Second International Conference on Sustainable Futures: *Environmental, Technological, Social and Economic Matters*

ICSF 2021

May 19-21, 2021
Kryvyi Rih, Ukraine

edp sciences

Statement of Peer review

In submitting conference proceedings to *Web of Conferences*, the editors of the proceedings certify to the Publisher that

1. They adhere to its **Policy on Publishing Integrity** in order to safeguard good scientific practice in publishing.
2. All articles have been subjected to peer review administered by the proceedings editors.
3. Reviews have been conducted by expert referees, who have been requested to provide unbiased and constructive comments aimed, whenever possible, at improving the work.
4. Proceedings editors have taken all reasonable steps to ensure the quality of the materials they publish and their decision to accept or reject a paper for publication has been based only on the merits of the work and the relevance to the journal.

Title, date and place of the conference

Second International Conference on Sustainable Futures:

Environmental, Technological, Social and Economic Matters (ICSF 2021)

May 19-21, 2021 | Kryvyi Rih, Ukraine

Proceedings editor(s):

Serhiy Semerikov, Serhii Chukharev,

Serhiy Sakhno, Andrii Striuk,

Andrii Iatsyshyn, Serhii Klimov, Viacheslav Osadchyi,

Tetiana Vakaliuk, Pavlo Nechypurenko,

Olga Bondarenko, Hanna Danylchuk

Date and editor's signature

June 15, 2021

Our sustainable pandemic future

Abstract. This is an introductory text to a collection of papers from the ICSF 2021: Second International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters, which held at Kryvyi Rih National University, Kryvyi Rih, Ukraine, on May 19-21, 2021. It consists of an introduction, conference topics review, and some observations about the event and its future.

ICSF 2021 at a glance

The International Conference on Sustainable Futures: Environmental, Technological, Social and Economic Matters (ICSF) is a peer-reviewed international conference, which is the premier interdisciplinary forum for social scientists, life scientists, engineers, and practitioners to present their latest research results, ideas, developments, and applications (Fig. 1).

Fig. 1. ICSF 2021 logo (designed by Dr. Andrii Striuk).

The ICSF occupies contributions in all aspects of sustainable development, focused on the intersection of sustainability, environment and technology, and their more significant implications for a corporation, government, education institutions, regions, and society both at present and in the future.

ICSF has two presentation levels, Pre-conference Workshops and Main Conference.

Ecochemistry Education for Sustainable Development Workshop

Ecochemistry Education for Sustainable Development Workshop (EcoChemSD-WS'2021) is a peer-reviewed international workshop that occupies contributions in all aspects of environmental chemistry and ecochemistry, ecochemistry education, and modern educational technologies.

EcoChemSD-WS'2021 main topics of interest are:

- Ecochemistry research for the sustainable development
- Environmental chemistry for the sustainable development
- Ecochemistry education for the sustainable development
- Green Chemistry
- Environmental remediation technologies
- Modern educational technologies in the chemistry education
- Chemistry teacher's training for the sustainable future

EcoChemSD-WS'2021 Program Committee chair is Dr. Pavlo Nechypurenko.

Geography for Sustainable Development Workshop

Geography for Sustainable Development Workshop (GSD-WS'2021) is a peer-reviewed international

* Corresponding author: semerikov@gmail.com

workshop. During the GSD-WS’2021, the researchers who are committed to the problems of geography for sustainable development can present their latest research findings, ideas, developments and programs.

GSD-WS’2021 main topics of interest are:

- Geographical bases of sustainable future: methodological bases
- Problems and prospects for the development of physical and socio-economic geography in the context of sustainable future
- Regional problems of sustainable future and local lore research of territories
- Cartographic research and geoinformatics: theory and practice
- Noosphere nature management is the key to a sustainable future
- The theory of sustainable future in geographical education.

GSD-WS’2021 Program Committee chair is Dr. Olga Bondarenko.

Water Management and Environmental Engineering Workshop

Water Management and Environmental Engineering Workshop (WaterManEnvE-WS’2021) is a peer-reviewed international workshop. WaterManEnvE-WS’2021 occupies contributions in all aspects of water management and environmental engineering, environmental education and modern educational technologies.

WaterManEnvE-WS’2021 main topics of interest are:

- Water Management and water resources use
- Monitoring of water resources
- Irrigation and Drainage
- Water treatment and water supply
- Hydraulic Engineering & Hydraulics
- Hydropower

WaterManEnvE-WS’2021 Program Committee chairs are Dr. Serhii Chukharev and Dr. Serhii Klimov.

Innovative Approaches for Solving Environmental Issues Workshop

Innovative Approaches for Solving Environmental Issues Workshop (IASEI-WS’2021) is a peer-reviewed international Sustainable Computing workshop focusing on advanced research on Sustainable Computing. The workshop occupies contributions in all aspects of sustainable computing, reflecting modern engineering and technological solutions of the information technology era in the sustainable development of society.

IASEI-WS’2021 main topics of interest are:

- Environmental protection.
- Nuclear and radiation safety.
- Complex, economic and technological solutions.
- Problems of training and advanced training.

IASEI-WS’2021 Program Committee chair is Prof. Andrii Iatsyshyn.

Main Conference

Workshop and Conference presentations are grouped into 11 tracks:

1. Geotechnical and Geoenvironmental Engineering [1-8]
2. Measuring, Forecasting and Monitoring Sustainability [9-18]
3. Sustainable Building and Architecture [19-25]
4. Sustainable Cities and Society [26-39]
5. Sustainable Energy [40-55]
6. Sustainable Environment and Environmental Management [56-65]
7. Sustainable Materials and Technologies [66-84]
8. Sustainable Mining [85-105]
9. Innovative Approaches for Solving Environmental Issues [106-129]
10. Water Management and Environmental Engineering [130-140]
11. Ecochemistry and Geography Education for Sustainable Development [141-155]

This volume contains the papers presented at ICSF 2021: Second International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters held on May 19-21, 2021 in Kryvyi Rih, Ukraine.

There were 217 submissions. Each submission was reviewed by at least 3, and on the average 3.2, program committee members. The committee decided to accept 155 papers.

ICSF 2021 program committee

Rovshan Abbasov, Kazar University, Azerbaijan

Leon Andretti Abdillah, Universitas Bina Darma, Indonesia

Khairulla Aben, KAZ Minerals, Kazakhstan

George Abuselidze, Batumi Shota Rustaveli State University, Georgia

Rajendran Sobha Ajin, Kerala State Disaster Management Authority, India

Tetiana Alokhina, SSI MARIGEOECOCENTER NAS UKRAINE, Ukraine

Abhineet Anand, Chitkara University, India

Dimitar Anastasov, University of Mining and Geology "St. Ivan Rilski", Bulgaria

Aleksej Aniskin, University North, Croatia

Yevheniia Anpilova, Institute of Telecommunications and Global Information Space of the NAS of Ukraine, Ukraine

Dmytro Antoniuk, Zhytomyr Polytechnic State University, Ukraine

Volodymyr Artemchuk, G. E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine, Ukraine

Vitalina Babenko, V. N. Karazin Kharkiv National University, Ukraine

Mila Baranovska, Kryvyi Rih National University, Ukraine

Alma Bekbotayeva, Satbaev University, Kazakhstan

Abdelmajid Berdai, Hassan II University of Casablanca, Morocco

Anatoliy Berezovsky, Kryvyi Rih National University, Ukraine

Valery Bliznyuk, Clemson University, United States

Serhii Boiko, Kryvyi Rih National University, Ukraine

Olga Bondarenko, Kryvyi Rih State Pedagogical University, Ukraine

Orkhontuul Borya, Mongolian University of Science and Technology, Mongolia

Liudmyla Burman, Kryvyi Rih State Pedagogical University, Ukraine

Altantuya Byambasuren, Mongolian University of Science and Technology, Mongolia

João Paulo de Castro Gomes, University of Beira Interior, Portugal

Yelizaveta Chernysh, Sumy State University, Ukraine

Serhii Chukharev, National University of Water and Environmental Engineering, Ukraine

Giuseppe T. Cirella, University of Gdansk, Poland

Hanna Danylchuk, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine

Kremena Dedelyanova, Scientific and technical union of mining, geology and metallurgy in Bulgaria, Bulgaria

Maryna Deineha, National University of Life and Environmental Sciences of Ukraine, Ukraine

Yuriy Denisov, Kryvyi Rih National University, Ukraine

Tetiana Derkach, Kyiv National University of Technologies and Design, Ukraine

Mamadou Alouma Diallo, Carmels Research Institute, Senegal

Mohamed Tafsir Diallo, Gamal Abdel Nasser University of Conakry, Republic of Guinea

Viktoriia Dmytrenko, National University "Yuri Kondratyuk Poltava Polytechnic", Ukraine

Alina Dychko, National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute", Ukraine

Mykhailo Filatiev, Volodymyr Dahl East Ukrainian National University, Ukraine

Hans-Bertram Fischer, Bauhaus-Universität Weimar, Germany

Branko Gluscevic, University of Belgrade, Serbia

Rajeshwar Goodary, Université des Mascareignes, Mauritius

Vita Hamaniuk, Kryvyi Rih State Pedagogical University, Ukraine

Ekadewi Anggraini Handoyo, Petra Christian University, Indonesia

Serhii Honchar, G. E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine, Ukraine

Teodora Hristova, University of mining and geology "St. Ivan Rilski", Bulgaria

Pavlo Hryhoruk, Khmelnytskyi National University, Ukraine

Andrii Iatsyshyn, Institute of Environmental Geochemistry of the NAS of Ukraine, Ukraine

Anna Iatsyshyn, Institute of Environmental Geochemistry of the NAS of Ukraine, Ukraine

Iryna Kameneva, G. E. Pukhov Institute for Modelling in Energy Engineering of NAS of Ukraine, Ukraine

Kamal Khandakji, Tafila Technical University, Jordan

Mykola Kharytonov, Dnipro State Agrarian and Economic University, Ukraine

Oleh Khomenko, Dnipro University of Technology, Ukraine

Inesa Khvostina, Ivano-Frankivsk National Technical University of Oil and Gas, Ukraine

Liubov Kibalnyk, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine

Arnold Kiv, Ben-Gurion University of the Negev, Israel

Serhii Klimov, National University of Water and Environmental Engineering, Ukraine

Vitaliy Kobets, Kherson State University, Ukraine

Oleksandr Kolgatin, Simon Kuznets Kharkiv National University of Economics, Ukraine

Larisa Kolyvanova, Samara State University of Social Sciences and Education, Russia

Elena Komarova, Immanuel Kant Baltic Federal University, Russia

Valerii Korniyenko, National University of Water and Environmental Engineering, Ukraine

Valeriia Kovach, National Aviation University, Ukraine

Valentyna Kovalenko, State Institution “The Institute of Environmental Geochemistry of National Academy of Sciences of Ukraine”, Ukraine

Oksana Kovaljova, Francisk Skorina Gomel State University, Republic of Belarus

Ihor Kozakevych, Kryvyi Rih National University, Ukraine

Pavel Krivenko, Kyiv National University of Building and Architecture, Ukraine

Pankaj Kumar, G. B. Pant University of Agriculture and Technology Pantnagar, India

Nadezhda Kunicina, Riga Technical University, Latvia

Andrey Kupin, Kryvyi Rih National University, Ukraine

Olena Kuzminska, National University of Life and Environmental Sciences of Ukraine, Ukraine

Valeriy Kuznetsov, Railway Research Institute (IK), Poland

Khavalbolot Kyelgyenbai, Mongolian University of Science and Technology, Mongolia

Yurii Kyrylenko, State Scientific and Technical Center for Nuclear and Radiation Safety, Ukraine

Evgeniy Lavrov, Sumy State University, Ukraine

Maria Lazăr, University of Petrosani, Romania

Tetiana Lazarieva, Ukrainian Engineering Pedagogics Academy, Ukraine

Cristina Leonelli, University of Modena and Reggio Emilia, Italy

Yevhen Liulchenko, Kryvyi Rih National University, Ukraine

Nadiia Lobanchykova, Zhytomyr Polytechnic State University, Ukraine

Oleksandr Maevsky, Zhytomyr National Agroecological University, Ukraine

Nataliia Maksyshko, Zaporizhzhia National University, Ukraine

Zinovii Malanchuk, National University of Water and Environmental Engineering, Ukraine

A. Muthu Manokar, B. S. Abdur Rahman Crescent Institute of Science & Technology, India

Volodymyr Manyuk, Oles Honchar Dnipro National University, Ukraine

Anatolii Matsui, Central Ukrainian National Technical University, Ukraine

Ewa Matuska, Pomeranian University in Słupsk, Poland

Andriy Matviychuk, Kyiv National Economic University named after Vadym Hetman, Ukraine

Bård Borch Michalsen, UiT The Arctic University of Norway, Norway

Norbert Molitor, PLEJADES GmbH - Independent Experts, Germany

Roland Iosif Moraru, University of Petrosani, Romania

Andrii Mozgovuy, Kharkiv National University of Civil Engineering and Architecture, Ukraine

Oleksii Mykhailenko, Kryvyi Rih National University, Ukraine

Mykyta Myrontsov, Institute of Telecommunications and Global Information Space of the NAS of Ukraine, Ukraine

Ranesh Kumar Naha, University of Tasmania, Australia

Pavlo Nechypurenko, Kryvyi Rih State Pedagogical University, Ukraine

Kulzhamal Nogaeva, Kyrgyz State University of Geology, Mountain Affairs and Development of Natural Resources named after academician Usengazy Asanaliev, Kyrgyzstan

Kassym Yelemessov, Satbaev University, Kazakhstan

Juho Yliniemi, University of Oulu, Finland

Nataliia Zachosova, The Bohdan Khmelnytsky National University of Cherkasy, Ukraine

Stefan Zaichenko, National Technical University of Ukraine "Igor Sikorsky Kyiv Polytechnic Institute", Ukraine

Artur Zaporozhets, Institute of Engineering Thermophysics of NAS of Ukraine, Ukraine

Iryna Zinovieva, Kyiv National Economic University named after Vadym Hetman, Ukraine

Local Organization Committee: Serhii Chukharev, Serhiy Sakhno, Andrii Striuk, Volodymyr Morkun, Dmytro Brovko.

General Chair: Mykola Stupnik.

Conclusion

The vision of the ICSF 2021 is to create a leading interdisciplinary platform for researchers, practitioners and educators, to present and discuss the most recent innovations, trends, and concerns as well as practical challenges encountered and solutions adopted in the fields of sustainability.

The conference is a successfully performing forum for transferring and discussing research results among the academics, students, teachers, government, private sector, or industries. Participants and presenters from Azerbaijan, Belarus, Brazil, Bulgaria, Canada, China, Croatia, Czechia, Finland, France, Georgia, Germany, Hungary, India, Indonesia, Iran, Israel, Jordan, Kazakhstan, Kuwait, Kyrgyzstan, Latvia, Libya, Lithuania, Mauritius, Mongolia, Montenegro, Morocco, Netherlands, Nigeria, Norway, Poland, Romania, Russia, Saudi Arabia, Serbia, Slovakia, Svalbard and Jan Mayen, Tajikistan, Turkey, Ukraine, United Kingdom, United States, and Viet Nam have a conference experience to share their significant contribution in the research of the environmental, technological, social and economic issues of sustainable future.

We are thankful to all the authors who submitted papers and the delegates for their participation and their interest in ICSF as a platform to share their ideas and innovation [156]. Also, we are also thankful to all the program committee members for providing continuous guidance and efforts taken by peer reviewers contributed to improve the quality of papers provided constructive critical comments, improvements and corrections to the authors are gratefully appreciated for their contribution to the success of the conference. Moreover, we would like to thank the developers and other professional staff of Not So Easy Science Education platform (https://notso.easyscience.education), who made it possible for us to use the resources of this excellent and comprehensive conference management system, from the call of papers and inviting reviewers, to handling paper submissions, communicating with the authors etc.

We are looking forward to excellent presentations and fruitful discussions, which will broaden our professional horizons. We hope all participants enjoy this conference and meet again in more friendly, hilarious, and happiness of further ICSF 2022.

Abstract. The complex researches of schemes of extraction and storage of hydrocarbons and geothermal energy are executed in the work. In particular, according to the location, logistics and nature of the processes of generation, transportation, evacuation, injection and local utilization of hydrocarbon and geothermal energy sources, the scheme is divided into subspecies of consumer regional order of electricity, hydrocarbon and chemical energy and hydrogen. It is shown that the tasks of extraction of natural or synthesized hydrocarbons, geothermal energy and subsequent transformation into the required form of commodity resource can be unified with the organization of circuit-combined technologies. At the same time, the developed technological scheme implements the concept of storage of the required amount of energy resources on the one hand and regulation of production capacity for consumption – on the other. The reduction of current energy costs for the implementation and operation of systems with updated functional systems for a total of 20–45%. It is proved that the selection of the scheme of unified extraction and storage energy systems in accordance with the projected order of energy and energy resources, due to the capabilities of productive reservoirs, leads to minimization of capital costs for their construction on a modular basis. Research of application of combined technologies of dual extraction-storage of heat carriers-hydrocarbons is a perspective direction of researches.

1 Introduction

There is no doubt that there are geothermal resources available in the existing oil and gas sediments of Ukraine and other countries [1–2]. Recently, oil and gas companies, such as Chevron and Shell, have been working to production and exploit geothermal resources using a variety of advanced technologies. In this case, the conceptual and circuit approaches are determined by the choice of coolants and circuit organization of production [2]. The article analyzes the improvement and attempts to unify circuitry to improve the overall logistics of hydrocarbon and geothermal energy resources.

2 Review of the literature

Today, three main types of technological implementation of well geothermal systems (WGTS) and well geoenergy systems (WGS) are used [1–3]:

1. Power plants with a binary (double-loop scheme) cycle, as a working fluid for which not thermal water or steam is used, but another liquid with a low boiling point.

2. Instantaneous or flash steam evaporators, which receive hot water under high pressure and transport it to surface tanks with reduced pressure, where the water is converted into steam to power the turbine.

3) Dry steam power plants that receive steam to rotate turbines directly from a geothermal reservuare.

For oil and gas fields, which after depletion were converted into underground gas storage facilities (UGS), usually implement the first type of technological implementation based on binary schemes (a second circuit with low boiling point of the coolant is added) and thermodynamic Rankine cycle or Kalina cycle [2].

The geothermal system of the first type on the basis of objects of development of oil and gas fields can be realized according to the scheme of open combined WGTS with binary or simpler structure. The diagram in Figure 1 shows the real circuitry of operating systems with heat generation in Germany, Austria, Canada and others. countries where the temperature of geothermal sources reaches 100º C [3–4].

Figure 1 shows that the WGS circuit integrates the units of removal and chemical synthesis of various substances required as inhibitors or catalysts of processes, and additional heating of the working coolant before utilization

[*] Corresponding author: ukcdb@i.ua

in the consumption units (turbines and heat exchangers) is advantageously realized in parallel hydrocarbon coolant production. The authors of [2–3] did not show the technology unit (technology block) of accumulation and heating in the initial circuit of the formation geothermal fluid (in particular, to simplify understanding), but usually such a unit is used. Therefore, in Fig.1 this block-unit is shown.

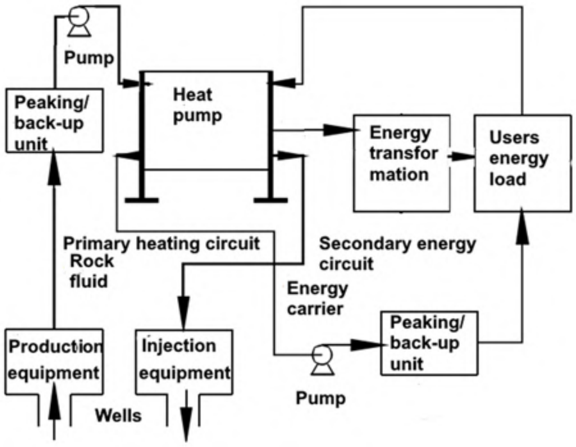

Fig. 1. System of direct use of extracted geothermal energy and formation water / fluid with heating in the peak boiler-accumulator and extraction of useful chemicals (fuel, metals, salt, etc.) near the wellhead.

If it need to generate and local utilize not only heat but also electricity, use combined WGS circuits (Fig. 2), in which the system shown above in Fig. 1 is one of the basic units (is a WGS subsystem). The essence is the multi-stage utilization of extracted geothermal energy in the following stages (as the circuit build-up development, circuit complication) [4]:

– utilization without heat pumps, absorption systems and turbines;

– utilization without turbines and absorption systems;

– utilization without absorption systems;

– complete utilization (using heat pumps, turbines, absorption systems, cogeneration heat exchangers).

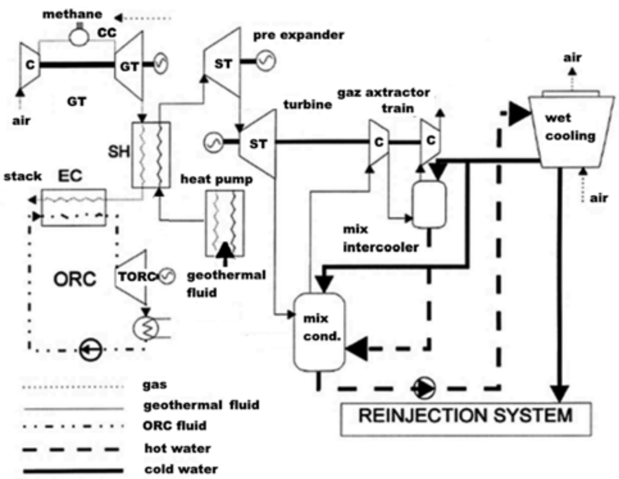

Fig. 2. Technological scheme of GeoPP of open combined type with heat pump and heat utilization of turbines operating on geothermal energy and extracted hydrocarbons (in terms of electricity generation and partial heat utilization) [4].

The scheme shown in Fig. 2 is typical for implemented projects in the USA, Italy, Russia, Iceland and others. countries where the temperature of the local geothermal source significantly exceeds 100 ºC [1–4]. But this scheme actually reveals a typical solution for the generation of power stations of the well-known company ENEL (stage of utilization at the level – without absorption systems), it is only half of the overall scheme in terms of utilization of thermal energy [4]. The turbine circuit often uses prepared water directly from the production well, which is not possible at downhole source temperatures below 100 °C., especially without the use of a methane fuel turbine or boiler. But the scheme is suitable for working with all the above three types of technological implementation, provided the organization of the binary principle. That is, it can be considered universal after some circuit upgrating, in particular the introduction of several circuits with a cycle of Rankine (or Kalina) and cogeneration heat exchangers.

The second half of the general functional scheme is well understood from Figure 3, which is explained in detail in [5] on the cascade principle of thermal energy utilization by a local consumers. Thus, the scheme in Fig. 3 complements the scheme of geothermal power plant (GeoPP) in Fig. 2 and gives a complete stheme picture of the double generation and utilization of electricity and heat in the case when actively extracting both local hydrocarbons and available local geothermal energy. Thermal energy in large quantities can be used as an auxiliary energy of technological processes in the extraction and transportation of natural gas and oil [6–7]. Unquestionably produced electricity can be used for the synthesis of useful fuels (hydrogen, methanol, gasoline) and synthesized methane on site. About the latter problems and the necessary circuit solutions will be discussed below.

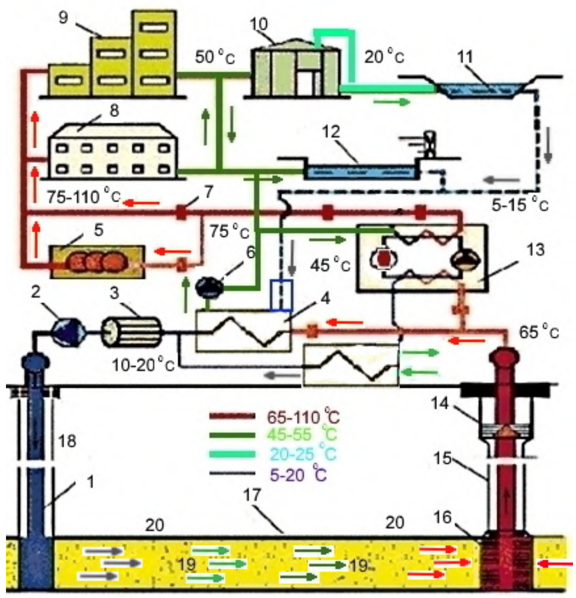

Fig. 3. Technological scheme of WGS of open combined type with heat pump and heat utilization of turbines operating on geothermal energy and extracted hydrocarbons (supplement of the scheme in Fig. 2 in part of full cascade local heat utilization of geothermal sources and emissions of GeoPP) [5].

In Figure 2, which generally repeats the circuit solutions from [4], one heat pump is added, which illustrates the possibility of implementing the operation of turbines on a liquid with a reduced boiling point. The signatures of the individual units have the following abbreviations: C – compressor, CC – hydrocarbon combustion chamber, ST – steam turbine, GT – gas turbine, TORC – turbine in the loop with the Rankine cycle; Cond. – condensing device; SH – superheater; EC – cogeneration heat exchanger.

In Fig. 3 part of the technology of Fig. 2 is shown conditionally in blocks 2–7. Consumers of heat of communaly and industrial-technological type 8–12 receive power both from the heat pump 13 and direct geothermal heat exchangers GeoPP 4, and from boiler rooms and turbines of GeoPP block 5. For mixing (combination) use switching and regulation by valves 7, pumps 2, 6, 14. The diagram also shows the line of the injection well – 1, hydrocarbon separator – 3, production and injection wells – 15 and 18, bottomhole – 16, reservoir – 19 with reservoir fluid – 17, impermeable reservoir roof – 20. The disadvantage of the scheme, which is fully disclosed in Fig. 1 and Fig.2 is the absence of heat accumulators and hydrocarbons in the primary and secondary circuits in the circuit implementation of the binary principle of extraction (the first type of technological implementation of WGS). Figure 1 shows the heat tank, but there are no hydrocarbon acummulation.

To improve the understanding of the consumer part of the modern technological scheme of WGS, we present the result of a simplified circuit design solution [8] in Fig. 4, which details the principle of combined WGS with GeoPP binary type. The diagram shows abbreviated: C – compressor, P – pump, T – turbine, CC – hydrocarbon combustion chamber, G – generator. The work [8] did not focus on the types of local energy consumption, so in Fig. 4 added units of electricity consumption (green) and energy of extracted hydrocarbons (yellow).

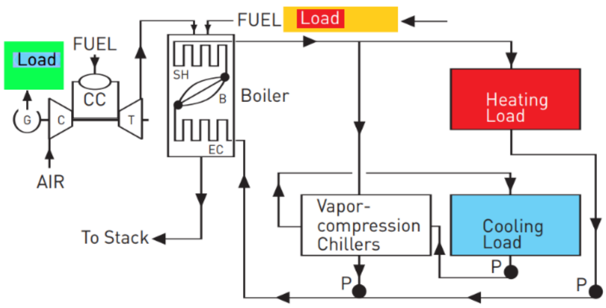

Fig. 4. Simplified technological scheme of GeoPP with shown consumers of energy resources of 4 types: consumers of cold (blue color), heat (red), electricity (green), hydrocarbons (yellow).

It is clear that consumers of cold and heat should be located near the WGS because the accumulation of a large number of such resources is technically difficult and economically unprofitable. It is not economically feasible to accumulate electric energy with the help of batteries at the current level of development of equipment and technologies in large quantities. But to accumulate hydrocarbon-type fuel and hydrogen is possible in large enough volumes and promising with the involvement of underground storage and gas generators. But in the known works the variant of using a combination of GeoPP and UGS from the above point of view is not considered [1–5].

The strategy for the development of geothermal energy in Ukraine states: "Substantiation of the possibility and feasibility of creating systems and installations for the combined use of geothermal heat (from 70 °C) and fossil fuels, as well as construction of special power plants (GeoPP) on promising fields" [5]. The strategy provides for the expansion of the use of such systems, which can be understood as the implementation of a functional chain in the form of: extraction, accumulation, storage, transformation, preparation for marketable quality and consumption or shipment. Earlier in [9–10] the possibility of utilizing electricity produced from subsoil heat for the synthesis of methane and hydrogen for long-term storage of fuel in special storage facilities was considered. In particular, [10] covers P2G (Power-to-gas) technology. In another paper [11], it is recommended to use the heat pump effect more widely for branched and networked pipelines.

In fact, if you install GeoPP and underground storage together, with the most unified scheme for work with extraction and storage of heat and hydrocarbons, and part of the electric generation used for the synthesis of methane and hydrogen (etc. required in current processes), it is possible to regulate basic energy and energy transformation processes to equalize the uneven consumption of both heat / cold and hydrocarbons (in terms of generation and storage capacity), to increase and develope circuit-modular thermo-power grids, which was not previously considered in detailing forms.

3 Research objective and tasks

The aim of the study is to develop a unified technological scheme for extraction and storage of heat and hydrocarbons, which would minimize current energy losses and capital costs for modular organization of production with full-fledged filling at the place of demand for energy resources: extraction, accumulation, storage, transformation, preparation and utilization or shipment.

To achieve this goal the following tasks are set:

1) to compare modern technological schemes of GeoPP and UGS from the point of view of possibility of minimization of quantity of technological units at simultaneous production of hydrocarbons and geothermal energy;

2) to select and add technological units to the scheme that will ensure the functioning of storage facilities and fields-regulators;

3) to estimate the forecast reduction of current energy consumption for operation of combined systems according to the developed scheme of functionally unified combined systems of hydrocarbon-geothermal resources extraction in comparison with similar volumes of individual (non-combined) extraction and consumption of hydrocarbon and geothermal resources.

4 Basic stages and research results

The object of the study is WGS on the basis of an oil and gas field equipped with underground storage facilities for depleted deposits. The comparison of such an improved hybridized system is made with the traditional WGS without underground storage, which schematically includes a binary GeoPP and uses only formation water as a heat carrier.

4.1.1 First stage of research

The developed unified technological scheme of modern WGS of open combined type with binary GeoPP is shown in Fig. 5. The first type of circuit-technological implementation is taken as a basis, with two series-connected turbines and one ORC circuit. For simplicity, the diagram does not show multistage turbines (shown in more detail in Fig. 2), multistage heat pumps (which can operate at the indicated positions of consumer heat exchangers, as shown in Fig. 3), heat recovery units with absorbent heat pump, but clearly three heat exchangers of municipal or technological heat consumers (marked on the diagram – heat exchangers of heat consumers).

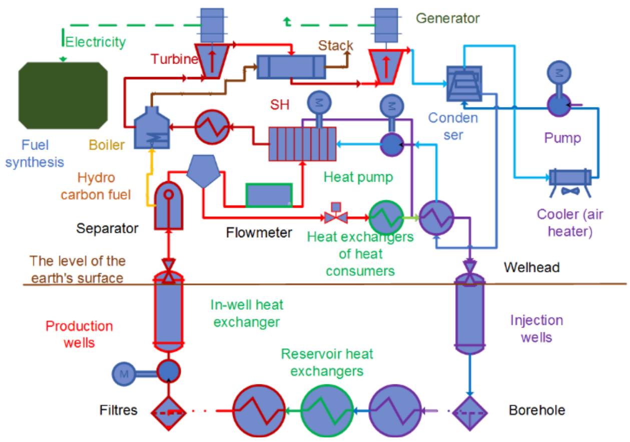

Fig. 5. Unified universal technological scheme of modern WGS of open combined type with binary GeoPP.

The diagram in Fig. 5 does not show (schematically not allocated for simplification) units of heat and electricity storage, as well as chillers – devices for cooling liquid coolant and supplying it by a pumping station through a system of pipelines to end users. In modern UGS and WGS systems, chillers are beginning to be widely used to regulate the main energy production and energy transformation processes and simultaneously equalize the uneven consumption of extracted/stored (taking into account the rate of extraction) heat and hydrocarbons.

Note that Fig. 5 is also, at first glance, not universal in the need to organize the thermodynamic cycle of Kalina in one of the circuits instead of the Rankine cycle. But according to [1], the Kalina cycle begins to be realized when only one gas-liquid separator and cogeneration heat exchanger are added inside the circuit. That is, the developed scheme (Fig. 5) is still unified but with a reduced set of technological components and unit, which in turn are implemented in terms of circuitry according to technical solutions [1, 4, 7, 8, 11, 12].

Scheme at Fig. 5 can be modified to a functional hybrid for simultaneous production and storage of natural gas in the gas cap of the reservoir of a partially depleted oil and gas field and extraction of geothermal energy with conversion into synthesized gas (methane or hydrogen) through the groundwater line (Fig. 6).

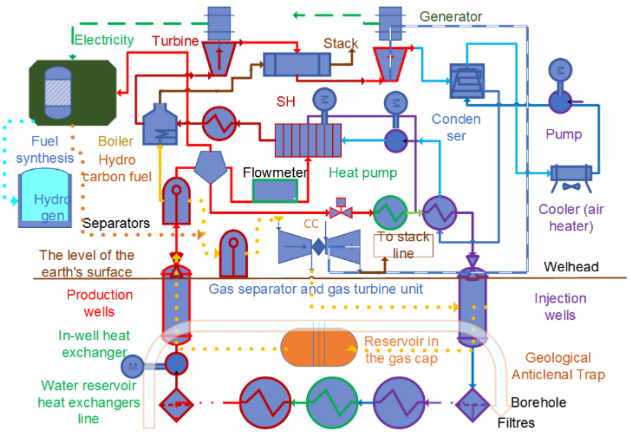

Fig. 6. Unified technological scheme of hybrid WGS of open combined type with binary GeoPP and UGS of water-pressure / gas mode of cyclic operation.

4.1.2 Second stage of research

The developed combined technological scheme of hybrid WGS can be realized under the condition of the available water pressure mode of development of oil and gas field or at artificial flooding and maintenance of pressure of a gas cap of an oil and gas deposit at technologically necessary level.

It is envisaged that wells, separators, as well as a line with a pump for the preparation and injection of separated formation water are used in combination. Electric generators and turbines, as well as other WGS units, also work to synthesize additional volumes of methane and fuel, which may be in high demand during the UGS filling season and peak consumption periods. Thus, for the use of a unified scheme for simultaneous storage of natural gas (methane), extraction of oil residues from the reservoir (flooding technology) and gas condensate (cycling process) added only two technological units: finishing preparation by gas separator and gas compressor with gas turbine drive (gas turbine unit – GTU).

The aircooling device (ACD) present in the classic UGS schemes does not make sense (absent) in the developed scheme because all excess heat is removed by the scheme for electricity generation and synthesis of artificial gases. In addition, when implementing the circuit-technological solution shown in Fig. 6, the geothermal field with UGS acquires a new economic meaning – it can add volumes of synthesized methane (other fuels by gas–to–liquids (GTL) and mini-refineries) or hydrogen. The scheme works smoothly during the gas injection season for storage or in the mode of regulating consumer demand for energy types at the place of their using.

At the end of the second stage of the study, one feature of the case was found – to obtain synthetic oil or LNG, you need to change the average carbon / hydrogen ratio in the hydrocarbon feedstock (mini–refinery by hydrocarbon-hydrogen conversion), and the necessary hydrogen is easiest to take from reservoir water. In this case, the combination of "water" geothermal energy and "hydrocarbon" energy production / storage according to the hybrid scheme (Fig. 6) becomes even more profitable on a regional scale. To do this, the scheme (Fig. 6) shows the supply of prepared water to the methane (and others. fuel) synthesis unit .

According to the obtained circuit technical results, for the developed hybrid scheme the number of modules of the whole WGS decreased by four units: 1) separation module for mechanical impurities, water and oil; 2) GTU; 3) gas heating unit during reduction in the sampling/production mode: 4) ACD. To implement the storage of gas / energy resources and control the production of hydrocarbons / energy resources, we add only one gas separator. Minimization of modular units in capital construction and a corresponding reduction in the cost of the entire technical complex of WGS and increase its manufacturability are obvious.

4.1.3 Third stage of research

When using cogeneration units that produce both electricity and heat, the efficiency can reach 60–80% (achievable efficiency at both ends “power–power”). This became possible with the implementation of reversible solid oxide fuel cells under pressure [13]. When converting in the scheme of Fig. 6 electricity–gas–heat / electricity (with a pressure of up to 50–80 atm. Under the standard main natural gas pipeline) work [14–17] more pragmatically announce the average efficiency of 43–68%. In the diagram in Fig. 6, one power energy unit is added – a turbine for pumping gas for its storage and maintaining the required level of pressure in the reservoir. The efficiency of gas–tube compressors averages 23–28% [19]. But important for the future of combined hydrocarbon–geothermal energy system may be the fact that turbines in GeoPP schemes are enough, they are also multi–stage. That is, in the technological scheme of the hybrid type the compressor is added only schematically, and mechanically it will rotate on the existing shafts. Let's analyze this circuit solution in more detail. The diagram in Fig. 2 separately shows a gas turbine unit running on methane (top left in the diagram), which is used to increase the efficiency of GeoPP in normal mode. Undoubtedly, in general, the WGS will have additional losses on the compression of hydrocarbons for injection to well (2–3% – fuel gas) of the GTU [19], but this is incomparably less than acquired. That is, for traditional incompatible operation in the GeoPP + UGS pair, the turbines will operate with double energy loss according to the efficiency, and during the operation of the unified developed scheme, the efficiency losses in the WGS will be reduced by an average of 23%. This ratio of energy losses is performed as accurately as possible in the conditions of the Proletarsky UGS (Dnipropetrovsk region, Ukraine), where the potential power of geothermal energy is close to the power in the hybrid circuitry involved GTU. Therefore, the current energy consumption of combined systems of extraction / storage of hydrocarbon–geothermal resources according to the developed hybrid scheme in comparison with similar volumes of individual (non–combined) extraction / storage of hydrocarbon and geothermal resources will be reduced by 20–45%. Since the ranges of energy consumption by technological units individually have significant differences according to data from different sources, it is not possible to estimate the energy positive more accurately.

5 Conclusions

1. The developed unified scheme of combination of GeoPP and UGS on the basis of oil and gas partially-depleted deposit with residual water characteristics is characterized by the minimum number of additional technological units to GeoPP for realization of simultaneous extraction and storage of hydrocarbons and evacuation / transformation of geothermal energy.
2. For maximum efficiency of hybrid WGS of open combined type with binary GeoPP and UGS of water-pressure / gas mode of cyclic operation in the circuit solution it is important to use the synthesis gas unit and the compressor of gas injection into the gas cap of the oil and gas development object. Production of synthetic gasoline and LPG, and not only compressed natural gas (CNG) for local internal combustion engines is realized by schemes of mini–refineries and GTL–technology.
3. The forecast of reduction of current energy costs of combined systems of extraction / storage of hydrocarbon-geothermal resources in comparison with similar volumes of individual (not combined) extraction / storage of hydrocarbon and geothermal resources showed 20–45%.

The authors thank the management of the Gas Transport Institute of Ukraine and Ukrainian Institute of Natural Gas for its assistance in conducting research.

Deposits of the hydrocarbon raw materials of the Republic of Kazakhstan, where it is possible to introduce a microbiological method for stimulating the formation

Olga Kuderinova[1,*], *Makhambet* Shmanov[1], and *Mykhailo* Filatiev[2]

[1]Karaganda Technical University, Development of Mineral Deposits Department, 56 N. Nazarbayev Str., 100027, Karaganda, Republic of Kazakhstan
[2]Volodymyr Dahl East Ukrainian National University, 59a Central Ave., Severodonetsk, 93406, Ukraine

Abstract. The article is devoted to the analysis and systematization of data on hydrocarbon deposits in the Republic of Kazakhstan, highlighting those aspects that will allow the use of this method. The microbiological method of exposure refers to the chemical methods of the tertiary stage of development of oil reservoirs. It has already proven its effectiveness in highly depleted, waterflooded formations with irregular, diffuse oil saturation. Its main advantages are its relative cheapness, it does not require additional equipment during injecting of the microorganisms into the reservoir, and for their nutrition, as a rule, food industry waste is used, and its implementation cannot cause harmful effects on the environment. Also, a fairly extensive database was compiled, according to which various classifications of the republic's deposits were created.

1 Introduction

The purpose of the study was to identify the parameters needed for the introduction of the method of microbiological influence on oil reservoirs, justification of the need for its use, as well as collection, analysis and systematization of data on all known this type deposits of the republic.

Nowadays, when the reserves-to-production ratio is declining in all countries, which are advanced in oil production, the introduction of methods of improving oil recovery is more urgent than ever before.

Well-known are thermal (steam, hot water, formation combustion are used), gas (carbon dioxide, air, natural gas, nitrogen, flue gases, etc. are injected directly into the formation), chemical (oil is displaced by using surfactants, polymers, alkalis, acids and other reagents), hydrodynamic (water is injected), physical (using wave and electromagnetic radiation, hydraulic fracturing, drilling horizontal wells) and, naturally, combined methods.

Due to extensive application experience, their disadvantages are also known: when pumping steam and hot water, chemical reagents of various types, gases, equipment quickly wears out; and the use of physical methods initially requires the installation of expensive additional equipment.

In addition, when igniting the formation and using chemicals, it is impossible to avoid harmful effects on the environment. In the first case, combustion is difficult to control and as a result, instead of liquefied heavy hydrocarbons, only a dry residue, consisting only of low fractions can be obtained, which will no longer be removed, plus gases that can be extremely hazardous to health will be released. And chemical solutions can permanently poison underground waters, which will entail the death of all flora on the surface.

2 About the method of the microbiological enhancement oil recovery (MEOR)

This method of exposure is of two types:

1. Method of the biostimulation – injecttion of nutrients for the development of populations of microorganisms already existed in the oil reservoir.
2. Method of the bioaugmentation – injecti on of both microorganisms, and nutrients.

These bacteria are aerobic and anaerobic, in the process of their development and life, they liquefy hydrocarbons, absorbing some of them and emitting gases.

Also, their colonies, growing, form biofilms, reducing the possibility of water crossflows, therefore this method is effective when applied in heavily flooded fields.

In comparison with the methods mentioned earlier, it is environmentally friendly, and this is one of the most important advantages today.

To implement it, there is no need to purchase additional equipment, you can simply use the existing one.

Bacterial nutrients can be food waste such as milk serum and molasses.

3 Data about the characteristics of deposits, where the microbiological method was implemented

In order to derive general characteristics for the use of the above-mentioned method, articles about deposits were studied, where it had already been tested.

These are the projects of San Andres, Queen Sand, Tupunyato Refugio, Huabey, Xinjian [1], Norne [2], Romashkinskoe [3], Pirallahi [4, 5], Lisbon, Novo-Elkhovskoe, Pervomayskoe, Ersubaikinskoe, Berezovskoe, Sterrap [6] , White Tiger [7], Bokor [8].

San Andres Project (U.S.A.): it was discovered in 1945, was produced by solution gas drive until the waterflood was started in 1967.

The Microbial EOR started in October 1994 oil in place was 239 bbls/ac-ft with an oil saturation of 41%. Current formation pressure is estimated at 1,000 psi. Rock properties are relatively inhospitable to microbes. The low 1.7 md average horizontal permeability would normally be indicative of pore throat sizes well below what microbes could enter. Reservoir temperature at 115°F is ideal for microbe growth. Average production per well is 14 barrels of oil per day at a 91% water cut.

After 19 months of microbe treating by 10% or 40 barrels per day are received.

Queen Sand Project (U.S.A.): it was discovered in 1984, this reservoir was quickly waterflooded due its very low solution gas content. Injection was begun in 1990 and oil production increased quickly from 200 to 2,500 barrels per day. This rate continued until late 1991 when a rapid decline began.

The Microbial EOR started in August 1992, oil in place was 758 bbls/ac-ft with an oil saturation of 56%. Rock properties are generally favorable for microbe colonization. Average permeability is 13 md with an upper limit of 300 md and provides adequate pore throat size for microbes to colonize. Additional permeability developed by fracture treatments with 60,000 gallons and 135,000 pounds of sand on initial completion provide excellent porous media for microbe colonization. Reservoir temperature at 110°F is ideal for microbe growth. Average production per well is 42 BOPD at 75% water cut.

After 24 months of treating by 43% or 300 barrels per day are received.

Tupungato-Refúgio Project (Argentina): it was discovered in 1930. The field was produced by a combination of solution gas drive, water drive and waterflood.

Microbial EOR was started on one well in June 1994 and on the other two wells in March 1995. At the start of the project oil in place was 625 bbls/ac-ft with an oil saturation of 47% and a gas saturation of 10%. The wells are on approximately 42 acre spacing. Rock and fluid properties are all favorable for microbe colonization.

After 14 months of treating by 29% or 60 BOPD are received.

Huabei Project (P. R. China): it contains seven wells located in the Huabei Petroleum Administration Bureau. The wells, in the later stage of being waterflooded, are scattered and not in the same reservoir. Therefore, while production data can be analyzed, reservoir performance cannot be determined for this grouping.

Microbial EOR started September 1994. The wells are rod pumped, with pumps set an average of 2,500 feet above the perforations. Reservoir and fluid parameters are all favorable for microbe growth.

Twelve months after the first treatment by 552% or 127 BOPD are received.

Xinjiang Project (P. R. China): it contains ten wells located in the Xinjiang Petroleum Administration Bureau. The wells, most in the later stage of being waterflooded, are scattered and not in the same reservoir. Therefore, while production data can be analyzed, reservoir performance cannot be determined for this grouping.

Microbial EOR started January 1995. The wells are rod pumped, with pumps set from 200 to as high as 6,000 feet above the perforations on one well. Reservoir and fluid parameters are all favorable for microbe growth.

Six months after the first treatment by 36% or 80 barrels per day are received.

Norne Project (Norway): was discovered in 1992, developing started in 1997. Oil density is 862 kg/m^3, Sulphur cintent is 0,21%, oil viscosity – 3 mPa·s.

The incremental oil recovery due to biofilm formation can be around 2 % OOIP.

In conclusion, an incremental oil recovery of almost 15 % OOIP can be achieved by the combined effect of surfactant, biofilm formation and the resulting microscopic fluid diversion. Each mechanism contributes to the overall effect, where the main contribution comes from production of surfactant.

Romashkinskoye Project (Russian Federation): production started in 1975, carbonate collector, depth 493–515 m, porosity – 9,8%; pressure – 6–7 MPa, temperature of stratum – 17–23 °C, oil density 903 kg/m^3, oil viscosity – 50–80 mPa·s, stratal water mineralization – 40–60 g/l.

The studying of the implementation of the Microbial EOR started in 1997. As the result 27% of residual oil can be recovered against 13% in the beginning.

Pirallahi Project (Republic of Azermaijan): the productiona started in 1902. Before Microbial implementation oil production in the 3-d quarter of 2009 comparing with the 1-st decreased on 30%, production rate was 0,39.

Microbial EOR started in August 2009. For the well number 931 production increased from 0,7 tons per day up to 1,8 tons per day.

Lisbon Project (U.S.A.): North Carolina state. It was the first implementation of the Microbial EOR in 1954, which also was successful.

Novo-Yelkhovskoye, Pervomayskoye, Yersubakiy-skoye, Berezovskoye Projects (Russian federation): they are operated by OJSC "TatNeft", water cut 90%, sandstone collectors.

After Microbial EOR implementation the produation increased on 59,8; 44,5; 9,3; 7,4 thousand tons.

Sterrap Project (U.S.A.): Kansas State, depth of occurrence – 1600 m, water cut – 95%.

After Microbial EOR implementation, the production increased on 50-55 thousand barrels.

White Tiger Project (Socialist republic of Vietnam): it is located in the shelf, it's flooded by sea water, salinity 35-37 g/l, reservoir temperature 120°C, pressure 4 MPa.

After Microbial EOR implementation, the oil displacement efficiency amounted to 57.4%. Using a combined physico-chemical and microbiological method increased oil displacement efficiency by 14.2%.

Bokor Project (Malaysia): high viscosity crude (4 to 10 cp) and low oil specific gravity of 20°API, low recovery factor in major reservoirs ranges from 19% to 25% of its original oil in place. Water depth of near 220 feet below msl; porosity – 15-32%; permeability – 50-4000 mD; oil gravity – 19-22°API in the shallower reservoirs (1500 – 3000 Ft. ss) to 37°API in the deep reservoirs (6300 Ft. ss).

After Microbial EOR implementation over 5 months period significant increase of the oil production rate and reduction of water cut were observed. The average oil production rate for the period increases by 270 b/d, which is equivalent to 47% oil incremental.

Summarizing the data of these articles, we can draw the following conclusions:

Table 1. Range of characteristics for the application of the microbiological method of impact on oil deposits.

Options	Range
Depth of occurrence, m	180 – 2500
Total thickness, m	3,88 – 18,2
Collector types	terrigenous, carbonate
Open porosity, %	7,9 – 24
Permeability, mcm^2	0,03 – 300
Temperature, °C	17 – 120
Pressure, MPa	0,344 – 7
Density, kg/m^3	830 – 914
Water type	calcium chloride
Mineralization of groundwater, g/l	8 – 235

Taking into account everything, mentioned before, it is obvious, that MEOR is applicable for most of the existing fields.

4 Low-profit deposits in Kazakhstan in accordance with the official data

Naturally, in order to offer this method, first you need to find potential customers, collect information about fields, where it is already required, to implement methods for improving the oil recovery.

Although it is known, that most of the republic's oil reservoirs have been in operation for a long time, and, as written in the many articles, they are at a last stage of operation. The search on state sites gave the following results: relating to the Resolution of the Government of the Republic of Kazakhstan No. 449 dated June 27, 2019, and also the estimates of the independent experts we receive the following table.

Table 2. List of low-profit fields.

Field	Location	Geological reserves, mln tons
1. Containing high viscosity oils		
Temir district, Aktobe region	Temir district, Aktobe region	Temir district, Aktobe region
Tupkaragan district, Mangistau region	Tupkaragan district, Mangistau region	Tupkaragan district, Mangistau region
Temir district, Aktobe region	Temir district, Aktobe region	Temir district, Aktobe region
Isatai district, Atyrau region	Isatai district, Atyrau region	Isatai district, Atyrau region
2. Low-income		
East Akshabulak	Syrdarya district, Kyzylorda region	n/d.
North Akshabulak	Syrdarya district, Kyzylorda region	n/d.
Yeszhan	Syrdarya district, Kyzylorda region	n/d.
Zhylankabak	Zhylyoi district, Atyrau region	n/d.
Zholdybay	Makat district, Atyrau region	1,5 recov. - 297 thousand tons
Kalzhan	Syrdarya district, Kyzylorda region	n/d.
South Kamyskol	Zhylyoi district, Atyrau region	n/d.
Kokzhide post-salt	Temir district, Aktobe region	50,9 on the 1st Jan. 2008 res.rec.res. – 12,5
Krykmyltyk	Zhylyoi district, Atyrau region	n/d.
Tobearal	Kurmangazy district, Atyrau region	n/d.
3. Waterflooded		
Uzen	Karakiya district, Mangistau region	1100
Kumkol	Ulytau district, Karaganda region	90 280 - geol., 130 – recov., 15 bln m^3 gas
East Kumkol	Ulytau district, Karaganda region	n/d.
Arman	Mangistau district, Mangystau region	30
Karaarna	Zhylyoi district, Atyrau region	27,6 25,4 - recov.
East Kokarna	Zhylyoi district, Atyrau region	6,8 4 – recov.
Matin	Makat district, Atyrau region	30
North Pridorozhnoe	Beineu district, Mangystau region	30
4. Irreplaceable (worked out)		
Zhaksymay	Temir district, Aktobe region	25
Shubarkuduk	Temir district, Aktobe region	n/d.

It turns out there are only 24 fields, at the same time there is an article by NOC Kazakhoil, which states that out of 45 fields they operate, at least two, Dossor and

Makat, are among the oldest in terms of exploitation time [9].

In this paragraph, the abbreviation "n/d." appears for the first time, meaning "no data", i.e., unfortunately, this information is closed for public use. It will often meet further.

5 Classification of the hydrocarbon deposits of the Republic of Kazakhstan

Further searches for the necessary information led to even more interesting discoveries – the number of deposits, published on the Wikipedia site is 216 deposits, and those found by mentions in media publications for five months – 269.

The database in Excel format was compiled, which includes information on 289 fields, of which 269 are Kazakhstani and 20 foreign, where the microbiological method of stimulating the formation has already been introduced. As a result, we've got the following table:

Table 3. Comparison results.

Deposit volume	Known number of deposits (site Wiki2.org)	Number of deposits mentioned on the Internet
Supergiant (more than 5 bln tons)	1	2
Giant (more than 1 bln tons)	3	3
Large (from 100 mln tons)	11	29
Medium (from 10 mln tons)	26	42
Others	more than 1000	40
No data	-	153

The difference is quite tangible. Especially considering that the second supergiant, the Kurmangazy field, discovered in Soviet times with reserves of 6,200 million tons of raw materials and then called Kulalinskaya, for some reason is only mentioned in Russian sources, although its estimated reserves are only slightly inferior to Kashagan, which is the largest in the world offshore field with reserves of 6,400 million tons.

It's needed to pay attention to the fact that there are no data on the geological reserves of 153 fields out of 269, i.e. more than half of the known deposits are in operation without disclosing their characteristics.

Another classification was drawn up in accordance with a slightly different division by geological reserves [10].

Table 4. Second classification.

Options	Q-ty	Deposits' names
Unique deposits (more than 300 mln tons of oil &/ or more than 300 bln m^3 of gas)	13	Bekturly, Darkhan, Kalamkas, Karachaganak, Kashagan, Khvalynskoye, Kurmangazy, Nursultan, Rakushechnoye-sea, Tengiz, Uzen, Zhanazhol, Zhetybai

Over the period of independence of the Republic of Kazakhstan, i.e. since 1991, only 42 fields have been discovered: Kashagan, Aktoty, Kalamkas-sea, Kairan, Aiyrtau, Asanketen, Auezov, Ashisay, Borkyldakty, Gremyachinskoye Yuzhnoye, Doschan, Vostochny Zhagabulak, Zhambyl, Zhanatan, Zhemchuzhina, Karabulakulak, Zapadny Karaturun North-East, Kemerkol, Kokzhide post-salt, Kyzylzhar East, Laktybay, Narmundanak South, Novobogatinskoe West, Nuraly North, Border, Pridorozhnoe (Mangistau region), Rakushechnoye, Rakushechnoye-sea, Severnaya, Rozhkovskoe, Rostoshinskoye, Western Tuzkol, Tulpar, Uytas, Isataisskoye, Khazar, Khvalynskoye, Centralnoye, Chinarevskoye.

During its time in the USSR – 158 deposits.

Could not find data on the year of discovery of 69 deposits.

In addition, the data on licensed field operators are often hidden, for example, the owners of 85 fields are unknown.

For a more complete picture, the phase states of the collectors have been added to the resulting database, since we are primarily interested in oil deposits.

Table 6. Classification of the deposits by phase state.

TOTAL	269

6 Additional information

Already after writing the chapter of the dissertation, and this article, an additional source of information was found. It is published in Moscow in 2010 the report “Current state and development trends of the oil and gas complex of Turkmenistan and other Central Asian countries of the Near Abroad” [11], which is known only in the circles of oil specialists, but also not in the public domain.

It says, that there are 304 hydrocarbon deposits in Kazakhstan, i.e. even more than was found by me, and this, of course, also expanded the already existing picture of the data.

In it deposits are listed and described by basins.

Table 7. Classification of the deposits by basins.

Basin name	Fields	Q-ty
Volgo-Uralsky	1 oil field, 1 oilgascondensate field	2
Zaisansky	1 gas field	1
Caspian	11 – gas fields, 6 – gascondensate fields, 98 – oil fields, 49 – oilgas fields, 15 – oilgascondensate fields	179
North Caucasian-Mangyshlak	10 – gas fields, 5 – gascondensate fields, 10 – oil fields, 19 – oilgas fields, 12 – oilgascondensate fields	56
North Ustyurt	12 – gas fields,, 4 – gascondensate fields, 3 – oil fields, 13 – oilgas fields	32
Turgay	2 – gas fields, 2 – gascondensate fields, 7 – oil fields, 11 – oilgas fields, 1 – gascondensate fields	23
Chu-Sarysu	9 – gas fields, 2 – gascondensate fields	11

7 Conclusions

After carrying out of this work, the following conclusions are suggested:

1. Based on the data in the Table 1, it can be concluded that the microbiological impact method is applicable to the most hydrocarbon deposits of the republic, namely, referring to the Table 6, at least 103, if not 172.

2. Table 5 shows that Atyrau and Mangistau regions of Kazakhstan are leaders in terms of the number of deposits and the volume of hydrocarbons contained in them, but at the same time, it can also possible to see that 8 other Kazakhstan regions out of all 14 also have their own hydrocarbon raw materials. For example, we, the residents of the Karaganda region, did not know that we also have deposits of this type. Moreover, one of them, Kumkol, with initial reserves of 280 million tons of oil and 15 billion cubic meters of gas, in accordance with prepared classification belongs to the large one.

3. The oil and gas industry of our republic is one of the most closed to the public. But the disclosure and publication of these data, perhaps, will help to improve this situation.

Abstract. This article focuses on the complex processing of quarry tuffs-stone to extract metals (iron, titanium, copper, silver, etc.) and obtain raw materials for construction and agriculture. The issue of tuff-stone softening was investigated and the analytical dependence of the regularity of tuff-stone softening at water saturation was established, which indicates that the saturation increases with increasing mass of the sample according to the logarithmic law, and the dehydration process occurs according to the parabolic law. Also in the course of researches the magnetic susceptibility of tuff-stone was defined, which depends on size of induction of a magnetic field. The magnetically sensitive part is up to 50% by weight of the sample, and the remaining silicate part at a magnetic field strength of 1.3 Tesla. Spectral analysis showed a high content of metals in the magnetically sensitive part of tuff-stone, which consists of iron (35-40%), titanium (2.5-4.0%) and copper in the silicate part (0.4-0.7%). It was found that the percentage of content representing commercial interest, and therefore it is appropriate complex processing.

1 Introduction

The unique basalt deposit in the Rivne region is usually accompanied by rich deposits of tuff-stone, which are the products of volcanic eruptions. Geologists' forecasts for tuff-stone raw material reserves are hundreds of millions of tons. As a mineral, they have already been widely used in agriculture to increase soil fertility and to decontaminate their radioactive contamination, as a feed additive for livestock and poultry, as well as a building material.

The growing interest in tuff-stone mining requires improving its processing and bringing to the finished product. The rich mineralogical composition of tuffs, the presence of trace elements of rare metals, high content of iron, titanium, native copper in the tuffs of Rivne-Volyn region of Ukraine necessitated their comprehensive processing, the initial stage of which is ore preparation of rock mass to extract useful components [1].

In the process of ore preparation and selection of tuffs from the dumps of the basalt quarry there is a need to study its particle size distribution for the selection of equipment for further processing. The established effect of softening of tuff-stone at repeated irrigation with water demands specification of its granulometric structure both in a dump massif, and as a result of the subsequent crushing and crushing [2-4].

The aim of the research was to establish the regularities of softening of zeolite-smectite tuffs of the quarry mining method and their magnetic susceptibility [5-9].

2 Methods

According to the results of previous studies, it was found [10] that the softening of quarry tuff-stone as a result of water saturation leads to its involuntary destruction, which contributes to its separation from the total dump rock mass by screening. In turn, the time of water saturation depends on the mass of the sample, so to control the process of destruction and preparation for the screening operation, it is necessary to establish such a relationship. Based on the data of the study of tuff-stone saturation with water, the saturation time was determined for samples of different masses. [11-14]. These data are presented in Table 1.

Analyzing the data shown in table 1, it was found that the saturation time increases with increasing mass. Analysis of the data suggests that the dependence can be described by logarithmic-linear regression of the form:

$$t_H = a + b \cdot ln(m), \tag{1}$$

where m – sample weight, t_H – saturation time.

* Corresponding author: malanchykzr@ukr.net

Table 1. Saturation time for samples of different masses.

Sample weight, kg	0,052	0,106	0,348	0,681	1,025	2,18	3,347
Saturation time, h	1	23	96	68	96	96	96

As a result of the received data the corresponding calculations are carried out and the following model is received:

$$t_H = 23{,}34 + 23{,}2 \cdot ln(m). \qquad (2)$$

The coefficient of determination of this model is indicative of its acceptable adequacy. Graphically, the dependence was obtained (Fig. 1), which confirms that theoretically the saturation time should continue to increase with increasing mass according to the logarithmic law.

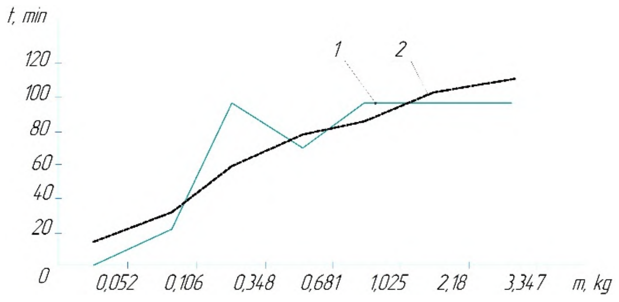

Fig. 1. The dependence of the time of saturation of tuff with water: 1 – according to the experiment; 2 – according to the calculation.

To model the process of softening of tuff-stone, it is of considerable interest to determine the analytical type of dependence on which the dehydration process takes place. Sample № 7 was taken for the study as the most characteristic for dump tuff-stone [15-17]. The analytical dependence of the species was established, and it is assumed that this dependence reduces the mass of the sample over time during dehydration.

As a result of the calculation, the following regression equation was obtained

$$m(+) = 3{,}54 - 0{,}00152t \ \text{ at } r^2 = 0{,}88. \qquad (3)$$

The obtained model has a fairly high level of adequacy, but the consistency of experimental and theoretical values $m(t)$n graphical form is not satisfactory (Fig. 2).

In this regard, a parabolic regression model of the species was calculated $m(t) = a + bt + ct^2$. This model, unlike the previous one, takes into account the nonlinear nature of the process. The result is obtained

$$m(t) = 3{,}569 - 0{,}00327t + 0{,}0000124t^2 \ \text{ at } r^2 = 0{,}98, \qquad (4)$$

which is significantly higher than for the linear model.

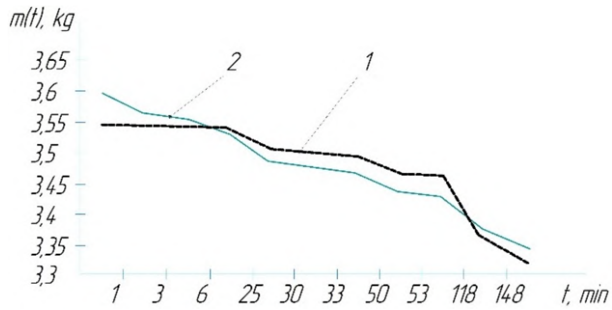

Fig. 2. Linear model of tuff-stone dehydration process: 1 – experimental; 2 – estimated.

The graph of actual and analytical parabolic dependences is given in Fig. 3, which shows their consistency. Thus, it can be argued that the process of dehydration is subject to the parabolic model, which is shown in Fig. 3.

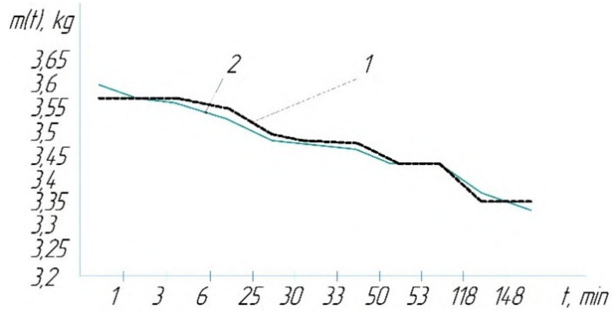

Fig. 3. Parabolic model of the process of dehydration of tuff-stone: 1 – experimental; 2 – calculated.

As a rule, in practice one cycle of saturation and dehydration is not enough for destruction of tuff-stone in a dump to the conditional sizes. Therefore, it is recommended to use a repeated cycle of saturation and subsequent dehydration naturally – drying [18-23].

Analysis of data on the re-saturation of tuff-stone with water and testing on these data of different regression models allowed to choose the most adequate of them:

$$m(t) = a + b_1 t + b_2 m_0 + b_3 m_0 t, \qquad (5)$$

where m_0 – the initial mass of the sample, before saturation; t – saturation time.

As a result of the calculations, the following model was obtained

$$m(t) = 0{,}0075 - 0{,}00004t + 1{,}0285m_0 + 0{,}00016m_0 t. \qquad (6)$$

Coefficient of determination $r^2 = 0{,}99$ and indicates an acceptable functional dependence $m(t)$. Given the rather large sample size (n = 56), this model can be adopted for further practical use. It takes into account not only the influence of time and mass of the sample separately, but also the combined influence of these factors. To illustrate the results in Fig. 4 shows the dependences of the mass of tuff-stone on time for three samples: $m_{01} = 1{,}025$ kg; $m_{02} = 2{,}18$ kg and $m_{03} = 3{,}347$ kg.

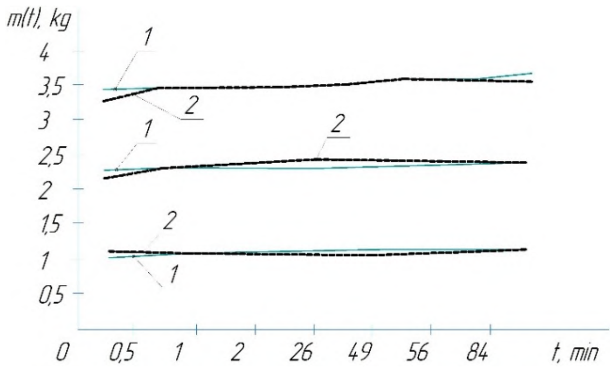

Fig. 4. The dependence of the mass of the tuff-stone sample on the re-saturation of three samples with water: 1 – according to the experiment; 2 – by calculation.

According to experimental studies, a regression model was obtained for the process of re-dehydration

$$m(t) = 0{,}00137 - 0{,}000045t + 1{,}0697m_0 - 0{,}000063m_0t \ . \tag{7}$$

Coefficient of determination is $r^2 = 0{,}99$.

Model m_0 – the mass of the sample after dehydration.

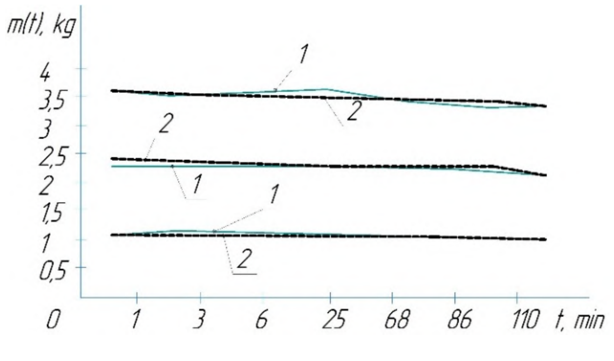

Fig. 5. The dependence of the mass of the tuff-stone sample during repeated dehydration for three samples: 1 – according to the experiment; 2 – by calculation.

In Fig. 5 shows the experimental data and the results of analytical calculations according to the above model. The high level of coincidence of graphs indicates the reliability of the chosen model and the possibility of its application in practice.

Thus, as a result of research the analytical dependence of the regularity of softening at water saturation was established, which shows that the saturation increases with increasing mass of the sample according to the logarithmic law, and the dehydration process occurs according to the parabolic law. tuff processing.

3 Investigation of the magnetic susceptibility of zeolite-smectite tuff-stone

In recent years, researchers' interest in tuffs in order to use them in industry has grown significantly. Therefore, there is a need for a detailed study of their properties, methods of extraction, processing and integrated use. In the process of research of zeolite-smectite tuffs, which occur in large quantities in Rivne-Volyn, their magnetic susceptibility was established, which is explained by the presence of iron and titanium. Quantitative and qualitative analysis of the content of these elements was performed experimentally using magnetic and spectral analyzes of crushed tuff-stone samples of different sizes at variable magnetic field strength to determine the level of its sufficiency in the ore preparation of raw materials for complex processing [24-27].

Studies have shown that tuff-stone contains native copper in the form of thin films or point inclusions, the extraction of which is possible only with fine grinding of tuff-stone for maximum separation of the silicate part from native inclusions. Since iron and titanium are also in the joints in the form of compounds, by fine grinding followed by screening to achieve maximum disclosure of minerals. Obtaining the maximum allowable degree of grinding of tuff-stone for reasons of the possibility of a hardware method of extracting metal compounds (magnetic and electric separators) allows to determine the content of silicate and metal parts in the composition of tuff-stone [28-30].

The purpose of studies of the composition of tuff-stone by magnetic and spectral analysis was to determine the particles of silicate and metal parts, as well as the influence of magnetic field strength on the extraction of the magnetically sensitive part and its composition.

Because zeolite-smectite tuffs are associated rocks in basalt mining and are not widely used, they are a waste rock in basalt quarries. From the point of view of complex extraction and processing of basalts with division into three components in the deposit (basalt, lavobrekcia and tuff), the Rafalivka deposit is perspective, therefore researches of zeolite-smectite tuff-stone of this deposit are executed in work. In the process of ore preparation for this method of tuff-stone processing it is important for rationalization to determine the basic particle size and chemical composition and reaction of rock mass to different types of influences [31-32].

For research, the tuff of the Rafalivka basalt quarry was crushed into three groups of size: (-2.5+0.63 mm); (-0.63+0.1 mm); and (-0.1 mm). Next, the weight fraction of each size class in the sample and the percentage of magnetically sensitive part in it was determined (Table 2). The magnitude of the magnetic field for each sample varied stepwise from 0.08 Tesla to 1.3 Tesla in five stages of exposure. The experimental technique involved increasing the induction of the magnetic field to determine the part of the tuff-stone separated from the total mass of the part that was attracted at a given intensity, and then, by spectral analysis, the content of the elements of each part was determined. This is due to the fact that the degree of susceptibility of tuff increases with increasing magnetic field strength. Factors influencing the process of magnetic separation are particle size distribution and chemical composition of tuff-stone [33].

Table 2. The distribution of the mass of tuff-stone in the sample depending on the induction.

№ research	Class +0,63 –2,5			№ research	Class +0,1 –0,63		
	Induction, B, Tesla	Susceptible mass, *m*, g	Percentage, γ,%		Induction, B, Tesla	Susceptible mass, *m*, g	Percentage, γ,%
1	0,08	63,2	19,1	8	0,08	30,5	14,6
2	0,16	59,5	18,0	9	0,16	37,0	17,7
3	0,3	51,7	15,6	10	0,3	37,7	18,1
4	0,44	49,7	15,0	11	0,44	31,9	15,3
5	0,58	44,8	13,5	12	0,58	32,5	15,6
6	1,3	6,1	1,8	13	1,3	5,8	2,8
7	nonmagnetic	56,4	17,0	14	nonmagnetic	33,4	15,9
	Total (sum)	331,4	100		Total (sum)	208,9	100
The total mass of the sample	331,4 + 208,9 + 104,5 = 644,8 g						

Since the third group of size (-100 microns) showed complete magnetic immunity, it is attributed to the non-magnetic part of the sample.

Based on the obtained results, the magnetically impermeable part of the sample is 49.1 % or 194.3 g. The different susceptibility of the metallized part of the crushed tuff-stone in relation to the magnitude of the magnetic field induction and size indicates product.

The nature of the heterogeneity of the composition was established by spectral analysis of all obtained fission products. The analysis was performed by spilling on the device STE-1 with a prefix USI-10. The results of the analysis are presented in Table 3 and Table 4. It should be noted the lack of accuracy in the percentage of some elements, in particular titanium (> 1.0 %), iron (> 15 %), and the lack of data on the presence of silicates and carbonates (SiO_2 and CaO) in samples. Their content was determined by chemical analysis. It was precisely established that the iron content in the samples of the first group is 36.2 %, and in the second - 39.6 %, respectively, titanium - 1.3 % and 4.1 %. The increase in the average percentage of native copper in the sample of the second group of size is explained by the fineness of its inclusions, but this indicator requires additional separate studies [34-37].

Table 3. The results of the analysis of the content of elements in the tuff-stone for the sample 1.

№	Induction, Tesla	The weight of the sample in the first group, g	The mass content in the sample, %	Content of elements, %							
				Fe	Ti	Cu	Mn	Ba	SiO_2	CaO	Ag, g/t

14	nonmagnetic	33,4	15,9			0,6	0,1	0,04	43,5	53,1	50
Σ		208,9	100			0,5	0,08	0,05	43,6	52,6	23

As the experiment showed, the discrepancy in the mass of the magnetically sensitive part (49%), which is due to the presence of titan magnetite and iron content in the samples obtained by chemical analysis (36.2-39.6%), is due to the presence of splices with hollow rock. The presence of copper in the magnetically sensitive part indicates the need to choose a rational degree of grinding of tuff-stone for a more complete separation of copper from the silicate part. At the same time the particles of titan magnetite are more fully revealed. Since magnetic separation allows to separate even finely divided iron particles (up to 44 microns) from crushed tuff-stone to a size of less than 100 microns, the electric separation of the silicate part of the product in copper extraction is most effective up to a size of 100 microns. This indicates that the re-grinding of tuffs in the ore preparation process leads to losses in the extraction of metals [38-40].

Thus, the performed researches established that the degree of grinding of tuff-stone in the process of ore preparation should be not less than 0.05-0.1 mm. The magnetically sensitive part reaches 49 % by weight of the sample, respectively; the silicate part is 50-51 %. During the extraction of the magnetically sensitive part is significantly affected by the magnetic field strength, which reaches 1.3 Tesla. The performed studies indicate the expediency of complex processing of not only basalts but also tuffs, as the percentage of basic elements is of industrial interest. Such elements are iron, titanium, copper, silver. The remaining silicate part is disposed of for construction and agriculture. This recycling technology is waste-free and resource-saving.

Conclusions

Analysis of experimental studies suggests that tuff-stone is a valuable raw material of interest to industry, as it contains valuable elements in the form of native copper, iron, titanium. Removal of these components is technologically possible and economically feasible.

For dump tuff-stone, an analytical dependence of the regularity of softening at water saturation is established, which indicates that the saturation increases with increasing mass of the sample according to the logarithmic law, and the dehydration process occurs according to the parabolic law.

As a result of the conducted researches the magnetic susceptibility of tuff-stone which depends on size of induction of a magnetic field was established. The magnetically sensitive part of tuff-stone, at a magnetic field strength of 1.3, Tesla is up to 50% by weight of the sample, and the rest is the silicate part. The spectral analysis showed a high content of metals in the magnetically sensitive part of tuff-stone, which consists of iron (35-40%), titanium (2.5-4.0%) and copper in the silicate part (0.4-0.7%). The percentage of these elements is of industrial interest, so it is advisable to comprehensively process dump tuffs in the Rivne-Volyn region of Ukraine.

Abstract. The article considers the features of the distribution of technological indicators (product output, content and extraction of copper) by size classes, the main factors influencing the crushing process are identified and regression dependences of productivity on influencing factors are received. The parabolic nature of the dependences of the output of crushed rock on the size class is established. The high adequacy of the obtained models was confirmed and the most promising classes of rock size for copper extraction were determined. The obtained results and models will allow to develop a generalized model of the process of native copper mining and to implement this process with rational and optimal parameters. Also, the received models will allow to carry out an estimation of productivity of a research site of processing of raw materials of basalt quarries.

1 Introduction

Historical and archeological data indicate that Volyn native copper was well known to the ancient Slavs. This is evidenced by the names of places (Midsk, Medishche, etc.) of Old Slavic origin (mid - copper), tools from ancient settlements and ancient basalt mines in the basin of the Goryn River. The first thorough written data on Volyn native copper appeared in the Polish geological literature in the late 1920s, although some publications as early as 1887 already mention Volyn native copper.

In addition to Volyn copper, several other rich manifestations of native copper have been discovered in Ukraine relatively recently. All these previously unknown ore occurrences were found on the Ukrainian Shield. In the early 1990s, native copper was found among polymetallic ores in the Precambrian carbonate rocks of the Volyn mega block (Kurchytsia ore occurrence), and at the beginning of the new millennium in the weathering crust of the Zhdaniv ultrabasic intrusion in the 2003 Berdychiv uplift and uplift. Chemerpil structure of the Podolsk block. Rare finds of native copper are known in the Carpathians, Azov, Donbass and Kryvyi Rih.

Xenomorphic native copper predominates in the ore manifestations of Ukraine due to a significant influence on the shape of its allocations in the crystallization medium. There is a significant variety of xenomorphic forms of native copper - lamellar, membranous, druse-, vein-, dendritic-, lump-, droplet-, wire-, sponge-, needle- and hair-like. Among the small allocations of copper are often perfect and imperfect polyhedra, their regular and irregular growths, dendrites and dendritoids.

The dominant method of growth of polyhedra of native copper of Ukraine is free crystallization, the tangential mechanism of growth of crystals prevailed. Crystals of hydrothermal copper from volcanic of Volyn grew in cubic layers, as well as crystals of hyper genic copper from the Zhdanovka ore occurrence, while crystals of hypergenic copper from the Chemerpil ore occurrence grew in octahedral layers.

In terms of chemical composition, copper from ore occurrences in Ukraine is a relatively pure mineral, especially in the case of hydrothermal native copper from volcanic of the Volyn copper ore district. Magmatic copper from volcanic of Volyn has a high content of impurities Ni, Co, Cr and Fe [1].

Important minerals-indicators of native copper mineralization in the volcanic of Volyn are native iron and silver, which have characteristic features of chemical composition: iron enriched with impurities Mn and Cr, silver – Hg. In terms of crystal morphological features, hydrothermal native copper from Volyn volcanic is most similar to native copper from Michigan deposits (USA), which indicates the close conditions of their crystallization [2].

Native copper of Ukraine belongs to several genetic types: a) hypo genic (magmatic and post-magmatic hydro-thermal) in the Vendian volcanic of the Volyn copper ore district; b) hyper genic in the oxidation zones of the Precambrian ultrabasites of the Zhdanovka and Chemerpil ore occurrences of the Podil block of the

* Corresponding author: kvja@i.ua

Ukrainian Shield; c) metamorphogenic in Precambrian metamorphic rocks ore occurrence of Kurchytsia of the Volyn megablock of the Ukrainian Shield [3-7].

2 Methods

As you know, the average copper content in the main geological and industrial types of copper deposits is from 0.2 to 6.0 % (for example, for cuprous sandstones and shale 1.0-6.0 %, for deposits of native copper 1.0-2.5 %) [8]. The lower limit of the conditions for copper ore is the copper content in the ore 0.35-0.50 %, for oxidized ores, according to world practice, this limit is higher - from 0.7-1.0 % at which its industrial use is technically possible and economically expediently [9].

Sulfide copper ores make up 90 % of all industrially processed copper ores. They are finely crushed and enriched by flotation, for oxidized ores the most common and cheapest method is hydrometallurgy (leaching and extraction of copper from solution), ore preparation of oxidized and native ores, as a rule, includes gravity methods [10].

Studies of rocks from basalt quarries in Volyn (Rafalovsky, Berestovetsky and some others) did not reveal the presence of sulfide copper ores in an amount sufficient for industrial processing, mainly copper is contained in the form of native mineralization and accompanying oxidized varieties [11]. Considering this, when extracting copper from basalt quarry rocks, the main thing is to create a strong, developed ore preparation scheme. Further, copper can be obtained from the concentrate of ore preparation, either by modifying it by hydrometallurgy or roasting-flotation concentration, or directly by smelting (pyro metallurgy).

Due to the fact that all three main rocks of the open pit are copper-bearing - tuff, basalt, lavobrekcia, it is necessary to clarify in advance, at least in general terms, whether the ore preparation scheme will be the same for all three rocks or will it be necessary to create separate processing lines. For this, the prepared representative rock samples were uniformly detailed (on a roller crusher) and dispersed into three narrow particle size classes.

To determine the nature of the distribution of native copper in different grades of the size of the crushed rock, studies of technological samples of lumpy lava breccia with pronounced numerous inclusions of copper were carried out [12]. Sampling was carried out on the blasted rock mass at different points along the face of the Rafalovsky basalt quarry. A total of 10 samples were taken, each weighing 10 kg in the form of a single piece or a set of separate pieces.

Crushing was carried out on a vibration-type jaw crusher with an adjustable slit for unloading the crushed mass. After crushing each sample, the resulting mass was vibrated and divided into six control size classes. The weight of the sample as a whole, the weight of each screening class and the weight content of copper in each of the classes and in the sample as a whole were measured [13-16].

3 Results and discussion

Experimental studies have shown that in all classes the copper content is not more than 4.1 %, that is, not excluding the presence of nuggets and pure grains of copper minerals in the classes, there is a lot of waste rock in all classes and, most importantly, there are many intergrowths of copper minerals with the rock. To destroy the aggregates, these classes will have to be crushed, otherwise the aggregates will be extracted during enrichment and the quality of the concentrate will be insufficient [17].

Based on the experiments carried out, for 10 samples of lavobrekcia, the cumulative (cumulative) characteristics of copper extraction into classes were constructed (Table 1).

