Let us consider the features used in visual analysis of remote survey materials or formalized in the methods of space images computer analysis. Decryption features can be divided into two main groups – brightness and structural. During visual analysis of images bright features group includes image photon (for monochromatic images), such color characteristics as color tone, color saturation and “lightness” (for color, spectrozonal and synthesized images). During decoding of digital images rendered on the display screen, brightness equivalents of image (for panchromatic), zonal brightness equivalents (for multi-zonal survey) and equivalent of effective scattering area (for radar images) are the brightness features. If synthesis procedure is being used in conditional colors for multi-zonal images visualization, then the color characteristics are also being analyzed.

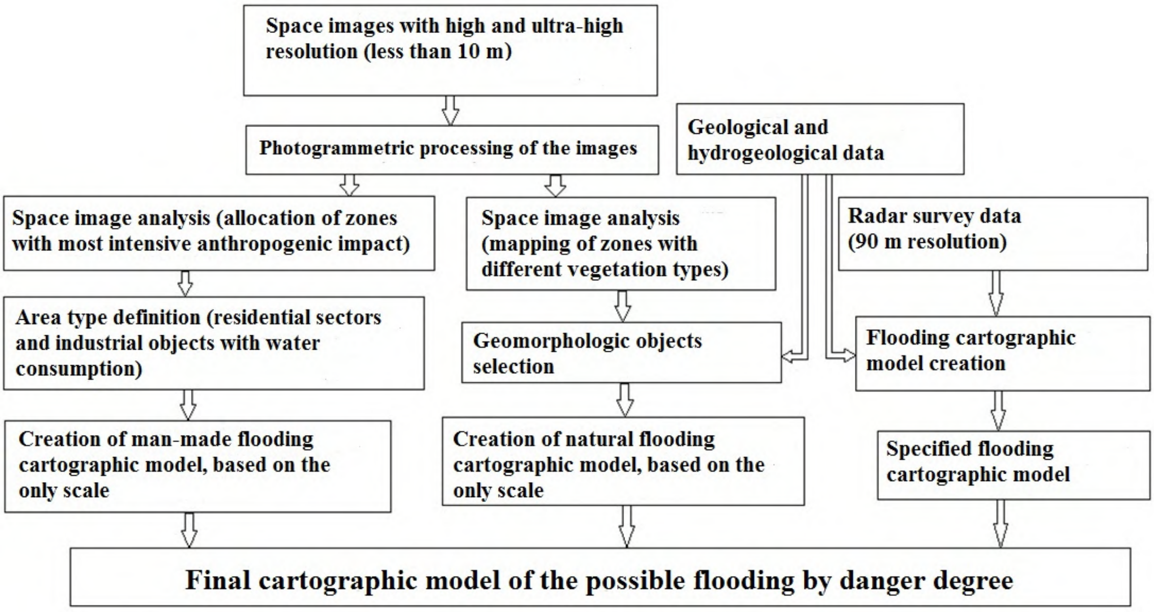

Fig. 2. Method of creating flood cartographic model by danger degree.

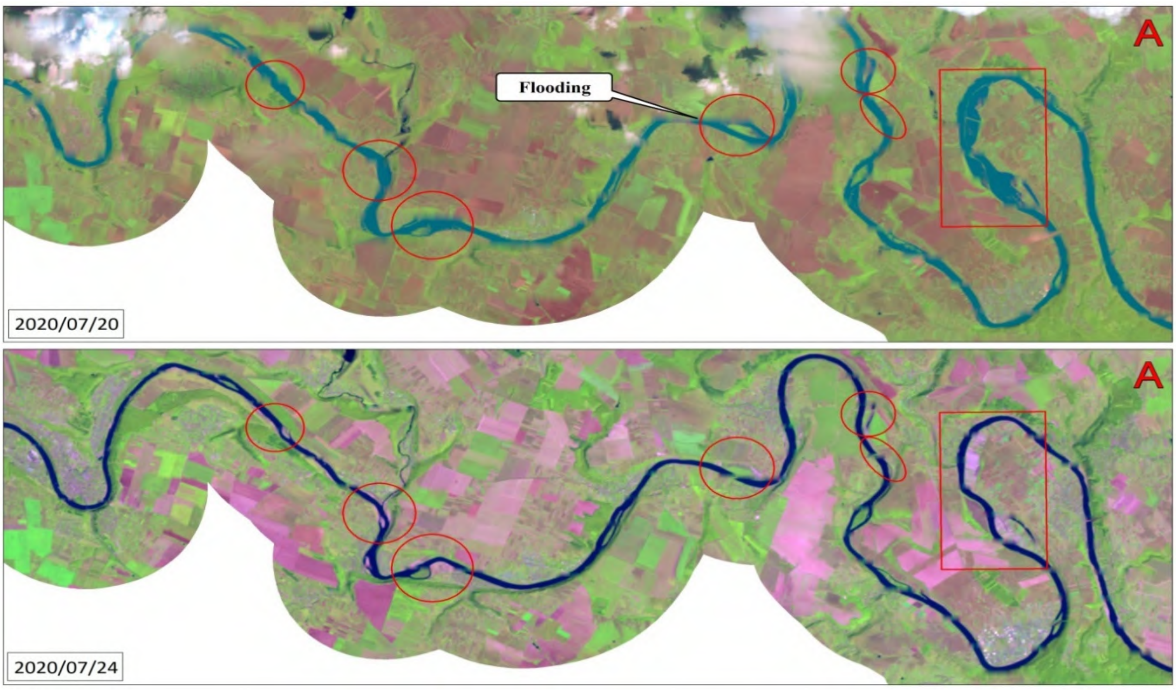

Fig. 3. Flooded areas in Dniester river basin between Dobrilyany and Ustia villages in 2020 is on a fragment of space image SENTINEL 2 (10 m resolution).

Structural features include the size and shape of object, brightness disposal within the object, image texture, some others [24-35]. The initial source for the space images thematic analysis is various thematic maps. Together they give information about localization of objects and spatial disposal of indicators. This disposal characterizes ecological situation in the environment or anthropogenic impact level in its components, localization of impact sources and its scale. Therefore, main processes in space images thematic analysis are represented as images segmentation for planar and linearly extended objects identifying, as Fig. 3 shows.

Remote sensing methods allow to make flood monitoring and to analyze its dynamics, but they have a number of disadvantages due to high difficulty of data analysis and delay in obtaining the space images.

Flooded zones localization on space images is carried out on indirect features, such as presence of floodplains, swamps and relief depressions. Flooded areas mapping is possible on threshold values of mathematical expectation and dispersion of color intensity on red, green and blue channels [36-49].

Digital panchromatic image with a 10 m-resolution (4800 x 4800 pixels) was analyzed in ERDAS IMAGINE software using controlled classification method.

3 Conclusions

Methods for geomodels making for probable flooded zones were developed and implement for territories in Dniester river basin. Its geomodels consider degrees of danger which formed in conditions of insufficient information.

Scientometric analysis of geomodels creating methods for flooded territories showed that possible flooded areas timely detection and prediction of dangerous accidents is possible only with complex use of remote and ground measurements with their subsequent rationing and analyze.

Possibility of available remote sensing data use allows reducing temporal and economic cost for conducting additional ground measurements for possible flooded areas determining. While the accuracy of predictive parameters do not reducing.

The developed cartographic models of possible flooding areas allow determining and visually assessing the degree of flooding under different modes of pressure horizons use, which have a hydraulic connection with groundwater. These methods of geomodels creation are realized for the territory of Dniester Canyon, the hydrogeologic feature of which is connected to the Upper Cretaceous horizon and groundwater.

Abstract. The problem of emergencies will not leave humanity as long as it exists, and therefore it is necessary to at least create conditions under which it is possible to reduce the risks of injuries, diseases and deaths of people who are in the emergency zone. This can be achieved by raising awareness of the nature of the emergency, the hazardous substances that are released in connection with it. Theoretical analysis of various remote means of assessing the impact of emergencies of man-made areas on the ecological state of the atmospheric air of the surrounding areas. It has been found that the use of remote sensing equipment greatly simplifies the procedure of operational monitoring of the environment during emergencies, as well as contributes to the health of professionals. A comparison of different remote means of environmental monitoring of air quality was performed: In particular, stationary automatic stations, mobile automatic stations, probes, and unmanned aerial vehicles (UAVs) were compared. It is proposed to use UAVs as remote means of operational monitoring of air quality. The functional scheme of UAV system implementation for the needs of operative ecological monitoring is offered. The legal features of the use of unmanned aerial vehicles as remote means of monitoring air quality during emergencies are analyzed.

1 Introduction

With the growth of the technological and economic crisis, the absolute number of the new man-made emergencies and accidents at enterprises and infrastructure of settlements is growing. The introduction of new technologies and timely modernization can reduce the number of accidents, but the risk of their occurrence cannot be reduced to absolute zero.

The rational usage of nature involves not only ecologically balanced management of natural resources, but also the creation and maintenance of a safe environment for future generations. This is achieved through the implementation of the provisions of the concept of sustainable development not only in the objects of entrepreneurial activity, but also in the processes of control and management of environmental quality.

The deterioration of qualitative and quantitative characteristics of the surface layer of air leads to negative consequences [1] not only for the biosphere as a whole, but also to increase the impact on public health [2] and the increasing number of diseases and allergies. The reverse effects observed by scientists around the world related to the SARS-CoV-2 epidemic are also possible [3-5].

Nowadays the solving of the problems related to the state of the environment involves the usage of the latest technologies and developments, as well as the application of approaches to sustainable development and the functioning of environmental quality management systems.

This is especially important for the control of man-made objects and territories, as well as for the detection and elimination of emergencies and their consequences. Within the framework of this direction the state programs are formed, important researches are carried out [6-9].

The related research requires the use of modern scientific and technological progress, the creation and use of the latest information-measuring and software-hardware complexes. The effectiveness of their use depends on the level of development, the use of hardware and software measurement tools and the ability to work effectively with the information obtained.

During emergencies at man-made sites, large volumes of mostly toxic substances are usually released into the air, but the low speed of response of specialists, as well as physical defects do not allow to quickly identify the location of harmful substances in the environment. As a result of lost time, the company, service organization or country incurs significant economic and social and labor losses for each unit of time.

The usage of remote multispectral and multisensory means will reduce the response time of specialists to a call in case of an emergency or threatening situation on the territory, as well as reduce the risk of injuries and diseases of specialists in performance of official duties.

The aspects of this issue were considered by many well-known scientists. Thus, O.O. Popov, A.V. Iatsyshyn, V.O. Kovach, V.O. Artemchuk, T.M. Iatsyshyn, A.O. Zaporozhets, V.M. Isaenko, S.M. Majd, J. Burgués, S. Marco, A. Arfire, A. Marjovi, A. Martinoli, N. Castell, M. Kobernus, H.-Y. Liu, P. Schneider, W. Lahoz, A.J. Berre, J. Noll and others were engaged in solving problems of ecological safety of energy and public utilities, but the issue of developing new or improving existing means to improve the environmental safety of man-made areas during emergencies in case of non-radiation pollution of surface air remain relevant and important for many developed countries.

The study was conducted to analyze the existing means of monitoring air quality during emergencies in man-made areas and potentially dangerous objects to develop and implement a more effective means of operational monitoring of atmospheric air.

Within the framework of the aim it is planned to solve the following tasks:

- identify the features of the mechanisms of the ecological management system of the techno-ecosystem;
- to analyze pollutants that require special control in the emergency area;
- Investigate approaches to the mathematical description of the movement of pollutants in the ground layer of the atmosphere;
- propose the approach to optimize crisis monitoring and management of the ground layer of atmospheric air in areas of emergencies or potential emergencies.

2 Materials and methods

This study was mainly conducted on the basis of domestic and foreign publications on methods of management and monitoring of man-made objects and areas during planned activities and during emergencies, as well as on the basis of the authors of this study.

The following research methods were used: method of comparative analysis, modeling and evaluation of the impact of emergencies on the quality of the ground layer of atmospheric air.

3 The research results

3.1 Ground layer of atmospheric air, features of definition

Nowadays there is no clear definition of the term "ground layer of the atmosphere" in Ukrainian terminology, so State standard of technical conditions of Ukraine (DSTU) 3513-97 “Meteorology: Terms” [10] indicates the surface layer of the atmosphere as "The lower part of the boundary layer of the troposphere, which interacts most intensely with the underlying surface". In spite of, this formulation is not very accurate and does not indicate the boundaries of the layer of the atmosphere that is most affected by the underlying surface, i.e. the habitat of most living organisms, and in particular humans.

According to Directive 2008/50 / EC of the European Parliament and of the Council of 21 May 2008 about air quality and cleaner air for Europe [11], the optimal level of measurement of pollutants to be considered safe or unsafe for human health the height of 1.5 m above ground level is determined, in other words, the average statistical height of a person. At the same time, for the description, modeling and forecasting of pollutant levels in the surface layer of the atmosphere, the data obtained from a height of 1.5 m is not enough, so it is necessary to determine the highest point of the range of air quality parameters.

O.G. Shevchenko performed studies [12] of the influence of physical processes potentially caused by the influence of the earth's surface on the concentration of pollutants: sulfur dioxide and nitrogen dioxide, at an altitude of 10 to 500 meters above ground level. According to this study, at altitudes of 251-500 m, pollutants that enter the atmosphere from high emission sources (enterprise flares) are significantly affected by meteorological phenomena and changes in the trajectory. At altitudes of 10 m to 250 m, low and medium emission sources are the main influence.

However, at heights from the direct underlying surface (conditionally zero height) to 1.5 m, there is also a significant and direct impact of the surface on atmospheric air: erosion of soils, evaporation of water, release of pollutants from leaks and exhaust pipes of some types of vehicles. Most of the substances released in this way after entering the atmosphere thus rise to a height of more than 1.5 m and are carried further.

Therefore, in accordance with the above, the authors consider that the ground layer of the atmosphere is the airspace at altitudes from 1.5 m to 500 m inclusive.

3.2 Features of the impact of emergencies on technogenically loaded objects on the environment

The peculiarities of the distribution of pollutants in the air were described in the 1970-s by M. Berland [13], who determined that the main factors influencing the spread of impurities in the atmosphere are wind and the distribution of air temperature with altitude.

Industrial emissions can come from sources of different heights: from industrial pipes (flares), from sources at ground level, and so on. If the temperature of the gas released from the source is higher than the ambient air, the former are characterized by a certain dynamism. According to the research of M. Berland, and a group of scientists led by O.O. Popov [14] in the vicinity of the emission source creates a field of vertical velocities, attenuating with distance from the source, which sometimes extends over long distances and helps to raise the impurity up.

The process of transferring impurities to the upper atmosphere is called atmospheric stratification and can be defined as the category of stability of the atmosphere.

The state of the atmosphere can be equilibrium, stable and unstable. The degree of stability of the atmosphere determines the behavior of the air particle (elementary

 https://doi.org/10.1051/e3sconf/202128009017

volume of air), removed from the original position, in the upper or lower layer of the atmosphere.

According to the laws of physics, a particle of warm air rises and a particle of cold air descends.

In the troposphere there is a decrease of temperature with increasing altitude, which has a direct impact on the "state of the atmosphere". The atmosphere in a particular place can be in several different states in their physical characteristics:

1) the state of equilibrium stratification – air particle moving in a certain direction, takes the temperature of the ambient air and its density becomes equal to the density of the surrounding particles, therefore, the cause of its rise or fall is leveled;

2) the state of stable stratification of the atmosphere – if the vertical temperature gradient in the atmosphere is less than at equilibrium, the particle moving up will cool and will soon become colder than the surrounding air, and heavier than it. Therefore, it will fall and return to its original position;

3) the state of unstable stratification – if the vertical temperature gradient is more than equilibrium, the air particle, starting to move up or down, will continue its movement with increasing acceleration. The farther it goes from the initial position, the more its temperature deviates from the ambient temperature [13]. In this case, we talk about unstable stratification.

Another characteristic of the description of the state of the atmosphere is the so-called inversion, which is defined as an increase in temperature with altitude. Temperature inversion can occur both near the earth's surface (surface inversion) and at a certain height (altitude inversion). If the inversion occurs at a certain height above the ground, it is called elevated. Increased inversion can create dangerous conditions for the population living in white man-made areas, due to the fact that emissions cannot rise above a certain level - the "ceiling", the effect of which such an inversion creates.

Information on the fundamentals of the functioning of the atmosphere in its various parts is very important for determining the qualitative and quantitative indicators of air quality at any time, in particular during the operational monitoring of air quality in the emergency zone or during a technogenical accident. It is especially important for forecasting the consequences [14] and effective environmental safety management in areas of such situations. For example, it is also important for the effective assessment and management of the atmosphere that pollutants enter the atmosphere not only from certain stationary or mobile sources of emissions, but can be discharged from the surface of the earth, which has been man-made and anthropogenic, in particular in Ukraine. scientists [16] on the territory of Boryspil International Airport.

3.3 Remote atmospheric research tools as the first and important link in the crisis monitoring system during emergencies

Unfortunately, modern measuring instruments do not provide enough attention in the scientific community, and the instruments used in the national practice of Ukraine are often difficult to call modern. This primarily affects the accuracy of measurements and, consequently, the reliability of control over the quality of the environment. At the same time, when it comes to technical means and systems of air pollution control, the most effective, accurate, operational are optical, in particular, multispectral systems and multisensory systems, that allow express and at the same time high-precision control of air pollution in selected research ranges.

Multispectral research devices are imaging devices (image or set of images) in which data are recorded in certain wavelength ranges in the electromagnetic spectrum [17]. Wavelengths can be separated by optical filters or by sensors sensitive to specific lengths waves, including light having frequencies outside the visible range, such as infrared and ultraviolet [18]. Spectral visualization allows you to get additional information that cannot be seen by the human eye with limited receptors for the vision of blue, green, red. Such tools are usually part of geographic information systems that are built on the basis of satellites [19].

In contrast, multisensory devices are based on a number of different types of sensors, including optical, which allow to obtain a more informative and accurate conclusion about the quality of atmospheric air in a particular study area.

When the research is performed manually, using any research tools, there is an error of measurement caused by the human factor. Proven accurate remote sensing tools should be used to minimize human exposure during studies that require high accuracy and time.

Remote means of environmental quality research (Fig. 1) can be in the form of meteorological probes, remote manned or automated robots, unmanned aerial vehicles (UAVs) with installed video, infrared cameras and almost any sensors.

The most common remote means of air quality control are state (municipal) systems built on the basis of a set of stationary automatic stations (Fig. 1 a). Such systems have proven to be the main means of systematic air quality monitoring of large cities, suburbs, industrial regions, protected areas, etc. They allow to conduct fundamental research [20-22] of the patterns of movement and deposition of various pollutants [10], as they have a very high accuracy of equipment, the ability to work around the clock. The main disadvantages of these systems are the high cost of placement and operation, stationary, the overwhelming inability to quickly disassemble and move the observation station to another location (extremely low mobility).

One of the rather new methods of studying the historical levels of air pollution is the method of dendrochemistry [23], which was considered by a group of Italian scientists led by Edoardo Alterio, who proved the convenience and accuracy of this method of historical analysis of air quality. Without regard to, this method is not suitable for determining the actual levels of air pollution at the time of measurement.

The use of small cheap analogues of stationary atmospheric air monitoring stations - portable stations - is also quite widespread. Based on a system of municipal (large) and portable cheap (small) stations, there are online services (Fig.2.) that disseminate information about the relative air quality at a certain point. These relative readings are called the "Air Quality Index", which is calculated [49-50] on the basis of basic measurable indicators - dust particles, carbon oxides, nitrogen and sulfur.

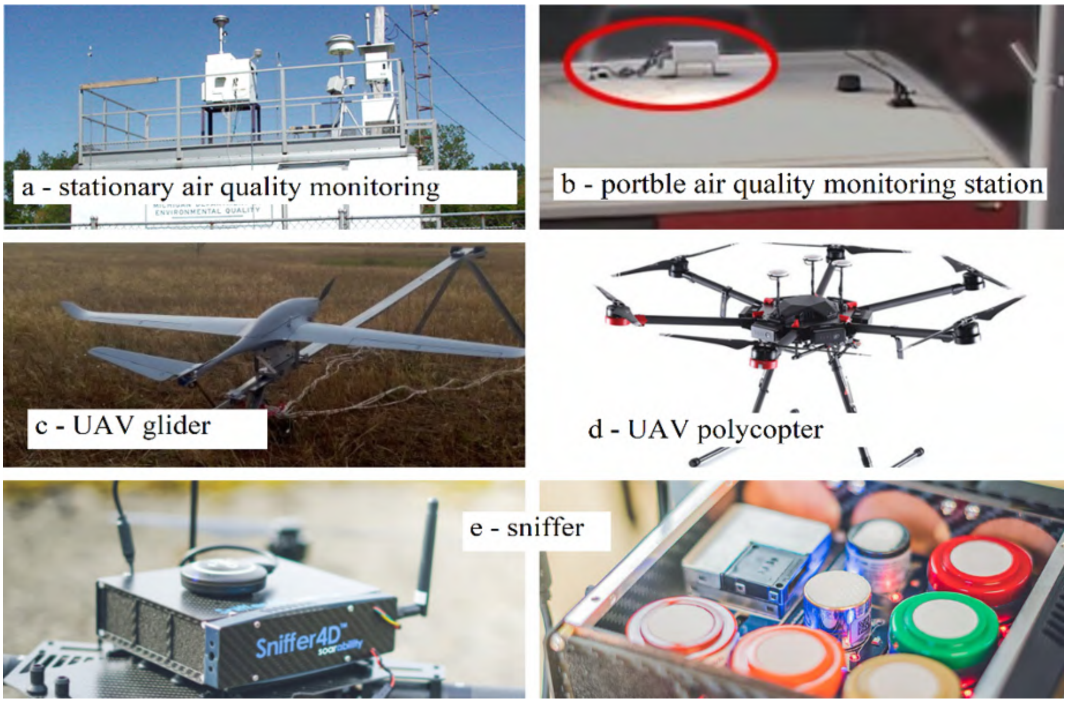

Fig. 1. Remote Environmental Monitoring tools [39,45-48].

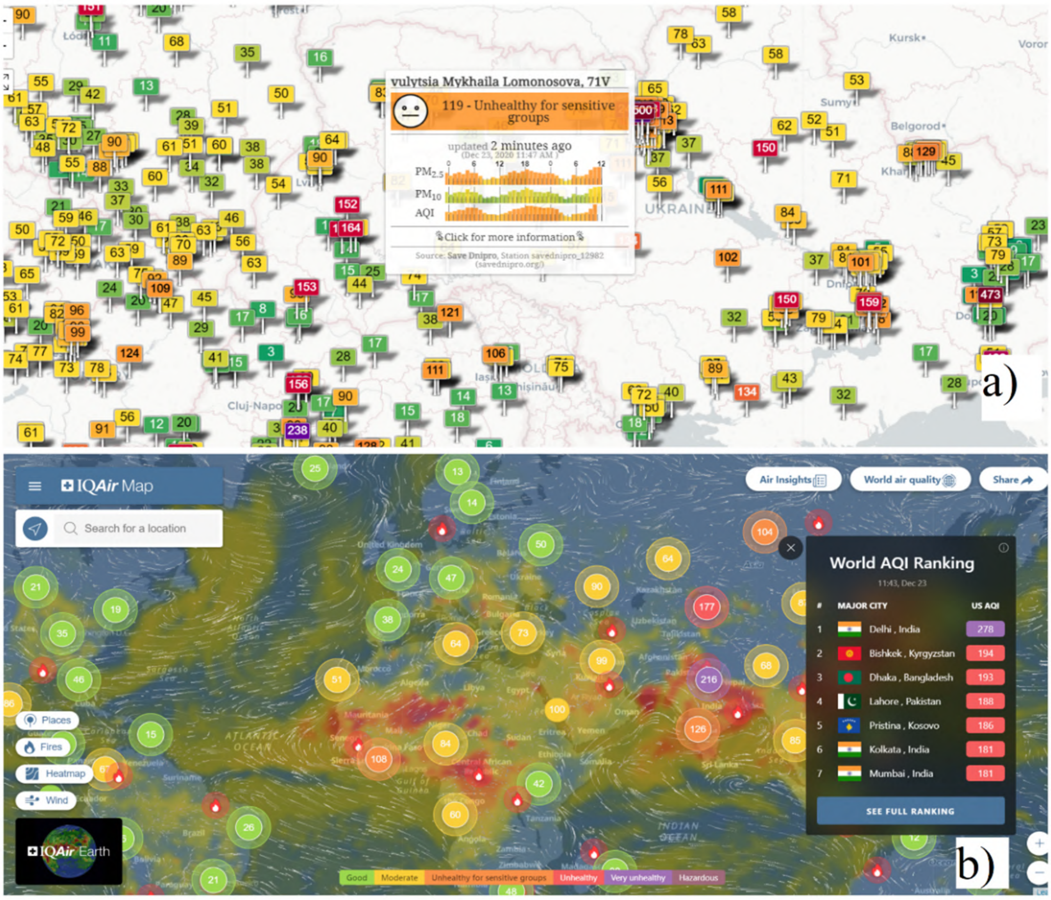

Fig. 2. Examples of online services for information about air quality and air pollution: a) aqicn.org and b) iqair.com.

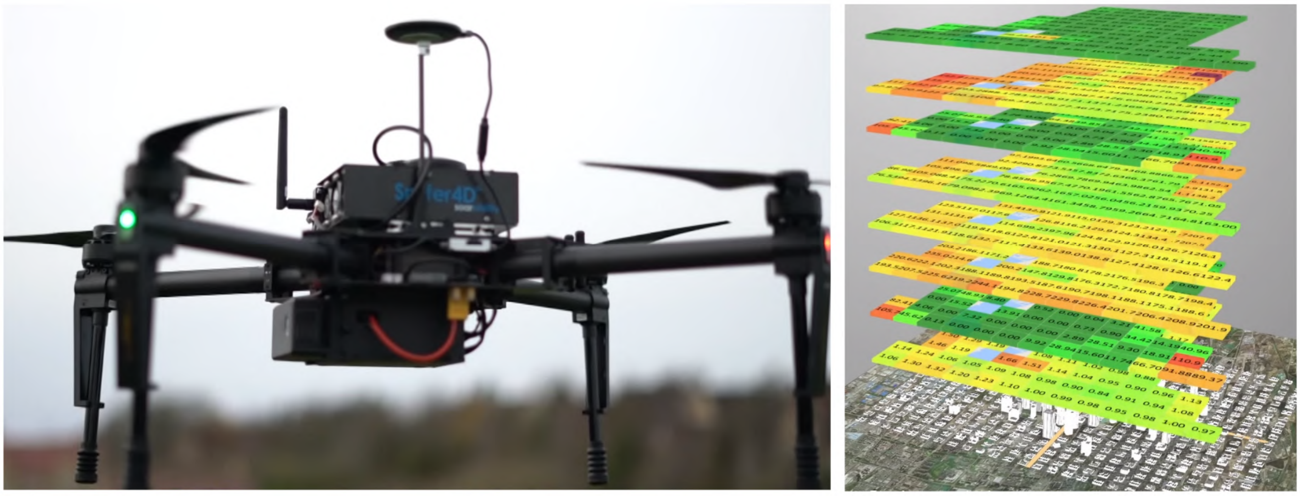

Fig. 3. Effective use of UAVs for manual air quality monitoring [39].

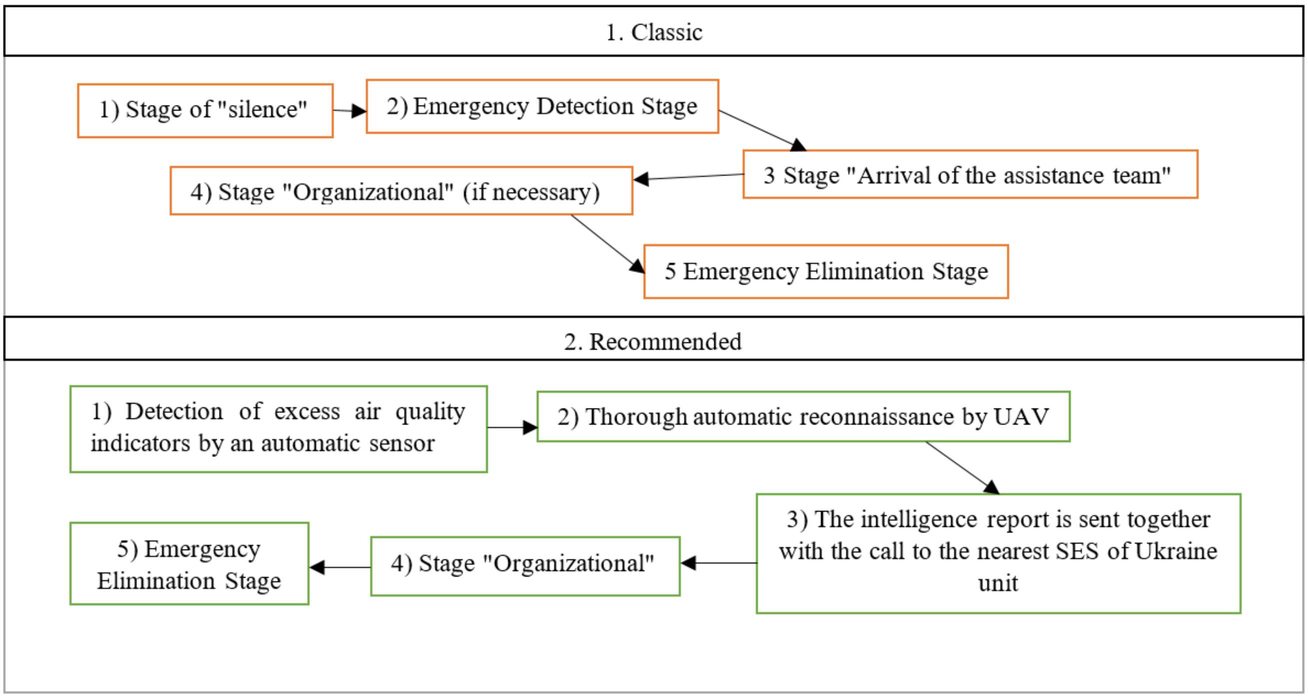

Fig. 4. Simplified response scheme of the rescue service (SES of Ukraine) to emergencies.

In the world of rapid development, the use of various sensors located in the systems of public, leased and private transport to study the parameters of air quality (Fig.1 b). In particular, A. Arfire, A. Marjovi, A. Martinoli, N. Castell, M. Kobernus, H.-Y. Liu, P. Schneider, W. Lahoz, A.J. Berre, J. Noll, L. Kang, S. Poslad, W. Wang, X. Li, Y. Zhang, C. Wang, G. Lancia, F. Rinaldi, P. Serafini, L. Liu, J. Duan, Z. Xiao, H.P. Raju, P. Partheeban, R.R. Hemamalini at al. have their scientific achievements in this field [24-30]. It is based on the use of the concept of the Internet of Things, to create and group sensor systems that are in some way placed on vehicles and combine them with computer centers that transmit information about the state of the air in the city to the Internet. Such systems are currently used successfully in cities and regions such as Chennai (India) [29], Lausanne and Zurich (Switzerland) [24] and Rome (Italy) [27]. Similar systems are also being tested in several regions of China [26, 28]. Such means of studying the quality of atmospheric air can be considered remote, due to the lack of a direct person-performer of measurements, the latter are performed automatically. In some systems, even the sensors are calibrated by a measuring device without assistance in an autonomous automatic mode [25].

Radioacoustic sounding of the atmosphere as a means and method of remote environmental monitoring, presented in the works of E.G. Tolstih [31]. This method is based on the passive radar spot of scattered electromagnetic oscillations and allows you to remotely measure such characteristics of atmospheric air as humidity, temperature, pressure and other physical indicators of air quality. Notwithstanding, radioacoustic sounding does not allow to determine the qualitative and quantitative values of aerosol and dust air pollution, as well as its chemical components in relative and / or absolute form - gases, water vapor, etc.

The studies based on the introduction of unmanned aerial vehicles into active scientific, industrial and public use have become very popular and widespread. At present contemporary UAVs are used: in biology to explore new, previously inaccessible corners of the planet and studied their flora and fauna [32]; in emergency services for the introduction of effective means of searching for victims of disasters and emergencies, in particular in the rubble of buildings [33-34]; in the fields of marketing and logistics for the development of services of delivery and dissemination of unimpeded provision of the population of remote places with the necessary means of subsistence [35], in the military sphere for search and general intelligence [36] and in the socio-cultural sphere for entertainment and leisure filming, video-blogging, photo and video shooting of sports competitions and concerts [37]. In the field of environmental safety, A.O. Zaporozhets, J.Burgués, S. Marco, R. Noori and D.P. Dahnil are using UAV-based technologies.

The use of UAV-based monitoring systems has found its use not only to study air quality, but also to perform research on the reliability of power grids and other energy and infrastructure facilities. [51-53].

Researcher of the Institute of Technical Thermophysics of the National Academy of Sciences of Ukraine A.O. Zaporzhets carried out a research project to create an air quality monitoring system based on the use of a set of methods for obtaining information on the state of the atmosphere: UAVs and the existing system of planned monitoring based on stationary and mobile air quality monitoring posts. In his work, he focused on planned, i.e. continuous monitoring of industrial facilities and proposes to study the air for the content of O_2, CO, CO_2, NO, NO_2, SO_2, H_2S at an altitude of 50m to 1km using UAV glider (fig. 1 c) and helicopter types [38].

Spanish scientists J. Burgués & S. Marco have developed an effective device (Fig. 1 e) for air sampling during monitoring of polycopter type UAVs - sniffer (sensor unit) of atmospheric quality [39], performing a significant analysis of research conducted today on the location and execution of sniffers for use in unmanned aerial vehicles during continuous scheduled monitoring of air quality in cities (Fig. 3.). The problem with their sensor unit is: too dense placement of sensors, which can affect the work of each other and interfere with the uniform blowing of all sensors, as well as the narrow specialization of the sniffer and the impossibility of its use on various unmanned aerial vehicles, as Burgués, J., & Marco, S specialized in their invention for use with only three models of helicopters brand DJI M100/210/600, as well as on cars.

Researchers R. Noori & D.P. Dahnil from the University of Malaysia Kebangsaan proposed the use of a six-beam polycopter (Fig. 1 d) for use in studies of environmental quality indicators [40]. In their work, they tried to test the efficiency of the polycopter to determine the effectiveness of various equipment for measuring the concentration of four indicators of air quality: smoke, hydrogen, carbon monoxide and liquefied petroleum gas given the turbulence of air generated by UAV propellers during its movement and optimize the complex these features. The scientists concluded that their system has the highest measurement accuracy only at UAV speeds up to 6 m/s, and at speeds above this value there is a significant decrease in the accuracy of the obtained data.

3.4 Legal features of the use of UAVs in the system of operational monitoring of the atmosphere during emergencies in Ukraine

As noted in the previous section, currently unmanned aerial vehicles have an unsurpassed impact on the speed and quality of research in various spheres of life: economy, industry, science, socio-cultural life.

The rapid development of the scope of UAVs has led to the rapid development of interception technologies for remote-controlled unmanned aerial vehicles. These technologies propagate a large number of signals in a certain frequency range, which prevents the exchange of information between the control station and the radio transmitter of the aircraft with a radius of several kilometers, but most modern unmanned aerial vehicles have protection against radio noise and interception. Radio interception can be hindered by the use of an autopilot module in the UAV, with a preset task of the desired flight route to the program of the aircraft, which in this case has a mediocre value of data exchange with the control station - can transmit real-time images and data not used during flight.

Anyhow, the use of UAVs for any purpose in Ukraine is clearly regulated by regulations, in particular: The Air Code of Ukraine [41]; Regulations on the use of airspace of Ukraine [42] and the Rules of use of airspace of Ukraine [43].

The State Aviation Service of Ukraine has published a map of zones [44] with restrictions on the flight of unmanned aerial vehicles. The UAV flight area has a specific character and is strictly regulated by such organizations as the State Agency of Civil Aviation and the Armed Forces of Ukraine. The result of regulation are areas where flights are prohibited in whole or in part limited by the size of the UAV or time of day. In accordance with the requirements of paragraph 4 of section II of the Rules of use of airspace [43], flights of unmanned aircraft weighing up to 20 kg inclusive are performed without submitting applications for use of airspace, without obtaining permits for use of airspace, without informing the Air Force of the Armed Forces of Ukraine and bodies of the joint civil-military system of air traffic organization of Ukraine, bodies of the State Border Guard Service of Ukraine, air traffic service bodies and departmental air traffic control bodies, subject to compliance with certain requirements space".

Though, emergencies may be defined by Ukrainian law as force majeure, or endangering the health and well-being of the population, and unmanned vehicles, which are registered on the balance of the State Emergency Service as means of performing special operations to search and eliminate emergencies, their consequences, as well as for the search for victims, as defined in the Air Code of Ukraine, section 4 “use of airspace of Ukraine”, Article 24, paragraphs 1-5 [41].

4 Discussion

After analyzing the above studies, we conclude that the most promising area of environmental research is the use of modern remote, including *multisensory*, means of prevention and during emergencies in man-made areas and facilities.

Comprehensive development and implementation of new remote multisensory and multispectral means technical means of environmental control, taking into account the impact of their characteristics and parameters on the effectiveness of the process of controlling ground air pollution and assessing the ecological state of the atmosphere of technogenically loaded areas and objects has the aim of operational monitoring of the quality of the ground layer of atmospheric air, reduction of risks to health and life of specialists working in the emergency zone, or one that requires rapid surgical intervention for further localization and elimination.

Based on the analysis, we propose an improved scheme (Fig.4) of work of units of the State Emergency Service of Ukraine (SESU), which shows two algorithms for responding to an emergency - classic and recommended. In classical algorithm we distinguish five basic steps:

- the first stage is the time from the objective beginning of the emergency situation, to the moment when the fact of the emergency is noticed by people;
- the second - starts from the moment of detection of emergency and attempt of independent reconnaissance by non-experts (people nearby) to a call of crew of SESU;
- the third is the arrival of the rescue service team and reconnaissance of the scene by specialists, with or without special means;
- the fourth is creation of a staff of liquidation of emergency situations, development of the plan of liquidation, adjustment of structure of crew, etc.
- the fifth stage, which is directly to take action to eliminate this emergency.

The classical algorithm has two main disadvantages. The first is the response time, which increases significantly in areas where there are no people, or their number is insignificant (for example, land plots of warehouses, landfills, slag dumps, and other objects of man-made origin). The second significant disadvantage is the high risks to life and health of all people in contact with the emergency zone, especially if they do not have adequate personal protective equipment against any dangerous effects that occur in this area. These two shortcomings are interdependent, as due to the increased response time, the scale of the emergency increases, and therefore not only the natural area but also the people there are more negatively affected.

In contrast to the classical response scheme, the recommended scheme, provided it is properly implemented, is as free as possible from the shortcomings of the classical response scheme, and significantly simplifies and speeds up the work of units of the SES of Ukraine.

5 Conclusions

Emergencies will accompany humanity as long as society exists, and therefore it is very important to pay attention to the sustainable development of the response to emergencies, including environmental ones.

The article considers the features of the study of the surface layer of atmospheric air, reviews the existing remote means of monitoring the condition of this layer and also proposes a new functional scheme of response of the State Emergency Service of Ukraine to emergencies.

In order to talk about the monitoring of the surface layer of atmospheric air, it was necessary to determine the boundaries of this layer. Based on literary and logical theses, the authors of the article determined that the airspace at altitudes from 1.5 m to 500 m inclusive.

Based on the comparison of different remote means of environmental air quality monitoring, it can be stated that of all analyzed means, in particular - stationary automatic stations, mobile automatic stations, probes and unmanned aerial vehicles, it is proposed to use the latter as a remote means of operational air quality control. time of emergencies at the enterprise.

The proposed functional scheme of implementation of the UAV system for the needs of operational environmental monitoring of Ukraine will significantly reduce the response time to emergencies at enterprises, although it requires closer relationships "enterprise-unit of the SES of Ukraine" than those that exist now - mostly verifiable. The problem of implementing this functional scheme is the predominant distrust of entrepreneurs to regulatory authorities, which also indicates the need to restructure and reorganize the state emergency service of Ukraine to strengthen its basic functions to protect the population and property of Ukraine from natural and unnatural factors.

Analyzed legal features of the use of unmanned aerial vehicles as a remote means of air quality control during emergencies suggest that the use of UAVs as an additional means of monitoring air quality in the enterprise, as well as its sanitary protection zone is not only possible but also easily implemented. the existing regulatory framework of the state.

The use of modern means of remote monitoring of environmental quality, including unmanned aerial vehicles, will make the field of operational (crisis) monitoring of Ukraine more effective and timely, compared to the existing system of emergency response, which could potentially be responsible for environmental disasters in the region, region, country or even in a cross-border arena. In addition, such optimization will not only optimize the response time to emergencies, but will also be the first link in the whore to develop the scope of rapid response in the concept of sustainable development.

Abstract. The results of investigations of chemical composition and emission rates of the welding fume, generated during welding using electrodes for copper alloys, are presented with the aim of improvement of their sanitary and hygienic characteristics. It is shown that in order to create new grades of welding electrodes with improved hygienic characteristics, it is necessary to have the data of the initial sanitary and hygienic evaluation in accordance with international standards. It was established that the use of binder based on pure lithium liquid glass in the coating of electrodes for welding copper alloys, increases the rate of welding fume emission into the air, as well as the content of manganese and copper oxides in it. The minimum rates of harmful emissions were recorded during the use of sodium-potassium binder, which is recommended for mass production of this type of electrodes.

1 Introduction

Manual arc welding of copper and copper alloys using coated electrodes is widely used in different industries, i.e. power engineering, metallurgy, foundry, etc. It is characterized by a number of harmful and hazardous factors that affect not only welder but also supporting personnel [1-3]. From a hygienic point of view, one of the most hazardous harmful factors is the presence of welding fume (WF) in the air, the toxic effect of which depends on the chemical composition of welding electrodes. The methodical standards DSTU ISO 15011-1:2008 [4] and DSTU ISO 15011-4:2008 [5] provide an opportunity to obtain the necessary information about the chemical composition of WF and approximately calculate the risk of their harmful effect on the body of welder.

2 Processes of welding fume generation during manual arc welding of copper and its alloys

A schematic view of the zone of manual arc welding is shown in Figure 1. Under the effect of the arc heat, at the end of the electrode a droplet of liquid metal is formed and growing, which is maintained by surface tension. Moreover, melting of the coating usually occurs little bit slower than melting of the electrode rod. As a result, a "casing" is formed, from which a partial evaporation of the coating materials and the metal melt occurs. A relatively small part of the metal evaporates as a result of a high boiling point of the metal and a significant heat of evaporation. A part of vapours is lost, getting into the atmosphere surrounding the arc, where the metal vapours condense into droplets, oxidize and transfer into fine solid particles of metal oxides, which form a fume and always surround the welding arc. [6].

3 Classification of welding fume according to degree of harm

During manual arc welding of tin bronzes, in the composition of WF such harmful substances as manganese, copper, their oxides and other components of welding material may be present. In all developed countries of the world, sanitary services control harmful substances in the air of the working area of production rooms for their compliance with the maximum allowable concentrations (MAC) according to special methodological standards. In particular, in Ukraine the MAC value for manganese, when its content in WF is lower than 20%, amounts to 0.2 mg/m^3, and when its content in WF starts from 20%, it amounts to 0.1 mg/m^3, the MAC of copper amounts to 1 mg/m^3. These elements belong to the second category of hazard. They may cause inflammation of the mucous membrane, problems with the nervous system and fever of metal smoke.

4 Choice of material and procedure of experiments

To investigate the rates of emissions and chemical composition of WF during manual arc welding of tin bronzes, the electrodes with a specific composition were used, which were developed at the E.O. Paton Electric Welding Institute [7]. Their composition is associated with the presence of chemically active substances related to the binder, such as liquid glass, components of sodium salts (hexafluorosilicate and hexafluoroaluminate), as well as non-traditional metal components (tin and copper-phosphorus powders).

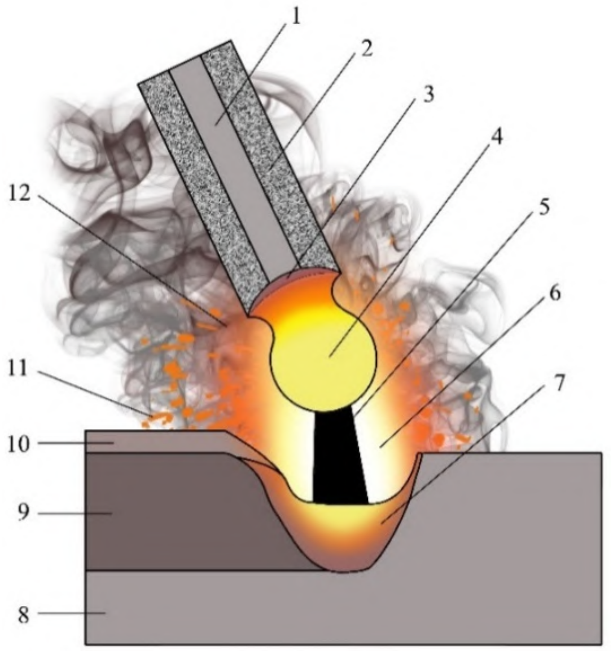

Fig. 1. Formation of welding fume: 1 - electrode rod; 2 - electrode coating; 3 - molten electrode rod and coating; 4 - droplet of electrode metal; 5 - arc column; 6 - arc flame; 7 - welding pool; 8 - base metal; 9 - weld; 10 - slag; 11 - sparks (splashes) of liquid metal and slag; 12 - gases and welding fume

The main aim of the study is to choose the optimal type of alkaline silicate binder, the properties of which largely determine the manufacturing technology, quality, welding and sanitary properties of electrodes.For this purpose, standard (sodium, potassium and mixed sodium and potassium) [8] and experimental (lithium and lithium-containing) samples of liquid glass were prepared, which provide unique properties to some grades of electrodes [9]. Their physicochemical characteristics are given in Table 1.

The experiments were performed on the electrodes, manufactured on copper rods, and a charge consisted of marble: cryolite, sodium silicon fluoride, tin, copper-phosphorus, nickel and manganese powders [10]. For comparison, the mass-production electrodes OZB-2 and UTP-32 were also studied.

Sampling of WF for their dissolution is carried out in accordance with the standard [5] applying the method of complete capture of the fume, generated during welding with the use of the special bench with the FPP filter installed on a way of movement of WF from a shelter of a welding zone. The following indices of WF formation were determined: intensity of V_a emission, g/min; specific emission of G_a, g/kg; chemical composition of WF, wt. %. For each variant at least three experiments were performed. Welding was performed at direct current (150 A) of reverse polarity using VDU-504 rectifier.

5 Results of investigations

The welding conditions and general indices of welding fume emission are given in Table 2.

As the results of the investigations showed, the highest general values of intensity and specific emission of the welding fume were observed during welding using mass-produced grades of electrodes UTP-32. Among the experimental electrodes, the highest values of V_a and Ga were observed during welding using the electrodes with a binder based on lithium glass. The mass fraction of chemical elements in the welding fume during welding using mass-produced and experimental electrodes for welding tin bronzes is given in Table 3.

According to the obtained results, the chemical composition of copper in the composition of WF does not differ significantly for all experimental grades of electrodes, whereas the intensity and specific emission are different (see Fig. 2-3). Moreover, the rate of emission of manganese differs both in chemical composition as well as intensity of its emission (see Fig.4-5). The lowest value of lithium among the experimental electrodes of grade ANBO with the content of lithium glass was obtained during welding using electrodes ANBO-Na-Li. Among the electrodes based on sodium glass, the highest value of sodium in WF was determined during welding using electrodes ANBO-Na. The content of potassium is the lowest in WF, obtained during welding using electrodes ANBO-Na.

Table 1. Physicochemical parameters of liquid types of glass [11]

Type	Density ρ, g/cm³	Toughness, η+20°C, MPa·s	Chemical composition, wt. %				Module
			SiO_2	Li_2O	Na_2O	K_2O	
Na	1.430	392	29.03	-	8.83	2.15	2.93
Na-K	1.435	606	28.80	-	6.94	4.56	2.99
K-Na	1.428	304	27.85	-	4.00	8.79	2.94
K	1.415	260	26.92	-	0.03	13.78	3.05
Na-Li	1.396	526	30.19	2.69	0.99	5.17	2.73
K-Li	1.421	554	27.93	1.42	0.94	10.67	2.65
Li	1.258	287	25.08	3.19	-	-	3.91

Table 2. Indices of emission rates of welding fume during welding of copper alloys

Grade of electrode	Iw, A	Uw, V	g, kg/min	V_a, g/min	G_a, g/kg
OZB-2,mass-produced, 4 mm diameter	120	24-28	0.0430	0.3359	7.59
UTP-32,mass-produced, 3.2 mm diameter	100	28	0.0336	0.7654	22.78
ANBO-Li, 4 mm diameter	120	28	0.0447	0.4693	10.50
ANBO-Na, 4 mm diameter	120	24	0.0413	0.3006	7.28
ANBO-K, 4 mm diameter	120	24	0.0366	0.3010	8.22
ANBO-Na-Li, 4 mm diameter	120	24	0.0380	0.2594	6.82
ANBO-K-Li, 4 mm diameter	120	24	0.0396	0.3948	9.97
ANBO-K-Na, 4 mm diameter	120	24	0.0304	0.2874	9.45

Table 3. Mass fraction of chemical elements in the welding fume.

Grade of electrode	Mass fraction in WF, %				
	Cu	Mn	Li	Na	K
OZB-2,mass-produced, 4 mm diameter	35.50	1.56	-	-	-
UTP-32,mass-produced, 3.2 mm diameter	36.78	2.93	-	-	-
ANBO-Li, 4 mm diameter	33.38	3.16	0.82	-	-
ANBO-Na, 4 mm diameter	33.42	2.50	-	9.14	-
ANBO-K, 4 mm diameter	33.35	2.40	-	-	13.15
ANBO-Na-Li, 4 mm diameter	33.49	2.81	0.68	7.57	-
ANBO-K-Li, 4 mm diameter	33.33	2.41	0.85	-	9.06
ANBO-K-Na, 4 mm diameter	33.26	1.95	-	7.82	12.34

The obtained results clearly show that the highest values of specific emission and intensity of WF formation were determined during welding using mass-produced grades of electrodes UTP-32 and experimental electrodes ANBO-Li.

To determine the final estimated indices of hygienic evaluation of welding materials in compliance with the standard DSTU ISO 15011-4: 2008, the limit value of the welding fume was determined by the following equation:

$$LV_{WF(A)} = \frac{100}{\sum_1^n \frac{i}{LV_i} + \frac{(100-\sum_1^n i)}{LV_{WF}}} \qquad (1)$$

where $LV_{WF(A)}$ is the total limit value of the welding fume, in mg/m^3; n is the number of main components of the welding fume; i is the fraction of *i-th* main component of the welding fume in %; *LVi* is the limit value (MAC) in mg/m^3 for *i*-th main component of the welding fume; LV_{WF} is the limit value in mg/m^3 for the welding fume, which contains chemicals with a low and medium toxicity, if such a limit was established, or a limit value in mg/m^3 for inhaled dust, if no limit value for the welding fume was established.

Due to the fact that the procedure [12] does not allow determining the content of all components of WF to bring its composition to 100%, it was assumed that in addition to the revealed components, the residue of WF represents a non-toxic dust with MAC of 10 mg/m^3. The results of the calculation are shown in Table 4.

Regarding the hygienic category of all test specimens of welding electrodes according to DSTU ISO 15011-4: 2008, determined by the formula 1, all of them belong to a one category 1b, except for the electrodes UTP-32, which belong to the category 1c (Table 4). It implies a harmful category "1" according to the limit value of WF (from 0.5 to 1.5 mg/m^3) and a moderate category "c" as to the level of its emissions (from 8 to 15 mg/s).

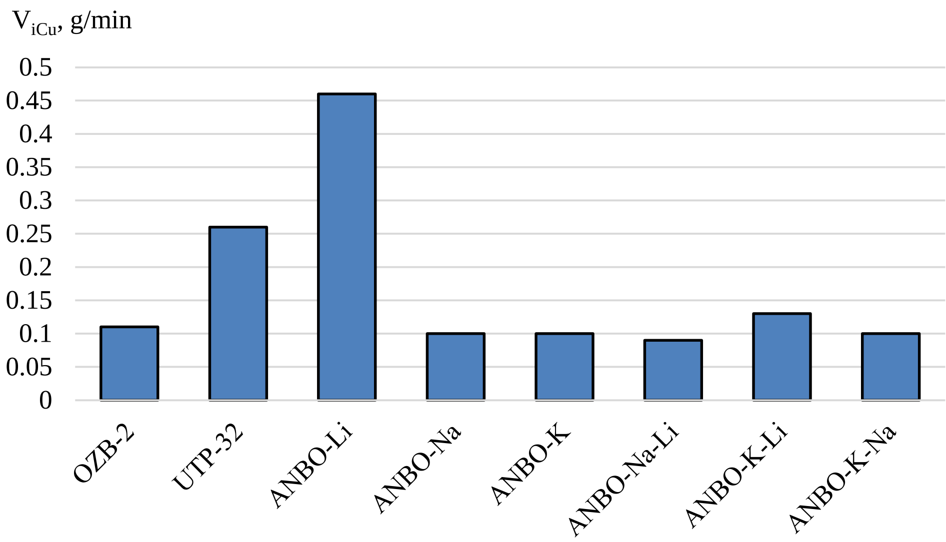

Fig. 2. Intensity of copper formation in the composition of WF.

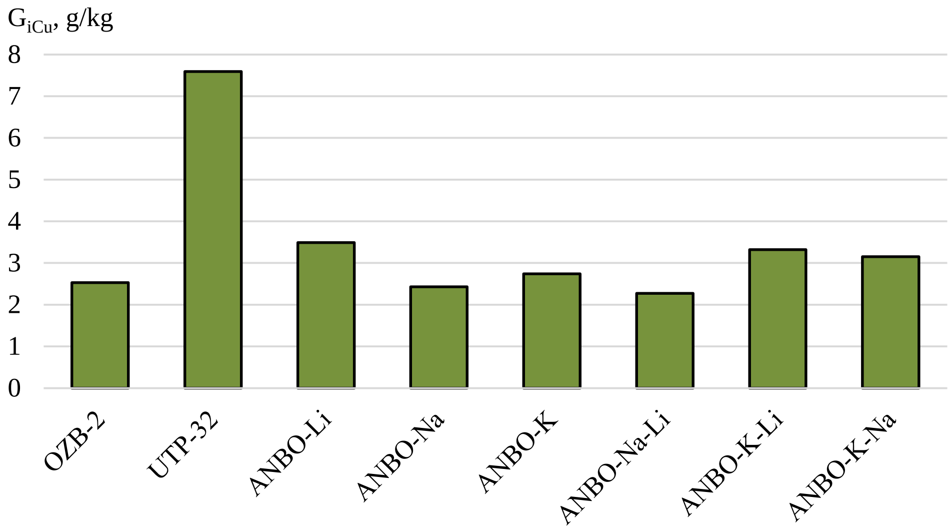

Fig. 3. Specific emission of copper in the composition of WF.

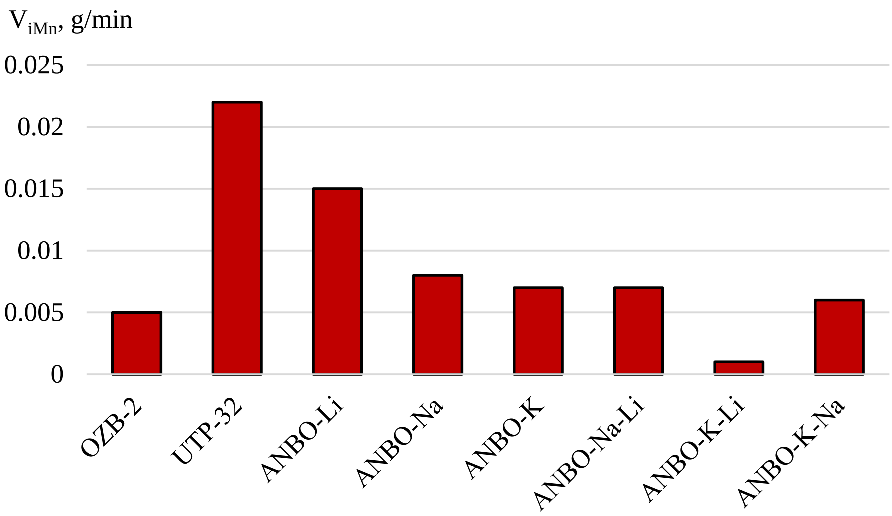

Fig. 4. Intensity of manganese formation in the composition of WF.

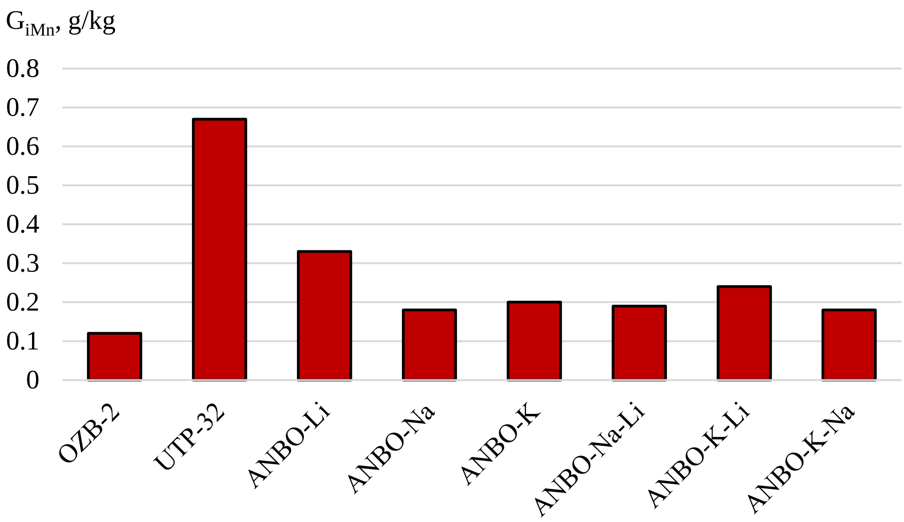

Fig. 5. Specific emission of manganese in the composition of WF.

Comparing the electrodes according to the total limit value of the welding fume, which is an index of toxicity, the most harmful grade of electrodes will be ANBO-Li, followed by mass-produced grades UTP-32 and ANBO-Na-Li.

As a result of investigations with the use of electrodes for welding tin bronzes, a high intensity of the welding fume emission was established, that is explained by existence of volatile compounds and a high basicity of a slag phase in the coating.

The performed analyses show that the basis of WF consists of such components as compounds of alkali and alkaline earth metals (Na_2O; K_2O; Li_2O), copper, manganese, etc. As to the total limit value of the welding fume, among the experimental electrodes, WF emissions are the least toxic during welding using electrodes ANBO-K-Na. During welding using electrodes made of potassium-sodium glass, the highest indices of welding-technological characteristics were also established [12]. Therefore, during the subsequent experiments the electrodes were used made on the basis of potassium-sodium type of glass, which were given the index EOF-50.

6 Methods of reducing emissions of harmful WF components into the working area during manual arc welding of tin bronzes

Reducing the harmful effect of welding fume on the body is fulfilled by the use of technological and sanitary-technical measures, as well as the use of means of individual protection [13, 14, 15]. A particular interest of developers of welding materials and technologies is attracted to technological methods of reducing the rate of WF emission, which are aimed in improvement of welding materials, technologies and equipment in terms of hygienic protection and selection of optimal welding conditions.

The carried out investigations on the effect of a type of electrode coating on hygienic characteristics of welding fume may be based on the calculation of the value of a required intensity of ventilation air exchange, which is denoted as NHL and expressed in m^3/min [16].

The further investigations were performed in accordance with the international standard DSTU ISO 15011-4:2008 using $LV_{\mathrm{WF(A)}}$ indices (see equation 1), category of welding material, intensity of WF emission, as well as *NHL*.

The results of NHL calculation are shown in Table 5.

The worst values according to the $LV_{\mathrm{WF(A)}}$ index were noted during welding using electrodes ANBO-Li, although not all experimental electrodes differ significantly as to the limit value, whereas *NHL* for electrodes UTP-32 one and a half times increases. As to the totality of these changes, in this case an increase in the degree of a harmful effect of WF on a human by about 1.5 times can be reported.

7 Conclusions

The main method to improve hygienic characteristics of welding materials is certainly a change in the chemical composition of welding material. This task is not easy, because the main requirement of the welding process is to provide a high quality and the required mechanical properties of a weld. Therefore, welding materials always contain toxic chemicals, without which it is impossible to provide the necessary properties of welded joints. However, some improvements in hygienic characteristics of welding materials (minimization of harmful emissions) can be achieved.

Table 4. Indices of hygienic evaluation of welding materials determined by the calculation method in accordance with the standard DSTU ISO 15011-4: 2008.

Grade of electrode	V_a, mg/s	$LV_{\mathrm{WF(A)}}$, mg/m^3	Category of electrode
OZB-2,mass-produced, 4 mm diameter	5.598	1.059	1b
UTP-32,mass-produced, 3.2 mm diameter	12.757	0.989	1c
ANBO-Li, 4 mm diameter	7.8217	0.978	1b
ANBO-Na, 4 mm diameter	5.01	1.01	1b
ANBO-K, 4 mm diameter	5.017	1.015	1b
ANBO-Na-Li, 4 mm diameter	4.323	0.994	1b
ANBO-K-Li, 4 mm diameter	6.58	1.014	1b
ANBO-K-Na, 4 mm diameter	4.79	1.038	1b

Table 5. Hygienic indices of WF emissions during welding of copper alloys using experimental electrodes.

Grade of electrode	Va, g/min	$LV_{\mathrm{WF(A)}}$, g/m^3	NHL, m^3/min
OZB-2,mass-produced, 4 mm diameter	0.3359	$1.059 \cdot 10^{-3}$	317.186
UTP-32,mass-produced, 3.2 mm diameter	0.7654	$0.989 \cdot 10^{-3}$	773.913
ANBO-Li, 4 mm diameter	0.4693	$0.978 \cdot 10^{-3}$	479.8569
ANBO-Na, 4 mm diameter	0.3006	$1.01 \cdot 10^{-3}$	297.6238
ANBO-K, 4 mm diameter	0.3010	$1.015 \cdot 10^{-3}$	296.5517
ANBO-Na-Li, 4 mm diameter	0.2594	$0.994 \cdot 10^{-3}$	260.9658
ANBO-K-Li, 4 mm diameter	0.3948	$1.014 \cdot 10^{-3}$	389.3491
ANBO-K-Na, 4 mm diameter	0.2874	$1.038 \cdot 10^{-3}$	276.8786

The emission rates and chemical composition of WF are determined by the content of chemical elements or compounds in welding electrodes. As a result of melting the coating and the electrode rod, at the end of the electrode evaporation of elements with a high vapour pressure occurs. One of the most harmful substances contained in WF, generated during welding of tin bronzes, are compounds of manganese and copper.

The analysis of the obtained results of the investigations and literature data allowed concluding that to provide the maximum improvement in hygienic characteristics of welding materials, it is necessary to be guided by a comprehensive approach. To minimize the harmful properties of WF and its effect on the body, it is necessary to choose the optimal combination of the following technological methods for reducing the rate of harmful substances emission:

1. If possible, it is necessary to use those types and grades of welding materials that provide a reduced level of WF emissions.

2. Taking into account hygienic characteristics while choosing electrodes for welding copper alloys, between the grades ANBO and UTP-32 the preference should be given to the first one. As far as during the use of the electrodes of experimental grades ANBO with a different type of binder, the specific WF emissions are 1.7-3.0 times lower as compared to the mass-produced grade UTP-32.

3. The obtained results of the carried out investigations can be used during calculation of the systems for mechanical ventilation: determination of amount of air L (m^3/h) which needs to be supplied or removed from the room. To calculate the ventilation of production rooms where welding is used, air exchange is required, which is usually determined by the calculation method based on specified data on the amount of harmful substances emissions.

Abstract. The article deals with the problem of the modern education system perfection and at the same time seeks to reach the limit of the possible in the transformation of the educational space to meet the demand of time, its ability to provide social consciousness in the conditions of the ongoing crisis and those changes that caused the intensification of the dialogue between Man and Nature. The development with the participation of humans becomes of a more targeted nature – noospheric and educational, global one. This is a new way obliges a modern general education institution to look for better approaches to the production of personality and promote the development of modern man – the carrier of new values. The state of society's consciousness should be inclined to act in the direction of its spirituality. The correlation between the social and morphological organization of a human being should not be beyond the problem of profile education. he human world to a large extent begins in a human being itself, therefore, the objective of this article is the search for ways to change the educational system of the region for the sake of further formation and development of the democratic society of the anthropospheric era.

1 Introduction

In the 21st-century mankind is rapidly turned into the active creator of the world due to their appropriately educated intelligence, as ideally, all people of the planet are dimensions, connected by education and mediated by God whose means the Word. The main issue for the contemporary school system is to retrieve this "correct" rule of education for the contemporary person.

At this time, all occurrences of our life can be dealt with success only via an empirical way of perception, but not hypothesizes into account. Only by doing so, we are able to introduce new opportunities, new principles, and axioms into science, according to the opinion of Vladimir I. Vernadsky (from Diaries, May 1921) [1]. At this moment we are approaching the stage of our development, whos has already been reached by the genius persona of Vladimir I. Vernadsky. Scientist left us an all-pervasive sign of the guidance of his supreme intelligence: life is omnipresent and ceaseless in time, the mineral essence of the world stems from the aspect of life itself and the geological role of the person in particular and humanity in general. This stage is a shift from the biosphere to anthroposphere and explosion-like viral spreading of scientific awareness. Meanwhile, the organization of science is the anthropospheric feature, provided by the appropriate education [2].

The research is the empirical summarization of the issues of the current time and is the complex hypothesis with the outlined attitudinal guiding lines, which interprets the tendencies of development of the contemporary educational system, that urgently and spatially requires the appearance of essential basic points of life projecting, based on the incomplete theory of the region of the biosphere.

It is worth noting, that the term "region" is common in many languages. Predominantly it is prone to reflective modelling of some imaginable locations on some territory and is more frequently used in the sphere of administrating or economics where it introduced as the separate dimension. In Ukraine there was a politically active "Party of the regions", but their policy has nothing to do with everything highlighted in this paper.

The *goal of this paper* is search of ways the improve the educational mechanism of formation of the personal potential, aimed for the successful and efficient changes of the educational system of the region of the biosphere for the sake of further formation and development of the democratic society in anthropospheric era.

2 Materials and methods

In 2018, the Club of Rome for its half-century anniversary prepared a report "Come On! Capitalism, myopia, population and the destruction of the planet". The report, at first sight, was in line with the ideas of Vladimir I. Vernadsky, but in view of a probable procedure, its solution did not correspond to the humanist scientist's plans who upheld the triumph of the individual in the biosphere and believed in the possibility of scientific piloting of the biosphere.

The co-author of the report "Come On! …" was Elvir Weizsäcker, who emphasized follow: "In the heart in our main idea is the difference between an empty world and a full one. In the period of the "empty world" mankind was small, and nature was many. This period ended in the 70s and 80s. Now we have a "full world", a huge number of people, three times more than in 1945. But the planet is not growing. This is one of the main problems that the Club talks about" [3].

His viewpoint in this issue Volodymyr I. Vernadsky expressed in 1925: such synergetic and dual entity surely causes the correct stream of the mind flow about making the demand for a decent education, "causes the element of creativity, which will engage the capital of knowledge, and ability to retrieve the necessary elements even from the strangest and the most unknown creatures for some person" [2, p. 125].

Therefore, in this study, it will have used follow methods such as theoretical analysis and generalization of worldviews of Vladimir I. Vernadsky [1], Lev N. Gumilev [4], Olexandr P. Kovalyov [5], Yuriy M. Lotman [6], Frederick Schelling [7], Oswald Spengler [8]; correlation and comparison of the theory of the biosphere region, the theory of the biosphere of Vladimir I. Vernadsky and the theory of the noosphere by Pierre Teilhard de Chardin [9]; as well as observation and modelling. These problems were comprehended and considered in publications of Vlail P. Kaznacheev [10], Olena O. Lavrentieva [11], Lina M. Rybalko, Oleh M. Topuzov [12], Anatoly Samondrin [13] and others.

The presented research is an empirical generalization of the issues of modern times in the design of the neo-sphere existence of the biosphere and outlines the trajectory of the formation of personal educational potential in modern educational institutions.

3 Theoretical background

The term "region" (de. Gebiet and Region f; lat. regio – kingdom, domain) – in the past was the name of the land, area, county, etc and nowadays this term denotes the big territorial unit, and in physical geography, it stands for the general name of the unit, which is the part of the physical and geographical division of any taxonomic rank, and in historiography, it means the historical and geographical region, as well as the name "economical region" used for economical for studies. Methodologists emphasize the validity of the geographical theory of regional development. The scientific perception of this definition remains unclear, especially concerning the pedagogical aspect, which has always been the supplementary element of social and economic development, but, unfortunately, not the core of projecting [13].

There are qualities that are taking place as factors defining the region as a complex social system. They cover the relative apartness, integrity, complexity, structurdness, the subordination of the single objective to ties with the external factors.

The term "region" was quite thoroughly explored by a Ukrainian scientist Olexandr P. Kovalyov. He made the following statement, that defines his biospheric essence comparing to others, examined by other researchers, namely: relatively closed territorial, non-state, socially-productive formation, that is characterised by the relative autonomy and capability of self-reproduction of socially-productive functions and that phenomena, what has the appropriate infrastructure and integrated into the functional structure of cosmobiotic geospacer [5].

In contemporary economical science, the classification of Ukrainian regions provides the following categories: problematic, underdeveloped, recessionary, and depressive ones. These terms are generally and contextually similar, but also bear several differences. The issue of clear classification of regions is very actual in a whole for the elaboration of the strategy of territorial development as well as for the construction of the model of educationally-studying space of a region.

On the current level of development of Ukraine, along with the central organs of administration, the local organs are engaged in more and more activities for the solution of the problems of economic and social development of the regions, for the implementation of modern mechanisms of their support. Primarily they are used for helping "depressive" and "recessionary" territories within the scope of the goals of sustainable development. Conditionally, the monitoring of the territory of the region can be performed by introduction of several indicators, which, depending on the variety of properties, will gain a certain level of "problematic", "underdeveloped", "recessionary" or "depressive" level [13]. We are going to clarify the general characteristics of their basic properties (see Fig. 1).

The *underdeveloped region* is that one, whose rates cannot keep up with the average state rates, more than one third.

The *problematic region* should be considered such one that retains the situation requiring the supplementary (usually external) aid for its solution. They can be the ecological conditions, proximity to the border, the availability of conflict occurrences, etc.

The *recessionary region* must be called such one in the case of the probability of irreversible tendencies to recession of production there, the increase of unemployment, the decrease of life standards, the deterioration of health conditions, the decrease of the index of life duration.

Recessionary territory, whose recessionary state is retained for a long time, must be classified as a depressive one. *Depressive territory* cannot overbear the crisis without external aid. Such territory might be switched to the steady development stage only in the case of obtaining complex support and the accumulation of all resources (internal aid and the external one, gained from the greater organization, area or state).

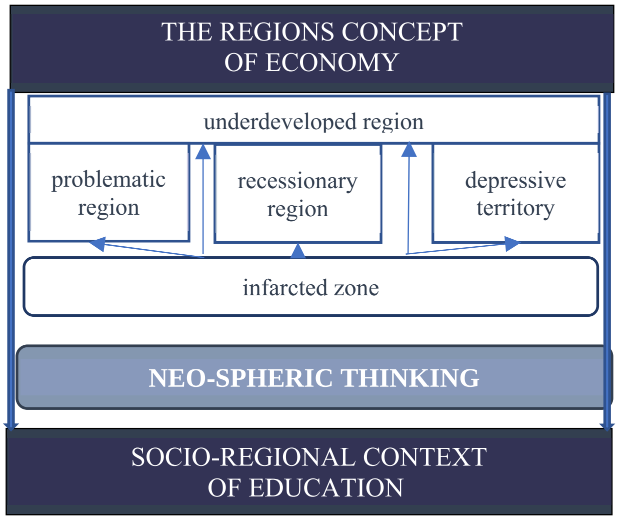

Fig. 1. The transformation of the regional concept in the sustainable development era.

It's worth noting, that recessionary and depressive territories can be part of relatively prosperous regions. Besides, the level of "underdeveloped", "problematic", "recessionary" and "depressive" levels of classification can be differentiated for various particular zones (Carpathian region, Donbas region, and Chornobyl region, etc).

One can freely state that today, the significant levers, improving the lives of the regions, are not the major driving elements of society namely education and science. Practice demonstrates the weak engagement of economical and administrative aid for the respective educationally-scientific base. Governing body of the regions regard the economy of education exclusively as the "provision of educational services for some amount of money" [5].

Moreover, all territories require individual approach and construction of certain strategy as a programme of development for a future prospect, bearing the internal nonlinear dynamics. There is a particular part of territories in the region, which are characterised by the complexity of administrative management, when a metropolis lies within the range of several administrative provinces, interacts with the territories of several agricultural districts (city-states), etc. The cultural development of the population from such regions becomes deformed. The contemporary village blindly and mechanically "delivers" its capital of labour force to the bordering country, another administrative province, single-handedly approaching its own demise. In this case, the problem of reforming borders or appropriate coordination policy of the range of regions arises.

As a rule, depressive and recessionary territories are situated near (or right in) the zones of ecological disaster, whose management requires the different quality and concentration of administrative decisions, aimed at preserving and replenishment of natural resources. The interaction between metropolis (a city or a system of cities) and polis (city-states e.g., settlements or villages) is remarked by the availability of "*infarcted zone"* spreading from the centre of a metropolis in a concentrated way (pollution of the atmosphere, subsoil waters and poisonous leakages of technical fabrication). Relating to the agricultural sector it can be presented as the phenomenon "on the brink" [10]. Usually, it is a certain segment that bears its own dynamics of development. This exact territory requires the most scrupulous attention during the process of estimation, carried out by specialists, and the real state of this territory and the estimation of this state create the largest disproportions of the estimation of development of the certain region, impacts on compensatory factors and, subsequently, on the level of improvement of living standards.

Today such "infarcted" territory exists in the country, although, it lies out of the rules of the estimation, made for assessment of regional development. The scientific and educational capital of the country must be focused primarily on the support of such territories for the solution to the problems of sustainable development.

It should be noted, a modern person does not control the biosphere, they only participate in its evolution, which means that they evolve as a part of the biospheric system. The scientific approach as a natural feature fundamentally changes the energetics of the planet. This stream of energy has its own velocity, which is provided by the educational system as a primary source. Anthroposhere is active in real-time and it is not the sphere of technologies, people or society. It is the sphere of intelligence as an evolutionary process in the biosphere, that is ongoing by human influence within some region. That is why the biospheric region itself becomes the basis and the beginning of certain anthroposheric educational channels.

Further, it will have considered the possibilities of socio-regional design of educational systems for the implementation of sustainable development goals.

4 The main directions of creating educational systems of anthropospheric type

4.1 Education as an anthroposhere phenomenon

Anthroposhere is the seizing of the biosphere by human intelligence with the purpose of provision of the constant development of ecumene. It is the last stage of the numerous ones of the evolution of the biosphere in geological history is the contemporary stage. It is the sphere of the interaction of society and nature, where intelligent and aware human activity becomes the crucial factor of development. It is the process, where anthropotisation is transformed into anthropologisation, within the whole planet. Anthroposhere is also the sphere of intelligence as the evolving process in the biosphere, that is performed personally in some particular region (it shown at Fig. 2).

The education of the era of anthroposphere must be anthroposophical. Anthropospheric education is aimed at the creation of the general synthesis of the human spirit, the inclusion of human consciousness and human activity into the global Universum, the formation of the inner world of personality, of mental freedom for realisation and mental responsibility for their doings. By means of it, science transforms from the tool of the technical progress into the natural element of social and cultural development, that features not only the human attitude towards nature but also the attitude of the personality towards other people and themselves [13]. It is also a particular programme that centrally the emphasised objective is society's development. In this way, the educational system becomes the completed mindset, which is capable to provide both the appropriate ecological awareness and mental part at the same time and consequently forms *personality's anthropospheric mindset.*

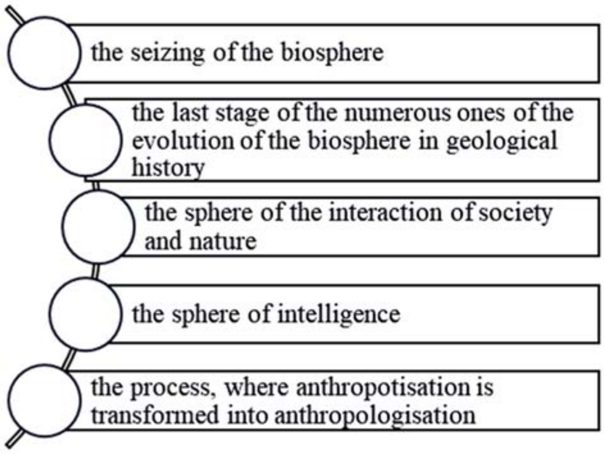

Fig. 2. The concept of Anthroposhere.

Anthropospheric the educational process is multi-vectored; at the same time, it is the multi-levelled system due to its naturally open and organised methods of setting objectives. It is included in anthropospheric culture and based on the principles of the creative evolution of personality. It is the *profile education* that is the channel of the anthroposheric educational system, that outlines the path of the evolution of Intelligence against the background of Space, the object, that it be defined as the "*true person*". In heart of this education is an idea that means a person is a central object of the study of anthroposphere [14].

The significant social request to the educational system during the period of anthroposphere is the organisation of the regular school, which would not only be focused on obtaining some extent of knowledge by pupils in the course of the educational and disciplinary process but also on *personality's development* (the role of this process is defined as the leading one, whereas any other co-occurring processes have to be perceived exclusively as the supplementary ones) and additionally on their *capability of vital creativity in the World*. In fact, the educational system has to clearly *restate the answer to every individual* "What is a person?" [13].

We know that *socialisation* is, primarily, the transformation of the personal one into the general one, which is also am "impersonal one" and a "commonly neglected one". Socialisation is a bilateral process, as it not only includes the assumption of social experience, but also the personal realisation of social ties by a person. Their sociological essence is focused on the combination of the adaptive and separative images, that leads to the preserving of a person's autonomy in the environment of a certain society. On the stage of reforming by society, the personality can lose their uniqueness [12]. The schools of the 21st century mechanically perform such activity, mainly because of the principle of the "pedagogical conveyor", but due to the resistance of the personality, combine the method of socialisation, (the habitual method of industrialisation era) with the neoteric method of *sociamisation* (the natural process of the rise of the anthropospheric era, whose fast implementation happens because of the rapid integration of the achievements of the IT industry in people's lives), which is the process and the result of the formation of active and creative personality in combination with their equal and full-fledged integration to the society, as the unity of the citizens respecting the democratically adopted regulations and rules of the life. Sociomisation of graduates includes the fulfilment of values such as integrated ecological thinking, general liability, sense of justice, spirituality and cultural abundance, independence, initiativity, adaptive capability and readiness to manifest mobility on the labour market with the help of one's secondary education. Together with the obtained speciality and level of training added to the previous requirements, the ultimate result of sociomisation will be the "*life competence*" of a person [14].

The pedagogical science of the 21st-century states, the *profile training* (it usually includes a naturally-scientific basis, rests upon the leading type of person's activity, as well as the level of their cognitive development, polyvariety of the studying process, etc) is the basis of sociomisation and is also the best way of the realisation of the principles of differentiation and individualisation of the educational process, which is capable to embrace the issue of the development of particular personality with the help of integrative education in conditions of the contemporary development of civilization [11].

Presumably, it must be defined that *educational profile* is the synthesis of conceptions "en face" (fr. en face – with one's face forward) and "profile" (fr. profil, which stems from Latin – filum – "string" and "side view") is quite complex pedagogical construction, which provides for the organization of democratically basis for development of the educational content, centralised and decentralised management of the educational system, educational institution, some particular kind of organisation of didactic entities, the corresponding pedagogical culture. It represents the certain technology of assistance for mental training. The profile can be found in the personality, who explores themselves with the help of the educational system [15].

The technology of organising profile training as a process is quite scientifically-based and requires significant intellectual resources of the educational system for its implementation. As a result, the principle that has proven to be the most adaptive in this situation on all levels of management is a *static principle* (or the principle of template) for the organisation, which is focused on internal regulation, accordance, and interaction of the entity parts, and is caused by its structure and objectives as a part of educational material as the steady and invariable basis. It can be called a "paper specialisation". At the same time there is necessary organising as an ongoing process – *the accumulation of deliberate actions*, that stipulate the creation of indispensable ties "inside the personality" and on the way of their development, where there is a valid principle of *pedagogical organization of the biosphere region as the organization of types of education, the formation of real profiles (the offers) for the real trajectories of personality's development (i.e., the personal demand)*.

In fact, from the beginning, any child's development must be regarded as a complex process, which is additionally optimised by a propaedeutic function of their own origin, as well as that one from the community or some social groups. What is more, the child must be correctly "placed" in the technological sense of this word. This targeted continuum of their destination must be described as "Self-concepts" in its epicentre, and "I in the segment of Space" is about their closest social partners – the family, the native school, and the agency of psychological aid agency [13].

The active segment of the trajectory of the ceaseless education, where the speciality-focused approach is realising, is a regular school (educative and pre-professional type) and a higher (speciality-based) school. In light of this opinion, the pedagogical science ideally shaped approaches to the formation of personality within the scope of their genetic origin, as well as examined the objectives of the preparation of the person for the social life as a creative personality, who is fully aware of the meaning of their own life and adequately realise their intentions in some particular field of professional activity. However, the most progressive pedagogical technologies, which rely on the theory of development, are poorly studied by the total pedagogical community and can occasionally be disharmonised with their definitions, and therefore, they may be problematic for frequent usage. But only they explored the concept of personality and the pedagogical steps in a thorough way and deserve being common. This occurrence encourages further modernizing changes to the educational system (including the postgraduate one) [8; 13].

It should be emphasized, the necessity of searching activity, self-identification, the awareness of one's own social prospects are the important needs of the young person and the tasks of implementation of the system of profile training as the structural and dynamic organisation of cooperation between personalities. At the same time, such organization requires a much broader vision of the school along with the integration of the social and psychological basis of management as the *social-and-ecological-and-pedagogical system of the biospheric region*.

Such *synergetic and dual phenomenal occurrence* surely causes the correct stream of the mind flow about making the demand for a decent education, "causes the element of creativity, which will engage the capital of knowledge, and ability to retrieve the necessary elements even from the strangest and the most unknown creatures for some person" as Vladimir I. Vernadsky said in 1925 [1].

Authors agree with the scientist about the understanding of democracy as a social organization of the popular rule, whose main objective is to increase the level of knowledge of the popular masses, according to the requirements of some particular period, and share scientists' views of the main educational tasks. The leading of them is to create "the studying populace", which has to be done immediately, right on this stage of the development of the educational system that is projected during the conditions of biospheric cells. Otherwise, due to the interaction of the generations, different by age, significant internal resistance is likely to occur [16].

4.2 Features of the socio-regional aspect of education

Nowadays is the time of born the *biospheric regionology*. As it can be clearly seen, that the viability of the region is tightly dependent on the knowledge of regional information and the ability to apply it in the course of the process of regional management. Let us look at the experience of Switzerland, the USA, Sweden, Germany from this viewpoint [13].

In Switzerland, the educational and scientific spheres are highly prioritised. The country, where the total population barely reaches 7.5 million people, there are 1.1 million school children and students. With its 26 cantons united (cantons, are basically, "mini-states" or regions of the biosphere) Switzerland became the place of the fusion of three major cultural and linguistic traditions – German, French and Italian ones. Approximately 65% of the population speaks German language, French is spoken by 19% of people and Italian speakers are estimated to be 12% of the total population. However, Swiss people can never be called separated because of their multilingual cultural feature. In the 19th century, the compulsory secondary education was introduced as the "greatly important social task of the decent guidance of new generations" and all cantons adopted their own educational legislation, whose basic regulations are preserved until now. That is the reasons why Switzerland has 26 cantonal "educational systems" [13].

The USA does not have any standardised educational system. Each of the states has its own particular organization of the educational system and their own special aspects, that is why the main trait of the educational system in this country is decentralization [17].

The remarkable property of the educational system of Sweden is a democratic approach, which is all about the development of the new generation as modern Europeans. The democratic character of the educational system in Sweden is manifested with the freedom of choice on all levels of education without exceptions and the fact that any pupil is free to choose not only the subjects, that they want to study, but also the study modes, the language of studying (Swedish or English) and even a teacher. The Swedish legislation clearly defines the regulations concerning the teachers' behaviour and the forms of teaching, which means that teacher must not impose their opinion on the pupil or perform any kind of pressure on them. A teacher must only share their knowledge with their pupils and provoke their need and abilities of independent thinking and description of their vision of the verity [17].

The sphere of the culture and education in Germany belongs to the jurisdiction of the lands (there are 16 of them in total in the country), that is why the conditions and the programmes of studying in different lands can differ one from another. Germany possesses not only the framed Law of the education but also has 16 educational constitutions, which uniquely characterise each of their lands [17].

The issues of the educational system belong to the competency of the special organ – the Constant conference of the ministers of the culture of the lands. The mentioned organ inspects the quality of the educational system all over the country in order to maintain it on a decent level.

Ukraine is also on its own way to the differentiated educational system, because of its multiculturalism and historical regional originality. Nowadays the new form of the reflection of objective reality becomes more distinctive and particularly, social and regional one with its possibility of *informational reflection and creation informational and social polygons* for performing different kinds of social experiments as social projecting, making the new models of development of reality and a possibility to control it. *Informational regionology* provides for the creation of the common informational space of the objects of the research – the region, that realises the informational reflection of social space with its all ties within the scope of the biosphere [13].

In that way, the *region* is regarded as the social system with its all incoming and outcoming features, functions, that provide its viability. The *informational regionology* provides for the solution of problems of the region with the usage of informational technologies as a system of methods of collection, accumulation, storage, search, transmitting and processing of the information with the relying on the usage of IT means. It allows the creation of the united automatized informational system, the united IRC (informational resourcing centre) for the solution of regional problems [19]. Moreover, the informational system, reflecting the social space of the region, additionally becomes the educational polygon of the social projecting and construction of the models of management is based on such projecting. The elaboration of the mechanisms of the realization of projects and discovering the tendencies of the regional development as a part of the biosphere and as a neighbour of other regions.

For the educational study, the region is represented as an integrated, spatially-organised form of the vital function of society as a system. This process is a sophisticated and complex entity and a segment of the life sphere (biosphere). Such kind of form has its own content. The *regional content of education* cover parts, that presented at Fig. 3.

For this reason, the simple upgrade of educational programmes in this sphere will not lead to manageable anthroposhere. It is vital to assure the appearance of the conditions when the population can unanimously be on the stage of studying. This issue is based on anthroposheric mindset and provides for the following primary steps for construction of the educational system within the certain region for getting the result of appearing of profile education:

– it is the development of enlightenment – the perception, understanding and responsible attitude of the popular masses towards the ongoing events;

– it is the cultivation of the idea of the unity between the person and nature;

– it is the focus on the educational on conceiving of fundamental natural principles;

– it is the supplement the principle of anthropocentrism in the educational process by the principles of biocentrism and cosmocentrism, as well as with principle of anthropocosmism as a final result of their fusion.

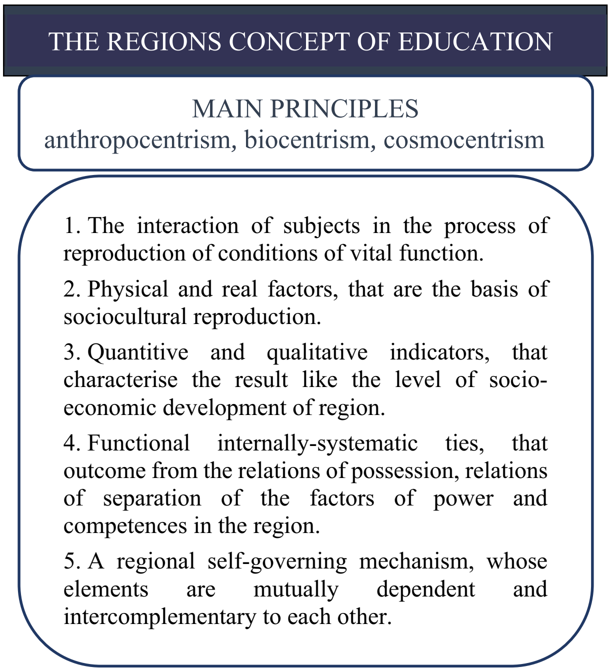

Fig. 3. The concept of region educational content.

4.3 The process of regionalization in the context of the formation of educational area

The environment, where the human is being and existing, is classified with a certain organization (it named as geographical one). It includes several special complex dynamic elements – geosystems, which create a unique space (geographical chronospace) because of their interaction. The formation of this process is tightly related to the term of "*geoprocess*", which denotes the process of *geospatial self-organising*. Exploring the geospace, a person generates its reflection in their consciousness for the regulation of their economic activity.

Economic sphere encourages people to aim their own activity at the culturally-economical evolution, which leads to the creation of regional anthroposhere, as well as the regional cell. However, this process primarily impacts on a person. It manifests the phenomenon of regionalization as a process of initiation and formation of anthropospheric structure. Nowadays, the point of leading the regional policy is stuck with the task of provision of educational system for some region, and with the problem of the elaboration of the best methodology. The methodology has to answer on the question how in the best way to find the fundamental points, around which will be founded on learning any particular person and population in general. Clearly, regionalisation is a process of infringement of the symmetry of geospace, which initiates its renovation and stands out as an excess of anthropotisation and raises the problem of anthropologisation [12].

On the other hand, human activity, which can be involving or not involving the energy from outside (if it is concerning several ecosystems), tends to several spatial correlations and modelling (enforcing or weakening) of some coherence. In this way, the region transforms from the socially-productive sphere (with the support from the scientific sphere) toward a socially-natural organization. Additionally, the understanding of the distinctive features of some region expects the adress of biospheric and productive pedagogics. Anthropotised territory must create separate autonomous production (autotrophy) instead of the assumption of different economies (heterotrophy) [12].

Regionalisation as a biospheric feature embraces the whole range of processes of anthropic type, which can be quite or very complex themselves because of their interaction with each other and interplay between the processes of evolution and deformation of the environment. These processes are self-organising and are carried out as an evolution of geospace. Regional infrastructure bears its own topology, which eventually evolves towards quite repetitive productive cycle. According to the result of our analysis, in the course of self-organising, geospace (besides the tendency to unite into one system), tends to autonomy and relative independence, which is represented as an objective reality. Energy, as well as the information (with the educational systems included), is the common and different feature, that the region contains.

The educational system of the region gradually reflects the whole range of cultural traditions about the interaction with other regions and subregional creations, as well as the competition with other regions for energy, raw materials, population, territory, productive, cultural functions, and whatever. It gradually evolves into the global structure of anthroposphere with the elements of complementation, cooperation, and connection with other regional structures, and is included to the cultural sphere which leads to the creation of the second nature (in this way the process of ceaseless separation of the person and nature takes place).

The production net (the labour source), which is accompanied by the appropriate education, capable to reverse the person back to their connection with nature, becomes a major correlator and determiner of the development of the region. In the course of evolution of anthropospheric educational system the biosphere region functions like a cell of nature (in other words it is harmonically), but only in the case of having the consciously intelligent completion of the connection between a person and nature, as a part of the regional educational component. Analysis of the geosphere clearly indicates that the *points of growth of anthroposphere* create the *ethno-cultural clusters* inside biosphere that provoke the huge "quality leap" – the shift from the regional humanity to self-management of biospheric regions-cells like a movement *from anthropotisation toward anthropologisation of the territory*. The places of the cultural gaps manifest the wholly different picture: there is a tendency to biospheric federalization and autonomisation of societies [13]. This process is shown in fig. 4.

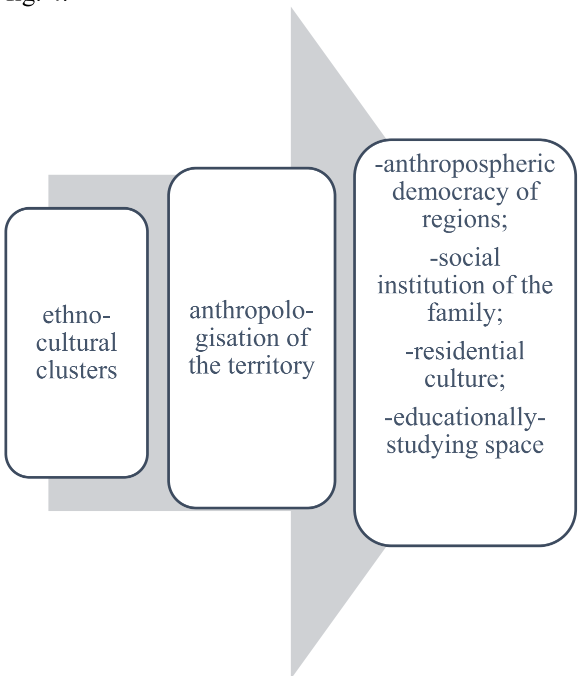

Fig. 4. Process of anthropologisation of the territory.

The particular ethnocultural "pluripotential" cluster of anthroposphere of the planet in 2019 (Top-20 countries of the world where the average life duration is 75 years for male and female population together: Japan, Singapore, Switzerland, Spain, Andorra, Australia, France, Italy, Iceland, Israel, Luxembourg, Norway, Sweden, Canada, Finland, the Netherlands, Austria, New Zealand, Malta and England (material is taken from Wikipedia). The named countries abide by the *democratic mode of governing*, are sufficiently wealthy with the high level of cultural development, based on the scientific, educational and religious spheres.

So, the *criteria of formation of ethnocultural anthropospheric synthesis* can be named as "several average durations of life, achievable for ethnocultural class", which currently is a duration of 75 years for male and female population together on the condition of democratic lifestyle. The vocation of "new paradigm" or "anthropospheric educational paradigm" being drafted to unite the world population into one entity, has not elaborated the *tradition of anthropospheric democracy of regions as a culture of projecting* due to the absence of methodology (authors consider this fact by). At the same time, unfortunately, some nationalities' mentality still bears the intermission, pause, some indifference, primarily caused by the change of some guidelines of evolution, relative to which the local educational systems are being late [13].

The most specific problem for anthropospheric educational system is the *social institution of the family*, which not only serves for the satisfaction of the main human instinct of preserving and reproduction of their kind as well as the tradition of the existence of the family. The institution of the family also represents the state of creative human evolution, which involves the implementation of new "anthropospheric order" in the *mental atmosphere of residential culture* in general, and particularly the familial orders. In this way the code of the regulations and rules insides the society will historically and democratically change in order to get the further preserving and harmonization of the social space.

As it could be seen, philosophy, science, education and religion are yet to agree on the integration of their own subcultures into the anthropospheric one as a potential of enforcement of cephalisation with the result of the creation of anthropospheric democracy.

The alternative to globalization with the creation of global monoculture (term by Vladimir I. Vernadsky) is a biospheric regionalization of ethnocultural development as a part of multicultural, interregional cooperation of educational and labour systems, is partially carried out as an ethnocultural clustering with the formation of united territorial hromadas (UTH). The next step is the formation of territorial districts or lands. However, the *regional component of educational content* in Ukraine is delayed in both its elaboration and implementation. Such a step would be able to relieve the tension in bordering lands like Zakarpattia, Donbas, the Crimean Peninsula, etc [19].

This statement must urge *the creator of a new textbook for pupils* to initiate the objective dialogue, primarily with the fundamental science, with the actuality of 25-30 years ahead in the given study material, along with the elaboration of the instruction about the application of didactic means during the pedagogical process. Without the correct objective, the educational process is focused on the study content, that is the historical trap, which cultivates civility instead of civilization, and consequently opens the way to *necrosphere* (term by Vlail P. Kaznacheyev [10]), to the devastation of residential culture.

People created the culture as a "second nature" or "symbolic universe" and this way of perception presents culture as a consequence, not as a cause. Cultural baggage should be noticed, relying on the causes, which provoked its creation or formation. In this way all school subjects must be created. Terms, meanings, artefacts and cultures, uniting them are the product of human personality's activity, as a part of Vernadsky's "Live liquid" *as the basic principle of the selection of educational content for the construction of pedagogical mindset* [18]. The presentation of knowledge and its perception during the course of studying humanitarian subjects, in the majority of cases is being the process of "turned upside down" that is the key problem of linguodidactics.

The educational process for the upcoming new generation must be constructed substantively and the main method of studying must be the *method of problematic studying*. The educational process for adults must be formed according to the professional problems, and the main method of perception must be the *substantive vision*: concrete, critical, systematic, the vision of synergy, vision of a project and the vision of effect [17].

The *humanitarian education*, as a part of educational profiles, ideally must become the anthropospheric education, the one, that accompanies the development of the pupil, both synchronically and diachronically, as a state of trophism, and on the base of complementary principle.

The real criteria of success of educator of the 21st-century is not only their lesson, their subject and his authority (category, title and academic degree) but also our life, measured by human development index "HDI" (combines the indicators: gross domestic product per capita, literacy rate and life duration) as a part of the biospheric region. These indicators can be used as a proof of the pedagogical efficiency during the switch to anthropospheric pedagogics.

4.4 Synergetics in the design of the educational process

Considering the fact that phylogeny transforms into ontogeny not in an accidental way, but in the case of a certain amount of visible external conditions, we are likely to deal with the sufficiently imbalanced educational process, that tends to be even more imbalanced at the beginning of the 21st-century. It is in the course of a search of the model for internal restructuring and new reorganization. Hence, using the language of synergy, the task is to generate the administrative decision as to the preparation of ordering of all elements of the pedagogical system – internally-systematic moving to the goal: to generate the educationally-studying space and provide the reality of "understanding the understandable one" on the deeper level and subjectively level toward lead the studying process to the laws of informational systems.

Educationally-studying space from the synergetic point of view is a differentiated quantum (it is being in the particular state) self-regulating and open macroscopic system, subordinated to laws of development in the material world (in its whole manifestation), where the pedagogical energy is spread for harmonic construction of the image by the educational system. More exactly, it is the system of ties between the personality and the Universum, like the objective reality in time and space. The state of this system should be comprehended as a multitude of relations of independent properties, which characterise the system at some particular temporal moment [12].

The multitude of states of this system forms the space of states. The course of educationally-studying space from one state toward another (new) state is a particular trajectory of motion (a complicated attractor) in the space of states (it means states of the educational system and state of learning). The transition from one state to another one can be done in two ways: 1) the accidental transition when the term "objective" cannot be applied to such action; 2) the deliberate one when the action does with a

https://doi.org/10.1051/e3sconf/202128009019

concrete purpose. In the second case, the deliberate movement towards the goal is determined from outside or by the state of the internal environment of the system (the state of studying in this particular case). But the constructed system does not tolerate the imposing of external structures. During the creation of the new educational system, there is one remaining thing to do: to assume the laws, that are used for running such systems and create managing impacts, whose functional character is close to the character of the functionality of the targeted system [13].

Therefore, educational space with its internal element possesses the space of teaching, and its external element – the space of studying. Education is represented as the state of consciousness, as the measurer of information, the state of accumulation and arrangement of the information of the internal system (it is the system of teaching) and the state of connection with the general informational net (it is the current state of society of anthroposhere).

To manage educational space, one must possess the theory, which can be the base for the operation of planification and prediction of the multisided vital process. The development of personality stimulates their personal educationally-studying space to develop along, that is a balanced part between the educational space of the society and educationally-studying space of the particular region (see Fig. 5).

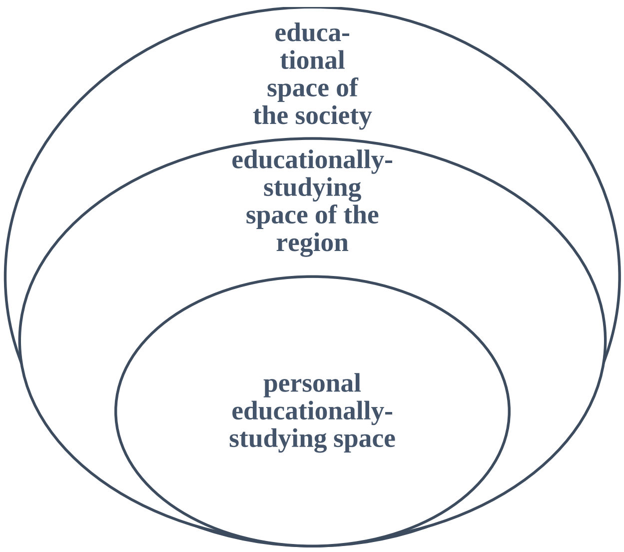

Fig. 5. The personal development space.

Thus, the personal development is realised as the intersection of the global informational net (educationally-studying space of the region) and personality's educationally-studying space [20].

Due to ordering of the person via to the sort of action, in the social cooperation will create, within quasi-ceaseless process, "the critical factor of potential action" – the activation of thinking and, as a result, the explosion of creativity, and finally as the stream of kindred work – the innovative activity.

This process is provided by the educational system via the system of promising concepts of educating and developing of a particular individual and the society in general. The sense of life of the modern Person is their adaptation to Space with the mediation of the identification of the personal aspect into the social one, along with the creation of synthesis of public and professional mindset in conditions of vastly-growing oikumene, ruled by Intelligence.

5 Conclusions

Any nation possesses not only the local geographical dimension (within intersection of physical and economical geography) – as a country on the global map and a state, but also the global and spatial ones – its body, soul and spirit. Their point of intersection is an aware and reflecting person. To become a nation the nationality must assume the humaneness as a mindset and invoke their culture and mental efforts. The *following ideas are included in the anthropospheric humanism of Ukraine*:

1) Projecting of the future as a part of educational and ideological triad like "social state – civic society – ecological mindset" must be initiated in the conditions of the educational system of the region as a completely natural territory, where the public, regional and studying components of the content of education (academic and supplemental parts) are function.

2) Educational system of the country has to be ruled by the framed law about education, as well as the regional educational specimens – the regional educational constitutions. At the same time, studying component of the educational content must be elaborated on the base of regulatory documents of the educational institution, created and coordinated by the community in a favour of some particular personality's development.

3) The educational path begins as a psychologically-pedagogical issue and the part of some personality; it lasts as the polymorphism of interests (formless one – broad one – vital one) towards the possibility of their realisation with the help of social efforts via the profile mode of educational.

4) The beginning of comprehension is cultivated by the correct immersion of personality into nature, as well as into life by means of the creation of ecological tracks with the points for contemplation and examination of an environment with the possibility of comparing the things to the ideal. This way allows to deepen of the content of educational material, realises decomposition of the problem of the life quality perfecting on the base of scientific emphasis of the method.

5) The educational environment has to develop according to democratic principles, where the atmosphere of justice is present, the balancing of all branches of government on all level of organisation is available as well as the respect towards the personality is exist.

6) Anthropospheric educational system of profile type releases the potential of the synthesis of natural and historical processes, considers the rate of formation of global democratic social relations as a combination of labour, intelligence, and scientific research, related to the religious context in favour of civilization.

7) Awareness is a result of evolution, whose origin bear genealogical character, personal embodiment and collective usage, which can be direct and indirect. A

person's world predominantly begins inside them, is constructed by them "settles down" inside them on the final stage of its development, that is why the profile of learning must be mentioned as the duration, where the vital energy circulates.

8) The new motivating of human life as the immortality of personality, who is a part of space is necessary because the comprehension of something possible, the awareness of something necessary and scientific clarification of something conceived is one unanimous idea of the people from the planet Earth.

Abstract. In the era of sustainable economy, the environmental responsible companies provide an important background both for particular industry and national economy competitiveness. In particular, mechanical engineering plays an important role in the economy of Ukraine. In accordance with national statistic, the Ukrainian mechanical engineering provides 6.4 % in total volume of industrial products and ~4 % of the gross value added in the GDP of Ukraine. At the same time, the global mechanical engineering industry environmental friendly activity is related to SDG 9 and SDG 12. In March 2020, the Cabinet of Ministers adopted its Programme, reaffirming the commitment to the SDGs and their importance for Ukrainian economy development. Thereby, research problem lays upon the financial potential of innovative mechanical engineering enterprises in Ukraine providing the background to increase the potential of their environmental responsibility. The paper aims to provide scientific support on mechanical engineering industry representatives that tend to be environmental friendly. The research methodology is based on Ukrainian mechanical engineering enterprises data (5 years and 337 industry representatives) processed by statistical analysis. The financial and environmental indicators are represented in results section on the basis for six groups of mechanical engineering enterprises' analysis, namely: big unstable – 16; big stable – 17; medium unstable – 44; medium stable - 26; small unstable – 188; small stable – 46. Thus, the environmental dimension is increasingly taken into account by Ukrainian innovative mechanical engineering enterprises to be competitive. Big and medium stable enterprises are organizationally oriented to be environmentally sustainable. The main disadvantage of big and medium unstable enterprises is lack of financial resources for achieving sustainable goals. Small enterprises are lack of general capacity to conduct environmental support policy, but they are the most flexible ones that provide advantages in environmental management. The study results can be used within industrial and business programs of environmental responsible activity and its financial support. In relation to other branches or countries, more extensive study is required.

1 Introduction

1.1 Research question

In the global economy, the 21st century brought forth new social challenges along with the technical problems and their solutions. New technological advancements and communications tools make new innovative ideas available in a wide range of social and economic areas. However, the technological progress often causes the lack environmental and societal ethics within business structures.

Profitability is at the heart of our understanding of successful business. At the same time, determining the impacts of vast expansion of economic activity into the environmental decline is becoming important worldwide. The economic activity is consuming vast quantities of resources from the environment, simultaneously returning the vast quantities of waste products into the environment. However, in the new global economy, the issue of environmental friendly business has received considerable critical attention. It is rather important to pay attention both to the financial prosperity and environmental policy of the company. Despite economy and ecology are often pitted against each other in the "profitability versus environment" debate, the modern companies are taking care of financial prosperity and environmental influences.

Reduction of man-caused load on the environment with simultaneous preservation of production capacity can be realized through a comprehensive greening of production processes in all sectors of the economy. Greening of production depends on greening of its individual components, the most important of which are technological solutions.

* Corresponding author: iuliiagern@ukr.net

Modern economic realities prove that mechanical engineering is one of the most important branches for national economy development, because it plays an important role in accelerating both scientific and technological progress. Mechanical engineering provides the means of production to other sectors of the national economy, contributing to the renewal and accumulation of capital. In addition, mechanical engineering is one of the leading industries, concerning product value, investment attractiveness and employment increase globally. However, serious environmental problems are caused by activity within mechanical engineering, including environmental pollution, soil erosion and deforestation and climate changes. Thereby, the concept of profitable and environmental friendly mechanical engineering industry is at the heart of sustainable development understanding.

Since 2015, world leaders at the United Nations agreed to the 17 Sustainable Development Goals (SDGs) covering the three main dimensions of sustainable development: economic, environmental and social [1]. In particular, sustainable manufacturing, including sustainability of mechanical engineering industry, is related to SDG 9 and SDG 12 [2].

In accordance with SDG 9 "Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation", environmental investments are among key business themes within sustainable society development. By 2030, the SDG 9 contain the measure of targets, including the following ones: to promote inclusive and sustainable industrialization, and raise significantly industry's share of employment and GDP in line with national circumstances; to upgrade infrastructure and retrofit industries to make them sustainable, with increased resource use efficiency and greater adoption of clean and environmentally sound technologies and industrial processes, all countries taking action in accordance with their respective capabilities [3].

SDG 12 "Ensure sustainable consumption and production patterns" suggests that societies need to find just and equitable ways to meet individual needs and aspirations within the environmental limits of the planet. Sustainable practices in the production phase of products and services will not provide sufficient responses to meet science-based emissions reduction targets, natural resource constraints or the growing demand for basic needs such as food, water and sanitation, and access to energy. Furthermore, demand for materials will likely outpace efficiency gains in supply chains as well as overwhelm already stretched ecosystem services. Consumption patterns need to be made sustainable, particularly lifestyles in industrialized societies, and reduce their environmental footprint to allow for the regeneration of natural resources on which human life and biodiversity depend. By 2030, the primary targets of this SDG contain substantially reduce waste generation through prevention, reduction, recycling, and reuse; encourage companies, especially large and trans-national companies, to adopt sustainable practices and to integrate sustainability information into their reporting cycle [4].

Mechanical engineering is one among the leading industries in Europe and globally. For instance, the industry produces about 9.1 % of all production in manufacturing industries in European Union. The mechanical engineering companies are characterized by a relatively high manufacturing depth. The share of mechanical engineering value added of total manufacturing is higher than that of production, reaching around 11.5% [5]. Thus, mechanical engineering has both rather high financial potential and potential of environmental responsibility. Thereby, it is important to pay attention to above-mentioned issues within theoretical researches and applied conclusions.

Although the scientists payed attention to questions of sustainability within mechanical engineering industry. However, there is a great diversity of interpretations and ideas associated with the concept of sustainable manufacturing, including the consideration of financial potential and potential of environmental responsibility [6 - 8].

In light of recent trends of sustainable manufacturing, it is more difficult to find studies that provide a comparative analysis of indicators of its financial and environmental capacity and potential for further development. Thus, the current study tends to highlight the tendencies of mechanical engineering in Ukraine, namely their financial capacity and potential of environmental responsibility. The genesis of this thesis can be traced back to the time the authors became interested in sustainable development of innovative mechanical engineering enterprises in Ukraine and abroad.

1.2 Previous researches

Several previous studies and international organizations reports have found that innovative mechanical engineering enterprises have a significant potential to support sustainable development worldwide, including boosting social growth and environmental protection [9-11].

More recently, some governments, non-governmental organizations (NGOs), companies and academics have defined the unsustainability of our development model as one of the main problems faced in our society [2; 12]. In particular, the connection between growth of industrialization activity, increase in natural resource consumption and pollution was analyzed by Robinson et al. [13]. At the same time, the essence and industrial nature of sustainable development are also concerned within analytical reports of international organizations. In particular, the significant milestones of sustainable development, including environmental component, are considered within the "Our Common Future" report by the United Nations [14]. The above-mentioned researches created the basis for further applied researches, including estimation of the 17 Sustainable Development Goals (SDGs) covering the three key dimensions of sustainable development: economic, environmental and social [1].

Due to the industrialization widespread, there is also a measure of researches on sustainable mechanical

 https://doi.org/10.1051/e3sconf/202128009020

engineering issue. So far, however, there has been little discussion about the mechanical engineering activity influence on environment. A search of the literature revealed few studies which define the potential of environmental responsibility of entities. However, there are some detailed investigations and published researches on cluster concept, considering sustainable development of mechanical engineering. In particular, the "cluster concept", based on sustainable development, is determined within the researches of Ketels and Schmitz [15, 16]. Bergman and Edward paid attention to economic, social and ecological components of industrial clusters development [17]. The macroeconomic patterns of industrial entities development are considered within Steiner and Hartmann researches [18].

The above-mentioned patterns consider the nature of the anthropogenic impact of the cluster on the environment and determine the potential of such impact widespread. To ensure main consideration of the industry patterns, the definition of the term "metallurgical industrial cluster" was mentioned.

However, there is still a rather little published researches on financial potential and potential of environmental responsibility of mechanical engineering enterprises. Thus, the chosen problem is of a significant scientific interest nowadays.

1.3 The scientific problem

The scientific problem of this article lays upon the potential of providing flexible environmental support policy by innovative mechanical engineering enterprises, providing the basis for sustainable industry development in Ukraine. The hypothesis of the paper has both theoretical and applied background, concerning the profitable industry impact on sustainable development process, including influence on environmental conditions, which aims to activate sustainable development strategies implementation by innovative mechanical engineering enterprises. *The aim* of the current study is to identify similarities and differences, discover the best sustainable practices and present the strengths and weaknesses of the different groups of mechanical engineering enterprises in Ukraine to develop both financial potential and potential of environmental responsibility, based on their statistic. The *object* of the research is sustainable development boost within different groups of innovative mechanical engineering enterprises in Ukraine. The *subject* is financial potential and potential of environmental responsibility of above-mentioned industrial entities, contributing the social and economic growth of national and global economies.

1.4 The research methodology

The *research methodology* is based on Ukrainian mechanical engineering enterprises' data processed by statistical analysis. Data on financial position and indicators of effectiveness were collected by authors directly from financial and non-financial statements. A time period of research is 6 years: 2014 – 2020; the number of mechanical engineering enterprises: 337. During the analysis, the following data were studied: indicators of production and productivity, income and expenditures, profitability and profit margin, EVITDA, the indicators of business sustainability, environmental and energy efficiency, estimation on ecological management practices. The financial and environmental indicators are analyzed on the basis of six groups of mechanical engineering enterprises definition, namely:

Big unstable – 16 (big mechanical engineering enterprises with rather unstable trends and indicators of activity);

Big stable – 17 (big mechanical engineering enterprises with stable trends and indicators of activity);

Medium unstable – 44 (medium mechanical engineering enterprises with rather unstable trends and indicators of activity);

Medium stable -26 (medium mechanical engineering enterprises with stable trends and indicators of activity);

Small unstable – 188 (small mechanical engineering enterprises with rather unstable trends and indicators of activity);

Small stable – 46 (small mechanical engineering enterprises with stable trends and indicators of activity).

The scientific novelty of the methodology is as follows: in the study, both the financial indicators and indicators of environmental influence of different groups of innovative mechanical engineering enterprises are analyzed through compartment of their strengths and weaknesses. On the one hand, this provides opportunity to define the role of financial stability for enterprises' sustainability for each group representative. On the other hand, this allows to estimate the influence of concentration of efforts on sustainability into the risks of failure and financial results.

1.5 The current research structure

The current research consists of the following parts: primarily, the theoretical and applied framework based on financial indicators of Ukrainian mechanical engineering enterprises activity is provided; secondly, the sustainable development phenomenon is described; the current situation of Ukrainian mechanical engineering enterprises' efforts concentration on sustainable development, including environmental challenges, is represented; then, the research conclusions on environmental and financial potential of mechanical engineering enterprises in Ukraine are provided.

The research practical implication is that results can be used within national innovative environmental strategies to accept community challenges both on national and regional levels.

2 Main theoretical and applied assumptions of the research

2.1 Concepts of innovative enterprises ecological management

The concepts of ecological management provide a useful account of how the theoretical background for ecological potential development by innovative enterprises. The primary modern investigation on environmental responsible activity by profitable enterprises dates to the end of the XX century. At this time Nelson, Winter, Silverberg and other researchers formed an evolutionary economic theory, in which economic development was provided in the form of a non-uniform, impulsive process, most of which consisted of innovative and innovative changes affecting "natural" capital. The economic processes are considered as stable and depended on external factors [19]. The emphasis is made mainly on the periodic change of innovation within the above-mentioned theories. At the same time, the attention is paid on the interdependence of economic processes and environmental phenomena.

