality management systems.

5. To stabilize the casting technology in the in-line production of cast parts for agricultural machinery, the following tasks were solved:
   - a method was developed, and production and statistical research was conducted to study the parameters of dispersion of the technological properties of molding mixtures;
   - mathematical models of the formation process of properties of molding mixtures were built;
   - Practical recommendations for improving the technological process of production of castings were developed and implemented.
6. A method for stabilizing the casting quality parameters was developed. It has been shown that it is more efficient to stabilize the strength and improve the dimensional accuracy of the casting simultaneously. With the existing casting production process, the dimensional accuracy of the casting corresponds to Grade 11 according to GOST 26645-85. With the increase of the dimensional accuracy grade, the metal content of the casting can be reduced by 16.3% after reaching Grade 10, by 20.4% after reaching Grade 9, and by 24.2% after reaching Grade 8.

Abstract. The technology of forming a thermite alloy layer on the basis of Fe-Cr-C system on a metal basis by self-propagating high-temperature synthesis is offered, which allows to obtain cast functionallayers withphysico-mechanical and exploitativeproperties. The optimal technological parameters of the forming a wear-resistant layer of thermite alloy process are determined: the amount of metal filler with the maximum yield of suitable alloy, the heating temperature of the thermite charge and the mold to obtain additional heat, the temperature ranges of the melt to melt the metal base with further formation of the functional layer. Metallographic studies of the obtained wear-resistant layer of thermite allo[y showed that the zone of formation of the functional layer is characterized by the stability of the macrostructure and the positive effect of non-metallic inclusions in the form of Al_2O_3, which influences the formation of chromium carbides in the obtained alloy by creating the effect of inoculative modification of thermite alloy.

1. Introduction

In foundry production, the “classic” (basic) technology for obtaining a liquid melt which is poured into the mold is metal smelting in a steelmaking unit (for example, in an arc steelmaking or induction furnaces) [1, 2]. Overheating of the obtained metal is not allowed primarily due to increased wear of the furnace lining and increased soot of the alloying elements. It is known that it is optimal to pour molten metal into a mold with a temperature close to the crystallization temperature, but even so it is not possible to obtain two-layer bimetallic castings due to the lack of a quality zone for the formation of functional layers [3–5]. That is why the use of self-propagating high-temperature synthesis (SHS) to form a wear-resistant layer of thermite alloy on a metal basis can be a cost-effective alternative for the production of bimetallic products.

The main physical parameters of the SHS process are the maximum combustion temperature at the level of 8004000 °C and the linear combustion rate of 1-150 mm/s. The combustion process consists of two main stages: reduction of oxides with the formation of metal (metallothermic stage) and the stage of direct synthesis of elements [6].

The mechanism of structure formation and product formation in self-propagating thermite reactions is described in Orrù et al [7–9]. In order to obtain a dense SHS material with high physical and mechanical characteristics, it is necessary to take into account the patterns of the reaction mixture combustion, the formation of chemical and phase compositions of the final product, the crystallization behavior of the alloy [10].

A general overview of thermite reactions, which are exothermic redox reactions involving metal and oxide, is presented by Wang et al [11]. Scientists have presented theoretical and experimental results related to ignition and combustion in self-propagating high-temperature synthesis.

In [6] the technology of materials synthesis based on combined (self-propagating high-temperature synthesis plus metallothermy) processes is described. The author considers theoretical issues of synthesis and technological features of running the combined processesfor micro fusion conditions. Reactions based on the proposed charge compositions led to the synthesis of carbidosteels, which contained a binder component and high-speed steel, and a base tungsten carbides. The parameters of carbide steel yield from the charge were experimentally established, and the microstructure, features of chemical composition, mechanical and technological properties were investigated for the synthesized alloys.

The issue of synthesis of steels and cast irons by metallothermy is considered in more detail in [12]. In particular, the synthesis of different types of steels: heat-resistant, tool, spring and others, as well as different types of cast iron: grey, white and high-strength. The author shows that the mechanical properties of thermite steels are better than those of industrial analogues and reveals the influence of the metallothermic method of synthesis on the features of the microstructure and phase composition of thermite steels. Theoretical and experimental studies have also shown the possibility of using thermite cast irons not only to obtain castings, but also for thermite welding technology.

In [13] the results of experimental and theoretical studies of the combustion of iron-aluminum thermite mixtures for iron and composites based on ironwas given. The effect of granulation and addition of flux on the combustion process, composition and structure of final products was evaluated. The author proposed a method of burning thermite mixture with bottom ignition and a model of a combustion plant. Also, the results of research on the combustion of granular thermite mixture are given in [14, 15].

The study of Coffey et al [16] is devoted to the use of additives and fluxes in metallothermicprocesses in self-propagating high-temperature synthesis.

Lonsdale [17] presents an overview of the features of thermite welding rails, and in particular, the practical and technical advantages and disadvantages of welding and focuses on improving the quality of thermite welding. Welding aspects of railway connections by means of thermite welding or aluminothermic welding are also considered in [18].

The research of the obtaining steelcomposites of the Fe-TiC system using aluminum thermic reactions of the SHS process possibility are presented in the study [19].

The work of Yeh and Wang [20], which considers the effect of stoichiometry on the formation of intermetallic compounds of the Nb-Al type is also of particular interest. The authors investigated the production of various niobium aluminides (such as Nb_3Al, Nb_2Al and $NbAl_3$) using extruded samples from Al and Nb_2O_5 powder mixtures using the SHS process.

The study by Sereda et al [21] is devoted to the thermodynamic analysis of reactions possible in the production of intermetallic nickel-aluminum alloys in high-temperature synthesis. Thermodynamic analysis showed that for the nickel-aluminum system, the adiabatic combustion temperature is at the level of the melting point of the final product such as intermetallic one, which is the sufficient condition for the SHS reaction under normal conditions.

We should note the scientific achievements of Sereda et al [22], which considered modelling of production processes of alloys based on TiAl and NiAl in the SHS process.

The work of Belokon and Belokon [23] is devoted to the study of the regularities of high-temperature synthesis of intermetallic compounds, in particular Ti-Al, and it is shown that the synthesis of metals and alloys based on them can take place under conditions of thermal explosion. The compositions of SHS mixtures and technological modes of self-propagating high-temperature synthesis proposed by the authors allow to create intermetallic alloys based on titanium aluminides.

Therefore, there is reason to believe that the issue of determining the optimal technological parameters of the process of forming a wear-resistant layer of thermite alloy based on the Fe-Cr-C system has not been given sufficient attention. This area of research is quite relevant in the production of bimetallic products.

2. Materials and methods

When considering the technology of forming a layer of thermite alloy based on the Fe-Cr-C system on a metal basis using the SHS process, next materials were used as components of the charge (table 1): scale, aluminum powder of the PA-2 brand (GOST 6058-73) with the fraction of 45 μm, iron powder of the PZHRV 2.300.28 brand (GOST 9849-86) with the fraction below 300 μm, chromium powder of the PHA brand (GOST 14-00186482-051-2005) with the fraction of 300 μm and carburetor in the form of a modifier by MK91A brand with the fraction up to 5 mm. Calcification of rolled scale to remove grease and oxidation was performed in a muffle furnace SNOL 7.2/900 at a temperature of 600 °C for 30 min.

Table 1. The composition of the charge for forming a layer of thermite alloy.

Batch composition, kg	Batch 1	Batch 2
Cinder	100,00	100,00
Iron powder of the PZHRV brand 2.300.28	45,64	–
PA-2 aluminum powder	30,00	30,00
PHA chromium powder	–	16,60
MK91A brand modifier	8,90	6,30

The study of the process of a thermite alloy surfacing on a metal base was carried out in a mold consisting of a sand-clay shell with a lid (figure 1).

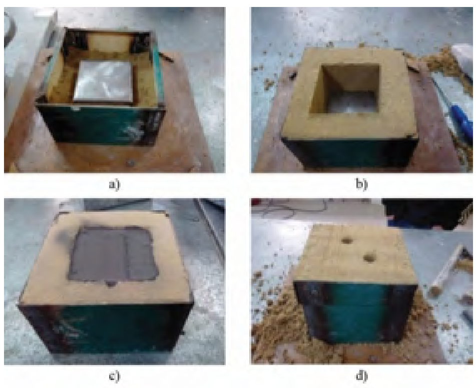

Figure 1. Experimental mold: (a) installation of a metal basis in the form on model; (b) sand-clay form with a cavity for thermite charge; (c) compacted thermite mixture in the form; (d) form assembled with a hole for burning thermites and gas removal.

To remove moisture, the mold was subjected to a drying process at a temperature of 524 K for 1.5 hours. To control the temperature, four tungsten-rhenium thermocouples were installed in the mold (figure 2). Sealing of the thermite alloy was performed on a vibrating table.

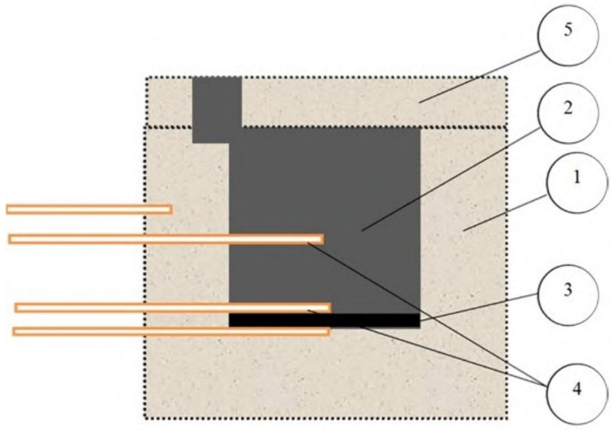

Figure 2. Scheme of experimental mold: 1 molding mixture; 2 thermite mixture; 3 metal base; 4 thermite charge; 5 lid of the mold.

To study the kinetics of thermal processes occurring in the mold during the formation of a layer of thermite alloy during the SHS process, an experimental laboratory setup was additionally developed (figure 3). The temperature measurement range lasted from the moment of ignition of the thermite charge (873 K) to the temperature of the combustion wave of the thermite charge (2774 K). Thermocouples were insulated with ceramic tubes with two holes with a diameter of 0.3 mm and connected to a high-speed self-recording device H 32-4.

3. Results and discussion

In the study of the influence of the mold heating time on the change in temperature, the prepared mold was heated in a preheated to 873 K laboratory muffle furnace SNOL 7.2/900. The data in figure 4 show that the temperature of the mold wall, after installing it in the oven, increases rapidly to 873 K. During the first 40 min the rate of temperature rise is 13.5 K/min and gradually decreases to 3.7 K/min in the heating time range from 40 min to 80 min. Upon further finding the form in the furnace, the heating rate increases at a rate of 5.3 K/min.

To accelerate the heating time of the mold with direct contact of open surfaces with the heated atmosphere of the furnace, a mold with an open metal base in the lower part was made (figure 5). The use of this design has reduced the heating time of the mold from 120 min up to 90 min. However, it should be noted that the open surface of the metal base in the lower part of the mold makes significant changes in the course of self-propagating high-temperature synthesis. After initiating the combustion of the thermite mixture, for 0.5 min from the beginning of the process, there is a sharp decrease in the temperature of the lower surface of the metal base to the ambient temperature (4-5 °C), which persists for 3.5-4 sec (figure 6, curve 1).

Analysis of these thermocouples installed on the upper surface of the metal base (figure 6, curve 2) showed that the total combustion time of the thermite charge is 8.5 sec, where the combustion front reaches the surface of the metal base and its temperature for 1 sec, rapidly increases to 2024-2054 K, which indicates the beginning of the formation of a thermite alloy. This temperature is maintained for 5-7 sec, which contributes to the fusion of the liquid phase and the metal base. At 15.5 sec from the beginning of the process, the temperature of the formed layer decreases to the temperature of crystallization of iron, and the tendency to decrease the temperature is observed up to the 20th sec.

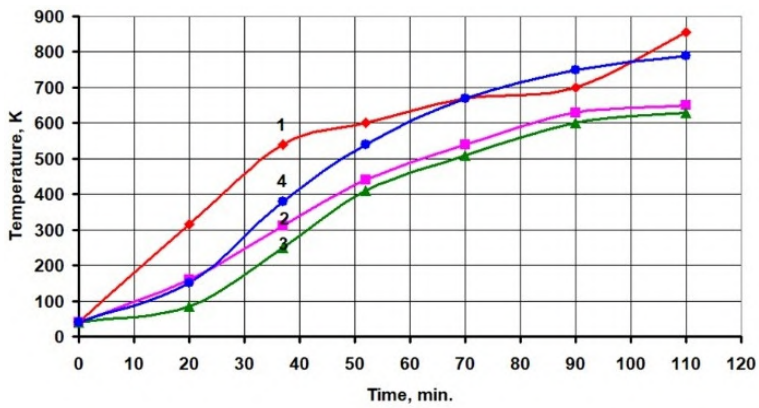

Figure 4. Influence of time of heating of a mold on change of temperature: 1 heating of a wall of a form; 2 heating under the plate; 3 heating of the thermite charge over the plate; 4 heating of the thermite charge in the middle of the mold.

Studies of the temperature behavior of the molding mixture (figure 6, curve 3) showed an initial rapid (within 0.5-1 sec) decrease in temperature from 873 K to 723 K, but with its subsequent increase at a speed of 284-286 K/sec for the next 10 sec. The tendency to maintain

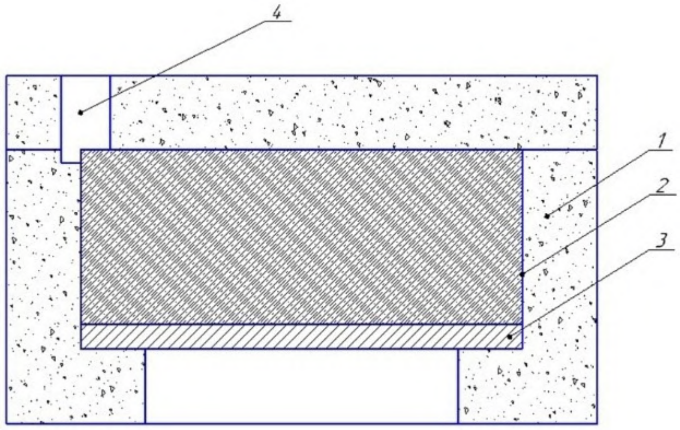

Figure 5. Foundry mold with an open metal base in the lower part: 1 molding mixture; 2 thermite charge; 3 metal base; 4 hole for igniting the thermite charge and exhaust gases.

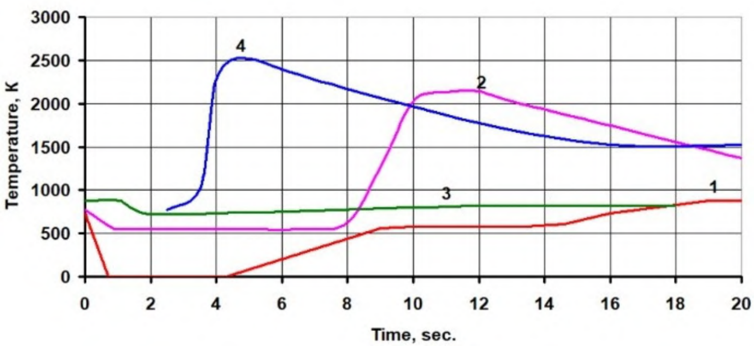

Figure 6. The effect of heating time of the mold with an open metal base in the lower part on the temperature change: 1 the lower surface of the metal base; 2 the upper surface of the metal base; 3 molding mixture; 4 temperature of the working medium thermite; charge-thermite alloy.

the temperature at 823 K must be preserved till complete crystallization of the metal.

The process of burning thermites takes place at a temperature of 3100-3200 K, which exceeds the boiling point of iron. This, in turn, allows you to add to the charge of the metal filler in such a volume that the temperature of the melt to form a functional layer was not lower than 2474-2674 K (figure 6, curve 4).

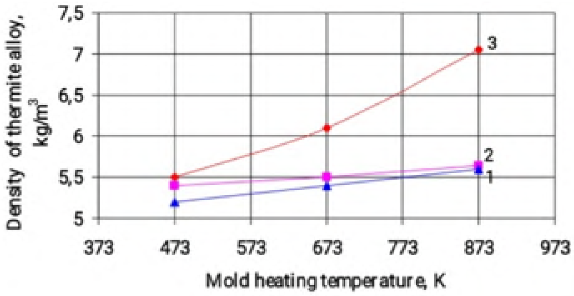
It should be noted that the open metal base in the lower part of the mold accelerates the preheating of the mold in the muffle furnace, but on the other hand there is also cooling of both the molding mixture and the metal base after firing the thermite charge. Thus, the analysis of thermo-grams from thermocouples of the mold shows that for 20 sec depending on the location of the thermocouple, there is an abrupt fluctuation of the temperature behavior.

When determining the optimal technological parameters of the process of forming a wear-resistant layer of thermite alloy based on the Fe-Cr-C system during SHS process, it was noted that the temperature of the thermite alloy after the combustion wave should not exceed the boiling point of iron, and the lower temperature limit of thermite alloy should exceed crystallization of the alloy not less than 1000 °C. The increase in the temperature of the thermite alloy directly depends on both the preheating of the mold and the amount of metal filler in the thermite charge. It should be borne in mind that the introduction of a very large amount of metal filler reduces the yield of a suitable thermite alloy. Therefore, the optimal content of metal filler in the thermite charge heated to 873 K is a composition of 40%.

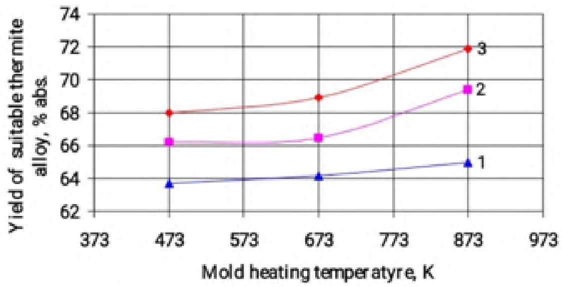
It was experimentally determined that the mass of the formed wear-resistant layer of thermite alloy obtained from the charge 1 and the charge 2 was 97.94 kg and 68.9 kg, respectively.

The obtained samples of thermite alloy were investigated for structural properties such as density in accordance with GOST 20018-74, porosity in accordance with GOST 9391-80, and macro-structure evaluation in accordance with GOST 10243-75.

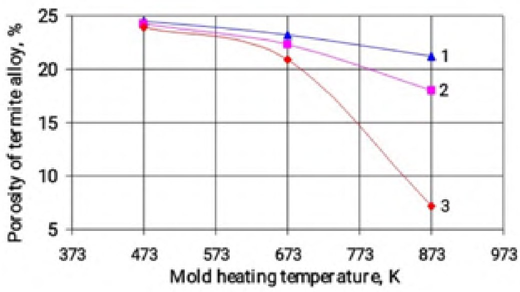
So in (figure 7, a) the dependence of the density of the thermite alloy on the heating temperature of the mold and the content of the metal filler is showed.



a



b



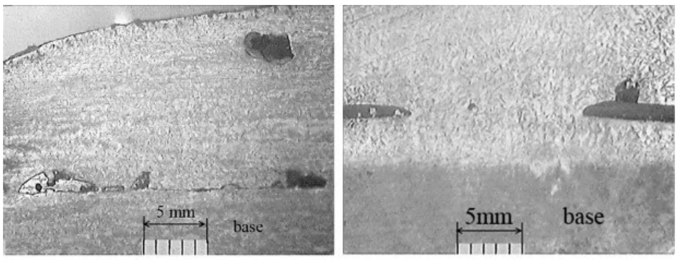
c

Figure 7. Dependence of density (a), yield of suitable (b) and porosity (c) of thermite alloy on heating temperature of mold and content of metal filler: from 1 to 20% of metal filler; from 2 to 30% of metal filler; from 3 to 40% of metal filler.

It is shown that increasing the amount of metal filler in the charge from 20% to 40%, when heating the mold to 873 K, increases the yield of suitable thermite alloy to 71.9% by weight of the original charge (figure 7, b) and it increases the density to 7.05 kg/m^3. Increasing the amount of metal filler to 40% and it also reduces the porosity of the formed thermite alloy to 5.5% (figure 7, c).

Metallographic studies of the samples of the obtained wear-resistant layer were performed in order to analyze the influence of the heating temperature of the mold on the process of formation of macrostructure defects in the zone of formation of functional layers. Metal graphic studies of samples of the mixture based on chromium (charge 2) were performed on an optical horizontal microscope of MIM-8 brand (light field mode). The samples were pre-cut at the level of the part by a water-cooled abrasive cutting wheel. When studying the quality of the connection of functional layers and analysis of structure formation, the samples were ground on the surface, baited on the macrostructure by electrical chemical etching in a saturated solution of ferric chloride (cathode a plate of corrosion-resistant steel).

In metal graphic studies of the formation zone of the thermite alloy layer based on the Fe-Cr-C system with a metal base at a heating temperature of the mold below 473 K, there was a loose connection of layers with the base, there were inclusions of slag, and in the upper part there were shrinkage shells (figure 8, a).



a b

Figure 8. Metal graphic studies of the formed wear-resistant layer of thermite alloy based on the Fe-Cr-C system: (a) when heating the mold to 473 K; (b) when heating the mold to 873 K.

Layered, perpendicular and elongated crystallization (movement of the crystallization front in the form of terraces parallel to the crystal surface) was observed in the formed layer of thermite alloy.

In the analysis of samples obtained by heating the mold to 673 K, in the zone of formation of functional layers, a line of discontinuities was observed, the metal base was not welded, because the aluminum thermic reaction products did not float to the alloy surface due to rapid cooling of the thermite alloy layer.

For samples obtained by heating the mold to 873 K, the liquid state of the thermite alloy was longer, the time to crystallization was 16 sec. The surface of the metal base melted, and the slag consisting of Al_2O_3 (corundum) emerged from the zone of formation of the functional layer (figure 8, b) [24]

Thus, the zone of formation of the functional layer is characterized by the stability of the macrostructure and the positive effect of corundum, which, creating the effect of inoculating modification of the thermite alloy, in turn contributes to the formation of chromium carbides.

Thus, the result of the proposed technology of forming a layer of thermite alloy based on Fe-Cr-C system by self-propagating high-temperature synthesis are obtained samples of thermite alloy, on the surface of which when the mold is heated to 873 K in the slag phase metal inclusions are formed in separate spherical shape (figure 9).

This is due to the rapid stage of combustion and is accompanied by intense spraying of the resulting synthesized metal. The results of the study of adding to the thermite charge a 40% of the metal filler when heating the mold to 873 K are presented in (figure 10).

When the thermite charge contains more than 40% of metal filler, regardless of the heating temperature of the mold, there is a decrease in melt temperature, which leads to its significant porosity, as well as the presence of oxidized areas in the joint that did not melt (figure 11).

Figure 9. Samples of the formed layer of thermite alloy obtained by SHS process (heating of the mold to 873 K) with different amounts of metal filler: (a) 20% metal filler; (b) 30% metal filler.

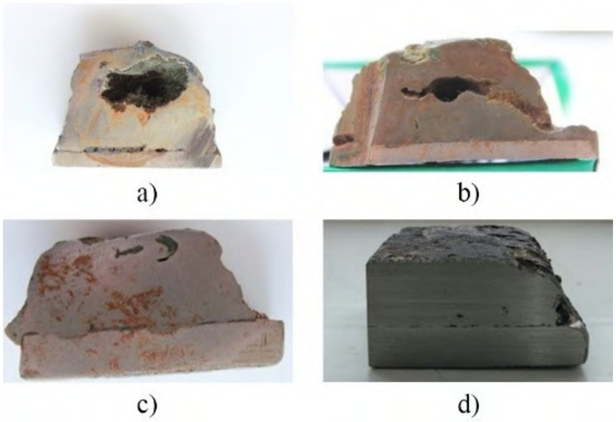


Figure 10. Section of samples of the formed layer of thermite alloy obtained by SHS process (40% metal filler) at different heating temperatures of the mold: (a) without heating; (b) when heated to 473 K; (c) when heated to 673 K; (d) when heated to 873 K.

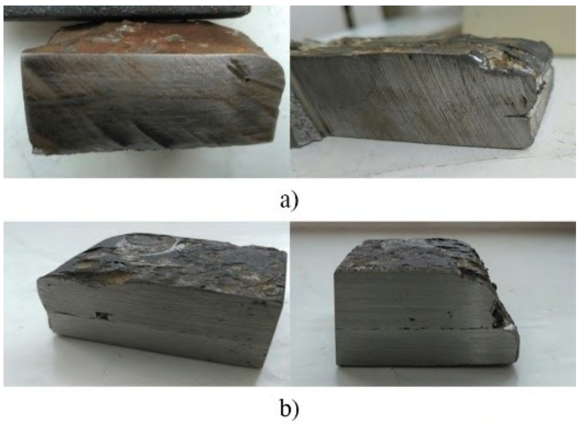

Figure 11. Section of samples of the formed layer of thermite alloy obtained by SHS process when heating the mold to 873K: (a) samples with 40% metal filler; (b) samples with more than 40% metallic filler.

4. Conclusions

The technology of forming a thermite alloy layer on the basis of the Fe-Cr-C system on a metal basis by SHS process is offered, which allows to obtain cast functional layers with improved physical and mechanical, and operational properties. It is shown that the use of open mold in the lower part for the needs of foundry production has a negative effect on the SHS process and maintaining the temperature of the metal base, which is associated primarily with the flow of air from the environment in the lower cavity of the mold due to reactive jet of gas released from the mold through the outlet in the lid during the combustion of the thermite mixture.

The optimal technological parameters of the process of forming a wear-resistant thermite alloy layer are determined: the amount of metal filler with the maximum yield of suitable alloy, the heating temperature behavior of the thermite charge and the casting mold to obtain additional heat, the temperature ranges of the melt to melt the metal base. It is established that the optimal amount of metal filler in the mold, heated up to 873 K for the formation of a wear-resistant layer of thermite alloy is 40%. It is shown that increasing the amount of metal filler from 20% to 40% affects the structural properties of the formed layer of thermite alloy: increases the density of the alloy by 33% and decreases porosity of the alloy by 17.3%, while the yield of suitable thermite alloy increases to 71.9 absolute percent. It should be noted that lowering the heating temperature of the mold below 873 K degrades the quality of the formed layer of thermite alloy: thermite alloy does not separate from the slag and is released into separate spherical formations.

Metallographic studies of the obtained wear-resistant layer of thermite alloy penetrating into the metal base to a depth of 3 mm showed that the zone of functional layer formation is characterized by macrostructure stability and positive effect of corundum (as a residue of aluminothermic reaction product) in the obtained alloy. In this case, non-metal inclusions in the form of corundum, creating the effect of inoculating modification of the thermite alloy, in turn contribute to the formation of chromium carbides.

Abstract. Biologically active polymer hydrogel transdermal materials based on gelatin, sodium alginate, modified by humic acids, were designed and researched. Literature review was carried out and it was proved that humic acids using is perspective for the functional effect on the biologically active polymer hydrogel transdermal properties. It has been found that effective processes for receiving biologically active polymer hydrogel transdermal materials based on gelatin, hydroxypropyl cellulose and sodium alginate can be carried out in different humic acids concentration while achieving an effective increase in hydrogel polymers structuring processes. It can be seen efficiently increasing biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate conditional viscosity and the specific electrical conductivity with an increase of humic acids content: from 114 to 135 sec and from 2350 to 2850 mkS/cm, respectively. Humic acids modification in biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate caused structure formation with high density, and resistance and with larger agglomerates in hydrogels. It was found that the gelatin-based biopolymer hydrogels modification by humic acids makes it possible to receive biologically active polymeric hydrogel transdermal materials with higher swelling degree. It is shown that the application of new biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate modified by humic acids allows improving the skin moisture-lipid balance. From the initial values of 34-36% moisture and 8-10 skin fat, they increase to 58-66% and 52-60%. So, designed polymer hydrogel based on gelatin, sodium alginate, modified by humic acids, are transdermal materials with good properties.

1. Introduction

The modern sustainable development trend in area of biologically active polymers and materials based on them is the technology that allows creating effective systems for drugs and active substances transdermal delivery into the human body [1].

Transdermal delivery systems based on biologically active polymer materials cause increased interest in the drugs introduction through the skin, for local therapeutic action on the affected skin during systemic local drugs delivery. They are also widely used as biologically active materials in the form of various polymer hydrogels [2]. Hydrogels are three-dimensional polymer networks held together by cross-linked covalent bonds and weak cohesive forces in hydrogen or ionic bonds form. This hydrophilic polymeric materials shows an inherent ability to swell in water and some other solvents and is able to absorb and retain more than 10 percents of its weight in water in a gel structure. Hydrogels together with other chemical compounds can form a biologically active composition that can find several local applications on the body and hair surface [3]. Bioadhesive hydrogels using for skin care has important advantages, such as a longer residence time at the application site and a lower product introduction frequency.

Until now, several biologically active hydrogels compositions containing biologically active ingredients have been produced. The selected hydrogels are bioadhesive hydrogel compositions for skin application. Used in biologically active preparations hydrogels can be based on numerous biopolymers, such as collagen, gelatin, hyaluronic acid, alginate, chitosan, xanthan gum, pectin, starch, cellulose and its derivatives.

Based on biopolymers hydrogels are used to design new biologically active agents, such as so-called “beauty masks”. It is claimed that these masks moisturize the skin, restore its elasticity and promote rejuvenation. Superabsorbent hydrogels, particularly acrylate-based materials, are widely used in personal hygiene products to absorb liquids because of their ability to lock moisture away from the skin, promoting skin health, preventing diaper rash and providing comfort.

Today, several types of materials are used to design effective biologically active hydrogels. Both synthetic and bio polymers are widely used. Natural biopolymers fully implement the principle of sustainable development and demonstrate higher biocompatibility and activity compared to synthetic polymers [4].

The transdermal delivery mechanism in such biologically active polymeric hydrogel is that active substances in the hydrogel is delivering to the skin by diffusion. The most effective modern biologically active polymeric hydrogel make of hydroxypropylmethylcellulose [5], hyaluronic acid [6], carboxymethyl cellulose [7], polyvinylpyrrolidone [8] and polylactic glycolic acid [9] and other polymers [10]. For high stability and strength while thermal contact with human skin [11], biologically active polymeric hydrogel actively use their functional modification [12] with various inorganic [13]and organic substances [14]. In our previous works, it was determined that humic substances have a functional effect on the hydrogel biopolymer materials based on gelatin and hydroxypropyl cellulose properties [15]. Especially for increasing structuring processes and strength characteristics [16]. Therefore, it is interesting to study the possibilities of effective modification of biologically active polymer hydrogel materials based on gelatin and sodium alginate with humic substances for receiving systems for active substances delivery systems into the human body.

The *aim* of the article is designing and researching of biologically active polymeric hydrogel transdermal materials modification by humic acid.

2. Materials and methods

The study’s objects for biologically active polymeric transdermal hydrogel designing were:

- food gelatin brand R-11 (Ukraine);
- sodium alginate (China);
- humic acid, were received by extraction from lignite.

The research conditions are the procedure and determination toluene extract output and free humic acids.

First, a gelatin solution (7 % wt.), a defined amount of polymer was placed in 50 mL of distilled water (preheated at 90 ± 2 °C) and stirred to obtain a clear solution. For the co-mixture of gelatin and sodium alginate, a defined amount of sodium alginate (2.5 % wt.) was added in the previously prepared gelatin (7 % wt.) solution and allowed to mix homogeneously on a magnetic stirrer (Jisico Co. Ltd., South Korea). After that, by mixing, solutions with humic acids were obtained, in which the concentration of the latter was 2.5, 5 and 7.5 % wt.

Conductometric studies of biologically active polymeric hydrogel solutions were carried out on a combined TDS-meter HM digital COM-100 (USA), scale range: specific conductivity: from 0 to 9990 mkS/cm; temperatures: from 0 to 55 °C; Error: ± 2%.

Microscopic studies of biologically active polymeric hydrogel were carried out using the electron microscope Digital Microscope HDcolor CMOS Sensor (China).

The viscosity of biologically active polymeric hydrogel was determined according to ISO 2431. The method is based on determining the viscosity of a solution of biologically active polymeric hydrogel solution with free flow is taken as the time of continuous flow in seconds test material (50 cm^3) through a calibrated nozzle with 4 mm diameter of a viscometer (VZ-246) at a certain temperature.

The swelling degree of biologically active polymeric hydrogel transdermal materials was calculated according to formula (2) [15]:

$$Q = 100 \cdot \frac{m_1 - m}{m}, \tag{1}$$

where m_1 is the mass of the swollen sample, g.; m is the mass of the sample before standing in an aqueous solution, g.

To determine the moisture-lipid skin balance a professional skin moisture and oiliness analyser SK-92 (China) was used. This device operates on the basis of the Bioelectric Impedance Analysis (BIA) method – measuring the skin resistance tissues under the electric current. The moisture-lipid balance was measured in the area around the eyes before and after applying biologically active polymeric hydrogel transdermal materials for 15 minutes in five 23-year-old women (figure 1).

The skin moisture and oiliness range is from 0 to 99.9%, accuracy: 0.1%.

3. Results

The biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate conditional viscosity and conductivity dependence from on the different humic acid content is shown in figure 2.

Next studies were carried out to determine the humic acids modification effect on the most important operational properties of biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate: swelling degree and effect on the skin moisture-lipid balance. Table 1 shows the operational properties of biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate modified by humic acids.

Table 1. Operational properties of biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate modified by humic acids.

Humic acid content (%wt.)	Swelling degree (%wt.)	Moisture/lipid, %
Pure gelatin-sodium alginate composition	19.82	58-60/52-54
2.5	27.17	60-62/55-56
5	26.83	62-64/56-58
7.5	23.21	64-66/58-60

Figure 1. Model (women) with biologically active polymeric hydrogel transdermal materials in the area around the eyes.

4. Discussion

In hydrogel materials for transdermal delivery it is very important to ensure prolonged bioavailability of target biologically active substances through the skin barrier while high adhesion to the skin, stability of their geometric dimensions and shape preservation in temperature conditions throughout the entire period of exposure to human skin. Such properties of hydrogel materials for transdermal delivery can be achieved by researching hydrogels viscosity, electrical conductivity and structural formation optimized level. For example, in [17] it was shown that by increasing the viscosity and structuring of polyacrylamide-polydopamine hydrogels with mesoporous silica nanoparticles, hydrogel patches with high adhesiveness for transdermal drug delivery were obtained. Therefore, the initial studies consisted in determining the conditional viscosity and electrical conductivity dependence of bioactive humic-polymer hydrogel transdermal materials based on gelatin and sodium alginate, as well as based on hydroxypropyl methylcellulose and sodium alginate, on the different humic acids content in them. According to [18], the electrical conductivity of bioactive humic polymer hydrogel transdermal materials, which is related to the content of ionogenic substances, can actually be used as hydration level measure using a high-density and rigid network in water-soluble polymer hydrogel materials. Therefore, it is important to study non-cytotoxic alginate–gelatin hydrogels modified with humic acids as biomaterials with good mechanical strength and biocompatibility, which are advisable to use in transdermal patches, microcapsules for bioactive compounds, cells and preparations, as well as in regenerative medicine (for example, for bone tissue regeneration) or as a soft tissue patch for wound healing. From the data in the figure 2 it can be seen increasing biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate conditional viscosity and the specific electrical conductivity with humic acids content increase: from 114 to 135 sec and from 2350 to 2850 mkS/cm, respectively. Such changes

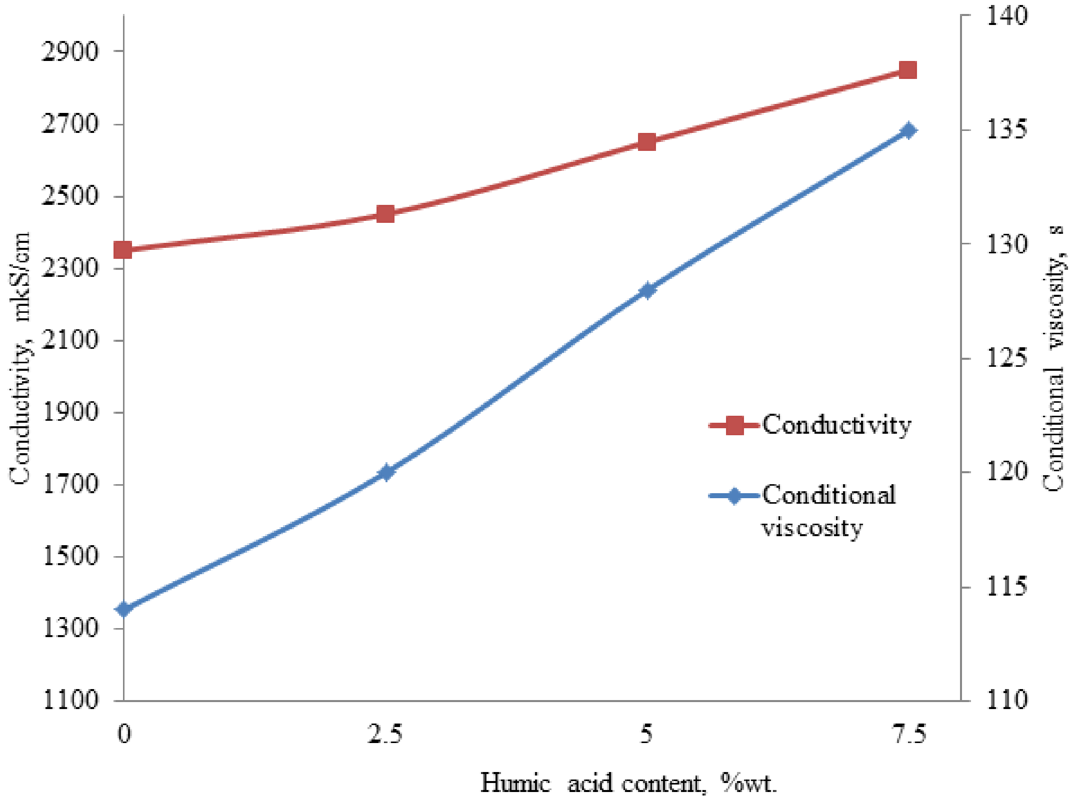

Figure 2. The conditional viscosity and conductivity dependencies of biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate with different humic acid content.

indicate the following features humic acids modification of the structure formation processes in biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate: more density [19] and rigid network of biologically active polymeric hydrogel [20]. Also the larger number agglomerates formation [21] in biologically active polymeric hydrogel [22] (figure 3).

Table 1 shows that the modification of gelatin-based biopolymer hydrogels by humic acids makes it possible to obtain biologically active polymeric hydrogel transdermal materials with an increased swelling degree. The larger number agglomerates formation in biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate on the different humic acid content is clearly visible from the microscopic studies results. It should be noted that the hydrogel delamination in biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate on the different humic acid content into the aqueous phase and the structured polymer phase does not occur. Increasing the degree of swelling when modified with humic acids due to more rigid network hydrogels formation makes it possible to achieve long-term prolonged transdermal release of drugs, stability of their geometric dimensions and shape in temperature conditions throughout the entire period of exposure to human skin, and easier separation from the skin after application. So, it is important to note that the using new biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate modified by humic acids allows to improve the skin moisture-lipid balance. So, from the initial values of 34-36% moisture and 8-10 skin fat, they increase to 58-66% and 52-60%. As it can be seen in table 1, the improvement in skin moisture-lipid balance became more with an increase in humic substances content. Actually, modification with humic acids makes it possible

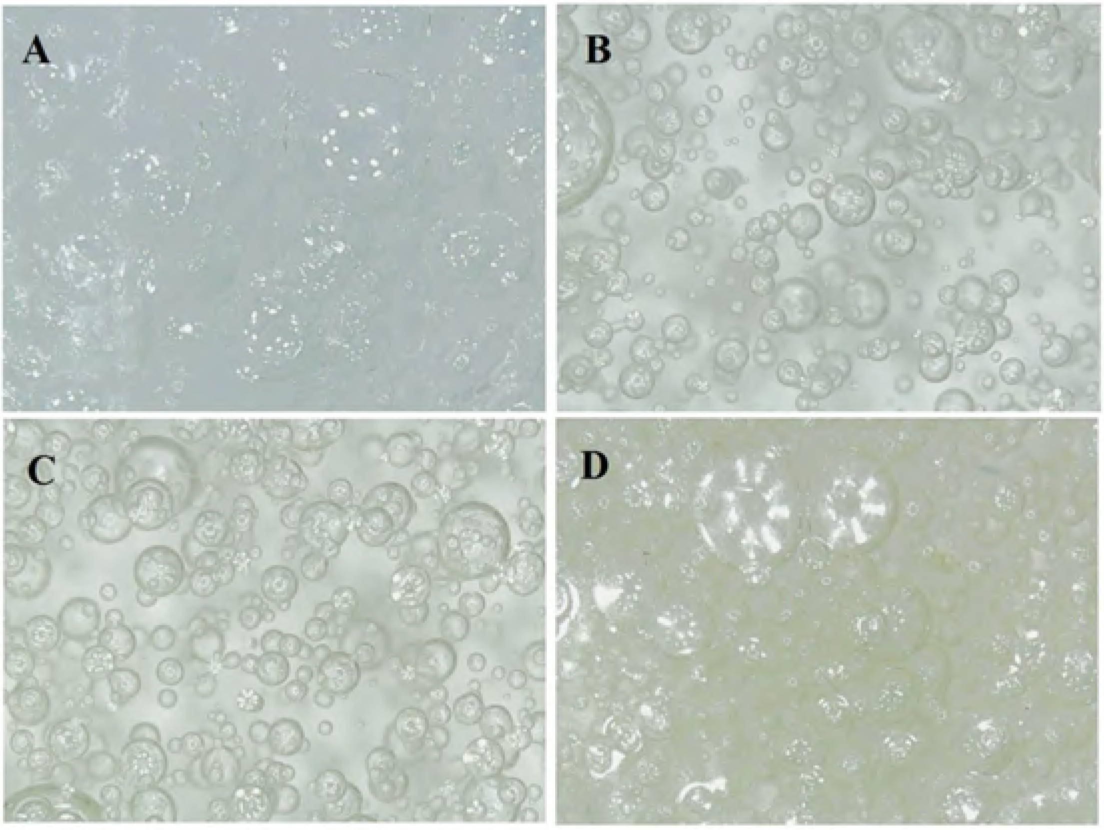

Figure 3. Microscopic studies of of biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate on the different content of humic acid: A – pure gelatin and sodium alginate hydrogel; B – gelatin and sodium alginate hydrogel + 2.5 % wt. of humic acid; C – gelatin and sodium alginate hydrogel + 5 % wt. of humic acid; D – gelatin and sodium alginate hydrogel +7. % wt. of humic acid.

to obtain hydrogel transdermal materials, which, when applied to the human body, will allow to regulate skin moisture-lipid balance uniformly and for a long time.

In fact, thanks to the biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate modified by humic acids using, it becomes possible to transfer the skin from slightly moist-fatty hard to highly moist-fatty elastic condition. The moisture-lipid balance skin improving increases with increasing the humic substances content.

5. Conclusions

The effective biologically active polymeric hydrogel transdermal materials based on gelatin and sodium alginate, modified by different humic acid content, were received and researched. By carrying out rheological, conductometric and microscopic studies, it was found that the modification of gelatin-sodium alginate systems by humic acids allows receive polymer hydrogels with high structuring degree. Modification of gelatin-based biopolymer hydrogels by humic acids makes it possible to obtain biologically active polymeric hydrogel transdermal materials with an increased swelling degree and ability to improve the skin moisture-lipid balance: from the initial moisture 34-36% and fatness 8-10%, they increase to 58-66% and 52-60%. In future researching is perspective to determine transdermal level of designed biologically active polymer hydrogels for most important medicine and cosmetic biologically active substances.

Abstract. The possibility of designing mechanical properties of ceramic-inorganic polymer composites for protection against electromagnetic radiation is considered. As a result, the mechanical properties of polymer composite based on polyamide, modified with ceramic-inorganic graphite-ferromagnetic fillers (silicon carbide, chromium oxide Cr_2O_3 and graphite) was received and optimized. The strength characteristics complex of ceramic-inorganic polymer composites with silicon carbide SiC, chromium oxide Cr_2O_3 and graphite content in diapason 5-15 % wt. were studied. It was established that the optimal strength characteristics can be received using binary modification of polyamide with ceramic-inorganic graphite-ferromagnetic fillers: polyamide 6 – SiC 10% wt. – Cr_2O_3 10% wt. and polyamide 6 – SiC 10% wt. – graphite 10% wt. Using mathematical modeling, it was established that the polyamide 6 – SiC 10% wt system is the most optimal for three-component complex modification with ceramic-inorganic graphite-ferromagnetic fillers – Cr_2O_3 10% wt. – graphite 10% wt. By design experimental-statistical mathematical models in equal regressions, mathematical optimization of mechanical properties of polymeric ceramic-inorganic composites contains for protection against electromagnetic radiation was carried out. Designed polymer ceramic-inorganic composites for protection against electromagnetic radiation according to their strength characteristics can be used for modern radio absorbing materials production.

1. Introduction

Nowadays, the production of various radio-electronic equipment is actively expanding. The main direction is radio-electronic equipment improving properties: reducing the size and energy losses, better accuracy and speed, etc. Many technologies are already transit to a higher frequency range. So there is a need for materials with appropriate electromagnetic characteristics, which are necessary for matching and protecting various electromagnetic ranges components.

As now there is no single-component material that could achieve a high absorption capacity in a wide frequency band. Such composite materials are used for: biological objects protection, the electromagnetic devices compatibility [1], electromagnetic waves reflection reducing [2].

Composite materials of various nature are actively used to ensure protection against electromagnetic radiation. It is also correspond the sustainable development conception. The main feature of composite materials is that they represent a combination of two or more constituent components and have new properties different from the components separately properties. Composites are easy to production and provide new, unattainable for traditional materials, physico-chemical properties, such as flexibility, high strength, elasticity, as well as unique new characteristics [3].

Typical materials for absorbing electromagnetic radiation are:

1) conductive powdered materials (coal, carbon black, graphite, metals – steel, cast iron, iron, aluminum, cobalt, lead, zinc, tin, copper, etc. [4], metal salts) with spherical, cylindrical, flaky, etc. shape of particles [5];
2) conductive carbon, metal and metal-carbon fibers, carbon fabrics, metal threads, plates, foil strips, wire scraps, meshes of a complex shape, gratings, resonant elements in the form of cross-shaped dipoles [6] or closed conductors (rings) etc. [7];
3) metallized carbon and polymer fibers, fabrics, films, macrospheres;
4) magnetic fillers – ferrites of different chemical composition (mostly magnetically soft), as well as magnetic powders of metals and amorphous Fe alloys, Fe-Co-Ni alloys; perm, etc.) [8];
5) dispersed semiconductors: charred organic silicon fabrics and fibers [9],
6) dielectrics, in particular, easily polarized organic substances (retinyl Schiff salts) [10], biopolymers (chitin), etc.

In modern scientific literature, many compositions of ferrite components for absorbers of various ranges are described [11]. These materials are intended for the electromagnetic radiation range of 0.5-12 GHz. The size of particles of ferrite powders that effectively absorb electromagnetic radiation at frequencies of 0.5-1.5 GHz is 1.65-0.7 mm, and in the range of 2.5-12 GHz – 0.1 mm. The advantage of ferrite absorbers is their small thickness (several millimeters). However, they are time-consuming to manufacture and non-technological, as it is necessary to stick ferrite plates on the surface of the metal part being protected. In addition, such absorbers have an insufficiently wide band of operating frequencies [5].

By varying fillers concentration it is possible to achieve the required electromagnetic properties: high absorption coefficient, complex dielectric and magnetic permeability, and shielding level. In modern scientific sources, there is a lot of research on receiving materials for protection against electromagnetic radiation. Most research concerns the design effective materials for protection against electromagnetic radiation based on mixtures and composites of fillers with magnetic properties (such as ferrites [3], metals [6]) and various dielectrics – ceramic, polymer and other matrices [7]. As an active phase (filler) of composites, carbon-containing materials (carbon nanotubes [7], graphite [12], carbonyl iron, fullerenes, etc.) [8], ferrite powders [9] are used widly. The composite materials research based on ferroelectrics [10] and multiferroics is actively developing [11].The material absorbing high-frequency electromagnetic radiation based on barium hexaferrite substituted with diamagnetic ions are demonstrated [13]. It is shown that absorbing high-frequency electromagnetic radiation in such barium hexaferrite substituted to higher frequencies due to an increase in the magnetocrystal anisotropy [14].

Thermoreactive polymer composites containing silicon carbide [12], carbon fibers [15], carbon black [16] and carbon nanotubes [17] are also effective. They provide protection as radio shielding materials and coatings due to the absorption mechanisms combination [18]: natural ferromagnetic resonance, resonance of domain boundaries movement, eddy current losses and repolarization, multiple imprints and etc.

Such materials effectively provide protection against electromagnetic radiation, but their disadvantages include the complexity synthesis and high cost.

Therefore, polymer composites for protection against electromagnetic radiation based on various thermoplastic matrices (polyvinylbutyral [19], polypropylene [20], polyvinylidene chloride [21], etc.) have been recently designed. In such polymer composites, inorganic ferromagnetic fillers are used. They have better technological, operational and economic characteristics.

In our previous work [22], polymer composites for protection against the electromagnetic radiation absorption based on thermoplastic polyamide 6 and silicon carbide were received. This polymer composites are transparent in the millimeter frequency range (approximately 3 dB, this is a 2-fold attenuation), have a small absorption coefficient but low mechanical properties.

Overall efficiency electromagnetic radiation absorption for received compositions was insufficient. So further research in the framework of complex ceramic-inorganic graphite-ferromagnetic fillers application was carried out as expedient.

The *aim* of the article is ceramic-inorganic polymer composites mechanical properties designing for protection against electromagnetic radiation.

2. Materials and methods

For polymeric ceramic-inorganic composites research, that can be used for electro-magnetic protection coating production:

- polyamide 6 brand Durethane (Bayer, Germany);
- silicon carbide SiC powder – size 50-65 microns;
- chromium oxide Cr_2O_3 powder – size 2-5 microns;
- graphite powder – size 20-25 microns, which was received from graphite samples (were used standard graphite blanks).

After analysis, the graphite sample was additionally crushed to 100% to the class content less than 0.075 mm using a cylindrical mill on elastic hangers and scattered on a mechanical disperser on 0.02 mm grids.

Quality indicators of carbon graphite sample and scattering results (2 samples) are given in table 1 and table 2.

Polymer composites were production by extruding.

Strength characteristics determination was carried out according to ISO 180 and ISO 178. Complex strength characteristics determination of polymeric ceramic-inorganic composites for electromagnetic radiation absorption was carried out on pendulum copra at a temperature of 20 °C. For each composition, 20 parallel measurements were made.

Table 1. Quality indicators of carbon graphite sample.

Characteristics	Symbol, unit of measurement	Value %
Total moisture	W_t^r,%	0.10
Analytical moisture	W^a,%	0.10
Ashiness	A^d,%	0.18
Carbon content	C^d,%	99.06
Hydrogen content	H^d,%	0.76

Table 2. Results graphite grid analyses.

Class, mm	Value, %
less of 0.02	31.4-43.2
0.02-0.075	56.8-68.6

Optimization experimental-statistical mathematical models construction in equal regressions form was carried out using the STATISTICA software.

3. Results and discussion

Primary studies were directed at studying the SiC, Cr_2O_3 and graphite impact on strength properties complex of polyamide 6 compositions. From previous work [22], it was found that increasing the content of SiC in polyamide 6 led to an increase in both IR and BSDB.

Optimal content of fillers for those was found at level 5%wt. But overall efficiency of received compositions protection against electromagnetic radiation was insufficient, this article researched compositions with a higher content of SiC – 10% wt., and optimized the content of Cr_2O_3 and graphite in the range of 5-15 % wt. Also, to establish the synergistic effect the three different ceramic-inorganic graphite-ferromagnetic fillers integrated effect, polyamide 6 – SiC – Cr_2O_3 – graphite systems were studied. In the table 3 shown the filler's level impact of polymer ceramic-inorganic composites based on the polyamide 6 – SiC – Cr_2O_3 – graphite system on the IR and BSDB. From the data in table 3, it can be seen that the introduction of polyamide 6 – SiC 10% wt. into the system of chromium oxide Cr_2O_3 and graphite increases their IR and BSDB.

Table 3. Filler's level impact of polymer ceramic-inorganic composites based on the polyamide 6 – SiC – Cr_2O_3 – graphite system on the IR and BSDB.

Composites	IR, MPa	BSDB, MPa
Polyamide 6 – 10 % wt. SiC	38	175
Polyamide 6 – 10 % wt. SiC:		
5 % wt. graphite	43	183
10 % wt. graphite	52	190
15 % wt. graphite	50	185
Polyamide 6 – 10 % wt. SiC:		
5 % wt. Cr_2O_3	40	180
10 % wt. Cr_2O_3	45	185
15 % wt. Cr_2O_3	44	182
Polyamide 6 – 10 % wt. SiC:		
5 % wt. Cr_2O_3 – 5 % wt. graphite	42	185
10 % wt. Cr_2O_3 – 10 % wt. graphite	47	188

The maximum level of the studied strength characteristics is typical for the systems of polyamide 6 – SiC 10% wt. – graphite 10% wt. Also high level of strength is also observed in the triple complex system of ceramic-inorganic fillers polyamide 6 – SiC 10% wt. – Cr_2O_3 10% wt. – graphite 10 % wt. It can be concluded that binary modification with ceramic-inorganic graphite-ferromagnetic fillers of composites based on the systems polyamide 6 – SiC 10% wt. – Cr_2O_3 10% wt. and polyamide 6 – SiC 10% wt. – graphite 10% wt. is optimal for increasing its strength characteristics. For three-component complex modification with ceramic-inorganic graphite-ferromagnetic fillers, the polyamide 6– SiC 10% wt. – Cr_2O_3 10 % wt. – graphite 10 % wt. system is the most optimal. Also, while studying the spectral characteristics of the polymeric ceramic-inorganic composites, it was established that the highest level of reflection coefficient over 23 % is typical for polyamide 6 systems of 6-10% wt. silicon carbide – 10% wt. chromium oxide Cr_2O_3 – 10% wt. graphite, which is related to the complex nature of the action of various ceramic-inorganic graphite-ferromagnetic fillers. This system is almost 2.5 times superior to previously obtained composites [20] in level of spectral characteristics.

For building a mathematical model to optimize mechanical properties of ceramic-inorganic polymer composites for protection against electromagnetic radiation, an analysis datas given in the table 3 was carried out. Ninth experiments were made, the composition of the composite varied within the following limits: polyamide 6 + SiC 10 % wt. – from 83.32 to 100 % wt.; graphite – from 0 to 13.04 % wt.; Cr_2O_3 – from 0 to 13.04 % wt. At the same time, the IS values ranged from 38 to 52.5 MPa, and the BSDB values ranged from 175 to 190 MPa. Table 4 shows the pairwise correlation coefficients between indicators.It can be concluded that the indicators of IS and BSDB are interrelated, which is confirmed by the high value of the pairwise correlation coefficient between them (0.860).

Table 4. Pairwise correlation coefficients of mathematical model for composition mechanical properties optimization.

	IR	BSDB	Polyamide 6-SiC 10%wt.	Graphite	Cr_2O_3
IR	1.000				
BSDB	0.860	1.000			
Polyamide 6-SiC 10%wt.	-0.655	-0.716	1.000		
Graphite	0.788	0.663	-0.524	1.000	
Cr_2O_3	-0.102	0.088	-0.524	-0.451	1.000

Polyamide 6 + SiC 10 % wt. content increasing leads IR and BSDB decreasing. The same time, graphite content increasing leads IS and BSDB increasing. The Cr_2O_3 content impact on mechanical properties is insignificant.

Table 5 shows the calculated mathematical equations that describe content of polyamide 6 + 10%wt. SiC, graphite and Cr_2O_3 impact on the IR and BSDB, as well as statistical indicators.

Table 5. Mathematical equations and statistical indicators of mathematical model for composition IR and BSDB optimization.

Mathematical model	R	R^2
IR=69.682-0.303(polyamide 6+ SiC 10%)+0.584graphite+0.02Cr_2O_3	0.838	0.702
BSDB=69.682-0.440(polyamide 6+SiC10%wt.)+0.359graphite+0.01Cr_2O_3	0.792	0.627

Multiple correlation indicators R and R^2 of the developed models are high enough ($R = 0.792 - 0.838; R^2 = 0.627 - 0.702$), and level of standard error 2.921-3.115 MPa allow to use built equations for the IR and BSDB prediction of designed ceramic-inorganic polymer composites for protection against electromagnetic radiation.

4. Conclusions

The article considers the possibility to receive polymeric ceramic-inorganic composites for protection against electromagnetic radiation. As a result the polymer polyamide composites modified with ceramic-inorganic graphite-ferromagnetic fillers: SiC, Cr_2O_3 and graphite were received.

The strength complex characteristics of compositions with carbide SiC – 10%wt . were studied. For them content of Cr_2O_3 and graphite in range 5-15%wt. was optimized. It was found that the optimal strength characteristics shows composites based on the systems polyamide 6 – SiC 10%wt. – $Cr_2O_3$10%wt. and polyamide 6 – SiC 10%wt. – graphite 10%wt. when it is binary modification with ceramic-inorganic graphite-ferromagnetic fillers. For three-component complex modification with ceramic-inorganic graphite-ferromagnetic fillers, the most optimal system is polyamide 6 – SiC 10%wt. – $Cr_2O_3$10%wt. – graphite 10%wt with highest mechanical and spectral properties. By design experimental-statistical mathematical models in equal regressions, mathematical optimization of polymeric ceramic-inorganic composites mechanical properties for protection against electromagnetic radiation was carried out. Received polymeric ceramic-inorganic composites for absorbing electromagnetic radiation can be used for radio-absorbing materials production according to their strength and spectral characteristics.

Abstract. The results of studies of the flushing fluids influence on the capacity-filtration characteristics of carbonate rocks are presented. It was found that hydrogel-magnesium fluids using desulfurized bischofite are the optimal flushing fluid for opening carbonate-type formations. Solutions of the hydrogel-magnesium type, with a relatively small depth of penetration into the formation, are distinguished, among others, by a high coefficient of recovery of permeability. After the application of such solutions and subsequent acid treatment, the pore space of the formation can be almost completely restored. The effect of the presence of sulfate ions in the bischophyte on the permeability and recovery coefficient of the carbonate core was investigated. It was established that in the presence of sulfate ions in bischophyte, the permeability and formation recovery in the presence of formation water decreases by 11.53 times, and when using pure bischophyte – only by 1.29 times. An improved method of preparing bischofite for use in washing liquids has been developed. The results of industrial use of the developed method are given.

1. Introduction

Ukraine has significant deposits of developed mineral deposits. Nowadays, 90 types of minerals have been explored, which are concentrated in almost 8,000 deposits. For sustainable development, it is necessary to increase the efficiency of the natural resources using [1–3].

Provision of own energy resources is a guarantee of not only energy, but also state independence of Ukraine. Unfortunately, in recent years, gas production in Ukraine has begun to steadily decrease. In 2020, 20.23 billion cubic meters of gas were produced, which is 2.2% less than in 2021 (19.79 billion cubic meters), in 2022 Ukraine is going to produce 18.5 billion cubic meters. m of gas, which is 6.6% (1.3 billion cubic meters) less than in 2021. The bloody war between Russia and Ukraine in 2022 radically changed the national gas sector: there was a significant decrease in both consumption and production due to Russian bombing of our gas fields.

Also, the reasons that prevent the realization of the domestic hydrocarbon potential are the depletion of deposits (by 65 – 70%), which causes a sharp drop in production and difficult access (the average depth of the deposits exceeds 3500 m) and the dispersion of a large number of small fields – reserves 89% of deposits do not exceed 5 billion m^3. At the same time, in order to ensure the sustainable development of the oil and gas sector, the annual growth of the raw material base should be 2 – 3 times higher than the production level [4].

The drilling of oil and gas wells leads to a destruction of the natural balance of fluid saturation of productive layers. As a result of the penetration of leachate and the solid phase of washing or process fluids, the character of the saturation of the pore space of the rocks in the bottomhole formation zone of the formation changes, processes occur that are caused by the physical and chemical interaction of drilling muds with the rock and formation fluids, which significantly worsen the filtration properties of the rocks [5].

The influence of flushing fluids on productive formations is due to penetration into the pore space of the filtrate collector and dispersed phase, swelling of clay cement, formation of solid sediments and emulsions during interaction with formation fluids, reduction of effective pore volume [5, 6]. All this leads to deterioration of productive characteristics of wells. Therefore, the question arises of preserving the natural productive properties of formations during the construction, repair and restoration of wells. An equally important task is the choice of means and methods for restoring to the initial level and improving the filtration properties of rocks contaminated with drilling fluids.

2. Problem statement

Drilling muds play an important role in ensuring the growth of drilling volumes and hydrocarbon production. Contamination of the bottomhole formation zone of the formation during primary and secondary opening and the associated deterioration of natural reservoir properties can lead to a significant loss of well productivity and, conversely, minimization of such contamination can allow obtaining industrial products from deposits, the production of which, even recently, was impossible for technical or economic reasons [5–9].

A significant contribution to research of the fundamental physico-chemical processes occurring in the wellbore and in the area around it, in relation to the issues of the stability of the shaft, the hydrodynamics of flushing and cleaning of the outcrop, and the qualitative opening of productive horizons were made by number of researchers. The development of these provisions regarding the conditions of drilling wells in the deposits of Ukraine is reflected in [7, 8]. These scientists have developed and implemented a large number of various formulations of drilling muds aimed at effective drilling of wells and high-quality opening of productive horizons in difficult mining and geological conditions.

According to modern ideas, clay-free biopolymer systems provide the highest quality of opening productive horizons among water-based drilling muds [10–12]. This is due to the biodegradable polysaccharide composition and acid-soluble solid phase, as well as unique rheological, structural-mechanical and filtration properties. In addition, clay-free biopolymer drilling muds create almost no man-made load on the environment, ensure successful passage of horizontal and inclined wells, uncomplicated opening of zones with abnormally low formation pressures, avoidance of scree, absorption and differential adhesions.

For carbonate-type collectors, which are typical for the gas condensate field of the Zahoryanska area of the Dnieper-Donetsk rift, it is advisable to use a polymer-potassium low-clay type, a clay-free polymer-magnesium type liquid on a polyacrylamide basis, and a hydrogel-magnesium type liquid using bischofite.

The use of bischofite solutions as part of flushing fluids is promising. Estimated resources of bischophite only within the Orchykiv depression of the Dnieper-Donetsk rift amount to about 10 billion tons. In practice, the use of bischofite at gas production enterprises is often limited due to its irrational use. Salt deposits, when bischophite enters the formation, can form in the pores of the rocks of the bottomhole formation zone, reducing their permeability and porosity [13, 14]. The chemical composition of inorganic deposits is represented mainly by calcium sulfates and carbonates, oxides, carbonates, oxides, and iron sulfide [10, 11].

The main reasons for the formation of salts are:

- a decrease in pressure and an increase in the temperature of mining fluids, which leads to the release of dissolved carbon dioxide into the gas phase:

$$Ca^{2+} + 2(HCO_3^-) \rightarrow CaCO_3 \downarrow + CO_2 \uparrow + H_2O;$$

- mixing of incompatible waters:

$$Ba^{2+}(Sr^{2+}, Ca^{2+}) + SO_4^{2-} \rightarrow BaSO_4 \downarrow (SrSO_4, CaSO_4);$$

- supersaturation of fluids is limited by soluble salts and their salting out.

Considering the above, there is a need to study the influence of flushing fluids on the capacity-filtration characteristics of carbonate rocks and to improve the method of preparing bischofite solution for use as part of flushing fluids when drilling wells.

The main direction of research was to determine the type of liquid that will be used as a flushing agent in carbonate-type rocks and at the same time will maximally preserve the capacity-filtration properties of the pore space.

3. Materials and methods

The following drilling muds were studied: polymer-potassium low-clay type fluids, clay-free polymer-magnesium type fluids on a polyacrylamide basis, and hydrogel-magnesium type fluids.

The influence of the flushing fluid on the properties of carbonate rocks was evaluated according to the standard methodology at the UDPK-1M installation (figure 1).

The research was carried out on carbonate core material taken from the drilling interval 4935 – 5090 m of well №1 of the Zahoryanska area, which corresponds to the interval of well №3, which needs to be opened. Before conducting the research, the core was wetted with formation water of the chlorcalcium type ρ=1.18 g/cm^3, typical for deposits B24-25 of the Zahoryanska field. Repression on the formation during the research was 250 – 300 atm, that is, the conditions of maximum repression on the formation under dynamic loads during the drilling process were modeled.

According to some data, under the influence of process fluids based on bischofite, the filtration properties of the reservoir often deteriorate due to the formation of insoluble sulfate deposits in the pore space as a result of the interaction of filtrates and reservoir fluids [2]. In the second series of experiments, the effect of the presence of sulfate ions in bischophyte on the properties of carbonate collectors was studied. In order to detect the process of pore blocking by chemically formed gypsum, the core was wetted with formation water of chlorcalcium type ρ=1.18 g/cm^3. Up to 20 volumes of the pore space of purified and untreated bischofite ions SO_4^{2-} were passed through the core.

Bischofite solutions with a mass fraction of $MgCl_2$ of 24% from well №1 of the Zahoryanska area were used for research. The chemical macro-composition of bischofite solutions from well №1 of the Zahoryanska field is presented in table 1.

In order to find components that accelerate the precipitation of gypsum deposits, studies were conducted to determine the effect of surface-active substances on the process of calcium sulfate deposition.

Studies were conducted with surface-active substances: 1) KI-1-M – a mixture of catapin and urotropin; 2) SRK – aqueous solution of sulfur adduct of saturated fatty alcohol; 3) EM-1 – an aqueous solution of cationic and amphoteric surfactants; 4) Stentex – cationic surfactant; 5) CAPB – cocamidopropylbentain belongs to amphoteric surface-active substances.

Before conducting the experiment, $Na_2SO_4 \cdot 10\,H_2O$ was added to the bischofite solution with a mass fraction of $MgCl_2$ of 24% at the rate of 28.38 g/dm^3. In a measuring cylinder with a volume

Figure 1. Permeability test setup core in reservoir conditions (UDPK-1M).

of 100 ml, the necessary amount of the prepared solution of bischofite with a mass fraction of $MgCl_2$ of 24% and with an additive of surfactant concentration of 0.1% was placed. The calculated amount of calcium chloride dried to a constant mass was added to the solution. Some time, after the initial turbidity, massive spontaneous formation of solid phase nuclei occurred. At

Table 1. Chemical macro-composition of bischophyte solutions from well №1 of the Zatyryno field.

Cations	**C, g/l**	**w, eq. %**	**Anions**	**C, g/l**	**w, eq. %**
Potassium + Sodium	1.0610	0.58	Chlorine Sulfine	273.04 11.65	69.90 3.05

Total	97.9090	100.00	Total	284.90	100.00

this stage, the contents of the measuring cylinder were mixed. After the onset of sedimentation, stirring was stopped and further sedimentation took place under static conditions.

The resulting solutions were kept in a thermostat at a temperature of 20 ℃ for 168 hours. The content of sulfates in the sediment was determined by the gravimetric method. After 7 days, the sediment was filtered through a "blue tape" filter, decanted, washed with hot distilled water until there was a negative reaction to the chloride ion. After that, the filter was dried on a tile in a crucible, charred in a crucible furnace at a temperature of 500 ℃, fired at a temperature of 800 ℃ and weighed after cooling. The degree of deposition of calcium sulfate X in % was determined by formula 1:

$$X = \frac{m}{m_0} \cdot 100\%, \tag{1}$$

where m – is the mass of calcium sulfate in the sediment, g; m_0 – is the mass of calcium sulfate, which corresponds to the initial concentration of sulfate ions in the solution, g.

At the same time, the nature of the deposition was visually determined by the change in the volume of the sediment and the structure of the crystals under an Olympus BX 41 microscope (2005, Japan) with a magnification of 100 times.

4. Experimental laboratory results

From the conducted research, it can be concluded that solutions of clay-free polymer-magnesium type on polyacrylamides have the greatest depth of penetration into the formation. At the same time, they are characterized by a low coefficient of reservoir recovery. In addition, after processing the core with an acid solution, insoluble polymer structures are formed, which almost completely calm the formation.

Solutions of the polymer-potassium type, although they have a small penetration depth, but this effect is achieved by calming the pores with a solid insoluble clay phase, which is part of these solutions. Due to this, the formation recovery rate after using such solutions is also low.

Solutions of the hydrogel-magnesium type, with a relatively small depth of penetration into the formation, are distinguished, among others, by a high coefficient of recovery of permeability. After the application of such solutions and subsequent acid treatment, the pore space of the formation is almost completely restored. They do not contain an introduced solid phase that would irreversibly calm the pore space. Carbonate blockers are formed during the preparation of this flushing fluid and do not calm the pore space.

Table 2 presents the results of studies of the influence of flushing fluid on the capacity-filtration characteristics of carbonate rocks.

Bischophyte is a component of the investigated solutions. A study of the influence of the presence of sulfate ions in bischophyte on the properties of carbonate reservoirs was carried out. The influence of sulfate ions on the permeability and recovery coefficient of the carbonate core is shown in Table 3. It is noted that in the presence of sulfate ions in bischofite, the permeability

Table 2. Results of studies of the influence of flushing fluid on the capacity-filtration characteristics of carbonate rocks.

Clay-free polymer-magnesium solution	15-18	45-60	15-30	3-7
Hydrogel-magnesium solution	12-17	40-50	70-85	92-98

Table 3. The influence of sulfate ions on permeability and recovery indicator of carbonate core.

Drilling mud	Permeability, md	Recovery indicator of carbonate core, %
Bischofit with sulfate ions	26.50	93.90
Bischofit with sulfate ions + formation water	1.62	6.20
Bischofit without sulfate ions	20.59	96.47

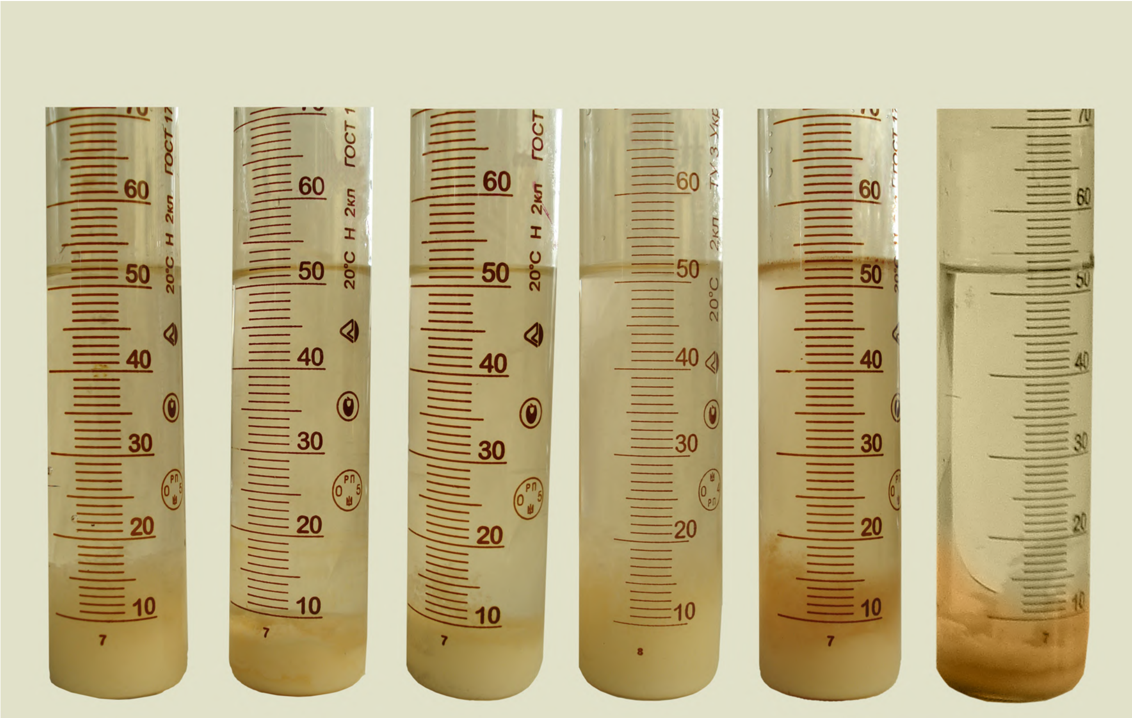
and recovery of the formation in the presence of formation water decreases by 11.53, and when using pure bischofite – by only 1.29 times.

Thus, as the research results showed, it is not necessary to use desulfated bischofite for the preparation of polymer-magnesium solutions. To solve this problem, it is necessary to use precipitation catalysts, which make it possible to simultaneously carry out rapid desulfation of bischofite and prevent salting out of chlorides. The crystallization of calcium sulfate from an aqueous solution of bischofite with a mass fraction of $MgCl_2$ of 24% in the presence of surface-active substances was investigated. The processes of calcium sulfate crystallization in the presence of various surface-active substances differ significantly (figure 2) [15, 16].

In figure 3 shows unwashed and washed from chloride precipitates on the filter. Precipitates with the addition of amphoteric surfactants have a visually smaller volume compared to the control experiment, and those with the addition of cationic surfactants have a more fragile structure and large crystals.

In the unwashed sediment formed from pure bischofite, without the addition of surfactant, a group of closely spaced crystals of various shapes is formed. Addition of cationic surfactants (KI-1M, St) to the initial solution leads to a decrease in extraneous formations and the precipitation of needle-like crystals of different lengths.

The structure of calcium sulfate crystals without the addition of surfactants and with the addition of cationic surfactants is approximately the same. Crystals are needle-shaped and vary in length. However, the addition of amphoteric surfactants (EM and CAPB) and cationic surfactant SRK leads to the formation of larger lamellar crystals, the diameter and thickness of which increase significantly, and the length decreases (figure 4).



1 2 3 4 5 6

Figure 2. Sedimentation in bischofite solution with a mass fraction of $MgCl_2$ 24% during elimination of sulfates in the presence of surfactants, the mass fraction of which is 0.1%: 1 – without surfactants; 2 – EM; 3 – SRK; 4 – St; 5 – KI-1M; 6 – CAPB.

After calcination of the precipitate at a temperature of 800 ℃, the structure of the crystals with different additives of surfactant and the control experiment is approximately the same.

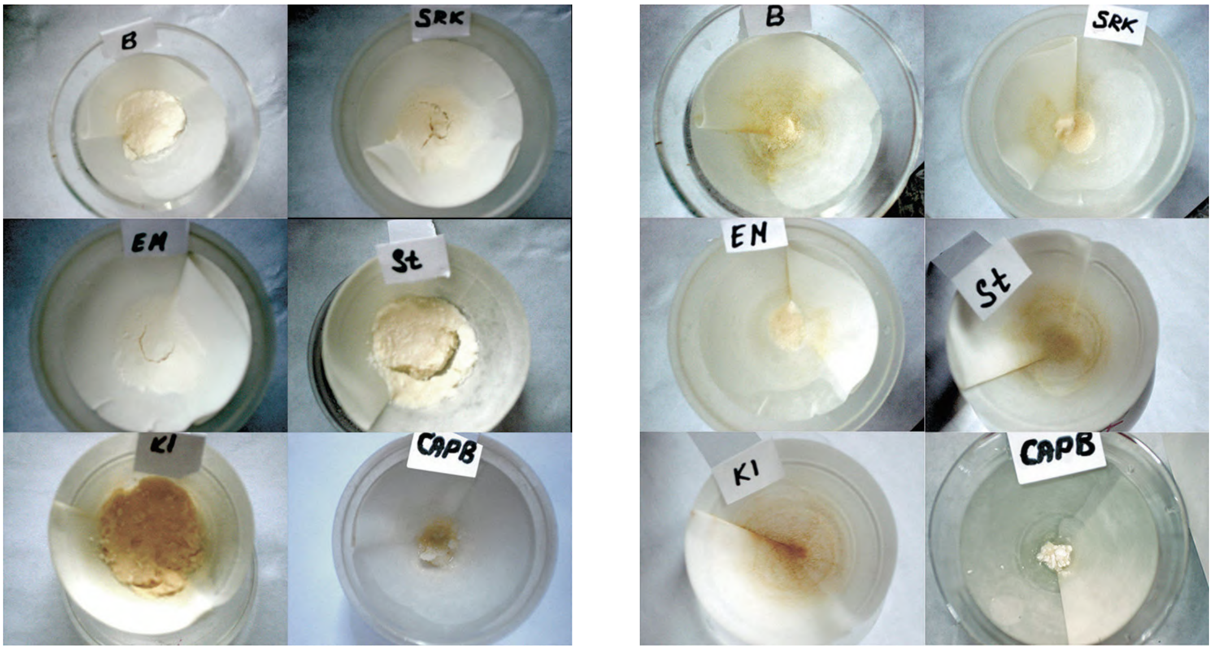
The positive effect of surfactant additives is obvious, since in the presence of these reagents the sediment is formed in the form of a fine dispersion, which, unlike amorphous sediment, can be easily removed from the container where bischofite desulfation takes place.

As can be seen from table 4, the degree of precipitation of calcium sulfate from an aqueous solution of bischofite with a mass fraction of $MgCl_2$ of 24% in the presence of surface-active substances (w = 0.1%) decreases in the following order: CAPB > EM > SRK > St > KI-1M, and the sediment volume, on the contrary, increases in this order.

The lower value of the calcium precipitation degree of sulfate relative to the volume of sediment in the presence of St and KI-1M can be explained by the fact that the process of salting out chlorides prevails over the chemical reaction of precipitation of sulfates.

Analysis of the influence of the amount of precipitant on the rate of separation of solid and liquid phases showed that EM, CAPB and SKR surfactants also have close results in terms of the rate of precipitation. Phase separation takes place within 0.5–1 h, the solid phase settles to the bottom of the vessel, a clear separation boundary between the phases is visible. Over time, the volume of sediment does not increase, and after 5 days its compaction is observed. In the presence of cationic surfactants KI-1M and St, phase separation occurs very slowly, the sediment is loose, occupies 2/3 of the cell volume.

The results of the study showed that the excess introduction of precipitant $CaCl_2$ by more than 4 times in the presence of all surface-active substances leads to a decrease in the degree of precipitation of $CaSO_4$, while the volume of the precipitate does not change.



a b

Figure 3. Filter residue: a – unwashed; b – washed from chlorides.

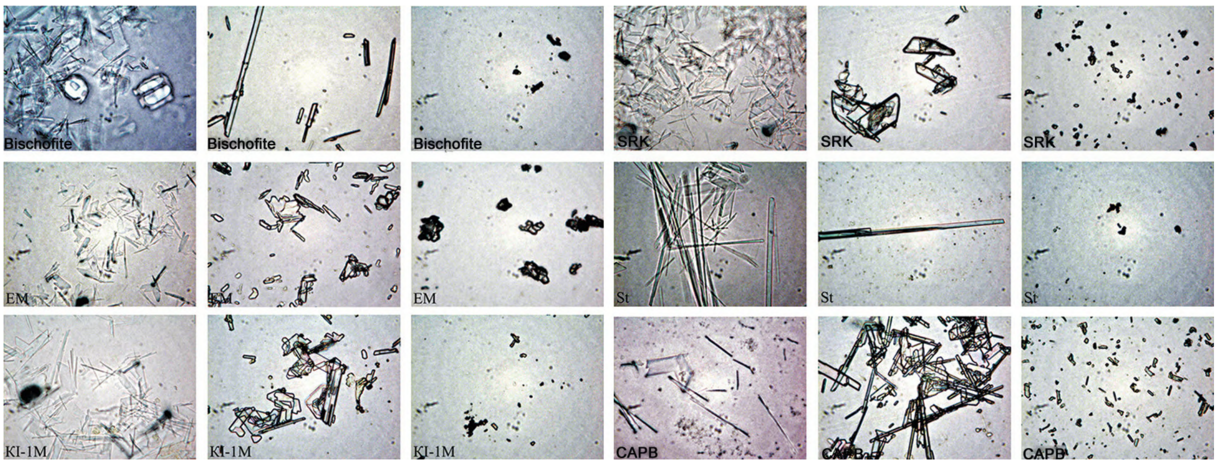


Figure 4. The structure of sediment crystals (mass fraction of surfactant – 0.1%).

The results of the experiments show that among the investigated surface-active substances EM, CAPB and SKR are effective catalysts of sulfate precipitation and inhibitors of salting out chlorides. Therefore, in order to accelerate the process of precipitation of $CaSO_4$ during the desulfation of bischofite intended for the preparation of the flushing fluid of the primary opening of the carbonate deposits of the Zahoryanska area of well № 3, the catalyst cocamidpropylbentaine was used. Due to the addition of this reagent in a volume of 0.1% to bishofite at the time of introduction of calcium chloride, the precipitation process was accelerated four times. Thus, the precipitate of $CaSO_4$ in bischofite without the addition of a catalyst was formed in a vertical container with a volume of 36 m^3 for 20 days, and with a catalyst – for 5 days.

In addition, in order to fully use the $CaCl_2$ introduced into the first portion of bischofite, at the

Table 4. The influence of the amount of precipitant on the degree of calcium sulfate of precipitatio in the presence of surfactants (w=0.1%).

Bischofite solution ($w(MgCl_2)=24\%$)	–	20.00	5.60	29.02	12.10	30.10	15.21
	KI-1M	16.92	1.60	23.07	3.60	24.60	2.66
	St	23.08	4.80	38.46	10.30	39.50	6.37
	SKR	3.08	19.96	13.84	48.20	15.20	49.54
	EM	3.01	28.65	12.30	68.20	13.80	49.51
	CAPB	1.50	40.31	3.08	88.96	3.90	62.34

rate of 4 tons per 140 m^3, i.e. in a fourfold excess in relation to the content SO_4^{2-} in bischofite, the second portion of desulfurization of bischoffite was carried out by introducing 0.1% into non-desulphated bischoffite cocamide-probilbentaine and $CaSO_4$ sediment, which, according to chemical analysis, contained up to 100 g/l of ions Ca^{2+}, which made it possible to speed up the desulfation process and ensure maximum purification of bischofite from sulfate ions.

Thus, in industrial conditions, for the first time, the catalyst for the precipitation of $CaSO_4$ during the desulfation of bischofite was tested and the technology of preparation of bischoffite was applied by reusing $CaSO_4$ sediment with an excess content of $CaCl_2$, which made it possible to reduce the cost of the preparation process and accelerate the precipitation by 4 times.

5. Conclusion

Based on the above, the following conclusions can be drawn:

1. Hydrogel-magnesium fluids using desulfurized bischofite are the optimal flushing fluid for opening carbonate-type formations.
2. The opening of productive layers in depressions using a solution of desulfurized bischofite allows to preserve the natural filtering properties of the collectors and increase the efficiency of extraction of hydrocarbons from the subsoil. In the presence of sulfate ions in bischophyte, the permeability and formation recovery in the presence of reservoir water decreases by 11.53 times, and when using pure bischophyte – only by 1.29 times.
3. When preparing bischofite, it is recommended to use the amphoteric surfactant CAPB as a catalyst for precipitation of sulfates and an inhibitor of salting out chlorides at a mass fraction of 0.1%. This makes it possible to increase the degree of precipitation of $CaSO_4$ by 76.86%, to reduce the volume of the formed sediment by 9.4 times.
4. Industrial tests showed that the preparation of bischofite solution using CAPB ensures a 4-fold reduction in bischofite preparation time, a 7.5-fold increase in the degree of calcium sulfate removal, and a 3-fold decrease in sediment volume.

Abstract. Natural gas in the gas hydrates form is proposed to be stored in improved shell gas-resistant structures. The improvement of the construction and the operation method of these buildings consists in the use of liquid foam as a thermal insulation material. The design and operation technology of a terrestrial shelter facility for the accumulation and storage of natural gas as a gas hydrate is proposed, the main element of which is a frameless gas-resistant shelter in the form of at least two dome-shaped gas-tight soft shells on a thermally insulated base, the space between which is filled with liquid foam. The use of these hydrate shelters will significantly increase the efficiency and competitiveness of natural gas storage technology in the gas hydrates form.

1. Introduction

As is known, at relatively low temperatures and a certain pressure, water molecules form a three-dimensional structure that can be occupied by gas molecules (for example, methane, ethane, carbon dioxide, etc.) [1]. This type of compounds are known as clathrates or inclusion compounds [2]. Today, a number of technologies are known in which gas hydrates are an intermediate or target product. These are the so-called gas hydrate technologies (transportation and storage of natural gas in gas hydrate form [1], gas hydrate fractionation, concentration using gas hydrates of any aqueous solutions [3, 4], etc.).

At the same time, the natural gas storage in gas hydrate form in many cases becomes a real alternative to traditional technologies.

Storage of gas hydrate requires maintenance of appropriate thermobaric conditions. However, gas hydrate can exist in a metastable state for some time as a result of the self-preservation effect or due to preservation by a ice layer of [4–6].

In addition, a compulsory condition for the reliable gas hydrate storage is the organization its high-quality thermal insulation and sealing. Such conditions should be ensured in specialized hydrate shelters. There are a number of projects, which involve the use of surface or partially buried capital structures built from traditional building materials.

However, warehouses made of traditional metal or reinforced concrete structures cannot provide effective sealing and thermal insulation. In fact, these structures can only perform the role of a skeleton for attaching insulating and sealing elements. At the same time, a relatively thin layer of porous material (foam, mineral wool, etc.) can provide effective thermal insulation, and a polymer film can provide high-quality sealing [7, 8].

Based on this, it is proposed to use gas-resistant pneumatic structures as hydrate storages [9]. At the same time, modern coatings allow maintaining their operational characteristics for a long time (up to 15-20 years) [10]. In addition, they can be easily dismantled, transported and quickly assembled, that is, they can be considered as mobile technological objects.

These buildings are structures supported by a gas cushion. However, the pressure in them is higher than atmospheric only to ensure the force for the formation of a dome-shaped form and to compensate for the mass of the shell itself (in the range of pressure – 0.01-1.0 MPa) [11, 12].

However, the thermal resistance of such structures is insignificant [11]. Therefore, they need their conditioning (cooling). Taking into account the costs of cold production, it is impractical to operate such buildings without the organization of additional thermal insulation. A variant of increasing the thermal resistance of these structures is the use of two- and three-layer coatings. However, the thermal resistance of the barrier gas layer increases noticeably only up to its thickness of 0.3 m [9]. For example, the coefficient of thermal conductivity of the two-layer shelters considered in [11] was 2.8-3.4 $W/(m^2 K)$. Therefore, regardless of the external temperature, a significant heat flow will enter the storage even through a double-layer coating.

2. Improvement of the storage-shelter thermal insulation system

It is known that the thermal insulation properties of materials are determined by their porosity. The pores are filled with gas of low thermal conductivity. As thermal insulation, among others, materials are used, which are polymers, foamed before the start of hardening. Hardening, in this case, is required for the production of heat-insulating panels of a certain shape and size for the convenience of their use and transportation.

However, the phase state of material bubbles does not affect its thermal insulation properties. Therefore, the use of solid porous thermal insulation materials is due to the convenience of their use. In the case of gas-resistant shell structures, the use of solid heat-insulating materials will be unacceptable, as this will significantly complicate the construction and duration of the shelter installation.

Therefore, it is suggested to use liquid polymer foams as a material for thermal insulation of gas-resistant shell structures – shelters for gas hydrates. At the same time, in the case of using a transparent shell-shelter, the foam will allow part of the scattered sunlight into the storage-shelter. This will make it possible to regulate the supply of energy to the storage to some extent. The schematic diagram of such a storage-shelter, supplemented by a complex of appropriate equipment for the implementation of the technological process of gas hydrate storage and regasification, is presented in figure 1.

Its main elements are shelter, base and auxiliary equipment. The shelter of the hydrate storage-shelter consists of a liquid foam layer between several impermeable to gas and water canvases 2 and 4 with a sun-reflective layer on top.The shelter is fixed by a net made of ropes 5. The storage-shelter is equipped with the following systems: foam generation and selection of products its destruction; storage conditioning (cooling and heating); gas and water selection.The foam generation system involves supplying the produced foam to the upper part of the space between the inner and outer shells. At the same time, a system for selecting of foam destruction products is placed between the shells at the base level.

For the maximum energy efficiency of the technology, the level of gas hydrate cooling in the production process is determined, taking into account the duration and parameters of transportation and storage.

The flow of thermal energy from the ground through the base of the storage at its average value of 17 W/m^2 [13] will be 0.03 MW. Thermal insulation of the base will allow to reduce it to 9 kW. After the preparation of the site, the base of the storage-shelter is arranged by sequentially laying a layer of thermal insulation 9 (figure 1), a coating of water- and gas-tight material 8, a heat exchanger in the form of a system of pipes 16, a system of gutters and perforated pipes 6

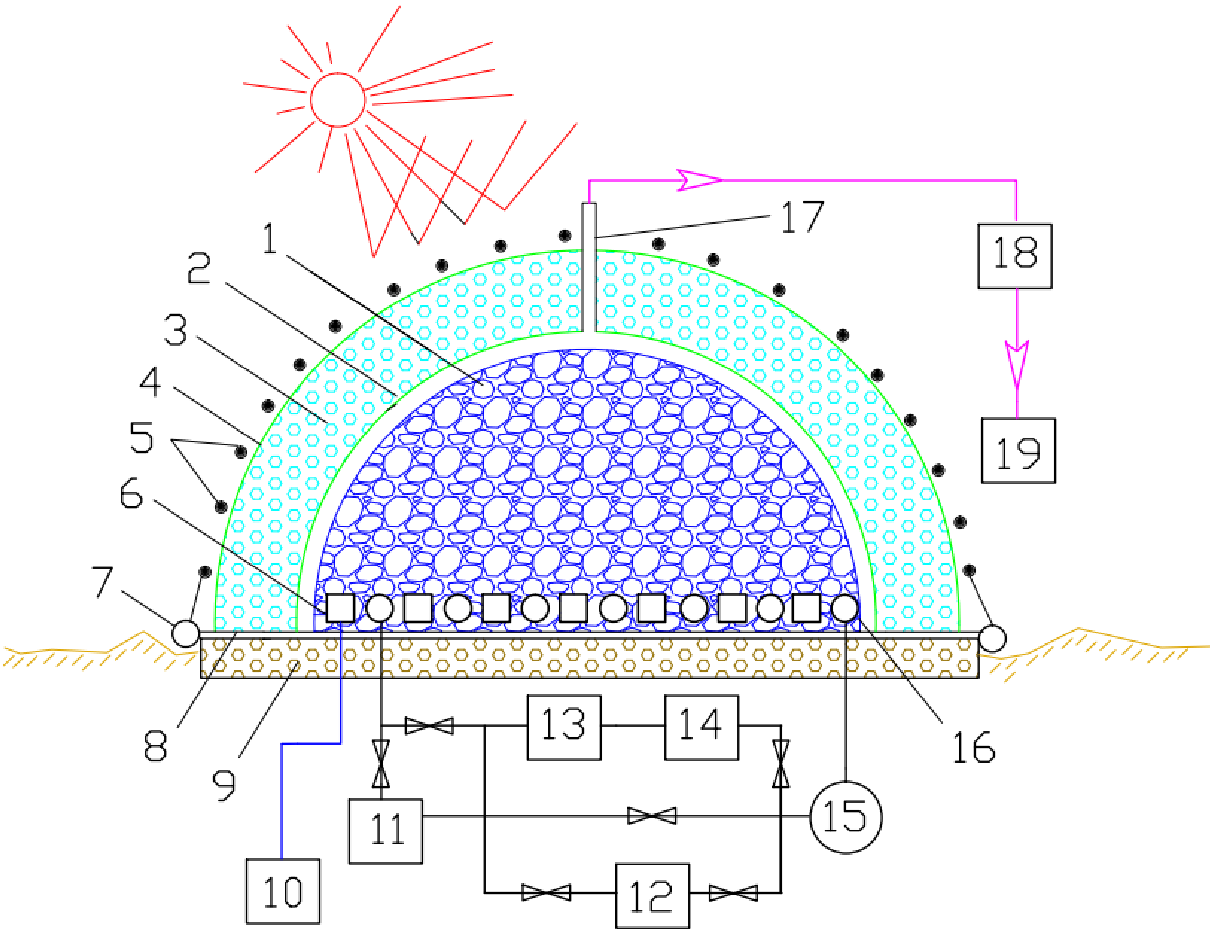

Figure 1. Schematic diagram of hydrate storage-shelter at the gas hydrate storage stage: 1 – gas hydrate; 2 – the lower fabric for the shelter; 3 – a liquid foam layer; 4 – the upper fabric for the shelter; 5 – a system of external reinforcement of the shelter in the form of a net made of ropes; 6 – perforated pipes of the gas and water extraction system from under the gas hydrate stack; 7 – a hermetic connection system of the cover sheets and the base; 8 – base covering made of material impermeable to gas and water; 9 – heat-insulating coating of the base; 10 – water collection tank; 11 – system of heating the coolant based on the solar collector; 12 – coolant heating block; 13 – unit of the refrigerating unit; 14 – air cooling system; 15 – circulation pump; 16 – heat exchanger pipe system; 17 – gas selection system; 18 – gas compression unit; 19 – gas consumer [9]

for the removal of gas and water.

For reliable sealing of the hydrate storage-shelter, system 7 seals the connection between the shelter sheets and the base. The isolated space formed is connected to the compressor 18 by the gas discharge line 17. The temperature regime of the hydrate storage is ensured by the accumulated cold in the gas hydrate and the additional air conditioning system. Hydrate dissociation is proposed to be carried out directly in the storage at the expense of solar energy. The temperature of the gas hydrate (cooling during storage and heating in the process of gas extraction) is maintained by pumping the cooled or heated coolant through the heat exchanger 16 at the base of the hydrate storage-shelter.

The coolant is cooled by a refrigerating unit 13 or an air cooling system 14. Cooling or

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012012 doi:10.1088/1755-1315/1254/1/012012

heating of the coolant is carried out in the solar collector 11, heater 12, refrigerating unit 13, air cooling system 14. Gas selection is carried out as a result of controlled dissociation of gas hydrate when pumping the coolant through the heat exchanger 16. Water is discharged from the storage-shelter to the tank 10 by the collector 6. (In addition, it is possible to organize the inflow of solar energy through the transparent areas of the shelter).

Gas through the selection line 17 enters the compression unit 18. Then it is consumed by the gas distribution network. The pressure in the line is limited by the mechanical strength of the shelter and lies within 0.2-0.4 MPa. The mobility of the storage-shelter will allow them to be placed directly near the objects of consumption. This will allow the gas during pressure dissociation to be sent to the gas distribution network without additional compression.

3. Calculation of storage-shelter operational parameters

The thermal resistance of the coating, which characterizes the heat-shielding characteristics of the gas-resistant storage-shelter, is determined by the formula:

$$R_{stor} = \frac{1}{\alpha_1} + \frac{2 \times \delta_{shel}}{\lambda_{shel}} + R_{barr} + \frac{1}{\alpha_2},$$

where R_{stor} – reduced thermal resistance of the storage-shelter shell, m^2 K/W; α_1, α_2 – coefficients of heat transfer of external and internal air, respectively,W/K m^2;δ_{shel} – thickness of the gas-tight shell fabric, m; R_{barr} – thermal resistance of the barrier layer, m^2 K/W; λ_{shel} – coefficient of thermal conductivity of the shell fabric, W/m K.

The average temperature for the forest-steppe zone of Ukraine for January is 265 K, July – 293 K [14], [15]. The thermal resistance of the storage-shelter cover R_{stor} in summer will be 0.27 m^2 K/W, in winter – 0.35 m^2 K/W. Then, during the winter period, energy will flow into the storage-shelter:

$$q_w = \frac{1}{R_{stor}} \times (t_{out} - t_{instor}),$$

where t_{tout},t_{instor} – air temperature, respectively, outside and in the storage-shelter, K.

$$q_w = \frac{1}{0.35 \times (265 - 248)} = 48.6.$$

The heat flow in the hydrate storage in the summer (q_s) will be [16]:

$$q_s = q_{av.d} + kA_d = \frac{1}{R_{stor.s}}(((t_s + \frac{p_{rad} \times I_{rad}}{\alpha_{surf}}) - t_{instor}) + K(0,5AK_m + \frac{p_{rad}(I_m - I_{rad})}{\alpha_{surf}})),$$

$$q_s = 150.0,$$

where A_d – daily fluctuation of heat energy flow, W/m^2; $q_{av.d}$ – average daily heat energy input to the storage, W/m^2; k – daily coefficient of change of heat flow A$_d$; t_s, t_{instor} – the temperature of the outside air in July and inside the storage, respectively, K; p_{rad} – coefficient of absorption of heat of solar radiation by the external surface of the storage; I_{rad} – average daily amount of solar radiation reaching the storage surface in the warmest month, MJ/m^2; α_{surf} – coefficient of heat absorption of the external surface of the storage for the warm period of the year; K_m – the maximum amplitude of daily air temperature fluctuations in the warmest month of the year, K; I_m, $I_{av.d}$ – maximum and average daily value of the amount of solar radiation, respectively, MJ/m^2.

The results of calculations of thermodynamic parameters for gas hydrate storage in a storage-shelter with a two-layer coating and an air barrier layer are given in table 1.

Table 1. Gas hydrate storage parameters in a double-layered storage with an air barrier layer.

Thermodynamic parameters	Winter	Summer
Thermal resistances, R_{stor}, m^2 K/W:	0.35	0.27
Heat flow to gas hydrate without thermal insulation layer, q, W/ m^2	48.6	105.0

Taking into account the thermal resistance, the thermal inertia of the two-layer cover of the hydrate reservoir will be [11]:

$$D_{ther.in} = 0.27 R_{stor} \sqrt{\lambda \rho c},$$

where $D_{ther.in}$ – thermal inertia; R_{stor} – thermal resistance, m^2 K/W.

$$D_{ther.in} = 0.27 \times 0.27 \sqrt{0.0244 \times 1.29 \times 717} = 0.4; D_{ther.in} < 1.5$$

Therefore, such a coating is inertialess. Let's consider the option of reducing the heat flow through a two-layer coating when filling the space between them with stable foam (foam density 4.0 kg/m^3, layer thickness δ_{coatl} – 1.5 m, coefficient of thermal conductivity λ_{coatl} – 0.041 W/(m·K)) using an example storage with a capacity of 3,000 tons of gas hydrate (5.4 million cubic meters of natural gas).

The coefficient of thermal conductivity λ_{coatl} of a two-layer reinforced coating with a thickness of 2 mm is 0.16 W/m K [16]. Then its thermal resistance R coat1 will be at the level of 0.0125 m^2 K/W. The thermal balance of the storage-shelter is described by the equation:

$$Q_1 + Q_2 - Q_3 - Q_{add} = 0,$$

where Q_1 – heat flow into the storage through the shell, J; Q_2 – heat flow from the base of the storage, J; Q_3 – cold accumulated by gas hydrate, J, Q_{add} – additional heat removal (cooling), J.

The reduced thermal resistance of the coating is determined by the formula:

$$R_{stor.coat} = \frac{1}{\alpha_{out}} + \frac{2 \times \delta_{coat1}}{\lambda_{coat1}} + \frac{\delta_{coat2}}{\lambda_{coat2}},$$

where $R_{stor.coat}$ – reduced thermal resistance of the storage-shelter shell, m^2 K/W; α_{out} – coefficients of heat transfer of outside air, W/K m^2; δ_{coat1} – coating layer thickness, m; λ_{coat1} – thermal conductivity coefficient coating, W/m K; δ_{coat2} – thickness of the foam layer, m; λ_{coat2} – coefficient of thermal conductivity of the foam layer, W/m K.

Therefore, the reduced thermal resistance of the storage-shelter cover ($R_{stor.coat1}$ and $R_{stor.coat2}$) for winter and summer will be 37.78 and 37.62 m^2 K/W, respectively. Then, in winter, the heat flow into the storage from the outside will be:

$$q_{w1} = \frac{1}{R_{stor.coat1}} \times (t_{out} - t_{instor}),$$

where t_{tout},t_{instor} – air temperature, respectively, outside and in the storage, K.

$$q_{w1} = \frac{1}{37.78 \times (265 - 248)} = 0.45.$$

The total heat flow into the storage-shelter through the coating (Q_{w1}) in the winter period will be 1.76 kW.

The heat flow to the storage in the summer (q_{s1}) was determined by the formula:

$$q_{s1} = \frac{1}{R_{stor.coat2}} \left(t_{out} + \frac{p_{rad} \times I_{rad}}{\alpha_{surf}} - t_{instor} + K \left(0.5AK_m + \frac{p_{rad}(I_m - I_{rad})}{\alpha_{surf}} \right) \right),$$

$$q_{s1} = 1.33,$$

The total heat flow into the storage through the coating (Q_{s1}) in the summer period will be 5.23 kW.

The heat flow that enters the gas hydrate from the base (Q_2), with its average annual value for mid-latitudes of 0.17 W/m^2 [15], will be 0.3 kW. Its insulation will reduce heat input to 0.25 kW.

In the table 2 shows a comparison of the calculated parameters of gas hydrate storage in ground-based gas-resistant storages in variants of the air layer between shells and foam.

Table 2. Comparison of gas hydrate storage parameters in ground gas-resistant storage-shelters depending on the level of thermal insulation.

Thermodynamic parameters	Winter	Summer
Thermal resistances, $R_{stor.coat}$, m^2 K/W:		
– air between the fabrics of the shell	0.27	0.35
– a layer of foam between the fabrics of the shell	37.78	37.62
Heat flow to storage-shelter, q, W/m^2:		
– air between the fabrics of the shell	48.6	48.6
– a layer of foam between the fabrics of the shell	0.45	1.33
Heat flow to storage-shelter, Q_1, kW:		
– air between the fabrics of the shell	189	408.0
– a layer of foam between the fabrics of the shell	1.76	5.23
Energy costs for cooling, Q_3, kW:		
– air between the fabrics of the shell	190.2	409.2
– a layer of foam between the fabrics of the shell	2.1	5.5

Therefore, the required capacity of the additional cooling system of the storage-shelter for storage of gas hydrate without its dissociation (at a temperature of 258 K) is 0.9 kW in the winter period, and 4.44 kW in the summer period.

4. Modeling of heat exchange processes

Let's set the temperature on the surface of the gas hydrate as a result of the arrival of heat flow, as a process of heat transfer through a multilayer coating. On one side of the coating is the external environment with a temperature of T_p, and on the other – cooled to a temperature of T_g gas hydrate (figure 2).

Formulation of the problem. Let's assume: the initial temperature of the gas hydrate (T_0) is 248 K; the gas hydrate stack has the shape of a hemisphere with a base radius (R_g) of 23.5 m; the surface of the gas hydrate is covered with a 1.5 m layer of foam ($R_s - R_g = 1.5$ m); the initial temperature of the foam is 248 K; there is thermal contact between the foam and the hydrate; the temperature of the outer surface of the storage-shelter (T_{out}) is constant and is 293 and 265 K for summer and winter, respectively.

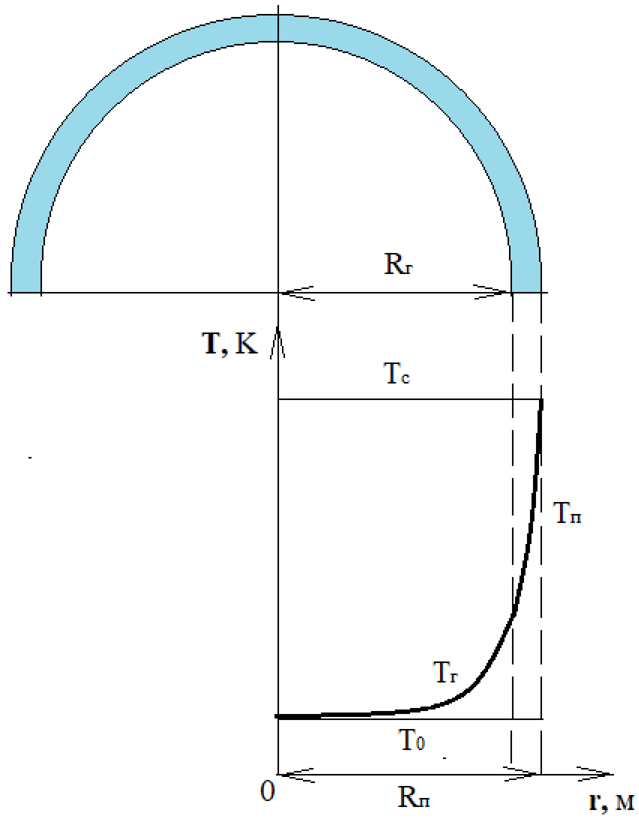

Figure 2. Scheme of the gas hydrate heating process in the storage-shelter.

It is necessary to find the temperature distribution over time and establish the moment when the temperature of the surface of the gas hydrate reaches 258 K (equilibrium temperature).

This process is described by a system of differential equations. The change in gas hydrate temperature is described by the equation:

$$\frac{\partial[rT_g(r,\tau)]}{\partial\tau} = a_g \frac{\partial^2[rT_g(r,\tau)]}{\partial r^2}$$

$$(\tau > 0, 0 < r < R_g)$$

Temperature change in the foam layer as a result of heat exchange with the gas hydrate and the external environment:

$$\frac{\partial[rT_s(r,\tau)]}{\partial\tau} = a_s \frac{\partial^2[rT_s(r,\tau)]}{\partial r^2}, \qquad (\tau > 0, R_g < r < R_s);$$

$$\frac{\partial[rT_s(r,\tau)]}{\partial\tau} + \alpha(T_{out} - T(R,\tau) = 0$$

Initial conditions of the process:

$$T_g(r,0) = T_0; T_s(r,0) = T_0.$$

Boundary conditions of the process:

$$T_g(R_g,\tau) = T_s(R_g,\tau); \lambda_g \frac{\partial T_g(R_g,\tau)}{\partial\tau} = \lambda_s \frac{\partial T_g(R_g,\tau)}{\partial\tau};$$

$$T_s(R_s, \tau) = T_{out}; T_g(0, \tau) \neq \infty.$$

where r – variable (current) value of the radius of the storage base, m; R_g – radius of the base of the storage-shelter located under the gas hydrate embankment, m; R_s – the radius of the base of the storage-shelter, which is located under the gas hydrate mound and the foam layer, m; T_o – storage temperature of gas hydrate, initial temperature of gas hydrate and foam layer, ($T_o =$ 248), K; T_{out} – ambient temperature (293 K in summer, 255 K in winter); T_g – variable over time (current) gas hydrate temperature, K; T_s – variable over time (current) temperature of the foam layer, K; τ – the time of the heating (cooling) process of gas hydrate and foam; λ_g – coefficient of thermal conductivity of gas hydrate, W/(m K);λ_s – coefficient of thermal conductivity of foam, W/(m K); a_g – coefficient of thermal conductivity of gas hydrate, m^2/s; α – heat transfer coefficient, W/K m^2; a_s – coefficient of gas hydrate thermal conductivity, m^2/s.

In order to evaluate the thermal insulation characteristics of the foam and the dynamics of the temperature change of the gas hydrate in the gas-resistant storage-shelter, its computer simulation was carried out (figures 3-6). The above storage calculation parameters were taken as the starting point.

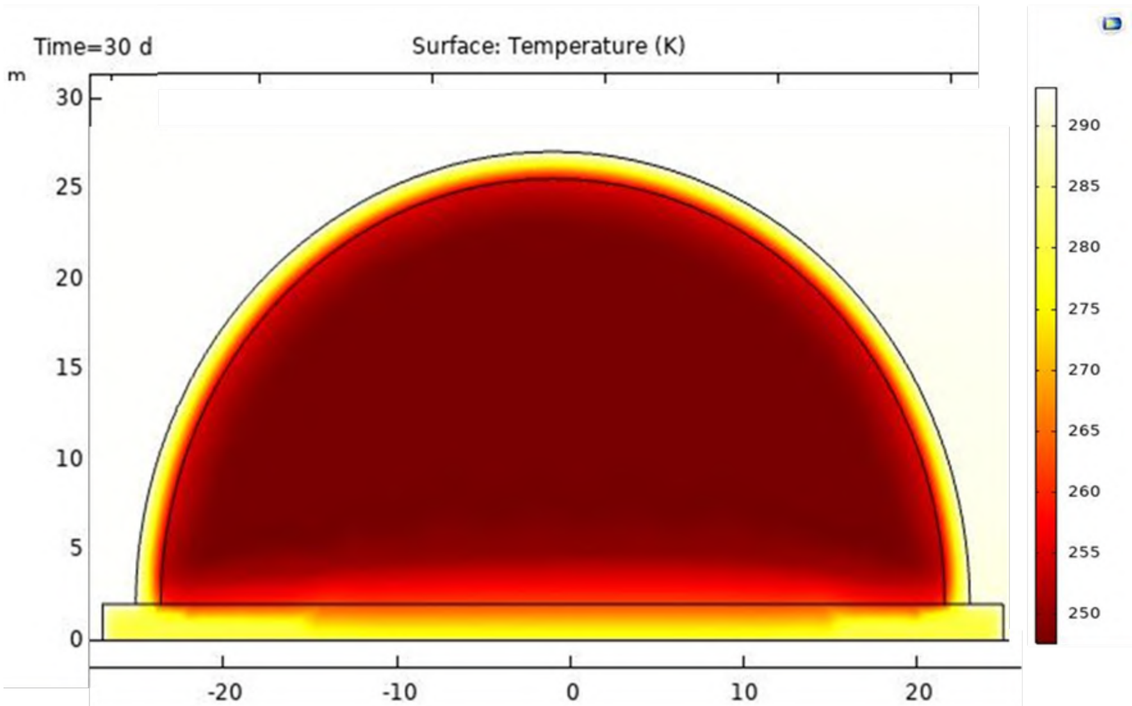

Figure 3. Simulation of heat exchange in summer (external temperature 293 K) of gas-resistant hydrate storage-shelter thermally insulated with liquid foam without additional cooling after 30 days of storage.

Therefore, with an initial temperature of gas hydrates of 248 K, its additional cooling when stored in a storage-shelter facility insulated with foam, even in the summer months, will be necessary after 30 days of storage (to maintain the temperature of the gas hydrate at a level not higher than 258 K).

5. Conclusions

Thus, gas storage in gas hydrate form is proposed to be implemented in improved shell gas-bearing structures. This improvement consists in the use of liquid stable foams as a thermal

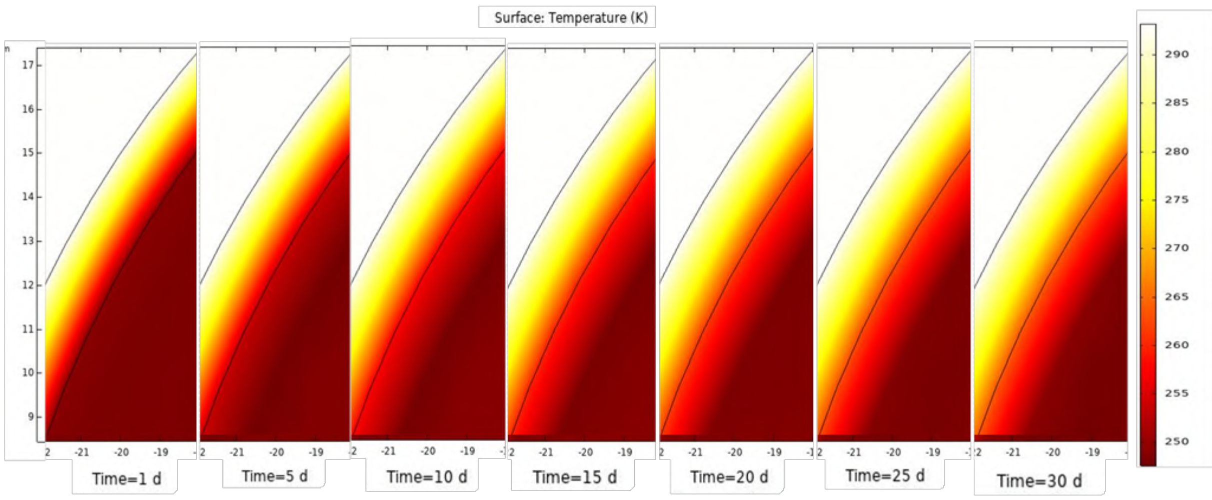

Figure 4. Dynamics of changes in the temperature of the gas hydrate surface and the foam layer in the hydrate storage-shelter in the summer ($T = 293$ K) without additional cooling.

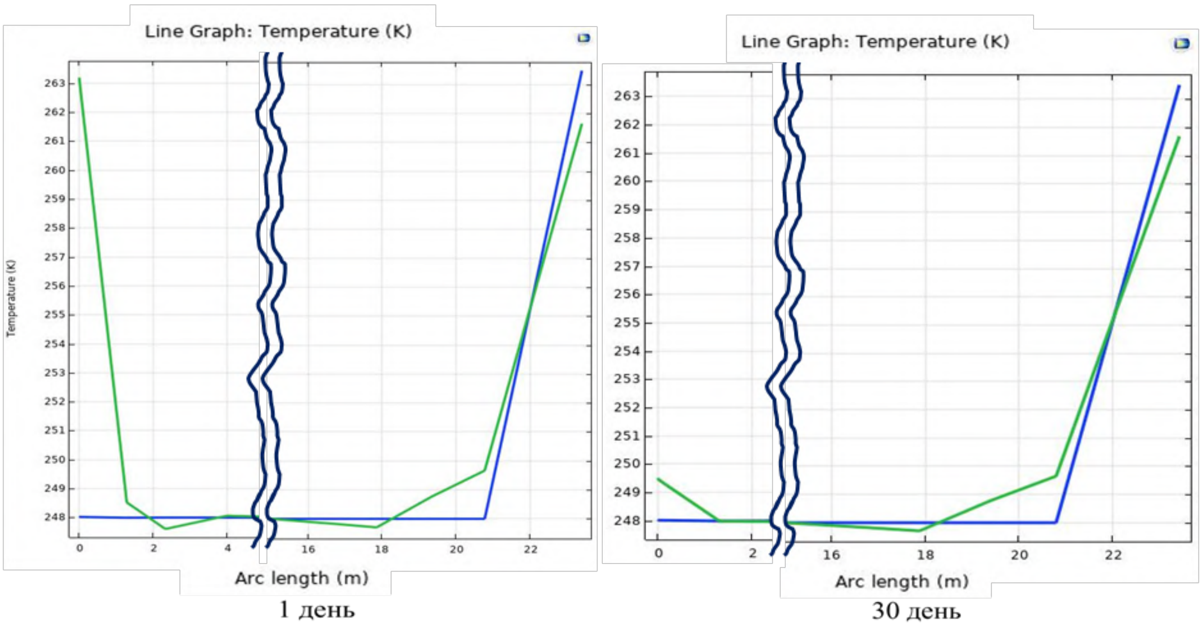

Figure 5. Dynamics of changes in the temperature of the gas hydrate (with an initial temperature of 248 K) from the surface to the center of the sole of the stack in the summer period of storage ($T = 293$ K) without additional cooling, provided that it is thermally insulated with a layer of foam 1.5 m thick: a) at the end of the first days of storage; b) at the end of the thirtieth day of storage.

insulation material. The main design elements of this storage-shelter facility are a frameless gas-resistant shelter in the form of at least two dome-shaped gas-tight soft shells on a thermally insulated base, the space between which is filled with liquid foam. The use of these hydrate storages will significantly increase the efficiency and competitiveness of natural gas storage technology in the form of gas hydrates.

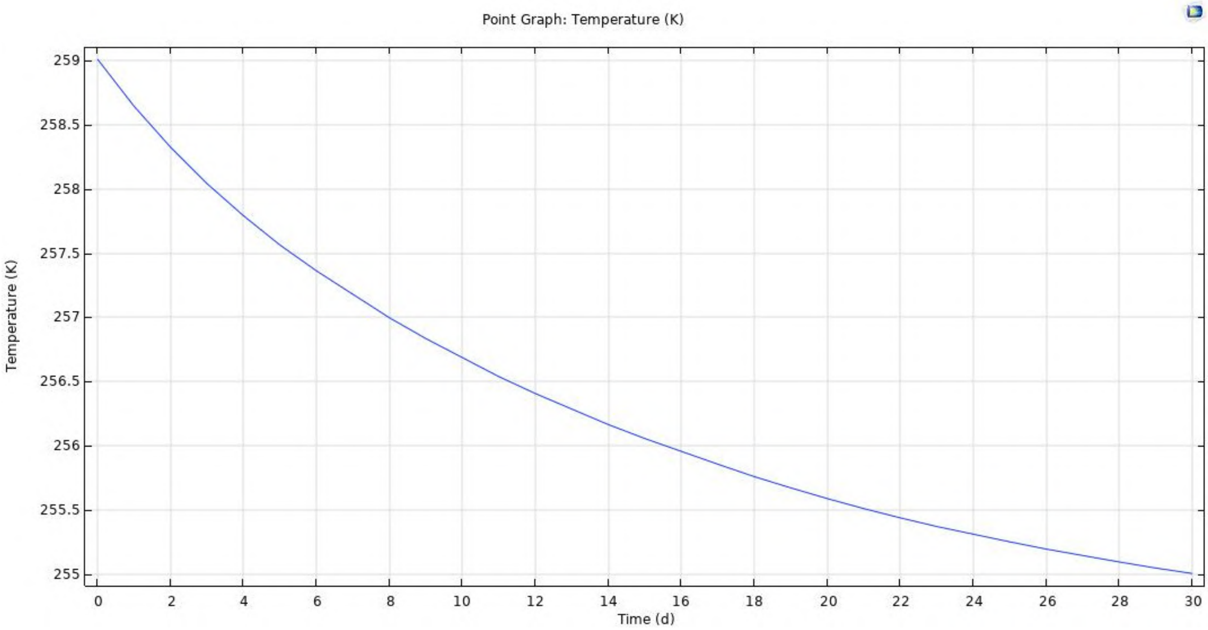

Figure 6. Dynamics of changes in the temperature of the gas hydrate surface (with an initial temperature of 248 K) during thirty days in the summer storage period (T = 293 K) without additional cooling, provided that it is thermally insulated with a layer of foam 1.5 m thick.

Abstract. The great cormorant (*Phalacrocorax carbo* L.) is a bird species that, due to the peculiarities of its biology, can significantly affect the natural environment. First of all, due to the fact that the species is an obligate ichthyophage and feeds exclusively on fish (causing, in some places, quite significant damage to both the fishery and the natural fish resources of the seas), a large amount of potassium, nitrogen and phosphorus compounds accumulates in its feces. Because of this, the caustic excrements of cormorants have a detrimental effect on herbaceous and woody vegetation in the colonies of this species, near them, as well as in the resting places of the birds. Considering the fact that the nesting colonies of the great cormorant can be quite numerous, reaching tens of thousands of nests (such as the settlement on the Obytichna spit in the Berdyansk district of the Zaporizhzhia region), the impact is observed to be very significant. At the same time, tree vegetation suffers from mechanical damage during the construction of nests, and trees die after 2-3 years. Another type of influence of cormorants is their interaction with other bird species in nesting areas. The high number of cormorants leads to a reduction in the number of some other bird species, the impoverishment of nesting bird complexes (herons, terns); in the conditions of a shortage of nesting sites on the islands, only (*Larus cachinnans* can nest together with the great cormorant (with its high number). We observed a similar situation in most nesting settlements of the species.

1. Introduction

The scientific literature has accumulated a lot of information about the impact on the environment (including its physico-chemical and biological regimes) of various organisms [1]. The environment-forming activity of birds is most significantly and visibly manifested in the places of their mass gatherings. Large colonies play an important role in soil formation, bringing a large number of organic substances with the products of life (mainly guano). Special ornithogenic soils are formed in places of bird gatherings, in which the concentrations of phosphorus and nitrogen can exceed the corresponding background indicators by two times, and zinc and potassium – by one and a half times. Under the influence of atmospheric precipitation, leaching of easily soluble compounds of phosphorus, nitrates, sulfates and chlorides occurs from the litter.

The participation of birds in the transport of biogenic substances from aquatic to terrestrial ecosystems is indisputable. Japanese scientists analyzed the long-term consequences of the nesting of the great cormorant (*Phalacrocorax carbo*) and its participation in the nitrogen cycle [2]. These birds feed on fish in fresh water bodies, and nests are built on trees in the forest. In nesting places, trees die, and in the territories of former cormorant settlements, the increased content of nitrogen in litter, soil and plants remains for a long time. Similar pictures are observed in many places along the coasts of different seas. Birds' excrements entering the water sometimes affect the dynamics of biogenic substances so significantly that some foreign colleagues began to use a special term – "guanotrophication".

Another important type of impact of the great cormorant is its relationship with other species of birds, especially, the wetland complex birds, which depends, first of all, on the characteristics of the species that nest in mixed settlements with the great cormorant, as well as the specifics of the nesting sites – the type of nest biotope, shortage of suitable nesting area, etc. The impact can be both direct and indirect, and can be both negative and, in some cases, positive. The material presented below is based on the results of own expedition trips and analysis of literary sources [3, 4].

2. Material and methods

Researches of the ecological impact of the great cormorant were conducted in the Azov-Black Sea region of Ukraine in 22 nesting colonies of this species in the period from 2012 to 2021 (figure 1). Most of the expedition work was carried out using the methods of fixed vehicle, boat and pedestrian census. Surveys were made with Etherna binoculars (10x) and Nikon ACULON A211 10x50 and VIXEN Geoma telescope (20-60x80). Mapping of bird gathering places and spatial characteristics of routes were made using a GARMIN GPSMAP 78s navigator. Biotopes and birds were photographed with Canon EOS 450D and Nikon D700 cameras. The photographs were exported to the FastStone Image Viewer programme, which together with the camera software in the Exif metadata mode made it possible to control the geolocation data of the photographs taken, the date and conditions of shooting. Linear dimensions between objects and object heights were measured using a Nicon Forestry 550 laser altimeter. Statistical processing of the obtained data was carried out in Microsoft Excel 2010 and Statistica Release 8 (Basic Statistic module) programmes.

In general, such a phenomenon as the influence of the great cormorant on natural and anthropogenic complexes, in particular, the negative impact on vegetation, other species of colonial wetland birds, pond fish farms, technical structures, etc., is quite well known and repeatedly described in the scientific literature. Also, many different publications and studies are devoted to issues of human influence on the number and distribution of the great cormorant, methods of regulating its number. Therefore, the purpose of this research is only to provide data available in Ukraine on the impact of the cormorant on vegetation, soil and ornithocompexes.

3. Results

The biocenotic significance of great cormorant colonies and their negative impact on vegetation is mentioned in the works of many authors. The forms and scales of this phenomenon depend on the number of cormorants, the method of nesting (tree, shrub or ground colonies), the species diversity of accompanying species, the duration of the impact (intraseasonal and perennial aspects) and other factors.

3.1. Impact on vegetation

3.1.1. Terrestrial colonies. One of the most comprehensive researches in Ukraine on the study of the biocenotic influence of ground colonies of the great cormorant was conducted in 1997-2003 on the Lebedyni islands. They made it possible to conclude that this species has a decisive influence on the composition, structure and distribution of vegetation on the islands. Cormorants are most destructive to vegetation during the period when they are building their nests. Nests are completed and renewed during the entire reproductive period, but their building is especially active during the laying and hatching of eggs. Birds collect nesting material within a radius of

Dubovyi between o. Khortytsia and Dnieper Hydroelectric Station.).

up to 2 km from the colony. Some birds find the material in the immediate vicinity of the nest, others collect it on neighboring islands and some "steal" it from the nests of other cormorants. The cormorant uses *Artemisia* sp., as well as last year's shoots of *Atriplex tatarica*, *Pontic catrana*, rhizomes and stems of *Phragmites australis*, pulling them out of the soil to build their nests. The influence of the cormorant on vegetation is not limited to nest-building activities, it experiences a depressing effect as a result of trampling by birds, compaction of the soil, as well as "burning" with excrement, since raw bird feces contain up to 16.3% of nitrogen, 15.4% of phosphorus, 8.5 – potassium, 24.0 – calcium and 7.4% manganese. At the locations of the colonies, there is a change in vegetation cover, while in the first year, as a result of strong nitrification of the substrate, species that prefer nitrogen-rich soil prevail. In the following years, even in the absence of birds, communities dominated by spring or winter annuals are observed in the colony for a long time, the vegetation cover is transformed, including the impoverishment of the coenotic and floristic structure of the island complexes. The restoration of communities with the participation of perennials, including *Artemisia* sp., *Crambe pontica* and *Leymus sabulosus*, does not occur in the first 10 years, and during this period, areas with disturbed plant cover in the conditions of the Lebedyni islands are most often washed away as a result of a decrease in the turf of the substrate, an increase in the influence of wind erosion, decrease in wave resistance of accumulative shores.

A similar situation is observed for the islands of Tendra and Yahorlyk bays, where the ground nesting sites of the cormorant very quickly become devoid of any vegetation cover, which is connected both with the direct destruction of the vegetation used for building nests, and with accumulation in the soil out-of-boundary concentrations of phosphorus and nitrogen that enter there from bird feces. At the same time, even after the cessation of the existence of the colony, the restoration of vegetation occurs after at least 2 years. Another negative consequence of the destruction of vegetation at the place of cormorant colonies, if they are located near a water cut, is the acceleration of the erosion process of the coastal edge of the islands and, as a result, a gradual decrease in the area of the islands, including those suitable for nesting.

On Kryva spit, the great cormorant usually occupies nesting sites at the very beginning of the growing season of the main types of plants of the Kryva spit, such as *Leymus sabulosus*, *Melilotus* sp., and *Crambe pontica*. As a result of the impact of cormorant feces, all vegetation in the territory of the colony dies, while in neighboring areas it can reach up to 1 m in height.

3.1.2. Arboreal colonies. The largest colonies of great cormorants located on trees are located on the coast of the Sea of Azov – the Kazantyp Peninsula (Mysove Forestry), Obytichna spit, the Dnipro reservoirs – Kakhovka (Velyki Kuchuhury), Kremenchuk, Kaniv, Kyiv reservoirs, as well as in a number of other places. Everywhere, the negative impact of the nesting of this species, both on herbaceous and tree-shrub vegetation, is noted, which in the case of large colonies acquires a significant scale. The most thorough studies of the influence of cormorant colonies on tree and shrub vegetation were conducted by S. M. Podorozhnyi in June-July 2008 on the islands of Velyki and Mali Kuchuhury, and the previous results were confirmed by our expedition trips in 2012-2017.

They showed that the tree vegetation on the islands is represented by two types of plantings. The first is the most common and is represented by trees located along the coastline of large and small islands that are part of the reserve. *Salix alba* is the dominant species here. *Populus alba* and *P. nigra* were much less common in these stands. The height of the stands of these species is 18-20 m, and the average age is 50-60 years. *Morus nigra*, *Acer negundo*, *Fraxinus excelsior* can be found singly in these plantings. The vast majority of these are low-growing trees of coppice origin. The shrub layer of coastal tree plantings is represented by *Sambucus nigra* and *Amorpha fruticose*.

Coastal plantings suffer the most from the settlements of the great cormorant, as they are chosen by the birds for placing their nests in the first place. Tall *Salix alba* and *Populus* sp. trees with a good view and an uncomplicated approach to the nest are chosen as nesting biotopes. Nests, as a rule, are arranged in the upper and middle parts of the crown of trees at the base or middle part of branches of the second order. The negative impact on the growth and development of trees is primarily associated with the impact of bird feces with a high concentration of nitrogen, phosphorus and potassium on the vegetative organs of plants during the entire nesting period. This leads to the death of leaves and young shoots as a result of burns. In the first year of the appearance of nests on trees, the leaves of the upper and partly the middle part of the crown "burn". As a result, the bark of the skeletal branches in the upper part of the crown peels off and the tree begins to dry out.

The next year, the upper dry parts of the trees, in most cases, are used by the cormorant as a roost, and the nests are moved to the middle part of the crown, where the leaves are still partially preserved. By the end of the growing season, the leaves and one-year shoots of the middle and lower part of the crown "burn", the bark of the perennial shoots peels off, and the tree dries up completely.

In the future, dead trees are used by cormorants as roosts, and nests are moved to nearby living trees. In the absence of trees, cormorants begin to use shrubs (mainly *Sambucus nigra*) with a height of 2.5-4.0 m as nesting biotopes. Much less often, tree forms of trees are used for placing nests – *Acer negundo*, *Morus nigra*, etc. with a similar height. *Amorpha fruticose* and coppice forms of trees die in the first year after placing nests on them. *Sambucus nigra* is more stable and, depending on the intensity of the impact, can vegetate for several seasons, but in the future it also dies.

Monodominant thickets of *Phragmites australis* later form on the site of dead shrubs, which, as a rule, are not used by cormorants as nesting biotopes.

Thus, we can state the fact that the nesting of the great cormorant on the islands of Velyki and Mali Kuchuhury leads to the degradation of coastal tree plantings and their replacement by unproductive monodominant thickets of *Phragmites australis* with low biological diversity. In addition, the degradation of coastal tree plantings is extremely negative, as it can lead to the intensification of coastal erosion processes, which endangers the existence of the islands themselves. Dead trees cannot perform the functions of shore protection and shore fortification. To a much lesser extent, it is performed by shrubs and, even more so, reedy coenoses, which is the last stage of succession.

The second type of tree plantations is found in the interior of large islands with a more elevated topography. They are limited to inter-arena depressions and hollows with close groundwater, forming so-called “groves” or “kolkas”. The structure of tree and shrub plantings here depends on the degree of moisture in the central part. Kolka plantings are used by the great cormorant as a nesting biotope only when there is a shortage of them in the composition of coastal tree plantings. Cormorants choose tall *Salix* sp. and *Populus* sp. trees in the central part for nesting. In dry depressions, *Betula* sp. and *Populus* sp. are used to build nests.

The activity of cormorants directly and indirectly affects the natural complex of the Obytichna spit. Arboreal colonies of the great cormorant are a relatively new phenomenon here, and very detrimental to artificial forest plantings on sandy soils. The high content of nitrogen, phosphorus and other chemical elements in bird feces, and their accumulation during the nesting period (from the end of February to the middle of June) leads to the death of almost the entire grass cover. Instead of natural associations, for the 2nd-5th year, ornithogenic ones are formed, represented by lush thickets of weeds (*Chenopodium* sp., *Melilotus* sp. etc.). In some areas, vegetation disappears almost completely. According to our observations, restoration of herbaceous vegetation at the site of the colony occurs in the second or third year when the impact is stopped.

Similar processes take place in other colonial settlements of the species, both in Ukraine and abroad.

3.2. Impact on soil cover

Waterbirds, such as the cormorant, are very important intermediate links in some food chains and a factor that facilitates the dislocation of matter between aquatic and terrestrial ecosystems. From one perspective, cormorants exclude biogenic elements (along with fish) from aquatic ecosystems. Although cormorants hunt at a fairly large distance from colonies, within a radius of up to 30 km, they leave feces in a relatively small area below the colony and near the lake shore. Nesting colonies of fish-eating birds affect the habitats and phytocenoses they occupy in different ways. During the breeding season, cormorants transfer large amounts of biomass and chemicals from the aquatic environment to colonies located on land. The consequence of the introduction of allochthonous matter into the terrestrial ecosystem can be significant enrichment of soil and plants with nitrogen (N), phosphorus (P) and potassium (K). Elevated concentrations of N and P within the colony may accumulate in the soil and be transported with groundwater or surface runoff to lakes. The range and rate of changes that occur depend mainly on the species of nesting birds, the density and the age of the colony. In addition, cormorants break branches during nest construction, resulting in defoliation of the soil under trees. In areas with high bird density, feces cover herbaceous vegetation, limiting photosynthesis and ultimately leading to plant extinction.

It should be noted that the initial impact of introduced organic elements in the colony leads to an increase in the biological diversity of plants. An assessment of changes in the amount of nutrients accumulated in soils and groundwater, and changes in the floral composition of the forest phytocenosis, which occurred 5 years after the cormorants left the colony, was carried out. The colony, located on a small (0.6 ha) island in Lake Wielkie, has been inhabited by cormorants since the 1980s. The maximum indicated number was about 200 nesting pairs. Research on the impact of the former nest colony on the ecosystem of the island and the surrounding lake was conducted in 2009-2010. Compared to the control station, significantly increased concentrations of nitrogen, phosphorus and potassium were found in the soil under the colony. The highest concentrations of nitrogen were noted in the surface organic layer of soils under the colony. Organic nitrogen dominated among different nitrogen forms (ammonium nitrogen and nitrates were present in the surface layer in much lower concentrations – approximately 200 mg $N\text{-}NH_4$ kg^{-1} and 40 mg $N\text{-}NO_3$ kg^{-1}, respectively). Regarding phosphorus, the highest concentration was found in the deeper soil layers below the colony. Statistically, the concentrations of chemical elements in the soil profiles located in the areas under the colony were significantly different from the concentrations at the control stations (ANOVA, $p < 0.005$). Moreover, an increased concentration of nutrients and other chemical elements in comparison with the control stations was found in the groundwater under the cormorant colony. The underground water under the colony contained a significantly larger amount of dissolved mineral salts – the electrolytic conductivity was almost 5 times higher than at the control station. In addition, nitrogen and phosphorus concentrations in groundwater were significantly higher. Comparing the abandoned colony with the control station (an island not occupied by cormorants), it was found that the floristic composition of the phytocenosis of the forest is very low. All trees were destroyed by birds, and the island is covered with nitrophilous *Sambucus nigra*. A dense canopy of *Sambucus nigra* trees created shading, so there are no grasses at all. Only in the transition zone between the land (colony) and the lake ecosystem are some herbaceous plants: *Urtica dioica* and *Phragmites australis*. Plant biodiversity noted on the control island is much higher – 6 species of trees and shrubs and 17 species of herbaceous plants.

Marion et al [5] found large differences in nutrient content between soil within bird colonies and areas without them at Lake Grand Lieu (western France) (8 times more nitrogen and 42 times more phosphorus at nesting colony sites). In Poland, despite a small proportion of nutrients introduced by cormorants directly into the Dobczyce Reservoir, a high concentration of nutrients was found in the soil and sediments within the cormorant colony [6]. In another research, soil from an island occupied by birds was characterized by higher concentrations of NO_3^-, NH_4^+, and total N than soil from an island without colonies [7]. Similarly, soil samples in the area of cormorant colonies had many times higher content of all investigated chemical elements compared to control samples. The amount of NO_3^- in the soil of the great cormorant colony in Kąty Rybackie (northern Poland) was 94-216 times higher in the surface layer and 7-12 times higher in the deeper layer than in the control plots. The high concentration of NO_3^- showed that nitrification is a very important and intensive process in soil exposed to bird colonies [8].

3.3. Impact on ornithocompexes
The relationship of the great cormorant with other waterbirds depends, first of all, on the characteristics of the species that nest in mixed settlements with the great cormorant, as well as the specifics of the nesting sites – the type of nesting biotope, the lack of suitable nesting areas, etc. The impact can be both direct and indirect, and can be both negative and, in some cases, positive.

The analysis of the available data on the 56 species associated with the great cormorant in 20 mixed settlements (table 1) allows us to state that, depending on the colony, the composition of the avifauna complex can vary greatly, ranging from 3 to 20 species.

On the Obytichna spit, the growth of the great cormorant population affects the species composition and the number of other satellite birds, although this is clearly manifested only at high values. The limited nesting of great cormorants on 1-2 islands (until 2002) did not affect other nesting bird species, but after the spread of cormorants on 5 islands (2007-2008), significant changes in bird communities became noticeable. The number of species of the avifauna complexes of the Obytichna spit is inversely proportional to the increase in the number of great cormorants. Until 2002, 8-11 species of waterbirds nested here, and in 2007-2008 – only three species. Since 1993, the cormorant has gradually displaced such species as *Egretta alba*, *Egretta garzetta* and *Ardea cinerea*, as well as *Sterna hirundo* and *Sterna albifrons* from the nesting sites. In conditions of scarcity of nesting sites on the islands, only *Larus cachinnans* can nest together with the great cormorant (with its high number). Experiencing territorial competition, he nevertheless takes advantage of joint nesting by eating clutches, cormorant nestlings and collecting food scraps in his colonies.

After the cormorant changed its nesting strategy from terrestrial to arboreal, predation by gulls became even more active. Research conducted during 2015-2021 showed that the first gulls appear in the colony even before sunrise, at 4 o'clock in the morning. After 1.5-2 hours, massive wave-like raids of gulls begin with a frequency of about once an hour. They show the following tactics: while one part of the birds circles over the nests, scaring the cormorants, the other destroys the nests. At the same time, cormorants are reluctant to defend their nests, in most cases they simply fly away or sit on nearby trees.

The intensive increase in the number of cormorants on the spit provides, in addition to Larus cachinnans, a number of other species, in particular, *Pica pica* and *Corvus cornix*, as a food base. Pica pica on the islands steal eggs from terrestrial colonies of cormorants ($n = 12$), *Larus cachinnans* ($n = 3$), Sterna hirundo, Talasseus sandvicensis ($n = 32$), and in reeds – eggs from nests of herons (*Ardea cinerea*, *Egretta alba*, *E. garzetta*) ($n = 5$), warblers (*Acrocephalus arundinaceus*, *A. scirpaceus*) ($n = 3$), small nestlings of great cormorants and herons are occasionally dragged ($n = 7$). Therefore, in the conditions of the spit, *Pica pica* have developed and maintain new specific biocenotic relationships. During the nesting period, she actively gathers food in the nearest colonies of great cormorants, gulls, terns and herons on sea outcrops along the edge of the water, makes significant flights, up to 500-2000 m from the nest outside the nesting territories (data from route records and visual observations).

Corvus cornix is also an active predator of cormorant eggs and young nestlings. This, possibly unintentional, "cooperation" between *Corvus cornix* and *Larus cachinnans* has often been observed: when gulls raid the colony, scaring the cormorants and forcing them to leave their nests, the nests are simultaneously "visited" by crows, which take out eggs and nestlings. The increase in the number of *Corvus cornix* on the Obytichna spit is directly correlated with the increase in the number of cormorant colonies observed in recent years. To a lesser extent, similar behavior is characteristic of *Corvus cornix*, for example, on the Velyki and Mali Kuchuhury islands, where it is a companion species for all cormorant colonies known here.

We observe a different situation in Syvash. The competition of species for nesting territories determines the conditions of their existence, which we traced on the islands of Central and Eastern Syvash for the great cormorant and *Larus cachinnans*, as the most massive colonial species. Research (retrospective analysis and own data) covers the period from the late 1990s to 2021, when the location, number and species composition of colonial bird settlements were characterized by the method of absolute records.

The main perennial nesting sites of this pair of species have been identified. In Central Syvash, this is Kytai island, and in the East – the islands of Chonhar, Koyanly, Arabat spit, Soleprom and Polyhonna spit. The analysis of the dynamics of the number of species showed the relationship of these areas, expressed in the redistribution of colonies, in which the increase in the number in Eastern Syvash led to its decrease in Central and vice versa. Territorial relations between birds nesting on the Kytai island, are determined by the limited capacity of nesting biotopes, and in the pair "great cormorant – *Larus cachinnans* there is a noticeable inverse correlation ($r = -0.54$), which confirms the territorial competition of these species. At the same time, in relation to Larus ichthyaetus, which also nests on the Kytai island, such competition is not observed.

The great cormorant forms 5 sub-colonies on the island among the associations of *Suaeda salsa* and *Halocnemum strobilaceum*. *Larus cachinnans* also forms 5 sub-colonies in the areas devoid of vegetation, as well as among *Suaeda salsa* and *Ajuga chia*. *Larus ichthyaetus* forms 2 sub-colonies among the associations of Hordeum murinum and *Cerastium holosteoides* with interspersed *Matricaria perforate*. At the same time, 1 subcolony of *Larus cachinnans* and 2 subcolonies of the cormorant were located in the immediate vicinity of the subcolony of *Larus ichthyaetus*, among the areas occupied by *Hordeum murinum* and *Cerastium holosteoides*. Due to the fact that neither *Larus cachinnans* nor the cormorant occupies the nesting stations of *Larus ichthyaetus*, but its number is decreasing, it can be assumed that there is some reduction in the areas occupied by *Hordeum murinum* and *Cerastium holosteoides* by the cormorant and *Larus cachinnans*, which start nesting before *Larus ichthyaetus*. The conducted studies prove this: these types of plants are subject to intense trampling and the influence of guano, which leads to a reduction in areas.

On the Chonhar islands, with a noticeable increase in the number of great cormorants with a maximum in 2012 (2.500 nests), there was no noticeable decrease in the number of subdominant species, among which *Larus cachinnans* is traditionally present ($r = -0.31$). The maximum number of colonial birds on the Koyanly islands is about 17.000 nests, with smaller numbers there is no territorial competition. A regularity was revealed, in which the increase in the number of cormorant species not only does not lead to a decrease in its number, but also significantly correlates with it ($r = 0.57$). A similar picture is observed on the Polyhonna spit. On the islands of Soleprom, a significant decrease in the number of associated species has been observed over the past 15 years due to joint territorial pressure from *Larus cachinnans* and the great cormorant. The cormorant occupies large areas, and *Larus cachinnans* acts as an active predator in relation to other species. Thus, between the great cormorant and *Larus cachinnans*, with a shortage of suitable nesting areas, the competition is fully manifested in Central Syvash. To a lesser extent, competition exists on the islands of Eastern Syvash, where situations where these species did not compete were also observed. Rarer and more interesting were the facts of the joint influence of great cormorants and *Larus cachinnans* on the species accompanying them in the colony.

On the islands of Tendra and Yahorlyk bays, according to the nature of the impact of the great cormorant on the most massive species of the island bird complex, the latter can be divided into two groups: 1 – species on which the great cormorant has a negative impact to varying degrees; 2 – species on which the nesting of the great cormorant has a positive effect. First of all, it should be pointed out that the great cormorant is a strong territorial competitor and the places occupied by the colonies of this species, as well as the areas adjacent to them, become inaccessible for nesting of most of the traditional for the islands' colonial *Charadriiformes* species. In addition, great cormorant nesting sites attract many *Larus cachinnans* to the island, whose predation usually makes nesting on the same island almost impossible for other species of gulls and terns, with the exception of *Larus ichthyaetus* and *Sterna hirundo*. Also, the cormorant's ground nesting places on the islands very quickly become devoid of vegetation. Destruction of vegetation makes areas where cormorants' nest unsuitable for nesting ducks. The great cormorant has a definite positive effect on *Pelecanus onocrotalus*. This species is the center of social attraction for the pelican. Other researchers believe that the nesting colonies of the great cormorant for *Pelecanus onocrotalus* are a marker of the security of the nesting territory. In any case, the presence of nesting colonies of the great cormorant turns out to be an important factor in the restoration and further preservation of the nesting settlement of *Pelecanus onocrotalus* in the Black Sea Biosphere Reserve.

Another species on which the great cormorant has a positive effect on the islands of Tendra and Yahorlyk bays is *Larus cachinnans*. And although, at the first stages of the formation of a nesting settlement on the Kins'ki islands, the great cormorant displaced the gulls from their traditional nesting biotopes in the lower part of the island, where a rather significant death of its nestlings due to rushes was noted, in the future the joint the nesting of these two species turned out to be very beneficial for *Larus cachinnans*. Colonies of great cormorants are a very rich source of food for gulls, which they obtain here both by kleptoparasitism (passive and active) and by predation on eggs and nestlings. It should also be mentioned that some species can use old abandoned colonies of the great cormorant. *Pica pica* and *Somateria mollissima* can nest in the nests of old colonies, and within the abandoned colonies themselves, where the vegetation has not yet had time to recover, sometimes nesting *Thalasseus sandvicensis* and *Sterna hirundo*. According to the above-mentioned authors, in the conditions of low-lying islands, often flooded during rains and driving winds, such a strategy can increase the survival of these species. However, the scale of such a positive effect is extremely insignificant and is completely neutralized by the whole set of negative effects of the great cormorant on the valuable components of the island avifauna complexes of the Tendra and Yahorlyk bays.

4. Conclusion

An analysis of both published and original information concerning the great cormorant in the region allows us to draw the following conclusions:

1. The activity of cormorants affects various components of the natural complexes of the Azov-Black Sea region of Ukraine. Since the great cormorant is an obligate ichthyophage, it exerts a certain influence on the fish productivity of the coastal zones of the Azov and Black seas; fish resources experience a heavy load from the species, especially during the feeding of nestlings.
2. Its impact on herbaceous vegetation is manifested both in a change in the species composition of phytocenoses and in the subsequent disappearance of vegetation in certain areas. Tree vegetation is also negatively affected – mechanical damage to trees by birds when collecting branches for nests, their destruction under the weight of nests, drying of trees due to the effect of large doses of nitrogen and phosphorus compounds from birds' excrements. And in the case of a large area and number of cormorant colonies, the drying of trees occurs on large areas, which can reach tens of hectares, which undoubtedly causes damage to forestry.
3. The high number of cormorants leads to a reduction in the number of some other species of birds, impoverishment of nesting bird complexes (herons, terns); in the conditions of a shortage of nesting sites on the islands, only *Larus cachinnans* can nest together with the great cormorant (with its high number).

Abstract. At present among environmental toxicants, endocrine-disrupting compounds (EDCs) gained the widest distribution due to their presence in chemicals in consumer products and food contact materials, pharmaceuticals, personal hygiene products, and as mycotoxins and phytoestrogens. They are used in animal husbandry as growth promoters and in crop production as pesticides and herbicides. EDCs pollution of water sources is becoming alarming due to the imperfection and difficulty of removing pollutants using traditional water and wastewater treatment processes. Given the EDS activity and genotoxicity, the discharge of these effluents may realize a high risk to aquatic organisms in the receiving environment. Natural and synthetic estrogens are among the most potent endocrine-disrupting compounds found in urban wastewater. The purpose of this work was to determine the concentration of hormones, namely estradiol and cortisol, in Procambarus virginalis hydrobionts of different ages from the Dnipro River in the city of Dnipro. In the presented work, based on a review of modern scientific sources and the results of our own research, emphasis is placed on the need to monitor the accumulation of hormone-like compounds in the tissues of aquatic organisms, namely crustaceans as markers of pollution of aquatic ecosystems by EDCs. The influence of substances destroying the endocrine system is especially dangerous during critical periods of the body's development. In ecological conclusion, EDC accumulation in hydrobiont's species may have a negative impact on species conservation. In hygienic aspect, these substances can affect humans through the food chain as consumers of fish products and seafood contaminated with such toxicants.

1. Introduction

Ecosystem pollution is a serious problem worldwide. Aquatic ecosystems are extremely important for biota, fauna, flora, and humans. In recent decades, there has been a worldwide concern for the environment due to the difficulty of removing pollutants through traditional water and wastewater treatment processes. Among environmental toxicants, endocrine-disrupting compounds (EDCs) encompass nearly 800 different chemicals, including both natural and synthetic compounds, including pesticides, chemicals in consumer products and food contact materials, pharmaceuticals, and personal hygiene products. They alter the activation, synthesis, secretion, and binding of endogenous physiological hormones, thereby influencing several hormonal and metabolic processes. More specifically, they work by mimicking hormones, binding to their receptors and promoting inappropriate responses at inappropriate times or directly blocking their effects [1, 2]. Their progressive exponential occupation and, as a result, waste determine their diffusion and accumulation in the environment. Some EDCs persist in the environment for long periods of time, even after their ban (as an example, the pesticide DDT), due to their insolubility, lipophilicity, and high resistance to degradation [3]. A large number of pollutants that can have an endocrine effect are present in the water environment both individually (in different concentrations) and in complex mixtures [4, 5].

The main source of water pollution is wastewater from various industries. Hormonal activity and genotoxicity of various effluents from textile, paint, electronic and electroplating plants, pulp and paper mills, chemical plants, and municipal sewage treatment plants were evaluated. The results showed the presence of EDS in most industrial effluents. The importance of the city as a huge source of pollution was also confirmed [6]. Municipal sewage, the pharmaceutical industry and hospitals are the biggest sources of steroid estrogens too. Municipal landfills are also sources of organic pollution and may contain leachates with significant amounts of dissolved organic matter, which is partly composed of steroid hormones and other pollutants. In addition to urban pollution, some treated industrial wastewater from processing plants contained phytoestrogens. The filtrate is able to penetrate into groundwater.

Existing wastewater treatment technologies do not fully address the growing water pollution situation from wastewater discharges, especially with the increased use of personal care products and pharmaceuticals in private households and the healthcare sector. The urgency of solving the problem of organic pollutants is taken into account in Directive 2013/39 / EU. In addition, Decision 2015/495 of March 20, 2015 defined a list of 10 pollutants. This list includes several chemicals, including the pain reliever diclofenac and the hormones $17beta$-estradiol and $17alfa$-ethinylestradiol. In addition, it is necessary to take into account the formation and transformation of by-products. Unfortunately, most methods currently in use are unable to completely remove such critical compounds [7].

Endocrine-disrupting chemicals have been found in aquatic environments around the world. Given the EDS activity and genotoxicity, the discharge of these effluents may realize a high risk to aquatic organisms in the receiving environment. Aquatic organisms are particularly affected by anthropogenic pollutants, the effects of which can last a lifetime and are mediated through several pathways, including through the skin and gills, or through feeding on contaminated sediments and bioaccumulation. Aquatic pollutants can compromise reproduction, development, immune response, and other physiological processes that can ultimately affect aquaculture survival. In addition to the direct impact of water pollutants on the population of aquatic organisms that are included in the food chain when used by humans and wildlife, they realize a risk to human health and negatively affect the economics of fisheries and aquaculture [8].

Crustaceans are among the most ecologically significant species in aquatic ecosystems and food webs, playing a crucial role in aquatic ecosystems in transporting food web energy. In addition, these species play an important role as bioindicators in toxicological studies of water pollution. Metabolism of many xenobiotics occurs more slowly in invertebrates than in fish, and therefore invertebrates retain higher levels of contaminants. Therefore, EDS, accumulating in organisms, are a danger to the entire ecosystem through the food web [9].

Bisphenol A (BPA), phthalates (DEHP), polyvinyl chloride (PVC), pesticides, herbicides, and organotin compounds show estrogenic activity. Estrogenic disruption of tissue mineralization in aquatic organisms can have a wide range of consequences, such as increased skeletal abnormalities, altered bone density and mineral homeostasis, which can affect swimming and prey capture and predator avoidance. In addition, a violation of homeostasis can affect the reproduction of wild and cultivated species in aquaculture [10].

Along with estrogens, such a hormone as cortisol, which is a key mediator of the hypothalamicpituitary-adrenal response to stress, has a significant impact on living organisms. While acute changes in its circulating levels are necessary to maintain homeostasis under dynamic environments, its chronic elevation can affect immunity, behavior, and reproduction [10].

The marbled crayfish Procambarus virginalis belongs to freshwater crayfish species. P. virginalis is a popular pet species in Europe and North America. P. virginalis is an invasive species in the Dnipro River in Ukraine. Now the species has been introduced into the natural ecosystems of the Dnipro near the city of Dnipro. Through the parthenogenetic method of reproduction and polytrophic omnivorousness, P. virginalis can withstand low winter temperatures in the European temperate zone.

Studies indicate the need for monitoring to assess certain classes of pollutants, such as EDS, which are known to realize serious toxicological hazards to aquatic biota at low concentrations [4].

The purpose of this work was to determine the concentration of hormones, namely estradiol and cortisol, in Procambarus virginalis of different ages as hydrobiont from the Dnipro River in the city of Dnipro.

2. Methodology

The concentration of estradiol and cortisol was determined by the ELISA method on the Stat Fax 303 plus enzyme immunoassay (Awareness Technology, USA) using standard reagents "EstradiolIFA", "CortisolIFA" (HEMA LLC, Ukraine) according to the instructions for the reagent set. Estradiol level was determined in caviar, embryos, young crustacean carcasses samples of Procambarus virginalis, and the muscles of one-month-old (young) crustaceans, five-month-old (mature) and year-old (older) ones. Cortisol level was fixed in gills and muscles of different age crustaceans, roe, embryos and juveniles of marbled crayfish.

The statistical analysis was performed using the program Statistic 6.0 for Windows. The statistical significance was considered at $p<0.05$. [11, 12].

3. Results and discussion

Endocrine control of homeostasis results from the ability of neurons to integrate diverse sensory and hormonal inputs to coordinate autonomic, behavioral, and endocrine responses in their key regulatory centers responsible for the cascade of hormonal events required to modulate critical body functions such as metabolism, reproduction, growth, water balance etc. [13]. Originally, EDCs were thought to exert their effects primarily through nuclear hormone receptors, i.e. estrogen, androgen, progesterone, thyroid, and retinoid receptors. Further studies have highlighted that they also act through non-nuclear receptors for steroid hormones (e.g., membrane estrogen receptors); non-steroidal receptors (for example, serotonin, norepinephrine, or dopamine receptors); orphan receptors (for example, aryl hydrocarbon receptors); enzymatic pathways involved in steroid biosynthesis and/or metabolism, as well as numerous other mechanisms that overlap with the endocrine and reproductive systems. Some EDCs have a genotoxic effect, causing deoxyguanosine hydroxylation and/or DNA strand breaks (both single and double), thereby promoting the malignant transformation of affected cells. Numerous endogenous and exogenous factors, such as environmental pollution and diet lead to the deterioration of the reproductive health of individuals of all links of the food chain [3, 14, 15].

It is known that reproductive processes in crustaceans are controlled by the endocrine system. These hormones play a significant role in normal growth and development. Water pollutants can impair reproduction, development, immune response, and other physiological processes, which can ultimately affect the survival of aquatic organisms. 17beta-estradiol (E2) is important for the development of crustacean ovaries. Ovaries, hepatopancreas, hemolymph, and nervous tissues have been shown to be target organs for compounds with estrogenic activity in crustaceans, and concentrations of 17beta-estradiol in various tissues are closely related to vitellogenesis in the ovary and hepatopancreas during ovarian development [16, 17].

Epigenetic programming established during development can be altered by exposure to EDCs during sensitive periods such as the preovulatory and ovulatory phases and cause immediate adverse outcomes. In addition, changes in methylation profiles and acetylation landscapes that occur during these periods may predispose to the development of pathologies that occur later in childhood or adulthood and, more dramatically, may even be transmitted from generation to generation [3].

According to the results of our research, the average level of estradiol in caviar samples of Procambarus virginalis was 2107 ng/g fresh weight, embryos – 2876 ng/g, and young crustacean carcasses – 4924 ng/g.

In the muscles of one-month-old (young) crustaceans, the average level of estradiol was 4634 ng/g of fresh weight, five-month-old (mature) – 4854 ng/g, year-old (older) – 4877 ng/g of fresh weight. These results highlight the ubiquitous bioaccumulation of estrogens in aquatic invertebrates depending on the duration of exposure.

The distribution of estradiol in the muscles of Procambarus virginalis can directly and effectively reflect the effects of EDC. Xenoestrogens can act on several mechanisms simultaneously. Estrogenic xenobiotics also disrupt the physiology of aquatic organisms, biochemical processes as triggers of oxidative stress, can affect their reproductive development, cause transcriptional effects, and they are also quite powerful initiators of signal cascades from membranes. Transfer of estradiol from the digestive system of Procambarus virginalis to muscle may pose a potential risk to aquaculture, wildlife and human health associated with the consumption of aquatic meat. Finally, they contribute to the general accumulation of estrogen in the environment.

It has been shown that herbicides, namely atrazine, which is commonly found in water bodies, affect the reproductive process of the corresponding fauna, acting as an endocrine disruptor. In this sense, it is suspected that this herbicide affects the secretion of some neurohormones involved in gonadal growth and also changes the circulating levels of steroid hormones that promote the synthesis of vitellogenin for ovarian growth. In addition, atrazine-induced sexual differentiation of young crayfish towards a greater proportion of females reduced offspring production, as well as several embryonic abnormalities, and had a genotoxic effect on crayfish. Finally, some metabolic imbalances, such as reduced energy stores, are observed in some species along with oxidative stress and histopathological effects. as well as suppression of the cortisol response [18].

Cortisol functions as both a glucocorticoid and a mineralocorticoid, which is explained by the unusual structure of its receptors, particularly in fish. This hormone affects the metabolism of carbohydrates, proteins and fats, and also performs important functions related to osmoregulation, growth and reproduction. It is commonly called the hyperglycemic hormone, which ensures the presence of a certain level of glucose in the blood. In aquatic animals, it is an important component in the stress response. Thanks to the timely correction of metabolic processes by this hormone, there is an even distribution of energy resources among target tissues under critical life conditions. Cortisol regulates the processes of osmoregulation through a mediated increase in the activity of enzymes involved in ion metabolism, in particular, Na-K-ATPase [19]. This may indicate its stimulating role as an activator of ion-exchange enzymes, particularly in gill tissues, where the highest activity of these enzymes is observed. It should also be noted that cortisol affects the final maturation of oocytes in the preovulatory period [20]. It is believed that the deposition of cortisol by the maternal body together with its local production by the ovaries may participate in the regulation of oogenesis. There are two critical stages when cortisone can have a modulating effect on oogenesis. The first stage occurs during vitogenesis when maternal cortisol is incorporated into the yolk, and the second stage occurs during maturation and ovulation, when cortisol can play a regulatory role, causing maturation [21]. It has been shown that the stress-induced increase in cortisol, associated with a decrease in estradiol, affects the functions of granulosa cells in the follicle, worsening the quality of oocytes [15]. Recent studies suggest that this hormone may act as a key factor linking the stimuli of the social environment and the onset of sex change, initiating the transition in steroidogenesis from estrogen to androgen. In addition, there are significant differences in glucocorticoid content between marine and freshwater crustaceans. Organotin compounds at different doses can inhibit the activity of 11*beta*-hydroxysteroid dehydrogenase isoenzyme 2, which is responsible for the inactivation of cortisol, which can increase glucocorticoid levels [13, 22].

Crayfish gills play an important role in the transport of respiratory gases, excretion of nitrogen compounds and osmoregulation. The gills are the first barrier to waterborne pollutants. Gill tissue condition is generally considered a good indicator of water quality and suitable for environmental impact assessment. Its changes can lead to a decrease in oxygen consumption and a violation of the function of osmoregulation. A marked decrease in oxygen consumption can lead to internal hypoxia, which affects metabolism and movement [23].

Based on the results of the study, it was established that the level of cortisol in the gills of Procambarus virginalis increases ($p < 0.05$) (by 5.7 and 10 times) depending on age (figure 1A). In contrast, there was a probable decrease ($p < 0.05$) in the muscle of 2.2- and 3.2-fold with age, respectively (figure 1B). This is related to the distribution of energy between tissues. Cortisol is known to be involved in the development of stress reactions, regulation of water-salt balance, and carbohydrate metabolism in vertebrates, particularly fish. Significant difference between the cortisol content in roe, tissues of embryos and juveniles of the investigated crustaceans wasn't found (figure 1C). It can be assumed the hormone level changes of in this samples are related to the direct influence of the surrounding water environment.

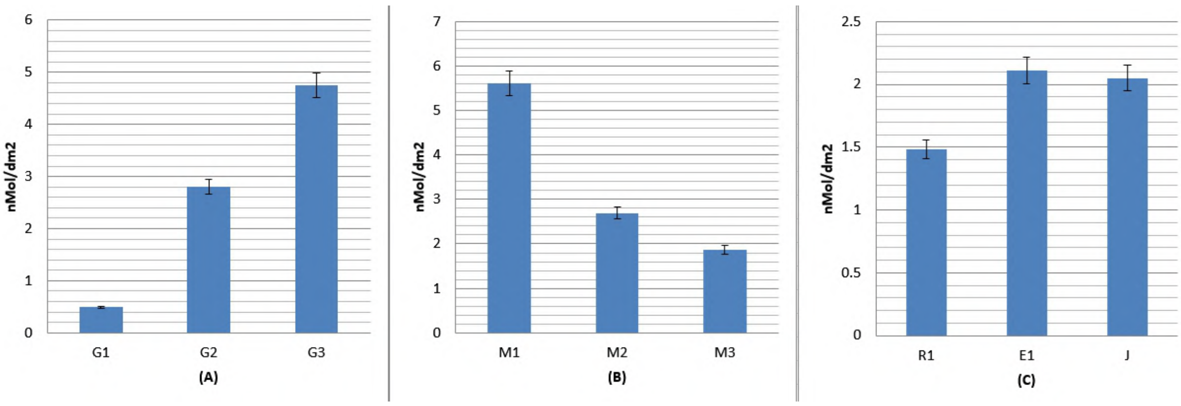

Figure 1. The content of cortisol in tissues gills (A), muscle (B), roe, embryos and juvinale (C) of marble crayfish.

4. Conclusions

The obtained results emphasize the widespread bioaccumulation of EDS, namely compounds with estrogenic activity, in aquatic invertebrates depending on the duration of exposure, which may indicate the role of the aquatic environment in the bioaccumulation of xenoestrogens. The study demonstrates the need to monitor exposure to EDC contaminants due to their effects on water quality degradation and serious toxicological effects on aquatic biota and human health to inhibit such potential. Estrogens are clearly necessary for normal fauna and human physiology but can have serious negative consequences if allowed to accumulate in the environment.

A link between chronic exposure to low concentrations of chemicals via the environment or food chain and reproductive health in animals has been demonstrated. Xenobiotics, including parent compounds and their metabolites in aquatic ecosystems, can cause developmental delay, malformations, behavioral changes, and mortality in non-target organisms.

The main source of exposure to EDCs for humans is food, particularly of animal origin. Concerns have been raised about estrogens entering the human food chain, which in turn is related to how aquatic organisms consumed as food absorb and metabolize estrogens. In epidemiological studies, EDCs have been associated with immunotoxicity and neurobehavioral deficits both in consumers of contaminated products, including aquaculture, which accumulated these substances directly from the environment and in children exposed to EDCs in utero and through breast milk. The possibility that the bioaccumulate properties of persistent organic chemicals with hormone-like activity and chronic low-level exposure may contribute to the overall risk of breast cancer in women, as well as reproductive and developmental effects in humans, has serious implications for the prevention of these diseases. If consumed at levels above safe thresholds, they can cause metabolic diseases in humans. But, taking into account the fact that hormones act at very low doses, especially during sensitive stages of life, this concept can be extrapolated to EDCs, for which the biological significance of doses of certain EDCs below regulatory "safe" levels has been shown. These findings may have serious public health implications, as exposure to EDCs is still occurring worldwide, possibly affecting future generations and leading to the development of previously unreported diseases.

The tissues of aquatic organisms may contain a mixture of several ecologically toxic compounds, in addition to endocrine-disrupting contaminants, due to the widespread contamination of surface waters with poorly treated municipal and industrial wastes. This phenomenon can have additive, synergistic or antagonistic effects, which can explain their ultimate biological activity.

Thus, it is possible to note two important aspects related to the issue of contamination of aquatic biota with compounds that cause the destruction of the endocrine system. The first aspect concerns the impact of EDCs on the reproduction of wildlife populations, including aquatic organisms, which may have a negative impact on species conservation. The second aspect is that, since the effects of EDCs are realized on humans in different ways, primarily through trophic link food chains, further research is needed for public health policy planning.

Abstract. The paper uses the method of geospatial biodiversity assessment in the Danube region based on an expert evaluation of the distribution of species richness of fish, amphibians, reptiles, birds and mammals. The 10-point grading scale was used to evaluate the number of species in 200 sample plots of the study region. Points from 1 to 10 were separately calculated for the species in each taxonomic group. The analysis showed a close relationship between the Lower Danube floodplain and the small steppe river basins, which together make up a single natural region. A practical testing of the geospatial assessment of the species richness was done for the first time in the Danube region. An important applied result of the research is the opportunity to assess missing elements in the environmental network of the region. This approach will justify the need to designate various types of protected areas, both at the national level (natural reserves) and at the international level (the Emerald network sites and wetlands). The areas could further be used to develop a unified ecological framework, thus contributing to the protection of rare and endangered species of the region.

1. Introduction

The conservation, and moreover the restoration of biodiversity, is one of the global environmental challenges facing humanity. For Ukraine, with its valuable natural regions, such as the Carpathians, Crimea, Danube, Polissia and others, the biodiversity assessment is an initial step in deciding the further conservation strategy.

The Danube region is regarded as one of the valuable regions in terms of biodiversity, but traditionally considered in a narrow aspect, only within the boundaries of the Danube Delta. Based on the centuries-old history of the reciprocal development of the delta, the sea shelf and the mainland, in this paper we consider the Danube region in a broader aspect, taking into account the past natural connection of the small steppe rivers of the region and the Danube lakes with the unique Danube delta.

The history of biodiversity studies in the Danube Delta has a long tradition [1–3]. Nevertheless, only a few works are dedicated to the biodiversity components of the other areas of the Danube region [4, 5].

Until recently, biodiversity assessment was based on the absolute values of the number of species and their abundance, as well as on various indices of species abundance and biodiversity in general. However, the possibility of using geospatial biodiversity assessment has significantly expanded the practical application of the obtained data. Nowadays, the methods of geoinformation systems are widely applied for biodiversity analysis all over the world [6–11]. As a result, these approaches significantly increase the effectiveness of protected area planning [12–14].

The *purpose* of this research is a spatial assessment of the biological diversity of the Danube region by the example of zoological taxa and the development of a methodological approach for such work.

2. Study area, material and methods

We consider the Danube region as a combination of the small steppe river basins, the left tributaries of the Danube in the lower reaches, and a chain of their final reservoirs (the Danube lakes, which used to be estuaries): Kahul, Kartal, Kuhurlui, Yalpuh, Katlabuh, Kytai and adjacent areas of the Lower Danube (figure 1). The region is studied within the administrative boundaries of Ukraine, so the basins of some small steppe rivers are not fully included. As the runoff of such small rivers as the Kohylnyk and Sarata affects Zhebrianska Bay with its rich flora and fauna (the Danube avandelta), their basins and Sasyk Reservoir are included in this natural region. The total study area covered 975,425 ha. The region is characterised by complex ecological relationships among various natural components and their mutual influence.

The Danube River, with its unique and fastest-growing delta in Southeast Europe, is a pivot

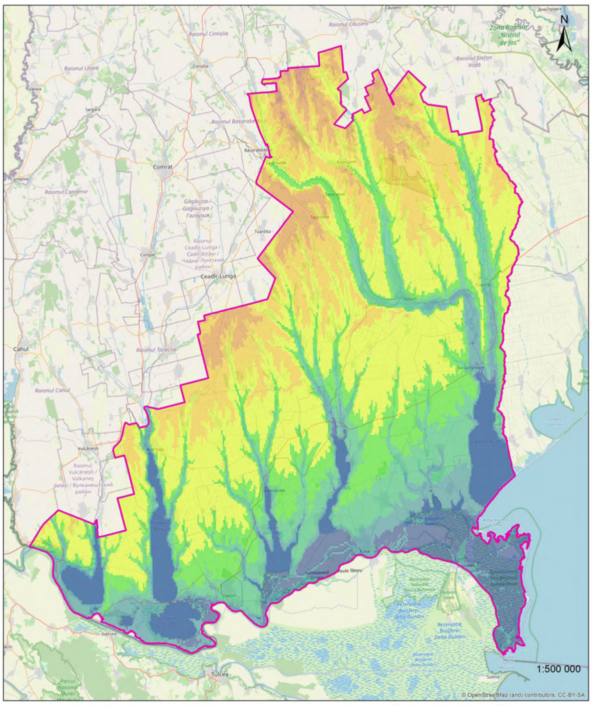

Figure 1. The study area.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012015 doi:10.1088/1755-1315/1254/1/012015

of the region. Together with the adjacent small river basins, they have formed a valuable natural community with different landscape types that contribute to the development of rich biodiversity. However, the delta and its adjacent areas have also suffered from considerable man-made transformation. Vast coastal areas were embanked and converted into agricultural lands. Small rivers were transformed into a set of reservoirs, ponds and canals. Canals and hydrotechnical facilities were intensively built, focusing on transporting the Danube water to various parts of the region. Most of these activities had a negative impact on the integrity of natural communities and led to a decrease in regional species abundance.

Vertebrate taxa such as fish, reptiles, amphibians, birds, and mammals (except for Chiroptera) were chosen as biodiversity indicators. Compared with other taxa, they are more often on top of the ecological pyramid and are sensitive to the slightest changes in ecosystems. Their status makes it easier to judge the environmental processes in the natural region, and the concentration of their species abundance can diagnose the degree of importance or transformation of various spatial areas.

The assessment of selective zoological diversity is based on the results of regional fieldwork carried out during 1970-2022.

A grading scale for species abundance within each taxon was developed to assess diversity. First, each type of taxon was associated with its own habitat. Then, using QGIS methods, a regular grid was made for the region, consisting of 200 hexagons, each with an area of about 5 thousand hectares. According to the ratio of habitats in one or another hexagonal polygon, a quantitative assessment of the species abundance for a particular taxon in the polygon was made. Given the significant differences in species abundance among birds, reptiles, amphibians, fish and mammals, ranked scores were determined for each taxon to standardise and align the obtained data. For this purpose, the share of species abundance in a given hexagon was correlated with the total species abundance of a given taxon in the region. Based on the scores in each taxon, a table of the integral zoological value of the species abundance in each polygon was formed. Therefore, the data from zoological studies were correlated with the obtained regular grid. For the integral assessment, the method of heat maps was also used in accordance with the scores within the hexagon, which, on the one side, gives a smoother picture, and on another side, reliably identifies the most critical parts of the region.

The analysis of the region transformation used the open data on land use classification posted by the European Space Agency “ESA WorldCover” [15]. According to this classification, the following types of land surface with different land use are distinguished in the Danube region: 1) tree vegetation; 2) shrub vegetation; 3) herbaceous vegetation; 4) agricultural land; 5) buildings; 6) areas without vegetation or with sparse vegetation; 7) reservoirs with a permanent presence of water; 8) wetlands and reservoirs overgrown with vegetation. We also classified types 4 and 5 as significantly transformed and the remaining ones as natural and semi-natural.

Spatial analysis was conducted using the QGIS software.

3. Results

Based on the developed method, we have received maps of species abundance for some taxonomic groups in the Danube region (figures 2-5). Colour gradation shows the score range of species diversity: dark green (1), light green (2-3), yellow (4-5), orange (6-8) and bright red (9-10 points).

There are some peculiarities in the distribution of fish species abundance in the region (figure 2). Thus, the Danube floodplain houses the highest species diversity. In most drainage basins, the fish species composition is extremely poor. Small rivers are drying up, but the embanked areas still preserve some species abundance in their middle reaches. Only in the Kohylnyk and Sarata rivers (the easternmost ones in the figure), the water content of which is

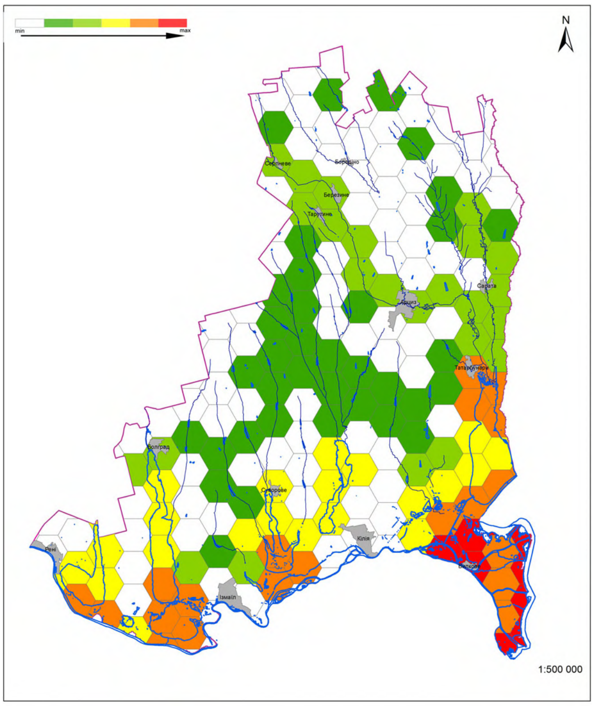

Figure 2. Abundance of fish species.

higher, relatively low species diversity persists throughout the entire length of their channels (the Kohylnyk River) almost to the regional borders.

The highest diversity index of reptiles and amphibians is recorded in the Danube floodplain (figure 3) as all the amphibian species typical for the region are available there, along with water reptiles (the European pond turtle *Emysor bicularis* Linnaeus, 1758, dice snake *Natrix tessellata* Laurenti, 1768, grass snake *Natrix natrix* Linnaeus, 1758). Suitable habitats for reptiles and amphibians are located not only along the slope landscapes of small rivers but also along numerous forest belts in agricultural lands that ensure a much wider distribution of the optimal species composition of reptiles compared with fish in the middle reaches of small steppe rivers.

Birds form the basis of the species richness of vertebrates in the region (figure 4). The avian diversity is represented by more than 320 species. A deeper colour of the Danube floodplain indicates the predominance of waterbirds, although their distribution is limited along small rivers. The species composition of this taxonomic group is very dynamic and depends on the landscape diversity and seasonality. Birds, due to their plasticity and mobility affected by external factors can quickly disperse within the Danube region of Ukraine and outside its boundaries.

The areas of high mammal biodiversity (figure 5) are concentrated in latitudinal zones along the Danube floodplain and in the north of the region. This diversity is most affected by the heterogeneity of landscapes and habitats. Thus, the northern part of the Danube region is located on the elevation, streaked with channels of small rivers, gullies and ravines, with vast Tarutinska Steppe and forest tracts. This determines the high species diversity of mammals, mainly rodents (Rodentia). The landscapes of the Danube floodplain are highly mosaic, with large areas of riverine forests, meadow ecosystems and floodplain lakes that ensures a high species abundance of all orders of mammals typical for the region. Moreover, the inaccessibility of the territory together with the border control and environmental regimes, contribute to the

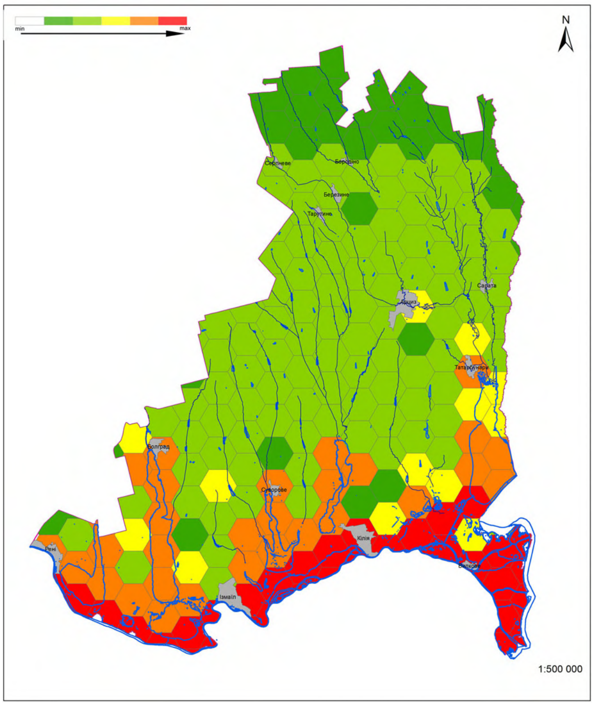

Figure 3. Abundance of herpeto- and batrachofauna species.

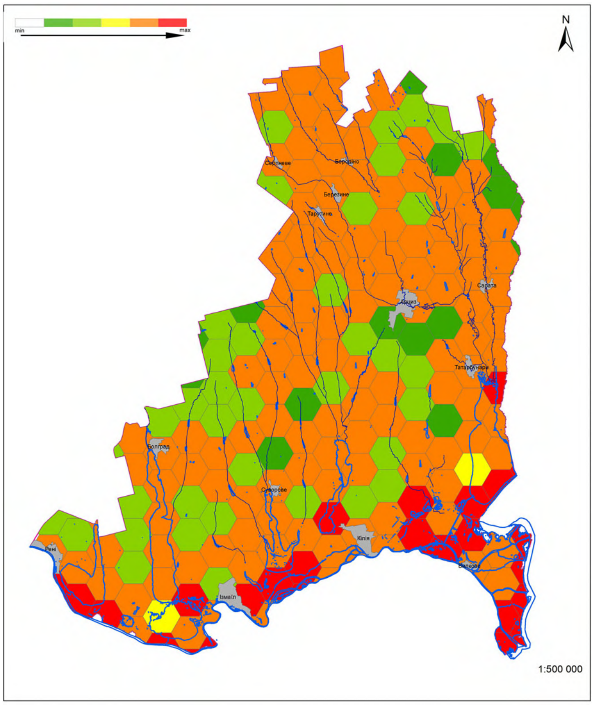

Figure 4. Abundance of avifauna species.

conservation of biodiversity.

An integrated assessment of the whole zoological diversity (figure 6) quite fully illustrates the cohesion of this natural region, the absence of any hiatuses and clear latitudinal demarcation

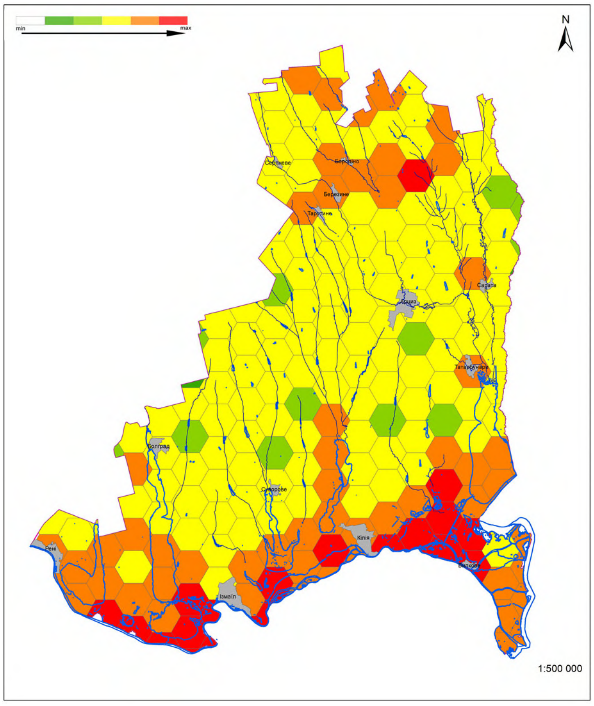

Figure 5. Abundance of mammal species.

lines from the stripes of hexagons with low species abundance, including the transition from the Danube floodplain to the small steppe basins. This is especially pronounced when species diversity within the ecological framework is reflected using GIS grids. However, some biodiversity loss is recorded in the interfluvial areas and the middle reaches of the rivers flowing into Lake Katlabuh and Stensivsko-Zhebrianski Plavni.

4. Discussion

Geospatial assessment of the ichthyofauna species diversity (figure 2) clearly shows the consequences of water flow regulation in small rivers, or more precisely in their intermediate reservoirs of the Danube lakes and, consequently, almost complete isolation of them from the Danube floodplain, especially during floods. It has caused a rapid depletion of the ichthyofauna in the lakes and rivers, formerly used for upstream migration by spawning shoals of semi-anadromous fish species. More than half a century of isolation led to a decrease in the previous abundance of fish species. The current negative situation can only be solved if the water exchange between the basins of small rivers and the Danube floodplain is restored. It will improve the water content of small rivers and progressively restore their slopes and the underground springs blocked by layers of landslide soils.

The concentration of a high diversity of amphibians, reptiles and mammals in the Danube floodplain (figures 3, 5) indicates the need to restore the channels and slope sections of small rivers. Acting as ecological corridors, they will promote the unimpeded dispersal of species in the meridional and latitudinal directions. Otherwise, it is impossible to maintain the population homeostasis of representatives of the batracho-, herpeto- and mammal fauna, predominantly rare and vulnerable species.

Birds, as the most mobile zoological component of biodiversity, easily colonise well-preserved discrete natural areas along the floodplains and slopes of small rivers (table 1), thus determining the "elongation" of integral grids of optimal and high species diversity along the channel sections

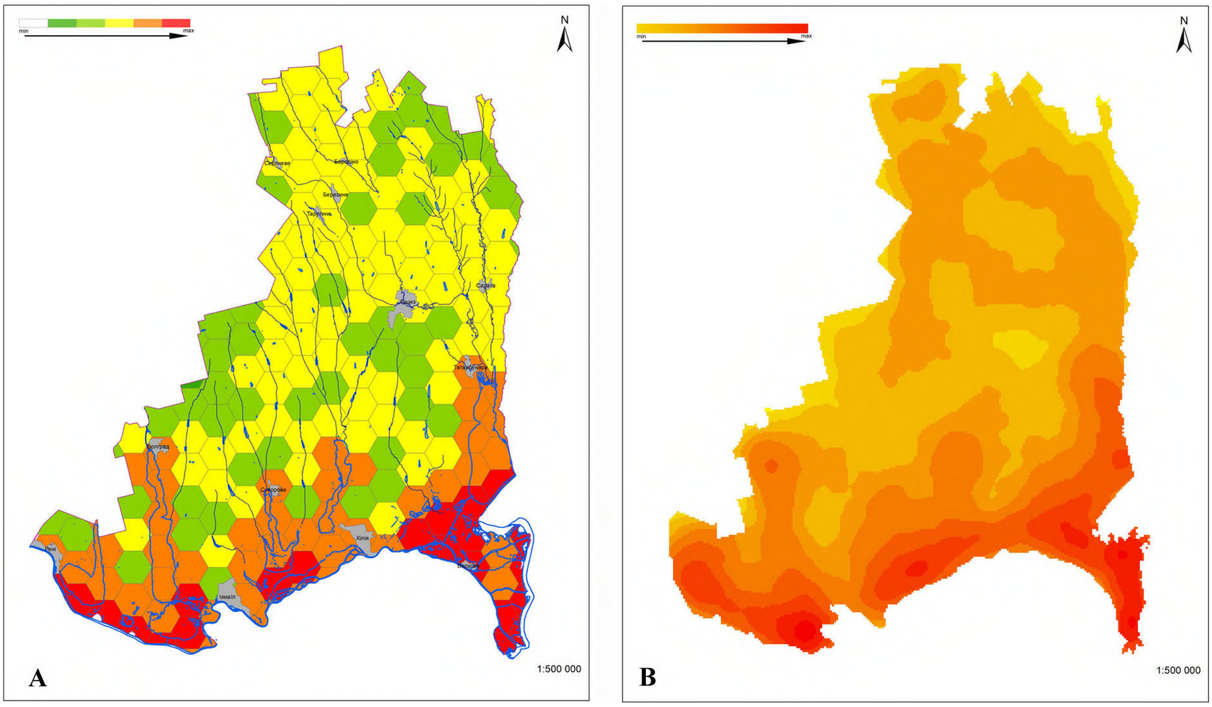

Figure 6. Integral assessment of the abundance of zoological species (A – regular hexagons; B – grids of integral diversity).

of small rivers in figure 6B.

Table 1. The share of natural habitats, in percent of the total area of riverine-floodplain habitats of the main steppe rivers in the Danube region.

Main rivers of the basin	Name of the basin	Percent of natural habitats
Kahul	Lake Kahul	58.5
Velykyi Yalpuh	Lake Yalpuh	82.7
Velykyi Katlabuh	Lake Katlabuh	56.8
Kyrgizh-Kytai	Lake Kytai	60.1
Drakulia	Stensivsko-Zhebrianski Plavni	44.9
Kohylnyk	Sasyk Reservoir	70.6

The preserved natural state of some channels and floodplains of small rivers supports the survival of many animal species, including Ukrainian red-listed ones, thereby enabling the potential expansion of the genetic exchange corridors between fragmented populations and subpopulations of animals (except birds).

However, the critical destruction of steppe and meadow areas, converted to agricultural lands, has led to the loss of many stenobiont animal species. In general, the noticeable predominance of anthropogenically transformed lands and the isolation of individual natural areas hamper the protection of regional species diversity. An essential element of biodiversity conservation in natural communities is the network of protected sites with different statuses. The region encompasses protected areas of national significance, wetlands of international importance and the Emerald network sites. The regional ecological network is also developed, focusing on integrating valuable areas (cores) into a single system through ecological corridors.

The available data on the biodiversity distribution and existing boundaries of natural conservation areas enable the identification of gaps and the development of a more effective system of protected sites. The data analysis indicates the need to designate three new wildlife reserves and significantly expand the regional ecological network. Total area recommended for the nature conservation areas is 45,934 ha.

This approach will facilitate the complete restoration of the mutual influence between the Lower Danube floodplain and small steppe rivers, expand ecological corridors and biodiversity cores, and contribute to the conservation of fauna populations of this unique natural region.

5. Conclusions

A large-scale geospatial assessment of the Danube region biodiversity has allowed identifying the most valuable areas, naturally located in the Danube Delta and the lower part of the Danube lakes, and the areas with an urgent need of restoration.

A holistic view of the region also showed the role of small steppe rivers in the species exchange and the formation of ecological corridors. The dominance of the Lower Danube floodplain in terms of the animal species abundance may also be associated with the availability of protected areas of different statuses.

Despite the significant transformation of the region (a high percentage of agricultural land use, embankment of the Danube lakes-estuaries, conversion of some sections of small river channels, the Danube region still remains an important area for biodiversity conservation, not only in its key part - the Danube Delta, but also within the boundaries of the adjacent small river basins.

The use of a holistic spatial approach to biodiversity assessment provides wide opportunities for management decision-making, such as identifying potential protected areas, areas for restoration, etc. The data analysis indicates the need to designate three reserves with a total area of 18,178 ha and expand ecological corridors with a total area of 27,756 ha.

Acknowledgments

The authors are grateful to Dr. of Biological Sciences Josef Chernichko for his valuable advice in preparing the manuscript for publication.

The research was carried out within the framework of the European Endangered Landscapes Program and the project “Renewal of wetlands and steppes in the Danube Delta region” (2019-2023), which is being implemented by Rewilding Europe NPO.

Abstract. Saline soils make up almost 25% of the entire earth's surface. Their areas, unfortunately, have a steady tendency to expand due to the aridization of the climate and the global increase in the average annual air temperature of the planet. The increased concentration of salts in the soil limits the diversity of cultural and conditions the poverty of natural flora, forms areas of risky agriculture in the south of Ukraine. Seeds are a unique product of evolution, the main generative organ of plants, characterized by a number of morphological, physiological and biological features, among which there is adaptation heterogeneity. It is established that by the number of germination days (the seeds of the cultural flora sprouts for 7–10 days, and in wild representatives this indicator extends to 10–12 days) the plants can be arranged in the following order: seven days –*Secale cereale* L., *Triticum durum* L., *Avena sativa* L., *Hordeum vulgare* L., *Helianthus annuus* L., *Matricaria recutita* L.; ten days – *Beta vulgaris* L., *Phaseolus vulgaris* L. and twelve days – *Valeriana officinalis* L. It is found that the most optimal for germination is the aquatic environment, so the plants are arranged according to the list: *Helianthus annuus* L. → *Avena sativa* L. → *Triticum durum* L. → *Matricaria recutita* L. → *Secale cereale* L. → *Hordeum vulgare* L. → *Beta vulgaris* L. → *Valeriana officinalis* L. → *Phaseolus vulgaris* L. It is proved that Na+ and Cl–ions differentially affect the seed germination energy: at a concentration of 0.1% NaCl – *Triticum durum* L. → *Helianthus annuus* L. → *Hordeum vulgare* L. → *Secale cereale* L. → *Phaseolus vulgaris* L. → *Avena sativa* L. → *Matricaria recutita* L. → *Beta vulgaris* L. → *Valeriana officinalis* L.; at a solution concentration of 0.2% NaCl – *Secale cereale* L. → *Triticum durum* L. → *Helianthus annuus* L. → *Avena sativa* L. → *Matricaria recutita* L. → *Hordeum vulgare* L. → *Phaseolus vulgaris* L. → *Valeriana officinalis* L. → *Beta vulgaris* L. The results obtained indicate that the chloride load in the seeds of plants manifests itself in the form of distress as well as eustress. It has been proved that the diagnostic features of chloride hermesis were more clearly manifested in the representatives of the cultural flora than the natural ones.

1. Introduction

Due to increasing anthropogenic pressure on the environment, the climatic conditions on the planet Earth are changing [1]. Saline soils make up almost 25% of the earth's surface (about

$9 \cdot 10^8$ ha). Unfortunately, their areas tend to expand due to climate aridization and an increase in the average annual temperature of the planet [2, 3]. In Ukraine, about 1 million hectares of land have varying degrees of soil salinization. The south of Ukraine forms a zone of risky agriculture characterized by temperate continental climate with hot summers, high solar insolation and significant water deficit [4, 5]. Poverty and specificity of both natural and cultural flora is conditioned by the presence of the sea area (sea, estuaries), intensive evaporation of water during irrigation, soil salinization [6, 7]. Seeds are a unique product of evolution, the main generative organ of plants, characterized by a number of morphological, physiological and biological features, among which there is adaptation heterogeneity [8, 9]. Therefore, research on the similarity of plant seeds to salt stress is becoming increasingly relevant.

Hence, the *research aim* is to find out the seeds' similarity of natural and cultural flora under chloride load in southern Ukraine.

2. Material and methods

The researches object was the seeds of the following plant species that prevail in the herbaceous cultivated and wild vegetation of southern Ukraine: *Beta vulgaris* L., *Secale cereale* L., *Triticum durum* L., *Avena sativa* L., *Phaseolus vulgaris* L., *Hordeum vulgare* L., *Helianthus annuus* L., *Valeriana officinalis* L., *Matricaria recutita* L. The artificial level of salinity in the laboratory and vegetation conditions was created by adding the appropriate amount of salt to the water when wetting and subsequent irrigation according to the scheme: K – natural conditions, option 1 – vegetation and laboratory control (growing seeds in water), option 2 – growing in 0.1% NaCl salt solution, option 3 – growing in 0.2% NaCl salt solution of. The choice of concentration of chloride salts is explained by the fact that such percentage is considered stressful for seeds [4, 10]. Representatives of cultural flora are hybrids and varieties, which are located in the south of Ukraine [6]. The seeds of the experimental plants of the wild flora were collected from hills associations of Zaporizhzhya region (Bogatyr, Terpinnia). The physiological aspects of determining the germination energy of the experimental plants and their similarity were performed according to conventional methods [9]. Laboratory and vegetation experiments were conducted on the basis of the Bogdan Khmelnitsky Melitopol State Pedagogical University, and the field experiments on the basis of Novotroitsky Farm "Niva". Statistical analysis of the obtained data was performed using Microsoft Excel and Statistica 8.0. For comparison of samples, arithmetic mean (M) and standard error from mean (SEM) were calculated. The difference $p \leqslant 0.05$ was considered statistically significant for all indicators.

3. Results

Due to the irrigation of crops, the number of saline soils is increasing annually [6, 11]. Therefore, the study of the adaptive capacity of seeds of representatives of natural and cultural flora to different concentrations of chloride salts will bring us closer to understanding the strategy of adaptive transformations.

The obtained experimental data showed that the seeds of *Secale cereale* L. sprouted 93% in aqueous solution for 3 days (figure 1, A), 89% – in 0.1% NaCl solution, 95% – in 0.2% NaCl solution. At 5 days, this indicator had the following values: in aqueous solution – 93%, in 0.1% NaCl solution – 95%, in 0.2% NaCl solution the number of sprouted seeds increased to 100%. At 7 days, the percentage of seed germination did not change. Our data are in agreement with the opinion of several authors [12], that cereals during germination have a classic effect of gibberellins, associated with the release of seeds from a resting state, and gibberellin "start" formation of amylases is a prerequisite for germination.

The experimental data (figure 1, B) showed that the seeds of *Triticum durum* L. sprouted well in NaCl solutions with a concentration of 0.1% and 0.2% by the third day. It is shown that in the aquatic environment 98% of the seeds sprouted on the 3rd day; the percentage did not

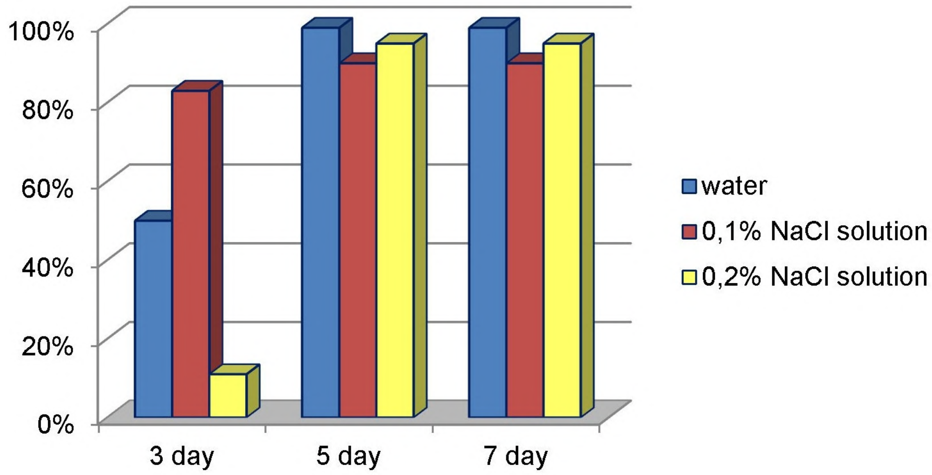
Figure 1. Seed germination energy (%): A – Secale cereal L., B – *Triticum durum* L.

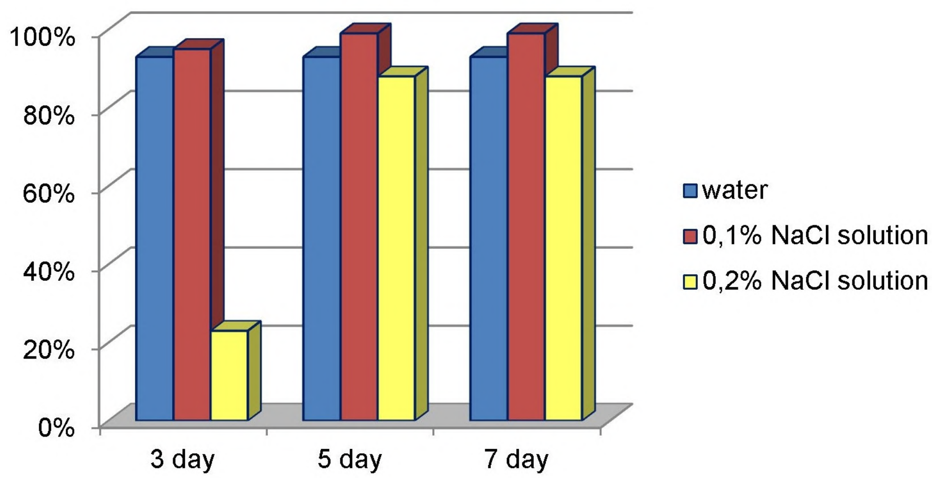
change on the 5th and 7th days. In NaCl solutions with a concentration of 0.1% and 0.2% 100% of the seedlings sprouted on the third day, which may be due to the activation of protective reactions under the action of lections [13], gibberellins, which stimulate the processes of grain germination [14].

Seed germination of *Avena sativa* L. (figure 2, A) showed that on the 3rd day the number of sprouted seeds in water was 50%, on the 5th and 7th day it increased to 99%. In 0.1% NaCl solution on the third day germinated – 83%, the fifth and the seventh – 90%, but in 0.2% NaCl solution on the third day – 11% of seeds, the fifth and the seventh – 95%. During the seven–day period, the largest amount of seeds sprouted in water, although on day 3; 0.1% NaCl solution was the best conditions for the seeds. Germination was more stable in 0.2% NaCl solution. It is known that lections are involved in the process of seed germination and ripening [13].

The obtained results proved that the germination of seeds of *Hordeum vulgare* L. began on the third day (figure 2, B), with the highest values observed in 0.1% NaCl solution – 95%, in the aquatic environment – 93%. This pattern remained for the fifth and seventh days of the experiment. In 0.2% NaCl solution, the smallest number of grains sprouted: 23% on the third day, and on the fifth and seventh – 88%. The faster the germination process occurred with the



A



B

Figure 2. Seed germination energy (%): A – *Avena sativa* L., B – *Hordeum vulgare* L.

seeds that germinated in water, the longer the germination occurred in solutions.

Thus, our results illustrated that Na^+ and Cl^- ions at 0.1% concentration stimulate seed germination for the third day after sowing, this position is confirmed by the works of several authors [7, 11]. Water, penetrating through the pollen and the skin into the intercellular spaces and cells, removes the seed germ from a state of rest. Organic compounds present in the endosperm undergo certain changes, in particular, increased respiration and activated enzymes, under the influence of which the spare substances are converted into easily digestible forms.

It has been proved [9, 14] that in cereals during germination there is a classical effect of gibberellins associated with the release of seeds from rest. After the seeds absorb through the micropyle of water, the embryo in the area of the shield begins to synthesize GA3, GA4 gibberellins, which are transported to the aleurone layer surrounding the endosperm, and stimulate the formation of hydrolytic enzymes (α–amylases, etc.). Enzymes begin to break down the spare starch of the endosperm to the simple sugars used for embryo growth and development. Thus, gibberellin "start" formation of amylases is a prerequisite for seed germination. The mechanism of this process is not fully understood. Gibberellins are thought to stimulate amylase–specific m–RNA synthesis.