Table 1. Cumulative characteristics of copper recovery in size classes of crushed mass of lavobrekcia.

Classes, mm / Sample No.	**Total copper recovery, %**										**Average**
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	
+10	21.4	14.7	17.2	15.7	20.0	26.0	29.0	24.3	22.0	22.2	21.3
-10 +5	44.7	42.3	46.8	36.2	35.6	58.5	60.3	53.5	50.9	48.3	47.7
-5 +1.0	70.7	64.6	71.9	64.4	55.6	70.0	85.8	73.5	74.1	72.4	70.3
-1.0+0.5	85.4	78.8	84.9	81.1	76.8	86.2	92.2	88.0	90.5	84.8	84.9
-0.5+0.1	94.1	89.8	93.3	90.4	89.0	100	96.5	95.5	97.6	93.5	94.0
-0.1 +0.05	100.0	100.0	100.0	100.0	100.0	-	100.0	100.0	100.0	100.0	100.0

Table 1 shows that, on average, the total extraction of copper in the top three classes -10 + 1 mm is 70.3 %, in classes -10 + 0.5 about 85 %, and in classes -10 + 0.1 mm – 94 %. This concentration of copper in relatively large grades is typical for native deposits.

Using the obtained data on extraction, two conclusions can be drawn, firstly, regarding the structural diagram of the developed ore preparation technology, and secondly, about the expected performance of copper concentrate.

The nature of the extraction (Table 1) suggests the possibility of using a variant of the technology for separate enrichment of lavobrekcia, when the raw material is divided into two streams - large and small classes, each of which is enriched separately. The decision on which size to accept as the boundary will depend on the chosen method of enrichment, since the enrichment equipment operates at a certain lower limit of the feed size. For example, grades +0.5 mm, where copper recovery is 85%, are easily enriched by gravity methods, for example, jigging [18-23]. Classes +0.1 mm, the recovery in which is higher than 94 %, are well enriched on concentration tables and corona electrostatic separators [24].

The second possible variant of the technology is simpler - it is possible, without dividing the raw material into two streams, in the head of the diagram from large classes to isolate native formations by gravity methods. This approach is often used for gold-bearing ores - native mineralization is extracted by gravity, or, as they say in the practice of beneficiation, the valuable component is removed, that is, a rich gravity concentrate is obtained, and the remaining product is enriched in the usual way.

Extraction, as a technological indicator, characterizes not so much the raw material as the method or equipment for enrichment. In the practice of beneficiation, the concept of extraction is rarely used, since it is a complex indicator that does not provide information either on the yield of the concentrate or on its quality - the copper content in it. In practice, they strive to achieve a maximum of both yield and quality, and they do not operate on extraction. However, extraction, as a complex indicator, is indispensable for making forecasts and estimates.

So, using the recovery rate, it is possible to predict the possibility of obtaining standard copper concentrate with a content of 15 % from lavobrekcia Cu (according to GOST 52998-2008, copper concentrate must contain at least 15 % copper (sometimes 12 %)). To determine the yield (amount) of concentrate, let us set the copper content in the feedstock and the extraction.

As the copper content in the original product (α), we take from table 2 the highest copper content in the samples is 1.5 %. Let's set the final recovery of 85%. Let us make a preliminary remark regarding this extraction figure.

According to the practice of enrichment of copper ores, recovery of 85 % is a very high indicator. Thus, the most efficient flotation method today provides recovery of 70-80 %. For example, ε = 70 % for the main copper flotation at the Krasnouralsk plant, ε = 75 % for the collective flotation of the Udokan mixed oxidized and sulfide copper ores. In about 10% of cases, flotation yields 82 % recovery and very rarely 85 %. The same applies to the gravitational enrichment of non-ferrous metals, where the typical recovery is 60-70 %, not higher than 80 % [25-28].

Thus, in the best case, with $\alpha = 1.7\%$, $\varepsilon = 85\%$, the yield of concentrate from lavobrekcia will be $\gamma = \frac{\alpha \cdot \varepsilon}{\beta} = \frac{1.7 \cdot 85}{15} = 9.6\%$.

It follows that the original sample must be reduced by at least 10 times to obtain a concentrate with a quality of 15%. If the recovery is less, then the yield of the concentrate will be less.

For example, for the same high-grade ore, with $\varepsilon = 70\%$, $\gamma = \frac{\alpha \cdot \varepsilon}{\beta} = \frac{1.7 \cdot 70}{15} = 7.9\%$.

Also, the poorer the feedstock, the lower the concentrate yield will be, since the more waste rock must be discarded to obtain a concentrate of a given quality. For example, with a copper content of 0.5 % in the original and a high $\varepsilon = 85\%$, the yield of a concentrate with a quality of 15% will be only $\gamma = 2.8\%$.

The average technological characteristics of raw materials were calculated - for all 10 samples of crushed lava breccia (Table 2).

Table 2 shows that all size classes contain a lot of copper (more than 0.35 % - the industrially necessary minimum), that is, none of the classes can be removed from the redistribution of copper concentration.

Also, the data in Table 2 show the highest absolute copper recovery of 21 – 26 % for the three upper classes -10 + 1 mm. The same classes have the highest copper content of 1.1 - 1.5 %. According to the norms, it is required to obtain a standard concentrate with a copper content of at least 10-12 times more (the quality of standard copper concentrates is from 15 to 28 % Cu). In principle, it is possible to divide raw materials according to the 1 mm class, and everything that is finer can be subjected, for example, to direct enrichment by hydrometallurgy (leaching), but everything that is larger will first have to be crushed and only then enriched. When grinding large grades, copper will not disappear, it will go into smaller grades, which can already be effectively enriched.

Table 2. Average values for 10 samples of lavobrekcia.

Classes, mm	**Output, γ, %**	**Copper content, β, %**	**Extraction of copper, ε, %**	**Total extraction**	
				Output, %	**Cu, %**
+10	18.0	1.3	21.3	18.0	21.3

-0.1+0.05	11.5	0.6	6.0	100.0	100.0
Total	100.0	1.06	100.0		

Let us carry out an estimated calculation of the amount (yield) of standard copper concentrate from lavobrekcia. As you can see from the table. 2, the average copper content for 10 tests was 1.06%. To obtain a standard concentrate with a lower quality limit of 15% at a recovery of, for example, 70%, the initial quantity of raw materials must be reduced to $\gamma = \frac{\alpha \cdot \varepsilon}{\beta} = \frac{1.06 \cdot 70}{15} = 5.0\%$

Even with ε = 90% (not achievable in practice), the yield of the standard concentrate will be small, only 6.4%. The estimated yield values obtained show that during ore preparation it is necessary to strive to reduce the mass of raw materials as much as possible, but without losing the valuable component. So, with a copper content of 0.5–1.7% in lavobrekcia, to obtain a concentrate with a quality of 15 %, the mass of raw materials must be reduced to 5–10% of the original amount [29].

Thus, 10 representative samples of lavobrekcia from the Rafalovsky basalt quarry with a copper content of 0.5 to 1.7 % were experimentally studied, which were separately subjected to crushing on a vibration-type jaw crusher with an adjustable discharge slot and vibrating screening with division into six control size classes. As a result, the main technological indicators were established – the yield, content and extraction of copper in narrow grain size classes of crushing products and the dependences of the distribution of these indicators by size classes were obtained [30].

The cumulative sieve characteristics showed that the crushing size was 20% cell -0.1 mm, on average 11.5% cell -0.1 mm.

The dependences of the distribution of copper by size classes showed that the content of copper in small classes -1 mm is less than in large ones +1 mm (8 samples out of

10). In large grades of -10 + 1 mm, the distribution of copper content is almost uniform. In general, the distribution of copper by size class, with sufficient accuracy for practice, is described by a logarithmic relationship, which is pronounced for rich samples ($\beta \geq 1\%$) (6 samples). For poorer samples ($\beta \approx 0.5\%$), the logarithmic dependence flattens out and, with an accuracy sufficient for practice, can be considered linear (4 samples). More precise mathematical approximations of the distribution of the mass of raw materials and the amount of copper by size will be considered below. All grades of lavobrekcia size, including the thinnest -0.1 + 0.05 mm, have a standard copper content and cannot be removed from the copper concentration redistribution.

The dependences of copper recovery on the particle size showed that with an increase in the size, the recovery monotonically increases up to a certain limit and, starting with a particle size of about 1-2 mm, the nature of the dependences flattens out. The total extraction of copper in the upper size classes -10 + 1 mm is 70.3%, in the wider class -10 + 0.1 mm – 94%.

When the copper content in the lavobrekcia samples is 0.5-1.7 % to obtain a concentrate with a lower quality limit of 15 % (GOST 52998-2008), the mass of the rock must be reduced to 5-10 % of the initial amount of raw materials. Two variants of the technological scheme can be considered as promising - with the separation of a rich gravity concentrate in the head of the process and with separate enrichment of large and small classes according to the main and sludge scheme.

For the development of ore preparation technology, it is important to determine the calculation formulas that provide, in particular, the forecast of the copper yield depending on the crushing size. Previous studies have established experimental dependences of the yield, grade and recovery of copper on the size for 10 samples of crushed lavobrekcia. In this case, the grain size distribution of each initial sample was arbitrary and the samples were subjected to crushing. Since after crushing the output of the rock mass into each of the 6 classes of sieving (vibrating screening was used) was different for each of the 10 samples, then to obtain a generalized characteristic, it is necessary to establish the regularities of the distribution of the rock mass output and the output of native copper from the size. The initial experimental data for determining these patterns are given in Tables 3-7.

For such studies, first of all, the assumption about the subordination of the yield of the breed to the class to the normal distribution law is checked. To check compliance with the theoretical distribution law, the criteria of agreement of Pearson, Kolmogorov, Shapiro-Wilk, and others are applicable. However, most of these criteria are suitable only for medium to large samples. In our case, the sample is small (*n* =10), these criteria are not applicable.

The studies carried out were based on the well-known method of analysis of small samples [31], according to which selective without bias and kurtosis can be used for an approximate test of the hypothesis of the normal distribution.

Sample values of without bias and kurtosis are compared with the standard deviations of asymmetry and kurtosis, and the results of the comparison are used to judge the agreement with the normal distribution law [32-36].

The yield of classes is not given (%), but the yield of copper per class of the total amount of copper in the sample (%). The yield of the size class and the yield of copper in the class are different indicators. The calculation of the extraction for the specified yield of copper in the class is incorrect (the balance is not observed).

The calculation procedure in this case is as follows.

A sample is given (testing results):

$$x_1, x_2 ..., x_n, \qquad (1)$$

where n – sample size.

We calculate the following indicators:

- average value:

$$\ddot{x} = \frac{\Sigma x_i}{n}; \qquad (2)$$

- variance:

$$S^2 = \frac{\Sigma x_i^2}{n} - \ddot{x}^2; \qquad (3)$$

- standard deviation:

$$S = \sqrt{S^2}; \qquad (4)$$

- asymmetry:

$$A_S = \frac{\Sigma\left(x_i - \ddot{x}\right)^3}{n \cdot S^3}; \qquad (5)$$

- excess:

$$E = \frac{\Sigma\left(x_i - \ddot{x}\right)^4}{n \cdot S^4} - 3; \qquad (6)$$

- standard deviation for asymmetry:

$$S_{AS} = \sqrt{\frac{6 \cdot (n-1)}{(n+1)(n+3)}}; \qquad (7)$$

- standard deviation for kurtosis:

$$S_{AS} = \sqrt{\frac{24 \cdot (n-2)(n-3)n}{(n-1)^2 (n+3)(n+5)}}. \qquad (8)$$

If the absolute values of without bias and kurtosis do not exceed their standard deviations, then the hypothesis about the agreement of the sample with the normal distribution law is confirmed.

Calculation results for the rate of rock mass (rock) yield into classes γ_{ni}, 1, 2,…, 6 (Table 8).

Table 8. Dependence of rock yield on controlled size classes.

Class number, *N*	Size limits in class, mm	Average breed yield in the class, X_m, kg	Average sample weight in a class of 10 samples, X_m, kg	Standard deviation, S	Asym-metry, A_S	Excess, *E*
1	0.1-0.05	0.115	1.15	0.634	–0.280	–1.200
2	0.5-0.1	0.135	1.35	0.743	–0.025	–0.584
3	1.0-0.5	0.175	1.75	0.844	0.187	–1.300
4	5.0-1.0	0.205	2.05	0.567	–0.196	–0.753
5	5.0-10.0	0.190	1.90	0.663	0.370	–0.780
6	+10	0.180	1.80	0.400	–0.328	–0.336

We have for the sample size n = 10:

$$S_{AS} = 0.615; \; S_E = 0.922. \qquad (9)$$

Comparing without bias and kurtosis with these critical values, we note that in the overwhelming majority of cases, the condition of agreement of the sample with the specified distribution law is satisfied. Only in two cases does excess exceed the critical value (for classes 1 ... 0.5 mm and 0.1 ... 0.05 mm), but this excess can be considered insignificant [37].

Thus, it can be argued that the rock yield is consistent with the normal distribution law.

This distribution law is symmetric with respect to the mathematical expectation; therefore, the generalizing characteristic of the yield of rock mass in a class is its average value.

Figure 1 shows the dependence of the rock mass yield on the size class.

This dependence is parabolic:

$$\gamma_n(i) = 0.053 + 0.0611 \cdot i - 0.0066 \cdot i^2, \; i = 1, 2, ..., 6. \qquad (10)$$

The coefficient of determination R^2 = 0.926, which indicates a high level of adequacy of this model.

Similar studies were carried out for the yield of copper in a single sample of each size class. First of all, the agreement with the normal distribution law was checked. The calculation results are shown in table 9.

Table 3-7 shows that, with the exception of class 1-0.5 mm, agreement with the normal distribution law can be considered satisfactory.

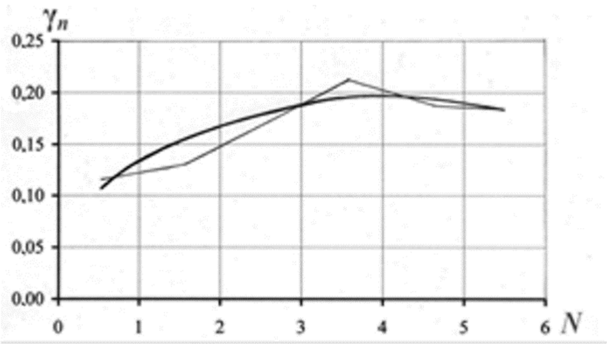

Fig. 1. The nature of the dependence of the yield of crushed rock on the size class.

Table 9. Dependence of the copper yield on the controlled size classes.

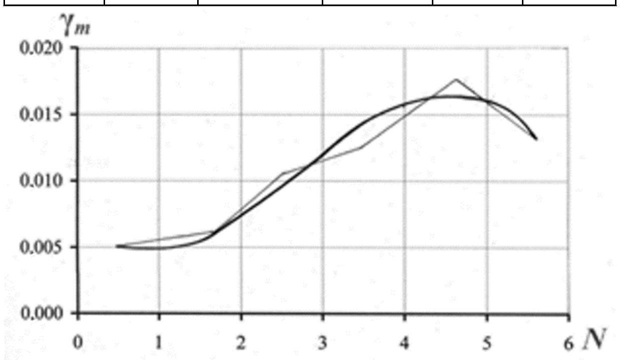

Fig. 2. Dependence of the copper yield on the size class.

It was found that the dependence of the copper yield $\gamma_м(i)$ from class *i* with a high level of adequacy obey the cubic parabola law:

$$\gamma_m(i) = 0.01063 - 0.009334 \cdot i + 0.004351 \cdot i^2 - \\ -0.000449 \cdot i^3, R^2 = 0.9682. \quad (11)$$

For the sake of completeness, let us consider the indicator “copper yield in the class by the cumulative total in relation to the entire sample”, which was defined as

$$\gamma(i) = \gamma_n(i) \cdot \gamma_m(i) \quad (12)$$

The calculation results for the output of copper in the size classes by the cumulative total in fractions and percentages are given in Table 10 and Fig. 3.

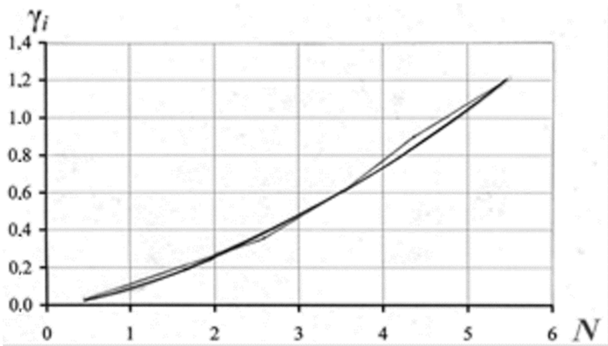

Fig. 3. Dependence of the distribution of the yield of copper by size classes by the cumulative total.

As can be seen from Fig. 3, the dependence of the cumulative copper yield on the size class with a high level of adequacy is described by a quadratic parabola:

$$\gamma(i) = -0.0384 + 0.0479 \cdot i + 0.0263 \cdot i^2, \ i = 1, 2, ...6; \\ R^2 = 0.994 \quad (13)$$

The resulting graph in Fig. 3, as well as the dependences in Fig. 1, 2, confirms the highest efficiency in terms of copper yield in classes 1-5 and 5-10 mm [38, 39].

Thus, the performed studies made it possible to establish that for lavobrekcia, the regularity of the yield of crushed mass from the size class is parabolic (R^2 = 0.926), and the distribution of the copper yield from the size class obeys the cubic parabola law (R^2 = 0.9682). The indicated high values of the coefficients of determination R^2 indicate a high degree of adequacy of these models [40].

The obtained regularities of the distribution of rock mass and copper yield by size class are relevant and can be used for predictive calculations in the development of an integrated technology for ore preparation [41, 42].

Conclusions

The considered features of distribution of technological indicators (output, copper content and production) on size classes allow defining the basic factors influencing process of crushing. The regression dependences of copper yield on the influencing factors are obtained.

Thus, the performed studies made it possible to establish that for lava breccia, the regularity of the yield of crushed mass from the size class is parabolic (R^2 = 0.926), and the distribution of the copper yield from the size class obeys the cubic parabola law (R^2 = 0.9682). The indicated high values of the coefficients of determination R^2 indicate a high degree of adequacy of these models.

The high adequacy of the obtained models was confirmed and the most promising size classes of rocks for copper mining were identified.

The regression dependences of copper yield on the influencing factors are obtained. The obtained results and models will allow to develop a generalized model of the copper mining process and to implement this process with rational and optimal parameters. Also, the received models will allow carrying out an estimation of productivity of a research site of processing of raw materials of basalt quarries.

Abstract. The article considers the determination of the final contours of the open pits. One of the problems of development of iron ore deposits at the present stage of development of opencast mining is described, which consists in the fact that in most open pits their working contours on the surface have reached final position. In these conditions, it is necessary to reevaluate the capabilities of the raw material base for further operation of mining enterprises. The analysis of scientific achievements in the decision of the final definition of the open pits` contours is executed. The well-known principle of determining the boundaries of opencast mining, the principle of which is to determine the boundaries based on a comparison of the allowable cost of ore production with the expected for the designed open pit. On the example of the open pits, which reflect the characteristic features of the development of steep-dipping deposits of Ukraine, the influence of current overburden ratio of the existing open pits on the economic overburden ratio, which serves as the main criterion in determining the boundaries of opencast mining for the designed open pits. A method for determining the boundaries of the open pits has been developed, which provides for the use of the economic overburden ratio of opening as a value not constant but variable over time, and one that depends on the change of current coefficients of opening in open pits-competitors. As a result, the theory in the field of determining the final contours of the open pits is improved. The new method differs from the known ones by taking into account the change in the economic overburden ratio over time, as well as determining the impact of technological indicators of open pits - competitors on the final depth of the designed open pit.

1 Introduction

One of the main parameters in the design of opencast mining is the boundaries of the open pit.

At present, the upper horizons of most iron ore open pits are approaching their design boundaries. Therefore, the work of open pits will be characterized by the achievement of the highest operating overburden ratios.

This will lead to the fact that the cost of ore and in general the cost of production of concentrate will reach the acceptable values. Based on this, the value of the operating overburden ratio, which determines the final boundaries of the open pits, can be reduced by choosing the direction of development of mining operations and determining the rational contours of the open pits on the surface. Reducing the operating factor will expand the final boundaries of the open pits, thereby increasing the ore reserves in the contours of the open pits and the industrial potential of mining and processing plants [1].

It should be noted that timely determination of the final contours of the open pits allows you to plan the need for land for surface buildings and technological structures that ensure the normal operation of mining and processing plants for a long time [2]. At the same time, the social factor is also important.

The need to determine the promising final boundaries of the open pit is due to the fact that after the upper horizons to the final contour of the open pit will work in the mode of annual reduction (disposal) of production capacity, and to prepare the overlap of such disposal it will take 5-7 years at any method of development. It will increase the depth of development of the deposit, and most of the upper horizons of the working area will be repaid, which will require attracting much more investment in the development of reserves in the approved by the designed contour of the open pit.

With the definition of promising final contours of the open pit there will be a change in the volume of overburden, ore and its quality, at which it is necessary to establish its production capacity and the period of the plant operation.

2 Object and methods of research

Significant achievements [3-16] in the theory of designing the boundaries of opencast mining belong to M.I. Goberman, W.W. Rzhevsky, V.S. Khokhryakov, O.I. Arsentiev, M.S. Chetverik, V.G. Blizniukov. Of course, the determination of the boundaries of open pit mining should be carried out taking into account the conditions of stability of the massif of boundary rocks, which are performed by modern remote methods [17, 18]. When determining the boundaries of the open pits according to known calculation principles, the economic calculating ratio is calculated according to technical and economic indicators, which are achieved at the time of design and its value is constant [19-21].

In study [22], a method was proposed to determine the economic overburden ratio, which allows avoiding of the influence of unnatural and non-technological factors on the price of concentrate. The developed method allows to bring prices at the cost of one percent of iron in 1 ton of concentrate and to avoid the influence of subjective factors while the determining the boundaries of opencast mining.

Analysis of the work of mining and processing plants showed that their economic indicators and overburden ratios change over time [23]. It was found that the existing methods of determining the boundaries of the open pits do not take into account the possibility of changing the economic overburden ratio due to the inconsistency of technical and economic indicators, in particular, the cost of ore production in a competitive environment [24].

The enterprises develop minerals in an open way there is a constant change in the volume of overburden per ton of the extracted ore, which entails significant changes in the cost of marketable products [25, 26]. Ignoring the change in the economic overburden ratio over time can lead not only to exceed, but also to the reduction of economic sense depth of the designed and existing open pits.

Therefore, the idea was put forward to take into account the dynamics of the external competitive environment of the mining company and determine the boundaries of opencast mining, based on the fact that the cost of ore mining in the designed open pit in every operation period should be no more than on other enterprises of the same industry, that conduct mining operations both open and underground methods.

Therefore, the goal was to prove that economic overburden ratio is not constant, but changes over time and will significantly depend on the final depth of the open pit.

3 Results

Many calculation principles for determining the boundaries of the open pits are based on the condition - the allowable cost of ore mining (c_m) should be more or equal to the cost of ore mining in the designed open pit:

$$c_m \geq c_a,\ \text{UAH/t}. \qquad (1)$$

It should be noted that the allowable cost is the cost of ore of one of the basic mining companies-competitors with an open method of deposit development. Moreover, the allowable cost of ore is taken as it is at the time of designing a new open pit or reconstruction of an existing one.

The expected cost of ore for the designed open pit is calculated depending on the value of the overburden ratio (n_d) by the formula:

$$c_a = a + b \cdot n_d,\ \text{UAH/t}, \qquad (2)$$

where a – the cost of ore production without the overburden cost, UAH/t; b – overburden cost, UAH/m^3; n_d – overburden ration in the designed open pit, m^3/t.

After substituting the expected value of the cost of ore mining and transformation the inequality (1), formula (2) will take the following form:

$$\frac{c_a - a}{b} = n_d,\ \text{m}^3/\text{t}. \qquad (3)$$

The left part of expression (3) determines the value of the economic overburden ratio (n_e) and then, taking into account expressions (1, 2 and 3), we obtain the inequality

$$n_e \geq n_d,\ \text{m}^3/\text{t}. \qquad (4)$$

Based on the above mentioned, the condition of competitiveness of the designed open pit can be formulated as follows: the overburden ratio in the designed open pit should not exceed the economic overburden ratio, which takes into account the economic performance of the existing (base) company.

It should be noted that in the regulations providing the work of mining companies with an open method of development [27], the calculated economic overburden ratio to determine the final depth of the open pit is taken as a constant value. However, the basic enterprise-competitor continues its work, and its economic performance will change over time [28], in our case - the cost of ore. The reason for this is the change in the current overburden ratios upward or downward.

Consider the example of two conditional basic open-pits-competitors possible changes in current overburden ratios (Fig. 1 and 2).

Conditional basic open pit-competitor №1 develops ore deposit, in which: the incidence angle is 80°; horizontal width – 350 m; length – 2700 m. Open pit parameters: angle of inclination of the working side – 16°; the angle of inclination of the designed side – 45°; the final depth of the open pit is 630 m. It should be noted that in this open pit the surface boundaries have already approached the design position and further development of the open pit is carried out with the development of mining only in depth.

Conditional basic open pit-competitor № 2 (Fig. 2) develops an ore deposit in which: the incidence angle is 80°; horizontal width – 120 m; length – 4500 m. Parameters of this open pit: angle of inclination of the working side – 16°; the angle of inclination of the designed side – 45°; the final depth of the open pit is 345 m.

In the conditional base open pit-competitor № 2, in contrast to the considered conditional base open pit-competitor № 1, the boundaries on the surface have not yet approached the design position and further development of the open pit is carried out with the mining works development, both in the horizontal direction, and in depth.

In the figures 1 and 2, the numbers 0, 30, 60, 90, 120 indicate the steps of reduction of mining works in conventional base open pit-competitors every 30 m. The position of the working side of the open pit at step "0" characterizes the current state of mining works in the open pit and serves as a starting point for further research of their development.

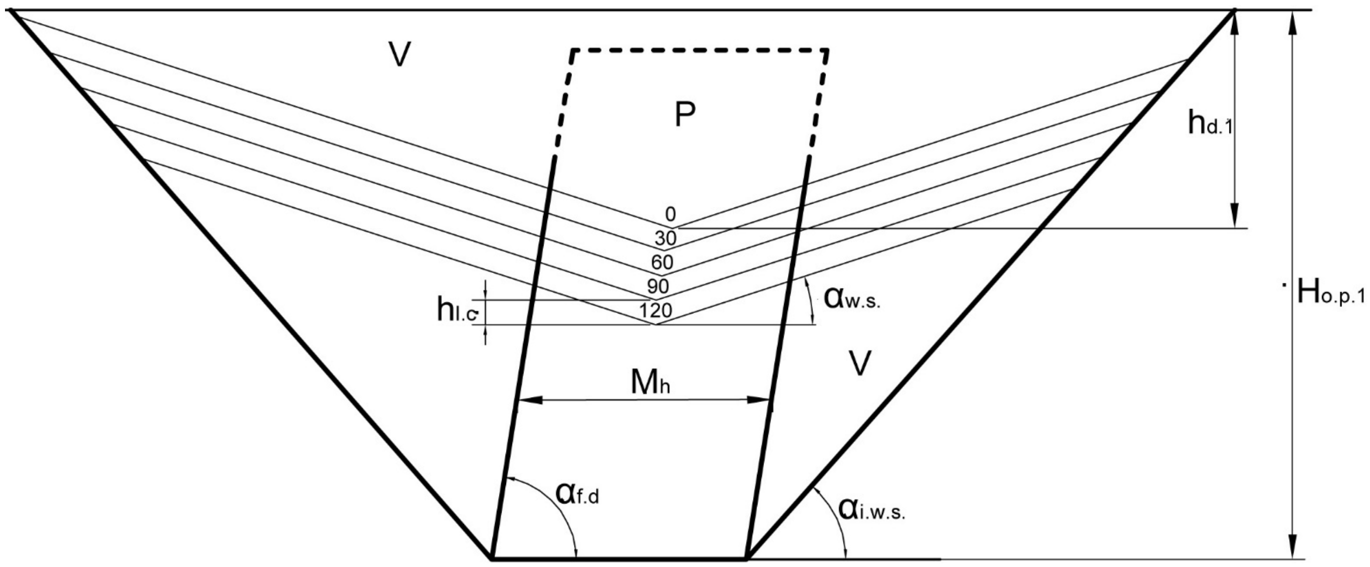

Fig. 1. Open pit-competitor № 1: V – overburden rocks; P – ore; $h_{d.1}$ – current depth of mining works; $h_{l.c.}$ – step of reduction of mining works; $\alpha_{w.s.}$ – angle of inclination of the working side of the open pit; $\alpha_{i.w.s}$ – angle of inclination of the designed side of the open pit; $\alpha_{f.d.}$ – incidence angle of ore deposit; M_{h1} – horizontal width of the deposit; $H_{o.p.1}$ – final depth of the open pit; 0, 30, 60, 90, 120 – step of reduction of mining works in the open pit.

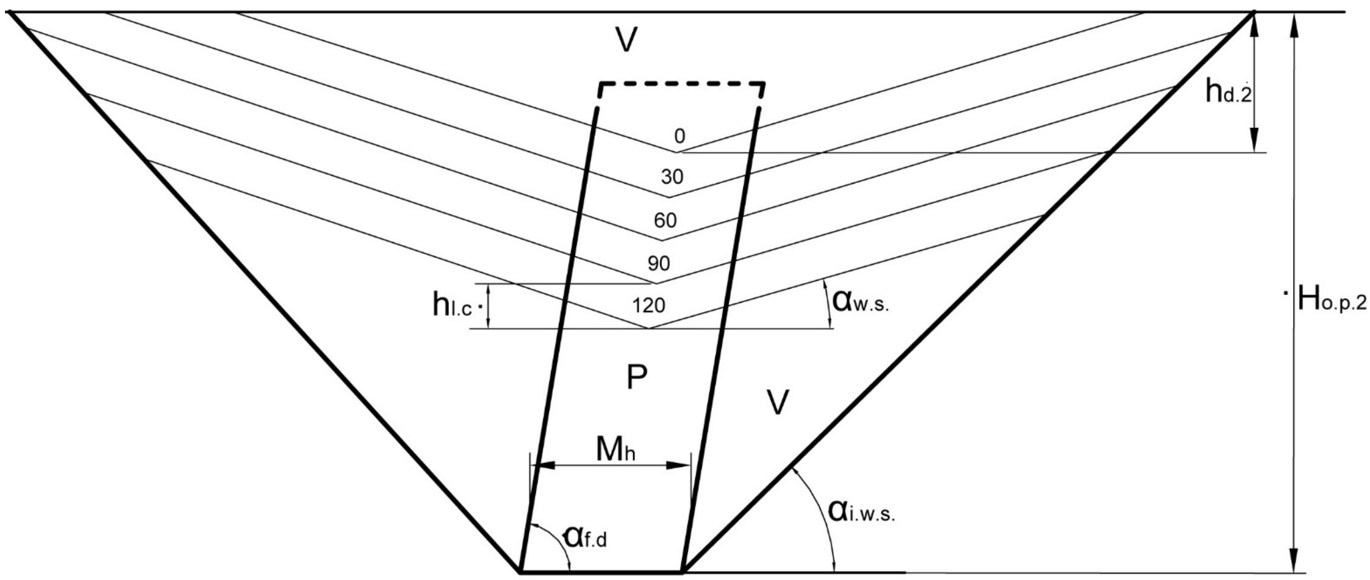

Fig. 2. Open pit-competitor № 2: V – overburden rocks; P – ore; $h_{d.2}$ – current depth of mining works; M_{h2} – horizontal width of the deposit; $H_{o.p.2}$ – final depth of the open pit.

The positions of the working sides of conventional base open pits-competitors at the zero step are selected so that the ore bodies were cut to full horizontal width, and the value of the current coefficients was the same as the value of the calculated economic overburden ratio.

When designing a new open pit, it is necessary to determine the prospective depth of opencast mining first: it will determine the boundaries of the open pit on the surface and the possible productivity of the open pit for minerals. The condition for determining the prospective boundaries of the designed open pit is to obtain economic indicators of the designed open pit not worse than the economic indicators of the existing open pits. This condition is written by inequality (4).

To determine the final depth of the future conditional (designed) open pit, a typical section of the deposit is selected in which: the incidence angle is 80°; horizontal width – 230 m; length – 3200 m. All open pits exploit the reserves of the same type of mineral with the same quality, and the existing technology allows them to work with relatively equal costs for extraction of one ton of overburden and mining of one ton of ore.

As on the conditional base open pits-competitors №1 and №2, and for the conditional open pit that is designed, from the position of the working sides at the zero step we rebuild their further position at the steps of mining development every 30 m in depth. At each step we determine the volumes of ore and overburden with the definition of the current overburden ratio, the results of the calculations are entered in Table 2.

Table 1. Volumes of ore and overburden, as well as current overburden ratio according to research options.

Deepening of the open pit, m	Conditional basic open pit № 1			Conditional basic open pit № 2			Conditional designed open pit		
	Ore, m^3	Overburden, m^3	Overburden ratio, m^3/m^3	Ore, m^3	Overburden, m^3	Overburden ratio, m^3/m^3	Ore, m^3	Overburden, m^3	Overburden ratio, m^3/m^3

For the designed open pit and basic operating open pits, we build a schedule of changes in the current overburden ratio according to the stages of reduction of mining works of conventional basic and conditional designed open pits (Fig. 3). Also we reconstruct on the graph the line of the calculated economic overburden ratio (line 1).

Based on the accepted mining and geological conditions of development of conditional deposits, the current overburden ratio in the further operation of the conditional base open pit №1 will decrease. In the further operation of the conditional base open pit №2, the current overburden ratio will increase until the design boundaries of the open pit on the surface are reached, and then gradually decrease. This change in the current overburden ratio is shown in Fig. 3 lines 2 and 3.

In these cases, the current overburden ratio of conditional base open pits №1 and №2 will be the cutoff ratio for the conditional (designed) open pit. If we calculate economic overburden ratio for the newly designed open pit without taking into account the time-varying current overburden ratio of the base open pits №1 and №2, as accepted for the present research, it will be constant, line 1 in Figure 3. Intersection of these lines (lines 1, 2, 3 in Fig. 3) with a line of current overburden ratio of the conditional open pit (designed) (line 4 in Fig. 3) gives the decision of definition of final depth of the given open pit mining.

As we can see from the presented graph (Fig. 3) for the conditional open pit (designed), there are three values of the final depth of its development:

– $H_{1d.o.p}$ – the final depth of the open pit, which is determined by a constant economic overburden ratio and is 560 m;

– $H_{2d.o.p.}$ – the final depth of the open pit, which is determined by the current overburden of the conditional base open pit №1 and is 485 m;

– $H_{3d.o.p}$ – the final depth of the open pit, which is determined by the current overburden ratio of the conditional base open pit №2 and is 800 m.

The graphical solution for determining the final depth of the conditional open pit (designed) is presented in Fig. 4.

From Fig. 3 and 4 we can see that the deviation of the final mining depth of the designed conditional open pit, which is determined on the basis of comparing its current overburden ratio with the current overburden ratio of conventional basic open pit-competitors, from the final mining depth determined by constant overburden ratio from 14 to 45%.

It follows from the above that to determine the boundaries of the designed open pit, the designed economic overburden ratio must be determined taking into account the possible change in the volume of overburden extraction and ore mining at basic enterprises-competitors, that means to take into account changes in their current overburden ratio.

To confirm this, the design data of the open pits of Kryvbas were analyzed, which are presented in Table 2. The clarity of the dynamics of the current overburden ratio reflects the presented graph in Figure 5.

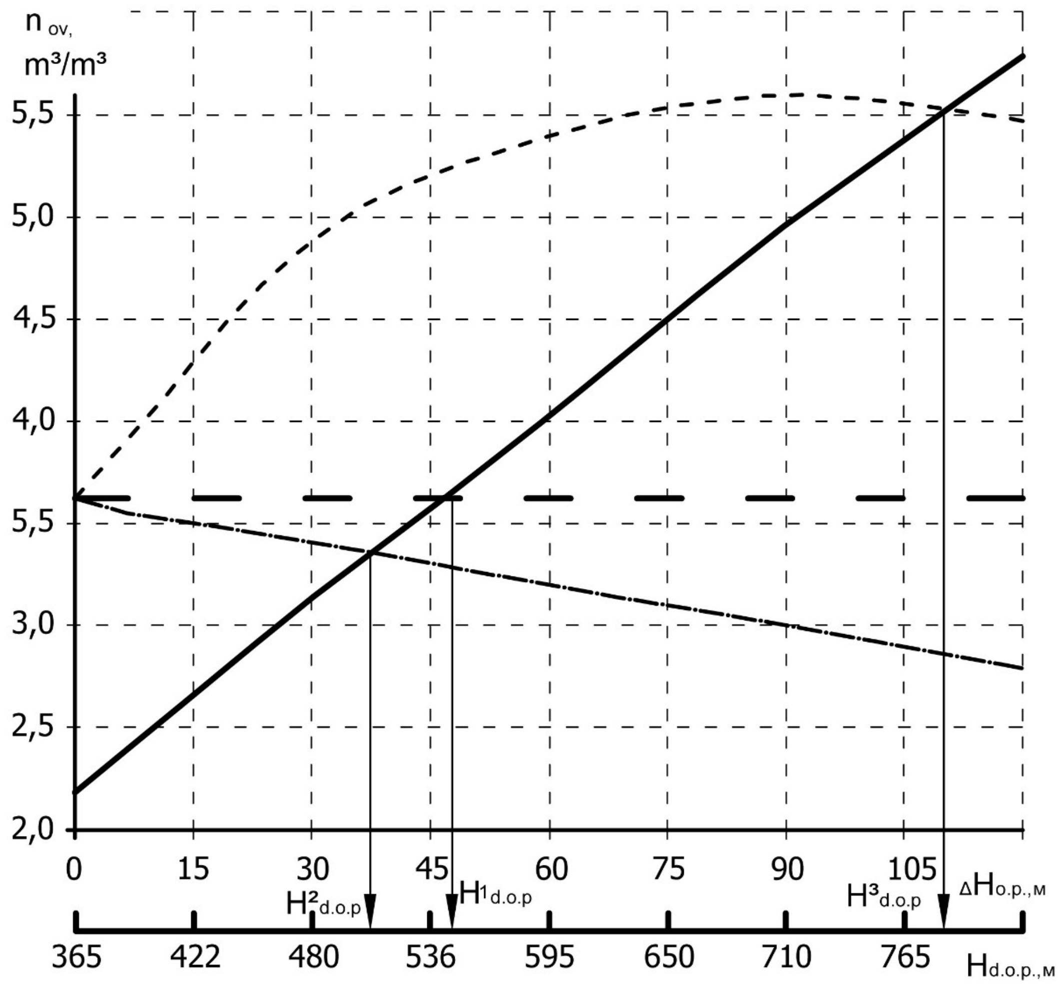

Fig. 3. Determination of the final depth mining of conditional open pit (designed): 1 – constant economic overburden ratio; 2 – current overburden ratio according to the conditional base open pit № 1; 3 – current overburden ratio according to the conditional base open pit № 2; 4 – current overburden ratio according to the conditional open pit (designed).

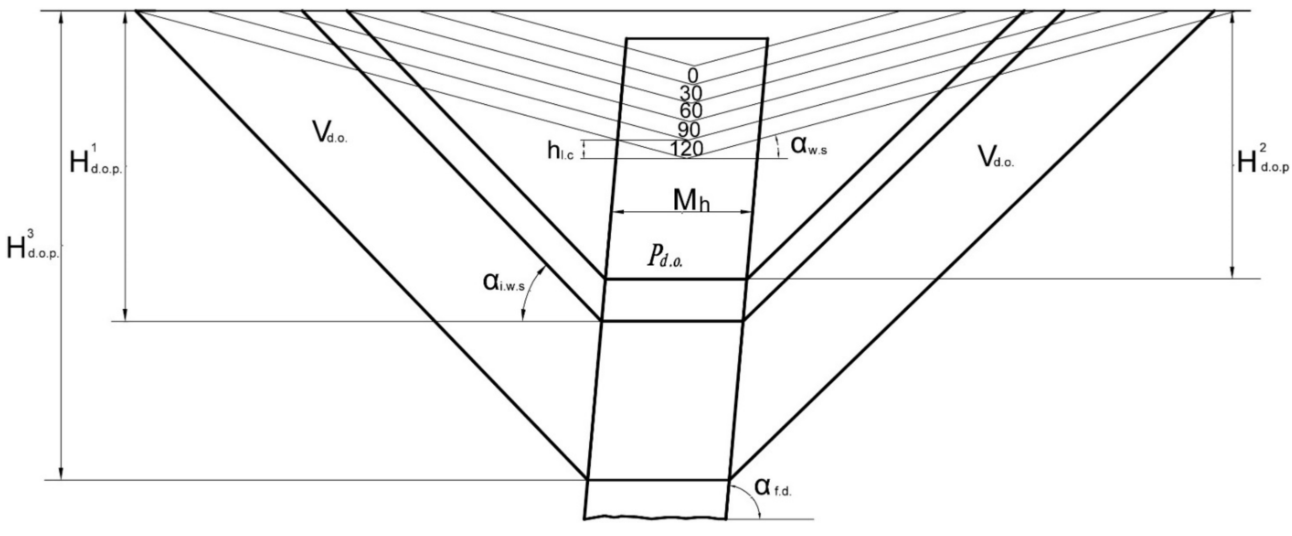

Fig. 4. Cross section of the deposit, that will be developed by the designed conditional open pit: $V_{d.o.}$ – overburden in the design contours of the open pit; $P_{d.o.}$ – ore in the design contours of the open pit; $H_{1d.o.p.}$ – the final depth of the open pit mining, which is determined by a constant economic overburden ratio; $H_{2d.o.p.}$ – the final depth of the open pit, which is determined by the current overburden ratio of the conditional basic open pit-competitor №1; $H_{3d.o.p.}$ – the final depth of the open pit, which is determined by the current overburden ratio of the conditional basic open pit-competitor №2.

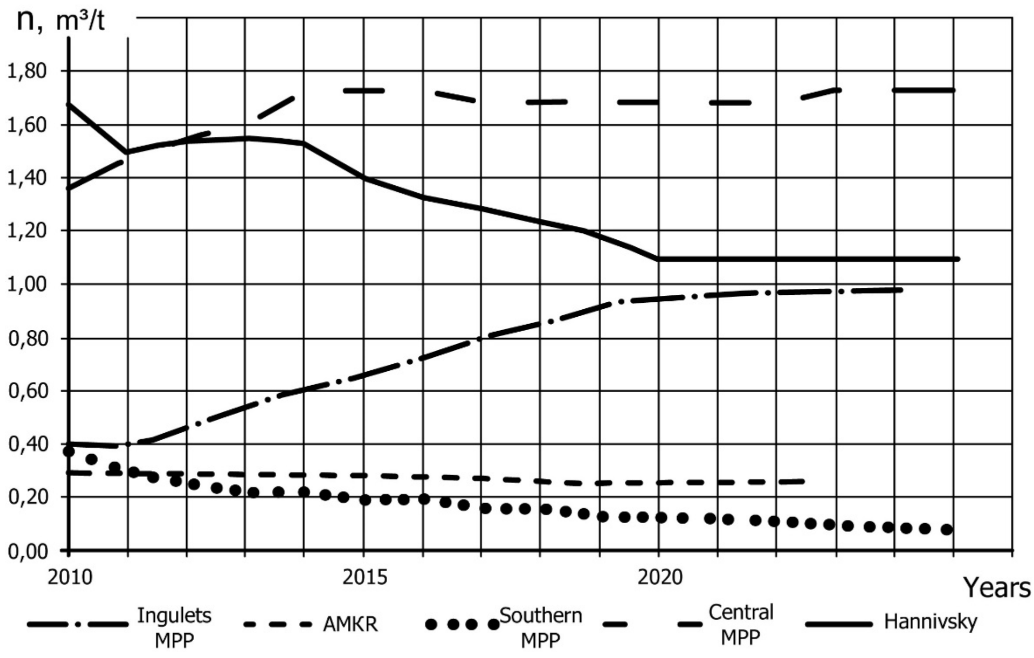

Fig. 5. Dynamics of the current overburden ratio on the open pits of Kryvbas on years of exploitation.

As we can see from the table, the current overburden ratios at the basic enterprises are changing over time. In addition, the indexes of every enterprise are open to different trends: they can grow, decrease or be relatively constant. It depends on whether the open pits have reached their contours on the surface, and whether the reconstruction or reactivation of the sides of open pits was carried on.

5 Conclusions

A new method for determining the final contours of mining the open pit has been developed, which differs from the known ones by taking into account the change in the economic overburden ratio in time, as well as determining the impact of technological indicators of open pits-competitors on the final depth of the designed open pit. It is proved that the deviation of the final depth of working of the designed conditional open pit, which is determined on the basis of comparing its current overburden ratio with the current overburden ratio of conventional basic open pits-competitors, from the final

Abstract. In this work, the problem of water inflow reduction in Ukrainian coal mines, which are distinguished by difficult hydrogeological conditions, was considered. A numerical study of the change in water inflow into a mine working when it crosses a tectonic fault was carried out. The cases when the permanent working was supported by frame supports and roof bolts were considered. The calculation of stress fields, zones with inelastic deformations and coefficients of permeability, which depend on the stress state and takes into account tectonic and natural permeability of the rocks, was performed. The results of calculating the water pressure and water inflow into the mine working in all considered cases are presented in the article. Analysis of the calculated data showed that a disturbed area, which covered water-bearing ricks, was formed in the roof of the mine working with the frame support. Within this area, water can move towards the contour of the mine working. The filtration permeability of the host rocks increases significantly when the mine face approaches the tectonic disturbance. The flow rate of water reaches critical values. The use of roof bolting restrains the unloading of the boundary rocks from the rock pressure and keeps them in a triaxially compressed stress state. The permeability value decreases by the value of its technological component. In different areas of the intersection of tectonic disturbance, the water inflow into the mine working with roof bolting is 3-8 times less than in the working, supported by frame supports. Therefore, the use of roof bolting allows not only to keep the mine working in a stable state, but also to significantly reduce water inflows at complicated hydrogeological conditions.

1 Introduction

Ukrainian coal mines are notable for complicated geological conditions due to the great number of tectonic disturbances and flooded rocks. Different forms of geological structures, both plicate and disjunctive, characterize Donbas. Most of the Donbas coal mines are concentrated in large synclinal folds [1]. There is a failure of rocks integrity and an increase in their permeability in zones of local folding [2]. Permeability of rocks reaches its maximum in areas with the highest concentration of tectonic stresses [3]. Type and forming conditions of the faults determine their influence on the filtration properties of rocks. If joint fissures are formed under conditions of stretching of the earth's crust (mainly faults), then they increase permeability of the coal-bearing deposits in the zone adjacent to the fault [4].

The hydrogeological structure of the Western Donbas is a system of aquifers and complexes that cover the entire sedimentary layer and the upper part of the fractured zone of crystalline rocks. The total thickness of the flooded rocks ranges from 20 m to 1660 m and more, and it increases in the direction of rocks deepening to the axis of the Dnipro-Donetsk trough [5]. Water inflow into the mine workings mainly depends on the features of the geological structure of the mine fields and particularly on the tectonic disturbance of rocks, the number of aquifers, their thickness, pressure and filtration permeability [5-7]. For example, water production in the N.I. Stashkov Mine (the most water-flooded one in the Western Donbas) is 1640 m^3/h. When the edge rocks are flooded, they become soaked and their strength decreases. This leads to a loss of workings stability and requires additional finance for water extraction and supporting of mine workings [8-9].

In recent years, the researchers of the Institute of Geotechnical Mechanics named by N. Poljakov have done a lot of work to improve the roof bolting technology [10, 11]. The modified technology makes it possible to preserve the enclosing rocks in their natural, monolithic state and ensure reliable and safe functioning of mine workings throughout their operation [12]. The experience of coal production shows that technological operations can influence on filtration processes in the disturbed zone of the rock mass [13]. So, the use of roof bolting allows to prevent the process of crack formation in zone of the mine working influence and to reduce intensity of filtration flow [14-16].

* Corresponding author: igtm@ukr.net

In this article, the authors consider a possibility to use roof bolting in the mine workings in order to reduce water inflows from the undermined water-bearing rocks when crossing tectonic faults.

2 Methods and problem definition

Deformation of the coal-rock massif can be described by the equation:

$$c_g \frac{\partial u_i}{\partial t} = \sigma_{ij,j} + X_i(t) + P_i(t)\,, \tag{1}$$

where u_i is displacements, m; c_g is the damping coefficient, kg/(m^3·s); $\sigma_{ij,j}$ are the derivatives of the stress tensor components along x, y, Pa/m; t is time, s; $X_i(t)$ is projections of the external forces acting on the volume unit of solid body, N/m^3; $P_i(t)$ is projections of forces caused by gas pressure in the porous fractured space, N/m^3.

Deformation of rocks during mining operations leads to a change in their filtration permeability [17-20]. The change in the values of the permeability coefficients depending on the components of the principal stress tensor can be described as follows:

$$k_{tech} = f(\sigma_{ij}), \tag{2}$$

where k_{tech} is coefficient of permeability, which depends on the mine working driving, D; $f(\sigma_{ij})$ is a function which the authors defined in the work [19].

The process of water filtration in disturbed rocks is described by the following equation:

$$\frac{\partial p}{\partial t} = \frac{K}{\mu \cdot \beta \cdot m_p}\left(\frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial y^2}\right) + q(t)\,, \tag{3}$$

where p is the water pressure, Pa; K is the permeability coefficient, D; μ is water viscosity, Pa·s; β is water-compressibility factor, 1/Pa; $q(t)$ is the water release function.

The coal and rocks are ground and have an initial tectonic permeability on 10-20 m from both sides of the fault. Some rock layers are also initially permeable and they have permeability k_{nat}. Technological permeability k_{tech}, which is formed during the mine working driving and depends on the stress tensor components, is superimposed on the tectonic k_{tect} and natural k_{nat} permeability fields:

$$K = k_{tech} + k_{tect} + k_{nat}. \tag{4}$$

As an example, let's consider a longitudinal section of a permanent working of 4 m high, which is driven at complicated conditions, similar to the conditions of the eastern main entry of the N.I. Stashkov Mine. There is a watered fractured coal band with a thickness of 0.4 m and watered sandstone with a thickness of 2.2 m in the mine roof. There is watered sandstone with a thickness of 0.8 m in the mine face. The permanent working intersects a disjunctive tectonic fault with displacement amplitude of 1 m.

The central fragment of the finite element mesh for this problem is shown in Figure 1.

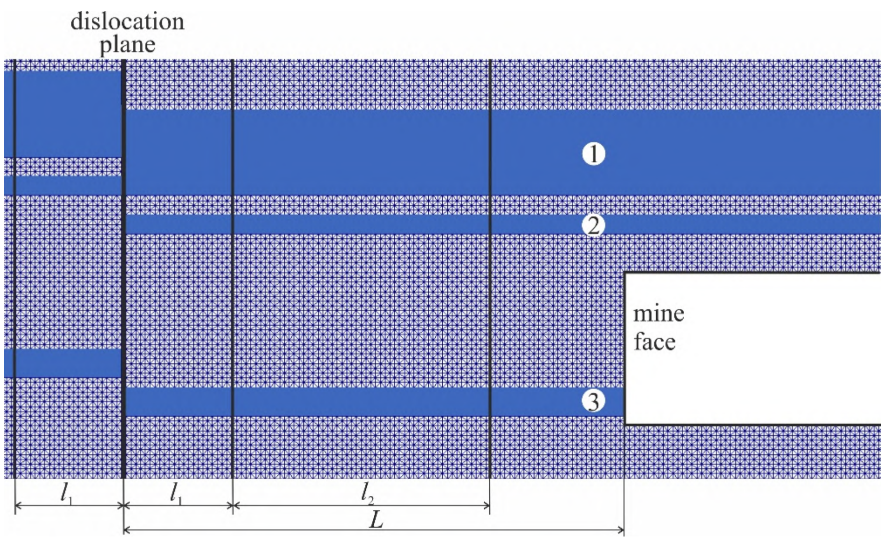

Fig. 1. The central fragment of the finite element mesh: 1, 3 – the watered sandstones; 2 – the watered fractured coal band.

The initial and boundary conditions for the task set:

$$\begin{gathered} \sigma_{yy}\big|_{t=0} = \gamma H; \quad \sigma_{xx}\big|_{t=0} = \lambda\gamma H; \\ u_x\big|_{\Omega_1} = 0; \quad u_y\big|_{\Omega_2} = 0; \\ p\big|_{\Omega_3} = 0.1\ \text{MPa}\,; \quad p\big|_{\Omega_3, t=0} = p_0\,, \end{gathered} \tag{5}$$

where σ_{xx}, σ_{yy} are components of the stress tensor, Pa; γ is the average weight of the overlying mine rocks, N/m^3; H is the mining depth, m; λ is the side thrust coefficient; u_x, u_y are components of the displacement vector, m; Ω_1 is vertical boundaries of the outer contour; Ω_2 is horizontal boundaries of the outer contour; Ω_3 is the contour of the permanent working; Ω_4 are the watered sandstones and coal seam; p_0 is the water pressure in the virgin massif, Pa.

The finite element method is widely used to solve geomechanics problems [21-23]. It is a powerful tool for simulating the coupled processes in rocks during mining operations. We solve the problems (1)-(4) with initial and boundary conditions (5) by the finite element method in the elastoplastic formulation by using the Coulomb-Mohr strength condition. To analyze the stress state of the rock massif, we use parameter $Q^* = (\sigma_1 - \sigma_3) / \gamma H$. This parameter characterizes diversity of the stresses field components.

We assumed that initial permeability of the watered sandstones is 0.002 mDa, initial permeability of the watered coal band is 0.005 mDa; permeability in the area l_1 = 3 m from displacement plane is 0.5 mDa; in the area l_2 = 7 m is 0.1 mDa; p_0 =3.5 MPa. Let's consider the cases when permanent working is supported by the frame support and roof bolting, and its face is located at different distance L (Figure 1) from the tectonic fault:

a) L = 12 m, $L > l_1 + l_2$, the permanent working is outside the influence of tectonic fault;

b) L = 7 m, $l_1 < L < l_1 + l_2$, the permanent working is in the slightly disturbed area;

c) L = 1 m, $L < l_1$, the permanent working is located in the most disturbed zone of tectonic fault.

3 Results and discussion

3.1 The stress state of the host rocks

As a result of the modeling, fields of stresses and zones of inelastic deformations were obtained, Figure 2.

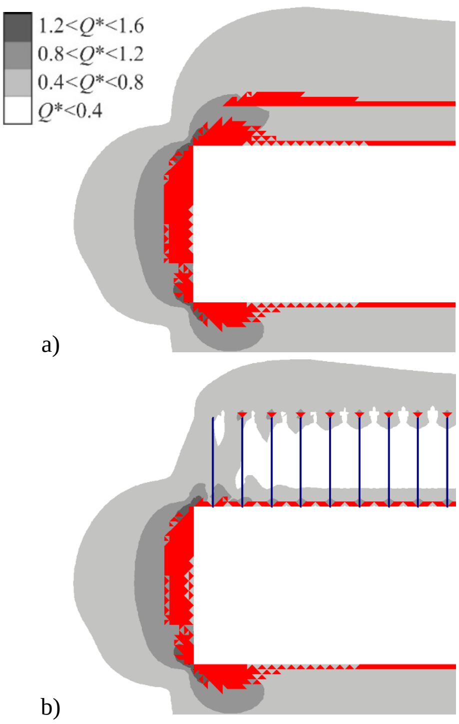

Fig. 2. The distribution of parameter Q^* values and inelastic deformation zones: a – the permanent working with frames; b – with roof bolting.

Hereinafter, the calculation results are given for t = 1 day after the mine face movement.

The Figure 2 shows that area of increased diversity of the stress field components is formed around the mine working. Single defects, not interacting between each other, are accumulated in zone where $0.4 < Q^* < 0.8$. In areas where $0.8 < Q^* < 1.2$, the process of intense cracking develops. Here, uncontrolled growth of cracks takes place, and deformations rapidly increase due to the propagation of cracks and loosening of the rock [24]. Zone of inelastic deformation (is shown in red) surrounds the permanent working contour, hence, indicating the destruction of rocks.

In the mine roof with frame support (Figure 2 a), the disturbed zone includes both coal band and sandstone. Here, weak coal band is completely destroyed.

When using roof bolting (Figure 2 b), zone of inelastic deformations is significantly reduced in boundary rocks of the roof and completely disappears in the coal band. In the anchored area, rocks and bolts form a slab, where $Q^* < 0.4$. Here, both the rocks and the weak coal band are in a triaxially compressed state that keeps them from destruction.

3.2. Filtration permeability of the host rocks

The results of the permeability coefficient calculation are shown in Figures 3 and 4. In these figures, we can see dark zones of tectonic permeability and lighter zones of natural permeability in water-flooded sandstones and coal band.

A filtration area up to 2.4 m deep is formed in the mine roof with frame support (Figure 3) to where the watered coal band enters completely and sandstone enters partially. Inside this filtration area, water can move towards the contour of the mine. When the working face approaches the disjunctive disturbance, Figures 3 b and 3 c, it moves into the zone of disturbed rocks, which stratify easily and are destructed during undermining. The bearer support is not able to suppress this process, and filtration permeability is significantly increases in this zone.

Contours of the filtration area are changed when bolts are installed in the mine roof, Figure 4. The use of roof bolting restrains the unloading of the boundary rocks from the rock pressure and keeps them in a triaxially compressed stress state. Therefore, in all cases of the mine face location relative to the tectonic fault plane, the resulting permeability K decreases by the value of its technological component.

Outside of the influence of the tectonic fault (Figure 4 a), depth of permeable zone in the mine roof is reduced by 7-8 times in comparison with the same zone in Figure 3 a. The impermeable rock-bolt slab is preserved between the watered layers and the roof of the permanent working. As a result, the process of water filtration from aquifers into the mine working is inhibited.

In disturbed zone near the fault, action of the steel-polymer bolts only is not sufficient to form an impermeable slab. For this purpose, injection anchors, for example, could be used here. However, in the roof of the permanent working with roof bolting (Figures 4 b and

 https://doi.org/10.1051/e3sconf/202128001006

4 c), the permeability is significantly lower than in zone with the frame support (Figures 3 b and 3 c), which should reduce water inflow into the mine working in the hazardous zone.

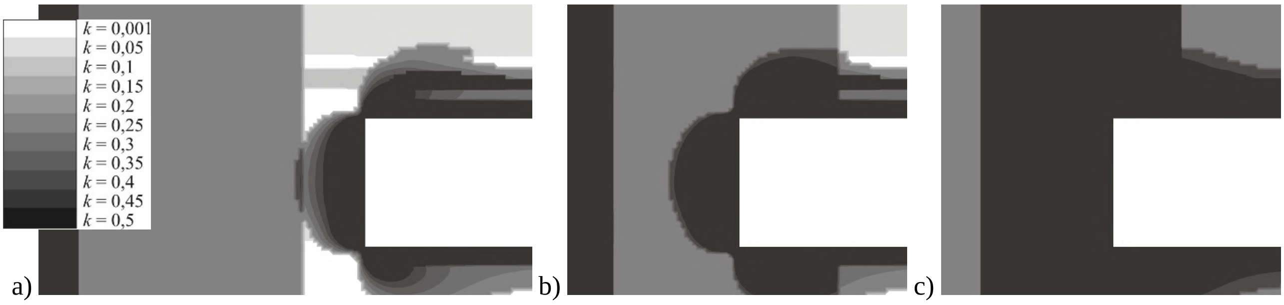

Fig. 3. The distribution of permeability coefficients around the permanent working with frame support: a) L = 12 m, permanent working is outside of the fault influence; b) L = 7 m; c) L = 1 m.

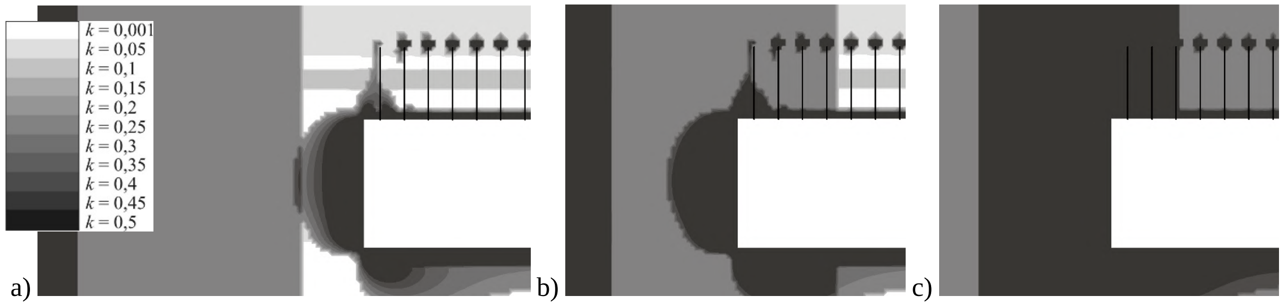

Fig. 4. The distribution of permeability coefficients around the permanent working with roof bolting: a) L = 12 m, permanent working is outside of the fault influence; b) L = 7 m; c) L = 1 m.

3.3 Analysis of changes in filtration parameters

The distribution of water pressure values are shown in Figures 5 and 6. It can be seen that water pressure in the watered beds near the fault is significantly reduced as compared with formation pressure, Figures 5 b and 6 b. As practical experience shows, the increased permeability of rocks in zones of tectonic faults causes the movement of deep pressured water along the plane of displacement in the vertical direction.

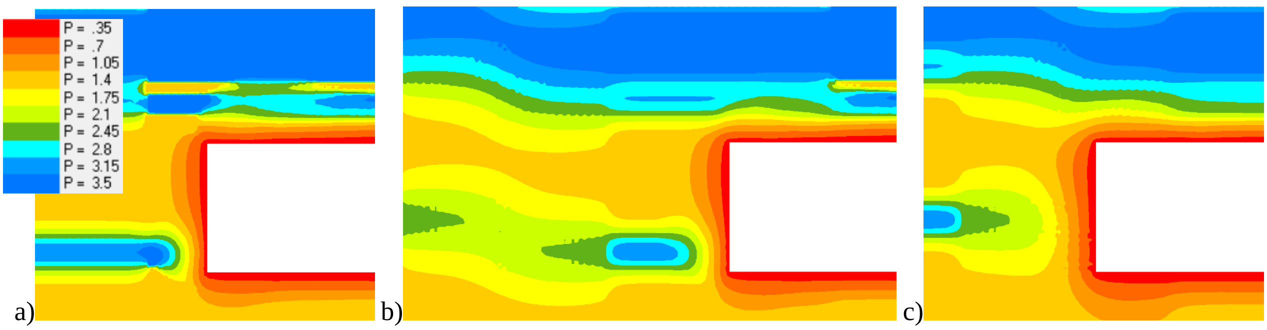

Fig. 5. Water pressure; permanent working with frame support: a) L = 12 m; b) L = 7 m; c) L = 1 m.

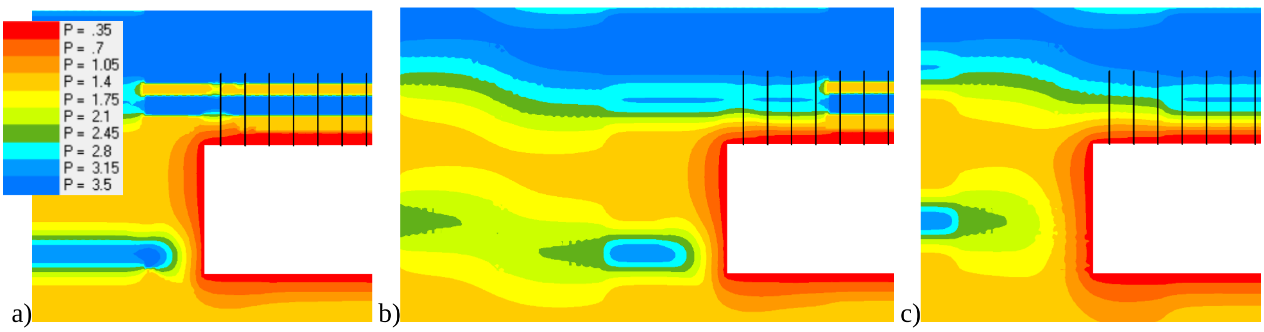

Fig. 6. Water pressure; permanent working with roof bolting: a) L = 12 m; b) L = 7 m; c) L = 1 m.

In the mine roof with frame support, the process of water filtration is actively taking place both outside the disturbed zone and near the tectonic fault. Water pressure in the undermined watered coal band and in part of sandstone decreases, Figure 5. Water moves from areas with higher pressure to the mine working where the pressure is minimal. When the mine face approaches the fault and enters the disturbed zone, the intensity of the filtration process increases, Figures 5 b and 5 c. The water inflow into the permanent working from the roof is doubled, Figure 7, and from the watered sandstone in the mine face increases by 1.5 times, Figure 8.

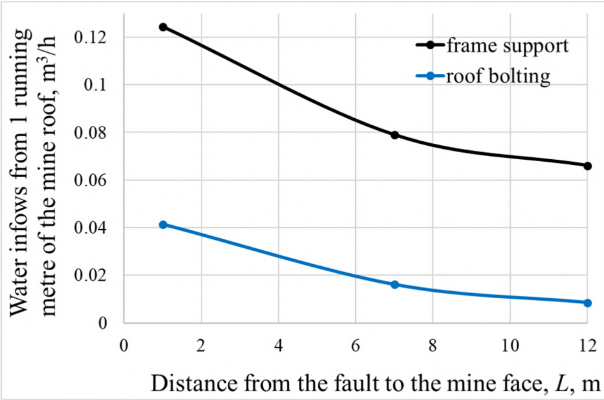

Fig. 7. Water inflow from the undermined roof rocks (per 1 running meter of permanent working).

If the roof bolting is used, the coal band pressure and sandstone pressure practically do not change in the mine roof, in the area outside the zone of influence of tectonic disturbance, Figure 6 a. This indicates a significant decrease in the intensity of the filtration process. The water inflow from the roof into the anchored mine working is almost 8 times less than into the mine working with frame supports, Figure 7. We can assert that outside the zone of fault influence, the impermeable rock-bolt slab in the roof reduces water inflow into the mine working to a minimum.

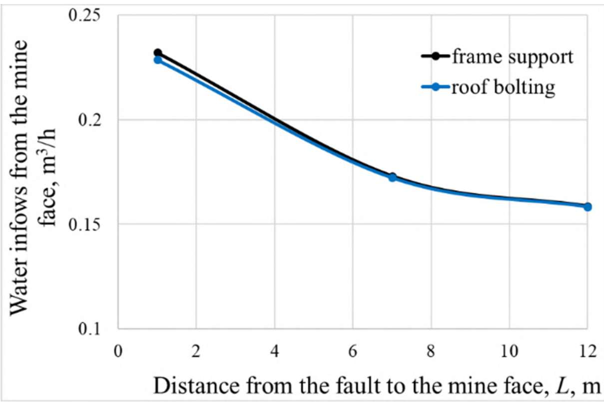

Fig. 8. Water inflow from the mine face.

When the mine face approaches the tectonic fault, where the roof rocks have already been disturbed as a result of tectonic impact, the roof bolts can only reduce the value of the filtration permeability by the value of k_{tech}. However, this is sufficient to reduce the water inflow by 5 times at L = 7 m and by 3 times at L = 1 m, Figure 7.

The water flow rate from the watered sandstone in the mine working face increases by 1.5 times when it approaches the fault and does not depend on the kind of roof supporting, Figure 8.

Roof bolting in mine workings at difficult hydrogeological conditions, when they cross tectonic faults, allows to reduce permeability of tectonically disturbed host rocks, slow down the water filtration process and reduce water inflow from the undermined watered rocks into the mine workings by 3-5 times. Outside the zone of disturbance influence, an impermeable rock-bolt slab in the mine roof stops water inflow into the mine working almost completely.

4 Conclusions

The problem of water inflow reduction in Ukrainian coal mines, which are distinguished by difficult hydrogeological conditions, was considered. A numerical study of the change in water inflow into the mine working when it crosses a tectonic fault was carried out. The cases when permanent working was supported with frame supports and roof bolts were considered.

Stress fields, zones of inelastic deformations and permeability coefficients, which depended on the stress state and took into account tectonic and natural permeability of rocks, were calculated. The results of calculation of water pressure and water inflow into the mine working in all considered cases are presented.

Analysis of the calculated data shows that filtration area, which covers water-bearing rocks, is formed in the roof of the mine working with frame support. Within this area, water can move towards the contour of the mine working. Filtration permeability of the host rocks increases significantly when the mine face approaches the tectonic disturbance. The flow rate of water reaches critical values.

The use of roof bolting restrains the unloading of the boundary rocks from the rock pressure and keeps them in triaxially compressed stress state. Permeability value decreases by the value of its technological component. In different areas of the intersection of tectonic disturbance, water inflow into the mine working with roof bolting is 3-8 times less than in the working with the frame supports. Therefore, the use of roof bolting allows not only to keep the mine working in a stable state, but also to significantly reduce water inflows at complicated hydrogeological conditions.

Abstract. This paper deals with two relevant and interrelated directions of coal mining development. Firstly, the resource-saving complete extraction of reserves, and secondly, the intensification of mining activity through mining operations conducted on several seams. The objective of overworking of mine workings with a real representation of mining-and-geological and mining-engineering conditions has been formulated. Five peculiarities of the geomechanical models construction for overworking of mine works have been revealed and substantiated. The technology for performing a series of computational experiments is proposed. The task of the protecting pillar influence, which is located in overlying coal seam, on the state of mine working placed in the underlying coal seam has been solved. An optimal scheme for its maintenance is proposed.

1 Introduction

The research purpose relevance is conditioned by the necessity for geomechanical substantiation of various engineering decisions in mining the series of strata based on two main directions of coal mining development: resource-saving complete extraction of reserves due to their partial preparation in favourable mining-geological and mining-engineering conditions; intensification of mining activity through mining operations conducted simultaneously on several seams.

The term “complete extraction of reserves” means the extraction of various types of protecting pillars on the overlying horizons remaining after the transition of mining operations to the underlying horizons. These protecting pillars are to some extent delineated by mine workings, in which, from one side, a mined-out space (after the stope works of previous periods) with a consolidated massif of previously collapsed rocks is located. The mechanical properties of such rocks are essentially different from the holistic massif, which, according to studies [1-5], leads to the “smoothing” of stresses, their more uniform distribution, which increases the stability of the noted delineating mine workings. Moreover, when mining protecting pillars, new anomalies of rock pressure will have a reduced intensity of action due to the damping properties of previously collapsed and consolidated rocks. The above trends as a whole contribute to lowering the costs for maintaining the mine workings delineating the pillar, if there is a necessity for their further use according to the mining plan. This is confirmed by a number of studies [6-9].

The technology of two or three coal seams joint mining has more widespread experience in practical implementation, for example, in the Western Donbas. This is conditioned by a motivation to radically increase the stope works intensity with the corresponding technical-and-economic benefits [10-16].

2 Problem statement and solution

Both resource-saving coal mining trends in terms of the parameters substantiation suggest the development of geomechanical models that differ by sufficient complexity and multifactority. Most mining-engineering situations under study require the spatial models construction in order to reflect mine workings network which includes, as a rule, stope and preparatory mine workings, having a mutually perpendicular direction. This is the first peculiarity of this class of problems.

The second peculiarity is the significant dimensions of geomechanical models, in which to achieve the required level of their adequacy and reliability of the results obtained, the following should be reflected:

– in a direction perpendicular to the longwall face length (it is denoted by the coordinate X), the frontal bearing pressure zone ahead of the stope face and the unloading zone behind it at distances that provide attenuation (or stabilization) of the stress-strain state components (SSS) to the level of the permissible error of their deviations; according to this condition, the considered direction should be not less than $X = 120 – 150$ m;

– in a direction parallel to the longwall face length

* Corresponding author: kovalevska_i@yahoo.com

(coordinate Z), at least half of its length should be placed, extraction mine working and part of the massif in the side opposite to the stope face to a width, which ensures the SSS components stabilization in the area of the model vertical bound; the massif texture is not essential here – holistic or collapsed and consolidated rocks; the fulfilment of such a condition implies a model size not less than 150 – 180 m, taking into account sufficiently symmetrical initial and borderline conditions relative to the axis X located in the centre of the longwall face length, since with significant asymmetry the size Z will have to be doubled;

– the model height (coordinate Y) should be chosen according to the reflection condition (with a certain margin) of all characteristic zones of rock pressure anomalies and the related texture transformations of the surrounding rock massif; in the coal seam roof, the model height should corresponds to the height of the frontal bearing pressure zone ahead of the longwall face with at least one-and-a-half margin for various SSS distortions types, conditioned by the vertical geostatic load application; behind the longwall face, in the mined-out space, three characteristic zones should be placed [2, 7, 18]: uncontrolled collapse, hinged-block displacement and smooth deflection of layers without discontinuity; in the seam bottom, also with a one-and-a-half fold margin, the zones of frontal bearing pressure and unloading are provided; meeting these conditions usually requires a model height of at least 60 – 80 m; when modelling the joint mining of several coal seams, the height Y should include all of the above elements for the upper seam in the roof and the lower seam in the bottom, plus the thickness of partings; here it is necessary to choose a height Y for each specific case, but it definitely increases by 2 times or more.

The third peculiarity of the considered group of geomechanics tasks is the necessity to represent the mining operations consequences for the previous periods – it mainly relates to the development of previously left protecting pillars. Here it is necessary to take into account the parameters of residual rock pressure anomalies acting in the borders of the protecting pillars and the areas of the mined-out space contacting with them together with the delineating mine workings.

Existing studies [1, 2, 19-23], note a tendency toward a decrease in the activity of the rock pressure anomalies action over time t that has passed since the end of the stope works. The parameters of anomalies in the borders of the protecting pillars substantially depend on the rheological phenomena of creep deformations and stresses relaxation; but there is one more important factor here – the process of shrinkage (consolidation) of previously collapsed rocks in the mined-out space under the geostatic pressure action. Experimental research on the process of rocks shrinkage in the uncontrolled collapse zone in the Western Donbas [19] show the development of this process to 45 – 55% of the initial height; at the same time, the resistance of consolidated rocks can increase to 10 – 15 MPa, which approximately corresponds to 40 – 60% of the compressive resistance of argillite and siltstones of the Western Donbas in the holistic state. Relative to the deformation modulus of collapsed and consolidated rocks, then (in accordance with experimental data) it increases from 5 – 10 MPa in the initial stage of consolidation to 100 – 300 MPa in the final stage of shrinkage development.

Thus, massif of collapsed and consolidated rocks over time t becomes more rigid and more actively resists to the geostatic load. In qualitative terms, the tendencies in the influence of rheology and consolidation factors of collapsed rocks are shown in the scheme of Figure 1. Thus, at the end of the previous period of coal extraction (formation of a protecting pillar $t = t_1$), the vertical geostatic pressure σ_y distribution corresponds to traditional concepts: from the side of the pillar, there is a lateral bearing pressure zone with concentration σ_y of at least several units from the initial state $\sigma_y = \gamma H$ of virgin massif (where γ – weight-average unit specific gravity of rocks to depth H of the pillar location). Above the mine working and from the side of the mined-out space, the component σ_y sharply decreases with its gradual growth in the depth of the uncontrolled collapse zone. Then, over time ($t = t_2 > t_1$), the concentrations σ_y in the border of the protecting pillar decrease, and from the side of the mined-out space σ_y grows near mine working due to the collapsed rocks consolidation and an increase in their resistance to the vertical rock pressure. After a long period of time ($t = t_3 > t_2$), usually calculated in years, the process of the so-called collapsed rocks consolidation is stabilized repulsing the rock pressure at the level of about half of the holistic rocks compressive resistance in the coal seam roof. This is usually quite enough to reach the initial state of virgin massif $\sigma_y = \gamma H$: from the side of a pillar, the concentrations σ_y in the larger zone of the lateral bearing pressure are maximally reduced, and from the side of the mined-out space, small concentrations σ_y are formed near mine working (a kind of lateral bearing pressure zone). In general, rock pressure anomalies are “smoothed”, which contributes to the increase in stability of delineating mine workings.

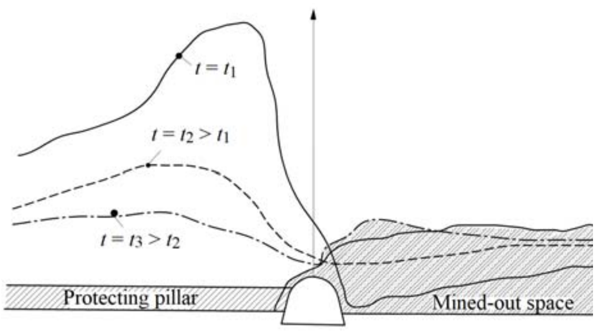

Fig. 1. Change in time t of the vertical stresses σ_y distribution near the border of the protecting pillar.

Such a mechanism for converting rock pressure anomalies after previous periods of stope works is expedient to be reflected in the geomechanical model at the last stage, that is, after a long period of time when the protecting pillar mining is planned. This process is taken into account by changing the mechanical characteristics of collapsed and consolidated rocks in accordance with their behaviour over a long period of time after disintegration. In the first approximation, for the Western

Donbas conditions, it is recommended to accept the following mechanical characteristics of collapsed and consolidated rocks:

– compressive resistance σ_{compr} in the range of 40 – 60% of that for the holistic lithotype state;

– tensile strength σ_{str} is practically absent; for unambiguous calculation procedure, $\sigma_{str} \leq 0.1$ MPa can be accepted;

– deformation modulus E_d is accepted in the range of 5 – 10% of the value for the holistic lithotype.

The fourth peculiarity of the studied geomechanical problems class is the necessity to take into account the texture transformations of the adjacent rocks of the main roof (the so-called hinged-block displacement zone) that have occurred above the uncontrolled collapse zone in previous periods of stope works. Texture transformations in the hinged-block displacement zone signify the development (in the process of roof rock layers bending) of a system of predominantly vertically directed fractures that divide the lithotype into a series of rock blocks, from which a kind of thrust system is formed. It can lose stability at a certain value of the rock layer deflection, and, when the flexure strains are restricted (by means of a bearing from the side of underlying massif), this thrust-block system has a significant load-bearing capacity and actively resists to geostatic vertical rock pressure. The formation mechanism of thrust systems constituting the hinged-block displacement zone is described in sufficient detail in the works [19, 24-28], and the adequate reflection of this zone in models of this class of geomechanics problems is of great interest for us.

The importance of adequate hinged-block displacement zone modelling is determined by its significant influence on the displacement processes in the coal-overlaying formation both in the course of stope works and when maintaining the extraction mine workings (in case of the operational necessity) behind the stope face. The texture transformations in the studied zone lead to a sharp increase in the flexure strains of the thrust system as a whole without a significant change in the mechanical properties of the lithotype within the rock block itself; this is the fundamental difference of changes in the behaviour and properties of rocks and, for example, the zone of uncontrolled collapse.

Techniques for modelling the hinged-block displacement zone are as follows. Within the zone thickness, there is a differentiated division of each rock layer into blocks. The most reliable prediction of the zone thickness is expedient on the basis of stability analysis of the main roof rock layers with the use of mining-and-geological sections in the area of location, for example, of protecting pillars, as well as a gained experience in the stope works operations on this coal seam or series of strata. As a rule, the hinged-block displacement zone is propagated (in the Western Donbas conditions) to a height of 10 – 15 m and most often its top border is a very thin coal seam or interlayer, which has virtually no adhesion to either the overlying or underlying lithotypes. Thus, the thickness of the hinged-block displacement zone is assessed in each specific mining-engineering situation, but with the obligatory consideration of the weakening factors, such as water cut and fracturing which actively influence on the lithotypes stability.

On the practical level, each rock layer is being broken up into a number of blocks by tension cracks simulators, on the surfaces of which adhesion is completely absent, and the interaction of the blocks with each other is performed due to normal forces and shearing friction stresses. By means of this geometric construction, the adequacy is ensured of the process of thrusting the rock blocks due to the possibility of their repetition relative to each other: when maintaining the previous mechanical characteristics within the rock block, an increased deformability of the thrust system is realized at a level ten times higher than the flexure strain (without destruction) of the holistic rock layer.

The question remains relative to the geometrical parameters of the hinged-block displacement zone, which are recommended on the basis of existing concepts on the mechanism of the rocks displacement in the coal-overlaying formation with specification for the Western Donbas conditions in accordance with studies [19, 24-28]. To clarify the geometric parameters substantiation, the schemes are presented in Figure 2 of the hinged-block displacement zone propagation in two mutually perpendicular directions, for example, along the strike and to the dip (rise) of a coal seam. In the coal pillar cross section (along the strike of the seam), the hinged-block displacement zone is propagated to its depth by 12 – 20 m and blocks in each rock layer should be modelled over this distance. From the side of the mined-out space (previous periods of stope works operation), the hinged-block displacement zone is constantly present, but stabilization of the SSS components distribution occurs, as a rule, at a distance of 15 – 20 m due to the significant deformability of the thrust-block systems; therefore, with some margin, it is recommended to accept $Z = 25 – 30$ m.