The theoretical backgrounds on environmental problems and their financial solutions are considered within the following approaches (Figure 1):

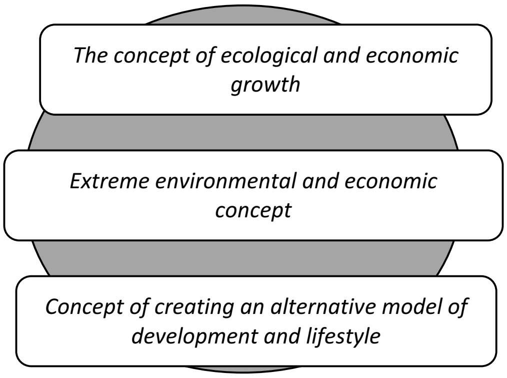

Fig. 1. The concepts on environmental growth.

The extreme environmental and economic concept represents concepts that are based on rather negative attitude to social and economic development on the basis of environmental component (Forrester, Meadows, Boulding, Michelle, Dame, Mansholt, Taylor, Puru). The concept of ecological and economic growth represents the system of sustainable development (Baroque, Jenks). The concept of creating an alternative model of development and lifestyle focuses on the social factors and environmental development (Reimers) [20-22].

The environmental concepts of a relatively stable dynamic system of equilibrium is based on the principle of systematic development. In accordance with above-mentioned principle, the "ecosystem" concept as the combination of both inorganic and organic factors of economic and financial development is introduced by Tensley. The issues of systematic development and equilibrium are also considered within the concept of "environmental sustanability", which represents a qualitative and quantitative ratio of human-modified and natural environmental components and processes. At the same time, the definition of "ecosystem" becomes widespread within the business development concepts. According to Boyet, in order to succeed in business, the manager has to develop the "environmental awareness" along with managerial goals. The attention is also paid to "business ecosystem", which provide the environment for strategic business development. The definition of the concept of "environmental management system" was primarily defined in the UK Standard BS 7750 (Environmental Management Systems) in 1992 and described as part of a generalized management system, which includes planning processes, organizational structure, practical work, division of responsibilities, as well as resources and procedures for the development, implementation and evaluation of the obtained results (ISO 14001. Environmental management systems - Specification with guidance for use).

The American Society of Mechanical Engineers (ASME) paid attention to the social (including, environmental) responsibility in mechanical engineering. The principles of force, energy and motion are being concern, mechanical engineers use their knowledge of design, manufacture, and operational processes to advance the world around us, improve safety, ability to manage economic with strength and responsibility throughout the world [23, 24].

The Mechanical Engineering Industry Association (VDMA) analytical researches provide evidence on the role of the mechanical engineering industry growth for sustainable development and growth within the European economy. In particular, the importance of investment into the inclusive growth and ecological development within mechanical engineering industry is considered by industrial experts in developed economies [25].

The environmental management in Ukraine is considered as a market-oriented (economic) mechanism for improving the environment at all levels of management and is contrasted to the administrative-command mechanism of environmental regulation. This creates a number of "ambiguities" that make it impossible to perform the main task of environmental management, namely the introduction of an effective system of environmentally friendly management at the enterprise level.

2.2 System for mechanical engineering entities environmentaly responsible development management

Taking into account the targets of sustainable development of the enterprise, including reducing the burden on the environment, increasing environmental competitiveness, it is important to justify the mechanism of environmentaly responsible development management and financing (Figure 2).

The basic element of the proposed system is a chain of "environmentally responsible development goals - processes of environmental and economic drivers' mobilization – financial and environmental results", which characterizes the internal existing and potential of the enterprise and the possibility of its implementation. The complex application of functional, systemic, parametric, target and process approach is based on certain principles of ecological and economic management. Achieving priority goals is possible by mobilizing resource-saving drivers and optimizing the ratio of growth rates of the final product and the cost of natural resources: increasing the resource-saving effect of the introduction of new technology; ensuring the integrated use of raw materials, the introduction of advanced technologies for its processing; gradual dematerialization of production.

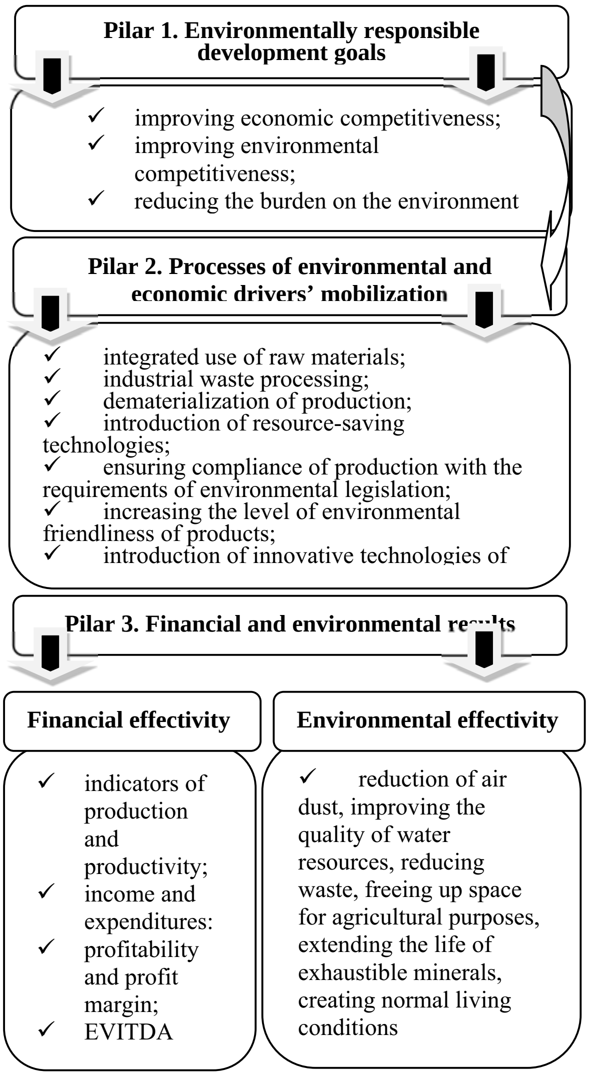

Fig. 2. Mechanism of environmentaly responsible development management: mechanical engineering case.

3 Research results

3.1 Groups of mechanical engineering enterprises and indicators of their financial potential

The potential of innovative development of mechanical engineering enterprises depends on the main economic characteristics that determine the features of their current activities and the prospects for their further development. The current research is based on the mechanical engineering enterprises classification in accordance with the criteria of their size and stability.

The primary indicators of financial potential are trends of changes in the average values of revenue from sales for each group of mechanical engineering enterprises (Figure 3).

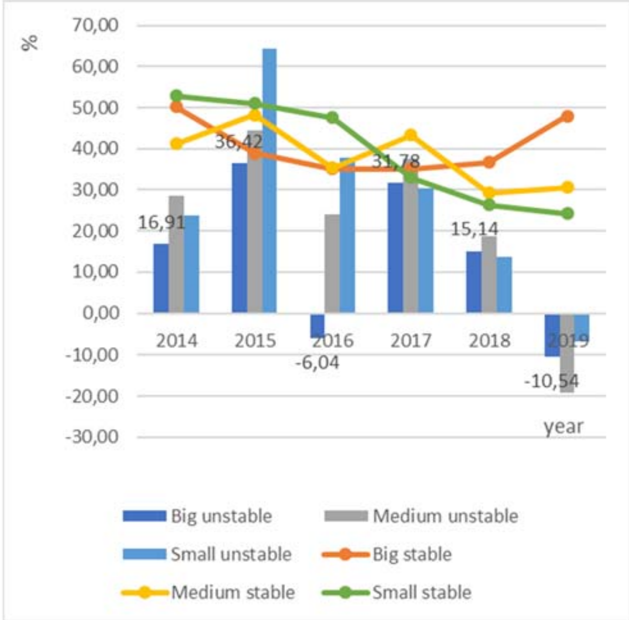

Fig. 3. The average values of revenue from sales.

The maximum growth rates are typical for 2015 and 2017. In 2019, we observe a slight decrease, which does not affect the overall upward trend during the study period. Such trends create the financial conditions for further implementation of innovation. However, the general tendency for unstable companies represents the maximum decrease in revenues in 2016 and 2019 years. Thereby, in accordance with the revenue indicator, currently the Ukrainian stable companies, independent of their size, have financial potential for environmental policy conduction.

At the same time, the tendencies to change the degree of depreciation of fixed assets are quite contradictory for Ukrainian mechanical engineering enterprises. It is possible to observe an increase in the degree of fixed assets deterioration over the last five years. The trend of the rate of outdated fixed assets increase is rather negative for further environmentaly responsible development and innovative growth. However, in this case there is a growing potential to replace these outdated fixed assets with innovative ones that will create the basis for innovative and environmentally responsible growth on a new technological basis.

The share of intangible assets in the total value of assets is insignificant, averaging from 0.3% to 0.5% during the chosen timeframe. These tendencies are available due to the peculiarities of the mechanical engineering industry. At the same time, this characterizes the contradictory basis for innovative development. However, the share of fixed assets in the total value of assets ranges on average from 25% to 35%. This makes fixed assets the basis for future environmentally responsible and innovative growth on a scientific and technical basis.

Due to the above-mentioned contradictory tendencies of mechanical engineering enterprises in Ukraine, the trend of changes in revenue and asset value per employee becomes an important indicator of financial potential (Figure 4 and Figure 5).

 https://doi.org/10.1051/e3sconf/202128009020

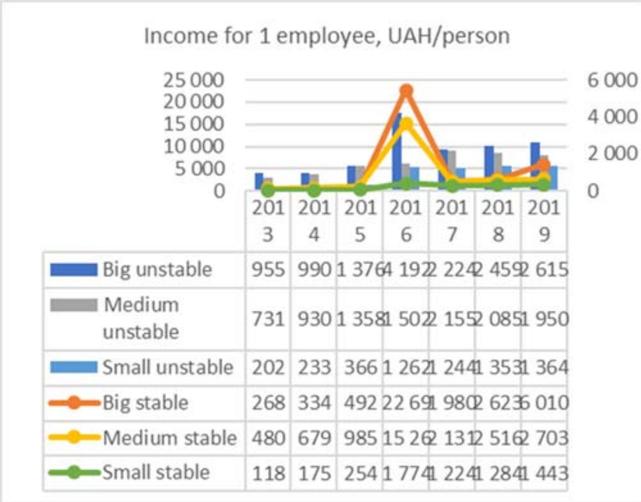

Fig. 4. The average values of revenue from sales per employee.

The compartment of data from different groups of representatives shows that the main increase of indicator is typical for stable big and medium enterprises. At the same time, instead of their stability, the small stable mechanical engineering enterprises have rather low indicators of revenue per one employee. Thus, they are the weakest ones for achieving environmentally responsible development goals in the group of stable enterprises in accordance with revenue indicator.

The second important indicator is the average asset value per employee (Figure 5).

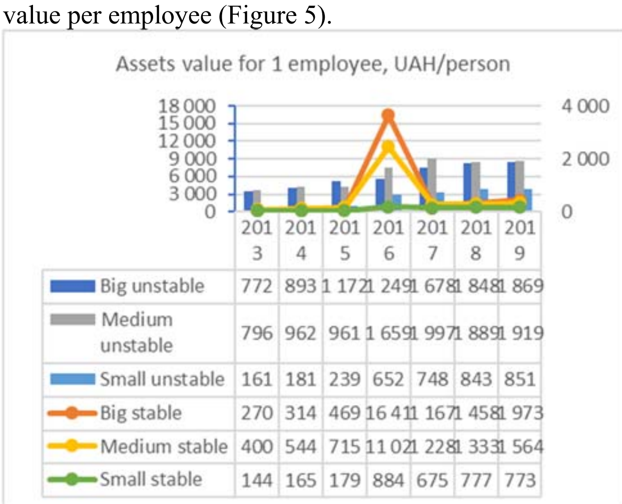

Fig. 5. The average assets values per employee.

The tendency of average assets values per employee is the same as the above-mentioned tendency of revenue changes. Thus, the enterprises that represent the group of big and medium mechanical engineering enterprises have the most appropriate basis for innovative activity implementation and environmentally responsible goals achievement.

One more important indicator of financial potential is the value added indicator that represent the key to assessing the effectiveness of existing innovative solutions and technologies (Figure 6).

The maximum value added indicators are appropriate for big stable enterprises. The medium stable enterprises represent the growing tendencies of increase. Both the small stable and small unstable enterprises have the weakest positions in accordance with value added indicator.

Fig. 6. The value added indicator.

At the same time, the value added trends are not always comparable to EBIDTA and EBIDTA profitability (Figure 7).

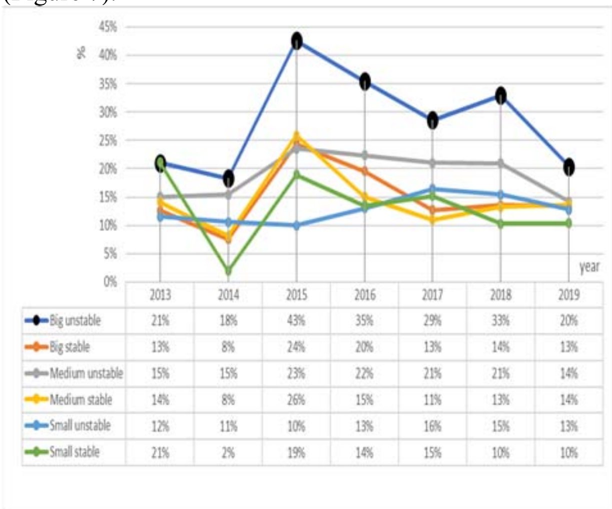

Fig. 7. The changes of indicators of EBIDTA profitability

The indicators of EBIDTA profitability have the increase tendency for all groups of mechanical engineering enterprises. This shows the available financial for further environmentally responsible development of industry in Ukraine. At the same time, the represented indicators of financial potential show that the groups of big and medium stable enterprises have the highest potential for further environmentally responsible development.

3.2 Indicators of Ukrainian mechanical engineering enterprises' potential of environmental responsibility

The potential of environmental responsibility of mechanical engineering enterprises in Ukraine is estimated, based on evaluation of social responsibility strategies and their effectiveness in mitigating environmental impacts.

https://doi.org/10.1051/e3sconf/202128009020

The research is conducted for each group of mechanical engineering enterprises, namely big stable, big unstable, medium stable, medium unstable, small stable and small unstable. The research methodology is based on the following set of indicators:

– the level of environmental friendliness of production;

– a quantitative indicator of the *i*-th type of contamination of environmental components due to production;

– a specific indicator of economic losses caused by the unit of the *i*-th type of pollution;

– a quantitative indicator of the *j*-th type of eco-destructive influence on landscapes;

– specific indicator of economic losses caused by the unit of the *j*-th type of eco-destructive impact on landscapes;

– a quantitative indicator of the *z*-th ecodestructive effect directly on the human body:

– a specific indicator of economic losses caused by a single indicator of the *z*-th ecodestructive impact on the human body;

– a quantitative indicator of irrational extraction of minerals from the extracted rock mass;

– specific indicator of economic losses caused by irrational use of minerals;

– a quantitative indicator of the *g*-th type of environmental impact on biological objects;

– specific indicator of economic losses caused by this type of eco-destruction;

– the volume of production that caused the processes of eco-destruction.

Currently, only the primary three components of losses can be fully estimated. Thereby, the current research is based on analytical estimation of environmental friendliness level of production, estimating the social and environmental expenses of mechanical engineering enterprises (Figure 8).

	2014	2015	2016	2017	2018	2019
Big unstable	10,87	-1,58	-23,60	30,46	20,30	12,96
Medium unstable	51,13	21,77	-28,62	25,28	27,32	12,37
Small unstable	12,32	29,55	-2,15	12,65	9,47	11,65
Big stable	39,41	13,24	0,44	21,97	41,49	39,00
Medium stable	11,22	10,43	-22,40	69,61	53,09	43,91
Small stable	13,76	23,55	-11,03	76,23	19,05	8,98

Fig. 8. The social and environmental expenses changes of mechanical engineering enterprises.

The above-mentioned data represent the tendency of mechanical engineering enterprises' expenses on achieving social and environmental goals. Thus, the most stable growth is represented by big stable enterprises. However, the worthiest timeframe in the context of environmental support was 2016 year. Simultaneously, the worthiest financial potential of mechanical engineering enterprises was also in 2016. Thus, there is dependence between financial potential of mechanical engineering enterprises and potential of their environmental responsibility.

3.3 Ukrainian mechanical engineering enterprises' straights and weaknesses (SWOT analysis)

In accordance with this new trend of promoting environmental friendly remanufacturing and social responsible business, it is essential to tackle the design of strategies and new technological developments to advance the mechanical engineering enterprises' innovativeness. It is clear that all of this is going to have a great impact on how the national mechanical engineering industry will be involved within national and global innovative process. The increasing attention should be paid to the strengths and weaknesses, represented for each group of enterprises, dependent on their financial potential and potential of environmental responsibility.
These strengths and weakness are analyzed in accordance with SWOT-analysis (sustainability SWOT - sSWOT) within the context of financial potential and potential of environmental responsibility. This will assist within driving action and collaboration on environmental challenges creating real business risks and opportunities. Moreover, this may motivate entrepreneurs for sustainable activity, particularly those with limited knowledge of environmental issues or corporate sustainability.

In accordance with previous research, big and medium stable mechanical engineering enterprises are the most environmentally sustainable. However, there are also some weaknesses along with strengths (Figure 9).

Strengths	*Weaknesses*
Financial capacity for achieving environmental goals Possibility to manage separate branch that is responsible for sustainable development Availability of environmental strategy Progressive informative support system	Large-scale production that influences environment Lack of environmental problems' understanding by some employees Failures in the performance of functions by individual units, duplication Marketing system that may be ineffective
Opportunities	*Threats*
Low competitiveness within the group representatives Availability of high technological and environmental standards	Taxation policy, concerning environmental influence High requirements to entrepreneurs' social and environmental responsibility

Fig. 8. Sustainability SWOT for big and medium stable enterprises.

Big and medium unstable enterprises are also rather important environmental friendly players. However, their instability creates some problems, concerning lack of financial resources for environment protection (Figure 9).

Strengths	*Weaknesses*
Rather strong market position Highly qualified staff that concern environmental sustainability as one of competitive advantages Organizational culture and image that makes the basis for further sustainable activity	Outdated equipment in some areas Lack of financial resources for environment protection during the instable timeframes
Opportunities	*Threats*
Availability of high technological and environmental standards Barriers for potential competition to entry the segment	Instability of social and economic development within global and national economy Demand instability

Fig. 9. Sustainability SWOT for big and medium unstable enterprises.

Both stable and unstable small enterprises are rather flexible in their decisions on environment protection. However, these enterprises have insufficient financial capacity to boost progressive initiatives on environment protection and sustainable development support (Figure 10).

Strengths	*Weaknesses*
Flexibility in environmental management Flexibility in environmental strategies building	Lack of product range Insufficient range of innovative technologies implementation Lack of financial resources for environment protection
Opportunities	*Threats*
Upward trends in the target market Demand on innovative ideas both at national and global markets	High-quality substitutes High competitiveness, concerning price policy

Fig. 10. Sustainability SWOT for small enterprises.

Thus, the environmental dimension is increasingly taken into account by Ukrainian innovative mechanical engineering enterprises to stay competitive. However, primarily big and medium stable enterprises are organizationally oriented to be environmentally sustainable. The main disadvantage of big and medium unstable enterprises is lack of financial resources for achieving sustainable goals. Small enterprises are lack of general capacity to conduct environmental support policy. At the same time, small enterprises are the most flexible that provide advantages in environmental management.

4 Conclusions

Given all that has been mentioned so far, one may state that environmental potential is getting growing importance within sustainable society. The primary analytical research of Ukrainian statistics shows the increasing deepening of mechanical engineering enterprises' environmental responsibility from their financial capacity.

There is an urgent need to concentrate more efforts on the potential of environmental responsibility of all groups of mechanical engineering enterprises in Ukraine. In accordance with the research sample, the mechanical engineering industry in Ukraine has the following structure:

– big stable enterprises make about 5 %, but this group representative have both financial capacity and experience in achieving environmental goals;

– around 18 % of Ukrainian mechanical engineering enterprises may be concerned as big or medium, but unstable. Their environmental responsibility is particularly influenced by such instability, creating the barriers for sustainable development;

– 8% of medium stable enterprises also have enough financial capacity to be environmentally friendly and growing rapidly;

– the main part of mechanical engineering enterprises is small, namely 13 % of them are concerned as stable and 55 % of them are unstable. However, these enterprises produce the smallest share of production. They are rather flexible to be innovative, but have the lowest financial potential to support environmental friendly activity.

The study results of the current research can be used by their top-managers and spatialized branches that provides organizational and financial support for innovative projects in part of environmental protection.

In particular, the Ukrainian mechanical engineering industry stakeholders tend to pay attention on the following activities:

– stimulating the development of environmental management system within mechanical engineering enterprises;

– ability of top-managers to gather a network of enthusiastic stakeholders, who will assist at the initial stage of environmental support campaign, despite the lack of financial resources;

– ability of project managers to provide an environmental friendly business plan and its clear explanation for future stakeholders;

– creation of a centralized national system of informing the national business entities and investors regarding the need and advantages of environmental support;

– ability to provide an effective system for environmental stakeholders' stimulation at the national level;

– intensification of cooperation between public and private sector, concerning the strength of environmental support policy.

The essence of environmental responsibility potential is both applied and theoretical question. Thereby, there is a need for further research, considering environmental responsible model's practical implication within mechanical engineering enterprises activity. In particular, in relation to other countries, these studies should be applied with caution due to the national economies peculiarities. More extensive study is required. Thereby, this is the subject for future researches.

Abstract. The article is devoted to the analysis of legal framework and theoretical provisions of the landscape approach to the formation of the system of ecologically balanced use of natural resources, the definition of its essence and content, highlighting of conditions and principles of its functioning. Proposals for elimination of legal problems in the field of development and realization of the concept of ecologically balanced use of natural resources are covered. It is determined that the legal formulation of landscape approach principle to the use of natural resources will ensure unity, integrity, comprehensiveness of nature management, coherence and balance of interests in this area, implementation of ideas for the formation of system of environmentally sustainable use of natural resources and sustainable development concept, and the adoption of relevant regulations will solve our state's urgent task on the path to further European integration.

1 Introduction

The priority of further development of civilization is the harmonization of interactions of society and nature. However, the ecological situation continues to deteriorate relentlessly thus posing a real threat to the existence of mankind. And unrestrained pursuit of economic growth is leading to the destruction of natural resources potential. Intensive development of scientific and technological progress has led to a number of global environmental problems, each of which can threaten the destruction of our civilization.

Simultaneous resolution of environmental protection and socio-economic development issues is one of the main activities of any civilized state nowadays. Today there is a dilemma – how to combine the interests of nature conservation with the interests of economic development and social sphere, how to ensure systematic consideration of environmental and economic interests, which is a condition for sustainable (well-balanced) development as a new paradigm of interaction between society and nature (Fig. 1). It is necessary to solve a difficult task – to find a balance in the system «environment – economic development».

There is a need to develop and implement the concept of environmentally sustainable use of natural resources which should be based on reaching a compromise between economic, environmental and social needs of society and on the principles of sustainability. For this purpose, the need to develop the legal framework of landscape principle in nature management, which involves changing approaches to the use of natural resources taking into account negative consequences of human intervention in natural processes and the balance of interests of nature and society development, acquires special urgency.

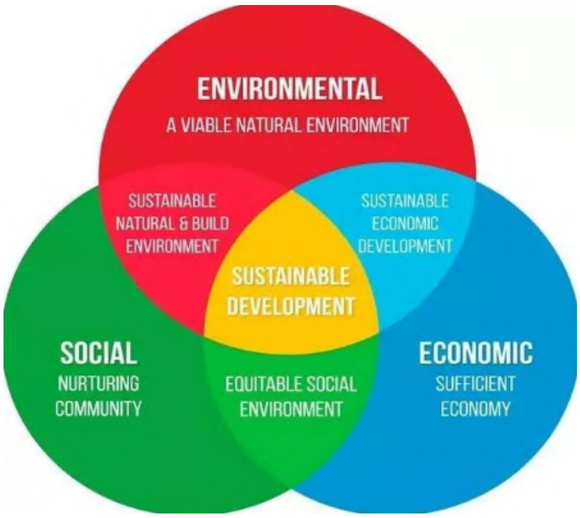

Fig. 1. Sustainable development [1].

The formation of the system of ecologically balanced use of natural resources is the subject of research by the following nature and economics scientists. Legal aspects of environmentally sustainable use of natural resources concept remain a little-researched problem. Specific proposals and projects of models of legal mediation of landscapes as a component of environment, as a source of satisfaction of ecological interests of humans and society as a whole were substantiated in scientific works.

The purpose of the article is to analyse the legal framework and theoretical provisions of the landscape approach to the formation of the system of ecologically

* Corresponding author: marinad@meta.ua

https://doi.org/10.1051/e3sconf/202128009021

balanced use of natural resources, the definition of its essence and content, identification of conditions and principles of its functioning.

2 Results

In 2015, the UN Summit on The issue of environmentally sustainable use of natural resources was first addressed at the World Summits on Environment and Development: in Rio de Janeiro in 1992 and Johannesburg in 2002. However, a breakthrough at the civilization level has not been achieved. Therefore, the XXI century should become a bifurcation point in the system «society – nature» that should be accompanied by specific human actions to harmonize the relationship between society and nature.

In 2015, the UN Summit on Sustainable Development adopted «Sustainable Development Goals» (hereinafter – SDG) – key areas of countries development for the period up to 2030 with 17 Global goals and 169 targets relevant to them (Fig. 2). Among the Global goals are: «Sustainable consumption and production patterns» (goal 12) aimed at reducing the impact on the environment by changes in production patterns and consumption of natural resources; «Conservation of marine resources» (goal 14) which involves conservation and sustainable use of oceans, seas and marine resources in the interests of sustainable development; «Protection and restoration of terrestrial ecosystems» (goal 15) aimed at promoting their rational use, rational forest management, combating desertification, stopping and reversing the process of land degradation and halting biodiversity loss, and others.

Fig. 2. Sustainable Development Goals [2].

Ukraine, like other UN member states, joined the global process of sustainable development. At the initiative of the Cabinet of Ministers of Ukraine and with the assistance of the UN system in Ukraine, an open and inclusive process of adaptation of the SDGs continued for a year. In 2017, the Cabinet of Ministers of Ukraine presented the National Report «Sustainable Development Goals: Ukraine» which defines basic indicators for achieving the SDG. The report presents the results of the adaptation of 17 global SDGs (86 tasks and 172 indicators of national development by 2030) taking into account the specifics of national development. Among the tasks envisaged by the National Report, the need to reduce the resource intensity of the economy, reduce the volume of waste generation and increase the volume of their processing and recycling based on innovative technologies and industries is identified under the Goal 12 «Sustainable consumption and production patterns».

However, the economic growth that everyone in the country aspires to and which is expected by the society will inevitably lead to an increase in natural resources use and consumption waste which in its turn will increase the anthropogenic burden on the environment. The understanding of the importance of responsible consumption and production implementation is present in the country but a balanced settlement of these issues requires a balanced and long-term political and economic effort focused on both production and consumption. According to the National Report, the National Policy should be based on 10 Year Framework of Programmes on Sustainable Consumption and Production Patterns (Rio, 2012), which is a global platform for capacity building and partnership in sustainable production and consumption.

The Law of Ukraine «On the Basic Principles (Strategy) of State Environmental Policy of Ukraine for the Period up to 2030» of 28.02.2019 defines as one of the main tasks the creation ecologically balanced system of natural resources use. The draft Strategy for Sustainable Development of Ukraine until 2030 envisages achieving a balanced and efficient use of natural resources and reducing the resource intensity of GDP by 40%. At the same time, the formation of the system of ecologically balanced use of natural resources is possible, first of all, in case the provisions of the concept are implemented in strategic and programme documents.

In this regard, there appears a need for a scientific study of the essence and content of the system of ecologically balanced use of natural resources, defining the conditions and identifying the basic principles on which this system should be based (Fig. 3).

Fig. 3. Balance of nature [3].

In 1972, Secretary General of the Stockholm Conference M. Strong, covering the essence of the concept of ecological development, for the first time at the official level made a demand for the balance of use of natural resources, the possibility of economic growth within acceptable ecological and economic balance, when society controls the regulatory balance «between total anthropogenic impacts on the natural environment with its

https://doi.org/10.1051/e3sconf/202128009021

self-renewable capacity, with its endurance in relation to these impacts» [4, p. 95].

The scientific definition of ecologically balanced use of natural resources was first covered in the works of economist P.G. Oldak. The scholar described the equilibrium (balanced) use of natural resources as the one in which «society controls all aspects of its development, ensuring that the total anthropogenic load on the environment does not exceed the self-renewable capacity of natural systems» [5, p. 24].

M.M. Prykhodko researches the problems ofthe formation of the system of ecologically balanced use of natural resources (resource use). The scientist notes that ecologically balanced use of natural resources is an equilibrium ratio between the use of renewable natural resources and the intensity of their restoration, as well as the economical use of non-renewable natural resources [6, p. 93]. In the context of ecologically balanced use of natural resources it is very important to comply with the regulatory balance between the available amount of natural resources (resource potential) and the amount allowed for use, which is determined by the ecological potential of ecosystems, their self-renewable capacity [6, p. 94] Thus, ecologically balanced use of natural resources should be based on economic activity in the cycle «extraction of natural resources – resource-saving production with low resource intensity – economical use – expanded reproduction – waste disposal».

In this regard, ecologically balanced use of natural resources should meet the following conditions: use of natural resources with minimal labour costs, with simultaneous contribution of funds for their renewal and taking protection measures; full use of natural resources (without losses during extraction, transportation, processing); renewal of natural ecosystem from which a natural resource is extracted; use of renewable natural resources only in the amount of their annual growth; use of non-renewable natural resources only to meet the most urgent needs; waste-free production.

The related scientific literature also distinguishes the principles on which ecologically balanced use of natural resources should be based: the principle of systematic approach to the use of natural resources; the principle of consideration of natural conditions and resources zonality; the principle of integrated management of natural resources; the principle of conservation, restoration and reproduction of naturalness and biodiversity; the principle of inexhaustibility (annual use of renewable natural resources should not exceed 10 % of their total amount); the principle of waste minimization (introduction of low-waste production, use of recyclables, waste disposal); the principle of observance of laws, rules and principles of natural resources use [6, p. 95].

Introduction of ecologically balanced system of nature management is directly related to the application of landscape approach to the use of natural resources. According to scientists, the landscape approach to the use of natural resources contributes to the restoration of ecosystems, mitigation and adaptation to climate change [7, p. 203], and can bring positive social benefits (e.g. employment or the return of valued wild species) and potentially contribute to improvements in human health and wellbeing [8, p. 21].

Legal codification of the principle of landscape approach to nature management is stipulated by Pan-European Biological and Landscape Diversity Strategy (1995), according to which the countries of European Community took responsibilities to significantly reduce the threat to biological and landscape diversity in Europe, of which Ukraine is a part. The strategy was proposed by the Maastricht Declaration «Conserving Europe's Natural Heritage» (1993), which was based on the European Nature Protection Strategy (1990), the results of Dobris and Lucerne Environment Ministers Conferences (1991 and 1993) and the UN Conference on Environment and Development (1992), etc.

In 2000, to ensure the sustainable development based on balanced and harmonious relationship between social needs, economic activity and the environment, the European Landscape Convention of 20.10.2000 was adopted, ratified by the Law of Ukraine of 07.09.2005. Pursuant to Article 1 of the Convention, «landscape» is defined as an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors.

According to the Convention, Ukraine is obliged to: 1) to recognise landscapes in law as an essential component of people's surroundings, an expression of the diversity of their shared cultural and natural heritage, and a foundation of their identity; 2) to establish and implement landscape policies aimed at landscape protection, management and planning through the adoption of the specific measures; 3) to establish procedures for the participation of the general public, local and regional authorities, and other parties with an interest in the definition and implementation of the landscape policies; 4) to integrate landscape into its regional and town planning policies and in its cultural, environmental, agricultural, social and economic policies, as well as in any other policies with possible direct or indirect impact on the landscape.

As a party to the European Landscape Convention and other international agreements, Ukraine has committed itself to implementing landscape policy into national law. However, currently, the landscape as an object of legal regulation in the legislation of Ukraine is defined only in the Laws of Ukraine «On Environmental Protection» of 25.06.1991, «On Approval of National Programme of Formation of National Ecological Network of Ukraine for 2000–2015» of 21.09.2000, «On Ecological Network of Ukraine» of 24.06.2004 which contain general norms related to legislative provision of use and protection of landscapes.

The concept of a landscape approach to nature management, the recognition of the landscape as an object of legal regulation and the need to protect it began to develop in the scientific literature in Soviet times. In 1983, the first attempt was made to disclose the legal meaning of the «landscape». I.A. Brinke, exploring the essence of the legal regime of landscapes, described the landscape as a set of legally defined areas of land or water consisting of interacting natural or natural and anthropogenic components characterized by typicality or beauty, which are protected by the state in the interests of science, education, culture and recreation [9, p. 9].

Landscape relations are the subject of research of many foreign scientists. Thus, in particular, N. Ockendon characterizes landscapes as large, heterogeneous and multifunctional environments that provide diverse services and values to multiple stakeholders [7, p. 199]. Ch. Albert defines the landscape as the result of the action and integration of natural and/or human factors [10, p. 15].

In national science of environmental and land law, the problem of recognizing the landscape as an object of legal regulation is just beginning to be discussed. In scientific works, the term «landscape» is explained from different points of view. V.I. Andreitsev, V.V. Nosik, M.V. Shulga define the concept of «landscape» by describing the legal significance of land as a national value, the object of property rights of Ukrainian people, the most important part of environment. So V.I. Andreitsev considers landscapes as complex objects of legislation, points out that national land value is the immensity of its properties for meeting physical, spiritual, aesthetic, cognitive, health and medical, recreational, historical, cultural and other needs, formation of natural and natural-anthropogenic landscapes [11, p. 15].

At the same time, as noted by S.V. Yelkin, the mentioned views of the above scholars on the definition of the landscape as a whole do not reveal its legal features. In legal sense, the concept of «landscape» is physical and legal features of the landscape set out in the law, as well as the competence of a subject of law on the landscape, where physical features are objective factors that will directly affect the definition of the specifics of the legal regime of the landscape, the absence of which does not allow to formulate the definition of the landscape as a legal category [12, p. 11]. S.V. Yelkin characterizes the landscape as a territory with a set of natural and artificial components, which form a single whole and are in the optimal quantitative ratio as defined by law, where land acts as a spatial basis [12, p. 14].

Comparative analysis of legal regulation of landscape protection in Ukraine and the European Union was carried out by O.V. Lozo who characterized the landscape as a territorial complex with a specific location recognized by existing legislation and law, within which natural and/or anthropogenic components are in constant interaction and adaptation to each other and constitute a united system [13, p. 7]. The scientist recognizes natural resources (land, water, flora, fauna, subsoil, air, etc.) as natural components of the landscape to the extent they affect it; buildings, transport routes, other man-made objects – as anthropogenic ones [13, p. 9].

Thus, the landscape as an object of legal regulation is a holistic natural or natural-anthropogenic system, which is characterized by relative homogeneity of interacting structural elements.

It should be noted that nowadays landscape planning is actively spreading as one of the ecologically oriented means of nature management in most developed countries of the world (Fig. 4). For example, the Wicken Vision in the Cambridgeshire fens, Cairngorms Connect project in the Scottish Highlands, Wild Ennerdale [7, p. 206]. In our country, only the first steps are being taken to introduce landscape planning into the policy of territorial development. In the future this will help to strengthen the relationship between environmental requirements in the field of nature management and economic, social and cultural interests of people, encouraging them to adhere to the sustainable development goals.

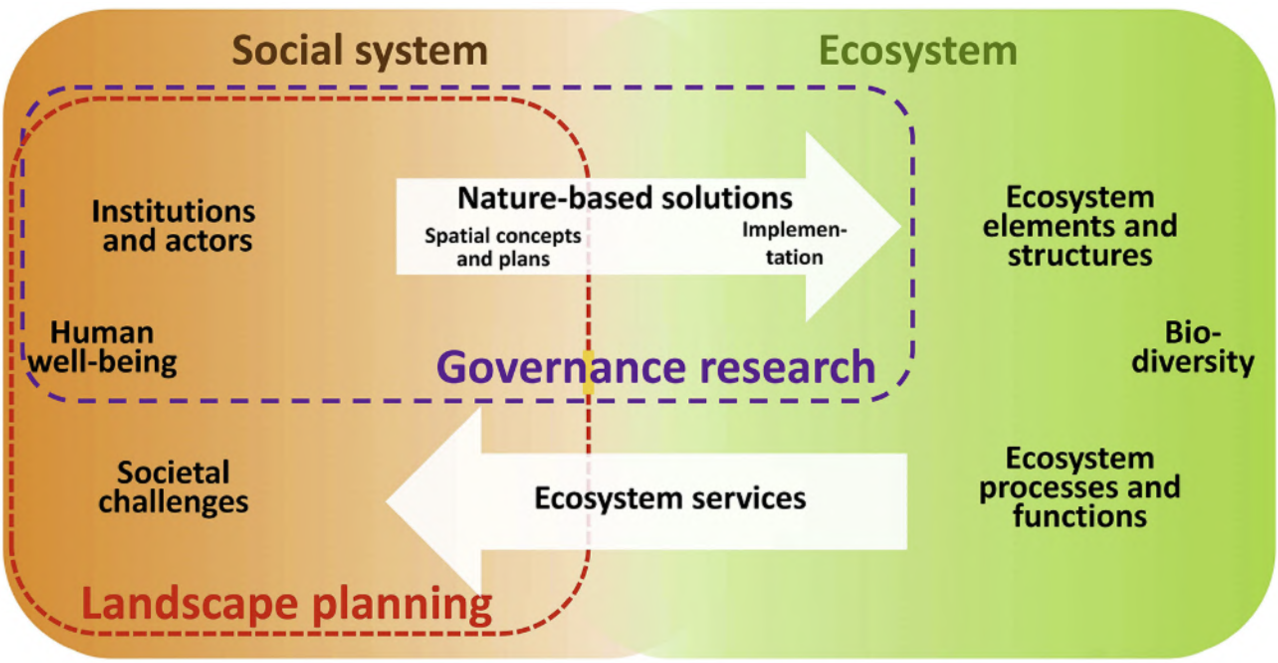

Fig. 4. Landscape planning [14].

Indeed, the need to implement the principles and approaches of modern landscape planning (especially in its European sense) into the practice of national natural resource planning is a close relationship of landscape planning with the concept of sustainable development, which Ukraine adheres to. Landscape planning is a strong forward-looking action to design, enhance or restore landscapes that serves at the interface between science and practice [10, p. 13]. According to the draft Law of Ukraine «On Landscapes», landscape planning itself is designed to ensure sustainable nature management. Besides, the spatial planning procedure in Ukraine is characterized by the dominance of town-planning approach, a strict focus on general schemes and the subordinate role of environmental requirements. This imbalance will help to correct the implementation of the principles of landscape planning.

According to the draft Law of Ukraine «On Landscapes», landscape planning is the development of a project for use of landscapes or a project to change the goals and methods of their management using a set of methodological tools used to build such a spatial organization of society activities in specific landscapes, which ensures sustainable nature management and preservation of basic functions of these landscapes as a life support system. As it is seen from this definition, landscape planning is becoming one of the primary tools for ensuring sustainable development in Ukraine.

Landscape planning has a potential to suggest land use options to achieve environmental objectives, to explore the respective impacts, and to provide recommendations for implementation in practice [15, p. 152]. One aim of landscape planning is to craft comprehensive and spatial strategies for developing multifunctional landscapes that minimize societal challenges and provide diverse ecosystem services to different groups of people [10, p. 16].

Taking into account that landscape planning ensures the implementation of the basic directions of sustainable development policy, it is deemed necessary to form and implement landscape policy in Ukraine, develop legislation, as well as intensify research in the field of landscape planning and its practical use.

Research and analysis of scientific approaches to the outlined sphere of public relations allowed to define the principle of the landscape approach in nature management as an ecologically oriented system of means of planning, designing and organization of landscapes used for construction of such spatial organization of nature management that will provide sustainable and complex use and reproduction of natural resources, preservation of their main functions as a source for meeting material and spiritual needs of humans and the society. This principle has not yet become widespread in the field of natural resources legal relations, only the first steps are taken to enact it in the norms of natural resources legislation. At the same time, the Constitution of Ukraine emphasizes that the most important environmental relations, in particular, the principles of using natural or partially altered landscapes, should be regulated exclusively by laws.

On 14.06.2011, the Verkhovna Rada of Ukraine approved in principle the draft Law of Ukraine «On Landscapes» aimed at ensuring protection, regulation and planning of landscapes. According to the draft Law, a landscape is defined as an integral comprehensive natural-territorial (geographical) complex which is the result of action and interaction of natural and/or anthropogenic factors and consists of interacting natural or natural and anthropogenic components and complexes of lower taxonomy rank. The draft Law formulated the goals and principles of legal regulation of landscape planning and protection, legal aspects of state regulation, the system of legal measures in the field of landscape protection, etc. However, on 15.03.2012 the draft Law of Ukraine «On Landscapes» was rejected as inconsistent with the Constitution of Ukraine, legislation framework in the field of environmental protection, as the one that does not provide for comprehensive settlement of the outlined issues and does not introduce fundamentally new approaches to landscape protection.

Indeed, the legalization of the principle of a landscape approach to the use of natural resources will ensure the unity, integrity, comprehensiveness of nature management, coherence and balance of interests in this area, implementation of ideas for an ecologically balanced system of natural resources and the sustainable development concept put forward at the UN conference in Rio de Janeiro in the «Agenda for the XXI century» (1992), and the adoption of relevant regulations is a necessary step towards solving the urgent task of our state on the path to further European integration.

3 Conclusions

At the beginning of the XXI century, Ukraine still ranks first in the world in terms of consumption of natural resources per GDP unit and has the highest rate of industrial waste per capita. As a result, our country has an extremely degraded natural resource potential. And the mechanisms for regulating the natural foundations of life are not effective and efficient. As a result, natural foundations of socio-economic development are undermined, ecological conditions of human life and their health are rapidly deteriorating. At the same time, Ukraine's natural resource potential is estimated as one of the largest on the planet. It is determined that under conditions of efficient use, Ukrainian lands are able to feed 6 times more people than we have today. However, occupying only 6 % of Europe, Ukraine has 35 % of its diversity [16, p. 9].

Therefore, the most important task is to optimally and rationally use this potential in the interests of well-being of present and future generations. We are talking about the possibility of balanced environmental development of Ukraine based on an innovative model of economic development. It should include the latest achievements of science, modern knowledge-intensive high-tech industries, advanced energy and resource-saving technologies and provide for the application of environmentally sound principles of development.

It is time to form a system of nature management, ensuring its strategic orientation on sustainable development principles. The main strategic direction of Ukraine's development should be the ecological restructuring of its economy and the priority elimination of excessive technogenic pressures on the environment.

Ecologically balanced use of natural resources is a decisive factor in preserving the life and health of every human, ensuring the national security of the country.

Abstract. The article is devoted to the scientific and theoretical analysis of the current state of legal provision of drinking water quality in rural areas. It was stated that in recent years there has been a steady trend of deteriorating quality of water used for drinking in rural areas, including due to increasing levels of nitrate pollution. Proposals have been made for: further implementation of Council Directive 98/83 / EU on the quality of water intended for human consumption and Council Directive 91/676/ EEC on the protection of waters against pollution caused by nitrates from agricultural sources in national legislation; elimination of substantive inconsistencies between State sanitary norms and rules 2.2.4-171-10 "Hygienic requirements for drinking water intended for human consumption" and National Standards of Ukraine 7525: 2014 "Drinking water. Requirements and methods of quality control "in terms of drinking water quality indicators; inclusion in the subjects of state water monitoring of the central executive body that implements the state policy in the field of health care (regarding the monitoring of drinking water); development of the Procedure for state monitoring of nitrate content in surface and groundwater as a component of state water monitoring; forecasting at the level of the National Target Program "Drinking Water of Ukraine" for 2021-2025 "development and operation of a single state information resource - Interactive map of drinking water quality in Ukraine.

1 Introduction

Currently, one of the urgent problems facing Ukraine is to provide the population with drinking water of proper quality and in sufficient quantities. Our country already has a water shortage, ranking 111th in the world out of 152 in terms of available water resources [1]. From year to year, there is a process not only of reducing water supplies in general, but also the rapid deterioration of its quality characteristics, which makes it impossible to use such water for human consumption or has a very negative impact on public health. There are many reasons for this, including intensive pollution of water sources with wastewater and other industrial emissions, and unsatisfactory condition of water mains, aging and wear of water treatment systems, and weakening of state control over the state of drinking water sources, and so on.

The situation is especially difficult in rural areas, where only 32.3% of residential buildings are equipped with centralized water supply [2, p. 222], and most residents of villages and settlements use drinking water from wells, wells, catchments of springs. Published official data (the latest - as of 2019) on the state of sources and systems of drinking water supply in rural areas clearly illustrate the existing problems in terms of providing drinking water to the rural population of Ukraine (Fig. 1 and Fig. 2) [3, p. 71].

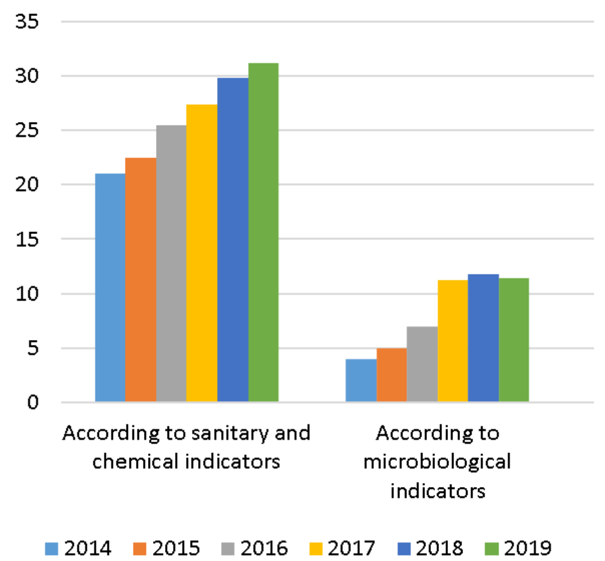

Fig. 1. Proportion of non-standard drinking water samples taken from rural centralized water supply sources, %.

* Corresponding author: tomanovak1980@gmail.com

https://doi.org/10.1051/e3sconf/202128009022

The problem of contamination of drinking water sources in rural areas with nitrates should be singled out, as agricultural activity is the main cause of this type of pollution, and drinking water with excessive content of these substances is potentially dangerous for all, and especially harmful for children, provoking water-nitrate methemoglobinemia, other diseases.

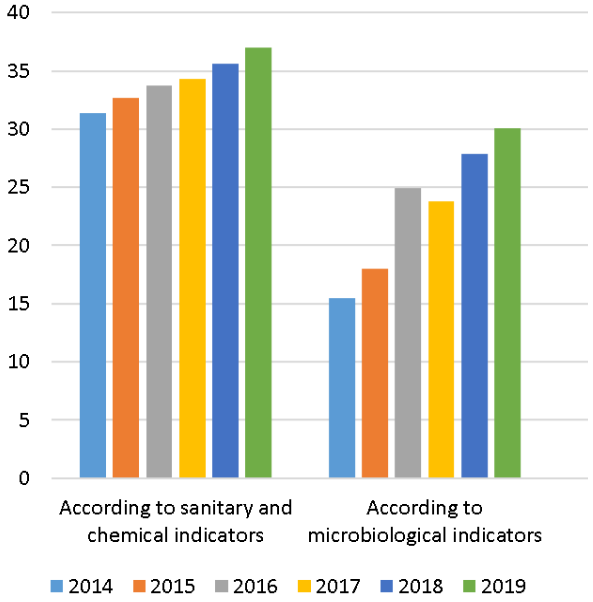

Fig. 2. The proportion of non-standard samples of drinking water taken from mine wells, %.

Data on monitoring the content of nitrates in water for 2016-2019 are shown in Fig. 3 [3, p. 73].

According to statistics, the number of registered cases of nitrate poisoning is growing: if in 2018 there were three, in 2019 there were already seven cases of nitrate poisoning, non-communicable disease of water-nitrate methemoglobinemia (in Zhytomyr, Poltava, Kharkiv and Chernihiv regions) [3, p. 74]. From the given data the wide geography of distribution of nitrate pollution of sources of drinking water supply is visible.

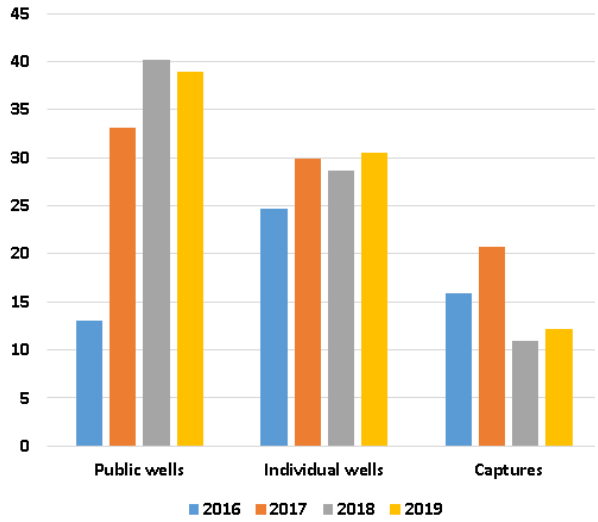

Fig. 3. The proportion of drinking water samples taken from rural decentralized sources of drinking water supply that do not meet the requirements for nitrate content, %.

Data on the average content of nitrates in artesian and groundwater in different regions of Ukraine are shown in Fig. 4.

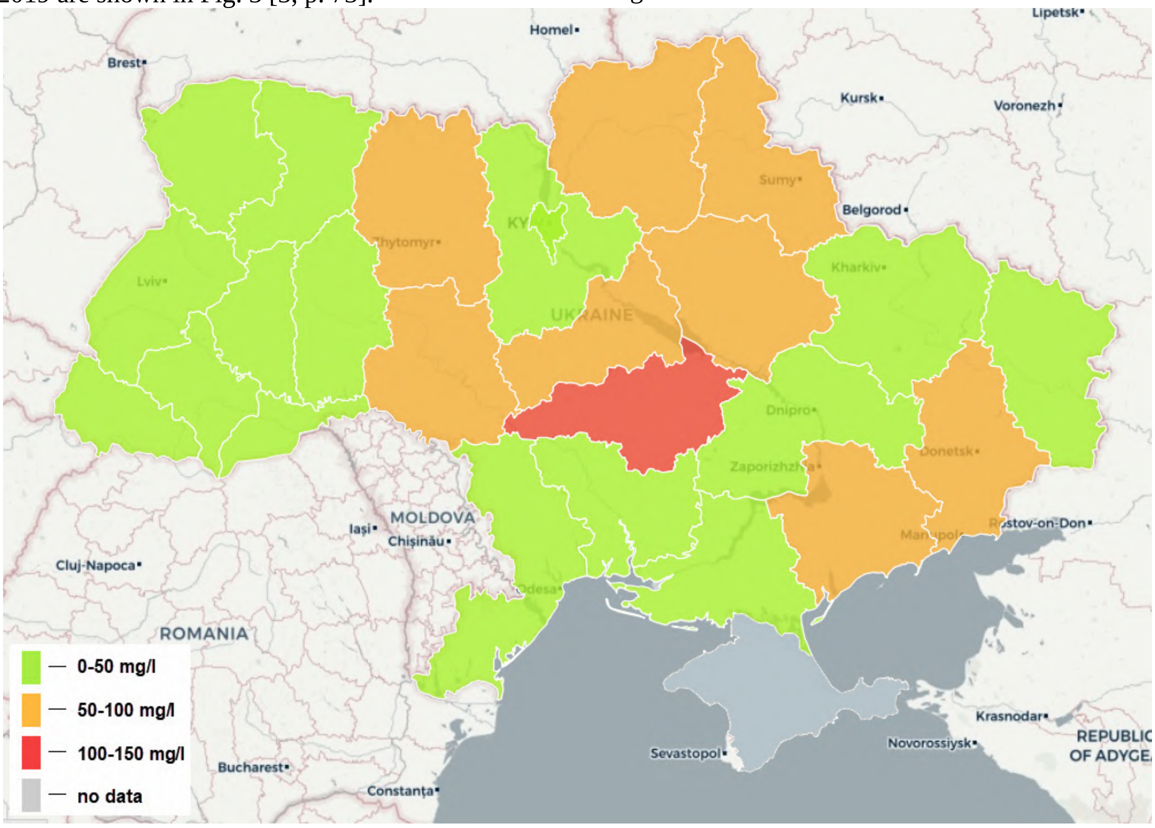

Fig. 4. Average nitrate content in artesian and groundwater in different regions of Ukraine (according to: https://waternet.ua/quality_map).

Along with the above, in 9 regions of Ukraine (Dnipropetrovsk, Donetsk, Zaporizhia, Ivano-Frankivsk, Kirovohrad, Mykolaiv, Odesa, Poltava and Kherson) imported water is used for drinking [4].

One of the ways to improve drinking water supply in rural areas should be clear and effective legal regulation. And the basis for developing an effective mechanism for providing the rural population of Ukraine with quality drinking water should be: establishing criteria for drinking water quality and regulation at the regulatory level of monitoring in the field of drinking water and drinking water supply in rural areas to determine relevant data on drinking water sources. The study of these issues and the formulation of relevant proposals is the purpose of this article.

2 Results

According to the international (Article 4 of Council Directive 98/83/EU on the quality of water intended for human consumption [5]) and domestic (Article 1 of the Law of Ukraine “On Drinking Water, Drinking Water Supply and Sewerage” of 10.01.2002) legislation, drinking water is considered safe and clean if it meets the established requirements for organoleptic, microbiological, parasitological, chemical, physical and radiation parameters. These indicators are regulated: firstly, at the international level - in Annex I, parts A and B of Council Directive 98/83/EC, and secondly, at the national level. Ukraine has State sanitary norms and rules 2.2.4-171-10 “Hygienic requirements for drinking water intended for human consumption”, approved by the order of the Ministry of Health of Ukraine dated 12.05.2010 № 400 and National Standards of Ukraine 7525: 2014 «Drinking water. Requirements and methods of quality control” [6].

As the generalization of the results of existing scientific research shows, the above-mentioned State sanitary norms and rules 2.2.4-171-10 and National Standards of Ukraine 7525: 2014 do not fully take into account international standards for drinking water, although the Implementation of Council Directive 98/83/EU Articles 360-363, 365, 366, Annex XXX of the Association Agreement between Ukraine, of the one part, and the European Union, the European Atomic Energy Community and their Member States, of the other part (hereinafter referred to as the Association Agreement) [7], and the introduction to the National Standards of Ukraine 7525: 2014 explicitly states the implementation of the basic requirements of Council Directive 98/83 /EU.

As rightly noted by O.S. Pronevych State sanitary norms and rules 2.2.4-171-10 in terms of fixed indicators of drinking water quality are generally correlated with Council Directive 98/83/EU, but the domestic document differentiates the requirements for tap water, water from wells (catchments of springs) and packaged water, in contrast to Council Directive 98/83/EU, which sets uniform general requirements for indicators of drinking water quality and safety. In our opinion, the approach enshrined at the international level is more correct, as the basic minimum requirements for drinking water quality should be the same regardless of the source of such resources. Differentiated (for sources of centralized and decentralized drinking water supply), it is advisable to set additional requirements or expand the list of indicators of quality and safety of water intended for human consumption. Another significant drawback: the establishment of State sanitary norms and rules 2.2.4-171-10 permissible levels in drinking water from wells and catchments of nitrite sources (not more than 3.3 mg/l), while Council Directive 98/83 / EC allowed the content of these substances is not more than 0.50 mg / l [8, p. 183]. Note that the National Standards of Ukraine 7525: 2014 sets the standard for nitrite content in water of decentralized drinking water supply at a level not exceeding 0.02 mg / l. Another significant difference between State sanitary norms and rules 2.2.4-171-10 and Council Directive 98/83 / EU - domestic sanitary rules, in contrast to the international standard, do not provide for control of the content of benzopyrene, bromate, cyanide in drinking water, epichlorohydrin, tetrachlorethylene and trichlorethylene, vinyl chloride. At the same time, National Standards of Ukraine 7525: 2014 sets permissible standards for all these substances, except epichlorohydrin and vinyl chloride.

In addition, between the National Standards of Ukraine 7525: 2014 and State sanitary norms and rules 2.2.4-171-10 there are other inconsistencies in terms of epidemic safety indicators, the maximum allowable content of chemical and toxicological indicators [9, p. 401]. In order to eliminate such conflicts, in our opinion, it is first necessary to bring State sanitary norms and rules 2.2.4-171-10 in line with Council Directive 98/83 / EU in terms of drinking water quality indicators, and the next step should be to bring National Standards of Ukraine 7525: 2014 in accordance with State sanitary norms and rules 2.2.4-171-10. This follows from the fact that the State sanitary norms and rules 2.2.4-171-10 are binding on the executive authorities, local governments, enterprises, institutions, organizations, regardless of ownership and subordination, whose activities are related. with the design, construction and operation of drinking water supply systems, production and circulation of drinking water, supervision and control in the field of drinking water supply, and citizens. This provision is enshrined both in the State sanitary norms and rules 2.2.4-171-10 (paragraph 1.1 of the Section “General Provisions”) and in the basic Law of Ukraine “On drinking water, drinking water supply and drainage” (Articles 9, 23, 28, 38, 39, etc.). As for the National Standards of Ukraine 7525: 2014, at present in accordance with Art. 4 of the Law of Ukraine “On Standardization” of 05.06.2014, national standards are applied voluntarily, unless otherwise provided by regulations. The instruction on the recommended nature of application is contained in the National Standards of Ukraine 7525: 2014 (item 1.2). In addition, the Law of Ukraine “On Amendments to Certain Legislative Acts of Ukraine in Connection with the Adoption of the Law of Ukraine” On Standardization “of September 20, 2019 in the text of the Law of Ukraine” On Drinking Water, Drinking Water Supply and Sewerage “ and “standard” in all cases is replaced by the words “state sanitary norms and rules”, thus putting an end to the question of the type of document that sets requirements for drinking water quality.

The next aspect we would like to focus on is the legal regulation of monitoring the quality of drinking water in rural areas. Currently, the Law of Ukraine “On Drinking Water, Drinking Water Supply and Sewerage” provides in Art. 39 state monitoring in the field of drinking water and drinking water supply, determines the entities authorized to implement this measure and delimits their competence. However, in fact, monitoring in the field of drinking water and drinking water supply is carried out within the framework of state water monitoring. We will note that in 2018 for replacement of the Order of implementation of the state monitoring of waters (approved by the resolution of the Cabinet of Ministers of Ukraine from 07/20/1996 № 815), the resolution of the Cabinet of Ministers of Ukraine from 09/19/2018 № 758 the Procedure for implementation of the state monitoring of waters was approved. This document corresponds to Annex XXX to Chapter “Environment” of Chapter V “Economic and Sectoral Cooperation” of the Association Agreement, and to Directive 2000/60 / EU of the European Parliament and of the Council of 23.10.2000 establishing a framework for Community action in the field of water policy [10]. According to experts, the new procedure eliminates duplication of functions between different subjects of monitoring, provides a clear procedure and systematic approach to monitoring the status of terrestrial, groundwater, marine waters, expands the list of biological, hydromorphological, chemical and physicochemical indicators for monitoring [11].

Considering the provisions of the current Procedure for state water monitoring through the prism of monitoring in the field of drinking water supply, we consider as a shortcoming the lack of a list of subjects of state water monitoring of the central executive body implementing state health policy. Thus, in the previous Procedure for state water monitoring, monitoring of sanitary norms of chemical, bacteriological and radiological indicators of water bodies used for drinking purposes was entrusted to the State Sanitary and Epidemiological Service of Ukraine, which until 2017 was part of the executive branch. in the field of health care and ensured the implementation of state policy in the field of sanitary and epidemiological well-being of the population. The consequence of such institutional transformations has been a significant reduction in the material, technical and human resources of laboratories engaged in the analysis of water quality indicators. This, in turn, led to a decrease (compared to 2014) in the number of samples from mine wells (2.6 times) and from catchments of springs (1.5 times) [12], and we have already indicated that it is decentralized sources drinking water supply is essential for providing rural settlements with drinking water. Given all the above, we support the existing proposals on the need to separate from the structure of the State Service of Ukraine for Food Safety and Consumer Protection of the State Sanitary and Epidemiological Service of Ukraine and propose to include this body in the state monitoring of water (for drinking water).

Also important for determining the state of drinking water sources in rural areas is the issue of monitoring the nitrate content in surface and groundwater. The obligation to carry out such monitoring is provided by Council Directive 91/676/EEC of 12 December 1991 on the protection of waters against pollution caused by nitrates from agricultural sources [13].

Implementation of the Nitrate Monitoring Program in Surface and Groundwater for Ukraine is provided for in Annex XXX to Ch. 6 of the Association Agreement and included in the Action Plan for the implementation of the Association Agreement between Ukraine, on the one hand, and the European Union, the European Atomic Energy Community and their Member States, on the other hand, approved by the Cabinet of Ministers of 25.10.2017 № 1106. However, despite the expiration of these tasks on 31.12.2020, they remain unfulfilled at present. So far, only draft documents have been developed that indirectly affect the protection of water resources from nitrate pollution from agricultural sources. These are the draft Methodology for identifying areas vulnerable to nitrate compounds and the draft Code of Best Agricultural Practices [14]. Accordingly, no work is being done to identify nitrate-vulnerable areas; creation of their register, as well as monitoring of nitrate content in surface and groundwater [15, p. 46].

As noted in Art. 39 of the Law of Ukraine “On Drinking Water, Drinking Water Supply and Sewerage” the purpose of state monitoring in the field of drinking water and drinking water supply is “collection, processing, storage and analysis of information on drinking water quality, status of centralized drinking water supply, forecasting its changes and development of scientifically substantiated recommendations for making appropriate decisions in this area”. In turn, one of the principles of state policy in the field of drinking water, drinking water supply and drainage of Art. 6 of the same law calls for free access to information on the quality of drinking water, the state of sources and systems of drinking water supply and drainage, and in Art. 9 - every consumer of drinking water is guaranteed the right to free access to information on drinking water quality. To do this: 1) the central executive body that implements state policy in the field of housing and communal services prepares and publishes the annual National Report on drinking water quality and drinking water supply in Ukraine (according to the Procedure approved by the Cabinet of Ministers of Ukraine from 29.04.2004 № 576); 2) provides interested public authorities, public organizations, enterprises, institutions, organizations and citizens with information on cases and causes of drinking water pollution. These provisions correlate with international requirements - Art. 13 and other Council Directives 98/83/EU and directly relate to the realization of the human right to drinking water.

We would like to note that the human right to drinking water is recognized in the world as one of the fundamental rights. Thus, UN General Assembly Resolution № 64/292 of 28 July 2010 and the comments of the UN Committee on Economic, Social and Cultural Rights № 15 of 2002 defines the right to drinking water and adequate sanitation as a mandatory component of the fundamental human right to life and health [16]. Another document, the UN Declaration on the Rights of Peasants and Other Persons Working in Rural Areas, identifies the right to safe and clean drinking water and sanitation for this category of people as fundamental to a full life, the exercise of all human rights and human dignity. 17]. To ensure this right, as K.D. Yanishevska and A.D. Skoryk absolutely rightly prove, it is necessary to ensure the connection between the right to information, primarily environmental, and proper management, public participation in decision-making by public administration bodies [18, pp. 701].

In our opinion, the above methods of informing the population about the quality of drinking water through the publication of the annual report and in case of pollution of drinking water do not fully guarantee compliance with the right to information about the state of drinking water. For example, the National Report on Drinking Water Quality and the State of Drinking Water Supply in Ukraine in 2019 has been published so far, ie we have official information a year ago, so to speak, in retrospect. Prompt informing the population about the current state of drinking water quality is very limited, and available resources vary in the amount of information and presentation. For example, the website of Kyivvodokanal constantly updates microbiological and physico-chemical indicators of drinking water quality control at control points of the distribution water supply network of Kyiv [19]. The website of Ternopilvodokanal contains average microbiological and sanitary-chemical indicators of drinking water quality as of the third quarter of 2020 [20]. There are also data on the quality of drinking water in some observation points (water intakes) (Fig. 5). With regard to rural settlements, there are no such resources in free access at all.

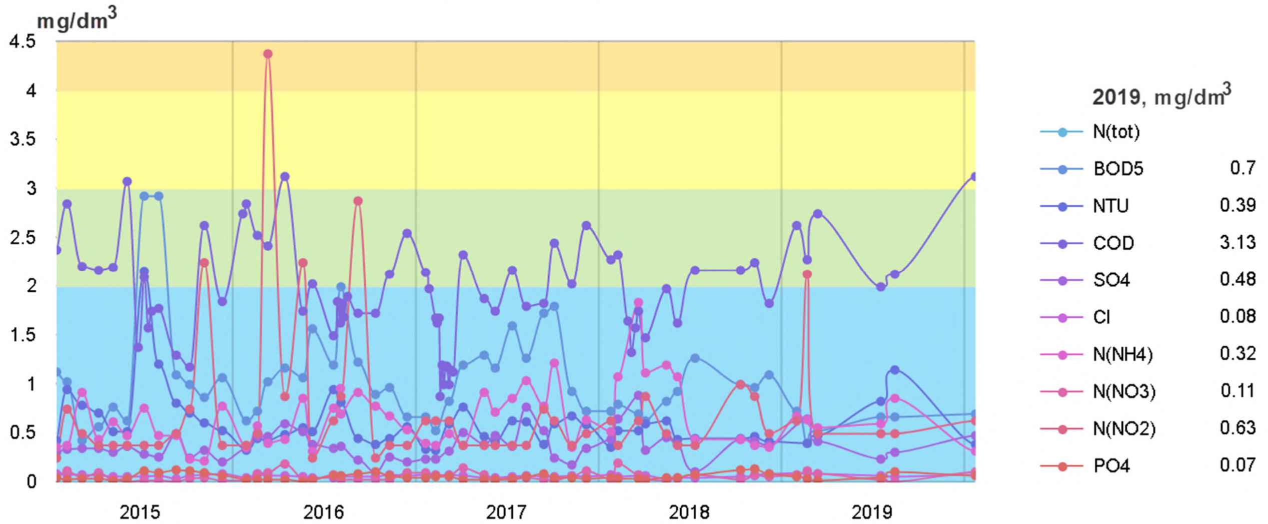

Fig. 5. Data on water quality (water intake of Kyiv). Full name of the observation point: Dnipro, 897 km, Vyshhorod, Kyiv HPS, drinking water intake, Kyiv (according to http://openenvironment.org.ua/).

Instead, commercial structures propose the development of a very important and promising tool for local communities to accumulate data on the state of drinking water sources, influence those responsible for the provision of water supply services and plan measures to improve drinking water quality, drinking water supply, protection of sources and systems, drinking water supply, restoration of drinking water supplies - interactive maps of drinking water quality [21]. However, these initiatives remain unpopular in practice due to limited local budgets. Hence, we propose to include in the National Target Program "Drinking Water of Ukraine for 2021-2025", the project of which is currently being developed [22] as a separate measure to develop an interactive map of drinking water quality in Ukraine and providing funding.

3 Conclusions

Thus, the priority measures to improve the legal regulation of providing the rural population of our country with quality and safe drinking water should be the following. Continue work on the implementation of Council Directive 98/83/EU on the quality of water intended for human consumption into national law. Elimination of substantive inconsistencies between State sanitary norms and rules 2.2.4-171-10 "Hygienic requirements for drinking water intended for human consumption" and National Standards of Ukraine 7525: 2014 "Drinking water. Requirements and methods of quality control "in terms of drinking water quality indicators. Inclusion in the subjects of state water monitoring of the central executive body that implements the state policy in the field of health care (for drinking water monitoring) and development of the Procedure for state monitoring of nitrate content in surface and groundwater as part of state water monitoring. Provision at the level of the National Target Program "Drinking Water of Ukraine for 2021-2025" to develop and ensure the functioning of a single state information resource - Interactive map of drinking water quality in Ukraine.

Abstract. The article describes the leading world trends and factors of state regulation of “green” energy development as a key element of energy safety of mankind at transition stage to globalized society. Paradigm change of energy safety of mankind, problems and obstacles on the way to abandon hydrocarbons use as the main energy sources and replace them by renewable environmentally friendly sources are analyzed. International and national normative legal documents regulating functioning and “green” energy development are characterized. Mechanisms for strengthening Ukraine’s energy safety by acceleration stimulating of construction of new generation power plants using exclusively renewable energy sources in our country were proposed.

1 Introduction

The modern world is characterized by two interrelated global phenomena: level of energy consumption and level of environmental pollution. Ozone holes in the atmosphere, entire continents of floating wastes in the ocean, emissions of carbon and other harmful substances at the present stage of human development are acute issues of human existence safety.

Today, it is clear that focus on hydrocarbon energy sources - coal, oil, gas - as dominant in energy production, has exhausted itself and can lead to death of humanity. Oil and gas economy reached its historical impasse. Global problems of economic, energy and environmental safety of all mankind and the vast majority of countries around the world are interconnected. It is especially felt in modern Ukraine, where the war in Donbass demonstrated all helplessness of the national economy with its almost dominant energy dependence on the aggressor country (at the level of 60% [1]). Yes, Russian aggression exposed all problems of energy safety of our country. It forced the Ukrainian government to start reforms to diversify energy sources, but these measures are unsystematic and insufficient. Level of their implementation does not meet today’s challenges. It is evidenced by at least such shameful statistics for us, given in December 2018 by the authoritative financial analytical center “Carbon Tracker” (Fig. 1): heat generation in Ukraine is the most inefficient and most expensive in the world (the cost is higher than European Union prices by 40% and from the Russian Federation by 75%!) [2, 3]. Therefore, it is important to study the world’s advanced approaches, mechanisms and tools of state regulation of “green” energy development as a key element of energy safety.

Issue of world energy modernization in the direction of gradual abandonment of hydrocarbons and transition to environmentally friendly renewable energy sources as a guarantee of further energy, economic and environmental safety of mankind was debated in scientific discourse of the early XXI century. In particular, among recent publications in this field it is worth noting such foreign researchers as Born [4], Sopian and Khan [5], Mateus and Tan [6], Nahi [7], Kherbs and Frih [8], Tvidell [9]. A number of important issues regarding the functioning of energy facilities and their impact on the environment are disclosed in articles [10-24]. In recent years, in Ukraine following scientists have researched issue of “green” energy development: Benedyk [25], Bila [26], Herasymchuk [27], Kudria [28], Kuzmina [1, 29], Lehka [30], Prokip [31], Riazanova [32], Stoian [33], Tkachuk, Rechun and Priadko [34], Trofymenko [35], Cherniak [31] and other. We will try to generalize their scientific achievements in this article.

The research aim is to analyze and summarize the world’s leading trends and factors of state regulation of “green” energy development as a key element of energy safety of mankind at stage of transition to a globalized society.

2 Results

Beginning of the third millennium was marked by transition to new energy policy of the world's leading states and international community capable to ensure sustainable development and energy, environmental and economic future. J. Bjorn said that states and governments need to make difficult choices in the shortest possible time and these government decisions will forever change not only energy and economy, but also environmental, social, cultural, etc. living conditions of mankind [4].

According to Stoyan transition to green economy and Ukraine's integration into the world energy space given need to form effective system of mechanisms for state regulation of renewable energy development in our country [33]. This opinion is shared, in particular, by A. Prokip. He is convinced that in this case the cumulative effect of developing measures to ensure energy and national safety, in addition to minimizing the country's dependence on energy suppliers and concern for the environment, will reduce social tensions [31].

It should be noted that given existing disparities in needs and opportunities for obtaining fuel energy resources, there are four models of energy safety:

1. Model of guaranteed energy safety (is typical for countries that are not only able to fully meet their own energy problems, but also have their significant reserves for sale: UAE, Venezuela, Russia, other OPEC countries);

2. Model of self-sufficient energy safety (typical for countries whose own energy resources are sufficient for domestic needs, but not enough for exports, e.g. India);

3. Model of insufficient energy safety (typical for countries whose energy needs require import of energy and measures aimed at diversifying energy sources, stimulating the introduction of alternative energy technologies. Such countries include the EU, Ukraine, etc.).

4. Model of crisis energy security (when a country is forced to import more than 50% of the required amount of energy, e.g. Japan).

The European Union's policy on energy supply safety in the European energy space due to the EU countries among the third group of countries with insufficient energy security is formed in several directions with the main goal - to accelerate transition to the second group (self-sufficiency) obtaining and consuming the necessary energy. M. Kuzmina names following components of the EU energy security system: energy saving and energy efficiency, diversification of energy resources both own and imported (natural gas, coal, oil, RES) [1].

What is the key difference between a traditional economy and a "green" one? Traditional economy was based on use of non-renewable energy sources such as wood, coal, oil and gas. According to N. Riazanov generation of fossil fuel-based electricity was the most important driver of economic development since the beginning of the industrial revolution. Environmental consequences of this development were not taken into account for a long time, until nature declared itself: rising world temperatures, rising sea levels, ocean pollution and other effects of climate change began to seriously affect coastal areas and coastal countries. Existence of many communities and biological life support systems on the planet was threatened. Growing negative effects of climate change increasingly led to the realization that if you follow the previous course of development without taking into account environmental imperatives it will lead to catastrophic consequences [32].

https://doi.org/10.1051/e3sconf/202128009023

So-called "green economy" (term of journalistic nature) or "alternative energy economy" (scientific publications also have another synonymous definition "energy economy based on renewable energy sources") abandons dominance of non-renewable hydrocarbon resources in favor of virtually endless sources. Renewable energy sources (RES) include wind and solar energy (wind and solar power plants); aero-, geo- and hydrothermal (heat extraction from atmospheric air, from the surface of the earth and from the surface waters of terrestrial reservoirs); river, tidal and ocean energy (small hydropower, tidal power plants); biomass and biogas (biological share of products, waste and residues of biological origin from agriculture, including plant and animal substances, forestry and related industries, including fisheries and aquaculture, as well as the biological part of industrial and domestic waste; gas from organic waste, gas from treated wastewater, etc.).

Key advantages of renewable energy sources are their environmentally friendly nature, practical inexhaustibility of stocks over historically long period, availability of modern energy services in rural areas, climate change mitigation, promoting "green jobs" and improving quality of life. That is why J. Matheus and H. Tan call renewable energy technologies one of the most important strategies in addressing sustainable development of mankind [6]. In order to set large-scale tasks and develop new markets O. Chernyak notes international cooperation and active investment in RES by all countries of the world are necessary. The use of RES worldwide is an important step towards stable future for all mankind [36].

It is no coincidence that these issues are periodically raised and important political and legal decisions are made regarding the transition of mankind to energy based on renewable energy sources (RES) at the planetary level. Thus, at the Paris Climate Conference on November 30, 2015, 100 of the 195 participating countries (including Ukraine) supported the decision to move to 2050 for the full use of renewable energy sources [36]. However, the commitments are quite divergent, especially in terms of the pace of such a transition. For example, Ukraine, as a member of European Energy Community made the lowest commitment to increase the share of RES in the country's energy balance by only 11% by 2020 (and the current situation shows that Ukraine will not reach half of the planned), while Switzerland plans to have 49% of renewable energy in 2020, Latvia - 40% Finland - 38% Austria - 34%.

Fig. 2 shows the breakdown of primary energy that is shown based on the 'substitution' method which takes into account inefficiencies in energy production from fossil fuels. Particular one is based on the global energy production for 2019 year. It can be seen that in 2019, almost 16% (15.7% if to be precise) of global primary energy came from low-carbon sources. Low-carbon sources are the sum of nuclear energy and renewables – which includes hydropower, wind, solar, bioenergy, geothermal and wave and tidal [38]. 11.4% came from renewables; and 4.3% came from nuclear. Hydropower and nuclear account for most of our low-carbon energy: combined they account for 10.7%. Wind produces just 2.2%, and solar 1.1% – but both sources are growing quite rapidly. Despite producing more and more energy from renewables each year, the global energy mix is still dominated by coal, oil, and gas. Not only does most of our energy – 84% out of it – come from fossil fuels, we continue to burn more each year: total production has increased from 116,214 to 136,761 TWh in the last 10 years [37].

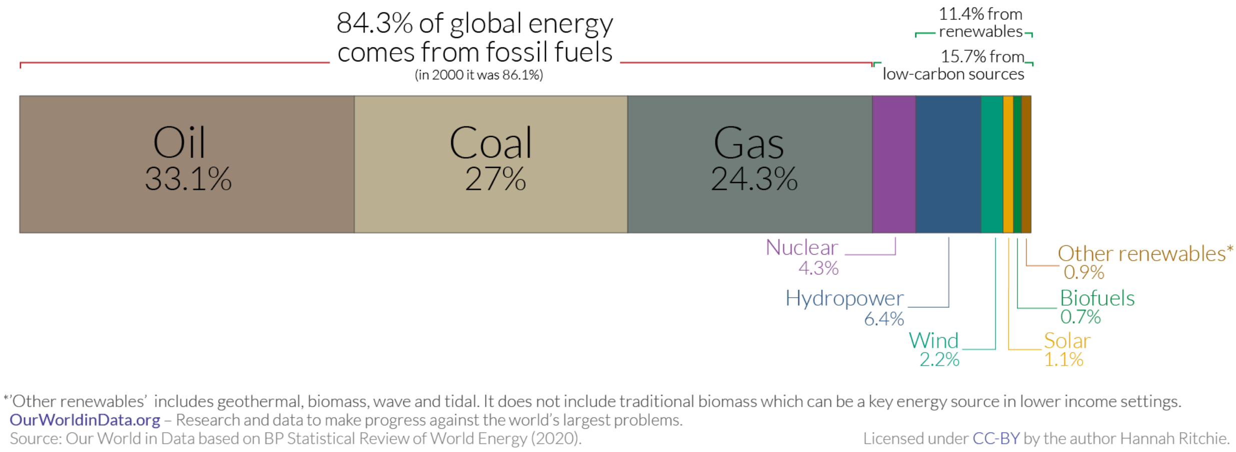

Fig. 2. Global primary energy consumption by source [37].

Numerous international and intergovernmental organizations coordinating in the field of "green energy" were established. International Energy Agency, established in 1974, is the central intergovernmental institution in the field of energy in addition to aforementioned European Energy Community. Initially, the organization was created to consolidate efforts of developed countries to maintain their own energy safety. Today, as J. Benedyk notes, this agency is at the heart of global energy dialogue, providing authoritative statistical reports, analyzes and recommendations, focusing on four areas, the so-called "4":

• energy safety - by promoting diversification, efficiency and flexibility in all energy sectors;

• economic development - by ensuring stable energy supplies to member countries and free markets development to stimulate economic growth and eliminate energy poverty;

• environmental awareness - through analysis of possible policy decisions and measures to compensate negative impact of energy production and consumption on the environment and climate change;

• global engagement worldwide - by ensuring close cooperation with countries that are not members of the IEA, especially with the largest producers and consumers, to find solutions to common energy and environmental problems [25].

B. Nagy in the book "The Age of Clean Energy" prioritizes following among the main areas of institutional support for international economic cooperation in the development of renewable energy: organization of international consultations on framework programs development for use of renewable energy; promoting development of technology and knowledge transfer in the field of renewable energy; creation of regional centers for research, development and exchange of experience in the field of renewable energy development; dissemination promoting of successful world experience in the renewable energy use; planning of financial support of renewable energy sources (RES) programs; collection and processing of statistical data in the field of renewable energy development; monitoring and adjustment of plans (strategies) for renewable energy development [7].

An important place in transition regulating to "green energy" dominance is occupied by state, interstate and international programs to stimulate research, technological and practical developments in the field of RES. Thus, S. Bila notes that the EU countries are characterized by such incentives use that facilitate transition from traditional to renewable energy: tariff benefits ("green" tariffs - FITs, and "green" surcharges - FIPs); quotas regulation on electricity production and use of "green certificates" system sold on the market and promote the attraction of free investment funds in the field of renewable energy (TGC); soft loans, grants and credit guarantees, government subsidies and investment grants [26].

Positive results are observedt. In particular, share of renewable electricity in the German economy is growing steadily. If in 2000 share of German RES was 7%, then in 2010 - 17%, by 2020 this figure will increase to 35% and in 2050 - up to 80%. However, the world leader is already China and, according to J. Matheus and H. Tang, this leadership will only grow due to the huge public investment in the renewable energy sector [6].

The director of the Institute of Renewable Energy of the National Academy of Sciences of Ukraine, Doctor of Technical Sciences S. Kudria, claims that our country has all prerequisites for large-scale development of technologies based on renewable energy sources. First of all, it has significant energy potential (wind, solar energy, small river energy, biomass, geothermal energy and environmental energy), as well as a developed scientific, technical and industrial base. In addition, the key factors in the development of RES in Ukraine are need to improve environmental situation; exhaustion of traditional fuel and energy resources; urgent need to overcome dependence on energy imports; international obligations; need for urgent renovation of fixed assets of energy equipment in the country. This industry is one of the most attractive for investment [28]. V. Gerasymchuk and O. Romanyuk estimated annual potential of Ukraine's renewable energy at 100–110 million tons. In particular, average annual potential of solar energy in Ukraine exceeds average of countries such as Poland and Germany. It determines significant prospects for use of solar panels in Ukraine. Also, one of the most promising and investment-attractive areas in Ukrainian alternative energy is production of solid biofuels. Characteristic feature of solid biofuel market is the significant demand for products in the European Union, which made the industry export-oriented [27].

However, process of development of renewable energy in Ukraine is very slow despite significant potential. Share of energy produced from renewable sources in total energy at the end of 2017 was only about 2% [24].

Fig. 3 shows energy consumption by source in Ukraine [37]. Primary energy consumption is measured in terawatt-hours (TWh). An inefficiency factor (the 'substitution' method) has been applied for fossil fuels, meaning the shares by each energy source give a better approximation of final energy consumption.

This situation requires urgent measures of state stimulation of "green energy" sector development in Ukraine. Among such measures O. Cherniak names:

• exemption from profits taxation of companies that produce electricity only from RES;

• introduction of "green" tariff;

• land tax reduction for enterprises using renewable energy;

• exemption from import duties when importing certain types of equipment for renewable energy;

• exemption from taxation of operations on import of certain types of equipment for renewable energy [36].

K. Lehka also offers at state level:

• to increase attractiveness of those RES development that have high probability of economic payback in future and are the most promising in terms of production in Ukraine;

• to support development and implementation of competitive technologies;

• to stimulate localization of production and the necessary equipment [30].

In turn, O. Trofimenko groups tools for implementing of state regulation mechanism of strategic development of renewable energy into three main parts:

• fiscal (preferential tariffs, government spending, income tax, financial instruments for the regulation of renewable energy);

• organizational (rules, organizational, legal norms and standards that determine state regulation of renewable energy, duties, rights and responsibilities of state regulators, organization of their activities, including organization of fiscal tools to implement the mechanism of state regulation of strategic development of renewable energy);

• methodical (set of measures to improve methodology of selection of renewable energy projects, methodological approaches to assessing the level of development of renewable energy, energy saving potential, study of the status and ranking of regions and industries by energy security, system of measures for renewable energy development at the methodological level) [35].

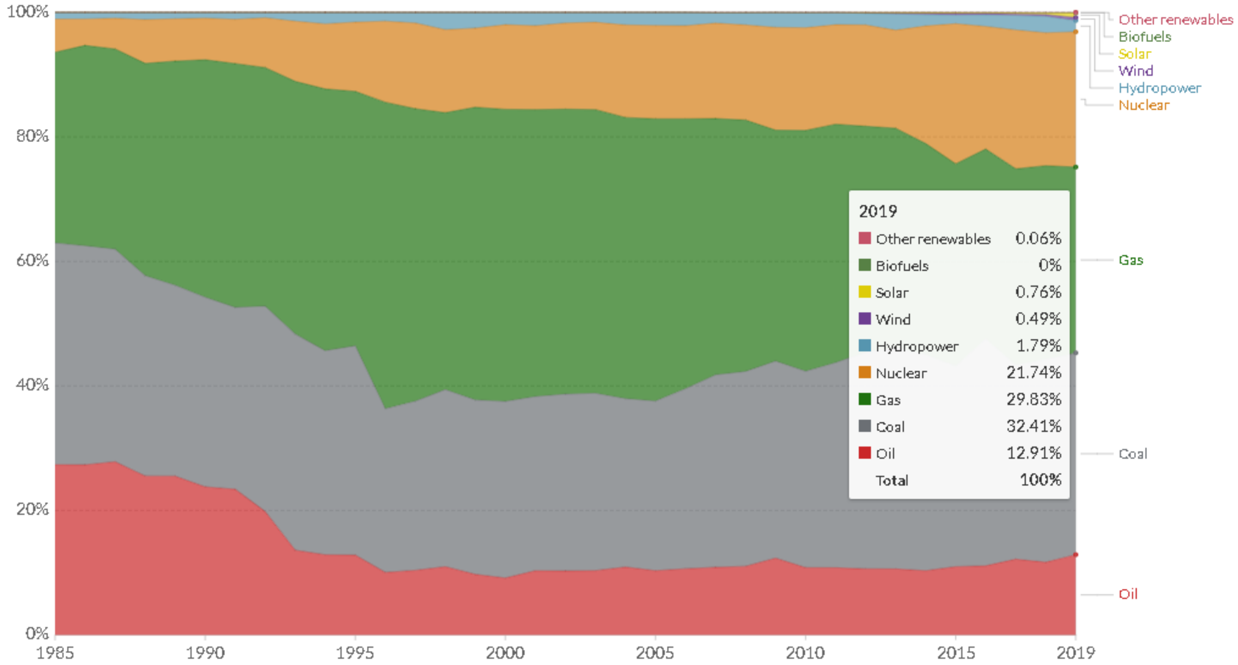

Fig. 3. Energy consumption by source, Ukraine [37].

According to V. Tkachuk, O. Rechun and O. Pryadko following measures can provide prospects for renewable energy development in Ukraine:

• energy safety level increasing of Ukraine by diversifying and depoliticizing supply of energy resources;

• burden reducing on the environment;

• environmental awareness raising of Ukrainian citizens, because "green" energy is not only improving environment, but preserving human health and prolonging life on Earth [34].

Thus, in the course of our research we identified leading trends of interstate and state regulation of green energy as a key element of mankind energy safety in the transition to a globalized society. They are embedded in the global strategy of human civilization through abandonment of hydrocarbons in favor of renewable energy.

3 Conclusions

Thus, we can conclude that rapid depletion of natural traditional energy resources on the planet and their constant price rise in the face of growing human needs for electricity will inevitably lead to rapid replacement of hydrocarbon economy by "green economy" based on renewable energy sources [39]. The world's leading countries actively develops alternative energy as a factor in energy safety improving. It improves environment, increases standard and quality of life.

Ukraine should to develop and actively implement new energy strategy based on effective state regulators and aimed at diversifying energy dependence on Russia and a gradual transition to the dominance of renewable energy sources. Our state should provide comprehensive legal, fiscal, tax, financial, informational and organizational support for creation and use of energy power plants, grant and investment support for scientific and technological developments in this area.

Abstract. The article analyzes issue of strategy forming of state development through prism of state environmental safety, preservation of its natural capital in the process of formation and implementation of state environmental policy. Basic ecological, economic, social principles of natural capital preservation of Ukraine are considered. Possibilities of ecological network development of Ukraine are investigated. A comprehensive knowledge framework for the management of natural capital is shown.

1 Introduction

Consideration of state development strategy of modern countries is impossible without taking into account such important component as natural capital - the natural environment of mankind, our noosphere. It should be understood as a whole societal organism. People and products of their activities are in unity and interconnection. They perform simultaneously number of important functions of societal self-organization (e.g. biological - as a habitat for biological objects; physiological - as a source of physiological needs of all living beings on Earth; socio-economic - as means of production, basis for placement of various spheres of human activity, cognitive - as an object of scientific research and cognition, etc.).

It is no coincidence that the Sustainable Development Goals (SDGs) [1] approved at the United Nations Summit on Sustainable Development and the adoption of the Agenda for Development in September 2015 [1] and revised Sustainable Development Goals for Ukraine adopted in accordance with them in four key areas:

1. Fair social development;
2. Sustainable economic growth and employment;
3. Effective management;
4. Ecological balance and development of sustainability [2].

As we can see, one of these key areas directly reflects the content and purpose of the environmental function of the state. Moreover - 6 of the 17 main goals of sustainable development for Ukraine in one way or another relate to natural capital, environmental protection (Objective 6 - Clean water and sanitation; Objective 7 - affordable and clean energy; Objective 12 - responsible consumption and production; Objective 13 - climate change mitigation, Objective 14 - conservation of marine resources and Objective 15 - protection and restoration of terrestrial ecosystems). According to these goals the effective preservation of Ukraine's natural capital for present and future generations is possible only through clearly planned and organized measures for formation and implementation of modern state environmental policy including preservation of natural capital and development of ecological network. It seems possible based on development of clear methodology for conservation of natural capital based on system of principles, methods and tools.

One of the most important principles of sustainable development is to ensure safe environment for life and health. One of the main criteria in this direction is the preservation of natural capital taking into account given environmental problems, economic instability and number of other factors. All this necessitates further development of preservation methodology of natural capital.

The article aim is definition of methodological principles and methods of natural capital conservation on the basis of foreign experience. The object of this scientific research is main components of the natural capital of Ukraine. The subject of scientific research is process of forming the methodology of public administration for natural capital preservation.

2 Results

The term 'natural capital' was proposed by David Pearce [3], as a way to underline the role of nature in supporting the economy and human well-being. It is now recognised that human well-being depends on different types of resources or assets, which can be categorised in relation to four broad types of capital. All of these capitals support the economy and human well-being [3-5]:

• Manufactured or 'man-made' capital: assets used to produce goods and services, such as machines, tools, buildings and infrastructure. Financial capital includes money and other financial assets, and is sometimes seen as a distinct additional category.

• Human capital: assets in the forms of knowledge, education, motivation and work skills, mental and physical health.

• Social capital: includes social trust, norms and networks that facilitate social and intellectual interactions and solutions to common problems, e.g. neighbourhood associations, civic organisations and cooperatives, and the political and legal structures of a society.

• Natural capital: comprises of the ecosystems and abiotic assets of the planet that provide people with exploitable resources, e.g. solar radiation, fossil fuels and minerals, and generate a flow of benefits via ecosystem services, e.g. food, climate regulation and recreation.

While all four types of capital are needed to support human well-being, natural capital is arguably the most important one because it supports and underpins the other forms of capital. For example, minerals, metals and energy are needed to build the components of manufactured capital. Human and social capitals are heavily dependent on the physical health of individuals who are dependent upon ecosystem services to maintain good health. These services range from food, freshwater, timber and fibres, regulating ecosystem services, e.g. water purification, nutrient cycling, mitigation of floods, and benefits from open landscapes and urban parks that support recreation and well-being.

Natural capital: includes biotic and abiotic elements and comprises of all natural resources that human society draws upon. A sound analysis of ecosystem processes, combined with the general principles of environmental accounting, is the foundation for developing a natural capital accounting approach. Fig. 1 illustrates the main components of natural capital as currently understood – this has been developed from the natural capital figure in the first EU MAES report on the 'Mapping and Assessment of Ecosystems and their Services' [6].

Fig. 1 makes a distinction between ecosystem capital and abiotic resources. In reality, there is no clear-cut boundary between biotic and abiotic components [9]. For example, water is an abiotic factor but is included under ecosystem capital as living organisms play a modulating role in its cycle and water plays a key role in all ecosystem processes [7, 8]. However, this distinction helps to identify and classify different types of natural capital, which is important in the context of developing a natural capital accounting approach. Another dimension in Fig. 1 is the relationship between the concepts of 'assets' and 'flows'. According to standard economic theory, natural capital is the sum of the different physical assets of nature, e.g. mineral deposits or tonnes of biomass, and benefit flows would not really be part of natural 'capital'. However, for ecosystem capital in particular, the same natural processes govern ecosystem assets and ecosystem services, so it is often difficult to draw a line between the two. Secondly, in the context of monetary accounting, the value of the asset stock is often derived from the flows it generates. Lastly, in many less-specialist discussions, flows are considered as part of natural 'capital'. For these reasons, Fig. 1 shows ecosystem and abiotic assets and flows in the same colour but with different background shading. The second key feature of assets and flows is their depletability. Some are, under current circumstances, unlimited, i.e. 'non-depletable' – for example, sun light and wind depend on solar radiation, which humans cannot influence. Most abiotic assets are, for obvious reasons, classified as 'depletable' because they do not renew themselves and their stock is therefore reduced over time by exploitation, e.g. fossil fuels and minerals. Ecosystems and associated service flows are also 'depletable' since over-exploitation can lead to the extinction of species or depletion, e.g. fish stocks. Outright habitat destruction, e.g. the conversion of forests or grassland to urban areas, ultimately destroys ecosystems and the regulation and maintenance, or other services, they generate. Ecosystem capital is particularly vulnerable because many species and habitats depend on specific conditions being maintained, and human society heavily exploits it via agriculture, forestry and other land uses. This part of natural capital can therefore be considered as a component for which society has a particular 'duty of care' – it is fragile, and human actions have already negatively impacted much of it. However, with suitable management and care ecosystems are capable of delivering a sustainable flow of flow of ecosystem service benefits into the foreseeable future [9].

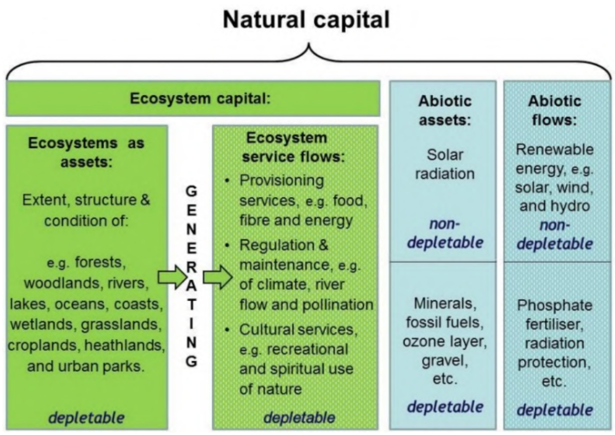

Fig. 1. Components of natural capital [9].

Strategy of natural capital preservation is defined by modern science as one of the most important functions of the state - fundamental component of the building process legal democratic state with developed market economy [10]. According to T.I. Pishenin, "Currently there are two approaches to solve the environmental problem. Globalist approach is based on the principle that developed countries with great potential can destroy the whole world, and therefore other countries to ensure environmental security. Most developed countries try to reap obvious globalization benefits. Current approach is based on recognizing of national safety priority reached through self-sufficiency through the by sustainable development of their own environmental safety of production. Existence of such approach is explained by the fact that in the modern world the main factor in making most important decisions are still nation-states. Therefore, acting on the world stage, each state cares primarily about their own interests" [11].

However, manifestations of Ukraine's conscious position on its environmental interests, clear strategy, and what is more importantly - appropriate actions since independence can not be traced as far as O. Palienko notes: "Ukraine is one of the most environmentally unreliable countries in Europe. The country's economy was formed without taking into account objective needs and interests of the population, while the protection of environmental measures was carried out on a residual basis. As a result, its economy is oversaturated with chemical, metallurgical and mining industries [10].

At the same time, it can not be said that our state did not have its own environmental policy at all. Thus, number of legislative and normative legal acts were adopted. The Law of Ukraine "On the Ecological Network of Ukraine" (2005) deserves special attention in the light of the chosen issues [12]. This Law regulates relations related to formation, preservation and rational, inexhaustible use of the ecological network. According to this law the ecological network is only territorial system formed to improve conditions for formation and restoration of environment, increase natural resource potential of Ukraine, preserve landscape and biological diversity, habitats and growth of valuable species of fauna and flora, genetic fund, ways of migration of animals through combination of territories and objects of the nature reserve fund. Also other territories with special value for environmental protection and are subject to special protection.

Development of science and technology due to formation and accumulation of intellectual capital allows more efficient use of natural capital- says O. Badrak. Along with emergence of new technologies that determine efficiency of natural resources in production processes there are previously unaccounted factors in the formation of gross national product. They still do not have a socio-economic status. Special role in this process belongs to economical use of natural resources in economic activity and environment protection from possible negative socio-environmental effects and risk prevention. It will contribute to collection of environmental rents and "green" taxes [13].

Concept of ecological network is manifestation of such environmental innovation aimed at more efficient use and preservation of natural capital. Structural elements of this network include:

• territories and objects of nature reserve fund;
• water fund lands, wetlands, water protection zones;
• forest lands;
• field protective forest strips and other protective plantings;
• health-improving lands;
• recreational lands;
• territories that are places of residence or growth of species of fauna and flora listed in the Red Book of Ukraine, etc. [12].

The legislator provided that inclusion of territories and objects in the list of territories and objects of ecological network does not lead to change in form of ownership and category of land for relevant land plots and other natural resources, their owner or user. At the same time the issue of ecological network management arises. Ukrainian researcher R. Miroshnichenko proposes to differentiate state regulation in the field of environmental safety on three levels. The first level according to researcher includes management of central public authorities of the state by a set of mechanisms. Their activities are aimed to monitor environmental situation in the country and nature of global impacts on it. Second are aimed at formation of socially adequate state policy on environmental safety management methods and ensuring effective functioning of mechanisms of public administration and state control over compliance by all authorities, institutions and organizations and individuals with current legislation [14].

In our opinion it is quite obvious to single out the third level - regional government; the fourth - level of local public authorities and self-governing institutions of territorial communities, civil society organizations and, finally, the fifth - level of specific economic entities and environmental facilities. It will comply with legal norms. It stipulates that public administration in the field of formation, preservation and use of the ecological network is carried out by:

• The Cabinet of Ministers of Ukraine;
• The Council of Ministers of the Autonomous Republic of Crimea,
• specially authorized central executive body for environmental protection, environmental safety, protected areas, as well as hydrometeorological activities and its territorial bodies;
• other central executive bodies;
• local executive bodies;
• local governments [13].

Numerous NGOs are also involved in this process. Formation, preservation and use of the eco-network is carried out according to the following basic principles:

a) ensuring of ecosystem functions integrity of components elements of ecological network;

b) conservation and environmentally sustainable use of natural resources on the territory of the ecological network;

c) stopping loss of natural and semi-natural areas (occupied by plant groups of natural origin and complexes changed in the process of human activity), expansion area of the ecological network;

d) state support providing, stimulating subjects of management when creating territories and objects on their lands nature reserve fund, other subject areas special protection, development of the ecological network;

https://doi.org/10.1051/e3sconf/202128009024

e) ensuring participation of citizens and their associations in the development of proposals and decisions on the formation, preservation and use of eco-network;

e) ensuring connection of the national eco-network with the eco-networks of neighboring countries that are members of the Pan-European Eco-network, comprehensive development of international cooperation in this field;

f) improving composition of the lands of Ukraine by providing scientific relationship between different categories of land;

g) systematic consideration of environmental, social and economic interests of society [12].

It should be noted that idea of the ecological network as an environmental technology arose in the 80s of last century. In 1993 Dutch experts proposed creation of European Ecological Network (EEN) at the international conference on the environment in Maastricht. The EEN program was a part of the Pan-European Strategy for the Conservation of Biological and Landscape Diversity, adopted in 1995 at the Conference of Ministers for the Environment of European countries in Sofia.

Structural elements of the EEM should be the so-called ecological nuclei, ecological corridors and buffer zones. Ecological nuclei are small, ecologically valuable and large in size. They usually have natural conservation status. Their main task is to preserve biological and landscape diversity in the reference natural areas, to help maintain the ecological balance in the region. Ecological cores should be interconnected by ecological corridors - strips or massifs of relatively unchanged, restored or artificially created natural landscapes. These can be river valleys, lakes, swamps, gullies, forests and strips, reclamation canals, etc. Buffer zones with regulated limited management are created in order to prevent negative impact of human economic activity on natural complexes.

Thus, from the above three structural components a kind of network is formed. It is more or less evenly covers the region. Such ecological network creates acceptable conditions for the preservation of biological and landscape diversity of a particular natural - territorial complex. The latest along with other environmental measures greatly contributes to maintaining sustainability of regional ecosystem. The ecological networks of individual states in particular the National Ecological Network of Ukraine are an integral part of the European ecological network. Its creation is provided by the Law of Ukraine "On the national program of formation of the ecological network of Ukraine for 2000-2015".

Scientists highlight following conditions for principles improving of state environmental policy and state regulation of environmental safety in Ukraine [14-29]:

• intensification of social factors use of environmental protection;

• formation of public opinion on building positive image of ecologically sustainable development of citizens in the state;

• carrying out measures to promote environmental activities among the population and positive attitude towards the environment;

• integration of regions and their ecological potential into single system with clear definition of development priorities;

• education of ecological thinking of citizens;

• application of the best international experience of developed countries of the world in combination with national features;

• creation of single methodological basis for the formation of normative indicators with their legislative consolidation;

• attraction of economic incentive instruments for preservation of natural capital (grants, bonuses, eco-grants, eco-credits, emissions trading, introduction of "green economy" instruments), etc.

Thus, concern for natural capital preservation of the Earth is increasingly coming to forefront of human civilization development of and its very existence. The first cosmonaut of Ukraine Leonid Kadenyuk was the most successful in this regard, noting: "It should finally be understood that environmental safety is an integral part of overall safety, prosperity and peace on Earth and prerequisite for sustainable development" [30].

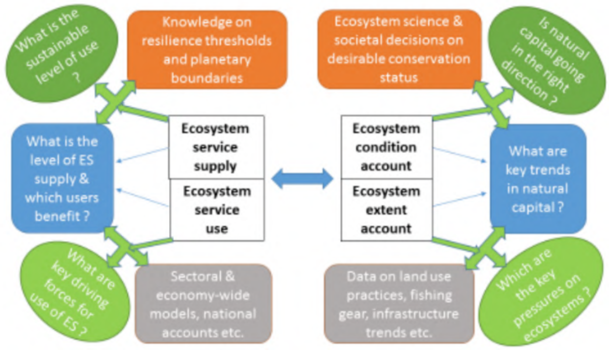

Fig. 2. A comprehensive knowledge framework for the management of natural capital [9].

Fig. 2 illustrates that various analytical tools need to be combined to enable the different analytical angles to manage natural capital in an integrated perspective via a range of policy instruments. Natural capital accounts remain central to the overall analytical approach but are complemented by other knowledge sources. A brief summary of the benefits and limitations of natural capital accounting brings up the following key points [9]:

Benefits of the ecosystem accounting developing:

• Better information flow on status and trends as for the ecosystems.

• More thorough approach to describe and to measure ecosystem services.

• More integrated support and perspective in understanding our links with natural capital.

• Underpins the analysis of environment with its links to economy.

• Helps in bringing consideration into ecosystem as a part of economic policy making.

Ecosystem accounting and its outputs are only positive as:

• Our ecological and modelling knowledge of ecosystem processes.

• Actual in-situ biodiversity monitoring data and other data input.

• Related tools and analysis that help translate it into policy decisions.

3 Conclusions

Conducted scientific research provides grounds for grouping principles of natural capital conservation by the following three components: biological (environmental), economic, organizational (managerial). Since the organic world on Earth consists of separate complex formations of different levels. Each formation has specific problems, so different levels of biological principles are identified. It is also proposed to include sustainability principle (ecological balance) anddevelopment of "green economy". Economic principles of natural capital conservation can be mandatory (licensing, taxation, payments) and incentives (grants, market assistance, bonuses, grants, insurance, etc.). Organizational principles are related to implementation of public administration mechanisms in the field of natural capital conservation.

Improving and applying methodology of natural capital conservation on the basis of the best foreign experience, taking into account national characteristics and the current regulatory framework will create an effective mechanism for natural capital conservation in Ukraine.

Abstract. Due to the growth of man-caused pollution, there is a need to use modern methods of water purification. It is advisable to use sorption methods for the extraction of heavy metals, which are considered to be particularly dangerous. It is established that sorbents based on magnetite are quite effective in the extraction of copper ions. It is shown that the sorption capacity of magnetite-based sorbents towards copper ions depends on the ratio of concentrations of Fe^{2+} and Fe^{3+} ions in the reaction mixture, and increases with increasing this indicator from 1/2 to 2. The sorption capacity of the sorbent towards copper ions increases by 4.4 times. It is shown that the efficiency of copper ions removal onto magnetite increases for sorbent modified with sodium sulfide. The proposed scheme provides the possibility of sorption treatment of large volumes of water from copper ions to the norms for the discharge of wastewater into fishery reservoirs. Post-productional magnetite is dehydrated and supplied to metallurgical enterprises for processing. The developed technology of water purification from copper ions is environmentally safe and energy efficient.

1 Introduction

The end of the XX and the beginning of the XXI century were marked by both scientific and technical achievements and a significant deterioration of the environment as a result of massive pollution. The state of the hydrosphere is becoming more and more worrying every year.

The problem of protection of hydro-ecosystems from pollution in Ukraine is especially acute, where, despite the decline in industrial production, the intensity of natural water pollution is growing [1–4].

The problem of pollution of water bodies with pollutants of various natures is now arising in many countries around the world. Heavy metals come to natural sources with effluents from various enterprises (galvanic, instrument-making and chemical industries, mining and processing plants and thermal power plants). A significant increase in the allowable discharges of heavy metal ions is observed in the discharges of nuclear power plants [5–9].

When discharging untreated or insufficiently treated galvanic effluents into rivers, lakes and other surface water bodies that contain a significant amount of heavy metals in their composition, enormous damage is caused to the environment: significant damage is caused to aquatic organisms and the ability of reservoirs to self-clean [10–17]. Some heavy metals are incapable of decomposition and accumulate in food chains.

Greening of processes for the introduction of low-waste methods is one of the key trends in the development of modern technologies. They are aimed at obtaining new highly selective, multifunctional materials to ensure environmental safety. Despite the presence of a large number of already known methods and techniques of synthesis, most of them occur with the participation of toxic reagents and are ineffective and dangerous to the environment. Traditional methods allow obtaining materials with the limited functional properties. This problem is becoming more important not only for Ukraine, but for the whole world [18–21].

The latest alternative types of multifunctional materials include nanomaterials and composite materials based on them, namely sorbents for water purification from organic impurities and heavy metals [22, 23].

Therefore, the development of methods for obtaining highly efficient sorbents, in order to ensure the rational use of natural resources in the application of new technologies, the progressive organization of low-waste and non-waste industries is extremely important.

Since heavy metals are priority contaminants, there is a need for modern methods that can provide high efficiency of purification from heavy metal ions [24–27].

When choosing a method of water purification, data on the volume of effluents, composition and content of impurities in them and technical and economic analysis were used [28, 29].

2 Analysis of previous studies

Extraction of copper ions from water with a high degree of purification, as well as the water purification from other heavy metals is quite difficult. Known methods of water purification from heavy metal ions are accompanied by the formation of toxic sludge, which is difficult to dispose of, or liquid waste, the processing of which requires significant costs. In addition, most of the known methods of water purification from heavy metal ions do not possess the necessary extraction efficiency. It is known that in fishery reservoirs, the maximum allowable concentration of copper ions reaches 1 μg/dm^3. Therefore, even when discharging relatively clean wastewater from power plants, where the content of copper ions reaches ~ 50 μg/dm^3, there is a risk of exceeding the maximum concentration limit in such reservoirs. However, most of the known methods of water purification from copper ions do not provide the required efficiency of water purification. The problem is complicated by large volumes of wastewater containing copper ions [30, 31].

Electrochemical methods are characterized as effective and advanced water purification technologies. Installations are quite compact and high-performative, while control and operation processes are simply automated. Electrochemical methods allow one to extract valuable components from effluents with a relatively simple automated technological scheme of treatment, often without the use of chemical reagents. The main disadvantage of these methods is the high cost of electricity [32–42].

Among the advantages of baromembrane methods are: low energy consumption, simplicity of construction of devices and installations, as well as their small size. The devices are easy to operate and consumed energy is mainly spent on creating high pressure over the solution. Disadvantages include the occurrence of the phenomenon of concentration polarization, which leads to a deterioration in the characteristics of membrane devices and the need for preliminary preparation of solutions [43–53].

Purification methods based on ion exchange using natural and synthetic materials are widely used. However, the main disadvantage of the ion exchange method is the need to supply to ion exchange units wastewater, pre-treated from suspended solids, cyanides, iron ions, petroleum products and other organic substances [54–57].

Sorption methods of wastewater treatment are highly efficient and are among the most environmentally friendly methods. The main criterion when choosing a material for wastewater treatment is its sorption properties, porous structure and efficiency. Therefore, the presented work is aimed at developing and improving methods of sorption purification of water from the heavy metals [58–62].

3 Results of the study

The aim of the work was to study the processes of copper ions extraction from water using sorbents based on magnetite, in order to determine the optimal conditions for modification of sorbents to achieve effective purification of water from copper ions to the maximum allowable concentration.

It is known that magnetite-based sorbents provide efficient extraction of heavy metal ions from water. They are quite effective in removing heavy metal ions in the presence of hardness ions [63]. Typically, magnetite obtained at a ratio of iron (II) and iron (III) ions in the reaction mixture of 1 : 2 is used, although it is known that with increasing iron (II) content, magnetite has a more amorphous structure, which should affect its sorption capacity. Therefore, magnetite was used in this work, at a ratio of Fe (II) / Fe (III) 1 : 2; 1 : 1 and 2 : 1. To increase the sorption capacity of magnetite, sodium sulfide was added at a concentration of 1 and 2 %.

When purifying water from copper ions when using sorbents based on magnetite, the sorption capacity of magnetite (K = 1 : 1) for copper is almost 10 % greater than when using magnetite obtained at K = 1 : 2.

The sorption capacity of magnetite increases with increasing ratio K = [Fe^{2+}] / [Fe^{3+}] in the range 1 : 2; 1 : 1 and 2 : 1. Thus, at K = 1 : 2 the sorption capacity of magnetite did not exceed 100 mg/g in the entire range of selected concentrations.

At K = 1 : 1, the sorption capacity of magnetite reached 108 mg/g for sorption from distilled water and 134 mg/g for sorption from tap water.

At K = 2, the sorption capacity of magnetite in both distilled and tap water exceeded 200 mg/g. This suggests that with increasing ratio K, magnetite has more amorphous structure, which causes an increase in its sorption capacity. In addition, it is obvious from the above data that calcium and magnesium ions are practically not sorbed on magnetite and therefore do not affect the sorption of copper ions. This is very important because with such properties of the sorbent it can be used to extract heavy metal ions from both natural and wastewater containing hardness ions. When using magnetite, only heavy metal ions are sorbed without removing hardness ions. When using cation exchange resins, hardness ions and heavy metal ions are sorbed together, and the ratio of the capacity of the cation exchange resin to hardness ions and heavy metal ions is close to the ratio of the concentrations of these cations in solution. And if we take into account that the concentrations of hardness ions in water are often tens of times higher than the concentrations of heavy metal ions, then it becomes clear that the use of ion exchange resins is appropriate only with deep softening of water. This approach is inappropriate when it comes to wastewater treatment.

To implement the method of sorption water purification, it is necessary to have detailed relationships between the main parameters of the process in optimal conditions. Therefore, the regression equations were calculated to illustrate the dependence of the sorption capacity of magnetite on the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions.

The calculation was based on a complete factor plan (CFP) type 2^2. The plan-matrix CFP 2^2 and the results of the experiment of the sorption capacity of magnetite from the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in distilled water are shown in table 1.

Table 1. Plan-matrix CFP 2^2 and the results of the study of the extraction of sorption extraction of copper ions from distilled water.

Planning matrix		Natural value of factors		Value of parameters
x_1	x_2	Ce, mg/m^3	К	a, mg/g
−1	−1	2.0	0.5	34.23
+1	−1	104.0	0.5	66.89
−1	+1	2.0	2.0	23.98
+1	+1	104.0	2.0	210.00

As a result of appropriate calculations and after checking the conformity of the study results, assessing the significance of the obtained coefficients and checking the regression equation for adequacy, the unknown dependence is as follows:

$$Y = 83.775 + 54.670 \cdot X_1 + 33.215 \cdot X_2 + 38.340 \cdot X_1 \cdot X_2 \quad (1)$$

After replacing the code values in the obtained equation with natural ones,

$$X_1 = (C_e - 53)/51 \quad (2)$$

$$X_2 = (K - 1.25)/0.75 \quad (3)$$

we obtained the following regression equation:

$$Y = 38.009 - 0.181 \cdot C_e - 8.808 \cdot K + 1.024 \cdot C_e \cdot K \quad (4)$$

The obtained dependence is presented in Fig. 1 in the form of a plane on which lies the solution of the given equation. The figure shows the dependence of the sorption capacity of magnetite on the ratio of Fe (II) / Fe (III) and the initial concentration of copper ions in distilled water.

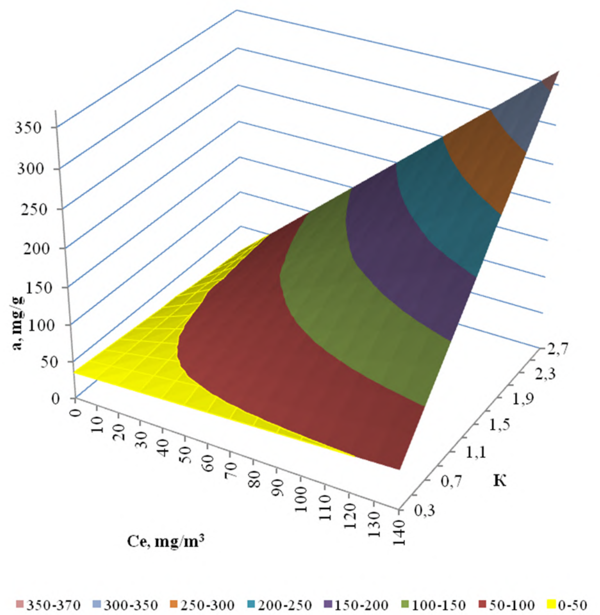

Fig. 1. Graphical representation of the results of CFP type 2^2 dependence of the sorption capacity of magnetite on the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in distilled water.

The analysis of the presented graphs shows that the experimental points that were used in the calculation of the regression equation are on the constructed plane of solutions, which indicates the adequacy of the equation used. Using the data of the regression equation, it is quite easy to calculate the optimal ratio of Fe (II) / Fe (III) for effective purification of the solution from copper ions.