Our studies showed that during the germination of *Beta vulgaris* L. seeds (figure 3): the first sprouts appeared on the fifth day in pure water – up to 30%, in 0.1% NaCl solution – up to 20% and the smallest amount was observed in 0.2% NaCl solution – up to 2%. On the 7th day the highest amount of seeds sprouted in water was 70%, 60% in 0.1% NaCl solution, and the smallest in 0.2% NaCl solution up to 30%. On the tenth day the most seeds germinated in water 80%, 75% in 0.1% NaCl solution, and in 0.2% NaCl solution – 35%. Therefore, in *Beta vulgaris* L., the best germination occurs in water and in 0.2% NaCl solution the worst.

It is found that the seedlings of *Phaseolus vulgaris* L. began to appear on the third day (figure 4) in the sample with water and in 0.1% NaCl solution. Up to 50% of seeds have sprouted in the aqueous medium for 5 days, less than 40% in 0.1% NaCl solution, and 20% in 0.2% ones. On the seventh day, in all samples, the number of sprouted seeds increased: 60% – in water, 65% – in 0.1% saline, 45% – in 0.2% NaCl solution. El Amrani et al [15] have investigated the physiological role of seed lections – phytohemagglutinin (PHA). The protective role of PHA in germination of seeds, based on the ability of lection to be released into the environment, and, due to specific interaction with the constituent cell walls of pathogenic bacteria, is shown to cause a delay in their growth.

According to the results of germination of seeds of *Helianthus annuus* L. it was found that for 3 days the most seeds germinated in aqueous medium, in 0.1% NaCl solution – 60%, 0.2% NaCl solution – more than 20% (figure 5). On the fifth and seventh days, 100% of the seeds sprouted in all samples. Consequently, low–concentration salt solutions at the initial stage of germination promote rapid unfolding of physiological and biochemical processes in seeds [12]. It is proved that the rate of germination of *Helianthus annuus* L. seeds is characterized by inversely proportional dependence on the salt concentration in the medium.

Analysis of the experimental results obtained from germination of *Valeriana officinalis* L. seeds (figure 6, A) showed that by 3 days the highest amount of 20% sprouted in 0.2% NaCl solution, the smallest in water (10%) and 0.1% NaCl solution (0%), on the fifth day of the seeds is located in aqueous medium and solution of salts with a concentration of 0.1% NaCl the percentage of germination did not change, but 20% reached the germination energy in saline solution of 0.2% NaCl. Seed germination of *Valeriana officinalis* L. was observed for twelve days, but during this period the highest values were obtained in the aquatic environment, the lowest – in 0.1% and 0.2% saline solutions. Therefore, it can be assumed that, under the action of water, the seed cell enzymes have gone from an inactive state to an active and insoluble

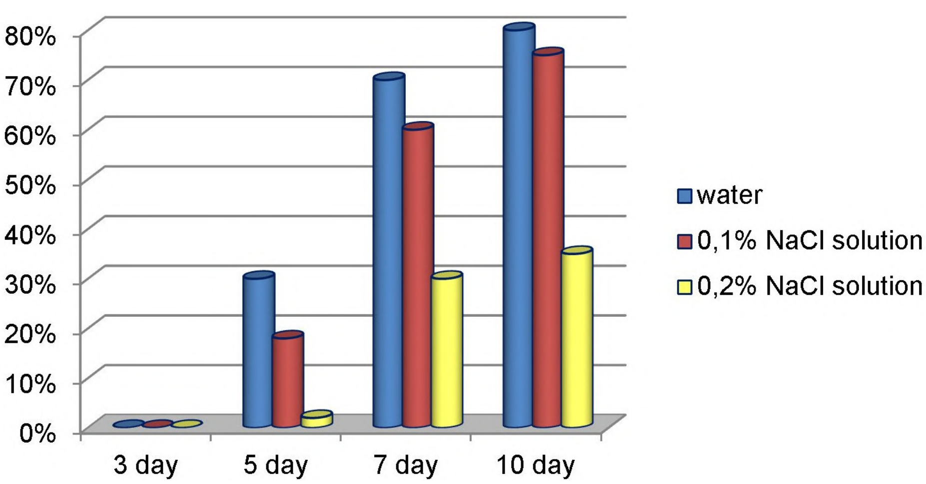


Figure 3. *Beta vulgaris* L. seed germination energy (%).

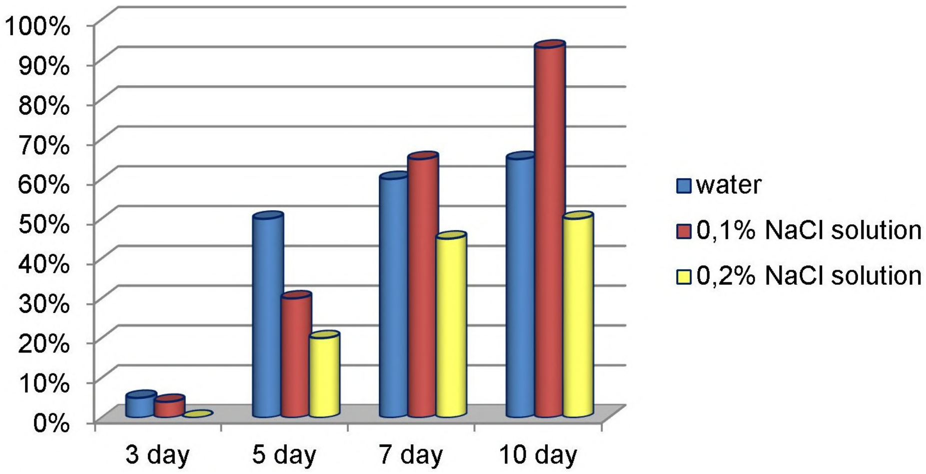

Figure 4. Germination energy of *Phaseolus vulgaris* L. seeds (%).

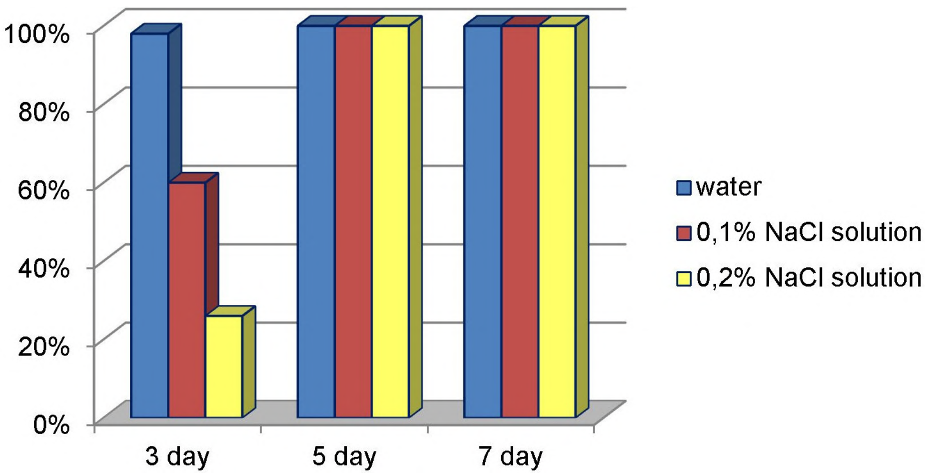

Figure 5. Germination energy of *Helianthus annuus* L. seeds (%).

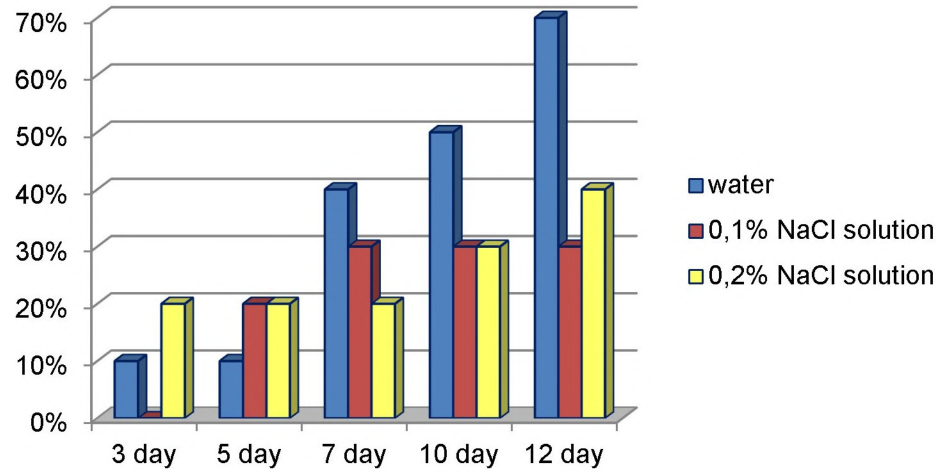
spare substances have become soluble (starch – into sugar, fats – into glycerol and fatty acids, proteins – into amino acids). The embryo, using soluble organic compounds, began active growth and development [3].

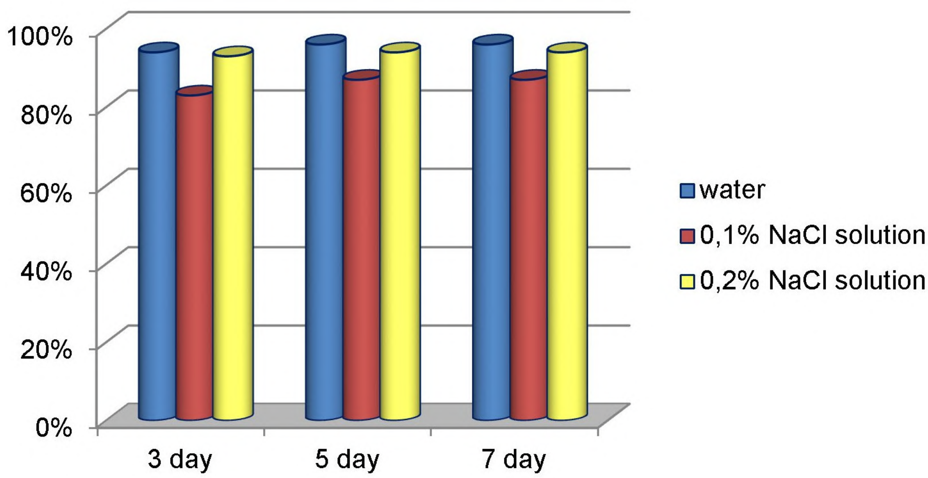
The results of germination of *Matricaria recutita* L. seeds in water; 0.1% and 0.2% NaCl solutions had the following values: on the third day the seeds germinated intensively in the aquatic environment and were more than 90%, less intensive germination occurred in 0.2% solution salts – more than 93%, the lowest amount of 83% was observed in 0.1% NaCl solution (figure 6, B).

On the 5th day in water, the percentage was more than 95% in the aqueous medium, in 0.2% NaCl solution – 94%; in 0.1% NaCl solution – more than 85%. At 7 days the number of germinated seeds in the studied media did not change. For the entire germination period, which was seven days, the highest values were observed in water, the average values were in 0.2% NaCl solution and the lowest values were in 0.1% NaCl solution. This is explained by the fact that when germination of seeds in water and solutions of salts with different concentrations, gibberellins are activated in different periods of growth and development [13, 16].

The analysis of the results shows that the stress tolerance of plant seeds to salinization



A



B

Figure 6. Seed germination energy (%): A – *Valeriana officinalis* L., B – *Matricaria recutita* L.

is already manifested in the germination phase, thanks to the realization of genetically–laid potential.

4. Conclusions

The study of seeds' salt hermesis of natural and cultural flora in the conditions of southern Ukraine showed that the number of days of germination (seeds of cultural flora germinates for 7–10 days, and in wild representatives this indicator is extended to 10–12 days) plants can be arranged in the following order: seven days – Secale cereal L., *Triticum durum* L., *Avena sativa* L., *Hordeum vulgare* L., *Helianthus annuus* L., *Matricaria recutita* L.; 10 days – *Beta vulgaris* L., *Phaseolus vulgaris* L. and 12 days – *Valeriana officinalis* L.

The aquatic environment is the most optimal for germination, but the numbers of sprouted seeds plants are in accordance with the list: *Helianthus annuus* L. → *Avena sativa* L. → *Triticum durum* L. → *Matricaria recutita* L. → *Secale cereale* L. → *Hordeum vulgare* L. → *Beta vulgaris* L. → *Valeriana officinalis* L. → Phaseolus vulgargaris L. → *Phaseolus vulgaris* L.

The study of seed stress tolerance demonstrated the differentiation of the influence of Na^+

and Cl^- ions (at a concentration of 0.1%) on physiological and biochemical processes, which led to the appropriate distribution of plants: *Triticum durum* L. → *Helianthus annuus* L. → *Hordeum vulgare* L. → *Matricaria recutita* L. → *Beta vulgaris* L. → *Valeriana officinalis* L. The concentration of 0.2% NaCl solution revealed the following sequence: Secale cereal L. → *Triticum durum* L. → *Helianthus annuus* L. → *Avena sativa* L. → *Matricaria recutita* L. → *Hordeum vulgare* L. → *Phaseolus vulgaris* L. → *Valeriana officinalis* L. → *Beta vulgaris* L.

The results obtained indicate that the chloride load in the seeds of plants manifests itself in the form of distress as well as eustress. It has been proved that the diagnostic features of chloride hermesis are more clearly manifested in the representatives of the cultural flora than the natural ones, which is caused by the implementation of the interrelation of the genetic program and phenotypic manifestations, which are related to the special climatic conditions of southern Ukraine (soil salinity, air and soil drought, etc.), which is of practical importance when developing strategies for growing crops on saline soils.

Abstract. The study is focused on gathering information to monitor sustainable land development and biodiversity. The article discusses the objectives and measures required to achieve Sustainable Development Goal 15 "Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss". This paper shows the results of the analysis of key indicators and values for Ukraine. It also contains the developed conceptual diagram for managing the sustainable development of ecosystems and biodiversity. There were identified the main sources of statistical information, including traditional enterprise-level data and big data, and analyzed changes in indicators for monitoring the achievement of the Sustainable Development Goals at micro level under section "Environmental area". The study also identified potential sources of information for calculating the presented indicators and explored the use of big data to develop an information base for monitoring, evaluating, and policy development related to sustainable land development and biodiversity. Further research and studies are needed to determine the algorithms of data processing, modelling and constructing of integrated indicators.

1. Introduction

On September 25-27, 2015, the UN Summit was held in New York within the framework of the 70th session of the General Assembly of the United Nations. During the high-level meeting on sustainable development, 193 member states of the United Nations (UN) officially adopted a new program in the field of sustainable development, entitled "Transforming our world: The 2030 Agenda for Sustainable Development". The program officially entered into force on January 1, 2016 [1].

The term "sustainable development" was first used by the International Commission on Environment and Development in 1987 and was defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." The concept of sustainable development was adopted at the UN Conference on Development and Environment in Rio de Janeiro in 1992 [1].

To achieve sustainable development, it is extremely important to coordinate three main components – economic growth, social integration and environmental protection. These components are interconnected and extremely important for well-being of individuals and society as a whole. Therefore, sustainable development is defined as development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs.

UN member states have identified 17 sustainable development goals (SDGs) for the period up to 2030 and 169 tasks. These goals and objectives can be applied to any society. Achieving the SDGs requires all countries to integrate them into their national strategies and plans [1]. SDGs are not legally binding. It is assumed that governments of all countries take responsibility and create national mechanisms that will contribute to the achievement of the stated goals. In order to promote prosperity and protect the entire planet, the SDGs call for action by all countries without exception – poor, rich and middle-income countries. They are global in nature and universal in application, but at the same time take into account development specificities, national potential, as well as national strategies and priorities. Since they are interrelated, efforts to achieve them should be comprehensive.

At the global level, a set of indicators is used to monitor and review the process of implementing goals in the field of sustainable development and tasks of the new agenda [1]. Countries bear the primary responsibility for follow-up and review of progress in the implementation of goals, and for this it is necessary to ensure the collection of high-quality, accessible and relevant data.

Biodiversity is a key theme of the UN's 2030 Agenda for Sustainable Development which corresponds to SDG 14 and 15.

SDG 14 is dedicated to "Conserve and sustainably use the oceans, seas and marine resources".

SDG 15 is dedicated to "Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss".

2. Aim and methodology

Aspects of information provision of sustainable development were reflected in the works of Ukrainian statisticians [2].

Issues related to biodiversity monitoring, aspects of the importance of ensuring the long-term preservation of and access to data are considered in the works of Hardisty et al [3], Alblas and van Zeben [4], Alkemade et al [5], Navarro et al [6], Barral and Guillet [7], Moersberger et al [8], Schmeller et al [9], Schmidt et al [10], Blanco-Zaitegi et al [11], Brörken et al [12], Xie et al [13], Lu et al [14], Cipullo [15], Estoque et al [16], Ren et al [17], Tóth et al [18], Kong et al [19], Li and Lei [20], White et al [21], Spangenberg [22].

Study of Hardisty et al [3] is devoted to the issues of Essential Biodiversity Variables (EBV) – the fundamental variables that can be used for assessing biodiversity change over time, for determining adherence to biodiversity policy, for monitoring progress towards sustainable development goals, and for tracking biodiversity responses to disturbances and management interventions.

The research of Navarro et al [6] contributes to deepening of the understanding of coordinated observing system adopted by GEO BON, focusing on two interconnected core components – the Essential Biodiversity Variables as a standard framework for biodiversity monitoring, and the Biodiversity Observation Networks that support harmonized observation systems – while highlighting their societal relevance.

Moersberger et al [8] presented two key clusters of needs in Europe over the next 5-10 years: 1) biodiversity data are needed to ensure integrated cross-sectoral policies; 2) biodiversity data are needed to increase policy impact and effectiveness to fulfil goals of the EU Biodiversity Strategy.

Schmeller et al [9] presented a globally coordinated approach is needed for biodiversity monitoring that is linked to environmental data and covers all biogeographic regions. They identified nine requirements that they believe are necessary for developing and implementing such

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012017 doi:10.1088/1755-1315/1254/1/012017

a global terrestrial species monitoring program: 1)designing and implementing an integrated information chain from monitoring to policy reporting; 2) capacity-building to create a comprehensive spatial monitoring program; 3) implementing minimal data standards to capture EBVs; 4) implementing common monitoring protocols; 5) developing and optimizing semantics and ontologies for data interoperability; 6) integrating emerging technologies (monitoring, data management and analysis); 7) coordinating diverse but complementary local nodes; 8) facilitating and securing funding.

Schmidt et al [10] reviewed different sampling strategies, methods of data collections and analysis according to the monitoring of habitat distribution, species population, species trends, etc.

Tóth et al [18] proposed frameworks of soil-related sustainable development goals and related indicators which can be monitored in current monitoring schemes.

Spangenberg [22] suggest simple ordinal scale index for monitoring of land use intensity changes. It is based on the hemeroby concept, measuring the human impact as deviation from naturalness. This makes it an information collection and presentation tool for those working in landscape planning and management.

Our research is devoted to information provision for monitoring the sustainable development of the land and biodiversity, which is primarily related to monitoring the achievement of the SDG 15.

Parties of the United Nations Convention on Biological Diversity are making efforts to ensure functioning of the global biodiversity conservation system for the period after 2020, the goal of which is to stabilize the loss of biodiversity by 2030 and fully restore natural ecosystems by 2050.

The purpose of sustainable development management ecosystems and biodiversity can be formulated as ensuring adaptability of society to preservation and improvement of the environment, responsible use of ecosystems and restoration of biodiversity.

3. Method

The use of statistical methods provides an opportunity to assess the level of achievement of the above-mentioned goal and outlines methods of accounting for aspects of sustainability.

Conceptual block diagram of information provision for the regulation of sustainable development of ecosystems and biodiversity which characterizes structure and sequence of operations aimed at justifying management decisions, is shown in figure 1.

A necessary condition for ensuring a systematic study of sustainable and responsible use of ecosystems and restoration of biodiversity is the formation of a single open database as an information source for ensuring management.

The content of analytical work consists of bringing disparate information to a logically constructed system of relationships, which makes it possible to give a reasonable assessment of both the entire set of facts and each of them separately, and to determine their role in solving the investigated problem.

The analysis of the dynamics of development components forms the basis of an objective assessment of the identification of trends and regularities.

The use of statistical methods makes it possible to translate many management problems into plane of accurate quantitative display with qualitative content, based on real information provision of calculations in accordance with user needs.

Appropriate software speeds up and improves information processing, significantly expanding the range of tasks that can be solved using statistical methods in the management process. This provides a creative approach to the performance of specific management tasks, the search for new ways to improve the quality and validity of management decisions, and the development of measures to improve efficiency in all areas of activity.

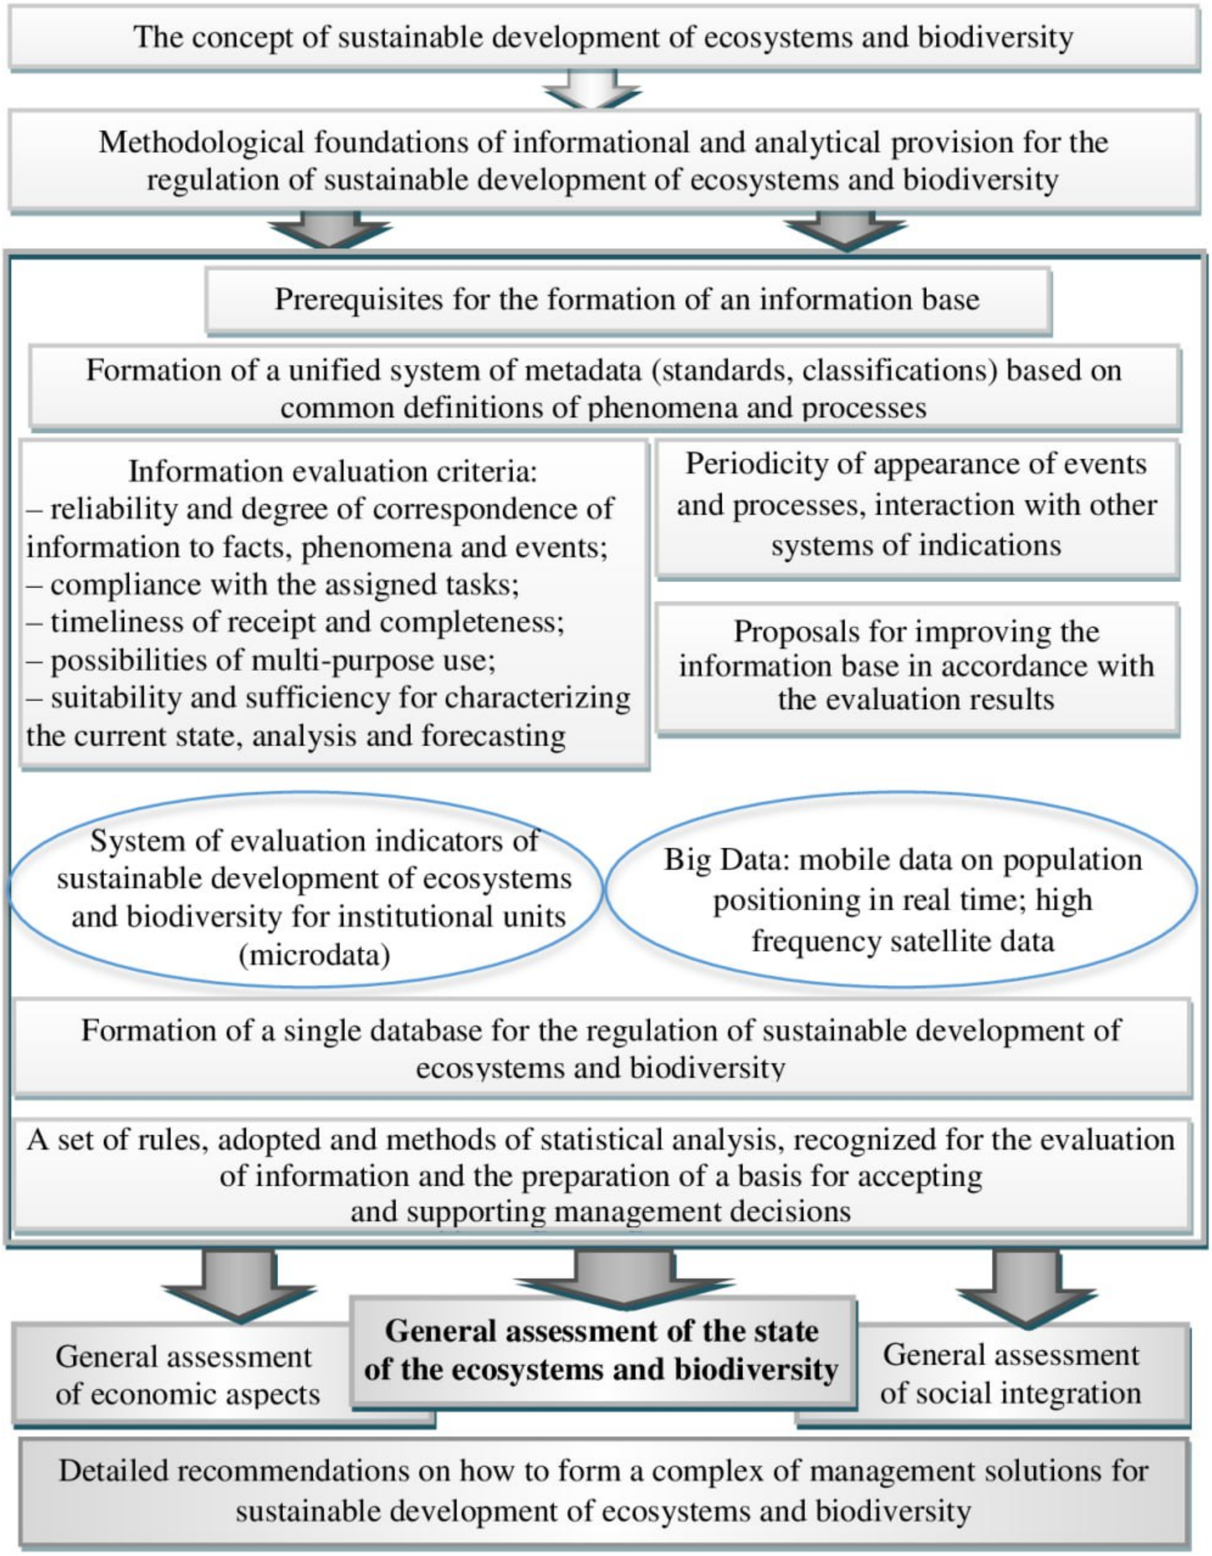

Figure 1. Conceptual block diagram of information provision for the regulation of sustainable development of ecosystems and biodiversity.

Statistical analysis should be used to determine the relationships between phenomena, the influence of the main factors on them, among which, in particular, those that arise as a result of the action of objective laws and cause the emergence of risks are distinguished. To do this, statistical models of various types of relationships are used – functional, stochastic, correlational.

On basis of the above directions of analysis, possibility of comprehensive usage of their results to reveal the mechanism of socio-economic phenomena and processes is determined. In particular, this refers to the economic efficiency of the information obtained based on the ratio of results and costs for obtaining it.

Based on the results of the statistical analysis, the main directions of management aimed at ensuring sustainable use of ecosystems and restoration of biodiversity are determined, taking into account objectively existing potential opportunities. At the same time, a list of tasks is formed, the sequence of their execution, methods of solving and mutual consistency of these tasks are determined. This creates a methodology for substantiating management decisions using statistical methods.

In this way, information provision of the system interconnection of target complex programs is formed: socio-economic, scientific-technical, digital, environmental, investment, regional, etc. in the system of ensuring sustainable use of ecosystems and restoration of biodiversity. It should be noted that in the process of developing and using information provision for sustainable development, it is necessary to use international standards, classifications and unified definitions (interpretations) of phenomena and processes that summarize modern world experience, as well as contribute to the prompt implementation of national analogues.

The problem of training modern specialists in statistics, who are able to perform the functions of analysts, experts and consultants in the field of management, is connected with the rapid development of the information society and the widespread introduction of information and communication technologies. Statisticians-analysts must be aware of availability of the necessary sources of statistical information in accordance with the formulated management tasks, systematize and classify it; apply the methods of its processing, generalization and drawing conclusions, as well as creatively use the obtained results of the analysis to prepare management decisions regarding sustainable local development and evaluate in real time the consequences of such management decisions.

4. Research results

4.1. Microdata

Company reporting is an important source of data for the Central Bank monitoring system. As the primary source of information on company performance, reporting can significantly improve SDGs monitoring mechanisms by providing stakeholders such as governments, investors and businessmen with instruments to assess the economic, environmental and social impact of companies on sustainable development. Accounting data for the formation of key indicators should be collected at the level of an institutional unit and aggregated by region.

Institutional units usually consist of several different units that produce different products/services and have different locations. In the system of national accounts, they are called establishments, and when tied to a certain territory – a local kind-of-activity units – LKAU [23]. This is especially true for large enterprises. The collection of data by individual institutions enables organizations with the necessary flexibility to meet a number of reporting requirements and facilitates compilation of environmental indicators.

For example, collection of data on environment at the level of individual objects will allow more detailed determination of areas of increased environmental danger. If an entity has facilities in different locations, it is likely that they operate under different conditions and have different environmental impacts. Therefore, it is useful to collect and compile environmental indicators for each facility first and then aggregate the reporting of institutional unit.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012017 doi:10.1088/1755-1315/1254/1/012017

Development of a unified list of main indicators for reporting by institutional units to ensure monitoring of SDGs achievement was initiated by UNCTAD (United Nations Conference on Trade and Development) in 2016 and extended in 2017 and 2018 [24]. In 2022, guidelines were issued on the definition and calculation of the main indicators for monitoring the achievement of the SDGs at the micro level [25].

The results of a detailed analysis of the changes in the indicators presented in the guide for 2016-2022 at the level of the group "Environmental area" are shown in figure 2.

Based on the results of case studies, discussions at the Advisory Group meeting and taking into account key international developments in this area, UNCTAD revised the main indicators of the SDGs. As a result, in 2022 minor changes were made to the measurement methodology and normalization of indicators, as well as clarification and elimination of inconsistencies. However, the main result was the addition of the main indicators of the SDGs with an indicator on land and biodiversity.

In the group of indicators "Ecology" of the micro level was added subgroup B.6 "Land and biodiversity", which includes indicator B.6.1 "Lands Used Near Biodiversity Sensitive Areas". This indicator is defined as the number and area (in hectares) of plots owned, leased or managed in protected areas and/or key biodiversity areas (KBA) or adjacent to them, i.e. those areas on the planet, which are critical to the survival of unique plants and animals, as well as ecological communities.

Indicator B.6.1 measured in accordance with the proposal set forth in [26]: "KBAs provide a science-based and internationally recognized means of identifying sites that make a significant contribution to global biodiversity conservation, while protected areas indicate nationally (and often internationally) recognized areas of ecological or cultural importance, typically with special legal protection. Conducting operations in or near such areas indicates an increased risk of adverse impacts on biodiversity and an increased risk of associated legal or reputational risk."

For reporting on this indicator B.6.1, the reporting entity must [25]:

- determine the location of surface and underground lands that may be owned, leased or managed by the organization;
- assess whether the land owned, leased or managed is located in protected areas/KBA and/or is adjacent to a protected area/KBA and/or contains parts of a protected area/KBA;
- determine amount and size of land owned, leased or managed, which is located in protected areas/KBA and/or is adjacent to a protected area/KBA and/or contains parts of a protected area/KBA, expressed in the number of hectares.

Among the potential sources of information, the following were identified.

(i) Information about the location of KBA (figure 3) can be found at [27].
As we can see that for Ukraine the information is presented for the year 2000.

(ii) Information on protected areas (figure 4) can be found by searching the global database at [28].

A number of events at the international level have changed format and framework of reporting on sustainable development. Attention should be paid to the fact that in November 2021 at the twenty-sixth Conference of the Parties within the framework of the UN Conference of the Parties on Climate Change [29] the International Sustainability Standards Board (ISSB) was announced. This new international body is engaged in the creation and development of international financial reporting standards related to sustainable development, which should become mandatory for institutional units in many countries of the world. Therefore, Ukraine should accelerate national efforts to create, establish or strengthen the technical capacity that will ensure compliance with the new reporting standards [30].

Sub-Area	Indicators 2016	Indicators 2022	Measurements (2022)	Relevant SDG indicator
B.1. Sustainable use of water		B.1.1: water recycling and reuse	Total volume of water recycled and/or reused by a reporting entity during the reporting period in absolute amount and in % terms	6.3.1
	B.1: water consumption per net value added	B.1.2: water use efficiency	Net value added divided by the water use in the reporting period as well as change of net value added divided by the change of water use between two reporting periods	6.4.1
		B.1.3: water stress	Water withdrawn with a breakdown by sources and with reference to water-stressed or water-scarce areas in absolute amount and in % terms	6.4.2
B.2. Waste management		B. 2.1: waste generation	Change in the entity's waste generation per net value added in % terms, in terms of change and in absolute amount	12.5
	B.2: waste generated per net value added	B.2.2: waste reused, remanufactured and recycled	Total amount of waste reused, remanufactured and recycled in absolute amount, in % terms and in terms of change	12.5.1
		B.2.3: hazardous waste generation	Total amount of hazardous waste, in absolute terms, as well as proportion of hazardous waste treated, given total waste reported by the reporting entity	12.4.2
B.3. Greenhouse gas emissions	B.3: greenhouse gas emissions (scopes 1–2) per net value added	B.3.1: greenhouse gas emissions (scope 1)	Scope 1 contribution in absolute amount, in % terms and in terms of change	9.4.1
		B.3.2: greenhouse gas emissions (scopes 2)	Scope 2 contribution in absolute amount, in % terms and in terms of change	9.4.1
B.4. Chemicals, including pesticides and ozone-depleting substances		B.4.1: ozone-depleting substances and chemicals dependency	Total amount of ozone-depleting substances (ODS) (bulk chemicals/substances existing either as a pure substance or as a mixture) per net value added.	12.4.2
B.5. Energy consumption		B.5.1: share of renewable energy	Renewable energy consumption as percentage of total energy consumption in the reporting period	7.2.1
	B.5: energy consumption per net value added	B.5.2: energy efficiency	Energy consumption per net value added	7.3.1
B.6. Biodiversity		B.6.1: land use adjacent to biodiversity sensitive areas	Number and area (in hectares) of sites owned, leased or managed in or adjacent to protected areas and/or key biodiversity areas	

Figure 2. Core Sustainable Development Goal Indicators: Environmental area.

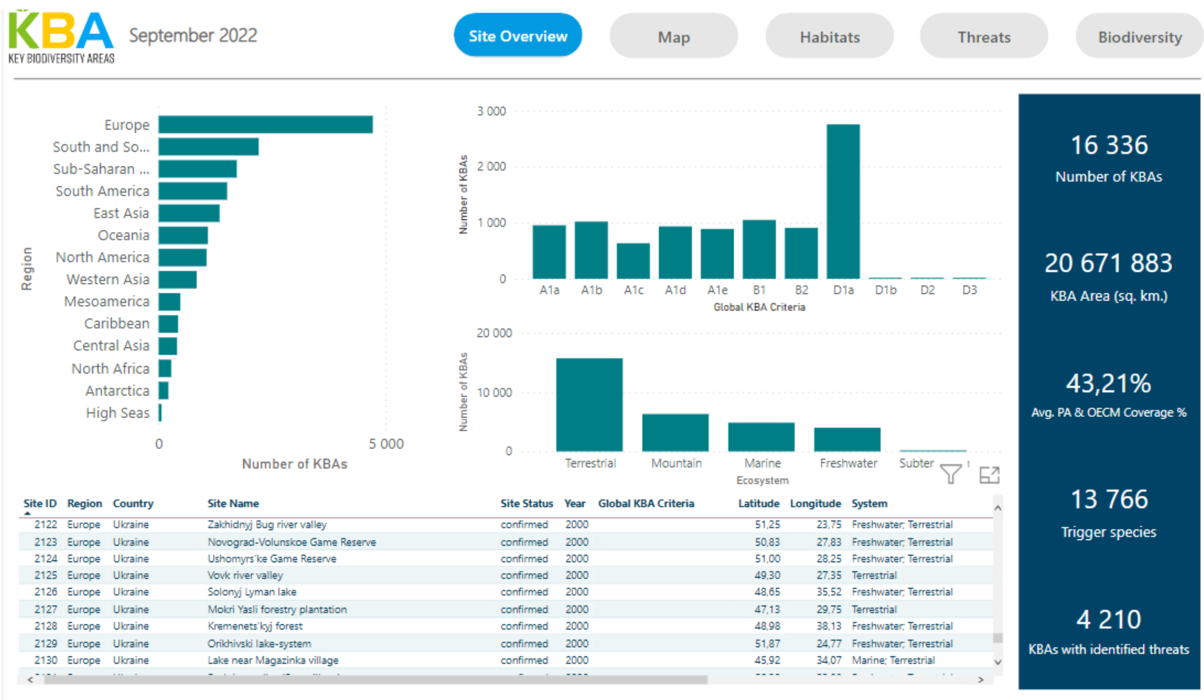

Figure 3. Key Biodiversity Areas (KBA) database.

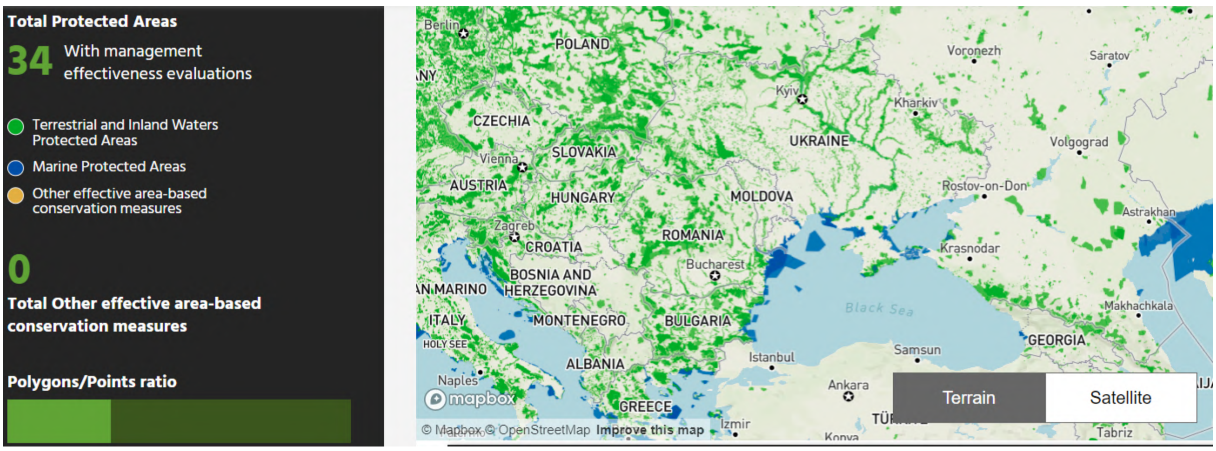

Figure 4. Protected areas from the Protected Planet global database.

Recent world events have reinforced the need for guidelines to support policymakers in building a robust national sustainability reporting infrastructure. This would ensure high quality reporting and support the implementation of future ISSB standards. All of the above confirms the relevance and importance of transparent measurement and disclosure, as well as comparability and reliability of information on sustainable development.

But it should be taken into account that placing an excessive burden on institutional units may harm the involvement of the private sector in obtaining quality information necessary to monitor the achievement of the SDGs. Therefore, it is recommended to apply a step-by-step approach, according to which, for the selected indicators, first the problems that the institutional unit controls and for which it collects relevant data are identified, or situations in which the company has unimpeded access to relevant sources of information.

4.2. Big data

The emergence of “big” data is closely related to the development of information and communication technologies. In today’s hyper-connected digital world, people and things leave “digital footprints” in many different forms, creating ever-increasing streams of data, including commercial transactions, private and public records that companies and governments collect and store, created by users online materials such as photos, videos, tweets and other messages, as well as traces left by the Internet of Things (IoT), i.e. those uniquely identifiable objects that can be tracked.

There is no single, unique definition of this relatively new phenomenon known as “big data”. At the most basic level, big data refers to data sets whose volume, velocity, or diversity are very high compared to the types of data sets that have traditionally been used. It is appropriate to refer to such definitions of the essence of this concept, with which most scientists agree. The first definition was proposed by Marv Adrian in 2011 in an article for Teradata Magazine: “Big data is data that cannot be collected, managed and processed with the help of the most commonly used hardware environments and software tools within the time allowed by the user” [31].

The data revolution, which includes the open data movement, new ICTs for data collection and the availability of big data, together with the emergence of artificial intelligence and the Internet of Things, has led to a radical transformation of society. Recently, “big data” began to be processed and analyzed in order to find relationships in economic and social systems, which was previously carried out with the help of surveys, experiments and other types of data collection, on the basis of which solutions were developed and forecasts were built.

Real-time mobile population positioning data and high-frequency satellite data are just main examples of big data that can be used to monitor the achievement of SDG 15.

Fixed and mobile telecommunications network operators, including Internet service providers, are an important source of data, and all forms of telecommunications big data (volume, speed or diversity) are considered for analysis purposes. Most telecommunications data can be considered as the result of an action (for example, making a call, sending an SMS, accessing the Internet or recharging a prepaid card).

An example of how mobile network data can track population movements is the 2010 Haiti earthquake. Figure 5 shows the number of people estimated to be in Port-au-Prince (PaP) on the day of the 2010 Haiti earthquake and outside the capital 19 days later [31].

One of the main projects aimed at integrating the development of big data for monitoring, evaluation and policy development within Group on Earth Observations Biodiversity Observation Network (GEO BON) is UN Biodiversity Lab [32], a geospatial information platform that maps natural resources and monitors environmental risks in real time using existing data and new digital technologies.

As part of the above-mentioned project, in 2022 the calculated data sets and indicators were included in the existing decision support system based on the UN Biodiversity Laboratory. Project data and indicators will be regularly updated until 2030 through the UN Biodiversity Lab [32]. The project is also a demonstration of the Observations for Sustainable Development Goals initiative [33]. The results of the project are expected to provide modern digital foundation for scaling up this forecasting methodology to more countries around the world working to monitor progress towards SDG 15. The project envisages widespread use in 170 UNDP partner countries of datasets, a brief the characteristics of which are presented in figure 6.

Within the framework of this study, the available statistical data on the considered data sets, included in the existing decision support system, using the electronic database of the UN Biodiversity Lab [32]. Below, for example, the results for several main blocks are presented.

Global Forest Change. Many organizations deal with forest change issues, so the

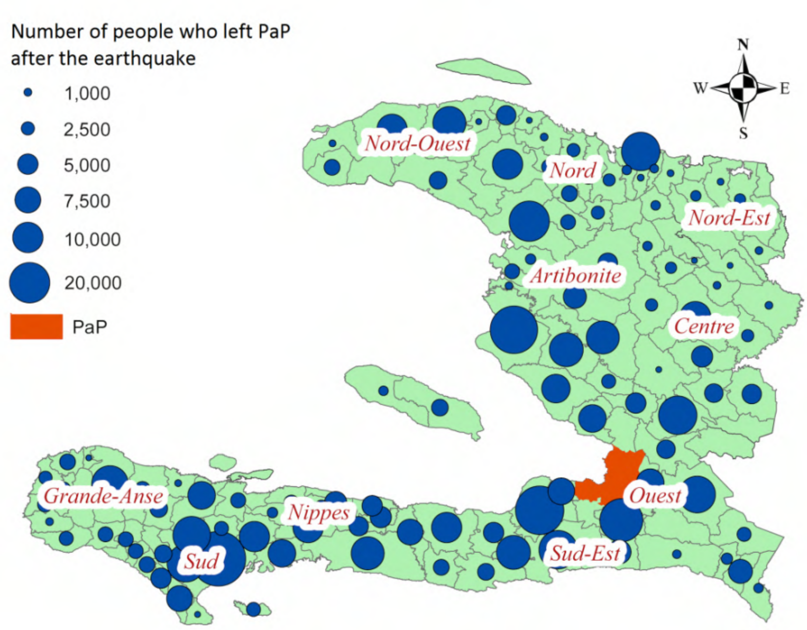

Figure 5. Tracking the mobility of the population in emergency situations using mobile phones (circles are shown for communes that received at least 500 persons).

definitions related to this concept are important and should be unified during the information provision of the study. Below are the definitions used by the FAO Forestry Department:

- Forests are lands of more than 0.5 hectares, with a tree canopy cover of more than 10 percent, which are not primarily under agricultural or urban land use.
- “Deforestation” is conversion of forest to another land use or long-term reduction of tree canopy cover below the 10% threshold.
- “Afforestation” is the conversion from other land uses into forest, or the increase of the canopy cover above the 10% threshold.
- “Reforestation” is re-establishment of forest formations after a temporary condition with less than 10% canopy cover due to human-induced or natural disturbances.
- “Forest degradation” is a reduction of the canopy cover or stocking within a forest.
- “Forest improvement” is the increase of the canopy cover or stocking within a forest.

Figure 7 shows changes in forest cover in Ukraine for 2001–2020.

Over the past twenty years (2001–2020), Ukraine lost 10.8 thousand square km, which was 1.8% of the forest cover in 2000.

Biodiversity Intactness Index. Biodiversity intactness index reflects the results of modeling the average number of originally present biological species, expressed as a percentage of their total number in a pristine ecosystem. Initially, the data was only available for 2015, but is now available in a time series covering the period 2000-2015.

Figure 8 shows value of the index for Ukraine in 2015.

Enhanced Vegetation Index (EVI). The Extended Vegetation Index (EVI) reflects the state of the vegetation during one year. High values of this index (closest to 1) represent dense and stably productive vegetation. Conversely, low values (close to 0) represent sparse vegetation with low productivity.

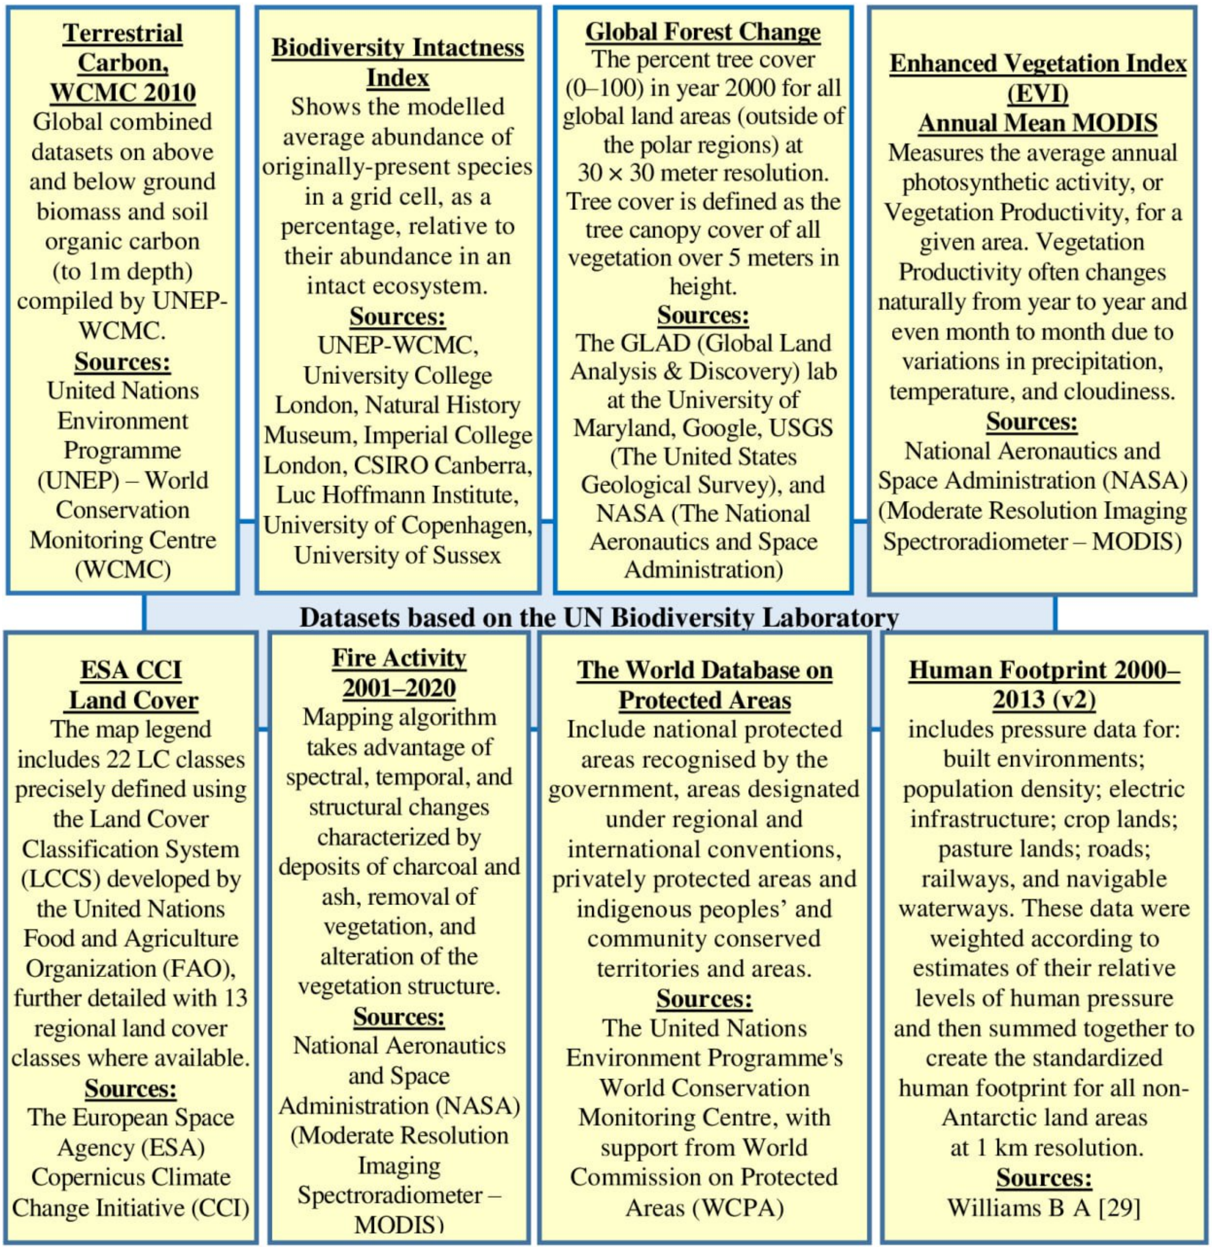

Figure 6. Datasets, included in the existing decision support system based on the UN Biodiversity Laboratory.

Average annual EVI values characterize the average annual photosynthetic activity, or vegetation productivity, for a certain area.

Vegetation productivity often varies naturally from year to year and even from month to month due to fluctuations in precipitation, temperature, and cloudiness.

With long-term observations, such assessments allow inferences about abnormal conditions, such as changes in land use or drought.

Figure 9 shows changes of Enhanced Vegetation Index in Ukraine in 2000-2021.

ESA CCI Land Cover. The European Space Agency and Copernicus Climate Change produced global land cover (LC) maps from 1992 to 2020 at 0.002778° (approximately 300 m)

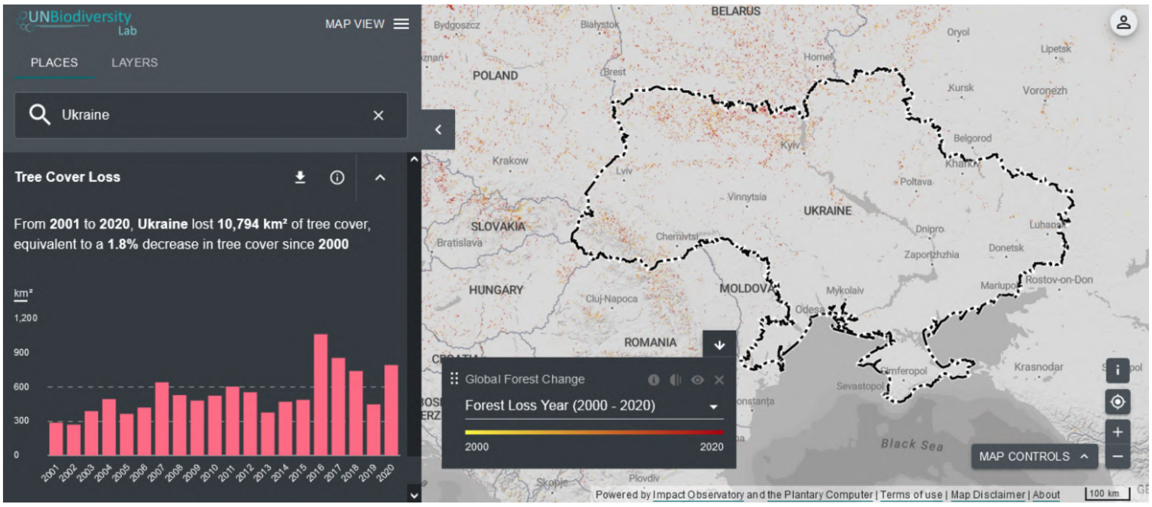

Figure 7. Forest change in Ukraine in 2001–2020.

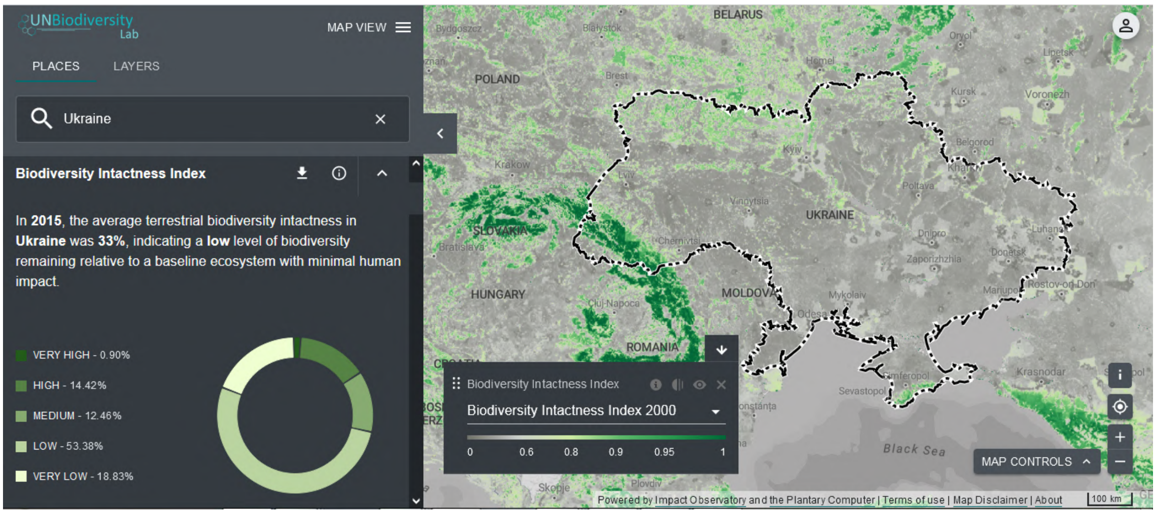

Figure 8. Biodiversity Intactness Index in Ukraine in 2015.

from the complete 300 m and 1 km multi-mission Earth observation (EO) archives. The map legend contains 22 LC classes that are precisely defined using the Land Cover Classification System (LCCS) developed by the Food and Agriculture Organization of the United Nations (FAO). 13 regional soil cover classes are detailed.

Figure 10 shows Ukraine's Land Cover in 2020.

Methodological decoupling of LC classification and LC change detection (LCC) ensures temporal and spatial consistency between successive maps. A new land cover map is created every year 9 months after the start of the year and is reviewed within a maximum of 3 months after publication. A user tool was developed to convert the LCCS nomenclature into plant functional type distributions used in various climate models.

5. Conclusions

Information provision for monitoring the sustainable development of land and biodiversity should be based on an understanding of the integrated use of statistical, administrative data sources,

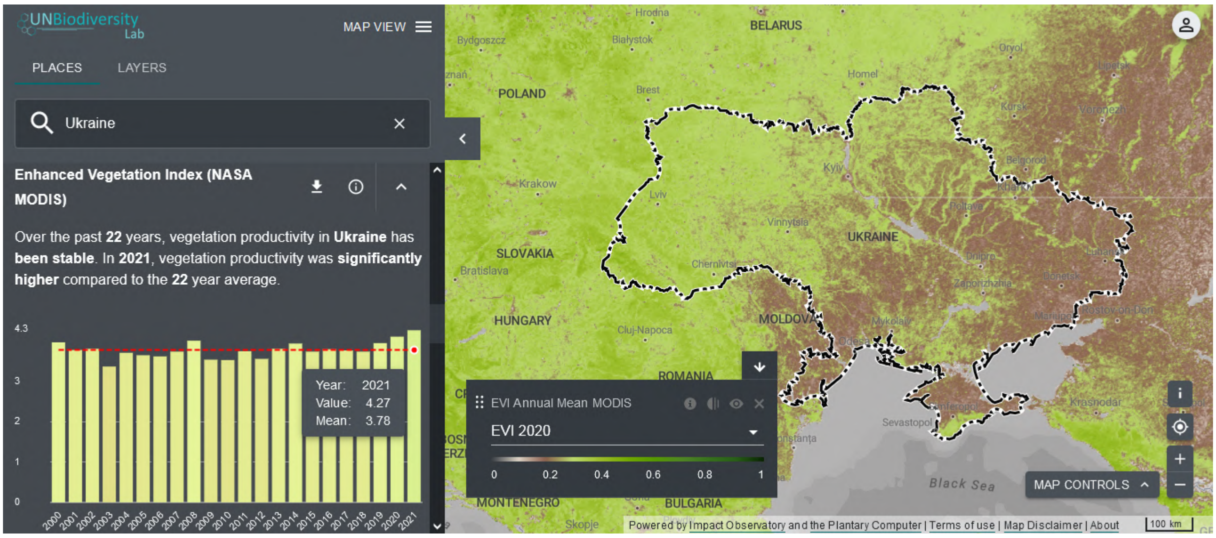

Figure 9. Enhanced Vegetation Index (NASA MODIS) in Ukraine in 2000-2021.

Figure 10. Ukraine's Land Cover in 2020.

metadata for their qualitative use, as well as a combination with big data, such as satellite images and data from mobile operators.

Recently, special attention should be paid to the collection of information on impacts on biodiversity in a specific place. Understanding the local context where an organization interacts with biodiversity is necessary to assess its impact, as well as to identify key drivers of biodiversity loss (overexploitation of resources, pollution, land-use change and climate change, etc.). It is also necessary to develop a program of actions that the organization needs to take to manage its impact on biodiversity.

Advances in computing and data science make it possible to process and analyze big data in real time. Integrating big data with traditional data should yield high-quality information that is more detailed, timely, and relevant. New insights derived from such data analysis can complement official statistics and survey data, adding depth and nuance to information in the course of monitoring the achievement of the Sustainable Development Goals.

Analysis of relevant trends over the long term can help maximize efforts to ensure sustainable land development and biodiversity conservation, and minimize environmental degradation and other potential negative consequences of increasing human impact on ecosystems.

The algorithms of data processing, modelling and constructing of integrated indicators would be the future research subject.

A system of environmentally important decision-making for the sustainable use of marine estuaries in the conditions of anthropogenic and climatic changes

V O Demchenko and N A Demchenko

Institute of Marine Biology of the NAS of Ukraine, 37 Pushkinska Str., Odesa, 65048, Ukraine

E-mail: demvik.fish@gmail.com

Abstract. Sustainable use of marine water areas is one of the priorities of preserving biodiversity and the environment as a whole. The problem of a clear plan of rehabilitation measures, which would be based on complex and balanced solutions arises for their effective restoration and further functioning. These decisions should take both environmental and economic aspects into account. Estuaries, unlike marine water areas, are more sensitive to anthropogenic and climatic changes. They are characterized by shallow water level, functioning in the conditions of limited water exchange, dependence on river flow and greater anthropogenic load compared to marine water areas. These features are the cause of more intensive changes in the structure of biocenoses, rise in emergency situations, loss of productivity and sustainability of ecosystems as a whole. Thus, there is a need to introduce environmental management for these reservoirs, which should be based on a multi-component decision support system. This system will make it possible to develop clear plans for the restoration of marine ecosystems and prevent negative changes and degradation in them. The proposed scheme for developing plans for the restoration of the ecosystems of estuaries is represented by three blocks. The first "Block of data collection" involves the implementation of 3 stages: assessment of the current state of the reservoir; definition of problems and their ranking; assessment of ecosystem services. The second block "Search for a solution" is based on 4 components: Component 1. Database management system; Component 2. Geoinformational system; Component 3. Mathematical and predictive models; Component 4. Informational and management system for choosing strategic and operational decisions. The third block "Implementation of measures" involves the implementation of 4 stages: environmental assessment of decisions and projects, implementation of environmental measures, evaluation of effectiveness, search for new solutions and their improvement. The proposed scheme will enable a comprehensive approach to the restoration of estuarine ecosystems and ensure their sustainable use.

1. Introduction

The United Nations has declared 2021–2030 as the International Decade on Ecosystem Restoration. The goal of this decade is to bring together all interested parties to prevent, halt and reverse the degradation of ecosystems on every continent and in every ocean. This initiative provides many areas of work that will draw attention to the problems of restoring ecosystems and ensure their sustainable use in the future [1].

The experience of European countries in the management of ecotones, lagoons and estuaries is quite broad and has several main directions. All of them are based on the basic principles of the role of water bodies as ecosystems that provide many ecological, cultural and economic benefits and advantages for people.

Most approaches to the estuary management are based on the implementation of clear measures to optimize the hydrological regime, reduce the anthropogenic load, protect certain biotopes or species, educational measures, etc. [2–6].

In general, most countries are trying to systematically solve the problems of managing coastal and marine ecosystems both at the legislative level and at the sectoral level (fisheries, recreation, nature protection). This approach involves giving a certain status to the water body and subsequently developing a clear management plan that depends on the specifics of the ecosystem use.

Unfortunately, in Ukraine, approaches to the systematic management of the water bodies are not carried out. Plans for the management of individual river basins are only partially implemented [7–9]. This work is carried out within the framework of the implementation of the approaches of the EU Water Framework Directive implemented by Ukraine. For estuaries, separate attempts to develop management plans were carried out exclusively within the framework of management plan development for wetlands of international importance or touched on the management of hydrological or hydrochemical regimes [10].

Unfortunately, marine ecosystems, especially the coastal ones, have been significantly transformed over the past 50–60 years due to pollution, construction of industrial facilities, intensive development of recreation, et cetera. The speed of negative developments was intensified by the impact of threatening climate changes, which have also intensified in recent years. Estuaries are especially sensitive in this context since they, unlike marine water areas, are shallower, function with limited water exchange, depend on river flow and are characterized by a greater anthropogenic load.

From a scientific point of view, these water bodies are important for the possibility of control and implementation of various management measures to regulate and restore hydrological, hydrochemical and hydrobiological regimes. The possibility of introducing active measures aimed at stabilizing and improving ecological processes is an important condition for restoring transformed ecosystems to their natural state [11] .

For a long time, the management of these water bodies took place spontaneously and was aimed at the formation of various ecological states. Most of the feasible anthropogenic transformations have changed the course of natural processes in these ecosystems. Some ecosystems were radically transformed, isolated from sea waters, changed both at the level of abiotic characteristics and at biocenosis level [12–16].

That is why we propose a systematic approach to the environmental management process, the main element of which should be a multi-component decision support system. This scheme will enable to develop clear plans for the restoration and sustainable use of marine ecosystems, as well as to prevent negative changes and degradation of marine water areas.

2. Results and discussion

Despite the obvious need to develop a systematic approach to decision support in estuary management, there are currently no complete step-by-step schemes that allow for a comprehensive solution to the tasks of ecological management. The main defects and problems of modern ecological solutions implemented in Ukraine are:

- lack of systematic scientific studies of the state of water bodies, which should be implemented on the basis of the basin approach and the requirements of the Water Framework Directive;

- lack of works on the assessment of ecosystem services as a tool for understanding the ecological, social and resource value of water areas;
- insufficient use of elements of the mathematical modelling of hydroecological and socio-economic processes;
- lack of understanding of the need to involve experts of appropriate qualifications by the customers and their reluctance to finance the full scope of the development at the design stage;

Taking the lack of systemic solutions in the management of estuaries into account, there is a need to develop a complete step-by-step scheme that will allow to comprehensively solve the problems of ecological management. Water body management has long gone beyond purely ecological problems and today should be based on a combination of not only ecological indicators and criteria, but also include social, economic, political and legal instruments. In general, the functioning of this scheme should be based on a number of principles:

- *The principle of a holistic approach towards assessing the state of aquatic ecosystems.* It involves a comprehensive assessment of the body of water and the factors affecting it. It is important to analyse all key factors that determine the ecological state of the body of water, and not the individual components.
- *The principle of the basin approach.* The approach assumes that the drainage basin together with the body of water forms a single geoecosystem with transit and accumulative functions and directly affects the formation of the ecological status-class of hydroecosystems.
- *The principle of sustainable development.* Sustainable development is considered as a compromise between economic, environmental and social spheres. The concept of sustainable development is based on three main principles [14]:
  - ensuring a balanced economy and ecology;
  - ensuring the balance of the economic and social spheres in the human dimension, which means the maximum use of the resources provided by economic development in the interests of the population;
  - solving tasks related to development not only in the interests of the current generation, but also of all subsequent generations that have equal rights to resources.

The proposed scheme has three blocks: a data collection block, solution search block, and a measure implementation block (figure 1). These blocks are sequential and must be implemented in stages.

Stage 1. Assessment of the current state of the body of water. This stage is associated with the need to conduct complex hydroecological studies. It is important to note that in Ukraine on September 19, 2020, the Resolution of the Cabinet of Ministers of Ukraine approved the Procedure for State Water Monitoring. State water monitoring is carried out in order to ensure the collection, processing, preservation, generalization and analysis of information about the state of the bodies of water, forecasting its changes and developing scientifically based recommendations for decision support in the field of water use, protection and reproduction of water resources. It is important to note that this monitoring is based on the basin principle and is regulated by the EU Water Framework Directive. Today, unfortunately, the water monitoring system is not fully implemented. Modern works performed by authorized bodies relate to the formation of reference indicators. At the same time, the assessment is based on the comparison of the current values of hydrobiological, physicochemical and hydromorphological indicators, determined in the monitoring process, with their reference values, that is, those that could exist in the absence of anthropogenic influence [15].

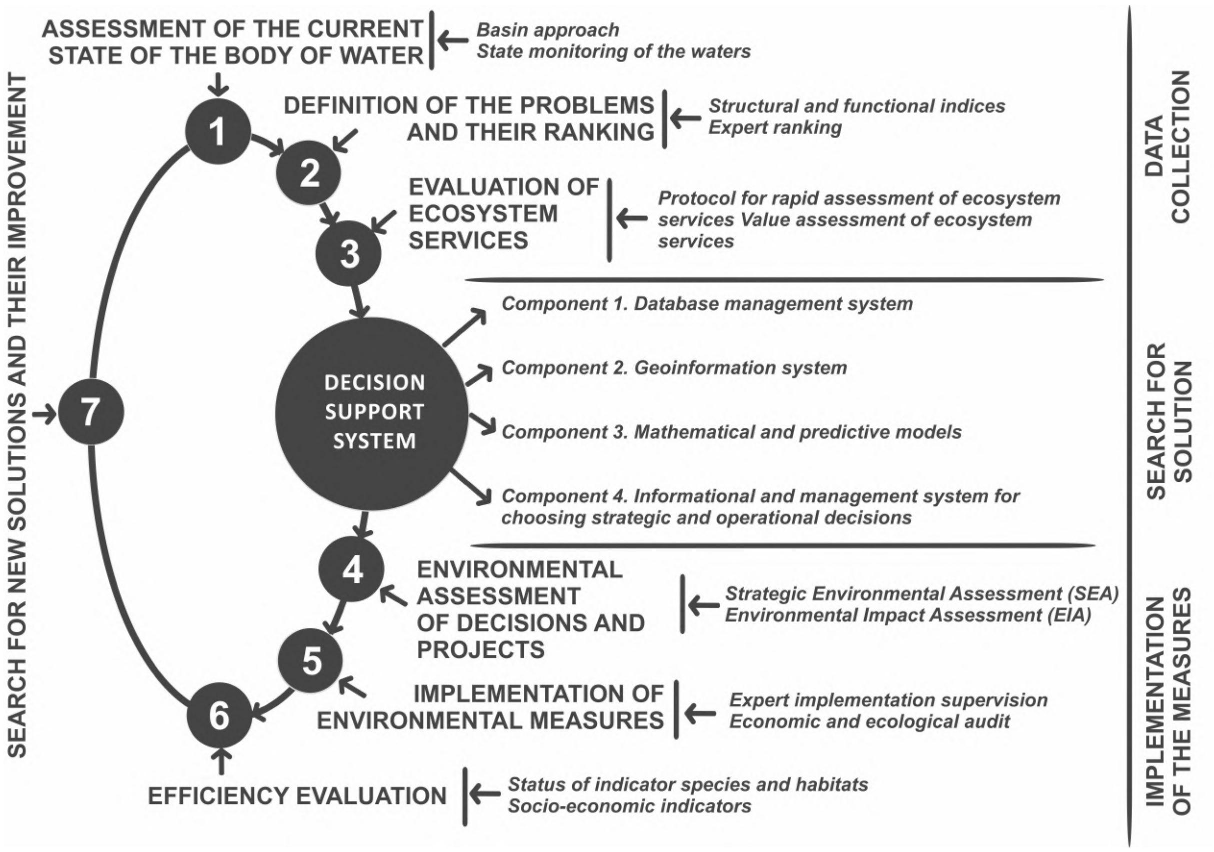

Figure 1. Scheme of the stages of making systemic decisions on estuary management

Stage 2. Definition of the problems and their ranking. Work in this stage involves the use of integrated structural and functional indicators that allow assessing problems in the ecological state of estuaries or the imperfection of management decisions. At the same time, there are cases when it is necessary to give prospective assessments to qualitatively new processes and phenomena that have not been encountered before and about which, of course, there is no information. The possibility of solving the mentioned problems, even in the absence of theoretical justifications, is achieved due to the skilful use of experience, intuition and knowledge of specialists, scientists working on solving the relevant problems. This method is called the method of expert evaluations [16]. It allows to rank ecological problems and to determine environmental management priorities. According to the results of this stage, priority problems will be determined, the solution of which will have the greatest cumulative effect.

Stage 3. Evaluation of ecosystem services. Ecosystem services are all the benefits that humanity receives from ecosystems. In other words, these are services for providing humanity with natural resources, a healthy habitat, and other ecologically and economically significant “products”. Among the numerous ecosystem services, those that provide resources (food, water, forest, raw materials), regulate processes in ecosystems (impact on the climate, control over floods, natural disasters, quality of water resources, etc.), provide cultural and social services (aesthetic and spiritual values of nature) and support the functioning of ecosystems (soil formation, photosynthesis, nitrogen cycle, etc.) can be selected. Unfortunately, the modern paradigm of environmental management does not take this assessment into account and, accordingly, the adoption of an ecologically important decision is evaluated unilaterally and does not take all aspects of the use of the estuary ecosystem into account. Today, there are various approaches to the assessment of ecosystem services. Thus, the Ramsar Committee, within the framework of wetland management, proposed a rapid assessment of ecosystem services (Resolution XIII.17). RAWES (Rapid Assessment of Wetland Ecosystem Services) practical approach was designed as a simple and rapid assessment system that draws on data from existing research but does not include detailed quantitative assessment. For a more efficient and quantitative assessment of ecosystem services, a cost evaluation should be used [17, 18].

The **second block** of the systemic decision-making scheme for estuary management is based on the implementation of the ***decision support system***. The essence of the management process is to make a decision – it is the choice of a course of action from a set of existing alternative options. In such conditions, the problem of choosing the most rational and effective solutions, that is, the best solutions, becomes one of the most important tasks of production management [16].

This system is designed to support various types of activities when making decisions on sustainable estuary use, restoration and management of the ecological state of the marine environment with achieving socio-ecological and economic profit. The application of the system ensures a thorough and objective analysis of the subject area when making decisions in difficult conditions. In modern conditions, this approach helps to make management decisions, taking more than one environmental factor into account and makes it possible to assess the short- and long-term effects of the implementation of management measures. The multi-vector and holistic approach of this information technology allows state management bodies, private investment institutions, and local communities to decide on the most appropriate scenario for managing local marine ecosystem in order to obtain the best socio-ecological and economic effect.

This system is based on 4 components:

Component 1. Database management system. Provides the ability to accumulate and process primary data. It includes the following databases: climatic, hydrometeorological, water quality, diversity of flora and fauna, natural resources and their use, recreational resources and their use.

Component 2. Geoinformational system. Allows to visualize the decision-making process and demonstrate the scale of changes or potential consequences from the implementation of management decisions.

Component 3. Mathematical and predictive models. This component is based on the broad involvement of mathematical modelling of all processes that are observed during the interaction of living beings with each other and the environment under the conditions of intense anthropogenic load.

Component 4. Informational and management system for choosing strategic and operational decisions. Provides an opportunity to predict possible changes in the ecosystems based on database analysis using hydrological and climate models. This, in turn, allows to form possible scenarios of ecosystem development. With the use of dynamic flow charts, it will be possible to choose a strategic and operational decision or a specific management measure, which will be aimed at overcoming environmental and socio-economic risks.

The **third block** of the systemic decision-making scheme for estuary management is dedicated to the implementation of the decisions made and includes 4 stages.

Stage 1. Environmental assessment of decisions and projects. This stage involves the completion of legally regulated evaluation processes of planned measures. Depending on the type of activity, Strategic Environmental Assessment and Environmental Impact Assessment are distinguished. Strategic Environmental Assessment (SEA) is a procedure that is necessary in order to determine, describe and evaluate the consequences affecting the environment and the health of the population through the implementation of state planning documents (urban planning documentation: a master plan, a detailed plan of the territory or a territory zoning plan, schemes of district planning, strategies, national programs, state target programs and other programs and program documents that are developed and/or subject to approval by the state authority, local self-government body), development of measures to prevent, reduce and mitigate possible negative consequences [19]. The Environmental Impact Assessment procedure (EIA) is designed to identify the nature, intensity and degree of danger of the impact of any type of planned economic activity on the state of the environment and the health of the population [20].

Stage 2. Implementation of environmental measures. As part of this stage, the planned activities for solving environmental problems of a specific body of water are being implemented. It should be noted that expert supervision of measure implementation and ecological and economic audits are integral tools within this stage. Quite often, non-compliance with technological processes or changes in design solutions occur during the implementation of measures.

Stage 3. Efficiency evaluation. The effectiveness measure implementation of measures is the final condition of ecological management. Thus, estuary management aims to solve not only environmental problems, but also take social and economic aspects into account. That is why efficiency evaluation should be based on the assessment of the state of indicator species and habitats, as well as on socio-economic indicators in the region of implementation of ecological management projects.

Stage 4. Search for new solutions and their improvement. The cyclic nature of ecological management is an important component of the continuous development and preservation of the natural resource potential of estuaries. Given that the estuaries of the region are complex natural multicomponent systems, changes in which can occur quite rapidly, it is necessary to include constant improvement of control elements. It is also important to note that our knowledge and management methods are constantly improving, and this, in turn, can contribute to the search for more effective measures to restore these hydroecosystems.

3. Conclusions

The Azov-Black Sea coast is represented by a significant number of estuaries and bays, which functioned for a long time thanks to an artificial connection with the sea. Molochny, Berezansky, Tyligulsky, Tuzlovsky estuaries, Eastern Sivash, and others are among them. They have important scientific, social and environmental significance. Most of them are included in the nature protection territories of Ukraine as national parks and have the status of wetlands of international importance. On the other hand, they are important from the socio-economic point of view, since reproduction and feeding of fish takes place in their water areas, and in the future, fishery.

The functioning of most estuaries in the region has always been related to the level of water exchange through artificial channels with Azov or Black Sea. For a long time, the management of these bodies of water took place spontaneously and was aimed at the formation of various ecological states. The lack of a systemic concept in the development of estuary management plans does not make it possible to make the necessary management decision. An important element in choosing the necessary solutions is the evaluation of ecosystemic services, as a tool for finding a balance between ecological, social and economic directions of estuary use. These assessments should determine the development vector of the estuary ecosystem, which will ensure the rational use of its natural resource potential.

Despite the obvious need to introduce a systemic approach to decision-making for estuary management, there are currently no methods of holistic assessment of their condition and decision-making strategies within the framework of ecological management. The proposed comprehensive approach is a practical tool for ensuring balanced nature management of the investigated hydroecosystems. Developed scheme of stages of systemic decision-making for estuary management is based on the implementation of successive stages, with a multi-component decision support system functioning in its centre. This scheme is cyclical and requires constant improvement of the decisions made and evaluations of the effectiveness of measures.

Abstract. This paper provides the comparative morphological analysis of *P. ridibundus* chromosomes in different population systems of southern Ukraine. A certain variability and heteromorphism of individual homologs and of whole chromosome pairs was established. The chromosomes of *P. ridibundus* in populations consisting of a single species (Crimea, Zalisne, Arabat Spit) are relatively stable in quantitative and qualitative terms. Karyotypes are more variable in the lower reaches of the Dnipro River and Kharkiv Region, where the hybridogenic taxon *P. esculentus* lives together with *P. ridibundus*. It is assumed that such a relative constancy of chromosomes of southern Ukrainian *P. ridibundus* in pure RR-systems indicates both a high potential of their resistance to factors and an intraspecific genetic balance. This study is especially important in terms of conservation and enhancement of genetic and biological diversity, which mainly ensures the sustainability of ecosystems functioning.

1. Introduction

The South of Ukraine is characterized by a unique biological and genetic diversity of both typical widespread species and rare ones, which can preserve their unique relict nature with their own mechanisms of evolution and speciation [1]. What is interesting here is the hybridogenic speciation as a special source of increasing biological diversity, and this requires a new strategy for its assessment, protection and preservation. *Pelophylax ridibundus* (Pallas, 1771) is involved in all these processes. It is the most common typical species of amphibians of freshwater reservoirs of southern Ukraine and one of the parent species of the hybridogenic complex of green frogs of the genus Pelophylax. The vast majority of "pure" RR populations of *P. ridibundus* are distributed in the southern and southeastern parts of Ukraine. In other regions, it is often found in a complex with other species, namely P. lessonae and the hybrid taxon *P. esculentus*.

It is known that *P. ridibundus* is considered to be a complex of cryptic species. According to the analysis of mitochondrial and nuclear DNA, it was established that this species, in particular in the south of Ukraine and Crimea, is represented by two genetically differentiated forms – "western" (= Central European – *P. ridibundus*) and "eastern" (= Anatolian P. cf. bedriagae) [2, 3]. On the basis of our morphological studies and the latest literature data, it has been preliminarily proven that P. cf. bedriagae lives in Crimea, while *P. ridibundus* lives in the lower reaches of the Dnieper and further to the north and west. We also assume that P.

cf. bedriagae, might inhabit southeastern Ukraine, connected with the small rivers of the Azov region. Almost all known studies in this area are based on molecular and genetic data. It is quite important at this stage to establish more "visible" diagnostic traits, in particular at the level of ecology, morphology, and chromosomal indicators. The latter are important given the fact that amphibians are characterized by stable chromosomal conservatism, in which the same number of chromosomes is characteristic not only for species, but also for genera and families. Since it is the karyotype that ensures the stability of the existence of the species, therefore it is important to investigate how karyologically stable this species is, especially in the conditions of southern Ukraine. The importance of such features is essential from the point of view of protection, preservation, and increase of biological diversity, which is based on complex invisible genetic mechanisms, which can have great potential for understanding the role of hybridization as a source of speciation.

2. Research aim and objectives

The aim of the study was to identify specific characteristics at the level of karyotypes and to conduct a comparative morphological analysis of *P. ridibundus* chromosomes from different populations of southern Ukraine, including the Crimea.

3. Material and methods

The study was carried out in accordance with all modern requirements for the handling of experimental objects. Eight individuals of *P. ridibundus* were used in the study. For comparison of karyotypes, typical populations of *P. ridibundus* were selected (figure 1): Kherson Region, Henichesk District, Arabat Spit, recreation center "Valok" – 1 specimen (point 1); Kherson region, Hola Prystan District, near Stara Zburyivka village – 2 specimens (point 3); Crimea, Bakhchysarai District, village Zalisne (the material was collected before 2013) – 3 specimens (point 4) and a more distant point where the relevant population systems are widespread – Kharkiv Region, Izium District, near Snizhkivka village – 2 specimens (point 2).

A total of 49 metaphase plates were analyzed, 20 of which were selected for morphological

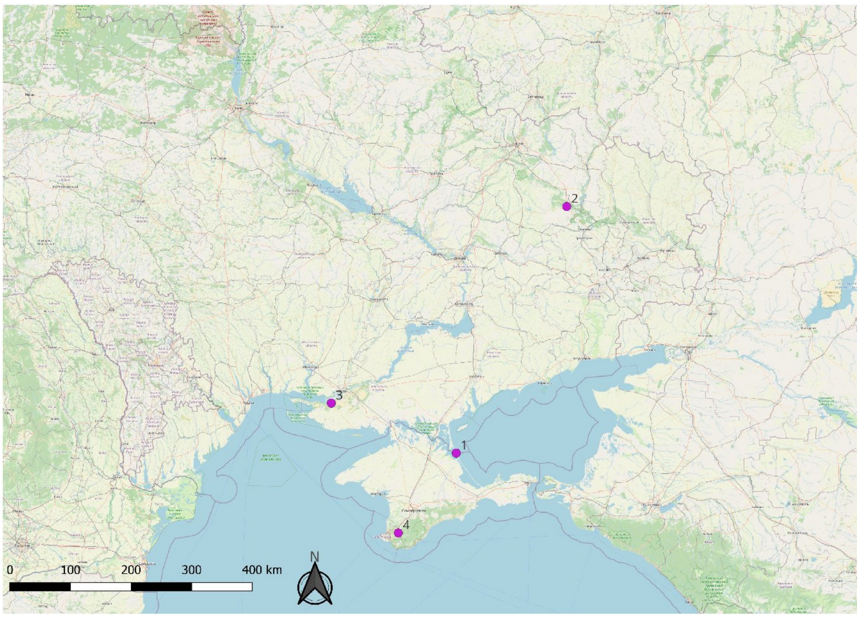

Figure 1. Populations of *P. ridibundus* used for analysis (the points are described in the text).

analysis. The preparation methods of karyological preparations, video recording, analysis and karyotyping of chromosomes, peculiarities of homologues selection and their typing are described in detail in our previous works.

4. Results

The standard karyotype of *P. ridibundus* is symmetrical and represented by two-armed chromosomes. It is characterized by the diploid number of 2n = 26, and the number of arms of N.F. = 52. The karyotype includes 5 pairs of large and 8 pairs of small chromosomes. The 1^{st} is a large metacentric, the 2^{nd}, 3^{rd} and 4^{th} pairs of chromosomes are submetacentric, the 5th pair is the smallest metacentric in the group of large chromosomes. The 6^{th} and 7^{th} pairs are also metacentrics among small chromosomes. The 8^{th} and 9^{th} pairs are represented by subtelocentric chromosomes (on some plates they can be submetacentric), especially the 9^{th} pair, which is characterized by a certain variability, since there is a secondary band on its long arm. The 10^{th}, 11^{th}, 12^{th}, and 13^{th} pairs are submetacentrics. The formula of the *P. ridibundus* karyotype is 4 meta-(m) + 7 submeta-(sm) + 2 subtelocentric-(st), 2n = 26, N.F. = 52.

First of all, it should be noted that all the analyzed metaphase plates and karyograms correspond to the standard karyotypes of *P. ridibundus*, but at the same time there is a certain variability and heteromorphism of individual homologs and of whole chromosome pairs. Particular attention should be paid to the study and clarification of the standard types of the last 4 pairs of chromosomes. Regarding the 10^{th} pair, it can be said that, in contrast to the indicated submetacentric type, in the vast majority it is represented by subtelocentric homologs. All analyzed plates show secondary bands on the long arm of the 9^{th} chromosome pair, which is not always characteristic of other closely related species, such as the hybridogenic *P. esculentus*. The chromosomes of *P. ridibundus* from Crimea and the Arabat Spit are relatively more stable in terms of quantity and quality (figure 2). Homologs are easily selected, even with total coloring.

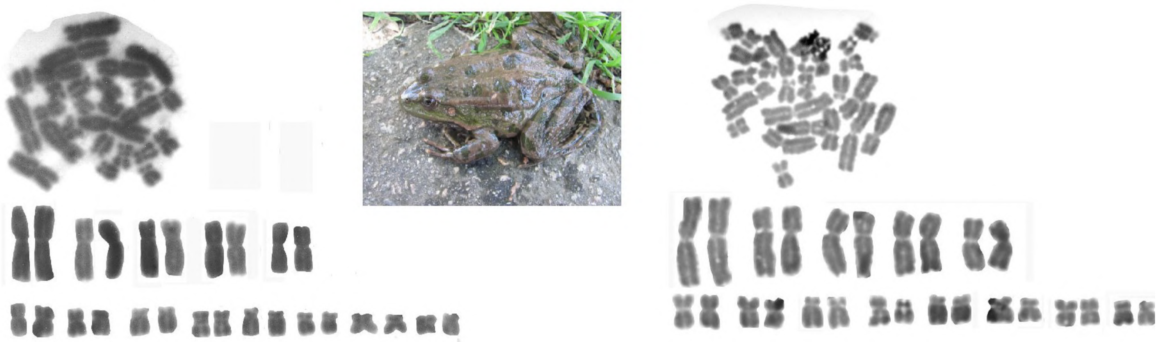

Figure 2. Metaphase plates and karyograms of *Pelophylax ridibundus* from southern Ukraine (Crimea, Bakhchysarai District, Zalisne village and Kherson Region, Arabat Spit).

The chromosomes are more variable in the karyotypes of *P. ridibundus* from the lower reaches of the Dnipro and Kharkiv Region (figure 3). Pairs often include chromosomes, which are different in size, but identical in morphology. This may be typical for the first pair of chromosomes, which was repeatedly emphasized in our previous studies. Heteromorphism of individual pairs and homologs is also found among the group of small chromosomes, especially the 6th, and the last three (11^{th}, 12^{th}, 13^{th}). Incomplete sets are often found, which is typical for all analyzed populations. More often homologs or even whole pairs are lost among the small chromosomes (figure 4). Among the large ones, homologs of the 5th pair can be lost occasionally (figure 5).

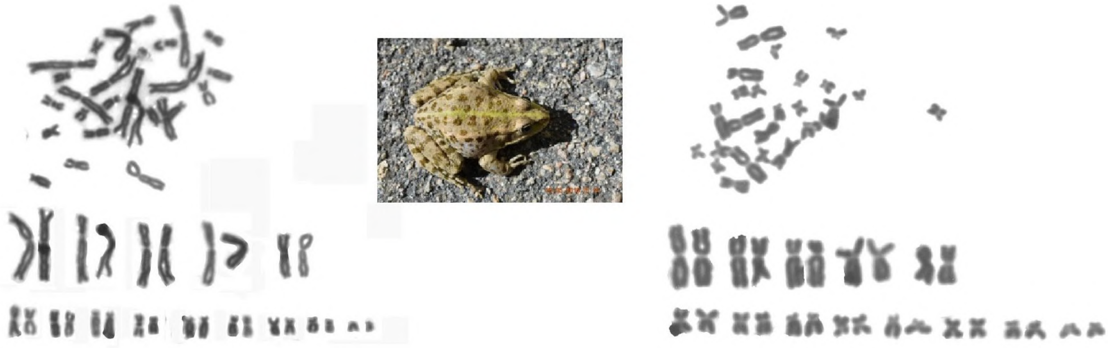

Figure 3. Metaphase plates and karyograms of *Pelophylax ridibundus* from Kherson region, Hola Prystan District, near Stara Zburyivka village, and Kharkiv Region, near Snizhkivka village.

Figure 4. Metaphase plates and karyograms of *Pelophylax ridibundus* with incomplete sets of chromosomes (Kherson Region, Hola Prystan District, near Stara Zburyivka village (1–2) and Kharkiv Region, near Snizhkivka village (3)).

Figure 5. Metaphase plates and karyograms of *Pelophylax ridibundus* with incomplete sets of chromosomes (Crimea, Bakhchysarai District, Zalisne village (1–3) and Kherson Region, Arabat Spit (4).

5. Discussion

First of all, the prevalence of population systems of green frogs in Ukraine should be mentioned. There are pure and mixed populations of parental species – RR, LL, RL, hemiclonal mixed – RE, LE, REL, and hybridogenic EE-type systems. In southern Ukraine, the most common are populations of *P. ridibundus* (RR) and mixed semi-clonal systems – RE and REL with different ploidy, abundance, and specific sexual structure. In different parts of their range, they have corresponding percentages, genetic structure, and other specific population characteristics [4].

The main result of the conducted comparative morphological analysis is the relative stability of *P. ridibundus* chromosomes in RR-populations (Crimea, Arabat Spit). Perhaps in such populations *P. ridibundus* has a more homogeneous genetic structure, which is manifested in the relative uniformity of chromosomal parameters, while incomplete sets are still present. Populations in which individuals with mosaic, i.e. with di-, tri-, and more, and aneuploid cell lines [5] are found mostly majority in *P. esculentus* and in all mixed population systems. One of the reasons for this may be a violation of the process of genome elimination or other mechanisms that arise during multidirectional hybridogenic speciation. According to our data, such karyotypes are also present in RR populations. As noted, *P. ridibundus* from southern Ukraine has an ambiguous systematic status, in particular in the Crimea there are two genetically differentiated forms [3,6] that can make their own adjustments of gamete production, introgression, genome composition, which can be manifested at the chromosomal level. It is interesting that alleles of the "western" form are less common than the "eastern" form in the south, moreover, it is believed that the territory of Crimea was inhabited by *P. ridibundus* of the Anatolian lineage, directly from the Caucasus. Probably, the extensive delta systems, which were formed in the regressive stages of the Black Sea basin during the Holocene, Pleistocene, to the southeast and west of the Crimea, contributed to this.

The karyotypes of *P. ridibundus* in the lower reaches of the Dnipro River and Kharkiv Region are much more variable. In this part of Ukraine *P. ridibundus* lives together with hybridogenic taxon *P. esculentus*. The RE-type population system has a very diverse genetic structure, with the presence of polyploids, a large diversity of parental genomes that are produced, transmitted, and inherited through complex genetic mechanisms [7–10]. Therefore, all these factors can be manifested in the variability of homologs, the qualitative and quantitative characteristics of chromosomes. Of course, we allow for the possibility that our results are related to geographical variability, different nature spiralization and condensation of the chromosomes and their individual parts, which can lead to heteromorphism of homologs.

6. Conclusion

The results of the study suggest that such a relative constancy of chromosomes of the southern Ukrainian *P. ridibundus* in pure RR-systems indicates a high potential of their resistance to factors and their intraspecific genetic balance. At the same time, we allow for the possibility of introgression between the "eastern" and "western" forms. *P. ridibundus* in mixed RE-systems has a certain genetic and ecological interaction in the process of hybridogenic reproduction that directly affects the morphology of the karyotype, which is manifested in the variability of homologs, their qualitative and quantitative characteristics. The presented materials are only preliminary and require confirmation with the use of comparative statistical methods of the relevant chromosomal indicators. It is also necessary to investigate the composition of the genome, the genetic structure, to what extent molecular variability is comparable with chromosomal variability, and how it is reflected in different populations of green frogs. This is especially important from the point of view of preserving and increasing the genetic and biological diversity, which mainly ensures the sustainability of ecosystems functioning.

Abstract. The peculiarities of the transformation of river ecosystems in the reservoir at the construction of mini-hydropower plants have been found out. It was also found that the large-scale hydraulic engineering in the second half of the XX century caused significant changes in environmental conditions in the waterbodies, which has led to negative dynamics of species richness of aquatic organisms in general and phytoplankton in particular. Reservoir building has a significant negative impact on river ecosystems: currents slow down and disappear, canals become silted up, harmful substances of household and industrial waste gradually accumulate. The transformation of rivers into lake-type reservoirs is also accompanied by changes in the species composition and structure of phytoplankton. Eutrophication of reservoirs becomes typical. All this leads to significant degradation in aquatic ecosystems.

1. Introduction

At the beginning and in the middle of the XX century, small hydropower plants (MHPPs) were built on a large number of small and medium-sized rivers in Ukraine. In the 1930-1980-s, there were estimated more than 1,500 of them, now there are only 98 ones [1]. The building of reservoirs has caused radical changes in the ecological condition of rivers. Currents slowed down or disappeared completely on large sections of riverbeds, water exchange began to be determined by the mode of operation of hydroelectric power plants. This dramatically changed, first of all, the hydrological and hydrochemical regimes of rivers [2]. Another consequence was siltation and accumulation of harmful substances from industrial, agricultural and domestic effluents, which also leads to changes in the hydrochemical regime, mainly due to increased concentrations of biogenic substances [3, 4].

At the beginning of the 21st century, scientists around the world came to the conclusion that rivers need to be revitalized. In practice, it is necessary to study each individual case in detail, and only after that a conclusion can be made about the feasibility of existing hydraulic structures. In the United States, about 900 dams were dismantled between 1990 and 2015. France and

Canada have also completed important dam removal projects. In Japan, the dismantling of dams began in 2012 [5–7].

Due to the plans for significant expansion of hydraulic engineering on small rivers of the Forest-Steppe of Ukraine, it is extremely important to find out the nature of the impact of MHPP on hydrochemical and hydrobiological regimes. An important aspect of the study is to identify patterns of composition, structure and functioning of hydrobionts under the conditions of transformation of river ecosystems into ponds and lakes. It appears extremely necessary to develop measures to minimize the harmful effects of HPPs for optimizing the state of reservoir ecosystems. This study is relevant in the framework of the European Framework Directive (WFD), adopted in 1992 in order to intercalibrate rivers and ensure the synchronization of research and the possibility of comparison and generalization of information [8, 9].

2. Material and methods

The study was conducted at 7 MHPP reservoirs located on Koropets River (Koropetske reservoir), Hnily Tikich River (Zvenygorodke and Lotashivske reservoirs), Hirsky Tikich River (Yurpilske and Hordashivske reservoirs) and Ros River (Steblivske and Korsun-Shevchenkivske reservoir). In accordance with the existing classification, small hydropower plants (SHPPs) include hydroelectric power plants with a capacity of 1 to 10 MW, mini-HPPs – from 200 to 1000 kW, micro HPPs – no more than 200 kW. So, the reservoirs of mini-hydroelectric power stations described in the article are: Koropetskaya HPP (250 kW), Zvenigorodskaya HPP (400 kW), Lotashiv HPP (420 kW). Yurpolska (not functioning), Gordashivska HPP (400 kW). Steblivska HPP (3.0 MW) and Korsun-Shevchenkivska HPP (1.2 MW) are already small HPPs.

The selection of material was carried out during expeditions in 2013-2020 in the warm period (from April to September). Data from hydrological yearbooks, kindly provided by the Geophysical Observatory of the Hydrometeorological Service of Ukraine in Kyiv, were used to study the dynamics of hydrological conditions of reservoirs in the region. Processing of hydrochemical water samples (64 samples) was carried out in a specialized chemical laboratory of the Ukrainian Hydrometeorological Institute UkrGMI. Temperature, hydrogen index (pH), and the amount of dissolved oxygen in water were determined directly on the reservoirs using the certified electronic device Ecotest-2000 (№ 19027-99 in the State Register). To examine phytoplankton, a Rutner bathometer was used (water samples were taken from a surface layer and a 1.5 m layer). Water was fixed with a 2% formalin solution. After settling, the sample volume was increased to 30-100 cubic using a siphon. Determination of the species and quantitative composition of algae was carried out jointly with the staff of the Institute of Hydrobiology of the National Academy of Sciences of Ukraine according to standard methods [10–12]. Assessment of water quality of fishery reservoirs and reservoirs of complex purpose was carried out according to SOU 05.01-37-385: 2006 [13]. Hygienic classification of bodies of water was carried out according to State Sanitary Rules and Regulations 2.2.4-171-10 2010 [14]. Ecological assessment of surface water quality was carried out using generally accepted methods [10, 15].

3. Results and discussion

Hydrochemical characteristics are important markers of the ecological status of waterbodies. In terms of the content of basic chemicals, the water of the reservoirs of the Forest-Steppe MHPP meets the state fishery standards (MPC) in most indices. A slight excess of the MPC for magnesium (in 1.09–1.15 times) was observed in the Yurpil and Korsun-Shevchenkivsky reservoirs. Exceeding the MPC for this element together with calcium leads to increased water hardness. However, the increasing change of water hardness has a positive effect on the state of aquatic organisms, and the decrease – on the contrary. In terms of salt composition, the water

of the studied reservoirs belongs to the bicarbonate-calcium type. Bicarbonates predominate in all investigated reservoirs (table 1).

According to the criteria of pollution by components of a salt composition, water in reservoirs, on average, was determined as having an index – 2.0, which applies to class II of category 2 (good, clean). According to ecological and sanitary indices (State Sanitary Rules and Regulations 2.2.4-171-10), the average value of the water quality category of reservoirs was determined as 3.66 (4.0), which applies to class IV of category 4 (satisfactory, slightly polluted).

Considering the biogenic substances, there was detected a significant excess of concentrations of nitrites and phosphates. Exceeding the MPC was observed for the following indices: in the reservoirs Koropetske (nitrite by 3.5 times), Steblivske (nitrite by 5.0 times) and Korsun-Shevchenkivske (nitrite by 20.0 times and ammonium nitrogen by 1.4 times). All this indicates significant decay processes or significant industrial and domestic effluents. Excess MPCs for phosphates are also related to this. The worst situation is observed in Steblivske (phosphates by 10.6 times) and Korsun-Shevchenkivske (phosphates by 10.2 times) reservoirs. The high levels

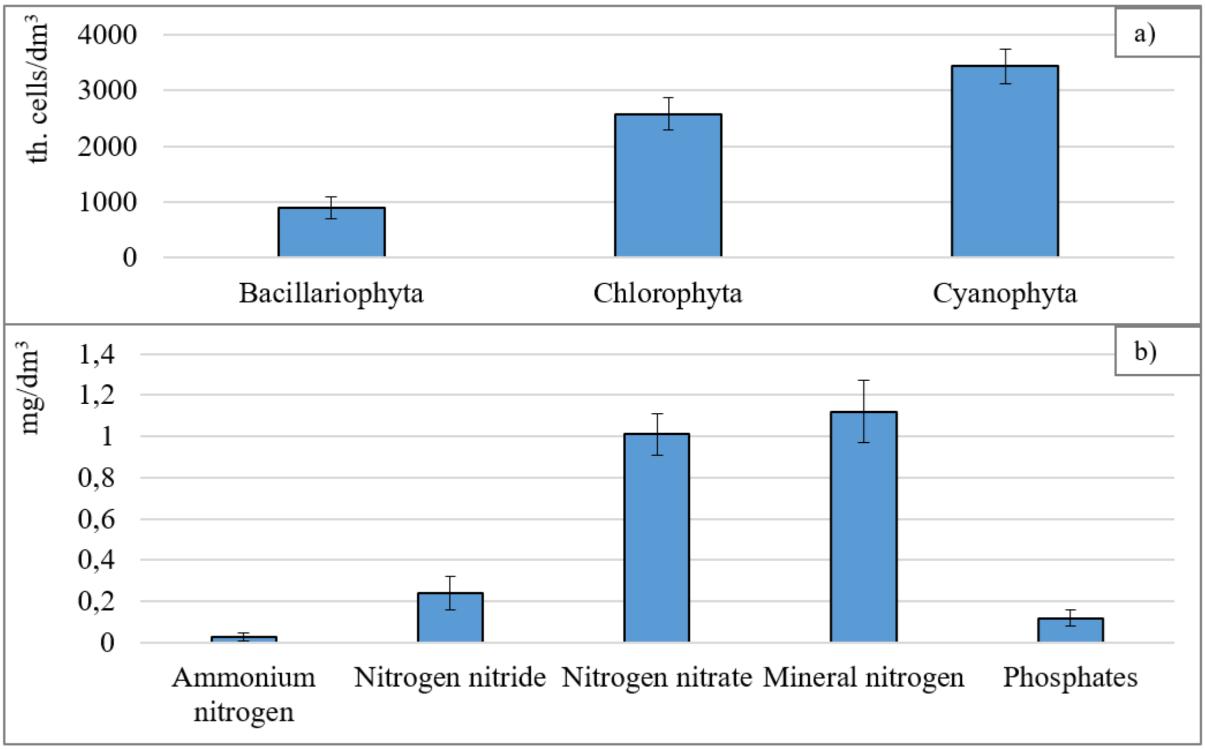

Figure 1. The ratio of the main groups of phytoplankton (a) and the amount of biogenic substances (b) in the Koropets reservoir.

(by 3.4–8.6 times) of phosphates were also detected in the rest of the reservoirs (table 2).

Phosphates are known to be primarily associated with detergents, so they are most abundant in reservoirs located in densely populated areas. The situation with biogenic substances is complicated by the regulation of river runoff arising as a result of reservoirs creation. Slowing down and disappearing of currents leads to the accumulation of harmful substances from runoffs. The lower parts of reservoirs and the reservoirs in the lower part of rivers are the most polluted.

The upper reaches of reservoirs are characterized by minimal indices of biogenic substances (nitrites – 0.054 ± 0.001; phosphates – 0.233 ± 0.02), middle parts (0.129 ± 0.01; 0.366 ± 0.03), lower parts (0.157 ± 0.015; 0.417 ± 0.04). These data clearly reveal the consequences of river regulation by the dams. The current is maintained in the upper reaches, and the nearest territory has a minimum amount of settlements. The middle and lower parts contain a predominant number of settlements, which are related to industrial, agricultural and domestic effluents. The decomposition of organic matter during eutrophication, which is the source of biogenic substance accumulation, is also the most significant there.

The above-mentioned hydrochemical parameters play an important role in the formation of groups of aquatic organisms, primarily phytoplankton. The phytoplankton excessive development (eutrophication) correlating with a significant excess of the MPC for biogenic substances, especially phosphates, was observed. A rectilinear dependence of the number of cyanophytes from the number of biogenic substances has been proved. On the other hand, an exaggeration of the amount of phosphates leads to inhibition of the activity of algae, especially diatoms. As shown above, the amount of phosphates depends on a number of reasons, among

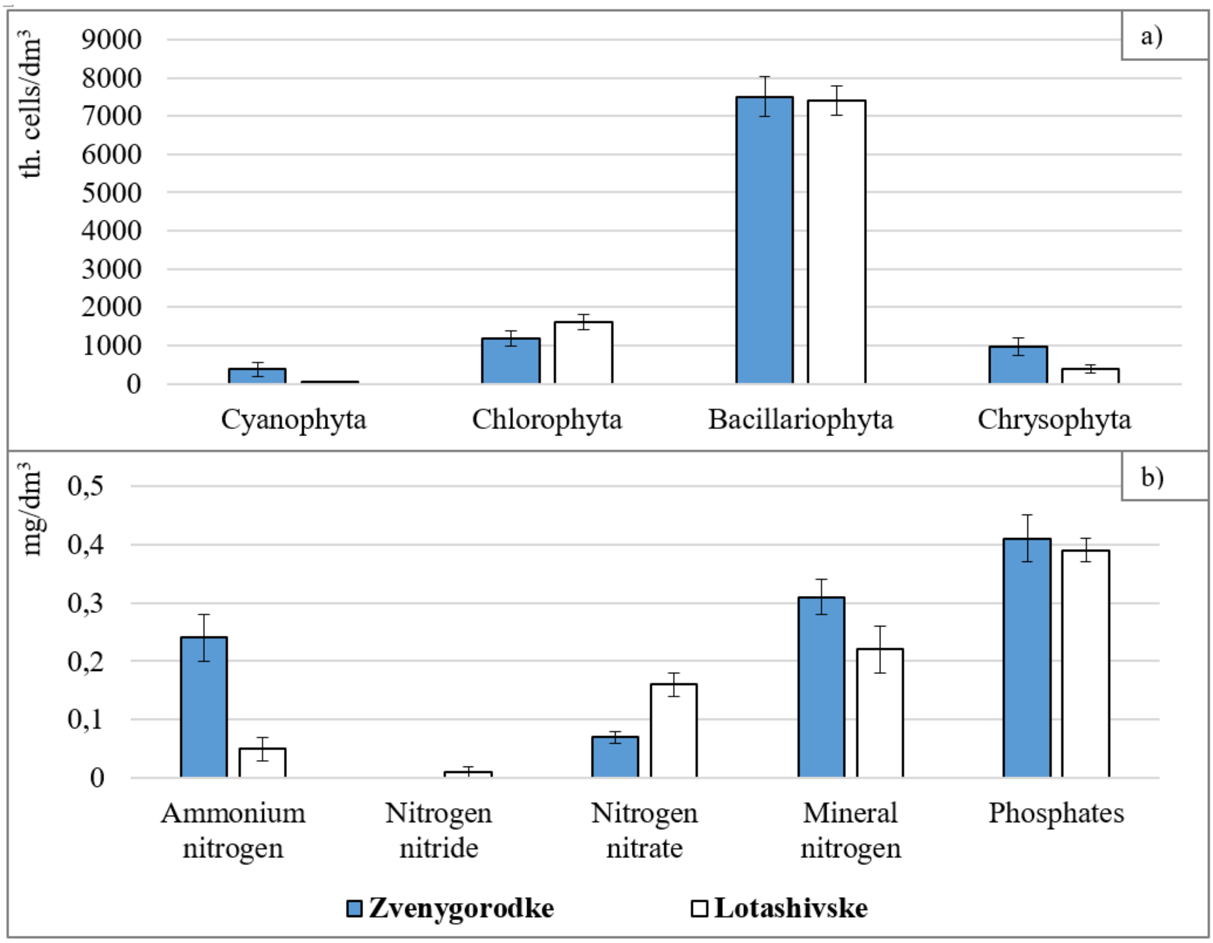

Figure 2. The ratio of the main groups of phytoplankton (a) and the amount of biogenic substances (b) in the reservoirs of Hnily Tikich River.

the most important are the size of the reservoir, the density of settlements on the banks and the area of reservoirs along with the flow. The same factors are observed highly influencing the phytoplankton abundance.

The amount of phosphates is not significant in the small Koropetske reservoir, but cyanophytes predominate there (figure 1).

The quantitative ratio of different taxonomic groups of algae in general and cyanophytes in particular differs in the reservoirs of the Gnily Tikich River. There is observed an another pattern. Thus, one of the two studied reservoirs on the Gnily Tikich River – Zvenigorodske one is located within the settlements and Lotashivske reservoir is located in sparsely populated areas. In addition, the Lotashivsky reservoir is upstream, and Zvenigorodske one is in the middle part. Having almost equal amounts of phosphates in these reservoirs, Zvenigorodske reservoir has 372 ± 23 thousand cells/dm^3 of cyanophytes while Lotashivske reservoir shows the minimum number of cyanophytes ($56 \geq \pm 11$ thousand cells/dm^3) and up to their total absence in the upper and middle parts (figure 2). There are much more diatoms in the studied reservoirs: 5960 ± 35 thousand cells/dm^3 in Lotashivsky reservoir and 7400 ± 43 thousand cells/dm^3 in Zvenigorodske reservoir (figure 2).

Similar results were obtained on the Hirsky Tikich River. Yurpilske reservoir is located in the upper reaches in sparsely populated areas. There is a minimal amount of biogenic substances and no cyanophytes. The number of diatoms is 4586 ± 41 thousand cells/dm^3. The Gordashivske reservoir is surrounded on two sides by settlements. Exceeding the MPC of phosphates was

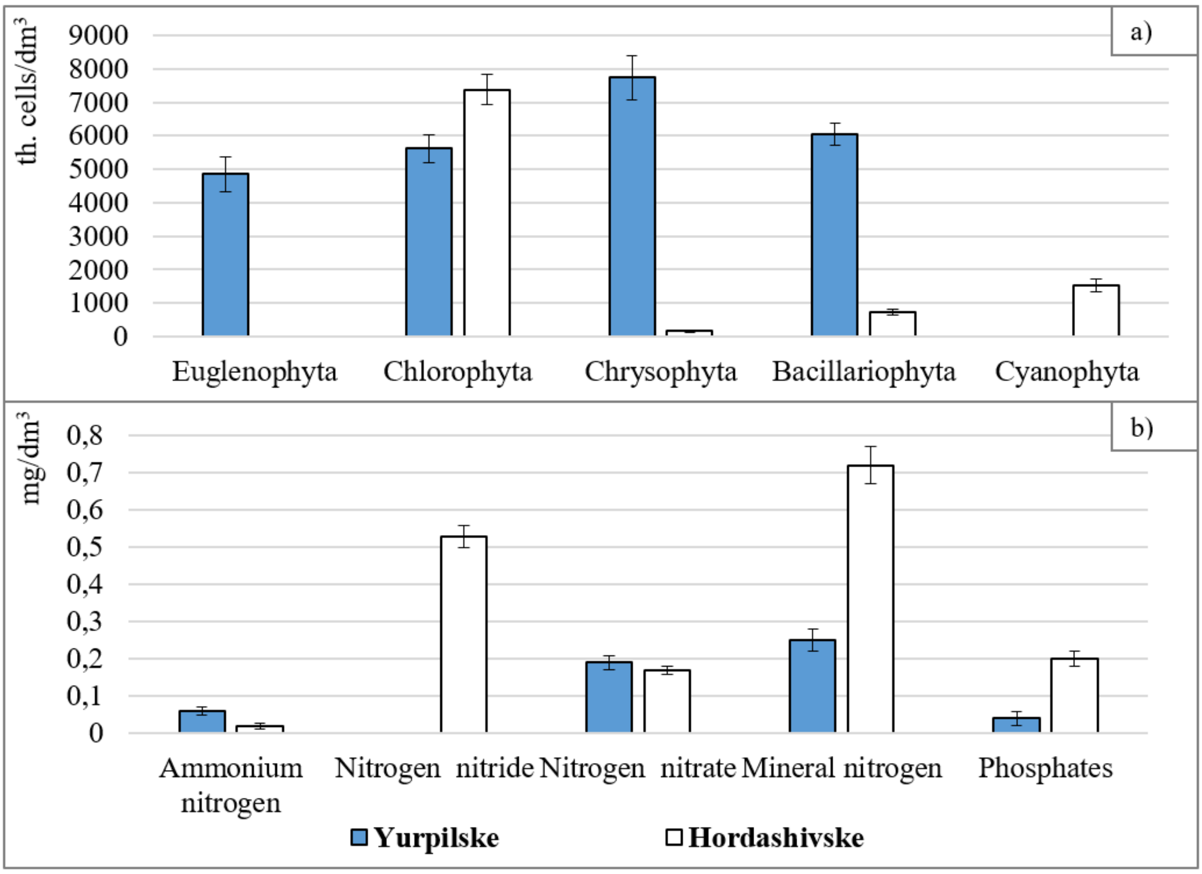

Figure 3. The ratio of the main groups of phytoplankton (a) and the amount of biogenic substances (b) in the reservoirs of Hirsky Tikich River.

observed there by 4 times. The cyanophytes (1529 ± 16 thousand cells/dm^3) were observed throughout the reservoir. The number of diatoms was observed by 6-9 times lower (730 ± 23 thousand cells/dm^3) comparing the previous reservoirs (figure 3).

The Steblivske and Korsun-Shevchenkivske reservoirs are located in the densely populated lower part of the Ros River. As shown above, there was observed a significant exceedances of the MPC for biogenic substances in these reservoirs. This significantly affected the species composition and abundance of phytoplankton: the number of cyanophytes is 3272 ± 45 thousand cells/dm^3 (Steblivske reservoir) and 5173 ± 52 thousand cells/dm^3 (Korsun-Shevchenkivske reservoir). The number of diatoms is much smaller: 1232 ± 21 thousand cells/dm^3 (Steblivsky reservoir) and 1366 ± 27 thousand cells/dm^3 (Korsun-Shevchenkivske reservoir) (figure 4).

The relation between the concentration of nitrites and phosphates and the amount of cyanophytes according to the results of correlation analysis is characterized as close ($R = 0.861$) (figure 5). The observed reservoirs were classified as β-mesosaprobic and β'-mesosaprobic in terms of saprobity and as mesotrophic (predominant type) in terms of trophicity.

4. Conclusions

In terms of the content of basic chemicals, the water of the reservoirs of the Forest-Steppe MHPP meets the state fishery standards (MPC) in most indices. A slight excess of the MPC for magnesium (by 1.09–1.15 times) was observed in the Yurpilske and Korsun-Shevchenkivske reservoirs. According to the criteria of pollution by components of a salt composition, water in reservoirs, on average, was determined as having an index – 2.0, which applies to class II of

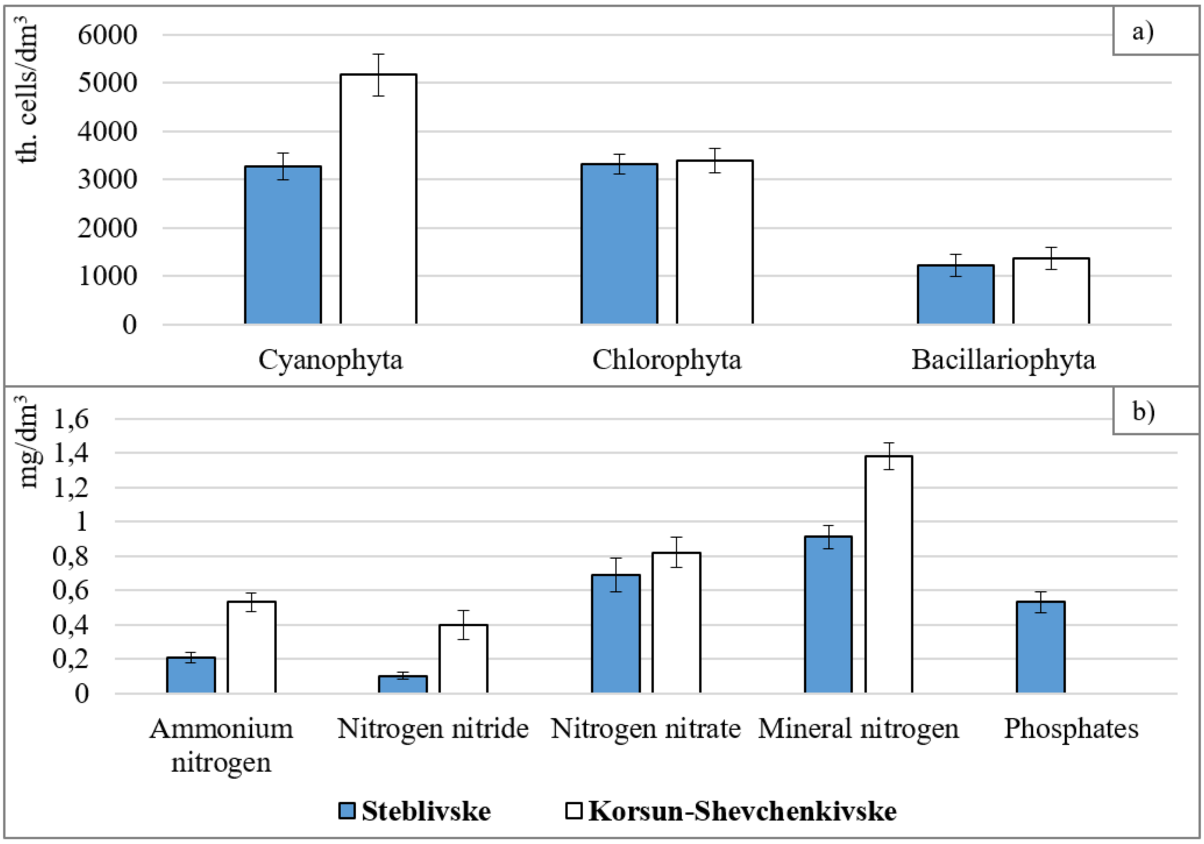

Figure 4. The ratio of the main groups of phytoplankton (a) and the amount of biogenic substances (b) in the reservoirs of Ros River.

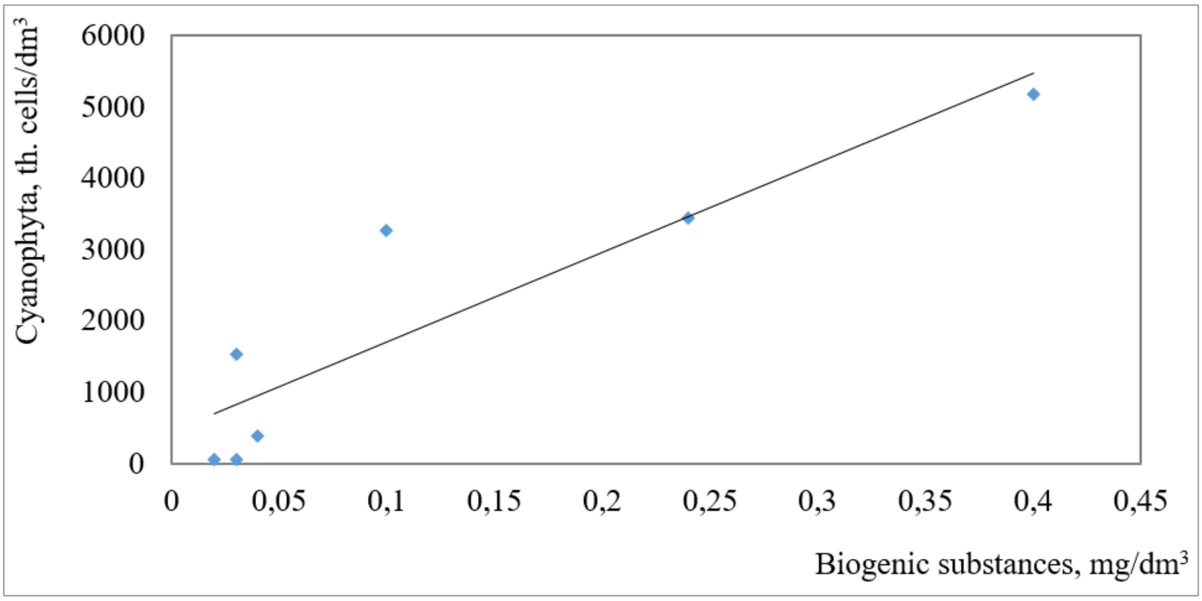

Figure 5. Correlation between the density of cyanophyte groups and the amount of biogenic substances in the studied reservoirs.

category 2 (good, clean). According to ecological and sanitary indices (State Sanitary Rules and Regulations 2.2.4-171-10), the average value of the water quality category of reservoirs was determined as 3.66 (4.0), which applies to class IV of category 4 (satisfactory, slightly polluted).

Hydrochemical indices of some basic chemical parameters and most biogenic substances exceeded or reached the MPC.

Thus, in the Koropetske reservoir the excess of biogenic substances is by 1.5–2.2 times; in the reservoirs of the Gnily Tikich River – by 1.2–12.0 times; in the reservoirs of the Gorsky Tikich River – by 1.4–3.3 times; in the reservoirs of the Ros River – by 1.4–40 times. This in turn causes excessive development of phytoplankton, leading to "blooming" of water with excessive development of cyanobacteria.

A close relation has been figured out between the concentration of cyanobacteria and the amount of biogenic substances in the water, which depends on the territorial location of the reservoir. The effect of cyanobacteria on certain groups of algae and other aquatic organisms has been elucidated. Four groups of algae (Euglenophyta, Chrysophyta, Chlorophyta, Bacillariophyta), the overall density of which reaches 7000 thousand cells/dm^3, are found in case of absence or minimum number of cyanobacteria (up to 3000 thousand cells/dm^3) in the reservoirs. This was observed in the Yurpilske, Lotashivske and Zvenyhorodske reservoirs. On the contrary, if the density of Cyanophyta increases over 5000 thousand cells/dm^3, it remains only two groups of algae (Chlorophyta and Bacillariophyta) with an overall density of 1000–3000 thousand cells/dm^3. This was observed in the reservoirs Steblivske and Korsun-Shevchenkivske. During the intensive "blooming" of water in the studied reservoirs, the suffocations periodically occurred, leading to the death of fish, crustaceans and other aquatic organisms.

Abstract. In 2019-2020, research on the vocal activity of bats was carried out on the territory of the Wind Farm LLC wind park (800 MW), which is planned to be built near Mariupol (Donetsk region, Ukraine). There were used three methods of material collection: research on the vantage points, on transects and at a stationary point throughout the night. The total number of registered voices is 1554 signals, 695 of which are recorded in 2019 and 859 in 2020. The article shows the dynamics of voice activity by seasons and phases of the life cycle. Based on the activity index of mice, the dynamics of this indicator by months is shown. Forage and migratory behaviour of bats, calculated by determining the index of their activity, shows the average values. An analysis of the territorial distribution shows that bats confined to settlements and open water bodies. The species composition of bats, identified for 1235 signals registered in the territory of the projected wind farm, is stable and represented by widespread at least 10 species belonging to 6 taxonomic ranks. There were revealed some wind turbine generators near which the implementation of minimization measures is required. In total, according to forecasts, there are 10-16 such wind turbine generators within the Wind Farm LLC wind park. Monitoring the state of bats in the project area both during the construction of the wind farm and its operation is mandatory for the development and implementation of measures to minimize the possible negative impact on bats.

1. Introduction

The main purpose of the methodological approaches is to summarize the basic requirements for studying the activity of bats for the needs of the Project, which relates to the construction of a wind farm together with ancillary infrastructure including a power transmission line.

2. Material and methods

Methods for collecting and analyzing information on the behavior of bats are based on national and international practices [1–3].

2.1. Research area

The research area is located 17 km west of Mariupol (Donetsk region, Ukraine), where the construction of the wind farm is planned (figure 1). The research area covers the entire territory of the Wind Farm LLC wind park together with the 330 kV power transmission line (PTL-330).

The current location of the planned project with the proposed location of vantage points is presented in figure 1 and their characteristics is in table 1.

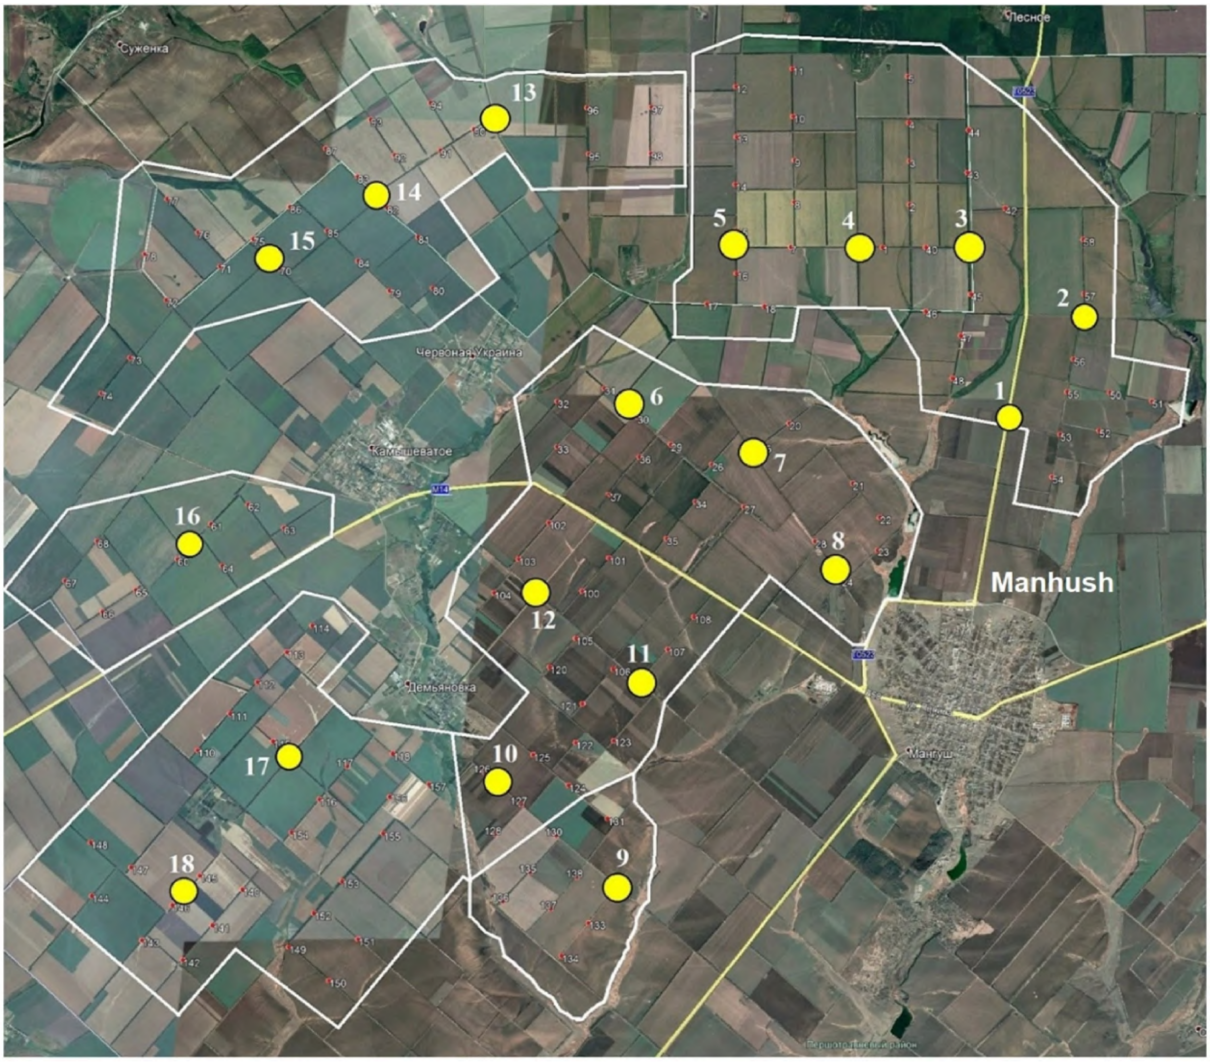

Figure 1. Location of bat detector vantage points within the Wind Farm LLC wind park (a white line – wind farm boundaries; grey circle is a wind turbine generator (WTG); white circle are the bat detector vantage points).

2.2. Duration and survey methods

Detector monitoring of bat activity is carried out within one year from the moment when bats come out of hibernation (March) and until the cessation of autumn migration and search for winter roost sites (October-November).

Table 1. Characteristics of bat detector vantage points within the Wind Farm LLC wind park (number according to figure 1).

2.3. Main provisions of the methodological approaches
Determination of monitoring sites was carried out taking into account the main habitats presented within the wind farm. There were used ultrasound detectors. Surveys were carried out in the period shortly before sunset and for at least three hours after dark.

Three research methods were initiated: ultrasound detection in separate vantage points; ultrasound detection on transects: ultrasound detection at a stationary vantage point throughout the night.

To characterize the Bat fauna of the region, there were used retrospective data obtained both within the project area and in adjacent areas.

2.4. Main requirements for environmental safety of the local populations of bats
All surveys were carried out within the wind farm after coordination of the work schedule and basic methods with the land users. During surveys in all cases there were used headlamps with electric light. Duration of surveys did not exceed the time intervals established by the method. No catching was carried out during surveys. Number of researchers was 1-2 persons. Within the project study area there was not found any colony of bats and swarming sites for day rest or hibernation. During the study period certain individuals, roosts, potential habitats of bats were not adversely affected by.

Taking into account the peculiarities of behaviour and biology of certain species of bats, to determine the species composition, vocal activity and patterns of distribution of the Priazovie species, the results of research in the adjacent areas were analyzed, which correctly characterizes certain aspects of the existence of bats at the Wind Farm LLC wind park.

2.5. Method 1. Ultrasound detection in separate survey vantage points

The study of territorial distribution, species composition, migration activity of bats was carried out according to generally accepted methods, using mainly their remote component. The studies were performed when bats were coming out of hibernation, during seasonal migrations and in the breeding season. In the twilight, as far as the lighting allowed, visual observations were made, and as darkness fell, there was used a "Pettersson D 240x" ultrasound detector. While driving, certain vantage points were detected counting the number of bat signals received for 10 minutes and capturing geographical coordinates with the "GARMIN GPSMAP 78s" navigator for their further processing in the Google Earth computer program. The signals of bats were recorded with a "ZOOM HandyRecorder H2" digital device.

The spatial distribution and flying activity of bats within the wind farm and buffer zones were determined at 18 vantage points counting the number of signals perceived by the ultrasound detector for 10 minutes of detecting (table 1; figure 1).

All 18 vantage points are located within the wind farm in places with the highest density of future wind turbines in accordance with the planning scheme. To compare the results of the research, the vantage point number 19 was located in the village of Nova Yalta.

Thus, the total number of vantage points, the information from which we used to characterize the activity of bats, is sufficient to objectively assess the status of chiroptera complexes of the project area. Driving the car from point to point, the visual observation, as far as the lighting allowed, has been carried out. This further characterized the altitudes and flight directions of the animals.

2.6. Method 2. Ultrasound detection on transects

Taking into account the recommendations of "Surveillance and Monitoring Methods for European Bats Guidelines produced by the Agreement on the Conservation of Populations of European Bats (EUROBATS)", as well as the example of carrying out similar surveys in Germany [4], 6 transects with a total length of 46 km were created within the Wind Farm LLC wind park (figure 2; table 2).

Table 2. Characteristics of transects within the Wind Farm LLC wind park.

Area	VP at a transect	Length, km	Approximate time of passage
1	1-8	21.0	1 hour 00 minutes
2	13-15	10.5	0 hours 30 minutes
3	11-12	3.5	0 hours 10 minutes
4	9-10	3.5	0 hours 10 minutes
5	16	3.0	0 hours 10 minutes
6	17-18	4.5	0 hours 15 minutes
Total	1-18	46 km	2 hours 15 minutes

Transects are located so as to cover the main habitats. Agricultural lands, which are divided into separate fields by forest belts, dominate within the Wind Farm LLC wind park. In the north-eastern and south-western parts of the wind farm there are ravine-beam systems in the relief and from the point of view of cracks, caves or underground roosts, these areas are not very attractive for bats, but can serve as forage places for animals. Among the transport infrastructure elements, there are two asphalt roads with medium load within the wind farm. High-voltage power transmission lines and a network of dirt roads also run through the territory.

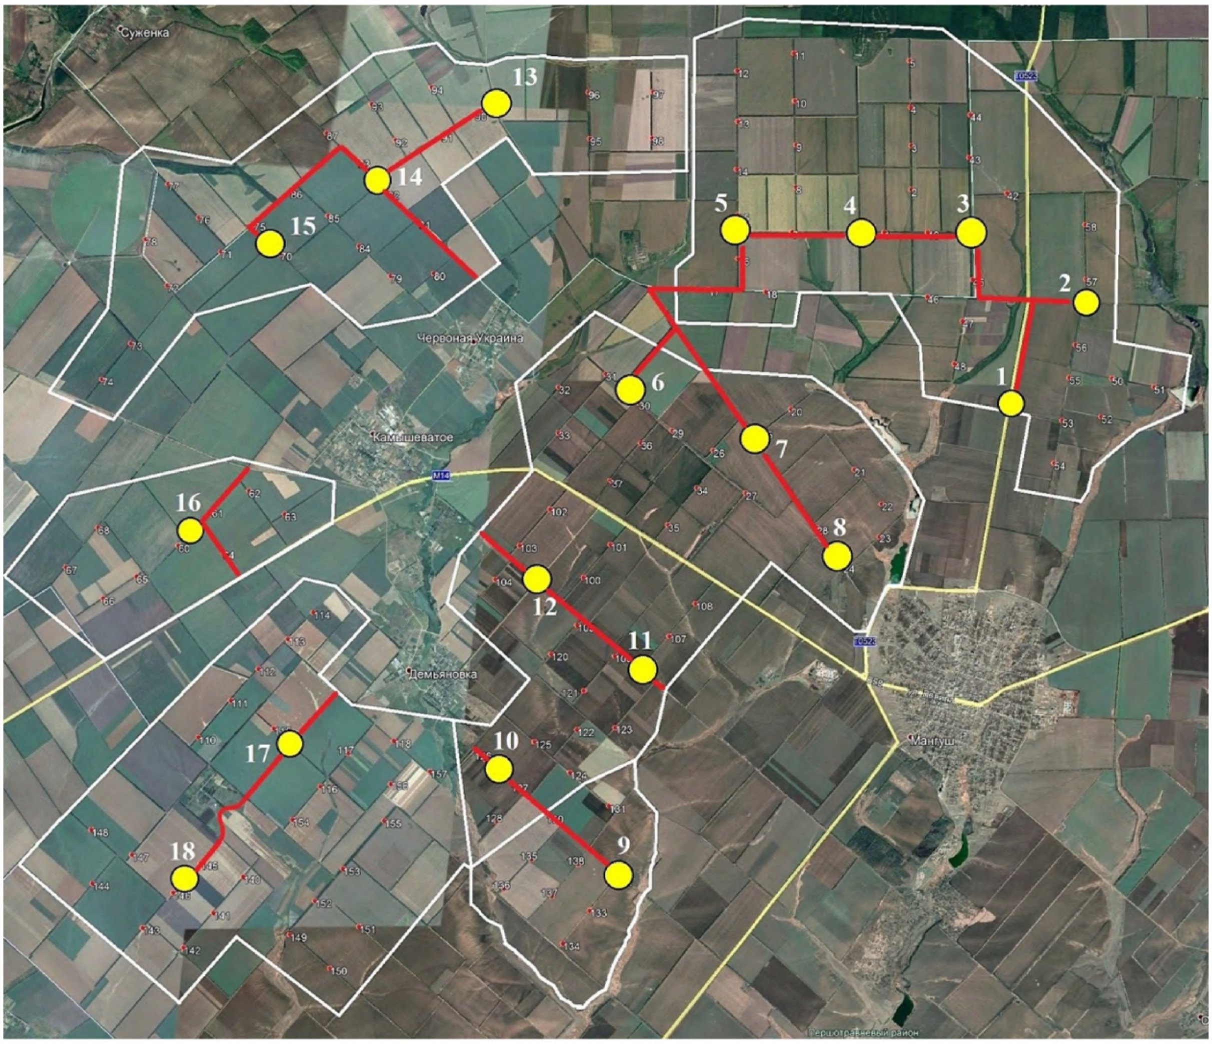

Figure 2. Location of transects (a double white line) for detection of the vocal activity of bats within the Wind Farm LLC wind park (a white line) in comparison with vantage points (1-18).

The main criteria for selecting transects. Taking into account the approximate standard of 1 km of transects for every 500 hectares of the project area, the transect of 46 km covers about 23.0 thousand hectares, which fully reflects the needs of research. Within this transect there are 18 vantage points, the distance between them is approximately the same. The frequency of detection is determined 10 times a year (1 – start of bat activity after hibernation; 3 – spring migration; 2 – breeding season; 1 – summer period; 2 – autumn migration; 1 – search for winter roost sites). When planning expeditions, favourable weather conditions for bat activity were taken into account.

According to the functional zones, each transect is 100% located within the wind farm.

2.7. Method 3. Ultrasound detection throughout the night at a stationary vantage point

There was also used the Pettersson D500x ultrasound detector, which was installed to determine the daily activity of bats on the wind farm territory not far from the planned location of the wind turbine generator № 130 (figure 3).

SAMP. FREQ. = 500
PRETRIG. = OFF
REC. LEN = 5

Figure 3. Installation location of the Pettersson D500x ultrasound detector and its settings.

Working conditions. Detector installation height – 2.0 m. Parameter settings of the Pettersson D500X ultrasonic detector (figure 3). Duration of detection from 18:00 to 06:00. Frequency of detection – March (1), April (3), May (2), June (1), August (1), September (4), October (4), November (1); total 17 nights. Weather conditions did not interfere with the free behaviour of bats (no precipitation, strong winds, low temperatures).

2.8. Analysis of collected data

Data analysis was performed according to generally accepted methods of statistical, mathematical, tabular, graphical, cartographic and photographic processing using the following services: Microsoft Office Excel; Microsoft Office Word; Foxit Phantom; STATISTICA 8; Google Earth Pro; FastStone ImageViewer 4.9 Final.

2.9. Determination of bat activity indicators

It is a common international practice to carry out such studies to determine activity indicators in order to assess the possible impact of a project wind farm on bats objectively.

Based on the results, the activity index for all bats is determined using the following formula:

$$I_x = N_x \cdot 60/T,$$

where: I_x – activity indicator for the species or group of echolocation “x”; N_x – number of bat flights of the species or group of echolocation “x” observed during registration at the vantage point / transect (or during all registrations taken into account); T – total duration of the analyzed registration at the vantage point / transect (or all registrations taken into account), indicated in minutes.

Such calculations make it possible to characterize the periods of minimum and maximum activity of bats for further action and measures for the management of natural environmental complexes.

3. Results

3.1. Research at vantage points (Method № 1)

During expedition trips to the project area from September 2019 to August 2020, 18 detections were carried out at separate vantage points. Detailed characteristics of the obtained field data are given in table 3.

Table 3. Characteristics of the intensity of bat signals in 2019-2020 at the vantage points of the Wind Farm LLC wind park.

Total	1770	190	6.44	1706	173	6.08	3476	363	6.21

Notes: T – survey duration, min; N – number of registered signals; I_x – index of bat activity (see the Method). ND – (no detection) surveys were not carried out due to a sharp drop in temperature and lack of animal activity.

Thus, in 2019, 190 signals were received at vantage points, and in 2020 – 173. To determine the role of separate vantage points, we'll analyze the number of registered signals at each of them. We will remind that VPs 1-18 are located within the project wind park, and VP 19 is in the village of Yalta (Donetsk region, Ukraine). As we can see from the results of surveys (table 3 and figure 4), in 2019-2020 the total number of recorded signals of bats was in the range of 6-35, on average 17.22 signals for a vantage point. At five points the total number of signals was less than 10, at 8 VPs it reached 11-20 signals, two points showed a result of 21 and 22 signals and 3 VPs had more than 30 signals. The vantage points that gained maximum values were located as follows. VP 2 was next to the wind turbine generator 57, VP 8 – between the WTG 28 and the WTG 24 (in the north of Manhush and not far from the pond), and VP 10 – next to the WTG 126 near the village of Demianivka. In our opinion and according to the results of previous studies in the Azov-Black Sea region, such a relatively high activity of animals is associated with the close location of the water area and settlements where bats have the opportunity to rest and forage in the lighted areas. This assumption is confirmed by the results of detection at VP 19 near the village of Yalta, where in total 53 signals were registered.

One of the indicators of animal behaviour is the activity index, which characterizes the theoretical possibility of registering bats over a period of time. Figure 4 shows how the values of this index change at separate vantage points. However, international practice focuses on the

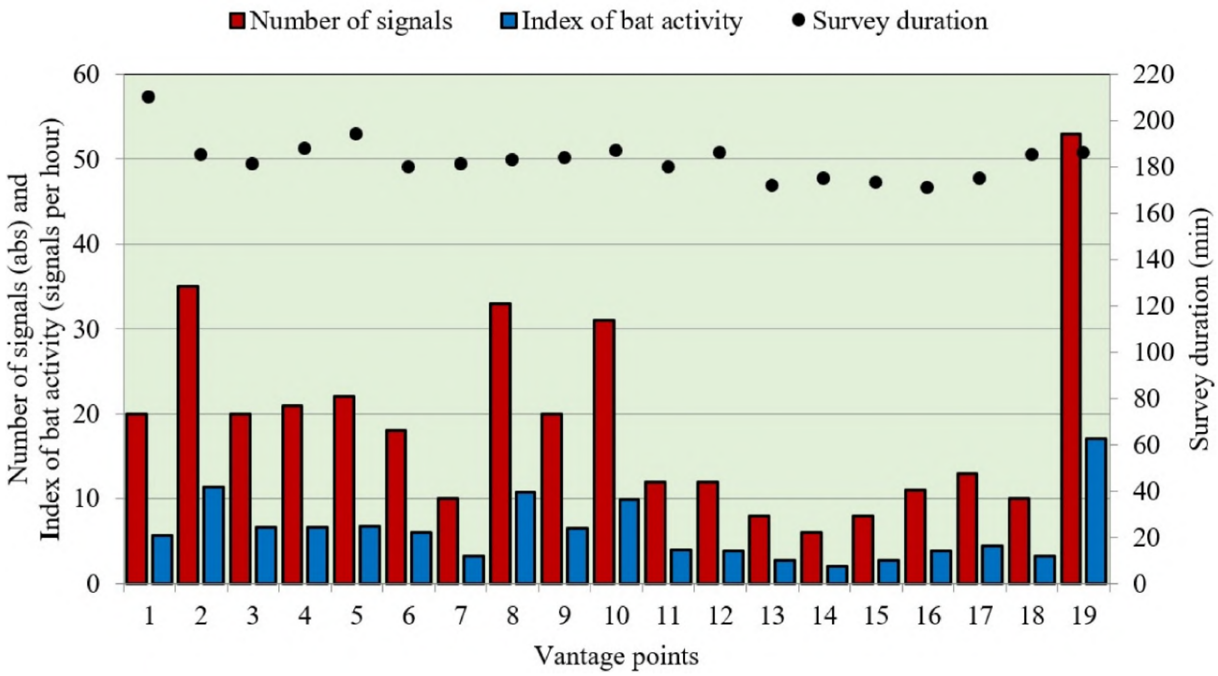

Figure 4. The ratio of the survey duration to the number of signals and the index of bat activity at the vantage points of the Wind Farm LLC wind park in autumn 2019 and in 2020.

Table 4. Monthly dynamics of vocal activity of bats at the vantage points of the Wind Farm LLC wind park in autumn 2019 and in 2020.

Year	Month	Duration, min	N	Activity index, I_x
2019	September	801	142	10.64
2019	October	779	45	3.47
2019	November	190	3	0.95
2020	March	124	0	0.0
2020	April	584	33	3.39
2020	May	405	42	6.22
2020	June	198	27	8.18
2020	August	395	71	10.78
2019-2020	Total	3476	363	M = 6.27

monthly dynamics of the bat activity index, which we calculated in table 4.

As we can see from table 4, the activity of animals, depending on the phenological phase of their annual cycle, ranged from 0 signals per hour up to 10.78 signals per hour. Such indicators are quite typical for the region and indicate the absence of natural and anthropogenic conditions for increased activity of bats within the wind farm. The maximum activity of animals was registered in August (10.78 signals per hour) and in September (10.64 signals per hour), which is also traditional for bats, as it is during this period that the first migratory movements and peak migrations for some species take place. The complete absence of signals at vantage points in March, when nighttime temperatures drop sharply in relation to daytime temperatures, is a fairly expected picture, in contrast to the relatively low values of the activity index in April –

only 3.39 signals per hour. This can be explained by fluctuations in air temperature and atypical weather conditions (at night in the second half of April, air temperatures dropped to + 3-4°C). Surveys in May and June revealed no differences from the average annual bat activity indicators in the region.

3.2. Vocal activity of bats on transects (Method № 2)

The study of vocal activity of bats on transects was carried out during 12 expedition trips in the period from November 2019 to August 2020. A total of 104 signals of bats were recorded. The amplitude of vocal activity indicators within a single transect ranged from 0 to 10 sounds.

The characteristics of the vocal activity of bats during different phases of the life cycle indicate the absence of periods of unconditional dominance. Thus, on April 13-14, 2020, a maximum of 20 signals was recorded on transects, and 10 of them were registered on the transect №1. This is not a very typical picture, as according to our retrospective data in the region in mid-April, activity indicators are not maximum. Instead, in May the activity of animals has always been high, but within the transects in the project area we can see a rather unusual picture when at night of May, 11-12, 18 signals were recorded, and the next night of May, 12-13, only 11.

The lack of results during the research in March and November is expected, because during these periods bats are not very active and located near winter roosts, which are situated more often than other places in the settlements, outside the transects. A more detailed description of the summary results of research on transects is shown in tables 5-6.

Using the methodology of research on transects, data on the activity of animals in settlements and at crossings between transects were additionally obtained. The LunaBAT DFR-1 PRO ultrasound detector did not turn off during the entire route, and the capabilities of the built-in GPS module allowed to “tie” each signal to the terrain. Thus, table 6 presents the results of research obtained not only on transects but also in adjacent areas.

As we can see from table 6, the number of signals recorded in the settlements (Manhush, Demianivka, Komyshuvate) is equal to 60, which is a high indicator compared to the short travel time of these settlements. During the crossings between the transects, 73 signals were

Total, %	43.88	25.32	30.80	100.0	

received, which also indicates the high activity of bats, but this is due to the presence of two large water bodies along which the expedition car was moving at a low speed. It is above the waters of these reservoirs that bats find a satisfactory forage base.

To reflect the level of activity of bats within the transects, we use not only absolute values, but also the calculated index of activity, which takes into account the detection time. Table 7 presents the results of such calculations. We can see that despite the largest absolute number of signals within the transect № 1 (51 signals), the activity index here is equal to 4.25 signals per hour, which is considered the average result. Within the transects № 2 and № 5, the activity of animals is the lowest – 2.5 signals per hour. A total of only 15 signals were recorded on the transect № 6 during the research period, which gives us a result of 5.0 signals per hour taking into account the transect length and the duration of detection. Although this is the highest indicator of bat activity on all transects, these values are average in terms of the possible negative impact of wind turbines on animal populations.

Speaking of the average calculated indicator of vocal activity of bats, we state that for a 46-kilometer total transect within the Wind Farm LLC wind park, 3.85 signals can be recorded per hour of detecting, which is considered to be a low number of animals.

3.3. Surveys at a stationary vantage point (Method № 3)

The method of obtaining additional information is to survey at a stationary vantage point throughout the night using the Pettersson D500x ultrasound detector. Such studies primarily provide information on the species composition of bats and their daily activity. In previous years, such studies have given us a complete list of bat species in the Azov-Black Sea region. Moreover, we have consolidated results from the territories of the Prymorsk wind farm (2 years), the Botiievo wind farm (7 years), the Orlovka wind farm (2 years), the Prymorsk wind farm-2 (2 years), the town of Melitopol (5 years), the village of Stepanovka-Persha (fragmentary), the Obytichna Spit (fragmentary). Comparison of the species composition allows us to state a fairly stable list of species, so it is absolutely correct to use such consolidated regional data to characterize the species composition and vocal activity of bats for any area of the Pryazovie region.

For example, the stationary Pettersson D500x ultrasound detector has been recording the signals of bats in automatic mode from 18: 00 to 06: 00 (for 720 minutes). A total of 14 surveys were carried out (6 in 2019 and 8 in 2020).

Analyzing data presented in tables 8-9, we state that the activity of bats in their seasonal dynamics was rather unstable. Thus, in March and November the lowest rates are traditional, but behaviour of bats in April was extremely contrast. Even within neighbouring nights of the detection we can see that in April, 13-14, 106 signals were registered, and the next night under the same weather conditions there were only 6 signals. Sharp cooling in the second part of April affected the results of the detection when on the night of April, 22-23, the device recorded only one signal. Since May, the activity of animals was traditional for the region showing maximum values in September, 2019 and August, 2020.

Surveys during all night allow to give characteristics of a daily behaviour of animals and define periods of the highest activity and periods of attenuation.

Table 8 presents data regarding moments of the first and the last registration of bats according to the duration of activity and shows the time of the median of signals (50 % of their total).

Analysis of tabular data (table 8) shows that half of the sounds heard throughout the night was recorded before 24:00, and on colder nights (March, first half of April, October and November) bats are active only during 2-3 hours, then their vocal activity decreases sharply. In August and September, the duration of the period of animal activity is the largest (more than 8 hours), but the peak of this activity is at the first 2.5-3.5 hours. Such calculations are the basis for specific well-grounded recommendations to minimize the possible negative impact of operating wind turbines and the basis for environmental management measures.

4. Species diversity of bats

To obtain information on the species composition of bats that occur in different seasons within the Wind Farm LLC wind park, three methods of data collection were used: ultrasound detection on transects, detection at vantage points and a stationary method of detecting automatically with a detector throughout the night. To these data there were added the signals obtained as a result of their recording in settlements (accidental counts), during crossings between transects and vantage points. A total of 1687 signals were obtained, 1235 of which were identified to the species, using the most modern techniques [5]. Characteristics of counts, the number of signals of certain species and their dynamics in 2019–2020 are shown in figure 5.

The species diversity of bats on the territory of the Wind Farm LLC wind park in autumn

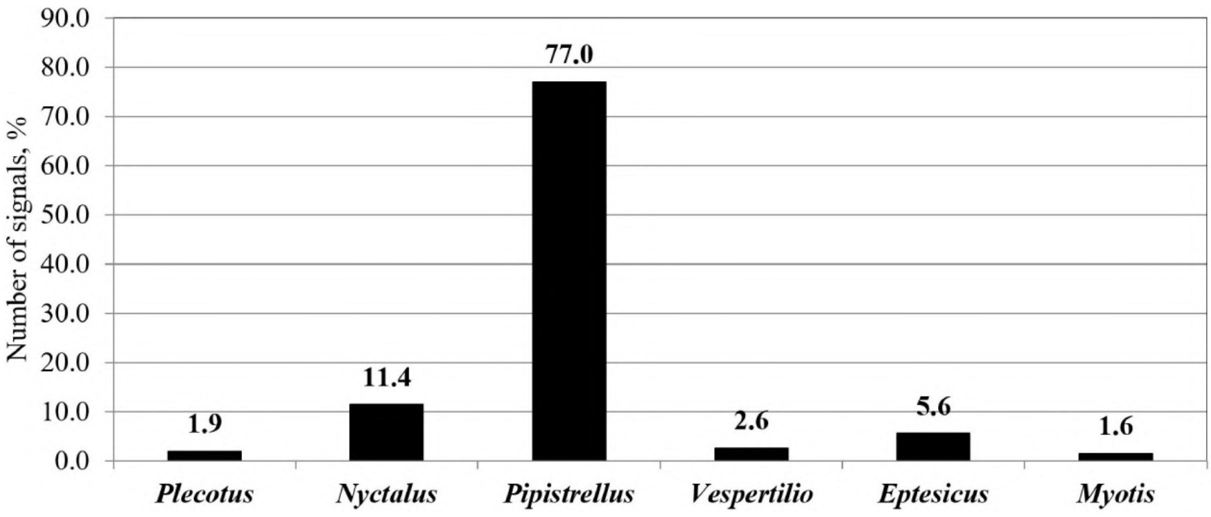

Figure 5. Species diversity of bats on the territory of the Wind Farm LLC wind park (taxonomic rank).

2019 and in 2020 is characterized by at least 10 species that belong to 6 taxonomic ranks. *Pipistrellus kuhlii*, the part of which was 61.1% of the whole complex, was the undisputed dominant. Within the group of *Pipistrellus*, there also were *Pipistrellus nathusii* (23 signals, 1.9%), *Pipistrellus pipistrellus* (28 signals, 2.3%) and *Pipistrellus pygmaeus* (3 signals, 0.2%). Bats, not identified to the species, from the group *Pipistrellus kuhlii – Pipistrellus nathusii* amounted to 10.4% (128 signals). Thus, we state that within the project area at least 4 species of *Pipistrellus* overall in 2019-2020 amounted to almost 77% of all registered signals.

The subdominant was *Nyctalus noctule* with 138 signals, or 11.2%. *Eptesicus serotinus* was

Table 9. Indicators of the bat activity index at a stationary vantage point within the project area of the Wind Farm LLC wind park.

N	Date	Number of signals	Night duration*, min	Activity index, I_x	Activity duration**, min	Activity index, I_x
1	11-12.09	107	612	10.49	472	13.60
2	19-20.09	120	639	11.27	571	12.61
3	20-21.09	155	642	14.49	413	22.52
4	11-12.10	70	711	5.91	381	11.02

13	08-09.06	95	415	12.3	267	19.1
14	15-16.08	167	521	19.23	477	21.01
Total	abs.	1087	415-805	0.11-19.23	1-571	0.62-22.52
Average	per night	77	597	8.37	368	12.7

Note: * – night duration is calculated according to the astronomical calendar as the interval between civil twilights; ** – activity duration is the interval between the first and last registration of bat signals.

recorded 68 times, which is 5.5% of the total. Other species were extremely rare and each of them did not score 3% of the total number of signals. This situation is typical for the entire south of Ukraine and the Sea of Azov region in particular [6].

In relation to all species of bats in Ukraine, the bats of the project area are less than 40%, which is a sign of relatively low species diversity.

5. Discussion

5.1. Assessment of the impacts caused by the construction and operation of the Wind Farm LLC wind park (800 MW) on bats in 2019-2020

To assess the possible impact of the wind farm during its construction, an important indicator is the index of animal activity at the project area. Tables 3-9 show the results of such calculations. As we can see, the index of bat activity calculated from the results of surveys at separate vantage points, at the stationary vantage points and within the transects was quite diverse.

Thus, with a time-limited study of the vocal activity of bats (the first 4-5 hours after twilight) using detection methods at vantage points, the activity index on average was equal to 6.27 signals per hour (lim: 0.0-10.78). During the detection on transects, this indicator was slightly lower – 3.85 signals per hour. A possible explanation for this is the presence of repeated sounds of one individual in the records of signals for 10 minutes of the detection in one place, which is almost impossible to assume when recording signals, constantly moving in the car across transects.

Stationary detections throughout the night gave a little more importance, but we should take into account some features of such calculations. Table 9 shows the results of the vocal activity of animals taking into account the time interval between the first and last registration of bats (period of activity) on the one hand, and the night duration (interval between evening and morning twilight) on the other hand. In our opinion, the latter index is more indicative, as it theoretically includes periods when bats are active but were not in the coverage area of the detector. Thus, using the method of the stationary detection, we obtained the activity index which amounted to 12.65 signals per hour for the period of activity, and 7.80 signals per hour for the dark period of the day (per night).

The estimated total activity index, taking into account the results of three research methods, was 6.93 signals per hour, which characterizes the project area as the average attractiveness for bats (table 10).

Table 10. Estimated total index of bat activity on the territory of the Wind Farm LLC wind park in autumn 2019 and in 2020.

Month	Total signals	Survey duration, min	I_x VP	I_x Transect	I_x Stationary VP	Average I_x
March	2	930	0.0	0.00	0.18	0.13

August	252	1051	10.78	6.22	19.23	14.39
September	541	2964	10.64	3.78	12.11	10.95
October	128	2494	3.47	1.78	3.11	3.08
November	26	1130	0.95	0.00	1.71	1.38
Total	1554	13454	6.27	3.85	7.80	6.93

5.2. Research area zoning in terms of bat sound density

To obtain more specific information on the territorial distribution of bats in the project area, we used the Kernel Density method for point objects. The result of applying this technique is the construction of zones of increased activity of bats, both in certain periods and for all observation seasons, on a cartographic basis.

Such zoning allows to identify places of potential risk for bats and to provide appropriate recommendations on environmental management and minimization of impacts. The Kernel Density method was described by us in previous articles [7–9].

5.3. Characteristics of the functional zones of the Wind Farm LLC wind park (800 MW)

5.3.1. The period of leaving winter roosts by animals (13-14.03.2020). In total, only one signal was registered in the vicinity of Manhush, an urban-type settlement. Bats were not registered within the wind farm, which may indicate the absence of conditions for wintering animals. According to our surveys, the activity of bats in this period depends on weather conditions. In the Azov-Black Sea region in all the areas where research has been carried out during the last 10 years, the activity of animals was minimal. The forage base for bats in this period was also depleted. We state that during the period when the animals leave their winter roosts, no negative impact of the operating wind farm is expected on them.

5.3.2. The period of the spring migration and the formation of breeding colonies (13-14.03 – 13-14.04.2020). The increase in the number of signals, as an indicator of the activity of bats, occurred in the next phenological period after the March studies – the spring migration and the formation of breeding colonies. There were obtained a total of 29 signals, which were unevenly distributed throughout the project area. Thus, 20 signals were recorded on transects within the wind farm, 6 signals in settlements and 2 signals in adjacent areas.

The highest density of signals was obtained in the following areas: 1) between the wind turbine generators № 45, 47 and 57; there is a small beam system with wet areas, which presumably attract bats; 2) northeast of the village of Ukrainka, where the nearest wind turbine generator № 17 is located at a sufficient distance to reduce the negative impact; 3) in the vicinity of the village of Manhush near the pond with a large area of open water; the nearest wind turbine generator is № 24 which is in the zone of increased signal density.

5.3.3. The period of reproduction and the peak activity of local bat populations (22.04-13.05.2020). During this period, 58 signals were recorded. Analysis of the distribution of bats and identification of areas of high signal density show us the following picture:

- the village of Demianivka and the forest in its vicinity, this zone includes the wind turbine generators № 118, 125, 126 and 157;
- with a lower density of points is the next zone which includes the branch of the village of Demianivka (southwest); no wind turbine generator entered this area;
- within the transect № 1 between the vantage points № 2 and № 3 in the wet descent there is a zone of medium density, which includes the wind turbine generators № 45 and 47.

5.3.4. The period of summer flights (08-09.06.2020). During this period, we have information about 35 signals, 14 of which were registered on transects within the wind farm. The rest of them were in the settlements and during crossings between transects. This number of signals allows to outline zones of high density of bats:

- the village of Demyanivka and its vicinity close to the wind turbine generator № 126; the wind turbine generators № 157 and 118 are also in the zone of impact;
- the vicinity of the village of Manhush near the pond with a large area of open water; the nearest wind turbine generator is № 24 which is in the zone of increased signal density.

5.3.5. The period of the disintegration of colonies, the beginning of autumn migrations and grouping in flocks (15-16.08.2020). The maximum indicators of the vocal activity were obtained during the beginning of autumn migrations – 42 signals. Analysis of the registration points of these signals allows us to show the areas of the wind farm with the highest density:

- the zone of maximum density is located northwest of the village of Manhush; the wind turbine generators № 21, 22, 23, 24, 27 and 28 are in this zone;
- the medium density zones are located on the transect № 1 (wind turbine generators № 17 and 34), the transect № 4 (wind turbine generators № 126, 127 and 130) and near the village of Demianivka (outside the wind farm and transects).

5.3.6. The period of autumn migrations and grouping in flocks (11.09 – 19.10.2019). 71 signal recorded in this period showed that the greatest density is located in the following locations:

- the vicinity of the village of Manhush, wind turbine generators № 23, 24 and 28;
- the village of Demianivka and the forest in its southern vicinity; wind turbine generators are absent.

5.3.7. The period of the last flights between roosts and the beginning of hibernation (12-13.11.2019). The decrease in the activity of bats during this period led to accidental registrations of animals. We operate with only 2 signals that did not have places of high density. Both signals were recorded outside the wind farm on the Yalta-Manhush highway. Thus, the activity of the wind farm during this period will not have a negative impact on bats.

5.3.8. Analysis of the density for the entire study period (September, 2019 – August, 2020). Thus, applying the Kernel Density technique, we will show the zones of maximum indicators of bat activity within the project area. Figure 6 shows these areas.

Most bats were registered in the north-western vicinity of the village of Manhush where the transect № 1 partially passes, and there is a large pond too. This zone can also be divided into areas (subzones) with different levels of impact on bats. The red, most dangerous subzone includes wind turbine generators № 23 and 24. The lower risk subzone (orange) includes wind turbine generators № 22 and 28. The yellow and green subzones are not endangered for animals.

The next thickening of bat registration points is located near the wind turbine generators № 45 and 47 (the transect № 1).

Also within the transect № 1 between VPs № 5 and 6 there is another accumulation of bat registration points, but this zone lies outside the wind farm and none of the wind turbine generators is planned to be installed here.

In the village of Demyanivka and around it there was another zone of average frequency of bat counts. There is only one wind turbine generator № 126, the rest of the turbines are at a safe distance.

The least risk zone is located at the beginning of the transect № 4, near the Yalta-Manhush highway. Bats were found here quite regularly, but this area lies outside the wind farm. No wind turbine generator will be installed there either.

5.4. The impact of the Wind Farm LLC wind park on the life of bats

5.4.1. Impacts caused by the construction. The construction of the wind farm is carried out in a way that involves the location of the wind turbines in the forest belts. The quality of the forest belts within the project area in some places is quite high, so site clearing for separate wind turbine generators can have a negative impact on bats, dendrophiles.

1. *Emissions of harmful substances.* In the open environment the concentration of pollutants is not higher than in industrial centers with a high level of air pollution, where bats live permanently. In addition, during the construction emissions of harmful substances will not exceed the permissible norms due to the absence of stationary sources of pollution and a relatively short period of construction work. There is no negative impact on migrating bats.
2. *Deterrence by visual effects and noise.* Periods of daily activity of builders and bats may not coincide. Humans and bats coexist in large cities, where traffic does not stop around the clock. There are equally significant sources of noise in the surrounding areas (settlements, agricultural machinery, roads). Judging by the fact that we have registered animals everywhere, deterrence by visual effects is not threatening and the impact of these factors on resident bats and migrants is at least insignificant.
3. *Occupation of the territory by the working sites and equipment.* There is plenty of space on the working sites to avoid obstacles. In addition, the distribution of working sites and equipment is insignificant and does not interfere with forage flights of the bats because of the great wind farm area and and big distances between the wind turbine generators (up to 500 m). Negative impact on bats from temporary placement of equipment is absent.
4. *Loss of breeding sites.* The roosts of bats, where they spend the day and breed, are usually located in settlements and farm buildings among the agrocenosis. If the buildings are

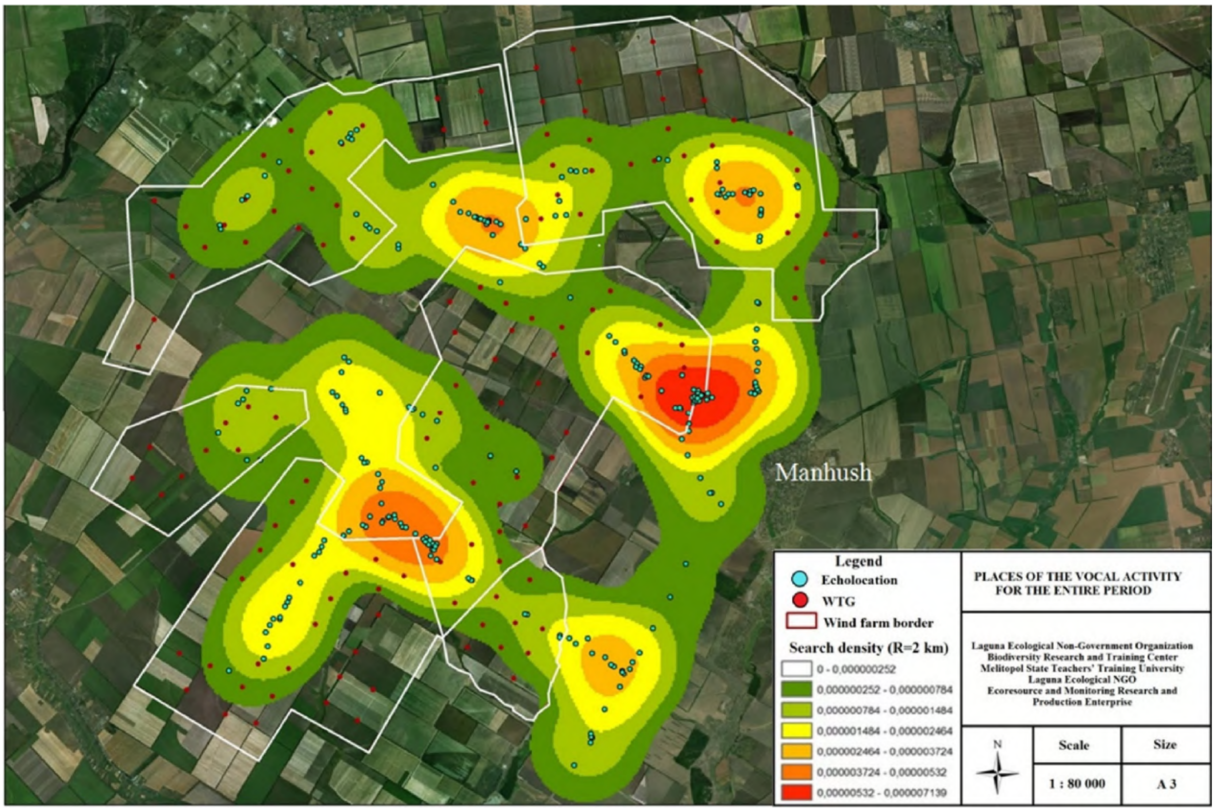

Figure 6. Kernel Density of count points of bats within the Wind Farm LLC wind park in autumn 2019 and in 2020 (12 expedition trips; 237 signals).

not subject to liquidation during the construction process, the breeding sites are not lost. Certain risks of loss of breeding sites exist for bats of the dendrophile group (Pipistrellus), when areas of forest belts will be cut down to install some wind turbine generators. This phenomenon is mosaic in nature, continuous deforestation is absent in the project, so for most bats there is an opportunity to find alternative forest belts for breeding. It is for this group of bats during the breeding period that the risk of negative impact is assessed as medium, and it is absent during the periods of migration and hibernation.

5. *Loss of individuals of certain species.* The space on the sites is quite enough to bypass the obstacles by the animals that have echolocation. As a rule, forage migrations were registered at altitudes not exceeding 20 m and this altitude interval is safe for bats. Migrants are represented by widespread species and the loss of individuals, which in one way or another occurs in nature, will not lead to a critical status of populations as a whole. The negative impact on migrating bats is characterized as low. Thus, the impact on bats during the construction of the wind farm is from medium to minimal, and after this short period it is absent.

5.4.2. Impacts caused by equipment

1. *Long occupation of the territory and change of characteristics of the territory.* Among the equipment used in the construction of the wind farm and its infrastructure, heavy machinery (trucks, tractors, cranes, etc.), cars, and storage of construction materials can impact on bats. These types of work are accompanied by the formation of large amounts of dust, which

can be an obstacle for bats if the work is carried out at night. According to our surveys, the night work at the already built megawatt-class wind farms lasted a short period of time and was limited to small sites. Thus, the negative impact on bats during foraging had signs of medium level, and for breeding individuals it was insignificant.

2. *Deterrence by mast vertical structures.* A high-voltage power transmission line runs near the wind farm. Visual and detective surveys did not reveal a negative impact on migrating bats from both vertical structures (supports) and horizontal ones (electric wires). The influence of dense power transmission lines in settlements, which are the main habitats of bats, has not been recorded either. There is enough space on the wind farm and in the buffer zones to bypass the barriers by animals that have echolocation and are easy to maneuver amid obstacles. There is no negative impact on bats that make forage and migration flights.
3. *Barrier effect and obstacles for flight.* Bats do not have a well-established narrow forage migratory corridor, their movements depend more on a satisfactory forage base (insects), which, in turn, is directly related to crop rotations in agrocenoses. There is a certain element of a chaotic movement of bats through the wind farm. The distance between the wind turbine generators is from 550 meters and more, and does not constitute any barrier effect for small animals, like bats, which have echolocation and are easy to maneuver even in forests. Obstacles to the flight from the construction of the power transmission line are also minimal, as the power transmission lines of different capacities are laid throughout the region, and no negative impact on the bat population has been established.

The negative impact on bats is low, and during their reproductive cycles it is absent.

5.4.3. Impacts caused by the operation of the wind farm (at the level of forecasts)

1. *Deterrence due to the rotor movement, flickering shadows, glare of light.* The analysis of researches shows that the altitude interval within the wind farm during the forage flights for the vast majority of bats does not exceed 20 m. Deterrence due to the rotor movement, flickering shadows and glare of light according to our surveys are not recorded. Thus, the negative impact due to the rotor movement, flickering shadows, glare of light effects is estimated to be low. The effect of these factors require further study, but surveys show that they are characterized as low and this is due to the small number and vocal activity of bats during the main reproductive cycles.
2. *Additional development of the territory.* Potentially, bats can use various niches in the wind farm structures and technical constructions for day roosts. The negative impact on bats is estimated to be low.
3. *Disturbance due to the night illumination.* Bats, on the one hand, avoid light and, on the other hand, hunt near lanterns which attract insects with their light. Within the wind farm, night illumination is localized at amplifying stations, offices and other infrastructure buildings, as well as at the wind turbine generators (at altitudes above 100 m). In the settlements it is proved that near the illuminated areas the vocal activity of bats is higher than near the unlit ones. Disturbance due to night illumination is unknown. The negative impact on bats is low.
4. *Collision with wind turbine generators.* The low number of bats in the local group, insignificant forage movements on the territory of the wind farm, the lack of transit migration routes give grounds to assess the impact of this factor as low. However, according to the literature, cases of collisions of bats with wind turbine generators are known for the entire species spectrum of animals encountered in the study area, and this makes them potentially dangerous animals. After the commissioning of the wind farm, the effect of this factor should be studied additionally. The probability of collisions of bats with wind turbine generators is prognostically left at the average level of danger.

6. Conclusion

Thus, a comparison of the data obtained in autumn 2019 and in 2020 concerning the study of foraging behaviour and vocal activity of bats allows us to draw the following conclusions:

1. The total number of registered voices is 1554 signals, 695 of which are recorded in 2019 and 859 in 2020.
2. Index of bat activity depending on the research methodology ranged in the interval 3.85 (on transects) – 7.80 (at a stationary vantage point), and was in average 6.93 signals per hour (for comparison: Myrne wind farm (the Kherson region) – 7.14 signals per hour; Kalanchak wind farm (the Kherson region) – 6.62 signals per hour; Overianivka and Novotroitsk wind farms (the Kherson region) – 10.53 signals per hour; Prymorsk wind farm (the Zaporizhzhia region) – 7.07 signals per hour; Prymorsk-2 wind farm (the Zaporizhzhia region) – 8.10 signals per hour; Botiievo(the Zaporizhzhia region) – 6.70 signals per hour; Zaporizhzhia wind farm (the Zaporizhzhia region) – 8.30 signals per hour).
3. Forage and migratory behaviour of bats, calculated by determining the index of their activity, shows the average values.
4. The distribution of bats in the project area, defined as the difference between the number of recorded signals in individual habitats, indicates the attraction of animals to settlements and open waters, while the wind farm area is less attractive to them.
5. The species composition of bats, identified for 1235 signals registered in the territory of the projected wind farm, is stable and represented by widespread at least 10 species belonging to 6 taxonomic ranks. The undisputed dominant was Pipistrellus kuhlii, the part of which was 61.1% of the whole complex. According to the Eurobat commission, this species is in the group with a low risk of collisions with wind turbine generators, while Nyctalus noctula with 138 signals, or 11.2% of the whole bat complex, has a high risk of falling under a moving rotor.
6. There are no species of the category “endangered” among the identified bats. The distribution areas of all species of the project area are quite wide. Within the Wind Farm LLC wind park there are no endemic species or unique habitats of their existence.
7. Analysis of the bat distribution, carried out by the Kernel Density method, revealed several areas of the increased activity of animals. Most bats were attracted to the settlements (Manhush, Demianivka, Ukrainka) and to open waters. There were revealed some wind turbine generators near which the implementation of minimization measures is required. In total, according to forecasts, there are 10-16 such wind turbine generators within the Wind Farm LLC wind park 800 MW.

We state that the construction and operation of the Wind Farm LLC wind park at the level of objective forecasts will not have a negative impact on the bat populations of the study area.

Monitoring the state of bats in the project area both during the construction of the wind farm and its operation is mandatory for the development and implementation of measures to minimize the possible negative impact on bats.

Abstract. Global climate change affects the conditions of ecosystems. However, the nature of changes induced by climatic factors remains unknown due to the complex nature of climatic transformations. The global trend of temperature increase is associated with an increase in precipitation and changes in its rhythm. The dynamics of plant communities under the influence of climate occurs against the background of natural successional phenomena. The aim of the study is to develop methodological approaches in order to identify aspects of vegetation variability that are caused by global climate change and give them an ecological interpretation. Geobotanical descriptions of vegetation in steppe ecosystems were carried out over the last 20 years. Exactly in this period dramatic climatic changes were observed, which allows to compare climatic and vegetation trends. For ecological interpretation the results of ordination of plant communities were explained with the help of phytoindication scales. Plant communities exhibit dynamics that are driven by endogenous and exogenous causes. These aspects of community dynamics were differentiated using the ordination procedure as different ordination axes. The axes that reflect endogenous dynamics were described using temporal variables. The axes that reflect exogenous dynamics were described using phytoindication scales. The phytoindication scales made it possible to assess the ecological directions of plant community transformation under the influence of global climate change. The transformation of the plant community under the influence of global climate change is inconsistent with the concepts of desertification. The revealed temporal patterns of the plant community have a complex and multidirectional trajectory. The plant community studied over the twenty-year investigation period exhibited a dynamic that is a superposition of two processes that are driven by the temperature and precipitation. The temperature trend is directional and reflects the tendency of global warming. This trend is accompanied by an increase in species richness and projective cover of the plant community. At the same time, thermophilicity and continentality of the community increase against the decrease of soil trophic status, acidity increase and soil carbonation decrease. Obviously, along with the mineralization of organic matter, the soil decarbonization can also be the cause of increased carbon dioxide emission into the atmosphere as a result of global warming. The trend, which is regulated by precipitation, is oscillatory. This trend changes the regime of moisture, light and cryoclimate of the plant community.

1. Introduction

The main feature of today's climate is increased global warming since the second half of the 1970s [1]. The global air temperature is predicted to increase steadily through the end of this century due to continued increases in greenhouse gases such as CO_2, and changes in land use such as deforestation of natural forests [2]. Due to global climate change, which affects the transformation of regional climate and the value of individual meteorological variables, the average monthly air temperature in Ukraine over the past decades differs from the values of the climatic norm. The air temperature has become higher for most months and for the year as a whole, only in September, November and December it decreased insignificantly [3]. The amount of atmospheric precipitation for the territory of Ukraine has not changed significantly, but the nature and intensity of precipitation has changed markedly [3]. The variability of precipitation dynamics affects the productivity of plant communities [4–6]. Recently, the number of cases where half or a month's worth of precipitation falls in a few hours has increased [3]. The forms of ecosystem transformation as a consequence of global climate change are accelerated desertification [7, 8]. The change of water regime in steppe ecosystems strongly affects ecosystem functioning, productivity and photosynthetic capacity [9–12]. The intensification and increased frequency of extreme climate change events, including high summer temperatures and increased precipitation variability, threaten sustainable development in semi-arid and arid regions through both biophysical and socioeconomic factors [13]. The stability of terrestrial ecosystems will be further threatened by the increasing frequency and severity of extreme climatic events [14, 15]. An increase in air temperature and uneven distribution of precipitation, which is stormy, localized in the warm season and does not provide an effective accumulation of moisture in the soil, can lead to an increase in the frequency and intensity of droughts. Changes in precipitation frequency, intensity, and pulse size, as well as seasonal changes in precipitation, affect arid ecosystem functions, including carbon flux [16–19], water exchange, and plant physiological status [20]. There are also changes in the values of extreme (maximum and minimum) temperatures. The minimum temperature has increased in almost all months and in the whole year. In the secular course of the maximum temperature in winter months, especially in January, there was a tendency to its growth. In summer months and for the year as a whole, the trend of maximum temperature change in the trend is insignificant, but in recent years, the maximum temperature increases. The particularly affected areas include grassland and desert ecosystems of semi-arid and arid areas [21–23]. A loss of biodiversity is an obvious consequence of climate change [22, 24]. The warming is evolving according to positive feedback dynamics. The combination of heat waves and variability in precipitation dynamics affect carbon exchange [25]. The global climate change is initiated by an increase in atmospheric concentrations of greenhouse gases, but the warming continuously stimulates the emission of carbon dioxide into the atmosphere [26–28]. An increase in air temperature leads to soil evaporation [8, 29–31]. The intensification of heat waves and abnormal precipitation led to the functional and structural degradation of particularly sensitive terrestrial ecosystems. The heat waves affect the intensity of plant growth [32–34]. Consequently, a water deficit occurs, further exacerbating ecological vulnerability and sensitivity and reducing resilience to rapid degradation in steppe regions [35,36]. An increase in precipitation in the steppe zone can improve the carbon balance, thereby mitigating the negative effects of a warming climate [37, 38]. The warming climate and increased precipitation variability can regulate the function and structure of ecosystems in steppe ecosystems. The transition from vegetation dominated by grasses to vegetation dominated by shrubs or tree species can be predicted [24]. The most important indicators of terrestrial ecosystem function are the primary production of aboveground plants and the activity of soil microorganisms [39]. The activity of soil microorganisms, which transform the biomass created by plants, determines the intensity of carbon sequestration and carbon dioxide emission into the atmosphere. The precipitation quantity affects the condition of the soil biota. Biomass, activity and composition of the microbial community are sensitive to the effects of environmental factors [40–42]. The water balance and temperature regime affect the functional state of soil biota [39, 43–45]. The biomass of soil biota decreases with warming [46–48], but increases with increased precipitation [49]. Estimating the balance of carbon, water, and energy in terrestrial ecosystems under conditions of climate change is possible only if the importance of microbial activity in ecosystem processes is elucidated [50].

2. Research aim and objectives

Grasslands provide many critical benefits to humans, including forage for livestock, food, biodiversity, carbon storage, and recreation [51]. Studies of the long-term dynamics of plant communities in steppe ecosystems are largely absent, and such studies are urgently needed to assess ecosystem responses and feedbacks to climate change [52].

The aim of the study is to develop methodological approaches in order to identify aspects of vegetation variability that are caused by global climate change and give them an ecological interpretation.

3. Material and methods

The Stone Graves reserve is located on the border between Donetsk and Zaporozhye regions, near the village of Nazarovka of Mariupol district on the Priazovsky upland, in the upper reaches of the Karatysh river, which is a tributary of the Berda river. The Stone Graves reserve has an area of about 400 hectares, of which almost 300 hectares are part of the Donetsk region and 100 hectares are part of the Zaporozhye region. The most part of the reserve area, about 200 hectares, falls on powerful granite rocky outcrops of Azov-Podolsky crystalline massif, towering above the surrounding steppe, which is the largest intrusive area in Donbass and Azov regions [53]. The rock outcrops are represented by the Western and Eastern ridges with absolute height of separate tops up to 100 m. According to landscape-geochemical zoning, the landscapes of the Stone Graves reserve are localized on eluvio-deluvium of crystalline rocks. According to the generic classification, these are loess uplands tending to erosion processes, so the migration of chemical elements here is weak and occurs when soils are washed away. The landscapes of the territory are characterised as self-purifying. The reserve is located in an area of elevated plains, where upward and downward radial migration of chemical elements takes place. The accumulation elements are Mn, Co, Sn, and the removal elements are Pb, Zn, Ni. Soil-forming rocks are clay and clayey sediments and loamy rubbly formations on eruptive and metamorphic rocks. The soils of the Stone Graves reserve are typical sparse humus black earths on loess-like loam and weathering products of crystalline rocks, which are the most productive along the bottom of the depression between two parallel ridges of rocks. Soil thickness decreases along the rock slopes along with disappearance of loess rocks and increase of area of weathering products of crystalline rocks to the day surface. The bottom of the basin between the ridges is dissected by gullies [54].

The stationary plot No.1 was created on July 14, 2000 to study the phenological development of steppe vegetation. The plot is located on the slope of 3° of eastern exposition along the upper edge of the amphitral catchment of the central gully of the inter-ridge trough at its headwaters. The geographic coordinates of the area center are N 47.310° E 37.076°. The elevation is 179 m above sea level. Vascular plant species lists were recorded for each 10 m × 10 m (the area is 100 m^2) sampling polygon along with a visual assessment of species coverage using a Braun-Blanquet scale [55]. The projective cover of plant species was measured at soil level. Plant taxonomic names follow the Euro+Med Plantbase resource (`https://europlusmed.org/`). Meteorological data obtained from NOAA climate data using the rnoaa package [56] for a language and environment for statistical computing R [57]. Based on the data obtained, indicators such as average spring temperature (figure 1, a), average temperature of the coldest month of the year (figure 1, b), and the amount of precipitation during the spring period of the year (figure 1, c) were calculated. The range scales values according to Y. Didukh [58] were used for phytoindication. Further, for phytoindication of environmental factors, we used the ideal indicator method of G. Buzuk [59]. Statistical calculations were carried out using the software Statistica 12.0 [60].

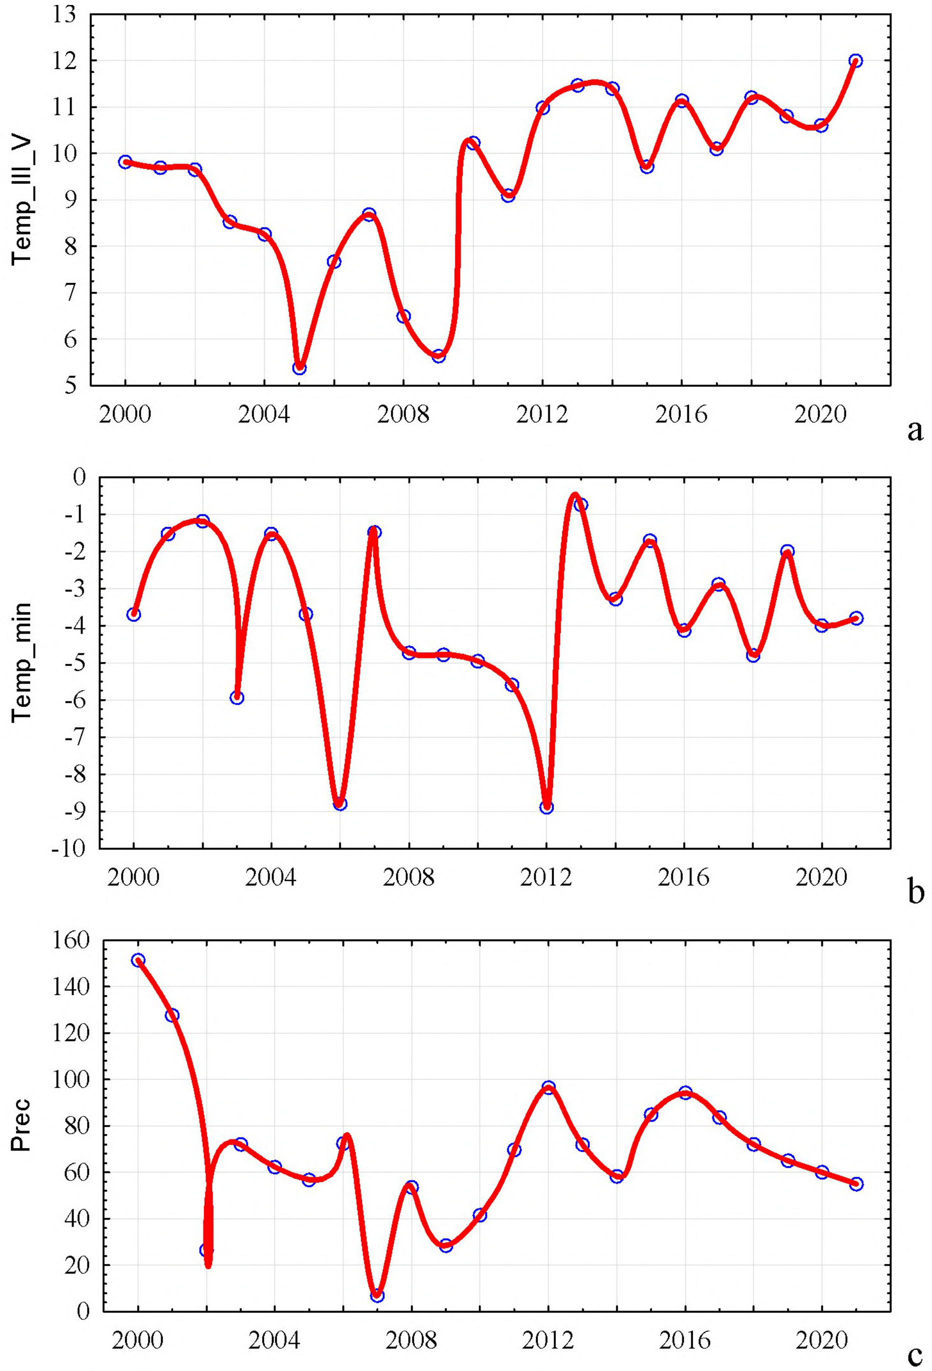

Figure 1: Dynamics of meteorological parameters during the study period 2000–2021: (a) average temperature during the spring period, °C (March-May); (b) the average temperature of the coldest month of the year, °C (January or February); (c) total spring precipitation (March–May), mm.

4. Results

The 79 plant species were found within the study area during the study period (table 1). The number of species in the community varied between 51 (in 2007) and 66 species (2014 and 2015). The number of species increased over time. There was a positive correlation ($r = 0.77$, $p < 0.001$)

between the number of species in the community and the order of years. The regression analysis revealed that the average rate of increase in the number of species in the community was 0.62 species per year. The projective cover of the community ranged from 70 to 85%. The projective cover showed an increasing trend. A statistically significant correlation ($r = 0.42$, $p = 0.05$) was found between the projective vegetation cover and the order of years. The projective cover increased on average by 0.4% with each year.

The phytoindication score of soil water regime ranged from 3.69 to 3.98 (table 2), corresponding to plant available moisture of 32–33% (figure 2). This indicator did not show a stable linear trend of variability over time, as indicated by the lack of statistically significant correlation with the order of years (r = –0.04, p = 0.85). It depended on spring precipitation (r = 0.64, p = 0.001) and on precipitation in the preceding year, which can be described by regression equation: Hd = 32.0+0.00754 $Prec_{spr}$ + 0.00178 –$Prec_{prev}$ ($R^2_{adj} = 0.47$, $p < 0.001$), where $Prec_{spr}$ is the total spring precipitation in current year; $Prec_{prev}$ is the total precipitation in preceding year. The amount of precipitation that the region receives on average is sufficient to accumulate significant water reserves, if the soil properties allow it. The soils on which the community under study has formed have a very low water-holding capacity, so the plant species that make up the community are highly xerophilous.

Table 2: Descriptive statistics of phytoindicator estimates of environmental factors.

Ecological factor	Mean±st.error	Minimum	Maximum	CV, %
Soil water regime (Hd)	3.81±0.019	3.69	3.98	2.30
Variability of damping (fH)	5.93±0.043	5.47	6.24	3.38
Soil acidity (Rc)	9.75±0.067	9.18	10.49	3.25
Total salt regime (Sl)	7.45±0.079	6.80	8.34	4.98
Carbonate content in soil (Ca)	11.46±0.033	11.22	11.73	1.36
Nitrogen content in soil (Nt)	3.22±0.086	2.68	3.98	12.54
Soil aeration (Ae)	5.40±0.041	4.96	5.71	3.53
Thermal climate (Tm)	10.24±0.087	9.63	11.29	4.00
Humidity or ombroclimate (Om)	9.94±0.075	9.25	10.46	3.52
Continentality of climate (Kn)	12.38±0.073	11.87	13.15	2.78
Cryo-regime (Cr)	8.87±0.068	8.30	9.52	3.62
Light regime (Lc)	8.91±0.007	8.87	8.96	0.39

The moisture contrast regime was characterized by indices that were in the range of 5.47–6.24. The moisture contrast regime exhibited a steady linear trend of decreasing indices over time, as indicated by a negative statistically significant correlation with the order of years (r = –0.49, p = 0.02). The soil acidity was characterized by phytoindicator scores that ranged from 9.18–10.49, which corresponded to a soil acidity pH of 6.8–7.2. The acidity decreased linearly with time (r = –0.69, $p < 0.001$). It should also be noted that acidity was negatively correlated with mean spring temperature (r = –0.47, p = 0.027). The overall salinity regime was characterized by phytoindication scores, which were in the range of 6.8–8.34, which corresponded to a salt content of 0.031–0.060% in the soil solution. The overall salinity regime showed an increasing trend with time (r = 0.68, p = 0.001) and was also positively correlated with mean spring temperature (r = 0.62, p = 0.001). The content of carbonate in soil was characterized by phytoindicator indices, which were in the range 11.22–11.73, which corresponded to the content of carbonate in soil 8.6–11.3%. The carbonate content in soil showed a decreasing trend with time (r = –0.71, p = 0.001), and was also negatively correlated with mean spring temperature (r = –0.62, p = 0.001). The soil nitrogen content was characterized by phytoindicator indices, which were in the range 2.68–3.98, which corresponded to the content of plant-available nitrogen in the soil of 0.044–0.11%. The soil nitrogen content showed a decreasing trend with time (r = –0.87, p = 0.001), and also negatively correlated with mean spring temperature (r = –0.74, p = 0.001). The soil aeration regime was characterised by phytoindication indices, which were in the range 4.96–5.71, corresponding to an aeration porosity of 65–77%. This index was stationary over time.

The thermal climate was characterised by phytoindicator indices that ranged from 9.63–11.29, which corresponded to a radiative balance of 2016–2250 MJ m^{-2} year^{-1}. The radiation balance estimate showed an increasing trend with time (r = 0.66, p = 0.001) and was also positively correlated with mean spring temperature ($r = 0.65$, $p = 0.001$). The ombroclimate was characterised by phytoindicator indices that ranged from 9.25–10.46, corresponding to a difference between precipitation and evaporation of –722 – –485 mm. The ombroclimate assessment was positively correlated with the average temperature of the coldest month ($r = 0.41$, $p = 0.05$). The continentality was characterised by phytoindication indices, which were in the range 11.87–13.15, corresponding to a continentality index of 159–172%. The continentality score showed an increasing trend with time ($r = 0.75$, $p = 0.001$). The phytoindication of the cryo-climate score corresponds to the average temperature of the coldest month –6 – –3°C and correlates positively with these meteorological indices measured instrumentally ($r = 0.51$, $p = 0.016$). Lighting regime was characterised by scores of 8.87–8.96. The lighting regime was stationary during the study period.

The principal component analysis identified two components, which together describe 53.1% of the variation in the original variables (figure 3). The principal component 1 describes a trend of increasing number of species in the community, thermal regime, soil salinity and continentality over time and decreasing indicators of plant nitrogen nutrition, carbonation and acidity. The principal component 2 reflects a positive effect of precipitation and temperature in the coldest month of the year on moistening, ombrorheme and cryoregime and a negative effect on aeration and lighting regimes.

5. Discussion

In dynamic ecosystems, such as steppes, environmental fluctuations determine community composition [61, 62]. Grasslands are also affected by ongoing climate change [63–65]. Anthropogenic impacts result in significant changes in environmental factors that affect the composition and functioning of plant communities [66]. Identifying the causes that drive changes in the structure of plant communities is critical because the composition of plant communities affects important ecosystem functions and services [67,68]. Fluctuations are short-term changes in the structure of plant communities on the scale of several years [69, 70]. In contrast to succession, these changes are characterized by the absence of long-term trends in the structure of communities in one direction or another, the possibility of returning to a state close to the initial one, and the absence of significant changes in the floristic composition. Most often fluctuations are considered as changes occurring within one solar cycle (about 11 years) [71]. Fluctuations can be caused by various factors. The fluctuations can be ecotypic, anthropic, zoogenic, phytocyclic, phytoparasitic [72]. The ecotopic fluctuations are caused by variability in meteorological and hydrological conditions [73, 74]. Ecotope changes can cause a chain of different mechanisms of impact on vegetation cover. Drought is associated with higher temperatures and increased salinity in arid regions [75–77], and can also cause mass development of locusts that consume a significant portion of organic matter [78]. Drought has the greatest impact on plant communities developing on sparse soils [79–81].

The potential to interpret and predict the response of plant communities to global change is complicated by many factors, such as the type of driver of global change and the ecological context [82–84]. The phytoindication of the moisture content indicates that conditions within the study area are favourable for peroxerophytes and xerophytes. These conditions are characteristic of steppe herbaceous communities on rocky ground. In conditions of precipitation deficit on stony soils petrophytic communities are formed which specificity consists in high level of species and syntaxonomy endemism [53]. The precipitation levels observed in the study area can allow for the formation of significantly larger water reserves. However, the unfavourable water-physical properties of soils formed on rocks do not allow for the accumulation of water in larger quantities. As a result, the plant community is formed by species that are able to tolerate water deficits. The phytoindication assessment of moisture depends on the precipitation conditions of the current and previous year. The ecological structure of the plant community also changes according

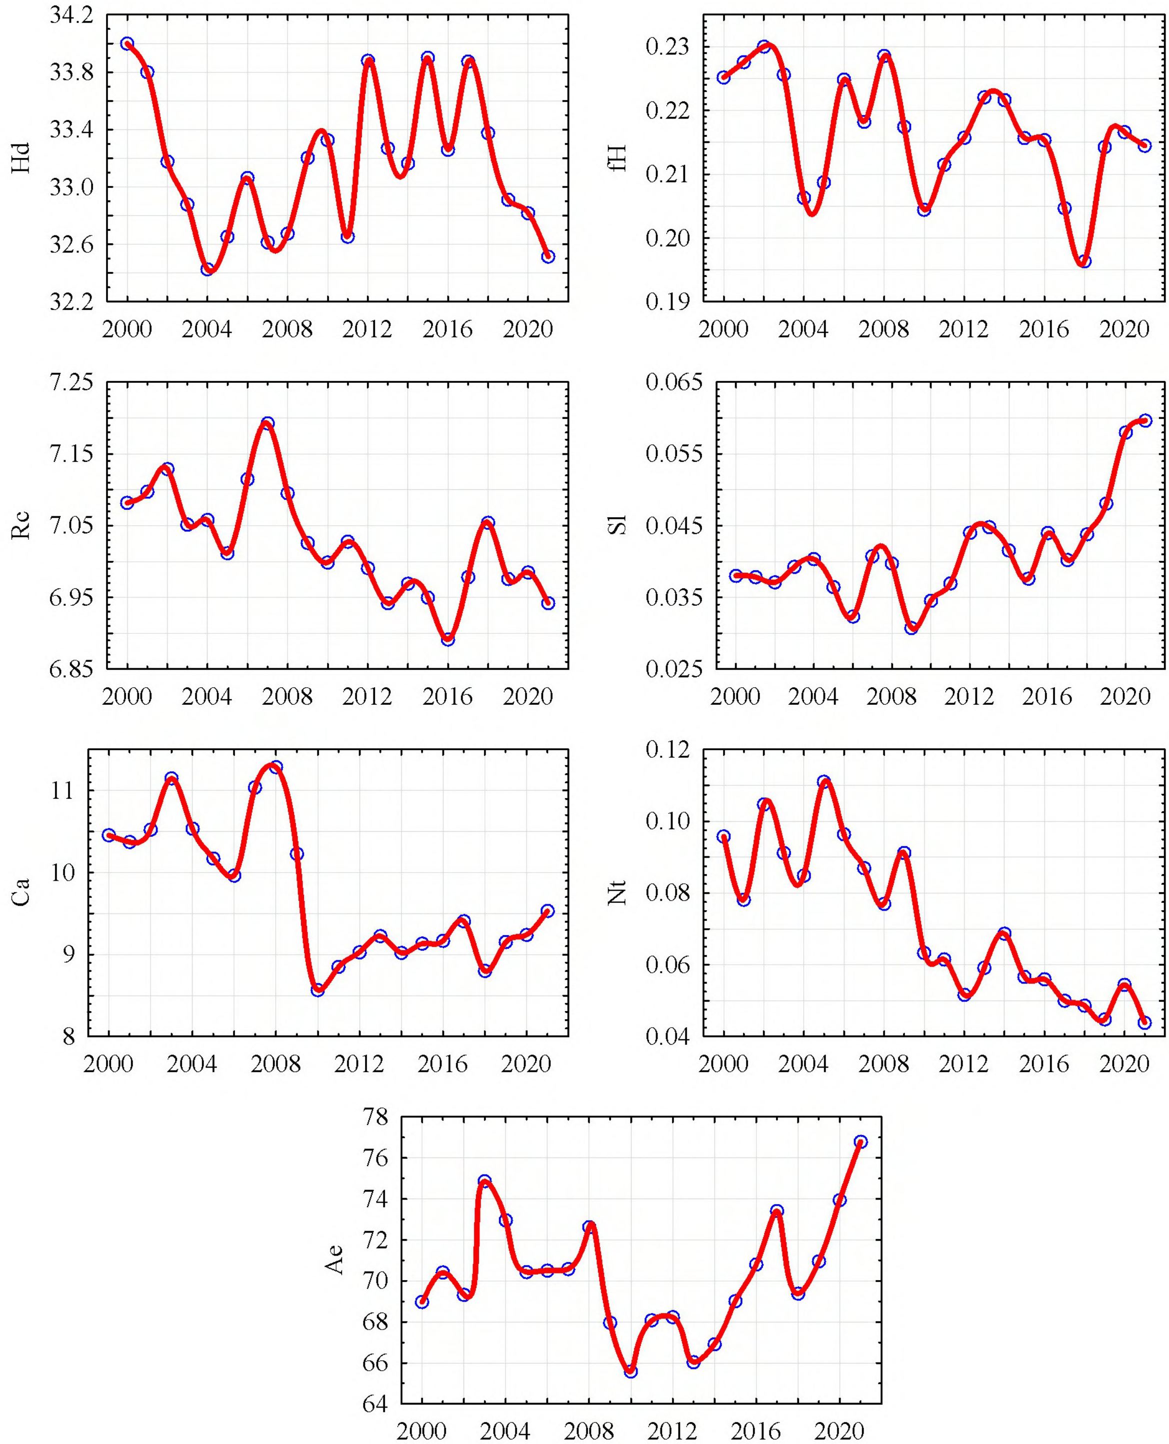

Figure 2: Dynamics of soil environmental factors assessed by phytoindication: Hd is the plant available soil water content, %; fH is the index of variability of damping, which varies from 0 to 0.5; Rc is the soil acidity (pH); Sl is the salt content in the soil solution (mg/l); Ca is the carbonate content in soil (%); Nt is the content in soil plant accessible forms of nitrogen (%); Ae is the aeration porosity (%).