The blocks dimensions along the strike in each layer are different, and their value is partially chosen arbitrarily, based on the tendency: the greater the lithotype thickness, the more it is resistant to bending loads and is able to form rock cantilevers with an increased length. Moreover, the blocks length can be substantiated using a two-staged modelling technology [29, 30]: at the first stage, the SSS of holistic layers is studied and the areas of destructive stresses concentrations impact are determined, where the layer is most likely to be divided into blocks; at the second stage, the SSS of an already block system of all layers is calculated according to the thickness of the hinged-block displacement zone. However, this approach also has some uncertainty, since the curves of the SSS components distribution are changed quite smoothly. Hence, it is difficult to set (according to various criteria of discontinuity) the exact coordinate of the main crack location, which separates one or another lithotype.

At the same time, the studied ambiguity in the rock blocks dimensions has an insignificant influence on the rocks SSS of the hinged-block displacement zone. Such a conclusion has been made on the basis of multivariate SSS calculations of this zone, for example, [19], where its essence is revealed: the main peculiarity of the thrust systems is their yielding property – the layer rigidity is reduced tenfold, and the value of this decrease is relatively independent on the blocks dimensions, since the length of the thrust systems is at least an order of magnitude greater.

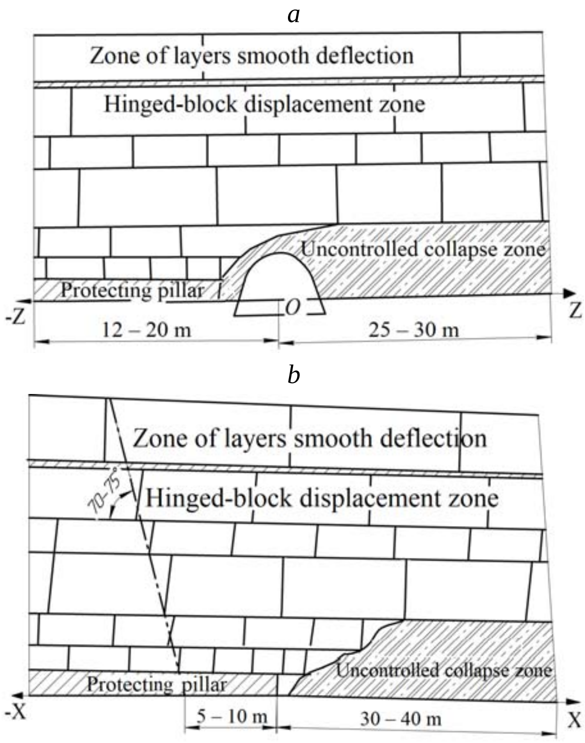

Fig. 2. Schemes for texture transformation of the coal-overlaying formation in a cross (*a*) and longitudinal (*b*) protecting pillar sections.

In the protecting pillar longitudinal section (for example, to the rise of the seam), the same principles to substantiate the block dimensions (usually from 2 m to 8 m) are recommended with a different general tendency of the block length increase when removing from the coal seam. Here, according to [24-26], the maximum stresses concentrations in the former frontal bearing pressure zone are propagated to depth of a pillar by 5 – 10 m. Over time, the line (by the coal-overlaying formation thickness) of their maxima is located at an angle of 70 – 75º to the horizontal, which will be the boundary of the hinged-block displacement zone from the side of the seam rise. From the opposite side, the vast dimensions of the mined-out space with a sufficiently constant texture of the hinged-block displacement zone make it possible to restrict the dimensions of its reflection to 30 – 40 m.

Based on these parameters, it is recommended to construct geomechanical models of the massif initial state before mining the protecting pillars; in the process of their stope extraction, the dimensions should be increased to the peculiarities of modelling, previously indicated in the second paragraph. However, when calculating such models with vast sizes, provided that it is necessary to consider the structural transformations of adjacent roof rocks, one usually has to deal with a lack of computational resources and, for this reason, stop the calculation procedure.

The accumulated experience of modelling such geomechanical situation has led to two ways of its solution without significant damage to the calculation accuracy. The first way is to restrict the extension (in coordinates *X* and *Z*) of the rock layers of the hinged-block displacement zone, where they are broken up into rock blocks; the sizes of these restrictions are shown in Figure 2. The second way is to break up into blocks only the lower layers of the zone, the number of which is determined experimentally by the criterion of the possibility to perform the calculation procedure. As for the remaining upper layers of the zone, the deformation modulus should be reduced by an order of magnitude for cumulative account of this technogenic fracturing in accordance with studies [31-33].

In general, modelling of the second, third, and fourth peculiarities of the protecting pillars extraction process will allow for acceptable (for mining-engineering calculations) adequacy of the real research object reflection and the reliability of the SSS calculation results of the coal-bearing massif.

Another group of geomechanics tasks related to the joint mining of two or three coal seams, quite reasonably uses (for constructing the models) the principles studied above, but taking into account the specifics of mining operations. Thus, in the works [17, 19], the following algorithm for performing a computational experiment:

– a coal-bearing stratum composed of holistic rock layers is modelled with a reflection of the uncontrolled collapse zone during extraction of an overlying coal seam; based on the results of the SSS calculation, the parameters of the hinged-block displacement zone of the main roof rocks and the block texture in the soil rocks of the overlying coal seam are substantiated;

– a geomechanical model is being constructed with a reflection of the roof and bottom rocks continuity of the overlying seam; the SSS of the entire coal-bearing stratum is calculated with the definition of the influence areas boundaries (on the underlying coal seam) of the rock pressure anomalies caused by the overlying seam extraction;

– the underlying coal seam extraction is modelled with the reflection of the uncontrolled collapse zone behind the longwall face, as well as all discontinuities caused by mining the overlying coal seam;

– according to the SSS calculation results from the previous stage, the parameters of massif discontinuities related to the underlying seam extraction are introduced. Then, the SSS of the coal-bearing stratum is calculated and analysed with an assessment of the degree of parting rocks stability;

– the final conclusion is made on the extent of the overwork influence on the state of the massif around mine workings of the lower horizon; the most dangerous areas along their length are determined and initial data are generated for constructing the geomechanical models of maintaining mine workings in the conditions of their overworking.

Thus, despite the significant differences in the tasks being solved in the two directions under study (extraction of protecting pillars and joint mining of coal seams in the suite), the principles for approaching their solution have a common implementation algorithm in terms of reflecting similar peculiarities of the coal-bearing massif discontinuities. The same common peculiarities exist for the final stage of research, which is formulated as the fifth peculiarity of the computational experiment – constructing a model, calculating the SSS and its analysis for the adjacent massif and the support of the overworked mine working. The peculiarity consists in the multi-scale modelling of the geomechanical "massif – support" system, because adequate reflection of the support elements (special interchangeable SCP profile of the frame support, roof-bolts, means for strengthening the fastening structures, etc.) requires finite elements mesh that differ by two – three orders from those for the adjacent massif.

The noted reason is decisive (in the conditions of a limited computational resource) for finding a compromise solution to the problem of failure-free computational experiment. The essence of the compromise is as follows. It is necessary to adequately reflect the real design of the fastening system of the overworked mine working for subsequent assessment of its elements state with a sufficient for practice reliability degree. A small-scale mesh of volume finite elements is required here. On the other hand, the loading of the fastening structure is conditioned by the surrounding rock massif deformation, where a larger-scale finite element mesh can be used, but with differentiation in reflection of different-sized texture peculiarities, including areas of discontinuity.

The model adequacy and the reliability of the SSS calculation results of the "massif-support" system will depend on the dimensions of the modelled massif surrounding mine working and the conditions of its loading at the borders. The general tendency is that, the larger the model dimensions, the less distortion in the fields of the SSS components distribution. Therefore, as a rule, it is necessary to perform several stages of calculating the SSS with a gradual decrease in the model dimensions (or, on the contrary, their increase) in order to search for such maximum permissible values, at which the calculation procedure stability within the available computational resource is still ensured.

When the maximum permissible model dimensions are determined, the borderline conditions of its loading are specified in the form of functions of vertical $\sigma_y(x, z)$, horizontal $\sigma_x(y, z)$ and $\sigma_z(y, x)$ stresses distribution along the model boundaries. These functions are determined from the calculation of the initial (general) model, which includes all the previously described peculiarities of mining-engineering situations of the protecting pillars mining or joint mining of coal seams in the suite.

Thus, the final peculiarity of modelling the fastening structure of overworked mine workings provides for the general two-staged performance of calculations:

– the first stage is a reflection of the mining-engineering situation as a whole using a geomechanical model with the required dimensions (it is sometimes called a "macro model") in a coal-bearing massif, but without reflection of mine workings fastening structure; insignificant error from such an assumption is substantiated, for example, in the works [34-36];

– the second stage – constructing of the so-called subordinate model with a detailed reflection of the fastening structure of the overworked mine working with the search for its maximum permissible dimensions; on the model bounds, the load functions are specified, determined when calculating macro model.

The calculation schemes and certain results of solution in one of the studied directions of the protecting pillars mining are given as examples of the proposed principles implementation for solving the geomechanics problems class on overworking of mine workings.

Figure 3 presents the macro model of mining the protecting pillar left in the previous periods of stope works along the seam C_6 in order to protect the underlying steep-dipping ventilation crosscut No. 1 (SVC No. 1) located in the bottom of the seam $C_5 + C_5^{top}$ (MM "Dniprovske", PJSC "Pavlohradvuhillia", Ukraine). Such a mining-engineering decision is conditioned by two reasons: moderate thickness of a parting and low strength characteristics of the constituent lithotypes, some of which are exposed to the active influence of weakening factors, namely, moisture saturation and fracturing. Now the task set is to assess the degree of the stope works influence in case of the protecting pillar extraction on the state of the SVC No. 1, the further maintenance of which ensures reliable functioning of ventilation systems in this area of the mine field.

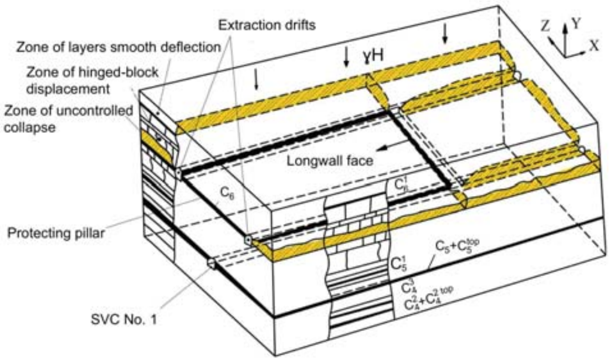

Fig. 3. Macro model of the protecting pillar extraction above the SVC No. 1.

The macro model (Figure 3) is being constructed with the maximum size along the strike (coordinate *Z*), although a sufficiently symmetric SSS components distribution is assumed here with respect to the axis *X* drawn along the centre of the pillar width. Therefore, it is entirely permissible to consider only half of the macro model by the coordinate *Z*, which will significantly save the computational resource. It is appropriate to recall that when calculating the macro model, the fastening structure of the SVC No. 1 is not modelled, and the main task is to determine the fields of σ_y, σ_x and σ_z distribution around the SVC No. 1 at a distance of up to several tens of meters from it. These fields of the SSS components distribution serve as borderline conditions when constructing the subordinate model.

The subordinate model (Figure 4) has been constructed with account of a stage-by-stage search for its maximum permissible dimensions by the factor of failure-free computational experiment. As a result, its dimensions have been determined by the coordinates: $z = 25$ m, $x = 4.5$ m, $y = 29.8$ m. The lower horizontal bound is modelled as a rigid base; on all other bounds, the loads are specified in the form of distribution curves $\sigma_y(x, z)$, $\sigma_x(y, z)$ and $\sigma_z(y, x)$ at the corresponding distances of the subordinate model boundaries from the contour of the

SVC No. 1. In the mine working itself, the frame support is modelled (10 sets with a step of setting 0.5 m) in full compliance with the technical documentation.

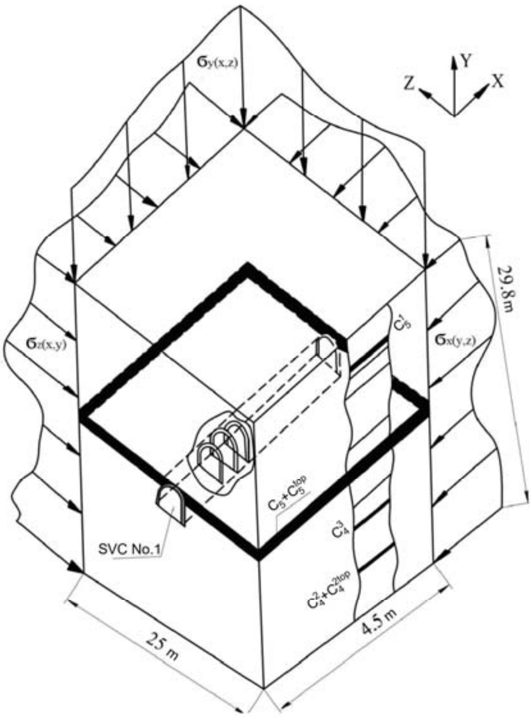

Fig. 4. Subordinate model for maintenance of the SVC No. 1.

The results of calculating the SSS of subordinate model can be illustrated by several options, for example, in the form of curves of the stresses components σ_y, σ_x, σ_z distribution, as well as an integral indicator – stresses intensity σ. But, the distribution of the relative indicator σ/σ_{yield} along the frame support contour is a more evident final result of the analysis performed. This indicator (σ_{yield} – the estimated yield limit of the SCP steel of the frame support) most informatively assesses the frame support state in terms of approaching the maximum permissible value σ_{yield} or even exceeding this value.

On the practical level, according to the curve of the indicator σ/σ_{yield} distribution, it is possible to judge about the areas of the frame contour that are in a stable state and, on the contrary, about the areas requiring the frame support strengthening. For example, Figure 5 shows that in the cap board of the frame, in the central part of the arch of 1.5 – 1.6 m long, the indicator σ/σ_{yield} varies in the range of 64 – 85%. This indicates a stable state in the central area of a cap board. At the same time, when approaching the peripheral areas of the cap board, the indicator σ/σ_{yield} increases to 87 – 98%, and in separate local intervals of length to 100 – 106%. Consequently, the occurrence of the limiting state of SCP steel with the exhaustion of load-bearing capacity of the cap board is predicted here. Obviously, it is necessary to strengthen the peripheral areas in the cap board, for example, by setting a pair of oblique roof bolts in each side of mine working.

An even more dangerous state is along the length of the rectilinear part of the frame prop stays: the indicator σ/σ_{yield} reaches 113 – 137% and characterizes the widespread occurrence of the limiting and superlimiting state of SCP steel (Figure 6).

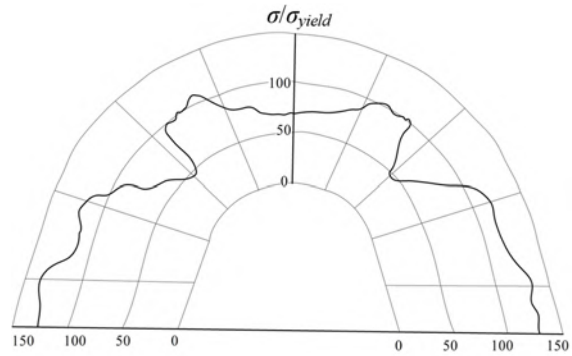

Fig. 5. Relative stresses intensity σ/σ_{yield} distribution in the frame support of the SVC No. 1.

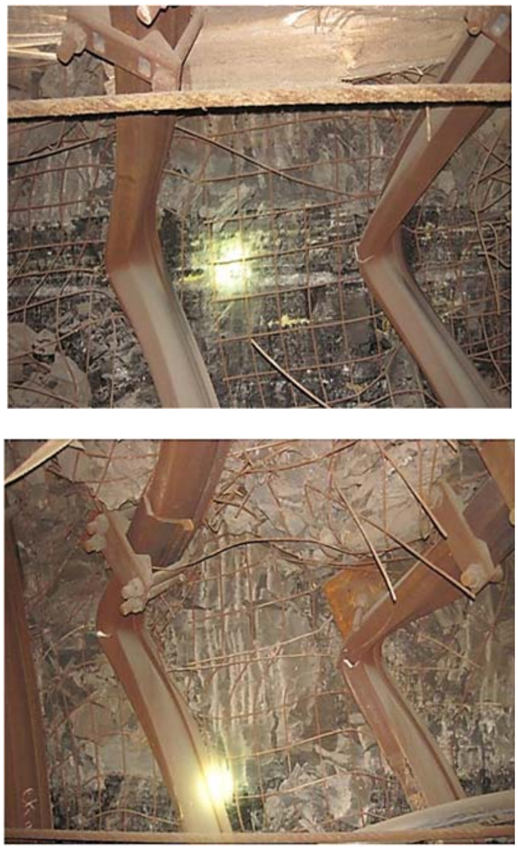

Fig. 6. Deformation of the frame stays.

This contributes to the loss of a stable form by the prop stays and the activation of their convergence with a significant reduction in the residual cross-sectional area [37]. It is also recommended to set predominantly horizontally directed roof bolts, strengthening the border lateral rocks; in addition, it is expedient to tie the tail joints of the roof bolts with the frame prop stays, which will effectively restrict their convergence (Figure 7).

Thus, using a specific example of the protecting pillar extraction, a structure has been developed for conducting a computational experiment from a macro model with vast sizes to the substantiation of practical recommendations for ensuring the overworked mine working stability.

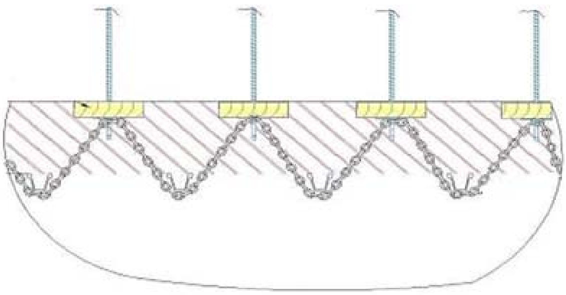

Fig. 7. Improvement of fastening technology.

3 Conclusions

1. The tasks of geomechanics on overworking of mine workings are distinguished by the sufficient complexity of reflecting the mining-and-geological and mining-engineering situation adequately for three main reasons:

– the necessity of modelling a network of underground mine workings at different horizons of mining operations;

– it is required to consider the parameters of rock pressure anomalies (zones of bearing pressure and unloading) when mining an overlying coal seam. This determines not only the spatial problem setting, but also the significant model dimensions by all three its coordinates;

– the stope works, conducted at different periods on overlying coal seams, have led to radical transformations of some lithotypes texture of the coal-bearing stratum, which has a significant effect on its SSS as a whole and, therefore, requires adequate reflection in geomechanical models.

2. Five peculiarities of the geomechanical models construction on overworking of mine workings have been substantiated and revealed, the implementation of which predicts obtaining the reliable results for determining SSS within the accuracy sufficient for mining-engineering calculations.

3. A stage-by-stage algorithm is proposed for solving this class of problems, which differ in the scale of the modelled objects (the dimensions of volume finite elements vary by two or three orders of magnitude). The technology of sequential performance of a series of computational experiments to operate the parameters of the so-called macro model (reflects the studied object as a whole) has been substantiated, followed by obtaining the results for constructing and calculating a subordinate model. Here, the parameters of the overworked mine working and its fastening structure are reflected in full compliance with the technical documentation on conducting and exploitation of mine working.

4. An example is presented of the task solution of the protecting pillar influence of the overlying coal seam on the state of a mine working located in the underlying coal seam. The state of the overworked mine working support has been assessed and recommendations are formulated for its maintenance in operational condition.

The authors express their gratitude to the management of DTEK Coal Unit for their help in organizing the experimental research.

Abstract. The paper provides numerical simulation of the influence of dynamic loading on the stress-strain state of the natural and geoengineering technogenic environment taking into account the soil basis for forecasting its use as the basis of the structure. Paper demonstrates the impact of static and dynamic loading on the subsidence of the landfill. To take into account the liquid phase of the waste and the visco-plastic medium, Darcy's law is used as an equation of balance of forces. The body of the landfill is modeled by weak soil taking into account the creep, using the Soft Soil Creep model. The covering and underlying soil layers are described by the Coulomb – Mohr model. An effective method for calculating the sedimentation of natural and geoengineering environment on the example of a solid waste landfill, based on numerical modeling of the stress-strain state of the landfill and underlying soil using finite elements is developed. It is demonstrated that the largest subsidence is experienced by the landfill with sand, as the base soil, but in percentage terms the amount of subsidence with the maximum load relative to the initial subsidence without loading is the largest in clay (33.7%). The obtained results must be taken into account when using landfills as a basis for buildings, structures, routes, recreational areas, etc.

1 Introduction

Due to the continuous growth of industry and, as a result, the increase in industrial and household waste, dumps and tailings of the mining industry, the area allocated for them is growing accordingly. For example, currently in Ukraine only landfills for solid waste occupy 160 thousand hectares of land.

Therefore, the question of the sustainability of such *natural-technogenic* geoengineering areas for their possible use in the future as a basis for engineering buildings and structures. As a result, scientists are faced with the task of assessing and predicting stability under static and dynamic loads [1].

Analysis of the literature demonstrated that experimental methods for assessing the resilience of *natural-technogenic* environments are costly and are not always effective. It is most expedient to apply mathematical modeling to take into account the stress-strain state of such medium, taking into account the underlying soil arrays and dynamic loads.

Mathematical models used to predict subsidence can be divided into rheological models, empirical models, models based on soil mechanics and models that take into account biodegradation.

Although properties of hard domestic wastes differ from properties of traditional soils, Kockel and Jessberger set that the landfills can be modelled by weak soil [2, 3]. Sowers and Edil were the first, who applied principles of ordinary mechanics of soils for the estimation of sinking as a result of primary compression [4].

Marquez developed a composite rheological model to take into account the primary and secondary mechanisms of compression [6].

Park and Lee proposed a sedimentation model that takes into account time-dependent biodegradation of waste [7].

A common feature of mathematical models [8, 9] is that they take into account only waste, their behavior and properties, neglecting such an important component of the landfill as the soil underlying it. Type, strength, deformability, geotechnical properties of the underlying soil determine the stability of the natural and geoengineering environment, because it feels the greatest load. Currently, this issue is not studied.

The aim of the research is to substantiate theoretically the stability of the natural and geoengineering environment as the basis of structures, taking into account the stress-strain state of the underlying soils and dynamic loads to predict the stability of the landfill as the basis of structures.

To achieve this goal, the following research objectives are formulated:

– to research the impact of static and dynamic loading on the subsidence of the landfill using the developed methodology for selecting and predicting the

* Corresponding author: aodi@ukr.net

possible use of the landfill as a basis for construction after its closure;

– to study the influence of the underlying soil and its stratification on the deformation of the landfill body using the developed mathematical model and methods of calculating the stress-strain state.

Sediment simulation taking into account the dynamic load predicts the suitability of a particular closed landfill for use as a road, highway, expressway, etc.

2 Materials and methods

Numerical modeling of the stress-strain state of the solid waste landfill and the soil base is carried out to predict the possibility of its use as the basis of a building or structure. To take into account the liquid phase of the waste and the visco-plastic medium, Darcy's law is used as an equation of balance of forces:

$$-\nabla P - \frac{\eta}{K}\vec{u} + \rho\vec{f} = 0, \tag{1}$$

where P – external pressure; ρ – density; η – dynamic viscosity; g – acceleration of free fall; $\vec{u}$ – filtration rate; $\vec{f}$ – field of external forces; $K = \eta k/\rho g$ – the permeability coefficient, which characterizes the ability of a porous medium to pass fluid.

The complete system of equations of filtration of incompressible liquid includes the equation of incompressibility:

$$div\,\vec{u} = 0, \tag{2}$$

and the continuity equation:

$$div\,\rho\vec{u} = -\rho m, \tag{3}$$

where m – the porosity of the soil.

It is assumed that the compressibility of the skeleton and pore fluid is small, which leads to a linear dependence of soil porosity on pressure.

The covering and underlying soil layers are described by the Coulomb – Mohr model, in which the complete yield condition consists of six flow surfaces and six plastic potential functions [10]:

$$\begin{aligned}
f_{1a} &= \frac{1}{2}(\sigma'_2 - \sigma'_3) + \frac{1}{2}(\sigma'_2 + \sigma'_3)\sin\varphi - c\cos\varphi \le 0;\\
f_{1b} &= \frac{1}{2}(\sigma'_3 - \sigma'_2) + \frac{1}{2}(\sigma'_3 + \sigma'_2)\sin\varphi - c\cos\varphi \le 0;\\
f_{2a} &= \frac{1}{2}(\sigma'_3 - \sigma'_1) + \frac{1}{2}(\sigma'_3 + \sigma'_1)\sin\varphi - c\cos\varphi \le 0;\\
f_{2b} &= \frac{1}{2}(\sigma'_1 - \sigma'_3) + \frac{1}{2}(\sigma'_1 + \sigma'_3)\sin\varphi - c\cos\varphi \le 0;\\
f_{3a} &= \frac{1}{2}(\sigma'_1 - \sigma'_2) + \frac{1}{2}(\sigma'_1 + \sigma'_2)\sin\varphi - c\cos\varphi \le 0;\\
f_{3b} &= \frac{1}{2}(\sigma'_2 - \sigma'_1) + \frac{1}{2}(\sigma'_2 + \sigma'_1)\sin\varphi - c\cos\varphi \le 0,
\end{aligned} \tag{4}$$

where $\sigma'_1, \sigma'_2, \sigma'_3$ – normal stresses.

The condition f_j=0 for all surfaces of fluidity together shows a hexagonal cone in space of main tensions.

In addition to the surfaces of fluidity, the model of Coulomb – Mohr is presented by six plastic potential functions g:

$$\begin{aligned}
g_{1a} &= \frac{1}{2}(\sigma'_2 - \sigma'_3) + \frac{1}{2}(\sigma'_2 + \sigma'_3)\sin\psi;\\
g_{1b} &= \frac{1}{2}(\sigma'_3 - \sigma'_2) + \frac{1}{2}(\sigma'_3 + \sigma'_2)\sin\psi;\\
g_{2a} &= \frac{1}{2}(\sigma'_3 - \sigma'_1) + \frac{1}{2}(\sigma'_3 + \sigma'_1)\sin\psi;\\
g_{2b} &= \frac{1}{2}(\sigma'_1 - \sigma'_3) + \frac{1}{2}(\sigma'_1 + \sigma'_3)\sin\psi;\\
g_{3a} &= \frac{1}{2}(\sigma'_1 - \sigma'_2) + \frac{1}{2}(\sigma'_1 + \sigma'_2)\sin\psi;\\
g_{3b} &= \frac{1}{2}(\sigma'_2 - \sigma'_1) + \frac{1}{2}(\sigma'_2 + \sigma'_1)\sin\psi.
\end{aligned} \tag{5}$$

The corner of dilatancy ψ is needed for the design of positive plastic volume to deformations, that are in dense soils. The corner of internal friction φ is used for the design of effective friction in soil in combination with the effective coupling of *c*.

The body of the landfill is modeled by weak soil taking into account the creep, using the model Soft Soil Creep (SSC) [11-12].

Advantage of this model before other is that she takes into account not only a primary compression but also creep and secondary compression, that is especially important for the grounds of hard domestic wastes, in that a secondary compression plays a major role. Its duration can present 10-30 years. It must be taken into account on the stage of planning of building of construction on the basis of ground. The feature of body of ground is him high compressibility. The large primary sinking of foundations and embankments, as a rule, is accompanied by the substantial sinking as a result of creep in later years. In such cases it is desirable to estimate a creep by means of eventual elements method.

Basic descriptions of model of SSC are: dependency inflexibility; a difference is between the primary loading and unloading-overload; secondary, dependency upon time compression; taking into account of pre-consolidation tension; criteria of destruction of Coulomb – Mohr. The feature of design of ground is linear dependence of his tension on odometric inflexibility.

The total volume deformation ε_v, caused by the increase of effective stresses from the initial value p_0' to p' for the period of time t_c+t', consists of elastic ε_v^e and viscoplastic ε_v^{vp} components. The viscoplastic component is the sum of the deformation during the consolidation $\varepsilon_v^{vp}{}_c$ and after the consolidation $\varepsilon_v^{vp}{}_{ac}$. The relationship between deformations is expressed as follows:

$$\varepsilon_v = \varepsilon_v^e + \varepsilon_v^{vp}{}_c + \varepsilon_v^{vp}{}_{ac}; \tag{6}$$

$$\varepsilon_v^e = \kappa^* \ln\left(\frac{p'}{p'_0}\right); \tag{7}$$

$$\varepsilon_v^{vp}{}_c = (\lambda^* - \kappa^*) \ln\left(\frac{p'_{pc}}{p'_0}\right); \tag{8}$$

$$\varepsilon_v^{vp}{}_{ac} = \mu^* \ln\left(\frac{\tau_c + t'}{\tau_c}\right), \tag{9}$$

where μ^* – modified creep coefficient; τ_c – consolidation time, which depends on the geometry of the sample under study; t' – elapsed time since the start of landfill loading; κ^* – modified swelling coefficient; λ^* – modified compression ratio (compression); t_c – time of completion of the initial consolidation; p' – initial effective voltage; p' – effective voltage; p'_{pc} – effective pre-consolidation voltage.

Izotropic effective tension of p' is determined after a formula:

$$p' = \frac{1}{3}\left(\sigma'_{xx} + \sigma'_{yy} + \sigma'_{zz}\right). \tag{10}$$

Attitude of model parameters following toward the internationally rationed parameters

$$\mu^* = \frac{C_\alpha}{2{,}3(1+e_0)}; \quad \lambda^* = \frac{C_c}{2{,}3(1+e_0)}; \quad \kappa^* = \frac{2C_s}{2{,}3(1+e_0)}, \tag{11}$$

where C_c – coefficient of compression, C_s – swelling coefficient, C_α – coefficient of creep, e_0 – initial coefficient of porosity.

The equations for determining the free surface of the filtration flow when calculating the unstable filtration in the body of the landfill, taking into account the infiltration, must satisfy the following boundary conditions: 1) the pressure is equal to atmospheric; 2) the normal velocity component on the surface is missing. At the boundaries between the landfill layers and the soil base, the conditions of equality of normal stress components and filtration rate occur.

The initial conditions are: the filtration rate in the layers of the landfill and the underlying soil is zero; atmospheric pressure acts on the surface, each layer of waste and soil has its own initial physical and mechanical properties, the initial geometric parameters of the landfill are set.

3 The results of studies of the stress-strain state of the natural-technogenic environment under dynamic loads

The finite element method is used to solve the problem numerically. The calculation area is divided into 5200 triangular elements.

The landfill for which the simulation is performed consists of ten layers of waste, the thickness of each layer is 3 m. Sedimentation is determined taking into account the step-by-step load of the landfill for 30 years after its closure.

Sand, loam and clay are considered as underlying soils, the physical and mechanical parameters of which are given in table 1.

The physical and mechanical parameters of wastes are given in table 2.

Table 1. Physical-mechanical parameters of soils.

Parameter	Soil		
	Sand	**Loam**	**Clay**
Deformation module, E_{ref}	18000	10000	9000
Poisson's ratio, ν	0,34	0,34	0,34
Specific gravity of soil, γ_{unsat}	18,0	13	19,0
The proportion of water-saturated soil, γ_{sat}	20,7	14,6	21,8
The filtration coefficient in the horizontal direction, k_x	0,5	0,006	0,004
The filtration coefficient in the vertical direction, k_y	0,5	0,006	0,004
Coupling, c	2	13	17
The angle of internal friction, φ	31	14	13

Table 2. Physical-mechanical parameters of wastes.

Parameter	Size
Specific gravity γ_{unsat}, (kN/m^3)	7,504
Specific gravity of water saturated soil γ_{sat}, (kN/m^3)	10,0
Specific coupling c, (kPa)	25
Corner of internal friction φ, (degree)	20
Initial coefficient of porosity, e_0, (unit)	0,4268
Coefficient of compression, C_c, (unit)	0,3987
Coefficient of swelling, C_s, (unit)	0,0394

In [9], the sedimentation of the landfill without load is calculated. For the landfill with clay base, it is 3.83 m, with loam – 4.47 m, with sand – 4.95 m. These data are used to determine the stress-strain state of the landfill 30 years after its closure and predict the possibility of its use as the basis of the road surface.

As a result of numerical calculation it is established that if the value of the vertical load is 50 kPa, it can be observed that deformations are achieved equal to 4.19 m for clay (Fig. 1) and 5.06 for sand (Fig. 2).

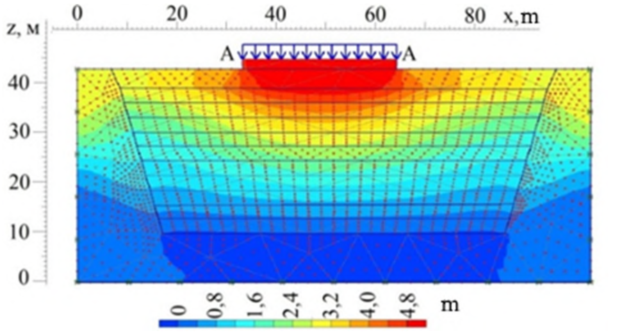

Fig. 1. Vertical deformations of the landfill with a vertical distributed dynamic load of 50 kPa (clay at the base).

With an increase in the load up to 100 kPa, the sediment of the landfill with a sand base increases by 4.2% (5.27 m) (Fig. 3), with clay – by 4.8% (4.39 m) (Fig. 4).

It is established that at dynamic loads the underlying soils have a similar effect on the subsidence of the landfill, but the amount of subsidence is less than 0.5-4% depending on the underlying soil.

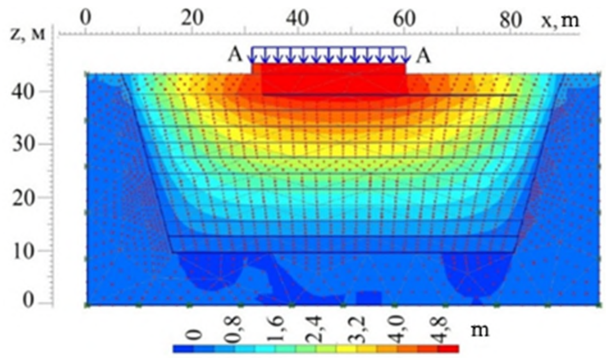

Fig. 2. Vertical deformations of the landfill with a vertical distributed dynamic load of 50 kPa (sand at the base).

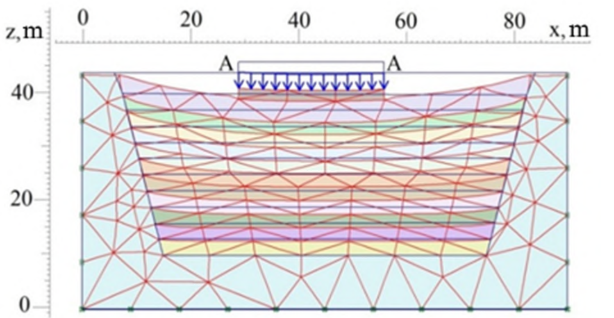

Fig. 3. Deformed calculation area of the landfill with a vertical distributed dynamic load of 100 kPa (sand at the base).

The landfill with sand as the base soil undergoes the greatest vertical deformations. The amount of sedimentation with the maximum load in relation to the subsidence without load is the largest in clay (28.7%), the minimum – in sand (18.6%). It is established that with increasing load from 5 to 180 kPa, the sedimentation increases by 1.2-17.4% for sand and by 2.5 - 21% for clay.

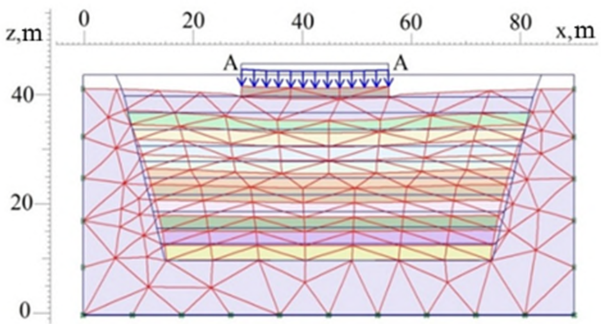

Fig. 4. Deformed calculation area of the landfill with a vertical distributed dynamic load of 100 kPa (clay in the base).

Analytical dependences of subsidence of the landfill with different underlying soils on the value of static loads (Fig. 5) are obtained:

for sand

$$y = 0{,}0243x^2 + 0{,}0686x + 3{,}79,$$

for loam

$$y = 0{,}0043x^2 + 0{,}2129x + 4{,}29\ ,$$

for clay

$$y = 0{,}0277x^2 - 0{,}008x + 4{,}945 \qquad (12).$$

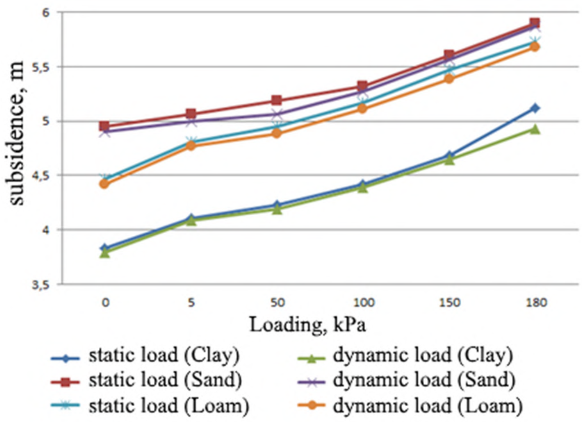

Fig. 5. Dependence of landfill subsidence with clay and sandy base soil on vertically distributed static [10] and dynamic loads.

Analytical dependences of subsidence of the landfill with different underlying soils on the value of dynamic loads (Fig. 5) are obtained:

for sand

$$y = 0{,}035x^2 - 0{,}0516x + 4{,}928;$$

for loam

$$y = 0{,}0068x^2 + 0{,}1922x + 4{,}266;$$

for clay

$$y = 0{,}0096x^2 + 0{,}1491x + 3{,}672. \qquad (13)$$

These dependences make it possible to predict the subsidence of landfills in order to assess their stability under static and dynamic loads of different nature: roads, highways and more.

For practical application of the worked out methodology the calculation of sinking was implemented on the example of landfill, located in Boryspil, Kyiv region.

A landfill was put into an operation in 2003 in accordance with a project in place of exhaust sand-pit, its area folds 6,5 hectare. The landfill's capacity of solid household waste was about 85 thousand tons per year. The total amount of waste is estimated in 0.723 million tons, the average depth is 18-20 m.

 https://doi.org/10.1051/e3sconf/202128001008

Sediment is determined in landfill site (50x50 m), taking into account the step-by-step loading of the landfill with waste during 30 years after its closure, as approximately 90% of sediment occurs within the first five years and may continue for 25-30 years at a slower rate.

Clay and sand are in different parts of the landfill at its base. Modeling is performed for two options: with intermediate sand pouring every 3 m of waste and without it.

The calculated deformed area of the landfill with a clay underlying layer is presented in Fig. 6 and vertical deformations of the landfill with a sandy underlying layer is presented in Fig. 7.

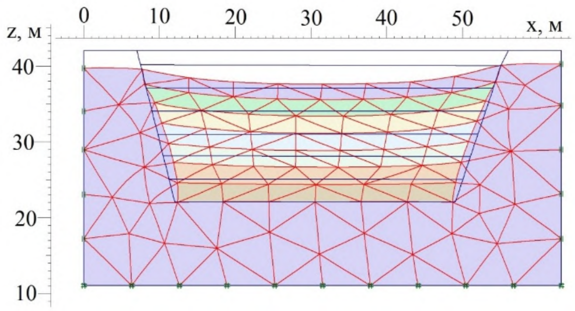

Fig. 6. Deformed calculation area of the landfill with a clay underlying layer.

From the analysis of numerical calculations it follows that the maximum vertical deformation at the clay base of the landfill is 2.27 m. In case of sand as the underlying layer, the deformation increases significantly up to 2.61 m.

It is found that at the landfill with overflow there are much smaller deformations compared to the landfill without overflow: 32% less at the landfill with a clay base, 30% less at the landfill with sand. Thus, if the underlying layer is clay (Fig. 8), then vertical deformations in 1.55 m are achieved, and in case of sand as the base (Fig. 9), – it is 1.82 m. The percentage of sediment to the height of the landfill is 14.2% and 15.26% respectively.

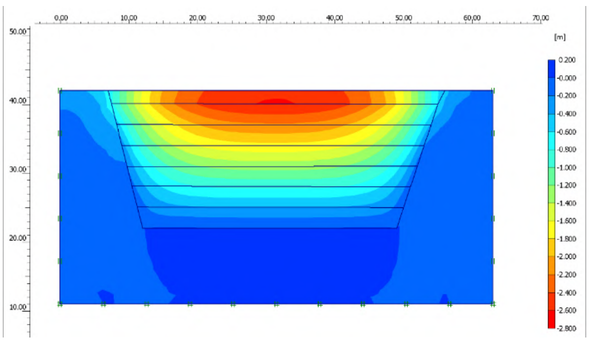

Fig. 7. Vertical deformations of the landfill with a sandy underlying layer.

It is established that at the same parameters of the landfill body during pouring, the landfill with a sand base is subject to greater sediment than the landfill with a clay base (13%). There is a significant effect of overflow on the amount of deformation. Thus, for the clay base the sediment increases by 32%, for the sand base – by 30%.

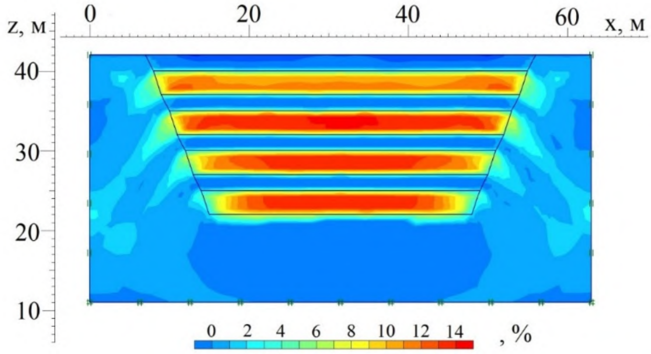

Fig. 8. Vertical displacements of the landfill with overflow and with a clay underlying layer (in percents).

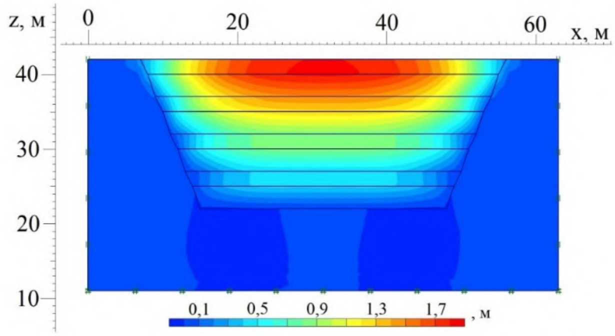

Fig. 9. Vertical deformations of the landfill with overflow and with a sandy underlying layer.

4 Discussion of the results of the research

As a result of numerical calculation, it is established that if the value of the vertical load is 50 kPa, it can be observed that deformations are achieved equal to 4.19 m for clay (Fig. 1) and 5.06 for sand (Fig. 2).

With an increase in the load up from 50 to 100 kPa, the sediment of the landfill with a sand base increases by 4.2% (5.27 m) (Fig. 3), with clay – by 4.8% (4.39 m) (Fig. 4).

It is established that at dynamic loads the underlying soils have a similar effect on the subsidence of the landfill, but the amount of subsidence is less than 0.5-4% depending on the underlying soil.

As it follows from Figure 5 the landfill with sand as the base soil is subjected to the greatest vertical deformations. However, in percentage, the amount of sedimentation with the maximum load in relation to the initial subsidence without load is the largest in clay and is 33.7%, the same figure in the sand – 19.2%.

It is established that in the landfill with overflow there are much smaller deformations compared to the landfill without overflow: 32% less in the landfill with a clay base, 30% less in the landfill with sand. Thus, if the underlying layer is clay (Fig. 8), then vertical deformations of 1.55 m are achieved, and if the base is sand (Fig. 9) – 1.82 m. The percentage of sediment to the height of the landfill is 14.2% and 15.26% respectively.

This is due to the fact that the more porous unstable soil of the sand base has reached the maximum subsidence in 30 years and is subsequently deformed to a lesser extent than the clay, which has not yet reached the final deformation. This established fact must be taken into account when designing and operating buildings for various purposes, built on closed landfills.

5 Conclusions

An effective method for calculating the sedimentation of natural and geoengineering environment on the example of a solid waste landfill, based on numerical modeling of the stress-strain state of the landfill and underlying soil using SSC models for the landfill and Coulomb-Mora for the soil base using finite elements is developed.

For the first time it is proposed to take into account the underlying soil when calculating the stability of the landfill, as it is one of the main factors in the formation of subsidence.

It is demonstrated that the largest subsidence is experienced by the landfill with sand, as the base soil, but in percentage terms the amount of subsidence with the maximum load relative to the initial subsidence without loading is the largest in clay (33.7%).

It is established that in the landfill with overflow there are much smaller deformations compared to the landfill without overflow: 32% less at the landfill with a clay base, 30% less at the landfill with sand.

The obtained results must be taken into account when using landfills as a basis for buildings, structures, routes, recreational areas, etc.

As a result of the research it can be concluded that in the preliminary planning of the landfill it is necessary to provide for the overlapping of landfill layers with soils to choose areas with denser underlying soil to be able to use it after closure as a foundation. If there has been no prior planning and / or the basis is weak soil, it is necessary to use different methods of compaction or use it with less load (parks, recreational areas, golf courses).

Abstract. Although research on hotel booking intention has been carried out in the last decade, the research that reveals the role of hotel reservation information through online consumer reviews in the millennial generation is still very rare. This study aims to determine the factors of online consumer reviews that affect hotel booking intentions for the millennial generation in Bali, Indonesia. This study uses a quantitative approach by distributing questionnaires to 385 respondents through a non-probability sampling technique, namely purposive sampling. The data analysis technique of this research is a multiple linear regression analysis processed using the SPSS 25.0 program. The results reveal that usefulness, timeline, and comprehensiveness have a significant effect on hotel booking intentions. Meanwhile, the volume of online reviews, the positive valence of online reviews, and the negative valence of online reviews are not significant for hotel booking intentions. The research findings reveal the characteristics of the millennial generation which are in line with the theory of reason action that they have their views in making decisions. The research implications are discussed in the paper.

1 Problem statement

Tourists traveling to Indonesia during 2019 were mostly young tourists aged 15-24 (24.2%), 25-34 years (15.3), and 35-44 years (18.8) (Central Bureau of Statistics) 2018) [1]. The increasing number of young tourists from year to year is the largest market segmentation for the hotel and tourism industry so it is important to understand the character and needs of these millennial travelers.

In making buying and selling transactions, the millennial generation has an interesting pattern. Where to purchase after reading reviews by searching for information through social media, e-commerce sites, or online travel agents. Due to the nature of product experience, online reviews have become an increasingly popular source of information in travel planning and have a major influence on consumer purchasing decisions, especially in hotel bookings [2].

Online reviews provide information about goods or services that are different geographically and have experience with the goods or services in question [3]. Consumers prefer to read reviews and recommendations from experienced customers before buying a product or service that significantly influences consumer buying decisions [4].

Online surveys are central in tourism, tourism sustainability in turn affects the environment and economies of countries, taking into account the needs of consumers and sustainable changes in consumer behaviour. Environmental factors in choosing a hotel do not play a key role in contrast to basic factors (such as location, price, etc.), but the development of green tourism over time should change this situation.

Due to the intangible nature of tourism products, prospective tourists buy hotel rooms that have a high level of risk and uncertainty [5-6]. Although the information guidance provided on the website is very limited, the role of information in decision making has not been studied much. Thus, hotels are expected to show uniqueness that is characteristic of increasing competitive advantage [7].

Before deciding to book a hotel room, consumers first seek information about the desired hotel either through family, friends, travel agents, or the Internet to help make decisions [8]. In the tourism industry, tourists rely on information whether it is obtained online or offline.

This study will try to close the existing research gap, namely, first, although several studies have identified the individual role of information cues, such as scarcity, popularity, and consumer ratings [9], research investigating the effect of different information is still scarce. Therefore, it is important to check which information clues (i.e. usefulness, timeline, volume, positive valence, negative valence, and comprehensiveness) have a significant influence on potential traveler booking intentions.

* Corresponding author: wayanediarsawan@pnb.ac.id

The second gap is for tourists, searching for information via the Internet both from the official hotel website and online consumer review (OCRs) provides a lot of information. However, the online reviews that are presented have various characteristics, how online reviews are measured, both in quality and quantity, and how detailed and specific the information is uploaded on the website. This leaves tourists with many confusing perspectives [10]. As a result, hoteliers and travel agents are challenged to provide comprehensive facilities on online consumer reviews (OCRs), such as categorizing relevant OCRs to help consumers get the right information to make decisions.

The third gap is in the field of study relating to Indonesian millennial consumers, which is currently the largest target hotel market. Millennial consumer hotel reservation intentions have not been well researched, especially those influenced by online consumer reviews factors. Although millennial consumers are a very attractive consumer segment, not much research has been conducted on millennial consumer hotel booking behavior caused by online consumer reviews.

Based on this, it is important to conduct this research, which is to find out more details about which factors or attributes of OCRs can affect booking interest [11], especially consumers from the millennial generation, get a better experience when they look for relevant information about hotels that want to be visited and make it easier for them to make decisions. The effect is that the hotel manager or travel agent can implement a better marketing strategy, especially related to OCRs.

Online consumer review as a form of e-WOM have become an important factor in shaping consumer behavior. Through online reviews from other consumers, sharing review platforms can influence consumer buying interest [12, 13]. Online reviews have a positive and significant impact on hotel booking intentions so online reviews must be managed as a strategic communication channel [14].

2 Research methods

This research was conducted in Bali Province, Indonesia with respondents are the millennial generation, the generation aged 20 to 39 years, or those born in 1980-2000 [1]. The sample was determined using non-probability sampling, namely purposive sampling, that is the millennial generation, having or planning to book hotels, have read online reviews.

The reason for choosing the millennial generation is because it has a strong potential to read online consumer reviews first before booking a hotel according to the theory of experts, is a productive age group (15 - 64 years) to book high hotels, read online hotel reviews and conduct hotel booking. The data collection technique of this research is through distributing questionnaires with a Likert scale of 1-5, which were analyzed by multiple linear regression analysis.

The methods of questionnaires of hotel services customers and analysis are used in the research and they show that consumer resilience don not reflect the primary importance for OCRs, since most online reviews do not contain information stability and do not influence hotel booking, unlike other factors that are detailed in the article.

3 Literature review

The usefulness of an online review refers to the quality or level of usefulness of an online review. Park and Lee [15] suggested that usefulness is how far consumers believe online reviews will facilitate their purchasing decision-making process. An online review will have a useful value for consumers if it contains additional information that contains information that is relevant, useful, neutral in nature, and comes from the perspective of consumers Abdullah et al. [16]. One of the reasons travelers look for information about hotels online is to plan their trip, so they need precise information that can describe hotel conditions based on previous consumer experiences. This is an organizational competitive advantage through the dissemination of appropriate information [7].

H1 = Usefulness of online review has a significant positive effect on hotel booking intention

Timeline refers to "whether the message is current, timely and up to date" Cheung et al. [17]. During the process of searching for information, consumers may be faced with relevant information but in large quantities and originate from different times. Thus, the website must be updated on an ongoing basis to provide useful information for consumers/users. The results also reveal that in the current e-commerce era, the most recent product reviews will get more attention from users [18]. Consumers will follow the latest news developments from hotels of interest through OCR or hotel social media. , the latest information will describe the current condition of a hotel which can affect the purchase decision [19].

H2 = Timeline of online review has a significant positive effect on hotel booking intentions

Review volume refers to the number of reviews that a product or service gets from reviewers of Davis and Khazanci [20]. The number of reviews given by reviewers is another attribute of the word of mouth because it displays reviews from different reviewers. The higher the volume of reviews, both positive and negative reviews, in the context of online communication, this will attract the attention of information seekers which can then increase product awareness [21].

H3 = Volume of online reviews has a significant positive effect on hotel booking intentions

Online positive reviews are a form of response that usually can be in the form of recommendations from consumers for their satisfaction with the services they received previously. Previous research has highlighted the importance of customer recommendations in the context of service delivery, as it has been illustrated empirically that one recommendation can be sufficient to convince someone to try a recommended service provider [22]. Reviews with a very positive rating will lead to significant growth in product sales (Clemons et al. (2006) [23]. Consumer purchase intentions increase if the quality of reviews is maintained. The more quantity of positive reviews, the more likely it is to influence consumers to book hotels [24].

H4 = Positive valence of online review has a significant positive effect on hotel booking intentions

Several researchers have analyzed the negative impact of online reviews on hotel bookings and found that a large number of negative reviews on a hotel lead to negative attitudes towards hotel bookings [25]. Negative reviews are generally written in response to consumer dissatisfaction which can harm business [26] because it is considered to be more dangerous than complaints and complaints, which are largely invisible. goods [15]. The results of other studies reveal that negative online reviews can reduce consumer attitudes towards hotels that are in demand, although online negative reviews will be able to increase their consumers' awareness of that hotel [25].

H5 = Negative valence of online review has a significant negative effect on hotel booking intentions

The completeness features in the online review have a relationship with the online review recommendation itself and are an advantage in being able to measure how detailed and complete a review is [17]. For consumers, especially the first When going to make a purchase, it certainly requires complete information about the product or service to be used and as a basis for deciding whether to purchase or not, which means that the detailed and comprehensive features of online reviews have a significant contribution to consumer hotel booking intention [27] Another study stated that online review completeness is one of the most effective elements of online posting in terms of the extent to which people are willing to accept and adopt online reviews, as well as the factors that drive adoption [17].

H6 = Comprehensiveness of online review has a significant positive effect on hotel booking intentions.

4 Results of research

Before distributing the questionnaires, the first 30 respondents tested the validity and reliability. After that, the questionnaire was distributed via google forms, and distributed via email, social media by including a cover letter about this research. From 385 data obtained for approximately 9 months (September 2019- May 2020), information was obtained that as many as 63% of respondents were women and 37% of respondents were men. The age category ranges from 20-24 years (43.4%), 25-29 (36.4%), 30-34 years (16.9%) and 35-39 (3.4%). Besides, 3-star hotels dominate the respondents' choices for the category of hotels that are preferred and often chosen when traveling with a percentage of 43.6%, 4-star hotels (29.8) and 5-star hotels (26.6) (see Table 1).

Table 1. Demographic of respondents (*n*=385)

Criteria	Amount	Percentage
Gender		
Male	143	37
Female	242	63
Ages		
20-24	167	43,4
25-29	140	36,4
30-34	65	16,9
35-39	13	3,4
Hotel Classification		
3*	168	43,6
4*	115	29,8
5*	102	26,6

4.1 Classic assumption test

The normality test is carried out to find out whether the data to be used is normally distributed or not. The results of the normality test are seen from the Asymp value. Sig. (2-tailed) of 0.761, which exceeds the value of the level of significance of 0.05, so it can be concluded that the data in this study were normally distributed.

Tabel 2. Heteroscedasticity and multicollinearity test.

Model	Sig.	Tolerance	VIF	Remarks
(Constant)				
Usefulness of online review (X_1)	0,138	0,877	1,140	Free
Timeline of online review (X_2)	0,965	0,930	1,075	Free
Volume of online review (X_3)	0,862	0,920	1,087	Free
Positive valence of online review (X_4)	0,773	0,942	1,062	Free
Negative valence of online review (X_5)	0,142	0,907	1,102	Free
Comprehensiveness of online review (X_6)	0,074	0,942	1,061	Free

A heteroscedasticity test is performed to test whether the regression model has inequality of variants from the residuals of one observation to another (see Table 2). The heteroscedasticity test was tested using the Glejser test, namely by regressing the absolute residual value on the independent variable. The significance value of the variable usefulness (0,138), timeline (0,965), volume (0,862), positive valence (0,773), negative valence (0,142), and comprehensiveness (0,074) is greater than 0.05. This means that there is no influence between the independent variables on absolute residuals so that the model made does not contain symptoms of heteroscedasticity.

Multicollinearity (see Table 2) between independent variables does not occur if they have a VIF of less than 10 and a Tolerance number of more than 0.1. The results show that the tolerance values for the usefulness variables (1.140/0.877), timeline (1.075/0.930), volume (1.087/0.920), positive valence (1.062/0.942), negative valence (1.102/0.907), and comprehensiveness (1.061/0.942) are greater than 0.1 and have a VIF value that is smaller than 10, so it can be said that there are no multicollinearity symptoms in this study.

4.2 Multiple regression analysis

Multiple regression analysis is used to examine the effect of two or more independent variables on the dependent variable. The independent variables in this study are the variable usefulness (X_1), timeline (X_2), volume (X_3), positive valence (X_4), negative valence (X_5), and comprehensiveness (X_6). Meanwhile, the dependent variable is hotel booking intentions. Based on the results of the multiple regression test in Table 1, the multiple linear regression equation in this study is as follows.

$$Y = 0{,}796 + 0{,}272\ X_1 + 0{,}183\ X_2 - 0{,}068\ X_3 + 0{,}096\ X_4 - 0{,}055\ X_5 + 0{,}189\ X_6 + e \quad (1)$$

Table 3. Multiple regression analysis.

	Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	0,796	0,439		1,820	0,072
	Usefulness[X_1]	0,272	0,057	0,246	4,904	0,000
	Timeline[X_2]	0,183	0,055	0,166	3,402	0,001
	Volume[X_3]	-0,068	0,062	-0,058	-1,128	0,261
	Positive Valence [X_4]	0,096	0,048	0,097	1,955	0,054
	Negative Valence [X_5]	-0,055	0,046	-0,062	-1,209	0,229
	Comprehensiveness [X_6]	0,189	0,053	0,178	3,719	0,000
R Square		0,158				
Adjusted R Square		0,145				
F value		11,688				
Sig. F		0,000				

In Table 3 information is presented that the adjusted R Square value is 0.145 which means that 14.5% of hotel booking intentions variations can be explained by the variables usefulness, timeline, volume, positive valence, negative valence, and comprehensiveness, while the remaining 85.5% is explained by other factors beyond this research model. The significance value of F is 0.000. The significance value is lower than the value of $\alpha = 0.05$. This means that the research model involving usefulness, timeline, volume, positive valence, negative valence, and comprehensiveness variables is feasible to estimate hotel booking intentions variables.

4.3 Hypotheses testing

Hypothesis testing as presented in Table 3 explains that the usefulness variable of the Sig. 0.000 is smaller than $\alpha = 0.05$ with a positive regression coefficient of 0.272. This shows that the usefulness variable has a significant positive effect on hotel booking intentions so that H_1 is accepted. This shows that the higher the usefulness of online reviews, the more interest in hotel bookings will be. The usefulness of online review will be considered important and useful if the information submitted in the OCR is related to the hotel, the content is reliable, neutral and reflects the reviewer's heart, according to experience, presents useful information, is related to the hotel, is not confusing and impartial. The results of this study are in line with the research [27, 28] that the usefulness of online reviews has a positive effect on hotel booking intentions.

The timeline variable is Sig. 0.001 is smaller than $\alpha = 0.05$ with a positive coefficient of 0.183. This shows that the timeline variable has a significant positive effect on hotel booking intentions so that H_2 is accepted. This shows that the more up to date an OCRs will increase interest in hotel bookings. This condition illustrates that consumers are very concerned about uploading reviews, loading the latest information, following the latest news developments that affect purchasing decisions [19]. This is in line with what was stated by Jindal and Liu [18] who found that in the current e-commerce era, the latest online reviews will get more attention from other consumers. Consumers will get information about the development of hotel services through OCRs, which has been around for a long time. As for the company, this will help build the company's reputation in terms of responsiveness when answering consumer reviews. The results of this study support the research of Zhao et al. [27] that the timeline has a significant effect on consumer interest in hotel booking intentions.

The volume variable (X_3) is the Sig. 0.261 is greater than $\alpha = 0.05$ but the negative coefficient value is -0.068. This shows that the volume variable has a negative and insignificant effect on hotel booking intentions, so H_3 is rejected. This means that the number of online consumer reviews (OCRs) cannot increase interest in hotel bookings. Respondents assumed that the amount of OCRs does not guarantee the information that is informative, original, and following consumer expectations. On the other hand, consumers often only read a portion of reviews before deciding to purchase because they are more focused on new reviews [30]. Another factor is opinion leadership where consumers do not care or pay much attention to volume but rather trust the opinions of influential people [20]. The findings of this study confirm the characteristics of the millennial generation who are more easily influenced by the opinions of influential people such as the public figure.

The positive valence variable is Sig. 0.054 is greater than $\alpha = 0.05$ and the regression coefficient is positive at 0.096. This shows that the positive variable has a positive but insignificant effect on hotel booking intentions, so H_4 is rejected. Positive comments written by reviewers are a response to the satisfaction of the service received but unable to attract online bookings. The results of the study contradict the results of the research of Tsao et al. [3] who found that reading positive comments has a strong influence on booking intentions.

This condition can occur because positive valence expresses subjective opinions so that consumers do not pay attention to the number of positive reviews. Besides that, the number of positive online consumer reviews that is too much can also cause doubts to consumers about the credibility of the online consumer reviews. This may be caused by companies that pay reviewers to write reviews according to the company's wishes to help their sales [30], where the valence of these reviews can be adjusted according to the seller's needs. The results of this study refute the results of the study by Tsao et al. [3] that positive reviews are the most influential in determining interests and attitudes to decide [34].

The negative valence variable is Sig. 0.229 is greater than $\alpha = 0.05$ and the negative regression coefficient value is -0.055. This shows that the negative valence variable has no significant effect on hotel booking intention, so H_5 is rejected. This shows that negative valence does not affect hotel booking intentions. Negative reviews are a response to dissatisfaction with the service perceived by consumers and have a negative impact on business interests [26] so that these negative comments can be handled properly, it will increase room bookings/hotel room sales [32-35].

The variable comprehensiveness value is Sig. 0.000 is smaller than $\alpha = 0.05$ and the regression coefficient value is positive 0.189 so that H6 is accepted. This shows that the more complete and detailed the contents of an online consumer review (OCR) will increase interest in hotel bookings. When consumers are unfamiliar with a product/service, consumers will need more detailed and specific information to help them make decisions [32].

Consumers are more interested in a complete and detailed OCR which contains information such as the experience of staying, reviews of the hotel's superior facilities, information about the location, prices, and services provided by the hotel based on the customer's perspective. Consumer behavior should be aimed at achieving more sustainable results and achieving sustainable consumer behavior, which includes simplification of consumption [31-33]. This means that the assessment from the reader side is an important indicator in decision making [2] because it is proven that comprehensiveness of online reviews is an important attribute among the attributes of OCR that can influence consumer purchase interest [17, 27].

5 Conclusion

Theoretically, the results of this study add to the body of knowledge in the hotel booking intentions literature while closing the research gap. First, that the model formed from the variable usefulness, timeline, volume, positive valence, negative valence, and comprehensiveness contributed significantly to online booking intention in industrial hotels.

The results of this study also succeeded in closing the second gap in how hotel websites and online travel agents paid high attention to the quantity, quality and detail of information so as to present comprehensive and not confusing information. This information provides an important impact on how consumers take attitudes and determine decisions for hotel bookings. Last, to closing the third gap, the results of the present study also provide insight that the behavior of the millennial generation is unique, a characteristic that is aware of technology and tends to follow leadership opinions from influential figures. The results of the study illustrate that OCR has a significant effect on the online booking intentions of hotels. Overall, our findings show that the perspective of the millennial generation is important in considering hotel booking intentions.

Given the complexity of the online environment, several variables may influence the intentions to purchase online. The theory of reason action (TRA) provides a structure for the model adopted in this study and helps to focus on the main antecedents of online ordering intentions. TRA is one of the most widely used theories for predicting attitude-behavior relationships and has been widely adopted in tourism studies. The concept underlying TRA is that individuals evaluate the implications of their reasoned actions before they decide to engage in certain behaviors. In particular, this theory proposes that behavioral intentions is the main element responsible for consumer behavior.

Managerially, managers can carry out strategies at two levels, namely, at the individual level, by increasing knowledge sharing between units that manage the website so that it becomes more innovative, creative, up to date and interesting. managerial is by implementing:

1) adding the usefulness voting feature of existing online reviews, so that readers can judge which reviews they think to help their information search process;

2) use review categories by entering the time sequence category to display the latest reviews from reviewers;

3) hotel managers or travel agents are advised not only to focus on a large number of reviews but also pay attention to the quality and valence (positive or negative) of online reviews;

4) pay more attention to negative reviews or complaints from consumers;

5) provide information in the form of a summary from written reviews, such as graphic information that shows the percentage of reviewers who said they were satisfied with hotel services and other information.

Because millennial consumers tend to rely on categorical information because it is simple and easy to understand, the effect is that organizations have a culture of innovation to be able to maintain competitive advantage through the continuous system and website updates.

Abstract. Modern enterprises are dynamically developing due to the fourth industrial revolution, contributing to the introduction of innovative infocommunication technologies in most business processes, thereby shaping and developing the digital economy. The aim of the article is to substantiate the concept of sustainable development of enterprises in the context of digital transformations. The theoretical and methodological foundations of sustainable development at different levels of the hierarchy have been determined. The concept of sustainable development of enterprises has been developed, the implementation of which is aimed at harmonizing the economic, environmental and social activities of the enterprise. The stages of the process of implementing the concept of sustainable development of enterprises are highlighted, providing for the justification of an inert, neutral, progressive or forced vector. Ensuring the implementation of the concept of sustainable development is expected through the use of applied models, in particular, the implementation of a parametric model of joint deployment of enterprise infrastructure with other infrastructure facilities in economic activity, taking into account technical, geographical, organizational and socio-economic factors to strengthen financial stability; building a model for ensuring a balanced balance between economic efficiency and environmental and social responsibility of an enterprise using a mechanism for managing transformation processes in the process of transition to sustainable development in the context of digitalization.

1 Introduction

Modern enterprises are dynamically developing due to the fourth industrial revolution, contributing to the introduction of innovative infocommunication technologies in most business processes. Given the conditions for the transition of the Ukrainian economy to a digital development strategy, where the main driving force is digital trends, smart products and services, the issues of sustainable development of enterprises are being actualized. The implementation of the concept of sustainable development of enterprises is due to the constantly growing needs of consumers of telecommunications services in the global digital revolution, the need to comply with the goals of sustainable development of Ukraine, modification of the economic, social and environmental activities of enterprises.

Therefore, there is a scientific and applied problem of theoretical substantiation, methodological support and practical implementation of the process of sustainable development of enterprises for their harmonized evolution, reducing the existing digital divide and the qualitative development of the economy in the context of digital transformations.

2 Analysis recent research and publications

The possibility of enterprises' transition to sustainable development is associated with the solution or mitigation of a number of fundamental contradictions between the interests of the world community, the interests of individual countries and regions, national-state interests and the interests of enterprises in various spheres of economic activity. Therefore, such a transition requires the formation of effective models or mechanisms for ensuring sustainable development of enterprises [1-3].

The theoretical aspects and practical approaches to the essence of the balanced development of enterprises, the prerequisites for the transition to sustainable development, the problems of ensuring the social and environmental responsibility of enterprises, the directions for ensuring the sustainable development of economic systems are devoted to scientific works: K. Andriushchenko, A. Buriachenko, O. Rozhko et al. [1],

R. Sharma, A.-R. Fantin, N. Prabhu, C. Guan, and A. Dattakumar [2], J. Mao, C. Li, Y. Pei, L. Xu [3], Y. Zaloznova, N. Trushkina [4], T. Osburg, C Lohrmann [5], I.W.E. Arsawan et al. [6] and others. Paying tribute to the importance of scientific achievements of foreign and domestic scientists, it should be noted that the issues concerning the features of ensuring sustainable development of enterprises in the context of digital transformations remain insufficiently studied. The complex and multifaceted issue of ensuring sustainable development of enterprises should be investigated on the basis of economic efficiency and environmental and social responsibility.

3 Methods

The conceptual and methodological basis of the work is formed by the fundamental provisions of foreign and domestic scientists on the theory and practice of the concepts of sustainable development of enterprises. The study is based on a set of general scientific and special methods of cognition of the theoretical, methodological and conceptual foundations of sustainable development of enterprises: The article uses methods of dialectical cognition, generalization, scientific abstraction, formalization of structures and a system-situational approach in substantiating the concept of sustainable development of enterprises in the context of digital transformations through the definition of a set of prerequisites, motives and goals for the transition to this concept.

The aim of the article is to substantiate the concept of sustainable development of enterprises in the context of digital transformations.

4 Results

The globalization ecological transformations of the last century made it possible to understand that society has overcome the permissible ecological boundaries and, over time, human dependence on the laws of the biosphere is increasing, which affect the use of natural resources, the course of the ecological and social crisis [7-8].

With the beginning of the development of digital technologies and the formation of the digital economy, a new round of globalization transformations began, based on electronic products, the sale of which is carried out by a network of business entities through the flow and process of "digitizing" objects and the creation and exchange of digital assets (virtual assets) using electronic means, which are the backbone of the digital economy. The activities of business entities are subject to significant perturbations of the rapidly changing states of international markets, since the impact of globalization and digital transformations is directed not only to the microeconomic systems themselves, but also to the existing and emerging interconnections between them, leading to their unpredictable behavior [9].

The ICT development index (IDI) [10] has been used to measure the information society in the world for over 10 years 66; it is intended to be global and reflect changes in countries with different levels of development (Table 1, Table 2) and is a composite an index that combines 14 indicators (covers 81 indicators for telecommunication / ICT services).

Table 1. Dynamics of the ICT Development Index according to ITU regions and countries with different levels of development (based on data from [10]).

Regions	Years				
	2013	**2014**	**2015**	**2016**	**2017**
IDI by ITU Region					
Africa	2,31	2,31	2,30	2,48	2,64
South and North America	4,86	4,88	4,89	5,13	5,21
Arab countries	4,55	4,59	4,63	4,81	4,84

Russian Federation	6,82	6,91	6,91	7,07
Georgia	5,02	5,25	5,59	5,79
Ukraine	5,18	5,23	5,31	5,62

IDI as a comprehensive indicator measures the level and evolution of ICT development in countries to build a ranking of countries and is used as a tool for comparative analysis of progress in ICT development, digital divide etc. [10]. That is, IDI can be used as an indicator for determining the information technology support of business entities.

The IDI is on the rise in many countries, but the constraints are the link between levels of ICT development and income levels, which requires better government policies and legislation for developing countries to stimulate competition and promote foreign direct investment.

Considering the convergence of communications and informatics, which led to progressive changes both in the production and consumption of goods and services, it provided a new stage in the development of not only all sectors of the national economy and relevant economic entities, but also social life in various directions.

Infocommunications have a system-forming role in the formation of a single digital economy and ensuring sustainable development of enterprises in various spheres of economic activity. At the same time, considerable attention should be paid to the issues of ensuring the sustainable development of these enterprises from the standpoint of their compliance with the global and national strategic goals for sustainable development.

For the first time, the UN was engaged in the search for ways out of the crisis and determination of the further movement of civilization, created the International Commission on Environment and Development in order to develop a “global program of changes”, which pointed out the connection between economic and social development problems with environmental problems.

At the same time, an important contribution was made by the scientific reports of the Club of Rome, which formulated the ideas of the transition of civilization from exponential economic growth to a state of “global dynamic equilibrium”, from quantitative to qualitative growth and a “new world economic order.”

All this served to form a new the institutional component – the ministries and departments responsible for environmental policy and the environment. As a result, there was a large-scale spread of “sustainable development” in order to long-term satisfaction of basic needs with the rational use of natural resources and formations go down to 2030, within which 17 Sustainable Development Goals Based on the principles of sustainable development defined by these documents, the world has begun the process of approving its own program initiatives to ensure it, taking into account national characteristics.

In Ukraine, the processes of forming a regulatory framework on environmental policy and ensuring sustainable growth began with the adoption of certain legislative initiatives in the field of environmental protection. Important legal documents in this direction are the Concept of Sustainable Development of Human Settlements, according to which socially, economically and environmentally balanced development of urban and rural settlements is assumed, and the Comprehensive Program for the Implementation of Decisions at the National Level was adopted directly. It should also be noted the approval of the National Action Plan for Environmental Health for 2000-2005, the Program for the Use of Production and Consumption Wastes for the Period until 2005, the Ukraine-EU Action Plan, which contains important initiatives to harmonize Ukrainian legislation with norms and standards. EU, ensuring the country's economic, social and environmental growth, and then the National Environmental Action Plan for 2011-2015. and a range of other fragmented initiatives towards environmental and social sustainability.

In addition, several legislative attempts were made to approve the concept of sustainable growth in Ukraine, in particular in 2001, 2004 and 2012. Now the achievement of balanced sustainable growth is identified as a strategic development priority both at the level of the national economy and regional and business ecosystems. Therefore, at the state level, the strategic guidelines for the balanced development of the country are outlined in the Sustainable Development Strategy “Ukraine 2020”, which defines the implementation of 62 reforms and development programs of the state within four vectors of movement: development, security, responsibility and pride. It should also be noted on the Concept of Ukraine’s transition to sustainable development, the purpose of which is to ensure a high quality of life for current and future generations based on a balanced solution to the problems of socio-economic development, preservation of the natural environment, rational use and reproduction of the state's natural resource potential. The modern transformation of the Ukrainian economy in the process of integration into the world society and the country's active participation in globalization processes necessitate a balanced development of domestic enterprises based on the preservation of their structural features, potential and capacity. This requires the participation of various stakeholders and stakeholders in order to develop balanced consumption in view of the principles of consistency and the like.

4.1. Justification of the concept of sustainable development of enterprises in the context of digital transformations

The content of the concept of sustainable development of an enterprise should be formed on the basis of a system-process approach. It should be based on the synthesis of three basic components: economic, social and environmental, and represent a model of economic growth of an enterprise, in which the use of resources is aimed at meeting the needs of the enterprise while ensuring a stable balance of the socio-ecological-economic system (Fig. 1).

The general idea of the concept is the sustainable development of the enterprise (SDE), the object is the economic, environmental and social activities of the enterprise, and the subject is the management system for the economic, environmental and social development of the enterprise under the influence of external and internal factors. At the same time, the paradigm is the provision of sustainable development of the internal and external environment through the harmonization of economic, environmental and social activities through the phased implementation of the concept in order to substantiate the development vector and its most overwhelming trajectory.

Since the concept is a systematization of all generated ideas for understanding the development and has to answer the question of how to achieve the general idea, it is advisable to present the process of its implementation, consisting of the following stages [11-13]:

1. Determination of the regulatory and information base regarding the legal framework and strategy of the country for the transition to sustainable development, the main trends in the world of enterprise development in the use of digital technologies.

2. Identification of factors of positive and negative influence on the activities of the enterprise of the processes of globalization and identification of existing problems in ensuring sustainable development.

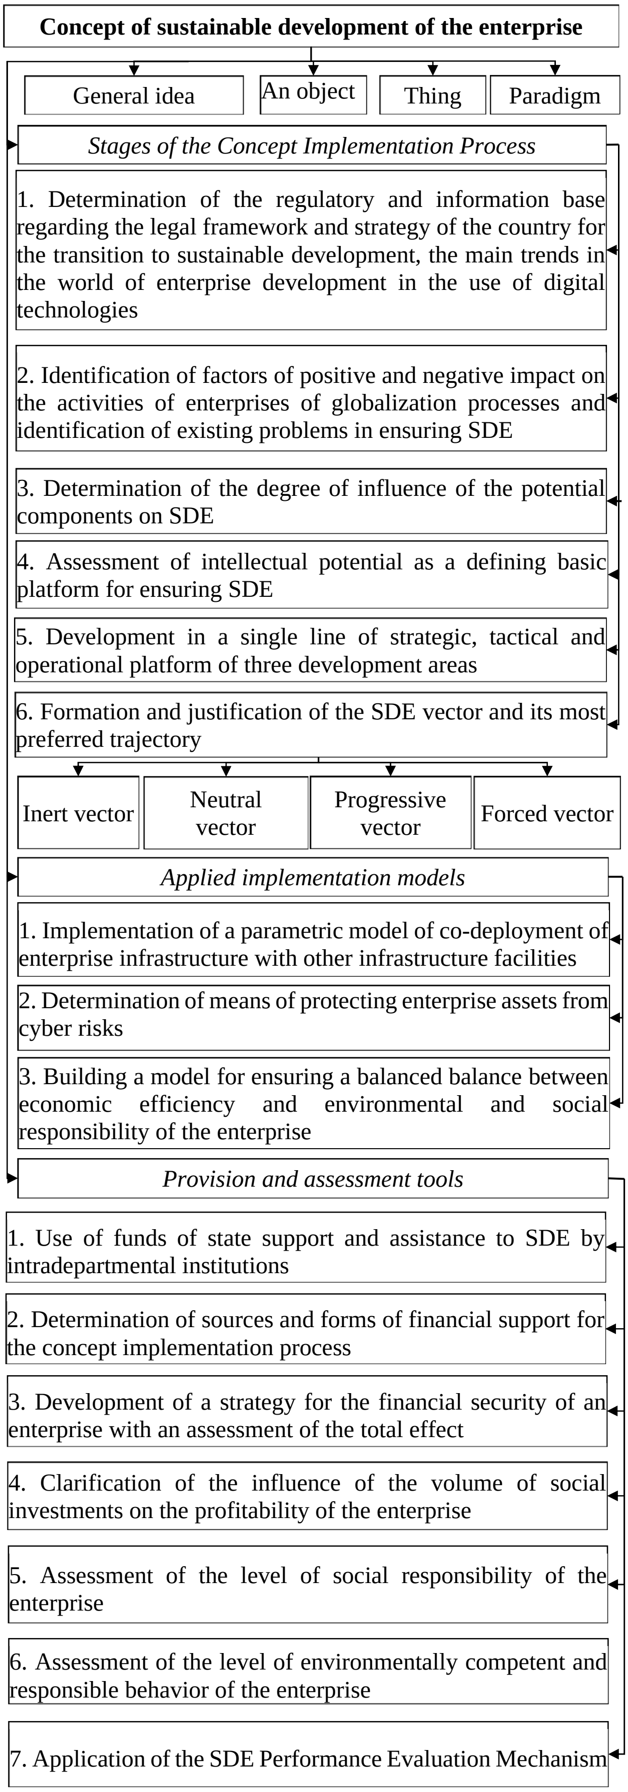

Fig. 1. Concept of sustainable development of the enterprise.

3. Determination of the degree of influence of the components of the potential on the sustainable development of the enterprise to determine the synergistic effect of sustainable development, taking into account digital transformations and the uniqueness of the communication and informatization sphere, taking into account the degree of economic, environmental, social, technological and intellectual potential. This analysis provides background information for identifying the benefits of the current state of the enterprise and modeling future states in a space-time aspect.

4. Assessment of intellectual potential as a determining base platform for ensuring sustainable development of the enterprise.

5. Development in a single channel of a strategic, tactical and operational platform of three directions of development – economic, environmental and social with modeling of possible states: the potential for survival, the potential for sustainability and development. They should provide for a set of strategic and tactical measures to implement the transition from an initial level to a new quality one in accordance with the chosen vector along a certain trajectory.

6. Formation and substantiation of the vector of sustainable development and its most overwhelming trajectory, that is, the direction of the enterprise. Sustainable development of an enterprise as a projection of its goals and capabilities in the context of the need to adapt to transformational changes can occur by:

– the inert vector, which is characterized by the situation of resistance to the process of sustainable development of the enterprise from the stakeholders of the near and far circle, consists in reducing the performance indicators of the enterprise, weakening the internal and external positions, the significant influence of unfavorable factors requiring immediate elimination of threats and restoration of the dynamic consistency of business processes

– a neutral vector, which can be considered as a transitional / waiting state in the short term for the formation of the necessary basis for further development, which is characterized by a controlled delay in development and a local concentration of the enterprise's activities aimed at forming sufficient financial support for the implementation of appropriate social and environmental investments;

– a progressive vector, is determined by the transition to frontal development, which provides for both economic development and fundamental socio-ecological development and covers various functional subsystems of the enterprise, based on the intensification of the use of the development basis, maximum use of existing opportunities in order to gradually achieve hierarchical strategic goals and the formation qualitative potential state;

– a forced vector, which provides for the transition to a comprehensive sustainable development of the enterprise, aimed at ensuring, maintaining and maintaining the balance of qualitative development in order to repel negative and absorb positive impulses from the external environment with the aim of further sustainable functioning and performance of economic, social and environmental functions within the formed harmonious space by focusing the enterprise not only on internal business processes and building internal potential, but also on ensuring the development of society.