If we look at Fig. 1, we can say that in this case the mechanism of activated adsorption takes place. The reason for this is that the copper ions are included in the crystal lattice of magnetite. At low concentrations of copper at K = 1: 1 and 2: 1, almost complete extraction of copper is observed, which can be explained by this mechanism of sorption. In this case, heavy metal ions are practically not desorbed from magnetite without acid treatment and destruction of the structure of the sorbent.

Regression equations were calculated for the dependence of the sorption capacity of magnetite on the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in tap water.

Plan-matrix CFP 2^2 and the results of the experiment of sorption capacity of magnetite from the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in tap water are shown in table 2.

Table 2. Plan-matrix CFP 2^2 and the results of the study of sorption extraction of copper from tap water.

Planning matrix		Natural value of factors		Value of parameters
x_1	x_2	Ce, mg/m^3	К	a, mg/g
−1	−1	2.0	0.5	44.1
+1	−1	104.0	0.5	70.0
−1	+1	2.0	2.0	36.0
+1	+1	104.0	2.0	219.0

As a result of appropriate calculations and after checking the conformity of the study results, assessing the significance of the obtained coefficients and checking the regression equation for adequacy, the unknown dependence is as follows:

$$Y = 92{,}275 + 52{,}225 \cdot X_1 + 35{,}225 \cdot X_2 + 39{,}275 \cdot X_1 \cdot X_2 \quad (5)$$

After replacing the code values in the obtained equation with natural ones,

$$X_1 = (C_e - 53)/51 \quad (6)$$

$$X_2 = (K - 1.25)/0.75 \quad (7)$$

we obtained the following regression equation:

$$Y = 47.319 - 0.2595 \cdot C_e - 7.4536 \cdot K + 1.0268 \cdot C_e \cdot K \quad (8)$$

The obtained dependence is presented in Fig. 2 in the form of a plane on which lies the solution of the given equation. The figure shows the dependence of the sorption capacity of magnetite on the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in tap water.

Increasing the sorption capacity of magnetite towards copper with increasing the ratio of K from 1 : 2 to 2 : 1 in addition to the positive value has significant disadvantages. First of all, magnetite obtained at K = 1 : 2 has the highest magnetic characteristics, which simplifies its separation from water, has the highest sludge density and the highest chemical resistance, because it has a

 https://doi.org/10.1051/e3sconf/202128010001

crystalline structure. As the value of K increases, the contribution of amorphous elements to magnetite increases, which impairs its magnetic properties, reduces chemical resistance and leads to an increase in the volume of sediment due to a decrease in its density. Therefore, to increase the sorption capacity of magnetite obtained at a ratio of K = 1 : 2 in the process of its synthesis was modified with sodium sulfide. These substance, which is partially included in the structure of magnetite, contain functional groups Me = S, which are able to form complex bonds with heavy metal ions (with d-metals), do not interact with hardness ions and are able to increase the sorption capacity of magnetite. The results shown in Fig. 3 confirm this assumption. Modified forms of magnetite are dominated by unmodified magnetite, when copper ions are sorbed from tap water. Similar results are observed in the extraction of copper from distilled water. The equilibrium adsorption increases during the transition from unmodified magnetite to magnetite modified with sodium sulfide. Sodium sulfide provides the value of the limiting adsorption at the range of 332–388 mg/g, and is also a very affordable and cheap reagent and quite resistant to hydrolysis in alkali solutions.

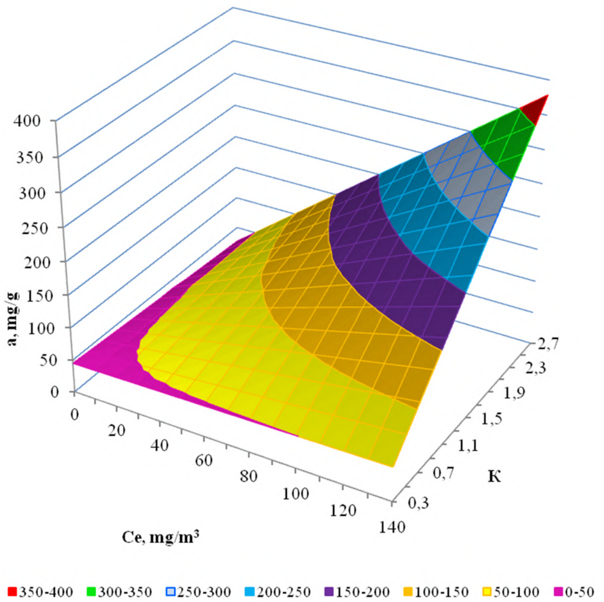

Fig. 2. Graphical representation of the results of CFP type 2^2 sorption capacity of magnetite from the ratio of Fe (II) / Fe (III) and the equilibrium concentration of copper ions in tap water.

Regression equations for the dependence of the sorption capacity of magnetite on the equilibrium concentration of copper ions in tap water and the concentration of sodium sulfide were calculated.

Plan-matrix CFP 2^2 and the results of the experiment of the sorption capacity of magnetite from the equilibrium concentration of copper ions in tap water and the concentration of sodium sulfide are shown in table 3.

As a result of appropriate calculations and after checking the conformity of the study results, assessing the significance of the obtained coefficients and checking the regression equation for adequacy, the unknown dependence is as follows:

$$Y = 164.5525 + 98.6475 \cdot X_1 + 24.9475 \cdot X_2 + 43.852 \cdot X_1 \cdot X_2 \quad (9)$$

Table 3. Plan-matrix CFP 2^2 and the results of the study of the extraction of copper from tap water using magnetite modified with sodium sulfide.

Planning matrix		**Natural value of factors**		**Value of parameters**

−1	+1	1.0	2.0	47.0
+1	+1	250.	2.0	332.0

After replacing the code values in the obtained equation with natural ones,

$$X_1 = (C_e - 125.5)/124.5 \quad (10)$$

$$X_2 = (C\ (Na_2S) - 1.5)/0.5 \quad (11)$$

we obtained the following regression equation:

$$Y = 122.884 - 0.26434 \cdot C_e - 38.5145 \cdot C\ (Na_2S) + 0.70446 \cdot C_e \cdot C\ (Na_2S) \quad (12)$$

The obtained dependence is presented in Fig. 3 in the form of a plane on which lies the solution of the given equation. The figure shows the dependence of the sorption capacity of magnetite on the equilibrium concentration of copper ions in tap water and the concentration of sodium sulfide used to modify the sorbent.

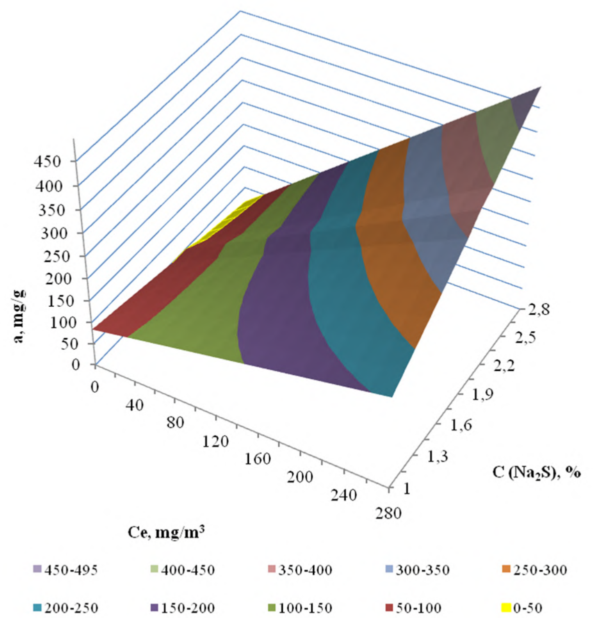

Fig. 3. Graphical representation of the results of CFP type 2^2 sorption capacity of magnetite from the equilibrium concentration of copper ions in tap water and the concentration of sodium sulfide used to modify the sorbent.

The research was conducted to determine the effectiveness of the developed sorbents depending on the ratio of the amount of sorbent and the volume of the solution. It was taken into account that the main problem is the extraction of copper ions from dilute solutions. Therefore, sorption was performed at doses of magnetite

500–10000 mg/dm^3. When sorbing copper from solutions with copper concentrations of 10 and 50 mg/dm^3, the sorption capacity of the sorbent increases with increasing dose of adsorbent. Higher values of adsorption were observed for magnetite at K = 2. Sorption increases during the transition from unmodified magnetite to magnetite modified with sodium sulfide. In the case of using magnetite modified with sodium sulfide, the sorption capacity only slightly depends on the ratio of K.

Modification of magnetite with sodium sulfide significantly affects the equilibrium concentrations of copper in purified water. When using unmodified magnetite at K = 1/2, the equilibrium concentrations of copper reach values of 2.0 – 6.7 mg/dm^3 and only at a dose of magnetite 10 g/dm^3 the equilibrium concentration decreased to 0.55 mg/dm^3. At a ratio of K = 2 at doses of magnetite 2.5 – 10.0 g/dm^3 at an initial copper concentration of 10 mg/dm^3, the equilibrium concentrations were in the range of 0.00 – 0.75 mg/dm^3. But at lower doses of magnetite, they still increased to 2 – 5mg/dm^3. When using magnetite modified Na_2S at K = 1/2 equilibrium concentrations of copper at an initial concentration of 10 mg/dm^3 decreased to 0.08 – 0.28 mg/dm^3 at all used doses of magnetite, and at K = 2 they were generally at the level of 0.0 – 0.1 mg/dm^3. Even at an initial copper concentration of 50 mg/dm^3 using modified magnetite (K = 2) at doses from 1.25 to 10 mg/dm^3, the equilibrium concentrations were at the level of 0.00 – 0.12 mg/dm^3.

4 Economic justification

In this case, we can say that modified with sodium sulfide magnetite is a fairly affordable synthetic inorganic sorbent with high efficiency for copper ions.

Given the high quality requirements for water purification from heavy metal ions, especially when discharging them into fishery reservoirs or when preparing drinking water, it was interesting to determine the minimum concentrations that can be achieved when using magnetite-based sorbents. When using magnetite modified with sodium sulfide, the concentration of copper was reduced to 5.44 μg / dm^3 at K = 1 : 2 (table 4, 5).

Table 4. Dependence of the efficiency of extraction of copper ions from tap water on the ratio [Fe^{2+} / Fe^{3+}] in magnetite, without modification with sodium sulfide.

Fe^{2+}/ Fe^{3+}	C Cu^{2+}, mg/dm^3		a, mg/g	Degree of extraction
	initial	Equilibrium		
1:2	10.00	0.7500	6.3000	92.50
1:1	10.00	0.1500	7.3888	98.50
2:1	2.00	0.0166	1.4875	99.17

When using sulfide-modified magnetite obtained at K = 2, and the copper concentration was reduced to 1.2 μg / dm^3.

Waste should be disposed of as part of building materials. Dehydrated waste of spent magnetite can be used as a thermal additive in the manufacturing of various heat-resistant materials.

Table 5. Dependence of the efficiency of extraction of copper ions from tap water on the ratio [Fe^{2+} / Fe^{3+}] in magnetite when modified with sodium sulfide

Fe^{2+} / Fe^{3+}	Na_2S, %	C Cu^{2+}, mg/dm^3		a, mg/g	Degree of extraction
		Initial	Equilibrium		
1:2	1	1.63	0.00540	1.0292	99.67
1:2	2	1.63	0.04688	0.9960	97.12
1:1	2	10.0	0.05600	7.4580	99.44
2:1	2	2.0	0.00120	1.4991	99.94

5 Conclusions

The application of modified sorbent based on magnetite for water purification from copper ions is the promising direction of sorption technologies, which allows to increase the efficiency of the process. When using modified sorbents based on magnetite, it is possible to reduce the concentration of copper to μg dm^3. Given the high capacity of the sorbent on copper ions, it will be possible to implement low-waste technology of water purification from heavy metals during its use.

The use of modified magnetite is a cost-effective way to purify water from heavy metals. The spent sorbent is utilized at the metallurgical enterprises.

Based on the complete factor plan, a regression equation is obtained, it has a linear character, which allows to optimize the calculation of the magnetite dose for efficient extraction of copper ions from aqueous solutions.

Given the constant increase in the concentration of hazardous pollutants in water bodies, the next step will be the development and implementation of methods for extracting a mixture of heavy metals from water and developing a mathematical model of the process to find optimal desalination parameters.

Abstract. Water is a renewable natural resource, but vulnerable and limited in terms of quantity and quality, which is why its exploitation must be done rationally, so as to ensure a complex recovery and a balanced distribution, depending on needs. The water management activity, which has as object the establishment and application of measures for rational use and control of water resources, quantitative and qualitative, is closely related to meeting the requirements of current legislation on exploitation and protection of water and aquatic ecosystems. In this context, the present paper presents a study carried out during 2019, having as the main objective the qualitative characterization of the Jiu River on the administrative territory of Dolj County (Romania). For this purpose, several water sampling campaigns (12, one for each month) from three control sections, established in partnership with the Jiu - Craiova Water Basin Administration, were carried out. The collected samples were analyzed in the analytical laboratory of the same institution and, on the basis of the obtained results, also considering the main existing sources of pollution, conclusions were drawn regarding the Jiu River water quality in the analyzed sector. Also, we applied an alternative control method whose purpose was to validate the initial conclusions.

1 Introduction

The central objective of the European Water Framework Directive is to achieve a "good status" for all bodies of water, both surface and underground, with the exception of heavily modified and artificial bodies, for which the goal is to achieve a "good ecological potential" [1]. Based on the principles contained in this directive, at the level of the Jiu - Craiova Water Basin Administration, a management plan is under development, a plan that has to solve the main problems related to water management, both quantitatively and qualitatively. Water management must provide solutions to ensure the current and future water needs of the population and the economy, starting from the renewable but limiting nature of freshwater resources [2].

For the sustainable management of water resources, the international community recommends that governments apply the following principles [3-5]:

1. The basin principle. Water resources are formed and managed on river basins. Rational management of water resources requires a global approach, combining social issues and economic development with the protection of natural ecosystems. Sustainable management of water resources can only be achieved at the level of the entire river basin, by taking into account all water users.
2. The principle of unitary quantity-quality management. The two sides of water management being in a close connection, it appears necessary a unitary approach, leading to optimal technical and economic solutions for both aspects.
3. The principle of solidarity. Planning and development of water resources requires the collaboration of all factors involved in the water sector: the state, local communities, users, water households, etc.
4. The "polluter pays" principle. All expenses related to water and environmental pollution, implicitly those of removing the effects and restoring the previous conditions, are borne by the one who produced the pollution.
5. The economic principle “the beneficiary pays”. Water has an economic value in all its forms of uses and must be recognized as an economic good. Managing water as an economic good is an important way to achieve efficient and equitable exploitation and to preserve and protect water resources.

These principles underpin the concept of integrated water management, which combines the problems of water use with those of protection of natural ecosystems [5].

Sustainable management of water resources, especially from a qualitative point of view, takes into account a number of objectives [3, 4], among which we mention:

- Ensuring the continuous supply of water with adequate quality of uses and, in particular, of the population requirements;
- Refurbishment of production processes by using clean, non-polluting technologies;
- Construction of new treatment plants and modernization of existing ones, in order to reduce pollutants discharged into surface waters and/or groundwater;

* Corresponding author: izabelamaria.nyari@yahoo.com

https://doi.org/10.1051/e3sconf/202128010002

- Elaboration of a normative framework necessary for the creation of hydrological and hydrogeological reserves, in order to protect vulnerable basins and aquifers;
- Implementation of methods and means to prevent, limit and reduce the effects of accidental pollution;
- Improving education for a clean aquatic environment;
- Improvement and creation of habitats corresponding to biodiversity conservation;
- Ensuring appropriate flows on watercourses, in order to protect aquatic ecosystems;
- Ensuring the continuity of the flow on the watercourses, in order to facilitate the migration of the fish species.

2 Description of the studied area

Jiu H.B. (hydrographic basin) has a length of approx. 260 km and an average width at the top of approx. 60 km and approx. 20 km at the bottom (figure 1).

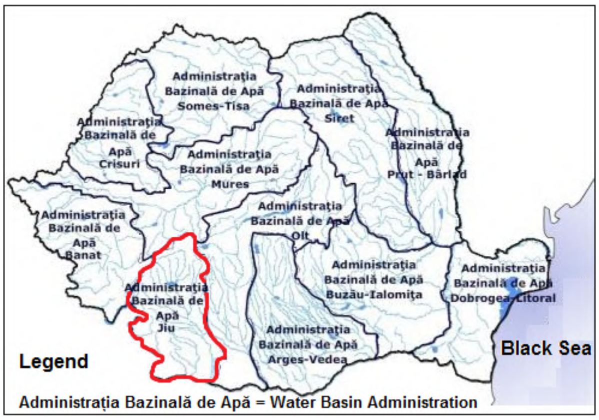

Fig. 1. Delimitation of hydrographic basins in Romania [6].

A feature of Jiu H.B. is the elongated form. The hydrographic network has a length of 3,876 km and a density of 0.34 km/km^2 [7].

The average altitude of the Jiu H.B. varies between 1,649 m in the northern area and 24.1 m in the confluence area. The average slope of the basin is of 5‰ [8].

On the right side, Jiu River, receives 31 tributaries (of which the most important: Tismana, Jilț, Motru and Raznic), while from the left side it receives 21 tributaries (of which the most important: Sadu, Cioiana, Gilort and Amaradia) [9].

The complex geological composition and the differentiated action of the climatic factors contributed to the formation of a wide variety of relief forms: mountains, hills, plains and swamps. These units are distributed in broad areas whose altitude declines from north to south (figure 2).

In relation to the altitude, more than 21% of the area, namely the northern and the northwestern parts, are occupied by mountain areas. The hills, belonging to the Getic Plateau and the Mehedinţi Plateau, occupy about 47%, the plain area being of over 32% [2].

The mountainous region has different characters due to the complex geological and lithological structure and determines a proper distribution of all elements of the natural environment (climate, vegetation, soils, etc.)

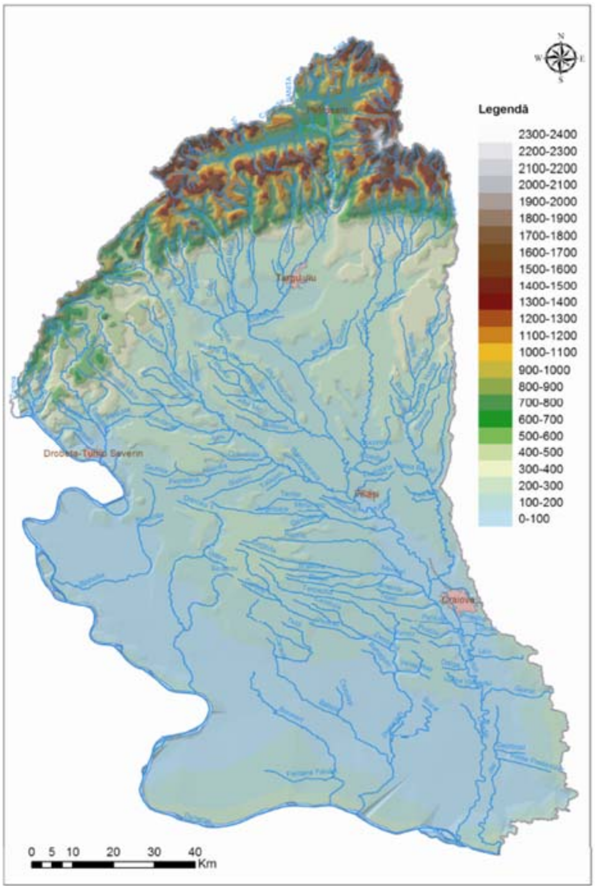

Fig. 2. Morphology of Jiu H.B. [7].

Subcarpathian depression includes:
- The depression of Celei - Novaci;
- Subcarpathian hills;
- Intercolinary depression Câlnic - Tg. Jiu - Câmpu Mare - Tg. Cărbuneşti;
- The piedmont hills in the south.

The piedmont area is represented by the Mehedinţi Plateau, located immediately in the south-east of Mehedinţi Mountains and represents a geographical individuality, although it is an organic continuation of the respective mountains.

The Getic Plateau is a large morphological unit extending south of the sub-Carpathian area up to the northern limit of the plain.

Oltenia Plain as a morphological subunit of the Romanian Plain is located in the south and southwest of the analyzed area, being delimited by the Danube and Olt rivers. As genesis and evolution, the Oltenia Plain is exclusively a creation of the Danube, the predominant forms of the relief being represented by the Danube meadow and terraces, the Jiu valley, to which the plain is added and, as a specific note, the relief of dunes.

The geological deposits that appear at the surface are of Miocene, Pliocene and Quaternary age, predominant being the siliceous type of rocks. The limestone rocks appear on limited areas, in the mountainous area, as well as in the northern part of the Bahna and Topolnița sub-basins.

 https://doi.org/10.1051/e3sconf/202128010002

3 Material and methods

3.1 Pollution sources

In line with the Water Framework Directive, significant pressures are considered to be those that result in the failure to meet environmental objectives for the studied water body. Depending on how the body of water is operating, we can know if a pressure can cause an impact [10, 11]. Thus, in the present study, 4 major categories of problems were identified: pollution with organic substances, pollution with nutrients, pollution with priority and/or dangerous substances and hydromorphological alterations, described below:

Point sources of significant pollution

1. Urban pollution sources/human agglomerations

Urban wastewater contains, in particular, suspended matter, organic substances, nutrients, but also other pollutants such as heavy metals, detergents, petroleum hydrocarbons, organic micropollutants, etc. [2].

The industrial wastewaters similar to those from urban sources, contains the same pollutants but in different proportions, depending on the types of industry, as well as the pre-treatment level of the industrial waters collected in the sewer system (figure 3).

In terms of pollutants releases into surface water resources, table 1 show the monitored average quantities.

The organic substances are expressed as CCO - Cr and CBO_5, while the nutrients as total nitrogen and total phosphorus (data between 2014 and 2017 per categories of agglomerations).

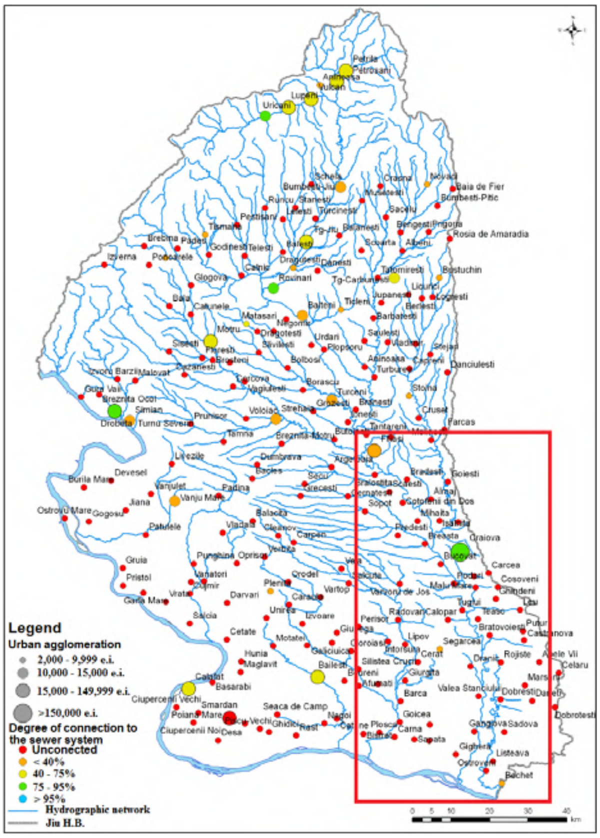

Fig. 3. Urban point sources of pollution (domestic and similar wastewaters) [7] (modified).

Table 1. Average discharges of organic substances and nutrients from human agglomerations into Jiu River [7].

Number of inhabitants (equivalent inhabitants)	Organic substances (CCO-Cr)	Organic substances (CBO_5)	N total	P total
	t/year	t/year	t/year	t/year
>100.000	8061.424	3428.233	1836.405	868.688
10.000 – 100.000	1166.029	569.761	217.800	18.318
2.000 – 10.000	63.298	38.247	14.801	1.494
<2.000	-	-	-	-
Total	9290.751	4036.241	2069.006	888.500

2. Sources of industrial and agricultural pollution

Sources of industrial and agricultural pollution contribute to the degradation of water resources by evacuating pollutants specific to the type of activity carried out (organic substances and nutrients: food industry, chemical industry, fertilizer industry, pulp and paper, livestock farms, etc.; heavy metals: extractive and processing industries, chemical industry, etc.; dangerous organic micropollutants: organic chemical industry, petroleum industry, etc.) [7] (figure 4).

The most important and significant point sources of industrial and agricultural pollution identified in the studied area are:

- C.S. Craiova Energetic Complex - Işalniţa Electric Power Plant;
- C.S. Craiova Energetic Complex - Craiova II Electrocentrale Branch;
- C.S. Automotive Subassemblies Craiova S.A.;
- C.S. Eco Sud Ltd.;
- C.S. Zahărul S.A. Podari;
- Petrom S.A. - Member of OMV Group. Petrom Craiova - DOLJCHIM Craiova;
- Leamna Pneumoftiziology Hospital;
- C.S. FELVIO Ltd. Bucovăţ (chicken intensive growth);
- A.N.P.- Pelendava Craiova Penitentiary (agriculture, zootechny, meat and milk processing);
- C.S. GIM CO Ltd. (chicken intensive growth);
- Sadova Socio – medical Facility;

In terms of releases of pollutants into surface water resources, table 2 shows the monitored average quantities of organic substances (expressed as CCO-Cr and CBO_5) and nutrients (total nitrogen and total phosphorus) between 2014 and 2017 per categories of pollution sources. Table 3 also shows the same situation, given the quantities of heavy metals measured and monitored.

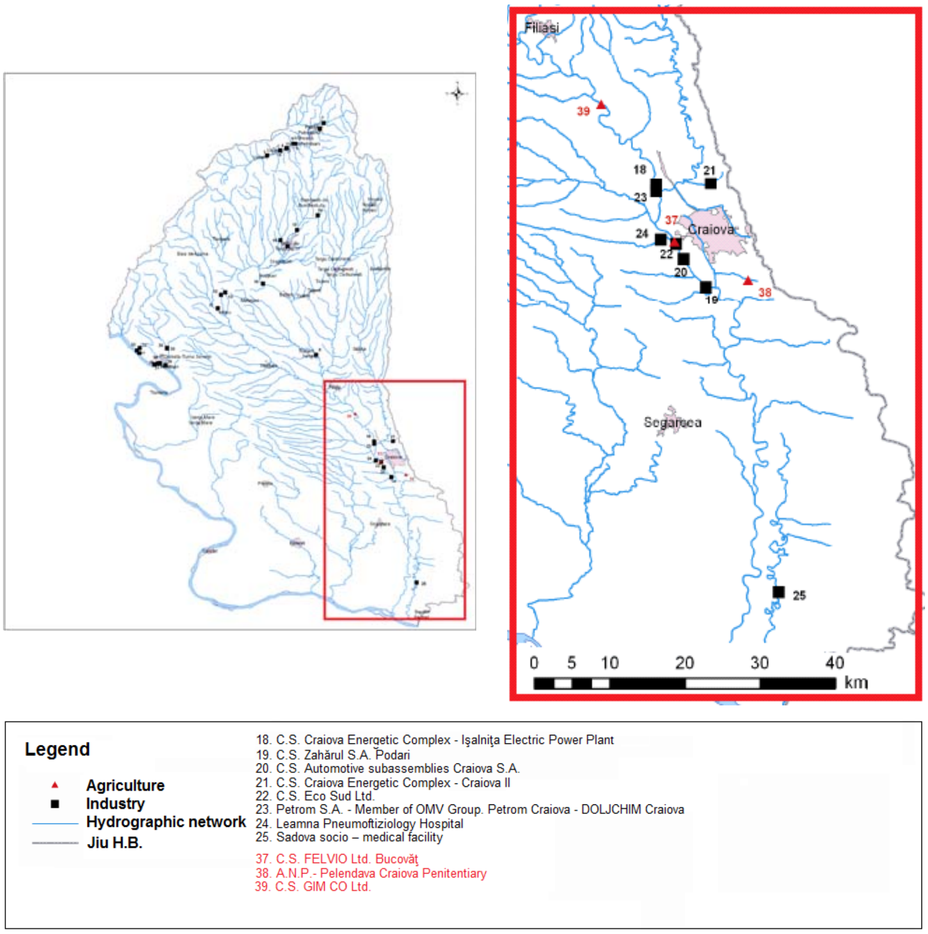

Fig. 4. Industrial and agricultural point sources of pollution [7] (modified).

*IPPC – Industrial activities as defined by the Integrated Pollution Prevention and Control Directive [12]

Significant diffuse sources of pollution

The way of using the land within the hydrographic space afferent to the Jiu Waters Administration is influenced by the physical-geographical conditions, as well as by the anthropic factors (figure 5) and, in turn, it influences the types and quantities of diffuse pollutants that reach the Jiu River waters.

Predominant in Jiu H.B. are arable lands (48.96%), the forests being representative for 28.74% of the surface of the river basin [8]. Agricultural lands are predominant in the river basins of the most important direct tributaries (54.12%). Perennial crops have a relatively uniform development, occupying 5.16%. The other areas occupy much smaller areas. Thus the water tables occupy only 1.0% [7].

The main categories of sources of diffuse pollution are represented by [2]:

1. Human agglomerations/localities that do not have wastewater collection systems or adequate systems for collecting and removing sludge from sewage treatment plants as well as localities with non-compliant household waste dumps.

2. Agriculture - agrozootechnical farms that do not have adequate manure storage/utilization systems, communes identified as vulnerable or potentially vulnerable to pollution by nitrates from agricultural sources, pesticide units that do not comply with the legislation in force, other units/agricultural activities that can lead to significant diffuse emissions.

The specific quantities of chemical fertilizers (expressed in active substance) used in 2016 were about 10% higher than the situation in 2012, when at the level of Jiu hydrographic basin there were used average quantities of approx. 6.910 kg N/ha of agricultural land, respectively 1.410 kg P/ha of agricultural land. In contrast, in 2016, compared with 2012, the specific quantities of natural fertilizers used decreased by approx. 10% [7].

3. Industry - warehouses of raw materials, finished products, auxiliary products, non-compliant waste storage, units producing diffuse accidental pollution, abandoned industrial sites.

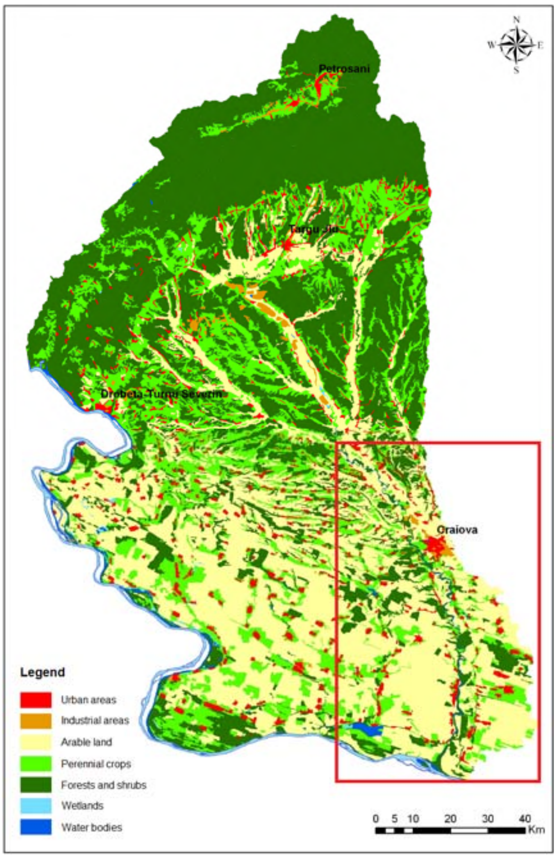

Fig. 5. Diffuse sources of pollution depending on the type of land use [7] (modified).

3.2 Establishing the control and sampling sections

Water samples were collected between January and December 2019, according to SR ISO 5667-6/2014 Water quality. Sampling Part 6: Guide for sampling of rivers and streams [13] (figure 6).

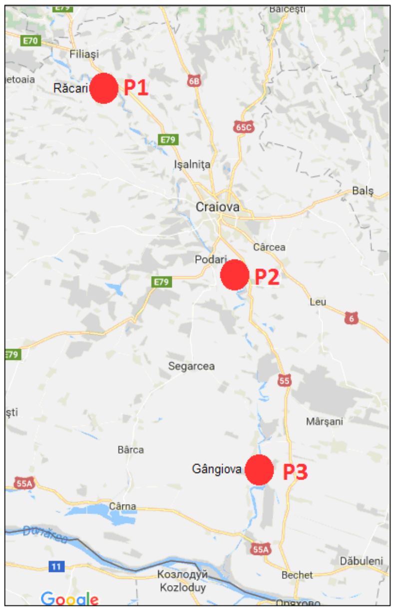

Fig. 6. Location of the sampling sections [15] (modified).

Establishing sampling locations has been done to allow for a comparative analysis. Sampling points can be located using fixed landmarks or GPS. Sampling points were clearly marked to avoid any confusion [2].

In establishing the sampling points the legal methodology was considered [14], as well as the location of the most important points in which untreated waste waters are discharged into the Jiu River on the territory of Dolj County.

For the collected of samples to be analyzed, in order to determine the quality of Jiu River in Dolj County, three control sections were established together with the Romanian Waters Administration (figure 6):

P1 - in Răcari de Jos village - downstream of Filiaşi, at the entrance to Dolj County;

P2 - in Podari village - downstream of Craiova City;

P3 - in Gângiova village - approx. 15 km upstream of the confluence with the Danube.

The collected water samples were transported to the authorized laboratory of the Romanian Water Administration - Craiova where the analyses were carried out according to the norms in force, the results of which are presented in the following paragraph.

3.3 Quality classes of surface waters

The surface water classification is based on the results of water quality monitoring and provides for a surface water classification a system divided in five quality classes defined by Order 161/2006 [16]:

Class I (very good) - surface waters where there are no (or very low) alterations in the physical-chemical and biological quality values. Concentrations of synthetic pollutants do not affect the functioning of aquatic ecosystems and do not harm human health. Surface waters corresponding to Class I can be designed for all types of use. Graphic representation uses blue color [16].

https://doi.org/10.1051/e3sconf/202128010002

Class II (good) - surface waters that have been affected to some extent by human activity, but nevertheless ensure all uses in an appropriate manner. The functioning of aquatic ecosystems is not affected. Simple methods of treatment are sufficient to prepare drinking water. Graphic representation uses green color [16].

Class III (polluted) - surface waters whose high quality physical-chemical and biological values deviate moderately from the natural water quality background due to human activities. There are moderate signs of disturbance of the functioning of the ecosystem. The necessary conditions for the *Salmonidae* family can no longer be ensured. Simple treatment is not sufficient for the use of drinking water for normal treatment methods. Graphical representation uses yellow color [16].

Class IV (polluted) - surface waters that show evidence of major alterations in physical-chemical and biological quality values from the natural water quality background due to human activities. The conditions for the *Cyprinidae* family can no longer be assured and do not meet the requirements for drinking water without applying advanced treatment methods. Graphic representation uses orange color [16].

Class V (very polluted) - surface waters that show evidence of major alterations in physical-chemical and biological values from the natural water quality fund due to human activities. Biological components, especially fish, are damaged and water can not be used for drinking purposes. Graphic representation uses red color [16].

From the ecological point of view, the five qualities are the following:

- Class I quality - very good ecological status;
- Class II quality - good ecological status;
- Class III quality - moderate ecological status;
- Class IV quality - poor ecological status;
- Class V – very poor ecological status.

Table 4 presents the maximum admitted concentrations (M.A.C.) of pollutants and the quality class in which surface waters fall into according to these concentrations [16].

Table 4. Quality classes according to Order 161/2006 (extract).

MU – measuring unit; ns - not standardized.

4 Results and discussions

4.1 Water quality of Jiu River in 2019

In order to assess the Jiu River water quality in Dolj County, we have performed a comparative analysis of the characteristic quality parameters for the three sampling points (P1, P2 and P3) presented in tables 5 - 7.

The analyses regarding the water quality of the Jiu River were performed by the qualified personnel of Jiu – Craiova Water Basin Administration.

In a previous study, conducted in May 2017 [2], it was found that the quality of Jiu River in Dolj County is medium (moderate ecological status).

Analyzing the data presented in tables 5 – 7, several conclusions can be drawn:

- The dissolved oxygen shows values which are consistent to the first class of quality except for two determinations made in P2 and P3 in July. Thus, the degree of saturation in P1 is of 82.45%, which also qualifies Jiu River in the first quality class. This parameter is affected, by a decrease in value, so at point P3 the value reaches only 75.96%. This evolution is due to the organic pollutant load added between the sampling sections;
- CBO_5 is a parameter in correlation with dissolved oxygen (its evolution is in the opposite direction). At sampling section P1 we have low average oxygen biochemical consumption (5.73 mg/l), which increases in P2 to 6.14 mg/l and in P3 to 6.34 mg/l. The determined values place Jiu River in the third class of quality, a moderate ecological state;

- The chemical oxygen consumption puts Jiu River in the second category of quality, except for March when, in P2 and P3, it falls into the third category;
- The pH value falls within the range of variations characteristic to natural water courses, with a slightly basic character that can be explained by the intake of waters rich in carbonates;
- The temperature of Jiu River varies between 3 and 21ºC (lowest in February at P1, Răcari and P2, Podari, respectively, highest in June and July at P3, Gângiova). This variation is normal, and it is attributed to the influence of air temperature as can be seen from the tables. We do not consider that the discharge of waters with slightly higher temperature from the two power plants (Ișalnița and Craiova II Electric Power Plants) have a significant influence on the overall temperature of the river. We can also observe a small increase in temperature for each individual month from P1 towards P3. However this increase is also attributed to the increase of air temperature in between sampling;
- The nitrates concentration suffers a negative change (the average concentration rising from 0.63 mg/l in P1 to 1.14 mg/l in P3), suggesting that sewage discharges occur between the analysis sections (or wastewaters from zootechnical farms);
- The nitrites concentration suffers a negative change. The average concentration places Jiu River in the first quality class in P1 and in the second class in P2 and P3 (it increases from 0.008 mg/l in P1, to 0.014 mg/l, reaching 0.027 mg/l in P3). This evolution confirms that discharges of sewage and zootechnical wastewaters occur between the sampling sections;
- The evolution of the total nitrite concentration follows the same pattern as the concentrations of nitrates and nitrites (from an average of 0.92 mg/l in P1, corresponding to the first quality class, up to 1.87 mg/l in P3, corresponding to the second quality class);
- The average phosphate concentration increases between P1 (from 0.047 mg/l – first quality class) and the next two sampling sections (up to 0.062 mg/l in P2 and 0.159 mg/l in P3), corresponding to the second class of quality;
- The average total phosphorus content also increases from P1 towards P3. In the first two sampling sections the average concentrations (of 0.060 mg/l in P1 and 0.074 mg/l in P2) places Jiu River in the first quality class, while for the third sampling section, with a average concentration of 0.225 mg/l, Jiu River falls into the third quality class.
- Turbidity evolution is influenced in turn by domestic wastewater spillage and due to the high hydraulic stability of the suspended particles, favored by the predominantly laminar flow regime.
- The concentration of total dissolved salts (determined by the conductivity) is similar in evolution (increases in P3 compared to P1), appreciating that this is achieved mainly by the intake of wastewaters with higher content of salts.
- From the point of view of fecal coliforms, Jiu River falls into the second category of quality, having a good ecological status;

- For the rest of the analyzed parameters Jiu River falls into the first quality class.

As a general conclusion, considering the water quality of Jiu River in the analyzed sections, in terms of the determined values of the selected parameters compared with those listed in Order 161/2006, and taking into account the recommendations from it, we can say that the wastewater generated by industrial, agricultural and household activities and which are discharged directly into it, have a negative influence. However, the quality of Jiu River does not suffer a significant worsening, falling into the third category in all three control sections.

4.2 Control method

Another way of assessing the quality of Jiu River water for the three control sections is based on the calculation of the Water Quality Index (WQI).

The WQI was conceptually defined in the early 1970's by the US National Sanitation Foundation (NSF) to compare water quality from different water sources and to monitor water quality variations over time. For this purpose, 142 experts carried out 25 different tests and selected 9 indicators, with the main objective of aggregating individual indicators (expressed in physical units) into a single water quality index (on a conventional scale 0 - 100) [17]. The steps to achieve the set goal were as follows:

- Translating each of the 9 indicators into a quality index;
- Performing a weighted average of the obtained values.

This method involves the interpolation of the result of the water quality parameters analysis with a series of predefined curves (shown in the literature) to obtain the value of Q indicators, after which to the Qi values will be assigned a given weight Wi, and the quality index is calculated by the formula WQI = ΣQiWi [18, 19].

For each sample a table is produced with all the results for the water quality parameters, and then using the scale of quality (table 8) we determine the quality of the water according to the calculated score [20, 21].

Table 8. Quality scale for WQI [17] (modified).

Points	Quality	Category	Correspondence with Ord. 161/2006
91 - 100	excellent	A	I
71 - 90	good	B	II
51 - 70	medium	C	III
26 - 50	poor	D	IV
0 - 25	very poor	E	V

Table 9 presents the data which are at the base on the calculation of the water quality index for the three control sections considered on the Jiu River, and table 10 presents the values determined for Q in order to characterize its quality in Dolj County (for the three control sections). As can be seen, for the calculation of the water quality index additional analyzes were performed for the determination of fecal coliforms, turbidity and dissolved solids.

Table 9. Indicators required for WQI calculation (average values)

No.	Indicator	UM	Sampling section		
			Răcari	Podari	Gângiova
1	Dissolved oxygen	%	82.45	82.41	75.96
2	Fecal coliforms	colonies/100ml	180	268	280
3	CBO_5	mg/l	5.73	6.14	6.34
4	pH		7.84	7.89	7.85
5	Nitrates	mg/l	0.63	1.00	1.14
6	Temperature	ºC	17	17	17
7	Total phosphates	mg/l	0.047	0.062	0.159
8	Turbidity	NTU	28	58	61
9	TDS	mg/l	0.35	0.71	0.79

Table 10. Calculated values for determination of WQI.

No.	Indicator	P1 Răcari			P2 Podari			P3 Gângiova		
		Value Q_i	Proportion W_i	Total	Value Q_i	Proportion W_i	Total	Value Q_i	Proportion W_i	Total
1	Dissolved oxygen	90	0.17	15.3	90	0.17	15.3	80	0.17	13.6
2	Fecal coliforms	50	0.11	5.5	42	0.11	4.62	41	0.11	4.51
3	CBO_5	52	0.11	5.72	51	0.11	5.61	52	0.11	5.72
4	pH	89	0.11	9.79	89	0.11	9.79	89	0.11	9.79
5	Nitrates	97	0.1	9.7	95	0.1	9.5	90	0.1	9
6	Temperature	25	0.1	2.5	25	0.1	2.5	25	0.1	2.5
7	Total phosphates	99	0.1	9.9	98	0.1	9.8	95	0.1	9.5
8	Turbidity	52	0.08	4.16	34	0.08	2.72	33	0.08	2.64
9	TDS	80	0.07	5.6	80	0.07	5.6	80	0.07	5.6
10	**TOTAL (WQI)**	-	-	**68.17**	-	-	**65.44**	-	-	**62.86**

Using the three values calculated for the WQI, the chart in figure 7 was constructed, which allows us to observe how the Jiu River water quality evolves on the section investigated in Dolj County.

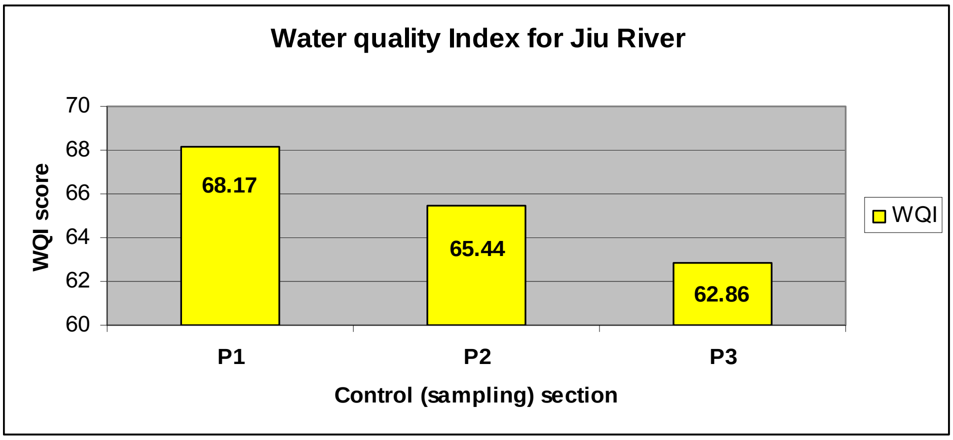

Fig. 7. Values of the Water Quality Index in the three control sections.

Although the value of the Water Quality Index falls slightly from P1 to P3, from the point of view of classification, the water of the Jiu River remains of medium quality (class C or IIIrd of quality) according with the methodology.

5 Conclusions

In the context of sustainable development, the protection of surface water quality occupies a major place, considering that water, which has long been considered an inexhaustible and renewable resource, is becoming increasingly obvious as one of the limiting factors in the socio-economic development of the modern society. As a major environmental factor and major vector of local and cross-border pollution propagation, as a vital resource of life support, water quality monitoring has gone through many stages in terms of organization and implementation.

The main anthropogenic sources of pollution from the monitored sections of Jiu River were identified and their impact on the quality of the water was analyzed. As shown in the present study, the main sources of pollution are industrial and agricultural activities, followed by wastewater discharged into the Jiu River without proper treatment.

From the present study, carried out on the Jiu River, the water quality in Dolj County on the Răcari - Gângiova sector, a series of general conclusions with theoretical and practical significance can be revealed:

1. Considering the total phosphate concentrations and the biochemical oxygen demand, it falls within the third quality class - moderate ecological status.
2. Depending on the concentration of nitrates and coliforms, it falls in the second quality class - good ecological conditions.
3. Depending on the temperature, pH and dissolved oxygen it falls into the first quality class - very good environmental status.
4. Based on the importance of the analyzed quality parameters, we believe that Jiu River should be classified in the **third quality class (or C according to the WQI methodology)**.

Analyzing through the Water Quality Index, all three points show that the water has a medium quality, and therefore the overall quality of Jiu River on the analyzed sector is medium.

In other words, both methods used to determine the quality of the Jiu River in Dolj County led to the same result, namely medium-quality water.

This highlights that it is absolutely necessary to implement urgent measures to bring the Jiu River to a higher quality level, in line with the European objectives in the field, namely to ensure at least a good ecological potential. In order to achieve this goal, the authors recommend:

- Connection of households to sewage and treatment systems to prevent river pollution by domestic wastewater drainage, directly into the river and pollution of the groundwater through infiltration into the soil;
- Ensuring efficient systems for evacuation of rainwater and waste water;
- Increase the efficiency of operation of sewage systems and wastewater treatment plants;
- Apply less polluting and/or more water-efficient technological processes, save water through recycling, and in some cases - extract useful substances from waste water and sediments and avoid waste and/or losses of water;
- Progressively reduce discharges of priority substances and priority hazardous substances (including the total exclusion of priority hazardous waste discharges).

The authors would like to thank the Jiu – Craiova Water Basin Administration for performing the instrumental and chemical analyses and providing the data regarding the quality parameters of Jiu River during 2019.

Application of superheated water as a soil remediation media: a review

Reihaneh Mashhadi Ebrahim[1,*]

[1]Department of chemical engineering, Islamic Azad University South Tehran Branch, Tehran, Iran

Abstract. Water is a unique solvent cause its highly hydrogen-bonded structure, and at room temperature it has a high boiling point for its mass, a high dielectric constant and high polarity. At the higher temperatures, its permittivity, viscosity and surface tension decreases, but diffusion rate increases. Superheated water is a general term to denote the region of the condensed phase between 100 ˚C and the critical point. Liquid water at elevated temperatures above its boiling point has been used for many years as an industrial solvent and cleaning agent in applications ranging from enhancing the extraction of oil shale, the extraction of sulphur from ore bodies in the Frasch process, to degreasing. In recent years, there has been an interest in using superheated water for soil remediation. In this paper, a review on this area of application has been performed.

1 Introduction

Unfortunately, one of the inseparable outcomes of rapid population growth are environmental pollutions. In many cases ignoring the polluted areas or regions at risk of pollution, will have irreparable effects on the environment and subsequently on the health of the human beings. In different areas in the country, especially the oil-rich ones, the local and sometimes wide-area pollutions due to the oil spill or carelessness in oil compounds transfer can be seen. Chemical industries, despite having so many benefits for providing welfare and comfort for the life of modern man can cause different diseases, including cancer, by entering the food cycle of humans; As in different studies, the carcinogenicity and mutagenetic effects of various hydrocarbon compounds have been proven. Soil, as the basis for producing needed foodstuffs for humans, is of great importance, and sometimes is ignored by this much. Entering various pollutants directly and indirectly (through the water and air) can cause some changes in this medium, and just like other elements of nature, the soil is always acting against these changes; But sometimes, the balance of the soil is disrupted, and we face the challenge of soil pollution. In these situations, human interventions in order to help the natural clearing processes and accelerating them seem necessary [1]. Diseases including cancer, by entering the food cycle of humans; As in different studies, the carcinogenicity and mutagenetic effects of various hydrocarbon compounds have been proven. Soil, as the basis for producing needed foodstuffs for humans, is of great importance, and sometimes is ignored by this much. Entering various pollutants directly and indirectly (through the water and air) can cause some changes in this medium, and just like other elements of nature, the soil is always acting against these changes; But sometimes, the balance of the soil is disrupted, and we face the challenge of soil pollution. In these situations, human interventions in order to help the natural clearing processes and accelerating them seem necessary [1]. In other words, soils are considered as the refiners for nature. In addition to being a food supplier, soils also have purifying properties. These properties are originated from their physical properties (water diffusion through pores), chemical properties (adsorption and evaporation), and bio-based properties (decomposition and spoilage of organic matter). Contamination of soil with different chemical wastes is one of the most important environmental issues in various areas, which, due to the toxicity, carcinogenicity, and causing mutagenetic changes, there are vast concerns regarding their presence in nature [2]. These pollutants can be adsorbed on the surface of the soil or organic particles existing in it, which can enhance their concentration and subsequently cause their entrance to the surface waters along with the surface streams. On the other hand, these compounds may enter the groundwater and consequently lead to disorder in the food cycle of plants, humans, and animals, so they must be removed from the environment in some way [3]. Soil pollution factors include four major parts:

1- Agricultural factors
2- Oil contaminants
3- Industrial activities
4- Trash

Regarding the soil pollution in Iran, according to the statistics, a few percent of industrial and domestic effluents are refined, and the major part of industrial and domestic effluents are discharged to the environment untreated. This manner can cause soil and groundwater pollutions, which increasing the nitrate content in well waters is a clear example for such consequences. One of the soil pollutions factors, which fortunately is not common in our country is acid rain. One of the actions of the department of environment to prevent acid rain is strong opposition to the establishment of a coke factory in the Savadkuh region. The atlas of soil pollution in Iran is being prepared, which provides accurate statistics on the amount of soil pollution in the country. Up now, the following regions are reported to be the most polluted regions in Iran: Isfahan province, south of Tehran, Asaluyeh in Bushehr, lands in the vicinity of the Mes-e Sarcheshmeh, Sistan and Baluchestan province, and Khuzestan province [4].

2 Modeling

The mass transfer mechanism of the extraction of soluble component is as follows: The soluble component attached to the solid network (by physical and chemical forces), have to be transferred to the solvent phase via liquidation or desorption. Then, the soluble component/solvent mixture diffuses to the solid surface and finally passes the static layer adjacent to the solid particles to reach the solvent phase.
Since the contents of the solid particles vary with distance and time, the diffusion coefficients of the soluble component existing in the solid particles can be determined by observing the changes of concentration in the vicinity liquid with time. There are four mass transfer steps in general, which the diffusion of the soluble component in the solid particles toward the solvent is usually the determinative step of mass transfer [36].

Initially, there is a rapid extraction period with a constant intensity, which is stable in the mass transfer and controls the resistance intensity of the mass transfer film. Then, an unstable descending step with a very lower extraction intensity occurs. In this stage, the diffusion in the solid particles controls the intensity of the extraction process [36]. In industrial operating units such as extraction, a specific component in one phase diffuses to the contact point of two phases and then enters into the other phase. Transfer of one phase to the other phase continues until the two phases reach equilibrium point [37]. The results obtained by Fick's second law were analyzed as a mathematical model. Since the modeling is performed in fluid phase, the following assumptions are considered:
1- Fluid moves with uz velocity.
2- Solid-phase is static.
3- There is no reaction.

In the fluid phase, movement is in z-direction, so the system is differentially modeled in this direction. According to the fluid stream, the diffusion term is ignored in this direction, and the convection term is considered as the determinative factor and described as follows:

$$u_z \frac{\delta c_{i,l}}{\delta z}$$

However, in radial direction, there is no movement, and lumped method is used for modeling, which only contains mass transfer flux:

$$u_z \frac{\delta c_{i,l}}{\delta z}$$

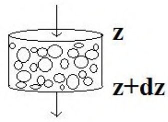
Now, the general relation of mass balance (input–output=accumulation) is shown below:

$$ka(c_i{}^* - c_{i,l}) + u_z \frac{\delta c_{i,l}}{\delta z} + \frac{dc_{i,l}}{dt} = 0$$

The initial and boundary conditions are as follows:

$$c_{i,l}(0,t) = 0$$
$$c_{i,l}(z,0) = 0$$
$$c_{i,s}(0) = c_{i,s,0}$$

Changes are considered only in the z-direction, and concentration variations in other directions are neglected. The following image is showing the considered system for mass balance schematically.



By considering a cylindrical shape element with a base area equals to the tower base area and with a height equals to dz, the mass balance is written. At the element input, we have:

$$N_{i,z}.A$$

Where $N_{i,z}$, and A are the i element flux in z-direction and tower base area, respectively. At the element output, we have:

$$N_{i,z+dz}.A$$

On the other hand, the mass transfer flux from the solid phase to gas phase is described as follows:

$$(dz.A)ka(c_i{}^* - c_i)$$

Where k is the mass transfer coefficient, a is the specific surface area, and c_i and c_i^* are the i component concentrations in the liquid phase and solid phase surface, respectively. By substituting the mentioned equations on this base that the total mass transfer from the gas phase to the liquid phase is equal to output rate minus input rate plus accumulation rate, we have:

$$\frac{\partial N_i}{\partial z} + \frac{\partial c_i}{\partial t} = ka(c_i^* - c_i)$$

By dividing both sides of the above equation by dz.A, the following relationship is obtained:

$$N_{i,z+dz}.A - N_{i,z}.A + dz.A\frac{\partial c_i}{\partial t} = (dz.A)ka(c_i^* - c_i)$$

By considering the below equation:

$$N_i = u_z c_i + J_i$$

Furthermore, by defining J_j as follows:

$$J_i = -D_l \frac{\partial c_i}{\partial z}$$

In the above equations, u_z and D_l are the fluid velocity in the z-direction and the axial distribution coefficient. By substituting the above equations, we will have:

$$\frac{\partial(u_z c_i)}{\partial z} - \frac{\partial}{\partial z}(D_l \frac{\partial c_i}{\partial z}) + \frac{\partial c_i}{\partial t} = ka(c_i^* - c_i)$$

By assuming that the axial distribution coefficient does not depend on z-direction, we will have:

$$c_i \frac{\partial u_z}{\partial z} + u_z \frac{\partial c_i}{\partial z} - D_l \frac{\partial^2 c_i}{\partial z^2} + \frac{\partial c_i}{\partial t} = ka(c_i^* - c_i)$$

By considering the continuity equation and assuming that the fluid density is constant:

$$\frac{\partial u_x}{\partial x} + \frac{\partial u_y}{\partial y} + \frac{\partial u_z}{\partial z} = 0$$

Since the velocity in x and y directions are zero, the above equation turns into the following equation:

$$\frac{\partial u_z}{\partial z} = 0$$

Finally, we have:

$$\frac{\partial c_i}{\partial t} = D_l \frac{\partial^2 c_i}{\partial z^2} - u_z \frac{\partial c_i}{\partial z} + ka(c_i^* - c_i)$$

The above equation is the one to be solved. To solve such an equation, two boundary conditions and one initial condition are needed.

The boundary conditions are described as follows:

$$c_i(0,t) = 0$$
$$\frac{\partial c_i(z,t)}{\partial z} = 0$$

The initial condition is determined as follows:

$$c_i(z,0) = 0$$

In this study, the mass transfers of naphthalene, phenanthrene, fluoranthene, and pyrene from soil to the super-hot water were investigated. The information about molecular weight and solubility of these compounds are illustrated in the Table 1 [38].

c_i^* is the solubility of *i* component in groundwater. Therefore, given that the solubilities at 25 ºC can be found in literature, the solubilities at 100, 150, 200, 250, and 300 ºC should be calculated. To calculate the solubilities, the following equation is used [36]:

$$ln\, x_2\,(T) = \frac{T_0}{T} ln\, x_2\,(T_0) + 15(\frac{T}{T_0} - 1)^3$$

Where $x_2(T)$ is the solubility at the temperature of T in the form of molar fraction and $x_2(T_0)$ is the solubility at the specified temperature of T_0, and the temperature unit is Kelvin. To calculate the D_l, the following equation is used:

$$D_l = \frac{ud_p}{\varepsilon Pe}$$

Table 1. The information of the compounds used in this study.

Compound	Molecular weight	Solubility in water at 25 ºC (mg/L)	Molecular volume (m^3/kmol)
Naphthalene	2.128	32	407.0
Phenanthrene	2.178	3.1	554.0
Fluoranthene	3.202	2.0	6195.0
Pyrene	1.202	1.0	626.0

Where d_p is the particle diameter, which is considered 2 mm in this study, the bed height is considered 10 mm, which is consistent with the empirical data, ε is the porosity coefficient (due to the presence of particles in soil), which is considered 0.4 in this work, and "u" is the entering velocity of the fluid. Four different flow rates, including 0.5, 1, 1.5, and 2 cm^3/min, are considered in this work. Moreover, Pe is the dimensionless number of Peclet and can be calculated using the following equation [24]:

$$Pe = 1.634\, Re^{0.265}\, S\, c^{-0.919}$$

According to the following equations:

$$\mathrm{Re} = \frac{\rho u d_p}{\mu}$$

$$Sc = \frac{\mu}{\rho D_{AB}}$$

It is needed to know the viscosity and density at the specified temperatures. In order to determine these values, we use the equations below:

$$\rho = 858.03 + 1.2128T - 0.0025T^2$$

$$\mu = \exp(-10.2 + \frac{290970}{T^2})$$

The units of temperature, density, and viscosity in the above equations, are Kelvin, kg/m^3, and Pa.S, respectively.

To calculate the diffusion coefficient (D_{AB}), the following equation can be used:

$$D_{AB} = \frac{(117.3 \times 10^{-18})(\varphi M_B)^{0.5} T}{\mu v_A{}^{0.6}}$$

Where M_B is the molecular weight of solvent (water in this case), φ is the correlation coefficient of solvent, which is equal to 2.26, and V_A is the molar volume of the soluble, which can be obtained from v_c and can be seen in the Table 1.

$$v_A = 0.285(v_c)^{1.048}$$

To calculate the mass transfer coefficient (k), the dimensionless number of Sherwood (Sh) is used:

$$k = \frac{Sh\,.D_{AB}}{d_p}$$

Where the Sherwood number can be obtained from [24]:

$$Sh = 0.38\,\mathrm{Re}^{0.83}\, Sc^{1/3}$$

3 Results and discussion

3.1 Time effect

The extraction time in the method of extraction with super-hot water is short. To extract compounds from plant samples or investigate the environmental samples, in 5 min to 2 hr in a dynamic state and 5-10 min in a static state, suitable efficiency can be achieved [3]. By increasing the extraction time, the efficiency will increase up to a constant value. The extraction time depends on the kinetics of the process and the time needed to reach the equilibrium. It is expected that by increasing the extraction time, the efficiency increases. The effect of time on the extraction of hydrocarbons or multiple-ring aromatic is shown in Figures (1,2).

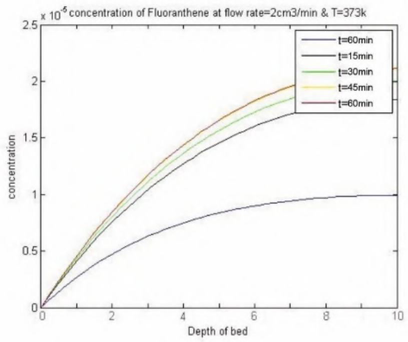


Fig. 1. Changes of fluoranthene concentration along the tower at different times at 373 K.

As it is obvious, by increasing the extraction time, the concentrations of hydrocarbons in the liquid phase are increased. In fact, from a specific time to further, there is no change in the curve by increasing the time, which means it reached equilibrium. Also, it can be concluded that by increasing the time, the change rate of concentration increases, which can be ascribed to the contact time of two phases. In other words, the sufficient time needed for mass transfer is provided by further increasing the extraction time.

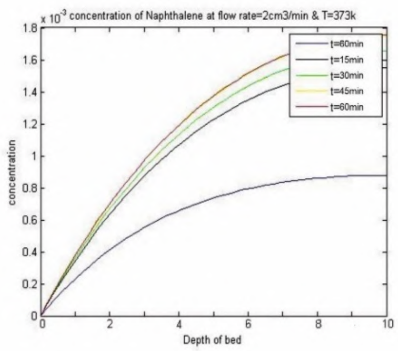

Fig. 2. Changes of pyrene concentration along the tower at different times at 373 K.

3.2 Flow rate effect

The intensity of extraction enhances by increasing the flow rate. It is expected that a more flow rate can mitigate the resistance of the fluid phase. Thus, the amount of mass transfer from the solid phase to the fluid phase increases. In the following figures (Figures (3-6)), the effect of changes in flow rate in the range of 0.5-2 cm^3/min is shown for the four mentioned compounds.

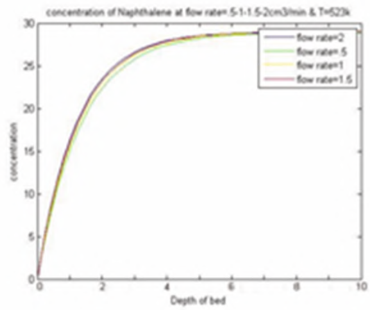

Fig. 3. The effect of flow rate on the concentration of phenanthrene.

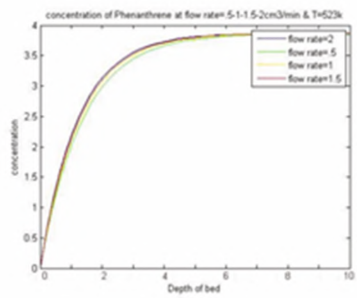

Fig. 4. The effect of flow rate on the concentration of fluoranthene.

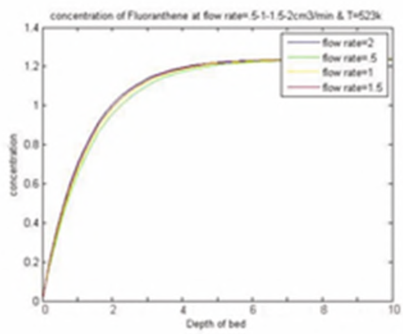

Fig. 5. The effect of flow rate on the concentration of naphthalene.

As can be seen in Figures, the variation of flow rate is not determinative on the amount of concentration. Also, for various compounds, there is no significant change in concentration, which can be concluded that the main resistance against mass transfer is the internal resistance, no the external one. In other words, the diffusion in the solid phase and reaching to surface, feel the most resistance. Overall, the resistance of the liquid phase is negligible.

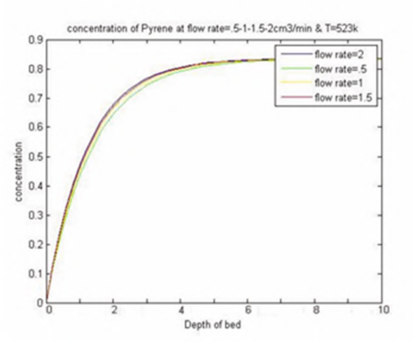

Fig. 6. The effect of flow rate on the concentration of pyrene.

3.3 Temperature effect

The most important parameter that affects the super-hot water system is temperature because by changing the temperature of the solvent (water), its properties will change [11, 39, 40]. By increasing the temperature, the surface tension and viscosity decrease, whereas the diffusion of the soluble compounds in the water enhances. In other words, more sufficient mass transfer will be provided by increasing the temperature, which can improve the extraction efficiency. This phenomenon is even more important in weak-polar or non-polar compounds because their solubility in water is negligible in low temperatures. Temperature can affect the solubility in water, axial distribution coefficient, and diffusion coefficient. So, significant changes in concentration are expected by varying the temperature. At the 25 ^{o}C temperature, as can be seen in the previous section, water has a weak capability to dissolve these kinds of hydrocarbons. As the temperature increases, the dielectric constant decreases, and consequently, the solubility increases. Therefore, it is expected that by increasing the temperature, the solubility of this group of hydrocarbons in the liquid phase enhances.

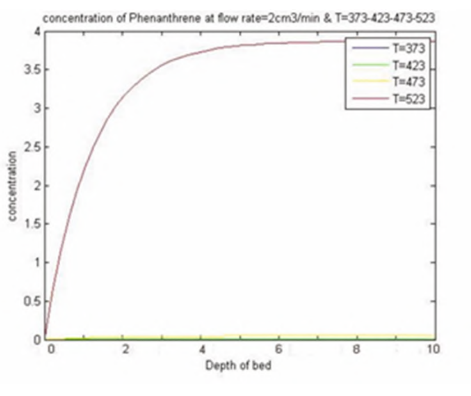

Fig. 7. The effect of temperature on the concentration of phenanthrene.

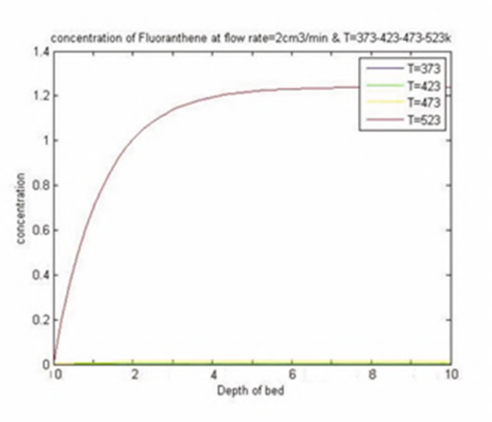

Fig. 8. The effect of temperature on the concentration of fluoranthene.

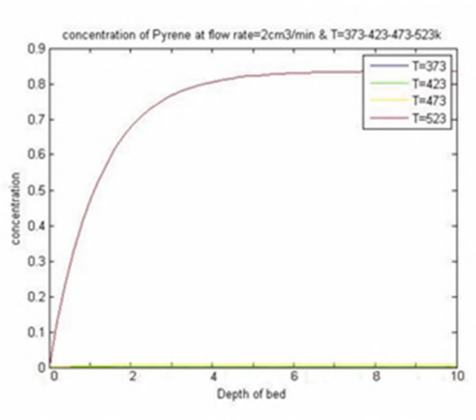

Fig. 9. The effect of temperature on the concentration of pyrene.

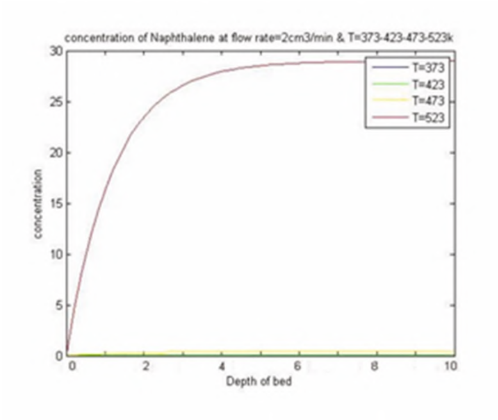

Fig. 10. The effect of temperature on the concentration of naphthalene.

As shown in Figures, by increasing the temperature ranging from 200 to 250, the concentration variations were significantly affected. This phenomenon can be assigned to the effect of these compound's solubility, which by increasing the temperature, the solubility enhances significantly, and this is obvious in Figures.

 https://doi.org/10.1051/e3sconf/202128010003

The following figure provides a comparison between the concentration changes of the four compounds at 2 cm^3/min flow rate and 150 °C temperature. As can be seen in Figure, the concentration changes of naphthalene are more than others, and phenanthrene, fluoranthene, and pyrene come next, respectively. This order exactly originates from their solubility which is in the order of naphthalene, phenanthrene, fluoranthene, and pyrene, from higher to lower. On the other hand, the molecular weight of naphthalene is lower than others, which influences on its diffusivity in the liquid phase.

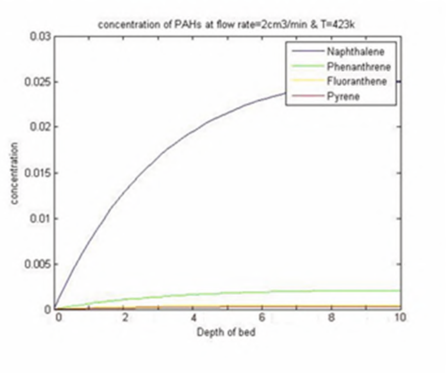

Fig. 11. A comparison between the concentration changes of the four compounds.

3.3.1 Review of experimental studies

This review is done for the compounds of naphthalene and phenanthrene [41].

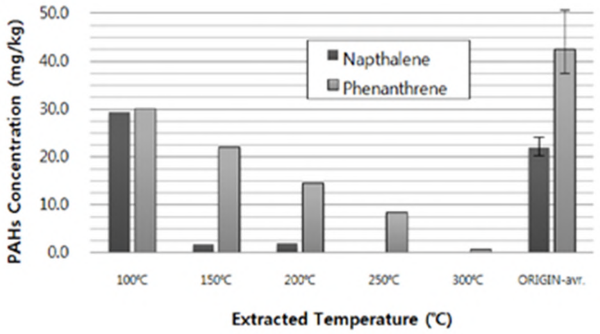

Fig. 12. Comparing the concentration of naphthalene and phenanthrene in the initial soil and the treated soil.

The concentrations of remaining naphthalene were 29, 1.8, 1.9, 0, and 0 ppm, at 100, 150, 200, 250, and 300, respectively. This means that the concentration of remaining naphthalene at 100 degrees, is slightly more than its concentration in the initial soil, and at 150 degrees, is significantly decreased to a value of 2 ppm. This evidences that the extracted naphthalene does not separate from soil in 100 °C. But, over 150 °C, it will be easily separated from the soil. There are some other reasons that why naphthalene does not separate from the soil at 100 °C. One of them is that the physical properties of soil up to 100 °C temperature and 100 atm pressure will change, and this variation can cause a change in the separation fraction of methanol from the soil and subsequently will affect the separation of remaining naphthalene from the soil. As another reason, the lack of homogeneity in the concentration of initial soil, which is heated up to 100n °C, can be mentioned. The concentration of remaining naphthalene was also decreased from 30 ppm at 100 °C, to 0.74 ppm at 300 °C. As can be seen in Figure 2, the separation of phenanthrene from the soil needs more heat than the value needed for naphthalene, which originates from the properties of phenanthrene that, in comparison with naphthalene, has a lower solubility in water and higher molecular weight and melting point.

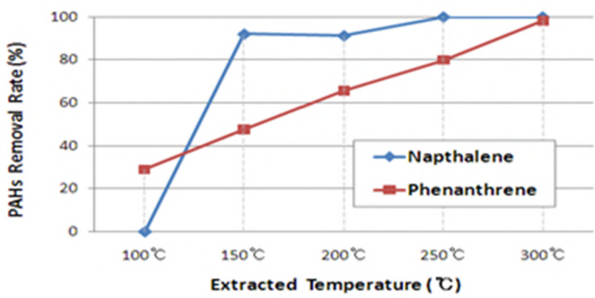

Fig. 13. The percentage of clearing soil from pollutants in different temperatures.

To clear a naphthalene-contaminated soil, 150 °C is sufficient. To clear a soil polluted with PAHs such as phenanthrene, anthracene, etc.

4 Conclusions

No need for organic solvent or negligible assumption of organic solvent is the most prominent characteristic of extraction with super-hot water. Accessibility, low-cost, and non-toxicity of water as the main solvent, and no need for drying the wet samples are other characteristics of this method. In many cases, this method in comparison with other methods, is more clear, cheaper, and faster. Extraction with super-hot water has showed lots of benefits in term of no need for organic solvents in environmental extractions. The equipment needed for this method is relatively simple and there is no need for applying high pressures, as the extraction with supercritical fluid. In this study, a simple mathematical model was presented for the fluid phase, which evaluated the extraction efficiency in terms of temperature, time, and flow rate. Also, the amount of concentration changes for naphthalene, phenanthrene, fluoranthene, and pyrene were measured with the parameters of temperature, flow rate, and time. Among these parameters, temperature was the most determinative one, and the amount of extraction is increased by increasing the temperature. It can be mentioned that almost 95% naphthalene was extracted at 100 bar. Because naphthalene was resistant in soil at 100 ºC and does not separate from the soil, but at 150 ºC and higher temperatures, due to its physical properties, which is changed in this condition, it can be easily separated from soil. As in this study, significant changes in concentration were observed in the temperatures of 200 and 250 ºC, which is ascribed to the effect of solubility of these compounds that increases by increasing the temperature. Also, the variation of flow rate has a negligible effect on the concentration for all compounds, which means that the internal resistance is determinative, comparing with the external one. In other words, the diffusion in the solid phase and reaching to the surface feel the most resistance. Overall, the resistance of the liquid phase is negligible. By increasing the extraction time, the rate of concentration changes increases, which can be assigned to the contact time between two phases. By a meaning, sufficient time for mass transfer can be provided by increasing the time. Short extraction time, high-quality extract, low cost of indicators needed for extraction, and compatibility with the environment are other prominent characteristics of this method.

5 Limits and suggestions

According to this fact that the solvent used in the extraction with super-hot water is water, the more assumption of water comparing with other methods can be mentioned as one of the disadvantages of this method, which is suggested that to overcome this issue in future studies, this should be included in the technical and economical calculations.

Also, as one of the limits of this method, high temperature and pressure can be mentioned, which can be a serious drawback regarding utilizing this method in more wide applications, so it is needed to be studied more.

Corrosion is also another important factor that should be considered. For example, stainless steel, as one of the most applicable material that is usually used in the equipment of super-hot water is corroded. So, for dealing with super-hot water, utilizing special materials is needed, which are more expensive than common materials in the industry. According to the discussed contents, it is hoped that the existing problems to be solved or mitigate in future studies, to facilitate the more application of this technology in industry.

Morphometric parameters based prioritization of a Mid-Himalayan watershed using fuzzy analytic hierarchy process

Mallika Joshi*, *Pankaj* Kumar, and *Purabi* Sarkar

G. B. Pant University of Agriculture and Technology, Udham Singh Nagar, Pantnagar, Uttarakhand 263153, India

Abstract. Watershed prioritization has become increasingly crucial for managing natural resources, especially the watersheds. A useful decision support tool to provide appropriate weights to different morphological attributes with lineage with soil erosion is required to identify environmentally stressed areas for the watershed resources. This study examines the Western Nayar watershed delineation and further examination of the watershed's morphometric parameters. The morphometric parameters were quantified under the linear, areal, and relief heads for the watershed. The prioritization of sub-watersheds was done by the fuzzy analytic hierarchy process (FAHP). The study included nine morphometric parameters for forming a pairwise comparison matrix. The fuzzy analytic hierarchy process was employed for assigning the suitable weights to morphometric parameters, and further, these weights are normalized to assign the final ranks to the sub-watershed. In Western Nayar, SW9 got the highest priority, and SW1 was categorized as the least priority. The results were validated by the consistency ratio index, which depends on the matrix consistency index's size that should be less than 10%. The consistency index of the present study was found to be 2%.

1 Introduction

The morphological and climatic characteristics of a basin govern its hydrological response to a considerable extent. The morphological characteristics of watershed represent its measurable attributes, which are useful for synthesizing hydrological response. The importance of the morphological factors cannot be overlooked as an accurate prediction of runoff in concerned. Hence, linking the morphological parameter with the basin's hydrological characteristics can lead to a useful and straightforward procedure to simulate the hydrological behavior of the various basins, particularly the ungauged ones. Quantitative and rendition of various drainage parameters enable qualitative evaluation of surface runoff, infiltration, and susceptibility to erosion within the basin [7].

Morphometric science is the measurement, quantitation, and mathematical reckoning of the earth's surface layout, shape, and the dimension of its landforms. [8]. The analysis of morphometry of a watershed provides a quantitative description of the drainage system, which is an essential aspect for the characterization of watersheds [16]. Morphometric analysis requires measurement of linear features, areal aspects, the gradient of channel network, and contributing ground slopes of drainage basin [17]. The remote sensing technique is a convenient method for morphometric analysis. Large areas of synoptic view are easily procured through satellite imagery, and these are very useful in analyzing drainage basin morphometry. Pioneering work on the drainage basin morphometry has been carried out by Horton [10; 13], Miller [12], Strahler [16]. Some recent studies on morphometric analysis using remote sensing techniques have been carried out [1; 3; 4; 5; 9; 15; 17]. Geomorphological parameters such as stream order, stream length, stream frequency, drainage density, texture ratio, farm factor, circulatory ratio, elongation ratio, bifurcation ratio, and compactness ratio have been widely used for the prioritization of subwatersheds in a watershed [1].

Watersheds prioritization is the ranking of different sub-watersheds for varying levels of conservation treatments to be given to such watersheds. Once the watersheds are prioritized, the quantitative assessment of hydrological parameters of the watershed, such as peak flow and runoff volume, serves as necessary information for adopting suitable soil and water conservation measures in the watershed. The basin lies land use/land cover's physical characteristics influence these hydrologic parameters broadly, which are dynamic. The latest advances in remote sensing technology have provided handy tools for surveying, identifying, classifying forms of earth resources.

GIS-based multi-criteria decision analysis (GIS-MCDA) is a process of decision making in which geographical data and value judgments are brought together to obtain more information for the decision-makers [15; 17]. The fuzzy analytic hierarchy process (AHP) has proved to be an advantageous method in multiple criteria decision-making in fuzzy and has found various applications in recent years. Its applications use a crisp point estimate method, which includes fuzzy preference programming (FPP) based nonlinear method

* Corresponding author: pankaj591@gmail.com

https://doi.org/10.1051/e3sconf/202128010004

for fuzzy AHP priority derivation. The present study attempted to study different morphometric characteristics and implement GIS techniques through Fuzzy analytical hierarchy process (FAHP) techniques to identify critical sub-watershed in the Nayar River watershed. The morphological parameters were ranked according to the value and weights, which is evaluated by deriving the relationship between morphological parameters obtained by classification of all the sub-watershed by associating the strength of fuzzy. FHAP approach for identifying sensitive zones is found useful for implementing land and water resource conservation practices for sustainable development [2; 18].

This study explores the application of fuzzy AHP approach to prioritize the Western Nayar watershed sub-watersheds situated in the fragile Mid-Himalayan ecosystem using open source GIS tools and remote sensed DEM data. The results were validated by the consistency ratio index for a matrix of nine morphometric parameters.

2 Materials and Methods

2.1 Study area and data procurement

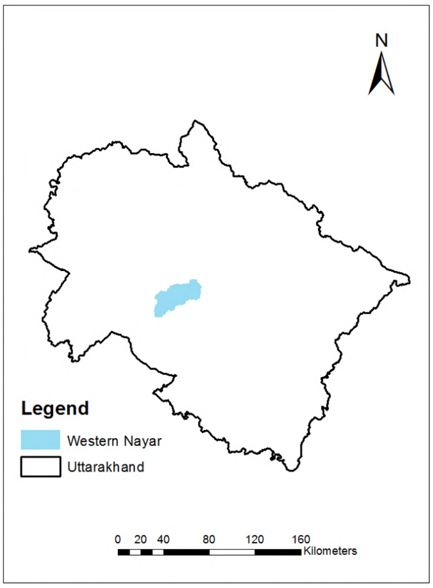

Fig. 1. Location map of study area.

The analysis has been practiced in the Western tributary of Nayar River, a non-glacial river in the Uttarakhand state of India. Nayar East and Nayar West are the two tributaries of the Nayar river. The Western Nayar lies between 29054’40’’N-30012’80’’N latitude and 78043’40’’E-7909’0’’ E (Fig. 1). The source comprises Nayar East, which is at an elevation of 2900 m, and the second source, which is Nayar West, has an elevation of 2800 m. Eastern Nayar's length is about 94 km, whereas Western Nayar's length is about 91 km. Eastern Nayar meets Western Nayar at Satpuli. Both of these tributaries join the Ramganga river in the lower Himalayan mountains for around 100 km further. Remote Sensing data used in this study are google maps of the study area, and Digital Elevation Model (DEM) obtained from Shuttle Radar Topography Mission (SRTM). QGIS 2.16, open-source software, is used for geospatial analysis.

2.2 Morphometric analysis

The formulas used to estimate morphometric parameters viz Stream frequency, Mean bifurcation ratio, Texture ratio, Length of overland flow, Elongation ratio, Circulatory ratio, Form factor and drainage density are presented in Table 1.

Table 1. Description of morphometric parameters used for FAHP prioritization/

Sl. No.	Parameter	Definition/Formula	Reference
1	Mean bifurcation ratio	$R_b = \frac{N_u}{N_{u+1}}$ where, N_u = complete number of stream order u, N_{u+1} = complete number of stream segment of next higher order	Schumm, 1956
2	Texture ratio	$T = \frac{N_1}{P}$ where, N_1 is complete number of first order stream and P = watershed perimeter (km)	Horton, 1945
3	Stream frequency	N_f = It is the number of streams per unit area of the watershed	Horton, 1945
4	Length of overland flow	$L_o = 0.5\frac{A}{L_b}$ where, A = watershed area (km^2) and L_b is length of watershed	Horton, 1945
5	Elongation ratio	$R_e = \frac{2}{L_b}\sqrt{\frac{A}{\pi}}$ where, A = watershed area (km^2) and L_b is length of watershed	Schumm, 1956
6	Circulatory ratio	$R_c = 12.57\frac{A}{P^2}$ where, P = watershed perimeter (km), A = watershed area (km^2)	Miller, 1953
7	Form factor	$R_f = \frac{A}{L_b^2}$ where, A = watershed area (km^2) and L_b is length of watershed	Horton, 1932
8	Drainage density	$D_d = \frac{L_u}{A}$ where, A = Basin area (km^2), L_u = complete stream length of all order	Horton, 1945
9	Relief	vertical distance between the lowest and highest points of a watershed (H)	Schumm, 1956

2.3 Prioritization of sub-watershed using FAHP

Present study focuses on the use of Fuzzy analytical hierarchical process (FAHP) along with the extent analysis method to prioritize the watershed. Fuzzy AHP is believed to obtain a crisp priority vector from a triangular fuzzy comparison matrix. Linear parameters such as bifurcation ratio, texture ratio, have a positive correlation with erodibility, higher value, more soil erodibility. Areal aspects parameter such as circularity ratio, form factor and compactness coefficient have an inverse relationship with erodibility.

The hierarchy process, by the method of extent analysis, each criteria is taken and extent analysis for each criterion, gi; is performed respectively. The M extent analysis values to each criterion evaluated by full notation

$$\dot{F}_{gi}^{1}, \dot{F}_{gi}^{2}, \dot{F}_{gi}^{3}, \dot{F}_{gi}^{4}, \dots \dots \dots \dots \dots \dots \ \dot{F}_{gi}^{n} \qquad (1)$$

where, g_i is the goal set (i=1,2,3,4…..n) and $\dot{F}_{gi}^{j}$ (j= 1,2,3,4,….m) are the members of triangular fuzzy number system (TFNs).

Keeping this in view, the preference values for each morphometric parameter are designated according to the FAHP rating scale, which determines the relative strength of each parameter over other parameters (Saaty 1980). By estimating the consistency ratio (CR), which can be calculated by the following equation, the consistency of judgment can be checked:

$$CR = \frac{CI}{RI} \times 100 \qquad (2)$$

Where the consistency index is a CI, and the random consistency index is a RI. The consistency index is a unit less number, which can be calculated using following equation, depending on the matrix's size (number of parameters).

$$CI = \frac{\lambda_{max} - n}{n-1} \qquad (3)$$

Where, λ_{max} is the principal eigen value obtained from priority matrix and n is the size of comparison matrix.

3 Result and discussion

3.1 Quantification of morphometric parameters

The morphometric parameters estimated for each of the sub-watersheds are given in Table 2. These values were acquired as defined in the section on materials and methods and were used in FAHP to construct a pairwise comparison matrix. In the form of a hierarchical tree, nine morphometric assessment indices were used for prioritizing sub-watersheds. Fuzzy analytical hierarchy process (FAHP) was used to evaluate the relative weights of parameters' character traits to prioritize sub-watersheds. The Western Nayar watershed is delineated The Western Nayar watershed is delineated into 11 sub-watersheds using QGIS 2.6.0 software(Fig.2). The Western Nayar watershed was found to be of fourth-order(Fig. 3). The analysis of the drainage network map reveals that there are 163 first-order streams having a total stream length of 219.72 km, 39 second-order streams with 129.80 km stream length, 11 third-order streams having 97.05 km stream length, and 1 fourth-order stream with 48.33 km stream length.

The perimeter of Western Nayar is estimated as 46.25 km. The sub watershed-wise basin length varies from 6.44 km to 20.88 km. As per Strahler's approach, the total numbers of streams for watershed are 216, out of which 163 belongs to first order, 39 are of second-order, 11 are of the third order, 1 is of fourth-order. It revealed that the highest number of streams are found in SW 7 (41), and the lowest number of streams is found in SW 4 (9). The stream frequency of the Western Nayar watershed sub-watersheds varies from 0.20 to 0.54; the highest stream frequency is observed in SW 4 (0.54/km^2), which indicated that it has the least infiltration capacity and thus highest erosion susceptibility in terms of N_f. Stream frequency is observed the lowest in SW 9 (0.20/km^2), which indicated it possesses the least erosion susceptibility. The mean bifurcation ratio of all the sub-watersheds is high, which indicates that all the sub-watersheds are structurally complex and have low permeability. Among the SWs, the highest mean bifurcation ratio is observed in SW 2 (5.642), which indicated that it is structurally complex and has low permeability and thus the highest erosion susceptibility in terms of R_{bm}. R_{bm} is observed the lowest in SW 4 (2.5), which indicated that it has the least erosion susceptibility. In the Western Nayar watershed, the lowest texture ratio is observed in SW 4 (0.14/km), which indicated that it has the highest infiltration capacity among the other SWs or conversely, it has the least susceptibility to erosion if the T is taken as a criterion for erosion susceptibility.

Table 2. Sub-watershed wise morphometric parameters for Western Nayar watershed.

Basin	A	P	L_u	R_{bm}	D_d	N_f	R_c	R_f	C_c	R_e	R	L_o	T

The highest texture ratio was observed in SW2 (0.50/km), which indicated that it has the lowest infiltration capacity and thus highest erosion susceptibility in terms of T. L_o is less for steeper slopes and high for gentle slopes and thus

directly related to the slope of the channel. In the study area, the highest length of overland flow is observed in SW 10 (0.89km^2), which indicated that it has the highest potential to erode the land in a single stretch. L_o is observed the lowest in SW7 (0.64 km^2), making it the least susceptible to erosion as far as L_o is concerned.

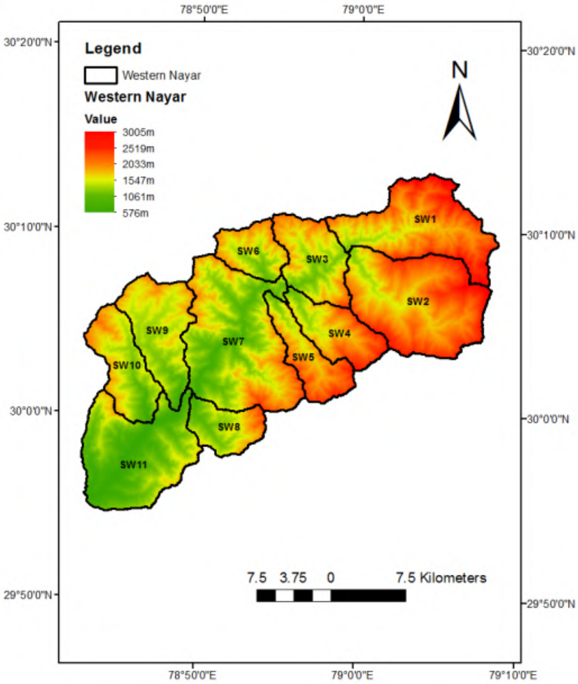

Fig. 2. Digital Elevation Model (DEM) map of western Nayar watershed.

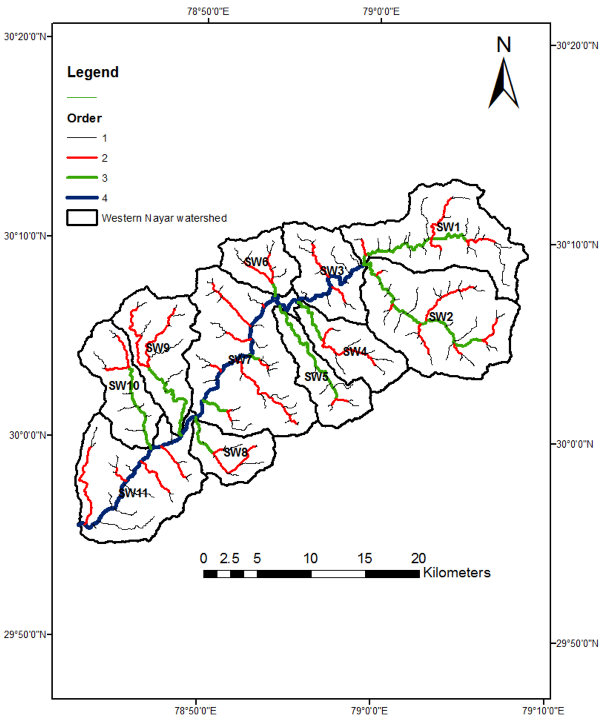

Fig. 3. Drainage network map of Western Nayar watershed.

Areal aspects of the morphological study of watershed include the description of the arrangement of areal elements. The total area of the Western Nayar watershed is estimated as 749.65 km^2 . The area of SWs varies from 30.74 km^2 to 134.62 km^2 (Table 2). In the Western Nayar highest elongation ratio is observed in SW6 (0.97), indicating that it has the least susceptibility to erosion in terms of R_e. R_e is observed the lowest in SW 9 (0.50), indicating the highest susceptibility. Among the SWs of the Western Nayar watershed highest Circulatory ratio is observed in SW2 (0.41), indicating low infiltration capacity and more erosion susceptibility in R_c terms. R_c is observed the lowest in SW 5 (0.22) indicates that it possesses low relief and higher infiltration capacity and resulting in lower susceptibility. The basins with high form factors have peak flows of shorter duration, whereas an elongated watershed with low form factors has a longer duration peak flow. Among the SWs of the Western Nayar watershed, the highest form factor is observed in SW 6 (0.74), indicating that it has peak flows of shorter duration and is least susceptible to erosion in terms of R_f. R_f is observed the lowest in SW 9 (0.20), indicating the highest susceptibility. Among the SWs of the Western Nayar river, the highest Compactness coefficient was observed in SW5 (2.13), indicating it's least susceptible to erosion in terms of C_c. C_c is observed the lowest in SW 2 (1.56), indicating the highest susceptibility to erosion.

The relief aspect is a three-dimensional characteristic of a watershed that is expressed in terms of the area, volume, and altitude of watershed landforms. The values of Stream frequency, mean bifurcation ratio, Texture ratio, Length of overland flow, Elongation ratio, Circulatory Ratio, form factor, drainage density and watershed relief are presents in Table 2. Linear parameters such as drainage density, stream frequency, bifurcation ratio, texture of drainage, have a positive correlation with erodibility, higher value, more erodibility. Areal parameters have negative correlation with erodibility, higher value, lower erodibility (Agarwal 1998; Srivastava et al. 2004, Bhattacharya et al 2020).

3.2 Prioritization of sub-watersheds using fuzzy analytical hierarchy process (FAHP)

The size of the comparison matrix as presented in Table 3 in Saaty's FAHP is equal to the number of parameters (n) and is in the form of a square matrix. The relative importance between the two factors can be scaled qualitatively between 1 and 9. Weightage 1 indicates the equal importance to both factors, while 9 indicates that one factor is more important than others. The comparison of each parameter with others is made to complete the comparison matrix of size (n × n) and the total no. of comparison comes out to be ${}_nC^2$. For filling the upper triangle of the matrix, each time two parameters were considered one by one, and considering the relative importance, a value between 1 and 9 is assigned. The lower triangle of the matrix was filled by reciprocal values of upper triangles.

The degree of importance between two factors in the matrix is filled based on field experience. When

https://doi.org/10.1051/e3sconf/202128010004

elongation ratio and form factor are used in a pair-wise comparison and it is decided that elongation ratio is important than form factor, a number 2 will be used to fill the element in the upper part of comparison matrix. The elements in the lower part of the matrix can be filled by taking the reciprocal of corresponding elements in the upper matrix. Having the weightage assigned to nine morphometric parameters using FAHP which are 0.238 for Relief (H), 0.184 for the length of overland flow, 0.189 for drainage density, 0.126 for mean bifurcation ratio, 0.080 for stream frequency, 0.054 for texture ratio, 0.049 for elongation ratio, 0.045 for circulatory ratio and 0.030 for form factor as presented in Table 4. The final priority of each sub-watershed is computed using normalized values of morphometric parameters and their respective weightage.

Table 3. Pairwise comparison matrix.

The normalization of morphometric parameters for the prioritization of subwatersheds of Western Nayar using FAHP revealed final prioritization ranks (Table 5). The final priority map of the Western Nayar after calculating the final ranks is presented in Fig. 4. The decreasing order of priority of subwatersheds are SW-9(0.969), SW-6(0.881), SW-10(0.831), SW-11(0.792), SW-5(0.784), SW-8(0.767), SW-3(0.752), SW-4(0.751), SW-7(0.725), SW-2(0.692), and SW-1(0.690).

4 Conclusions

The present study shows the Geographical Information System (GIS) feasibility and Fuzzy Analytical Hieratical Process (FAHP) approaches in morphometric-based sub-watershed prioritization Mid-Himalayan watershed. Prioritization centered on FAHP assessment was investigated systematically, which plays a significant role in explaining the issue by integrating environmental resources-causing risk assessment parameters. This assortment could be a suitable and effective strategy for developing efficient, sustainable development and management practices, particularly in the conventional watershed prioritization approach. It has been identified in this study that the subwatershed, SW9, and SW6 fall into the top priority category; therefore, these sub-watersheds should be given preeminence for conservation by policymakers.

Abstract. The quality of surface waters of small rivers of the Ukrainian regions of right-bank Polissia, belonging to the basin of the river Pripyat, was estimated. The study was conducted via systematic observations based on the ecological classification of surface water quality of land and estuaries of Ukraine, which includes a set of hydrophysical, hydrochemical, hydrobiological and other indicators, which were grouped into three blocks of indicators: salt composition of water; tropho-saprobiological (ecological-sanitary) block; specific substances of toxic action. The integrated (ecological) index was determined, by which the class and category of surface water quality were established. The results of observations on the quality of surface waters of the rivers of the Ukrainian regions of right-bank Polissia indicate their satisfactory condition. Surface waters, on average, correspond to the II class of water quality, and the worst - to the III class. Water protection measures have been proposed to improve the ecological condition of small river basins in specified region.

Introduction

Deteriorating ecological conditions of river systems in Ukraine, as a result of irrational use of water resources and technogenic impact, are an ever-present problem, a problem for present and future generations. The main sources of pollution of river basins are industrial and municipal waste waters, agricultural runoff, surface runoff and atmospheric precipitation [1; 2].

The growing anthropogenic impact on the environment, its pollution by industrial waste, leads a significant deterioration of the ecological conditions of all riplatter, the most vulnerable being small rivers, which are used primarily for communal, agricultural purposes and industrial purposes, while also being points of wastewater discharge. This leads to continuous deterioration of natural environment, especially that of river basins, as they undergo constant changes. This is primarily due to their intensive, irrational use. The quality of surface waters in both large and small rivers depends on the degree of their contamination by industrial waste and utilities, as well as surface runoff from settlements, industrial facilities, agricultural lands, etc. After all, small rivers create the preconditions for the zonal regularity of the formation of water resources of large rivers. Thus, the problem of pollution of small rivers and their hydroecological analysis are quite relevant today [3; 4].

The urgency of assessing the surface water quality of small rivers in the Ukrainian regions of right-bank Polissia stems from the high anthropogenic (industrial and agricultural) load on these ecosystems and continuous deterioration of surface waters quality there. In the basins of small rivers, the resilience of natural landscapes has decreased, and in most cases there is an ongoing decline of water quality from class I to class III. The current regulatory framework is not able to stop these processes; furthermore, when compared with similar regulatory framework of advanced European countries, it can be considered obsolete. In this regard, there is an urgent need to develop a new regulatory framework and, above all, to conduct immediate environmental assessment and establish new environmental standards for water quality of rivers belonging to the Ukrainian regions of right-bank Polissia. Creation of new framework will concentrate efforts of all subjects related to water management on development and implementation of new environmental measures addressing ecological status of rivers in the regions, while also establishing new scientifically based indicators of surface water quality, representative of river’s natural state [5; 6].

Monitoring environmental conditions of surface waters is one of the key tasks of the state’s environmental activities, calling for joint efforts and resources of neighboring states, aiming to preserve, rationalize use of surface waters, as well as facilitate mutual “integration” of national and international laws, standards, and allow for continuous international environmental cooperation. Therefore, it is necessary to conduct timely observations of the qualitative condition of the surface water of the river basins and to analyze and summarize information about the condition of water bodies and predict its changes [2; 7-9].

The purpose of this paper is to give assessment of the surface water quality of small rivers of the Ukrainian regions of right-bank Polissia (Vyzhivka, Turiya, Tsyr, Stokhid, Styr, Lypa, Prudnyk, Serna, Chornoguzka, Horyn, Putylivka, Sluch, Ubort, Uzh, Noryn).

Methods

The evaluation of ecological condition of water quality of rivers belonging to the Ukrainian regions of right-bank Polissia was carried out according to the «Methodology of ecological assessment of surface water quality by relevant categories» [10], that allows to compare water quality in individual bodies of water and in bodies of water situated of different regions, on the basis of uniform ecological criteria. It includes three blocks of indicators: block of salt composition (I_1), block of tropho-saprobiological (ecological-sanitary) indicators (I_2), block of indicators for specific toxic substances (I_3). Block indicators for salt composition (I_1) includes chlorides, sulfates, mineralization value. Block of trophic and saprobiological (ecological and sanitary) indicators (I_2) includes: suspended matter, nitrates, nitrites, ammonium nitrogen, phosphates, dissolved oxygen, hydrogen index – pH, chemical oxygen consumption, biochemical oxygen consumption for 5 days. Block of indicators of content of specific toxic substances (I_3), which has one (general iron) to eight components (general iron, copper, zinc, manganese, total chromium, phenols, petroleum products, synthetic surface active substances).

The average values for the three block water quality indices are determined by calculating the average number of categories for all indicators of specific block, the three worst values for the block are determined by the relatively worst indicator among all indicators of this block. The results of the environmental assessment are presented in the form of a combined value, which is based on the final figures in the three blocks. Conducting a combined water quality assessment for a particular water body as a whole, or for its individual parts, is a prerequisite to determine an integrated environmental index (I_E) of said body.

An integral (ecological) index (I_E) is calculated using values of block indices to determine the class and water quality category. The procedure for determining the categories of water quality according to the ecological classification for each hydrochemical indicator by average values allowed the absolute quantitative values to be converted into unified, integral indicators of water quality (indices, categories, subcategories, classes), which reflect the essence of the process. This one the changes in the conditions for the formation of water quality under the influence of anthropogenic factors were fixed by the indices, and were defined boundaries of fluctuations of ecological indices of water objects which have important for the decision of issues of water management, implemetation of environmental protection and restoration measures (Fig. 1).

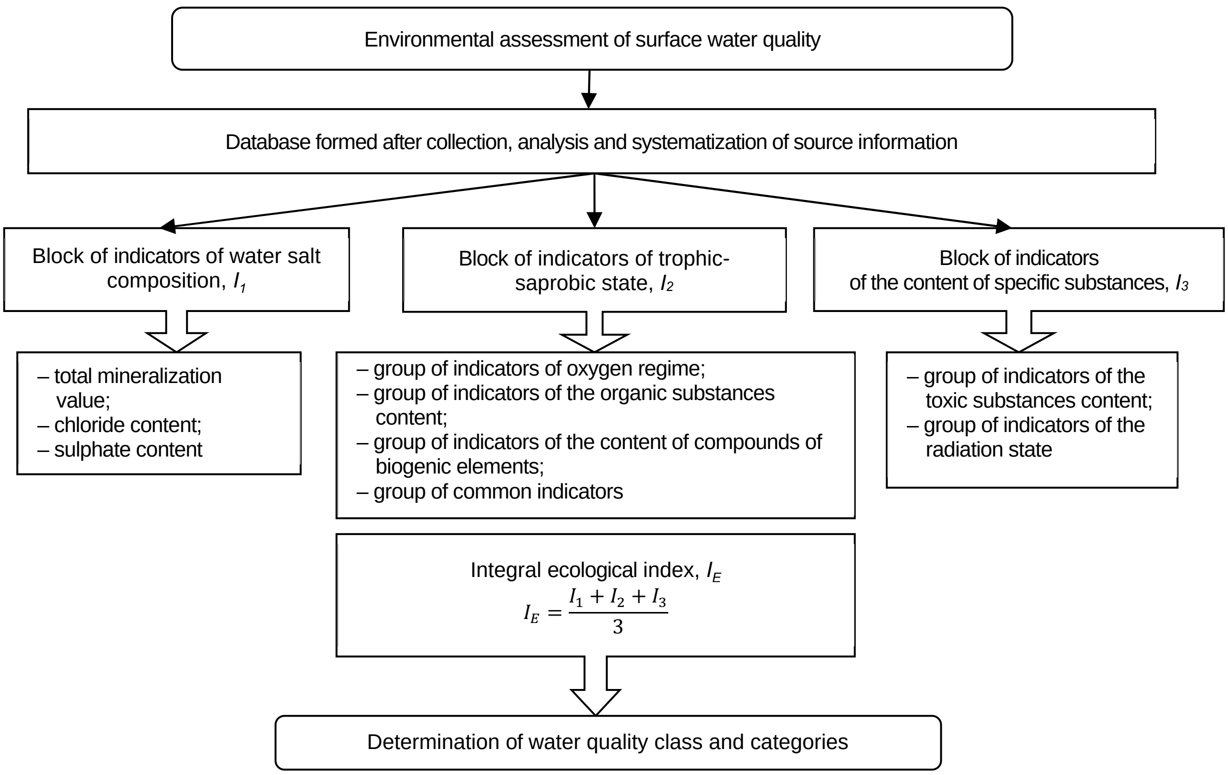

Fig. 1. Flowchart of the environmental assessment of the surface of small rivers belonging to the Ukrainian regions of right-bank Polissia.

The condition of small rivers belonging to the Ukrainian regions of right-bank Polissia was studied by us during 20-year period, from 1999 to 2019. Resulting materials include statistical and cartographic data on the ecological condition, use of land and water resources in small river basins.

 https://doi.org/10.1051/e3sconf/202128010005

Assessment of water quality by salt composition (I_1) in selected sections of rivers of the studied basins included evaluation of river water quality by examination of their levels of mineralization, chlorides, sulfates and determination of ionic composition of river waters. For this purpose, according to «Methodology…» [10], a list of the following classifications was used: classification of surface water quality according to mineralization criteria, surface water quality classification according to ionic composition criteria, fresh hypo- and oligogaline water quality classification according to salt composition pollution criteria.

Assessment of water quality of the tropho-saprobiological block (I_2) was conducted using hydrophysical, hydrochemical parameters and saprobity indices. The end result of the assessment is the determination of trophic and saprobity zones of waters according to the ecological classification of surface water quality according to tropho-saprobiological criteria [10].

In «Methodology…» [10] when testing the water for specific toxic substances, the quantitative characteristics of 10 metals, as well as fluorides, cyanides, petroleum products, volatile phenols and synthetic surfactants, a total of 18 elements was screened for. However, the available information does not allow to give a sufficiently objective evaluation of the water quality of the Ukrainian regions of right-bank Polissia according to the criteria for toxic substances. Therefore, the following materials should be considered as indicative, and need further supplementation and clarification.

Calculated values of integral ecological indices (I_E) were compared against the environmental classification, with qualitative condition of water and the class and category of its quality being determined. In general, water quality is divided into five classes, which are accepted in many European countries. These classes have certain characteristics and a corresponding colour of the designation, which allows to clearly illustrate the ecological condition of the reservoir (table 1).

Table 1. Classes and categories of surface water quality according to the ecological classification [13].

Value of indicator I_E		1.0–1.50	1.51–2.50	2.51–3.50	3.51–4.50	4.51–5.50	5.51–6.50	6.51–7.00
Water quality classes and categories by their natural condition	class	I	II		III		IV	V
		excellent	good		satisfactory		bad	very bad
	category	1	2	3	4	5	6	7
		excellent	very good	good	satisfactory	mediocre	bad	very bad
Classes and categories of water quality by the degree of its cleanness (pollution)	class	I	II		III		IV	V
		very clean	clean		polluted		dirty	very dirty
	category	1	2	3	4	5	6	7
		very clean	clean	fairly clean	slightly polluted	moderately polluted	dirty	very dirty

Results

Rivers, together with their catchment areas, are complex interconnected systems. Any changes in the catchment area will inevitably lead to change in the river itself. As a result, all the main factors influencing catchment area of a small river (forest cover, wetlands area, humidity, percentage of arable land, presence of pollution, reclamation works, etc.) make it possible not only to evaluate the state of its ecosystem, but also to predict major trends in its development and determine the set of necessary measures that can improve water quality, environmental conditions of rivers and the state of coastal areas. Significant factors influencing small rivers are: presence of municipal, industrial and agricultural runoff. Their impact is rather dangerous, as in some cases the volume of runoff may be the same or even greater than that of a small river [9; 11].

The main ecological problems of small rivers of the Ukrainian regions of right-bank Polissia are: inflow of pollutants into rivers from the territories of settlements, industrial facilities and agricultural lands; soil erosion in the catchment areas; discharge of untreated and insufficiently treated wastewater into water bodies [3; 12].

Water quality assessment by indicators of salt composition (I_1). The formation of the chemical composition of the riverbeds of the rivers of the Ukrainian regions of right-bank Polissia takes place in conditions of excessive moisture, prevalence of carbonate-enriched Upper Cretaceous rocks and groundwater present in them, draining into riverbeds. This predetermines the hydrocarbonate-calcium composition of their waters: the relative concentration of HCO_3^- varies between 27-40% eq., And Ca^{2+} - 33-45% eq.

The salt composition of the water of small rivers of the Ukrainian regions of right-bank Polissia is formed in conditions of high humidity and presence of carbonate and gypsum rocks that form the basis of the catchment area. Therefore, the water of most rivers under natural conditions corresponds, according to the classification of O.O. Alokin, to hydrocarbonate class, calcium group oftype II-III, $C^{Ca}_{II\text{-}III}$.

The waters of the right tributaries of the Pripyat have an average mineralization (in the amount of ions) of 156-350 mg/dm3. In the waters of the main riverbed of the Pripyat and its tributaries, the content of chlorides is up to 30 mg/ m^3, sulfates - up to 50 mg/dm^3. On average, the waters of most rivers have low (200 mg/dm^3) and moderate mineralization (200-500 mg/dm^3). The increase in the amount of ions was observed only in places of discharge of insufficiently treated and untreated wastewater from municipal, industrial and agricultural facilities (Turiya, Kovel 424 and 514 mg/dm^3; Styr, Lutsk 400 and 480 mg/dm^3; Horyn River, below the discharge of WTP«Prolisok» 410-440 mg/dm^3; Ustya River, Rivne 702 mg/dm^3; Ubort River, Yemilchyne urban-type settlement 510 mg/dm^3).

On average, the water of the of small rivers of the Ukrainian regions of right-bank Polissia in terms of average and worst values of the sum of ions, belongs to category 1 "excellent" in class, "very clean" in degree of purity. It should be noted, that in areas where the highest values of the worst values of mineral content of water belong to category 2, which is caused by the anthropogenic activity.

The content of chlorides and sulfates depends on the natural conditions under which the chemical composition of water forms, as well as on the degree of intensity of anthropogenic activity in the catchment area. On average, in the Pripyat basin, the chlorides levels range from category 1 «excellent», «very clean», starting at the sources, to category 3 –«good», «fairly clean» in the middle reaches. With the exception of the waters of the rivers Ubort (Yemilchyne) and Noryn' (Ovruch), with average and worst chlorine ion content (97.2-143.0 and 79.8-104.5 mg/dm^3, respectively) classified as category 4 («satisfactory», «slightly polluted» waters), which is caused by the discharge of insufficiently treated wastewater from municipal enterprises of the urban-type settlement of Yemilchyne and city of Ovruch.

As for sulfates, according to the average and worst values of this indicator, the waters of the rivers of the Ukrainian regions of right-bank Polissia are in between 1 and 2 quality categories and varies from «excellent», «very clean» to «very good», «clean».

Evaluation of situation in the water bodies of the Ukrainian regions of right-bank Polissia by the criteria of pollution by components of the salt composition indicates that situation is quite good. The calculated indices of salt composition (I_1) indicate that the water of the main riverbed of the Pripyat on the average and worst values of I_1 is characterized as «excellent», «very clean» ($1{,}0 \leq I_1 \leq 1{,}3$), «very good», «clean» water ($1{,}7 \leq I_1 \leq 2{,}0$). There is only some deterioration in the water quality of the Ubort and Noryn' rivers, where the indices are in the 1,7-3,0 and 2,0-2,7 ranges respectively. That is, water quality varies from «very good», «clean» to «good», «fairly clean» (table 2).

Table 2. Water quality assessment of small rivers of the Ukrainian regions of right-bank Polissia according to the worst and average values of block indices (I_1, I_2, I_3)

№	River*	The value of indices					
		I_1		I_2		I_3	
		avg.	max.	avg.	max.	avg.	max.
1	Pripyat	1,0	1,3	4,6	5,3	3,5	4,5
2	Vyzhivka	1,0	1,7	4,8	5,5	3,4	4,6
3	Turiya	1,0	1,3	4,8	5,2	3,9	5,0
4	Tsyr	1,7	1,7	4,8	5,3	3,3	4,6
5	Stokhid	1,3	1,3	4,1	4,9	3,0	4,7
6	Styr	1,3	1,3	4,7	5,2	3,9	5,0
7	Lypa	1,3	1,7	4,6	4,9	2,2	3,5
8	Prudnyk	1,0	1,0	4,9	5,2	3,5	4,8
9	Serna	1,0	1,0	3,8	3,9	2,2	3,0
10	Chornoguzka	1,3	1,3	4,0	4,0	2,1	2,5
11	Horyn	1,3	1,3	4,6	4,8	2,2	3,9
12	Putylivka	1,3	1,7	4,4	4,9	2,7	3,6
13	Sluch	1,3	1,7	4,1	4,7	3,3	3,4
14	Ubort	2,0	2,3	4,4	4,8	-	-
15	Uzh	1,7	2,0	3,7	4,3	4,6	5,0
17	Noryn	2,0	2,7	4,8	5,0	3,0	3,2
On average in the river basin		1,3	2,0	4,4	4,8	3,1	4,1

Note: * - on average along the river. I_1 – block index of salt composition; I_2 – block tropho-saprobiological index; I_3 – block index of specific toxic substances; I_E – ecological water quality index.

Water quality assessment by tropho-saprobiological (sanitary and hygienic) indicators (I_2). The water quality of small rivers of the Ukrainian regions of right-bank Polissia, assessed by the worst values of tropho-saprobiological indicators, belonged to category 5, subcategory 5(6), i.e. eupolytrophic waters with slant to polytrophic waters of ά'-mesosaprobic and ά''-mesosaprobic zones. The water quality evaluated by the average values of the same indicators, belonged to subcategory 4-5, i.e. in the transitional state from eutrophic to eupolytrophicwaters of the transitional β''-mesosaprobic to ά'-mesosaprobic zone.

The waters of small rivers of the Ukrainian regions of right-bank Polissia as a whole are also assigned quality category 5 «mediocre», «moderately polluted», but if they are evaluated by the worst values of the indicators they would unconditionally belong to the eupolytrophic waters of the ά'-mesosaprobic zone, while judging by the average values of these indicators - to the eupolytrophic waters with a slope to eutrophic waters of the ά'-mesosaprobic zone with a slant to β''-mesosaprobic zone. That is, within the 5th category of water quality, these rivers vary only by some differences in the worst and average values, expressed at the subcategory level.

Overall, the water quality in the rivers of small rivers of the Ukrainian regions of right-bank Polissia, assessed according to tropho-saprobiological criteria, corresponds to class III («satisfactory», «polluted»). The main reason for the current state of the rivers is the excessive content of nitrogen and phosphorus compounds in the water, i.e. intensive eutrophication (table 2).

Water quality assessment by indicators of specific toxic substances (I_3). The index of specific toxic substances (I_3) indicate a considerably high levels of pollution of the waters of the rivers of small rivers of the Ukrainian regions of right-bank Polissia by specific toxic substances. The value of I_3 for the Pripyat River varies in the range of 4,4-5,2 by its worst value («satisfactory», «slightly polluted», - «mediocre», «moderately polluted» water), and the average - 3, 1-3.7 («good», «fairly clean» - «satisfactory», «slightly polluted»). According to the worst values of this index, the water of the Pripyat basin corresponds to the III class of quality «satisfactory», «polluted», and according to the average - II-III class and is assessed as «good», «fairly clean» - «satisfactory», «slightly polluted».

The waters of the rivers Vyzhivka, Turiya, Tsyr,Stokhid, Styr, Prudnyk, Uzh have the highest average and worst values of I_3: the worst values (I_3 = 4,6-5,0, category 5, subcategories 4-5 and 5) is graded as «mediocre», «moderately polluted», class III quality «satisfactory», «polluted» water, and its average value (I_3 = 3,0-3,9, categories 3 and 4) as «good», «fairly clean» - «satisfactory», «slightly polluted», II-III class «good», «clean» - «satisfactory», «polluted» (table 2).