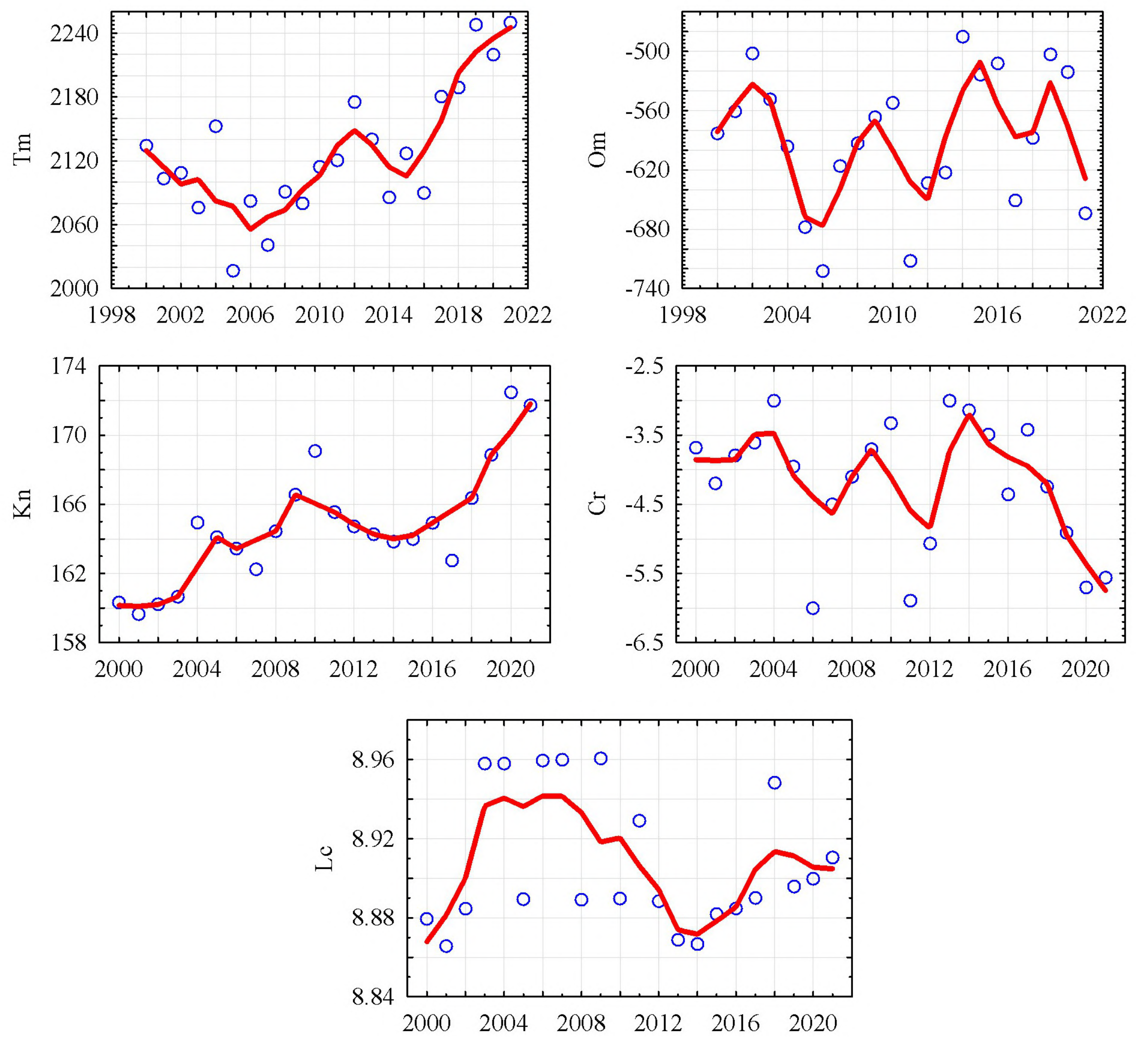

Figure 3: Dynamics of climatic factors assessed by phytoindication: Tm is the radiation balance (m^{-2} $year^{-1}$); Om is the humidity index determined as a difference between annual precipitation quantity and evaporation (mm); Kn is the index of continentality (%); Cr is the mean temperature of the coldest month of the year (C); Lc is the light regime in 9-grade scale.

to precipitation trends. These changes have a fluctuational character, as they do not show a stable directional trend. The level of soil moisture is naturally inversely correlated with soil aeration conditions. Accordingly, the level of soil aeration does not show a directional trend. Rainfall levels in the spring are coordinated with the temperature of the coldest month of the year. The warmer the winter in a given year, the better the soil moisture conditions will be. This relationship is the reason for the correlation of phytoindication estimates of moisture, ombroclimate and cryoclimate. This relationship is the reason for the correlation between the phytoindication estimates of cryoclimate and instrumental temperature measurements. Higher temperatures in winter months and higher precipitation contribute to lower light levels in the plant community. Obviously, these factors contribute to an increase in the phytomass of the plant community and thus a decrease in its illumination. Once again, the variation in precipitation and temperature during winter time did not show a directional temporal trend. These variables are described by variation in principal component 2, which is characterised by autocorrelation with

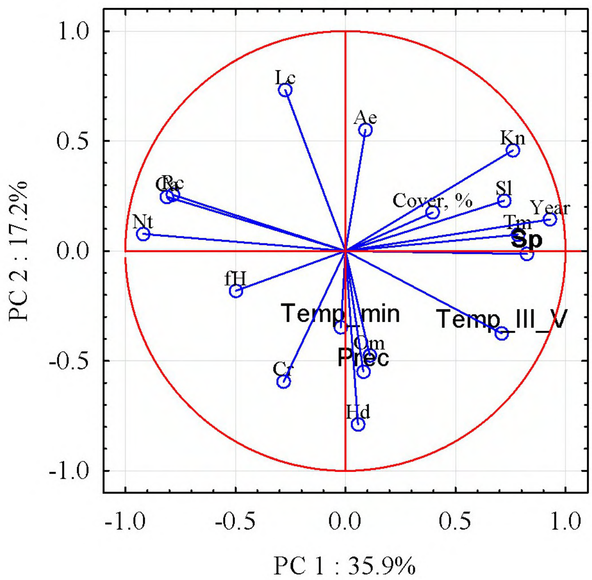

Figure 4: Principal component analysis of variation in phytoindicator estimates of environmental factors, species richness, projective cover of the plant community, average temperature of the coldest month of the year, average temperature and amount of precipitation in spring.

lags of 1, 13 and 14 years (positive autocorrelation) and 6–7 years (negative autocorrelation). The presence of an oscillatory process is fully consistent with the notion of plant community dynamics as a fluctuation. The species composition of plants in a dry grassland in Central Europe showed marked dynamics from year to year in response to weather conditions in the previous two years. These changes in the community are undirected and have contributed to the stability of this community, which has not changed significantly over the past 90 years. However, increased drought frequency due to ongoing climate change may lead to directional changes with the expansion of ruderal species [69].

Environmental changes and resource availability are key mechanisms that support biodiversity [85–87]. Weather fluctuations prevent competitive exclusion between species co-occurring at a site and, at the same time, allow species with different strategies and from different climatic regions to co-exist at the edge of their ecological niches [61]. Differences in response to climatic extremes between species with different ecological strategies can lead to non-equilibrium coexistence due to stochastic fluctuations between years [88]. When weather conditions are favourable for a certain type of species strategy, other species may be reduced and confined to small areas partly because of direct response to the environment and partly because of competition. As soon as the weather shifts to a state favourable to other types of strategies, species with those strategies spread out again, compensating for their losses in the previous period of time [85]. This is particularly true for dry grasslands on shallow, stony soils with low water retention, which are characterised by considerable species turnover in response to weather fluctuations, but remain stable in the long term [89].

Other ecological factors and species richness of the community show a consistent directional trend of change over time. Climate change is considered a leading threat to biodiversity because it may increase the rate of species extinction. In addition to extinctions, the distribution of species is predicted to shift as a result of variations in temperature and precipitation around the world [90]. Climate change is also expected to increase weather fluctuations within and between successive years. Extreme climate events and increased seasonal variations have already been reported around the world [91]. This trend is driven by directional changes in temperature regime and is described by principal component 1. After extracting the linear trend, principal component 1 did not exhibit an oscillatory component. Over the study period, the species richness of the community and projective cover increased together with the thermoclimate, continentality and salinity of the soil solution. Also such indicators as the level of nitrogen compounds supply to plants, acidity, moisture regime variability and soil carbonate content decreased throughout the study period. Variations in the availability of resources, such as atmospheric carbon dioxide, nitrogen, and precipitation patterns, can have significant consequences for the structure of plant communities [92].

Biotic processes, such as shifts in competitive dominance or susceptibility to herbivory, and abiotic factors, such as environmental filtration, affect the richness and composition of plant communities at local scales [93–95]. The conditions of soil moisture variability are favourable for hemicontrastophobes, which are characteristic of ecotopes with moderately uneven moistening of the root-containing soil layer, which is completely soaked by precipitation only in some rainy seasons. The steppe zone of Ukraine is generally characterised by uneven precipitation and rainfall that is of a torrential nature. Such meteorological features lead to an extremely uneven soil moisture regime against a background of water scarcity.

Community composition and change in richness varies from place to place depending on the environment, as well as fluctuations in weather conditions, combined with inherent population and community dynamics over time [96]. Such dynamics can best be understood with detailed long-term observations at stationary plots [69,97,98]. The phytoindication method estimates soil acidity as being in the pH range of 6.8–7.2. This agrees with the results obtained experimentally. The acidity of soils in the reserve is pH7.0 and ranges from pH5.9 to 7.6 [54]. This result confirms the high accuracy of phytoindication assessments of environmental factors, which can be achieved by studying multi-species plant communities. It is legitimate that the decrease in soil acidity was accompanied by a decrease in soil carbonate content. It should be noted that carbonates are an important carbon reserve in the soil. The decrease of carbonate content in the soil due to global warming is an important source of its supply to the atmosphere. It is obvious that decarbonisation of soil is accompanied by transition of insoluble calcium and magnesium salts into soluble forms that is accompanied by increase in indicators of mineralisation of a soil solution. The mineralisation of the soil solution is not significant, so this factor cannot act as a limiting factor. Increased environmental stress can have various effects on plant community composition, either shifting or increasing niche availability. The repeated removal of plant material by haying can increase species richness by increasing light availability and creating favorable conditions for species that can tolerate aboveground removal. Increased drought or temperature stress can reduce the species richness of plants because many species will not be able to persist under these new conditions [99, 100].

Empirical data and theoretical evidence suggest that the response of ecosystem functions attenuates as the number of simultaneously introduced factors increases due to the leveling out of positive and negative effects on functions such as productivity and nutrient cycling [101,102]. Adding resources (e.g., nutrients) is predicted to reduce plant species richness and change plant community composition due to alterations in competitive interactions between species for remaining limiting resources (e.g., water or light) [103, 104]. The nitrate content of the reserve's soils is 179 µg/g and varies between 93 and 348 µg/g [54]. A decrease in the supply of soil nutrients, mainly nitrogen compounds, may be a factor in stimulating an increase in the species diversity of the community. Obviously, an increase in temperature leads to an equilibrium shift in the processes of mineralisation and humification of organic matter in the soil towards mineralisation, which leads to a decrease in nutrient reserves. In turn, this transformation initiates a decrease in soil acidity and decarbonization as a consequence of increased soil respiration and destruction of soil carbonates. The combined effect of multiple transforming factors causes a stronger effect on the plant community [105, 106].

6. Conclusion

The plant community studied over the twenty-year investigation period exhibited a dynamic that is a superposition of two processes that are driven by the temperature and precipitation. The temperature trend is directional and reflects the tendency of global warming. This trend is accompanied by an increase in species richness and projective cover of the plant community. At the same time, thermophilicity and continentality of the community increase against the decrease of soil trophic status, acidity increase and soil carbonation decrease. Obviously, along with the mineralization of organic matter, the soil decarbonization can also be the cause of increased carbon dioxide emission into the atmosphere as a result of global warming. The trend, which is regulated by precipitation, is oscillatory. This trend changes the regime of moisture, light and cryoclimate of the plant community.

Abstract. The ecomorphic approach was developed to analyze the structure of natural plant communities. This method was applied to analyze the ecological structure of an artificial park plantation in an urban environment. Urban parks perform important and diverse functions in the urban environment. As anthropogenic objects, urban parks should be subject to adequate and effective management that can increase the functional value of forest plantations in the city and ensure their sustainability. In this regard, the choice of the quantitative parameters of the park plantation to be managed is crucial. We hypothesize that ecomorphic analysis can be the basis for selecting optimal quantitative criteria for parkland management. Therefore, the goal of our study was to assess the informational value of ecomorphic analysis for characterizing park plantation in urban environments. In the park, 166 species of vascular plants were found, which are represented by phanerophytes (19.9%), nannophanerophytes (8.4%), hemicryptophytes (40.4%), geophytes (11.4%), theorophytes (18.7%) and geolophytes (1.2%). Sylvants (35.5%) predominate among the coenomorphs, with slightly less pratants (22.3%), ruderants (18.7%) and stepants (14.5%). Cultivants (3.0%), psammophytes (3.0%) and paludants (3.0%) were occasionally found. The proportion of xeromesophytes and mesophytes was the highest (32.5 and 31.3% respectively). The proportion of mesoxerophytes was also relatively high (28.3%). The proportion of other hygromorphs was relatively low. The trophomorphs were represented mainly by mesotrophs (71.1%) and a slightly smaller proportion of megatrophs (22.3%). The oligotrophs were found occasionally (6.6%). Sciogeophytes (57.2%) and heliophytes (30.1%) prevailed among heliomorphs. The proportion of sciophytes and heliosciophytes was much lower (3.6 and 9.0 %, respectively). Entomophilous plant species were the most common among the vegetation cover of the park (71.7%). Anemophilous plants were significantly inferior to them (26.5%). Autogamous and hydrophilous plants were found occasionally (1.2 and 0.6% respectively). Ballistic diasporeochores prevailed among diasporeochores (39.8%). The proportion of anemochores and endozoochores was somewhat lower (27.7 and 12.0% respectively). The results obtained allow to discover the essential ecological features of the park plantation. The park plantation has many features that bring it closer to natural forests. The similarity consists in a significant proportion of silvants, shade-loving species, and mesotrophs. A significant level of anthropogenic impact can be diagnosed on the basis of information about the increased proportion of ruderants in the plant community. The differential analysis of the ecomorphic structure in the section by climorphs is of considerable value. This approach allowed to detect an increased role of the zoogenic factor in the distribution of diaspores of phanerophytes and nannophanerophytes and an increased role of wind in the dispersal of geophytes and therophytes. The role of wind is reduced in the dispersion of hemicryptophytes in the urban environment.

1. Introduction

The urban environment indirectly affects the formation of flora by changing the living conditions. There is also a direct impact through the physical destruction of plants, turning the flora into a variegated conglomerate of elements of both local and alien origin [1, 2]. Urban flora is a set of species that exist independently in the urban area. From the point of view of modern floristics it is a local flora or elementary flora of the regional level [3]. Hemeroby is the resilience of plants and their response to anthropogenic impact. From this point of view, there are two main categories [4–6]. Hemerophiles are species that respond positively to anthropogenic interference and increase their number in its presence [7]. Hemerophobes are species with a strongly negative reaction to anthropogenic factors [8–11]. A more detailed classification is also used [12], which includes the following categories. Agemerobic species are unstable to the impact of urbanization. Frequently these are forest and marsh species, which for various reasons are not adapted to life in urban conditions. Oligogemerobic species are weakly resistant. Mesohemerobic species are moderately resistant, withstand extensive anthropogenic impact. Intensive anthropogenic impact can be withstood by β-euhemerobic species. In turn, α-euhemerobic species inhabit meadows that are fertilized or in highly degraded forests and field weeds. Polyhemerobic species are typical ruderal plants, and metahemerobic species live in completely disturbed habitats [13, 14].

There are four most important types of factors of anthropogenic impact on the living ground cover in recreational forests. Mechanical damage (up to complete destruction) when trampling the ground organs of plants, including renewal buds. The least protected plants with tall succulent shoots and renewal buds located above the soil surface or at its surface suffer the most. Relatively more resistant are species with rosette arrangement of leaves, low elastic shoots, with sufficiently protected buds of renewal. Changes in physical parameters of the soil – moisture, aeration, density, temperature, etc. [15]. As a result, the normal functioning of underground plant organ systems is disrupted. In this case, the nature of underground organs is of great importance: the depth of their penetration and distribution in the soil profile, strength, etc. Cutting off ground shoots and digging up plants that attract the attention of recreationists with their decorative effect. At the same time, generative shoots of flowering plants are particularly affected, which inhibits the process of natural reproduction of the species' cenopopulation. Berry picking, harvesting of food or medicinal raw materials. Obviously, the last type of anthropogenic impact with rare exceptions (for example, mass harvesting of cranberries) does not have a decisive impact on forest ecosystems of urbanized areas. However, it is impossible not to take into account the existence of this factor.

Stress is a process of internal changes in the body systems in response to any strong or prolonged environmental impact [16, 17]. There is a broader interpretation of this term. Stress is a nonspecific response of the organism to any requirement presented to it, accompanied by the restructuring of protective forces [18]. From the point of view of this concept, the change in the nature of plant growth and development can be considered as an adaptation syndrome, which characterizes the degree of restructuring of the plant organism under the influence of anthropogenic pressure, as a compensatory reaction, on the one hand, to the deterioration of living conditions, and on the other hand, to reduce the intensity of competitive relations. The adaptation syndrome is a combination of three phases [19]. The phase of the primary stress reaction is a signal to activate the body's defenses. The phase of adaptation, or resistance, occurs during prolonged exposure to a factor that can cause stress. The degree of stress effect is determined by the level of restructuring of the organism – the more significant the impact, the more the organism changes. At this stage, plants show different forms of growth, can increase the intensity of growth and reproduction. The phase of exhaustion, which occurs after prolonged exposure to the stimulus, when the body loses the achieved adaptation. Reduction of resistance to the source of stress is expressed in a decrease in the size of individuals, in reducing the intensity of their growth and reproduction. Ultimately, the plant may die. The duration of a particular phase is determined by the adaptive capabilities of the species. In some species the stage of depletion occurs quite quickly, in others the phase of adaptation is relatively long. Species with greater plasticity are more stable. An expressive indicator of the state of a species is the type of its cenopopulation in a particular community, determined by the ratio of individuals of different age groups – the age spectrum [20].

Woody plants in urban areas can grow in various kinds of green spaces (in yards among residential buildings, on streets and highways, in squares, gardens and parks, in forest parks and in so-called urban forests) [21–24]. Forests in urbanized areas perform a variety of functions: environmental, sanitary and recreational [25–28]. The forest plantations have a positive impact on the atmosphere and climate of the city. They are able to change air temperature, illumination, wind speed, etc. Of course, this impact is more significant, the better the preservation of plantations [25, 29]. The forest transforms various climatic components while changing the radiation regime to the greatest extent [30–32]. Under the forest canopy, the illumination is much less, and in different types and in different parts of the forest it is different, because the composition of the rocks, the light permeability of the canopy, and the completeness of the stand differ. The total radiation is sharply reduced, because a significant part of it is intercepted by the crowns of trees and shrubs [33, 34]. The lighting becomes very variegated, which depends not only on the tree and shrub canopy, but also on the movement of the sun during the day, on the swaying of trees by the wind, on cloudiness [35]. The changes occur throughout the growing season due to the onset of different phenological phases [36]. At the same time, each type of forest has its own specifics, primarily due to the unifier species and the structure of the ecosystem. In artificial plantations (forest crops), the main species and planting density have a decisive influence on the light regime [37,38]. Wind speed is decreasing in the forest [39]. Inside the forest, at a distance of 30–50 m from the edge of the forest, the wind speed decreases to 30–40%, at a distance of 120–240 m, there is complete calm, especially if there is undergrowth in the plantation [40]. In summer, in cloudless and calm weather, in the contact zone between the city and neighboring green spaces, there is often a so-called breeze is a local breeze directed from the forest towards the city buildings during the day, and at night it blows in the opposite direction [41]. It is able to reduce the air temperature by several degrees. The reason for its occurrence is the difference in the thermal regime of the forest and urban development. As a result of this movement, the air in the city is cleaned and humidified, which also contributes to the improvement of the ecological situation [42, 43].

Urban green spaces and suburban forests play an important, though not decisive role in maintaining the stability of the atmospheric gas composition [44]. The amount of carbon monoxide absorbed by the green mass and the amount of oxygen released by it depend on the condition of the plantation, its age, species composition, completeness and a number of other factors [45]. Green spaces serve as a reliable filter that cleans the air from dust [46]. In the forest, dust particles settle on trunks and branches, on the surface of leaves, stick to resinous secretions. The efficiency of dust collection is determined by the structure of plantations and their species composition [47]. The leaf surface is of great importance. Dust is retained more on rough, pubescent or sticky leaves than on smooth leaves, and even more so on needles. Small leaves usually trap dust better than large ones. Leaves of complex configuration clean the air more efficiently. On average, 1 hectare of forest can retain from 30 to 70 tons of dust. Multi-tiered plantations are more effective than single-tiered ones, deciduous forests are more effective than coniferous ones, but conifers retain their dust trapping functions all year round [48].

Forests clean the air from industrial and transport emissions, which are often toxicants [49]. Among them is sulfur dioxide, which can cause serious damage to the human respiratory system. On average, 1 hectare of forest can annually retain up to 400 kg of this compound. Lead emissions contained in exhaust gases are very dangerous for human health. Lead in particularly large quantities accumulates in plants growing in the immediate vicinity of transport routes. Sharp-leaved maple and small-leaved linden are among the tree species that accumulate toxic substances in the largest quantities. Coniferous species such as pine, spruce and larch are highly sensitive to toxicants [50–52].

Noise is a negative factor in a big city [53, 54]. The constant exposure to noise can lead to the development of neuroses, insomnia, hypertension, reduced performance, especially in older people. Forest plantations dampen sound waves, eliminate the most harmful high-frequency sounds and reduce noise levels. The level of noise pollution reduction depends on the density of crowns, the structure of plantations, their species composition. The most effective in noise absorption are sharp-leaved maple, poplar, linden, oak, elm, birch; a little less effective are coniferous stands. Mixed plantations with shrubs growing under the trees have the best screening properties. The loose soil surface also increases the noise absorption potential of the forest [55, 56]. Plants secrete phytoncides – volatile or water-soluble substances that can destroy pathogens or delay their development. The activity of phytoncides is closely connected with the species composition and age of plantations, with the physiological state of trees, with the season, time of day and many other factors. It is established that for most people, 5–7-hour stay in the forest improves tone and well-being. However, negative feelings may also appear. For example, a high content of turpentine vapors in a coniferous forest on a hot sunny day can worsen the condition of people suffering from cardiovascular diseases; it is better for them to rest in oak forests [57]. Recreation is one of the factors of forest formation, which often has a rather negative impact on forest ecosystems [58, 59].

2. Research aim and objectives

Thus, urban parks perform important and diverse functions in the urban environment. As anthropogenic objects, urban parks should be subject to adequate and effective management that can increase the functional value of forest plantations in the city and ensure their sustainability. In this regard, the choice of the quantitative parameters of the park plantation to be managed is crucial. We hypothesize that ecomorphic analysis can be the basis for selecting optimal quantitative criteria for parkland management. Therefore, the goal of our study was to assess the informational value of ecomorphic analysis for characterizing park plantation in urban environments.

3. Material and methods

3.1. Data collection

The study was carried out in the recreational zone of the Botanical Garden of Dnipro National University named after Oles Gonchar, Dnipro City, Ukraine (48.43°N 35.05°E). The urban park was created after World War II on the site of a natural thermophilous oak forest [60,61]. Vascular plant species lists were recorded for 3×3 m sampling point, along with a visual assessment of species coverage using a Braun-Blanquet scale [62]. The projective cover of plant species was measured at soil level, understory (up to 2 m in height), and canopy (above 2 m in height). All species were identified to species level at all sites. Plant taxonomy is based on Euro+Med Plantbase (https://europlusmed.org/).

3.2. Ecomorphes

Belgard [63] created a typology of forests of the steppe zone of Ukraine in the late 40s of the last century, which is a vivid example of the effectiveness of the application of the principles of biogeocenology and in this sense, this concept should certainly be recognized as structuralist. The typology was supplemented by the system of plant ecomorphs. According to the ideas of Belgard, the ecomorph reveals the relationship between organisms and the environment and reflects the adaptation of individual plant species to the most important elements of biogeocenosis: to the phytocenosis as a whole and to each of the structural elements of the ecotope (thermotope, heliotope, trophotope, hygrotope, thermotope) separately. Any system of life forms (biomorph, ecomorph) has the following broad philosophical basis [64]: a) plants have different ecological amplitudes, i.e. they are more or less limited in their ability to tolerate different environmental conditions; b) there is often a correlation between morphology and adaptation; c) a plant in its successful existence represents what can be called an automatic physiological integration of all factors of its environment. The term ecomorph is preferred because the life form usually refers to adaptations that are expressed in the appearance of the plant, while adaptations not to all structural elements of the biogeocenosis have physiognomic manifestation. Belgard considered ecotope as a combination of climatope and edatope (or edaphotope). He divided climatop into thermotop and heliotop (space factors), edatop (or edaphotop) is divided into trophotop and hygrotop (terrestrial factors).

3.3. Coenomorphes
The plant coenomorph characterizes the adaptation of a living organism to the biogeocenosis as a whole. The plants of the steppe zone of Ukraine are represented by the following coenomorphs:

1) stepants (St) are steppe plants;
2) sylvants (Sil) are forest plants;
3) ruderants (Ru) are plants of weed communities;
4) psammophytes (Ps) are plants of sandy communities;
5) pratants (Pr) are meadow plants;
6) paludants (Pal) are plants of marsh plants;
7) petrophytes (Ptr) are rock plants;
8) halophytoids (Hald) are plants of salt marshes;
9) halophytes (Hal) are plants of salt marshes;
10) calcophytes (Clc) are plants of communities of chalk outcrops;
11) chasmophytes (Chs) are plants of communities of gravelly outcrops;
12) aquants (Aq) are aquatic plants
13) culturants (Cul) are cultivated plants.

In other geographical zones, such coenomorphs as tundrants (Tn) are tundra plants, montants (Mont) are mountain plants, littorants (Lit) are littoral plants on the sea coasts, desert plants (Ds) are desert plants can also be distinguished.

The forest species include the most typical species that make up forest communities. In addition to woody and shrubby plants, sylvants also include grasses, mosses and lichens, which are closely related to the forest environment. Stepants are represented mainly by herbaceous species, as well as some shrubs, mosses and lichens. The vast majority of steppe species are drought-resistant and light-loving, preferring soils with neutral or slightly alkaline reaction. The meadow species (pratans) are herbaceous perennial mesophytes. Pratants differ from forest species by their light ecology. The forest grasses also disappear after the destruction of the forest canopy, and meadow grasses, on the contrary, develop more rapidly. Paludants include mainly herbaceous and moss species that grow in conditions of excessive moisture. Halophytes include semi-shrubs and herbaceous species that live on saline soils and are characterized by light-loving and, as a rule, significant osmotic pressure of cell sap. Ruderants are weeds with diverse ecological properties and usually gravitate to soils with high nitrogen content.

3.4. Terrestrial and cosmic factors

Along with coenomorphs, other ecomorphs are distinguished by the criterion of adaptation to the most essential environmental factors. According to Williams [65], the factors of life of green plants should be divided into two groups:

1) cosmic factors are light and heat;
2) terrestrial factors are water and food.

Therefore, Belgard's system distinguishes ecological groups of plants similar in adaptation to certain cosmic factors:

1) climamorphs are adaptations to climate conditions in general;
2) heliomorphs are adaptations to lighting conditions;
3) thermomorphs are adaptations to the conditions of thermal climate regime.

And ecological groups of plants are similar in adaptation to certain terrestrial factors:

1) trophomorphs are adaptations to soil fertility conditions
2) hygromorphs are adapted to the conditions of humidity regime.

3.5. Climamorphs

Belgard used Raunkiaer life forms [66, 67] as climamorphs: phanerophytes, chameophytes, hemicryptophytes, cryptophytes (geophytes, hydrophytes), therophytes, epiphytes. When choosing the features of life forms for recognition and classification of relationships between plant life and climate, Raunkiaer was guided by three basic rules: a) the feature must be structural and essential; it must represent an important morphological adaptation; b) the trait must be obvious enough to be easily seen in nature to which life form the plant belongs; c) all the life forms used must be of such a nature that they constitute a homogeneous system; they must represent a single viewpoint or aspect of the plants and thus enable comparative statistical treatment of the vegetation of different regions.

Considering these requirements, Raunkiaer differentiated life forms according to the type and degree of protection provided to the growth points of perennial buds, which are responsible for recovery after an unfavorable season. With the exception of some tropical climates that are constantly warm and humid, all of them show a certain seasonal rhythm with alternating periods that are favorable or unfavorable for growth. When comparing two climates, the difference between them in the favorable season may be relatively small, while the differences in the unfavorable season can be significant and of great importance. The unfavorable seasons may be caused by cold or drought, or both, they may be short or long, they may be one or two per year, but it is likely that those structural differences between plants that allow them to survive the unfavorable seasons are a good indicator of the plant climate. Based on these facts, Raunkiaer developed his classification of life forms, which depends primarily on the degree of protection provided to the perennial bud. The system consists of the following five main classes, arranged in accordance with the increased protection of the buds: phanerophytes, chameophytes, hemicryptophytes, cryptophytes and therophytes. Raunkiaer believed that life forms are formed historically as a result of adaptation of plants to climatic conditions of the environment. The percentage distribution of species by life forms in plant communities in the study area is called the biological spectrum. Biological spectra for different physiographic zones and countries serve as indicators of climatic conditions. Raunkiaer classified plants according to where the growing point is located in less favorable seasons, provided that the plant retains the ability to survive these difficult conditions. Depending on the place on Earth, this unfavorable period can be, for example, in the cold winter period or in the dry summer time. In temperate regions, the growth point during the unfavorable season corresponds mainly to winter buds.

3.6. Trophomorphs
Among trophomorphs are distinguished:

1) oligotrophs (OgTr) are adapted to poor soils;
2) mesotrophs (MsTr) are adapted to moderately rich soils;
3) megatrophs (MgTr) are adapted to rich soils;
4) alkalitrophs (AlkTr) are plants of saline physiologically poor soils;
5) parasitic plants (Par), semiparasitic plants (S/par), saprophytes (Sapr) and calciphiles (Ca).

3.7. Hygromorphs
Among hygromorphs are distinguished:

1) euxerophytes (EuKs) are highly drought-resistant species;
2) xerophytes (Ks) are drought-resistant species;
3) mesophytes (Ms) are plants of moderate moisture environment;
4) hygrophytes (Hg) are amphibious species;
5) pleistophytes (Pl) are aquatic plants with floating leaves;
6) hydatophytes (Hy) are plants completely immersed in water.

The transitional forms can be named through the combination of two hygromorphs that are located next to each other. In this case, the leading mode is denoted by the second one, and the auxiliary mode is denoted by a prefix, for example: xeromesophytes – mesophytes that are more drought-resistant than ordinary mesophytes, or: mesohygrophytes – hygrophytes that are able to exist in more arid conditions.

3.8. Moisture variability
The ecological analysis of floodplain ecosystems cannot be complete without taking into account the floodplain factor. Therefore, it is necessary to distinguish between floodplain ecomorphs, namely:

1) extra-floodplain species – occur mainly outside the floodplain;
2) short floodplain – characteristic of floodplains where the flood lasts no more than 10 days
3) medium floodplain – species can withstand floods that last no more than 40 days;
4) long floodplain – withstand floods that last more than 40 days.

The duration of the flood depends on the size of the river: in small rivers it lasts no more than 10 days, in large rivers the flood can last more than 40 days. The number of species that are able to adapt to flooding decreases in proportion to its intensity. Therefore, the species diversity of floodplain communities decreases from short floodplain ecosystems to long floodplain ecosystems. Therefore, the diversity of plant communities in short floodplain ecosystems of small rivers is higher than in long floodplain ecosystems of large rivers.

3.9. Heliomorphs
Among heliomorphs are distinguished:

1) heliophytes (He) are light-loving species;
2) scioheliophytes (ScHe) are light-tolerant species;
3) heliosciophytes (HeSc) are shade-tolerant species;
4) sciophytes (Sc) are shade-loving species.

3.10. Thermomorphs

Among thermomorphs are distinguished:

1) microtherms (MT°) are species originating from the polar geographical climatic zone;
2) mesotherms (MsT°) are species originating from the temperate zone;
3) megatherms (MgT°) are species originate from subtropical or tropical zones;
4) eurytherms (EuT°) are species that can grow in almost all climatic zones of the Earth.

3.11. Generative ecomorphs

These ecomorphs mainly reflect adaptation to growth conditions, so they can be called vegetative. Along with vegetative ecomorphs, there are generative ecomorphs, which characterize the attitude of species to pollination and spread of diasporas. The problem of creating a system of generative ecomorphs was solved by Tarasov [68].

Pollenochores are groups of plants that are distinguished by the type of pollination (for spore plants – by the type of gamete transfer). Among them are distinguished:

1) autogamy plants (Ah) – self-pollinated;
2) hydrophilous plants (Hdph) – pollination is carried out with the help of water;
3) gametohydrophilous plants (Hdgph) – gamete transfer occurs in the aquatic environment;
4) anemophilous plants (Anph) – pollen is distributed by wind;
5) entomophilous plants (Ent) – pollen is distributed by insects;
6) protandrous plants (Pa) – earlier maturation of pollen compared to the stigmas of pistils in plant flowers. It is an adaptation to cross-pollination.
7) protogynous plants (Pg) – earlier maturation of stigmas in the flowers of plants compared to pollen.

Diasporochores (ecobiochores) is a group of plants that are distinguished by the types of plant diaspora dispersal. According to the ways of diaspore dispersal, they are distinguished:

1) endozoochory (EndZ) – transfer of seeds by animals after eating and defecation;
2) synzoochory (SynZ) – transfer of plant fruits by animals when they harvest stocks.
3) myrmekochory (Myrm) – transfer is carried out by ants;
4) epizoochory (EpZ) – transfer on the surface of animals, diaspores are tenacious;
5) anemochory (Anch) – spreading of seeds, fruits and plant spores by air;
6) hydrochory (Hdch) – diaspores are transported by water;
7) autochory (Ach) – self-dispersing plants spread fruits, seeds, spores and vegetative parts of the plant organism with the help of the plant itself without the action of external agents; distinguish between active seed dispersal from a cracked ripe fruit (mechanochory), burying of fruits in the soil (geocarpy), shedding of fruits and seeds only under the influence of gravity (barochory);
8) barochory (Bar) – a kind of autochorus, shedding of fruits and seeds only under the influence of gravity;
9) ballistochory (Bal) – diaspores are scattered by elastic stalks when shocked;
10) geochory (Gch) – diaspores crawl and burrow into the ground, changing their shape;
11) cryptogeochory (KrGch) – hidden geochorus;
12) pervolvent (Perv) – movement of a plant under the influence of wind due to its rolling (tumble-field);
13) anthropochory (Antrch) – spreading of seeds, fruits and plant spores by humans.

4. Results

4.1. Climamorphs

In the park, 166 species of vascular plants were found, which are represented by phanerophytes (19.9%), nannophanerophytes (8.4%), hemicryptophytes (40.4%), geophytes (11.4%), theorophytes (18.7%) and geolophytes (1.2%) (figure 1). *Acer negundo* L., *Acer platanoides* L., and *Robinia pseudoacacia* L. were the most common among phanerophytes. Among nannophanerophytes, *Parthenocissus quinquefolia* (L.) Planch. and *Sambucus nigra* L. were the most common. The most numerous among hemicryptophytes were *Alliaria petiolate* (M.Bieb.) Cavara et Grande, *Anthriscus sylvestris* (L.) Hoffm., *Chelidonium majus* L., *Geum urbanum* L., and *Viola odorata* L.. Among therophytes the most numerous were *Galium aparine* L., *Impatiens parviflora* DC., *Stellaria media* (L.) Vill. Among geophytes the most numerous were *Cirsium arvense* (L.) Scop. and *Humulus lupulus* L. Helophytes were represented by only two species – *Phragmites australis* (Cav.) Trin. ex Steud. and *Sium latifolium* L..

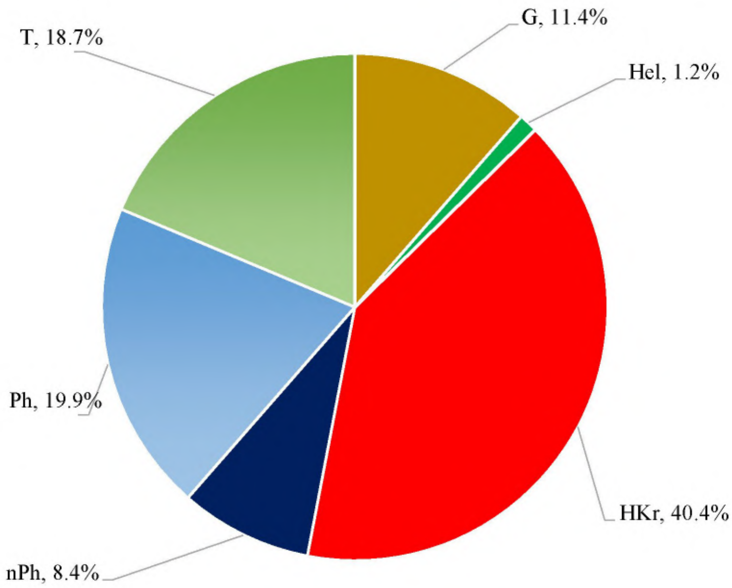

Figure 1. Structure of life forms according to Raunkier (climamorphs): Ph is phanerophyte; nPh is nannophanerophyte; Ch is chameophyte; HKr is hemicryptophyte; T is therophyte; G is geophyte, Hel is helophyte.

4.2. Coenomorphs

Sylvants (35.5%) predominate among the coenomorphs, with slightly less pratants (22.3%), ruderants (18.7%) and stepants (14.5%). Cultivants (3.0%), psammophytes (3.0%) and paludants (3.0%) were occasionally found. Sylvants prevail among phanerophytes (figure 2). The proportion of sylvants among nannophanerophytes was also high. The proportion of stepants, which varied in the range of 12.9–21.4% was established for nannophanerophytes, hemicryptophytes, geophytes and therophytes. The pratants dominated among hemicryptophytes (35.8%). The ruderants dominated among therophytes and geophytes (31.6 and 45.2% respectively). Helophytes were represented by paludants. The highest coenomorphic diversity was found for hemicryptophytes (2.24), with a slightly lower diversity for therophytes and geophytes (2.02 and 2.26, respectively). The lowest coenomorphic diversity was characteristic of phanerophytes and nannophanerophytes. Naturally, the diversity of helophytes,

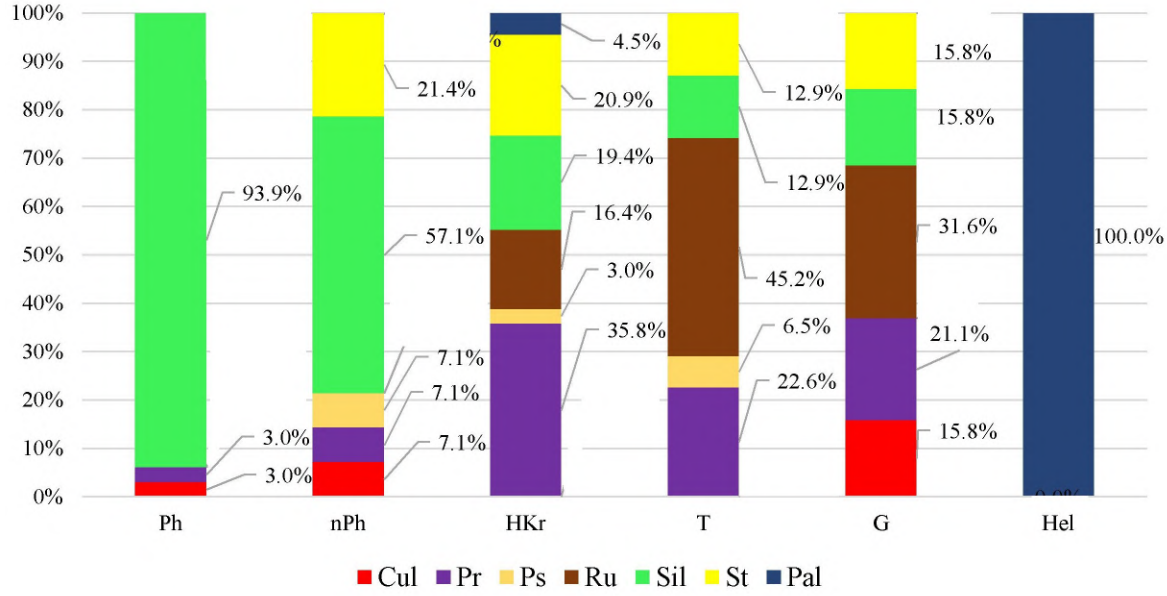

Figure 2. Structure of coenomorphs: Cul are culturants; Pr are pratants; Pal are paludants; Ps are psammophytes (psamants); Ru are ruderals; Sil are silvants; St are stepants. Ceonomorphic diversity: Ph – 0.39, nPh – 1.75, HKr – 2.24, T – 2.02, G – 2.26, Hel – 0. Specific diversity: Ph – 0.08, nPh – 0.46, HKr – 0.37, T – 0.41, G – 0.53, Hel – 0.

which are represented by only two species, was equal to zero. The lowest specific diversity was characteristic of phanerophytes, and the highest was characteristic of geophytes.

4.3. Hygromorphs

The proportion of xeromesophytes and mesophytes was the highest (32.5 and 31.3% respectively). The proportion of mesoxerophytes was also relatively high (28.3%). The proportion of other hygromorphs was relatively low. The hygromorphic structure of phanerophytes and nannophanenophytes was almost identical. These climamorphs were represented mainly by the mesophytes. The hygromesophytes were represented among hemicryptophytes and geophytes (6.0 and 10.5 % respectively). The therophytes were characterized by a low proportion of mesophytes due to the increase in the proportion of xeromesophytes. The helophytes were represented by the hygrophytes and mesohygrophytes. The hygromorphic diversity was the highest among hemicryptophytes, and the lowest among therophytes and helophytes. The lowest specific diversity was typical for phanerophytes, and the highest was typical for geophytes. The specific diversity of climamorphs showed no significant differences.

4.4. Trophomorphs

The trophomorphs were represented mainly by mesotrophs (71.1%) and a slightly smaller proportion of megatrophs (22.3%). The oligotrophs were found occasionally (6.6%). The proportion of megatrophs was the highest among phanerophytes (30.3%) and hemicryptophytes (26.9%) (figure 4). Accordingly, these climamorphs were the most demanding to soil fertility. The proportion of oligotrophs was the highest in nannophanerophytes (14.3%). The helophytes were represented exclusively by the mesotrophs. The level of trophomorph diversity was at the same level for all climamorphs, except for helophytes.

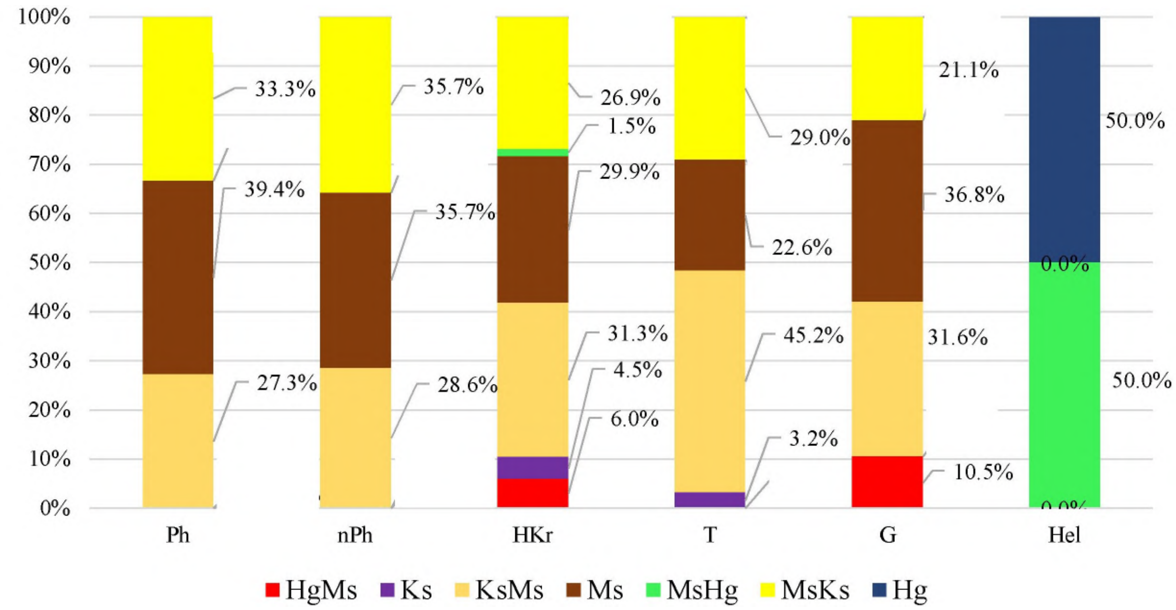

Figure 3. Structure of hygromorphs: Ks are xerophytes; MsKs are mesoxerophytes; KsMs are xeromesophytes; Ms are mesophytes; HgMs are hygromesophytes, MsHg are mesohygrophytes. Hygromorphic diversity: Ph – 1.57, nPh – 1.58, HKr – 2.09, T – 1.68, G – 1.87, Hel – 1. Specific diversity: Ph – 0.31, nPh – 0.41, HKr – 0.34, T – 0.34, G – 0.44, Hel – 1.

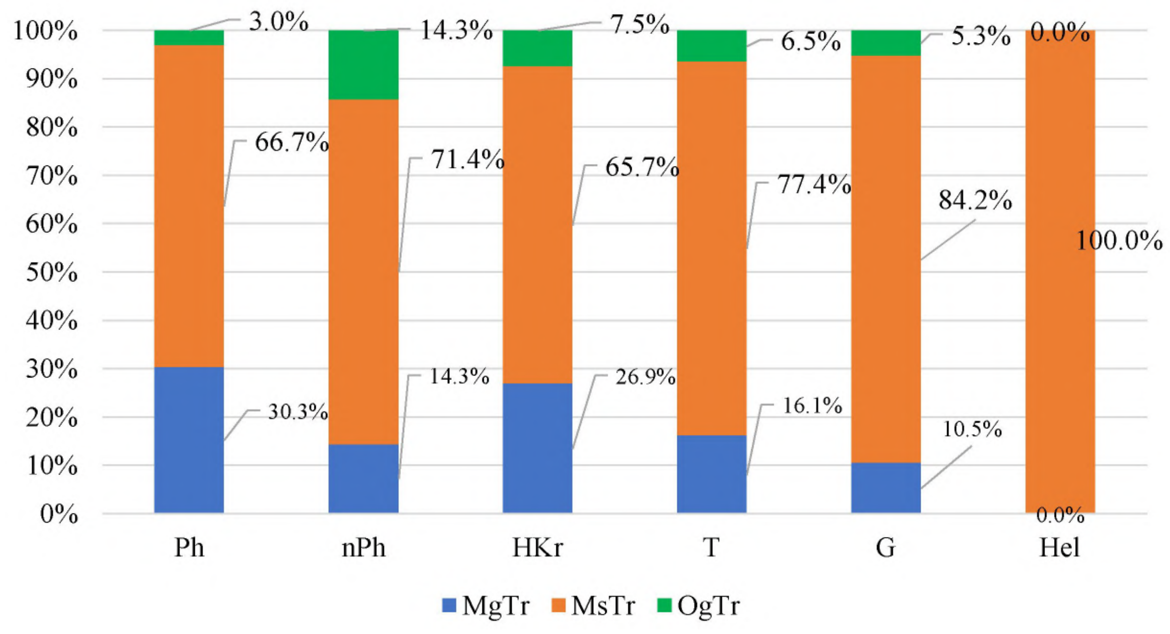

Figure 4. Structure of trophomorphs: MgTr are megatrophs; MsTr are mesotrophs; OgTr are oligotrophs. Trophomorphic diversity: Ph – 1.06, nPh – 1.15, HKr – 1.19, T – 0.97, G – 0.77, Hel – 0. Specific diversity: Ph – 0.21, nPh – 0.3, HKr – 0.2, T – 0.19, G – 0.18, Hel – 0.

The greatest diversity was typical for the hemicryptophytes. The lowest specific diversity was characteristic of the geophytes, and the highest was characteristic of the nannophanerophytes.

4.5. Heliomorphs

Sciogeophytes (57.2%) and heliophytes (30.1%) prevailed among heliomorphs. The proportion of sciophytes and heliosciophytes was much lower (3.6 and 9.0 %, respectively). The proportion of heliophytes was the highest among terophytes, geophytes and helophytes (figure 5). The proportion of heliophytes was lowest for nannophanerophytes. The highest proportion of sciophytes was found for hemicryptophytes. Sciophytes should be noted to be also found among the therophytes and geophytes. The highest proportion of heliosciophytes was among phanerophytes. The greatest heliomorphic diversity was typical for the hemicryptophytes. This diversity was also quite high for therophytes and geophytes. Nannophanerophytes were the least diverse in terms of light level preferences. The lowest specific diversity was typical for nannophanerophytes, and the highest was typical for geophytes.

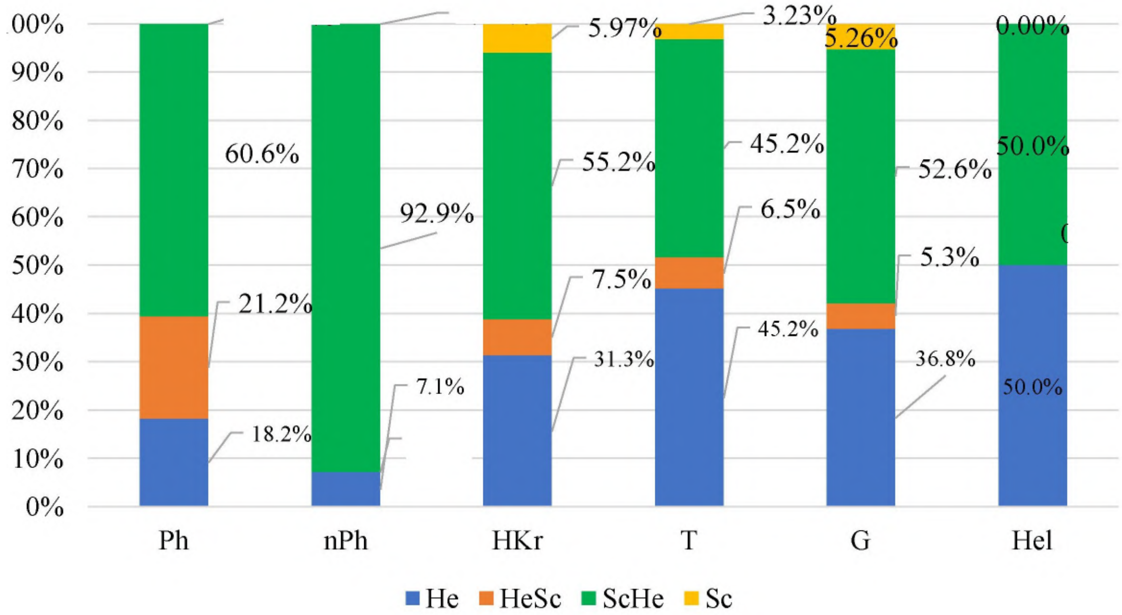

Figure 5. Structure of heliomorphs: HeSc are heliosciophytes; ScHe are scioheliophytes; He are heliophytes, Sc are scioheliophytes. Heliomorphic diversity: Ph – 1.36, nPh – 0.37, HKr – 1.52, T – 1.45, G – 1.47, Hel – 1. Specific diversity: Ph – 0.27, nPh – 0.10, HKr – 0.25, T – 0.29, G – 0.34, Hel – 1.

4.6. Pollenochores

Entomophilous plant species were the most common among the vegetation cover of the park (71.7%). Anemophilous plants were significantly inferior to them (26.5%). Autogamous and hydrophilous plants were found occasionally (1.2 and 0.6% respectively). The entomophilous species were most common among nannophanerophytes (92.9%) (figure 6). The anemophilous species were most commonly found among phanerophytes and helophytes (39.4 and 50.0%, respectively). The hydrophilous species were found among geophytes. The autogamous species were found among therophytes. Pollenochoric diversity was the highest among geophytes. The lowest specific diversity was characteristic of nannophanerophytes, and the highest was characteristic of geophytes.

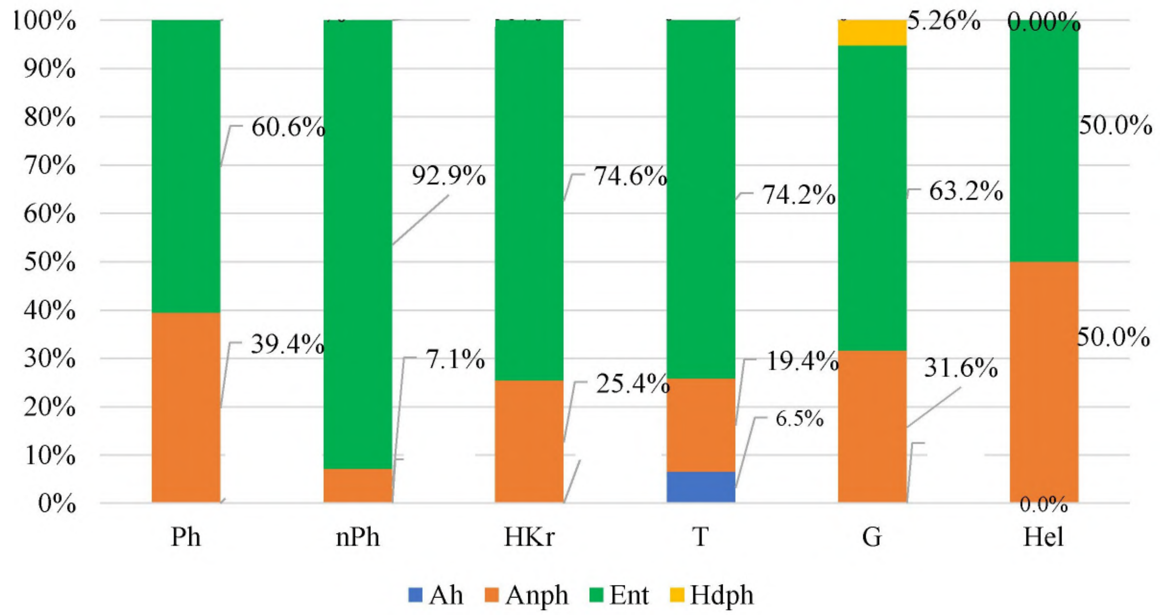

Figure 6. Structure of pollenochorus: Ah are autogamous plants; Anph are anemophiles; Ent are entomophiles, Hdph are hydrophilus plants. Pollenchoric diversity: Ph – 0.97, nPh – 0.37, HKr – 0.82, T – 1.03, G – 1.17, Hel – 1. Specific diversity: Ph – 0.19, nPh – 0.1, HKr – 0.13, T – 0.21, G – 0.27, Hel – 1.

4.7. Diasporochores

Ballistic diasporeochores prevailed among diasporeochores (39.8%). The proportion of anemochores and endozoochores was somewhat lower (27.7 and 12.0% respectively). Other diasproochores accounted for 0.6–4.8 of the total number of species. Endozoochores were mainly found among nannophanerophytes (78.6%). Among phanerophytes, anemochores were mainly found (60.6%). Among herbaceous species, ballistic species prevailed (47.4–56.7%). The highest diasporechoric diversity was found for hemicryptophytes. The lowest specific diversity was characteristic of nannophanerophytes, and the highest was characteristic of geophytes.

5. Discussion

In ecology, there are two alternative perspectives on the nature of ecological communities: continualism and structuralism [69].

Continualism considers the response of an organism to the effects of environmental factors as a species-specific property, which is generally described by a bell-shaped curve [70–72]. Hence, it is natural to conclude about living organisms as indicators of environmental properties, which became the basis for the creation of many indicator scales [73]. One of the first such scales was created by Ramenskiy, the founder of continualism [74]. Other phytoindicator scales differ in their resolution, the list of environmental properties indicated, and the aspect of the species response curve to an environmental factor: whether it is an optimum zone based on which Ellenberg scales are indicated [75–77], or whether it is the range of the factor within which the species can exist, as provided in the range scales of Tsyganov [78] or Didukh [79]. The principles of phytoindication are a practical consequence of biotope theory [80–82] according to which biocenosis [83,84] depends on the observed physical properties of the environment [85–87]. And an ecosystem, in turn, is a combination of biotope and biocenosis. Within the framework of structuralism, environmental factors take a second place and the intrasystem interactions

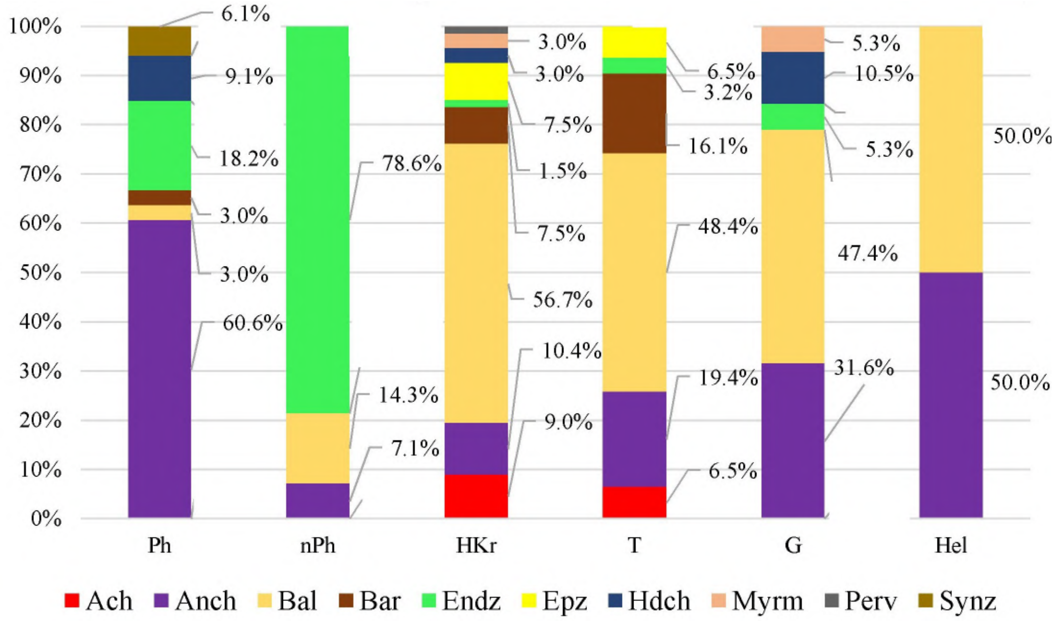

Figure 7. Structure of diasporochores: Ach are autochores; Anch are anemochores; Bal are ballistae; Bar are barochores; Endz are endozoochores; Epz are epizoochores; Hdch are hydrochores; Myrm are myrmecochores; Synz are synzoochores. Diasporochorous diversity: Ph – 1.75, nPh – 0.95, HKr – 2.16, T – 2.06, G – 1.82, Hel – 1. Specific diversity: Ph – 0.35, nPh – 0.25, HKr – 0.36, T – 0.42, G – 0.43, Hel – 1.

are advanced, which leads to explaining the observed boundaries of plant communities as those of an endogenous nature [88]. The most orthodox branch of structuralism is Sukachev's biogeocenology [89–91].

More recently, the conflict between continuism and structuralism has taken the form of a competition between ecological niche theory [92] and neutral diversity theory [93]. The constructive position of this confrontation is to soften the problem, namely, which of the alternative representations is the only true and which is false [94]. The solution moves to the question of under what circumstances one of the views explains a greater range of observable facts than the other, and under what circumstances the priority goes to the competing viewpoint.

Biogeocenosis is a combination of biocenosis and ecotope [91]. The term ecotope was coined by Vysotsky [95], but in English-language literature Sørensen [67] or Tansley [96] are considered as its authors. An ecotope is the smallest unit of the Earth's surface that possesses homogeneity of at least one property of the geosphere: atmosphere, vegetation, soil cover, rocks, water, etc., with a non-extreme variation of other properties [97]. Ramensky [98], along with ecotope (habitat), which is determined by direct acting factors (heat, light, aeration, nutrient, soil reaction, salinity), distinguishes entopia (location), which is determined by the indirect topological conditions. In the tradition of biogeocenology, an ecotope includes a climatope and an edaphotope. The climatotope, in turn, consists of a heliotope and a thermotope, and the edaphotope consists of a hygrotop and a trophotope [89]. Sukachev [90] considers a biotope as the zoological equivalent of the botanical term ecotope. However, the history and practice of using these terms allow them to be interpreted as the equivalent of abiotic properties of the environment within the framework of continuism (biotope is a component part of the dimensionless concept of ecosystem) and abiotic properties of the environment transformed by biota (ecotope is a component part of biogeocenosis as ecosystem within the boundaries of phytocenosis) within structuralism. In the late forties of the last century, Belgard [63] created the typology of the forests of the steppe zone of Ukraine, which is a bright example of the effectiveness of the principles of biogeocenology and in this sense this concept should certainly be recognized as structuralist. The typology was supplemented by the system of plant ecomorphs.

According to Belgard's ideas, an ecomorph reveals the relationship between organisms and the environment and reflects the degree of their adaptation to the most important elements of the biogeocenosis. The term ecomorph is preferred because the life form usually refers to adaptations that are expressed in the external form of the plant, whereas adaptations to all structural elements of the biogeocenosis do not have a physiognomic manifestation. The key feature of the Belgrad system of ecomorphs is the coenomorph which is the adaptation of plant species to the phytocoenosis as a whole [99]. The ecomorph system has been extended to other components of the biogeocenosis [100–103], which allows us to interpret coenomorph as adaptation of biotic and bioinert component of biogeocenosis to the biogeocoenosis as a whole. In turn, the adaptivity is defined as the responses of various objects to the environmental factors, which manifests itself in changes in the structure and functions of responding objects and their groups in response to various changing conditions, resulting in the maintenance of their existence [104]. Coenomorphs are distinguished along with adaptations to the most essential environmental factors such as climate (climomorphs), light regime (heliomorphs), thermal regime (thermomorphs), soil fertility (trophomorphs), and moisture regime (hygromorphs) [105]. The boundaries of the gradations of the corresponding factors are determined by the internal integrity of such categories as forest type, which in essence is equivalent to the concept of biogeocenosis type [106]. These gradations were proposed by Matveev [107] to represent in a score form and use for the purpose of phytoindication of the corresponding environmental factors. However, Belgard developed a system of ecomorphs primarily to assess the condition of the biogeocenosis as a whole. The spectra of hygromorphs, trophomorphs, climomorphs, thermomorphs, heliomorphs within a particular coenomorph illustrate the idea that under conditions of varying environmental properties a biogeocenosis can preserve its integrity and identity [108, 109]. Therefore, attempts to interpret coenomorphs as a tool for phytoindication of biotopes [110] are somewhat inconsistent with the purpose of this concept and the nature of ecological groups that are denoted by this term. Assuming that coenomorphs are discrete representations of the ecological continuum of plant organisms, this concept carries no additional information and is therefore degenerate for indicating biotope properties. In such a case, there is no objective criterion for distinguishing coenomorphs and, ultimately, their number and quality can be arbitrary. Often, a concept such as an ecological and cenotic group is used as an equivalent of the term coenomorph, or they refer to the ecological and cenotic relationship of a species. However, such a position is subject to criticism on the basis of the conceptual essence of the term, which implies the conditions of existence of biological objects, rather than their association with something [111]. Therefore, it is critically noted that the floristic studies should either abandon the use of community names to denote the habitat of individuals or their populations at all, or justify the possibility of their use in an ecological sense [112, 113]. If coenomorphs are discrete classes of plant species that are separated from each other to a greater extent than can be assumed based only on the continuum nature of ecological differences between species, then information on the coenomorphic membership of a species and, consequently, the coenomorphic structure of a community, can carry additional information for indicating the properties of an ecotope [114, 115].

Our results indicate a high level of plant community diversity within the city park. The plant community is represented by the different ecological groups. The tree layer is represented by phanerophytes, in the undergrowth predominantly nannophanerophytes are represented. The grass stand is represented by hemicryptophytes, geophytes, therophytes and helophytes. The wide ecological diversity of plant climomorphs in the park plantation indicates a potential for sustainability of this plant complex. On the other hand, the climomorphic structure indicates the presence of a permanent disturbance regime in the park plantation, which manifests itself in an increase in geophytes and thermophytes. It should be noted that the helophytes are represented by only two plant species. In the natural state along the thalweg of the gully, on the basis of which the city park was formed, a stream flowed, so the diversity of helophytes could be much higher. The low diversity of helophytes indicates a significant transformation of the landscape cover of the urban environment.

The ecomorphic analysis is applied to analyze the plant community as a whole. We applied the ecomorphic approach to the differential analysis of plant community climomorphs. The climomorphs were found to differ significantly in their ecomorphic structure. Thus, phanerophytes and nannophanerophytes differ from herbaceous layer plants in their coenomorphic structure. The phanerophytes are expectedly represented by the silvants. The diversity of coenomorphic structure of nannophanerophytes increases due to the growing proportion of steppants. The steppe shrubs usually form marginal complexes of forest communities in steppe, which ensures their ecological stability. An increase in the proportion of steppes among nannophanerophytes can be regarded as an element of maintaining the sustainability of artificial forest plantations in urban environments. Among herbaceous plants, the proportion of steppe and meadow species is systematically high, while the proportion of forest species is insignificant. This structure emphasizes the amphicenotic nature of the plant community structure. The cenotic elements of different nature have priority in different horizontal layers of the community. Among the therophytes, the ruderants predominate. This advantage is carried out against the background of a decrease in the proportion of silvants. Thus, the disturbance of ecological regimes, which provide the forest type of the cycle of substances and energy flow, leads to ruderalization of the ecological environment of the park plantation.

Phanerophytes and nannophanerophytes are represented by the mesoxerophytes, xeromesophytes and mesophytes. In plant layers the proportion of both mesoxerophytic and mesophytic hygromorphs decreases, but the proportion of xeromesophytic hygromorphs increases. This trend should be regarded as a decrease in the tolerance of herbaceous cover to the moisture conditions. The structure of trophomorphs is rather stable in the section of climomorphs. The plant community of the park plantation is mesotrophic.

The plant community is dominated by sociogeliophytes and the highest proportion of this heliomorph is characteristic of nannophanerophytes. The diversity of phanerophytes in comparison with nannophanerophytes increases at the expense of heliophytes, and the diversity of the herbaceous layer increases at the expense of both heliophytes and sociophytes. It is obvious that the forest stand of park plantation forms a wide variety of crown architectonics, which creates conditions for life of both light-loving and shade-loving species of herbaceous plants. A competitive strategy for the tree species is to adapt to the deficit of light under the canopy of other tree species. Obviously, a mosaic of light conditions is a characteristic of park plantings. Continuous park plantation management procedures prevent the development of a dense canopy of woody species that is observed in natural forests.

The predominance of entomophilous plant species in park plantations raises the problem of comprehensive protection of the animal component in urban forests. It is also important to note the potential of the plant community as a factor supporting animal diversity in the urban environment. Significant differences are observed between phanerophytes and nannophanerophytes with respect to diaspore structure. The diaspores of park plantation phanerophytes are distributed predominantly by wind, while the diaspores of nannophanerophytes are distributed predominantly by animals. The phanerophytes of the regional flora are represented by anemochores in 59.6% of cases and by endozoochores in 19.2% of cases, which is fully consistent with the values found in the park plantation. In turn, among phanerophytes in the park, there are almost twice as many synzoochores as in the regional flora (6.1% vs. 3.85%). The endozoochores are also more typical for the park plantation nannophanerophytes than for this climomorph in the regional flora as a whole (78.6% vs. 66.67%). At the same time, the nannophanerophytes of the park plantation are twice as rarely represented by the anomochores as is observed in the regional flora (7.1% vs. 14.6% in the regional flora). Among the hemicryptophytes, the anemochores occur much less frequently than in the regional flora (10.4% vs. 20.8% in the regional flora), whereas among the park's therophytes and geophytes, the anemochores occur more frequently than in the regional flora (19.4% vs. 9.9% in the regional flora for therophytes and 31.6% vs. 20.8% in the regional flora for geophytes). Thus, the park plantation has a specificity of its diaspore structure. It consists in the increased role of zoogenic factor for diaspore dispersal for phanerophytes and nannophanerophytes, the increased role of wind in geophyte and terrorophyte dispersal and the decreased role of wind in hemicryptophyte dispersal.

6. Conclusion

The ecomorphic approach was developed to analyze the structure of natural plant communities. This method was applied to analyze the ecological structure of an artificial park plantation in an urban environment. The results obtained allow to discover the essential ecological features of the park plantation. The park plantation has many features that bring it closer to natural forests. The similarity consists in a significant proportion of silvants, shade-loving species, and mesotrophs. A significant level of anthropogenic impact can be diagnosed on the basis of information about the increased proportion of ruderants in the plant community. The differential analysis of the ecomorphic structure in the section by climorphs is of considerable value. This approach allowed to detect an increased role of the zoogenic factor in the distribution of diaspores of phanerophytes and nannophanerophytes and an increased role of wind in the dispersal of geophytes and therophytes. The role of wind is reduced in the dispersion of hemicryptophytes in the urban environment.

Abstract. Methods of using on-board energy storage system on rolling stock are considered. Their use ensures a reduction in energy consumption and reduces the impact on the environment. Concepts of managing energy flows in the traction system of an electric rolling stock equipped with onboard energy storage systems are considered. It is proposed to apply the concept of control on an electric locomotive for quarry railway transport, which consists in reducing the current consumption from the traction network during the acceleration of the rolling stock and compensating the power during movement with the lowest voltage on the current receiver. For the selected control concept, a simulation of the train movement on the test section was carried out while varying the value of the limit current consumed by the electric locomotive from the traction network. The power of the energy storage device and its working energy capacity is determined. Based on the results of the study, it is justified to limit the current consumed by the electric locomotive of the traction network at the level of 600 A.

1. Introduction

Increasing the efficiency of quarry railway transport is an important direction for achieving the goals of decarbonization and sustainable development of mining enterprises.

A well-known method of increasing the efficiency of electric traction systems is the use of recuperation [1]. For this, it is necessary to use energy storage systems in the electric traction system. For electric traction systems of quarry transport, it is expedient to use on-board energy storage systems (OESS), because, firstly, it allows the most effective use of recuperation energy, and secondly, it provides the possibility of autonomous movement of electric rolling stock in non-electrified sections.

The concept of managing energy flows in the electric traction system is important for the effective use of OESSs. The analysis of the sources shows that the structure and parameters of the traction electric drive and OESS depend on the type of rolling stock and its operating conditions [2].

Nowadays, several types of an electric rolling stock equipped with OESS are in operation.

The traction electric drive MITRAC Energy Saver [3] is designed for use in urban electric transport. OESS is built using supercapacitors. Discharge of the supercapacitor occurs when the tram accelerates. During electrodynamic braking and at a stop, the OESS is charged. The EV-E301 regional railcar train of Japan's JR East [4] operates on a route that has a non-electrified section. The strategy of control is as follows: when moving along an electrified section, the traction and auxiliary systems of the train are powered and the OESS is charged from the catenary network. When moving through a non-electrified section, the traction and auxiliary systems of the train are powered by the OESS. During electrodynamic braking, auxiliary systems are powered and OESS is charged. At the stop, auxiliary systems are powered and the OESS is charged from the contact network. Accumulators are used in OESS.

A feature of the Flexity 2 tram system developed by Bombardier for Nanjing [5] is that the contact network is available only near the stops. Therefore, the operating algorithm of the OESS is similar to that described above: when moving under the contact wire, the tram accelerates and the OESS is charged. Movement between stops is carried out with the power supply of the traction and auxiliary systems from the OESS. OESS is built using accumulators.

The tram system of the CAF development in Birmingham [6] functions similarly. The OESS of the rolling stock is built based on supercapacitors.

When the BEC-819 train, created by Hitachi [7] is moving in the traction mode, the traction and auxiliary systems are powered from the contact network through active rectifiers. There is no energy exchange with the OESS in this mode. When moving in coasting mode, charging of the OESS from the contact network begins. In the mode of electrodynamic braking, the OESS is charged. When moving along non-electrified areas, traction and auxiliary systems are powered by OESS.

The Combino Plus tram manufactured by Siemens [8] is equipped with a hybrid OESS, which includes batteries and supercapacitors. During acceleration, the tram systems are powered by supercapacitors. Power is supplied from the batteries in the driving mode with speed maintenance or coasting. During electrodynamic braking, supercapacitors are charged. At the stop, batteries and supercapacitors are recharged from the contact network.

Let's consider the algorithms of OESS operation on autonomous rolling stock.

A diesel train produced by Hitachi [9] uses battery-based OESS. OESS feeds the traction and auxiliary system during acceleration. After a speed of 30 km/h, a diesel generator connects, which provides energy to the diesel train system. During electrodynamic braking, OESS is charged. At a stop, auxiliary systems are powered from the OESS.

The tram produced by CRRC for Tangshan [10] is equipped with fuel cells and hybrid OESS. The fuel cell works with a certain power during the entire movement. When accelerated, the traction system is additionally powered by supercapacitors. In steady motion mode, if necessary, the traction system is powered by batteries. During electrodynamic braking, supercapacitors are charged. At the stop, OESS is recharged from fuel cells.

To ensure long-term autonomous movement of rolling stock on non-electrified sections, as well as in the case of a battery power source, OESS is built based on batteries of various types [11–15]. For the most part, this rolling stock is in trial operation, including checking and finalizing OESS management strategies.

It is worth noting that inertial energy accumulators were used on rolling stock [16, 17]. However, their exploitation was more of an experimental nature and they did not become widespread.

A generalization and analysis of energy exchange control concepts for electric traction systems can be found, for example, in [18–20]. Here we note that one of the methods of controlling the OESS consists in reducing the current consumption from the main power source during the acceleration of the rolling stock and ensuring optimal operating modes of the main power source. This OESS concept of control can be applied to an electric locomotive for quarry railway transport and is based on the following.

Observation of the operation of traction units at mining enterprises shows that the voltage on their current receivers can significantly decrease – down to a minimum voltage equal to 7.5 kV in the case of an alternating current electric traction system. Mostly, this happens when a loaded train is moving uphill. To prevent the minimum voltage protection from triggering, the control system or the driver limits the electric locomotive's current consumption from the traction network. As a result, the speed of the train decreases, and the passage time of the section increases.

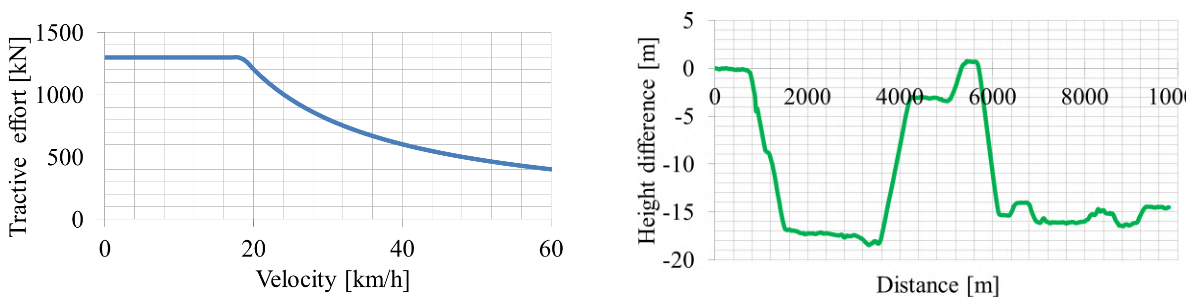
To eliminate the above situation, it is possible to use an OESS, which, in case of reaching a certain value of current that the electric locomotive consumes from the catenary network, will feed the traction electric drive and auxiliary systems. Thus, there is a problem with researching the processes of energy exchange in the traction system of an electric locomotive with an onboard OESS while limiting the current consumed from the contact network and determining the parameters of the OESS.

2. Research material and results

Direct modeling of the processes of energy consumption by an electric locomotive with an asynchronous traction electric drive during the movement of a train on a section of the track will not ensure high reliability of the results, since the traction network has a complex topology, its parameters cannot be determined with high accuracy, the nature of the movement of trains along the feeder zone is random. Therefore, let's assume that the movement of the electric locomotive under study in the section takes place at a voltage of 7.5 kV, that is, it is carried out at the minimum value of the voltage on the current receiver. Such a scenario corresponds to the worst conditions of the power supply of electric rolling stock.

The current consumed from the contact network is determined both by the mode of operation of the traction electric drive and by the power consumed by auxiliary systems. Let's assume that when a certain value of the current consumed by the electric locomotive from the contact network is exceeded, the OESS must be connected to power its systems. We will calculate the power and working capacity of the OESS at different limit values of the current that can be consumed from the network.

For example, let's study the electric locomotive described in [21]. Its traction characteristic is shown in figure 1a, and the profile of the section from the crushing plant to the reloading point is shown in figure 1b.



(a) (b)

Figure 1. Traction characteristics of the electric locomotive (a) and profile of the track section (b).

To solve the traction task, a mathematical model of train movement on a section of the track, given in [22], was used. With its help, the dependence of the tangential power was received for the case of the movement of a loaded train from the loading point to the crushing plant (figure 2).

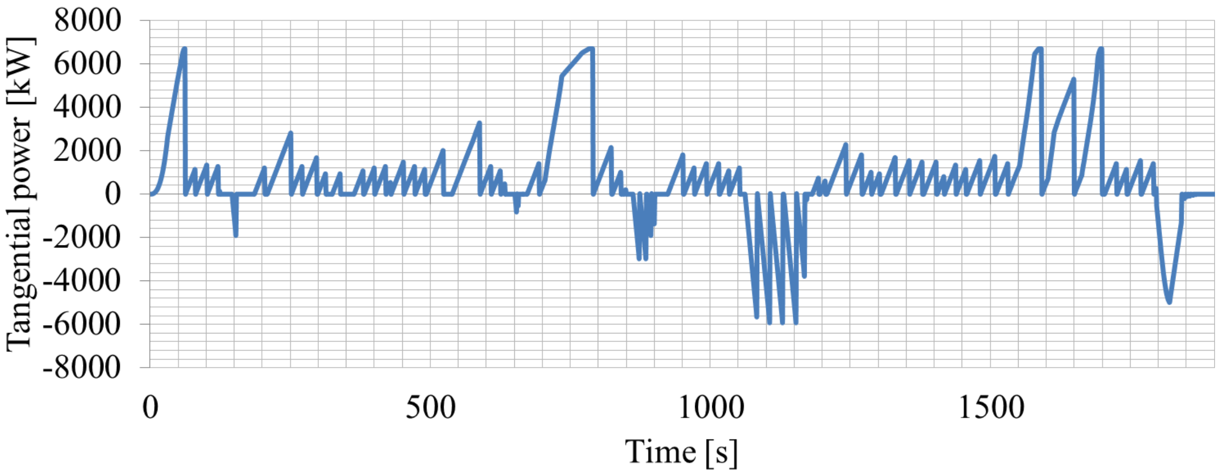


Figure 2. Dependence of the tangential power of the electric locomotive.

One of the variants of the structure of the traction system of the electric locomotive under study, in which power compensation from the OESS is ensured, is shown in figure 3. Here the intermediate circuit, to which the traction electric drive and auxiliary systems are connected, is fed jointly from the input converter and the OESS.

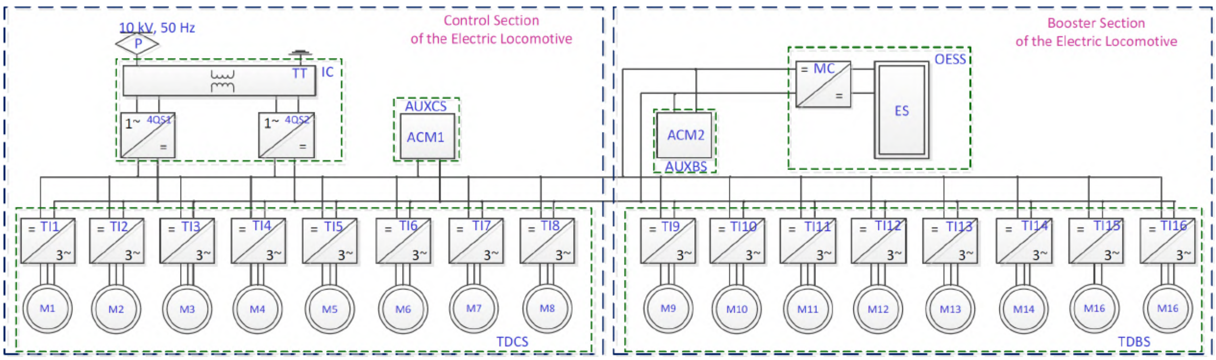

Figure 3. Structural diagram of the traction system of the electric locomotive: P – pantograph, IC – input converter, TT – traction transformer, 4QS1, 4QS2 – four-quadrant converters; AUXCS – auxiliary systems of electric locomotive control, ACM1 – auxiliary converter module of control section, ACM2 – auxiliary converter module of booster section, OESS – energy storage system, ES – energy storage, MC – matching converter, TDCS – traction electric drive of the control section, TDBS – traction electric drive of the booster section, TI1...TI16 – traction inverters, M1...M16 – traction induction electric motors.

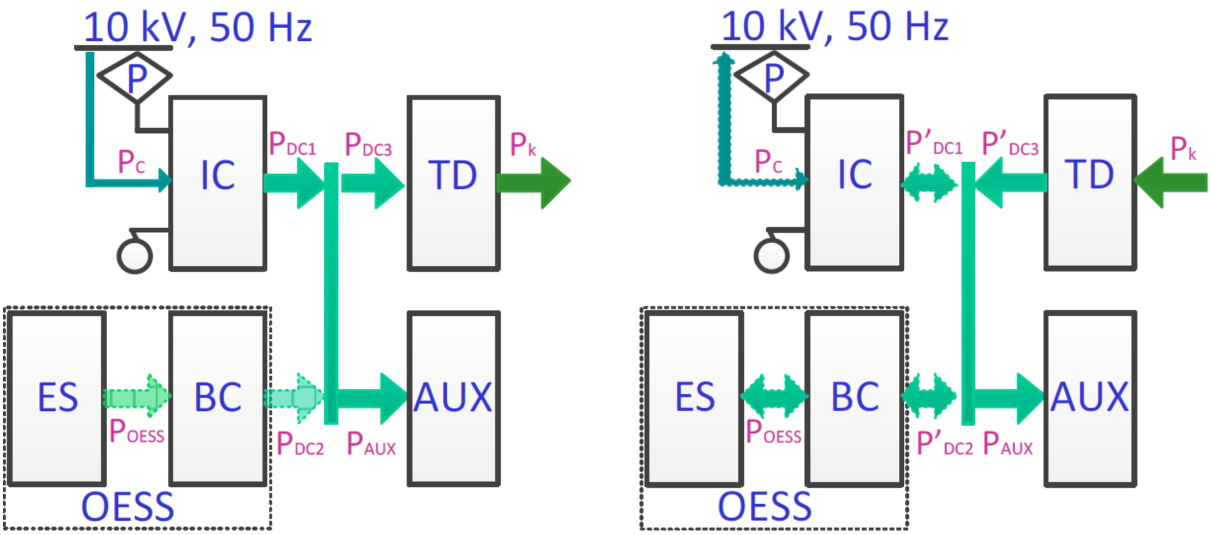
The power flow management algorithms are as follows.

In traction mode (figure 4a), the power consumed from the traction network is determined through the active component. If the total load is a tangential power and auxiliary systems, exceed this power, then the OESS is connected to the power supply of the load.

In the electrodynamic braking mode (figure 4b), the energy coming from the traction electric drive can be used to power the auxiliary systems of the electric locomotive (priority use), charge the OESS, and recuperate into the traction network (in case there is an excess of the total power of the auxiliary systems and the power, with which the energy storage (ES) is charged). If there is not enough energy to power auxiliary systems, the rest is compensated from the traction network. If during braking, the power coming from the traction electric drive exceeds the total power of auxiliary systems and OESS, the excess energy is recovered to the traction network. At the same time, the latter is possible if there is an OESS power limit.



(*a*) (*b*)

Figure 4. Energy flows in the traction system of an electric locomotive is traction mode (*a*) and EBD mode (*b*): P – pantograph, IC – input converter, TD – traction electric drive, OESS – on-board energy storage system, ES – energy storage, BC – matching converter, AUX – auxiliary systems, PC – power that is consumed from the traction network, P_{DC1} – power that enters the intermediate circuit from the input converter, P_{DC2} – the power that comes from to the intermediate circuit from OESS, POESS – power that is consumed from ES, P_{DC3} – power that is transmitted to the traction electric drive, P_{DAUX} – power consumed by auxiliary systems, P_k – tangent power of the electric locomotive, P'_{DC3} – power that comes from the traction electric drive, P'_{DC2} – the power that is transferred to the OESS, P'_{DC1} – the power consumed from the traction network in EDB mode.

To perform the calculations by the above, energy flow management algorithms were developed, the block diagram of which is shown in figure 5. The diagram does not show the calculation of the energy that is recovered to the traction network.

As mentioned above, two scenarios of operation are possible in EDB mode.

In the first scenario, the capacity of ES is sufficient to store all available energy. In this case, the power must ES meet the condition

$$P_{OESS} \geq P_{Lnom}\eta_{TD}\eta_{DC} \tag{1}$$

where P_{Lnom} – nominal tangent power of the electric locomotive, η_{TD} – the efficiency of "traction converter – electric motor – reduction gear" is taken as equal to 0.9; η_{BC} – the efficiency of the matching converter of the OESS assuming to be equal to 0.9.

The second scenario foresees that the storage capacity is selected from the condition of power compensation in traction mode. The storage capacity in this case is calculated using

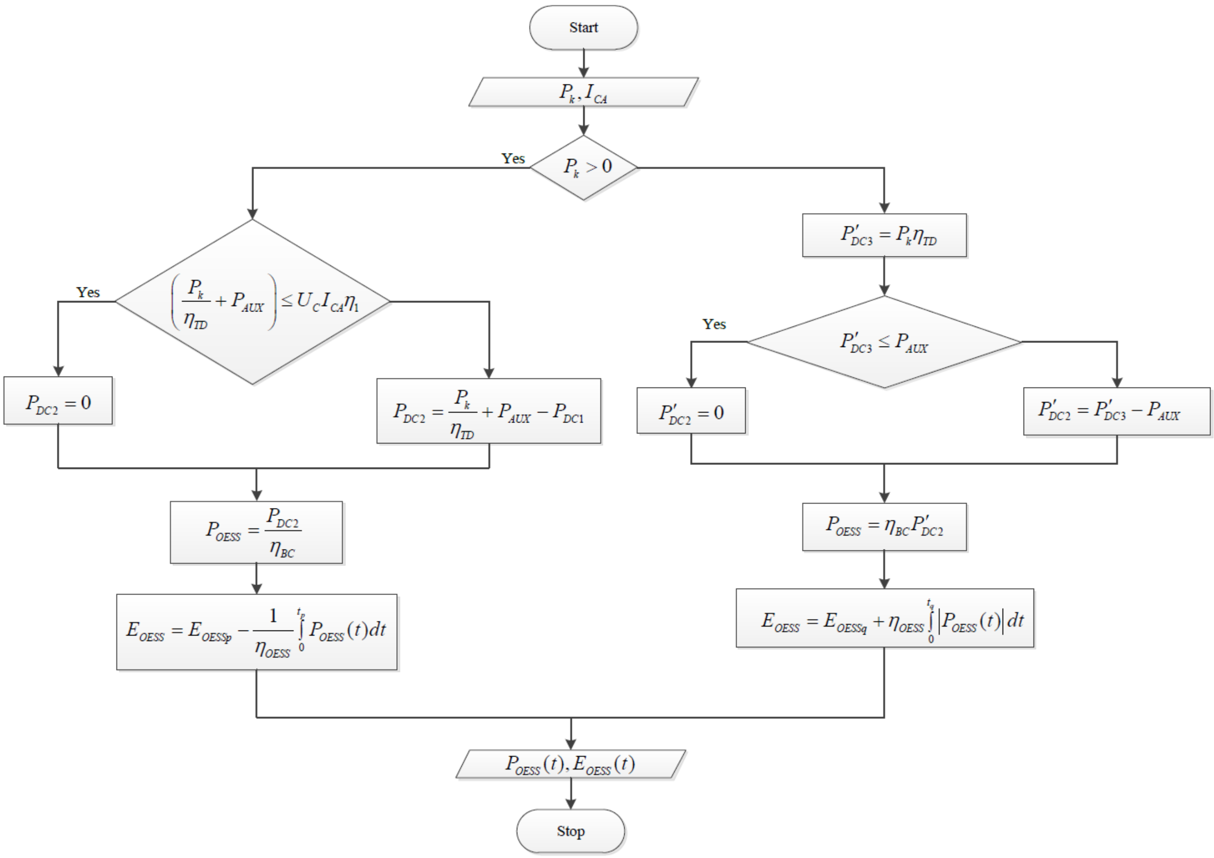


Figure 5. Block diagrams of the energy flow management algorithm in the traction system of the electric locomotive.

the expression

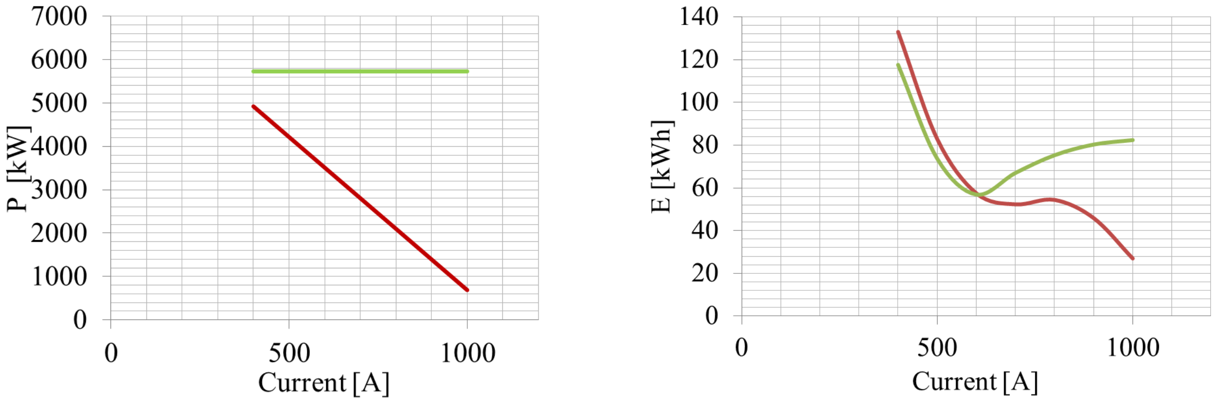
$$P_{OESS} \geq \frac{\frac{P_{Lnom}}{\eta_{TD}} + P_{AUX} - U_C I_{CA} \eta_1}{\eta_{BC}} \tag{2}$$

where η_1 – the efficiency of the "traction transformer – input converter – filter" link is taken as 0.95; P_{AUX} – the power of auxiliary systems of the electric locomotive is assumed to be equal to 300 kW, U_C – the lowest voltage on the current receiver, equal to 7.5 kV, I_{CA} – the limit current consumed by the electric locomotive from the traction network.

Figure 6 shows the dependence of the power of the ES (figure 6a) and the working energy capacity of the ES (figure 6b) on the limited current consumed by the electric locomotive. The calculations have been provided for the limit current range of 400...1000 A. The power of the ES and the working energy capacity were determined during the calculations. The corresponding dependencies are shown in figure 6.

The analysis of dependencies in figure 6 shows that in the first scenario – determination of the OESS power from the condition of complete energy absorption in the EBD mode – the ES power is a constant value. The working energy capacity in this case has a non-linear character with a minimum of about 600 A.

For the second scenario – determining the power of the energy storage device from the condition of power compensation while limiting the current consumption – the power is ES a linear dependence. The dependence of the working energy capacity is non-linear, and in the current range of 600...800 A it has a shade with an almost constant value.



(a) (b)

Figure 6. Dependencies of power (a) and and working energy capacity (b) of the energy storage (green line – scenario 1, red line – scenario 2).

It should be noted that the power values calculated according to (1) and (2) at a certain value of the limit current of the electric locomotive give the limits of the range in which the power can be ES. If the power is ES less than calculated by expression (2), then the power compensation mode will not be provided. If the ES power is greater than calculated according to (1), then there will be an irrational use of ES, since this value is the maximum ES power with which it can work in the case under study.

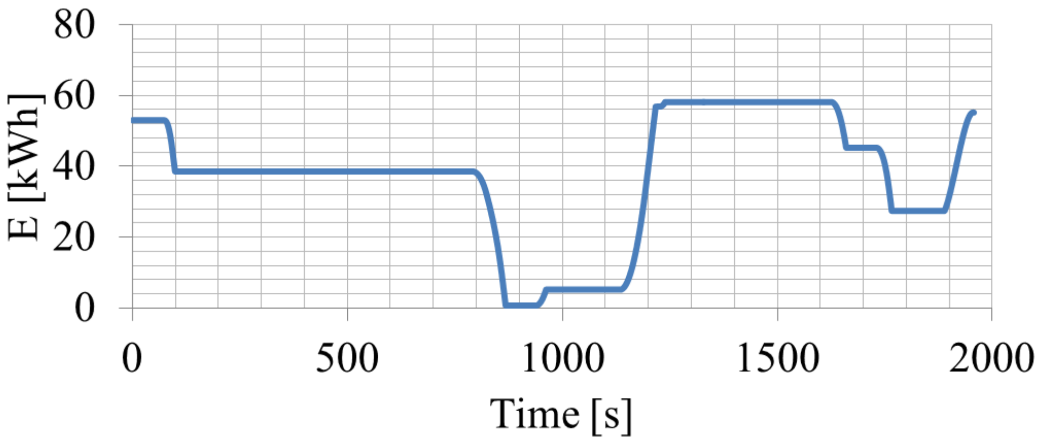
Thus, the determination of ES power and working energy capacity requires additional research. In general, both determining the parameters of the ES and determining the parameters of the entire traction system is a complex task [23–25].

Regarding the determination of the limit current of an electric locomotive, which can be consumed by an electric locomotive from the catenary network, the following must be taken into account.

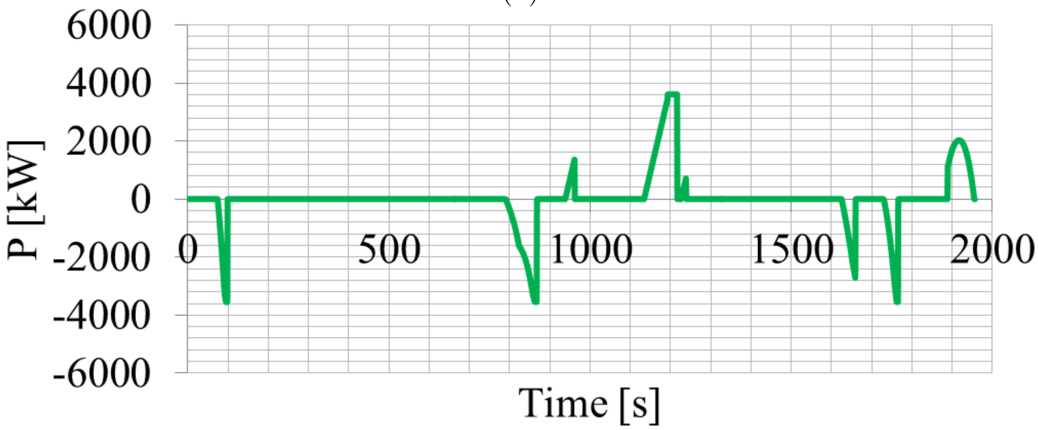
1. A system of copper contact wire and a bimetallic supporting cable is used in the contact suspension on the quarry railway transport. The continuous current of the PBSM-95+MF-100 contact network is 660...820 A depending on the degree of wear of the contact wire [26, 27], while an increase in current by 1.3 times is allowed if the duration of its flow does not exceed 3 minutes. Since the actual degree of wear of the contact wire is unknown, and, in addition, there may be several electric locomotives on one feeder zone, it is advisable to take the limiting current close to the lower limit of the range.
2. It is shown in [21] that when moving along the investigated section of the track, the movement of an electric locomotive with nominal power in the traction mode is carried out only uphill, and most of the time – 70.5% of the total time of movement in the traction mode – the traction drive operates with a power that does not exceed 1500 kW. The maximum value of the tangent power on flat areas is 3500 kW, which is 52.2% of the nominal power. That is, in speed maintenance modes, about 50% of the power of the electric locomotive is sufficient. Based on this, the current of the electric locomotive will be

$$I_1 = \frac{P_k}{U_1 \eta \cos\varphi} \tag{3}$$

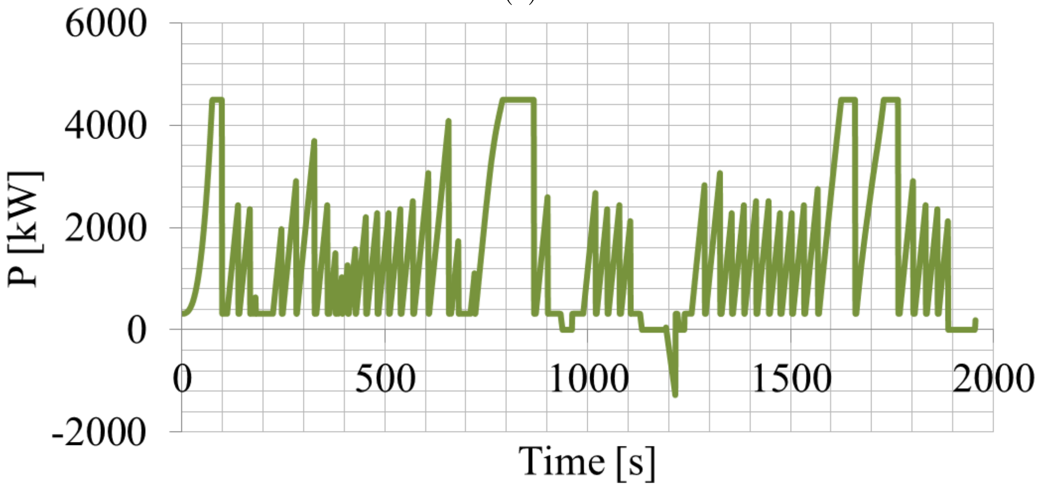
where P_k – tractive power, which is equal to 3500 kW; U_1 – the voltage on the current receiver, equal to 7.5 kV; η – efficiency factor of the electric locomotive, which can be taken



(a)



(b)



(c)

Figure 7. Dependencies of changes in energy (a), power (b) of the energy storage, and current consumed by the electric locomotive from the catenary network (c).

as equal to 0.86, $\cos\varphi$ – the power factor of the fundamental harmonic, which is assumed to be equal to 0.95.

After performing the calculations, we will get that the fundamental harmonic of the network current of the electric locomotive is about 570 A.

3. Decreasing the limit current of the electric locomotive leads to a reduction in the power – and therefore the cost – of the traction transformer of the input converter and the filters associated with it. However, it leads to an increase in the power and capacity of the OESS. Since the cost of electrical equipment is unknown, this aspect is not taken into account when determining the limiting current.

Thus, by comparing the first two aspects and the results of the calculation of the ES parameters, the limit current of the electric locomotive can be taken as equal to 600 A.

For example, figure 7 shows the dependencies of the change in the energy of the ES (a), its power (b), and the current consumed by the electric locomotive from the catenary network (c). The current limit is set to 600 A.

As can be seen from figure 7, when a current of 600 A is reached, the ES "switches on" to work. This happens during acceleration and movement on hills. In the EDB mode, when driving downhill, braking at the end of the movement, the energy enters the ES and even returns to the contact network. At the same time, the current that the electric locomotive consumes from the contact network does not exceed 600 A.

Thus, the algorithm described above can be used to determine the parameters of the onboard energy storage during working with current limitations. It is rational to simulate the movement of the train during the entire half-passage, as well as maneuvering during loading and unloading if during these operations the power is supplied from the onboard energy storage. To improve the accuracy of calculation results, it is necessary to improve mathematical models, in particular, to determine the losses in the traction electric drive.

3. Conclusions

The concepts of onboard energy storage management have been analyzed. Their use on rolling stock allows for storing of the energy during braking, which is later used during the movement of rolling stock.

For the electric locomotive of quarry railway transport, it is proposed to implement the mode of operation to limit the current consumed by the electric locomotive from the catenary network, and the energy exchange processes for this method of control have been investigated.

Calculations have been made and a justification has been provided for determining the limit current that can be consumed by an electric locomotive from the catenary network. Restriction of the limit current to 600 A is rational for the electric locomotive under study.

Abstract. This scientific paper provides an analysis of the current state of biogas production and potential for improvement through optimizing biogas production and diversifying production. The analysis uses data from open sources and reports, such as EBA's Statistical Report and analytical reports on market and digestate analysis. The authors present a comparison of electricity costs and biogas plant distribution in Europe, confirming that the higher the cost of electricity, the more widespread the introduction of biogas plants as an alternative energy source. The paper also discusses the potential of green ammonia production during anaerobic digestion, which can increase the efficiency and sustainability of biogas production technologies. The innovative technology of ammonia production from livestock waste during anaerobic treatment reduces the amount of water needed for dilution and transforms dissolved ammonia, which is toxic for anaerobic fermentation, into a useful final product. The paper highlights the potential for economically attractive approaches that use existing infrastructure and can contribute to energy independence and sustainability. The authors conclude that optimization in terms of more optimal process conditions and diversification of production approaches can increase the sustainability of biogas production technologies and ensure broader use.

1. Introduction

The decrease in carbon dioxide emissions and adherence to green energy production has been in focus of European community for decades [1]. That adherence is declared in sustainable development programs by the EU and worldwide. For example, the strategies Europe 2020 [2], Europe 2030 [3], and The Long-term Strategy of the United States [4] declared the EU's and US's goals for CO2 emissions decreasing. However, the recent actions of the European Union related to Russian invasion of Ukraine has added a new focus on urgent solving of energy issues and development of new approaches of energy production.

Therefore, it is relevant to provide evaluation of the economic potential of the new energy production methods. Ammonia is an energy source that has recently received much attention due to its advantages, including decreed emission. However, using it as an energy source nowadays is irrelevant due to high production costs. However, recently, a new carbon-free method of ammonia production has been proposed [5] that may be more efficient compared to the traditional process of ammonia production.

2. Materials and methods

The current state of biogas production is analyzed using reports and data of open sources. The estimation of the amount of biogas in Europe was taken from EBA's Statistical Report [6, 7]. The location of the biogas plants in Ukraine was collected and aggregated in online Google Map layer. The potential of the ammonia and market analysis was calculated based on the USA's and the EU's statistical data. Market analysis of the digestate was taken from the analytical report [8] and evaluated through calculations based on the statistical data on farm animals.

3. Results and discussion

3.1. Current state of biogas production from organic waste in Ukraine and in the EU

Current energy crisis creates the conditions that needs the development of the energy production systems solving urgent current needs and that are sustainable in long-term. And economic efficiency is one of the most significant factors driving the development of specific technologies. This statement is confirmed by comparing data on electricity cost and biogas plants' distribution. There is a correlation that the higher the cost of electricity, the more widespread the introduction of biogas plants as an alternative energy source. Thus, the most developed biogas production has place in Germany and Italy, where the cost of electricity is the highest among EU countries, 140 and 135 €/MW [9], respectively (figure 1). It is also important to note that a significant part of the structure of electricity prices in these countries is a tax (that is, the price of energy purchase is artificially increased to fill countries' budgets and prioritize energy efficiency). Accordingly, if the activity is profitable, the entrepreneur will carry out such activity. The crisis requires precisely these conditions of dependence on the energy resources of the Russian Federation and the food crisis caused by the war in Ukraine. It seems relevant to provide approaches that are economically attractive and use existing infrastructure.

The development of anaerobic technologies in Europe is spread unevenly (figure 2). In some countries, there is an oversaturation of the market with biogas plants, in particular, focused exclusively on the production of energy, which can be unsustainable [10]. At the same time, there are countries where anaerobic fermentation is not widespread, and there is significant

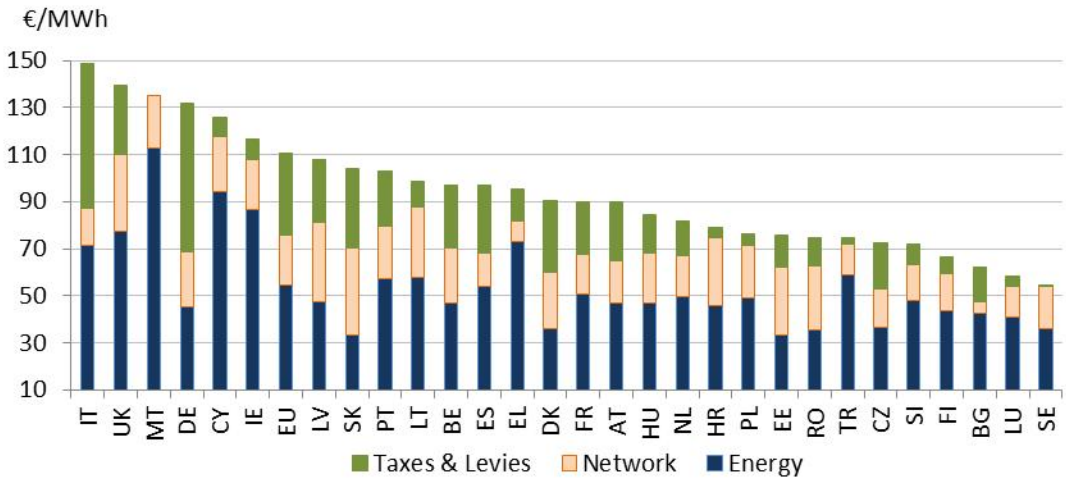

Figure 1. Average industry retail electricity prices in 2015 [9].

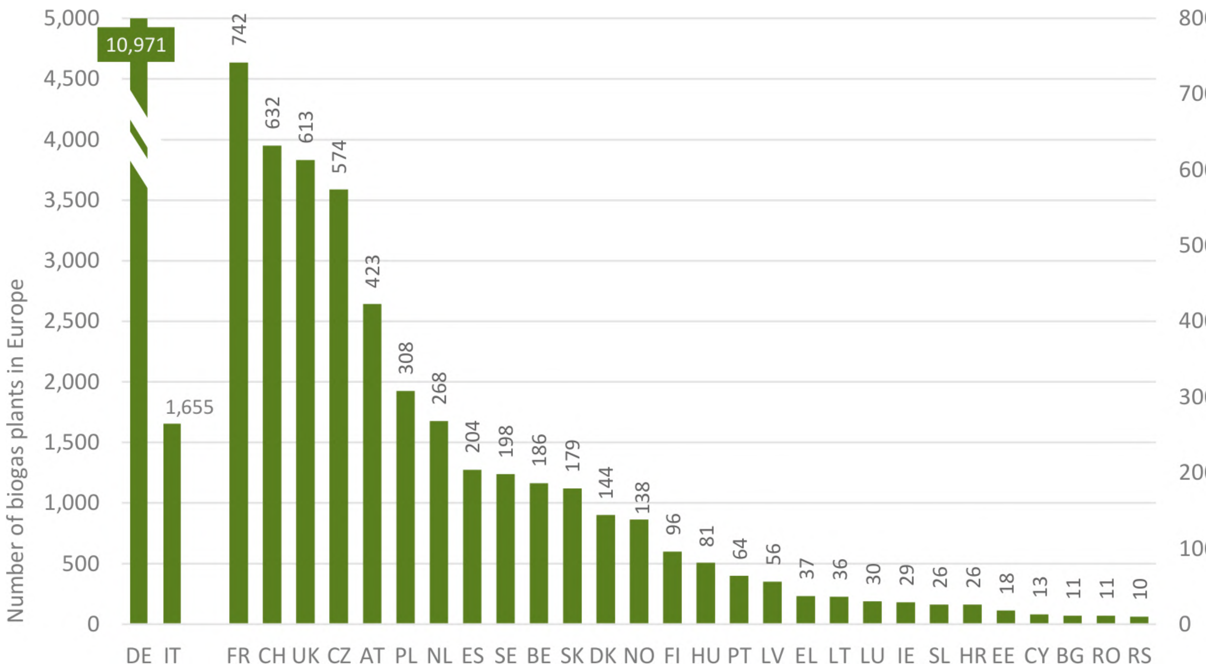

Figure 2. Number of biogas plants in European countries, arranged in descending order [6].

potential for its introduction. Thus, more than 11,000 biogas plants are operating in Germany and more than 1,600 in Italy. However, for example, in Romania and Bulgaria, the number of such plants is about 10 units per country, despite the relatively large territories of these countries.

In general, as of 2018, more than 50 facilities were producing biogas operated in Ukraine, of which 33 used organic waste. The total capacity of biogas plants was 44 MW. It is planned to build several biogas plants, particularly under the Ukrainian companies MHP and Danosha. The location of biogas facilities in different regions of Ukraine is presented in (figure 3).

3.2. Increasing economic efficiency of anaerobic fermentation for energy production

3.2.1. The potential of production of green ammonia during anaerobic digestion. Increasing economic efficiency by optimizing biogas production and diversifying production is the requirement for the anaerobic treatment technology to ensure energy independence of states. Both of these approaches will increase the sustainability of the approach and ensure the broader use of biogas production technologies [10]. Optimization in terms of more optimal process conditions is carried out quite widely and is inherent in many studies [11–13]. Here we will discuss the use of biofertilizers obtained in the process of anaerobic fermentation and the production of ammonia during the anaerobic fermentation of waste with a high nitrogen content.

Modern approaches make it possible to obtain additional products from organic waste when using anaerobic fermentation and ensure an increase in the efficiency of the process. The problem of accumulating a significant amount of ammonia in the anaerobic fermentation process, which leads to inhibition, has been known for a long time [14]. In order to reduce the inhibitory effect, there is a need to dilute the waste with water in an amount that could reach up to 12 times compared to the original substrate, which leads to additional costs and environmental impact. Using a sustainable technology of biogas production from livestock waste, it is possible to obtain such ammonia as a pure product, which can later be used as a fuel on a par with green hydrogen. The essence of the innovative ammonia production technology is the absorption of

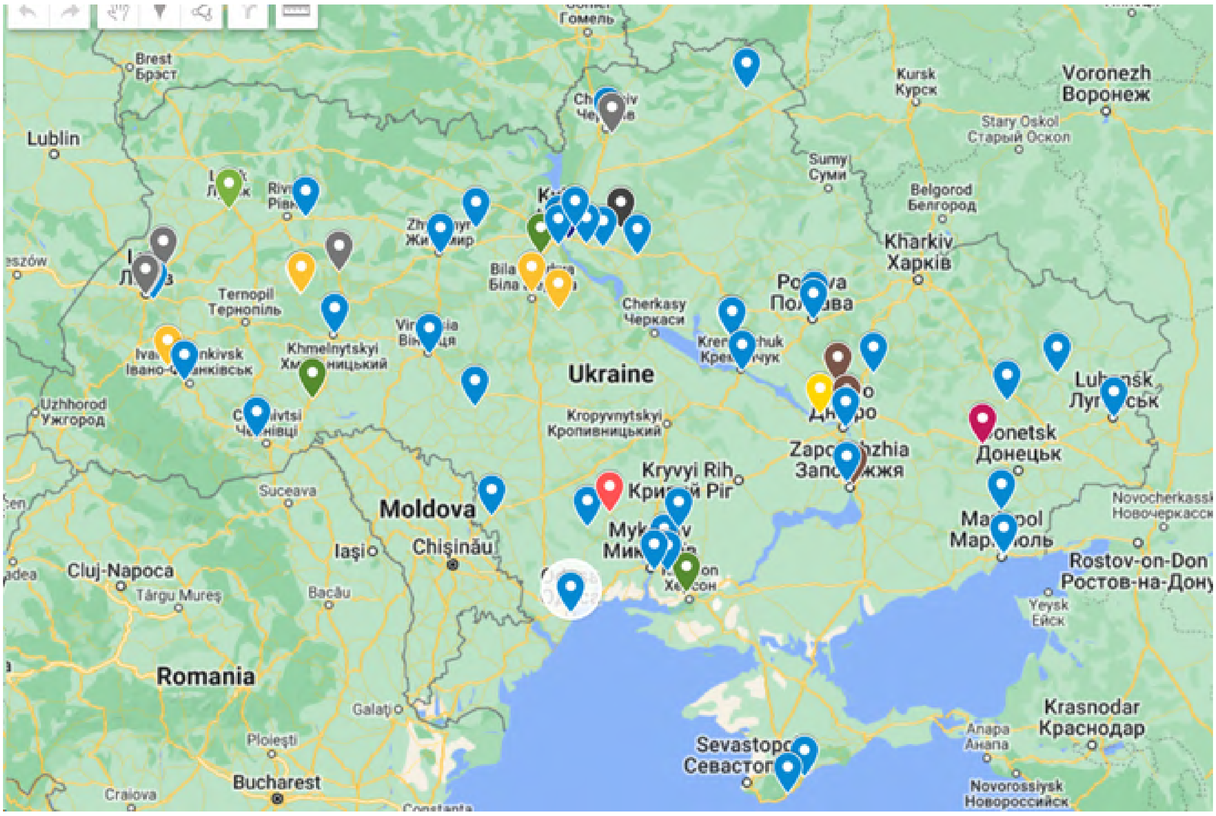

Figure 3. Location of facilities producing biogas in Ukraine.

ammonia during destruction in the process of anaerobic fermentation by the sorbent placed in the reactor and its subsequent regeneration (figure 4) [5]. Therefore, this approach reduces the amount of water needed for dilution and ensures the transformation of this dissolved ammonian which is toxic for anaerobic fermentation, into a final helpful product.

It is important to note that such technologies have high potential because, for example, the technology can, for the first time, ensure the production of ammonia cheaper than when using the Haber-Bosch process. In addition to anaerobic fermentation, there were other methods of obtaining ammonia from livestock waste, for example, using Escherichia coli [15] or using a hydrothermal approach [16]. However, they probably use not fewer resources than the traditional ammonia production approach.

The European Commission currently encourages the use and various production methods of green ammonia. Thus, there are projects funded by the European Commission on the electrochemical production of ammonia [17] and the use of ammonia in fuel cells for marine vessels [18].

The global market for green ammonium is 17 million dollars [19]. However, such relatively small market indicators are related precisely to the fact that there was no technology on the market that would be cheaper than the production of ammonia by the traditional method. It is predicted that the cost of green ammonia will gradually decrease, mainly due to the discovery of methods that make production cheaper and the introduction of ammonia production approaches in the industry. Thus, the price over 30 years may drop several times from the estimated average cost of 1,000 $ per ton to 500 $ per ton, potentially making it cost-competitive with ammonia obtained by traditional technology [20]. Figure 5 shows the forecast for the cost of ammonia until 2050.

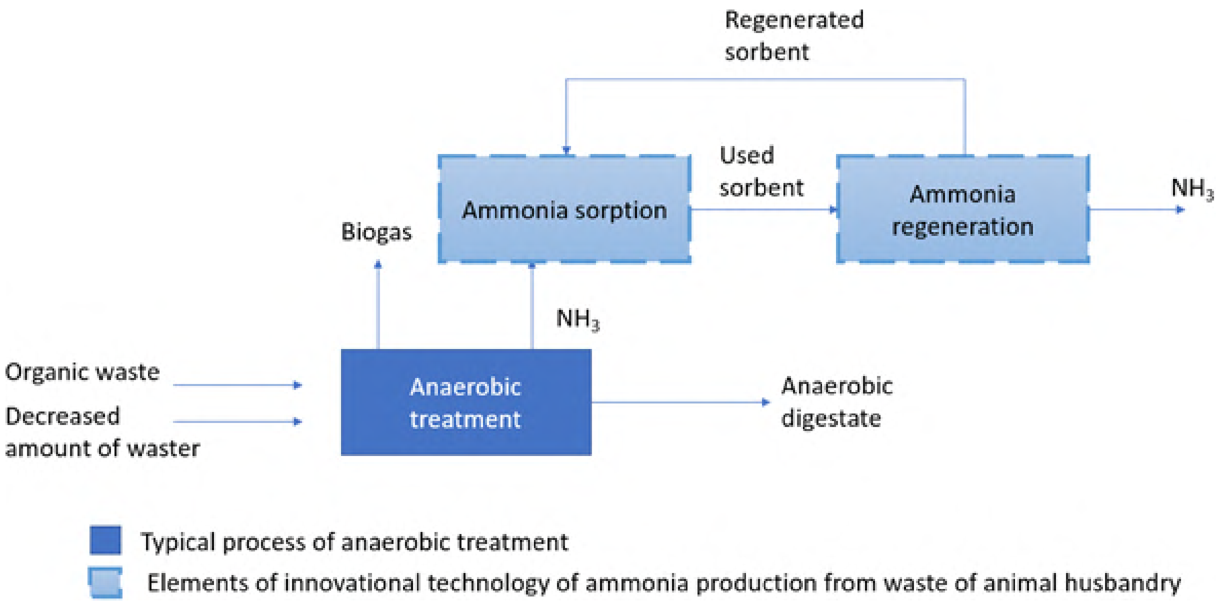

Figure 4. An innovative method of producing ammonia from livestock waste during anaerobic treatment [5].

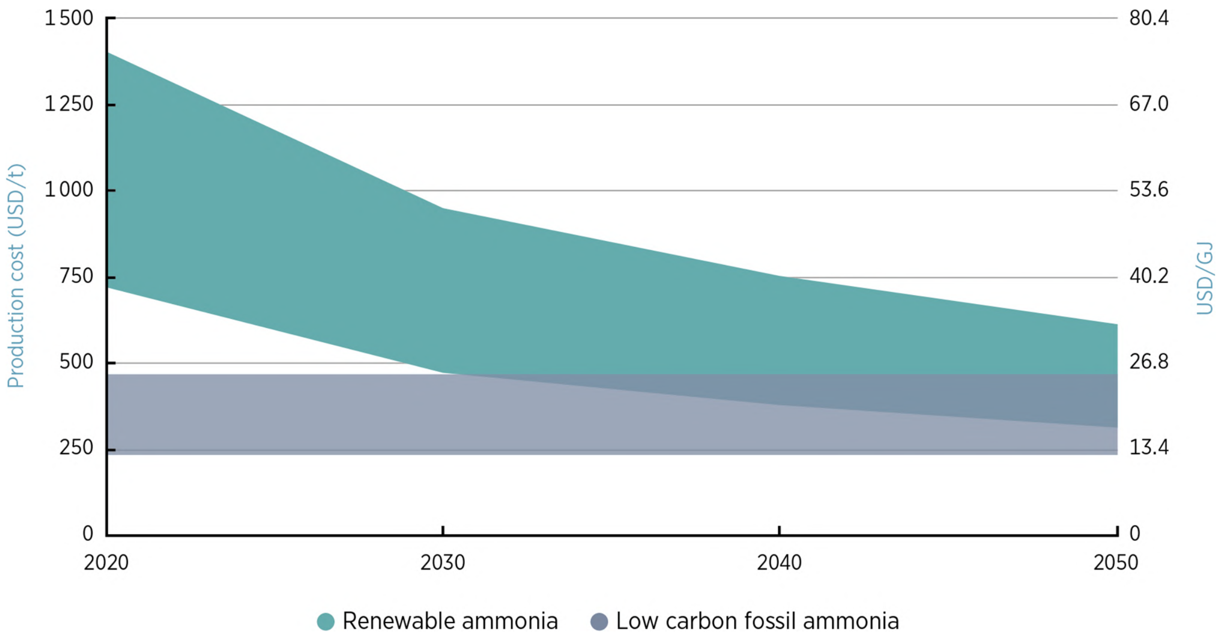

Figure 5. Ammonia cost forecast until 2050 [20].

In Europe, the potential of ammonia production from livestock waste by anaerobic fermentation reaches 10 million tons per year [21]. Ammonia production potential in the USA is commensurate with European ones (figure 6).

It is important to note that today the production of energy from ammonia produced by the Haber-Bosch process is considered unprofitable. So, the amount of energy required to produce a ton of ammonia by the Haber-Bosch method is 38 GJ. At the same time, 22.5 GJ of energy can be obtained from one ton of ammonia [22].

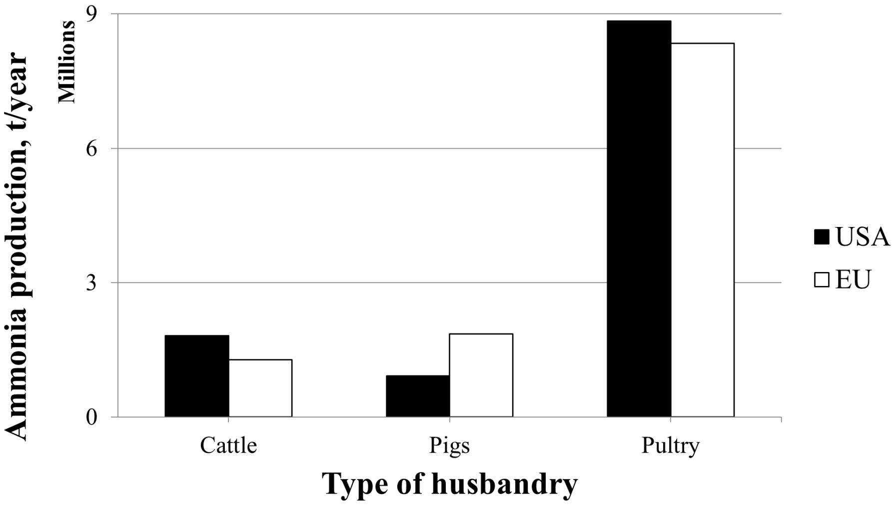

Figure 6. The potential of ammonia production using anaerobic fermentation technology from livestock waste in the USA and the EU [5].

In Ukraine, this method's potential for ammonia production can reach up to 0.1 million tons per year. Vinnytsia, Cherkasy, and Kyiv regions have the most potential for ammonia production due to the location of many livestock complexes.

Considering that the cost of ammonia is about 1,135 dollars per ton [21], the potential market for ammonia produced in this way can be about 11 billion dollars for Europe and the USA and about 0.11 billion dollars per year for Ukraine.

3.2.2. The potential of anaerobic digestate production. The anaerobic fermenters biofertilizers market is estimated at 45 Bn $ as of 2019, with a compound annual growth rate (CAGR) of 7.8% and a growth potential of over 75 Bn $ in 2026 (figure 7) [8].

However, the indicated figures look incomplete, as both the European Union and Ukraine have additional potential for the production of biofertilizers. The cost of the solid fraction of biofertilizers is 122 $ per ton [22], which is significantly cheaper than other types of fertilizers. The generated waste is 5,913,382 tons and 234,547 tons per day in Europe and Ukraine, respectively. Therefore, the market of biofertilizers can potentially reach about 263.3 and about 10.4 Bn $ per year in the EU and Ukraine, respectively. It is worth noting that the provided calculations were carried out using a rough methodology, assuming that all waste was sold as a solid fraction without considering mass changes in waste during fermentation. The calculation of the potential of the biofertilizer market in Europe and Ukraine is presented in table 1 and table 2. Data calculated considering that one animal of poultry, pigs, cows produces 0.16, 5.10, 55.00, kg of waste per day, respectively [23].

Also, the efficiency of the process may be enhanced by using addition technologies such as waste catalysis [26, 27], the use of nanoparticles [28–35] to provide additional purification. In addition optimization could be reached by using modern decision-making tools such as ontologies [36–39].

4. Conclusions

In conclusion, ammonia production by anaerobic fermentation of livestock waste has a high potential for Ukraine and the European Union. It is one of the promising ways to Ukraine's role in ensuring Europe's energy security, especially considering that the existing infrastructure of pipelines does not require significant modernization for the transportation of ammonia.

Figure 7. The economic potential of the biofertilizer market in the European market [8].

Table 1. Market potential of biofertilizers in the European Union.

Animal waste type	Number of animals, thousands of heads [24]	Waste production, t/day	Biofertilizer market potential, Bn \$ per year
Poultry	1570000	251200	11.19
Pigs	150320	766632	34.14
Cattle	89010	4895550	218.00
Cows	1809330	5913382	263.32

Table 2. Market potential of biofertilizers in Ukraine.

Animal waste type	Number of animals, thousands of heads [25]	Waste production, t/day	Biofertilizer market potential, Bn \$ per year
Poultry	251200	35278	1.57
Pigs	766632	29210	1.30
Cattle	3092	170060	7.57
Cows	229305	234547	10.44

Implementation of the modern approaches that correlate with sustainable development goals and the concept of circular economy may be an effective approach to solving European energetic challenges caused by Russian invasion of Ukraine.

Abstract. Recently, hydro units are used in maneuverable modes, which leads to an increase in the load on all elements of hydro units. It can lead to unpredictable failure of their components and even failures in the operation of the hydroelectric power plant. Therefore, the use of diagnostic systems is appropriate for solving such problems. The most promising non-destructive diagnostic systems are vibration diagnosis systems. However, the effectiveness of their use depends on the diagnosis algorithms, which depend on the features and functioning of the diagnosed unit of the power unit. In this work, some models of vibration signals of hydraulic units and features of the construction of vibration diagnostics systems of hydrogenerator units are considered

1. Introduction

Using the machine in maneuverable modes, which modes can lead to premature or unpredictable failure of their components and even to failures in the operation of the hydroelectric power plant. The ISO 19283:2020 standard [1] provides a comprehensive standardized description of test procedures that allow for a comprehensive approach to the diagnosis of the condition of hydraulic units based on the monitoring and diagnosis of the structural elements of the of the structural elements of the hydroelectric power plant. The requirements for automated monitoring and diagnostic systems are defined in the ISO 61850-7-410 standard [2] and other standards [3–7]. In addition, when building a system for monitoring and diagnosing hydro generators, it is necessary to take into account that a significant number of hydro generators are low-speed machines with a low frequency of rotation of the hydro generator up to 150 rpm. Such features of the machine should be taken into account when choosing a diagnostic method. A significant part of the problems related to control and diagnostics of power equipment can be considered as problems of pattern recognition in the diagnostic space. However, on the other side of the problems that arise during an operation and repair of power equipment, the methodologies used during the implementation of smart control and diagnostic systems should be divided into two separate groups:

- detection of a change in the technical condition caused by defects at an early stage of their development, when damages have not yet appeared in a clear form;
- search for defects based on their already identified signs.

Based on the assessment and with the knowledge of probable processes, it is possible to carry out remaining useful life prediction of the equipment and plan possible maintenance actions based on the actual technical condition of the equipment. The application of forecasts in practice allows flexible changes to be made to plans for reorganizing the use of generating power plant equipment to cover demand both on the electricity market and to meet one's own needs.

2. The structure of power equipment maintenance system

The main prerequisite for forecasting the remaining useful life prediction of hydro unit is the availability of information about the technical condition of the equipment or its components [8,9]. To obtain primary information, modern monitoring and diagnostic systems are equipped with smart sensors [10, 11]. Smart sensors provide the possibility of self-monitoring, which ensures obtaining data without abnormal values, which can be used without preprocessing to determine the state of the equipment or its units.

The obtained data are intended for use as input data for analysis systems of means of diagnosing the technical state of the component. The technical condition of the component depends on the actual conditions in which the generator operates. Actual conditions are determined with the help of additional sensors that are part of Smart sensors. As a rule, the assessment is performed by comparing the measured or calculated state with the permissible values under which the correct operation of the equipment occurs.

This significantly allows you to expand the possibilities of existing methods to ensure the solution of the previously mentioned maintenance tasks according to failure prediction.

The structure of the maintenance system according to the actual technical condition of the equipment is represented on figure 1 [6].

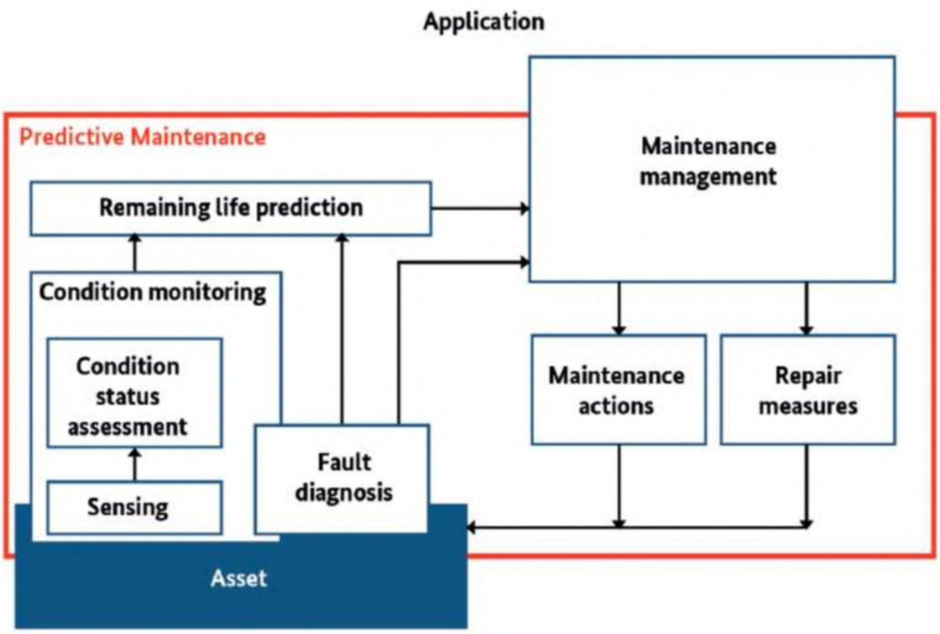

Figure 1. The principle functional structure of fault diagnosis system with predictive maintenance.

3. Physical and mathematical models

For the solution of problem of the remaining useful life prediction of hydro units, it is necessary to build models based on individual quantitative data describing the state of a specific unit of a specific machine, taking into account the history of its use. If there are no physical diagnostic models, the analytical or computer modeling methods are used, which based on the appropriate algorithms [12–17].

Therefore, to elaborate algorithms for the functioning of monitoring and diagnostics systems, it is advisable to use the processes of autoregression (AR process), which have become widely used during the implementation of mathematical models of various types information signals and allow to elaborate algorithms for diagnosing technical objects that have a low frequency of shaft revolutions [18, 19]. A theory of the same processes has been considered in the papers [20–28].

By definition, a stationary linear autoregressive (AR) process is defined as

$$\xi_t + a_1\xi_{t-1} + \ldots + a_p\xi_{t-p} = \zeta_t \tag{1}$$

where $\{a_j, a_j \neq 0, j = \overline{1,p}\}$ are autoregressive parameters; p is the order of autoregressive; $\{\zeta_t, t \in Z\}$ is a stationary random process with infinitely divisible distribution, it has independent values, $P\{\zeta_0 = 0\} = 1$. This process is often called as the generating process. It is assumed that the process is stationary in the narrow sense and ergodic theorems are fulfilled [19].

Linear stationary autoregressive processes can be given by

$$\xi_t = \sum_{\tau=1}^{\infty} \phi_{ar}(\tau)\zeta_{t-\tau} \tag{2}$$

where $\phi_{AR}(\tau)$ is a kernel of the linear AR process [19].

It is assumed that

$$\phi_{ar}(0) = 1; \sum_{\tau=1}^{\infty} |\phi_{ar}(\tau)|^2 < \infty \tag{3}$$

Kernel $\phi_{AR}(\tau)$ is connected with parameters of autoregression [19]:

$$\phi_{ar}(\tau) = \begin{cases} 0 & k < 0 \\ 1 & k = 0 \\ \sum_{\tau=1}^{k} a_\tau \phi_{ar}(k-\tau) & k = \overline{1, p-1} \\ \sum_{\tau=1}^{p} a_\tau \phi_{ar}(k-\tau) & k = \overline{p, p+1} \end{cases} \tag{4}$$

where: $\phi_{AR}(\tau)$ – is a kernel of linear stationary autoregressive process.

The process ξ_t is assumed to be strictly stationary random process, and ergodic theorems are carried out [13]. The process ξ_t has a Kolmogorov representation one-dimensional form logarithm of characteristic function (CF):

$$lnf_\zeta(u,t) = lnf_\zeta(u,1) = im_\zeta u + \int_{-\infty}^{\infty} \{e^{iux} - 1 - iux\} \frac{dK_\zeta(x)}{x^2} \tag{5}$$

where parameter m_ξ and spectral functions of jumps $K_\xi(x)$ define unequivocally the characteristic function of the random process.

It is necessary to remark that special installations are constructed for experimental research [29–36]. A special experimental stand was created at the Institute of Electrodynamics of the National Academy of Sciences of Ukraine. It was used for carry out practical research on vibration analysis. Figure 2 shows a general view of the experimental stand. It was used for research of the influence of the operation of bearing assemblies of electric machines (EM) in different speed modes of its operation on the components of vibration processes that accompany the operation of the machine. The main goal of the research is to experimentally identify the connections between typical defects such as misalignment, eccentricity, lubricant quality, damage to the outer or inner ring of the bearing as a result of metal pitting (pitting) and the parameters of diagnostic signs that clearly allow the defect to be detected.

Figure 2. Installation for vibration tests of bearings.

Experimental setup consists of three parts: an electric drive, a massive shaft, a mounting unit and vibration measurement instruments of the tested bearing. Rotation of the tested bearing, installed in the attachment and vibration measurement unit, is provided by a direct current electric motor of the P-51 type through a massive shaft. Motor 11 kW ensures rotation of the tested bearing at speed is in the range 10 to 1000 rpm. Usage of a special coupling with rubber fingers makes it possible to reduce the vibrations caused by the operation of the electric motor. The reduction of the vibrations of the shaft of the experimental installation is facilitated by usage of sliding bearings. The bearings are made of PTFE. Three units of the experimental installation were placed on a massive plate. The main purpose of the bearing assembly and vibration measurement is the ability to artificially reproduce the main defects of the bearing and the placement of primary vibration-transducing equipment (accelerometers). To measure the vibration accelerations of the bearing under study, an accelerometer type ABC-017 was used, which made it possible to measure the acceleration of vibrations of the bearing in the frequency band of 20 Hz . . . 30 kHz. It is installed in the radial direction in relation to the tested bearing. Research was carried out on rolling bearings of type 309 ESH2 with various types of defects (skew, lack of lubrication, defects of inner and outer rings, rolling bodies caused by metal spalling due to its fatigue). When carrying out experiments on the influence of the angular velocity of EM shaft rotation on quantitative assessments of the main diagnostic features, the speed mode of shaft rotation varied directly with the values $v_{rot} \in (250, 500, 750, 1000)$ rpm. Autoregressive parameters were used as diagnostic features. A bearing misalignment type defect was modeled. Educational groups were formed in the diagnostic space a_1, a_2. Two-dimensional histograms corresponding to the selected test conditions are presented in figure 3 and figure 4.

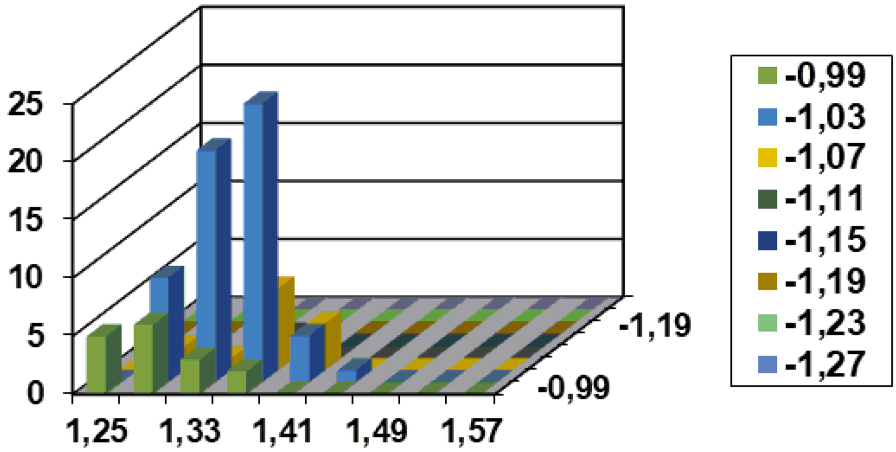

Figure 3. Histogram of diagnostic parameters of the serviceable bearing.

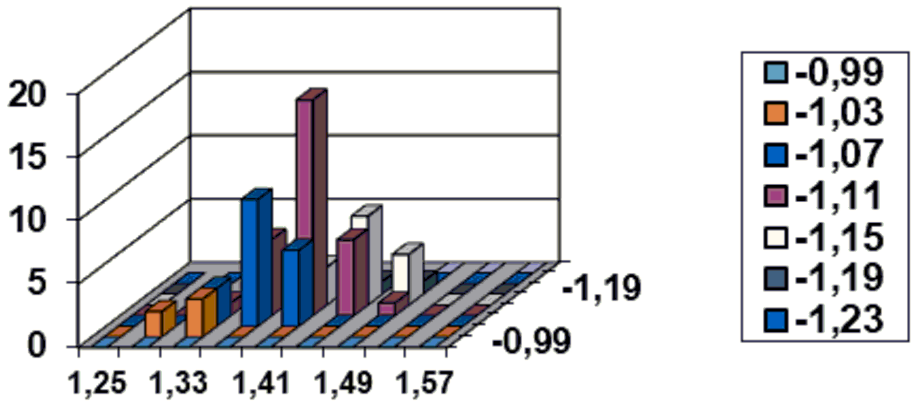

Figure 4. Histogram of diagnostic parameters the misaligned bearing.

4. Algorithms of diagnosis

Figure 5 illustrates algorithm in training mode.

The learning algorithm, first, an evaluation of diagnostic signs is carried out. Then, on the basis of these populations, a vector of estimates of their mathematical expectations, an estimate of variances, and the construction of covariance matrices of correlations between diagnostic parameters and an assessment of the characteristics of the distribution of diagnostic signs were built. If necessary, linear transformations of covariance matrices and normalization of covariance matrices are performed to construct effective decision rules [19].

At the stage of planning the experiment (figure 6), the threshold C and the required number of observations N are calculated.

In the diagnostic mode, diagnostic signs assessed and a decision made on the technical condition of the diagnostic object based on the constructed solving rules (figure 7).

Abstract. The concept of a continuous-time conditional linear random process involves a random kernel being integrated stochastically by a process with independent increments, which is often called a "generative process". In cases where the "generative process" is Poisson, the resulting model represents an investigated signal as a sum of numerous stochastically dependent random impulses each of which occurs according to some inhomogeneous Poisson arrival process. This model can be applied to represent various processes related to energy consumption, such as electricity loads of electrical power systems, gas and water consumption, and other energy resources, while also considering the signals' cyclostationarity, which is usually caused by the rhythmic nature of consumer behaviour. A member of the discrete-time conditional linear cyclostationary random processes class is the random coefficient periodic autoregressive (RCPAR) model, which is appropriate for use in energy informatics, including estimation, forecasting, and computer simulation purposes. The primary objective of the paper is to establish a procedure for simulating the hourly electricity consumption of small and medium-sized enterprises using the RCPAR model, which has periodic parameters and creates cyclostationary properties while also accounting for the investigated process conditional heteroscedasticity. The statistical estimation step of the proposed procedure uses the general methodology for estimating the parameters of the RCPAR model and the methods of statistical analysis of cyclostationary signals. This step is used to identify the simulation characteristics. The simulation step is based on the methods of cyclostationary white noise generation and its transformation by a digital linear filter with random parameters. The last ones are obtained using the Gaussian random vectors computer simulation methods, taking into account the cyclostaionarity property.

1. Introduction

The development of mathematical and computer-based models for stochastic signals, processes, and noises is a crucial step in the creation of information measurement and control systems within the electric power industry [1, 2], as well as automated systems for energy consumption analysis (electric, gas, water consumption), information technology for monitoring and diagnosing the technical conditions and environment of energy facilities, etc. The models form the theoretical foundation for the design and implementation of such systems and technologies, and provide the basis for signal processing algorithms, diagnostic decision-making methods, and energy consumption forecasting. An adequate mathematical model must accurately represent the physical mechanism behind the signal or process, enable theoretical analysis, and facilitate the detection and estimation of informative characteristics of energy objects. Moreover, it should also be suitable for creating computer simulation models to solve practical problems.

Modern problems and challenges in the energy sector, which are associated with the volatility and partial controllability of sustainable energy generators, the uncertainty of the behaviour of energy consumers (which is no longer necessarily in line with traditional load profiles), decentralization, modification of the dynamic characteristics of sustainable energy systems, require comprehensive scientific applied research in the domain of energy informatics, which combines computer science, control systems, and energy management systems in a single methodology [3]. Important areas of energy informatics are the collection, analysis, deployment, and exploitation of energy status data, modelling, simulation, and prediction of the behaviour of energy objects and processes [3], including energy consumption computer simulation. Energy consumption data analysis and simulation are also useful instruments for the problems of user segmentation based on energy consumption behaviour, electricity consumption pattern (load profiles) analysis, power consumption forecasting, etc. Modelling, computer simulation, digital twin technology [4], etc. can be interconnected to create a complex digital energy ecosystem called as "Energy Metaverse" [5].

Mathematical models represented as continuous-time or discrete-time linear random processes (LRP) are very useful for solving the above problems in energy engineering [6, 7]. In the mentioned above application domains, the different implementations of linear periodic random processes [6, 7] are also very useful, which allows taking into consideration the cyclostationarity of the studied signals or processes, caused, for example, by the rhythmic daily (weekly, yearly, etc.) behaviour of electricity, gas, or water consumers, vibrations of the bearings of energy facilities, and other energy objects that are subject to monitoring and diagnosis.

Linear random processes are commonly used for mathematical modeling of signals that are additively comprised of a large number of independently occurring independent impulses (with random parameters) forming a Poisson flow [6]. However, when these impulses are dependent random functions, a more appropriate model would be a conditional linear random process (CLRP) [8], which is defined as a stochastic integral of a random kernel driven by a 'generative' inhomogeneous process with independent increments (LRP has a similar construction, where the kernel is a deterministic function).

For the problems of statistical monitoring, forecasting, diagnostics, and computer simulation, discrete-time LRP is mostly used in the form of an autoregressive sequence, and for cyclostationary processes as periodic autoregression [6, 7, 9]. Similarly, the random coefficient autoregressive (RCA) model [8, 10] is an effective tool for the statistical analysis of CLRP. Properties, methods of the parameters estimation of the RCA model in the case of its stationarity, and corresponding computer simulation methods have been studied by many authors (a comprehensive review of corresponding results is given in [10]). The random coefficient periodic autoregressive (RCPAR) model has been defined as RCA model with periodic coefficients. The periodicity conditions of its moment functions and multidimensional distribution functions have been established. Expressions for estimating the parameters of the periodic autoregression model with random coefficients in the general case have been obtained in [8], and the properties of the estimates have been confirmed by the results of computer simulation modelling.

The primary objective of the paper is to develop the method of computer simulation of electricity consumption using random coefficient periodic autoregressive model.

2. Conditional linear random processes

A real-valued conditional linear random process $\xi(\omega, t),\ \omega \in \Omega,\ t \in (-\infty, \infty)$ (where $\{\Omega, F, \mathbf{P}\}$ is some probability space) has been defined in [11] as follows:

$$\xi(\omega, t) = \int_{-\infty}^{\infty} \varphi(\omega, \tau, t) d\eta(\omega, \tau),\ \omega \in \Omega,\ t \in \mathbb{R}, \tag{1}$$

where Ω is a sample space; $\varphi(\omega,\tau,t),\ \tau,t\in\mathbb{R}$ is a real-valued two-dimensional random field, which is called *kernel*; $\eta(\omega,\tau),\ \tau\in(-\infty,\infty)$ is a stochastically continuous process with independent increments, expectation and variance of this process have the following properties: $\mathbf{E}\eta(\omega,\tau)=a(\tau)<\infty$ and $\operatorname{Var}[\eta(\omega,\tau)]=b(\tau)<\infty,\ \forall\tau$; random field $\varphi(\omega,\tau,t)$ and random process $\eta(\omega,\tau)$ are *stochastically independent.*

The representation (1) exists in the sense of mean-square convergence of the sequence of appropriate integral sums if and only if the following holds [8]:

$$\mathbf{E}(\xi(\omega,t))^2=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\mathbf{E}\left(\varphi(\omega,\tau_1,t)\varphi(\omega,\tau_2,t)\right)da(\tau_1)da(\tau_2)+\int_{-\infty}^{\infty}\mathbf{E}\varphi^2(\omega,\tau,t)db(\tau)<\infty. \tag{2}$$

If kernel $\varphi(\omega,\tau,t)$ is deterministic function then $\xi(\omega,t)$ is LRP [8].

Conditional (conditionally) linear random process (1) has been characterized for the first time by Pierre [12] for the case of a homogeneous and compensated 'generative' process $\eta(\omega,\tau)$. In particular, Pierre studied the central limit theorem for the sequence of linear functionals from conditionally linear random processes with continuous and discrete time with application to the problems of mathematical modelling of radar clatter.

If defined above random process $\eta(\omega,\tau)$ is a Poisson process, then the expression (1) in the following form:

$$\xi(\omega,t)=\sum_{k=-\infty}^{\infty}\varphi(\omega,\tau_k(\omega),t), \tag{3}$$

where ... $<\tau_{k-1}(\omega)<\tau_k(\omega)<\tau_{k+1}(\omega)<$ ... are the times of jumps of the Poisson process, which are equal to the times of random impulses $\varphi(\omega,\tau_k(\omega),t)$ occurrence ($\varphi(\omega,\tau_k(\omega),t)=0$ if $t<\tau_k(\omega)$), and random functions ..., $\varphi(\omega,\tau_{k-1},t)$, $\varphi(\omega,\tau_k,t)$, $\varphi(\omega,\tau_{k+1},t)$, ... are stochastically dependent (at nonrandom time moments ... $<\tau_{k-1}<\tau_k<\tau_{k+1}<$ ...).

The modelling of power system loads as a linear periodic random process is based on the representation of the studied process expressed as the sum of a numerous independent impulses (with random duration and amplitude) occurring at Poisson moments of time. According to the results of experimental studies [8] it is shown that the processes of electricity consumption of individual households are stochastically dependent. This confirms the adequacy of the CLRP model for the tasks of mathematical modelling, forecasting, and simulation of electricity consumption processes at the level of households, residential areas and enterprises. Moreover, taking into account the cyclic behavior of energy users, it can be shown that the investigated electricity load process will be cyclostationary [9] with a period of $T=24$ hours, that is, n-dimensional ($n\geq 1$) cumulative distribution function $F(x_1,\ x_2,\ ...,\ x_n;t_1,\ t_2,\ ...,\ t_n)=\mathbf{P}\left(\xi(\omega,t_1)<x_1,\ \xi(\omega,t_2)<x_2,\ ...,\ \xi(\omega,t_n)<x_n\right)$ of the random process is periodic by its time arguments [9]:

$$F(x_1,\ x_2,\ ...,\ x_n;t_1,\ t_2,\ ...,\ t_n)=F(x_1,\ x_2,\ ...,\ x_n;t_1+T,\ t_2+T,\ ...,\ t_n+T).$$

Let $\xi(\omega,t),\ t\in(-\infty,\infty)$ be the energy system load, mathematical model of which is represented above as a cyclostationary CLRP. Then

$$\xi_t(\omega)=\int_{(t-1)h}^{th}\xi(\omega,s)ds,\ t\in\mathbb{Z},\ h=\frac{T}{L},\ L\in\mathbb{N}$$

is the discrete-time random process which is equal for each $t\in\mathbb{Z}$ to *electricity consumption* during time interval $[(t-1)h,\ th]$. In particular, if $h=1$ hour, then $\xi_t(\omega),\ t\in\mathbb{Z}$ is *hourly* *electricity consumption.* If $\xi(\omega, t),\ t \in \mathbb{R}$ is cyclostationary continuous-time process with the period of T, then $\xi_t(\omega),\ t \in \mathbb{Z}$ is cyclostationary discrete-time process with the period of L.

Discrete-time conditional linear random process is represented as [8]:

$$\xi_t(\omega) = \sum_{\tau=-\infty}^{\infty} \varphi_{\tau,t}(\omega)\eta_\tau(\omega),\ t \in \mathbb{Z}, \tag{4}$$

where $\varphi_{\tau,t}(\omega),\ \tau, t \in \mathbb{Z}$ is an infinite dimension random matrix (kernel), $\eta_\tau(\omega),\ \tau \in \mathbb{Z}$ is sequence of independent random variables (white noise) with finite variance; $\varphi_{\tau,t}(\omega)$ and $\eta_\tau(\omega)$ are stochastically independent, also in the present paper only the case of centered $\eta_\tau(\omega)$, is considered, that is $\mathbf{E}\eta_\tau(\omega) = 0$, then the series (4) is mean-square convergent if the kernel $\varphi_{\tau,t}(\omega)$ satisfies the condition of $\mathbf{E} \sum\limits_{\tau=-\infty}^{\infty} |\varphi_{\tau,t}(\omega)|^2 < \infty$, $\forall t \in \mathbb{Z}$.

Discrete-time linear random process can be obtained from (4) if $\varphi_{\tau,t}(\omega)$ is nonrandom function.

3. Random coefficient periodic autoregressive model

Our idea of statistical estimation of characteristics of CLRP (4) is founded on the following assumptions. A discrete-time LRP can be represented as the response of a linear digital filter (with non-random coefficients that generally change over time, for example, periodically) to an input signal which is white noise in the strict sense. Very important case for practical applications is linear random process in the form of an autoregressive sequence, which is the output of a recursive digital filter to input white noise.

Discrete-time CLRP (4) can be represented as the output of digital filter with random coefficients (because impulse response $\varphi_{\tau,t}(\omega)$ is random function) on the input white noise $\eta_\tau(\omega)$. If this filter is created so that it has only a recursive structure, then the random signal at its output will be a sequence of autoregression with random coefficients.

Random coefficient autoregressive model of the order $p \in \mathbb{N}$ is represented as follows [8, 10]:

$$\xi_t(\omega) = \sum_{k=1}^{p} (a_{k,t} + \alpha_{k,t}(\omega))\xi_{t-k}(\omega) + \eta_t(\omega),\ t \in \mathbb{Z}, \tag{5}$$

where $\eta_t(\omega)$ is centered strict-sense white noise with the finite variance $\mathrm{Var}\,(\eta_t(\omega)) = \sigma_t^2 < \infty$; $\mathbf{a}_t = (a_{1,t},\ a_{2,t},\ \ldots,\ a_{p,t})'$ is a sequence of vectors of nonrandom coefficients (here and further $\mathbf{A}'$ is a matrix, which is transposed to the matrix $\mathbf{A}$); $\boldsymbol{\alpha}_t(\omega) = (\alpha_{1,t}(\omega),\ \alpha_{2,t}(\omega),\ \ldots,\ \alpha_{p,t}(\omega))'$ is a sequence of independent centered random vectors with the covariance matrices $\mathbf{R}_t = \mathbf{E}(\boldsymbol{\alpha}_t(\omega)\boldsymbol{\alpha'}_t(\omega))$; $\boldsymbol{\alpha}_t(\omega)$ and $\eta_t(\omega)$ are independent.

As we already mentioned above, the most comprehensively studied is the case of the stationary RCA model, for which we have $\mathrm{Var}\,(\eta_t(\omega)) = \sigma_t^2 = \sigma^2$, $\mathbf{a}_t = \mathbf{a} = (a_1,\ a_2,\ \ldots,\ a_p)'$, $\mathbf{R}_t = \mathbf{R}$, that is, characteristics are not time varying.

The discrete-time random process (5) is called random coefficient periodic autoregressive model (RCPAR), if there exists the number $L \in \mathbb{N}$ (period), such that

$$\sigma_t^2 = \sigma_{t+L}^2, \mathbf{a}_t = \mathbf{a}_{t+L}, \mathbf{R}_t = \mathbf{R}_{t+L}. \tag{6}$$

The methods for characteristics estimation of RCPAR model have been studied for the first time by Franses et al [13], but with some boundaries, in particular non-random parameters $a_{1,t},\ a_{2,t},\ \ldots,\ a_{p,t}$ were considered as cosine function with the period L (and the parameters of that functions were estimated), moreover, in their model $Var\,(\eta_t(\omega)) = \sigma^2 = const$, elements of the vector $\boldsymbol{\alpha}_t(\omega)$ are independent and also have constant variances. The method of statistical

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012027 doi:10.1088/1755-1315/1254/1/012027

estimation for the RCPAR model in general case have been developed in [8] and can be used for parameters specification for the applied problems of electricity consumption computer simulation.

Thus, having the results of experimental observations (or measurements) of $\xi_t(\omega)$, we need to estimate the elements of the vector $\mathbf{a}_t = (a_{1,t},\ a_{2,t},\ \ldots,\ a_{p,t})'$, $t = \overline{1,L}$, variances $\sigma_t^2,\ t = \overline{1,L}$, and also elements of covariance $(p \times p)$-matrices $\mathbf{R}_t,\ t = \overline{1,L}$. Note that since each matrix $\mathbf{R}_t$ is symmetric, then we need to estimate only $p(p+1)/2$-sized vectors $\gamma_t = vec(\mathbf{R}_t),\ t = \overline{1,L}$ [8].

For the convenience of further explanations, we write (5) in the following form [8]:

$$\xi_t(\omega) = \sum_{k=1}^{p} a_{k,t}\xi_{t-k}(\omega) + u_t(\omega) = \mathbf{x'}_{t-1}(\omega)\mathbf{a}_t + u_t(\omega), \tag{7}$$

where $u_t(\omega) = \sum\limits_{k=1}^{p} \alpha_{k,t}(\omega)\xi_{t-k}(\omega) + \eta_t(\omega) = \mathbf{x'}_{t-1}(\omega)\alpha_t(\omega) + \eta_t(\omega);$ $\mathbf{x'}_t(\omega) = (\xi_t(\omega),\ \xi_{t-1}(\omega),\ \ldots,\ \xi_{t+1-p}(\omega))$.

Let $(\xi_{1-p}(\omega),\ \ldots,\ \xi_0(\omega),\ \xi_1(\omega),\ \ldots,\ \xi_{qL}(\omega))$ be the sample (sample size is equal to $qL+p$) of sequence (7) observations, where $q \in \mathbb{N}$ (number of cycles) and period L are considered to be known.

A two-stage algorithm for estimating the coefficients of the stationary RCA model by the method of least squares has been justified by Nicholls and Quinn [8, 10, 14]. The obtained estimations are consistent and asymptotically normal. The approach for statistical estimating the coefficients of the RCPAR model has been developed in [8], it is based on the above results, but takes into account the cyclostationarity properties of the sequence (7).

Taking into account the periodicity of probability distribution of the process (7) and periodicity of its parameters, let us consider L nested subsequences, that is:

$$\zeta_{l,s}(\omega) = \xi_{(s-1)L+l}(\omega) = \mathbf{x'}_{(s-1)L+l-1}(\omega)\mathbf{a}_{(s-1)L+l} + u_{(s-1)L+l}(\omega),\ l = \overline{1,L},\ s = \overline{1,q}. \tag{8}$$

Every l-th sequence from (8) is stationary (as a function of s) random sequence, moreover, all that sequences are jointly stationary.

Thus, on the first step the least squares method is used [8] to (8) for every $l = \overline{1,L}$ obtaining the estimations $\hat{\mathbf{a}}_l(\omega) = (\hat{a}_{1,l}(\omega),\ \hat{a}_{2,l}(\omega),\ \ldots,\ \hat{a}_{p,l}(\omega))'$, $l = \overline{1,L}$ of non-random parameters of RCPAR model on the following form:

$$\hat{\mathbf{a}}_l(\omega) = \left(\sum_{s=1}^{q} \mathbf{x}_{(s-1)L+l-1}(\omega)\mathbf{x'}_{(s-1)L+l-1}(\omega)\right)^{-1} \sum_{s=1}^{q} \mathbf{x}_{(s-1)L+l-1}(\omega)\xi_{(s-1)L+l}(\omega),\ l = \overline{1,L}. \tag{9}$$

On the second stage, using the estimations $\hat{\mathbf{a}}_l(\omega),\ l = \overline{1,L}$ the following has been obtained:

$$\hat{u}_{(s-1)L+l}(\omega) = \xi_{(s-1)L+l}(\omega) - \mathbf{x'}_{(s-1)L+l-1}(\omega)\hat{\mathbf{a}}_l(\omega),\ l = \overline{1,L}. \tag{10}$$

According to [8] statistical estimations $\hat{\gamma}_l(\omega)$ and $\hat{\sigma}_l^2(\omega)$ of the parameters γ_l and σ_l^2, $l = \overline{1,L}$ have the following form:

$$\begin{gathered}\hat{\gamma}_l(\omega) = \left(\sum_{s=1}^{q} \left(\mathbf{z}_{(s-1)L+l}(\omega) - \bar{\mathbf{z}}_l(\omega)\right)\left(\mathbf{z}_{(s-1)L+l}(\omega) - \bar{\mathbf{z}}_l(\omega)\right)'\right)^{-1} \times \\ \times \sum_{s=1}^{q} \hat{u}^2_{(s-1)L+l}(\omega)\left(\mathbf{z}_{(s-1)L+l}(\omega) - \bar{\mathbf{z}}_l(\omega)\right),\ l = \overline{1,L},\end{gathered} \tag{11}$$

$$\hat{\sigma}_l^2(\omega) = \frac{1}{q}\sum_{s=1}^{q} \hat{u}^2_{(s-1)L+l}(\omega) - \bar{\mathbf{z}}'_l(\omega)\hat{\gamma}_l(\omega),\ l = \overline{1,L}, \tag{12}$$

where $\mathbf{z}_t(\omega) = \mathbf{D}' vec(\mathbf{x}_{t-1}(\omega)\mathbf{x}'_{t-1}(\omega))$, $\bar{\mathbf{z}}_l(\omega) = \frac{1}{q}\sum_{s=1}^{q} \mathbf{z}_{(s-1)L+l}(\omega)$, $l = \overline{1, L}$; $\mathbf{D}$ is a duplication matrix [8] of size $p^2 \times p(p+1)/2$, which are created in the following way: $\mathbf{D}' = \sum_{i=1}^{p}\sum_{j=1}^{i} \mathbf{v}_{ij}(vec(\mathbf{T}_{ij}))'$; $\mathbf{v}_{ij}$ is a vector, consisting of $p(p+1)/2$ elements, among them $[(j-1)p + i - j(j-1)/2]$-th element is equal to one, and other elements are equal to zero $(1 \le j \le i \le p)$; $\mathbf{T}_{ij}$ is a $(p \times p)$-matrix, where (i, j)-th and (j, i)-th elements are equal to one, and other elements are equal to zero.

4. Hourly electricity consumption simulation

The general approach for the computer simulation of electricity consumption based on RCPAR model has been illustrated on the figure 1.

We should emphasize that characteristics of RCPAR model (Setting 2 – Setting 4) have

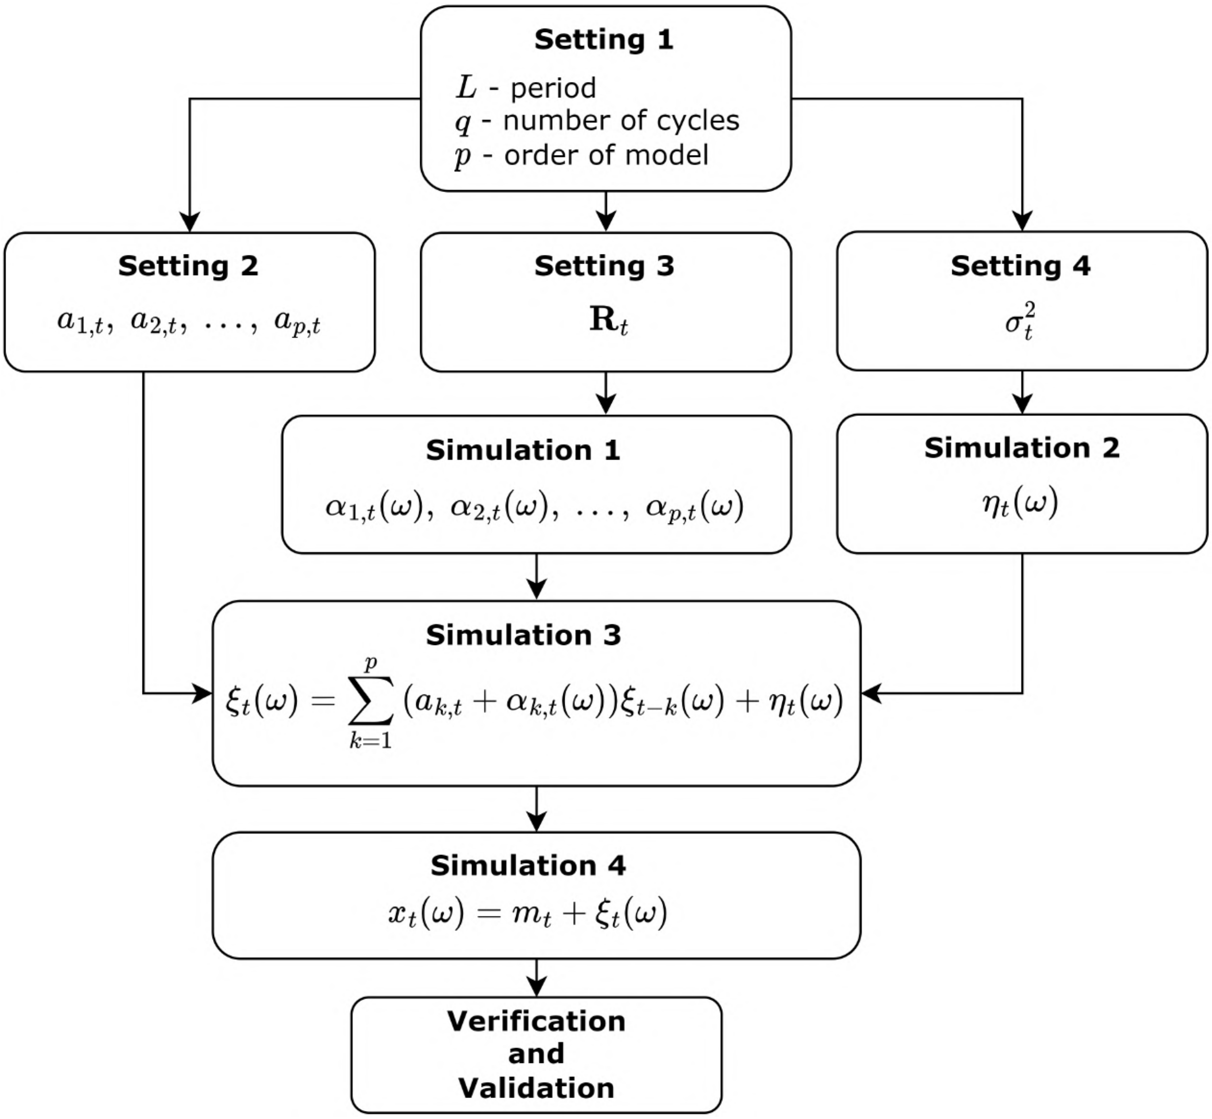

Figure 1. Structure of electricity consumption simulation using RCPAR model.

to be specified as periodic function (see formula (6). The characteristics can be obtained from statistical analysis (estimation step) of electricity consumption data using the expressions (9) – (12). Before performing the estimation procedure according to (9) – (12) the electricity consumption time series data should be centered by the periodic mean estimation (the usual averaging estimator [15] can be used).

In stage Simulation 1 the simulation of centered independent random vectors has to be performed with a given covariance matrix. We recommend generating them as normally distributed random vectors. The method of multivariate normally distributed random vectors simulation is well known and is considered, for example, in [16], we should take into account only that the covariance matrix is time-varying and periodic. That is, according to [16] (section 6.2) step Simulation 1 should be performed for each time stamp in the following way:

- simulation of the vector (the size depends on the order of RCPAR model) of independent standard normal random variables;
- performing the Choleski decomposition of the covariance matrix given in the Setting 3 step;
- simulation of the centered normal random vector (see step Simulation 1), using the linear transformation of the vector of independent standard normal random variables by the lower triangular matrix, which is obtained using the Choleski decomposition.

In stage Simulation 2 the centered white noise should be simulated with periodic variance, given in step Setting 4. The probability distribution is recommended to be normal as well. The well-known methods (e.g. polar method, described in [16], section 5.3) can be used for this simulation, taking into account the time-varying periodic variance of simulated white noise. That is, step Simulation 2 should be performed for each time stamp in the following way: simulation of the standard normal random variable and then multiplying it by the standard deviation given in step Setting 4.

In stage Simulation 3 the RCPAR sequence is simulated using the random objects obtained in the previous steps. Taking into account the mentioned relationship between the random coefficient autoregressive model and digital filters stage Simulation 3 can be performed in the following way:

- design the linear recursive digital filter with random coefficients, given and simulated in steps Setting 2 and Simulation 1;
- feed the white noise from Simulation 2 to the input of this filter;
- output is the computer simulation of RCPAR sequence.

In stage Simulation 4 the deterministic component should be added, which is also a discrete-time periodic function. This function is the mathematical expectation of simulated electricity consumption time series. It has the same period as other above periodic functions.

The verification and validation stages cover checking the computer code for any programming errors, comparing simulated and real data visually (realizations, probability characteristics and parameters) and using the statistical estimations and tests, etc.

The realization of hourly electricity consumption of the enterprise belonging to the category of SME (small and medium-sized enterprises) has been represented in the figure 2 (A). On the same figure 2 below (B) the realization of computer simulation model of the first order has been represented. Mean absolute percentage error (MAPE) is one of the most common performance criteria to validate simulation models [17] and time series forecasting [18]. For the presented example MAPE is equal to 15.12 percent.

We should emphasize the difference between the RCPAR-based computer simulation model of electricity consumption and other close established constructive models such as periodic autoregressive (PAR) model [6, 7] (or more general periodic moving average (PARMA) model

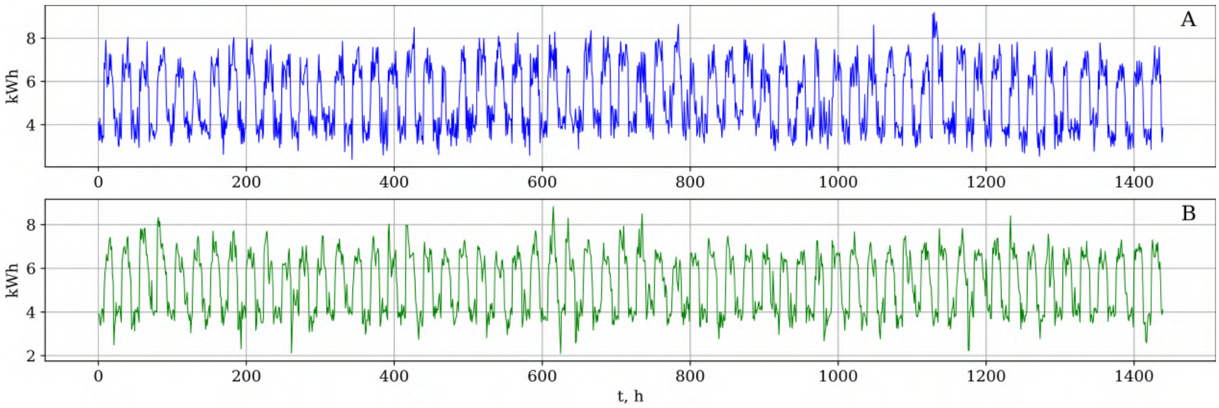

Figure 2. Time series of hourly electricity consumption of SME (A) and its computer simulation model (B).

[6]) and seasonal autoregressive moving average (SARMA) model [18]. All these models can be used both for computer simulation of electricity consumption, as well as for its forecasting. PARMA and RCPAR-based simulation models have periodic parameters, and they are cyclostationary sequences while SARMA is a wide-sense stationary model with constant parameters. PARMA and SARMA models are linear while RCPAR can simulate the nonlinear dynamics representing both periodic heteroscedasticity and conditional heteroscedasticity (random conditional variance) of electricity consumption. Finally, the RCPAR-based computer simulation model follows from a physically reasonable mathematical model of electricity loads in the form of a conditional linear cyclostationary random process. The experimental comparison of the above models is a task for future research.

The prospective research should be also related to estimation (and utilizing in simulation process) of order of the model, which can be periodic function, also the probability distribution of random objects on the stages Simulation 1 and Simulation 2 can be analyzed as different from normal.

The developed computer simulation model as presented above doesn't consider the very important and widespread case of additional weekly (168-hour) cyclicity of electricity consumption, caused, for example, by the days off. A possible way of improvement, in our opinion, is the use of a multivariate random coefficient periodic autoregressive model. For the hourly simulation, the corresponding model would be 24-variate with the period equal to 7.

5. Conclusion

The mathematical model of electricity loads has been represented in the form of cyclostationary conditional linear random process, which made it possible to justify the model of hourly electricity consumption as a cyclostationary discrete-time conditional linear random process.

Random coefficient periodic autoregressive model, as a particular case of discrete-time CLRP, has been used to create the computer simulation method of hourly electricity consumption of SME, taking into account its cyclostationarity (periodic heteroscedasticity) and conditional heteroscedasticity.

The first step of this method is statistical estimation of the periodical characteristics of RCPAR model, taking into account its cyclostationarity. The estimations are then analyzed and used for the simulation model parameters specification. RCPAR-based simulation is performed as digital recursive filtration (with random coefficient) of input cyclostationary white noise.

The improvements of the model are possible in the direction of using the non-gaussian distributions of filter coefficients or input white noise and also taking into account the weekly cyclicity of electricity consumption.

Abstract. Understanding the overall magnitude of the deviations that may occur within the results of one or more codes allows avoiding discrepancies in decision making in the context of emergency preparedness and response. The uncertainty of the assessment input data plays a significant role in this. Currently, emergency centers around the world use a number of atmospheric dispersion modelling and dose projection tools that have the same functionality, are used for the same purpose, but may produce different results. This article reveals the problem of uncertainty in the results of atmospheric dispersion modelling and dose projection, which are laid down at the stage of input data for actual software products and decision support systems. The paper lists the main factors that can affect the uncertainty of the assessment results. On the example of the JRODOS system, possible options for describing the source for the spectrum of emergency events at NPPs are considered. Special attention is paid to assimilation of radiation monitoring results and response to hostilities.

1. Introduction

Modern approaches to the emergency response to radiation accidents at nuclear facilities worldwide are coherent. They aim to prevent human losses and establish control over the source of releasing radioactive substances. Mechanisms and procedures for responding to similar accidents are not designed for casualties of a terrorist or military nature, taking into account the principle of peaceful use of atomic energy. The existence of software evaluation tools and decision-making support systems for population protection during radiation accidents is no exception. These tools are the most effective if they provide the full range of input parameters to run the models [1, 2]. However, the response procedures require decision-making based on incomplete data or within the scope of information currently available to the decision-maker in unforeseen conditions.

Today, world emergency centers use modern assessment tools such as the European ARGOS system [3] or the American regulatory RASCAL software complex [4]. The development of a complex real-time decision support system for off-site response to radiation accidents RODOS has been actively supported and coordinated since the beginning of the 90s within the framework of the European Commission's scientific programs. The Java version of this system is called JRODOS [5]. Currently, the further development of this product is continued. Its improved versions are periodically presented by the leading developer of JRODOS – Forschungszentrum Karlsruhe GmbH – on behalf of the JRodos Developers Consortium. It includes 15 institutions from different European countries. Since 2013 this system has been successfully used in the emergency centers of Ukrainian NPPs and regulatory body during emergency response measures for nuclear and radiological accidents. The JRODOS system consists of several mathematical models and databases for conducting predictive calculations on the consequences of possible radiation accidents and planning urgent and early countermeasures for protecting the public. This system is increasing the technical and strategic capabilities of responding to national and cross-border emergencies. The JRODOS models and databases can be adapted for different characteristics of the NPP location and geographical, meteorological, and environmental conditions. Using this system in a state of continuous arrival of numerical weather prediction data, timely information on the chronology and activity of the release allows prompt forecasting of radiological consequences on local and global spatial scales.

2. Uncertainties problem

Some decision support systems (DSS) have a flexible interface and allow to specify output data of the simulation in several ways. Variability of the data entry approach facilitates prompt response to incomplete information regarding the state of the affected object. The package of the primary input data includes source term data, meteorological conditions, calculation settings, and desired results list or their format.

Figure 1 presents the impact of uncertainties regarding the release under unstable meteorological conditions. Case zoes for taking immediate countermeasures for population protection in the case of a severe accident may differ significantly depending on the release moment.

The magnitude and radionuclides mixture are distinguished in addition to the chronological uncertainty of the temporal distribution of emissions. It may also differ significantly and depend on the initial activity of the dose-forming radionuclides in inventory. Currently, various views are considered in the framework of many international projects. This type of uncertainty can be significantly leveled at the stage of emergency preparedness by comparing existing approaches, such as [6], unlike the chronological one.

The World Meteorological Organization investigates uncertainties associated with the numerical data of the meteorological forecast [7]. Some modern DSS allows analyzing of consequences of cases for several variants of meteorological conditions or source terms. Such studies make it possible e to determine the influence of the forecast quality on the final result. It includes zone configuration for the adoption of urgent countermeasures for population protection. In practice, comparative analysis of the calculation results obtained by various organizations is carried out mainly within the framework of international projects and less often within the framework of special emergency exercises. The work [8] contains a list of examples and approaches for comparing results obtained using different codes or DSS.

3. Radionuclide vector, physical and chemical forms

Radionuclide mixes and physicochemical forms of release depend on a complex of factors such as activity of radionuclides in the reactor core and spent fuel pool, features of safety systems, phenomenological stage of fuel damage, etc. Grouping by physico-chemical classes describes the behavior of radioactive vapor-gas mixture within containment. More generalized distribution of radionuclides by physico-chemical forms is also characteristic at the modeling stages of the

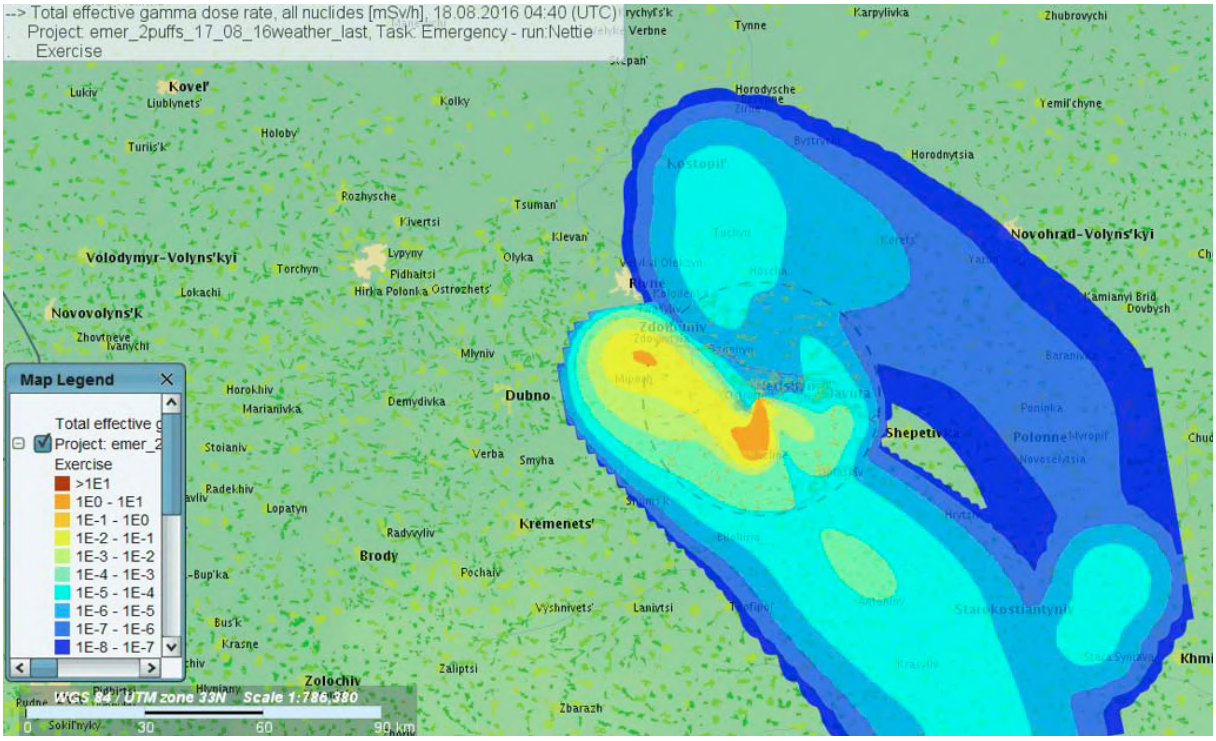

Figure 1. Chronological uncertainty effect.

atmospheric path of distribution and transport along food chains – nobel gases, aerosols, and organic and molecular forms of iodine. Moreover, the same radionuclide (for example, ^{131}I) in different forms has a different nature of deposition on the underlying ground surface. It also plays a different role in dose formation for different pathways of exposure.

Several mathematical models based on the processes of heat and mass transfer and aerodynamics are used to describe radionuclides transport in the closed emergency room of nuclear enterprises. These models are part of integrated calculation software products such as MELCOR [9], MAAP, CONTAIN, etc. These codes use analytical and numerical solutions, operating with empirical and semi-empirical relations. Transport of nuclear fuel fission products is described; the power and composition of the emission of radioactive substances from the premises of emergency objects into the atmosphere are calculated with the help of such tools. The leading representatives of integral codes of this group have a similar structure and cover the main stages of modeling the transport of radioactive substances in process rooms for most design and post-design accidents that are considered during the safety analysis of nuclear power plants.

For example, MELCOR [9] is an integrated computer code at the engineering level. It stimulates the severe accident at a nuclear power plant with light water reactors. This code was developed at Sandia National Laboratories for the US regulatory body. The International Atomic Energy Agency (IAEA) member countries, including Ukraine, actively use this code. MELCOR allows the simulation of a wide range of emergency processes at a nuclear facility. The code enables modeling the transport of fission products along with such processes as the thermal-hydraulic reaction of safety systems and adjacent structures, degradation and movement of fuel masses, the interaction of core melt with concrete of building structures, generation, transportation, and combustion of hydrogen, etc. The modeling basis with this code is a nodalization scheme. It is a spatial division of the power unit objects into separate

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012028 doi:10.1088/1755-1315/1254/1/012028

volumes according to the principle of priority of this or that equipment/room contribution to the determining parameters of the emergency process. Thermal-hydraulic parameters within the same book at a particular moment are considered the same—chemical properties group MELCOR fission products. The behavior of chemical elements and their isotopes is regarded as the same within the same class.

There are the following ways of obtaining data on the radionuclide mix in a radioactive release:

1) receiving information from actual measurement points of releases control subsystem (vent stack);
2) use of the general JRODOS library for the formation of source term;
3) analytical assessments of source term according to the phenomenological stages of fuel damage.

The other two paths are preferred but not mandatory if the information provided by the first path is sufficient for the current calculations in the JRODOS system. During the shortage of information (whole or partial), using the two named ways of data formation is necessary.

Initial data for the source term estimating are data on reactor inventory, or data on the radionuclide vector and activity of the coolant, in the absence of more than normative damage to the occupied zone [10, 11]. Data from the JRODOS general library can be used to generate data. It should contain source term according to defined chronological stages:

- coolant release;
- gas gap release;
- fission products release due to partial fuel damage of the reactor core;
- fission products are released due to reactor core melting (in-vessel and ex-vessel phases).

Parameters of the release during accidents with different degrees of damage to the reactor core are determined by several chemical elements and the site of their release into the coolant in case of reactor core damage. The document NUREG-1465 [12] provides information on the approximate relative share of the fission products released from reactor core into the containment air space at various stages of fuel damage for PWR and BWR-type reactors.

Special attention is paid to the distribution of iodine radionuclides during the assessment of the release parameters. This radionuclide is a dose-forming radionuclide by the physicochemical forms of the most critical pathway of exposure. It is necessary to consider the distribution of iodine according to its physical and chemical conditions to determine the rate of dry deposition and the iodine washing from the radioactive cloud. The JRODOS system makes it possible to take into account three forms of iodine:

- aerosol (CsI);
- elementary/molecular (I_2);
- organic (CH_3I).

In modern approaches to realistic forecasting of the radiological consequences of accidents at water-water reactors, the following distributions are distinguished according to 2 ways of exiting the vapor-gas mixture: containment and a fast-acting reduction unit for releasing steam into the atmosphere. A higher amount of organic iodine distribution is chosen for a conservative assessment (especially for transboundary transport).

4. Leakage pathways

Radionuclides can bypass such a barrier as containment during an accident. They can also first enter the air space of the containment and only then enter the environment due to the leakage of the containment (figure 2). The first pathway of propagation is typical for accidents caused by the flow of the primary circuit into the second (failure of steam generator collector). At the same time, radionuclides bypass the containment, immediately entering the second circuit and entering the atmosphere without purification. Another path of propagation is characteristic of accidents associated with the rupture of pipelines of the first circuit up to the maximum design accident.

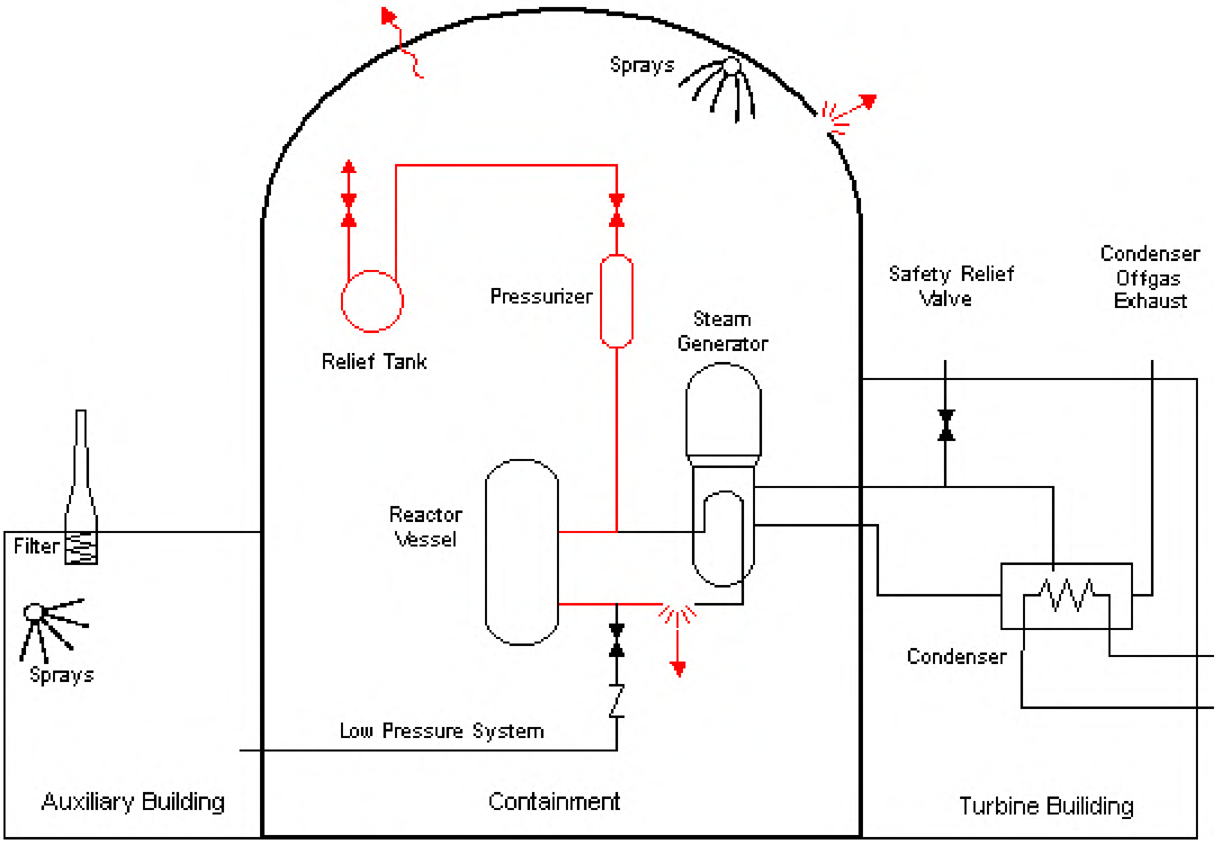

Figure 2. Leakage ways scheme of the steam-gas mixture.

It is necessary to consider the presence or absence of retenrtion to correctly assess the radionuclides released from the containment to the environment. The discharge may be subjected to various mechanisms of retention of radionuclides by safety systems (sprinkler system, bubbling) and under the influence of natural retention mechanisms (sedimentation, decay), depending on the release pathway. At the same time, the activity depends on the length of radionuclides delay before the release. The retention factor refers to the activity ratio of iodine and long-lived aerosols released into the environment to the activity created due to the accident (data from NUREG-1228 [6]).

The efficiency of the filtering system through which the vapor-gas mixture passes is considered in the case of emissions after cleaning with filtering means. It happens if their efficiency is preserved during the course of the accident. At the same time, radioiodine distribution by physicochemical forms changes dramatically. Practical calculations show that the dose-forming groups will be noble gases (Kr, Xe) and organic compounds of radioiodine during accident scenarios with operating filtered containment venting system (FCVS). At the same time, in such methods, the delay time before release into the atmosphere plays a significant role in the radiological consequences results.

Speed radionuclides entering the containment depend on a containment leakage rate. The following intensities of leakage from the containment are accepted in international practice:

- 0.1 – 0.3%/day (normal leakage for PWR-type reactor containments, 0.3%/day – VVER-1000);
- 100% per day (failure of containment isolation valves);
- 100% per hour (corresponds to the containment destruction of).

The delay time of radionuclides before the release into the atmosphere is a determining factor in the calculation of poblic exposure doses in the part of external exposure from nobel gases (dose from the cloud) and radioiodine (dose from inhalation). It is possible to find the activity at any time after the shutdown of the reactor or movement of the steam-gas mixture at any time of its exposure in the free space of the containment knowing the inventory at the end of compaign.

5. Effective release height

Methodological approaches to assessment of the effective release height in various literary sources are presented quite ambiguously. However, we note that all these approaches introduce the following concepts:

- release from tall pipes;
- release from low pipes (guideline №. 50-SG-S3 of the IAEA [13]).

The dawnwash effect can be also considered (estimation of the initial parameters of the atmospheric dispersion) in the second case to increase the realism degree of the calculation.

The plumerise as a component and as a result of the heat energy of the release according to the current parameters is defined by the pre-programmed calculation procedures (Mathcad/Excel) as a part of the real-time calculation. They are used regarding to the IAEA method № 50-SG-S3 for cases:

- unstable and neutral stability class (medium and high boundary of the mixing layer);
- for conditions of a stable atmosphere (low boundary of the mixing layer).

It should be noted that reducing the effective height of the release increases the degree of conservatism in the assessment results of radiological consequences in near range.

The JRODOS system allows the setting of the total release height. It considers the plume rise as a dynamic component and a result of the heat energy of the release. It uses the additional parameters: thermal power of the release, vertical flow rate, and cross-sectional area (nozzles, vent stacks, etc.).

6. Types of input data entry

Modern DSS have a reasonably flexible policy for entering initial data. It allows entry of the source term in terms of release fractions and reactor core inventory at the time interval or the integral release activity without reference to reactor core inventory.

Modern DSS is moving to the IRIX (International Radiological Information Exchange, [14]) format source library standard. The standard significantly facilitates data exchange between organizations and in an international context (table 1).

Table 1. Types of source terms by methods of input data entry on the share/activity of the emission of modern DSS JRODOS [5].

Data entry type	Description
F1	Release fraction [%] on the time interval from the initial activity in the fuel (reactor core inventory).
F2	Released activity [Bq] on the interval from the list of the JRODOS radionuclides.
F3	Released activity [Bq] on the time interval for ^{131}I and the sum of activity for noble gases and aerosols (including the possibility of distribution setting by aerosol fractions).
F4	Released activity [Bq] on the time interval for iodine, noble gases, and aerosols (including the possibility of distribution setting by fractions of aerosols).
F5	Released activity [Bq] on the time interval individually for each nuclide concerning the reactor core inventory.
F6	Released activity [Bq] on the time interval individually for each nuclide without reference to the reactor core inventory.
F7	Activity release rate [Bq/s or Bq/h] on the interval individually for each nuclide without reference to the reactor core inventory.

TECDOC-955 was one of the first international documents covering the systematization of source temrs for NPP severe accidents. The source selection algorithms are based on the events tree concept according to branching criteria. It corresponds to the factors affecting the release intensity (power unit status, operation of safety systems, retention and filtration of the vapor-gas mixture, etc.). Such algorithms are implemented in the International InterRAS system and its subsequent evolution as a software product, RASCAL.

7. Assimilation of radiation monitoring data

Application of radiation measurement data near the emergency power unit (monitoring grid, mobile vehicles, etc.) contributes to the validation of the model and the results confirmation of atmospheric dispersion modeling and dose projection. However, these systems may be partially unavailable in the case of military attacks or occupation. The reliability of the information provided by the radiation monitoring stations remains a separate issue.

Ukraine still needs an integrated automated monitoring system for detecting, analyzing, and forecasting possible radiological consequences of accidents. Accident release may spread beyond the sanitary protection zones of nuclear power plants, other atomic installations, and radiation-hazardous objects in Ukraine and beyond. However, the development of an integrated automated radiation monitoring system is planned until 2024 [15].

There are currently many challenges to developing real-time radiation impact assessment tools. Now, one of the ambitious directions of DSS development is solving the inverse problem of determining coordinates and characteristics of the emission source based on the results of field measurements. The practice of calculations for a wildfirefire in the Chornobyl exclusion zone shows that it is usually possible to estimate the integral characteristics of the release quite quickly if measurement data are available in the near range. However, this procedure requires considerable time to collect and process data to provide an inversion calculation in relatively large spatial scales.

Conducting inverse modelling for events on a large spatial scale requires the involvement of specialized software tools and separate methodological approaches. In addition, the task is complicated because the format and completeness of the output data are individual in each case. Also, there currently needs to be methodical approaches regarding the consideration of radiation monitoring data in the constructed models of atmospheric dispersion of the DSS and its subsequent correction or refinement in real-time. The issue of forming universal approaches to inverse modelling remains open.

8. The problem of forecasting radiological consequences of military causes

The emergency preparedness and response phases are divided by the principle criteria (an announcement of the event class) according to the current IAEA classification for peacetime conditions. The classification of events as objects of the first threat category (for example, nuclear power plants) under martial law declared is not regulated by national or international regulations. It can be assumed that the situation around the Zaporizhzhia NPP is intermediate, given the repeated activation of Ukraine's crisis center's regulatory body during the first nine months of the full-scale invasion. It includes synthesizing elements of both the readiness and the response phases. Some examples of air mass movement trajectories modeling for the Zaporizhzhia NPP are presented in fig.3.

Today there is no experience in international practice on performing safety analyzes of nuclear installations under the war conditions. It includes a lack of methodology and initial data for their conduct (intensity of shelling, degree of damage to buildings and structures from the impact of various types and calibers of ammunition, action personnel, and population behavior in conditions of hostilities and extreme stress, etc.).

Several conditional reference scenarios of severe damage to the reactor core at the VVER-1000/B-320 type reactor plant were considered a representative event for NPP industrial sites considering the above. The creation of the emissions library made it possible to simulate multi-unit scenarios, such as total station blackout for all power unit on-site.

Also, the accident at a spent nuclear fuel dry storage facility was considered, given the assumption of a possible mechanical destruction of spent fuel cask (as a result of hostilities or a terrorist attack), additionally for the Zaporizhzhia NPP. It was considered for one VSC-24 container containing 24 spent fuel assemblies with a minimum spending time of 5 years.

The question of the results ambiguity of atmospheric dispersion modeling and the prediction of radiation doses is based on several uncertainty factors from the input information to the endpoints report on the results. The following can be distinguished among them:

- detail and completeness of input data for assessment and analysis of the situation (state of the nuclear installation, source term, pathway and effective height of the release, time resolution, physical and chemical forms, number of calculated radionuclides, etc.);
- provider and completeness of parameters of numerical weather data of (spatial and temporal resolution, completeness of the list of meteorological parameters);
- atmospheric dispersion model and parameterization;
- dose models, number of reference groups by age, exposure routes;
- model of countermeasures, form, and completeness of the final results presentation of the assessment or forecast (scale, data format, deterministic or probabilistic interpretation);
- type and completeness of accompanying databases (height of roughness of the underlying ground surface, population density, land use, types of shelters, features of the infrastructure, dose coefficients, etc.);
- degree of experience and qualification of the expert.

9. Author contributions

The research results presented in this publication are the culmination of the collective efforts and distinct contributions of each author:

- *Volodymyr O. Artemchuk*: Conceived the research idea, provided the rationale for its relevance, and played a pivotal role in drafting the article. Additionally, contributed to the formulation of key conclusions.
- *Yurii O. Kyrylenko*: Conducted extensive research on the radionuclide composition and the physical and chemical forms involved. Developed a comprehensive diagram illustrating the paths of steam-gas mixture leakage and contributed significantly to the corresponding report.
- *Iryna P. Kameneva*: Undertook a comprehensive review of contemporary assessment tools used in global crisis centers, providing valuable insights. Focused on the intricate issues of uncertainty and conducted research related to the assimilation of emergency monitoring data.
- *Valeriia O. Kovach*: Conducted in-depth studies aimed at determining the effective height of discharges and provided detailed descriptions thereof. Furthermore, played a significant role in defining input parameters.
- *Andrii V. Iatsyshyn*: Supported the justification of the research's relevance and played a crucial role in conducting research related to the prediction of radiation consequences in military events. Additionally, contributed to the formulation of key conclusions.

Each author's unique expertise and dedication have been instrumental in the completion of this research, enriching its depth and breadth.

10. Conclusions

Consequences of acts of nuclear terrorism or military attacks on nuclear facilities may significantly impact the public and environment. They are associated with high uncertainties or insufficient initial data for calculations. Modern emergency preparedness and response modeling tools (as DSS) are not designed for use under conditions of such uncertainty.

At the same time, there are many methodical approaches to the deriving source term during accidents accompanied by significant release of radioactive substances into the environment. These approaches help to approximate and sometimes re-analyze a dynamic picture of radionuclide concentrations in the air and total fallout. They also allow the conduct of comprehensive assessment on impact on the public and environment. A review of their application features showed that the development of approaches to the source term description is an effective tool for providing initial data in various variants and forms necessary for calculating radiation consequences in DSS and other software tools.

The main characteristics of the source term represent a package of initial data for modeling atmospheric dispersion and dose projection during a severe accident at a nuclear power plant. It was found that there needs to be a universal methodology and procedures for responding to events with a high degree of uncertainty, particularly in the data regarding the source term.

The problem of uncertainties requires further research and analysis from the point of view of the experience gained during the response since the beginning of the full-scale invasion of the Russian Federation, the military attack, and the seizure of the Zaporizhzhia NPP at the beginning of March 2022.

Abstract. Currently, the problem of improving results of short-term forecasting of electricity imbalances in the modern electricity market of Ukraine is a current problem. In order to solve this problem, two types of neural networks with recurrent layers LSTM and LSTNet were analyzed in this work. A comparison of the results of short-term forecasting of daily schedules of electricity imbalances using LSTM and LSTNet neural networks with vector autoregression model (VARMA) was carried out. Actual data of the balancing market were used for the research. Analysis of the results shows that the smallest forecast error was achieved using the LSTM artificial neural network architecture.

1. Introduction

Today, one of the important factors affecting the reliability and efficiency of the Integrated Power System (IPS) of Ukraine [1, 2] is the instability of electricity imbalances, which has been observed since the implementation of the new model of the wholesale electricity market [3].

Electricity imbalance – calculated in accordance with the rules of the electricity market [4] for each calculation period, the difference between the actual volumes of sale or consumption, import, export of electric energy of the party responsible for the balance, and the volumes of purchased and sold electric energy registered in accordance with the market rules. The overall electricity imbalances includes: the error of the forecast of the consumption of electric energy, the error of the forecast of the volumes of generation of renewable energy sources (RES) [5], the difference between the actual release of balancing service providers and the dispatch team, interruptions in power supply due to emergency situations in the power system.