Determining the trajectory of the enterprise's development allows us to find out how realistic it is to approach the upper limit of dynamic equilibrium in the process of enterprise development, for which it is necessary to establish a list of economic, social and environmental measures that contribute to this, without losing stability and reducing the level of security of the enterprise (staffing, information protection). The plane of socio-ecological and economic sustainability changes in the process of enterprise development, providing the necessary level of flexibility and adaptability, which is due to the variability of external and internal conditions of functioning. The concept of sustainable development of the enterprise provides for the implementation of applied models in the activities of the enterprise, in particular [14-16]:

1. Implementation of a parametric model of joint deployment of enterprise infrastructure with other infrastructure facilities into economic activity, taking into account technical, geographical, organizational and socio-economic factors to strengthen financial stability and security.

2. Determination of means of protecting enterprise assets from cyber-attacks (based on the identification of the most vulnerable assets and the formation of a matrix for systematizing cyber threats by determining the degree of cyber-attacks.

3. Building a model for ensuring economic efficiency and environmental and social responsibility of an enterprise using a mechanism for managing transformation processes in the process of transition to sustainable development in the context of digitalization of activities.

4.2 Implementation and assessment tools

The tools for ensuring the implementation of the concept and assessing its effectiveness are:

1. Use of funds of state support and assistance to sustainable development of enterprises by intradepartmental institutions. Support and promotion of sustainable development by enterprises should take place on the principles of public-private partnerships to form social dialogue, the widespread introduction of corporate social responsibility, which, in turn, will facilitate effective cooperation and fulfillment of obligations to ensure sustainable consumption and production. That is, government regulation should stimulate the activation and actualization of the use of all types of available resources, revealing modern potential market and social opportunities, organizing stimulating conditions for intensification, maintaining a favorable environment for increasing the efficiency of business and improving the quality of services provided [17].

2. Determination of sources and forms of financial support for sustainable development of enterprises. The sources for the implementation of the concept can be as own financial resources: profit, income, depreciation charges, insurance funds; and attracted financial resources on various terms of return: credit funds of financial institutions and other organizations, issue of shares, investments, sponsorship; while the forms of financial support can be external financing and self-financing. Financial support for the sustainable development of enterprises should occur through constant analysis of the compliance of the financial condition of the enterprise with a certain plane of sustainable space. The choice of each source and form of financial security must be justified in accordance with its characteristics, taking into account the disadvantages and advantages that can significantly affect the functioning of the enterprise. Depending on the vector of development and its trajectory, the volume of each source of financing will change in the total volume of financial resources of the enterprise.

3. Development of a strategy for the financial security of an enterprise with an assessment of the total effect of its implementation. Financial resources are one of the basic conditions for ensuring sustainable development of the enterprise and the formation of positive results of its functioning. Therefore, the existence of an effective financial security strategy that will protect the enterprise from threats requires careful consideration by the enterprise. The strategy of the economic security of the enterprise is an integral part of the formation and implementation of the general strategy of the enterprise development, since it is responsible for the goals, directions, sources and objects of financing. It provides all the main directions of the development of financial activities and financial relations of the enterprise.

4. Clarification of the influence of the volume of social investments on the profitability of an enterprise in order to form more perfect and effective ways to increase the competitiveness of enterprises and their value.

5. Assessment of the level of social responsibility of an enterprise involves taking into account the basic, corporate and higher levels of social responsibility in order to determine the effectiveness of the path of social investment.

6. Assessment of the level of environmentally competent and responsible behavior of the enterprise, taking into account the management's policy in helping to maintain the desired state of the environment by: implementing measures aimed at motivating changes in the behavior of its stakeholders, aimed at reducing the negative impact on the environment and human health; search for solutions that do not contradict the goals of sustainable development of the country.

7. Application of a mechanism for assessing the effectiveness of sustainable development of an enterprise in the context of digital transformations, based on the principles of building neural networks and aimed at determining the generalized multiplier of the effectiveness of sustainable development of an enterprise.

Thus, the scientific and practical meaning of the concept of sustainable development based on the system-process approach is substantiated, it is contained in the triad “existing initial state – development potential – change in the qualitative state” and makes the management of individual subsystems of enterprise development, constitute a single integral socio-ecological economic system of sustainable development [18-19]. This approach will optimize the methods and tools used, increase adaptability to fluctuating conditions, and will also serve as a guarantee of responsibility to the owners of the enterprise (receipt of dividend income), employees (a decent level and timeliness of remuneration, career growth, socio-cultural development), partners (successful and effective long-term cooperation), local and state authorities (ensuring long-term development and participation in charitable events in the regions of presence, replenishing the budget with tax revenues), as well as consumers (ensuring and raising people's awareness of the possibilities of using IT services, promoting the popularization of services, training citizens, environmental and socially responsible business) [20].

5 Conclusions

Using the system-process approach as a scientific basis, the content of the concept of balanced development, taking into account the peculiarities of the activities of a telecommunications enterprise, is generalized, based on the synthesis of three basic components: economic, social and environmental, and is aimed at ensuring their harmonization. The process of implementing the concept is aimed at choosing the most optimal (in existing conditions) trajectory of balanced development, is selected from inert, neutral, progressive, forced vectors. The concept of balanced development of enterprise is implemented through the use of applied models and tools to ensure and assess the effectiveness of sustainable development. Ensuring the implementation of the concept of sustainable development is expected through the use of applied models, in particular, the implementation of a parametric model of joint deployment of enterprise infrastructure with other infrastructure facilities in economic activity, taking into account technical, geographical, organizational and socio-economic factors to strengthen financial stability; building a model for ensuring a balanced balance between economic efficiency and environmental and social responsibility of an enterprise using a mechanism for managing transformation processes in the process of transition to sustainable development in the context of digitalization.

Abstract. The need for sustainable development of Ukrainian regions is due to the global threat of environmental degradation, the unstable situation in the world economy, low socio-economic indicators of the country and weak innovation activity. An important factor that has an influence on the economic development of regions is the ecological state of the environment. It plays one of the most important roles in the conducting of economic activities that require the use of natural resources. According to the results of the investigation, four clusters were formed. Cluster analysis made it possible to conduct a general assessment of the state of the regions of Ukraine, to form groups by similarity and to draw sound conclusions about the existence of similarities in the economy. The formation of clusters and the development of sustainable development policies for individual clusters, which should have significant differences, taking into account their specifics, will contribute to the more effective achievement of sustainable development goals.

1 Introduction

Currently, sustainable development is becoming an important component of the development of Ukraine and its regions. However, the unstable economic situation in the country, raw materials, and export-oriented nature of the country's economy do not allow it to effectively use the mechanisms of sustainable development policy developed for developed countries.

Ecological and economic aspects of sustainable development are in fact the separation of production processes and environmental protection. When developing a policy for the sustainable development of regions, it is important to take into account both the socio-economic and environmental interests of the local population. Underestimation of the environmental factor and environmental constraints in the development of sustainable development documents leads not only to numerous negative consequences in nature management, but also deep long-term disparities between economic, social, and environmental development of different levels, affects the quality and efficiency of environmental regulation. In this regard, taking into account the environmental factor in the management of sustainable development of the region becomes especially important.

In crisis and an unstable external environment, the regions of Ukraine are faced with the problem of sustainable and stable socio-economic development. Sustainable regional development in a crisis is of particular importance and significance, since without clear goals and guidelines for movement, the achieved results can be negative. The cluster approach, which allows government bodies to achieve a long-term competitive advantage, can become the basis for sustainable development of the region. The idea of the investigation is to substantiate a theoretical and practical approach to assessing the need to form the regional potential of cluster formation for sustainable regional development. The purpose of the study is to use data mining tools to identify patterns and relationships based on data on air pollution in the regions of Ukraine. Spatial data mining involves identifying interesting and potentially useful templates from databases by grouping objects into clusters.

2 Sustainable development of Ukrainian regions

The need for sustainable development of Ukrainian regions is due to the global threat of environmental degradation, the unstable situation in the world economy, low socio-economic indicators of the country and weak innovation activity. The basic aspects of sustainable development policy, goal setting and interaction between them, as well as the experience of developed countries are presented in studies [1-7].

Competitive regions of Ukraine are a source of growth for the whole country, a pillar of national policy to reduce regional disparities, promote more balanced development and promote sustainable development of the country. In general, ensuring sustainable development of the country is possible only when sustainable development of all regions is achieved. The policy of sustainable development of the regions provides for the formation of such conditions and the use of such mechanisms under which the natural basis of this development is not

* Corresponding author: marina.nehrey@gmail.com

destroyed, the preservation and reproduction of the environment is ensured.

Sustainable development of the region is an activity of planning, organization, coordination of economic, social, technical-technological, ecological, and other processes, aimed at effective use of its economic potential in order to improve the quality of life and working conditions of economic entities. not only present but also future generations. Moreover, this activity is carried out both within the region and abroad. Analysis of sustainable development of regions, their features and prospects for implementation are presented in [8-17]. Measurement of various aspects (ecological, financial, technical etc.) of regional development and analysis of their impact on sustainable development presented in the papers [18-23].

Sustainable development policy at the regional level should be aimed at achieving the following goals:

– greening of the economy;
– improving the quality of the environment;
– improving the quality of life of the population;
– restoration of natural resources.

The main tools for developing sustainable development policy are:

– at the state level – coordination of infrastructure development, granting special status to certain territories, direct financial support (subsidies, transfers);

– at the regional level – strategic planning of regions in order to balance socio-ecological and economic development, limiting the creation of environmentally harmful enterprises in densely populated areas;

– at the community level – cooperation between communities to join forces to accelerate development.

3 Cluster analysis as method of organizing groups of objects

Cluster analysis is used in various fields and industries. It works even when there is little data and the requirements for the normality of the distribution of random variables and other requirements of classical methods of statistical analysis are not met. It is useful when you need to classify a large amount of information.

Cluster analysis has a number of advantages over other methods of data classification. First, it allows to break down objects by a single feature or by a whole set of features. Moreover, the influence of each of the parameters can be quite simply enhanced or weakened by making the appropriate coefficients in the mathematical formulas. Second, cluster analysis does not restrict the type of grouping objects and allows to consider many data source of almost arbitrary nature. Third, the peculiarity of clustering is that most algorithms are able to independently determine the number of clusters into which you want to break down the data, as well as to identify the characteristics of these clusters without human intervention, only using the algorithm used. The essence of the cluster analysis procedure is that the objects are represented by a vector (set) of individual features of these objects in the form of a table “object-property”, on the basis of which the matrix of distances (similarity, proximity) is calculated, which is carried out by clustering. This solves the problem of classifying data using a well-formed mathematical apparatus.

Cluster analysis of the spatial distribution of objects allows to reduce the dimensionality of data, to make it clear. Thus, whenever a large amount of information needs to be classified into groups suitable for further processing, cluster analysis is very useful and effective. The main task of cluster analysis is the formation of homogeneous groups in multidimensional space.

Clustering algorithms are usually built as a certain way to search the number of clusters and determine its optimal value in the search process and include 5 basic steps:

1. Sampling for clustering.
2. Determining the criteria by which objects will be evaluated in the sample.
3. Calculation of values of one or another degree of similarity between objects.
4. Application of cluster analysis to create groups of similar objects.
5. Verification of the results of the cluster solution.

Today, there are many methods of dividing groups of objects into clusters. There are several dozen algorithms and even more modifications. But most often the methods of cluster analysis are divided into two large groups: hierarchical and non-hierarchical.

When choosing between hierarchical and non-hierarchical methods, it is necessary to take into account their features. Non-hierarchical methods show higher resistance to noise and emissions, incorrect choice of metrics, the introduction of insignificant variables in the set involved in clustering. The price to pay for these benefits of the method is the word "a priori". The analyst must determine in advance the number of clusters, the number of iterations or the stop rule, as well as some other clustering parameters. This is especially difficult for novice professionals. If there are no assumptions about the number of clusters, it is recommended to use hierarchical algorithms. However, if the sample size does not allow this, a possible way is to conduct a series of experiments with different numbers of clusters, for example, to start breaking down the data set from two groups and, gradually increasing their number, to compare the results. Due to this "variation" of the results, a fairly high flexibility of clustering is achieved. Hierarchical methods, in contrast to non-hierarchical ones, refuse to determine the number of clusters, and build a complete tree of nested clusters. Complexities of hierarchical clustering methods: limiting the scope of the data set, choosing the degree of proximity, inflexibility of the obtained classifications. The advantage of this group of methods compared to non-hierarchical methods is their clarity and the ability to obtain a detailed representation of the data structure.

Thus, the following conclusions can be drawn: cluster analysis is a universal tool that can be used in regional modelling. With its help, you can analyse data on the similarity of objects. The results of the analysis are presented in a convenient visual form, which facilitates decision-making to determine the optimal number of factors and the relationship of various clusters.

4 Regions of Ukraine clustering by ecological and economic indicators

4.1 Regions of Ukraine clusterization by the level of air pollution

An important factor that has an influence on the economic development of regions is the ecological state of the environment. It plays one of the most important roles in the conducting of economic activities that require the use of natural resources. Personnel potential often depends on the ecological condition of the region, people have a desire to live and work in cities with good environmental performance, access to drinking water, and clean air.

For investigating the economic potential of the regions, it is advisable to form a comprehensive assessment of the regional environmental conditions according to several indicators that are most important. To characterize the quality of the ecological state, the regions should be classified according to several diverse quantitative characteristics in order to identify homogeneous and unique objects by the obtained values. The most effective method for such a multicriteria classification is cluster analysis.

The subject of this investigation is the application of clustering methods for the formation of cluster groups from the regions of Ukraine. The comprehensive assessment will be based on the comparison of all regions, the formation of groups on the similarity of their characteristics with each other, using the techniques of multidimensional classification of economic objects to combine them into homogeneous classification groups on selected characteristics.

The aim of the investigation is a clustering of regions of Ukraine by air pollution. Statistical data from the Statistical Yearbook Environment of Ukraine 2018 (published by the State Statistics Service of Ukraine) on air pollution in the regions of Ukraine by emissions of nitrogen dioxide (thousands of tons) and emissions of sulfur dioxide (thousands of tons) are used [24].

Unlike controlled learning, where there is a base of values to assess the effectiveness of the model, the cluster method k-means does not have a solid evaluation metric that we can use to evaluate the results of different clustering algorithms. Moreover, the k-mean method requires an input number k, and this value is not calculated from the values that need to be evaluated. As a result, there is no right answer to what number of clusters we need to build. Sometimes subject knowledge or intuition can help you choose the number k, but this is not always true. According to the methodology of cluster forecasting, we can assess how well the models work based on different numbers of clusters. In this paper, we will consider 2 indicators that can help us estimate how many clusters we need to use in the k-mean method: elbow method and Silhouette analysis.

The Elbow method will help calculate the optimal number of clusters based on the sum of the squares of the distances between the data points and the centroids. When visualizing this method, the optimal value is where the curve is the first bent, and then gradually aligned.

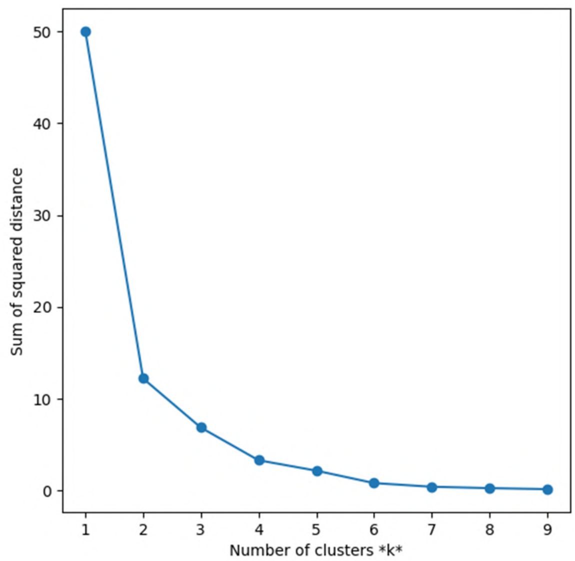

Fig. 1. Calculation of the number of clusters with the Elbow method.

As we can see, the graph from Fig. 1 indicates that the number of clusters should be 2. However, sometimes it is difficult to determine the exact number of clusters, because the curve may fall monotonically and will not be visually visible moment of its “fracture” or “elbow”.

Silhouette analysis can be used to determine the degree of division between clusters. For each example you need:

1. Calculate the average distance from all data points in one cluster (a^i).
2. Calculate the average distance from all data points in the nearest cluster (b^i).
3. Calculate the coefficient:

$$\frac{b^i - a^i}{\max(a^i, b^i)}.$$

The coefficient can take values in the range [-1; 1]:

– If it is equal to 0 – then the element is very close to neighboring clusters.

– If it is equal to 1 – then the element is far from neighboring clusters.

– If it is equal to -1 – then the element is improperly classified, belongs to the wrong cluster.

As we see from Fig. 2 – 4, the coefficient from the Silhouette analysis method is closest to 1 when constructing two clusters and is equal to 0.8 (Fig. 2). We obtained good results, which confirm the result of the previous method Elbow method, that the optimal number of clusters for clustering our data by the k-mean method is the number 2. So, both Silhouette analysis method and Elbow method has given the same result for the number of the clusters, that’s why regions of Ukraine were grouped in two clusters.

Clustering results:

1. The first cluster includes Donetsk, Dnipropetrovsk and Ivano-Frankivsk regions.
2. The second cluster includes Vinnytsia, Volyn, Zhytomyr, Zakarpattia, Zaporizhia, Kyiv, Kirovohrad, Luhansk, Lviv, Mykolaiv, Odesa, Poltava, Rivne, Sumy,

Ternopil, Kharkiv, Kherson, Khmelnytsky, Cherkasy, Chernihiv and Chernivtsi, Kyiv.

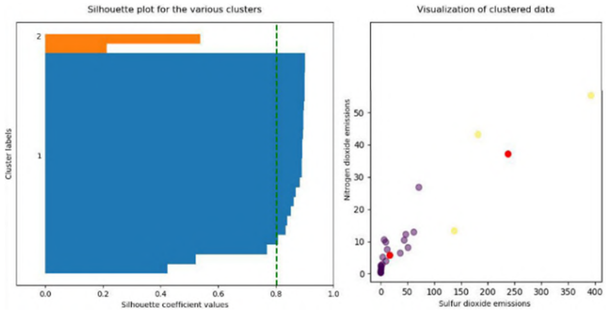

Fig. 2. Silhouette analysis for two clusters.

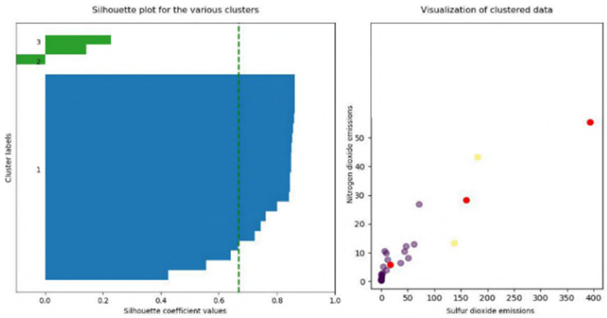

Fig. 3. Silhouette analysis for three clusters.

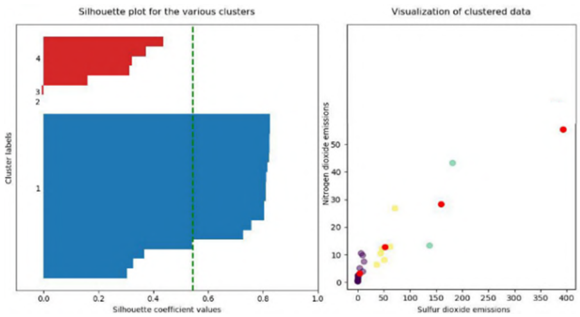

Fig. 4. Silhouette analysis for four clusters.

The centroid for the first cluster contains a pollution value of 237.5 thousand tons of sulfur dioxide emissions and 37.2 thousand tons of nitrogen dioxide emissions into the atmosphere; for the second cluster 16.54 thousand tons and 5.83 thousand tons, respectively.

4.2 Clustering of Ukraine regions by environmental factors

It is obvious that the ecological condition of the regions of Ukraine depends not only on the state of air pollution. Therefore, in addition to the characteristics of air purity, the study includes the number of green areas, the degree of environmental pollution and the capacity of treatment plants.

The criterias that will characterize the state of the environment in all areas and prospects for its improvement:

– emissions of pollutants into the atmosphere from stationary sources of pollution by region (t / km^2);

– area of forests reproduction by regions (ha);

– waste incineration by regions (thousand tons);

– capacity of treatment plants by regions (million m^3).

All statistical indicators are taken from Statistical Yearbook Environment of Ukraine 2018 (by the State Statistics Service of Ukraine) [24].

Four clusters were obtained by the hierarchical clustering method:

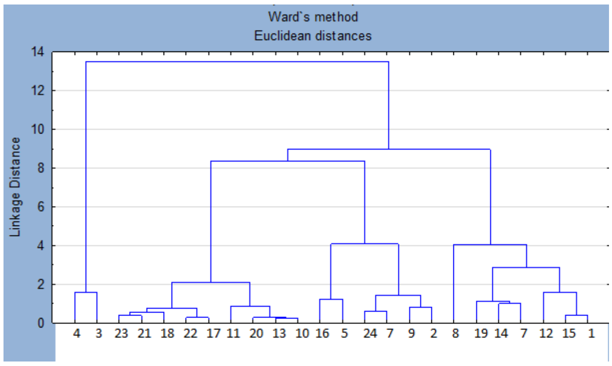
– The first cluster. Donetsk and Dnipropetrovsk regions;

– The second cluster. Chernivtsi, Khmelnytsky, Ternopil, Cherkasy, Sumy, Luhansk, Kherson, Mykolaiv, Kirovohrad regions;

– The third cluster. Rivne, Zhytomyr, Chernihiv, Zakarpattia, Kyiv, Volyn;

– The fourth cluster. Ivano-Frankivsk, Kharkiv, Odesa, Zaporizhia, Lviv, Poltava and Vinnytsia regions.

The dendrogram is shown in the figure 5.



1 – Vinnytsya, 2 – Volyn, 3 – Dnipropetrovsk,4 – Donetsk, 5 – Zhytomyr, 6 – Zakarpattya, 7 – Zaporizhzhya, 8 – Ivano-Frankivsk, 9 – Kyiv, 10 – Kropyvnyckyi, 11 – Luhansk, 12 – Lviv, 13 – Mykolayiv, 14 – Odesa, 15 – Poltava, 16 – Rivne, 17 – Sumy, 18 – Ternopil, 19 – Kharkiv, 20 – Kherson, 21 – Khmelnytskiy, 22 – Cherkasy, 23 – Chernivtsi, 24 – Chernihiv.

Fig. 5. Diagram of hierarchical cluster of regions of Ukraine by environmental conditions.

For the accuracy of the study, we form four clusters using another method – k-means.

We get the result, where for each cluster there is the region and the distance from the cluster center:

– the first cluster: Dnipropetrovsk 0.393, Donetsk 0.393;

– the second cluster: Zakarpattia 0.377, Kropyvnyckyi 0.268, Luhansk 0.344, Mykolayiv 0.378, Sumy 0.103 Ternopil 0.293, Kherson 0.310 Khmelnytsky 0.194, Cherkasy 0.1, Chernivtsi 0.186, Chernihiv 0.544;

– the third cluster: Volyn 0.332, Zhytomyr 0.548, Kyiv 0.544, Rivne 0.462;

– the fourth cluster: Vinnytsia 0.376, Zaporszhzhya 0.538; Ivano-Frankivsk 1,202; Lviv 0,527, Odessa 0.416, Poltava 0.529, Kharkiv 0.653.

The means of the emissions of pollutants into the atmosphere from stationary sources of pollution by cluster for the first cluster is 702,25 for the second cluster is 21,07$ for the third cluster is 21,13 and for the fourth cluster is 104,9 t / km^2.

The means of the area of forests reproduction by regions for each cluster respectively are 245,5; 1389,9; 6185,25 and 1537 ha.

The waste incineration by clusters are 15; 17,25; 37,1 and 65,35 (thousand tons);

The capacity of treatment plants by clusters are 792,5; 85,63; 110.2; 250,56 (million m^3).

As we can see, the two regions with the largest number of industrial facilities in Donetsk and Dnepropetrovsk, are immediately combined into one group, which can be explained by voluminous emissions of pollutants into the atmosphere from production, a large amount of incinerated waste, and a small area of the forest reproduction, given the location in the steppe zone.

In the second cluster, there are the objects that have the closest connection with each other – these are the regions of the central and partly western part of the country. They have a similar relief, the average man-made load on the environment. They can be described as areas with an ecological situation that needs improvement, due to the planting of forests and increasing the number of treatment facilities. It should be noted that this includes the Zakarpattia region, which does not have a large number of industrial facilities, but there is a problem of mass deforestation, which has grown into a real environmental disaster.

The third group is formed in regions that have a medium close connection with each other. These are the regions of Ukraine where the ecological situation is considered the best. Volyn, Zhytomyr, Rivne regions have the best indicators of air purity, there are no heavy industry enterprises that carry out large-scale emissions of waste. The areas are located in a forest area, which only benefits the ecology of the areas.

The fourth cluster regions, as well as the previous one of medium-density connections between objects. These are the regions of the southern and western parts of Ukraine, without a large number of industrial facilities with emissions of harmful substances. Areas of forest and steppe zones, with treatment facilities of medium capacity.

4.3 Regions cluster analysis taking into account the gross regional product

For investigation the relationship between environmental indicators and economic potential, we will carry out clustering of regions based on gross regional product (figure 6).

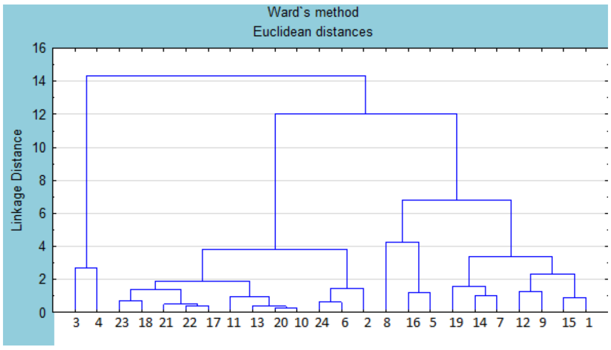
Three groups of objects are now clearly distinguished by similarity. The first cluster remained unchanged: Donetsk and Dnipropetrovsk oblasts, while the second was supplemented by Chernihiv, Zakarpattia, and Volyn oblasts as a result of the reduction of distances to the cluster center. The other three areas in the third group became similar to the objects in the next cluster.

For a more detailed distribution we use the method of k-means:

– the first cluster: Volyn 0.822, Transcarpathian 0.822, Kropyvnyckyi 0.288, Luhansk 0,358, Mykolayiv 0.414, Sumy 0.08, Ternopil 0.314, Kherson 0.345, Khmelnytsky 0.203, Cherkasy 0.219, Chernivtsi 0.352, Chernihiv 0.42;

– the second cluster: Dnipropetrovsk 0.608, Donetsk 0.608;

– the third cluster: Vinnytsia 0.382, Zhytomyr 1.257, Zaporizhya 0.696, Ivano-Frankivsk 1.189, Kyiv 0.764, Lviv 0.324, Odessa 0.633, Poltava 0.516, Rivne 0.462, Kharkiv 0.959.



1 – Vinnytsya, 2 – Volyn, 3 – Dnipropetrovsk,4 – Donetsk, 5 – Zhytomyr, 6 – Zakarpattya, 7 – Zaporizhzhya, 8 – Ivano-Frankivsk, 9 – Kyiv, 10 – Kropyvnyckyi, 11 – Luhansk, 12 – Lviv, 13 – Mykolayiv, 14 – Odesa, 15 – Poltava, 16 – Rivne, 17 – Sumy, 18 – Ternopil, 19 – Kharkiv, 20 – Kherson, 21 – Khmelnytskiy, 22 – Cherkasy, 23 – Chernivtsi, 24 – Chernihiv.

Fig. 6. Diagram of the results of cluster analysis taking into account the gross regional product.

The distance to the centers of clusters has increased for all regions, which is due to the addition of another characteristic of the studied objects. The number of groups also changed, with an increase in the similarity between the objects of each group. This indicates that we have been able to explore in more detail the relationship between environmental performance and economic development. The greater the similarity of the regions with each other in terms of the environment, the greater the similarity between them in economic characteristics.

Cluster analysis of the data made it possible to conduct a general assessment of the state of the regions of Ukraine, to form similarity groups, and to make reasonable conclusions about the existence of similarities in economic development and shortcomings that should be addressed.

5 Conclusions

According to the results of the investigation, four clusters were formed, the first of which included regions with developed heavy industry: Donetsk and Dnipropetrovsk, which characterizes them as regions with the worst environmental status. The second cluster – 12 regions of central and eastern Ukraine with a lower level of pollution than in the previous group, but still not with the best performance. This group includes the objects with the closest connection. The other two clusters have a medium-tight relationship, and are characterized by some of the best environmental performance. Cluster analysis made it possible to conduct a general assessment of the state of the regions of Ukraine, to form groups by similarity and to draw sound conclusions about the existence of similarities in the economy.

The sustainable development policy design should be implemented taking into account the specifics of the regions. In some regions, the pace and timing of changes and development may be different. The features of sustainable development are due to the fact that the goals and conditions of socio-economic development, the use of natural resources, and environmental protection are inextricably linked with a certain territory, which is characterized by specific geographic, demographic, and economic conditions. The regions of Ukraine differ significantly from each other in the area of territories, population size, volumes of industrial and agricultural production, the average per capita real incomes, which predetermines the differentiation of regions in terms of the available economic potential, level, and populations life quality.

This explains the fact that a universal sustainable development policy for all regions cannot be developed. Therefore, each region needs to design its own sustainable development policy as part of the country's overall sustainable development policy. The formation of clusters and the development of sustainable development policies for individual clusters, which should have significant differences, taking into account their specifics, will contribute to the more effective achievement of sustainable development goals.

Abstract. The development of the ideology of sustainable development stimulated the emergence of companies' Performance Management Systems with an emphasis on the environmental aspects of their activities. Benchmarking, as a modern management tool, is often used for competitive analysis and setting development goals. This study's scientific problem is to assess the feasibility of applying benchmarking studies to assess the global industry's environmental aspects. The purpose of the study is to identify the prerequisites for using benchmarking to improve environmental performance, as well as to identify best practices among world-leading companies. For benchmarking, a logical information model is proposed in the study. On its basis, eight world leaders were selected, trends in the industry's development were analysed, and reference values of environmental indicators were established. For environmental performance assessment, it is proposed to use such indicators as greenhouse gas emissions, energy consumption, material efficiency, environmental management systems. Comparative benchmarking analysis of world leaders and 16 largest Ukrainian companies allowed determining the reserves for increasing environmental performance. The directions for increasing environmental performance are Investment in resource-saving technologies, production of higher value-added products, investments in energy-saving and new technologies, improvement of management systems, and certification. These ideas are complemented by recommendations for improving environmental performance, based on the Circular Economy Concept's philosophy and Industry 4.0. The study's practical significance is that Ukrainian companies can use their results to achieve higher environmental and economic outcomes.

1 Introduction

1.1 Research question

Metallurgy is a factor in the success of national economies and the basis of global sustainable development, as well as a driver of related industries – shipbuilding, aviation, transport and heavy engineering, defence industry, energy, construction. In addition, the metallurgical industry is a source of environmental problems, as it produces harmful emissions into the atmosphere, wastewater and generates waste that pollutes the soil in the surrounding areas. Due to the extraction of ferrous and non-ferrous metals, there is a subsequent degradation and land quality change. The metallurgical industry is also responsible for thermal pollution.

The scale of world trade, the transnational nature of leading manufacturers, and their predominant export orientation confirms the industry's global nature.

According to the results of 2019, Ukraine is one of the leading producers of metallurgical products in the world. It ranks 13th (in 2016 – 7th) among the top exporters of metal products in terms of total exports (13.5 million tons) and fourth after China (60.9), Japan (31.2), and Russia (24.9) in terms of net exports (the difference between the number of exported and imported products of the industry). In 2019, the products of the metallurgical industry amounted to 20.5% (2nd place) in the total structure of exports from Ukraine.

The peculiarities of the development of the metallurgical industry in Ukraine are excessive capacities and technological backwardness, dependence on foreign trade, as well as a high level of openness of the industry (the coefficient of openness of foreign trade in Ukraine is 5.2 versus 0.7 in China, 1.8 – in the Russian Federation and 2.8 – in the USA). In addition, Ukrainian metallurgy produces a relatively small share of finished products with a large production of semi-finished products. As a result, Ukrainian products are not competitive enough. The industry is also characterized by low use of secondary raw materials and high capital and energy consumption. The industry is highly monopolized, led by vertically integrated holdings. Six manufacturers account for 84% of the industry's sales. Significant differences in productivity levels are observed between the largest holdings and other domestic producers.

* Corresponding author: vlave@ukr.net

The last decade has been characterized by the spread of the ideology of sustainable development with the simultaneous digitalization of the economy. This has led to the emergence of new models and indicators for companies' Performance Management Systems (PMS) and has identified critical areas for improving their business models. As part of sustainable development, PMS has been dubbed “Sustainable and Resource Efficient Business Performance Measurement Systems” (SuRE BPMS). Enterprise performance and the methods used to measure and manage it are studied in theories of management, organization, and information systems (in particular, in business process management or BPM) [1]. Performance management is a multidisciplinary topic and assumes the existence of differentiated approaches to implementing tools to ensure it. One such tool, which is not widespread enough to solve environmental problems, is benchmarking.

The research question in this paper is to analyze the possibilities of improving performance based on global benchmarking and attention to issues of sustainable development. The use of benchmarking for sustainable development will allow metallurgical companies to calculate the quantitative parameters of the changes needed to increase competitiveness, including the environmental vector.

1.2 Previous researches

The basis of modern Sure BPMS systems is the concept of global effectiveness of sustainable development “Triple Bottom Line” [2], which is used to assess sustainable development strategies based on a set of economic, social, and environmental indicators (Figure 1). This concept maintains a balance between the three goals.

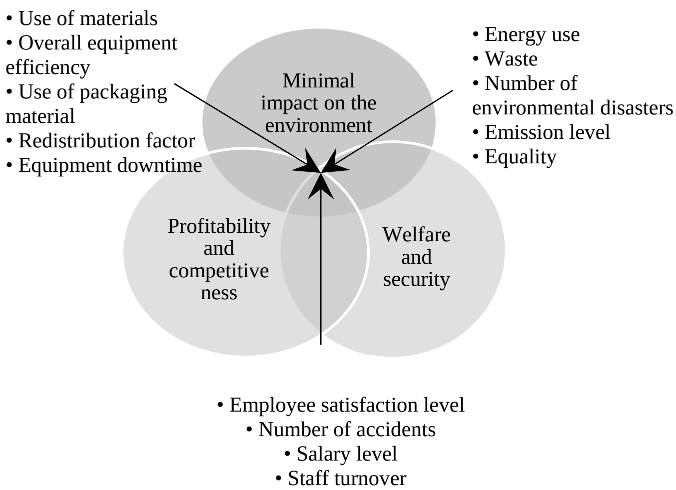

Fig. 1. The concept of the global performance of sustainable development “Triple Bottom Line” [2].

First, maximizing economic performance. This goal can be measured by traditional financial criteria (revenue, profitability, cash flow, economic value-added, market value-added, etc.).

Second, maximizing social performance, which requires taking into account the interests of all stakeholders. Third, the increase in environmental performance involves activities that do not create harmful effects on the environment [3].

According to the concept, a sustainable corporation strives for low environmental impact, cares about staff and society as a whole while remaining competitive. The basis for sustainable production is to create more value while using fewer resources. Resource efficiency is a consequence of every production operation. The resources spent do not add value to the client and represent costs for the enterprise and society. The critical challenge is to link improvements in resilience at the operational level to financial performance and stability at the corporate strategic level.

Central to today's process-oriented models developed in the BPM concept is the Measurement and Performance Management Lifecycle Model proposed by Bourne & Bourne in 2011, which consisted of four phases: design, implementation, use, and revision. This model was supplemented by Landström et al. [4] in 2018, the fifth stage – the cycle of double learning. Central to the model is the choice of adequate performance indicators for specific prospects for implementing the corporate strategy.

The development of the ideas of the “Triple Bottom Line” and the Bourne & Bourne Life Cycle Model is manifested in the System of Measuring Enterprise Performance Based on Sustainable Development by Almström et al. [5]. The authors note that performance measurement systems' use and improvement are closely linked to management systems, such as environmental protection, quality, occupational health and safety, and operational development programs. The integration of management systems and operational development programs involves the development and maintenance of appropriate PMS. In practice, management systems and operational development programs are not fully integrated and contain different key performance indicators. Success factors for operational development from the authors of the model's point of view can be the participation of management, training, education, empowerment of workers, and coordination of long-term strategy.

Thus, modern SURE models reflect PMS development's last stage, forming a modern philosophy of integrated performance measurement concept, which combines BSC elements, process-oriented life cycle models, and business excellence models, and subordinating PMS to a single system of strategic management. According to the authors, performance indicators should provide the right feedback for strategic decisions. At the heart of the benchmarking methodology, as you know, is the process of comparing the potential of a particular object of analysis (enterprise, industry, etc.) with the potential of competitors. Therefore, the use of benchmarking, in our opinion, can be considered an instrumental implementation of modern models of performance management.

1.3 The scientific problem

The scientific problem is the possibility of using benchmarking studies of the global industry to improve the performance of national manufacturers based on the philosophy of sustainable development and the use of relevant models of Sustainable and Resource Efficient Business Performance Measurement Systems. The article's *hypothesis* has both a theoretical and an applied basis concerning the practicality of using benchmarking results and the technology of using its consequences in the global market. *The purpose* of this study is to identify the prerequisites for using benchmarking to influence the environmental performance of market participants, identify best practices and their carriers among world-leading companies and test the proposed toolkit for Ukrainian companies. *The research object* is the environmental, social, and economic performance of companies in the metallurgical sector in the world and Ukraine.

1.4 The research methodology

The research is based on the data on metallurgy from global and national statistics of Ukraine, as well as data from top global and Ukrainian producers of metallurgical products, collected directly from companies and processed by statistical methods.

The analysis of global trends covers 1980-2019, with details for the period 2007-2017.

To monitor environmental, economic, and social performance for benchmarking the metallurgical industry, we have selected eight largest world companies representing the TOP countries of the industry sample of comparisons and key areas: 1) Production of iron, steel, and ferroalloys: ArcelorMittal (Luxembourg), Nucor (USA), POSCO (South Korea), China Baowu Grou (China), Nippon Steel & Sumitomo Metal Corporation (NSSMC) (Japan), OJSC Novolipetsk Metallurgical Plant (NLMK) (RF) 2) Production of light metal packaging: Crown Holdings, Inc. (USA) 3) Manufacturing of metal structures and products: Lindab group., Inc. (EU).

To test the use of benchmarking for national manufacturers' performance, we formed a sample of 16 largest Ukrainian companies, which provided 88% of the total sales of the metallurgical industry of Ukraine. The first six (Metinvest Holding, ArcelorMittal Ukraine, Privat Group, EastOne Group (Interpipe), Donbass Industrial Union (ISD), and DCH-Evraz) accounted for 84% of industry-wide sales. The 16 largest companies accumulate 80% of assets and 56.6% of employees in the industry.

The sample proportion fully corresponds to the scale of enterprises' activities, both globally and nationally.

The methodology's scientific novelty is as follows: Authors propose identifying three groups of benchmarking parameters, which reflect environmental, social, and economic performance. To assess the environmental performance, the authors of this article proposed to use such indicators as Greenhouse gas emissions, Energy consumption, Material efficiency, Environmental management systems.

An analysis of the environmental aspects of the metallurgical sector showed that Environmental requirements should be viewed as an incentive for innovation and as a source of competitive advantage. Environmental requirements are also a push to eliminate structural crisis phenomena.

For benchmarking, the article proposes a logical information model, the main elements of which are the selection of a narrow range of players in the metallurgical market as carriers of “best practices”, analysis of trends in the global development of the industry, setting benchmark targets, and their comparison with the indicators of Ukrainian companies.

1.5 The current research structure

This study consists of the following parts:

– first of all, a theoretical basis is presented, based on the study of modern models of performance management in the context of sustainable development; on this basis, a logical-informational model of benchmarking and a group of indicators for assessing environmental, economic, and social performance are proposed;

– secondly, the prerequisites for the use of benchmarking for the analysis of the metallurgical industry were investigated; trends in the development of metallurgy at the global and national levels were revealed;

– thirdly, the results of the analysis of performance indicators for two groups of companies – global leaders and Ukrainian manufacturers are presented, and recommendations for improving environmental performance based on the results of global benchmarking are proposed;

– further, the ideas of improving environmental performance are considered through the prism of the Concepts of the circular economy and Industry 4.0.

The study's practical significance lies in the fact that its results can be used to achieve higher environmental and economic results by Ukrainian companies and, as a result, to create and maintain competitive advantages in the world market through the use of benchmarking in management practice.

2 Main theoretical assumptions of the research

2.1 Environmental, economic, and social performance under the ideology of sustainable development

Following the doctrine of sustainable development, we propose identifying three groups of parameters for benchmarking, which reflect the environmental, social, and economic performance, and determine the socially-oriented strategic management on the corporate social responsibility principles. According to the authors' approach, this approach to community-based management is an extended modification of the “Eight

Global Economic, Social and Environmental Indicators" of WSA Sustainability [6].

Indicators of environmental performance are given in table 1.

Table 1. Indicators for assessing environmental performance (based on the benchmarking of global industry leaders).

Indicator	Calculation
Greenhouse gas emissions	tons of CO_2 per ton of steel
Energy consumption	GJ per ton of steel
Material efficiency	The ratio of the mass of the obtained scrap to the mass of residues and production waste, %
Environmental management systems	Share of personnel and contractors working at certified production facilities, %

The greenhouse gas emissions (CO_2 / t) show tons of CO_2 emissions normalized against production (tons of manufactured metallurgical products in crude steel equivalent). The calculation is based on the specific energy trajectory and intensity of CO_2 emissions for the main production routes. Reducing greenhouse gas emissions in steel production needs to be addressed globally. Reducing CO_2 emissions requires breakthrough technologies. Metal products play an essential role in a low-carbon economy due to their long life cycle, 100% recycling, and innovative qualities.

Energy intensity, GJ per ton of steel, shows the energy consumed, normalized to production (equivalent to a ton of crude steel), and reflects energy-saving policies' effectiveness.

Material efficiency reflects the share of recycled (primary and secondary by-products) residues of production, and therefore the company's commitment to the circular economy's values.

Environmental management systems are estimated as the share of personnel and contractors working at production facilities certified according to international EMS standards such as ISO 14001 or EMAS. The indicator characterizes the degree of responsibility and compliance of the production process with modern requirements.

Among the indicators of social performance, we propose to include the coefficient of the frequency of injuries with a temporary disability, staff training, and wages (Table 2).

Table 2. Indicators of social performance (based on the benchmarking of global industry leaders).

Indicator	Calculation
The coefficient of the frequency of injuries with a temporary disability	Injuries/ million hours of work
Employee training	Training days/employee
The average salary	The ratio of labor costs to the number of staff, thousand dollars

Trauma with loss of working time is an incident that prevents a person from returning to work. The rate of injuries with a temporary disability, including deaths, reflects the number of incidents per million person-hours. With the help of the indicator, it is possible to determine the state of working conditions.

Employee training indicator measures the total average number of training days per employee and does not focus on safety and health, but should include it. Training can consist of different development programs: seminars, computer training, self-study, or on-the-job training. Training programs should aim to expand employees' knowledge and skills and help them make the most of their talents.

The average level of wages is calculated by the ratio of labor costs to the number of staff. Characterizes the level of well-being and is a motivating factor for achieving better results.

The proposed indicators of economic performance are (Table 3):

Table 3. Indicators of economic performance (based on the benchmarking of global industry leaders).

Indicator	Calculation
Investments in new processes and products	Cost of investment in capital expenditures and R&D, % of revenue
Creating added value	The ratio of gross value added to revenue, %
Distributed economic value	value distributed to society (direct and indirect), % of revenue

Investments in new processes and products are the amount of investment in technical and technological innovations and research and development, % of revenue; reflect the company's commitment to continuous improvement.

The value-added indicator is defined as the ratio of gross value added to revenue, %, and reflects the level of the economic value of the company for the country's economy

Distributed economic value is an indicator of the quantitative assessment of the value sent to society by industry. It includes direct and indirect contributions (taxes, dividends to shareholders, employee salaries, direct payments, etc.)

All these indicators should be evaluated in the process of comparison with the reference global average.

The proposed indicators cover the critical prospects for achieving the best results in the metallurgical industry. Further research aims to model the field of optimal outcomes for domestic enterprises based on benchmarking of global industry leaders and analyze their actual performance, focusing on world leaders' performance.

2.2 Global benchmarking for monitoring environmental, economic, and social performance

The study and identification of factors influencing the performance of metallurgical enterprises, in our opinion,

https://doi.org/10.1051/e3sconf/202128002004

should be based on empirical global experience of best practices in the industry.

To create an adequate scale and perception of data in the global situation, we have developed a conceptual logic and information model of benchmarking (Fig. 2). According to this model, the basis of comparison is a narrow range of players in the metallurgical market as carriers of "best practices."

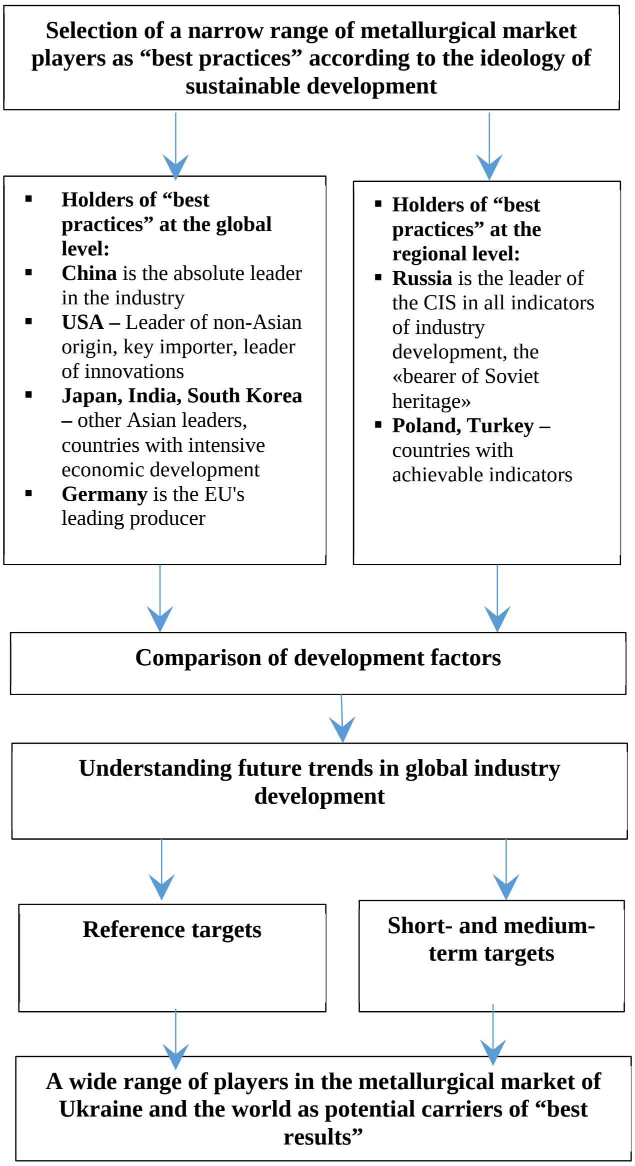

Fig. 2. Logical-information model of benchmarking.

These companies represent China as the most powerful country in the global metallurgical sector, the United States as a leading country of non-Asian origin, and the Russian Federation as a country with identical historical foundations for the industry and the CIS leader.

Also, to understand future trends in global development and Ukraine's place in it, it is necessary to consider a wider range of players.

For this purpose, other Asian leading manufacturers from Japan, India, South Korea, as well as companies from Germany – as a European regional leader, Poland, and Turkey – as countries close to Ukraine's level of economic development.

3 Research results

3.1 Global benchmarking of the steel industry on the ideology of sustainable development and environmental performance

According to the WSA, the top ten places in the world ranking of steel producers in 2013-2017 are stably occupied by the same companies. The first place is occupied by the multinational corporation "ArcelorMittal SA", whose production facilities are located, including in Ukraine, producing in 2017 97 million tons of steel (5.86% of world production), the second – the Chinese China Baowu Group (3.9 %), the third – the Japanese "Nippon Steel & Sumitomo Metal Corp" (2.8%). The twenty largest steel companies (their share in world steel production is 38%) include 10 Chinese companies, two metallurgical companies in Japan, India, South Korea, and companies in the United States, Russia, and Brazil. Thus, the development of Chinese metallurgy has a significant impact on the balance of power in metallurgical products' world market. If in the period 1980-2017. world steel production increased 2.4 times – from 716 to 1690 million tons, then in China over the same period, production increased more than 22 times: in 1980, China smelted 37 million tons of steel (5% of world volume), and in 017 – 831 million tons (50% of world volume). The growth of world steel production in the amount of 974 million tons during this period by 85% is due to China's formation as the largest player in the world steel market.

The significant acceleration in steel production growth in the last decade has led to a sharp increase in demand for raw materials, particularly iron ore, coal, coke, scrap ferrous metals, and various alloying elements. *In our opinion, this, in turn, is a factor in the development of the circular economy*.

Environmental requirements as an incentive for innovation

According to the WSA and the International Energy Agency (IEA), ferrous metallurgy accounts for 6.7% of the world's total carbon dioxide (CO2) emissions, averaging 1.8 tons of CO2 per tonne of molten steel. WSA experts note that the reduction of emissions of CO2 and other harmful substances in the future is possible only through the development and implementation of radically new steelmaking technologies (electric arc furnaces recycling) [7]. Strengthening environmental requirements provokes the introduction of environmental innovations. This is manifested in the use of continuous metal production processes and other innovations in line with the circular economy.

Global trends in the metallurgical industry are the growth of metal production (Fig. 3) against qualitative technological transformations.

An essential ecological innovation of global metallurgical production is the refusal to use the open-hearth method of steel production (Fig. 4), which has long occupied a production monopoly, giving way to a more productive oxygen-converter process in the late 1960s.

The transition from the open-hearth process to the oxygen-converter process saves a significant amount of energy and dramatically reduces the environment's burden. According to the results of 2017, the oxygen-converter method in the world produced 71.4% of steel, 27.9% – electric arc, 0.4% – open-hearth (and this method is used only in the former CIS – up to 6.7% of production In Ukraine, this figure is much higher – 21.4%.

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017
Metallurgical production: cast iron	961	949	933	1,034	1,104	1,123	1,207	1,188	1,162	1,165	1,180

Steel pipes, Δ %	-2.7	8.2	-12.5	15.1	9.8	0.1	10.3	6.2	-3.2	-0.8	0.6

Fig. 3. Global dynamics of metallurgical production, million tons, % (according to WSA statistics).

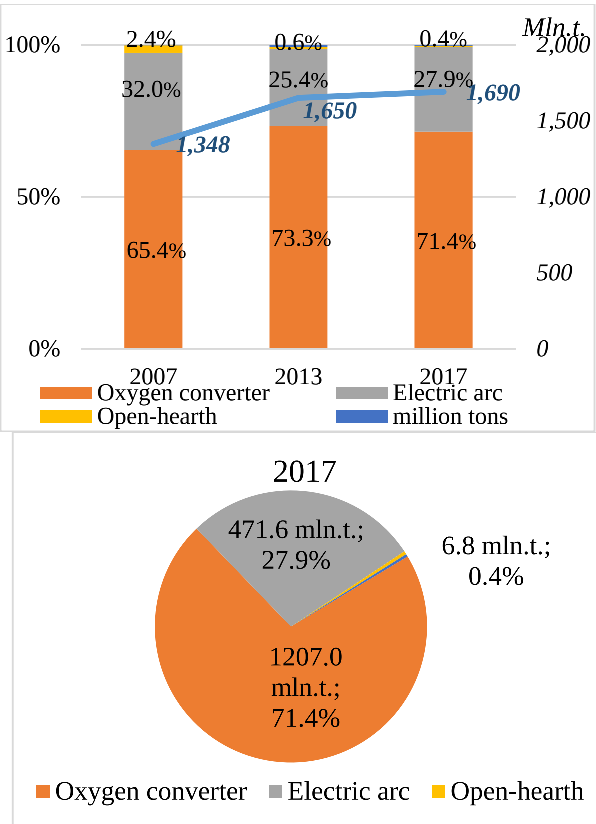

Fig. 4. Metallurgical production by processes, 2007-2017, % (according to WSA statistics).

Also, the world is intensively developing and implementing the *production process of continuous casting, which can also be attributed to the features of the circular economy*, covering in 2017 about 96% of steel produced. In Ukraine, as of 2017, this method produces only 48.8% of metal products, in Russia – 81.9%, the United States and Turkey – 99.9%, Germany – 95%, India – 85.8%, Italy – 94.8%, China – 98.3%.

Environmental requirements as a source of competitive advantage

Due to more lenient environmental requirements for production, individual countries gain a competitive advantage that reduces production costs. This leads to a change in the geography of global metallurgy. Director of the IEA N. Tanaka notes that "the introduction of restrictions on carbon emissions in some countries in the absence of similar measures in others threatens unfair competition, can lead to carbon leakage, facilitate the relocation of production to regions with less stringent environmental requirements" [8].

According to the OECD, the metallurgical industry has shifted its major metallurgical industries to Asia, North Africa, and South America in the 21st century [9]. If in 1980, the leading countries in steel production included the USSR (21% of world steelmaking), Japan (16%), the United States (14%), Germany (6%), China (5%), Italy (4%), France and Poland (3%) [10], then in the XXI century, according to the WSA, China came in the first place by a huge margin (in 2017 with a figure of 50% of world steel production). The share of the following 11 producer countries is 43.7%: EU (10%, of which 1/3-Germany), Japan and India (6%), USA (5%), South Korea and Russia (4%), Turkey and Brazil (2%), Italy (1.4%), Taiwan and Ukraine (1.3%) (Fig. 5).

China also has a significant share in the production of pig iron (60%), and the top 10 includes Japan (6.9%), India (5.42%), Russia (4.45%), and South Korea (4%), Germany (2.35%), Brazil (2.23%), in eighth place – Ukraine (2.04%), then – the United States (1.92%), and Taiwan (1.28%). It should be noted that China is a world leader in all metallurgical markets: steel and steel pipe production, the export of metal products, non-ferrous metallurgy markets (nickel, aluminum), while four countries occupy the 2nd-5th places in various markets: Japan, India, Russia, and the United States.

Environmental requirements as a push to eliminate structural crisis phenomena

Overcoming excess capacity is a necessary condition for more environmentally sustainable conditions for doing business in metallurgy. This will allow the industry to meet long-term challenges better and continue investing in value creation, adapting to the fundamental changes in economic activity caused by the "next production revolution".

Global output growth has led to steel overproduction and under capacity, and the associated imbalance between supply and demand in the global metal market. As of

January 1, 2018, the world's nominal steel production capacity reached 2,251.2 million tons, with more than 68% of nominal production capacity concentrated in Asia (of which 46.5% in China) and 12% in Europe. 7% – in North America, 6% – in the CIS, 7% – in the rest of the world. The world share of available Ukrainian capacities is about 1.9% (Fig. 6). According to the results of 2017, the level of world average capacity utilization does not exceed 75%, leaving more than 600 million tons of excess steelmaking capacity (Fig. 6).

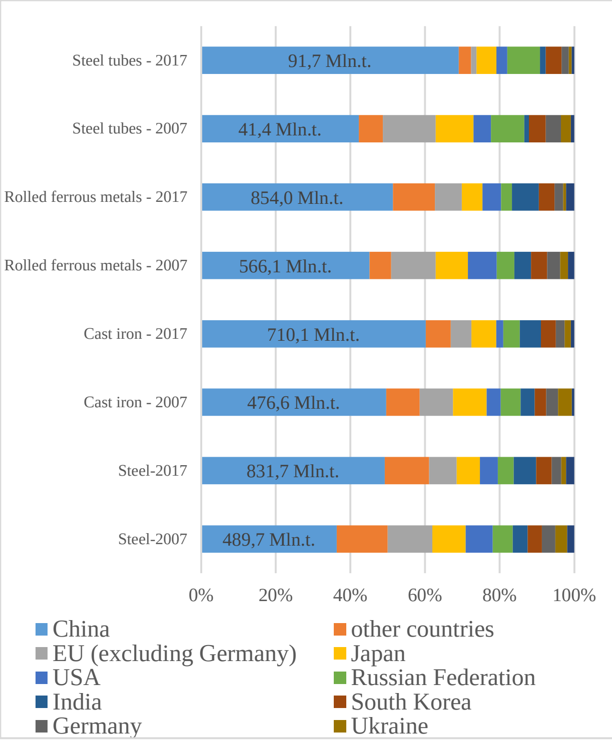

Fig. 5. Production of metallurgical industry products by regions of the world in 2013, 2017 (top countries), % (according to WSA statistics).

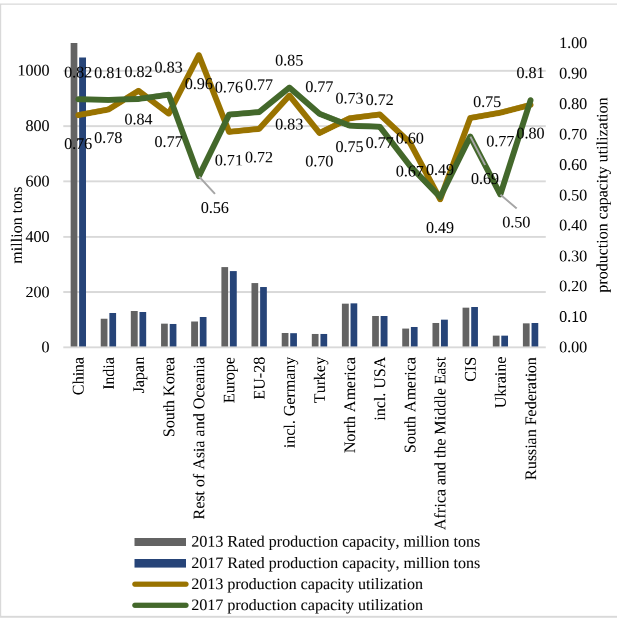

Fig. 6. Use of metallurgical capacity, 2013-2017 (according to [9]).

As shown in Fig. 6, the maximum use of production capacity in the world is only 80%. At the same time, Ukraine is characterized by a much larger excess of production capacity, resulting in a significant part of them (50%) is not used. Such data indicate the need to rethink and develop targeted actions to increase the efficiency and effectiveness of the industry's production potential and its optimization. In general, in most regions of the world, there is a positive trend in reducing overcapacity. However, overcapacity continues to be a major concern for the steel industry globally. Their presence affects profitability, creates trade imbalances, creates regional imbalances, and undermines the fight against environmental challenges.

3.2 Environmental performance of the metallurgical industry in Ukraine

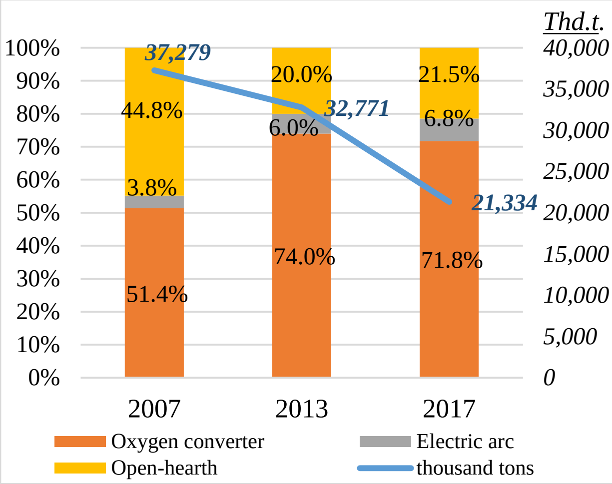
Metallurgy is one of the strategically important sectors of the economy in Ukraine, providing, in 2017, 2.4% of GDP, 7% of industrial production, and 19% of exports. As a consumer of natural monopolies' products and services, the industry used 22% of electricity, 25.4% of heat, 6% of natural gas from the country's total domestic consumption. It accounted for 43% of rail freight [11].

The main activities in the Ukrainian metallurgical production are the production of cast iron and steel. In current conditions, cast iron, steel, rolled products, ferroalloys, and pipes occupy 25% of the country's total industrial production (18% is steel production, 5% – iron ore production, 2% – coke production) [12].

Ukraine's metallurgical industry's peculiarities are the large size of production of semi-finished products and the critically small relative share of finished products. 36% of metallurgical production is the production of cast iron (16.5 million tons in 2018), .39% – steel (21 million tons), 22% – rolled products (12.2 million tons), 2% – steel pipes (1.2 million tons) and only 1% – other finished products 90.6 million tons). This is *one of the reasons for low environmental performance.*

Ukrainian ferrous metallurgy structure differs significantly from the structure in developed countries, and this has immediate environmental consequences. Production processes in Ukraine are characterized by technological backwardness: the use of outdated technologies and units, primarily all-open-hearth production process (21.5% of the steel in 2017). At the same time, on a global scale, top producers have already completely abandoned it except for the Russian Federation.

According to data for 2018, in Ukraine only 51.6% of metal products are manufactured using continuous casting technology. This is the lowest level of use of this technology globally (against 96% in the world). In total, as of January 1, 2019, the main operating production facilities are in operation: 20 out of 21 blast furnaces, 8 out of 9 open-hearth furnaces, 15 out of 16 converters, 6 out of 15 electric furnaces, and 15 out of 15 continuous casting machines.



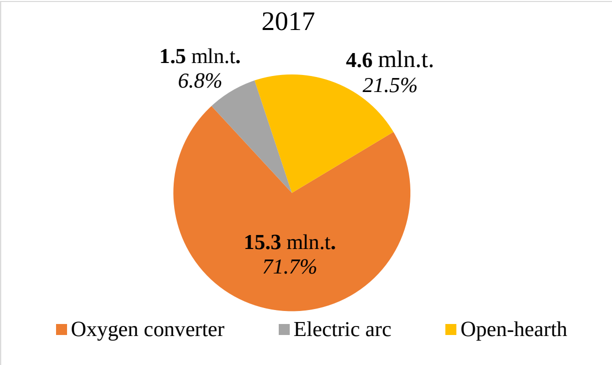


Fig. 7. Steel production by processes in Ukraine (WSA Steel Statistical Yearbook 2009, 2014, 2018).

The technological state of Ukrainian metallurgy is largely explained by the fact that the ferrous metallurgy of Ukraine is the "heir" of this branch of the USSR. In 1990, it accounted for up to 40% of the all-Union production of all product groups [13]. The aging of fixed assets in the industry is accompanied by increased costs for fuel and energy and material resources, reduced productivity, deteriorating quality of finished products, large increases in repair costs, and a significant amount of capital investment in the reconstruction and renovation of equipment. Because of technological backwardness, finished metal products of Ukraine are not competitive enough in foreign markets. Ukraine is forced to sell it at discounted prices, which causes anti-dumping lawsuits, because of which Ukraine loses billions of dollars annually. More than 70% of the industry's output is exported annually. In comparison, about 30% of domestic consumption of metal products is imported, determining the dependence of the structure and dynamics of production on foreign trade in metal products.

Energy consumption as an ecological problem of metallurgical industry in Ukraine

The energy consumption of the metallurgical industry is one of the most significant factors influencing its environmental performance. It should be noted that in Ukraine, metallurgy is one of the most energy-intensive industries. Metallurgical production accounts for 52% of total electricity consumption and 28% of heat in the processing industry (corresponding shares: 25% and 24% of total industrial use, 26% and 15% of total use). On average for the year (according to 2018), metallurgists consume about 1840 million cubic meters of natural gas, 11.76 billion kWh of electricity. The characteristic feature of metallurgical processes is that the most significant part (up to 80 – 90%) of energy resources is spent on processes of own technological needs. The main energy raw material is coal and coke (the share of consumption of this raw material by metallurgy is 93.5% of the volume consumption by the industry as a whole, and 22% of the total supply of this type of energy to the Ukrainian market) and natural gas (60% and 6% in 2017, respectively).

The factor of limited resources explains the current trend of increasing the share of expenditures on the energy component due to hostilities in the east of the country and the anti-terrorist operation, as well as the price factor at the global level. Between these two factors, there is a close relationship. Given that the primary raw material for the metallurgical industry is iron ore and coal, which turns into coke in the production process, it is important to understand the trends in the provision of metallurgical enterprises in Ukraine (Fig. 8).

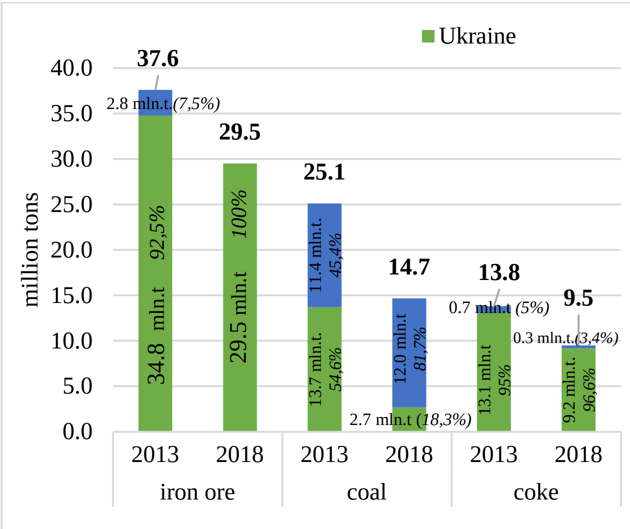

Fig. 8. Provision of metallurgical enterprises of Ukraine with primary raw materials in 2013 and 2018.

This situation with the energy intensity of products dictates the need for a targeted energy-saving policy. Strategic approaches should be associated with the reconstruction of production and the introduction of new energy-saving technological processes. In this regard, some measures that are successfully used in metallurgical enterprises of developed countries should be noted. In Western countries, to reduce the cost of production allows the widespread use of some advanced energy-saving technologies, including the continuous casting of steel (lowers energy costs by 20%), dry quenching of coke (in foreign practice, wet quenching of coke). Evaporative cooling of metallurgical units reduces energy costs by two to three times compared to the open cooling scheme [14].

According to the Ukrainian Center for Economic and Political Studies named after Razumkov, the greatest reserves for energy efficiency in ferrous metallurgy are cast iron and steel production. We are talking about reducing unit costs by about 25%, or 5 million tons of conventional fuel per year with production volumes at the level of 2013 (for cast iron) and reducing unit costs by about 70%, or 1.5 million tons of conventional fuel per year – on steel.

3.3 Recommendations for improving environmental performance based on the results of global benchmarking

The external environment analysis emphasizes the global nature of the industry and the high dependence of performance indicators on the actions of global competitors, who act as leaders and “engines of progress”. The lagging position of domestic metallurgy in terms of innovative changes, the reactive nature of achieving competitive advantages in and purely production orientation determine the feasibility of using the strategy of “following the best world practice”.

The use of benchmarking research can help realize domestic enterprises' potential and achieve higher economic results by creating and maintaining competitive advantages in the global market. We believe that the results of benchmarking of global industry leaders should be used to apply Ukrainian metallurgical enterprises' targets. The use of benchmarking is in line with the philosophy of Sustainable and Resource Efficient Business Performance Measurement Systems (SuRE BPMS).

For benchmarking of the metallurgical industry, we have selected eight largest world companies (Table 4): ArcelorMittal (Luxembourg), Nucor (USA), POSCO (South Korea), China Baowu Grou (China), Nippon Steel & Sumitomo Metal Corporation (NSSMC) (Japan), JSC Novolipetsky Metallurgical Plant” (NLMK) (RF), Crown Holdings, Inc. (the USA), Lindab group., Inc. (EU). The proportion of the sample is fully consistent with the scale of enterprises' activities, both globally and nationally.

The selected companies are the leaders in the national context among companies, ahead of almost all industry values indicators. According to the selected companies, the performance indicators described in 2.1 are calculated. Table 5 presents the results of the calculation of environmental performance indicators.

To test the use of benchmarking to improve Ukrainian enterprises' functioning, we formed a sample of 16 largest companies, which provided 88% of total sales of the metallurgical industry of Ukraine. The first six (Metinvest Holding) (43%), ArcelorMittal Ukraine (16.2%), Privat Group (9.2%), EastOne Group (Interpipe) (7%), Donbass Industrial Union (ISD) (4.8%) and DCH-Evraz (3.8%)) accounted for 84% of industry-wide sales.

The 16 largest companies accumulate 80% of assets and 56.6% of employees in the industry. The results of calculations in terms of environmental performance analysis and possible directions for its improvement are presented in table 6.

Table 4. A sample of global industry leaders as bearers of “best practices” for achieving environmental performance (based on company data, WSA, CSI).

Company / Country	Geography of activity	World share of crude steel production,%
ArcelorMittal / Luxembourg	60 countries (18 of which have production facilities, including 47 integrated plants and mini-mills)	5.8%
Nucor / USA	25 scrap processing mini-mills in North America, production facilities in Italy and Mexico (under construction)	1.3%
POSCO / South Korea	40 Korean subsidiaries, 139 foreign subsidiaries and 111 associates and joint ventures	3.6%
China Baowu Group / China	90.7% of assets are in China, the rest – 27 foreign branches and 8 PJSCs in the regions: USA, Japan, Germany, Singapore, Thailand and Hong Kong.	3.9%
Nippon Steel & Sumitomo Metal Corporation (NSSMC) Group /		
Japan	13 metallurgical plants of Japan + capacities in 15 countries (USA, Brazil, China, Mexico, etc.)	2.8%
PJSC “Novolipetsk Metallurgical Plant” (NLMK) / RF	20 production sites located in Russia, USA, Belgium, Denmark, Italy, France and India.	1.0%
Crown Holdings, Inc. / USA	36 countries (America, Asia, Europe, Africa): 143 subsidiaries	8.9%
Lindab group., Inc. / Sweden, Germany	32 countries, 136 branches in the European market	11,0%

The directions for increasing environmental performance are an investment in resource-saving technologies, production of higher value-added products, investments in energy-saving and new technologies, improvement of management systems, and certification. These recommendations complement ideas for improving environmental performance based on the philosophy of the Concept of Circular Economic and Industry 4.0.

In addition, a tool for improving environmental performance should be a regular environmental audit of production activities and investment projects of Ukrainian enterprises, including for compliance with the ISO 14001: 2015 “Environmental Management System” standard. Based on the audit, complemented by global benchmarking of industry leaders, it is proposed to develop programs to improve environmental performance. An important component of the program should be increasing the level of environmental awareness of staff and stakeholders. This is achieved by publishing the results of environmental audits, developed programs on the websites of Ukrainian companies, which is not yet available.

Application of the Concept of Circular Economy to solve environmental problems of metallurgical enterprises

Metallurgical products are recognized as one of the most circular materials due to their endless processing properties. Broader implementation of the circular economy's principles, such as reduction, reuse, and restoration of production, will have a long-term impact on the metallurgical industry due to its impact on demand in metal-intensive sectors [16].

Price fluctuations for primary resources and finished products, combined with the inability to respond flexibly to changes in demand, increase the need to find ways to improve existing resources' efficiency, develop alternative production technologies based on traditional and universal resources, and resource utilization technologies.

Table 5. Monitoring the environmental performance of world leaders in the industry.

Company	Result / deviation / direction of correction	Indicator			
		Greenhouse gas emissions	Energy consumption	Material efficiency	Environmental management systems
Average		1,9	19,1	97,6	97,1
ArcelorMittal	2019	2,1	23,8	88,6	98,1
	ARC*,%	-0,9	-0,8	13,3	0,1

Lindab group., inc.	2019	7,9	1,8	89,0	97,0
	ARC*,%	-13,2	-4,4	0,0	0,0
	↑↓	↑	↑	↓	↓

* Annual rate of change

In other words, the main trend of metallurgical producers should be the production of products by processing secondary raw materials instead of using mineral resources. Such ideas are an element of the Concept of Circular Economics [17].

Table 6. Benchmarking of environmental performance indicators of world industry leaders and Ukrainian companies.

Indicator	Greenhouse gas emissions	Energy consumption	Material efficiency	Environmental management systems
World leaders	1,9	19,1	97,6	97,1
Ukrainian companies	2,2	25,3	62,7	n/d
Directions of influence for environmental performance increase	*Investments in resource-saving technologies*	*Production of higher value-added products, investments in energy-saving and new technologies*	*Following the principles of circular economy*	*Improvement of management systems and certification*

Today in Ukraine, the regulation of the circular economy is still in its infancy. Such regulation is at different stages of development in different regions of the world. The EU Circular Economy Action Plan provides a solid basis for accelerating the transition to a circular economy and sustainable growth. In China, thinking based on a circular economy has been part of legislation and regulations for at least the last ten years. In other regions, such as Brazil, Japan, and Korea, the circular economy's principles are gaining momentum and changing business laws. In general, the transition of a society to a circular economy is only at an early stage. However, this change will likely accelerate in the light of recent trends: the globalization of the economy, changes in government legislation, and innovative business models of the circular economy.

The many advantages of scrap metal as an important steel resource are based on its high-energy efficiency, low carbon emissions, and easy recycling. For the sustainable development of ferrous metallurgy, more attention should be paid to the use of steel scrap in the steel production process. Making full use of scrap metal resources can play a key role in easing pressure on mineral needs. The recycling of steel scrap can significantly reduce iron waste and environmental pollution [18]. The benefits of using scrap metal include the optimization of both energy costs and metal products, demonstrating the ETSAP-TIAM global energy scenario assessment model and the scrap availability assessment model (SAAM).

Application of the Industry 4.0 Concept to increase the environmental performance of metallurgical enterprises

To increase efficiency, productivity, sustainability, sound process management, and optimal use of resources, Ukrainian metallurgists need to make the most of the Industry 4.0 Concept's capabilities. In this context, the advantages for the metallurgical industry can be such: vertical integration based on Cyber-Physical Production System (CPPS), 100% traceability of intermediate and

https://doi.org/10.1051/e3sconf/202128002004

final products, "Intelligent" product with knowledge of its quality and production history (one aspect of systems engineering), horizontal integration inside and outside the company, appropriate processing and use of all data, decentralized solutions, self-organization.

Using the Industry 4.0 Concept changes interactions with suppliers and customers using new online platforms, applications, and other systems that offer order tracking and other services. This, in turn, opens up opportunities for entirely new business models and provides for the development of a whole digital "production ecosystem" in which the accumulated data is included in the value chain, helping to maximize the level of environmental performance.

Examining innovations in analytics, mobile solutions, and automation at the global level, we can conclude that the following trends will further contribute to a significant increase in efficiency in the metallurgical industry. First, it is an exponential rise for data available. This leads to a wider implementation of a range of different sensors, including vibration, optics, and sound sensors, reducing storage costs. Second, increasing computing power and developing new analytical methodologies. Traditional statistical methods give way to machine learning methods to simultaneously analyze multiple factors, even if they do not have a linear relationship. Third, mobile technology's deployment to the shop floor contributes to a significant increase in productivity through more efficient field management and process optimization. Fourth, greater automation of support functions combined with data analytics to provide greater flexibility and performance.

4 Conclusions

Considering all of the above, we can say that the development of sustainable development ideology has stimulated the emergence of relevant models for Performance Management and Measurement Systems. Such models pay significant attention to environmental problems and approaches to their measurement. Another feature of modern performance assessment models is the use of indicator systems. The use of benchmarking is an instrumental implementation of performance measurement systems since it allows you to set targets for improving performance. We have tested benchmarking to develop the philosophy of tripl sustainable and resource-efficient systems for improving business performance (SuRE BPMS) for development.

With sufficient attention to the formation of indicator systems for management purposes based on the philosophy of sustainable development, sectoral and environmental aspects require further study and implementation. As a global industry, Metallurgy generates its unique opportunities and threats that need to be applied in appropriate performance management models. This article substantiates the need to identify indicators in three areas: for assessing Environmental performance; indicators of Social performance, indicators of Economic performance. To evaluate the environmental performance, we proposed to use such indicators as Greenhouse gas emissions, Energy consumption, Material efficiency, Environmental management systems.

An analysis of the metallurgical sector's environmental aspects showed that Environmental requirements should be viewed as an incentive for innovation and as a source of competitive advantage. Environmental requirements are also a push to eliminate structural crisis phenomena. Environmental performance efficiency of the metallurgical industry in Ukraine is insufficient, and Energy consumption is the most painful point of metallurgy in Ukraine

To conduct the benchmarking, the article proposes a logical and informational model, the main elements of introducing a high-tech spectrum of metallurgical markets, analysis of tendencies in the global development of metallurgy, the establishment of standard Ukrainian companies, demonstrations of the best practices.

For benchmarking of the metallurgical industry, we have selected eight largest world companies: ArcelorMittal, Nucor, POSCO, China Baowu Grou, Nippon Steel & Sumitomo Metal Corporation (NSSMC), JSC Novolipetsky Metallurgical Plant ", Crown Holdings Inc., Lindab group. Inc. and compared their results in terms of the proposed environmental performance indicators with the values obtained from the analysis of the activities of 16 Ukrainian companies, which together account for about 90% of production volumes in Ukraine. Environmental benchmarking of the metallurgical industry made it possible to formulate recommendations for Ukrainian companies.

The scientific novelty of this work lies in the substantiation of a methodological approach to benchmarking tools, adapted taking into account the global nature of the industry and the specifics of environmental problems in it. It should be noted that the implementation of benchmarking in the global industry is somewhat simplified due to the "openness" of world-leading companies, which in general allows collecting the necessary information for analysis. At the same time, it is more efficient to implement the benchmarking information into management practice on an ongoing basis. It is possible to implement it in the context of digital tools, which allows us to maximize the quick presentation of strategic forms of transformation of global solutions the scope of activity of the enterprises.

Promising questions for further research in this direction, in our opinion, are the development of empirical models of target results of the industry; establishment of correlation-regression links between indicators of environmental performance and the variables that determine them (proxy variables); development of management mechanisms that support the introduction of benchmarking research into management practice.

Abstract. The paper considers accidents and potential hazards of the world chemical enterprises, and provides statistics of accidents and human casualties. The authors investigate harmful factors affecting the production process and a human-operator, showing the central role of a human in the technological process (both as a source of errors and as an active element that eliminates errors, failures and cyber attacks' consequences). We essentially consider automated technological complex as a Human-Machine-Environment system, thus a human-system approach should be applied. The authors developed a complex of systemic components and morphological models, which describe the human-machine system in the sections required for analysis, to ensure sustainable and reliable design with initial data. The authors also propose a method and information technology for interfaces' ergonomic assessment; the principles for adaptive interfaces design; and mathematical models and information technology to assess safety and timeliness indicators of the chemical production operators' activities. The models are based on the principles of the functional-structural theory by Anatoly Gubinsky, Vladimir Evgrafov, Akiva Asherov, Pavel Chabaneko and others, and on the mathematical apparatus of functional networks. Further, the authors develop an optimization model for decision supporting organizing the human-machine control technology, using the criterion of minimizing losses from unreliability and unsustainability. Both the models and the information technology have undergone extensive testing, including solving the tasks of: choosing the automation level for the control process; distributing functions between operators; control algorithms design; user interface design, design of agent-managers to support the operators' activities. The results can be used as the basis for a decision support system to ensure sustainability and reliability of automated technological systems in chemical industry.

1 Introduction

Recent years are associated with increasing risks and threats not only to the sustainable development, but to the existence of mankind [1-5].

The number of industrial accidents, environmental disasters, deaths and threats to their health is increasing [6-12].

In these conditions, the need for a radical improvement in the methods of safety management in complex industries increases [13-17].

2 Problem analysis and research goals setting

Chemical industry is one of the leading world's industries in terms of the number of accidents and the amount of damage [18-20]. Figure 1 shows the numbers of incidents and deaths in the chemical industry in OECD and non-OECD countries. Figures 2 and 3 show a fragment of accident rate statistics in the chemical industry of China.

Let us see an example that characterizes the scale of the problem, considering one of the most developed economies in the world – the United States. According to the American Federation of Labor, there are 2,178 OSH [21] inspectors to inspect 8 million American workplaces, i.e. each supervised object can be checked only once every 130 years. Therefore, American experts believe that the principle of the company's presumption of safety must be abandoned, and the socially responsible business must be obliged to demonstrate and prove the sufficiency of the measures taken to ensure industrial safety as a prerequisite for carrying out production activities [21].

[*]Corresponding author: prof_lavrov@hotmail.com

Analysis [22] of the accidents main causes makes it possible to identify the following interrelated groups of factors:

– Erroneous actions of the personnel (58%);

– Equipment malfunctions and failures (21%);

– Depressurization of storage facilities and other related issues (17%);

– External influences of natural and man-made causes (4%).