The rivers Horyn and Putylivka have the same characteristics (average values I_3 = 2,2-2,7, the worst values I_3 = 3,6-3,9). The water quality of these rivers corresponds to 2 and 3 categories, subcategories 2 and 3(2) with average values of I_3 and 4th category, and subcategories 3-4 and 4, by the worst, II and III quality class, «good», «clean» and «satisfactory», «polluted».

The waters of the rivers Sluch, Noryn' (Ovruch) and Ubort (Perga) are in the categories«good», «fairly clean» (category 3) and «satisfactory», «slightly polluted» (category 4), and by class quality–«good», «clean» (class II) and «good-satisfactory», «clean-polluted» (class II-III).

The waters of Chornohuzka and Serna (I_{3avg} = 2,1 and 2,2, category 2, I_{3w} = 2,5 and 3,0, category 3, respectively) are graded (by the value of the index of specific toxic substances) as the cleanst.

At 17% of the study sites located in the Pripyat basin, the index of specific toxic substances (I_3) was calculated only by determining the total iron content in river waters. Therefore, it makes no sense to use such insignificant information to calculate the integrated index of specific toxic substances.

Limited data available from field experiments in the block of specific toxic substances made it possible to determine only an approximate grade for water quality. The results displayed a tendency to reduction of anthropogenic impact on water by such compounds as iron and chromium, although the nickel content of water deteriorated from categories 2 and 4 to category 5 by average and the worst indicators. On average, the quality of water in the region has improved, in regards to pollution with specific toxic substances, as according to the average and worst indicators it has «appreciated»from categories 4 and 5 to category 3, quality class II, water «good», «clean».

Integrated environmental assessment of surface water quality (I_E). The essence of determining the joint grade of water quality in the of small rivers of the Ukrainian regions of right-bank Polissia as a whole and at individual observation points is to calculate the integrated ecological index (I_E), according to which, an unambiguous assessment of river water quality is performed. It is calculated for the average and worst values of block indices for individual items and on average for rivers (table 3). The analysis of calculations indicates that the values of integrated indices (I_E), calculated using average and worst values of block indices are: on the rivers of Pripyat – 3,0/3,7; Turiya – 3,2/3,8; Tsyr– 3,3/3,9; Stokhid – 2,8/3,6; Styr – 3,3/3,8; this classifies the waters of these rivers as intermediate between categories 3 and 4 «fairly clean» and «slightly polluted».

According to the water quality class of the main riverbeds of Pripyat, Turiya, Tsyr, Stokhid, Styr, Horyn, Sluch, Uborta, Noryn are rated as «good», «clean» and «satisfactory», «polluted».

During the study period, the best quality of water from the tributaries of the Pripyat according to the I_E came from the rivers Chornohuzka ($2,5 \le I_E \le 2,6$), Serna ($2,3 \le I_E \le 2,6$), Sluch ($2,5 \le I_E \le 3,3$), and Pripyat ($2,3 \le I_E \le 2,5$), and the worst quality in terms of these indices - rivers Vyzhivka ($3,1 \le I_E \le 3,9$), Tsyr ($3,1 \le I_E \le 3,9$) and Uzh ($3,7 \le I_E \le 3,9$). The waters of these tributaries belong to the II class according to the average and to the III class - according to the worst characteristics of I_E.

Thus, condition of water bodies in the basin of the Pripyat River has improved according to the worst indicators from class III «satisfactory», «polluted» to class II water «good», «clean».

Proposals that will help improve the ecological condition of water resources: 1) reconstruction of existing and construction of new treatment facilities; 2) termination of untreated effluents discharges into rivers; 3) strict following of current water protection legislation by all water users.

Conclusion

The results of observations on the quality of surface waters of small rivers of the Ukrainian regions of right-bank Polissia indicate their satisfactory condition. Water corresponds to the II-III class of water quality. Exceeding the MPC (Maximum Allowable Concentration) in the surface waters of small rivers of the Right Bank Polissia was recorded by tropho-saprobiological indicators. This is due to the high anthropogenic load in river basins, in particular discharges of insufficiently treated wastewater.

Table 3. Combined water quality assessment of small rivers of the Ukrainian regions of right-bank Polissia according to the worst and average values of the integrated ecological index (I_E)

№	River*	I_E		Grage by class		Degree of purity	
		avg.	max.	avg.	max.	avg.	max.
1	Pripyat	3,0	3,7	good	satisfactory	pure	polluted
2	Vyzhivka	3,1	3,9	good	satisfactory	pure	polluted
3	Turiya	3,2	3,8	good	satisfactory	pure	polluted
4	Tsyr	3,3	3,9	good	satisfactory	pure	polluted
5	Stokhid	2,8	3,6	good	good -satisfactory	pure	pure - polluted
6	Styr	3,3	3,8	good	satisfactory	pure	polluted
7	Lypa	2,7	3,4	good	good	pure	pure
8	Prudnyk	3,1	3,7	good	satisfactory	pure	polluted

10	Chornoguzka	2,5	2,6	good	good	pure	pure
11	Horyn	2,7	3,3	good	good	pure	pure
12	Putylivka	2,8	3,4	good	good	pure	pure
13	Sluch	2,9	3,3	good	good	pure	pure
14	Ubort	3,2	3,5	good	good -satisfactory	pure	pure - polluted
15	Uzh	3,3	3,8	good	satisfactory	pure	polluted
17	Noryn	3,3	3,6	good	good -satisfactory	pure	pure - polluted
On average in the river basin		3,0	3,7	good	satisfactory	pure	polluted

Determining the water quality of small rivers is important for assessing the ecological situation of bodies of water of the Ukrainian regions of right-bank Polissia, and main areas of water protection activities to improve the ecological status of each water body, as well as establishing environmental standards for water quality. Environmental assessment of the river water quality is important for generalizing information on the ecological condition of water bodies, forecasting its changes and developing scientifically based water protection recommendations for approving appropriate management decisions in the field of use, protection and reproduction of water re-sources. All this determines the prospect of further studies on the quality of surface waterof of small rivers of the Ukrainian regions of right-bank Polissia.

Abstract. The use of surface heating with heat exchangers significantly affects the temperature regime of the soil and the surface air layer. It is manifested in a change in the distribution of temperatures according to the soil horizon, in a considerable increase in the temperature of the soil and air, in a change of heat exchange between the soil and the surface layer of air. When using tunnel greenhouse, heating the soil with the coolant temperature of 25…30 ºC contributes to the creation of all necessary conditions in ground area equipped with a heat exchangers for shifting the vegetation period of ultra-early cultivation of agricultural crops, on average, by 1-2 months depending on the crop type. This allows for earlier sowing and planting of thermophilic crops and getting harvest earlier than usual, as well as increasing the amount of crop production and improving its quality. The thermal efficiency of soil heating with water-filled flexible sleeves was studied experimentally in a field model experiment performed in the climatic terms of the Ukrainian Polissya on sandy loam and chernozem soils. Strawberry of the "Festivalny" type was used as the main crop-indicator. The influence of soil heating with heat exchangers on the growth, development and yield of strawberries has been studied.

1 Introduction

The problem of getting early and permanent yields of agricultural crops, particularly vegetables and berries; flowers of saleable quality is one of the major socio-economic issue in agriculture of many countries. Climate change and weather conditions, which are becoming unpredictable, exacerbate the urgency of the problem. In the generally accepted tendency of global warming, experts also pay attention to the possibility of local temperature decreases in some areas, prolonged cold periods in spring, considerable fluctuations of weather conditions [1-4].

Studying the influence of possible climatic and weather changes on the development and productivity of agricultural crops production and developing measures to prevent the negative climatic and weather phenomena are becoming relevant in agriculture not only for researchers but also for professional practitioners

The role of climate in improving soil fertility is well-known, scientists have even introduced a concept "agricultural fertility of the climate" as the ability of the atmosphere and the underlying surface to provide a certain level of soil fertility and agricultural crops yield through climatic resources. It is thus emphasized that the soil properties, its natural and effective fertility are manifested only in the presence of certain amount of moisture in the soil and at a certain thermal regime [5-7].

Thermal resources play a significant role in yield formation. Each plant has its own strictly individual thermal-temporal structure of the development cycle from sowing to harvesting. The parameters of this cycle are strictly related to the corresponding level of temperatures in the soil and air. Therefore, purposeful control of plant ontogenesis can be possible by controlling the thermal regime of the microenvironment of its habitat. It is obvious that the thermal regime of the soil and the surface layer of air will be also decisive for the intensification of the processes of growth and early cultivation of crops.

The analysis of meteorological observations in the Ukrainian Polissya shows that the danger of low temperatures persists at night and in the early morning hours practically throughout the entire spring period. For instance, the frosts up to -10ºC took place daily until March, 25, the transition of minimum air temperatures to more than -10ºC took place on April, 10. During April, nighttime sub-zero temperatures of air persist. Even in April, the air temperature drops to -1 ºC [8, 9].

These features of temperature conditions of the Ukrainian Polissya do not allow the active vegetation to begin in March-April, especially for thermophilics crops, and force to postpone the active soils use to May. The task of heat supply for crop production in the early spring periods is traditionally solved by creating greenhouse facilities and by heating the soil. Thus, high-temperature sources of thermal energy are used for heating the soil and air in cultivation facilities, which are obtained by burning high-value fuels, primarily natural gas.

Significant increase in the price of natural fuels and thermal energy puts on the agenda the tasks of finding, justifying and developing alternative ways to regulate the thermal regime of the soil and air, sources of alternative

energy with the purpose of getting early harvests of agricultural crops.

2 Materials and methods

One option for solving this problem can be creation of soil areas heated by special thermal reclamation facilities using thermal wastes from industry. Hot water (heat-exchange water) from industrial and power-generating facilities with the temperature of 20-40 ºC and geothermal water can be used as attractive free sources of thermal energy [6, 10-12]. Their attractiveness is that such temperatures are optimal for the development of most crops.

In the 80s of the last century in many developed countries of the world, in the USA, France, Germany, the former Soviet Union, and in particular at our National University of Water and Environmental Engineering, long-term researches of the efficient use of the charged hot water from nuclear power plants and thermal power plants for heating the soil by the pipeline systems were conducted [13-23]. The pipeline systems showed sufficient efficiency in increasing the productivity of separate agricultural crops and enabling earlier harvesting. However, their thermal efficiency in relation to the surface layer of air was low (0,5…1,5 ºC), which did not allow them to find wide application as an effective method of heating reclamation, except for some engineering problems (cooling of water in soil, accumulation of heat in the soil, heating of sports grounds, etc.).

One of the promising and effective methods of thermal reclamation of adjacent areas, in our view, can be the surface heating of soil with warm water with the temperature parameters within 25…35 ºC.

The working scientific hypothesis is that the maximum thermal effects when using water with such temperatures should be expected with directing the water flows to the area of plants habitat. The transfer of thermal resource in the amount of 15…20 ºC to the environment "soil – air" will theoretically allow shifting the transition through 10ºC to the end of February – beginning of March (fig. 1).

Technologically, this technique can be implemented by directing the water flow in a thin layer on the soil surface, and can be technically executed with the application of special sleeves – heat-exchangers of various designs and geometry, made of thin, long lasting, flexible polymeric materials – films (fig. 2).

The thermal efficiency of soil heating with water-filled flexible sleeves was studied experimentally in a field model experiment performed in the climatic terms of the Ukrainian Polissya on sandy loam and chernozem soils [24-25]. Strawberry of the "Festivalny" type was used as the main crop-indicator. The soil was heated with specially heated warm water, which circulated by gravity-flow under a small initial pressure (10...20 cm) (fig. 2). The temperature of water in the sleeves was automatically maintained within 24…26 ºC in March with a subsequent increase in April and May up to 27…30 ºC.

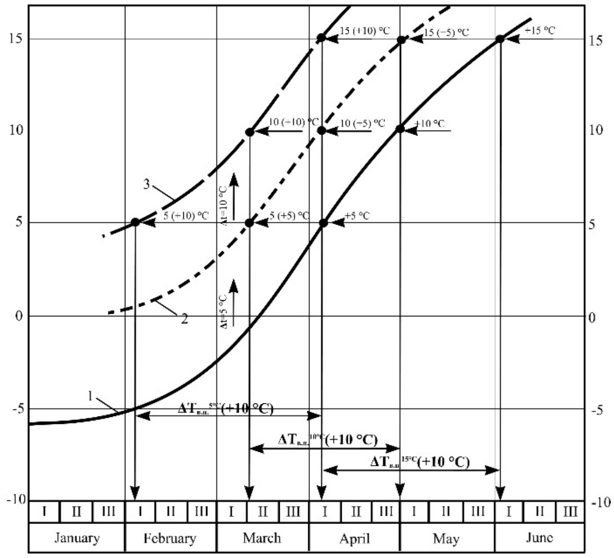

Fig. 1. Forecast of the efficiency of heat reclamation for the conditions of Ukrainian Polissya: 1 – average ten-day long-term temperatures of the surface air layer (Rivne); 2 – increased air temperatures by 5°C; 3 – increased air temperatures by 10°C.

Fig. 2. A general view of heat-exchanger with plants.

The temperature of the soil, air and water circulating in heat-exchangers was measured by precise laboratory meteorological mercury thermometers, by Savinov thermometers to the depth of 20 cm, by buried thermometers in depth, electric thermometers, and aspiration psychrometers. In the experiment, part of the heated adjacent areas was additionally protected by tunnel

https://doi.org/10.1051/e3sconf/202128010006

type film greenhouse (Fig. 2). For this purpose, polyethylene film with the thickness of 150 mkm was used. The water was heated by an automatic water heating device, the heated water supply was regulated by dampers and valves.

3 Results and discussion

The initial stage of soil heating by heat-exchangers was studied by us since March, 12, 2009 during two weeks. All parameters were measured twice a day at 7:00am and 7:00pm. The basic results of measuring the temperature of soil, water and air, are shown in Figure 3. An open heated ground in natural conditions was taken as a control option.

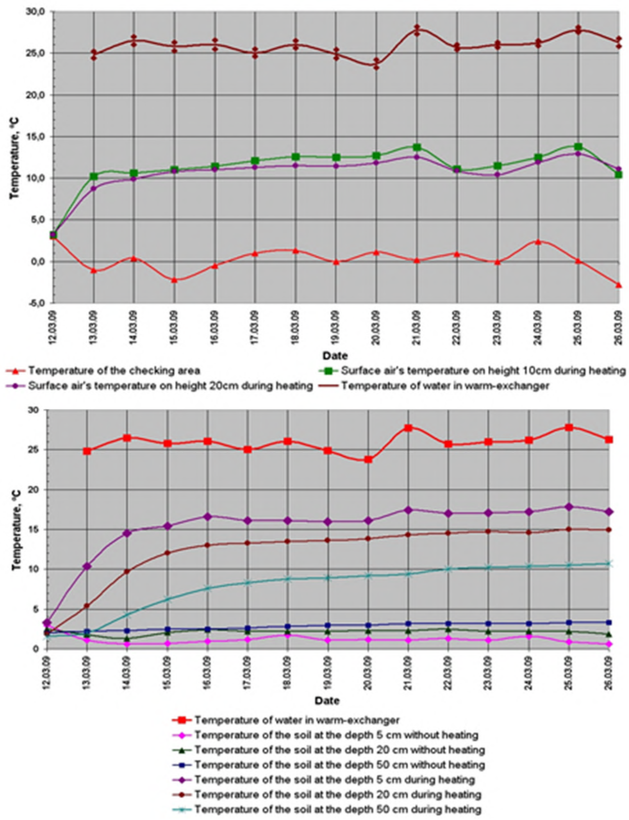

Fig. 3. The research results of surface air (A) and soil (B) temperature in March 2009.

The research results show that surface heating is an effective technical method of thermal reclamation of the plants habitat, which makes it possible to quickly and reliably increase the temperature of the soil and the surface air when using a film cover. On the third day of operation of heat exchangers, the temperature in the upper 20 cm soil layer rose to 10…14ºC. At the same time, due to the heat flow from the surface of heat exchangers upwards, the surface air layer warmed up to 8…11 ºC.

On the fourth-fifth day of the heating system operation, favorable temperature conditions were created at the level of 14…16 ºC in the upper 20 cm layer of soil and about 10…12 ºC in the surface layer of air, which were constantly preserved even on cloudy and frosty days. Therefore, heating with heat exchangers, which is very important, is guaranteed to maintain the positive air temperature at night and protect plants from frost.

The soils temperatures obtained as a result of constant heating (14…16 ºC) promote the germination and development of most vegetable and berry crops, even thermophilic ones. In this case, under natural conditions, soil and air temperature remain very low, varying from - 2 ºC to +3 ºC. The whole period of observations of the soil in natural conditions remained unprepared for agricultural use due to low temperatures. It should be noted that at this time there was precipitation in the form of snow and cold rain. The snow that fell remained on the surface of the control area, while on the surface of the film cover it melted and turned into water.

Heat-exchangers constantly consumed thermal energy, and consequently water cooled down. As a result of measurements and calculations of thermal energy, its consumption amounted to 700-800 Wt/h or 200-220 Wt/h per one square meter of soil which was heated, and water in the sleeves cooled down by 0,6...0,9 ºC.

Observations of the soil temperature have shown that the effect of heating extends to a considerable depth. Thus, according to the results of measurements in 2009, the soil temperature at a depth of 1 m under heat exchangers after two weeks of their operation rose to 6.4 ºC, while in the control area it amounted to 4 ºC (table 1).

Obviously, soil heating can be carried out at the depth of 2m and more. In this case, an array of heated soil is created under the heat exchanger, accumulating significant reserves of thermal energy. This reserve of thermal energy guarantees the protection of the upper root layer of the soil from penetration of negative temperatures from the lower soil layers.

Table 1. Temperature of the soil in the area that is heated and in the control area in different points of the soil profile, ºC (of March 26, 2009 at 7:00 am).

Depth, cm	Control area	Heated Soil
0.0	-0.3	15.4-22.8*
5.0	0.6	17.5
10.0	0.8	17.2
15.0	1.6	16.8
20.0	1.9	15.8
30.0	2.7	13.5
40.0	3.0	11.8
50.0	3.3	10.7
60.0	3.4	9.7
80.0	3.6	7.5
100.0	4.0	6.4

*Note: lower value corresponds to the soil temperature at input of the heat exchanger, higher one – to the temperature of the soil above the heat exchanger.

Great importance in assessing the temperature of the heated soil is attached to the peculiarities of its formation during the vegetation period (March-May), as well as during the day. According to the results of our research in 2004-2013, conducted on sandy loam soils of the Ukrainian Polissya, the influence of the surface heating is more noticeable in cold periods (March, April). The constant inflow of heat from the heating system prevents penetration of negative temperatures into the soil and maintains the temperature background in the habitat of plants at the levels close to optimal [6, 11, 26].

The temperature regime of the soil in the daily cycle, due to the frequency of receiving solar heat, is characterized by a slow change of temperature values from maximum to minimum, which changes with time and depth.

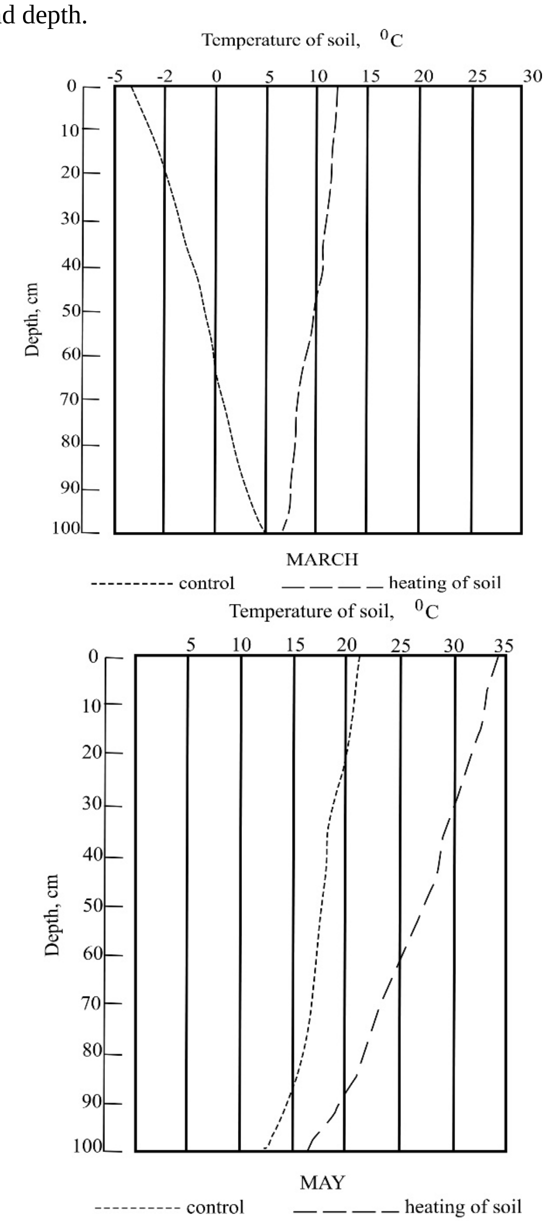

Fig. 4. Profile changes of average monthly soil temperatures in 2009.

In the course of our research it is found out that the general nature of temperature changes during the day, both in the heating section and in the control one it remained the same. For example, the maximum temperatures of soil at the depth of 5 cm for the heated area are reached at 4:00pm…6:00pm and are within 27…29 °C, while in the control area – at 5:00-6:00pm reaching the temperature 18…19°C. The minimum soil temperatures are observed in the heated area at 7:00-8:00am and are 19…20°C, and in the control area they reach 12…13°C at the same time. The process of heat exchange in the "soil-air" system and the direction of heat flows depend on the thermal gradient conditions in the soil. The heated soil is characterized by the presence of maximum temperatures in the area where heat exchangers are located (surface soil), therefore, the dynamics of merging gradients and their type of movement must be investigated for a considerable soil layer (fig. 4) [6, 27-28].

In March, 2009, soil temperature at the depth from 0 to 20 cm in the control area was below zero, while in the heated area it reached 11…13 ºC. In the layer from 20 to 80 cm, the temperature of control soil changed from 0,5ºC to 3.5 ºC, and in the heated area it ranged from 8ºC to 11ºC.

A completely different picture is observed in May. For example, in the soil layer ranging from 0 to 20 cm in the control area, the temperature is 20…21 ºC, and in the heating area – 31…34ºC. In the layer from 20 to 80 cm in the control area, the soil temperature is 16…20 ºC, and in the heating area – 26…32ºC.

Although heating with heat exchangers using warm water cannot create optimal temperatures in the upper soil layer immediately after starting the system, but in late March and early April contributes to its increase by 10°C and more, and in mid-April – by 15ºC and more. At the control site, the temperature reaches 10ºC in late April, and 15ºC in mid-May.

The increase in periods of soil heating and increase in absolute temperatures during these periods result in the increase in the sum of soil temperatures during vegetation period (table 2).

Table 2. The sum of soil temperatures more than 5, 10, 15 and 20 ºC at the depth of 20 cm, ºC

Temperature, °C	Heating with heat exchangers	Control
5	8125	6348
10	7240	5886
15	6430	4522
20	4055	1925

The obtained results demonstrate that from the point of view of positive temperatures accumulation, the option of soil heating with heat exchangers with the use of greenhouses provides very effective heat reclamation method.

The difference in sums of soil temperatures at the depth of 20 cm as compared to control area are more than 2000ºC.

As our research has shown for the heated soil, the relationship between its temperature (Y) at the depths of 5, 10, 20 cm, air temperature (X) and water temperature in heat exchanger (Z), can be described by the following empiric equations (for values of Z > 20 ºC):

$$Y_{0.05} = X + 0.14 \times Z - 0.48; R_{xyz} = 0.95 \quad (1)$$

$$Y_{0.1} = X + 0.15 \cdot Z - 1.76; R_{xyz} = 0.95 \quad (2)$$

$$Y_{0.2} = X + 0.12 \cdot Z - 2.4; R_{xyz} = 0.95 \quad (3)$$

When using tunnel type greenhouses, soil heating with heat exchangers with water temperature of 25…30 ºC helps create all the necessary temperature conditions for shifting the vegetation period and early growth of agricultural crops, on average, from one to two months depending on the type of crop.

The moment that determines the beginning and suspension of active vegetation of plants is the date of transition of air and soil temperature through 10 ºC. With the onset of the dates of temperature transition through 10ºC, the same patterns appear along with the beginning of active temperatures period. In the area of heating by heat exchangers, the date of temperature transition through 10ºC in the soil at the depth of 20cm in 2009 fell on April 1, and in the control area – on April 22, that is 21 days earlier.

It is known that the criterion for assessing the effectiveness of any measures, including heat reclamation is the yield of crops. As a result of application of surface heating in a root-containing layer, there is a change of a whole complex of processes which, in the end, influences the growth, development and formation of crops.

We studied the effect of surface heating on the growth and development of the “Festivalny” strawberry type. The results of observations during March-May 2009 showed that the first leaf on the strawberry appeared on March 19 and at the same time it increased the appearance of the second leaf, and the third one appeared on March 23. Strawberries beginning of stolon (runner) formation in the area of soil heating on April 3 (code 41 according to the BBCH-scale of strawberry) [29], and on April 6, 5 flowers appeared and mass flowering began on April 9 and lasted throughout the second decade of April. Mass bud forming of strawberries was observed on April 21, and the first crop of ripe berries was harvested on April 25.

The dynamics of the strawberry harvest during the study period is presented in Table 3.

Table 3. Dynamics of strawberry crop yield.

Date	**The mass of berries, g**	**The average weight of 1 berry, g**	**crop yield**	
			g / m^2	**g / meter of heat exchanger**

4 Conclusion

Field research has shown that heating the soil with heat exchangers circulating hot water with the temperature of 25...30°C increases the temperature of the arable layer by 12...16°C in the soil, and by 7...12°C – in the air, which provides sufficient conditions for plant growth and development in early spring.

It is proved that heating with heat exchangers allows the period of active soil use to start earlier in the spring by 40-60 days for sheltered soil, and also increases the amount of positive temperatures in the arable soil layer during the spring period by 1500 ... 2000°C. Close linear relationships are established between the temperatures of soil, air and water in the sleeves.

It is established that the joint action of surface heating and solar radiation during the day leads to a rapid increase in air temperature and the need for ventilation of tunnel greenhouses. Intense ventilation leads to the loss of moisture that evaporates from the plants and drying of the upper 10-cm layer of soil, which causes the need to replenish moisture in the soil during the increase in strawberry yield. It is recommended to carry out two or three waterings in late April and early May at the rate of 150-200 m^3/ha.

The influence of soil heating with heat exchangers on the growth, development and yield of strawberries has been studied. Under the conditions of soil heating, ripening of strawberry berries occurs to about 40 days earlier than in the control area without heating, the total yield increases due to heating by 50% or more when compared to the control area.

Assessment of the introduction of surface heating technology for soil on the area of 1 hectare as an innovative project based on the methodology for assessing net discounted income gives a net discounted income of 32 thousand dollars when growing strawberries. The payback period for capital investments does not exceed 3 years.

At the same time, a number of scientific problems need further research, in particular the issues of rational designs of surface heating systems, heat exchangers, methods of soil protection and structures of greenhouses (translucent shelters), water supply and collection regimes, methods of soil water regulation [30], automation, control and management, operation of heating systems and ventilation systems of greenhouses, technologies of cultivation of agricultural crops, development of methods of thermotechnical and hydraulic calculation, methods of technical operation, etc.

Abstract. This research focuses on the problem of water supply, and its solution requires scientific and practical approaches in environmental, engineering, economic and other fields. Practical recommendations to create an integrated water use system in Ukraine are based on the delimitation of its target subsystems. Special attention is paid to an integrated approach to water resources management, identification of key issues, clear conceptual modeling, strategy development, and production of 'useful' scientific information. It is important to study the role of coordinating government bodies in the field of water space monitoring. In particular, this mechanism involves the development of national program for monitoring the aquatic environment, the formation of budgets of all bodies and institutions; search for additional sources of funding and organizational methods. An important tool for improving the state of water resources is the implementation of international environmental standards and conventions. These strategic decisions are entrusted to the Ministries of Environment and other governing bodies. The use of software products generate significant amounts of data accumulated in various information banks. The main direction of the study is the concentration of information data in one key database. It will provide clear assess to the data aquatic environment and make analytical studies.

The problem of interaction between society and nature is one of the most important issues of humanity. It has required a lot of effort of scientists and practitioners in the environmental, engineering, economic and other fields. The results of previous public research [1-3] are significant progress in this direction: the transfer of environmental information has become much better, environmental monitoring and special studies in various fields of ecology and water use, a number of changes in environmental legislation in accordance with international agreements and conventions. However, it should be noted that despite the desire to improve the environmental situation, society still suffers from anthropogenic pressure.

The problem of water supply needs special attention. Saving of water resources and rational water use is the key to further economic growth and social welfare. Growing freshwater shortages and changing climates are increasingly comprehended as a major risk to the global economy [4]. Scientists point out the need for transition to sustainable water use, which requires appropriate government regulation, business sector initiatives, consumer responsibility [5, 6]. Significant progress in solving water use problems has been the concept of integrated water resources management. It has a number of shortcomings, but it is the basis for many environmental policies, strategies and management systems.

Taking into account the existing scientific achievements, we have shaped the main tasks for building a system of sustainable water use in Ukraine.

In this study, the system of sustainable water use is considered as a complex system that includes a set of simpler, to some extent isolated from each other subsystems with a clear hierarchy of goals, principles and mechanisms of interaction. We consider it expedient to differentiate the development and substantiation of practical recommendations for the creation of a system of sustainable water use in Ukraine according to its five target subsystems. These include the following:

1. development and ensuring the effectiveness of the water source;
2. modernization and ensuring the reliability of water management;
3. rationalization and efficiency of water use in resource constraints;
4. improvement of information and methodological support of water management processes;
5. certification of industries and technologies, as well as regions for the effectiveness of water management.

Sustainable water use requires integrated management. At the same time, special attention should be paid to the definition of key issues, clear conceptual

modeling, strategy development, scenario analysis, production of 'useful' scientific information [7].

To ensure the effectiveness of the first subsystem 'Development and effectiveness of the water resources' we have identified problems that need to be addressed and proposed appropriate measures. For example, there is a significant problem of cooperation between the Ministry of Environment and other ministries, state committees and parliamentary committees, as well as with regional and local authorities. Complex and lengthy procedures do not promote cooperation in the development of legislative projects. Therefore, in our opinion, the National Environmental Action Plan should be revised and refined to take into account the prospects of implementing a sustainable water use system in order to set clear priorities, goals and time frames in different sectors of environmental protection. This needs to be done in close cooperation with other ministries and stakeholders.

Despite the fact that the correlants of the Ministry of Environmental Protection of Ukraine are aware of the importance of international legislative instruments, the urgency of implementing the provisions and compliance with new norms and action plans, however, the latter is not a priority for this institution. A serious analysis of water use needs will clarify the objectives and ensure clear implementation of the obligations of related ministries and agencies. To improve the situation in this area, strategic plans for the implementation of agreements should be developed and agreed together with proposals for ratification, their implementation should follow the integration of international obligations into national law and include financial obligations to implement and comply with the provisions of Association Agreements of Ukraine with EU Member States. In addition, strategies and strategic plans need to focus on defining and justifying realistic goals, rather than developing unrealistic programs within the 'doctrinal foundations of sustainable development'.

The NGO sector includes not only independent organizations but also former state-supported research institutes. The current Public Council does not appear to be representative enough to be the Ministry's only partner for public consultation. Because of the Chernobyl accident, public environmental concerns and interest remain relatively, high compared to many other Central and Eastern European countries, although environmental protection does not seem to be a top priority given the problems of the economic crisis. Therefore, the Ministry of Environmental Protection of Ukraine should strengthen its coordination activities on environmental monitoring. Complete and coherent national monitoring systems need to be developed, which should be preceded by consistency of data systems and methodologies. Data needs to be systematized, integrated and prepared for management decisions. The European Environment Agency must be provided with aggregated data. Work on the development of an adequate information system should be accelerated in order to increase public and government concerns about environmental issues.

The Ministry can strengthen its position in public if it succeeds in meeting the high social interest in solving environmental problems. Although some laws provide for public participation, it is not significant in the environmental field, as adequate procedures are not developed. The expected ratification of the Aarhus Convention is the right step, which, however, cannot replace the procedural grounds for public participation. The Ministry of Environment should improve public access to environmental information in accordance with the Aarhus Convention and seek closer contacts with the entire NGO sector, including in the development of laws, policies and programs. Appropriate methods for enhancing public participation should be adopted in consultation with NGOs. Environmental impact assessment should be seen as one of the mechanisms to increase public participation in the decision-making process. The ministry must determine its contacts with the press. The public should be encouraged to exercise their environmental rights, and the development of procedures for public participation in environmental decision-making should be accelerated.

Although Ukraine is already a part of many international conventions, several have not yet been ratified, including the Convention on the Transboundary Effects of Industrial Accidents, the Convention on Cooperation for the Protection and Sustainable Use of the Danube River Basin and some protocols to the Convention on Long-range Air Pollution. Ratification of these agreements can be a tool for further development and strengthening of comprehensive environmental policy and legislation and international cooperation in these fields. Considering the ratification of these conventions as soon as possible, it should be borne in mind that a full and realistic assessment of their consequences is a prerequisite. The National Commission for Sustainable Development needs to intensify its activities. Meetings of the Commission should be regular so that it becomes an effective tool between sectoral coordination of environmental issues. Together with the world community, Ukraine should produce and consume ecosystem services [8].

Biogens and petroleum products, which come mainly from onshore local sources of pollution through rivers, undermine the environment of the Black and Azov Seas. Despite the significant number of water treatment facilities located in the coastal zone, a significant amount of untreated and incompletely treated industrial and domestic wastewater is still discharged into the sea. Largely, this pollution is a consequence of unsatisfactory technical condition and reduced efficiency of treatment facilities, as well as frequent accidents on sewerage networks and treatment plants. The reasons for this situation - mainly financial - stem from the general economic difficulties in the country. However, in the interests of marine water protection, sewerage networks and treatment facilities need to be repaired and upgraded immediately. Funding can be temporarily secured through mandatory contributions from profitable economic activities in the coastal zone.

The Ministry of Environmental Protection of Ukraine should build up its role as a coordinating governmental unit in the field of marine environmental monitoring. In particular, it should develop a mandatory overall national marine monitoring program and participate in the budgeting of all monitoring bodies and agencies; and ensure that other sources of funding and organizational arrangements are sought.

Ukraine has a significant number of water quality standards, which in some cases are very strict. This leads to a rather complex permitting system, which undermines the application and overloads the understaffed regulators. Therefore, the Ministry of Environmental Protection must ensure the coordination of monitoring programs, as provided for in Resolution № 391 (1998). The number of water quality standards needs to be lowered and they need to be implemented at true levels to enable their practical application.

Surprisingly, there are no formal consultations between national, regional and local authorities within the river basin. Such cooperation could help the overall cooperation between these bodies and would clearly contribute to a more coordinated management of water resources in the basin. These provisions should be taken into account when preparing the Ministry of Environmental Protection of Ukraine new proposals for the basin council for the implementation of the National Program for the restoration of the Dnieper basin and improving the quality of drinking water. The relevant draft resolution of the Cabinet of Ministers was sent for consideration to all interested national and regional authorities, scientific and environmental organizations. For each significant river basin, administrative bodies and committees should be established, and the principle of integrated water management should be implemented at the basin level. All national, regional and local authorities involved should be involved, if possible with international partners (e.g. the Republic of Moldova in the case of the Dniester). The institutional responsibility of the basin structure for water management should be supported by adequate financial funding so that water management objectives, particulary for wastewater, can be achieved at the local level. Financial revenues in the form of water payments collected in the basin should be used to improve water management in the same area.

It is known that in general, the quality of surface water is inappropriate for drinking, which is a consequence of pollution from municipal and industrial effluents, diffuse pollution from agriculture and the atmosphere. This problem cannot be solved in the nearest future. Groundwater is less vulnerable. Therefore, addressing the practice of using groundwater for drinking seems to be completed and balanced task; however, its solution requires modernization not only of the water complex, but also of the national economy in general.

Surface and underground hydrosphere is one of the important factors in the evolutionary development of the biosphere and man, its natural mechanisms and the preservation of their sustainable impact will contribute to the safe development of the economy and the state as a whole. A thorough analysis of the domestic structure of water use and its technical and economic indicators shows the low perfection of technological, environmental and existing regulatory mechanisms. There are 200 different regulations in this area, which are mainly of a recommended nature. In addition, a significant part of them is based on the use of different methodological principles and is not focused on the agreed levels of water-ecological assessments of surface and groundwater bodies, landscapes, natural and man-made systems, etc.

In order to arrange and implement a set of measures in the context of ensuring the effectiveness of the subsystem ‘Modernization and ensuring the reliability of water production’ we have proposed the following recommendations.

The responsibility for implementing international environmental standards and conventions lies primarily with the Ministry of the Environment. However, in many cases, ministries such as the Ministry of Finance, the Ministry of Economy, and the Ministry of Agriculture must also be involved. Ukraine does not properly analyze the effectiveness of international environmental assistance. A special center for environmental project management should become a tool at least for obtaining such valuable information, as well as for improved project management. Cooperation with the National Agency for Development and European Integration is essential in this regard. Implementation, compliance and application of environmental norms and action plans in relation to existing international obligations should be a priority of Ukraine’s environmental policy. Plans for ratification of new international environmental legislation should include an assessment of the cost of implementing them. Ukraine needs to continue working on ratifying all major international environmental conventions in line with national priorities. It should be borne in mind that some industries are special and need separate consideration. For example, the mining industry, which in Ukraine is almost not included in the system of sustainable water use. Instead, in the world this problem is raised [9].

In order to improve water management, the principle of river basin management needs to be further implemented. National action programs have already been developed for some river basins, such as the Dnieper. In developing the National Program for the Restoration of the Dnieper Basin and Improving the Quality of Drinking Water, the role of regional and local authorities was limited to providing information (suggestions) about the Dnieper to national authorities. Of course, measures taken (or not taken) from below will affect the measures proposed from above. The responsibility of water management bodies and the development of standards need to be streamlined. A clear responsibility for coordination should be defined and a mechanism for such coordination established. The establishment of a national body to unify standards and methods, i.e. the standardization body, needs to be considered.

Water consumption in Ukraine is quite high. At the same time, water prices for utilities and industry are relatively low. This is not surprising, as Ukrainian, law states that water is the exclusive property of the people of Ukraine, and water use is free. Only water supply, sewerage and wastewater treatment are paid moderately. However, this fee does not fully reimburse all costs, including investment. Significant efforts are needed to recoup the investment, maintenance and operation of water supply systems. Increasing tariffs for water use and discharges are important steps to ensure adequate funding for water infrastructure, such as the reconstruction of water treatment plants. Determining the price of water, which would fully reimburse the relevant costs, and the installation of water meters to detect the volume of its actual consumption would save significant amounts of water. At the same time, users' accounts are hardly affected by these measures, as they should pay a higher price but consume less. Such measures would help to improve the operation of treatment plants, as they would receive less water for processing. Therefore, the introduction of best available, low-cost technologies and / or technology-based emission standards should form the basis of pollution reduction strategies. For the construction and operation of sewerage networks and water treatment facilities, new financial support mechanisms adequate to real processes should be formed, with clearly defined responsibility of polluters.

To improve the efficiency of wastewater treatment, further training of personnel on the operation of facilities and equipment and process control is needed. Responsibility for urban wastewater management and sewage disposal should be clearly defined. Preference should be given to the use of silt in the form of fertilizers [10].

At the same time, the EU Directive on urban wastewater and the use of sludge in agriculture should be followed. In addition, trained personnel should manage treatment plants. Low professional level of staff is a common problem. Special training on the operation of facilities and equipment and process control could significantly improve the efficiency of treatment facilities. There is an urgent need for Ukraine to increase the level of professionalism and professional training of staff and management entities that take care of water use problems.

In order to improve the management of the marine environment, it is necessary to define clear environmental policy objectives and include them in the national program for the protection and restoration of the Black and Azov Seas. A wide network of administrative and scientific institutions has been formed to facilitate the management of the marine environment. At the same time, the developed institutional capacity at the regional and local levels cannot compensate for the lack of a specialized management structure at the national level. To improve the coordination of the efforts of numerous institutions aimed at improving the effectiveness of the protection of the marine environment, the Ministry of Environmental Protection of Ukraine should establish a special structural unit for the protection of the Black and Azov Seas.

Shipping and related activities are a major source of marine pollution, especially gasoline hydrocarbons. Another significant threat to the marine ecosystem is the penetration of exotic species, most often by removing ballast water. That is why it is necessary to develop special recommendations and implement appropriate measures.

Ecological optimization and sustainable development of the water management complex are and should be the main direction of improving the environmental parameters and safety of water bodies. The previous development of the water management complex of Ukraine on the principles of their maximum importance in economic circulation has led to destructive changes in water resources systems, deterioration of environmental parameters (hydrosphere, biosphere, lithosphere, atmosphere). To fundamentally improve the ecological level of water use within Ukraine, it is recommended to develop technological, regulatory and other documents based on the principles of maximum allowable water-ecological changes or loads.

In accordance with the provisions of the National Water Code, funds from the fee for water intake and discharge of wastewater into water bodies of local significance are paid to the local budget. Funds from the fee for water intake go to the national (80.0%) and regional budgets (20.0%). However, the majority of the population receives water from public facilities and most of the money goes to the state budget, while investment, operating costs and maintenance of water supply, sewerage and treatment systems must be provided at the local level. Therefore, a more balanced decentralization of responsibilities and budgets seems to be a prerequisite for more efficient water management.

In order to ensure the effectiveness of the subsystem "Rationalization and increase the efficiency of water use in resource constraints" we have made the following proposals.

There are a significant number of standards - in fact, thousands that cannot be tracked for both technical and economic reasons and compliance with which remains problematic. Therefore, from all points of view, it would be useful, taking practical expediency, to take appropriate legal and organizational measures to establish and apply standards. This requirement can be met relatively easily, as it requires virtually no funds. On the contrary, it would reduce costs. Therefore, it is necessary to identify effective economic tools for the introduction of the "polluter pays" principle. Research is needed to prepare for the transition to a clearly market-oriented fiscal and economic policy. It is important to find out what levels of environmental payments will be possible and effective and what time frames are needed to implement them.

The main problems exist in the field of financing environmental measures. The fundamental problem of creating a viable system of public revenues in Ukraine is the further complication of the situation with environmental expenditures, as there are more urgent priorities. Even more, the approach to solving the problem, which is to allocate certain categories of public revenues for environmental purposes, is not easy to apply, which creates limited transparency. Statistics on environmental expenditures, including funding sources, need to be improved.

The difficult financial situation is forcing more and more importance to be attached to foreign aid. The experience of other countries with weak economies shows that the management of environmental projects that have components of foreign aid often benefit much more from more specialized and effective administrative measures. The presence of a separate special center in the structure of environmental management, as a rule, contributes to the strengthening of environmental components in general assistance programs or projects. It also gives a better idea of all international environmental assistance and is therefore more useful for the process of setting national priorities in environmental policy. The activities of such a center should be coordinated with the National Agency for Reconstruction and European Integration. Among other things, the center transparently and efficiently should accumulate funds from environmental payments.

In modern conditions, it may be appropriate to consider the introduction of a national environmental fund and local environmental funds in order to manage both revenues and expenditures for environmental protection with the help of appropriate supervisory boards. Regional funds can be created by consolidating local funds, which should finance the costs of local environmental measures. Proceeds from such funds should come mainly in the form of environmental taxes, fees and penalties, as well as foreign aid.

Most cities and towns in Ukraine use treatment facilities for municipal and industrial wastewater. The quality and efficiency of wastewater treatment could be improved by increasing the capacity and technical condition of existing facilities. In particular, reducing water consumption would improve the operating conditions of treatment plants, as reducing the amount of wastewater would make it possible to process them more efficiently. This provision applies to both water treatment plants and treatment plants. In addition, the practice of sewage treatment is unsatisfactory and needs to be streamlined. These mules can never be returned to the rivers. The best option is to use them as fertilizers, provided that the metal content does not exceed the established limits. This means that some industrial wastewater must undergo a pre-treatment stage in order to remove toxic elements or not enter the treatment plant at all, but be treated in another way.

It should be noted that external water quality standards are currently used to calculate the maximum permissible discharges of pollutants from industry into water bodies, although technologies that do not require additional funds have not yet been defined and provided for by the National Water Code. The rational aspect of the standards required for Ukraine (focused on such technologies) is also to minimize, using existing technologies, discharges of used water. But, in contrast, the current practice in Ukraine is to bring industrial pollution to the level of certain standards for external sources instead of trying to constantly reduce emissions from industry. This practice in water management does not encourage a reduction in water consumption, as external targets can only be achieved by diluting wastewater. In addition, since a permit is issued for pollution of a particular environment, attempts are made to redirect pollution from the aquatic environment to another, such as the atmosphere, or to convert it into solid waste. That is why it is necessary to take into account the correlants and consider the introduction of an integrated permitting system, the introduction of which will significantly reduce financial costs. At the same time, the experience of wide implementation in Europe of emission standards based on advanced management technologies is useful for the environment and Ukraine.

Requires rationalization of pricing. The price of water should be transparent and realistic. It is necessary to introduce water meters for all water users, and the payment should be made in proportion to the amount of water used. The cost of water should correspond to the level of full reimbursement of all costs for investment, maintenance and operation of water infrastructure. Exceptions should be made for those who are unable to comply with these requirements.

When justifying the cost of water and the efficiency of its use, it is necessary to consider possible alternatives and reflect not only economic components, but also environmental and social factors.

Significant work has been done in recent years to develop new legislation. The new Water Code and special regulations for the protection of marine waters from pollution and clogging define the basic requirements for the protection of the marine environment. The lack of special norms and standards of sea water quality hinders control activities, permitting procedures and assessment of the state of the environment. At the same time the general specifications for surface waters are used. There is also a need to develop a common methodology for issuing permits for discharges into the sea, which could be used by regional authorities instead of giving specific tasks to research institutes. The new environmental legislation does not include funding mechanisms for environmental management.

National environmental authorities are fully aware of the need to integrate environmental policy development and management in coastal areas. Draft relevant documents on the implementation of the principle of integrated coastal zone management have been developed mainly within the framework of the Black Sea Environmental Program. The special needs of the marine environment should be reflected in special legislation on the protection of the marine environment. It should comply with relevant national and international norms and standards and include new mechanisms for the formation and replenishment of funds. Control over the operation, development and construction of new structures and facilities for the loading, transhipment and storage of petroleum products, chemicals and other hazardous substances needs to be strengthened. Ukrainian ports are equipped with water treatment plants for oil-contaminated waters and the necessary means to combat oil spills within its territory. The Ministry of Environmental Protection and Nuclear Safety and the Ministry of Transport have every opportunity to monitor activities in the coastal zone within the scope of their powers established by law. Improved management technologies and reporting on current, intermediate and final controls on the operation, development and construction of new structures and facilities for loading, transshipment and storage of petroleum products, chemicals and other hazardous substances need to be developed.

Increasing concerns about addressing both national and international environmental issues, conventions and strategies, and strengthening their links with many social and economic aspects of sustainable development must be given higher priority. This requires the improvement of information and methodological support, expansion of dialogue, development of communication channels. Achieving goals in this direction requires special programs and the use of adequate methodologies aimed at specific audiences, the integration of international environmental standards, reflected in many conventions ratified by Ukraine. Incorporation into national socio-political strategies will be significantly facilitated if the cognitive-informational aspects of the knowledge movement are streamlined.

To this we add that, as a rule, the monitoring of the marine environment is a by-product of the main activities of some agencies and research institutes, and these circumstances determine how it is carried out. According to national legislation, the Ministry of Environment of Ukraine is responsible for the overall coordination of monitoring processes that take place in the country at the national level, but, in practice, it can not participate in budget preparation to intensify all monitoring activities in the field of nature. The Ministry of Environment of Ukraine takes an active part in several international initiatives, such as the Black Sea Environmental Program, the Danube Program, and the Working Group on the Environment of the Black Sea Economic Cooperation. In addition, Ukraine has already signed some international agreements in this area, and the Ministry is now working to ensure their ratification and implementation. Therefore, applying the international agreements already signed by Ukraine and their existing structures, further management of the environment of the Black and Azov Seas should cover the entire catchment area. Ukraine should consider initiating a basin program and / or promoting closer cooperation between the Black Sea Environmental Program and all existing and planned programs for rivers flowing into the two seas, in order to ensure basin coordination of environmental management affecting the Black and Azov Seas. Adequate coordination mechanisms should also be developed for the Black Sea catchment area within the country.

In this regard, we have developed a set of measures for the implementation of the subsystem "Improvement of information and methodological support of water management processes."

The existing monitoring system is too fragmented: many institutions monitor a significant amount of pollutants, and outdated stations use incompatible methodologies. Often different institutions have to collect the same data because they cannot be exchanged due to data bank incompatibilities. Environmental audits of industrial enterprises should be used as a basis for the gradual development of an integrated permitting system covering water, air and waste permits. The organization of the various inspection services needs to be reviewed to improve their combined economic efficiency.

The amount of work required should not be underestimated, even taking into account all the experience of previous conferences, it should be used as an opportunity to involve many ministries, other government agencies, public and scientific institutions. In an economic depression, international environmental cooperation is certainly not a top national policy priority. In Ukraine, in addition, many managers, as well as the public, should pay more attention to environmental issues and international environmental cooperation, including their impact on other areas of activity, from the economy to health care. Coordination and cooperation between all institutions involved in the development and implementation of policy and management of international cooperation programs needs to be improved. Consideration should be given to establishing a special organizational structure for these purposes. An international task force should also be established, which will include, on a voluntary basis, representatives of partner countries wishing to assist Ukraine in its environmental activities. A clear focus on market measures and principles in the field of international cooperation is needed.

Groundwater monitoring needs to be improved. Individual monitoring networks, using different software products, generate significant amounts of data that accumulate in different information banks. As a result, the compatibility of monitoring data from different networks is very complicated. In addition, most monitoring data is not aimed at regulation, and in some cases it cannot even be used by regulators. Monitoring data are often collected and collected by regional authorities and are not available for decision-making at the state level. The Ministry of Environment of Ukraine is authorized to be responsible for the coordination of these monitoring activities in order to ensure better integration and control of water quality. The implementation of these provisions will not only save significant funds and harmonize the monitoring data obtained from different programs, but will also allow the full use of monitoring results for decision-making at all levels. The system and scale of monitoring networks in the field of water use need to be improved. Although various ministries and state committees have already set up several monitoring systems, their activities are aimed at achieving certain local goals. There is duplication of work, especially in the monitoring of chemical and bacterial parameters.

Providing the population with adequate drinking water that meets hygienic standards should be considered a priority. Therefore, public access to information on drinking water quality must be ensured. The use of water from relevant groundwater sources must increase significantly, and the protection of drinking water resources must be properly ensured.

Environmental certification plays an important role in strengthening the information and methodological support of water use management processes. Its implementation requires certain costs, so it must be objective, complete and useful for the business environment [11]. In Europe, there is a positive experience of voluntary environmental certification, implemented, for example, in Tuscany [12]. This helped to discuss policy measures aimed at environmental safety and increase the soundness of investment decisions.

The significant factor for decision-making is the value of information. Ukraine has a wide network of environmental monitoring, and it covers various executive bodies and scientific institutions. They are on the edge of surviving. Primarily because of broken ties with former Soviet partners and disintegrated monitoring system. It has also lost some methodological support, and suffers from severe budgetary constraints, while the activity of its various structural units is often duplicated. In order to reduce the cost of the monitoring system, it needs optimization. In the country, there are no procedures of self-controlling. The Ministry of Environmental Protection of Ukraine together with all executive bodies and the participation of all stakeholders should clearly create integrated coastline zone organization as an independent part of its new policy. It requires the creation of suitable tools for institutional cooperation and the involvement of academic staff, local business and the public to ensure integrated coastal zone management. A positive example of monitoring is the EMAS Regulation (Reg. 761/01 EC). It is an EU scheme implemented by the European Commission since 1993 and intended to integrate the Environmental Management System (EMS) [13]. There is a close connection between the implementation of the environmental management system and indicators of the ecological condition of the territory.

Given the semi-enclosed nature of the Black Sea, the high anthropogenic pressures and the vulnerability of its ecosystem, it is clear that only regionally coordinated action can actually improve its condition. In order to use new effective tools for managing the marine environment, Ukraine should participate in the development and implementation of a harmonized system of state port control in the Black Sea region (together with neighboring countries and entities) and, accordingly, in the development of a regional emergency plan.

Preferably, the environmental criteria of existing water regulatory or regulatory documents are based on the use of maximum permissible concentrations or levels of pollutants. Practically, until recently, these norms as regulatory criteria - are the only ones approved at the state level, which have scientific, methodological and analytical justification. Therefore, this requires the development of a new system of relative indicators to assess and forecast the effectiveness of water management, some of it should be introduced into the system of national accounts.

Regarding the implementation of the subsystem "Certification of industries and technologies, as well as regions by the factor of effectiveness of water management", in our opinion need to develop a universal application toolkit, reporting documentation forms, etc., which are recommended for different levels of government. At the same time it is necessary to provide reflection of a water trace and production of [14].

At present, there are questions about the possibility (or impossibility) of increasing and rationalizing the development of the strategic potential of Ukraine's economy, in general. It should be noted that currently the main source of information is the data of the State Statistics Service of Ukraine, Ministries of Economic and Regional Development of Ukraine, Ministry of Infrastructure, etc. and, as is known, the results of a comprehensive survey of state water farms, providing evidence in generalized form. The importance of primary data is determined by a system of indicators that should be used to assess the effectiveness of integrated water resources management [15]. Therefore, the development of passports is the subject of a separate scientific study.

Abstract. Ecological-reclamation state of rice irrigation systems harvest of cultivated crops determined by a number of factors, including natural (soil, topographical, hydrogeological, climatic factors) and technological (irrigation norm, designs and parameters of irrigation and drainage networks, etc.) factors. One of the main factors influencing the formation of rice yield which is traditionally grown by flooding technology is the efficiency of the rice irrigation system's design. Construction features of irrigation fields and their parameters (distances between the drains, depth of the drainage network) affect the intensity of the processes of salinization of soils and groundwater. Analysis of the components of salt balances of rice fields with different parameters and designs on example of the Danube rice irrigation systems showed that fields with the distances between the drains from 200 to 250 m have significant advantages over Krasnodar-type fields with the same parameters and over fields with 500 m distance between the drains creating optimal salt regime for rice and, accordingly, obtaining higher yields of rice. As on the card-checks with drainage with the distances between the drains 500 m uniform desalinization of soils on all area cannot be reached and yield of rice on them is close to 20 c/ha such card-checks with drainage must be converted into card-checks with drainage with the distances between the drains 250 m.

1 Introduction

The concept of the stable development of national economy envisages rational ecological and economic nature use guaranteeing the business operation without worsening environment and its preservation for generations to come. In this connection problems arising in the sphere of rice sowing in Ukraine are becoming of late especially urgent and call for speedy positive solutions.

In its time the main aim for creating native branch of rice sowing had been not only the satisfaction of the need for own rice but also the introduction in agricultural production of low efficient saline and bogged land in the Crimea, the Danube delta and areas adjoining the Black sea.

Industrial experiments have shown that such lands may be successfully used for rice irrigation systems (RIS) with obligatory application on them reasonable constructive decisions on ensuring a favorable ecological and reclamation condition on irrigated lands.

The construction of engineering rice irrigation systems in Ukraine began in the 70-s of the last century and at present their area amounts to about 62 thousand hectares (Crimea – 30.8 thousand hectares, Kherson region – 18 thousand hectares, Odessa region – 14 thousand hectares).

Modern RIS is a complex set of water supply, drainage, regulative and other elements connected by a single technological process in combination with the rice fields, where the leading crop of rice crop rotation - flooded rice and related overland crops are grown. The main element of any engineering rice system is a rice irrigation field. How well the design of the field is chosen and its parameters are selected depends on how successfully it will perform its functions, which are to create the optimal salt and water-air regime for rice and related crops.

The long-term studies have determined that drainage on saline lands RIS must meet the following basic requirements:

- ensure, for 2-3 years, the salinization of the upper layer of soil 1.0-1.5 m to create favorable conditions for growing rice and related crops of rice crop rotation;
- provide after drainage of the water from the checks the required norm of drainage not less than critical depth (1.5-1.8 m) at the beginning of the new irrigation season;
- exclude the possibility of secondary salinization of soils in the fields occupied by related crops;
- create and maintain in the rice field optimal filtration rates for removal of salts from the active layer of soil.

Research by a number of authors [1, 2, 3, 4, 5] showed that the desalination effect of the drainage network on the rice field cannot be estimated only by the amount of salts carried through it. In [6, 7, 8, 9, 10] the unreasonableness of the study of soil salinization without taking into account the change of salt reserves in groundwater, especially at their close occurrence, is emphasized.

Based on these provisions, the most reliable and complete idea of the direction of salt processes in soils and groundwater, and hence an objective assessment of the drainage network can be obtained by drawing up a salt balance, which would take into account changes in salt reserves in soils, groundwater, inflows of salts with irrigation water and their removal with drainage water, other components of both income and expendable parts of such balance.

2 Materials and methods

The studies were performed according to standard methods [5]. The salt balances were compiled for a 3-meter layer of soil and groundwater of each of the fields during the period of rice cultivation on them and based on water balance data.

The weighted average reserves of salts in soils and groundwater were determined on experimental fields also the period of related crops cultivation. In order to obtain comparable data, the thickness of the aeration zone was assumed to be 1.2 m, and the thickness of the groundwater layer in the balance layer - 1.8 m.

Studies of salt balance were conducted by us for 5 years in order to assess the effectiveness of rice fields with various parameters and designs on the Danube RIS located in the Odessa region (Fig. 1).

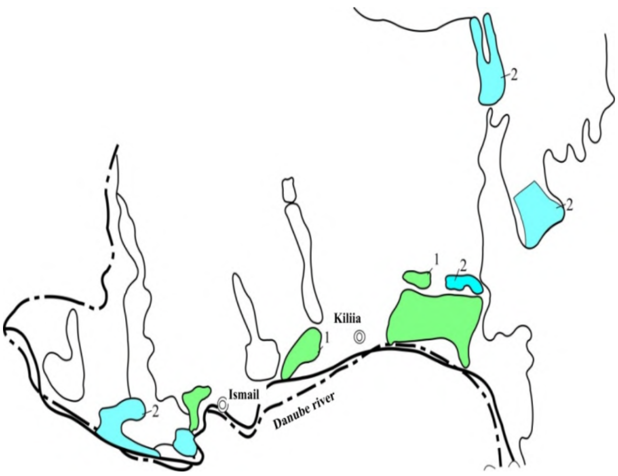

Fig. 2.1. Location of rice systems in Odessa region: 1 - existing; 2 - planned for the future

To solve the problems as the object of research was selected the Kiliia RIS with the total area of 3.45 thousand hectares, which is located on the territory of saline East-Kiliia floods of the Danube delta.

Soils are represented mainly by sandy loam falling to the first regional water confining layer.

Before the construction of the Kiliia RIS the depth of occurrence of groundwater level was in the range from 0.0 to 2.5 m and their overall slope is directed towards the Danube River.

The content of salts in groundwater was in the range of 10-30 g/l, reaching 70 g/l in individual cases. The mineralization of groundwater increased from swampy part of the floodplain to its central part.

During the long period of growing rice on the Kiliia RIS occurred desalination of groundwater. Their mineralization decreased to 1.5-15.0 g/l, which is explained by the relatively intense washing regime, which was created as the result of watering rice by flooding and drainage work. Only in small areas there was a desalinization of ground water up to 30 g/l.

The Kiliia RIS was built according to the well-known scheme of irrigation cards of the Krasnodar-type (KTC) and card-checks with drainage (CCD) with one-side and two-side command.

The distance between the channels, depending on the soil-hydrogeological conditions, was 200-500 m and the depth of the card drains – 1.5-1.7 m. The KTC is the most common type of irrigation cards in the RIS of Ukraine.

Schemes of CCD and KTC are given in Fig.2.

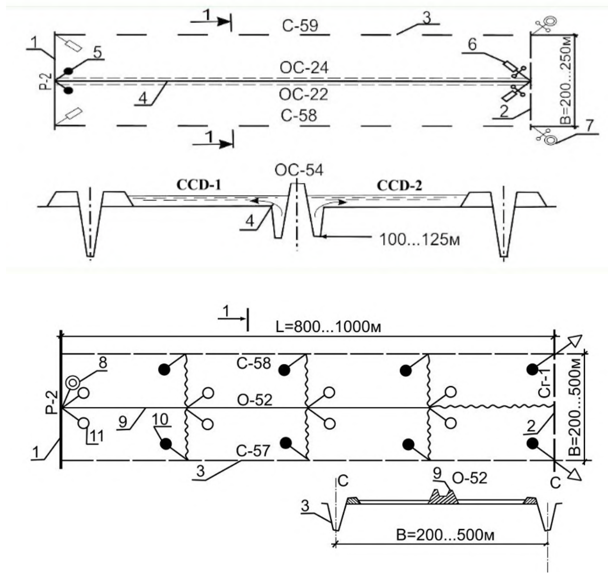

Fig. 2. Schemes of experimental card-check with drainage (CCD) and Krasnodar-type card (KTC) on the Danube rice systems: 1 - distribution channel; 2 - discharge channel; 3 – card-drain (CCD), or drain-discharge (KTC); 4 - irrigator-discharge of unilateral command; 5 - water outlet from the distribution channel to the irrigator-discharge; 6 - water outlet from the irrigator-discharge to the discharge channel; 7– water outlet from the card-drain to the discharge channel; 8 - water outlet from the distribution channel to the card-irrigator; 9 - card-irrigator; 10 - water outlet from the check to the discharge channel; 11 - water outlet from the card-irrigator to the KTC.

The research was conducted on three experimental sites. Shortened flooding was maintained in all areas during rice cultivation.

The first site consisted of two CCD with a one-way command irrigators-discharge, average depth of which was 0.7 m, and distance between the drains - 200 m. As a control, there was KTC with the card-irrigators of bilateral command and distance between the drains 200 m.

The second site also consisted of two CCD and KTC, but the distance between the drains was 250 m.

The third site consisted of two CCD with irrigators-discharge of unilateral command and the distance between the drains for the first CCD was 250 m, and for the second - 500 m.

Field studies conducted by us and other scientists [11, 12, 13, 14] on the rice systems of the Danube delta showed that features of motion of filtration streams on irrigation cards during the maintenance of the water layer is that in the part of their area formed a zone of groundwater lifting (along the irrigation channels) and a stagnant zone – in the center of the check, active movement of groundwater occurs only on the part of the area that adjoins directly to the drainage channel (Fig. 3).

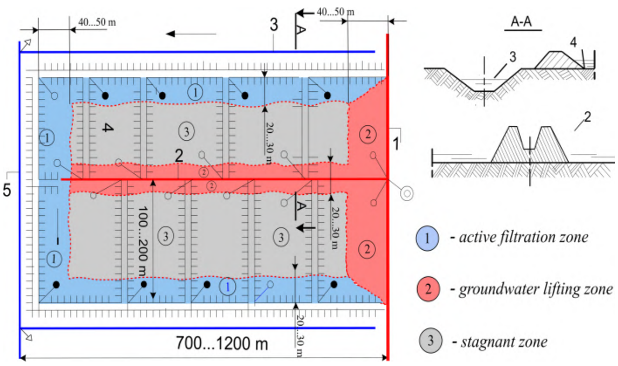

Fig. 3. Scheme of formation of characteristic zones of filtration on the rice check: 1 - distribution channel; 2 - card irrigator of bilateral command; 3 - card drainage and discharge channel; 4 - check; 5 - sectional drainage and discharge channel.

The dimensions of these zones are determined by the hypsometric characteristics of the irrigation channels, depth of drains and water levels in them, and by size of the irrigation card.

The presence of such zones indicates irregular drainage on the area of the irrigation card. The total area that is practically doesn't drained is more than 60% of the area of the irrigation card. Calculations of filtration losses from the drainage zone, according to the schedule of rates, indicated that their volume from the drained strip is about 70% of their total volume.

3 Results and discussions

On the basis of annual salt balances were compiled averaged salt balances for fields of various parameters and designs (Table 1, 2, 3). The analysis of salt balances was carried out by assessing the structure and dynamics of their main components.

Comparing the change in salt reserves in the 1.2 m layer of soils on CCD and KTC with distances between the drains 200 m (site № I), we can note a higher intensity of soil desalinization. In general, for the entire period of observations and for each of the irrigation seasons with treatment of rice with herbicides, it was higher than on KTC by an average of 4% (Table 1). In the site № 2 (distances between the drains 250 m) also recorded the removal of salts at 8% higher on CCD than on KTC on average for each of the seasons of rice cultivation (Table 2).

Table 1. Salt balance of CCD and KTC with distances between the drains 200 m (five-years observation period).

Elements of salt balance	**B = 200 m**			
	CCD		**KTC**	
	t/ha	**%**	**t/ha**	**%**
income part				
Reserves of salts in the soil in April in the layer 1.2 m	31.60	32.2	41.91	33.0
Reserves of salts in groundwater in April in the layer 1.8 m	55.53	56.5	74.70	58.8
Receipt of salts with irrigation water	9.63	9.8	8.91	7.0
Receipt of salts with fertilizers	1.50	1.5	1.50	1.2
Total salts in the balance layer (3m)	98.26	100.0	127.0	100.0
expendable part				
Reserves of salts in November in the layer 1.2 m	24.36	24.8	37.03	29.2
Reserves of salts in groundwater in November in the layer 1.8 m	40.25	40.9	61.21	48.2
Removal of salts with drainage water	34.07	34.6	24.35	19.2
Removal of salts with waste water	1.83	1.8	2.90	2.3
Removal of salts with the harvest	1.24	1.3	1.19	0.9
Salt exchange with the lower horizons	-3.49	-3.5	0.34	0.3
Total salts in the balance layer (3 m)	98.26	100.0	127.02	100.0

Comparison of the intensity of the reduction of salt reserves in the card- checks with distances between the drains 200 m, 250 m and 500 m can be carried out only in relative terms, because the initial salt reserves in these areas differed significantly. On average, during the rice growing season with flooding the salt reserves decreased on 7-9% for CCD, regardless of, practically, the value of distances between the drains. Although in the first years after the reconstruction of rice systems, during which there was a deepening of drainage network, the reduction of salt reserves was more intense.

At the same time, more intensive salt accumulation was observed the period of related crops cultivation on CCD with distances between the drains 500 m than on CCD with - 250 m and 200 m, which further negatively affected on the rice yield.

Observation of changes in salt reserves in groundwater of all experimental site showed that they are as well as changes in salt reserves in soils are characterized by a number of features caused by the deepening of the drainage network, namely: the highest intensity of salt removal in the first year of rice cultivation after reconstruction; significant reduction of salt reserves compared to the original. During the period of crop rotation cultivation there was some increase in salt reserves in groundwater.

Table 2. Salt balance of CCD and KTC with distances between the drains 250 m (five-years observation period).

Elements of salt balance	B = 250 m			
	CCD		KTC	
	t/ha	%	t/ha	%
income part				
Reserves of salts in the soil in April in the layer 1.2 m	41.49	41.2	38.42	38.5
Reserves of salts in groundwater in April in the layer 1.8 m	48.58	48.3	51.04	51.2
Receipt of salts with irrigation water	9.09	9.0	8.80	8.8
Receipt of salts with fertilizers	1.46	1.5	1.43	1.4
Total salts in the balance layer (3m)	100.62	100.0	99.69	100.0
expendable part				
Reserves of salts in November in the layer 1.2 m	32.33	32.1	37.65	37.8
Reserves of salts in groundwater in November in the layer 1.8 m	34.82	34.6	37.76	37.9
Removal of salts with drainage water	27.76	27.6	21.90	21.9
Removal of salts with waste water	1.77	1.8	2.20	2.2
Removal of salts with the harvest	1.25	1.2	1.15	1.1
Salt exchange with the lower horizons	2.69	2.7	-0.97	-0.9
Total salts in the balance layer (3 m)	100.62	100.0	99.69	100.0

Table 3. Salt balance of CCD with distances between the drains 500 m (five-years observation period)

Elements of salt balance	B = 500 m	
	CCD	
	t/ha	%
income part		
Reserves of salts in the soil in April in the layer 1.2 m	98.86	38.5
Reserves of salts in groundwater in April in the layer 1.8 m	147.54	57.5
Receipt of salts with irrigation water	8.55	3.3
Receipt of salts with fertilizers	1.50	0.5
Total salts in the balance layer (3 m)	256.45	100.0
expendable part		
Reserves of salts in November in the layer 1.2 m	79.02	30.8
Reserves of salts in groundwater in November in the layer 1.8 m	127.90	49.8
Removal of salts with drainage water	41.16	16.0
Removal of salts with waste water	2.14	0.8
Removal of salts with the harvest	0.88	0.3
Salt exchange with the lower horizons	5.35	2.0
Total salts in the balance layer (3 m)	256.45	100.0

Comparison of changes in salt reserves on CCD and KTC with distances between the drains 200 m showed that seasonal removal of salts from groundwater during the period of rice cultivation was higher on CCD on the average for all period of observation by 6.94% in comparison with KTC, and in separate years exceeded 10%. And although even if on KTC was a significant desalinization, but at the end of the study the salt reserves were higher than on CCD. This advantage of CCD is explained by its higher drainage during drying.

A similar situation with regard to the reduction of the amount of salts in groundwater was observed in the site № 2 (distances between the drains 250 m) where the CCD also showed a higher intensity of desalinization in comparison with KTC.

Comparison of the intensity of reduction of salt reserves for CCD with different distances between the drains 200 m and 250 m showed that it practically not differ and made 19.08-24.81% from the original salt reserves and in 2 times exceeding this indicator for distances between the drains 500 m, where it averaged only 11.41% of the original salt reserves. Given such a low rate of groundwater desalination at CCD with distances between the drains 500 m as well as the fact that at the end of the study the salt supply in the groundwater remained significant, we can conclude that under such circumstances it’s not possible to achieve the desired groundwater desalination even in the near future.

Annually, the experimental sites received an average of 8.55 to 9.69 t/ha of salts with irrigation water, which was up to 9.8% of the income part of the salt balance (Table 1, 2, 3) and, in practice it does not significantly depend on the parameters and designs of rice fields.

The receipt of salts with fertilizers on the experimental sites varied from 1.43 to 1.50 t/ha, which averaged up to 1.53% of the income part of the salt balance (Table 1, 2, 3) and has no significant effect on the formation of salt balance.

Removed salts from soils and groundwater of the balance layer of the experimental sites with drainage runoff varied during the observation period in a wide range, averaged up to 34.67% of the expendable part of the salt balance and was the main factor influencing the intensity of salt reduction in soils and groundwater.

Comparison of the amount of salts removed with the drainage runoff on the CCD and KTC with distances between the drains 200 m and 250 m showed the significant advantage of CCD. The average seasonal removal of salts on CCD with distances between the drains 200 m was higher by 13.9%, and with 250 m - by 2.4% higher than on KTC with the same parameters (Table 1, 2).

Comparison of the removal of salts with the drainage runoff on the CCD with different distances between the drains showed that with increasing the distances between the drains it decreases significantly. The main reason for the greater removal of salts with drainage runoff on CCD in comparison with KTC with distances between the drains 200 m and 250 m is the presence on the CCD the irrigator-discharge, which plays the role of shallow drainage during the part of the irrigation season. The amount of salts removed by the irrigator-discharge was up to 14.36% of the total amount of salts removed from the

CCD by the whole drainage network (Table 4).

If on the CCD along the irrigator-discharge there was desalinization of soils and groundwater, then on KTC in the central part there was contrary process - salinization. These facts indicate that there is a significant advantage of CCD over KTC in terms of ensuring optimal salt regime.

Removal of salts from the experimental sites with waste water there were in ten times less than removal of salts from drainage water. This averaged only 1.77-1.90 t/ha during the season and did not exceed 2.28% of the expendable part of the salt balance (Table 1, 2, 3). This indicator of the salt balance did not depend much on the parameters and designs of rice fields, but depended mainly on the original salinity of the upper soil horizon.

Removal of salts with the rice harvest over the years of research was 0.91-1.25 t/ha and did not exceed an average of 1.3% of the expendable part of the salt balance.

Table 4. Removal of salts from CCD on the experimental sites through irrigators-discharge during the season (April – November).

№ experimental site	№ CCD	Distances between the drains, m	Removed salts from CCD with the drainage runoff		
			total, t/ha	irrigator-discharge	
				t/ha	%
1	CCD-1	200	35.61	1.80	5.06
	CCD-2	200	32.53	1.58	4.85
2	CCD-1	250	28.65	3.70	12.94
	CCD-2	250	26.88	3.86	14.36
3	CCD-1	250	54.26	5.87	10.82
	CCD-2	500	41.15	4.41	10.72

Actual production data on ecological and reclamation condition on irrigated lands of the Danube RIS are given in Table 5.

Table 5. Ecological and reclamation condition on irrigated lands of the Danube RIS (at the beginning of the growing season of 2016).

Irrigation system		Area under control	Ecological and reclamation condition on irrigated lands, ha		
			Favorable	Satisfactory	Unfavorable
Kiliia region					
Kiliia RIS-1		3317	-	2894	423
Kiliia RIS-2		1515	605	910	-
Liskovska RIS		3859	-	3091	768
Kiliisko-Maiakska RIS		1026	-	1026	-
Michurinska RIS		1016	356	587	73
Rice area		135	-	135	-
Total	ha	10868	961	8643	1264
	%	100	9	80	12
Ismail region					
Kyslytska RIS		2810	638	1815	357
Total	ha	2810	638	1815	357
	%	100	23	65	12

Production data showed that according to assessment criteria of actual ecological and reclamation stability of irrigated lands (depth and mineralization of groundwater, their hydrochemical composition, degree of salinity of soils), a significant part of the Danube RIS area is unstable.

4 Conclusions

1. With the distances between the drains 200 m and 250 m on CCD there is a more intensive desalination of soils and ground waters, than on KTC with the same parameters. The intensity of desalination at CCD with distances between the drains 200 m and 250 m differs insignificantly. With the distances between the drains 500 m it is impossible to achieve high rates of desalinization of soils and ground waters even in the conditions of CCD.

2. The fact that the desalination of soils and groundwater in all years of observations in sites with the distances between the drains 200 m and 250 m was more significant on CCD than on KTC indicates the advantage of CCD in terms of creating more favorable reclamation situation. This advantage of CCD is explained by the fact that during part of the irrigation season and part of the not irrigation season it is drained around the perimeter, thanks to the irrigator-discharge arranged on it, which acts as a shallow (up to 0.7 m) drain.

3. Due to the fact that at CCD with the distances between the drains 200 m and 250 m desalination of soils occurred more intensively than on KTC the rice yield on them was on average 6 c/ha higher.

4. As on the CCD with the distances between the drains 500 m uniform desalinization of soils on all area cannot be reached and yield of rice on them is close to 20 c/ha such CCD must be converted into CCD with the distances between the drains 250 m.

Abstract. The paper presents the disclosure of the problem of calculating the friction factor. This problem exists in the calculations of head losses for a given flow discharge and the geometric parameters of the pipes. The analysis of the formulas recommended by known scientists is described. The article also presents the shortcomings of the formulas and the variance of the adequacy of the experimental data. These research data were obtained by J. Nikuradze for smooth pipes. We obtained a formula based on the method of dimensional analysis. This formula characterizes the inner surface of the pipes. Also, this formula describes the change in the friction factor from the Reynolds number. The accuracy of calculating the obtained formula is higher than the accuracy of existing formulas.

1 Introduction

To solve hydrodynamic problems, it is necessary to improve the hydraulic calculation of pipes. Due to the difference in geodetic marks or due to the energy that is transferred to the fluid when passing through the pumps, the fluid moves in the pipes. Hydraulic calculation of pipes is necessary to determine the head loss for the geometric dimensions of the pipes and a given of the flow discharge.

In 1752, Leonard Euler mathematically derived the Bernoulli equation for an elementary stream of real fluid

$$z_1 + \frac{p_1}{\rho g} + \frac{u_1^2}{2g} = z_2 + \frac{p_2}{\rho g} + \frac{u_2^2}{2g} + h_w, \qquad (1)$$

where, respectively, in sections 1 and 2 z_1 and z_2 - the position of the elementary stream relative to the plane of comparison, m; p_1 and p_2 - the value of pressure, Pa; u_1 and u_2 – flow velocity, m/s; ρ – density of liquid, kg/m^3; g – density of liquid, $g = 9{,}81$ kg/m^3; - acceleration of gravity, m/s^2. The equation includes the head loss h_w that occurs when the fluid moves due to friction forces.

In 1845 J. Weisbach and in 1857 A. Darcy proposed a formula for calculating the head loss [1]

$$h_w = \lambda \frac{l}{d} \frac{\bar{u}^2}{2g}, \qquad (2)$$

where λ – friction factor; $\bar{u}$ – average flow velocity, m/s, $\bar{u}^2/(2g)$ – velocity head, m.

Different types of flow are different forms of movement of flow particles. Flow types were experimentally studied by O. Reynolds. He identified the existence of two forms of flow. At low flow velocities, a layered flow is observed, and at high velocities in the form of small vortices with stirring. The first form of flow is called laminar flow, and the second form of flow is turbulent flow.

Classical experiments of O. Reynolds in 1868 and other scientists have shown that with a gradual increase in velocity, the laminar flow is maintained up to a certain flow velocity. After this velocity, the flow turned into a turbulent flow. When conducting experiments in reverse order, ie with decreasing velocity, the turbulent flow was also maintained up to a certain velocity, after which it passed into a laminar flow. O. Reynolds called this velocity critical, at which there is a change in flow. There are two critical velocities: the lower velocity $\bar{u}_{l.v}$, at which the turbulent flow turns into laminar, and the upper velocity $\bar{u}_{u.v}$, at which the laminar flow turns into turbulent. There is always inequality $\bar{u}_{l.v} < \bar{u}_{u.v}$.

For different types of flow, there are different dependencies between head losses h_w and average velocity $\bar{u}$. Figure 1 shows a graph of dependence $i = h_w/l = f(\bar{u})$ in logarithmic coordinates.

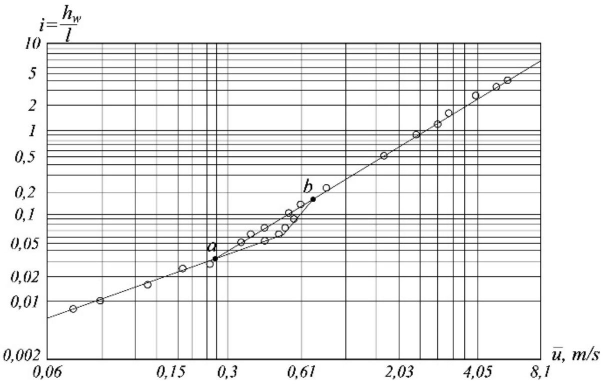

Fig. 1. Graphs of dependence $i = h_w/l = f(\bar{u})$.

* Corresponding author: l.r.volk@ukr.net

In laminar flow, the graph values of velocity less than $\bar{u}_{l.v}$ (point a) pressure loss along the length proportional to the first degree of velocity, and in turbulent, velocity values greater than $\bar{u}_{u.v}$ (point b) - flow velocities proportional to degree m, ranging from 1, 75 to 2. Between points a and b there is a transition zone within which there is a transition of a laminar stream to turbulent, or on the contrary.

Subsequent studies have shown that the presence of a laminar or turbulent flow depends not only on the flow velocity but also on the flow viscosity and on the geometric dimensions of the flow cross section. Therefore, the type of flow is characterized by the value of the dimensionless similarity criterion, which is called the Reynolds number

$$Re = \frac{\bar{u}d}{\nu}, \quad (3)$$

where d – pipe diameter, m; ν – kinematic viscosity of the flow, m^2/s.

In practice, the type of flow in the pressure pipes is determined by the lower critical Reynolds number ($Re_{н.к} = \bar{u}_{н.к}d/\nu = 2320$).

Extensive experimental studies of the dependence of the friction factor on the Reynolds number and the smoothness of the inner surface of the pipes in 1928-29 were performed by J. Nikuradze at the Kaiser-Wilhelm Institute under the direction of Dr. L. Prandtl [2,3].

J. Nikuradze investigated the influence of the Reynolds number on the friction factor in pipes with uniform granular roughness and in hydraulically smooth pipes on hydraulic installations [2, 3]. The results of his study of pipes with a uniform granular roughness are shown in Figure 2 in the form of graphs in coordinates $lg(100\lambda) = f(lgRe,\ r_0/\varepsilon)$.

The importance of this figure 2, which is called the Nikuradze graph, is that it shows the boundaries of laminar and turbulent flows and regions of hydraulically smooth, prequadratic and quadratic turbulence and the change in friction factor for each region.

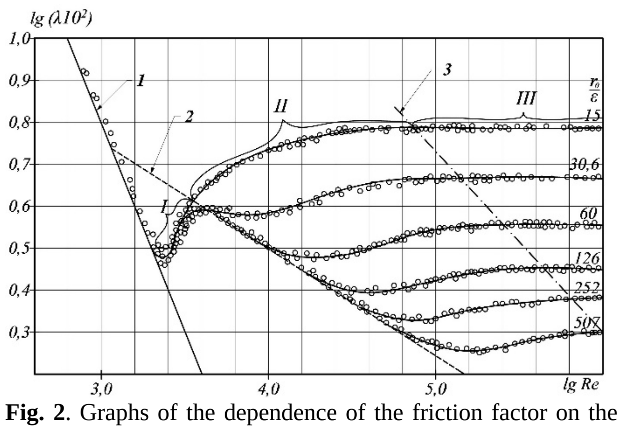

Fig. 2. Graphs of the dependence of the friction factor on the Reynolds number and the inner surface of the pipes (according to J. Nikuradze): 1 - laminar flow; 2 - region of hydraulically smooth turbulence (G. Blasius); 3 - the boundary between the regions of prequadratic and quadratic turbulence; I - transition region between the laminar flow and the region of hydraulically smooth turbulence; II - region of prequadratic turbulence; III - region of quadratic turbulence.

In the laminar flow, the fluid moves slowly and calmly. It flows around the roughness of the inner surface of the pipe. The values of local friction drag are small, so they can be neglected.

The friction factor of the laminar flow in the coordinates $lg(100\lambda) = f(lgRe)$ is described by a graph of a straight line (Fig. 2).

In 1838, Poiseuille studied currents in pipes of small diameter (capillaries) with distilled water at low flow discharges (Poiseuille flows). In 1846 he published a law determining the flow discharge of a steady stream of viscous incompressible fluid in a thin cylindrical tube of circular cross-section.

According to this law, the second volume flow discharge is proportional to the pressure drop $(p_1 - \mathrm{p}_2)$ per unit length of pipe l (pressure gradient in the pipe), the fourth degree of the pipe diameter d and inversely proportional to the dynamic viscosity of the flow

$$Q = K\frac{(p_1 - p_2)d^4}{\mu l}, \quad (4)$$

where K – coefficient of proportionality, $K = \pi/128$ – theoretically determined by D. Stokes in 1845; μ – dynamic viscosity, Pa·s.

It should be noted that in 1839 this law was first formulated by the G. Hagen. Therefore, equation (4) is called the Hagen – Poiseuille law. The flow discharge in the Hagen-Poiseuille formula was represented by the average velocity and diameter of the pipe, and the resulting expression was compared with the Darcy – Weisbach equation. The dependence on determining the friction factor was then obtained.

$$\lambda = \frac{64}{Re}. \quad (5)$$

If $Re \leq 2320$, then this formula is correct and describes the line of the laminar flow (Fig. 2). The graph of the given equation in ordinary coordinates has the form of a hyperbola, and in logarithmic coordinates is represented by a straight line.

Turbulent flow moves much faster than laminar flow. This leads to large velocity gradients between the flow layers of the turbulent core. As a result, a vortex flow is formed. All this leads to an increase in hydraulic friction, which in the laminar flow could be neglected.

The laminar layer is in the turbulent flow between the turbulent flow core and the inner surface of the pipe in the region of hydraulically smooth turbulence.

The thickness of the laminar layer of the total flow is greater than the height of the roughness. In this case, the roughness of the inner surface of the pipe has almost no effect on the turbulent core and the head loss does not depend on the roughness.

Many scientists have performed a large amount of experimental and theoretical research to determine the dependences of the influence of major factors on the value of the friction factor.

Currently, there is no general formula for determining the friction factor λ.

The topic of this article is the theoretical study of the dependence of the friction factor on the Reynolds number of turbulent flow in hydraulically smooth pipes.

Consider the basic formulas of the friction factor for the region of hydraulically smooth turbulence, which is in the range of values ($4000 \leq Re \leq 3 \cdot 10^6$).

G. Blasius in 1913 showed that the friction factor is determined by the dependence [1]

$$\lambda = \frac{0,3164}{Re^{0,25}}. \quad (6)$$

L. Prandtl in 1932 obtained the dependence on the logarithmic velocity profile and on the basis of the results of experimental studies [2]

$$\frac{1}{\sqrt{\lambda}} = 2\, lg\left(Re\sqrt{\lambda}\right) - 0,8. \quad (7)$$

In 1938, C. Colebrook proposed to determine the friction factor by the formula [3]

$$\lambda = \frac{1,63639}{(ln\, 0,142857Re()^2)}. \quad (8)$$

P.K. Konakov (1946) presented an empirical formula [4]

$$\lambda = \frac{1}{(1,8\, lgRe - 1,5)^2}. \quad (9)$$

G.K. Filonenko in 1948 recommended the following dependence [6].

$$\lambda = \left(\frac{0,55}{lg\frac{Re}{8}}()^2\right). \quad (10)$$

In 1962, M.Y. Ruzin proposed to determine the friction factor by the formula [5]

$$\lambda = \frac{0,246}{Re^{0,22}}. \quad (11)$$

F.A. Shevelyov in 1973 determined on the basis of experimental studies the dependence for steel pipes [6]

$$\lambda = \frac{0,25}{Re^{0,226}}. \quad (12)$$

Based on mathematical statistics, the Chinese scientist Guo Ningxiang proposed to determine the friction factor by a formula [7]

$$\frac{1}{\sqrt{\lambda}} = 1,689\, lgRe + \frac{0,35}{1 - 0,084Re}. \quad (13)$$

2 Problem statement

There are problems in calculating engineering hydraulic problems. When calculating the capacity of pipes, it is not enough to know the main factors: flow viscosity, pipe diameter, the roughness of the inner surface of the pipes. It is necessary to take into account the influence of the hydraulic regime on the value of the friction factor λ.

Analysis of the presented formulas, in addition to the formula of L. Prandtl (7), shows that in the region of hydraulically smooth turbulence the friction factor λ depends only on the Reynolds number, which is in the denominator and has a degree of about 0.25. The numerator of these formulas contains a coefficient, the physical meaning of which is not explained. The graphs of the above equations, in ordinary coordinates, have the form of a hyperbola, and in logarithmic coordinates are represented by a straight line.

In L. Prandtl's formula, the square root of the friction factor is described in an implicit form and is calculated, like the Reynolds number, under the sign of the logarithm. This form of the formula complicates the determination of the friction factor and does not show the influence of parameters on its value.

The formulas of the friction factor along the length of the pipe, which is included in equation (2) are the subject of our theoretical research.

3 Research results

To develop a general method of taking into account the head loss in the flow of real fluid, it is necessary to identify the dependence of friction forces on the main factors. These main factors are fluid density ρ, dynamic viscosity μ, hydraulic flow radius R, the complex of the linear dimensions that characterize the inner surface of the pipe wall (roughness height, the distance between roughness's and their shape) ε_i and average flow velocity $\bar{u}$.

Using the method of dimensional analysis, we have established a general view of the dependence of the friction forces on the inner wall of the pipe from these factors [1]

$$\tau_0 = k\rho^z\mu^m R^p\varepsilon^x\bar{u}^n. \quad (14)$$

In dimensional quantities, equation (14) has the form

$$\frac{Ml}{t^2}\frac{1}{l^2} = \frac{M^z}{l^{3z}}\frac{M^m}{l^m t^m}l^p l_i^x\frac{l^n}{t^n}, \quad (15)$$

where M – mass; l – linear dimensions; t – time.

Equated dimensionalities M, l, and t in the right and left parts of equation (15) have the form

$$\left.\begin{array}{c}\text{for the mass: } 1 = m + z \\ \text{for linear dimensions: } -1 = n + p - m - 3z + x \\ \text{for time: } -2 = -n - m\end{array}\right\}. \quad (16)$$

1 and 2 are known parameters and from the system (16), we will define other indicators of degrees

$$\left.\begin{array}{r}m = 2 - n \\ z = n - 1 \\ p = n - 2 - x\end{array}\right\}. \quad (17)$$

Substituting the found degrees through n and x in equation (14), we obtain the formula of tangential stresses on the inner wall of the pipe.

$$\tau_0 = k\rho\frac{\bar{u}^2}{Re^{2-n}}\left(\frac{\varepsilon}{R}\right)^x. \quad (18)$$

Based on experimental studies, it is known that in a turbulent flow, the value of degree $n = 2$. Then the tangential stresses on the pipe wall are

$$\tau_0 = k\left(\frac{\varepsilon}{R}\right)^x \rho \bar{u}^2 = 2k\left(\frac{\varepsilon}{R}\right)^x \rho g \frac{\bar{u}^2}{2g}, \qquad (19)$$

In order to simplify the calculations, A. Darcy proposed in equation (19) to replace the coefficient of friction $f = 2k\left(\frac{\varepsilon}{R}\right)^{x}$ by the coefficient of A. Darcy $f = \frac{\lambda}{4}$.

$$\tau_0 = \frac{\lambda}{4}\rho g \frac{\bar{u}^2}{2g}. \qquad (20)$$

The right-hand sides of equations (18) and (20) are the same and $x = 1$, $R = r_0/2$

$$\lambda = 8k \frac{2\varepsilon/r_0}{Re^{2-n}}. \qquad (21)$$

The obtained dependence (20) shows that the dimensionless coefficient in formulas (6) - (12), in addition to L. Prandtl's formula, characterizes the roughness of the inner surface of pipes with degree $n \approx 1{,}75$.

If in formula (20) take $k = 8$, $x = 0$, and $n = 1$, then we obtain the dependence (5) to determine the friction factor λ of the laminar flow

$$\lambda = \frac{64}{Re}.$$

Based on experimental studies, it is known that the degree takes its minimum value of $n = 1$ for laminar flow and the maximum value of $n = 2$ for turbulent flow in the region of quadratic turbulence. It is also known that the inner surface of the pipes affects the amount of friction factor.

We accept two hypotheses:

- degree n in the regions of hydraulically smooth and quadratic turbulence takes intermediate values in the range $1 < n < 2$;

- to characterize the inner surface of the pipe wall, namely: the average roughness height, the distance between the roughness and their shape is possible only using the relative parameters $2\varepsilon_i/r_0$.

Based on the accepted hypotheses, the dependence (20) will have the form

$$\lambda = 64\left(\frac{2\varepsilon_1/r_0}{Re^{0,75}} + \frac{2\varepsilon_2/r_0}{Re^{0,5}} + \frac{2\varepsilon_3/r_0}{Re^{0,25}} + \frac{2\varepsilon_4}{r_0}\right). \qquad (22)$$

Dependence (22) is obtained by the method of dimensional analysis and characterizes the inner surface of the pipes. This formula determines the friction factor depending on the Reynolds number.

The adequacy of equation (22) was verified by the experimental data obtained by J. Nikuradze and A.D. Altshul for the flow in smooth pipes.

J. Nikuradze performed experimental research on three experimental installations. These installations were built in the workshops of the Kaiser Wilhelm Institute.

For small Reynolds numbers from $3 \cdot 10^3$ to $60 \cdot 10^3$, the pressure in the pipe was created by an overflow tank. The water supply came from the general water supply system. The discharge of water consumption was determined by the volumetric method.

For Reynolds numbers up to $1400 \cdot 10^3$, the pressure in the pipe was created using a rotary pump.

To create an even larger Reynolds number (up to $2500 \cdot 10^3$), the pressure in the pipe was increased by compressed air in a closed pressure tank.

In the last two installations, the Reynolds number was further increased by increasing the water temperature.

When conducting experiments on such installations, J. Nikuradze expanded the range of research to large values of Reynolds numbers. The maximum possible value of the Reynolds number in the study was $Re = 3300 \cdot 10^3$.

The results of J. Nikuradze's experiments in the region of hydraulically smooth turbulence [2] are graphs in coordinates $lg(100\lambda) = f(lgRe())$ in Figure 3.

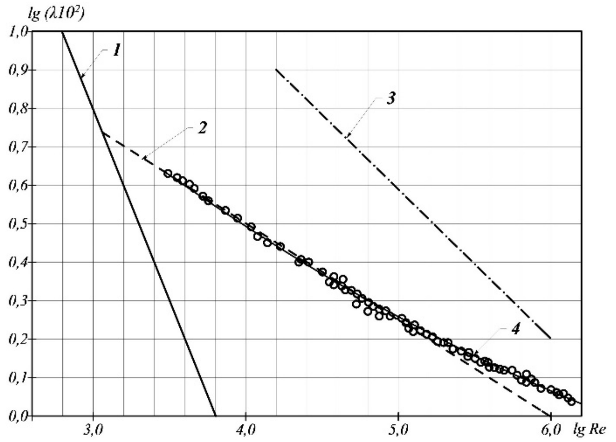

Fig. 3. Graphs of the dependence of the friction factor on the Reynolds number (according to J. Nikuradze): 1 - laminar flow; 2 - the region of hydraulically smooth turbulence (G. Blasius); 3 - the boundary between the regions of prequadratic and quadratic turbulence; 4 - according to the author's formula; ○ - experimental results of J. Nikuradze.

The figure 3 shows that the friction factor in coordinates $lg(100\lambda) = f(lgRe)$ depending on the main factors and the hydraulic regime within the regions takes different values.

Table 1 shows the diameters of the pipes and the Reynolds number, in the range of which hydraulic studies were performed by J. Nikuradze. The table also presents the dispersion of adequacy, which characterize the discrepancy of the experimental data relative to the theoretical formulas (6) - (12), (22).

The least squares method gave the values of the elements of the complex of relative parameters: $2\varepsilon_1/r_0 = 0$, $2\varepsilon_2/r_0 = 0{,}01034$, $2\varepsilon_3/r_0 = 0{,}003124$, $2\varepsilon_4/r_0 = 0{,}0000726$. Then equation (22) has the form

$$\lambda = 64\left(\frac{0{,}01034}{Re^{0,5}} + \frac{0{,}03124}{Re^{0,25}} + 0{,}0000726\right). \qquad (23)$$

The table 1 shows that the dispersion of adequacy of experimental data with the formula of G. Blasius increases with increasing Reynolds number. The dispersion of adequacy with the formulas of L. Prandtl, C. Colebrook, P.K. Konakov, G.K. Filonenko, F.A. Shevelyov and with the formula of the authors of this article decreases with increasing Reynolds number. The dispersion of adequacy of experimental data with the M.Y. Ruzin formula with increasing Reynolds numbers first increases and then decreases.

Table 1. The dispersion of adequacy of experimental data of hydraulic studies of smooth pipes obtained by J. Nikuradze, relative to the recommended formulas.

Author	Formula number	Dispersion of adequacy $D^2 \times 10^6$ for pipe diameters, mm and Reynolds numbers $\frac{Re\ \ mim \times 10^{-3}}{Re\ \ max \times 10^{-3}}$					
		10	20	30	50	100	10 – 100

If we analyze the dispersion of the adequacy of experimental formulas in Table 1, then at Reynolds numbers from 3070 to 1364000 - minimal errors give the formula of the authors of the article and the formula of L. Prandtl, C. Colebrook and G.K. Filonenko. The biggest errors are given by the formulas of G. Blazius and M.Y. Ruzin.

A.D. Altshul performed experimental research on hydraulic and aerodynamic installations [8].

Aluminum pipes had a smooth inner surface and were coated with oil. Before the experiments, they were washed with solvent and thoroughly wiped with rags. Pipes with a diameter of 350 mm had a small roughness, formed by insufficiently clean broaching (during their manufacture) and coating of alumina oxide.

The tested sections of pipes were always made of solid pipe (there were no joints on the section). The inlet and outlet sections were made of the same aluminum pipes as the measuring section.

The study of an aluminum pipe with a diameter of 26 mm was performed on a hydraulic installation, and with a diameter of 109.8 and 350 mm – on an aerodynamic installation.

The results of experimental studies of A.D. Altshul in the region of hydraulically smooth turbulence [8] are shown in Figure 4 in coordinates $lg(100\lambda) = f(lgRe())$.

Table 2 shows the diameters of the pipes and the Reynolds number, in the range of which hydraulic studies were performed by A.D. Altshul. The table also presents the dispersion of adequacy, which characterizes the discrepancy of the experimental data relative to the theoretical formulas (6) - (12), (22).

If we analyze the dispersion of the adequacy of experimental data (table 2) relative to the formulas for Reynolds numbers from 2844 to 338844, the minimal errors give the formulas of the authors of this article, L. Prandtl, C. Colebrook, G.K. Filonenko, and F.A. Shevelev.

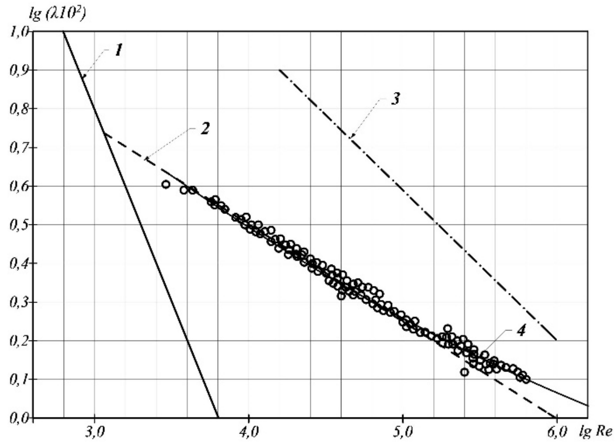

Fig. 4. Graphs of the dependence of the friction factor on the Reynolds number: 1 - laminar flow; 2 - the region of hydraulically smooth turbulence (G. Blasius); 3 - the boundary between the regions of prequadratic and quadratic turbulence; 4 - according to the author's formula; ○ - experimental results of A.D. Altshul.

Table 2. The dispersion of adequacy of experimental data of hydraulic studies of smooth pipes obtained by A.D. Altshul, relative to the recommended formulas

		$\frac{2884}{38905}$	$\frac{19486}{33113}$	$\frac{9550}{25119}$	$\frac{141254}{285102}$	$\frac{251189}{338844}$	$\frac{2884}{338844}$
G. Bla-sius	(6)	0,509	0,286	1,128	0,324	1,239	0,690
L. Pran dtl	(7)	1,420	0,249	2,207	0,078	0,192	0,571
C. Co-lebrook	(8)	1,879	0,265	2,373	0,050	0,204	0,651
P.K. Kona-kov	(9)	1,995	0,371	2,794	0,044	0,226	0,763
G.K. Filo-nenko	(10)	1,279	0,187	1,602	0,083	0,192	0,559
M.Y. Ruzin	(11)	0,866	2,675	0,353	2,176	0,874	1,595
F.A. Sheve-lyov	(12)	0,292	0,516	0,588	0,341	0,213	0,389
Guo Ning-xiang	(13)	1,609	0,264	2,234	0,078	0,192	0,612
Aut-hors of the ar-ticle	(23)	1,167	0,199	1,713	0,066	0,199	0,477

The biggest errors are given by the formula M.Y. Ruzin.

Table 2 shows that the dispersion of the adequacy of experimental data for the formula of G. Blasius with increasing Reynolds number increases. For the formulas of L. Prandtl, C. Colebrook, P.K. Konakov, G.K. Filonenko, F.A. Shevelyov, and the formulas of the

https://doi.org/10.1051/e3sconf/202128010009

authors of the article with increasing Reynolds number, the dispersion of adequacy decreases.

The good results of L. Prandtl's formula can be explained by the fact that this dependence is obtained theoretically from the logarithmic velocity profile.

All other formulas are obtained by statistical methods, so the determined results differ significantly from the experimental data.

The given experimental researches of J. Nikuradze and A.D. Altshul were performed for pipes of different material and diameter, on hydraulic and aerodynamic installations with the use of different measuring equipment.

The experimental data of A.D. Altshul (Figs. 3, 4) have a greater dispersion of adequacy. This can be explained by the fact that the experiments were performed using water and air. But all studies have a wide range of Reynolds numbers.

It should be noted that the determination of pipe diameters, pipe lengths between piezometric pressure sampling points, pressure drops, and water discharges were determined by calibrated equipment.

The accuracy of all experiments is high because there are no systematic errors. All experimental data are grouped only near one theoretical line by dependence (23). There are random errors, and they are greater in the experiments of A.D. Altshul.

We can conclude that the described experiments of J. Nikuradze and A.D. Altshul are sufficient for theoretical research.

The formula of the authors of the article gives good results because it is obtained on the basis of the method of dimensional analysis, characterizes the roughness of the inner surface of the pipes. This formula also takes into account the influence of Reynolds numbers on the friction factor.

4 Conclusions and prospects for future research

The article presents the results of theoretical studies of the flow friction factor in hydraulically smooth pipes. The dependence for the calculation of the friction factor based on the method of dimensional analysis is obtained. The adequacy of the author's equation and experimental data of J. Nikuradze and A.D. Altshul in the study of water flow in smooth pipes is determined.

It is shown that in almost all cases, formula (23) gives the best results. This formula is obtained on the basis of the method of dimensional analysis, which characterizes the roughness of the inner surface of the pipes. It also takes into account the influence of Reynolds numbers on the friction factor.

Therefore, formula (23) can be recommended to determine the friction factor of turbulent flow in the region of hydraulically smooth turbulence.

Future articles will present the results of theoretical studies of the friction factor for the regions of prequadratic and quadratic turbulence in steel and aluminum pipes.

The dam slope stability under the transient condition during an extreme flood

Svitlana Velychko[1,*], and *Olena* Dupliak[1]

[1]Kyiv National University of Construction and Architecture, Faculty of Engineering System and Ecology, 31 Povitroflotsky Ave., Kyiv, 03037, Ukraine

Abstract. Mountain Flood Control Reservoir (MFC Reservoir) is used to reduce the flood level in the mountainous area and protect settlements downstream. The special feature of this MFC Reservoir is the fast filling during 1-2 days, short storage time at the maximum level and speed falling of the water level. Simulation of the MFC Reservoir operation was carried out on the software Midas GTS NX. Two rockfill dam models were developed: with the core and with the screen. The fluctuation of the water level in the MFC Reservoir was taken as the transformed flood from 1% to 10% probability. The fast water level change in the MCF Reservoir creates the transient seepage condition during the flood. During the water level rising in the MFC Reservoir, the upstream slope stability gradually increases because of hydrostatic pressure. After the water level begins to fall with rate of 0.7 m/hour, the slope stability decreases. The core or screen location significantly affects the stability of the upstream dam slope. The simulation showed that the upstream slope of the dam with the core was more stable. Due to the high hydraulic conductivity, the upstream dam prism with the berm significantly dampens the pore pressure in the dam and increases the stability of the upstream slope.

1 Introduction

The floods take place both in winter and in the warm period, but cold floods have the higher flow rates in the Transcarpathian region. Due to the unstable temperature regime in winter, the frequent thaws are observed in the Tisza river basin, during which extreme cold floods are formed. In the mountainous part of the Tisza river basin floods have the high flow rate and short lag time, due to steep floodplain slopes and riverbed slope, the duration of flood does not exceed 3-5 days.

One of the active flood protection measure to lower water levels is using Mountain Flood Control Reservoir, which transforms the extreme flood flow of 1% probability to safe one. The safe flood flow which provides the sustainability of the river ecological system is estimated as Channel-forming flow of 5% - 35% probability for Tisza River basin according researchers in the work [1].

Mountain Flood Control Reservoir is created by dam with the bottom spillway. The spillway is designed for discharge of Channel-forming flow which passes without changing downstream. In the case of the extreme flood, the part of the river runoff that exceeded the Channel-forming flow is temporarily accumulated in the MFC Reservoir formed by the dam [2]. To save vegetation diversity inside the MFC Reservoir area, the duration of the water storage in the MFC Reservoir should not exceed 8-10 days, during which the water gradually flows downstream.

During the period of flooding the water level rises rapidly and the same rapid falls. During the rapid water rising in the MFC Reservoir, the pore pressure increases in the dam prism and the seepage is directed to the downstream slope. As the water level falls in the MFC Reservoir, the direction of seepage changes to the upstream slope with the gradual decrease in pore pressure. The rapid change of the water level in the Reservoir does not enable to stabilize the seepage, as the water penetration into the dam body is partial and transient [3, 4]. The depth of water penetration into the dam body affects the slope stability.

The calculations of authors [5-10] showed that the slope Safety Factor decreasing during the intense water level falling under the steady state seepage condition at the initial time, and if the water level was getting higher the Safety Factor increased in the water reservoir [11]. Decrease in slope stability is noted also under the transient seepage conditions as water penetrates into unsaturated soil during the rain that leads to increase of the phreatic surface [7, 12, 13]. In the article [14] is noted that Safety Factor of the clay slope during the rapid rising and falling (transient condition) decreases less than the Safety Factor calculated during the water falling from steady high level in the water reservoir. Therefore, it should be expected that Safety Factor of the upstream slope will decrease but the dam stability will be higher during the Mountain Flood Control Reservoir operation than when the water level falls suddenly after prolonged standing at a high level as in the typical water reservoir.

* Corresponding author: velychko.sv@knuba.edu.ua

https://doi.org/10.1051/e3sconf/202128010010

The transient analysis requires additional parameters of unsaturated soil, such as volumetric water content function, hydraulic conductivity function, residual water content [15]. Not all unsaturated parameters have a significant impact on the results of calculations, in the works [4, 16] were noted that saturated hydraulic conductivity had greater impact on the slope stability, than the volumetric water content function, which could be determined by theoretical methods. In the article [17] Safety Factors for slope at the different hydraulic conductivity and water falling rate were studied and established that the slope stability was not depend on the water falling rate if the saturated hydraulic conductivity of the slope was 0.2 m/hour and above.

To reduce construction cost, the dam of the Mountain Flood Control Reservoir is made of local materials, the quarries of which are located nearby. The most common building material in the mountainous part of the Carpathians is the gravel-pebble soil, the mechanical properties of which meet the requirements of the dam construction regulations. This material has the high saturated hydraulic conductivity of 30-50 m/day, which requires the use of the impermeable layer.

There are enough clay materials with low hydraulic conductivity of 0.01-0.07 m/day in Carpathians region, so two types of dam, the dam with the core and with the screen were considered in this article. The dam with screen simplifies the process of construction and operation of the dam, at the same time the dam with the clay core is more stable during seismic activity. Therefore, it is necessary to investigate whether the presence of the clay screen will affect the upstream slope stability and which of the impermeable structures will be more reliable for MFC Reservoir.

Mountain Flood Control Reservoir leads to the temporary intensive water level rising and falling during the extreme flood, which may reduce the upstream dam slope stability. This problem can be solved by simulating transient seepage by means of finite element method. Assessment of the slope stability under transient conditions is an urgent task that will ensure the reliability of flood protection. The stability of the upstream dam slope and transient seepage analysis were carried out by the Stress Analysis Method (SAM) and the Stress Reduction Method (SRM) using the software Midas GTS NX (version 2.1).

The purpose of the work is to simulate the possibility of dangerous landslide processes of the upstream dam slope during the MFC Reservoir operation under the transient seepage condition of unsaturated soil and to determine the optimal design of the impermeable structure of the rockfill dam.

2 Methods

2.1 Mountain Flood Control Reservoir

Expected location of the Mountain Flood Control Reservoir is the Irshava River of the mountainous part of the Tisza river basin. The main function of the MFC Reservoir to protect settlements of Brid, Zagattya, Irshava against floods and to lower flood water level in the river. The catchment area of the MFC Reservoir is 71.4 km^2. The height of the dam is 19.6 m. The upstream slope is 1:2.5, and the downstream slope is 1:2.25. Dam structure is shown on the fig. 1. The berms of 3.0 m wide are formed on the upstream and downstream slopes to increase the slope stability, and are used as cofferdam during construction period. The upstream slope is covered with the riprap. The base of the dam is strong dark grey Basaltic andesite, which is cracked near the surface with saturated hydraulic conductivity of 0.01-0.1 m/day.

The modern alluvial deposits of boulder-gravel-pebble materials on loamy aggregate which covers mountain base, should be removed out of the dam pit.

2.2 Extreme floods

Floods occur several times a year in Transcarpathian region, and extreme floods occur periodically: 1947, 1957, 1968, 1970, 1992, 1998, 2001, 2008, 2010, 2019. The flood of November 1998 is one of the most catastrophic in the recent years. It covered all the rivers of Tisza basin and it was formed by prolonged rains. Intense and prolonged rains led to the water levels rise up to 2.5-6 m in the rivers on the 4th of November, 2020.

To simulate the Mountain Flood Control Reservoir operation hydrograph of the flood of 1% probability was taken that was equal to 181m^3/s for the Irshava River. The flood water level raising to the maximum flow occurs in 12.4 hours, the level falls slower during 43.3 hours. The transformed flood flow, which flows through the bottom spillway to the downstream, is shown in fig. 2 (red line) and equal to 103m^3/s. The storage of the flood in the MFC Reservoir enables to reduce the flood flow twice due to stretching of the maximum flow in time. The water storage continues for the short time of 15 hours, then water level falls along 30 hours. The transformed flood hydrograph was converted into the relationship between water level and time by means of the flow rate and total head function.

This relationship between water total head and time was used to simulate MFC Reservoir operation during flood event.

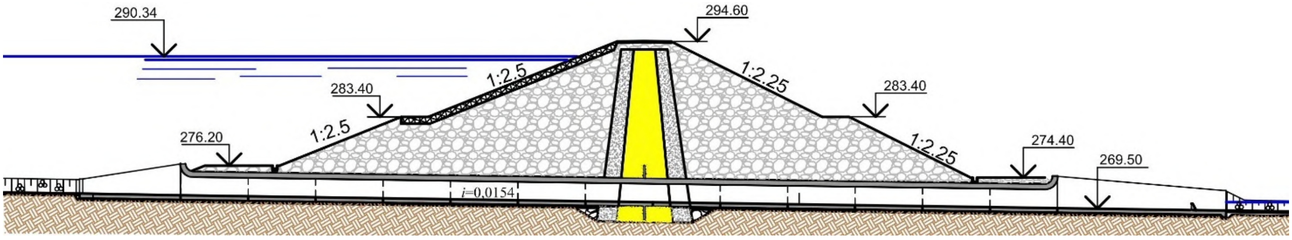

Fig. 1. Mountain Flood Control Reservoir dam with core.

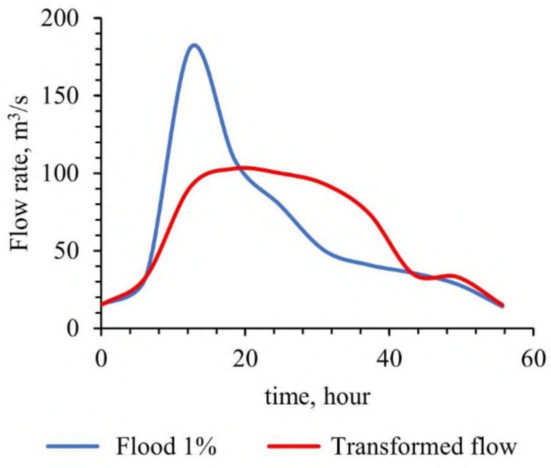

Fig. 2. The flood hydrographs of 1% and transformed flow downstream.

2.3 Soil properties of the dam and the base

The soil of the gravel-pebble with loamy aggregate for the dam prisms is classified as GM, the core and screen of heavy loam is classified as SC according to the Unified Soil Classification System. The base is Basaltic andesite cracked on the top and water saturated.

The mechanical properties of the soils of the dam and the base were obtained as a result of field surveys and laboratory processing of the samples. The soil property which were taken into account during simulation are shown in table 1.

Table 1. The soil properties of the dam and the base.

Propertied	Prism (GM)	Core, screen (SC)	Bedrock
Elastic Modulus, MPa	25	22	150
Unit Weight, kN/m^3	21.3	19.6	21
Cohesion, kPa	1	16	30
Internal friction angle, º	30	23	36
Hydraulic conductivity, m/day	19.9	0.067	0.001
Porosity, m^3/m^3	0.46	0.58	0.3

2.4 Transient seepage analysis of the Mountain Flood Control Reservoir

Simulations of the transient seepage in the dam during water level increasing and falling were made using the semi-coupled Seepage-Stress-Slope Analysis by the Midas GTS NX software. The Darcy`s equation is solved by the finite element method:

$$\frac{\partial}{\partial x}\left(k_x\frac{\partial H}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_y\frac{\partial H}{\partial y}\right)+Q=\frac{\partial\theta}{\partial t}, \quad (1)$$

where H is total head; k_x, k_y are the hydraulic conductivity in the horizontal and vertical directions, respectively; Q is boundary discharge; θ is the volumetric water content; t is the time.

The volumetric water content functions and the hydraulic conductivity functions of unsaturated soils for the prism GM, core (SC) and screen (SC) were set to simulate transient seepage analyses. The base was taken as saturated with the hydraulic conductivity according to table 1. It was assumed that the dam had already built and initial deformation was finished, for which the stage of zero initial deformations was entered during the calculations. The initial water level was set at the level of 1.0 m above the base of the dam which corresponded to the water level in the river before the flood, the initial stage of steady state seepage analysis was made to simulate water in the river. The influence of the rain and the possible evaporation from the surface of the dam were not simulated.

2.5 The upstream slope stability analysis

The Stress Analysis Method (SAM) is the limit equilibrium method, in which the Safety Factor is determined for the several circular sliding surfaces using the results of the stress calculation by the finite element method. The Safety Factor is calculated by equation:

$$SF=\frac{\int_s \tau_f d\Gamma}{\int_s \tau_m d\Gamma}, \quad (2)$$

where τ_m is shear stress, which determined as a result of calculation; τ_f is shear stress, which for the Mohr-Coulomb criterion is calculated by equation:

$$\tau_f = c+\sigma_n tg\varphi, \quad (3)$$

$$\tau_m = 0.5(\sigma_y-\sigma_x)sin2\theta+\tau_{xy}cos2\theta, \quad (4)$$

$$\sigma_n=\sigma_x sin^2\theta+\sigma_y cos^2\theta-\tau_{xy}sin2\theta, \quad (5)$$

where c is cohesion; φ is internal friction angle; θ is the angle between the sliding surface and horizon; σ_n is the total normal stress; σ_x, σ_y are normal stress in the horizontal and vertical directions, respectively; τ_{xy} – shear stress in x- and y-directions at the base centre.