At present, forecasting the value of overall electricity imbalances is a rather urgent task. In real time, the transmission system operator buys or sells the electricity needed to cover imbalances in the balancing market. According to the results of the balancing market sessions, the prices of imbalances are determined, according to which market participants get invoices for non-compliance with the declared volumes of electricity sales.

Access to prior information on electricity imbalance allows:

- the transmission system operator to improve the accuracy of creating the energy system operating mode. It also enables optimizing the balancing market and ancillary services market operations, thus increasing the reliability of the IPS of Ukraine functioning;
- market participants, including power companies, to determine their participation strategies in different market segments to reduce the cost of electricity [6];

- reducing the cost of imbalances for electricity suppliers, which has a positive impact on the retail electricity market and the prices of end consumers [7].

Previous developments to solve this problem were related to the study of autoregression models (ARIMA, ARIMAX, SARIMA, VARMA) [8]. Considering the widespread use of neural networks in various fields of application, it is appropriate to use this tool to solve the problem under study. Therefore, the purpose of this work is to develop and research models of artificial neural networks of deep learning for short-term forecasting of electrical energy imbalances of the power system and to compare the results with the results obtained using the VARMA vector autoregression model, which according to previous studies had the most accurate results.

2. Aim and methodology

Two types of neural networks with recurrent LSTM layers [9] and LSTNet [10] were built to predict electricity imbalances. After which two linear layers with hyperbolic tangent and sigmoid activation functions, respectively. Training was performed on 100 epochs and the ADAM optimization algorithm with a training step of 0.001.

The structure of the LSTM network is described using formulas (1-6) [11]. At the first stage, the information to be replaced is selected according to the conditions of the sigmoid layer (1). After that, the next layer determines the values to be updated (2) and builds a vector of values C'_t, which can be added to the state of the cell (3). Then the old state of the cell C_{t-1} is replaced by the new C_t according to equation (4). The last step is to calculate the source information using several filters (5, 6).

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_f), \tag{1}$$

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i), \tag{2}$$

$$C' = tahn(W_c[h_{t-1}, x_t] + b_c), \tag{3}$$

$$C_t = f_t C_{t-1} + i_t C'_t, \tag{4}$$

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o), \tag{5}$$

$$h_t = o_t tahn(C_t), \tag{6}$$

where σ is the activation function; W_f, W_i, W_c, W_o are weighting factors; b_f, b_i, b_c, b_o – shear coefficients; x_t – input data; h_{t-1}, h_t – forecast values; C'_t is the correction vector of the memory cell; C_t, C_{t-1} – state of the memory cell.

The memory vectors (C) and the LSTM output of the previous step (h) are initialized to zero values at each prediction step x_t. The vector C'_t represents a new version of the memory values, and the vectors f_i and i_i regulate the extent to which the memory vector is updated with new values. Due to the fact that the values of W_f, W_i and b_f, b_i are estimated during the learning process. The neural network regulates the update dynamics of C optimally from the point of view of minimizing the loss function. In addition, the presence of a memory vector makes it possible to reduce the effect of blurring or explosion of the gradient during the backpropagation of the error, while using a bypass connection, which smoothes the surface of the error of the neural network, significantly speeds up learning and allows to achieve a lower prediction error.

The built LSTNet network has the following components [10]:

1. *Convolutional.* The goal of an unconnected convolutional network is to extract short-term patterns in the temporal dimension.The output matrix simultaneously enters components 2 and 3.
2. *Recurrent.* Uses RELU as a hidden activation function. Result: hidden state for each timestamp.

3. *Recurrent-skip.* A repeating structure with temporal relationships to extend the temporal range of information, thus facilitating the optimization process. The structure of this layer is presented in the form of the following formulas:

$$r_t = \sigma(x_t W_{xr} + h_{t-p} W_{hr} + b_r), \tag{7}$$

$$u_t = \sigma(x_t W_{xu} + h_{t-p} W_{hu} + b_u), \tag{8}$$

$$c_t = RELU(x_t W_{xc} + r_t \otimes (h_{t-p} Whc) + b_c, \tag{9}$$

$$h_t = (1 - u_t) \otimes h_{t-p} + u_t \otimes c_t, \tag{10}$$

where p is the number of hidden cells;

4. *Temporal Attention Layer.* Learns the weighted sum of hidden representations at each window position of the input matrix. As a result, a concatenation of the context vector and the hidden representation of the last window together with a linear projection is obtained.
5. *Autoregression.* Breaks the final forecast into linear and non-linear components. The linear component solves the problem of local scaling, while the nonlinear one contains repeating patterns.

Both models are developed in the PyCharm environment using the Python programming language.

3. Results

Overall data include hourly volumes of positive and negative imbalances of the IPS of Ukraine for the period from 07/20/2020 to 07/16/2021 (a total of 8,784 values), training/test split is 90%/10%. The input vector includes 4 previous values; the forecasting horizon is 1 hour, the number of training epochs is 5000. The best prediction results were achieved with 20 hidden layer neurons. Data obtained from the official website of the National Energy Company Ukrenergo (balancing market and settlement of imbalances data). The test sample for comparison is 36 days. For comparison, the VARMA model was used.

Table 1 shows the average, maximum, and minimum relative errors for the test day of 07/20/2021 and the test sample as a whole, and table 2 shows the RMSE errors.

Table 1. Assessment of the accuracy of the studied models using MAPE, %.

Positive electricity imbalances						
	07/20/2021			Test sample		
	LSTNet	VARMA	LSTM	LSTNet	VARMA	LSTM
MAPE, %	46.95	40.86	20.73	132.78	140.84	66.25
δ, max, %	97.62	82.33	70.57	8253.21	5130.41	1789.01
δ,min, %	2.72	8.01	0.01	0.01	0.02	0.01
Negative electricity imbalances						
	07/20/2021			Test sample		
	LSTNet	VARMA	LSTM	LSTNet	VARMA	LSTM
MAPE, %	66.91	17.18	9.1	52.7	34.2	17.98
δ, max, %	78.62	35.55	23.05	221.43	322.16	279.56
δ,min, %	52.21	3.07	1.84	0.21	0.14	0.04

Figures 1-4 show daily values of MAPE, RMSE between actual ΔP_f and forecast values of electricity imbalances ΔP_p.

Table 2. Assessment of the accuracy of the studied models using RMSE, MW.

	Positive electricity imbalances			Negative electricity imbalances		
Model	LSTNet	VARMA	LSTM	LSTNet	VARMA	LSTM
07/20/2021	489.47	454.15	209.79	1015.72	342.87	163.74
Test sample	631.29	489.58	239.15	632.36	348.35	222.37

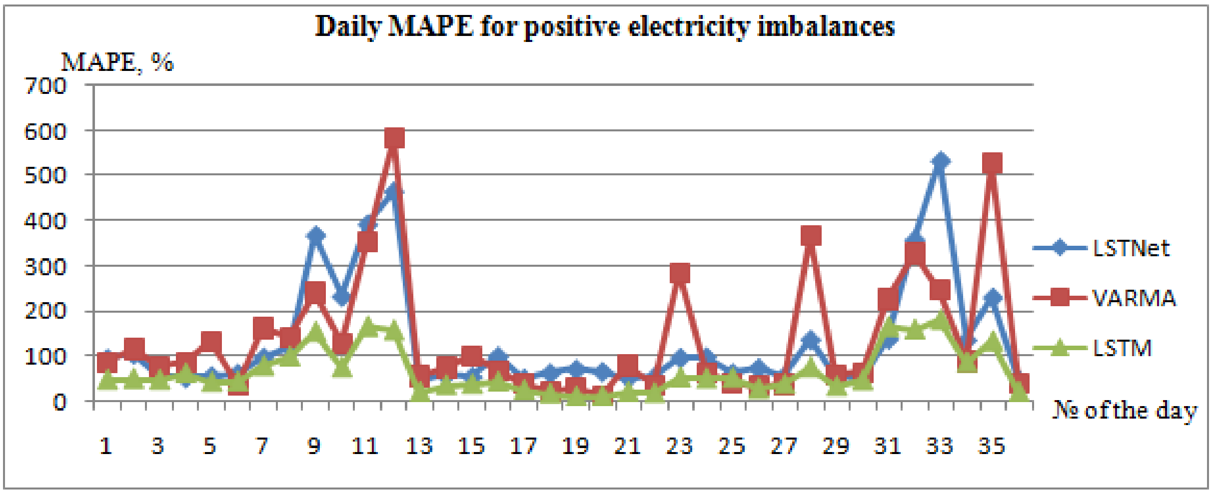

Figure 1. Daily graphs of MAPE values for positive electricity imbalances.

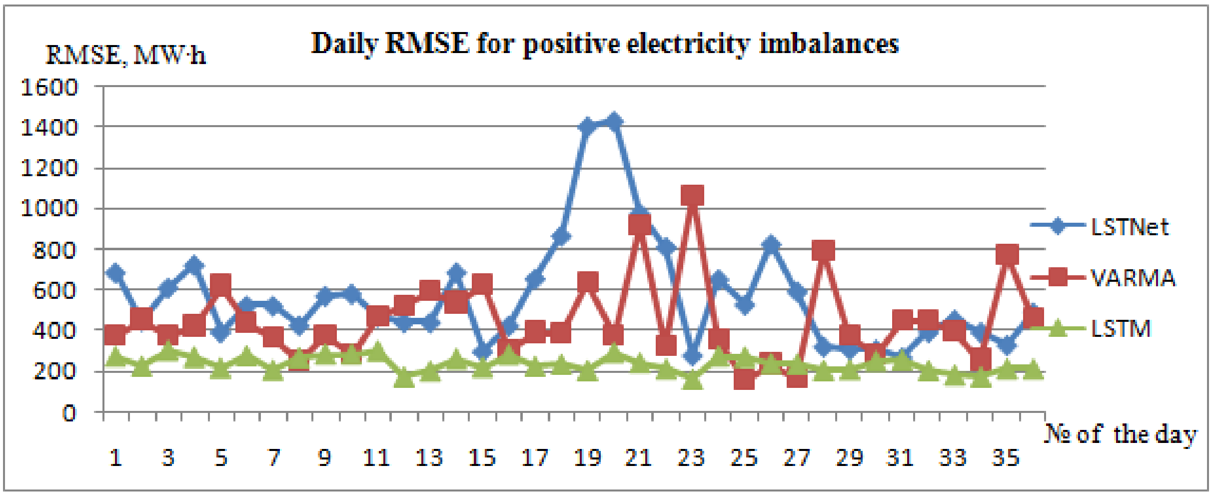

Figure 2. Daily graphs of RMSE values for positive electricity imbalances.

According to the data indicated in tables 1 and 2 and illustrated in figures 1-4, the most accurate forecasting results of both positive and negative electricity imbalances were obtained using the LSTM model. At the same time, the graphs of daily MAPE and RMSE errors for LSTM results have less pronounced local extrema, which indicates the preservation of the trend throughout the entire range of the test sample, i.e. greater stability of forecasting results. The results obtained with the LSTNet model are much worse: by 50% compared to the other models for positive imbalances and by 47% and 66% compared to VARMA and LSTNet, respectively, for negative imbalances.

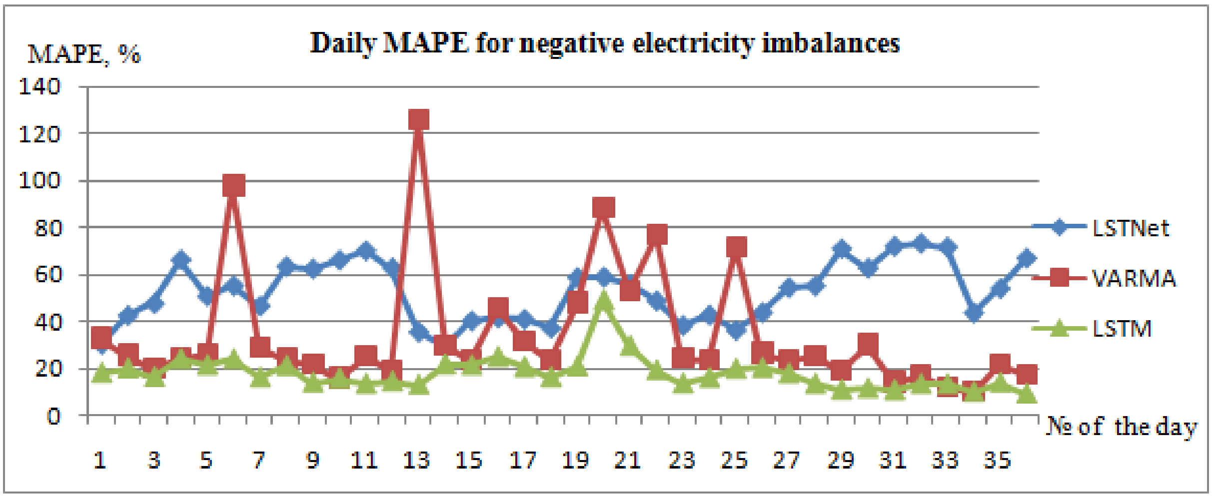

Figure 3. Daily graphs of MAPE values for negative electricity imbalances.

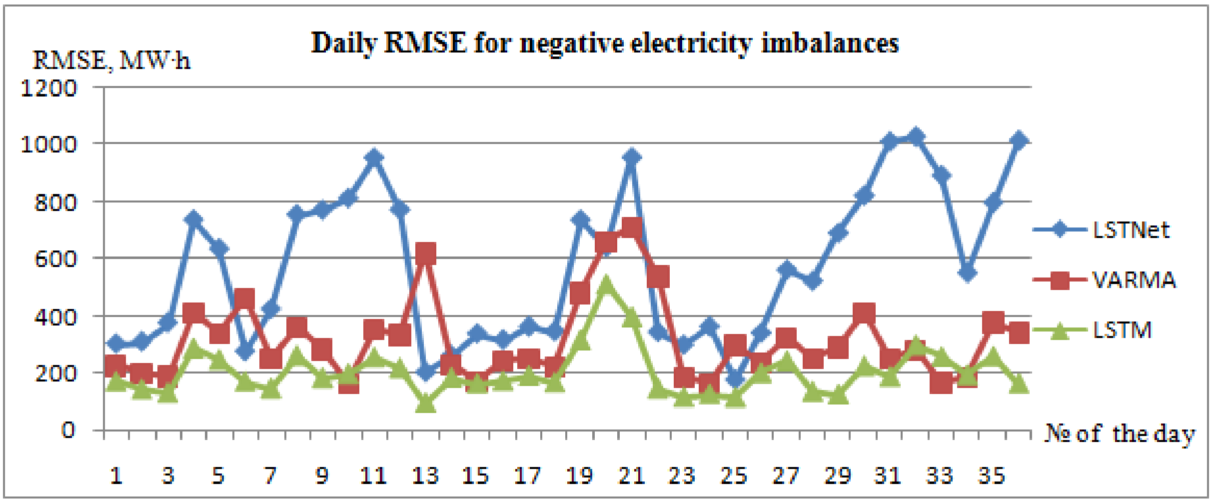

Figure 4. Daily graphs of RMSE values for negative power imbalances.

When forecasting positive electricity imbalances using the LSTM neural network, the errors of forecasting results increase slightly, with the exception of the third test day. This is due to the significant asymmetry of the distribution of positive imbalances. The use of the studied neural network for forecasting negative imbalances made it possible to reduce forecasting errors by 2÷5 times.

For example, figure 5 shows the values of electricity imbalances predicted using the built models, compared with the actual ones for 07/20/2021.

The analysis of the received forecasting results of the considered models shows the need to improve the method to include the impact of external factors on the value of electricity imbalances. Great asymmetry of imbalance data can be adverse in particular by finding other influencing factors and building a more flexible model of the connection between them. The significant asymmetry of the imbalance data suggests that data preparation can strongly influence the accuracy of forecasting results. Additional, some kind of mixture distribution models could be used for improving of forecast accuracy.

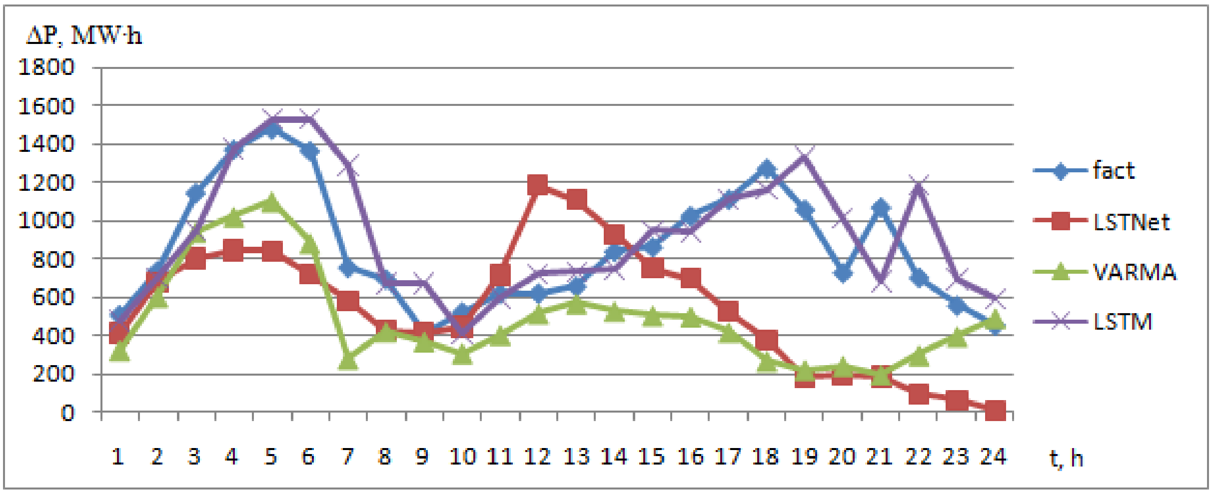

Figure 5. Graphs of electricity imbalance values, predicted using built models, compared with actual values for 07/20/2021.

4. Conclusions

The use of artificial neural networks made it possible to reduce the error of forecasting total electricity imbalances for different testing periods. LSTM shows the lowest values of MAPE forecasting error, for positive imbalances the daily forecast error is 20.73%, while for VARMA model the error is 40.86% and LSTM is 46.95%. When predicting negative imbalances, LSTM also has the lowest error value of 9.1%, compared to VARMA of 17.18% and LSTNet of 66.91%. The forecast on the entire data sample has significantly larger errors especially on the data of positive electricity imbalances, LSTM 66.25%, VARMA 140.84%, LSTNet 132.78% and for negative imbalance LSTM 17.98%, VARMA 34.2%, LSTMNet 52.7%. Therefore, the smallest error of forecasting results is achieved using an artificial neural network based on LSTM. In this way, the LSTM is the most effective method for imbalances forcasting in terms of flexibility and ability to model multivariate data, which essentially increases the effectiveness of forecasts.

The results of the conducted research prove the success of the proposed forecasting models and indicate the need for their further development taking into account additional factors.

Abstract. An analysis was carried out to examine the prospects for the integration of smart charging technologies, such as Vehicle-to-Grid (V2G), into the power system in Ukraine. The country is experiencing a growing concern regarding greenhouse gas emissions. The transport sector in Ukraine is one of the most energy-intensive sectors of the economy and contributes significantly to environmental degradation. The use of internal combustion engines in transport also increases the country's dependence on imported fuel due to the high demand for petroleum products. The integration of electric transport and smart charging technologies, particularly V2G, is seen as a critical solution with immense potential to mitigate climate change. V2G technology is becoming increasingly relevant as the world transitions towards a more sustainable energy future. V2G refers to the bi-directional flow of energy between electric vehicles (EVs) and the grid. With V2G, EVs can not only consume energy from the grid but also supply energy back to the grid during peak demand periods, helping to stabilize the grid and increase its resilience. Therefore, it is imperative to develop a stable policy to promote these technologies and compare the features of the policy of integrating electric vehicles and the energy system in Ukraine. A qualitative strategic planning methodology, Strengths, Weaknesses, Opportunities and Threats (SWOT) analysis, was used to evaluate the diverse measures and initiatives related to electric transport development and infrastructure while integrating them into the power system. This analysis identified problems associated with the impact of EV charging on the power system, such as the inability to provide increased energy needs or limiting the EV charging infrastructure load. However, a high percentage of renewable energy sources, increased social awareness of climate change, and reduced prices of electric vehicles could provide the necessary opportunities for developing electric transport in Ukraine.

1. Introduction

Today, the electrification of transport around the world is considered one of the key conditions for decarbonization for the implementation of the Paris Agreement and the implementation of nationally determined contributions, both in the countries of the world, Europe, in particular in Ukraine. The expansion of electric vehicles and renewable energy sources can greatly help in reducing the impact of climate change, but their effective integration is crucial. There is a widespread inclination to encourage electric vehicles by offering incentives at various levels, but a well-defined and consistent policy is necessary to foster the growth of electric mobility and related technologies. Of course, the widespread implementation, development and mass use of electric vehicles and its charging infrastructure should take place synchronously and in coordination with the corresponding transformation of the energy system.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012030 doi:10.1088/1755-1315/1254/1/012030

The purpose of this study is to review the current state and perform a comprehensive analysis of the prospects for the development of smart charging technologies for electric transport and their application in Ukraine. Also to consider the possibilities of creating new efficient energy transmission systems "electric transport – electric power industry", as well as to determine the main advantages and obstacles to the use of smart charging technologies in the electrical grids of Ukraine.

2. Modern state of the EV fleet and charging infrastructure development in Ukraine

In Ukraine, the transport industry, along with the energy sector, produces up to 28% of CO2 emissions. The volume of greenhouse emissions from the use of internal combustion engines (ICE), and with them the risks of global climate change and air pollution, make it expedient to widely introduce electric transport at all levels of transportation organization, and first of all it concerns the private use of electric vehicles and urban passenger transport (municipal fleet of electric buses, service road equipment, taxis, delivery services, etc.). This is also required by Ukraine's international environmental obligations.

While electrified transportation such as metros, electric trains, trolleybuses, and trams have been widely adopted for public transportation in many countries and are considered mature technologies, private electrified transportation like electric vehicles (EVs) have faced limited adoption in the past due to limitations in battery technology such as heavy weight, high price, short life, and long charging duration. However, recent breakthroughs in battery technology have made EVs a viable alternative to traditional gasoline vehicles, with fast declining prices and no local greenhouse gas emissions. EVs also boast high energy conversion efficiency compared to traditional vehicles, which suffer from inefficiencies associated with internal combustion engines. Many countries have implemented government programs that offer financial subsidies and tax exemptions to incentivize the purchase of EVs, while car manufacturers offer a range of EV models with varying specifications and prices, providing buyers with a wealth of options to suit their budgets [1].

According to the plans of the European Commission, by 2030, electric vehicles should make up half of all urban vehicles. It is expected that such a transition to an electric drive will significantly reduce emissions of noxious pollutants into the air and the level of acoustic pollution of the environment. According to the National Transport Strategy, Ukraine expects to completely switch to municipal transport with electric motors by 2030, completely replacing buses and fixed-route taxis.

Implementation of transport "greening" programs will allow Ukraine to significantly reduce greenhouse gas emissions, which is necessary to fulfill its obligations under the Paris Climate Agreement. According to the Ministry of Infrastructure of Ukraine as of 01.01.2022, there are about 10.2 million cars in the country. By replacing the Ukrainian motor transport system with an electric one, significant environmental results can be achieved.

The first electric cars in Ukraine were officially registered back in 2012. A noticeable increase in their number occurred in 2016 (1602 units against 470 units in 2015), which was associated with the beginning of the law on the abolition of duties on imports of electric vehicles from January 1, 2016. In 2021, 8,500 electric vehicles were registered in Ukraine. This is about 20% more than in 2020. The creation of a national infrastructure of charging stations will be an impetus not only for the spread of private electric transport, but also for municipal, and for the development of new services using electric vehicles, for example, in the field of logistics.

In 2022, the demand for electric cars in Ukraine increased 15 times due to the shortage provoked by military aggression and the rise in fuel prices. Due to the crisis in the fuel market in Ukraine, there was a rapid increase in demand for electric vehicles. Today, together with "hybrids", the number of electrified cars is more than 100 thousand (of which 42.3 thousand are

pure electric vehicles, and more than 10 thousand were registered during 9 months of 2022).

As of November 1, 2022, the number of registered electric vehicles in Ukraine was 43854 units, and even more than 70,000 hybrids were registered in Ukraine. [1]. As for the distribution of electric vehicles by regions of Ukraine, as shown in table 1, the list is leaded by Kyiv, where as of November 1, 2022 there were 8965 registered EVs. And in the entire Kyiv region, together with Kyiv, their number reaches 12277 units or almost 28% of the total number in the country.

Main specific of the Ukrainian EV market is that the vast majority of it (up to 85%) are used electric vehicles from the USA and European countries. The most popular and widespread EV model in Ukraine is Nissan Leaf [1].

As there are more and more electric vehicles in Ukraine every month, this brings the development of charging infrastructure to the forefront. Note that for increasing the number of electric vehicles, it is critically important to develop a dense network of charging stations near the place of residence and work. Having the opportunity to charge near the place of residence, the consumer is more likely to choose an electric car when buying a car mobile. At the same time, it is economically unprofitable for businesses to build networks of charging stations without a sufficiently developed electric vehicle market in the short term [2].

According to [3], EVs can be charged at various locations such as large charging stations, street chargers, workplace chargers, and private home chargers. However, this new load, which requires a large amount of electric energy from the power system in a short time, can have detrimental effects on the distribution network if not managed properly. Consequently, utility companies will need to make significant infrastructure upgrades, which can be an economic burden. Therefore, to mitigate these negative effects, it is essential to conduct comprehensive studies [4] to understand and assess the characteristics of EVs' load and their probable effects on the electric power system, particularly the distribution networks. Furthermore, optimal integration techniques of EVs into the power grid should be developed and incorporated into the design, operation, and planning processes [5].

For charging stations and connectors, monitoring and accounting at the state level is not yet available, and with the outbreak of hostilities it is impossible physically. Data from open sources show that compared to 2020. the number of stations and charging ports (each station may have several connectors of different types) has decreased. So, if as of 1.01.2021 there were 11.5 thousand connection points (or connectors) in Ukraine, then as of 1.11.2021 – 7.8 thousand, the total number of charging stations – 3244. This is due to the fact that in 2021 Ukrainian the charging infrastructure market significantly changed its configuration – some operators merged, others left the market [6]. However, even so, at the beginning of 2022 the ratio of the number of electric vehicles to the number of connection points in Ukraine is 4.2. This is a high index, at the level of the best among European countries (the same index is, for example, in the Netherlands).

3. Charging strategies and technologies for electric vehicles

The rise in the number of electric vehicles has made them a significant component of the power supply system, both regionally and nationally. As electric vehicles continue to develop, the integration of smart grid technologies and electrical networks is being done with additional requirements and restrictions to effectively integrate them into the hybrid power supply system. In Ukraine, similar to other developed countries, there are opportunities for integrating electric vehicles into the electrical network to regulate the load of the power system. This integration process involves considering the charging modes of traction batteries of the cars [6].

The strategy is to charge vehicle batteries mainly during the minimum load of the power system, and during peak periods of time – to generate energy from the battery to the network. The mass use of electric vehicles in this mode will reduce the demand for electricity during peak periods, which, in turn, reduces the need for peak power plants and helps reduce harmful emissions, Since such generating sources are usually more environmentally friendly and efficient compared to power plants, which provide a constant (base) load. This task is relevant both for many European countries and for Ukraine.

Load shifting (pick shaving and valley filling) using the charging and discharging electric vehicles on the principle is similar to the system-wide one using pumped hydroelectric energy storages. To determine the regulating potential for the use of EVs in real conditions of power consumption, it is necessary to take into account the pattern of use of electric vehicles in a particular case of the operational load mode of the substation (vehicle mode in motion, charge/consumer mode, discharge/generator mode). Subject to the increasing fleet of electric vehicles and the effective use of V2G technology, it will be possible to take into account when designing the electrical network given source of active load. The most potential locations for charge-discharge stations in cities are parking lots in residential areas, near shopping and entertainment centers, etc.

In general, the creation of conditions for the spread of electric vehicles in Ukraine and the development of proper infrastructure has already begun at the state level, because the National Transport Strategy until 2030 and the developed appropriate action plan provide for such stimulation of the use of electric vehicles so that their fleet will make up to 70% of the total number of cars [6]. In general, in addition to the total number of charging points, the quality characteristics of charging are no less important – in other words, whether there are enough “fast” connectors in the country now. Currently, there are about 24% of “fast” connectors in Ukraine – each of them accounts for three “slow” ones. On the one hand, the European average in 2020 was lower than Ukrainian and amounted to 1 to 9 (”high-speed” charging accounted for 11.1% of the total). On the other hand, increasing the number of DC points is critical for accelerating the pace of electric mobility in Ukraine. After all, the capacity of batteries in new models of electric vehicles is constantly growing, having reached 70-80 kWh today. There are also already powerful electric vehicles with a battery capacity of about 100 kWh (for example, Tesla).

It’s important to mention that the infrastructure of charging stations is concentrated mainly in large cities, and on intercity routes the number of charging points is extremely limited. Therefore, it is believed that electric cars are most convenient for movement within the city. Conventional outlets are located both at gasoline stations and in roadside establishments, but it should be borne in mind that the time to recharge the car in this situation will be about 8-10 hours. In the case when there is an urgent need to urgently recharge during the day, it is necessary to look for high-speed charging, which is quite difficult.

Considering the experience of other nations, it can be contended that the demand for electric vehicles is predominantly influenced by factors such as the cost of electric vehicles, infrastructure development, and government incentive programs. Commercial freight carriers and private electric vehicles need more detailed programs to encourage, support and subsidies from the state. In addition, the mass use of electric transport will have an important social and environmental consequence – it will contribute to improving air quality in cities, which is one of the urgent threats in large cities of Ukraine. As for freight electric transport, its use may be the most economically feasible in large cities and agglomerations with a high population density, when it is not necessary to overcome very long distances.

The implementation of measures and initiatives to promote the development of the EV market has already begun in Ukraine:

– From January 1, 2022, the relevant laws came into force, providing for amendments to the Tax (Law No. 1660-IX [7], temporary exemption of electric vehicles and related goods from VAT taxation until 2026) and Customs (Law No. 1661-IX [8], temporary, until 2031, exemption from import duty) codes to stimulate the development of the electric transport industry in Ukraine.
– At the beginning of 2022, the Ministry of Infrastructure of Ukraine initiated the development of key changes in state building codes in terms of the placement of gas stations on the roads [9].
– In June 2022, “The Cabinet of Ministers approved the order developed by the Ministry of Energy “On the creation by the state enterprise “National Nuclear Energy Generating Company “Energoatom” of a network of high-speed automobile electric charging stations [10]. It is assumed that within two years Energoatom will create 120 automobile electric charging stations: 40 – high power (from 160 kW) and 80 – average power (from 60 kW). Charging stations will operate in regional centers and on the main highways of Ukraine.
– The Cabinet of Ministers has approved the introduction of “smart grids” in Ukraine until 2035 and its implementation action plan, following the proposal of the Ministry of Energy on October 14, 2022 [11]. This concept and action plan provide a framework for the implementation of modern technologies in the Ukrainian electric power industry, including during the reconstruction and restoration of energy infrastructure damaged by the Russian aggression. The restored energy sector of Ukraine is expected to embody modern energy ethical technologies and meet European energy efficiency standards. The concept aims to

gradually reduce electricity losses in networks, decrease CO2 emissions, increase investments in the modernization of power grids, and improve the quality and reliability of power supply for electricity consumers, which will directly affect electric transportation and optimize its interaction with the power system.

As a result of Action Plan implementation of this Concept by 2035, it is planned to reduce electricity losses in the power grids in Ukraine as a whole from 11.6% to 7.5% or by 6 billion kWh, which is equivalent to 3 million tons of burned coal at thermal power plants [12].

To facilitate the transition to electric transport, there are several actions that need to be taken, such as obtaining funds from international financial organizations to acquire electric vehicles for Ukrainian cities, creating a system to partially cover the costs of purchasing electric vehicles, and implementing various measures to enhance the environmental sustainability of transportation. For instance, introducing a road toll system that depends on the car's level of environmental standards, restructuring the technical condition monitoring system, and more.

4. The main characteristics of V2G

To prevent negative impacts on networks and energy systems, the European approach to developing infrastructure for electric vehicles is based on Smart Grid principles – intelligent power supply networks where charging stations, charging management systems, and electric vehicles can be controlled by energy companies to address the following challenges in power systems: enhancing network infrastructure efficiency, balancing peak loads, and developing appropriate network intellectual infrastructure. Smart networks are a necessary condition for optimizing power supply system operations and ensuring energy efficiency in the energy industry. Their application enables control and optimization of the charging process and the regulation of the energy consumed by vehicles based on network status during charging. To establish a consistent technical policy for solving these issues in Europe, a set of standards is being developed that regulates different aspects of charging station and device operation.

To date, several modifications of the concepts of smart networks for vehicles have been developed, depending on the number and type of active elements and their interaction and charging schemes. These include the concepts of V1G (Unidirectional Smart Charging, vehicle – network, unidirectional charging) and V2G (Vehicle-to-Grid, vehicle – network, bidirectional charging) and V2B/V2H/V2X (Vehicle-to-Building, vehicle – building/ Vehicle-to-Home, car – private house/ Vehicle-to-Everything, car – anything, bidirectional charging). The V1G system allows you to control the charging of electric vehicles in such a way that, if necessary, the charging power is increased or decreased. Unlike the V1G concept, the V2G and V2B/V2H/V2X concepts need several elements to work, such as a bidirectional charger, a communication protocol for the interaction between the charger and the car, a vehicle with all V2G capabilities, and an efficient system control (see figure 1).

Vehicle-to-grid (V2G) is a specific type of energy storage system that utilizes the batteries of electric vehicles (EVs) to store and release electricity to and from the power grid. V2G systems can provide a range of benefits, including supporting grid stability and reliability, reducing peak demand, and enabling the integration of renewable energy sources. V2G systems work by allowing EVs to charge when electricity is cheap and plentiful, and discharge their stored energy back to the grid when demand is high and electricity prices are elevated. This enables EV owners to earn revenue by selling their excess electricity back to the grid, while also helping to balance the grid and improve its overall efficiency.

While V2G systems are still in the early stages of development, they hold significant potential for the future of energy storage and grid stability. As more and more EVs are introduced onto the market and integrated into the grid, the potential for V2G systems to provide a significant source of flexible, reliable, and cost-effective energy storage will only continue to grow.

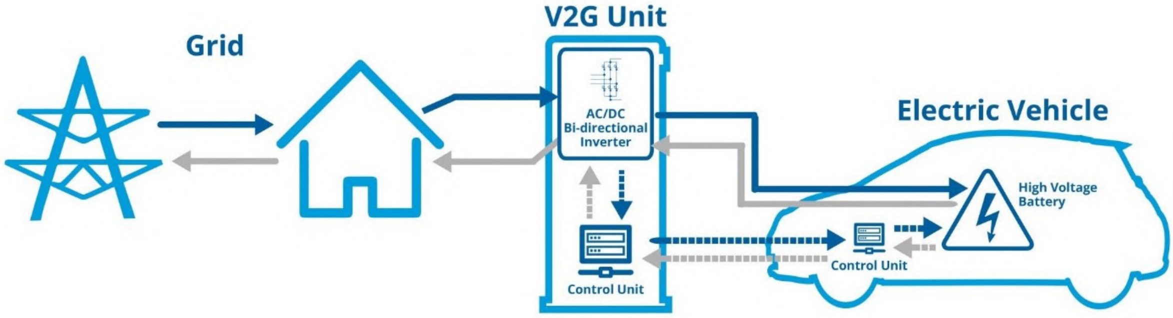

Figure 1. Scheme of bidirectional V2G charging [13].

Numerous research studies have been conducted to analyze the impact of uncontrolled electric vehicle (EV) charging on distribution networks. These studies take into consideration many uncertainties such as the start time of charging, charger power rating, charging location, EV battery capacity, EV battery state of charge (SoC) at the start of charging, penetration level, and the status of the distribution network [14]. These studies evaluated the impacts of uncontrolled EV charging on the distribution network's total power demand, transformer loading and lifespan, cable loading, voltage profile, power losses, voltage and current unbalance, and harmonics distortion. In addition, several studies have proposed potential solutions to integrate EVs optimally, such as delayed charging, smart charging, vehicle-to-grid (V2G) technology, vehicle-to-building (V2B) technology, and vehicle-to-home (V2H) technology [1,15–20]. These solutions could provide electrical services like frequency regulation, voltage regulation, and reactive power compensation, as well as peak shaving and valley filling, integrating renewable energy sources (RESs), spinning reserves, and improving power quality [1, 21]. With the continued growth of EVs, understanding their impact on the distribution network and exploring effective integration solutions is crucial for ensuring a stable and efficient energy system.

The process of charging electric vehicles can be divided into two broad categories (see figure 2): unidirectional and bidirectional charging. Unidirectional charging refers to the flow of energy from the grid to the electric vehicle, which can be either uncontrolled, delayed, or controlled charging. On the other hand, bidirectional charging refers to the flow of energy in both directions, allowing electric vehicles to not only draw power from the grid but also feed power back to the grid or to buildings and homes. This process is enabled by technologies like vehicle-to-grid (V2G), vehicle-to-building (V2B), and vehicle-to-home (V2H) systems.

Figure 3 provides a visual representation of the different charging and discharging methods impact on the power system. By implementing bidirectional charging solutions and other advanced technologies, the electric vehicle industry can work to minimize the negative impacts of uncontrolled charging on distribution networks while also providing a range of benefits to the power system and consumers alike.

The illustration depicted in figure 4 demonstrates how the profile of total power demand within the distribution system will be altered based on various charging and discharging methods. These methods include uncontrolled charging, delayed charging, controlled charging, as well as V2G, V2B, and V2H [22].

5. SWOT analysis of V2G implementation in Ukraine

The need to carry out a comprehensive assessment of all factors of influence of the external and internal environment to determine the possibilities and prospects for increasing electromobility in Ukraine is a condition for the development of an appropriate strategy, the basis for which is

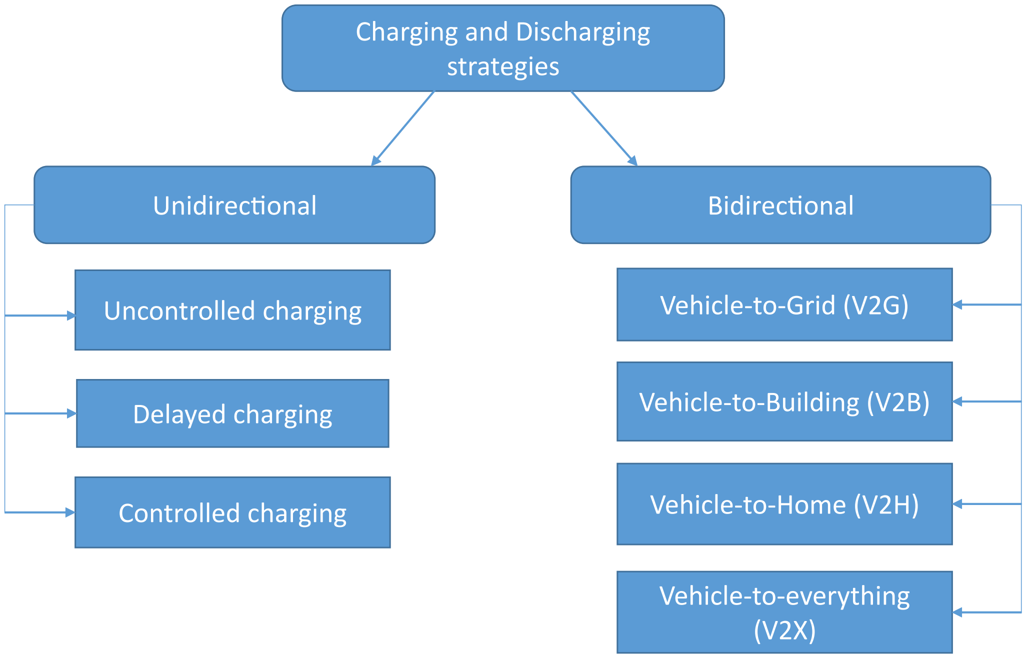

Figure 2. Different charging methods [22].

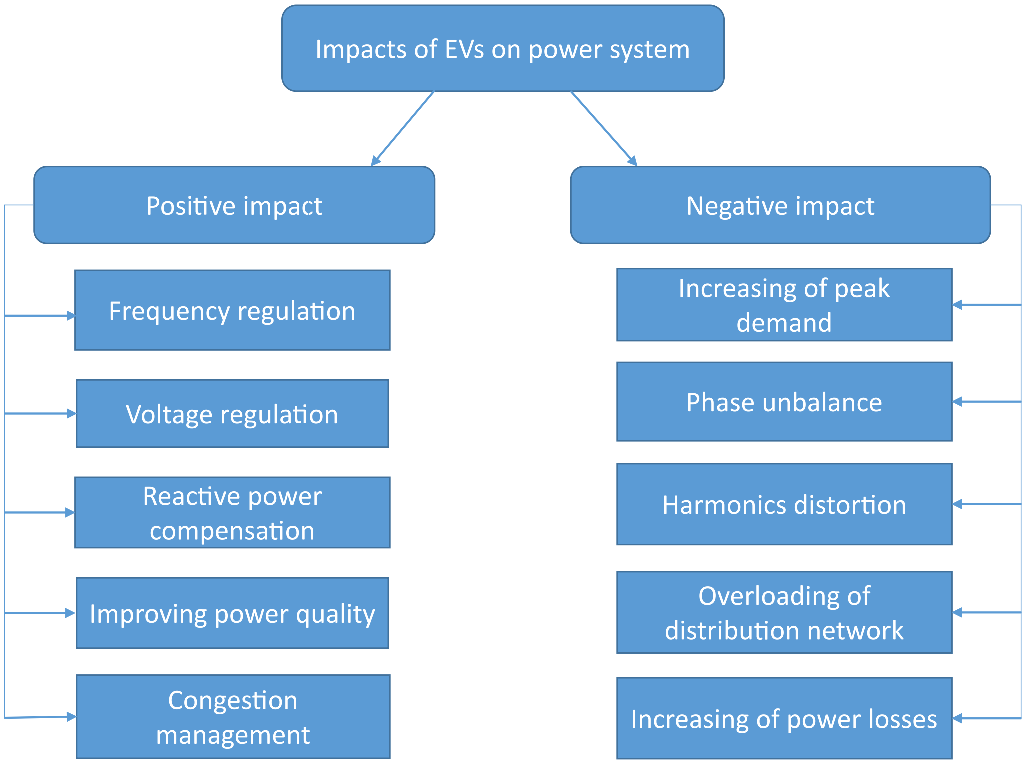

Figure 3. EVs charging impacts on power systems [22].

SWOT analysis [23].

The internal environment of the subject being analyzed is characterized by factors that can be considered as strengths (S) or weaknesses (W), which are influenced directly by the subject.

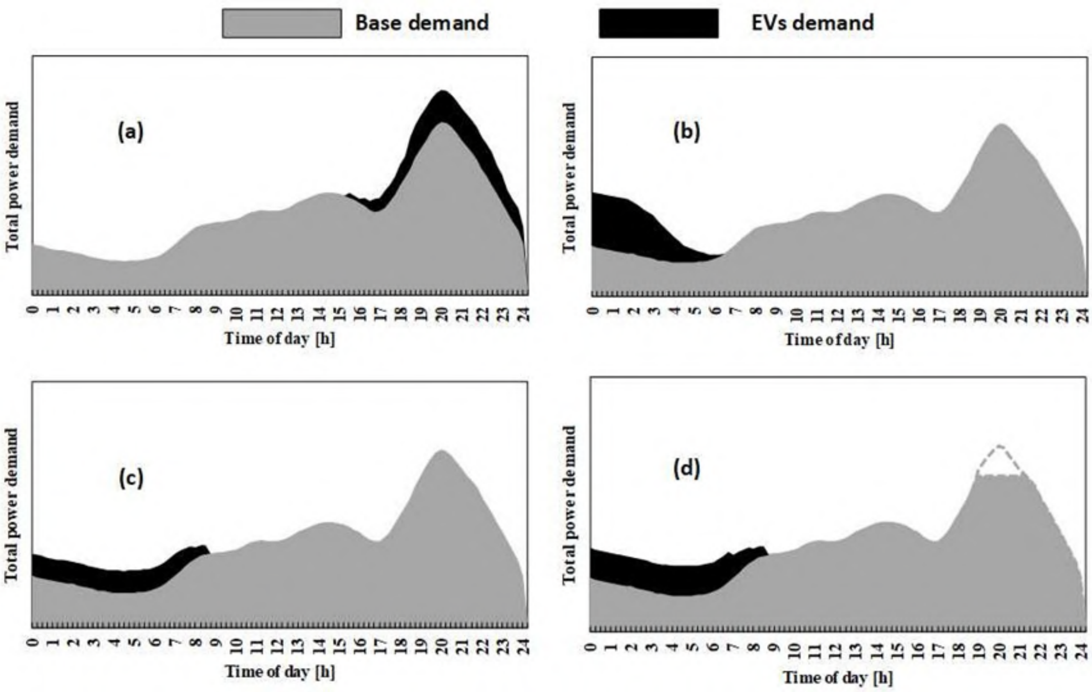

Figure 4. Power demand with uncontrolled (a), delayed (b), controlled (c), and V2G, V2B, V2H (d) charging methods [22].

On the other hand, the external environment is characterized by factors that are outside the subject's control and can be identified as opportunities (O) or threats (T) [23]. The advantages of the method: simplicity and the ability to spend small funds on its implementation, flexibility and the presence of many options, joint study of external and internal factors.

When considering the strengths of the development of electric transport and V2G technology, it was found that the use of electric vehicles instead of cars with internal combustion engines significantly reduces air pollution in cities. Traditional cars, even with high-quality petroleum fuels, emit a lot of pollutants. And electric cars are at the stage exploitation has no emissions. Emissions generated due to the generation of electricity are mostly left out of cities and sprayed to a significantly higher altitude, which is safe for public health.

Moreover, it was noted that V2G technology has the potential to lower the overall cost of owning electric vehicles and can be extended for localized use such as home energy storage and backup power in emergency situations. From the perspective of the grid operator, V2G provides a new resource for regulating and accumulating electricity, thereby offering a solution to the problem of fluctuations resulting from the increased use of renewable energy sources [2]. It also helps alleviate network congestion and obviates the need to modernize network infrastructure. Furthermore, V2G promotes a circular economy, enhances energy security, fosters a cleaner environment, and reduces noise pollution from vehicle engines. Consequently, the adoption of V2G technology and electric vehicles will trigger a significant shift in the way cities are structured, leading to substantial economic activity. For grid aggregators and operators, V2G technology creates new opportunities in the electricity sector, such as providing network balancing and renewable energy storage services in collaboration with utility companies, network operators, and consumers. Office and real estate owners can also benefit from V2G technology as it facilitates localized peak load reduction, load equalization, and balancing of electricity demand, ultimately reducing the total cost of electricity [2].

An electric engine with the calculation of losses during charging has an efficiency of about 85-90% of the electricity required from the network, which is 3 times higher than the efficiency of an internal combustion engine, which is about 30-35%. At the same time, if we take into account the losses in oil refining and the generation and transmission of electricity, then in terms of energy costs, these technologies are generally comparable. But for different countries and regions of the world, this balance is different depending on the structure of electricity generation. EVs through the driving specifics in cities are more efficient in terms of energy use than traditional cars.

Electricity is on average cheaper than gasoline and fluctuations in its price are insignificant compared to prices for motor fuel from oil. An electric car with the same characteristics will consume several times less fuel. As a result, depending on the country and energy source, the fuel costs of an electric car can be from 3 to 10 times lower. A car with an internal combustion engine has about 10,000 moving parts and components. In electric vehicles there are 1000-2000. The mechanics of parts of an electric car are much simpler and, accordingly, the wear of parts is less, and the cost of this is lower.

Also, an electric car is much easier to drive than a car with an internal combustion engine, due to one gear, a low center of gravity (due to the low location of the battery, which is usually located above the bottom of the car). Due to the absence of an engine in the front of the car, the electric car not only gives you additional space for the transport of goods, but also significantly increases the safety of the car.

Among the weaknesses is the cost of EV for its owner, which is still the biggest obstacle to its mass distribution. On average, the retail price of a middle-class car with an internal combustion engine is twice the price of an electric counterpart. In most models of electric vehicles, many parts are similar to cars with internal combustion engine. And the most expensive part of EV is a battery, which accounts for up to 40% of the final price of an electric car. EV battery cost decreasing will allow electric vehicles to become competitive in price. Furthermore, uncontrolled or haphazard charging of electric vehicles (EVs) can lead to a significant and uneven increase in the electrical load profile, particularly during the evening peak load. This is because most people tend to charge their EVs when they return home from work, resulting in an estimated increase of 8-10% in the evening peak load. This can pose a significant challenge for distribution networks. Moreover, the uneven geographical distribution of EVs and charging stations in cities and areas can also cause local substations to exceed their capacity, particularly in areas with a high concentration of EVs or charging stations [8].

Threats to the development of electric mobility are associated with the lack or limited access to the raw material base, including for the production of batteries, difficult political situation, strict national environmental standards and other regulatory requirements, restrictions on land use, insufficient development of related infrastructure, economic factors, etc. In addition, with the growing demand for electric vehicles requires new projects, and they are very expensive.

The results of fulfilled SWOT analysis are given in table 2.

After studying the successful experiences of countries that have implemented electric vehicles and V2G systems, it can be concluded that the demand for electric vehicles is heavily influenced by the cost for end-users, the development of necessary infrastructure, and government incentive programs. In order to encourage the use of electric vehicles in both commercial and private sectors, the government should provide detailed support programs and subsidies. Ukraine's implementation of transport "greening" programs would reduce greenhouse gas emissions and fulfill obligations under the Paris Climate Agreement. If Ukraine replaces 70% of its motor transport system with electric vehicles, it would achieve significant environmental results. However, the introduction of electric vehicles should be accompanied by infrastructure development, systems for interaction with the power system, and compliance with international environmental standards. Despite the higher initial cost of electric transport, its operating costs are expected to be lower in the long term, and as battery costs continue to decline, the share of

Table 2. Strengths, weaknesses, opportunities and threats of V2G implementation in Ukraine.

Strengths	Weaknesses
• Environmental friendliness, reduction of air pollution (especially in cities) • Sustainable growth of the electric car fleet in Ukraine, constant growth in demand • The efficiency of the electric motor is 85-90% (the efficiency of the internal combustion engine is 30-35%) • An electric car is more efficient in the urban cycle in terms of energy consumption • Electricity is much cheaper than fuel, characterized by lower price fluctuations • Favorable climatic conditions • Availability of existing electric transport and infrastructure • High share of private car ownership • Developed IT sector (smartphones, mobile applications, etc.) • Availability of a research base for the study of projects for the development of electric transport and infrastructure	• High price for new electric vehicles and the high price of replacing batteries • Low share of electric vehicles in the country's park compared to cars with internal combustion engines • Lack of additional incentives • 85% of electric vehicles are used, with partially degraded batteries • The need for daily charging, the need to determine the time and place • Relatively short mileage and additional reduction in power reserve in winter • Lack of a sufficient number of equipped parking areas for electric vehicles • Integration of electric vehicles with the power system is a complex long-term process that requires the development of rules and coordination of actions of all participants at all levels (charging infrastructure, energy market, renewable energy sources, energy supply companies, etc.) • Lack of own production of electric vehicles, batteries, V2G devices
Opportunities	**Threats**
• Reduction of CO2 emission (implementation of NVVP2) • Reducing the use of natural gas and petroleum products, reducing dependence on energy imports • Implementation and development of smart grid networks • The growing number of electric car models on the market • The growing popularity of electric vehicles • Implementation of the incentive and subsidy program • Use of electric transport as aconsumer-regulator of electrical load and as a distributed (mobile) storage of electricity • Increasing the flexibility of the power system • Use of batteries as a power reserve in emergency situations in the power system	• Probable rise in price of electricity • Further outflow of the solvent population without disabilities (due to war, economic downturn or lack of prospects for self-realization) • Large secondary market for more affordable cars with internal combustion engines • Charging electric vehicles directly depends on human life and increases the unevenness of the gene (especially in the evening peak zone) • Uncontrolled charging causes a number of negative effects in the power system (impact on grid stability and electricity quality) • Deterioration of distribution electrical networks • Accelerated battery degradation when participating in the V2G system (increase in charging-discharge cycles)

electric transport in the market is projected to increase.

Today there is an increase in demand for electric vehicles, but there are no economic and legal levers to stimulate the use of traction batteries as a maneuverable source, besides, V2G technology is not approved at the legislative level, there are no technical requirements for the relevant charging stations, and the network of standard charging stations is still underdeveloped [24].

The development of the infrastructure of powerful high-speed charging stations in Ukraine requires the modernization of the existing power grid and bringing it in line with European standards in order to ensure the ability of the power system to meet the needs of the charging infrastructure of electric vehicles, the number of which is constantly growing [25].

An action plan aimed at promoting electric vehicles in Ukraine should include several key measures. Firstly, it should encourage the innovative development of electric vehicles by stimulating their production in the country. Secondly, economic and other incentives should be introduced to promote the use of electric vehicles, including electric buses, bicycles, scooters, and other similar forms of transport in urban areas. Thirdly, a national network of high-speed charging stations for electric vehicles should be established along major international roads. Fourthly, incentives should be provided to carriers to reduce emissions of pollutants, greenhouse gases, and noise from vehicles. Fifthly, an interactive map should be created that identifies favorable locations for electric charging stations throughout Ukraine, including regional contexts. Sixthly, a monitoring system should be established to collect data on electricity consumption by charging stations to ensure the proper management and balancing of the energy system. Finally, there should be legislation determining the rights and obligations of operators of electric charging stations, the procedures and conditions for their participation in the electricity market, the rights and obligations of distribution system operators, suppliers, and consumers when using electric charging stations, as well as the procedure for connecting these stations to the electricity network.

In addition to all the above measures, it is also necessary to inform the public about state support for electric transport, in particular, timely and widespread information about benefits for electric vehicles and certain restrictions for cars with internal combustion engines. It is necessary to be widely informed about the advantages of electric vehicles in the media. For example, the fact that Tesla owners undergo a technical inspection remotely, which saves a lot of time, or that electric cars are much safer than cars with internal combustion engines, and this has been repeatedly proved by relevant tests. The policy of stimulating the widespread use of electric transport should be noted in all key development strategies of Ukraine: economic, energy, environmental, climate and infrastructure.

6. Conclusions

Using strategic planning methods, an analysis was conducted to examine the potential for implementing vehicle-to-grid (V2G) technology for electric transport and integrating it into the power system in Ukraine. The study showed that the transport sector in Ukraine has a significant impact on the environment, is energy-intensive, and contributes to the country's dependence on imported fuel. Electric vehicles (EV) and V2G smart charging technologies offer a promising solution to address climate change. Therefore, there is an urgent need to develop a stable policy to promote these technologies by comparing and determining the features of integrating EV and the power system in Ukraine.

A SWOT analysis was conducted to identify strengths, weaknesses, opportunities, and threats related to the development of EV and infrastructure integration with the power system. The study revealed potential problems related to the impact of EV charging on the power system, but opportunities such as a high percentage of renewable energy sources, public awareness of climate change, and lower prices for EVs can help promote their development in Ukraine.

The widespread adoption of EVs and related infrastructure, smart charging technologies, and adherence to international environmental standards can form a new sector of the economy and energy system in Ukraine (E-Mobility). The concept of developing electric transport in Ukraine should cover all types, including electric cars, minibuses, passenger buses, and trucks. Although EVs have a higher initial cost, their operating costs are significantly lower. As battery costs decrease in the future, the initial cost of EVs will be comparable to that of traditional vehicles, leading to an increase in their share in the country's total fleet.

In Ukraine, V2G technology is still in its early stages, with a limited number of pilot projects and trials currently underway. However, the potential benefits of V2G technology in Ukraine are significant, including the ability to reduce energy costs, improve grid stability and reliability, and support the integration of renewable energy sources. To fully realize the potential of V2G in Ukraine, there are several challenges that must be overcome. These challenges include a lack of infrastructure and investment, regulatory barriers, and the need for more research and development to optimize the technology. Overall, while there are significant challenges to overcome, the potential benefits of V2G in Ukraine are substantial, and efforts to develop smart technologies should continue to be one of the priorities for power sector.

Abstract. The world meets poly crises in climate, pandemic, energy, food, human rights, and migration; hot and cold wars have come in Europe and other regions. The scope of the tasks becomes unprecedented, and their complexity demands high-level skill sets and teaching culture. Education moves into epicentres of the fight for better sustainability and resilience. The United National Sustainable Development Goals Four (SDG4) supposes allocating and diligently using several trillion US dollars for the next decades. The ambitious goals drive the educational system to be at a decent level regarding outcome and process. Saving gratitude to functions of a fundamental human right, a public good, gender equality, and an absolute right to education for all, the author urges that high-quality education is the priority because it will help society to cope with a new level of challenges and even existential threats the climate-like. The article describes the methodology and the importance of soft-hard skills for teaching and learning. The secondary-based sources research illustrates practical results regarding the educational process. The Triple Bottom Line principle (Planet, Profit, People) encompasses many disciplines engaging the main aspects of sustainability and resiliency and climate change for the university curricula in a coherent way. The article considers future trends in high education and case studies connected with the European Green Deal, environmental, social, and governance (ESG) reporting and practical aspects of Green Growth and De-Growth Theory. The Quality of Education reflects the regulator's requirements and social and personal expectations. Life-long learning becomes a norm. The authors consider university products, processes and platforms through the lens of future trends, threats and opportunities. In times of turbulence, the results obtained through students' upskilling and reskilling programs should fit the demands of new jobs, technologies, and financial mechanisms.

1. Introduction

The world meets poly crises in many domains: climate, pandemic, energy, food, human rights, and migration; hot and cold wars have come in Europe and are filtering through other regions. The scope of the tasks becomes unprecedented, and its complexity entails high-level skill sets to meet demands.

Sustainability allows pursuing long-term value and raising resilience to turn disruptions into opportunities. Education is the universal recipe for operating in advance and when challenges emerge.

So, the high quality of education moves into epicentres of the fight for better sustainability and resilience. The United National Sustainable Development Goals Four (SDG4) supposes allocating worldwide and diligently using several trillion US dollars for the next decades. The ambitious goals drive the educational system to be at a decent level regarding outcomes and flexibility of teaching and learning processes.

The EU Green and Tweens transition [1] and Paris Agreement [2] have initiated a paradigm shift from short-term to long-term values to ensure the internalisation of environmental, social, and governance (ESG) *externalities*. The EU Council approved the Corporate Sustainability Reporting Directive (CSRD), marking it as an expansion of the corporate EU [3]. The latter impacts universities and academia to teach the board members and executives managers because non-financial ESG reporting has become mandatory for European companies. The same trend also prevails for the world. Under new regulations, large companies will include reporting on climate-related risks and the impact of activities on climate change. Mandatory disclosure comprises direct and indirect greenhouse gas (GHG) emissions, GHG reduction targets and how the companies plan to implement these goals. Enforcement of the new rule implies sufficient time to implement the new disclosure requirements. It shapes newly sizable requests for universities and academia to create new courses.

United Nations Sustainable Development Goal (SDG) [4] addresses $SDG4$ as "Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all". That is a heart for the achievement of all seventeen SDGs. $SDG4$ articulates gratitude to functions of a fundamental human right, a public good, gender equality, and an absolute right to education for all. During the poly-crisis, the author believes that high-quality education is the priority because it will help society cope with new challenges and even existential threats the climate-like.

The hard truth is that the world can slide into a new period of war, poverty and disease. The Russian aggression forced countries like Germany to increase their defence budget significantly, and countries like Sweden introduced military service again. Education, healthcare, and social workers funding will move to tanks, missiles and cybersecurity [5]. However, even today, most transformative digital companies rapidly scale educational platforms reaching millions of learners, companies, and institutions. Life-long learning becomes an avenue to find new roles, skills, and jobs in a time of uncertainty. Graduates and children need to access high-quality education in their lifecycle terms. These two drivers fuel further development.

Society, stakeholders, and students must obtain a spectrum of general, specific, and 'ready to use' knowledge across targeted domains: energy, climate, security, industries, transport, buildings, agro, and healthcare. For example, energy contributes heavily to achieving many SDGs. So, raising energy engineering awareness inside curricula becomes a priority. The same ambition applies to science and innovations, policy and industry retention. Capital flow follows government regulation and market signals to pursue the opportunity to achieve growth and scale. Whatever happens, people, enterprises, and institutions need to grow new leaders, employees and researchers. People deserve to get equal access to education for all.

2. Methodology

The system and critical thinking, the theory of changes, and social research methods are the methodologies of this work. Provided the social nature of the researched subject, the secondary sources [6] became the distinguish sources for practical examples. The system thinking approach includes classifying objects, elements, links, and tasks as a holistic system by thinking over models [7]. Critical thinking supports open-minded mode [8] and allows researchers to recognise fakes, biases, half-true statements and narratives, and omitted facts. On the one hand, students can learn this discipline in the framework of high-quality studies and training, and its systematic application helps decision-makers to justify the subjects from many angles, on the other hand. For planning and development, the theory of change (ToC) [9] gives an outcome-based concept directed to complete the list of actions with the following evaluation of strategic individual projects and programs. The ToC presented the results of inputs, activities (short-, medium-, and long-term changes), outputs, outcomes, and intended impacts. The author uses secondary data analysis as long as the primary public data collects sufficient foundation to process high-quality education for better sustainability and resiliency.

Following Elkington, the author of the Triple Bottom Line principle (Planet, People, Profit), this article does not consider the De-Growth theory as "a communistic narrative" [10]. Indeed, there are resource limits for growth in the world [11] Otherwise, some researchers believe that Green Growth for free does not exist [12] because there is no such thing as a "free lunch". Under some circumstances, brown growth, or sustainability and resilience necessities, could temporarily leave Green Growth and climate agenda behind. For example, it is compulsory during wars. Typically, "the quality of education" (QE) comprises the education system's characteristics, reflecting the degree of compliance of accurate educational results achieved with regulatory requirements and social and personal expectations. In this article, the concept of "the quality of education" refers to both the result (outcomes) and the process (offline, online, hybrid) of education. The SDG4 functions' QE' as a fundamental human right, a public good, gender equality, and an absolute right to get education for all have taken for granted.

Data works for those familiar with model thinking [13] G.E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine carry on a pioneer study of digital resiliency. Among others, the institute is simulating the future of critical infrastructure regarding the Internet and the decentralised electricity market of Ukraine. Behind these studies stand serious mathematics and topology methods [14]. It brings additional opportunities to spread models and methodology across national infrastructure for long-term planning. Such plans can touch not only energy and utilities but, correspondingly, ICT, finance, healthcare, food, water, transport, defence, databases, and manufacturing domains. The ultimate objective aims at increasing the digital resiliency of critical infrastructure. Digital resiliency is "the ability to anticipate, withstand, recover from, and adapt to adverse conditions, stresses, attacks, or compromises on systems that use or are enabled by cyber resources" [15].

Culture, philosophy, and individual mindset usually impact the context of sustainability and resilience in our perceptions. For example, the difference between resilience and anti-fragility defines differently depending on the consideration method. Resilience increases the system's stability, and anti-fragility targets it to become a different system. From more traditional standpoints, the subjects of resiliency and anti-fragility can overlap or possibly, be congruent. Culture and Philosophy help to translate ethical dilemmas related to the tsunami growth of artificial intelligence (AI), robots, the Internet of things(IoT), digital technology and uncrewed-driving cars and facilities. That is not an accident that the position of Chief Philosophical Officer (CPO) is a subject of discussion in the specialised literature [16]. Is the golden age of philosophy coming again? Behind granular theories and project management guidance, researchers will see better the big picture of technological systems, jobs and education.

3. Future skills: main trends

3.1. Future skills, educational process and life-long learning

The Council of Europe Charter on Education for Democratic Citizenship and Human Rights Education has adopted that all learners acquire the knowledge and skills needed to promote sustainable development according to $SDG4.7$, $Education for sustainable development$ and $global citizenship$ [17]. $UNESCO$ highlighted the educational system, teaching and learning processes with outcomes as core elements [18]. The educational system, the policy, institutions, regulation, monitoring, improvements, and resources mobilising complies with $SDG4$. Observing plenty of literature entails the "no consensus" on the definition of quality education, and the latter largely depends on the context. With the Sustainability, Resiliency, and Climate Change context, the quality of education addresses both the results, particularly to meet future skills for the labour market, and the education process.

Online education increased share compared with offline and hybrid education. It happened because of $COVID-19$ and the blossoming of technology: ICT – Information and communication technology, EFA – Education for all, DE – Distance education. An educational institution can capture this opportunity to teach and learn or sometimes in remote mode with the implication of the e-learning process [19]. When we talk about distance learning, we should indicate what we mean. Distance learning involves a particular program, for example, Moodle, with all the necessary theory, practical tasks, control or test tasks, instructions, and other materials. That allows students to learn the material, work out practical cases and check the material's absorption level. Unlike distance, someone began to call remote training "as not in the classroom", which is not entirely accurate from a methodological point of view. Indeed, personal contacts are hard during the study through Zoom, Google Meet, Teams, and Webex. However, remote or distance learning allows students from different countries to study the subjects and obtain knowledge.

For technology adoption and automation to create productivity growth in Europe, there are three main prognoses where the educational system and the governments have a role to play: 1. Reskilling and upskilling human capital of the people already in their working lives (more than 50% of the total number); 2. Tens of millions of new jobs; for instance, 80 million people have to retrain in heat pump installation. It is a small part of the clean tech sector. 3. Over 50 million jobs could be automated by 2030. There will be a critical need to create new and teach different jobs [20].

Most jobs requiring green skills represent annual growth within 8-20% and are fresh and new: Sustainability Manager, Wind Turbine Technician, Solar Consultant, Ecologist, Environmental Health and Safety Specialist, Compliance Manager, Facilities Manager, and Technical Sales Representative. Below are some examples of trends-evoking skills and prospective jobs to cover up-skill and re-skill deliverables for the trends. The topic of jobs gained and lost resulting in the technology adoption for the years ahead is always hot. Automatisation and AI will have a tremendous impact. Universities have enough work to maintain the transition from the current status of the workforce to the future architecture of skills aligned with the labour markets. Quite logical that new technologies will displace relatively easy automated workers. Occupations that require a combination of hard and soft skills can seek new employees, given that the last jobs for automation are full of social and emotional skills, creativity, and cognitive capacity.

3.2. Sustainability, resilience, and climate change

Poly-crises and climate change have initiated a paradigm shift from short-term to long-term values where non-financial externalities, environmental, social, and governance(ESG) are the unseparated part of any consideration, products, and practices. So, educational institutions can provide adaptation in their curriculums by measuring performance and return, managing operations, marketing, organisational leadership, incentives and governance [3] and dealing with ESG issues foreseen familiarity with bio-diversity, human rights, supply chain equality, diversity and inclusion, climate change mitigation and adaptation [21]. As never before, climate change literacy and numeracy come to the fore. A combination of hard and soft skills allows learners to achieve cross-disciplinary objectives, which causes a necessity to obtain emotional and social intelligence skills [22].

Developing sustainability, resiliency, and climate change initiatives with governmental support through ESG policy and blended finance will also impact the new technology and critical market infrastructure. That is an argument for why education has to re-educate the ESG teams. For instance, the solar PV industry creates an additional 1 300 jobs for each gigawatt capacity just for the manufacturing stage [23]. The culture of lectors and professors increases the ranking of the institutions. Academic honesty and an ability to create new approaches and absorb existing knowledge and International best practices save stakeholder time to achieve better sustainability and resiliency.

3.3. COVID-19: great reset

COVID-19 has taught society to raise awareness of automation and the urgent need to accelerate related processes towards more tech and digital. In 2016, some academics concluded that up to 86% of restaurants, 75% of retail and 59% of entertainment jobs could be automated by 2035 [24] incumbent understanding of digitalisation becomes much more profound and broader. The following justifications regarding trends and cyber-attacks confirm an increasing role of digitalisation, cybersecurity, AI and immersing technology awareness.

Here are selected business trends in 2023 and further years (selected) [25]: 1. E-commerce growth persists post-pandemic; 2. $5G$ vastly improves data collection and AI capabilities; 3. Employees actively seek out remote and hybrid work; 4. Companies focus on sustainability; 5. Businesses experiment with immersive technologies like augmented reality (AR), virtual reality (VR), and mixed reality (MR); 6. More people become freelancers and entrepreneurs; 7. Innovation impacts last-mile delivery – nearly all businesses suffered supply chain disruptions due to the pandemic; 8. Customers save costs through AI.

An increasing number of cyber-attacks on critical infrastructure, financial, healthcare, and other networked systems negatively impact ESG, environment and social justice. Regulators and the insurance industry cannot tackle cybersecurity. The World Economic Forum [26] suggests including cyber risks in ESG strategies because of three foundations: 1. It presents a threat to value, particularly intangible assets; 2. It presents a threat to society; 3. Insurance cannot mitigate the risk indefinitely.

3.4. Ukraine, rebuilding – a trillion-dollar challenges

Now post-war future of Ukraine is widely discussed in the world. There are plenty of project estimations that it takes hundreds of thousands to even one trillion dollars to rebuild and rehabilitate the country. The private-public-partnership (PPP) is one of the most practical ways for upcoming rebuilding [27].

Rebuilding Ukraine could be the biggest Western project since Marshall Plan after $WW2$ [28]. It looks like the venture with a long story of massively failed projects: big budgets, huge promises, big teams, and plans reminded documentation of fantasy. Do not forget to mitigate the risks of corruption. Ukraine and the West do not have the experience to manage these vast opportunities and risks. McGrath urges that learning is the only way out of the uncertainty trap.

Following her adopted advice, she did it together with Flyvjberg and Gardner [29]: 1. Work backwards, starting with the goal; 2. Understand odds. Most big ambitious projects fail; 3. Plan slow, act fast; 4. Lego blocks. Small steps best build big ones; 5. Build the Team; 6. Master the unknown unknowns. Dispel the myth that exact projects are unique; 7. Know that the most significant risk is the human factor.

Standardisation and regulation barriers frequently stand behind advanced practices, so the revision is urgent, especially for industries with a complicated and safety-significant supply chain [30]. It encompasses several technical, scientific, legal, financial, and military areas, professional education and study. The rebuilding plan for Ukraine should cover regulations much beyond the current status.

Not only Ukraine itself but any country and their unions don't have the traction to cope with the magnitude of the rebuilding objective Ukraine is facing. Behind this new chapter in Ukrainian history should stand advanced technologies and innovations such as new generation internet, modelling, AI, IoT, 5/6G, Data, Quantum computing and censoring, ML, Dl, blockchain, clouds, and others. Like any sizable or significant transformations, project leaders matchmake academic, educational, and industry within and across countries. In advance, therefore, the government and universities need to look for teachers, researchers, and experts from industry, academia, and entrepreneurs. That is a relatively frugal solution and sustainable for any country, even though it takes time.

3.5. R&D internalisation, energy system, and new generation of Internet
When Ukraine is now more into maintaining the energy system operational, the EU countries address thoughts to market design for fulfilling three objectives: fairness, optimal investment, and optimal operation. [31]. It brings us to analyse some specific concepts:

Overcentralisation vs decentralisation. A decentralised market model for the resilient energy system comes to the fore for scientists and practitioners because of overcentralised physical energy structure doesn't fit emergency and market needs. The war is a visible driver to zoom into decentralising the electricity, water, and power market models. With the introduction of new technologies, such as wind, storage, smart grids, solar, and prosumerism concept, these new becomes an integral part of a complex energy system, its elements, and interwoven grids.

Digital Resiliency and New Generation Internet. Producers and suppliers can exchange their roles, which gives impetus for prosumerism and smart-response and metering development. That is why digitalisation heavily impacts all processes in the electricity and affiliated markets. The flow of reliable data, in combination with nascent next-generation internet technologies, represents the start of the transition to a new norm.

R&D internalisation. Due to nations and companies having unequal access to new technologies, developed counties set up different incentives and institutional frameworks. The US Defence Advanced Research Projects Agency (DARPA) [32] is one of the best role models. Another excellent example is Canada's innovation ecosystem where the Mitacs (Monreal) [33] is a catalysing force with focus areas and application domains fitted to future challenges. Mitacs can engage the expertise of universities, academia, and thousands of experts in Canada and worldwide. What is unique, they deal with big names, such as Ericsson, Cisco, and Oracle. The technological giant Ericsson, for example, launched in Canada's Quantum hub to support research [34]. They also onboard people in the team after up-skilling and re-skilling them using the study's 5G and virtual reality technologies. This practice helps the company to design new processes, methodologies, technologies, and new ways of collaboration.

4. High-quality education: case-study
4.1. Disciplines and process
The effective incorporation of sustainability and resiliency concepts and principles through all levels of the education system may pose particular challenges. The global market only for green energy will exceed \$1.1 tn by 2027. Demand for jobs only for sustainability managers will rise 8% annually until 2030, with up to 14 Mio jobs in 2030 [35]. Such hectic demand for educational service couples with the multidisciplinary nature of the sustainability, resiliency and climate change issues. So, regulators, universities and academia also need to adjust their up-skilling and re-spilling program and standards for specific disciplines, generations, and demography. Targeted competencies find their reflection in the scientific and methodological materials of the courses. Moreover, as a rule, competencies do not depend on the form of training: full-time, distance learning or mixed form. The exception is social skills, which require different approaches to their formation in various processes and platforms for learning.

When it comes to distance learning, the regulatory acts sometimes are not aimed at improving the educational process. In particular, it concerns reducing the pedagogical burden of distance learning. It is always happened, for example, in Ukraine before the war. The factors of optimisation of distance learning include the increased role of visualisation of material (theoretical material presented in the form of video lectures, as well as some practical tasks using video and audio files). The pandemic time shows it is unrealistic to insist on this with a minimum of teaching hours, only relying on the teacher's enthusiasm.

Universities play a central role in developing knowledge, including many domains, such as engineering, sciences, architecture, law, management, economics, sociology and even philosophy. They share knowledge and deal with academia, research institutions, government agencies, civil society and the private sector to ensure better employability of students. The extensive range of disciplines and backgrounds requires different approaches, including the main aspects of sustainability, resiliency and climate change, in the curricula coherently.

4.2. Distinctive curricula

The distinct requirements arise from the need to address sustainability, resiliency, and climate change. In today's educational landscape, teachers play multifaceted roles, serving as mentors, interpreters of knowledge, and bridges between generations. Their influence significantly impacts students' personalities and values. Therefore, it is crucial for educational curricula to incorporate specific and general knowledge tailored to students' needs, encompassing the following aspects:

1. *Multidisciplinary and system thinking*: A modern education should equip students with the ability to prioritize effectively. In times of peace, addressing climate change might take precedence, while during periods of turmoil, focusing on the sustainability and resilience of territories or sectors becomes crucial. Universities now emphasize teaching critical thinking and problem-solving skills, as well as the theory of change. Learning is indispensable to navigate uncertainty in situations involving mega projects and potential risks, as evidenced by the case of Ukraine.
2. *Integrating culture and philosophy*: The culture of teaching plays a pivotal role in delivering quality education. Teachers not only impart knowledge but also mold students' personalities, instilling values and fostering critical thinking. Academic integrity is gaining prominence, with a growing emphasis on originality and the ability to express one's ideas. Ensuring academic honesty from the early stages of education fosters respect for others' work.
3. *Developing a comprehensive set of skills*: Training programs need to adapt to the evolving demands of the professional world. This includes equipping students with both hard and soft skills, understanding taxonomy, and cultivating effective stakeholder relations. Striking a balance between theory and practice becomes essential. Specific skills in handling data (primary, secondary, and treaty), sustainable finance, innovative financial mechanisms, and ESG (environmental, social, governance) policies are crucial. Additionally, cybersecurity literacy and numeracy are necessary to manage cyber risks effectively. Equipping students with game-changer and mega-project skills, legal knowledge for public-private partnerships, and financial and technological tools for strategic planning and risk management is essential for their future success.

Incorporating these elements into education enables students to be well-prepared for the complexities of a rapidly changing world and to contribute positively to society's sustainable development.

4.3. Digital learning and EdTech platforms

The software makes learning more modern and efficient. The pandemic boosted digital and remote learning all around the world. As never before, the Digital Learning and Edtech industry provides equal opportunity and access to education for all. About 150 best EdTech companies [36] reached over three billion people and generated approximately USD 20 billion in revenue. The Digital Learning market is steadily growing by double digits annually.

Zooms, Teams, Webex, Viber, Facebook, and others became survival facilities for most institutions and companies. The author got a first-hand experience as a lecturer at the university. Here are some pros and cons. In particular, Moodle allows a unified presentation of theoretical material, including video lectures, practical, test tasks, and methodical recommendations, allowing students to navigate more quickly in the material. Moodle presents an ability to process large amounts of information, including test surveys, and place and check different types of work. Professional Zoom allows the host to divide students into small groups, which is evident during the discussion.

Meanwhile, the teacher can visit subgroups and check how the task goes. Overall, both tools help to engage active methods of training. By conducting classes through Zoom, the lecture encounters some advantages and disadvantages. The advantages include good visibility and audibility of the material, which does not constantly occur in the old-school audience. The Zoom drawbacks are the difficulty obtaining quick feedback and the limited ability to lead a lecture-discussion.

All major universities and companies with good financial positions have advanced EdTech platforms. Let us consider the state of the arts regarding EdTech platforms and Digital Learning. For example, the Yale School of Management offers offline study and two online programs: delivered live and cohort-based asynchronous [37]. The Yale School delivers teaching and research dealing with two online certified learning providers 2U/GetSmarter's learning platform offers 24/7 assistance to fit into a busy lifestyle. Short courses typically last for six-eight weeks in a cohort-asynchronous manner to prepare future leaders. ExecOnline is helpful when the school conducts three or six weeks of courses integrated with interactive programmes with short videos.

The top 150 EdTech companies focus on three major sectors: Life-Long Learning, Higher Ed, and K-12 by leveraging technology to increase access and affordability of quality and outcomes for learners. Re-skilling is an adult consumer learning, as the Life-Long Learning workforce represents 42% of all categories. In parallel, EdTech leaders have achieved the highest Return on Education (RoE), having extraordinary growth and traction. Edtech companies include publicly listed digital learning companies Grammarly, Coursera, 2U/GetSmarter, Grand Canyon Education, Kahoot, Docebo, Upwork, ExecOnline, Afya, and Arco [38]. In other words, universities have a wide choice to pick out what is better for their students and teachers, and it is not easy because of financial reasons and technological items.

4.4. Case study

Some observers have noted signs of distrust in the levels of university qualifications. Ernst & Young, for example, did not find evidence that university success correlates with work performance achievement. It gives life to skills-based or competency-based hiring practices. Many large companies with extensive human resources (HR) departments can assess applicants for their skills in-house. Small and medium-sized companies, however, still rely on qualifications as they do not have the resources to conduct assessments in-house. Public-sector employers and regulated professions are obliged by law to value qualifications [39].

What can help universities and academia to deliver sustainability and resiliency education and increase the level of trust and quality for diplomas and certificates? The sustainability and resiliency skill requirements are highly innovative. The Hart Research Associates found that the critical skills that distinguish innovators most from non-innovators are creativity, critical thinking, and problem-solving. Linguistic patterns as "come up with new ideas and solutions", the "willingness to question ideas", the "ability to present ideas in the audience", "alertness to opportunities", "analytical thinking", and "ability to coordinate activities"; and the "ability to acquire new knowledge", these are actual signs labelled required non-routine skills [40].

Some selected examples illustrated were moving in the primary, secondary, and tertiary educational processes to cope with climate crises and for better sustainability and resiliency. The Harvard Business School [3] has excellent traction as it is also fair for Columbia Business School [41]. The Black Rock has 'In-House' learning and development programmes [42].

Here are the results of our secondary research regarding the expectation of bachelor students regarding education and the future labour market. The Institute of Sociological Research of the Kyiv National Economic University named after Badym Hetman conducted the primary research in 2022 from 25.01 to 05.04. For successful quality assurance in line with the Bologna Process, the institute used an internal and QA system based on proven ICT, online, and mobile technologies:

(i) *Offline study.* 79.3% of respondents consider themselves satisfied with studying at university students. If chosen by composition, then the most Satisfied with the role of the teacher: defence teacher and student – 86.2%, the level of teaching – 72.4%.The level of satisfaction with the theoretical (58.6%) and practical (55.1%) secondary training. Worst is the situation with students' social and everyday life and assessment of international relations university (35.4%). Yes, for social infrastructure, 34.5% of respondents were satisfied with the logistics use – 41.3% leisure visits, and 44.8% were students. The results demonstrate that the university's ranking largely depends on the culture of lectors and professors.

(ii) *Online learning.* When considering this synchronous (Zoom, Team, Meet) e-mode or classroom activity (Moodle and others), respondents equally distributed such difficulties, respectively, 51.7% and 55.2%. Answers indicate significant difficulties tackling hardware, computer tools, and communications equipment, and the software – programs themselves are not a subject of complaints. Such difficulties stem from poor communication because of the types of equipment, low bandwidth, or even zero access to the Internet. Such problems relate to financial or technical obstacles for the students and teachers working from their homes. Now the situation has turned from bad to worse because of the Russian invasion of Ukraine. Teaching and learning are almost impossible because of additional mobile connection problems.

(iii) *Hybrid learning.* Even though the respondents put first place the negative consequences of the "lack of constant access to the Internet", 34.5% answered emphasised an inconvenient distance learning platform (Moodle, MS Office 365) – 34.%. That is quite likely that the platform does not support the issue. Insufficient training of students and lectures on how to use the platform is the case. 20.7% of the respondents confirmed this opinion.

(iv) Interestingly, 79.3% of the students agreed that receiving current and controlled tasks is more convenient. Plus, 75.8% rated having more free time as a positive factor because they got additional time avoiding time-extensive travelling to the university, the road and inconvenient schedules (the availability of free time between classes, even an hour and a half), or long breaks between classes. The students are happy to get more flexibility for productive activity and at home, which indicates a necessity to better instruct the platform's users from the teaching and learning side.

5. Conclusions

The quality of education reflects the regulator's requirements and social and personal expectations, a fundamental human right to education as a public good based on inclusivity and gender equality. Quality refers to the content and results obtained through students' up-skilling and re-skilling. The process breaks down into offline, online, and hybrid. Universities should set up and hone their educational products, processes and platforms by covering the following items:

(i) These disciplines' sustainability, resiliency, and climate have come to the global cutting edge in different orders. The culture of teaching and teaching is paramount for the quality of education, and it impacts all human activities, including policy, law, technology, finance, industries, and a mindset of critical and system thinking and problem-solving. That is why universities must adopt curricula via environmental, social, and governance(ESG) considerations together with hard and soft disciplines.

(ii) Prioritisation. In a time of peace, climate change is the priority. In wartime or turbulence, sustainability or resilience can be a more important priority in the short and medium-term perspective. Under some circumstances, even brown technologies based on fossil fuel and other necessities could temporarily leave Green development behind. For example, during wars or severe energy and food problems, middle and low-income countries sometimes cannot find another choice to survive.

(iii) Wars and Education. The funding for 'classical' education in a time of peace inevitably succumbs to military and cybersecurity arrangements. The curricula, unfortunately, witness an increasing role of the military. However, ongoing digitalisation, cybersecurity, AI and immersing technology awareness still leave the opportunity for further development for denoted professions.

(iv) Demand for New Jobs in the labour market: Reskilling and upskilling human capital are urgent because about 50% of the total work will change; It embraces tens of millions of new jobs; for instance, 80 million people have to retrain only for heat pumps. Over 50 million jobs could be automated by 2030.

(v) The proposal to Teach the New Jobs: educational institutions should provide adaptation in their curriculums regarding transformation for better sustainability and resiliency, measuring performance and return, incentives and green governance.

(vi) Quality process of Education. Options: 1. The up-skill and re-skill programme for students and specialists. Environmental, social, and governance(ESG) are the unseparated part of any consideration today; 2. Online, Offline, Hybrid. Online education increased share compared with offline and hybrid education. Within online, universities have a choice to deliver live or cohort-based programmes. Eventually, educational institutions can capture teaching with the implication of market fit.

(vii) Educational Platforms. For successful quality assurance, conducting research and delivering teaching in line with the Bologna Process, the universities and academia need to have a system based on proven communication technology and access to online and mobile technologies. There are many current proposals from EdTech Platforms where the cost of licences and technical support are the main bottleneck.

Abstract. Green energy is a key factor for achieving global sustainable development goals. Energy safety is the basic condition for any state to function and for any economy to grow. Moreover, stable supply of energy resources is a pre-requisite for supporting adequate life quality level for the population, which is the main function of a state. In this context, the problem of training specialists in green energy has become an object of an increasing research interest in many countries, including Ukraine. Ukraine has not been experiencing any specific problems with energy security since gaining independence in 1991, except for minor issues with natural gas supply. However, in autumn and winter of 2022, the necessity to reconstruct the Ukrainian energy safety system became specifically acute. The factor having caused the problem is of a man-made nature and was brought forth by the neighboring state's military aggression. Russian military forces have been purposefully and methodically devastating the Ukrainian energy infrastructure with missile strikes over the past several months. Thanks to the technical and technological aid offered by partner countries and introducing emergency power outage schedules across the country, Ukrainian energy companies have managed to sustain the energy system in a relatively operational condition for three months by now. Nevertheless, we should envisage the future challenges and build a strategy for the post-war reconstruction of the Ukrainian energy system. Renewable energy sources have a colossal potential and may become a powerful force in the future development of Ukraine's energy industry. However, in practice, the energy industry must be supplied with a sufficient number of highly professional specialists to realize this opportunity. On the example of Ukrainian HEIs, this article offers an example and a methodology for analysing higher educational establishments' potential and preparedness to satisfy the predicted demand in personnel and to ensure sustainable development of the renewable energy market. Another finding of this research is the system of markers to measure the success of an educational programme in green energy which can be applied by educational institutions to build the programme enhancement strategy. Also, the authors define directions for perspective development of energy education in Ukraine.

1. Introduction

During the entire independence period, Ukrainian energy system has provided a stable and reliable footing for the economy. For instance, in the pre-crisis year of 2013, all areas of energy system operation collectively supplied 8.4% of the Ukrainian GDP [1]. This achievement became possible with significant natural deposits of energy minerals and fossil fuels (coal, natural gas, uranium) and the network of nuclear, thermal and hydroelectric power plants. The mentioned factors fully covered domestic consumer needs in energy resources and ensured industrial development. In addition, a share of Ukraine's energy resources was exported, which was an added source of replenishment for the state budget. Earlier studies reported that reserves of natural energy minerals in the bowels of the earth should have been sufficient for tens and even hundreds of years, which would guarantee stable energy security for Ukraine [2]. Ukraine did experience problems with supporting the economy's need in natural gas; nonetheless, the problems had been solved every time. Also, the energy sector was fully equipped with the full professional and qualification spectrum of specialists who were trained at about two hundred higher education institutions all over the country [3], although the the facilities inherent in the country's energy infrastructure still needed to be radically modernized to comply to the current national needs and global environmental requirements. At that time, the leading specialists and energy scientists were engaged in studying this issue, as well as in improving the country's energy strategy.

Russian ongoing aggression in 2014-2021 and an unprecedented large-scale military attack in 2022-2023 brought drastic and destructive changes to Ukraine's energy security. Ukrainian territories owning the greatest potential of natural energy resources and energy extraction enterprises were either occupied or annexed by the aggressor state. Since March 2022, Zaporizhzhia nuclear power plant in Enerhodar has been under occupation. While military units of the aggressor army are located on the plant's territory, they are undertaking provocative actions that undermine radiation and nuclear security [4]. Also, in the first months of the war, Kakhovka Hydropower Plant was occupied, and Okhtyrka Thermal Power Plant was demolished. As a result of airstrikes by missiles and unmanned aerial vehicles on the Ukrainian energy infrastructure, about three quarters of the country's energy production capacity had been destroyed by mid-January 2023 [4]. The experts conclude that most of the damaged objects belonging to the country's energy infrastructure cannot be reconstructed. Quite apart from the losses caused by war and hostilities, it is considered inexpedient to restore several individual objects since they were put into operation in Soviet times and by the time they were destroyed, they had reached a critical level of moral and physical wear. In the aftermath of the above-mentioned losses in the energy system, scheduled and emergency power outages for end users have been introduced throughout the country. Such measures are temporary, and their purpose is to prevent the complete failure of the Ukrainian energy system. Thanks to implementing these measures and significant technical and technological aid from the partner countries, Ukrainian energy companies manage to support the energy system of Ukraine in a relatively operational state.

The situation described above has created an impetus to realize the need for technological modernization and transformation of the Ukrainian electricity generation in the post-war period.

As can be inferred from a detailed analysis of the statements articulated by the leading specialists at the Ministry of Energy of Ukraine and the goals declared by the Energy Strategy of Ukraine until 2050, it is expected that nuclear energy will remain the basic component of energy generation in Ukraine [4]. What is more, alternative energy sources should progress, and new products and innovative technological solutions should be searched for. The above prompts us to predict that the specific share of renewable energy in the structure of the overall electricity generation will grow. The roadmap for introducing and advancing renewable energy sources will create conditions for sustainable development and satisfy the principal requirements of environmental friendliness and climate neutrality, accessibility and social justice. In addition, such an action plan fully meets the goals of integrating the Ukrainian energy system into the European ENTSO-E power grid.

Renewable energy strategies can be realized in Ukraine if two interrelated conditions are met. The first condition requires implementing technical means and innovative engineering solutions to develop renewable energy in Ukraine. These tools and solutions are costly, and it will be exceedingly difficult to implement such projects in practice independently and autonomously within a short period. Attracting grants and large-scale technical aid from developed countries together with searching for various other possibilities and sources will accelerate advancements in renewable energy.

The second mandatory condition is regular personnel supply. This condition requires from Ukraine independent and autonomous solutions. Therefore, it is urgent to assess the capacity of Ukrainian HEIs to train sufficient numbers of highly professional specialists in renewable energy on a regular basis. The success of the entire renewable energy development project in Ukraine will depend on the positive answer to this question.

Considering the above, this paper seeks to remedy these problems by analyzing the preparedness and capacity of Ukrainian HEIs to satisfy the expected demand for personnel in the growing renewable energy market.

2. Literature review

Education plays a key role in promoting environmental-friendly culture, primarily through perception and acceptance of ecological values by the youth. In recent years, this thesis has been attested by various methods and proved by scientists from such countries as the USA, China, Vietnam, Hungary, Brazil, Israel, India, Iran, Malaysia, and Nigeria [5–17]. Surveys such as those mentioned above prompted us to select the importance of educational policies in ensuring rational nature management in Ukraine as the main hypothesis of this study. In this context, growing knowledge about energy saving methods among young people and rapid transition of the economy to renewable energy sources within the framework of the practical implementation of the Sustainable Development Goals is particularly relevant.

Studies by Singh et al [8], Hoque et al [9], Friman et al [16] recommend familiarizing young people with the basics of renewable energy in primary and secondary schools through gamification, which will facilitate and promote a culture of rational energy resources use and is supposed to encourage teenagers to opt for higher education in the field of renewable energy. At the same time, Colmenares-Quintero et al [7], Kinol et al [17], and Eshiemogie et al [15] argued that significant attention should be paid to high-quality special training of energy engineering specialists by HEIs. Moreover, a study by Szeberényi et al has revealed that representatives of primary, secondary and higher schools believe that low-income families cannot afford using renewable energy sources [13]. Therefore, raising the living standard in the country is an effective factor in activating the transition to renewable energy sources. Taking into account the fact that a country's standard of living is significantly determined by the quality of higher education, sufficient attention should be paid today to improving the training quality of graduates in energy specialties at the universities. Colmenares-Quintero et al propose to improve the quality of training of energy engineers with Problem based learning and design thinking methods [7]. Ji has proved that the quality of higher education in the field of energy can be enhanced by increasing investments and strengthening the environmental component of training [11]. Saputro et al have substantiated introducing STEAM approach into the educational process that will deepen the students' comprehension of renewable energy sources [18]. Popescu et al. have indicated that introducing a pilot course on the technical, legislative and geopolitical aspects of the transition to renewable energy sources into the educational process of the university would be an advantageous approach [19]. We also fully support the conclusions made by Heffron and Foley that higher education should become the key tool for providing young people with specific knowledge and skills to prevent climate change on the planet [20]. To achieve this aim, as highlighted by Fartash et al, countries should develop a network of HEIs preparing a sufficient number of highly-qualified professionals in renewable energy and undertake in-depth research in this field [14]. It is also important for governments to foster interest and motivation among young people to obtain specific specialties in renewable energy.

3. Methods

The statistical data array analyzed in this study is drawn from five main sources.

The State Statistics Service of Ukraine has supplied data on the volume of the gross national product, the energy balance, and the number of people employed in various sectors of the economy [1]

The Unified State Electronic Database on Education in Ukraine has been used a source of information on the bachelor's and master's training programs in specialties 141 "Electrical power engineering, electrical engineering and electromechanics" and 145 "Hydropower engineering" in Ukrainian universities [3].

The normative framework has been outlined by the current legislative and regulatory acts issued by Verkhovna Rada of Ukraine and the Cabinet of Ministers of Ukraine, documents by the National Agency for Ensuring the Effective Use of Energy Resources and the International Renewable Energy Agency.

The data array obtained from the above sources served as the information base of this research. Both qualitative and quantitative methods were used in this investigation to visualize, prove and evaluate the information base:

(i) By employing the cartographic method, we attempted to visually represent the territorial distribution of Ukrainian HEIs, where training in specialty 141 "Electric power engineering, electrical engineering and electromechanics" is being delivered in the 2022-2023 academic year.

(ii) Selective and tabular methods were adopted to describe in detail the current educational programs for training bachelors and masters in the specialties 141 "Electric power engineering, electrical engineering and electromechanics" and 145 "Hydropower engineering" at Ukrainian HEIs, which focus on training professionals in renewable energy.

(iii) Logical generalization and comparative methods were used to explore and compare educational programs training specialists in renewable energy at Ukrainian HEIs with the highest contingent of students as of January 2023.

4. Results and discussion

Reducing or precluding any energy dependence of the country's economy on any other country is the basis for preserving independence, decision-making autonomy and provision for all domestic energy needs. This aspect is especially relevant if a country that owns significant reserves of energy resources pursues an overly aggressive foreign policy. The above exactly describes the situation Ukraine has recently found itself in, and one of the solutions that may be offered would be to realize the Ukraine's aspiration to autonomously provide for all the needs of the national economy in energy resources. This, among other things, can be achieved by diversifying the growing share of renewable energy in the total volume of energy generation in the country. Simultaneously, all areas of the country's life should transfer to the latest energy-efficient technologies. This will be an induced measure due to the fact that energy consumption per unit of manufactured products in the Ukrainian economy is 3-4 times higher than the similar indicators in the world's developed economies [21], whereas implementing the intended goals will allow to ensure an increase in the level of energy efficiency in Ukraine now and in the near future.

The idea of strengthening the role of renewable energy in the Ukrainian economy has been around for the past two decades and was not inspired by the war or the blackouts. In the Ukrainian legislation, the first normative documents highlighting certain aspects of developing renewable energy in the country date back to 2009. In fact, the first document discussing renewable energy in Ukraine was titled the Decree by the Cabinet of Ministers of Ukraine "On signing the Agreement on financing the program Supporting the implementation of the

Ukrainian Energy Strategy in the field of energy efficiency and renewable energy sources" No. 1524-p, dated December 16, 2009 [22]. The authority to secure the necessary financing under the 2010-2011 European Union aid program at the state level was entrusted to the National Agency for Ensuring the Effective Use of Energy Resources (now the State Agency for Energy Efficiency and Energy Saving of Ukraine [23]. In 2023, more than thirteen years after the decree was issued, the problem is still gaining momentum.

In October 2014, the Cabinet of Ministers of Ukraine approved the National Renewable Energy Action Plan for the period until 2020 [21]. Even though the deadline for implementing the plan has already passed, the document remains valid and relevant today. The document states that according to the calculations by the experts at the Institute of Renewable Energy at the National Academy of Sciences, the annual technically achievable energy potential of renewable energy sources in Ukraine is able to reach 50% of the total energy consumption in the country. In addition, the document envisaged increasing the share of renewable energy to 11.0% in the structure of Ukraine's own production. In the years preceding the war, the share of renewable energy in the structure of domestic production in Ukraine fluctuated within the range of 7.2-10.3% [24]. These data imply that it has not yet been possible to fully utilize the potential of renewable energy.

We believe that one of the reasons that did not allow the Ukrainian enterprises to unlock the utmost potential of renewable energy in Ukraine is the failure to attend to one of the most important and key components, that is, failure to provide the industry with highly qualified personnel. For instance, the National Plan had mentioned issues related to the personnel supply only twice – first, to assign the Ministry of Education of Ukraine, in collaboration with other institutions, to create educational and methodological support for the activities undertaken by centers for professional development and certification of specialists who install energy equipment that works on renewable energy sources; second – to recommend to include questions regarding the prospects for producing energy carriers from renewable energy sources and alternative types of fuel in Ukraine in the programs of educational institutions of all levels for the purpose of their popularization [21]. It follows that no questions related to training highly professional specialists in renewable energy were raised in the plan.

In December 2017, Ukraine joined the Charter and in February 2018 became a full member of the International Renewable Energy Agency (IRENA), founded in January 2009 [25, 26]. Participation in IRENA enabled Ukraine to access the world-class experience and knowledge in developing and implementing technologies for utilizing renewable energy. It is also important to receive specific practical recommendations on devising national policy provisions from the Agency's specialists. IRENA also implements measures that contribute to increasing the knowledge potential of participating countries, i.e., organizes special programs for training and education, and encourages scientific and research work. It is this function that is particularly important and relevant in the context of our research topic.

Thus, we can conclude that there is a clear understanding at the governmental level that development of renewable energy sources will become an indispensable condition for ensuring Ukraine's energy independence. In addition, renewable energy will save traditional fuel resources and improve the natural environment. However, a major step has not been taken at the regulatory level, namely, no prerequisites have been created to adequately staff the prospective renewable energy development projects.

The evidence suggests that alternative energy sources and renewable energy represent a lever for successful reconstruction of Ukraine, positive outcomes of which reach out far beyond the post-war period. However, there is a question that we cannot leave unanswered, that is, if Ukraine has sufficient human resources to achieve the ambitious goals set by the authorities. To answer this question, we will analyze the current situation in training renewable energy professionals in Ukraine. Training specialists capable of being directly engaged at renewable energy facilities in Ukraine is being delivered within two specialties: 141 Power Engineering, Electrical Engineering and Electromechanics; 145 Hydropower [3]. Specialists trained in other related specialties (142-144) can also be employed in the renewable energy sector, although after appropriate retraining.

As of January 2023, 56 institutions of higher education in Ukraine are training specialists for master and bachelor's degrees in specialty 141. The territorial distribution of educational institutions is presented in figure 1 [3].

Figure 1. Territorial distribution of educational institutions training specialists in specialty 141 "Electrical power engineering, electrical engineering and electromechanics" in the 2022-2023 academic year.

The largest number of educational institutions training students in specialty 141 are concentrated in the Ukrainian cities of Kharkiv, Kyiv and Dnipro. This distribution is natural and predictable, since these cities represent regions with a substantial number of energy infrastructure facilities and industrial enterprises that need a constant supply of personnel trained in general energy engineering. In addition, institutions of higher education in Kyiv supply specialists for the rest of Ukrainian regions, since educational degree received at one of the capital's universities is considered more prestigious.

According to our observations, training specialists in electricity is being conducted throughout Ukraine, including higher education institutions temporarily displaced due to hostilities or occupation. Examples of displaced HEIs are Volodymyr Dahl East Ukrainian National University (relocated from Luhansk to Syeverodonetsk in 2014, and later, in 2022, to Kyiv), State Higher Educational Institution "Donetsk National Technical University" (relocated from Luhansk to Pokrovsk in 2014, and to Lutsk in 2022), State Higher Educational Institution

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012032 doi:10.1088/1755-1315/1254/1/012032

"Pryazovskyi State Technical University" (relocated from Mariupol to Dnipro in 2022), Donbas State Machine-Building Academy (relocated from Kramatorsk to Ternopil in 2022).

Tables 1 and 2 demonstrate that only 15 Ukrainian HEIs deliver undergraduate and/or graduate educational programs specializing in renewable energy [3]. Two educational programs are not institutionally accredited. Only four HEIs offer both bachelor and master programs.

The fact that most educational programs in renewable energy are accredited until mid-2023 or mid-2024 is of significant concern. Thus, out of 11 bachelor's level educational programs, three are accredited until July 1, 2023, and two programs are accredited until July 1, 2024. The prospects seem even gloomier for the graduate programs, since out of eight educational programs, one program is accredited until July 1, 2023, and five programs are accredited until July 1, 2024. One of the factors explaining this situation is the martial law, which has been introduced in Ukraine and which made it impossible to perform the full scope of accreditation procedures. At the same time, it cannot be guaranteed that all the existing programs will successfully renew the accreditation after the martial law expires. In other words, there is a certain risk of curtailing the currently existing educational programs.

At present, only 394 students in total are enrolled on all accredited educational programs related to renewable energy in all the four years of study. By the time the students are awarded their bachelor's diploma, it will require six months for those who are in the fourth year of study now (the nearest graduation is expected in July 2023) and up to three and a half years for those who are in the first year of study (2022 entrants are expected to graduate in July 2026). Qualified graduated bachelors will enter the labor market gradually, which will not immediately satisfy the potential demand for the number of professionals required to enable the renewable energy sector to develop intensively. In addition, some of these students will continue their studies being enrolled on graduate programs after completing the undergraduate degree, which will postpone their entry into the labor market and add another one and a half or two years to the graduation date from the undergraduate courses. At the moment, 91 students are enrolled on the existing accredited master degree educational programs in renewable energy. If these students do not choose to continue their studies at any of the postgraduate schools, they will enter the Ukrainian labor market as certified specialists in January-February 2024 and 2025.

Thus, in 2023-2026, the industry will be replenished with 485 certified professionals provided that all renewable energy education programs are successfully accredited and all students currently enrolled in education programs at the two educational levels successfully complete their studies, are awarded bachelor's and master's degrees, and join the workforce instead of joining the next educational stage.

In addition to graduates majoring in renewable energy, the Ukrainian labor market employs graduates majoring in the specialty 145 "Hydropower". Only three Ukrainian HEIs train specialists in Hydropower at undergraduate and graduate levels. These are The National University of Water and Environmental Engineering (in Rivne), Zaporizhzhia National University (in Zaporizhzhia) and National Technical University "Kharkiv Polytechnic Institute" (in Kharkiv). At all the three universities mentioned, the titles of educational programs for bachelor and master levels coincide with the name of the specialty.

Table 3 below presents the numbers of students who are pursuing an educational degree in specialty 145 "Hydropower" at Ukrainian HEIs in January 2023 [3].

The situation with accreditation seems to threaten only one educational program, which we do not consider critical. However, the number of certified specialists who will replenish the army of hydropower professionals in 2023-2026 will be only 104 specialists even under favorable conditions.

The statistical data above suggest that Ukrainian higher education institutions do not possess adequate potential to prepare more than 589 graduates in two renewable energy specialties by 2026. This number may satisfy the need in covering staff turnover and staff rejuvenation at

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012032 doi:10.1088/1755-1315/1254/1/012032

Table 1. The contingent of undergraduate students majoring in Electric Power Engineering, Electrical Engineering and Electromechanics studying in educational programs in renewable energy as of January 2023.

HEI	Educational program, number of undergraduate students (persons) and state accreditation validity
O.M. Beketov National University of Urban Economy in Kharkiv	Alternative and Renewable Energy Sources 91 (accreditation valid until 01.07.2028)
Lviv Polytechnic National University	Energy Systems for Sustainable Development 77 (accreditation valid until 01.07.2023)
National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”	Alternative and Renewable Energy Sources 75 (accreditation valid until 01.07.2023)
Odesa National University of Technology	Alternative and Renewable Energy Sources 52 (accreditation valid until 01.07.2024)
Odessa Polytechnic National University	Renewable Energy Sources and Energy Complexes 51 (accreditation valid until 01.07.2029)
National Aerospace University “Kharkiv Aviation Institute”	Alternative and Renewable Energy Sources 33 (accreditation valid until 01.07.2024)
“Zaporizhzhia Polytechnic” National University	Renewable Energy Engineering 8 (accreditation valid until 01.07.2026)
Kyiv National University of Technologies and Design	Intelligent Systems in Renewable Energy and Electric Vehicles 7 (accreditation valid until 01.07.2023)
Ukrainian State University of Railway Transport	Alternative Energy Sources and Environmentally Friendly Transportation 0 (accreditation valid until 01.07.2027)
National University “Yuri Kondratyuk Poltava Polytechnic”	Renewable Energy and Power Supply for Electric Transport 8 (no accreditation data available)
Kyiv National University of Construction and Architecture	Alternative and Renewable Energy Sources 4 (no accreditation data available)
Total number of students pursuing the accredited educational programs	394

Table 2. The contingent of graduate students majoring in Electric Power Engineering, Electrical Engineering and Electromechanics studying in educational programs in renewable energy as of January 2023.

HEI	Educational program, number of graduate students (persons) and state accreditation validity
National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute"	Alternative and Renewable Energy Sources 16 (accreditation valid until 01.07.2024)
Odesa National University of Technology	Alternative and Renewable Energy Sources 20 (accreditation valid until 01.07.2024)
Odessa Polytechnic National University	Renewable Energy Sources and Energy Complexes 15 (accreditation valid until 01.07.2025)
National Aerospace University "Kharkiv Aviation Institute"	Alternative and Renewable Energy Sources 8 (accreditation valid until 01.07.2024)
Oles Honchar Dnipro National University	Alternative and Renewable Energy Sources 15 (accreditation valid until 01.07.2023)
Kherson National Technical University	Alternative and Renewable Energy Sources 13 (accreditation valid until 01.07.2024)
National Technical University "Kharkiv Polytechnic Institute"	Sustainable and Renewable Energy: Electrical Engineering and Microelectronics 4 (accreditation valid until 01.07.2026)
Yuriy Fedkovych Chernivtsi National University	Alternative and Renewable Energy Sources 0 (accreditation valid until 01.07.2024)
Total number of students pursuing accredited educational programs	91

the existing facilities. However, ensuring the expected increase in the share of renewable energy to 25% of the total volume of electricity generation in Ukraine is unlikely to be achieved in 2035 with these numbers of graduates. In addition, we should consider that highly professional specialists in renewable energy are highly valued in the labor markets of the world's developed countries. Since the salaries in these countries considerably exceed the salaries in Ukraine, the country may face the risk of young professionals' outflow.

To diminish the migration risks and increase the applicants' interest in studying educational programs in renewable energy at Ukrainian HEIs, we recommend to introduce success markers into their content. In order to determine such markers, we have analyzed three undergraduate educational programs and three graduate educational programs in renewable energy, which had the highest contingent of students at the corresponding educational level for the time of the study. The evidence received by analyzing specified educational programs [27–32] enabled us to formulate the following markers of the program's success:

Table 3. The contingent of students majoring in Hydropower as of January 2023.

HEI	Educational program, number of undergraduate students(persons) and state accreditation validity	Educational program, number of graduate students(persons) and state accreditation validity
The National University Water and Environmental Engineering	32 (accreditation valid until 01.07.2026)	12 (accreditation valid until 01.07.2026)
Zaporizhzhia National University	29 (accreditation valid until 01.07.2028)	10 (accreditation valid until 01.07.2028)
National Technical University “Kharkiv Polytechnic Institute”	16 (accreditation valid until 01.07.2025)	5 (accreditation valid until 01.07.2025)
Total number of students pursuing the accredited educational programs	77	27

(i) highly professional teaching staff involved in delivering the educational program, their high scientific potential and practical workplace experience in the field of renewable energy, command of foreign languages at a level sufficient to teach major disciplines

(ii) providing the educational process for the educational programs with modern certified laboratories with high-tech equipment, for example, Siemens, Kinco, Hitachi-Omron, Mitsubishi Electric. This can be seen in the case of Cherkasy State Technological University, where teaching specialists in energy has been significantly enhanced with the new equipment received under USAID program. A wide range of equipment, particularly, the demonstration stands, has been deployed to deliver disciplines “Electrical and structural materials”, “Energy-saving modes and technologies”, “Industrial electronics”, which enables students, for example, to calculate solar energy, improves their professional practical skills, increases their satisfaction with the quality of the educational services and enhances the overall efficiency of the educational process

(iii) close cooperation and the availability of double degree programs with universities in France, Great Britain, the Netherlands, Spain, Portugal, Greece within the framework of EUREC graduate programs; with the universities of the Netherlands, Denmark and Norway within the framework of the Erasmus Mundus graduate programs in wind energy, with the universities of the USA, Austria and Germany within the framework of the graduate programs in renewable energy sources and sciences in the field of solar energy, etc.

(iv) introducing a practice-oriented approach to education. This can be illustrated by a positive example of collaboration between the Department of Electric Power Engineering and Control Systems (Lviv Polytechnic National University), LLC “Sambir Solar Station” and PE “Art-Energo”. The laboratory of “Renewable Electricity” was equipped with modern equipment [28]. Another example is provided by the Renewable Energy Sources department (National Technical University of Ukraine “Igor Sikorsky Kyiv Polytechnic Institute”) who initiated the Ukrainian-Polish Center for the Improvement of Renewable Energy Sources and Energy Efficiency Technologies, thanks to which both teachers and students have been acquainted with the leading experience of Polish universities and companies who are engaged in developing renewable energy and energy efficiency [29]

(v) opening possibilities for the students enrolled on the educational programs in renewable energy to participate in international mobility programs initiated by universities in the UK, Germany, Poland, Spain, etc. (with 1-2 semesters mobility period)

Replication or targeting the previously listed markers should spur demand for the educational programs in renewable energy among young people, as well as demand for the graduates among the potential employers. Implementing high-quality educational programs in renewable energy will build an effective ecosystem of electric car service in Ukraine, which will become an additional factor in improving the quality of life for the population and improve the environmental situation in the country [33]. A high-quality education will also encourage graduates to launch their own business in the field of renewable energy.

5. Conclusions

In summary, the results of this research show that in the near future, if the current situation in the specialist training in renewable energy persists, it will not facilitate achieving the goals of intensive development of renewable energy announced by the Ukrainian government. On this basis, this study formulates the most effective directions for increasing the number of highly qualified specialists in renewable energy on the Ukrainian labor market in the post-war period:

(i) increasing the level of remuneration in the renewable energy sector in Ukraine

(ii) securing more investments into the development of human capital, satisfactory working conditions and sufficient social package at renewable energy enterprises in Ukraine. Special attention should be paid to the social protection of young professionals and the development of their talents

(iii) expanding opportunities for professional development and retraining for specialists from the primary and secondary labor markets trained in specialties referred to specialism 14 to match the operational specifics related to the field of renewable energy. In this context, it is important to deploy the experience of both international renewable energy organizations and Ukrainian experience in the field of professional retraining for energy engineers

(iv) enhancing the activities performed by the HEI representatives in compliance with the requirements for successful accreditation of all current educational programs in renewable energy. In this context, it is important to focus on the best practices of the world's leading universities in specialized courses and educational programs.

(v) enriching curricula with the disciplines that acquaint students with the leading global experience in the field of renewable energy, the basics of international energy standards, and sustainable development management. It would also be beneficial to design educational programs so as to ensure the possibility of academic mobility for students, their practical training at leading renewable energy companies

(vi) launching existing educational programs at all educational levels for those HEIs where exclusively bachelors or exclusively masters in renewable energy are being trained at the moment. This will significantly expand the contingent and improve the quality of educational services

(vii) launching new educational programs in renewable energy at both undergraduate and graduate levels in Ukrainian HEIs within the scope of specialty 141. In this context, it is important to increase the level of productive cooperation between Ukrainian HEIs where specialized educational programs can launch in collaboration with the enterprises that operate in the industry

(viii) increasing the professional and qualification level of lecturers and teachers participating in delivering renewable energy educational programs. It is also important to continuously update the methodological base of the courses taught within the educational programs

(ix) increasing the prestige of the entire spectrum of professions related to renewable energy in public opinion. Regional and local authorities should play a key role in the implementation of this direction.

Implementing the above measures and the directions listed above within a short period of time will fetch a significant socio-economic and ecological effect. The social component will be ensured by reducing the number of the unemployed population and increasing the level and quality of life in Ukraine. The economic effect will manifest itself in a different way, that is, from a reduction in the Ukrainian economy's need for external energy resources to an increase in the share of energy in the gross domestic product. The country will be able to obtain an ecological effect through reducing negative consequences for the environment, which will be achievable due to a reduction in the production of the traditional energy resources.

Abstract. Today, the world is transitioning to the 4th and 5th Generation District Heating (GDH) systems of heating networks. The main advantages of 4GDH and 5GDH are the reduction of the temperature of the coolant to +50 – +60°C and the use of various designs and operating principles of thermal energy storage. Therefore, special attention is devoted to the search for new types of coolants, heat-accumulating materials and research of their properties and determination of optimal operating modes. One of the energy storage systems that has become widespread in recent years is the mobile thermal energy storage (M-TES) that has tanks filled with heat storage material. Specially created heat storage materials are often used, which work under the necessary technological conditions and meet the strict conditions of safe transportation of liquids. This article is devoted to the search for new components for the creation of heat storage material, which will be used in capacitor-type TES together with the "thermal core", which is created from a material with a phase transition. As a result of experimental studies of the thermocycling process of water and aqueous solutions, depending on the components added, the priority components such as guar gum and xanthan gum were chosen.

1. Introduction

The rapid growth of energy consumption in industry and by the population has changed the requirements approaches to heat and power supply. To meet the ever-increasing demand, advanced economies are using more energy efficient 4GDH and 5GDH generation heating systems. Their main features are the environmental friendliness and economic expediency of the use of resources, the minimization of heat losses during heat supply, ensuring the stability of the energy and heat systems [1, 2]. The main advantages of 4GDH and 5GDH systems are:

- lowering the temperature of the coolant to +50 – +60°C, which saves energy costs for its heating;
- the use of various energy sources with a wide involvement of renewable generation sources operating with the use of thermal energy storages (TES), which makes it possible to stabilize the heat supply system and equalize peak loads [3, 4];
- the use of main pipelines to supply heat to the consumer in winter, as well as cold for the central air conditioning system in summer;
- high degree of automation and dispatching of process control.

One of the main elements in many links of energy supply are heat carriers and heat storage materials [5]. Nowadays, researchers pay great attention to the study of the thermal properties of common liquid heat carriers, heat storage materials and materials with a phase transition [6,7] and conduct active research to find new compositions as well [8, 9].

The most common coolant is water, since it has an abnormally high value of specific heat capacity of 4.2 kJ/(kg·K). This explains its ability to quickly heat up and cool down, respectively, the TES has a fast charge and discharge time. However, the main task of the TES is a long time of heat accumulation. To extend the accumulation time, multifunctional powders are used that are capable of forming water-soluble polymers (WRPs). Multifunctional powders due to their various chemical, physical and thermophysical properties are used in pharmaceutical, food, mining, paper textile, industries, as well as in construction, agriculture, oil production, etc. For research, the following substances were selected: carboxymethylcellulose, guar and xanthan gums, from which solutions were prepared with mass concentrations of 1% and 10%. The advantage is that they are able to form solutions with stable physicochemical parameters during thermal cycling. These solutions are characterized by low corrosivity, resistant to crystallization, economically viable, environmentally friendly and fire and explosion safe.

Liu et al [10, 11] propose a new approach to the heat supply system by creating M-TES, which will allow organizing a mobile heat supply process for enterprises and public utilities. Mobile heat supply is of particular importance during the war in Ukraine. The main element is a capacitive-type TES filled with accumulative substances for low-potential heating systems. For this, a test bench was created to study the process of thermocycling of heat carriers and heat storage materials.

The purpose of the research is to determine the possibility of using some components to create a heat storage material by thermocycling their aqueous solutions with subsequent use in heat storages and heat supply systems with an operating temperature range from 50℃ to 120℃.

2. Materials and methods

The choice of components for creating heat storage material was carried out taking into account the technological parameters and the specifics of its use in mobile thermal energy storage, namely:

- the rate of discharge and charge of thermal storage tanks M-TES;
- longer accumulation time;
- explosion and fire safety during transportation of M-TES;
- availability and economic feasibility of the used components.

Taking into account the specified technological requirements, some water-soluble polymers were selected for research, which we will consider in more detail [11, 12].

2.1. Materials

Carboxymethylcellulose [13,14] (CMC, food additive E466) is obtained by processing cellulose of the general composition $[C_6H_7O_2(OH)_{3-x}(OCH_2COOH)_x]_n$, where $x = 0.08 - 1.5$ (figure 1).

CMC (LLC "Khimpostachannya", China) is a substance with amorphous properties that acts as a weak acid. By its chemical nature, it is a highly polymeric ionic electrolyte.

CMC is a colorless substance that dissolves in water, has no odor and is safe to use. CMC is insoluble in vegetable oils and animal fats, does not decompose under the action of sunlight. But it dissolves in organic acids: formic, lactic and glacial acetic.

To obtain a homogeneous CMC solution, dry substances are soaked in water at a temperature of 80–85°C, then cold water is added. With an increase in temperature, the viscosity of CMC solutions decreases or phase separation or gel formation occurs.

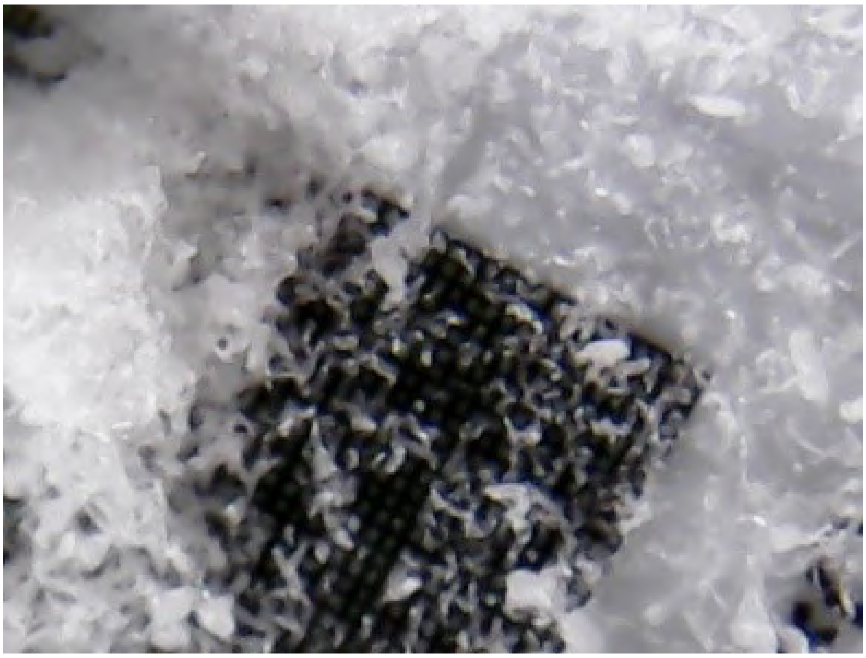

Figure 1. Carboxymethylcellulose.

Xanthan gum [15, 16] $(C_{35}H_{49}O_{29})_n$ is a natural chemical compound that is used primarily as a food additive E415 and belongs to the group of stabilizers. Xanthan gum (LLC "Khimpostachannya", China) is a linear hydrocarbon polysaccharide, the molecular weight and properties of which can be controlled by changing the living conditions of Xanthomonascampestris microorganisms (figure 2).

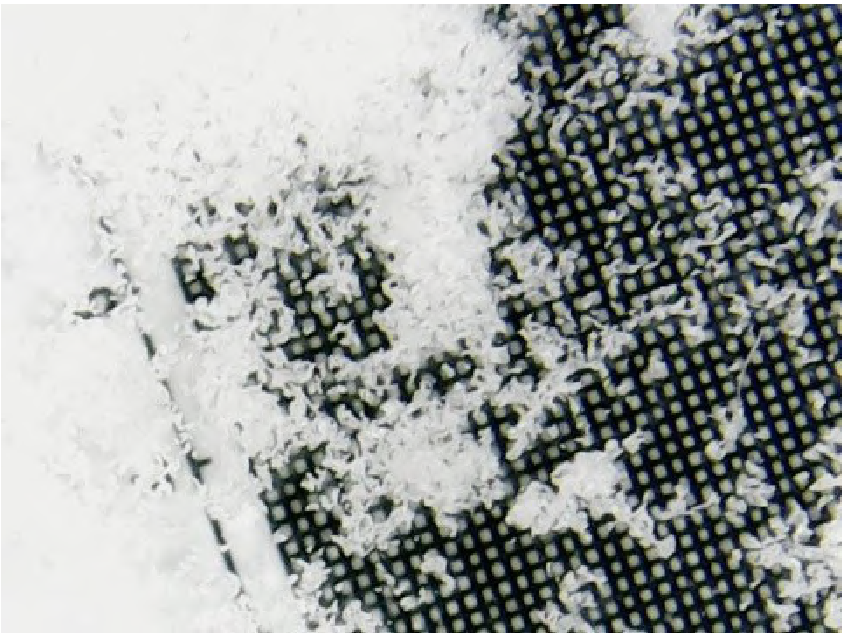

Figure 2. Xanthan gum.

Xanthan solution does not interact with alkalis and acids (except hydrochloric), alcohols and enzymes, and is also stable in the temperature range from 120 to 18°C. The water-soluble polymer (WRP) based on xanthan gum is characterized by high viscosity in the pH range from 2 to 12, therefore, a WRP with a dense structure is formed, which stabilizes foodstuffs for a long time and prolongs their shelf life.

Guar gum $(C_6H_{10}O_5)_n$ [17] is a white or yellowish powder with a characteristic odour. It is obtained from ground seeds of guar beans containing up to 70% gum (figure 3).

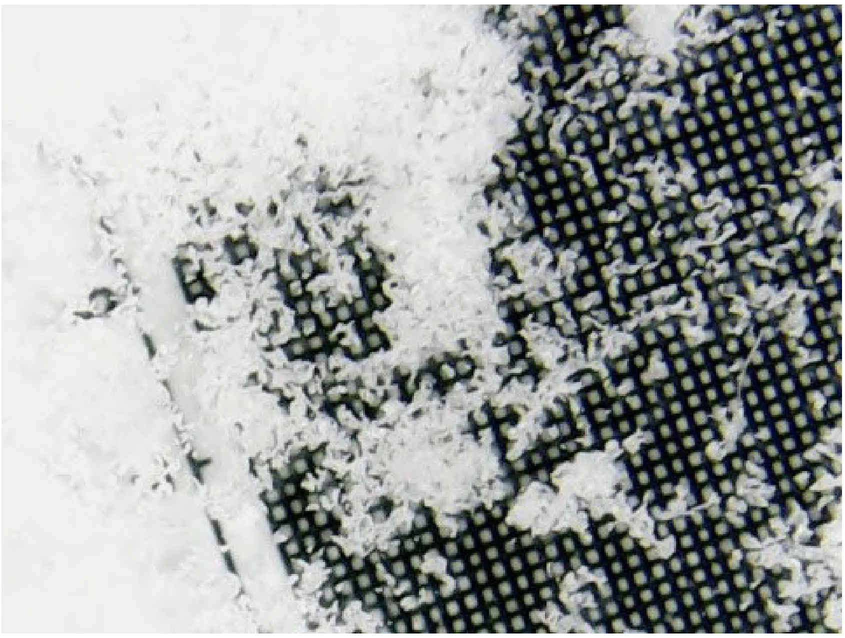

Figure 3. Guar gum.

Guar gum (TM "Zhyvy Zdorovo", Ukraine) is used as a thickening agent or stabilizer. The main advantage of natural plant polysaccharides is low cost, but their technological indicators are low, which narrows the scope of application. Therefore, chemically modified derivatives of guar, cellulose and starch are used, which have the necessary technological properties.

In the early 1970s, hydroxypropyl guar (HPG) was obtained, which became the most widely used thickener for process fluids. HPG makes it possible to obtain a polymer that is more viscous and resistant to high temperatures. Guar products typically contain 8 – 12% non-hydrated residue, HPG residue is 1 – 4%

In some experiments, a solution of sodium bicarbonate ($NaHCO_3$) with a mass concentration of 10% was used. In addition, antifreeze "DEFREEZE" (JSC "Bishofit", Ukraine) was added to the composition of the heat storage material. "DEFREEZE" is a non-toxic light yellow liquid, consisting of distilled water, natural magnesium hexahydrate, organic stabilizers and corrosion inhibitors. It does not contain synthetic and toxic substances, including ethylene, alcohols, amines, nitrites.

2.2. Test bench

The study of the thermocycling process of heat storage liquid was carried out on an experimental bench, the description of which is presented in [18]. The stand in a simplified form simulates the process that occurs in the heat storage capacity of M-TES [19]. The test bench can be represented as two containers installed one inside the other (figure 4).

A heat storage of the capacitive type has two metal containers:

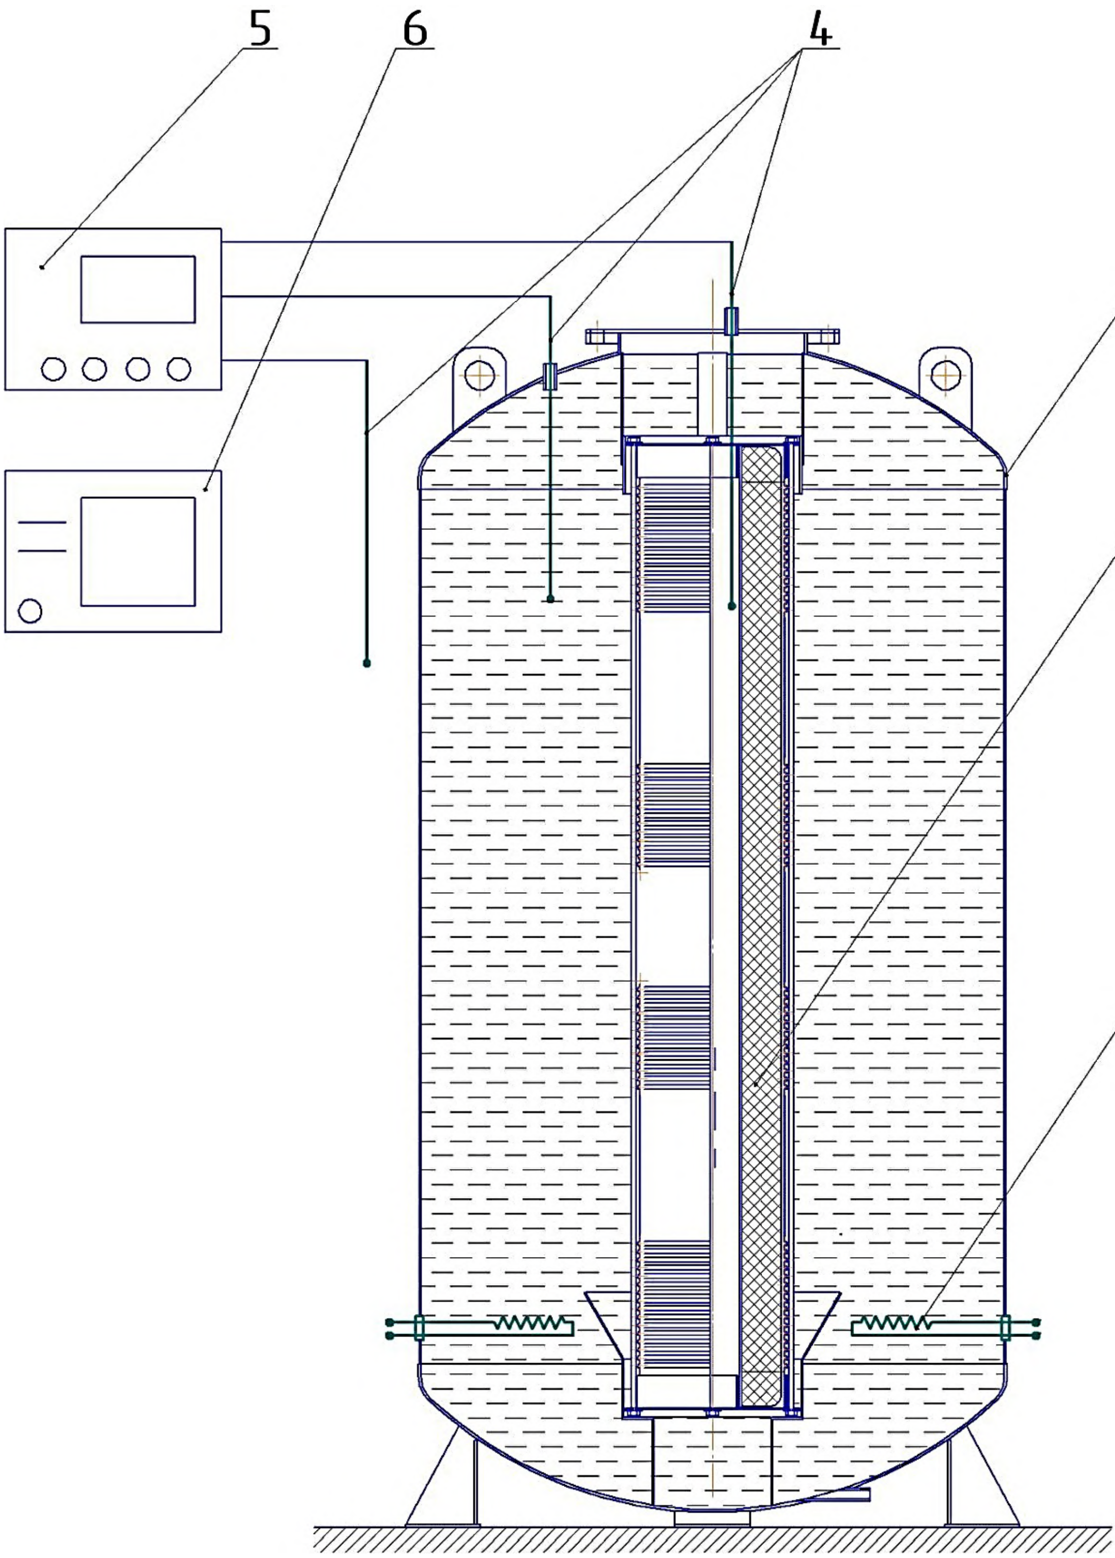

Figure 4. Test bench "Heat storage of capacitive type" (1 – tank 1, 2 – tank 2, 3 – electric heater, 4 – thermocouples, 5 – microprocessor module "TRITON 6004TS", 6 – electricity meter).

- external tank 1 filled with heat carrier (or heat storage material);
- tank 2, which is installed in the centre of tank 1, is filled with phase change material (PCM) and hermetically closed, similarly to the M-TES design. Tank 2 is called the "thermal core" and provides an increase in the heat storage capacity of the tank 1, equalizes the temperature field in the tank volume, reduces stratification by the height of the battery, shortens the "charging" time and extends the "discharging" time.

Ceresin was used to fill the "thermal core". Ceresin is PCM of natural origin, with a phase transition in the temperature range of 61 – 78°C, which coincides with the working temperatures of M-TES. Preliminary studies of specific heat capacity changes before and after thermocycling proved the feasibility of using this material [20]. Substances in tank 1 and 2 were heated by an electric heater 3 installed in the lower part of tank 1 (or an electric device in the case of an experimental stand).

The temperature was measured with thermocouples 4 using a microprocessor module "TRITON 6004TS" 5 (Scientific and Production Private Enterprise "TEREKS", Ukraine). The temperature was recorded using thermocouples and automatic cold junction temperature compensation. The main characteristics of the microprocessor module are shown in table 1.

Table 1. Technical characteristics of "TRITON 6004TS" microprocessor module.

Indicators	Value
Number of thermocouples to be connected	16 (8 diff.)
Types of used thermocouples	T, K, L, R, S and other
Input voltage range	5±19.5 mV, ±39.0 mV, ±1.17 V
Measurement cycle time	4 c
Bandwidth of input circuits	0 – 25 Hz
Cold junction compensation sensor type	PT100, PT1000
Data exchange interface	USB
Exchange speed by interface	to 115200 bit/c
The length of the communication line	to 5 m
Supply voltage	from USB, from 220 V 50 Hz
Dimensions	94 mm 160 mm 50 mm
Mass, not more than	300 g

Visualization of experimental studies was carried out using the Data Recorder software installed on a PC. Heat consumption was measured with an electric energy meter 6.

2.3. Research methodology

The studied substances in the specified combinations (table 2) are placed in tanks 1 and 2. In tank 1 samples of heat storage material with a volume of 1 liter are examined. Tank 2 contains PCM material with a volume of up to 100 ml, which was specially selected experimentally [20].

Tank 2 is the "thermal core". The volumes of the studied substances were selected in a ratio of 10:1 respectively. The containers are hermetically sealed with lids, on which are pre-installed thermocouples: t_1 is the ambient temperature; t_2 is the temperature of the water system in tank 1; t_3 is the temperature of the substance in tank 2.

Using the Data Recorder program, the visualization of the beginning of temperature measurements is observed. Meter 6 records the energy indicators. We record the indicators of the microprocessor module 5 and the heat meter 6.

Table 2. Order of heat storage materials combination when conducting experimental studies.

Number of experiment	Tank 1	Tank 2
Experiment 1	water	PCM
Experiment 2	water+antifreeze	PCM
Experiment 3	water+$NaHCO_3$	PCM
Experiment 4	water+$NaHCO_3$+antifreeze	PCM
Experiment 5	water+$NaHCO_3$+antifreeze+CMC	PCM
Experiment 6	water+guar gum (10 g)	PCM
Experiment 7	water+guar gum (1 g)	PCM
Experiment 8	water+antifreeze+guar gum (10 g)	PCM
Experiment 9	water+xanthan gum (1 g)	PCM
Experiment 10	water+antifreeze+xanthan gum (1 g)	PCM

Heating of the studied substances is carried out in the temperature range similar to the temperature load of M-TES. At the temperature of $t_2 = 85$℃, the heat supply is turned off and the temperature and power consumption continued to be measured. At the temperature $t_2 = 30$℃, the experiment is completed.

When conducting research, the following parameters are measured:

- temperature changes in the heat storage material in the tank 1, PCM in the tank 2 and the temperature of the surrounding air;
- heating and cooling time, which will allow to determine the charging and discharging time of the TES;
- energy consumption spent on heating heat storage material and material with a phase transition to the specified temperatures.

Each experiment was repeated four times. Graphical dependencies, which are based on the averaged data, are presented below.

Substances that can be added as components of the future heat-accumulating material were selected for study. The combination of substances in the tank 1 and the tank 2 are shown in table 2. The serial number of each experiment corresponds to the numbering in the figures presented in section 3 of this article.

3. Results

With the help of the "TRITON 6004TS" microprocessor module, graphical dependences of the temperature changes of the samples over time were obtained. Dependencies are built on their basis, which make it possible to evaluate the effectiveness of the components. Experiment No. 1 is chosen as a "reference" because instead of a heat storage material, water is used, the thermophysical characteristics of which are known. We will conduct a comparison relative to its results.

The energy consumption estimate for each of the experiments is shown in figure 5.

The maximum energy consumption per cycle was recorded in experiment No. 1, where water heats the PCM. The lowest energy consumption per cycle was observed in Experiment No. 10, where the heat storage material includes antifreeze and xanthan gum in the amount of 1%. The difference between these experiments is 27.3%, which is a significant difference for the average consumer and unacceptable for industry.

In experiments No. 4, No. 5 and No. 9, the energy consumption for 1 cycle is 21.5% less than in experiment No. 1 that confirms the effectiveness of using the CMC component, xanthan

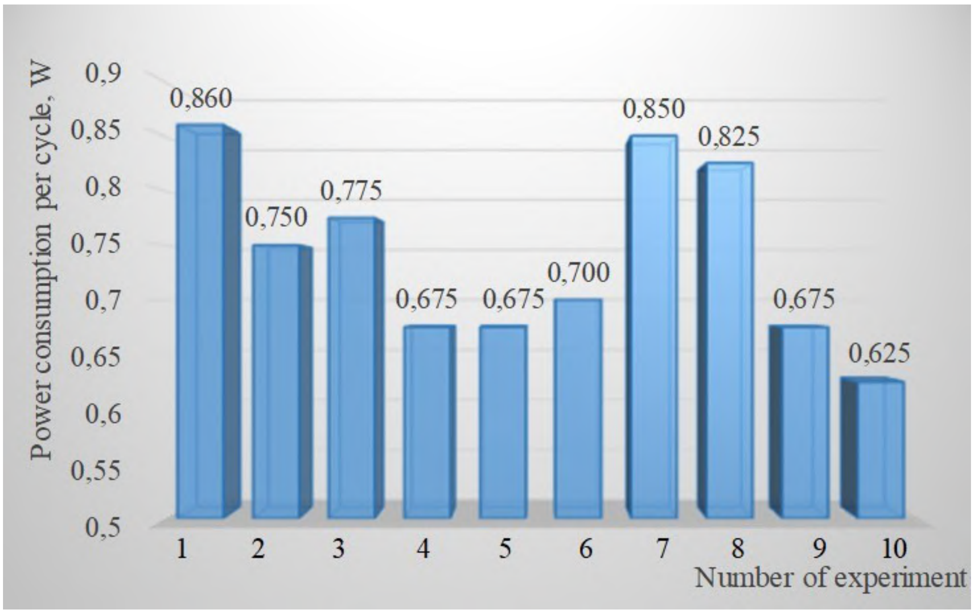

Figure 5. Average energy consumption per cycle.

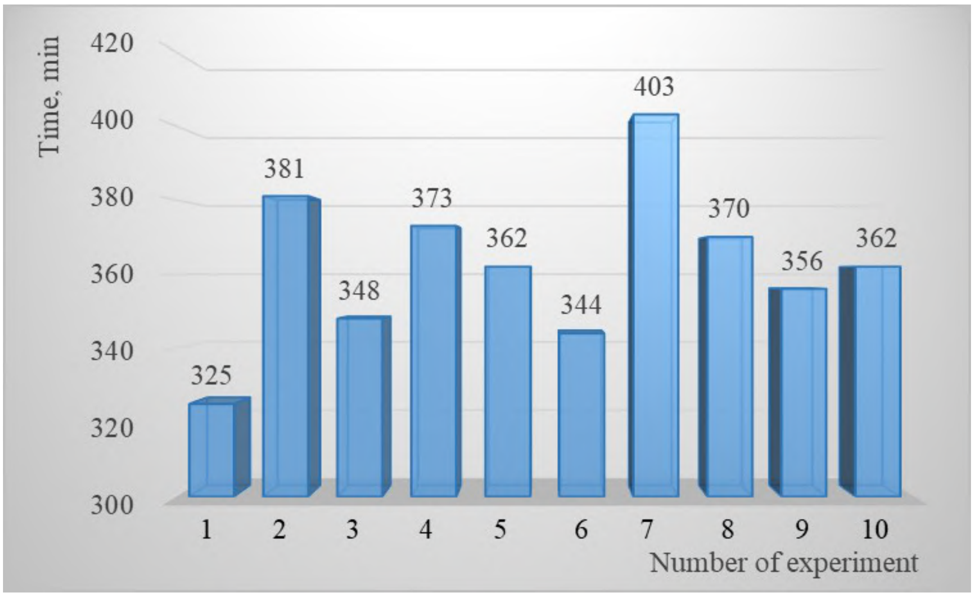

Figure 6. Average period of time per cycle.

gum, and $NaHCO_3$. In experiments No. 7 and No. 8, where guar gum is used, the results are identical to experiment No. 1.

The duration of one cycle for each experiment conducted in test bench is presented in figure 6.

The experiment time includes the heating time and the cooling time, which is equal to one cycle. It can be seen in figure 6 that the shortest cycle time was in experiment No. 1 where the water heated the PCM. This can be explained by the abnormally high specific heat capacity compared to any other liquid. In experiment No. 2, water was replaced with a heat storage material made of water and antifreeze, which extended the cycle time by 15%. But the longest cycle time is in experiment No. 7, which is 24% longer than experiment No 1, which indicates an extended period of accumulation due to the addition of 1% guar gum. Also, it is necessary to note experiments No. 4, 8, in which the cycle time is extended by 14.7% and 13.8%, respectively. But during the thermocycling process in experiment No. 4, foaming, an increase in the volume of heat storage material and a sharp smell were observed, which makes it impossible to use soda as a component. In experiments No 9 and No 10, the cycle time was increased by 9.5% and 11.4% respectively.

The ratio of the spent energy to the time of the "heating-cooling" cycle is presented in figure 7.

The ratio of the spent energy to the time of the "heating-cooling" cycle allows to assess the efficiency of the heat storage material. Therefore, experiment No. 1 is the least effective, as it

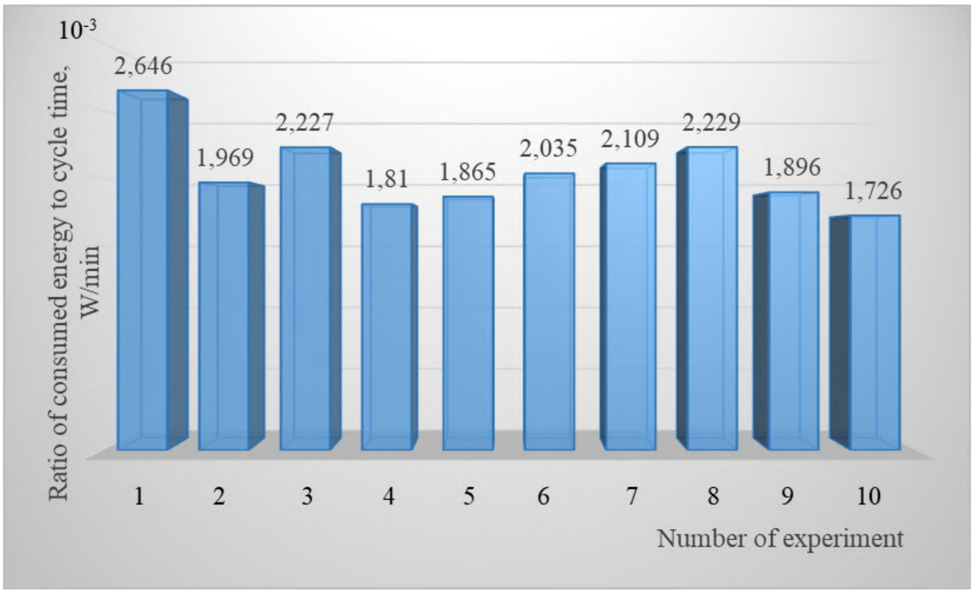

Figure 7. Ratio of energy consumption from time.

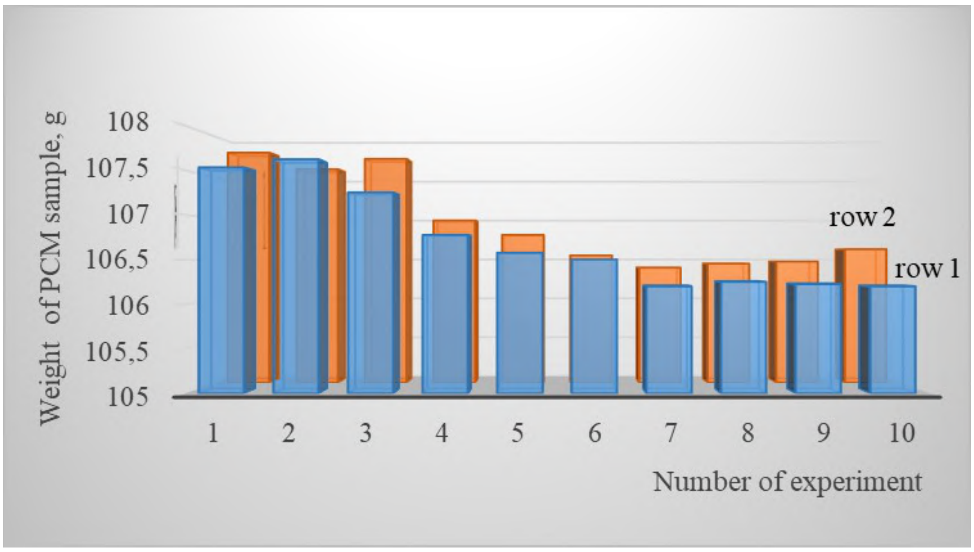

Figure 8. Dynamics of change in the weight of PCM materials (row 1 – initial mass of PCM, row 2 – final mass of PCM (after thermocycling)).

requires a significant supply of energy with a minimum accumulation time. Experiment No. 10 is the most effective, as it has the lowest value of the ratio, in general it is 34.8%. That is, when conducting further research, xanthan gum is one of the priority components.

The composition of the substance in experiment No. 2, which shows a difference from experiment No. 1 by 25.6%, is, as a rule, effective when used in heating systems of private houses. Experiments No. 4, No. 5 and No. 9 have similar results and are 31.6%, 29.5%, and 28.3%, respectively.

The dynamics of changes in the mass of PCM materials at the beginning of the research and after 40 cycles of thermocycling are shown in figure 8.

The PCM sample, in this case ceresin, was filled into container 2 and did not change throughout the entire cycle of experiments from experiment No. 1 to experiment No. 10. Weight measurements were carried out before and after thermal cycling. Samples were weighed on an Ohaus AX224 (USA) electronic balance (220g/0.1mg) with automatic calibration. The initial mass before Experiment No. 1 was 107.53 g, after the last Experiment No. 10, the mass was equal to 106.2 g. This means that in the process of 40 cycles of thermocycling (heating-cooling) the mass changed within 1 – 2% and this material can be used to fill the "thermal core" of M-TES. Such minor changes in mass, as well as the absence of volume expansion observed during the research, testify to the safety and reliability of this PCM.

4. Conclusions

The conducted experimental studies made it possible to draw the following conclusions:

- heat storage material, in addition to water and antifreeze, must contain guar gum, as they allow to create a substance that significantly extends the term of heat storage compared to water by 15 – 24%;
- the lowest energy consumption per cycle was noted with the addition of xanthan gum, this indicator decreases relative to the energy consumption of water by 27.3%. When the ratio of spent energy to the time of the thermocycling cycle is maintained, this trend is maintained and amounts to 34.8%;
- during long-term thermocycling of ceresin for up to 40 cycles, which fills the "thermal core" in the M-TES design, changes in the mass of PCM occur up to 2%, which indicates the safety and reliability of its use.

As a result of the conducted experimental studies, the expediency of using water, antifreeze, xanthan and guar gum as part of the heat storage material was established. Determining the concentrations of these substances will be the subjects of further research.

The safety of using ceresin in the "thermal core" was also confirmed by studying the change in mass before and after thermosetting.

Abstract. The intervals for determining the variables in the standard MILP-formulation of the UC-problem are analyzed. The need to take into account the state and load values in the pre-forecast and post-forecast time has been established. The suitability of the standard MILP-formulation of the UC-problem, problem with initial conditions, for solving dispatch control problems and the unsuitability of such a formulation for solving the generation capacity planning problems is shown. The standard MILP-formulation of the UC-problem on the cyclical forecasting interval is proposed. The suitability of the proposed MILP-formulation of the UC-problem for its application in the problem of planning the development of the generation capacity of power systems with a large share of RES is shown.

1. Introduction

The unit commitment (UC-) problem is probably the most important task in power system operation management [1–3]. The improvement of the quality of such management is provided by the use of mathematical models of the optimal load of units. The vast majority of mathematical formulations of the problem of effective management of power systems based on the criterion of minimum operating costs have the form of a problem of mixed integer linear programming (MILP) [1, 4]. The constant improvement of mathematical formulations of the UC-problem of the optimal load of units is due to the need to ensure acceptable adequacy of model solutions. In modern formulations of the UC-problem, operational characteristics of various technologies of electricity production and network restrictions on its transmission and distribution are taken into account in quite detail. In addition, each new mathematical formulation of the UC-problem is examined for its compliance with the conditions for the existence of a single optimal solution and the possibility of finding it using existing methods and available algorithms [3, 4].

Mathematical formulations of the UC problem are considered for a short-term forecast period lasting from one day to a week or a month, in some cases up to one year, with hourly reproduction of load modes of units, placement of power reserves on them, load of the transmission line network, etc. [1]

The different formulations of the UC-problem have one thing in common: they are all developed on the basis of linear time, where there are past, present, and future periods. UC-models establish a cause-and-effect relationship between the mode states of units in linear time and, as initial data, use available data on the state of units, the duration of their stay in such states, as well as on the volume of load of units and the amount of energy accumulated in electricity storage systems. Thus, known formulations of the UC-problem are problems with initial conditions.

Mathematical formulations of the UC-problem in the form of UC-constraints are used in the formulation of problems of planning the long-term development of power systems, especially power systems with a high level of penetration of renewable energy sources or extensive use of non-traditional energy storage technologies. Thus, operational costs for maneuvering, starting and stopping units, i.e. costs for ensuring the flexibility of power systems, are additionally taken into account in the formulation of the tasks of long-term development of power systems [5–10].

The planning of the development of power systems is carried out on the basis of optimization models of operating and capital costs for periods of time lasting several decades. In order to achieve the adequacy of the representation of the future load modes of power units in power system models, the costs of their start-up and power maneuvering are taken into account, which is extremely important in the conditions of penetration into the power system of a significant share of variable and unpredictable volumes of electricity production at the generating units of wind and solar power plants, as well as daily, weekly and seasonal irregularities in electricity consumption.

Usually, the simulation of load modes of power units is carried out in hourly, less often, half-hourly or fifteen-minute steps. Such detailing in time of load modes of power units is used for short periods of time lasting a day or a week and cannot be used for the entire multi-year planning period due to the excessive computational complexity of the mathematical problems that arise. Therefore, the model load modes of power units, determined on short-term forecast periods, are extended to monthly or seasonal periods, based on the assumption of periodicity of power unit load modes.

UC-models are used to simulate short-term load modes of power units. Such models were developed to solve the problems of dispatching control of the electric power system. UC-models are predictive models and require input data on the load of power units at the beginning of the forecast period, i.e., those that naturally characterize the current load mode of power units. The application of UC-models in the tasks of planning the development of power systems gives rise to two methodological problems: the first is the uncertainty of data regarding the load of power units at the beginning of each short-term planning period; the second is the non-periodicity of the model load modes of the power units.

These problems are solved below by formulating the power unit load model in the form of a UC-problem with boundary conditions.

2. Nomenclature

2.1. Indices and sets

$g \in \mathcal{G}$ Thermal generators.
$l \in \mathcal{L}_g$ Piecewise production cost intervals for generator g: $1,\ldots,L_g$.
$s \in \mathcal{S}_g$ Startup categories for generator g, from hottest (1) to coldest ($\mathcal{S}_g$).
$t \in \mathcal{T}$ Hourly time steps: $1,\ldots,T$.

The dimension of the set $\mathcal{G}$ is determined by the number of power units in the power system. The dimensions of the sets $\mathcal{L}_g$ and $\mathcal{S}_g$ are determined by the degree of detailing of the technical and economic characteristics of each power unit with regard to fuel consumption in different modes of its start-up and load. The dimension of the set $\mathcal{T}$ is determined by the duration of the simulation period and the time steps of its presentation. Usually choose a daily or weekly duration of such a period with hourly steps of its presentation.

2.2. Parameters

c_g^l	Cost coefficient for piecewise segment l for generator g (\$/MWh).
c_g^u	Cost of generator g running and operating at minimum production $\underline{P}_g$ (\$/h).
$D(t)$	Load (demand) at time t (MW).
$R(t)$	Spinning reserve at time t (MW).
$\overline{P}_g^l$	Maximum power for piecewise segment l for generator g (MW).
$\overline{P}_g$	Maximum power output for generator g (MW).
$\underline{P}_g$	Minimum power output for generator g (MW).
DT_g	Minimum down time for generator g (h).
UT_g	Minimum up time for generator g (h).
RD_g	Ramp-down rate for generator g (MW/h).
RU_g	Ramp-up rate for generator g (MW/h).
SD_g	Shutdown rate for generator g (MW/h).
SU_g	Startup rate for generator g (MW/h).
TC_g	Time down after which generator g goes cold, i.e., enters state S_g.
$\underline{T}_g^s$	Time offline after which the startup category s is available, ($\underline{T}_g^1 = DT_g$, $\underline{T}_g^{S_g} = TC_g$).
$W(t)$	Aggregate renewable generation available at time t (MW).

2.3. Variables

$p_g(t)$	Power above minimum for generator g at time t (MW), ≥ 0.
$p_W(t)$	Aggregate renewable generation used at time t (MW), ≥ 0.
$p_g^l(t)$	Power from piecewise interval l for generator g at time t (MW), ≥ 0.
$r_g(t)$	Spinning reserves provided by generator g at time t (MW), ≥ 0.
$u_g(t)$	Commitment status of generator g at time t, $\in \{0, 1\}$.
$v_g(t)$	Startup status of generator g at time t, $\in \{0, 1\}$.
$w_g(t)$	Shutdown status of generator g at time t, $\in \{0, 1\}$.
$c_g^{SU}(t)$	Startup cost for generator g at time t (\$), ≥ 0.

3. MILP formulation of the UC problem with initial conditions

We will use a MILP UC formulation based on [11]. We assume that the production cost is piecewise linear convex in $p_g(t)$, where L_g is the number of piecewise intervals and $\overline{P}_g^0 = \underline{P}_g$ is the start point of the first interval. Let generators have $UT_g > 1$. We then formulate the UC-problem as follows:

$$\min \sum_{g \in \mathcal{G}} \sum_{t \in \mathcal{T}} \left(\sum_{l \in \mathcal{L}_g} (c_g^l p_g^l(t)) + c_g^u u_g(t) + c_g^{SU}(t) \right) \tag{1a}$$

$$\sum_{g\in\mathcal{G}}(p_g(t)+\underline{P}_g u_g(t))+p_W(t)=D(t) \qquad \forall t\in\mathcal{T} \tag{1b}$$

$$\sum_{g\in\mathcal{G}} r_g(t)\geq R(t) \qquad \forall t\in\mathcal{T} \tag{1c}$$

$$p_g(t)+r_g(t)\leq(\overline{P}_g-\underline{P}_g)u_g(t) \\ -(\overline{P}_g-SU_g)v_g(t)-(\overline{P}_g-SD_g)w_g(t+1) \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1d}$$

$$p_g(t)+r_g(t)-p_g(t-1)\leq RU_g \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1e}$$

$$p_g(t-1)-p_g(t)\leq RD_g \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1f}$$

$$p_g(t)=\sum_{l\in\mathcal{L}_g} p_g^l(t) \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1g}$$

$$p_g^l(t)\leq(\overline{P}_g^l-\overline{P}_g^{l-1})u_g(t) \qquad \forall l\in\mathcal{L}_g,\ \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1h}$$

$$u_g(t)-u_g(t-1)=v_g(t)-w_g(t) \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1i}$$

$$\sum_{i=t-UT_g+1}^{t} v_g(i)\leq u_g(t) \qquad \forall t\in[UT_g,T],\ \forall g\in\mathcal{G} \tag{1j}$$

$$\sum_{i=t-DT_g+1}^{t} w_g(i)\leq 1-u_g(t) \qquad \forall t\in[DT_g,T],\ \forall g\in\mathcal{G} \tag{1k}$$

$$p_W(t)\leq W(t) \qquad \forall t\in\mathcal{T} \tag{1l}$$

$$c_g^{SU}(t)\geq c_g^s\left(u_g(t)-\sum_{i=1}^{T_g^s} u_g(t-i)\right) \qquad \forall s\in\mathcal{S},\ \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1m}$$

$$c_g^{SU}(t)\geq 0 \qquad \forall t\in\mathcal{T} \tag{1n}$$

$$p_g^l(t)\in\mathbb{R}_+ \qquad \forall l\in\mathcal{L}_g,\ \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1o}$$

$$p_g(t),r_g(t)\in\mathbb{R}_+ \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G} \tag{1p}$$

$$p_W(t)\in\mathbb{R}_+ \qquad \forall t\in\mathcal{T} \tag{1q}$$

$$u_g(t),v_g(t),w_g(t)\in\{0,1\} \qquad \forall t\in\mathcal{T},\ \forall g\in\mathcal{G}. \tag{1r}$$

Constraints (1b – 1r) are standard in UC problem formulations with time-varying startup costs [1, 11]. We use typical one binary formulation for startup costs using only the status variable u.

4. MILP UC formulation with initial conditions

Let's analyze the areas of definition of those restrictions, the effect of which does not coincide with the areas of definition of the unknown variables used in them.

In the functional constraints (1d), unknown values $w_g(T+1)$ of the functions $w_g(t)$ are used, which on the right go beyond the time domain of the definition of these functions. Therefore, the values of $w_g(T+1)$ should be considered as parameters, and the indicated constraints should be represented as follows

$$p_g(t)+r_g(t)\leq(\overline{P}_g-\underline{P}_g)u_g(t)- \\ (\overline{P}_g-SU_g)v_g(t)-(\overline{P}_g-SD_g)w_g(t+1) \qquad \forall t\in[1,T-1],\ \forall g\in\mathcal{G} \tag{2a}$$

$$p_g(t)+r_g(t)\leq(\overline{P}_g-\underline{P}_g)u_g(t)- \\ (\overline{P}_g-SU_g)v_g(t)-(\overline{P}_g-SD_g)w_g(T+1) \qquad t=T,\ \forall g\in\mathcal{G} \tag{2b}$$

In the next constraints (1e-1f), unknown values $p_g(0)$ of the functions $p_g(t)$ are used, which on the left go beyond the time domain of the definition of these functions. Therefore, the values of $p_g(0)$ should be considered as parameters, and the indicated constraints should be represented in the following forms

$$p_g(t) + r_g(t) - p_g(t-1) \le RU_g \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \tag{3a}$$
$$p_g(t) + r_g(t) - p_g(0) \le RU_g \qquad t = 1,\ \forall g \in \mathcal{G}. \tag{3b}$$

and

$$p_g(t-1) - p_g(t) \le RD_g \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \tag{4a}$$
$$p_g(0) - p_g(t) \le RD_g \qquad t = 1,\ \forall g \in \mathcal{G}. \tag{4b}$$

In constraints (1i), unknown values $u_g(0)$ of the functions $u_g(t)$ are used, which on the left go beyond the time domain of the definition of these functions. Considering the values of $u_g(0)$ as parameters, we will present the indicated constraints in the form

$$u_g(t) - u_g(t-1) = v_g(t) - w_g(t) \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \tag{5a}$$
$$u_g(t) - u_g(0) = v_g(t) - w_g(t) \qquad t = 1,\ \forall g \in \mathcal{G}. \tag{5b}$$

The area of definition of the $u_g(t)$ functions included in the constraints (1j) is shortened from the left by the value UT_g. To extend the effect of the constraints (1j) to the entire area of definition of the $u_g(t)$ functions, the unknown values $v_g(0),\ v_g(-1), \ldots, v_g(2 - UT_g)$ of the $v_g(t)$ functions should be considered as parameters, and the indicated constraints should be represented as follows

$$\sum_{i=t-UT_g+1}^{t} v_g(i) \le u_g(t) \qquad \forall t \in \mathcal{T},\ \forall g \in \mathcal{G} \tag{6}$$

Also, the area of definition of the $u_g(t)$ functions included in the constraints (1k) is shortened from the left by the value DT_g. To extend the effect of the constraints (1k) to the entire area of definition of the $u_g(t)$ functions, the unknown values $w_g(0),\ w_g(-1), \ldots, w_g(2 - DT_g)$ of the $w_g(t)$ functions should be considered as parameters, and the indicated constraints should be represented as follows

$$\sum_{i=t-DT_g+1}^{t} w_g(i) \le 1 - u_g(t) \qquad \forall t \in \mathcal{T},\ \forall g \in \mathcal{G} \tag{7}$$

Functional constraints (1m) contain values $u_g(0),\ u_g(-1), \ldots, u_g(1-TC_g)$, which should also be considered parameters.

Thus, in the presence of values of

$$w_g(T+1), \tag{8a}$$
$$p_g(0), \tag{8b}$$
$$v_g(0),\ v_g(-1), \ldots, v_g(2 - UT_g), \tag{8c}$$
$$w_g(0),\ w_g(-1), \ldots, w_g(2 - DT_g), \tag{8d}$$
$$u_g(0),\ u_g(-1), \ldots, u_g(1 - TC_g), \tag{8e}$$
$$\forall g \in \mathcal{G}$$

MILP UC formulation (1) with changes (1d) to (2), (1e-1f) to (3-4), (1i) to (5), (1j) to (6) and (1k) to (7) can be considered as a problem with initial conditions. In tasks of dispatch management, namely in tasks of short-term forecasting (a day, a week or a month ahead), the initial conditions of loading units of power system are naturally known. At the same time, the values of the $w_g(T+1)$ parameters are assumed to be zero [1].

Solving problems with initial conditions provides short-term forecasting of dynamic load modes of power system units. In general, the load regimes of the units at the beginning and at the end of the forecast period do not coincide. This means that the received forecast solutions cannot be propagated beyond the forecast interval by their periodic reproduction. Therefore, such prediction intervals are non-autonomous (figure 1).

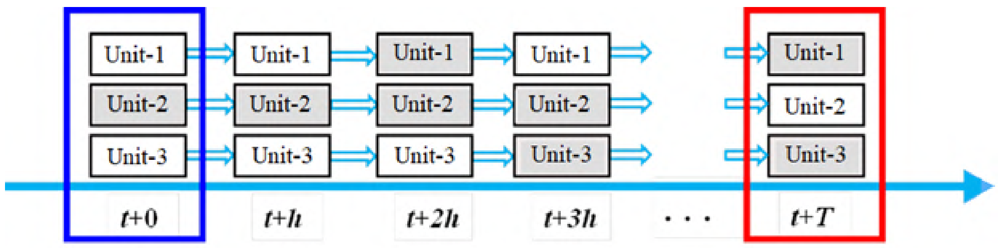

Figure 1. Non-autonomous period T of power units load in the UC-model. Loads of power units in $t{+}0$ and $t+T$ do not match.

5. MILP formulation of the UC problem with boundary conditions

Planning of long-term development of generating capacities of electric power systems is carried out on the forecasting time horizon, which is usually replaced by a representative set of short intervals of daily or weekly duration. Each short interval corresponds to a separate month or season of the selected forecast years. At such short intervals with hourly detail, the UC constraints of the optimization tasks of minimizing investment and operating costs for the entire planning horizon are formed. The UC constraints ensure the adequacy of optimization solutions in modern conditions of significant penetration of electricity production technologies from renewable energy sources and increased requirements for maneuverability and flexibility of electric power systems [2, 6–8, 10, 12].

A common drawback of the known MILP formulations of the UC problem defined on short autonomous intervals is the impossibility of providing their initial conditions. Therefore such conditions are either set arbitrarily, without justification, or are not set [2, 7, 8, 10, 12]. To avoid the need for initial conditions, the domains of the UC constraints that require such conditions are reduced. In both approaches, we have a methodological problem and its negative impact on the adequacy of solutions to the problems of planning the long-term development of electric power systems.

We propose a solution to this problem by an MILP formulation of the UC problem as an MILP formulation with boundary conditions. For this purpose let us assume that the load schedules of the power system units are periodic, that is, they repeat with a time period T (figure 2).

Taking into account the constraints (2) and equations of the type $w_g(T+1) = w_g(1)$ we

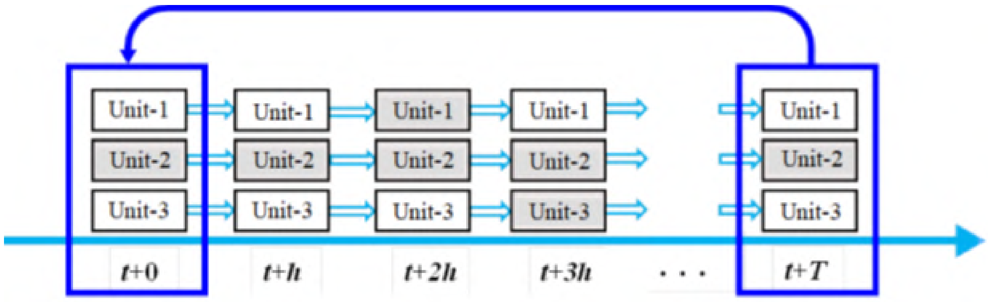

Figure 2. Autonomous period T of power units load in the UC-model. Loads of power units in t+0 and $t + T$ coincide.

obtain, respectively

$$\begin{aligned} p_g(t) + r_g(t) \le (\overline{P}_g - \underline{P}_g)u_g(t) - \\ (\overline{P}_g - SU_g)v_g(t) - (\overline{P}_g - SD_g)w_g(t+1) \qquad \forall t \in [1, T-1],\ \forall g \in \mathcal{G} \qquad (9a) \\ p_g(t) + r_g(t) \le (\overline{P}_g - \underline{P}_g)u_g(t) - \\ (\overline{P}_g - SU_g)v_g(t) - (\overline{P}_g - SD_g)w_g(1) \qquad t = T,\ \forall g \in \mathcal{G} \qquad (9b) \end{aligned}$$

Instead of constraints (3-4) with equations of the type $p_g(0) = p_g(T)$ we obtain respectively

$$p_g(t) + r_g(t) - p_g(t-1) \le RU_g \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \qquad (10a)$$
$$p_g(t) + r_g(t) - p_g(T) \le RU_g \qquad t = 1,\ \forall g \in \mathcal{G}. \qquad (10b)$$

and

$$p_g(t-1) - p_g(t) \le RD_g \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \qquad (11a)$$
$$p_g(T) - p_g(t) \le RD_g \qquad t = 1,\ \forall g \in \mathcal{G}. \qquad (11b)$$

Instead of constraints (5) with equations of the type $u_g(0) = u_g(T)$ we obtain

$$u_g(t) - u_g(t-1) = v_g(t) - w_g(t) \qquad \forall t \in [2, T],\ \forall g \in \mathcal{G}; \qquad (12a)$$
$$u_g(t) - u_g(T) = v_g(t) - w_g(t) \qquad t = 1,\ \forall g \in \mathcal{G}. \qquad (12b)$$

Instead of constraints (6) with parameters (8c) we obtain

$$\sum_{i=1}^{t} v_g(i) + \sum_{i=T-UT_g+t+1}^{T} v_g(i) \le u_g(t) \qquad \forall t \in [1, UT_g - 1],\ \forall g \in \mathcal{G}; \qquad (13a)$$
$$\sum_{i=t-UT_g+1}^{t} v_g(i) \le u_g(t) \qquad \forall t \in [UT_g, T],\ \forall g \in \mathcal{G}. \qquad (13b)$$

Similarly, instead of constraints (7) with parameters (8d) we obtain

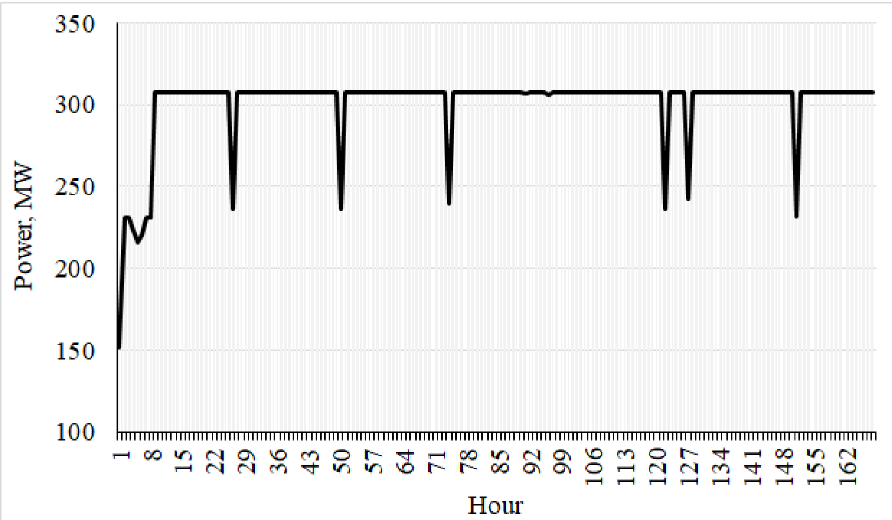
$$\sum_{i=1}^{t} w_g(i) + \sum_{i=T-DT_g+t+1}^{T} w_g(i) \le 1 - u_g(t) \qquad \forall t \in [1, DT_g - 1],\ \forall g \in \mathcal{G}; \qquad (14a)$$
$$\sum_{i=t-DT_g+1}^{t} w_g(i) \le 1 - u_g(t) \qquad \forall t \in [DT_g, T],\ \forall g \in \mathcal{G}. \qquad (14b)$$

Finally, instead of constraints (1m) with parameters (8e), we obtain

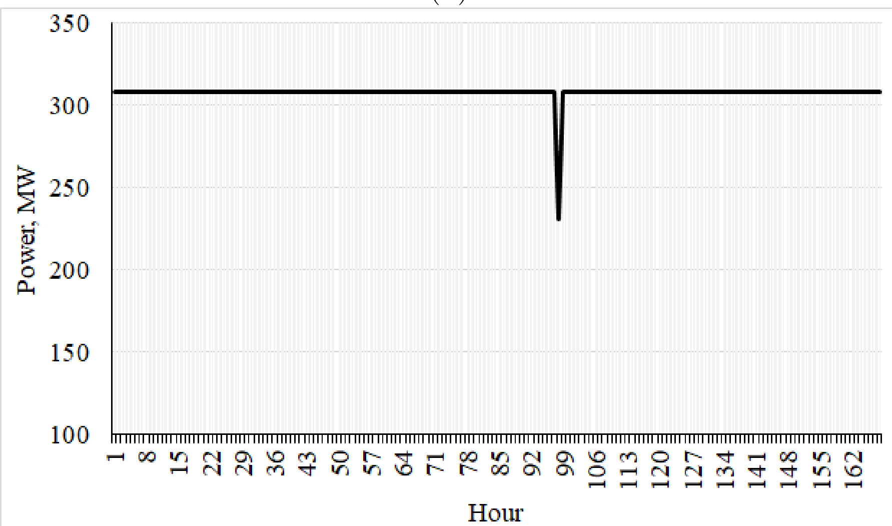
$$c_g^{SU}(t) \geq c_g^s \left(u_g(t) - \sum_{i=1}^{\underline{T}_g^s} u_g(t-i) \right) \qquad \forall s \in \mathcal{S},\ \forall t \in [\underline{T}_g^s + 1, T]\ \forall g \in \mathcal{G}; \quad (15a)$$

$$c_g^{SU}(t) \geq c_g^s \left(u_g(t) - \sum_{i=1}^{t-1} u_g(t-i) - \sum_{i=t}^{\underline{T}_g^s} u_g(T - \underline{T}_g^s + i) \right) \quad \forall s \in \mathcal{S},\ \forall t \in [1, \underline{T}_g^s],\ \forall g \in \mathcal{G}. \quad (15b)$$

MILP UC formulation (1) with changes (1d) to (9), (1e-1f) to (10-11), (1i) to (12), (1j) to (13), (1k) to (14) and (1m) to (15) can be considered as a problem with boundary conditions.



(a)



(b)

Figure 3. Weekly load schedules of NuScale power units obtained using models with (a) initial conditions and (b) boundary conditions.

The obtained MILP UC formulation is correct under the conditions

$$\underline{T}_g^s \leq T, \tag{16a}$$
$$UT_g \leq T, \tag{16b}$$
$$DT_g \leq T, \tag{16c}$$
$$\forall s \in \mathcal{S}, \forall g \in \mathcal{G}$$

Taking into account the values of the parameters $\underline{T}_g^s$, UT_g and DT_g of generating units of thermal and nuclear power plants, it is advisable to choose weekly forecasting intervals to fulfill condition (16).

6. Computational experiments with MILP formulation of the UC-problem with boundary conditions

To perform computational experiments, the MILP formulations of the UC problem with initial and boundary conditions were implemented in IBM ILOG CPLEX Optimization Studio.

The weekly graphs of the load of the generating units, obtained using the MILP formulations of the UC problem with initial and boundary conditions, are presented in figure 3. A comparison of these graphs indicates a fundamental difference between them. In the case of the MILP UC formulation with initial conditions, the graph is not autonomous and sensitive to these arbitrarily given conditions. In the case of the MILP UC formulation with boundary conditions, the graph is autonomous and can be reproduced periodically outside the weekly forecasting interval.

7. Conclusion

We proposed a new MILP formulation of the UC-problem with boundary conditions, which is intended for application on autonomous weekly time periods in the problems of planning the development of electric power systems.

The proposed UC problem with boundary conditions solves the problem of data uncertainty regarding the load of power units at the beginning of each short-term forecast period, as well as the problem of non-periodicity of power unit load modes in these periods and the impossibility of periodic distribution of such modes over much longer seasonal periods.

The proposed MILP formulation of the UC problem ensures the adequacy of planning solutions for the development of electric power systems in modern conditions of significant penetration of electricity generation technologies from renewable energy sources and increased requirements for maneuverability and flexibility of power units.

Abstract. On the basis of the Law on the Electricity Market adopted in 2017, the retail electricity market in Ukraine opened on January 1, 2019, and later, on July 1, 2019, the wholesale electricity market was launched. The day-ahead market (DAM) is one of the key segments of the Ukrainian electricity market. In order to implement trading strategy and successfully conduct business, to maximize the economic results in the specified market segment, it is important to understand the market situation and the structure of demand and supply. One of the indicators that must be taken into account when planning sales in the course of one's activity is the demand for electrical energy. Currently, there are no universal algorithms in Ukraine suitable for short-term (per day) forecasting of the amount of electrical energy that will be traded on DAM. Therefore, to solve such a problem, a specialized forecasting algorithm is proposed. The basis of the developed algorithm is the possibility of considering the formulated problem in a parametric form, where, as indicators, the forecast and real data of the hourly demand on the DAM are used. At the same time, in order to find the forecast hourly demand on the market "a day ahead" – the values of the unknown indicators of the problem – an iterative method of their search is used based on statistical data of the amount of electricity purchases on the DAM, using the principle of multi-iteration analysis of changes in demand for previous similar days. The proposed algorithm is implemented in the MS Excel package, which indicates its versatility and ease of use. The high speed of obtaining a solution to the formulated problem is shown.

1. Introduction

The single-buyer model of the wholesale electricity market was also replaced by a market model based on bilateral markets, day-ahead and intraday markets, as well as balancing and ancillary services markets, where participants can freely trade electricity and power companies can provide services that ensure the stability of the power system and supply electricity to the final consumer.

One of the main segments for electricity market subjects for its purchase and sale is the DAM. Trading on DAM takes place according to the principle of margin pricing – sellers submit orders at the minimum price at which they are ready to sell, buyers – at the maximum price at which they are ready to buy. According to the results of auctions on the DAM, sellers sell at a price no cheaper than their bid, and buyers sell at a price no higher than their bid.

Hourly demand for DAM is the hourly amount of electric energy that customers declare and want to buy on DAM at the respective hourly prices. This amount directly affects both the marginal price that will be created and the amount of electricity that will be bought and sold.

According to the law of supply and demand, the lower the demand for a product, the lower the price will be; the higher the demand, the higher the price will be.

This directly affects the volumes that will be accepted for sale for sellers on the DAM. If sellers incorrectly determine the declared demand volumes and set inappropriate prices in their sales bids – either their volumes will be accepted incompletely (in case of low demand) or accepted at a low price (in case of high demand value). At the same time, in Ukraine on the DAM, volumes for purchase are usually declared at the maximum possible price, so the value of the price is actually affected by the prices in the sellers' bids, and the incorrect determination of such a price affects the economy of the seller's enterprises.

Thus, there is a need to forecast the demand for DAM. But now in Ukraine there are no mechanisms, algorithms or mathematical models that would allow forecasting with a low forecasting error.

2. Aim and tasks

The purpose of the research is to determine an algorithm that will make it possible to forecast the hourly volumes of demand for DAM for the next day, and which will have a slight deviation of the forecast indicators from the real data (that is, it will be reliable and have a forecasting error within 10%).

The tasks of the research are:

1. Determination of various algorithms for calculating forecasted hourly volumes of demand for DAM;
2. Calculation of the prediction error of each of the identified algorithms;
3. Determination of the most accurate calculation algorithm;
4. Formulaic description of the calculation algorithm.

3. Approaches to forecasting hourly demand on DAM

Trading on DAM takes place at 12:00 for the following day (we will take studying day as D). Thus, on the D-2 day, it is possible to make a forecast for D. It is clear that such forecasting is short-term, so it is fully justified to use the most current and latest data available. The scope of the current research is 4 weeks.

It is necessary to understand that the demand on DAM depends on a large number of factors [1–3]:

1. Volumes of contracted bilateral agreements;
2. Seasonality;
3. Power outage due to the destruction of critical energy infrastructure facilities;
4. Day of the week;
5. Other factors.

To obtain forecast results that are closest to the real data, it is suggested to:

1. Use the trading results for the last available day;
2. Use the change in demand between the day for which the actual results are available and the day for which the forecast is made;
3. Take into account the change in demand, for example, over the previous 4 weeks between similar days of the week.

Given the possible volatility of the DAM, as well as the fact that from day to day the conditions of the DAM vary depending on both buy and sell bids, using as a basis for calculation the data of the most recent actual trading results is reasonable and appropriate. And taking into account that depending on the day, the consumption of electrical energy by consumers changes, there is a corresponding change in the demand for DAM. At the same time, usually, such a change in demand has a predictable nature – for example, on Saturday, under normal conditions, demand decreases compared to Friday. And on Monday, on the contrary, the demand increases significantly compared to Sunday.

Thus, to calculate the forecast hourly demand for DAM on D, it is necessary to calculate a certain value of the change in this demand between the corresponding days for previous periods, then add it to the actual value of the hourly demand for DAM in D-1. But the question arises – which algorithm to use to calculate this value of the change in demand. To answer this question, it is necessary to understand, firstly, the nature of the change occurrence, and secondly, how to take into account or balance these values for previous periods.

As already mentioned, the change in demand between days of the week can occur due to the natural change in consumption for the corresponding day of the week. But this is not the only factor. We can add the following indicators:

1. Contracting on the market of bilateral contracts;
2. Change in weather conditions;
3. Change in consumption of the final consumer due to independent conditions;
4. Manipulative behavior of buyers on the DAM;
5. Other factors (for example, an error when entering data on the trading platform).

It is clear that some of these indicators cannot be predicted and they can distort the final result of the calculation, worsening the accuracy of forecasting. But a certain mechanism or algorithm should be provided, which would allow either to reduce the influence of these indicators, or to reject these values.

Another aspect is the question of taking into account the value of the change in hourly demand for the calculation of the forecasting value. Actually, the answer to this question will give an understanding of how the calculation will be carried out. For comparison, 4 calculation options are considered:

1. As the arithmetic mean value of the change in demand;
2. As a weighted average value of the sum of positive and negative changes in demand, weighted by the number of days with a positive change in demand and a negative change in demand, giving preference to those days that are more in number (by increasing their weight) and that are closer to today's day. The essence of the algorithm is as following:
   (a) the number of days with positive and negative changes in demand is determined;
   (b) if all days have either a positive change or a negative one, then the arithmetic mean is calculated – there is no need for weighting;
   (c) if there are more days of a certain type, the weight of that type increases (one plus the ratio of the number of such days to the total number of days), and the weight of another type decreases (one minus the ratio of the number of such days to the total number of days);
   (d) if the number of days of both types is equal, then the arithmetic mean of the former two days, multiplied by 0.5, plus the arithmetic mean of the latter two days, multiplied by 1.5, is calculated).
3. As a weighted average value of the sum of positive and negative changes in demand, weighted by the number of days with a positive change in demand and a negative change in demand,

giving preference to those type of days that are more in number (by increasing their weight). The essence of the algorithm is as following:

(a) the number of days with positive and negative changes in demand is determined;
(b) if all days have either a positive change or a negative one, then the arithmetic mean is calculated – there is no need for weighting;
(c) if there are more days of a certain type, the weight of that type increases (one plus the ratio of the number of such days to the total number of days), and the weight of another type decreases (one minus the ratio of the number of such days to the total number of days).

4. As a weighted average value for positive and negative changes in demand, taking into account the deviation from the arithmetic mean of the absolute values of changes in demand to determine atypical days (determined by the author by experimental method to remove such atypical days). The calculation algorithm is as following:
   (a) the sum and number of positive and negative days are calculated, the arithmetic mean of absolute values among changes in demand is determined;
   (b) an iterative process of discarding non-typical days to reduce the influence of non-representative values on the final value of the forecast. For this, the so-called "deviation weight" is calculated by calculating the inverse of the relative deviation for each value of the change in demand from the calculated arithmetic mean. If the calculated value is less than 0, such an indicator of the change in demand is rejected and a recalculation is made, starting from the first stage, but already without this indicator. After the iterative process, the average value of the "deviation weight" is calculated separately for positive changes in demand, separately for negative changes in demand;
   (c) adjustment of the weight of positive values of changes in demand (or negative values – the value of the adjustment will be reversed for positive values – there is no significant difference). Weight values for positive changes in demand are adjusted by this factor. After that, the weighted average forecast value of the change in demand for the day under study is calculated, where the weight is the adjusted values of the "deviation weights".

It is worth to mention that in practice the most accurate forecasting results come from similar hours from previous day. Such principle is behind reasoning of using previous day (D-1) as a basis for adding certain value of change in demand between the corresponding days for previous periods.

For calculations in the algorithms and comparison of forecast calculated values with real data, real data of hourly demand based on the results of auctions on DAM in the period from July 30, 2022 to August 31, 2022 are used. In order to simplify the calculations, verify the reliability of the proposed algorithms and achieve the set goals, the depth of the analysis of the change in demand is 4 previous weeks, therefore, the actual hourly demand data based on the results of the DAM trades from July 1, 2022 were used for the analysis in the calculations.

4. Algorithms calculation results

Calculations for the proposed algorithms were performed in the MS Excel software package. This ensures the universality and ease of use of the specified calculations, is clear and shows a high speed of solving the tasks and low or even zero costs for the implementation of the algorithm.

The results of the calculations are presented in the form of a comparative table. Figure 1 shows an example of the results of the forecast calculation and real data based on the results of the DAM auctions.

Figure 2 shows an example of the absolute deviations of each of the algorithms from the real data based on the results of the DAM auctions: real data minus forecast data. At the same

Day	Hour	Forecast 1	Forecast 2	Forecast 3	Forecast 4	Real data
30.07.2022	1	1 496,300	1 626,500	1 626,500	1 501,200	1 243,000

30.07.2022	19	1 044,000	1 044,000	1 044,000	1 015,800	1 316,400

Figure 1. Calculation results of every algorithm and real data.

time, the most accurate algorithm is highlighted in green, and the least accurate in red.

It should be noted that this calculation will be used both to determine the relative error of forecasting (figure 3), and further to determine which of the algorithms turned out to be the most accurate both in terms of the smallest deviation for the entire period and in terms of the number of hours, in which it was more accurate.

Table 1 presents a comparison of the calculation results of all four algorithms. Presented data on the sum of absolute values of absolute deviation and the number of times such algorithms were more accurate than others. There should be noted two things:

1. If more than one type of algorithm was the most accurate in one hour (the same result of the forecast calculation) – all such algorithms are considered as more accurate for the corresponding hour. The larger the value, the greater the number of times the algorithm was more accurate;
2. Regarding the sum of absolute values of absolute deviations – this value is exclusively informative for comparing all algorithms and determining the one that was closer to the real data based on the results of the auctions on the DAM. The smaller the value, the more accurate the algorithm.

As can be seen from the table 1, Algorithm 4 shows both the smallest deviation from the real data and the largest number of times when it was more accurate. At the same time, the application of algorithm 4 allows both the rejection of atypical days (which is impossible when applying algorithm 1) and the monitoring of atypical behavior of market participants when submitting bids on the DAM.

Table 2 illustrates the calculation results and accuracy of algorithm 4 for a typical day.

Day	Hour	Absolute deviation 1	Absolute deviation 2	Absolute deviation 3	Absolute deviation 4
30.07.2022	1	-253,300	-383,500	-383,500	-258,200

Figure 2. Calculation results of every algorithm and real data.

Table 1. Algorithms calculation results comparison of aggregated deviation data and number of more accurate calculations.

Parameter	Algorithm			
	1	2	3	4
Sum of modules of absolute deviations	224 284.7	249 400.7	249 763.7	219 057.9
Times of being more accurate	322	201	196	360

5. Description of the most accurate algorithm

Calculations can be made in D-2 after receiving the actual results of the auctions on the DAM in D-1. It should be noted that all calculations are performed separately for each hour h.

1. Calculating demand change on the DAM for the previous 4 weeks w for the following days d: D-6 and D-7, D-13 and D-14, D-20 and D-21, D-27 and D-28:

$$\triangle A_w^h = A_{d+1}^h - A_d^h \tag{1}$$

2. Calculating sum of positive and negative A_w^h separately:

$$A_{w,pos}^h = \sum \triangle A_w^h \texttt{ for } \triangle A_w^h > 0 \tag{2}$$

$$A_{w,neg}^h = \sum \triangle A_w^h \texttt{ for } \triangle A_w^h < 0 \tag{3}$$

3. Calculating separate number of positive N_{pos}^h for $\triangle A_w^h > 0$ and negative N_{neg}^h for $\triangle A_w^h < 0$.

Day	Hour	Relative deviation 1	Relative deviation 2	Relative deviation 3	Relative deviation 4
30.07.2022	1	-20%	-31%	-31%	-21%
30.07.2022	2	-4%	-4%	-4%	-4%
30.07.2022	3	-10%	-10%	-10%	-8%
30.07.2022	4	-11%	-19%	-19%	-4%
30.07.2022	5	-10%	-10%	-10%	-12%
30.07.2022	6	-15%	-21%	-21%	-17%
30.07.2022	7	8%	8%	8%	8%
30.07.2022	8	32%	39%	39%	43%
30.07.2022	9	42%	50%	50%	47%
30.07.2022	10	51%	65%	65%	57%
30.07.2022	11	63%	79%	79%	71%
30.07.2022	12	65%	82%	82%	69%
30.07.2022	13	57%	56%	57%	55%
30.07.2022	14	54%	53%	54%	54%
30.07.2022	15	66%	82%	82%	73%
30.07.2022	16	68%	84%	84%	74%
30.07.2022	17	63%	76%	76%	69%
30.07.2022	18	49%	57%	57%	56%
30.07.2022	19	21%	21%	21%	23%

Figure 3. Calculation results of every algorithm and real data.

4. Calculating arithmetic mean of absolute values $\triangle A_w^h$:

$$A_{aver,abs}^h = \frac{\sum |\triangle A_w^h|}{N_{pos}^h + N_{neg}^h} \tag{4}$$

5. Calculating first iteration of absolute value of inverse relative deviation $|\triangle A_w^h|$ from $A_{aver,abs}^h$ for all $\triangle A_w^h$ (so-called "weight of deviation"):

$$D_{w,weight,I}^h = 1 - \left| \frac{|\triangle A_w^h| - A_{aver,abs}^h}{(A_{aver,abs}^h} \right| \tag{5}$$

If value $D_{w,weight,I}^h < 0$ then $\triangle A_w^h$ significantly deviates compared to other indicators, so it must be discarded, zeroed and recalculation should be done (II iteration) and calculate $N_{pos,iter-last}^h$, $N_{neg,iter-last}^h$ and $D_{w,weight,iter-last}^h$. Such recalculations (iterations) are performed until there are no significant deviation. Maximum number of iterations in this example will be four (equalizes to the number of analyzed $\triangle A_w^h$).

6. After the final iteration average value of the sum $D_{w,weight,iter-last}^h$ is calculated separately for positive and negative A_w^h, if the number of such values is not 0:

$$D_{w,weight,iter-last,pos}^h = \frac{\sum D_{w,weight,iter-last}^h}{N_{pos,iter-last}^h} \text{ for } \triangle A_w^h > 0, N_{pos,iter-last}^h <> 0 \tag{6}$$

$$D_{w,weight,iter-last,neg}^h = \frac{\sum D_{w,weight,iter-last}^h}{N_{neg,iter-last}^h} \text{ for } \triangle A_w^h < 0, N_{neg,iter-last}^h <> 0 \tag{7}$$

Table 2. Accuracy of algorithm 4 on the example of one day (04.08.2022).

Hour	Demand forecast	Real data demand	Absolute deviation	Relative deviation
1	1 328.6	1 305.1	-23.5	-2%
2	1 039.4	1 090.7	51.3	5%
3	956.1	992.8	36.7	4%
4	920.4	907.1	-13.3	-1%
5	890.6	933.9	43.3	5%
6	1 031.4	1 058.0	26.6	3%
7	1 277.8	1 245.4	-32.4	-3%
8	1 454.2	1 452.9	-1.3	0%
9	1 810.3	1 719.0	-91.3	-5%
10	1 840.6	1 835.4	-5.2	0%
11	1 961.5	1 926.2	-35.3	-2%
12	1 939.0	1 887.2	-51.8	-3%
13	1 860.3	1 864.7	4.4	0%
14	1 735.1	1 755.5	20.4	1%
15	2 037.0	1 954.4	-82.6	-4%
16	2 082.8	1 923.4	-159.4	-8%
17	1 867.0	1 855.4	-11.6	-1%
18	1 685.6	1 649.8	-35.8	-2%
19	1 669.9	1 625.0	-44.9	-3%
20	1 723.2	1 807.2	84.0	5%
21	1 697.2	1 856.9	159.7	9%
22	1 721.9	1 930.2	208.3	11%
23	1 505.5	1 575.0	69.5	4%
24	1 592.3	1 542.2	-50.1	-3%
Total	37 627.7	37 693.4	65.7	0%

7. Calculating the value of corrected weight for positive $\triangle A_w^h$:
   (a) if $N_{pos,iter-last}^h = 0$ or $N_{neg,iter-last}^h = 0$ or $N_{pos,iter-last}^h = N_{neg,iter-last}^h$ then
$$W_{corrected}^h = 1 \tag{8}$$
   (b) otherwise
$$W_{corrected}^h = \frac{N_{pos,iter-last}^h}{N_{neg,iter-last}^h} \cdot \frac{D_{w,weight,iter-last,neg}^h}{D_{w,weight,iter-last,pos}^h} \tag{9}$$
8. Calculating corrected value of $D_{w,weight,corrected}^h$ for positive $\triangle A_w^h$:
$$D_{w,weight,corrected}^h = D_{w,weight,iter-last}^h * W_{corrected}^h \text{ for } \triangle A_w^h > 0 \tag{10}$$
$$D_{w,weight,corrected}^h = D_{w,weight,iter-last}^h \text{ for } \triangle A_w^h < 0 \tag{11}$$
9. Calculating average weighted value of demand change $\triangle A_{weighted}^h$ on the DAM:
$$\triangle A_{weighted}^h = \frac{\sum \left(\triangle A_w^h * D_{w,weight,corrected}^h \right)}{\sum D_{w,weight,corrected}^h} \tag{12}$$

10. Calculating forecasted value of the demand on the DAM:

$$A_D^h = A_{D-1}^h + \triangle A_{weighted}^h \tag{13}$$

This concludes formulaic expression of researched algorithm. Provided that there is one of the main goals of EU as being climate neutral by 2050, companies need to achieve such goal and remain economically profitable at the same time. Therefore it is necessary to conduct business with the aim of maximizing its finances at the every possible situation and market – such as DAM [4].

6. Conclusions

To this day, achieving environmental goal as being climate neutral for most EU countries is still a challenge, taking into account the need to get rid of one of the most largest sources of emissions – coal – by 2030. Although the increase in energy resource prices and their shortage in Europe during the last months of 2022 has created new challenges for achieving environmental goals in the EU and Ukraine.

Forecasting the demand on the DAM is one of the components that must be carried out for successful business and optimization of business processes of trading companies in the electricity market. Given that quite often the income of such companies depends on how they will sell on the DAM, the choice of the correct approach to forecasting is quite acute.

In the article, four algorithms for forecasting the hourly demand for DAM are considered, corresponding calculations are performed, and a comparative analysis of the calculation results is carried out. For each of the algorithms, their prediction errors were calculated and the most accurate algorithm out of four was determined.

A formulaic description of the most accurate algorithm is given – as a weighted average value for positive and negative changes in demand, taking into account the deviation from the arithmetic mean of the absolute values of changes in demand to determine atypical days. Forecasting is carried out on the basis of statistical data on the amount of electricity purchases on the DAM, using the principle of multi-iteration analysis of changes in demand for previous similar days of previous months (with the possibility of increasing the sampling depth to quarters or years). At the same time, it should be noted that all calculations were performed in the MS Excel package, which indicates their ease, availability, speed, as well as the low or zero cost of implementing such an algorithm.

As a result of the application of the specified algorithm, there is also the possibility of tracking atypical behavior of market participants on the DAM, which will require additional attention and research.

Abstract. In the paper showing that one of the main way for Ukraine electric power industry evolution is electric power networks and systems improvement and construction considering Smart Grid concept. The main idea of Smart grid is the reliable, energy-efficient and high-quality energy supply system. To implement the idea, it is necessary to create a high-performance information and computing infrastructure. The main components of Smart Grid is emergency mode diagnostics and damage monitoring. Providing fault diagnostics and fault monitoring can improve the power supply reliability and quality to consumers. So, the task of quickly and accurately determining the place of damage is important. In the article showing that emergency detection tools in sections of both cable and overhead electrical networks it's a way to improve efficiency of the networks. The diagram of the placement of damage indicators on the section of the electrical distribution network is presented, which allows determining the direction of the search for the location of the damage. A comparative analysis of measuring current transformers of optical and electromagnetic type was carried out. It is shown that a significant number of advantages of optical measuring current transformers, which can be used in damage indicators, can be provided by measuring current transformers of the electromagnetic type. Creating fault indicator based on the Smart Grid concept lets do to reduce searching time for the cause and location of an emergency situation to a minimum. In this concept application fault indicator in energy grid ensure it connection to operating overhead and cable lines without removing voltage by connecting the output of the secondary winding of the measuring current transformer of the detachable design to the measuring converters directly placed near the current measuring transformers with the help of a mechanical spring fastener. A block diagram of a specialized information-measuring system with a damage indicator was created, taking into account the requirements of the Smart Grid concept, which allows to reduce the time of searching for the cause to a minimum.

1. Introduction

Ensuring the effective and safe functioning of the electric power complex of Ukraine largely depends on the stability of the work of its individual components, which are united by a common mode of production, transmission and distribution of electric and thermal energy with common centralized control [1]. The existing course ”smart grids” position concept's implementation in Ukraine until 2035 is aimed at the active development of Smart Grid systems in the energy system of Ukraine and is fully in line with the priority directions of energy development in the EU.

Thus, one of the important directions of the development of the electric power industry both in the world and in Ukraine is the improvement and construction of electric power networks and systems according to the Smart Grid concept [2,3]. The main idea of Smart grid is the reliable, energy-efficient and high-quality energy supply system. To implement the idea, it is necessary to create a high-performance information and computing infrastructure.

Violation of the operation mode of any of the components of the energy system leads to the emergence of various emergency situations. The most common types of damage are accidents caused by short-circuits and short-circuits to the ground. It is believed that accidents caused by short-circuits make up 70–80% [4]. One of the most common places of damage in electrical networks is cable and overhead power lines (power lines).

Therefore, monitoring the parameters of the emergency modes of cable lines and power lines in various sections of electric networks is one of the most important tasks for ensuring the reliability of electricity supply to consumers, which is implemented through the development and implementation of specialized information and measurement systems (IMS) as a component of Smart Grid systems [5, 6]. The urgency of implementing such systems is due to the fact that the occurrence of emergency situations leads to disruption of the normal power supply of consumers associated with interruptions in power supply, as well as a decrease in the quality of electric energy. In turn, the deterioration of the quality of electrical energy can lead to the failure of equipment of electrical networks and consumers. The effective solution of this problem gives a significant economic effect due to the reduction of interruptions in electricity supply, the reduction of transport costs for bypassing the PL and KL, minimizing the total time of organizing repair and restoration works [2]. An effective way for time to cut of searching for a power line damaged section fault indicators with organized as network is to use [6–10]. Fault indicators it's devices for monitor the electromagnetic field around the power transmission line and record the fact of damage to the line.

The use of damage indicators is most relevant for distribution networks from 10 kV to 110 kV [6]. The main characteristic of these networks is their long length, which is due to a significant number of branches and the presence of areas with difficult access to routes such as overhead and cable lines. During the elimination of emergency situations in distribution electric networks, in particular, during the elimination of accidents associated with the failure of power transmission lines as a result of hostile actions, timely identification of the damaged section of the network acquires primary importance. Detection of a damaged section of the network and in most cases consists in finding the optimal way to bypass all nodes of the topological graph (in the case of overhead power lines bypass all sections of the line [6,7,11,12]. In case of damage in the most remote area [13], it is necessary to ensure inspection of the line along its entire length [6].

Therefore, determining the places of occurrence of an emergency situation, the reason that led to its occurrence and the development of measures to eliminate it is a complex and complex problem, the solution of which has become a daily operational task of dispatching services of electrical networks and systems.