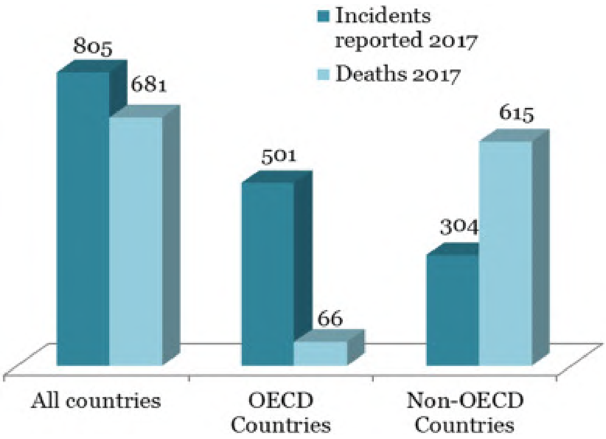

Fig. 1. Chemical incidents occurredin2017 and reported in the global media [18-19].

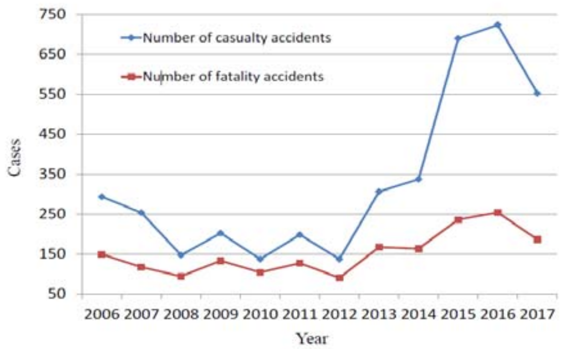

Fig. 2. Number of casualty and fatality accidents in China (2006 – 2017) [20].

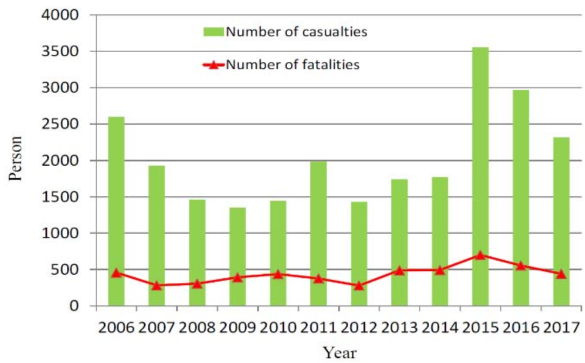

Fig. 3. Number of casualties and fatalities in China (2006 - 2017) [20].

According to other data, for example [23-25], about 80 percent of accidents are caused by human-operator errors.

The percentage values characterizing the causes of accidents may differ. However, it is obvious that the factors are interrelated and a significant reduction in the accident rate is possible only if we consider the chemical production system as an integrated Human-Machine-Environment system, in which a human can be [25]:

– a potential source of problems,

– an active element capable of eliminating and preventing problem situations.

It should be borne in mind that each person has individual psychophysiological characteristics, experience, and motivation. Besides that a human-operator works:

– with specific equipment,

– with specific user-interface,

– in specific environmental conditions (chemical, physical, psychological),

– in the context of possible sabotage, and cyber-attacks.

Taking into account and optimizing the mutual influence of these elements will make it possible to develop measures aimed at minimizing risks.

Many studies are devoted to the development of methods for assessing and optimizing individual elements of human-machine systems. Among them are the analysis of working conditions [26], the design of interfaces [25], anthropometry and the impact of production equipment on health and injuries [27-31], activity intensity [32-34], ergonomic expertise [35-39] and others [40-42].

As the analysis of the papers shows, the authors investigate only individual local issues related to human work in complex man-machine systems. At the same time, as a rule, researchers collect statistics on accidents and the influence of certain factors on human health; analyze the severity of injuries that occur in the process of equipment control; study the reach zones for operators; analyze methods of improving the psychological climate in the teams of operators; describe technologies for professional selection and training of operators, develop methods for monitoring the functional state of operators and solve other important problems. In addition, unfortunately, researchers do not study issues related to the activity concept of investigating sustainability and reliability [23], when a human operator is studied in a comprehensive manner, taking into account the algorithms of activity and the functional structure of the chemical production management system as an element of the "human-technology-hazardous environment" system.

Thus, it is obvious that today there is increasing attention to the issues of reliability of the human operator, technical means, computer equipment, software for control processes, as well as technological processes of chemical production. However, a computer-oriented system for complex modeling of human-machine interaction, focused on supporting decision-making to ensure the sustainability and reliability of critical-type systems (including automated systems in chemical industry), and taking into account the entire complex of influencing factors, have not yet been developed.

In this regard, in the present work we set the task of developing models that can be used as the basis for decision support systems for managing the sustainability

https://doi.org/10.1051/e3sconf/202128002005

and reliability of automated systems in the chemical industry, taking into account the reliability of personnel, automation tools, and software.

3 Results

3.1 Human-system approach to reliable design of control systems

In practice, the following approaches to the sustainable and reliable design of human-machine systems are used [22, 43]:

– system-engineering approach – the system is considered as consisting only of technical elements, the person is taken into account as a factor of the external environment;

– equal-element approach – the system is considered as consisting of equal elements "human" and "technology";

– human-system approach – the main element of the system is a human, and technology is a subordinate means of labor;

– narrowly anthropocentric approach – the system is considered as consisting only of the "human" element without taking into account the elements of "technology";

– narrow technical approach – the system is considered as consisting of technical elements, the "human" son is not taken into account.

Taking into account the central role of a human in the management of chemical production and the many diverse influencing factors (see Fig. 4), it is advisable to apply a human-system approach, the basic principles of which are formulated as follows:

– human-operator is the central element of the system that determines the reliability of production processes, which is determined by a set of interrelated factors (Fig. 4),

– potential risks are minimized based on the assessment and optimization of operators' activities, taking into account the effects of the environment, the reliability of automation equipment, software and information support, as well as the psychological characteristics of group activities (activity approach),

– sustainability and reliability of the technological process is ensured by a decision support system, including a system for ensuring ergonomic quality.

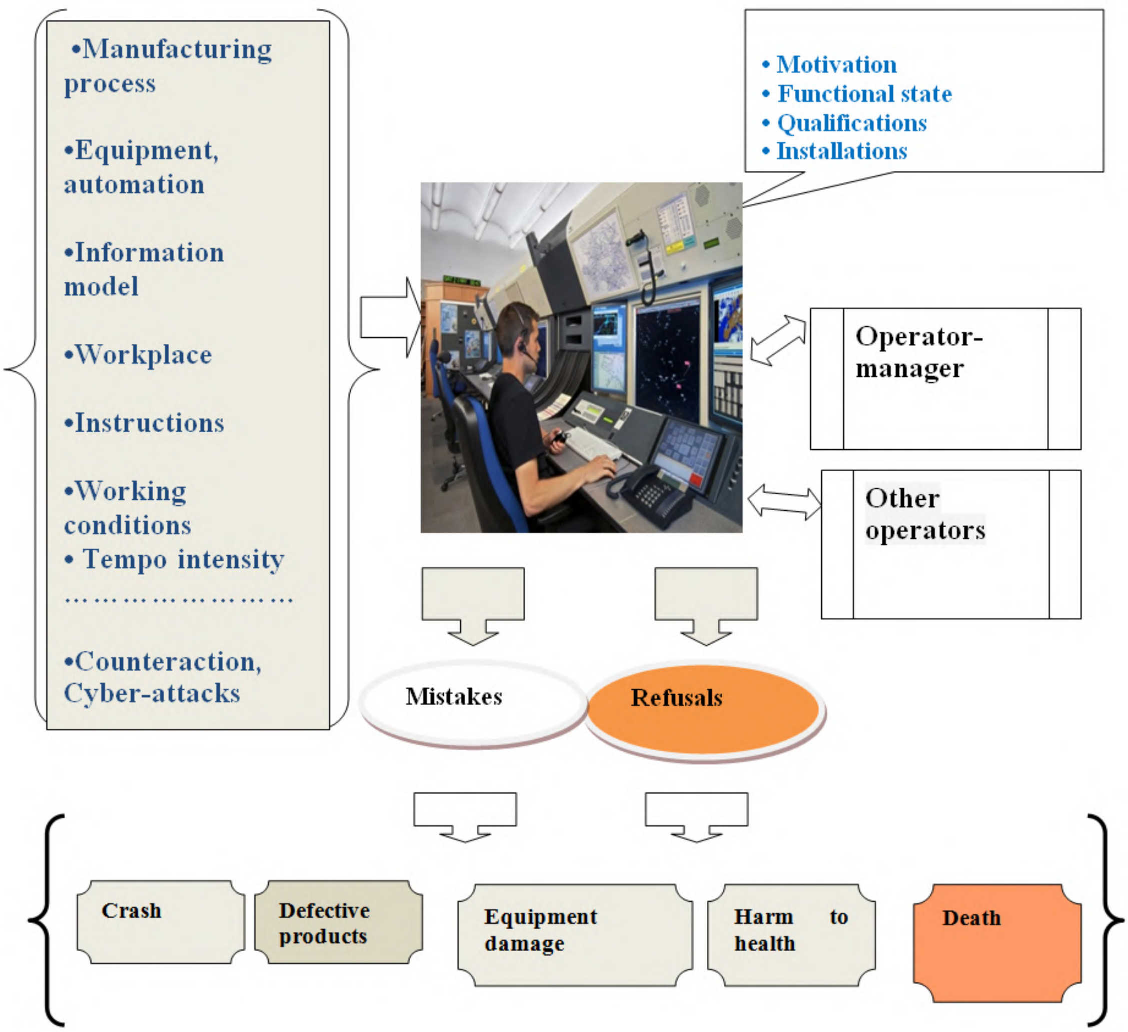

Fig. 4. Computer control system for chemical production as a human-machine system (influencing factors and risks).

3.2 Models for system analysis of an automated technological system in chemical industry (as a human-machine system)

Modeling risks in a human-machine system (MMS) is possible only if there is complete information support about functional and structural elements, about the connections between them, about the required characteristics, etc.

No modeling in a decision support system will be successful if the data are not available.

To form the structures of knowledge bases and data about the system, we use the approach of the scientific school of Professor Anatoly Ilyich Gubinsky [22, 43], who proposed to describe MMS in all required sections (human, technology, environment, connections between them, goals, technologies, damage from violations, etc. etc.), while highlighting two types of models – component (KB), describing all the necessary entities, and morphological (MP), describing all possible relationships between entities, incl. processes of implementation of functions, working conditions, how elements interact with each other, what are the reliability characteristics of structural and functional elements.

One of the possible models we use to solve the problems of reliable and ergonomic support of chemical-technological systems is as follows [43] (for notation, see Fig. 5):

$$MMS =< CSs, CFs, CRs, CEs, Err, Rs, Ft, OpFt,$$

$$VPo, FKv, Mpl, MCo, MPro >$$

We gave a complete description and structure of the models in [44]. Thus, the system of MMS models allows a formalized (in the form of functional networks [22,43,45]) to describe the hierarchical system of functions (model ***Ft***) with options for their implementation and provides the process of calculating and optimizing reliability with all the necessary initial data for structural and functional elements with taking into account all significant influencing factors.

For different tasks, some modification of the models composition and structure is possible, however, the component-morphological approach to modeling and the predicate description [23, 44] of the system can certainly be recommended for widespread use in decision support systems for managing the sustainability and reliability of technological processes in the chemical industry and other advanced industries.

3.3 Decision support for ensuring the ergonomic quality of chemical production management system interfaces

Our survey of a number of chemical enterprises revealed in a number of cases the developers' ignorance of the ergonomic principles of user interface design (Fig. 6).

Therefore, we offer the following models and computer technologies:

Int_1 – Interface assessment and certification,
Int_2 – Adaptive interfaces design.

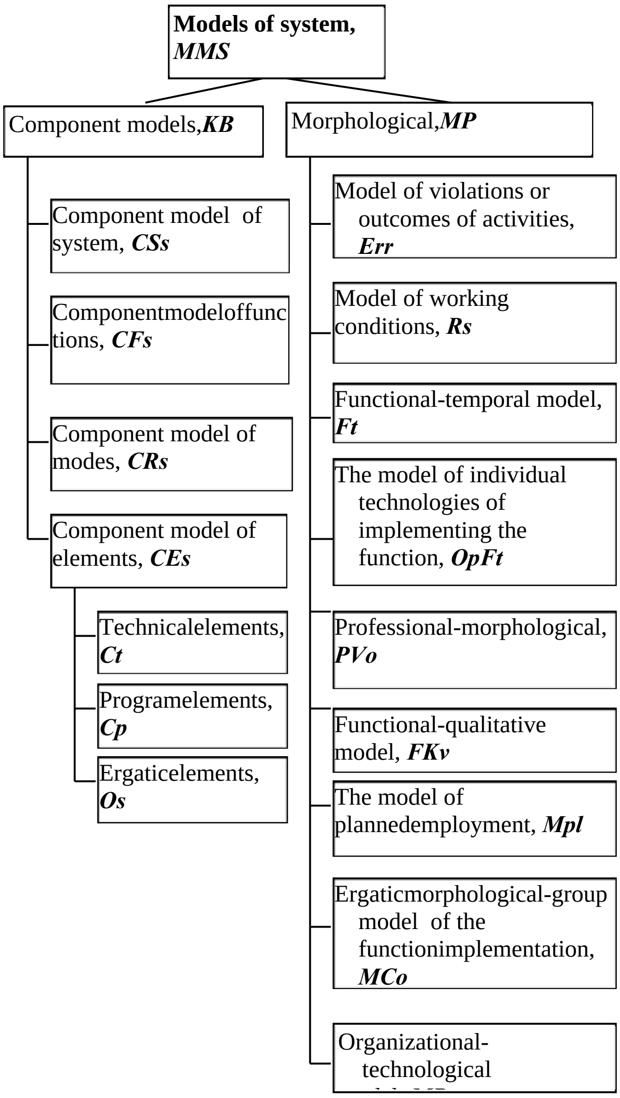

Fig. 5. Models for system analysis of control systems in the chemical industry (a fragment).

<u>Int_1technology principle (Fig. 7):</u>

- Formation of a group of qualified experts;
- Formation of a set of local criteria for interface assessment;
- Formation of a convenient system for assessing the quality of local criteria (visual interface with a customizable dialogue system – both numerical input and qualitative assessment;
- Automatic assessment of the ergonomic quality of the interface using a database of models (fuzzy inference, hierarchy analysis method, etc.);
- Only certified interfaces are accepted for operation.

We have developed a hierarchical classification of local indicators (more than 100 indicators, one can ajust the classification for each specific case).

See below an example of local quality indicators of the interface for process control systems in chemical industry:

- Visual design (graphics, aesthetics);
- Graph-design, font design;
- Animation for attention control;
- Convenience of navigation and options menu;
- Interactivity (including script customization);
- Simplicity and intuitive clarity (ease of use);
- Standardization (design consistency), uniformity of fonts, colors;
- Feedback (the possibility of dialogue with the support service and the operator-manager);
- Completeness (variety of information and services);
- The breadth of the information field, variety of ways to access information;
- Reliability (resistance to errors, crashes, and freezes);
- Sustainability.

Int$_2$ technology principle:

- Preliminary testing of the psychophysiological characteristics of operators with the determination of the optimal modalities for information presentation;
- Clustering operators with taking into account:
  - o psychophysiological characteristics;
  - o work experience, attitudes (for faultlessness or speed);
  - o the need to control actions by the operator-manager;
- Creation of alternative scenarios for dialogue interaction and alternative options for interfaces;
- Prompt (on-line) determination of the optimal dialogue scenarios that maximize the probability of error-free performance of the activity, taking into account the time constraints and limitations on the degree of the operator's cognitive comfort.

The degree of cognitive comfort characterizes the degree to which the presentation of information meets the expectations and preferences of the operator. We define it in the range from 0 to 1, for estimation we use a special system of knowledge bases about users and interfaces (see Figure 6) and a system of fuzzy inference. A fragment of this dependence one can see in Fig. 8.

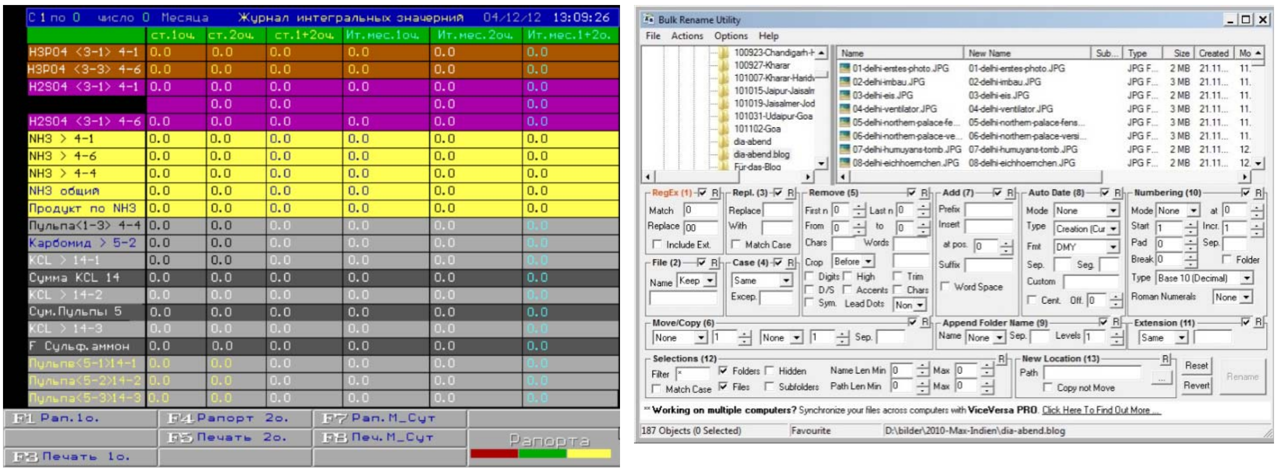

Fig. 6. Examples of interfaces to be improved.

3.4 Reliability assessment of human activity

To describe the human-computer dialogue in the management system for hazardous chemical production, we use the alphabet of typical functional units (TFU):

- functionaries who correspond to the performed actions – operations:
  - o workers
  - o control the correct functioning,
  - o equipment diagnostics,
  - o database and software diagnostics,
  - o diagnostics of the human-operator's functional state,
  - o organizational control, etc.
- composers who establish logical and temporary connections between functionaries (organize parallel processes, cyclic processes, etc.)

Using TFU and combining them together into a single functional network (FN) using the methodology of Professor Anatoly Ilyich Gubinsky [22,43,45,46] allows one to model almost any discrete processes in the management of chemical production:

- pre-production,
- implementation of the main functions of the production process control,
- diagnostics and equipment repair,
- detection of cyber-attacks and security incidents management.

For typical functional structures (TFS), i.e. the most common combinations of operations (57 of them were identified, and the library is constantly expanding) we obtained a set of calculated dependencies to assess the probability of error-free performance and the characteristics of the task execution time as of a random variable. Examples of the dependencies one can see in Table 1.

FN allows one to describe both the system's functioning in normal modes, and the processes of the human errors' occurrence and elimination, malfunctions and failures of technical and software-informational facilities.

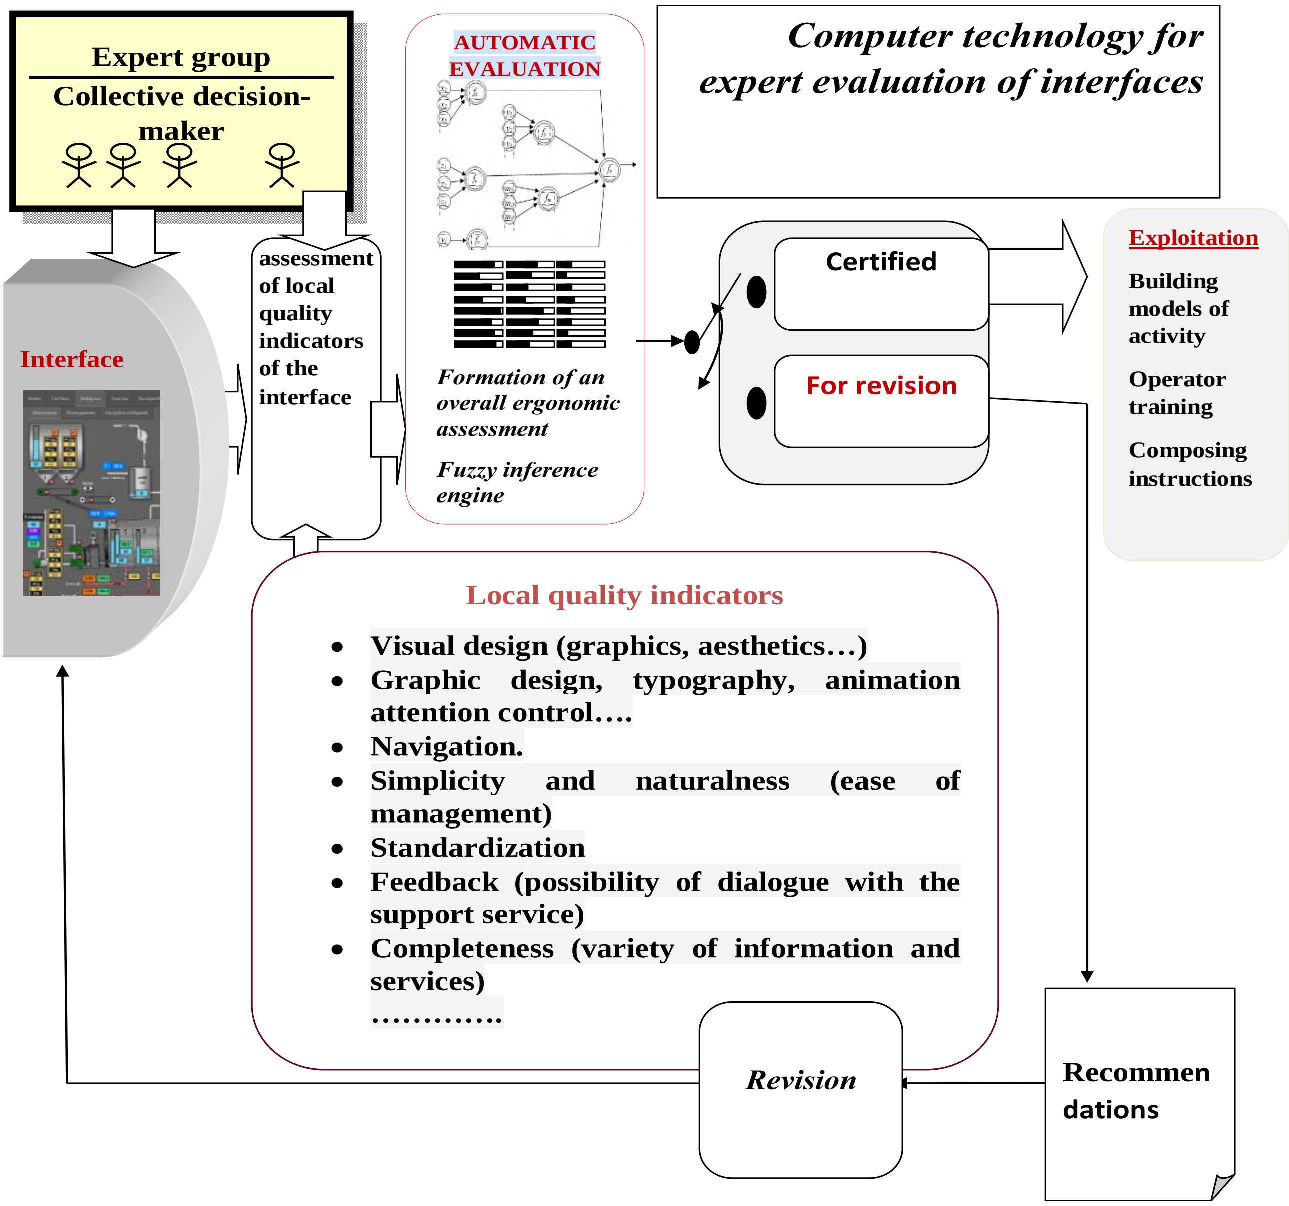

Fig. 7. Information technology for ergonomic quality analysis and interface certification.

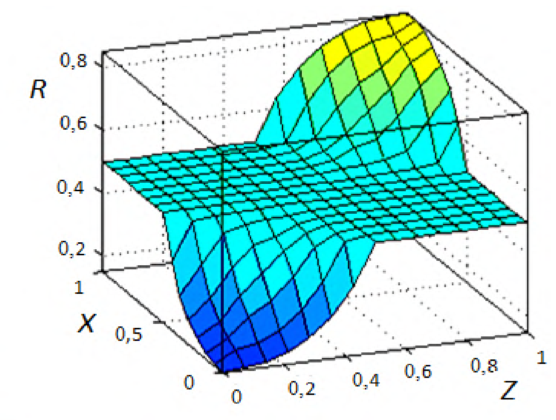

Fig. 8. Assessment of cognitive comfort (R) depending on the correspondence of the interface to the characteristics of the human-operator by the visual (X) and verbal (Z) components (developed with the help of N.L. Barchenko).

For the variant modeling of activity, a special computer technology has been earlier developed [47-50]. The reliability assessment is carried out by identifying the TFS and “reducing” the activity algorithm (FN). In this case, we use the same models as shown in Table 1. All calculations (parsing of activities, reduction and evaluation) are carried out fully automatically.

Example. We considered the production process of fertilizer of the complex mineral fertilizer “Superagro”. A joint neutralization of sulfuric and phosphoric acids with gaseous ammonia is carried out, the resulting pulp is enriched with urea, which contains a coloring pigment and is sent for granulation and drying of the resulting pulp with feeding the external recycle of NPK-fertilizer and potassium chloride to the spray zone. The dried product is classified with the release of the marketable fraction of granules. Let's consider a fragment of the operator's activity “Setting parameters and starting a technological process.”Possible options for the structure of activities one can see in Fig. 9.

Table 1. Examples of typical functional structures*

Content of typical functional structure	TFS diagram	Index	Formula for computation
1.Consistent implementation of operations		Probability of error-free operation	$B = \prod_{i=1}^{n} B_i$
		Expected value of the time of operation	$M(T) = \sum_{i=1}^{n} M(T_i)$
		Dispersion of the time of operation	$D(T) = \sum_{i=1}^{n} D(T_i)$
2.Cyclic functional structure “An operation with action control without restrictions on the number of cycles”		Probability of error-free operation	$B = B^1 * K^{11} * \frac{1}{1-(B^1 * K^{10} + B^0 * K^{00})}$
		Expected value of the time of operation	$M(T)=(M(T_p)+M(T_к))*M(L)$ $M(L) = \frac{1}{1-(B^1 * K^{10} + B^0 * K^{00})}$.
		Dispersion of the time of operation	$D(T)=D(T)*(M(T_p)+M(T_к))^2 +$ $(D(T_p)+D(T_к))*M(L)$ $D(L) = \frac{B^1 * K^{10} + B^0 * K^{00}}{(1-(B^1 * K^{10} + B^0 * K^{00}))^2}$
3. Functional structure “An operation with action control and without restrictions on the number of cycles”		Expected value of the time of operation	$B = B_1^1 * K^{11} +$ $(B_1^0 * K^{00} + B_1^1 * K^{10}) * B_2^1$
		Expectation value of the time of operation	$M(T) = M(T_{p1}) + M(T_к) +$ $(B_1^0 * K^{00} + B_1^1 * K^{10}) * M(T_{p2})$
		Dispersion of the time of operation	$D(T) = D(T_{p1}) + D(T_к) +$ $(B_1^0 * K^{00} + B_1^1 * K^{10}) * D(T_{p2}) +$ $(B_1^0 * K^{00} + B_1^1 * K^{10}) *$ $(B_1^1 * K^{11} + B_1^0 * K^{01}) * M^2(T_{p2})$

* operations symbols from [23]; P – working operation; K –functional check

Where:

- B^1 – Probability of error-free performance(work operation),
- K^{11} – Probability that correctly executed work operation during control will be recognized as completed correctly,
- K^{00} – Probability that an incorrectly executed work operation during control will be recognized as completed incorrectly,
- $M(T)$ – math. expectation of the random runtime,
- $D(T)$ – dispersion of the random runtime variable,
- Subscript shows the action number.

Operations description:

- Implementation of a request for the history of the previous shift operator (work step P1),
- Print data from the previous shift operator’ work. (work step P2),
- Transition to the Setting Work Parameters form. (work step P3),
- Setting values for ammonia (work step P4),
- Monitoring values for ammonia (control operation K1),
- Setting values for sulfuric acid (work step P5),
- Monitoring values for sulfuric acid (control operation K2),
- Setting values for phosphoric acid (work step P6),
- Monitoring values for phosphoric acid (control operation K3),
- Monitoring values of all parameters (control operation K4),
- Start of the technological process (work step P7).

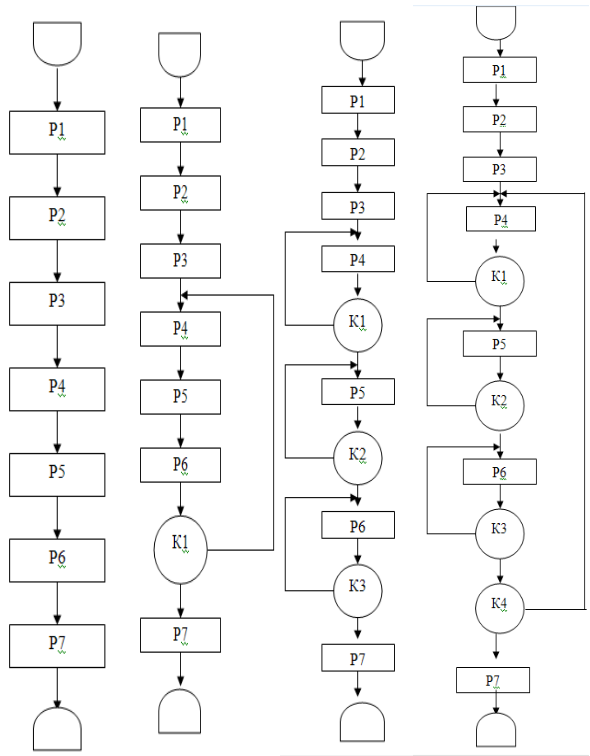

Fig. 9. Variants of the model (fragment) of the operator’s activity in the technological process of manufacturing NPK-fertilizer “Superagro” brand 15:15:15 (developed by student Alesandr Skidanenko).

Initial data for calculations (from the statistical databases of the company) are given in Table 2 and Table 3.

Table 2. Reliability-time indicators for the technological process operator of NPK-fertilizer production. Working operations.

Indicator		Operation						
		P1	P2	P3	P4	P5	P6	P7
FaultlessnessB[1]		0,988	0,978	0,998	0,987	0,997	0,997	0,998
Time	M, s	41	100	55	27	25	30	40
	D, s^2	0,3	0,4	0,7	0,4	0,5	1,1	0,8

Table 3. Reliability-time indicators for the technological process operator of NPK-fertilizer production. Monitoring operations.

Indicator		Operation			
		K1	K2	K3	K4
Monitoring quality	K^{11}	0,997	0,997	0,997	0,996
	K^{00}	0,995	0,995	0,995	0,998
Time	M, s	40	40	40	50
	D, s^2	0,7	0,8	0,8	0,9

One can see the calculation results (carried out automatically by a computer program) in Table 4.

Table 4. Calculation results*

Indicator	Dir. time	Opt.1	Opt.2	Opt.3	Opt.4
B		0,9821	0,9928	0,9929	0,9930
M, s		318	439,8	376	473,07
D, s^2		4,2	4,8	5,1	7,5
P_t	400	1	0,0002	0,9778	0,00001
	430	1	0,1950	0,9998	0,0068
	450	1	0,8106	1	0,0934
	600	1	1	1	1
B*P_t	400	0,9821	0,0001	0,9771	0,00001
	430	0,9821	0,1935	0,9927	0,0067
	450	0,9821	0,8047	0,9929	0,0920
	600	0,9821	0,9928	0,9929	0,9930

*B – probability of error-free execution, M and D – expected value and variance of execution time,

P_t – probability of timely execution,

B*P_t – probability of error-free and timely execution

Thus, it is obvious that mathematical models and computer technology provide a variant modeling of an automated technological complex functioning processes.

Since the qualifications of an operator, the functional state, the technical characteristics of the equipment, the quality of the interface, and the degree of cognitive comfort, determine the quality of the performance of individual operations, the influence of all these features is taken into account at the stage of forming the initial data (see component and morphological models in Fig. 6).

3.5 Optimization models of human-machine interaction processes to minimize damage risks

Obviously, in the case of a large number of options, it is rather difficult to solve the problem of choosing the organization of activities by evaluating all options for activities. In this regard, we have developed a bank of all kinds of models for optimizing activities, which are well tested for various human-machine systems. Here we will focus on a model that takes into account the multiple disruptions of the technological process typical for chemical production. To formulate the problem, we will use the technique of transition from a work graph (for example, as in Fig. 10) to an event graph. In this case, the events will be the results of the execution of individual operations – without violations or with violations of certain types.

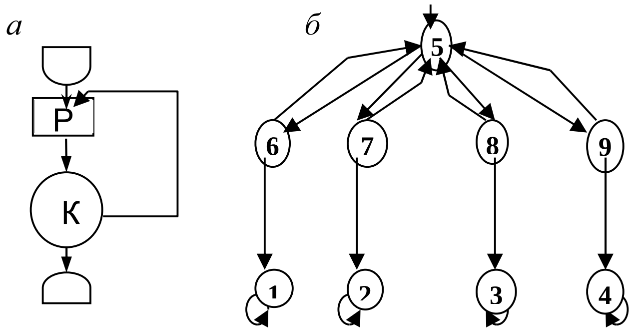

Fig. 9. An example of transition from a work graph to an event graph. *a* – work graph, *b* – event graph (on the event graph, absorbing vertices correspond to: 1 – process execution without errors, 2 – type 1 error, 3 – type 2 error, 4 – type 1 and type 2 errors occurring simultaniously).

Let N be a total number of vertices. At every vertex i there are K_i options to perform an operation, i.e., each solution corresponds to it's specific set of transitions, characterised by $P_{ij}^{(k)}$ -the probability of transition from the vertex i to the vertex j when choosing the k–solution, $k \in K_i$. Moreover: $\sum_j p_{ij}^{(k)} = 1$ for all i and for all $k \in K_i$.

$T_{ij}^{(k)}$ – average execution time of the i-operation within k-solution when transiting to the vertex j. Average expected time for the i-operation within the k-solution: $T_i^{(k)} = \sum_j P_{ij}^{(k)} T_{ij}^{(k)}$. To each variant of the end of functioning on the graph of events, we associate an absorbing vertex. We number the absorbing states with first r natural numbers (r – is the number of absorbing vertices). We consider vertices $s, m, \ldots, n$ being dependent if the operator needs to make the same decisions. For non-absorbing vertices, we set the vector of initial probabilities: $a = (a_{r+1}, a_{r+2}, \ldots, a_n)$:

$$\sum_{i=r+1}^{N} a_i = 1 \cdot$$

It is necessary to choose such a solution at each vertex that will ensure minimum losses from unreliability. Let L be a set of all possible combinations of types of violations, and $B^0{}_l(X)$ – the probability of performing an activity with errors determined by the combination $l \in L$; α_l – the amount of damage from the implementation of the function with violations $l \in L$. The value of damage from errors of different types will have the form:

$$V(X) = \sum_{l \in L} \alpha_l \sum_{s_l} \sum_{i=r+1}^{N} \sum_{k \in K_i} P_{is_l}^{(k)} x_i^{(k)},$$

where:
$x^{(k)}{}_i$ – is a variable that characterizes the choice of solution: $x^{(k)}{}_i > 0$, if in the i-vertex to execute the operation the k-solution was chosen, and $x^{(k)}{}_i = 0$, in the other case. To take into account dependent vertices, we use boolean variables $\delta_i^{(k)}$ (for the k-solution in the i-vertex). Then, the problem can be formalized as follows :

$$V(X) = \sum_{l \in L} \alpha_l \sum_{s_l} \sum_{i=r+1}^{N} \sum_{k \in K_i} P_{is_l}^{(k)} x_i^{(k)} \to \min$$

$$\sum_{k\in K} x_j^{(k)} - \sum_{i=r+1}^{N} \sum_{k\in K} P_{ij}^{(k)} x_i^{(k)} = a_j \,,$$

$$j=r+1, r+2, \ldots, N$$

$$\sum_{i=r+1}^{N} \sum_{j} \sum_{k\in K_i} P_{ij}^{(k)} T_{ij}^{(k)} x_i^{(k)} \le T_0$$

$$\sum_{k\in K_i} \delta_i^{(k)} = 1 \qquad \text{for all } i,$$

$$\delta_s^{(k)} = \delta_m^{(k)} = \ldots = \delta_n^{(k)} \qquad \text{for all } k\in K_i$$

$$x_i^{(k)} - M\delta_i^{(k)} \le 0 \qquad \text{for all } i \text{ and all } k\in K_i.$$

$$x_i^{(k)} - m\delta_i^{(k)} \ge 0 \qquad \text{for all } i \text{ and all } k\in K_i$$

$$\sum_{j=1}^{r} \sum_{i=r+1}^{N} \sum_{k\in K_i} P_{ij}^{(k)} x_i^{(k)} = 1 \,,$$

$$x_i^{(k)} \ge 0 \qquad \text{for all } i \text{ and all } k\in K_i.$$

Let m be a tiny, and M – a very large number, then for each i only one $x_i^{(k)}$ will not be zero, and, in this way, we find the optimal solution at each vertex.

The convenience of the proposed model is that the problem is reduced to a linear programming problem and can be easily solved in any software environment.

Different variations of target functions and limitations are possible, which can be used in various problem situations.

In the database of the decision support system, we recorded 56 various ready-made templates of optimization (single-criterion and multi-criteria problems), used by the decision-maker, depending on the task at hand.

In addition, the optimization problem is embedded in the agent-manager, which prompts the operator in the process of work based on the analysis of the technological process, and on the available reserve of time and resources.

3.6 Approbation

Models and information technology are used in the design and operation of automated control systems for chemical production and other critical systems (gas pumping stations, machine building) in Ukraine and Russia.

Models are used to solve problems:

- Selecting the level of process automation,
- Distribution of functions between operators,
- Control algorithms design,
- User interface design,
- Designing agent-managers to support operator activities.

The implementation of the results made it possible to significantly reduce the risk of accidents and improve the quality of products, as well as (according to surveys) – to increase the degree of cognitive comfort of operators and the attractiveness of their work.

Practical research has shown that the reliability of assessing the probabilistic indicators of error-free and timely implementation of algorithms of activity is determined only by the quality of the initial statistical data and the error does not exceed 0.019%.

In addition, the results are introduced into the educational process of the Ukrainian Engineering and Pedagogical Academy and Sumy State University and are used in the preparation of bachelors (discipline “Decision Theory”, “Theory of Risks” and in the preparation of masters (discipline “Ergonomics of Automated Systems”), as well as in the diploma designing.

4 Conclusions

Accidents and damages in automated production systems of a critical type (which include, among other things, chemical plants) actualize the task of finding reserves for increasing the reliability and sustainability of technological processes.

The human-operator in automated systems is both a source of errors and an active corrective element.

The sustainability and reliability of the entire system significantly depends on the organization of activities and working conditions of the operator.

At enterprises of the chemical profile, decision support systems should be introduced, related to ensuring the sustainability and reliability of technological processes and the ergonomic support of operators' activities.

The decision support system should include system models of an automated technological complex (as elements), in the form of component and morphological models that describe the complex in the required sections and are a source of initial data for modeling.

For the interface design and certification (acceptance into operation), expert groups should be created to carry out a comprehensive assessment and certification.

Automated control systems should provide mechanisms for adaptation to the characteristics of operators, built on the basis of formalized models of operators.

To evaluate and optimize the activities of operators of automated complexes, it is convenient to use the formalisms of functional networks.

The models and information technology proposed in the work make it possible to choose design solutions aimed at minimizing losses from unsustainability and unreliability.

The scientific novelty lies in the fact that, in contrast to the well-known models of sustainable and reliable design, the proposed set of models takes into account the joint functioning of technical and ergatic elements and ensures decision-making using objective quantitative indicators. The practical significance lies in the fact that models and information technology have been developed to allow solving a set of problems of assessing and optimizing reliability, and are convenient for use both at the design and operation stage of automated technological systems, and are minimizing the risks of losses from unreliability

The reliability of the results we ensure by:

- Using the proven mathematical apparatus of functional networks
- Analytical derivation of dependencies (for tasks of calculating reliability)
- Using approved models for solving linear programming problems.

The reliability of the results is confirmed by the high convergence of the assessment results with experimental studies (the error is determined by the quality of the initial data and does not exceed 0.019% for the probabilistic indicators.

The proposed method is associated with additional costs for ensuring sustainability and reliability; however, it makes it possible to reasonably economically substantiate the system of measures, taking into account the reduction of losses from unsustainability and unreliability.

Models for assessing and optimizing reliability and sustainability, as well as approbation, were carried out for technological systems of chemical production, however, the approach and information technology are universal and can be used for a wide class of technological processes.

Research prospects we relate to:

- Comprehensive analysis of losses from cyber-attacks and modeling the activities of attackers, as well as models for identifying security threats based on machine learning methods,
- Contactless methods of monitoring the functional state of employees to prevent negative consequences,
- Integration of analytical models with simulation and Data Mining models.

The authors dedicate this article to the memory of their teacher the first president of the Soviet Ergonomic Association, Doctor of Technical Sciences, Professor Anatoly Ilyich Gubinsky (1931-1990, St. Petersburg, Russia), who was the founder of the scientific school “Efficiency, quality and reliability of human-machine systems” and who first formulated the ideas that formed the basis of our study.

Abstract. While implementing state support mechanisms for renewable energy deployment, each country faces the problem of assessing and forecasting their consequences and must timely adjust their set to ensure sustainable energy development. The article estimates the price for sustainable development of the renewable energy sector on the example of Ukraine based on evaluating the effectiveness of the key mechanism of state support for the industry advancement - the feed-in tariff. The comparison of feed-in tariff rates with the LCOE indicators for the electricity generated from solar and wind power plants has shown that the current feed-in tariffs for two of the most popular renewable energy technologies are inflated several times and do not meet global trends in reducing the cost price of electricity generated by these technologies. The consequence of applying economically unreasonable tariffs is the annual over-expenditures of the state budget of Ukraine, which recently count hundreds of millions of euros. In the context of the country's growing green energy generation, the conditions for further use of the feed-in tariff and the transition to other state support mechanisms are substantiated.

1 Introduction

Renewable energy (RE) deployment is a progressive trend in modern world development that contributes to the achievement of the Global Sustainable Development Goals #7 "Affordable and clean energy" and #13 "Climate action" [1]. However, RE technologies' technical imperfection still causes the high generation cost of green energy compared to its analog generated from fossil fuels. The higher price significantly reduces the RE competitiveness in the global market and hinders the implementation of green energy technologies in business entities and households' everyday activities. Therefore, while developing the RE sector, countries apply state support mechanisms for the RE generation and consumption. The most popular schemes include feed-in tariffs, renewable portfolio standards, net metering, green auctions, tax, financial privileges, etc. [2-8].

When choosing and implementing support instruments, it is advisable to consider the stage of the RE development in a country and the energy policy goals as well as estimate possible social, economic, environmental and political consequences of the introduced levers. Unreasonable and inconsistent application of economic mechanisms for the RE development can not only fail to achieve the state green energy policy goals but also negatively affect the national economy through state budget overspending, deteriorating the investment climate, discouraging business entities and households from introducing RE technologies, etc. In particular, Spain is an example of such a negative experience. In the early 2000s, the country faced a heavy financial burden on the state budget due to high feed-in tariffs introduced for developing the RE sector. To solve the problem, the national legislation was changed, and feed-in tariffs were cut. However, the country was forced to pay compensations to the RE projects' investors close to 1 billion euro on lawsuits won for violations of their rights due to changes in the RE legislation [9]. Thus, each state that implements state support mechanisms for green energy faces assessing and forecasting their consequences and must timely adjust the toolset for the RE sector's sustainable development.

Organizational, legal, economic, and other RE deployment mechanisms in different countries of the world are studied in plenty of research papers, for example [2-6; 10-11; 12]. The authors of [5; 13-15] note the high efficiency of the feed-in tariff application at the initial stages of national RE sectors' development since these tariffs could provide sufficient profits to the owners of green energy generating facilities. Therefore, at the expense of feed-in tariffs, it is possible to ensure the RE supply's formation on the domestic energy market. Many scientists indicate that the application of

* Corresponding author: insotnik@gmail.com

quota obligations or RE portfolio standards is an effective mechanism to provide both supply and demand for green energy [16-19]. However, this scheme must be supported by net metering and financial instruments (in particular, credit lines, partial compensation of loans for the construction of RE facilities by local and state authorities) to encourage active RE development. As the green energy sector expands, it is advisable to use green auctions and tender systems to ensure the creation of a competitive environment in the field [7; 20-22].

Overall, the necessity of evolutionary changes in management mechanisms for sustainable development of the national RE sectors is highly recognized by the researchers. However, few papers examine the feasibility of using specific state support schemes and the criteria for the transition from one tool to another to ensure sustainable RE deployment. As a rule, scientists focus on assessing the benefits and basic parameters of the RE development mechanisms while paying far less attention to the consequences of such incentives for countries' state budgets. For example, E. Dijkgraaf et al. [23] studied the feed-in tariff impact on the green energy advancement by modeling the duration of feed-in tariffs' implementation, their rates, government targets in the RE field, etc. P. del Río [24] evaluated the dynamic efficiency of feed-in tariffs considering technology-specific fixed-tariffs, their degression in the long-run, cap and floor prices, reductions of support over time for existing RE plants, the burden of green energy costs to consumers, maximum RE plant size, and other factors. The author noted the need to cut feed-in tariffs over time to reduce the financial burden on energy consumers while not quantifying such an impact.

S. Matsuda and H. Kubota [25] proposed the concept of "marginal cost of power facility" to analyze the effectiveness of the feed-in tariff mechanism in Japan. They justified the need to take the effect of replacing imported fossil fuels with green energy into consideration. P. Milanés-Montero et al. [26] analyzed the feed-in tariff influence on Spanish companies' profitability, noting its positive impact on business development. M. D. Leiren and I. Reimer [22] substantiated the transition from feed-in tariffs to green auctions in Germany in a historical institutionalist perspective.

Thus, the recent scientific literature has a gap in research concerning quantitative assessments of the price for sustainable RE sector development based on the feed-in tariff and other economic support tools' use. The lack of these studies negatively affects the effectiveness of national energy policies for the RE advancement, causing management errors and reducing the results of the state support instruments' implementation.

Hence, the purpose of this research is to estimate the price for sustainable development of the RE sector on the example of Ukraine based on evaluating the effectiveness of the feed-in tariff as a key state support mechanism for the industry deployment and justifying the feasibility of its further use in the country. To our knowledge, this is the first attempt to substantiate the feed-in tariff implementation regarding the financial loading on the Ukrainian state budget.

2 Problems of the feed-in tariff application to ensure sustainable RE development in Ukraine

Considerably depending on energy import, Ukraine has been actively developing the RE sector over the last decade, using several mechanisms of economic support, including [27]:

1) credit/loan programs offered by commercial banks in Ukraine and the European Bank for Reconstruction and Development (EBRD);

2) tax and customs incentives (value-added tax exemption for equipment and components used for green electricity generation; custom duty exemption for the imported materials, equipment and components used for the production of alternative fuels or green energy);

3) long-term fixed feed-in tariffs;

4) an allowance to feed-in tariffs for using domestic equipment during the RE plants construction;

5) the guaranteed purchasing of 100% of electricity generated from RE sources;

6) free license obligation for connecting household RE plants to the grid;

7) the simplification of the procedure for connecting new RE plants to the electrical grid.

Today the feed-in tariff, which rates are the highest in Europe [28], is the main support scheme used in Ukraine. Legislatively introduced for enterprises in 2008 and households in 2014, the feed-in tariff ensured the active RE development in the domestic business and residential segments in 2009–2020. In particular, the most significant growth in RE capacities and the amount of green electricity generated was in the last 5-6 years (2014–2020) and was caused by several reasons. The first one is high feed-in tariff rates, which are fixed until the end of 2029 and make RE projects economically profitable. The second reason is the 100% guarantee of green electricity purchase by the state. The third one is the governmental plan to reduce feed-in tariffs gradually in the next decade, which encourages investors to construct RE facilities today and obtain higher feed-in tariffs.

The RE deployment's intensification based on the feed-in tariff application has exacerbated financial problems related to the payments for green electricity generated in the country. The growth of RE generation significantly increases the burden on the state budget. As the legislation of Ukraine does not indicate special sources for the feed-in tariff financing, the rise in the green electricity generation causes an increase in payments for it, which are made at the expense of all taxpayers. This affects the escalation of the weighted average price of electricity in the country, necessitating an increase in electricity tariffs for all consumers. Given the energy poverty of a large part of the Ukrainian population, it threatens to worsen the national socio-economic situation and provoke social protests.

The issue with the payment for the generated green energy was especially aggravated in spring 2020 during the first lockdown. On the one hand, RE generating capacities continued to operate as usual while the overall energy demand decreased due to enterprises' partial shutdown. At that time, it would be expedient to partially turn off the RE facilities and replace expensive green energy with the cheapest one generated by nuclear power plants. However, due to the 100% guarantee of green electricity purchase by the state, the lack of sufficient maneuverability in the Unified Energy System's capacities, and the reluctance of RE plants owners to lose their profits during the lockdown, the share of expensive RE in the overall energy mix increased significantly. The latter caused the deficit growth of SE "Guaranteed Buyer," which paid for the green energy to its suppliers on behalf of the state. At the end of 2020, this enterprise's deficit reached 24.6 billion hryvnias, threatening the national energy billing system collapse [29]. Hence, the current situation requires reforming the economic mechanisms used to support the RE industry in Ukraine. In particular, it is advisable to move to a green auctions system, which the Ukrainian government has not yet launched due to many obstacles [30].

Another alternative is urgently revising the feed-in tariffs and cutting them to a greater extent than planned by law. However, the reduction of feed-in tariff rates is possible only for new RE projects to keep green energy facilities owners and potential investors' trust. In addition, the feed-in tariffs can be cut only based on an objective assessment of the real cost price of green electricity generation, distribution, and supply regarding the stage of RE technologies development. Suppose such a reduction in feed-in tariff rates does not balance the state budget payments for the generated green electricity. In that case, it is expedient to involve other economic incentives for the RE deployment in Ukraine.

Given the above, the research questions are: (1) whether the current feed-in tariff rates in Ukraine are economically justified in terms of ensuring sustainable RE development; (2) how the changes in feed-in tariff rates and green energy generation volumes affect the financial loading of RE on the state budget and (3) whether it is advisable to involve new economic levers to regulate the national RE sector advancement.

3 Approaches to assessing the feed-in tariff economic feasibility

The justification of the feed-in tariff financial burden on the country's state budget can be conducted based on the compliance of the feed-in tariff rates set by the government for a certain RE technology with the average cost price of electricity generated with this technology. In the study, the green energy cost price estimation is based on the Levelized Cost of Electricity (LCOE) method [31]. Carrying out the comparisons for all RE technologies used in the country and determining the weighted average values on their basis make it possible to identify both the degree of feed-in tariffs' justification and their financial burden on the state budget. However, the feed-in tariff rates should be higher than the average cost price of electricity generation for a particular RE technology, as they must at least consider the normal profitability of green energy facilities.

To justify the feed-in tariff rates, the factor of feed-in tariffs' proportionality to the real cost price of green electricity generation (k_{REit}) is proposed. It can be calculated as the ratio of the feed-in tariff for the *i*-th RE technology in the *t*-th year to the cost price of green electricity generated with the *i*-th RE technology in the *t*-th year:

$$k_{REit} = \frac{FIT_{REit}}{LCOE_{REit}}, \qquad (1)$$

where FIT_{REit} is the feed-in tariff for the *i*-th RE technology (or the weighted average feed-in tariff for all RE technologies used in the country) in the *t*-th year, euro/MWh; $LCOE_{REit}$ is the cost price (calculated with the LCOE method) of green electricity generated with the *i*-th RE technology (or the weighted average cost price of electricity generated with the set of RE technologies used in the country) in the *t*-th year, euro/MWh.

The euro was used to calculate the indicators included in the proportionality factor formula. It is due to the fact that feed-in tariffs are fixed in euros in Ukraine to avoid hryvnia devaluation risks. This precaution guarantees a stable income from the operation of RE generating capacities to their owners.

The proposed proportionality factor reflects the degree of the state pricing policy efficiency in the RE sector in the current period. It can be calculated for both the RE technologies mix used in the country and a certain RE technology. If the proportionality factor values are far from 1, there is a divergence between the feed-in tariff rates and the real cost prices of green electricity generation. It indicates the ineffectiveness of the state pricing policy in the RE field. On the contrary, the convergence of the proportionality factor components and its values close to 1 indicates growing compliance of feed-in tariffs with the real green energy cost price and, accordingly, optimizing the feed-in tariff financial burden on the state budget.

It is important to monitor and analyze the value of the proportionality factor in dynamics as the development of the RE sector technological base can significantly reduce the cost price of green electricity generation over time. It should be reflected in the periodic review and adjustment of feed-in tariff rates in order to reduce state budget expenditures.

The amount of the country's state budget over-expenditures (OE_{sbREit}) associated with excessive payments at inflated feed-in tariffs for the *i*-th RE technology in the *t*-th year can be calculated as:

$$OE_{sbREit} = (FIT_{REit} - LCOE_{REit} \times (1 + k_{adREit})) \times Q_{REit}, \qquad (2)$$

where k_{adREit} is a coefficient that considers additional economically justified factors influencing the increase in the unit price of electricity generated in the *t*-th year with the *i*-th RE technology (for example, the normal profit of the RE facility owner, the risk of doing business in the country, credit risks, etc.); Q_{REit} is the amount of green electricity generated in the *t*-th year with the *i*-th RE technology.

The amount of the state budget over-expenditures can be calculated both for an individual RE technology and their set used in the country. Over time, the growth of this indicator shows an increase in unreasonable state budget expenditures due to unbalanced feed-in tariffs.

4 Evaluation of the feed-in tariffs' economic feasibility in Ukraine

Based on the above indicators, let us assess how reasonable the Ukrainian feed-in tariffs and the corresponding state budget expenditures are on the example of large solar power plants (with a capacity of more than 10 MW) and wind power plants (with a capacity of more than 2000 MW per turbine). Solar and wind power plants have been chosen for calculations due to the following considerations. First, feed-in tariffs for solar and wind power plants in Ukraine are the highest compared to other RE technologies. Attractive tariffs have led to the predominant development of solar and wind power facilities, which today provide most of the green electricity generation. Accordingly, state payments for them are the largest. Second, the cost price of generating electricity for large solar and wind power plants is lower than for small and medium-sized RE facilities that should be reflected in feed-in tariffs. Third, the last decade has been marked by significant progress in reducing the cost price of solar and wind energy technologies on the world market. Therefore, it is important to ensure that the change in feed-in tariffs is consistent with the downward trend in these technologies' cost prices (other things being equal) since the growing volume of green electricity generation significantly affects the state budget expenditures.

The initial data for assessing the economic feasibility of feed-in tariffs for large solar and wind power plants are given in Table 1. Data on LCOE [32-33] are provided in euros, taking into account the euro / US dollar exchange rate of the European Central Bank [34] in the relevant period.

Table 1. Initial data for feed-in tariffs' economic justification (developed by the authors based on [27; 32-33]).

Year	Feed-in tariff on electricity, euro cent/kWh		LCOE, euro cent/kWh	
	SPP*	WPP**	SPP	WPP
2009	25.85	11.31	25.74	9.68
2010	25.85	11.31	18.71	9.35
2011	25.85	11.31	11.28	5.10
2012	25.85	11.31	9.73	5.60
2013	18.85	11.31	7.83	5.27
2014	18.85	11.31	5.95	4.44
2015	16.96	10.18	5.86	4.96
2016	15.99	10.18	4.97	4.25
2017	15.03	10.18	4.43	3.98
2018	15.03	10.18	3.64	3.56
2019	15.03	10.18	3.57	3.66

Table notes: *SPP – solar power plants with a capacity of more than 10 MW; **WPP – wind power plants with a capacity of more than 2000 MW per turbine.

Fig. 1 presents the results of calculating the proportionality factors of feed-in tariffs to the real cost price of green electricity generation obtained on the LCOE basis for two RE technologies, according to formula (1).

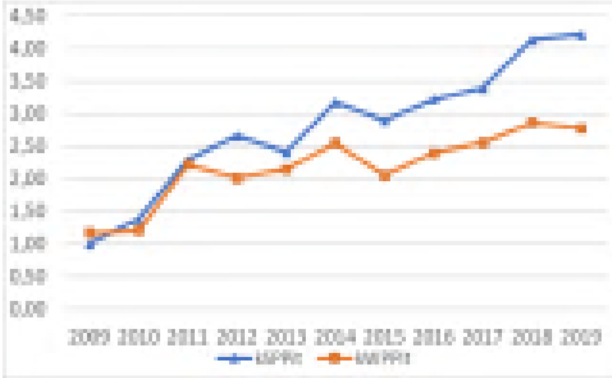

Fig. 1. Proportionality factors of feed-in tariffs to the real cost price of green electricity generation (by the LCOE method) for solar power plants (capacity of more than 10 MW, k_{SPPit}) and wind power plants (capacity of more than 2000 MW per turbine, k_{WPPit}) in Ukraine in 2009-2019 (calculated by the authors).

The calculations show that the feed-in tariff for solar power plants with more than 10 MW capacity was almost equal to LCOE in 2009 while slightly exceeding its value. In that year, the feed-in tariff for wind power plants with a capacity of more than 2000 MW per turbine exceeded LCOE by 17%, which is acceptable in ensuring a normal return on the investment and considering the risks of doing business in the country. Thus, the starting feed-in tariff rates were economically justified. During the study period, there was an increase in the divergence between feed-in tariffs and LCOE for the corresponding RE technologies. This is evidenced by the growing values of the proportionality factors. In 11 years, the gap between feed-in tariff and LCOE for solar energy increased to 4.21 times, whereas for wind power plants up to 2.78 times in 2019. Thus, in 2009–2019, there were formed essential reserves to reduce feed-in tariff rates. They indicate the state RE pricing policy's inefficiency and the economic unreasonableness of current feed-in tariffs, which are significantly inflated and need to be corrected. The obtained results are consistent with the trends of cutting feed-in tariffs in the 2000s by developed countries' governments, which actively deploy the RE sector, due to the cost price reduction of RE technologies [22; 35].

5 Estimation of financial over-expenditures of the state budget of Ukraine due to inflated feed-in tariffs

To calculate the state budget over-expenditures for each of the two considered RE technologies in 2009–2019 due to inflated feed-in tariffs, it is necessary to make several assumptions. First, taking into account the Ukrainian realities (credit risks, the profitability of the green energy business, and other factors), economically justified feed-

https://doi.org/10.1051/e3sconf/202128002006

in tariffs should exceed the cost price (LCOE) at least by 25%. Thus, k_{adREit} = 0.25. Secondly, the calculations will be performed only for the business sector, excluding households as the technical, economic, and other operating conditions of RE facilities for these two types of energy suppliers differ significantly. Third, open and detailed statistical data concerning green energy generation by solar power plants with a capacity of more than 10 MW and wind power plants with a capacity of more than 2000 MW per turbine are absent for 2009–2019. Therefore, it is assumed that all volumes of green energy generated by solar business facilities were provided by the operation of solar power plants with the capacity of more than 10 MW. The same assumption is applied to the green electricity generated by wind energy facilities. Feed-in tariffs for large power plants are usually lower than for smaller power plants, considering lower specific fixed and investment costs. Therefore, our estimates of budget overruns, calculated for the entire energy generation of the respective solar or wind sector, can be counted as the state budget financial losses' minimum threshold. The results of calculations according to formula (2) are given in Table 2.

Table 2. Estimates of the state budget over-expenditures on electricity generated by solar and wind power plants in Ukraine in 2009–2019 due to inflated feed-in tariffs (calculated by the authors based on [36-42]).

Year, *t*	Solar energy sector			Wind energy sector		
	k_{adSPPt}	Q_{SPPt}, mln kWh	OE_{sbSPPt}, thousand euro	k_{adWPPt}	Q_{WPPt}, mln kWh	OE_{sbWPPt}, thousand euro
2009	0.25	0.0	0*	0.25	41.1	0*
2010	0.25	0.5	12	0.25	49.2	0*
2011	0.25	30.0	3526	0.25	89.0	4392
2012	0.25	334.0	45720	0.25	257.5	11085
2013	0.25	562.8	50999	0.25	636.4	30049
2014	0.25	485.2	55394	0.25	1171.5	67462
2015	0.25	475.2	45795	0.25	973.7	38788
2016	0.25	492.2	48132	0.25	924.5	45045
2017	0.25	714.7	67879	0.25	973.5	50630
2018	0.25	1080.0	113171	0.25	1180.2	67680
2019	0.25	2932.0	309728	0.25	2022.0	113274

Table notes: k_{adSPPt}, k_{adWPPt} are coefficients of additional energy price factors for solar and wind power plants respectively; Q_{SPPt}, Q_{WPPt} are amounts of green electricity generated by solar and wind power plants respectively; OE_{sbSPPt}, OE_{sbWPPt} are the state budget over-expenditures for feed-in tariffs for solar and wind power plants respectively; 0* means no overspending.

Thus, the obtained data (Table 2) show an exponential increase in state budget overruns for green electricity generated by solar facilities in 2016–2019, while budget over-expenditures for green electricity generated by wind turbines are much lower. In particular, in 2018, with the ratio of electricity generation by solar and wind power plants 0.92:1, the proportion of state budget overruns was 1.67:1. This indicates extremely high feed-in tariffs for solar energy even compared to feed-in tariffs for wind energy, which are also inflated. It confirms that Ukrainian legislators do not monitor the downward trend in the cost price of electricity generation from renewables and do not adjust feed-in tariffs on time. The result is irrational spending of taxpayers' money, which is recently counted of millions of euros. Today all Ukrainians pay for green energy, and only a few oligarchic clans receive extra profits from it. It threatens the sustainable development of the RE industry in the near future.

It is worth noting that each country, which deploys green energy through the feed-in tariff introduction, faces the problem of budget overspending due to the RE volumes' growth and high feed-in tariffs. In particular, Spain, Germany, the Netherlands, and other developed states had to solve this issue at a certain stage of their RE advancement [9; 22; 35]. A national government's task is to monitor the existing feed-in tariffs' compliance with trends in reducing the green energy cost price. On this basis, the government should timely adjust the set and parameters of state support instruments for RE development while avoiding or minimizing state budget overspending.

6 Prospects for change of feed-in tariffs in Ukraine

Based on the data from Table 1, in 2019, the cost prices of generating electricity from solar energy became lower than from wind energy for the considered types of solar and wind power plants for the first time. While maintaining the current trends of cheapening technologies until 2030 (Fig. 2), the cost price of solar energy generation per unit will be 1 euro cent/kWh, and the cost price of wind energy generation per unit will be 2 euro cents/kWh. In addition, both green energy cost price indicators will be lower than their analogs for energy generated from non-renewable sources.

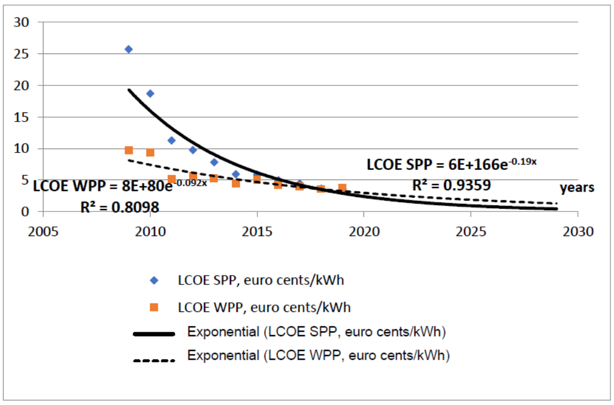

Fig. 2. Cost price reduction forecast of green electricity generation (by the LCOE method) for solar power plants (capacity of more than 10 MW, *LCOE SPP*) and wind power plants (capacity of more than 2000 MW per turbine, *LCOE WPP*) in 2020-2029 (calculated by the authors).

According to the planned decline in feed-in tariff rates in Ukraine in 2021–2029, the lowest feed-in tariff will be 12.01 euro cents/kWh for the considered solar power plant type and 7.92 euro cents/kWh for the considered wind power plant type starting 2025 [27]. Compared to the forecast data on LCOE, feed-in tariff rates will be several times higher than the expected LCOE for the two RE technologies. That is, in the absence of the further legislative revision of the feed-in tariff rates, the divergence between tariffs and the real cost price of green energy generation will increase. The consequence will be continuing excessive growth in the state budget overspending covered by Ukrainian taxpayers.

Given the projected significant reduction in the cost of green electricity, the latter may gradually become a real competitor for traditional electricity. Under such conditions, the feed-in tariff as an economic support instrument for the development of solar power plants with a capacity of more than 10 MW and wind power plants with a capacity of more than 2000 MW per turbine will exhaust itself. It should be abolished for new similar projects in the RE field in Ukraine. However, the feed-in tariff may be preserved for small and medium-sized RE plants, which have a higher cost price of green electricity generation. Relevant practices for small RE facilities are successfully used by many countries worldwide, ensuring the decentralization of energy supply by involving green energy sources [22; 24; 35; 43].

7 Conclusions

The study results on the example of large solar and wind power plants show that current feed-in tariffs in Ukraine are inflated several times and do not correspond to the economically justified level. Such an imbalance in pricing policy for the RE sector causes the disproportionate development of large green energy capacities in the country and devastates the state budget, the losses of which are already estimated at hundreds of millions of euros. Today ordinary Ukrainians pay an exorbitant price for green energy. Preservation of existing and planned reduction of feed-in tariff rates threatens sustainable RE sector development and may cause the industry's financial crisis.

On the one hand, to avoid the mentioned negative consequences, it is advisable to revise the current feed-in tariffs and bring them in line with global trends of the cost price reduction for green electricity generation. However, it is important to consider the additional factors that can increase the unit price for green electricity and refer to the conditions of doing RE business in Ukrainian realities.

On the other hand, with the preservation of feed-in tariffs, the amount of electricity generated by RE facilities operating on feed-in tariffs will only increase. Consequently, state budget expenditures will rise further even with fair feed-in tariffs. Therefore, it is necessary to gradually move away from using the feed-in tariff mechanism, which ensured the successful start of RE development in Ukraine, and apply other levers to regulate sustainable RE development. The latter may include introducing green auctions, renewable portfolio standards, net metering, green certificates market, and other instruments, which will ensure the continued sustainable advancement of the RE sector without creating excessive loading on the Ukrainian state budget.

The publication was prepared in the framework of the research projects "Formation of economic mechanisms for sustainable development of renewable energy in the conditions of global and local threats to energy security of Ukraine" (No. 0120U104806) and "Stochastic modeling of road map for harmonizing national and European standards for energy market regulation in the transition to a circular and carbon-free economy" (No. 0120U104807) funded by the National Research Foundation of Ukraine.

Abstract. To ensure the sustainable development of an enterprise, it is necessary to properly analyze the enterprise development, to ground the plans and management decisions on effective diagnostics and prediction of current and future economic situation at the enterprise. The article presents a study on the application of fuzzy time series forecasting methods. A new approach is applied to forecasting an enterprise's net income using a fuzzy technique. For testing the methodology, there were used statistical data on the enterprise net income level of the Ukrainian enterprise from 2002 to 2017. In the method of Stevenson and Potter, it is proposed to use as the universe of discourse, in the process of applying the method for all defined fuzzy sets, the intervals of variation of such indicator as growth rate. The same background as in Stevenson and Porter's model is used in this article for forecasting the time series levels using the growth rates of the actual data as the universe of discourse. The forecasting results, obtained by this approach, are supposed to have more accuracy rate than other fuzzy time series models. Some modifications of this technique are proposed to obtain a higher accuracy rate and a point forecast one step forward.

1 Introduction

To strengthen its market position in a competitive environment and guarantee sustainable development, each company must constantly seek reserves to improve its efficiency. The methodology of decision-making processes under the uncertainty in various sectors of the economy are based on the different forecasting methods and models. However, the conditions of uncertainty and variability of the external environment require the use of scientifically sound approaches to management decisions at all stages of production process management, which requires quality planning and forecasting of most important production indicators, as well as systematic adjustment of current and future plans.

As we know, a forecast is any statement about the future, and economic forecasting is a huge subject [1]. Any operational theory of economic forecasting must allow that any characteristic of the data moments (especially measures of averages and spread) might alter because of changes in technology, legislation, politics, weather, and society [1]. The aim of numerous recent researches is to develop effective and reliable methods for economic forecasting. But the most existing forecasting models impose considerable limitations on the random sequences describing the change of economic indicators (Markovian property, stationarity, monotony, scalarity, etc.) [2]. Therefore, the main requirement for forecasting methods, which can be used in decision-making processes, in the absence of any significant restrictions on random sequences that describe changes in economic indicators.

Nowadays, time series forecasts are used in a wide range of economic activities, such as setting monetary and fiscal policies, state and local budgeting, financial management, and financial engineering [2]. At the same time, these forecasting methods use economic theory mainly as a guide to variable selection and rely on past patterns in the data to predict the future [2].

After the publication of Zadeh's fundamental paper on the basics of fuzzy set theory, this theory has become widespread in many areas of research, including economic.

In the latter years, a wide variety of methods have been developed and implemented using fuzzy sets for a description of the uncertainty present in the values of time series. Using fuzzy methods allows to improve the adequacy of description of real-world processes and obtain the sound forecasts of future levels.

* Corresponding author: ecvgor@ukr.net

The main objectives of this study are: comparing forecasts based on the obtained models; determining the point estimator for the future net income level obtained by the applied methods for the analysis of this time series of economic indicators; providing recommendations for further use of fuzzy forecasting methods for short-term and operational forecasts of similar economic indicators for economic analysis and modeling of state of the enterprise.

This article consists of six sections. The first section contains the background of the study. The second one provides an overview of the scientific literature on the topic of research. The third part reveals the theoretical details of the proposed fuzzy time series method. The sequence of the study and its main results are presented in the fourth and fifth parts of this work. The final part contains conclusions based on the research results and discussion of further research areas in the field of studying fuzzy time series methods and adapting them to an enterprise economic indicator predicting tasks.

2 Literature review

In modern conditions, the importance of forecasting in various spheres of human activity does not require additional substantiation and proof. Forecasting plays a leading role in management decision-making processes. Forecasting gives a certain idea of the future state of various objects and processes, which allows with some confidence level to assess the possible consequences of certain decisions.

Naturally, any forecasting does not give 100% confidence that the state of objects will be exactly as predicted. That is because any forecasting result contains some uncertainty. Furthermore, the data on which the forecast is based are rarely so deterministic that it is possible to say that there is no uncertainty in them. The uncertainty in the actual data makes it necessary to find new methods of taking it into account.

Fuzzy set theory has been applied to problems of forecasting in different branches of science. The first application of forecasting using fuzzy set theory appeared in Economakos [3]. A simulation-based model was used to forecast the demand for electrical power when load components at various times of the day were described in linguistic terms [4]. Interest in fuzzy forecasting has grown considerably since this initial article [4]. Research on fuzzy forecasting is divided into three categories: qualitative forecasting by the Delphi method, quantitative forecasting by time series analysis, and regression analysis [4]. The second category is the subject of our study.

In particular, the uncertainty of the fuzzy nature is investigated in the so-called fuzzy time series. Many papers on fuzzy time series prediction appeared between 1993 and 2013 (later works mainly developed existing techniques), and many researchers have turned their attention to the fuzzy time series models. Most of the papers published so far have used enrollment data from the University of Alabama as a test sequence over a nearly 20-year period, and proposed models have been compared by the criteria AFER and MSE to choose the best technology by its accuracy rate.

It should be noted that the first work in this direction belonged to Song and Chissom [5]. They introduced the method of creating the time-invariant and the time-variant fuzzy time series models for forecasting the enrollment of the University of Alabama [5]. There were considered the stationary and time-varying fuzzy forecasting models, which provided average forecasting error rates (AFER) of 3.18% and 4.37%, respectively.

Then, Chen [6] developed three heuristic rules ("informal, intuitive strategies" that express the expectations of expert analysts regarding the trend of student enrollment next year) to calculate the forecasted values by using the midpoints of intervals to derive the forecasted values [7]. Chen's model revised Song and Chissom's time-invariant model in order to simplify the calculations and obtain precise forecasting results. The proposed model used arithmetic operations instead of max-min composition operations found in Song and Chissom's model. As a result, this technique provided an average forecasting error rate of 2.38%.

After that, Huarng [8] improved Chen's model by designing an average-based length method for effectively determining the appropriate interval length. In this direction, Li and Chen [9] proposed a new interval partitioning approach that applies the rule of natural partitioning (4-3-2) to the enrollment data of the University of Alabama.

The next solution was presented by Jilani et al [10], where the first order and time-variant model was built by the frequency density-based partitioning of the historical enrollment data of the University of Alabama, and applied improved fuzzy metric for forecasting [10]. For this purpose, the universe of discourse was initially divided into equal intervals and a weighted aggregation of the historical enrolments was obtained in each interval [11].

Then, that approach was modified, and a new method was presented by Stevenson and Porter [12], also applying it to modeling enrollment of the University of Alabama using year-to-year percentage change as the universe of discourse (UoD).

Abd Elaal et al [13] proposed model employed eight main steps in time-invariant fizzy and time-variant fuzzy time series for selecting membership functions based on fuzzy clustering [7]. Ismail Z. and Efendi R. [14] presented the weighted fuzzy time series based on a collection of variations of the chronological number in the fuzzy logical group for forecasting trend series data [7].

A summary of most fuzzy forecasting applications in the field of time series forecasting is presented in table 1 [4, 7].

In these applications, the fuzzy set theory allows taking into account the uncertainty in the actual data and the different parameters of the models. In general, the structure and application of fuzzy forecasting models are relatively simpler than non-fuzzy models, which makes these models more user-friendly.

Finally, we can confirm that the main goal of all modifications of the original Song and Chissom's model [5] was the reduction of the average forecasting error rate, but some models give the same or not better results than the original model. At the same time, a number of techniques have been developed that have significantly improved the accuracy of fuzzy time series models. Some applications of the proposed methods to real problems are presented in [21-27], which confirms the practical value and prospects of these model's application.

3 Research methodology

In our research, we used Stevenson and Porter's model with some modifications made to improve the accuracy rate and obtain the forecast point estimate one step forward. We used the same background as in Stevenson and Porter's model for forecasting time series using percentage change of the actual data as the universe of discourse (UoD).

In the method of Stevenson and Potter, it is proposed to use as the universe of discourse [12], on which fuzzy sets are given, the intervals of variation of such indicators as the percentage change of year to year rates [12], which we will hereinafter call "chain growth rates" or "growth rates".

Consider the time series of a certain economic indicator, which levels are denoted by $y_i,\ i=\overline{1,n}$.

To model time series, the proposed method uses the following dynamics indicator as a chain growth rate:

$$T_i = \left(\frac{y_i}{y_{i-1}} - 1\right) \times 100\%,\ i=\overline{2,n}. \qquad (1)$$

The algorithm of proposed by Stevenson and Porter method contains the following steps [12]:

Step 1. Determine the universe of discourse as the set $U = \left[\min_{i=\overline{2,n}} T_i;\ \max_{i=\overline{2,n}} T_i\right]$, and divide it into m equal intervals (in the Stevenson and Porter's model $m = 7$). It is desirable to round the boundaries of this set to the nearest integer values. But, in our case, for better accuracy, we left the calculated values without correction.

Step 2. Find the frequency distribution of the values of the growth rates that fall into each interval of the partition. By the rule of natural partitioning (4-3-2), for the three largest values of frequencies that fall into certain intervals, make an additional dividing of these intervals into smaller 4, 3, and 2 sub-intervals, respectively. The number of intervals m recalculates here, and it takes a new value.

Step 3. Define fuzzy sets $X_j,\ j=\overline{1,m}$ on each partition interval as triangular fuzzy numbers, which carriers are described by three values: lower limit, middle point, and upper limit. For the actual data of the time series, determine which fuzzy set will describe each value, thereby fuzzifying the data of the initial series.

Step 4. Perform the defuzzification of fuzzy data using the formula:

$$t_j = \begin{cases} \dfrac{1+0.5}{\dfrac{1}{a_1}+\dfrac{0.5}{a_2}}, & j=1 \\ \dfrac{0.5+1+0.5}{\dfrac{0.5}{a_{j-1}}+\dfrac{1}{a_j}+\dfrac{0.5}{a_{j+1}}}, & 2 \le j \le m-1 \\ \dfrac{0.5+1}{\dfrac{0.5}{a_{j-1}}+\dfrac{1}{a_j}}, & j=m \end{cases} \qquad (2)$$

where a_{j-1}, a_j, a_{j+1} are the middle points of the intervals of the carriers of fuzzy sets X_{j-1}, X_j, X_{j+1}, respectively.

Step 5. Determine the predicted values of each level of the series, using the obtained t_i and consistently applying them to previous levels by the formula:

$$\hat{y}_i = y_{i-1}\left(1+\frac{t_i}{100}\right),\ i=\overline{2,n}. \qquad (3)$$

As shown on the data of the University of Alabama enrollment [12], the forecasting results, obtained by this approach, are supposed to have more accuracy rate than other fuzzy time series models.

 https://doi.org/10.1051/e3sconf/202128002007

4 Case study: Net income forecasting using fuzzy time series

Consider such an indicator of the enterprise production activity LLC (Limited Liability Company) "Ukrelektroaparat" (Khmelnytskyi) as net income (revenue) from sales. Data on the net income (revenue) from sales in cash equivalent for the period from 2002 to 2018 were obtained from the reporting documentation of the enterprise LLC "Ukrelektroaparat" from open sources of information and presented graphically in Figure 1.

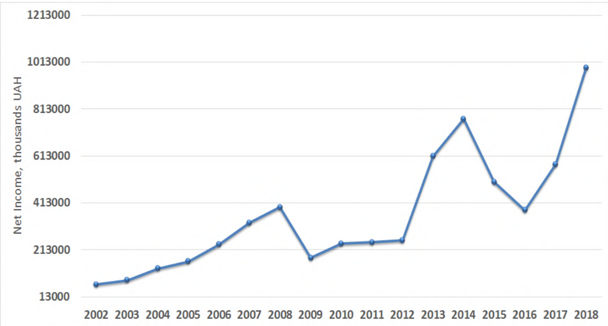

Fig. 1. Dynamics of the net income in 2002-2018.

So, we considered this time series of a real economic indicator and applied to it the fuzzy time series forecasting method described above. Firstly, the growth rates were calculated and aggregated in Table 2.

Table 2. Actual values and the growth rates of net income.

Year to Year	y_i	Growth rate, T_i
2002-2003	82576	28.02
2003-2004	132605	60.59
2004-2005	163642	23.41
2005-2006	235708	44.04
2006-2007	327632	39.00
2007-2008	393463	20.09
2008-2009	178079	-54.74
2009-2010	239518	34.50
2010-2011	244659	2.15
2011-2012	253295	3.53
2012-2013	610840	141.16
2013-2014	769940	26.05
2014-2015	501278	-34.89
2015-2016	382031	-23.79
2016-2017	576795	50.98
2017-2018	986778	71.08

Given the actual interval of variation of the growth rates from -54.74% to 141.16%, it is proposed to determine the universe of discourse as the set U = [-54.74; 141.16], and divide it into the seven intervals. The frequencies of growth rates in occurred in each interval are calculated and presented in Table 3.

Then, we applied the rule (4-3-2) of natural partitioning. As we can see, the largest numbers of net income growth rates have fallen in the fourth, fifth, and sixth intervals, which we divided then into 4, 3, and 2 equal subintervals, respectively. Finally, we obtained the fuzzy sets with triangular membership functions as described in Figure 2.

Table 3. Actual values and the growth rates of net income.

Interval number	Lower limit	Upper limit	Frequency
1	-54.74	-26.76	1
2	-26.76	1.23	1
3	1.23	29.22	1
4	29.22	57.20	6
5	57.20	85.19	4
6	85.19	113.17	2
7	113.17	141.16	0

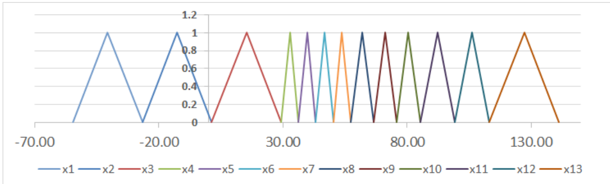

Fig. 2. Fuzzy sets with triangular membership functions.