The Stress Reduction Method (SRM) is based on the gradual decrease in shear stress until the slope reaches limit equilibrium state, the minimum value of the Safety Factor using the Mohr-Coulomb criterion is determined by the equation:

$$SF=\frac{c+\sigma_n tg\varphi}{\frac{c}{SRF}+\sigma_n tg\varphi_f}, \quad (6)$$

$$\varphi_f = tg^{-1}\left(\frac{tg\varphi}{SRF}\right), \quad (7)$$

where SRM – Stress Reduction Factor.

The Stress Reduction Method enables to simulate the sliding surface which is close to the real form of sliding surface without preliminary adopted potential sliding surfaces that is the great advantage over the other methods in which it is necessary to set sliding surfaces [18, 19].

The two-dimensional model was used to simulate the Mountain Flood Control Reservoir operation. Since the size of the mesh affects the calculations accuracy before the simulation, the optimal mesh size was accepted by gradually reducing the mesh size from 2.0 m to 0.5 m. The simulation was carried out for dam with core. The mesh size of 1.0 x 1.0 m was set for dam, and the variable mesh

https://doi.org/10.1051/e3sconf/202128010010

from 1.0 m to 2.0 m for the base as further mesh reduction significantly increases the calculation time and practically does not increase the Safety Factor accuracy, the similar result was obtained in the work [20].

The Mohr-Coulomb model was used for the soil simulation. Two dam construction were simulated: the location of the impermeable layer in the middle of the dam (dam with core) and the impermeable layer location near the upstream prism (dam with screen). The flood hydrograph was divided by regular intervals every 5 hours. The following assumptions were made during the simulation:

- the parts of the model (prism, core, screen, base) were accepted as homogeneous and isotropic;
- the mechanical soil properties in saturated and unsaturated condition were assumed to be the same;
- the hydraulic conductivities are isotropic;
- the maximum hydraulic conductivity is equal to the water permeability;
- the seepage inside the dam is transient;
- the initial water level is set at the level of 1.0 m above the base.

3 Results and discussion

The phreatic surface location inside the dam during the rise of water level at first 30 hours of the flood is shown in figs. 3A and 4A. The high-water level keeps for 10 hours from 25 to 35 hours, during which the phreatic surface does not reach the steady state position (the steady state phreatic surface is shown in figs 3 and 4 in dark red). The water rise rate of 0.7 m/hour does not enable to establish steady state seepage in the prism of the dam with the core (fig. 3A), so the water saturation of the soil in the core is less than in the screen soil, which is located closer to the upstream slope. The screen is saturated with water more intensely even at the first 20 hours of the flood.

After the short period of high water, the water level begins to decrease, the falling rate reaches of 0.78 m/hour at the time period from 35 hours to 55 hours (figs. 3B and 4B). The direction of water movement changes: part of the water continues to seep through the downstream slope, as evidenced by the gradual increase in water level inside downstream prism and approaching the steady state position, the second part changes direction to the upstream slope. The figs. 3 B and 4 B show that the reduction of pore pressure in the dam prism occurs almost simultaneously with the water level decrease in the MFC Reservoir, and the lag time of the phreatic surface is formed due to the low hydraulic conductivity of the core and screen. The location of the impermeable layer (screen) near the upstream slope significantly affects the pressure gradient during the water level falling.

Therefore, from the point of view of reliable operation of the MFC Reservoir, the impermeable layer should be moved away from the upstream slope to decrease the pressure gradient and fast the pore pressure damping in the dam prism.

The fig. 5 presents the results of upstream slope stability calculations by the SAM for the dam models with core and screen and the change of water levels in the MFC Reservoir, which corresponds to the transformed flood hydrograph. The zero time corresponds to the upstream slope stability at the steady state water level of 1.0 m above the dam base. The Safety Factor of the upstream slope of the dam is 1.5 at the zero time, which is lower than the SF of the MFC Reservoir filled with water due to the stabilizing effect of hydrostatic pressure. At the begin of the flood (from 0 to 10 hours) during the slow water raising, the SF of the upstream slope decreases slightly due to increasing pore pressure in the dam prism, the next time period with increasing water level the stability of the slope increases to 1.57 for the dam with core and to 1.5 for the dam with screen.

After 35 hours of the flood, the water level begins to fall, the water level in the MFC Reservoir falls faster than the phreatic surface in the dam body and the slope stability decreases, reaching a minimum value at the 50th hour of flood, which corresponds to the highest gradient of phreatic surface (figs. 3B, 4B). The upstream slope of the dam with the screen loses stability faster than the dam with the core and Safety Factor reaches the limit value at which the slope is kept stable at 50th hour. At the same time, the dam with the core has the safety margin.

Dam stability simulation by the SRM demonstrates the similar trend of Safety Factor change with the maximum value at the highest water level in the MFC Reservoir during the flood and the minimum value of the upstream slope stability at the 50th hour (the end of the flood). At the end of the flood, the upstream slope is stabilized with the gradual restoration of the initial Safety Factor. The results of calculations are shown in the fig. 6.

Calculated sliding surfaces by SRM and SAM had circular shapes. The location of the critical sliding surfaces determined by the SRM and SAM were situated on the upstream berm. The sliding surface determent by SRM is located deeper and has bigger radius than surface designed by SAM. The sliding area created by SRM is bigger.

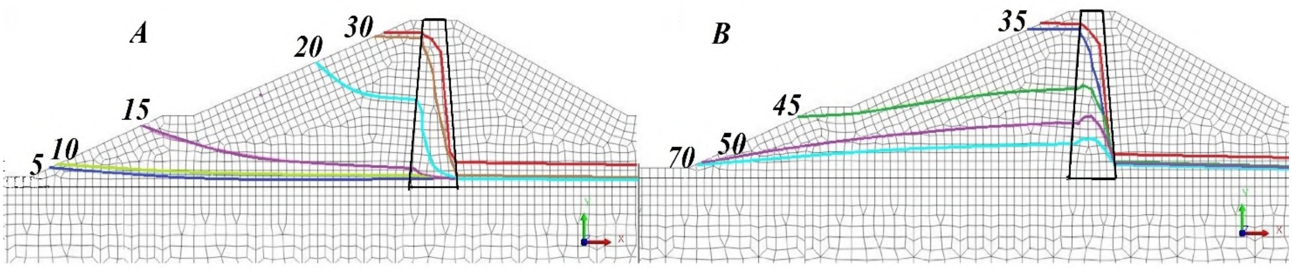

Fig. 3. The phreatic surface location at the 5, 10, 15, 20, 30, 35, 45, 55 and 70 hours of the flood inside the dam with the core.

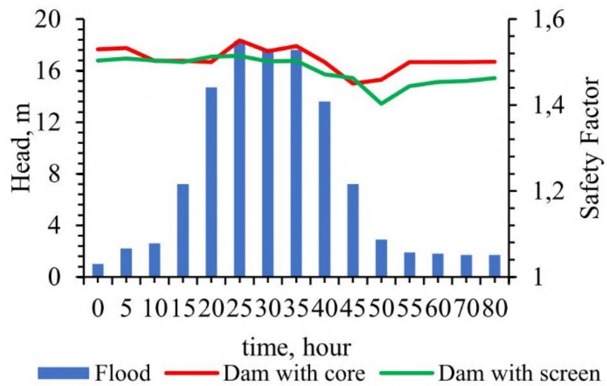

Fig. 6. The Safety Factor of the upstream slope of the dam with core and screen calculated by SRM.

4 Conclusions

Floods in mountainous areas have a sudden nature and the short period of 2-3 days, with a significant water rise in short time and the same rapid water level falling. Construction of the Mountain Flood Control Reservoir requires rockfill dam. Two different type of the impermeable layer of the dam were used for simulation: the dam with core and the dam with screen.

When the water level rises to the maximum value and then falls, there is the water lag time in the impermeable layer, especially great seepage gradient takes place in the dam with the screen.

The dam prism with the hydraulic conductivity of 20 m/day leads to pore pressure damping, so in a dam with the core phreatic surface are gentler, and the seepage point almost coincides with the water level in the MFC Reservoir. In the dam with screen, the water lag in the screen soil leads to the larger values of pore pressure near the upstream slope, and the seepage point is situated above the water level in the MFC Reservoir.

The Safety Factor of the upstream slope of the dam is 1.5 for initial position, when the MFC Reservoir is empty and the initial river water level is 1.0 m above the base.

Seepage analysis of the rockfill dam with impermeable layer showed that the maximum values of the Safety Factor is achieved by setting the high-water level in the MFC Reservoir. The flood condition does not enable to form of steady state seepage due to the low hydraulic conductivity (0.067 m/day) of the impermeable layer and the high-water level changing rate in the MFC Reservoir. Therefore, simulation of the MFC Reservoir operation must be carried out using transient seepage analysis, taking into account the unsaturated properties of the soil.

Simulations of the dam with core under transient condition of water level rising and falling showed that the upstream slope stability significantly depends on the position of the phreatic surface in dam prism. On the example of the dam with core on the Irshava River, the simulation using SAM showed that the water level falling at the end of the flood reduces the slope stability, the Safety Factor was 1.31 when the minimum water level is reached.

The water level falling under transient condition in the unsaturated soils by SRM also leads to the decrease of the upstream slope stability, but the minimum value of the Safety Factor was 1.48 for the dam with core.

The dam with screen as impermeable layer has operational advantages, but in the case of transient seepage condition, the screen saturation leads to the significant increase in the phreatic surface gradient that reduce the slope stability to unacceptable Safety Factor values of 1.06. Therefore, the rockfill dam with the clay core significantly increases the reliability and safety of the structure and ensures the upstream slope stability. The dam prisms should have high hydraulic conductivity and the slopes should be divided with berms of 3.0 m width.

Calculations of slope stability by SAM and SRM show the circular sliding surface and not the same location of the critical sliding surface. The values of the Safety Factor under the same conditions differ due to the different radius of the sliding surface and location. The values of the Safety Factor calculated using the SAM are lower than the value determined by SRM under similar conditions.

The overestimated Safety Factor by SRM were obtained in the works [20 - 24], that explained sensitive to the nonlinear solution algorithm and its incapable of determining other failure surfaces near critical value.

Since the Safety Factor values defined by SAM lower, they were taken to assess the upstream slope stability.

Abstract. Bioindication assessment of water bodies of Ukraine can be carried out using the ratio of males and females of mollusks of the genus *Viviparus*. In practice, it is very convenient to determine the sex of mollusks by the differences in their shell. Male and female freshwater snails *Viviparus viviparus* (Linnaeus, 1758) and *V. contectus* (Millet, 1813) are shown to have reliable differences in shell morphology depending on their age. There is almost no sexual dimorphism by shell morphometrics and indices in Viviparus snails aged one to three years. After three years of life, mature females have significantly larger shell width, higher body whorl, and size of the aperture. Females of *V. viviparus* at the age of two to five years may be differentiated from males by the relationship of mean shell width and shell height, which is statistically significant higher than in males. This difference is explained by the different size of the mantle section genital organs of mature male and female. The obtained results should be taken into consideration in establishing the sex of viviparid snails.

1 Introduction

Mollusks of the genus *Viviparus* Montfort, 1810, namely *V. viviparus* (Linnaeus, 1758) and *V. contectus* (Millet, 1813) are quite common in the rivers, floodplain lakes and large ponds of Ukraine, in which they can accumulate significant numbers and biomass [1]. The freshwater pond snails are essential in the maintenance of water ecosystems, as part of various trophic chains, particularly as intermediate hosts of many bird parasites [2]. Also, these prosobranch gastropods with filtration and sedimentation cleanse water bodies from suspended matter, depositing it on the bottom [3, 4].

Viviparid snails were found useful for bioindication of water bodies of Ukraine [5]. For that, the ratio of males to females in the mollusk population is used. The sex structure of freshwater pond snails in water bodies with an increased organic matter content (alphamesosaprobic and polysaprobic zones) is characterized by an increase in the number of females, less often young (1–3-year-olds individuals) males [1]. In practice, it is important to clearly distinguish between male and female freshwater pond snails when conducting bioindication studies.

The representatives of the genus *Viviparus* are dioecious freshwater snails with exact sexual dimorphism: in males, the right tentacle is shorter, thickened and blunt (transformed into copulatory organ), while in females the right and left tentacles were of the same shape and size. Sex chromosomes in both species were not identified, but there are statistically significant differences in dimensions of homological chromosomes of *V. viviparus* and *V. contectus* males and females [6, 7].

The studies about sexual dimorphism in the shell morphology of *Viviparus* are contradictory. For example, sexual dimorphism was not found in the shell sizes of *V. sphaeridius* (Bourguignat, 1880) and *V. viviparus*, collected in the Southern Buh river [8, 9]. However, statistically significant sex differences in the conchological characters of these species in the Bucha river were noted in that study. Examination of five species of the genus *Viviparus* (*V. viviparus, V. contectus, V. acerosus* (Bourguignat, 1862), *V. ater* (Christofori et Jan, 1832), and *V. hellenicus* (Clessin, 1879)) revealed no dimorphism between male and female snails in the shell shape [10].

At the same time, a number of studies point out the presence of such differences. In particular, females of *Viviparus* are usually larger than males, with more convex whorls, and wider aperture [11–13]. T. A. Andriychuk [6] revealed sex differences in the shells of *Viviparus* using discriminant analysis and dispersion statistical analysis.

Geometric morphometric analyses of three shell characters (ventral/aperture, dorsal, and top/whorl portion) indicated sexual dimorphism in the shape in *V. angularis* (O. F. Müller, 1774) [14]. Sexual dimorphism in the shell sizes was also noted for the

* Corresponding author: tetianavakaliuk@gmail.com

American endemic species *V. subpurpureus* (Say, 1829) [13]. Females of this species have relatively lower shell spire, more convex whorls and larger size of the aperture compared with males. In *V. viviparus* [15] and *V. contectus* [16], there were marked sexual differences by the allometric coefficients of the relationship between shell height, shell diameter (width) and aperture height.

However, there also are reports [such as 17], according to which male snails are larger than females and these differences are statistically significant.

Taking into account the discrepancies in the literature about sexual dimorphism in the shell morphology, we decided to carry out our own study.

The purpose of our work was to study sexual dimorphism in the shell morphology of *V. viviparus* and *V. contectus,* taking into account the age of mollusks.

2 Material and methods

The materials for the study were the samples of *V. viviparus* (Fig. 1a) from the Irsha river (city of Khoroshiv, Zhytomyr region, Ukraine; 50°60'31" N, 28°45'42" E) and *V. contectus* (Fig. 1b) from the floodplain of the Tnya river (village of Nesolon, Zhytomyr region, Ukraine, 50°56'08" N, 27°92'81"E) collected in August, 2016. The mollusks were collected at a depth of 1 m. At each station, at least three samples were taken [18].

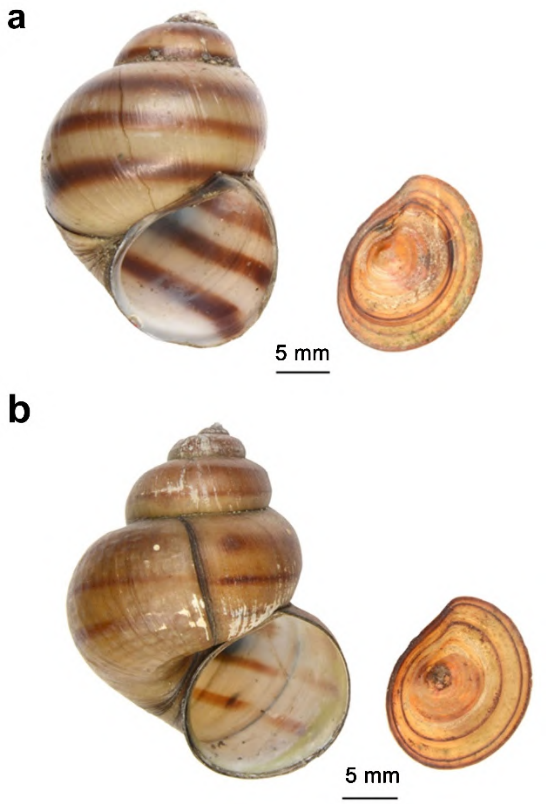

Fig. 1. Shell and operculum of *Viviparus viviparus* (Linnaeus, 1758) (a) and *V. contectus* (Millet, 1813) (b).

Snail species were identified according to P. Glöer [19] and F.W. Welter-Schules [20].

We studied males and females of viviparid snails with different the shell size and age. The age of the mollusks was determined by the number of concentric dark structure on the operculum, which marks the slower snail growth in winter [1]. The snail sex was determined by the shape of the right tentacle [21].

The shells were measured using a caliper with the accuracy of 0.1 mm. Five shell morphometric parameters were analyzed: shell height (SH), shell width (SW), aperture height (AH), aperture width (AW) and body whorl height (BWH) (Fig. 2) [15]. According to these measurements, the following indices were calculated: SW/SH, BWH/SH, AH/SH, AW/SH.

The received digital data are processed using standard methods of variation statistics [22]. Descriptive statistics was conducted using the program STATISTICA 6.0. Significant differences between the values were assessed by the Student's *t*-test.

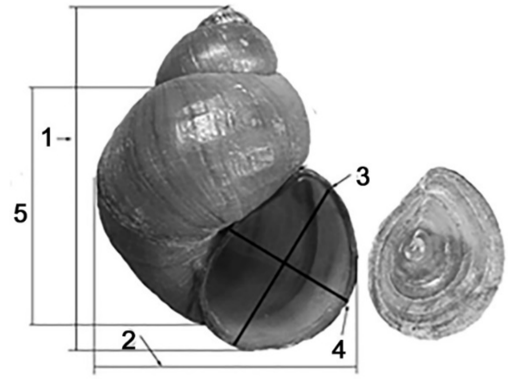

Fig. 2. Measurements on shell morphometric parameters of viviparid snails: 1 – shell height, 2 – shell width, 3 – aperture height, 4 – aperture width, 5 – body whorl height [15].

3 Results and discussion

At adverse conditions (prolonged colder winter temperature), the growth of viviparid snails is inhibited. As a result, the ion exchange and sedimentation of CaCO3 decrease or even completely cease, which leads to the formation of a clear dark concentric structure on the operculum and spiral bands on the shell that are more visible than other formations of different origin.

The river snails under a year in age (0+ age) do not have specific sculpture elements on their shells and dark structure on the opercula, because they have not experienced a winter period of slowed growth (Figs. 3, 4). At the same time, the operculum of shell of all age classes, including the one-year-old snails, bear the so-called embryonic mark (Figs. 3e, 4e). It is more or less pigmented and formed during the embryonic development in the body of parent female in winter.

Snails with one spiral band on their shells and one-year-old concentric structure on the operculum are here designated as 1+; accordingly, 2–6-year-olds are designated as 2+, 3+, 4+, 5+ and 6+. Figures 3 and 4 depict the operculum of the *V. viviparus* snails (age from 0+ to 5 years) and *V. contectus* (age from 0+ to 6 years) from different populations to visualize their variations in pigmentation, clarity and thickness of annual concentric structure.

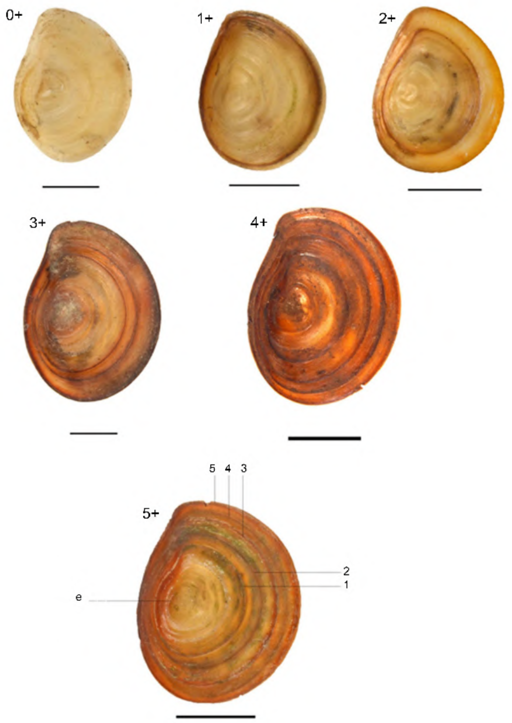

Fig. 3. Winter marks on the operculum of *V. viviparus:* 0+, 1+, 2+, 3+, 4+, 5+ − the 1, 2, 3, 4 and 5 year old specimens, respectively*;* 1−5 – post-embryonic marks; e – embryonic mark. Scale is 5 mm.

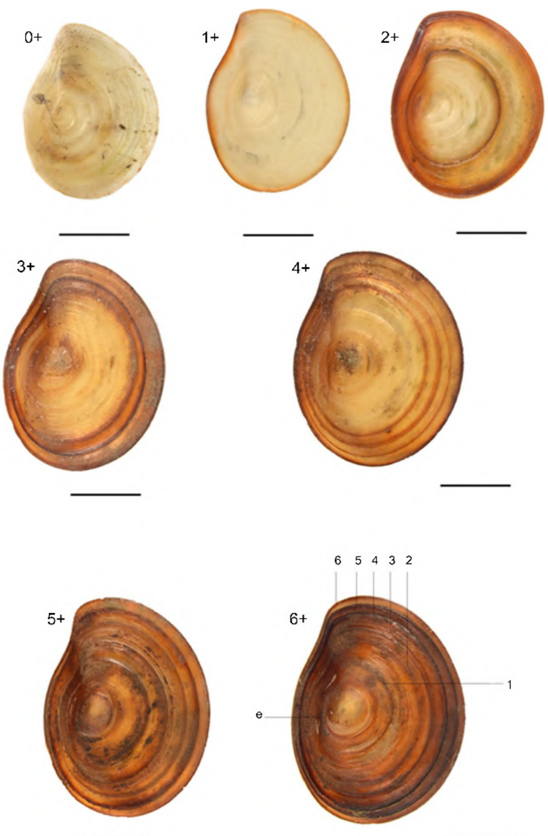

Fig. 4. Winter marks on the operculum of *V. contectus:*0+, 1+, 2+, 3+, 4+, 5+, 6+ − the 1, 2, 3, 4, 5 and 6 year old specimens, respectively; 1−6 – post-embryonic marks; e – embryonic mark. Scale is 5 mm.

In the water bodies of Ukraine, the maximum age of *V. viviparus* mollusks was 5 years and that of *V. contectus* snails was 6 years [1].

We analyzed the representative samples of *V. viviparus* males and females of each age class from one population (Irsha river). When comparing the average values of the shell height, it was found that young (0–2-year-olds individuals) have no sex differences in this parameter, at the age of 3, the males were larger than females, and at the age of 4-5 years, the females were larger than males (p >0.05) (Table 1).

Table 1. Sex differences in shell morphometrics and indices ($x \pm m_x$) of *V. viviparus* of different age collected in August, 2016 in the Irsha river (city of Khoroshiv, Zhytomyr region).

Notes: 1 − conchological parameters are described in “Material and methods”; the numerator presents the measurements for males, the denominator for females; *n* — quantity of studied specimens; * — statistically significant difference between sexes (p<0.05).

The average values of the shell width in young individuals (0+ to 1 year old) of both sexes are almost the same. These parameter tend to increase in the females since the age of both when they become mature. At the age of three to five years, this difference is statistically significant (p = 0.05).

We analyzed the limits of variability of the shell width for *V. viviparus* males and females of different age (Fig. 5a). The minimum and maximum values of this trait parameter for both sexes often overlapped.

The body whorl height is higher in older females than in males, with statistically significant difference (p = 0.05) in 3−5 year old snails. There was no statistically significant difference in the aperture height between sexes of viviparid snails. As for the aperture width, in older (3–

5-year-olds) females this parameter is significantly (p = 0.05) higher than in males.

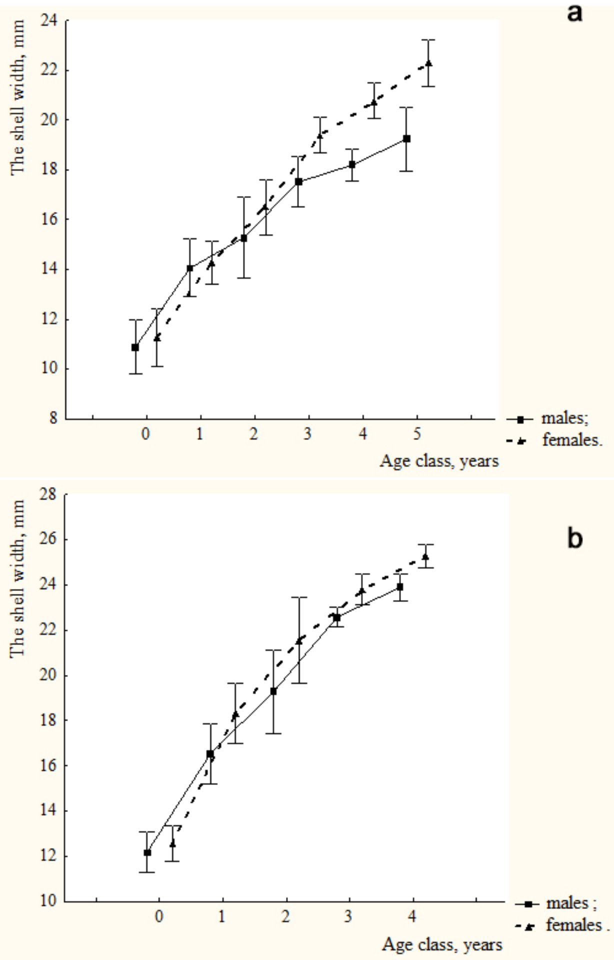

Fig. 5. Relationships of age and shell width in males and females of *V. viviparus* from the Irsha river (city of Khoroshiv, Zhytomyr region) (a), and *V. contectus* from the floodplain of the Tnya river (village of Nesolon, Zhytomyr region) (b) in August 2016.

As for the relative values of the conchological character of *V. viviparus* males and females, starting at the age of 2 years, the most reliable for sex differentiation is the SW/SH index. Only at the age of 3 years, the indices of BWH/SH and AW/SH are significantly (p = 0.05) higher in females compared with males.

During the morphological study of the conchological parameters of *V. contectus* in the population from the floodplain of the Tnya river, only one 5-year-old male was found, and 6 years-old snails were not recorded at all. Therefore, we did not statistically analyze the age class of 5−6 years.

It should be noted that in other populations of *V. contectus*, as well as *V. viviparus*, males of this age are also very rare. The reasons for the number of males decreasing with age in the populations of Viviparus remain unclear. Possibly, one of the causes are trematode infections. After all, higher infection rates are noted for older males than females of the same age. There is an evidences that males are less resistant to parasitism in general and to trematodes in particular [23]. Lower ratio of males in the freshwater snail populations may also be associated with less favourable conditions for their existence in the modernized transformed water bodies of the Ukraine, where females exhibit greater viability. V. A. Geodakyan [24] considers that male individuals of many animals in the populations have less sustainability to influence of unfavorable environment factors. The revealed changes in the sexual structure of the viviparid populations can be considered an adaptive strategy for reproduction in a transformed environment.

No significant sexual differences were noted in the shell height of *V. contectus* snails (Table 2). Shell width from the age of one year, and body whorl height from the age of three years were significantly higher (p = 0.05) in females than in males. We also analysed the variability range of shell width for *V. contectus* males and females with different ages (Fig. 5b), and noted that the minimum and maximum values of that character often overlapped in both sexes.

Table 2. Sex differences in shell morphometrics and indices ($x \pm m_x$) of *V. contectus* of different ages collected in August 2016 at the floodplain of the Tnya river (village of Nesolon, Zhytomyr region).

Note: the designations as in Table 1; dash — no data available

In older (3−4-year-olds) females of *V. contectus*, the size (height and width) of aperture is larger than in males. As for the shell indices, a significant (p = 0.01) sex difference was found only for SW/SH index in 2-year-olds *V. contectus*.

Correct identification of sex is an important component of wildlife management because changes in sex ratios can affect population viability. Most malacologists, studying sexual morphological dimorphism of snails, take into account the absolute and relative indices of the shell and do not consider the age of individuals. For the first time, considering the age of *V. viviparus* and *V. contectus*, the analysis of the conchological parameters of their males and females was performed, and differences in adults were revealed.

Populations of *V. viviparus* from the Irsha river (Khoroshiv, Zhytomyr Region, Ukraine) are similar to populations of this species from other geographical areas – the Dnepr river (Smolensk, Russian Federation) and the Shokhonka river (Ples, Ivanovo region, The Russian Federation) [15].

The revealed pattern of sexual conchological characters in adult snails is noted by malacologists for other members of Caenogastropoda as well. Such a pattern has been found for *Melanoides tuberculatus* (Müller, 1774) from Israel [25], for *Buccinanops globulosus* (Kiener, 1834) from Argentina [26].

Differences in the shell morphology of *Viviparus* males and females are explained by different sizes of mantle section of the male and female reproductive system, located in the body whorl. Pregnant females have a large brood pouch, filled with egg capsules with embryos, which may be quite numerous [1, 27, 28]. The brood pouch is located in the upper part of the mantle cavity and occupies almost the entire volume of the body whorl. The ejaculatory chamber is located in the bottom of the male mantle cavity, and in the inactive state, it occupies a much smaller volume within the body whorl. Other researchers have the same opinion about Viviparidae and other Caenogastropoda [15, 26, 29, 30]. According to results, Viviparidae mollusks can be used as bioindicators in environmental assessment of water bodies. Average shell height of mature (2 to 3 year old) snails and sex ratio in populations of Viviparidae are the population characteristics which are the most informative in bioindication with this species (mostly by organic pollutants). Primary sexual structure (age class 0+) of *V. viviparus* expressed as 1 : 1. Reservoirs are characterized by the best conditions for hydrobionts and hydrochemical parameters of water within the limits of norm at equal correlation of mollusks sexes (secondary sexual structure). There is a rejection of this index toward the increase of number of females, rarer – young males in the conditions of environment, less favorable for the organisms. Such reservoirs are characterized by rejections in hydrochemical parameters (concentration oxygen, content of organic matter). Forming of greater amount of females at large anthropogenic influence on reservoirs is adaptive strategy of populations *V. viviparus* in the changing conditions of environment.

4 Conclusion

Therefore, the analysis of morphometric conchological characters of the two *Viviparus* species revealed sexual dimorphism for adult individuals (3−5 years old): females mostly have a wider shell and aperture, and more convex body whorl than males. Differences in the shell morphology of males and females are explained by different sizes of mantle section of the male and female reproductive system, located in the body whorl. However, these parameters often overlap in males and females and do not always permit to identify them reliably. This may be due to the different growth rates of individuals. Hence, we recommend taking into consideration not only the specifics of shells of male and female viviparid snails, but also their head tentacle in the course of bioindication assessments.

Abstract. This paper presents the results of new composite materials based on polylactide and coffee grounds sorption characteristics study. New material, that include coffee grounds as additive material is cheaper than one of common polylactide. All types of dishes cam be made from new material and they also will be biodegradable, as made from polylactide. The sorption properties and characteristics were tested in different liquid medium. The last was chosen among the most wide spread mediums which are contact with dishes during its operational life. It was found, that optimal content of coffee grounds is 40 wt.% as for level of impact strength also for complex of sorption characteristics.

1 Introduction

The modern paradigm of global economy and industry is directly related to the concept of “Zero Waste”, based on minimum waste generation principle at each stage of material or product production, operation and disposal [1,2]. That is why today we are talking about the widespread use of so-called “eco-” or “biomaterials” that do not harm the environment. This trend can be found both in various branches of modern industry and in ordinary household spheres of human life: food, hygiene, entertainment industry and others. We faced with wastes every minute in our life. Even common phenomenon such as making coffee at home or in a restaurant leads to the generation of waste’s large amounts, that usually called coffee grounds.

Coffee consumption in Ukraine is more than 15,000 tons per year and continues to grow on average by 5% per year [10]. Today, coffee is a popular raw material for making broad range of beverages, as well as the provision of various additional services in hotel and restaurant industry. Its fruits contain a large number of substances that one of various chemical nature: proteins, carbohydrates, organic acids, fats, alkaloids, in particular caffeine.

High demand for this species marketable products, leads to the emergence of new production plants in our country instant coffee. And like any industry, coffee production cannot be waste-free. The main waste of this class of enterprises is coffee grounds or coffee cake. Coffee grounds is a product obtained from the industrial production of instant coffee or waste remaining after the preparation of a beverage from ground coffee. Coffee grounds is a valuable organic raw material and contains a large number of nutrients, primarily proteins. In the production of one ton of dry instant coffee, the yield of absolutely dry cake is 1.5 tons. Wet thicket molds quickly, so storage is required its additional drying. According to the generally accepted classification of waste, it is household organic waste [3]. In terms of the Zero Waste concept, most developed countries in the last 20 years have begun to actively use coffee grounds as a valuable resource that corresponds to the concept of sustainable development.

World trends analyze allowed to outline the main directions of coffee grounds:

– utilization in agriculture in the form of additives in fertilizers or soils. however, this direction of dry coffee grounds use is rather limited because it is not studied transformation of useful substances from a field to soil. That is why, you can find a lot of amateur information about the use of coffee grounds in some farms, but thorough research has not yet been conducted. You can also find information about the general harm of coffee grounds due to its acidic pH level, at the same time, it is generally studied to use wet coffee grounds as a basis for growing mushrooms, in particular champignons and coffee grounds using as fuel;

– use as an abrasive material in the manufacture of cosmetics, including creams, scrubs, soaps, etc. Manufacturers of so-called “green” or “eco” cosmetics prefer to use coffee grounds. However, this direction is able to dispose a limited amount of coffee grounds waste;

– use of coffee grounds in modern art, including for the production of jewelry, painting and various installations;

– use as an additive to polymeric materials to reduce the cost of the final product. The most forward-looking conception is to produce biodegradable polymer dishes,

* Corresponding author: vladimirlebedev1980@ukr.net

https://doi.org/10.1051/e3sconf/202128011001

which is dominated by an organic additive - coffee grounds.

The last conception allows to utilizate a large volumes of coffee grounds the same time to achieve the principle of “Zero Waste” when using bioplastics. The concept of sustainable development implies the recycling of materials that were previously considered waste. The criterion for the expediency of using waste as a resource can be not only the economic component, but also a decrease environmental impact. At the same time, the life cycle of a new material object should not increase the environmental impact. Coffee grounds, getting to landfills for solid household waste, within three days become a breeding ground for mold, which quickly spreads to other elements of the landfill.

Using of coffee grounds waste as a filler, you can get a product that haven’t negative environmental impact with low price. That is why the development of biodegradable polymer composite materials based on bioplastic such as polylactide (PLA) and coffee grounds waste is very relevant.

2 Literature data analysis and problem statement

Today, there is a significant number of scientific studies of coffee grounds as a filler in polymer composite materials [4, 5, 6, 7]. At the same time, research in the field of using coffee grounds as filler for new biodegradable composite materials is rarely found [8, 9]. The objective of this research was to determine the effect of spent coffee grounds filler on the physical and mechanical properties of PLA bio-composite film. The bio-composite film was fabricated by a twin-screw and blow film extruder.

In researc [9] characterizes and compares coffee chaff and spent coffee grounds, the two most useful coffee waste products, and evaluates their performance as fillers and/or reinforcing agents in polymer composites.

We have previously studied [10] chemical, physical, mechanical and operational properties of new high-filler composite based on PLA. As shown, the highest performance indicators were characterized for compositions with a content of coffee grounds filler from 40% to 60% wt. It is also noticed, that using coffee grounds as fillers for polymer materials can decrease the total volume of it at landfills faster than any other method of coffee ground reuse. Further research the level of sorption stability for developed materials to the most characteristic environments of their operation is perspective.

3 Study purpose

The aim of the research was study sorption resistance of biodegradable polymer composite materials based on PLA and coffee grounds waste.

To achieve this aim in the work it was necessary to perform the following tasks:

- to study the effects of coffee grounds waste on the mechanical characteristics of biodegradable polymer composite materials based on PLA;
- to research the sorption characteristics of the developed materials to the most characteristic environments of their operation.

4 Materials and methods

The objects of study were:

- extrusion PLA of the Terramac TP-4000 brand;
- coffee grounds waste, gathered in 8 different coffee shops in Kharkiv and dried to moisture content 50% Coffee grounds waste have a polyfractional composition in the particle size limit from 0.5 to 1 mm. Using IR spectroscopy methods, it has been shown [10] that coffee grounds, in their chemical composition, are characterized by up to 6% or more content of caffeine, alkaloids and their companions, up to 1% of chlorogenic acids and their derivatives content.

Composites were obtained by extruding pre-prepared raw materials in a single-screw laboratory extruder at a temperature of 170–200 ° C and a roll rotation speed of 30–100 rpm. The L / D ratio of the extruder is 25, and in order to increase the uniformity of dispersed waste distribution in the finish compositions, 2 mass passes were used to obtain finished samples. It was made 20 parallel experiments for each composition, statistical processing was made by characteristics such as arithmetic mean, standard deviation and variation coefficient.

The study of impact strength and breaking stress during bending of the samples without notching at a temperature of 20 ° C was carried out on a pendulum head according to ISO 180 and ISO 178, respectively.

Microscopic studies were carried out using the electron microscope Digital Microscope HDcolor CMOS Sensor (China).

The chemical method for determining the porosity of the paint coating is to identify violations of its continuity in the formation of points of the turnbule salt in the reaction of the reagent - red blood salt K_3 [Fe (CN) $_6$] with Fe^{2+} (pH ≤ 7), which occur due to corrosion of steel and diffuse to the surface of the coating. To assess the destruction of the coating from the formation of bubbles, coating samples applied to a steel substrate measuring 10x15 cm and sealed at the edges are placed in the operating environment for 7 days at a temperature of 20 ºC.

The method of evaluation is to determine the surface area of the coating, which is destroyed by bubbles and the linear size of the bubbles (diameter and depth of the lesion). The degree of destruction of the coating due to the formation of bubbles is assessed on a five-point scale.

Sorption characteristic of the samples was determined as the amount of reagents absorbed by the sample (size 15x10x1.5–4.5 mm) as a result of its stay in the model liquid (water, drink Coca-Cola, 5% surfactant) for 30 days at room temperature (about 18–20 ° C).

5 Results

The first step was to investigate the physical and mechanical properties of the obtained biopolymer composite material: impact strength and breaking stress during bending (figure 1). It is well known, filled polymeric materials must have a higher impact strength than homopolymers. Our new materials has shown the same properties - the impact strength for coffee-filled composite (40 wt.% coffee grounds on 60 wt.% PLA) is 2.5 times more than for the sample without coffee grounds. the value of impact strength has tendency to increasing with increasing volume of coffee grounds.

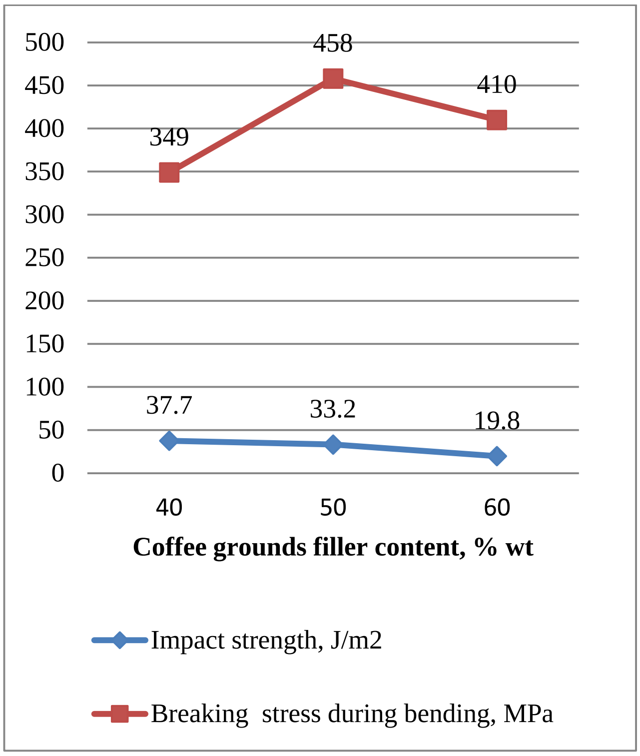

Fig. 1. Physical and mechanical properties of designed composite material based on PLA.

Level of impact strength influence the possibility for forming various products of composite material. As we see, for new composite material impact strength is within the required value [10].

The next step was sorption properties study of new composite material. Note that the samples with the lowest porosity were selected using a microscope, because in the laboratory a significant part of the samples have an uneven surface with large pores and cavities, which will distort the data on water (and any other liquid) absorption [11].

At the first stage of the sorption characteristics study for new composite material, its porosity was determined and the tendency to form pulp bubbles in two types of operating media - water (non-purified drinking water) and 5% surfactant solution (surfactant) was evaluated. It is in these types of media PLA-based dishes with coffee grounds will be immersed during operation (washing dishes, pouring into the dishes of coffee or other beverages) [11].

Table 1 shows the results of the study of compositions based on PLA with different content of coffee grounds on the porosity and tendency to making bubble. Data analysis of table 1 allows to choose as optimal for further operation a composition with a content of coffee grounds 40 wt. %, because it demonstrate the same properties as its original polymer without adding the condensate [11]. The increase in the content of coffee grounds leads to its uneven distribution in the surface layer of the composition and high porosity of the samples.

Table 1. Porosity study of compositions based on PLA with different content of coffee grounds.

№	Coffee grounds contents, wt.%	Porosity of the coating, score, in the environment		Destruction of the surface due to the formation of bubbles, A, in the liquid medium	
		water	5% surfactant solution	water	5% surfactant solution
1	40	1	1	A1,00	A1,00
2	50	2	2	A0,95	A0,93
3	60	3	3	A0,85	A0,79
4	0	1	1	A1,00	A1,00

A necessary and standard characteristic for all polymeric materials, which determines their performance properties, is to determine the diffusion coefficient of the liquid, for which long-term experiments are performed according to the method described in [11]. The samples were immersed in water and periodically measured changes in their mass and geometric shape. The results are shown in table 2.

Table 2. The resistance study results of compositions samples based on PLA with different content of coffee grounds to water at a temperature of 20 ° C.

Cycle		The increase in the mass of the samples by numbers,%			
	coffee grounds contents, wt.%	40	50	60	0
A day later					
- 1		1,35	2,74	3,77	0,01
- 3		1,50	2,75	3,85	0,74
- 7		1,55	2,77	3,95	0,75
-15		1,60	2,78	4,10	0,76
-30		1,65	2,79	4,20	0,77

As can be seen from table 2, the original polymer and composition with a content of 40 wt. % show a small weight gain, which after two months does not exceed 2%. With increasing content of coffee grounds, the increase in the mass of the samples, their water absorption, reaches 5%. But even such indicators are not critical for the manufacture of dishes. However, the composition containing 40 wt. % thick is the most resistant to operating loads [11].

Sorption characteristics study of the compositions to the action of aggressive environments was also performed. An analysis of the market for beverages found in coffee shops alongside natural coffee has clearly identified Coca Cola as the most common. The pH of this drink is 2.5, so it is an acidic environment. Table 3 shows the results of increasing the mass for composition after immersion in Coca Cola.

Table 3. The resistance study results of compositions samples based on PLA with different content of coffee grounds to Coca Cola at a temperature of 20 ° C.

Cycle		**The increase in the mass of the samples by numbers,%**			
	coffee grounds contents, wt.%	**40**	**50**	**60**	**0**
A day later					
- 1		4,0	6,8	5,2	0,22
- 3		10,1	11,3	18,2	1,1
- 7		15,2	20,2	24,4	1,8
-15		28,9	36,5	40,1	2,3
-30		62,5	71,2	82,5	3,0

All samples became very brittle after 30 days, and their surface became porous. The increase in the mass of all samples indicates an easier way for the middle of the samples to penetrate the aggressive medium after three days of exposure [36]. As expected, the original polymer has the lowest weight gain, and among the compositions, such properties are inherent in compositions with a coffee grounds content of 40 wt. %.

Sorption characteristics study of the compositions to the action of water and a temperature of 100 ° C was made. Table 4 shows the results of increasing the mass for composition after immersion in the water.

Table 4. Sorption characteristics study results of the compositions to the action of water and a temperature of 100 ° C.

Cycle		**The increase in the mass of the samples by numbers,%**			
	coffee grounds contents, wt. %	**40**	**50**	**60**	**0**
A day later					
-1		5,2	7,8	10,9	0,35
- 3		5,9	8,5	11,8	0,38
- 7		7,8	9,3	12,5	0,42
-15		15,2	24,3	30,8	0,55

- 40		28,5	42,8	52,1	0,77

The composition, which contains 50 and 60 wt. % of coffee grounds compared to that containing 40 wt. % during 15 days of immersion in boiling water, shows an increase in weight of almost 2% more. This is not critical given this figure, but still should prefer a composition with a lower content of thick.

Sorption characteristics study of the compositions to the action of aggressive media in the form of anionic-type surfactants at a concentration of 5 % and a temperature of 75 ° C was made. Table 5 shows the results of increasing the mass for composition after immersion in the surfactant. As you can see from the results of the study, after 7 days the weight gain is slow and does not exceed the average for all samples with coffee grounds - samples with 40, 50 and 60% coffee grounds waste content of 0.09% per cycle.

Starting from 8 days, the increase in weight can be up to 0.9% per cycle, constantly increasing to 40 days. For the original PLA polymer, there is also an increase in the rate of weight gain starting from 15 days. This behavior of the compositions and the original PLA is due to the ability to biodegrade products from them under the condition of creating a temperature greater than 65 ° C. That is, the results obtained prove, including the actual ability to biodegrade compositions with a thicker based on PLA.

Equilibrium, the end of the water absorption process during the study period was not reached, but the tests are ongoing. The equilibrium state will be characterized by a straight line on the graph or no increase in the mass of the samples. Based on experimental data according to the method described in [11], the diffusion coefficient for the samples was calculated (table 6).

Table 5. Sorption characteristics study results of the compositions to the action of aggressive media (surfactants of the anionic type at a concentration of 5 %) and a temperature of 75 ° C.

Samples number	**PLA content, wt. %**	**coffee grounds contents, wt. %**	**D·1010, sm^2/s**
1	60	40	0,72145
2	50	50	0,81526
3	40	60	0,86998
4	100	0	0,63085

The data in table 4 indicate the hydrophobic nature of the surface of both the source polymer material PLA and compositions based on them [11].

In fig. 2-4 shows surface's photomicrographs of new compositions before and after the sorption characteristics study in different model environments.

As can be seen from Figure 3-5, the smallest changes in the surface can be observed for compositions with a coffee grounds content of 40 wt.%, which, as shown above, have the best sorption characteristics in different model environments.

6 Conclusions

The designed and studied in article polymer composites on the basis of PLA and coffee grounds solve the problems of recycling food industry waste in the form of coffee grounds and expand the possibilities of its rational utilization for agriculture. The use of coffee grounds as a filler for biodegradable polymeric materials can significantly reduce its quantity at landfills and obtain a new material that will be biodegradable. Thus, as a result of the conducted researches the rather high level of sorption resistance of the developed eco-friendly polymer composites on the basis of PLA and coffee grounds is shown. It is founded that the optimal strength characteristics have compositions with a content of coffee grounds waste of 40 wt.%. The study of compositions based on PLA with different content of coffee grounds on the porosity and tendency to making bubble is presented.

https://doi.org/10.1051/e3sconf/202128011001

Sorption characteristics study of eco-friendly polymer composites based on PLA and coffee grounds waste are shown for different liquid media: water, surfactants and Coca-Cola. The obtained dates indicate the hydrophobic nature of the surface of both for PLA and compositions based on them. It is shown that the composition with a content of 40 wt.% is most resistant to operating loads in different model liquid mediums. According to their sorption characteristics, the studied composites can be recommended for the production of reusable tableware and kitchen utensils, food containers and packaging. The study of the developed eco-friendly polymer composites for their main performance indicators in the conditions of field tests looks prospective.

Abstract. Conditions of the planning of open-pit mining objects have been identified, making it possible to reduce the need in the allotted land area during mineral extraction. The research results have allowed proposing a methodological approach to determine economic expediency of the increase in the technogenic land reclamation level under conditions of open-pit mining, being the reserves to expand the technogenic land areas returned to the economic use.

1 General statement of the problem

In Ukraine, level of land reclamation in terms of the land area disturbed by open-pit mining is not more than 50%; the rest of the mining area is excluded from the economic use for decades or even for ever resulting in considerable losses for further land use in a mining region and leaving the unsolved problem of negative environmental impacts of mining activities. First of all, reclamation is topical for those mining areas requiring the lowest costs for their restoration. Due to the fact that a great share of the disturbed lands is not restored, a mining enterprise is to compensate the land owners their losses of land resources that form the grounds for conflicts related to the land allotment for mining purposes. Thus, current topical problem is to search for the possibilities to increase a specific land share to be restored in terms of a general area of mining allotment along with the substantiation of technological solutions to plan mining operations aimed at reducing the disturbed land area while mineral mining.

2 Analysis of recent studies and publications

Scientists, dealing with the problems of the reduction of mining-related environmental impacts, pay considerable attention to the development of ecological and economic criteria of administrative decision-making concerning mining object planning. Implementation of the measures for land reclamation after open-pit mining should favour the mining industry transfer into the sustainable mode. That is the sustainable development of the mining sector which should be determinant for the activities related to the mineral use for national economy [1]. Thus, the development of main mining processes should be in compliance with the measures for the negative mining effects compensation in both environmental and social terms since negligence of the environmental-saving requirements is the reason of sharpening economic and social problems in the mining sector.

Source [2] indicates that mining effects on the environment should be overcome partially by creating investment-attractive technogenic lands and partially by activating the processes of natural self-restoration of the disturbed terrains. Nevertheless, following problem is still unsolved: what share of mining allotment should be covered with the lands to be returned for the economic use. It is obvious that it requires the elaboration of certain criteria to evaluate the expediency of restoration of specific mining objects in terms of the land use purposes.

Litvinov [3] highlights the necessity of such planning of mining objects in terms of which it will be possible to restore as many disturbed land areas as possible. According to the researcher, it is the level of lands under reclamation that should be one of the main criteria to evaluate the efficiency of different technological schemes for deposit mining.

However, a problem, concerning the following, still lacks its solution: evaluation of possibilities to improve the land preservation level in terms of open-pit mining at the expense of both limited shares of disturbed lands for the construction of open-pit mining objects and search for the resources to improve economic attractiveness of

* Corresponding author: ebabets@gmail.com

disturbed land restoration according to the specific land use purposes.

Irrespective of the considerable scientific findings as for improving the efficiency of activities related to the restoration of environmental objects within the mining allotment area, insufficient attention has been paid to the identification of economically expedient reserves for the increase in mining-related land restoration according to the land disturbance. An issue concerning substantiation of technological schemes for planning mining objects in terms of land preservation criteria should be considered more as well.

The research objective is to substantiate theoretically the grounds and develop recommendations concerning the specification of technological trends in providing the limited disturbance of the mining allotment lands as well to assess economically expedient reserves of land reclamation for the areas disturbed while open-pit mining to reduce the land losses in terms of the land disturbance area.

3 Statement of the main research material

Mineral mining is still of high importance for the economic development of industrial countries. The mining sector is a factor for increasing a level of capital investment in tangible assets in all the technologically related industries; it favours overall economic growth of the countries with the developed mining sector [4].

However, planning of mining enterprises requires paying considerable attention to the development of measures to limit the mining impact on the environment. Those negative effects are inevitable; their amount depends on the demand for some specific products offered by the mining sector [5, p. 494].

Along with the economic effects from the deposit development, among other things, a society has environmental damages in the form of disturbed land resources. While accumulating at a certain level, the damages result in the necessary costs for their elimination, and the costs may exceed the effect of the mineral use [6].

Thus, legislation of the majority of mining countries obliges mining enterprises to restore the lands so that they will be of the same state before mining operations [7]. To do that, it is required to determine the factors stipulating the extent of mineral-mining land disturbance and identify the possibilities to implement economically expedient activities for technogenic land restoration.

Horizontal open-pit mining, resulting in more intense land disturbance in reliance on the mass unit of the extracted mineral, is of the highest loss for land resources and for the ecosystem in general. According to [8], constant tendency to open-pit operations is peculiar for current world mining development. There is about 73% of total mineral output extracted by open-pit mining worldwide. In its turn, surface mining development is accompanied by the increasing concentration of production, deepening open pits, and, correspondingly, volumes of the rock mass removal. Open-pit mining is mostly used to extract ore minerals, lignite, rock for construction materials, kaolin, rare earth metals etc. In terms of Ukraine, about 75% of mineral output is extracted by open-pit mining. As for the iron-ore industry, the figure is 85% [9, p. 1]. For instance, Dnipropetrovsk region encloses 100 open pits and mines. Total area of the disturbed land within the region is 27 thousand ha.

Generally, each million tons of the extracted manganese ore result in the disturbance of more than 600 ha of land. In case of iron ore, the figure is 640 ha; coal – up to 43 ha, and non-metallic minerals – up to 580 ha. If the open pit depth is down to 150…200 m, then about 100 ha are to be disturbed totally with the formation of the mined-out space. If the open pit depth is 450 m, more than 250 ha are to be disturbed [10]. To fill that space, about 80 mln m^3 of the overburden rock are required. Analysis of international practice shows that even in terms of the involved cutting-edge technologies, the most efficient land restoration is impossible if there is no economic motivation. In this context, Table 1 represents the balance of mining land use in Rhine lignite basin as of the late 2012.

Table 1. Balance of the land use areas in Rhine lignite basin [11, p. 41]

Area of allotment, ha	Area of restored lands, ha/%	Including the land area restored for agricultural purposes, ha/%	Area of disturbed land, ha
31512, 2	22248.4 / 70.6%	11839.2 / 53.2%	9265.8 / 29.4 %

Land losses in German are mostly tried to be cut by reducing the environmental hazard of land use and by developing environmentally non-exhausting types of land use. However, considerable share of technogenic terrains is still inaccessible for public. To reduce land losses due to mining objects, certain technological solutions should be approved and measures should be taken to create the most favourable conditions for further land reclamation for the lands which disturbance is inevitable right at the stages of open pit planning, stripping operations, and mining operations.

Technological objects, which location required natural land allotment, are demonstrated schematically in Fig. 1. Depending on the mineral type to be mined and the appropriate deposit mining scheme, different land areas are subject to disturbance (Table 2). Thus, it is possible to have certain effect on general land disturbance area in terms of mining allotment at the level of technological solutions as for the mining object planning (e.g. by internal waste dumping as opposite to external waste dumping, transfer of the transportation routes inside the open-pit field etc.).

Thus, while developing a manganese-ore deposit and depending on the occurrence depth of the ore deposit, it is required to have 163…228 ha of natural lands for stripping and dumping. According to the open pit objects, that area is distributed as follows: permanent trench – 3.5…4.5%; transport incline – 8.6…8.4%; working trench – 57.0…56.1%; and construction waste dump – 31.0%. Consequently, the majority of residual mine workings (about 90%) is accounted for the working trench and construction waste dump.

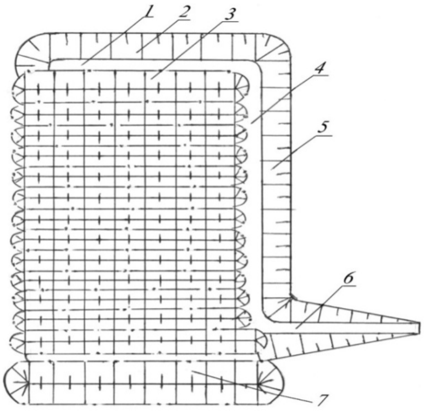

Fig. 1. Schematic of technological structure of open pits while developing a horizontal deposit: 1 – residual mined-out space; 2 – mining flank of an open pit; 3 – internal waste dump; 4 – transport incline; 5 – non-mining flank of an open pit; 6 – permanent trench; 7 – construction waste dump.

Reserves of the land area reduction should be determined by optimizing parameters of land allotment for the open-pit technogenic objects. In their turn, the parameters depend on the geometry of the open-pit field, system of its stripping and mining. Degree of the land resources use is defined by the ratio of the areas of lands being returned and lands being allotted for technological open pit objects during all the deposit mining stages. Such an approach makes it possible to determine the reserves of land resources preservation by reducing the area of land allotment to the scientifically substantiated standards and by increasing the areas of restored sites within each of the mentioned technological objects.

Losses of land resources $\Pi_з$ due to the open pit objects are the target function of the parameters $S_{нi}$, S_{pi}, $S_н$, being formed during all the stages of deposit development. In general, the function may be represented as follows:

$$\Pi_з = f\,(B, L, \Phi, \Gamma, \Pi, T, C, P) \qquad \min \quad (1)$$

where B, L, Φ is width, length, and shape of the open-pit field respectively; Γ is mining and geological conditions of the ore deposit occurrence; Π is technological parameters of the formation of an open-pit working zone; T is technical facilities for production processes; C is stripping and mining system for the deposit; and P is topography of the mining allotment area.

Table 2. Distribution of the land allotment area in terms of technogenic objects of a manganese open pit [12]

Open pit depth, m	Area of the permanent trench on top, ha	Area of the transport incline on top, ha	Area of the working trench on top, ha	Construction waste dump			Total allotment area, ha
				height, m	base width, m	waste dump area, ha	
50	5.6/3.4*	14.1/8.6	93.0/57.0	73	253	50.6/31.0	163.3
60	7.8/4.0	16.6/8.5	110.5/56.4	88	304	61.0/31.0	195.9
70	10.3/4.5	19.1/8.4	127.9/56.1	101.7	352	70.5/30.9	227.8

Note: numerator – total area of the mining allotment, ha; denominator – share in % within the total allotment area.

Identification of the land preservation reserves should rely on the development of mining technologies, rational selection of the striping and dumping parameters. It means that nowadays reserves of the reduction of land resource losses are connected first of all with reaching the parameters of open-pit technological objects. Development of current technologies and mining systems for certain deposits should be oriented to the rejection of a fixed transport incline along with the search for possibilities to form mostly internal waste dumps.

Basing on the expression (1), reserves for reducing losses of land resources are connected with the parameters of technological objects of a mining enterprise. Thus, the objects are to be designed taking into consideration their location on the earth's surface. In general, rational land use parameters are stipulated by certain ratio between the parameters of operating objects and their elements as well as other objects in the context of mining and concentration complex, when the lowest land capacity $З_e$ and the highest reclamation coefficient K_p are reached.

According to the rates of ore bed mining, the internal waste dumps are restored and returned for their further use; here, there are no technological problems. There are other solutions in case of using the residual mine workings and construction mine dump. They can be filled and reclaimed mostly when the deposit is mined out; that is due to a great volume of labour-intense and costly operations. The operating mining and concentration complexes use land resources at the level of theoretical land capacity. As for reclamation of the mined-out land, it is performed within the considerably smaller areas comparing to the potential ones; that is due to the necessity of significant costs for overburden removal for filling the working trench.

To specify the main parameters of technological objects to mine horizontal deposits that stipulate the losses of allotted land areas, the report data of mining and engineering reclamation of lands within the manganese open pits of Pokrovskyi mining and concentration complex (PGZK) have been analyzed. Effect of the area of open-pit field $S_{в.о}$, area of the residual mine workings $S_в$, coefficient of reclamation $K_р$, and land capacity $З_е$ upon the land losses $\Pi_з$ has been considered. The mentioned parameters have been taken into account in terms of each open pit and on average in terms of the complex (Table 3). Following equation of regression is obtained for the statistic data represented in Table 3:

$$\Pi_з = 26.4 + 0.0008\, S_к - 0.0026\, S_в - 33.8\, K_p + 0.21\, З_e, \text{ ha/mln t of ore.} \qquad (2)$$

Table 3. Land use in terms of open-pit fields of Pokrovskyi GZK.

Open pit	*S_к*, ha	*S_{в.о}*, Ha	*S_в*, ha	*K_p*, ha/ha	*З_е*, ha/mln t of ore	*П_з*, ha/mln t of ore
Alexandrovsky	904	735	169	0,81	44,10	8,25
Bogdanovsky	1335	765	570	0,57	27,53	11,76
Zaporizhzhya	1320	800	520	0,61	30,7	12,10
Shevchenkovsky	1637	1263	374	0,77	29,02	6,62
Pivnichnyi	1510	1050	460	0,70	31,92	9,47
Chkalovskyi-1	1182	771	411	0,65	34,36	11,96
Chkalovskyi -2	1796	976	820	0,54	30,13	13,77
Pokrovskyi	700	556	144	0,79	21,67	4,46
Average of PGZK	1298	864	433	0,68	31,18	9,80

The equation does not contain $S_{в.о}$; it shows that there is no connection between land loss and area of internal waste dumps. Such a conclusion can be explained by the fact that the internal waste dumps are formed throughout the whole open pit area, and its effect on the land loss is considered with the help of parameter $S_к$. Adequacy of each of equation regressors (2) has been defined with the help of Student statistic t. During the comparison with table values t = 3.18 for the number of degree of freedom n = 3, regressor $S_в$ has the lowest adequacy. It means that the area of residual mine workings has minor effect on the loss value $П_з$ in the mining allotment, and this parameter may be also excluded from the regression model. Thus, we obtain the equation:

$$П_з=26.4+0.0008S_к-33.8K_p+0.21З_е, \text{ ha/mln t of ore.} \quad (3)$$

If statistic value is t = 2.78, all the regressors of equation (3) are significant, and the resulting feature $П_з$ is closely connected with the factor features $S_к$, $K_р$, and $З_е$ (R^2 = 0.98), which, according to Fisher's ratio test, represent adequately their influence on the result (F = 61.1).

Thus, it can be concluded that the value of the land losses in terms of open-pit mining is stipulated first of all by the open-pit field area, coefficient of reclamation, and land capacity of the mining operations. Consequently, it is possible to reduce overall level of land losses for mining enterprises by increasing the level of land reclamation in terms of the area of land disturbance, by the development of mining technology towards the reduced external dumping, and by the creation of more favourable conditions to restore technogenic lands.

It is necessary to spend different sum of money for the reclamation of mining objects; correspondingly, that causes unequal motivation to the formation of certain-purpose lands within the territory of a specific mining object. Table 4 show classification of the open-pit mining objects according to the economic expediency of their reclamation for economic purposes.

Table 4. Classification of the open-pit mining objects according to economic expediency of their restoration for economic purposes

Object	Ratio in the mining allotment area, %	Location of the object	Characteristics*
Internal waste dumps	38...40	Surfaces of the internal waste dumps	The lands are subject to mining and engineering as well as biological reclamation
Construction waste dump	30.5...31.5	Surfaces of the external waste dumps	
		Surfaces of the washery refuse storage	
		Surfaces of the slopes of external waste dumps	The lands are irretrievably lost for agriculture
Transport incline on top	8...9	Sites for transportation communications (automobile and railway roads, electric networks)	The lands are subject to reclamations upon the condition that the mentioned objects are liquidated
Working trench on top	16...17	Surface of the residual working trench	The lands are not subject to reclamation for agricultural purposes
Permanent trench	3...4.5	Surfaces of the external transport (permanent) trenches	The lands can be restored in case of economic expediency by using fertile soil from other open pits

Note*: made up involving the data from source [13].

Thus, there are the surfaces of external waste dump slopes and partially the surfaces of external transport (permanent) trenches which are the territories being often left without any reclamation. However, expediency of land restoration should be determined by the ratio of costs for land reclamation according to certain economic purpose and market monetary estimation of the reclaimed lands, being represented by the following expression:

$$К_{ei} = \frac{Ц_{зi}}{В_{Гi}+В_{Рi}+В_{Бi}+В_{к.я}+В_{рем.i}}, \quad (4)$$

where $К_{ei}$ is coefficient of efficiency of costs for land reclamation in terms of ith reclamation purpose; $Ц_{зi}$ is market monetary estimation of a unit of the restored land in terms of ith reclamation purpose; $В_{Гi}$, $В_{Рi}$, $В_{бi}$ are losses for mining and engineering as well as biological reclamation and maintenance within the land area in terms of ith reclamation purpose respectively; $B_{к.я}$ is payment for the deteriorated quality of the land reclaimed in terms of ith reclamation purpose; and $B_{рем.i}$ is costs for repair operations due to land restoration.

The highest value $К_{ei}$ will stimulate for more complete restoration of the technogenically disturbed lands. However, if the degree of land surface disturbance requires growing costs for reclamation (first of all, for agricultural purposes), that will reduce motivation to reclaim corresponding mining objects. As a result, technogenic lands are of nonuniform structure, being the combination of reclaimed sites and the sites left without any reclamation due to their more serious disturbance. Generally, land reclamation for agricultural purposes is the most costly one, and market value of those lands in Ukraine is reduced (Fig. 2).

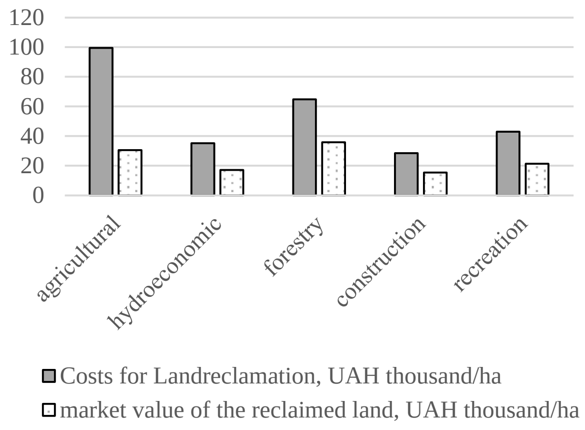

Fig. 2. Ratio of costs for reclamation and standard monetary estimates of technogenic lands in terms of land use purpose.

Market value of the land is defined by actual state of supply and demand for the land; it is specified upon consultation between the sales parties. At the same time, liquidation of different technological mining-related objects will require different costs per unit of the reclaimed area. From the viewpoint of cost cutting, a mining enterprise is interested in reclamation of nothing but the sites where the highest coefficient of efficiency of reclamation costs will be obtained. Only the changing land purpose will make it possible to consider the sites being unattractive for agricultural-purpose reclamation as the ones which reclamation may provide the appropriate degree of efficiency. Thus, depending on the land reclamation purpose, economically expedient reserves of land restoration throughout the disturbance area will experience certain changes (Table 5).

The lowest costs for land reclamation are meant for hydroeconomic and forestry purposes; in their case, the requirements concerning soil quality and land topography relative to technogenic terrains are not so strict. For instance, a depression in the land surface, being the result of mineral extraction, may be fit for a reservoir as that depression favours the accumulation of water resources. Combination of hydroeconomic and forestry purposes for land reclamation makes it possible to restore practically all area of mining allotment.

Correspondingly, combination of different land use types will help replace the purposes of land reclamation with one another, if some purpose turns to be inexpedient; thus, there will be possible to use land reclamation reserves to the maximum. The most disturbed sites should be allotted for natural process of self-restoration with the preliminary measures for their chemical purification. In the context of reclaimed lands, it is possible to use 10…15% of the mining area for that purpose. At the same time, land reclamation for the forestry purposes will make it possible to activate soil-forming processes and favour the preservation of nutrients in the soil thickness.

Land reclamation performed timely and properly will be the basis for further land use for the post-industrial purposes. However, it is more important to have such planning of mining operations which will allow reducing the need of a mining enterprise in the involvement of land resources in mineral mining. That will be possible owing to the selection of proper technological schemes of stripping, mining, and cleaning-up of an open-pit field from the viewpoint of total area of land disturbance by a mining enterprise.

Table 5. Economically expedient reserves of land reclamation in terms of open-pit mining.

Reclamation purpose	**Economically expedient reserves of land reclamation**	**Mining objects to be reclaimed**
Agricultural	60…70% of the disturbed area	Internal and construction waste dumps
Forestry	78...80% of the disturbed area	Internal and construction waste dumps, transport incline and permanent trenches on top
Construction	70…80% of the disturbed area	Internal and construction waste dumps, transport incline on top
Hydroeconomic	30% of the disturbed area	Working and permanent trenches, transport incline
Sanitary	60% of the disturbed area	Internal waste dumps, working trench, and transport incline on top
Recreation	90 % of the disturbed area	Internal and construction waste dumps, working and permanent trenches, transport incline
Succession	100% of the disturbed area	Internal waste dumps, construction waste dump, transport incline on top, working trench on top, permanent trench

Basing on the results of the carried out research [2], certain technological solutions to mine the PGZK operating open pits have been proposed. While analyzing land resources from the viewpoint of market conditions of the mining enterprise economy, following parameters are proposed to assess the efficiency of the technological solutions:

1) Economic expediency of land preservation that characterizes a level of value conservation (monetary value) of natural lands:

$$E_{з.с} = \frac{100 \cdot Ц_р \left(1 - П_{з.р}\right)}{Ц_{пр}}, \%, \qquad (5)$$

where $Ц_р$, $Ц_{пр}$ is monetary value of the reclaimed and natural (undisturbed) lands respectively, UAH/ha; and $П_{з.р}$ is losses of land resources in terms of the area, a unit share;

$$П_{з.р} = \frac{\left(1 - К_р\right) \cdot Б_{пр}}{Б_р}, \text{ unit share;} \qquad (6)$$

where $Б_{пр}$,$Б_р$ is bonitet (quality) of the natural and reclaimed lands respectively, %; and $К_р$ is coefficient of reclamation (a unit share);

2) Economic expediency of land reclamation as a payback parameter for the reclamation costs:

$$Е_р = \frac{100 \cdot Цр \cdot \left(Б_р\right) \cdot К_р}{В_р}, \%, \qquad (7)$$

where $Ц_р$ $(Б_р)$ is monetary estimation of the reclaimed lands according to their bonitet, UAH/ha; and $В_р$ is reclamation prime cost of the disturbed lands, UAH/ha;

Along with the use of those parameters, Table 6 represents technological approaches aimed at reduction of natural land areas being used and at the creation of favourable conditions for mining and engineering reclamation as well as increase in the land areas returned to the national economy. Firstly, that objective was reached by considering the possibility to locate stripping mine workings in the middle of an open-pit field; secondly, it was reached by changing the procedure of advance of the working front of stripping, extracting, and dumping benches along with the location of the stripping mine workings relative to one another.

Table 6. Conditions of the use of technological schemes while mining horizontal deposits.

Technological approach	**Conditions of the technological scheme application**	**Land-preservation efficiency**
Filling the gap between the edge of the working trench and slope of the external waste dump	Stage of open pit construction; depth of mineral seam occurrence is 10 … 40 m; seam thickness is compared to the stripping thickness. High-capacity transportation and dumping facilities.	The mining allotment area for construction waste dump is reduced by 12.8 ha; reclamation costs are cut by UAH 1034 thousand.
Using internal permanent trenches	Stage of construction; ramps are located along the working trench length. Open pit depth is down to 100 m. Low-capacity transportation means for cyclic mining operations.	The mining allotment area for open pit construction is reduced by 20 … 25 ha; that results in the compensation payments cut by UAH 4000 thousand.
Basing on changes in the procedure of open-pit field mining: - combining the mined-out space with the transport incline *- reclamation of mine workings in terms of the external transport incline* *- combination and reclamation of the residual mined-out space in terms of the external transport incline*	Stages of construction and operation. Mining of two adjacent open pit fields or one field by blocks. Stripping thickness is not more than 50 m. High-capacity transportation and dumping facilities. At all the operation stages. Mining of two adjacent open pit fields or one field by blocks. Open pit depth is 50 … 70 m. Stripping shovels – draglines, motor transport for mineral blocks. Construction and operation stages. Open pit depth is 50 … 70 m. Cyclic mining and transportation facilities.	Surface of the residual mine workings decreases by 45 … 103 ha. Costs to compensate agricultural losses are reduced by UAH 67200 ... 94200. Complete filling of the residual mine workings. Land disturbance decreases by 112 … 147 ha, costs to compensate agricultural losses are reduced by UAH 10048 thousand Land disturbance decreases by 112 … 157 ha. Costs to compensate agricultural losses are UAH 67.2 ... 94.2 thousand, costs for mining and technical reclamation are cut by UAH 7168 ... 10048 thousand. Economic efficiency of reclamation grows from 10.6% up to 13.1%.
Basing on the division of an open-pit field into two blocks (sites)	Stage of clearing-up. Depth of the open pit is 40 ... 60 m. Length of the working trench is 1.5 ... 2 km. Reduced open-pit mineral output. High-capacity transportation and dumping facilities.	The surface area of the residual mined-out space for reclamation experiences two-fold increase. In terms of Chkalovskyi open pit, the surface increases by 159.2 ha.

Thus, preservation of land resources is connected with the dimensions of stripping workings and waste dumps, places of their locations as well as the direction of front advancing of mining operations within the open-pit field. Consequently, selection of certain mining system determines the cutting method and limits the number of technologically possible and economically expedient technological systems of deposit mining.

3 Conclusions and prospects of the research development

1. Planning of the open-pit mining objects should involve the implementation of those technological schemes which make it possible to avoid additional land disturbance and preserve the planned output according to the demand for

mineral. It has been specified that it is the selected mining system and technological scheme of stripping operations (i.e. parameters of permanent, transport, and working trenches) of the open-pit field which are of essential effect on the amount of disturbed lands of mining allotment. According to that fact, technological approaches have been proposed concerning the change in parameters of technological objects within the open-pit field aimed at reduction of the disturbed land area.

2. A criterion has been offered to identify economic expediency of land reclamation in terms of economic purposes. It has been determined that economic expediency of the disturbed land reclamation will depend on the degree of land surface disturbance within the mining allotment and purpose of its restoration. Economically expedient reserves of technogenic land reclamation in terms of open-pit mining should be specified by the most favourable ratio between the expected market value of the reclaimed lands and total costs for their reclamation disturbed by open-pit mining, basing on the classification of technogenic mining objects as for their suitability for reclamation at the economically attractive level.

3. There is the following prospective issue for further research in terms of the outlined problem: quantitative estimation of the amounts of value losses reduction for land resources resulting from the implementation of technological schemes of deposit mining in the context of land preservation.

Abstract. The article presents the results of large-scale studies of the content and distribution of natural and man-made radionuclides in the sediments of the rivers flowing into the Dnieper-Bug estuary. The article also presents the results of the granulometric analysis of the surveyed water bodies. The data about natural radioactive elements in the sediments rivers flowing into the Dnieper-Bug estuary obtained in this research are demonstrated moderate specific activity, which, however, clearly correlates with the granulometric composition of sediments. The ^{137}Cs determined by us is contained in the sediments of all studied water bodies and the places of it greatest concentration coincide with the areas in which the sediment is represented mainly by the pelitic fraction. The data obtained in this research can serve as a baseline data in natural radionuclides concentration in sediments rivers flowing into the Dnieper-Bug estuary. The obtained data can also be used for further monitoring of the specific activity of man-made radionuclides, in particular ^{137}Cs.

1 Introduction

Aquatic ecosystems play an important role in the migration of both natural and artificial radionuclides, as well as in their redistribution. On the one hand, they play the role of transport arteries for migration radionuclides within the reservoir and adjacent ecosystems, on the other hand, they are natural barriers to the deposition of a certain amount of radionuclides [1].

The barrier role of hydroecosystems is determined by the nature of the reservoir, the quality and intensity of the processes that take place in it. The main ones are the volume and depth of the water column, the flow rate, biological productivity, the composition of sediments, the intensity of sedimentation, the presence of geochemical barriers, as well as the amount of biomass and species composition of aquatic organisms. Equally important for the value of the barrier function of aquatic ecosystems are the physicochemical and biogeochemical properties, the mobility of the radionuclides themselves, the intensity of their sorption and accumulation by the abiogenic and biogenic components of aquatic ecosystems [2].

Bottom sediments of reservoirs and watercourses, to a large extent, fulfill the mission of depositing substances entering the water from catchment areas during coastal erosion and runoff from adjacent areas. Thus, composition of sediments reflects the ecological state of rivers and their catchment areas. Natural radionuclides in bottom sediments reflect the geochemical features of the region. Man-made radionuclides, which include ^{137}Cs and ^{90}Sr, are of artificial origin, the pollution by them is carried out mainly by air way, to a lesser extent, waterways.

The relevance of the presented studies is determined by the decision to build the E-40 channel [3, 4]. The E-40 waterway is a transnational initiative aiming to link the Baltic and Black Seas by an approximately 2,000 km long navigable connection running from Gdansk in Poland to Kherson in Ukraine. This proposes that the route would go through the river systems of Vistula, Bug, Pina, Pripyat and Dnieper. Several parts of planned route would need to be straightened, dammed, dredged, or drained.

Analysis of radioactivity in Polesia has been carried out by experts from «Association pour le Contrôle de la Radioactivité dans l'Ouest» (ACRO) [4, 5]. More than 35 years after Chernobyl accident, residual radioactive contamination is such that people are prohibited to live in an extensive exclusion zone. At the present time, contamination is dominated by cesium-137, strontium-90 and various isotopes of the highly toxic plutonium. Cesium-137 binds to clay sediments (pelitic fraction), while strontium-90 is more mobile.

The whole Pripyat-Dnieper watershed was contaminated by nuclear fallout. Dominating contaminants are cesium-137 and strontium-90. First one has tend to be fixed in bottom sediments, unlike second is continuously transported down to the Black Sea through the Dnieper cascade. Sediments contaminated by cesium-137 have been slowly covered by less contaminated and clean sediments, offering a natural shield to this pollutant. The International Atomic Energy Agency (IAEA)

* Corresponding author: Alohkina@gmail.com

recommends leaving these sediments in place and avoiding processes that will lead to their resuspension.

Downstream of the Chernobyl exclusion zone, the Dnieper river serves as a water source for approximately 8 million Ukrainians and its waters are used to irrigate crops consumed by as many as 20 million people.

The section of the E-40 waterway running from the Kiev reservoir to the Black Sea would require regular dredging work. However, the feasibility study on the proposed E-40 waterway failed to consider some of the major dangers posed by radiation. Experts provided an initial evaluation of the impact of the construction and maintenance of the E40 waterway on the distribution of radioactive material. Among other things, they point to, that E-40 waterway risks disturbing several radiation hotspots. International Atomic Energy Agency recommends leaving contaminated sediment undisturbed [4, 5].

Thus, ***the aim of our researches*** were determination of specific radioactivity and distribution of natural and man-made radionuclides in modern sediments of the rivers flowing into the Dnieper-Bug estuary. The data obtained in this study may serve as a baseline data of radionuclide concentration in modern sediments of the researched rivers and water reservoirs.

2 Literature review

Determination of specific radioactivity and total β-activity of sediments allows to establish the intensity of anthropogenic impact, identify areas with high content of natural or man-made radionuclides, monitor the level of contamination of areas - i.e. is a widely used method of environmental research.

River sediment depositions on the bottom of rivers most frequently consist of sand and gravel particles with different grain sizes, which make them particularly valuable for the building construction. Knowledge of radioactivity present in building material enables one to assess any possible radiological hazard to mankind by the use of such materials. In the review [6], the natural radionuclide (^{238}U, ^{232}Th and ^{40}K) contents have been analyzed for the sediment samples of Ponnaiyar River. In the presented study, the dose rate was calculated, as well as the mineralogical characteristics of the sediment were investigated. The results obtained in the study suggest that the level of natural radioactivity of the present sediments mainly depends upon the amount of kaolinite (clay). Mineral characterization of various grain sized sediments show clay and magnetic minerals are rich in lower grain sized ($\leq$120 μm) samples.

The effect of sediment grain size, mineralogy, composition of the acid-extractable materials on the distribution of ^{7}Be, ^{10}Be, ^{137}Cs, and unsupported ^{210}Pb in detrital sediment samples collected from rivers in China and the United States were examined by authors in the presented research [7]. Acid-extractable materials (made up predominately of Fe, Mn, Al, and Ca from secondary minerals and grain coatings produced during pedogenesis) are positively related to the abundance of fallout radionuclides in sediment samples. Grain-size dependency of fallout radionuclide concentrations was significant in detrital sediment samples. Authors conclude that time-dependent geochemical, pedogenic, and sedimentary processes together result in the observed differences in nuclide distribution between different grain sizes and substrate compositions. These findings likely explain variability of measured nuclide activities in river networks as well as spatial and temporal differences in erosion rates and processes.

Discharges from the Krasnoyarsk Mining and Chemical Industrial Complex near Krasnoyarsk resulted in radioactive contamination of sediments of the River Yenisei. Between 1999 and 2006, 16 sediment cores were collected at different positions 15-1500 km downstream from the discharge point. Contamination levels of artificial radionuclides were decreasing with increasing distance downstream the Krasnoyarsk Mining and Chemical Industrial Complex: the fastest decrease of average activity by a factor of 10 over a distance of 300 km was observed for ^{241}Am, whereas for ^{137}Cs this decrease occurred over a distance of 1100 km. Sequential extraction experiments revealed that in all depths and at all distances the studied radionuclides were tightly bound to the sediment [8].

The results of a radioecological study of six small rivers located in the impact zone of the Beloyarsk Nuclear Power Plant (BNPP) and the cooling reservoir of the BNPP are presented [9]. The activity of 21 radionuclides was determined, as well as the total α- and β-activity in the main components of aquatic ecosystems. It is shown that after the decommissioning of blocks I and II of the BNPP, the content of ^{137}Cs in water, bottom sediments, ichthyofauna and macrophytes of the Beloyarsk reservoir decreased by tens and hundreds of times. The fundamental significance of this phenomena lies in the fact that in a large time range two mechanisms work: self-purification of the aquatic ecosystem from radionuclides due to the decay of radioactive substances and mechanism of redistribution of radionuclides from water to other components, primarily into bottom sediments.

The report [10] is devoted to the study of the activity of the natural radionuclides ^{40}K, ^{232}Th, ^{226}Ra and technogenic ^{137}Cs radionuclide in the river sediments of watercourses around the Lomonosov diamond deposit (northwestern Russia). Samples of river sediments and surface waters were taken from the Zolotitsa River and its tributaries in the area of the diamond deposit. The average activity of ^{137}Cs, ^{226}Ra, ^{232}Th and ^{40}K were 5,4; 9,0; 11,2; 318.8 Bq/kg, respectively. Several patterns of radionuclide accumulation have been found depending on the physicochemical parameters of river sediments. These patterns are due to the technogenic influence of the mining and beneficiation complex. The performed studies present the evaluation of the impact of diamond mining on natural radionuclides' distribution and accumulation in the river sediments within the adjacent territories.

The report on the concentrations of radionuclides ^{40}K, ^{137}Cs ^{232}Th and ^{226}Ra in river sediments along the Arvand river of Iran for future environmental monitoring was shown. Sediments were collected from 20 sites. The mean concentration activity for ^{40}K, ^{137}Cs ^{232}Th and ^{226}Ra, were

280,91; 5,96; 16,47 and 16,10 Bq/kg dry weight, respectively. The values of radiation hazard parameters were comparable to the world averages and below the recommended values. The data obtained in this study will serve as a baseline data in natural radionuclide concentration in sediments along the Arvand river [11].

In the paper [12] authors present distribution of natural gamma-active nuclides (^{40}K), elements of uranium ^{238}U rows (^{214}Pb, ^{214}Bi, ^{226}Ra), elements of thorium ^{232}Th rows (^{212}Pb, ^{212}Bi, ^{228}Ac, ^{208}Tl), and technogenic ^{137}Cs in the bottom sediments of the small rivers of the National natural park «Zacharovannij kraj». It is shown that content of these elements in the bottom sediments is relatively stable and can be examined as base-line, it is proportional to the siltation level of the small rivers and largely depends on their morphology. Total specific activity of natural gamma-active nuclides (without taking into account ^{40}K) in the bottom sedimentations is within of 126-184 Bq/kg. Averaged data of heavy metals content and specific activity of radionuclides in the bottom sediments of the small rivers are used for mapping of this protected territory and for the prediction of migration. Also these data apply for identification of the investigated areas of the rivers taking into account the geochemical features of the region.

The Rhone River is one of the most nuclearized river in the world. Radionuclide concentrations in water and suspended sediments transferred to the marine environment were intensively monitored in this river over the last decades (2002–2018). While >60% of plutonium, americium, cesium, cobalt, silver, beryllium and actinium radioisotopes are carried by sedimentary particles, sodium, tritium, antimony and strontium are mainly exported as dissolved species (>90%) due to their low affinity with particles. The concentrations of numerous anthropogenic radionuclides originating from nuclear industries significantly have declined since the beginning of the 2000s were shown [13]. If no change of the current anthropogenic and climatic pressures, the time required for a reduction by half the concentrations in the downstream part of the Rhône River, would be close to 6 years for most artificial radionuclides. The exception is for tritium and other artificial radionuclides conveyed to the river by soil leaching and erosion (^{90}Sr, ^{241}Am, plutonium isotopes), their half-life would be far longer.

Vertical profiles of environmental radionuclides (^{210}Pb, ^{137}Cs, ^{238}U, ^{232}Th, ^{226}Ra and ^{40}K) in a sediment core (Y1) of the Yellow River Estuary wetland were investigated to assess whether environmental evolutions in the coastal wetland could be recorded by the distributions of radionuclides. Based on ^{210}Pb and ^{137}Cs dating, the average sedimentation rate of core Y1 was estimated to be 1.0 cm y^{-1}. Vertical distributions of natural radionuclides (^{238}U, ^{232}Th, ^{226}Ra and ^{40}K) changed dramatically, reflecting great changes in sediment input. Concentrations of ^{238}U, ^{232}Th, ^{226}Ra and ^{40}K all had significant positive relationships with organic matter and clay content, but their distributions were determined by different factors. Environmental changes such as river channel migrations and sediment discharge variations could always cause changes in the concentrations of radionuclides. Frequent seawater intrusion decreased the concentration of ^{226}Ra significantly. The value of ^{238}U/^{226}Ra tended to be higher when the sedimentation rate was low and tide intrusion was frequent. In summary, environmental evolutions in the estuary coastal wetland could be recorded by the vertical profiles of natural radionuclides [14].

Thus, it can be noted that the determination of the specific activity of natural and man-made radionuclides in sediments is used to solve various scientific and applied problems.

A study which determined the activity concentration of ^{137}Cs in sediments contaminated by effluents from the Chernobyl accident which had collected along the coast of the Eastern Black Sea region in Turkey was carried out in 1993. Marine sediment samples were collected in 2015 from the same fifteen sampling points, and the activity concentrations of ^{226}Ra, ^{232}Th, ^{40}K and ^{137}Cs were determined for the sediment samples. The activity concentrations ranged from 10,94–25,95, 12,14–33,05, 265,74–459,89 and 2,08–37,45 Bq/kg for ^{226}Ra, ^{232}Th, ^{40}K and ^{137}Cs respectively. The results showed that there was a steep decline in ^{137}Cs within the sediment at most of the sampling sites from the Eastern Black Sea region during the 22-year period [15].

A recent study along the northern Black Sea coast with combined using of artificial (^{137}Cs, $^{238,239+240,241}$Pu, ^{241}Am) and naturally occurring (^{210}Pb/^{226}Ra, ^{40}K) radionuclides as tracers for dating has allowed to reveal in sediment increase radioactive contamination of this basin with 137Cs after the Chernobyl accident. This is presumably caused by the prolonged input of the man-made radionuclides that showed a rise in the late 1990s – early 2000s, and by a possible post-deposition remobilization of ^{137}Cs from the seabed [16].

Radiation contamination sediments of the rivers flowing into the Dnieper-Bug estuary occurred due to aerosol falls on the water area, as well as a result of partial removal of radionuclides by the Dnieper and Southern Bug and due to leakage from polluted watersheds. Thus, according to the National Report on the state of man-made and natural safety in Ukraine [17], the radiation status of water bodies in the Dnieper basin in 2016, as in other years after the Chernobyl accident, was determined mainly by man-made radionuclides.

The main route for the entry of radionuclides into the Kyiv Reservoir with subsequent migration along the Dnieper River is the waters of the Pripyat River. Along the length of the Dnieper cascade of reservoirs due to the processes of sedimentation and dilution of the Dnieper water with cleaner waters of the side tributaries, the content of radionuclides decreases. In the water of the Kakhovka Reservoir near the town of Nova Kakhovka, the average concentration of ^{90}Sr in 2016 was 21 Bq/m^3, which is 4,2 times less than in the water of the Pripyat River. The average concentration of ^{137}Cs was 0,72 Bq/m^3, which is 47 times less than in Pripyat water. In the Dnieper-Bug estuary near the town of Ochakiv, the average ^{90}Sr content per year was 10,4 Bq/m^3, and ^{137}Cs – 4,8 Bq/m^3. The average concentration of ^{90}Sr in the water of the Southern Bug near Mykolayiv was 6,7 Bq/m^3, ^{137}Cs – 2,7 Bq/m^3.

 https://doi.org/10.1051/e3sconf/202128011003

As a result of sedimentation of water-suspended particles, radionuclides migrating from the Pripyat River along the Dnieper are deposited and accumulate in sediments. Thus, the research presented below reflects the content of radionuclides in the sediments of the lower reaches of the rivers of the Dnieper-Bug estuary basin.

3 Objects and methods

Large-scale studies of modern sediments lower reaches of the Dnieper and the Southern Bug, as well as their lower tributaries − Inhulets and Inhul, respectively, have been carried out. The sediments of the Dnieper-Bug estuary and two reservoirs also were studied: Karachunivsky reservoir on the Inhulets River and Sofiyivsky reservoir on the Inhul River. The choice of the researched area was due to large anthropogenic pressure on hydroecosystems, owing to the location of significant industrial and agricultural capacities in this region (Figure 1).

The sampling points were located along profiles that crossed the investigation objects. The Dnieper river research area was the lower reaches, below the Kakhovka hydroelectric station; 36 samples were selected. The research area of the Southern Bug was from 143 km above the delta (below the Voznesensk city) and before falling into the Dnieper-Bug estuary; 30 samples were selected. The Inhulets River and the Inhul River both were surveyed from the top to the mouth; 52 and 48 samples were selected, respectively. In the Karachunivsky reservoir 3 profiles were laid and 35 samples were selected; 3 profiles were laid and 29 samples were selected in the Sofiyivsky reservoir. Samples of sediments from the Dnieper-Bug estuary were selected along its perimeter in the section of the coast and Kinburn Peninsula with Kinburn Spit; 32 samples were selected. Overall analyzed 262 samples of sediments.

Samples of sediments were taken with the special cylindrical equipment. Samples with intact structure were taken by soil tube, samples along the shores were taken by drilling. The thickness of the sediment layer selected for analysis was 0,1-0,35 m. The selected samples after drying were subjected to averaging at the points of selection.

The determination of granulometric composition of bottom sediments was carried out on the basis of standard technique by a sieve method. The particle size distribution is the main indicator of the type of bottom sediments, which characterizes the influence of hydrodynamic processes on the structural framework of the samples.

After sieving with the laundering, 12 fractions were allocated, which in the process of analyzing the data were grouped into 4 fractions: psephite, psammite, silts and pelity.

The specific activity of natural (^{238}U, ^{235}U and ^{232}Th, as well as ^{40}K) and artificial (^{137}Cs) γ-emitters was determined by means of a gamma-ray spectroscopy system SEG-50 with Ge (Li) detector DGDK-110. Spectroscopy measurements were carried out in the geometry of a "Marinelli conteiner" with a volume of 1 dm^3, which provided the maximum sensitivity of the analysis. The specific activity of ^{90}Sr was determined by means a selective β-radiometer RUB-91. The total β-activity of bottom sediment samples was determined using a UMF-1500M device (in thin layers with a SBT-13 counter). Since the research required a large amount of starting material, data on specific radioactivity were not obtained for some of the research sites.

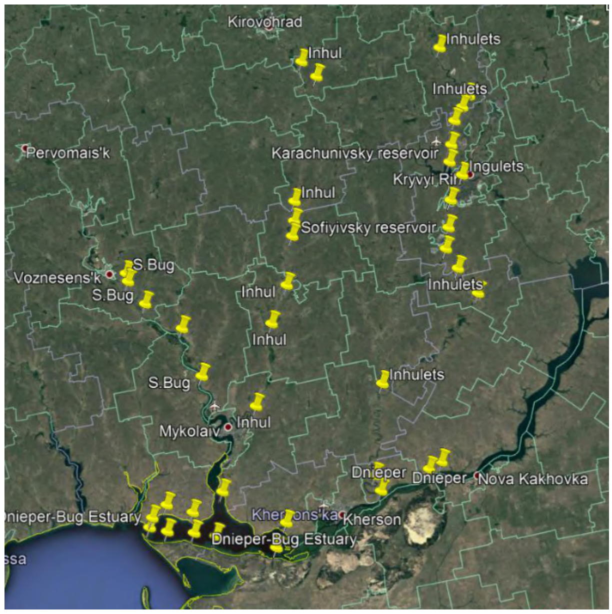

Fig. 1. The research area.

4 Results and analysis

The Southern Bug River is the largest river, the basin of which is completely located on the territory of Ukraine. The Southern Bug River originates in the Podillia Upland, then flows along the Black Sea lowlands and flows into the Black Sea, forming the Dnieper-Bug estuary with the Dnieper. A feature of the Southern Bug is the almost complete absence of significant tributaries. The Southern Bug River in the lower reaches has a wide channel and minor meanders. The research area is located in the Bug-Dnieper region of the Black Sea lowland of the Black Sea southern steppe province. On this section of the river 3 transverse profiles were laid. The sediments of the selected samples are dominated by pelity fraction (Figure 2).

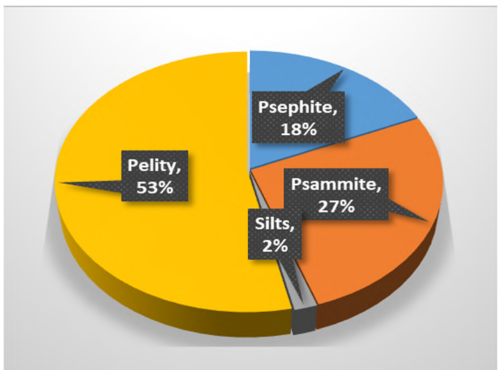

Fig. 2. Granulometric composition of the Southern Buh River sediments.

 https://doi.org/10.1051/e3sconf/202128011003

The generalized results of determining the specific radioactivity of sediments (by individual radionuclides) of the lower reaches of the Southern Bug River are presented on the diagrams (figures 6-11). The specific activity of natural radioactive elements in sediments of the Southern Bug River occupies an intermediate position between the Dnieper River and the Inhulets and Inhul Rivers. Whereas the content of artificial strontium-137 in the Southern Bug River is the lowest among all surveyed objects. The total β-activity and isotopic ratios of radionuclides of the sediment samples are presented in table 1.

Table 1. Total β-activity (Bq · kg^{-1}c^{-1}) and isotopic ratios radionuclides of the sediment samples.

Object of study	The researched indicators, M±m				
	Σ_β	^{238}U / ^{226}Ra	^{232}Th / ^{238}U	^{212}Pb / ^{214}Pb	^{40}K / ^{238}U
The Southern Bug	38,0±5,0	4,3±1,0	0,5±0,1	2,3±0,5	4,6±0,9
The Inhul River	45,0±6,5	2,9±0,5	0,4±0,1	-	3,7±0,7
The Sofiyivsky reservoir	50,5±7,0	3,6±0,8	0,4±0,1	1,6±0,3	3,3±0,7
The Dnieper River	27,5±5,0	1,6±0,6	0,8±0,2	0,9±0,3	18,2±5,1
The Inhulets River	40,0±7,0	3,6±1,1	0,4±0,1	1,4±0,3	4,3±0,9
The Karachuniv-sky reservoir	51,2±8,0	4,8±1,7	0,3±0,1	1,3±0,3	2,1±0,4
The Dnieper-Bug Estuary	47,8±5,2	3,1±0,9	0,6±0,1	1,5±0,3	6,2±2,5

The Inhul River is the largest left tributary of the Southern Bug, which originates on the southern slope of the Ukrainian Shield. The Inhul River flows into the Bug estuary within the city of Mykolaiv. The territory through which the Inhul River flows belongs to the Dnieper and Kirovohrad metallogenic provinces, within which a considerable number of uranium deposits and manifestations are concentrated [18]. During the works, three sections of the river were investigated. The first of the researched areas, approximately 12 km long, was located at a distance of 80 km from the source of the Inhul River, i.e. in the upper reaches. This river section is characterized by a narrow channel with numerous rapids and a fairly fast flow, despite the over-regulation. Upstream the first researched area, on the southern outskirts of Kropyvnytskyi (earlier Kirovohrad), there are dumps of uranium mine of the Michurinsk deposit [19]. The second river section, about 15 km long (in the middle course of the river), is characterized by an expanded watercourse, slower flow, no rapids. The third, the longest studied area (in the lower reaches of the river) is located outside the Ukrainian Shield. The Sofiyivsky Reservoir, which is built on the Inhul River, was studied separately. The sediments of the first and second sections of Inhul River are represented mainly by psammite, which are replaced by pelity sediments within the Sofiyivsky Reservoir. Pelity fraction of sediments also dominates in the mouth of the Inhul River.

The share of large fractions naturally decreases from the top to the mouth and, accordingly, the share of fine fractions increases. Although on some profiles of the third section are deviations from this pattern, probably due to the features of the relief. The results of determining the particle size distribution of the Inhul River sediments and the Sofiyivsky Reservoir are shown in the Figure 3.

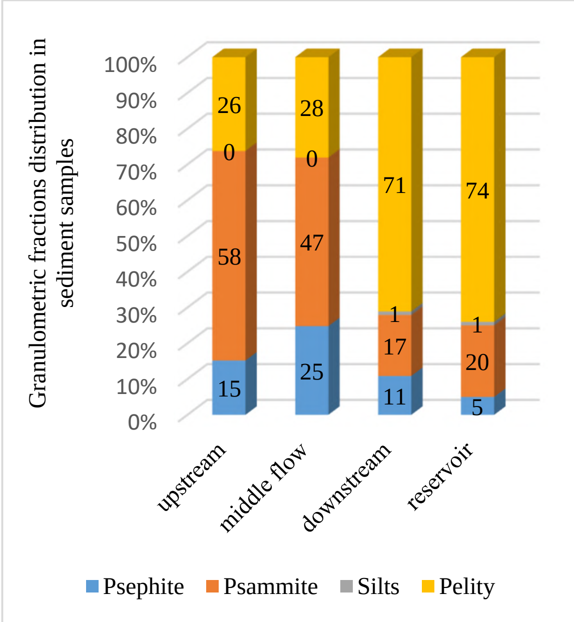

Fig. 3. Granulometric composition of the Inhul River and the Sofiyivsky reservoir sediments.

The results of determining the radionuclides content in the sediments samples of the Inhul River researched areas are presented in table 2.

Table 2. Specific radioactivity of the Inhul River sediments, Bq/kg dry matter.

Nuclide	Upstream		Middle flow		Downstream	
	Min* / max	M	Min / max	M	Min / max	M
^{238}U	61 / 107	79,0	87 / 150	117,0	47 / 182	107,0
^{226}Ra	47 / 53	50,0	24 / 40	29,0	23 / 34	27,5
^{232}Th	29 / 35	31,7	34 / 78	54,0	33 / 96	46,0
^{235}U	5,1 / 6,6	5,6	2,3 / 5,4	3,1	1,8 / 5,0	3,5
^{40}K	191 / 355	285,0	402 / 528	423,0	345 / 475	420,0
^{137}Cs	2,5 / 4,4	3,4	1,7 / 6,0	3,7	0,8 / 4,1	2,5

*the numerator of the pseudo-fraction is the minimum values of the indicator, the denominator is the maximum

Specific activity of ^{238}U in the sediments gradually increases along the Inhul river flow, as is shown by the results. Similarly, ^{232}Th is distributed, while the content of ^{226}Ra decreases almost twice along the river flow. Other radionuclides demonstrate a multidirectional nature of distribution in the bottom sediment.

The Sofiyivsky Reservoir was built on the Inhul River in the Novobuzhsky District of the Mykolaiv Region in 1968. The channel type reservoir is the largest in volume and closes a cascade of reservoirs on the Inhul River. The

 https://doi.org/10.1051/e3sconf/202128011003

reservoir is used for drinking water supply. The Sofiyivsky Reservoir sediments are presented by the pelity fraction, the latter is characterized by adsorbing properties, including adsorption of radionuclides (see Figure 6-11).

The Dnieper River is a typical plain river with a slow and calm flow. A powerful anthropogenic offensive significantly changed the configuration of the banks of the Dnieper in the twentieth century. In a large section, this river has turned from clear watercourse with fast stream into a polluted lake-type reservoir, which is gradually but relentlessly silt up (Figure 4). Regulation of the Dnieper River runoff by a cascade of reservoirs has significantly changed the conditions of functioning of the lower river ecosystem.

The spring flood became less expressed, but the unstable runoff regime due to the uneven operation of the Kakhovka hydroelectric power station during the day acquired ecological significance. As a result, even in the main watercourse of the lower reaches of the Dnieper River there are short-term fluctuations in water levels. The negative changes were shown by researches of the ecosystem of the lower Dnieper River in recent years [20, 21]. Eutrophication of watercourse, siltation, overgrowing with aquatic vegetation are determined.

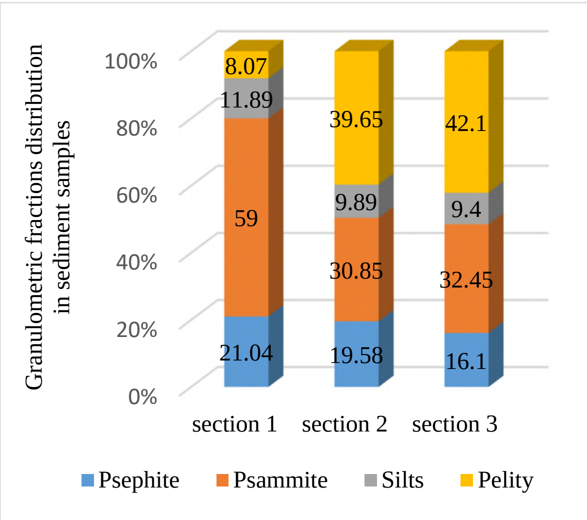

Fig. 4. Granulometric composition of the Dnieper River sediments.

The data of the performed radiological analysis of the Dnieper River are presented in figure 6-11. It should be noted that the profiles were laid down by us were below the entire cascade of Dnieper reservoirs, which in total retain more than 96% of all terrigenous runoff of the Dnieper. That is why, in our opinion, the specific activity in the bottom sediments of the research section of Dnieper River is the lowest among all the studied objects.

The highest concentrations of ^{137}Cs, most likely of Chernobyl origin, however, as well as concentrations of ^{238}U and ^{226}Ra tend to the right less flowing bank of the Dnieper. The equilibrium state in a chain of uranium is characterized by some lack of ^{226}Ra. However, given the rather high measurement errors of extremely inactive samples, it can be assumed that these nuclides are in equilibrium. The greatest variability is shown by the ratio $^{40}K/^{238}U$, which is explained by the diversity of the lithological composition of the studied samples. After all, practically "clean" quartz sands border on sandy loams, dark-colored sands, shells, etc. Total β-radioactivity and isotopic ratios of samples of bottom sediments of the Dnieper River; lower right tributary − the Inhulets River and Karachunivsky reservoir are presented in table 1.

The Inhulets River is a lower right tributary of the Dnieper River, originating on the southern slope of the Ukrainian Shield. Analysis of previous researches [22] allowed to conditionally divide the river valley by zones with different ratio of natural and man-made components in the sediments, which in turn is due to different degrees of anthropogenic presser.

The first zone is the upper reaches of the river, where it flows through metamorphic and ultrametamorphic rocks of the Ukrainian Shield. This area is represented mainly by agricultural areas. The second zone of the Inhulets River is located parallel to the elongated in the meridional direction of the Kryvyi Rih iron ore basin. In this area, the Inhulets River basin is exposed to strong man-made impact from numerous mining and processing enterprises. In the second zone, the Inhulets River receives a tributary − the Zhovta River, which drains the dumps of mines and tailings of hydrometallurgical production of Zhovti Vody [21]. Also in this area is a powerful mining complex of the Kryvyi Rih. The third zone is located below the Kryvyi Rih. The Inhulets River here is characterized by a plain slow-moving current.

The granulometric composition distribution of the researched areas sediments reflects changes in the hydrodynamic regime of the Inhulets River. In the area of the reservoir is a change in the hydrodynamic regime from lotic to lentic, which is recognised in more than 75% of the pelitic fraction of the sediment (Figure 5).

The minimum and medium particle size recorded for the upper and lower reaches of the river, where the content of man-made material in the sediments is low. Psammite fraction in sediments dominates in the second zone, which is due to the man-made impact of mining and processing enterprises. Our previous studies [22] have determined that this is caused by the presence of a man-made component (tails of ore benefication) in the sediments.

When interpreting the results of radiological analysis of the sediments of the Inhulets River, it should be taken into account that the basin of this river is located within the uranium-bearing province of the south of the Ukrainian Shield. Radiological analysis was performed for bottom sediments of the second (middle flow) and third (downstream) zones [23]. The results of radionuclide content study in samples of the Inhulets River sediments are presented in Table 3. Data analysis shows that the specific activity of all natural radionuclides is higher in the second zone, except for ^{238}U.

The results of gamma-spectrometric studies of the Inhulets River sediments demonstrate significant variability in the specific activity of natural radioactive elements. As for technogenic radionuclides in the samples, ^{137}Cs was determined in the second technogenic zone of Inhulets River and Karachunivsky reservoir.

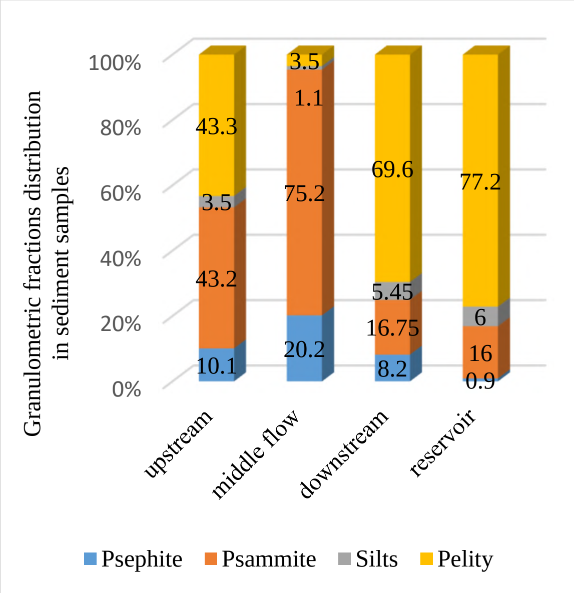

Fig. 5. Granulometric composition of the Inhulets River and Karachunivsky reservoir sediments.

Table 3. Specific radioactivity of the Inhulets River and Karachunivsky reservoir sediments, Bq/kg dry matter.

Nuclide	Average value of specific activity, M±m		
	Middle flow (second zone)	**Down-stream (third zone)**	**Karachunivsky reservoir**
^{238}U	58,0±22,0	68,0±10,1	129,0±15,2
^{226}Ra	19,1±2,2	16,0±2,2	27,0±3,1
^{232}Th	28,0±3,2	21,0±2,1	37,4±3,9
^{235}U	1,7±0,4	1,4±0,4	3,4±0,8
^{214}Pb	19,2±11,8	16,3±8,1	15,0±9,0
^{214}Bi	21,3±10,5	17,0±10,4	14,0±12,0
^{228}Ac	30,1±17,8	21,3±9,2	19,0±11,0
^{212}Pb	28,0±9,9	21,0±12,0	20,0±9,7
^{212}Bi	46,4±17,2	24,1±15,4	*bml
^{40}K	297,5±37,0	241,0±31,7	268,5±14,0
^{137}Cs	4,6±0,7	*bml	42,5±9,2

*bml – below the measurement limit

The Karachunivsky reservoir is the closing reservoir in the cascade on the Inhulets River and due to its largest volume serves as the main regulator of river flow. The reservoir is used for drinking water supply, as well as irrigation of adjacent lands. Construction of the Karachunivsky reservoir on the Inhulets River began in 1932 and commissioned in 1939. It is located in the zone of influence of technogenic factors of the mining complex of Kryvyi Rih. During 1950-1958 years, the reservoir received its modern shape. The reservoir is very silted up. Thus, the age of sediments of the most stagnant part reservoir exceeds 50 years. In the studied samples, the uranium content usually significantly exceeded the radium content. It is known that the mobility of the latter in the zone of hypergenesis is somewhat limited, except for environments with low pH values.

The specific activity of ^{137}Cs of Chernobyl origin varies widely. Since caesium-137 migrates mainly in the form of a suspension (adsorbed on clay pelitic particles), its accumulation sites in bottom sediments coincide with stagnant zones, where the flow is minimal and suspended particles fall out of the water. The specific activity of ^{137}Cs in the Karachunivsky reservoir exceeds similar values in other researched rivers on an average in ten times (Figure 11). Also, ^{90}Sr of Chernobyl genesis was determined in single samples of precipitation from the Karachunivsky reservoir. In contrast, natural ^{226}Ra is somewhat chemically similar to calcium and strontium. It is known that molluscs build their shells from calcium compounds and are also able to capture strontium and radium from solutions of compounds. Thus, radium-226 can be eliminated from the solution and bound in the shell material. Compounds of uranium and thorium are not usually used by living organisms to build a skeleton. The accumulation of the above-mentioned elements in biogenic sediments is mostly associated with later stages of lithogenesis and occurs due to purely chemical processes.

The Dnieper-Bug estuary is the largest estuary of the north-western Black Sea coast and at the same time it`s a complex natural open type hydroecosystem. In the estuary, as in the water area with limited water exchange, changes occur in hydrological, hydrochemical and hydrobiological conditions of sedimentation from river to sea, the effect of the geochemical barrier is enhanced. The estuary is a place of intensive transformation of sedimentary material in the form of suspended matter, the main source of which is terrigenous runoff. The most of the suspended matter is retained at the stage of mixing river and sea water and enters the sediment. Subsequent transformation of sedimentary material takes place on the river-sea geochemical barrier. Sedimentation substances in open estuaries have different origins. First of all, these are the products of river runoff, abrasions of shores and seabed, the development of bios in the estuaries themselves, as well as substances brought by seawater. The most common type of sediments in the Dnieper-Bug estuary is siltstone silt with a medium degree of sorting, which essentially constitutes the lithological background of bottom sediments. Demolition of this material occurs mainly due to the Dnieper and the Southern Bug [24, 25].

The granulometric composition of the bottom sediments of the Dnieper-Bug estuary is heterogeneous. Samples taken along the Kinburn Peninsula and Kinburn Spit are represented by homogeneous well-sorted quartz sand, which does not contain clay impurities and is 98% composed of psammites. Samples from the section of coast are represented by different particle size classes. So, psammites dominate in the samples taken on the shelf and pelites predominate in the samples taken on the shore. The latter are composed of fine clay particles. This fact is probably the result of constant transgression of the sea. The samples from the profile that crosses the mouth of the Southern Bug are exceptions. In these samples, psammites predominate in the granulometric composition distribution.

The results of determination of radionuclides in the bottom sediments of the Dnieper-Bug estuary are shown in table 4. Distribution of radionuclides in the sediments depending on the particle size was clearly demonstrated in the presented results.

Table 4. Specific radioactivity of the Dnieper-Bug estuary sediments, Bq/kg dry matter.

Nuclide	The researched district	
	Section of the coast	Kinburn Spit and Kinburn Peninsula
	M±m	M±m
^{238}U	69,6±30,5	21,9±7,1
^{226}Ra	22,4±4,2	11,1±2,1
^{234}Th	55,6±10,5	28,2±7,3
^{235}U	1,7±0,5	0,6±0,2
^{214}Pb	18,2±2,8	15,1±3,1
^{214}Bi	17,5±2,0	14,4±1,5
^{228}Ac	28,1±3,1	16,5±1,5
^{212}Pb	27,7±3,0	15,5±1,7
^{212}Bi	32,6±6,7	18,8±6,1
^{208}Tl	11,1±1,5	6,4±0,7
^{40}K	350,0±29,0	214,0±20,5
^{137}Cs	2,0±0,5	0,5±0,2

Thus, the specific activity of ^{238}U from the section of coast samples on an average in three times more than from Kinburn Spit samples. ^{234}Th in the "continental" samples is slightly higher than in the samples from the spit (on an average in two times). In general, the content in the sediments samples of the Dnieper-Bug estuary ^{228}Ac is stable and relatively low. As for ^{235}U and its decay products, it content in the researched samples is quite insignificant, although it varies in a wide range from 0,18 to 2,83 Bq/kg.

Relatively low concentration of ^{137}Cs of Chernobyl origin was determined, in the studied samples of sediments, although the specific activity of this nuclide varies widely – the fluctuations were about 15 times. Due to the predominance of psammitic fraction in bottom sediment samples, this may lead to low concentrations of ^{137}Cs.

Determination of total β-activity showed a range of variations from 16,5 to 96,0 Bq · kg^{-1}c^{-1}. The difference between the samples taken from the water and on the shore is about 2 times.

5 Discussion

The origin of sediments is essential in interpreting the results of γ-spectrometric measurements. The state of equilibrium in the natural decay chains of uranium and thorium depends on how certain deposits were formed – by mechanical precipitation of the suspension or by chemical or biochemical precipitation of the solution. If such an equilibrium exists, the specific activities of all members of the radioactive chain are equal to each other, and vice versa, when deposits are formed by chemical accumulation of aqueous solutions of radionuclides different in chemical properties – age equilibrium cannot exist in principle. Given the significantly different yields of gamma quanta on the decay of a radionuclide, the sensitivity of their determination by the γ-spectrometric method varies in a very wide range. Under the same measurement conditions, the daughter products ^{226}Ra are determined with the highest sensitivity: ^{214}Pb and ^{214}Bi; ^{137}Cs; subsidiaries ^{232}Th: ^{212}Pb, ^{228}Ac, ^{212}Bi and ^{40}K. Much worse conditions for determining the nearest uranium decay products: ^{234}Th and ^{234m}Pa. However, at high concentrations of this element in the studied samples, the use of ^{234m}Pa is quite appropriate and justified, because this nuclide is almost always in equilibrium with the parent ^{238}U.

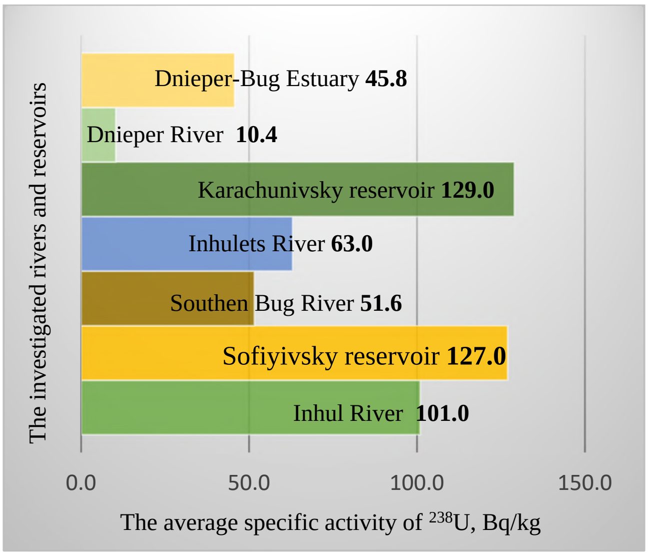

Fig. 6. The averaged values of ^{238}U specific activity in the samples of sediments.