The paper *aim* is to analyse the ways of increasing the reliability of electricity supply to consumers and the effectiveness of restoring electricity supply by operators of distribution systems, by developing a structure of means of identifying emergency conditions in distribution electric networks of IPS of Ukraine [14].

2. Materials and method

The construction of information and measurement systems (IMS) with primary transducers based on indicators with means of communication and information transmission reduces the time of searching for an accident to a minimum. When damage occurs, all indicators installed in the damaged areas between the data center and the damage site will send response signals to the dispatch center, which allows you to immediately determine the emergency zone and take immediate action.

In this case, the basis of the IMS is the measuring transducers that ensure the determination of emergency mode parameters. In the electrical networks of European countries, damage indicators have been found widely used as measuring transducers (measuring operational parameters in electrical networks) [12, 15]. The use of damage indicators in the structure of the IMS. So compatible with the means of pre-processing, communication and information transmission, allows to reduce the time to eliminate the cause of the emergency situation to a minimum, which allows immediate identification of the emergency area and the implementation of operational actionist of the research.

Damage indicators, which have found application in electrical distribution networks, are based on different principles of operation. The simplest option of damage indicators are devices that record the exceeding of a certain short-circuit current threshold by the measuring transformer. The distance to the emergency site is determined based on the known calculation parameters of the network, namely the voltage values in the network and the value of the transient resistance at the point of damage. Usually, the indicated indicators for determining the distance to the place of damage on the distribution lines are ineffective due to several branches, which is due to the small values of the short-circuit currents and the length of the electrical networks. This problem is solved by installing damage indicators at the beginning of the branches of each line. In this case, by combining information about the distance to the accident site with information from damage indicators, the exact location of the damaged section of the network is obtained. The disadvantages of such devices are the need for additional calculations and the use of an electromagnetic type measuring transformer. The use of a measuring transformer in many cases is associated with difficulties in their implementation and ensuring operation in the conditions of a continental climate on the territory of Ukraine. Which is characterized by hot summers and frosty winters with significant temperature drops. Information and measurement systems with optical indicators of damage do not have this drawback [16]. The principle of operation of optical indicators is based on the use of electro- and magneto-optical effects. The use of the stability of the manifestation of the physical effect of the influence of magnetic or electric fields, which arise under the action of the measured current or voltage on the parameter of optical radiation, allows to ensure high accuracy of measuring currents and voltages. The conversion of the measured electrical values into the parameter of optical radiation takes place directly in the high voltage zone, then, using optical communication channels, the measurement information from the high voltage zone is transmitted to the low-voltage part of the IMS located in the safe zone. A directly measurable value when using electro- and magneto-optical effects is the parameter of optical radiation, the measurement of which can be carried out with high accuracy [17]. The obtained results do not depend on external meteorological factors. The main advantage of optical damage indicators is a wide signal bandwidth, high resistance to interference, durability, stability and simplicity of the optical element, as well as the ability to determine very short values of short-circuit currents in the millisecond range [7]. Such values of short-circuit currents occur in cases of short-circuit to the ground, for example, during the occurrence of a short-circuit of a phase to the ground or to a neutral wire under the influence of natural elements. A significant disadvantage of optical damage indicators is the high cost of optical damage indicators, which is due to a number of reasons [18]:

- the high cost of the manufacturing technology of optical elements and means of measuring their output values;
- insignificant power of the output circuits, which is insufficient to activate the existing sets of electromechanical protections, and the need to use additional hardware to increase it;
- lack of protection terminals and metering devices produced by domestic and many foreign manufacturers, corresponding inputs for connecting optical converters;
- lack of national standards that regulate the verification and determination of the accuracy

class of optical sensors and transducers in general;
- lack of sufficient statistical data on the use of these devices, which makes it much more difficult to determine their reliability;
- the high cost of projects due to the high cost of converting devices and network equipment, as well as the organization of current and voltage circuits in digital form.

Since a significant number of advantages of optical damage indicators can be provided by traditional measuring current transformers, the most effective is the construction and use of fault indicators employ measurement of the magnetic field induced by the current in the current measuring transformer network. The working principle of fault indicators is based on: signal from the secondary winding of the measuring current transformer is proportional to the primary induced current and shifted relative to it by a phase angle close to zero.

Existing damage indicators based on the measuring current transformer, due to the peculiarities of their designs and ensuring the possibility of monitoring them during operation and minimizing measurement errors, are mostly installed only in large nodes of generation and distribution of electrical energy, such as stations and substations. Moreover, the measuring transformer is usually a component of closed and open distribution devices. In addition to the mentioned restrictions on the place of placement, their disadvantage is a long time of installation, adjustment and the need to remove voltage during their installation and maintenance.

3. Results

To ensure the creation of a damage indicator, which allows you to reduce the time of searching for the cause and the place of occurrence of an emergency situation to a minimum, as well as to ensure connection to operating overhead and cable lines without removing voltage by connecting the output of the secondary winding of the measuring current transformer of the detachable design to the measuring transformers -creators placed directly near the measuring current transformer with the help of a mechanical spring mount. The connection diagram of the current transformer is shown in figure 1, which shows: the load current sensor (LCS) and the measuring system (MS). The IMS contains: a non-invasive current sensor, which consists of an inductive current transformer with a collapsible core (1), a resistor designed to convert the current value into a voltage (2), a shift reference voltage stabilizer implemented on analog elements (3). The system contains: an ATmega328 microcontroller (4), an interface converter chip (5), a 2x16 character liquid crystal display (6) to ensure the display of information in case of need, an LED (9) intended for global indication of a normal and emergency situation on the power line. LCS and VS, together with a personal computer (7) or other specialized means of information processing, on which specialized software is installed, form the IMS of control and monitoring of emergency parameter s of power transmission lines in distributed electric networks. The personal computer (7) is located in the control center in the case of remote access to the IMS or in the immediate vicinity of the IMS in a safe area.

The data collected from the measuring transducers of the LCN indicators are transmitted to the network part of the IMS. Using the obtained data with the help of unit 7, it is possible to monitor the magnitude of the electric current, to recognize the reason for the sudden increase in current strength: the connection of a new load or the appearance of a short-circuit current, and when conducting additional coefficients, to determine the approximate amount of consumed (released) electricity in the sector – divided network and easy to adjust taking into account possible peak loads in branched. Each indicator is equipped with LED 9 to provide a visual indication of the state of the lines, in the case of normal operation of the line, the LED continuously lights up in green color, in the event of an emergency, the LED switches to the red code glow mode. The type of code glow is determined by the type of emergency on the line.

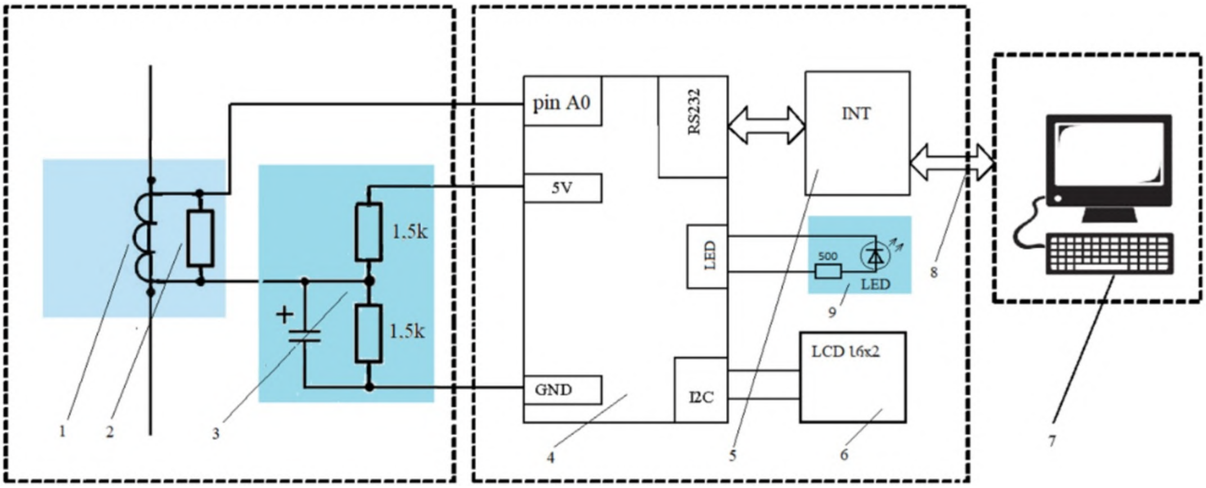

Figure 1. Block diagram.

The use of LCS indicators, which have means of communication and information transmission (units 5 and 8), ensure that the time for searching for an accident is reduced to a minimum. In the event of damage, the LCS indicators installed on the damaged areas and send appropriate signals from place of damage to the dispatch center, which allows immediate identification of the emergency area and immediate action to eliminate the emergency situation.

In order to verify the results of the research on the components of the system of the intellectualized emergency meter for the identification of damage to overhead and cable lines, test and demonstration stand was created, the photo of which is shown in figure 2.

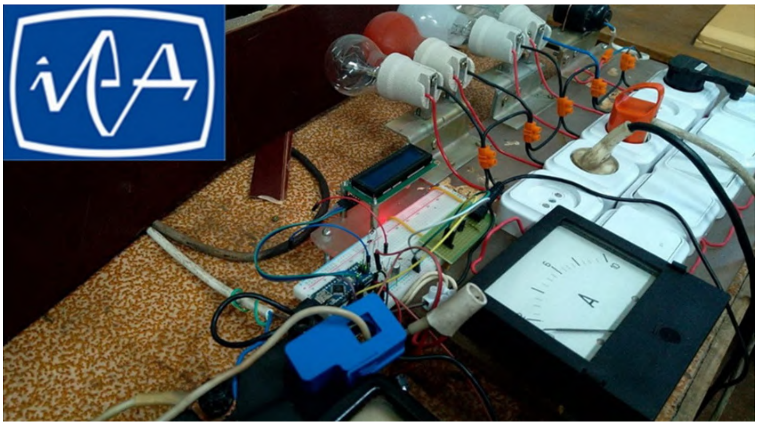

Figure 2. Test and demonstration stand.

The test was carried out by the method of direct comparison with an exemplary meter of the information component. The ProsKit MT-1270 device with an accuracy class of 0.5 for determining the current value and an ammeter E59 with an accuracy class of 0.5 were used as sample meters. The obtained measurement results are shown in figure 3.

The obtained results (figure 3) confirm the functionality of the intellectualized emergency condition meter for distribution electrical networks in a single-phase cable network with a collapsible core.

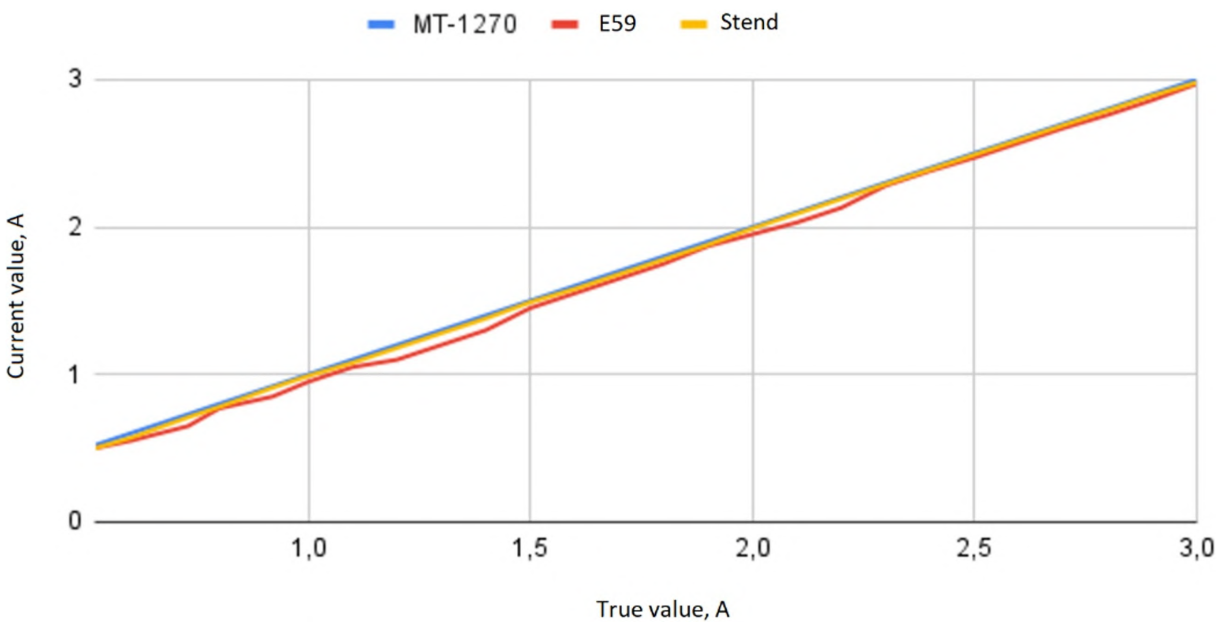

Figure 3. Research results.

4. Conclusions

Fault indicators are used to determine different types of damage in cable and overhead lines of electrical networks of different voltage classes, allow visual indication of the damaged section of the line, and in the case of the presence of a suitable interface, transmit this data remotely. Schematic and technical solution for the construction of damage indicators makes it possible to ensure connection to operating overhead and cable lines without removing voltage, and also, unlike existing damage indicators, due to additional coefficients, to determine the estimated amount of consumed (released) electricity in the sector of the distributed network and to easily adjust taking into account possible peak loads in the branch.

The development and implementation of such indicators is the basis for the construction of specialized information and measurement systems in electrical networks, the use of which reduces transport costs during the search for places of damage, minimizes the total time of organizing restoration and repair works, which in turn allows to increase electricity supply reliability to consumers and receive a positive economic effect by reducing of interruptions in their energy supply.

Abstract. Despite of all hardware capabilities, optimization of software always was one of actual tasks. Usually optimization of software was aimed to reduce an execution time. But recent decades it's possible sometimes also to reduce energy consumption and/or energy efficiency of computing because of enhanced energy saving capabilities. Indeed, if computations are made faster, CPU can suspend unusual computational and control blocks. In case of parallelization which is one of optimization techniques, power consumption can raise in short periods of computations because of using multiple CPUs simultaneously. At once execution time can be decreased dramatically so energy efficiency of computing still increasing. In the paper the authors provide the experiments on small size mini PC Raspberry Pi 3B which show that using of optimization tiling method not only speed up a processing but also increase energy efficiency of computing. For such low power systems this can be useful to increase power on time with a battery power source.

1. Introduction

The problems of computer systems power consumption have been taking attention for a long time. There were several reasons for this. First, a requirement to increase computing performance has increased the number and activity of nodes in computer systems. Second reason is a development of a different purpose computing system such as stand-alone computing units, mobile devices or on-board computers. Development and research of embedded computing systems have brought particular attention to energy use issues [1]. The third reason worth mentioning is a development of systems based on multiprocessor computing systems, such as network servers, data centers, multi-machine complexes for high-performance computing demands. The feature of this class of systems is a requirement to organize a special infrastructure with support for sustainable power, cooling, etc.

Andrae and Edler [2] show various projected scenarios of data centers power consumption by 2030. On the basis of this increase in power consumption by data centers and structure of this demand, it can be concluded that a comprehensive approach has to be taken to address the problem of reducing electricity consumption in this sector. In addition to measures to reduce computing costs, solutions to reduce energy consumption by data center infrastructure should be implemented. This is true for both high-performance computing and global information networks.

Ciancarini et al [3] showed that activities in various sectors of economics are increasingly being digitized. Human activities are increasingly dependent on information technology, resulting in increased energy consumption. Usage of smartphones, tablets and other mobile devices significantly expands a number of active users.

Gupta and Singh [4] shows the power consumption structure of a personal computer including printer and communication system. The authors presented a technical overview of minimization methods of energy consumption by computer systems. Based on the methods of calculation of energy consumption using hardware, software, processor and various algorithmic approaches, a conclusion is presented that there is a great need to change of operating system work at moments of inactivity. Available options in power circuits of computers and peripherals are based on a timeout approach. This is not enough to solve the problem of minimization of energy consumption.

Szydlowski and Chvála, Jr [5] give a fairly detailed study of power consumption of personal computers and workstations. The study should be taken into account, even though the data may appear to be outdated at first glance due to evolving technologies. With a load of 75 to 175W standard PC consumed 144 W, and standard workstation takes 173W. Peripheral equipment such as printers and modems accounted for only 16% of the total workstation consumption. This information indicates that energy-saving measures should focus on computers (50% of total consumption) and monitors (35% of total consumption). Laser printers at 12% of total workstation consumption, also require attention because they are involved in the work, usually 24 h/day. The paper presents a problem of software optimization as a component of the complex solution for the problem of reduction of energy consumption. A focus of the research is on solutions for design and use of mobile and embedded systems. There is an additional point for research in a field of energy efficiency of devices.

An issue of increasing energy consumption has affected on field of mobile information technologies. A growth of energy consumption has outpaced of development of energy storage technologies, in particular, a capacity of batteries. This is reflected in a significant reduction in a lifetime of mobile device batteries while increasing their functionality. Thus, the challenge of improving the energy efficiency of information technology is not only to save energy, but also to extend the battery life of mobile devices.

Hassan et al [6] shows a dependence of a performance and energy consumption of computer systems on quality of program code. The authors demonstrated that in order to ensure the best performance indicators for computer systems, there is a balance between performance, capacity and energy consumption and a choice of a right coding style together with “right” compiler determines an achievement of this balance.

In this article, the approach of the authors is defined by three provisions. First, in a transistor gate in general, two types of power dissipation can be distinguished: static and dynamic. Static power dissipation is measured in opened or closed states of transistor switch. Dynamic losses occur during transistor switching from one state to another. Dynamic losses account for up to 80% of total digital circuits power dissipation. Second, when analyzing of algorithms of computing systems, it is clear that most of computational time of software happens to a cyclic loops of algorithms. By improving of cyclic loops or sections, it is possible to reduce an activity of electronic components and, accordingly, dynamic losses of digital circuits. And third, algorithm transformations should be done at system level. This provides a significant benefit in terms of reducing the impact of poor program source code on a performance of computer system. So, the main idea of the author’s approach is to make transformation of program sources taking into account program loop operators and making source-to-source transformation.

Further, in the first section the authors present modern methods and approaches used in the optimization of computer programs. The next section provides hardware and software tools for estimation of execution time of initial and optimized test programs. The results of the optimization method of tiling and parallelization, which show the change in the performance and energy efficiency of calculations, are given in the latest section.

2. Motivation

From the very beginning of computational systems' development, a lot of efforts were spent to make hardware smaller and to consume less power. Such methods as dynamic clock rate, unused block hibernation, lower operation voltage, comprehensive electric layers' design were used and also are used now to reduce power consumption.

At the moment most of electronic components are built by using complementary metal-oxide semiconductor (CMOS) technology. This technology was discovered by different authors [7, 8] and all effects which lead to higher power consumption are known. All sources of CMOS digital circuits power dissipation can be divided onto 4 groups.

(i) Short-circuit current
(ii) Parasitic leakage current
(iii) Static dissipation
(iv) Dynamic dissipation

Dynamic dissipation is a main dealer of power dissipation and it can dissipate up to 80% of total energy dissipation [9]. Formula for dynamic power dissipation is depicted below:

$$P_{dynamic} = C \cdot V^2 \cdot k \cdot f, \tag{1}$$

where C is a total capacity of a circuit, V – voltage span, k – activity factor and f – switching frequency. Dynamic dissipation take place when a circuit switches from one digital state to another. Dynamic dissipation is linear to switching frequency. If there is no switching – dynamic power will be absent. More active elements involved – higher dynamic dissipation occurs [10].

In terms of software optimization, it can be concluded that every method which reduces register or memory usage or functional blocks is involved as well, in theory can reduce dynamic dissipation. Software optimization methods are aimed on different software parameters. Often main goal of optimization is a reducing of time execution of program. It allows to perform computational tasks faster or to increase a functionality of a software by adding new features to it which were not possible with slow computations. Most of execution time software spends in computational loops which perform the same computational operations for different data. Improvement of any single operation will lead to improvement of every computation in it. Thus, optimization methods targeted on execution time are developed to implement them in computational loops. Some of software optimization methods are listed below.

- fission/distribution;
- fusion/combining;
- interchange/permutation;
- inversion;
- loop-invariant code motion;
- parallelization;
- reversal;
- scheduling;
- skewing;
- splitting/peeling;
- software pipelining;
- tiling/blocking;
- unrolling.

Mentioned methods provide different approaches to speed up a computational loop. Some of them are intuitively clear like parallelization when data are distributed between CPUs for faster execution. Some methods are not so clear. For example, tiling method, practical usage of which will be discovered below, is not so evident. For mathematical description and handling of different optimization methods several models were proposed. One of most used is a polyhedral model [11]. This model represents a loop or loop nest as a defined mathematical abstraction [12]. Every loop is described with a set of inequalities and limits. Such approach allows to alter one or several loops by changing their parameters and convert model back to code. Polyhedral model can handle tiling method. Tiling method is an optimization method which divides iteration space onto smaller parts named tiles. Computation of data on smaller range provides better data locality and less cache misses. This can lead to faster execution time. Another promising factor that during tiling usage a software natively obtains a different computational blocks which is possible to distribute on different CPUs if there are no data relations between them. Combining of tiling method and parallelization can have synergistic effect.

3. Hardware and software set

As it mentioned above, a lot of optimization methods are used to gain different improvements: faster execution time, lesser data or code memory usage etc. But what to do if desired goal of optimization is a lesser power consumption or better energy efficiency? How to change a software to reach it?

Because computational system is a comprehensive set of many hardware sub-parts which consume energy, there is no single target parameter available in code to optimize. A possibility that some optimization methods can to influence on energy consumption should be discovered.

The authors performed several experiments to verify it. First, software optimization method should be chosen. The authors have chosen tiling method which uses polyhedral model as a mathematical description. Main idea of the method is to reduce iteration space onto smaller parts which are called tiles (figure 1). It produces better usage of cache memory and improves data locality. Also, to reveal a power of multi-core CPU a parallelization method was used in addition.

Usually, an optimization is performed by compiler or manually. There is another way to

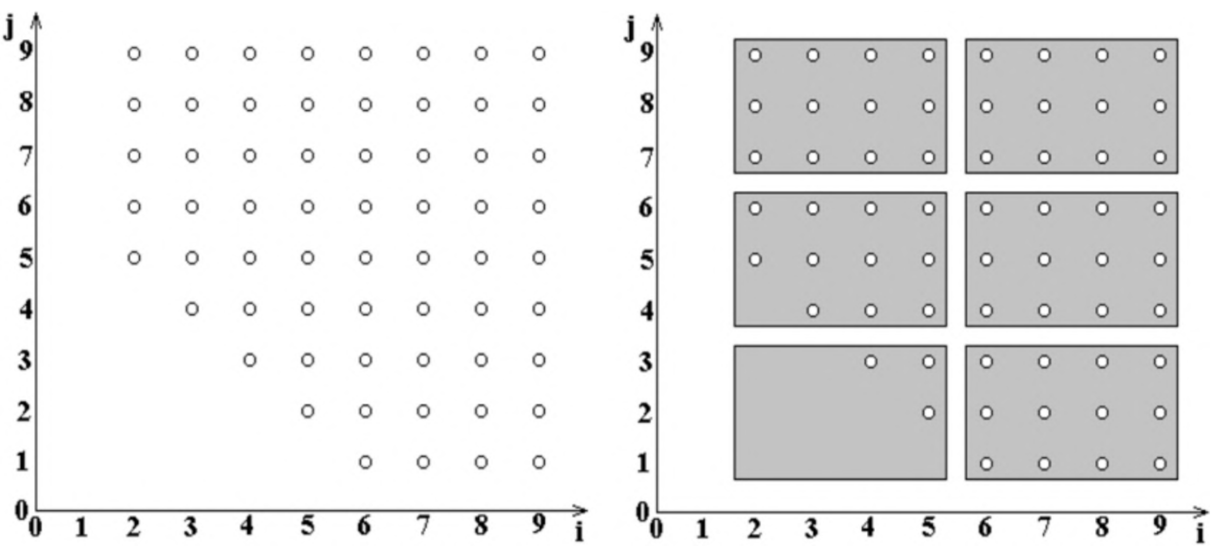

Figure 1. Example of original and tiled iteration spaces. Obtained tiles are selected in gray rectangles.

optimize source code without using compiler's features.

To apply tiling method, the authors used Pluto framework [13]. This is a set of tools which automatically can apply several tiling methods and parallelization as well. This is achieved by transformation of C source code to another source code by some rules. After it a new code should be compiled as usual. Such code-to-code transformation allows researchers and developers to be focused and to improve specific optimization methods. No changes to compiler are required. Moreover, all compiler's optimization methods also are applied on a stage of compilation.

Next, to verify any optimization some test applications are required. In common case, any optimization aimed to execution time reduction or energy consumption can be only verified on real execution of software. The authors chosen Polybench [14] set of test applications. It includes about 30 tests of linear algebra, simulation, vector and matrix computations. The tests have embedded tools to measure execution time. By altering the tests by source-to-source transformation and to compile and execute a new code it's possible to measure and compare new execution time.

Finally, a Raspberry Pi 3B board was chosen as a hardware platform for tests (figure 2). This credit size mini PC has 4 ARM based CPUs, 1 GB of RAM, video, audio outputs and general purpose input/output signals (GPIO). This PC can operate on Linux based distributives and usually is chosen for home automation, home or NAS server and IoT. Figure 2 (b) also shows the Raspberry Pi hardware structure.

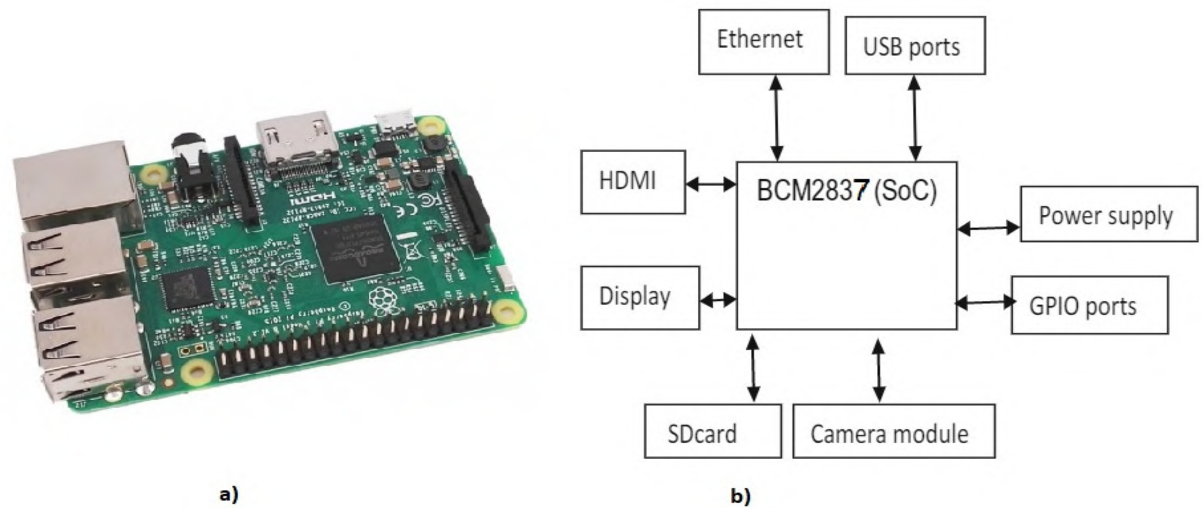

Figure 2. Raspberry Pi 3B mini computer (a) and its hardware structure (b).

Main idea of the tests is to measure a speedup of execution time, energy consumption and to calculate energy efficiency of optimized tests.

4. Experiments

To evaluate an energy efficiency, it is not enough to measure only execution time. Because an optimized software can use less or more electric power i.e. in case of multi-core optimization and be faster or slower an electrical power consumption also should be taken into account. Energy which is required to compute any result is an integral of electric power on time or, in simplified form, when exact power consumption in time is not known, equals to a multiplication of average power by time of computation:

$$E = P \cdot T, \tag{2}$$

where P is an average power consumption, T – execution time. To estimate energy efficiency coefficient for non-optimized and optimized version it's necessary to compare required energy in both cases. When required energy is lower than before then coefficient of energy efficiency will be more than 1, if higher – then less than 1. If to apply previous formula, we can obtain:

$$K_E = \frac{E_{original}}{E_{optimized}} = \frac{T_{original}}{T_{optimized}} \cdot \frac{P_{original}}{P_{optimized}}, \tag{3}$$

To evaluate an energy efficiency coefficients two measurements were made. First measurement was a measurement of execution time and second one was a measurement of average power consumption. Both measurements were made for non-optimized and all versions of optimized test programs. Optimized version was made with different tiling options of Pluto software. After applying of formula above were obtained energy efficiency coefficients which were composed in table 1.

As it follows from the table, different coefficients of energy efficiency were obtained. For better readability the data are shown on figure 3. There are test programs on the horizontal axe. On the vertical axe there is a coefficient of energy efficiency. For non-optimized program it's always 1. The different optimization methods are depicted by the different color lines. Some of optimization methods are only a variation of tiling method but also some of them are combined with parallelization. In that case name “parallel” is presented inside its name.

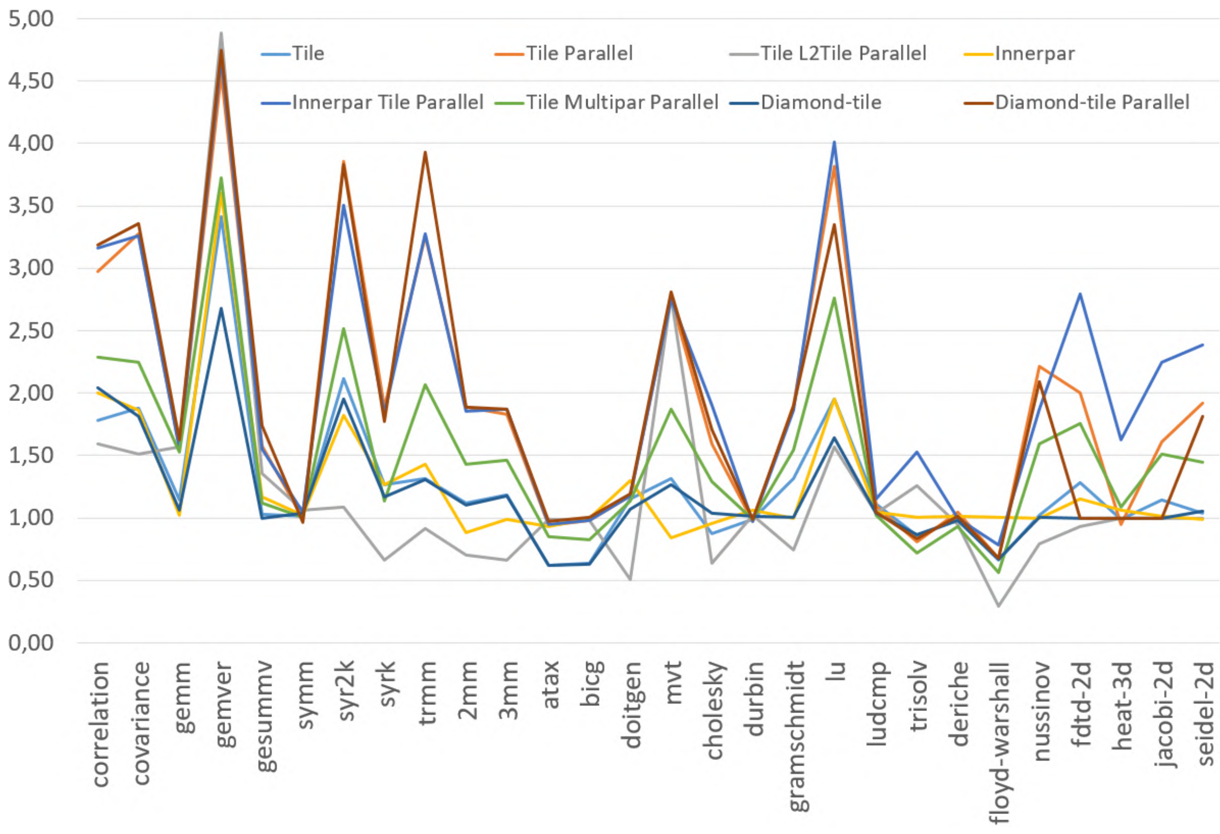

Figure 3. Coefficients of energy efficiency for different test programs and optimization methods.

If to look onto the plot it can be recognized that some of the optimization have much better results than other. Often this is a blue and red lines which mean “Tile Parallel” and “Innerpar Tile Parallel” methods. Both of them have parallelization option. It means that parallelization

on Raspberry Pi 3B which has 4 cores works quite good and all CPUs share computational tasks in that cases.

As it follows from the figure, quite often it's possible to obtain an energy efficient coefficient more than 1. It means that optimized software requires less energy to compute the same algorithm. On other hand there are several algorithms which didn't receive any reducing of total required energy. For example, Floyd-Warshall algorithm which is an algorithm for finding the shortest path between all pairs of vertices in a weighted graph, didn't get better energy efficiency in any applied optimization method.

5. Conclusion

If to review the obtained results it should be concluded that optimization methods provide better energy efficiency in most cases. Usually, it's provided by significant speed up of execution time with slightly increased power consumption. Together these results produce better energy efficiency of computing. In some particular cases test program didn't react on optimization methods and in such cases energy efficiency was the same or even worse.

Big difference of energy efficiency on the different tests and different optimization methods shows that in any particular case optimization method should be chosen carefully. Several experiments should be done with different optimization methods. Also measurement for original non-optimized software should be done. If there is no speed up of execution time for several tiling methods, then no tiling methods will boost it. Another optimization method should be chosen.

The authors also performed such experiments on other hardware platforms with tiling methods. In common, CPU has bigger cache – bigger speed up of execution can be obtained.

To summarize all the tests, it's necessary to highlight that optimization of software can really improve energy efficiency of computing by reducing of CMOS circuit switches. It improves program locality and this reduces dynamic and thus total power dissipation.

Abstract. In this article, the author presents an original approach to analyzing the dynamics of power plants' development with renewable energy sources. This approach is based on the characteristics of their connection to (high-voltage or distribution) power transmission networks during both the pre-war and post-war periods. The article describes the impact of military aggression on the current status of power generation from alternative energy sources. The article not only suggests the main directions of post-war reconstruction but also defines approaches to developing regulatory mechanisms to promote the growth of renewable energy at the regional power system level of the United Energy System of Ukraine.

1. Introduction

Economy, energy, and ecology are areas that play a significant role in society. Energy is of great importance because it influences both the development of the economy and ecology. It determines, to a great extent, the economic potential of the state, the well-being of its population, and also has the most significant impact on the environment (all environmental problems directly or indirectly related to the production or use of energy).

In recent years, both in Ukraine and worldwide, there has been steady development of small or low-capacity power plants using renewable energy sources (RES), which gradually replace traditional methods of generation. According to data from the State Agency for Energy Efficiency and Energy Saving of Ukraine [1], the installed capacity of power generators from alternative energy sources increased by 9.5 from 2014 to 2021, as shown in figure 1.

However, after Russia's full-scale invasion, Ukraine's energy industry has faced difficult times. Some of the generation facilities and energy infrastructures have been damaged, destroyed, or are located in the occupied territories, including renewable energy generation facilities. After the war, the energy industry needs to be restored and significantly expanded. Therefore, it is crucial to find approaches and methods to support and develop RES producers in the war and post-war period.

There has been a hectic discussion in various professional circles about decentralizing the power system [2] in the context of post-war reconstruction reflections. The concept of decentralization includes measures to ensure reliable power supply to critical infrastructure objects, houses, etc. in case of damage to important objects of the power system.

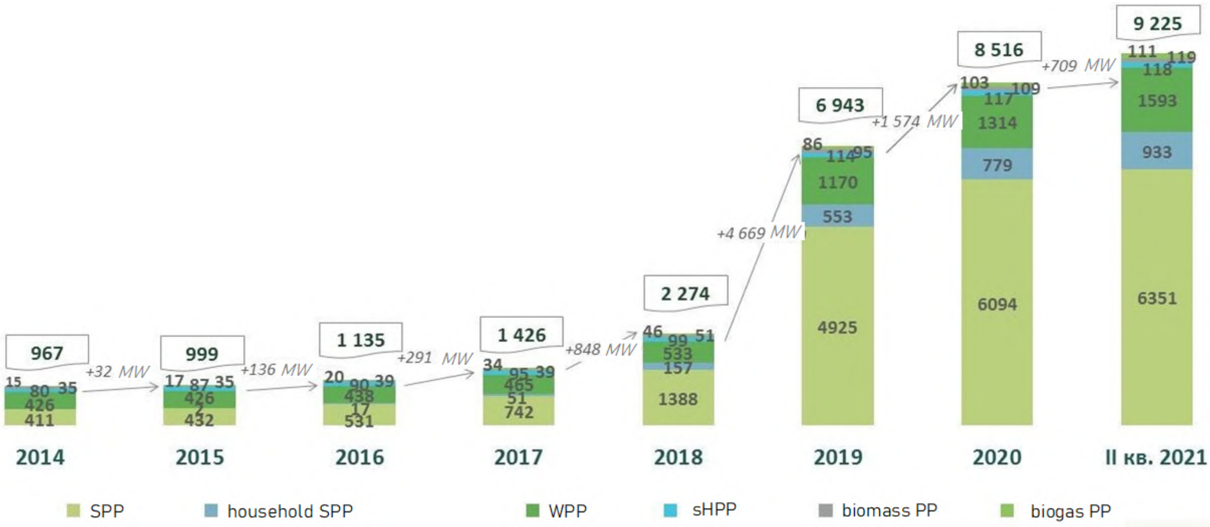

Figure 1. Installed capacity of renewable energy sources for 2014-2021 [1].

Distributed power generation is defined as an energy production and transmission system that involves a large number of consumers who, at the same time, are producers of electricity and heat for their own needs. They have the ability to transfer excess energy produced to the general power grid. According to the Law of Ukraine "On Electricity Market"distributed generation is defined as "a power plant with an installed capacity of 20 MW or less, connected to the electrical energy distribution system" [3].

To conduct research on the development of distributed generation in Ukraine and introduce new approaches and methods of supporting renewable energy in the war and post-war periods, it is essential to have data on the current state of renewable generation, as well as information on the capacities of RES facilities that are connected to the distribution network.

There are a number of scientific publications and information resources that analysed the dynamics of the development of alternative energy in Ukraine and the world. For example, the energy development strategy of Ukraine is reviewed in [4], the analysis of prospects for the development of renewable energy in Ukraine, the influence of military actions on the state of the industry, ways of development of RES in the post-war period, etc. are reflected in studies [5–11]. Also the analysis of using of renewable energy sources on the development of energy systems, using of "smart technologies"for renewable energy are shown in research [12–18]. However, none of them studies the state of alternative energy in terms of data on the connection of RES facilities to power transmission networks.

At the same time, in the research of Lukashevych and Evdokimov [19] describes the information system for monitoring the state and dynamics of development of RES power plants, its characteristics and structure. Besides, the described information system contains already formed and implemented in Excel data fields about RES objects of Ukraine, which should be used for the analysis of previous experience in development of power generation, its current state and formation of proposals for directions of post-war reconstruction.

The aim of the research is to analyze the dynamics of the development of alternative energy facilities in terms of their connection to power transmission networks.

The tasks of the study are:

- to determine the distribution structure of RES in terms of connection to the power grid in the pre-war period;
- to describe the impact of military aggression on the state of alternative power generation;

- to identify the approaches and methods of support and development of RES producers in the wartime and postwar periods.

2. Analysis of alternative generation in terms of connection to power transmission networks by 2022

The research [19] contains information about main RES facilities (name, address, type of source, amount of installed capacity of the facility), including data on the type of power transmission network to which the stations are connected – high-voltage or distribution. The data on the connection of individual renewable energy generation plants to the distribution or high-voltage comes from the analysis of all PPA contracts (Power Purchasing Agreements – long-term contracts for the purchase of electricity from renewable energy sources) signed by alternative energy producers with the state-owned company Guaranteed Buyer (SE "Guaranteed Buyer") from 2019 to 2022. However, the system does not yet include information on alternative generation facilities of households that have signed power purchase and sale agreements with universal service providers (USPs).

Based on the available information, we can perform an analysis of the dynamics of development of alternative energy facilities in terms of their connection to the high-voltage or distribution power transmission networks. The calculations were performed for operating plants (for power generation) that have a "green" tariff, without taking into account households that sell electricity to the USP.

Figure 2 shows the dynamics of the development of renewable energy producers for the period from 2019 to July 2022.

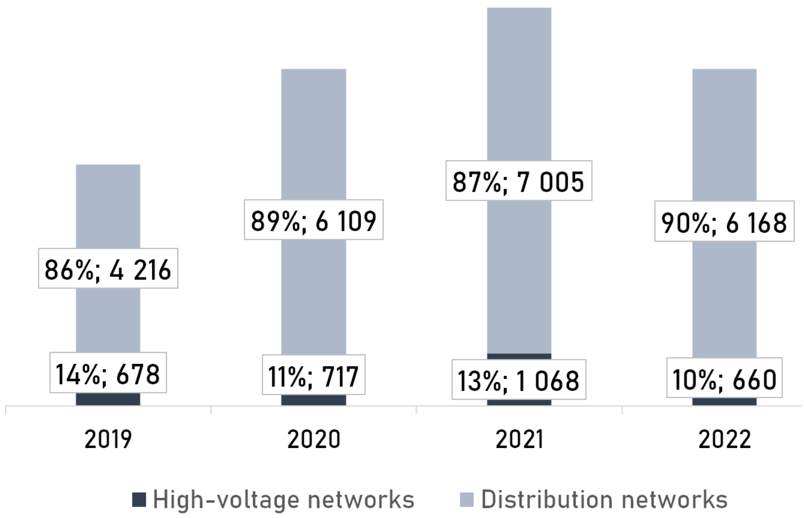

Figure 2. Distribution of installed capacities of operating alternative generation stations in terms of connection to power transmission networks for 2019-2022, MW.

The installed capacity of operating renewable energy production facilities increased from 4896 MW in 2019 to 8072 MW in 2021. However, due to military aggression in July 2022, only 6828 MW of operating capacity of alternative generation facilities remained in the unified energy system of Ukraine.

Also figure 2 illustrates the changing structure of RES producers in terms of their connection networks, with capacity connected to high-voltage networks increasing from 678 MW in 2019 to 1068 MW in 2021, and decreasing to 660 MW in July 2022. Correspondingly, capacity connected to distributed generation increased from 4261 MW in 2019 to 7005 MW in 2021, and decreased to 6168 MW in 2022. Thus, there is a trend towards the predominant connection of alternative generation plants to distribution grids, likely due to the low installed capacity of RES producers (with 98% of the total number of RES plants having an installed capacity of less than 50 MW) and the relative simplicity and cost-effectiveness of connecting to the distribution grid compared to the high-voltage grid.

Additionally, figure 2 shows that alternative generation peaked in 2021.

The distribution of installed capacities of operating alternative generation stations in 2021 is presented in figure 3.

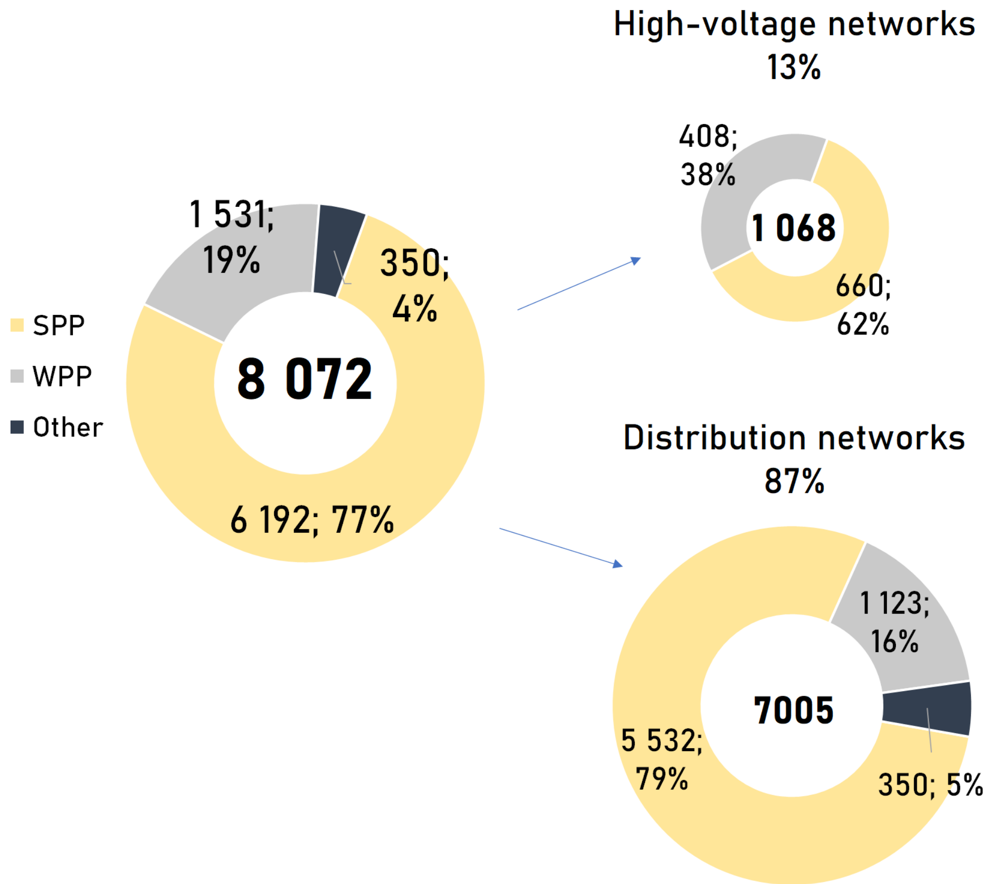

Figure 3. Distribution of installed capacities of operating alternative generation stations by sources of alternative energy and connection to power transmission networks in 2021, MW.

In 2021, 77% of total power generation came from solar power plants (SPP), 19% from wind power plants (WPP), and 4% from other power plants (small or micro hydropower plants; power plants using energy from biomass, gas from organic waste, sewage gas: biogas, etc.). 1068 MW or 13% of all alternative generation capacities were connected to the high-voltage grids, including 408 MW of wind power plants and 660 MW solar power plants. RES plants connected to the high-voltage networks were located in the Dnipro, Lviv, Mykolaiv, Kherson, and Khmelnytskyi regions, as shown in figure 4.

5532 MW of solar power plants, 1123 MW of wind power plants and 350 MW of plants generating electricity from other sources were connected to the distribution grid. These plants are distributed throughout the territory of Ukraine, taking into account the geographical and climatic conditions of the regions, as shown in figure 5.

Figure 4. Distribution of installed capacities of operating stations of alternative generation connected to high-voltage networks in 2021.

Thus, the development of solar energy can be observed practically on the entire territory of Ukraine, with the predominance of central and southern regions, wind power generation mainly in the south, small or low-power hydroelectric plants along riverbeds in the northwestern, central and eastern regions, and power plants using energy from biomass or biogas throughout the country. Separately, it is worth noting the relatively low development of RES in the northern and eastern regions of Ukraine.

In general, in 2021, the share of electricity generated from RES in Ukraine's energy balance was 12.8 TWh or 8%, of which 56% was generated by solar radiation, 33% by wind energy, almost 8% by biomass and biogas combustion, and 3% by small hydropower [20].

3. Analysis of the impact of military operations on alternative sources producers

In 2022, as a result of the military invasion, some of the alternative generation facilities were destroyed, damaged, or landed in occupied territories. Thus, the vast majority of renewable energy facilities currently installed in the country are located in the southern and southeastern regions of Ukraine, where active combat operations have being taken place in the last six months. According to various expert estimates, as of August 2022, 30-40% of RES in these regions has already been affected in one way or another [20].

For example, according to the Ukrainian Wind Energy Association, more than three-quarters of Ukraine's wind energy capacity has been shut down since the war began, and five wind turbines in the Kherson region installed at the wind farms in Myrne, Siva, and Novotroitsky have been destroyed now. Due to the damage of 330 kW of power transmission lines in Melitopol, almost 600 MW of wind power capacities in Zaporizhzhya region are also out of service. More than 1 MW of bioenergy capacity in Chernihiv was damaged, while bioenergy plants with total capacity of 2 MW are located in occupied areas of Donetsk region, namely in Volnovakha and Mariupol.

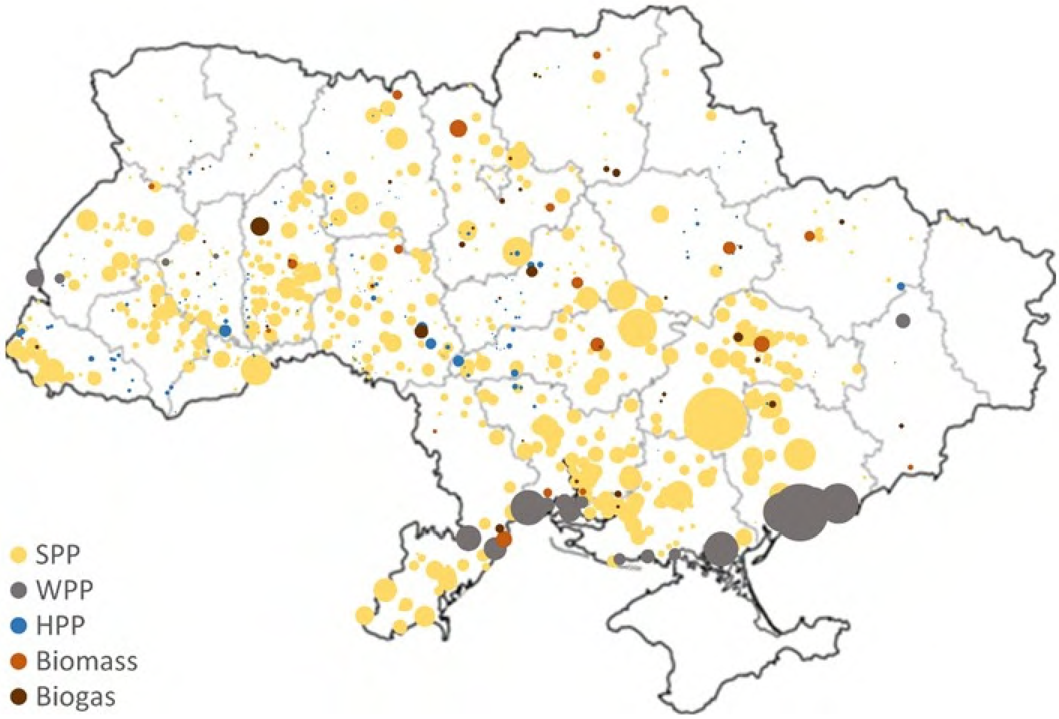

Figure 5. Distribution of installed capacities of operating alternative generation stations connected to distribution networks in 2021.

Fortunately, the small hydroelectric power plants, located mainly in the western regions of Ukraine, were not affected by the hostilities and continue to supply electricity [20].

As shown in figure 6, as of July 2022, 6828 MW of operating stations were connected to the United Energy System of Ukraine, of which 88% were SPPs, 7% were WPPs, and 5% were energy stations generating electricity from other sources. 660 MW of solar power plants in Dnipro, Lviv, Mykolaiv, and Khmelnytsky regions remained connected to the high-voltage network, which makes up 10% of all capacities of RES producers. The structure of stations connected to distribution networks is as follows: 5358 MW – SPPs, 476 MW – WPPs, and 334 MW – others.

Overall, wind and solar power generation has declined by more than half from pre-war levels. The following factors may serve as explanations: first, the destruction of power generation as a result of direct hostilities; second, the increasing problems related to the destruction of demand and the high inflexibility of power generation, especially solar power generation, considering that the cumulative capacity of solar power generation has currently exceeded 6 GW; and third, problems related to damage to energy infrastructure – networks, substations, etc. – will increase.

At the same time, the financial crisis in the RES market is deepening and the percentage of payment under the "green"tariff is decreasing. According to SE "Guaranteed Buyer" – as of December 26th, 2022 – the overall level of settlements with RES producers for the supplied electricity in 2021 was 99%, while in 2022 this indicator is 53.5% [21].

4. The directions of the post-war reconstruction of the RES producers

Renewable energy is one of the components of Ukraine's energy independence. Their potential can be used to create new jobs, boost the economic activity of regions, and renew outdated main production facilities in the power industry. Currently, the only mechanism to promote the development of RES in Ukraine is the "green"tariff – a special tariff for the purchase of

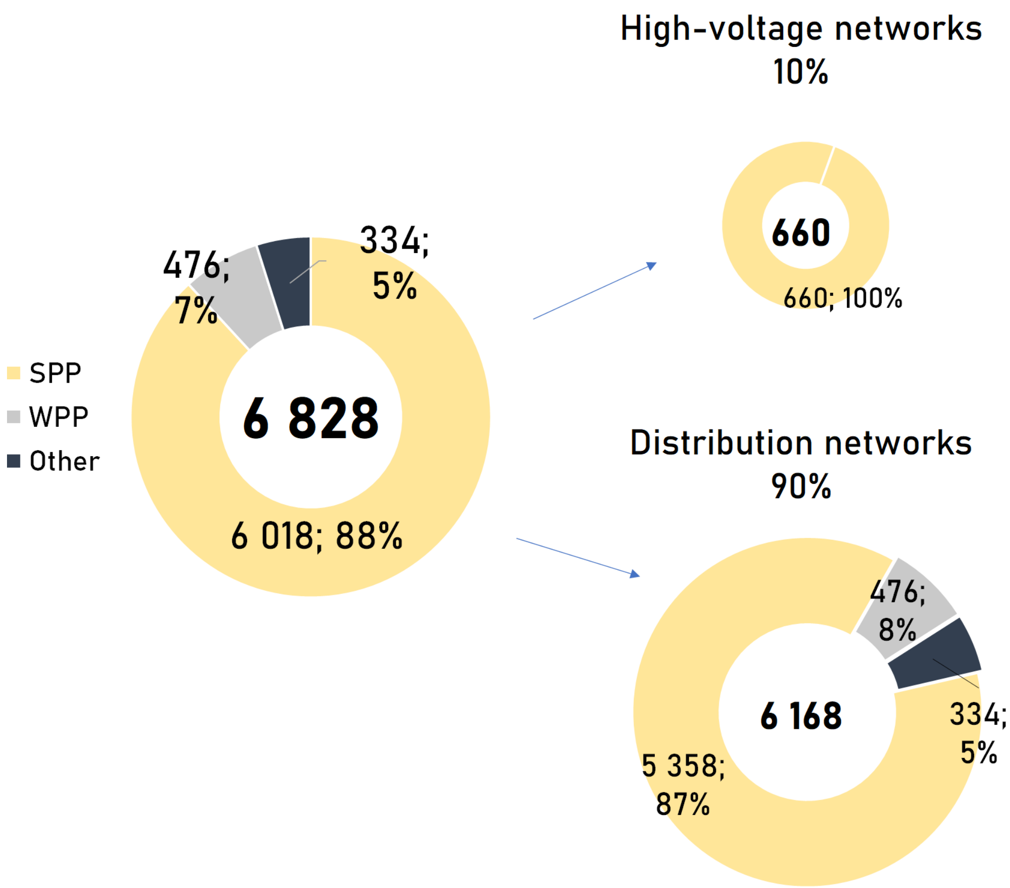

Figure 6. Distribution of installed capacities of operating alternative generation stations by sources of alternative energy and connection to power transmission networks in July 2022, MW.

electricity from RES. The implementation of this mechanism is carried out by SE "Guaranteed Buyer", which is obliged to purchase all electric energy from RES generators at a special tariff on the basis of the Law on the Electric Energy Market [3] adopted in 2017. Since March 2022, a number of legislative changes were introduced, which significantly changed the "green"tariff (in particular, the peg to the euro was removed), the conditions and the mechanism of payments were changed as well. As mentioned above, the state's debt to producers under the "green"tariff increased significantly due to the military actions. Therefore, the question arises whether the state will be able to support such a mechanism in the future. Therefore, it is extremely important and urgent to find new mechanisms and ways to develop RES producers.

According to the Ten-Year Plan for Reconstruction of Ukraine [22], published by the National Council for Reconstruction of Ukraine after the consequences of war and presented for the first time at the URC 2022 (Ukraine Recovery Conference) on July 4-5, 2022 in Lugano, Switzerland, the main directions of development of the Ukrainian energy industry are defined as follows:

- Integration with the energy systems of EU countries;
- Decarbonization;
- Optimization of the energy mix and balancing of the energy system;
- Increase of energy efficiency.

In particular, the Plan presents the project of the National Program "Energy Independence and Green Course" [23], which includes points such as the construction of an additional 30 GW of RES and batteries, the construction of smart grids.

As the research shows, 90% of the capacities of producers from alternative sources are connected to distribution networks. Therefore, the development of renewable energy is one of the important points on the way to a decentralized energy system. Also, the government proposes to provide "mini power plants and small generation facilities that will be integrated into the existing power grid" [24]. In particular, the development of distributed generation will provide energy independence and an increase in the security of energy supply to the communities of Ukraine.

Another step towards the development of distributed generation and the development of RES is the introduction of virtual power plants. A virtual power plant is a high-tech system that combines electricity from several producers and consumers at once. Producers in this case can be distributed generation facilities. Consumers are electricity consumers who have refrigeration units, air conditioners, drainage pumps, crushing units, etc. It should be noted that such objects of consumers and producers must be flexible in the production or consumption of electricity. The virtual power plant does not intervene directly in the production process. It regulates facilities that provide support to the power system when the balance between production and consumption is disturbed.

In addition, the concept of creating a cellular energy network (CEN) is being considered for territorial associations [25]. CEN is a set of energy generation and storage centers connected to each other and to consumption centers in a given area.

Considering the experience of the development of RES, i.e., the spread of such facilities throughout the territory of Ukraine, it is reasonable to take into account the available data when studying the above approaches to the development of the national power industry. At the same time, the implementation of these ideas can be one of the methods of support and development of RES producers. Therefore, the approaches of decentralization of the power supply system or creation of a power supply system are promising for solving some consequences of military aggression on the territory of Ukraine and require further research.

5. Conclusions

The analysis of the dynamics of renewable energy development in Ukraine in recent years was carried out, taking into account the specifics of connecting plants to high-voltage or distribution networks. Also, the research shows the distribution of the capacities of RES facilities in the regions of Ukraine.

As a result of Russia's armed aggression, the power industry of Ukraine in general, and more than 1000 MW of RES capacity in particular, need restoration. At the same time, the existing methods of supporting RES producers are insufficient. Renewable energy needs new mechanisms and methods of development of the industry.

One direction for the evolution of the domestic power industry is the development of a decentralized energy system to provide energy independence and security for the citizens of Ukraine. The results of research show that about 90% of generation capacities are connected to distribution networks and only 10% to high-voltage networks. Accordingly, renewable energy is an important part of the distribution network.

Therefore, the issues of supporting alternative generation and the development of distributed generation are interrelated, mutually complementary, relevant, and require further research.

Abstract. The relentless penetration of information and communication systems into all spheres of life and the widespread use of digital technologies has been called "digital transformation". Different systems demonstrate a different ability to effectively resist risks of any origin and nature, adapt to changes in the environment, maintain rapid recovery and return to maximally stable functioning. Such properties are generally called resilience. If these properties are acquired or enhanced through the use, application and development of digital technologies, we call them digital resilience. To analyze digital resilience, it is suggested to consider digital subscribers, digital needs, digital tools and their dependencies. Practical examples of such dependencies are given, which are formed under the influence of systematic missile attacks of the aggressor on the power energy system of Ukraine. The foundation was laid for a combined digital resilience assessment methodology that includes a metric approach and the theory of topological spaces.

1. Introduction

A society is being transformed to help individuals and communities use knowledge and ideas that help people realize their potential and realize their aspirations [1]. Digital transformation is a characteristic feature of a digital society whose economy is based on information technologies. The semantic field of digital transformation includes such concepts as the digital economy, digital skills, digital rights, e-government, digital innovations and much more. The digital component of existence acquires significant value and becomes an object of attack. The one's ability to resist a direct or indirect impact on the digital component of their being is known as "digital resilience". By the ability to resist, we mean the dynamic property of the individual or a system, which is embedded in its organization (functional scheme) and which serves as the basis for the ability to overcome negative impacts arising from risks, as shown on figure 1 and well-explained in [2]. Digital resilience characterizes how successfully and constructively one overcomes challenges of any origin and nature, adapts to changes in the environment, maintains stable functioning, quickly recovers to the desired balance and evolves after crisis situations based on the use, application and development of digital technologies. Digital resilience can be a property of an individuals, communities, businesses, society, the state as a whole. It is subject to analysis, measurement and improvement. In [3] authors describe the role of digital social support, digital health, and digital identities in the process of adjusting to a new reality for refugees.

Thus, much attention is spent to the resilience of cyber systems. For example, in [4] authors describe resilience metrics which link national policy goals to specific system measures,

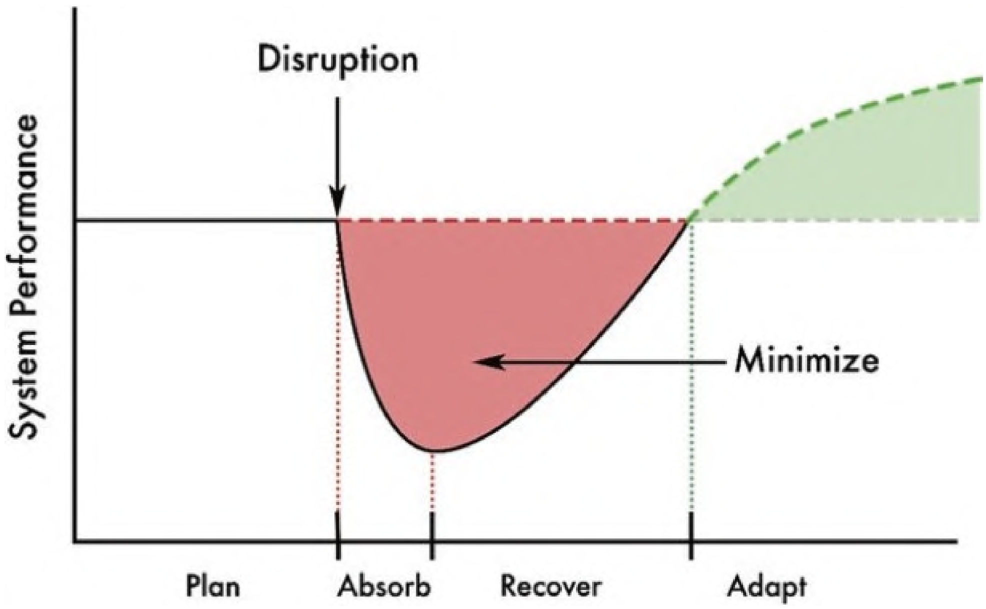

Figure 1. Stages of resilience according to National Academy of Sciences proposal.

such that resource allocation decisions. Being cyber-physical systems, power energy grids have mutual dependencies of their resilience and resilience of both electronic communications and information systems. Clark and Zonouz [5] are noted that resilience of is based on the assumption that a sophisticated intrusion may succeed to evade the deployed protection and runtime detection mechanisms and impact the underlying system services and assets excepting the core functionalities. Based on power systems case study, authors formulate cyber defense policies that ensure the resilience conditions are satisfied.

The experience of Ukraine is extremely valuable for the study of digital resilience. Ukraine is a state that was among the leaders of digital transformation before the large-scale Russian invasion. Unprecedented missile attacks on the main facilities of the power industry lead to massive emergency power outages, which are controlled by the enormous efforts of power network operators. Businesses, telecommunications operators and the general population are trying to adapt to the continuously declining level of electricity supply.

Currently, Ukraine is in transition: instead of scheduled power outages for several hours a day, scheduled inclusions for several hours a day are introduced. In December, 2022 multi-day outages took place. Each business and each household must constantly review their survival options during the growing impact of this negative factor, which directly brings us to the need for resilience analysis. In our opinion, science should contribute to the development of mechanisms for absorption of negative impact, adaptation to the new state and evolution of information and communication systems. This requires the collection, analysis, and systematization of existing experience (especially sectoral) in order to reduce the number of trials and errors in the future when creating resilient information and communication systems in conditions of limitations and uncertainties.

2. Research aim and methodology

To develop methods of increasing the resilience of information and communication systems to threats related to the electric power industry, the following tasks must be solved:

- investigate the most sensitive digital needs of digital subscribers;

- analyze the cyber threats that large-scale power outages pose and how they affect digital needs;
- analyze network architectures, types of electronic communications, data transmission systems, topologies, and determine which combinations can increase the resilience of information and communication systems (ICS) involved in providing the most sensitive information needs of the population and business.

As a result of the analysis, sets of digital subscribers – DS, digital needs – DN, and digital means (or digital tools) – DT will be obtained as depicted on Figure 2. These three sets will form a variety of tuples of three elements each $(ds \in DS, dn \in DN, dt \in DT)$, as well as from two elements based on existing and available combinations:

(i) digital subscriber and one's needs: $(ds \in DS, (dn_1, dn_2, dn_3, ..., dn_n) \in DN)$;

(ii) digital subscriber and available digital means$(ds \in DS, (dt_1, dt_2, dt_3, ..., dt_n) \in DT)$;

(iii) digital needs and acceptable digital means for obtaining them $(dn \in DN, (dt_1, dt_2, dt_3, ..., dt_n) \in DT)$;

(iv) digital means and subscribers that can use them $(dt \in DT, (ds_1, ds_2, ds_3, ..., ds_n) \in DS)$;

and this list is not final.

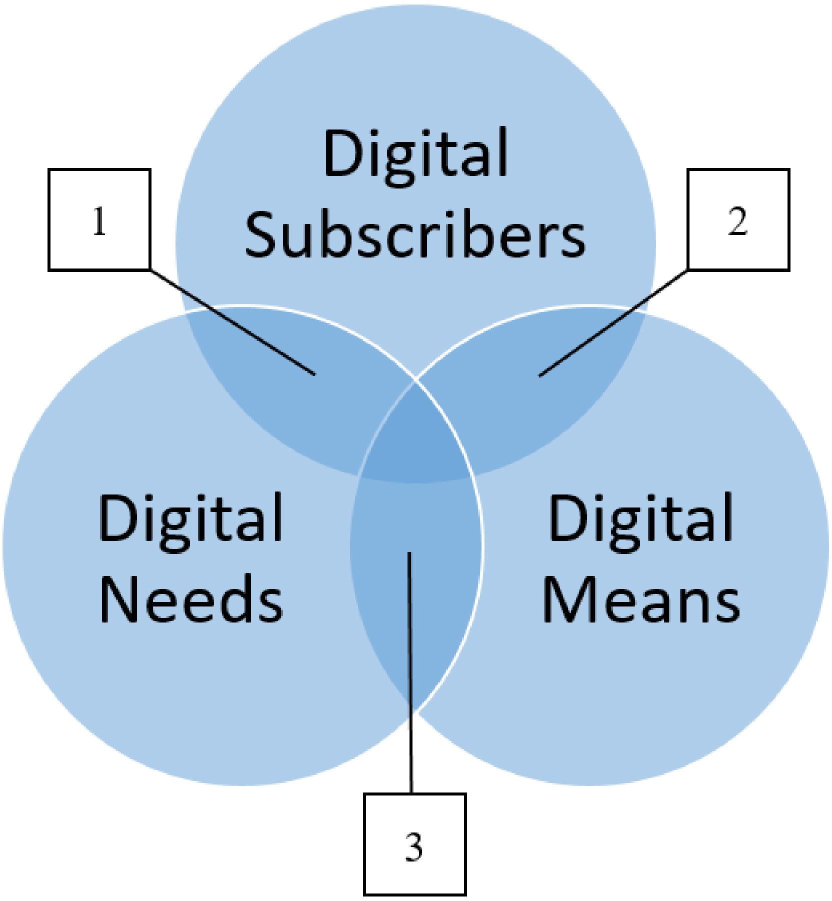

Figure 2. Overlapping sets create tuples: 1 – digital subscriber and one's digital needs; 2 – digital subscriber and available digital means; 3 – digital needs and acceptable digital means for obtaining them.

Let there exist a set $\mathfrak{D}$ such that $\forall ds \in \mathfrak{D}, \forall dn \in \mathfrak{D}, and\ \forall dt \in \mathfrak{D}$. Let there exist a system of elements of this set $\mathfrak{T}$, which includes all possible combinations of these elements, unions and intersections of these sets: $\exists \mathfrak{T} : \emptyset, \mathfrak{D} \in \mathfrak{T}; \forall \mathfrak{D}', \mathfrak{D}'' \in \mathfrak{T} : \mathfrak{D}' \cup \mathfrak{D}'' \in \mathfrak{T}; \mathfrak{D}' \cap \mathfrak{D}'' \in \mathfrak{T}$.

Then $\mathfrak{T}$ corresponds to the definition of topology on the set $\mathfrak{D}$, and a couple $(\mathfrak{T}, \mathfrak{D})$ corresponds to the definition of topological space. Individual elements of the topology represent network structures [6], that can be researched using graph theory, complex network theory, and topological space theory to develop models and methods for enhancing digital resilience.

Let's look inside of those structures. For the operation of an ordinary business, for example, a chain of retail stores, the local ICS of each store, the ICS of the head office, usually the ICS of the operator of the datacenter where ERP system resides, and several more ICSs belonging to the operators of electronic communications may be involved (modern data transmission systems are mostly convergent [7], and therefore have their own information communication systems). The functioning of the mass media (including broadcasting systems), state information services for the society, transport, healthcare, education are connected with ICS. It is also important to realize the main role of ICS in personal communication and the possibility of being in touch. First of all it's about global software platforms of instant messengers and social networks. These examples testify to the existence of an open set of cyber-social systems, the functioning of which is a component of the resilience of the entire society.

In the vast majority of cyber-social systems, the user gets access to digital services via the Internet. Therefore, sufficient connectivity and bandwidth of the global network is the most important factor in the stability of ICS, and therefore in digital resilience. Thus, the availability of Internet access is the most important factor of information security, which affects the availability of information.

3. Examining examples of dependencies between power grid and digital resilience

The Ukrainian power energy industry is unique in Europe due to the presence of a large transport system with nodes whose capacity reaches 3 GVA, as well as unique 750 KV transformers which are custom design equipment. However, these main nodes are the easiest prey to the enemy due to missile terror (figure 3).

Massive Russian terrorist missile attacks on Ukraine's electricity industry lead to massive blackouts that are difficult for power grid operators to control. One of the major missile attacks led to a blackout of the country's entire power grid for 12 hours [9]. Degradation of electricity supply goes through several stages. At the end of November 2022, instead of planned power outages (for several hours per day), planned power-ups for several hours per day were introduced, as shown on figure 4. By weekdays in rows, we can see darkest cells representing planned outages, gray ones show possible outages in case of overloads in the energy system, and pairs of bright cells mark hours of guaranteed provision of power. In fact, the schedule is rarely followed.

Russia widely uses a variety of munitions: from cheap Iranian barrage munitions (Shahed 136 drones) to complex hypersonic missiles of great destructive power. Despite the huge successes of the air defense of Ukraine, during each massive enemy strike, several munitions reach the target, causing new destruction to the energy system [10]. In the future, new missile attacks and regular multi-day outages are expected. This is a real test for the modern digital society based on information technologies and electronic communications.

Figure 5 shows a generalized individual-centric digital chain that connects a digital actor with a set of digital needs using a set of digital means. As we can see, the key element of digital resilience is the means of electronic communications (dt set). The initial element of digital resilience is the digital subscriber (dt set) – consumer of digital services. This is either an individual or a legal entity, the needs of which vary, and the availability of tools for them is also slightly different.

The risks associated with the lack of electricity power affect all elements without exception,

Figure 3. Power autotransformer destroyed by missile strike in Rivne region [8].

but not to the same extent. Let's consider what lessons Ukraine learned during the last few months of 2022.

3.1. Problems on the subscriber's side

The main component that an individual needs to meet digital needs is the electrical power supply of one's office or home or other place where private information communication systems reside. The majority of Ukrainians live in apartment buildings, they have no redundant power supplement systems or local generation facilities. To cover multi-hour power outages, private individuals and small offices massively purchase or construct *uninterruptible power supplies* (UPS). Typical UPS models for home or small office not designed for long-term autonomous operation. Their batteries designed to provide electric current for a maximum of tens of minutes. The use of non-standard batteries of large capacity leads to overheating the UPS both during long-term autonomous operation and during charging of such enormous batteries. Ignoring this danger could result in battery explosion and fire.

The use of systems based on *car batteries* has also gained popularity. Car starter batteries proved to be ineffective as a source of long-term supply of electric current. This is related to the chemical properties of acid batteries. They are prone to sulfation during deep discharge, so they can relatively reliably deliver only 0.3 part of their nominal capacity. In addition, their presence and use indoors causes additional safety problems due to the evaporation of harmful substances from the battery [11].

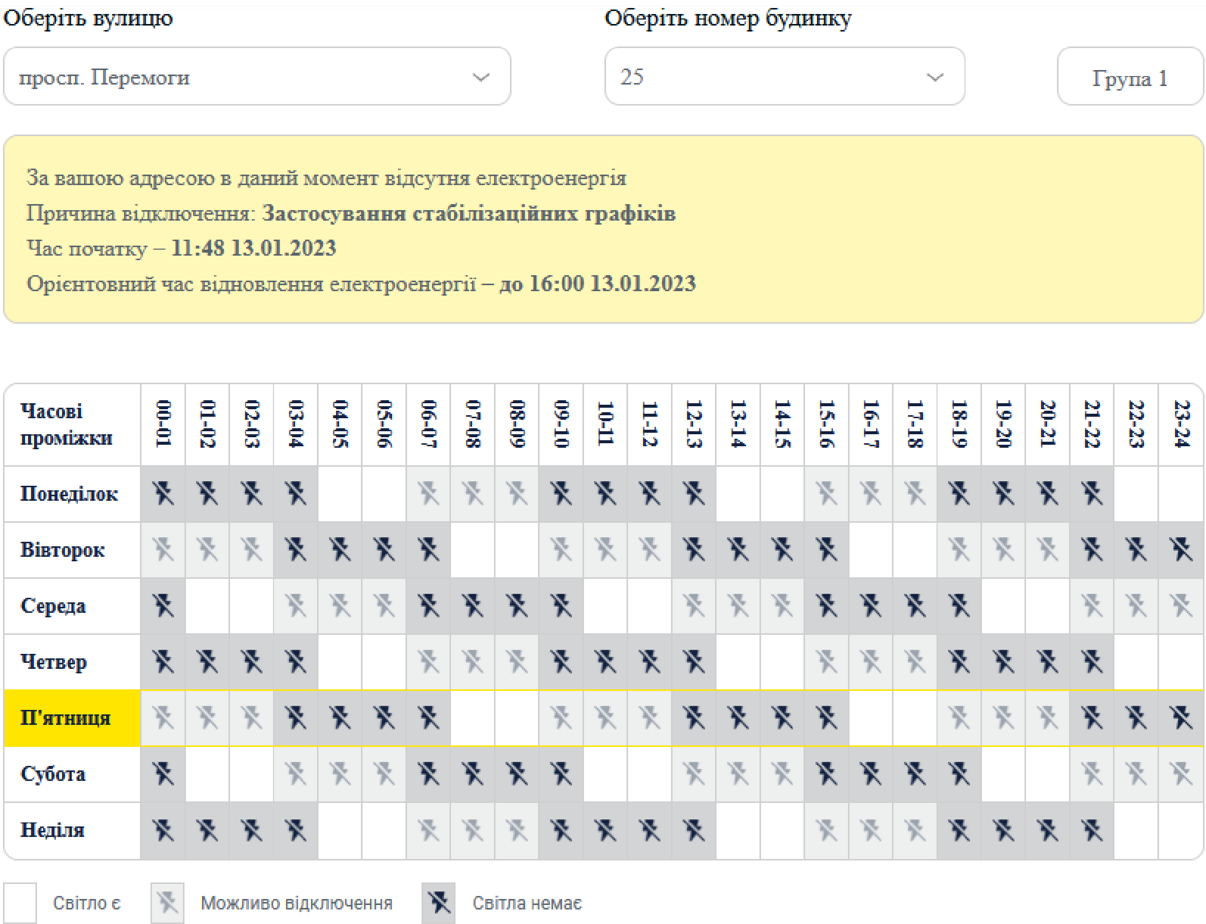

Figure 4. The real-life schedule of planned and emergency power outages for average district of the Kyiv city introduced by power distribution company DTEK (`https://dtek-kem.com.ua`).

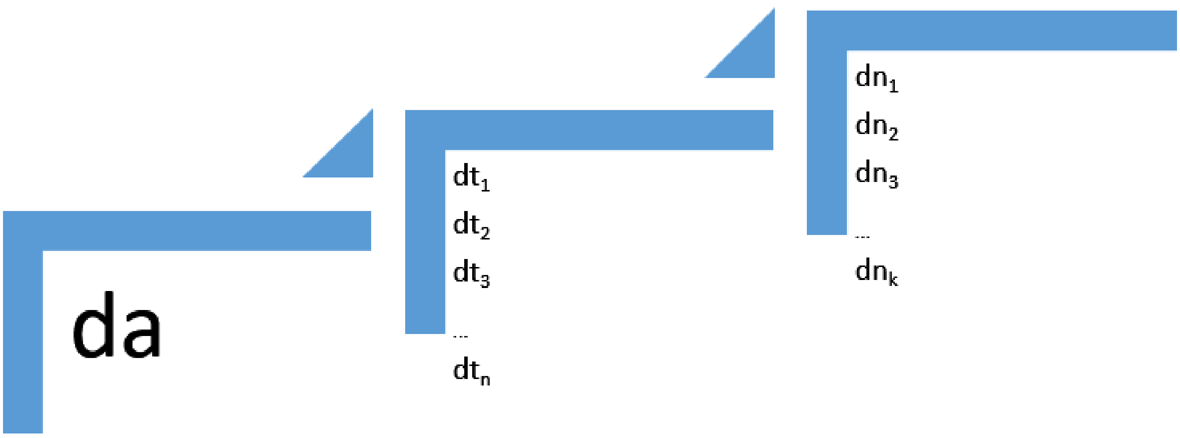

Figure 5. Generalized "digital chain" from digital actor to digital needs.

The use of *specialized low-power UPS* for individual devices, primarily for home wireless routers, has become popular. This makes sense if the local Internet provider has ensured the operation of its network during continuous power outages. The issue of Internet providers will be discussed below. In terms of human safety, this is a very attractive solution. But it turned out that in the mode of long-term power outages, accelerated degradation of batteries of all main types occurs.

Attempts to use alternative generation (primarily *solar generation*) cause many purely technological difficulties. Residents of individual apartments who are able to place solar panels on the outside and face south can count on partial success. But Russians began their missile terror against critical civil infrastructure in mid-autumn, when the duration of daylight shortens and cloudy days increase. Therefore, the effectiveness of the panels until spring will be very low, even for the lucky ones. Solar panels should be centrally located on the roofs of high-rise buildings. It is clear that such a solution requires large project works at the level of the entire building, not a separate apartment.

The use of *generators based on gasoline or diesel engines* requires major decisions at the level of entire buildings. There are strict sanitary and fire regulations for the installation and operation of such generators. In addition, there is a significant problem of legal storage of fuel stocks, since in Ukraine this type of activity requires obtaining a license.

The use of *mobile Internet* by end users is the most popular. There are two main factors. First is that mobile Internet access in Ukraine is cheap comparing to Europe. Besides, after declaration of martial law mobile operators opened a free roaming between their networks. Second factor is that end mobile devices (4G modems, smartphones, tablets, laptops, POS terminals) have their own batteries, which can be additionally recharged from pocket power banks. However the operators' networks are affected by problems which will be described below.

3.2. Problems of the access to digital needs

Problems of the access to digital needs are mostly related to problems of architecture and topology of local Internet access provider networks. Let's review a few most common ones.

Ethernet – the main technology for Internet access in high-rise buildings. UTP cable and fiber optics are used. A typical network is divided into 2 or 3 layers – core, distribution and access. While the core layer equipment is always located in places with redundant power supplement, the equipment of other layers is closer to subscribers and much more suffers power outages. These are Ethernet switches serving the connection for several apartments (typically from 16 to 48). An attempt to provide them with large-capacity batteries ran into problems of rapid degradation of batteries due to long power outages and insufficient charge as a result. The use of the most modern type of LiFePo4 batteries with charge controllers of the appropriate power has not yet been widely introduced due to the high cost of these devices and insufficient saturation of market [12].

DOCSIS – another "last mile access" technology widely used in Ukrainian cities. DOCSIS is based on the use of coaxial cable (HFC), which used to branch out the terrestrial television signal. The architecture is shown in figure 6 and provides for the presence of a cable management telecommunication system (CMTS) per group of subscribers, as well as repeaters (amplifiers). All these devices require power supply. According to the reviews of users of the operator Volia Cable in Kyiv, this operator does not have any particular advantages in network stability in time of continuous power outages.

ADSL is a technology based on the use of a physical landline telephone network (plain old telephone service). This is a legacy technology for Ukraine, which, however, is still widespread in the developed countries of Europe [13]. Its attractiveness is that the network uses rather long last miles (up to several kilometers) without repeaters, and the operator's equipment is located next to the PSTN (telephone stations), which is always a priority consumer in the power grid and is provided with backup power as critical infrastructure. The main disadvantage of ADSL is the limited speed (usually up to 3 Mbps upstream, and 8 to 20 Mbps downstream). Many Ukrainian Internet users would prefer to return to this technology due to the inability of other

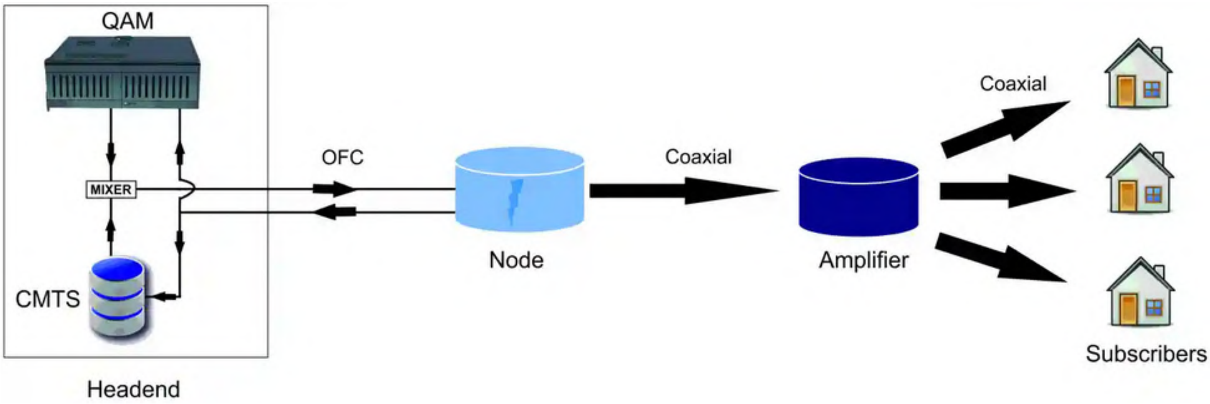

Figure 6. DOCSIS topology requires CMTS at provider's site and amplifiers at customers' buildings to be supported by uninterruptible power supplies.

providers to support networks. But it turned out that in the course of the gradual degradation of landline telephone communication, the infrastructure of copper cables is often broken and destroyed.

Passive optical networks, known as PON, is a widely known and efficient optical network architecture. Its main advantage is coverage of the widest range of subscribers using the minimum number of ports on the operator's side. This achieved by using totally passive devices called optical splitters for creating mixed tree topology, as shown on figure 7. So only optical line units (OLT) at provider's side and optical network terminals (ONT) at subscriber's side require power supply.

The problem with PON is that it is a relatively new technology. It is widely used to build new broadband Internet access networks, while the main urban networks are result of merges and acquisitions of small networks of past and keep growing on old technologies. At the moment, old networks are already physically interfering with the laying of new communications. The process of abandoning Ethernet and DOCSIS will obviously continue for many years.

Mobile (cellular) networks also suffer from power outages. 3G and 4G technologies require a high density of base stations from operators. Their location mostly does not provide for the possibility of using backup generators, and their power excludes the possibility of long-term operation from batteries. In the city of Kyiv, operator networks can be overloaded during power outages, especially in uptowns and suburbs, where the density of base stations is lower. According to the adopted decisions, the mobile operators consider the provision of voice communication as a priority service. Other services may degrade to the level of 20 percent of the nominal [15].

A review of access technologies would be incomplete without *satellite systems*. The use of a fixed or mobile satellite Internet system is also gaining popularity. Several satellite operators do their business in Ukraine. But above all, the leader is Starlink. The supply of Starlink terminals takes place under several international programs at the expense of the state budget of Ukraine, international partners and sponsors. In addition, a significant number of Starlink terminals were purchased by private consumers [16]. The advantages of such a solution are independence from local networks and operators, relative connection reliability and bandwidth which fully meets the needs of a private user or, with some restrictions, a group of consumers. The disadvantages are that in cities with high-rise buildings, users have a problem with the location of antennas (figure 8) and their power supply at the level of a particular residence. Solving problems requires centralized solutions, but Starlink terminals have proprietary limitations that require significant costs to obtain the possibility of collective use of the station for the benefit of several consumers

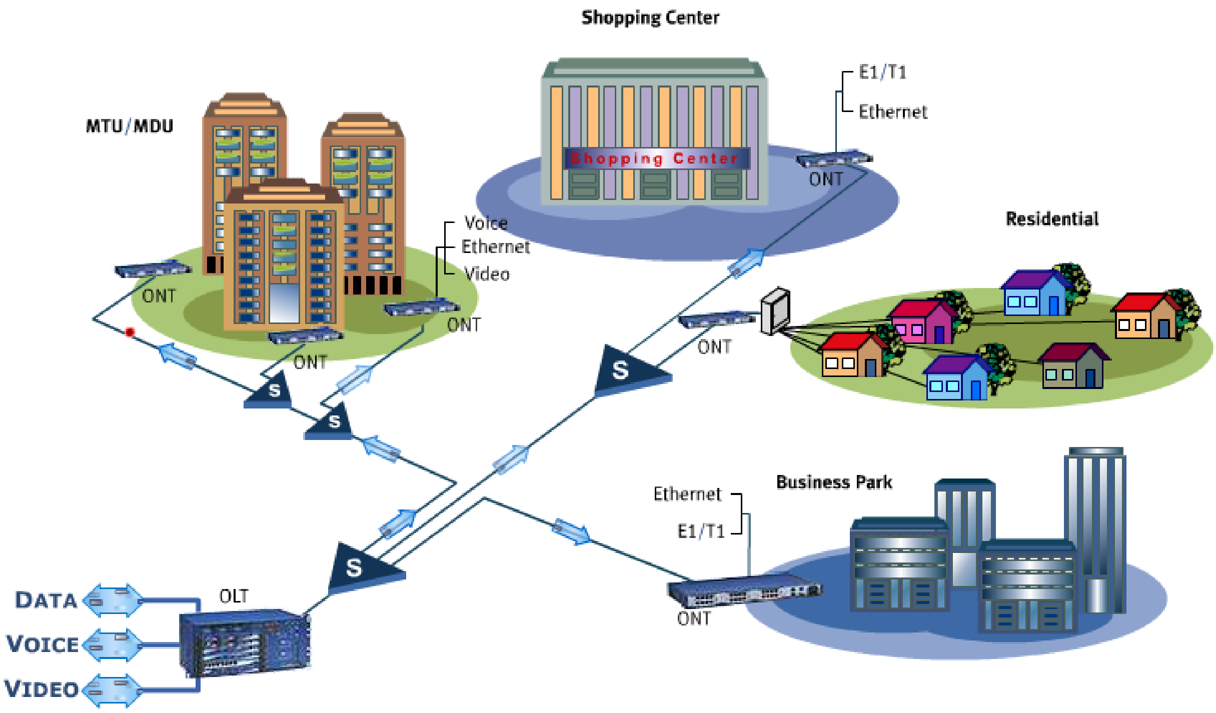

Figure 7. In Passive Optical Network topology passive optical splitters (S) are widely used. Optical line units (OLT) at provider's side and optical network terminals (ONT) at subscriber's side require power supply [14],

Figure 8. Examples of antenna installation of Starlink stations in cities of Ukraine (photo by `https://highload.today`).

(several apartments or offices).

Also worth noting that Ukraine has widely announced the deployment of so-called "*Invincibility points*", designed to provide heating, hot drinks, electricity for charging private devices and, in some places, Internet access. The following structural elements are necessary for the successful functioning of "Invincibility point":

- professional electric generator capable of working continuously for a long time (which is not provided by widespread household gasoline generators). Its output power capacity must correspond to the expected electricity consumption;
- structured cable system for the possibility of safely connecting several dozen devices with lithium batteries. For instance, the charge of a modern laptop consumes up to 65W, connecting 50-100 laptops requires a serious attitude to the cable system and load calculation;
- reliable Internet access, taking into account the features of operator technologies, which were observed above;
- professional equipment for building a Wi-Fi network capable of serving dozens and hundreds of devices at the same time (home Wi-Fi routers and access points are not suitable for this).

The practical experience of the city of Kyiv is that the premises of catering establishments, schools, etc. receive the status of "Invincibility points". Figure 9 demonstrates this. Each institution independently solves the problems of heating, energy, sanitary requirements, access to the Internet. "Invincibility points" are effective from the point of view of digital resilience, but their impact cannot be called significant.

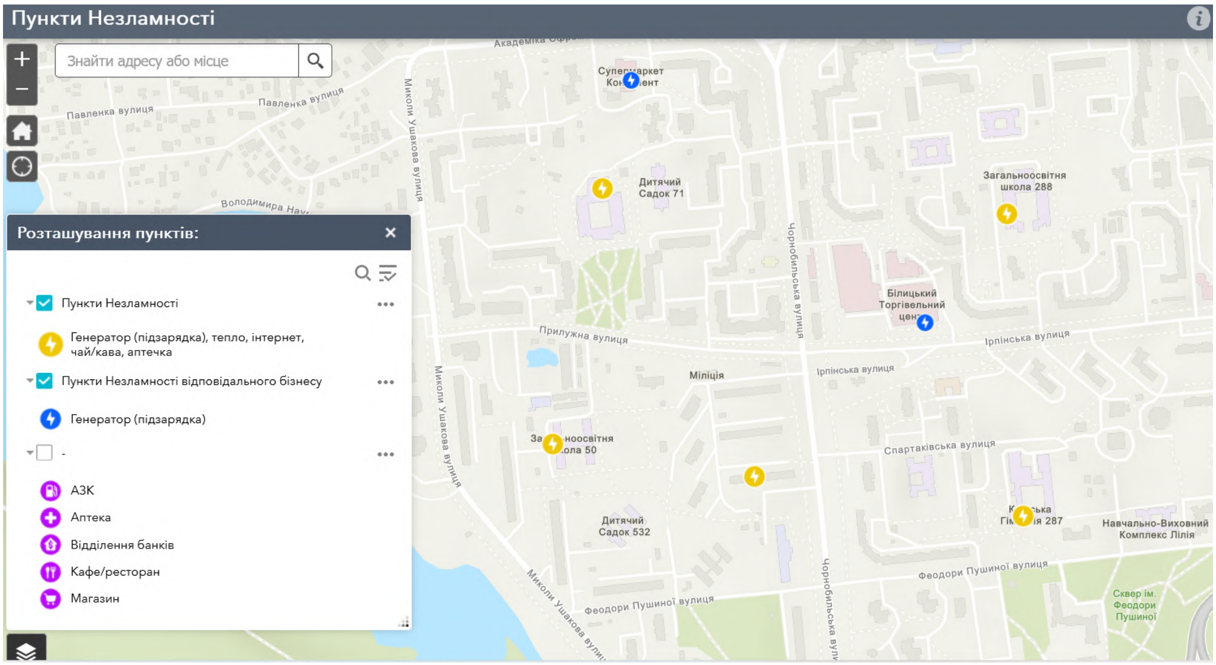

Figure 9. Map of Invincibility points in random Kyiv uptown district with population 45..60 thousand residents. Blue signs point to local stores and tell there is only charging available. Yellow signs mean that Internet access and hot drinks also available, and they point to school buildings and one social services office [17].

3.3. Generalization of the given examples

According to the proposed classification, the chain from a digital subscriber to a digital need at the very initial stage contains a large number of options for ensuring the digital resilience of the subscriber itself and their means. Each digital tool can be analyzed and compared with others that provide a similar result. This can be, for example, a SWOT analysis. But to generalize the result, the most promising is the development of metrics that characterize the most effective resilience tools, based on their availability, cost, time of implementation, reliability and other properties. Such metric approach approved by many researchers, e.g. Linkov et al [4] and Clark and Zonouz [5]. Whereas this approach was applied for evaluation of most secure paths combination in [18], it was combined with risk management theory applied to global network topology. Such risk-aware metrics can be also introduced to evaluation of digital resilience. For this purpose, we offer to review each property of a digital tool as a component of risk, either a factor of cost or factor of likelihood. For example, let's define some of properties for digital tools as discrete:

- cost c_{dt} – how much does it cost to get this digital tool and use it;
- accessibility a_{dt} – implementation agility, or how easy it is to access this tool (or switch to this tool);
- reliability r_{dt} – a measure of the ability to perform the required functions in the given modes and conditions of this tool's use;
- power autonomy p_{dt} – how much independent this tool is from power outages in comparison to other functionally equivalent digital tools.

Then it's possible to evaluate digital resilience $\mathfrak{R}$ for an average household digital tools, which include redundant power supplies (dt_1), diversified Internet access providers (dt_2), personal awareness how to alternate power source for Internet access equipment (dt_2) and so on:

$$\mathfrak{R} = f(dt_1, dt_2, dt_3, ...dt_n),$$

where dt_n is tied to $(c_{dt}, a_{dt}, r_{dt}, p_{dt})$ in a some way which should be analysed and formalized on future steps of this study.

Similar considerations can be made when analyzing network providers, and data centers, and each element of the entire chain between the consumer and the service. This leads us to generalisation of metric evaluation of digital resilience.

4. Conclusions

Representation of individual components of the digital world in the form of a topological space opens the way to the study of the problem of digital resilience through the study of group properties, characteristics, dynamics of a large number of network structures.

In the future, the study provides an analysis of means and measures to ensure the resilience of digital service providers (from online stores to large data centers) during the crisis of the electric power industry. In addition, it is necessary to develop metrics that characterize the effectiveness of resilience tools, based on their availability, cost, implementation agility, reliability and other criteria.

Abstract. In the materials of the article, the parameters of the higher harmonics of the groove frequency are analyzed, which affect the reliability of the operation of electrical equipment and the loss of electrical energy in active-adaptive networks. The influence of higher harmonics of rotary electric machines on the modes of operation of active-adaptive networks and their power equipment is considered. It was established that this influence depends on the energy level of higher harmonics and the modes of operation of active-adaptive networks. A technique is proposed that allows determining the levels of groove harmonic components in the phase windings of electric machines. The calculation of the energy level of higher harmonics was carried out taking into account the electromagnetic asymmetry of rotating electric machines and asymmetric modes of operation of three-phase electric networks using the method of phase coordinates. The obtained results are based on theoretical and experimental studies of the influence of higher harmonics of rotating electric machines on the modes of operation of electrical networks and power energy equipment.

1. Introduction

The quality of electrical energy significantly affects the reliability and efficiency of electrical networks and power equipment. One of the important indicators of the quality of electrical energy is the level of higher harmonics, which causes non-sinusoidal modes of operation of electrical networks [1, 2].

The nature of higher harmonics is diverse. The influence of higher harmonics of rotating electric machines (synchronous generator, asynchronous motor, etc.) on the operating modes of the electric network has not been sufficiently investigated. The relevance of this issue is increasing with the development of active-adaptive networks and the introduction of wind power plants [3, 4].

The theoretical and practical relevance of the problem of higher harmonics in electrical networks is confirmed by a number of publications, both by foreign [5, 6] and domestic specialists [7, 8].

Significant losses in power supply systems associated with low quality electrical energy require additional research into the nature of higher harmonics at industrial enterprises [9, 10]. The results of research into the nature of higher harmonics in power inverters and means of combating them are effectively implemented [11, 12]. Extensive theoretical and practical experience in the quality of energy resources is reflected in normative documents taking into account the European education for the electric power industry of our country.

Modern trends in the development of electrical networks, namely, the introduction of active-adaptive networks, introduce new aspects regarding the quality of electrical energy [13, 14]. This requires constant control of power quality parameters, and in particular the levels of higher harmonics, in real time [15, 16]. The study of the nature of individual harmonics is of significant practical importance. This is confirmed by the study of, for example, third (saturation of the magnetic circuit) and toothed harmonics, which appear as a result of the unevenness of the air gap of rotating electric machines [17, 18]. Therefore, the study of groove harmonics is relevant.

The purpose of the study is to obtain scientific results regarding the nature of groove harmonics of rotating electric machines and to establish the characteristics of their distribution in distribution electrical networks. To achieve the purpose, the following objectives were set:

- to develop a methodology for calculating currents and electromotive force of the groove frequency of rotary electric machines for active-adaptive networks;
- determine the dependences of the levels of groove harmonics of the electrical network.

2. Results

Higher harmonics of distribution electrical networks have a constructive or technological nature. Each harmonic component has one or more sources and a defined propagation space. The amplitude value of the higher harmonic and its flow paths are determined by the interaction of the inductive and capacitive elements of the electrical network. The most unpleasant case is the case of resonance of higher current or voltage harmonics in electrical networks and large enterprises. The manifestation in time determines the random or systematic nature of higher harmonics [19, 20].

In the process of operation, electric rotary machines generate groove harmonics in the electrical network [21, 22]. The appearance of these harmonics is related to the magnetomotive force of the rotor winding. Their frequency can be determined by the expression:

$$\omega_n = \omega_1 \cdot \left[\frac{z_n}{p} \cdot (1 - S) \pm 1\right], \tag{1}$$

where ω_1 is the cyclic frequency; z_n is the number of grooves on the rotor; p is the number of pairs of poles; S is the slip.

The amplitude value of these harmonics is determined by the design parameters of the electric machine and the network voltage. The significant danger of groove harmonics is caused by the dependence of these frequencies on the network frequency and slippage, which can lead to resonance phenomena [23, 24].

Determining the levels of higher harmonics by experimental removal of curves taking into account electromagnetic asymmetry on real electric machines is associated with a large amount of labor, due to the need to manufacture special calibration stands [25, 26].

Finding by calculation the values of higher harmonics corresponding to the maximum permissible asymmetry of the electric machine allows to avoid working with bulky calibration stands. In this case, only verification tests of several electric motors are required [27, 28].

The method of calculating the energy level of higher harmonics in the form of the sum of the squares of the electromotive force of the groove harmonics, taken when each of the three phases of the stator winding is turned off in sequence, is based on the determination of the dependence of magnetic losses from the groove harmonics of the magnetic field in the air gap on the degree of electromagnetic asymmetry [29, 30].

The energy level of the slot frequency induction harmonics characterizes the magnetic losses in steel from the slot order magnetic field. Specific magnetic losses in steel are determined by the expression:

$$P_{mg} = \varepsilon_g \cdot \frac{f}{50} \cdot B^2 + \sigma \cdot \left(\frac{f}{50}^2\right) \cdot B^2, \tag{2}$$

where P_{mg} is the specific magnetic losses in steel; ε_g is the specific losses from hysteresis at $f = 50$ Hz and $V = 1$ T; σ is the specific losses from eddy currents at $f = 50$ Hz and $V = 1$ T; B is the magnetic induction; f is the frequency of magnetic induction.

The specific magnetic losses in steel from the groove harmonics of induction are determined by the expression:

$$P_{mg} = \varepsilon_g \cdot \frac{f}{50} \cdot \frac{1}{2\pi \cdot T_z} \cdot \int_0^{2\pi}\int_0^{T_z} B_n^2(\varphi, t) d\varphi \cdot dt + \sigma \cdot \left(\frac{f_n}{50}\right)^2 \cdot \frac{1}{2\pi \cdot T_n} \cdot \int_0^{2\pi}\int_0^{T_n} B_n^2(\varphi, t) d\varphi \cdot dt, \tag{3}$$

where $f_n = \frac{\omega_n}{2\pi}$ is the electrical frequency of the groove harmonic of induction; $T_z = \frac{2\pi}{\omega_z}$ is the the period of the groove harmonic of the induction; $K_n = \varepsilon_g \cdot \frac{f_z}{50} + \sigma \cdot (\frac{f_n}{50})^2$ is the power loss factor; $B_n(\varphi, t)$ is the spatio-temporal distribution of magnetic field induction in a gap with electromagnetic asymmetry; ω_n is the angular frequency of the groove harmonic of induction (upper and lower).

Will find the specific magnetic losses from the upper slot harmonic of the induction with frequency $\omega_{up} = \omega_1 \cdot [\frac{z_n}{p} \cdot (1 - S) + 1]$ in the three-phase mode of operation, substituting the expression for the spatio-temporal distribution of the slot frequency induction for the three-phase mode:

$$P_{mgup} = K_n \cdot \frac{1}{2\pi \cdot T_n} \cdot \int_0^{2\pi}\int_0^{T_n} B_{up}^2(\varphi, t) d\varphi \cdot dt, \tag{4}$$

Integrating within the range from 0 to 2π and taking into account that for an even whole number, all components containing factors of the form $\sin k \cdot \pi \cdot (Z_1 \pm n)$, where k and n are the integers, obtain the final expression for specific magnetic losses from the upper slot frequency of induction, taking into account the spatial distribution of conductivity air gap with asymmetry and the obtained expressions for the coefficients of the series $\lambda_{\alpha 0}$ and λ_n :

$$P_{mgup} = \frac{1}{16} \cdot K_n \cdot (\lambda_0 \cdot \lambda_{j1} \cdot F_1)^2 \cdot \left(\frac{1}{2} \cdot \lambda_{\alpha 0}^2 + \frac{1}{4} \cdot \lambda_{\alpha 0}^2 + \lambda_{n1}^2 + \frac{1}{2} \cdot \lambda_{i1}^2 \cdot \lambda_{n1}^2\right), \tag{5}$$

In this expression $\frac{1}{2} \cdot \lambda_{\alpha 0}^2 + \lambda_{n1}^2 = K_{\alpha 1}$ there is a coefficient of losses due to magnetic asymmetry, taking into account only the first term of the series λ_n . According to mathematical transformations:

$$K_{\alpha 1} = \frac{8 - 2 \cdot a_m^2 - 8 \cdot \sqrt{1 - a_m^2}}{a_m^2 \cdot (1 - a_m^2)}, \tag{6}$$

where a_m is the coefficient of relative electromagnetic asymmetry.

Carrying out similar transformations taking into account the first two and three terms of the series, it is possible to obtain the corresponding coefficients $K_{\alpha 2}$ and $K_{\alpha 3}$, which refine the calculation:

$$K_{\alpha 2} = \frac{1}{2} \cdot \lambda_{\alpha 0}^2 + \lambda_{n1}^2 + \lambda_{n2}^2; \tag{7}$$

$$K_{\alpha 3} = \frac{1}{2} \cdot \lambda_{\alpha 0}^2 + \lambda_{n1}^2 + \lambda_{n2}^2 + \lambda_{n3}^2. \tag{8}$$

In the general case, taking into account all terms of the Fourier series, the expression for the specific magnetic losses from the upper slot frequency of induction will have the form:

$$P_{mgup} = \frac{1}{16} \cdot K_{\alpha n} \cdot (\lambda_0 \cdot \lambda_{j1} \cdot F_1)^2 \cdot \left(1 + \frac{1}{2} \cdot \lambda_{i1}^2\right) \cdot K_{\alpha n}, \tag{9}$$

where $K_{\alpha n}$ is the electromagnetic asymmetry coefficient taking into account the terms of the Fourier series λ_n.

$$K_{\alpha n} = \frac{1}{2} \cdot \lambda_{\alpha 0}^2 + \sum_{n=1}^{\infty} \lambda_n^2 = \frac{4}{1-a_m^2} \cdot \left[\frac{1}{2} + \sum_{n=1}^{\infty} \left(\frac{1-\sqrt{1-a_m^2}}{a_m}\right)^{2n}\right]. \tag{10}$$

Since at any values $0 < a_m < 1$ the values of the function $q = \left(\frac{1-\sqrt{1-a_m^2}}{a_m}\right)^2$ are also in the range from 0 to 1 (figure 1), the sum will have a finite value and the expression for $K_{\alpha n}$ in its final form will have the form:

$$K_{\alpha n} = \frac{4}{1-a_m^2} \cdot \left[\frac{1}{2} + \frac{1-\sqrt{1-a_m^2}}{a_m^2 - (1-\sqrt{1-a_m^2})^2}\right]. \tag{11}$$

Thus, the specific magnetic losses from the upper slot harmonic of the induction depend on the value of the relative electromagnetic asymmetry. The nature of this dependence is completely determined by the nature of the graph.

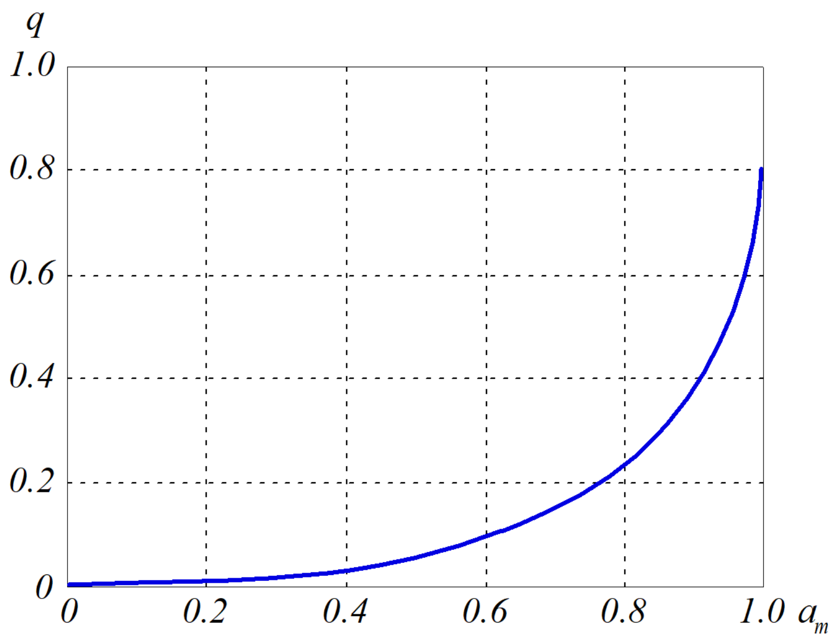

Figure 1. Range of function values $q = \left(\frac{1-\sqrt{1-a_m^2}}{a_m}\right)^2$.

When determining the losses by the coefficient $K_{\alpha n}$, taking into account only the first two members of the harmonic series λ_n the relative error of the calculation γ_n with an electromagnetic asymmetry of up to 50% does not exceed 2%, and then it begins to grow monotonically, and in the region of large asymmetry ($a_m = 80 + 90\%$) is 10 + 25% (figure 2).

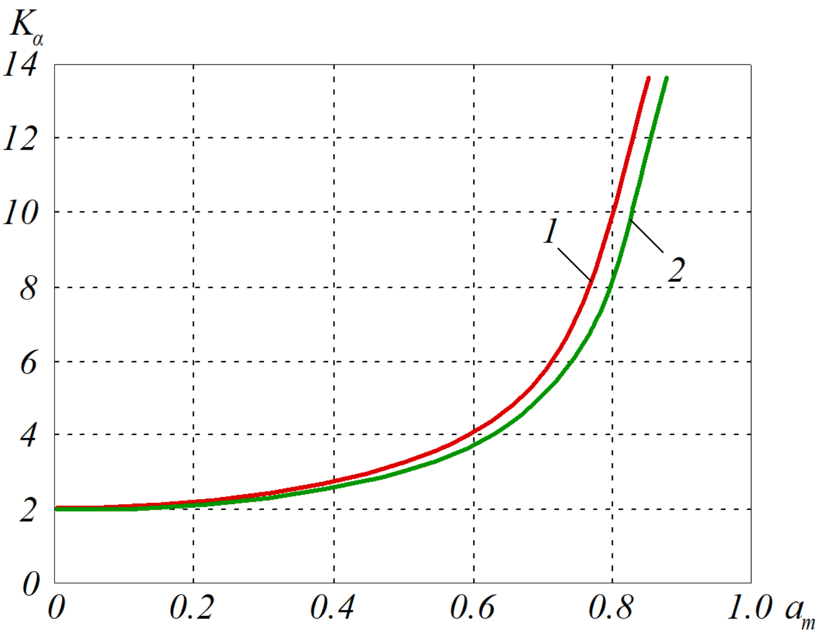

Figure 2. Dependence of magnetic loss increase coefficients on electromagnetic asymmetry: 1 – dependence $K_{\alpha n} = f(a_m)$;, 2 – dependence $K_{\alpha 1} = f(a_m)$.

Calculation of the third term of the harmonic series λ_n significantly increases the accuracy of the calculation. The error $\gamma_{\alpha 2}$ in determining losses by the coefficient $K_{\alpha 2}$ does not exceed 2% with asymmetry up to 80% and increases to 8 + 10% with an increase in electromagnetic asymmetry up to 90% (figure 3).

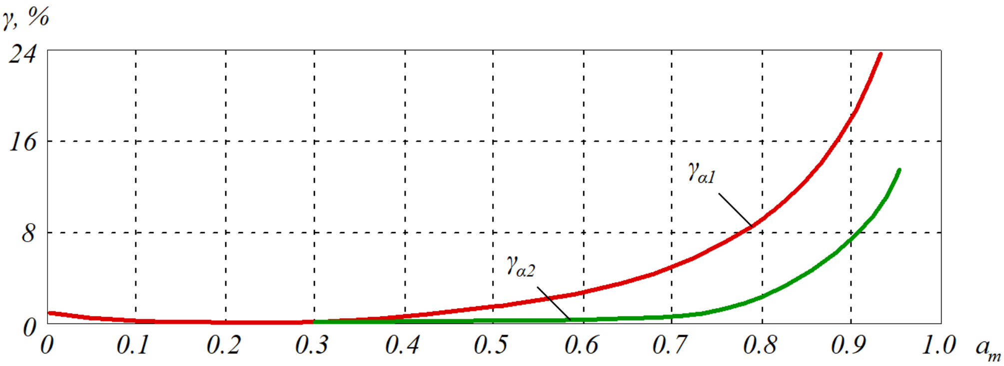

Figure 3. Change in the relative errors of the calculation of magnetic losses from groove harmonics of the field by coefficients.

Let us determine the specific magnetic losses in steel from the first groove harmonic of induction when the electric motor is operating in the phase-disconnected mode, substituting the expression for the spatio-temporal distribution of the groove frequency induction in (4) for the single-phase mode, taking into account the full distribution λ_n:

$$P'_{mgup} = K_n \cdot \frac{1}{2\pi \cdot T_n} \cdot \int_0^{2\pi} \int_0^{T_n} B^2_{fup}(\varphi, t) d\varphi \cdot dt. \tag{12}$$

Opening the brackets and integrating in a similar way, obtain the final expression for specific magnetic losses in steel from the first (upper) slot harmonic of induction in the form:

$$P'_{mgup} = \frac{1}{32} \cdot K_n \cdot (\lambda_0 \cdot \lambda_{j1} \cdot F_f)^2 \cdot \left(1 + \frac{1}{2} \cdot \lambda_{i1}^2\right) \cdot K_{\alpha n}, \tag{13}$$

where F_f is the magnetizing force when working on two phases; $K_{\alpha n}$ is the coefficient of electromagnetic asymmetry.

Thus, the nature of the dependence of the specific magnetic losses in steel on the groove harmonics of induction when the machine is operating in the mode with a disconnected phase is similar to the nature of this dependence for the three-phase mode and is determined by the type of function $K_{\alpha n} = f(a_m)$.

The quantitative ratio of losses during the operation of the electric motor in three-phase mode and in the mode with a disconnected phase can be estimated through the coefficient of proportionality of losses:

$$P'_{mgup} = K_f \cdot P_{mgup}, \tag{14}$$

where K_f is the proportionality factor $K_f = \frac{P'_{mgup}}{P_{mgup}}$; I_{vf} is the phase current in the phase-disconnected mode; I_{tf} is the phase current in three-phase mode; W is the the number of turns in a phase; k_o is the winding ratio.

Assuming that the phase resistance complexes at the fundamental frequency are approximately equal and the linear voltage to the root of three is greater than the phase voltage, obtain:

$$K_f = \frac{2}{3} \cdot \left(\frac{\sqrt{3}}{2}\right)^2 = \frac{1}{2}. \tag{15}$$

In a similar way, the specific magnetic losses from the lower groove harmonic of the induction, which varies in time with the frequency ω_n , can be calculated for both modes of operation of the machine. The total specific magnetic losses from the groove fields of the first order will be equal to the doubled value of P_{mgup} and P'_{mgup}.

Electromagnetic asymmetry significantly affects the nature of the distribution of the magnetic field in the air gap of the electric machine. In the presence of non-symmetry, the amplitudes of groove harmonics of magnetic induction increase.

The increase in the amplitude of the magnetic induction of higher harmonics of the magnetic field causes a sharp increase in magnetic losses from groove harmonics with an increase in electromagnetic asymmetry in accordance with the dependence $K_{\alpha n} = f(a_m)$. A significant increase in additional losses with an increase in electromagnetic asymmetry is also confirmed by a number of experimental studies.

The groove harmonic components of the magnetic field in the air gap induce electromotive force in the stator windings with frequencies ω_n.

In the conductor of each groove of the stator winding, an electromotive force of the groove frequency is induced, which is proportional to the change in induction. Accordingly, the square of the electromotive force will be proportional $B_n^2(\varphi, t)$ and proportional to the pulsation losses in the steel from the groove harmonics of induction P_{mgn} in the elementary volume of the groove zone near the k-th groove. Then the sum of the squares of the electromotive force in the conductors of all the slots of the stator winding will be proportional to the total magnetic losses of the electric machine from the slot harmonics of the field in the gap, and since the level of pulsation losses depends on the degree of electromagnetic asymmetry, the value will, other things being equal, be proportional to the energy level of the slot harmonics and will by some asymmetry function.

The dependence of the magnetic losses of the slot induction field from the similar dependence in the three-phase mode differs by a constant volume factor by summing the squares of the

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012040 doi:10.1088/1755-1315/1254/1/012040

electromotive force of the slot frequency, given in all three phases of the stator winding, when each of them is sequentially disconnected, it is possible to obtain an indirect diagnostic parameter, that is a function of the unevenness of the electromagnetic system, since in the case of the specified summation, all n grooves of the stator winding are taken into account, which is similar to the integration over the stator boring circle. The degree of change of the obtained parameter with increasing electromagnetic asymmetry is determined by the nature of the dependence of pulsating magnetic losses on the asymmetry of the electromagnetic system.

The electromotive force of the groove frequency arising in the coil of the stator winding, which contains W turns, the sides of which lie in the grooves with angular coordinates φ_k and φ_n is defined as the time derivative of the flux linkage:

$$e_{kn}(t) = -\frac{d\psi_n}{dt}, \tag{16}$$

where ψ_n is the magnetic flux and flux coupling of toothed harmonics with turns of the stator winding.

In its general form, this expression can be given by the formula of harmonic oscillation:

$$e_{kn}(t) = E_{kn} \cdot \sin(\omega_{up} \cdot t - Q_{kn}); \tag{17}$$

$$E_{kn} = \sqrt{\left(\sum_{i=1}^{18} E_i \cdot \cos Q_i\right)^2 + \left(\sum_{i=1}^{18} E_i \cdot \sin Q_i\right)^2}; \tag{18}$$

$$\begin{cases} \arctan = \dfrac{\sum\limits_{i=1}^{18} E_i \cdot \sin Q_i}{\sum\limits_{i=1}^{18} E_i \cdot \cos Q_i}, & \text{if } \sum\limits_{i=1}^{18} E_i \cdot \sin Q_i \neq 0; \sum\limits_{i=1}^{18} E_i \cdot \cos Q_i \neq 0; \\ \frac{\pi}{2}, & \text{if } \sum\limits_{i=1}^{18} E_i \cdot \sin Q_i = 0; \sum\limits_{i=1}^{18} E_i \cdot \cos Q_i > 0; \\ \frac{3\pi}{2}, & \text{if } \sum\limits_{i=1}^{18} E_i \cdot \sin Q_i = 0; \sum\limits_{i=1}^{18} E_i \cdot \cos Q_i < 0, \end{cases} \tag{19}$$

where E_i is the amplitudes of harmonic components of the electromotive force coil; Q_i is the initial phases of harmonic components of the electromotive force coil.

The total electromotive force induced in the disconnected phase without parallel branches can be found by summing the electromotive force of the turns that make up the phase winding.

When disconnecting the next phase and determining the electromotive force of the groove harmonic in its winding, the value ψ_f and coordinates of the distribution of turns change.

If the disconnected phase of the stator winding contains N parallel-connected coil groups, then the electromotive force of the groove harmonic phase is equal to:

$$e_f(t) = \frac{1}{N} \cdot \left[e_{r1}(t) + e_{r2}(t) + ... + e_{rn}(t)\right], \tag{20}$$

where $e_{rn}(t)$ is the electromotive force of coil groups, defined as the sum of the electromotive forces of the component turns.

In the case of mixed connection of coil groups in phase, the electromotive force of parallel sections is determined by expression (17) and then summed up with all groups connected in series.

The amplitude of the electromotive force of the groove harmonic of a separate phase of the stator winding can either increase with an increase in electromagnetic asymmetry ψ_α with respect to the distribution of the turns of a given phase, or decrease, while the sum of the squares of the electromotive force of the groove harmonic of all three phases uniquely increases with increasing α, reflecting an increase in pulsation losses at presence of asymmetry, close to quadratic in nature.

Thus, according to the proposed method, the energy level of higher harmonics can be estimated by the sum of the squares of the electromotive force of the groove harmonics, taken when each of the three phases of the stator winding is turned off sequentially when the tested machine is idling. In order to exclude the influence of saturation phenomena on the control result and to reduce current overloads of the electric motor when operating in the mode with a disconnected phase, the measurement must be carried out when the two working phases of the winding are powered with a reduced single-phase voltage.

To refine theoretical calculations near the extreme points of the range of asymmetry values, a technique for presenting the amplitude of groove harmonics of magnetic induction in an air gap with two-way groove through the Carter coefficient, taking into account its dependence on electromagnetic asymmetry, is proposed:

$$B_n = B_m - B_{\alpha v}, \tag{21}$$

where B_n is the amplitude of the groove harmonic of induction; $B_{\alpha v}$ is the average value of induction with electromagnetic symmetry; B_m is the maximum value of induction.

Coefficients determined by the ratio of the groove opening width to the gap size:

$$\gamma_1(\varphi) = \frac{\left[\frac{B_{s1}}{\delta(\varphi)}\right]^2}{5 + \frac{B_{s1}}{\delta(\varphi)}}; \tag{22}$$

$$\gamma_2(\varphi) = \frac{\left[\frac{B_{s2}}{\delta(\varphi)}\right]^2}{5 + \frac{B_{s2}}{\delta(\varphi)}}. \tag{23}$$

Obtain the final expression for the amplitude of the groove harmonic of magnetic induction in an air gap with two-sided groove:

$$B_{\alpha v} = \frac{5 \cdot (t_{z1} \cdot B_{s2}^2 + t_{z2} \cdot B_{s1}^2) \cdot \delta(\varphi) + B_{s1} \cdot B_{s2} \cdot (t_{z1} \cdot B_{s2} + t_{z2} \cdot B_{s1} - B_{s1} \cdot B_{s2})}{\left[t_{z1} \cdot (5 \cdot \delta(\varphi) + B_{s1}) - B_{s1}^2\right] \cdot \left[t_{z2} \cdot (5 \cdot \delta(\varphi) + B_{s1}) - B_{s2}^2\right]}; \tag{24}$$

Using the method of determining the electromotive force, will obtain a general final expression for one phase of the upper groove frequency of the first order in the form of harmonic oscillation:

$$e_f(t) = E \cdot \sqrt{A_t^2 + B_t^2} \cdot \sin\left[\omega_{up} \cdot t + \arctan\left(-\frac{A_f}{B_f}\right)\right]; \tag{25}$$

$$E = E_t = -\frac{3 \cdot \sqrt{2} \cdot \mu_0 \cdot I \cdot l_\delta \cdot D_c \cdot W^2 \cdot k_b \cdot \omega_{up}}{4 \cdot \pi \cdot \delta_0 \cdot N_k \cdot p}; \tag{26}$$

$$A_f = \sum_{N=1}^{N_k} \int_{\varphi_k N_f}^{\varphi_n N_f} [k_\delta(\varphi) - 1] \cdot \sin(Z_2 + p) \cdot \varphi \cdot d\varphi, \tag{27}$$

where D_c is the stator diameter; N_k is the number of turns in the phase.

Accordingly, for the mode of operation of an asynchronous electric motor with a disconnected phase:

$$E = E_f = -\frac{\sqrt{6} \cdot \mu_0 \cdot I \cdot l_\delta \cdot D_c \cdot W^2 \cdot k_b \cdot \omega_{up}}{2 \cdot \pi \cdot \delta_0 \cdot N_k \cdot p}; \quad (28)$$

$$A_f = \sum_{N=1}^{N_k} \int_{\varphi_k N_f}^{\varphi_n N_f} [k_\delta(\varphi) - 1] \cdot \cos(p \cdot \varphi - \psi_f) \cdot \sin Z_2 \cdot \varphi \cdot d\varphi, \quad (29)$$

$$B_f = \sum_{N=1}^{N_k} \int_{\varphi_k N_f}^{\varphi_n N_f} [k_\delta(\varphi) - 1] \cdot \cos(p \cdot \varphi - \psi_f) \cdot \cos Z_2 \cdot \varphi \cdot d\varphi. \quad (30)$$

The dependence of the electromotive force of the groove harmonic of individual phases and the sum of the squares of their amplitudes on the magnitude of the electromagnetic asymmetry was calculated on an electronic computer. The calculation algorithm is built on the basis of the above mathematical apparatus using the given expressions.

As expected, the graphical form of the theoretical dependence of the sum of the squares of the electromotive force of the groove harmonic on the electromagnetic asymmetry, calculated according to the given mathematical model, is similar to the dependence $K_{en} = f(e)$.

The proposed technique allows determining the energy levels of higher harmonics not only taking into account the value of absolute and relative asymmetry, but also taking into account the direction in space of the plane of asymmetry in relation to the distribution of the stator windings.

The initial value for determining the spatial angle of the direction of the plane of asymmetry is obtained from the expression of the electromotive force of the groove harmonic from any disconnected phase of the stator winding, assuming that α, δ_0, E_{nA} are the values obtained by the expressions:

$$E_{nA} = E \cdot \sqrt{A_A^2 + B_A^2}; \quad (31)$$

$$A_A^2 + B_A^2 = \frac{E_{nA}^2}{E^2}, \quad (32)$$

where E is the general constant that does not depend on φ and t; A_A, B_A are the sums of definite integrals.

The algorithm for calculating the dependence of the electromotive force of the groove harmonic on the electromagnetic asymmetry is presented in (figure 4).

By replacing and introducing a new variable and bringing similar terms, will finally get the equation in the canonical form:

$$x^4 + a \cdot x^3 + b \cdot x^2 + c \cdot x + d = 0; \quad (33)$$

$$a = \frac{2 \cdot (A \cdot B + C \cdot D)}{A^2 + D^2}; \quad (34)$$

$$b = \frac{2 \cdot A \cdot M + B^2 + C^2 - D^2}{A^2 + D^2}; \quad (35)$$

$$c = \frac{2 \cdot (B \cdot M + C \cdot D)}{A^2 + D^2}; \quad (36)$$

$$d = \frac{M^2 - C^2}{A^2 + D^2}; \quad (37)$$

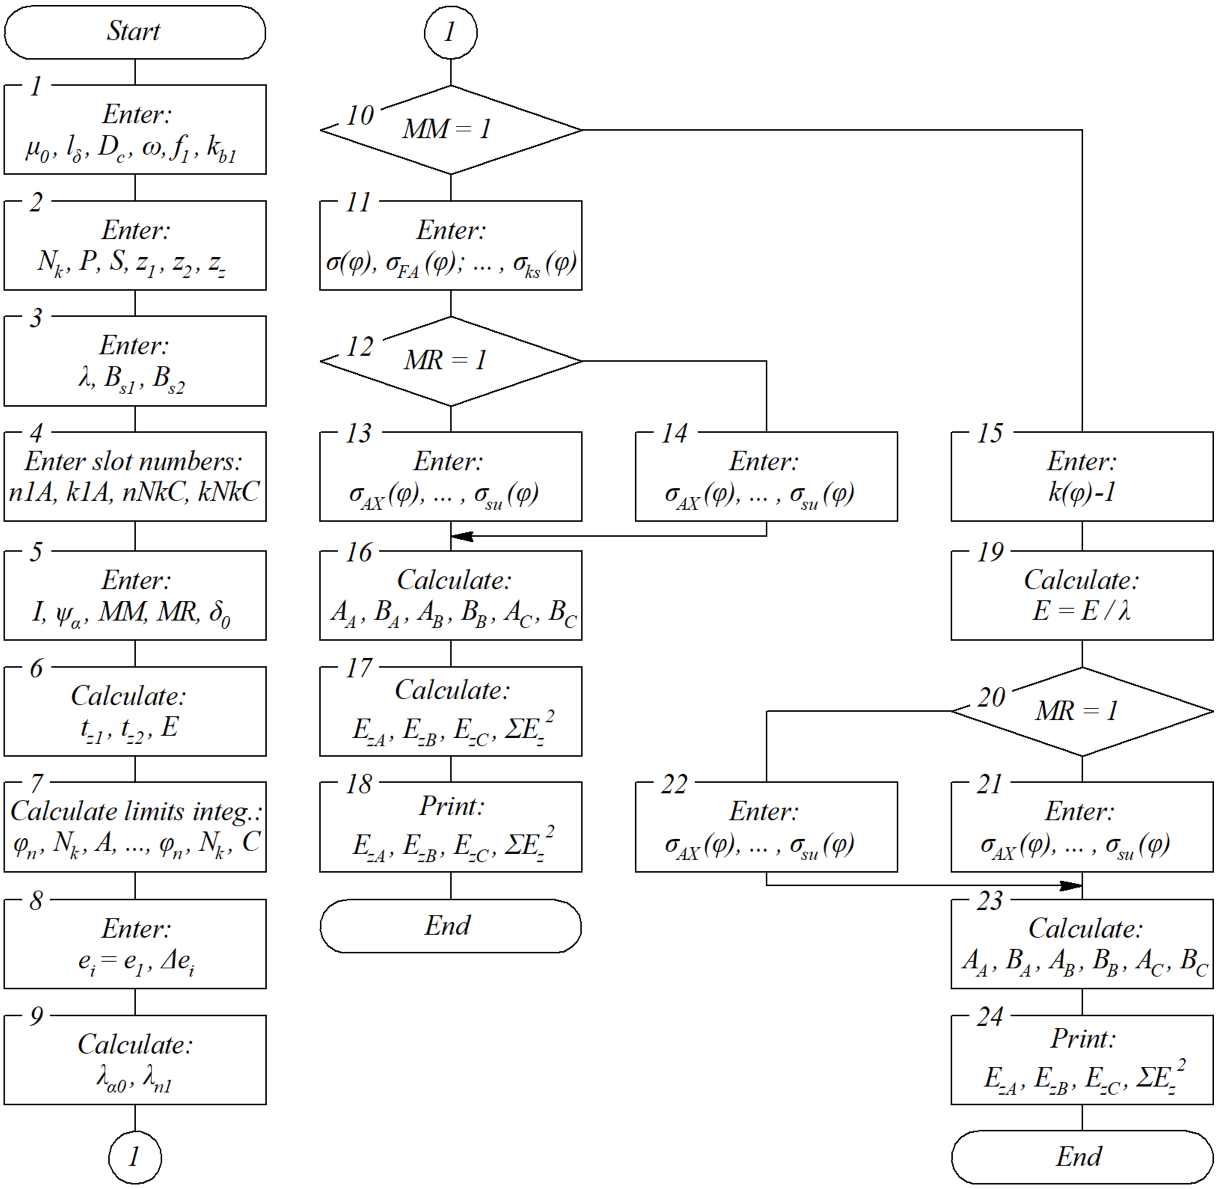

Figure 4. Calculation algorithm.

$$A = \lambda_{n1}^2 \cdot (C_2^2 + C_5^2 - C_3^2 - C_6^2); \tag{38}$$

$$B = \lambda_{\alpha 0} \cdot \lambda_{n1} \cdot (C_1 \cdot C_2 + C_4 \cdot C_5); \tag{39}$$

$$C = \lambda_{\alpha 0} \cdot \lambda_{n1} \cdot (C_1 \cdot C_3 + C_4 \cdot C_6); \tag{40}$$

$$D = 2 \cdot \lambda_{n1}^2 \cdot (C_2 \cdot C_3 + C_5 \cdot C_6); \tag{41}$$

$$C_1 = \sum_{N=1}^{N_k} \int\limits_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \sin Z_2 \cdot \varphi \cdot d\varphi; \tag{42}$$

$$C_2 = \sum_{N=1}^{N_k} \int\limits_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \cos\varphi \cdot \sin Z_2 \cdot \varphi \cdot d\varphi; \tag{43}$$

$$C_3 = \sum_{N=1}^{N_k} \int_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \sin\varphi \cdot \sin Z_2 \cdot \varphi \cdot d\varphi; \tag{44}$$

$$C_4 = \sum_{N=1}^{N_k} \int_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \cos Z_2 \cdot \varphi \cdot d\varphi; \tag{45}$$

$$C_5 = \sum_{N=1}^{N_k} \int_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \cos\varphi \cdot \cos Z_2 \cdot \varphi \cdot d\varphi; \tag{46}$$

$$C_6 = \sum_{N=1}^{N_k} \int_{\varphi_k N_A}^{\varphi_n N_A} \sigma'_A(\varphi) \cdot \cos Z_2 \cdot \sin\varphi \cdot \varphi \cdot d\varphi. \tag{47}$$

Thus, the desired angle ψ_α is determined through the roots of the reduced equations:

$$\psi_\alpha = \arccos x. \tag{48}$$

Of the four roots of expression (33), two are imaginary, and the two real roots give, respectively, a positive and a negative angle ψ_α calculated from the stator boring from the axis that coincides with the axis of the phase A winding.

The developed technique makes it possible to determine the levels of groove harmonic components in the phase windings of electric machines. These harmonics, depending on the connection scheme of the asynchronous motor windings (star, delta), the scheme and the load of the electrical network, spread over the electrical network, creating current harmonics or voltage harmonics. When analyzing asymmetric and non-sinusoidal modes at individual frequencies, various harmonic components arise, which leads to the emergence of specific current and voltage harmonics. All these phenomena must be taken into account when analyzing the modes of distribution networks.

The current level of development of electronic computers and their software allows to form mathematical models of the electrical network at the groove frequency in asymmetric modes, considering all its elements as three-phase. At the same time, equations in phase coordinates serve as mathematical models of both the network as a whole and its individual elements – equations containing mode parameters (voltages, currents, phase powers) as sought and set values.

Equations in phase coordinates refer to the electrical network, the elements of which are three-phase longitudinal and transverse branches. Longitudinal branches are contained in the schemes of substitution of sections of power transmission lines, three-phase windings of generators and transformers, transverse branches correspond to schemes of substitution of load nodes, transverse conductances of sections of overhead lines, branches of magnetization of transformers.

Each branch of the three-phase network is characterized by a matrix of own and mutual resistances of the phases:

$$[Z]_{ij}^F = \begin{bmatrix} Z_{aa} & Z_{ab} & Z_{ac} \\ Z_{ba} & Z_{bb} & Z_{bc} \\ Z_{ca} & Z_{cb} & Z_{cc} \end{bmatrix}_{ij}, \tag{49}$$

where the diagonal elements Z_{aa}, Z_{bb}, Z_{cc} reflect the active and inductive resistances of the respective phases, and non-diagonal resistances – the mutual induction between phases, and mode parameters – currents, voltages, electromotive forces of the phases.

$$[I]^F_{ij} = \begin{bmatrix} I_a \\ I_b \\ I_c \end{bmatrix}_{ij}; \tag{50}$$

$$[U]^F_{ij} = \begin{bmatrix} U_a \\ U_b \\ U_c \end{bmatrix}_{ij}; \tag{51}$$

$$[E]^F_{di} = \begin{bmatrix} E_a \\ E_b \\ E_c \end{bmatrix}_{ij}. \tag{52}$$

In asymmetric emergency modes, loads are characterized by conductance matrices in the node to the ground:

$$[Y_H]^F = [Z^F_H]^{-1}. \tag{53}$$

In non-symmetric operating modes (non-linear model), the load conductivity matrices (53) are kept unchanged only at the step of the iteration process and are adjusted during the iterations in such a way that the total consumed power of the three phases becomes equal to the set power at the node.

The component equations of the elements of a three-phase network in phase values have the form:

- for longitudinal branches:

$$[Z]^F_{ij} \cdot [I]^F_{ij} = \left([U]^F_i - [U]^F_j\right); \tag{54}$$

- for transverse branches:

$$[Z]^F_{Hi} \cdot [I]^F_{Hij} = [U]^F_i; \tag{55}$$

- for branches with a source of electromotive force:

$$[Z]^F_{di} \cdot [I]^F_{di} = \left([U]^F_{di} - [E]^F_{di}\right). \tag{56}$$

These equations are a generalization of Ohm's law for a three-phase branch and differ from similar equations of elements of a single-phase circuit only in that resistances, currents, electromotive force and voltages of three-phase elements are not characterized by numbers, but by corresponding matrices.

Matrices of both longitudinal $[Z]_{ij}$, and transverse $[Z]_{i0}$ elements can be asymmetrical, symmetrical or, in a separate case (a group of single-phase elements), diagonal. All types of longitudinal and transverse asymmetry (non-transposed overhead lines, network elements operating with an incomplete number of phases, asymmetric loads, etc.) are reflected in the parameter matrices $[Z]$ of the corresponding elements.

A three-phase network can be matched by a graph, the branches of which correspond to three-phase branches, and the nodes to three-phase nodes. Then, for three-phase circuits and three-phase nodes, Kirchhoff's laws can be represented in the form:

$$\sum_{i=1}^{N} [I]^F_{ij} = 0; \sum_{i=1}^{N_k} [\Delta U]^F_{ij} = 0. \tag{57}$$

where $[I]_{ij}$ is the the currents in the branches adjacent to the three-phase node; $[U]_{ij}$ is the voltage drop on the three-phase branches forming a closed circuit in the three-phase network.

If for all independent three-phase nodes of the electrical networidraw up the current balance equation, solve the component equations of the three-phase branches adjacent to each of the nodes with respect to the currents and substitute them into the first of the equations, then for a network containing n independent three-phase nodes, get the system of equations of the electrical network in the asymmetric stationary mode in phase coordinates:

$$\begin{bmatrix} Y_{11} & Y_{12} & ... & Y_{1n} \\ Y_{21} & Y_{22} & ... & Y_{2n} \\ ... & ... & ... & ... \\ Y_{n1} & Y_{n2} & ... & Y_{nn} \end{bmatrix}^F \cdot \begin{bmatrix} U_1 \\ U_2 \\ ... \\ U_n \end{bmatrix}^F = \begin{bmatrix} J_1 \\ J_2 \\ ... \\ J_n \end{bmatrix}^F . \tag{58}$$

The elements of this system of equations are the 3×3 matrices of the own $[Y_{ii}]$ and mutual $[Y_{ij}]$ conductances of three-phase nodes, the vectors of phase voltages in the nodes of the three-phase network $[U_i]$ and set currents $[J_i] = [Y_i] \cdot [E_i]$ in the nodes of the connection of generating elements.

All asymmetric emergency damage in the electrical network (disconnection of phases, short circuits of individual phases to each other and to the ground, etc.) can be displayed quite simply when forming nodal equations, taking into account the corresponding commutations in nodes and branches of a three-phase network. Moreover, the presence of several asymmetric damages does not lead to any complications in the algorithms for forming and solving nodal equations compared to the case of local damages. Therefore, mathematical models based on equations in phase coordinates are more flexible and universal, applicable for the analysis of non-symmetric modes of operation with both simple and complex asymmetry.

In the linear model of the network (when applying loads with constant phase resistances Z_n = const), the phase voltages in the nodes of the network in the asymmetric mode under consideration are determined by a one-time solution of the equations, in the non-linear model (with the specified powers consumed and generated in the network nodes) the phase voltages are refined during of the iterative process until the sum of the powers of the three phases in each node of the network becomes equal to the given value. It was established that the levels of groove harmonics are determined by the structure and modes of the electrical network, the geometry of the groove zones of the air gap of the electric machine, and its magnetic properties. Theoretical propositions have been confirmed by experimental studies.

3. Conclusions

A method of calculating currents and electromotive force of the groove frequency of rotary electric machines for active-adaptive networks has been developed. Calculations are based on the analysis of the electromagnetic field of the electric machine and methods of calculating non-symmetrical and non-sinusoidal modes of distribution electric networks (phase coordinates method). It was established that the levels of groove harmonics are determined by the structure and modes of the electrical network, the geometry of the groove zones of the air gap of the electric machine, and its magnetic properties.

Abstract. Sediments on the technological surfaces of the recirculating water supply system (RWSS) of enterprises are considered. The kinetic equation for the activity concentration of the main sediment component – Ca^{2+} ions in circulating water (CW) is discussed. Based on this equation, expressions were obtained for the rate of formation of $CaCO_3$ from CW and the stability index of CW, which is expressed by the activity concentration of free Ca^{2+} ions not bound in $CaCO_3$. These values are determined by measuring parameters of the quality of CW and the mode of operation of the recirculating system, which are provided for by the regulations for the operation of the RWSS Current information on the value of the stability index makes it possible to calculate the rate of $CaCO_3$ precipitation and, if necessary, to develop quantitative parameters of operational measures to stabilize CW. The algorithm for calculating the stability index was applied to the RWSS of one of the HPPs, where softening of the feed water and bypass softening of CW are used. The calculated value of the index adequately reflects changes in the stability of the CW during variations in the operation mode of the RWSS. The stability index was used to calculate the parameters of CW acidification, which ensure the desired level of its stability.

1. Introduction

Today, the vast majority of large enterprises, thermal and nuclear power plants (HPPs, NPPs) are equipped with reversible water supply systems (RWSS). Almost 95% of water consumption there used for cooling of technological equipment. Considering the large consumption of cooling water (about 170,000 m^3/hour per 1000 MW unit), natural, untreated water is used for cooling. Such water is capable of releasing solid sediments (mainly $CaCO_3$ on process surfaces, in particular, on pipe systems (PS) of turbine condensers (TC) [1, 2].

The coefficient of thermal conductivity of sediments is ten times lower than that of the PS material, so that already at a thickness of (1.2-1.6) mm, the heat transfer coefficient of heat exchangers (HE) decreases by (30-40)%, and this leads to a decrease in the efficiency of power units by (0.5-1.2)% [3], excessive consumption of fuel by (1.5-3.5)% and the need to clean TCs, reducing the electrical load of the units.

Note that for a 1000 MW power unit, the corresponding annual electricity losses are (120÷245) million kWh, which roughly corresponds to the energy consumption of a city with a population of (40-80) thousand people. Excessive consumption of fuel at HPPs, along with economic losses, results in excessive emissions of heat, greenhouse gases, and harmful substances into the environment.

To reduce the intensity of sediments partial or complete softening of the feed water, adding of mineral acids to the water and dosing of sediment inhibitors are used. The effect of the inhibitors is associated with blocking the growth centers of $CaCO_3$ crystal nuclei, providing them with an additional charge and thus stabilizing the $CaCO_3$ dispersion, which is expressed in a decrease in the intensity of deposits on the PS of heat exchangers [4, 5].

2. Formulation of the problem

An important problem in the reagent stabilization of circulating waters of thermal power plants and nuclear power plants is the lack of reliable operational control of the ability of CW to form sediments.

The regulations [6] suggest using the Langelier index, LSI, or the CW supersaturation index with respect to $CaCO_3$, SI [7, 8]. The mentioned indices are represented by expressions:

- Langelier index:

$$LSI = \mathrm{pH} - \mathrm{pH}_s = -\lg \frac{(H)}{(H)_s}, \tag{1}$$

$(H)_s$ – activity concentration of hydrogen ions when the water system is in equilibrium with the environment; (H) – measured activity concentration.

Today pH measuring is not difficult, but the calculation of pH_s depends on the selected model of the bicarbonate system and does not always correspond to reality.

Because of this, pH_s are recommended to be determined experimentally [9].

It follows from formula (1) that if $LSI < 0$, there is an excess of hydrogen ions in the water system and it is corrosively active and capable of dissolving carbonate sediments. If $LSI > 0$, on the contrary, there is a lack of hydrogen ions in the system and it emits $CaCO_3$. Of course, at $LSI = 0$, the hydrocarbonate system (HCS) is stable.

Unfortunately, knowing the LSI, we do not get a quantitative assessment of the degree of deviation of the HCS from the balance. That is, the LSI provides qualitative information about the state of the HCS and does not directly indicate the quantitative characteristics of measures to correct the stability of the CW. In addition, if we are talking about the RWSS, the LSI is not directly related to the operation mode of the RWSS.

- Index of CW supersaturation in relation to $CaCO_3$: it is calculated by the formula,

$$SI = \frac{(\mathrm{Ca}^{2+}) \cdot (\mathrm{CO}_3^{2-})}{L_{\mathrm{CaCO}_3}}, \tag{2}$$

$(\mathrm{Ca}^{2+}), (\mathrm{CO}_3^{2-}), L_{\mathrm{CaCO}_3}-$ activity concentrations of calcium and carbonates ions and the solubility product of the $CaCO_3$.

It follows from the physical content of formula (2) that with $SI > 1$, there is an excess of carbonate and calcium ions in the water system and it can release $CaCO_3$. If $SI < 1$, on the contrary, there is a lack of ions in the system and it dissolves $CaCO_3$. Of course, at $SI = 1$, the hydrocarbonate system is stable. However, as in the case of the Langelier index, the SI calculation gives only qualitative information about the state of the HCS, this information refers to the CW and does not reflect its status as an element of the RWSS.

At NPPs, the following ratio is used to characterize the stability of the CW

$$\varepsilon \geq \frac{C_{\mathrm{Cl}}}{C_{\mathrm{Cl0}}} - \frac{Ht}{Ht_0}, \tag{3}$$

ε is a given value, for example, $0.1 \div 0.3$; Ht, Ht_0 is the total hardness of circulating water and feed water, the same for chloride concentrations $C_{\mathrm{Cl}}, C_{\mathrm{Cl0}}$.

The value of ε is mostly not substantiated, and the use of hardness ($Ca^{2+} + Mg^{2+}$) instead of Ca^{2+} concentration leads to additional errors (overestimation) of CW stability.

Therefore, today there is no generally accepted method for determining the quantitative degree of stability of CW, which could be directly used as a characteristic of the deviation of the state of CW from the equilibrium state, when a dynamic equilibrium is established in CW between the processes of $CaCO_3$ generation and its dissolution, and the rate of sediment growth is minimal (ideally, it goes to zero).

It is important that this method of determining the degree of stability of CW clearly depends on the regime parameters of RWSS and the quality of CW. Having such a parameter (by analogy with (1) and (2), we will call it the stability index), it would be possible to form an algorithm for calculating the doses of reagents or the level of softening of the feed water depending on the degree of deviation from the equilibrium state. It would be most convenient to obtain this value on the basis of operational information about the state of CW based on the data of regular measurements of RWSS regime parameters and CW quality parameters conducted at enterprises, in particular at HPPs and NPPs.

The formulation of the methodology for calculating the CW stability index in relation to the re-lease of $CaCO_3$, and the application of the results of its determination in the real conditions of a specific TPP are considered in this work.

3. Calculation method

It was shown in [1] that the main component of the sediments is calcium carbonate $CaCO_3$. Accordingly, the procedure for determining the stability of CW should be based on monitoring the dynamics of the concentration of Ca^{2+} ions in CW. To obtain the kinetic equation for the concentration of Ca^{2+}, we use the balance of the number of moles of calcium in the circulating water of the RWSS and take into account that the concentration of calcium changes in the CW due to water exchange, water evaporation, and the formation of $CaCO_3$. Other channels of changes in the concentration of Ca^{2+} ions in CW are neglected.

Let us denote the rate of $CaCO_3$ formation by $R(t), \mathrm{mole}/(\mathrm{dm}^3 \cdot \mathrm{s})$, then for a simple RWSS we can write an expression for the rate of change of the activity concentration of Ca^{2+} ions in CW,

$$\frac{\mathrm{d}C(t)}{\mathrm{d}t} = \frac{1}{T_f(t)} \cdot \left[C_0(t) - \frac{C(t)}{\phi(t)}\right] - R(t), \tag{4}$$

$$\phi(t) = \frac{k(t)}{1 - k(t) \cdot T_f(t) \cdot \frac{\mathrm{d}}{\mathrm{d}t} \ln\left[C_{\mathrm{Cl}}(t)\right]}; \quad T_f(t) = \frac{V(t)}{Q_f(t)}, \tag{5}$$

$C_0(t), C(t)$ – activity concentrations of calcium ions in feed and circulating waters; $Q_f(t), V(t)$– feed water flow rate and water volume of the RWSS; $T_f(t)$ is the time of filling the RWSS with feed water. The parameter $\phi(t)$ in formula (4) is called the dynamic factor. As it follows from (5), for the stationary mode of operation of the RWSS, when $\frac{\mathrm{d}}{\mathrm{d}t} \ln\left[C_{\mathrm{Cl}}(t)\right] \approx 0$, this value approaches the concentration coefficient $k = \frac{C_{\mathrm{Cl}}}{C_{\mathrm{Cl0}}}$ of circulating water and is determined by the standard method by measuring the concentration of chloride ions.

Let's transform (4) to the form that shows how Ca^{2+} ions are distributed in CW,

$$C_0(t) \cdot \phi(t) = T_f(t) \cdot R(t) \cdot \phi(t) + T_f(t) \cdot \frac{\mathrm{d}C(t)}{\mathrm{d}t} \cdot \phi(t) + C(t). \tag{6}$$

The left part (6) is the activity concentration of calcium ions, what it would be in CW in the absence of $CaCO_3$ formation. The first term on the right is part of the concentration of calcium ions that have changed to the state of $CaCO_3$ during the time T_f – the stay of the feed water in the RWSS. The third term is the excess (that exists at the moment of time t) activity concentration of free calcium ions in CW, which can be determined by any available method.

After dividing both sides of (6) by $C_0(t) \cdot \phi(t)$, let's convert it to the form

$$G_{inst}(t) + \Psi_{st}(t) = 1; \tag{7}$$

$$G_{inst}(t) = \frac{T_f(t) \cdot R(t)}{C_0(t)}; \quad \Psi_{st}(t) = \frac{C(t)}{C_0(t) \cdot \phi(t)} \cdot \left[1 + \phi(t) \cdot T_f(t) \cdot \frac{\mathrm{d}\,[\ln C(t)]}{\mathrm{d}t}\right] \tag{8}$$

The first expression (8) is the fraction of calcium ions of the feed water, which during its stay in the RWSS passes into the state of $CaCO_3$. Let's call this value the factor of instability of water with respect to the precipitate of $CaCO_3$.

The second expression (8) is the fraction of calcium ions from the feed water that does not change to the $CaCO_3$ state during its stay in the RWSS. It is natural to consider this value as an index of the stability of circulating water in relation to the release of $CaCO_3$. For a stationary state, when $dC(t)/dt = 0$, the stability index takes the form

$$\Psi_{st}(t) = \frac{C(t)}{C_0(t) \cdot \phi(t)}; \quad \phi(t) = \frac{C_{\mathrm{Cl}}(t)}{C_{\mathrm{Cl0}}(t)}, \tag{9}$$

it is equal to the fraction of the concentration of free Ca^{2+} ions remaining in the CW relative to the amount of Ca^{2+} ions that would be in the CW in the absence of $CaCO_3$ formation.

For transient processes controlled by external conditions, provided that the value of the second term in square brackets (8) is proportional to unity

$$|\ \phi(t) \cdot T_f(t) \cdot \frac{\mathrm{d}\,[\ln C(t)]}{\mathrm{d}t}\ | \approx 1, \tag{10}$$

the value of the stability index will depend on the sign (10) and will reflect the influence of external factors unrelated to the formation of $CaCO_3$. That is, the stability index introduced by us adequately describes the process of carbonate release for the operating mode of RWSS close to stationary.

By the way, having determined the stability index, we can use (8) to calculate the rate of formation of $CaCO_3$ from circulating water,

$$R(t) = [1 - \Psi_{st}(t)] \cdot \frac{C_0(t)}{T_f(t)} = [1 - \Psi_{st}(t)] \cdot \frac{C_0(t) \cdot Q_f(t)}{V(t)} \tag{11}$$

Note that in the case of the use of bypass softening of CW such that a part of CW is removed from the circulation flow, softened in a special bypass clarifier and returned to the circulation flow again, the expression for calculating the stability index changes,

$$\Psi_{st}(t) = \frac{C(t)}{C_0(t) \cdot \phi(t)} \cdot \left\{1 + \phi(t) \cdot P_{bp}(t) \cdot [1 - b_{bp}(t)] + \phi(t) \cdot T_f(t) \cdot \frac{\mathrm{d}\,[\ln C(t)]}{\mathrm{d}t}\right\} \tag{12}$$

$$P_{bp}(t) = \tfrac{Q_{bp}(t)}{Q_f(t)}, \quad b_{bp}(t) = \tfrac{C_{bp}(t)}{C(t)},$$

$Q_{bp}(t)$ – water consumption through the bypass clarifier, $C_{bp}(t)$ – activity concentration of calcium ions at the outlet of the bypass clarifier.

The characteristic feature of bypass clarifier that is important when using sediment inhibitors is the absorption of a part of the inhibitors from CW. Moreover, the concentration of inhibitors can decrease in the CW stream by (30-40)%. Therefore, the loss of inhibitors must be compensated for by a corresponding increase in their dosage in circulating water.

4. Application example

The proposed methodology for calculating the CW stability index for the formation of $CaCO_3$ will be applied to characterize the CW condition and minimize the growth rate of CW precipitation at one of Ukraine's HPPs. For this purpose, we use the CW parameters that were measured in accordance with the operating regulations of the RWSS, namely:

$$\left(\mathrm{Ca}^{2+}\right)_0, \quad \left(\mathrm{Ca}^{2+}\right), \quad \left(\mathrm{Cl}^{-}\right)_0, \quad \left(\mathrm{Cl}^{-}\right), \quad Q_f, \quad V \tag{13}$$

Taking into account the high hardness of natural water $(9.5 - 14.5)\frac{\mathrm{mg-eq}}{\mathrm{dm}^3}$ before feeding into the RWSS, approximately 85% of the feed water is softened so that its calcium hardness at the entrance to the RWSS was $\approx 2.1\frac{\mathrm{mg-eq}}{\mathrm{dm}^3}$, and in the CW reached $\approx (4.0 - 4.4)\frac{\mathrm{mg-eq}}{\mathrm{dm}^3}$, with a concentration factor of $k = 3.0 - 3.5$.

During the 300-day RWSS studies, see figure 1 it worked in standard mode (without bypass) with an inhibitor concentration of $C_i = 3.5\frac{\mathrm{mg}}{\mathrm{dm}^3}$. The stability index before turning on the bypass calculated according to formula (9) was in the range of $\Psi_{st} \approx (0.60 - 0.63)$, which was clearly insufficient for the normal operation of power units. The turbine condensers had to be cleaned every 3 months, and due to the need to reduce the electrical load during cleaning, the station suffered significant losses. To increase the current stability, starting from the 300th day of observation, the bypass clarification of the CW with the following parameters was included:

$$P_{bp} = 0.18, \quad b_{bp} = 0.4, \quad \phi = 3.2, \quad C_0 = 2.1\frac{\mathrm{mg-eq}}{\mathrm{dm}^3}, \quad C = 4.2\frac{\mathrm{mg-eq}}{\mathrm{dm}^3}.$$

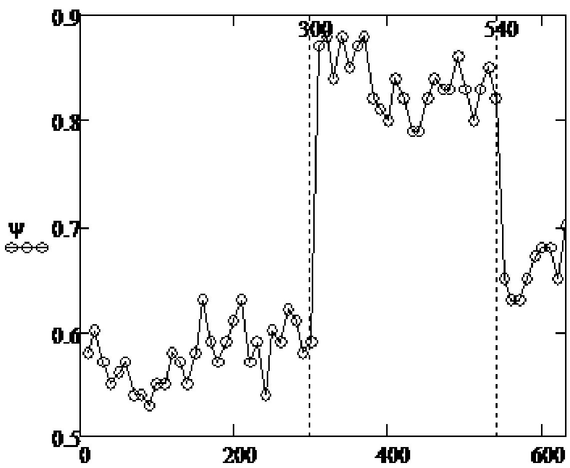

Figure 1. Dependence of CW stability index Ψ_{st} on the number of the measurement day. Vertical lines 300 and 540 indicate the moments of CW clarification switching on and the reduction of inhibitor dose.

The results of the calculation of the stability index according to formula (12) is shown in figure 1. We see that the use of bypass clarification of the CW increases the stability of CS up to 87% while maintaining the same inhibitor concentration in CW of $3.5\frac{\mathrm{mg}}{\mathrm{dm}^3}$.

Note that the expression for the stability index in the bypass mode, formula (12), allows us to calculate the amount of CW consumption for bypass required to ensure the desired level of stability.

After reaching $\Psi_{st} \approx 0.82 - 0.88$, the precipitation rate decreased by almost three times, which made it possible to clean TCs during scheduled preventive repairs.

In order to make sure of the effectiveness of choosing the right dose of the inhibitor and the adequacy of the algorithm for calculating the degree of stability, starting from the 540th day, the dose of the inhibitor was reduced by 30%. Accordingly, the calculated stability of CW also decreased by $\approx$ 30%. This indicates that the method of calculating the stability of CW adequately reflects the processes in CW.

The results presented here indicate the possibility of operational control of the stability of CW based on the data of regular measurements of its quality parameters and parameters of the operating mode of the RWSS.

5. An example of application for correcting the stability of CW with acid

Let's consider an alternative option of stabilizing CW by acidifying it, for example, with sulfuric acid. Assume that the CW stability after softening was 60%. Considering it insufficient, we calculate the amount of sulfuric acid dose that must be added to the feed water to achieve the desired level of stabilization $\max \Psi_{st} = 0.87$.

To do this, we take into account that each gram mole of the acid binds an equivalent number of calcium ions, that is, the expression for the desired value of the stability index is presented as

$$\max \Psi_{st} = \frac{1}{\phi \cdot C_0} \cdot (C + \Delta C) = \Psi_{st} + \frac{\Delta C}{\phi \cdot C_0}, \tag{14}$$

ΔC is the part of the concentration of Ca^{2+} ions that is bound by the acid, it is equal to the added concentration of the acid C_A in the CW; Ψ_{st} is the existing stability of CW before acidification.

From expression (14), we determine the concentration of the acid that must be added to CW, $\frac{\text{g-mole}}{\text{dm}^3}$,

$$C_A = C_0 \cdot \phi \cdot (\max \Psi_{st} - \Psi_{st}). \tag{15}$$

Considering that the amount of acid in CW due to concentration is ϕ times higher than in feed water, we get the acid concentration for feed water,

$$C_{A0} = C_0 \cdot (\max \Psi_{st} - \Psi_{st}). \tag{16}$$

According to (15), we find the mass concentration of sulfuric acid (100%), which must be added to the feed water,

$$C_{A0} = 2.1(0.86 - 0.6) \cdot 49 \ \frac{\text{mg}}{\text{dm}^3} = 26.8 \ \frac{\text{mg}}{\text{dm}^3} \approx 27 \cdot 10^{-3} \ \frac{\text{kg}}{\text{m}^3}$$

We compare it with the consumption of the inhibitor during simultaneous bypass (take into account the increase in the dose of the inhibitor by 1.4 times due to its absorption by the bypass clarifier),

$$C_{i0} = 1.4 \cdot C_i/k = 1.4 \cdot 3.5/3.2 = 1.53 \cdot 10^{-3} \ \frac{\text{kg}}{\text{m}^3}$$

We obtain that the mass concentration of the inhibitor is 17.6 times lower than that of the acid. That is, in this case, it might be more expedient to limit, after softening the feed water, its acidification instead of two procedures of adding an inhibitor and bypass softening.

The calculations presented here are intended to show how useful the concept of the stability index is, as it allows obtaining a quantitative level of stability of CW and simplifies the estimation of the number of reagents needed to achieve the desired level of stabilization of CW and makes it possible to compare stabilization options without much difficulty.

6. Conclusions

- To quantitatively characterize the degree of stability of CW, we suggest using the stability index. It has a clear physical meaning – it is equal to the relative part of the concentration of Ca^{2+} ions that remains free in the CW, not bound in calcium carbonate. The calculation procedure is also simple and clear.

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012041 doi:10.1088/1755-1315/1254/1/012041

- It should be kept in mind that the stability index adequately describes the process of $CaCO_3$ formation in the case when there are no sharp changes in the concentration of Ca^{2+} ions in the RWSS, see (10), caused by external conditions (the established mode of operation of the RWSS).
- For operational control and determination of the level of stability of CW, it is necessary to measure the parameters of water quality and mode of operation of the RWSS in the established mode of operation of the RWSS: $\left(\mathrm{Ca}^{2+}\right)_0$, $\left(\mathrm{Ca}^{2+}\right)$, $\left(\mathrm{Cl}^{-}\right)_0$, $\left(\mathrm{Cl}^{-}\right)$, Q_f, V.
- It follows from expression (12) that the rate of formation of $CaCO_3$ is proportional to the concentration of calcium ions in the feed water, its consumption, and is inversely proportional to the water volume of the RWSS. In other words, RWSS with a larger water volume are less sensitive to contamination of heat exchangers than with a smaller one. In particular, this concerns to RWSS with cooling ponds.

Abstract. Ukraine strives to be a full member of the EU and competitive in its market space, including energy markets. However, the UA electric power sector lags behind the EU common one. To prove this input-output model of electricity flows was constructed, Sankey diagrams were built, and qualitative indicators were determined. Based on the Eurostat dataset we found contradictions in Ukrainian electric power sector development against the European common one from 1991 to 2020. Mainstream trends in EU electric power sector development are decarbonization, development of highly efficient cogeneration, increasing energy efficiency at all stages, decentralization, increasing energy dependency, and all-round electricity penetration. At the same time, key tendencies in the UA electric power sector development were: gas-coal switching, reducing quality and quantity of cogeneration, stable too-low energy efficiency, centralization, isolation and self-sufficiency, and deindustrialization. Comprehending these contradictions determines the way for achieving sustainability in the UA electric power sector after the war.

1. Introduction

The electric power sector development of Ukraine is considered in the context of its integration into the European energy space. The result of such integration will be the receipt of significant benefits by European and Ukrainian electricity consumers in terms of quality, reliability of supply and cheaper prices under the pressure of competition. For nowadays Ukraine is being a member of the Energy Community and since the mid-2019 the pro-European model of the electricity market has been implemented but it does so in a quasi-competitive way [1]. Since the February 24th, 2022 Ukrainian electric power system has been synchronized with the entire European one and since March 16th 2022 Ukrainian transmission system operator has become an observer member of ENTSO-E. Nevertheless that now the Ukrainian electric power grids technically fulfil the European rules, its electric power sector remains still outdated and its development is not following European trends. The shortcomings of the Ukrainian electric power sector cast doubt on its success in the competitive struggle in the open European space and require a solution to the problem of finding priority areas for its future development.

The problem of electric power sector development has been strongly exacerbated by the Russian invasion of Ukraine. Currently, it is impossible to analyze the damage of electric power sector due to cybersecurity requirements (all data are closed since the February, 24th 2022 3 p.m.). However by the estimation of BBC the Ukrainian electric system suffered more than 250 strikes and there is no one thermal or hydro power plant left that would not be damaged [2].

Regardless, it is needed to explore Ukrainian previous experience to rebuild the electricity power sector after the war according to European pillars without neglecting national interests.

It is possible to analyze the state and trends of the Ukrainian electric power sector in the European space by developing the input and output electricity flows and comparing Ukrainian trends with European common ones and determining their similarities and contradictions, pros and cons of their development.

The input–output model is widely used application for quantitative assessment interdependencies between different sectors of a national economy or different regional economies [3] and electricity is public used good by all without exception spheres of economy [4]. Chong et al is considered that the input–output model is a suitable method for analyzing complex network data structures and Sankey diagram is its visualization tool [5]. Historically it referred to Leontief input–output model 1936 [6] and Sankey diagram was firstly constructed Hohmann in 1949 [7]. Nowadays the Sankey diagram is pointing up inefficiencies and potential for savings in connection with resource use [8], analyzing the energy balance and energy efficiency of an energy system [9], programming data-processing method for mapping energy allocation Sankey diagram and introduced primary energy quantity converted factor to connect end-use energy consumption and primary energy consumption [10]. These methods are commonly used in other different fields [11–13], but in most cases, it is applied for analysis of the energy and greenhouse gas emission flows [14–17]. So, Eurostat has developed an Sankey diagram to build and customize general energy balance and the main energy flows of a certain territory [18], but it could not be decomposed by types of energy sources or energy carriers.

The aim of the research is to develop methodological support for the analysis of input-output electricity flows and compare key trends in the electric power sector development in Ukraine with the EU common ones. Its hypothesis is formulated as follow: existence of significant contradictions in the electric power sector development of Ukraine and the EU.

The rest of paper is organized as follows. Section 2 contains the materials and methods used for the construction of input-output model of electricity flows. Section 3 provides authors' key findings on the contradictions of the UA and EU electric power sector development. Section 4 presents a discussion and conclusions of these contradictions and also recommendations for solving them.

2. Methodology and data

So, comparative analysis of input-output electricity flows in Ukraine and the EU can be carried out on the basis of Sankey diagrams, which are possible to build using Power BI software (developed by Microsoft Corp. [19]). The dataset of the research is the Eurostat database [20], which is compiled with Regulation (EC) No 1099/2008 [21] and ensures the unification and comparability of data by the dimensions of the electric power system, energy sources and types of activity. The dataset includes the data from 1991 to 2020 for Ukraine and EU-27 (currently it is impossible to refresh data for Ukraine due to the cybersecurity requirements during the war-time). But the use developed input-output model of electricity flow will allow for quick updating of data and slicing them for time periods and countries. Constructed input-output model of electricity flows is depicted in figure 1, based on it the Sankey diagrams of the inputs and outputs electricity flows are built by the stages of the electric power system. Data validation of the input-output model of electricity flows is based on the thermodynamic laws of conservation energy which requires for all energy in the electric power chain from the supply of primary energy resources to the final electricity consumption must be allocated or lost.

Based on the developed input-output model of electricity flows, it is possible to determine qualitative indicators of the electric power sector development, which can be divided into 3 groups: energy efficiency, structural, and security and integration (table 1). All these indicators can also be calculated in the Power Bi software space using measures.

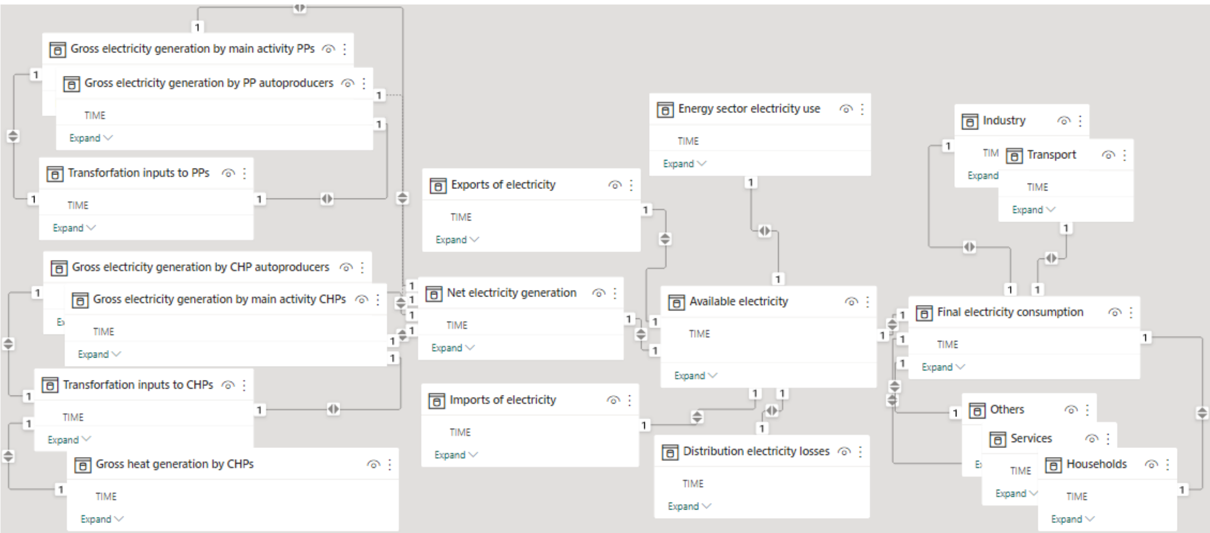

Figure 1. Input-output model of electricity flows in Power Bi software space: PP – power plant; CHP – combined heat and power plant.

Table 1. Qualitative indicators of the electric power sector development.

Group indicator	Indicator
Energy efficiency indicators	Energy efficiency of transformation by PPs Energy efficiency of transformation by CHPs Energy efficiency of generation Energy efficiency of transportation electricity General energy efficiency of electric power sector
Structural indicators	Share of RES in transformation inputs of electric power sector Share of OFF in transformation inputs of electric power sector Share of cogeneration in gross electricity generation Share of autoproducers in gross electricity generation Share of commercial electricity consumption Share of non-commercial electricity consumption
Security and Integration indicators	Self-sufficiency of electric power sector Export dependency of electric power sector Import dependency of electric power sector

RES – renewable energy sources; OFF – organic fossil fuels.

The expected result of the research is the finding of the contradictions in the UA and EU electric power sector development, which must be overcome during the rebuilding of Ukraine's electric power sector after the war-time.

3. Results

3.1. Input-output models of electricity flows in Ukraine and EU

In this paper, the Sankey diagrams of electricity flows are depicted of Ukraine and the EU (figure 2, figure 3), which contain eight stages described below.

The first stage presents primary energy sources which were used for electric power generation

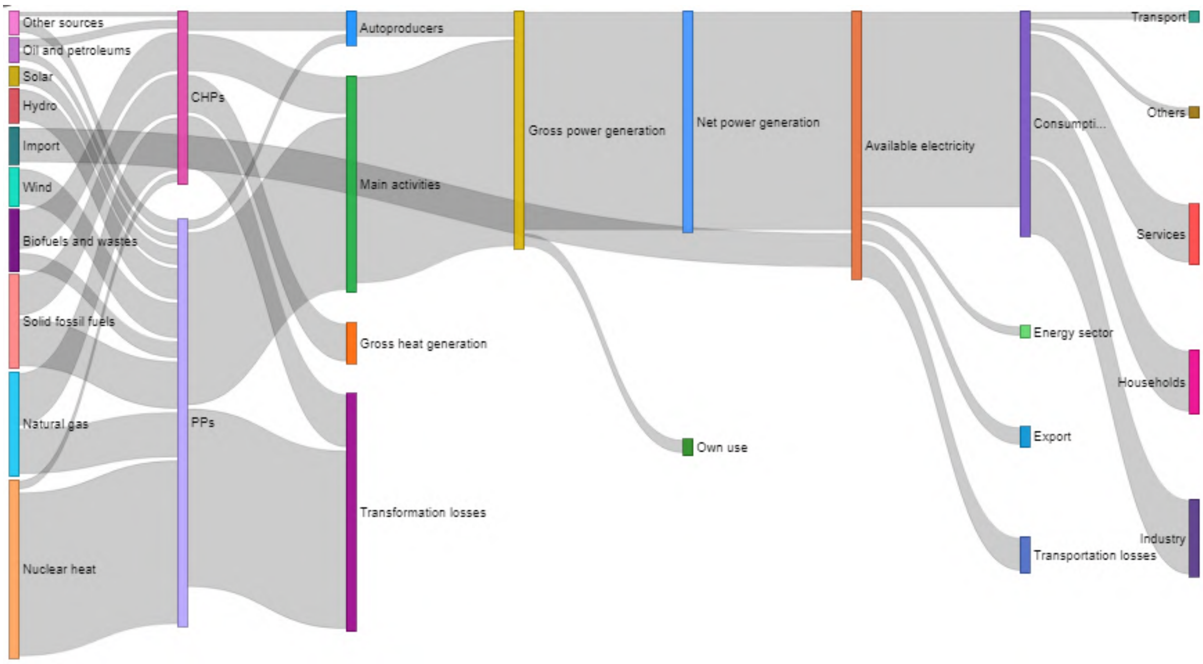

Figure 2. Sankey diagram of the EU electric power sector in 2020 (based on [20]).

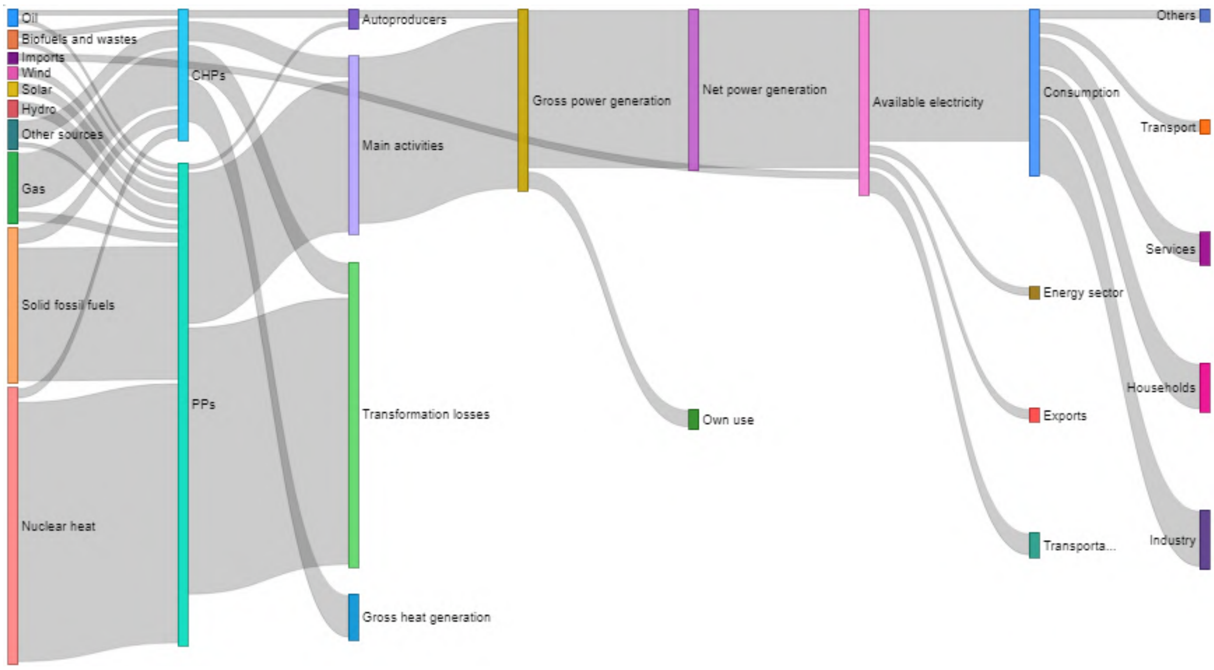

Figure 3. Sankey diagram of the UA electric power sector in 2020 (based on [20]).

(solid fossil fuels, nuclear heat, renewables etc.) and also the import of electricity as an external source of it. They are allocated between PPs and CHPs (the second stage). The third stage contains gross main and autoproducers' power generation, gross heat generation and transformation losses. In the fourth stage, the summarized gross output of power generation, which depends on the level of the state-of-the-art of used technologies. In the fifth stage, net power generation is presented as deducted sum from the gross output of electricity the own use of PPs and CHPs. The sum of net power generation and import of electricity gives the total available electricity for consumption (the sixth stage). But from the sum of available electricity is deducted electricity, which is exported, used for energy sectors and also volumes of distribution losses (the seventh stage). And in the eighth stage, final electricity consumption is allocated among final users: industrial and transport serctors, serives, households and others.

Comparison of electricity flows between stages of the the Sankey diagram allows to provinde qualitative assessment and determine contradictions of electric power sector development (table 2).

Table 2. Qualitative assessment of the EU electric power sector development (based on Sankey diagram analysis).

3.2. Mainstream trends of the EU electric power sector development

The EU strives to be a leader in implementing a climate-neutral policy. The main emphasis is dealt with electricity, which can be produced in a carbon-free way and will satisfy all the energy needs of each branch of society. For this purpose, appropriate transnational legislation, regional and national energy strategies are implemented. Consequently, significant structural shifts are taking place in the EU electric power sector in the direction of achieving the objective of carbon neutrality by 2050 [22]. Based on the Sankey diagram analysis, 6 mainstream trends in the EU electric power sector development can be admitted from 1991 to 2020.

Above all is *the decarbonization of the EU electric power sector*. Firstly, in 1991-2000, there was a shift towards nuclear energy and its share exceeded the share of power generation based on solid fossil fuels. In 2010-2020, the share of nuclear energy (considering the events at the Fukushima Daiichi in 2011) returned to the previous values of 34-35 %, while the share of power generation based on solid fossil fuels continued its decline.

Replacement of power generation based on solid fossil fuels also occurred due to the deployment of gas-fired electricity generation, and its share stabilized in 2010-2020 at the level of 19 %. The primary the deployment of gas-fired power generation was due to its higher energy efficiency and climate friendliness, but later it began to play the role of supporting RES-based power generation and only with the integration of national electricity markets, the requirements for the growth of gas-fired power generation went down. There was a permanent tendency to abandon oil-fired power generation based, down to 2 % in 2020.

The active deployment of unconventional RES-based power generation began in the 2000s starting with wind and biofuels. In 2020, the total share of all types of unconventional RES-based power generation reached 20 %, including 10 % based on biofuels and wastes and 10 % based on intermittent RES power generation (solar and wind). The share of hydropower generation will remain relatively stable, at the level of 5 %, aiming to secure the natural conditions of European water basins.

Thus, the structure of EU power generation accounted for 60 % of low-carbon energy sources in 2020. In absolute terms, the volumes of all types of fossil-fired power generation, except for gas, declined, while unconventional power generation grew rapidly.

With the first trend is strongly connected the second one, which is *deployment of highly efficient cogeneration*. In 1991-2000, there was an insignificant reduction in the share of cogeneration due to the abandonment of outdated cogeneration technologies based on solid fossil fuels. Recovery of cogeneration took place in 2000-2010, which occurred through the development of gas-fired cogeneration, and cogeneration based on biofuels and wastes. In 2010-2020, the share of cogeneration slightly decreased, as well as due to the growth of cogeneration based on biofuels and wastes, and the reduction of cogeneration based on solid fossil fuels.

There were also structural shifts towards an increase in the share of power generation in the structure of the gross output of cogeneration, on 40 % in absolute terms, while the share of heat generation, on the contrary, decreased on 10 % in absolute terms.

In general, the development of cogeneration is considered a way to reduce the useful losses of the electric power sector imposed by the technological limitations of mono-power generation technologies. Structural and technological changes made it possible to increase the energy efficiency of cogeneration from 55 % in 1991 to 63 % in 2020.

The third trend is *increasing the energy efficiency of the electric power sector at all stages*. In addition to increasing the energy efficiency of cogeneration, changes in the mono-power generation led to a reduction in transformation losses, which were down to 50 % in 2020. Firstly, this happened due to the deployment of intermittent RES-based power generation, the input and output energy flows of which are equated. Secondly, there was also an increase in the energy efficiency of gas-fired power generation up to 53 %, mainly due to the development of combined steam-gas cycles and the improvement of the working characteristics of gases. The fastest growth rates of energy efficiency were fixed for biofuel-based power generation up to 34 %, which was due to the advancements in biofuel preparation technologies.

At the same time technological and commercial limitations restricted changes in the energy efficiency of nuclear and solid fossil fuel power generation, which increased slightly.

Increasing the energy efficiency of power generation can be confirmed by the increasing net output from gross power generation. In 2020, the efficiency of electricity production increased by 2% compared to 1991. The most significant growth was achieved over the past 10 years, by 0.8 %, while over the previous 20 years this rate increased only by 1.1 %.

The useful electricity flows are also reduced by its losses in the grids, which in the EU nonetheless increased up to 13 % in 2020 (reasons for this originated from the 4th trend of the EU electric power sector development).

The above-mentioned led to the general energy efficiency increase of the EU electric power sector from 29 % in 1991 to 40 % in 2020.

Decentralization is the fourth and distinctive trend of the EU electric power sector. The causes of the growth of transportation electricity losses are straightly associated with increasing electricity flows through distribution grids, which a priori have larger losses against transmission ones. In absolute terms, distribution losses more than doubled in 1991–2020.

This trend can also be confirmed by the share of autoproducers in the total EU power generation. Their production increased by 28 % in absolute terms in 2020 against 1991. Reduction of autoproducer generation happened in 1991-2010 and associated with rapid declining mono-power generation, and was stopped only in 2010-2020 through the deployment of RES-based power generation. Compared to PP autoproducers, CHP autoproducers were continuously increasing the power generation. Their volumes increased in 2.7 times and in 4 % by share.

Thus, more and more EU electricity consumers aimed at being prosumers and self-providing their own electricity and heat needs. Surplus electricity is transmitted through the distribution network.

Opening the boundaries of the national electricity markets of the EU member states and increasing their electricity dependency form the fifth trend, that should be viewed in a comprehensive manner. The development of market trading, the deployment of RES-based power generation, and the desire to create a single market space on and beyond the EU initiated the growth of external electricity flows. Thus, the import and export of electricity increased more than double in 1991-2020. Subsequently, the self-sufficiency of the EU electric power sector decreased to 93 %, import dependency increased to 13 %, while export dependency remained approximately the same in 2020. So, the EU electric power sector goals caused the need for redistribution of electricity surpluses and shortcomings of national electric power systems.

Awareness of the value of electricity in modern society forms sixth trend – *its penetration in all spheres of economy.* EU final electricity consumption increased by 26 % in absolute terms from 1991 to 2020. There had been made significant structural shifts in the final electricity consumption structure. Firstly, these shifts were associated with responsible electricity consumption by industry. The plateau of industrial electricity consumption was reached in 2000-2010, while it decreased in 2010-2020, returning almost to the level of 1991 in 2020. Therefore, the share of industrial electricity consumption decreased from 45 % in 1991 to 37 % in 2020. At the same time, the improvement of the quality of life led to increasing electricity consumption by the services and households, the volumes of which increased by 1.7 times and 1.4 times respectively in 1991-2020. Therefore, it can be admitted the ongoing convergence of the shares of the three types of activity in the EU: industry, services, and households.

3.3. Key tendencies of the UA electric power sector development

The European course of the national policy of Ukraine has been consistently implemented in the energy sector since 2010, as a member of the Energy Community. However, the implementation of the European energy policy in Ukraine requires significant changes in electric power sector through its reconstruction, modernization and integration into the European energy space. Ukraine strives to catch up with European development trends and achieve carbon neutrality by 2060. The key trends in the UA electric power sector compared with EU ones can be defined as follows.

Compared to the EU the first one Ukrainian trend can be stated as *gas-to-coal switching of the electric power sector of Ukraine.* The UA power generation decreased by 49 % in 1991-2020 as a request of decreasing electricity demand. In the structure of transformation inputs for power generation, a significant increase in the share of solid organic fuel happened in the 2010s down to 36 %. The share of gas-fired power generation, after a slight increase in 1991-2000, gradually decreased after 2000 to 11-12 % in 2010-2020 aiming to decline the gas dependency of Ukraine. The share of nuclear heat in power generation has been constantly growing from up to 53 % in 2020, but in absolute terms it remained approximately the same, having increased only by 3.5 %.

The share of other energy sources increased only by 1 for hydro-, bio-, solar and wind generation. In absolute terms, solar power increased by 513 times, and wind power by 62 times, while hydropower and bioenergy decreased by 42 % and 35 % respectively, in 2010-2020. Oil-fired power generation declined to almost zero in 2020.

Therefore, Ukraine is forced to abandon the more climate-friendly gas-fired power generation, and support dirty power generation based on solid fossil fuels at a sufficient level, and limit hydropower generation for the deployment of RES power generation. This phenomenon nowadays is known as the green-coal paradox.

In contradiction to the EU, the second Ukrainian trend is *reducing the volumes and energy efficiency of cogeneration.* Power generation by cogeneration decreased by 47 % from 1991 to 2020 and was accompanied by a 37 % decrease in heat generation due to the lack of sufficient heat demand in the CHPs-related territories. Despite this, the share of transformation inputs for cogeneration increased from 12 % in 1991 to 17 % in 2020, while the share of cogeneration in gross electricity generation remained unchanged at the level of 11 %.

Thus, the energy efficiency of cogeneration decreased to 68 % in 2020 and was associated with a decrease in the heat share in gross output, and the physical obsolescence of cogeneration.

Significant shifts considered in the structure of cogeneration, gas-fired cogeneration decreased to 45 % by the share, and 51 % in absolute terms in 2020. The share of coal-fired cogeneration, on the contrary, increased to 10 %. The share of nuclear cogeneration remained significant and unchanged at the level of 5 %. Noteworthy the share of other energy sources for cogeneration increased to 12 % in 1991-2020, which meant a significant unclassified part of cogeneration.

Stable too low energy efficiency alienates the Ukrainian electric power sector from the European common one. Transformation losses of the mono-power generation underwent an insignificant reduction from 68 % to 64 % in 1991-2020. So, the energy efficiency of mono-power generation increased only from 32 % to 36 %. This was largely made by the deployment of RES-based power generation, as well as the reconstruction of several coal-fired steam turbine power units with their transfer to the technology of supercritical parameters. Thus, the efficiency of power generation in the coal-fired power industry increased from 30 % in 1991 to 33 % in 2020.

The Ukrainian power generation is physically and morally obsolete, which also leads to significant electricity for the own use of power plants. Through the time the energy efficiency of power generation declined from 94 % in 1991 to 92 % in 2020.

The physical outdated and lack of modernization of power networks also led to high electricity losses through its transmission and distribution. However, the share of electricity losses steadily decreased from 13 % to 9 % in 1991-2020 (as in the EU case, the cause can be found in the next trend).

In general, the energy efficiency of the UA electric power sector accounted for 26 % in 2020, increased only by 3 % compared to 1991.

Centralization is the fourth key trend of the UA electric power sector development, distinct from the EU. Electric power sector of Ukraine is a Soviet heritage of a centralized type. Since the independency of Ukraine, only transmission networks have undergone upgrades to synchronize with ENTSO-E, while distribution networks remain obsolete. This fact is associated with a decrease in transport losses of electricity.

The deindustrialization of Ukraine has led to a greater centralization of the electric power sector by the closure of a number of autoproducers of electricity. Their share in the structure of gross output decreased by 65 % in absolute terms, incl. CHP autoproducers by 62 % and PP autoproducers by 74 % in 1991-2020.

Isolation and self-sufficiency of the UA electric power sector can be recognized as fifth trend. Ukraine's electric power sector has been and remains self-sufficient, the net power generation has always exceeded consumer needs. In 1991 this level was at 102 %. There was its growth to 122 % in the 2000 and Ukraine actively traded electricity with the CIS countries. The part of the Ukrainian electric power system was synchronized with ENTSO-E since 2002. This led to the opening of electricity exports to Europe. Electricity trading with the CIS countries was close to zero level in the 2010s and there were only technical electricity flows. The opening of electricity imports from Europe to Ukraine became possible after the implementation of the European electricity market model in Ukraine in mid-2019. In 2020, the import dependency of the Ukrainian electric power sector was at 2 %, while the export dependency was at 12 %.

Currently, Ukraine has limited opportunities for electricity trading with neighbouring countries, which are limited by cross-border transmission and inconsistencies with European trading rules, even despite the full synchronization of the Ukrainian energy system with the European common one.

Deindustrialization of the UA alters electricity consumption patterns and is the sixth trend. It can be admitted similar structural shifts in Ukrainian final electricity consumption compared to the EU, but the reasons of these are great differ. Final electricity consumption in Ukraine decreased by 43 % in 1991-2020. At the same time, a similar drop was already fixed in 1991-2000, which was stopped in 2000-2010, reaching an 18 % increase in electricity consumption in 2010. However, the occupation of part of the territories and the economic potential of Ukraine decreased the final electricity consumption by 15 % in 2020 against 2010.

The falling industrial production led to a reduction in industrial electricity consumption by 76 % in 1991-2020, although there was an increase of 9 % in 2000-2010, and a decrease of 31 % in 2010-2020. Consequently, the share of industrial electricity consumption in Ukraine has decreased from 68 % in 1991 to up to 40 % in 2020. The declining industrial activity led to a reduction in transport flows.

Electricity consumption by the service sector, on the contrary, decreased only by 38 % in 1991-2000, while their volumes increased by 144 % in 2000-2020, led to an increase in its share to 19 % in 2020. Notwithstanding the socio-economic conditions, household electricity consumption increased all time in 1991-2020. And even the loss and occupation of part of the territories of Ukraine led to a reduction in household electricity consumption only by 0.5 % in 2020 compared to 2010. The share of household electricity consumption reached 32 % in 2020.

Consequently, in 2020, the total share of non-commercial electricity consumption exceeded the share of commercial electricity consumption by 6 %, although in 1991 this ratio was reversed exceeded 4 times, in 2000 – 2 times, and in 2010 – 14 times.

4. Discussion and conclusions

It is difficult to overestimate the role of the electric power sector in ensuring the energy transition to sustainable energy in the future. In each country, the electricity sector is unique, which depends on the specific technical conditions of the electric power system, the climate and natural conditions of the related territory, and government regulation of electricity market. But there is a common vision of the future, and it is possible to highlight the general trends and characterize individual transformation processes on the path of sustainable development. This study proposes methodological support for the analysis of the electric power sector development, which includes the following.

- Input-output model of electricity flows, which considers different stages of the electric power chain starting from primary energy sources and ending with electricity consumption by types of activity;
- Sankey diagram analysis of electricity flows in MS Power BI software that allows slicing data for time periods and countries.
- Qualitative assessment of electric power sector development, which is provided by three group indicators such as energy efficiency, structural, and security and integration.

Ukraine aims to be a full member of single European community and comply with the European framework of economic policy, including the energy sphere. But there is still a significant gap between Ukraine and European member-states. By comparing the UA and EU trends of electric power sector development it was possible to determine the contradictions of the Ukrainian one with the general vision of the EU. Understanding of these contradictions is a background for solving them and making comprehensive decisions for rebuilding electric power sector after the war-time. Among them are the following.

- The first one is that Ukraine is forced to keep coal-fired generation for demoting gas dependency and as for supporting RES-generation. At the same time the EU prioritizes the development of ecology-friendly generation, both gas and renewable, looking for more favourable market conditions to meet primary energy source needs.
- The second one is the falling of cogeneration in Ukraine while as the EU strives to support deployment of highly-efficiency cogeneration. But the solution to this issue in Ukraine depends on the comprehensive development of electric power and district heating sectors.
- The third one is outdated and low energy efficient electric power generation in Ukraine, while in European countries development of highly efficient generation supporting through capacity remuneration mechanisms or even green auctions. In Ukraine, such mechanisms aren't implemented yet.
- The fourth trend is the centralization of the UA electric power sector vs the decentralization of the EU one. Ukrainian electricity consumers have restricted investment abilities and legal obstacles in deploying their own generation, while the EU strives to support the development of distributed generation.
- The fifth one is differentiation on energy security: whereas the EU aims at create single European electricity market, disregarding electricity dependency of member-states, Ukraine remains isolated but self-sufficient due to the lack of cross-border capacities. Synchronization of the Ukrainian electricity system with the European one poses new challenges for Ukraine: where and how to integrate into the European space.
- And the last but not least trend is divergence in the electricity consumption patterns in Ukraine and the EU. Unfortunately, it cannot be solve internally inside the electric power sector and it has to adopt to these challenges: through the develop more flexible capacities, provide incentives for consumers of levelling the electricity consumption schedule.

The general conclusion of this research is following: although Ukraine strives to adhere to European trends of the deployment of RES-based electric power generation, however, other trends were contradictory, intensive shifts were insignificant and were complicated by the physical and moral obsolescence of electric power system.

As can be seen, the solution of of the most of contradictions greatly depends on the public authority actions and should be included in the national energy policy of Ukraine. It can be supposed that these contradictions will be exacerbated after the war-time but the synchronization of Ukraine with the ENTSO-E is the great challenge but also the window of opportunities. Thus, government decisions have to be made for the rebuilding of electric power sector.

Abstract. The Third and Fourth EU Energy Packages, as well as the Energy Strategy of Ukraine "Safety, Energy Efficiency, Competitiveness" until 2035, define the development of electricity production using renewable energy sources among the priorities of the energy sector. In this situation, the decision-making process on the integration of renewable energy sources into the electricity supply system is of particular importance. The article develops a fuzzy model for assessing the risks of connecting (integration) renewable energy sources to the power supply system. The toolkit, based on logical rules, allows modeling various connection options. The data obtained can then be used to set requirements for the parameters of the electrical installation at the stage of issuing technical specifications to the customer. The modeling results demonstrate the adequacy of the developed knowledge base and the possibility of using it to develop a methodology for the controlled and efficient connection of renewable energy sources to the power grid.

1. Introduction

In the past, national energy planning involved the development of a centralized infrastructure investment program for a certain period of time. However, in the current geopolitical context, environmental damage, depletion of fossil fuels and territorial imbalances are factors that require a change in the energy mix, and the introduction of measures to invest in energy diversification and the integration of renewable energy sources (RES).

At present, the construction of clean energy generation facilities is carried out solely from the standpoint of commercial attractiveness, but not from the standpoint of the country's economic development, environmental friendliness and consumer interests. The rapid development of green energy is taking part without consideration of the real needs of Ukraine's energy system for additional generating capacity. This can lead to destabilization of its functioning and the possibility of emergencies.

Decision-making on the integration of RES into the electricity supply system should be based on an analysis of the modes and processes that arise under different options for connecting RES. However, decision-making will almost always take place in conditions of incomplete information, which will cause some uncertainty about the results of these connections. In such circumstances, the use of fuzzy logic elements in the process of assessing risk factors is justified.

2. Purpose and objectives

The purpose of the article is to develop a methodology that allows for a controlled and efficient connection of RES to power grids based on a risk profile. The objective of the article is a study of the use of fuzzy logic for risk assessment in the connection of RES to the electricity supply system, namely, a comprehensive consideration of the influence of factors.

3. Research material and results

According to a report by the International Renewable Energy Agency (IRENA), 3064 GW of renewable generation capacity was in operation worldwide at the end of 2021 [1]. Of this volume, 40% is accounted for by hydroelectric power plants, 28% by solar power plants and 27% by wind power plants. However, solar and wind power have dominated the expansion of renewable energy capacities lately (figure 1).

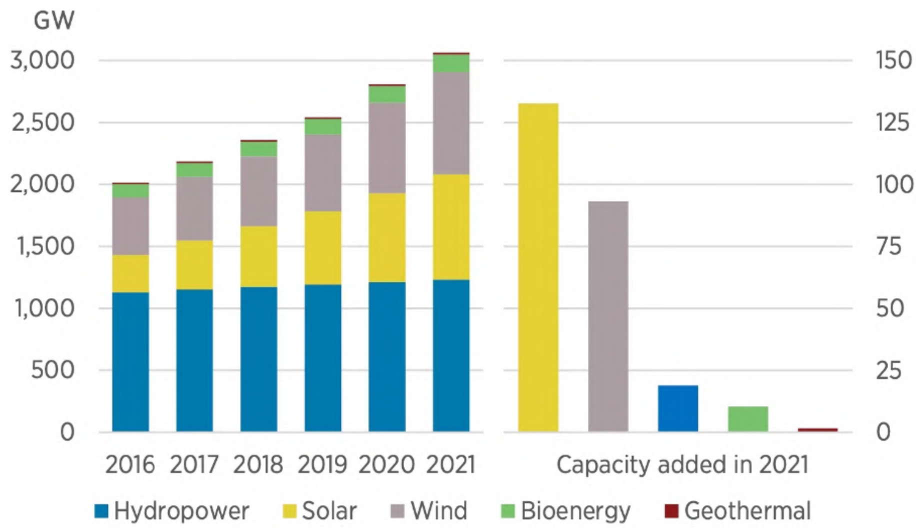

Figure 1. Growth of RES capacities [2].

The studies [3, 4] has shown that further development towards increasing the share of solar and wind power plants in the generation of the power system poses significant challenges to ensuring reliable electricity supply and efficient management of the distribution system. In view of this, as well as the growing technical capabilities of RES and related equipment, there is a need to set requirements for the main equipment or to install additional equipment for flexible and dynamic regulation of RES operation.

Unfortunately, there is currently no effective, comprehensive system for assessing and managing risks in the integration of RES into the electricity supply system. The practical aspects of risk management in this segment have not been sufficiently researched and covered, considering the experience of the world's leading countries and the grid specifics of the electricity supply system. There is an urgent need to create a comprehensive risk management system for the integration of RES, which will be adapted to the current realities of the Ukrainian power system.

In the energy sector, decision-making often takes place with significant incomplete information, lack of statistical estimates, and in poorly formalized conditions. In these circumstances, many researchers suggest using fuzzy logic for decision-making.

Courtecuisse et al [5] use this method because it facilitates the analysis and definition of fuzzy control algorithms adapted for complex hybrid systems. In addition, the fuzzy logic method is adapted to solve the problems of forecasting energy production from RES and changes in grid frequency with load changes. This allows them to avoid accurate and detailed models of different sources and system topology.

Dimitroulis and Alamaniotis [6] presents a fuzzy logic-based energy management system for residential prosumers, who produce electricity for their own consumption and sell it to the grid. The use of a mathematical model based on fuzzy logic allows reducing energy consumption costs and increasing profits from the sale of excess energy to the grid. This was confirmed by the results of practical implementation.

The article [7] addresses the problem of optimal control of energy storage systems to maintain voltage/frequency in distribution power grids, considering the degradation of batteries. Liu et al propose an optimal fuzzy control method that maximizes the useful effect, reduces power losses, and minimizes battery degradation.

Yahyaoui et al [8] proposes and evaluates a methodology based on fuzzy logic for energy management in autonomous installations with photovoltaic panels and limited battery capacity. The decision-making process includes consideration of the system's autonomy, battery protection against deep discharge and overcharge, and power supply stability.

Ziemba [9] also use a fuzzy logic model, and more exactly, a modified fuzzy TOPSIS method for multi-criteria assessment of investments in onshore wind farms in Poland. This method is also used to determine the most cost-effective investment. The fuzzy TOPSIS method allows capturing the uncertainty of input data as well as conflicting criteria.

Pankovits et al [10] uses fuzzy logic algorithms to integrate renewable energy generation and storage units, using the example of a railway substation. This made it possible to contribute to limiting the excess of the estimated capacity from the grid and to promote local consumption of renewable energy through empirical supervision parameters. The multi-criteria approach, including energy, environmental and economic constraints, was implemented at different time levels.

De Carvalho et al [11] presented a methodology using fuzzy logic to optimize the control of an embedded power system. The system under consideration was equipped with a supercapacitor energy storage device that performs the function of power smoothing and peak reduction. The optimization goals were to minimize the voltage fluctuations of the DC circuit and to improve the system efficiency by reducing power dissipation.

In turn, Baqui [12] formulated an automated decision-making model for the allocation of power grid resources using fuzzy logic algorithms. The rule base was created on the knowledge of the subject area and analysis of the operator's decision-making activities.

The article of Ibrahim et al [13] is devoted to the development of a fuzzy logic-based energy management system for hybrid energy sources. The proposed system uses fuzzy logic to make decisions on load distribution between different energy sources depending on external conditions and consumer requirements. In addition, the system can adapt to changing operating conditions and ensures optimal energy utilization. Studies have shown that the proposed fuzzy logic-based electricity consumption management system is effective and can reduce electricity costs.

Castillo-Calzadilla et al [14] describes a methodology for assessing positive energy districts (PEDs) based on fuzzy logic. A PED is an area where most of the energy consumed is provided by renewable sources and excess energy is transferred to the grid. The use of this methodology can help determine the degree of sustainable development and energy security in different PEDs. The results of the study demonstrate the effectiveness of the proposed methodology and the possibility of its use to assess positive energy districts in different regions and cities.

Fuzzy logic has also been used to evaluate crops that can be grown profitably for bioenergy production. Lewis et al [15] used a fuzzy spatial suitability model with physical and economic variables to identify non-agricultural areas that could be profitably cultivated with bioenergy crops that are more resilient to environmental conditions.