The final partition of the universe of discourse, the description of the fuzzy sets' carriers with corresponding triangular membership functions and the defuzzified values, are given in Table 4.

Using the obtained defuzzified indicators t_i we determined the predicted values for each time series level, consistently applying them to the previous levels by the formula (3).

The results of calculations of the predicted levels for the considered time series are summarized in table 5. Also, there are represented the determined average forecasting error rates (AFER) obtained by the proposed method by the formula:

$$AFER = \frac{|y_i - \hat{y}_i| / y_i}{n} \times 100\% \,. \tag{4}$$

Table 4. Fuzzy sets and their parameters.

Fuzzy set	Carrier of fuzzy set			Defuzzified value, t_j
	Lower limit	Middle point, a_j	Upper limit	
X_1	-54.74	-40.75	-26.76	-23.54
X_2	-26.76	-12.76	1.23	-34.61
X_3	1.23	15.22	29.22	47.85
X_4	29.22	32.71	36.21	26.31
X_5	36.21	39.71	43.21	39.08
X_6	43.21	46.71	50.20	46.18
X_7	50.20	53.70	57.20	53.46
X_8	57.20	61.87	66.53	61.54
X_9	66.53	71.19	75.86	70.58
X_{10}	75.86	80.52	85.19	80.43
X_{11}	85.19	92.18	99.18	91.88
X_{12}	99.18	106.18	113.17	106.53
X_{13}	113.17	127.16	141.16	119.30

The values of the initial time series and the obtained forecasted levels are represented in Figure 3, and they also can be compared with the values of the simple moving average (Figure 4), which shows that deviations of fuzzy forecasting results from initial values are much lower than of the moving average.

Table 5. Forecasting results for the net income.

i	y_i	T_i	X_j	t_j	$\hat{y}_i$	$AFER$
1	64500	–	–	–	–	–
2	82576	28.02	X_3	47.85	95364	0.1549
3	132605	60.59	X_8	61.54	133396	0.0060
4	163642	23.41	X_3	47.85	196058	0.1981
5	235708	44.04	X_6	46.18	239206	0.0148
6	327632	39.00	X_5	39.08	327833	0.0006
7	393463	20.09	X_3	47.85	484407	0.2311
8	178079	-54.74	X_1	-23.54	300838	0.6894
9	239518	34.50	X_4	26.31	224939	0.0609
10	244659	2.15	X_3	47.85	354130	0.4474
11	253295	3.53	X_3	47.85	361731	0.4281
12	610840	141.16	X_{13}	119.30	555485	0.0906
13	769940	26.05	X_3	47.85	903133	0.1730
14	501278	-34.89	X_1	-23.54	588689	0.1744
15	382031	-23.79	X_2	-34.61	327767	0.1420
16	576795	50.98	X_7	53.46	586281	0.0164
17	986778	71.08	X_9	70.58	983882	0.0029
Total		–	–	–	–	2.831
AFER		–	–	–	–	17.7%

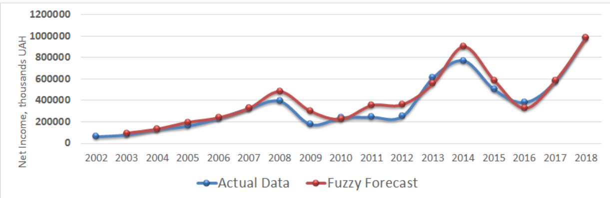

Fig. 3. Comparison of the modeling results with the actual data.

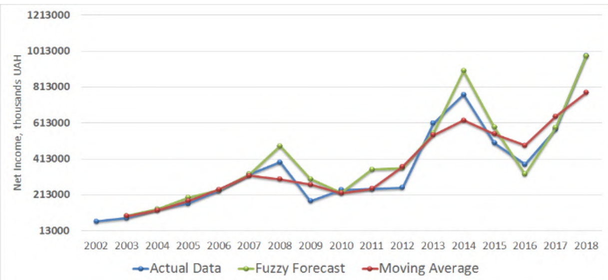

Fig. 4. Forecasted levels compared with the simple moving average.

Another way to test this methodology is to take the time series values from 2002 to 2017 as the initial values and to build the fuzzy time series model on them. Using the fuzzy sets describing the predictive level of each time series level, we can consider a defuzzified value of the time series as a point forecast estimate for each level. Therefore, we suggest calculating the forecasted value for 2018 using the last fuzzy set definition X_7 (for the year 2017), and to obtain the predicted value by the formula:

$$\hat{y}_{17} = y_{16}\left(1+\frac{t_7}{100}\right). \tag{5}$$

The result of estimation is $\hat{y}_{17} = 899733$ thousand UAH (Figure 5), and the average forecasting error rate for this model is AFER = 9.8%, which is slightly lower than for the previous model (table 4). The actual value for 2018 is 986778 thousand UAH, so the relative error is 8.8%.

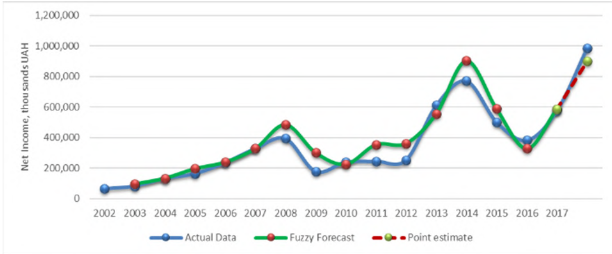

Fig. 5. Point forecast estimate of the net income for 2018.

The accuracy of this forecasting model could be improved if we try to minimize the average forecasting error rate by adjusting some of the values in the defuzzification formula (2). We suggest using four parameters $\alpha_1, \alpha_2, \beta_1, \beta_2$ instead of the values 0.5 in (2):

$$t_j^{adj} = \begin{cases} \dfrac{1+\alpha_1}{\dfrac{1}{a_1}+\dfrac{\alpha_1}{a_2}}, \; j=1; \\[2ex] \dfrac{\beta_1+1+\beta_2}{\dfrac{\beta_1}{a_{j-1}}+\dfrac{1}{a_j}+\dfrac{\beta_2}{a_{j+1}}}, \; 2 \le j \le n-1; \\[2ex] \dfrac{\alpha_2+1}{\dfrac{\alpha_2}{a_{j-1}}+\dfrac{1}{a_j}}, \; j=n. \end{cases} \tag{6}$$

These parameters could be optimized using the Excel Solver GRG Nonlinear method, where AFER is to be set as the objective function, which needs to be minimized. In our study, one set of the obtained adjusted values is: $\alpha_1 = -0.104$, $\alpha_2 = -0.334$, $\beta_1 = 0.076$, $\beta_2 = 0.325$. These values are not unique for each case, but we tried to achieve better accuracy for our model. For the obtained adjusted values, the average forecasting error rate is equal to 5.5%, which is much less than this accuracy indicator for the previous model. These results are illustrated in figure 6, where we can see the forecasted values obtained by the formula (6) with the adjusted parameters.

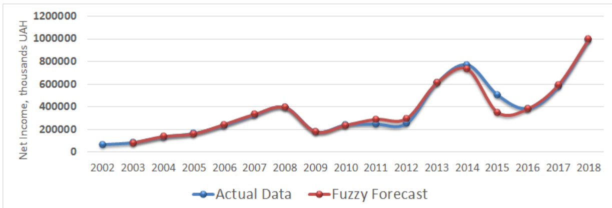

Fig. 6. Net income forecasting model with adjusted parameters.

Comparing to the previous results in Figure 3, this chart shows the closer points to the actual time series levels, which demonstrates the better accuracy of the last obtained model.

5 Results and discussion

As we can see, Stevenson and Porter's method can be applied to the time series of the enterprise's net income level and gives a relatively small error of the result. The conducted analysis shows that the proposed algorithm is quite simple, which makes further searches for the effective methods for modeling time series using fuzzy approach promising, and we should look for the most accurate and convenient fuzzy estimation procedures for time series of economic indicators which take into account the uncertainty of the original data.

Besides, the proposed modification of this technique allows to obtain a point forecast estimate one step ahead, which will give us a piece of information about the possible future level of the time series considered in the research and could be useful for short-term and operational forecasts of similar economic indicators for economic analysis and modeling of state of the enterprise.

6 Conclusion

The presented in the article method of fuzzy time series modeling allows obtaining the forecasting estimates by analyzing the growth rates of the actual time series levels using fuzzy estimation based on the fuzzy sets. This approach makes it possible to use all available information on the dynamics of any economic indicator presented with time series, and achieve a relatively low value of the average error rate.

Further research in this direction should be aimed at developing a unified general formula for defuzzification purposes, which will include a set of parameters, which optimization will allow to obtain better accuracy of the predicted values compared to the actual ones. Another priority for further study is to find possible ways to obtain forecasts a few steps ahead, as there is currently a lack of works in this field. Moreover, a lot of published studies have shown that the accuracy of forecasting is directly affected by the method of the partitioning of the universe of discourse into the set of fuzzy subsets. So, the recommendations should also be developed for the optimal distribution of values over split intervals. Therefore, the use of fuzzy time series approaches opens wide prospects in the field of simplifying the analysis and modeling of time series of economic indicators. Improving such methods will provide an opportunity to implement better forecasting procedures in decision-making systems on enterprises.

Abstract. In modern conditions the successful operation of enterprises and maintaining the sustainability of their development depend on the adaptive model of strategic management of the enterprise. The development of such a model using traditional econometric approaches was proposed in the paper. It was suggested by the authors to take into account the prerequisites and specifics of operating activities using the method of PLS (Partial Least Squares), when it is possible to find several important (result) indicators out by the transition from the original set of features to the set of major components of a smaller dimension while maintaining causal relationships allows. The PLS-PM model of sustainable development of the mining enterprise as a complex economic system was done. The essence of latent variables and the relationship between them were identified and substantiated as well as the numerical modelling was performed using the methods of scientific generalization and abstraction.

1 Introduction

The PLS-PM tool (Partial Least Squares Path Modeling) allows to build complex models of causal interactions between latent variables on the basis of component-oriented approach as well as to evaluate general factor models that can be part of multicomponent analysis in addition to this [4, 6, 12]. Moreover, the use of PLS-PM modeling can turn the interaction between implicit indicators and generate predictive values of quantitative changes off.

The stages of identifying model variables and determining the relationships between them proceed without the involvement of the software. The need for the use of software products arises at the stage of determining development scenarios, when direct calculation of the characteristics of the built model are in progress. The researchers are engaged in the processes of interpretation and analysis of the results.

Partial least squares path modeling (PLS-PM) has begun to achieve a widespread practical usage [4-7] if there is a need to make a model of the social contribution of enterprises to the development of the territories or regions. In this study a set of indicators to assess the strategy of sustainable development of the enterprise and further modeling was formed using the resulting and attributive approaches. This means that it can be used to analyze any complex systems that depend on available statistics.

Maintaining the sustainability is possible through a combination of traditional econometric approaches, taking into account the prerequisites and specifics of operating activities on different levels (including the regional one) [2]. So it should be noted that latent variables are considered to be general qualitative indicators, while explicit variables are statistics ones. The model of the description of the target variable consists of quantitative indicators and implicit variables.

Considering the features of building a regression model using the least squares method it should be noted that this mathematical method helps to minimize the sum of the squares of the deviations of some functions from the variables that are searched [10]. This method can be represented as a set of four successive stages: 1) collection of statistical data; 2) determination of correlation coefficients between variables; 3) estimation of regression parameters; general estimation of the model relevance.

The PLS-PM method differs from covariance-based modeling (variability of random variables) since it is not about the constructing a general model of factors for data. On the contrary this method corresponds to composite (consolidated) modeling [8]. This means that it can be used to analyze large data sets to assess the performance of the latent variables.

It is worth noting that there is no need for statistical distribution of variables and random deviations while using the method of projection on latent structures for modeling.

The modeling is performed according to the following algorithm: hypotheses about the existence of latent variables and the relationship between them are put forward, whereupon their indicators are determined and numerical modeling and evaluation of the model quality is performed, followed by interpretation of the obtained results.

* Corresponding author: yaroslavayakovenko@gmail.com

The task for modeling using the PLS-PM method has the form of a data matrix Z of the dimension $Z_n \times Z_i$:

$$Z = \begin{matrix} z_{11} & z_{12} & \cdots & z_{1i} \\ & z_{22} & \cdots & z_{2i} \\ & & \ddots & \vdots \\ & & & z_{ni} \end{matrix}, \qquad (1)$$

where n – the number of modeling objects, a_i – the number of features.

Although the formal development of the composite models [4, 8] and the projection on the latent structure using PLS-PM/PCA-PM methods [1, 7] have been studied previously, the use of an adapted composite model for modeling complex economic systems (in our case - mining enterprises) was not considered.

Each data array Z can be divided into blocks. If to take the fact that each artifact is modeled as a composite as a basis – then it is determined by a unique block of Z_{ni} – indicators.

Table 1. Variable PLS-PM models of sustainable development.

Latent variable	Explicit variable	Designation / unit of measurement
Sustainable development	Number of jobs in the industry	k_{1sd} / thsd
	The structure of gross value added in the gross domestic product	k_{2sd} / %
Economy	Profitability of activity	k_{1econ}/ %
	Return on investment	k_{2econ}/ units
	Equity maneuverability ratio	k_{3econ}/ units
	The ratio of capital investment to gross output	k_{4econ}/ %
	Labor productivity in value terms	k_{5econ}/ thsd UAH
	Costs for modernization and implementation of innovations	k_{6econ}/ (yes/no)
Society	Remuneration with deduction for social insurance	k_{1soc}/ %
	Pension liabilities	k_{2soc}/ thsd UAH
	Deductions for social events	k_{3soc}/ thsd UAH
Ecology	Revenues to the state from emissions of pollutants into the atmosphere	k_{1ecol}/ thsd UAH
	Use of fuel and energy resources	k_{2ecol} / %
	Rent for special use of water	k_{3ecol} / thsd UAH
	Initiatives to reduce the impact of production on the environment	k_{4ecol} / (yes/no)
Integrative dimension	Coefficient of stability of economic growth	k_{1int} / %
	Payments in favor of the state	k_{2int} / thsd UAH
	The relative share of the enterprise in the market of iron products (industry market)	k_{3int} / share units

Sustainable development of a mining enterprise should be considered on the basis of an integrated approach as an integration of all of the components (economic, environmental, social, integrative). In this study four latent variables associated with explicit (quantitative) variables are used (see Table 1): the level of the sustainable enterprise development (Sustainable Development); the level of economic development (Economy); the level of social development (Society); the level of ecological development (Ecology); the level of integrative development (Integrative dimension).

At the same time the intra-block covariance matrix Z_{ni} is not limited (latent variables are related to each other), which allows the indicators of one block to effectively perform covariance.

In contrast to the intra-block covariance matrix, the inter-block covariance matrix is limited because the composites (latent variables) carry information between the respective blocks.

2 Method

A feature of analytical research of such a multifaceted phenomenon as sustainability of development is the use of both quantitative and qualitative indicators. Therefore, the indicators for comparison were separated according to this principle. The dynamic (time) series are represented by a set of statistical indicators in a chronological order.

Step by step one can assess the level of sustainable development of enterprises on the example of the Ukrainian mining enterprises (Metinvest Group (Ingulets, Central and Northern GOK), Arcelor Mittal (AM Kryvyi Rih), Ferrexpo AG (Poltava GOK) and DCH Group (Evraz Sukha Balka) taking into account the period for the last 5 years starting from 2014. Since the value of explicit variables of the largest GOK for five years is taken into account, the representativeness of the sample is confirmed by sufficient volume and quota (a certain number of variables in each direction) [9].

It is assumed that each block Z_i is associated with a latent (implicit) variable LV_i. Taking into account that latent variables are abstract, the internal model of relationships between variables can be presented analytically:

$$LV_{sd} = \alpha_0 + \alpha_1 LV_{econ} + \alpha_2 LV_{soc} + \alpha_3 LV_{ecol} + \alpha_4 LV_{int} + \beta_{sd}, \qquad (2)$$

where LV_{sd} – a latent variable of sustainable development; α_0 – a free member; $\alpha_1 ... \alpha_3$ – path coefficients to indicate the strength and direction of communication between latent variables; LV_{econ} – a latent variable of the economy; LV_{soc} – a latent variable of society; LV_{ecol} – a latent variable of ecology; LV_{int} – a latent variable of integrative dimension; β_{sd} – a residual member.

The internal model must meet a number of requirements, in particular: the system of linear equations is characterized by recursiveness; random deviations are allowed; the model itself is regressive.

The initial model is shown in Fig. 1 (latent variables are represented by colored rectangles, and explicit variables are not).

Analyzing the sustainable development of mining enterprises on the basis of reporting data, one can identify a number of indicators that characterize the components of the sustainable development (these are explicit variables from Fig.1, the source of which were the official financial and non-financial published reports of the mentioned enterprises (Metinvest Group (Ingulets, Central and Northern GOK), Arcelor Mittal (AM Kryvyi Rih), Ferrexpo AG (Poltava GOK) and DCH Group (Evraz Sukha Balka) for the period of 2014-2018).

The relationship of latent variables is an internal model while the relationship between latent and explicit variables is an external model.

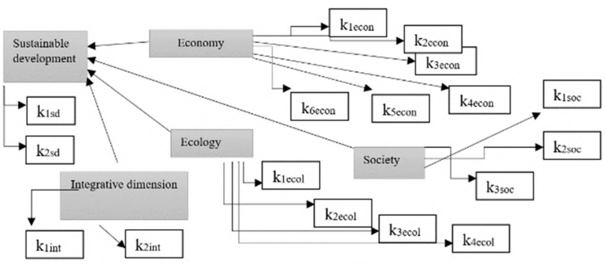

Fig. 1. The initial model of sustainable development.

The external model characterizes the relationship between explicit and latent variables. There are two types of external models by types of connections – reflective (preference is given to latent variables) and formative (latent variables arose due to explicit) one.

In the method of modeling path coefficients using the Partial Least Squares method, the concept of estimating the latent variable (linear combination of the corresponding explicit variables) arises.

Since each latent variable is directly related to two or three explicit variables, the external model of the reflective type in this case can be presented in a form of a system of equations:

$$\left\{\begin{array}{c} Z_{k1sd} = \alpha_{0k1sd} + \alpha_{1k1sd} LV_{sd} + \beta_{k1sd} \\ Z_{k2sd} = \alpha_{0k2sd} + \alpha_{1k2sd} LV_{sd} + \beta_{k2sd} \\ \dots \\ Z_{k1econ} = \alpha_{0k1econ} + \alpha_{1k1econ} LV_{econ} + \beta_{k1econ} \\ Z_{k2econ} = \alpha_{0k2econ} + \alpha_{1k2econ} LV_{econ} + \beta_{k2econ} \\ \dots \\ Z_{k1soc} = \alpha_{0k1soc} + \alpha_{1k1soc} LV_{soc} + \beta_{k1soc} \\ Z_{k2soc} = \alpha_{0k2soc} + \alpha_{1k2soc} LV_{soc} + \beta_{k2soc} \\ \dots \\ Z_{k1ecol} = \alpha_{0k1ecol} + \alpha_{1k1ecol} LV_{ecol} + \beta_{k1ecol} \\ Z_{k2ecol} = \alpha_{0k2ecol} + \alpha_{1k2ecol} LV_{ecol} + \beta_{k2ecol} \\ \dots \\ Z_{k1int} = \alpha_{0k1int} + \alpha_{1kint} LV_{int} + \beta_{k1int} \\ Z_{k2int} = \alpha_{0k2int} + \alpha_{1k2int} + \beta_{k2int} \\ \dots \end{array}\right. \quad (3)$$

where $Z_{k1sd}...Z_{k2int}$ – explicit variables; $\alpha_{0k1sd}...\alpha_{0k2int}$ – free members; $\alpha_{1k1sd}...\alpha_{1k2int}$ – load factors; $\beta_{k1sd}...\ \beta_{k2int}$ – residual members.

Latent variables are not directly measured, so in order to denote their evaluation Y_i is used:

$$Y_i = \widehat{LV}_i = \sum_n^i \gamma_{in} Z_{in}, \quad (4)$$

$$\begin{array}{c} LV_{sd} = Y_{sd} = \delta_{k1sd} Z_{k1sd} + \delta_{k2sd} Z_{k2sd} \\ LV_{econ} = Y_{econ} = \delta_{k1econ} Z_{k1econ} + \delta_{k2econ} Z_{k2econ} + \delta_{k3econ} Z_{k3econ} + \\ + \delta_{k4econ} Z_{k4econ} + \delta_{k5econ} Z_{k5econ} + \delta_{k6econ} Z_{k6econ} \\ LV_{soc} = Y_{soc} = \delta_{k1soc} Z_{k1soc} + \delta_{k2soc} Z_{k2soc} + \delta_{k3soc} Z_{k3soc} \\ LV_{ecol} = Y_{ecol} = \delta_{k1ecol} Z_{k1ecol} + \delta_{k2ecol} Z_{k2ecol} + \delta_{k3ecol} Z_{k3ecol} + \\ + \delta_{k4ecol} Z_{k4ecol} \\ LV_{int} = Y_{int} = \delta_{k1int} Z_{k1int} + \delta_{k2int} Z_{k2int} + \delta_{k3int} Z_{k3int} \end{array} \quad (5)$$

where $\delta_{k1sd}...\delta_{k3int}$ – external scales of the model.

Therefore we can distinguish the main stages of calculation in the process of PLS-PM-modeling, in particular: external scales of the model to obtain estimates of latent variables, path coefficients of the internal model and correlation coefficients between latent and explicit variables.

The first stage of PLS-PM modeling is an iterative process. Therefore to obtain the values of the estimates of the latent variables Y_i, the initial values of the external weights $\delta_{k1sd}...\delta_{k3int}$ are set.

It should be noted that this stage is a key one, because the calculation of the values of external weights allows the evaluation of latent variables. After this stage the system of linear equations can be solved using the PLS method and the correlation coefficients can be calculated.

Taking into account the weights (to the required degree of convergence of external weights) the results of recalculation of values of estimates of latent variables using internal rather than external model (one calculate the values of estimates of latent variables as linear combinations of estimates of other latent rather than explicit variables) can be described like:

$$V_i = \sum_{n<->j} e_{nj} Y_n, \quad (6)$$

where V_i – the sum of the estimates of those latent variables, which are related to n-latent variable; e_{nj} – internal scales of the model.

Accordingly, the recalculation of the values of external weights for the external model of the reflective type can be described according to the formula:

$$\delta_{jn} = (Y_j' Y_j)^{-1} Y_j' Z_{jn} \quad (7)$$

It is important to note that with each new step of the iterative process the degree of convergence (convergence) of external weights also changes.

Similarly, the calculation of the path coefficients of the internal model can be described according to the formula:

$$\alpha_{jn} = (Y_n' Y_n)^{-1} Y_n' Y_j \quad (8)$$

Regarding the calculation of load factors they are equated to the correlation coefficients between latent and explicit variables.

Modeling by the method of PLS-PM and the necessary calculations were implemented in the software environment SmartPLS 3.0, using which one can present the visualization of the coefficients of external loads of the external model.

The authors do not take into account the variables of the PLS-PM models of sustainable development k_{6econ} (the costs of modernization and innovation) and k_{4ecol} (the initiatives to reduce the impact of production on the environment) which have constant binary values.

Analysis of the model of sustainable development by the PLS-PM method involves the sequential implementation of the following steps: 1) verification of the blocks for internal consistency; 2) assessment of the significance of external variables; 3) detection of cross-correlations of variable blocks with latent variables of other blocks; 4) studying of the consistency of the internal model; 5) checking the quality of the model; 6) further optimization.

The first stage (verification of blocks for internal consistency) in the framework of PLS-PM modeling can be done by using several criteria, in particular: Cronbach's alpha coefficient, a structural reliability and an average variance extracted (AVE).

The acceptable value of the AVE indicator is in the range starting from 0.50 and above because the constructed model explains more than half of the variance of the indicator values in this case. The blocks “Ecology” and “Sustainable Development” meet this criterion.

It is shown in the Table 2 that the blocks “Economy”, “Ecology” and “Sustainable Development” have high values of Cronbach's alpha coefficients and blocks “Society” and “Integrative Dimension” are characterized by low internal consistency.

Table 2. Checking internal consistency in blocks.

Block	Cronbach's alpha coefficient	Composite reliability (CR)	Average variance extracted (AVE)
Economy	0,277	0,472	0,269
Society	-0,370	0,468	0,301
Ecology	0,755		0,493
Integrative dimension	-0,363	0,315	0,332
Sustainable development	0,875	0,014	0,824

As for the Cronbach's alpha coefficient – it characterizes the reliability and internal consistency of the model based on the existing relationships between the observed variables.

The calculation is performed on the basis of ranking the indicators according to the level of reliability provided by the algorithm of the PLS-PM method. If its value is greater than 0.5, it indicates confirmation of the assumption of equal reliability of all indicators.

All observed variables show the existence of a load on the corresponding component, which confirms the convergent validity. The variables of the block “Sustainable development” are characterized by the greatest reliability.

At the same time the Cronbach's alpha coefficient in the case of an increase in the number of objects of observation may slightly contribute to the underestimation of the internal consistency in the calculations.

Therefore, to assess the degree of compliance of indicators with latent variables the composite reliability indicator is used with the help of which it is possible to trace the degree of compliance of indicators included in the model with latent variables [11].

In this case, some indicators of the model have a fairly high value (for example, for the economy – 0.472, for the society – 0.468), which suggests the presence of high structural consistency.

It is also important to determine the validity of the model, i.e. the degree to which the indicators correspond to the planned characteristics, namely the numerical expression of aspects of sustainable development.

3 Results and discussion

In order to ensure that the model characterizes the phenomena not covered by other components, one can use not only the average extracted variance. The Fornell-Larker test [5] and the heterotrait-monotrait ratio are the other estimates, which are also based on a step transition. Since latent variable models do not contain conceptually similar constructs, one can use both.

The Fornell-Larker calculation criterion is shown in Table 3. As we can see, the square of correlations between each pair of components of the model of sustainable development is less than the average extracted variance, so this meets the requirements of the criterion.

Table 3 The Fornell-Larker criterion.

	Ecology	**Economy**	**Society**	**Integrative dimension**	**Sustainable development**
Ecology	0.702	-	-	-	-
Economy	0.324	0.518	-	-	-
Society	0.384	0.362	0.549	-	-
Integrative dimension	0.440	0.007	0.406	0.576	-
Sustainable development	0.606	0.598	0.549	0.524	0.908

Estimates by the criterion of hetero- and monocharacteristics, shown in Fig. 2, indicate the presence of discriminant validity of blocks (when the value of the criterion is less than 0.90). It follows that the used reflective evaluation construct is discriminant-valid.

As for the course of further hypotheses – the impact of four latent variables on sustainable development will be used. The adequacy of the constructed model with the actual data for the period from 2014 to 2018 will be established by Fisher's criterion, which evaluates the statistical significance of the determination index R_2. In this case the estimate is 0.0014, which is less than the specified level of significance (0.05). This means that factors significantly affect the provision of sustainable development.

The verification of internal consistency also occurs by determining the eigenvalues of the correlation matrix of explicit variables (Table 4).

All blocks have a positive correlation with the latent variable, which indicates the internal consistency in the blocks. Once we have obtained the consistency indicators of the model, we can present the schemes of correlations.

	Ecology	Economy	Society	Integrative dimension	Sustainable development
Ecology	-	-	-	-	-
Economy	1.005	-	-	-	-
Society	1.113	0.884	-	-	-
Integrative dimension	1.542	1.046	1.155	-	-
Sustainable development	0.729	0.798	0.605	0.734	-

The second stage is the assessment of the significance of external variables, which is possible using the software capabilities of the SmartPLS 3.0 package. In particular, the external model was tested (Table 5).

Shown in Fig. 3 correlation coefficients of explicit variables and latent variables (by blocks) indicate the following: low correlation (close to or equal to zero) is observed for one variable in the blocks "Integrative Dimension" and "Ecology", which leads to internal inconsistency.

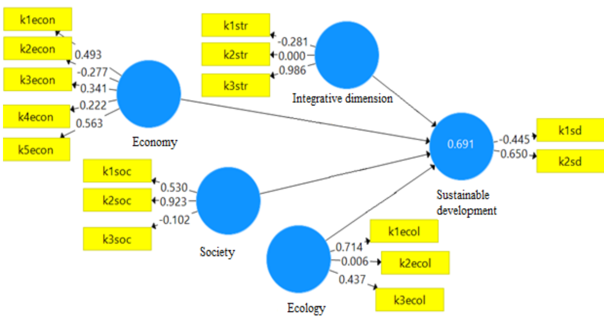

Fig. 3. External scales of the model.

To assess the significance of the obtained values of external weights and their relevance by the method of bias correction (BC), one can obtain additional information for the analysis of the reliability of the results (Table 6).

Since the given values of the coefficients differ from zero, there is a significant strength of the links of exogenous structures with endogenous.

The third stage is the verification of cross-correlations. Such verification is necessary to trace the relationships of explicit variables with latent ones within the respective blocks and, if necessary, to exclude those indicators whose connection with the latent variables of other blocks is higher in comparison with a similar variable of the corresponding block. In this case, no significant deviations in loyalty to the variables of certain blocks were detected (except for isolated cases with k_{1sd}, k_{2econ}, k_{2ecol}, k_{1int} and k_{2int}) which indicates the admissibility of their consideration. The presence of deviations is explained by the fact that the method of "convenient sampling" was used, which serves as a limitation due to the objective difficulties of data collection. It means that the presented results are an analytical (not a statistical) generalization.

Table 6. Offset of confidence intervals.

Trajectories	Initial sample	The average value for the sample	Offset	
			2.5%	97.5%
Ecology → Sustainable development	0.245	0.217	-0.187	0.523
Economy→ Sustainable development	0.464	0.004	-0.650	0.637
Society → Sustainable development	0.143	0.084	-0.322	0.413
Integrative dimension → Sustainable development	0.355	0.342	-0.089	0.716

The presence of lateral collinearity (when the model is estimated by several interrelated high-probability variables) can be traced if we pay attention to the maximum within the sample values of the variance inflation factor (VIF) [3]. In this case, the value of this indicator for the blocks "Ecology" and "Society" are 1.445 and 1.439 and the internal values of each indicator of the block are less than the threshold (<5%).

In the fourth and fifth stages, we will consider the internal model of sustainable development, check it on the index of compliance and obtain estimates of latent variables in the form of a system of equations.

Since the "path" coefficients and values of R^2 for endogenous latent variables (in this case $R^2 = 0.691$) are significant, that indicates a close relationship between the performance trait and the studied factors, ie the model explains approximately 69% of the variance of this indicator, and only 31% explain other factors. It is also assumed that the latent variable determines the variance of each indicator by at least 50%.

Checking the quality of the model involves the following procedures: calculation of the coefficients d_ULS (square Euclidean distance) and d_G (geodetic distance) [4]. Both coefficients characterize the quality of internal and external models of the system and serve as an indicator of the predictive reliability of the model. The d_G criterion is based on the calculations of the eigenvalues of the PLS model. A model is considered to be qualitative when the difference between the correlation matrix resulting from the model and the empirical correlation matrix is so small that it can be attributed to the sampling error. If this difference is insignificant (criteria d_ULS and d_G are higher than 0.05), then the model is qualitative. In our case both criteria are much higher than the minimum allowable values (d_ULS = 4.409; d_G = 2.749), which indicates the prognostic reliability of the model.

The sixth stage is the further optimization. The PLS-PM simulation method is used for multidimensional data analysis (however there is no data distribution) which can cause standard errors. Therefore structural modeling of results is performed additionally on the basis of a nonparametric statistical method, which does not require a normalized data distribution. This means that a bootstrap is used to check the significance of the coefficients. At this stage the estimates of path coefficients are analyzed as well as the results of checking the criterion of T-statistics (the ratio of the original sample to the standard deviation).

The values of the cumulative effect of the coefficients of the trajectories (Table 7), indicate the validity of the selected trajectories. According to the generally accepted approaches, the limit values of P (significance) are considered to be the following: for the value of T-statistics over 1.65 - 10%, over 1.96 - 5%. It is a consequence of the statistical probability of error in cases where the empirical value of significance exceeds the norm.

Table 7. The values of the cumulative effect of the coefficients of the trajectories.

Trajectories	Original sample	The average value for the sample	STDEV	T-statistics	P
Ecology → Sustainable development	0.245	0.217	0.185	1.327	0.185
Economy→ Sustainable development	0.464	0.004	0.452	1.027	0.305
Society → Sustainable development	0.143	0.084	0.189	0.760	0.448
Integrative dimension → Sustainable development	0.355	0.342	0.193	1.842	0.066

By estimating the magnitude of the effect f^2, it is possible to investigate the relevance of the components to substantiate exogenous influencing factors. Such an analysis is possible by excluding a certain component of the model to assess the impact of the removed element on the stability of the structure. It is assumed that the value of f^2 at a level above 0.02 means the presence of a significant effect of the latent variable. In our model the value of f^2 in all cases exceeds 0.02 (the magnitude of the effect of the components "Economy", "Society", "Ecology" and "Integrative dimension" for the endogenous latent variable "Sustainable Development" are 0.539, 0.046, 0.134 and 0.281). This shows that all of the components have a significant impact on the sustainable development.

As for the interpretation of the obtained results, the performed modeling revealed the following feature: in the absence of stable trends in the object of modeling (mining enterprises) changes in trends will not be recognized in case of a sharp change in development conditions. Thus, the chosen approach to building a multidimensional model that reflects the most significant and stable internal and external relationships was correct. At the same time, the assessment and analysis of the strategy of sustainable development of the enterprise in case of changing external and internal parameters requires a study of whether there can be a transition from stable to unstable state. So enterprise sustainability management should include a rapid response to threats and risks.

Based on the principle that it is better to prevent a crisis than to eliminate its consequences, the policy of modern business should include the following steps: reducing the level of disparities (paying more attention to only one aspect of sustainable development); the ratio of resource consumption and recovery or renewable changes (for non-renewable); increasing the level of innovation implementation; increasing the level of social and environmental responsibility of the enterprise.

4 Conclusions

The scientific novelty of the obtained results is to provide the organizational and informational strategy of sustainable development of the enterprise, the elements of which are the development of a qualitative model of sustainable development strategy taking into account the industry characteristics and the forecasting mechanism using latent variables and the method of private least squares in order to build a PLS-PM model of sustainable development of the enterprise as a complex economic system, which allows to assess the degree of impact specific quantitative and implicit qualitative indicators on a particular phenomenon (sustainable development of the enterprise) by the introduction of explanatory variables.

Therefore, during the calculations to verify the relevance of the PLS-PM model of the sustainable development, it was proved that the tripartite approach, relevant for macroeconomic objects requires specification by highlighting additional aspects (considering the integrative dimension) of sustainable development at the micro level. The proposed component of sustainable development includes the provision and balance of resources, the state of property and an innovation activity. Accordingly it is proposed to include production and technological subsystems that were not taken into account in the components which were mentioned above.

Using the methods of scientific generalization and abstraction the essence of latent variables and the relationship between them was identified and substantiated as well as the numerical modeling was performed. Using the method of abstraction it was possible to seemingly separate the characteristics of sustainable development that are irrelevant for modeling from itself (such as binary indicators for the costs of modernization and implementation of innovations and initiatives to reduce the impact of production on the environment).

Abstract. The present paper provides the assessing scale of the actual state of the geoengineering complexes and the model for predicting the behavior of supporting structures. To predict accidents in geoengineering and water treatment facilities it is proposed to apply the results of the theory of catastrophe theory, fuzzy sets, chaos theory and the theory of possibilities for the selection of optimal models of system behavior for a particular situation. It is shown that determination the limit boundaries in which the operation of the system can exist is impossible without the consideration of geoengineering treatment facilities and their components as fractal structures, functioning under conditions of “chaos”. To minimize risks of damages of sewage geoengineering systems the monitoring with measurement of the toxic gases concentration and comparing it with the obtained one should be provided. The use of models of internal and external corrosion which includes the elements of the theory of fuzzy sets helps to evaluate completely the state of water supply and treatment facilities network.

1 Introduction

In the processes of water treatment and water purification, there are very often the problems that are clearly nonlinear and, at the same time, can not be analysed with the methods used in “classical” nonlinear systems, or give the results that are far from the optimal ones (and even plausible). These problems include quasiperiodic changes in the states of shallow water basins (such as, for example, water intakes and artificial seas), which may receive stormwater or wastewater; behavior of biological treatment systems; general behavior of the entire complex of water treatment systems in different spatial and temporal boundaries and scales, etc.; and finally, the behavior of individual components of treatment facilities, pipelines and collectors under the conditions of a man-made disaster emerging in their depths. All these problems can be successfully solved only when we turn to the use of a new mathematical apparatus based on the results of the theories of fuzzy sets, catastrophes, fractals and chaos [1-5].

The aim of the work is to determine the conditions that ensure the normal functioning of a complex system under conditions of uncertainty, as well as an effective assessment of its parameters.

As the World Health Organization underlines, corrosion monitoring is very important for the water supplies functioning [6]. Concrete corrosion is one of the most significant failure mechanisms of sewer pipes, and can reduce the sewer service life significantly [7]. Result of presented research indicate that water is corrosive at 10.6%-89.4% of drinking water supply reservoirs [6].

The wastewater system as a system functioning under conditions of fuzzy data needs the regular monitoring and control of its parameters. The proposed performance-rating system evaluates each parameter and combines them mathematically through a weighted summation and a fuzzy inference system that reflects the importance of the various factors [8].

An analysis of the results of observations and analogies suggests that the structures and functioning of natural and geoengineering water treatment systems demonstrate in a broad sense the self-similarity of water purification processes from pollution both in natural conditions and in engineering treatment facilities – the same principles are applied, the only difference is in productivity and quality of treatment. In other words, both those and other systems more or less equally fit into a wide range of spatial, temporal and quantitative scales, which indicates the presence of a certain symmetry of the scales. In this case, for the study of such systems, one can fully use the methods of fractal analysis and elements of the chaos theory [9-10]. But such an approach is suitable not only for analysing the structures of water treatment and the processes occurring in them, but also for optimizing the geometry of tree-like configurations of water distribution systems, for displaying contamination isolines caused by man-made accidents and natural disasters, and also for using similar displays obtained at

* Corresponding author: aodi@ukr.net

different stages of monitoring and to analyse the dynamics of pollution migration.

It is also perspective to use the methods mentioned above in the analysis of a number of biological catastrophes associated with changes in water quality under the influence of external factors. Finally, it is interesting to apply the proposed approach together with the results of the theory of fuzzy sets and the theory of possibilities for the selection of optimal models of system behavior for a particular situation. The proposed approach also assumes the use of catastrophe theory, fuzzy set theory and chaos theory to predict accidents in geoengineering and treatment facilities.

2 Reliable assessment of the state of geoengineering structures

Let's consider some special cases of the proposed approach implementation. The behavior (dynamics) of the bottom layer and bottom sediments in shallow lake ecosystems, as well as in most artificial seas formed during the construction of hydroelectric power plants, is an example of a classic catastrophe with several attractors [11]. Usually two different states of such shallow water bodies are identified. In the state of the bottom layer under conditions of high transparency, there is a vegetation ecosystem at the bottom. With an increase in the intake of biogenic components of wastewater (municipal wastewater or storm water), turbidity in the water increases and the ecosystem crosses the catastrophic threshold and transforms into a hypertrophic turbid phytoplankton ecosystem in bottom sediments. In reality, there are lakes that regularly pass from one state to another (Lake Ontario in North America, for example, regularly experiences similar cataclysms). In some water bodies, the beginning of spring (loading of biogenic components) determines the state of the ecosystem in summer. This is an example of a bifurcation in the behavior of an ecosystem when it gets to the point of return of the seasonal “eight” (see Fig. 1).

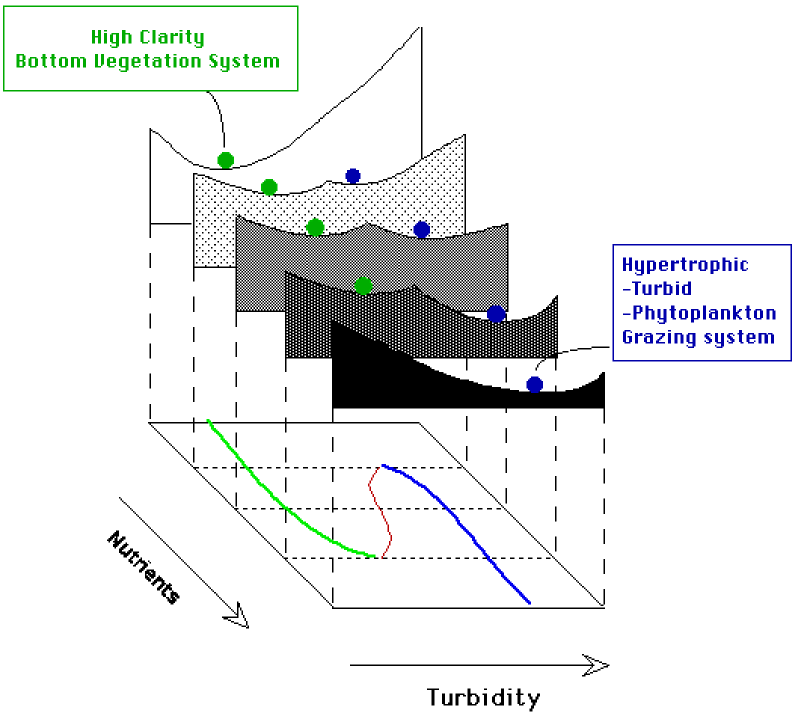

Fig. 1. Ecological disaster such as a catastrophic leap, when small changes in the value of the manager (nutrients supply) major changes in the state value (turbidity).

Discontinuous transitions from one mode to another regimes occur when the parameter in the system changes smoothly:

$$F(x; a, b) = (1/4)\cdot x^4 + (1/2)\cdot a\cdot x^2 + b\cdot x \quad (1)$$

with a phase state variable (turbidity *a*). On the plane of values of the parameter *b* (nutrients) and the phase variable, stationary modes form a smooth curve, which can be described by the equations:

$$(-a/3)^{1/2} = (b/2)^{1/3}, \quad (2)$$

$$(-a/3)^3 = (b/2)^2, \quad (3)$$

$$(a/3)^3 + (b/2)^{2\,=\,0}. \quad (4)$$

Its projection onto the parameter value axis has some peculiarities. When the parameter changes, one of the stable equilibrium positions disappears, merging with the unstable one, and the system is forced to jump to a new regime with sharply different characteristics. Understanding the essence of a disaster allows to anticipate a leap and develop heuristics that either prevent bifurcation or change the water treatment technology (by

https://doi.org/10.1051/e3sconf/202128002009

using other reagents, their concentration or the sequence of using different treatment technologies).

Predicting the behavior of supporting structures (columns, supports, brackets, etc.) of a treatment plant complex is an extremely important task, and the amplitude of the initial bending of the supporting structure can serve as a hazard indicator. In other words, the safe load is determined by the maximum safe bend (deforiation) [2]:

$$\Delta V(a_1=s;\, F_s,\varepsilon) = \varepsilon + \tfrac{1}{2}(\pi/l)^2(F_1 - F_s)s + (3/2^4)F_s l(\pi/l)^4 s^3, \quad (5)$$

where
$$F_s = F_c(s) - k(s)\,\varepsilon, \quad (6)$$

$$F_c(s) = \{F_1/(l - 3/8[as/l]^2)\}, \quad (7)$$

$$k(s) = \{(2/l\text{-}s/l)(l/\pi)^2\}/\{l\text{-}3/8(\pi s/l)^2\}. \quad (8)$$

Here $F_c(s)$ – the safe load in the absence of defects, F_1 – the maximum bearing capacity at which the bending amplitude reaches s, l – the coordinate of another end of the supporting structure, ε – the coefficient of dynamic sensitivity to defects, k – a positive constant.

Thus, the problem of assessing the actual state of the geoengineering complexes that are part of water treatment systems can be considered as a procedure for finding the maximum safe bend (stress), for which it is possible to use the data of a set of measurements (observations) of features studied in order to classify the state of structures as or another cluster. The first step in the assessing procedure is to define a scale of states (for example, a five-point one), where "0" corresponds to the absence of any problems (according to all estimates, the structure meets the requirements of the standard), and "4" – to an emergency state requiring destruction and reconstruction of the structure. All intermediate classes of states provide appropriate recommendations for repair and restoration work. From the point of view of the theory of fuzzy sets, these classes (d) can be characterized using Table 1.

The amount of physical wear is associated with the cost indicators of the structure. So, with an increase in physical wear, the initial cost of the structure decreases by the same percentage. Considering the fact that overhaul eliminates physical wear to a certain extent (if we do not take into account the general physical aging of structures, which is a consequence of the manifestation of material fatigue), there is an economic feasibility of overhaul if the cost of this repair does not exceed 40 % of the primary cost of the structure.

The set of signs suitable for classifying or assessing the state on the basis of visual inspection may include the identification of deformations and cracks in columns, beams, joints, etc. In addition, during the assessment of the state of structures there should be considered building materials, the height of structures, the actual duration of operation after next repair, as well as external conditions, conditions and total operating time, characteristics of the soil and foundation.

The formulation of the state evaluation problem is related to the method of decision-making under difficult conditions, when the information received from experts is characterized by uncertainty. It mostly determines the final decision, which has the nature of an inaccurate or approximate conclusion pursuing the achievement of the most reliable answer to the problem. If to take the numerical form of expressing the intermediate diagnosed state in the form, for example, of the function of membership $\mu(d)$ to the corresponding problem, requiring major repairs (see Table 2), and to interpret the values of the estimation truth in the following form: 0 – not true; 0.1-0.3 – weak level of truth; 0.4-0.5 – significant level of truth; 0.6-0.7 – high level of truth; 0.8-0.9 – the truth is almost revealed; 1.0 – the revealed truth, then it is possible to use the following scoring rule:

IF (the number of cracks *CN* is estimated at the level 0.3) *OR* (the presence of large cracks *LC* – at 0.2) *OR* (excessive deformation of structural elements – at 0.1), *THEN* (the overhaul of the *CN* is not needed);
or
IF (*CN* is estimated at 0.6) *OR* (*LC* is at 0.5) *OR* (deformation of structural elements – at the level of 0.5), *THEN* (overhaul of the *CN* is necessary).

Table 1. Scale for assessing the deterioration of structural elements.

Classes, *d*	Physical wear, %	Assessment of technical conditions	General characteristics of technical condition
1-2	0-20	Good	No damages or deformations. Some faults that do not affect operation and are eliminated during routine repair
3-4	21-40	Satisfying	The elements of the structure are generally serviceable, but in need of repair
5-6	41-60	Not satisfying	Operation of the elements of the structure is possible only under the condition of urgent repair
7-8	61-80	Decrepit	The state of the load-bearing structural elements is emergency, and of the not load-bearing ones is very decrepit. The limited performance by the elements of the structure of their functions is possible only under conditions of restrictive and protective measures, or the complete replacement of these elements
9-10	81-100	Kaput	Elements of the structure are in an unusable state. The structure needs to be demolished or radically rebuilt

Table 2. Evaluation of the overhaul problems.

$\mu(d)$	0,2	0,5	0,7	1,0	0,8	0,2
d	2	3	4	5	6	7

Belonging to the state corresponding to the need for the overhaul can be determined from the expression

$$\mu = max\{\mu_1, \mu_{2,\dots} \mu_n\}, \quad (9)$$

where the need for overhaul for data group *n:*

$$\bigcup_{ш=1}^{b} B_i \, , \quad (10)$$

where B_i – the state requiring the overhaul, obtained in accordance with the *i-th* data group (*i*=1 – information on the registered cracks, *i*=2 – data of physical measurements of stresses in structures, etc.).

B_i can be considered as the algebraic sum of damages to each of the components of the structure $j(j \leq n)$*:*

$$B_i = \sum_{o=1}^{m} D_{ij} \, , \quad (11)$$

where *Dij* – the state of serious damage to the *j-th* component, and

$$\mu(B_i) = 1 - \prod_{j=1}^{n} (1 - \mu_{Dij}), \quad (12)$$

For example, if there are three main components with the registered cracks, for which it is known that μ_{D11}=0,2, μ_{D12}=0,8, μ_{D13}=0,6, then

$$\mu_{B1} = 1 - \{(1\text{-}0{,}2)(1\text{-}0{,}8)(1\text{-}0{,}6)\} = 0{,}984. \quad (13)$$

Another approach is also possible. Let $X = \{x_1, x_2, \dots x_k\}$ – a set of signs, for example, x_1 – a big amount of cracks, x_2 – large cracks, x_3 – large deformations. Let $Y = \{y1, y2, \dots y_m\}$ – a set of types of potential damages, for example, y_1 – damage from fatigue or breaking, y_2 – plastic deformation, y_3 – instability, y_4 – progressive damage. Let *Z* – a state of severe damage. If we can find fuzzy relations *R* (from *X* to *Y*) and *S* (from *Y* to *Z*), then the signs of *X* can be associated with the state of severe damage to the structure *Z* using the composition $R \cdot S$. If to set the relationship *R* and *S* by data from the Tables 3 and 4, then the result can be presented in the form of Table 5.

This result indicates that the presence of the characteristics x_2 (large cracks) and x_3 (large deformations leads to a high assessment of the degree of belonging to a set of structures in a state of severe damage.

Table 3. Fuzzy relation *R.*

		y_1	y_2	y_3	y_4
R =	x_1	0,9	0,2	0,4	0,4
	x_2	0,8	0,3	0,7	0,8
	x_3	0,3	0,8	0,9	0,7

Table 4. Fuzzy relation *S.*

		Z
S =	y_1	0,4
	y_2	0,3
	y_3	0,8
	y_4	1,0

Table 5. Relationship *R* and *S.*

		Z
$R \cdot S$ =	x_1	0,4
	x_2	0,8
	x_3	0,8

In other words, if large cracks and large deformations are observed, then the structure is classified as badly damaged and requiring replacement or overhaul.

The considered approach allows for a more qualified and more reliable assessment of the state of treatment structures and at the same time taking into account the influence of individual components on the state of structures as a whole, which helps to minimize accidents and the corresponding environmental consequences.

3 “Chaos” and unpredictable development of events problem elimination

In the concrete vaults of the gravity collectors of the city sewage system, there is a specific problem: microbiological corrosion of concrete due to biogenic acid aggression (under the influence of hydrogen sulphide escaping from the collector vaults) reduces the resource of these objects in 3-3.5 times (i.e., from 50 up to 10-15 years). Up to 74% of accidents on reinforced concrete pipelines of drainage systems are caused by just such corrosion. Concrete, of course, is protected by waterproofing anti-corrosion coatings, but the last ones do not fulfill their role fully, mainly due to the presence of microcracks. The concentration of hydrogen sulfide C_{H2S} (mg/m^3) in a membrane of condensate moisture on the surface of a concrete structure, exposed to biogenic hydrogen sulfide aggression, at which the coating still retains its properties, can be determined from the following empirical formula:

$$C_{H_2S} = \left\{\frac{414{,}6 * t_{real}}{t_{demand}}\right\}^{0{,}45}, \quad (14)$$

where t_{real} – the real durability of the coating (in days), t_{demand} – the required durability of the coating (in days).

It should be noted that the standard deviation of the concentration C_{H2S} from the mathematical expectation of this concentration in the atmosphere of real sewerage facilities is $\sigma = \pm$ 50%, which, if the distribution of concentration values is close to the normal law, corresponds to a data uncertainty bandwidth of about 33%. Thus, periodical measurement of the C_{H2S} concentration and comparing it with the obtained one in accordance with the above formula, allows to determine the limit to which operation is permissible without changing the coating, i.e. with minimal risk.

It is also should be noted that the activity of microorganisms that ultimately cause the corrosion is carried out cyclically, and since the initial conditions for each cycle, as a rule, are not the same, there are opportunities for the emergence of “chaos”, that is, unpredictable development of events [1], which is very typical for biological treatment systems. In other words, in such systems it is only possible to predict the boundaries within which the processes can occur. These boundaries are set by "strange attractors". So, for example, the development of a population is under conditions of different initial data characteristic for the operation of treatment facilities, the expected population density of biologically active bacteria N at the time t+1, $Nt + 1$ can be represented as a nonlinear autoregressive model

$$N_{t+1} = N_t[1 + \check{r}(1 - N_t/K)], \quad (15)$$

where N_t – population density at time t, $\check{r}$ – the internal growth rate of the population (Malthusian parameter), and K – the maximum volume of a given population, possible under these conditions.

After certain transformations, this model can be represented as

$$x_{t+1} = rx_t(1 - x_t), \quad (16)$$

and

$$x_t = N_{t\check{r}} / [(1 + \check{r}K)], \quad (17)$$

$$r = 1 + \check{r}, \quad (18)$$

so that x_t turns out to be a dimensionless quantity characterizing the population. If the given model is used to carry out a number of iterations, choosing the values of r in the range 3-4 and at the same time changing the initial conditions, it is possible to obtain solutions within a fairly wide range, which, on the one hand, do not allow to unambiguously predict the result ("chaotic" solution), on the other hand, they determine the boundaries within which this result can be expected.

At the minimal value of r, the first type of dynamic behavior is observed (stable stationary state), in the interval middle, different limit cycles are realized. With a further increase in r, chaotic regimes arise (the values of x_n randomly fill a certain interval), alternating with the so-called r-windows in which limit cycles are observed. Each r-window is characterized by its main limit cycle with the smallest period. This limit cycle allows to determine the boundaries in the middle of which the system behaves to a certain extent predictably, which allows to assess the reliability of the data of specific measurements.

In water distribution systems, disasters such as pipe breaks often occur. Elimination of the consequences is associated with significant resource costs and interruptions in providing consumers. However, it is not giving much attention to how the process of gradual transition from the normal operation mode to the accident development mode is carried out in time, as well as under what qualitative and quantitative variations of variables and factors. Moreover, it is generally accepted that an accident occurs "suddenly", "inevitably", "accidentally".

If to ignore such factors as terrorism, sabotage or natural disasters (earthquake, flood, tornado, etc.), any technogenic accident develops in the bowels of a normally operating system as a result of negligence and lack of professionalism, because factors such as aging, wear, drift of parameters, etc. should be taken into account at all stages of operation of any systems. In other words, along with the performance of their direct functions, automated systems and personnel should ensure constant monitoring of the state of both each system as a whole and all its main components. Here, monitoring should be understood not only as a periodical fixation of the current state of each of the components of the system, but also the use of models of the behavior of these components in time and as a function of internal and external factors to predict future changes in the state of certain components and the system as a whole. Thus, for the state of the water supply network, it is necessary to use models of internal and external corrosion, which have the following general form:

$$\Delta h = 0{,}5\ \{d_o k_o C_o \exp\left(\frac{\alpha_o t}{\tau T} E\right) - d_i k_i C_i \cdot \exp\left(1 - \frac{\alpha_i t}{\tau_i T} E\right)\}, \quad (19)$$

where Δh – total decrease in pipe thickness due to internal and external corrosion, k_i and k_o – rate constants of oxidation reactions inside and outside the pipe, C_i i C_o – concentrations of oxidants accordingly, α_i and α_o – transfer coefficients (constants) that determine the influence of other factors on the exponential dependence of the reaction rate E accordingly, τ – time constant of the system in which this other reaction occurs, T – absolute temperature outside the pipe and the temperature of the carrier (water), t – operating time of this line link, d_i and d_o – internal and the outer diameters of the pipe (Fig. 2).

Taking into account the indicators of the soil (or insulation), in which the pipe is laid, and the water flowing in the pipe, as well as the corresponding temperatures, the date of commencement of operation of a particular section of the network, or it's the weakest link, as well as the maximum allowable total reduction in the thickness of the pipe Δh_{max} and the corresponding deterioration of the structure of the pipe material, it is possible to envisage the time when the strength characteristics associated with the thinning of the pipe walls due to corrosion and deterioration of the structural characteristics of the pipe material reach the limit Δh_{max}, beyond which (in the presence of certain transient processes in system) the pipe can break.

This model should also take into account pressure fluctuations (including dynamic shocks) and pumping rates. The heuristics for determining the need to update the pipeline are as follows:

IF [($h_1 > h_{1\ min}$) *AND* ($VaR(\Delta p/h_1) < VaR\ (\Delta p/h_1)_{max}$)*]*
OR [($\sum\Delta p < \sum\Delta p_{\ max}$)

AND

($Turb\ LF < Turb\ Lf_{max}$)*], THEN* (*«norm»*) *ELSE* (*«renewal»*) (20)

Here h_1 – actual or predicted pipe thickness; $h_{1\ min}$ – minimum permissible pipe thickness under operating conditions; $\Delta p/h_1$ – expected operational pressure surges in the pipeline related to the real or predicted pipe thickness; $(\Delta p/h1)_{max}$ – maximum allowable value of $\Delta p/h_1$; $\sum\Delta p$ – integral assessment of stresses that take place during the observation interval; $\sum\Delta p_{max}$ – maximum allowable integral stress for the entire life cycle of the pipeline; *Turb LF* – current (predicted) turbulence in the pipeline; $Turb\ Lf_{max}$ – maximum permissible turbulence.

But turbulence is a consequence of the fractal structure (tree structure) of the water distribution network, imperfect conditions for the flow of water, accompanied by pressure and velocity fluctuations. Therefore, *Turb Lf* and $Turb\ Lf_{max}$ should be determined on the base on the apparatus of the theory of fractals and chaos.

By the way, the tree-like structure of the network, one of the conditions for preventing (or weakening) of the turbulence, presupposes the fulfillment of the condition

$$\Sigma s_n \geq S_O, \tag{21}$$

where Σs_n – sum of the cross-sections of n branch pipelines coming out of this (root) pipeline with a cross-section S_O.

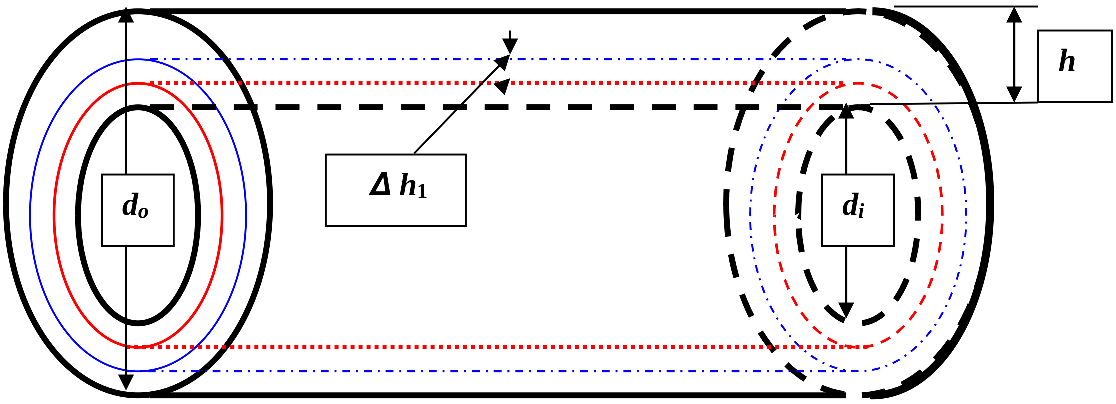

Fig. 2. Change in Δh under the influence of internal and external corrosion.

Conclusions

The consideration of geoengineering treatment facilities and their components as fractal structures, functioning under conditions of “chaos”, allows, on the one hand, understanding the processes and connections, and on the other hand, to identify the limit boundaries in which these processes and connections can exist.

The constant or periodical monitoring with measurement of the toxic gases concentration and comparing it with the obtained one allows to determine the limit to which operation is permissible without changing the coating, i.e. with minimal risk.

For the complete evaluation of the state of water supply and treatment facilities network, it is necessary to use models of internal and external corrosion, which includes the elements of the theory of fuzzy sets.

The intergovernmental relations and their regulation in the context of decentralization of fiscal policy

George Abuselidze[1,*]

[1]Batumi Shota Rustaveli State University, 35/32 Ninoshvili/Rustaveli Str., Batumi, 6010, Georgia

Abstract. The suspension of economic relations as a result of the global pandemic has severely affected the country's peripheries. Unequal development of territorial units and overcoming socio-economic problems is the biggest challenge of any country. To address these challenges, the country needs to mobilize large amounts of finance and make optimal allocations. Intergovernmental relations play an important role in the effective implementation of the transformation of the country's economic and political system. The aim of the paper is to study the characteristics of revenue mobilization and distribution between the levels of the fiscal system. There are developed some recommendations for improving inter-budgetary relations based on the experience of different countries. The recommendations proposed as a result of the research analysis can be used for both theoretical (for lecture) and practical (for legislative) purposes.

1 Introduction

The virus originated in 2019 has taken the form of a global pandemic by 2020. As a result, the global world is facing the conditions of the greatest economic recession and economic crisis has arisen in many countries (Fig. 1). Especially, developing and small open economy countries found themselves in a particularly difficult situation [1-4].

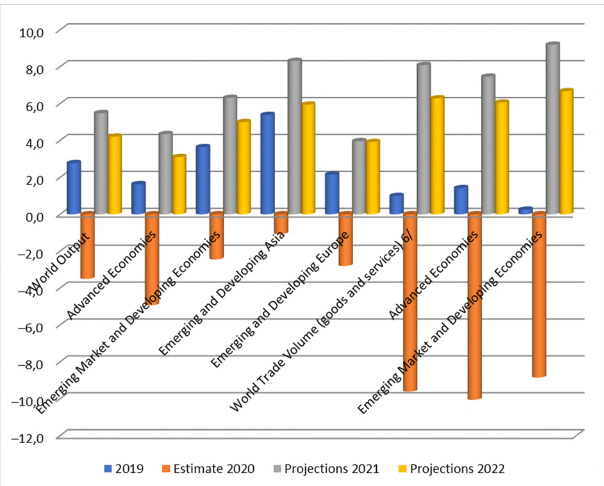

Fig. 1. World Economic Outlook [1-3]

Socio-economic problems are especially evident in territorial units. The suspension of economic relations has further aggravated the social situation and it increased unemployment, inflation and etc. To address these issues, states have implemented relevant budget policies. So, funding for the management and regulation program is reduced and funding for the subsidy program is increased [5, 6]. Despite the model of budget arrangement to get out of the economic recession of the country and achieve economic growth, it is very important to provide financial resources to the budgets of local self-governing units (municipalities), where one of the most important places is inter-budgetary relations. Inter-budgetary relations include not only economic subsidies, but also a fair distribution of revenues and expenditures between levels of the fiscal system.

In my opinion, to organize of inter-budgetary relations should be based on the following principles:

– Equality of rights and responsibilities of all municipalities must be protected in the process of financial relations with the centre;

– Areas of financial activity and responsibilities should be divided between the state government and all levels of local self-government;

– Different levels of government should not depend on subsidies, but also they should be able to receive revenues from their own sources and dispose of these funds independently.

Thus, the scope of the policy should be redistributed between the centre and the local self-government bodies. The centre should define the relevant legislative framework for action, within which local self-government will be free to make decisions, especially in solving socio-economic tasks.

Fiscal autonomy of local government is a relative concept that is determined by whether governing bodies have a sufficient amount of their own revenues and whether they have the right to manage them independently the functions they have to performed. This does not mean that they are completely isolated from each other. On the contrary, the centre and the municipalities have common interests for the public good and relevant coordinated strategic actions in economic and political priorities [7].

2 Methodological foundations

2.1 Legislative regulation

The economic and financial basis of self-governing units is regulated by five main laws: the Local Self-Government Code of Georgia [8], the Budget Code of Georgia [9], the Tax Code of Georgia, the Law of Georgia on Grants and the Law of Georgia on Local Fees [10-12]. In addition, Georgia has ratified the European Charter of Self-Government and self-governing legislation is based on it.

Fiscal relations are mainly regulated by organic laws: the Local Self-Government Code, the Tax Code of Georgia and the Budget Code.

Local self-government is the right and opportunity of the citizens of Georgia to regulate and manage issues of local importance in accordance with the interests of the population through local self-government bodies. The Code of Self-Government defines the powers of self-government, which are divided into delegated, self-governing and voluntary categories [8].

In order to minimize socio-economic inequality between different territorial units, it is necessary to analyse the welfare conditions of the regions and adopt legal norms.

2.2 Literature review

The theoretical-methodological basis of the research is the papers of various scientists on the research problem, where the inter-budgetary relations [13], financial mechanisms for the development of territorial units [14-25], the characteristics of state fiscal arrangement models are studied [26-34]. This includes works by Aidt and Dutta, Ehrlich, Enikolopov, Ejobowah, Gaizatullin, Kline, Sow, Staehr, and others [35-38]. They studied in depth and published the issues of formation and improvement of the state governance system, budget regulation, financial equalization and organization of budget relations [30, 39-58]. These scientists have identified problems in this field, but the fiscal arrangement and fiscal system require continuous improvement and research.

3 Discussions

Decision-making at a low hierarchical level has a great importance for the establishment and improvement of the state governance system. This in turn is a prerequisite for decentralization. Understanding systemic actions at the level of territorial units, laying out appropriate ways and developing real self-government play a major role in the proper and efficient functioning of the state. In particular, the formation of stable sources of revenue for territorial units, the implementation of an objective and transparent process of redistribution of funds between upper and lower level budgets creates a precondition for stabilization of the country. Local self-government will inform the interests of the society at a high hierarchical level and will create a driving force for the effective implementation of relevant socio-economic policies.

One major theoretical issue that has dominated the field for many years is the absence of a well-grounded strategy leads to a further deterioration of the situation and a manifestation of the severity of fiscal policy [59]. Any action and any policy implementation at a high state or low hierarchical level, takes place within the existing legal space. It is the correct definition of this legal space that means avoiding the contradictions between the defined priorities of the common welfare in the society, as well as the contradiction between the common tactics and the strategy of action [5, 59].

The legal aspects that are of great importance for the harmonization of interests and actions between the governing bodies of the country are the budget legislation [9], according to which territorial (regional) budgets are independent and theoretically the supreme governing bodies have no right to interfere within their competencies (Budget Code of Georgia, Article 7) [9]. In fact, the budgets of territorial units (regional) are significantly dependent on the budget of the upper (central).

According to the Budget Code of Georgia, the legislation was limited to listing the sources of revenue of territorial budgets [9] and ignored a number of methodological and organizational issues of inter-budgetary relations. At the present stage, many things are disorganized and faulty in the relationship between different levels of the budget. In particular, the rights and responsibilities of each level in revenue mobilization and spending are not clearly defined. Also, the division of taxes between the centre and the budgets of the regions is not strictly defined, as well as the issue of economic subsidies and many other things. All of this leads to numerous misunderstandings and difficulties between the centre and other levels of budgets. It seems in the amount of tax revenue mobilization at the budget levels and their ratio to GDP (Fig. 2).

The lack of local budget funds in Georgia, which is filled with regulatory revenues, is the result of minimizing the quality of tax authority for local self-government. The centre is still trying to mobilize financial resources entirely in its own hands, while delegating its responsibilities for financing various activities entirely to entities and territorial unit budgets.

3.1 Foreign experience of fiscal arrangement

Over the past two decades, fiscal arrangement reform has taken place in all Central and Eastern European countries. However, the redistribution of powers and finances between central and local governments is still the subject of active debate in many countries.

The fiscal system of Germany as a state with a high degree of decentralization includes three levels: federal, land and local [40].

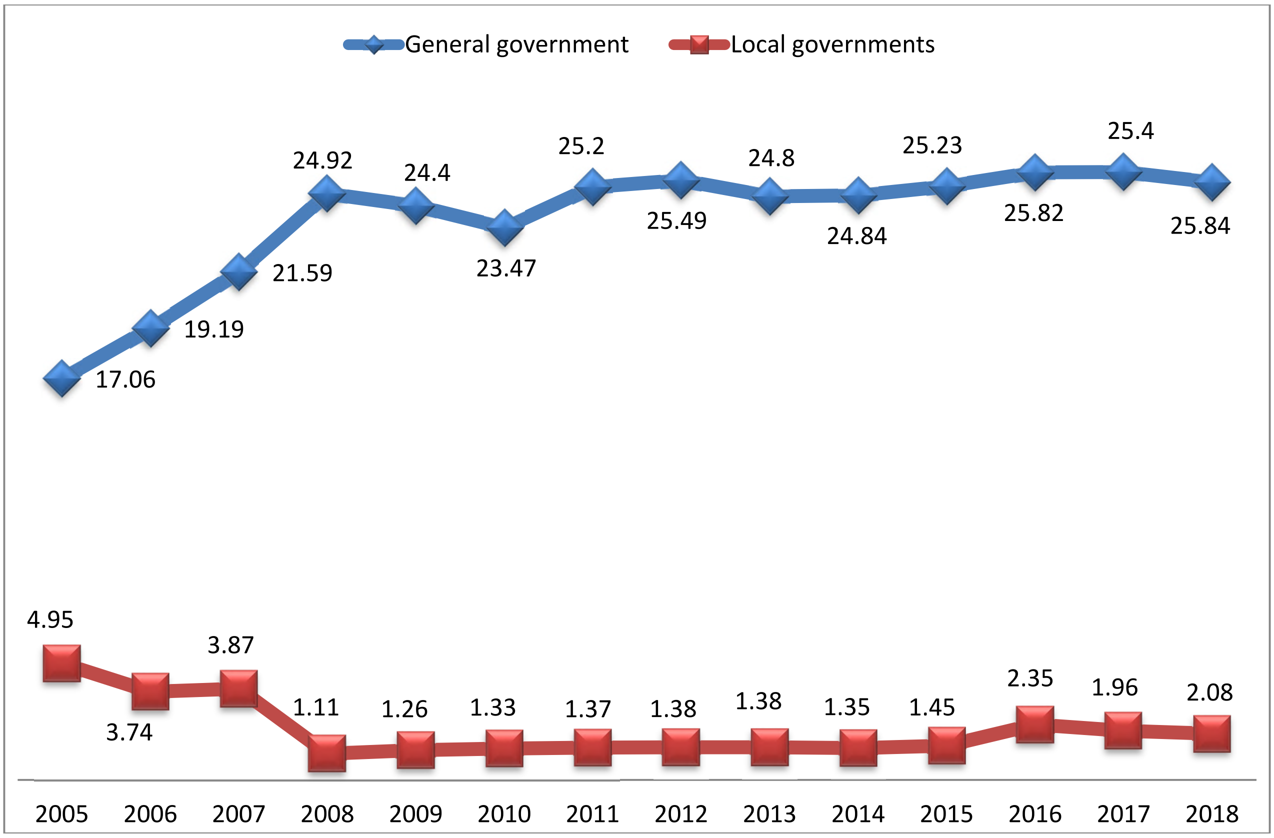

Fig. 2. Distribution of tax revenues between the budget levels of Georgia, % of GDP [60].

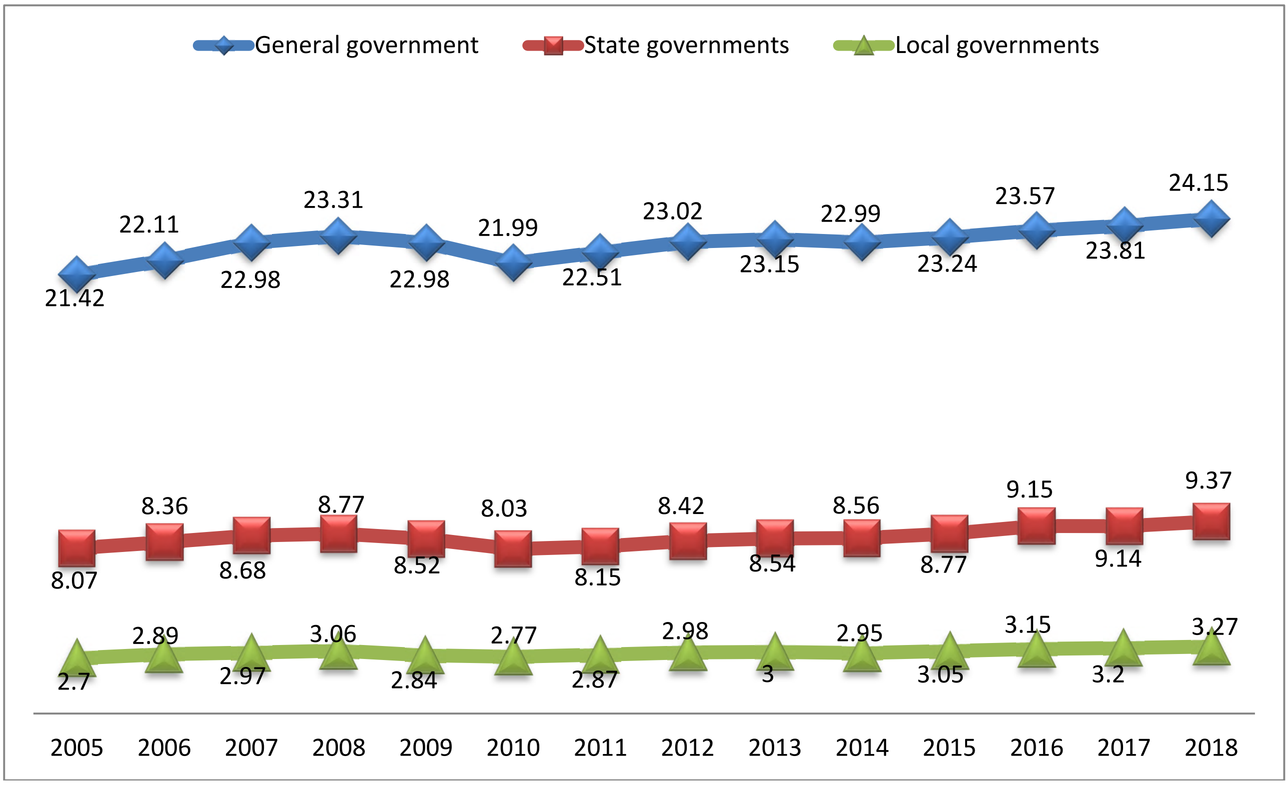

Fig. 3. Distribution of tax revenues between German budget levels, % GDP [60].

The tax revenues of the three levels of the budget of Germany in 2005-2018 are as follows (Fig 3). The German local government finances its own expenditures mainly from the local budget, whose tax revenues account for about 13.5% of total national tax revenues.

The Austrian fiscal system is divided into three levels: central government, land and local self-government. In accordance with the Budget Law, the amounts received from the income tax are distributed in the following proportions: 60% of the funds go to the central budget, 22% to the land budgets and 18% to the local self-government budgets. Also, 69% of value added tax go to the central budget, 19% to the state budget, and 12% to the local government budget (Fig. 4).

France, although a unitary state, is divided into regions, departments and municipalities. Municipalities and departments receive revenue from all taxes, while the region is financed by land and business taxes. The tax revenues of the three levels of the budget of France in 2005-2018 are as follows (Fig. 5).

Since 1990, the central government has delegated important powers to all three levels of regional government (region, department, commune) planning and developing areas such as infrastructure, education, health, culture, regional economic development, employment, etc. which are financed from local budget revenues (Fig. 6).

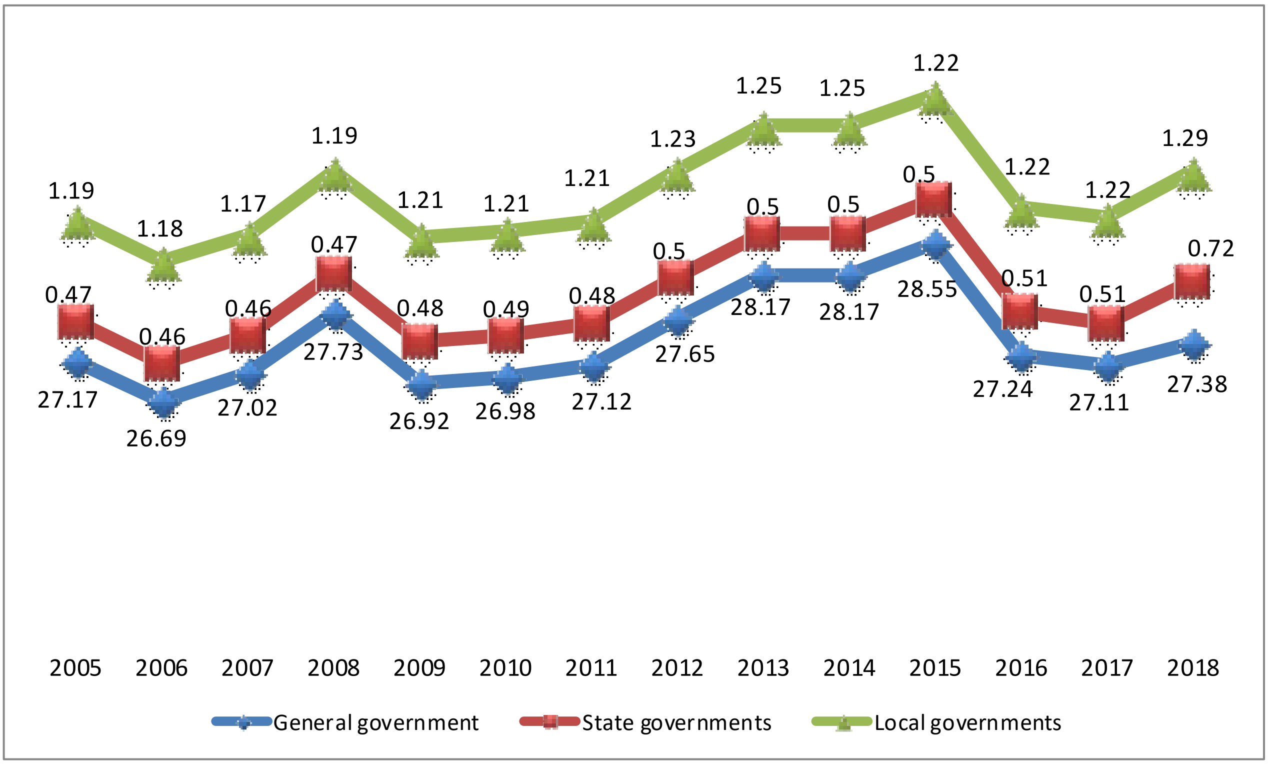

Fig. 4. Distribution of tax revenues between Austrian budget levels, % GDP [60].

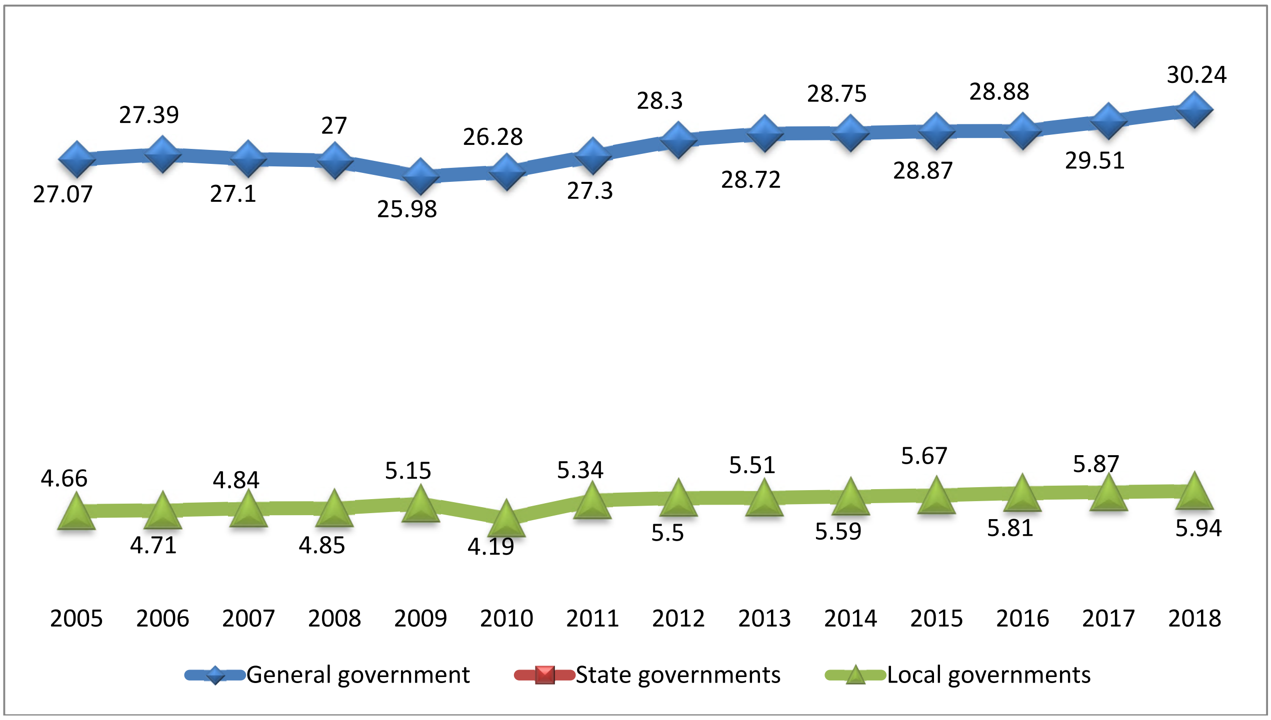

Fig. 5. Distribution of tax revenues between French budget levels, % GDP [60].