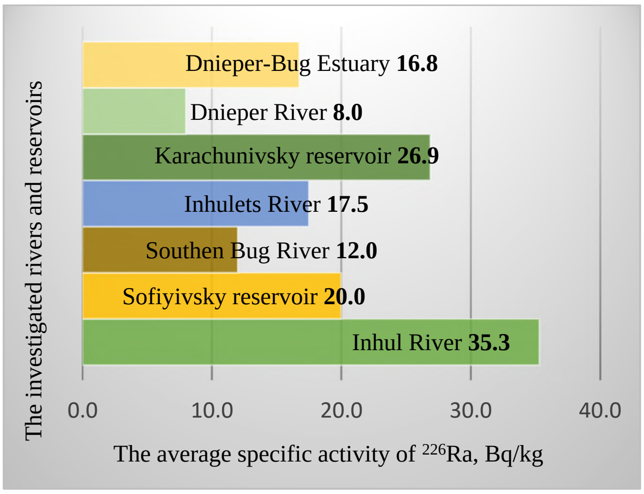

Fig. 7. The averaged values of ^{226}Ra specific activity in the samples of sediments.

The mobility and bioavailability of radionuclides of accidental origin in the terrestrial and aquatic environment are governed by their chemical forms in fallout and site-specific environmental characteristics. The latter determine rates of leaching, fixation-remobilisation, as well as sorption-desorption of the mobile fraction (its solid-liquid distribution). After deposition on the surface of water bodies, radionuclides are subject to physicochemical and biological processes, which leads to changes in their speciation. Dissolved radionuclide is adsorbed on the solid phase by ion exchange. Exchangeable radiocaesium transforms into the fixed form [26].

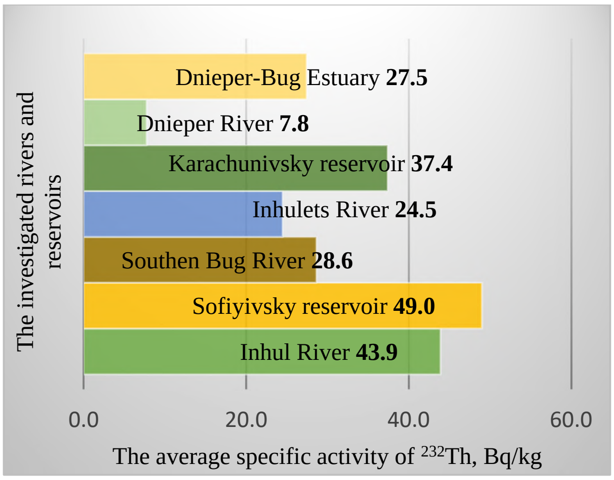

Fig. 8. The averaged values of ^{232} Th specific activity in the samples of sediments.

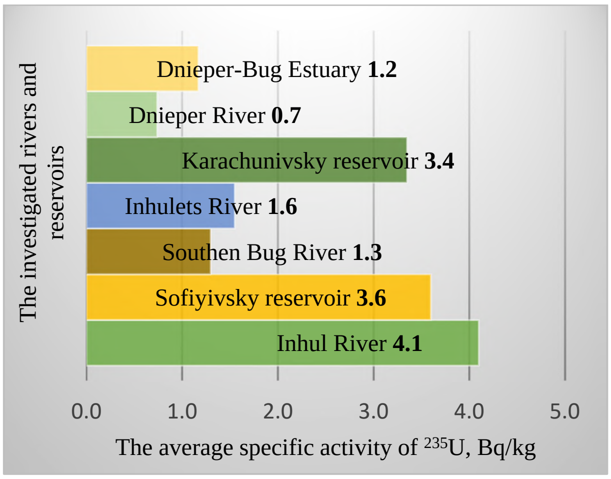

Fig. 9. The averaged values of ^{235}U specific activity in the samples of sediments.

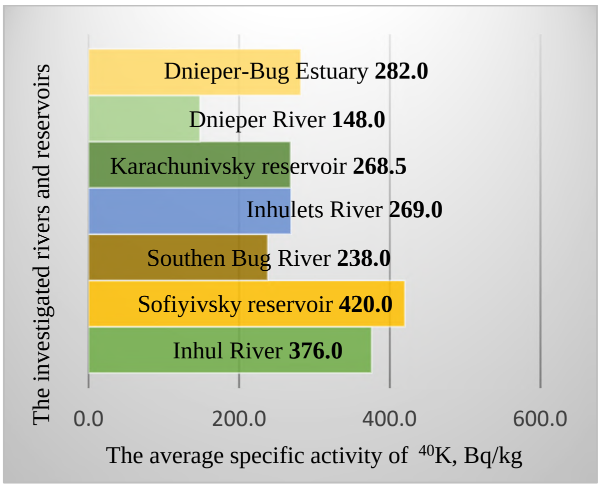

Fig. 10. The averaged values of ^{40}K specific activity in the samples of sediments.

It is now well established that the high retention of radiocaesium in soil and bottom sediments is largely determined by two different processes: fixation and reversible selective sorption. Fixation describes the ‘‘permanent’’ (or at least long-term) replacement of interlattice K- by Cs-ions due to collapse of expanded edges of mineral's crystal lattice interlayers.

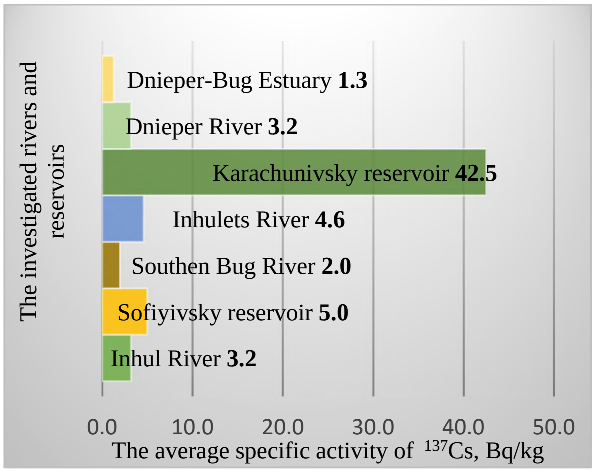

Fig. 11. The averaged values of ^{137}Cs specific activity in the samples of sediments.

The data for long-term transformation of chemical forms of radionuclides in soil and sediment in the long-term after the Chernobyl accident indicate the existence of a remobilization process that is the reverse of fixation [27]. After deposition of radiocesium the fraction of its exchangeable form does not decrease to zero, as should happen during irreversible fixation, in theory. Radiocesium decreases to a certain level, independent of the amount of radionuclide applied, and then does not change significantly because of an equilibrium steady state between fixated and remobilized fractions [28].

6 Conclusions

1. The data obtained in this research can serve as a baseline data in natural radionuclides concentration in sediments rivers flowing into the Dnieper-Bug estuary. The obtained data can also be used for further monitoring of the specific activity of man-made radionuclides, in particular ^{137}Cs.

2. The data shows a significant variation in grain size and at the same time make it possible to identify a tendency to increase pelitic fraction in sediments. According to this indicator can arrange rivers in the following row: Dnieper < Southern Bug < Inhulets < Inhul. However, despite the tendency to silting, in general, natural facial distribution of sediment has preserved, except are areas within a border of large industrial cities (e.g. Inhulets within Kryvyi Rih).

3. The presence of natural radioactive elements in river sediments is due to geological, hydrological and chemical factors. Purposeful sampling into undisturbed sections near the dam of reservoirs makes it possible to reconstruct the history of the formation of radioactive contamination of bottom sediments and, accordingly, catchment areas.

4. In general, data about natural radioactive elements in the sediments rivers flowing Dnieper-Bug estuary

obtained in this research demonstrates moderate specific activity. Which, however, clearly correlates with the granulometric composition of bottom sediments.

5. The radiocaesium of Chernobyl origin determined by us is contained in the sediments of all studied water bodies. The places of its greatest concentration coincide with the stagnant areas of reservoirs, in which the sediment is represented mainly by the pelitic fraction.

6. The section of the E-40 waterway, which plans to construct from the Kiev reservoir to the Black Sea will require regular dredging work. Sediments contaminated by cesium-137 of Chernobyl origin have been slowly covered by less contaminated and clean sediments, offering a natural shield to this man-made pollutant. The International Atomic Energy Agency (IAEA) recommends leaving these sediments in place and avoiding processes that will lead to their resuspension and entrance into water.

Abstract. Environmental management emerged as a consequence of an unprecedented strain on the Earth by humans. Each our activity leaves a trail, such as pollutions of air and soil, contamination of water, deforestation, and also tons of wastes. We are confronting environmental problems that are more taxing than ever before. Now we have everyday changes of the climate which is why there is an urgent need to find ways of life that is less damaging to the Earth. Waste management is a particular specialization of the environmental management which studies how to achieve a zero-waste life. The difference between the situation with waste in Ukraine compared to other developed countries is the large volume of waste generation and the lack of infrastructure for waste management. At the same time, the availability of such infrastructure is an essential feature of all economies of developed countries. Also, it is showed to increase of the amount of illegal and uncontrolled landfills and to degrade of the condition of existing dumps. This paper is aimed to explain how the Ukrainian government could educate people about problems of wastes and encourage us to change our habits.

1 Introduction

By adopting the concept of sustainable development, Ukraine has agreed that economic growth and sustainable development require an urgent reduction in environmental impact through changes in the production and consumption of resources and goods [1]. Effective management of natural resources, as well as methods of utilization of waste and pollutants are important tasks to achieve this goal. Furthermore, the modern individual behaviors of the discarding of waste are often deeply rooted in habits of the population [2]. Therefore, encouraging consumers, businesses, industries, countries to reduce waste and their rational utilization should be a priority of every government program. Separate researches propose to modify the current waste management process based as on active participation of citizens and considering the local people and expert's viewpoints [3], as on people who spend time on volunteer activities are also likely to spend time on waste management efforts [4]. An intervention is needed to bring stakeholders together to solve these waste challenges [5].

In this way, following modern studies [6, 7, 8, 9] systematic environmental management including waste management is required. This is especially true given that there are an accumulation of waste in both the industrial and domestic sectors, which has a negative impact on the environment and human health; improper disposal and removal of hazardous waste; disposal of household waste without taking into account possible dangerous consequences; inadequate level of waste use as a secondary raw material due to imperfect organizational and economic principles of their involvement in production; inefficiency of implemented economic instruments in the field of waste management in Ukraine.

Besides awareness of the consequence of waste management practices to the environment is limited as many are not conscious of the connection between waste management and the environment [10].

Researching waste management issues in Ukraine, the situation of closing the Lviv landfill should be considered in detail. Waste from Lviv and some settlements of the region was stored at the Hrybovytsia landfill, which has been operating since 1957, occupies more than 33 $\times 10^4$ m^2, and is the third largest in Europe and one of the largest polluters in the Lviv region.

In 2003, the chief state sanitary doctor of the Lviv region issued a resolution to terminate the operation of the landfill for the city of Lviv. In following years, there were repeated instructions to stop the operation of the landfill, but they were ignored by the city authorities and challenged in courts, as a result of which the landfill continued to accept waste. According to the resolution of decommissioning since 2006 landfill ran illegally.

Despite the landfill ban, in 2006, a few months after being elected mayor, Andriy Sadovyi said the landfill was almost full, but asked the Hrybovychi community to agree

* Corresponding author: alla.iarova@knu.edu.ua

to continue operating the landfill for next five years, after which he promised to close it. Instead, promises to solve waste recycling problems were not fulfilled for next 10 years, and some work was directly sabotaged or banned by Andriy Sadovyi and his team. Thus, in 2007, the city authorities banned degassing of landfills - primary measures for its reclamation and closure.

In May 2016, after the fire was extinguished, rescuers who were investigating causes of the fire were killed at the landfill due to a landslide with waste. In November 2016, a court ordered the Lviv authorities to close the Hrybovytsia landfill. As of June 2017, monthly volumes of waste have accumulated in some areas of the city. In total in the city - about 9×10^3 tons of waste.

Hence, goal of the research is a development at the government level organizational measures for effective waste management in Ukraine.

2 Presentation of the main materials of the research

The situation with waste management in Ukraine is a rather difficult. Because it is at an initial stage, there are only legislatively approved norms and regulations. Thus, it is proposed to utilize the practice of the European union.

Table 1. Hierarchy of waste management in European union.

Position in the hierarchy	Waste management	
	action	essence
1	Prevention	promote and support sustainable production and consumption models;
		encourage the design, manufacturing and use of products that are resource-efficient, durable, reparable, re-usable and upgradable;
		target products containing critical raw materials to prevent that those materials become waste;
		encourage the re-use of products and the setting up of systems promoting repair and re-use activities;
		encourage the availability of spare parts, instruction manuals, technical information, or other instruments, equipment or software enabling the repair and re-use of products without compromising their quality and safety;
		reduce waste generation in processes related to industrial production, extraction of minerals, manufacturing, construction and demolition, taking into account best available techniques;
		reduce the generation of food waste in primary production, in processing and manufacturing, in retail and other distribution of food, in restaurants and food services as well as in households;
		encourage food donation and other redistribution for human consumption, prioritizing human use over animal feed and the reprocessing into non-food products;
		promote the reduction of the content of hazardous substances in materials and products;
		reduce the generation of waste, in particular waste that is not suitable for preparing for re-use or recycling;
		identify products that are the main sources of littering, notably in natural and marine environments, and take appropriate measures to prevent and reduce litter from such products;
		prevent and significantly reduce marine pollution of all kinds;
		develop and support information campaigns to raise awareness about waste prevention and littering.
2	Preparing for re-use and recycling	promote preparing for re-use activities, notably by encouraging the establishment of and support for preparing for re-use and repair networks, by facilitating, where compatible with proper waste management, their access to waste held by collection schemes or facilities that can be prepared for re-use, and by promoting the use of economic instruments, procurement criteria, quantitative objectives or other measures;
		promote high-quality recycling;
		set up separate collection of waste: for paper, metal, plastic, glass and textiles from households and possibly from other origins;
		promote selective demolition in order to enable removal and safe handling of hazardous substances and facilitate re-use and high-quality recycling by selective removal of materials, and to ensure the establishment of sorting systems for construction and demolition waste for wood, mineral fractions (concrete, bricks, tiles and ceramics, stones), metal, glass, plastic and plaster;
		consider the setting of preparing for re-use and recycling targets for construction and demolition waste and its material-specific fractions, textile waste, commercial waste, non-hazardous industrial waste and other waste streams, as well as preparing for re-use targets for municipal waste and recycling targets for municipal bio-waste.
3	Recovery	ensure that waste undergoes preparing for re-use, recycling or other recovery operations;
		collecting certain types of waste together does not affect their potential to undergo preparing for re-use, recycling or other recovery operations because separate collection does not deliver the best environmental outcome when considering the overall environmental impacts of the management of the relevant waste streams.
4	Disposal	ensure that, where recovery is not undertaken, waste undergoes safe disposal operations;
		regulating disposal operations, including through possible restrictions, and to consider a disposal reduction target, to ensure environmentally sound waste management.

By definition of the European Union in the Directive 2008/98/EC on waste "waste management means the collection, transport, recovery and disposal of waste, including the supervision of such operations and the after-care of disposal sites, and including actions taken as a dealer or broker" [11]. That is, waste management (or waste disposal) include activities and actions required to manage waste from its inception to its final disposal [12].

This Directive proposes the following waste management hierarchy which reflected a priority order in waste prevention and a measure of the safety of waste management's results which are shown in Table 1 [11].

There is the National Strategy of Waste Management in Ukraine until 2030. And all of these actions exist there but just formal. Accordingly, the practice of waste management is needed to improve by the side of the government. Firstly, it will be the organization of waste management, precise in households.

In Ukraine, according to the Ministry of Regional Development, about 10 million tons of waste are dumped annually, of which only 600000 are recycled or burned. The rest is buried in landfills, of which, according to official data, there are more than 6000 in Ukraine. They occupy 9000 $\times 10^4$ m^2; another 1000 $\times 10^4$ m^2 are unauthorized landfills.

In order to assess the state of waste management in Ukraine, we use the following types of information (from official statistic resource of Ukraine):

1. Expenditures on environmental protection by type of economic activity in 2019 (shown in Fig. 1).
2. Waste generation and management from 2010 to 2018 (shown in Fig. 2)
3. Expenditures on environmental protection by types of environmental measures in 2019 (shown in Fig. 3).

Consideration of Ukraine's expenditures on environmental protection by types of economics activity can give us enough answers about how much Ukraine spends on each of them and what type of activity takes the biggest percentage of the expenditures.

It should also be noted that the analysis of expenditures on environmental protection by type of environmental measures shows us which types of measures are the most sponsored. From which we can draw conclusions about the rationality of such expenditures for environmental protection by types of environmental measures.

However, we must remember that expenditures management is an important and one of the most difficult issues in country's waste management activities. The level and dynamics of environmental expenditures depend on country's profits or losses and the level of efficiency of waste management.

The analysis of such information allows us to assess the effectiveness of waste management and expenditures on environmental protection in modern Ukraine. In addition, the analysis of waste generation and management can show us do we rationally manage our waste and how much Ukraine forms, utilizes, burns and deletes to special places or objects all types of waste.

The pie chart shows expenditures on environmental protection by type of economic activity in 2019. In 2019 the number of expenditures on environmental protection was up to 43735862,1$\times 10^3$ hryvnias. The largest percentage was the cost of processing industry, that is 26,701%. Water supply; sewerage, waste management take the second place in the pie chart by percentage of expenditures on environmental protection at the level of 22,173% that is not very higher then percentages of supply of electricity, gas, steam and air conditioning and mining and quarrying which have following percentages.

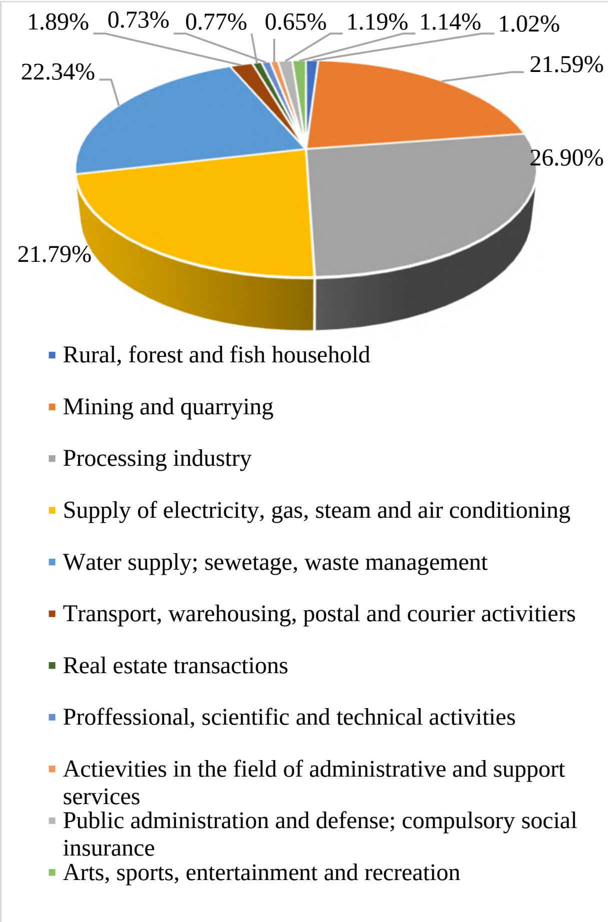

Fig. 1. Expenditures on environmental protection by type of economic activity in Ukraine in 2019.

According to the letter from the Ministry of Ecology and Natural Resources "Regarding specially designated places or objects for waste disposal", we determine that special places or objects - places or objects (waste disposal sites, storage facilities, landfills, complexes, structures, subsoil areas, etc.), for the use of which the permission of specially authorized bodies for waste disposal or other waste operations has been obtained [13].

21,626% and 21,427%. Paying attention to remaining indicators, we can see that ten of them do not gain even 1%, and other do not exceed level of transport, warehousing, postal and courier activities, that is 1,873%.

Analyzing official data of expenditures on environmental protection by type of economic activity, there is not separately waste management. This fact makes it difficult to see the real state of these expenditures.

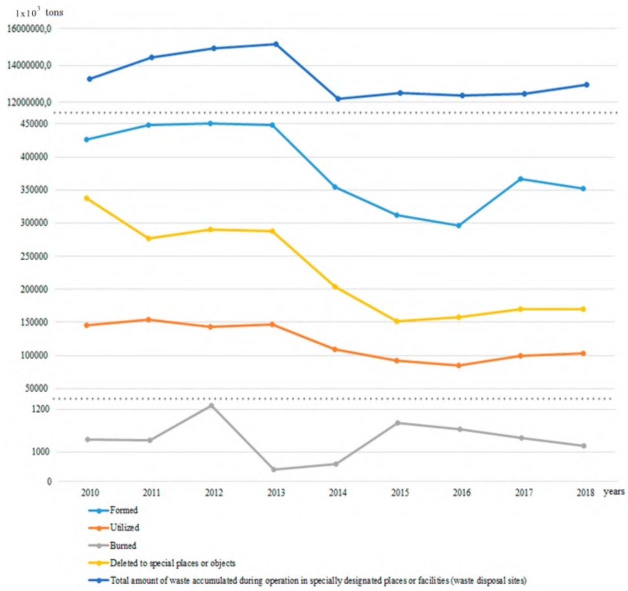

Fig. 2. Waste generation and management in Ukraine in 2010-2018.

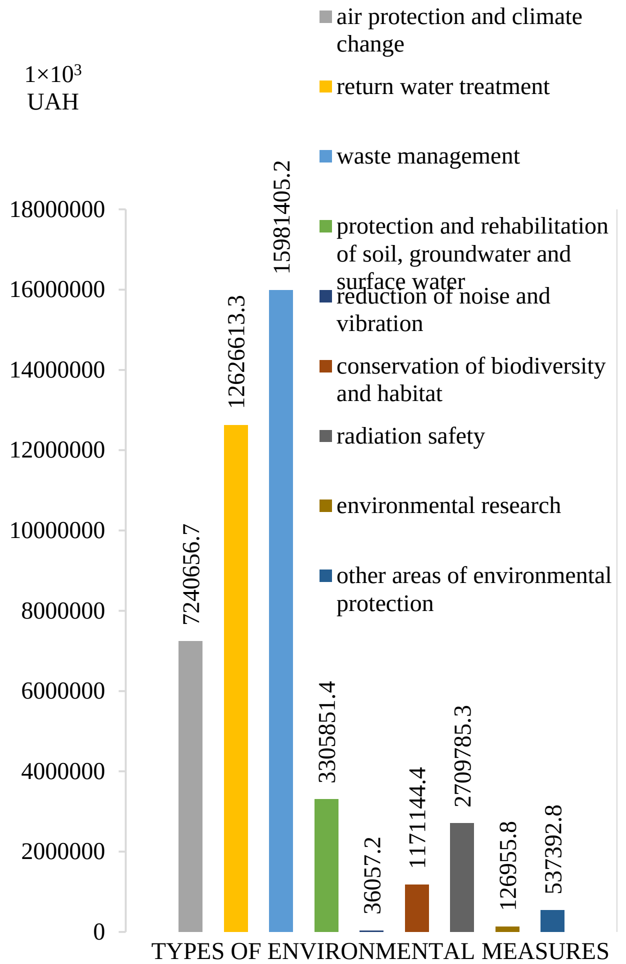

Fig. 3. Expenditures on environmental protection by types of environmental measures in Ukraine in 2019.

The graph shows us waste generation and management in Ukraine by years. We can see that we have extremely high level of total amount of waste accumulated during operation in specially designated places or facilities (waste disposal sites). From 2010 to 2013, the growth trend of this indicator is clearly visible, but in 2014 there was a sharp decline in its level. After which this indicator was stable within limits with the lowest indicator 12205388,8 $\times 10^3$ tons (in 2014) and the highest 12972428,5 $\times 10^3$ tons (in 2018). Also, as in situation with total amount of waste accumulated during operation in specially designated places or facilities (waste disposal sites) we can see that from 2010 to 2013 this indicator had been growing until 2014.

However, in 2014 it had a really sharp decreasing until 2016 after that it had fast growth in 2017 and a little decreasing in 2018. The line of the deleted to special places or objects has decreasing from 2010 to 2011 after that it has enough stable condition until 2013. The amount of deleted waste began gradually decrease until 2015 and then it was stable within limits until 2018. That limits were from maximal 169801,6 $\times 10^3$ tons (in 2017) and minimal 157379,3 $\times 10^3$ tons (in 2016). As we can see data about utilized waste is almost on the same level for each year but also a barely noticeable decrease from 2013 to 2016 in the amount of utilized waste. The maximum value of this indicator is 153687,4 $\times 10^3$ in 2011 and minimal in 2016 is 84630,3 $\times 10^3$ tons.

Summarizing this information, we can tell that the indicator of waste generation is regular higher than the indicator of utilized, deleted and burned wastes.

Thanks to this bar chart, we can consider the amount of expenditures on environmental protection by types of environmental measures in Ukraine in 2019. The total amount of these expenditures is 43735862,1 $\times 10^3$ hryvnias. In general, there are following types of environmental measures: air protection and climate change, air protection and climate change, return water treatment, waste management, protection and rehabilitation of soil, groundwater and surface water, reduction of noise and vibration, conservation of biodiversity and habitat, radiation safety, environmental research and other areas of environmental protection. The largest amount of expenditures compared to others are: waste management, return water treatment, air protection and climate change. Waste management is the biggest and takes the first place in the bar chart with indicator 15981405,2 $\times 10^3$ hryvnias. The second place belongs to return water treatment which is 12626613,3 $\times 10^3$ hryvnias. On the third place are air protection and climate change with indicator on level of 7240656,7 $\times 10^3$ hryvnias. Noise and vibration reduction are the lowest and least influential in the chart and takes only 36057,2 $\times 10^3$ hryvnias. It should also be noted that in comparison with all these indicators environmental research also has a fairly low mark of 126955,8 $\times 10^3$ hryvnias, which is very negative because such researches will help reduce the cost of all other types of environmental measures.

From this bar chart, it is seen that expenditures for waste management is occupied the largest share of total expenditures on environmental measures, and this is a positive trend in waste management at the state level in Ukraine. Worth remembering, new waste management goals require significant changes in the waste management system structure which introduces new problems and one of them is an increase in the costs for the system users (citizens) [14].

The system of general scientific and special, empirical and theoretical research methods is used in the work. In particular, the following methods were used: analysis-synthesis; explanation; formalization; generalization; comparison; deduction, induction; grouping, graphic, systematization etc. In addition, the analogy method was used to consider the existing systems of waste management in the European Union and Ukraine in order to shed light on problematic issues in garbage management in Ukraine.

3 Results

In this paper for increasing the efficiency of waste management, it is offered organizational solutions for household waste management for the Ukrainian government.

When organizing a system of household waste management, we must remember the interconnectedness and responsibility of the government (authorities of different levels of government), business entities and citizens. Only the coordinated interaction and understanding of these subjects of household waste management will allow in the near future to get an effective system that takes into account all the requirements of the present, and sustainable development, and the needs of future generations.

Therefore, we propose to pay special attention to the prevention of household waste management by raising the level of public awareness through such organizational measures that should be implemented at different levels of government in the country and among businesses and citizens (shown in Table 2).

Such measures will help to increase the level of waste management culture among the population. It should be noted that the level of education of the population in matters of household waste management directly depends on the state initiative and active public position of each citizen.

4 Discussion

The problem this article aims to solve in the need to decide the critical situation that has developed with the formation accumulation, storage, processing, utilization and disposal of waste and is characterized by the further development of environmental threats.

Such circumstances lead to a deepening environmental crisis and aggravation of the socio-economic situation in society and necessitates reform and development taking into account domestic and world experience of the entire law and economic system which is regulating the use of natural resources in general and waste management in particular.

The high level of waste generation and low rates of their use as secondary raw materials have led to the fact that in Ukraine every year in industry and utilities accumulate significant amounts of solid waste of which only a small part is used as secondary material resources, the rest end up in landfills.

Table 2. Recommendations about organization of prevention of household waste generation to Ukrainian government.

Sphere	Recommendation
Waste accumulation	every citizen should receive from the waste collection company a memo on the management of household waste with detailed instructions on their sorting and specially equipped places;
	place information on the rules for preparing waste for sorting on each special sorting tank;
	on specially equipped sites for sorting of household waste there should be clear indications about their types;
	carrying out explanatory work to the population directly in places of separate waste collection.
Education	conducting educational events in all schools, universities and crowded places (shopping malls, markets, recreation areas, etc.) about the sorting of household waste and ways to re-use, recycling;
	mandatory introduction of issues related to household waste management in schools and universities.
Production and consumer sphere	create conditions for anti-wastefulness promotions in supermarkets;
	gradually transfer the consumption of food and life by the population on the terms of sustainable nutrition / development, taking into account the regionality and seasonality of products and goods;
	due to the large amount of packaging in household waste to oblige each manufacturer to indicate on the packaging about its danger in case of getting into unsorted waste.
Digitalization	by the concept of "Country in a smartphone" to develop a waste application, aimed at informing the population of the settlement about the place, time and assortment of waste collection; activation of the eco-activity function nearby is possible.

The article provides recommendations on how best to organize the process of preventing the generation of household waste. Further research should be aimed at improving the efficiency of waste management such as: industrial, construction and repair waste, hazardous, agricultural waste, specific types of waste (packaging, waste electrical equipment, batteries and accumulators, medical waste).

5 Conclusions

The proposed organizational mechanism for household waste management should be the first practical step towards the implementation of an effective management system for all types of waste at the government and regional levels. This will create conditions for raising living standards by introducing a systematic approach to waste management, reducing waste generation and increasing its recycling and reuse.

Zebrafish as a suitable model for studying the mode of action and harmfulness of organophosphate pesticides

Halina Falfushynska*, *Oksana* Bodnar, *Ihab* Khatib, *Halyna* Kovalska, and *Serhiy* Hulyk

Ternopil Volodymyr Hnatiuk National Pedagogical University, 2, M. Kryvonosa Str., Ternopil, 46027, Ukraine

Abstract. The aim of the present work was to investigate the response of zebrafish to the effects of widely-used organophosphates roundup and chlorpyrifos and putative effectiveness of chlorella in terms of decreasing pesticides toxicity. Studied organophosphate pesticide roundup and chlorpyrifos in ecologically relevant concentrations, both individually and in a mixture, evoked the prominent suppression of catalase and total antioxidant capacity in the liver of *Danio rerio* which were consistent with higher levels of lipid peroxidation, protein carbonylation, and DNA strand break. Also, both roundup and chlorpyrifos provoked endocrine disorders registered as induction of vitellogenin and depletion of triiodothyronine as well as neurotoxicity appeared as inhibition of acetylcholinesterase after individual action or activation after combined action. The rate of apoptosis observed by caspase 3 activity was decreased, but in different manner depends on the exposure. The potency of toxicity followed the order: roundup > chlorpyrifos > roundup + chlorpyrifos (due to some kind of antagonistic action between chlorpyrifos and roundup in the binary mixture). Based on the results of CART analysis triiodothyronine, TBARS and caspase 3 were determined as the most significant indices for discrimination of the studied groups. The introduction of *Chlorella vulgaris* in the amount of about 100 thousand cells L^{-1} into the environment did not show a significant bioremediation effect on the harmful effect of studied pesticides for *Danio rerio*, which does not exclude the positive impact of algae on the functioning of the ecosystem as a whole and requires further comprehensive research.

1 Introduction

In case of complex pollution, inherent in natural fresh water reservoirs, the measurement of hydrochemical parameters, as well as the determination of the toxicant concentration in organisms may not be sufficient criteria for hazards assessment [1]. The issue is especially urgent in case of organic pollutants, in particular pesticides, personal care products, etc., which are difficult to detect due to persistent chemical transformations. Also, due to key points of Program on Pesticides and Sustainable Pest Management OECD countries have been working together on methodological approach of the risks of individual pesticides evaluation more quickly and thoroughly (www.oecd.org).

The world population is predicted to rise to 9.7 billion by 2050, which is 30% more than in 2017. Increasing population requires an increase in food resources, 80% of which, according to US Food and Agriculture Organization expectations, will be provided by expansion of agricultural land area, and thus by growing use of chemicals for crops treatment (https://www.who.int/). Pesticides are extremely important in the agrochemical sector and their global production is growing by 11% annually, from 0.2 million tons in 1950 to more than 5 million tons in 2000 (FAO, 2017). As of 2019, Ukraine ranks 6th in the world in terms of pesticide use (https://www.worldometers.info/food-agriculture/pesticides-by-country/). Due to their cumulative properties and long half-live (e.g. 45-60 days for roundup) most pesticides circulate in ecosystems and can be accumulated in non-target organisms and be included in food chains, showing signs of toxicity [2]. Following primary effect, the pesticides' residuals which remain in the environment, are able to exert long-term harmful effects for physiological and biochemical systems of non-target animals. Nevertheless, promotion of green growth strategies and action plan for sustainable use of pesticides that contributes to further risk reduction all over the world, studies conducted by US Environmental Protection Agency showed the presence of micromolar amounts of atrazine and roundup in about 30% of 154 analysed river water samples (https://toxics.usgs.gov/highlights/glyphosate02.html). Moreover, roundup exists in rivers (0.1-0.7 mg/l), sediments (0.0-4.9 mg/kg) and soil (0.5-4.3 mg/kg), sometimes even at concentrations close to toxic [3].

Take into account abovementioned huge amount of pesticides that are using, a promising technology for reducing the risk of chemical pollution of water reservoirs is urgently needed [4]. It is known that microalgae can reduce the level of water and soil pollution by adsorption, accumulation and metabolism of pesticides up to safe levels or their transformation into less harmful or harmless compounds and substances [5]. As an example, unicellular green algae *Chlamydomonas mexicana*,

* Corresponding author: falfushynska@tnpu.edu.ua

Micractinium reisseri, *Scenedesmus obliquus* and *Chlorella vulgaris* managed to decrease in residual concentrations of atrazine in the environment after 14 days of co-treatment [6].

Therefore, the aim of our work was to investigate the response of zebrafish to the effects of widely-used organophosphates roundup and chlorpyrifos and putative effectiveness of chlorella in terms of decreasing pesticides toxicity. We suggest to use the cyprinid fish *Danio rerio*, as a conventional biological model for mechanistic and toxicological studies. Zebrafish demonstrate universal to vertebrates' responses to stress and toxicants, which make these organisms important in extrapolating the results for assessment of the biosafety of human environment. The state of the body was assessed by the indicators of stress and toxicity validated in our previous studies [7-9]. In particular, the oxidative stress block included catalase activity, total antioxidant capacity, lipid and protein peroxidation. The rate of cytotoxicity was determined by DNA strand breaks, acetylcholinesterase (neurotoxicity), vitellogenin-like proteins (endocrine disorders).

2 Materials and methods

2.1 Animal collection and exposures

A toxicity of pesticides was evaluated on the adult zebrafish. Experiments were followed the rules of laboratory animal welfare and were approved by the animal ethics committee of Ternopil V. Hnatiuk National Pedagogical University (No. 2; 11 June 2020). The experiment was conducted according to the National and International animal protection policy. The zebrafish (3.4 ± 0.4 cm and 1.5 ± 0.2 g) used in this study were purchased from the local supplier. Zebrafish were maintained in aquarium tanks with 12 h/12 h light/dark cycle. The fish were fed with commercial food (Aquarius, Kharkiv, Ukraine) daily and water was changed once every three days. The mean values of selected hydrochemical parameters were: temperature 18±0.5ºC, dissolve oxygen around 8.1 $mg \cdot L^{-1}$ (7.9÷8.3 $mg \cdot L^{-1}$), pH 7.6±0.3.

Fish were divided into three experimental groups (30 fish each) and a control group which treated by any of studied pesticides or their combination. Meanwhile, experimental fish were exposed to roundup (R, 15 $\mu g \cdot L^{-1}$), chlorpyrifos (ClP, 0.1 $\mu g \cdot L^{-1}$), and their mixture (R+ClP, 15 $\mu g \cdot L^{-1}$+0.1 $\mu g \cdot L^{-1}$) for 14 days at 20 °C. All exposures were used in the environmentally relevant concentrations. The fish were randomly distributed into 10 L glass aquaria, 15 specimens in aquarium. The trial was duplicated. All studied groups of *Danio rerio* were treated by *Chlorella vulgaris* suspension (100 000 $cells \cdot L^{-1}$) [10]. During the experimental procedure no fish mortality was registered. Also, electrical conductivity, hardness, chloride and oxidizability were analyzed by standard methods and didn't exceed permitted value for fresh- and tap-water.

When the exposure ended, the animals were killed and liver and brain were immediately dissected on ice.

2.2 Oxidative stress assay

Catalase (CAT) activity was determined in the supernatant of liver tissue homogenate (1:10 w:v) by following the decrease in hydrogen peroxide at 240 nm [11]. CAT activity was calculated using the extinction coefficient, $\varepsilon = 40\ M^{-1}\ cm^{-1}$, and referred to the soluble protein. The free radical scavenging capacity of the liver tissue homogenate (1:10 w:v), calculated as percentage inhibition of $ABTS^{+}$, was equated against a Trolox standard curve [12]. Lipid peroxidation was determined in the 10% liver tissue homogenate by the production of TBA-reactive substances (TBARS) as described in [13] at 532 nm. A molar extinction coefficient of $1.56 \cdot 10^{5}\ M^{-1}\ cm^{-1}$ was used. The protein oxidation by the protein carbonyls (PC) was evaluated in the trichloroacetic acid-treated 10% liver homogenate using 2,4-dinitrophenylhydrazine at 370 nm [14]. The protein carbonyls amount was calculated with $\varepsilon_{mM} = 2.2 \cdot 104\ M^{-1}\ cm^{-1}$. Data were expressed as μmol $PC \cdot g^{-1}$ fresh weight (FW).

2.3 Assays of cytotoxicity and apoptotic activities

DNA fragmentation was assessed by the levels of protein-free DNA strand breaks in the (1:10 w:v) liver tissue homogenate in 50 mM Tris-EDTA buffer, pH 8.0 which contains 0.5% sodium dodecyl sulphate (SDS) by the alkaline DNA precipitation assay using Hoescht 33342 dye [15]. Probe fluorescence signal was detected at Ex/Em of 360/450 nm.

For the characteristics of apoptosis, activities of both cytosolic and lysosomal proteases were detected. The activity of an apoptosis executor caspase-3 was assayed at 405 nm ($\varepsilon_{mM} = 10.5\ mM^{-1} \cdot cm^{-1}$) [8, 16].

Acetylcholinesterase (AChE) activity was spectrophotometrically determined in the supernatant of brain tissue homogenate (1:10 w:v) as an increase in optical density of the sample measured at 412 nm [17] with acetylthiocholine applied as a substrate.

Vitellogenin-like proteins were estimated as the alkali-labile phosphate level in blood plasma as described in [18]. The phosphomolybdenum assay was applied to determine the level of free phosphates.

The blood serum triiodothyronine concentration was measured with diagnostic ELISA kit using the 96-well-plate solid phase competitive system (Sigma-Aldrich, USA) according to the manufacturer's instructions. The absorbance was measured at 450 nm in an ELISA reader (Biorad Microplate Reader, USA).

2.4 Statistical analysis

The data are presented as means ± standard error (SE). The normality of data were approved by Kolmogorov-Smirnoff test and, if possible, were normalized the by Box-Cox transforming method. To the data following a non-normal distribution, non-parametric tests was employed. The P-value <0.05 was considered significant.

All statistical operations were performed using Statistica v. 12.0 and Excel 2016.

3 Results and discussion

The antioxidant parameters namely total antioxidant capacity and catalase activity in *Danio rerio* liver were significantly decreased after exposure by organophosphate pesticides when compared with the correspondent control (Fig. 1). Meanwhile, studied chemicals provoked an increase in lipid peroxidation and protein carbonylation level with the most prominent changes found in the R-group. No significant differences were shown in fish responses to individual and combine action of organophosphates.

Roundup and chlorpyrifos caused an increase in DNA fragmentation and caspase 3 activity in hepatocytes and a decrease in AChE activity in fish brain when compared with the control animals (Fig. 2). The cytotoxic signs after combined action of pesticides were differed from individual one. It is highly likely that there was antagonistic relation while combined action. The generally higher level of vitellogenin in male specimen particularly in ClP-group and T3 concentration indicates an endocrine disrupting effect of media.

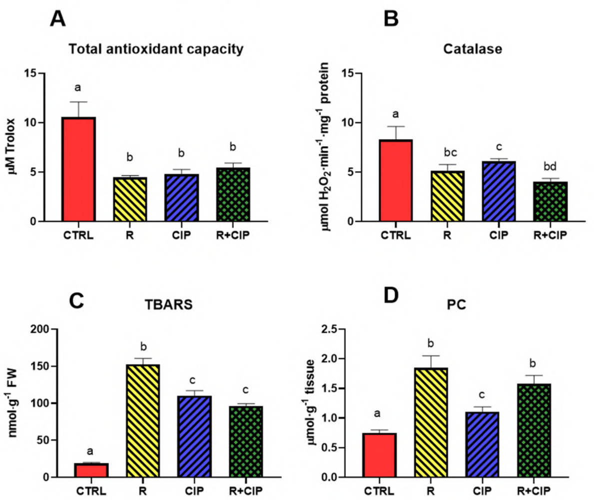

Fig. 1. Oxidative stress parameters in the liver of *Danio rerio* after the effect of roundup (R), chlorpyrifos (ClP) and their combination along with presence of Chlorella vulgaris in the media. Data for A: Total antioxidant capacity, B: Catalase, C: TBARS, D: protein carbonyls, are present as means ± SD (n = 8). The columns that share the same letters indicate the values that are not significantly different (P > 0.05).

Classification tree was built using CART analysis of all studied biological parameters identified 3 splits and 4 terminal nodes (Fig. 3A). Overall, the CART analysis supports an important role of the triiodothyronine in the response and adaptation of animals to deteriorated effects of pesticides even in low environmental realistic concentration. TBARS and caspase 3 activity also pertained to the most important parameters discriminating the experimental groups. No classification mismatch was observed between the experimental groups.

The discriminant analysis helped us to find out the similarity of animals responses to different pesticides ($F_{27,35} = 17.2$, $p < 0{,}0001$). Fish had affected by organophosphorus-containing pesticides reacted similarly. Danio treated by the combination of two pesticides were alike in the response to individual roundup action. The most prominent parameters for discrimination of studied groups were quite close to that selected by CART analysis and included TBARS, T3 and Vtg.

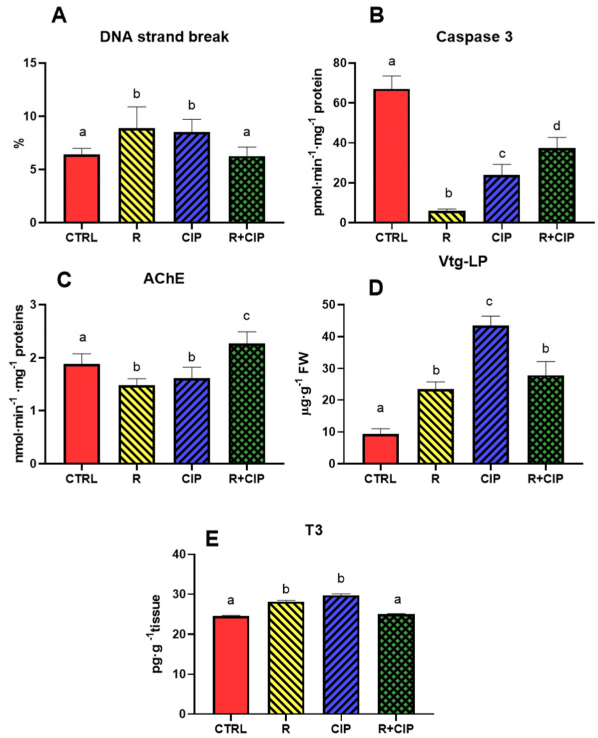

Fig. 2. Biomarkers of cytotoxicity in the liver and brain of *Danio rerio* after the effect of roundup (R), chlorpyrifos (ClP) and their combination along with presence of *Chlorella vulgaris* in the media. Data for A: DNA strand break, B: caspase 3 activity, C: acetyl cholinesterase activity; D: vitellogenin-like proteins; E: triiodothyronine are presented as means ± SD (n = 8).

Organophosphates pertain to the most usage pesticides in the world, particularly glyphosate which takes the first place according to the amount of sale [19]. However, numerous signs of acute toxicity in wide range of non-targets have been reported. When neurotoxicity of organophosphates is well-defined, endocrine disruption is being worth noting. In particular, acute long-term (21 days) exposure of zebrafish at 10 mg·L^{-1} Roundup or glyphosate induced changes in gene expression of *cyp19a1* and *esr1* in the ovary and *hsd3b2*, *cat*, and *sod1* in the testis [20]. Also, 5 mg·L^{-1} glyphosate exposure in Japanese medaka provoked alterations of neuroendocrine-related genes *kiss1* and *kiss2* in female brain in addition to reproductive, developmental, and epigenetic modifications [21]. Compatible effect was also shown for chlorpyrifos after subacute treatment of *Danio* [22]. In present investigations we have proved that both studied organophosphate pesticides namely roundup and chlorpyrifos in very environmentally realistic concentrations interfere with steroid hormones' biosynthetic pathway and have prominent endocrine disruption effect on adult *Danio rerio*. Our conclusion doesn't correspond to EPA statement that chlorpyrifos poses no endocrine disruption risks and is recommended no further testing (https://www.epa.gov/sites/production/files/2015-06/documents/chlorpyrifos-059101_2015-06-29_txr0057162.pdf).

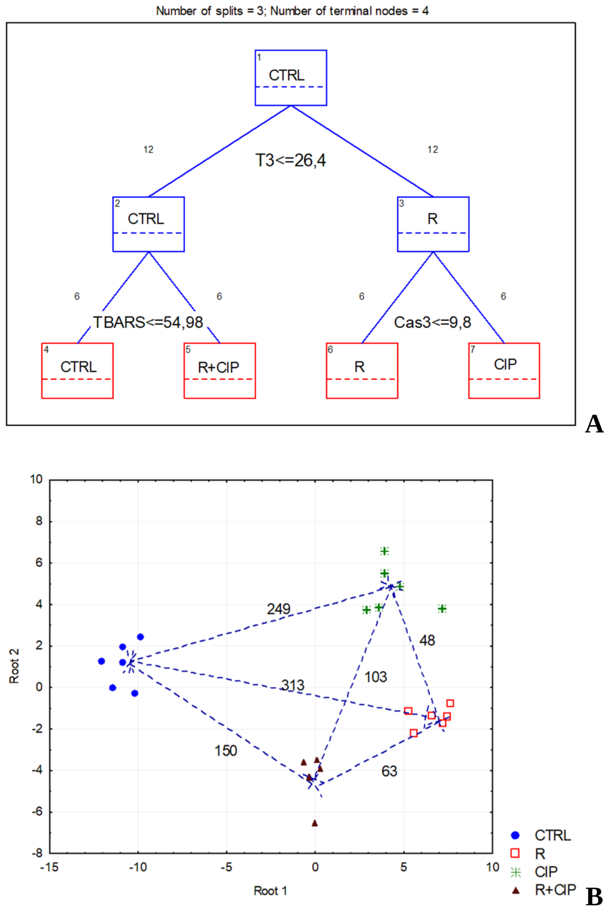

Fig. 3. Classification and regression tree analysis (CART) (A) and discriminant analysis (B) biplots integrating all biological traits of zebrafish *Danio rerio* from different pesticide treated groups.

As we have shown, roundup and chlorpyrifos affect not only steroidal hormones pathways but also hypothalamus-pituitary-thyroid axis. Besides that, triiodothyronine includes into set of most important parameters that distinguish studied groups in CART analysis (Fig. 3A). In fish, thyroid hormones are involved in the regulation of metabolic pathways, somatic growth, skeletal development, reproduction, and behavior [23] and some organophosphates have been reported to alter the thyroid system. As an example, malathion provoked a decrease in thyrotropin synthesis and secretion, reduction of thyroxine and triiodothyronine levels, decline the plasma T_3 levels and T_3/T_4 ratio which caused serious disrupting effects in developmental and growth patterns, behaviors, fitness and survival in catfish and *Senegalese sole* [24, 25]. It might be that organophosphate pesticide not only blocks the T_4 secretion, but also inhibits the thyroidal conversion of T_4 into T_3 [26, 27]. This suggestion is corroborated by some of immunohistochemical studies of thyroid follicles and T_3 and T_4 immunoreactivities in colloid, plasma, and in follicle-surrounding epithelial cells [26].

As was expected AChE activity significantly reduced in fish brain after individual exposure to roundup and chlorpyrifos. Our results keep in line with previous reports devoted to organophosphate pesticide action on fish species including cyprinids. In particular, profenofos exposure (60 μg·L^{-1}) during 60 days caused prominent AChE inhibition in the brain of *Labeo rohita* [28]. A sublethal exposure of *Astyanax aeneus* (Characidae) and stinging catfish *Heteropneustes fossilis* to ethoprophos and Envoy 50 SC correspondingly caused a significant reduction of brain cholinesterase activity [29, 30]. However, in the present study the inhibitory effect of studied organophosphate was appeared in case of chronic exposure rather than acute exposure. Indeed, harmful effects related to the mode of action of the pesticides can be triggered in environmental realistic concentrations that are in times lower than lethal ones.

Despite the inhibitory effect of roundup and chlorpyrifos on AChE activity after their individual action, the combine exposure caused opposite effect, an increase in the enzyme activity. Moreover, this apparent increase in AChE activity was in a good correlation with increasing of caspase 3 activity (r=0.72, p<0.01), key enzyme of apoptosis when compared with individual pesticide action. Some would prove that AChE might be involve in the promotion of various types of apoptosis [31] and very 55 kDa AChE protein induced during apoptosis [32]. Thus, it is plausible that AChE mediates of apoptosis in zebrafish, but further studies are needed to confirm this hypothesis.

A lot of pollutants provoke oxidative stress in animals, including cyprinid fish, which is considered to be one of the main mechanisms of non-specific effects of pollutants [2, 8, 33]. It has been shown that organophosphate pesticides stimulate the generation of ROS and cause lipid peroxidation and/or protein carbonylation. In particular, in neotropical fish *Prochilodus lineatus* after acute exposure (6, 24 and 96 h) to 10 mg·L^{-1} of Roundup [34], in *R. quelen* after 96 h of exposure to 0.2 and 0.4 mg·L^{-1} of Roundup [35], and in *Channa punctatus* [36] after the effects of three sublethal concentrations 3.25 - 6.51 mg·L^{-1} of Roundup the concentration of TBARS in liver and gills tissue was higher than in the correspondent control. Our results support previous findings and reinforce the idea even in low environmental realistic concentration. Moreover, prominent oxidative damage has been in a good agreement with oppression of antioxidant defense estimated by a decrease in activity of catalase and total antioxidant capacity. This phenomenon points out clearly an increased pro-oxidant status in affected fish. These data corroborate evidence that oxidative stress has been arising after glyphosate and chlorpyrifos attenuate detoxification system of animals and potentially follow on neurotoxicity, cardiovascular toxicity, and reproductive toxicity [37].

In general, an increase in TBARS and PC was accompanied by increase of DNA damage in liver of zebrafish, except of R+ClP-group. Thus, it is highly likely that roundup and chlorpyrifos would have caused alterations in DNA integrity of *Danio rerio*. Our data corroborate with previously reported pesticide-mediated DNA damage in different fish species [2, 8]. However, when fish were exposed by mix of organophosphate pesticides unexpected DNA strand break level in line with control was disclosed. Commonly, animals are fitted out with independent cascades of enzymes to alleviate oxidative stress and repair damaged cells produced as a response to exposure to xenobiotics. Meanwhile the combined action of pesticides obviously was powerful enough to trigger apoptosis for eliminating damaged cells.

Discriminant analysis revealed that the response of *Danio* to individual action of chlorpyrifos and roundup was quite similar, because they belong to the same class of pesticides (Fig. 3B). When we compared the effects of organophosphate pesticides in terms of their individual and combined action, no significant signs of additive effect on oxidative stress parameters were disclosed. In the same time, cytotoxic parameters were differed in case of individual and combined pesticide treatment, but no clear dependence was depicted. This however, may be attributed to the antagonistic action of chlorpyrifos and roundup in the mixture. Some would say that the effects of binary mixtures of pesticides are variable and sometimes contradictory [38]. It has been shown the significant antagonistic effects on mortality ratios in *Cnesterodon decemmaculatus* treated by Glifoglex and Glextrin formulations. These authors demonstrated a strong inhibition of Glextrin toxicity, almost completely overridden by Glifoglex formulation. All of these allow us to deduct that it might be some kind of antagonistic action between chlorpyrifos and roundup in the binary mixture, that suppress the predictable effects of the individual compounds.

It has been shown that there is a synergic relation between green algae as a low-cost biosorption and filter material for removal of heavy metals [39]. Meanwhile, information related to organic pollutants including pesticides are controversial. In particular, there was no significant overall reduction of 37 different wild-used pesticides after short-term exposure (1 h). However, long-term exposure to growing cells of *C. vulgaris* significantly reduced the amount of pesticides in water [40]. On the other hand, *C. vulgaris* was exposed to organophosphate pesticides in subacute concentrations, has been reported the most sensitive from different species of diatom, cyanobacteria, and chlorophyta [41]. Obviously, it might have been a reason that in the present study we haven't shown positive bioremediation effect of *Ch. vulgaris* on roundup and chlorpyrifos toxicity to *Danio*. It points to uncertainty of the ratio of commonly used organophosphate pesticides and algae in water media and emphasize the importance of further studies.

4 Conclusion

Thus, the action of ecologically relevant concentrations of roundup and chlorpyrifos, both individually and in a mixture, caused the suppression of antioxidant defense systems in striped zebrafish, consistent with higher levels of lipid peroxidation, protein carbonylation, and DNA damage. Also, exposures provoked endocrine disruptions registered as expression of vitellogenin and depletion of triiodothyronine and neurotoxicity. It might be some kind of antagonistic interaction between chlorpyrifos and roundup when they are in the same media. In general, observed changes in cellular and molecular responses varied in magnitude and frequency, and in some cases suggested causal relationships among studied indices. The introduction of *Chlorella vulgaris* in the amount of about 100 thousand cells $\cdot L^{-1}$ into the environment did not show a significant bioremediation effect on the harmful effect of studied herbicides for *Danio rerio*, which does not exclude the positive impact of algae on the functioning of the ecosystem as a whole and requires further comprehensive research. Thus, runoff from agricultural lands into the surface water that contains even background concentrations of organophosphate herbicides may pose a risk to non-target organisms, and the use of algae in detoxification processes requires more detailed hydrobiological analysis in favor of finding a prospective approach for the removal of pesticides from freshwater bodies as an efficient tool for sustainable development and pollution control [42].

This work was supported by the National Research Foundation of Ukraine (#2020.02/0270, 69/02.2020), Ministry of Education and Science of Ukraine (research grant for young fellows MV-2) and partially by the Alexander von Humboldt Foundation to H.F. Abstract. The article evaluates the importance of trade and economic relations between countries in economic growth. At a time of globalization has been identified the existing problems of the international division of labor for Georgia. Substantiated that the development of trade and economic relations is an important challenge in the condition of a low level of food provision for the population of Georgia. From this perspective, it is relevant to analyse the export-import of agriproducts with those European countries that have similar resource potential, geographic proximity, socio-economic and political characteristics to Georgia, among of which is the Czech Republic. Based on the theories of international trade, in order to assess the trade and economic potential between Georgia and the Czech Republic and to determine trends of development, has been studied main indicators of the above-mentioned countries. Comparative analysis of the data showed that quantitative indexes are similar between these two countries, while the qualitative data in the Czech Republic is higher as compared to Georgia. The paper discusses the agriculture of Georgia as one of the main sources of economic growth, therefore, to increase the resource potential of the sector needs to develop foreign trade and economic relations with the agriproducts. Based on analysis of data on export-import of agriproducts between Georgia and the Czech Republic, has been concluded that the trade balance between the countries is variable and trade and economic relations are at the development stage. The main challenge in agriproduct trade between the countries is a low level of import-export diversification of agriproducts. At the same time, it is substantiated, that the cooperation with the Czech Republic perspective for Georgia not only in trade but also in the sphere of investments and modern technologies. The article argues the need for an optimal ratio of exports and imports in the development of trade and economic relations. Through the empirical studies the current challenges of export and import of agri-food products between Georgia and the Czech Republic have been identified; export-import ratios have been analysed by product type; and the ways to improve trade and economic cooperation between the two countries have been outlined. Promising areas of economic relations and export-import between Georgia and the Czech Republic have been developed.

1 Problem statement

Today, almost every country in the world is involved in the international division of labour; otherwise it would be impossible for a country to provide its own population with agri-food products. An important challenge for any country is the development of trade and economic relations. However, it should be borne in mind that in the context of the international division of labour, a country always needs to import resources, consumer goods and services, and the main source of covering import costs should be export earnings. Export earnings are the main sources for covering import costs in order to maintain the food security [1].

Nowadays, the development of trade and economic relations between the countries is taking place against the background of irreversible globalization processes, which has a certain impact on the modernization of the political and economic environment of Georgia. In view of the above, it is necessary to take into account the experience of economic and political transformation of the leading industrialized countries.

2 Research methods

In the process of research has been used various methods of research, particularly:

- Based on bibliographic and empirical research has been analyzed scientific papers of Georgian and foreign researchers, publications of the National Statistics Office of Georgia, Policy documents of the Parliament of Georgia, analytical reports, etc.;
- Based on comparative method has been determined similarities and differences between Georgia and the Czech Republic in terms of social and economic and other indexes;

* Corresponding author: gechbaia.badri@bsu.edu.ge

https://doi.org/10.1051/e3sconf/202128011006

- Analysis, synthesis, induction, and other methods allowed to select and group the data, identify the trends, similarities, and differences;
- Based on statistical methods has been calculated average export and other indexes of agriproducts;
- Based on the grouping method has been determined export material groups by Georgia and the Czech Republic;
- Based on interviews with the experts of the agriproduct sphere has been assessed and refined quantitative and qualitative indexes;
- Based on the household research database has been defined the order between analytical and statistical assessments;
- Based on the household research database, statistical data, materials of the Ministry of Environmental Protection and Agriculture of Georgia, data from ministries of economic profile has been defined the order between analytical and statistical assessments.

3 Background

Production of agro-food products in Georgia is a traditional field; however, a particularly difficult social background among economic problems is related to food security, rising food prices, inflation, negative trade balance between exports and imports of agri-food products [2]. Self-sufficiency in local agri-food products in Georgia is low. According to the data for 2018, the self-sufficiency ratio in wheat is especially low – 15%, corn – 71%, vegetables – 59%, potatoes – 102%, grapes – 152%, meat – 52% (beef – 77%, pork – 45%, poultry – 34%), eggs – 99%, milk and dairy products – 81% [3].

In Georgia, the share of food exports in total exports is low. This figure averaged 9% in 2018. For the first three quarters of 2019, the same indicator is 7.5%, which is lower than the corresponding indicator for the previous year [3].

In Georgia, the share of household spending on food in total consumer spending is high. In 2018, this figure was 42% [3]. Also, a comparative analysis of the recent data revealed that price indexes of food and non-alcoholic beverage are on the upward trend. Prices for most of the food products also went up [3]. As of 2018, the share of household monetary income from the sale of agricultural products was 5.5%, while in 2015 this indicator was 7.1%. Average monthly income also decreased – from GEL 68.5 (2015) to GEL 57.4 (2018) [3]. The poverty rate remains high in the country. The share of the population below the absolute poverty line was 21.9% in 2018 [3].

One of the important factors for improving the economic situation in Georgia and achieving food security is to search for the ways to increase export potential and develop trade and economic relations, especially with European countries. Development of trade and economic relations between Georgia and the leading countries of the world, including ensuring the optimal balance of exports and imports, will have a positive impact on the political and social situation of the countries, especially on the welfare of their population. In this regard, it is promising to share the experience of successful countries and identify opportunities for the development of trade and economic relations between countries. As noted above, it is especially important for Georgia to share European experience and identify current problems of export and import of agri-food products with a country with similar economic and political characteristics, as well as determine the prospects for the export potential of these products. The Czech Republic is included in the list of such countries; therefore the purpose of the study is to identify problems in the export and import of agri-food products between the two countries based on the study of trade and economic relations between Georgia and the Czech Republic and make recommendations on development prospects.

4 Data and empirical analysis

Comparison, analysis, induction and other methods have been used in the research process. The export potential has been estimated using the respective models by commodity groups and by the countries (Georgia and the Czech Republic).

Georgia belongs to a number of small countries. A study by A. Smith [4] identified the importance of the size of a country for its economic development. Countries with large areas, due to the great potential of diverse climatic and natural resources are more capable to secure their own economic self-sufficiency than small ones. According to the same theory, a country should manufacture the goods production of which will cost less compared to other countries, and import the goods production costs of which are higher [4]. D. Ricardo's theory, according to which all countries can benefit from international trade due to differences in production costs, should also be considered. According to David Ricardo, personal interests merge with public interests, and exchange turns all nations / states of the civilized world into one universal society. The arguments put forward are to some extent the basis of the modern theory of trade, and therefore they are so interesting today, even in the conditions of the global economy [5].

The role of trade and economic relations between countries is important to enhance economic efficiency. However, when developing foreign economic relations, it is necessary to take into account not only the costs of export and import, but also the consumer properties of the products purchased. In addition, it is necessary to compare the level of labour costs to the production costs of the exported product with that can be replaced by import.

Export promotion and import substitution [6] are considered as an alternative to the development of international trade and the choice between them depends on the level of development of countries [7], their natural resource potential, the demand and supply situation, the level of development of food markets [8].

The export structure of a country depends largely on the demand in the importing countries. First of all, for the export of products it is necessary to saturate the domestic market, and for the successful sale of the product the structure of demand should be similar to the structure of demand in the exporting country [9]. Modern approaches to international trade theory are based on the "economy of scale". Such conceptual approaches are especially important for Georgia.

Almost every country in the world is engaged in international trade. In line with modern challenges and processes in the international division of labour, countries are in constant need to import resources and consumer products. Georgia, as a participant in the above processes, should look for ways to increase its resource potential, especially in the agri-food sector, where imports are more than three times higher than exports, and the country has many socio-economic and environmental problems [10-13].

As the globalization of the world economy deepens, the effectiveness of international trade is largely determined by the geographical proximity to European countries and the further development of historical and economic cooperation with them [14-15]. Based on theories of international trade, to assess the effectiveness of foreign economic relations between countries and identify current trends in the development of international trade, the current potential and future opportunities of exporting agri-food products between Georgia and the Czech Republic have been analyzed. To identify effective trade and economic potential, the key indicators of the two countries were initially evaluated (Table 1).

Table 1. Key Indicators of Georgia and the Czech Republic (based on [3]).

	Georgia	**The Czech Republic**
Area	69,700 km^2	78,866 km^2
Population	3.7 million people	10.6 million people
Density	58 people/km^2	134 people/km^2
Economic Growth	4.8%	4.3%
GDP Total	$15.086 billion	$215.735 billion
GDP per capita	$4,046.8	$20,368.0
Area of agricultural land in common land fund of the country	49.0%	55.0%
Share of agriculture in GDP	7.7%	2.2%
Share of those employed in agriculture	47.0%	3.0%
Unemployment rate	13.9%	2.5%
Investment in agriculture (of total investment)	0.6%	4.3%
Inflation rate as of 2017	6.0%	2.4%
Added value created in agricultural business	Less than 10.0%	2.2%
Expenditure on education / overall European rate 5-12% /	2.5%	4.0%

Georgia and the Czech Republic are small countries by territory, the area of the Czech Republic is only 1.1 times the size of Georgia, and its population is 2.9 times larger. Both countries are also almost identical in terms of the share of agricultural land in the total land resources: in Georgia this figure is 49%, in the Czech Republic – 55%. The Czech Republic and Georgia show similar economic growth rates: Georgia's growth rate is 4.8%, the Czech Republic's – 4.3%. The opposite situation exists for the key economic indicator – gross domestic product (GDP). GDP of Georgia is 15,086 billion US dollars, of the Czech Republic – 215,735 billion US dollars. GDP per capita are 4 046.8 USD and 20 368 USD, respectively. Thus, the volume of GDP in the Czech Republic is 14 times, and GDP per capita is 5 times higher than in Georgia.

In the Czech Republic, the share of people employed in agriculture is quite small (3%), but the volume of manufactured goods significantly exceeds the respective figure of Georgia. In Georgia, almost half (41.3%) [3] of the population is employed in this sector, accounting for only 7.7% of GDP.

Indicators of investment in agriculture also differ in the two countries. If the volume of investments in agriculture in Georgia is 0.6% of the total investments, then in the Czech Republic it is 4.3%.

Unlike the Czech Republic, Georgia has a high unemployment rate, but it should also be taken into account that the unemployment rate in Georgia is reduced at the expense of the self-employed people. In fact, most of the self-employed people produce the products only to meet their own needs. The latter is partially reflected in the added value created in agricultural business [17-18]. Spending on education in Georgia are also lower (2.5%) than in the Czech Republic (4.0%). In the Czech Republic, this indicator is close to the average European level of spending on education (5-12%).

Thus, the comparative analysis showed that there was a similarity in quantitative indicator between Georgia and the Czech Republic, while the qualitative indicators in the Czech Republic are higher than in Georgia. By developing trade and economic relations with the Czech Republic both countries will be able to enhance e the parameters of production of local agri-food products, increase the welfare of population, and through cooperation develop better access strategies to the European markets, etc.

In Georgia, agriculture is often considered as the main source for growing the country's economy; however, the results claim the opposite [11]. The sector's share in the Georgian economy is declining in dynamics. Moreover, the sector is low-productive, overall output volume is small and growth rates are quite low. In 2004 [12], the agricultural sector of Georgia produced goods worth GEL 1.9 billion, this figure increased to GEL 4.0 billion by 2018 [3], while the average growth rate in the country remaining low. Financing of the sector has increased since 2012, but, on the contrary, both sown area and livestock decreased. In 2017-2018, the annual decline of the sector was about 3% (see Figure 1) [3].

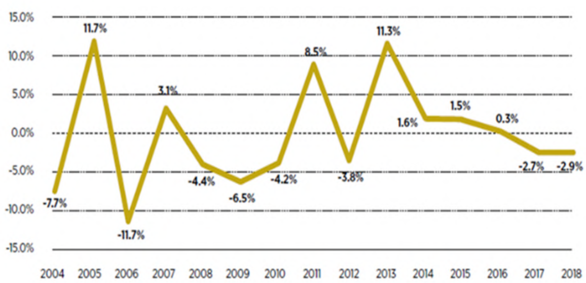

Fig. 1. Annual growth of agriculture in Georgia (%)
Source: National Statics Office of Georgia [3]

Under these conditions, export opportunities for agri-food products are obviously limited. As of 2018, most of the exports (41%) accounted for the CIS countries, with EU countries accounting for 28.3% [3].

The share of agri-food products in the structure of the largest export goods in Georgia is small (see figure 2) [3].

Fig. 2 .Share of agri-food products in exports in 2000-2018 (%). Source: National Statics Office of Georgia [3]

There are only hazelnuts, wines and spirits represented in the top ten export products. Structural changes have recently been made in the export of Georgian agri-food products, in particular, in 2017, hazelnut crop was significantly damaged, and for the first time in many years it fell out of the top five export products of Georgia.

As noted, the import rate of agri-food products is significantly higher than of export and this trend remains unchanged in dynamics (see figure 3) [17].

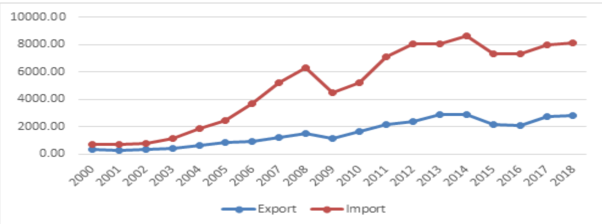

Fig. 3. Dynamics of Export and Import in Georgia in 2000-2018 (million US Dollars). Source: Ministry of Environmental Protection and Agriculture of Georgia

Georgia has a low level of export diversification, which is one of the main constraints in trade and economic relations between the countries. At the same time, the study of the dynamics of diversification of Georgian exports showed that it increased in 2011-2013. However, in recent years there is still a decreasing trend (see figure 4).

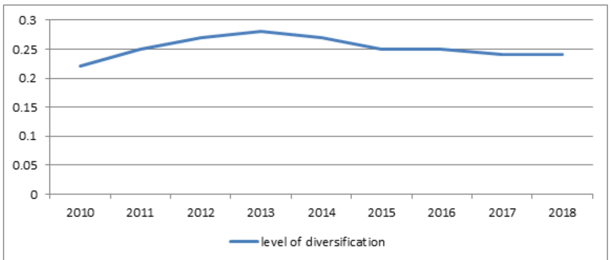

Fig. 4. Dynamics of Export and Import in Georgia in 2000-2018 (million US Dollars). Source: Ministry of Environmental Protection and Agriculture of Georgia [18]

An analysis of trade in agri-food products between Georgia and the Czech Republic showed that the share of agri-food products in the total exports of the Czech Republic in 2018 was 0.6%. According to the data for 2019, agricultural products worth 5.4 million US dollars were exported from Georgia to the Czech Republic. This indicator increased by 55% compared to the previous year, but it is lower than in 2015 and also lower than in 2017 (see figure 5) [25].

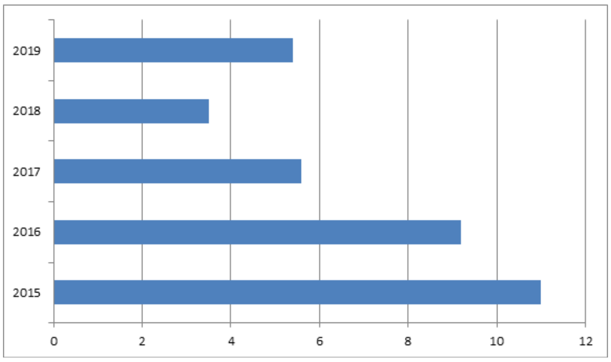

Fig. 5. Dynamics of Export of Georgian Agri-Food Products to the Czech Republic (million US Dollars). Source: Ministry of Environmental Protection and Agriculture of Georgia [18]

89% of exported products from Georgia to the Czech Republic are hazelnuts. In 2019, the export value of this product increased by 53% compared to the previous year. Thus, the main reason for the increase in the export of agri-food products from Georgia to the Czech Republic is the increase in the export of hazelnuts. In previous years, this indicator was characterized by a downward trend. It is also worth noting that in 2019, wine, spirits, fruit jams, dried fruits, soft carbonated drinks, etc. were also exported to the Czech Republic.

In 2019, exports of alcoholic beverages increased almost six fold compared to the previous year. In the export of wine and alcoholic beverages, the trend was slightly downward; in particular, in 2019 this figure was 8% higher than in the previous year. In contrast, in 2018, wine exports to the Czech Republic decreased by 65% compared to 2017, while exports of alcoholic beverages decreased by 62%.

In 2015-2019, import rates for agri-food products from the Czech Republic to Georgia are also of varying tendency (see figure 6).

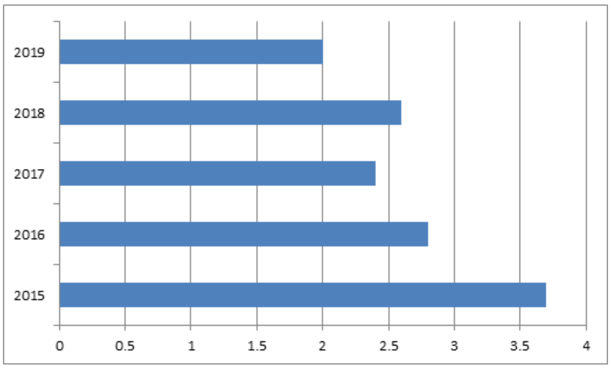

Fig. 6. Import of Czech agri-food products to Georgia [26]. Source: Ministry of Environmental Protection and Agriculture of Georgia

As of 2019, the Czech Republic accounts for 0.2% share in total agri-food imports. This year, agri-food products worth $ 2.0 million have been imported from the

Czech Republic to Georgia, which is $ 0.5 million less than the previous year. In general, in 2015-2019 the import rate is characterized by a decreasing trend.

Thus, trade and economic relations between Georgia and the Czech Republic are in the process of development, and the dynamics of the export-import balance in 2012-2019 fluctuates (see table 2).

Table 2. Georgia's external trade with the Czech Republic in the agri-food sector.

(thousand US Dollars)								
	2012	**2013**	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
Export	6,804	9,373	9,986	11,037	9,217	5,559	3,483	5,402
Import	1,808	2,366	4,652	3,664	2,799	2,373	2,580	2,048
Balance	**4,996**	**7,007**	**5,335**	**7,373**	**6,418**	**3,186**	**904**	**3,353**

Source: Compiled by the authors on an official data [3]

In 2019, the volume of export of Georgian agricultural and food products to the Czech Republic is higher compared to the previous year, but significantly lags behind the data of 2012-2016, for example, in 2012 the volume of exports amounted to 6.8 million US dollars, in 2013 – 9, 4 million US dollars, in 2014 – 9.98 million US dollars, in 2015 – 11.0 million US dollars, in 2016 – 9.3 million US dollars.

The dynamics of export and import volumes vary according to the types of agri-food products. The change in export volume is shown in figure 7.

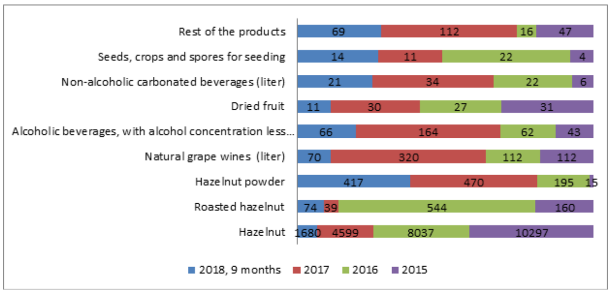

Fig. 7. Export to the Czech Republic by types of agri-food products (thousand US dollars). Source: Ministry of Environmental Protection and Agriculture of Georgia [18]

Hazelnuts predominate in the export of agri-food products (see figure 8).

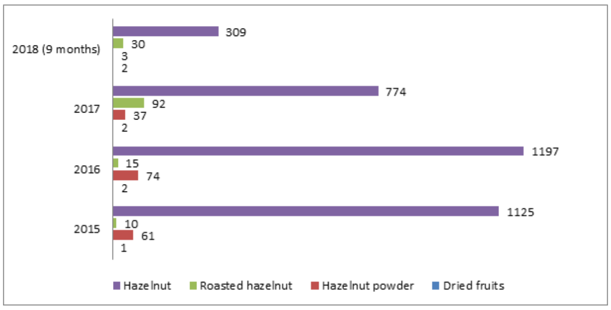

Fig. 8. Hazelnut export to the Czech Republic (tones). Source: Ministry of Environmental Protection and Agriculture of Georgia [18]

The largest share (60%) of top 25 hazelnut export markets of Georgia falls on European countries. The Czech Republic ranks third among the top five countries (Kazakhstan – 1,622 tonnes, Ukraine – 638 tonnes, Czech Republic – 343 tonnes, Slovakia – 274 tonnes, Germany – 256 tonnes) in terms of exports of hazelnut kernels from Georgia.

It should be borne in mind that the European market is characterized by high growth rates. Most of the imported hazelnut kernels in the countries of this region are processed, only a small part is sold in retail networks in the form of packages. Production costs in Europe have been rising lately, making it easier for European companies to purchase finished hazelnut products (e.g. roasted hazelnuts, skinned hazelnuts, diced hazelnuts, raw and roasted hazelnut powder and hazelnut paste) rather than importing hazelnuts directly.

In 2019, the export of hazelnuts to the Czech Republic amounted to 1238.6 tonnes, which is higher than in the previous year (688.9 tonnes in 2015, 794.0 in 2016, 931.9 in 2017, 1082.7 tonnes in 2018).

Various types of agri-food products are imported from the Czech Republic to Georgia: beer, sugar, non-alcoholic beverages, food additives, malt, etc. During the analyzed period, the volume of imports of food additives and beer decreased significantly. The volume of imports of these products to Georgia in 2019 compared to 2018 decreased by 17% and 20%, respectively. In addition, the volume of sugar imports in 2018 amounted to 132 000 US dollars, in 2016 – 1.1 million US dollars, and in 2019 sugar was not imported from the Czech Republic. Such a sharp decline in sugar import is the main reason for the decline in the value of imported agri-food products from the Czech Republic. Over the same period, imports of malt and non-alcoholic carbonated beverages increased, in particular, in 2019, compared to the previous year, the volume of imports of malt increased by 36%, and of non-alcoholic carbonated beverages – 12 times.

As of 2019, agri-food products worth 2.0 million USD are imported from the Czech Republic to Georgia, which is 0.2 million USD higher than in 2012, although lower by 2.6 million USD compared to 2014 (the highest volume of imports was recorded this year – 4.6 million dollars). An analysis of 2013-2016 showed that the volume of imports over this period showed a downward trend.

Different types of agri-food products are imported from the Czech Republic to Georgia (see figure 9, figure 10).

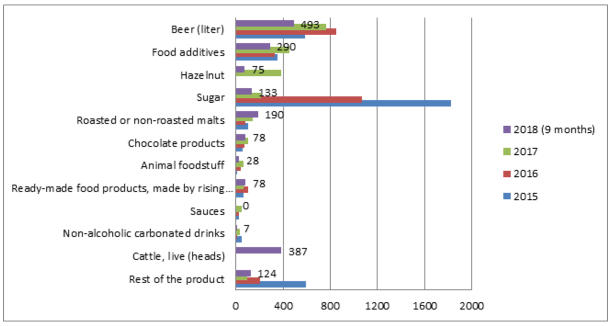

Fig. 9. Import from the Czech Republic by product types (thousand US dollars). Source: Ministry of Environmental Protection and Agriculture of Georgia [18]

5 Conclusion

Thus, the Czech Republic is one of the important partners of Georgia in terms of trade and economic relations. The doubling of relations between Georgia and the Czech Republic is actively discussed at the government level in Georgia. In this regard, Georgia's cooperation with the Czech Republic is promising not only in trade, but also in investment and modern technology. It is also important to diversify the export-import of agri-food products between the Czech Republic and Georgia, on the one hand, and transfer Czech production and modern technology to Georgia.

- Trade and economic relations between Georgia and the Czech Republic are in the process of development. It is expected that the assessments of the development trends of export and import of agri-food products will bring the economic ties between the countries to a qualitatively new level in the future.
- The markets of European countries, including the market of the Czech Republic, have been characterized by high growth rates in recent years. However, these markets are highly sensitive to price and quality. Prices formed on Georgian agri-food products will have a significant impact on export growth. In view of the above, it is necessary to study the factors affecting the value chain of agricultural products, as well as the pricing mechanism.
- The main food products exported from Georgia to the Czech Republic is hazelnut. Given the fact that the confectionery industry began to replace this ingredient with cheaper hazelnuts and raw materials, as well as processed products found in new export markets, it will be necessary to set the direction of formation and improvement of the effective value chain of nuts. However, food safety requirements are high in European countries that exporters of agri-food products, including the hazelnut exporters, must consider [19-22].
- Types of products are limited in the volume of exports and imports of agri-food products between Georgia and the Czech Republic. For the further development of trade and economic relations, diversification of export and import products will be required.
- The characteristics and changes of globalization in trade and economic relations require the development of appropriate government policies. It is extremely important to determine the direction of stimulating economic competitiveness and increasing added value in the country.
- In the future, trade and economic relations between Georgia and the Czech Republic are expected to double. In such circumstances, cooperation with the Czech Republic will be promising for Georgia both in the field of trade, and in the field of investment and the use of modern technologies. In the short term, it will be necessary to diversify the export-import of agri-food products between the Czech Republic and Georgia and begin the process of transferring Czech production and / or modern technologies to Georgia.
- Currently, the data on export statistics of Georgia's foreign trade are incomplete, which creates significant obstacles to the assessment of trade and economic processes between countries and hinders effective cooperation. Adjustment of the database of prices for export-import goods will create a reliable information base for calculating foreign trade indices, facilitate the implementation of foreign trade and bring it into line with international standards.

Abstract. In the present paper is analysed opinions about the tools for sustainable development and the ways to reduce inequality. Has been estimated the importance of regional development programs and strategies as the settlement of the economic and social issues, provided proof of their role in the effective development of regional economic policy. Has been determined the concentration level of economic activity by regions using distribution index to estimate equal development of regions. Has been made the conclusion that none of the regions of Georgia is notably specialized. The concentration level of business sectors in regions is substantiated by the distribution curve. In distribution curve was considered retail and wholesale distribution, as an example of maximally near to ideal distribution. It is proved by the analysis of distribution of curves, that the concentration level of business sectors in Georgian regions is quite unequal and none of them could be highlighted in industry specialization. The paper identifies the problems related to sustainable and equal development of regions, provided conclusions and recommendations to settle the mentioned issue by their estimation. In the process of study has been determined the factors of endogenous development of regions and advisable to improve the quality and efficiency of regional development institutions through the development of trial-programs for regional development.

1 Problem statement

Historically Georgia is a country with a regional system. The regional structures are adapted to the economic, social, cultural, ethnic, and other factors. According to the above-mentioned, there are 12 historical-statistical regions in the country. At the same time, Georgia is distinguished by many difficulties in terms of regional arrangement and a high level of inequality between the regions. Even more, inequality is visible not only between the regions but between municipalities within the regions. The regions differ from each other by areas, population, potential of natural resources, economic development, demographic specifics, social spheres, investment environment, traditions, and other signs.

Sustainable and equal development of regions is a relevant issue for researchers. The unusual difficulties and obstacles are characterized by the developing events in the modern world. At the same time, global economic development, including the economic situation of any country, is assessed based on aggregated data of its constituent and carried out planning of efficient regional policy. The effectiveness of the policy depends on a deep analysis of the object's spatial-territorial characteristics of the policy itself and the usage of sustainable and equitable development mechanisms of regions.

The Association Agreement between Georgia and the European Union obliges Georgia to emphasize and focus on the development of poor regions and territorial cooperation in the field of regional policy [1]. The attempt to develop poor territorial units and achieve equality between the regions may cause a step back from the potential development of economic growth for developing countries. Therefore, the questions to be answered are the following: What factors lead to unequal development of regions? What causes the high and constant level of social inequality between the regions? What mechanisms could be used for equal development of the regions? What factors are the main drivers for the sustainable development of the regions? To answer the questions above, it is needed to provide research.

Recommendations developed based on the research will support in mid-terms the implementation of integrated territorial measures in Georgia, achievement of regional development policy goals, increase competitiveness of the regions, balanced social-economic development and improvement of living conditions in the regions, improvement of infrastructure for support of sustainable development, support particular territories and identify endogenic factors of development, increase the quality and efficiency of regional institutions, development of trial-programs for regional development.

On the assumption of relevance of the issue, we have aimed to identify the challenges of the regions of Georgia in sustain and equal development and elaborate recommendations of its solution.

2 Research methods

In the process of research has been used methods of analysis, synthesis, and comparison.

The analysis of the documents of the strategy has been made using a comparison model. For achieving the goal and objectives of the study has been conducted desk survey. The existing theoretical and methodological approaches related to issues have been studied through reports, researches, and scientific articles. During the study, statistical calculations were carried out based on official sources (World Bank, Eurostat, Faostat, Geostat, and other); The primary materials necessary for publication were obtained from the National Statistical Office, the Ministry of Economy and Sustainable Development, the Ministry of Environment and Agriculture, the Ministry of Regional Development and Infrastructure of Georgia and various agencies.

For enhanced interviews and focus groups, various guides and questionnaires were developed, depending on the content of each task. The latter relied on information obtained as a result of desk research. The respondents in the research process were: representatives of local and international non-governmental organizations working on regional development issues, professors and researchers from universities and other research institutions; Representatives of the Ministry of Regional Development and Infrastructure and other government agencies; Industry experts, locals, and the representative of the business sector.

To determine the concentration of business activity and level of equal development in the regions has been used different indexes, including distribution and specialization indexes. Also has been used qualitative research tools (semi-structured interviews and meetings with focus groups).

3 Literature review

Finding tools for sustainable development in the regions and ways to reduce inequality is an important area of research in the scientific community nowadays. Sustainable development is in connection with the identification of territorial inequality issues. In this regard, the researchers analysing relevant issues of sustainable development and territorial fairness of the regions [2].

Currently, regions of the world are actively participating in the planning of sustainability with the following three main components: environment, economics, and capital. At the same time, researchers proposed ways to solve the issue related to the inequality development of the regions [3].

In European countries, it is especially important to study sustainable development issues of the regions from the perspective of sustainable resource management and fairness of social security. The researches in this field support and contribute to the formation of an equal society. In this regard, by studying different stages of regional development of Slovenia, researchers identified the connection between sustainable development of the region and health inequality overcoming [4].

Commonly, the concept of sustainable development of the regions is reflected integrated development of society (social, economic, and environmental protective). This type of conception is the basis of sustainable development of the regions in European countries. Scientists have analysed those tools, which are supporting the sustainable development of the regions in economic initiative framework, consequently scientists proposing the ways of sustainable development of the regions [5].

To achieve sustainable regional development and reduce regional inequality, it is important to elaborate on respective programs and strategies. Such programs and strategies are assessed by researchers based on economic and social issues, justified their role in elaboration of effective regional economic policy, identified the differences by location, culture, and other factors [6].

Sometimes, equality between the regions, in developing countries, is achieved through economic development. Frequently issue of disputes becomes on how effective-oriented regional policy supports the distribution of wealth between the regions and vice versa, could it be that equality becomes the main reason for ineffectiveness [7].

Scientists investigate the forms of relationships between the constituent parts of the region for the sustainable development of regions. The movement of a product, labour, or capital within a region may be random and may not indicate a specific direction of flow. [8]. The research literature also provides slightly different views on the definition of a functional region [9].

The main criteria to identify a functional region is the level of its isolation from other regions. The movement of product, labour, or capital not necessary to be explicitly organized within a functional region [10]. Worth mentioning that the regions make a significant contribution to the development of the process of manufacturing diversification in terms of social and cultural heritage, especially in mountainous regions [11].

The scientific papers include discussions on theoretical and empirical issues of economic growth in the regions, researches of the conceptual basics of economic growth, assessments of the paradigms, and trends of the regional development. At the assessing stage of the regional economic policy are discussed issues related to the difference in per capita income, also is sustained the role of areal structure in the formation of the labour market.

Research of equitable development of regions is especially relevant from the density of population and enterprises study prospective. The concentration of population and businesses obviously depends on land price, its characteristics, and constraints. In the case of Georgia, based on these factors, the issue requires deeper research.

However, in the field of spatial economics, should be made the following conclusions: land prices are more expensive the closer the sales market is, costs of housing and relocation increases the bigger the city size is, which reduces the real income of the population. The latter is the main reason why part of the population not willing to live in big cities [12]. We can say that only in a few cities of Georgia are the tendency of cost increase in terms of housing and relocation. Most cities are still less attractive to the citizens and businesses. Consequently, the price of land is relatively low, which allows the creation of centres and achieve high rates of agglomeration.

Nowadays, even more effective planning of regional development policy is a significant challenge for many countries worldwide. The goals of regional "equality" and "efficiency" are the main issues of discussion among the researchers in the field of regional policy. The subject of research and controversy is whether a regional policy guided towards efficiency contributes to an equal distribution of wealth among regions or vice versa, whether an approach guided towards equality can be the cause of inefficiency [13].

The goal of efficiency is to maximize the growth of the national economy and the optimal allocation of resources over time, while the goal of equality focuses on reducing unequal levels of income, wealth, and economic growth between regions. In certain cases, these goals could be compatible, but the significance of unequal development in regions requires the policy providers to focus on one main goal. Therefore, regardless of the choice of policy providers, the necessity to study the factors causing inequality is unavoidable. At the same time, it is necessary to make a benefit and cost analysis that will be obtained as a result of changing the economic growth direction with government intervention.

The effectiveness of regional structures in Georgia in terms of economic development policy objectives has not been studied. Evaluation criteria are accordingly not defined. Research is also complicated by the fact that the regional level of government is not defined by law, but historical districts/regions are subject to policy planning [14].

4 Results of research

The transformation of the economy of Georgia influenced the strategy of regional development, which takes into consideration the solution of their economic, social, and environmental issues. Georgia has certain guidelines for the sustainable development of the regions, for the expansion of regional markets [15]. Strategies and programs for the development of the regions of Georgia were developed. Based on analysis of these documents and the primary data received from the persons who were participated in the elaboration of the aforementioned documents, has been identified that mostly, documents include descriptive data about the regions [16].

However, should be mentioned that Georgia announced its readiness with the other countries of the UN to achieve sustainable development aims and targets by 2030 [17].

Mountainous regions have a key role in the socio-economic development of Georgia. Accordingly, based on an analysis of the socio-economic situation and existing potential, the Strategy for the Development of Mountain Settlements of Georgia presents a strategic vision for the inclusive and sustainable development of regions with an emphasis on the need for equal socio-economic development of the regions [17].

It is very important to determine the levels of governmental bodies for sustainable and equal development of the regions. As of now, Georgia considers four-level government: central, regional, district, and municipal. In terms of institutional and functional aspects, from the named levels, mostly developed the first level.

The second one, the regional level, is determined by historical, cultural, geographical, economic, ethnic, and other signs, and such a division has preserved the centuries. At the same time, it is significant to create steady food manufacturing conditions in the regions. Regional features still firmly bare in minds of the population. The process of regionalization still is irreversible, and it is effective to manage the country and stabilize economic conditions through the regional institutions [18; 19] and optimizing knowledge [26]. However, at the regional level institutional structures, undeveloped infrastructure, cluster relations [20; 21] are weak, there are no conditions for sustainable development, and the difference in wealth fare indexes between the regions is obvious.

By territories largest region is almost 5.6 times bigger than the smallest one. By population of the smallest region as compared to the largest is almost 17 times less [23]. There is a deficiency of urban-type mid-size territories in the country, which causes social-economic inequality between the regions.

By combining assessments of various approaches, theories, and models of sustainable and equitable regional development, we have identified the main characteristics of the regions of Georgia:

- regions are characterized by economic similarity; there are some central places, so-called "Centers of gravity";
- natural resources, ecosystems, or other geographic features within a region are similar;
- the regions are characterized by similar impacts under the influence of various external and internal factors;
- each region includes a small number of high demand settlements and a large number of low demand settlements and it is characterized by manageability.

The grouping of settlements in the regional context showed that the number of different types of settlements is quite asymmetric, moreover the spatial difference in consumer demand between urban settlements, and rural settlements is huge and the regions do not correspond to this index of inequality (see Table 1).

The distribution of GDP across regions is also asymmetric (see Figure 1).

Relatively high GDP is reflected in regions with self-governing cities and industrialized zones. For example, the Autonomous Republic of Adjara, Kvemo Kartli, and Imereti in Georgia. The indicators are especially low in the regions of Guria, Samtskhe-Javakheti, Mtskheta-Mtianeti, Racha-Lechkhumi and Kvemo Svaneti in Georgia.

The growth rate of the GDP of Georgia was 5.1% in 2019 [20]. During the pandemic, there are expectations that this indicator will keep decreasing, according to

 https://doi.org/10.1051/e3sconf/202128011007

experts, mostly vulnerable and impacted sector will be tourism, which will lead to more inequality between the regions [20].

Table 1. Grouping of settlements by number (pcs.) and average population (people) by regions

Regions	Number of cities	Average population living in 1 city	number of towns	Average population living in 1 town	number of villages	Average population living in 1 village	Spatial difference in consumer demand in urban settlements from rural settlements
Autonomous Republic of Adjara	2	84,693	5	3,078	322	463	189
Guria	2	10,590	5	2,145	186	438	29
Imereti	11	23,168	2	1,834	535	515	49
Kakheti	9	7,947	0	-	333	742	11
Mtskheta-Mtianeti	2	7,054	5	1,430	480	153	56
Racha-Lechkhumi and Kvemo Svaneti	3	2,008	2	474	251	100	25
Samegrelo-Zemo Svaneti	8	15,535	2	2,557	521	387	47
Samtskhe-Javakheti	5	9,107	7	1,304	259	409	25
Kvemo Kartli	7	24,731	5	1,401	351	695	38
Shida Kartli	4	23,589	2	5,428	373	424	68

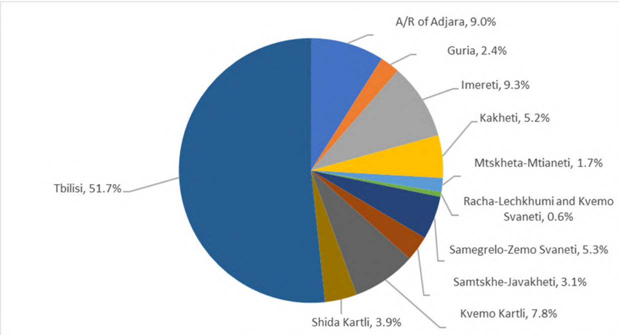

Fig. 1. Regional structure of GDP of Georgia [17; 23]

Significant inequality in GDP for the regions of Georgia was observed even before the pandemic: GDP per capita hovers 2.7 times between the richest and poorest regions. Tbilisi has the largest share in the country's GDP (49%) [20]. In addition, 72% of the total turnover of the business sectors comes from companies operating in Tbilisi. This index is 2.5 times more than other company’s index operating in other regions of Georgia. Georgian economy is quite diversified by its structure, but the economy of Tbilisi is more competitive. 86% of foreign direct investments come to the Tbilisi region of Georgia. Meanwhile, there is a decrease tendency of foreign direct investments in most of the regions of Georgia, such as Guria, Racha-Lechkhumi and Kvemo Svaneti, Shida Kartli, and Mtskheta-Mtianeti [16; 17; 20]. This kind of concentration of the economy is the biggest challenge for Georgia and its regions.

The study of the needs and potential of regional development showed that Georgia, on the one hand, has many challenges for further development, and on the other hand, has significant potential that can be effectively used for deepening of economic development and improvement of the quality of life of its citizens.

To find the ways of equal development of the regions it is vital to know what concentration of economic activity in the regions is.

We have measured the concentration of specific sectors in the regions by using a distribution index, took into consideration regional inequality characterized by the small countries [24]. Analysis of the results showed that none of the regions is notably specialized.

Among the relatively concentrated types of economic activity in the regions, there is only agriculture, forestry, and fish farming, as well as the mining industry, and quarrying. In this regard, the regions of Racha-Lechkhumi, Samegrelo-Zemo Svaneti and Kvemo Kartli stand out. In terms of mining and quarrying, this sector is especially concentrated in the Kvemo Kartli and Imereti regions.

The level of concentration of business sectors in the regions has been precise by distribution curves [20; 25]. In time of making distribution curves has been considered that retail and wholesale is as an example of maximally near to ideal distribution. In this case, involvement in business sectors from the regions is proportionally equal. The deviation from this curve reflects a high concentration in one or more regions (see Figure 2).

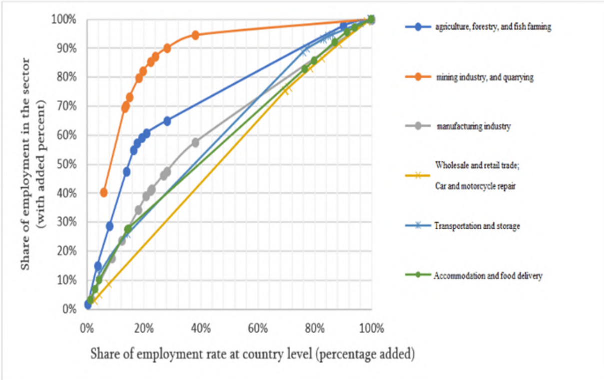

Fig. 2. Distribution curve by regions of Georgia by five sectors [20]

The distribution of the curves also affirmed that the level of concentration of business sectors in the regions of Georgia is rather unequal. This means that none of the regions are distinguished by industry specialization, only a relatively high specialization observed in the Kvemo Kartli region, the merit of which is existing natural resources and "support" on the issuance of permissions for their extraction.

5 Conclusion

Consequently, for the sustainable and equitable development of regions in Georgia, for the effective functioning of the regions is needed strong correlation between the components of the population, the business sector, and the territory. The above mentioned will create and strengthen regional relations, interdependencies, create conditions for sustainable development and a basis for a relatively equal concentration of economic activity.

Based on the results of the study, the following conclusions and recommendations were made:

- indicators of economic activity in the regions of Georgia are very different from each other. These figures are affected by the decision of the population and the business sector about their place of residence, work, and sphere of economic activity. Consequently, the possibilities for sustainable development of regions should be determined not by the principle of territorial similarity, but by the spatial characteristics of territorial units;

- one of the obstacles to the possible benefits of spatial concentration and economic agglomeration is the land price. Most cities in Georgia are less attractive for the population and business, therefore the price of land is relatively low. At this stage of development, low land prices will create an opportunity to create centers and achieve a high speed of the agglomeration process;
- the analysis of distribution indexes by the regions of Georgia showed that the concentration of sectors is not typical for none of the regions, and economic activity between regions is diversified. To increase the concentration and rapid development of the municipality recommended the following: to organize the infrastructure with a focus on the centers of the municipality; Develop and expand ties between municipalities; Create appropriate infrastructure connecting territorial units around municipal centers; facilitate migration to settlements if needed, etc.

In planning regional policy, it is necessary to choose between the goals of "equality" and "efficiency". Should be noted that the EU's “rapprochement” policy is more focused on achieving the goal of “equality”. By the policy of rapprochement with the EU, reducing inequality between regions should be the high priority of Georgia's strategic goals.

Unequal development and weak territorial ties are obvious between the regions of Georgia. It is necessary to establish and develop functional interdependencies between territorial units. Especially, should be improved links between regional centres and the capital city.

The following approaches should be used to identify opportunities for equal development in the regions: a clear focus on efficiency; Concentration of economic activity as a strong side of regional development; Replacing the sectoral approach with a multi-sectoral policy, focused on territorial development; Promotion of specialization, clustering, etc.

The analysis of growth opportunities of the regions of Georgia has proved that the perspective of rapprochement and equal development is more short-term for those regions which have economic centers. In case the regions do not have strong centers, it is recommended that regional policy was initially focused on the creation and development of such centers.

The analysis of the existing four-level government in Georgia (central, regional, district, and municipal) has been proved, that the regionalization process is irreversible nowadays and that is possible to achieve equal and sustainable economic development through regional institutions; lack of mid-sized urban areas aggravates further inequality problem.

Comparison of territorial, demographic, economic, social and other factors of the regions of Georgia showed that there is harsh inequality between social-economic development levels between the regions.

The Study of the needs and potential of regional development showed that Georgia, on the one hand, has many challenges for further sustainable and equal development, and on the other hand, has significant potential to improve economic development and quality of life of its citizens.

Abstract. One of the elements that ensure the sustainability of the environment is the vegetation cover. The vegetation cover contributes to the balanced functioning of ecosystems. It is the national parks rich in phytodiversity that attract the attention of scientists. The article presents an ecological analysis of the flora of the Kremenets Mountains National Park. The research was carried out in the areas of the mountains Divochi Skeli, Strakhova, Masliatyn, Chercha, Zamkova, Bozha. 10 florocoenotypes were identified in the study areas. The most numerous is the nemoral forest coenotype. The flora was analyzed for abiotic factors such as light, temperature, humidity, soil. It is these indicators that have an important impact on the formation of vegetation cover and the life processes of plants. It was found that facultative heliophytes, mesothermal plants, mesophytes, and mesotrophs predominate in the study areas. The vegetation cover has clear forest-steppe features. The classification of life forms of plants is given. Relicts and endemics are confined to steppe and calcepetrophilic areas. Flora synanthropization is observed on the study areas.

1 Problem statement

Vegetation cover as an autotrophic component provides energy through photosynthesis and together with the heterotrophic component is the key to the normal functioning of ecosystems.

In natural ecosystems, the vegetation cover is represented by a wide variety of species and life forms. In all ecosystems, vegetation plays a particularly important environmental and self-organizing role. It determines the spatial, visual boundaries, their structure, internal climate, soil characteristics, the set and distribution of animals and microorganisms, corrects and transforms external interactions, balances and extinguishes them and directs the energy metabolism as a whole. Green vegetation is the only generators of primary organic matter and the main energy storage, on the basis of which chemical reactions, physical and biological processes in ecosystems take place [1].

From an ecological point of view, the study of flora and vegetation cover is important, first of all, in the aspect of that specific, only inherent work, which they perform in the ecosystem as a material component. Of particular importance are the functions of the vegetation cover, such as the absorption of various substances and energy from other components of ecosystems and their synthesis into primary organic substances used for building the bodies of plants and for their internal catabolism; the release of waste products by vegetation, and with them part of the captured energy during their formation; the return to the atmosphere and soil of a part of the accumulated energy and substance during the death of organs or whole plants; transformation by vegetation cover of the properties and states of other components of ecosystems in the process of growth, absorption, accumulation and release of substances and energy [2].

All the parameters of the atmosphere that make up terrestrial ecosystems are under the control of the vegetation cover: air humidity, thermal regime, illumination, gas composition. Moreover, the higher the vegetation, the denser its thickets and the more complex the structure, the more noticeable its role in the transformation of the atmosphere. Plants also affect the thermal regime of soils, moisture, their structure, the nature of organic matter, pH, especially its upper horizons saturated with roots. The performance of the listed functions of phytocenoses is associated with physiological processes: photosynthesis, respiration, transpiration, absorption of water, minerals, and growth. From an ecological point of view, the results of these processes and their impact on the overall ecosystem process are important [3, 4].

It is important the environmental stabilization value of vegetation cover, soil-protecting, water-saving, landscape, aesthetic, scientific and educational. Plants provide protection for rare populations. A rare species can be preserved only within the framework of certain phytocenoses, and hence the need arises for the protection of the phytogenofund and phytocenofond. Many rare and endangered plant species are consortium associated with rare representatives of the animal world. The study of their ecological and biotic properties also contribute to the preservation of populations of endangered species of fauna [5, 6].

Aboriginal species and their populations, which make up the natural flora, are concentrated in groups united by a common growth conditions and ecological-coenotic relationships, forming certain florocoenotypes. Such an analysis makes it possible to understand the features and confinement of certain groups of natural species to certain coenoecological niches, to show the advantage of certain floroceno-ecological complexes, their interpenetration, the genesis of the peculiarities of the formation of a certain flora. An important indicator of the ecological characteristics of phytocenoses is their relation to abiotic factors of the environment (especially light, temperature, humidity and soil), and plant life forms, which are important for plant life, since they affect the course of physiological, biochemical and other processes.

2 Materials and research methods

Stationary research was carried out in the most interesting and typical, in terms of phyto-diversity, mountain areas: Divochi Skeli, Strakhova, Masliatyn, Chercha, Zamkova, Bozha. The main research methods were: morphological-geographical and ecological-phytocenotic description of species and plant communities. The definition of the species composition and the nomenclature of Latin names are filed according to Chronicle of the nature of the Kremenets Mountains National Nature Park [7] and Keys to higher plants of Ukraine [8]. Ecological and cenotic characteristics of flora and vegetation cover according to B. V. Zaverukha [9]. Classification of life forms of plants is filed by Raunkier.

3 Results and discussion

On the territory of the studied mountains, we have identified the following floroceotypes: boreal forest, nemoral forest, meadow, meadow-steppe, steppe, calcepetrophilic, psamophilic, xerophytic-shrub, hygro-hydro swamp, agro-ruderal (Table 1, Fig. 1).

The boreal forest florocoenotype unites 41 species (5%), it is characterized by Holarctic species, which have areas associated with light coniferous and partially mixed coniferous-broad leaved forests: *Pinus silvestris* L., *Juniperus communis* L., *Calluna vulgaris* (L.) Hull., *Rumex acetosella* L., *Pyrola media* Sw., *Orthylia secunda* (L.) House., *P. rotundifolia* L., *Jasione montana* L., etc.

The most numerous nemoral forest coenotype includes 239 (29%) florocenoelements: *Quercus robur* L., *Fagus sylvatica* L., *Betula pendula* Roth., *B. klokovii* Zaverucha, *Carpinus betulus* L., *Corylus avellana* L., *Asarum europaeum* L., *Anthyrium filix-femina* (L.) Roth., *Stellaria holostea* L., *Dryopteris filix-mas* (L.) Schott., *Anemone nemorosa* L., *Hepatica nobilis* Mill., *Clematis recta* L., *Actaea spicata* L., *Rumex sylvestris* (Lam.) Wallr., *Viola reichenbachiana* Jord. ex Boreau, *Dentaria glandulosa* Waldst et Kit., *Lunaria rediviva* L., *Euphorbia amygdaloides* L., *Astragalus glycyphyllos* L., *Astrantia major* L., *Atropa bella-donna* L., *Laserpitium latifolium* L., *Scopolia carniolica* Jacg., *Betonica officinalis* L., *Convallaria majalis* L., *Lilium martagon* L., *Carex pilosa* Scop., *Poa nemoralis* L., etc. This florocoenotype is distinguished by a certain heterogeneity typical for hornbeam-oak, oak and beech forests.

Table 1. Ecological and coenotic characteristics of the flora of the study areas.

No.	Floroceotypes	Number of species
1	Boreal forest	41
2	Nemoral forest	239
3	Meadow	123
4	Meadow-steppe	115
5	Steppe	18
6	Calcepetrophilic	34
7	Psamophilic	19
8	Xerophytic-shrub	18
9	Hygro-hydro swamp	53
10	Agro-ruderal	165
	Total	825

The meadow florocoenotype is represented by 123 (14.9%) florocenoelements. There are almost no relict and endemic species here, but there are many widespread species of the temperate latitude type, mainly of Holarctic and Palaearctic nature: *Equisetum pratense* Ehrh., *Coronaria coriacea (Moench.)* Schischk., *Herniaria glabra* L., *Polygonum bistorta* L., *Lathyrus pratensis* L., *Lysimachia nummularia* L., *Geranium pratense* L., *Centaurea jacea* L., *Hieracium umbellatum* L., *Agrostis stolonifera* L., *Bromus mollis* L., *Phleum pratense* L., *Poa trivialis* L., *P. pratensis* L., *Festuca pratensis* Huds., etc. This florocoenotype is due to the small area of meadows, large areas of the former meadows have been plowed up, some of them have been converted into pastures.

The meadow-steppe florocoenotype includes 115 (13.9%) florocenoelements, there are accumulated species of mainly forest and steppe zonal types: *Ranunculus auricomus* L., *Dianthus andrzejowskianus* Zapal., *Thalictrum flavum* L., *Helianthemum nummularium* (L.) Mill., *Filipendula vulgaris* Moench., *Potentilla patula* Waldst., *P. argentea* L., *Medicago procumbens* Bess., *Polygala comosa* Schkuhr., *Trifolium dubium* Sibth., *Galium verum* L., *Onosma subtinctoria* Klok., *Verbascum thapsus* L., *Salvia dumetorum* Andrz., *Veronica incana* L., *Campanula sibirica* L., *Poa angustifolia* L., etc.

The steppe florocoenotype is small in number 18 (2.2%) species, it consists mainly of Mediterranean and Pontic cenoelements: *Euphorbia seguieriana* Neck., *Polygala podolica* DC., *Asperula cynanchica* L., *Aster amellus* L., *Trinia multicaulis* Schischk., *Helictotrichon desertorum* (Less.) Nevski, *Stipa cappilata* L., *S. pennata* L., etc.

The calcepetrophilic florocoenotype unites 34 (4.1%) species; it is represented by the florocenoelements of chalk, limestone, gypsum deposits and steppe groups:

Asplenium ruta-muraria L., *Minuartia aucta* Klok., *Aurinia saxatilis* (L.) Desv., *Helianthemum canum* (L.) Baumg., *Alysum gmelinii* Jord., *A. calycinum* Stapf., *Sempervivum ruthenicum* Schnittsp. et C.B. Lehm., *Euphorbia volhynica* Bess. ex Szaf., Kulcz.,*Sedum acre* L., *Anthyllis schiwereckii* (DC) Blocki, *Galium exoletum* Klok., *G. besseri* Klok., *Allium strictum* Schrad., *Salvia cremenecensis* Bess., etc.

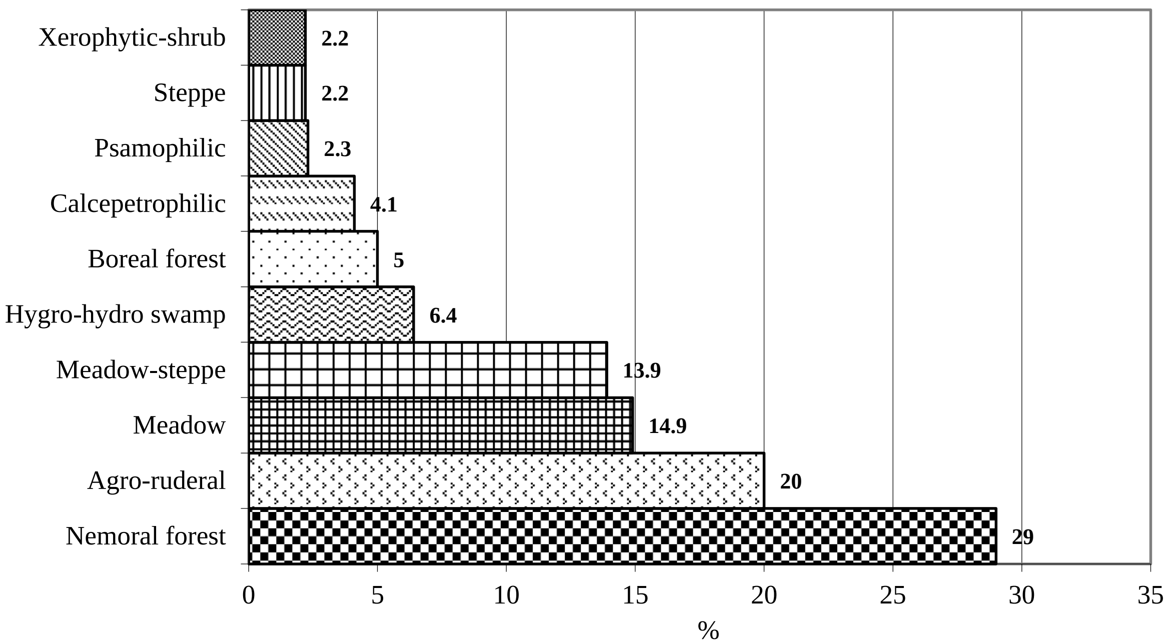

Fig. 1. The ratio of florocoenotypes in the study areas (%).

The psamophilic florocoenotype includes 19 (2.3%) species, these are species of sandy deposits: *Gypsophila paniculata* L., *Cardominopsis arenosa* (L.) Hayek, *Astragalus onobrychis* L., *Potentilla arenaria* Borkh., *Thymus serpyllum* L., *Verbascum densiflorum* Bertol., *Onobrychis arenaria* (Kit.) DC., etc.

The xerophytic-shrub florocoenotype is represented by 18 (2.2%) species: *Spiraea media* Franz. Schmidt, *Crataegus praearmata* Klok., *C. lipskyi* Klok., *Cerasus fruticosa* L., *Rosa livescens* Bess., *R. czackiana* Bess., *R. jundzillii* Bess., *Prunus stepposa* Kotov., *Padellus mahaleb* (L.) Mill., etc.

The hygro-hydro swamp florocoenotype contains 53 (6.4%) florocenoelements: *Ranunculus sceleratus* L., *Caltha palustris* L., *Filipendula denudata* (J. et C. Presl) Fritsch., *Potentilla erecta* (L.) Raeusch., *Lythrum salicaria* L., *L. virgatum* L., *Juncus geniculatus* Schrank., *J. inflexus* L., *Veratrum lobelianum* Bernh., *Molinia careulea* Maench. ex Steud., *Acorus calamus* L., *Phragmites australis* Trin. ex Steud., etc. This florocoenotype includes mainly typical species of sedge and herbaceous-sedge bogs.

The agro-ruderal florocoenotype is formed from segetal and ruderal plants. It contains 165 (20%) florocenoelements: *Fumaria officinalis* L., *F. parviflora* Lam., *Sinapis arvensis* L., *Atriplex prostrata* Boucher., *Thlaspi arvense* L., *Euphorbia helioscopia* L., *Erysimum cheiranthoides* L., *Erodium cicutarium* (L.) Her., *Nonea pulla* (L.) DC., *Strophiostoma sparsiflora* Turez., *Mentha arvensis* L., *Lycopsis arvensis* L., *Carduus crispus* L., *Solanum nigrum* L., *Cirsium oleraceum* (L.) Scop., *Bromus secalinus* L., *Urtica dioica* L., *Setaria pumila* (Poir.) Schult., *S. viridis* (L.) Beauv., etc.

In relation to the light conditions in the study areas, we identified the following ecological groups of plants. The most numerous are facultative heliophytes (shade-tolerant ones - they can tolerate more or less shading, but grow well in the light), these are 538 species (65.2%). These are such species as *Botrychium lunaria* (L.) Sw., *Trollius europaeus* L., *Phyllitis scolopendrium* (L.) Newm., *Anemone nemorosa* L., *A. ranunculoides* L., *Cerastium holosteoides* Fries, *Corylus avellana* L., 8 species of the genus Viola, *Calluna vulgaris* (L.) Hull, *Helianthemum nummularium* (L.) Mill., *Rhodococcum vitis-idaea* (L.) Avror., 5 species of the genus Euphorbia, 5 species of the genus Crataegus, 7 species of the genus Rosa, 4 species of the genus Inula, *Galanthus nivalis* L., *Tragopogon major* Jacq., many species of the Orchidaceae family, *Calamagrostis canescens* (Web.) Roth., etc.

Heliophytes (light-loving - plants of open, well-illuminated areas), their number is 256 species (31%): *Larix decidua* Mill., *Aquilegia vulgaris* L., *Pinus sylvestris* L., *Adonis vernalis* L., *Minuartia aucta* Klok., *Silene vulgaris* (Moench) Garcke, *Gypsophila paniculata* L., *G. fastigiata* L., *види роду Alyssum, Sedum acre* L., *S. ruprechtii* (Jalas) Omelcz., *Hypericum perforatum* L., *H. elegans* Steph. ex Willd., *Fragaria viridis* Duch., *F. vesca* L., *Scabiosa ochroleuca* L., *Potentilla arenaria* Borkh., *Scorzonera purprea* L., *Aster amellus* L., *Stipa capillata* L., *S. pennata* L., etc.