Alekhya et al [16] consider risk assessment using fuzzy logic. This study proposes a risk assessment methodology that uses fuzzy logic to model and analyze uncertainty. This methodology involves creating a mathematical model that includes a set of factors and fuzzy rules to assess the degree of influence of each factor on the project cost. The use of fuzzy logic allows modeling uncertainty and ambiguity in risk assessment. The results of the study demonstrate the effectiveness of the proposed methodology and its ability to more accurately assess the risks of project cost overruns.

In the tasks of risk assessment when connecting RES and decision-making under uncertainty, problems arise that are difficult to solve using traditional methods. In a real-world model, there is always a technological scatter of parameters due to the complexity of the system. To solve this problem, it is necessary to use fuzzy concepts and knowledge that describe the control process using productive if-then rules. The most important advantages of this method of evaluation include the ability to use the expert's experience without drawing up differential equations. The use of fuzzy logic for decision-making is most useful for systems with poorly formalized processes [17].

The advantages of using a fuzzy logic model in decision-making are as follows:

- fuzzy logic methods make it possible to describe risk factors in a qualitative, verbal way by introducing the concepts of linguistic variables, the meaning of which is understandable to the expert;
- the use of fuzzy sets allows formalizing more flexible relationships between the factors of each of the risks under study. This is more in accordance with the nature of the real interactions studied in the electric power industry;
- fuzzy methods make it possible to make decisions under conditions of incomplete information by synthesizing and analyzing qualitative values. This is important for decision-making in connecting RES to the power supply system.

In general, the mechanism of logical inference includes four stages [18]: introduction of fuzziness (fuzzification), fuzzy conclusion, composition and reduction to clarity, or defuzzification (figure 2). Fuzzy inference algorithms mainly differ in the type of rules used, logical operations, and the type of defuzzification method.

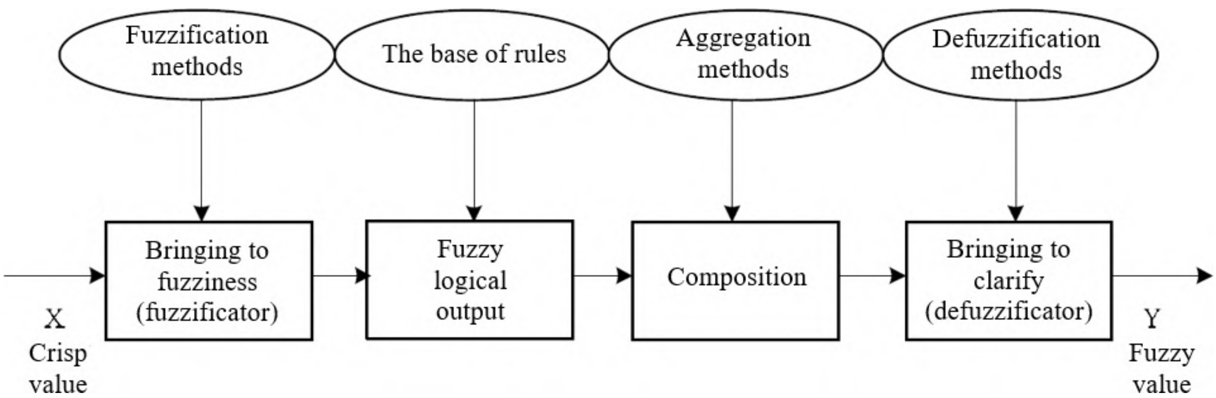

Figure 2. System of the fuzzy logic model.

Despite the complexity of the mathematical apparatus embedded in the algorithms, this approach allows for a fairly flexible model that will operate with numerous input arguments and provide a resultant value. The resulting value can be considered objective with a certain degree of approximation. Because there are a variety of subjective things, such as the assessment of specific threats by experts [19].

The Mamdani algorithm was used to create a risk profile for the integration of RES into the power supply system. The application of this algorithm allows us to qualitatively describe the possible causes (processes or phenomena) that contribute to the connection problem. Subsequently, with this information about the factors, it is possible to build a functional correspondence.

In Mamdani's model, each rule has a degree of execution ω_i, which is calculated as follows:

$$\omega_i(x_1, ...x_{n_x}) = \bigwedge_{j=1}^{n_x} \mu_{j,i}(x_j),\ i = 1...n_r, \tag{1}$$

where $\wedge$ – a fuzzy conjunction operation that corresponds to the "AND" operator in the rules; n_x – number of inputs; $\mu_{j,i}(x_j)$ – the membership function on the j-th input in the antecedent of the i-th rule; n_r – number of rules.

After the degrees of rule fulfillment are calculated, the fuzzy values of the rule constituents are calculated using implication (in Mamdani systems, the minimum operation is usually used).

Then, using the aggregation operation (in Mamdani systems, the maximum operation is usually used), the fuzzy output value with the membership function $\mu_{Yout}(y)$ is calculated according to the expression:

$$\mu_{Yout}(y) = \bigvee_{i=1}^{n_r} (\omega_i(x_1, ...x_{n_x}) \wedge \mu_{Yi}(y)), \tag{2}$$

where $\vee$ is an aggregation operation that corresponds to the union of fuzzy rules by ELSE, which is equivalent to a disjunction in the Mamdani system; $\wedge$ – implication operation (equivalent to a conjunction in the Mamdani system); $\mu_{Yi}(y)$ - is the membership function of the concatenation of the i-th rule.

After the rule inputs have been processed by the algorithm described above and the fuzzy output $\mu_{Yout}(y)$ is obtained, it is necessary to find the corresponding crisp value using defuzzification y^*. The main methods of defuzzification are the center of gravity, center of sums, and average maximum methods.

4. Practical application

The Matlab environment used in the study is a specialized package Fuzzy Logic Toolbox [20]. It is used to create and further use a fuzzy logic system in an interactive mode.

To assess the risks of integrating RES into the power supply system, indicators reflecting the impact of these sources on the system are used. These elements include such factors as: the occurrence of higher harmonics (Ku), voltage deviation from Un (ΔU) and reactive power flow ($\cos\varphi$). The occurrence of higher harmonics was defined by an ordered term set of values consisting of three terms: "low", "medium" and "high". The terms are listed in order from the most negative to the most positive. According to the tasks set, it is enough to select 3 linguistic variables to describe the aspects of the factor for further application of the fuzzy logic method. This scale is also used for other indicators (table 1).

Table 1. Scale for assessing linguistic variables.

Factors	Range	Scale (L) (M) (H) in rel. units		
Higher harmonics	0 % ...10%	0.90 ...0.94	0.92 ...0.98	0.96 ...1.0

Reactive power flow	0.75 ...1.0	0.75 ...0.85	0.80 ...0.95	0.90 ...1.0

A distinctive principle of the Mamdani method is that its rules of logical inference contain fuzzy values (membership functions) in their concretions (on the right side). The Matlab module includes 11 built-in membership types. However, in practice, it is convenient to use those membership functions that allow an analytical representation in the form of some simple mathematical function. This simplifies not only the corresponding numerical calculations, but also reduces the computational resources required to store individual values of these membership functions [21]. Therefore, in our study, we considered the triangular, trapezoidal, and simple Gaussian membership functions.

The triangular membership function (figure 3) is formed using a piecewise linear approximation.

A triangular function (for example, for the "medium" term of ΔU) can be given analytically

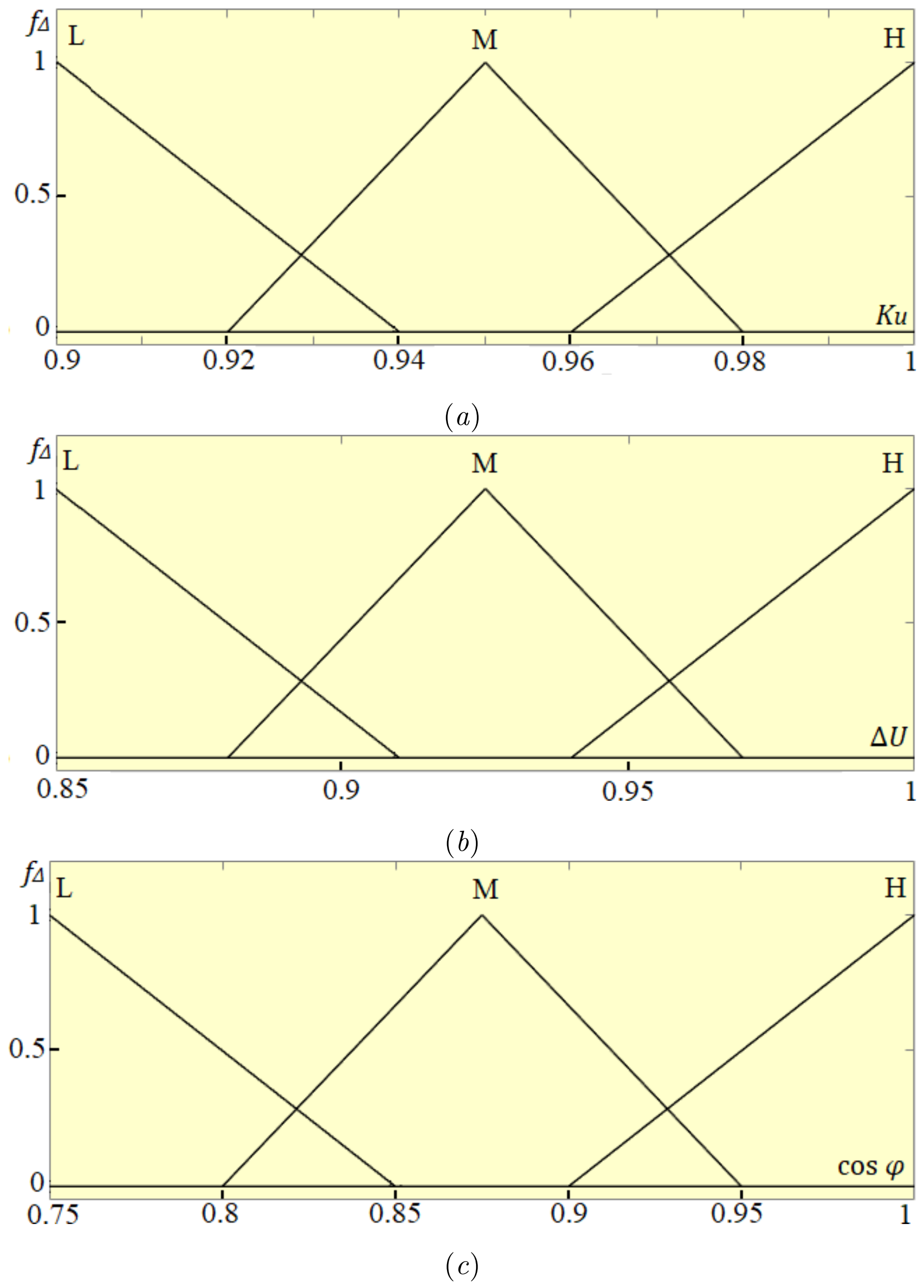

Figure 3. Graphs of the triangular membership function for variables $Ku(a)$, $\Delta U(b)$, $\cos\varphi(c)$.

by the following expression:

$$f_{\Delta}(\Delta U_m; a, b, c) = \left\{ \begin{array}{cc} 0, & \Delta U_m \leqslant a \\ \dfrac{\Delta U_m - a}{b - a}, & a \leqslant \Delta U_m \leqslant b \\ \dfrac{c - \Delta U_m}{c - b}, & b \leqslant \Delta U_m \leqslant c \\ 0, & c \leqslant \Delta U_m \end{array} \right\} =$$

$$= \left\{ \begin{array}{cc} 0, & \Delta U_m \leqslant 0.88 \\ \dfrac{\Delta U_m - 0.88}{0.925 - 0.88}, & 0.88 \leqslant \Delta U_m \leqslant 0.925 \\ \dfrac{0.97 - \Delta U_m}{0.97 - 0.925}, & 0.925 \leqslant \Delta U_m \leqslant 0.97 \\ 0, & 0.97 \leqslant \Delta U_m \end{array} \right\}.$$

The parameters a and c characterize the base of the triangle, and the parameter b characterizes its vertex. As you can see, this membership function generates a normal convex unimodal fuzzy set with a carrier – the interval (a,c), the boundaries $(a, c) \setminus \{b\}$, the kernel b and the mode b.

The following is a trapezoidal membership function (figure 4).

In turn, the trapezoidal (also for the term "medium" of ΔU) can be given analytically by the following expression:

$$f_T(\Delta U_m; a, b, c, d) = \left\{ \begin{array}{cc} 0, & \Delta U_m \leqslant a \\ \dfrac{\Delta U_m - a}{b - a}, & a \leqslant \Delta U_m \leqslant b \\ 1, & b \leqslant \Delta U_m \leqslant c \\ \dfrac{d - \Delta U_m}{d - c}, & c \leqslant \Delta U_m \leqslant d \\ 0, & d \leqslant \Delta U_m \end{array} \right\} = \left\{ \begin{array}{cc} 0, & \Delta U_m \leqslant 0.88 \\ \dfrac{\Delta U_m - 0.88}{0.91 - 0.88}, & 0.88 \leqslant \Delta U_m \leqslant 0.91 \\ 1, & 0.91 \leqslant \Delta U_m \leqslant 0.94 \\ \dfrac{0.97 - \Delta U_m}{0.97 - 0.94}, & 0.94 \leqslant \Delta U_m \leqslant 0.97 \\ 0, & 0.97 \leqslant \Delta U_m \end{array} \right\}.$$

The parameters a and d characterize the lower base of the trapezoid, and the parameters b and c characterize the upper base of the trapezoid. In this case, this membership function generates a normal convex fuzzy set with a carrier – the interval $(a,\ d)$, the boundaries $(a, b) \cup (c, d))$ and the kernel $[b,c]$.

A commonly used method of generating a membership function is to apply a Gaussian curve. Based on the Gaussian distribution function, two types of membership functions can be constructed: a simple Gaussian membership function (figure 5) and a bilateral one formed using different Gaussian distribution functions.

The symmetric Gaussian function for the "medium" term of ΔU is given analytically by the following expression:

$$f_G(\Delta U_m; \sigma, c) = e^{\dfrac{-(\Delta U_m - c)^2}{2\sigma^2}} = e^{\dfrac{-(\Delta U_m - 0.925)^2}{2 \cdot (0.015)^2}}.$$

In this expression, c is the coordinate of the maximum of the membership function; and σ is the concentration coefficient of the membership function.

The accuracy of risk assessment in the integration of RES depends on the completeness of the knowledge base. The flexibility of the analysis process is achieved by setting key decision-making rules. The course of logical inference is formed at the stage of defuzzification, in our case, using expert data obtained in the study [3]. For each rule, the membership functions of the input variables and the output variable are displayed (figure 6).

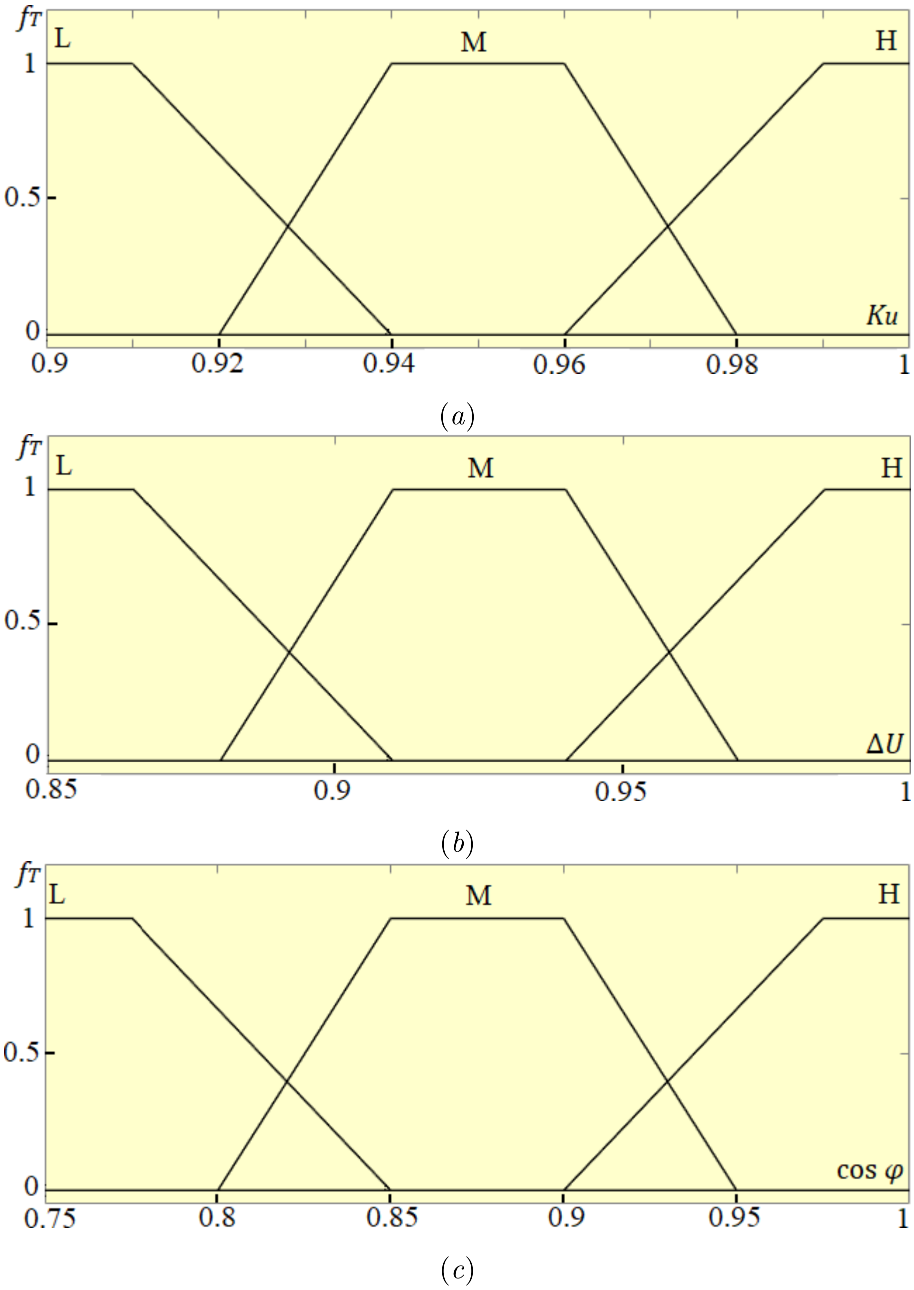

Figure 4. Graphs of the trapezoidal membership function for variables $Ku(a)$, $\Delta U(b)$, $\cos\varphi(c)$.

Considering the respective possibility of occurrence and the level of consequence of the realization of factors, the results of building fuzzy logic are obtained. In this case, they are based on the identified 27 rules. To analyze the results of the model, a graphical interpretation of the rules was made. This made it possible to see how the model works for the three output parameters Ku, ΔU, $\cos\varphi$ (figure 7).

The level of integration of RES into the electricity supply system reflects how efficiently and reliably the grid is provided with energy from RES. The integration of RES into the electricity supply system can have different levels, depending on the type and capacity of the installed equipment of these sources, as well as on the size and characteristics of the electricity grid.

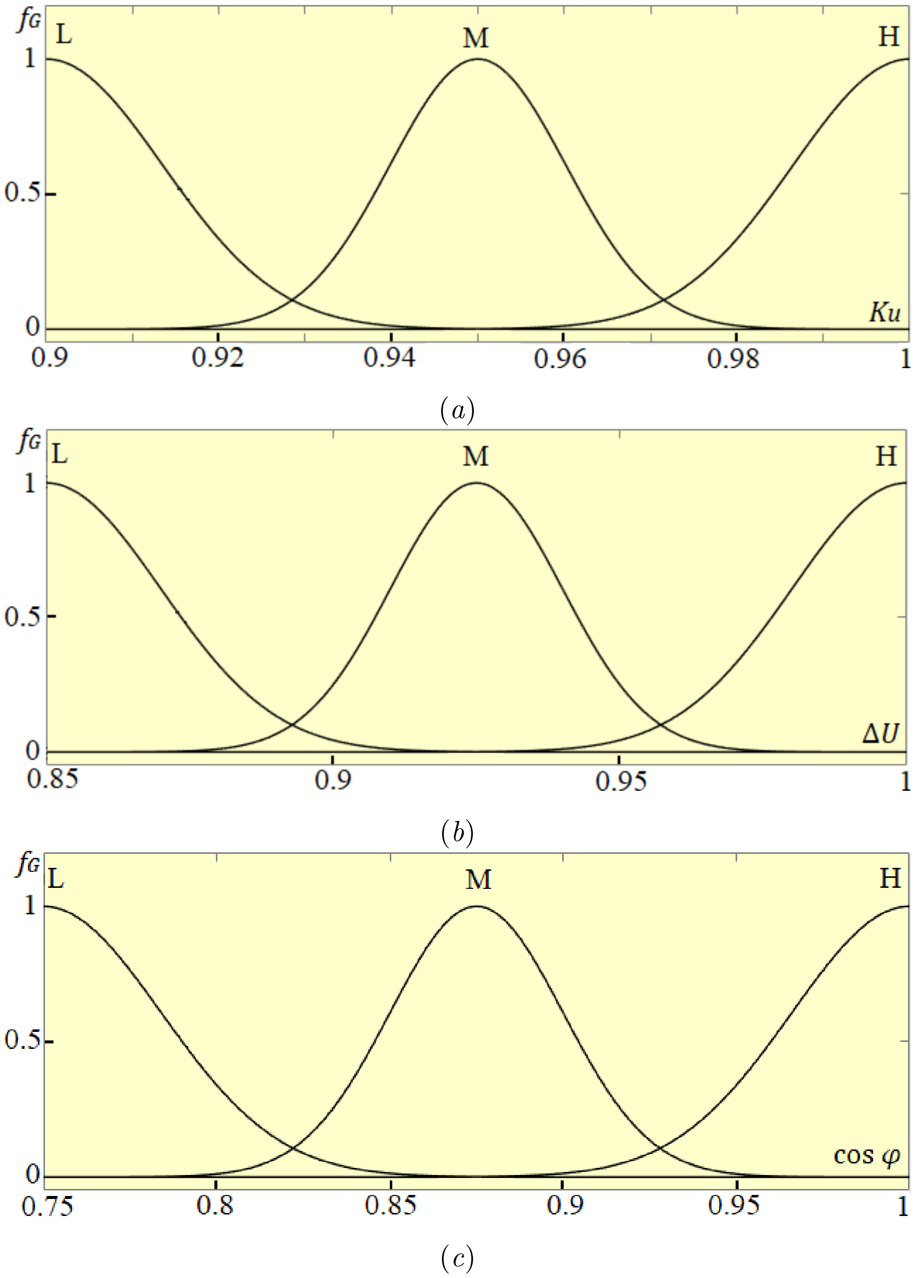

Figure 5. Graphs of a simple Gaussian function membership function for variables $Ku(a)$, $\Delta U(b)$, $\cos\varphi(c)$.

According to the results, the level of integration at the same values of the system parameters for the three selected membership functions is in a small range of deviations. For the triangular membership function with relative values Ku=0.94, ΔU=0.95, $\cos\varphi$=0.92, the level of integration is 0.763, for the trapezoidal function – 0.757, and for the simple Gaussian function it is 0.725. The small range of deviations indicates the adequacy of the developed model.

It should be noted that the method used allows us to track the level of RES integration at different values of system parameters. For example, for a triangular membership function with other parameter values (Ku=0.91, ΔU=0.92, $\cos\varphi$=0.91), the integration rate decreases to 0.537. That is, a mechanism for making a generalized decision when integrating renewable

26. If (Ku is H) and (ΔU is H) and (cos_φ is M) then (level_of_integrarion is VH) (0.895)
27. If (Ku is H) and (ΔU is H) and (cos_φ is H) then (level_of_integrarion is VH) (1)

Figure 6. Fuzzy logic rule base

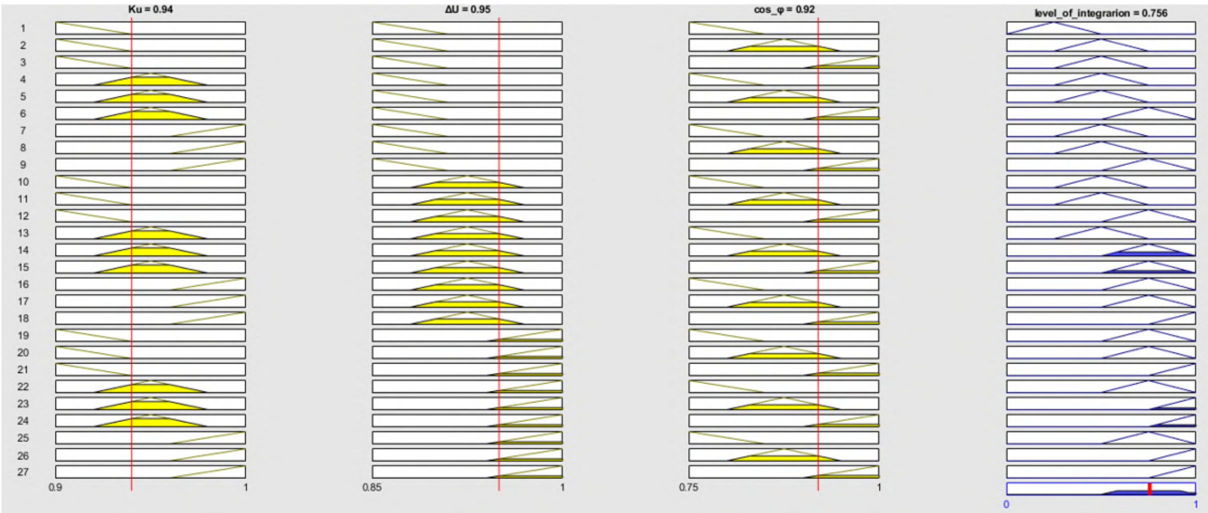

Figure 7. Results of calculating fuzzy logic for 27 rules of the triangular membership function.

energy sources into the power supply system appears. In the future, this will be used to develop a methodology for the controlled and efficient development of renewable energy.

The Matlab functionality makes it possible to view the input-output surface corresponding to the synthesized fuzzy system. However, when we go beyond the three dimensions, we begin to face problems with the full display of the results. Since our system has three inputs and one output, the program can only generate a three-dimensional output surface where any two inputs change, but one of the inputs must remain constant (figures 8-10).

The fuzzy inference surface makes it possible to visually assess the probabilities of a situation that may result from the connection of a particular RES installation. In order to obtain the highest efficiency of RES, it is necessary to adhere to the parameters that form the yellow and green zones of the profile. The blue zone, on the contrary, is characterized by the greatest risks to the normal functioning of the system and shows a categorically unacceptable integration of the system and RES under these parameters. Getting into the blue zone is also not recommended, as it shows low efficiency from RES and a higher probability of risk consequences. The graphs have a local decrease in the level of integration, which is explained by the number of logical variables and rules. With their increase, the model will more accurately reflect the level of integration for making decisions on RES connection, which will be done in further research.

The developed system makes it possible to quickly carry out the evaluation procedure based on fuzzy logic tools and quantify the level of integration. It can also be supplemented or modified by an expert by introducing other rules, adjusting membership functions for variables,

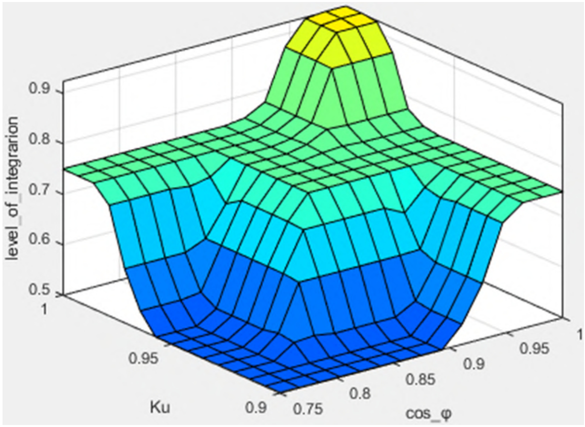
Figure 9. The fuzzy inference surface of the trapezoidal membership function with input parameters ΔU, Ku at $\cos\varphi = 0.92$ (a) and $\cos\varphi = 0.97$ (b).

and adding new parameters. Therefore, using this toolkit based on logical rules, it is possible to model various connection options, and then use the data obtained to set requirements for the parameters of the electrical installation at the stage of issuing technical specifications to the customer.

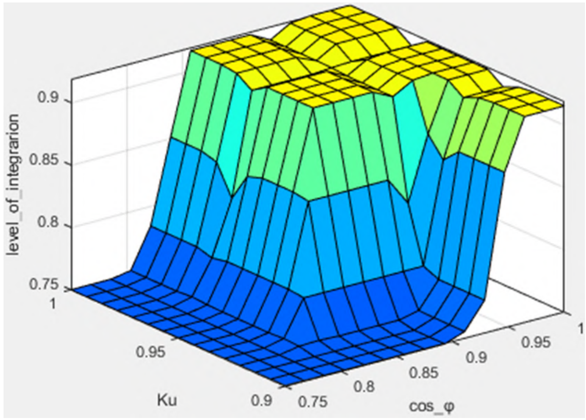
The results of the fuzzy logic system in the Matlab environment show that the program tools allow tracking the level of RES integration at different values of system parameters. The modeling results demonstrate the adequacy of the developed knowledge base and the possibility of its use for the controlled and efficient connection of renewable energy sources to power grids.

5. Conclusions

The growing role of intermittent generation from RES, the need to reduce the use of fossil fuels, and the different profile of consumer demand create a number of risks for the system. They relate to the impact of RES sources on the planning, organization of operation, and



(*a*)



(*b*)

management of power grids. At present, the construction of clean energy generation facilities is carried out solely from the standpoint of commercial attractiveness, not from the standpoint of the country's economic development, environmental friendliness and consumer interests. The rapid development of "green" energy is taking place without considering the real needs of Ukraine's energy sector for additional generating capacity, which may lead to destabilization of the country's energy system and the possibility of emergencies.

In the tasks of risk assessment in connection of RES and decision-making under uncertainty, problems arise that are difficult to solve using traditional methods. In a real-world model, there is always a technological scatter of parameters due to the complexity of the system. To solve this problem, it is necessary to apply the mathematical apparatus of fuzzy logic theory. One of the most important advantages of this method is the ability to use the experience of an expert without drawing up differential equations.

We have developed a fuzzy model for risk assessment in the integration of RES into the electricity supply system based on expert data. To formalize the initial data, we used triangular, trapezoidal, and simple Gaussian membership functions for the input variables. According to the results, the level of integration at the same values of the system parameters for the three selected membership functions is in a small range of deviations, which indicates the adequacy of the developed model. In the future, it can be supplemented or modified by an expert by introducing other rules, adjusting the membership functions for the variables, and adding new parameters.

The use of fuzzy logic allows tracking the level of RES integration at different values of system parameters. The toolkit, based on logical rules, allows modeling various connection options. The data obtained can then be used to set requirements for the parameters of the electrical installation at the stage of issuing technical specifications to the customer. The modeling results demonstrate the adequacy of the developed knowledge base and the possibility of its use for the controlled and efficient connection of renewable energy sources to power grids.

E-mail: ivan_na@i.ua

Abstract. This paper studies the potential impact of electric transportation charging modes on Ukraine's Integrated Power System operation and emission levels. The non-linear integer least-cost model developed by the Institute of General Energy was used. Three electric transportation charging modes were analyzed. Calculations illustrate mainly positive effect of electric transportation on the energy system operation, particularly reduction of fuel consumption and emissions of greenhouse gases and pollutants. The results would support the development of strategies for electric transportation development.

1. Introduction

Nowadays the humankind is facing the dramatic challenges – the limited technologically available resources of fossil fuels and global climate change. Implementation of electric transportation is effective way to address these problems. Naturally, the part of electricity is produced from fossil fuel combustion, but there are alternative sources of electric energy integrated in national power systems, i.e. nuclear energy, hydro, wind, solar and other renewable sources. Also it should be noted that electric transportation charging stations equipped by solar batteries do not use any fossil fuel and do not produce any greenhouse gases (GHG) and pollutant emissions.

The fleet of electric transportation (ET) rapidly increases worldwide [1, 2]. The number of electric vehicles per 1,000 residents in EU significantly varies. For example, in 2020 this indicator totals 6.5 in France, 8.5 in Germany, 20.6 in Sweden and 81 in Norway. Ukraine is significantly behind in the number of electric cars (approximately 0.75 numbers of electric vehicles per 1,000 residents). Now Ukrainian government plans to develop national strategy and programs for electric transportation implementation.

The common practice is to compare emissions from ET with petrol cars using average consumption of electricity/fuel per 1 km and specific emissions of GHG and pollutants from electricity/fuel [3–6]. Similar approach is used for evaluating economic efficiency of electric vehicles exploitation. This approach is not comprehensive. We should take into account that ET charging is additional load on energy system operation. Therefore electric transportation causes changes in energy system operation and consequently changes in the emission level.

Although ET presents several environmental advantages, a massive introduction of them could create several issues in the power grid, which has been studied by several researchers [7]. For example, in [8], the impact of different penetration levels of plug-in electric vehicles in a distribution system was considered, and it was demonstrated that a significant ET load leads to voltage drop and voltage deviations. In [9], it was demonstrated that charging ET considerably increases the distribution load and, so, the total power losses. Furthermore, ET charging increases the daily peak load. Shafiee et al [10] indicated that ET generate substantial investment costs in distribution systems, and that power losses can reach up to 40 percents for an EV penetration of 62 percents. Lucas et al [11] exposed that ET fast charging leads to harmonic issues and failure to respect IEEE standard limits. Turker et al [12] proposed that the life durations of low-voltage transformers are reduced with a high penetration of ET.

Although ET presents several environmental advantages, a massive introduction of them could create several issues in the power grid, which has been clarified by Clairand et al [7]. For example, smart charging of ET is an important area of study, which allows EV users and grid operators to properly manage ET charging profiles in order to obtain technical and economic benefits, as well as considering the specific demand-side management of ET [13]. Some other researchers have focused on the management of ET charging stations. In particular, it is crucial to locate the optimal placement of ET charging stations to meet technical grid constraints, considering customer wait times [14, 15].

So the fundamental study of the influence of electric transportation implementation on Ukraine's Integrated Power System (IPS) is needed for developing strategies of ET fleet increase. The experience of other countries is not applicable for Ukrainian circumstances. The Ukraine's IPS is unique complex system with different energy sources, partly obsolete equipment etc.

The main factors to consider are the volume of ET and ET charging modes. The specific feature of electric transportation is the opportunity to vary the charging load during the day due to implementing different regulatory and/or incentive measures.

The *aim* of the paper is to estimate the effect of different ET charging modes on the IES operation, fossil fuel consumption, GHG and pollutant emissions.

2. Methodology

Author use program and information complex simulating the operation of Ukraine's Integrated Power System developed in the Institute of General Energy of the National Academy of Sciences of Ukraine [16].

This complex is based on non-linear mixed integer least-cost dispatch model. It contains information of all power units in the Ukraine's IPS mentioned below.

Nuclear energy provides a reliable base load and covers more than half of the electricity production in Ukraine (55.5% in 2021). There are four nuclear power plants (NPPs) in Ukraine with a total installed capacity of 13,835 megawatt (MW) (15 reactors in total, including 13 reactors with a capacity of 1,000 MW and two reactors with a capacity of 415 MW and 420 MW, respectively) [17].

At the beginning of 2022, there were 12 thermal power plants (TPPs) in Ukraine with a total installed power capacity of 21.5 gigawatt (GW). Most TPPs are using coal as a primary fuel. In 2021, the TPPs' share in electricity production was 23.8% [18]. At the beginning of 2022, the total installed power capacity of combined heat and power plants (CHPs) was 6.1 GW. Most CHPs are using natural gas as a primary fuel. In 2021 the share of CHPs and cogeneration units in electricity production was 5.5%.

At the beginning of 2022, there were ten large hydropower plants (HPPs) with a total installed power capacity of about 4.7 GW (101 units in total) and three pumped storage plants (PSPs) with an installed capacity of 1.5 GW (11 units ranging from 33 MW to 324 MW per unit). Hydropower plays a crucial role in the functioning of the Ukrainian power system, as HPPs and PSPs are the main providers of auxiliary services to meet the peak demand of the power system and balance intermittent Renewable Energy Source (RES) capacities. PSPs also contribute to flattening the night "gaps" of electricity consumption. In 2021, the share of HPPs and PSPs in electricity production was 5.8% and 0.8%, respectively [19].

The photovoltaic (PV) sector had the highest growth rate among other renewable energy sources in Ukraine during 2019-2021. At the beginning of 2022, the total installed PV capacity reached 7.6 GW or 80% of the total RES installed capacity in Ukraine (including 45,000 prosumer installations with a total capacity of 1.2 GW) [20].

At the beginning of 2022, Ukraine's total installed capacity of wind power plants (all onshore) was 1.6 GW. Almost all wind power plants in Ukraine were built in the southern regions nearby the Azov and Black seas coasts (Kherson and Zaporizhzhia regions), where natural conditions

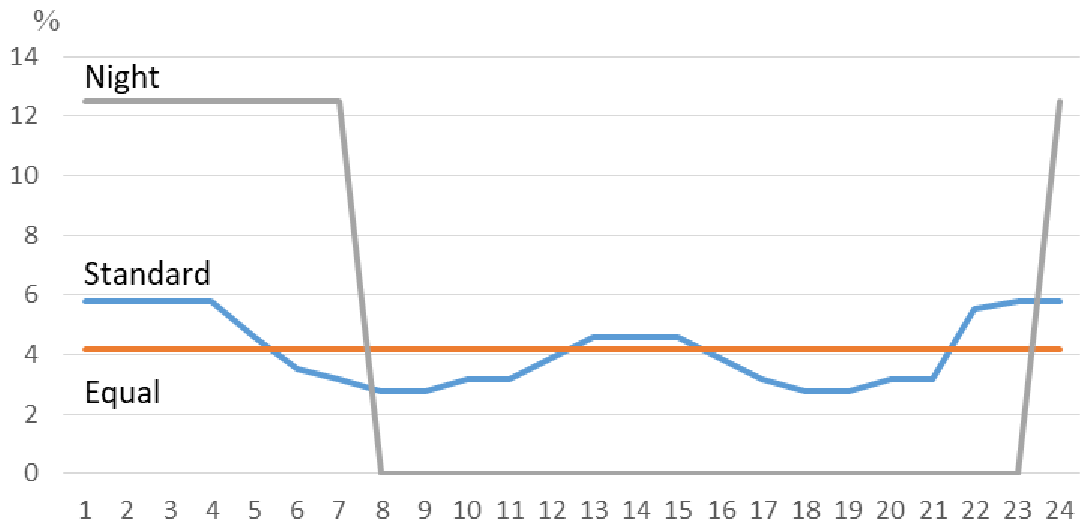

Figure 1. Electric transportation charging modes.

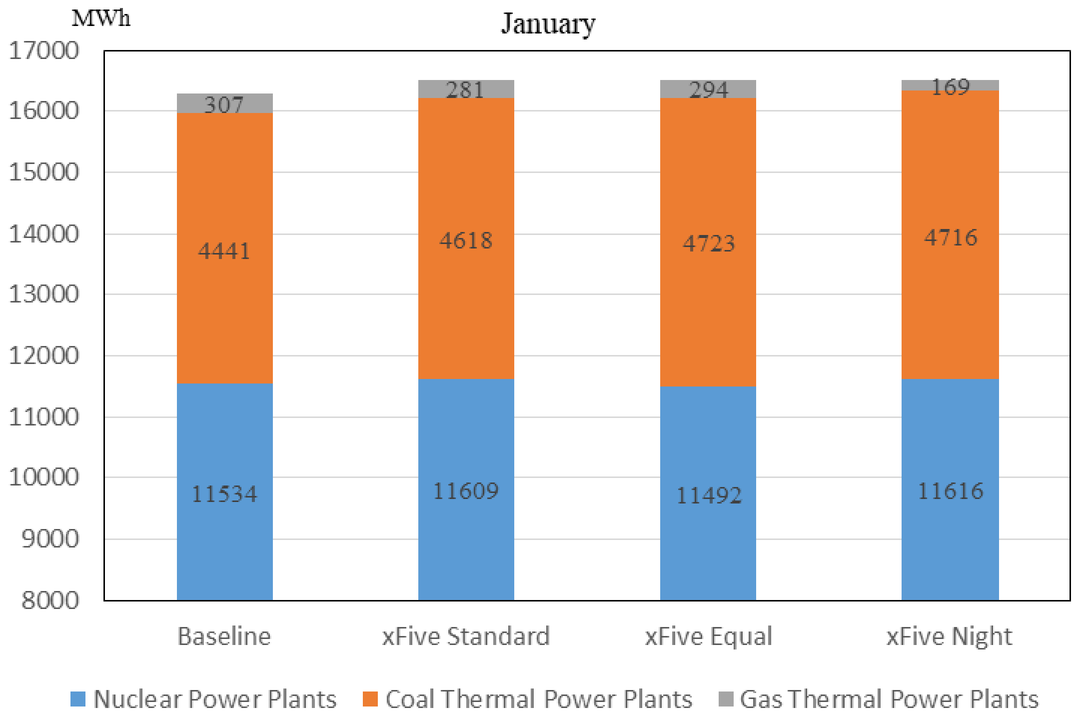

Figure 2. Structure of Ukraine's IPS operation in January.

for wind power plants are the most favorable.

A set of calculations was carried out for assessing influence of electric transportation charging modes on Ukraine's IPS functioning, fuel combustion and emissions of carbon dioxide and

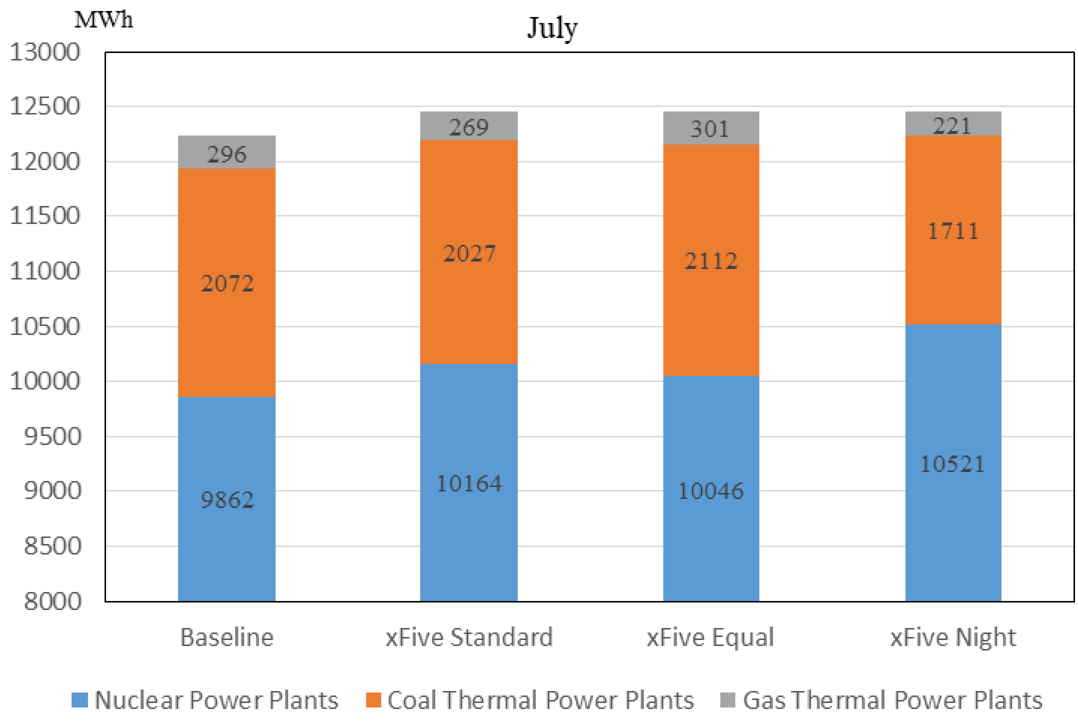

Figure 3. Structure of Ukraine's IPS operation in July.

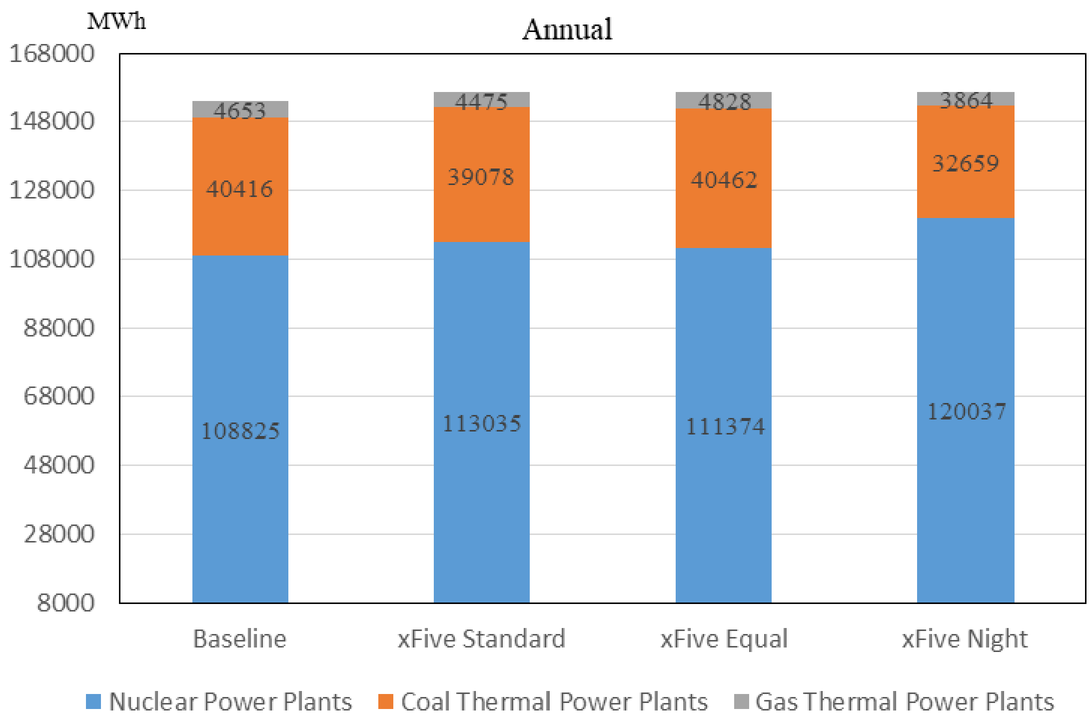

Figure 4. Annual Structure of Ukraine's IPS operation.

pollutants.

Four scenarios were considered. First scenario assumes the ET fleet at the 2020 level (Baseline). Next three scenarios assume that a number of EV in Ukraine increases by five times and consider three charging modes; standard (xFive Standard), equal (xFive Equal) and night (xFive Night) (figure 1). Evidently, two last modes are ideal and not achievable really. However, the results indicate the direction for development of strategy and regulatory acts to get better results.

3. Results

Diagrams at the figure 2, figure 3 and figure 4 illustrates structure of Ukraine‘s IPS operation under four scenarios in January, July and annual. Author choose January and July, because usually these months differ each other significantly in consumption level, as well as wind, solar and hydro characteristics.

The results show that the share of nuclear power plants increases practically for all scenarios except for the scenario xFive Equal in Winter. Therefore it is expected the decrease of fuel consumption as well as GHG and pollutants emissions. The table 1 (January), table 2 (July) and table 3 (annual) illustrate this fact. The figure 5 and figure 6 show the behavior of fuel

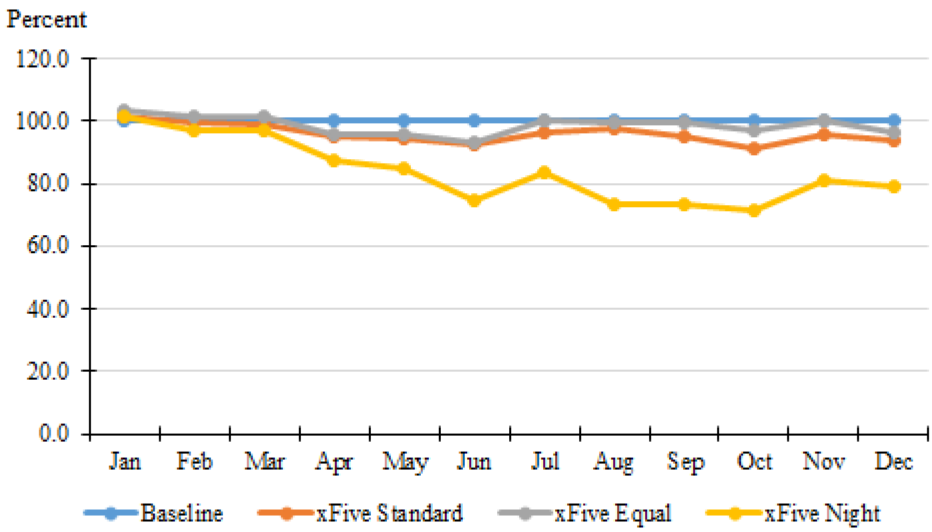

Figure 5. Energy intensity compared to baseline.

intensity and carbon dioxide emissions throughout the year. Fuel intensity increases in Winter for all scenarios, because the share of ET load is smaller than in Summer. In Summer and annually the decrease of of fuel intensity and emissions reaches up to approximately 14 percent (xFive Night). For scenario xFive Equal GHG and pollutant emissions increase despite of decrease of fuel intensity. This is explained by the larger share of coal thermal power plants compared to gas thermal power plants. It should be noted that such trends are observed exclusively for Ukraine due to specific structure of Ukraine's with the large share of nuclear energy.

4. Conclusions

Electric transportation (ET) volumes rapidly increase around the world. Ukrainian government also plans to develop strategies for ET implementation. For these purposes, it is necessary to study the influence of ET as additional load on Ukraine's Integrated Energy System operation. The main factors to consider are the volume of ET and ET charging modes.

ET implementation may affect both positively and negatively the IES operation depending on the share of additional ET load. The calculations were carried out using information and

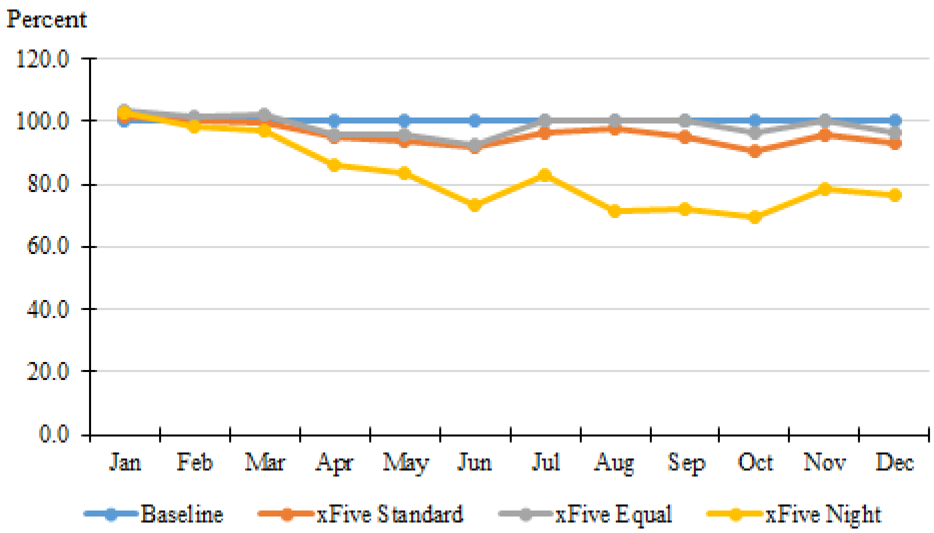

Figure 6. Carbon dioxide emissions compared to baseline.

program complex developed in the Institute of General Energy. This paper analyzed the influence of ET charging modes on fuel consumed by IES, fuel intensity and emissions levels. Three charging modes were considered, specifically standard, night and equal. Evidently, two last modes are ideal and not achievable really. However, the results indicate the direction for development of strategy and regulatory acts to get better results.

Abstract. The article is devoted to an automatic data preparation method for setting up a distribution network model, which is used to develop training tasks for distribution network personnel. The main goal in creating the method is to reduce the time for developing a simulator task by leveling the human error during the stage of filling in the structural data of the distribution network components. To interact with the automatic method and the already pre-created component library that was used in the previous method, it was necessary to change the internal structure of the double winding and three winding transformer components. Also, a new structural component was added to the library – Connection. The program algorithm of the automatic method consists of three cycles that go through all the components transferred from the library to the distribution network model. For a better understanding and perception of textual information about each cycle, a graphical representation of cycle process diagrams is presented. In conclusion, information is provided on the time spent when creating a task with manual data preparation and the developed automatic one, as well as suggestions to reduce computer resourced used during model run.

1. Automatic method of preparation of data

Rapid advances in technology have also affected the energy industry. In the components of energy distribution networks, characteristics and properties change dynamically, and the networks themselves undergo frequent changes in the number of components and structural changes. Given these changes, employees need to learn new knowledge and test current skills. The lack of skills and lack of qualifications of personnel in this area threatens the safety of people and the failure of networks [1, 2]. Accordingly, it was necessary to speed up the process of developing simulator tasks, as well as take into account innovations in the energy sector [3]. Significant results in this matter have been achieved with the help of the distribution network model.

The distribution network model is a program that was created using a graphical editor that contains a graphic field and a library of distribution network components with which it is possible to create a mnemonic diagram model that will completely duplicate the existing distribution network. The model can be run on any device with the Windows operating system, which is beneficial from an economic point of view [1, 4–6]. The model of distribution network modes does not require the presence of a programmer at the task development stage, since all the processes that require the programmer's work (calculation of current or voltage values, mode switching, functions of the distribution network components) were done before the task development stage [7–9]. Previously, the task was developed simultaneously by a programmer and an energy specialist who does not have programming skills, which significantly slowed down the development. A specialist in the energy field can contact a programmer to add a new distribution network component by providing the necessary technical documentation about the component. The new component will be added to the library from the next version of the model, and the developer of simulation tasks will be able to use the new components to train personnel.

At the stage of preparing data for calculating the model of the distribution network, initially, the developer manually enters the structural parameters (number of copies of components, branch indices). The main disadvantage of this method of preparing mode model setting data is the possibility of errors when entering this data. These errors can occur if the task developer copied a ready-made parameter, pasted it, but forgot to change the value to the required one. Therefore, several parameters will have the same values of node numbers or branch indices, which will lead to an error in calculating the mode values. It can take a long time to find invalid parameter values. An error in the calculation of modes makes this training task irrelevant in the process of training the personnel of the distribution network, which leads to a decrease in the competence of the personnel. Therefore, it was decided to develop a new data entry method that would eliminate the human factor in the process of entering structural parameters. This method has been called the automatic data entry method for setting up the mode model. Unlike manual preparation, in automatic preparation, a copy of the node component receives its number in the process of adding it to the mimic (the copy that was added first gets number 0, the copy that was added second gets number 1, etc.).

2. Library of components

As in manual data preparation, the automatic one uses a library of distribution network mnemonic diagram components, which is created by graphical editor. The library contains the following components (figure 1):

(i) Structural Components
- Node
- Branch
- Line
- Connection

(ii) Technological components
- Double winding transformer
- Three winding transformer
- Switch
- Disconnector

(iii) Output Components
- Current pointer
- Node load power pointer
- The field for outputting the value of the load current of the node
- Voltage value output field
- Current value output field

For automatic preparation, the following components of the mnemonic diagram have been changed: Double winding transformer and a three winding transformer. Also, a new structural component was added to the mnemonic diagram component library – a connection.

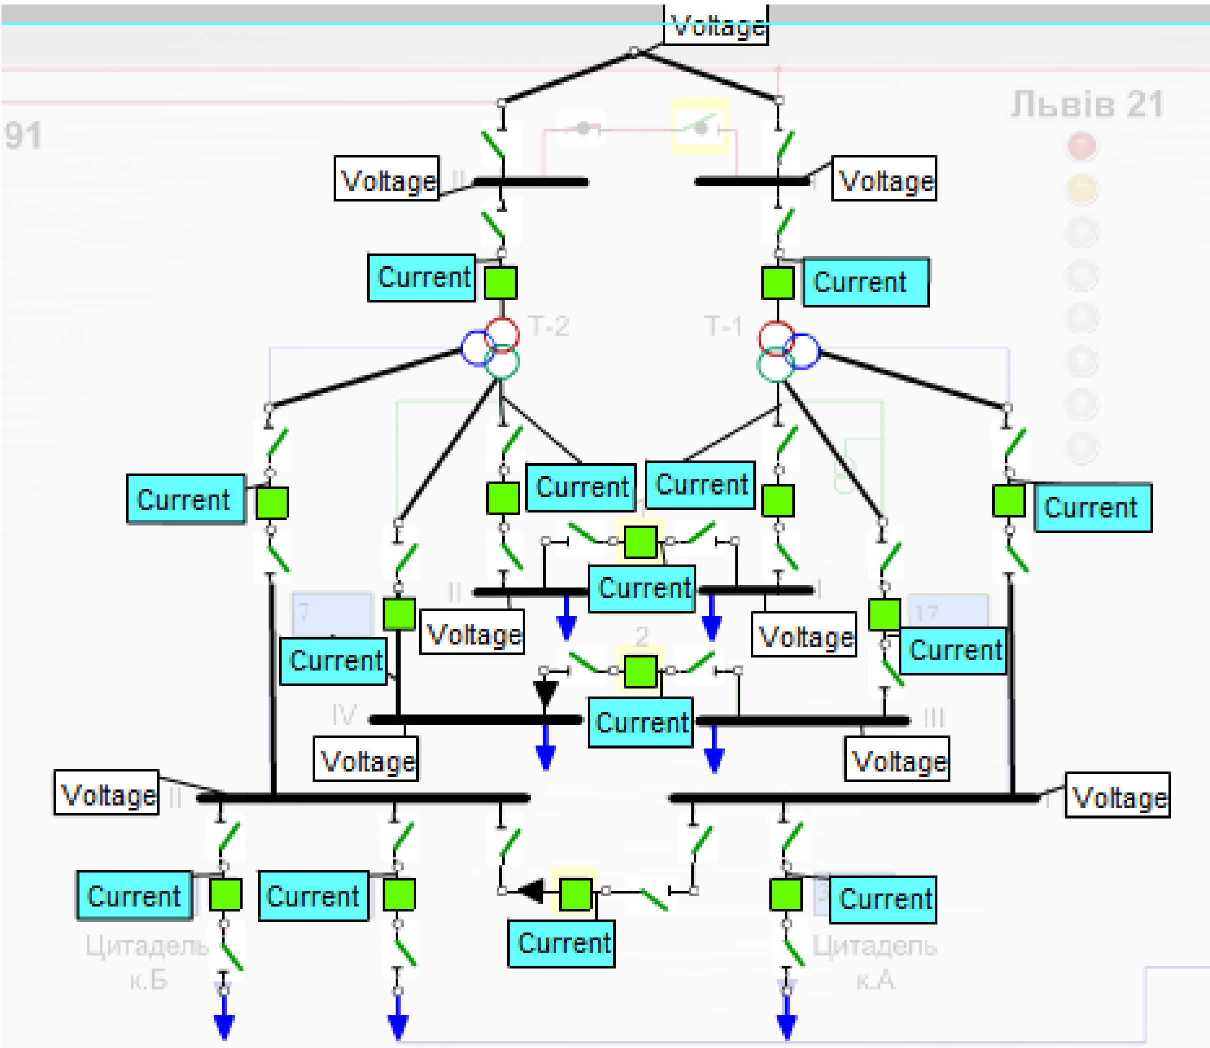

Figure 1. An example of a fragment of a mnemonic diagram of a distribution network.

2.1. Double winding and three winding transformers

When mimic diagram components were transferred from manual to automatic data preparation, the double winding transformer and three winding transformer components had a problem with assigning a number to the transformer nodes and assigning an index to the transformer branches. This issue has been fixed by adding transformer Nodes and transformer Branches inside transformer component copies. Unlike ordinary branches and nodes, transformer ones have a technological one – the transformation ratio parameter. Also, transformer branches are not visible on the mnemonic diagram, as they are located in the inner layer of the transformer [10, 11].In transformers, it is possible to set technological parameters, such as conductivity and transformation ratio [11, 12] (figure 2).

2.2. Connection

The connection component performs the function of transferring the structure parameter from node or branch copies to voltage or current output component copies. When constructing a mnemonic diagram, a copy of the connection component must be placed so that one end of the line enters the node or branch, and the other end of the line must enter the instance of the

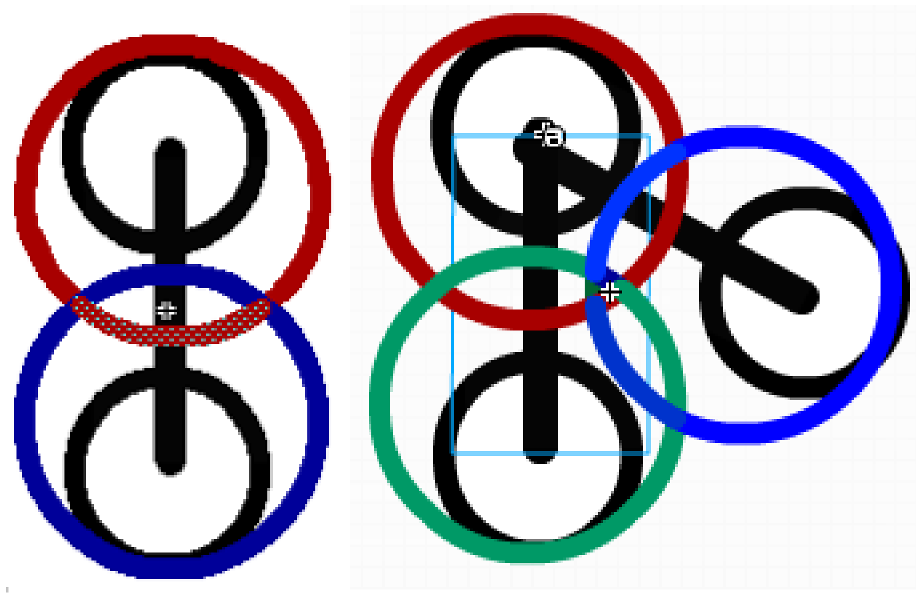

Figure 2. Inner layers of double winding and three winding transformers.

voltage or current output (figure 3) [13]. If this condition is not complete, the transfer of the structural parameter does not occur and the output will show an incorrect result (the value will be permanently equal to 0).

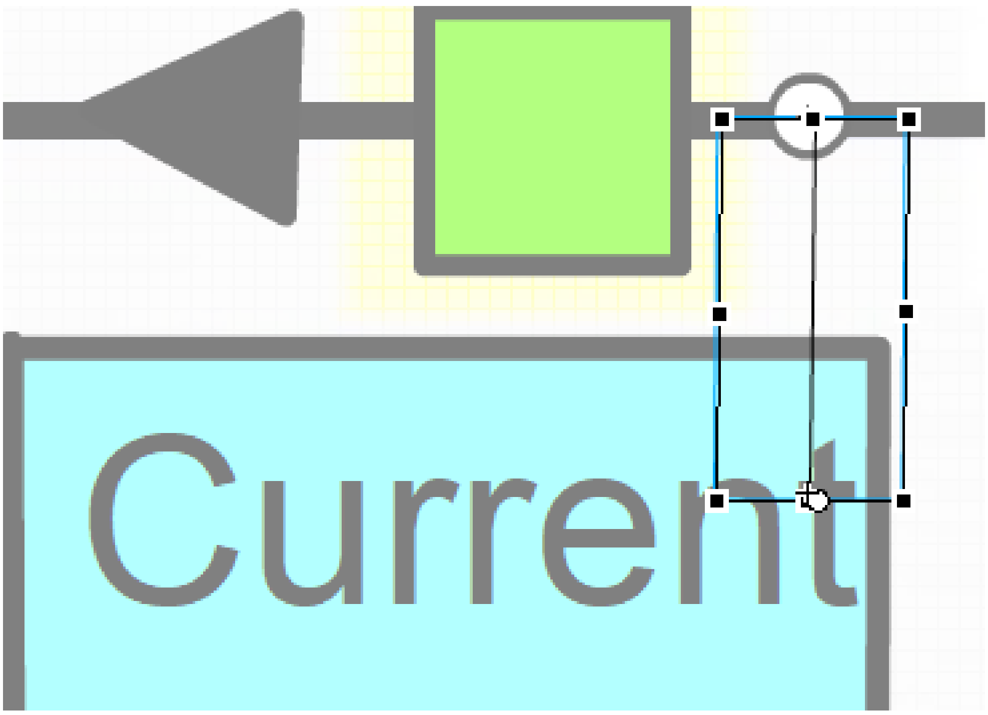

Figure 3. Visual view of the Connection component.

3. Construction of a mnemonic diagram

After getting acquainted with the modified library of components, the developer of the training task can proceed to the construction of a mnemonic diagram. This process is shown in figure 4.

A visual representation (specification) of this process and three cycles of data preparation was created using Bizagi, based on the BPMN 2.0 standard.this standard is often used to represent program process [14–16]. The following components are used from this standard [17, 18]:

- Data Object – data array
- Start Event – start of the process of constructing a mnemonic diagram
- User Task – task performed by the developer of the training task [19]
- Inclusive Gateway – gateway with condition. Depending on the fulfillment of the condition, the branching of the process depends
- End when message is send
- Start when message is received
- Sub Processes – task that contains other tasks
- Service Task – a task that is performed automatically
- End Event – completion of the mode calculation model process

The first step the developer selects from the component library is the component copies necessary to construct the mnemonic diagram. Unlike manual provisioning, in automatic, the developer does not need to set structural parameters, since the program automatically assigns structural parameters after the program starts. After adding and placing all the components on the mnemonic diagram and filling in the technological parameters for copies of the mnemonic diagram components, the program must be started. The next step is the automatic preparation of structural parameters and links. The last step is the mode calculation model, in which the value of voltages and currents is mathematically calculated. After each switching, the value of currents and voltages is recalculated [7–9, 20].

3.1. First loop through component copies

The Service task of preparing structural parameters and links consists of three cycles. In each of the cycles, structural parameters are assigned to the copies of components. Using the function of browsing all copies of the mnemonic diagram components, the process of reading the type of the mnemonic diagram component is in progress. While browsing all the components, the array of components is filled. After the array is filled, it loops over it. On the first iteration, the nodes, node buses, and transformer nodes of the mnemonic diagram are automatically assigned unique numbers and displayed on the mnemonic diagram. The switch and disconnector component copies are set to state. These components can be in two states: 1 (disabled) and 2 (active). The developer can change the state by clicking the left mouse button on the component copy (figure 5).

3.2. Second loop through component copies

In the second cycle, the component copies: capacity of node, branch, transformer branch, line, are automatically assigned structural parameters. Numbers are assigned to capacity of node, and indexes are assigned to branches, transformer branches and lines. The capacity of node number duplicates the number of the host node. The value of the index parameter depends on the numbers of nodes that are between the branch or line. Further, the structural parameters are entered into the adjacency list, and the links to the components into the link array (figure 6).

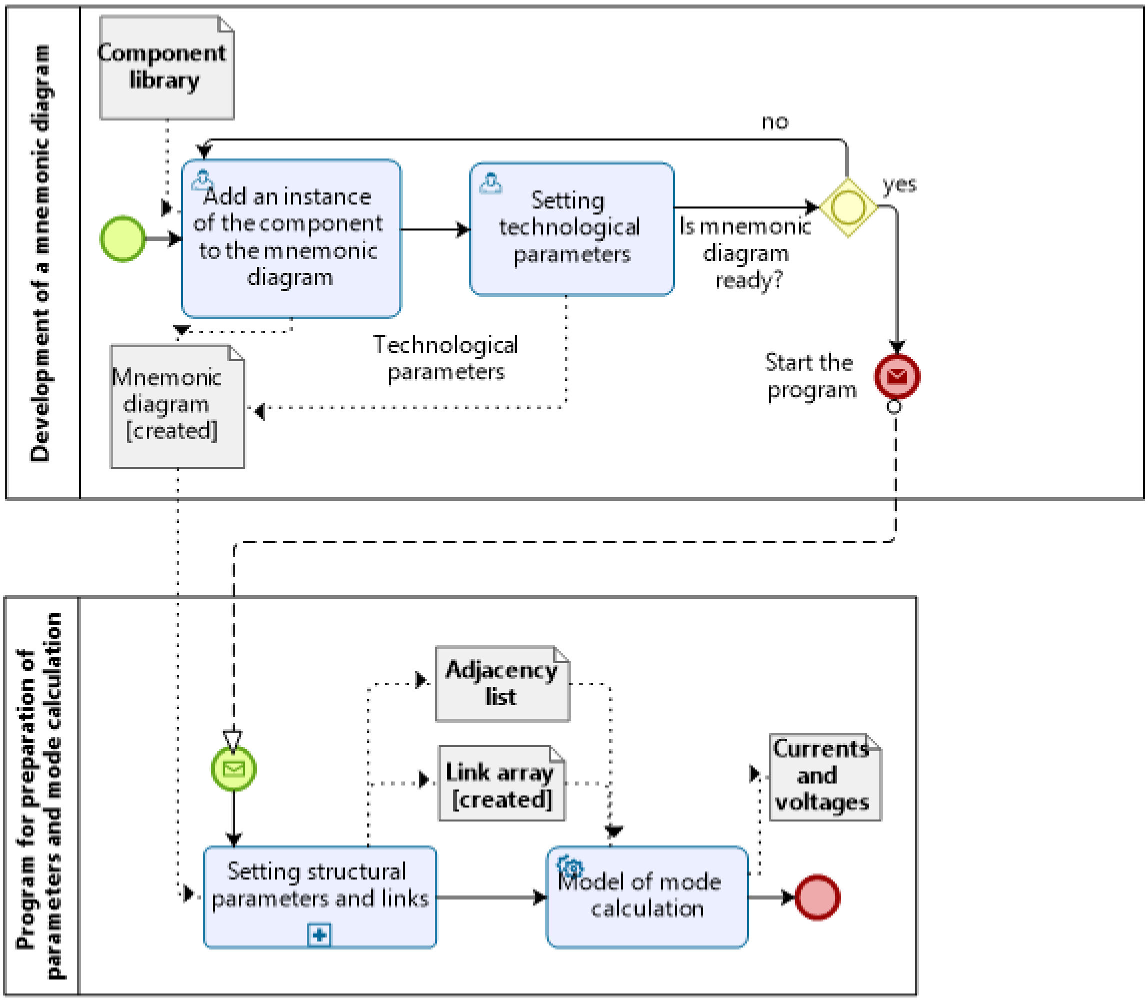

Figure 4. Visual The process of constructing a mnemonic diagram, preparing parameters, links and a mode calculation model.

3.3. Third loop through component copies

The third iteration through the component array begins by assigning indexes to the switch, disconnector, and current pointer component copies. The index of these components duplicates the index of the placement branch. The direction of the pointer is also automatically set by readout the direction of the mains current. The last process in the third cycle is the transfer of the structural parameter of the current or voltage output copies using the connection component (figure 7).

4. Conclusions

The disadvantage of the automatic method of preparing data for setting up the mode model is the increase in the time for placing component copies on the mnemonic diagram in comparison with manual preparation. This increase in time is due to the addition of a new communication component and its location on the mnemonic diagram. An error of incorrect placement of a connection component is easier to notice than an error when filling in structural parameters. The average time to fix this error is 7 seconds, but the average time to find this error is 2 seconds, and unlike the structural data filling error, there is no need to check the “Properties” menu and

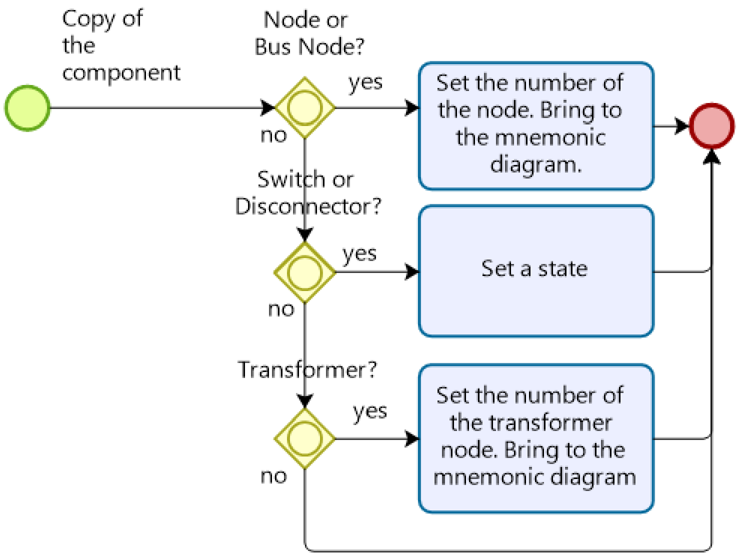

Figure 5. First loop through component copies.

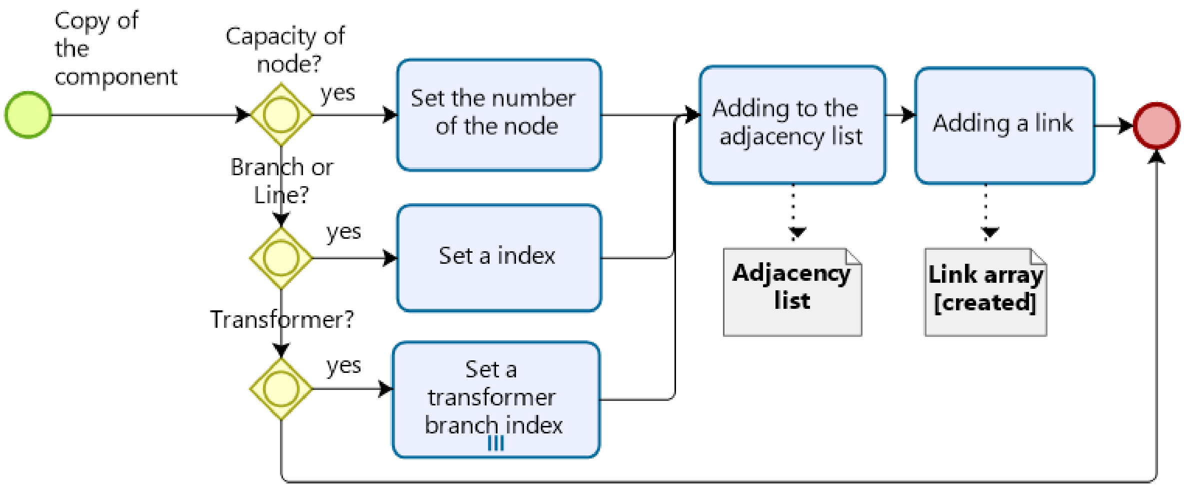

Figure 6. Second loop through component copies.

the structure parameter field for each mimic component copy. In automatic data preparation, the average time to find and correct an error is reduced by 15 minutes. The advantages of automatic data preparation are: the leveling of human error during the filling of structural parameters and the reduction of the development time of the training task. The average time to fill in the structural parameters per copy of component is 8 seconds. Depending on the number of component copies, the time to create a training session is reduced from 10 minutes to one hour. Automatic method of preparation of data for setting the model can be improved by reducing the number of cycles that go through all copies of the mnemonic diagram model. The number of cycles can be reduced to one, which will reduce the amount of computer resources needed to run the model.

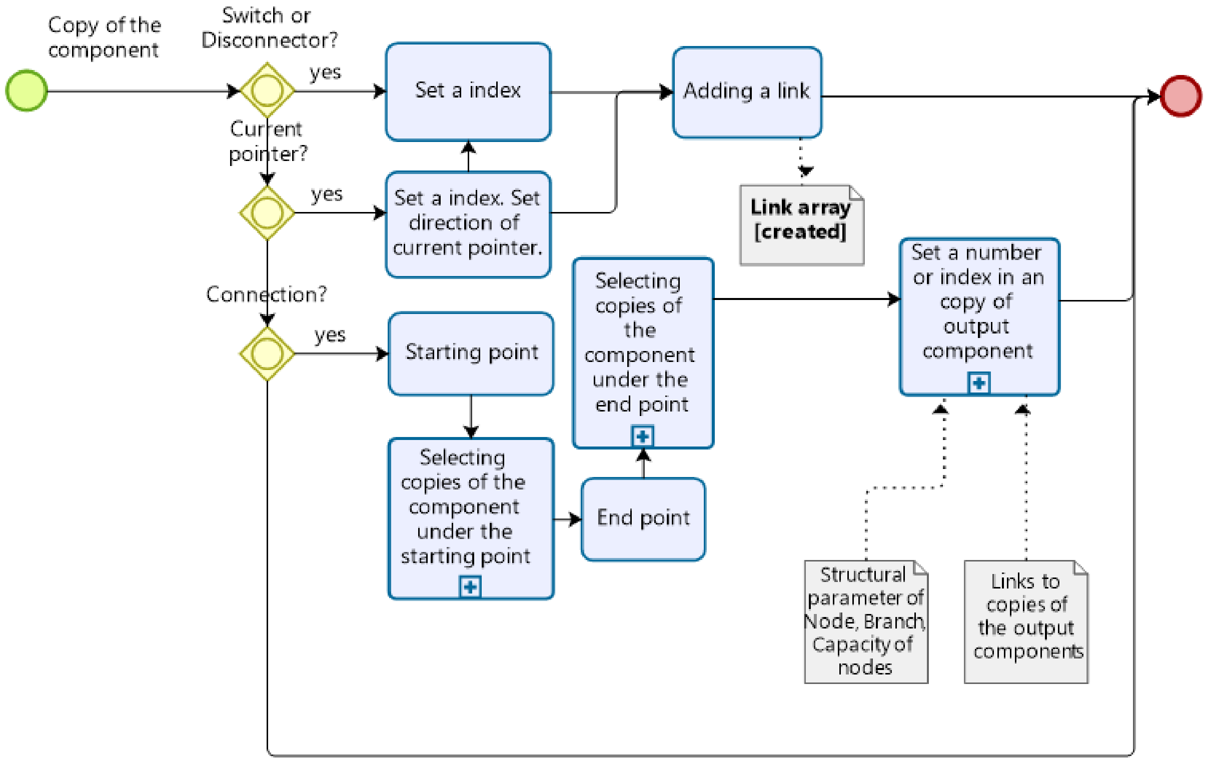

Figure 7. Third loop through component copies.

Abstract. The article considers synthesis of an expert system for controlling electric power consumption by pumps of main water drainage facilities of an underground mine on the basis of the Mamdani fuzzy inference algorithm. The proposed system has a MISO-structure (multiple-input, single-output) with two input variables, such as water inflow and power cost as well as one output coordinate – power of pumping units. Two bases of fuzzy rules such as conjunction (AND) and disjunction (OR) are formed. By simulation modelling, a comparative analysis of fuzzy control systems for power consumption by water drainage facilities is carried out, as well as a system without control, when the pump performance is stabilized, during week and month periods. It is established that OR-rule based systems can reduce power costs by 1.89% during a week and by 2.28% during a month, and AND-rule based systems by 4.13%, as well as by 5.43% during week and month, respectively. At the same time, we note that the economic effect is achieved not through a decrease in power consumption, but by adjusting the operation mode of the water drainage facility, which involves ensuring maximum efficiency of groundwater drainage when the power cost is high, and minimum efficiency when it is low.

1. Introduction

Creation of the power market in Ukraine and widespread introduction of distributed generation facilities has resulted in a radical change in principles of mutual financial settlements between distribution operators and consumers due to rapid improvement of power production technologies using renewable sources. Dynamic pricing in determining power prices has provided ample opportunities to develop new algorithms for controlling power supply and consumption in power systems of various hierarchical levels. Given that the most energy-intensive objects are industrial enterprises, there are great prospects for improving energy efficiency specifically for them.

Simultaneously, the constant change in power costs requires a significant revision of principles of managing technological operations, which have traditionally remained unchanged for many years. In particular, this concerns main water drainage facilities of underground mines designated to pump groundwater from internal working spaces of enterprises engaged in underground mineral mining. Their operation is critical for creating safe working conditions for personnel, so water drainage is controlled through ensuring maximum efficiency of pumps.

At the same time, energy efficiency is improved by optimizing performance characteristics of technological units using an automated electric drive. Design features of mine water drainage, namely reservoir for accumulating mine water, make it possible to implement a different approach to controlling the system. It will involve limiting the performance of pumps and, as a result, power consumption, in certain periods of time when the power cost is high and its significant use is economically inefficient. In this case, the main limitation will involve preventing overflow of reservoirs in case of an intensive water inflow that can cause flooding of the underground mine.

The power system, regardless of its architecture and operation algorithm, aims to reduce the cost of purchasing power from an external distribution operator. Given that for enterprises power cost can vary widely during the day, it would be logical to ensure maximum power consumption during the period of the minimum power cost. However, this is not always possible to implement for consumers, because their operation is related to ensuring safe working conditions for personnel of a certain production facility, in particular, mine water drainage. If during the enterprise operation there is a significant or abnormal water inflow into the underground mine, it is required to pump water with maximum efficiency, despite high or average power costs. Therefore, the power control system of main water drainage facilities of underground mines should have two input actions: water inflow and power cost (or the cost of power generation in case of availability of sources of distributed generation). The initial coordinate is the power of electromechanical complexes of pumps that are simultaneously in operation, i.e. their total power.

2. Literature review

A number of works are devoted to controlling multi-pumping systems.

Thus, [1–7] consider various aspects of functioning of pumping systems with several pumps using both group and individual electric drives. At the same time, some works specify parameters of pumps and the hydraulic system. In particular, Arun Shankar et al [7] looks into cavitation and water hammer, and Vodovozov et al [4] – pressure. Papers [1–3, 5] are devoted to control with the optimal operating point of the system determined by pump efficiency. Additionally, practical implementation of control using industrial logic controllers is proposed. Beshta et al. [6] is worth highlighting as it directly considers the process of controlling pumps of main water drainage facilities of the underground mine. At the same time, we note that the authors focus on improving efficiency of the pumping system in terms of its performance, but the control over power consumption depending on power costs is not sufficiently considered.

Gong and Zhu [8] optimizes operation of a group of pumping stations operating in parallel, according to the criterion of minimizing losses for power consumption by the entire technological complex. Efficiency of water drainage and flows between individual units of each pumping station are considered as limitations. A multifactor optimization criterion is proposed, which takes into account power costs in a certain period of time. The authors consider a three-tariff system with differentiation by time periods. The optimization procedure includes determining the best conditions for the functioning of each individual station according to the developed criterion using a genetic algorithm, followed by their aggregation. As a result, power costs decrease for all stations. Meanwhile, on one of them, the savings amount to almost 20%. Besides, power consumption is regulated by frequent starting/stopping of individual pumps, which, as the authors themselves note, significantly affects their reliability.

Wang et al [9] deals with development of an algorithm for controlling a multi-level system for pumping water in an urban environment during heavy rains or floods using the Particle Swarm Optimization method. As optimization criteria, the number of starts/stops of pumps and duration of their operation are considered. The proposed algorithm has significantly reduced the number of pumps, so it can be used to improve the multifactor optimization system shown in [8].

Bordeașu et al [10] explores the algorithm for controlling a multi-pump irrigation system powered by a distributed generation power system, which includes a centralized electrical grid and power production facilities using renewable energy sources, in particular, photovoltaic panels. The proposed system is multi-level. The top-level subsystem determines the procedure for starting/stopping individual pumps depending on the level of filling the tanks with water and the amount of power available for consumption. Lower-level subsystems implement a smooth start and frequency regulation of the rotation speed of the electric drive of each pump. One of the indicators of assessing efficiency of the system is the hourly level of power consumption. It is compared with the periods of different power costs. As in [8], the authors consider three-zone tariffs for different time periods. At the same time, when forming the control, the power cost is not directly used as a parameter for adjusting the algorithm, but is considered because of the power available for consumption. As a result, the system does not function in the peak tariff period. Thus, such a system is impractical to use for mine water drainage for safety reasons.

The papers [11–14] consider the control of industrial and household consumers power supply, taking into account fluctuations in the power tariff during the day.

To date, the most promising control methods include those based on fuzzy logic, artificial neural networks and machine learning, which are usually classified as smart. Moreover, in problems when an object has several input variables, it is advisable to apply a fuzzy logic inference due to simplified synthesis and control algorithms implemented. On its basis, there are developed irrigation control systems [15, 16], pumping facilities powered from autonomous power plants using renewable energy sources [17–22], control systems of wind turbines electromechanical equipment [23], urban water supply [24], cascades of multi-pump systems [25], as well as the electric drive of a separate pumping unit [26].

As mentioned earlier, the power control system of main water drainage facilities of the underground mine can be represented by a MISO-structure (multiple-input, single-output) with two input (water inflow and power cost) and one output (the power of pumps) variables. Moreover, all three coordinates are subject to expert evaluation. As a result, it is advisable to develop a smart power control system for main water drainage facilities using the Mamdani fuzzy logic inference algorithm.

The research paper aims to synthesize a system for controlling power consumption levels by electromechanical equipment at main water drainage facilities based on the Mamdani fuzzy logic inference algorithm to reduce power costs of an industrial enterprise for the power supplied by an external distribution operator.

The developed fuzzy algorithm can be applied to controlling a peak pumped-storage power plant of main water drainage facilities of underground mines [27, 28].

3. General characteristics of main water drainage facilities of the underground mine as a fuzzy control object

The synthesis of a fuzzy control system for power consumption by main water drainage facilities as part of a mining enterprise can be clearly demonstrated on the example of the Kryvorizka underground mine (Kryvyi Rih). Main water drainage facilities are placed on appropriate levels and include several pumps, usually of the same type and power. On the same levels, there are additional water reservoirs, the size of which allows accumulating required volumes of mine water entering a specific level from others (deeper ones).

A 500 m water drainage level is adopted as a control object (figure 1). Given that this level is the final stage before pumping water to the surface, where water from the entire internal space of the underground mine enters, it is equipped with the largest water reservoir and consequently the most powerful pumps. As a result, it is one of the most energy-intensive consumers of water drainage and the entire underground mine as a whole. The water drainage section of the 500m level contains seven pumps of the CNS-300x600 type with a nominal power of 800 kW each.

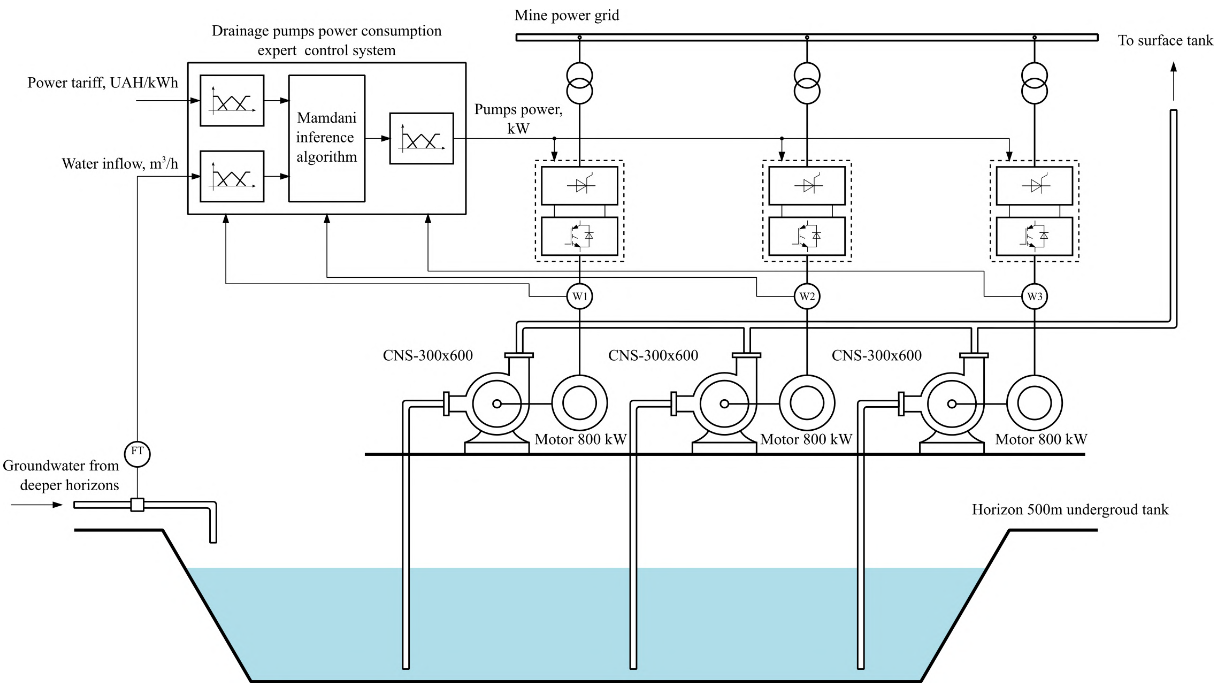

Figure 1. Water drainage facilities of the 500 meters horizon of the Kryvorizka underground mine.

Table 1. Annual groundwater inflow into the Kryvorizka underground mine for 2016-2021.

No	Year	Water inflow, m^3/year
1	2016	3281132
2	2017	3709753
3	2018	4416601
4	2019	4619121
5	2020	4784339
6	2021	4673021

Due to the reduced production volumes, compared to the design ones observed in recent years, there is a decrease in water inflow to the underground mine (table 1). This caused the need to simultaneously use only three pumps at the maximum water inflow into the working spaces and one or two under normal conditions.

After taking into account the above features during fuzzification of the fuzzy system for controlling power consumption by electrical equipment of the 500 m level, let us consider this procedure in more detail.

4. Development of a smart expert system for controlling power consumption by main water drainage facilities of the underground mine

4.1. Fuzzification of linguistic variables of a fuzzy control system

Each coordinate of the fuzzy logic inference MISO-structure, namely "water inflow", "power tariff" and "pump power" are represented by corresponding linguistic variables.

A finite set Q, used to form the membership functions of the linguistic variable "water inflow", is defined on the interval $\{q_i \in \mathbb{R} \mid q_{\min} \leq q_i \leq q_{\max}\}$, where $q_{\min}$ and $q_{\max}$ are the minimum and maximum levels of groundwater inflow into the underground mine. We assume that the linguistic variable includes three fuzzy sets: "low inflow" (Q_L), "medium inflow" (Q_M), and "high inflow" (Q_H). Membership functions to the above-mentioned fuzzy sets are formed by piecewise linear functions. This reduces computational complexity while implementing a fuzzy logic inference algorithm. The membership function for the fuzzy set "medium water inflow" is defined as triangular, for the set "high water inflow" as S-shaped, and for the set "low water inflow" as Z-shaped.

When parametrizing membership functions, the average value of water inflow over 6 years (table 1) is taken as the mean value, which is $q_m = 484.85$ m^3/h. We assume that the high water inflow exceeds 2.5 times the medium one, while the low water inflow is twice smaller, and make $q_l = 1212.13$ m^3/h and $q_h = 242.43$ m^3/h respectively. At the same time, we set the minimum value at the level of $q_{\min} = 0$ m^3/h, and the maximum value of $q_{\max} = 1500$ m^3/h.

The membership function to the fuzzy set Q_M is defined by the following expression:

$$\mu_{Q_M}(q) = f(q; q_l, q_m, q_h) = \\ = \max\left[\min\left(\frac{q - q_l}{q_m - q_l}, \frac{q_h - q}{q_h - q_m}\right), 0\right], \tag{1}$$

while:
core $(Q_M) = \{q_m\} = 484.85$ m^3/h;
supp $(Q_M) = \{q \in \mathbb{R} \mid q_l \le q \le q_h\} = 969.71$ m^3/h.

Here is an expression for determining the membership function to the fuzzy set Q_L:

$$\mu_{Q_L}(q) = f(q; q_{\min} - 1, q_{\min}, q_l, q_m) = \\ = \max\left[\min\left(\frac{q - (q_{\min} - 1)}{q_{\min} - (q_{\min} - 1)}, 1, \frac{q_m - q}{q_m - q_l}\right), 0\right], \tag{2}$$

while:
core $(Q_L) = \{q \in \mathbb{R} \mid 0 \le q \le q_l\} = 242.43 m^3/h$;
supp $(Q_L) = \{q \in \mathbb{R} \mid 0 \le q \le q_m\} = 484.85\ m^3/h$.

Here is the expression for determining the membership function to a fuzzy set Q_H:

$$\mu_{Q_H}(q) = f(q; q_m, q_h, q_{\max}, q_{\max} + 1) = \\ = \max\left[\min\left(\frac{q - q_m}{q_h - q_m}, 1, \frac{q_{\max} + 1 - q}{q_{\max} + 1 - q_{\max}}\right), 0\right], \tag{3}$$

while:
core $(Q_H) = \{q \in \mathbb{R} \mid q_h \le q \le q_{\max}\} = 287.86$ m^3/h;
supp $(Q_H) = \{q \in \mathbb{R} \mid q_m \le q \le q_{\max}\} = 1015.15$ m^3/h.

Given the membership functions to the fuzzy sets Q_L and Q_H, both the upper and lower reference values go beyond the limits of the finite set Q, that is, they increase and decrease by one respectively. This is done to avoid dividing by zero cases.

A diagram representation of membership functions to the fuzzy sets of the linguistic variable "water inflow" is shown in figure 2.

The fuzzification of the linguistic variable "power tariff" is performed on the basis of the following considerations. In compliance with the Law of Ukraine On the Electric Power Market [29] as of January 07, 2019, a new power cost system for industrial enterprises and distributors was established. This system involves the introduction of an hourly tariff mode, where power cost changes every hour depending on the market condition. What is more, one day in advance, an enterprise orders from a distributor the amount of power that is expected to

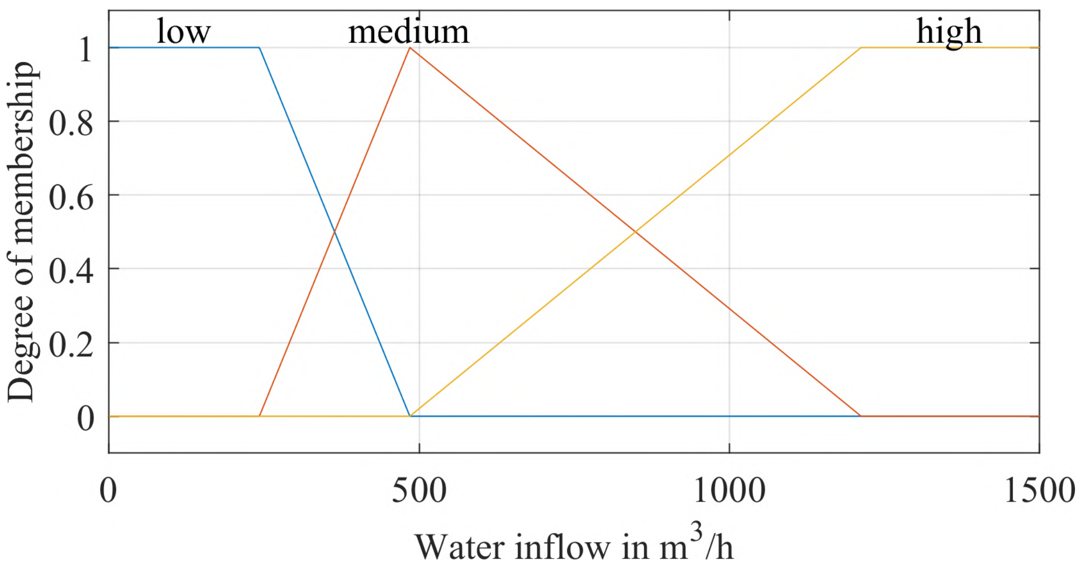

Figure 2. Membership functions to the fuzzy set "water inflow".

be consumed during each hour of the following day. This approach is fundamentally different from payments according to tariffs differentiated by time periods, which were in effect before, when the power cost was fixed. At the same time, the analysis of the hourly payment structure allows us to state that it is appropriate to distinguish three zones based on power cost, when its level is high, medium or low. Moreover, the day periods when the specified zones are virtually active coincide with peak, half-peak and night periods. This is explained by the nature of the power load schedule, namely, a high level of power consumption in morning and evening hours, a low level at night and a medium level during daylight hours. Thus, in order to formalize the fuzzy control algorithm, we differentiate the power cost in the "peak", "half-peak" and "night" zones.

As reference values for assigning membership functions for the linguistic variable "power tariff", we will use the tariff values set by the power distributor DTEK Dniprovski Elektromerezhi [30]. Also, we use the data for the case of centralized power supply and for the case of the installed distributed generation facilities. In the latter case, this variable is equivalent to the cost of power production.

For the consumers of the first voltage type, namely from 35 kV and higher, at the limit of balance distribution, which includes the Kryvorizka mine, the tariff of $c_{HP} = 0.13788$ UAH/kWh has been effective since January 01, 2022. This value will determine the power cost in the "half-peak" zone. Accordingly, the "peak" tariff is 1.5 times higher than the "half-peak" one, and the "night" tariff is 0.4 times lower. They are $c_{PK} = 0.20682$ UAH/kWh and $c_{NT} = 0.055152$ UAH/kWh respectively. These three values are used as references when forming membership functions and their further parameterizing.

The linguistic variable "power cost" is defined by a finite set on the interval $\{c \in \mathbb{R} \mid c_{\min} \leq cq \leq c_{\max}\}$, and $c_{\min} = 0$ UAH/kWh, $c_{\max} = 0.3$ UAH/kWh. Let us represent the variable as three fuzzy sets – "night zone", "half-peak zone" and "peak zone".

The membership function to the fuzzy set "night zone" is defined as Z-shaped:

$$\begin{aligned}\mu_{C_{NT}}(c) &= f(c; c_{\min}-1, c_{\min}, c_{NT}, c_{HP}) = \\ &= \max\left[\min\left(\frac{c-(c_{\min}-1)}{c_{\min}-(c_{\min}-1)}, 1, \frac{c_{HP}-c}{c_{HP}-c_{NT}}\right), 0\right],\end{aligned} \tag{4}$$

where:
$core\,(C_{NT}) = \{c \in \mathbb{R} \mid 0 \le c \le c_{NT}\} = 0.055152$ UAH/kWh;
$supp\,(C_{NT}) = \{c \in \mathbb{R} \mid 0 \le c \le c_{HP}\} = 0.13788$ UAH/kWh.
The membership function to the fuzzy set "half-peak zone" is triangular and has the following characteristics:

$$\mu_{C_{HP}}(c) = f(c; c_{NT}, c_{HP}, c_{PK}) = \\ = \max\left[\min\left(\frac{c - c_{NT}}{c_{HP} - c_{NT}}, \frac{c_{PK} - c}{c_{PK} - c_{NT}}\right), 0\right], \tag{5}$$

while:
$core\,(C_{HP}) = \{c_{HP}\} = 0.13788$ UAH/kWh;
$supp\,(C_{HP}) = \{c \in \mathbb{R} \mid c_{NT} \le c \le c_{PK}\} = 0.151668$ UAH/kWh.
The membership function to the fuzzy set "peak zone" is S-shaped and has the following characteristics:

$$\mu_{C_{PK}}(c) = f(c; c_{HP}, c_{PK}, c_{\max}, c_{\max} + 1) = \\ = \max\left[\min\left(\frac{c - c_{HP}}{c_{PK} - c_{HP}}, 1, \frac{c_{\max} + 1 - c}{c_{\max} + 1 - c_{\max}}\right), 0\right], \tag{6}$$

while:
$core\,(C_{PK}) = \{c \in \mathbb{R} \mid c_{PK} \le c \le c_{\max}\} = 0.09318$ UAH/kWh;
$supp\,(C_{PK}) = \{c \in \mathbb{R} \mid c_{HP} \le c \le c_{\max}\} = 0.16212$ UAH/kWh.
A diagram representation of membership functions to the fuzzy sets of the variable "power tariff" is in figure 3.

The output coordinate of the fuzzy power consumption control system is the total output power consumed by the drainage pumps. Moreover, it is advisable to focus on the value of this electrical parameter, and not on the number of units that are operated at a time as modern electric drives of pumps are equipped with semiconductor frequency inverters making it possible to adjust the output power of flow-generation mechanisms over a wide range.

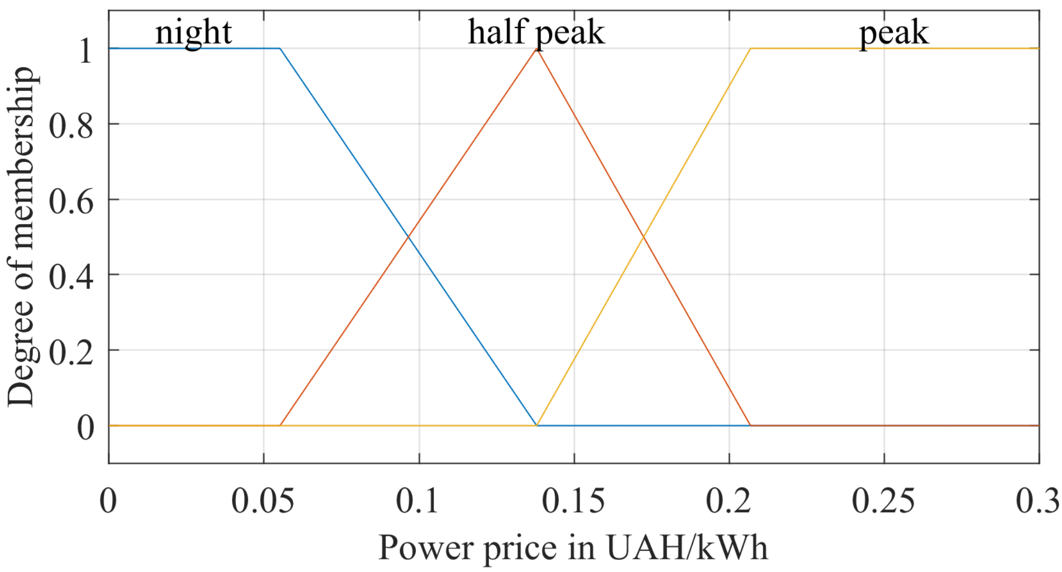

Figure 3. Membership functions to the fuzzy set "power tariff".

According to the static characteristics $P = f(Q)$ of the CNS-300x600 pump, its operating performance for the nominal angular rotation frequency of 1485 rpm is within efficiency limits of $220 - 360$ m^3/h with a power change range of $625 - 825$ kW. Taking into account the fact that one to three pumps are used for water drainage, the final set for the linguistic variable "pump power" should be determined on the interval $\{p \in \mathbb{R} \mid p_{\min} \leq p \leq p_{\max}\}$, where $p_{\min} = 625$ kW is a lower level of drainage power consumption, which corresponds to the minimum power of one CNS (centrifugal) pump $p_{\max} = 2475$ kW, i.e. when all three pumps work with the highest performance and at maximum power.

During fuzzification, we represent the linguistic variable "pump power" as three fuzzy sets corresponding to the total power consumed by one, two or three pumps. All three membership functions to the fuzzy sets are defined as triangles and the fuzzification procedure is performed.

The membership function to the fuzzy set "power of one pump" is defined by the following expression:

$$\begin{aligned} \mu_{p_{ON}}(p) &= f(p; p_{\min}, p_{nom}, p_{\max} + p_{\min}) = \\ &= \max\left[\min\left(\frac{p - p_{\min}}{p_{nom} - p_{\min}}, \frac{p_{\max} + p_{\min} - p}{p_{\max} + p_{\min} - p_{nom}}\right), 0\right], \end{aligned} \tag{7}$$

while:

$core\,(P_{ON}) = \{p_{nom}\} = 800$ kW;

$supp\,(P_{ON}) = \{p \in \mathbb{R} \mid p_{\min} \leq p \leq p_{\max} + p_{\min}\} = 825$ kW.

The peculiarity of this function is that the upper reference value is taken in such a way that one pump is supposed to work at maximum power, while the second one additionally drains water with the minimum permissible power consumption, i.e. $p_{\max} + p_{\min} = 1425$ kW.

The following membership function to the fuzzy set "power of two pumps" is formulated from the following considerations. The reference value of the lower limit is taken considering the fact that both pumps will work simultaneously at the minimum of their operating characteristics, so their power will be $2p_{\min} = 1250$ kW. The reference value of the upper limit is set assuming that two pumps will work simultaneously at the maximum working section of the static characteristics, and the third is put into operation at the minimum, i.e. $2p_{\max} + p_{\min} = 2275$ kW. As a result, the membership function is as follows:

$$\begin{aligned} \mu_{p_{TW}}(p) &= f(p; 2p_{\min}, 2p_{nom}, 2p_{\max} + p_{\min}) = \\ &= \max\left[\min\left(\frac{p - 2p_{\min}}{2p_{nom} - 2p_{\min}}, \frac{2p_{\max} + p_{\min} - p}{2p_{\max} + p_{\min} - 2p_{nom}}\right), 0\right], \end{aligned} \tag{8}$$

while:

$core\,(P_{TW}) = \{2p_{nom}\} = 1600$ kW;

$supp\,(P_{TW}) = \{p \in \mathbb{R} \mid 2p_{\min} \leq p \leq 2p_{\max} + p_{\min}\} = 1025$ kW.

Similarly, the membership function to the fuzzy set "power of three pumps" is given. At the same time, it is assumed that the reference value for the lower limit involves the operation of three pumps with the minimum power consumption of $3p_{\min} = 3 \cdot 625 = 1875$ kW, and for the upper limit – three pumps with the maximum power $3p_{\max} = 3 \cdot 825 = 2475$ kW:

$$\begin{aligned} \mu_{p_{TR}}(p) &= f(p; 3p_{\min}, 3p_{nom}, 3p_{\max}) = \\ &= \max\left[\min\left(\frac{p - 3p_{\min}}{3p_{nom} - 3p_{\min}}, \frac{3p_{\max} - p}{3p_{\max} - 3p_{nom}}\right), 0\right], \end{aligned} \tag{9}$$

while:

$core\,(P_{TR}) = \{3p_{nom}\} = 2400$ kW;

$supp\,(P_{TR}) = \{p \in \mathbb{R} \mid 3p_{\min} \leq p \leq 3p_{\max}\} = 600$ kW.

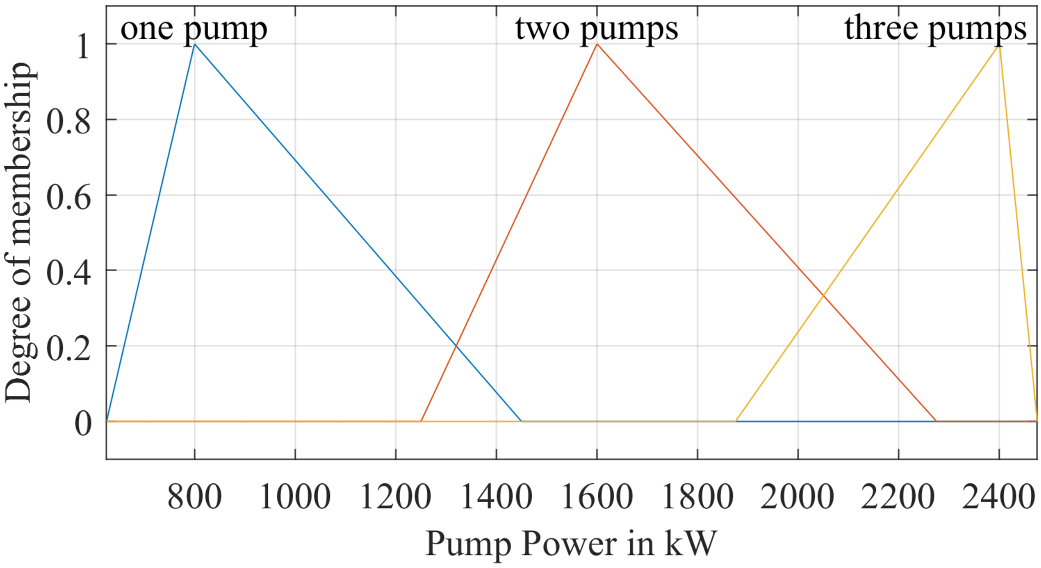

Figure 4. Membership functions to the fuzzy set "pump power".

For the first two membership functions, the upper limit includes an extra pump operation with a minimum power consumption, when intervals that do not belong to any fuzzy set defined for the linguistic variable emerge in the system of fuzzy logic inference in the domain of the finite set. For example, the upper reference value for the membership function to the fuzzy set "power of one pump" should be given at $p_{\max} = 825$ kW. However, the lower limit of the function to the fuzzy set "power of two pumps" is $2p_{\min} = 1250$ kW. As a result, the power range from 825 kW to 1250 kW does not belong to any fuzzy set, which greatly reduces control flexibility.

4.2. Synthesis of the rule base for the fuzzy inference system

On completing the fuzzification phase, it is necessary to form the rule base of the Mamdani fuzzy inference system. This procedure is carried out taking into account technological requirements for operating modes of mine water drainage. The key requirement is to ensure the efficient groundwater pumping, depending on intensity of its inflow into the underground mine. This is done to avoid flooding a shaft and mine levels, as it creates a danger to human life and makes it impossible to carry out technological operations of rock mass mining. Therefore, the highest level of significance is given to those comprising the fuzzy set "high inflow".

Since the system has two inputs, the conditional part of the base rules uses fuzzy AND conjunction operators to establish a logical relationship between the input variables of the fuzzy inference system.

Let us formalize the rules.

In all cases, if there is a high water inflow into the underground mine, all three pumps must be put into operation, regardless of the current power tariff. Moreover, the significance of this block of rules is 1, which determines the highest importance of these rules. As a result, they have the following form:

R1: **IF** $(q \text{ is } H)$ **AND** $(c \text{ is } NT)$ **THEN** p is TR;
R2: **IF** $(q \text{ is } H)$ **AND** $(c \text{ is } HP)$ **THEN** p is TR;
R3: **IF** $(q \text{ is } H)$ **AND** $(c \text{ is } PK)$ **THEN** p is TR.

Given a medium water inflow, the output power consumption of pumps depends on the current tariff. It is expedient to pump out water with maximum efficiency at the "night" tariff with all three pumps of a level, at the "half-peak" tariff with two, and at the "peak" tariff with only one. The significance of this block of rules is 0.75. As a result, the rules have the following form:

R4: **IF** (q is M) **AND** (c is NT) **THEN** p is TR;
R5: **IF** (q is M) **AND** (c is HP) **THEN** p is TW;
R6: **IF** (q is M) **AND** (c is PK) **THEN** p is ON.

Regardless of power costs, it is advisable to drain water with only one pump at low water inflow, so the following set of rules looks like this:

R7: **IF** (q is L) **AND** (c is NT) **THEN** p is ON;
R8: **IF** (q is L) **AND** (c is HP) **THEN** p is ON;
R9: **IF** (q is L) **AND** (c is PK) **THEN** p is ON.

The significance of this block of rules is 0.75 as well.

Table 2 summarizes the fuzzy rules.

Table 2. AND-type rule base of the fuzzy system controlling power consumption by water drainage facilities.

	NT	HP	PK
L	ON	ON	ON
M	TR	TW	ON
H	TR	TR	TR

The output surface of the Mamdani fuzzy inference system with nine AND rules is shown in figure 5.

For comparison, let us synthesize the rule base using the fuzzy disjunction operator OR. Water drainage facilities will consume the maximum power either at high water inflow or during the “night” tariff, and the minimum power either at low water inflow or at the “peak” tariff. Similarly, we formulate the rule for medium water inflow and the “half-peak” tariff. The resulting rule base is as follows:

R1: **IF** (q is L) **OR** (c is PK) **THEN** p is ON;
R2: **IF** (q is M) **OR** (c is HP) **THEN** p is TW;
R3: **IF** (q is H) **OR** (c is NT) **THEN** p is TR.

The first rule R1 has the significance of 1 and the other two – 0.75. It should be noted that this approach does not cover all possible combinations of value pairs of input variables.

The output surface of the Mamdani fuzzy inference system with three OR-type rules is shown in figure 6.

5. Modelling the expert system for controlling power consumption by main water drainage facilities of the underground mine

Let us analyze the efficiency of the fuzzy power consumption control system of the 500 m level. To do this, we will implement the system in MATLAB/FuzzyLogicToolbox and simulate its operation.

As a test signal for the input coordinate “water inflow”, we use a stochastic process of a random variable. The law of probability distribution is assumed to be normal with mathematical expectation $E[Q] = 500\text{m}^3/\text{h}$ and variance $\sigma^2 = D[Q] = 200\text{m}^3/\text{h}$ The state of the pseudorandom number generator is recorded by the software to ensure representativeness when comparing several control systems. Therefore, the stochastic process implementation will be conditionally constant for all experiments.

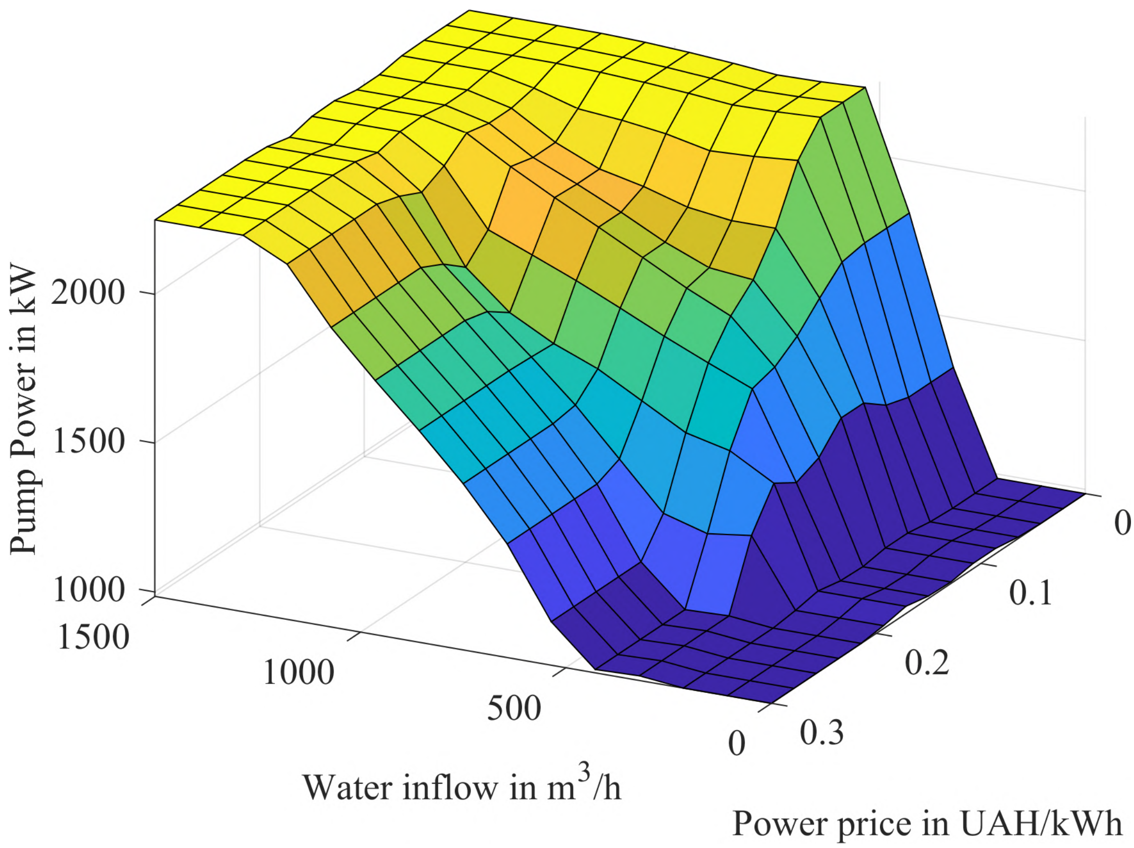

Figure 5. Output surface of fuzzy inference system.

The test signal for the input variable "power tariff" is generated by distributing tariff zones during the day. That is, the "night" zone is effective for 8 hours from 23.00 to 7.00, the "half-peak" zone – 11 hours from 7.00 to 8.00, from 11.00 to 20.00 and from 22.00 to 23.00, the "peak" zone – 5 hours from 8.00 to 11.00, from 20.00 to 22.00. To simplify, we assume that the underground mine is supplied with electric power in a centralized way by an external distributor, so the test signal has a stable periodic nature.

A comparative analysis will be performed for fuzzy logic inference systems with AND- and OR-type rule bases, as well as with a system without power consumption control, in which two

Table 3. Modelling results of power consumption fuzzy control by the water drainage facilities of the level over 7 days.

Power consumption control type	Medium power, kW	Maximum power, kW	Power consumption, kWh	Power cost, UAH

pumps with nominal performance and power are simultaneously operated on the level throughout the day.

The system operation is modeled during a week and a month.

The results of the experiments are summarized in table 3 and table 4 and presented in figure 7 – 10.

The obtained results of the water drainage modelling over a week (table 3) demonstrate that when using fuzzy power consumption control systems, power costs decrease, compared to the system without such control.

The controlled system that uses the fuzzy inference algorithm with the OR-type rule base

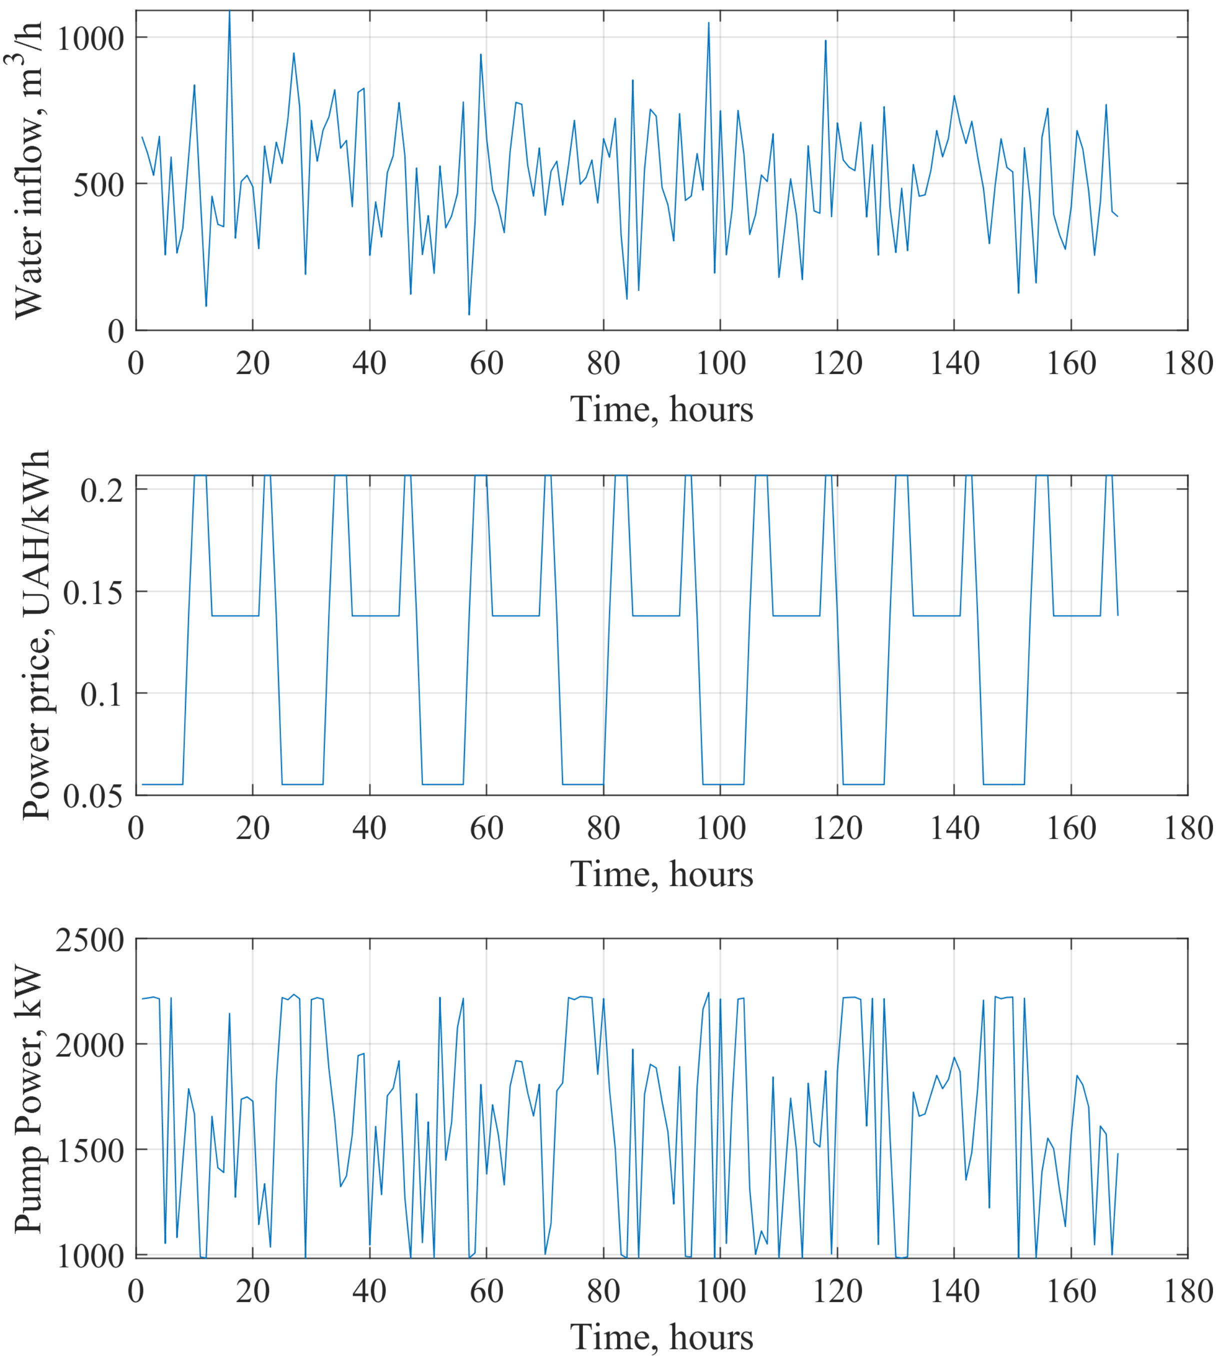

Figure 7. Results of modelling the operation of the water drainage power consumption control system based on the Mamdani fuzzy inference algorithm with the AND-type rule base over 7 days.

provides 1.89% (or UAH 632.18 in monetary value) lower level of power cost over a week than the uncontrolled one, and the use of the AND-type rule base – by 4.13% (or by UAH 1.384). If we compare smart expert systems with each other, the system with the AND-type rule base is more cost-effective. It provides 2.29% (UAH 752.63) lower power costs than the system with the OR-type rule base.

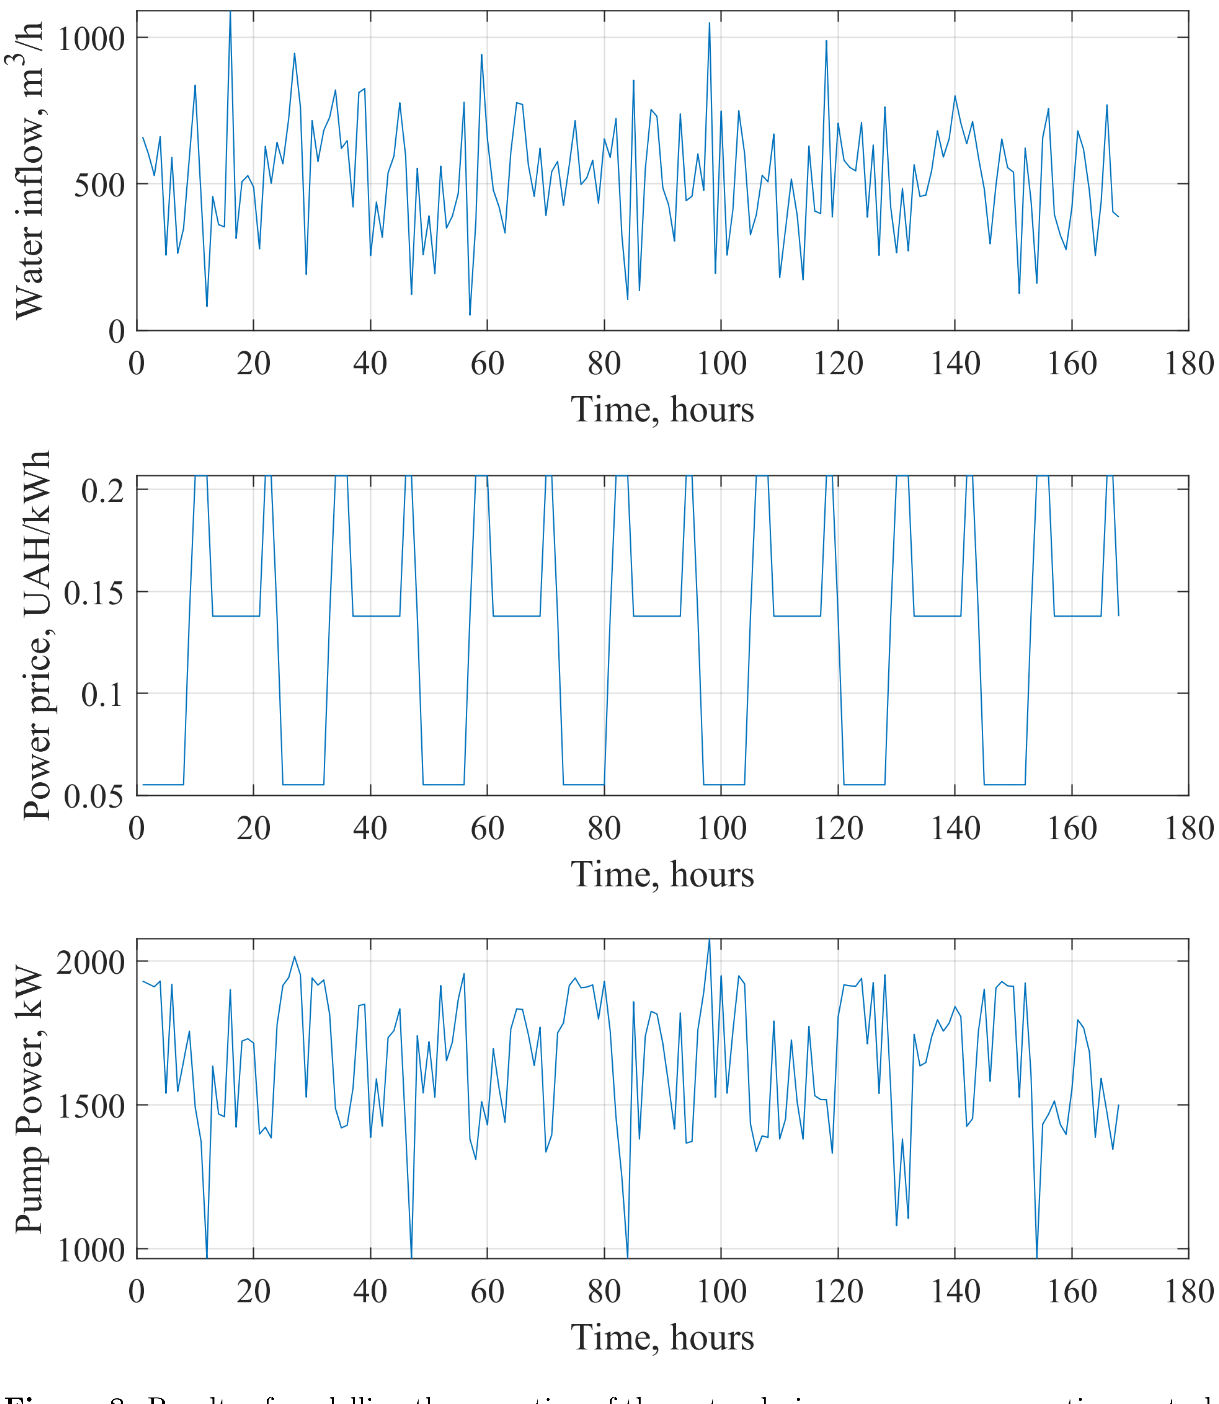

Figure 8. Results of modelling the operation of the water drainage power consumption control system based on the Mamdani fuzzy inference algorithm with the OR-type rule base over 7 days.

This trend persists if we consider a longer period, for example, a month (table 4). Moreover, the level of savings on power costs is only increasing. Thus, the fuzzy system with the OR rule base allows reducing power costs by 2.28% (by UAH 3379.66), the system with the AND-type rule base – by 5.43% (by UAH 8058.36). That is, the percentage ratio increases for both systems by 0.39% and by 1.3% compared to the week's operation. The cumulative nature of the economic effect is observed. At the same time, the AND-type rule base system provides 3.23% (or UAH

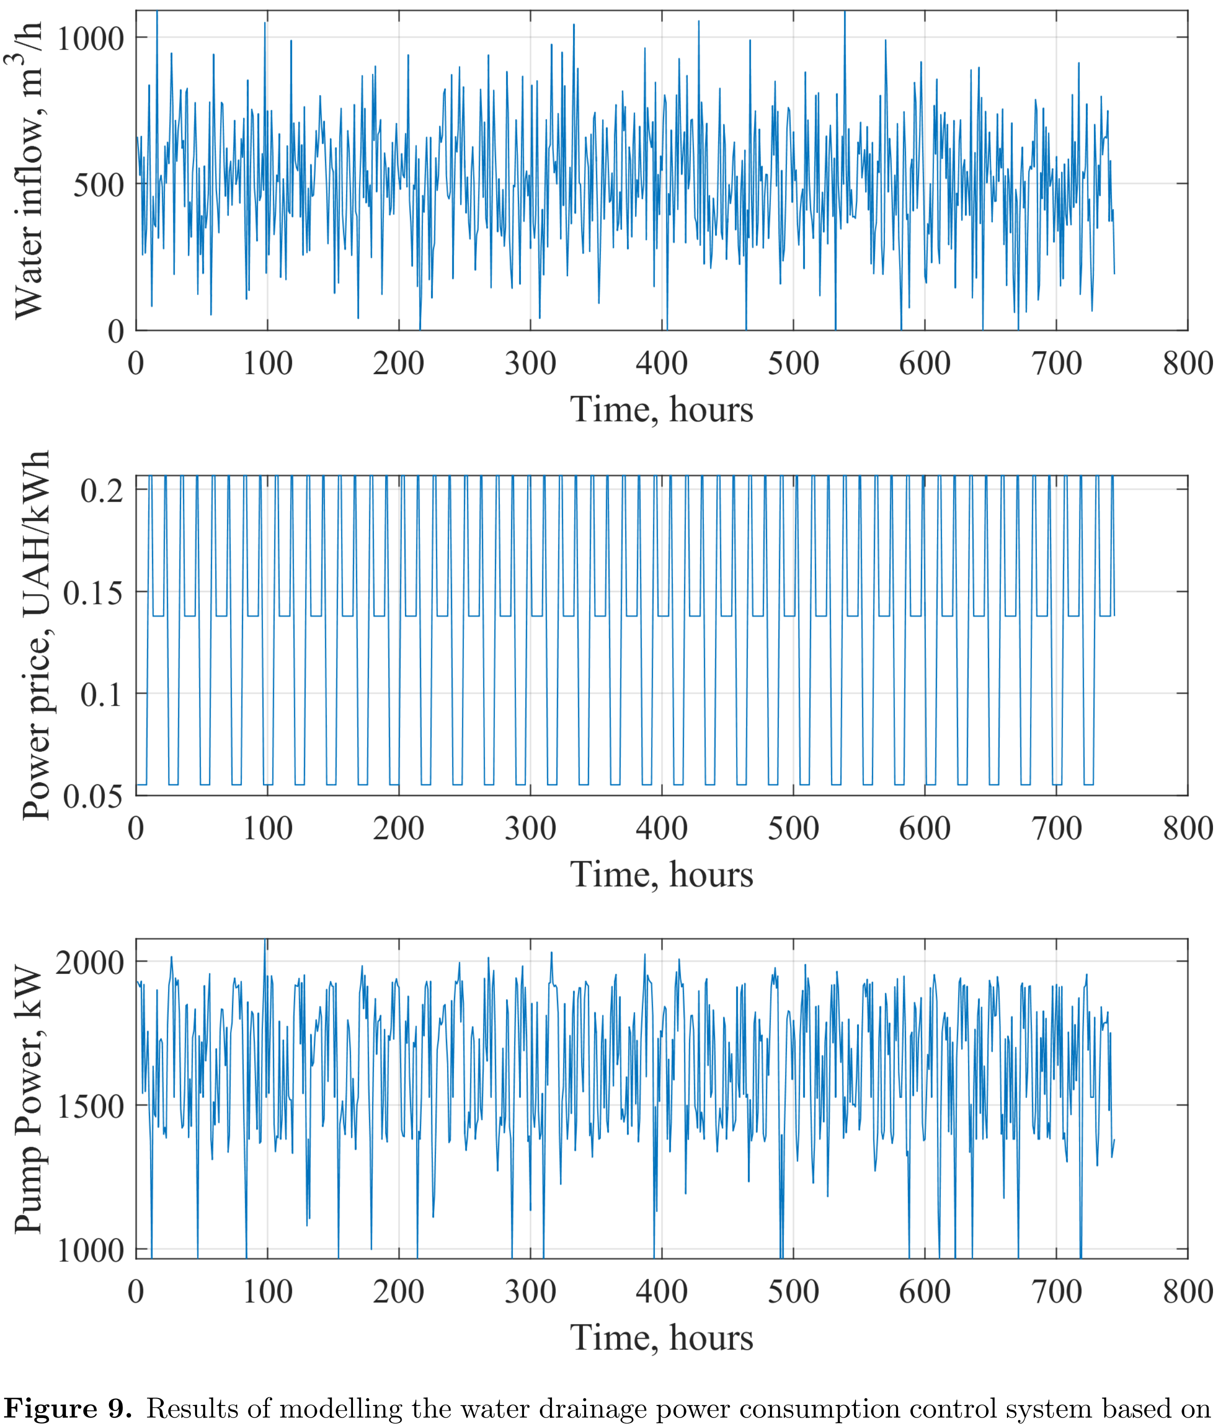

Figure 9. Results of modelling the water drainage power consumption control system based on the Mamdani fuzzy inference algorithm with the OR-type rule base over 31 days.

4,678.7) lower total cost of the produced power compared to the OR-type rule base system.

Two characteristic features of fuzzy control systems of water drainage power consumption at underground mines should be noted. The average power of the facilities at the mine level almost does not deviate from 1600 kW during the considered periods of operation. What is more, the power consumption level of uncontrolled systems is lower. This is due to the fact that in fuzzy control systems, power is consumed unevenly and there are long periods when the water inflow

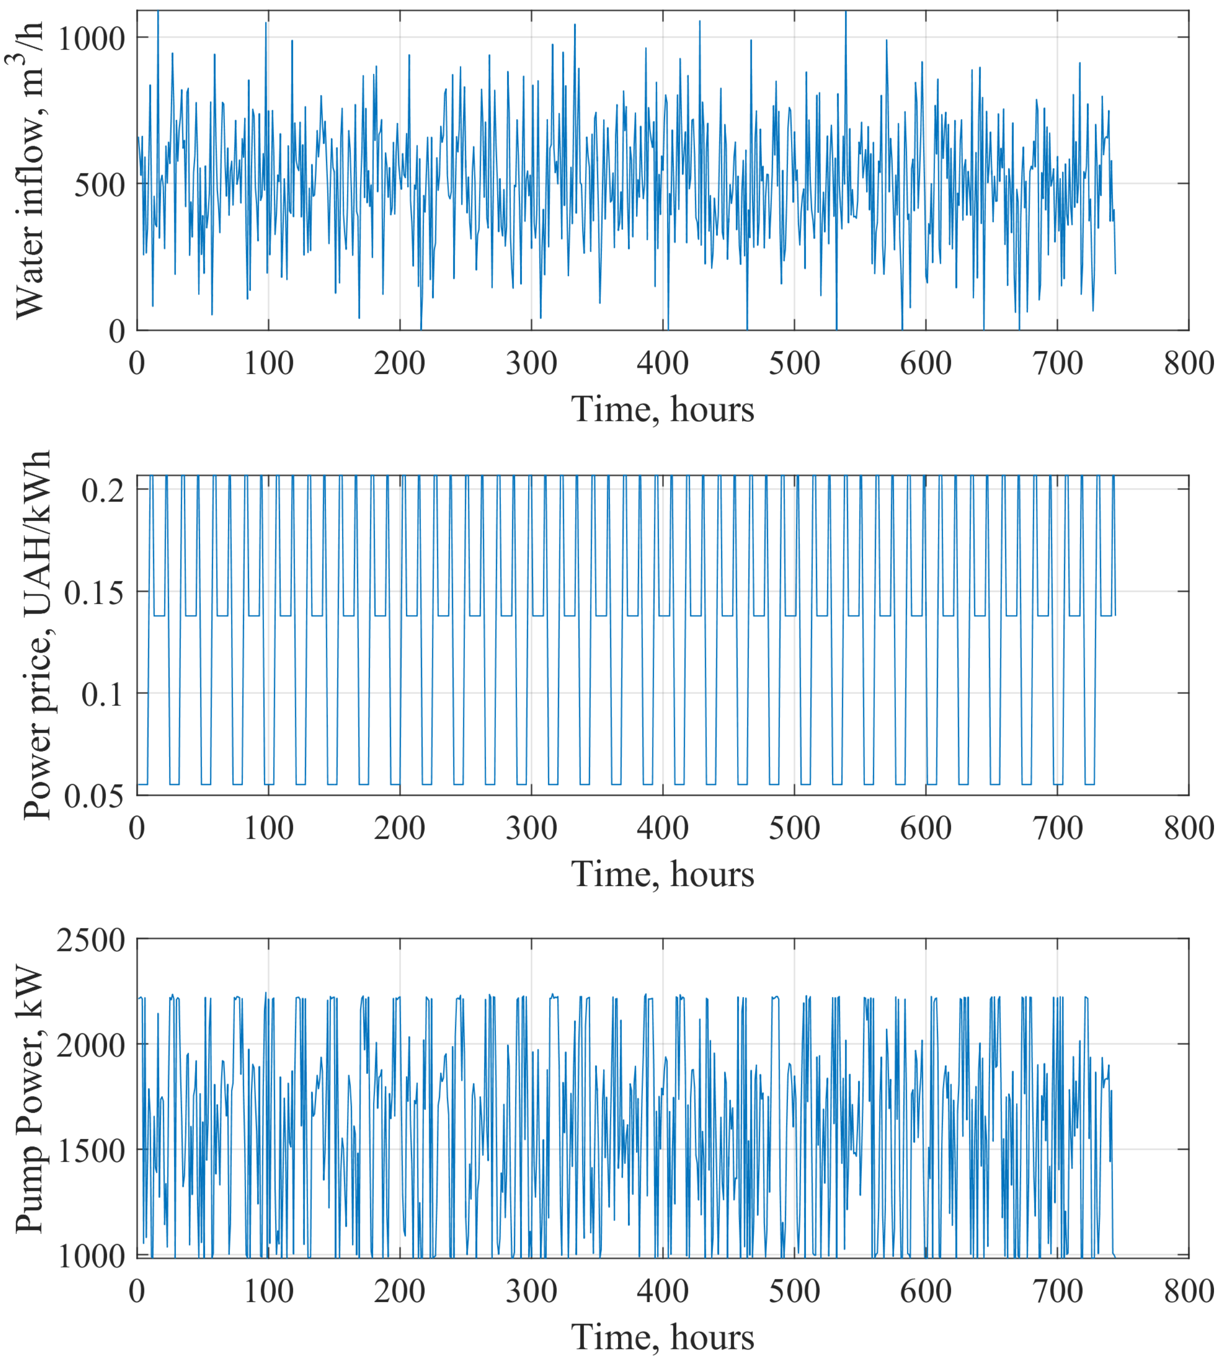

Figure 10. Results of modelling the water drainage power consumption control system based on the Mamdani fuzzy inference algorithm with the AND-type rule base over 31 days.

is high and three pumps are running at the same time, which leads to an increased level of power consumption. However, the fuzzy control algorithm allows increasing economic efficiency of the system due to the transfer of the high power consumption period to the “night” tariff time, thereby reducing the total cost of produced power.

6. Conclusions

The proposed expert control system of power consumption by main water drainage facilities of the underground mine based on the Mamdani fuzzy logic algorithm demonstrates its expected economic efficiency. Correspondingly, it is to be recommended for implementation at the relevant facility of iron ore underground mines.

The higher quality of control is demonstrated by the system with a conjunction-type fuzzy rule base. The level of power consumption in the uncontrolled system is lower due to uniformity of output power distribution by electromechanical drainage facilities during the day.

Further improvement of fuzzy control systems consists in increasing energy efficiency, i.e. reducing power consumption by main water drainage facilities of underground mines, which can be achieved by introducing an additional limitation for the power level of pumps running simultaneously during fuzzification of the corresponding linguistic variable.

Abstract. The paper provides a theoretical description of the solid particles movement process along with the horizontal flow of slurry within the hydraulic classifier flow part. Three modes of movement of solid particles are described: deceleration relative to the slurry flow at a constant speed or its increase, acceleration relative to the slurry flow at a decrease in its speed, with the speed of the slurry flow. The complex equation of solid particles motion in a horizontal co-flow of liquid. A graphic description of the process is given. A laboratory installation was developed to study the interaction of the hydraulic classifier flow part with the slurry flow. Experimental studies were carried out and quantitative process parameters were determined during the movement of rolled quartz solid particles in the size range < 1.8 mm and < 0.2 mm. For the first time in crisis economic conditions, in order to confirm the reliability of previously obtained analytical dependencies to determine the rational parameters of hydraulic disintegrators and determine the operational characteristics of equipment, full-scale experimental studies of the JPD 300-120 suction dredger equipped with an innovative ejector soil suction head with a jet disintegrator system were carried out.

1. Introduction

The processing of fine-grained materials is traditionally carried out in gravitational apparatus with a horizontal movement of the carrier flow: horizontal classifiers, deslimators, screw classifiers, decanters, horizontal settling tanks, etc. [1]

Despite the mass nature of the work aimed at studying the process of falling solid particles in a stationary liquid, the process of motion of solid particles relative to a moving horizontal flow of a carrier slurry remains practically unexplored. Unprovenly considered that in a carrier horizontal flow solid particles move with a flow velocity [2].

It is known that the rational size for gravitational processing, for example, quartz particles, is $0.15 < d < 5$ mm. In this case, the separation range for horizontal classifiers can be considered the fineness $0.1 < d < 0.2$ mm [3].

Thus, to justify the rational parameters of the apparatus for the gravitational processing of granular materials in a horizontal flow, it is sufficient to simulate the movement of solid particles which have a size withing the separation range expected values [4, 5].

2. Methodology

The work used a complex research method. A theoretical study of the interaction process between the hydraulic classifier flow part and the flow of solid particles that move along with the horizontal flow of the slurry is made in the form of physical and mathematical modeling. The process of co-movement of solid particles and slurry is described using the Lagrange method.

Experimental study of the process was carried out on the developed laboratory installation [6, 7]. Processing and analysis of experimental data were performed using the methods of mathematical statistics and planning of experiments, and the approximating dependences were obtained by the least squares method. Measurements of technological and design parameters were carried out using standard metric equipment.

3. Results and discussion

3.1. A theoretical study

The characteristic modes of movement of solid particles in a horizontal slurry flow during hydraulic classification in a horizontal flow are:

- movement of particles with deceleration relative to the carrier flow at a constant and increasing speed of its movement;
- movement of particles with acceleration relative to the carrier flow with a decrease in the speed of its movement;
- movement of particles with the speed of the carrier flow.

To describe the process of interaction of the horizontal hydraulic classifier flow part with a slurry flow that includes suspended solid particles moving along, we apply the Lagrange method. Let a solid particle move under the action of a horizontal fluid flow along it (figure 1). The horizontal projection of the velocity vector of a solid particle is directed along the motion of the liquid. The horizontal motion of a solid particle is characterized by its mass in a liquid m, force of the hydrodynamic pressure F_{av} at the velocity of the carrier flow U_x and resistance force P, at the speed of movement of a solid particle relative to the carrier flow v_x (figure 1).

$$m\frac{U_x}{dt} = F_{av} - P \tag{1}$$

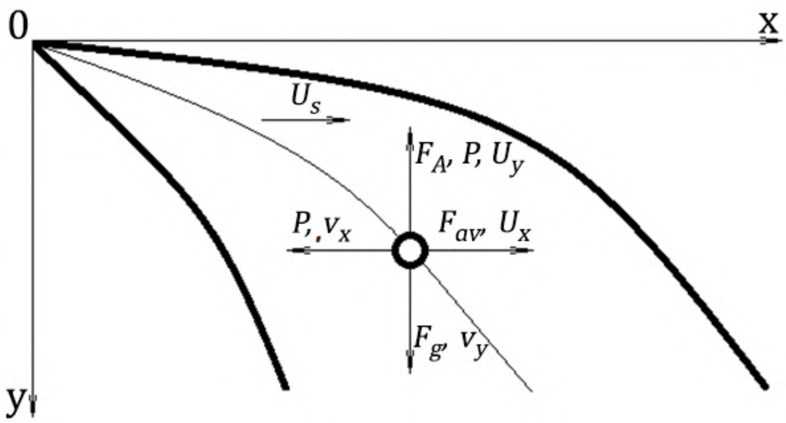

Figure 1. Scheme of the process of a solid particle motion in a horizontal liquid flow.

After transformations, the equation of motion of a solid particle in a horizontal liquid flow will take the form

$$U_x^p = \left(\frac{3}{4} \cdot \frac{\rho_s}{\rho_q - \rho_s} \cdot \frac{C_f}{d_g}\right) \int (U_x^2 - v_x^2)dt + C. \tag{2}$$

The integration constant C is defined as the initial velocity of the solid particle U_{x0}^p.

Let us analyze the obtained dependence and consider three modes of motion of a solid particle relative to the carrier flow.

Let the solid particle be motionless, that is $U_x^p = 0$. In this case, the velocity of the liquid relative to the solid particle U_x is equal to the velocity of the solid particle relative v_x

$$U_x = v_x. \tag{3}$$

The connected movement of a solid particle and a carrier flow can occur in the range $U_x > v_x \geq 0$, in this case, the equation of motion (2) takes the form

$$\begin{gathered}U_x^p = \left(\frac{3}{4}\cdot\frac{\rho_s}{\rho_q-\rho_s}\cdot\frac{C_f}{d_g}\right)\int(U_x^2 - v_x^2)dt + C \qquad \text{if } U_x^p < U_x,\\ U_x^p = \left(\frac{3}{4}\cdot\frac{\rho_s}{\rho_q-\rho_s}\cdot\frac{C_f}{d_g}\right)\int(U_x^2 + v_x^2)dt + C \qquad \text{if } U_x^p > U_x,\\ U_x^p = \left(\frac{3}{4}\cdot\frac{\rho_s}{\rho_q-\rho_s}\cdot\frac{C_f}{d_g}\right)\int(U_x^2)dt + C \qquad \text{if } U_x^p = U_x, v_x = 0.\end{gathered} \tag{4}$$

The counter motion of a solid particle and a carrier flow is characterized by the mode of motion $U_x < v_x$, while the equation of motion will retain the form (2).

Graphical representation of this process, in the absence of relative motion of the carrier flow and solid particles in the original cut, that is $U_{x0}^p = U_{x0}$, $v_{x0} = 0$ shown in the figure 2.

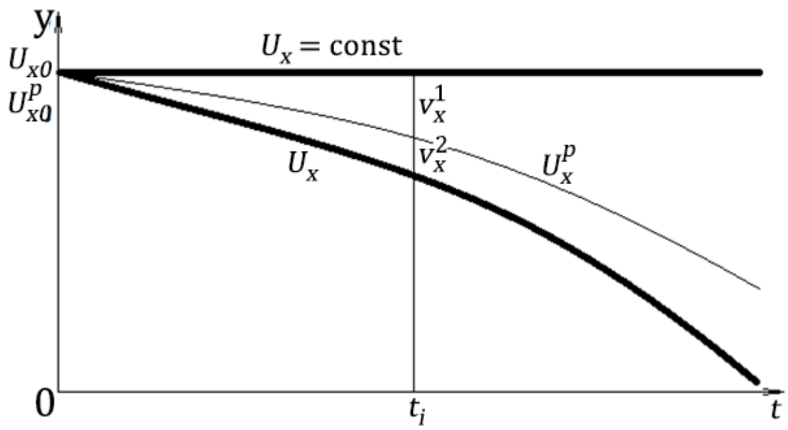

Figure 2. Scheme of the process of co-movement of a solid particle and a horizontal liquid flow.

Process analysis shows that within time t the function U_x^p is limited by the functions $U_x = const$ and U_x. The speed of a solid particle movement, in the i-th section, relative to the carrier horizontal flow, moving at a constant velocity, is taken as v_{xi}^1, but with relation to the decelerating flow v_{xi}^2 (figure 2).

The graphical representation of this process is built on the basis of the following hypothesis. Carrier flow moves in laminar mode. At a time interval t, at a constant velocity of the carrier flow a solid particle can move with relative deceleration, that is $U_x = const \geq U_{xi}^p$. When the carrier flow slows down, the solid particle can move with relative acceleration, $U_{xi}^p \geq U_{xi}$. That is, the particle velocity function is within $U_x = const \geq U_{xi}^p \geq U_{xi}$.

The theoretical substantiation of the process of relative movement of solid particles and the carrier horizontal flow is very difficult. A rational and more informative method of modeling the process, in a narrow designated area, can be considered an experimental study, which will allow to determine the values of relative velocities v_{xi}^1, v_{xi}^2.

One of the important factors influencing the process of relative motion of a solid particle in an carrier flow is the particle form. However, in the designated area of motion velocities and size particles, characterized by the number Re, there is a mode of motion of a solid particle close to laminar, at which, in accordance with the data of [6], the form of the particle has an insignificant effect on its motion.

The vertical projection of the particle velocity vector is characterized by the sediment process, and is determined by the absolute value of the particle weight in the liquid and the resistance force in liquid, directed in the direction opposite to the direction of movement (figure 1).

$$F_g - F_A = P$$

where F_g – gravity, H; F_A – strength of Archimedes, H; P – resistance force, H.

Due to the traditional nature of the use of raw materials with a high content of rounded quartz particles (construction and glass sands), the investigated area of fineness $0.15 < d < 5$ mm turned out to be the most studied experimentally. The literature sources provide data from different authors who obtained experimental values of the velocity of free fall of quartz particles [8]. Thus, in view of the presence of a sufficient amount of experimental material, in further studies, the final velocity of the fall of quartz particles will be taken according to the experimental data known in the literature. It should also be noted that at the indicated velocities of the carrier flow, the sedimentation process time is much longer than the time of unsteady motion of a solid particle, so this factor is not taken into account in the model.

When taking into account the relative displacement of a solid particle driven by a horizontal carrier flow in the horizontal and vertical directions, the formula for constructing the particle trajectory will take the form

$$x = \int \frac{U_x \pm v_x}{U_y - v_y} dy + C.$$

Let us replace the parameter that takes into account the relative vertical displacement by the experimental value of the falling velocity of a solid particle in water $U_y - v_y = \omega$ then

$$x = \int \frac{U_x \pm v_x}{\omega} dy + C.$$

where ω is experimental value of the speed of free fall of a solid particle, m/s.

The integration constant C characterizes the initial conditions for the motion of a solid particle, and, when the origin of coordinates is located in the initial position of the solid particle, the constant $C = 0$.

Let us assume that the movement of a liquid and a solid particle proceeds without mutual displacement, that is $v_x = 0$. Thus, we simplify the consideration of the process and equate the horizontal projection of the velocity of a solid particle and the velocity of a liquid $U_p^x = U_x$. Then the equation of motion of a solid particle under the action of a horizontal flow takes the form

$$x = \int \frac{U_x}{\omega} dy + C.$$

and after integration

$$x = \frac{U_x}{\omega} y \tag{5}$$

3.2. Experimental studies

Laboratory studies of the interaction process of the horizontal hydraulic classifier flow part with a pulp flow that includes suspended solid particles are performed on the basis of specialized laboratory equipment. Laboratory equipment for studying the processes of gravitational processing of granular materials is based on the use of a horizontal multi-section classifier HMC. With the use of the HMC classifier, fundamental laboratory studies were carried out to study the movement of granular material particles in a horizontal carrier flow. Laboratory installation based on the HMC classifier, consists of a horizontal multi-section classifier 1, a jet feeder 2, a water supply system (figure 3).

The horizontal multi-section classifier is an elongated vessel of rectangular section 1, in the lower part divided into 12 compartments 3, equipped with discharge nozzles 4. Power is supplied through the intake pipe 5, the sludge is drained through the drain pipe 6.

The jet feeder 2 is designed to prepare the slurry of specified parameters and feed it into the inlet pipe 5 of the horizontal multi-section classifier 1.

Preparation of the slurry in the jet feeder 2 is carried out by supplying water through a pipe branch with irrigation nozzles 7, the transport of the prepared slurry is carried out by means of a jet pump 8. For water supply of the pipe branch 7 and the jet pump 8, a water supply system is used.

The water supply system consists of a main valve 9, a control valve 10 and a pressure gauge 11 of the water supply system of the pipe branch 7, a control valve 12 and a pressure gauge 13 of the water supply system of the jet pump 8. Transportation of water and sludge is carried out through flexible pipes 14. The equipment is installed on support frames 15, 16. The source of water for the operation of laboratory equipment is the plumbing.

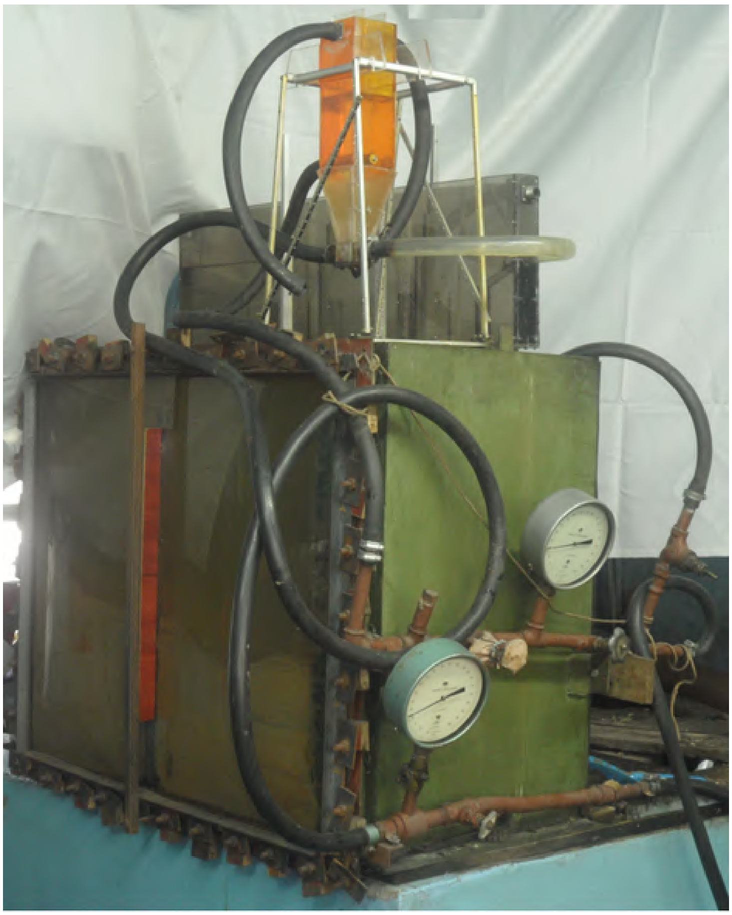
The following equipment was used to perform the necessary measurements:

1. Precision pressure gauge type MZM with a division value of 0.005 kgf/cm^2 (accuracy class 0.6).
2. Laboratory cylinder with a volume of 1 liter with a measurement accuracy of 2 ml.
3. Stopwatch "Agat" with a measurement accuracy of 0.5 s.
4. Scales VNC-2, a measurement accuracy of 2 g, TU 25-06-2068-82.
5. Scales RN-10C13M, a measurement accuracy of 5 g, GOST 7327-55.
6. Laboratory sieve SL-200 with cell of 0.1 mm, 0.2 mm, 0.315 mm, 0.4 mm, 0.5 mm, 0.63 mm, 1.25 mm, 2.5 mm.
7. Laboratory sieve shaker.
8. Drying cabinet.

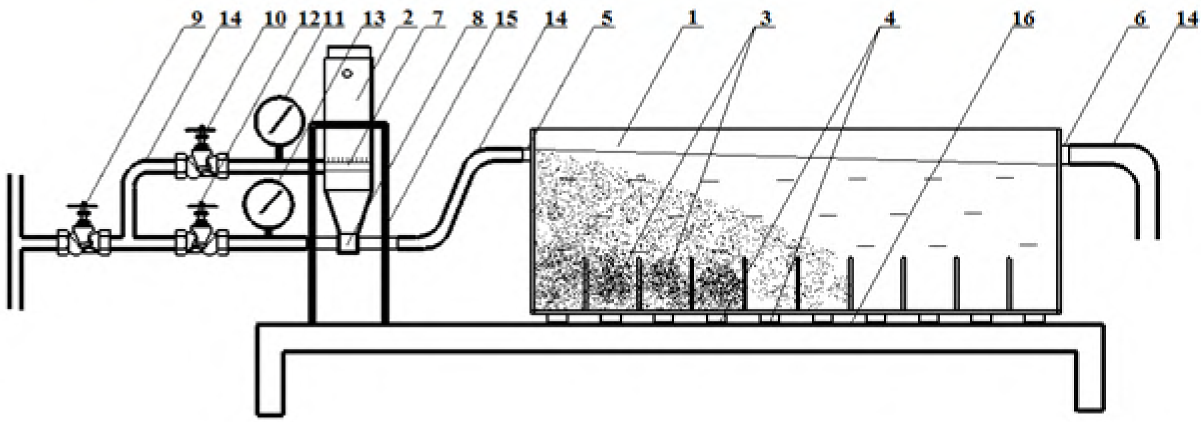
The complexity of modeling the process of gravitational processing of granular materials in a carrier horizontal flow lies in the need to take into account the horizontal and vertical movement of solid particles. At the same time, the following factors may have some influence on the solid particles motion process: co-flowing relative vertical and horizontal motion of solid particles; constraint of the solid particles movement; movement of solid particles relative to the carrier horizontal flow.

In order to take into account the above factors and quantify their influence on the process of granular materials gravitational processing, the obtained experimental data were processed. At the same time, the tasks of quantifying and assessing the need to take into account such factors were solved:

- movement of solid particles relative to the carrier horizontal flow;
- constraint of the solid particles movement;
- movement of solid particles in various parts of the gravity processing process in a horizontal flow.



(a)



(b)

Figure 3. Laboratory installation for the study of gravitational processing of granular materials based on HMC: (a) the general view of the installation; (b) a circuit scheme of the installation.

4. The movement of solid particles relative to the carrier flow

The study of the movement of solid particles from this size range was devoted to experimental studies carried out on a laboratory installation using a horizontal multi-section classifier HMC

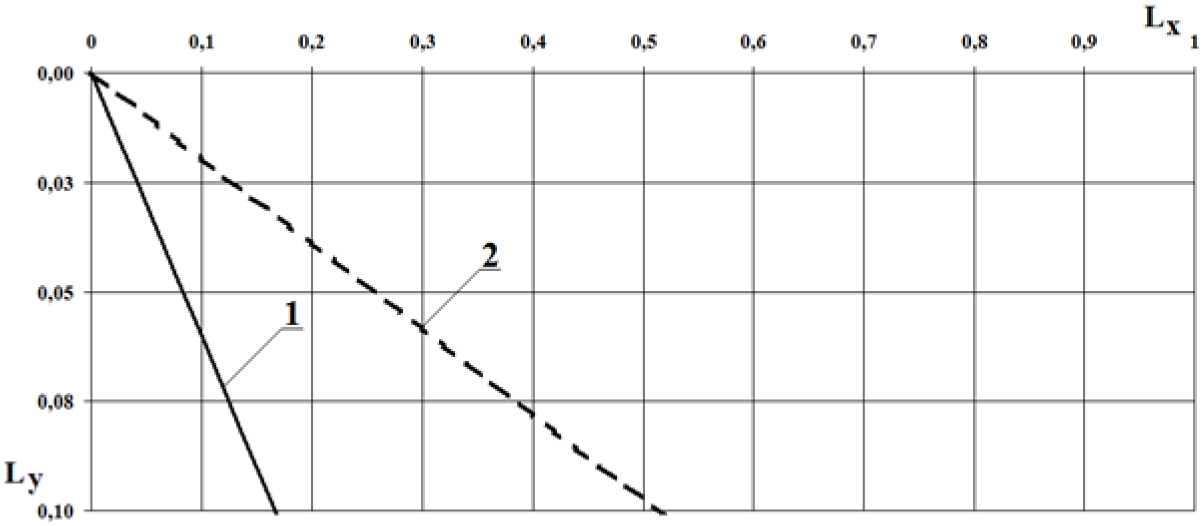


Figure 4. Theoretical trajectory of motion of rounded quartz particles: 1 – trajectory of movement of rounded quartz particles with size 0.2 mm; 2 – trajectory of movement of rounded quartz particles with size 0.1 mm

Table 1. Parameters of deposition of quartz particles with a particle size of < 0.2 mm, %

Slurry concentration, %	№ of the HMC compartment								$\sum$ №2-6
	2	3	4	5	6	7	8	9	91.2
3.0	37.4	18.4	14.9	12.1	8.4	4.7	2.7	1.4	94.1
6.0	44.1	18.6	14.1	10.5	6.8	3.5	1.6	0.8	92.0
10.0	40.1	18.8	14.2	11.1	7.7	4.3	2.5	1.2	93.4
13.0	42.3	18.6	14.0	11.0	7.6	3.6	2.0	1.0	89.7
19.0	36.0	18.0	14.6	12.2	9.0	5.6	3.2	1.5	91.2

(figure 3).

As a result of laboratory studies, the movement of rounded quartz particles in the size range < 1.8 mm and < 0.2 mm was studied. The calculation of the theoretical trajectory of particle motion was performed using the dependence (5) (figure 4).

The sedimentation process proceeded at an average horizontal flow velocity of 0.03 m/s. Processing of the experimental data showed that in the size range < 0.2 mm, more than 90% of solid particles sedimented in compartments No. 2-6, located in the theoretical area of sedimentation of rounded quartz particles with a size of 0.2 ... 0.1 mm (table 1, figure 5). Thus, the minimum value of the probability of sediment of a rounded quartz particles with a particle size of 0.2 ... 0.1 mm in the theoretical area of deposition is 90%. And when taking into account the presence of particles smaller than 0.1 mm in the used raw material, the theoretical area expands and the probability tends to 100%.

The purpose of laboratory studies was also to determine the effect of the concentration of solid particles in the feed on the deposition process. Processing of experimental data showed that the concentration of solids affects the constraint of particle movement, causing a decrease in the fall velocity (figure 6). In a detailed study of the mass characteristics of the material deposited in the area with a 90% probability of sediment of rounded quartz particles with a particles size of 0.1 ... 0.2 mm the average value of the mass difference in compartments No. 2-6 at a solid concentration in the slurry of 3% and 19% was 3%.

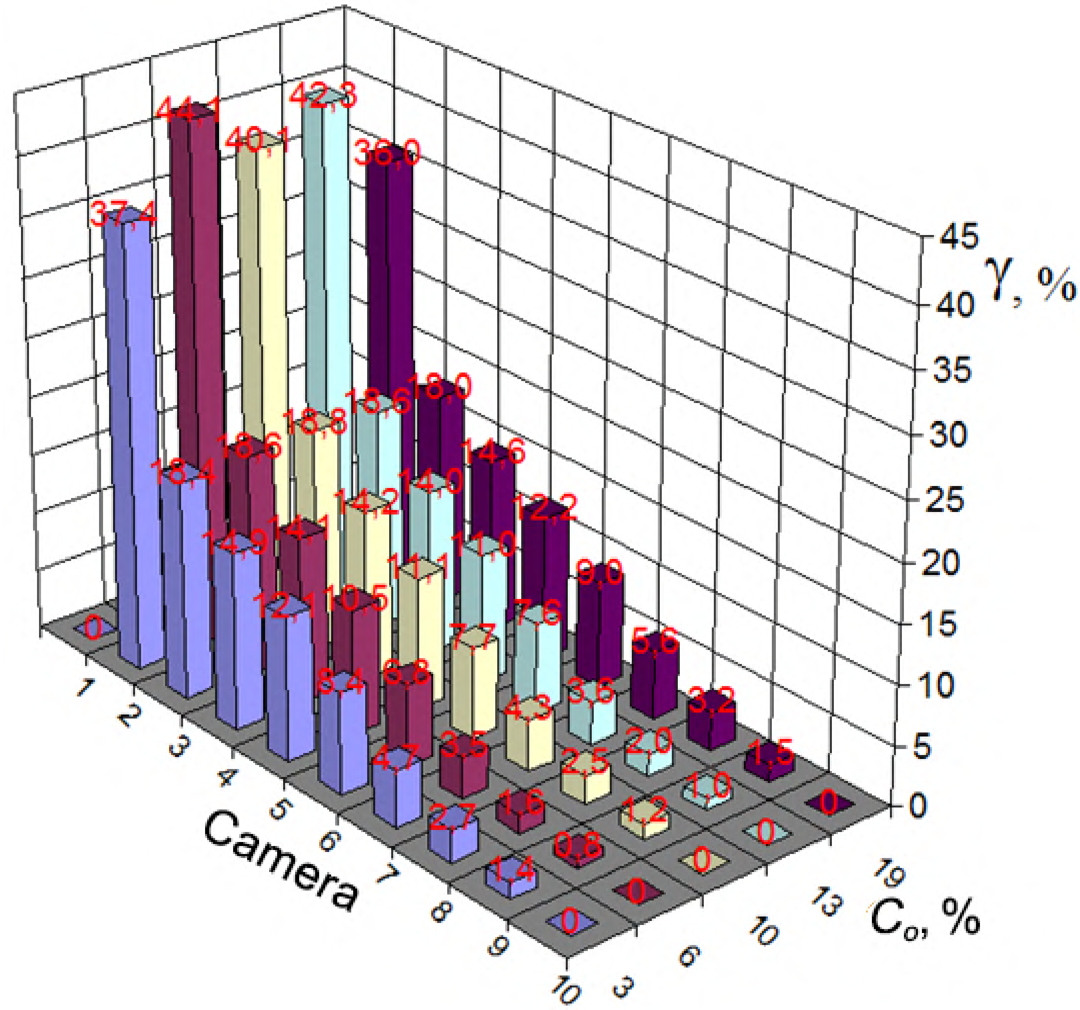

Figure 5. Sedimentation of rounded quartz particles with a particle size of < 0.2 mm when fed with a volumetric concentration (C_o, %).

Table 2. Average size of deposited quartz particles with a size of < 1.8 mm, %.

Slurry concentration, %	№ of the HMC compartment					
	1	2	3	4	5	6
3.0	0.41	0.337	0.285	0.24	0.202	0.174
6.0	0.404	0.341	0.278	0.229	0.192	0.165
10.0	0.398	0.347	0.276	0.227	0.19	0.165
13.0	0.403	0.36	0.283	0.231	0.194	0.164
19.0	0.391	0.361	0.28	0.232	0.197	0.168

An analysis of experimental data from laboratory studies of the movement of rounded quartz particles with a particle size of < 1.8 mm showed, that the influence of the solid concentration in the slurry within 0 ... 20% on the average size of the granular material deposited in the compartments does not go beyond 5%, and the average error is 1.6% (table 2, figure 7, 8).

This value indicates the fact of the insignificance of the influence of this factor on the process

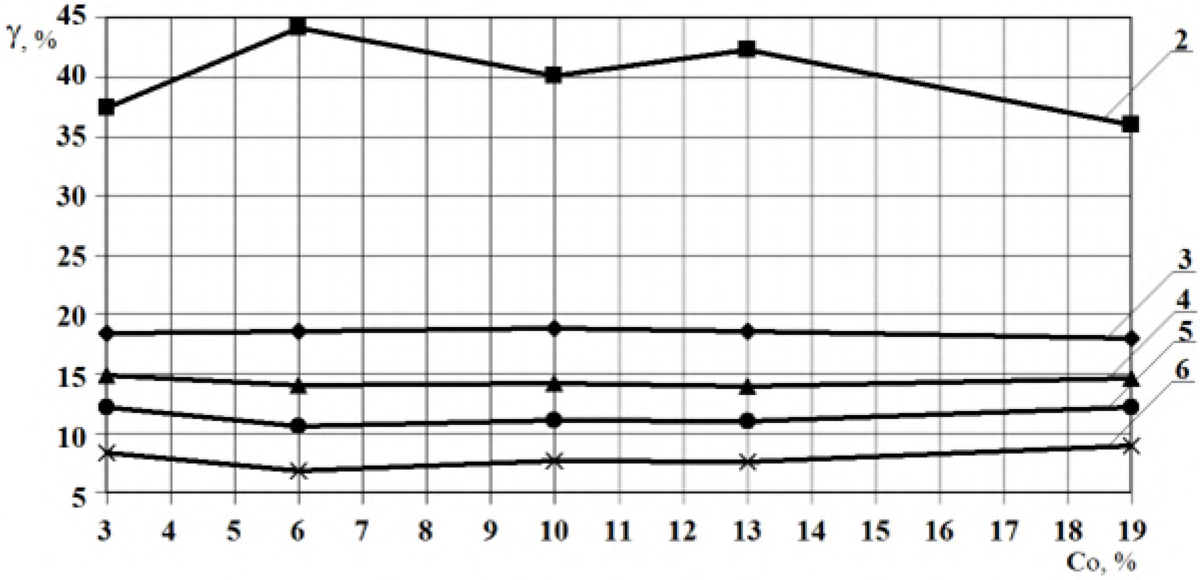

Figure 6. Influence of slurry concentration on the process of sedimentation of rounded quartz particles with a particle size of < 0.2 mm: 2, 3, 4, 5, 6 – compartments.

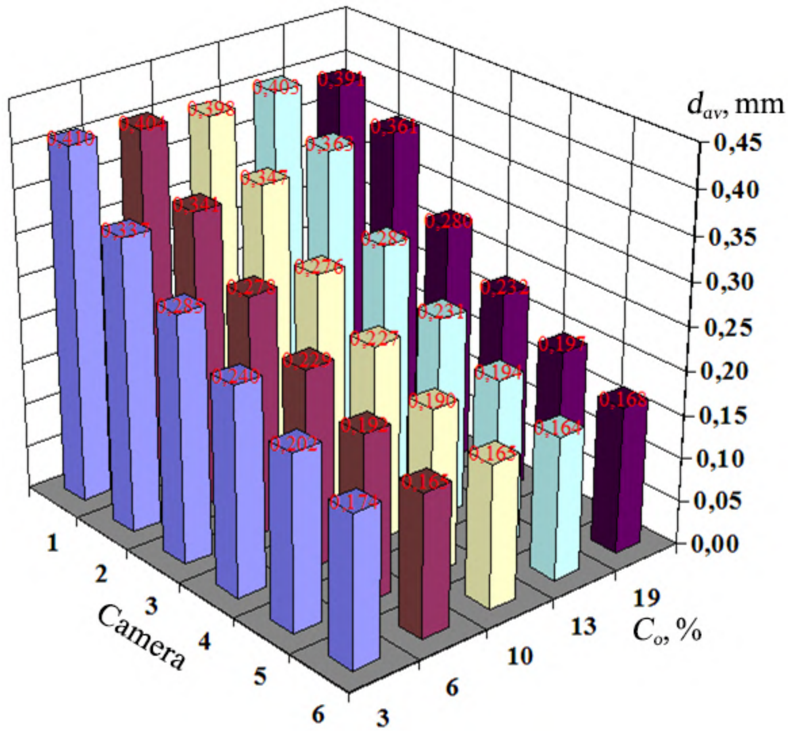

Figure 7. Sedimentation of rounded quartz particles with a particle size of < 1.8 mm when fed with a volumetric concentration (C_o, %).

of the solid particles sedimentation in the concentration range of 0...20%. Thus, the performed laboratory studies of the rounded quartz particles deposition process, under the influence of a horizontal carrier flow, confirm the relevance of the application of dependence (5) to calculate

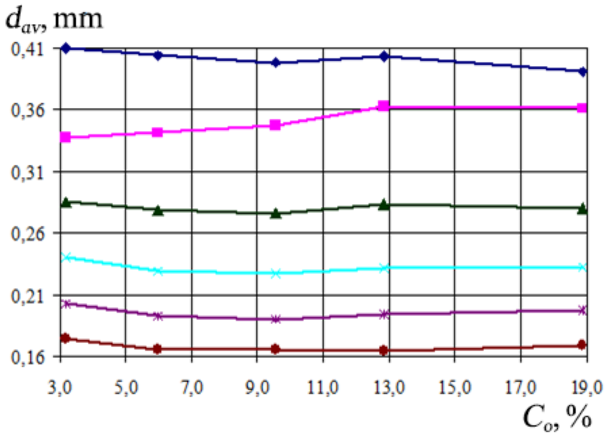

Figure 8. Influence of slurry concentration on the process of sedimentation of rounded quartz particles with a particle size of < 1.8 mm: 2, 3, 4, 5, 6 – compartments.

the parameters of the solid particles sedimantation with particle size < 1.8 mm and < 0.2 mm in the concentration range 0...20%.

5. Conclusions

The results of the theoretical studies of the interaction process between the flow part of a horizontal hydraulic classifier and the laminar slurry flow, which includes suspended solid particles, allow us to make the following conclusions:

1. The basis for the theoretical description of the gravitational sedimantation of solid particles during its passing and counter motion relative to the horizontal carrier flow was the Lagrange method.
2. At the velosity U_x of v_x the liquid movement, and the speed U_x^p of movement of the solid particle relative to the liquid, the absolute speed of the solid particle in passing motion with the carrier flow can be in the ranges: $1 - U_x^p < U_x$; $2 - U_x^p > U_x$; $3 - U_x^p = U_x, v_x = 0$.
3. An initial theoretical dependence was obtained to determine the path traveled by a solid particle under the conditions of gravitational sedimantation under the action of a horizontal carrier flow, which takes into account possible scenarios for the relative motion of a solid particle and liquid.

Abstract. Currently, in the Quang Ninh coalfield, exploiting the seams with medium thickness and dip angle of over 50 degrees is often difficult, so labor productivity and safety are low. It is necessary to research and apply advanced mining technology to medium thickness seams with dip angle of over 50 degrees in order to improve efficiency and safety. Studying the actual production in the Mao Khe coal mine shows that the mining technology for the condition of the seam with medium thickness, and dip angle over 50 degrees is mainly mining technology by drilling and blasting. This technology has the disadvantage of low labor productivity and unsafety. In this paper, the authors have researched and proposed mining technology by the combination of ANSH equipment to exploit the longwall in Seam 6 of Mao Khe coal mine. This is a fully mechanized mining technology, coal cutting by plow, combined with shield. Analysis of economic and technical indicators shows that this technology has been more effective and productive than the mining technology currently applied in other coal mines. This application will benefit not only Mao Khe coal mine, but also to other coal mines of Quang Ninh coalfield with similar coal seam conditions.

1. Introduction

Fully mechanized mining technology is a type of technology that uses shearer or plow with mechanized shield to extract coal seams [1–3]. This technology has been used in many countries, especially in China and European countries [4], where mechanized mining techniques applied to coal seams are also relatively effective.

In recent years, mechanized mining technology that uses shearer has been applied to a number of underground mines in the Quang Ninh coalfield, Vietnam and it has achieved certain initial effects [5–9]. However, the fully mechanized mining technology that uses a plow is still a new technology and has not been adequately researched and invested in underground mines in the Quang Ninh coalfield. This is a mechanized mining technology that is applied to the seams with medium thickness and dip angle of over 50 degrees.

Currently, in Quang Ninh coalfield, there are many underground mines managed by Vietnam national Coal - Mineral industries Corporation. In which, the reserves of coal seams of medium thickness and dip angle of over 50 degrees account for a relatively large proportion [10]. The condition of these seams belongs to most coal mines such as: Mao Khe, Nam Mau, Vang Danh, Uong Bi, Ha Lam, Nui Beo, Hon Gai, Duong Huy, Thong Nhat, Ha Long, Quang Hanh, Mong Duong and Khe Cham. Due to the geological conditions of the seams at different coal mines, the Vietnam national Coal - Mineral industries Corporation has also selected and applied many different types of mining technologies and methods, but it has not yet brought about the expected efficiency [11]. Mining technology by drilling and blasting is the main technology that has been applied to coal seams of medium thickness, dip angle of over 50 degrees, this is a manual mining technology. The disadvantages of this technology are low safety, interruption in the technological chain, releasing harmful gases, and low productivity.

To eliminate the disadvantages of the drilling and blasting mining method, along with the determination to modernize technology in underground mining. For many years, the Vietnam national Coal - Mineral industries Corporation has coordinated and directed coal mines in Quang Ninh coalfield to actively research and select suitable and effective mining technologies for coal seams of medium thickness, dip angle of over 50 degrees. From the above practical issues, the article has researched and proposed a mining technology by the combination of ANSH equipment for longwall in Seam 6 of Mao Khe coal mine. Mining technology using a combination of ANSH equipment has been applied in some Eastern European countries and has brought good results when exploiting coal seams of medium thickness, dip angle of over 50 degrees. This is a fully mechanized mining technology, coal cutting by plow, combined with shield and it is applied to the seams of medium thickness, dip angle of over of 50 degrees. On the basis of the research results of the article, Mao Khe coal mine can apply and deploy these proposal designs in actual production to improve working efficiency in the longwall face, thereby increasing mining efficiency and productivity.

2. Geological features of the longwall in Seam 6 of Mao Khe coal mine

The thickness of the seam varies from 0.8 to 3.75 m, with an average of 1.82 m, belonging to the medium thickness and very unstable type. The dip angle of the seam varies from 57° to 70°, with an average of 61°.

Roof: located directly on the seam, there is a claystone layer interspersed with coal- clay and thin layers of coal forming a layer with a thickness of $0.2 \dots 2.2$ m, which is easy to collapse and separate during mining, followed by layered siltstone with a total thickness of $8 \dots 25$ m of medium stable hard rock. Many interstitial places in the siltstone are thin layers of sandstone. Next, the siltstone is a thick and stable layer of sandstone.

Floor: located directly below the seam, it is a soft rock layer consisting of: claystone interlaced with coal-clay lenses with a total thickness of $0.21 \dots 1.8$ m. The weak rock layer is followed by a thin to medium layered siltstone layer with a total thickness of $14 \dots 20$ m. The distribution under the siltstone is a layer of fine to medium grained sandstone with a total thickness of $5 \dots 30$ m. Rocks are sustainable.

Table 1. Some average physical and mechanical parameters of the roof and floor [12].

Rock unit	σ_n (Mpa)	σ_k (Mpa)	γ (T/m^3)	φ (degree)	C (Mpa)
sandstone	94.2	10.1	2.64	33	12.1
siltstone	45.8	5.8	2.6	32	10
claystone	17.1	2.9	2.57	24	8.9

3. Mining technology by the combination of ANSH equipment

3.1. Mechanized equipment in the longwall

3.1.1. Combination of equipment type ANSH Currently, in Eastern European countries, two types of mechanized mining equipment combinations have been manufactured and applied for coal seams with medium thickness, dip angle of over 50 degrees. Combinations include: 1ASHMG, 1ANSH and 2ANSH. The basic technical characteristics of the above equipment combinations are shown in table 2.

Table 2. Technical characteristics of ANSH mining equipment combinations [13].

No	Parameters	Unit	1ASHMG	1ANSH	2ANSH
1	Applicable seam thickness	m	1.2 ... 2.2	0.7 ... 1.3	1.1 ... 2.2
2	Applicable seam dip angle	degree	50 ... 80	35 ... 90	35 ... 90
3	Load capacity of shield for 1 m^2, (not less than)	kN/m^2	200	170	240
4	Load capacity of the shield (not less than)	kN	500	800	800
5	The displacement of the shield (not more than)	m	0.63	0.63	0.63
6	Step of installing a shield (not more than)	m	1.0	1.0	1.0
7	Height of the shield (min-max)	mm	1000 ... 2200	670 ... 1300	980 ... 2200
8	Width of the shield	mm	960	960	960
9	The length of the complex	m	45	60	60

Based on the geological conditions of the mine, on the basis of the technical characteristics of the mining equipment combinations, select the 2ANSH combination or the type with equivalent technical characteristics for the application of coal seam mining of medium thickness, dip angle of over 50 degrees at Mao Khe coal mine. Through analysis and field survey, it is shown that this equipment combination is suitable for the conditions of the longwall in Seam 6 of Mao Khe coal mine.

3.1.2. Shield The shield used in this equipment complex is the 2ANSH shield combination (figure 1) and the technical characteristics are shown in table 2.

3.1.3. Coal cutting To extract coal in the longwall in Seam 6, the Mao Khe coal mine has chosen the plow 1ASHM (figure 2) with specifications shown in table 3.

Table 3. Technical characteristics of coal plow 1ASHM.

No	Parameters	Unit	Value
1	Plow productivity	T/minute	2.5
2	Plow speed	m/s	1.6
3	Engine power	kW	140
4	Plow width	mm	760
5	Plow length	m	6

Figure 1. 2ANSH shield complex [14].

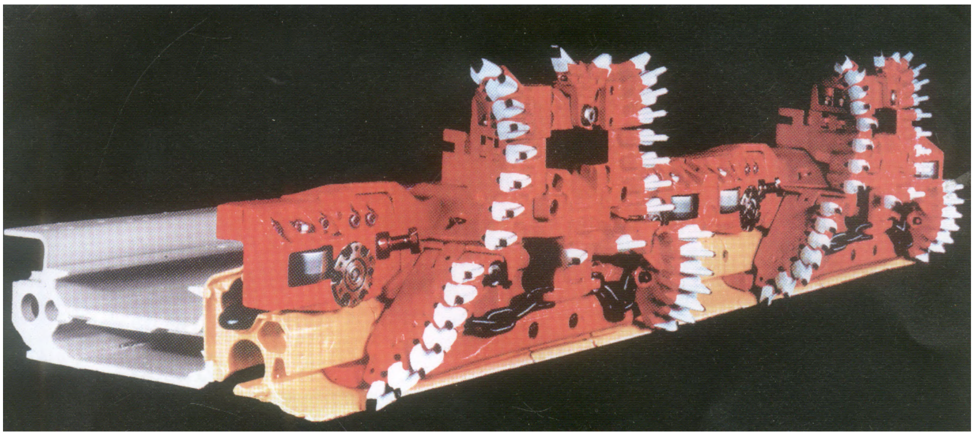

Figure 2. Coal plow 1ASHM [14].

3.1.4. Emulsion pumping station To provide emulsion for equipment in the longwall, Mao Khe coal mine has selected pump code CND-200/32, its basic technical characteristics are shown in table 4.

Table 4. Characteristics of CND-200/32 pumping station.

No	Parameters	Unit	Value
1	Rated pressure	Mpa	32
2	Engine power	kW	2x 55
3	Volume of solution tank	liter	1600
4	Pump size (length x width x height)	mm	2700 x1200 x 1000
5	Solution tank size (length x width x height)	mm	3200 x 1200 x 1100
6	Pump weight	kg	2000
7	Solution tank weight	kg	1600

3.2. Technological process of mining in the longwall face

The process of this mining technology is carried out in 3 stages as follows:

3.2.1. Stage 1: exploiting to install the shields Exploiting to create space to install the shields is done by manual drilling and blasting method, supporting the longwall face by wood. When cutting and supporting in the strike direction of 4 web cuts, install the first shield, then exploit in the strike direction of one web cut to continue installing the next shield. The work of cutting and installation of shields is carried out sequentially until the number of installed shields is completed in the longwall. During the process of cutting and installing the shield, the distance from the longwall face to the shield position must not exceed 3 meters. Next, install the plow system, pumping station, communication signal equipment, automatic control device and other auxiliary equipment.

3.2.2. Stage 2: exploiting the longwall using a combination of shield Coal cutting in the longwall follows in dip direction of the seam, the cutting of coal in the longwall face by the plow system. The plow moves along the longwall face and cuts coal from the floor to the roof of the longwall. After cutting the entire length of the longwall face, the plow is returned to its original position before moving the shield.

3.2.3. Stage 3: dismantling the shield complex, moving to the next mining lift When the longwall is exploited to about 8 to 12 meters from the transport level, proceed to create a space for the longwall face to dismantle the shield system. The work of dismantling the shield is carried out in turn from the ventilation brake incline to the transport brake incline. The recovery shields are transported to the ventilation level to be installed in service of mining for the new lift.

The diagram of mining technology by the 2ANSH shield system is shown in figure 3 and the process of coal cutting in the longwall face using a plow is shown in figure 4.

3.3. Support plan for the longwall face in Seam 6 of Mao Khe coal mine

3.3.1. Arrangement of shield (figure 5) Based on the mine pressure of the longwall face, the load capacity of the shield (the load capacity of the rig for 1 m^2 is greater than 240 kN/m^2 and the load capacity of the shield is not less than 800 kN). At the same time, based on the experience of exploiting the longwall using a combination of shield equipment from a number of Eastern European countries and Ukraine, the design of the support plan for the longwall face is as follows:

- The length of the longwall (a lift): 60 m.
- Distance between shields in the complex: 1.0 m.
- Number of shields in the complex: 60 shields.

3.3.2. Moving the shield in the longwall Moving process of the hydraulic shield is as follows: Two adjacent auxiliary shields on each vertical segment are depressurized by hydraulic control series. Auxiliary shields are pushed toward the face by stretching of the hydraulic jacks. Then, the main shield groups are depressurized by hydraulic control panels and the main shields are pulled toward the face by the shrink of the hydraulic jacks. Main and auxiliary shields are set in a straight line by hydraulic jacks. The process of moving the shield is shown in figure 6.

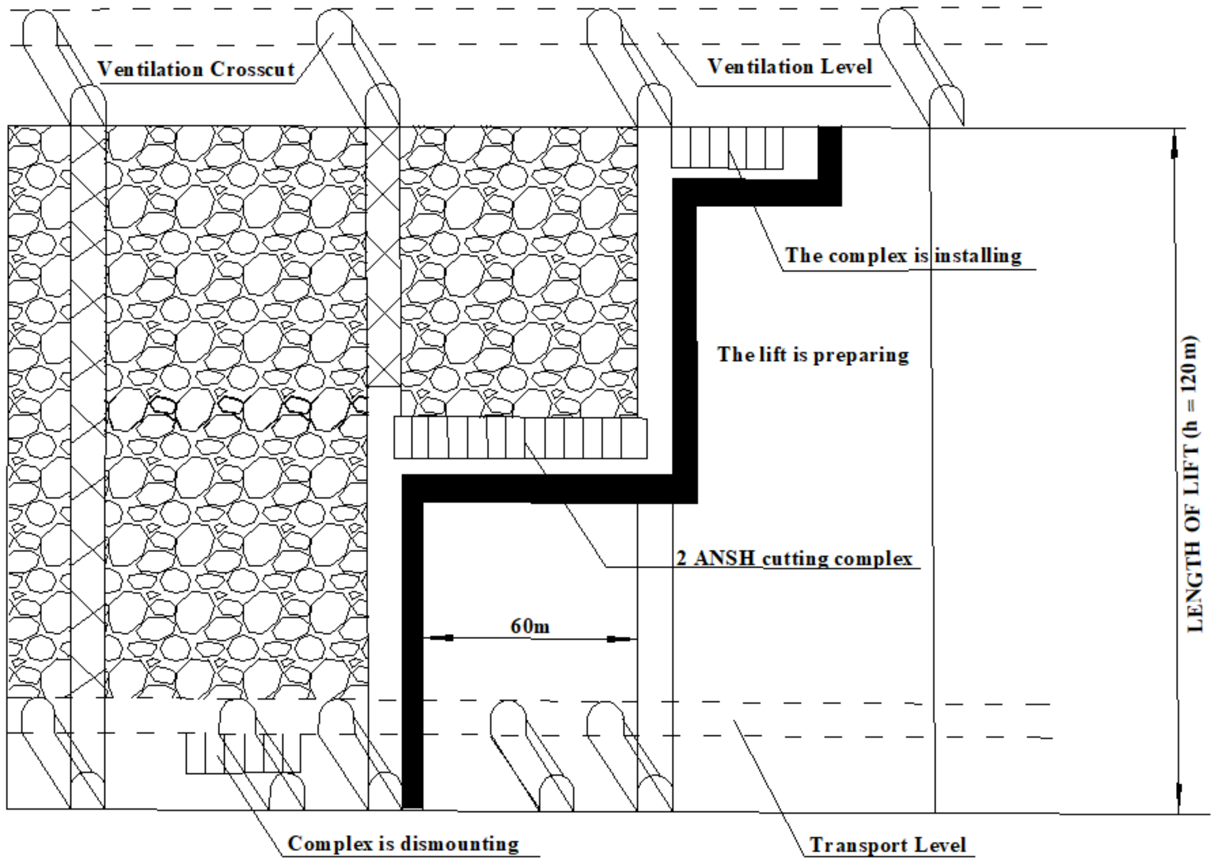

Figure 3. Diagram of mining technology applying 2ANSH combination [15].

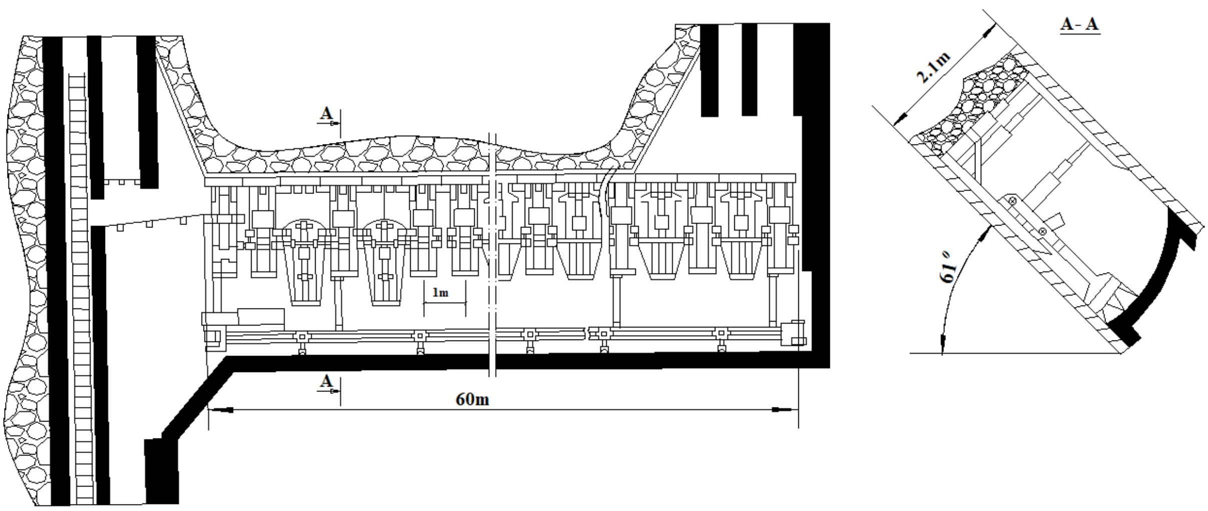

Figure 4. Process of coal cutting in the longwall face using a plow [15].

3.4. Operation scheme and human resource arrangement for the longwall in Seam 6 of Mao Khe coal mine

The production tasks in the longwall in Seam 6 are organized and performed in cycles. A cycle of eight web cuts is completed within three shifts, equivalent to the face moving progress of

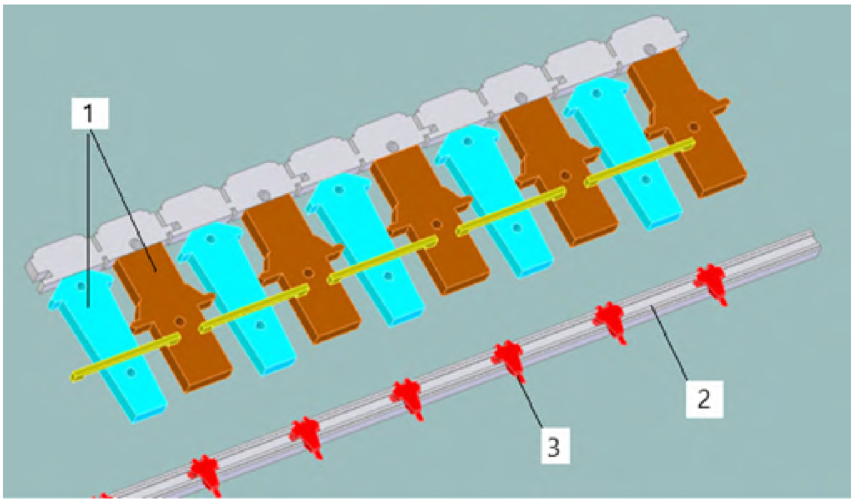

Figure 5. Arrangement of shield in the longwall [16]: 1 – shields; 2 – frame of scraper conveyors; 3 – coal plow.

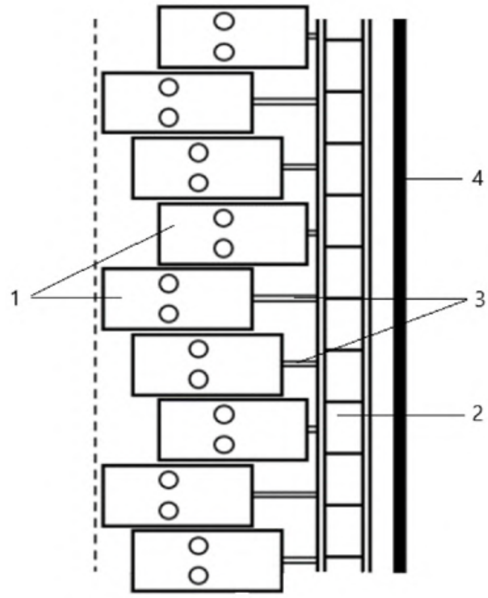

Figure 6. The process of moving the shield in the longwall: 1 – shields; 2 – scraper conveyors; 3 – hydraulic jacks; 4 – longwall face.

four meters per day (figure 7). A web cut includes the following stages: cutting face and shield shifting with an advance rate of 0.63 m, strengthen the longwall and preparing for a new web cut. The inspection and maintenance of equipment complex are carried out at the end of shift III, including maintenance, repair, and replacement of spare parts if necessary for the plow, roof supports, conveyors, electrical equipment and emulsifier pump systems, dust filter system, power supply system, water supply system, methane warning system, and pressure test of roof supports. The number of workers in the longwall face is arranged depending on the specific work of each shift. According to calculations, the required number of workers is 48 people, in which, each shift is arranged for 16 people (figure 8).

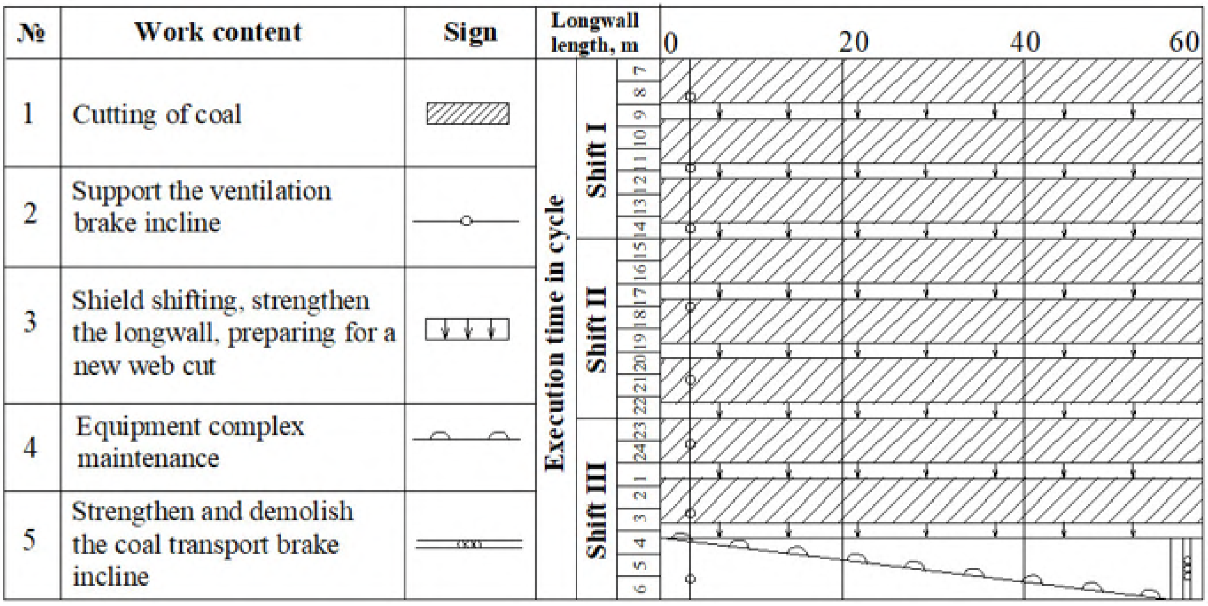

Figure 7. The operation scheme in the longwall in Seam 6 of Mao Khe coal mine.

3.5. Economic and technical indices

After researching and application of mining technology by the combination of ANSH equipment to longwall in Seam 6 of Mao Khe coal mine, which is exploited by fully mechanized technology, with the above equipment combination, the calculated main economic-technical indices are shown in table 5.