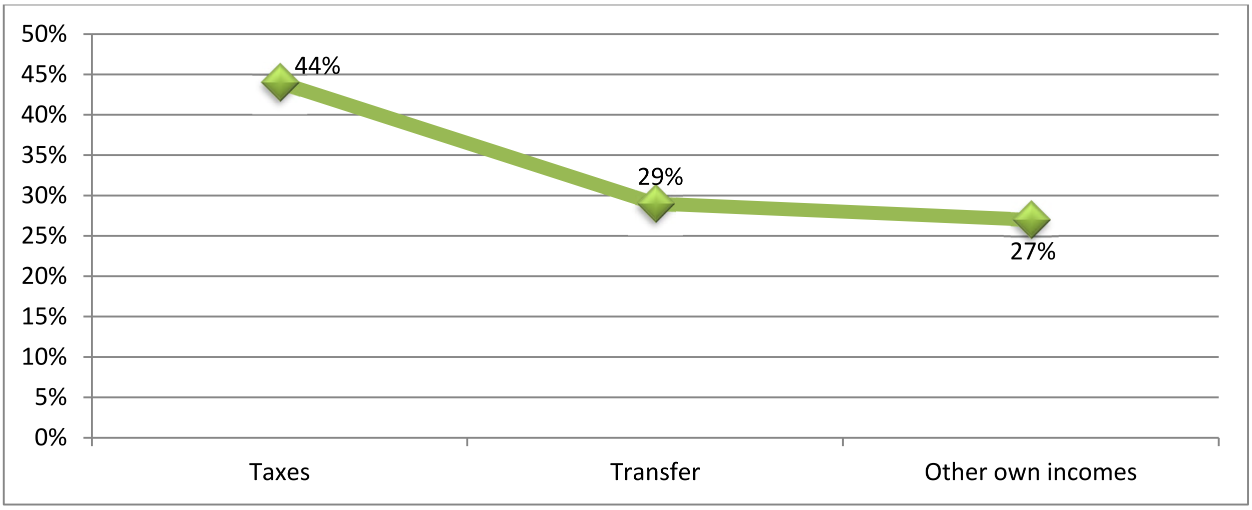

Fig. 6. French local budget revenue sources [61].

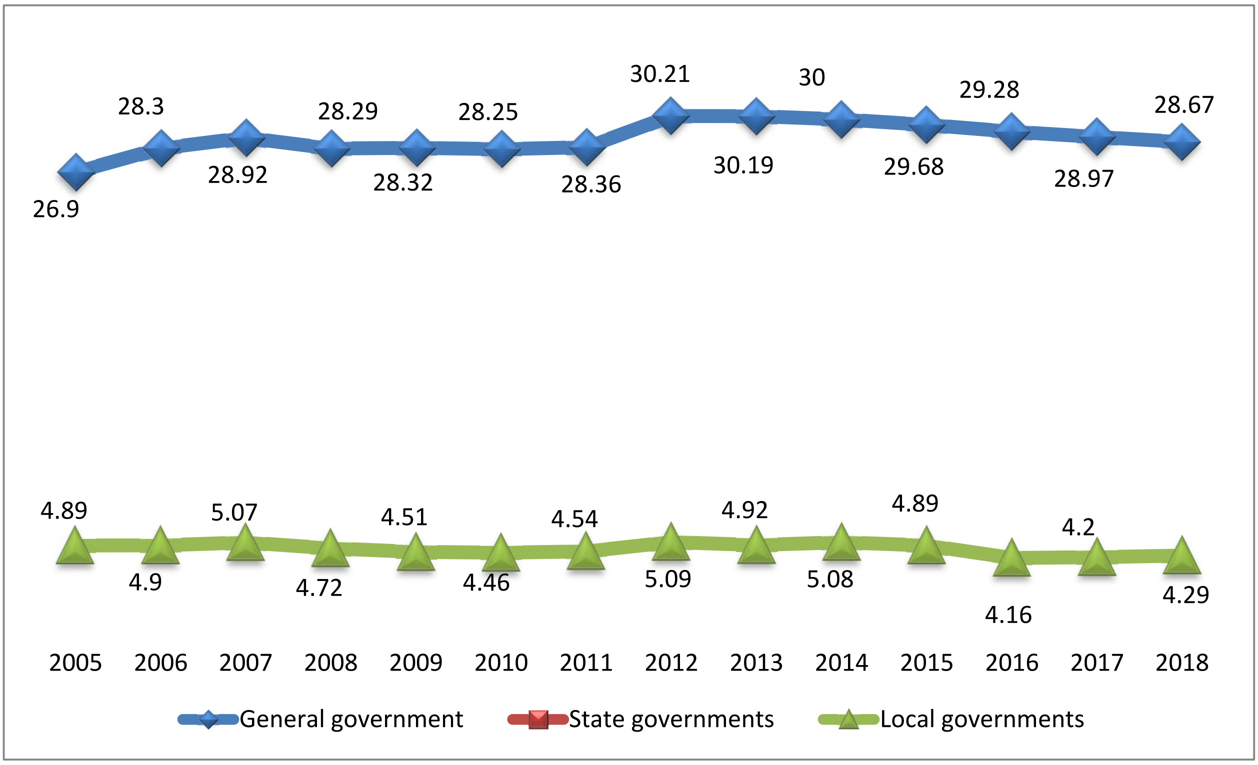

Fig. 7. Distribution of tax revenues between Italian fiscal levels, % GDP [60]

Table 1. German fiscal system.

Federal Budget	Land Budget	Local Budget
Income tax 42.5%	Income tax 42.5%	Income tax 15%
Corporate tax 50%	Corporate tax 50%	
Value-added tax	Value-added tax	
Industrial tax	Industrial tax	Industrial tax
Customs tax	Property tax	Land tax
Other federal taxes	Other land budget	Other local budget
48% of total tax revenue	34% of total tax revenue	13% of total tax revenue

Like France, the unitary parliamentary republic is Italy, which is divided into regions, provinces and municipalities [62]. Management functions are distributed at all levels. The ratio of tax revenues in the budget of Italy in 2005-2018 to the country's GDP looks as follows (Fig. 7). Local budget revenues consist of own taxes, shared taxes and transfers, and other revenues (Fig. 8).

Fiscal independence in Sweden is very high and 69% of tax revenues remaining in local self-government budgets. The budget revenues of the counties are: amounts received from taxes (68%), transfers (7%), amounts received from fees and taxes (25%). Tax revenues are formed entirely from income tax. The income tax rate is set by the county itself. The sources of revenue of the municipal budget are: funds received from taxes (60%), transfers (14%), funds received from fees and taxes (23%). Tax revenues are formed entirely from income tax (99.5%), while 0.5% comes from sales tax on goods and services (Fig. 9).

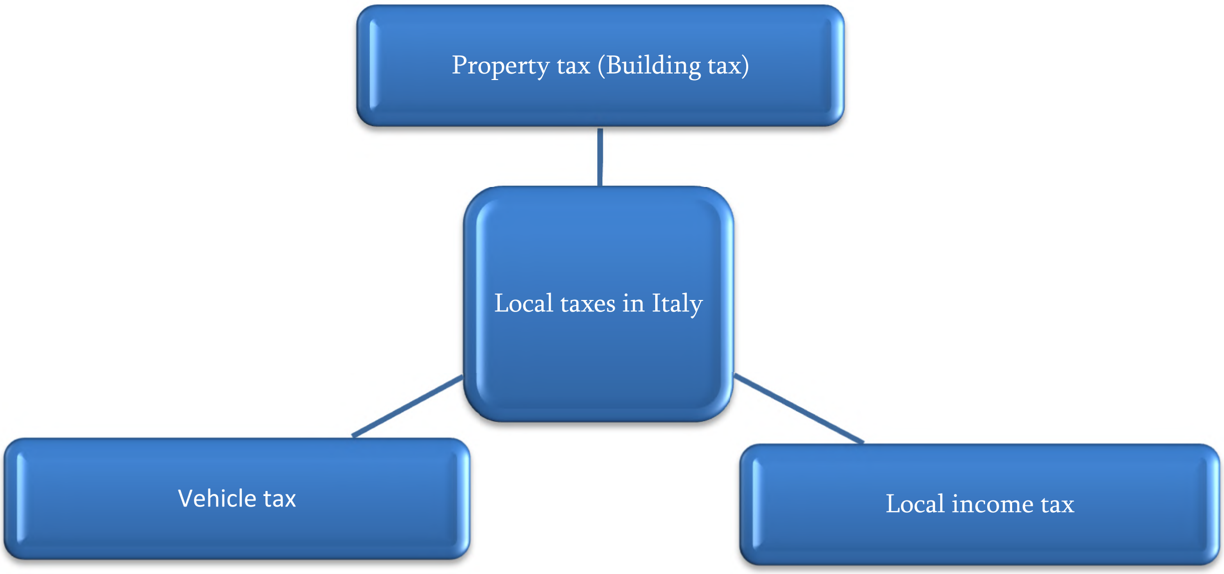

Fig. 8. Italian fiscal system.

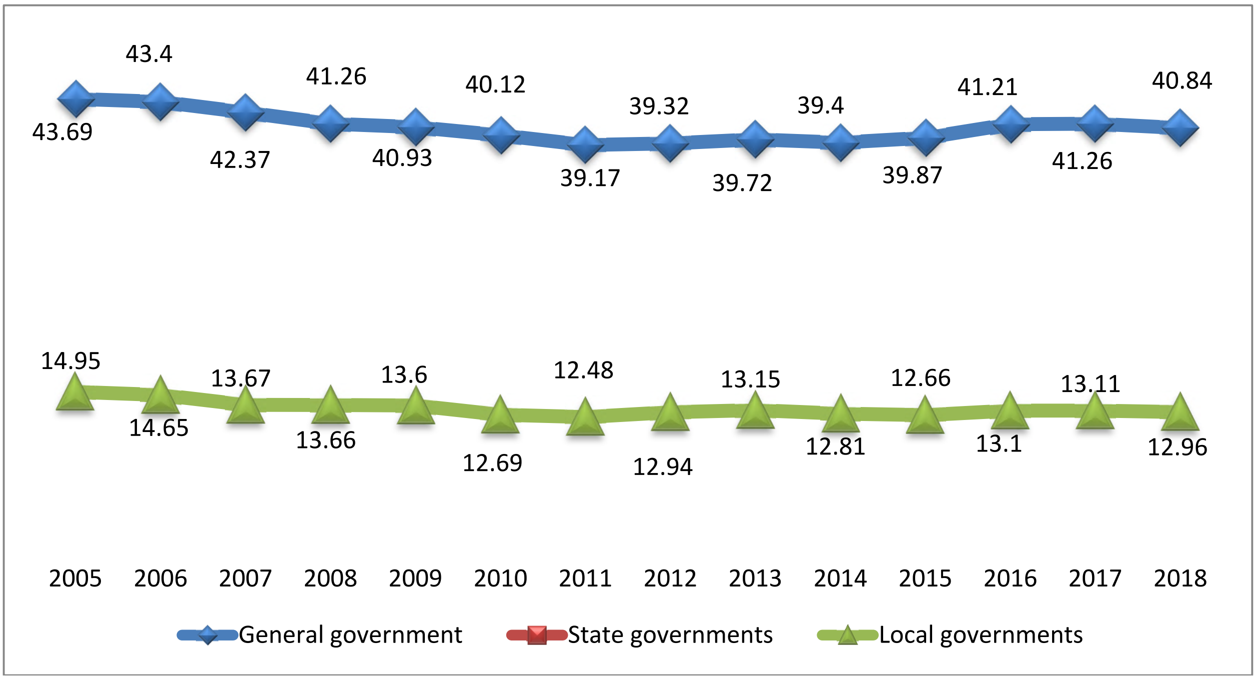

Fig. 9. Distribution of tax revenues between Swedish fiscal levels, % GDP [60].

The sum of tax revenues of the central budget of Estonia in 2014 is 6 656 949 euros, which is characterized by a growing trend in the coming years and by 2018 it amounted to 8 821 243 euros. As for the tax revenues of local self-governments, this figure is 859,527 euros in 2014, in the following years the budget tax revenues will also increase and reached 1,173,550 euros for 2018. As for the ratio between levels - the sum of tax revenues of local budgets is about six times less than the state budget. And the ratio of fiscal levels to tax revenues in relation to the country's GDP looks like this (Fig. 10).

Poland was one of the first to make the transition from the post-socialist system to the European system, which from the very beginning focused on the development of self-government and, unlike many other Eastern European countries, made it a priority to move to a decentralized model. Today, it is one of the most decentralized countries in Europe and it is far ahead of many European countries.

The territorial arrangement of Poland is based on three levels - region, side and municipality. The sources of revenue generation for each level are: 1) own revenues, mainly local taxes, the rate of which is set by the local government based on the right granted by law. However, at the same time the maximum rate is set by Parliament. 2) Shared income and profit taxes; 3) Basic and special transfers. The ratio of fiscal levels to budget revenues in relation to the country's GDP is as follows (Fig. 11).

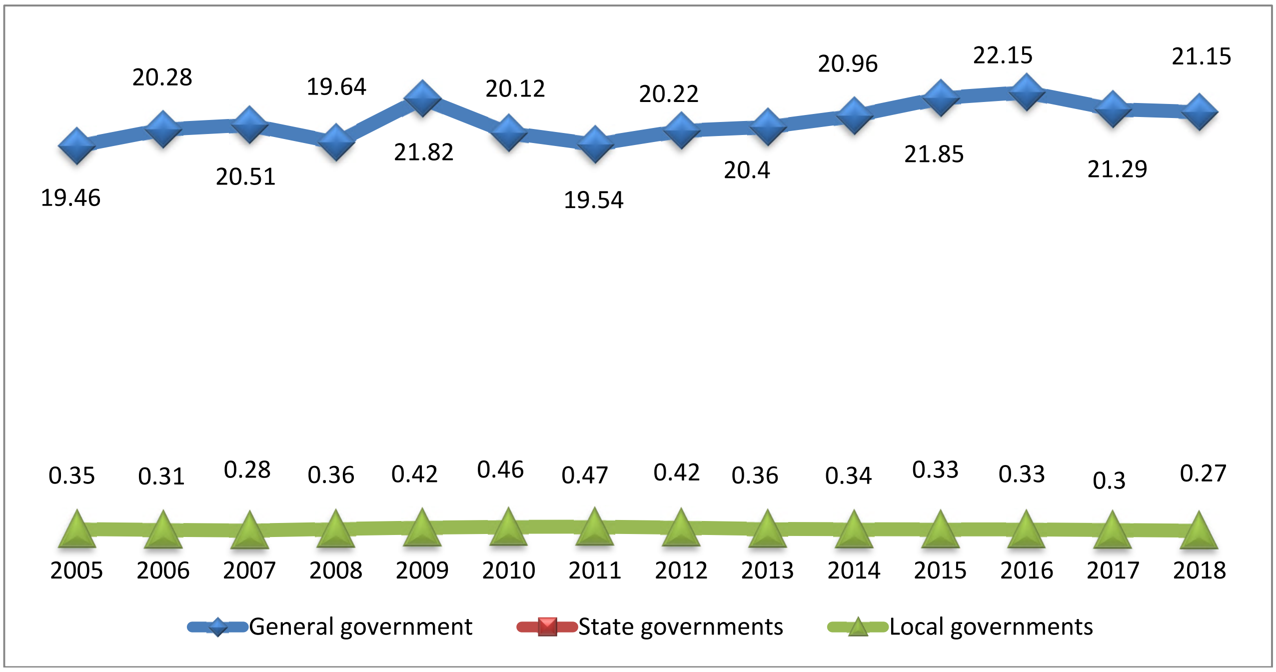

Fig. 10. Distribution of tax revenues between Estonian fiscal levels, % GDP [60].

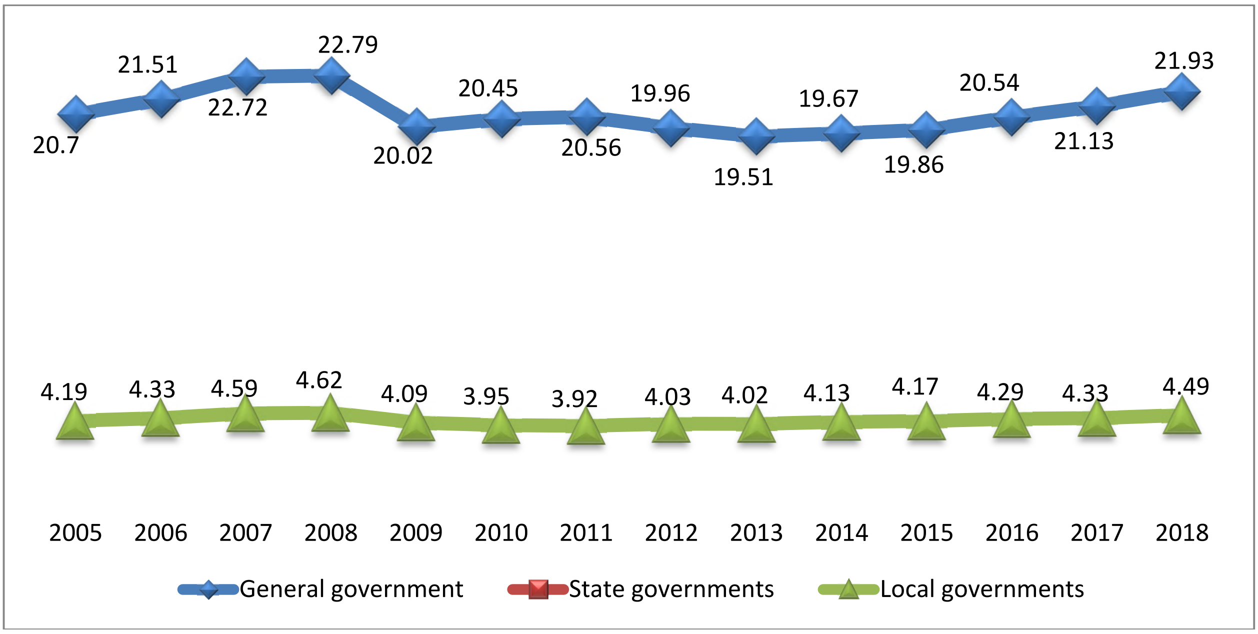

Fig. 11. Distribution of tax revenues between the fiscal levels of Poland, % GDP [60].

3.2 The peculiarities of the countries of the Caucasus and the Black Sea Region in fiscal arrangement

In Armenia, as a unitary, partially decentralized country, self-government operates only at the municipal level. They can set the tax rate within the limits set by law. Property and land taxes are 100% accumulated in the municipal budget. Profit tax and various fees are shared with the local budget each year. However, the ratio of tax revenues to GDP for 2005-2018 looks as follows (Fig. 12).

Azerbaijan is a unitary, partially decentralized state. Local self-government operates only at the lowest level - the level of the municipality. According to the constitution, municipalities have the right to impose local taxes and fees. Local taxes are: land tax, property tax, profit tax, which is taxed on municipal property. The share of own taxes and fees in the local budget is about 25%, tax revenues are a major part of them (about 22%), while the share of transfers in local budgets is about 10% [61] (Fig. 13).

In Turkey, municipal expenditures account for 11% of total state expenditures and revenues for 7%. Municipalities are funded from three main sources: 42% from general government taxes, 6.8% from utility taxes, 35.5% from non-tax revenues and 10% from local taxes. The central government collects the following types of taxes: personal income tax, corporate income tax, profit tax and value added tax. Local governments are left with 9.25% of the collected income taxes. Real estate tax accounts for 54.9% of tax revenues collected by local governments (Fig. 14).

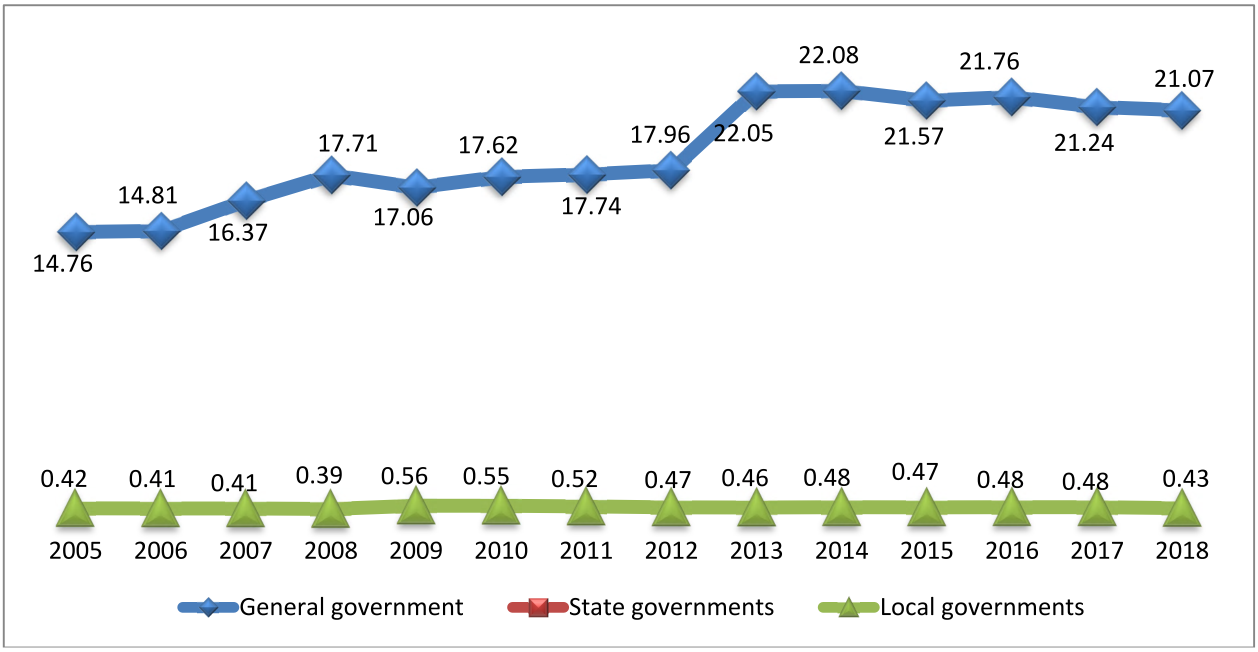

Fig. 12. Distribution of tax revenues between fiscal levels of Armenia, % GDP [60].

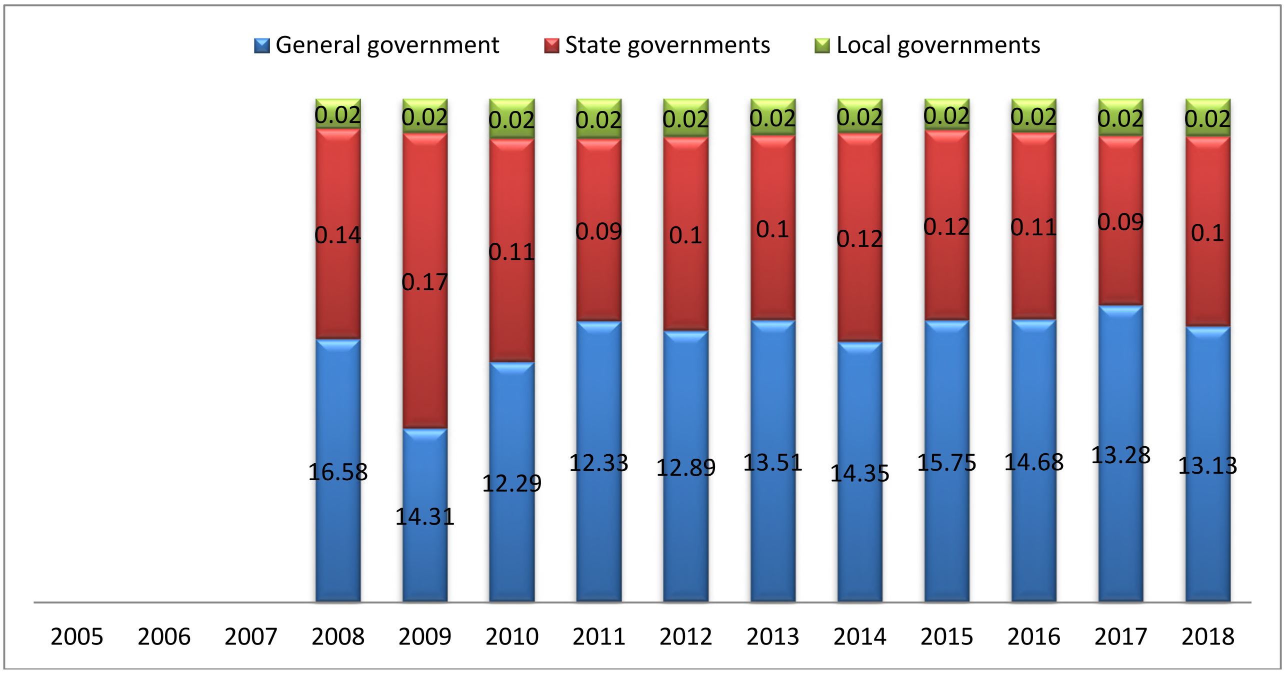

Fig. 13. Distribution of tax revenues among the fiscal levels of Azerbaijan, % GDP [60].

4 Research results

The research of the experience of different countries revealed that it was especially difficult to implement fiscal decentralization reform in post-socialist countries, where the pre-existing administrative-planning structure was characterized by a high degree of centralization. Successful implementation of decentralization requires a relevant institutional environment and development. Especially, in post-socialist countries where state institutions are at an early stage of development, the implementation of decentralization reform has solved some problems. Most of these countries have not yet emerged from these problems. In Central and Eastern European countries, the main goal of economic policy at the initial stage of transformation was to ensure macroeconomic stability. This was accompanied by structural changes in the economy, political and ethnic conflicts, which created an unfavorable conditions for fiscal decentralization [61].

 https://doi.org/10.1051/e3sconf/202128002010

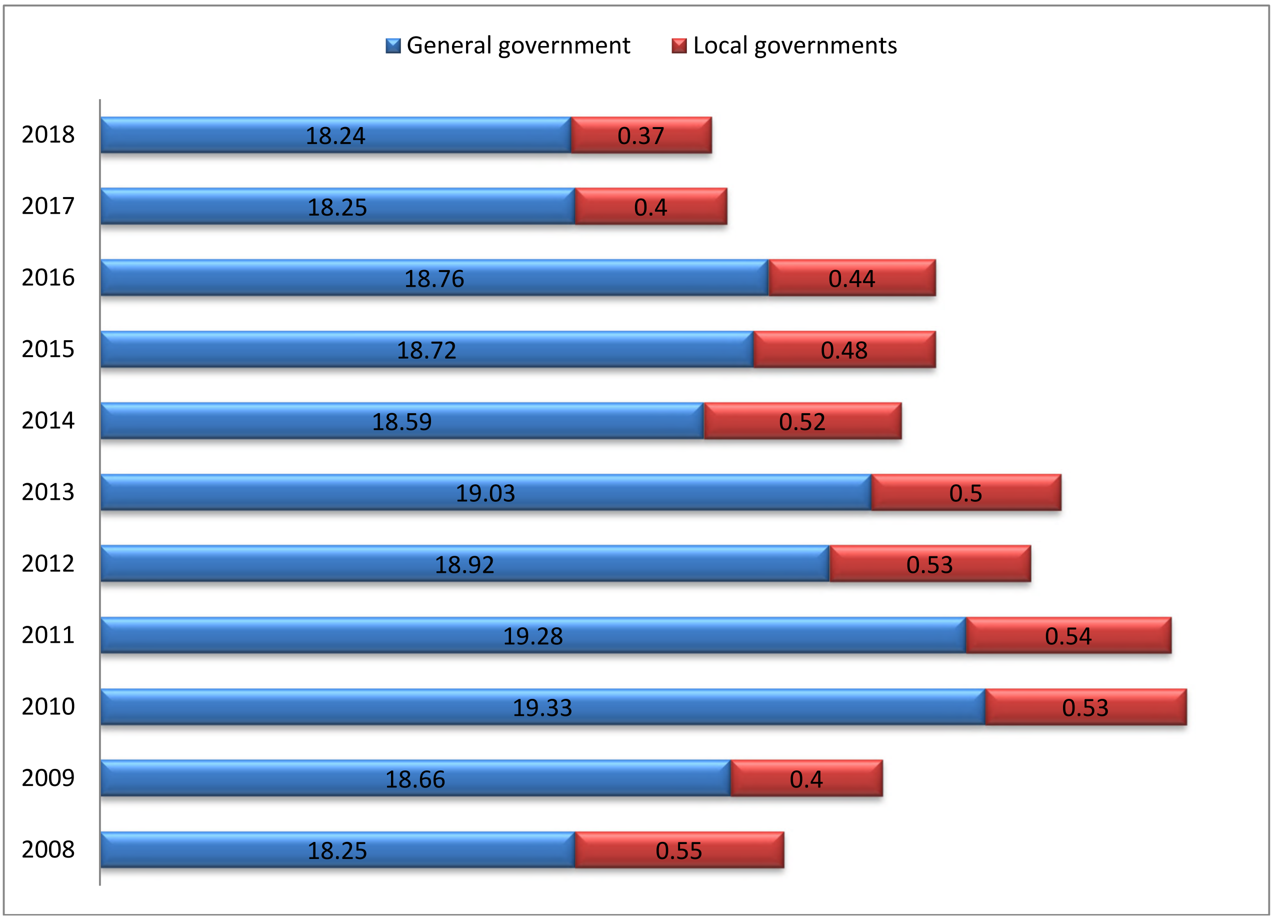

Fig. 14. Distribution of tax revenues between fiscal levels of Turkey, % GDP [60].

Local governments in Central and Eastern Europe have been financed through shared taxes and transfers. Income tax goes directly to local government in the Nordic countries and Switzerland. Income tax is shared in many countries, for example Austria, Germany, Hungary. In these countries the tax is levied by the central government and distributed to local governments.

Due to the simplicity of property tax administration, in almost all European countries, property taxes go entirely to the local budget [61].

Table 2. Distribution of taxes between budget levels [61].

Types of taxes	Local is in the following countries
Income tax	
a) direct	Nordic countries, Switzerland
b) shared	Austria, Germany, Poland
Income tax	Austria, France, Germany, Norway, Portugal
Property tax	All European countries (except Sweden)

Only a few developed countries have reached local governments autonomy in revenue, but they used to receive and still receive assistance in the form of transfers. In Slovakia, Hungary and Poland, for example, own revenues account for up to 40% of total revenues. Local budget revenues in local budget revenues are highest in Sweden, France, Italy, Germany, Poland and the Czech Republic (Fig. 15) and the smallest in Austria, Estonia, Georgia, Azerbaijan, Turkey, Armenia.

Inter-budgetary relationships vary according to different models. In particular, in Anglo-Saxon model countries (USA, UK, Canada, Sweden) regions have high fiscal autonomy and local taxes dominate budget revenues. In the Continental model countries (Germany, France, Italy, Spain, Belgium) the fiscal autonomy of the regions is relatively limited and the principle of financial equalization (granting subsidies and subsidies) is essential [5, 63].

Policies in the field of municipal finance should be directly related to the economic activity of the self-government. In this regard, against the background of the general crisis, the municipalities in Georgia are in a particularly difficult condition. Their situation is further aggravated by the price disparity in industrial and agricultural products, the monopolization of privatized processing enterprises and the lack of profitable enterprises. Many of the problems facing the territories are caused by the fast and reckless privatization of the service sector of processing enterprises and other sectors. Problems of economic development are particularly acute:

1. A general decline in production, which leads to a reduction in budget revenues;

2. Limited economic base in rural areas, which is manifested, first of all, in the absence of profitable enterprises in the territories;

3. Changes in municipal ownership caused by the transfer of social sphere facilities to local administrations;

4. Uncertainty in the status of branches of enterprises and organizations located in the districts;

5. Restriction of rights to natural resources of local authorities.

In our opinion, in order to improve the financial situation of the municipalities, it is necessary to solve the following problems: 1. Expanding the tax base of the area; 2. Ensuring social equality in the distribution of subsidies and the implementation of social protection measures for the population; 3. Resolve the territorial issues related to the relations between the local administration and the governing bodies of the republic.

Due to the tourism potential of Georgia and the large flow of tourists, the establishment of a tourist fee can be one of the important sources of income for self-governments. This type of fee is used by many European countries: including: Spain, Italy, Croatia, Belgium and others on average 0.15-7.5 euros per day. Tourist tax in Dubai ranges from $ 2 to $ 6. From November 1, 2015, a similar tax was introduced in the Emirate of Ras Al Khaimah. Also, every tourist who stays at a hotel in Abu Dhabi pays a daily fee of $ 5 and it does not matter what type of hotel they stay at. Tourists arriving in Rome have to pay from 1 euro to 7 euros as a tourist tax for overnight stay at the hotel and it depending on the type of hotel. According to the National Tourism Agency, up to 4.8 million tourists entered Georgia in 2018 (individuals who voluntarily travel outside their permanent residence for leisure, recreation, business or other purposes for at least 24 hours and not more than one year. And whose travel is not refund from the financial sources of the place of temporary stay). If we take the minimum tariff of 1 GEL per tourist (regardless of the number of days), it means an additional income of 4.8 million, and on average 3 GEL additional 14.4 million. This will significantly help self-governments to better meet public needs, implement infrastructure and other projects.

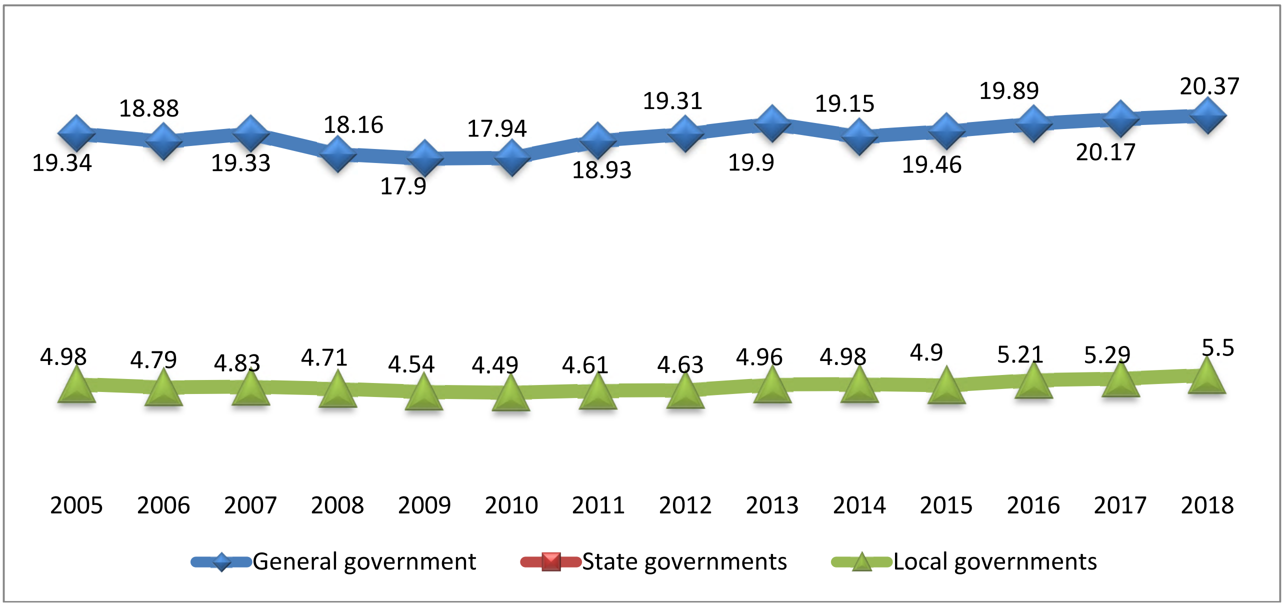

Fig. 15. Distribution of tax revenues between fiscal levels of Czech Republic, % GDP [60].

The second important issue of strengthening self-governments is the transfer of property to them. Only the transfer of finances and leaving taxes on the places will not lead to the development of the economy and will not create additional value on the places. Financial decentralization creates a mechanism to make economic activity profitable for municipalities [64-69]; And economic activity is possible only if land, property and other resources are transferred to local governments. With financial instruments, self-governments need to be motivated to see benefits and financial gains by using the property transferred to them in authority, to create investment projects, to find investors and to promote employment.

Georgia is one of the Post-Soviet countries in Eurasia, which has been actively involved in EU integration processes [5]. Therefore, for the success of the reform, it is necessary that the transfer of finances and property be carried out in parallel, and as soon as the new tax system enters into force. The municipalities will have the property resources by which they will be able to increase economic activity and revenues. Of course, such an approach does not mean the phasing out of both types of decentralization, when the rate of tax rates left on the ground and the transfer of property take place according to a plan outlined for a certain period of time. It should also be noted that due to the unequal economic development of municipalities, leaving part of the income tax on the ground can have a positive impact on only a small part of municipalities where the share of employees is relatively high. For some self-government, in terms of revenue growth, the transfer of agricultural and/or non-agricultural lands and natural resources may be more important. Therefore, creating the necessary basis for the economic development of municipalities requires a complex approach and focusing on only one area (either finance or property) will ultimately have less effect. One of the tasks of the policy should be, at the initial stage, to identify the municipalities that, through their economic development, can exercise their powers independently of the central budget. At the same time, the government should be given the opportunity to pursue an effective equalization policy for the development of economically weak, depressed economies [8].

One of the important issues of local self-government financial independence is the right to borrow, especially in terms of low income they have. As it is known, local self-governments have the right to economic activity, which is difficult to believe without the full right to take a loan. According to Article 21 of the Budget Code of Georgia, "Autonomous Republics and local authorities have the right to borrow from the Government of Georgia and/or other sources only with the permission of the Government of Georgia." The caution of legislators with respect to borrowing by the municipality based on negative practice when a local government took a loan from a commercial bank and then could not repay it, or it was repaid from a targeted transfer. In fact, in most cases, borrowing was done with the intervention of the central government for various political reasons. Consequently, the Budget Code continues to be a bad practice and the central government continues to restrict borrowing by the self-government. In our opinion, local self-government should have the right to take a loan. While exercising this right, there may be different conditions and mechanisms in this Code or other normative act defined by law.

Thus, it is important that the powers of the municipality should be adequate to its sources of revenue. However, this should not be understood in such a way that since the municipality does not have sufficient budget revenues, the scope of its authority should also be reduced. On the contrary, municipalities should be given the authority to address issues of local importance as much as possible and adequate funding should be provided for this. In this context, in addition to tax revenues, it is important that the municipality be given as much property of local importance as possible, the conditions for the proper use of which the municipality will have additional opportunities to generate revenue.

5 Conclusions and recommendations

Creating a universal model of decentralization is practically impossible, as every country has its own history and specifics of self-structuring. Thus, each of them must individually define the principles of separation of functions of central and local government and the degree of autonomy of self-governments.

The main function of fiscal policy in any arrangement state was and is to ensure the socio-economic status (welfare) of the society. The level of welfare of a country depends on how developed its economic system is and what security guarantees are created. Prosperity is defined by the material goods and services necessary for a comfortable and secure human life. The material progress and prosperity of a nation is achieved only if it leads to the moral and material well-being of each citizen.

Therefore, when forming the municipal budget, the following approaches should be taken into account:

1. Extended tax discretion of the self-government. Local governments should have the authority to impose both direct and indirect taxes. Basic tax categories should be introduced (one is not sufficient, property tax). Such segregation / attribution of tax revenues will minimize redistribution processes and establish a stable relationship between the centre and the municipalities.

2. Establishment of fixed interest rates for tax revenue sharing based on the starting economic indicators of self-governing units. In this case, tax revenues are divided between the autonomous state and local budgets according to certain types/percentages. This method will increase the ability to optimally allocate resources. Regions under the influence of the centre receive certain budgetary tax benefits by differentiating their respective interest rates.

3. Determining the percentage of transfers from the total amount of taxes collected in the territorial units to the budget of the centre.

Abstract. The main idea of jet grouting technology is the implementation of processes aimed at changing the characteristics of soils, creating materials with the necessary properties on their basis and forming underground elements with specified parameters from these materials. The high pressure of the cement mortar jet leads to soil blending and its continuous destruction within the radius of impact of the jet. According to some authors, the jet outside the destructive radius does not affect the surrounding soil environment. In compliance with practical studies performed at construction sites in Kyiv, Ukraine, the data on changes in the physical and mechanical characteristics of the soil surrounding the soil-cement column were obtained. This fact led to a more detailed study of the effect of a high-pressure jet on the surrounding soil during the execution of columns using jet technology.

1 Introduction

Jet grouting is the destruction of the structure of the soil or soft rock and blending or partial replacement of it with a cementitious substance, while the destruction of the soil occurs due to a liquid jet with high energy, and the liquid itself performs a cementing function [1].

The research of the phenomenon of destruction of the natural structure and soil blending by jet grouting is well-known and provided by many scientists [2-27].

Jet grouting technology allows it to be used in solving various tasks of underground construction, namely: underground load-bearing and anti-filtration structures, horizontal or inclined slabs, elements of buildings and structures, artificial basements, walls and floors of sunk premises, including underground garages, the installation of roots of ground anchors, when strengthening the pinning of existing buildings and structures, retaining walls, pit fences, horizontal underground anti-filtration screens, anti-landslide structures, fixing ground massifs for sinking underground tunnels, wells of large diameter with bottoms and many other structures. Jet grouting elements are also used for reinforcing ground bases in earthquake-prone areas.

A high-pressure jet, striking the ground, destroys its original structure and according to Kanematsu research [28] the zones of a high-pressure jet (in the experimental work of a water jet) are: zone 1 – the core, the hydrodynamic pressure in which is constant, zone 2 – an intermediate zone and, as a rule, the distance to the end of zone 2 is 300 nozzle diameters, zone 3, where the flow loses focus, becomes intermittent and cavitation effects begin to prevail.

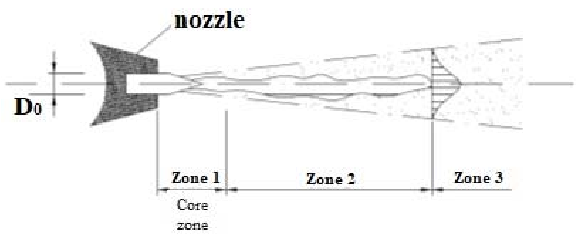

Fig. 1. Characteristics of the water jet according to Kanematsu.

The distribution of hydrodynamic pressure in zone 3 along the jet axis decreases with exponential distance. If you release a jet of water into a dense environment or clean water, it appears that zone 3 does not exist. This circumstance is typical for most cases of jet grouting.

The high pressure leads to soil blending and its continuous destruction within the radius of impact of the jet. Therefore, based on his findings, Kanematsu suggested that the use of jet grouting does not affect the stress-strain state in the soil beyond the impact radius. In fact, even when working with very high pressure, the injection process only leads to an increase in pressure within the collapsing area (zone 1 and 2). The same opinion is supported by C. S. Covil and A. E. Skinner [10].

At the same time, practicing organizations, based on experimental data, have shown that the implementation of jet grouting elements of circular cross-section affects the surrounding soil mass outside these elements.

Consolidamenti E Pali in Italy performed a series of laboratory tests of the soil surrounding the well made of intersecting jet injection columns (Fig. 2).

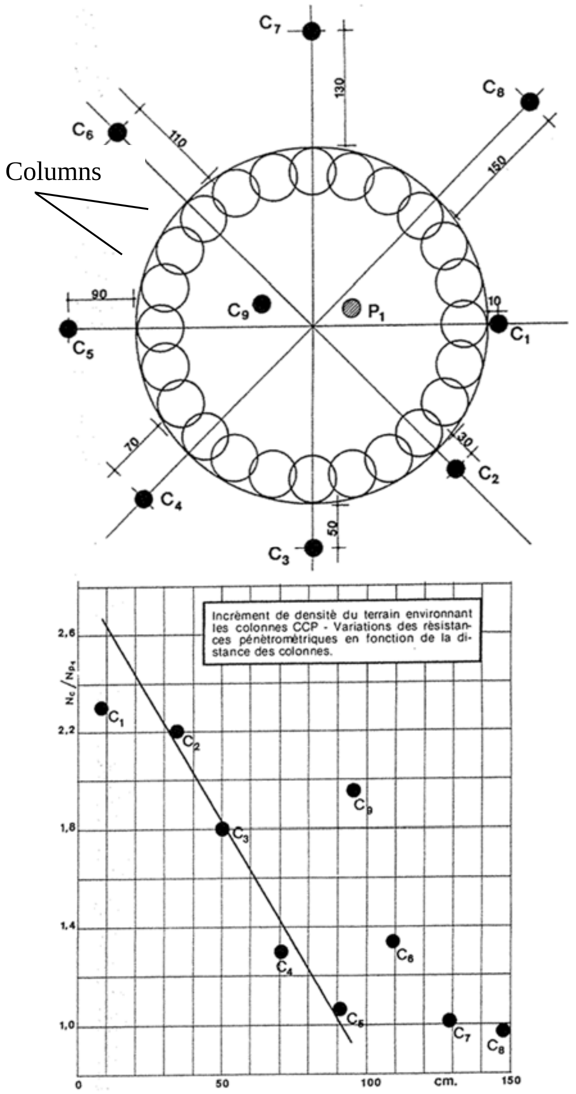

Fig. 2. Soil density around the jet grouting column depending on the radial distance.

The maximum effect of the high-pressure jet on the surrounding soil mass is observed at a distance of 10 and 30 cm (samples C_1 and C_2), the maximum effect on the physical and mechanical characteristics of the soil is observed at a distance of 110 cm (C_6), 130 cm (C_7) and 150 cm (C_8).

2 Research methods and results

During the implementation of the project to strengthen the ground base of the historical monument of architecture, St. Andrew's Church, in Kyiv, studies of soil samples from the space between jet grouting columns were performed. Physical and mechanical examination of the selected soil samples showed that there is a zone with improved characteristics around the column. The density of soil (sandy loam) increased from 1.6 t/m^3 to 1.65...1.67 t/m^3, and the impact zones reached 30 cm from the surface of the column. Analysis of experimental data and comparison with the statements of some authors about the absence of influence on the surrounding soil actuate the question of the future studying the effects of the implementation of jet grouting elements on the surrounding soil environment.

A jet of cement mortar coming out under high pressure from the nozzle located on the hydraulic monitor rotates and destroys the surrounding soil, mixing it with the cement mortar. If at the first rotation the jet destroys the soil, then at the second rotation the jet is already in the cement mortar and can be considered as a drowned jet of liquid.

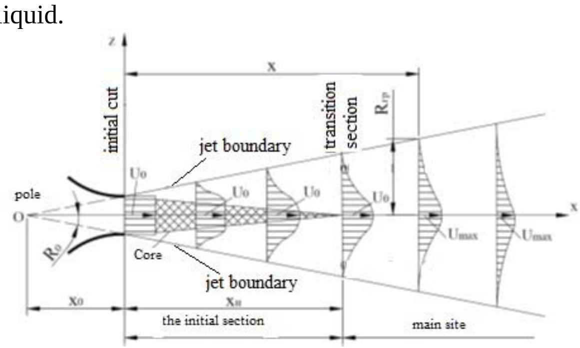

Fig. 3. Diagram of a drowned free turbulent jet.

For the design scheme, the nozzle radius is $R_0 = 1.2$ mm (the nozzle diameter located on the hydraulic monitor is 2.4 mm)

Speed of the cement mortar jet at the nozzle outlet:

$$U_0 = \frac{4 \cdot Q_p/(\pi \cdot d_c{}^2)}{n_c} = \frac{(400 \cdot 100)/(6 \cdot 3{,}1416 \cdot 2{,}4^2)}{2} = 184 \ {}^{m}/_{s} \quad (1)$$

Given that the diameter of the soil-cement column is 0.6 m, the destructive radius is $x = 0.3$ m.

Speed on the axis of the main section:

$$U_{max} = \frac{0.96}{\frac{a \cdot x}{R_0} + 0.29} U_0 = \frac{0{,}96}{\frac{0{,}08 \cdot 0{,}3}{1{,}2 \cdot 10^{-3}} + 0{,}29} 184 = 8{,}71 \frac{m}{s} \quad (2)$$

where a is the structural coefficient of 0.08.

Half of the height of the jet at a distance of $x = 0.3$ m from the nozzle:

$$R = \left(3.4 \frac{a \cdot x}{R_0} + 1\right) R_0 =$$

$$= \left(3.4 \frac{0.08 \cdot 0.3}{1{,}2 \cdot 10^{-3}} + 1\right) 1{,}2 \cdot 10^{-3} = 0.083\, m \quad (3)$$

Based on the fact that we know the fracture radius of the jet, to calculate the residual pressure acting on the surrounding soil that has not been destroyed, we calculate the hydrodynamic pressure of the liquid jet on the wall:

$$P = \rho_p \omega U^2 = 1500 \frac{3{,}14 \cdot 0{,}166^2}{4} 8{,}71^2 = 2458\, H \quad (4)$$

where ρ_p is the density of the solution, ω is the cross-section of the flow, and U is the average flow rate of the liquid.

When calculating the jet per 1 m^2, we obtain a residual hydrodynamic pressure of $P = 113.8$ kN/m^2.

The calculated data of the residual pressure that causes a high-pressure jet of cement mortar on the surrounding soil are used to create a model in the Plaxis 3D Foundation software package.

Engineering and geological characteristics of the soil and geometric characteristics of jet grouting columns made using jet technology are taken on the example of the object "strengthening foundations during the reconstruction of St. Andrew's Church in Kyiv", on the territory of which experiments were conducted on soil samples taken in the intercolumnar space.

The design solution for strengthening the foundations of St. Andrew's church was developed in 2009 and it was the implementation of soil-cement columns in the base from the middle of the under-porch, from the outside of the stylobate and from the middle of the church and stylobate premises with a total of 259 pieces, a length of 10.8 to 13.5 m with angles of inclination from 7° to 13° and a diameter of 600 mm with an extension of 800 mm, a step of 1.0–2.7 m. A schematic diagram of strengthening the foundations of the church is shown in Figure 4:

We accept the Mohr-Coulomb model for the soil and body material of the jet grouting column. To simulate the process of performing a jet grouting column and the effect on the surrounding soil, the column material is given low characteristics to reflect its liquid state.

The thickness of the experimental layer in which the samples were taken is IGE – 4–8 m. In the column model – 5 m and there is still 3 m under the columns. The introduction of soils below the experimental layer would not give a result, since they did not take soil samples, that is, it would be a mistake to compare them with the experimental results and assert the correctness of the simulated data obtained.

Characteristics of solid sandy loam: $\gamma = 1.6$ t/m^3, $\phi = 23^o$, c = 33 kPa, E = 17 MPa. Characteristics of the jet grouting column: $\gamma = 1.55$ t/m^3, $\phi = 3^o$, c = 3 kPa, E = 0.15 MPa.

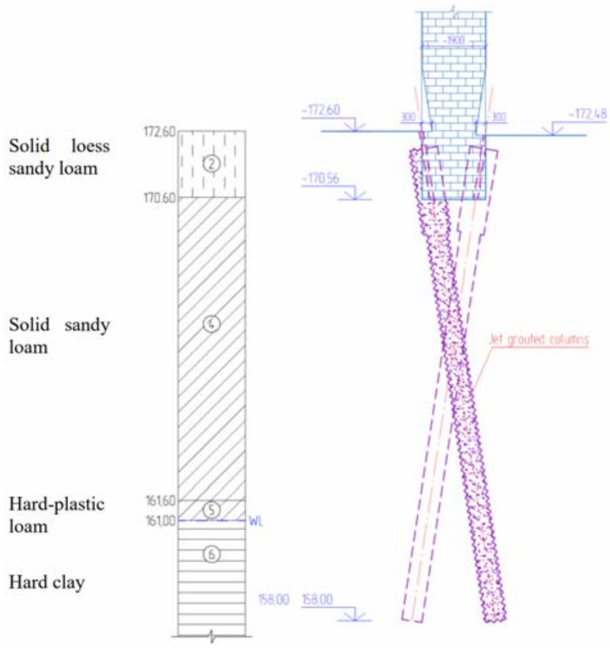

Fig. 4. Schematic diagram of strengthening foundations.

The model is the 5 meter column, the diameter is 0.6 m, the intercolumnar distance is 0.85 m, the pinning is brick, the depth is 2 m. The study of soil samples took place from the basement at a foundation depth of 2 m, the level of occurrence of the selected soil samples – 2.5 m from the basement floor level. In accordance with the software capabilities of the geotechnical design complex, the jet grouting columns are set vertical.

The main purpose of the simulation was to study the effect of the residual pressure of a high-pressure jet of cement mortar, a pressure that is directed horizontally. The platform for research is the inter-column space, and therefore only two columns are introduced in the model. That is, with the same soil environment, the same distance and the same residual pressure value (constant technological parameters when performing a column), the results of exposure in the inter-column space would also be the same.

The model reproduces experimental conditions: pitch, soil, depth of occurrence of the selected samples.

A calculated residual pressure $P = 113.8$ kN/m^2 is applied along the contour of the surface of the jet grouting column.

Figure 5 shows the deformed grid of the created model and the total displacements that occur in it. The maximum value of the total displacement is 8.5 mm and it occurs on the surface of the jet grouting column, and figure 5 clearly separates the deformation zones, i.e. the zones of impact that arise from the residual pressure of a high-pressure jet of cement mortar. The dimensions of these zones are 29.5 and 26.5 cm (Fig. 6). In comparison with the experimental data obtained during the study of soil samples taken in the intercolumnar space, the maximum impact zones were 15 and 30 cm from the surface of the first and second jet grouting columns.

If we select a single volume of deformed soil in the column space, we can calculate the change in the volume weight of the soil.

Soil density:

$$\gamma = \frac{m}{V} \quad (5)$$

Let's denote γ_1, V_1 the density and volume of soil before the columns are made, which is equal to 1.6 t/m^3, γ_2, V_2 is the soil that was compacted. Let's assume that the weight of the soil has not changed and equate the density expression for the first and second soils:

$$\gamma_1 V_1 = \gamma_2 V_2, \text{ hence} \quad (6)$$

$$\gamma_2 = \frac{\gamma_1 V_1}{V_2} = \frac{1{,}6\cdot(0{,}295\cdot1\cdot1)}{(0{,}295-0{,}008)\cdot1\cdot1} = 1{,}65\ t/m^3 \quad (7)$$

Returning to the results of testing soil samples from the object "reconstruction of St. Andrew's church", the density of the selected soil varied from 1.64 to 1.67 t/m^3. As a result of modeling the impact of performing jet grouting columns, the value (7) of changes in soil density from the impact zone was obtained – 1.65 t/m^3, which corresponds to experimental data (table 1).

When studying the object of reconstruction of St. Andrew's church, numerical values of the zone of influence equal to 15 and 30 cm were obtained, and the following results were obtained during modeling: 29.5 and 26.5 cm, corresponding to full-scale experiments. The results obtained in accordance with the simulation and experimental data are entered for comparison in Table 1.

Figures 7–9 show the effect of performing a jet grouting column using jet geotechnology on the stress-strain state of the surrounding soil environment.

3 Conclusions

To perform numerical modeling of the formation of zones with improved physical and mechanical characteristics in soil massifs, a hydraulic calculation of the drowned jet of cement mortar was performed. Using research data from the described construction sites and knowing the destructive radius of the jet, the residual pressure that causes a high-pressure jet of cement mortar on the surrounding soil mass is calculated after the destructive energy is spent on the destruction and removal of the soil during the formation of the jet grouting column.

The obtained residual pressure calculations were used to create a model in the Plaxis 3D Foundation software package.

In accordance with the research data on the object of reconstruction of St. Andrew's church, Kyiv, the zones of influence on the surrounding soil environment were *15* and *30* cm, and the simulation obtained results are *29.5* and *26.5* cm.

As a result of modeling the impact of performing jet grouting columns, the value of the change in soil density from the impact zone was obtained - *1.65* t/m^3 (before the impact of the jet *1.60* t/m^3), which corresponds to experimental data (the change in soil density after performing jet grouting columns on the construction site varied from *1.64* to *1.67* t/m^3).

A field study and simulations performed to study the impact proved the presence of improved soil zones around the jet grouting columns.

Abstract. The article presents study of wind effect on silo parks, which was carried out by computer simulation methods. A special modeling technique was created as a software module for the Ansys Workbench platform. A finite element mesh was developed in accordance with two requirements. Through the use of this mesh, which doesn't contain needless elements which can be used for simplification of calculations and reduction of execution time, it is possible to describe the turbulent airflow in sufficient detail. The dimensions of all mesh elements are determined by special relations as the functions of the silo diameter and the Reynolds number. The major stage in this investigation was modeling of various options for flowing silos and their groups. As a result of the study, we have obtained aerodynamic characteristics of individual silos as part of silo parks and plotted charts of the distribution of pressure coefficients over the cylinder surface, changing the size of the silos, distances between them and local wind regime. Based on these data, we have drawn a conclusion about the optimal space planning locations of silos for different wind directions. Visualizations of turbulent flow around models at different speeds have also been obtained in this study.

1 Introduction

Construction of industrial buildings and structures requires significant resource spends. Effective use of materials is possible through rational design, construction, and operation practices, which is very important for sustainable development of modern industrial construction. One way to implement these approaches is to develop calculation methods, which must be based on accurate data. Computer simulation tools may help to obtain such data that cannot be predicted in real situations. This applies to the object of study of this article - silage parks under the influence of wind flow.

Empty cylindrical silos are very sensitive to wind loads. Their determination is performed according to normative methods [1-5]. There are also a lot of theoretical and experimental studies of these issues [6-10]. In general, the behavior of wind currents near the buildings of simple geometric shape is well studied [11-14]. However, a lot of factors related to modern silo complexes are not taken into account. It should be noted that, first of all, the issue of mutual influence of silos in groups has not been properly examined yet. The nature of the action of the wind flow on the silo park will be different from the action on the isolated cylindrical object [15, 16]. Strong suction forces, which are not taken into account in the classical calculation, arise between the silos. The silo can also be located in the area of wind shade from other objects. The second problem is the rough structure of the silo, as it has a corrugated wall and a large number of stiffeners. Wind exposure to such a structure causes complex wall effects, which, in its turn, will increase the load on the silo body and the roof.

Different experimental methods are often used to study such issues. However, the real blowing in the wind tunnel has a significant disadvantage, as it is impossible to reproduce the supercritical flow regime at Reynolds numbers greater than 10^7. Therefore, it is advisable to use the methods of construction aerodynamics, in particular computer modelling, in order to take into account the adverse effects of wind action. In order to achieve correct results, it is necessary to take into consideration a lot of factors, such as computational mesh generation and the choice of a mathematical model of air flow turbulence, which will give consistent results. The size of this computational mesh greatly affects the accuracy of the calculation and the computation time. It ought to be noted that a highly refined mesh increases the accuracy, but complicates the calculation. The next aspect is the formulation of the simulation problem, which can be flat (2D) and three-dimensional (3D). The calculations can be performed in stationary and non-stationary formulation with different time sampling steps. It is also necessary to consider different layouts of silos in groups, which can have different sizes, locations and positions in the wind flow. The last aspect is the form of the result. Numerical aerodynamic characteristics (wind pressure coefficient, drag and lateral force), which were found for a certain wind

* Corresponding author: pasargada1985@gmail.com

direction and specific position of the models, are not very informative. It is appropriate to present the results in the form of graphs, similar to building standards. Also, different computational situations for common silo configurations can be combined into an aerodynamic atlas. This form is convenient and has practical benefits.

2 Method

This article presents a computer simulation procedure in ANSYS CFX program for flow around the models of various cylinder configurations that schematize a silo park. Aanalysed silos, the sizes of which are most often built: from 11 meters to 30 meters. The roughness of the silo surface was taken equal to the height of the corrugation of the silo body. In general, the problem of aerodynamic calculation was considered in three versions. At first, the simplest case of a flat 2D flow was examined. The height of the computational domain was taken as one cell of the finite element mesh.

With a more complex quasi-two-dimensional flow, the height of the computational domain was taken to be equal to the two diameters of the model (silo). The last step was to perform spatial three-dimensional flow (Fig. 1).

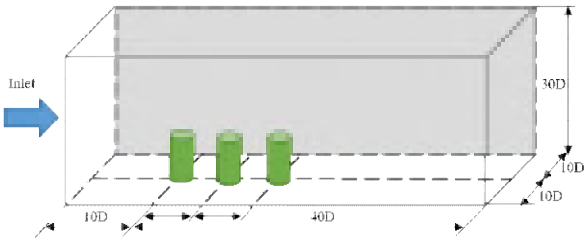

Fig. 1. 3D Geometry of the computational domain in case of three-dimensional modeling.

2.1. Justification of the calculation

For turbulent flows around cylindrical silos, which are characterized by wide separation zones, four mathematical models of turbulence are analyzed. These are Menter's Shear Stress Transport (SST), Slapart-Allmaras Turbulence Model (SA), Large Eddy Simulation (LES) and Detached Eddy Simulation (DES). Comparison of calculations showed a discrepancy in the results up to 40% when using different turbulence models [16]. However, the most consistent results are observed between the SST and DES turbulence models, which are recommended for use in construction aerodynamics.

A parametric form was used to build a finite element mesh as well as to set the dimensions of the fluid domain in the form of a parallelepiped (Fig. 1). In such a case, the dimensions of the mesh elements will depend on the Reynolds number and on the diameter of the silo, while the dimensions of the computational domain will depend only on the diameter of the model.

At this stage, the mesh quality was checked during the simulation. For this purpose, we have taken the initial data which had already been applied in numerical or physical experiments in a wind tunnel in previous works [17-19]. Subsequently, a number of verification tests based on SST and DES turbulence models was carried out for various types of meshes.

The task was to simulate on computer flow around a cylinder in two- and three-dimensional formulation and to obtain the pressure coefficient, drag and lift force. The results were compared with experimental data [17-19]. The optimal variant of the mesh was determined not only by the solution convergence, but also by the computation time. The maximum discrepancy of the obtained data when calculating the accepted variant of the finite element mesh was up to 15%.

Additionally, a comparison of wind pressure coefficients was performed for 5 points on the surface of silo body (Table 1) and for 4 points on surface of conical roof (Fig. 2). Table 1 above shows the data obtained by a full-scale field experiment in a wind tunnel [11]. Shown below are the data of the author's numerical modeling.

Table 1. Verification test results.

Angle β°	Point number			
	1	2	3	4
0	0,87 0,92	1,0 1,0	1,0 1,0	0,96 1,0
30	0,30 0,26	0,20 0,27	0,25 0,33	0,46 0,53
70	-1,54 -1,42	-1,89 -0,96	-1,64 -1,50	-1,15 -1,07
90	-1,96 -2,03	-2,09 -2,20	-1,80 -1,69	-1,30 -1,15

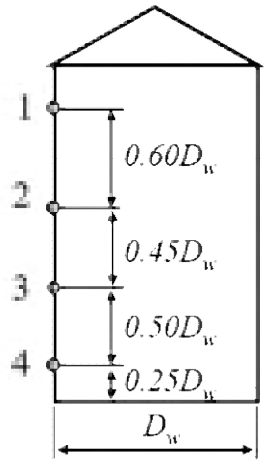

Fig. 2. Computational points on the silo surface.

2.2 General simulation diagrams

The main advantage of 2D modelling is the calculation speed. This procedure can be used for simple tasks when the silos of the same diameter are arranged in one row (Fig. 3).

Variable bench-mark data are wind speed and wind direction, the number of models, their diameter and the distance between them. The height of the silos is not taken into account in this calculation.

In the problems on modelling, the flow velocity at the input was given in the form of the Reynolds number.

Fig. 2. Arrangement of silos in a row at the warehouse of the enterprise.

In total, we have examined a sample of two, three and four silos with equal and various distances between. The position of each silo was expressed parametrically along two axes (Fig. 4). The size was expressed by the ratio of the peculiar distance between the centres of the cross sections of the silos to their diameter.

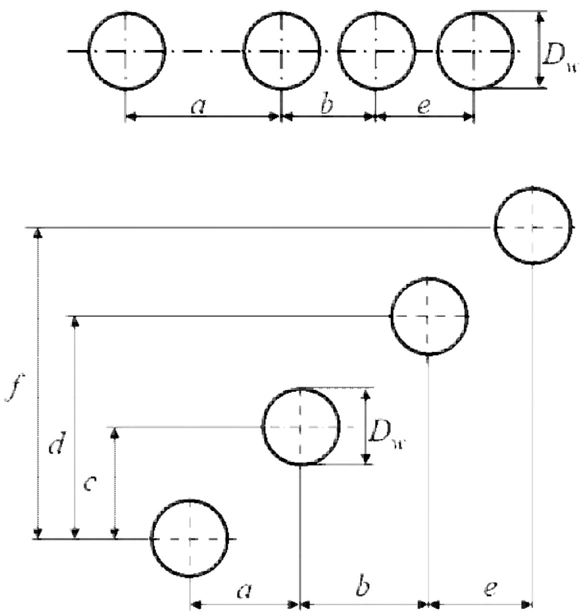

Fig. 4. Examples of silos layouts.

The results showed significant differences in the behavior of three-dimensional flow in near of silos at different initial data. For example, Fig. 5 shows wind flow isosurface for a variant of three silos with different initial data.

For all above considered options we have obtained wind pressure curves for each of the silos. For example, Fig. 6 shows a curve of changes in aerodynamic coefficients for two silos, located one after another.

Another experimental variable was the coefficient of drag C, the value of which was also found for all the schemes considered in the modelling process. A part of obtained results is summarized in table 2.

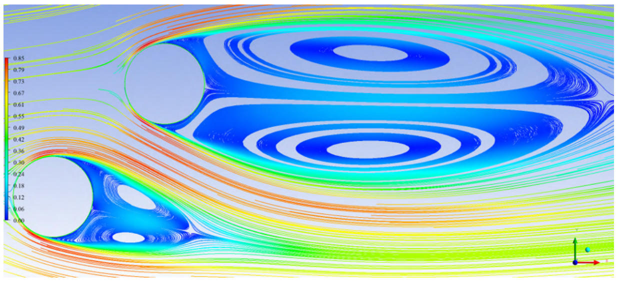

Fig. 5. Visualization of the flow around two silos.

3D modelling is often used when it is necessary to describe in full the actual building in near of the storage capacity. However, this causes big problems, as the development of detailed models of the silo park, taking into account the surrounding buildings and relief, is quite difficult and the calculation itself is time consuming.

This technique is also based on the construction of the optimal ratio of the parametric computational grid, the selection of turbulence models and special computational algorithms. In the interest of time, it is advisable, in the first instance, to perform a computation of a simplified two-dimensional model of a silo or a silo park. This would enable taking a tentative assessment of the design pressures on the body and conical roof of the silo in the park and subsequent generating three-dimensional loads based on the results of 2D-calculation.

Special macros and software modules should be used for fast and accurate calculations. This allows us to combine the necessary calculation procedures and to simplify them.

Based on the obtained results of modeling of any type, it is possible to determine the most dangerous wind directions, perform a preliminary assessment of the calculated loads and export loads to the strength analysis program.

2.3 Results

The nature of the placement of silos and the distance between them greatly affect the distribution of pressure on their surface. The result differs from those indicators that are taken for single structures and declared in the design standards.

For paired silos, modelling was carried out for various options with a stepwise increase in the distance between centres a from $1{,}1D_w$ to $10D_w$.

The formation of symmetrical stationary vortices of different elongation and shape was observed in the pattern of distribution of isosurface of closely spaced silos. These symmetrical stationary vortices are located near the leeward side of each of the flow bodies. Behind the first cylinder, two oversize side vortices and two middle vortices, which practically disappear at $a = 1{,}6D_w$, are clearly visible. With regard to the second cylinder, the classic formation of two elongated stable vortices is observed (Fig. 7).

An increase in the distance between the silos leads to the narrowing of the eddy zone, and at $a/D_w > 3{,}5$ they form a narrow isthmus with separation.

The graph of variance of the pressure coefficient for the first cylinder takes the typical shape. However, the aerodynamic coefficient curve for the second silo is completely in the negative zone. The value of the aerodynamic coefficient at an angular coordinate of 0º is $C_p = -0{,}98$ at $a/D_w = 1{,}1$. Subsequently, the values beyond the surface of the cylinder decrease very slowly, reaching a minimum at 50º $C_p = -1{,}05$ (the zone of medium vortices silo 1), and then increases more sharply at 45º-80º with the maximum $C_p = -0{,}38$ (the zone of lateral vortices silo 1).

After this point, the influence on the aerodynamic coefficient is exerted by the own eddy zones of the silo 2. With further increase in size between the models, the effect of silo zone 1 predictably decreases.

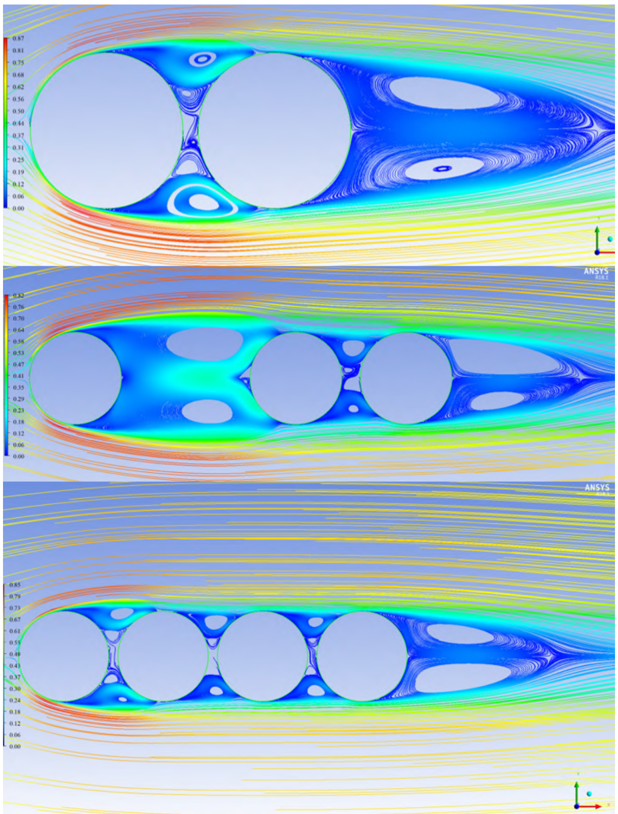

Fig. 7. Simulation of wind action on a system of silos, located in succession.

As the distance increases, the drag coefficients of silo 1 change within 19%, and for silo 2 they change doubly.

For a group of three and four cylinders in series, the flow pattern is similar. For silo 3, the graph of variance of aerodynamic coefficient is also in the negative zone. This is caused by the windy patch from silo 2. Quantitative values change slightly. For the distance $b/D_w = 1{,}2$, there is one maximum at 50º ($C_p = -0{,}1$) and one minimum at 95º ($C_p = -0{,}42$). At the distance of $a/D_w = 5$, the graphs C_p of silo 1 and silo 2 converge.

Graphs of variance of aerodynamic coefficients for silos placed in a group of four bodies can be projected (Fig. 8). Quantitative characteristics do not exceed the values for the groups of three bodies.

The instantaneous blowing pattern for the case of different direction of the wind flow is shown in Fig. 9. To simulate the flow, at first two silos were selected with the distance between the centres of $0{,}2D_w$, which was then increased. The visualization shows how a bevelled flow zone with high velocities is formed. The eddy zone of one silo is longer and has an asymmetry in the area close to the second silo. For the second silo, the eddy zone is smaller and develops sideways. Such nature of the flow causes combination of the stall points and zones of maximum pressure.

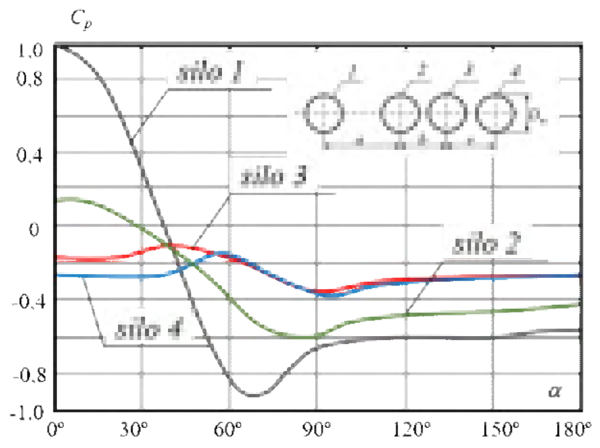

Fig. 8. Simulation $a/D_w = e/D_w = 5{,}0$, $b/D_w = 1{,}2$.

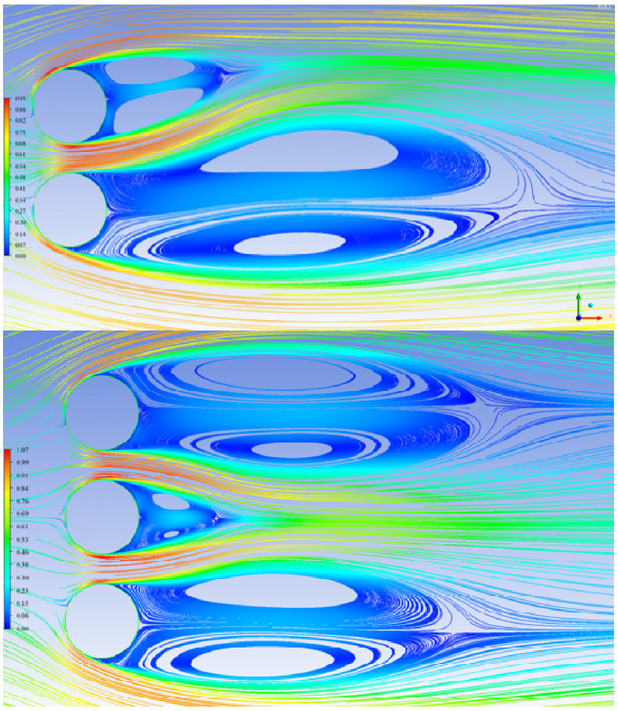

Fig. 9. Simulation of wind action on the system of parallel silos.

At $c/D_w = 1{,}1$ the value of aerodynamic coefficients of the upper silo, which has smaller eddy zone, up to 25%, is greater than the corresponding indicators of the neighbouring silo. With increasing distances between the silos, this difference is less noticeable. At $c/D_w = 2{,}5$ the graphs of the opposite parts are almost convergent, and at $c/D_w = 3{,}5$ they coincide. This indicates that there is no screening effect.

When three cylindrical bodies are placed in parallel, the specific formation of two huge vortices is observed in the windward area of the middle silo. Between the vortices there arise symmetrical flows, the air velocity in which reaches maximum values.

At the distance of $> 2{,}5D_w$, three independent flow regions are formed around each silo. For the aerodynamic coefficient, such an arrangement of the containers causes the following changes. With an equal distance between the centres of the silos, the middle silo has a symmetrical graph C_p .

At the minimum point, it reaches the values of $C_p = -1{,}7...-1{,}95$ at the distance between the centres $1{,}1D_w - 1{,}2D_w$, and at the distance of $c/D_w = 1{,}4$; $d/D_w = 2{,}8$ the minimum value of $C_p = -2{,}3$ is reached. For outer silos, the graphs are asymmetric for the upper and bottom surfaces.

With a very close arrangement of the silos (up to $1{,}4D_w$), a negative minimum of $C_p = -2{,}38$ is reached at around 100º. At the distances of $> 1{,}6D_w$, the graphs of aerodynamic coefficients are smoothed and drawn closer together.

A variant of simulation with diagonal arrangement of silos is shown in Fig. 10.

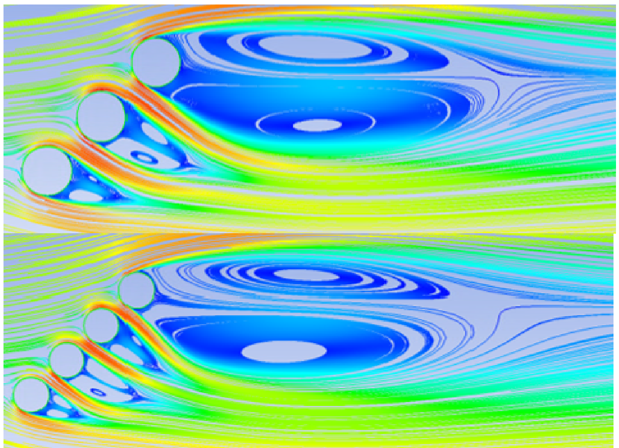

Fig. 10. Simulation of wind action on the system of diagonally located silos.

The position of the silos was regulated by the given values of the distances a/D_w , c/D_w (for two silos). The picture of the eddy zone changes. There is clear deviation of the isolines into the lateral side between the flow objects. As in the previous blows, two vortices are formed behind each of the cylinders in the windward zone; however, they are different in size and for the first object they are distinguished with discernable asymmetry and lateral direction. For the second silo, which is located more remotely, the asymmetry of paired vortices is practically indiscernible. The total length of the wake boundary is four times greater.

The distribution curve of aerodynamic coefficients also lacks symmetry. For the first silo the difference in zero points of the aerodynamic coefficient on the lateral surfaces is 15º, while for the second silo it is only 6º. At $a/D_w = c/D_w = 1{,}1$, the maximum values of the aerodynamic coefficient are within $C_p = -1{,}1...-1{,}16$, at $a/D_w = 1{,}2$, $c/D_w = 2$, they grow to $C_p = -1{,}15...1{,}27$, at $c = 3D_w$ they practically do not change $C_p = -1{,}18...-1{,}25$. The shape of pressure distribution graphs for three silos is asymmetrical in its upper and lower parts. It should be noted that angular displacement along the contour is caused by various stall points. Quantitatively, t aerodynamic coefficients are large. For the distances of $1{,}1D_w$ between the centres, the minimum aerodynamic coefficient of the middle cylinder is $C_p = -1{,}55$, for the most distant silo it is $C_p = -1{,}40$ and it will be $C_p = -1{,}38$ for the nearest one. At a distance, the minimums of silo 1 and silo 2 reach $C_p = -1{,}5$.

Development of the flow for a row of four silos is similar. It is characterized by the presence of two large-scale concentrated vortices behind silo 4 and curved eddy zones for the rest silos. At a distance of $1{,}0D_w$ in both directions, the maximum values of the aerodynamic coefficient were in silo 3 - $C_p = -1{,}38......1{,}5$, with the increase to $2{,}5D_w$ for silo 3 - $C_p = -1{,}3$. For other silos, the values did not exceed this value.

3 Conclusion

1. In computer modelling of the wind action on silos, it was found that the value of the aerodynamic characteristics (pressure, drag and lift coefficients) of experimental models depend heavily on the appropriateness of the taken turbulence model and on the quality of the computational meshes.
2. Based on the carried out verification tests, a special technique was developed for constructing finite element meshes for the tasks of modelling wind action on silos.
3. Simulation of two-dimensional and three-dimensional flow around simple silo parks at high Reynolds numbers has been performed.
4. Based on the results, the studying of the kinematic spectrum and interferential interaction of models of groups of two, three and four silos (400 variants of blowing) were carried out at various angles of attack of the wind current within the framework of 2D modelling.
5. We have obtained wind pressure curves for each of the cylindrical bodies in the group for different initial conditions. The analysis of their values has also been carried out in this academic research.
6. It has been discovered that wind actions on a silo in a silo park can significantly exceed the action on a separate silo.

Abstract. Among many tasks to be done by the state, the most significant is a social-economic one i.e. provision of its citizens with affordable, long-lasting, energy- efficient and economical housing. One of the ways of doing the given task is the application of concrete-filled steel tubular (CFST) structures, for the elements of a building, of circular, square or rectangular type. It is also possible to use such structures not only for a new housing stock but in the reconstruction of present one at the expense of additional storeys (about 20); without demolition and total resettlement of tenants of the house under reconstruction. Alongside with this, there is an opportunity to increase total area of residential houses and make new types of comfortable place of various purpose.

1 Introduction

At present buildings from monolithic reinforced concrete in shallow and large-panel formwork are erected using large-block and frame construction technology. Volume of brick, panel and frame-panel house construction has declined strongly. Expansion of monolithic-framing house construction causes considerable capital investments connected with frameworks, depends on weather conditions, it is characterized by big material consumption and accordingly construction cost and terms.

In foreign construction practice the most widely used are not bearing monolithic building envelopes or reinforced concrete columns but as well as combined frame-core system with a bearing core made of monolithic reinforced concrete and external frame made as a bearing shape of columns peripherally located to a building, which is rationally combined with horizontal outrigger-foundation frame work located in every 15-25 storeys [1-4].

In Australia the first residential building (46 storeys) was built in 1990 in Melbourne. The core of the building was formed with steel concrete shafts. 24 CFST columns were located peripherally the building. In Japan 57-storey building was built with the use of concrete-filled steel tubes. The base of the building is a CFST framing. Concrete-filled steel tubes are widely used in China in the last decades. A large number of skyscrapers were built in China using CFST frames.