The least numerous group is sciophytes (shade-loving - plants of the lower tiers of shady forests, caves), their number is 31 species (3.8%): *Ophioglossum vulgatum* L., *Cystopteris fragilis* (L.) Bernh., *Athyrium filix-femina* (L.) Roth., *Dryopteris filix-mas* (L.) Schott., *Pteridium aquilinum* (L.) Kuhn., *Asarum europaeum* L., *Asplenium* *ruta-muraria* L., *A. trichomanes* L., *Dentaria glandulosa* Waldst. et Kit., *Hepatica nobilis* Mill., etc. (Fig. 2).

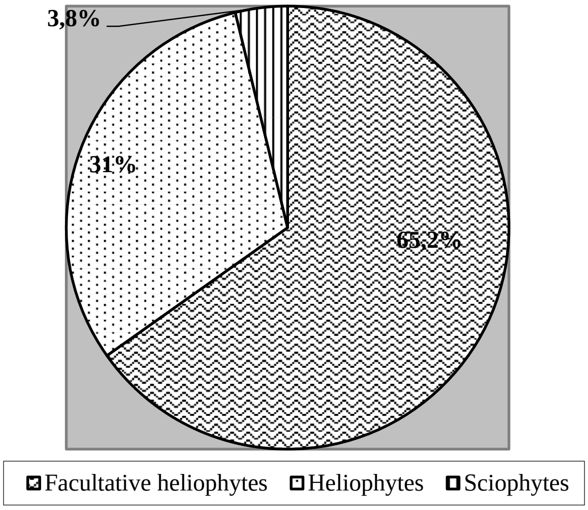

Fig. 2. The ratio of ecological groups of plants in relation to light in the study areas.

In relation to temperature, in the study area, the following groups of plants can be distinguished: mesothermal (the most common), their number is 535 species (64.8%). These are such as *Larix decidua, Actaea spicata* L., *Malva pusilla* Smith., *Daphne mezereum* L., *Polygala podolica* DC., *Staphylea pinnata* L., *Centaurea jacea* L., *Pyrethrum corymbosum* (L.) Scop., *Poa angustifolia* L., etc.

There are 241 species of thermophilic plants (29.2%): *Helianthemum canum* (L.) Baumg., *Sempervivum ruthenicum* Schnittsp. et C. B. Lehm., *Alyssum gmelinii* Jord., *Euphorbia volhynica* Bess. ex Szaf., Kulcz. et Pawł., *Chamaecytisus austriacus* (L.) Link., *Galium exoletum* Klok., *Eryngium planum* L., *Jurinea pachysperma* Klok., *Helichrysum arenarium* (L.) Moench, *Festuca valesiaca* Gaud., etc.

The least numerous group is cryophilic plants, there are 49 species (6%): *Orthilia secunda* (L.) House, *Hedera helix* L., *Pyrola media* Sw., *Lathraea squamaria* L., *Scirpus sylvaticus* L., *Orchis militaris* L., *Arum besseranum* Schott, etc. (Fig. 3).

Depending on the humidity regime in which the plants grow, we identified the following ecological groups in the study areas (Fig. 4). The humid and moderately warm climate of this territory determines the advantage of mesophytes (plants living in conditions of medium humidity), these are 705 species (85.4%). This includes most trees and shrubs, meadow and forest grasses: *Pinus sylvestris*, *P. banskiana* Lamb., *Fagus sylvatica* L., *Quercus robur* L., *Q. petraea* (Mattuschka) Liebl., *Corylus avellana, Dianthus carthusianorum* L. A smaller group is hygrophytes (plants that live in conditions of excessive moisture), this includes 60 species (7.3%): *Caltha palustris* L., *Potentilla erecte* (L.) Rausch., *Coronaria coriacea* (Moench) Schischk. et Gorschk., *Filipendula denudate* (J. et C. Presl) Fritsch, *Myosotis palustris* L., *Valeriana stolonifera* Czern., *Veratrum lobelianum* Bernh., *Pedicularis palustris* L., *Orchis militaris, Molinia careulea* (L.) Moench., etc.

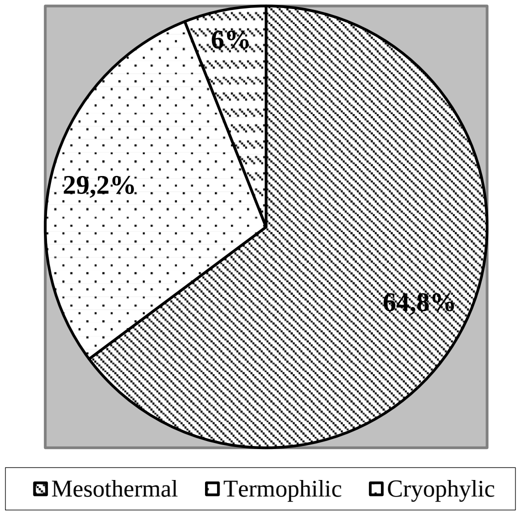

Fig. 3. The ratio of ecological groups of plants in relation to temperature in the study areas.

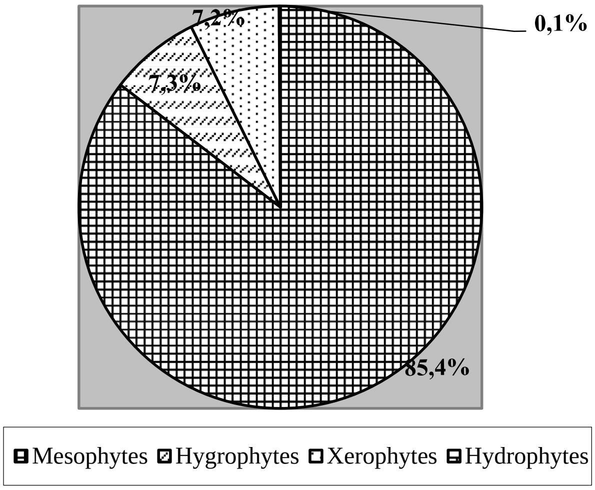

Fig. 4. The ratio of ecological groups of plants in relation to humidity in the study areas.

Xerophytes are plants in arid areas that are able to withstand prolonged atmospheric and soil drought, 59 species (7.2%): *Minuartia aucta* Klok., *Alyssum gmelinii, A. calycinum* L., *Gypsorhila paniculata, G. fastigiata* L., *Sempervivum ruthenicum, Carlina biebersteinii* Bernh. ex Hornem., *C. vulgaris* L., *Sedum ruprechtii, S. acre, Asparagus verticillatus* L., *Stipa capillata, S. pennata* , *Koeleria glauca* (Spreng.) DC., *etc.*

The least numerous group is hydrophytes includes 1 species (0.1%). These are higher aquatic plants attached to the soil and submerged in water only with their lower part: *Phragmites australis* (Cav.) Trin. ex Steud.

Depending on the autoecological characteristics of plants in relation to the gross chemical composition of the soil, the following ecological groups have been identified in the study area (Fig. 5). The most numerous are mesotrophs (plants are moderately demanding of soil nutrients), this includes 368 species (44.6%). These include: *Picea abies* (L.) Karst. *Populus alba* L., *Euonymus verrucosa* Scop., *E. europaea* L., *Chaerophyllum temulum* L., *Tragopogon* major, *Laser trilobum* (L.) Borkh., *Lilium martagon, Ferulago* *sylvatica* (Bess) Reichenb., *Festuca ovina* L., *Bromopsis inermis* (Leyss.) Holub, etc.

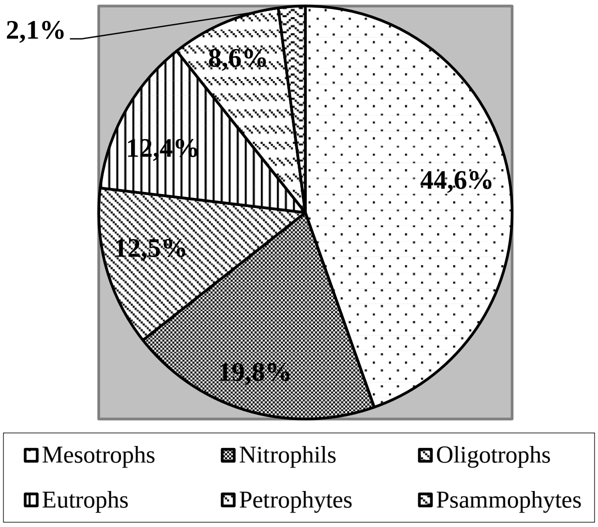

Fig. 5. The ratio of ecological groups of plants in relation to soil in the study areas

Nitrophils (plants are especially demanding for an increased nitrogen content in the soil), this includes 164 species (19.8%), these are mainly weeds, pasture plants, species that settle in forest clearings, garbage places: *Chenopodium album* L., *Ch. bonus henricus* L., *Urtica dioica* L., *Rumex crispus* L., *Chamaerion angustifolium* (L.) Holub., *Atriplex prostrata* Boucher, *Solanum dulcamara* L., *Heracleum sibiricum* L., *Elytrigia intermedia* (Host.) Nevski, etc.

Oligotrophs (plants growing on barren soils), this includes 103 species (12.5%): *Pinus sylvestris, P. bancsiana, Orthylia secunda* (L.) House, *Calluna vulgaris, Pyrola media* Sw., *P. rotundifolia* L., *Ononis arvense* L., *Geum rivale* L., *Gratiola officinalis* L., *Epilobium hirsutum* L., etc.

Eutrophs (plants growing on nutrient-rich substrates), these are 102 species (12.4%): *Fagus sylvatica, Quercus robur, Q. petraea, Q. austriaca* Willd., *Anemone nemorosa, A. sylvestris* L., *Corydalis bulbosa* (L.) DC., *Ficaria verna* Huds., *Stellaria media* (L.) Vill., *Daphne mezereum* L., *Lunaria rediviva* L., *etc.*

A small group of petrophytes or lithophytes (plants that grow on rocks and stony places) are 71 species (8.6%): *Euphorbia volhynica, E. seguieriana* Neck., *Gypsophila paniculata, G. fastigiata, Minuartia aucta, Helianthemum canum, Rosa czackiana* Bess., *R. pimpinellifolia* L., *Cerasus fruticosa* Pall., *Sempervivum ruthenicum, Sedum acre, S. ruprechtii, Salvia cremenecensis* Bess., *Anthyllis schiwereckii, Astrantia major, Dracocephalum austriacum* L., *etc.*

The least numerous group of psammophytes (plants that have a special adaptation to life on the sands) are 17 species (2.1%): *Potentilla arenaria* Borkh., *Cardaminopsis arenosa* (L.) Hayek., *Onobrychis arenaria* (Kit.) DC., *Trifolium arvense* L., *Hieracium pilosella* L., *Linaria genistifolia* (L.) Mill., *Festuca rubra* L., etc.

The flora of the study areas is characterized by a variety of life forms (Fig. 6). Phanerophytes (trees and shrubs) are 74 species (9%). Hamephytes are 25 species (3%): *Helianthemum canum, Calluna vulgaris, Rhodococcum vitis-idaea, Orthilia secunda, Pyrola media, P. rotundifolia, Vinca minor, Thymus serpyllum, Th. pulegioides, Th. Marchallianus*., etc. Hemicryptophytes are 428 species (51.9%): Dracocephalum austriacum, *Astrantia major, Phyllitis scolopendrium*, etc. Therophytes are 228 species (27.6%): *Anagallis arvensis, Xanthium strumarium ,Papaver rhoeas, P. argemone, Bidens tripartita* L., *Herniaria glabra* L. etc. There are 70 species of cryptophytes (8.5%). This includes most types of families Liliaceae, Iridaceae, Alliaceae, Orchidaceae.

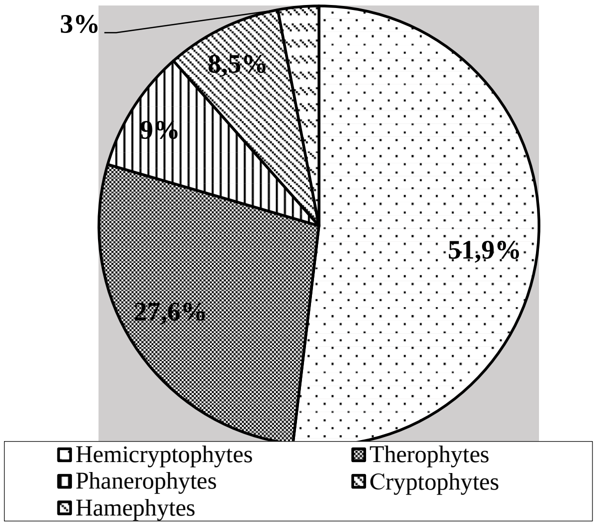

Fig. 6. The ratio of life forms of plants in the study area.

When studying the specificity of the flora of a certain region, the phenomenon of endemism is of great importance. The proportion of endemics in a particular flora characterizes the degree of individuality of a given flora. An indicator of the originality of a particular flora is the presence of a significant number of endemics. The problem of flora endemism is one of the most important indicators in plant geography, both in the scientific and practical sense.

The age of the phytobiota of the Kremenets Mountains National Nature Park can be attributed to the middle Miocene. Already in the lower Tortonian, the ecologically determined development of the flora proceeded in the direction of creo- and xerophytization. In the Upper Miocene and at the beginning of the Pliocene, a dissected landscape with forest-steppe vegetation was formed.

By the middle of the Pliocene, the forest-steppe flora in the region was replaced by the steppe flora, and calceopetrophyton developed. The next mesophytization of the climate, the invasion of the coreal flora forced the plant remains of the favorable period to migrate to the storages - steep, heavily projected slopes with a calcium substrate. The Pliocene was characterized by the development of the calceo-xeromorphic complex with the transformation of the ancient subtropical-forest complex into a modernized xeromesophytic temperate forest complex. During the Pleistocene, the flora underwent several periods of cooling and warming. The results of studying the genesis of the flora indicate that during the Pleistocene, under conditions of a dissected relief, there were constant changes in the ecological conditions of a microrefugium nature, which contributed to the preservation of many ancient species [10].

During the last millennium, two complexes of adventive plants have been formed: archaeo- and neophytes. Endemic species of different ages were formed on the basis of the autochthonous nucleus.

The leading genesis complexes of flora formed at the end of the Pliocene. Then the nemoral, calceopetrophilic, psamophilic, hydrophilic, savanoid- meadow-steppe flora was formed. After xero-cryophytic transformation during the Pleistocene, a steppe complex is formed, a complex of coniferous and birch forests, which acquired a modern composition in the Holocene [10].

In the studied territories, we identified 32 relics (3.9% of the total number of species), of which 7 species are tertiary relics, 25 species are glacial and interglacial, and 60 are endemic (7.2% of the total). The richest in the number of natural endemic species are the families Orchidaceae - 10 species, Rosaceae - 10 species, Poaceae - 9 species, Lamiaceae - 7 species.

Most of the endemic species are coenoelements of calceopetrophyton, calceopetrophilic meadow-steppe areas, steppe and calceopetrophilic shrub groups. The formation of the main autochthonous core of the flora took place in the depths of the old paleocalcepetrophyton, on the basis of which the main primordial complexes arose: savanoid-meadow-steppe, ancient-steppe, and ancient-shrub. The second basis for the formation of one of the main components of the flora was the prsnemoral and prashrub.

The approximate time of the emergence and formation of paleoendems of the flora of the studied territories refers to the period from the Middle to Upper Miocene and the beginning of the Pleistocene, these are such species as *Galium exoletum, Minuartia aucta, Jurinea pachysperma,* etc. In their depths appeared: *Euphorbia volhynica, Galium besseri, Salvia cremenecensis, Betula klokovii*, etc. The group of mesochronoendemics is determined by the period from the beginning of the Pliocene to the middle of the Pleistocene, these include *Salvia dumetorum, Chamaecytisus blockianus.*

In the group of paleoendemics, the oldest, which have ancient subthetic roots, indicate the connection of our flora in the past with the ancient Mediterranean. Some of the endemics are associated with the deciduous forests of Central Europe.

4 Conclusions

The study of the vegetation cover is necessary to maintain the normal functioning and evolution of ecosystems, the stability of biogeochemical processes, the spontaneous development of biota and the preservation of the ecological balance both at the local and global levels.

Both the number and the ratio of florocoenotypes have clear and pronounced forest-steppe features. The meadow-steppe, steppe and calcepetrophilic groupings of the study areas contain a significant number of relict and endemic aboriginal florocenoelements. In the studied territories, there is a significant share of the agro-ruderal florocoenotypes - 20%, which indicates a significant synanthropization of the flora. Now this situation is more and more common in Ukraine.

A general overview of the specificity of the flora of the studied territories indicates its significant heterochronism, heterogeneity, and originality. In the flora of the region, among the prevailing species, neoendemics are manifested, and a number of relics testify to the connection between the modern flora of the ancient flora, the age of which begins from the end of the Tertiary period.

The great natural diversity of ecotopes in the studied territories creates appropriate favorable opportunities for the formation of viable populations of a large number of plant species, very different in their autoecological properties. Such a unique natural ecological situation requires intensifying efforts in the field of protecting the regional environment from ill-conceived anthropogenic interference and creating conditions for the conservation and natural distribution of rare plant species.

Abstract. Based on the generalization and systematization of scientific and accounting data, the article considers agriculture as one of the leading sectors of the Ukrainian economy, providing 50% of foreign exchange earnings from exports of all goods from the country. The structure and geography of agricultural exports from Ukraine are analyzed. The existing export potential of the studied sector of the national economy and the level of self-sufficiency of Ukraine in agri-food products are revealed. Four specialization types of agricultural exports from Ukrainian regions are established: areas with dominance in export of animal origin products; areas with a dominance in the export of plant products; areas with a predominance in the export of animal or vegetable origin fats and oils; area, with mixed export specialization. Recommendations for the re-profiling of agricultural production in a number of the country's regions in order to increase exports of this product type.

1 Introduction

The agricultural sector is a competitive sector of the economy, able to fill the budget of Ukraine along with such traditional industries as metallurgy, chemical industry, mechanical engineering and others. At present, agriculture is a strategically important part of the country's economy, which forms a significant share of export earnings. By estimation of some world leading economists, Ukraine is able to provide food to more than 150 million people according to its scientific and resource potential [1].

To ensure further growth of agricultural exports and increase of its efficiency, a detailed scientific approach is necessary, taking into account the regional specifics of agricultural development in Ukraine. The issues of commercial and geographical structure of agricultural exports were investigated, the export stream guidelines of agricultural goods were considered in these works. The available export potential of the studied sector of national economy and Ukraine's agri-food products self-sufficiency level were analyzed in them [2, 3, 4, 5, 6, 7].

The research and publications analysis indicates that scientists do not pay attention to the questions concerning the geographical features of agricultural export specialization of Ukrainian regions, the solution of which may contribute to the development of regional export strategy of the country's agro-industrial complex. In general, this provided the timeliness of this work.

The purpose of the study is to highlight the geographical features of agricultural exports from Ukraine.

The information basis of this work was a variety of statistical material collected from various official sources: the State Statistics Service of Ukraine, the State Fiscal Service of Ukraine, the State Customs Service of Ukraine, the Ministry of Agrarian Policy and Food of Ukraine, the UN Food and Agriculture Organization [8, 9, 10, 11, 12,13,14].

The actual material was processed by methods of mathematical statistics [9]. Cartographic material was obtained by using geo-information systems [15].

2 Results and discussion

The potential of Ukraine's agriculture today exceeds coniderbly the needs of the domestic market. As a result, there is a sharp increase in the share of agricultural products in the country's good exports (Fig. 1): less than 15% in 2010 and more than a third of total exports in 2019. Thus, agricultural industry owing to higher yields, the increased agricultural production along with extending demand for it among foreign consumers and opening new markets, has recently become one of the leading sectors of Ukraine's economy. And all this is being observed with an evident decline in other sectors of the economy. According to the State Statistics Service, in January 2020 the share of agricultural products in Ukraine's total exports reached 50% [9].

In monetary terms, foreign exchange earnings from agricultural products in 2010 amounted to $ 4.75 billion, and more than $ 14 billion in 2019.

As for the structure of exports of Ukrainian agricultural products, as presented in Fig. 2, the majority

* Corresponding author: mantulenkokdpu@ukr.net

are crop products (68%). Fats and oils account for 25% and animal products for only 7%.

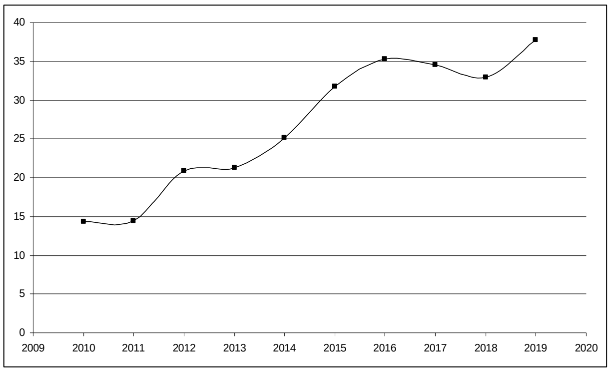

Fig. 1. The share of agricultural products (in%) in exports of goods from Ukraine in the period from 2010 to 2019 (according to the State Statistics Service of Ukraine).

Analyzing the dynamics of agricultural product exports from Ukraine for the period from 2010 to 2019 (Fig. 3) it is obvious that animal products exports remained practically at the same level. There was only a slight decline in the period of 2015-2016. In general, this decline is typical for all agricultural products exports and is associated primarily with hostilities in the Donbass and the loss of the Russian market. Later on, a significant rise of plant origin products, fats and oils export one can observe. This especially relates to crop products. Thus, in 2019, the exports of plant origin agricultural products exceeded in monetary terms almost three times in 2010. For fats and oils - almost twice.

There are several reasons for this. Firstly, new markets are being developed by Ukrainian farmers. Secondly, the cultivation of agricultural products, that are in demand abroad, is significantly increasing. Thirdly, the attitude of state and commercial organizations to agricultural producers as potentially promising players in the foreign exchange market is changing.

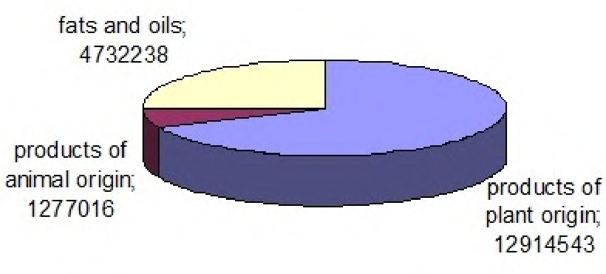

Fig. 2. The structure of Ukrainian agricultural exports in 2019 (in thousands of $, according to the State Statistics Service of Ukraine).

Among products of plant origin, exports are significantly dominated by grain crops - almost 75%. In 2019, they were exported from Ukraine worth $ 9.63 billion.

Every year, Ukraine exports up to 60 million tons of grain crops, being the third largest exporter of grain in the world. Over the past 10 years, Ukraine has increased grain exports by almost 4 times. So in 2019, this figure was 56.7 million tons, and in monetary terms - almost 10 billion dollars. In terms of crops, grain exports in 2019 are represented by wheat, rye, corn, barley and a small amount of legumes.

It is important that according to the State Statistics Service of Ukraine, the sown areas under wheat and corn have remained virtually unchanged over the past five years.The increase in production of these crops is due to the gradual increase in their yield. For example, wheat productivity has increased by almost 20%. In general, the average grain yield in 2019 increased by 2.2 quintals per hectare.

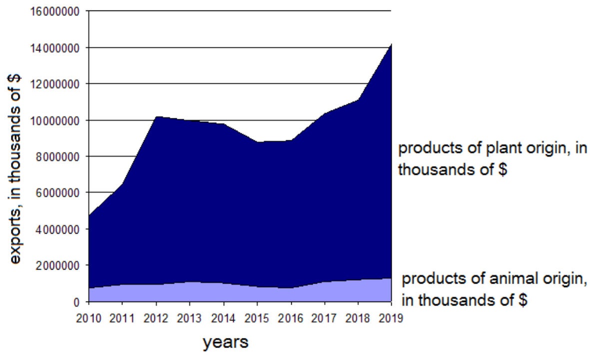

Fig. 3. Dynamics database providing export indicators of agricultural products having animal and vegetable origin from Ukraine in the period from 2010 to 2019 (according to the State Statistics Service of Ukraine).

According to the State Statistics Service of Ukraine, in 2019 the country exported oilseeds worth more than $ 2.5 billion, which is 32% more than in 2018. And the volume of export deliveries increased by more than 40% and amounted to 6.9 million tons. Here, Ukraine confidently holds a leading position in the world food market.

Exports of other plant products (vegetables, live trees and plants, edible fruits and nuts, etc.) from Ukraine are also growing steadily, however, in view of their small volumes, their impact on overall exports is minimal.

Ukraine is a world leader in the supply of sunflower oil to foreign markets. Thus, Ukraine's share in the world exports of sunflower oil amounted to 54.9% in 2019. For comparison, Russia's share in this market at the end of the season was 26.2%, Argentina – 6.2%, the European Union – 5.1%, Turkey – 3.3%. And this occurs despite the fact that the world exports of sunflower oil for the season increased to 11.49 million tons, which is 15% higher than in 2018. Accordingly, Ukraine increased product supplies to foreign markets by 14% up to 6.04 million tons, which in monetary terms amounted to almost $ 4.7 billion. Unfortunately, most of the sunflower oil comes from Ukraine as a raw material, after which it is refined and bottled under local brands. As a result, Ukrainian sunflower oil is sold abroad at a price 3-5 times higher than the purchase price.

The share of animal products in the structure of agricultural exports from Ukraine is extremely small. Despite some growth observed for this group of goods in the period 2017 – 2019, their contribution does not exceed

7%. Such a small share in exports is primarily due to the industry low development level. And if the country's crop products are produced in excess, the domestic demand for livestock products is covered by imports from other countries.

The significant decline in exports of this group, which was observed in the period 2014 – 2016, is primarily due to the closure of the Russian market. For example, if the products of animal origin at worth $ 559.5 million were exported to Russia in 2012, then only at $ 1.7 million in 2016.

The main exports of animal products are meat (55%) and dairy products (36%), including poultry eggs and natural honey (Fig. 4). The share of other products does not exceed 3 – 5%.

Meat in exports is represented mainly by meat and edible poultry offal. In 2019, this is more than 90% of all exported meat. According to the results of 2019, Ukraine has become one of the top three exporters of poultry meat to the European Union countries. 134,262 tons of poultry meat were exported, which is 8.6% more than in 2018. And as the current results of 2020 show that Ukrainian producers continue to increase their sales abroad.

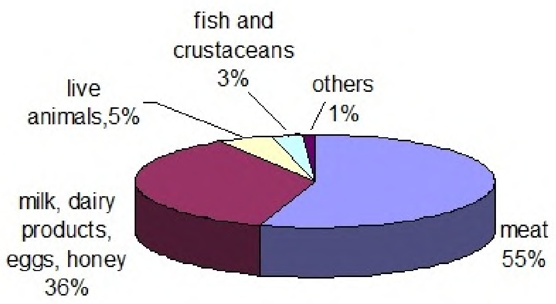

Fig. 4. Structure of livestock exports, 2019 (according to the State Statistics Service of Ukraine).

Next in weight in the structure of exports are a group of goods milk (dairy products), poultry eggs and natural honey. Within this group, about 30% are exports of honey, 23% – exports of chicken eggs and 22% – exports of milk and dairy products.

Ukraine ranks first in Europe and fifth in the world in terms of honey production. Annually, Ukraine produces about 100 thousand tons of honey, which is 6% of the world output. As a result, our country is one of the top exporters of this product.

The geography of agricultural exports from Ukraine has undergone significant changes in recent years. Thus, if until 2014 the CIS countries, including Russia, were one of the main consumers of Ukrainian agricultural products (up to 40%), then as can be seen from the diagram shown in Fig. 5, in 2019 this figure is slightly higher than 7%, as in 2018. This is due to the fact that since 2014, in connection with Russia's aggression, Ukrainian farmers have worked hard to find new markets.

Today, Asian countries are key partners of Ukraine in this area. Purchases of agricultural products by Asian countries in 2019 increased by almost 18% (to $ 9.4 illion) and amounted to 42.6% of total agro-exports of Ukraine.

The volume of agricultural products to African countries increased by 43% and amounted to 14.2% (about $ 3.3 billion) in 2019 [16,17].

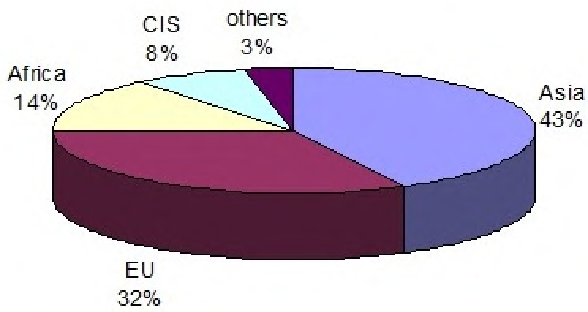

Fig. 5. Geography of agricultural products exports from Ukraine (according to the State Statistics Service of Ukraine).

If analyzed by country, the main consumers of Ukrainian agricultural products are China and Egypt. In 2019, these countries (as well as Turkey) increased the volume of purchasing these products by almost 1.5 times. As a result, they pushed to third place India, which for three years was the leader in this list. In addition to these countries, the main consumers of Ukrainian agricultural products are Turkey, the Netherlands, Spain, Germany, Poland, Italy and Belarus.

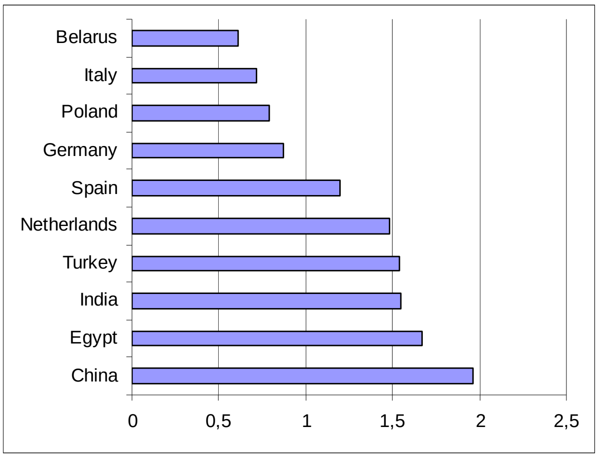

Fig. 6. The main importers of agricultural products from Ukraine in 2019 (in billion dollars, according to the State Statistics Service of Ukraine).

The formation of agricultural production specialization is determined primarily by the natural and climatic features of the region and its resource potential in their interaction with socio-economic factors [3]. The result is the territorial specialization of agricultural production. All this, no doubt, should affect the specialization of the agricultural export potential in the regions of Ukraine. Let's analyze this.

The map analysis of the agricultural export volume by regions of Ukraine (according to 2019) clearly

https://doi.org/10.1051/e3sconf/202128011009

demonstrates the spatial differentiation of this indicator (Fig. 7).

Thus, the regions with the highest indicators of agricultural exports geographically form an "axis" stretching from south to north (Odessa, Mykolaiv, Vinnytsia and Kyiv Regions). Further to the east are regions with average exports of agricultural products. Western regions are characterized by low rates. This includes the eastern regions of the country (Donetsk and Luhansk Regions), but this is due primarily to their partial occupation, as well as hostilities.

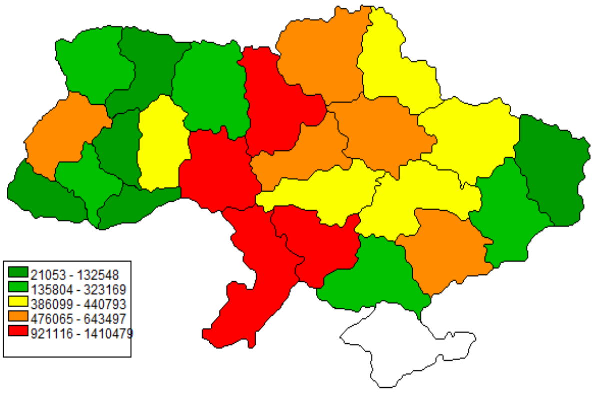

Fig. 7. The size of agricultural exports from the regions of Ukraine in 2019 (in $ thousands, according to the State Statistics Service of Ukraine).

The geography of plant products exports from Ukraine is quite remarkable (Fig. 8). Thus, the regions with the largest exports of these products (Kyiv, Vinnytsia, Odesa and Mykolayiv Regions) form the same conditional vertical "axis", which divides the territory of Ukraine into two symmetrical parts. Around this "axis" are areas with average exports of crop products (Zhytomyr, Chernihiv, Cherkasy, etc.). At a distance from the "axis", in the west and east of the country, are the areas with the lowest exports of plant products (Transcarpathian, Volyn, Donetsk, Luhansk, etc.) The exceptions are Lviv and Zaporizhia Regions.

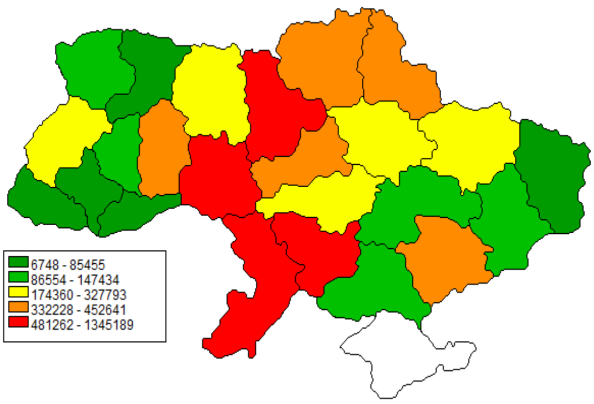

Fig. 8. Exports of plant products from the regions of Ukraine in 2019 (in thousands of $, according to the State Statistics Service of Ukraine)

Such a symmetrical model of spatial differentiation reflects a very ambiguous interaction of natural-climatic and socio-economic factors that determine the specialization of crop production in Ukraine.

Thus, the regions with the same natural and climatic conditions (for example, Vinnytsia and Kirovohrad Regions) differ significantly in export indicators. The main reason for this is economic one. Obviously, the conditions for favorable development of farming are being created in different ways. This means both purely organizational and financial support for this sector of agriculture.

As for livestock products, the picture is much more complicated (Fig. 9). The core of the regions with the largest export indicators (Kyiv, Vinnytsia and Cherkasy Regions) is clearly distinguished in the center of the country. Most poultry farms, which provide the bulk of exports of these products, are concentrated here. Indicators in other regions are distributed very unevenly, without any patterns.

Analyzing the geography of animal or vegetable fats or oils exports by Ukraine's regions (Fig. 10) it is clear that the regions with the highest indicators (Vinnytsia, Kirovohrad, Cherkasy and Dnipropetrovsk Regions) are in the center of the country. The regions with average indicators are located to the south (except for Kherson Region) and to the east (except for Luhansk Region). Western regions have the lowest values of exports of this type (except for Lviv Region).

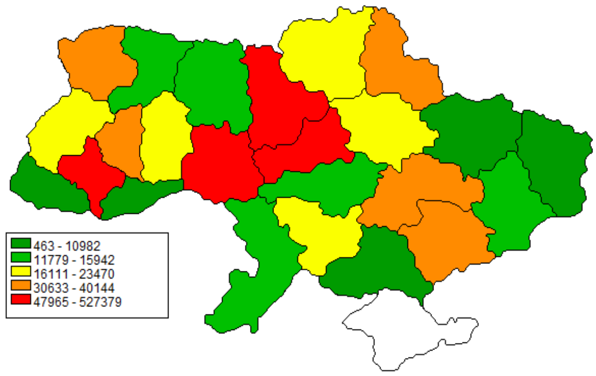

Fig. 9. Exporting products of animal origin from the regions of Ukraine in 2019 (in thousands of $, according to the State Statistics Service of Ukraine)

In general, this zoning corresponds to the natural and climatic characteristics of the regions, which allows to grow oilseeds and, above all, sunflower. High performance in Lviv Region is mainly due to the presence of a large number of commercial entities engaged in the resale these products abroad from the central regions. At the same time, Kherson Region does not use its potential, as well as for the export of other agricultural products.

In order to identify specialization in the exports of agricultural products of the Ukrainian regions, a triangular diagram was made, which shows the ratio of the three main types of products in the exports of Ukrainian regions in 2019 (Fig. 11). The analysis of the diagram allows to establish 4 types of specialization in agricultural exports of Ukrainian regions.

The first type includes the areas with a predominance in the animal origin products. These are: Kyiv, Ivano-Frankivsk, Ternopil, Volyn and Rivne Regions.

The second type is the areas with a predominance in exports of plant products. These include: Chernihiv, Zhytomyr, Zakarpattia, Mykolaiv, Sumy, Kherson and Chernivtsi Regions.

The third type is the areas with a predominance in the export of animal or vegetable origin fats and oils. These include: Dnepropetrovsk, Lugansk, Donetsk and Kirovograd Regions.

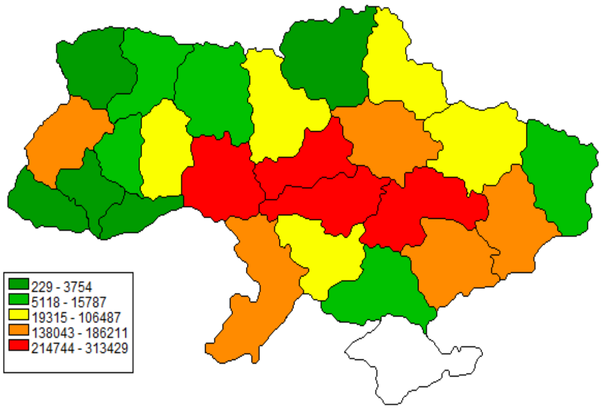

Fig. 10. Exporting fats and oils of plant and animal origin from the regions of Ukraine in 2019 (in $ thousands, according to the State Statistics Service of Ukraine)

The fourth type includes the areas with mixed export specialization, mainly vegetable products, as well as fats and oils. These are: Odessa, Kharkiv, Poltava, Cherkasy, Lviv, Vinnytsia and Zaporizhia Regions.

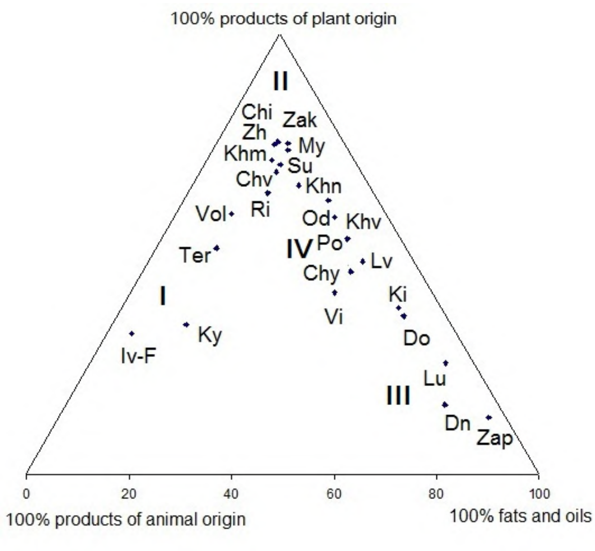

Fig. 11. Specializations in the agricultural export of the Ukrainian regions in 2019 (according to the State Statistics Service of Ukraine)

Spatial localization analysis of each specialization type allows to draw the following conclusions:

1. Products of animal origin dominate the exports of the western Ukrainian regions. The exception is the Kyiv region, in the export of which the products of poultry farms play an important role.

2. Regions whose exports are dominated by fats and oils are localized in the form of a strip stretching from the center of Ukraine to the east.

3. The areas with exports of products mainly of vegetable origin are located in the form of a strip extending from the southwest to the northeast of Ukraine and partly in the southern region of the country.

4. The regions with a combined specialization type of agricultural exports are located in the central and southern parts of Ukraine. The exception is Lviv Region, which specializes in customs transit of products abroad.

Table 1. summarizes data on the value of agricultural export indicators of Ukrainian regions with specialization types. Its analysis allows us to draw the following conclusions:

1. According to the value indicators of agricultural exports, all regions can be divided into three groups:

– the regions with the largest value of agricultural exports over $ 500 million (Kyiv, Mykolaiv, Vinnytsia, Cherkasy, Lviv, Odesa, Zaporizhia);

– the regions with an average export value of agricultural products from $ 150 to $ 500 million (Zhytomyr, Khmelnytsky, Sumy, Chernihiv, Dnipropetrovsk, Donetsk, Kirovohrad, Kharkiv, Poltava);

– the regions with the smallest value of agricultural exports from $ 150 to $ 500 million (Ivano-Frankivsk, Ternopil, Rivne, Volyn, Zakarpattia, Kherson, Chernivtsi, Luhansk).

Table 1. Correlating the values of agricultural export indicators of Ukrainian regions with export specialization.

Agricultural products that dominate exports	Areas with the value of agricultural exports over $ 500 million	Areas with the value of agricultural exports from $ 150 to $ 500 million	Areas with an export value of agricultural products less than $ 150 million
Live animals, products of animal origin	Kyiv Region	–	Ivano-Frankivsk, Ternopil, Rivne, Volyn Regions
Vegetable products origin	Mykolaiv Region	Zhytomyr, Khmelnytsky, Sumy, Chernihiv regions	Transcarpathian, Kherson, Chernivtsi Regions
Fats and oils of animal or vegetable origin	–	Dnipropetrovsk, Donetsk, Kirovograd Regions	Luhansk Region
Combined	Vinnytsia, Cherkasy, Lviv, Odessa, Zaporozhye Regions	Kharkiv, Poltava Regions	–

2. The regions with mixed (fourth) type of specialization have the highest export rates. Exceptions are Kiev (the first type – the dominance of animal products) and Mykolaiv (the second type – the dominance of crop production).

3. The lowest indicators of exports are the regions with a predominance of animal origin products (the first type of specialization) and plant origin (the second type of specialization).

4. Areas of the third specialization type (fats and oil) belong mainly to the regions with average values of agricultural exports.

According to these criteria, the geography map of agricultural exports from Ukraine's regions was built, combining indicators of the total exports value and its specialization (Fig. 12). In fact, it reflects the results of interacting natural and climatic features of the regions and their resource potential with socio-economic factors. It is clear that:

– the central and southern regions of Ukraine have the greatest potential in the development of agricultural exports;

– an exception from this rule is Kherson Region, which is the result of socio-economic factors impact and, above all, insufficient attention from the regional leadership and farms to the development of this extremely important area of the region and the country as a whole;

– to increase the export of agricultural products in these regions it is required to have a balanced combination of crop production (mainly grain) and the cultivation of oilseeds. Thus in the Kirovograd, Dnipropetrovsk and Donetsk areas, for today, it is necessary to make an emphasis first of all, on grain, and in Mykolaiv Region – on oil crops;

– in Zakarpattia and Chernivtsi Regions for increasing agricultural products exports there should be paid more attention to the development of animal husbandry.

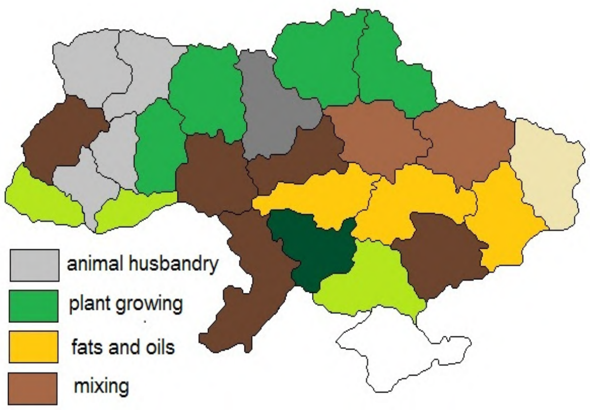

Fig. 12. The geography map of agricultural exports from the Ukrainian regions (according to the State Statistics Service of Ukraine) in 2019. The colors reflect the types of export specialization (4 types), and their intensity – the total value of agricultural exports in the region (3 groups).

3 Conclusions

As a result of the research performed it was established the following:

Agriculture has recently become one ofthe leading sectors of Ukraine's economy, currently providing up to 50% of foreign exchange earnings from exports of all goods from the country.

Given the dynamic characteristics of the agricultural exports growth from Ukraine, we can assume that the country in the coming years may become one of the most important players in the world market of agricultural products.

In the structure of Ukrainian agricultural exports, the majority are crop products (68%), fats and oils (25%), and animal products (only 7%).

Four specialization types of agricultural exports from Ukrainian regions are established: the first type is the areas with dominance in the exports of animal origin products; the second type is the areas with dominance in the exports of plant products; the third type is the area dominated by exports of animal or vegetable origin fats and oils and the fourth type is the area with a mixed specialization of exports, mainly products of vegetable origin, as well as fats and oils.

The geographical analysis of agricultural exports from the Ukrainian regions allowed to develop recommendations for the re-profiling of agricultural production in a number of the country's regions in order to increase exports of this product type.

In this way, by agricultural products geography export expansion Ukraine will be able to create a competitive, export-oriented agricultural industry, and food-processing industry would produce competitive foodstuffs in accordance with the international safety and quality standards. In the result of these transformations, Ukraine will strengthen its positions at the traditional export markets and will trade its new export products with new partnership countries, which will facilitate positive farm products balance of trade. This, in turn, will have a positive impact on the development of our country's economy agrarian sector.

Abstract. At the present stage, digital information technologies create a new education system focused on the global educational space. In general education schools, in connection with the adoption of the updated program, the section Geoinformatics and cartography provides for the use of developing a map-scheme, modeling and conducting small studies on the topic under study. As a result, digital technology has a place in geographical education. This is due to significant changes in the pedagogical and methodological approach in teaching geography and other disciplines. As a result, the education system has changed, the content of education has been updated, a new approach has appeared, a new attitude to geoinformation technologies in schools. The article discusses the importance of computer technologies in the education system, including the effectiveness and necessity of using geoinformation technologies. The article substantiates the relevance of the use of geoinformation technologies in the teaching of geography.

1 Introduction

It is quite obvious that without modern information technologies it is impossible to achieve competitiveness in the market. The most important of them is the lack of a single or unified market for joint software tools, which would allow partners to use the resources accumulated in different automation systems. Currently, digital technologies are rapidly developing. The number of sites is growing daily. Search engines already refuse to name the exact number of them, citing the impossibility of accounting.

In the modern world, geoinformation technologies are widely used in geography, tourism and many other spheres of human activity. To improve the quality of education in Kazakhstan, the State Program for the Development of Education for 2011-2020 has been developed. The law on the status of a teacher was adopted [1].

In this regard, reforms and policies, changes and innovations in the country's education system can become the basis for every pedagogical community to think, reflect on the past and present. Work with new ideas and face the challenges of an updated program. “Geography” in high school (grades 10-11) - is, creating conditions for students to apply geographical knowledge, skills and abilities aimed at solving geoecological, geo-economic, social, geopolitical and global problems that arise at all levels of geographical space [2].

Technology (from greek. “techno” – art, “logos” – thought, reason, technique, method of production) – a set of methods, processes and materials used in any branch of activity, as well as a scientific description of the methods of technical production [3]. Geographical information – information about objects and phenomena that take place in the surrounding space on the territory of the planet Earth and are accompanied by geographical coordinates (longitude, latitude). The combination of geographic information and computer technology has led to the creation of geographic information technologies or geographic information systems (GIS) [4].

GIS is “... information systems that ensure the collection, storage, processing, display and dissemination of data, as well as obtaining new information and knowledge about spatially coordinated phenomena...”.

Therefore, we offer technologies for using GIS mapping. Here, the main place is occupied by satellite images and remote sensing of the Earth. In our practical work for the last 2-3 years, we have been using this method to develop tourist routes and to draw up map schemes for some sections of geography. When developing routes using remote sensing and GIS technology, we determine the state of the route, the terrain, and dangerous mountain areas for safety purposes. In the research works of graduate students and doctoral students, there is a mandatory requirement to apply remote sensing methods.

Here is a concrete example of how to use remote sensing and GIS technologies in the educational process. From a scientific point of view, this moment has been tested, and is used in the dissertation work of the doctoral student A. Demeuov.

For the first time, the term “geographic information system” appeared in English-language literature and was

* Corresponding author: panteleeva4y@gmail.com

used in two versions, such as geographic information system and geographic information system, very soon it also received the abbreviated name GIS.

2 Initial data and research methods

A breakthrough in the field of creating geographic information systems and the beginning of the development of geoinformatics is the development and creation of the Canada Geographic Information System (Canada GIS). Its history begins in the 60s of the last century and to this day this large-scale geoinformation system is being developed and maintained.

The components of the geographic information system include:

1) data (spatial data);
2) hardware (computers, peripherals, network equipment);
3) software (software);
4) methods;
5) specialists.

There are many examples of using GIS. Currently, almost every Internet user has at least once accessed map resources (such as Google Maps, Bing, OpenStreetMap, Yandex Maps, etc.) that provide information on a free basis. This area is called web mapping.

Along with web mapping, there are network GIS, as well as desktop GIS. Their use in areas of human activity, such as the extraction of natural resources, the study of the environment and climate, as well as education, is growing every day. They are widely distributed all over the world. The Republic of Kazakhstan is also no exception.

For example, in the Russian Federation a closed JSC “Design Bureau Panorama” developed educational-methodical complex “Living Geography”, including a dedicated set of satellite images, guidelines.

The analysis of changes in various spheres of activity over the past decades allows us to speak about the progress that has allowed us to move rapidly in various sectors of the economy. The search for solutions to some problems leads to innovative methods. Innovation impresses with its growth rate and becomes an integral part of our lives.

Online information technology strategies require innovative approaches and organizational restructuring. In order to take advantage of the Internet and counter the risks associated with it, it is necessary to adopt new approaches. Only those who innovatively use traditional advertising strategies or offer fundamentally new concepts can achieve success in the Network. For example, Interactive maps and photos. With the help of several sites, you can get into the universal GlobeXplorer library, which contains satellite aerial photographs of almost the entire surface of the Earth. MapQuest is the first brand to introduce this technology. With the help of GlobeXplorer technology, the consumer sees interactive aerial photos of many cities, rural areas and major tourist attractions. The combination of aerial photography and digital mapping makes it easy for tourists to navigate unfamiliar terrain. For example, AOL (America Online) members and MapQuest users planning a trip can design a travel itinerary, then view the map and see the selected location from a bird's eye view. With the navigation features provided by MapQuest and GlobeXplorer, the tourist can easily navigate the site in all directions and visually find roads, rivers and other landmarks. An attractive and fundamentally new project for promoting the tourist opportunities of our country should be the “Interactive Tourist Map of Kazakhstan”.

The principle of its construction should be that a potential tourist can get comprehensive, interactive information about the country, its tourist opportunities and attractive tourist sites in all regions. An interactive tourist map of Kazakhstan should provide an opportunity for a potential tourist to make a virtual trip along the route chosen and interesting to the client, or excursions, to have a complete idea of the tourist center, this or that attractive tourist object.

Innovation is an implemented innovation that provides a qualitative increase in the efficiency of processes or products that are in demand by the market. It is the end result of a person's intellectual activity, imagination, creative process, discoveries, inventions and rationalization [3]. Since tourism is an important sector of the economy, which is one of the main sources of income in many countries of the world, innovations have also affected its development. Innovation in tourism brings new ideas, services and products to markets.

The main directions of innovative activity in the field of tourism are the release of new types of tourist products, the use of new equipment and technology, marketing, management; identification and use of new markets for products. Tourism is a multi-faceted phenomenon that carries an economic function and the function of satisfying the spiritual needs of a person.

Innovative activities in tourism with the use of high-tech equipment for remote sensing of the Earth (ERS), new materials have influenced the nature and structure of modern tourism. The new era of information technologies has expanded the scope of their application. One of the most striking examples of this is GIS technology.

Geographic information system – a system for collecting, storing, analyzing and graphically visualizing spatial (geographical) data and related information about the necessary objects [4].

At first glance, GIS is a tool for preparing digital maps and printing them on paper or polymer media. However, the real range of GIS applications is much wider, since these technologies are currently used in various fields of activity, including tourism.

To solve the problems of tourism development, interactive maps using GIS technologies are needed. They will mark major resorts, recreation centers, plans of resort areas and adjacent territories, give characteristics of tourist and recreational facilities, information about the quality of service, photos of the room stock, cuisine, beaches, etc. This would provide potential tourists with comprehensive information, since it is believed that GIS is a technology that answers questions instantly. In addition, in some countries GIS tools are used for planning the development of regional tourism [5].

In the opinion of the authors, the work on the creation of tourist GIS can be successful if they focus on the creation of so-called Internet services using GIS technologies.

A big advantage of these services is their popularity among a large mass of Internet users, as well as the availability of detailed maps of major cities. However, according to the authors, the lack of these services for the development of tourism in the Republic of Kazakhstan is the lack of specialized information about tourist and recreational facilities located both within urban areas and outside them and related various attribute information.

In order to solve the problem of increasing income from inbound tourism, there are various strategic programs at the state level in the Republic of Kazakhstan, covering various activities, including the creation of tourist information Internet portals. As an example, you can use the website www.VisitKazakhstan.kz implemented by relevant departments. The site provides a large amount of useful information about tourist and recreational facilities, routes, and so on. However, users often require the presence of interactive tourist maps.

Since, in the current conditions of the world economy, tourism is becoming one of the leading and dynamically developing industries, the relevance of the chosen topic is not in doubt.

According to the UNWTO, tourism ranks fourth in world exports of goods and services (7.4 %). However, in Kazakhstan, unfortunately, tourism is still not perceived as a full-fledged branch of the economy and the subject of scientific analysis. In general, the concept of “tourism” in the republic is more often associated with sports and health promotion, rather than with an economic sector that generates significant revenues, primarily in hard currency. After all, in fact, tourism is a complex multi – faceted manifestation of public life, but first of all, it is a “spatial socio-economic phenomenon”, also in many ways “spatial cognition”, firmly connected with the territory of the country and its individual regions.

3 Results and discussion

In Kazakhstan tourism, it is necessary to pay more attention to poorly developed, but no less interesting tourist products. A striking example is the city of Ridder (Figure 1). It has a unique tourist potential. A strong point in terms of tourism development are: a convenient geographical location (proximity to Russia and China), also this unique mountain area for Kazakhstan is located close to the regional center – Ust-Kamenogorsk, and the presence of a developed transport infrastructure – the city has its own railway station “Leninogorsk” [6].

The environs of Ridder include: Ivanovsky and Stanovoy ridges, the upper reaches of the Black and White Uba rivers. Here is located the West Altai State Nature Reserve, the main object of protection of which are typical for the Western Altai landscapes, in particular-the black taiga. The area of the protected area is 54533 hectares. The region has 8 recreation centers, 2 ski resorts, 4 public organizations of tourist orientation, 4 children's camps.

When visiting Ridder and its surroundings, the priority types of tourism can be distinguished: active (mountain, ski and ski, bicycle and car, sports, equestrian and hiking); ecological and educational (amateur photo safari, spa treatment, fishing and hunting, village, ethnic and ethnographic). The territory of the mountain suburbs of Ridder is suitable for organizing almost all types of geotourism.

Fig. 1. Survey image of the research area (Google Earth).

Free and quick access to the vicinity of Ridder (no special pass to the border zone is needed), allows you to organize tours of short duration up to 2-3 days (“weekend tours”). So, the recreation centers “Belaya Uba”, “Gromotukha” and “Klimovka” serve just such tourists. A wide range of interesting places is covered for making routes of various nature and complexity (mountaineering, mountain tourism, horse tourism, rafting, sport hunting, cycling). In terms of tourism, the Ivanovo and Stanovoy ridges, the upper reaches of the Black and White Uba Rivers are attractive. Here is the largest number of recreation centers, more prepared infrastructure [7].

The most popular places to visit, in the general structure of land use of the city, include water resources – the sources of many Altai rivers: the Gromotukha (spring rafting), Tikhaya, Bystrukha, Zhuravlykha and Filippovka rivers, merging, form the Ulba River (rafting), Lake Kedrovoye (fishing), Malouba Reservoir (trekking, historical tourism, skiing), the Turgusun River (rafting).

The tourist significance of mountain ranges lies in the fact that under the influence of endogenous and exogenous factors, various natural and territorial complexes were formed. Objects of the mountain environment (typical unique mountain complexes, natural monuments) that are of great educational, sports, health, religious and scientific interest. This includes the highest mountain peaks and peaks, passes, bizarre rocks, grottoes, boulders, etc.

One of the most famous tourist places in the vicinity of the city is the “Black Knot” - the junction of the three main ridges of the district (Koksuisky, Ivanovsky and Kholzun). Here is a unique natural monument – the Museum of Giant Stones “Kamennaya Skazka”. At an altitude of 2000 m, stone statues of the most bizarre shapes froze. Here are the “Line Pillars”, “Maryin Utes” and “Stone River”, where the filming of the famous TV series “Eternal Call” took place.

This region is also known for sports tourism. Since 2009, Ridder has hosted auto and motorcycle races 3...4 times a year. They bring together participants and spectators from all over Kazakhstan and some regions of the CIS. Thanks to these events, the city became known as the "Capital of motor racing in East Kazakhstan".

The region is an important destination for skiing and alpine skiing tourism. It is not at all inferior, and perhaps, in terms of technical characteristics, it is somewhere superior to many ski and ski slopes. In the suburbs of Ridder, there are many so-called mountain squirrels, where snow lies almost all year round. For example, the well-known Vyshivanovsky Belok (Voroshilov Peak) (trekking, mountain tourism, summer ski camps, eco-tourism). Ridder is the pearl of East Kazakhstan for skiers.

The first project of a high-mountain base in Kazakhstan-a shelter located far from the benefits of civilization, surrounded by the pristine nature of the Western Altai-is located on the passable protein (1800 m) [6]. In the "Ridderhutte" develops an extensive list of priority areas of tourist activity, which is developed by the sports project of the base, aimed at promoting the development of skiing in Kazakhstan. It allows athletes to train in the summer at home, without going abroad and without incurring huge financial costs.In the vicinity of the 2nd district of Ridder, there is a ski center equipped with an anchor cable lift. Restored ski lift in the Upper Harutoki.

If we consider the development of Ridder as a ski and ski resort, it should be noted that this is a large-scale project, the implementation of which is currently unthinkable without geoinformation support [7]. The relief of the mountainous surroundings of Ridder has a huge tourist potential. For the protection and rational use of this potential, it is necessary to map it at the level of modern science and technology. The objects of research and cartography should be mountain slopes, which will serve as the basis for creating tourist trails in the future.

Ensuring the design, construction, and in the future – the successful operation of many tourist facilities, requires timely and high-quality cartographic support. At the same time, at the stage of development of project materials, it is necessary to solve problems related to the selection of sites of spatial location of various tourist objects and structures. On the one hand, special requirements are imposed on them (for example, for ski routes – slopes for various types of competitions, features of wind characteristics for springboards, etc.), and, on the other hand, transport accessibility must be ensured while minimizing the violation of the unique natural conditions of the region.

The accuracy and other qualities of the compiled map depend on the cartographic source used and the methodology used. Maps should be compiled on the basis of a number of cartographic sources: general geographical, physical, geomorphological maps of the Ridder area of different scales, tourist schemes, extensive use of specialized literature and departmental materials.

Modern GIS technologies allow you to create tourist GIS, i.e. systematized data for the organization of tourist activities [8]. Every tourist visiting Ridder will be able to quickly get any information in the form of maps, digital models, graphs, diagrams and other types of information using GIS materials.

For this purpose, in the preparation of this article was used software QGIS v2.4.0 and data on the topography of the open-source ASTER GDEM v2.0.

So, with the use of tools for morphometric analysis were analyzed the topography of the study area and the resulting maps of the exposure of the slopes (Figure 2), shaded relief, and ruggedness.

Analysis of the exposure of the slopes of the area showed the predominance of south-western and north-eastern orientation, which is clearly demonstrated on the map.

At the heart of the initial stage of the formation of the design of Ridder as a ski resort is the translation of previously obtained by traditional methods of cartographic materials of the city and its mountain surroundings into an electronic cartographic form with their subsequent unification on the basis of a single cartographic basis. In the future, these blocks of the geoinformation system are increased by electronic cartographic data obtained directly in solving the problems of developing a mountain climate resort, including updating data on the results of monitoring (environmental, geological, technological, service, etc.).

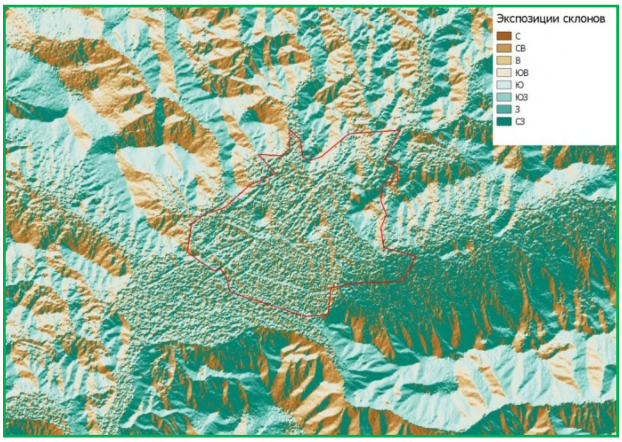

Fig. 2. Slope exposure map.

The second feature of the work on the creation of a block of detailed electronic cartographic materials is the need for 3D data from specialists who perform work on engineering and environmental surveys, design, engineering protection of the territory from dangerous hydrometeorological and geological processes. 3D data has significant advantages in providing information about the nature of the surface and its inhomogeneities. These heterogeneities are caused by the complex geological structure of the region and formed, at present, as a result of the development of geological processes, including requiring consideration in the design of various buildings and structures.

These materials related to 3D data should fully reflect the three-dimensional structure of the mountain area under consideration for ski tourist trails and other auxiliary facilities (Figure 3).

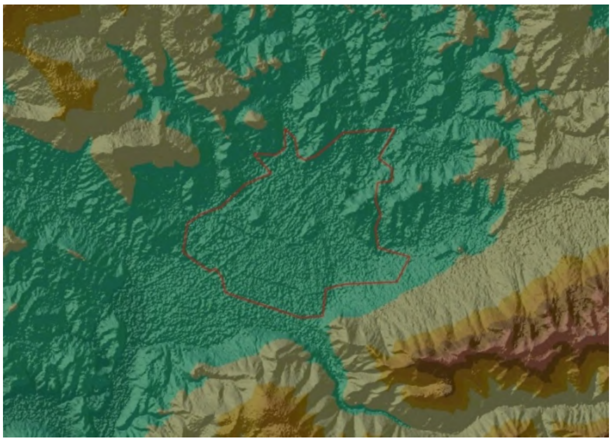

Fig. 3. Washing of the relief of the research area.

For example, economic geography reveals the features of the geographical location of the city – this specific resource, perhaps the most important for development. It obliges to consider the city together with the environment, acting as its partner and at the same time addition, as well as the sponsored territory that it is obliged to serve and take care of. Changes in the city cause a response in the environment. By managing the development of the city, you can also manage the development of adjacent territories. The city, as an object of research, is important for geography, which finds application in it for subsidiary sciences and can realize the potential of an integrator science. Being a set of enterprises and devices that have a strong impact on the environment, the city not only becomes an area with a tense environmental situation, but also a factor that changes the environmental situation within a vast space [8].

The capital of the Republic of Kazakhstan is Nur-Sultan, located in the center of the country in the steppe zone. From the point of view of the relief of the earth's surface, the city is located on the low above-floodplain terraces of the Yesil River, which is the main waterway of the city. The climate is characterized as sharply continental with long cold winters and hot summers.

Nur-Sultan today is an example of sophistication of architectural style, striving to achieve the harmony of an environmentally friendly metropolis. The area of the capital's “green belt” around the city is regularly increasing, it has become a kind of oasis in the center of the steppe. Nur-Sultan is also the political, administrative, business and cultural center of the country, where the central authorities, diplomatic missions, universities, modern medical institutions and cultural centers are located [9].

Currently, the role of the city as a transport, logistics and communication center in the center of Eurasia is increasing. Despite the short period since the beginning of the historical change of the capital, Nur-Sultan became the main city of Kazakhstan during the formation of the young state (Table 1).

In this regard, the role of the city as one of the centers of tourism has increased, as the flow of tourists seeking to visit the capital of our country increases from year to year. According to some foreign tourists, the architectural appearance of Nur-Sultan is at the same time similar to Dubai (UAE) and Tokyo (Japan), and is something in between. The unique architecture of the capital of Kazakhstan embodies the so-called “eclecticism”, i.e. a mixture of different styles. This has been achieved over the past 15 years with the involvement of internationally recognized architects Sir N. Foster and K. Kurokawa, as well as many other architects.

Table 1. Classification of some tourist and recreational facilities in Nur-Sultan.

№	Name	Type of tourism	Subspecies of tourism
1.	Ethno-memorial complex “Atameken”	Historical and cultural	Architectural culture tourism
2.	Palace of Peace and Reconciliation		
3.	Independence Monument		
4.	The Palace Of Independence		
5.	Palace of Creativity “Shabyt”		Tourism of the urban environment and culture
6.	National Museum		Architectural culture tourism
7.	“Astana Opera” Theatre		Tourism of the urban environment and culture
8.	“Khan Shatyr” Shopping Center		Architectural culture tourism
9.	The Monument “Baiterek”		
10.	“Alau” Ice Palace		Tourism of theme parks of culture
11.	“Astana Arena” Stadium		
12.	The Cycle Track “Saryarka”		
13.	Hippodrome “Kazanat”		
14.	Stella “Astana Zhuldyzy” (Stars of Astana)		Architectural culture tourism
15.	Nazarbayev University		Tourism of theme parks of culture
16.	Triumphal Arch (Mangilik El)		Architectural culture tourism

The full list of places offered for visiting is about 70. However, for objective reasons, this article contains only part of the specified list of tourist and recreational facilities.

Currently, the achievements of science and technology offer various tools for human activities to increase efficiency, including for tourism. Such a tool can be called GIS or geographic information systems designed for the collection, storage, analysis and graphical visualization of geographical data. Since there are a lot of materials on this topic in open sources, the authors of the article did not stop at explaining the terminology, but preferred to focus on the results of the work. As mentioned above, geographic information systems have a number of functional properties that allow you to enter, store, process and visualize geographical data. In this regard, the authors of the article used software with an open license Quantum GIS v.2.6.1 [10].

The scheme was based on the list of tourist and recreational facilities compiled earlier. The objects were plotted on space images provided in the public domain through the Google Maps service. Keep in mind that GIS data is stored in layers in vector and raster formats. Thus, in the future, a point layer with the image and names of objects is obtained, as well as a linear layer with the image of the route line. Then the attribute tables of these layers were integrated with the above table of tourist and recreational objects of the research area, the symbols were set, and the layout of the scheme was prepared for printing.

The scheme was based on the list of tourist and recreational facilities compiled earlier. The objects were plotted on space images provided in the public domain through the Google Maps service. Keep in mind that GIS data is stored in layers in vector and raster formats. Thus, in the future, a point layer with the image and names of objects is obtained, as well as a linear layer with the image of the route line. Then the attribute tables of these layers were integrated with the above table of tourist and recreational objects of the research area, the symbols were set, and the layout of the scheme was prepared for printing.

In the work carried out, the map of the city of Nur-Sultan was used, covering the objects of tourist infrastructure (Figure 4).

Fig. 4. Scheme of a complex tourist route on the territory of Nur-Sultan.

As a result of the work, a map of the tourist route within the city of Nur-Sultan was drawn up, which covers the above types of tourism (Figure 4).

This method of work can be useful both for educational activities in the field of tourism, and for drawing up route diagrams in the development of tourist products using hardware and software tools to obtain high-precision data.

GIS significantly speeds up many stages of mapping. Tourist maps compiled in the GIS environment are characterized by good design, accuracy, attractiveness, speed and production options [11; 12]. In addition, it is possible to analyze any component of the mountain route separately, create a digital terrain model (DEM), organize e-tourism, disseminate information, etc.

4 Conclusions

The use of GIS technology in geographical education is thus acceptable in the development of tourist maps, at school and at university. In practice, we were convinced that high school students in the geography sections together with teachers can use GIS in geography lessons, and we were convinced of the possibility of creating a unified geoinformation system for Ridder and its districts as a mountain climate resort.

The creation of a unified geographic information system of Ridder and its districts as a mountain climate resort should be carried out in several stages, starting with the formation of a block of medium-scale electronic cartographic materials, which is clearly demonstrated in this article. By saturating the unified geographic information system with detailed electronic cartographic materials from various performers, which are received as engineering and environmental surveys are completed at individual sites, it is easy to create a large-scale map of Ridder as a tourist destination in Kazakhstan.

At the moment, we are developing an application for tourist sites in certain regions of Kazakhstan. Internet services using GIS technology were demonstrated in some sectors of the economy during the world exhibition EXPO-2017 in Nur-Sultan.

The use of GIS technologies in educational activities, both in the specialty “Geography” and “Tourism”, and in other specialties, increases the accuracy of data, their reliability, and also clearly demonstrates the current situation and makes it possible to create various models. In turn, the above allows you to improve the quality of higher education.

Abstract. In the new socio-economic conditions in the education system, forms of organization of tourist and local history activities are developing, which are based on traditions, experience of extracurricular and extracurricular work, taking into account the changes that have occurred in the country. Life requires that the tasks facing educational institutions are resolved quickly and have not just any solution, but one that optimizes the pedagogical process. At the same time, these requirements come into conflict with the state of the education system, the limited ability of most parents to create conditions for the full development of the child. The tasks facing the education system can be implemented in tourism and local history activities. The main task is to create the necessary conditions for the comprehensive development of the child's personality, his social adaptation in the process of participation in various types of tourist and local history activities. However, the school teacher is not ready to organize and conduct tourist and local history activities at school, as he is not professionally prepared for this activity. Questions of the organization, forms and methods of teacher training for the organization of tourist and local history activities are practically not reflected in the educational and methodological literature. There are no scientific studies that would allow us to effectively solve the pedagogical tasks of preparing the organizers of tourist and local history activities in the school.

1 Introduction

Pedagogically correct organized and structured tourist and local history work allows the teacher to implement the local history principle of teaching the subject. Collection and accumulation of local history material for use in the classroom, as a rule, is carried out in hikes and excursions, in the process of search work. Local history is closely related to the development of the basics of science, with the practical application of the basics of geography, biology, mathematics, and other subjects. Contributing to the acquisition of knowledge about the phenomena of the environment and life on the material of the local region. It is the most rational means of learning the general laws of nature by introducing students to the basics of production, makes it possible to link theory with practice, helps to develop practical skills. Local history contributes to the deepening of inter-subject relations in the educational process. For the first time in Kazakhstan, the training of geography teachers and organizers of tourist and local history work has been started since 1987 [1].

The use of local material in the process of perception and comprehension of knowledge helps to resolve the pedagogical tasks of the teacher: its use enriches the content of the teacher's explanation, gives it a specific character, and promotes education in the minds of students the concepts as the answer to new questions for which previous knowledge is not enough; the use of local material depending on lesson plans, changes the relationship between teacher and students.

The involvement of local history material in the process of transferring new knowledge creates a favorable problem situation when students come to a conclusion based on known facts, compare a number of scientific facts and phenomena with the facts of the environment, have the opportunity to critically comprehend and perform independent work.

During the study of local lore, schoolchildren learn the peculiarities of their own character, such important personality traits as mutual assistance, mutual assistance, responsiveness, responsibility, discipline, and tolerance are formed in them. In the course of the implementation of the collective form of activity, students develop a moral consciousness and an idea of the system of norms of moral behavior. So local history activity can act as a means of implementing the tasks of moral education.

In the process of tourist and local history activities, pedagogical directed influence, as a result of systematic and purposeful educational work, positive experience of behavior is accumulated, while favorable conditions are created for the formation of moral qualities of the child's personality. Tourism and local history in their modern understanding are physical development, health improvement and knowledge of the surrounding reality, the formation of valuable spiritual qualities of the individual [2].

* Corresponding author: arman_demeuov@mail.ru

The education of such moral qualities as a sense of duty, responsibility for the assigned task, diligence, commitment, initiative, independence, contributes to the performance of permanent and temporary official duties by young tourists - commander, guide, treasurer, caretaker, kitchen attendant, etc. Mastering these skills also contributes to the formation of a conscious attitude to work, helps in choosing a profession.

Performing local history tasks on the route, constantly being in the natural environment, communicating with the local population, getting acquainted with the monuments of nature, history and culture contribute to the education of spiritual and moral qualities, patriotism. Thus, a system of tourist and local history activities was created.

In this article, we offer only one of the models of the tourist and local history cycle for students "Geography-Tourism", where the whole process is shown in the diagram.

The first course – field practice in topography, geology, botany, meteorology.

The second course year-practical training in zoology, cartography, soil geography, hydrology and geomorphology.

Third year – performing the practice according to the Figure 1.

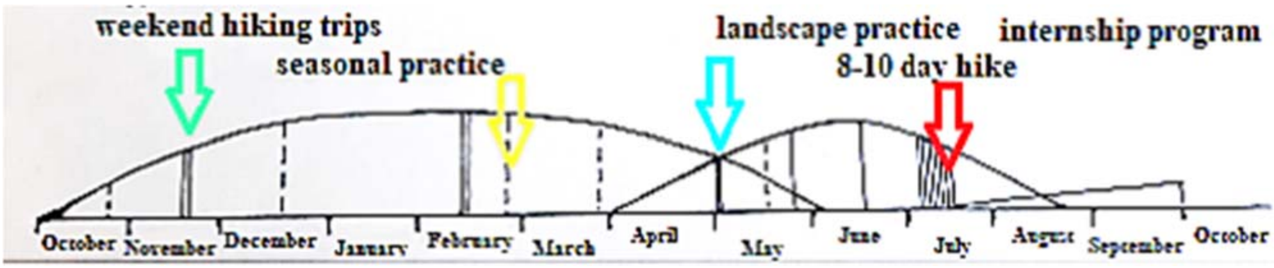

Fig. 1. Tourist and local history cycle for students of the Faculty of Natural Geography.

A. Special training "Big cycle" - instructive and methodical, economic, tourist and local history and physical training.

B. Small cycle. Practical work on the ground, improvement of tourist equipment and tactics. There is a special course on tourist and local history work at the school. Visiting schools and extracurricular institutions.

The fourth year – pedagogical practice at school (tourist and local history work in educational institutions).

Pedagogical universities using this model can prepare future geography teachers for the TLhA.

The novelty of the research is the application of this approach to the educational process at the university.

Using the model of interpretation, we focus on dual education, there is a practice-oriented approach. Students understand, are able and know the importance of tourist and local history work. [1]

Tourism and local history activities (TLhA) are an important means of improving the health and physical development of students. With the current unfavorable ecological state of cities and towns, high noise levels and other traumatic factors, as well as a significant time spent by children in closed rooms, a one-day or two-day hiking trip is an effective means of improving health and preventing diseases. Tourist trips, tourist competitions held in nature, distract them from strenuous educational activities, relieve stress and tension. The days spent in the fresh air give the children a powerful charge of cheerfulness and energy, allow them to work at school with creative enthusiasm and good mood. After a pedagogically well-organized hike, the teenager feels physically well and calm for several days. All this contributes to improving the quality of the educational process [3].

Visiting nature reserves and national parks is particularly popular in Canada, Kenya, the United States and China.

The common distinguishing features of European children's and youth tourism centers are a rich excursion and educational program with a wide range of sports and wellness services. In educational institutions in England, France, Germany, Austria and other countries, when studying individual subjects, teachers use walks and trips to nature in their work with students. Such methods allow students to acquire and maximize the need for knowledge, creativity, and self-determination personally and professionally. Youth tourism has become an integral part of the lifestyle of the younger generation in Germany. A wide network of youth tourist bases within Germany itself (more than 600 youth bases and 400 homes for young nature lovers) is provided for the services of young people, whose stay is very inexpensive for young residents of Germany. In Japan, during the school holidays, students go out to learn various folk crafts. Such excursions, on the one hand, foster respect for work, expand the understanding of the economic potential of the country. On the other hand, such trips can have an important utilitarian purpose - to help with the choice of a future specialty [4].

In Kazakhstan, tourism and local history activities are becoming a mass movement of the younger generation, parents and the pedagogical community in order to learn about the environment and through tourism. The state network of children's institutions of additional education of tourist and local history profile in Kazakhstan began to form in the 60s of the XX century. During the years of independence, the education system of the Republic of Kazakhstan has developed and operates a system of tourist and local history work.

https://doi.org/10.1051/e3sconf/202128011011

Over the past decades, there has been a positive trend in the development of tourism and local history (2004-9 stations, 2019-37 stations).

More than 800 thousand children and teenagers participate in the implementation of such programs of the tourist and local history movement of students as “Atameken”, “Bolashak”, “Zhasurpak”, “Shugyla”, “Tugan elge tagzym” and others. Within the framework of the tourist and local history expedition of schoolchildren “Menin Otanym-Kazakhstan”, dozens of hiking, skiing, water, cycling trips, expeditions and excursions are held annually, in which thousands of young tourists and their adult mentors participate. Every year, more than 1,300 specialized yurt and tent camps are organized in the republic, where 140 thousand children have a rest and get tourist skills [5].

In the process of tourist and local history activities, pedagogical directed influence, as a result of systematic and purposeful educational work, positive experience of behavior is accumulated, while favorable conditions are created for the formation of the moral qualities of the child's personality. First of all, these are the qualities that are brought up as part of a tourist group that exists in an autonomous mode-collectivism, responsibility and mutual assistance.

The authors have conducted experimental studies on the possibility of TLhA for 30 years. The result is the training of teachers-organizers on the basis of geographical education in a pedagogical university.

2 Results and discussion

Currently, 37 stations and centers of young tourists-local historians carry out tourist and local history educational activities in the Republic, 23529 schoolchildren are engaged in them. Between the ages of 6 and 18, 651,409 students are engaged in palaces and kindergartens, and 33988 students are engaged in tourist and local clubs and school associations. In general, 57517 children are covered by tourist and local lore directions, which is 1.96% of the total number of schoolchildren in 2018 (Figure 2).

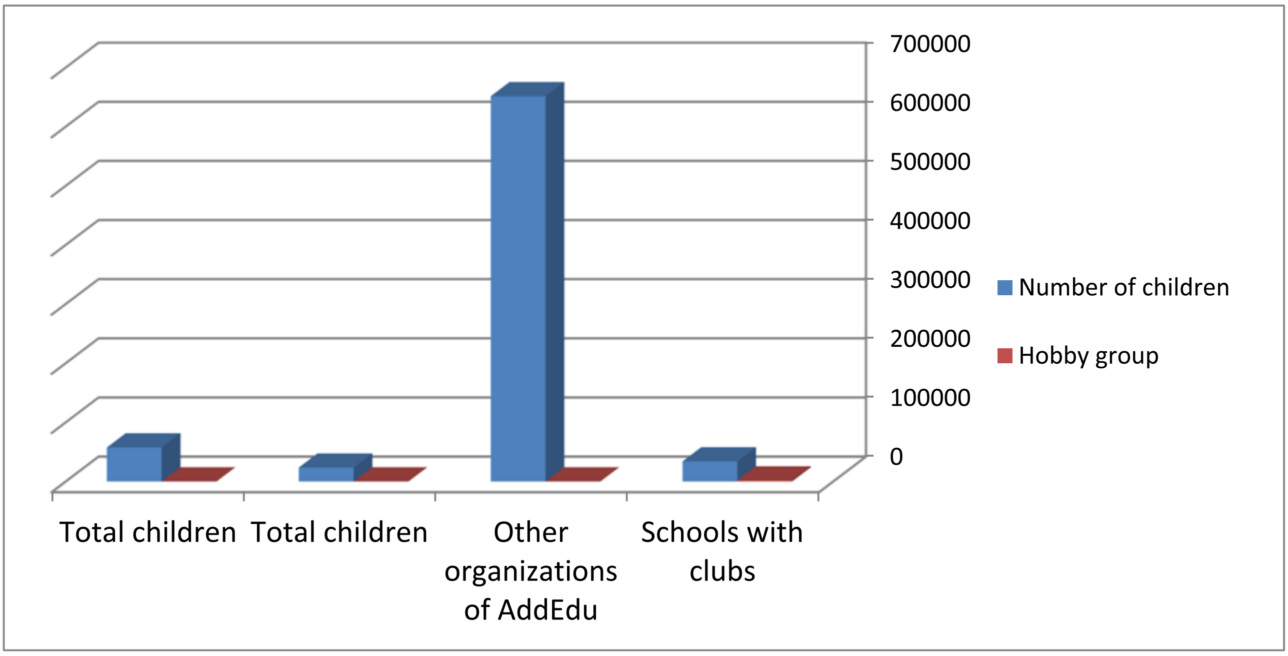

Fig. 2. The number of children employed in tourist and local history circles.

It is well known that with scientific, technical and social progress, the need for a person to assimilate a large amount of diverse information, quickly update knowledge, and improve skills increases. In these conditions, the role of tourist and local history activities, which integrates all the main pedagogical processes, is sharply increasing.

At this time, as a result of the research, the specialty “Geography – Tourism” was opened in the Republic of Kazakhstan, where the methodology of preparing future teachers for the leadership of the TCD of schoolchildren was tested. Similar work is being carried out at the Kryvyi Rih State Pedagogical University, where there is a specialty “Geography. Tourist and local history work”.

The relevance of the development of children's and youth tourism is due to the fact that it allows you to solve many other problems, and one of them is hypodynamia - a sedentary lifestyle, since the current younger generation lives in the era of computerization, modernization of technocracy.

Research scientists confirm the fact that as a result of the achievements of scientific and technical progress, computerization in all spheres of human activity has increased the number of cases of students, the amount of stress and disruptions in learning and behavior as a result of prealablement, insufficient exposure to fresh air, improper organization of leisure and recreation. After all, human health is closely related to the effects of the natural environment on the body and therefore tourism is the best way to solve this problem, which, unlike a variety of sports programs, has all the necessary natural components for health. This is communication with nature, a change of environment, psychological relief, and most importantly physical activity. Tourism is easy to organize, does not need specially equipped halls and platforms. The best sports ground was and still is nature! It is available for people of any age, is a feasible sport, because the load in it is well dosed with rest, and at the heart of ordinary walking. Being one of the most popular sports, it contributes to the education of a healthy and seasoned person, enriches the spiritual life neither in words, but in deeds, cultivates love for the native land. And in order for Kazakhstanis to love their land, it is necessary to instill this love from childhood. Most of all, this is facilitated by hikes, expeditions and trips, in which students have the opportunity to get acquainted with local attractions, with the past and present of their native land, with the traditions and customs of their people, to study the cultural heritage of their ancestors, conducting search activities.

In the educational organizations of the republic there are 7,668 deputy school directors for educational work, 18,402 teachers of additional education, including 851 teachers of tourism and local lore (698 of them with higher pedagogical education; 42 with higher professional education, 84 with secondary special pedagogical education and 27 with secondary special professional education (Figure 3) [6]. Tourist and local history activity is a pedagogical system, in the design of which a model of the system of continuous tourist and local history education was developed.

Engaging in various types of tourism since childhood allows you to cultivate a sense of citizenship, tourist culture and develops the ability to perceive the ideology of hospitality as a national idea, with the implementation of which it is possible to really develop tourism as an effective sector of the economy, ensuring sustainable development of the state with minimal consequences for nature and society [7].

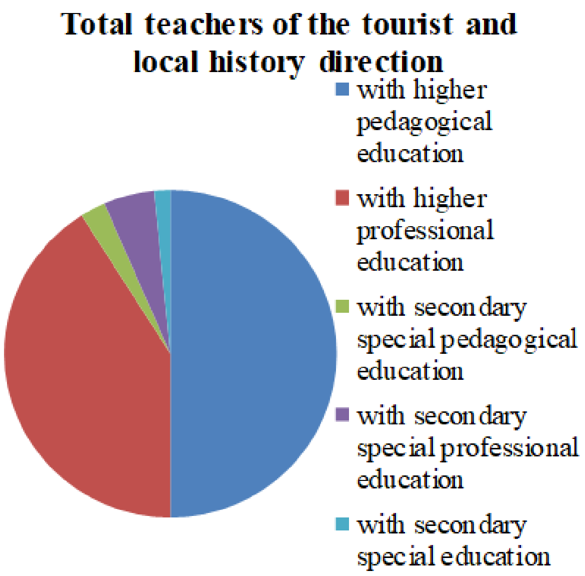

Fig. 3. Number of teachers of tourism and local lore in the Republic of Kazakhstan.

The developed tourist and local history activity is a pedagogical system, in the design of which the model of the system of continuous tourist and local history education is used.

The model of the system of continuous tourism and local history education (SCTLE) is a system of interrelated elements aimed at ensuring the main goal of continuous tourism and local history education-the formation of a harmonious personality and a healthy lifestyle.

SCTLE consists of four main stages of education: kindergarten, school education, additional education, vocational schools and universities. For each stage, goals and objectives are defined according to three parameters: training, education and development.

Kindergarten is the initial stage in the system of continuous tourism and local history education. The main tasks in the field of preschool education are:

- protection and promotion of children's health;
- mental development, physical, moral, aesthetic, environmental, economic, labor education;
- strengthening the role of the family in the upbringing of children.

During this period, children are laid the starting tourist skills, the basics of ecological culture, they receive initial information about their native land, the initial concepts of a healthy lifestyle.

The main tasks of the current stage of development of school education are:

- education for all-orientation of educational programs to high-quality education, upbringing and development of all children;
- the development of creative, spiritual and physical abilities of the individual, the formation of strong foundations of morality and a healthy lifestyle;
- education of a citizen, formation of a system of values and relations corresponding to a multinational society, Kazakhstan's patriotism; formation of a person with a rich spiritual, social and moral potential, capable of perceiving and developing national and world achievements in all spheres of life (fig. 4).

At the school stage of training, children undergo primary and secondary tourist training, learn the culture of behavior in nature, acquire the skills of local lore, research search and scientific design, join a healthy lifestyle, receive comprehensive education, pre-profile and profile training.

An integral part of continuing education and education is additional education, which is implemented on the basis of extracurricular organizations.

The purpose of the modern system of additional education is to create conditions for the formation of a versatile personality, including both modern (initiative, sociability, adequate adaptability, flexibility of behavior, mobility, leadership, organizational qualities, socio-psychological competence) and moral qualities (spirituality, sensitivity, attentiveness, honesty, responsibility, patriotism, tolerance, aesthetics).

The main tasks of additional education are defined:

- involvement of groups of student youth in the process of continuous education, familiarization with the achievements of national culture and sports;

- stimulation of diverse harmonious development, creativity and activity;
- organization of unregulated social communication, rational recreation and entertainment, adaptation to life in society.

Studying in clubs and sections of organizations of additional education, children have the opportunity to study local history, learn the traditions and rituals of their native land, improve and improve tourist skills, learn the basics of ecological culture.

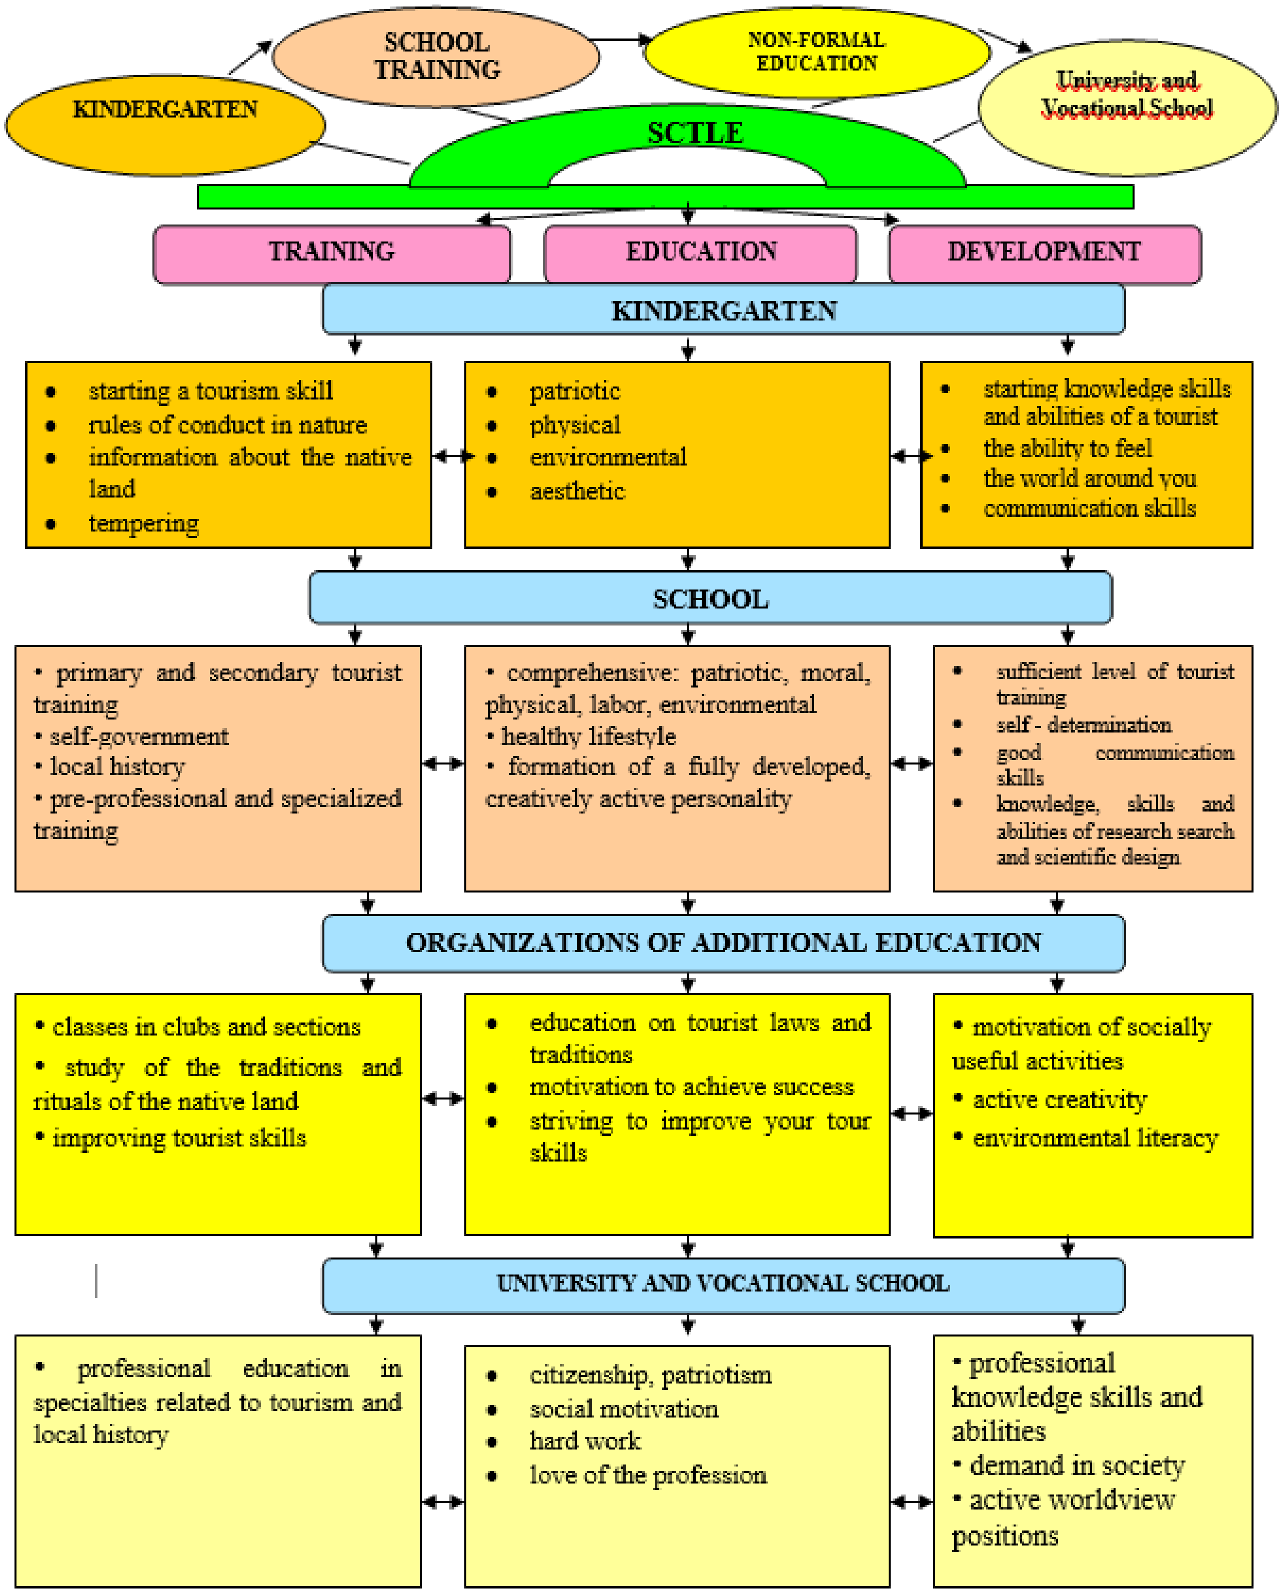

Fig. 4. The system of continuous tourist and local history education (SCTLE) [3].

At the stage of professional education in universities and vocational schools, students receive specialization in professions related to tourism and local history. The purpose of education at this stage is to provide conditions for the development of professional and social adaptation of the future specialist, the formation of a multicultural, humane and moral, physically healthy, highly intelligent, competitive, and therefore creatively developed holistic personality., able to independently formulate problems and practically solve them from high civil positions based on the use of national traditions and the latest achievements of world experience.

An important element of the professional training of a future teacher of geography and organizers of tourism and local history work at school can be the introduction of a special course "Organization of local history work at school" into the training system. The main tasks of this course are students awareness of the importance of tourism and local history work with schoolchildren, students mastery of various methods of studying their native land and readiness for local history and tourism work with students of different age groups. An important component of attracting students to tourism and local history work is their participation in educational excursions and tourist trips.

It is important, at the same time, to attract students to participate in excursions and hikes of various types: object-based (excursions and hikes to certain geographical objects studied in higher education); methodical (excursions and hikes on which students develop the ability to organize and conduct various tourist and local history events at school and out-of-school educational institution) and product (excursions and hikes that a student is able to develop as a finished tourist product that goes beyond the school curriculum, having an age limit) [8].

In the preparation of organizers of tourist and local history work at school, in our opinion, it is necessary to adhere to certain pedagogical conditions identified by O.V. Bondarenko:

- providing the goals of preparation for local history work of personal meaning;
- stimulation of positive motivation of students in mastering generalized local lore knowledge and skills to use them in solving problem situations and cognitive tasks activation of students;
- activity on the basis of personality-oriented and imitation-game approaches;
- a variety of forms and methods of local lore work with the provision of future teachers the freedom to choose ways to solve educational problems and situations of success [9].

Based on a comprehensive approach to modeling continuous tourism and local history education, we can identify the main pedagogical conditions for improving its effectiveness: the implementation of a systematic approach in tourism and local history activities; inclusion of students in various types of TLhA through ensuring the unity of educational and educational work; training of teachers to solve problems and implement TLhA.

In order to identify the effectiveness of the proposed model, the search and selection of indicators of all types of education of the child's personality was carried out. The following indicators of types of education were determined:

- moral-love for the Motherland, respect for state symbols, internationalism, tolerance, respect for the traditions and customs of the people, citizenship;
- physical – starting tourist knowledge, skills and abilities (KSA), strengthening of the musculoskeletal system, lung development, endurance;
- labor – conscientiousness in the execution of labor orders, the manifestation of personal initiative in the performance of duties;
- ecological – love of nature, knowledge of the rules of behavior in nature, understanding of the need for environmental protection;
- aesthetic – the development of aesthetic taste, the ability to observe nature and enjoy the beautiful, the ability to display what you see in creative works.

The indicators of all types of personal education are measured by standard diagnostic tasks developed according to the levels of complexity, taking into account age characteristics, on the basis of which the level of training of pupils (LTP in %) was determined at the stages of ascertaining and forming experiments in the control and experimental groups. High (when reaching 100-81%), medium (80-61%), and low (60-40%) levels were determined to determine LTP.

CG-control group – a part of the group that receives standard tourist and regional knowledge, its participants participate in fragmentary events of the TLhA.

EG-experimental group — part of the group engaged in specialized programs [10].

The competence approach in education originated in the scientific and journalistic literature in the late 1980s. To date, there is a multivariance in the definition of the terms "competence", "competence", which are used with the related concepts of "professionalism", "qualification", "education", etc. Most researchers hold the view that competence is an opportunity not just to have knowledge,but rather to potentially be ready to solve problems with knowledge.

The essential features of competence include the level determined by a combination of the following criteria:

- the level of assimilation of knowledge and skills (quality of knowledge and skills); the range and breadth of knowledge and skills;
- ability to perform special tasks;
- ability to rationally organize and plan your work;
- ability to use knowledge in non-standard situations (functional literacy).

Competence is a parameter of a social role, which in personal terms manifests itself as competence, the person's compliance with the place and time occupied; the ability to carry out activities in accordance with social requirements and expectations.

Tourist and local lore competencies are a parameter of a person's social experience that determines tourist and local lore knowledge, skills and abilities in accordance with the time, place, and surrounding society [11]. The formation of tourist and local history competencies of the younger generation of children provides for the acquisition of behavioral and survival skills in nature, the development of personal qualities (sociability, leadership, strong-willed qualities), motivates self-realization, self-knowledge, cooperation, and a healthy lifestyle.

We consider a comprehensive approach to the education of a well-developed personality in SCTLE at the preschool and school levels along two verticals that reflect all types and forms of TLhA.

During the implementation of the model of the system of continuous tourist and local history education at the stages of preschool and school education, organizational and pedagogical conditions were provided for all types of education: moral, patriotic, physical, labor, environmental, aesthetic.

We consider organizational and pedagogical conditions as a set of elements that contribute to the comprehensive development of the individual.

Organizational conditions are forms of organization and activity of preschoolers and schoolchildren. We refer the content, methods and technologies of the educational process organization to the pedagogical conditions.

We are confident that the measures taken will make it possible to use the entire arsenal of youth and youth tourism to educate the country's comprehensively developed younger generation, form a tourist culture among Kazakhstan's youth and commit to a healthy lifestyle. Tourism and local history have always been a powerful tool in the system of education and upbringing of the younger generation, the formation of a healthy lifestyle, the organization of recreation, leisure and restoration of spiritual and physical strength. After all, Ya. A. Komensky in his writings wrote: “Education is a process of life, not a preparation for the future life» [12].

TLhA in a school develops if it has a tourist organizer from among the teachers. When appointing a school tourism organizer, the school administration should be guided by the candidate's presence of the following important indicators:

- the strength of belief in the great importance of tourism for the school, in the need for it;
- the nature of views on the essence of children's tourism, i.e. the position, the candidate's approach to tourism and local history from the point of view of the tasks of the school, pedagogy;
- the level of tourist qualifications-personal experience of hiking, knowledge of tourism techniques, knowledge of the methods of organizing this work;
- such personal qualities as perseverance, perseverance, but also, at the same time, flexibility, the ability to correctly assess the moment, trend and prospect of the case.

The tourist organizer of the school needs to solve the problem so that, over time, a small but strong tourist asset will form around him from among teachers, parents, students, and production workers. The school needs a group of 3-5 people who are ardent supporters of tourism, who are truly passionate about this form of educational work with children. A school with a developed TLhA system is always distinguished by a large, friendly and strong asset of tourists-schoolchildren, first of all-high school students. As practice shows, in such a school, each class has its own class tour organizer, and the school-wide tourist self-government is implemented through the Headquarters or the Tourism Board.

The role of the student asset, its forms and structure in modern pedagogical science are practically not developed. However, it is possible to distinguish two completely independent factors, two separate, but interrelated goals that are inherent in the existence of a children's tourist asset:

- practical benefits for the organization of tourist and local history work in the school, which gives the labor contribution of the children's assets to the organizational work;
- pedagogical benefits, which gives the work of children in the education of their own social activity.

The activity of the school tourist asset gives a great pedagogical return: the children work for pedagogy and at the same time, working in the field of education, they themselves fall under the influence of the educational process. In this way, through the TLhA, an important task is solved: with the help of the children themselves, to conduct the pedagogical process in cooperation with them, without alienating them from “adult” affairs. Here we have a moment of cooperation in the pedagogy of the teacher with the students, a connection so far in the miniature of the state and public administration of school affairs.

The concept of a tourist asset can be classified according to the following parameters: by the nature of the activity; by the legal type of relations to the activity; by the scale of the activity; by the profile of the activity (specialization); by the level of training; by the duration of the activity. At each stage of the development of the system of tourist and local history work, the school should have its own corresponding structure of the asset and its own content of its work, since the discrepancy between these components of the system creates unnecessary contradictions and leads to failures in the development of the system.

In order to establish a system of tourist and local history work in the school, much is needed, but most importantly-you need a teacher who is ready for a hike, who is able to properly organize and competently conduct a tourist trip with children. In universities, teachers are not trained to conduct tourist work, they are mainly taught the methods of teaching the subject and very little is taught about the necessary practical skills. Therefore, class teachers, in the vast majority, are not ready for a variety of extracurricular educational work with children and do not want to engage in an unfamiliar business, especially in such a peculiar direction as TLhA. It is not enough to teach a teacher only a variety of tourist technologies, it is still necessary to educate him, to instill a taste for tourism pedagogy-the direction of educational work.

In the end, you need to achieve the following three conditions:

- the teacher's awareness of the usefulness of tourism (hiking) for performing their professional tasks;
- the teacher's confidence in their ability to go hiking with children;
- the teacher's sense of comfort in hiking, based on the guaranteed provision of everything necessary for such activities.

When planning work on tourist training, it is necessary: - to study the available personnel, to determine the positions of each employee to be trained, the level of his knowledge, i.e. to assess the degree of readiness of class teachers, teachers, educators to solve the tasks that are set at the first stage of the development of the TLHA system; - to determine the content, training programs, who to teach what, who to convince of what; - to outline specific forms, methods, methods, means of training; - to choose a leader, lecturers, instructors.

It is necessary to approach the tourist training of teachers in a differentiated way: first, to take into account the individual capabilities of each class teacher, and secondly, the needs of the school itself (children) in the development of the TLHA system. When organizing this work, it should be taken into account that school tourism is divided into two independent and interrelated parts - mass and circle tourism. The development of the circle branch of tourism is possible if there is even one well-trained teacher in the school, whose work can be supported by invited part-time circle leaders. It is necessary to attach a young teacher to an experienced teacher-circle leader for individual training and internship, who in a few months will be able to lead the circles in the lower grades. This tandem is also useful because in a large multi-day hike with a group of students, there must be two adults-the head and his deputy. The main concern is the development of the “Mass Tourism” branch, which requires that all class teachers and educators have at least the most minimal training and experience in tourism - personal experience of hiking.

Therefore, the main task is to pass through the tourist training of teachers, without which it is impossible to improve the TLhA system in the school. According to the results of the study, it was found that the weakest link in the training of teachers, as a rule, is the pedagogy of tourism - the teacher's approaches to the content of hikes, goals, and methods.

The educational campaign is held in order to remove the teacher's fear of the campaign, before everything unusual, unusual, which is associated with the campaign and the accompanying pedagogical work. You can only be convinced of the benefits of a hike by participating in it. The hike should be carried out in good weather on a beautiful route, should not be difficult, and in the cognitive aspect very informative. Its program must necessarily include orientation on the terrain using a compass and a map, the most simple (for the first time) obstacles, acquaintance with nature and with a bright excursion object, bivouac breaking (choosing a place, making a fire, cooking, etc.). Important is the preparation of the campaign-the motivation for choosing the route, the distribution of hiking duties, questions of equipment and equipment.

In summing up the results, it is an important stage of the events held. For popularization, the most common and acceptable forms are lectures and seminars. The school should develop its own seminar program based on the existing ones and taking into account individual needs. It is necessary to plan a series of theoretical and practical classes with teachers per year and taking into account the prospects for the growth of tourist qualifications. The seminar on tourist work at school is the simplest option for training teachers, but its fruits are not too weighty, because it mainly takes place in the mode of studying theory. A more effective form of tourist training of teachers is a field seminar, which can be held on the basis of another school, the House of Creativity, the regional Syutur, the local history museum. Significant advantages in the organization of a productive educational process is such a form as a training camp, when participants for a day, for two or even for a longer period break away from the home environment and move to a certain place where they live and study all these days. According to the nature of the organization of the educational process, training camps are divided into a training camp-seminar and a training camp-hike. In the first case, the participants mainly listen to lectures, exchange experiences, and conduct practical exercises on the ground and indoors. In the second case, in addition to the short lecture part of the collection, a full-fledged tourist trip is held for one or two or more days, and at the end - an analysis of the results. A valuable form of systematic consulting assistance to teachers is a tourist corner, equipped in the recreation area of schools or in a special office of the school. The teacher should always have a self-service source of information on tourism and local history at hand. In the tourist corner there should be a map of the district, region, and surrounding areas of the city, a shelf with books and brochures, folders with methodological materials on various topics, forms of documents, tools for copying and working with maps, etc.The most important form of training teachers in tourism is the analysis of the practice of living specific tourist work. And if any of the above forms of training can be applied by choice, then the analysis of practice, the exchange of experience must necessarily be used in addition to all the others. It is necessary to fully draw pedagogical conclusions from the analysis of the work practice: to objectively reveal not only the results, but also the course of the pedagogical process in the campaigns, through the vision of which one can understand both what a friend has achieved and how he achieved it [6].

3 Conclusions

The peculiarity of the organization of training today is the fundamental issue of the organization of the educational process in educational institutions of all levels: from preschool to higher education. This primarily concerns the increase in such forms and methods of teaching that form key competencies, create conditions for development and the ability to make decisions on their own, to learn throughout life. In our opinion, the organization of continuous tourism and local lore education will make it possible to realize these goals. The model created and described in the paper demonstrates the step-by-step nature of educational work. Certain tasks make it possible to choose the most effective forms and methods of work for each level.

The peculiarities of the organization of tourism and local lore work at the stages of preschool, school and additional education should be mass character, the implementation of educational and educational goals, the acquisition of healthy lifestyle skills, the formation of a need for active knowledge of the world around. The organization of such activities should complicate and take into account the age characteristics of children. For example, in kindergarten, from walking to category hikes in high school. The results of tourist trips are used for the local history approach in the subjects of geography, biology, history, literature and a number of other subjects.

In higher educational institutions, the main task is to prepare students for planning and organizing tourism and local history work with children. Therefore, work at universities should be aimed at the formation of subject-specific tourist and local history competence through a specially developed block of academic subjects (methods of organizing tourist and local history work, sports tourism techniques, methods of conducting educational excursions). The second, no less important part should be the acquisition of personal experience in organizing tourist activities. To do this, it is important to organize educational tourist, local history practices, hikes and excursions. Carrying out such work will create a strong motivation for future teachers and a willingness to organize tourist and local history work.

The conducted research confirms that tourist and local history work is a universal means of education and upbringing. And preparation for the management of the implementation of activities is necessary for future subject teachers.

Abstract. The exploration industry of Ukraine is experiencing a protracted crisis. It is confirmed by the curtailment of funding for the development of country mineral resources by 60% last year which causes the closure of exploration companies. The range of problems traditionally solved by the geography of mineral resources is significantly reduced. These reasons encouraged us to consider the main methodological approaches to the study of mineral potential of specific regions. The studied approaches such as natural-geographical, economic-geographical, ecological-geographical, and complex structural-geographical lie in the domain of geographical science. The article emphasizes the urgency to develop structural and geographical course of research, which is based on the studies of mineral resources and the approaches mentioned above including geological one. The structural and geographical course of research is supposed to create real models of mineral resources of the country regions and to suggest specific measures of their structure optimization alongside prospects of their development following modern world tendencies. The research may result in the creation of a long-term concept of balanced development of the mineral complex of the region, the prevision of the use of mineral resources, the justification of resource-saving technologies. A systematic approach to such a concept will ensure the rational use of resources, the formation of new infrastructure, conditions for environmentally safe function of the economy, sustainable and balanced development of the economic complex of the region.

1 Introduction

The geography of mineral resources as a sphere of study does not currently develop in Ukraine. There are almost no publications with the results of natural and geographical studies on the regularities of formation and territorial localization of deposits of different types of minerals, and analysis of their impact on the formation of mining complexes. The problems of effective functioning of regional mineral complexes and optimization of their structure are scientifically neglected. We believe that it is obvious and long overdue the need for a comprehensive (constructive-geographical) approach to the study of mineral resources (MR) of definite regions and the country as a whole. The efficient use of mineral resources based on modern technologies with combination of the economic efficiency of exploration and processing of mineral resources with minimum negative environmental impact can lead to optimal solutions of present complex economic and social problems. In this context the authors suggest a brief overview of methodological approaches to the study of mineral resources and their opinions on the constructive and geographical direction of their study.

To provide a comprehensive systematic approach to constructive-geographical studies of mineral resources of specific regions, it is essential to include the following basic interrelated areas of research: geological-mineralogical, natural-geographical (geo-morphological, paleo-geo-morphological, paleo-geographic, landscape, etc.), economic-geographical and geographical ones.

The geological and mineralogical course of MR research is the most extensive and elaborated approach, and involves a comprehensive study of mineral resources from the material composition study to the development of general concepts of prospecting and exploration of minerals in continental areas, oceans, certain administrative units. The analysis of the development of geological and mineralogical research of the MR universally and in Ukraine is the subject of special consideration which goes beyond the scope of this publication.

The natural and geographical studies made by Ukrainian researchers explore: paleo-geographic and paleo-landscape conditions of mineral formation and forecasts of their deposits by M. Veklych [1, 2].

E. Palienko [4], M. Volkov, V. Palienko, I. Sokolovsky [5], V. Palienko [3] study paleo-geo-morphological, geo-morphological, morpho-structural

*Corresponding author: panteleeva4y@gmail.com

and neo-tectonic criteria for prospecting and exploration of mineral deposits. Landscape-geochemical approaches to the study of mining areas were substantiated by E. Ivanov [7, 8, 18] and others.

The economic and geographical direction of the MR study in Ukraine is represented by the works of I. Gorlenko [10, 11], V. Mishchenko [26], M. Palamarchuk, I. Gorlenko, T. Yasnyuk [12]; M. Palamarchuk, O. Palamarchuk [13]; L. Rudenko, V. Palienko, L. Shevchenko [14, 15, 16] and others.

Ecological and geographical research. We notice that a relatively small number of thorough researches are devoted to the issues of subsoil protection during exploration and mining works. The significant number of publications studies the problems of the negative environmental impact of mining generally or discretely. These are the works of G. Rudko, L. Shkitsa [20], G. Rudko, E. Ivanov, I. Kovalchuk [8] and others. These works consider environmental problems of mining in the context of general environmental issues, propose methodological approaches to their solution, and analyze reasons of ecological crisis situations in certain regions.

The historical course of MR research is represented by works exploring the issues of formation and development of mineral sciences, history of discovery and study of mineral resource potential of definite territories, history of mining in the context of general civilization process, etc. (M. Syvyj [19] and others).

Constructive-geographical approach to the study of mineral resources and related issues are actively promoted in the works of: L. Rudenko, V. Palienko, L. Shevchenko and others[14], L. Rudenko, V. Palienko, V. Baitala and others [15], L. Rudenko, V. Palienko, M. Barshchevsky and others [16], M. Syvyj [17], M. Syvyj, I. Paranko, Ye. Ivanov [18], and others.

Research methods. Research was based on such general principles of cognition as objectivity, causality, universal connection, evolutionary. From the traditional general scientific methods, the following were used: observation (field method), analysis and synthesis, induction and deduction, comparison and analogy, generalization and abstraction, modeling and forecasting.

Within the framework of a constructive-geographical approach to the study of the mineral resource base of the Podillia region, natural-geographical, economic-geographical and ecological-geographical approaches were used, which made it possible to learn the specifics of the mining and industrial nature management of the region and substantiate the principles of its optimization.

The principles of constructive-geographical research of regional environmental management, developed in the works of I. Horlenko [10, 11, 12], I. Kovalchuk [8], V. Paliienko and L. Rudenko [14, 15, 16], H. Rudko [8, 20, 21] and others.

Constructive-geographical analysis, assessment and forecasting of the development of the region's mineral resources complex were carried out on the basis of the proposed algorithmic research schemes. Such schemes made it possible to optimize the research process, to provide a diversified study of mineral resources on the basis of formalization, automation and unification of analytical and synthesizing studies, bringing them to the level of guidance or instruction.

2 Results and discussion

Natural and geographical studies using geological exploration data make it possible to establish and detail the genetic patterns of formation and localization of different types of minerals in the region, predict the location of deposits in new areas and increase reserves within known deposits. They also may determine mining, geological and geo-ecological conditions for future exploitation of deposits, and predict the change in the qualitative characteristics of mineral resources in the area of deposits, etc.

An important form of natural and geographical studies is paleo-geographic reconstructions, which help to reproduce the components of ancient nature of a region: paleo-geology, paleo-relief, paleo-hydrology, paleo-climates, flora and fauna, facile complexes, etc. Paleo-geographic, paleo-landscape and lithological-facile maps based on the results of such reconstructions give an idea of the conditions of mineral accumulation in specific areas and can reliably predict the area of its localization.

M. Veklich [1, 2] carries out paleo-geographic and paleo-geo-morphological studies to predict titanium, zirconium, rare earth deposits within the Ukrainian Shield, as well as studies the conditions of formation of manganese ore deposits in the Nikopol Basin and Cenozoic lignite deposits in Ukraine.

Geo-morphological studies solve a number of important problems while search, exploration and development of mineral deposits. At the stage of geo-morphological search, two types of geo-morphological objects are studied: resource-containing and resource-informative [3, 4]. The former include modern or hidden landforms of various origins, which contain deposits of minerals: placers, building materials, peat, coal, oil, gas, etc.; the latter indicative landforms that allow targeted exploration for minerals. At the stage of field exploration, the assessment of the relief of the location area is prioritized to organize the infrastructure of mining enterprises and to prevent the dangerous geomorphological processes that can reveal in productive and adjacent areas. At the stage of mineral deposit development, the main concern is natural resource rational use, protection and preservation of the natural environment.

Morpho-structural and neo-tectonic studies find particularly successful application in the search for structurally conditioned oil fields in the oil and gas provinces of Ukraine [5, 6]. They are accompanied be the solution of the problems dealing with the determination of optimal structural and geomorphological conditions of hydrocarbon accumulation, neo-tectonic conditions of their migration, etc.

Morpho-structural studies in areas of active tectonic disturbances contribute to the identification of belts and nodes of ore formation of tin, lead, copper, nickel, tungsten, uranium and other ore minerals.