Table 5. Economic and technical indices of the longwall face in Seam 6 of Mao Khe coal mine.

No	Indices	Unit	Amount
1	Average thickness of seam	m	2.1
2	Average dip angle of the seam	Degree	61
3	Volumetric weight of coal	T/m^3	1.61
4	The length of the longwall (a lift)	m	60
5	The length in dip direction (a lift)	m	120
6	The height of coal cutting (longwall)	m	2.1
7	The length in strike direction	m	540
8	Face advance in one web cut	m	0.63
9	Face advance in a day and night	m	4.0
10	The type of shield used in the longwall (shield complex)		2ANSH
11	Coal output of a day and night	ton	777
12	Cycle completion coefficient	-	0.8
13	Face advance in a month	m	104
14	Capacity of longwall face	ton	207.790
15	Number of workers in a day	worker	48
16	Direct labor productivity	T/labor	16.1
17	Consumption of wood for 1000 tons of coal	m^3	28.7
18	Consumption of roadway preparation for 1000 tons of coal	m	6.5
19	Consumption of emulsifying oil for 1000 tons of coal	kg	13.7
20	Consumption of clean water for 1000 tons of coal	m^3	13.1
21	Consumption of cutting teeth for 1000 tons of coal	unit	3.0
22	Consumption of compressed air for 1000 tons of coal	m^3	433
23	Coal loss	%	28.9

4. Conclusions

(i) According to the general assessment of geological and technical conditions, reserves in Quang Ninh coalfield are about 3 billion tons, of which coal reserves of steep seams account for more than 30%. At the Mao Khe coal mine, the steep seams account for about 47.5%, of which the thick seams are 51% and the remaining 49% are the medium thick ones. Therefore, it is very necessary to research and select mining technology to ensure the economic and technical requirements to exploit the seams of medium thickness and dip angle of over 50 degrees at Mao Khe coal mine.

(ii) In the condition that the coal seam has an average thickness of 1.8 to 2.5 m, the dip angle of the seam is from 45° to 90°, some countries such as Ukraine have applied the mining technology diagram in the slope direction, mining technology uses a combination of mechanization with a plow, and support for longwall face by the shield. In fact, the advantage of this mining technology is to reduce the unsafety risks from the collapse of roof during the exploitation of thin to medium-thick seams, dip angle of over 45°. This complex has a small cutting step and the movement of the combination is due to the self-sliding mechanism on the slope due to the impact of the collapsed rock mass above the shield and the self-weight of the equipment combinations. Based on the geological conditions of the mine and the technical characteristics of the mining equipment combinations, this study proposed and selected a combination of 2ANSH equipment or a type with equivalent technical characteristics to exploit coal seam of medium thickness, dip angle of over 45° at

Mao Khe coal mine.

(iii) The application of mining technology using a combination of 2ANSH equipment to the condition of the longwall in Seam 6 of Mao Khe coal mine, according to calculations, it has met the requirements of economic and technical indices when mining. Labor productivity 16 tons/worker-shift, low coal loss, high safety level (table 5).

Acknowledgments
Hereby, the authors would like to thank the Board of Directors of Mao Khe coal mine in Quang Ninh coalfield, Vietnam for providing the Seam 6 documents. Mao Khe coal mine is acknowledged for approval of the field visit at the longwall in Seam 6.

Abstract. Obtaining a powder product from brittle materials is associated with significant difficulties: an insufficient number of production capacities as well as with their low efficiency. This indicates relevance and need for research aimed at creating new designs and technological schemes. Glass containers were selected for research from among all types of glass waste. Presented are a structural diagram and description of a horizontal pendulum impact tester, on which studies were carried out on destruction of a bottle by impact load. The impact tester gives an opportunity to determine impact energy, impact speed, acceleration, movement of the impactor. An analysis of the above figures shows that one blow is enough to destroy a bottle. Rational mode is when impact load is distributed along the length of the bottle. This mode can be implemented in a vibratory jaw crusher with an inclined crushing chamber, which includes the following main elements: a passive jaw located on shock absorbers, an active jaw pivotally mounted in the body and connected to it by means of elastic links, a two-shaft inertial vibration exciter. The presented granulometric characteristic of the crushed bottle shows a high efficiency of using a vibratory jaw crusher. The yield of the product sized less than 5.5 mm was 95%, and that sized less than 100 microns - 16%. The crusher has enough parameters to adjust particle size distribution over a wide range.

1. Introduction

In nature, there are a number of materials (quartzite, basalt, marble, etc.) with high compressive strength and low resistance to impact loads. At the same time, a significant percentage of the equipment used for their disintegration consist of jaw and cone crushers, in which the destruction of the material is carried out by compression [1]. In high-tonnage production, these metal-intensive overall machines currently have no adequate replacement. In the technological schemes for obtaining fine-grained and powder materials with a productivity of 1…10 t/h and a size of the raw material corresponding to average crushing, there is a need to improve existing grinding methods [2] and develop new grinders that combine crushing and grinding operations in one design.

Ideally brittle materials, along with diamond and quartz, include glass, which can serve as a standard in determining the efficiency of using crushing and grinding equipment. At the same time, interest in obtaining glass powder is currently growing in the world. This problem is relevant, because it is associated with a wide range of properties that make simple and special purpose glass powders a versatile material [3–5]. Depending on their composition, powders can meet a variety of requirements and can be used in the sphere of electrical insulation, sealing or bonding of various materials, for 3D printing of complex glass bodies, as additives in polymers, concrete, etc. [6–8]. Powder production is a complex and energy-intensive process [9], which includes all stages of glass production. The raw materials for glass production are low-iron quartz sands, soda ash, limestone, dolomite, etc., which require preliminary enrichment, washing, drying, and grinding. The resulting glass mass is again subjected to crushing, grinding, separation, which creates a high cost of production.

At the same time, hundreds of thousands of tons of glass waste are generated annually, but only a small part of them goes into secondary resources [10]. It is known that one ton of cullet saves 1.5 tons of mineral glass raw materials, incl. 100-130 kg of soda ash, 40-50 kg of sodium sulfate and 300-350 kg of quartz sand. Recycling glass allows to save huge areas of land that otherwise should turn into environmentally hazardous landfills [11]. This testifies to the relevance and necessity of carrying out analytical, experimental, design developments aimed at increasing efficiency of obtaining fine-grained and powder materials directly of glass wastes.

Study purpose is to evaluate the effectiveness of using vibratory jaw crushers for processing brittle materials to obtain a fine-grained and powder commercial product.

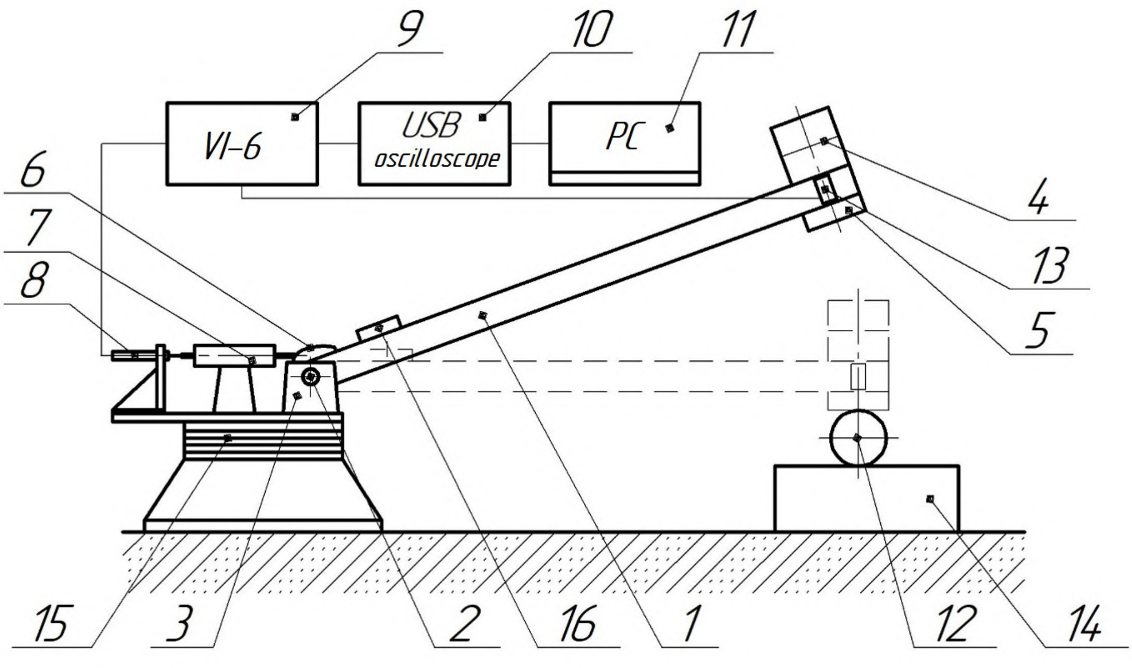
2. Results

A distinctive feature of glass is its high compressive strength and low impact resistance [12, 13], therefore, glass is destroyed by mechanical action without noticeable plastic deformation, which predetermines the development of crushers with the impact principle of loading the material.

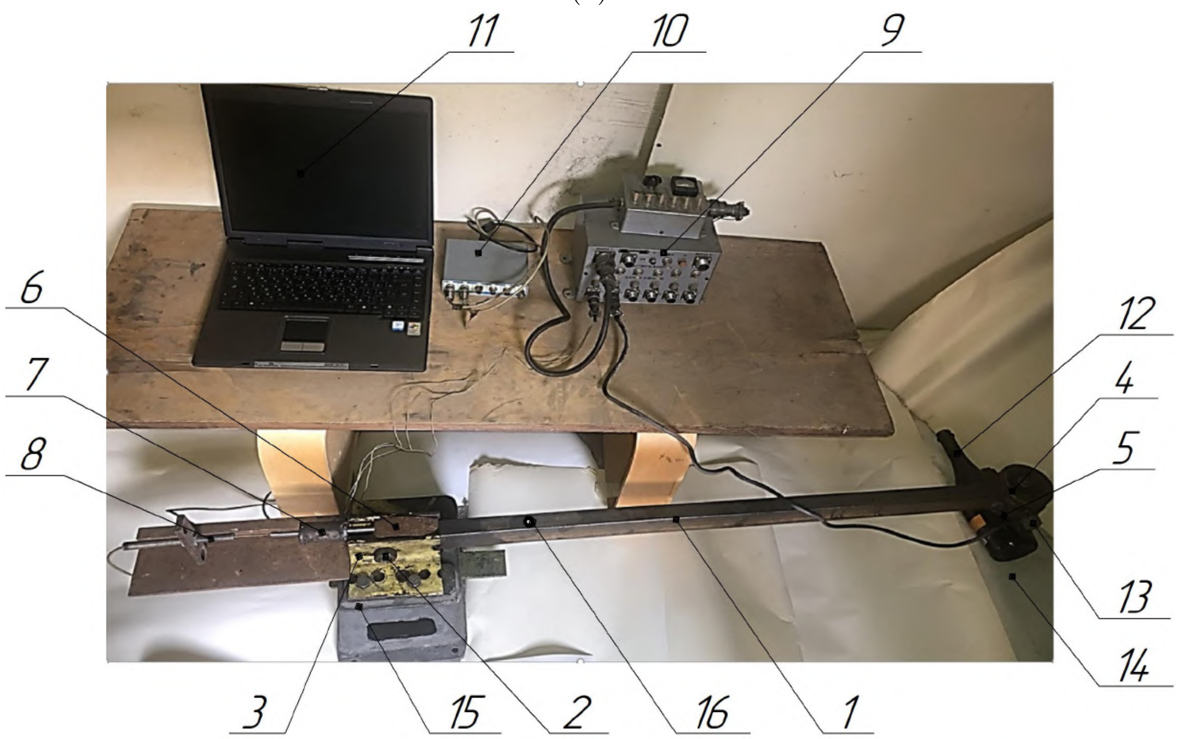
From among all types of glass waste, glass containers were selected for the research; they have a fairly well-developed collection scheme at collection points [14]. It was also taken into account that the volumetric shape leads to a sharp change in filling of the crushing chamber with material during the process of loading.

Interaction of bottles with the impactor was studied on the developed laboratory installation for destruction of rocks, which is a horizontal pendulum impact tester; its structural diagram is shown in figure 1.

The laboratory installation includes a pendulum (1) with its suspension axis (2) fixed in the bearing units of the housing (3). At the free end of the pendulum there is an impact assembly, consisting of a replaceable load (4) and an impactor (5). The centers of mass of the load and the impactor are located on a common vertical axis at a distance of 1 m from the axis of the pendulum suspension. Fastening of the impactor allows you to set various profiles of the working surface that interacts with glass. The lifting (dropping) height of the impactor is determined by a measuring system containing a curvilinear bar (6) rigidly connected to the pendulum suspension axis and a following mechanism (7). The mechanism is presented in the form of a cylinder with a piston and a clamping spring inside. The rod fixed on the piston has one end in contact with the curvilinear bar, and the other end is connected to the displacement sensor (8). The system works as follows. When the pendulum is raised, the curvilinear bar rotates along with the suspension axis, and so it moves the following mechanism rod according to the given dependence. Accordingly, the displacement sensor rod also moves; the signal from this sensor passes through the VI 6-6tn (9) vibration measuring equipment, the USB oscilloscope (10) and it registers the height of the load drop on the laptop screen (11). This system also allows you to track the nature of interaction of the impactor with the material under study (12). For the same purpose, an acceleration sensor (13) is fixed on the impact assembly; it records changes in acceleration in the vertical plane. At the initial moment of testing, the working surface of the impactor is installed on the surface of the sample located on a massive base (14). Next, the pendulum suspension axis is moved to a position at which the longitudinal surface of the pendulum rod is set in a horizontal position. Movement of the suspension axis is carried out



(a)



(b)

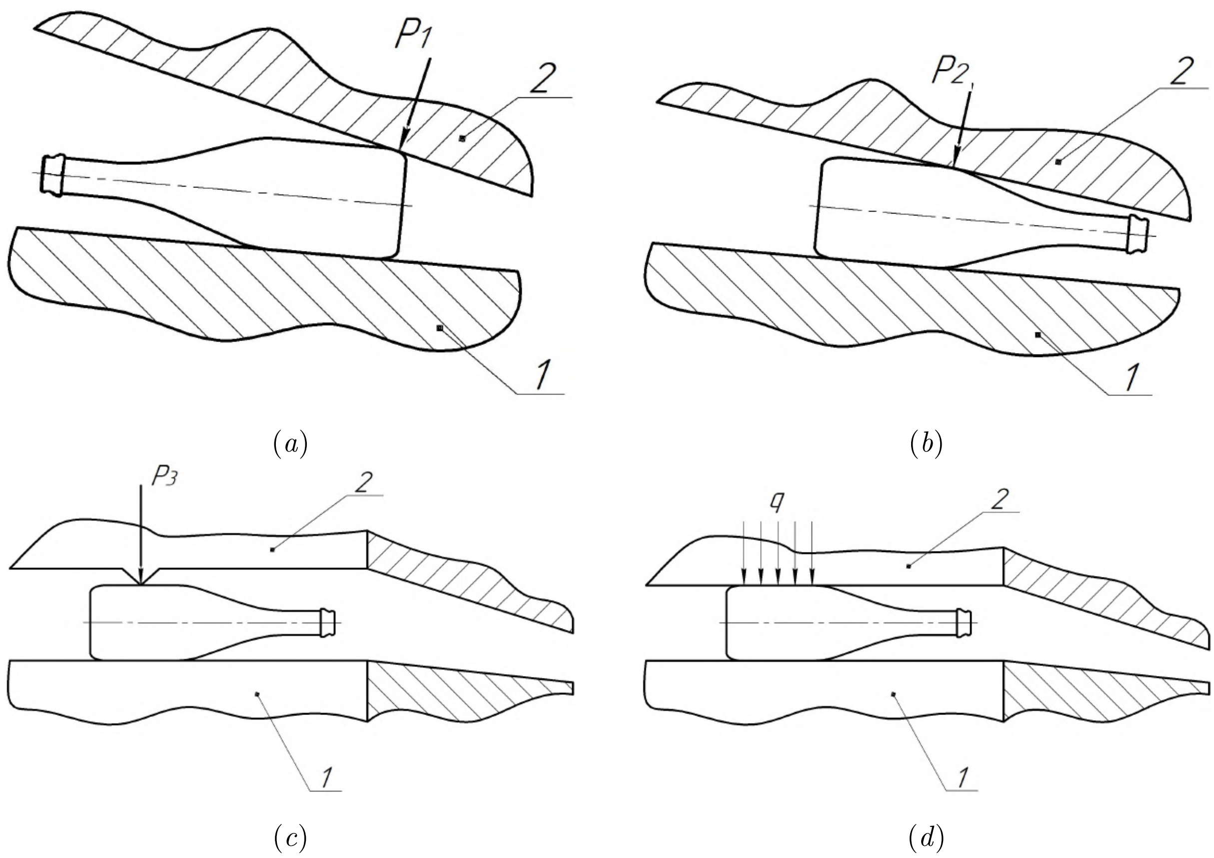

Figure 2. Schemes of the initial contact of the bottle with the working surface of the upper jaw, 1 – lower jaw; 2 – upper jaw.

by means of gaskets 15 (or a screw connection). The horizontal setting of the pendulum rod is controlled by a level (16).

Results of a single impact of a flat impactor on bottles for sparkling wines are given as an example. Impactor mass is 5 kg, drop height is 0.7 m.

The initial application of the load was simulated with different method of feeding the bottle into the inclined crushing chamber of the vibratory jaw crusher. When feeding the bottle into the crushing chamber with the bottom in the direction of the unloading window (figure 2, a), the first impact occurs when the working surface of the upper jaw comes into contact with the ring of strength of the bottle (force P1).The implementation of such a scheme on a pendulum impact tester showed that the bottle is destroyed (figure 3) by a single impact, however more than 50% of the glass breakage has convex shapes, which reduce the filling factor of the transporting container.

When feeding the bottle into the crushing chamber with the neck in the direction of the unloading window (figure 2, b), the first impact occurs when the working surface of the upper jaw comes into contact with the bottle shoulders (force P3). When the impact of the pendulum impact tester interacted with the bottle shoulders, a product with a size of more than 50 mm with a destroyed neck and a whole bottom was mainly formed (figure 4).

The bottle can be loaded into the crushing chamber in a position where the longitudinal axes of symmetry of the bottle and the chamber are perpendicular (figure 2, c, d). When the cylindrical surface is affected by a point load P2 (figure 2, c), with sufficient destruction of the

Figure 3. Impact on the bottom (P1).

Figure 4. Impact on the bottle shoulders (P2).

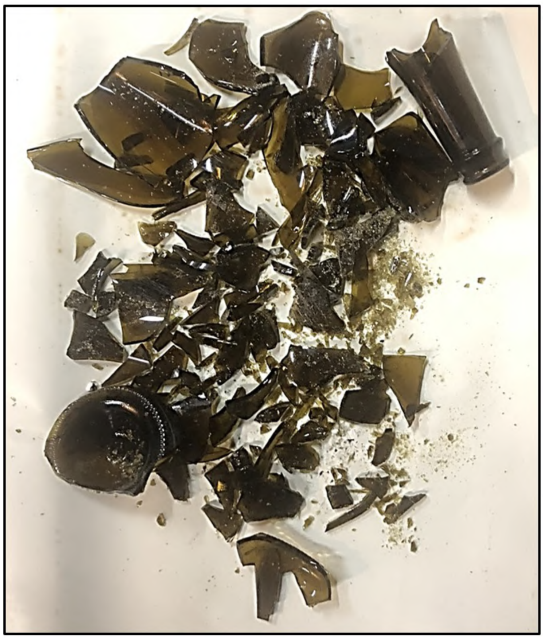

Figure 5. Impact in the middle (P3).

Figure 6. Impact on the plane (q).

cylinder, the neck and bottom are not subjected to destruction (figure 5).

The preferred result is obtained when the surface of the bottle interacts with a distributed load q (figure 6).

The result obtained shows sufficiency of one impact for the effective destruction of a brittle material with internal cavities, which predetermines the need to create small-sized crushing plants. Conversion of bottle convex shapes into a flat state allows you to significantly increase the filling factor of the shipping container and have a high-quality initial product for processing into commercial products.

The experience of using vibratory jaw crushers to obtain fine-grained materials shows the possibility of implementing the results obtained in similar designs [15, 16].

Crushers of this type have a pronounced impact nature of the load applied to crushed materials, as well as the advantages of jaw and rotary crushers. In general terms, the design scheme of vibratory crushers is an oscillatory system with vibrations of 16–32 Hz communicated to the crusher jaws [17, 18].

The material crushing process is effectively controlled in a vibratory jaw crusher with an inclined crushing chamber [19]. The crusher (figure 7) includes a passive (lower) jaw (1) mounted on elastic elements (5) and simultaneously performing the function of the housing. The active jaw (3) is installed in the racks of the passive jaw by means of the suspension axis (2), relative to which it can perform rotational vibrations. Vibrations of the jaws are generated by a two-shaft inertial vibration exciter (4). Destruction of the material crushed occurs in the crushing chamber formed by the working surfaces of the passive jaw (1) and the active jaw (2).

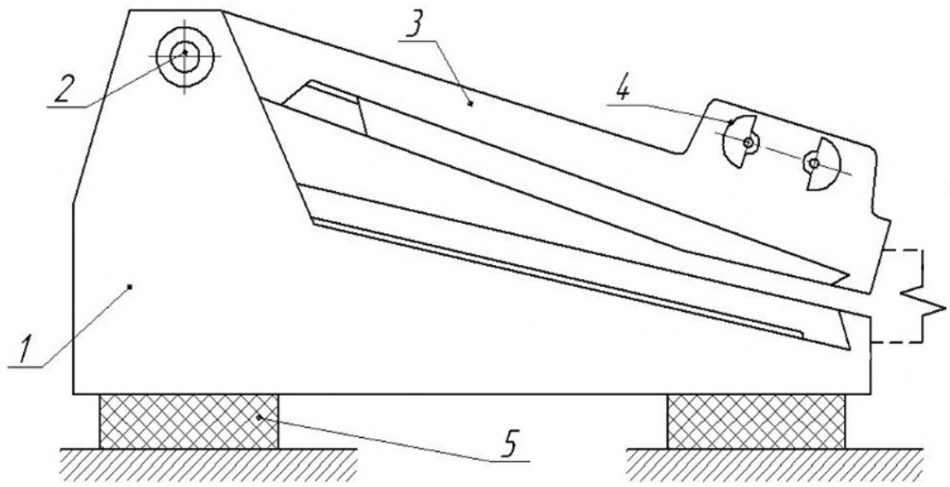

Figure 7. Structural scheme of the vibratory crusher.

Grinding was carried out on a laboratory sample of a vibratory jaw crusher with a large set of adjustable parameters: the frequency and amplitude of oscillations of the jaws, the magnitude and direction of the disturbing force, the weight of the jaws, the size of the unloading gapt, the rigidity of the elastic elements, the profile of the working surface of the jaws, the grip angle, the angle of inclination of the conveying surface. Crushing was carried out on bottles with a cylinder diameter of 90 mm, identical to those studied on a pendulum impact tester. Based on the fact that the width of the crushing chamber of the laboratory sample is less than the height of the bottle, its loading was carried out according to the scheme of figure 2, a.

At the first contact of the bottle with the working surface of the jaw, the process of bottle destruction corresponded to the destruction on the impact tester. Obtained was a high-quality mass of a flat shape suitable to fill the transport container. However, a feature of the crusher is the possibility of producing marketable products. Subsequently, the resulting flat material moved in the crushing chamber to the discharge window, receiving a high-frequency impact. The resulting presentation of fine-grained material from a crushed bottle is shown in figure 8.

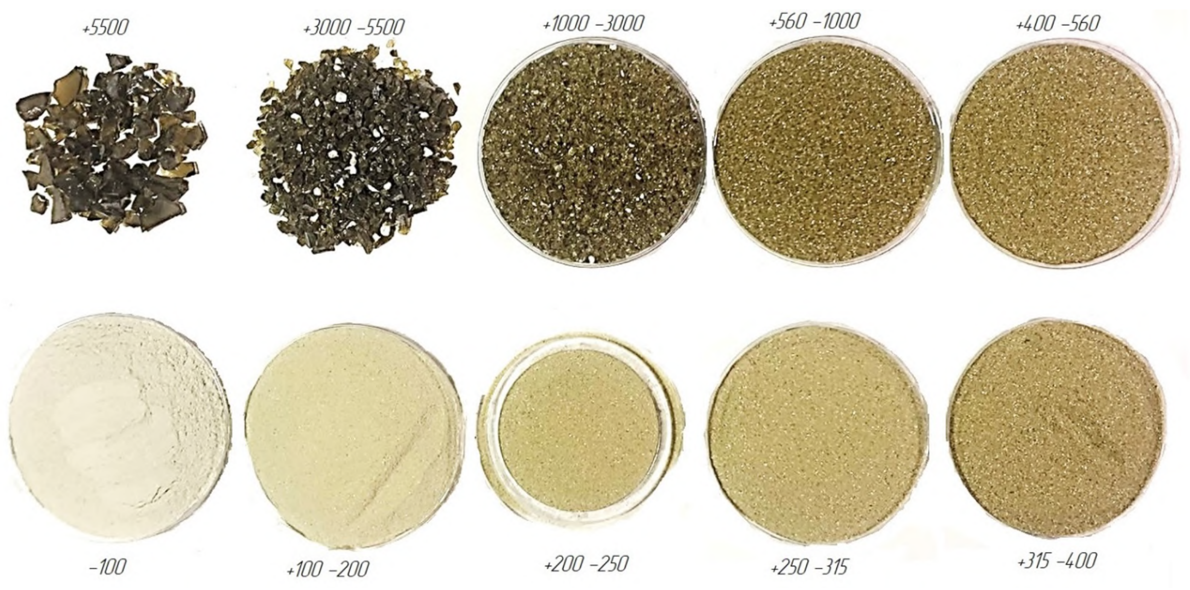

Figure 8. Fine-grained material from a crushed bottle (μm).

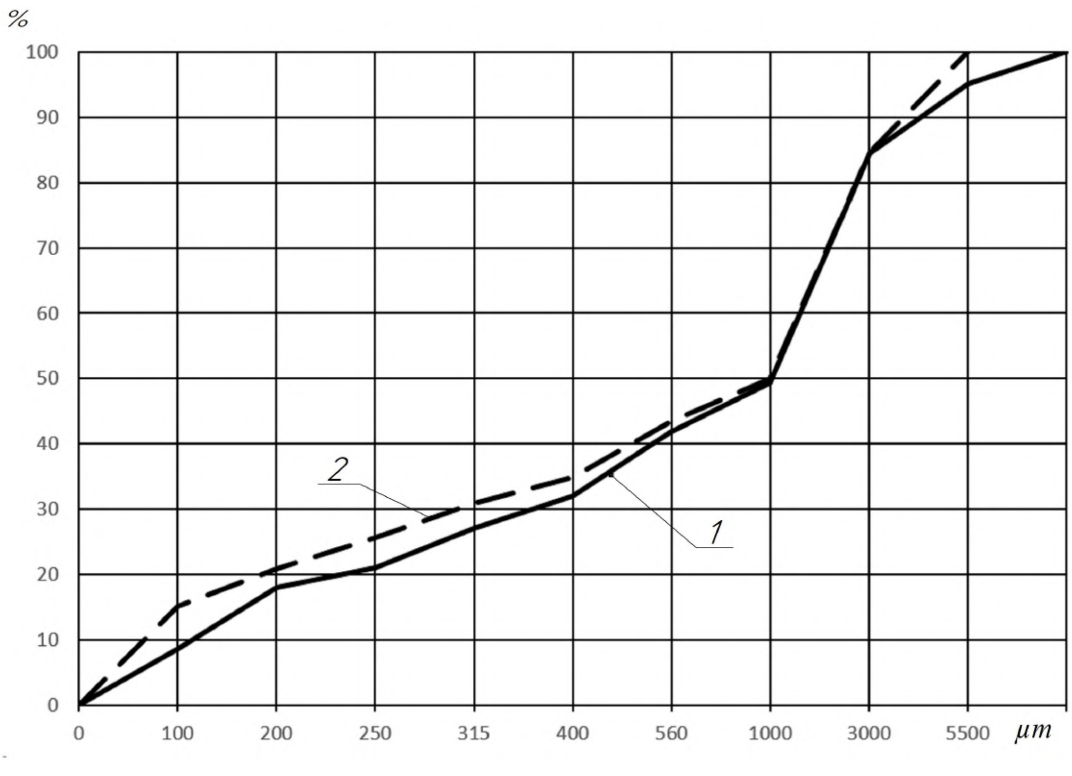

Figure 9. Crushed bottle presentations.

A wide range of adjustable parameters allows you to control the process, create rational crushing modes and obtain the required granulometric composition of the finished product. Figure 9 shows the characteristics of crushed glass at a frequency of jaw oscillations of 17 Hz (curve 1) and 21 Hz (curve 2). The mass of the movable jaw is 97 kg, the width of the crushing chamber is 120 mm, and the length is 550 mm.

As can be seen from the graph, increasing the oscillation frequency to 21 Hz (curve 2) eliminates the +5.5 mm class, narrows the size range of the crushed product and increases the yield of powder material.

3. Conclusion

According to the purpose of the work, the studies carried out on the example of glass container destruction substantiated efficiency of crushing brittle materials in a vibratory jaw crusher with an inclined crushing chamber.

Feeding a cylindrical feedstock with a diameter of 90 mm into the crusher and obtaining a fine-grained product shows the prospects for creating a small-sized vibrating jaw crusher with the implementation of medium, fine crushing and grinding in it, which will significantly reduce the number of units in the production process chain, reduce their cost and expand the range of products obtained fine-grained and powder materials.

A laboratory plant with a horizontal type pendulum impact tester allows you to pre-select the profile of the working surface of the jaws, get a physical picture of the destruction of the material and determine the main dynamic characteristics of the crusher.

Abstract. The article studied the issue of improving the scientific and methodological base in the field of design and planning of open-pit mining by developing new and adjusting existing methods for determining the ore productivity of an open-pit, which should take into account the interconnection between the mining schedule and the productivity of an open -pit for ore, based on the condition for ensuring the standard volume of finished to the extraction of reserves. When choosing the production of an open-pit for ore, it is necessary to take into account the impact of the interconnection between the schedule of mining and production, based on the conditions of regulatory regulation of the volume of mining for the excavation of reserves, on the cost of ore mining and concentrate production. With an increase in ore productivity, the cost of ore mining, as well as the cost of production of concentrate reduction. At the same time, the very possible productivity of the open-pit for especially minerals is achieved, the economic efficiency of the development of deposits is achieved with the chosen direction of the open -pit. A decrease in productivity for a common mineral by 20 and 40% entails a decrease in profit from the development of the deposit by 10 and 20%, respectively. It has been determined that an increase in the slope angle of the working side of the open-pit significantly reduces the economic efficiency of the development of the deposit due to the fact that the operation of the open -pit with a large slope angle entails not only a decrease in the current stripping ratios as a result of an improvement in the mining schedule, but also a decrease in ore productivity, which reduces the present value of marketable products due to an increase in the period of development of the deposit. The results of the studies performed can be used by design organizations and mining enterprises in determining the ore productivity of an open-pit.

1. Introduction

To select the productivity of a open-pit, which ensures the maximum efficiency of field development, a comprehensive technical and economic analysis of the operation of the enterprise is required [1–3], taking into account, among other things [4, 5], the influence of the time factor on the evaluation of the results of its work [6, 7].

The existing relationship between the parameters of the development system [8, 9], which provide the norm of reserves ready for excavation in a open-pit [10, 11], determines, with a change in productivity for a mineral, a change in stripping ratios [12–14]. In turn, the change in stripping ratio is reflected in the volumes of rock mass and their distribution over the years of operation, which ultimately is one of the main factors affecting the economic indicators of a open-pit mine [15–17]. At the same time, the maximum productivity for ore also determines the maximum or close to maximum productivity for the rock mass, which leads to an increase in the cost of developing the deposit. Thus, an increase in the productivity of a open-pit for a mineral is accompanied by an increase not only in income, but also in costs [18, 19].

In this regard, the question arises whether there will be profitability in terms of economic efficiency [20–22] of operating a open-pit with the maximum possible productivity for a mineral [23, 24].

2. Object and methods of research

Most studies aimed at establishing the impact of open-pit productivity on the economic indicators of development, the existing relationship between the development of mining and mining operations in a open-pit [25–27], is considered only on the basis of the condition that a change in the angle of slope of the working side of the open-pit [28] leads to a change in the current stripping ratios [29–31]. This does not take into account the need to ensure the standard volume of reserves ready for extraction [32–34].

It is known that as the production capacity of a open-pit increases and its lifetime decreases, with the same reserves, the specific semi-fixed costs change [35], which means that the cost of ore mining also changes [36]. Therefore, it is necessary to investigate the change in the cost of ore mining and the production of final marketable products, taking into account changes in stripping ratios with an increase in ore productivity.

Therefore, the goal was set: to improve the scientific and methodological base in the field of design and planning of open pit mining by developing new and corrections existing methods for determining the productivity of a open-pit by ore, which should take into account the interconnection between the mining mode and the productivity of a open-pit by ore, based on the condition for ensuring the standard volume stocks ready for extraction.

3. Results

The creation of normal working conditions for a open-pit for various ore productivity options, within the maximum possible value, is possible by changing the width of working benches [37,38], which ensures the standard of reserves ready for excavation. At the same time, an increase in the width of working benches leads to a decrease in the number of working benches within the deposit and, accordingly, to a change in the length of the mining front, both in ore horizons and in overburden, which largely determines the distance of transporting the rock mass in the open-pit. With an increase in the width of the working bench, the transportation distance increases both on ore horizons and on overburden. This is due to the fact that with an increase in the width of the working bench, the ore front is concentrated on a smaller number of benches in the lower part of the open pit. At the same time, the overburden front of mining operations increases due to an increase in the number of underlying overburden benches. Therefore, when determining the cost of ore mining and the production of final marketable products, it must be taken into account that with an increase in ore productivity, the width of working benches will increase, as well as the haulage arm from the faces to the opening working. Therefore, even a small increase in the distance of transportation with significant volumes of traffic will lead to a significant increase in costs.

For conditions close to the mining and processing plants of Krivbass, let us analyze the impact of the productivity of an open-pit on the cost of production of the final marketable product. We investigate the work of an open-pit developing a steeply dipping mineral deposit. Let's divide the open-pit field by depth into zones, within which the pattern of changes in the volume of rock mass with a decrease in mining operations remains constant.

The studies carried out allow us to establish the measure of the influence of various costs on the production cost of the concentrate when changing the productivity of the open pit for ore.

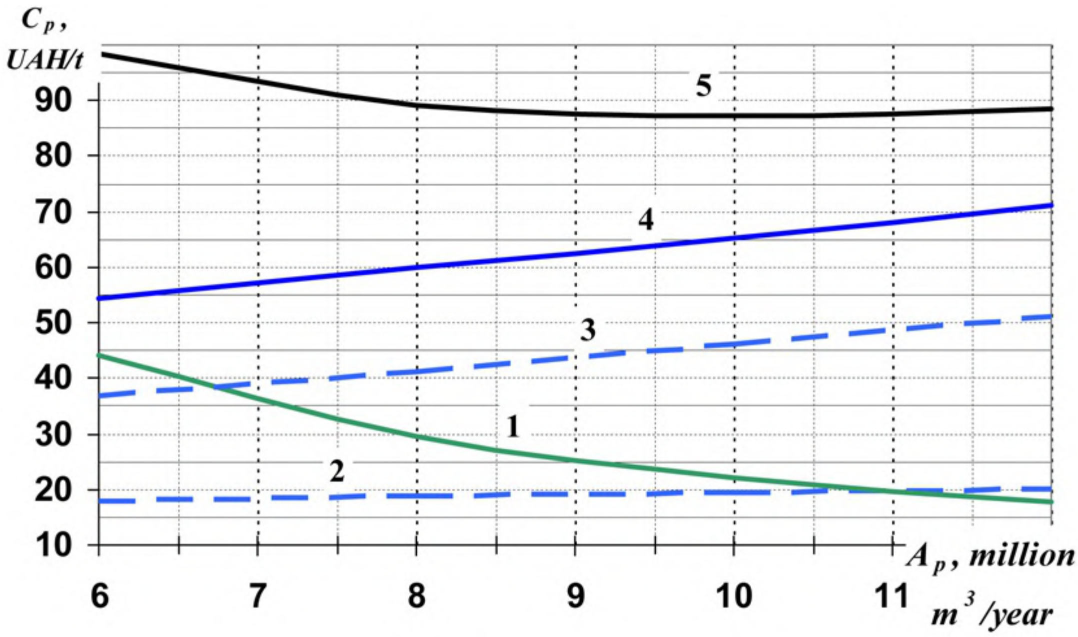

Figure 1. Influence of open pit productivity in terms of ore on the production cost of ore mining and its components at the first stage of its operation: 1 – unit semi-fixed costs for ore mining; 2 – unit conditionally variable costs for ore mining without overburden costs; 3 – unit conditionally variable costs for the excavation of overburden; 4 – unit conditionally variable costs for ore mining; 5 – unit production cost of ore.

From figure 1 and figure 2, it can be seen that the unit semi-fixed costs for ore mining (line 1) are the same in both the first and second periods and decrease with an increase in ore productivity.

However, in the second period, due to a decrease in stripping ratios, the specific conditionally variable costs for ore mining with an increase in productivity slightly decrease (line 4, figure 2).

Curve 5 (figure 2, figure 2) shows the change in the production cost of ore depending on the ore productivity of the open pit with the already chosen direction of development of mining operations and indicates the presence of an optimal productivity value. On figure 3 shows the change in the cost of production of concentrate from the productivity of an open-pit for ore for the first (line 1) and second (line 2) periods of work. It can be seen from the figures that with an increase in ore productivity, the cost of ore mining, as well as the cost of concentrate production, decrease.

However, the cost cannot fully characterize the increase in production for which development is being carried out. The main purpose of the enterprise is to make a profit. Therefore, it is more rational to solve the problem of determining the optimal productivity of an open-pit based on the profit from the sale of commercial products of the mining and processing plant. Profit from the sale of marketable products (concentrate) was taken as an optimality criterion when comparing options. For the commensurability of costs and incomes at different times, they were brought to one moment of evaluation.

We calculate the costs and revenues from the development of a mineral deposit and the production of a concentrate when operating an open-pit with different productivity values and a price for a concentrate, while for each performance option we set certain rates of deepening of mining operations. At the same time, when changing the ore productivity of an open-pit, it is necessary to take into account a change in the angle of slope of the working side of the

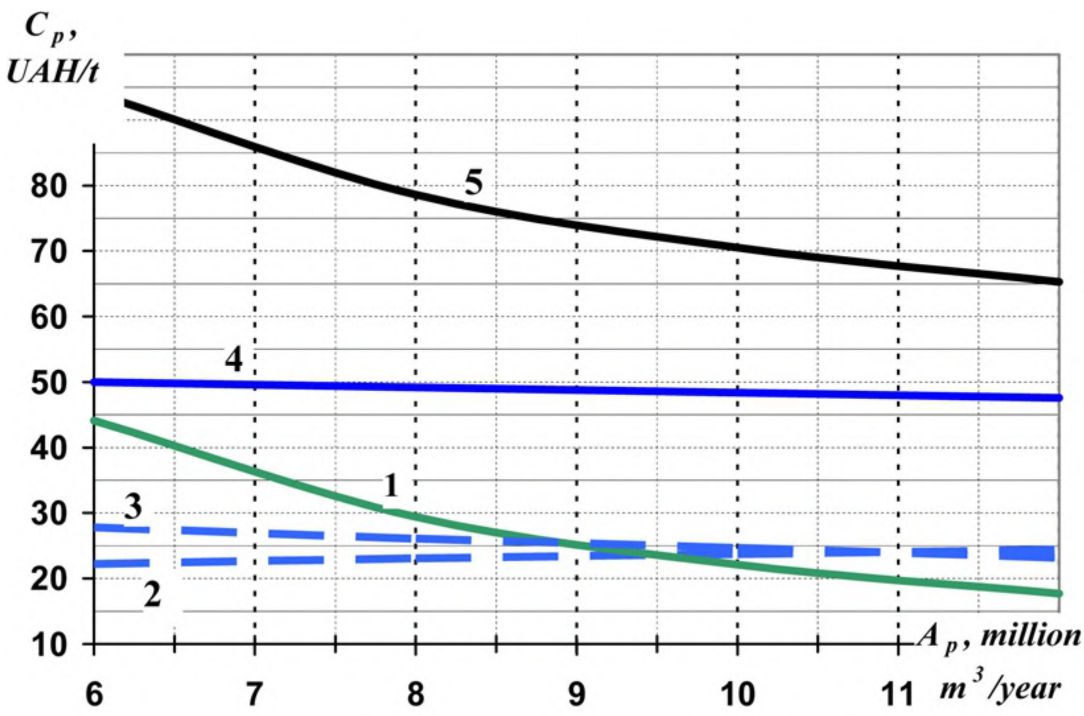

Figure 2. Influence of open pit ore productivity on the production cost of ore mining and its components at the second stage of its operation: 1 – unit semi-fixed costs for ore mining; 2 – unit conditionally variable costs for ore mining without overburden costs; 3 - unit conditionally variable costs for the excavation of overburden; 4 – unit conditionally variable costs for ore mining; 5 – unit production cost of ore.

open-pit due to changes in the parameters of the development system that ensure the standard of reserves ready for excavation in the open-pit. That leads to a change in the stripping ratios and the distance of transportation of the rock mass.

These calculations are made for a certain variant of the development of mining operations in an open-pit and only indicate the presence of optimal productivity. A change in the direction of development of mining operations entails a change in the calendar distribution of the volumes of overburden and mining operations.

The calculation results are shown in figure 4. From the graphs of the function $K=f(A_p)$, $C_o=f(A_p)$ it can be seen that the given total capital (K) and operating (C_o) costs increase with the increase in the production capacity of the open pit.

The curve $PR_p=f(A_p)$, which characterizes the change in the reduced profit depending on the productivity of the open pit, shows that the maximum possible productivity of the open pit for minerals ensures the maximum economic efficiency of the development of the deposit in the chosen direction of the deepening of the open pit. In this case, the maximum profit is provided with a productivity of 12 million m^3/year. A decrease in productivity for minerals by 20 and 40% entails a decrease in profit from the development of the deposit by 10 and 20%, respectively.

On figure 5 shows the influence of the slope angle of the working side of the open pit on the reduced profit from the development of the deposit when the norm of reserves ready for excavation is provided in the open pit. It can be seen from the graph that an increase in the slope angle of the working side significantly reduces the economic efficiency of field development. This is explained by the fa ct that the operation of an open-pit with a large slope angle of the working side entails a decrease in productivity not only for waste rocks, but also for ore, which

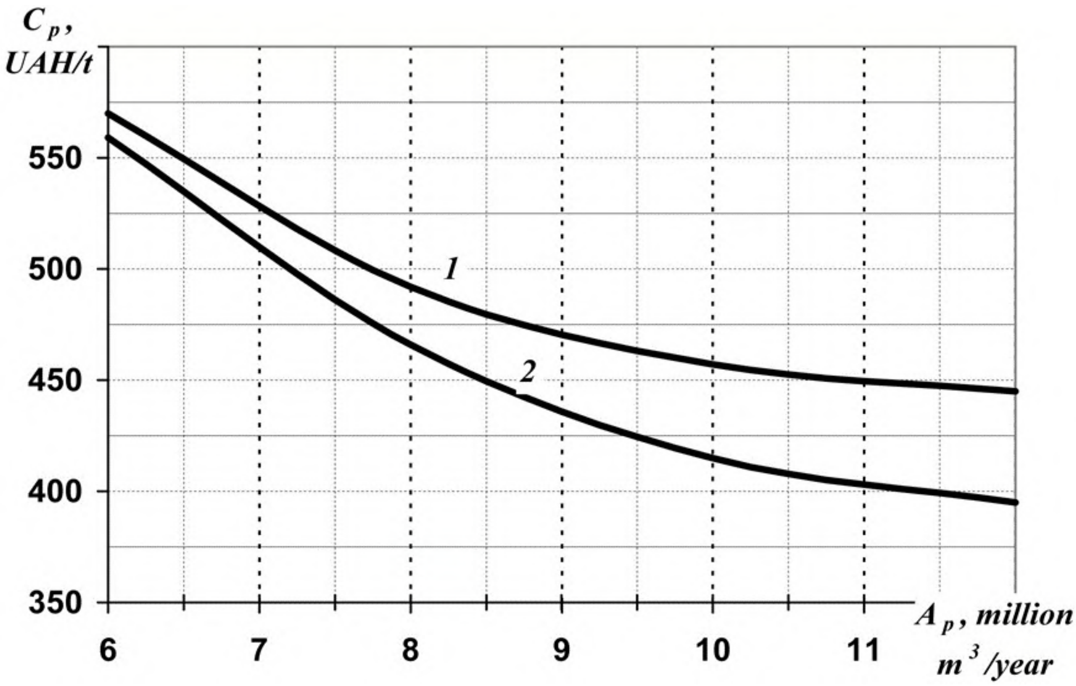

Figure 3. Influence of open pit ore productivity on the production cost of the concentrate at the first (1) and second (2) stages of open pit operation.

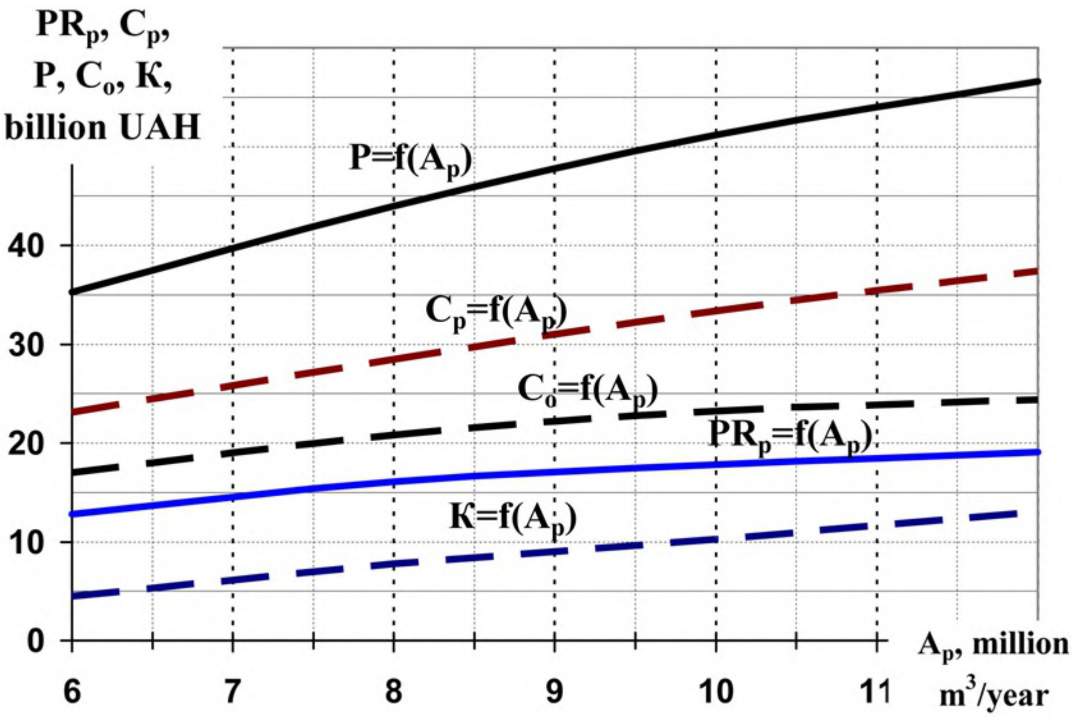

Figure 4. Change in costs and income from the development of a mineral deposit and the production of a concentrate, depending on the ore productivity of an open-pit.

Figure 5. Graph of changes in profit from the development of the field, depending on the angle of slope of the working side of the open pit.

reduces the present value of marketable products due to an increase in the development period of the deposit.

4. Conclusions

An increase in the slope angle of the working side significantly reduces the economic efficiency of the development of the deposit due to the fact that the operation of an open-pit with a large angle of slope entails not only a decrease in the current stripping ratios as a result of a change in the mining schedule, but also a decrease in ore productivity, which reduces the present value of marketable products due to an increase in the period of development of the field.

The maximum possible productivity of an open-pit in terms of minerals ensures the maximum economic efficiency of the development of a deposit in the chosen direction of deepening the open-pit. A decrease in productivity for minerals by 20 and 40% of the maximum value entails a decrease in profit from the development of the deposit by 10 and 20%, respectively.

Abstract. The paper considers the expediency of complex processing of zeolite-smectite tuffs using the method of borehole hydro-mining. The basic information about deposits of zeolite-smectite tuffs in the Rivne-Volyn region of Ukraine and the main areas of their application in industry are presented. Also, the method of calculating the parameters of the process of hydraulic erosion of tuffs and underlying rocks by the method of borehole hydro-mining is given, and the dependence of the specific consumption of the working agent during erosion of tuffs and underlying rocks on the diameter of the nozzle at variable pressure is presented. The dependences for determining the rational forms of recess chambers with the specified erosion radius are given.

1. Features of occurrence of zeolite-smectite tuffs in the Rivne-Volyn region

At the current stage of development of mining science, intensive research and industrial development of Ukraine's raw resources are being carried out [1–5]. The Rivne-Volyn region of Ukraine is rich in deposits of zeolite-smectite tuffs, which are of great interest to the industry of Ukraine. Currently, their industrial extraction is not carried out, however, in the development of basalt deposits, in particular (Berestovetske deposit, Ivano-Dolynsk basalt deposit (Rivnen district), Rafaliv basalt deposit (Varas district)), tuffs are the host rock, and, as a rule, when loading the blasted basalt mass for processing tuffs are sent to the dump [6–9].

Tuff deposits are known in Iceland, Italy, New Zealand, Azerbaijan (Gyuzdek, Garadag district), USA (Yellowstone National Park).

Those tuffs that have low sound and thermal conductivity are loose and porous. Calcareous tuffs are used as building materials, floor and facing tiles are made from travertine. Calcareous tuff is used for the construction of buildings as a light building stone, thermal insulation material, for the production of lime.

At the same time, the zeolite-smect tuffs of these deposits deserve special attention and study. Their use in the national economy is already widely known as a feed supplement for animals and poultry, to increase soil fertility and their deactivation in radioactively contaminated soils, and wastewater treatment. In construction, tuffs are used to make bricks, roof tiles, ceramic tiles, and as a pigment for paints. Zeolites have valuable physical and mechanical properties, in particular, resistance to aggressive environments and ionizing radiation, reversible

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012051 doi:10.1088/1755-1315/1254/1/012051

low-temperature dehydration, high mechanical strength, absence of toxic compounds and contamination by microorganisms, the ability to readsorb water, gaseous tuffs are prone to easy ion exchange of cations at normal temperature and pressure [10, 11].

According to the forecasts of geologists of the Rivne expedition, the tuff resources of the Rivne region amount to hundreds millions of tons and lie along the western flank of the Poliska saddle and the western slope of the Ukrainian crystalline shield in the form of a strip 1...10 km wide at depths 5...200 m. On the territory of the Rivne region, in particular, the Rafaliv basalt deposit (figure 1), tuffs lie at a depth 4...60 m and are stretched in the form of a strip from north to south.

Figure 1. The Rafaliv deposit near the villages of Polytsi and Ivancha, Rivne region (taken from open sources).

The mineralogical and petrographic characteristics of these tuffs, their mineral composition (table 1), structural features have been studied in sufficient detail [12–14], which allows them to be used purposefully and effectively.

Complex processing of zeolite-smectite tuffs should be carried out in two ways: well hydraulic production and quarrying. The mine method is not considered due to the high cost of works, difficult mining and geological conditions, high level of groundwater [15, 16].

2. Development of a methodology for calculating the parameters of the hydroerosion process of tuffs and underlying rocks by the method of borehole hydro-mining

The influence of well-known laws of mechanics is manifested in the conditions of borehole hydro-mining (BHM). They are expressed in the manifestation of the balance law of mining pressure work, the results of which, in the conditions of hydraulic mining, are proportional to the loss of minerals in the subsoil [17]. Based on this, the main task of mountain pressure management is to maximize the share of work that goes to the safe deformation of the massif outside the excavation chambers, and to minimize it – to the deformation of the roof and protective units. The specifics

Table 1. Content of elements in tuff samples at different quarries, concentration, %.

The name of the elements	Rafaliv quarry	Berestovtsk quarry	Ivano-Dolynsk quarry
Aluminum	0.03	10.2	3.0
Silicon	30...32	57.2	42.0
Phosphorus	0.1	0	0.15
Sulfur	1,2	0.3	0
Potassium	1.3	2.4	4.8
Calcium	6.4...12.1	15	37.5
Titanium	2.8...4.0	1.3	0.5
Chrome	0.2	0.05	0.1
Manganese	0.070	0.12	0.07
Iron	48...50	12.8	7.0
Nickel	0.2	0.1	0.01
Copper	0.4...0.7	0.17	0.6...1.0
Zinc	0.05	1,2	0.07
Strontium	0.07...0.1	0.07	0.07

of field testing and development by these methods is to conduct excavation chambers without fastening. Continuous extraction of chambers followed by collapse is rational [18, 19]. In the process of excavation, an unloading zone is formed in the roof of the chambers, which perceives only the mass of the roof directly, the pressure of which is mainly transmitted to adjacent massifs and collapsed rocks of the produced space [19–21]. Using this solution, it is possible to reduce the pressure of the roof on the security cells by up to 10%.

For systems with different shapes of recess chambers, the limit erosion radius R is set as a function of the limit span of the roof:

- for a round chamber
$$R = \frac{L}{2}, \tag{1}$$
- for a rhomboid chamber
$$R = \frac{L}{\sin\alpha}, \tag{2}$$
- for a square camera
$$R = \frac{L}{\sqrt{2}}, \tag{3}$$

  where L – the ultimate length of the jet, m; α – the angle of inclination of the jet to the horizon, °.

The most rational parameters $R = f(L)$ there are systems with round and square chambers in which $R \leq L$. Magnification $R > L$ (systems with rhomboid chambers) leads to a significant increase in the consumption of the useful component on the bottoms of the chambers:

$$R = \frac{3.9dH^{0.526}}{8.02 + 4.34 \cdot 10^{-2}dH^{0.843}}, \tag{4}$$

where R – the radius of tuffs erosion in the chamber, m; d – nozzle diameter, m; H – the pressure of the working agent (WA) in the nozzle, Pa.

Checking the axial dynamic pressure of the jet at the distance of the washout radius is carried out according to the equation:

$$P = H\left(\frac{l}{R}\right)^{t}, \tag{5}$$

where P – axial dynamic jet pressure, Pa; l – the length of the initial section of the jet, m; t – the indicator, which for a camera at a distance of 5…7 m, is recommended to be equal to 0.25 m.

The productivity of erosion of tuffs P is determined from the equation:

$$P = K\left(\frac{65.39H^{1.8}}{0.313dH^{-0.5}}\right)e^{0.101dH^{-0.4}}, \tag{6}$$

where K – the coefficient that takes into account the strength properties of rocks, K = 0.0356...0.042; e – the base of the natural logarithm.

The specific consumption of the working agent (WA) and the energy consumption during washing of tuffs:

$$Q = a + bd + cd, \tag{7}$$

where a, b, c – constant approximations, the values of which are given in the table 2.

Table 2. Value of constant approximations.

The pressure of WA before the nozzle, MPa	Constant approximations					
	Searched expense			Energy consumption		
	a	b	c	a	b	c
1.0	-0.5	0.652	-0.014	-1.0	0.240	-0.005
1.6	-1.5	0.415	-0.007	-1.6	0.271	-0.005
2.2	-1.8	0.367	-0.006	-1.2	0.227	-0.004

In figure 2 the dependences of the specific consumption of the WA when washing tuffs on the diameter of the nozzle at variable pressure in the range of 1…2.2 MPa are presented. As a result, we can draw a conclusion about the linear dependence of these parameters.

The erosion radius of the underlying rocks R_1 is calculated according to empirical relationships:

$$R_1 = \frac{10.2H}{1.88 - 4.2\cdot 10^{-2}d + 12.85d^{-1.24}Hd^{-1.24}}. \tag{8}$$

Erosion productivity of underlying rocks P_1:

$$P_1 = 6.36\cdot 10^{-3}d^{3.2}H^{0.725}l_1^{\frac{d-2.66}{200.72H^{0.3}}} + 1.21\cdot 10^{-2}d^2H, \tag{9}$$

where l_1 – the distance of the nozzle to the hole, m.

The specific consumption of the WA for erosion of the underlying rocks is equal to:

$$q = akH^b + c, \tag{10}$$

where a, b, k, c – constant approximations, the values of which are presented in the table 3.

The specific energy capacity of erosion of the underlying rocks E is equal to:

$$E = 1.835\frac{l}{d} + 0.3837H^{0,7} \tag{11}$$

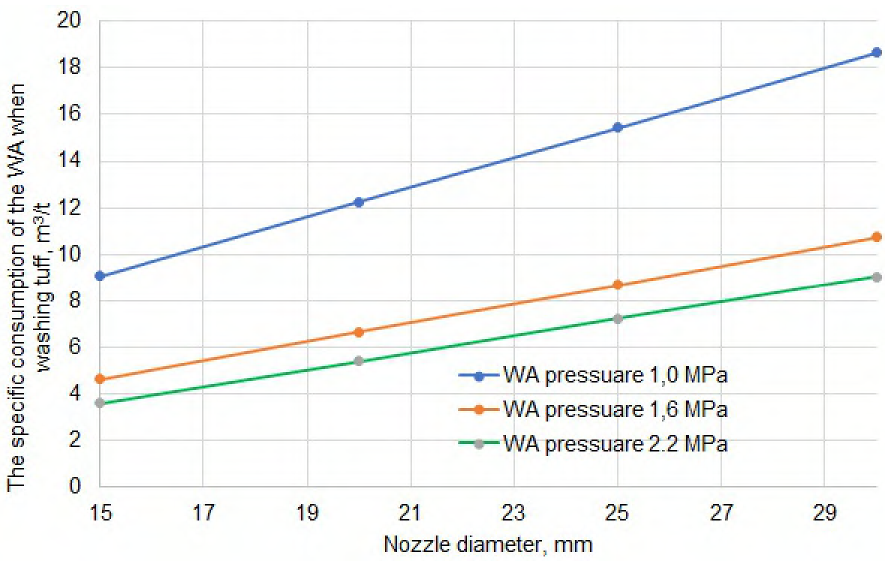

Figure 2. Dependencies of the specific consumption of the WA when washing tuff on the diameter of the nozzle at variable pressure.

Table 3. Value of constant approximations.

Nozzle diameter, d, mm	Constant approximations a	k	b	c
15	99.3	0.0536	-1.26	0.77
20	111.5	0.03216	-1.48	1.16
25	173.3	0.01426	-1.83	1.47
30	252.6	0.05134	-2.27	1.87

According to the results of research in figure 3 the dependences of the specific consumption of WA during washing of the underlying rocks on the diameter of the nozzle at variable pressure in the range of 1...2.2 MPa are presented.

The amount of minerals loss on the surface of the underlying rocks is determined by dependence:

$$P_2 = l \cdot 10^{-4}(10.2H)^{0.11d-42.84}\sqrt{0.02dHl^{1.184dH^{0.55}}} + m + \frac{9l}{(10.2H)^{0.1d}}, \qquad (12)$$

where P_2 – the productivity of the hydraulic elevator, m^3/t; m – a constant value characterizing the level of minimum consumption of minerals on the surface of the underlying rocks; for tuffs $m = 10\%$.

The results are presented in figure 4.

The working time of the excavation chamber is set as a fraction of the volume of the excavation chamber divided by the productivity of erosion of minerals (6) plus the volume of the underlying rocks that are being eroded by the depth of the timing of the useful component, divided by the productivity of erosion (10).

The working time of the excavation chamber is equal to the time of the roof collapse. If the working time of the camera exceeds the time of collapse, the correction of the camera span is made in the direction of its decrease, and the means of strengthening the security cells at depths

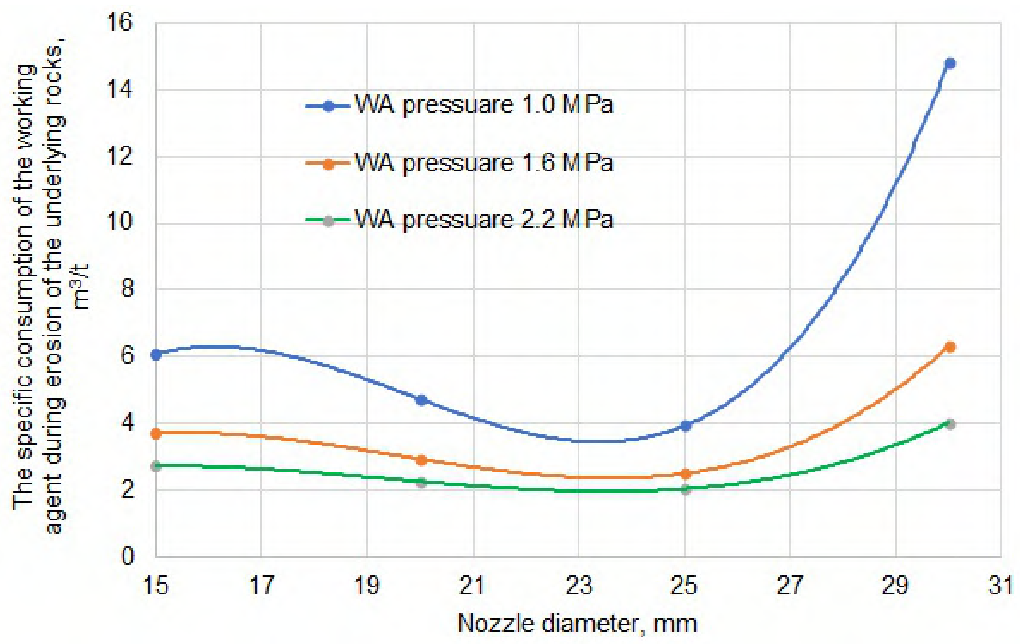

Figure 3. Dependencies of the specific consumption of WA when washing the underlying rocks on the diameter of the nozzle at variable pressure.

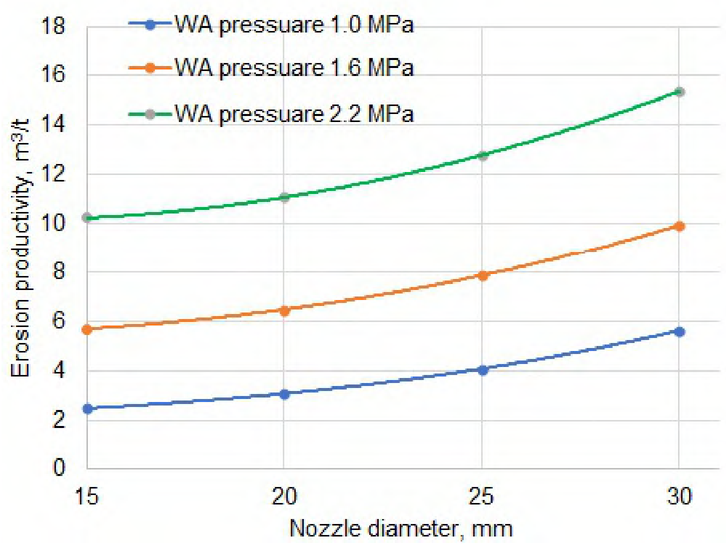

Figure 4. Dependence of hydraulic washing productivity on nozzle diameter at variable pressure.

of 50 m are provided by dividing the size of the reservoir capacity by the number of layers with the subsequent paving of the produced space.

The proposed technology of hydroerosion of tuffs and underlying rocks by the method of borehole hydro-mining has been experimentally investigated within the Rafaliv basalt deposit and is at the stage of implementation at PrJSC "Rafaliv Quarry" (Ivanchi village, Varas district, Rivne region, Ukraine).

3. Conclusions

Zeolite-smectite tuffs are increasingly used in the national economy, and due to their trace element composition, they are valuable raw materials for industry. Significant man-made reserves of tuffs in basalt quarries can be selectively extracted due to their weakening with water and subsequent screening, and with the well method of mining, weakening allows to increase the productivity of the process.

Based on the calculation of the hydroerosion process parameters of tuffs and underlying rocks, the shape of excavation chambers with the specified radius of erosion is recommended. The most rational forms of cameras, formed taking into account the radius and length of the span, are round, star-shaped and square.

The dependence of the productivity of tuff erosion in the chamber is presented, taking into account the working time, rock strength properties, chamber geometry, water consumption by the hydromonitor and air lift, and the energy consumption of the process. At the same time, the working time of the excavation chamber is adjusted with the time of the roof collapse and the strengthening of the security cells.

Acknowledgments

This work would not have been possible without the support and help in conducting experiments provided by the National University of Water and Environmental Engineering, rector V. S. Moshinsky and PJSC "Rafaliv Quarry". The research was carried out on the basis of the National University of Water and Environmental Engineering (NUWEE, Rivne, Ukraine) and with the participation of specialists from PJSC "Rafaliv Quarry" (Ivanchi village, Varas district, Rivne region, Ukraine).

Abstract. In the Republic of Kazakhstan, there is a noticeable shortage of water resources, which is a consequence of the natural features of its territory and climate. In particular, there are big problems in the water supply to the Mangystau region. The main source of water in the region is the Samskoye groundwater field. In this work, the conditions of the Samskoye field are typified, the method and technological parameters for drilling a typical well are selected and substantiated. It has been established that rotary drilling with reverse circulation in the conditions of the Samskoye field has significant advantages. The maximum possible production rate of drilling with reverse circulation, taking into account the limited thickness of the aquifer, is 4.3 times higher than with rotary drilling with direct circulation and 2.5 times higher than with percussion drilling. With the same filter pipe diameter, the greatest possible thickness of the gravel pack layer in reverse circulation drilling is 15 times greater than for conventional rotary drilling and 3.7 times greater than for percussion drilling. Thus, the use of rotary drilling with reverse circulation will solve an important problem – the provision of domestic and drinking water supply to the area.

1. Introduction

Water resources play a crucial role in the economy of any country. An important resource is groundwater extracted from boreholes. The problem of the development and protection of groundwater of the Planet Earth is in the focus of attention of special UN organizations [1]. In the Republic of Kazakhstan, there is a noticeable shortage of water resources, which is a consequence of the natural features of its territory and climate. A significant part of its vast territory, including the center, south and west, belong to the zones of deserts and semi-deserts, characterized by rare precipitation and underdeveloped river networks. The earth's surface is often covered with salt marshes, and the permeable layers close to the surface contain waters with high mineralization and cannot be used for drinking purposes.

Since 2002, the country has been consistently implementing the programs "Drinking Water" for 2003-2010, "Ak-Bulak" for 2011-2020 and the State Program for the Development of Regions for 2020-2025.

The "Drinking Water" Program started in 2002. The goal of this program was the complete provision of drinking water to more than 7,000 settlements, including the installation of water

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012052 doi:10.1088/1755-1315/1254/1/012052

supply systems in 174 villages and 86 towns. It lasted 8 years for its implementation, 195 billion tenge was allocated from the budget [2].

The second program, which was supposed to help provide Kazakhstan with clean drinking water, was launched in 2011 for a period of 9 years. The program was supposed to provide by 2020 with high-quality drinking water from centralized water supply systems the rural population of Kazakhstan by 85% and the urban population by 100%. For these purposes, it was planned to allocate a total of 1.3 trillion tenge. In 2011-2018, within the framework of the state program for the development of regions, 2015 projects were implemented from the republican budget for the development of water supply and sanitation systems [2].

Unfortunately, for a number of reasons, the implementation of these programs did not allow solving the problems of water supply in certain regions.

Mangystau is an industrial region. The basis of the economy is the oil and gas sector. In the structure of industry, the main share is occupied by the mining industry and quarrying, the share of which at the end of 2020 amounted to 85%. The industry employs about 25% of the population of the region, the share of the industry in the gross regional product is about 50%. Regional enterprises annually produce more than 10% of the industrial output of the country [3].

Based on the current demographic situation and the development of the region as a whole, the need for water supply in the region is growing every year. The water supply of the region is carried out from the Astrakhan-Mangystau water conduit and desalinated sea water, since there are few sources of natural groundwater. To date, drinking water consumption is 149 thousand m^3/day. There is a deficit in the region's water supply in the amount of 51 thousand m^3, and given the development of the region by 2025, the need will be 250-260 thousand m^3, and the deficit will be 100-110 thousand m^3 [4].

The implementation of the 2nd stage of bringing the capacity of the desalination plant "Kaspiy" to 40 thousand m^3/day has begun. JSC NC KazMunayGas is building a plant with a capacity of 17 thousand m^3/day at the Karazhanbas field.

To supply the city of Zhanaozen in the area of Kenderli and the village of Kuryk, it is planned to build desalination plants with a capacity of 50 thousand m^3/day, and on the territory of MAEC-Kazatomprom LLP with a capacity of 24 thousand m^3/day. It is planned to build a desalination plant with a capacity of 5 thousand m^3/day in the city of Fort Shevchenko [3].

Drinking water supply is provided by three sources and their share in the total volume of water consumption has the ratio:

- sea water – 52.4%;
- Volga water – 12.5%;
- groundwater – 35.1% [5].

2. Literature review

The Samskoye field is the main source of groundwater for the city of Zhanaozen. The field has been in operation since 1970. In 1979, the established total water withdrawal was only 0.02 thousand m^3/day, mainly due to private wells dug by the local population. Currently, the withdrawal of groundwater in the city of Zhanaozen has increased to 6.4 thousand m^3/day, which is 18% of the resources of the Samskoye field, although the problem of high-quality water supply to the city is still acute [6].

This problem can be solved only by significantly increasing the number of water wells and obtaining the maximum flow rate of groundwater of standard quality at the lowest cost.

Established according to the report [7] and approved for category B, the operational groundwater reserves are 21.2 thousand m^3/day for fresh water and 14.3 thousand m^3/day for slightly brackish water. The same values appear in modern documents [6].

For successful drilling of a well in the conditions of the Samskoye field, it is necessary to justify the drilling method, select drilling equipment, composition and parameters of the drilling fluid, rock cutting tools and drilling mode parameters.

As a rule, the main directions of scientific research are carried out in two main directions: solving issues related to the technology of cleaning a well from cuttings [8] and developing optimal parameters for the operation of a rock cutting tool [9].

Most often, drilling with direct circulation of drilling fluid is used for water wells. This technology is simple to organize, does not require additional equipment, and allows efficient use of the energy of the drilling fluid for the destruction of rocks [10].

However, with this circulation method, low drilling fluid flow rate, poor particle retention, low drilling efficiency, and severe wear of the drill bit are observed [11].

Another huge problem with this method is the high time and cost involved in combating fluid losses [12].

Usually, to eliminate this complication, the installation of casings or plugging of the absorbing layer in various ways is used [13]. However, when drilling wells for water, the use of these methods will only lead to unjustified expenditures of time and money.

The use of reverse circulation effectively solves the problem of drilling fluid losses in the well [14].

Reverse circulation drilling has proven to be highly effective in drilling wells for various purposes.

Thus, this method was successfully applied for the extraction of uranium ore by underground borehole leaching at operating technological wells of Volkovgeologiya, with an average total depth of 300-500 m [15].

There are examples of its use even in mine exploration instead of traditional core drilling, where reverse circulation drilling has high drilling efficiency and low cost [16].

According to [17], compared with traditional core drilling, drilling with reverse air circulation increased drilling efficiency by 70-90% while reducing costs by 30–50%, the number of accidents during drilling decreased by 60-70%.

It should be noted that the reduction of accidents is the most important factor in improving the efficiency of drilling wells, since the cost of repairs significantly increases the cost of well construction [18].

Airlift reverse circulation drilling showed high efficiency when drilling geothermal wells [19].

The application of airlift reverse circulation drilling technology is possible even in the construction of well with a depth of 4200 m, which is the deepest geothermal well in China [14].

Note that another possible application of reverse circulation with the help of an airlift is not drilling a well, but expanding it with the help of jet jets [20].

The experience of using this technology in drilling wells for gas hydrates is also known [21].

Thus, in recent years there has been a steady trend towards expanding the scope of drilling wells with reverse circulation of drilling fluid. This is due to the fact that this method has a number of significant advantages.

Thus, the use of reverse circulation drilling allows drilling wells with a diameter of up to 1500 mm [22].

Reverse circulation drilling technology is much more efficient, has better technical support and will play an increasingly important role in water well drilling in the future [23].

When using this method, the well production rate increases by about 30% compared to direct circulation drilling [24].

The key parameters of the drilling technology with reverse circulation and airlift gas injection are the volume of gas injection and displacement of the drilling fluid, the change of which regulates the bottomhole pressure [25].

It should be noted that reasonable recommendations do not include a choice of parameters for reverse circulation mechanisms and a large number of design flaws hinder the wide practical application of this drilling method [26].

Thus, the **purpose of the article** is to typify the conditions of the Samskoye field, choose the drilling method and justify the technological parameters of drilling a typical well, which will solve an important problem – providing household and drinking water supply to this area.

3. Results

On the territory of the Mangystau peninsula, surface water is practically absent. Since the sixties, exploration work has been carried out here, which made it possible to discover a number of groundwater deposits suitable for development.

A typical field is the Samskoye field. In the course of exploration work for 1968-1969, according to the report [7], this field has the following features. It has a total area of 1500 km^2 and is composed of Quaternary field of the North Ustyurt trough. Water-bearing formations have the form of lenses of various shapes and sizes. They are represented by fine-grained sands with small admixtures of medium and fine-grained sands.

The field has been in operation since 1970. A number of wells have been drilled, mainly by hand, as well as by UGB-50 drilling rigs. These wells are characterized by a low flow rate; their depth does not exceed 50 m, and their diameter is 150 mm.

According to the degree of water mineralization, the deposits are divided into two groups. The first group includes fresh waters with salinity up to 1 g/l (in fact, mineralization from 0.2 to 1 g/l occurs). These waters belong to the hydrocarbonate-chloride-sodium type. The second group includes slightly brackish waters with salinity up to 3 g/l. Waters of the first type are suitable for drinking needs of the population, waters of the second type can be used for technical needs and for the needs of cattle breeding.

Water-bearing rocks are mainly represented by fine-grained sands with small admixtures of medium– and fine-grained sands. Aquifers are generally highly homogeneous. The values of the filtration coefficient in general are in the range from 1 to 12 m/day, but in most cases they do not go beyond the range of 5.6-7.0 m/day. Waters are characterized by low pressure.

Roof and bottom rocks for aquifers are usually loams, less often they are represented by sandy loams, sandstones on lime cement and clays.

The depth of occurrence of fresh waters established by the mentioned studies is in the range from 1.5 to 44 m, the thickness of aquifers, according to modern data, reaches 39 m with an average value of 14 m. Aquifers of weakly brackish waters are located below the aquifers of fresh waters and are separated from them by layers of aquicludes.

In the article [27] based on the study of the geological and technical conditions of the Samskoye field, it was substantiated that the use of a rotary drilling method with reverse circulation makes it possible to multiply the well flow rate; reduce their required number; improve the quality of produced water; drastically reduce the well completion time; significantly lengthen the time of operation of wells; provide high rate of penetration (ROP); reduce the cost per cubic meter of produced water. Below, in support of this proposal, mathematical algorithms are given that allow obtaining the necessary numerical characteristics.

In order for the mathematical apparatus to be focused on the specific geological and hydrogeological conditions of the considered groundwater deposit, a basic model of a water well was built, which must meet the requirements of the following factors.

Economic factors:

- the maximum possible production rate of water;
- the maximum degree of its purification from mechanical impurities;
- minimum costs for the equipment of the water intake and for experimental pumping;

- minimum costs for current and workover of the well;
- maximum ROP;
- minimal time spent on round trips and drill string extensions;
- minimum cost of the drill string;
- the possibility of exploration and development of productive layers located below those that are known at the moment.

Geological and hydrogeological factors:

- depth of the productive aquifer;
- productive formation capacity;
- its mineralogical composition;
- filtration coefficient;
- reservoir pressure;
- types of rocks included in the well section;
- drillability of rocks.

Technological factors:

- ensuring the speed of the upward fluid flow, which guarantees the cleaning of the bottomhole from cuttings and a high ROP;
- using an airlift method to create a reverse circulation;
- ensuring the efficient operation of the airlift at the greatest planned depth of the well;
- taking into account the fact that the maximum height of the updraft corresponds to the upper position of the swivel on the mast.

Taking into account the above requirements, the following typical model for drilling a water well was adopted

The depth of a typical well is assumed to be 200 m.

This is justified by the following arguments:

- Established by earlier studies, the depth of fresh water (with salinity below 1 g/l) at the Samskoye field reaches 44 m, and the thickness of aquifer lenses reaches 39 m. Summing up these two figures, we obtain the depth of the base of the aquifer 83 m. The fact that the aquifers are composed, as a rule, of fine-grained sands, we take the length of the settling tank to be 15 m. Thus, the maximum depth of a well drilling into fresh water that exists at the moment can be 98 m;
- In addition to fresh water, it is also planned to use waters with a higher (up to 5 g/l) salinity. Such waters are used for technical and agricultural needs. According to the exploration work carried out, the brackish water aquifers are located below the fresh water aquifers and are separated from them by layers of aquicludes. Thus, the maximum required depth may be significantly greater;
- The given parameters of water wells refer to exploration work carried out before 2012 [6]. The possibility of discovering exploitable aquifers when drilling wells to great depths should hardly be ruled out;
- The study of the features of drilling water wells by the proposed method to a depth of 200 m (and possibly even more) will allow a more complete assessment of the proposed method of drilling.

The depth of the roof of the productive aquifer is assumed to be 170 m.

Based on the previous paragraph, in which, according to the considerations given there, it was decided to take the depth of a typical well equal to 200 m, the location of the aquifer was accordingly shifted down.

The aquifer has a thickness of 14 m.

According to available materials, this is the average thickness of productive aquifers containing fresh water.

The filtration coefficient of permeable rocks of the aquifer is 6.3 m/day.

The aquifers of the Samskoe field are composed of homogeneous fine-grained sands and are characterized by the indicated average value of the filtration coefficient.

The static head of a productive formation penetrated by a typical well is assumed to be 100 m.

This is justified as follows:

- the available materials do not allow to establish the average value of the static head for the drilled wells of the Samskoye field;
- since the depth of a typical well is assumed to be 200 m, which is at least 100 m higher than the depth of water wells drilled to date, then, accordingly, the water in this well may have a static head of the order of 100 m.

The diameter of a typical well is assumed to be 800 mm.

This is justified as follows:

- according to the literature data [28], the diameters of water wells drilled by the rotary method with reverse circulation can be in the range from 300 to 1500 mm;
- most often such wells have a diameter of 500 or 800 mm;
- with an increase in the diameter, the possible flow rate of the well increases;
- the required length of the receiving part of the well is reduced;
- the quality of mechanical water purification is improved due to the creation of a powerful layer of gravel;
- simplifies the technology of creating gravel;
- the required time of experimental pumping is reduced;
- at the same time, with an increase in the diameter of the well and, accordingly, the volume of the destroyed rock, the required amount of circulating drilling fluid increases;
- when passing through permeable layers, there is a high degree of absorption of drilling fluid in the walls of the well, which requires the continuous supply of new volumes of water;
- the ROP decreases;
- taking into account the above, and also, taking into account the low filtration coefficient, in the water-bearing rocks of the Samskoye field, which causes a relatively small loss of circulation, the largest of the two most commonly used diameters is 800 mm.

A drill string is accepted from commercially available pipes with a diameter of 146 mm (inner diameter 136 mm).

This is justified as follows:

- according to literature data [28] for rotary drilling with reverse circulation, drill pipes with a diameter of 127, 146, 168 and 219 mm can be used;
- with an increase in the bore section of drill pipes, the hydraulic resistance to the upward flow decreases sharply;
- the content of sludge in it decreases;

- at the same time, the required water supply is increased;
- sharply increase the time spent on round trips and build-up;
- commercially available pipes cannot be used in airlift drilling without significant modification, and their threaded connections are replaced with flanged ones, which drastically slows down the process of connecting pipes into a string and increases the total cost of work;
- the minimum diameter of the drill string, when implementing the proposed new solution, is 146 mm.

The height of the sludge-containing water-air mixture above the earth's surface is assumed to be 10 m.

This is justified as follows:

- the maximum lifting height of the cuttings-containing mixture corresponds to the height of the swivel at the moment of resumption of drilling after the drill string is built up;
- this height is equal to the height of the mast of the drilling rig, minus the dimensions of the blocks, hook, shackle, etc., as well as the distance that ensures the necessary maneuver (for example, raising the drill string above the clamp holding it before lowering it into the well);
- height of masts of rigs intended for rotary drilling with reverse circulation varies from 8.2 to 18.5 m [29] and averages 13 m; from installations of a similar purpose, the UGB3UK-OP installation has a mast height close to the indicated average value (14.2 m);
- thus, minus the average height of the mast 3-4 m, we get the average height of the swivel in its uppermost position, equal to 10 m.

The speed of the upward flow of water is 2.5 m/s.

This is justified as follows:

- the main advantage of rotary drilling with reverse circulation is the high speed of the upward flow, which ensures effective cleaning of the bottomhole from destruction products;
- this advantage is achieved due to a multiple decrease in the cross-sectional area of the channel through which the ascending flow moves;
- if during direct circulation speed of the upward flow rarely reaches 1 m/s, then according to the literature [28] during reverse circulation, it should be in the range from 1.5 to 3.5 m/s;
- at upstream speeds that do not reach the lower limit of this interval, the advantages of drilling with reverse circulation are lost, and in order to reduce the amount of cuttings formed per unit time, it is necessary to resort to reducing the diameter of the wellbore to normal sizes;
- when the upper limit of the specified interval is reached, the removal of large particles is ensured, the size of which is close to the inner diameter of the drill pipes and the discharge hose;
- aquifers of the Samskoe field are homogeneous in their mineralogical composition and, as a rule, are composed of fine-grained sands [7]; there is no information on the presence of large pebbles and, especially, boulders;
- for the indicated reasons, when drilling a typical well, the upward flow rate will be maintained at the level of the average value over the given interval – i.e. 2.5 m/s [30].

The value of the average ROP in the enclosing rocks is assumed to be 15 m/h.

This is justified as follows:

- when drilling in aquifers composed of fine-grained sands, the penetration rate may exceed 100 m/h;

- the limiting factor is the supersaturation of the upward flow with sludge and an unacceptable increase in its total density;
- a sharp increase in the density of the upward flow can negate the effect of aeration – the speed of the upward flow will drop to zero and the bit will be stuck with cuttings;
- in connection with the indicated risks, the ROP during the passage of the aquifer should be restrained to values that are typical for the host rocks;
- the rocks hosting the aquifers in the field under consideration are clays and loams, therefore the accepted ROP of 15 m/h is quite progressive for these rocks when drilling with reverse circulation and, at the same time, quite achievable;
- the calculations below will show that at this ROP there will be no unacceptable increase in the density of the updraft.

The depth of the mixer is assumed to be 2 m less than the depth of the well. This is justified as follows:

- fluid circulation in the airlift method is carried out due to the fact that at the mixer level a difference in hydrostatic pressures is created in the annulus filled with water and in the drill string filled with water-air mixture;
- at an extremely low (which corresponds to the stated ratio) location of the mixer, the maximum height of the mixture column is achieved, and hence the maximum value of the difference mentioned above;
- due to this difference, the maximum speed of the upward flow is created and, accordingly, the best cleaning of the bottomhole from cuttings;
- starting from a certain drilling depth, due to the limited pressure of the compressor, the resumption of airlift circulation after technologically necessary stops (for example, when building up the drill string) becomes impossible;
- to resume circulation, the immersion depth of the mixer has to be reduced;
- at the same time, the height of the mixture column and the difference in hydrostatic pressures inside and outside the drill string decrease with a corresponding decrease in the circulation intensity;
- the existing methods of separating the operating conditions of the compressor during the resumption of circulation and during the normal drilling process are reduced to significant complications in the design of the drill string.

Summarizing, we will present the main parameters of drilling a typical well in a summary (table 1).

Below are calculations of possible results of the practical application of the above typical model of rotary drilling with reverse circulation.

The well flow rate is determined by the possibility of creating the necessary drawdown on the productive formation. During pumping, this drawdown (i.e. pressure reduction) is created by lowering the water level in the pay zone near the wellbore. This reduction is:

$$S = h_D - h_S \tag{1}$$

where h_D is the dynamic level (i.e. the distance from the surface to the water in the well during pumping), h_S is the static level (the same level before pumping). The static level is also defined as:

$$h_S = h_p - H_S \tag{2}$$

where h_P is the formation top depth, H_S is the static head.

Table 1. Basic drilling parameters of a typical well.

No.	Parameter name	Meaning
1	Drilling depth, N, m	200
2	Depth of the roof of the productive formation, N_R, m	170
3	Reservoir thickness, m	14
4	Filtration coefficient, K_F, m/day	6.3
5	Static formation head, H_S, m	100
6	Drilling diameter, D, mm	800
7	Drill string diameters: out./in., d_O/d_i, mm	146/136
8	The height of the mixture above the surface, h, m	10
9	Upward water flow rate, U_W, m/s	2.5
10	Rate of penetration, ROP, m/h	15
11	Mixer immersion depth, L, m	2H

During pumping, the flow rate corresponding to the decrease (in m^3/h) is determined by the formula [31]:

$$Q_S = \frac{SK_F m}{36} \tag{3}$$

where m is the thickness of the aquifer in m; K_F is the filtration coefficient in m/day.

In confined aquifers, according to formula (2), the largest possible decrease is a decrease by the value of the static head.

$$S_{max} = h_P - h_S \tag{4}$$

In unconfined aquifers, this formula is reduced to:

$$S_{max} = h_F - h_S \tag{5}$$

where h_F is the depth of the base of the productive formation.

When trying to achieve the maximum flow rate from this particular well, an important limitation is to prevent catastrophic production of reservoir material from the walls of the well, caused by an excessively high rate of water withdrawal.

The criterion here is the maximum allowable rate of water filtration through the formation pores in the receiving part of the well. The maximum filtration rate (in m/h) is determined by the formula:

$$U_F = 2.71\sqrt[3]{K_F} \tag{6}$$

where K_F is the filtration coefficient in m/day.

From formula (6) it can be seen that the maximum allowable velocity drops sharply (in cubic dependence) with a decrease in the filtration capacity of the productive formation.

Taking into account the above limitation when pumping water from a given well, the maximum allowable flow rate in m^3/h is determined by the formula:

$$Q_{max} = FU_F \tag{7}$$

where F is the surface area of the well in m^2 through which water enters (corresponding to the area of the filter).

Subject to the condition of not exceeding the allowable filtration rate, the highest allowable well flow rate is achieved by varying the filter parameters.

Given the cylindrical shape of the well, formula (7) can be written as

$$Q_{max} = L\pi DU_F \tag{8}$$

where L is the length of the receiving part in m; D is the diameter of the receiving part in m.

Formula (8) shows that the surface F can be reached in three ways (or using their combination):

(i) By increasing the length of the filter – the most practical and least expensive way. The required length of the receiving part is equal to:

$$L_{max} = \frac{Q_{max}}{\pi DU_F} \tag{9}$$

However, the application of this method is limited by the thickness of the productive formation m. Taking into account the capacity, the maximum possible well flow rate is determined as follows:

$$Q_{max} = m\pi DU_F \tag{10}$$

(ii) By increasing the diameter of the receiving part, which is usually associated with complex additional operations to expand it:

$$D_{max} = \frac{Q_{max}}{\pi LU_F} \tag{11}$$

(iii) By drilling a well with a large diameter, which is ensured by the use of rotary drilling with reverse circulation.

We use the results of the methodology presented in formulas (1)-(11) to evaluate the effectiveness of the method of rotary drilling of wells with reverse circulation in comparison with two other drilling methods used in drilling water wells – a rotary method with direct circulation and a shock-rope method.

In a comparative assessment of drilling methods, the main role is played by the maximum possible diameters of the bits when using them (without taking into account the possibility of expanding the receiving part).

For rotary drilling with reverse circulation we accept the diameter value equal to 800 mm (table 1).

For rotary drilling with direct circulation in the case of using the widespread installation 1BA-15V, the final diameter (i.e., the one with which the productive aquifer is opened) can be a diameter of 190 mm [32].

When percussion drilling with a rig UKS-22 the size of the first casing cannot exceed 600 mm (i.e. 22 inches in inner diameter). When designing a casing telescope specific to percussion drilling, each subsequent casing must be at least 2 inches smaller than the previous one, with the protrusion of one casing from under the other increasing with decreasing diameter.

From table 2 it follows that when building a well with a depth of 200 m and a diameter of the first casing of 22 inches, the required depth can be achieved, taking into account the above conditions, by creating a telescope of 6 casings. In this case, the diameter of the receiving part of the well is equal to the outer diameter of the last (sixth) casing – i.e. columns with an outer diameter of 12 inches (324 mm).

The initial data given in lines 1-5 of table 1 were taken as the basis for comparative calculations.

Given in table 3 the maximum theoretical (excluding restrictions) flow rate of each of the 3 wells is determined by formula (3). The maximum possible value, namely the static head H_S, is taken as the reduction in S.

According to formula (6), the admissible filtration rate $U_F = 5.01$ m/h was obtained.

The results of comparative calculations are given in table 4.

Table 2. Typical design of a percussion-rope drilling well with a depth of 200 m.

Column number in descending order	1	2	3	4	5	6
Column diameter, inches	22	20	18	16	14	12
Exit (length of contact with rock), m	10	20	30	40	50	50

Table 3. General parameters used in the comparative analysis of three drilling methods.

No.	Parameter name	Meaning
1	Maximum possible theoretical flow rate, Q_S, m^3/h	245
2	Depression required to achieve it, H_S, m	100
3	Permissible filtration rate, U_F, m/h	5.01

Table 4. Main indicators of drilling water wells.

Parameter name	Rotary drilling	Percussion drilling	Reverse circulation drilling
Diameter of the receiving part D, m	0.190	0.324	0.800
Filter pipe diameter D_F, m	0.146	0.146	0.146
Sprinkling layer thickness δ, m	0.022	0.089	0.327
Required filter length at a flow rate of 245 m^3/h (table 3), L, m	82	48	20
The highest production rate (at reservoir thickness $m = 14$ m), Q_{max}, m^3/h	41	71	176

4. Conclusions

According to the results of the work, rotary drilling with reverse circulation in the conditions of the Samskoye field has such advantages.

The maximum possible production rate of drilling with reverse circulation, taking into account the limited thickness of the aquifer, is 4.3 times higher than with rotary drilling with direct circulation and 2.5 times higher than with percussion drilling. These results are ratios of accepted diameters. For this reason, the maximum achievable, according to formula (10), flow rate may increase or decrease depending on the thickness of the reservoir m, but the indicated ratio of maximum flow rates will remain the same.

If the reservoir thickness is not a limiting factor, then with the same flow rate (formula (3)), the indicated ratio will be valid for the required lengths of the receiving part calculated by formula (9). The larger the diameter, the smaller the required length (line 4 of the table), with a decrease in which the costs of both the equipment of the receiving part and its repair are reduced.

With the same diameter of the filter pipe (line 2 of the table), the maximum possible thickness of the gravel pack layer during reverse circulation drilling is 15 times greater than for conventional rotary drilling and 3.7 times greater than for cable percussion drilling.

Powerful gravel sprinkling provides the best quality of mechanical cleaning of the sampled water. The consequence of this is also the minimum time required for experimental pumping and the minimum length of the well sump. Such sprinkling also provides the maximum duration of overhaul operation.

It should be noted that with rotary drilling of large diameter wells with reverse circulation, labor costs for the manufacture of a gravel pack are minimized. As a rule, gravel is filled manually through the wellhead, since the large area of the annular space eliminates the possibility of plugging and failure of the filled material to reach the receiving part.

Acknowledgments
The research is carried out by Dnipro University of Technology (Ukraine) and Satbayev University (Kazakhstan) and Yessenov University (Kazakhstan). We express our gratitude to our colleagues who provided us with the required information and helped considerably complete the research.

Abstract. Dnipro University of Technology is a leading institution where an authoritative scientific school was formed to solve the fundamental issues of percussive-rotary drilling with the help of hydraulic hammers. This method makes it possible to intensify significantly the mining processes of rock mass breaking. In order to perform the specified function as fully as possible, hydraulic hammers are to work in a certain technological mode and have appropriate technical characteristics; the paper deals immediately with the analysis of those characteristics. The original designs of hydraulic hammers proposed by the authors are distinguished by a high degree of reliability of the interaction of individual parts and assemblies. Simulation of the operation of hydraulic hammers under appropriate mode-parametric support revealed a number of their significant advantages, i.e. in terms of creating effective conditions for rock mass disintegration. It has been proven convincingly that some features of the approaches to the implementation of a hydraulic well washing programme correspond to the stability of a high-quality process of the downhole work of percussion machines. As a result of the research, a composition of some rational formulations of flushing fluids, which contribute to a significant acceleration of the development of destructive processes, was clarified.

1. Introduction

Further sustainable innovative development of mining and other related industries is impossible without wide application of drilling well technologies. And for the latter, in the near future, there are no real technically and technologically justified alternatives [1].

In the generalized sense of this well-established and widely used terminological expression, drilling different-purpose wells helps solve a significant range of production and theoretical issues related to the need to search for promising structures for the available useful components and study the specific geological and technical conditions of stratified mineral deposits with further creation of powerful industrial complexes for their effective extraction and partial local processing [2].

Modern engineering and technologies of well construction face rather complex but extremely necessary tasks of obtaining comprehensive multifaceted information, which source, first of all, is represented by core samples of rock formations [3]. In relation to wells of the large number of operational wells, the main requirement is the formation of a communication channel suitable for long-term operation with a mineral deposit in the rock layer. Taking into account the above, the following can be stated confidently: completeness and perfection of the geological and industrial task of deposit development depends on the quality of operations related to well construction in the rock mass; moreover, the latter should contain comprehensive and concrete details.

The multi-factorial cycle of well construction with its indispensable component in the form of various bottomhole drilling processes (in other words, phenomena of rock mass breaking), will be effective only while observing a certain mode of interaction of a drilling rock-breaking tool with the rock mass. Thus, in terms of well layout, the connection links of a rock-breaking tool with the surface energy and power equipment, there is a significant number of functional elements designed to rationalize maximally each factor of the complex operation of rock bottomhole disintegration. The above should be supplemented by the fact that well technologies allow carrying out effectively a cycle of operations to solve complicated issues, e.g. preparation of territories for future construction of civil and industrial complexes as well as necessary technological support for proper execution of the specified operations [4].

Summing up, it is possible and necessary to highlight significant complexity of the structural design of drilling processes, which features are determined by the ultimate goal of well construction. Due to the fact that well drilling can have different purposes, the specified rock formations have a significant range of options for their dimensional design and spatial position in the rock mass. The well depths determined by the stratigraphic location of a specific mineral deposit or by special instructional requirements for the technology of drilling and testing differ greatly in their absolute values. As for the wellbore diametrical characteristics, their values are specified, in particular, by the requirements for the representative qualities of rock samples as well as the overall dimensions of the research and operational equipment of wells.

In such a formulation of the analysis of problematics of drilling operations, one can trace a clear need to apply the substantiated (from the standpoint of minimized capital costs) approaches to the development of regulations for their construction; that will also contribute to the complete avoidance of complications and accidents in shafts of the considered specific mining operations.

2. Related work

According to the conducted analysis of literature sources and information reports of production organizations engaged in drilling and related operations, it is possible to talk about current and prevailing trend – improvement of rock-destroying tools to increase their operating resource on the well bottom [5]. The following remark will be relevant here: a new rock-breaking tool is intended mostly for its use in terms of classic rotary drilling. The given data can be also explained by the fact that almost all technical means of drilling operations are designed and adapted to carry out corresponding operations using rotation (rotary, in case of oil-and-gas well construction) method of rock mass breaking. The latter is the most widely used one; though, it has significant defects, which essence is exclusively in those factors being the basis of functional principles of the method under consideration [1].

Generally, mechanical methods of rock mass breaking are distinguished by a too low coefficient of efficiency due to the fact that they are characterized by unjustified energy dissipation in most technological schemes of their implementation. That refers to large power losses due to drill string friction against the well walls during its necessary rotation as well as bottomhole interaction of a rock-breaking tool with the rock mass with further heat release. The described phenomena are objective and the ones that cannot be eliminated without fundamental transformations of a technological scheme of the rotary drilling method [4]. In fact, such a state of affairs has resulted in the development of a number of effective and promising non-mechanical methods that apply useful phenomena of physical or chemical origin to form breaking forces within the drilling tool-rock contact zone of a special design.

Modelling, extensive testing, and, in some cases, even industrial implementation of multifaceted forms of non-mechanical methods have proven their important potential advantages and wide opportunities. However, their relatively large-scale application in the practice of well construction is hindered by the need to make changes, sometimes quite significant, in the construction schemes of the corresponding technological cycles. It will be appropriate here to provide examples of partial application of some principles of non-mechanical methods of forming wells in rock mass. In particular, that refers to high-pressure jets of washing fluid, which hydraulic organs are woven organically into the drill bit structure [6]. In the context of such a technical solution, it is possible to intensify significantly a course of destructive processes and their further development in terms of effective drilling mud removal from the well bottom [7]. Additional introduction of interaction of high-pressure jets with a rock mass of various-origin abrasive materials into a circulation chain can bring significant positive changes at almost all stages of the formation of a rock mass breaking zone [8].

While applying this method, it is possible to observe an extremely intensive development of complex deformation and subsequent breaking phenomena in the rock mass; ultimately, that allows obtaining high indicators of the wellbore deepening. It can be explained by the significance of dynamic level of application of breaking forces to the rock, which cannot be achieved by other methods and techniques. The conducted studies proved the expediency of such an interpretation of effective rock-breaking methods, when the variants of conditional periodicity of applying the required values of axial load occurs due to the presence of not only abrasive-jet percussion effects but also the generation of directed shock pulses by special impact machines. A convincing advantage of the described modifications of the well formation methods is the possibility of controlled adjustment of the frequency characteristics to a higher degree of a dynamic process of the breaking element-rock interaction. It is implemented by complementing the design with special downhole machines and a corresponding complex tool of certain design of components, developed to act as a so-called downhole regulator as comprehensively as possible. They should function to coordinate the requirements of a well construction technology regarding the proposed combined drilling methods and capabilities of the drilling mechanisms. Percussion downhole machines are to form appropriate pulses of a clearly defined amplitude with the possibility of direct and operational adjustment from the surface; according to the general definition of this concept, a drilling tool should be able to relay and transform shock pulses to the rock bottomhole of the well as fully as possible [9].

The design and implementation of special measures of a hydraulic well flushing programme with the mandatory use of appropriately activated technological indicators of circulating drilling fluids is the additional and very influential factor for a proper downhole breaking process [10].

The represented reasoned data indicates indisputably the available urgent needs for further comprehensive development and industrial implementation of sufficiently effective technical means and technologies for well construction with the adequate multi-category indicators.

3. Results

A complex cycle of well drilling consists of several sequentially performed operations; rock breaking is the most responsible one from the viewpoint of reaching high production and economic indices [11]. A rock breaking method determines almost all technical and technological features of well drilling regulations. It is the method that influences directly the course of downhole breaking processes, which, under conditions of well construction in the rocks prone to manifestation of various complications, must be planned in a logical sequence to prevent violation of the execution completeness of all necessary well technological operations [12].

Overall, a drill well is a complex geotechnological structure that requires certain (and sometimes quite cumbersome) effective measures to maintain them in a certain working condition. Here, great attention should be paid to the needs of high rates of wellbore deepening [13]. In order to fulfil the specified criterion, it is necessary to create rational conditions for a stable flow of a rock breaking process with restrictions concerning the resource of the effective tool operation.

In the context under consideration, several approaches to optimization of percussive rock breaking can be mentioned, i.e.: use of a drilling tool with increased wear resistance (this includes a tool equipped with ultra-hard materials); use of the principles of toolless rock mass breaking (physical and chemical methods of rock disintegration are a characteristic feature of the case under consideration); involvement of highly mobile elements in the interaction with a wellbore with the possibility of their operational circulation replacement (principles of combined ball jet drilling are traced here); creation of certain conditions to intensify downhole breaking processes due to dynamic impact of a special tool (a drilling tool layout includes the machines generating shock pulses of different amplitudes and frequencies) [5].

A drilling tool made with the use of relatively wear-resistant cutting structures, is distinguished, for the most part, by a rather high cost, determined not only by a significant indicator of the consumable costs but also by the complexity of the technological manufacturing of tool structures. That is also complicated by special requirements for bottomhole operation of the latter. It narrows somewhat the area of possible rational use of such a drilling tool and requires preliminary analytical and laboratory studies regarding the expediency of its use in specific lithological variants of rocks [1].

In terms of limited funding for drilling operations and the need to construct wells in complicated geological conditions, other considered approaches to the optimization of bottomhole rock breaking, separately or in a complex combination, are seen as the most acceptable ones from many leading positions.

Further developments were based on a rational technological approach, meaning implementation of significant dynamic loads on the wellbore using a hydraulic energy source. That makes it possible to obtain the mode of well deepening characterized by the intensive formation of zones of rock mass breaking and re-breaking of a very effective volumetric nature [14]. It is possible to create such conditions due to the involvement of metal balls that move with the flow of washing fluid at high speeds and impact the rock downhole. According to the features of the methodology of a briefly described modernized principle of ball jet drilling, metal balls also perform the work of processing the peripheral wellbore areas together with the percussion machines under certain technical and technological regulations [5].

The considered combined drilling method was studied rather comprehensively by means of analytical and bench modelling. The following can be noted among its main results: the method is characterized by active development of breaking deformations in the form of cracks and holes; the method is characterized by a clear dependence of the scale of breaking processes on the application of axial load and its subsequent physical results (compared to cases of rock breaking in the absence of dynamism of axial load application). This is illustrated both qualitatively and quantitatively on the corresponding graphs in figure 1 and figure 2.

The developed ball jet or hydromechanical method is distinguished by its exceptional feature – it is the possibility of obtaining a wide range of load application speed v, which is known to determine usefully the effectiveness of breaking processes. Along with a gradual increase in v values, there is a natural increase in the scale of breaking process development, followed by the formation of corresponding breaking and re-breaking zones.

The data shown in figure 1 demonstrate clearly that the penetration depth of breaking disturbances h into the rock mass, in comparison with the case of static application of axial load, increases by approximately 1.3-1.4 times. Certain dependence of the results of breaking processes on the petrophysical characteristics of rocks was also revealed. In this case, influence of a mineral grain size can be observed (constant fluctuations between the absolute values of the depth of breaking hole formation h within the range of 6-14% is noted here), which is necessary to take into account while developing regulations for the operation of designed drilling devices for hydromechanical well drilling.

Pre-qualification studies of the devices under consideration have proved that they exclude

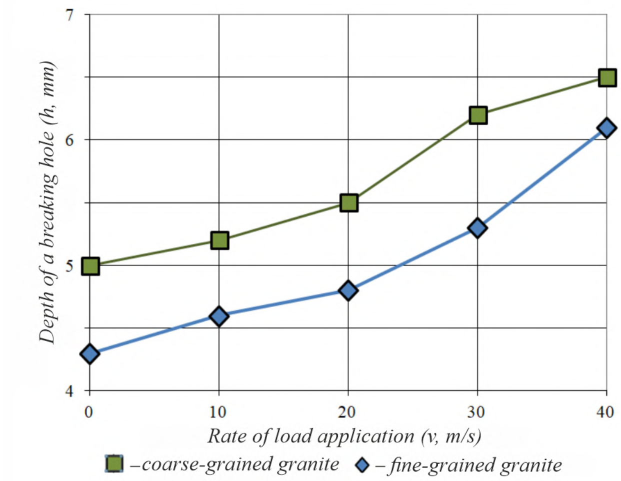

Figure 1. Patterns of the development of breaking processes for different mineralogical rock types under variable values of the axial load application rate.

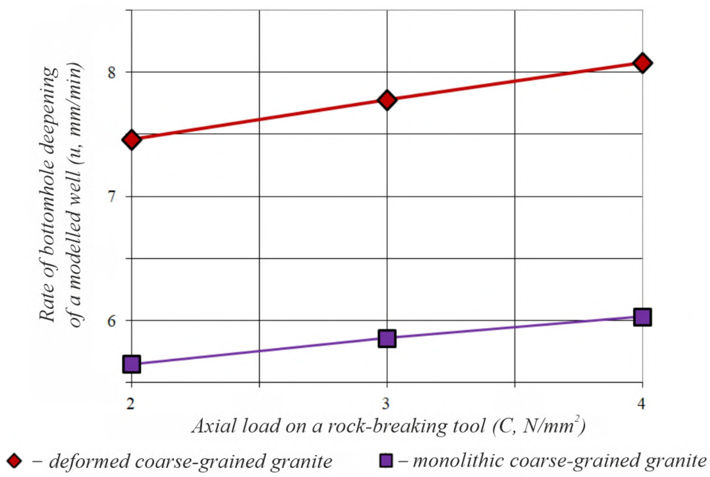

Figure 2. Influence of a physical state of rock mass on its breaking rate in terms of a modernized ball-jet method of well construction.

completely the most influential shortcoming of the ball jet drilling method – lack of proper treatment of the peripheral well zone. This is solved by complementing the device layout with a special design of rock-breaking organs, which, together with balls, form a well drilling contour. The effectiveness of this approach is the availability of an additional component in the complex downhole layout of a concrete hydromechanical drilling device. It allows forming the combined impact pulses on the rock mass deformed by active impacts of balls.

Under the proposed technical-technological scheme of drilling, there is a potential possibility of total exclusion of the suspension of well borehole deepening due to its complex curvilinear narrowing in the bottomhole part. Proper conditions for wellbore deepening are formed by the device rotation together with a rock-breaking organ and by creating the necessary static axial load with an active dynamic component (figure 2).

Thus, analyzing the data of figure 2 and statistics of the parametric values of stand studies, the following can be stated: by systematic increase in the rotation frequency n and axial load C, together with their reinforcement with dynamic pulses, it is possible to increase wellbore deepening rate u by approximately 30%. This is most clearly seen for a deformed bottomhole; in this case, growth of u is more than 40%.

A modernized ball-jet (hydromechanical) method of rock mass breaking (or abrasive-mechanical percussion method of rock breaking as we call it according to its technological essence), is the one that allows achieving high wellbore depth values, i.e. the main indicator that is the main criterion for the excellence of drilling operations; it is identified by a mechanical speed of drilling wells.

For its organic implementation in drilling practice, the method we have modernized does not require any significant technical and technological innovations and changes in the currently used layouts of the available drilling machines, mechanisms, tools etc. [15].

The design of a downhole rock-breaking tool adapted to the processing mode of the peripheral well zone is characterized by simple modification and work cycle stability. In addition to its simplicity, a ball jet device needs only some special hydraulic mode of operation; that was taken into account as much as possible while developing an additional percussion machine for it – a modernized hydraulic hammer [16]. In addition to the necessary clear synchronization of the interaction with a jet device, the reasons for its improvement included following significant defects peculiar for the majority of currently operated impact machines, i.e.: excessive complexity of the functioning of components and parts in a "valve-piston-hammer" system with the lack of sufficient technologically substantiated range of movement speeds of the latter. This provokes considerable and unpredictable, in terms of absolute values, pressure fluctuations in the device, reducing significantly the energy intensity of each individual act during the shock pulse generation. In most cases, hydraulic shock devices are also characterized by large alternating loads on power springs with their active wear and failure.

Figure 3 demonstrates a general scheme of the proposed hydraulic hammer, which includes: an upper locking adapter 1 with an internal thread 2 for the column nipple and recesses 3 for a drilling tongs as well as a central circulation channel 4. An adapter 1 with a casing bushing 24 connected by a thread 29 form an acceleration chamber 5. Casing bushings 24 and a cup 18, connected by a thread 31, form an impact chamber 8. In the internal part of the interconnected adapter 1, the casing bushing 24, and the acceleration chamber 5, the following operates: hammer 7, which contains a high-pressure pneumatic chamber 19, a through circulation channel 6, a drainage channel 26 with the circulation holes 25, rubber-metal sealing rings 27, and an anvil 11, which contains through holes 9 and a central circulation channel 10, external splines 16, shank adaptor 20, and sealing elements 21, 22, 28. To remove the washing liquid, the casing bushing 24 contains resettable circulation windows 23. A casing cup 18 in its lower part is equipped with internal splines 17 for the connection with the anvil 11, which also contains a metric thread 15, to which the lower adapter 12 with the recesses 31 for drilling tongs, a vertical circulation channel 13, and a tool-joint thread 14 are connected.

When lowering the hydraulic hammer in combination with the jet machine, with mandatory flushing fluid circulation when reaching the wellbore, the fluid moves as follows: the central circulation channel 4 of the lock adapter 1, the acceleration chamber 5, the through circulation channel 6 of the hammer 7, the impact chamber 8, the through holes 9, and the central circulation channel 10 of the anvil 11, the vertical circulation channel 13 of the lower adapter 12. When the assembly connected to the locking thread 14 of the lower adapter 12 reaches the wellbore, the axial movement of the adapter 12 and the anvil 11 connected to it by the metric thread 15 occurs, which unhindered and stable movement is ensured by the contact of the splined pair "outer splines 16 of the anvil 11- inner splines 17 of the casing cup 18". The occurrence of a hydraulic shock – a generator of shock pulses of the corresponding frequency, occurs when the anvil 11 is moved axially by a structural parametric value L, which overcoming leads to an instant increase in the liquid pressure in the acceleration chamber 5, being the result of blocking the liquid flow to the bottomhole with the help of through holes 9 in the anvil 11, which, together

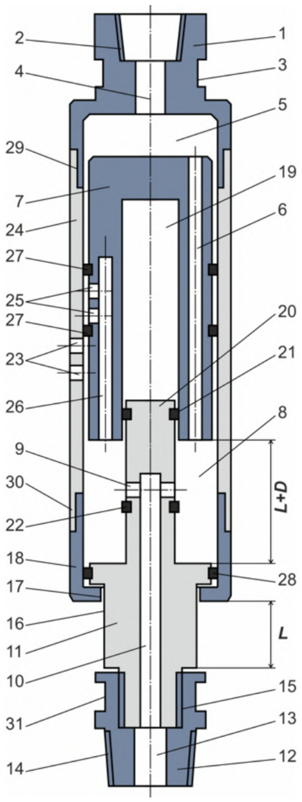

Figure 3. Layout diagram of a hydraulic hammer device.

with the shank adaptor 20, are immersed in the high-pressure pneumatic chamber 19 of the hammer 7. The consequence of the indicated interaction will be the rapid accumulation of the necessary kinetic energy reserve by the hammer 7, which will cause it to impact the anvil 11 with a given working movement by distance D.

The accuracy of impacting the anvil 11 is ensured by the anisobaric nature of the processes in the high-pressure pneumatic chamber 19, filled with compressed gas with a critical pressure of $P \geqslant 0.4$ MPa and its periodic compression (during the active washing liquid movement) or expansion (when the active movement stops), which corresponds to a specific stage of the circulation process in the acceleration chamber 5. Hermeticity of the high-pressure chamber 19 and insulation of the through holes 9 in the anvil 11 is ensured by the rubber-metal sealing rings 21 and 22. Constancy of the processes of forward and reverse movements of the hammer 7 is possible while fulfilling the conditions for flushing liquid removal from the impact chamber 8 by synchronizing the location of the resettable circulation windows 23 of the casing bushing 24 and the circulation holes 25 made in the drainage channel 26 of the hammer 7. The rubber-metal sealing rings 27 exclude unpredictable connection of the circulation holes 25 of the drainage channel 26 with the circulation windows 23 of the casing bushing 24. Smoothness and isolation of the movement between the pair of "external splines 16 of the anvil 11 – internal splines 17 of the casing cup 18" and the casing cup 18 itself is ensured by the sealing element 28. The technological manufacturing of the hydraulic hammer structure and the possibility of its maintenance are also facilitated by the available threaded connections 29 and 30 between the upper lock adapter 1, casing bushing 24, and casing cup 18, respectively. The installation operations with the lower adapter 12 are convenient as there is the recess 31 for the drilling sickle-shaped tongs on its surface. The principle of hydraulic hammer operation in the automatic mode and possible adjustment of the latter are based on the creation of a regular periodic flushing fluid circulation for the hydraulic hammer, which can be achieved by operational transformation of the drilling pump design – a combination of the technological scheme of operation and interaction of plungers, disconnection of a compensator, and modernization of the piston operation cycle.

An abrasive-mechanical impact method is the one that it allows its versatile technological enhancement. Since the basis of the operation of the drilling machines accompanying its technological cycle is transformation of hydraulic energy, which is supplied in the form of a directed flow of flushing fluid, it is important here to preserve maximally the original characteristic hydraulic parameter of the flow – pressure drop (produced by the surface drilling pump) to overcome the resistances in the circulation circuit of the drilling well, i.e. in the percussion machines themselves [17].

Special experimental studies were conducted at the Department of Oil and Gas Engineering and Drilling of Dnipro University of Technology. Their purpose was to clarify the patterns of influence of surface-active substances (surfactants) and polymer additives on hydraulic supports during the movement of liquid through a pipeline [18]. These studies were performed on a special stand (figure 4), where pressure drop ΔP was measured in a standard steel pipe with a diameter of 14 mm and a length of $L = 4.5$ m, through which the NB-11E pump pumped the studied liquids at different speeds (they were controlled with the help of a valve, marked as B in the diagram, figure 4). DT-10 pressure sensors (marked as M_1 and M_2 in the diagram, figure 4), VT-21 equipment complex, and an oscilloscope were used to measure pressure and determine its difference for the solutions and without surfactants and polymer additives at the tube inlet and outlet [19].

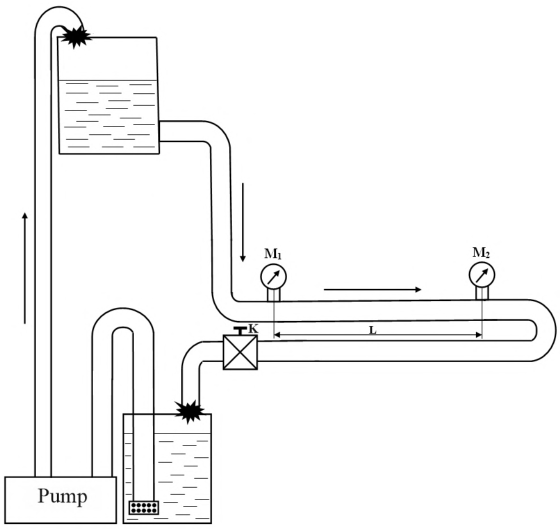

Figure 4. Schematic diagram of a laboratory stand to study hydraulic resistances when pumping liquid through a pipeline.

The next analytical stage of the research involved determining the value of resistance reduction to liquid movement through a pipeline (in%) [20], which we called hydraulic efficiency A calculated according to following formula

$$A = \left(\frac{\Delta P_0 - \Delta P_A}{\Delta P_0}\right) 100\%, \tag{1}$$

where ΔP_0 is drop in liquid pressure at the pipe ends without adding active impurities to the circulating medium; ΔP_A is pressure drop at the pipe ends due to addition of polymers and surfactants to the circulation medium.

Table 1 represents summary data on the determination of a generalized coefficient of hydraulic resistance and so-called hydraulic efficiency A.

Table 1. Influence of surfactants and water-soluble polymers on the values of a generalized coefficient of hydraulic resistance and hydraulic efficiency.

Active additive	Admixture concentration, %	Generalized coefficient of hydraulic resistance	Efficiency A, %
Sulphate soap	0.5 | 1.0 | 2.0	0.031 | 0.027 | 0.027	0 | 12 | 12
Ditalan	0.5 | 5	- | 0.018	- | 42
Metaupon	0.5	0.024	22
Polyacrilamid	0.01 | 0.05 | 0.10	0.027 | 0.017 | 0.015	12 | 44 | 52
Polyoxyethylene	0.005 | 0.010	0.015 | 0.015	58 | 58
Polyacrylonitrile	0.05 | 0.10 | 0.5	0.027 | 0.026 | 0.020	12 | 12 | 35
Polyacrilamid+sulphate soap	0.05 | 0.5	0.015	52
Polyacrilamid+tall oil+OP-10	0.05 | 0.5 | 0.25	0.015	52

While analyzing the data represented in table 1, following conclusions can be drawn: polymer additives and surfactants within a certain range of concentrations reduce hydraulic resistance but the degree of this effect depends on the polymer and surfactant types [21]. The greatest reduction of hydraulic resistances can be obtained with the use of polyacrylamide and polyoxyethylene additives. Moreover, it was found that plant polymers lose their effectiveness during the circulation through a pipeline as a result of so-called destruction of molecules, which is evidenced by a decrease in the solution viscosity. To maintain the duration of the effect of hydraulic resistance reduction, it is necessary to use polymers in combination with additives of special reagents-stabilizers [22].

In general, the task of planning an effective hydraulic washing programme means development of compositions and technology for preparing such washing liquids, which would have simultaneously the following most important properties: reducing the coefficient of internal friction, thereby reducing hydraulic resistance; decreasing the surface tension; reducing the manifestation of friction effect during the rotation and contact of a drillstring and a rock-breaking tool with the rock due to lubrication; and preventing swelling, wetting, and falling of clayey and other unstable rocks.

A significant and still insufficiently used reserve of intensification of downhole breaking processes [23] in terms of simultaneously decreasing power losses for the technologically necessary rotation of a drillstring in the wellbore (table 2) is in the possibility to use special flushing fluids treated with appropriate active reagents of complex effect.

Basing on the analysis of the experimental data shown in table 2, it can be stated reasonably that, of all the considered substances, the greatest reduction in the friction coefficient can be obtained when tall oil is added into the drilling fluid [24].

Since it is established and proven that a decrease in the surface tension of flushing fluids σ [25] contributes to the increased mechanical speed of drilling, complex studies were conducted to clarify the nature of the influence of active components on the technological properties of flushing fluids and the results of breaking processes in their application. The data on the laboratory-stand studied of these issues are represented in figure 5 and figure 6. The change in σ indicators must be considered in the context of complex effect of surfactants on the properties of washing liquids with the corresponding consequences.

Table 2. Results of studying the influence of various active additives in flushing fluids on a steel-rock friction coefficient (simulation of well rotational movement of a drill string).

Active additive (Name)	Active additive (Concentration, %)	Coefficient of friction on rocks (Sandstone)	Coefficient of friction on rocks (Argillaceous slate)
Water (Soap stock)	- | 0.5 | 1.0 | 2.0	0.52 | 0.18 | 0.12 | 0.11	0.40 | 0.34 | 0.23 | 0.15
Water (Sulfonol)	0.25 | 0.50 | 1.00	0.26 | 0.19 | 0.19	0.35 | 0.26 | 0.25
Water (Tall oil)	0.25 | 0.50 | 1.00 | 2.00	0.13 | 0.11 | 0.11 | 0.11	0.29 | 0.15 | 0.14 | 0.14

Clay mud of bentonite powder (Sulfonol)	0.25 | 0.50 | 1.00	0.25 | 0.53 | 0.52	0.46 | 0.46 | 0.45
Clay mud of bentonite powder (Tall oil)	0.25 | 0.50 | 1.00 | 2.00	0.32 | 0.23 | 0.21 | 0.16	0.27 | 0.21 | 0.20 | 0.20

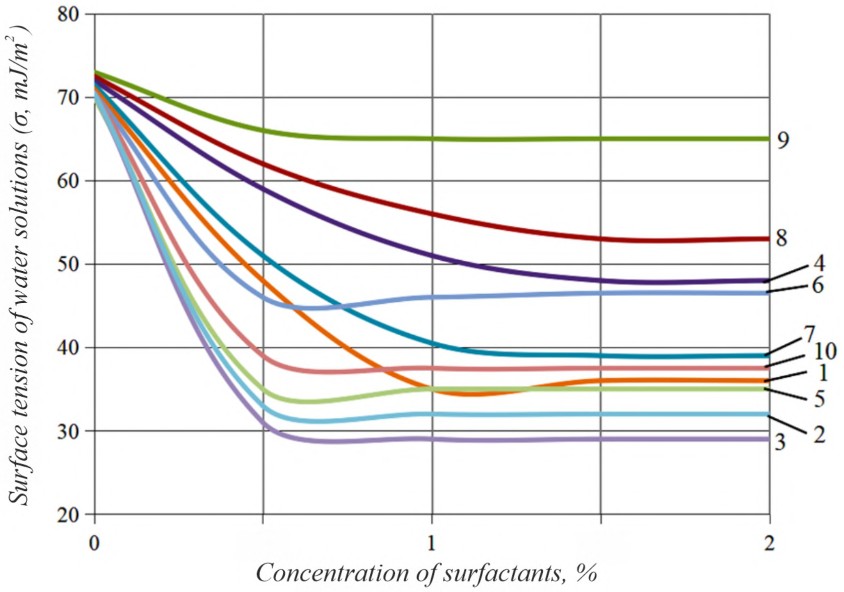

Figure 5. Experimentally determined dependence of surface tension σ of water solutions on the surfactant concentration: 1 – tall oil; 2 – tall oil + sulfonol; 3 – sulfonol; 4 – emulsol; 5 – sulfate soap; 6 – ditalan; 7 – mixture of tars; 8 – katapin; 9 – hydro processed oil sludge; 10 – HFA.

According to the complex experimental data shown in figure 5 and figure 6, following conclusions can be made: when processing washing liquids (in this case, technical water) with the studied surfactants, a decrease, sometimes quite significant, in surface tension σ [26] by 10-240% is observed, and such a transformation of σ indicator is noted in the concentration range of 0.5-1% surfactant (figure 5) [27]. Use of flushing fluids with a reduced σ index during the

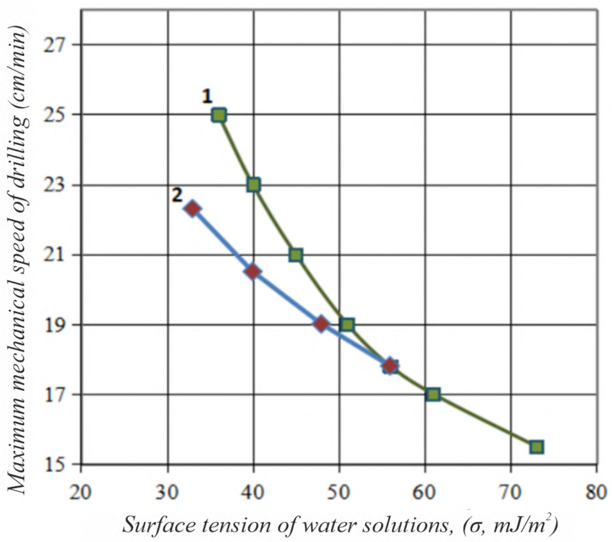

Figure 6. Dependence of the mechanical speed of drilling on surface tension σ of flushing fluids: 1 – percussive rotary drilling; 2 – rotary drilling.

rock mass breaking results in the increasing maximum possible mechanical speed of drilling by the basic 1.6 times for percussive-rotary drilling and by 1.3 times for the rotary method of well construction (figure 6) [28].

The considered technical solutions have a relatively simplified implementation, which, however, did not cause any violations of the completeness of a shock pulse generation cycle [29]. The above also concerns the use of special washing liquids with the activation of some of their general and special functional properties [30].

4. Conclusions

The perspective of thorough analytical development and wide industrial implementation of an innovative abrasive-mechanical impact method of obtaining suitable rock products is shown in the context of the need to increase a well construction rate along with simultaneous reduction of financial and material costs for drilling technological and, immediately, rock-breaking tools. Distinctive features of the specified method are that it requires the use of a special type of rock-breaking elements (in the form of special-design drill crowns and metal hard-alloy balls) as well as jet and percussion hydraulic machines. Such a comprehensively formed bottomhole layout allows intensifying and strengthening significantly the breaking processes and phenomena for rock mass. It can be characterized by current significant technologically controlled development of deformation disturbances in the form of cracks and rock chipping.

There are following particular components to regulate well deepening with the help of balls: speed of applying ball load v to the well bottomhole and axial load C on them during their subordinate movement in the peripheral zone of the well bottomhole. The results of breaking processes make it possible to confirm that the method under consideration demonstrates an increase in the mechanical drilling speed u by a weighted average of 20-30% and an increase in the volumes of breaking zones by 2 or more times in comparison with the corresponding values obtained for the case of static application of axial forces.

The paper represents a technical description of the percussion machine, which can be adapted especially to the conditions of implementation of the abrasive-mechanical percussion method.

The conducted studies show the prospects of using surfactants and polymers as hydraulic resistance reducers (up to 50% or more) in the circulation contour of the well, which will contribute to the additional strengthening of the effect of active washing liquid jets on the rock mass. The use of specified chemically active reagents as a component of flushing fluids also helps reduce significantly the power consumption for drill string rotation in the wellbore by minimizing a coefficient of friction (depending on the type of rocks and flushing fluids, it can be reduced by 1.1-4.0 times and even more). Treatment of flushing fluids with certain surfactant also contributes to the reduction of their surface tension σ, which has a positive effect on the results of destructive processes (due to this, it is possible to increase the mechanical drilling speed by a minimum of 30%, especially the indicated case relates to the technological reception of shock impact on the bottomhole).

Acknowledgments
The authors express their sincere gratitude to the scientific and engineering staff of individual structural divisions of Dnipro University of Technology and "Ukrnafta" PJSC for their constant active assistance during the conduct of complex experimental studies of the technical and technological aspects of some well drilling methods as well as valuable methodological recommendations during the analytical processing of the received data.

Abstract. Modern industrial production is aimed at the development of waste-free technological processes, wider use in the production of waste and by-products. The largest amount of waste is generated from the activities of mining and metallurgical enterprises. One of the problems of foundry production is the disposal of multiton solid waste, about 90% of which is spent molding mixture. Part of the spent mixture is reused as recyclable, but the main mass of it is collected at municipal solid waste landfills. This work is devoted to the study of the component composition of foundry production waste – spent molding mixture with the aim of its reuse. According to the results of the research carried out by the authors, mineralogical recommendations regarding its reuse were provided. Involvement in the reuse of spent molding mixture will allow to free up part of the solid household waste landfills, reduce the negative man-made load on the environment, and additionally obtain conditioned restored molding sands.

1. Introduction

Currently, Ukraine has accumulated about 45 billion tons of industrial waste, located on an area of more than 160,000 hectares. About 1.7 billion tons of new waste is generated every year, while 5-12% of waste is reused, while in developed countries industrial waste is used for 60-80% [1–3].

The largest amount of waste is generated from the activities of mining and metallurgical enterprises. One of the enterprises that uses the metallurgical cycle of processing raw materials is the Kryvyi Rih Repair and Mechanical Plant (Metinvest – KRMZ LLC) in the city of Kryvyi Rih, the main activity of which is the production of machines and equipment for the mining and mining processing industry, parts and components for it, as well as production of steel and iron castings, welded metal structures, stampings, non-standardized equipment for objects under construction or reconstruction. This enterprise includes a full production cycle, from metal smelting to the production of finished products in the form of machines and mechanisms.

The main waste of the enterprise, which can be involved in processing, is generated in the steel casting, mechanical assembly, repair and tool shops, and metal structures shop [4, 5]. The waste of these subdivisions includes: dust from gas cleaning traps (emissions from electric steel melting furnaces in the form of suspended particles undifferentiated by composition), foundry slag, slag, spent molding mixture, welding production waste, abrasive metal dust. Welding production waste and slag are completely disposed of at the enterprise for internal needs, all other generated waste is processed by the enterprise for its own needs in small quantities, and the main volume is transferred to third-party organizations or stored on the factory territory. One of the problems of foundry production is the utilization of multi-tonnage solid waste, about 90% of which is spent molding mixture, which currently belongs to substances of the 4th category of danger [6–8]. A part of the spent mixture is reused as a turnover, for the Kryvyi Rih Repair and Mechanical Plant, this indicator is 10percent of its total mass. The rest is collected at municipal solid waste landfills.

2. Methodology

The current state of production waste was analyzed and compared with global trends. Waste samples were selected by the authors. Chemical analyzes were carried out, granulometric and component composition and the content of impurity elements were investigated. The current state of the situation with industrial waste was analyzed and compared with global trends.

Detailed mineralogical studies of spent molding mixture waste (burnt earth) were carried out. According to the results of the obtained data, mineralogical recommendations for the technological scheme of the processing of the used molding mixture and its reuse are provided.

3. Results

The authors investigated the waste of the steel foundry shop – spent molding mixture (burnt earth), which is formed from foundry molds and rods during the production of metal blanks. After knocking out hardened castings from foundry molds on grids and sieving on sieves, metal blanks and waste are obtained in the form of burnt molding mixture. According to the technological regulations of the Kryvyi Rih Repair and Mechanical Plant, about 10% of the mixture is reused, the rest is transported by road transport to the temporary storage site (figure 1).

Figure 1. Site of temporary storage of industrial waste.

Based on the results of granulometric, chemical, and detailed mineralogical studies of the composition, structure, and texture of the used molding mixture by the authors, it was established:

- The spent molding mixture was represented by a loose, lumpy material of burnt sands of gray, dark gray to black color with a brownish, yellowish tint.

- The structure of the material is psammitic with a minor psephytic component content (figure 2).
- The size of the lumps varies from 1 to 10-20 cm, with mechanical action the lumps are destroyed.

Figure 2. The material of the spent molding mixture.

The lumpiness of the mixture (figure 3) is due to significant heating of the molding mixture during the pouring of the molds. The presence of a metal component (hooks, nails, forming pins) in the spent mixture is associated with their use as an auxiliary material in the assembly of casting molds. After knocking out on the grates, part of the hooks, nails, and forming pins remains in the mixture and falls together with the burnt sand to the temporary storage area.

(a) (b)

Figure 3. Lumpy particles (a) of the molding mixture with individual metal inclusions and metal pins (b) in its composition.

During the selection of initial samples, in addition to the above-mentioned metal objects in the composition of the used molding mixture, individual allocations of residual metal in the form of “beads”, dendrites, and irregular shapes were occasionally observed. The size of the discharges ranged from 1 to 10-20 cm. Large fragments are most often manually selected by the employees of the enterprise from the composition of burnt earth, were identified by the authors during the selection of initial samples at the enterprise and did not fall into the composition of the examined samples of burnt earth (figure 4).

(*a*) (*b*)

Figure 4. Separation of residual metal in the spent molding mixture.

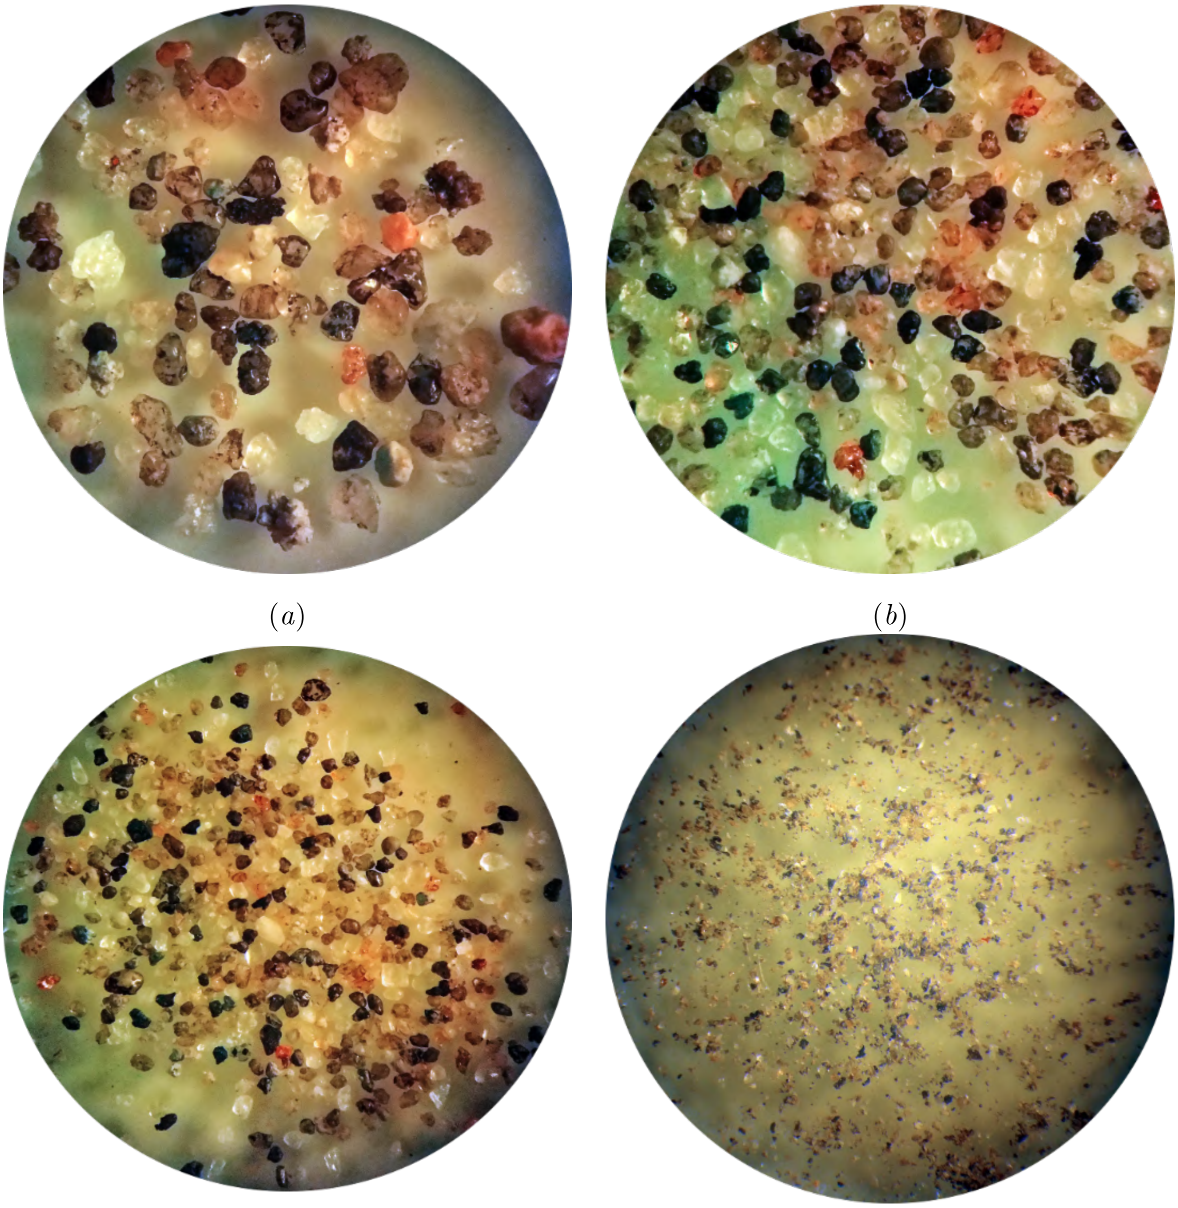
The authors established that the average content of coarse-grained material (particles larger than 0.5 mm) in the composition of burnt earth is 5.1%, the main part of the material (85.4%) is represented by particles with a size of -0.5+0.1 mm. The amount of the most fine-grained (siltstone-pelitic) component is 9.5% (figure 5).

Mineralogical studies were performed by the authors using macroscopic and microscopic methods. According to the results of detailed mineralogical studies, the average component composition of the used molding mixture was determined (table 1).

Table 1. The average component composition of the spent molding mixture.

Components	Content
quartz	91.6
carbonates	0.9
metal component	0.9
oxides and hydroxides of iron	0.4
Total	100.00

The results of a complete silicate analysis obtained by the authors for the material of the spent molding mixture revealed that the product-forming chemical component is silica, aluminum, iron and calcium oxides are of secondary importance (table 2).



(*a*) (*b*) (*c*) (*d*)

Figure 5. Material of selected granulometric fractions of burnt earth: (*a*) granulometric fraction +0.5 mm; (*b*) -0.5+0.25 mm; (*c*) -0.25+0.1 mm; (*d*) -0.1+0 mm.

The significant content of silicon oxide is due to the presence of quartz as the main mineral component in the molding mixture. The increased content of aluminum oxide is associated with the presence of silicates – products of thermal effects on the clay minerals of the primary molding mixture. A noticeable admixture of calcium and magnesium oxides is due to the presence of carbonates represented by calcite and dolomite. The presence of iron oxides is caused by several factors: the presence of iron-containing minerals (magnetite, ilmenite, hematite, goethite, chromite) in the sand of the primary molding mixture; migration of iron from the molten metal to the side of the mold; the presence of iron in the composition of substances used to ensure the strength of forms, their non-stick properties, etc. The relatively high content of alkalis (sodium,

zirconium	248	170	> 1.46

to a small extent potassium) causes the use of liquid glass in the composition of the original molding mixture.

The content of rare, scattered chemical components in the used molding mixture was determined by the authors using the method of semi-quantitative spectral analysis (table 3).

The obtained data were compared with the data on the concentrations of the corresponding chemical components, which reflect the average content of each of them in the composition of the earth's crust. The authors assumed that the Clarke number corresponds to the safe concentration of the corresponding chemical element in both natural and man-made formations. In order to compare data on the average content of chemical components in the composition of burnt earth and their clarke, the Clarke indices of concentrations were determined – by dividing the values of the average content of an element by its Clarke number (table 3). According to the obtained data, all the investigated chemical elements can be divided into three groups:

(i) impurity elements, the content of which is less than clarke (clarke concentration lower than 1.0): silver, cobalt, copper, niobium, nickel, porcelain, lead, zinc;
(ii) elements, the content of which is close to the Clarke number (clarke concentration from 1.0 to 2.0): germanium, tin, titanium, vanadium, zirconium;
(iii) elements, the content of which in the composition of burned earth significantly exceeds the Clarke number (clarke concentration from 5 to 250): bismuth, chromium, molybdenum.

According to the authors, the reasons for significant fluctuations in the content of impurity elements in the material of the spent molding mixture compared to the amount of these elements can be as follows:

– the presence of the investigated impurity elements in the primary material of the molding mixture;
– the presence of these chemical elements in the composition of substances used to ensure the strength of forms, their non-stick properties, etc.;
– different behavior of chemical elements in the technological process (redistribution between the mold and the product, transition to the gaseous phase and evaporation, etc.).

The raw material used in the manufacture of casting molds mainly contains quartz sand and clay minerals (kaolinite, beidelite, hydromuscovite, etc.). They are characterized by a low isomorphous capacity, which is why the content of impurity elements in their composition is very low: for the studied chemical elements, it usually does not exceed 1 · 10-3 – 1 · 10-6 wt.%. The sand may contain accessory minerals, which include the studied chemical elements (ilmenite, chromite, zircon, monazite, rutile, pyrolusite, etc.).

In the process of preparing foundries molds, in accordance with the features of the technologies used, the following chemical components are added to the molding mixture: liquid sodium glass; soluble sodium silicate; lignosulfonate grade A; PLH-1 brand refractory clay; chromite concentrate; furan resin SQG-120; phenolic resin SQJ610; Permabind CO phenolic resin; phenol-formaldehyde resin NOVANOL 160, 165N; zirconium and magnesite non-stick mixtures.

Thus, in the composition of the components that are added to the clay-quartz molding mass, it is possible to distinguish:

– inorganic substances that practically do not contain the studied impurity elements (sodium liquid glass, refractory clay);
– organic substances that do not contain the investigated impurity elements (lignosulfonate, furan resin, phenolic resin, phenol-formaldehyde resin);
– mineral components, which include investigated impurities (chromite concentrate, zirconium and magnesite non-stick mixtures).

That is, in the composition of substances added to the molding mixture, there are two of the 36 investigated chemical components – chromium and zirconium. The technological process is accompanied by:

– partial combustion of organic substances (lignosulfonate, furan resin, phenol resin, phenol formaldehyde resin) with the formation of amorphous carbon present in the form of "shirts" on quartz particles and their cementing substance;

- sublimation of parts of impurity elements characterized by low melting and boiling (evaporation) temperatures: bismuth (melting point 271°C, boiling point, evaporation 1564°C), phosphorus (respectively, 44°C and 277°C), zinc (420°C and 907°C), ytterbium (819°C and 1194°C), strontium (769°C and 1382°C), thallium (304°C and 1473°C), lithium (18°C and 1342°C), stybium (630°C and 1587°C), mercury (-39°C and 357°C);
- redistribution of a part of refractory elements-admixtures (chromium, manganese, titanium, cadmium, molybdenum, cobalt, nickel, zirconium, tungsten) between the outer surface of the casting and the inner surface of the mold.

4. Conclusions

One of the problems of foundry production is the disposal of multiton solid waste, about 90% of which is spent molding mixture [10, 11]. The existing methods of using the spent mixture can be divided into three groups:

(i) use of spent molding mixture without additional processing;
(ii) methods that ensure processing and recycling of production waste at the same enterprise;
(iii) methods of processing and utilization of spent molding mixture in various branches of the national economy.

According to the results of the research carried out by the authors, the following mineralogical recommendations were proposed regarding the technology of processing the spent mixture for the purpose of its reuse:

- due to the presence in its composition of spent mixture of metal inclusions (forming pins, nails, particles of excess metal in the form of beads, dendrites, formations of irregular shape) it is necessary to remove them from the composition of the mixture; at the same time, it is necessary to take into account that individual metal particles can be weakly or non-magnetic;
- the spent molding mixture is a loose, lumpy material of the sand fraction with an admixture of psephyto-siltstone-argillite and pelite components. The lumpiness is due to the presence of impurities used in the preparation of the molding mixture and its significant heating and sintering during the pouring of the molds;
- when drawing up a technological scheme for the processing of the mixture, it is necessary to ensure the destruction of lumpy aggregations of the mixture, the rubbing of quartz particles from silicate-hydroxide “shirts”, the reduction of the number of binding organic and inorganic components on the surface of quartz particles to a level that will allow the separation of aggregations into separate particles;
- restoration (regeneration) of the spent molding mixture can be carried out using mechanical, hydraulic or pneumatic methods.

The spent mixture without preliminary processing can be used as an additive in the production of construction and road construction materials, it must first be cleaned of metal inclusions. In the production of silicate bricks, the spent mixture can completely replace quartz sand. The use of burnt earth will increase the degree of sintering of the brick mass due to liquid glass and alkalis in its composition. Using the spent molding mixture, you can get building solutions, wall stone, concrete products, cinder blocks, foam concrete.

The spent mixture without preliminary treatment can be used for reclamation of spent quarries, backfilling of road surfaces, in the technological processes of solid household waste landfills for overlapping layers as an insulating material in the middle and upper parts of landfills. In road construction, the spent mixture, classified as a special soil and classified as man-made soil (industrial waste), can be used as a component of the upper part of the road surface, for the formation of embankments.

Modern industrial production is aimed at the development of waste-free technological processes, wider use of waste in production and by-products. The reuse of spent molding mixture will allow to free up part of the solid household waste landfills, reduce the negative man-made load on the environment, obtain additional commercial products for third-party consumers, and additionally obtain conditioned reclaimed molding sands.

Abstract. The article provides the basic foundations of the implementation of sustainable development approaches in the world society and their interpretation in mining activities. The study also analyzes the regulatory framework and organizational mechanisms for the implementation of these principles in the Ukrainian mining industry. An analysis of the current state of rational subsoil use and solid industrial waste management in Ukraine is given. The concept of a mining cluster and prospects for its formation in the region of the Kryvyi Rih iron ore basin are substantiated. An algorithm designed to optimize the schedule of mining operations in the mining cluster is described. The Ingulets iron ore deposit was analyzed from the standpoint of integrated development. The reserves of talc shale extracted from the open-pit and stored in a man-made deposit for further sale are separately allocated. The order of mining works for the development of man-made deposits is given.

1. Introduction

The 1992 United Nations Conference on Environment and Development in Rio de Janeiro, also known as the "Earth Summit", announced a new paradigm for human development aimed at implementing sustainable development approaches. One of the results of the conference was the Declaration on Environment and Development, which is largely consistent with the principles of its predecessor – the Stockholm Conference of 1972, as well as its successor – the "Rio+20" Conference held in 2012 [1, 2].

The third principle of this Declaration emphasizes that the right to development must be exercised in such a way as to adequately meet the developmental and environmental needs of present and future generations [1, 2].

With regard to mineral resources, this principle directs society to solve the problem of providing them after the exhaustion of rich mineral deposits. In the context of the mining industry, this means that the slower new mineral deposits are brought into development, the more this principle will be fulfilled. And until humanity finds ways to industrially synthesize materials in sufficient volumes, comprehensive development of mineral deposits is the main direction of the implementation of the third principle of the UN Declaration on the Environment and Sustainable Development.

At the same time, the mineral and raw material base of Ukraine is quite significant on a global scale. Almost 20000 deposits and occurrences of 117 types of minerals have been discovered in the domestic subsoil, of which 8290 deposits and 1110 objects of accounting for 98 types of mineral raw materials are of industrial importance and are recorded in the state balance of mineral reserves, 3349 deposits are being developed [3–5].

The mineral and raw material complex of Ukraine provides a significant share of the gross national product. 48% of the country's industrial potential and up to 20% of its labor resources are associated with the mining industry and the subsequent use of minerals [6–8]. These indicators are quite comparable to the indicators of developed countries with a powerful mining industry. For example, the level of production waste utilization in the advanced countries of the world it reaches 80%. Such tendency of using of secondary resources has place in the Republic of South Africa, Japan, Canada, USA, Great Britain, France, Germany and other industrialized countries [9–11].

Today, in Ukraine numerous minerals are mined in Ukraine, such as coal (1.7% of total world production), commercial iron (4.5%) and manganese (9%) ores, uranium, titanium, zirconium, graphite (4%), kaolin (18%), bromine, ocher, non-ore metallurgical raw materials (quartzites, flux limestones and dolomites), chemical raw materials (native sulfur, rock and potassium salts), facing stone (granites, gabbros, labradorites), glass sand etc [12–14].

At the same time, the difficult economic situation does not allow geological exploration to be carried out sufficiently to reproduce the mineral and raw material base. Since 1994, the increase in explored reserves of most strategic types of minerals in Ukraine has not compensated for their extraction [3, 15].

There are a total of 54 iron ore deposits in Ukraine, of which 22 are in operation. Rich iron ores and iron quartzites are mined in the deposits of the Kryvorizka, Kremenchuk, and Belozirsk iron ore basins. Explored (confirmed) reserves amount to 28 billion tons, their share in the world's confirmed reserves (139 billion tons) is 20% [3, 16–18].

At the same time, the annual volume of waste in Ukraine only in the solid phase is 600 million m^3. 25 billion tons (8,6 billion m^3) of solid industrial waste accumulated to date are located on an area of more than 50000 hectares [19–21].

All this emphasizes the high relevance and paramount importance of the development of iron ore deposits of Kryvbas as a powerful mining complex of Ukraine.

2. Materials and methods

In order to determine how the provisions of the Declaration are implemented by mining enterprises of Ukraine, an analysis of the regulatory framework regulating their activities was performed.

Decree of the President of Ukraine dated July 23, 2021 No. 306/2021 implemented the decision of the National Security and Defense Council of Ukraine, which includes a list of metallic and non-metallic minerals that are of strategic importance for the sustainable development of the economy and the state's defense capability [14]. Iron ores are included in this list.

In the Law of Ukraine "On the approval of the State program for the development of the mineral and raw material base of Ukraine until 2030" [3], among the ways of solving existing economic problems, the "implementation of rational methods of development of complex deposits and extraction of associated components" is listed as one of the main steps to overcome crisis phenomena in the economy.

The Law of Ukraine "On Subsoil" [22], among the main principles of policy in the field of subsoil use, encourages users of subsoil to "rational, integrated use of subsoil ... to ensure the safety of the natural environment".

The Code of Ukraine on the Subsoil, among other things, defines the concept of man-made mineral deposits as "places where the waste of extraction, enrichment and processing of mineral raw materials has accumulated, the reserves of which are estimated and have industrial value" [22].

It is also noted that these deposits may arise as a result of losses during storage, transportation and use of mineral processing products. After the reserves of the man-made deposit have been assessed as industrial, it is included in the State Fund of Mineral Deposits, and all previously assessed mineral deposits are the reserve of this fund. In the same document, it is noted that the exercise of state control over the formation and use of man-made deposits and the processing of mineral raw materials is the responsibility of the Cabinet of Ministers of Ukraine. In turn, the procedure for state accounting of mineral deposits is regulated by the Resolution of the Cabinet of Ministers of Ukraine "On Approval of the Procedure for State Accounting of mineral deposits, reserves and occurrences": "...reserves of minerals are subject to accounting in the state balance sheet separately for each object (deposit, section of a deposit, mine field, etc.) according to the main industrial types, grades, brands, technological groups of minerals in accordance with current state standards, as well as according to the method of development, with allocation of reserves of raw materials suitable for extraction by underground, opencast, hydraulic and other methods" [23].

At the same time, it is obvious that in the long term, the development of man-made objects reduces the environmental load, but during the period of mining operations, the impact on the environment will be greater than from dumps in a re-cultivated state. And according to the law of Ukraine "On environmental impact assessment" "... it is prohibited to carry out economic activity... the use of man-made deposits of minerals, if the full observance of environmental conditions is not ensured" [24].

Carrying out an analysis of the legislator's base on how to develop man-made objects, showing the real imperfection that can be looked over. The above factors make it difficult to transfer man -made objects to the status of man-made deposits with their further development.

The measures laid down in the National Program provide for "...continuation of work on the formation of a database of man-made deposits of Ukraine" [3] and "...geological and economic evaluation of man-made deposits..." [3]. As a result of the implementation of the National Program for the Development of the Mineral and Raw Materials Base of Ukraine until 2030, it was planned to attract an additional 15 million tons of man-made raw materials from 2021 to 2030, that is very little on the scale of waste accumulated annually.

Solving the technological aspects of rational subsoil use begins with determining the schedule of mining operations, which would take into account all types of minerals that make up the deposit. For powerful operating enterprises, the question of choosing the main direction of development of mining works in most cases is already on the back burner, since there are restrictions on objects on the day surface, transport communications in the pit and the current situation of mining works [25–27]. However, the choice of the schedule of mining operations for subsidiary minerals, as well as the determination of the volumes of their extraction and storage in man-made deposits is still relevant. Moreover, variation of volumes and places of extraction is possible not only within the limits of separate mining enterprise, but of an entire mining cluster.

A cluster refers to a set of mining enterprises located in the same region and having stable technological, logistical, economic and financial connections among themselves. The identification of such clusters usually becomes possible when mining enterprises belong to the same owner. Then the market competition between such enterprises disappears and the connections outlined above strengthen. In turn, this strengthens the market positions of enterprises and significantly releases technological potential. The integration of enterprises in such clusters is initially appears in the simultaneous development of natural and man-made deposits with the management of a joint schedule of mining operations, and later – in the management of the schedule of mining operations and the productivity of the entire cluster of enterprises.

The Kryvyi Rih mining region is confidently moving towards the origination of such a cluster. This is confirmed by the purposeful formation of man-made deposits of subsidiary minerals, which takes place despite the difficult economic and technological conditions in the country.

3. Results

The Ingulets ferrous quartzite deposit, which is developed by the open-pit of MPP "Inguletskiy", is complex, since, in addition to the main mineral – magnetite quartzites, it also includes deposits of oxidized ferrous quartzites, manganese ore, granites, talc shale, limestone, etc (figure 1).

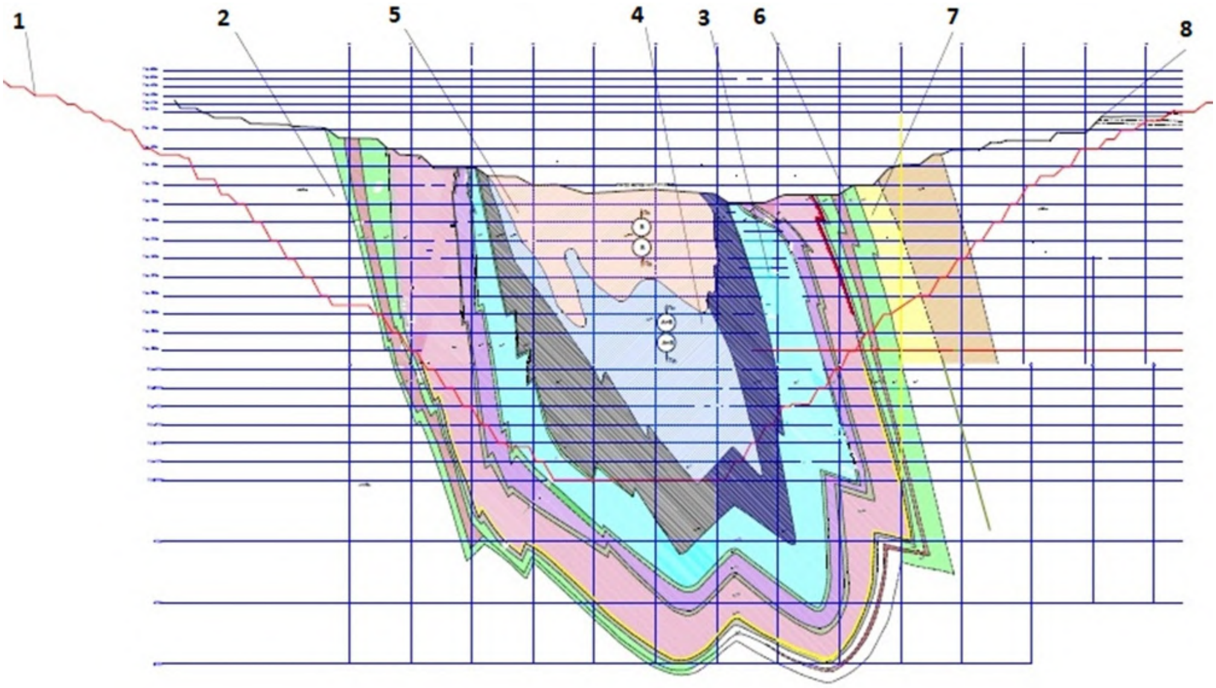

Figure 1. Geological section along surveying axis 70 of the pit of the MPP "Inguletskiy": 1 – project outline of the pit; 2 – migmatite; 3 – magnetite, silicate-magnetite quartzites; 4 – hematite-martite quartzites; 5 – oxidized quartzites; 6 – amphibolite-biotite schists; 7 – talc shale; 8 – the actual position of mining operations.

In addition, magnetite quartzite, which is the main useful mineral, is represented by seven grades of ore with different indicators of the content of the useful component and enrichment. This further complicates the separation of cargo flows by subsidiary minerals.

Moreover, the full realization of subsidiary minerals currently extracted from the open-pit is impossible without temporary storage. This is explained by the variability of demand for minerals and the complexity of managing the schedule of mining operations for them. The figure 2 shows the dynamics of current mining of granites and talc shale from 2013 to 2021. Therefore, there is a need for temporary storage of subsidiary minerals with the formation of temporary warehouses and man-made deposits.

At the same time, the following technological difficulties arise during the exploitation of man-made deposits:

- Selective placement of each type of subsidiary minerals requires alienation of large land areas.

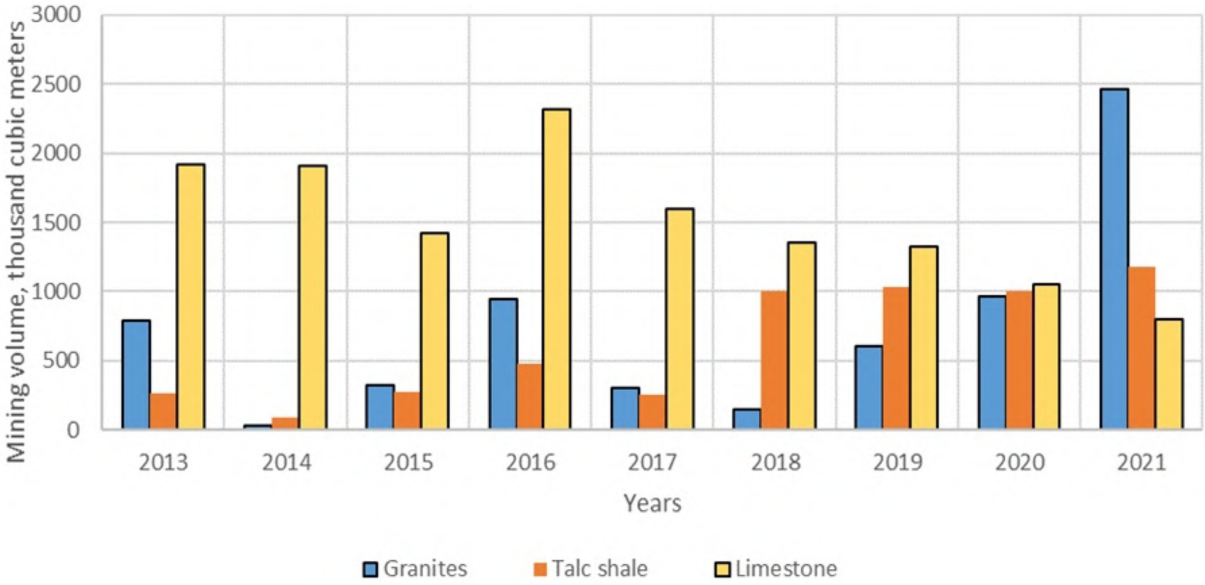

Figure 2. The dynamics of the production of transitory minerals in the open-pit of MPP "Inguletskiy".

- In fact, in the process of waste rock dump creating or storage of man-made raw materials, the accounting of its quality characteristics is not carried out in most cases, and the spatial placement is recorded inaccurately.
- Quantitative and especially qualitative characteristics of man-made raw materials can change over time under the influence of meteorological factors of the external environment (precipitation, groundwater, physico-mechanical and physical properties of the base rocks) and the mutual influence of stored mineral substances.
- Based on the factors outlined above, the geological exploration of man-made deposits is also complicated, since it is quite problematic to take samples in the stratum of a bulk lumpy deposit, and the laws of distribution in space of quality characteristics are not always predicted.

Taking into account all the technological complexities of the development of man-made deposits, the percentage of waste should be reduced as much as possible at the stage of its extraction from the subsoil, and the creation of man-made deposits must be carried out in accordance with the principles of their purposeful formation, and not gross waste formation.

At the same time, it is recommended to realize right out of the open-pit of subsidiary minerals extracted, but here the question arises of determining the schedule of mining operations by subsidiary types. Combinatorial optimization problems can be used to control the mode of mining operations in the mining system as a search for the best element in some discrete set. For this purpose, an algorithm for finding the optimal sequence of extraction of geological blocks was developed.

The proposed algorithm is based on the improved method of determining the schedule of mining operations by Arsentiev [28] in accordance with the principles of reducing the current and boundary stripping ratios [29]. According to the proposed algorithm, the input data is loaded first. In the simplest case, the problem can have a set of flat solutions for each unit of the cluster, which consists of quarries, man-made deposits, storages. Therefore, at this stage, a set of transverse or longitudinal sections should be selected, given in the form of a database of blocks, which contain information about their geometric coordinates, as well as the content of each mineral in each block. The next component of the input data is the forecast level of demand for each type of mineral, which must be satisfied by the regional mining cluster. It is usually projected based on long-term contracts and industry prospects.

Next, the main directions of movement of the bottom of the pits are chosen: behind both sides of the pit, along the hanging and lying sides of the deposit, and behind its center. According to the drawn lines of movement of the bottom of the pit, isolines of equal volumes of mining mass are constructed in automatic mode in accordance with the planned ones. Next, there are calculation blocks that intersect with this deepening line and the corresponding extraction cone is calculated, that is, the volume of rocks that must be removed to work this block. After all the cones for all the isolines are calculated, such cones are found that are characterized by minimal deviations of the actual volumes of extraction from the planned ones, and based on their set, the necessary version of the mining operation schedule is chosen.

Despite the organizational and economic difficulties in Ukraine, MPP "Inguletskiy" continues the policy of sustainable development and rational subsoil use. Thus, a large part of the granites extracted in the process of extracting ferruginous quartzites is used for the internal needs of the open-pit: for backfilling and ballasting of open-pit roads, as well as for the construction of the tailings dam.

Today, talc shale also belongs to the overburden rocks of the open-pit, but earlier they were part of the explored Inguletskiy deposit of brick raw material, which was located directly in the contour of the open-pit's mining diversion. Within the boundaries of the Inguletskiy deposit, the layer of talc shale has a sloping bed with an eastern dip. The thickness of the layer in the south of the site is 18 m, in the northern part -64 m, the most characteristic thickness on average -40 m figure 3.

The talc shale occurs according to the rocks of the first shale horizon and belongs to the

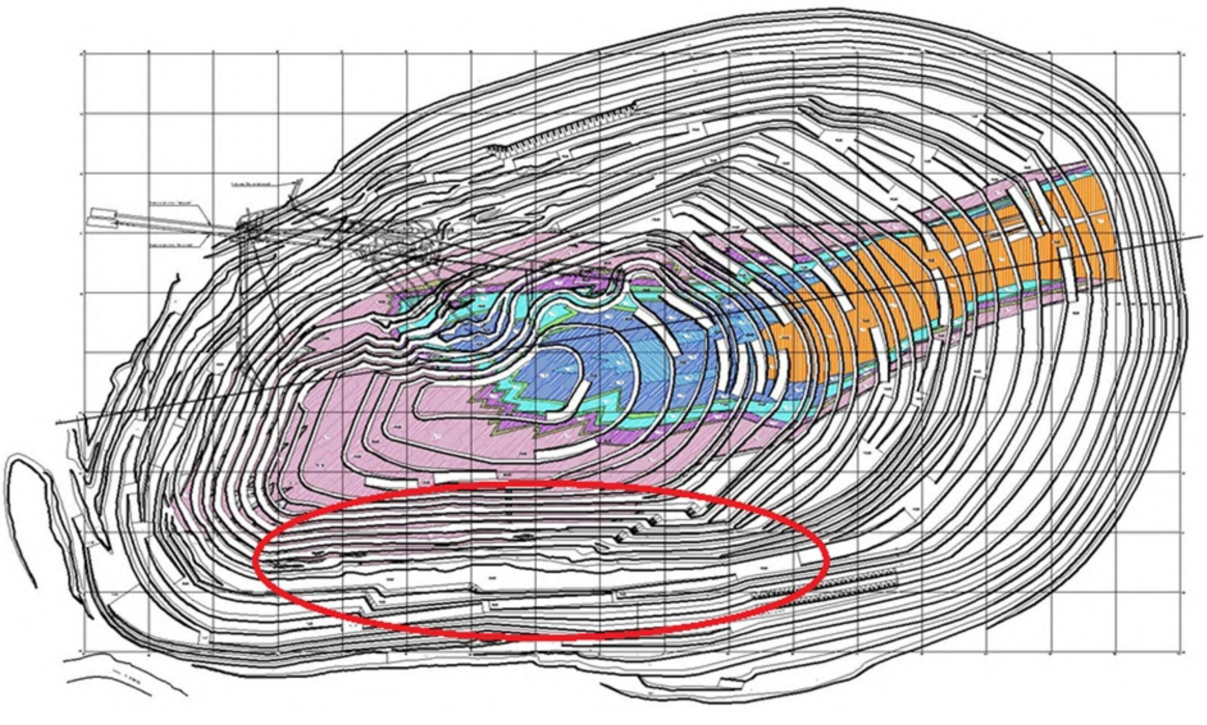

Figure 3. The state of the mining operations of the MPP "Inguletskiy" open-pit for 01.01.2022 with the marked zone of talc shale.

Skelevatska formation, which can be traced in the south of the deposit in the region of the closure of the fold behind the eastern and western wings. The chemical composition of talc shale is given in table 1.

Table 1. Chemical composition of talc shale according to the results of a detailed exploration.

No	Chemical composition	Contents, mass %
1	SiO_2	31.94-48.28
2	Al_2O_3	5.13-15.66
3	Fe_2O_3	0.14-8.43
4	FeO	3.48-13.92
5	MgO	14.28-27.74
6	CaO	0-7.7
7	TiO_2	0.321
8	SO_3	0.11
9	Na_2O	0.1
10	K_2O	0.1
11	others	8.47

According to preliminary estimates of the trust "Ukrgeology", the total reserves of talc shale in the Inguletsk deposit amount to 20-22 million tons with a volumetric weight of 2.6 t/m^3 [30]. Of these, about 200 thousand tons are stored in three sections of a separate part of the waste rock dump, which is a man-made deposit. Areas of storage have a height of 3-3.5 m, the slope angle is 34-38°. The hydrogeological and mining technical conditions allow working out the man-made deposit in an open-pit way. Shales do not require enrichment or processing. Talc shale is planned to be sold in raw form to consumers in Ukraine. MPP "Inguletskiy" plans to conduct their development at the same time in three areas depending on the demand for raw materials.

Considering the low productivity of 20 thousand tons per year, the man-made deposit is expected to be developed in one shift during daylight hours in accordance with the current demand for raw materials. The isolated character of the deposition of man-made raw materials determines the absence of capital and excavation works. To carry out loading work, the use of a CAT-993K loader with a bucket capacity of 10 m^3 or other similar equipment is envisaged. BELAZ-7540B dump trucks with a carrying capacity of 30 tons and BELAZ-7547 with a carrying capacity of 45 tons are accepted as rolling vehicles for internal transport, with further transshipment into railway vehicles.

Thus, the plant intends to ensure the rational use of natural resources, reduce the amount of overburden storage, freeing up space in dumps with an area of 2.68 hectares.

4. Conclusions

The Kryvyi Rih region has all the prerequisites for creating a mining cluster. For this, technological, logistical, economic and financial ties between the "Inguletskiy", "Pivdenniy", "Pivnichniy" and "Centralniy" mining and processing plants and their mineral bases should be strengthened. MPP "Inguletskiy" has significant success in this aspect and can become a driver of such transformations.

Further optimization of the schedule of mining operations within the system of "open-pit-technogenic deposits", and in the future within the mining cluster, will contribute to more complete extraction of subsidiary minerals due to the possibility of meeting demand in a timely manner. In turn, these measures ensure a more complete implementation of sustainable development approaches in the exploitation of mineral deposits by an open-cast method.

Abstract. The dissipative structure (DS) may follow irreversible processes, which occur in the open thermodynamic systems passing and transforming a sufficiently intensive flow of energy. DS can be detected as certain patterns of spontaneous organization in space and time. We consider the DS, which transposes during irreversible ground movement due to landslide or ground pressure manifestation. However, DSs may hide under stochastic noise that impedes their detection. We developed a new method for revealing of DSs in such a stochastic environment using a combination of k-mean clustering, Voronyi tessellation, and the optimal schedule of ground movement monitoring. The developed method has been successfully tested in the case of the irreversible ground movement in the vicinity of a longwall face.

1. Introduction

The majority of processes in the real life are irreversible. According to the modern theory of thermodynamics [1], open systems may spontaneously generate DSs if they pass and transform a sufficiently intensive flow of energy [2]. Investigation of DS promotes a better understanding of the deep mechanism and facilitates more effective control of the complex irreversible processes. In this paper, we consider such processes as landslides [3], sinkholes, and ground movement due to underground mining [4], which expose the environment to the big hazards but effective control of which is far from excellence. A distinctive feature of these processes is that DSs are hidden and it is not easy to reveal them confidently. Traditional approaches propose to describe these processes as definite events allowing their certain parameters [5, 6]. However the modern publications describe the ground movement as a stochastic process [7] and consider its parameters as probabilistic entities [8]. As far as we know, DS has not been revealed during irreversible movement of the ground so far. Recently, DSs were detected for the first time during instrumental observation of a slow landslide development [3] and microseismicity monitoring of the hydrofracturing process [4].

This presentation aims to develop a method that is available to detect DS reliably and unambiguously in processes of ground movement when DS patterns are hidden or veiled under stochastic noise.

2. Interrelation between components of the method

The history of irreversible ground movement depends on the loading path [9]. Therefore, one should monitor the irreversible ground movements as accurately as possible to detect essential features of the irreversible process. Physical modeling is the relevant approach to solve this task considering the trade-off between cost and results. For that reason, we investigated the irreversible ground movement on a physical model constructed of synthetic materials [10].

The height, width, and thickness of the model were 380, 360, and 19 mm correspondingly. We investigated the behavior of an underground opening in the geometric scale of 1:35.8. The synthetic material was made of sand, clay, chalk, and water in proportion 92.26:2.77:1.37:3.6 respectively. The thickness of the rock layers was 2.5–10 mm in the model or 0.089-0.358 m in situ.

The model has been consolidated under the pressure of 89.8 kPa during 15 minutes under vibration with the frequency of 50 cycles and magnitude of 2 mm. The applied pressure was three times as much compared in situ level of the ground pressure. This eliminated possible errors of the ground behavior modeling at the areas where abutment pressure concentrates. The uniaxial compressive strength of the rock was 0.67 MPa in the model or 41 MPa in the real rock mass. Ground pressure was simulated at the top of the model applying the load from 27 to 31 kPa. The movement of the surrounding opening rocks was monitored by a digital camera locating the position of special marks, whereby the standard deviation of the displacement measurement was 0.39 mm or 2.5 pixels on the digital frames. A confidence interval of four, five, and six pixels corresponded to 90.7%, 95.6%, and 99% reliability of the displacement measurement.

The trajectories of the three marks during model testing are demonstrate in figure 1.

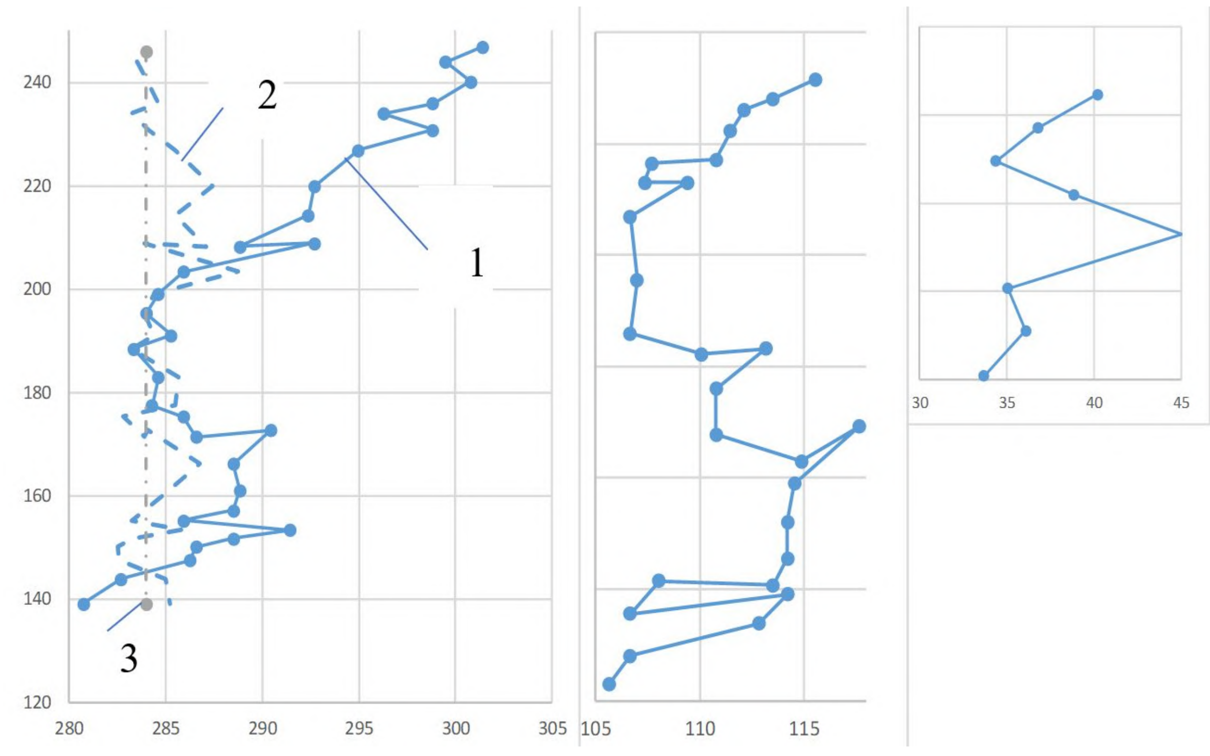

Figure 1. Trajectory of the selected marks.

The marks' coordinates are indicated in pixels. Ten millimeters in the digital picture corresponded to 12 pixels. A separate section of a trajectory reflects a path of the mark between consecutive pictures, which were made on the basis of the constant time interval. We characterize these elementary paths as incremental displacements. It may be seen that the marks change both directions of movement and velocity.

It is important to emphasize the stochastic nature of the displacements although the general tendency of the movement was down to the opening since the marks were selected in its roof. At the same time, one may notice the transversal movements of the marks, which are impossible to disregard. The transversal deviation of the marks is significant and their neglection may cause loss of important information that may be crucial for DS detection.

In the left fragment of figure 1, position 1 indicates the trajectory of the first mark, intermitted line 2 presents the magnitudes of the incremental displacements, and vertical line 3 limits of 90.7% confidence interval. Comparison of lines 2 and 3 shows that less than 10% of the measurements were made with insufficient confidence. However, an increase in the confidence interval simplifies the trajectory and many essential features of the trajectory might be lost. The more interval between successive sessions of monitoring the less valuable information remains. Frequently, researchers monitor the initial and the final state of a landslide that completely deprives any possibility to reveal DS [11, 12] (see the intermitted arrow in figure 2,c).

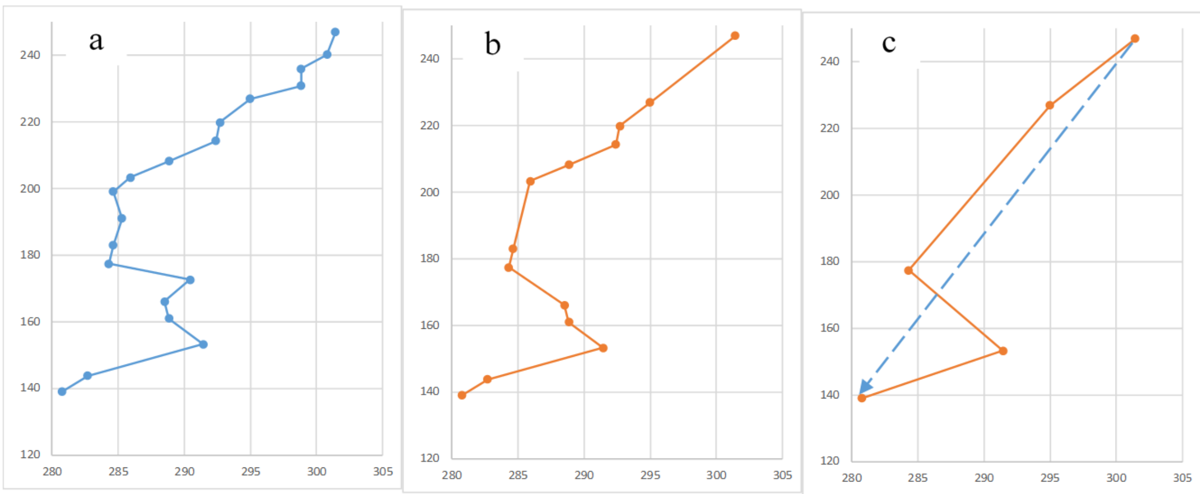

Figure 2. Trajectory of the same mark: a, b, c – 90.7; 95.6; 99% confidence interval.

That is why revealing DS in the ground movement process needs a special approach. First the most informative is the irreversible ground movement because it complies with the thermodynamics of irreversible processes [13]. According to Glansdorff et al [13], an open thermodynamic system strives to minimize the production of entropy if it is not far from equilibrium. The entropy is calculated as the production of thermodynamic forces and flows. Ground pressure and gravity stand for the thermodynamic forces and irreversible ground displacements for the thermodynamic flows.

Second, it is crucial to minimize the error of ground displacement measurements to reveal DS as a fine natural structure, which may hide in the stochastic noise. Evidently, the probability of DS detection is reversely proportional to the error of measurement.

Third, the periods of sequential monitoring sessions should be minimized and complied with the errors of measurements. There is an optimal period that maximizes the probability of DS revealing: a very short interval between sequential measurements increases the cost of monitoring whereas expansion of this period increases the probability that DS will be lost or mixed with other DS.

Finally, the density of the marks or monuments (in situ) in space should be optimized to prevent losses of the valuable information on one hand and to minimize the cost of the monitoring

IOP Conf. Series: Earth and Environmental Science 1254 (2023) 012056 doi:10.1088/1755-1315/1254/1/012056

on the other. The distance between adjacent monuments should be commensurate with the average dimension of the blocks comprising the ground body: shorter distance increases the cost of the detection but the oversized arrangement may cause to lose DS. As the first approximation, the distance between adjacent monuments should be in a range from 2 to 10 of the block's dimension. All the aforementioned conditions should be satisfied to develop a reliable method of DS detection.

3. Development of the method

We used a powerful method of variogram analysis [14] and k-means clustering [15]. The variogram is a statistical second-order moment that is widely used during simulation and analysis of spatial correlation. The variogram $2\gamma(x, x+h)$ for the value of a spatial variable $Z(x)$ at the two points x and $x+h$, which a separated by a vector h, is expressed by variation of the variable difference in the abovementioned points:

$$2\gamma(x, x+h) = E[|(Z(x) - \mu(x)) - (Z(x+h) - \mu(x+h))|2]. \tag{1}$$

where μ denotes an expected value.

Method k-means has been used for simultaneous variance minimization of distances between vectors within a cluster and maximizing of the distance variance between the clusters' centers. The distance between the vectors is determined in Euclid space that has arbitrary dimensions. Importantly, the task of classification of the random variables, and particularly for the detection of DS on a vector mosaic of the incremental displacements of the ground or the rock mass, has no single-entry solution. That is why the possible number of the clusters was first set equal to two and then increased until a certain condition has been satisfied. We controlled the classification process by the variance dynamics of the distances from the clusters' centers to the common center. Notably, we used interpolated field of the ground displacements to calculate the variogram, whereas only factual changes of the monuments' coordinates were involved for the cluster analysis.

The results of calculating the distances between clusters in Euclidean space at the stage when there were seven clusters are shown in the table 1. As the number of clusters increased, the length and orientation of the vectors changed as may be seen in figure 3. Some vectors demonstrated certain stability whereas the other disintegrated to the components. Essential variability of the vectors took place at the initial stages of clusterization.

Thus the only vector marked by a triangle remained almost unchanged when the number of the vectors increased from five to seven. The other vectors changed their length and/or orientation. The process of stabilization of the distances' variances occurs both between the vectors in every cluster and among the clusters as is illustrated in figure 4. The distance variance

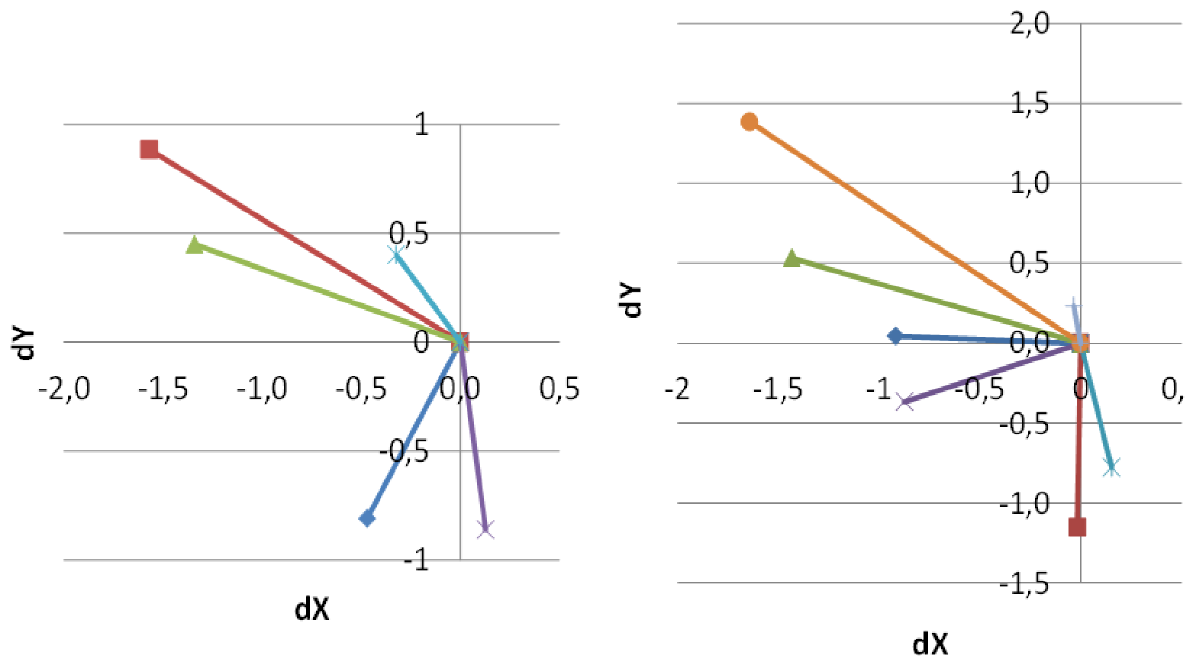

Figure 3. Evolution of the cluster parameters due to increasing of their number.

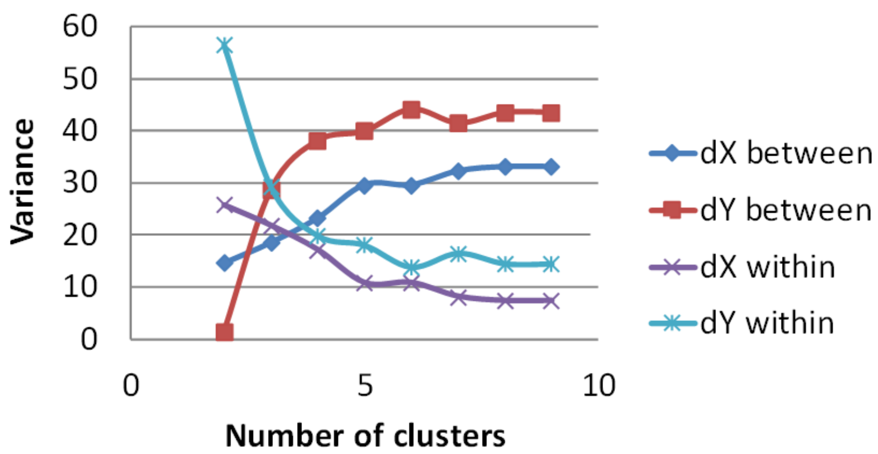

Figure 4. Illustration of the variance stabilization.

is shown separately along the X and Y-axis. Importantly, clusterization of the vectors was made according to their components separately.

As it can be seen the stabilization of the variances occurs for both components of the vectors after the number of the clusters increased to nine. Nonetheless, further prolongation of the clustering has shown that the k-means algorithm finds a more fine difference between clusters as the number of clusters grows. Evidently, the algorithms will start to classify the vector mosaic according to the signs, which have not physical but stochastic nature. Therefore, an auxiliary criterion is needed to determine the moment when the clusterization process should be terminated.

According to thermodynamics, the most probable state of ground corresponds to the maximum of its entropy [13]. This state can be expressed by the Boltzmann-Shannon formula:

$$S_i = -k \sum p_j ln p_j, \ 1 \leq j \leq N. \tag{2}$$

where S_i is entropy, p_j is the probability that j-th cluster will emerge, k is a constant, N is the total number of clusters.

The entropy S_i reaches the maximum when probabilities of all clusters will be equal, namely:

$$p_j = \frac{1}{N}. \tag{3}$$

In this case the entropy production $\frac{dS_i}{dt} = 0$.

In this situation, the results of monitoring have a certain error, and condition (3) is impossible to reach. Nevertheless, this condition is a threshold to which cluster probabilities may be reduced. In order to do this, we counted the number of cases when the same cluster occurred due to the increase of the clusters' number in the limits of measurement error.

Then we calculated the entropy according to formula (3) and reduced it to S_i. Tests demonstrated that it is possible to fix the moment when the entropy reaches the extremum and this is expedient to terminate the clustering process.

Another problem concerns the determination of the cluster boundaries. The practice has shown that adjacent clusters overlap and this introduces uncertainty. To solve this problem, we used Voronyi tessellation [16] that determines a crisp boundary between adjacent clusters as the lines, which are normal to the lines joining the clusters' centers. These locations of the boundaries correspond to condition (3) that minimizes the error of measurement of the monuments' position.

4. Testing of the method: a case study

We tested the developed model on a case of rock mass subsidence in the vicinity moving longwall face. A base friction modeling has been used to imitate the ground displacement due to a coal seam extraction.

Rock mass was modeled with discrete elements, which have been stacked on a desk within a rectangular frame. The gravity was simulated by the traction of the frame along the deck. We regulated the rate of the longwall movement by the incremental step of its advance along the coal seam. The more the step was between serial pictures the more the rate of the longwall advance.

At the first glance, the appearance of the model on both pictures in figure 5 is identical. However, the incremental displacements are essentially different.

The incremental displacements of the marks in the moments when the longwall was replaced from positions 5852 to 5853 and 5853 to 5854 respectively demonstrate figure 6, figure 7. The displacements, which are confined within the boundaries were registered with 90% reliability. The overlay of the vector displacements and Voronyi tessellation are depicted in figure 7.

Meaningful clusters of DS are marked with numbers from 1 to 6. The distances between clusters were calculated according to both orientations of the displacement vectors and their magnitudes (table 2). Seemingly, some clusters may contain different vectors (figure 7).

However, k-means method ensures that the difference among the vectors within a cluster will be minimal according to all their parameters. Analysis has shown that the developed method is efficient because the classification grasps the physical meaning of the irreversible process of the ground movement. For instance, clusters 1 and 2 are found beyond the zone of active movement. These clusters moved to the gob or zone of the smooth sagging where the ground pressure was on the way to its recovery. Displacement vectors of cluster 2 turned to the longwall advance direction whereas cluster 1 oriented downward and slightly to the gob. Cluster 4 is located at

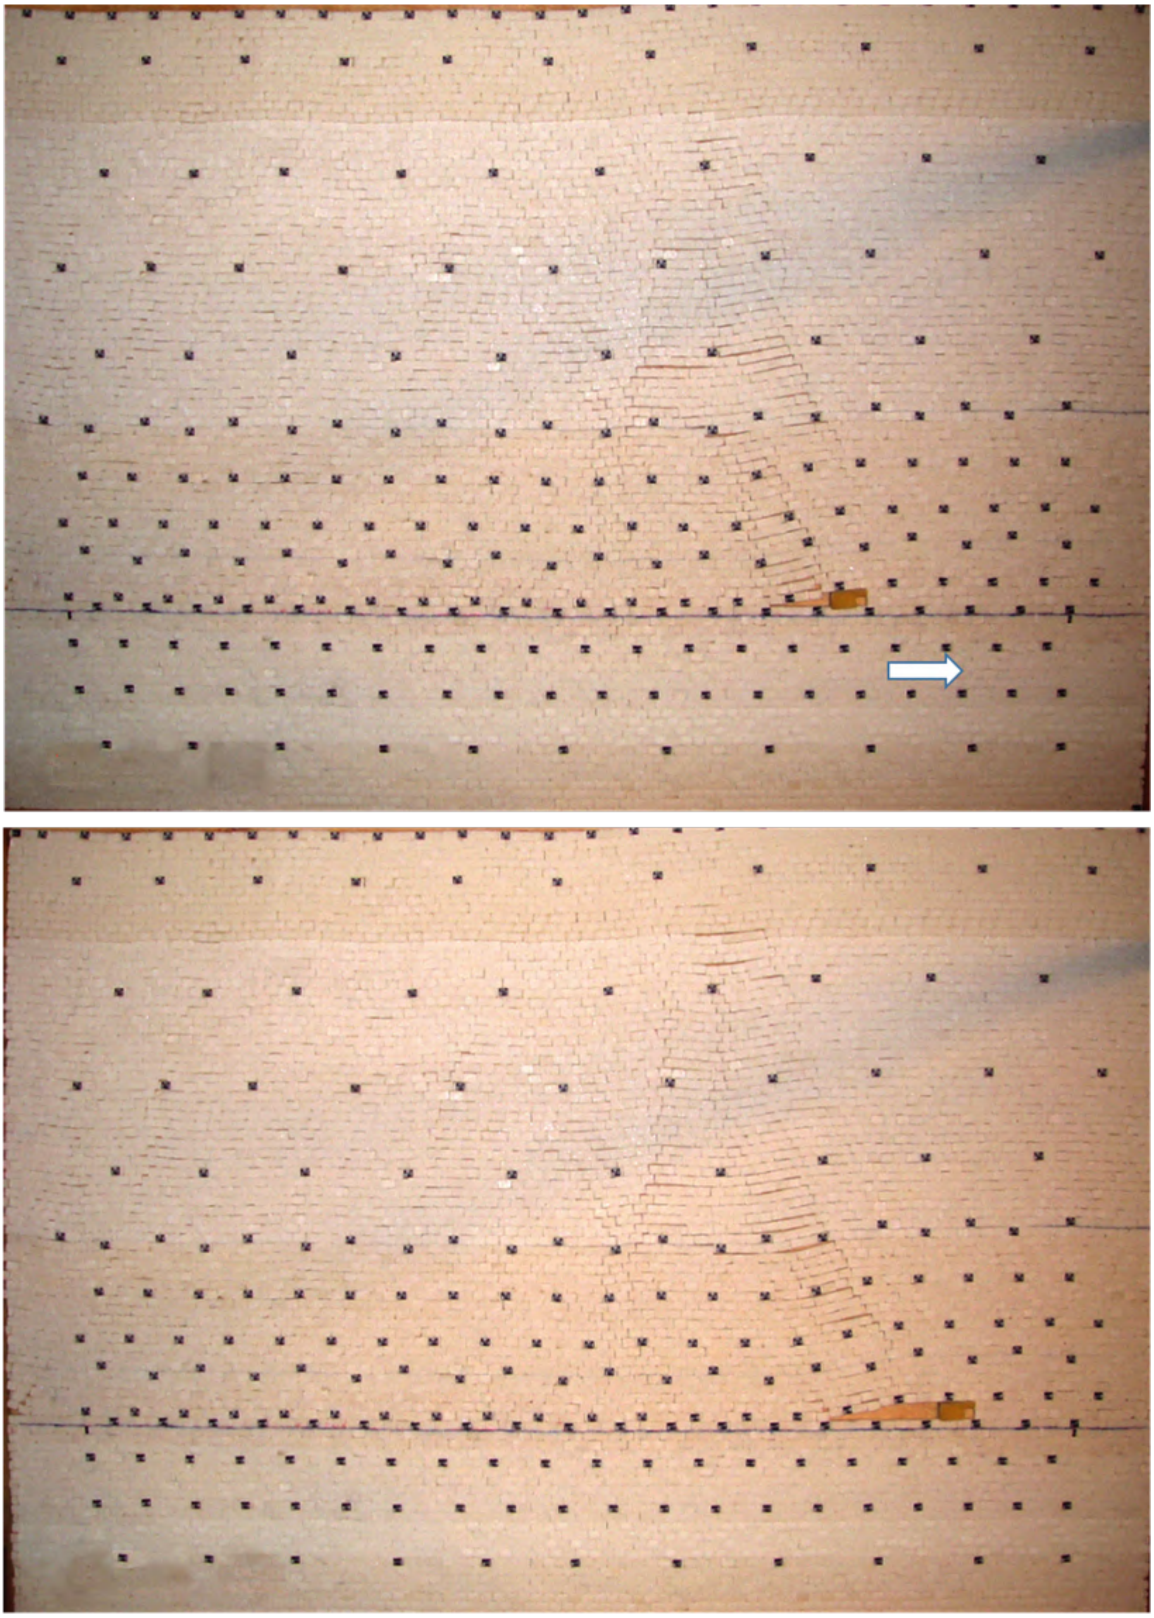

Figure 5. Digital pictures of successive positions of the longwall.

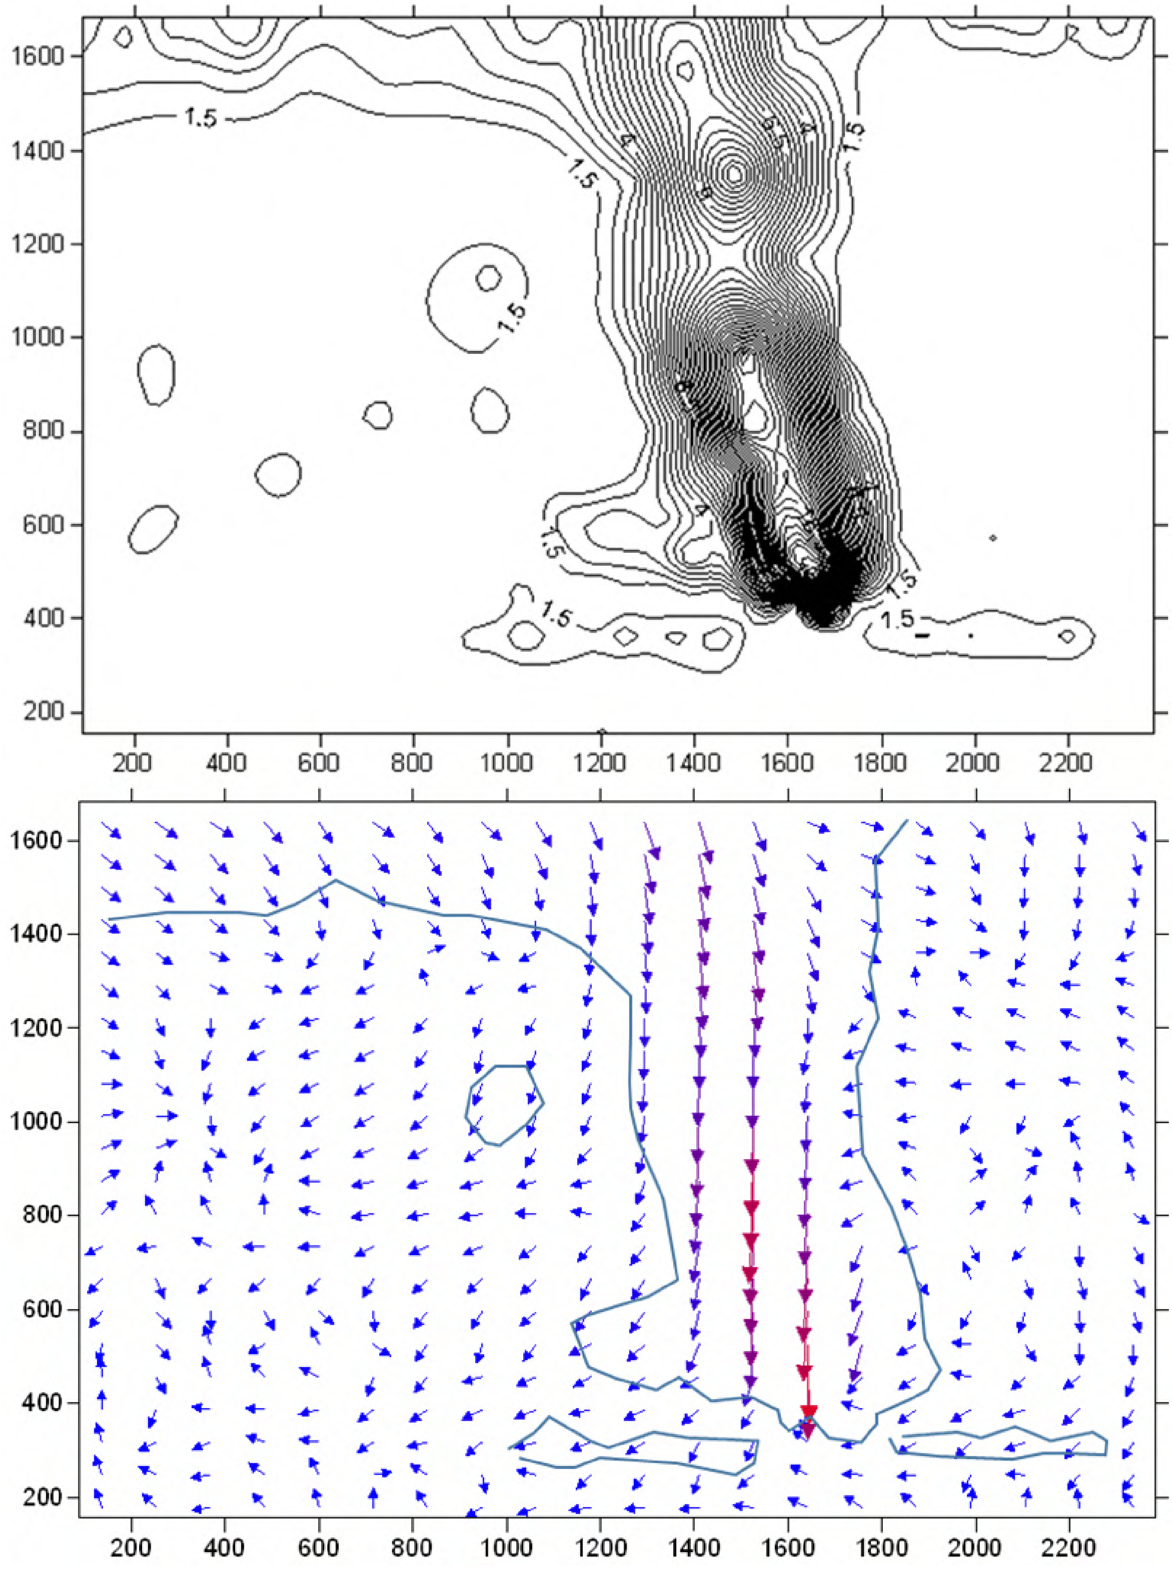

Figure 6. Incremental displacements of the rock mass between positions 5852 and 5853.

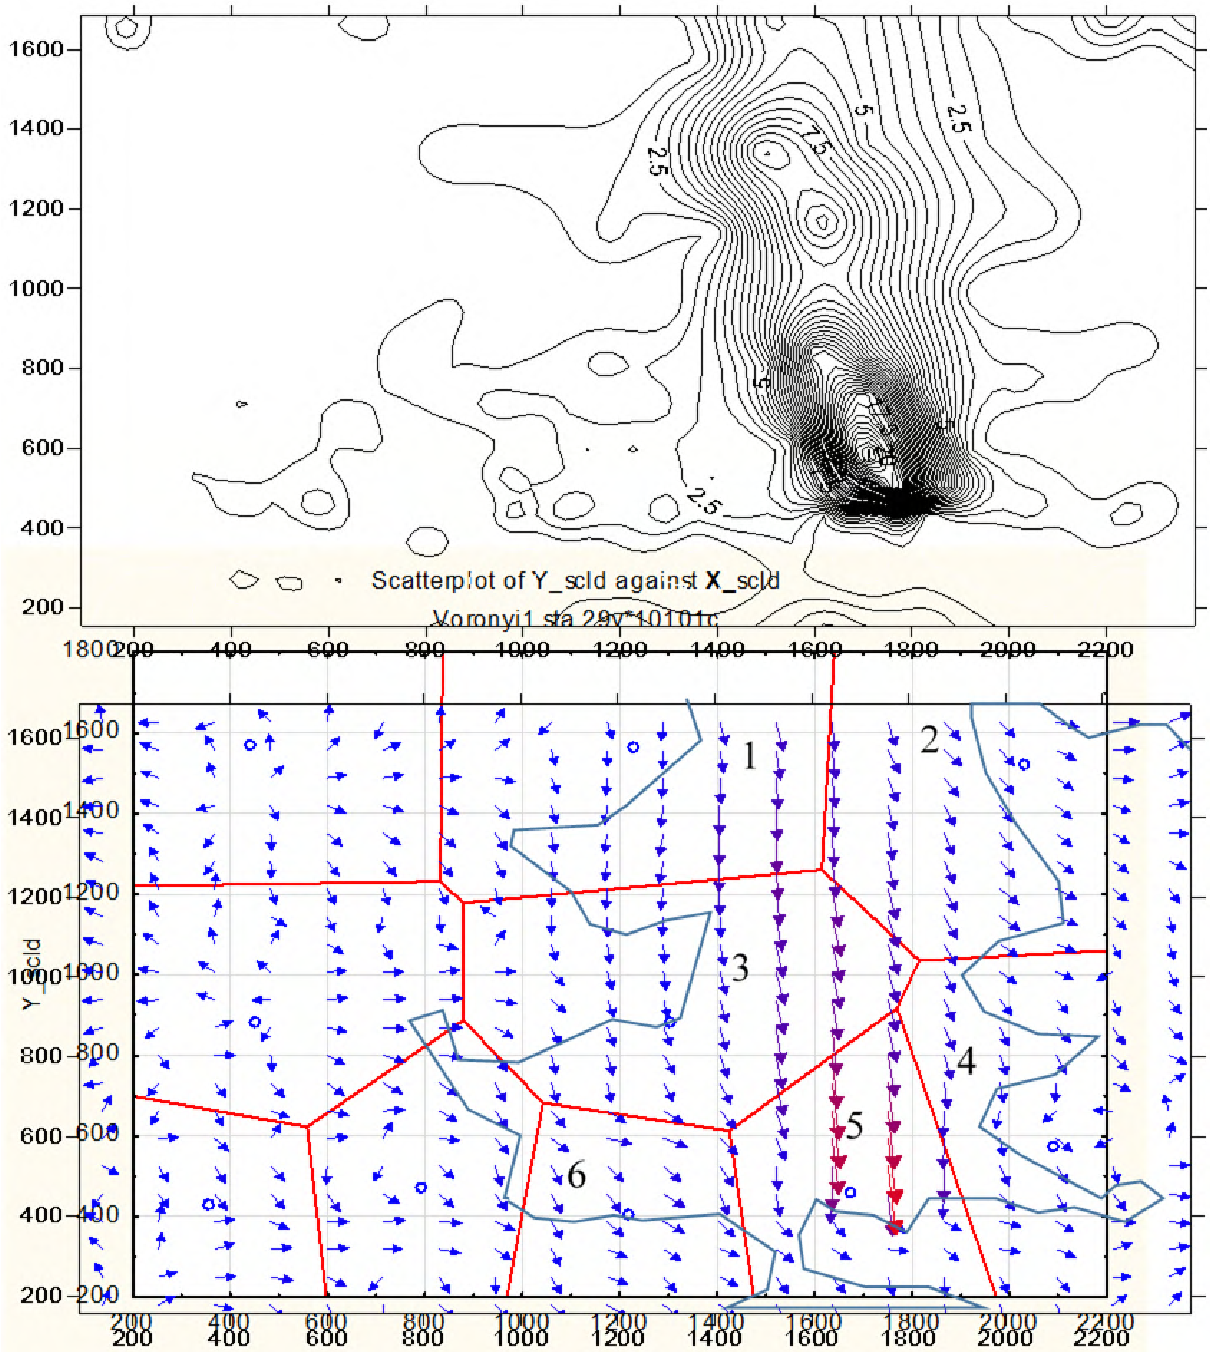

Figure 7. Overlay of incremental displacements of the rock mass between positions 5853 and 5854 and Voronyi mosaic.

the rib of the coal seam in the so-called abutment pressure zone. Cluster 5 encompassed the zone where the most active subsidence occurred over the longwall void. Clusters 3 and 6 shifted to the gob where the caved rocks consolidate, although the displacement vectors of cluster 6 have an apparently bigger component in the direction of the longwall advance. Therefore the developed method of clusterization facilitated the revealing of DS localizing not only the cluster boundaries but accounted for the physical meaning of the irreversible processes that follow the

Table 2. Distance between meaningful clusters.

Number of cluster	1	2	3	4	5	6

ground movement.

Let us pay attention to the position of the immediate roof that was at the distance of 4 m from the longwall face or at the rear part of the powered support canopy when the face was in the previous position (5852). However, this roof kept still hanging after the next step advance of the longwall to the distance of 4 m. It would seem the incremental displacements of the rock mass may be neglected, although DS can evolve essentially even for such a short period.

The dramatic difference between the displacement distribution is that all vectors are oriented downward and to the left or the gob in figure 6 whereas they turned to the right of the face at the next step increased by only 4 m. In addition, the area of the rock mass expanded where the incremental displacements were detected with the confidence of more than 90%. Such a difference is not random and may be explained from a physical point of view.

The maximal incremental displacements occur in the zone of maximum sag and possible delamination of the rock layers. The pictures in figure 5 and distributions in figure 6 highlight this zone that is inclined to the horizon under the angle of 700. This complies with a common vision of the subsidence mechanism. The strata caves as cantilever beams, which disconnect from the solid rock mass on one hand and rotate in figure 5 clockwise on the other. This rotation brings closer the rear end of the cantilever beams to the longwall face. These two opposite incremental movements prevailed by turn, in successive order: at the stage 5852-5853 the disconnection component moved the undermined strata to the left or the gob while the strata shifted to the right at the next step 5853-5854. Such maneuvers become possible due to DS evolution and our method allowed distinguishing this fine behavior of the rock mass. Let us stress that almost all displacement vectors abruptly turned from the left to the right dramatically changing the pattern of DS.

Based on [13] it may be suggested that such a sharp replacing of the DS pattern might be caused by a small fluctuation of the ground pressure. Some displacement vectors change their orientation to 10 pixels exceeding the error of measurements by order.

5. Conclusion

The ground movement is a typical irreversible process that exposes the environment to hazards during landslides, sinkholes, hydrofracturing, and other dangerous and poorly predicted events. According to thermodynamics, such irreversible processes may be followed by DS, which can be used to control the ground effectively. However, DSs are difficult to detect and identify because of the stochastic nature of the irreversible ground movement.

We have formulated several conditions that should be satisfied to develop a reliable method of DS detection. First the most informative is the irreversible ground displacements because they comply with the thermodynamics of irreversible processes. The irreversible displacements represent the thermodynamic flows, which generate the entropy acting together with the thermodynamic forces that are expressed as the ground pressure. Second, it is crucial to minimize the error of ground displacement measurements to reveal DS as a fine natural structure, which may hide in the stochastic noise. Third, the periods of sequential monitoring sessions should be minimized and complied with the errors of measurements. There is an optimal period that maximizes the probability of DS revealing: a very short interval between sequential measurements increases the cost of monitoring whereas expansion of this period increases the probability that DS will be lost or mixed with other DS. Finally, the density of the marks or monuments in space should be optimized to prevent losses of the valuable information on one hand and to minimize the cost of the monitoring on the other. The distance between adjacent monuments should be in a range from 2 to 10 of the rock mass block's dimension.

We used the variogram algorithm and K-means method of clustering to detect DS. The number of the clusters was assigned starting from two and sequentially increased until the minimum distance variance between the displacement vectors within the clusters and maximum of the variance between clusters stabilize. We proposed an auxiliary criterion for termination of the clustering process as the minimum entropy production.

The developed method of DS clustering has been tested successfully in the case of the irreversible ground displacement around moving longwall face. The new method not only revealed specific patterns of the DS but complied with the physical sense of the irreversible ground movement.

Abstract. Underground mining has a significant influence on ground movement, which induces serious environmental disturbances on land. Movements of the rock strata can be the cause of changes in the hydrogeological regimes of groundwater. As a result, the risk of flooding of the longwalls goaf increases. The specific phenomenon of the Ukrainian Donbas is the flooding of the underground roadway system at the result of the closure of the mines. Water saturation of rocks leads to a decrease in its strength. The result is repeated subsidence. The activation of the ground movement processes over the longwall goaf due to their flooding has not been studied enough. In this paper, for the geological conditions of thin coal seams typical for the Ukrainian Donbas, ground movement evolution caused by flooding of longwalls goaf was studied. Ansys code was used to analyze the evolution of surface displacement in different hydrogeological conditions. As a result of numerical simulation, it was found that full flooding of the longwall goaf leads to an increase in surface subsidence by 22.4%, while the length of the trough increase by 1.3%. Maximal inclination increases by 34.4%, and maximal curvature – by 74%. This contributes to a significant increase in hazards for surface infrastructure located on the edges of the subsidence trough. The control of the negative impact on surface infrastructure objects, water and agro-industrial objects can be ensured by a timely prediction of ground movement and the implementation of surface controlling methods to prevent critical surface deformations.

1. Introduction

The underground mining causes a failure of the equilibrium state in the rock strata, provokes irreversible deformations and movements of rocks in the undermining zone. Underground mining has a significant influence on ground movement (also known as subsidence), which induces serious environmental disturbances on land [1]. These phenomena have a negative impact on surface infrastructure objects, water and agro-industrial objects, specific objects mining companies such as waste rock dump [2].

In fact, back to the early days of the 1960s, the processes of ground movement and deformations in the zones of longwall undermining had been studied. The study of the subsidence phenomena and its negative impact on surface is carried out by the following methods:

- by field monitoring [3–6];

- by physical similar simulation [7–9];
- by numerical modeling [10–20].

Zhang et al. [3] presented a study of field measurement and numerical simulation on mining-induced subsidence in an area of Northwestern China. The panels with dimensions 241 m wide and over 3000 m long were extracted. It was showed that surface subsidence lags far behind panel extraction; the subsidence influence through the whole length of a longwall panel varies.

Guney and Gul [4] described and discussed the evaluating of the influence of subsidence on irrigation pipeline structure based on the field data using surface deformation prediction system software.

Zhao et al. [5] reported an analysis result of the eld investigation of the ground ssures and the establishment of GPS monitoring network. The ground deformation and damage has been monitored and researched for the 10 years. The maximal vertical displacement reached 1,720 mm and accompanied by the rapid development of ground ssures.

Nazarenko and Stelmaschuk [6] developed a spatio-temporal model of the formation of a displacement trough for the conditions of coal mines in Western Donbas based on the results of field instrumental monitoring. A new type of isolines is proposed - chronoisosediments, which characterizing the time and place of occurrence of subsidences.

Zhou and Yu [7] presented results of the physical simulation experiment. Based on the microseismic energy distribution cloud chart, the area of water-conducting fracture zone was divided. After fully mining, the overburden caving height was stable, and the height development range of the water-conducting fracture zone was 100120 m, which is consistent with the height of the overburden caving envelope.

Yanli et al. [8] studied the movements of rocks of the upper layers, which were provoked by mining operations, analyzed the regularities of the evolution of cracks using the methods of measurement and physical modeling.

Stupnik et al. [9] proposed a method to determine quantitative composition of the equivalent material for the study the rock mass stability in the laboratory conditions.

In world practice, the software package Surface Deformation Prediction System (SDPS) has gained wide popularity [10–12]. Based on empirical or site-specific regional parameters, the model quantifies a variety of ground deformation indices for both longwall and high extraction room-and-pillar mines [13].

However, since SDPS is based on statistical analysis, it does not provide an opportunity to investigate the mechanism of activation of subsidence in non typical geological conditions, for example during the flooding of mine roadway system.

Methods of numerical modeling have not these shortcomings. Various software systems are based on the finite difference method (FDM), (FLAC3D) [14, 15], finite element method (ANSYS) [16–20], method of discrete elements [21].

Jeromel et al. [14] presented results of the numerical simulations of sub-level coal mining by FLAC3D. The simulation results are comparable with the values obtained by the in-situ measurements during coal excavation in the Velenje Coal Mine.

Zhao et al [15] presented a case study on predicting the distribution of the ground ssures and water-conducted ssures induced by the coal mining. The analysis of the calculated by FLAC3D movement and deformation of ground surface and strata allowed to predict the distribution of ground ssures and water-conducted ssures.

A finite element analysis was performed by Marian et al [16] to study the state of stresses on the structures of buildings subjected to the impact of underground mining of hard coal seams in the Jiu Valley Basin.

The prediction of subsidence by the finite element method was in the center of attention of scientists of UkrNDMI. For example, Sakhno et al [17] presented the simulation results of ground movement and deformations, which is based on a numerical nonlinear solution by ANSYS. An example of the calculation of displacements for the conditions of the mine "Krasnolymanska" was given. Grishenkov and Golubev [18] presented the results of the numerical simulation of water inflow in mine roadway to the activation of subsidence over a single longwall. ANSYS code is widely used to analyze the stability of rock outcrops [19, 20].

Zhang et al. [21] proposed a locally adaptive remeshing method for FDM modeling of largely deformed surface subsidence induced by underground mining. The effectiveness of the proposed method has been veried by comparing the surface deformation for the Yanqianshan iron mine.

This analysis shows that modeling by numerical methods allows to visualize the process of deformation of rock and the surface and obtain sufficient accuracy of the modeling results.

The basic regularities of the subsidence are sufficiently well-studied and they are the basis of relevant normative documents that take into account regional character. For the conditions of the Ukrainian Donbas, the parameters of the subsidence trough are calculated in accordance with the DSTU 101.00159226.001-2003 "Rules of undermining Earth surface objects" [22]. This makes it possible to predict subsidence in conditions of homogeneous rock with sufficient accuracy.

However, geomechanical processes can differ significantly from idealized ones due to the presence of systems of geological fissures, rock heterogeneity, hydrogeological processes, etc. These special situations are the subject of research of scientists.

Movements of the rock strata can be the cause of changes in the hydrogeological regimes of underground and groundwater. As a result, the risk of flooding of the longwalls goaf increases.

Another phenomenon that is specific for the coal mines of the Ukrainian Donbas is the flooding of the underground roadway at the result of the closure of the mines and the increase in the mine water level. The risk of increased water inflows into roadways system due to mining stoppages caused by military operations is increasing. Flooding causes changes in the physical and mechanical properties of rock mass, provokes the development of deformation processes in the rock strata, and deepens the negative consequences of undermining.

The intensity of flooding and the geometry of flooded zones are determined by technological factors that depend primarily on the technology of longwall mining. Cavities and open cracks are the main ways of underground water transit.

Nowadays, scientists are paying more attention to the impact of undermining on groundwater system and on surface water objects. For example, Booth et al. [23] discussed the impact of mining on groundwater including decline and recovery of water levels. Dawkins [24] discussed potential management and rehabilitation requirements of environmental effects from longwall subsidence on streams, lakes, and groundwater systems.

However, the activation of the ground movement processes over the longwall due to their flooding has not been studied enough. Water saturation of rocks leads to a disturbance of the equilibrium in the rock stratum and to the destruction of previously formed equilibrium vaults, as a result of a decrease in the strength of the rocks. The deformation characteristics of the rocks are also changing. The result is repeated subsidence.

These phenomena show the importance of timely prediction of subsidence and the development of methods for the protection of surface infrastructure objects due to the flooding of the roadways system of coal mines.

In this paper, for the geological conditions of thin coal seams typical for the Ukrainian Donbas, through numerical simulation ground movement evolution at the result of flooding of longwalls goaf was studied. This study provides a characteristic on the influence of mine water rising level of longwalls goaf on the activation of subsidence.

2. Characteristics of the study area

The case study mine is located in the west-southern part of Pokrovsk region, Donbas, Ukraine.

The Selidove city is located near the western border of the mine field. The villages of Novomykolaivka, Mykhailivka and Kotlyarevka are located within the boundaries of the mine field and near it. Mykhailivka and Marynivka villages are located in the undermining zone.

The average annual water inflow is 500 m^3/year. The rock strata above the southern part of the mine field, namely 1 and 2 the southern longwall the l1 seam, are the objects of the study.

The average thickness of the coal seam in the studied area was 1.05 m, the dip angle varied from 11 to 13 degrees. The research area included two longwall goafs. The depth of the ventilation roadway of the 1th southern longwall of the l1 seam is 376 m; the depth of the conveyor roadway of the 1th southern longwall of the l1 seam is 476 m.

The Donetsk-Novogrodivka highway, Donetsk-Selydove highway and Mykhailivka village located on the undermining surface. The part of the mine plan with surface objects is shown in figure 1.

The highway Donetsk-Selidove is in the undermining zone of southern longwalls. At the same time, the highway located almost perpendicular to the seam strike line. This line is marked as a section line (figure 1) for a numerical simulation.

3. Methods

We used method of numerical simulation and method of engineering and graphic analysis to investigate surface subsidence in undermining zone.

During the analytical analysis of ground movement elements on land, calculations and graphic constructions were carried out, in accordance with the recommendation of normative document DSTU 101.00159226.001-2003 [22].

Traditional ideas about overburden deformation zones caused by longwall subsidence were accepted. The height of the caved zone was taken equal to 8 times the thickness of the seam. The height of the fractured zone was 60% of the length of the longwall, which corresponds to generally accepted ideas [25–27].

Mine water level rise and goaf flooding were modeled in two stages. At the first stage, the height of the flood level was 40% of the height of the fractured zone, at the second stage – 100% of the height of the fractured zone. Schemes of deformation zones caused by longwall subsidence and subsequent flooding are shown in figure 2.

Finite element analysis software system Ansys was used. The modeling was carried out in a volume setting on a natural scale. Due to the obvious symmetry of the model with respect to the length of the panel, the thickness of the model was assumed to be much smaller than its other dimensions and was 10 m. The sidewalls of the model were fixed from the corresponding normal displacement, the bottom boundaries – from vertical displacement. The model was loaded by gravitational forces. The Drucker-Prager model was used to simulate the behavior of rock mass.

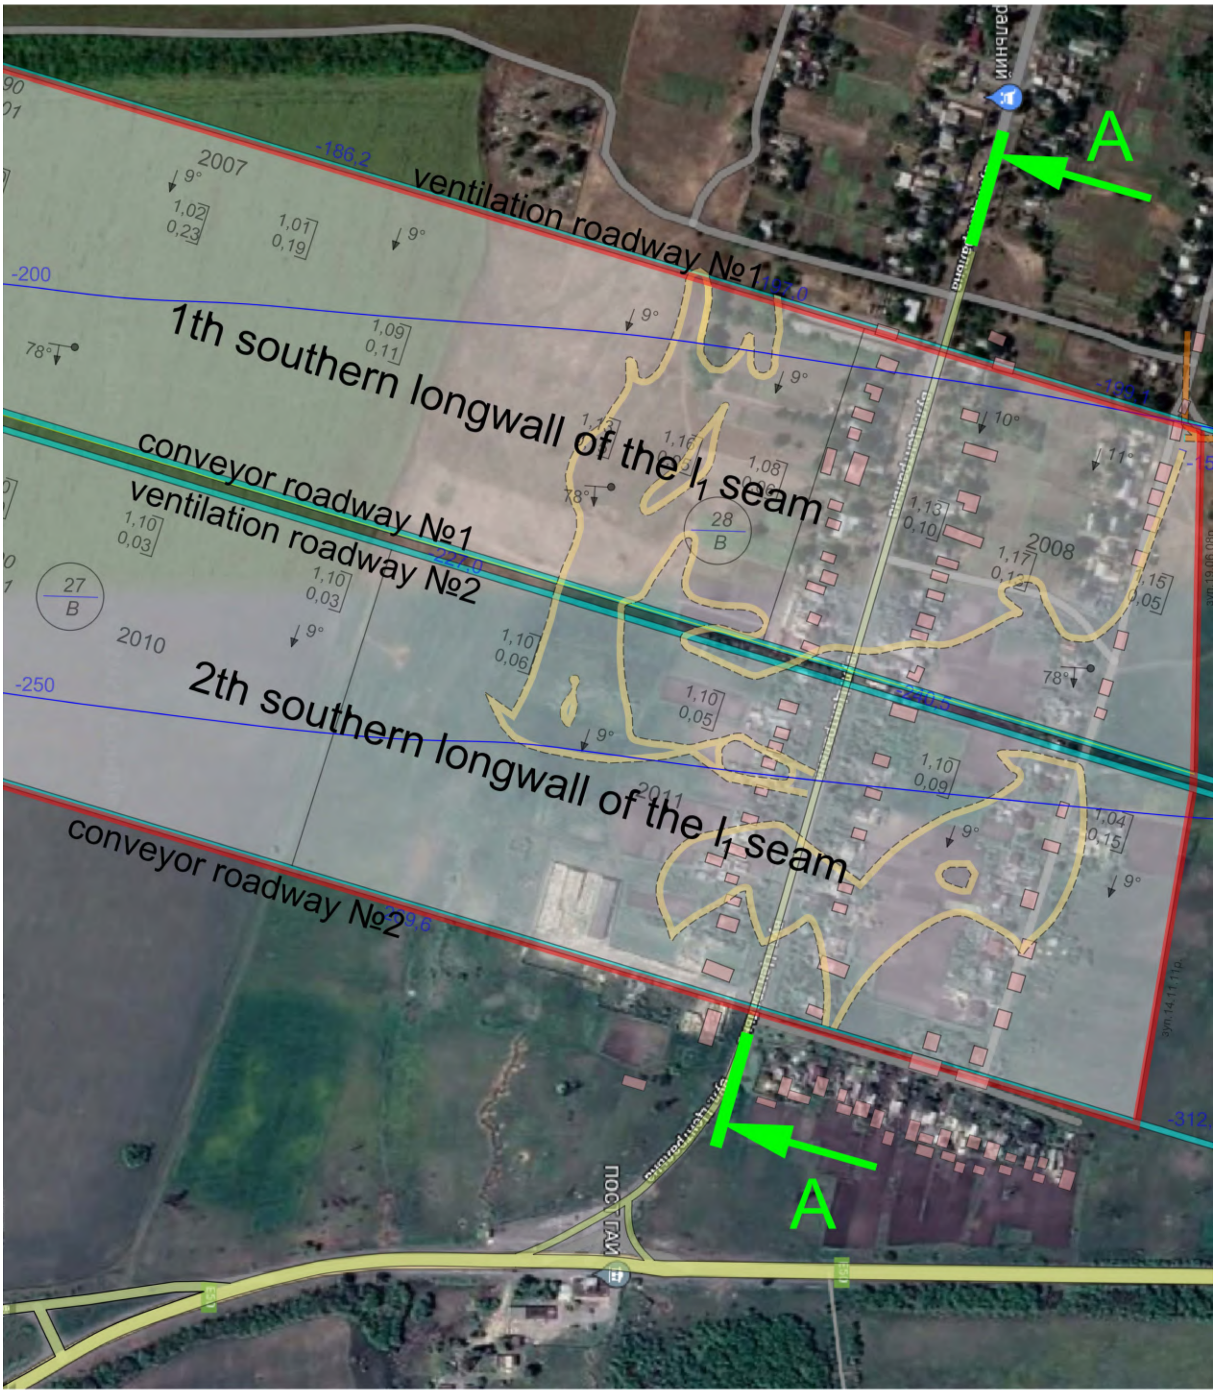
The initial data for numerical simulation (modulus of elasticity, Poisson's ratio, cohesion value, angle of internal friction and angle of dilatancy) were taken from the cadastre of physical rock properties [28], according to the stratigraphic column. At the same time, the rocks were modeled as heterogeneous. The variation of the physical and mechanical properties of rocks along and across the layering was determined according to the methodology proposed Sakhno et al [29], which is generally consistent with the research of Rzhevsky.

The excessive detail during modeling was avoided trough grouping of rock properties according to their strength, using average index. The rock strata were combined into groups, where their strength difference was less than 25%. This approach is permissible, since the aim of simulation was not to study the deformation of the rock strata in the undermine zone, but to analyze the surface subsidence.

The general view of the finite element model with its dimensions is shown in figure 3.

The study consisted of three cases:

(i) basic model (no flooding);



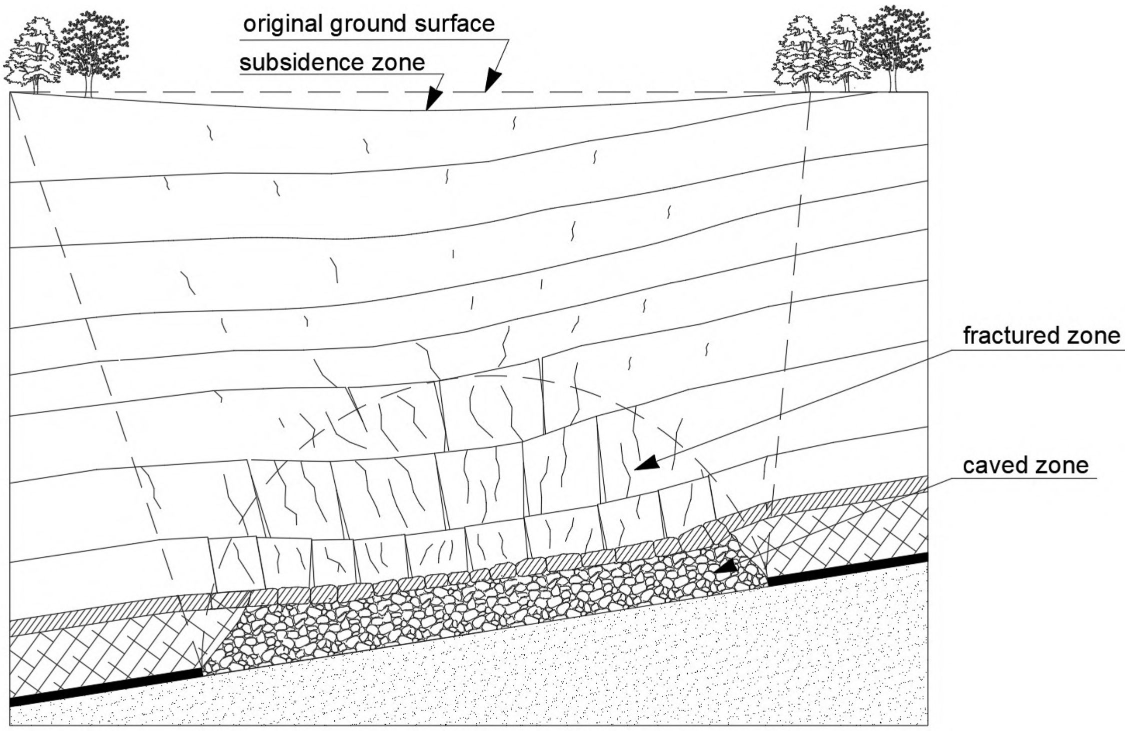
(*A-A – section line*)

Figure 1. Mine plan and the surface objects.

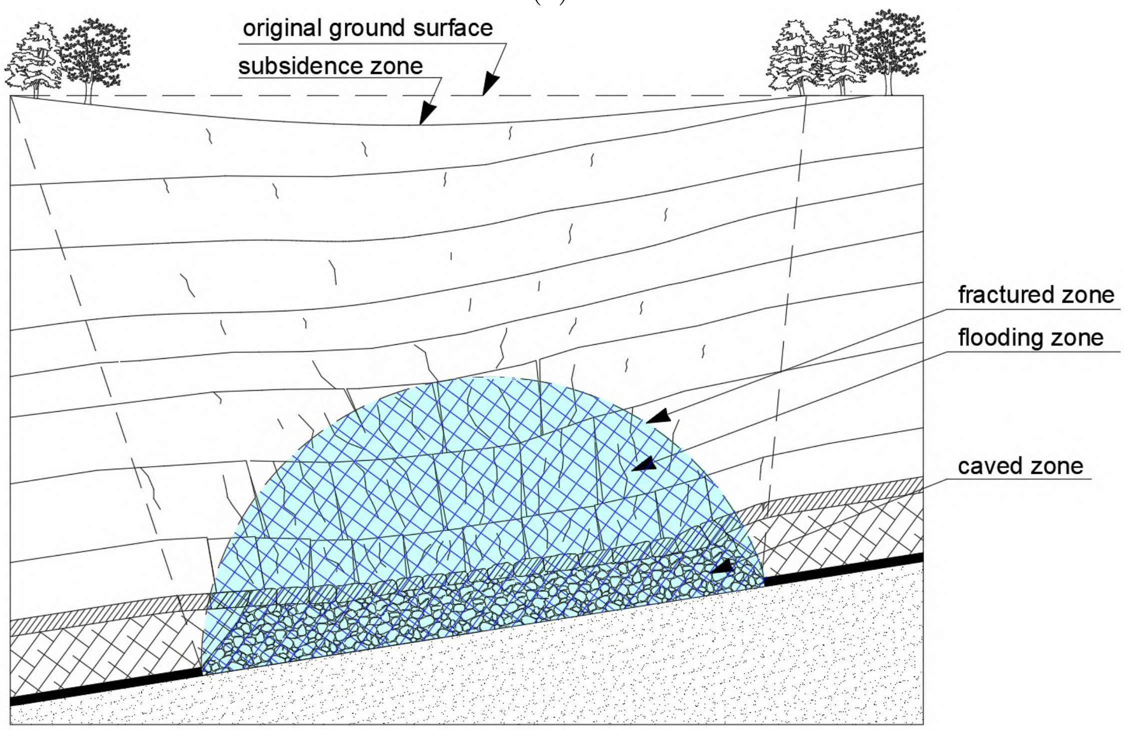
(ii) model with flooding of 40% of the fractured zone;

(iii) model with flooding of 100% of the fractured zone.

The geometry and grid of finite elements in the models were the same, which made it impossible to accumulate calculation errors.

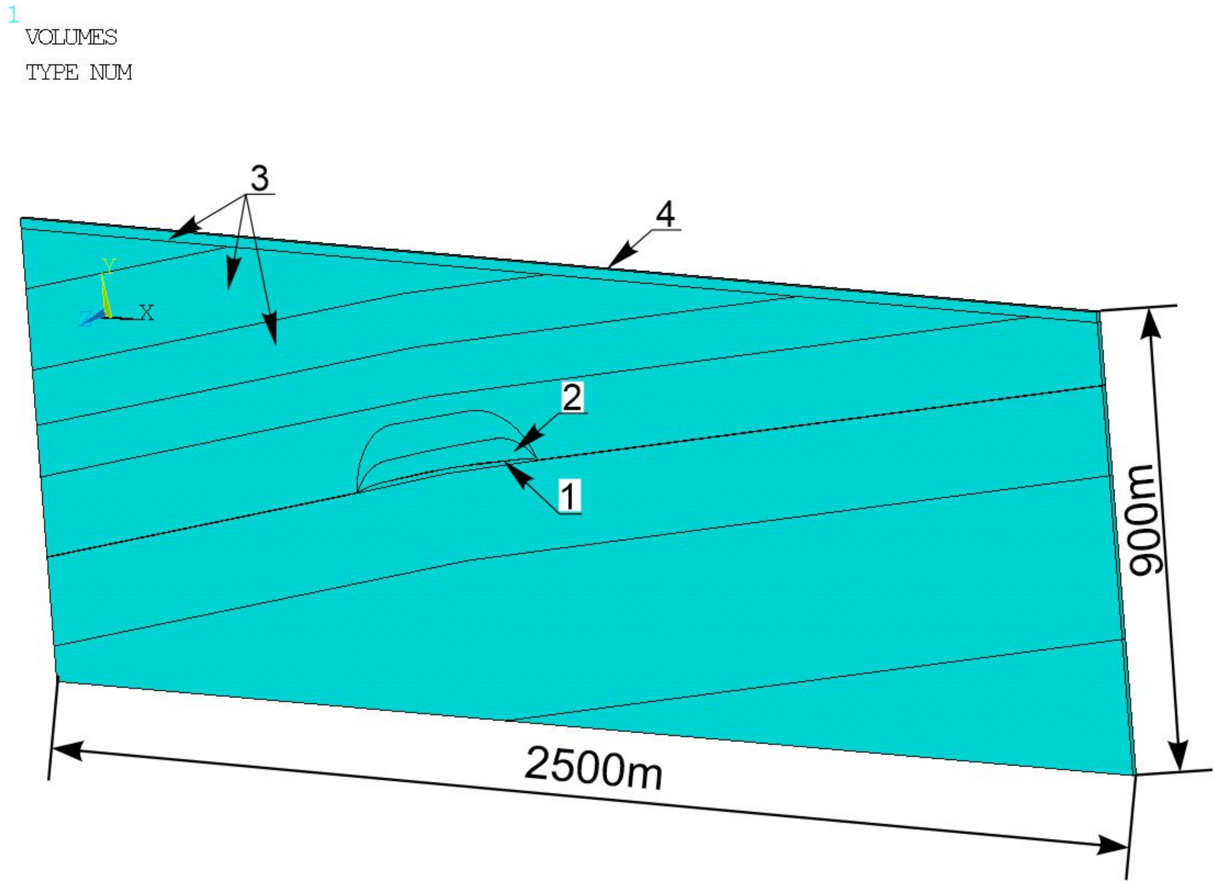


(a)



(b)

Figure 2. Overburden deformation zones caused by longwall subsidence: (a) before flooding; (b) after flooding.



(*1 – caved zone; 2 – fractured zone; 3 – rock strata; 4 – ground surface*)

Figure 3. General view of numerical model geometry.

The simulation was carried out step by step as follows.

Step 1: Loading the model with gravity, followed by writing the values of stresses and displacements in all nodes of the model to a file using the Inistate command in ADPL.

Step 2: Reading the recorded file with values and recalculating the model for zeroing displacement. In this case, a situation of the initial stress-strain state of the strata was obtained.

Step 3: Modeling of coal excavation and formation of caved zones and fractured zone (basic model).

Step 4: Simulation of flooding 40% of the fractured zone.

Step 5: Simulation of flooding 100% of the fractured zone. The patterns of vertical displacements in the model, which correspond to the described steps, are shown in figure 4.

To simulate the behavior of rocks in the caved zone and fractured zone, the correction of their properties was used, taking into account the fracturing. For this, the Hoek-Brown criterion was used [30].

To take into account the influence of moisture on the rock properties, the deformation modulus in the flooding zone was reduced and Poissons ratio was increase. The basis of this decision is

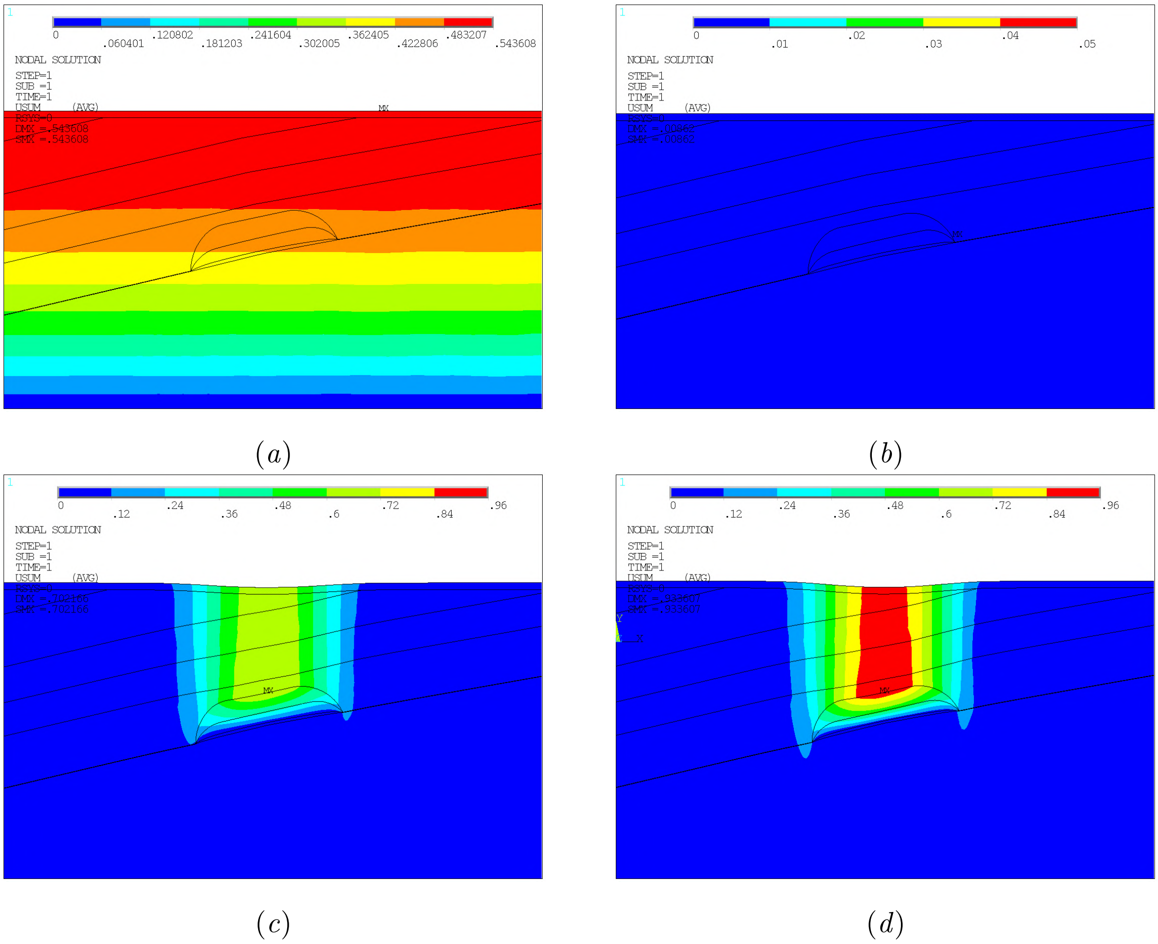


Figure 4. Displacement patterns with a step-by-step modeling (displacement scale 20:1): (*a*) step 1; (*b*) step 2; (*c*) step 3; (*d*) step 5.

numerous experimental study [31–34]. Obviously, this influence depends on many factors, first of all, on the type of rocks and the degree of water saturation.

Sakhno et al. [35] showed that the deformation modulus for wet rock (E_w) can be expressed as:

$$E_w = E1.0076e^{-0.239\Delta w}, \text{GPa} \tag{1}$$

where: E – deformation modulus of dry rock (MPa); Δw – water increase (%).

The rise of water level was simulated, therefore the maximum water saturation of the rocks was taken. The properties of the rocks that were used during the simulation are shown in table 1.

4. Results and discussion

The adequacy of any mathematical model is characterized by the divergence of the results obtained during its use with real values in-situ. Since monitoring of surface subsidence was not carried out in this study, the verification and calibration of the basic model were performed with predicted subsidence determined by normative document DSTU 101.00159226.001-2003 [22].

A safe depth 440m was calculated. It has been established that mining was conducted above the level of safe depth. That may cause subsidence of the surface exceeding the permissible ones.

Table 1. Input data for numerical modelling.

	Density, kg/m^3	Elastic modulus, MPa	Poissons ratio	Cohesion, MPa	Angle of internal friction, deg	Dilatancy angle, deg

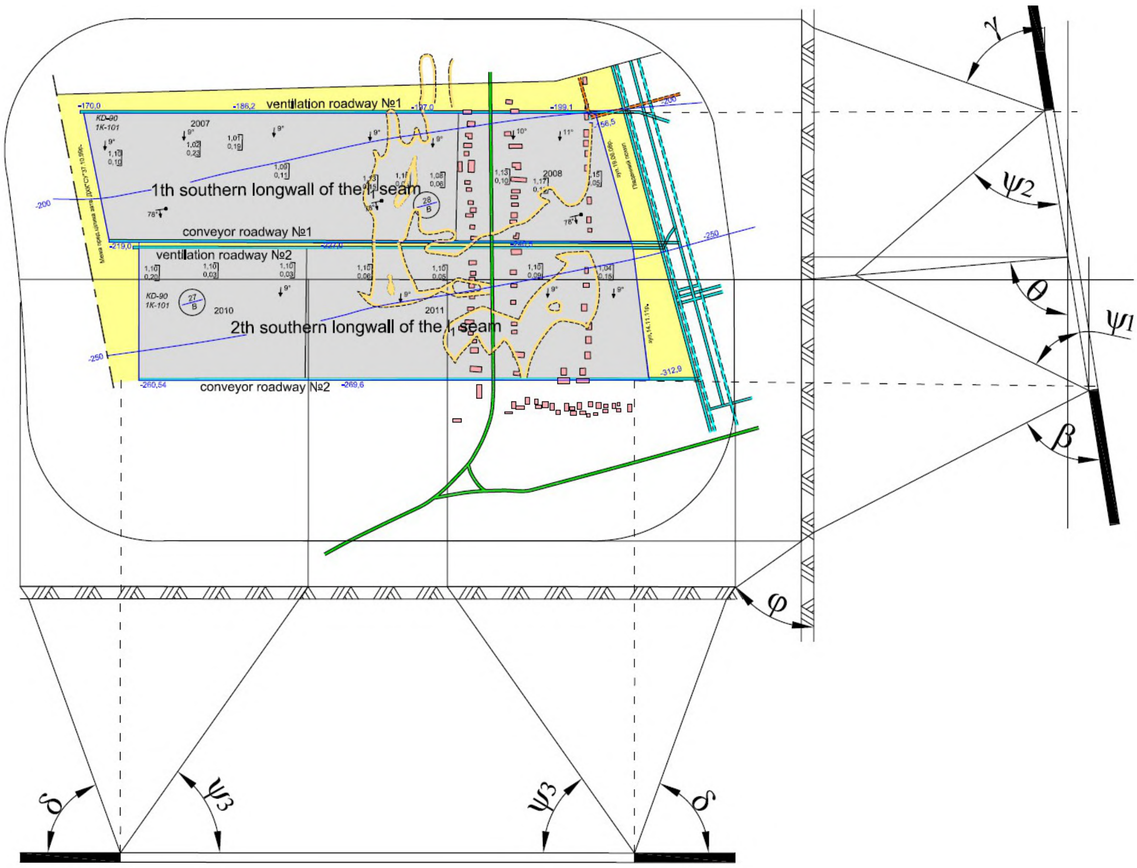

Figure 5. Subsidence trough (in accordance with DSTU 101.00159226.001-2003 [22]).

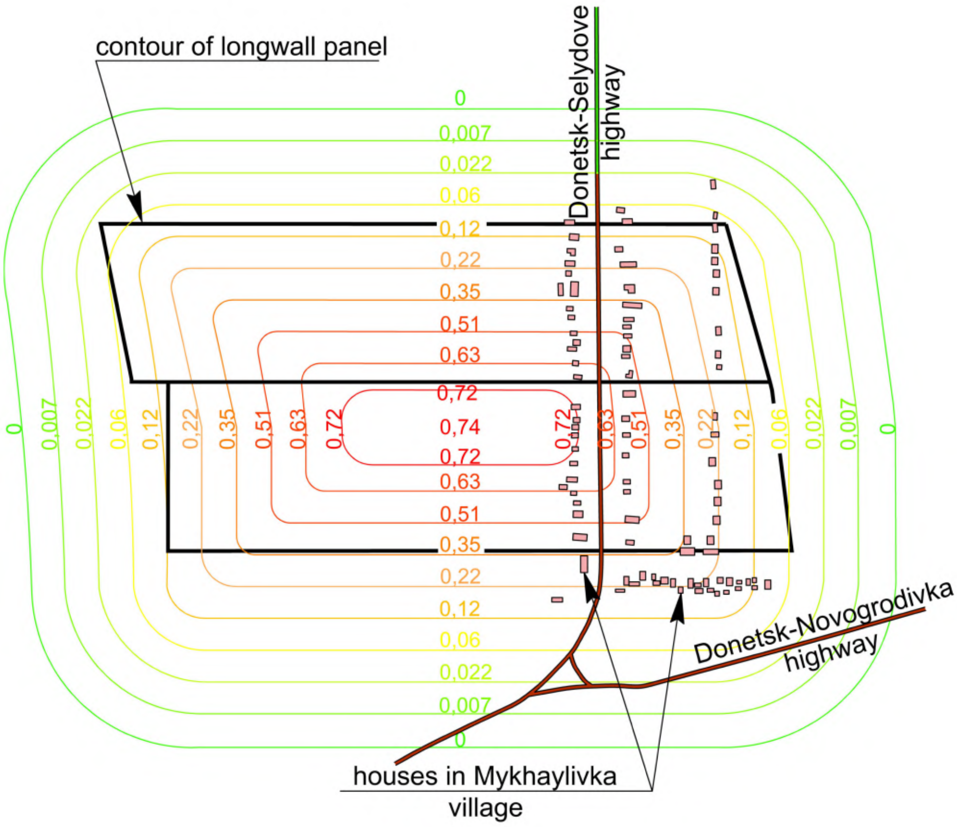

Figure 6. Isolines of subsidence caused by undermining.

The results of the graphic calculation of the subsidence trough with the corresponding cross sections are shown in figure 5.

Initial parameters of the subsidence process [22]: limit angle $\delta = 70^o, \gamma = 70^o, \beta = 63^o, \psi_1 = 55^o, \psi_2 = 58^o, \psi_3 = 55^o$, maximum subsidence angle $\theta = 83^o$, maximum possible surface subsidence $\eta_{max} = 0.74$ m.

Plan of subsidence isolines caused by undermining of 1th and 2th southern longwalls of the seam l_1 is shown in figure 6.

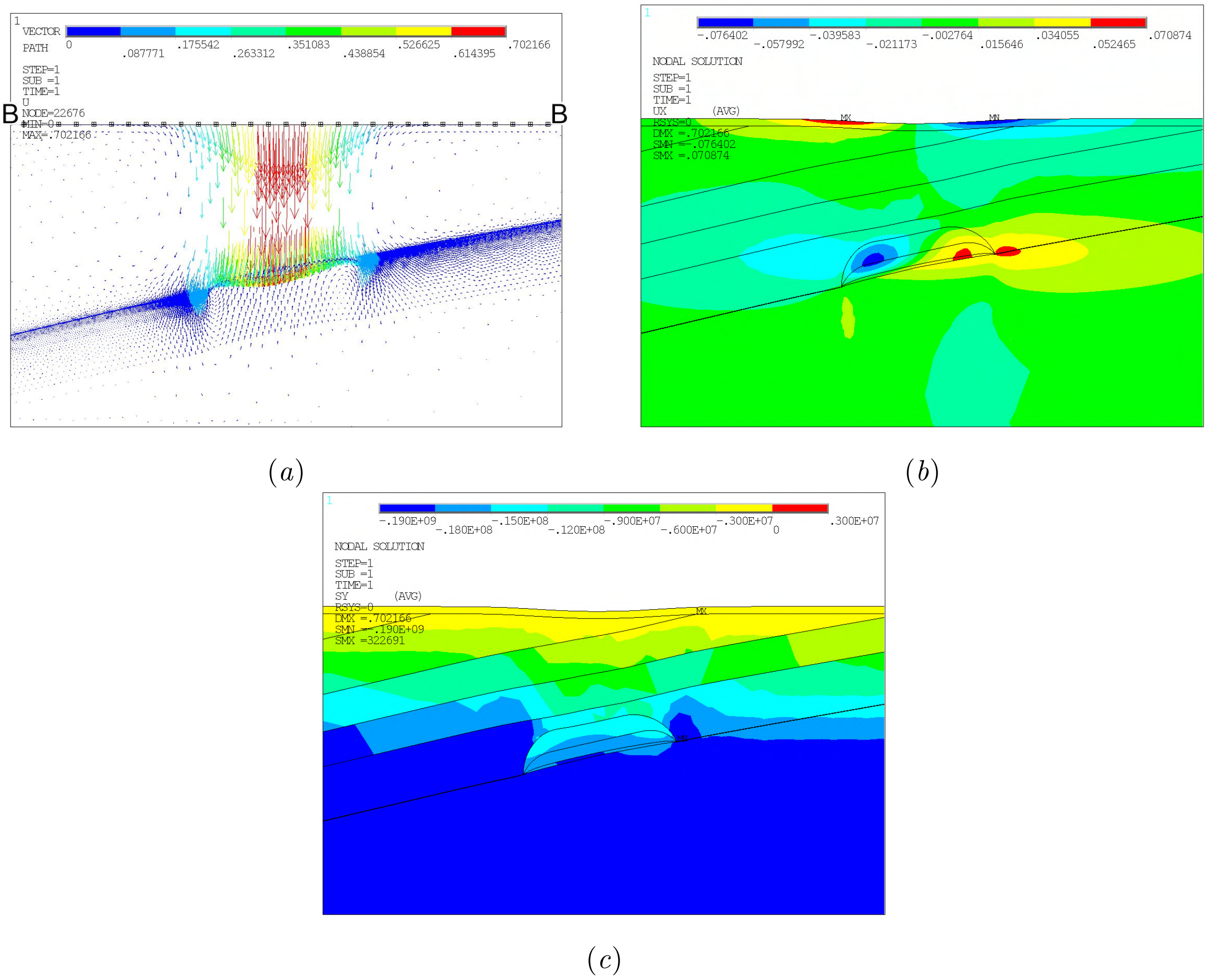
As can be seen from figure 6, Donetsk-Novogrodivka highway, Donetsk-Selydove highway and Mykhailivka village are located in the mining influence zone. Some houses are located above the zone of maximal subsidence. The results of numerical simulation for the base model are shown in figure 7.

The scale for converting colors in digital format is shown in the upper parts of the figures. Numerical designations on the scale line of figure 7a, b are given in meters, in figure 7c – in Pascals. In order to more clear display of the subsidence trough boundaries, the scale of displacement in figure 7 is increased by 20 times.

At the first stage of simulation process, the numerical model was calibrated. For this purpose, graphs of displacements and curvature along the B-B line were made (figure 8) and their convergence with the results of settlement calculations according to the DSTU 101.00159226.001-2003 was checked [22].

As can be seen from figure 8, the numerical model allows to adequately describe the process of surface deformation.

The maximal vertical displacement in the numerical model is 735 mm. The maximal vertical



(*B-B – monitoring line*)

Figure 7. Base model simulation results (displacement scale 20:1): (*a*) pattern of displacement vectors; (*b*) pattern of horizontal displacements; (*c*) pattern of vertical stress.

displacement that was calculated according to DSTU 101.00159226.001-2003 [22] is 738 mm. In the model, the displacement at the border of the trough subsidence is equal to 7 mm at a distance of 40 m from the longwall axis, according to normative document [22] – 380 m. Thus, the respective divergences are –0.2% and +4%.

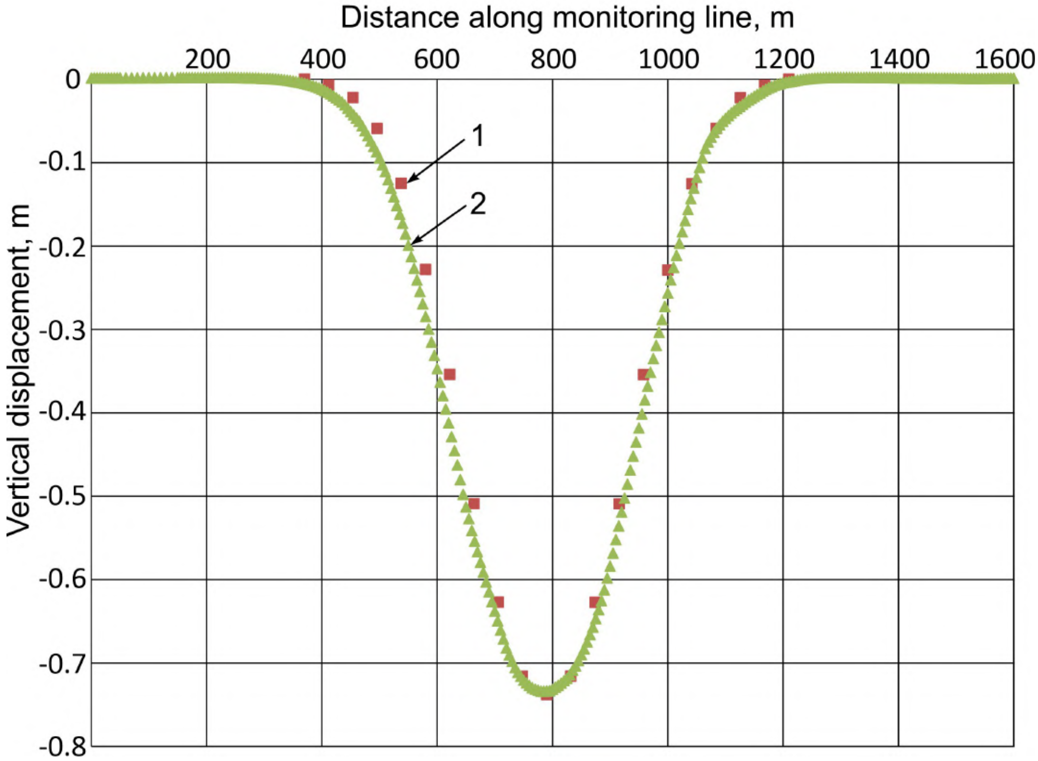
The maximal inclination in the model is 0.003082, calculated according to [22] – 0.003029; the divergence is 1.7%. The mean squared error of the simulation results for the inclination factor is 5.23%, for the vertical displacement factor is 5.1%. Such results are quite acceptable.

In the next stage of modeling, flooding of the longwall goaf was simulated in two stages (40% and 100% of the total height of the fractured zone). The simulation results are shown in figure 9.

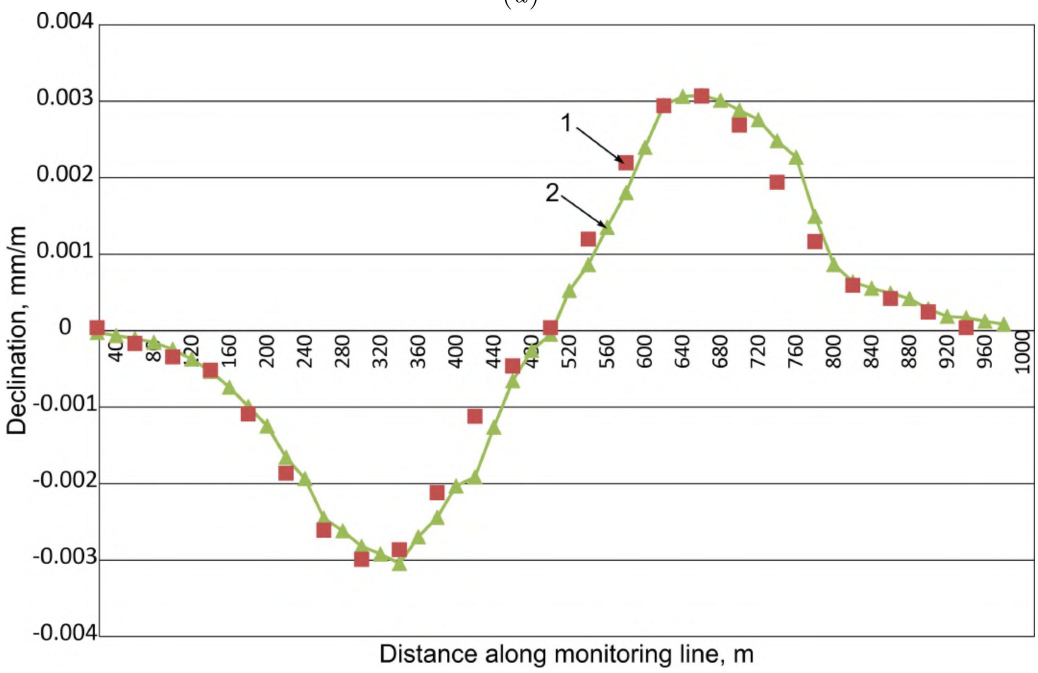
The graphs of subsidence, inclinations and curvatures are shown in figure 10.

After the first step of flooding, the maximal subsidence increases to 821 mm, i.e. by 86 mm (11.7%), after the second step of flooding – to 900 mm, i.e. by 165 mm (22.4%). At the same time, the length of the subsidence trough during flooding increases by only 5 m (1.3%).

The simulation result shows that the length of the subsidence trough increases less significant than the maximal subsidence, thus, flooding provokes the increase of inclination, curvatures and horizontal displacements.



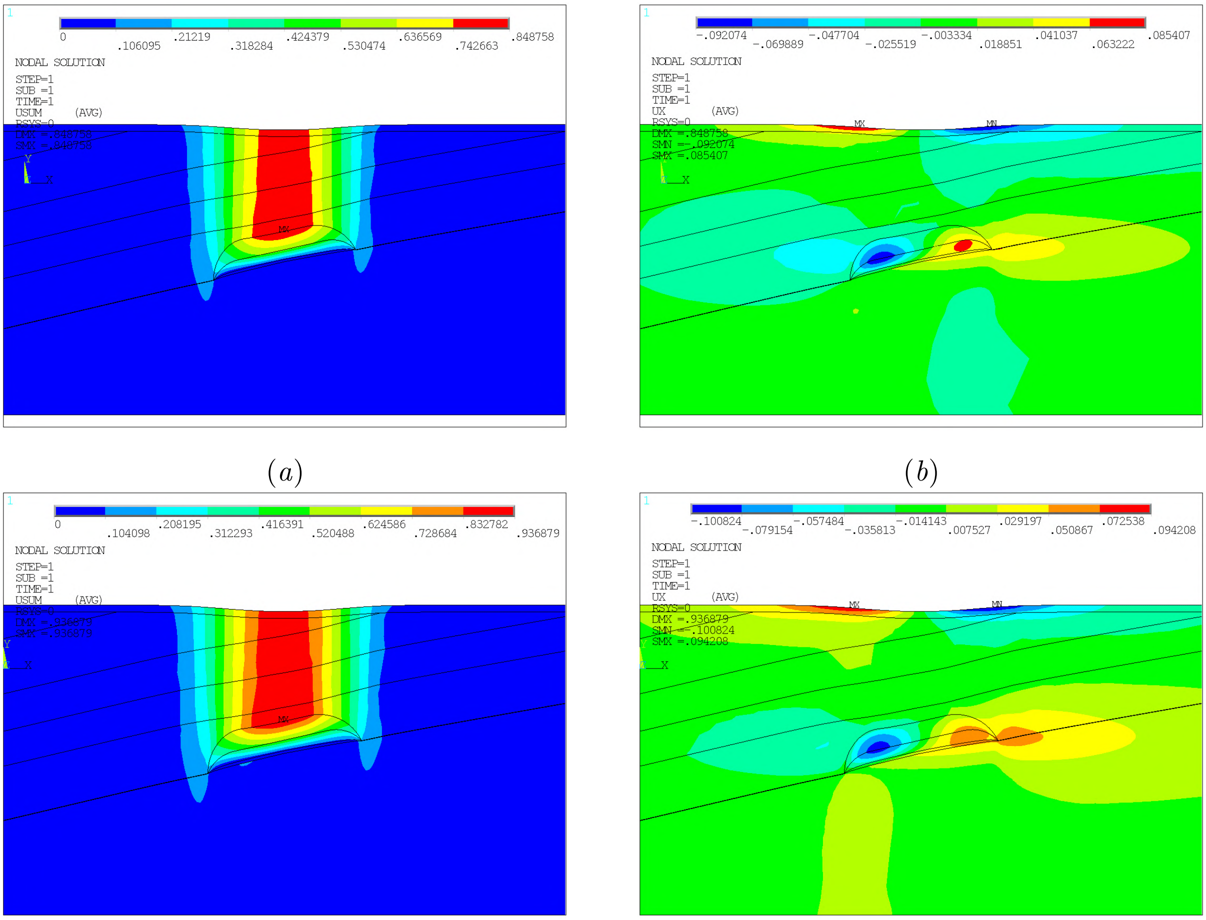
(a)



(b)

(1 – according to the DSTU 101.00159226.001-2003 [22], 2 – numerical simulation results)

Figure 8. Graphs of vertical displacements (a) and inclination (b) along the B-B line.



(a) (b)

(c) (d)

Figure 9. Distribution of vertical and horizontal displacement during the first (a, b) and second (c, d) steps of flooding (displacement scale 20:1).

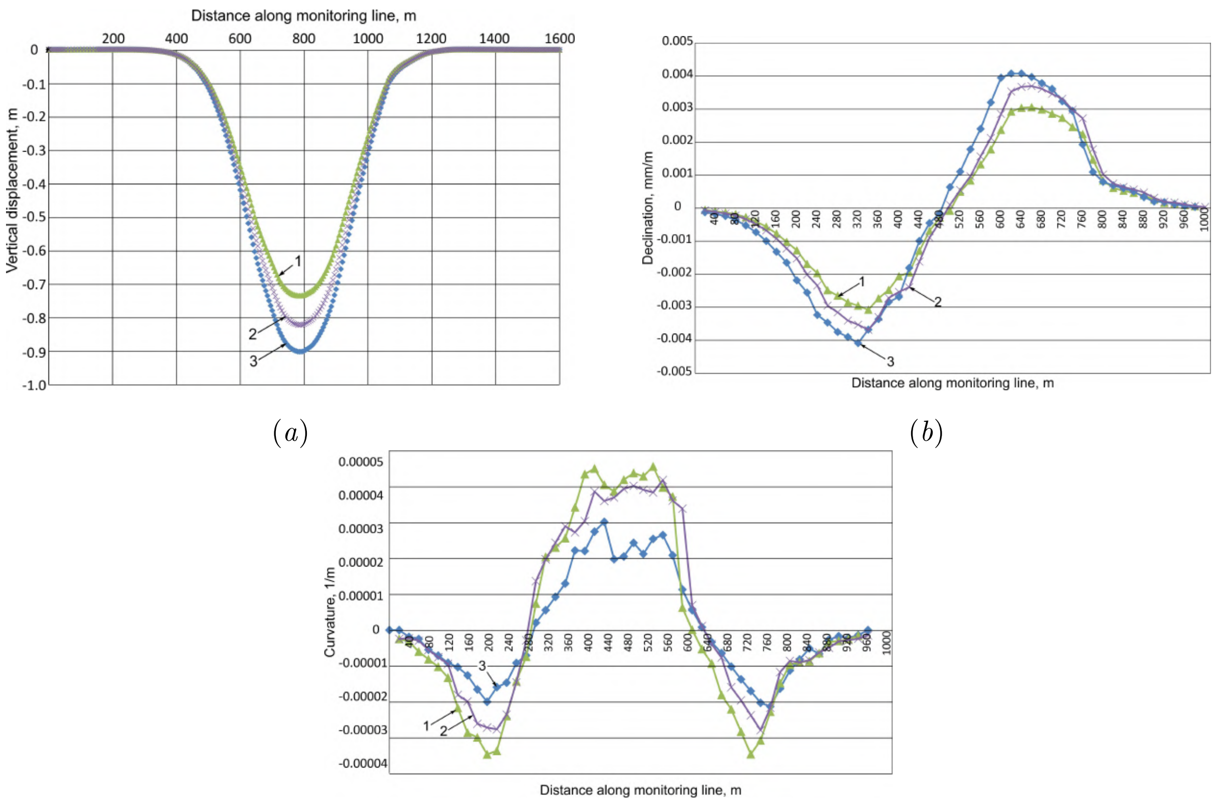
The maximal inclination as a result of full flooding of the fractured zone, according to the simulation results, increases from 0.00302 to 0.00406 (by 34.4%). Flooding by 40% of the height of the fractured zone leads to an increase in maximal inclination from 0.00302 to 0.00368 (by 21.8%).

Curvature at the edges of the trough subsidence increases from 0.0000200 to 0.0000348, and in the central part of the trough – from 0.00003032 to 0.00004525, by 74% and 49% respectively.

The increase of maximal subsidence, inclination and curvatures occurs disproportionately to the goaf flooding height. Thus, flooding by 40% of the height of fractured zone leads to an increase of maximal subsidence on 52.1%, maximal inclination on 63.4% and maximal curvature on 48.9% respectively.

Thus, flooding leads to activation of surface deformation. This cause increased hazards for surface objects, especially at the extension trough zone. For the case study, the risk of destruction of houses in the Mykhailivka village, which located in the subsidense prone land, increases. In addition, the risk of destruction of the Donetsk - Selidove highway, which is located in the area of subsidence impact, increases.

The current study is based on the results of numerical modeling and represents a theoretical solution. In the future, field monitoring is planned to confirm and verify the obtained results.



(*a*) (*b*)

(*c*)

Figure 10. The graphs of subsidence (*a*), inclinations (*b*) and curvatures (*c*) in the undermining zone (along monitoring line B-B) (displacement scale 20:1).

Modern methods of the surface monitoring allow making large areas observation quickly [3, 36]. This significantly save time and human resources for field measurement.

This study opens up opportunities for development of different ways of surface subsidence control. The goaf backfilling is one of the most well-known control methods of strata deformation. Backfilling in Ukraine is carried out mainly for the conditions of ore deposits [37, 38]. The theoretical studies are also carried out for coal deposits [39–41]. The presented study is planned to develop in this direction.

5. Conclusions

This paper presents the numerical simulation results of the longwall goaf flooding impact on the activation of ground movement during excavation of thin coal seams.

Based on the results of this investigation, the following conclusions can be drawn:

1. One of the characteristic phenomena with which the future of the Ukrainian Donbas is connected is the flooding of the longwalls goaf of coal mines. The risks of mine roadways flooding are increasing as a result of military operations in Ukraine. Therefore, save of the surface objects from the negative impact of undermining is becoming one of the urgent problems. Timely planning and development of control methods require an adequate prediction of subsidence evolution caused by mine roadways flooding.

2. The finite element model was created in the Ansys code, which allows to predict the ground movement caused by underground coal mining. The error of the trough subsidence calculation did not exceed 6%.
3. It was showed that the longwall goaf flooding leads to the activation of the subsidence process. As a result of the analysis, it was proved that the flooding on the full height of the fractured zone above the longwall goaf leads to an increase in subsidence by 22.4%, while the length of the trough increase by 1.3%. Maximal inclination increases by 34.4%, and maximal curvature – by 74%. This contributes to a significant increase in hazards for surface infrastructure located on the edges of the subsidence trough. Risk decrease for surface infrastructure can be ensured by timely prediction of subsidence and implementation of surface controlling methods.

Abstract. Conical monolithic thin-walled reinforced concrete blocks (shells) can be used as foundations for frame structures and buildings with load-bearing walls. As an analogue of columnar foundations, this type has the advantage of the speed of installation. It almost wholly excludes earthwork and formwork from the technological process, provided that the physical and mechanical properties of the soil base are improved. Shells are immersed in the supporting soil base with the help of dynamic or static loading. Additional soil base compaction occurs due to interaction with the conical outer surface of the shells. The work aims to develop the theoretical foundations for modelling, mathematical description and the possibility of optimizing the process of sinking monolithic thin-walled spatial reinforced concrete shells that model foundations for low-rise technological or residential facilities. Based on the analysis of the "hammer-head-shell-soil" system, an elastic-viscous-plastic model with an attached soil mass was developed and presented, which is used as a basis for developing a system of nonlinear differential equations of the second order. The article provides recommendations on the impact of structural and technological factors on the failure rate and the contact stresses in the hammer-shell zone. The following factors have a significant influence on the failure of the shell: the height of the hammer lift, soil resistance, and the ratio of the masses of the hammer and the shell. The effect of shock-absorbing elements is insignificant. The greatest influence on the magnitude of the contact forces in the zone of the hammer-shell has: the height of the fall of the hammer and the stiffness of the resilient gasket.

1. Formulation of the problem

Monolithic and prefabricated reinforced concrete foundations traditionally used at present, along with known advantages, have great complexity of erection on the construction site, high material consumption and, accordingly, cost. The use of monolithic thin-walled spatial reinforced concrete shells (MTWSRCS) as foundations for low-rise technological or residential objects is economically feasible from the point of view of reducing the volume of earthworks by up to 90%, abandoning the use of formwork, shortening the time for the concrete to gain strength. In addition, the use of MTWSRCS, in comparison with classical types and methods of laying foundations, allows you to significantly reduce the costs of concrete, reinforcement, and labor costs, which ultimately leads to a decrease in the estimated cost of zero-cycle works by up to 40% [1–7].

The issues of interaction processes of MTWSRCS with the soil of the foundation during dynamic or static immersion, as well as during the operation of the building, remain insufficiently researched and highlighted in the scientific literature.

2. Analysis of the latest sources of research and publications

There are some close, according to the physics of the process, the results of research on establishing the resistance of the foundation soils with the dynamic method of sinking classical reinforced concrete piles into it, conducted by: B.V. Bakholdin, L.Ya. Ginsburg, D.D. Barkan, etc. [8–12]. Most researchers recommend determining the soil base's resistance by considering the so-called viscosity coefficient.

In the work of L.R. Stavnitzer established the existence of a critical rate of soil deformation, beyond which the magnitude of the reaction of the soil base practically does not depend on the rate of its deformation. B.V. Bakholdin, L.Ya. Ginzburg proved that the value of the critical rate of deformation of the soil relative to the piles depends on the static resistance of the soil.

Immersion in the soil of MTWSRCS, similar to the process of immersion of a classic reinforced concrete pile, the layers of the soil base are pushed to the sides and bent down. Due to the significantly greater conicity of MTWSRCS compared to the old one, soil deformations are brighter and visually noticeable. This leads to additional compaction of the soil under the conical part of the MTWSRCS, which is accompanied by the destruction of the natural structure of the upper layers of the soil, their mixing and partial bulging upwards. The result is an artificial soil base with improved physical and mechanical properties and correspondingly higher bearing capacity. The prospects of this type of foundation with MTWSRCS for soil foundations that are not prone to frost heave, are not over moistened and are not located in a climatic zone with a long period of negative average daily outdoor air temperatures should be noted.

3. The goal of the work

Based on practical experience using monolithic thin-walled spatial reinforced concrete shells as foundations for low-rise technological or residential facilities, develop theoretical foundations for modelling, mathematical description and the possibility of optimizing the immersion process.

4. Research results

Immersion of MTWSRCS is possible by impact and static load in the form of discrete or continuous gradual loading. Immersion by impact is a complex energy process, during which the potential energy of the hammer is transformed into the kinetic energy of the impact, which leads to the overcoming of the resistance forces of the soil base to the final and elastic movements under the surface of the MTWSRCS [2, 3, 11–13].

At the same time, the impact energy developed by the falling load (hammer) is partially lost during the co-impact through the damper between the hammer and the shell, shaking the surrounding soil of the base, and only a part of it determines the final movements of the MTWSRCS.

During the impact of the shock load, the elastic deformation of the head C_1 , then the shell C_2 itself, and the soil of the base C_3 occurs, and only after that does the final vertical movement (immersion) of shell E occurs. After the shock pulse is exhausted, the elastic deformations are restored. Thus, the total elastic deformations are equal to:

$$C = C_1 + C_2 + C_3. \tag{1}$$

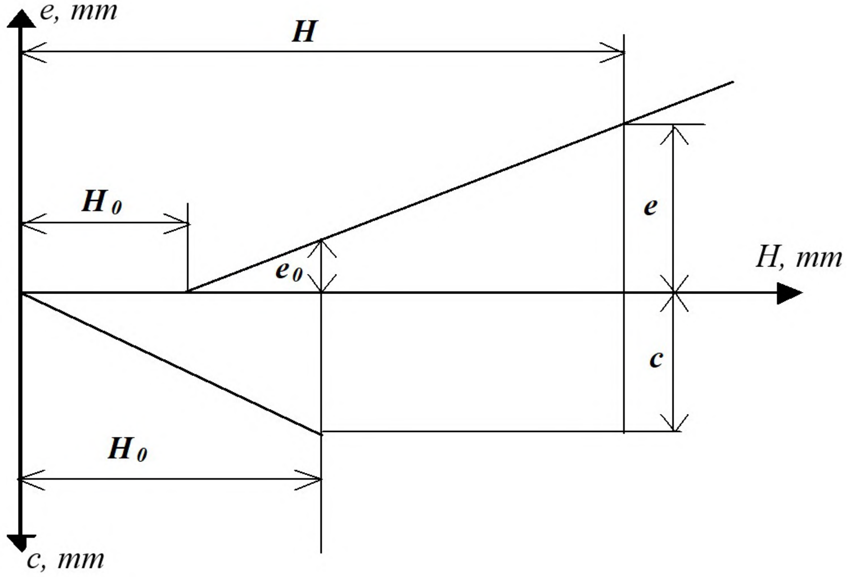

Figure 1. Scheme of the dependence of C and E failures on the height of the fall of the hammer H.

The values of C_1 and C_2 are usually small and can be neglected in many cases, i.e. take $C = C_3$. In the idealized schemes of changes in C and E as the impact energy of the hammer ϵ increases, the elastic part of failure C increases at $E = 0$, until it reaches the limit value C (figure 1). With a further increase in ϵ , the value of C remains constant. The final failure of E begins to increase. Thus, the ultimate elastic deformation of soil C does not depend on the immersion parameters Q and H and is a soil characteristic.

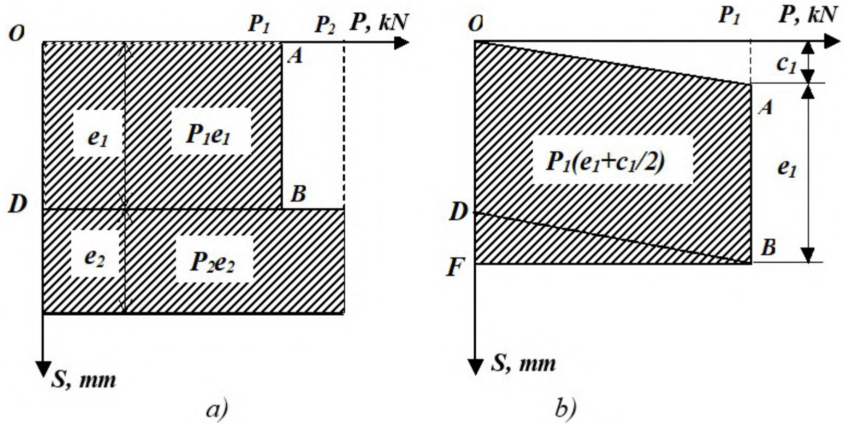

Figure 2. Dependence between the frontal resistance to movement of the shell P and its settlement S with different models of interaction: a) - plastic model; b) - elastic-plastic model.

The dynamic nature of the load application, which qualitatively changes depending on the ratio of the three phases of the soil base, significantly influences the soil's deformation and resistance to the immersion of the shells. Due to the impossibility of considering all the features of the upper layers of the soil base of the construction site and obtaining accurate analytical expressions of dynamic resistance, it seems appropriate to use modelling methods for this purpose. At the same time, it is proposed to apply simple models that could reflect only the main properties of the system, and a large number of temporary features would be taken into account in a generalized way or through the values of calculated indicators. To simplify this model, the initial state of the soil and the features of its changes during deformation may not be taken into account. Just to reflect the final influence of the features of this soil on the development of resistance forces may be reflected. Such simplest soil models for the analysis of the "hammer-head-shell-soil" system are plastic and elastically plastic [9, 11–15] (figure 2).

The plastic model is built considering the following assumptions (figure 2, a). It is an absolutely solid body, and the soil surrounding it is motionless. Resistance on the side surface P_b, etc. friction between the side surfaces of the shell and the soil, reduced to equivalent to all types of Coulomb dry friction (it is assumed that P_b, does not depend on the speed of movement of the shell).

As the tests showed, reducing the dynamic side friction to the equivalent dry friction makes it possible to obtain fairly stable soil resistance values.

The frontal resistance P_l is represented by a pinched weightless bottom. Overcoming the friction that develops on the side surface, the shell affects the bottom, which sinks if the force applied to it exceeds P_l.

The relationship between the frontal resistance to the movement of the shell and its subsidence is given in a simplified form - in the form of a broken line OAB, and it is assumed that the force P_l does not depend on the speed of movement of the shell. The area of the OABD diagram represents the work for one cycle of P_e (figure 2, a). Despite its simplicity, this scheme can be quite useful, as it does not require setting many uncertain parameters of elasticity and viscosity.

The elastic-plastic model is distinguished by the presence of elastic ties that simulate the elasticity of the soil and intermediate elements (figure 2, b). At this research stage, it is assumed that the elasticity of the soil is manifested mainly at the point of contact of the end of the shell with the soil [16–19]. Therefore, the assumption that the lateral resistance to immersion is characterized by dry friction remains valid for the scheme.

The mechanical model of frontal resistance is simplified as a bottom with a linear spring. When the casing is struck, the elastic deformation of the soil OA (compression of the spring) first occurs, and after the force in it reaches the value of the frontal resistance P_l, irreversible compression of the bottom AB begins (figure 2, b). After the load is over, the BD is restored. This graph generally shows well the interaction of the shell with the soil.

The positive properties of this model are also that when using the energy approach to determine energy costs, i.e. the area of the force-displacement diagram, the contours of this diagram, as well as the condition that $C = 0$ does not affect the accuracy of the results.

The considered model does not take into account the influence of soil inertia, which is quite significant. Therefore, for further clarification, an elastic-plastic model with an attached soil mass is adopted (figure 3, c). In this model, the surrounding attached soil mass is represented by an equivalent elastic body resting on elastic supports. In this case, the body's weight is equal to the attached soil's weight.

When the shell moves after impact, the attached mass moves together with the shell until the elastic forces of the springs reach the values of the resistance on the side surface P_b. After that, the shell begins to slide relative to these elements. Further interaction is similar to the interaction of the previous model.

The elastic-viscous-plastic model (figure 3, d) allows you to consider the soil's viscous resistance. Further, it is possible to clarify the nature of the change in the frontal resistance of the soil depending on the settlement during loading and unloading, which means applying instead of a simple Prandtl elastic-plastic model, an elastic-plastic model with compaction, etc. Thus, the number of possible variants of dynamic models can be pretty significant. These models will more and more fully reflect the influence of the main factors and their role in the

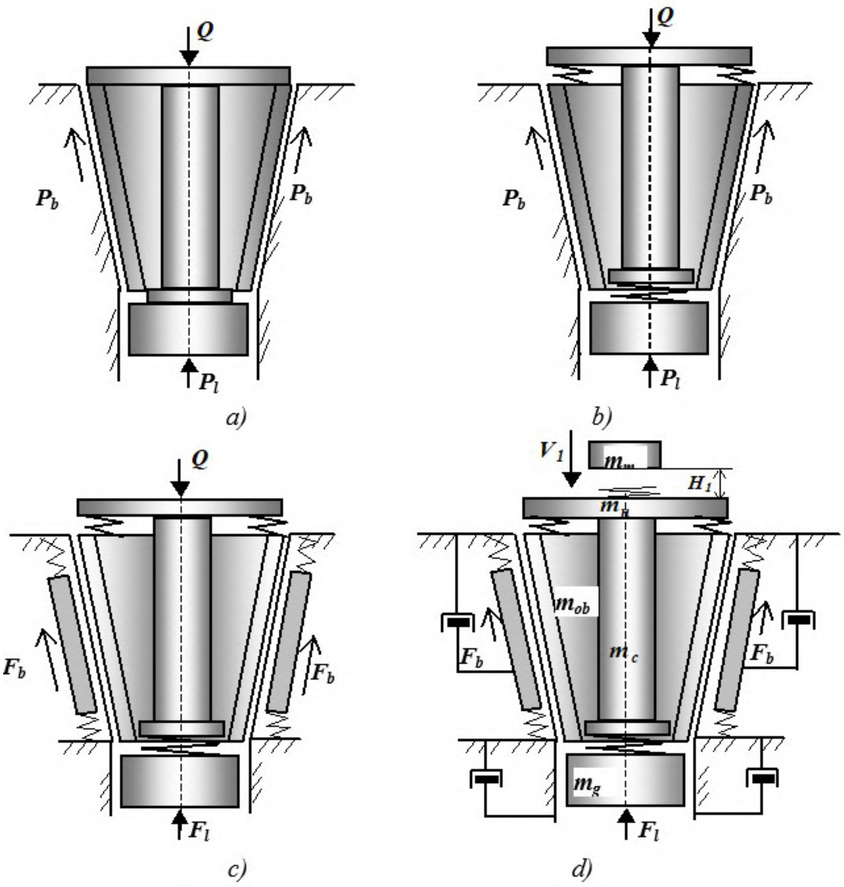

Figure 3. Dynamic models of the "hammer-head-shell-soil" system: a) - plastic model; b) – elastic-plastic model; c) – elastic-plastic model with attached soil mass; d) – elastic-viscous-plastic model with attached soil mass.

immersion process. In all models analyzed above, the shell is considered as a completely rigid body. However, upon impact, the shell has an elastic deformation. In addition, the usual impact on the shell is performed through the elastic headband. Therefore, a spring can also represent the shell and the headband's elasticity.

Evaluating the possibility of using complex models for practical calculations, it should be pointed out that currently, there is not a sufficient amount of experimental data for a reasonable assignment of the numerical values of many indicators characterizing these models. In addition, the obtained mathematical expressions of the interaction of the "hammer-shell-soil" system will become more and more complex with the complexity of the models, and this complexity will not always contribute to an increase in accuracy, i.e. practical purposes. Taking this into account, for further research, it is most appropriate to use an elastic-viscous-plastic model considering the attached mass of the soil and the elasticity of the shell and the head (figure 3, d). This scheme allows you to take into account the change in the value of the attached mass of the soil and the change in the nature of the interaction in connection with this.

Thus, the dynamic model of the "hammer-head-shell-soil" system with elastic-viscous-plastic resistance of the soil is presented as follows. The elastic shell, which is in the soil, is struck with a hard undeformed hammer through the elastic head.

Under the influence of the impact, the shell acquires a reserve of kinetic energy, which is spent on overcoming soil resistance: with each impact, the shell sinks, initially elastically deforming the soil by the amount C, and then the plate moves in the soil by the amount of final failure E. Elastic deformations are restored after each impact. Each blow is considered as a single one, isolated from others, which means that before each subsequent impact, the shell, hammer and soil are at rest. The shock is absorbed by the reduced mass of the shell, taking into account part of the mass of the soil attached to it, and the subsequent movement is carried out only by the shell. The hammer impact effect is represented as the transfer of some part of the kinetic energy of the impact ϵ, which goes directly to the immersion of the shell [16–18, 20].

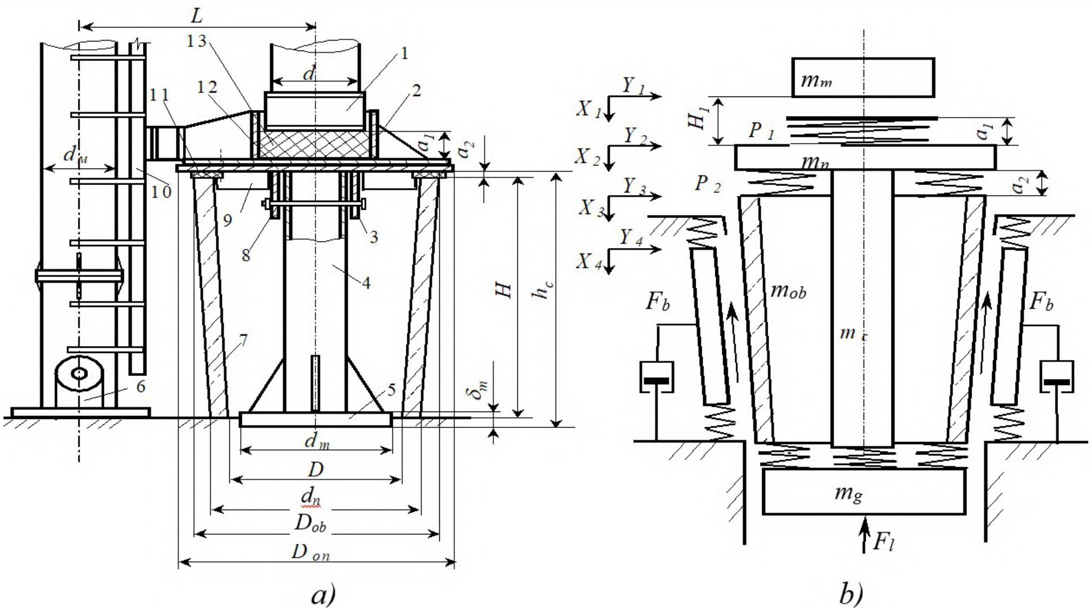

Figure 4. "Hammer-head-shell-soil" system: a) - real system; b) – calculation scheme: 1 - hammer; 2 - headrest; 3 - conductor; 4 - core; 5 - tamping plate; 6 - mast; 7 - shell; 8 - finger; 9 - stops; 10 - guides; 11 - gasket; 12 - transmission plate; 13 - shock absorber.

For the development of a mathematical model of the process of immersion in the ground base of conical-reinforced concrete shells, a calculation scheme is proposed (figure 4).

The mathematical model of this process is a system of nonlinear differential equations consisting of the equations of the "hammer-head" and "shell-soil" subsystems, which must be solved jointly.

The mathematical model "hammer-head-shell-soil" is a system of nonlinear differential equations of the second order:

$$\begin{cases} m_2 d^2X_2/dt^2 = Q_2 + P_{12} - P_{23}, \\ (m_3 + m_4)\, d^2X_3/dt^2 = Q_3 + Q_4 + P_{23} - F_l - F_b, \quad F_b \le R_b \\ X_3 = X_4, \\ m_1 d^2X_1/dt^2 = Q_1 - P_{12}, \\ m_3 d^2X_3/dt^2 = Q_3 + Q_4 + P_{23} - F_l - F_b, \\ m_4 d^2X_4/dt^2 = Q_4 + F_b - K_b X_4, \qquad F_b < R_b \end{cases} \tag{2}$$

where m_1, m_2, m_3, m_4 - are the masses of the hammer, head, and shell, respectively core and load;

Q_1, Q_2, Q_3, Q_4 - respectively, the weight of the hammer, head, and shell core and soil;

P_{12}, P_{23} - respectively, the forces acting on the contacts of the bodies, which collide;
X_1, X_2, X_3, X_4 - are, respectively, the coordinates of the hammer, head, shell and soil;
F_l, F_b - frontal and lateral soil resistance, respectively;
R_b - is the ultimate resistance of the soil on the side surface.

The solution of this system of equations gives the displacement and speed of all bodies, as well as the value of the forces acting on the contacts of colliding bodies at any moment in time.

Mathematical model (2) belongs to the class of simulation models, as it simulates in detail the submersion of shells by impact load. This nature of the model allows you to use it to study the process of computer immersion. In addition, implementing full-scale experiments on the immersion of shells is a rather expensive method that requires a lot of machine time.

Experience shows that the most interesting for practice is the study of the influence of the following factors on the immersion process:

- ultimate resistance of the shell on the soil;
- the ratio of the mass of the striking part to the mass of the submerged shell;
- the thickness of the elastic gasket in the headrest;
- lifting height of the impact part.

Wood or conveyor rubber can be used as cushioning material in the headrest. The soil's stiffness depends on the value of the lateral resistance so that the elastic failure does not exceed 1 cm. This value of elastic failure is most often encountered in practice.

Calculations on a computer were carried out for a hammer with a striking part weighing 500 kg. Mathematical planning of the experiment was used to organize calculations on a computer. The four-factor Hartley-Cohn plan was adopted [21,22]. In order to obtain analytical dependencies between the parameters of the studied system, a correlation analysis of the obtained data was carried out. The regression equations of the type were used for the analysis:

$$y = A + \sum_{i=1}^{n} B_i X_i; \tag{3}$$

$$y = A + \sum_{i=1}^{n} \left(B_i X_i + C_i X_i^2\right); \tag{4}$$

$$y = A + \prod_{i=1}^{n} X_i^B. \tag{5}$$

Co-impacts in the "hammer-head-shell-base" system are characterized by forces that appear at the contacts of the elements that are in direct contact during the impact. On (figure 4, a, b, c) graphs of changes in time of these forces, calculated with the same initial data for some time, at a level of 0,03 s after the first contact of the hammer with the head, are given. The impulse of impact forces is characterized by several peaks and has a complex damping character. The contact of the shocking part with the head is irregular. Thus, for a period of 0,06 s, 11 co-impacts occurred at the "hammer-head" contact and ten at the "head-shell" contact.

This way, we can talk about the presence of an oscillatory process in the "hammer-head-shell-shell-soil" system. The headrest oscillations are unstable. This follows from the fact that during slow, quasi-static immersion, oscillations do not occur. They occur only during impact and die out as the load decreases.

In real conditions, due to the inevitable eccentricities of load application, the headrest carries out not only translational movement along the vertical axis, but also angular oscillations. In the mathematical model, following the accepted assumptions, all movements occur only along the

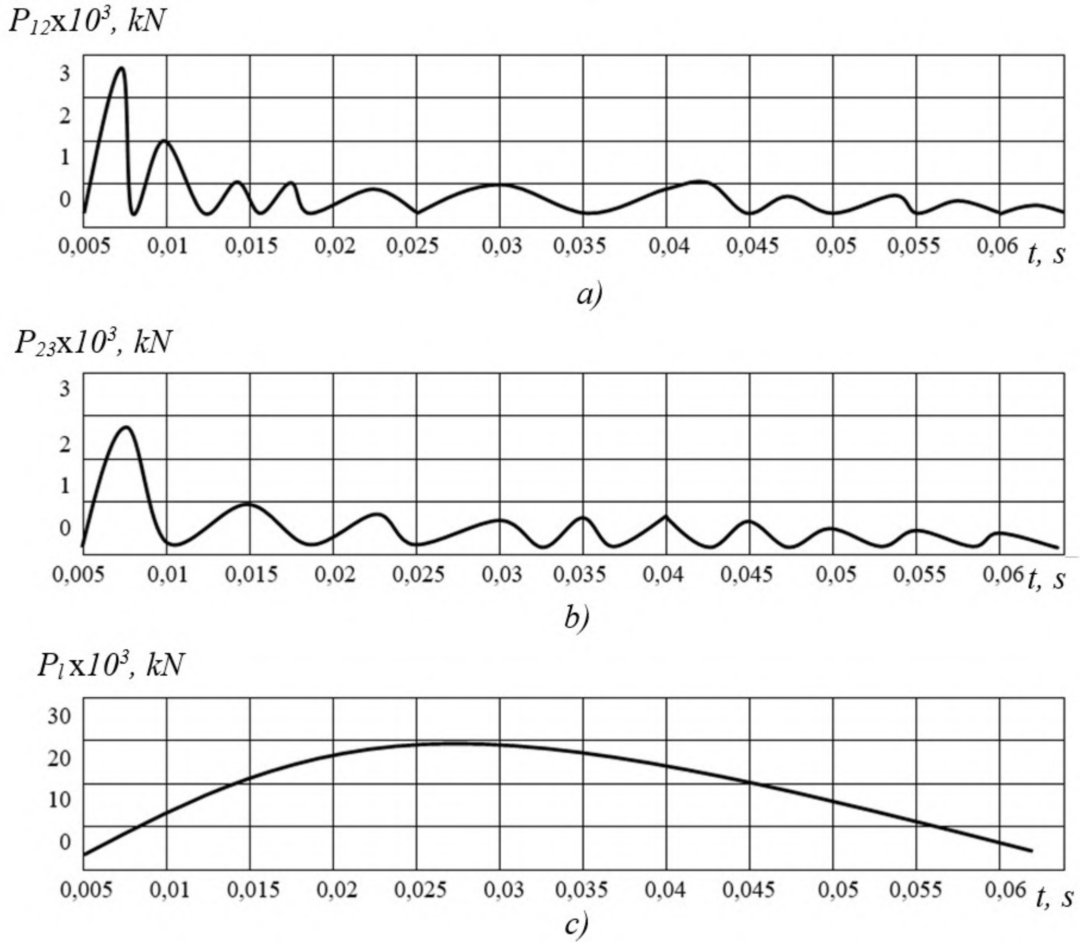

Figure 5. Forces acting on the contacts of colliding bodies: a) – hammer-head; b) – a head-shell; c) – is the frontal resistance of the soil.

vertical axis, so the graph of the impact force on the shell is divided into a number of separate co-impacts.

The observed multiple co-impacts of the headpiece with the shell are due to a significantly shorter period of the headpiece's own oscillations compared to the duration of the force impact. Therefore, the headpiece can be represented as a mechanical oscillator, brought out of equilibrium by mechanical co-impact with the striking part and then oscillating between two massive bodies: the striking part and the shell.

The regularities noted above were reflected in the correlation dependences for the impact force. The impact force on the "hammer-headset" and "headset-shell" contacts can be determined by the following dependencies:

$$P_1 = 314 m_m H_1 + 0.7R + 212\frac{m_m}{m_n} + 6131\frac{a_1}{S_1} + 950, \tag{6}$$

$$P_2 = 245 m_m H_1 + 0.97R + 522\frac{m_m}{m_c + m_{ob}} + 9231\frac{a_2}{S_2} + 637, \tag{7}$$

where $m_m, m_n, m_o b, m_c$ - are the masses of the hammer, head, shell, and core, respectively; a_1, S_1 , and a_2, S_2

- respectively, the thickness and area of the cushioning pads at the "hammer - headrest" and "headrest-shell" contacts;

H_1 - hammer lift height;

R - is soil resistance.

The correlation ratio of these formulas is at least 0,95. This testifies to the correct selection of varied parameters.

The analysis of the given dependencies shows that the force of the impact is mainly determined by the height of the impact part and the stiffness of the elastic gasket. The ratio of the masses of the hammer and the shell has a smaller influence on the immersion process. The influence of the physical and mechanical properties of the soil base is insignificant.

Despite the periodic nature of the force impact, the shell sinks into the soil base quite smoothly. This is explained by the significant mass of the shell, as well as the inertial stabilization properties of the soil base. The shell receives a positive acceleration under the influence of the first co-impact, and then the shell acceleration changes its sign, and its motion slows down.

For the value of the final failure, the best result is given by the dependence of the form:

$$\epsilon = 1.2 \frac{m_m H_1 \left(\frac{m_m}{m_n + m_c + m_o b}\right)^{0.2}}{R^{1.3} \left(10 a_1\right)^{0.64}}. \tag{8}$$

Analysis of the influence of various factors on the size of the failure shows that the impact of the stiffness of the shock absorber can be neglected since the reduction in failure when the thickness of the lining increases from 0,05 m to 0,25 m does not exceed 10%. Therefore, for practical purposes, dependence (8) can be simplified:

$$\epsilon = 1.2 \frac{m_m H_1 \left(\frac{m_n}{m_n + m_c + m_o b}\right)^{0.2}}{R^{1.3}}. \tag{9}$$

5. Conclusions

- The theoretical foundations for modelling, mathematical description and the possibility of optimization of the process of immersion of monolithic thin-walled spatial reinforced concrete shells in the soil environment have been developed.
- Evaluating the possibility of using complex models for practical calculations, it should be stated that, at the moment, there is not enough experimental data for a justified assignment of the numerical values of many indicators characterizing these models.
- The following factors significantly influence the failure of the shell: hammer lifting height, soil resistance, and the ratio of hammer and shell masses. The effect of shock-absorbing elements is insignificant.
- The most significant influence on the magnitude of the contact forces in the zone of the hammer-shell has: the height of the fall of the hammer and the stiffness of the elastic gasket. The influence of the ratio of the masses of the hammer and the shell, as well as the value of the soil resistance, is manifested to a much lesser extent.
- It is promising to establish the stress-deformation state of the soil base depending on the method of immersion and during the structure's life.

Abstract. Currently, the most widely used devices for measuring the level of liquids (float and non-float). Float gauges are generally more accurate than non-float gauges. However, the operating conditions of float level gauges are much more difficult due to the difficult operating conditions of floats in an aggressive environment with a large amount of mechanical impurities. Automation tools used to measure the weight of oil and oil products should provide output information in a form convenient for further processing, at the same time, these devices should be structurally simple and applicable to existing types of tanks. The amount of oil in tanks can be determined in two ways: by measuring the level of oil and its specific gravity; by direct measurement of the weight of a liquid. Each of these methods has its own advantages and disadvantages.Currently, the most widely used devices for measuring the level of liquids (float and non-float). Float gauges are generally more accurate than non-float gauges. However, the operating conditions of float level gauges are much more difficult due to the difficult operating conditions of floats in an aggressive environment with a large amount of mechanical impurities. The choice of this or that device is determined by the specific conditions of its operation, the required measurement accuracy, aggressiveness of the liquid, etc. Limit switches are installed on the level gauge, which, when the liquid level in the tank reaches the upper or lower limit mark, turn on the alarm circuit. The principle of operation of the level gauge is based on measuring the increase in the electrical capacitance of sensors when they are filled with a substance (oil product) that has a dielectric constant that is different from the dielectric constant of air. The measurement accuracy is achieved by the fact that the entire measured level is divided into separate equal sections and is determined, among other factors, by the length of each section.

1. Introduction

The amount of oil in tanks can be determined in two ways: by measuring the level of oil and its specific gravity; by direct measurement of the weight of a liquid. Each of these methods has its own advantages and disadvantages.

Currently, the most widely used devices for measuring the level of liquids (float and non-float). Float gauges are generally more accurate than non-float gauges. However, the operating conditions of float level gauges are much more difficult due to the difficult operating conditions of floats in an aggressive environment with a large amount of mechanical impurities [1].

The choice of this or that device is determined by the specific conditions of its operation, the required measurement accuracy, aggressiveness of the liquid, etc. Limit switches are installed on the level gauge, which, when the liquid level in the tank reaches the upper or lower limit mark, turn on the alarm circuit.

The principle of operation of the level gauge is based on measuring the increase in the electrical capacitance of sensors when they are filled with a substance (oil product) that has a dielectric constant that is different from the dielectric constant of air [2, 3].

Statement of the problem. The measurement accuracy is achieved by the fact that the entire measured level is divided into separate equal sections and is determined, among other factors, by the length of each section. The device consists of a receiver and a five-digit drum counter that counts the liquid level in the tank. The block diagram of the capacitive level gauge is shown in figure 1.

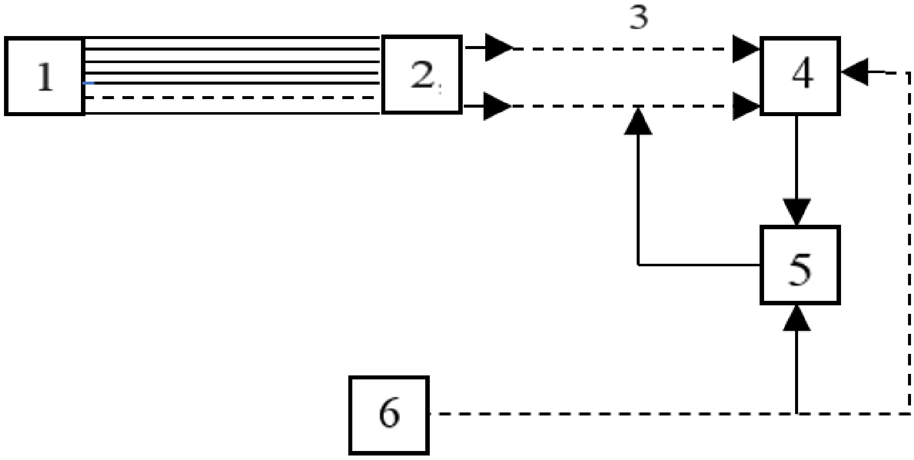

Figure 1. Block diagram of a discrete capacitive level transmitter.

It consists of a block of discrete sensors 1, a distribution block 2, a communication line 3, a measurement block 4, a control and registration block 5, and a power supply 6 [4].

The design of the sensors allows them to be attached to the fittings of the oil gauge glasses of the operated tanks. The sensors are pieces of two pipes of different diameters, located coaxially and isolated from each other by insulating washers. Sensors are grouped on a common pipe.

The pipe with sensors welded to it is inserted into the fittings of the oil gauge cocks. A threaded ledge emerges from the inner electrode of the sensor through an insulating sleeve, to which a filter is attached, consisting of an inductor, an isolation capacitor and a trimmer capacitor. The inductance of the filter, the capacitance of the sensor and the trimmer capacitor form a circuit tuned to the frequency of the generator of the measurement unit.

2. Results

The length of the section of each sensor is determined by the formula

$$1 \leq k\delta, \tag{1}$$

where l is the length of the section (sensor); k – coefficient; δ – permissible basic error.

For $k = 100$, the basic error is acceptable $\delta = 0.5$ cm, at $l \leq 50$ cm. Considering that the length of each gauge glass (between the respective fittings) is 1 m, then the number of sensors installed in each section should be $n_0 \geq 2$ [5, 6].

When manufacturing a level gauge with capacitive sensors, it is assumed that $n_0 = 3$; thus, 30 sensors were installed on the entire tank. The sensors are connected by a coaxial cable to the stepping finder of the distribution unit, installed at a distance of 10-15 m from them.

The distribution block is a piece of pipe with a flange and a cover. The step finder, when pulses are received from the programming device, alternately connects the sensors to the measurement unit.

The step finder with the measurement unit is also connected with a coaxial cable. To stabilize the parameters of the communication line and reduce additional errors associated with changes in temperature and humidity of the environment, the line is laid in a pipe, and part of the measuring unit to the step finder (distribution unit) is laid in the ground, and from the step finder to the sensor is covered with special thermal insulation.

The device is powered by 220 V AC mains. The measurement unit consists of a 100 W power transformer, a rectifier, and a discriminator generator [7].

An inductive circuit is connected to the anode of the generator lamp through a capacitor, which consists of two high-frequency transformers, the primary windings ($L1$ and $L2$) of which are connected in series. Each of the secondary windings $L3$ and $L4$ forms a circuit tuned to the frequency

$$f_1 = f_0 + (10 \div 20)\text{kHz}$$

Signals from the secondary windings go to the rectifier. The rectified currents are then fed for comparison to the input of an electronic potentiometer in the control unit. Parallel to the windings of the circuit $L3$ and $L4$, communication lines, additional inductances of low-pass filters, tuning capacitors and sensors are connected.

The variable load of the $L4$ winding is the capacitance of the main sensors, which are connected in turn to the winding by a stepper finder. Parallel to the winding $L3$, a control sensor located on the tank is permanently connected. Line connecting the control sensor with the winding $L3$, measuring block, has the same length as the line going to the main sensors and winding $L4$. Both lines are in the same conditions.

The above devices for automatic control of the amount of oil in tanks are based on the principle of measuring its level. Another method for determining the amount of oil in a reservoir is by weight.

The most convenient way to automate the measurement process is the so-called piezometric method (determining the weight of an oil product by its hydrostatic pressure).

Instruments designed for piezometric measurement of the weight of an oil product in a tank are compensatory pressure meters.

The operation of the device is based on the principle of force compensation, and discrete and continuous compensation is used to achieve the required high accuracy. Discrete compensation is carried out by weights, and continuous – by a lever with a movable weight.

As a sensitive element, which compares the measured and compensating parameters, a metal membrane with a rigid center, made of beryllium bronze, is used. The measurement error is mainly determined by the continuous compensation system, since discrete compensation is carried out with a high degree of accuracy. In this case, the total measurement error is the smaller, the more areas of discrete compensation for a given measurement range.

Indeed, if the entire range is divided into n parts, measured with a relative error δ_q and continuous compensation is performed with a relative error $\delta_{\text{continuous compensation}}$, then the largest total relative measurement error will be

$$\delta_0 = \frac{\delta_{\text{continuous compensation}} + \delta_{qn}}{1+n} \tag{2}$$

Having for the instrument $\delta_{\text{continuous compensation}} = 0.2\%$ and $n = 10$ and neglecting δ_q, because of its smallness compared to $\delta_{\text{continuous compensation}}$, we obtain the total compensation error up to $\delta = 0.02\%$. Then the accuracy of the device will be determined mainly by the stability of the characteristic and the sensitivity of the pressure element. The membrane used as a sensitive element has a linear dependence of the displacement force on the pressure within 0-1 kg/cm^2 and sensitivity 1-2 mm of water art., which provides the necessary measurement accuracy. The continuous compensation system is designed to create an accurate compensating force during the measurement process. During non-working hours, this system compensates for the weight of the plate, the elastic force of the rigid center, as well as the change in this force due to temperature and other external factors [8].

As noted above, during the measurement process, pulses are sent to dynamic errors from the system of discrete (coarse) and continuous (fine) compensation by the corresponding sensors. These pulses are fed to dynamic errors to the counting devices of the secondary device and the counting result is noted on the electroluminescent display. The block diagram of the secondary device is shown in the figure 2.

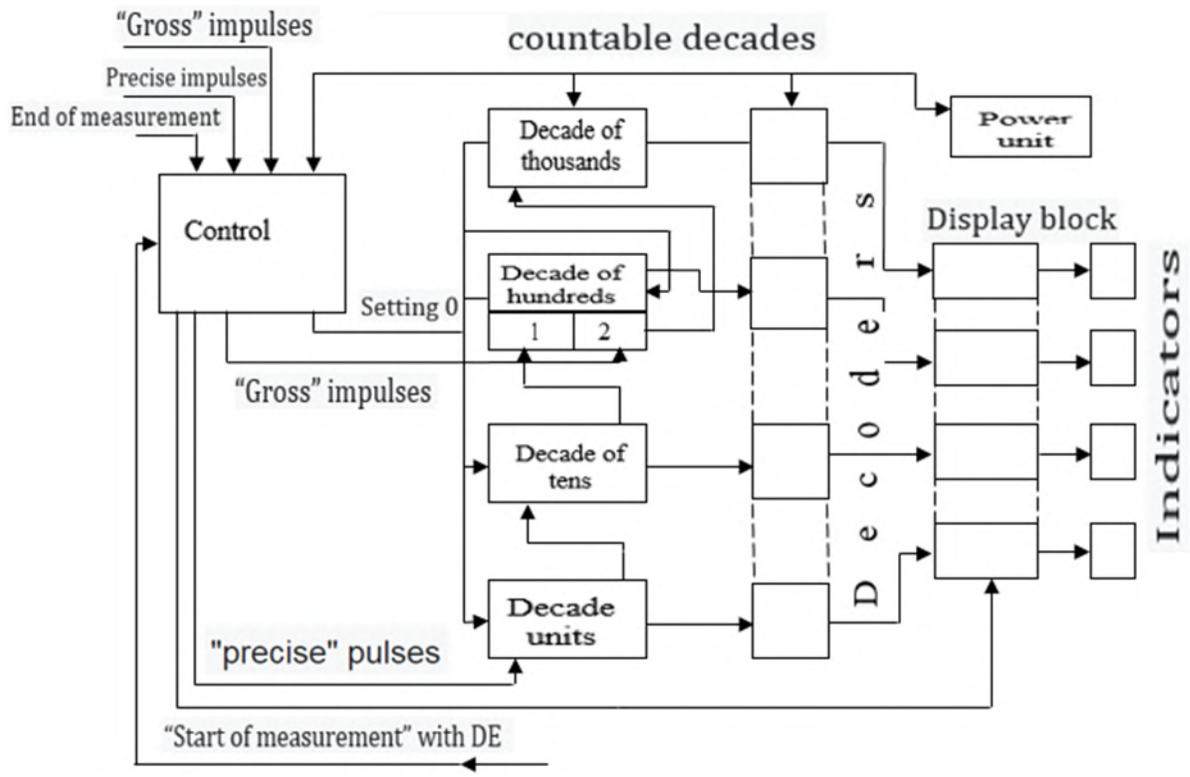

Figure 2. The block diagram of the secondary device.

The device consists of the following blocks: counting decades, decoder, indication, power supply and control.

The block of counting decades is a counter on non-contact triggers and carries out counting of impulses and storing results in the binary number system.

The decoder block, also made on non-contact semiconductor diode elements, decodes the results of the count in the decimal system. The decoded result of the count is transmitted to the display unit, consisting of four identical nodes with luminescent digital indicators (according to the number of decoder matrices), and is marked on it in the form of a four-digit number expressing the reading of the device.

The control unit sends pulses to start and end the measurement.

When compensation is reached, the null-organ turns off the lever motor, the counting of pulses stops.

After the pressure is removed, the discrete and continuous compensation systems return to zero.

With the piezometric method, the weight of the oil product in the tank is determined by the formula

$$G = pF_{av}(H), \tag{3}$$

where p is the hydrostatic pressure of the liquid column in the tank (determined by pulse counting), $F_{av}(H)$ – the average area of the tank at a given filling level H. The value of F_{av} is found from the expression

$$F_{av}(H) = \frac{Vh}{H} = \frac{1}{H}\int_0^H F(h)dh, \tag{4}$$

where $F(h)$ dependence of the tank section on height h. Value $F_{av}(H)$ variable in height and determined by calibration tables.

Thus, to find the weight G oil product with the piezometric method, it is necessary to know the filling height. For this purpose, the tanks must also be equipped with level gauges. However, in this case, the requirements for the accuracy of level gauges are low. Calculation of weight according to the reading of the weighing gauge with correction according to the data of the level gauge is simple and can be reduced to finding the weight according to pre-compiled tables [9].

This counting can be performed automatically by adding a computing device to the display unit that performs the multiplication operation.

To improve operational properties, explosion and fire hazard, as well as to simplify the design, the device measures directly the hydrostatic pressure of the oil product, and to it the air pressure supplied by the hydrostatic pressure transducer.

Thus, the process of measuring moisture content with the device is divided into two stages:

1) obtaining dehydrated oil (standard);
2) comparison of the dielectric constants of dehydrated oil (reference) and oil containing water.

Upon receipt of the standard (dehydrated oil), the investigated oil in the amount of 1 liter is placed in an autoclave and heated to a temperature of 170-180 °C.

The pressure in the autoclave is 7-8 kg/cm^2. Studies have established that this mode achieves the best separation of water and oil without changing its chemical properties.

To speed up the process of preparing the standard, forced cooling of oil in an autoclave is used. To do this, water is passed through a coil located inside the autoclave. Cooled to 38 °C, the oil enters the centrifuge, where the water is finally separated from the oil [10].

3. Conclusion

The article also deals with the design of sensor transducers for measuring various non-electrical quantities, as well as methods and devices for obtaining and processing measurement information.

The use of devices allows you to automate the process of pumping oil and the most important technological parameter – the dynamic level, which is especially important for marginal wells. In the experience, electrical automatic control devices, a variety of designs and schemes of measuring instruments were developed and applied.

Depth parameters of the wells, received the technological parameters of the drilling process and the geometric parameters of the wells. I obtained the greatest possibilities for controlling deep parameters during electric drilling, since the power channel connecting the deep-seated electric motor with surface equipment is at the same time a reliable communication channel for telemetry of deep parameters.

In the technological parameters of the electric drilling process, we obtained: the pressure of the tool on the bottom hole, torque, voltage on the downhole electric motor, the temperature of the clay solution, the temperature of the bottom hole, etc.

In this regard, during electric drilling, it is possible to control a complex of technological and geometric parameters of the drilling process and at the same time perform geophysical surveys of wells.

Abstract. The optimal geometrical parameters of boreholes in dimension stone quarries, whose impact on granite blocks separation and splitting efficiency, are determined, taking into account the stress-deformed state of rock massif. The crack initiation process is analysed considering the flat problem of elasticity theory. Determine destruction parameters of natural stone by borehole methods using the calculations of the required distance between the boreholes in the row along the splitting line with the specified borehole diameters, and created forces of stone destruction are proposed. The optimal shape of splitting block from massif depends on the specific plane of splitting is determined. The possible directions of borehole deviation from ideal ones, their extension due to drilling and tensions in the boreholes are studied. The introduction of the borehole's overlapping coefficient, which influences the weakening of the massif along the directed (designed) split line, is proposed to define further necessary tensions for mechanical ways of separating blocks. The equations for determining drilling operations parameters at granite blocks splitting from dimension stone quarries massifs are proposed. The coefficient of limit values of deviation angles is defined.

1. Introduction

Extraction of natural stone in dimension stone quarries consists of different processes such as: drilling, blasting, splitting, cutting, crushing, excavation, etc. Besides mining, many of those operations also apply to civil engineering [1].

Extraction technology of dimension stones is characterized by specific factors that aim to keep the physical and mechanical natural stone properties and get blocks with a straight shape and effective commercial size [2].

All used methods for dimension stone block extraction can be divided into crack-forming, split-shaping, physical, technical and combined methods. Still, the most common ones are crack-forming and split shaping.

Used split-shaping (fracturing methods) methods for the creation of critical tensions in the splitting planes are formed by drilling boreholes. Fracturing methods into splitting with shims, control blasting processes or thermal procedures and using non-explosive destructive mixtures are divided.

Using the technology of dimension stone extraction during the process of splitting blocks from the massif mostly the splitting methods by shims are used. In practice, due to drilling deformation and borehole deviation, the horizontal projections of the hole's tops and bottoms usually do not be projected one on one. Sometimes boreholes curvature causes the intersection of the next holes in the middle of the length or near their bottoms. In such case, it causes the formation of large rough surfaces after splitting on the block's surfaces, that result in significant losses of stone in further processing operations. The incorrect position of the boreholes' bottom causes the unequal concentration of splitting tensions. It is the result of diagonal fracture formation.

Extraction of natural stone blocks has a large amount of drilling. The quality of drilling operations performance determines the effectiveness of further operations for splitting blocks from the massif. Borehole deviation from the design position causes an increase in the volume of drilling operations due to an increase in the length of drilled boreholes. When using fracture-forming methods, the deflection of borehole axes causes a change in the geometry of splitting forces spreading, affecting the efficiency and quality of the splitting and separation process. Borehole deviation when performing drilling operations of stone massif drilling can cause increased separation area, tool costs, and poor quality of block production. The quality of drilling boreholes is determined by a number of indicators: mode parameters of the drilling process, type and condition of drilling tools, and state of the rock mass. One of the most promising directions of improving extraction processes is optimizing drilling operating parameters, considering the natural fracturing and physical and mechanical properties of dimension stone [3].

Thus, the research of the impact of these factors on the efficiency of drilling operations is a topical scientific and practical task, the solution of which will improve the efficiency of extraction natural stone technology and the quality of natural stone blocks.

2. Statement of the problem

Recently many researchers were based on such important operations as drilling, which was performed with different materials, particularly dimension stones drilling in quarries. Drilling is an important process during dimension stone extraction because an inefficient drilling process can cause huge operational losses [4]. That's why mining enterprises should attempt to optimize those losses. Optimizing drilling losses is also sufficiently effective for further developing mining technologies [5].

Many studies and research for increasing drilling process efficiency are based on determining the optimal speed of penetration of the drill steel (jackrod) and sintered diamond coring a bit into massif. It is based on the optimal choice of the type of drilling equipment according to the current condition of massif and determination of the sufficient force for penetration into the rock [6]. Assessing drilling efficiency considering rocks' properties is also an important part of research [7].

Another scientific and applied drilling problem is the problem of geometric linearity deformation and extension of the boreholes. During drilling, the drill steel and the sintered diamond core bit strike the rock mass, forming a borehole [8]. As a result, a circular borehole wall becomes deformed, and the total borehole area is also changing. This process can cause further crack creation and reduce tensions in the splitting plane [5].

Calculating the optimal tensions for splitting blocks from massif is also important to analyze the micro-cracking process. Particularly this analysis can be found in the following work [9, 10], where are described the micro-cracking process and analysis of mechanical features of rocks during splitting [11]. The crack creation and the process of further formation of cracks are described by Huang et al [12].

The optimization of technological mining parameters in the quarry for dimension stone blocks quality improvement, which is based on photogrammetric measurement techniques, is researched by Levytskyi et al [13].

During extraction of the dimension stone, it is important to study the massif's deformation mode (stress-deformed state) in detail. The boreholes drill along the splitting line of the monolith.

All previous studies do not indicate how much the hole deviation line from the designed direction reduces the coefficient of massif weakening. Also, the problem of the loss stone coefficient changing after the deflection of boreholes is not considered earlier as a result of a change in the shape of stone blocks, causing to increase in the costs of further processing.

3. Methodology

The method of determining the destruction of stone by hole methods is to determine the required distance between boreholes in the line of splitting with given borehole diameters, creating splitting tensions. Throughout the studies, full-scale measurements of lengths and diameters were carried out of boreholes. After the block was splitted off, the azimuths of boreholes deviation from the optimal directions and the dimensions of the directly extracted blocks with all inequalities were considered (figure 1).

Figure 1. Splitted block by hydro shims.

According to this method, it was determined that the optimal shape of the splitted block from the massif (the equality of splitting planes and their mutual perpendicularity) depends on the specific area of splitting, i.e. the correlation of the area formed by the split plane to the total area of splitted block or monolith.

4. Results

The study about the causes of the drilled borehole's deviation shows that it occurs due to geological, technical and technological factors. During the drilling of the borehole, deviations can occur due to the following reasons: encounter with a crack, a stress state factors of the massif, inaccuracies in the installation of the perforator, a clearance due to physical tool wear or structural defects in the particular part of the drilling machine and influence of the surface roughness on which the machine is installed for the accuracy of the installation.

The least studied and the most actual research on borehole drilling is the definition of the influence of the zone of overlapping holes on the deviation of the borehole according to the designed position [14].

The criterion for determining the maximum permissible values of the hole deviation angle from the vertical is the condition of excluding its intersection with the next holes. It should be noted that the limit criterion is valid in such cases when the borehole axis coincides with the plane of borehole lines. In case the difference between the azimuthal borehole axis angle and the plane of borehole lines, the maximum deviation angle will be determined by additional geomechanical determination of the stone blocks splitting process.

In practice, vertically drilled boreholes are over-crossed with one or a series of sub-horizontal cracks. Each of these cracks adds value to the axis deviation angle. For the linear drilling method, the criterion for the quality of drilling is also the geometric parameters, namely the orientation of boreholes that may intersect with each other.

Only for different dimension stones, the method of line drilling, which is combined with the mechanical stresses initiation in the boreholes, the quality of drilling operations will be determined in addition to the geometric parameters, also by parameters of formation of the stone massif tenses. Methods of calculation of the borehole parameters, which are based on practical experience and conducted scientific research, are used in the technology of dimension stone block extraction.

The dimension stone extraction calculation methodology by splitting boreholes method is determined by the required distance between holes within the boreholes line of the given diameter and splitting stone forces.

The research has established that the quality of the stone splitting from the massif (the equality of splitting planes and their mutual perpendicularity) depends on the specific splitting plane. That is the ratio of the area formed by the holes to the overall area of splitted block or the monolith.

One of the important technological parameters of the extraction of granite blocks is the required distance between the holes that are drilled in the designed splitting plane. These formulas were obtained empirically and analytically and provided a diagram of the stress state of the rock monolith, where the static stress acts inside the wells without stress concentrators.

For calculation of the distance between boreholes, it is proposed to use an equation that, when used further, obtains the most accurate results:

$$L = \frac{\pi d_h l_h p(t)}{2H\sigma_p k(t)}, \tag{1}$$

where d_h − diameter of the borehole; l_h − borehole length; $p(t)$ − pressure on the walls of the borehole; H − granite monolith height; σ_p − ultimate rock tensile strength; $p(t)$ − a coefficient that takes into account the reduction of the strength of the stone from the time of loading, which varies from 0,1 to 0,7, depending on the orientation of the splitting plane along the layer, or at an angle to it (anisotropic properties). During the drilling of the borehole line for splitting, in addition to the basic equations of the flat problem of elasticity theory, the plane of borehole displacement from its ideal location has to be considered. It means that the borehole has neither deviation in the azimuthal direction (α), nor in a circular direction (ϕ) (figure 2).

To determine the specific splitting area for one shim, a dependence which takes into account both geometric parameters of splitting and the anisotropic properties of natural stone, which makes it possible to use it in different deposits, was used:

$$S_0 = k_a \left(1 + \frac{PU}{\sigma_p r_g}\right) m^2, \tag{2}$$

where k_a− coefficient defines the anisotropic properties of the rock (for erupting rocks k_a = 0,2−1,0).

For the best splitting stone direction k_a = 1,0, and in the direction $\pi/2$, $3\pi/2$, for labradorite k_a = 0,6, gabbro-norite k_a = 0,2, granite k_a = 0,4; P − pressure in the system, Pa; r_g step between elements of hydro rock splitting systems installation, m; σ_p − tensile strength of granite,

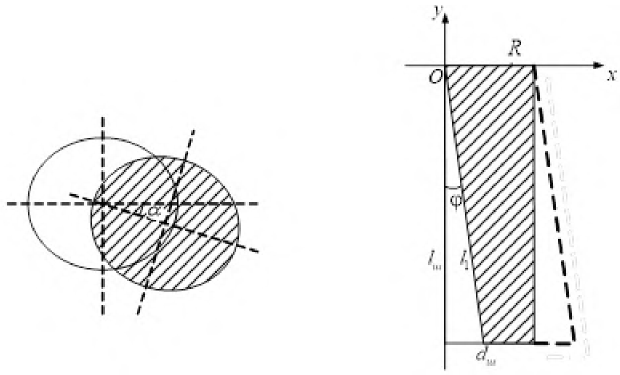

Figure 2. Borehole pattern.

MPa; U − specific relaxation ratio of the splitting plane by drilled boreholes, which depends on the location of the boreholes in the splitting plane:

$$U = \frac{zd_b}{S} = \frac{zd_b}{ah}, \tag{3}$$

where z − total drilled holes length in the splitting plane, m; d_b − diameter of the hole, m; S − the block cut-off area with the length (a) and the height (h), m^2.

The values of z are determined from the dependence:

$$z = (l_{bg}n_{bg} + l_{bp}n_{bp})k_{dr} = \left(\frac{a}{r_g} - 1 + k_n\left(\frac{a}{r_g} - 1\right)\right)hk_{dr}, \tag{4}$$

where l_{bg}, l_{bg} - length of boreholes where there are hydro rock splitting systems installed $(l_{bg} = h)$ and additional boreholes for massif weakening $(l_{bp} = k_n)$, m; n_p, n_{bp} – number of boreholes respectively for the installation of hydro rock splitting systems and additional boreholes for massif weakening; k_{dr} − uneven rate of drilling $(k_{dr} = 0,9)$; r_p − distance between additional boreholes for massif weakening, m; k_n − coefficient of reducing the length of weakening holes $(k_n = 0 - 1)$.

Reducing the above expressions and also taking into account that splitting is performed in the vertical plane of the dimension stone blocks with the length a and height h for $l_{bg} = h$ and $l_{bp} = h/3$, we obtain the following relation (correlation):

$$S_0 = k_a\left(1 - \frac{P(3r_p + r_g - 4r_gr_p)k_{dr}d_b}{3\sigma_pr_g^2r_p}\right), \tag{5}$$

As it seens from the expression, the specific splitting area by hydro rock splitting systems does not depend on the height h of the ledge.

The technological coefficient of losses from the drill-split shim method of separating granite blocks k_{tl} is determined by the following equation:

$$k_{tl} = \frac{\pi d_b^2 z}{4abh}. \tag{6}$$

An ideal borehole area and an actual overlapping area are introduced. The ideal borehole area can be described by equation $S_i = l_nd_n$. The actual overlapping area can be described by equation $S_n = f(l_h; d_h; \alpha\phi)$

The coefficient of splitting plane weakening: $K_{alap} = \frac{S_i}{S_h}$.

In the limit values at the maximum deviation, the coefficient of massif weakening will be for $\alpha = 0^0 - S_h = \pi R \frac{l_n}{\cos\phi}$, for $\alpha = 90^0 - S_h = \frac{\pi R}{2} l_2 = \frac{\pi R^2}{2\sin\phi}$. So in all other possible positions, the actual boreholes overlapping area will be:

$$S_h = \left[\frac{\int_0^3 (l_h; d_i; \phi) d\phi}{\int_0^{90} (l_h; d_i; \alpha) d\alpha}, \right. \tag{7}$$

Taking to according that the loss coefficient and the weakening massif coefficient depend on such parameters as hole diameter and depth, which in most cases equals the height of the bench. It can be argued that when splitting the block, it is also necessary to take into account the split-line direction if the designed directions of drilling operations are not kept.

As a result of field measurements, experimental values of the reduction of the weakening massif coefficient were obtained due to the deviation of holes from the designed direction. As a result, the values of the weakening coefficient were determined for different values of the directional angle and the vertical deviation angle; the graphic representation of this dependence is shown in figure 3.

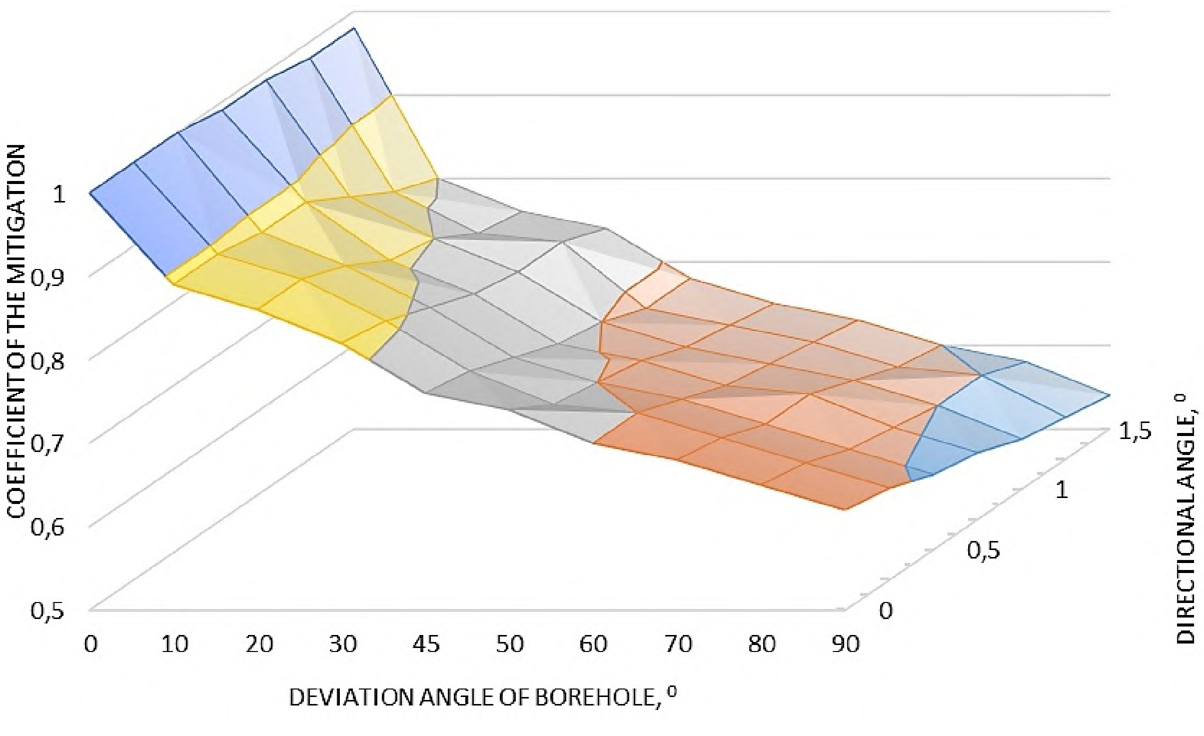

Figure 3. Change the coefficient of the massif mitigation.

The above formula of technological loss coefficients, Eq. (7), allows you to determine the coefficient of removal of blocks and the complex productivity of equipment for preparing blocks for extraction.

In an ideal three-dimensional model of massif cracking, the geological coefficient of loss kg.l = 0, since the main systems of cracks are parallel with each other and their planes intersect at right angles. Separate this three-dimensional model on the SQL, SQS, SSL planes, the simple models of individual location crack systems location in the dimension stone massif we obtained (figure 4).

Considering the absence of ideal conditions on natural stone deposits, a non-orthogonal model was introduced in which the basic systems of cracks do not intersect at a right angle γ. At the

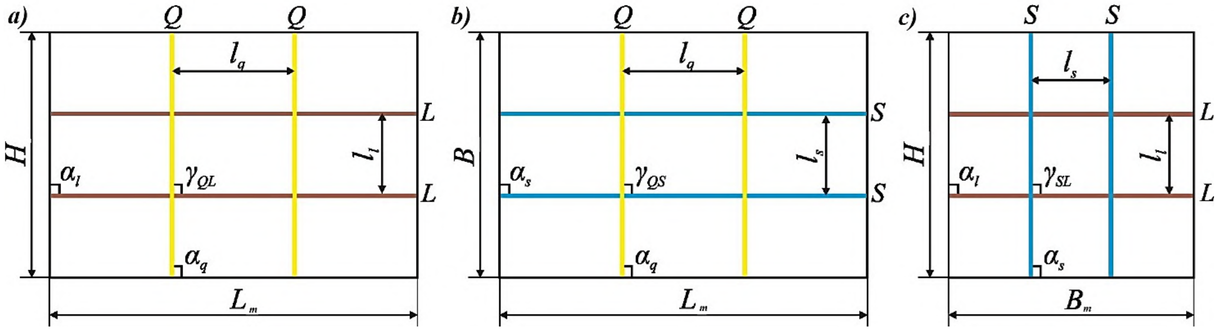

Figure 4. Orthogonal models of the propagation of Q_{LS} systems in the natural stone massif: a) the longitudinal vertical plane of S_{QL}; b) the blanket horizontal plane S_{QS}; c) the lateral vertical plane of S_{SL}.

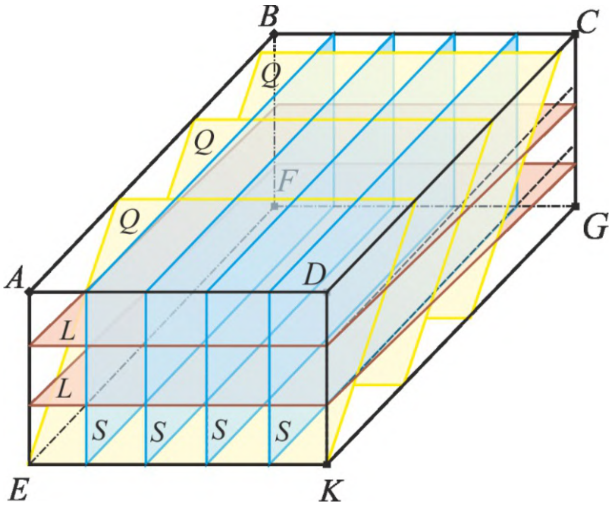

Figure 5. Three-dimensional model of a natural stone massif fracture.

same time, it is considered that the angles of falling cracks in the massif are constant; that is, all the cracks of one system are parallel. Given all the above, a three-dimensional model of the fracture of an array (figure 5) was developed, which will allow determining the most optimal directions of drilling operations with the subsequent minimal losses of minerals.

The following dependencies determine areas of separation planes in the case with:

$$S_m^{QL} = L_m H_m = \frac{1}{\sin\gamma_{QL}}\left[\frac{(n_l l_l)^2 \sin\alpha_q \cos\alpha_q}{\sin\gamma_{QL}} + n_l n_q l_l l_q\right]; \tag{8}$$

$$S_m^{QS} = L_m B_m = \frac{(n_q l_q \sin\gamma_{QS} + 0,5 n_l l_l \sin 2\alpha_q)(n_s l_s \sin\gamma_{QS} + 0,5 n_i l_i \sin 2\alpha_s)}{\sin\gamma_{QS}^2 \sin\alpha_q \sin\alpha_s}; \tag{9}$$

$$S_m^{SL} = B_m H_m = \frac{1}{\sin\gamma_{SL}}\left[\frac{(n_l l_l)^2 \sin\alpha_s \cos\alpha_s}{\sin\gamma_{SL}} + n_l n_s l_l l_s\right]. \tag{10}$$

where H_m, L_m, B_m – height, length and width of the monolith, respectively, m; n_q, n_s, n_l – amount of blocks between planes respectively of transverse Q, longitudinal S and smooth L cracks of the massif, within the linear dimensions of the monolith, units; l_q, l_s, l_l – distance between the planes of the corresponding systems of cracks, m; α_q, α_s, α_l – falling angles of the corresponding cracks systems, degrees; γ_{QL}, γ_{QS}, γ_{SL} – angles between the corresponding cracks systems that determine the non-orthogonally of the cracks systems with each other, degrees.

The indicator, which characterizes the overall geometric parameter of breaking, is the specific plane of splitting. In mining practice, the line of drilled holes in a certain vertical plane, due to some deviation of their axis, will only partially intersect the designed plane. Only in the case of a deviation of the hole along the planned plane of splitting its section throughout its length will it keep in this plane.

5. Conclusion

The value of the specific splitting area during the monolith preparation to the extraction will be less than the estimated, which effect to splitting parameters of blocks from the dimension stone massif. Therefore, the overall quality index of drilling can be taken as a performance criterion for splitting blocks from the massif.

The values of tensions allow analysing the conditions for the creation of cracks for splitting blocks from the dimension stone massif. It should be borne in mind that the theory of failure considers only the most significant stresses, not taking into account that other present stresses also affect the achievement of the critical state. The critical value is σ_γ for a dimension stone massif. It can be determined the critical tension initiates cracking formation.

The quality of the stone preparation for splitting depends first of all on the plane of designed split plane, the main characteristic of which is the specific value of splitting plane. As proved by the calculations, this value depends on the angle of borehole inclination. It was researched that boreholes have different values of deviations from vertical, which cause a decrease of the specific value of splitting plane, which depends on the azimuthal α and the zenith angles ϕ of hole axis along the designed split-line. It is obtained that the most negative values of the azimuthal angle α are observed in the range from 72° to 90°, and the zenith angle ϕ from 0,75° to 1,4°.

Abstract. The unfavorable situation that has developed in the economy due to the war in Ukraine, the difficult working conditions of workers in the mining industry, the lack of efficiency of labor protection measures taken lead to an increase in the level of occupational morbidity among employees of enterprises. The need for safety requires the setting of tasks, within which it is necessary to conduct a detailed analysis of a specific production activity, identify its inherent dangers and develop effective measures to protect the personnel. The purpose of the work is to develop a system of events for improving the level of safety in the mining industry on the basis of risk management, which will reduce the dynamics of occupational diseases at work. The importance of the work is in the implementation of a systematic analysis of the harmful production factors impact, taking into account working conditions, the intensity and duration of these factors impact on miners throughout their work experience in order to prevent, timely diagnose, and treat patients with occupational diseases. The introduction of methods and techniques to improve the level of safety at mining enterprises will ensure a decrease in the level of occupational morbidity among workers.

1. Introduction

Along with difficult mining and geological conditions, the level of accidents, injuries and occupational diseases is significantly affected by the crisis in the coal industry of Ukraine in terms of technical, economic, financial and social indicators. As of the beginning of the year, there are 148 mines in Ukraine, 102 of which are state-owned. Most of the mines are located in the territory not controlled by Ukraine (67), 2 more mines are not operating, 33 are operating (but only 4 are considered profitable). That is, about 30 mines are modern enterprises, and more than half of the mines operate without reconstruction, have complex ventilation networks and multi-stage underground transport. In the total fleet of operating downhole equipment, the share of mechanized mining complexes and road headers of a new technical level is only 2%. In general, the industrial and production assets of coal mining enterprises are worn out by an average of 65% [1].

The main reason for the crisis state of the industry is insufficient funding, when the volume of capital investments, which has decreased by more than 3 times, and the prices of materials and equipment have increased 2, 3 and more times. Low salary levels and delays in their payment have become the main reason for the outflow of qualified personnel [2]. In this connection, in the indicated crisis conditions, the role and tasks of the labor protection management system operating in the coal industry increases (the main goal of which is to create safe and healthy working conditions in accordance with the requirements of labor safety rules) [3].

High rates of occupational morbidity in the mining industry and insufficient efficiency of the measures taken for labor protection satisfy neither the owners, nor employees, nor the state. The dynamics of occupational morbidity indicators is evidence of the absence of trends in its decline, and the share of workers in the mining industry accounts for about 76% of diseases [4]. Solving the problem, a significant reduction in the level of occupational morbidity of workers at coal enterprises, is an urgent and priority task. The most vulnerable link in the current approaches to the prevention of occupational diseases was the lack of 1) a regulatory and methodological framework for calculating risks, building work regimes, 2) methods of stimulating economic interest in carrying out activities through the system of compulsory social insurance, 3) conducting in-depth medical examinations of miners and social rehabilitation measures [5]. In this regard, it is necessary to develop new conceptual approaches to the prevention of occupational diseases of workers of coal enterprises, based on the development of methodological principles for managing the risk of occupational diseases in coal mines, which make it possible to increase the effectiveness of preventive measures.

The aim of the work is to develop methodological principles for managing the risk of occupational diseases at mining enterprises, which make it possible to increase the efficiency of the occupational health and safety management system and measures to prevent occupational diseases of workers. The main idea of the work is to identify harmful production factors, based on the analysis of working conditions for the entire length of service of an employee of the coal industry. And also the formation of methods for the prevention of occupational diseases, based on the principles of taking into account risk factors for the development of occupational diseases, and establishing the dependence of their manifestation in order to predict (predict) a possible occupational disease. Development and implementation of measures to reduce the level of occupational morbidity of workers who work at mining enterprises.

The object of the research is the occupational health and safety management system and the prevention of occupational diseases of workers who work at mining enterprises.

Research objectives: analysis of the state of occupational morbidity in the coal industry and the regulatory legal framework for the investigation and registration of cases of occupational diseases; identification of indicators of the significance of harmful production factors; to establish the etiology and causation of occupational diseases at typical workplaces of workers in an underground group of coal mines; establishment of patterns of development of occupational diseases depending on specific working conditions (tension, severity) and development of risk management methods; development of a set of indicators for assessing the effectiveness of the functioning of the labor protection management system to reduce the risk of occupational diseases and the classification of working conditions and occupational diseases development of an algorithm for managing the risk of occupational diseases for workers who work at mining enterprises; development of methodological principles for managing the risk of occupational diseases, development of an algorithm and mechanism for transforming the existing system for the prevention of occupational diseases at mining enterprises.

The coal industry is considered one of the most dangerous sectors of the economy. Working conditions in coal mines are characterized by a number of factors that have a harmful effect on the human body. Harmful factors include rock dust, noise, vibration, sudden temperature changes, high air humidity, the need to work in a forced position, and harmful gases. The impact of these factors causes occupational diseases of workers and the number of occupational diseases in the coal industry is increasing.

In the structure of occupational morbidity of workers in the mining industry, the largest specific weight is made up of diseases of dust etiology, musculoskeletal system and vibration diseases. In industry, most of the industrial production personnel work at elevated levels of dust content – 58.4%, noise – 55.7%, vibration – 28.5%, chemical factors – 14.5%, humidity – 14.9% and temperatures that do not meet sanitary standards – 15.0% [6]. Figure 1 shows the structure by production factors that caused occupational diseases.

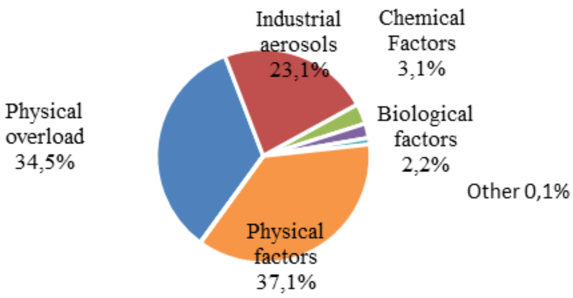

Figure 1. Distribution of harmful and hazardous production factors causing occupational diseases in coal mines.

.

High levels of indicators of the severity of the labor process (classes 3.1 – 3.3) are observed in working specialties and mid-level specialists. In the first group, high rates are due, first of all, to the lifting and movement of excess cargo masses by hand, forced tilts of the body at an angle of more than 30 and movements in space. In the second group, the need to use in the process of work a large number of portable control measuring instruments, which are used directly by the employee, and movements in space due to the technological process. High indicators of the severity of the labor process are a prerequisite for the development of diseases of the musculoskeletal system. High indicators of the intensity of the labor process are directly related to the specific conditions of underground work, which requires knowledge of a series of instructions both on labor protection and industrial safety, and on mining, and, in addition, with high emotional stress.

To assess the risks of occupational diseases, it is necessary to use effective methods of their identification, based on taking into account all hazardous and harmful production factors with the use of express methods for assessing the intensity and severity of the labor process, the Map of the working conditions of workers, as well as establishing the causal relationships of certain forms of diseases from exposure complex of harmful and dangerous production factors [7].

2. Results and discussion

As a result of research and application of mathematical methods of analysis, the regularities of the risk of occurrence of certain types of occupational diseases in workers were identified and presented, depending on the profession and work experience [8]. In the study, the risk of getting an occupational disease for workers in a certain profession is understood as the probability of an employee getting sick in relation to the total number of workers in reduced working conditions. Risk is calculated using the following formula (1):

$$R = \frac{N_d}{N}, \tag{1}$$

where N_d – number of workers with occupational diseases in a particular profession; N – total number of workers.

The processing of data on occupational diseases made it possible to obtain data on the risks of diseases for the main underground professions, depending on the length of service in hazardous working conditions (table 1).

Table 1. Risks of getting occupational diseases in mines.

Profession	The risk of occupational disease Work experience in adverse conditions, years					
	10-14	15-19	20-24	25-29	30-34	35-39
Tunneller	0.0012	0.0112	0.031	0.0410	0.0454	0.0462
Longwall miner	0.0010	0.0123	0.0291	0.0423	0.0491	0.0512
The operator of mining excavation machines (in the longwall)	0.0005	0.0121	0.0318	0.0407	0.0495	0.0497
Underground miner	–	0.0007	0.0041	0.0047	0.007	0.0081
Underground electrician	0.0004	0,0025	0.0053	0.0071	0.0072	0.0080
Mining master	–	0.0024	0.0087	0.0105	0.0132	0.0147
Mining assembly worker	–	0.0017	0.0026	0.0035	–	–

The results obtained make it possible to predict the occurrence of an occupational disease in workers, depending on the length of service at the enterprise. For this purpose, data on identified occupational diseases at more than 10 coal enterprises from 2015 to 2021 were used, taking into account the total number of workers employed in production. The resulting cumulative dependencies between these parameters are shown in figure 2.

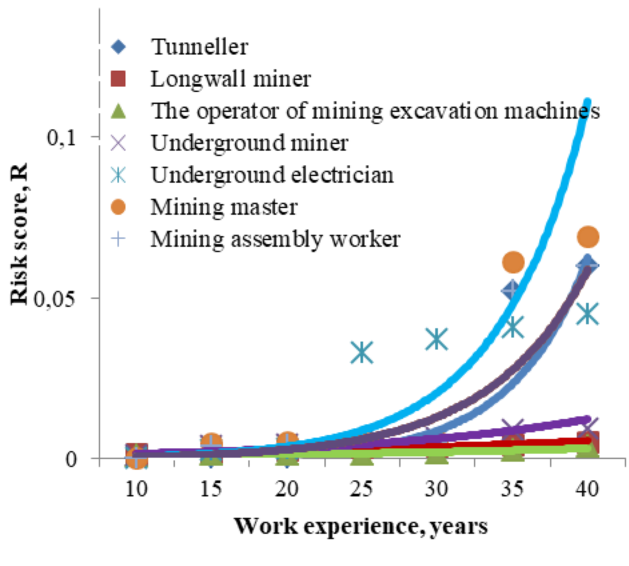

Figure 2. Cumulative dependence of occupational disease on the length of service in professions in coal mines.

Estimated data are described with the greatest accuracy by a dependence of the form (2):

$$y = a \cdot e^{bx}, \tag{2}$$

where y – an indicator of the risk of getting an occupational disease; x – work experience; a, b – regression coefficients.

The values of the coefficients a and b are presented in table 2.

Table 2. Values of indicators of the dependence of occupational disease on the length of service in professions in coal mines.

Profession	Coefficient values		Correlation	Student's coefficients

Mining assembly worker	0.00001	0.1815	0.72	8.75	2.02

The analysis of cases of occupational diseases in more than 10 enterprises made it possible to establish the critical period of work experience in the profession, in which the largest number of cases is observed.

For all professions, when assessing absolute values, it was 20-24 years. The decrease in the number of cases of occupational diseases after 20-24 years of professional activity of an employee is statistically due to the fact that the number of employees with a total length of service (in the total number of employees) is removed in connection with the release of a preferential pension and with an established occupational disease in earlier years of employment [9].

The obtained results of the study make it possible to develop diagnostic maps for assessing the risk of an occupational disease depending on the length of service, degree and type of exposure to harmful and dangerous working conditions on an employee in the main professions – longwall miner, drifter, operator of mining excavation machines (in the longwall), underground miner, mining foreman, underground electrician, miner (table 3).

Table 3: Diagnostic card for assessing the risk of occupational disease in longwall miners, depending on the length of service and diagnosis in coal mines.

– Minimal risk
– Acceptable risk
– Unacceptable risk

Thus, the revealed patterns of the risk of certain types of occupational diseases among workers, depending on the profession and work experience, are a sufficient and necessary basis for developing methodological principles for managing the risk of occupational diseases [10].

The paper developed methodological principles for managing the risk of occupational diseases at mining enterprises, proposed a coefficient of working conditions, according to which the classification of enterprises was carried out depending on the likelihood of exposure to harmful and dangerous production factors on workers. An algorithm for managing the risk of occupational diseases and approaches to improve the functioning of the labor protection management system in the field of reducing the risk of occupational diseases have also been developed.

The minimum risk of occupational diseases is understood as the value of the risk probability in the first class of the probationary exposure of the diagnostic card for assessing the risk of an occupational disease in which the disease is recorded.

The unacceptable risk of an occupational disease is understood as the maximum value of the risk probability according to the diagnostic chart for assessing the risk of an occupational disease [11].

The acceptable risk of an occupational disease is understood as the value of the probability of the risk of an occupational disease, which is between the minimum and maximum risk of a diagnostic chart for assessing the risk of an occupational disease.

The results obtained made it possible to identify the patterns of occurrence of occupational diseases among workers, depending on the length of service, profession, degree and type of exposure to harmful and dangerous working conditions, and also to develop an algorithm for managing the risk of occupational diseases [12].

Thus, taking into account risk factors (profession, length of service in hazardous conditions, type of exposure to harmful and dangerous production factors) of the occurrence of an occupational disease and establishing a dose-related dependence of the occurrence of a certain type of occupational disease in a particular profession, allows you to predict a possible occupational disease and redistribute the quality and level of control over working conditions and health of the staff [13].

The regional system of labor protection should have in its arsenal a set of effective management methods, the control over the work of which, as an object of management, includes mining enterprises that differ in natural, technical, technological and organizational conditions [14].

At present, classifications are widely used according to one attribute (and usually the most important), which determines the general level of danger of the mine and the technological principles of coal mining (methane content, gas emission) [15].

At the present level of development of the science of labor protection, it is possible to develop multidimensional classifications according to the factors that determine the level of danger to the health of workers [16]. This makes it possible to single out indicators of enterprise groups that are increasingly stable in terms of variability, which is a way to more accurately determine the rationality of applying certain methods of managing these objects [17].

Currently, most researchers prove that the probability of the implementation of occupational diseases should be considered as a set of random variables [18]. This circumstance, as well as the selective nature of the information used, determines the feasibility of a probabilistic-statistical approach to the classification of mining enterprises.

The main stages of the proposed methodology for classifying by the level of risk of occupational diseases are:

- the choice of parameters by which the object is delimited;
- formation of a training sample;
- choice of object delimitation method;
- establishing the homogeneity of the selected object.

One of the main tasks in the classification of objects is the choice of parameters by which the existing sample is distinguished into homogeneous groups. Studies have shown that working conditions are assessed by a fairly wide range of indicators [19].

The working conditions at the mine with a sufficient degree of objectivity can be characterized by the following indicators: tension, severity, harmful substances, microclimate, illumination, infrasound, vibration, noise.

Also in the work, a mechanism for improving the labor protection management system in coal mines, the results of testing the developed methods and proposed principles, as well as an assessment of the effectiveness of the proposed measures to improve the labor protection system are given. The study of the regularity of the occurrence of occupational diseases in coal mines made it possible to establish that they vary within a fairly wide range and their nomenclature is also different [20].

Theoretical and practical interest is to identify the relationship between working conditions in mines and occupational diseases [21].

To do this, it is advisable to introduce the concept of specific occupational morbidity M_s (the risk of getting an occupational disease), the value of which is calculated by the formula (3).

$$M_s = \frac{M_{gen}}{N}, \tag{3}$$

where M_{gen} – is the general morbidity at the mine; N – is the number of employees at the mine.

The sample of occupational diseases was formed according to the data of 10 mines. The resulting relationship between M_s and C_{work} (working conditions coefficient) shown in figure 3.

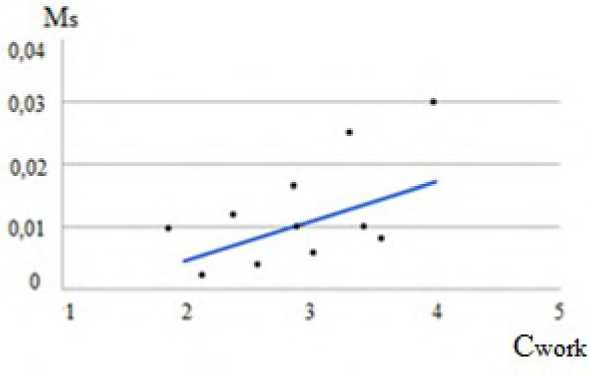

Figure 3. Dependence of the coefficient of working conditions and the value of specific occupational morbidity in coal mines.

The resulting dependence is most accurately described by the following formula of the form (4).

$$M_s = 0.2168e^{0.302C_{work}}. \quad (4)$$

The correlation ratio is 0.67, and the coefficient of determination is 0.45. This means that 55% of the occurrence of an occupational disease is explained by other factors.

One of these factors is the effectiveness of the functioning of the labor protection management system at mines. Thus, in order to characterize the level of efficiency of the functioning of the labor protection management system of an enterprise in terms of managing the risks of occupational diseases, it is proposed to use the efficiency coefficient of the labor protection management system (5).

$$C_e = \frac{C_{work}}{M_s}. \quad (5)$$

According to the value of this coefficient, 3 groups of coal mines can be distinguished:

- mines with an effective labor protection management system (C_e>300);
- mines with an inefficient labor protection management system (C_e<10);
- mines with an inefficient labor protection management system (10<C_e<300).

The conducted studies allowed to formulate methodological principles for managing the risk of occupational diseases in coal mines.

To manage the risk of occupational diseases based on taking into account long-term dependencies, predict possible occupational diseases and redistribute the quality and level of control over working conditions and health of personnel, it is necessary to adhere to such principles. This is a coordinated interaction of the key subjects of the coal mine – the owner of the capital, management, personnel, state supervision and control bodies. Ensuring the necessary and sufficient level of prevention of occupational diseases. Monitoring of risk factors for occupational diseases, including observation, assessment, control and forecast of the state of the working environment, equipment, technology and production organization. Purposeful formation of an information base of risk factors for occupational diseases and mechanisms of their development. Improvement of rehabilitation mechanisms and development of medical and social rehabilitation infrastructure. When using methods such as assessment of working conditions, assessment of the risk of occupational diseases, assessment of the effectiveness of the functioning of the labor protection management system, classification of coal mines according to working conditions and occupational diseases. assessment of the risk of an occupational disease depending on the profession, work experience in hazardous conditions and diagnosis, prediction of possible occupational diseases, assessment of the effectiveness of preventive measures [22].

Especially important is the choice of the way to change the labor protection management system – it is revolutionary, evolutionary and corrective. The revolutionary way of changing the labor protection system involves a radical change in the structure of the system, its functions, organization of activities, methods, methods and means of control. The evolutionary way does not require a fundamental change in the existing structure, but its functions must be reviewed. The corrective path is aimed at constantly maintaining a high level of efficiency of the existing system, searching for reserves and resources of the system in order to reduce costs and form an additional fund of funds for the prevention of occupational diseases of coal mine workers. To select the optimal management solution for the transformation of the labor protection management system, it is proposed to distinguish the effectiveness of its work into three levels (table 4).

Table 4. Choice of management decisions to improve the labor protection system.

Level efficiency labor protection management systems	Meaning efficiency ratio (C_e)	Required changes	Conversion Methods labor protection management systems	Necessary actions to move to a higher level of efficiency of the labor protection management system
High	C_e>300	Permanent corrective	Development of programs, research works, methods	Assessing the risks of occupational diseases, monitoring the state and potential the current labor protection management system
Middle	10<C_e<300	Evolutionary	Analysis and modification of the functions of the labor protection management system	
Low	C_e<10	Revolutionary (cardinal)	Analysis and change in the structure of the labor protection management system, formation of a new labor protection management system	

3. Conclusions

The high level of occupational morbidity among miners is due to the low efficiency of the functioning of the labor protection management system in coal mines, the increase of which requires a radical change in the methodology of its formation, transformation, adjustment and improvement.

The results of the investigation of cases of occupational morbidity indicate the insufficient effectiveness of their prevention. This is due, first of all, to the fact that the labor protection management system of enterprises is not aimed at preventing and preventing occupational diseases, but in fact at fixing them. The current systems are based on the concept of implementing a secondary prevention program, that is, carrying out measures to restore already significantly impaired physiological functions of the body under the influence of production activities.

To identify dangerous and harmful factors and assess the risks of occupational diseases, express methods have been developed and proposed for assessing the intensity and severity of the labor process, indicators of the significance of the main harmful and dangerous production factors.

Taking into account the risk factors for the occurrence of an occupational disease, which makes it possible to establish a time dependence of the occurrence of a certain type of occupational disease in a particular profession, makes it possible to predict a possible occupational disease and redistribute the quality and level of control over working conditions and the health of personnel.

To implement the principle of differentiated management of labor protection, it is proposed to classify mines according to working conditions and occupational diseases. The most effective method of such classifications is the method of principal components.

Necessary and sufficient conditions for the development and implementation of methodological principles for managing the risk of occupational diseases in coal mines and, on this basis, improving and developing the labor protection management system of enterprises are application of the principles of prevention of occupational diseases, based on the consideration of risk factors for the development of occupational diseases, the application of patterns of development of occupational diseases; depending on the specific working conditions (tension, severity), the use of a set of methods and criteria for assessing the effectiveness of the functioning of the labor protection management system, in terms of prevention occupational diseases; application of an algorithm for choosing the optimal set of preventive measures to reduce the risk of occupational diseases while maintaining the material well-being of the employee.

Abstract. This paper studies the ways of solving the resource-saving direction of the strategy for the mining industry development in Ukraine. The existing ideas about the patterns of changing stress-strain state (SSS) in the mass during the stope mining of minerals are analyzed. The problem of the host rock SSS formation and development is studied. The main directions of studying the relationship between the parameters of mass SSS anomalies in the area of stope operations and their technological parameters has been substantiated with the selection of a methodology for conducting multivariate computational experiments. A macromodel has been constructed to calculate the change in the distribution fields of the rock mass SSS components with subsequent substantiation of its idealizations. The principles of matching the macromodel and the subordinate models have been studied. A new methodical approach is proposed for taking into account the time technological parameters (average daily face advance velocity and the duration of its stoppage) through their relationship with the mechanical characteristics of the rocks. A test assessment of the adequacy of the performed calculations based on the spatial model SSS analysis for all stress components has been conducted. The degree of influence of the stope face advance velocity and the mass texture on the parameters of rock pressure anomalies has been studied, as well as the linking patterns in the area of conducting stope operations have been obtained: frontal and lateral bearing pressure zones and a zone of destressing behind the stope face. A base has been created for studying and predicting the rock pressure manifestations in critical areas in order to develop recommendations for choosing rational technological and design parameters for high-rate mining of coal seams.

1. Introduction

At present, the strategy for the development of the Ukrainian coal industry should be aimed at ensuring high-rate mining and, consequently, the use of high-performance stope equipment. In this regard, the problem of effective supporting of mine workings in the zone of stope operations influence, as well as their reuse, becomes relevant. A comprehensive solution to this issue provides a resource-saving focus on mining operations.

The patterns of changes in the coal-bearing mass state as the stope face approaches and retreats have been studied for many decades. Thus, certain ideas [1–5] about the parameters of

SSS anomalies depending on the mining-geological and mining-technical conditions for mining coal seams have been developed by now. There is no doubt that there are three main zones of the anomalous state of the coal-bearing mass around the stope workings and associated with them extraction drifts:

- frontal bearing pressure zone ahead of the face, where the vertical stress σ_y concentration is several times higher than the initial state of the undisturbed rock mass $\sigma_y = \gamma H$ (here σ_y – vertical stresses; H – mining depth; γ – weight-average unit specific gravity of coal-overlaying formation);
- zone of lateral bearing pressure that occurs in the side of the extraction drifts from the side of undisturbed rock mass; here, also, the vertical stress σ_y concentration is several times higher than the initial undisturbed rock mass state;
- destressing zone behind the stope face, which occurs when a cavity is formed after coal mining, into which the roof rock layers are lowered and then collapse; in this zone, vertical stresses can almost completely disappear ($\sigma_y = 0$) near the stope face, and as it retreats, the collapsed rocks are compacted and the rock pressure increases with stabilization at a certain distance at the level of the initial undisturbed rock mass state.

The parameters of the specified SSS rock mass anomalies usually include two interrelated indicators: the value of vertical stress concentrations $K_y = \gamma H$ and the distance of their propagation in the plane of coal seam bedding. Index "i" denotes a family of concentrations K_y (y is the vertical coordinate of the mass) of different values, which quite naturally propagate to different distances l_y.

The noted parameters depend on the mining-geological indicators of mining the coal seams, as indicated by numerous studies, for example, [6–14] in different periods of the coal mining industry development both in Ukraine and in other countries. Among the influencing mining-geological factors (in addition to the mining depth) are, first of all, the mass texture, taking into account the existing discontinuity and the mechanical characteristics of the rock layers at a distance of at least 20 m to the roof and bottom from the seam [15]. One of the main patterns of formation of anomalous SSS zones is considered to be determined, the essence of which is as follows:

- the occurrence in the roof of more thick (from 3 – 5 m and more) and increased hardness (hardness coefficient according to Protodyakonov scale is $f \geq$ 5–6) rock layers increases the propagation l_{y_i} of frontal and lateral bearing pressure zones with a simultaneous increase in vertical stress concentrations K_y near stope faces and in the side of the extraction drift from the side of the undisturbed rock mass;
- the same parameters of lithotypes occurring in the seam roof contribute to a deeper destressing of the mass above the stope face and behind it – the distance l_{y_i} of almost complete destressing ($\sigma_y = 0$) increases, as well as the length of the rock pressure stabilization area at the level of the undisturbed rock mass initial state;
- various types of discontinuity in the roof rocks (fracturing, small-amplitude breaks) act in the opposite direction of influence: the zones of frontal and lateral bearing pressure reduce their propagation in the bedding plane, and the vertical stress concentrations decrease; in the destressing zone, the length of areas of minimum rock pressure propagation, as well as the length of areas of rock pressure stabilization are reduced;
- more thin-bedded and less strong rock layers of the roof cause tendencies similar to the action of various types of their discontinuity.

The noted tendencies for the same region or even the mine field flank are clearly manifested when measuring in the extraction drifts such indirect indicators as the convergence value of the roof and the bottom rocks in the mine working, as well as in its sides. As an example, figure 1 shows graphs (constructed based on the results of measurements) of changes in the drift contour displacements as the stope face advances for two roof rock textures: predominantly thick-bedded and medium-bedded; predominantly thin-bedded and medium-bedded. Moreover, the measurements were carried out in the same driven entry of the seam C_6, Stepova Mine of PJSC DTEK Pavlohradvuhillya, where both types of roof rock textures are present in the length of the extraction site. As it can be seen from the graphs, with a thick-bedded texture, the frontal bearing pressure zone extends ahead of the stope face up to $a_1 = -73$ m in terms of the convergence of roof and bottom rocks $U_{R,B}$ and up to $C_{12} = -73$ m in terms of the convergence of the drift sides U_s. In the area of predominantly thin-bedded and medium-bedded texture of the roof rocks, the length of the frontal bearing pressure zone is significantly reduced: $a_2 = -33$ m (by 2.21 times) $C_2 = -47$ m (by 1.55 times). A similar situation is behind the stope face with regard to the stabilization distance of rock pressure manifestations. Thus, with a predominantly thick-bedded and medium-bedded texture of the roof rocks, the length of the area in terms of the parameter $U_{R,B}$ is 104 m, in terms of the parameter U_s, the distance increases to $d_1 = 124$ m. In the area (in length of the mine working) with a predominantly thin-bedded and medium-bedded texture, these indicators are reduced: $b_1 = 36$ m (by 2.89 times); $d_1 = 72$ (by 1.72 times).

These patterns are typical for various mining-geological conditions and Donbass regions [16–21]; therefore, they should be considered as sufficiently objective and taken into account in further studies.

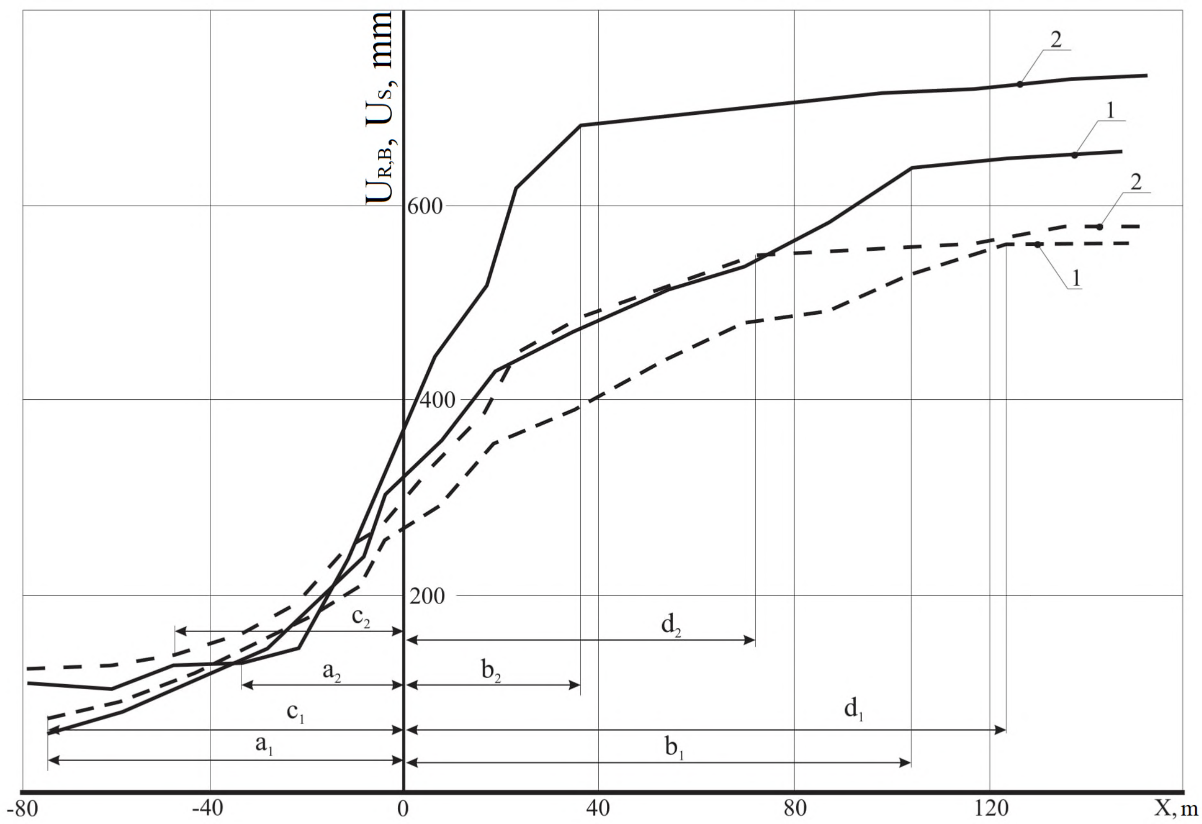

Figure 1. Dependences of the convergence development in the roof and bottom rocks sides of the drift with predominantly thick-bedded and medium-bedded (1), with predominantly thin-bedded and medium-bedded (2) texture of the roof rocks.

Among the variety of technological factors, two are distinguished [22–26], which combine a significant influence, on the one hand, and, on the other hand, are amenable to regulation in the process of stope operations: the average daily velocity V_d of the stope face advance and the duration t of its stoppage.

Thus, the presence of a significant influence of technological parameters (the velocity V_d of the stope face advance and the duration t of its stoppage) of mining the coal seam on the formation of the load on the powered support sections of the stope complex has been experimentally confirmed. The load itself is inextricably linked with the parameters of the SSS anomalies around the stope face, and for this reason, it can be concluded that there is interrelation between the distribution curves of the stress components in the vicinity of the stope face and the specified technological parameters of the coal seam mining. Determining the linking patterns in a numerical form is quite a difficult task due to the influence of many different factors. But, the relevance of studying this problem is undeniable: after all, the experimental results in the Western Donbass convincingly prove a decrease in the rock pressure manifestations by 23 – 47 per cent only due to a change in the velocity of the stope face advance, and this decrease increases the safety of mining operations and equipment life, thereby reducing the probability of accidents.

To date, two main ways have been formed to study the interrelation between the parameters of mass SSS anomalies in the area of stope operations and their technological parameters:

- full-scale experiments for measuring indirect rock pressure indicators and their analysis in order to determine the linking patterns;
- analytical research with the predominant use of numerical methods is the so-called computational experiment.

In this regard, many researchers use a combination of the above methods, for example, [27–29] which is justified by the desire to obtain more reliable results. Undoubtedly, the parameters of SSS anomalies and indicators of rock pressure manifestations are interrelated, and the nature of these relationships is revealed by a set of ideas about the mechanism of a coal-bearing mass displacement in the area of mining operations.

Thus, it seems the most appropriate way to solve the problem of studying the formation and development of SSS anomalies in the mass, which is substantiated by a three-stage structural-logical scheme: mine instrumental observations of the rock pressure manifestations in stope faces and extraction drifts; computational experiments to calculate the surrounding mass SSS and a linking element – the mechanism of rock displacements in the coal-overlaying formation, revealing the influence of the stope face advance velocity and the duration of its stoppage.

2. Substantiating the methodology for conducting multivariate computational experiments

To date, rich experience has been accumulated in measuring the indicators of rock pressure manifestations in various mining-geological conditions [30–32].

The main attention is paid to the substantiation of the methodology for modeling different velocities V_d of the stope face advance as the primary stage; further, the results of the mass SSS calculations are analyzed in conjunction with the parameter V_d and the patterns of its influence on the indicators of rock pressure anomalies in the vicinity of the stope face are determined.

When substantiating the methodology for conducting a computational experiment, we had to face a number of factors, the objective reflection of which in geomechanical models is conditioned by significant difficulties.

Firstly, the model of a stratified rock mass with two conjugated mine workings located in it (stope face and an extraction drift) is characterized, in addition to its extensive dimensions in space (figure 2), by a combination of significant heterogeneity of the geometric, mechanical and strength parameters of the elements that constitute this model. Thus, only the model of one rock mass includes a sufficiently large number of rock layers of the roof and bottom in the coal seam, differing from each other in mechanical properties. The strength characteristics of contacts of adjacent lithotypes for the Western Donbass conditions [33–35], as a rule, are very low, or there is no adhesion along the bedding planes at all. In addition, the research object is located in the zone of active influence of stope operations, where, along with significant vertical displacements of the coal-bearing mass, significant movements occur in the horizontal direction of the rock layers relative to each other.

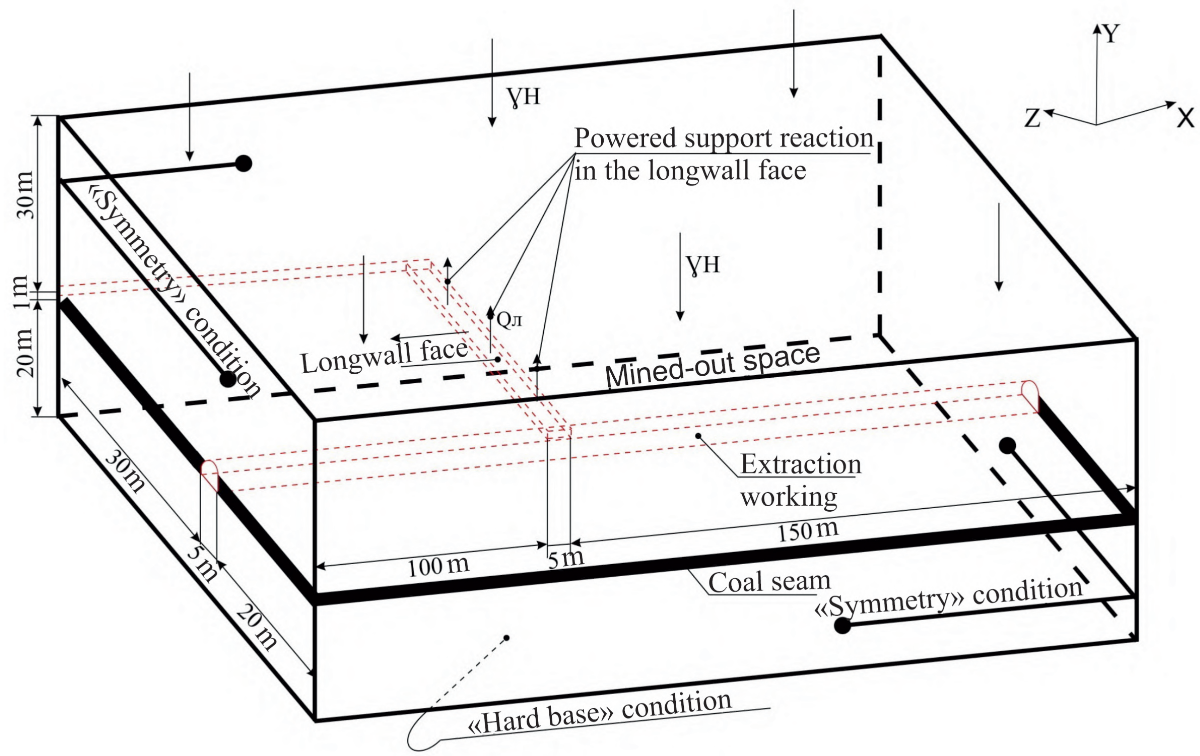

Figure 2. Macromodel for studying rock pressure anomalies in the area of stope operations.

The noted facts make it possible to predict the destruction of contacts between adjacent rock layers, and this leads to a significant change in the distribution fields of the rock mass SSS components [36]. In addition to these factors, it is also necessary to take into account the processes of weakening the rock layers (occurrence of tension cracks, partitioning into blocks and their partial caving into the mined-out space). More intense fracturing [37] and the occurrence of the so-called thrust-block systems in the roof increases their deformation capacity for more significant displacements, and rocks caved into the mined-out space radically change their mechanical characteristics [38–40]. These factors have been sufficiently tested using modern methodologies for modeling geomechanical processes [41, 42].

Secondly, it is necessary to more adequately and reliably represent the real mining-technical conditions of mining operations and to model in detail the objects for supporting mine workings (support of a stope face and extraction working, security structure, etc.) in accordance with their design and technological peculiarities. Each of these objects includes a set of elements with complex geometry, significant heterogeneity of mechanical properties and strength parameters. In this case, one of the main difficulties is the ratio of the scales of object elements and the rock mass texture parameters (the difference reaches two or three orders of magnitude), which is a serious obstacle to the stable conduct of a computational experiment.

Similar problems of the available degree of modeling idealization relate to the mechanized hydroficated support of a stope face. Undoubtedly, from the point of view of the reliability and adequacy of the research, it will be positive to reflect the actual design of the powered roof support used in a particular calculation, in accordance with its technical characteristics. However, when developing such a detailed model, it is necessary to overcome (for a long period of time) serious difficulties when reflecting the real operation modes of hydraulic prop stays and hydraulic cylinders, as well as hinged joints of the section elements. At the same time, a significant computing resource is required to calculate the SSS of only one powered roof support section, and in the stope plow set, for example, there are 196 such sections.

Thirdly, when taking into account the time factor (the stope face advance velocity and the duration of its stoppage), it is necessary to use an appropriate physical model (for example, viscoplastic) of the rock mass behavior (primarily) in combination with special technological methods (for example, regular changes in the parameters of the final element mesh) of a computational experiment [43,44]. This formulation of the problem is not only time-consuming, but also requires significant computing resources in the absence of guaranteed calculation process stability.

As a result of the analysis of three groups of factors influencing the computational experiment reliability, an opinion has been formed on the need to introduce a number of idealizations and simplifications into the geomechanical model, which would have a minimal effect on the adequacy and accuracy of the final SSS calculation results, but at the same time significantly save the computing resource.

The approach described above is associated, first of all, with the consistent implementation of interrelated studies, the essence of which is the division of tasks and their consistent solution by constructing a common macromodel and more detailed development of subordinate models. The methodology for performing phased studies is as follows.

The macromodel dimensions are indicated on the scheme and determined based on: previous experience in modeling geomechanical processes in similar mining-geological conditions; experimental studies of rock pressure manifestations in the extraction drifts of the Western Donbass mines; normative guidance documents.

Thus, the methodological approach in terms of the phased and continuity of research provides a reasonable construction of two groups of subordinate models with a high degree of detailing the fastening and security elements of extraction workings. The adequacy of the reflection implies modeling of real parameters: frame support of the TSYS series; roof-bolting system combined of resin-grouted rockbolts and rope bolts; security structure (behind the stope face); the central and side prop stays of the strengthening support.

When constructing subordinate models at the second stage of research, the following methodological approach has been developed.

Firstly, to ensure the stability of the SSS calculation, it has been decided to switch to flat models that reflect the section in the plane YZ, that is, the cross-section of the extraction working. The accumulated experience of calculating such models proves the high reliability of conducting the computational experiment.

Secondly, in the absence of a real possibility of a detailed reflection of the scheme elements for supporting an extraction working (in a spatial model) of considerable length, the two most critical areas of the drift has been selected, for each of which its own group of flat models is constructed:

- the first area is a zone of frontal bearing pressure at a distance of $3 - 5$ m from the stope face, where the maximum concentrations of vertical and other stress components act, provoking an active increase in the load on the fastening structure;

- the second area is the zone of stabilization of rock pressure manifestations behind the stope face, where the main part of the drift contour displacements has already been realized (figure 1), that is, the load approaching the maximum has been formed.

Thirdly, instead of the geomechanical system spatial construction in the critical areas of the drift, a set of flat models is proposed, each of which reflects the extraction working section (with a model thickness equal to a step of frame setting) with different supporting elements. The above is explained in figure 3 and figure 4, where one of the most effective schemes implemented in the Western Donbass mines is used as an example. The scheme for fastening and supporting extraction workings includes:

- in the area of frontal bearing pressure zone: a frame support made of special profile SCP-27 of the TSYS series, set with a step of 0.8 m; resin-grouted rockbolts placed symmetrically in each side of the mine working in the middle of the inter-frame space with a step of 0.8 m; rope bolts, set in a checkerboard pattern in length of the mine working in the middle of the inter-frame space with a step of 3.2 m (every four frames) according to the scheme in figure 3; central and side wooden prop stays of strengthening support, placed with a step of 0.8 m;
- additional fastening elements are set behind the stope face to support the drift for its reuse: side wooden prop stays of strengthening support are set continuously along the mine working and include two rows; there is one breaker-prop row on the drift berm.

The construction of three drift sections in each of the selected areas makes it possible to track changes in the SSS along the mine working in order to determine the degree of loading of fastening elements and identify their most dangerous sections.

Fourthly, in order to bring the loading conditions of flat models into conformity with the coal-bearing mass state, determined during the calculation of the macromodel, the following actions are performed. For the area with the maximum frontal bearing pressure (3 – 5 m ahead of the stope face plane), three flat models are constructed (figure 3), in which the dimensions (in the plane YZ), structure and boundary conditions completely coincide with those for the macromodel. The results of calculating the vertical stress σ_y distribution curve for a flat model and a macromodel are compared. As an object of comparison, the contact plane of the immediate and main roof of the seam are chosen, which is conditioned by the greatest influence of the rocks in this area (immediate roof and one or two layers of the main roof) on the state of the extraction working fastening elements. Next, an external load (geostatic pressure) is selected at the flat model upper boundary, at which the distribution curves σ_y have a minimum difference from each other, which contributes to a more adequate reflection (within the framework of a flat model) of the coal-bearing mass behavior in real three-dimensional measurement (macromodel). Similar actions are performed for flat models in the zone of stabilization of the coal-overlaying formation displacements.

Thus, the two-stage research makes it possible to determine two groups of patterns of the influence of the stope face advance velocity on the parameters of rock pressure anomalies near the stope face and the SSS of fastening elements of modern schemes for supporting extraction workings intended for repeated use. The analysis of these patterns is of significant practical value in the conditions of highly loaded stope faces.

To conduct a series of computational experiments for studying the influence of the stope face advance velocity V_d, an interval of 5 m/day $\leq V_d \leq$ 15 m/day is chosen, which most fully reflects both the mine conditions of coal mining using the previous generation of stope equipment, and the modern performance achieved using the equipment of latest generation. Three discrete values of the average daily velocity of the stope face advance (V_d = 5 m/day, 10 m/day and 15 m/day) are selected, for each of which a separate computational experiment is performed.

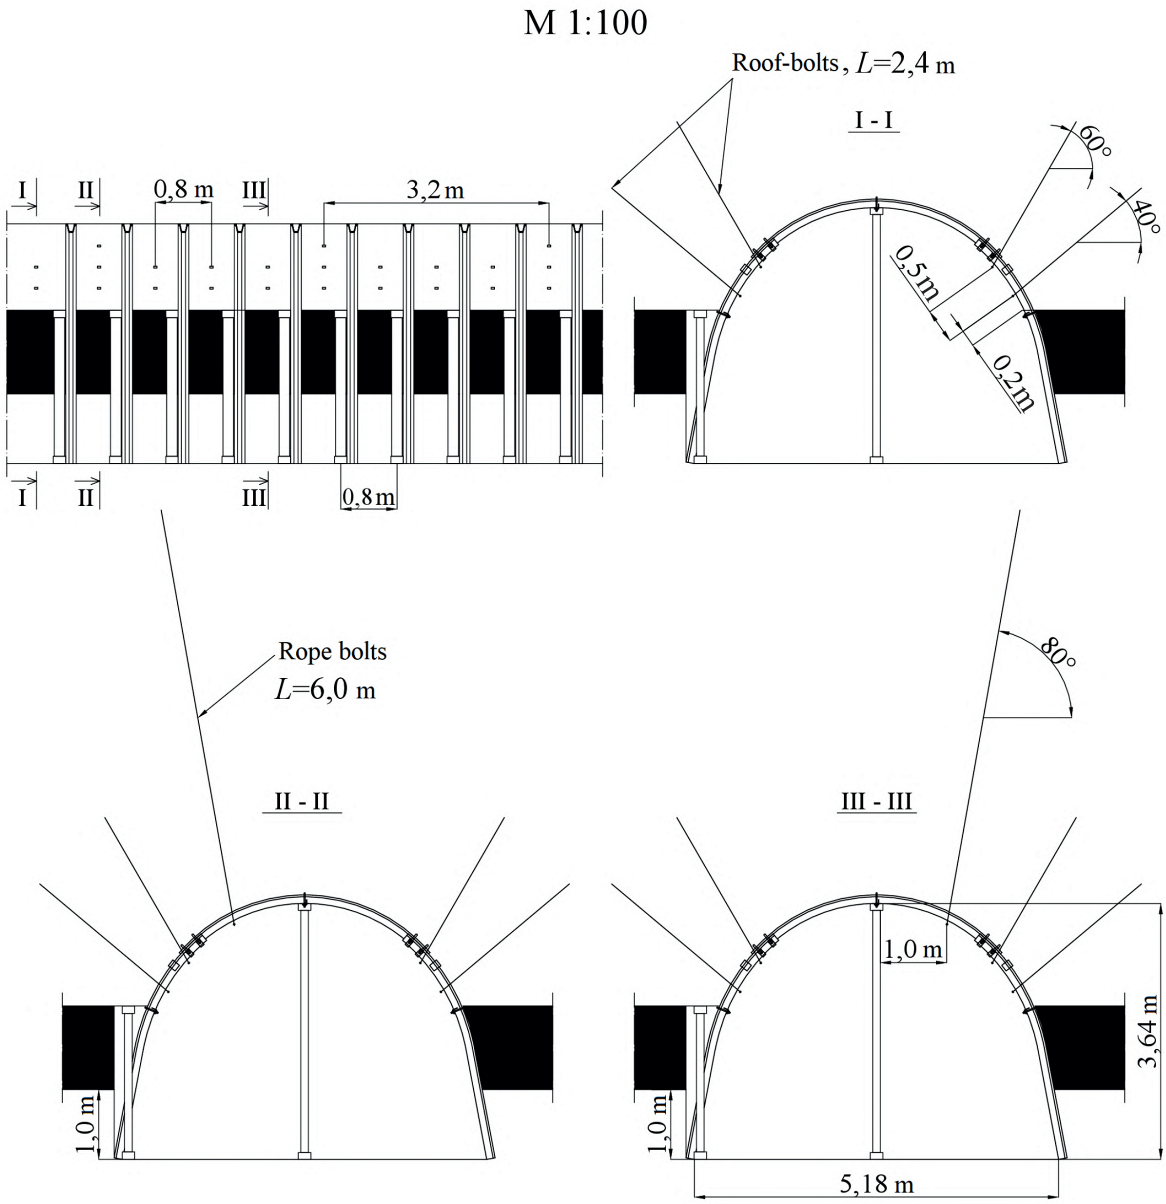

Figure 3. Scheme for fastening the extraction working in the frontal bearing pressure zone.

Within the framework of the second idealization, a methodology has been developed for "linking" all three values of V_d to the deformation modulus of each of the lithotypes included in the macromodel.

In modern computer programs, in particular ANSYS, the development of creep deformations ϵ_{creep} is usually represented in the form

$$\varepsilon_{creep} = C_1 \sigma^{C_2} t^{C_3} \tag{1}$$

where C_1, C_2, C_3 – approximation coefficients of experimental creep diagrams in the coordinates "deformation ε – loading time t"; σ – stress intensity; t – time of loading the rock samples.

Equation (1), along with a sufficient simplicity of written form, most objectively reflects the rheological process of the creep deformation development, since it uses the results of experimental

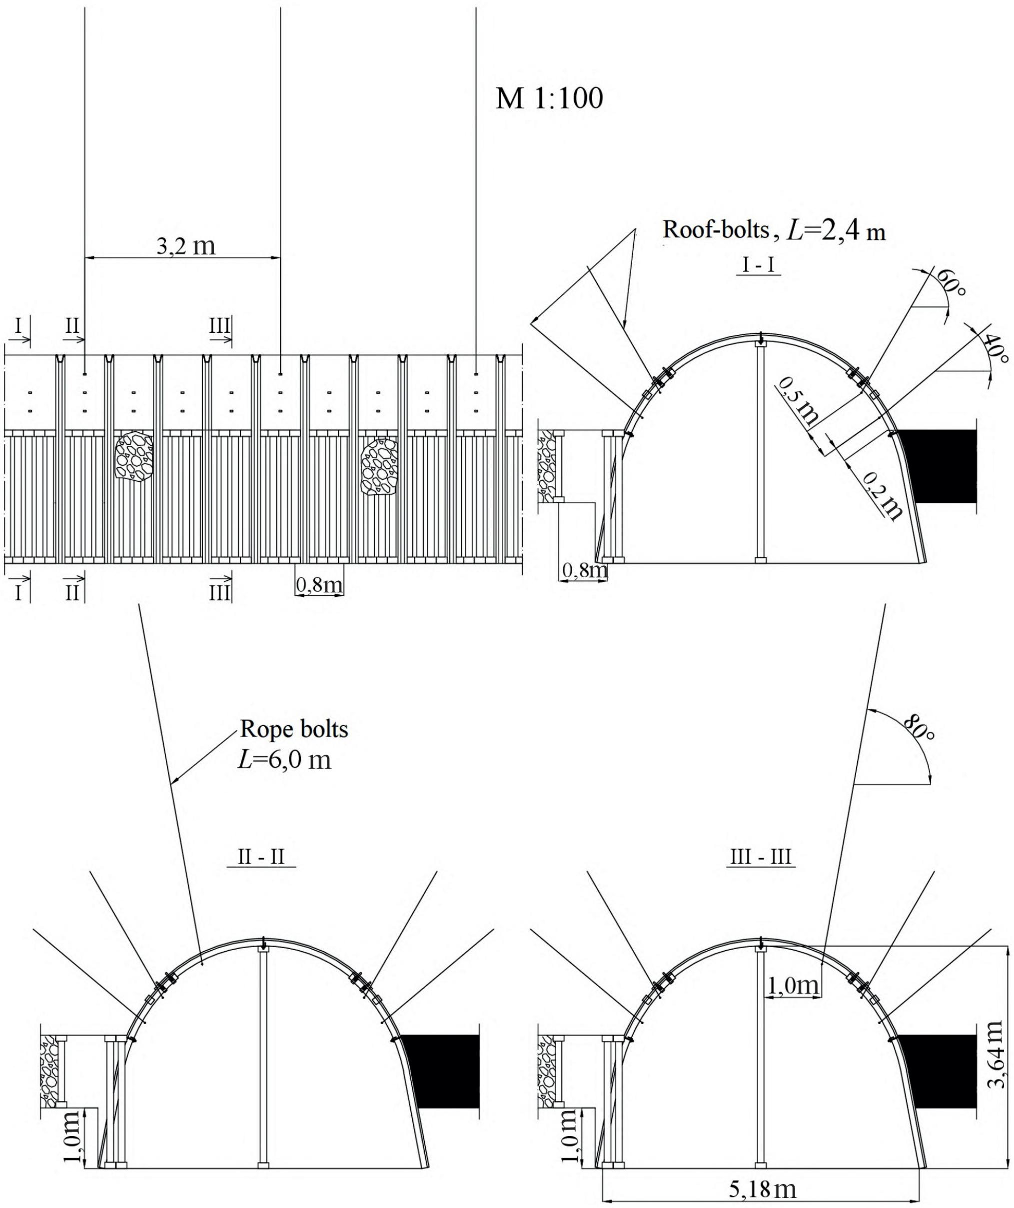

Figure 4. Scheme for supporting the extraction working in the displacement stabilization zone of the coal-overlaying formation behind the stope face.

studies accumulated to date. In this regard, one of the tasks is to match the parameters of the experimental diagrams “deformation – loading time” as reliably and adequately as possible with the parameters and coefficients included in equation (1).

3. Substantiation and studying the stress-strain state of “mass – support” geomechanical models

For a complete and adequate study of the process of formed rock pressure anomalies, the mass spatial model has dimensions (x = 255 m, z = 55 m, y = 50 m), which completely exclude the influence of boundary conditions and “edge” effects on its faces.

Based on the existing information provided by the geological surveys of the Western Donbass mines (stratified mass of weak rocks), the most common textural variants of the coal-bearing stratum are summarized and two types of its texture are formed: predominantly thin-bedded and medium-bedded; predominantly thick-bedded and medium-bedded. These two textural types are shown in figure 5 and accepted for research in order to determine patterns of influence on the parameters of rock pressure anomalies.

The data of geological surveys of mines, studies of M.S. Polyakov Institute of Geotechnical Mechanics NAS of Ukraine and a number of studies [18, 19], on the mechanical properties of the coal-bearing stratum; average characteristics for each lithotype are introduced into the geomechanical model.

The orientation in space of the stope face and the extraction working associated with it is fully reflected, taking into account the formation of bearing pressure and destressing zones.

The real parameters of the latest technology for supporting extraction workings have been modeled.

The developed algorithm of methodical methods makes it possible to assess the influence of the stope face advance velocity on the stress-strain state of the coal-bearing mass, the fastening and security structures of the extraction workings.

4. General analysis of the SSS of spatial models

Then, the assessment of rock pressure anomalies is studied that occur in the rock mass in the area of stope operations from the point of view of the correspondence of the computational experiment results for a spatial geomechanical model to existing ideas about the processes of coal-bearing rock mass displacements. Thus, the term “general SSS analysis” refers to a certain test assessment of the adequacy of the performed calculations.

The spatial model SSS analysis is carried out for all stress components, and the most informative ones are distinguished to illustrate the distribution curves: vertical stresses σ_y, horizontal stresses σ_z (along the extraction site) and stress intensity σ.

For the test analysis, fragments of the SSS calculation of one of the computational experiments (predominantly thick-bedded and medium-bedded mass with a relatively moderate stope face advance velocity of 5 m/day) are selected, since the general tendencies are qualitatively the same for other computational experiments with other initial data.

An analysis of the vertical stress distribution in the spatial model (figure 6, b) presents the following results.

Firstly, on the one hand, the spatial model clearly reflects all the main rock pressure anomalies in the vicinity of the stope: frontal and lateral bearing pressure zones; destressing zone behind the stope face. On the other hand, the selected spatial model dimensions ensure that the influence of the so-called “edge effects” arising from the application of boundary conditions on the model faces is absent. This factor improves the adequacy and reliability of the results obtained for the calculation of the geomechanical model SSS.

Secondly, the determined parameters of the frontal bearing pressure zone are quite consistent with the data range obtained by most researchers. Thus, the frontal bearing pressure developed into the seam roof is observed up to 23 – 25 m. More significant concentrations of the level 1.46 – 1.56 extend up to a height of 11.0 m, and individual local areas appear at a distance of up to 16.2 m. The width of this zone (with an average concentration in the area of 1.5) is 5.2 – 6.0 m, and the beginning of the stope face influence is manifested at a distance of 20 – 25 m, which is quite consistent with the results of mine observations in the Western Donbass.

Thus, for all generally recognized zones of rock pressure anomalies, there is a quite satisfactory correspondence with existing ideas, experimental and analytical studies of the coal-bearing stratum behavior in the area of stope operations.

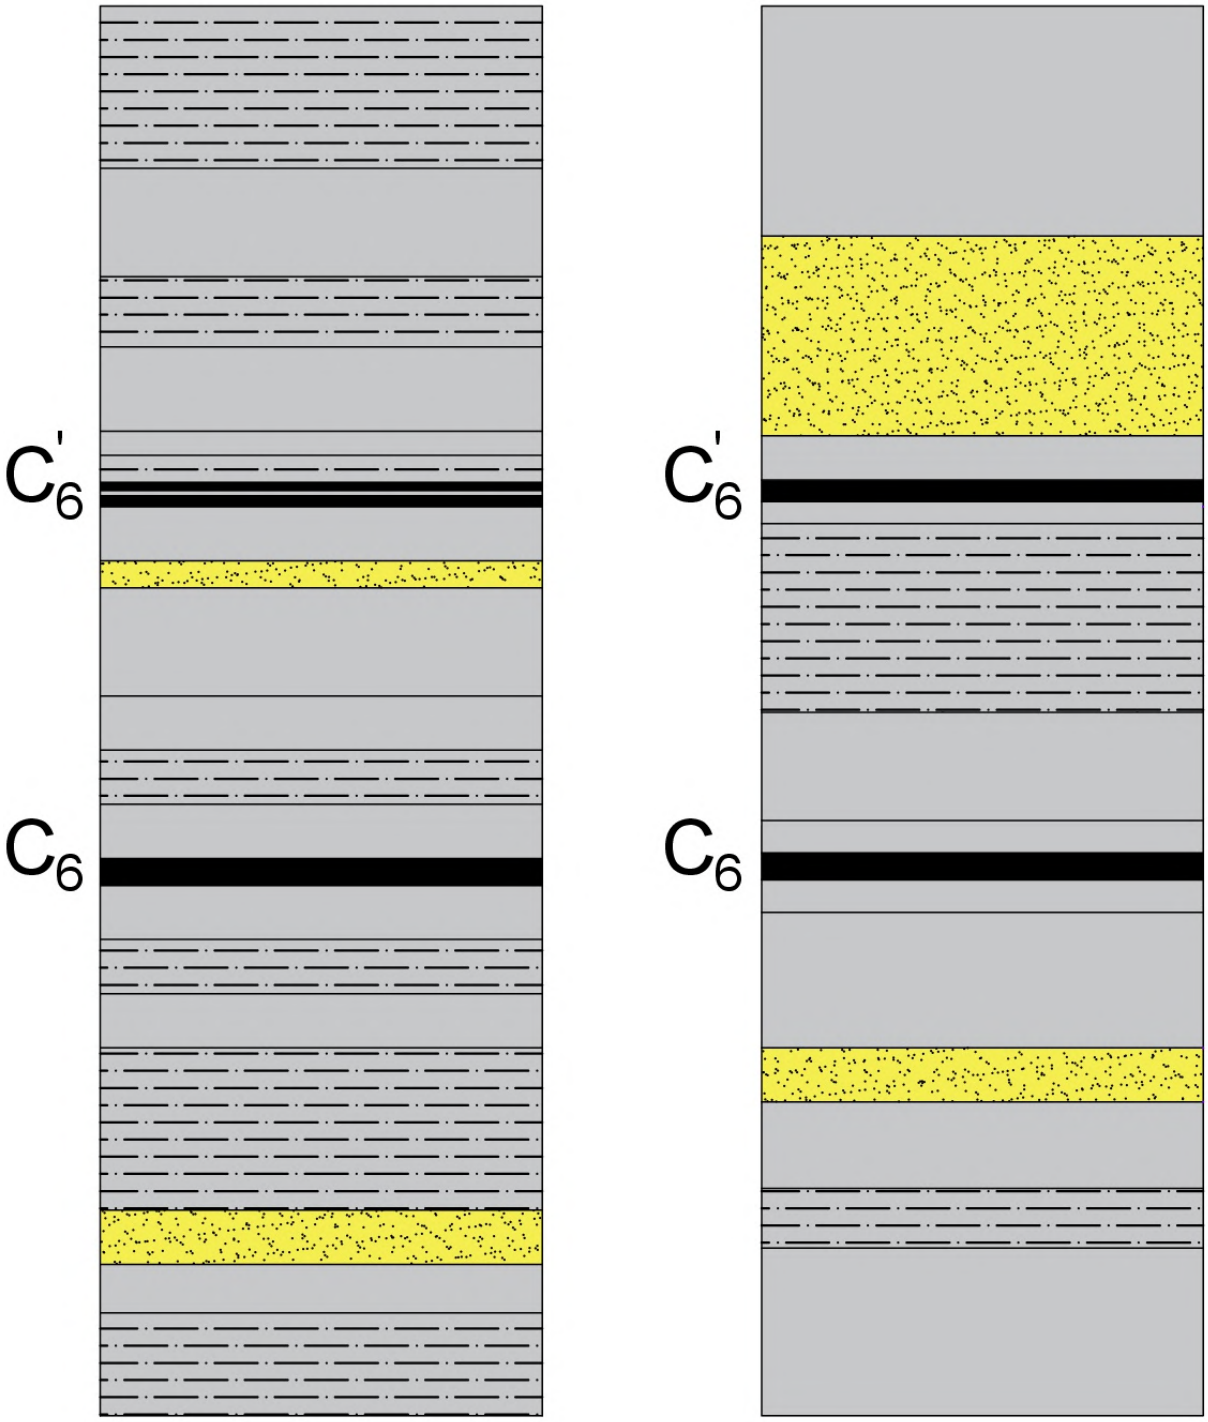

Figure 5. Textural types of the coal-bearing stratum: predominantly thin-bedded and medium-bedded; predominantly thick-bedded and medium-bedded.

5. Change in the SSS of spatial models at different stope face advance velocities

After substantiating the adequacy of the spatial models, six computational experiments is performed, the main task of which is to assess the degree of influence of the stope face advance velocity and the coal-bearing stratum texture on the parameters of rock pressure anomalies in