Complex morpho-metric, morpho-dynamic, historical and geomorphological studies are ultimately useful for search and exploration of deposits of diamonds, titanium, zirconium, gold, particularly within the Ukrainian Shield, and in other territories. Historical-genetic, paleo-geo-morphological studies are helpful in searching for brown and hard coal deposits, etc.

Among landscape studies, special attention should be paid to those that involve solving such problems as [7, 8]:

- analysis of the current landscape and geo-chemical condition in the mining regions of Ukraine;
- substantiation of landscape-geo-chemical approaches to the study of mining areas in order to predict the negative impact of extraction and processing of mineral resources on landscape complexes;
- development of recommendations for the preservation and restoration of the diversity of landscape complexes within the areas of extraction and in the territories nearby to the development sites.

Economic and geographical research is the necessary condition for determination of the areas of MR rational use. Such studies establish regional geographical patterns of mineral deposits [9], the degree of their study and degree of development, the structure of industrial relations between mining enterprises, the structure of sectoral and regional consumption of minerals, market conditions, etc. [10, 11, 12, 13]. Economic and geographical studies determine the feasibility and integrated development of mineral deposits, the degree and direction of processing of basic and related minerals, the possibility and effectiveness of mining waste utilization, and so on. They consider possibilities of formation of territorial-production complexes of mineral-raw material direction (as one of the most expedient and progressive forms of rational use of mineral resources) on the basis of separate explored deposits or their territorial groups. L. Rudenko, V. Palienko, L. Shevchenko and others [14] highlight extraordinary importance of formation of territorial-production complexes on the basis of minerals for Ukraine. Their research should be a priority in finding ways to improve resource use.

Generally, economic and geographical studies of MR are conducted in three directions: branch, functional and territorial [10, 11, 13].

Branch direction of the research involves considering the needs of mining industries, their role in structuring industrial complexes. Simultaneously, branch research establishes the level of concentration of certain types of territorial-production complexes, peculiarities of stock placement, mining and hydrogeological conditions, technical and economic indicators of field operation, possibilities and expediency of the complex development, and industrial processing of raw materials.

Branch division aims at the further development of industries based on the development of minerals, establishing their impact on the territorial division of labor and determining the optimal proportions, considering national interests. The results of the study enable to establish the scale of mineral use of a particular region, the potential of expanding and improving the relevant industries within the region.

The functional direction of the study of MR comprises two stages of research [13, 17, 18]. The first stage determines the complex-forming properties of minerals, the developmental prospects of territorial-industrial complexes; and clarifies the nature and degree of the mineral influence on the division of labor in the district.

The second stage of the functional direction of the MR study specificates their role in the functional structure of industry, in the formation of its main links – inter-sector production complexes. At this stage, complexes basing on the use of MR are formed. They are mineral orientated production complexes, such as coal and metallurgy, oil and gas, mining and chemical, etc. The study of mineral orientation systems allows identifying ways of improvement their sector functional structure and territorial organization on the basis of integrated use of minerals, including exploitation and processing of minerals, as well as ways to improve internal and external relations through the use of local resources, reduction of long-distance transportation of raw materials, and transport expanses accordingly.

Territorial direction of MR research involves the study of their impact on the territorial structure of production, especially on the formation of territorial production complexes. To identify the importance of mastering the forms of territorial concentration of mineral deposits in the development of the territorial structure of industry, the researchers distinguish territorial production complexes which are based on mineral resources: centers, nodes, agglomerations, areas of mineral orientation [10, 13, 17, 18]. The composition of minerals determines the production orientation of such complexes.

Peculiarities of deposits (structure, capacity of productive horizons, mineral-petrographic composition of minerals) also affect the role of the corresponding industrial complex in the territorial division of labor. The composition of the MR determines the number of specialization areas of such complexes.

The ultimate goal of the territorial MR study is to develop ways to improve the territorial structure of industry on the basis of rational use of mineral resources, which is necessary to ensure optimal territorial organization of production, the implementation of long-term spatial planning.

The geo-ecological (environmental) direction of the MR research developed predominantly due to the necessity to study the processes accompanying the exploration, extraction and primary processing of minerals [7, 8, 16, 20]. It was caused by the urgent needs of monitoring, analysis, forecasting and minimization of negative impacts of mining and processing industries on the environment. The development of rational schemes of ecologically safe functioning of mineral complexes in the general context of nature optimization added to its importance. Ecological and geographical research is aimed at studying the impact of mineral resource development on the ecological and geographical situation of the regions, substantiation of the principles of ecological policy of these regions to preserve and improve the environment and create favorable living conditions. The influence of mining complexes on all elements of the regions' environment is studied: disturbances and changes in the land fund, air pollution, soil and groundwater, violation of their hydrological regime, etc. The consequence of ecological and geographical studies of the mineral resource base should be the development of a set of measures to improve the quality and preservation of the region natural environment, and the solution of such an urgent environmental problem as justification of reclamation of mining landscapes [15, 16]. Research and publications on MR environmental issues primarily focus on seven issues: protection and rational use of subsoil, surface and groundwater, air, reclamation of lands destroyed by mining, utilization of mining waste, ecological and landscape problems of destroyed areas, resource security and sustainable development issues.

A comprehensive (constructive-geographical) approach to the study of mineral resources lies in the analysis and synthesis of factual data, theoretical and methodological developments of geological, natural, economic, geo-ecological and historical areas of MR study. It aims at solving a number of problems and issues as following: factual assessment of the state of study of the region mineral resource base, assessment of active and stand-by reserves of mineral resources, establishment of patterns of territorial distribution (territorial structure) of the MR, substantiation of opportunities to increase reserves of explored deposits and assessment of promising areas, diversification of the mineral resource of the region, recommendations on the policy of resource conservation and resource substitution in the region, substantiation of the main ways of using the region MR, determination of the place and role of MR in the economic complex of the region, studying the supplies of the region and its administrative units with certain types of mineral resources and recommendations for covering mineral deficit, selection of resource-saving technologies for extraction and processing of raw materials, development and implementation of programs for reclamation of destroyed lands and utilization of mining waste, optimization of environmental situation in the region, etc. [17].

It is obvious and long overdue the need for a comprehensive systematic approach to the study of mineral resources of particular regions, oblasts and districts. The efficient use of mineral resources by means of modern technologies combining the economic efficiency of exploration and processing of mineral resources with minimum environmental negative impact can be one of the ways leading to optimal solutions of present complex economic and social problems. The program of mineral resource base development of Ukraine for the period up to 2030 [24] provides the solutions for urgent problems of the mineral resource complex, the increase of primarily strategic mineral raw materials reserves to ensure stable operation of industrial and agro-industrial complexes in the future. The program suggests comprehensive (geological, engineering-geological, ecological-geological, etc.) study of the territory of Ukraine for the purpose of development of state nature protection policy and counteraction to dangerous natural and technogenic disasters and processes.

The constructive geographical researches with the focus on a comprehensive approach to the analysis of the state and development of mineral potential of the regions can pose an especial value.

Presently we consider very significant from a constructive and geographical point of view the design of the optimal correlation of the rate of development of mining enterprises (industries) and the growth (or creation) appropriate mineral resources. It is urgently required a scientifically grounded comprehensive near-term forecast of the state and regional needs of Ukraine in specific types of mineral resources, based on the actual possibilities of the extraction, the growth of reserves and the geo-ecological situation. The foundation of the economic policy of the state requires the assessment of the mineral potential and the possibilities of its most rational and cost-effective implementation.

On the basis of the above mentioned considerations, Ukraine relevant issues are related to a thorough and comprehensive analysis of mineral resources of some regions and the whole state in order to optimize the functioning of mining and processing industries, creating reliable and effective models of sustainable development, as well as issues of rational use of subsoil resources and solving environmental problems of mining areas.

This is the range of issues that science of *constructive geography* addresses, one of the key tasks of which is the scientific substantiation of rational use of nature in the regions of Ukraine; and the comprehensive study and consideration of zone, provincial and local natural resources and conditions. The area of interest issues of constructive geography relates to the accumulation, analysis and synthesis of all factual data concerning the study, distribution, development and primary processing of mineral resources and the solution of environmental problems provoked by the above processes. These tasks are under consideration of not only constructive geography, but also geology, mineragraphy, geomorphology, paleo-geography, economic geography, economic geology, hydrogeology, geo-ecology, which intermittently causes inconsistency of the proposed solutions.

Therefore, the essence of constructive-geographical research of mineral resources lies in a comprehensive analysis and evaluation of this type of resources being an important component of integrated natural resource potential of the territory. It also suggests the forecast of development trends and ways to optimize the functioning of mineral complexes, assessment the exploration and mining impact on the geo-ecological situation and substantiation of management decisions on the efficient use of mineral resources, utilization of mining waste and minimization of the negative consequences of mining operations in the regions [15, 17, 18].

For the solution of such tasks as constructive-geographical analysis, assessment of MR and the prospect of development of region mineral complexes, a number of algorithmic research schemes were compiled and tested [17]. These schemes enable the optimization of the research process; streamline the study of various aspects of MR with the simultaneous improvement of the result quality. They strive to formalize, automate and unify the analytical and synthesizing procedures of MR region research, changing them guidance or instruction.

Algorithms make it possible to identify the structure, the mechanisms of functioning of mineral complexes, and the trends in their development, to identify the ways of subsoil resources rational use, and to improve the region ecology. They provide for the solution of both theoretical and practical problems, primarily such as methodological justification of strategic directions of complex development, their role in economic complexes of regions, MR integrated use and utilization of mining waste, reduction of environmental tensions, etc.

An important element of the algorithms is the creation of an information database on the current state of the region MR. Scientific analysis and synthesis of information on mineral resources of the territory (region, economic area) requires a huge amount of statistical, cartographic, departmental, and literary data of the quality, quantity and cost parameters of resources. The creation of a data bank comprising information generalization on the territorial categories of three levels: local, oblast and regional ones is ultimately required.

The local level represents information on MR collected within administrative districts (or territorial communities presently). These are general data on individual deposits, ore occurrences, operating and stand-by mining and processing enterprises, as well as preliminary information on qualitative and quantitative parameters of mineral resources of each deposit, their mining-geological and hydro-geological characteristics, volume of production and sales, complexity of use of mineral raw materials, waste and environmental protection measures at each specific mining enterprise. The information allows making substantiated conclusions about the mineral potential of individual administrative districts, determination of the optimal directions of socio-economic development of grassroots territorial units.

The oblast level should provide the collection, accumulation and synthesis of information on MR of separate areas, their potential, ways of optimization use, and considering obtained data substantiates the directions of oblast mineral complexes development in the line with the national concept of mineral base development.

The regional level generalizes the information, combines data on several areas of the region (economic region) and assists the development of mineral resources of large regions of the country, determines the specifics of socio-economic development of large areas.

Thus, the first step in the study of region MR should be made in the creation of a database containing the most diverse and complete information about the object of study. It should be based on a combination of the component and territorial approaches to the formation of a single system of nature management, aimed at solving structural and geographical problems of study, rational use and protection of mineral resources.

Collection of source information in modern conditions is complicated by the fact that statistical authorities receive almost no formalized reports from exploration and mining enterprises and therefore the actual data have to be collected in separate organizations, which to some extent related to the study and exploitation of mineral resources.

The main source of information about mineral resources of Ukraine is the State Research and Production Enterprise State Information Geological Fund of Ukraine "*GEOINFORM UKRAINE*". It is an institution of the Ministry of Ecology and Natural Resources of Ukraine which collects stores and provides information accumulated in the process of geological study and subsoil use. *Geoinform Ukraine* has complete, reliable and objective information on the geological study of the territory of Ukraine, the current state and prospects of development of mineral resources and geological environment, the world situation of mineral resources, and legal aspects of subsoil use.

Regional state departments of ecology and natural resources accumulate information on environment protection measures carried out at mining enterprises (air, water environment, land protection and reclamation works, etc.).

The next stage of constructive-geographical study of region MR involves the analysis of the collected factual material. At this stage, the information is grouped by individual types of raw materials, appropriate cartographic models are built (preferably for each type of raw material), which allow to identify patterns of territorial concentration of deposits and manifestations of minerals within the region. The comparison of the constructed models on different types of mineral raw materials allows to allocate territories (areas, macro bushes and bushes) with the maximum accumulation of raw material resources and, on the contrary, the territories poor in mineral resources. Such models can serve as a reliable basis for optimization of the mining infrastructure of the region, the integration of production based on the rational use of mineral resources, etc. [17, 18].

The study of stratigraphic sections of individual deposits allows establishing their belonging to certain stratigraphic horizons, which helps define the prospects of mineral deposits of certain areas of the region.

Coefficients of industrial exploration of districts are determined: ratio of reserves of industrial categories to total explored reserves of mineral raw materials. The analysis of the development degree of the mineral deposits fund is conducted: assignment of deposits to certain categories (the developed deposits, deposits prepared for operation, reserved ones, deposits eliminated from the balance sheet, deposits aggravated because of certain circumstances: fully explored reserves objects, built-up objects, located on the territory of nature protection objects, etc). The coefficients of development of each mineral are determined (the ratio of reserves of developed deposits to the reserves of all explored deposits). The distribution of existing and reserve deposits within the region is studied, and it is analyzed the current level of extraction of certain types of raw materials at specific mining enterprises, administrative districts and regions. The trends in the extraction of certain types of raw materials are identified. The annual coefficients of provision of mining enterprises with explored reserves are calculated: the ratio of reserves of industrial categories to annual production volumes. It is also established the potential of extraction of definite types of mineral raw materials at the mining enterprises on areas, oblast and province. The ratios between the volumes of raw materials extracted by local enterprises and imported into the region are calculated. An important task of constructive-geographical study is the analysis of the state, region, districts and areas needs of specific types of mineral resources.

The results of analytical research help establish the actual and potential use of MR in the regional and state economy [17, 18] in modern conditions, and consider the ways of effective expanding use of MR.

The next element of constructive-geographical research of MR of regions is their constructive-geographical estimation.

N. Ratner [25] proposes to assess the mineral resource base from two standpoints: industrial and regional. The economic assessment of region MR applies some differences in its approach. If the purpose of the industrial assessment of the MR is to establish the supply of raw materials needed to meet the objectives of the industry, the regional assessment involves the rational use of mineral resources considering ecological balance, determining the role and place of each resource in economic development.

The assessment of mineral resources is based on a rational combination of regional and industrial principles, taking into account economic costs and effects, as well as a set of industrial and regional assessment factors.

Industrial factors (geological, mining, technical and economic) form the socially necessary costs and the estimated price of raw materials. Regional ones (production integration, infrastructure, environmental situation) determine the effect of territorial organization of production and the efficiency of regional use of production resources (labor, material, financial), necessary to achieve this goal [25].

The ideas presented above lie in the basis of consideration of the constructive-geographical assessment of region MR as a consistent solution to the following issues [18]:

- the determination of the industrial value of deposits and manifestations of minerals;
- the assessment of the MR provision of administrative units of regions;
- the assessment of the territorial-production structure of mineral complexes of the regions and the peculiarities of its functioning;
- the assessment of economic and territorial productivity of MR territories;
- the assessment of the rational use of MR;
- the assessment of the environment impact of mining companies in the regions;
- the management decision taking based on constructive and geographical assessments of region MR.

The assessment can be carried out in stages. Firstly, it is assessed the resources of definite industries, secondly, the resources of the region in general.

The ultimate result of such assessment of mineral deposits and their region manifestations is in making decisions on the feasibility of the operation of existing quarries (mining camps, mines), increasing the volume of extraction or conservation on the contrary; determination the prospects and sequence of the operation of the deposits; recommendations for the assessment of promising minerals and additional exploration of deposits with the depleted reserves.

This comprehensive approach to the study of each deposit forms a holistic view of the real value of the deposit regional fund and, accordingly, addresses the feasibility of their operation in modern market conditions or in the future, establishes the futility of individual deposits.

Construction of maps (models) of territorial density and MR security of administrative units of the region helps reliably estimate the saturation density (saturation coefficient - the ratio of the amount of explored industrial reserves to the area of the administrative unit, ton / acre) by individual types of raw materials and districts. The same approach is applied to the assessment of the supply (ton / person) of specific types of mineral resources of administrative units, as well as certain sectors of the economy of the region.

An important task of the research is to assess the needs of regions (at the present stage and in the near future, taking into account market conditions) in the products of local mining complexes; to determine the estimated supply of raw materials from other regions of Ukraine or abroad; to assess critically the existing use of mineral raw materials for various purposes and to justify the proposals on their efficient and rational use.

The further assessment is made on complexity of the mineral resource use of specific deposits and accumulated mining waste in the region. The following aspects should be taken into account: the total use of the main and related components of the deposits, the selective extraction, transportation and separate storage of extracted components, etc. The mining waste pollution maps of the region territory are built and on their basis such wastes are estimated as potential resources of various industries or agriculture. The scales and ways of region utilization of overburden rock, lateral rock and bedrock, enrichment waste and waste of secondary processing of mineral raw materials are also estimated. As a result of the listed evaluation procedures, a generalized prognostic assessment of the use of region mining waste is given both through the construction of recycling enterprises and the reorientation of the existing relationships between enterprises.

The procedure of economic and geographical assessment of region mineral resources mentioned above includes the typology of the latter; assessment of their component by types of raw materials and territorial structure, as well as the separation of territorial or mining production complexes with mineral orientation; assessment of their structure, relationships and features of functioning. As a result of economic and geographical research, it is substantiated the assessment of the production complexation possibilities on the basis of the optimization model of the structure of the mineral complex, rational approaches to the use of MR and mining waste in the region. The final stage of the MR assessment determines general negative environment impacts of mining production and perspective directions of reclamation measures in the region.

The ultimate result of constructive-geographical research should be a long-term concept of development of the region mineral complex, a forecast of the use of mineral resources [26], and the resource-saving technology justification. A systematic approach to the creation of such a concept may ensure the rational use of resources and the design of new infrastructure, maintenance of the conditions for environmentally friendly functioning of the economy, and balanced development of the region economic complex. The development of the concept aimed at forecasting the main events and tendencies in the mineral and raw material complex of the region should undoubtedly be carried out on a large scale, comprehensively, in line with the national decisions.

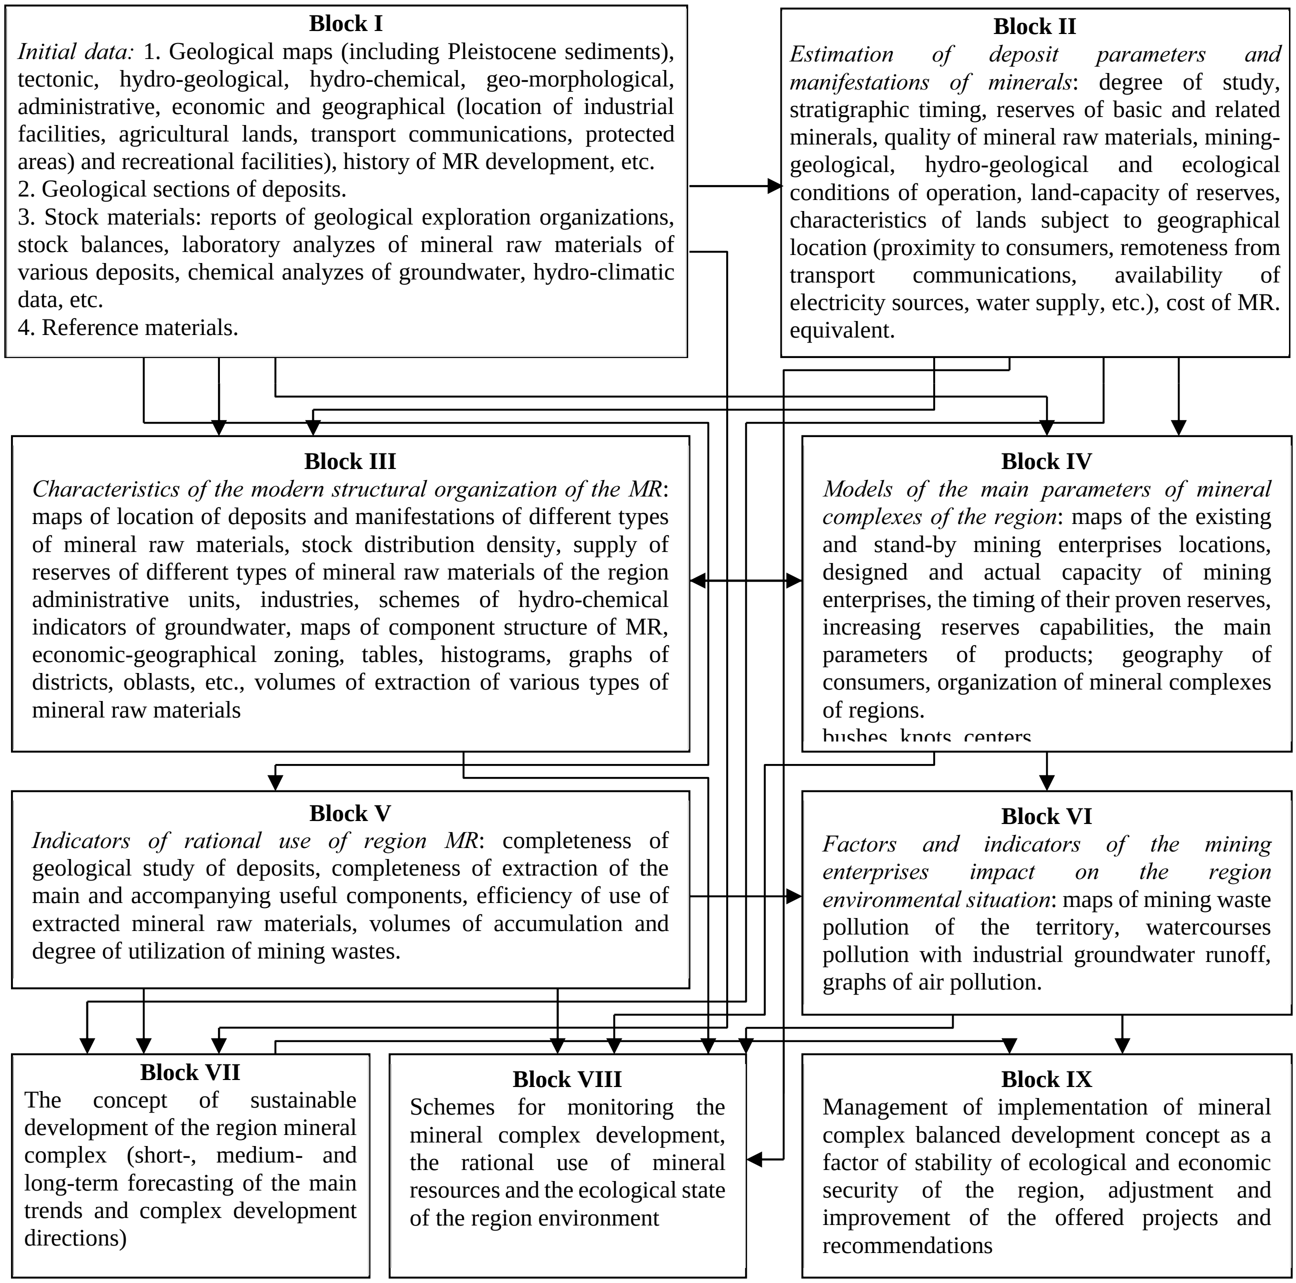

Fig. 1. Block diagram of structural and geographical studies of the regions.

We believe that the concept, concerning national priorities, should take into account the following range of issues:

1. Substantiation of long-term policy of socio-economic development of the region.

2. Proposals for optimal consumption of raw materials by various sectors of the economy, ways of covering the shortage of certain types of raw materials in future.

3. Substantiation of recommendations for the creation of mineral complexes on the basis of new, unusual for Ukraine types of raw materials (eg, saponites, apatites, granular phosphorites, glauconites in Podillya, etc.). The thorough preliminary structural and geographical analysis enables to offer a list of such deposits for investment and priority exploitation.

4. Development of scientifically substantiated forecasts of region needs of specific types of raw materials for the short, medium and long terms. The forecast takes into account the actual volumes of raw material extraction in the region, the possibility of increase or import from

other regions; the expediency of development of the deposits of certain types of raw materials explored in the region, which are currently imported from remote areas.

5. Submission of detailed recommendations on comprehensive, waste-free, rational use of mineral resources of the region.

6. Suggestion of the set of measures aimed at improving the environment in the areas of mining with minimization of its negative impact. Possible changes in the ecological state of the region are forecast considering the increase of production capacity at mining enterprises or the development of new mineral resources for intensively developing industries.

7. Anticipation and implementation of a system of monitoring of environmental protection measures carried out in the region and the consequences of their implementation.

8. Prediction of the socio-economic effect of the mineral resource base expansion, optimization of MR use, improvement of the region ecological condition.

9. Development of recommendations for the optimization of the infrastructure of the region mineral complex.

Generally a block diagram (Fig. 1) demonstrates the sequence and content of constructive-geographical studies of mineral resources of regions.

Constructive-geographical approaches to the study of mineral potential of certain regions of the country are actively introduced into the educational process of a number of higher education institutions of Ukraine (Lviv National University named after I. Franko, Chernivtsi National University named after Yu. Fedkovych, Kryvyi Rih State Pedagogical University, Ternopil National Pedagogical University and V. Hnatyuk). Ternopil National Pedagogical University and V. Hnatyuk delivers in particular a course "Geography of Mineral Resources of Ukraine" for Master degree students, in which methodology structural and geographical research lie in the basis of the presentation of educational materials on the characteristics of the main groups of minerals, the basic laws of their component, functional, territorial structure, their effective use, environmental problems of major mining areas.

3 Conclusions

1. Modern research of mineral resource potential of any territory is based on several basic methodological approaches: geological-mineralogical, natural-geographical, economic-geographical, economic, ecological-geographical, historical and complex constructive-geographical, each of which focuses on separate aspects of studying mineral resources (criteria for prospecting and exploration of minerals, quality composition of raw materials, mining and geological conditions of their extraction, problems of rational efficient use, structure of formed or forecasted economic complexes with clear mineral orientation, subsoil protection, ecological problems of mining areas).

2. We developed the main provisions of the actual constructive-geographical approach to the study of mineral resources of the regions. It consists of the factual data analysis and synthesis, theoretical and methodological findings of the above approaches. The constructive-geographical approach aims to identify spatial (territorial) and temporal-dynamic patterns of mineral resources and their role in the region economic complexes for substantiation of optimization proposals on the structure and efficiency. It also enables the assessment of the environmental stress in the regions caused by mining and processing, search for ways and means to minimize it, general improvement of nature management in the regions.

3. For the solution of the problems of constructive-geographical study of region mineral resource potential, we created and tested a number of algorithmic schemes in the Podolsk region which went through several successive stages. The first stage was devoted to the formation of the database containing various and the most complete information on the object of study at the local, area and regional levels. The database combines component and territorial approaches to the formation of a single system of nature management in the study area. The second stage of constructive-geographical study of region MR provided analysis of the collected factual material which enabled to create cartographic models of territorial concentration of different types of mineral raw materials, and determine the needs of region, oblasts, separate districts (territorial communities) in specific types of mineral raw materials in their economic complexes. The analysis of the collected factual material provided the consideration on the extra ways of efficient resource use. The third stage involved assessing the mineral resource potential of the territory done in stages. Firstly, the assessment of the resources of separate industries, then the general resources of the region was done. Secondly, the assessment of the complexity of mineral resources of specific deposits and accumulated mining waste in the region, then the typification of mineral resources, assessment of their component and territorial structure. Thirdly, the estimation of possibilities of complexing of manufacture on the basis of optimization model of structure of a mineral resource complex was proved. At the last stage a long-term concept of development of the mineral complex of the region was created, the forecast of use of mineral raw materials and substantiation of use of resource-saving technologies were offered. There were considered the possible changes of region ecological condition caused by production capacity increase at mining enterprises or development of new mineral resources.

4. The methodology of constructive-geographical study of mineral resource potential in recent years is actively introduced into the educational process of geographical departments of higher education institutions in Ukraine.

Abstract. The purpose of the research is to reveal current trends in modeling the location of new catering establishments in the study area. The relevance of research in the article is determined by the development of the tourism industry. This applies to catering establishments operating in the lower price category. Such catering establishments include fast food restaurants. The article proposes to use geographic information systems for spatial analysis using software. The researchers used ArcGis software, which allows you to visualize the results of the analysis. Visualization of the results will allow to make the necessary decision on the location of catering establishments. The research was conducted on the example of the Industrialny District of Kharkiv. Analysis of geostatic models can be used to process statistical data in any locality by using a geostatistical method to convert data from a discrete view to a permanent representation. With the help of geostatistics methods, data from a discrete form are transformed into a continuous form. Researchers present mathematical formulas for determining the index of concentration of the actual population in a given area or the projected index. These indicators can be determined on the basis of data obtained during the research. Indicators are presented using elements of the ArcGis software package in discrete form and permanent form. In the research the model of optimization of placement of public catering establishments was developed. It is proposed to place twelve new catering establishments in the studied area of the city with the exact indication of their location. The scientific conclusion of the study will further improve the service to the local population and the promotion of the city of Kharkiv as a object of tourism. The principle of developing a digital map and geodatabase is effective to address issues related to tourism infrastructure, so the developed model can be used in other cities. Further research in this direction may be related to improving geostatistic analysis of data and taking into account more factors..

1 Problem statement

The establishment of market relations in Ukraine, the economic crisis resolution requires restructuring of the national economy, change in the traditional proportions between its branches. Priority development should be given not only to the industries the products of which will satisfy human needs, but also to the non-production sphere. Most developed countries have already gone this way. Thus, over the past 50 years the US economy has undergone dramatic changes, as a result of which the country is mainly focused on the service-producing industries. Today, the service sector provides 70 percent of gross national income and ensures 75 percent of employment, and tourism ranks first in 47 states, depending on its development. It is no coincidence that for the first time in the history of Ukraine, the government has declared tourism one of the priorities of the national economy, as the tourism business is recognized as one of the most fast-payback and highly profitable businesses. The timeliness and expediency of creating a set of measures for the development of this area of activity is based on the adoption of legislation, the main of which are the Law of Ukraine «On Tourism», Resolution of the Cabinet of Ministers of Ukraine «On measures for further development of tourism», the Law of Ukraine on the creation of special economic zones of tourist and recreational type [1]. According to the results of research carried out by the World Tourism Organization, tourism is projected to take the first place among the largest sectors of the economy in terms of revenues. Ukraine, possessing numerous historical and cultural sites, unique recreational resources, will be able to achieve a significant economic effect in the tourism business. While in the developed countries this branch of activity has become a tourism industry, Ukraine is only taking the first steps in this direction. In the world practice, the concept of «tourism industry» includes infrastructure companies engaged in satisfying the needs of tourists, including household services, local industries that produce goods and souvenirs for tourists, goods and equipment for hotels, restaurants, cafes, and also semi-finished food products, etc. A special place in the infrastructure is occupied by hotel and restaurant enterprises because they contribute to meeting such important needs of tourists as accommodation and food.

Developing the tourism industry in Ukraine, trying to enter the international market of tourist services deservingly, it is necessary to reconstruct the existing, build new modern restaurants, able to compete with the

* Corresponding author: s.kobzan@gmail.com

https://doi.org/10.1051/e3sconf/202128011013

best restaurants in the world, to gain prestige and popularity.

The solution of this problem is impossible without the development of catering establishments (CE). Unfortunately, there are many problems in this area of the national economy related to the insufficient infrastructure development, inconsistency of quantitative and qualitative characteristics with world requirements and modern needs of not only foreign but also domestic consumers, despite the fact that their percentage of financial turnover in the structure of the tourist product ranges from 20% to 50%.

In addition, CE is an important element of the social sphere, which plays an important role in improving the efficiency of social production and, accordingly, the growth of living standards. They perform very important tasks that are related to health maintenance, leisure of citizens based on the conditions of rational use of time. Moreover, as entrepreneurial entities, they seek to increase productivity and competitiveness. The multifactorial environment of modern catering enterprises forces them to be constantly in search of new opportunities, entries into the market of food services, technology and consumers, an effective management mechanism that is sensitive and able to respond to change and act in conditions of uncertainty. In this regard, entrepreneurs should pay much attention to the organization of the catering establishment, the provision of various types of catering services, so that the establishment meets the requirements of the consumers.

One of the most important success factors, and in some cases even a dominant one, is the correct location of the catering establishment. Correction of a mistake related to a poor choice of location is possible only by re-opening the institution in another location, which entails considerable financial expenses. As a rule, the establishments operating in the lower price category, which primarily include fast food restaurants, depend on the place the most. The main principle of choosing a place for a restaurant, cafe, bar, fast food, etc. is to bring it as close as possible to the consumer. That is, the premises should be located near the places of residence of the potential consumer (near the house, near work, when walking around the city), should be accessible by transport and easy to find. Exceptions may be only super-conceptual establishments, where, according to the authors' suggestion, guests will purposefully gather from all over the city. Thus, the stated above considerations allow us to justify the relevance of finding a solution to the problem of choosing the best location for the catering establishment.

Various aspects of the problem of CE development are reflected in numerous publications of both domestic and foreign researchers. Thus, in [2] the author proposed a systematization of transformational changes of classifications of restaurants by nature of economic activity, types and classes. Also on the basis of comparison of domestic and international classifications the author concludes about the need to expand the classification of restaurants in Ukraine to allow accurate statistical accounting of all existing types of restaurant establishments and to obtain reliable information for the strategic development of the industry and individual restaurant business entities. The publication [3] identifies the directions of development of the main sectors of the restaurant industry. The work [4] is devoted to the problems of restaurant chains, related to the development of competitiveness. The author of the article [5] explores the experience of overcoming the crisis by restaurant enterprises. The article [6] highlights the state of development of the restaurant industry in Ukraine, analyzes the dynamics of changes in sales of products and services, assesses trends in the number of catering establishments of different types and their profitability, identifies features and prospects for restaurant enterprises basing on the analysis. Work [7] highlights the features and impact of the restaurant business on human health, the end results of people's work and the effectiveness of Ukraine's economy.

Quite a large number of publications [8 – 11] highlight the results of research on the development of the catering industry, both in the Ukrainian realities and based on the experience worldwide. The author of works [12, 13] presented the research results on the efficiency of management of restaurant business strategic development, and on their basis the author concludes that possibilities of development and use of potential of restaurant enterprises of Ukraine have considerable prospects, but the current state of economy and management policy of restaurateurs determine slow development of the restaurant industry, creating a large number of obstacles in its path. In the monograph [14] the development of the theory and methodology of the economic mechanism of public catering enterprises functioning formation is investigated, their role in tourism infrastructure is analyzed, theoretical and practical bases of structuring of the tourist branch management system are investigated, suggestions on improvement of a technique which defines volumes of tourist services are given, methodical approaches of a choice of investment policy in branch model efficiency are developed. Additionally, the issues of legal and regulatory support of tourist product market existence are considered and the socio-economic essence of tourism is revealed. However, researchers absolutely do not pay attention to the formation of models of optimal CE placement.

2 Method

Today in Ukraine, in contrast to previous years, the approach to the foundation of public catering establishments is becoming more practical and purposeful. One of the most important steps in decision-making when creating a catering establishment is marketing data and consumer research, i.e. the environment in which the establishment will have to operate. In addition, it is important to find out: location features, characteristics of traffic and pedestrian flows, competitive environment, information on residential, commercial, office infrastructure. Analysis of these data allows us to conclude what type of institution should be arranged in a particular place.

Let us take a look at the general criteria for assessing the area of the city, which is considered as a potential place of CE activity:

Territory: area, shape, compactness.

Type of district: central – business, tourist or leisure area, sleeping, industrial, area on the outskirts of the city or outside the city.

Trends in the development of the district: whether the district is promising, and whether it can attract more wealthy visitors in the future, whether growth and change for the better is expected, or the development of the district is weak.

Characteristics of the population: population, population density, population composition. It is desirable to identify groups of the population by age and type of employment, to determine whether there are trends in the composition of the population, its wealth, the structure of households. This analysis is performed for residential areas. Office areas are studied in a similar way, with such indicators as the differentiation of enterprises by type of activity, the stability of their work, the level of wages in the area. When studying traffic flows in the area it is needed to investigate: the number, intensity, composition of traffic flows, the presence of pendulum traffic, the state of highways, road congestion, the presence of traffic jams. An important component of the analysis of the district territory is the study of pedestrian flows, which are characterized by their type (residents of the district, office workers, visitors, etc.), the intensity of each flow and time. Car and pedestrian flows are plotted on a map for the possibility to determine which of them the planned enterprise can fully use. In addition, information on the movement of public transport in the area is collected: the number of modes of transport, routes, traffic intervals, stops. Availability and level of development of existing CE in the area: services congestion by formats and areas of specialization, uniformity, existing niches. Future competitors are also taken into account: projects that are under construction and development, as well as the availability of vacant plots prospective for the location of catering facilities, opportunities and conditions of delivery of goods in this area, labor resources in the given territory, a situation with attraction of the personnel for the created CE.

Unfortunately, the data that should be used in the study of the district are not always available or is fully reliable in the Ukrainian context. Such data include, for example, the level of income of the population and the volume of sales, which is on average in the CE area. Databases demonstrating the location of CE in the territory have not yet become widespread in Ukraine, but they may become more accessible in the future.

When exploring the area, not only a map is used, but also space and aerial photographs. Photogrammetry methods reveal many things which cannot be assessed with a topographic map, for example, when working with photography it is possible to identify disadvantaged and polluted areas, evening photographs reveal the need for light accents and suggest how pleasant and safe for visitors a visit to CE will be in night time.

That is, decision-making when choosing the location of a CE requires processing large amounts of information and using a set of information technologies designed to model and forecast the spatial development of infrastructure and facilities in the catering industry. Modern means of analysis of territorial location and modeling of spatial development are based on the use of geographic information technologies. Geographic information system (GIS) is an information model of real space according to the established list of features and characteristics, an active and multifunctional database that can be constantly complemented and updated. The main task of GIS is to support management decisions based on spatial analysis, mathematical and cartographic modeling, visualization, forecasting and evaluation. The use of GIS technology allows to create a detailed visualization and conduct a qualitative spatial analysis [15] of the CE placement with reference to the territory. The modeling, the results of which are presented in this paper, was done with the capabilities of the software product from Esri – ArcGIS.

Modern cities, as well as the city of Kharkiv, which was chosen as the object of study, are characterized by high population density, compact housing, the presence of four main areas of distribution: industrial, housing-administrative, utility and recreation areas. These areas involve the presence of different types of CE.

Determination of the peculiarities of the population distribution was carried out on the basis of its density indicators and concentration index. The population concentration index allows to investigate the distribution of the population by administrative units in relation to the general uniformity of its distribution across the territory. This index is calculated as the difference between the shares of the area and the population of the district:

$$IKH = \frac{\sum |P_ч - S_ч|}{2} \tag{1}$$

where IKH stands for population concentration index;

$P_ч$ – the share of the population of the district;

$S_ч$ – share of the district area.

Share of the destricts area:

$$S_ч = \frac{S_{р-н}}{S_{обл}} * 100\% \tag{2}$$

where $S_{р-н}$ – stands for area of the district;

$S_{обл}$ – area of the region.

Share of the population of districts:

$$P_ч = \frac{P_{р-н}}{P_{обл}} * 100\% \tag{3}$$

where $P_{р-н}$– stands for the population of the district;

$P_{обл}$ – the population of the region.

According to the results of calculations, the index of population concentration in Kharkiv region is 63.6%, what indicates the uneven distribution of the population throughout the region, i.e. the population of the region is concentrated mainly in the central part of the region, namely in Kharkiv and suburbs.

In order to assess the sufficiency of CE in Kharkiv city, areas of the city with a high concentration of population and housing density were identified. The diagram (Fig. 1) shows that the lowest population density is in the Kholodnohirsky and Osnovyansky districts of the city, and the highest is in the Moscowsky district.

In addition, the number of catering establishments in the districts of Kharkiv was analyzed. The results of the analysis are shown on the diagram (Fig. 2).

 https://doi.org/10.1051/e3sconf/202128011013

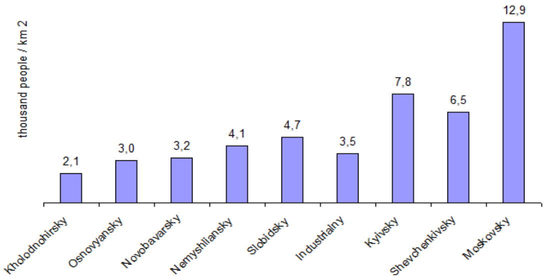

Fig. 1. Diagram of population density distribution by the districts of the city.

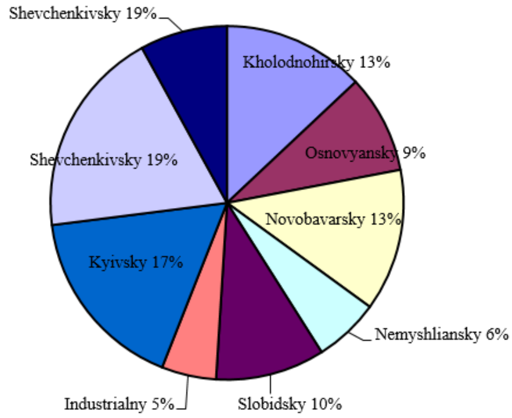

Fig. 2. Distribution of housing and communal services by districts of the city.

This diagram shows that the smallest number of CE is in the Industrialny district of Kharkiv. The obtained data were enough for further spatial analysis. As a result, a cartographic model of the territorial localization of CE was obtained (Fig. 3).

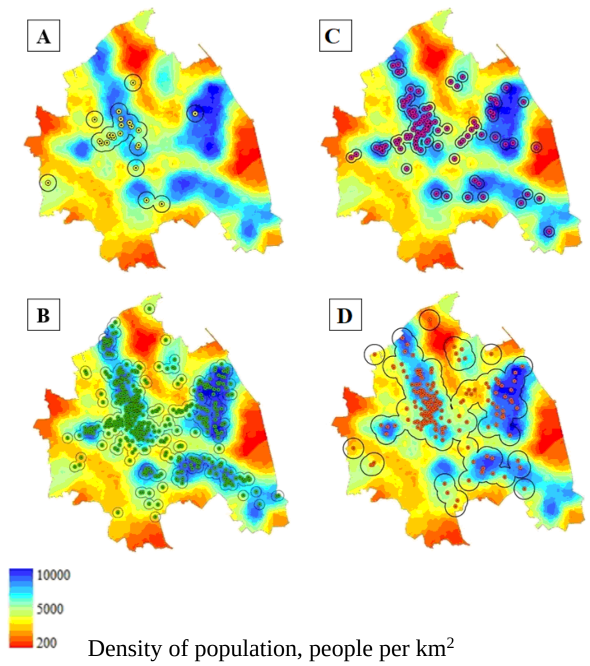

Fig. 3. Visualization of buffer zones for CE of Kharkiv in comparison with the indicator of urban population density. A – public dining rooms; B –cafes; C – fast food establishments; D – restaurants.

Figure 3 shows that most CE tend to densely populated areas, which is a regularity. Our attention was drawn to the Industrialny district of the city, because it has not the smallest number of inhabitants, but the number of CE is much smaller comparing to other districts. While, for example, in the Shevchenkivsky district the number of CE is more than 1 per 1,000 people, in the Industrialny district this ratio is 1 per 3,000 people. It can be concluded that in the Industrialny district of Kharkiv the system of public catering establishments is not properly developed.

Here is a brief historical background about the Industrialny district of Kharkiv. The Industrialny district is a relatively young district of the city. Its foundation dates back to the first five-year plan, when the construction of Kharkiv Tractor Plant was started on the eastern outskirts of Kharkiv. Before its construction, in 1930, there was a railway station «Losieve» with three apartments and a small village Losieve with two dozen yards. Until 1941 the total population of the district was 70 thousand people. In the postwar period, intensive construction of new industrial enterprises and housing estates began. Now the district is the largest industrial district of the city. The territory of the district is 4526,8608 hectares (12% of the territory of Kharkiv). It borders on 2 districts: Nemyshlyansky district in the west; Kharkiv district of the Kharkiv region in the south, north and east. It is one of the greenest areas of the city. The total area of greenery is 980 hectares (including 110,2 hectares of garden squares, parks, sanitary protection zone, etc.), 264 hectares are out of balance. Its population is 153,8 thousand people (10,8% of the population of Kharkiv). The population density amounts 3,397 thousand people per 1 km^2.

Let us consider the transport infrastructure of the area. On the territory of the district there are 150 roads amounting 133 km long, with a total area of 1 million 118 thousand square meters, including of: citywide significance – 203,97 thousand square meters, district importance – 659.76 thousand square meters, local importance – 346,7 thousand square meters. By type of coverage: with asphalt pavement length – 87,02 km, making up an area of 873,06 thousand square meters, with a gravel covering 32,55 km long, with an area of 210 thousand square meters, with a soil surface with length of 14,59 km, an area of 100,3 thousand square meters, with a cement coating length of 4,44 km, an area of 35.97 thousand square meters; railway stations – «Losieve-1», «Losieve-2», «Horyzont»; bus stations – «Zavodska». Characteristics of district roads – roads of citywide significance – 14,97 km, of district significance – 72,25 km, of local significance – 51,38 km.

The branch structure of the district has an industrial and commercial character and is represented by such branches as: food industry (production of soft drinks, milk and dairy products, sausages, collection, purification and distribution of drinking water); mechanical engineering (production of agricultural tracked and wheeled tractors, submersible electric motors and submersible centrifugal pumps, metal-cutting machines, bearings); construction (manufacture of concrete and reinforced concrete structures, special types of cement, expanded clay, gravel, ceramic tiles).

 https://doi.org/10.1051/e3sconf/202128011013

There are 21 pre-school educational establishments, 19 general educational establishments, two out-of-school educational establishments and one higher educational establishment and a machine-building college in the district.

Objects of trade and consumer services are represented in the district in the amount of: 174 – shops, 246 – retail facilities, 211 – consumer services, 119 – food objects, 5 trading platforms and one market.

The housing stock of the district is 5820 houses, with a total area – 5105.0 thousand m^2. There are 5107 private houses in the district with total area of 640 thousand m^2. There are 711 multi-storey residential buildings with the total area of 3882,7 thousand m^2.

There are 6 squares with a total area of 16,44 hectares on the territory of the district.

For a more detailed analysis of the Industrialny district of Kharkiv on the ratio of population density and location of the transport network and the existing CE, a pedestrian zone with a radius of 400 m for each public transport stop (Fig. 4) was built with the help of GIS.

The constructed model allows to recommend placement of new CE in the Industrialny district of the city of Kharkiv, proceeding from the following factors:

- population density;
- transport interchange (minimization of time spent on visits);
- the presence of existing CE.

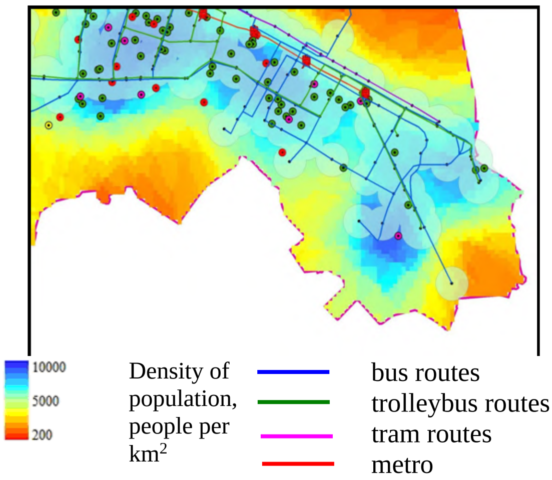

Fig.4. Outlook of buffer zones projected for public transport stops in comparison with CE sufficiency and population density indicators.

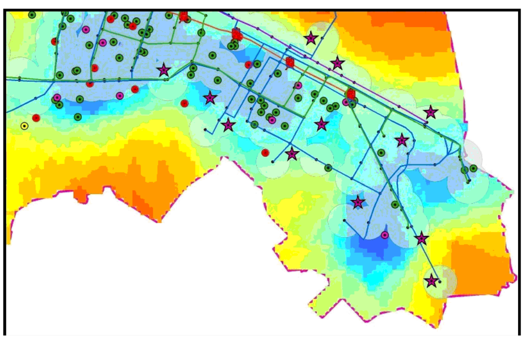

Fig. 5. View of the proposed new HVACs for the Industrialny District.

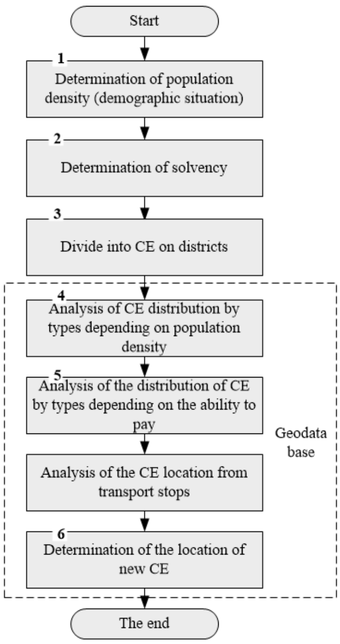

Fig. 6. Algorithm of optimization of CE placement.

As a result of the GIS analysis, 12 new catering establishments were proposed (shown by stars on the map). Particular attention when planning new CE was paid to the transport accessibility – at the intersections of large traffic flows, it was proposed to place larger restaurants, bars, cafes, snack bars and canteens and in larger numbers (Fig. 5).

One of the most important stages in creating an model of optimization (Fig. 6) for the location of CE is the development of a geodatabase, which would include a large number of influencing factors regarding the choice of location of the infrastructure object. The more influencing factors will be taken into account when creating a GIS model, the greater the opportunities will be provided in case of further spatial analysis.

4 Results

1. The digital geoinformation model of the Industrialny district of the Kharkiv city with introduction of a considerable quantity of attributive data is developed.
2. Calculations of the population concentration index in Kharkiv region are performed.
3. The analysis of the territory of a separate city district with the help of geographic information systems on the identification of the optimal number and rational placement of catering facilities is performed.
4. An model of optimization of CE placement based on the results of analysis of a number of factors has been developed.

5 Conclusions

The use of geoinformational technologies to model the location of new CE will allow to take into account many factors, namely, population density, purchasing power, distance from traffic stops, and to solve this problem with minimal time costs and with the least probability of error. It was with the help of spatial analysis performed in the ArcGis geoinformational system that the creation of twelve new catering establishments in the Industrialny district of Kharkiv was proposed, as in the least provided with such establishments district.

In the research, with the help of the ArcGis software package, an optimization model for the location of CE was developed and a map of the existing CE of the Industrialny district of Kharkiv was compiled. This map provided an opportunity to further establish the number and location of new CE. Further it will also allow not only to improve the service to the local population, but will also encourage the promotion of the city as a tourist attraction.

The very principle of building a digital map and database structure will be effective to address any issues related to tourism infrastructure, so the developed models can be distributed among any administrative units. In general, data mining of geostatic models can be used to process statistics in any locality by using a geostatistic method to convert data from discrete to permanent representation. Further research in this direction may be related to improving geostatistic analysis of data and taking into account more factors.

As an example, mathematical formulas were presented to determine the index of concentration of the actual population in a given area or the projected index. These indicators can be determined on the basis of data obtained during the study and presented using elements of the software package ArcGis in discrete and constant forms.

[1]Imam Abdulrahman Bin Faisal University, Environmental Engineering Department, 19082, Dammam, Saudi Arabia

Abstract. Contamination in subsurface environment is a serious environmental hazard. Main sources of the contamination are petrol, diesel fuel, gasoline at oil refineries, underground storage tanks, transmission pipelines and different industries. Permeable reactive barriers (PRBs), which is a promising technology to remediate groundwater in-situ, are filled with reactive materials for the removal of the contaminants present in groundwater. In this study, groundwater contaminated with toluene is treated in reactor columns by biological processes. This study was conducted to assess the impact of bioaugmentation (BA) and biostimulation (BS) on toluene degradation efficiency. After 44 days of treatment, toluene concentrations were decreased from 5 mg/l to 4.304 mg/l by the natural attenuation treatment (Reactor 2), which represents a 13.9% removal efficiency. Toluene was reduced to 0.0239 mg/l in the biostimulation and bioaugmentation treatment (Reactor 1), which represents a toluene removal efficiency of 99.5%. This study showed that the toluene removal efficiency in the combined BA and BS process was much higher than in natural attenuation (NA) process tested.

1 Introduction

Contamination in subsurface environment has become a serious environmental hazard in recent years. Main sources of the contamination are petrol, diesel fuel, gasoline at oil refineries, underground storage tanks, transmission pipelines and non-petroleum related industries. These hazardous contaminants are in the EPA's (U.S. Environmental Protection Agency) priority pollutant lists. Besides, some of that chemicals in the fossil fuels tend to persist in the environment for a long time. These persistent contaminants have several health risks to humans, animals, and other living organisms. Therefore, this threat needs to be removed carefully from the subsurface environment. Removal of contaminants, especially petroleum hydrocarbons, from soil and groundwater through bioremediation technologies has been commonly practiced by researchers and industry. One of the most common remediation technologies is bioremediation which uses microorganisms to biodegrade hydrocarbon. Bioremediation has been commonly used for cleaning up soil and groundwater contaminated sites and is an environmentally friendly and cost-effective remediation technology.

Total petroleum hydrocarbons consist of three components: aliphatic (or saturated), aromatic, and polar hydrocarbon fractions. Diesel fuels primarily contain a mixture of C10 through C19 hydrocarbons, which include 64% aliphatic hydrocarbons, l-2% olefinic hydrocarbons, and 35% aromatic hydrocarbons. All the above fuel oils contain less than 5% polycyclic aromatic hydrocarbons (PAHs). Biodegradation of petroleum hydrocarbons by microorganisms have been studied by scientists for many years. Microorganisms responsible for degrading crude and refined petroleum products are defined as either eukaryotic or prokaryotic organisms. Some of the species that are effective on biodegradation of petroleum hydrocarbons are *Nocardia, Pseudomonas, Acinetobacter, Flavobacterium, Arthrobacter, Achromobacter, Alcaligenes, Mycobacterium, Bacillus, Aspergillus, Fusarium, Penicillium, and Sporobolomyces.* Bioremediation method can be selected based on the properties of the polluting hydrocarbons and the characteristics of soil and the groundwater where the contaminant is spilled. It is preferred that the hydrocarbons contain carbon chain length of between C10 and C20, because these carbon chains are easier to break. On the other hand, hydrocarbons with C20-C40 carbon chains are hydrophobic, less soluble in water and resistant to biodegradation. Bioremediation is a technology that aims at cleaning a contaminated region by microorganisms and their enzymes. Specific contaminants such as chlorine containing pesticides can be also biodegraded by microorganisms. Microorganisms that degrade these hydrocarbons can be bacteria, protozoa, nematodes, and fungi. Bioremediation of a contaminated site by adding specifically selected microorganisms is called bioaugmentation.

Bioaugmentation technology is used effectively in soils and groundwater where there is not sufficient microbial population available for biodegradation. Bioremediation of a contaminated site by adding nutrients is called biostimulation. Some of the benefits of bioremediation can be summarized as; effective,

* Corresponding author: cyaman@iau.edu.sa

economic, environment friendly, less toxic byproducts, applicable directly on the contaminated area and friendly with the existing flora.

When hydrocarbon-containing contaminants spill on land, degradation by indigenous microorganisms progresses slowly due to low microbial population and activity. Bioremediation is recognized as one of the most cost-effective clean-up methods for the treatment of oil-contaminated soils and groundwater. For instance, bioaugmentation (BA) and biostimulation (BS) are the two main bioremediation technologies commonly used for soil and groundwater clean-up. Bioaugmentation works by introduction of exogenous microorganisms to the contaminated soil or water. Microorganisms may be inoculated with specially cultivated microorganisms with capabilities for degrading a certain contaminant. Biostimulation is used to describe the addition of nutrients, such as nitrogen and phosphorus, to stimulate the existing microorganisms that are capable of degrading contaminants. On the other hand, natural attenuation (NA) processes can include chemical reactions, volatilization, adsorption, and biodegradation.

Bioremediation is the process of using microorganisms to convert organic compounds such as crude oil into non-toxic substances such as CO_2 and H_2O. Any given bacteria can occur naturally and require specialized nutrients. In most cases naturally occurring microorganisms are not in sufficient concentrations to provide complete degradation. Thus, there exists an opportunity to enhance and accelerate the natural degradation by the introduction of additional microorganisms and nutrients. When mixed with water and applied as a slurry to contaminated soil or groundwater, microorganisms break down the molecular structures of the targeted hydrocarbons by utilizing their mass as a source of energy. Because of the high degree of interface between bacteria and the hydrocarbon, the rate of degradation tends to be quite rapid at first, but gradually diminishes as the more biodegradable hydrocarbon is consumed.

One of the most promising technologies for in-situ groundwater treatment is to use Permeable reactive barriers (PRBs). PRBs are filled with reactive materials and they must be permeable than the surrounding aquifer material. When compared to conventional pump and treat systems, PRB method is much cheaper because there is no continuous energy input is needed. The other benefit of PRBs is that replacement of the PRB material is always possible [1]. There are two types of PRBs, continuous PRBs and funnel and gate system PRBs. Continuous PRBs consist of a single reactive zone whereas funnel and gate PRBs consists of permeable gate (reactive zone) placed between two impermeable walls that direct the contaminated plume towards the reactive zone. The mechanisms of interaction in PRBs are degradation, precipitation and sorption. The types of reactive materials used in PRBs are those changing pH or redox potential, causing precipitation, materials with high sorption capacity, and releasing nutrients and oxygen to enhance degradation. Some of the reactive materials used in PRBs are activated carbon (AC), Al, ferric oxide, peat, zeolite, lignite, zero valent metals, fly ash, lime, limestone, sand, and clay.

PRBs consisting of zero valent iron (ZVI) can also be used to treat groundwater contaminated with chlorinated solvents, nitrate, chromium, uranium, and pesticides [2]. In another study, PRB columns filled with olive nut, sand and soil were usefully used to treat wastewater containing nitrate [3]. PAHs were successfully removed from water by using PRB materials of wheat straw and coconut shell [4]. Corn straw, fly ash, Fe-Mn, and zeolite were used as PRB materials to reduce the concentrations of Pb and Cd from groundwater [5]. Steel manufacturing basic oxygen furnace sludge (BOFS) was tested as a PRB material to remove Cr+6 from soil [6]. Two lab scale column studies used ZVI and ZVI + zeolite to treat leachate [7]. In one study, ZVI, zeolite and activated carbon were used as PRBs to treat groundwater contaminated with leachate [8].

Toluene, one of the BTEX (benzene, toluene, ethylbenzene, and xylene) compounds, is a clear, colorless liquid that becomes a vapor when exposed to air at room temperature. Toluene is typically used in a mixture with chemicals such as other solvents and paint pigments. Products that can contain toluene, such as paints, metal cleaners, and adhesives, are used in many industries. Gasoline and other fuels also contain toluene. The specific objective of this study was to investigate the toluene biodegradation efficiency in a freshly contaminated water by combined bioaugmentation and biostimulation processes and by natural attenuation. The term biostimulation is used to describe the addition of essential electron acceptors such as nutrients to enhance the microbial growth [9–11]. The term bioaugmentation is used to describe the addition of essential microorganisms. Several research studies have been conducted on the treatment of hydrocarbons by various microorganisms [12–18].

2 Methodology

2.1 Configuration of PRBs

Two reactors with the dimensions of 0.6 m height and 10 cm diameter are filled with coarse to medium sized sand. Each reactor column will have effluent port for water samples (Figure 1). The column reactors are operated as up flow. Reactor 1 (R-1) is inoculated with specific bacteria and required nutrients (N, P and K) are added. To maintain aerobic conditions, influent tank for reactor 1 is aerated as needed. Reactor 2 (R-2) is used as control and contains only sand and gravel but no bacteria and nutrients. No aeration is performed for reactor 2.

For each reactor, 5 mg/l toluene concentration is prepared as influent sample. All the reactors are fed at an influent flowrate of 1 mL/minute.

2.2 Reactive materials in PRBs

The reactive filler material in the PRBs consists of the following mixed materials (Table 1).

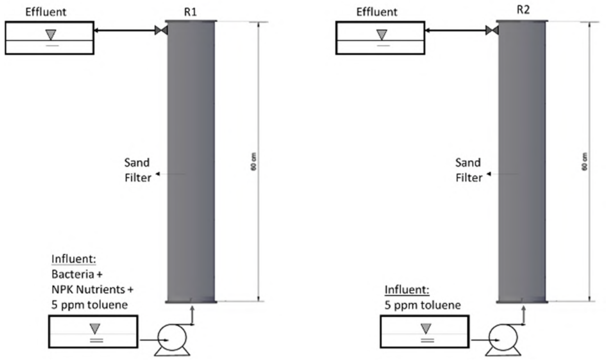

Fig. 1. The schematic of the PRB columns.

Table 1. Properties of filler material in PRBs.

Material	Diameter (mm)	% of SiO_2	% of acid solubility	Bulk density (t/m^3)	Specific gravity
Silica sand	1-2	98±1	1±0.5	1.5-1.70	2.55-2.70
Silica sand	2-3	98±1	1±0.5	1.5-1.70	2.55-2.70
Silica sand	3-6	90±1	10±0.5	1.5-1.70	2.55-2.70
Silica gravel	8-12	90±1	10±0.5	1.5-1.70	2.55-2.70

2.3 Analytical method

An HPLC chromatograph equipped with a UV detector was used for toluene analysis. The UV detector was set to 254 nm. The high-performance liquid chromatography column was a C18 Bond Pack 3 µm (25 cm-4.6 mm) analytical column. Chromatography was isocratic in a mobile phase composed of water-methanol (30-70). The flow rate was set at 1 ml / minute. All chemicals and water used were HPLC grade.

3 Results

3.1 Results of permeability tests

Permeability is the water and air conductivity of the soil or sand. The falling head permeability test is a common laboratory test method used to determine the permeability of fine-grained soils with medium to low permeability such as sand, silt, and clay. Permeability of soils can be performed by using falling head and, constant head methods. In this study, falling head permeability test was performed by using the equation below:

$$K=a.L/A.t.\ln(h_1/h_2) \tag{1}$$

where

K=permeability in cm/sec

a=cross sectional area of the tube used for water elevation change (cm^2)

L=length of the reactor (cm)

A=cross sectional area of the reactor (cm^2)

h_1=distance of the water elevation to the bottom of the reactor before the test (cm)

h_2=distance of the water elevation to the bottom of the reactor after the test (cm)

Reactor-1:

$a=\pi.r^2= \pi.(5)^2=78.5\ cm^2$, $h_1=70$ cm, $h_2=60$ cm, $t_{average}=39.33$ sec, A=78.5 cm^2, L=60 cm

K = 0.779 cm/sec

Reactor-2:

$a=\pi.r^2= \pi.(5)^2=78.5\ cm^2$, $h_1=70$ cm, $h_2=60$ cm, $t_{average}=40$ sec, A=78.5 cm^2, L=60 cm

K = 0.766 cm/sec

3.2 Results of pore volume and porosity tests

Pore volume and porosity tests are used to determine the volume and volume distribution of pores in sand filters on the apparent diameter of the pore inlets. In general, both the size and volume of pores affect the performance of sand filters. Therefore, the pore volume distribution is useful in understanding sand filter performance and determining a material that can be expected to perform in a particular manner.

Pore volume is the volume occupied by water in the reactor. To determine the pore volume, the reactor is filled with water and the amount of water was measured as pore volume.

Reactor 1:

Reactor volume= $\pi.r^2.h=3.14 \times (5)^2 \times 60=4710\ cm^3$

Pore volume=1.06 L=1060 cm^3

Porosity (ε)=1060/4710=0.225

Reactor 2:

Reactor volume= $\pi.r^2.h=3.14 \times (5)^2 \times 60=4710\ cm^3$

Pore volume=1.15 L=1150 cm^3

Porosity (ε)=1150/4710=0.244

3.3 Results of flow rate and hydraulic residence time tests

The hydraulic residence time (HRT) (t) is a measure of the average time a soluble compound remains in a sand filter. In engineering, volumetric flow rate is the volume of fluid passing per unit of time; it is usually represented by the symbol Q.

Hydraulic residence time is the ratio of total water volume pumped to the flowrate as shown below.

Reactor 1:

t=V/Q, where V=1.05 liter=1050 mL, Q=1.2 mL/minute so t=1050/1.2=875 minutes=14.58 hrs.

Reactor 2:

t=V/Q, where V=1.15 liter=1150 mL, Q=1.2 mL/minute so t=1150/1.2=958.33 minutes=15.97 hrs.

3.4 Toluene removal in reactors

Aromatic hydrocarbons such as BTEX compounds and their derivatives are among the most important contaminants of soil and groundwater. BTEX compounds are the most common groundwater pollutants among various petroleum hydrocarbons. BTEX compounds are released into the environment through spilled diesel fuel or gasoline and leaks from underground storage tanks and pipelines during transportation. BTEX compounds are listed as priority pollutants by the US Environmental Protection Agency and are among the top 100 chemicals on the hazardous substances' priority list. Therefore, the development or improvement of existing remediation methods that minimize the environmental damage caused by BTEX compounds has attracted the attention of environmental protection organizations. Biological treatment of contaminated groundwater is a well-established technique and is also known to be cost-effective and environmentally friendly. During the biological degradation process, microorganisms can directly reduce BTEX to less toxic compounds by depleting the carbons present within the structure of BTEX. The performance of the biological treatment method is affected by various environmental factors such as temperature, oxygen, pH and inorganic nutrients. Therefore, these factors must be optimized for the implementation of efficient biological treatment systems. Bioremediation process in the PRBs has two main processes: a) Biostimulation – bioremediation process is enhanced by adding nutrients (NPK) and oxygen. b) bioaugmentation –microorganisms are added.

3.5 Oxygen requirement

For toluene (C_6H_6), the biodegradation reaction will take place as follows:

$$C_7H_8 + 9O_2 \rightarrow 7CO_2 + 4H_2O$$

So, 1 mole of toluene requires 9 moles of oxygen. Since the total concentration of toluene is 5 ppm (5 mg/l), then the amount of oxygen required can be calculated as follows:

Molecular weight of toluene is 92 g. If 92 g of toluene requires 9 x 32 = 288 g oxygen, then 5 mg toluene requires 0.0156 g oxygen. The required oxygen is provided by ambient air through aeration for R-1, but R-2 was not aerated since it is used as control.

3.6 Nutrient requirement

Molecular weight of toluene is 92 g and 1 mole of toluene contains 84 g of carbon (C) per mole of toluene. If 92 g of toluene contains 84 g of C, then 5 mg of toluene contains approximately 0.00456 g of C. As a nutrient, mixture of ammonium chloride (NH_4Cl) and potassium dihydrogen phosphate (KH_2PO_4) as N and P sources, respectively, are used.

Based on the ratio of C:N:P of 100:5:1; if C is 0.00456 g, then N required is 0.000228 g and P required is 0.0000456 g. If 1 mole of NH_4Cl (53 g) contains 23 g of N, then 0.000525 g of NH_4Cl contains 0.000228 g of N, so the amount of NH_4Cl required is 0.000228 g. Similarly, 1 mole of KH_2PO_4 (136 g) contains 39 g of P, then 0.000159 g of KH_2PO_4 contains 0.0000456 g of P, so the amount of KH_2PO_4 required is 0.0000456 g.

In summary, to bioremediate 5 mg/l of toluene in R-1, 0.000525 g of NH_4Cl and 0.000159 g of KH_2PO_4 are required.

3.7 Bacteria requirement

To accelerate the biodegradation process in R-1, one of the commercially available BTEX biodegrading bacteria such as *Alcanivorax sp.* is added to the system as inoculant.

3.8 Toluene removal results

Toluene removal rates for R-1 and R-2 are depicted in Figure 2. Toluene concentration in the influent sample for both reactors were 5 mg/l. After 44 days of treatment, toluene concentrations were decreased from 5 mg/l to 4.304 mg/l by the natural attenuation treatment (R-1), which represents a 13.9% removal efficiency. Toluene was reduced to 0.0239 mg/l in the biostimulation and bioaugmentation treatment (R-1), which represents a toluene removal efficiency of 99.5%. The efficiency of biodegradation was the highest when the BS and BA processes were combined.

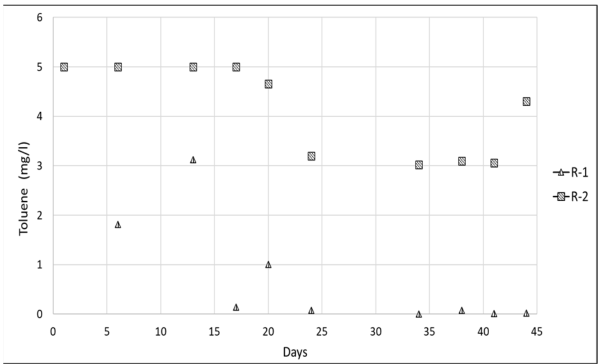

Fig. 2. Toluene removal rates in reactors.

4 Discussion

Bioaugmentation alone may not be effective to improve the remediation of hydrocarbon contaminated soils. Some research studies showed that bioaugmentation improves biodegradation efficiencies temporarily and that biostimulation seems to be a more preferred bioremediation technology to reach sufficient clean-up. Microbial populations are important in the remediation of petroleum hydrocarbon. Molecular methodologies provide help to understand the microbial community structure in remediation systems. Petroleum derived contaminants remaining in soil and groundwater for a long time after contamination along with costly treatment methods have made them one of the most important environmental pollutants. Improvement of hydrocarbon biodegradation is possible by applying different bioremediation technologies such as bioaugmentation and biostimulation alone or in combination. Biostimulation seems to be a more effective remediation methodology for BTEX removal than bioaugmentation alone.

Results of this study showed that combining BS and BA has a higher effect on biodegradation efficiency than NA process. Adding nitrogen and phosphorus, along with microbial inoculation and aeration can create an optimum condition for microorganisms to degrade toluene. This study assessed the effectiveness of bioaugmentation combined with biostimulation process on a freshly toluene-contaminated water. The results of this work justified that the bioaugmentation and biostimulation combined provided the accelerated biodegradation of toluene from the contaminated water through increased microbial biomass. Several different bacterial species would be needed to effectively biodegrade hydrocarbons. Single microbial species do not have the capacity to biodegrade more than two different compounds that are usually present in hydrocarbons. Conventionally, the higher the hydrocarbon degrading microbial population, the more hydrocarbon biodegradation takes place.

5 Conclusions

Petroleum hydrocarbons remaining in water for a long time after contamination along with costly treatment methods have made them one of the most important environmental pollutants. This study confirmed that it is possible to enhance the biodegradation of toluene in water by using different treatment methods such as bioaugmentation and biostimulation in combination. Analysis of toluene indicated that bioremediation of toluene contaminated water is very successful especially when BS and BA treatment are used together. In this study, the toluene degradation in the contaminated water was improved by bioaugmentation with genus Alcanivorax and biostimulation with nitrogen and phosphorus. The study also showed that bioaugmentation and biostimulation resulted in effective toluene removal within 44 days of treatment. The study highlighted the importance of in-situ groundwater treatment combined with bioaugmentation and biostimulation as a suitable strategy.

This research was funded by Imam Abdulrahman bin Faisal University (IAU) project No. (2019-037-Eng) throughout the Deanship of Scientific Research (DSR).

Chemistry of medicinal plants as an integral part of ecological education

Tetiana Derkach*, and *Hanna* Tarasenko

Kyiv National University of Technologies and Design, 01011, Kyiv, Ukraine

Abstract. The degree of variability in the composition of herbal medicines was studied on the example of the preparation of St. John's wort from various Ukrainian producers. The Cu and Zn contents were the most stable compared to other (Fe, Mn, Co, Cr, Ni, Pb, Cd) microelements among plants of different origins. The content of toxic elements (Pb, Cd) did not exceed the established standards. Meanwhile, a 2-3-fold concentration difference was observed for hyperforin, an active pharmaceutical ingredient in St. John's wort. Thus, the existing standards do not ensure the stability of the composition of herbal preparations. As a result, the quality of medicinal drugs can be significantly different. The key reason for the variation in plant composition is environmental influence, including anthropogenic factors. Existing training programs for prospective specialists of the pharmaceutical industry do not pay enough attention to the impact of the environment on the quality of herbal raw materials. Necessary changes to the syllabi of relevant disciplines are formulated to eliminate this shortcoming and ensure sustainable development of raw materials sources for the pharmaceutical industry.

1 Introduction

Medicinal plants have a long millennial history of use. However, even today, they remain an essential part of modern medicine [1]. Many synthesised medicaments were made from plant extracts. By some estimates, about 25% of medications used worldwide are obtained directly from medicinal plants. Besides, they are used by pharmaceutical companies and in food, confectionery, cosmetics, paints, and varnishes.

Most herbal medicines belong to the group of over-the-counter medication and are consumed by patients in self-medication. There is a widespread misconception among consumers that "natural" always indicates "safe", and the consumption of the natural product does not carry a risk [2, 3]. However, some medicinal plants are toxic, primarily due to low quality and non-compliance with standards [4]. Besides, some herbal medicines may have serious side effects or be ineffective [5]. For example, herbal remedies are not usually adequate to treat any acute illness [6].

In many cases, herbal medicines can be used to treat the same diseases as synthetic medicaments. However, a significant difference exists between these two categories of drugs. Synthetic medicaments usually contain one active pharmaceutical ingredient (API). Their characteristics, including chemical and elemental composition, are clearly defined. Clinical trials determine safe consumption doses. The ingress of foreign organic or elemental impurities into the drug is controlled at all pharmaceutical production stages. Unlike synthetic medicaments, each herbal preparation is always a polypharmacy source because it contains a mixture of metals, metalloids and compounds.

Standardisation of plant raw materials and herbal medicines is much more complex and acute than standardisation of synthetic drugs [7, 8]. The complexity is caused by the variability of plant raw materials [9, 10].

The composition and quality of plants simultaneously depend on several botanical, biological, physical and chemical factors [6]. Botanical factors determine colour, odour, taste, some other characteristics [11]. Their knowledge underlies the primary identification of a plant. Physical factors determine moisture, final ash and extractives and characterise the quality of vegetable raw materials [11]. Biological factors determine the level of contamination by microorganisms, such as bacteria and their spores, mould, yeast, viruses, and others [12, 13]. The intensity of microbiological contamination directly affects the quality and safety of medicinal plants. However, the greatest variety of influencing variables falls into chemical factors, affecting API content and inorganic elements in plants [14, 15]. The combined effect of organic and inorganic components determines the therapeutic activity and safety of herbal preparations.

Medicinal plants can contain large and variable amounts of organic compounds. Assessment of the quality of medicinal plants is mainly based on the availability and content of the API. Residues of pesticides, fertilisers and mycotoxins endanger the safety of medicinal plants [16].

Medicinal plants always contain elemental impurities. Chemical elements in plants can be divided into essential elements in biochemical processes and some other elements that do not participate in plant vital functions

* Corresponding author: derkach.tm@knutd.edu.ua

[17]. Essential elements, in turn, are divided into macro- and micronutrients. Macronutrients (N, P, K, Ca, Mg and S) are needed in large quantities for plant growth. Micronutrients are primarily B, Cu, Fe, Cl, Mn, Mo, Zn, and Ni. They are also crucial for plant development but are needed in small quantities. At optimal concentrations, the essential elements are useful while they can become toxic in excess. A plant poorly develops in deficiency of essential elements. In the meanwhile, the content of essential microelements is often not controlled in herbal medicines.

Some other elements (Ba, Be, Sr, Y, V and others) do not contribute to plant development. The role of some elements, e.g. Al and Co, is still being clarified [17]. Non-essential impurities are the product of the interaction of plants with the environment. Both essential and non-essential elements can be toxic to the consumers of herbal medicines. Some non-essential metals (As, Cd, Pb and Hg) are very harmful [18, 19]. Contamination with impurity elements can occur at all stages - from growing and collecting raw materials to herbal medicine production [20]. Monitoring toxic ingredients is vital to prevent the human body poisoning through their consumption of herbal medicines.

The concentration of elemental impurities varies widely depending on various botanical, geological and environmental factors. Plants simultaneously receive chemicals from the environment in several ways [21]. The most natural way is exchanging the plant and surrounding soil and water [17]. However, different plants have different attitudes to the accumulation of other elements; i. e. show different bioaccumulation rates. For example, some plants, known as excluders, maintain metal concentrations at constant and low levels over a wide range of soil composition. Other plants, known as accumulators, show the effect of hyperaccumulation of cadmium or other ions [18, 19]. However, even the high content of toxic elements can sometimes not affect plant appearance [22]. Therefore, contaminated and clean plants can be difficult or impossible to distinguish.

Many works were devoted to the study of plants collected in different geographical locations. Such results allow us to study the cumulative effect of local diversity of plant species within one botanical genus [23, 24] and also the impact on the environment [25, 26]. For example, pollution by heavy metals of small Ukrainian rivers was studied in [27, 28] from the viewpoint of polluted waters influence on the local plant growth.

Pollution of air, soil, and water by human economic activity products has a critical impact on plant development. The effect of agriculture increases the concentration of pesticides and other chemicals [29]. Metallurgy, mining and chemical industries place a heavy burden on the environment. Their activity can lead to emissions of a range of metals, which in turn, enter the plant tissue [30, 31]. Transport, railways and highways with heavy traffic are also essential sources of pollution of soils and waters [32].

Most studies usually indicate elevated concentrations of some elements in plants growing in areas with a high anthropogenic load. Sometimes, the opposite picture is observed when natural factors outweigh human-made factors [33, 34]. In Ukraine, approximately 50% of the bulk medicinal herb feedstock are cultivated under controlled conditions. The rest belong to wild plants [35]. However, cultivated plants are not undoubtedly cleaner than wild plants in impurities [36].

Botanical and geobiological factors can primarily affect API content and, therefore, the quality of herbal medicines. In contrast, environmental factors affect plant quality and the safety of their use due to possible contamination by hazardous substances and microorganisms. Under such conditions, medicinal plant quality cannot be considered separately from the requirements of cultivation and collection of plants, their chemical composition, which differ between producers. However, only limited general information is indicated by producers on the packaging of medicinal herbs. The attention of herbal medicine producers to quality control of plant raw materials is still insufficient. Meanwhile, the quality of plants is primarily ensured by the stability of the chemical and elemental composition.

Thus, the objective situation requires increased attention to the environmental friendliness of plant raw materials. In the long run, this problem can be solved by strengthening the ecological component and forming the necessary competencies in future pharmacists, pharmaceutical industry technologists and ecologists. Such competencies are developed at the theoretical level in learning environmental, analytical and pharmaceutical chemistry [37, 38, 39]. The discipline "pharmaceutical development" contributes to the formulation and study of existing applied problems. The discipline "pharmaceutical quality system" forms an understanding of the need to acquire new knowledge about plant raw materials and use them to improve the production process continuously.

The work aimed to study the variability of the chemical and elemental composition of medicinal plants in the example of St. John's wort. Particular attention is paid to the impact of environmental conditions of Ukraine and the identification of current problems of obtaining high-quality vegetable raw materials. The results allowed the authors to propose the necessary changes to the curricula of a few chemical and technological disciplines in future pharmacists and pharmaceutical technologists' training. The proposed changes aim to strengthen the ecological component of education to ensure the pharmaceutical industry's sustainable development.

2 Experimental

2.1 Sample preparation

The chemical and elemental composition variability was studied using the medicinal plant Hypericum perforatum L., known as St. John's wort (SJW), and purchased in pharmacies in Kyiv. Three well-known Ukrainian companies specialising in the manufacture of herbal medicines have been selected as suppliers. All three companies (hereinafter producers 1-3) harvest hyperici herba in the central, eastern and western parts of the

https://doi.org/10.1051/e3sconf/202128011015

country, respectively, located at a distance of 400-500 km from each other.

The elemental composition of similar herbal drugs was studied in [40, 41]. Comparing the results of current and previous works allowed us to assess the stability of the elemental composition of herbal preparations from different regions of the country. Besides the elemental composition, the content of hyperforin, one of the most important biologically active substances in SJW, was determined in the given work.

Before analysis, the herbs were ground in a high-speed rotary mill to obtain homogeneous samples with a grain diameter of ≤1 mm, which were then stored in plastic containers. All chemicals used in sample preparation belonged to the analytical class.

A sample weighing 2 g was placed in a Teflon reaction crucible to analyse the elemental composition. It was treated with 10 ml of a mixture of 30% hydrogen peroxide (H_2O_2) and concentrated 65% HNO_3 (1:4, v / v).

The sample decomposition was performed in a microwave system with a closed vessel by the following three-stage regime: 80% power for 15 min, 100% for 5 min and 80% power for 20 min. After cooling, the transparent solutions were quantitatively transferred to clean volumetric flasks and diluted to 50 ml with twice-distilled water.

Analysis of the hyperforin content was performed by spectrophotometry. Samples for hyperforin analysis (1.0-3.0 g of plant powder) were placed in a flask with a section with a capacity of 250 ml. 100 ml of hexane was added; the flask was connected to the reflux condenser and heated in a water bath at a moderate boil of hexane for 30 min. The flask is then cooled. Its content was filtered through a paper filter into a 100 ml volumetric flask. The volume of the solution brought up to the mark with hexane. Transfer 5 ml of the resulting extract to a 25 ml volumetric flask and dilute to volume with hexane.

2.2 Instrumentation

The elemental composition of plants was studied by flame atomic absorption spectroscopy (FAAS). A two-beam spectrometer Solaar S4 AA (Thermo Electron Co., USA) was used in the experiment. Standard conditions in air/acetylene flame, D_2 correction and external calibration method were applied. Other details of the experiment, including the spectrometer parameters (wavelengths, operating interval, characteristic concentrations, and the width of the slit), were given elsewhere [40].

Identification and quantification of hyperforin were performed by spectrophotometry following the Pharmacopoeia of Ukraine [42]. This technique outperforms others in terms of simplicity, moderate staffing requirements, speed and cost. The spectrophotometric determination used does not separate the content of different derivatives of hyperforin. All compounds, namely hyperforin, adhyperforin and furohyperforin, exhibit absorption maxima at the same wavelength (272 ± 2 nm). For this reason, the total content of all the above compounds was determined and denoted by the term "total hyperforin".

The experiments were performed using a spectrophotometer Optizen POP bio (South Korea). The optical density of the analysed solutions was measured at a wavelength of 272 nm. Quantitative determination was performed using standard solutions. For calculations, the specific absorption of hyperforin was taken to be 8200. SJW extracts were used to prepare standard solutions. California Gold Nutrition EuroHerbs produced extracts. They were certified by Advanced Botanical Consulting & Testing, Inc. (a US FDA Registered, Independent, Third-Party Labs). The concentrations of hyperforin in five reference samples ranged from 0.06 to 0.4 mg/ml.

Three independent samples were examined for each concentration. with different

A calibration graph was plotted to quantify hyperforin in the test samples. Experimental points for optical density in standard samples show high values of the coefficient of determination R^2 ($R^2 > 0.98$) with an approximation linear line. Thus, the selected experimental conditions (primarily the range of solution concentrations) provide linearity. Standard samples can quantify hyperforin.

2.3 Statistical analysis

Measurements of each sample in FAAS and spectrophotometry measurements were repeated at least three times for further averaging. Both own experimental results and the literature data were analysed by statistical methods using IBM SPSS 20. All data were checked for normal distribution using the Kolmogorov-Smirnov test. The results were then expressed either as means for data with a normal distribution or medians for data with asymmetric distributions. The standard deviations of the mean were calculated when necessary.

3 Results

3.1 Medicinal plants and herbal medicines on the officinal market of Ukraine

Medicinal plants and herbal medicines are widely represented in the market of Ukraine. As of November 2020, the State Register of Medicinal Products includes 14714 trade names of medicaments [43]. Of this number, 12561 positions belong to medicines of different pharmacotherapeutic groups. The rest 2153 items are medicinal substances.

Of the total number of registered trade names, 1507 (10.24%) are herbal preparations, comprising 1143 herbal medicines and 364 plant substances. Herbal medicines occupy leading positions among drugs of some therapeutic groups. Figure 1 illustrates the ratio of registered medicines of plant and synthetic origin on the example of five therapeutic groups. According to the international Anatomical Therapeutic Chemical (ATC) classification system, these groups include

1. A03 - means for treating functional gastrointestinal disorders;
2. A05 - means for treating diseases of the liver and biliary tract;

 https://doi.org/10.1051/e3sconf/202128011015

3. C01A - cardiac glycosides and C01E - other cardiac preparations;
4. G01 - antimicrobial and antiseptic agents used in gynaecology and G02 - other gynaecological agents;
5. R05 - remedies against cough and colds.

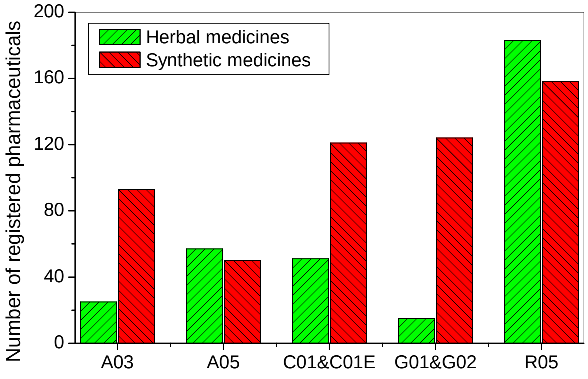

Fig. 1. Number of drugs of plant and synthetic origin for five therapeutic groups registered in Ukraine

The number of herbal medicines in groups R05 and A05 exceeds the number of registered synthetic drugs. Many herbal remedies are used to treat the cardiovascular system's diseases, upper respiratory tract, liver and biliary tract, genitourinary system, etc.

A total of 51 (29.65%) medicinal agents of the 172 registered drugs for the cardiovascular system treatment (groups C01A and C01E) are plant origin drugs. Among the registered drugs of group C01A Cardiac glycosides, all drugs are based on biologically active substances isolated from plant raw materials.

Most herbal medicines are presented on the market in prepared dosage forms - 977 items out of 1143 registered herbal drugs. For example, the range of herbal medicines is dominated by tablets (26% of all herbal medicines), capsules (11%), tinctures (9%), syrups (8%), etc. Of these, 642 positions (65.71%) are occupied by domestic drugs and 335 (29.31%) foreign production.

Only a small part, 166 (14.52%) of the names of finished drugs are presented in the form of officinal preparation (leaves, flowers, grass, fruits, seeds, roots, bark, etc.) of domestic production packaged in packs or packages, of which 32 medicines are teas. The distribution of registered drug substances by dosage forms best illustrates a typical way from herbal raw materials to the pharmaceutical market (Fig. 2).

Most plant raw materials enter the market after significant pre-treatment, including grinding and mixing different parts of the plant (Fig. 2). Then plants turn into powders, extracts, crushed mass, etc. This situation only increases the requirements for the quality of plant raw materials because it is much more difficult to identify plants, assess impurities, etc., at the stage of working with substances.

The analysis shows a rich source of raw materials for the manufacture of medicinal substances in Ukraine. Among 364 substances, 347 (95%) are substances of Ukrainian origin. A relatively high degree of processing of raw materials in the manufacture of a medicinal substance is striking. The primary forms (leaves, fruits, etc.) account for a little over a third of the available positions. The quality of pharmaceuticals depends on the quality of raw materials. In the next sections, such quality indicators as the stability of the elemental composition and organic compounds' content will be studied using some plant examples.

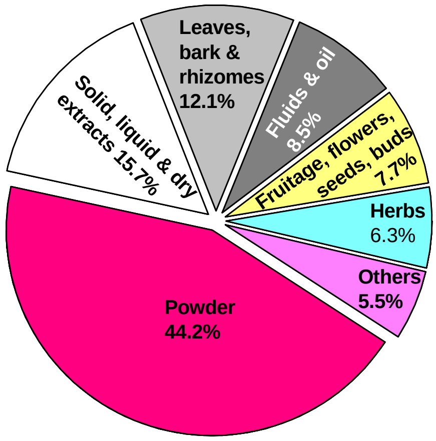

Fig. 2. Structure of registered herbal substances by dosage forms in the market of Ukraine.

3.2 Elemental composition of medicinal plants

Variability of concentration of chemical elements is investigated using the herb St. John's wort. The results of our research for SJW samples of different producers were analysed together with literature data. Among various works, only those were selected, where the authors studied the chemical composition of several (at least three) samples of SJW of different origins. SJW specimens purchased at markets or pharmacies (hereinafter named herbs) and representatives of aerial parts of wild plants collected in different geographical locations (shown as plants) are considered.

Due to natural and anthropogenic variability, the chemical composition of SJW of the same botanical species (Hypericum perforatum) significantly differs from each other, even in one study. Table 1 shows the intervals of the existence of chemical elements in SJW, according to various authors.

The values of R were calculated to quantify the width of concentration ranges for different elements. R is the ratio of maximum-to-minimum concentrations reported in the literature: $R = C_{max}/C_{min}$. The more extensive the concentration range, the greater the value of R.

The R values for Fe, Mn, Cu, Zn, Cd and Pb are illustrated in Fig. 3. The data are presented as histograms N(R), where N – is the number of considered published research. The R values for Cr, Ni and Co are not calculated due to the limited number of non-zero data for these elements.

In the case of copper and zinc, the vast majority of observations demonstrate $R < 5$. The N(R) distribution corresponds to the Gaussian; the average values of R_{av} are 4.41 and 4.15 for copper and zinc, respectively.

For iron and manganese, the picture is a little different. Plants with increased Fe content, when R values vary from 20 to 65, were detected in a significant number of observations. In most of the studied plants, R does not, however, exceed 6. The N(R) for Fe follows Gauss's law, the average value of R_{av} = 13.05. The Mn distribution curve is more extended than for Fe; most R occupies a broad band from 2 to 22. The distribution of N(R) significantly deviates from the normal law. For this reason, typical values of R for Mn are described by a median rather than an average. The median R_{med} = 3.9.

Table 1. The range of concentrations of some essential and toxic trace elements (in µg/g of dry weight) in samples of St. John's wort according to results of various authors.

Country	Sample	No of samples	Fe	Mn	Cu	Zn	Co	Cr	Ni	Cd	Pb	Source

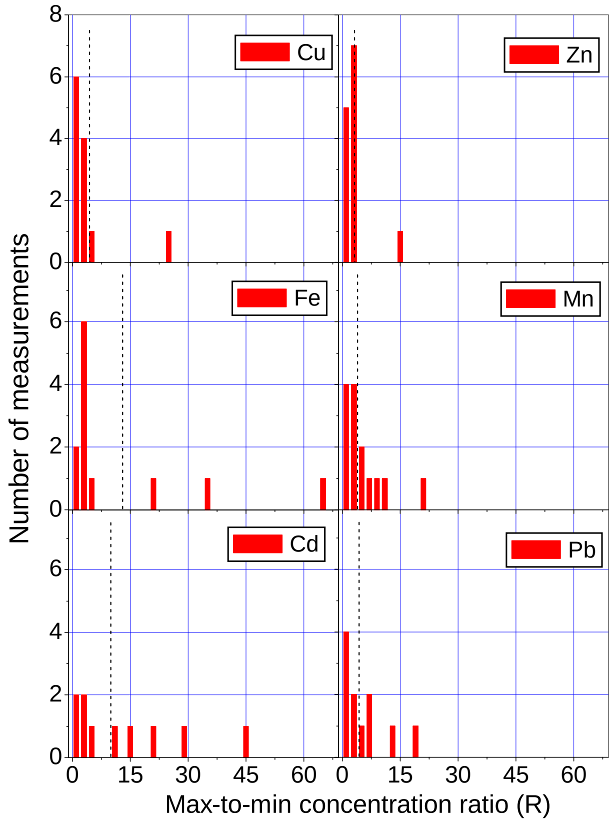

Fig. 3. Histograms illustrate the number of considered research N as a function of R, the ratio of maximum-to-minimum concentrations of elements in plants. Dotted lines show the mean values for components with a normal distribution (Fe, Cu, Zn) and medians for elements with asymmetric distributions (Mn, Cd, Pb)

Histograms for toxic impurities, Cd and Pb, significantly differ from histograms for essential trace elements. Both curves are characterised by an asymmetric, far from a normal distribution. The value of R for cadmium varies in a wide range from 1.2 to 44. It is impossible to determine an average R, which is perceived as the most probable Cd concentration. The median value for cadmium R_{med} = 10. Approximately the same pattern is observed for Pb. However, a significant part of the specimens demonstrates R values in the range from 1 to 7. The median for lead R_{med} = 4.3.

3.3 Hyperforin in Saint John's wort

The average concentrations of hyperforin (Fig. 4a) and some essential elements (Fig. 4b) are shown for herbal samples of different producers.

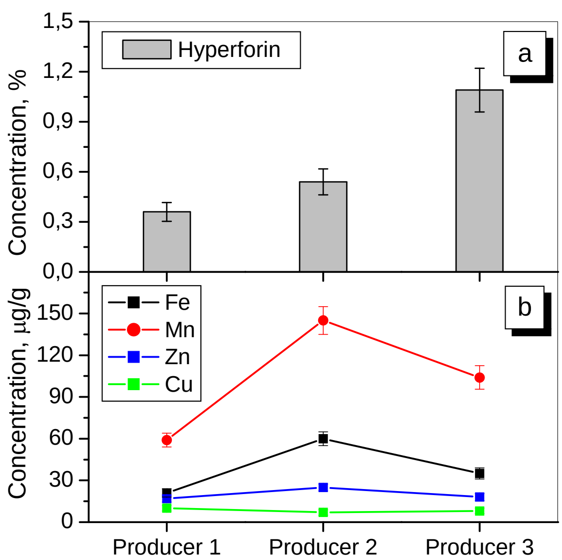

Fig. 4. Measured concentrations of hyperforin (a) and some essential microelements (b) in samples of producers 1-3.

In producer 3, the hyperforin content is almost three times higher than in specimens of producer 1. The indicators of producer 2 occupy an intermediate position, although still slightly closer to producer 1.

Figure 4b illustrates the detected scatter of concentrations of essential micronutrients in samples from different producers. Compared to others, zinc and copper concentrations show the most stable behaviour. In contrast, the concentrations of manganese and iron vary over a fairly wide range. Thus, the highest determined concentration of manganese in samples of producer 2 is actually 2.5 times higher than the lowest concentration of this element in herba of producer 1. A similar situation is observed for iron, where the maximum concentration (producer 2) is almost five times higher than the minimum concentration (producer 1).

The obtained results do not allow the authors to confirm the conclusions made earlier in [40] on the presence of anticorrelation between the concentrations of iron and manganese. However, similar to [40], samples of St. John's wort from producers 2 and 1 again show the highest and lowest concentrations of manganese and iron, respectively. At the same time, the levels of zinc and copper relatively weakly depend on plant origin.

A clear correlation between the concentration of hyperforin and elemental impurities is also not observed. The highest concentration of hyperforin is detected in samples with medium, although relatively high impurity content. Additional research is needed to formulate sound conclusions.

4 Discussion

4.1 Variability of the composition of medicinal plants

The origin of the variability of element concentrations will be considered using histograms shown in Fig. 3. As mentioned earlier, the value of the parameter R for copper mostly varies in a relatively narrow range of 1.1-5.6 and is subject to the normal distribution. It can be assumed that such fluctuations reflect the natural variability of copper concentration.

The effect of natural variability of chemical composition is well known and is inherent in virtually all plants. Native reasons cause it. On the one hand, this phenomenon is due to the biologically determined variability of plants belonging to the same family and genus and different species. On the other hand, the chemical composition variability is determined by the geochemical conditions of their cultivation, such as soil composition, underlying rocks, and natural waters [17]. The study of the causes of variability in plant composition goes far beyond the research topic. It is important to note for our purpose that the chemical composition of medicinal plants can vary widely. Human activity is one of the primary sources of chemical elements, including toxic heavy metals widely used in industrial products and waste, accumulated in plant tissues.

The plant body regulates the required level of copper as an essential trace element. Only one observation [45], covering 22 samples from the studied 136 probes, reports the increase of R to 25.9. The Cu concentration in some of these 22 samples can amount to 120 μg/g amid traditional Cu levels of approximately 5-27 μg/g. Most likely, the influence of anthropogenic environmental factors is observed in such cases.

Very similar behaviour is typical for Zn. In 101 cases among 136 studied samples, the Zn concentration varies in a relatively narrow range of 15-100 μg/g. It corresponds to the R ÷ 1.1-3.8. The increase of R to 14.1 was detected in work [48] only. Such an increase corresponds to the expansion of the concentration range to 12.9-181.6 μg/g. Among 35 samples in [48], the Zn concentration exceeded 100 μg/g in 7 plants only. The increase in Zn concentration above 50-100 μg/g is not typical for most observations. The influence of external environmental pollution may take place in these few samples described in [48].

The shape of histograms in Fig. 3 significantly changes with the transition to the other two essential elements, iron and manganese. For iron, the curve N(R) is still subject to the normal distribution in most samples. The parameter R varies from 1.1 to 5.5, which corresponds to a concentration range of about 20-80 μg/g. Meanwhile, many observations with elevated R are known from the literature [45, 46, 48]. These papers account for 72 samples from the studied 136 probes. More precisely, the iron content exceeded 80 μg/g in 43 plants [46, 48], while the results of individual measurements are not shown in [45]. In all 18 samples reported in [49, 52], the Fe concentration exceeded 80 μg/g despite the moderate value of R. Totally, high iron content was observed in almost half of the studied samples (at least 61 out of 136).

The R values typically vary between 1.1 and 10.2 for Mn, which corresponds to a concentration range of 10-150 μg/g. An expansion of this interval to 21.7 was observed in [48]. An increase of the Mn concentrations to 260 μg/g was observed in some reports [44, 45, 48, 52]. Besides, the distribution N(R) no longer follows the law of normal distribution.

The most likely explanation for the Fe and Mn behaviour seems to be the effect of environmental pollution on the concentrations of these two elements in plant tissues. Iron and manganese are among the most common elements in the earth's crust. Iron is the primary structural material of modern civilisation. The annual steel production is about 1.5 billion tons, tens or hundreds of times higher than the output of any other metals or non-metals. Manganese is widely used in the metallurgy, production of fertilisers, batteries and accumulators. The systematic processing of manganese wastes is established only in ferrous metallurgy. Waste products with Mn in all other applications do not have a well-established systemic utilisation. They mostly remain in the environment. Therefore, it is not surprising that these metals are among the primary contaminants of soil and water in Ukraine [25-28].

Cadmium and lead are not essential elements in plants but are very toxic impurities for the human body. It is impossible to determine the typical or most probable values or ranges of R. The distribution of N(R) is

https://doi.org/10.1051/e3sconf/202128011015

asymmetric. The R values non-systematically change in a vast range from 1 to 45 for Cd and vary between 1.1 and 19 for Pb. The R values for Pb are very low in some samples. In such probes, the Pb concentration is a nearby detection limit. The content of Cd and Pb measured in plants does not depend on the plant's needs. In turn, it is determined by the degree of contamination of the plant through contacts with the environment [18, 19, 24].

The hyperforin content was shown to change 2-3 times in samples of different Ukrainian producers (Fig. 4). The quantification of hyperforin is not yet prescribed in Ukraine and EU's Pharmacopoeias but is present in the US Pharmacopoeia. In recent years, it has become increasingly clear that hyperforin is one of the most valuable API of SJW. The detection of hyperforin is also essential for plant identification because it can be considered a promising SJW marker.

The results obtained for hyperforin were compared with the published literature data. The hyperforin concentrations in SJW samples of six Russian producers demonstrated a 2-3-fold variation [54]. The concentration range varied between 0.36% and 1.16%, which agrees well with the results obtained in this study.

Table 2 also compares the average levels of hyperforin in herbal remedies (SJW extracts) available on the German pharmaceutical market. These results were obtained by recalculating and averaging the primary data from [55]. The direct comparison of the current results with [55] is difficult because herbal samples and extracts were studied in these works, respectively. However, the concentration coefficients stated in [55] allowed us to estimate the range of hyperforin concentrations in the used plant raw materials (Table 2).

Table 2. The average content of hyperforin in medicines of the herb St. John's wort from European producers according to [55] and the estimated range of hyperforin in plant raw materials.

Trade name (producer)	Dosage form	Average hyperforin in herbal drugs, %	Concentration factor *	Estimated range of hyperforin in medicinal plants, %
Jarsin 300 (Lichtwer Pharma)	Sugar-coated tablet	2,49	4-7:1	0,36-0,62
Neuroplant 300 (Dr Willmar)	Film-coated tablet	4,14	2.5-5:1	0,83-1,66
Texx 300 (Krewel-Meuselbach)	Film-coated tablet	2,5	4-7:1	0,42-0,71
Felis 425 (Biocur)	Capsule	2,75	3.5-6:1	0,42-0,71
Futuran (Madaus)	Capsule	1,54	3.5-6:1	0,22-0,44
Helarium 425 (Bionorica)	Capsule	2,14	3.5-6:1	0,36-0,61
Laif 600 (Steigerwald)	Film-coated tablet	1,86	5-8:1	0,23-0,37

* concentration factor is the ratio of the mass of raw materials (St. John's wort) to the mass of the extract obtained from it

In most cases, this interval coincides with the results of the current work. Also, the results of [55] very well illustrate the high degree of variability in the content of hyperforin. For St. John's wort extract, the hyperforin content should be at least 3% [56]. Only the preparation Neuroplant 300 met this criterion among all products studied in [55].

4.2 Approaches to the safe use of herbal medicines

The obtained results and literature data give a clear idea of a sizeable difference in chemical and elemental composition between plants grown in different conditions. For example, the content of hyperforin in SJW, one of the most significant APIs, varied almost threefold in drugs from different producers. It gives reason to believe that the effectiveness of such medicines will also be different.

The findings of SJW studies mainly apply to other herbal medicines. However, a buyer of such drugs will not receive any information about API's content. The same problem applies to the variability of the elemental composition.

The outer packaging available to the consumer shows only plant name, producer name and address, keeping time, method of application, including features of use and dosage, contraindications, adverse drug reactions, and warnings.

More information can be found in the instructions for medical use of the drug, approved by the Ministry of Health of Ukraine. The main sections of the instruction (for example, the herb SJW) are as follows.

The composition of the drug: the active substance is herba hiperici. The manufacturer is specified. The dosage form is grass. Pieces of leaves, stems, flowers of various shapes and unripe fruits, greenish-yellow, greyish-green, green, dark green, bright yellow or yellow with black dots, greenish-brown, sometimes pink-purple.

The indicated pharmacotherapeutic group and code ATX A01AD11.

St. John's wort contains many compounds: tannins, flavonoids (hyperoside, rutin, quercetin, myricetin, leucoanthocyanidins), saponins, dyes (hypericin, pseudohypericin), essential oil, resinous substances, carotene, and ascorbic acid. This complex of APIs has astringent, anti-inflammatory and some antimicrobial action. It promotes tissue regeneration, has a moderate effect on bile secretion, stimulates gastric secretion and more.

Indications for use and contraindications, appropriate safety measures are also described. As mentioned above, there are no reservations about the variability of chemical and elemental composition.

The studied concentrations do not exceed the permissible limits in the studied Ukrainian samples. However, some literature data indicate the presence of severe contamination of SJW with toxic metals. For example, poisonous cadmium has been determined in commercially available medicinal plants or plants in food supplements. Concentrations up to 3 and 1.73 μg/g were found in some SJW samples in [44, 45], respectively. An even higher cadmium level, with 4.2 μg/g, was found in wild plants [50]. According to EU guides or US Department of Agriculture standards in medicinal plants and food additives, the maximum permissible concentration of Cd should not exceed 1 μg/g. WHO established even stricter standards for herbal medicines - no more than 0.3 μg/g [57].

A similar situation is observed for Pb. Instead of the allowable 2-5 μg/g in plant raw materials, 17 μg/g was observed in SJW stems [46]; 25 μg/g [50] and even 124 μg/g [48] in wild plants.

Exceeding certain limits applies not only to highly toxic impurities but also to some essential trace elements. Unlike the most poisonous metals (Pb, As, Hg and Cd), the toxicity of essential trace elements is much lower. Their permissible doses are not usually regulated in medicinal plants. However, many norms standardise optimal or safe consumption of these metals in functional and supplementary foods, spices, herbal supplements, etc. For example, adequate intake of Mn is recommended at 1.8-2.3 mg [57]. The minimum risk level or tolerable daily intake is 2-5 mg and 5 mg, respectively. Thus, the safe daily consumption of the most Mn-contaminated medicinal plants [44, 45] should not exceed 10 g of herba per day. Allowed consumption with minimal risk is approximately 20 g. Norms for iron are slightly milder than for manganese, but iron content is much higher in some plants. Therefore, according to the standards, the tolerable daily intake of some of the most Fe-contaminated plants [48] will be limited to only 5 g per day.

Among the essential trace elements, chromium is the most toxic. According to the Ministry of Health of Canada, this element is already standardised together with the most toxic metals. The consumption of wild SJW with a Cr content of 6.1 μg/g, studied in [53], maybe only about 5 g. The reason is the limitation of adequate intake at 25-35 μg [57].

In Ukraine, wild plants account for about 50% of plant raw material. The reason for collecting wild plants is primarily economic. The current situation will not change quickly, although the general direction of development is to increase the share of cultivated plants in the raw material.

Increased impurities in wild plants are usually associated with human economic activity. Excessive accumulation of toxic contaminants in plants does not always affect their appearance [22]. It creates an additional danger of consuming contaminated plants, which cannot be foreseen only by external inspection.

In addition to the direct effect of accumulated toxic impurities, the mutual influence of elemental composition on API content and vice versa was evidenced [58, 59]. The most straightforward mechanism that explains this effect is the formation of organometallic compounds, which reduce biologically active substances' concentrations.

The problems with unfavourable plant chemistry are part of a broader problem of damaging the ecology of regions. Solving the problem of plant quality cannot be resolved without solving environmental issues. Ecology's impact on the quality of plant raw materials is inherent in Ukraine and other countries. The presence of plant products from different countries on the Ukrainian market only exacerbates this problem. Thus, to ensure the sustainable development of a raw material base of the pharmaceutical industry, the formation of appropriate environmental competencies should be guaranteed in training future specialists in the field.

Standardisation could remove many questions about the stable quality of herbal medicines. However, different countries have different safety standards, and the medicinal plants are qualified according to various algorithms. In a sense, the lack of a single generally accepted method of standardising medicinal plants reflects the problem's complexity. Plants can be considered as "living factories" that produce a variety of chemicals. They include primary metabolites, i.e. those that are important for the growth of the plants themselves (proteins, amino acids, carbohydrates) and secondary metabolites (flavonoids, terpenoids, alkaloids, etc.). All these components work together, providing a synergistic effect in the finished herbal medicine.

All drugs are chemicals, whether they are synthesised in chemical laboratories or plants. Therefore, irrespective of their source, all medicinal chemicals must meet similar quality standards (identity, purity and stability) and ensure clinical efficacy and safety. Reliable and consistent quality is the basis of the efficiency and safety of herbal medicaments.

Due to the complexity and variability of plant products' components, it is not easy to establish a quality control parameter and maintain consistent quality from batch to batch. The variability of the properties of medicinal plants and herbal medicines in the absence of reference standards begins with collecting raw materials. It only increases during the storage and further processing of plant products. Evidence of both benefits and risks is specific to the product tested. It cannot always be extrapolated to other products, as is always the case for synthetic preparations.

The question of the quality of herbal medicines has two sides - external and internal [7]. The first external issue concerns possible contamination (toxic metals, microbes, pesticides, etc.), adulteration and misidentification.

The internal factor is related to the complexity and potential variability of the components of herbs. Implementation and compliance with Good Agricultural and Collection Practice (GACP) and Good Manufacturing Practice (GMP) reduce the risk of external factors adversely affecting herbal medicines. Ideally, standardisation procedures should cover the entire industry, from medicinal plant cultivation to their clinical application. However, there are currently no generally accepted approaches to creating a comprehensive quality assurance system [60]. Producers of herbal remedies apply their own experience and methods to quality assurance.

The influence of internal factors must be regulated through the use of modern analytical and pharmaceutical methods. Intensive use of modern instrumental analysis can significantly increase knowledge about the composition of plant raw materials. However, the availability and low price of herbal medicines are some of their main advantages. High cost due to the use of complicated and expensive analytical methods regularly offsets this advantage. The most promising way to improve standardisation procedures is the optimal ratio of technological operations' simplicity and dosed application of modern analytical techniques.

Controlled and stable API content, the absence of contaminants are the main factors that shape herbal medicines' quality. On the one hand, virtually all stages of obtaining raw materials and further processing are regulated in Ukraine by relevant guidelines. On the other hand, API content was shown to vary in the products of different producers. Thus, the existing requirements for medicinal plants do not fully meet modern needs, which are becoming more. The unpredictable variability of the composition combined with the lack of pharmacological and clinical data for most herbal medicines is the main obstacle to the broader use of natural products in medical practice.

4.3 Environmentally-affected chemistry of medicinal plants in the context of ecological education

Medicinal plants of Ukraine include about 2215 species, of which 233 (10.5%) are cultivated and introduced species; the rest are wild [61]. A significant amount of medicinal plants is grown in specialised and homestead farms. Among the total number of wild plants (about 1975 species), only 482 species have resource value, forming resource-significant massifs on large areas (> 1 ha) or have significant distribution. The studied above SJW has a significant distribution and large reserves within Ukraine.

The official medicine of Ukraine uses about 200 types of medicinal plants. The State Pharmacopoeia of Ukraine [62] includes 198 monographs on plant raw materials and 88 monographs on herbal medicines (extracts, tinctures, etc.).

Among medicinal plants, there are 44 wild species, 32 wild and cultivated species introduced into the culture due to limited reserves of raw materials, 33 cultivated sorts, and 89 imported plants. Increasing demand for herbal medicines necessitates the expansion of production, improved technology, expanded the collection of plant raw materials, and increased its quality requirements.

However, the number of certain types of medicinal plants is decreasing, and the natural reserves of some wild species are entirely or partially depleted. About 200 species are listed in the Red Book of Ukraine, and more than 70 are regionally rare [61]. Many wild medicinal plants have limited resources. More than 50% of them are significantly distributed but grow scattered or sporadically. Harvesting of such plants in natural places of growth is unprofitable.

The shortage of plant raw materials is due to the ecological load, changing climatic conditions, and anthropogenic factors. In addition to reducing plants' natural habitat, damaged ecology also deteriorates their quality due to contamination with various pollutants. The expansion of the base of raw materials is possible by their introduction into the culture. Therefore, the cultivation of plants essential for the pharmaceutical industry will enhance in the future.

The formation of professional knowledge, skills, and abilities related to medicinal plants is an essential component of training specialists for the pharmaceutical industry. They include understanding the chemical composition of plants, biosynthesis and accumulation of biologically active substances during plant ontogenesis, and quality control methods of plant raw materials.

The formation of the ability to anticipate changes that occur with raw materials under environmental factors is among the essential requirements. These skills are necessary to choose the optimal conditions for cultivation, harvesting, drying and storage, standardisation and quality control methods of plant raw materials and herbal medicines following the requirements of pharmacopoeias and national standards.

The competence that needs to be formed can be called the ecological thinking of a future specialist. It includes the desire to preserve the environment, the ability to act socially responsible and socially conscious, and the ability to assess and ensure the quality of professional work performed.

At present, the existing curricula of some related disciplines are not perfect. The introduction of particular environmentally-oriented educational elements in the programs of disciplines will contribute to the formation of the ability to operate in conditions of use of raw materials, the quality of which depends on the environment.

We propose to do this consistently, starting with the study of analytical chemistry at the bachelor's level and ending with developing particular components for the discipline of "pharmaceutical quality system" within a master's programme (Table 3).

Introducing the necessary topics into syllabi and the definition of expected knowledge and learning outcomes will ensure continuity and consistency in industry specialists' training.

The proposed approach allows the graduation of specialists who will meet the requirements for sustainable development of Ukraine in the coming decades. They will be able to predict changes in plant raw materials under the influence of environmental and climatic conditions, respond promptly, and take measures to prevent deterioration in pharmaceutical products' quality. They will also be able to move to models of balanced consumption and production of medicines based on medicinal plant raw materials.

Conclusions

1. The stability of elemental and chemical compositions of herbal medicines was studied using samples of herba St. John's wort of different origin. Own experiments were conducted using samples of three different Ukrainian producers purchased in pharmacies.

The measured chemical and elemental compositions of herbs were compared with the literature on SJW herbal preparations and wild plants.

2. Among the trace elements, the concentrations of copper and zinc in plants show the best stability, usually ranging from 10 to 100 μg/g. The normal distribution of the sample number vs Cu and Zn concentrations and relative stability of the composition suggests that the environmental influence on these elements' content is minimal compared to other elements.

3. In contrast, the concentrations of manganese and iron in St. John's wort vary over a broader range. Many plants demonstrated traditional concentrations range from 10-20 to 100-150 μg/g. In some studies, the content of Fe and Mn has increased tens or even hundreds of times. Both Fe and Mn are essential elements necessary for plant life. However, they are also among the most common metals used in modern civilisation. Therefore, the anthropogenic load on plants seems to be much higher concerning Mn and Fe compared to other elements. The state of the environment causes significantly higher iron and manganese content in some plants.

4. Usually, the concentrations of other studied essential trace elements, Ni, Co, Cr, do not exceed 1-1.5 μg/g. Concentrations above 2 μg/g were not found in the studied samples and are also abnormally rare in the literature. The slightest variation in the content of these elements in the soil or water tangibly affects their concentration in plants. This fact complicates understanding the causes of these elements' variability in plant tissues. The detected concentrations of these elements in plants do not exceed the existing norms concerning their content in dietary supplements or herbal preparations.

5. Toxic cadmium and lead are not vital elements in plants. Therefore, their content depends entirely on the environment of plant growth. The large concentration interval observed in various works reflects the environmental influence on the content of hazardous impurities. Among the herbal drugs, the Pb and Cd content met the existing standards in all studied cases. Some samples collected in the wild exhibited dangerously high levels of these elements.

Table 3. Proposed changes in the content of educational components for the formation of environmental thinking of bachelor and master students of pharmacy.

</table>

6. The content of hyperforin varies between 0.35 and 1.15%. The measured API concentration is almost three times higher in the samples of producer 3 compared to producer 1. There was found no clear correlation between the elemental composition and API content.

7. The existing standards governing collecting and processing herbal raw materials and manufacturing herbal medicines do not fully ensure the composition's stability and, therefore, herbal medicines' effectiveness. Accordingly, the environmental impact on the quality of plant raw materials needs increased attention in a narrow sense. In a broad sense, improving environmental knowledge is necessary among specialists involved in herbal medicines and other herbal preparations.

8. The problem can be solved by forming the required competencies in the training of prospective pharmacists and technologists of industrial pharmacy. Necessary changes to the syllabi of some fundamental (analytical and pharmaceutical chemistry) and technological (pharmaceutical development and pharmaceutical quality system) disciplines are proposed to ensure the pharmaceutical industry's sustainable development.