In practice of industrial construction in Ukraine CFST structures are used limitedly until now; there are single examples of the use of CFST columns in residential construction that proved their technological efficiency [5-7].

Concrete-filled steel tubes possess extremely high bearing ability herewith having significantly less cross section of a column. It is the bright example of complex materials that combines optimally strong sides of concrete and metal. Metallic shape functions as a permanent formwork in a CFST column and after concreting process, it reinforces the column either in cross or longitudinal direction that allows to meet any loads applied at any angles. Concrete in such a column is in an optimal state for itself, all-around compression and in such a condition, it withstands loads significantly exceeding its prism strength [1]. The fact is that CFST structures differ in their ability to withstand large loads for a long time in extreme conditions for high-rise and large-span buildings; unlike with steel and reinforced concrete structures losing their bearing ability immediately.

Concrete-filled steel tubes have also their constructive disadvantages. Because of differential Poisson ratios ($\nu s = 0.3$; $\nu b \approx 0.2$), one of the main problems is occurrence of significant enough tensile stresses on the border of concrete core and metallic shape. Such stresses as well as concrete setting can lead to the separation of concrete core from mantle pipe during operation process. When concrete separates, durability of an item is reducing and bearing ability as well in a certain level.

Taking into account such single buildings having been erected before, there was elaborated advanced construction technology using steel concrete framing [10;11], herewith we have an opportunity to reduce steel and concrete consumption as well as we can simplify the structure of braced steel concrete frame of a multi-storeyed building at the expense of the reduction of labour consumption and construction cost.

Technology improvement is provided with mutually perpendicularly located supporting columns and spandrel beams as well as their junction on flooring level; joints are pin connected and frame itself is provided with supporting systems as bracings, joint is pin connected between columns and spandrel beams. Making a frame as a steel concrete one with bracings that are fitted in every span and every storey by the height of a building, includes simultaneously the operation of vertical and horizontal stresses, all elements of framing – columns, spandrel beams, and bracings. Using concrete instead of steel in compression and its filling in compressed elements of a structure causes increasing of local strength of walls, resistance of local failure of thin-wall steel structures in assembling not only in columns and spandrel beams but in joints allowing to reduce total steel consumption.

Bracings are simultaneously interior supports for spandrel beams, that turns them into three-span whole beam, at the expense of that the value of bending moment reduces in spandrel beams and allows significantly (by 1.5…2 times) to reduce their height as well as spans of spandrel beams and columns grid. Pin-connected joint of spandrel beams allows with columns to unify the structure of spandrel beams and bracings, as strains in spandrel beams and bracings slightly differ by dimension independently on their location by the height of a building [3]. The essence of the base of technology is presented on Fig.1. Fig. 2 illustrates the erection stages and the plan of a typical storey.

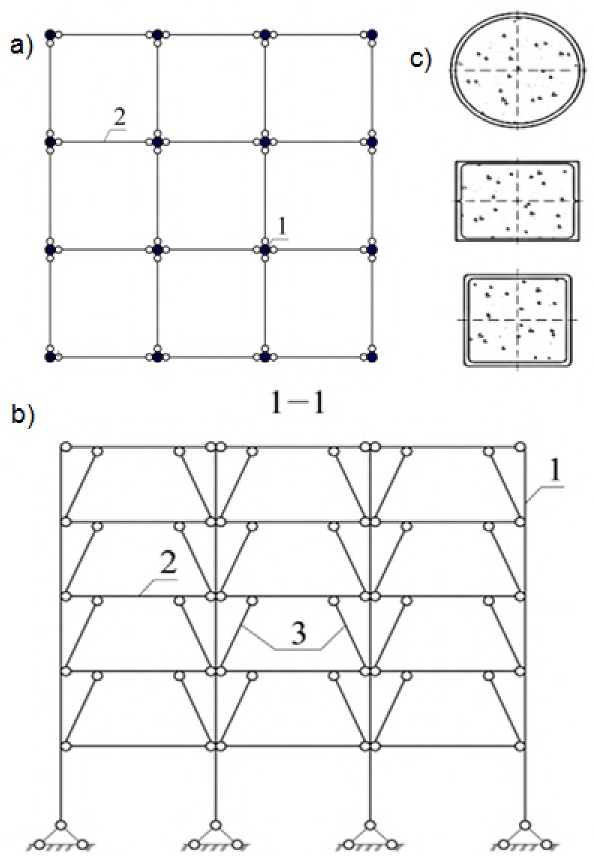

Fig. 1. a) cross section of bracing steel concrete frame; b) longitudinal section of bracing steel concrete frame; c) cross sections of a column and spandrel beams. Where: 1 – CFST column; 2 – spandrel beam; 3 – bracings.

Framing consists of steel concrete columns (1), steel concrete spandrel beams (2) pin-connected with columns and bracings (3), pin-connected with columns and spandrel beams. Therefore, the essential advantage of such a bracing steel concrete framing with bracings is a significant reduction of construction cost.

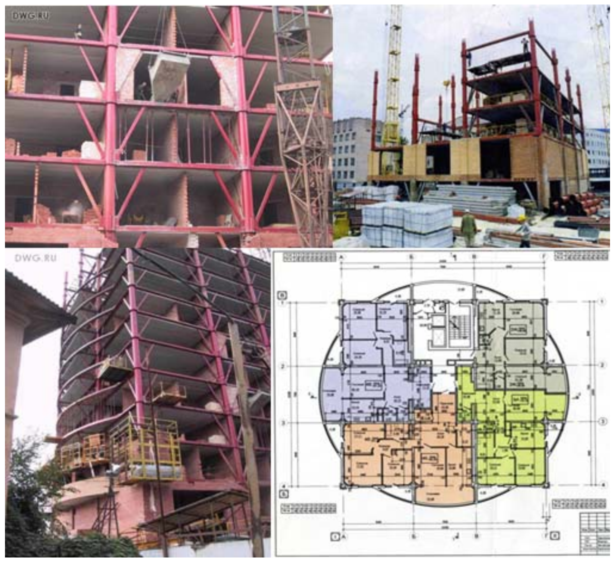

Fig. 2. Erection of buildings with CFST framing in various construction stages.

Reconstruction of residential buildings demands special attention to choose engineering solutions in the improvement of volume-constructive solutions and provision of operating factors with the demands of present regulations [8; 9; 10].

According to the present constructive solutions, there are three types of a superstructure (Fig. 3):

a) General, without strengthening a present building, superstructure is a high extension of a building saving its constructive scheme; it allows 2-3 additional storeys;

b) Changing its constructive scheme. The given method suggests redistribution of load transmission scheme from the weight of additional storeys and existing building on bearing members loading them equally allowing additional 4-5 storeys.

c) Superstructure plant that is not connected with bearing structures of the present building and supports on individual structures. Such a superstructure can be erected over any building. Essentially, with additional storeys their stress is given to reinforced concrete slab located on columns which are located uniformly by the perimeter of a building and support on their own foundations allowing to add 10-20 storeys. Fig.1 shows the considered variant of additional storeys. More often similar superstructures are made of reinforced concrete or metallic structures, however, in comparison with metal structures with the same bearing ability, metal consumption reduces twice on average for CFST members but comparing with reinforced concrete ones – section of shotcrete members and concrete consumption reduce twice.

In a technological way a steel pipe plays a role of a formwork that significantly simplifies work operations but constructively it plays a role of a case and longitudinal rigid reinforcement. Simple production technology, high construction velocity in the erection of monolithic buildings, essential metal economy at the expense of increased bearing ability and significant fire resistance make the structures made of steel pipes filled in with concrete more attractive. Researches show much higher strength of columns in comparison with traditional reinforced concrete ones; it is determined by concrete operation in the condition of triaxial compression. [12-16].

2 Methods

As concrete-filled steel tubes are a complex material, there are some difficulties in calculation complex. With this purpose we used the methods of unit stiffness, herewith section of a shotcrete member carried into an equivalent section of concrete with a diameter by the formula:

$$D_{red} = \sqrt[4]{D^4 + 8\alpha\delta D_s^3} \qquad (1)$$

where: α — ratio of inertia and concrete modulus of elasticity and outer metallic shape;

D_s – outer diameter of steel shape;

D_b – outer diameter of concrete;

D_{red} – outer given diameter of section.

According to the given method in calculation the presented value of concrete section increases by 2-5 cm depending on concrete grade, steel grade and thickness of a tube wall. Results are given in Table 1 [16].

Table 1 Presented section of CFST members.

Outer diameter of a pipe, cm	Thickness of a pipe wall, δ cm	Concrete grade, B	Outer presented diameter of outer presented section, D_{red}, cm	Modular ratio, α
42.6	0.5	B20	47	0.8

		B50	54	0.4
		B60	54	0.4

3 Results and discussion

As the possible variant of using steel reinforced concrete structures in mass civil construction of a new housing or the reconstruction of an old one, there was elaborated the structure of a superstructure of five-storey residential building (‘Khrushchev-era house’) with the aim of its redevelopment, its frame consists of CFST members.

The structure of a superstructure represents itself as a stack-frame with vertical bearing members, it is two-member columns connected between each other with П-shaped multi-layered frames by girder system, beams and bracings of shaped pipes of square and rectangular section filled in with concrete that ensure space stiffness of a building in cross and longitudinal directions. Step of portal frames was 6.3 and 8.4 m and associated with the location of partition walls in the present building (Fig. 4).

Loads on the present frame members were taken according to the present regulations. Joint between constructive members of the scheme is presented as pin-connected; eccentricity of load transmission from a girder to columns was considered in calculation as well. Strains occurring in the design model are given in Table 2.

According to DSTU (National Standards of Ukraine) I.1.2.-3:2006 «Bendings and motions» (v.4, p.1) regulations limited horizontal motion of multi-storeyed building should be at most h/500, i.e. – 100 mm.

according to the calculation results, minimum bending occurring in a superstructure does not exceed 34 mm. Mosaic of motions is presented in Fig. 5.

From designing experience and obtained results, it is known that shotcrete framing with flooring of hollow slabs allows to reduce cost of a frame 20-30% and shorten construction terms twice. Table 3 demonstrates the parameters of the used CFST frame members.

Flooring is made of pre-fabricated hollow slabs with connectors on lateral areas. Connectors taking main closing strains occurring during the operation of a stiff floor in covering can become monolithic. Provision of strain transfer between members and redistribution of locally applied stresses on neighbouring slabs excludes 'key' effect proper for flooring structures of pre-fabricated slabs without connectors on a lateral surface (Fig. 6).

Table 3 Section parameters of the members of CFST framing.

Column members	Sketch	Sections, mm	Supporting strains		Steel grade
			M kH×m	N kH	
Section “b, c’’		Pipes 630x10	From 234 to 288	From -890 to -5223	St3ps
Section “e”		Pipes 630x10	From 586 to -753	From -1390 до -8840	St3ps
Section “d”		Pipes 630x10	From 586 to 994	From -796 to 8940	St3ps
Girder members in all sections		200x200x6	-	From -343 to -1680	St3ps
		180x180x6	-	From -157 to -7776	St3ps
		100x200x11	From -51.3 to 47.5	From -1036 to 1010	St3ps

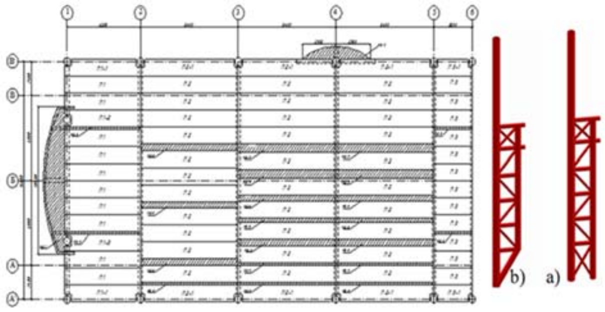

Fig. 6. Monolithic scheme of slabs (7-17 storeys) and two types of columns.

Statistically the floor is the only system where flooring slabs support on spandrel beams of framing and jointed at the expense of longitudinal linear pins. Only cross and longitudinal strains can be transferred through these pins. To make proper stiffness it is necessary to make monolithic stitches and connectors in floorings in vertical and horizontal directions. To reduce bendings it is necessary to make all the flooring members prestressed, herewith the possibility of uneven failures reduces significantly and thus conditions of cooperated work of floorings in slabs can improve. Flooring members acquire the ability to work with shear after hardening of mortar in all stitches.

Calculation of strains and section selection in the scheme elements were made in DK LIRA 9.6 R7. Two variants of a design model were considered (Fig. 9.): two-member lattice column with two supporting points on a foundation (a); lattice column with one supporting point on a foundation (b);

Having obtained strains in the complex LIR-STK there were selected sections of metallic profiled pipes.

Section of CFST members was selected by the methods of L.I. Storozhenko offered in the project of DSTU (National Standards of Ukraine) to DBN (Ukrainian National Construction Regulation) I.2.6 – 160 – 2010 «Steel reinforced concrete structures».

Metal consumption was: columns – 9.1 t; one girder – 3.7 t; whole framing - 423 t. The consumption of monolithic concrete (grade V40) for filling in columns and compressed forms– 355 m3

4 Conclusion

1. Saving steel at the expense of : usage of concrete instead of steel in compression not only in columns and spandrel beams but in bracings; filling in with concrete and increasing of local strength of pipe walls, resistance increasing to local failures of thin-walled steel structures in assembling; three-dimensional operation of framing under horizontal stresses; absence of significant bending moments in columns causing eccentricity in joints as a result of pin-connected spandrel beams with columns; reduce of bending moment in spandrel beams at the expense of bracings which are like additional intermediary supports.

2. Reduction of labour intensity for assembling, construction terms due to: reduced cost of borrowed financial means at the expense of transferring a large number of operations connected with steel structure production from a construction site to a plant, i.e. metal structures production, partial filling in with concrete; unification of steel concrete spandrel beams and bracings independently on the location of members by the height of a building; assembling of prefabricated structures, reduced length of weld seams as the result of pin-connected joints and absence of stiff joints.

3.Reduction of size and cost of foundations at the expense of: reduction of total mass of steel concrete framing in comparison with reinforced concrete framing; absence of bending moment in supporting pin-connected joint of a column and foundation.

Prospects of application of roller compacted concrete in hydro schemes of Ukraine

Svitlana Butnik[1,*], and *Andrii* Mozgovyi[2]

[1]Kharkiv National University of Civil Engineering and Architecture, Department of Building Technology, 40 Sumska Str., Kharkiv, 61002, Ukraine
[2]Kharkiv National University of Civil Engineering and Architecture, Department of Geotechnics, Underground and Hydrotechnical Structures, 40 Sumska Str., Kharkiv, 61002, Ukraine

Abstract. Prospects of application of roller compacted concrete in hydro schemes of Ukraine are considered. The number of dams erected with application of roller compacted concrete is growing year after year in the world. Roller compacted concrete is an especially dry concrete mixture with decreased content of cement and increased content of pozzolana (fly ash). The broad physico-mechanical peculiarities of roller compacted concrete depend not only on its composition but also on technology of its laying and compacting in dam. Rapid construction of gravity dams with use of equipment for earth-moving works enables the more economic construction of protective embankments. Prospects of application of roller compacted concrete during erection and restoration of existing protective embankments in regions with increased flood hazard in the west of Ukraine are considered. The use of roller compacted concrete allows reducing construction deadlines by a factor of 2–3, and, in so doing, reducing the labor content by a factor of 4–5 at the expense of full mechanization of works. Decrease in content of binder in composition of roller compacted concrete by 30–80 kg/m^3 favors decrease in heat release and, correspondingly, the occurrence of temperature contraction cracks, which in its turn favors economy during construction of hydro-technical structures of hydro schemes.

1 Critical review of the present state of art of application of roller compacted concrete in hydro-technical construction

Application of roller compacted concrete is the most important achievement in technology of erection of concrete dams over the last forty years. The use of roller compacted concrete allows reducing deadlines of construction of dams by a factor of 2–3 and, in so doing, reducing the labor content by a factor of 4–5 at the expense of full mechanization of works [1]. Besides, application of roller compacted concrete gives designers the possibility of economical restoration of existing concrete dams that do not have sufficient resistance against shear and require installation of counterforts, and also the possibility of reconstruction of dams made of soil materials.

Rapid worldwide acceptance of roller compacted concrete is a result of its economically successful application in combination with high technological properties. The idea of combination of advantages of laying of loose materials and concrete as a construction material for dams was developed in 1960s. Materials that can be considered as roller compacted concrete were used during 1960s–1970s [2–3].

The idea of roller compacted concrete arose not by chance, and already in 1961–1964 years in Italy in construction of gravity dam Alpe Gera (height 174 m, volume of concrete 1.7 million m^3), and also in 1969–1979 yr. in USSR in construction of Toktogul’skaya dam (height 215 m, concrete volume 3.2 million m^3), for the first time the technology of single-layer concreting (layers thickness 0.5–1 m) of big blocks with area up to 2.5 thousand m^2 was successfully used [4]. At the above-mentioned hydro schemes for the first time dry lean concrete with cement consumption of 115–150 kg/m^3 was used, which levelling was performed by small-sized bulldozers, and compaction – by suspended packs of vibrators.

Rapid construction of gravity dams with the use of equipment for earth-moving works including big rollers for compaction was proposed in 1965 as a viable approach to the more economical building of dams [5]. Nevertheless, it had not attracted big attention till in 1970 J.M. Raphael presented it as “optimum gravity dam” [6]. Later, a number of ideas based on the theory of soil cement were presented, and also the conception of laying and compaction of embankment with material enriched with cement with the help of complex equipment for compaction was proposed. In time, this resulted in considerable decrease in cross-section of dams made of roller compacted concrete compared with traditional rock-fill dams [3]. Later, the ideas of J.M. Raphael were realized by other engineers in application of enriched

* Corresponding author: butniksvet@gmail.com

mixtures instead of lean ones in upstream and downstream faces of dams [3].

In 1970s a number of organizations carried out a complex of laboratory tests to study properties of monolithic roller compacted concrete. In time, designing dams made of roller compacted concrete was developing in three different directions. Those were alternatives developed by Corps of Engineers of USA, British engineers, and the group of researchers from Japan. Corps of Engineers of USA developed the alternative of lean concrete on the basis of the technology of processing of soil. The British engineers concentrated on the method with high content of paste, and the group of Japanese researchers created a new conception known as RCD (dam of rolled concrete) [3].

The goal of the investigation is a critical review of tendencies of application of roller compacted concrete, existing in the world, in hydrotechnical construction, determination of main advantages and disadvantages of this technology. The tasks of the investigation are determination of the area of application of roller compacted concrete to erect new and restore existing hydrotechnical structures to satisfy vital needs in Ukraine.

2 Technological aspects of application of roller compacted concrete in hydro-technical structures

According to ACI 207.5R-89 terminology the roller compacted concrete is defined as "concrete compacted by roller rolling". Concrete mixture in unhardened state permits motion of construction machines over its surface [7]. Bulletin 126 ICOLD determines the roller compacted concrete as "concrete with non-shrinking consistency in its unhardened state, which is transported, laid, and compacted with the use of equipment for construction of earth-fill dams" [8]. Dynamics of increase of the number of dams of roller compacted concrete in the world by data [9–10] is presented in Fig. 1.

Technological peculiarities of roller compacted concrete are determined by the fact that it is concrete with zero shrinkage, which properties strongly depend on proportions of the mixture and on quality of compaction. Roller compacted concretes are produced from especially dry concrete mixtures that defy compaction by internal vibrators. Their compaction is performed by rolling by vibration rollers, heavy motor cars, pneumatic-tired rollers, and other mechanisms during laying mixtures 0.25–0.75 m [11].

The prepared mixture of roller compacted concrete must be so dry that heavy cars could move over it, and, in so doing, must contain enough water and binder to be amenable to compaction during rolling by mechanisms selected for this purpose.

Because lesser amount of water is used, lesser cement is necessary to prepare equivalent water-to-cement ratio. Lesser amount of water in the mixture causes decrease in shrinkage during solidification, and lesser amount of cement gives lesser heat generation. Decrease in shrinkage during solidification and in heat generation jointly decrease occurrence of temperature contraction cracks. Besides, decreased content of water and rolling by vibration rollers increase specific gravity of roller compacted concrete.

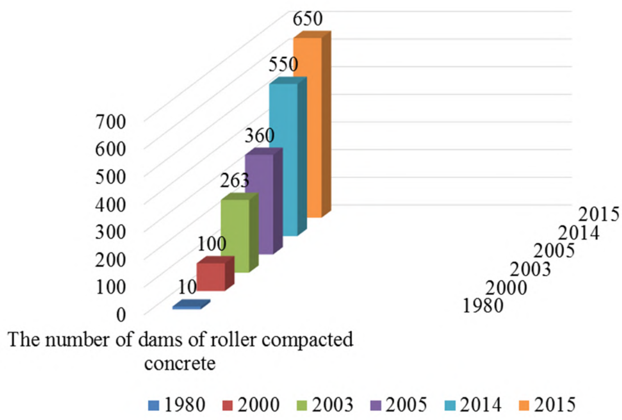

Fig. 1. Dynamics of increase of the number of dams of roller compacted concrete in the world.

Some mixtures of roller compacted concrete can have properties and characteristics similar to conventional concrete, but, for the most part, roller compacted concrete has unique properties that can substantially differ from properties and characteristics of conventional concrete. Roller compacted concrete, as a rule, is transported by trucks or by another way and is kept in heaps or spoil banks in the area of laying. During laying, roller compacted concrete is spread with layers with help of bulldozers and is compacted with help of vibration rollers.

Peculiarities that distinguish roller compacted concrete from conventional concrete are:

– binder content lesser by 30–80 kg/m^3;

– high initial strength, which ensures the possibility of motion of heavy cars and mechanisms over it (with unit pressure up to 1.0 MPa) immediately after laying and compaction;

– low shrinkage (1–5) × 10^{-4};

– low heat release, adiabatic increase of temperature for concrete with astringent content 100–130 kg/m^3 does not exceed 12–14°C;

– density is decreased by 1–5%;

– higher filtration coefficient $1\times10^{-4} - 1\times10^{-8}$ cm/24h;

– deformation modulus is lesser by 10–20%;

– increased nonuniformity: for grain size of aggregate up to 40 mm coefficient of variation of strength value C_v is 0.20–0.22, for aggregate grain size 100–200 mm – respectively 0.27–0.3.

Continuous increase of intensity of laying of roller compacted concrete is observed. Average intensity of laying at large dams reaches 10–14 thousand m^3/24h and 220 thousand m^3/month, which corresponds to intensity of filling of earth dams. Additional increase of intensity is possible at the expense of acceleration of delivery of mixture to a dam.

In world practice there is experience of application of roller compacted concrete not only to build high dams but also to restore small dams of earth materials with insufficient spillway power [12].

On this basis, roller compacted concrete in hydro-technical construction can be actively used in two directions – in new construction and to restore dangerous dams of earth materials.

3 Prospects of application of roller compacted concrete in hydro schemes of Ukraine

The authors of the paper ask themselves a question about prospect and expediency of application of roller compacted concrete in conditions of Ukraine. Proceeding from the real assessment of economic state of our country we consider that application of roller compacted concrete is the most expedient for new construction and also for repairs and reconstruction of existing hydro technical structures.

The performed analysis of existing hydro technical structures of Ukraine has proved that the most prospective direction is application of roller compacted concrete to restore the existing small hydroelectric power plants and to construct new dykes at territories that suffer from floods. Ukraine has significant potential in the field of small hydropower – more than 60 thousand small rivers in the country. This resource can be used to supply energy to both regional centers, and remote areas and villages. Experts from the United Nations and the International Center for Small Hydropower believe that more than 100 neglected Ukrainian small hydropower plants can be reconstructed, and several hundreds of small hydropower projects can be implemented. The relevance of such decisions is reflected in the "Energy Strategy of Ukraine for the period until 2030" and in the updated "Energy Strategy of Ukraine for the period until 2035" [13].

The Carpathian Mountains area is the most promising in terms of reconstruction of former small hydropower plants and construction of new ones. If we consider the most vulnerable elements of the existing dams of small hydropower plants, we should pay special attention to the dam spillways. Due to the use of roller compacted concrete, it is possible to solve a number of such problems as the arrangement of the overflow over the dam crest, the arrangement of the cascade spillway, which extinguishes the energy of the water flow effectively, and strengthening of the existing berm etc. This experience is thoroughly covered in [12].

The urgent issue for Ukraine is the construction of protective and enclosing structures to protect the areas from flooding. First of all, areas in western Ukraine are concerned. According to [14], the floods of 1995, 1998, 2008, 2010 and 2017 in this region caused losses of more than eight billion hryvnias. Large losses to this region were caused by the flood in the summer of 2020.

In Ukraine realization of several state target programs of complex flood protection in the basins of rivers Tisza, Dniester, Prut, and Siret is performed. To date, a complex of protective flood structures that includes 3.5 thousand km of embankments, 1.2 thousand km of coast-protecting structures, more than 600 pumping and compressor plants to pump over surpluses of water is already created. But the complex of protective structures at rivers and reservoirs is insufficient and requires substantial reconstruction of the operating and construction of new ones [15–17].

According to data [18] the protective flood structures are made from local materials, which substantially reduces the cost of construction (see Fig. 2).

Fig. 2. Arrangement of the downstream slope of an earth-filled protective embankment dam [18].

But in earth embankments during each moistening for many years, the smallest particles of ground are washed away, i.e. mechanical suffosion takes place, which leads to natural ageing of the dam and decrease of its reliability [19]. The most typical example of the destruction of the waterside slope protection is presented in Fig. 3. You can clearly see the fact of mechanical erosive leakage, exposure of the reinforcement and its surface corrosion.

Fig. 3. Damaged area of the waterside protection.

Among the 215 existing dams, 16 are in unsatisfactory condition and, correspondingly, require repair (see Fig. 4).

Fig. 5 presents the number of dams classified proceeding from the annual probability of exceeding (provision) the estimated maximum of water consumption.

The main number of dams that are in poor condition and need repairment were built in the 60s and 70s of the last centuries. Accordingly, they are in operation during 57 to 44 years.

Analysis of the number of dams in unsatisfactory condition is shown in Fig. 6.

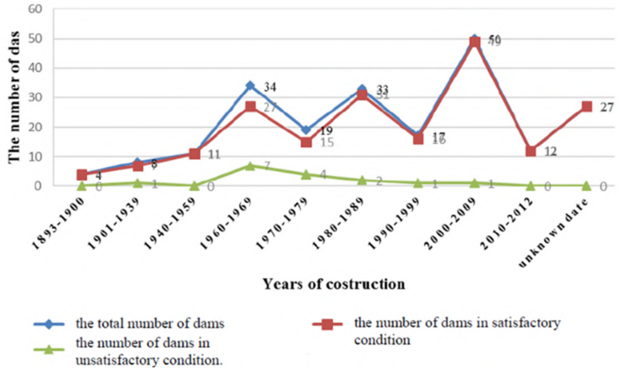

Fig. 4. Number and condition of protective dams in western Ukraine.

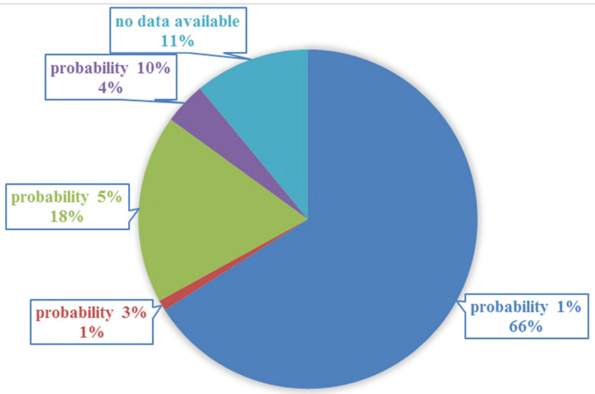

Fig. 5. The number of dams that are classified proceeding from the annual probability of exceeding the estimated maximum of water consumption.

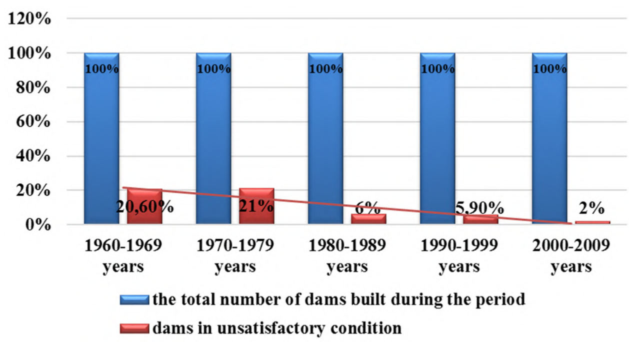

Fig. 6. Number of dams that are in unsatisfactory condition.

On average, 20% of dams that have been operating for more than 50 years are in unsatisfactory condition (see Fig. 6). And accordingly, the shorter the operating time, the lower the percentage of dams in poor condition is.

All these structures belong to the CC2 and the CC1 consequences classes [20]. Respectively, 66% of these dikes/dams belong to the CC2-1 consequences class, 1% to CC2-2 and 18% to CC1.

Assigned service life for buildings that belong to the CC2-2 and the CC1 consequences classes makes 50 years, and for CC2-1 – 100 years [20]. This means that almost half of the existing dikes are approaching their design life or their design life has already expired. Therefore, there is the need for implementation of modern technologies for the restoration or new construction of this type of protective structures.

Significant funds are allocated for repairs every year. But the main constructive decision on reconstruction and restoration of protective and enclosing dams is dumping of rock filling (Fig. 7) sometimes using tinning.

Fig. 7. Reconstructed protective dam to protect the city of Khust from floods (2011) [21].

The fair question arises, why a lot of money should be spent every year on repair and restoration work to face the same problem next year. Maybe it is better to make a reliable building that is resistant to destruction for many years and solve the problem of flooding in this region.

It is the technologies of roller compacted concrete that can solve the problems of construction of new protective dikes and give the possibility to perform high quality reconstruction of already existing ones.

When considering such indicator like the cost of construction, it is necessary to pay attention to accident-free operation of hydro technical protective structures for a long time. Protective structures made from roller compacted concrete are less amenable to eroding action of water stream and permit overflow over the crest unlike dams made of earth materials.

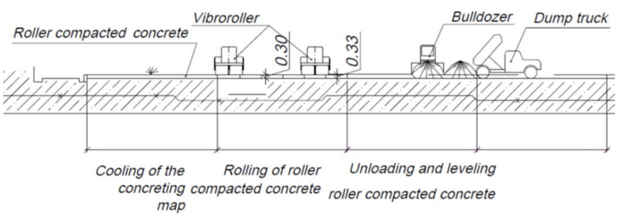

Fig. 8. Technology of roller compacted concrete placing.

Technology of erection of dams from roller compacted concrete should be considered as a part of the uninterrupted construction process with high degree of mechanization of transportation of concrete to the place of laying, its distribution by maps, and compaction. The minimum width of the area of concreting should be considered equal to two vehicle widths (see Fig. 8).

When performing work, it is recommended to have three sites at the same time:

– on the first site the rolling of the placed concrete mix should be performed;

– on the second site the unloading and spreading of the concrete mix should be performed;

– on the third site the preparation of the base for the concrete mix placing should be performed.

The dimensions of the concreting maps should be related to the performance of the mechanisms, concrete pouring intensity and thickness of the RCC layer.

The width of the maps is taken to be at least twice the width of the compacting mechanism, and the length coincides with one of the dimensions of the concreting unit. When compacting the adjacent map, the compacting mechanism must overlap the previous one by at least 0.2–0.5 m.

With limited supply intensity of the concrete mix, the minimum length of the grips should be such that the mix would be placed in a reasonable time and ensuring the effective operation of the compacting mechanism at the same time.

Regardless of the method of supplying of the hard-concrete mix on the concreting map – the height of the pile should not exceed 0.65 m.

When placing RCC, its screeding is done by bulldozers using flat dumps.

The layer should have a slight slope towards the downstream area.

The use of towed vibratory rollers is allowed, if the configuration of the structures allows.

Placing of the concrete mix should be conducted in layers of 33 cm, the calculated thickness of a layer in the compacted condition should be accepted equal to 30 cm (Fig. 8). The deviation of the thickness of the mix layer after screeding is ± 5 cm.

Rolling of the concrete mix requires 4-6 passes of a vibrating roller. The number of passes is specified during the research work.

The first and the last two passes must be made with the vibration exciter off.

One of the main factors that facilitates economic and high-quality construction of dams of roller compacted concrete is their relatively simple construction that requires minimal interference into the process of concrete placement and allows a contractor to perform construction without interruptions and quickly. Due to technology of roller compacted concrete it is not construction that influence technology but technology determines construction of structure. Flood protective dams have simple construction and the technology of roller compacted concrete is the most expedient for their erection.

Quick placement of roller compacted concrete has advantages also in reconstruction of dams that can have only limited time till completion of construction works before re-introduction of structure into operation.

New construction is performed by the traditional technology of roller compacted concrete. Delivery of concrete to a place of laying should be performed in dump trucks.

4 Analysis of composition of binding substances of roller compacted concrete

To prepare rolled concrete, it is necessary to use local materials, crushed stone, sand. Composition of roller compacted concrete is selected by experiment.

Replacement of a part of cement in a composition of roller compacted concrete by fly ash or by natural pozzolana will allow decreasing heat release, and correspondingly will decrease formation of cracks, increases longevity, and allows decreasing a cost of dam construction.

The world experience allows contending that it is due to inclusion of fly ash or pozzolana that this experience can be used in conditions of Ukraine [4]. The data are presented in Table 1.

Table 1. Statistical data on content of binder in roller compacted concrete of dams.

Co-untry	Num-ber of dams/ dikess	Cement consumpti-on, kg/m^3: average/ maximal	Pozzolana consumption, kg/m^3: avera-ge/ maximal	Total binder consumption, kg/m^3: ave-rage/ maximal
China	62	79 / 140	94 / 140	173 / 230
Brazil	52	70 / 80	15 / 50	85 / 100
Japan	41	87 / 96	35 / 78	122 / 130
USA	37	85 / 184	53 / 173	138 / 252
Spain	22	75 / 88	133/ 170	208 / 270

5 Analysis of results

The technology of layer wise erection of dams with the use of rolled concrete is the most effective for construction of concrete dams. It allows decreasing deadlines of construction of hydro schemes by a factor of 2–3 and to reduce the laboriousness by a factor of 4–5 due to full mechanization of concrete works with the use of present-day highly productive equipment, and also due to simplification and more rational organization of construction. Technology of rolled concrete allows creating firm reliable and safe dams (a number of such dams endured several strong earthquakes and did not get any damage).

Dams of roller compacted concrete can be erected in different natural and climatic conditions (hot climate, low temperatures, considerable amount of precipitation).

Regulated technological systems used in erecting dams by single-layer blocks are defined by increased reliability and durability, which allows planning concrete works accurately, and, in so doing, design and actual schedules of concreting as a rule concur. This allows using all highly productive equipment for concrete placement fully.

6 Conclusion

The presented investigations can be used for new construction and reconstruction of existing small hydro power plants and protective dams in regions with increased flood hazard primarily in the west of Ukraine.

In our country there is an urgent problem and potential opportunities for construction and restoration of a significant number of hydraulic structures. Thanks to modern and highly productive technology of roller compacted concrete it can be carried out in the minimum terms and with the maximum productivity.

Abstract. The approach to the formation of the analytical method of evaluation of the stress-strain state of complex rod bearing structural elements is considered in the paper. The prerequisites described cover all the fundamental features of deformation of the components in conditions of tube confined concrete with a strengthened core. This is confirmed by the results of our own experimental studies. The case of central axial compression is considered in detail. From the beginning of loading to destruction of a structural element, two fundamentally different stages of work are distinguished: in the beginning – elastic; closer to destruction – plastic. The method of variable elasticity parameters is used to describe the performance of concrete in the plastic stage. The mutual influence of components during deformation is revealed by solving the contact problem. The methodology was tested by comparing the results of our own experimental and theoretical results.

1 Introduction

Every day the world needs more resources conservation, more efficient use of materials and raw materials conservation. The construction industry is one indicator of this. Consider the use of tube confined concrete as one example.

It is known that in compressed tube concrete elements the active force is perceived by both a tube shell and concrete cores [1, 2]. If in some way to increase the carrying capacity of the core, then it is possible to reduce the cost of steel to obtain a tube confined element with a predetermined bearing capacity [3], which will lead to significant savings in the construction. However, conducting experimental research requires considerable material costs. In such circumstances, it is advisable to attract analytical and numerical research opportunities. Nevertheless, the question of calculating these structures is not straightforward, and there are different views on how to solve them.

The purpose of the presented studies is to formulate the prerequisites for performing the analytical calculation of compressed tube confined concrete elements with a strengthened core, taking into account the previously conducted experimental studies; as well as an assessment of the performance of structural tube confined concrete elements with strengthened cores compared to steel elements.

Analysis of research and publications. Today, buildings and structures that are designed and constructed using tube confined concrete are presented practically all over the world [4, 5]. At the same time, the question of ambiguity in the calculation of such structures hinders the widespread introduction of this combination of steel and concrete, including taking into account the strengthening of their cores.

Considering a number of advantages that draw attention to the presented structures [5-7], the previously conducted experiments were aimed at clarifying the mechanism of development of the stress strain-state of tube confined concrete elements with a strengthened core for a more accurate and specific evaluation of their characteristics [7, 8].

Thus, based on practical experience it is necessary to formulate the prerequisites and construct a general algorithm for the possibility of theoretical evaluation of the stress-strain state of tube confined concrete with strengthened cores.

2 Results

The above-mentioned material is based on the experimental studies conducted by the authors earlier [7-9]. According to the results of these experiments, it was possible to establish the nature of the destruction of the tube confined concrete with strengthened cores of

* Corresponding author: palyvoda87@ukr.net

different structural forms, the distribution of deformations at all stages of loading. Based on all this experience, the following prerequisites have been formed for the theoretical evaluation of the stress-strain state of a tube confined concrete with strengthened cores:

– the materials used for the manufacture of tube confined concrete elements, which are isotropic bodies;

– – work under load of steel reinforcing rod and steel shell is presented in the form of Prandtl diagram (Fig. 1);

– work under concrete loading is presented in the form of its own work diagram (Fig. 2);

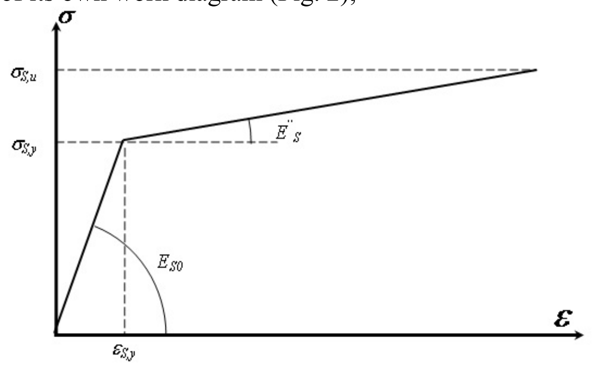

Fig. 1. Dependence of the steel shell deformation module on deformations.

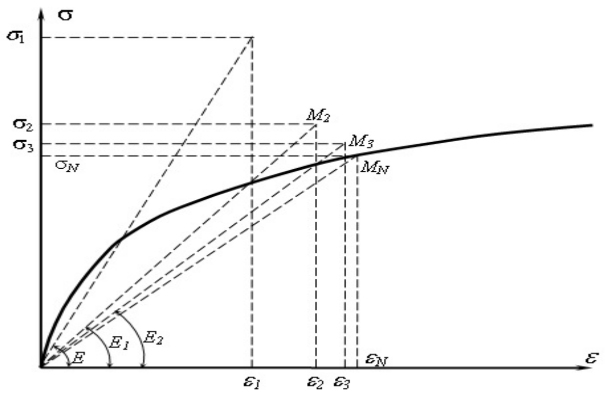

Fig. 2. Dependence of the concrete core deformation module on deformations.

– concrete core, core reinforcement and steel shells work together throughout the loading period;

– in tube confined concrete elements with strengthened cores due to high-strength concrete, the concrete core and the tube-shell work in parallel until the fluidity is reached in the tube-shell and do not affect each other;

– during the whole deformation process the concrete core works with structural and reinforcing steel jointly;

– the materials that make up the tube confined concrete element are considered as isotropic elastic-plastic;

– between stresses and strains in the materials of the tube confined concrete element, a linear dependence is assumed upon reaching the first limit state in strength;

– throughout the deformation process, the longitudinal axis of the concrete element remains straight;

– the flat section hypothesis is considered valid;

– the geometric dimensions of the cross-section and the physical properties of the materials along the length of the concrete element do not change;

– we consider tube-shell, concrete core and reinforcement deform jointly;

– static condition remains: the amount of effort on the longitudinal axis is zero;

– the tube shell works in a flat stress state; concrete core – in bulk; additional rod reinforcement – in uniaxial compression.

2.1. Stage of elastic work of materials

From the beginning, the work of tube confined concrete elements with strengthened cores under the condition of elastic work of steel and concrete is considered. In the general formulation, the task of evaluating the stress-strain state of tube confined concrete elements with strengthened cores is to find fifteen unknowns: displacement (u, v, w); deformation (e_x, e_y, e_z, γ_{xy}, γ_{yz}, γ_{zx}); stress (σ_x, σ_y, σ_z, τ_{xy}, τ_{yz}, τ_{zx}). In this case, a set of such unknowns must be found for each separate component of the tube confined concrete with a strengthened core.

The values of the unknowns must satisfy the equation of continuum mechanics in the area occupied by the experimental element [9]; in particular, the equation of equilibrium equation, and the conditions on the lateral surfaces and on the surfaces of the edges

$$\frac{\partial\sigma_x}{\partial x}+\frac{\partial\tau_{xy}}{\partial y}+\frac{\partial\tau_{xz}}{\partial z}=0;$$
$$\frac{\partial\tau_{yx}}{\partial x}+\frac{\partial\sigma_y}{\partial y}+\frac{\partial\tau_{yz}}{\partial z}=0;$$
$$\frac{\partial\tau_{zx}}{\partial x}+\frac{\partial\tau_{zy}}{\partial y}+\frac{\partial\sigma_z}{\partial z}=0,$$

$$\begin{aligned}&\sigma_x\cos(n,x)+\tau_{xy}\cos(n,y)=X_n=0; && \tau_{xz}=f_1;\\ &\tau_{yx}\cos(n,x)+\sigma_y\cos(n,y)=Y_n=0; && \tau_{yz}=f_2;\\ &\tau_{zx}\cos(n,x)+\tau_{zy}\cos(n,y)=Z_n=0, && \sigma_z=f_3,\end{aligned} \quad (1)$$

where f_1, f_2, f_3 – given functions on the edges with $z = 0$ and $z = l$.

The stresses are represented by deformations by Hooke's physical equations:

$$\begin{aligned}&\sigma_x=\lambda\theta+2\mu\varepsilon_x; \quad \sigma_y=\lambda\theta+2\mu\varepsilon_y; \quad \sigma_z=\lambda\theta+2\mu\varepsilon_z;\\ &\tau_{xy}=\mu\gamma_{xy}; \quad \tau_{yz}=\mu\gamma_{yz}; \quad \tau_{zx}=\mu\gamma_{zx},\end{aligned} \quad (2)$$

where

$$\theta=\varepsilon_x+\varepsilon_y+\varepsilon_z; \quad \lambda=Ev\big/\left[(1+v)(1-2v)\right]; \quad \mu=E\big/\left[2(1+v)\right]$$

Deformations are shown by moving along the equations of Copies:

$$\begin{aligned}&\varepsilon_x=\frac{\partial u}{\partial x}; \quad \varepsilon_x=\frac{\partial v}{\partial y}; \quad \varepsilon_x=\frac{\partial w}{\partial z};\\ &\gamma_{xy}=\frac{\partial u}{\partial y}+\frac{\partial v}{\partial x}; \quad \gamma_{yz}=\frac{\partial v}{\partial z}+\frac{\partial w}{\partial y}; \quad \gamma_{zx}=\frac{\partial w}{\partial x}+\frac{\partial u}{\partial z}.\end{aligned} \quad (3)$$

2.2 Stage of plastic work of materials

It is experimentally proved that the relationship between the compressive force and the deformation does not retain a linear dependence, when reaching 70-90% of N_{1i} and becomes curvilinear. The reason for this is the appearance of plastic deformation. Application of the provisions of the theory of elastic-plastic deformations, as pointed out by A.A. Ilyushin [10], is possible only in conditions of simple loading. That is, when all components of the strain tensor change in proportion to one parameter. Under these conditions, the law of generalized curves works. In any stress state, the diagram $\sigma_i - \varepsilon_i$ is similar to the diagram $\sigma - \varepsilon$ with uniaxial compression (Fig. 1, Fig. 2). In this case, the elasticity modulus is replaced by the variable module E':

$$\sigma_i = E' \cdot \varepsilon_i, \tag{4}$$

where σ_i – intensity of stress,

$$\sigma_i = \frac{1}{\sqrt{2}}\sqrt{\left(\sigma_x - \sigma_y\right)^2 + \left(\sigma_y - \sigma_z\right)^2 + \left(\sigma_z - \sigma_x\right)^2 + 6\left(\tau_{xy}^2 - \tau_{yz}^2 + \tau_{xz}^2\right)};$$

ε_i – intensity of deformations,

$$\varepsilon_i = \frac{\sqrt{2}}{2(1+\mu)}\sqrt{\left(\varepsilon_x - \varepsilon_y\right)^2 + \left(\varepsilon_y - \varepsilon_z\right)^2 + \left(\varepsilon_z - \varepsilon_x\right)^2 + \frac{3}{2}\left(\gamma_{xy}^2 + \gamma_{yz}^2 + \gamma_{xz}^2\right)};$$

$E' = tg\alpha$ – secant modulus of deformation.

In order to describe the work of steel tube shell and steel reinforcement, the dependence in the form is taken [8]:

$$\sigma_i = E'\left(1 - \omega\right) \cdot \varepsilon_i, \tag{5}$$

where $\omega = f\left(\varepsilon_i\right)$, – function of intensity of deformations, nonzero only after the appearance of plastic strains.

The diagram of the steel work is presented in the form of two-branch (Fig. 1). The first branch is the zone of elastic deformation and is characterized by a modulus of deformation $E' = tg\alpha = E_s$; the second is the zone of strengthening and is characterized by $E' = tg\alpha = E_s$. Then

$$\sigma_{si} = E_{s0}\left[1 - \lambda\left(1 - \frac{\varepsilon_{sy}}{\varepsilon_{si}}\right)\right]\varepsilon_{si}, \tag{6}$$

where $\lambda\left(1 - {}^{\varepsilon_{sy}}\!/_{\varepsilon_{si}}\right) = \omega$; $\lambda = 1 - {}^{E_s''}\!/_{E_{s0}}$;

$$\varepsilon_{si} = \frac{2}{3}\sqrt{\frac{1 - \nu + \nu^2}{\left(1 - \nu\right)^2}\left[\varepsilon_{sx}^2 + \varepsilon_{sz}^2 + \varepsilon_{sz}\varepsilon_{sx}\left(\frac{3\nu}{1 - \nu + \nu^2} - 1\right)\right]}$$

2.3 Determination of contact forces

In the case of transferring the load to the tube confined concrete element through a stamp on a complex section, the proportion of force is distributed between the concrete core and the shell in accordance with the ratio:

$$P = P_C + P_S, \tag{7}$$

where P_C та P_S – the proportion of the external force that is perceived by the separate parts of the cross-section of the tube confined concrete element, namely the concrete and the tube shell.

The intensity of the external load on the top edge:

$$q_Z = \frac{P}{A}, \tag{8}$$

where A – area of the complex section of tube confined concrete element.

External load intensity for separate section elements:

$$q_{cz} = \frac{P_C}{A_C}, \quad q_{sz} = \frac{P_S}{A_S} \tag{9}$$

The distribution of the external force between the concrete and the steel part remains unknown. Movement of the edge sections of concrete and steel along the Z axis occurs together:

$$\varepsilon_{cz} = \varepsilon_{sz}, \tag{10}$$

where $\varepsilon_{cz} = \frac{\sigma_{cz}}{E_c}$, $\varepsilon_{sz} = \frac{\sigma_{sz}}{E_s}$, $\varepsilon_{cz} = \frac{P_c}{A_c E_c}$, $\sigma_{sz} = \frac{P_s}{A_s}$.

Thus

$$\frac{\sigma_{cz}}{E_c} = \frac{\sigma_{sz}}{E_s}, => \quad \sigma_{sz} = \sigma_{cz}\frac{E_s}{E_c} = \sigma_{cz} \cdot n, \tag{11}$$

where $n = \frac{E_s}{E_c}$.

To determine the value of the contact force, we used the results reported in [11] D. Weinberg. Fig. 3 shows the geometric part of the problem.

Thus, if the length of the shell and the core are the same size, then the value of the contact pressure is equal to:

$$p = \frac{\frac{\Delta}{d}}{\frac{1}{E_1}\left(\frac{1+k_1^2}{1-k_1^2} - \mu_1\right) + \frac{1}{E_2}\left(\frac{1+k_2^2}{1-k_2^2} - \mu_2\right)}, \tag{12}$$

where Δ – the difference of the diameters of the contact surfaces before the joint, sm;
d – diameter of the contact surface, sm;
$k_1 = \frac{d_1}{d}$ – the ratio of the diameters of the inner body;
$k_2 = \frac{d_2}{d}$ – the ratio of the diameters of the outer body;
d_1 – the inner diameter of the inner body;
d_2 – the outer diameter of the outer body;
E_1, μ_1 – the deformation modulus and the coefficient of lateral distortion of the inner body;
E_2, μ_2 – the deformation modulus and the coefficient of lateral distortion of the outer body.

The calculation algorithm includes the following steps:

1. To identify the proportion of force which is distributed between the elements of the cross section of the concrete

 https://doi.org/10.1051/e3sconf/202128003005

(concrete, steel outer pipe, steel inner pipe, additional reinforcement), depending on the design of the prototype.
2. Evaluate the stress-strain state of the concrete core.
3. Evaluate the stress-strain state of the steel shell.
4. Evaluate the stress-strain state of the additional reinforcement.
5. Calculate the values and sign of the difference between the initial radius of contact surface between the concrete core and the steel tube.
6. Determine the value of the contact pressure between the concrete and the steel tube.
7. Return and carry out items 2-6.
8. Refine the values of the modulus of the materials elasticity and compare with the values at the beginning of the calculation.
9. In the case of differences in the values of the modulus of elasticity by more than 3%, repeat the items 2-8 with the specified values. Otherwise, proceed to item 10.
10. Compare the value of longitudinal deformation of a steel tube with a limit value (approximately 200×10^{-5}).
11. Subject to item 10, complete the calculation is and fix the value of the external force and the longitudinal stress in the concrete core. Otherwise, increase the external force by the incremental value (ΔN) and repeat the calculation according to items 2-10.

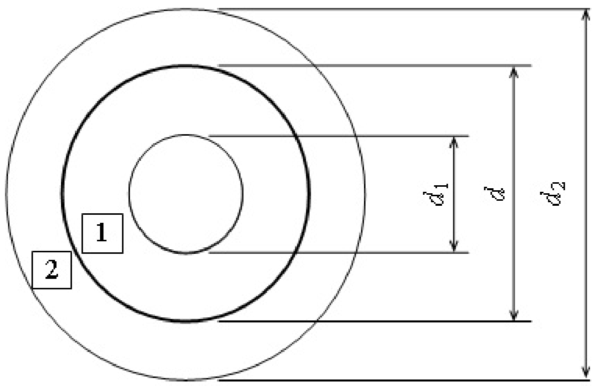

Fig. 3. Scheme before determining the value of the contact force between the elements of the cross-section of the tube confined concrete element.

Fig. 4 shows a block diagram for calculating the carrying capacity of tube confined concrete elements with strengthened cores.

2.4 Implementation of the methodology

Implementation of the methodology, including and design circuits of the elements is presented in detail in [8]. During the development of the method for evaluating the stress-strain state of the investigated structures, it was assumed that the tube shell and the concrete core work in parallel until the tube shell fluidity occurs. As experimental studies of tube confined concrete elements with a core of high-strength concrete have shown that by the time when fluidity occurs in the shell, the latter with the concrete core work in parallel. Later the concrete core and shell work together. Feature of deformation of prototypes is symmetry with respect to the central axis. For convenience, the stress-strain state is described with cylindrical coordinates.

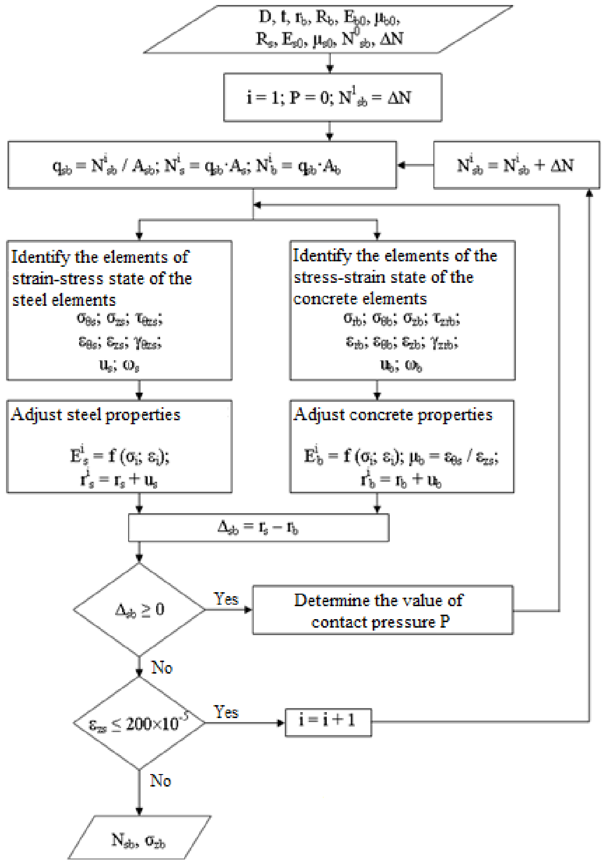

Fig. 4. Block diagram of the calculation algorithm of tube confined concrete elements with strengthened cores.

In addition, we consider it necessary to mention that several factors given in this paper have been taken into account in order to construct a method for evaluating the stress-strain state of a steel tube [8]. They are the following: the calculation of tube confined concrete is performed by an iterative method with changing the parameters of elasticity; within a separate stage of calculation, the work of the steel tube is considered elastic; we consider the stress-strain state of a tube as the sum of states at simple loads. So as simple loads we accept: longitudinal compression; uniform internal compression; uniform external compression. To do this, we use known results from [12].

2.5 Testing of methodology

During the experiments, the following series of samples were tested:

Samples series	Tube external diameter, D, [mm]	Tube wall thickness t, [mm]	Concrete strength, fck.prism, [MPa]
T-I-1	110,6	2,75	–
T-I-2	163,0	5,50	–
T-I-3	204,4	5,20	–
T-I-11	110,6	2,75	50,0
TC-I-12	110,6	2,75	64,2
TC-I-13	110,6	2,75	80,0

 https://doi.org/10.1051/e3sconf/202128003005

Samples series	Tube external diameter, D, [mm]	Tube wall thickness t, [mm]	Concrete strength, fck.prism, [MPa]
TC-I-21	163,0	5,50	50,0
TC-I-22	163,0	5,50	64,2
TC-I-23	163,0	5,50	80,0
TC-I-31	204,4	5,20	50,0
TC-I-32	204,4	5,20	54,2
TC-I-33	204,4	5,20	80,0

Experimental investigations of tube confined concrete elements with high-strength concrete cores have proven that, by the time of the appearance of fluidity in the shell, the latter with concrete core work in parallel. Therefore, when developing a method for evaluating the stress-strain state of such structures, we believe that the tube-shell and the concrete core work in parallel until the fluidity of the tube shell begins (Fig. 5). At a later stage, the concrete core and the shell work together.

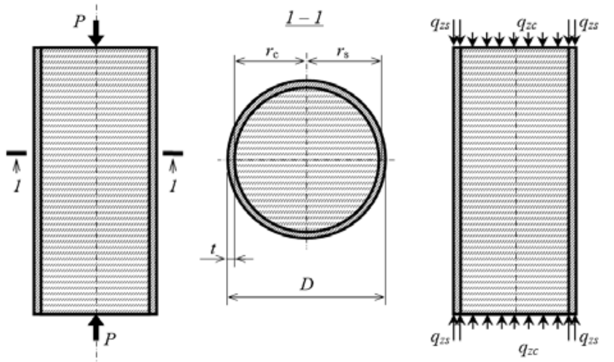

Fig. 5. Design diagram of tube confined concrete element with high-strength concrete core.

The peculiarity of the deformation of the studied samples is the symmetry about the central axis. For convenience, the stress-strain state is described using cylindrical coordinates. In this case, the components of the stress-strain state are not dependent on the angle θ (Fig. 6) [8].

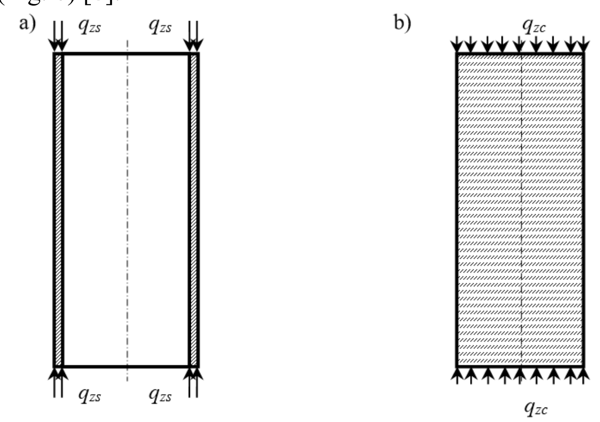

Fig. 6. Design diagram of tube shell (a) and high-strength concrete core (b).

Using the above calculation method, the carrying capacity of centrally compressed concrete elements with strengthened cores was calculated. The boundary condition is the moment of transition of the outer shell material from the elastic to the elastic-plastic stage of operation. The results of comparing the experimental results of the carrying capacity with the theoretical data are shown in Table 1.

Table 1. Comparison of theoretical and experimental data.

Sample series	Carrying capacity, [kN]		
	experimental	**theoretical**	**difference, %**
TC-***I***-11	652	567	-13
TC-***I***-12	716	652	-9
TC-***I***-13	869	834	-4
TC-***I***-21	1840	1693	-8
TC-***I***-22	2100	2016	-6
TC-***I***-23	2400	2160	-6
TC-***I***-31	2970	2584	-10
TC-***I***-32	3386	3251	-11
TC-***I***-33	3636	3163	-12

The rational use of tube confined concrete can also be judged by the efficiency coefficients [4, 5, 7]. The first of them characterizes the efficiency of the tube concrete element work as a whole ($m_{b,cf}$), the second coefficient takes into account the efficiency of concrete work in the tube confined concrete element ($\eta_{b,cf}$). Also in the research of this subject we use the coefficient n, which characterizes the relationship between the forces N_1, when the sample reaches the limit state of the bearing capacity when reaching the yield strength in the shell to the complete destruction of the sample N_2

Table 2 compares the results of determining the coefficient of the concrete work efficiency in tube confined concrete elements with strengthened cores.

Table 2. Comparison of theoretical and experimental data of the coefficient η values.

Sample series	Efficiency coefficient η		
	experimental	**theoretical**	**difference, %**
TC-***I***-11	4,13	3,22	-28,3
TC-***I***-12	4,11	3,56	-15,4
TC-***I***-13	3,69	3,31	-11,5
TC-***I***-21	1,75	1,66	-5,4
TC-***I***-22	1,60	1,54	-3,9
TC-***I***-23	1,51	1,59	+5,0
TC-***I***-31	1,49	1,23	-21,1
TC-***I***-32	1,42	1,42	0,0
TC-***I***-33	1,41	1,34	-5,2

3 Conclusion

An analytical method for determining the carrying capacity of tube confined concrete elements with strengthened cores by establishing the stress-strain state of separate cross-sectional elements has been developed. This approach allows us to establish the effectiveness of using concrete of different classes as a core. And also it is possible to evaluate the effectiveness of structural tube confined concrete element with strengthened cores compared to steel elements. The proposed methods for determining the carrying capacity and performance of concrete in tube confined concrete elements with strengthened cores ensure satisfactory coincidence of theoretical and experimental data.

Abstract. The advantages of metal silos in comparison with reinforced concrete are given. Types of silos depending on a wall design are considered. The construction of steel spiral-fold silos and the method of forming a cylindrical body are considered. The general design of a spiral-fold silo is illustrated. Features of the folding lock, its geometry and location are described. The specifics of the construction of spiral-fold silo, which affects their stress-strain state, are analyzed. Listed two calculation schemes of silo depending on the complexity of input information for the computer. The standard documents which regulates the design of steel silo tanks on the territory of Ukraine are analyzed. The main loads and influences which are accepted at calculation of silos are listed. The basic formula of check of the general durability of a wall of a silo is resulted, the components of the formula are decrypted. The algorithm for calculating the spiral-folded silage is given.

1 Introduction

There are many industries which are related with processing of raw materials. They are constantly developing their technologies. This requires the sustainable development of the construction industry, without which the existence of any industry is impossible. One of the most necessary stages in the technological process is material storage. Conventional store is not a rational solution, as it requires significant human labor costs to load and unload material. The solution to the problem was silos for bulk materials. The requirements for modern store for bulk materials are economy, environmental friendliness, larger capacity, rational operation.

For a long time, reinforced concrete structures were used to store the material. These include bunkers and silos, which are used in all industries, agriculture and transport. Silos can be used as warehouses for finished products, or as intermediate containers for storage of raw materials or semi-finished products. Metal silos for storage of bulk materials began to be used relatively recently and they have already confirmed their ability to meet all the requirements for warehouses of this type. In comparison with reinforced concrete silos, they have the following advantages:

– the possibility of factory production of structures;
– less mass;
– ease of transportation;
– speed of installation works;
– lower cost.

For now metal capacitive structures for storage of various types of bulk materials are one of the most common types of building structures. The dimensions of the silos, their shape, methods of support on the foundation, as well as the location in the plan, are assigned in accordance the requirements of the technological process, loading conditions and unloading, as well as based on technical and economic prerequisites. Silos are available in round, square, rectangular, hexagonal and multifaceted. Round silos are preferred due to ease of manufacture. With this shape, the walls work in mainly tensile forces. Therefore, their thickness can be small.

Depending on the type of wall, there are the following types of metal silos: welded silo, panel silos, spiral-fold silo.

The body of the welded silo (Fig.1) is formed of metal sheets, which are connected by welding The advantages of such silos are tightness and durability.

Welded silos are suitable for storage of bulk materials with the smallest sizes of firm parts, such as: cement, coke, slag and others. Disadvantages of these structures are high material consumption and a large number of welds.

The body of the panel silo (Fig. 2) is made of corrugated or smooth panels connected together with bolts. The advantages of panel silos are the opportunity to take large radial load on the material, no welds, high strength. The disadvantages of this option silos are a large number of bolted connections. This type of silo construction is most common in Ukraine and abroad.

One of the most advanced types of thin-walled spatial constructions are highly industrial and economical metal silos of the spiral-fold type (Fig. 3).

The development of these progressive structures is constrained by the lack of studies of the stress-strain state of these shells because these structures have a folding lock.

A number of domestic and foreign scientists have been engaged in the analysis of structures, calculation methods and experimental studies of cylindrical shells of metal silos for strength and stability [3-17]. Mileykovsky et al. [5] in their work presented a computational model of the shell in the form of a scan of a cylindrical surface, which is considered as a ribbed plate with inclined edges. To simplify the calculation, the folding ribs are placed horizontally. The solution of the problem is reduced to the calculation of a cylindrical shell with annular ribs for axisymmetric loading. Trofimov et al. [6] in their work presented the results of an experimental study on full-scale spiral-fold silos.

Studies conducted by the authors showed that the horizontal pressure around the perimeter of the tank can be taken as a uniform, and in height – according to the Jansen's formula with a coefficient of friction – 0,3. It was also found that the initial imperfection of the silo wall between the folding locks has the shape of a sinusoid, which is located symmetrically about the axis of the folding rib. Based on the obtained results, the authors concluded that the leakage of bulk material (grain) is uniform, and additional (ring or local) horizontal pressure can be ignored. Goldenberg [7] describes the experiment of stability of a closed cylindrical shell of a filled silo with often placed horizontal ribs of the folding type. The axisymmetric form of loss of stability of an isotropic shell is accepted. The most unfavorable combination of operating loadings which consider real conditions of deformation of a silo is considered: initial curvature of the wall and its compatible work with the elastic filler. In Heisen's work [8] was investigated the influence of initial imperfections of the surface of the silo shell on the local stability and strength of the wall in the stage of elastic deformation. Nascimento [9] in his work conducted a research of the horizontal pressure in a metal silo with a corrugated wall, and compared the obtained theoretical data, according to different standards. Coelho [10] presented software for calculating the pressure in cylindrical containers with different types of bulk material.

However, the development of spiral-fold silos is constrained by the lack of studies of the stress-strain state of these shells, as these structures have a number of specific design features. There are also no developments regarding the reliability of these silos, though the basic principles of calculation of reliability of metal constructions are developed [16].

The task of this article is to review the design features and analysis of the method of calculation of metal spiral-fold silos and the algorithm of their calculation.

2 Basic material and results

The construction of the spiral-fold silo was developed in 1968 by a German scientist Xavier Lipp, who used the special equipment for processing of sheet metal and used it for the construction of silos spiral-fold [18]. The first silo was built in 1969 in Germany (Fig. 4).

Since the late 60's in Europe they began using the silos with this type of construction. Within ten years of study and research, in practice, this technology has proved successful, and since the early 70's large-scale production of galvanized steel spiral-fold silos has begun.

Fig. 4. The first spiral-fold silo of Xaver Lipp, 1969, [18].

Process of assembling the silo structure is very simple. Steel coils, machines and accessories are transported to the building site where the silo is then constructed – the process is fast, efficient and flexible in terms of silo height and diameter. Unique technology allows for compact and fast installation of high-strength and hermetical silos directly at the construction site, without the use of bolts and welded joints (Fig. 5)

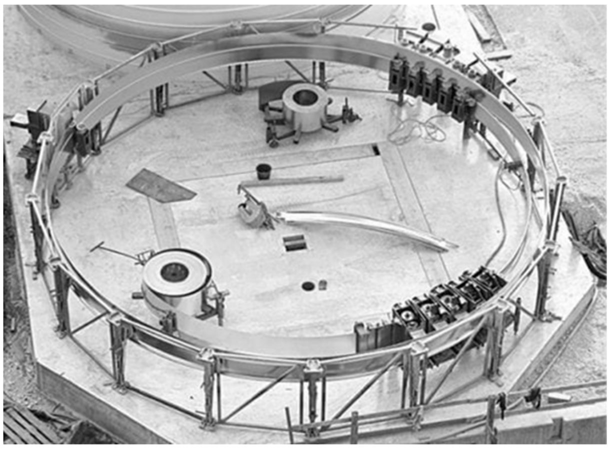
First step of construction (Fig.5, a) is two machines, steel coils and a profile ring are set up on the foundation slab. Once the profile ring and the two machines are in position and have been set up, the construction of the silo starts. The first machine (profiling machine) feeds the steel strip at a slight angle to form a profile. Once the steel strip has completed a revolution, the adjacent profiled strips are brought together in the second machine. They are then folded together tightly. The method of construction is comparable with a screw that moves forward with each revolution as the silo takes shape. The two machines remain in position feeding the steel strip while the silo is formed, growing higher in a spiral.

Second step of construction (Fig.5, b) starts when the silo has reached a height of approximately 2 metres, the top edge is cut level. The roof is then installed or further connectors and parts are fitted or openings are made.

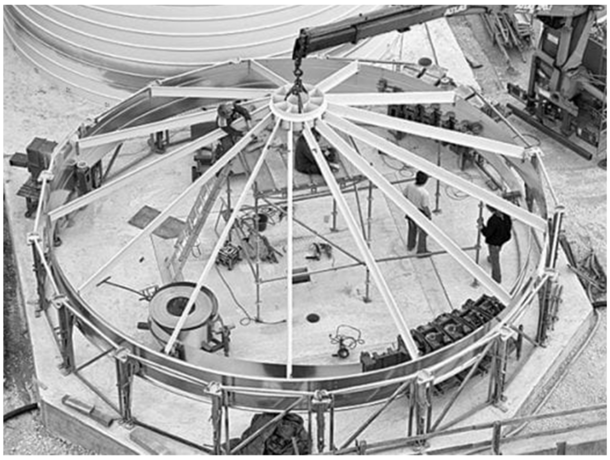
When the roof is installed then starts third step of construction (Fig.5, c). The silo will continue to be formed slowly until it reaches its predetermined height. Ladders and supports will be added during the construction process.

As soon as the desired height has been reached, the bottom edge is cut level and the components are removed from inside the silo. The silo is set down on the foundation slab by reversing the direction of revolution and is then fixed in position, marking the completion of the construction process.

The construction of the spiral-fold cylindrical silo is formed with the help of special equipment, which connects a metal strip (495 mm wide and 2-4 mm thick) in a spiral with the simultaneous formation of the folding lock. The folding lock is located outside the silo wall at a slight angle to the horizontal plane and forms annular ribs. Folding ribs have a height of l_0, consist of the upper and lower halves. They have different geometry, rigidity and pliability. The step of the ring ribs is 365 mm (Fig. 6).



a) first step



b) second step

c) third step

Fig. 5. Process of assembling the silo structure [19].

Spiral-fold silo shell designs are significantly different from traditional corrugated metal prefabricated silos with bolted joints.

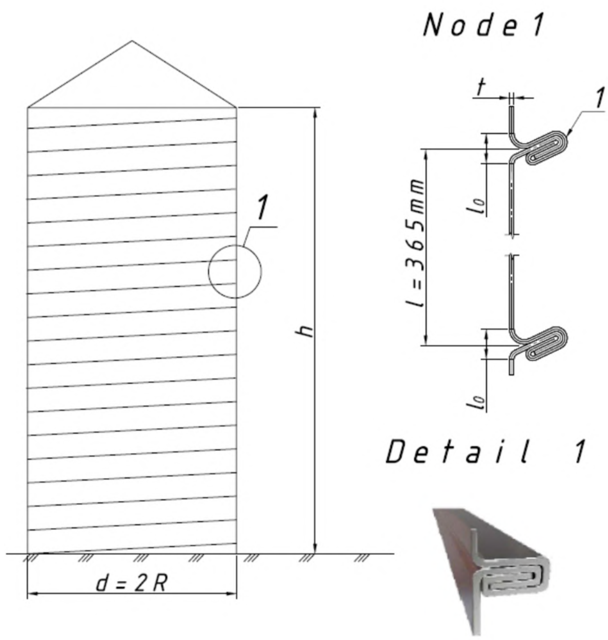


Fig. 6. Construction of a spiral-fold silo.

The specifics of the design of the spiral-fold silo, which affects to their stress-strain state, is as follows:

- The ribs are placed in a spiral, but at a slight angle of inclination of the folding lock, close to 1º.
- These folding ribs work in a complex stress state. They not only increase the rigidity of the silo shell structure in tension and bending in the annular direction, but at the same time reduce the stiffness of the structure, in the transition of the wall to the folding lock. Longitudinal forces generated in the wall of the cylindrical shell, at the location of the ribs, are transmitted from top to bottom with eccentricity, which leads to additional deformation, both in the wall of the shell and between the layers of the rib.
- Depending on whether the silo shell is extended or compressed along the forming line, the stiffness and pliability of the folding lock will be different. In some cases of external influences, such as wind load, requires consideration of the shell as a structural nonlinear system.
- Quite frequent placement of the ribs and the small angle of their inclination allow us to consider it as a system of closely spaced horizontal ribs, and the stress state of the filled silo as axisymmetric.

3 Analysis of normative documents of Ukraine on the calculation of metal spiral-fold silos

The main normative document in Ukraine that regulates the design of metal structures, including thin-walled shells is DBN B.2.6-198: 2014 [20]. This document contains general recommendations for assessing the strength and stability of torsion shells.

Another normative document in Ukraine that regulates the design of steel silo tanks, classification of their structures, determination of loads and forces in the elements is DBN B.2.2-8-98. [21], which was issued to replace SNiP 2.10.05-85 [22]. Additionally, some requirements are given in SNiP 2.09.03-85. [23].

The calculation of spiral-fold silos is considered in detail in [24]. In [24] the calculation scheme is accepted, which in the case of a filled silo, can be solved for all the loads specified in the DBN B.2.2-8-98. [21], both in a simpler and in a more precise formulation.

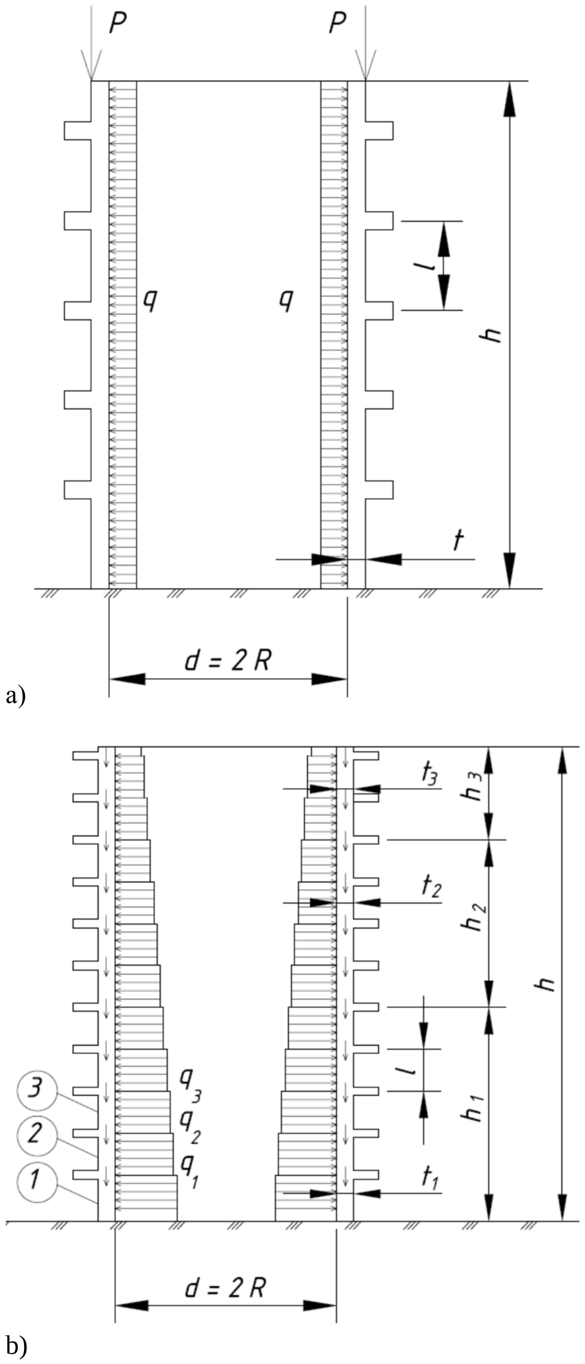

Fig. 7. Calculated schemes of silo a) Simplified; b) Precised.

Simplified calculation scheme (Fig. 7, a) (in the sense of entering the source information for the computer) is reduced to the calculation of a single shell under the assumption that the height of the same thickness, the calculated horizontal load and total vertical pressure are constant and equal to their maximum value. For the lower zone, the maximum values are taken at the level of the upper lower shell.

A more precise calculation scheme (Fig. 7, b) is reduced to the calculation of the entire silo as a cylindrical shell with frequent discrete placement of annular ribs. The calculation is performed on the action of horizontal and vertical load. In each shell, these loads are assumed to be constant and equal. The horizontal load corresponds to the maximum value of the design load at the bottom of each shell. The longitudinal force from the vertical load corresponds to the maximum value of force in this shell, which is applied to its lower edge.

As a calculation scheme of the whole silo, a component system of short shells connected by horizontal folding ribs is accepted (Fig. 6). The height of the short components of the shell is equal to 1^0. The height of folding lock is equal to l_0. It consists of the upper and lower halves, which differ in their geometry, rigidity and pliability.

The main loads and effects on the silo are:

– horizontal and vertical (due to friction) loads from the pressure of bulk materials, taking into account the central unloading of the silo;
– own weight of a construction;
– loads from snow on a covering;
– temperature fluctuation;
– loads from heat cables;
– loads from wind pressure (for unfilled silo).

These loads are temporary (long-term, and short-term), except for its own weight.

4 Algorithm for calculating the spiral-fold silo

Analysis of the normative literature allows to give the calculation algorithm. According to DBN B2.2-8-98 [21], the standard horizontal pressure of bulk materials (kg / m^2) which evenly distributed around the perimeter on the walls of the silos at a depth of Z (m) from the top of the backfill is determined by the formula:

$$P_h^n = \frac{\gamma\rho}{f}\left(1 - e^{-\lambda f z/\rho}\right), \tag{1}$$

where ρ – hydraulic radius of the cross section of the silo, m, which is determined by the formula:

$$\rho = \frac{A}{U} = \frac{\pi r^2}{\pi d},$$

where A, U – area and perimeter of the cross section of the silo, respectively, m^2 and m;
λ is the coefficient of lateral pressure of the bulk material, λ characterized by the ratio of the average values of horizontal and vertical pressure according to paragraph 4.6 [21] and is determined by the formula:

$$\lambda = tg^2\left(45^\circ - \frac{\phi}{2}\right),$$

where e is the basis of the natural logarithm;
γ is the specific weight of bulk materials, kg / m^3;
φ is the angle of internal friction, deg;
f is the coefficient of friction of bulk materials against the walls of the silo, which is taken in accordance with table A.1 [21].

Calculating the structures, the top of the backfill may be taken for silage with a diameter of 12 m and more – at the level of 1/3 of the bottom of the height of the backfill cone. In this case, the depth z (m) from the top of the backfill is determined by the formula:

$$z = h + \frac{d}{2} tg\phi \frac{1}{3}.$$

The annular horizontal pressure of bulk materials is taken to be evenly distributed around the perimeter of the wall with the height of the zone of the annular load equal to 1/4 of the diameter of the silo. The zone can occupy any position on height. Normative value of annular horizontal pressure P_{h1}^n determined by the formula:

$$P_{h1}^n = a_1 P_h^n, \tag{2}$$

where a_1 is the coefficient of local pressure increase, which is accepted in accordance with the requirements of 4.11. [21] depending on the ratio h / d.

The sum of the limit design values (the uniformly distributed horizontal pressures and the annular horizontal pressures) is determined by the formula:

$$\sum P_i = \gamma_{fm}(P_h^n + P_{h1}^n),$$

where γ_{fm} – load reliability factor.

The normative value of the vertical pressure of the bulk material, which transmitted to the walls of the silo by friction is determined by the formula:

$$P_f^n = f P_h^n.$$

The calculated vertical pressure is determined by the formula:

$$P_f^n = 1{,}3 f P_h^n.$$

Under the condition $h<1{,}5\sqrt{A}$, the walls of the silo must be tested for effort on the requirements of pressure, as the walls of the hopper, according to the formulas:

$$P_{hz}^n = \lambda\gamma Z, \; P_{fz}^n = f P_{hz}^n.$$

The calculated vertical pressure is determined by the formula:

$$P_{fz}^n = 1{,}3 f P_{hz}^n.$$

Depending on which results of the calculation of the load from the horizontal and vertical pressures on the wall are bigger (for the silo or for the hopper). Those values are taken into account in the calculations of the silo wall.

The change in the outside air temperature and the temperature difference in the wall thickness by additional horizontal pressure of the bulk material on the silo wall is also taken into account. In order to facilitate the calculations, the pressure is taken evenly distributed around the perimeter and height.

The normative value of this pressure P_{ht}^{n}, MPa (kg/cm^2), is determined by the formula:

$$P_{ht}^{n} = \frac{k_t a_t T_1 E_m}{\frac{d\,E_m}{2t\,E_c} + (1-\nu)}, \qquad (3)$$

where T_1 is the average daily amplitude of fluctuations in ambient air temperature (deg), which is accepted $2\theta_1$, where θ_1 is determined according to DBN B.1.2–2: 2006 [25];
E_m – the deformation modulus of compression of the bulk material is determined by the formula:

$$E_m = 250 \cdot (P_h^n)^{0,63},$$

E_c – modulus of elasticity of the material of the silo walls;
k_t – coefficient, which for steel walls is equal to 2.5;
α_t – coefficient of linear temperature deformation of the wall material, 1 / deg;
d is the inner diameter of the silo, m;
t – wall thickness, m;
ν is the initial coefficient of transverse deformations (Poisson's ratio).

The maximum design load from the additional horizontal pressure of the grain on the wall of the silo, taking into account the temperature difference is determined by the formula:

$$P_{ht}^{p} = \gamma_{fm} P_{ht}^{n},$$

γ_{fm} – load reliability factor.

The maximum calculated snow evenly distributed load is calculated in accordance with current building codes.

The maximum calculated wind is evenly distributed along the perimeter of the silo wall, depending on the type of terrain.

Checks of the total strength of the wall, which is in a momentless stress state, according to 14.1 [20] are performed by the formula:

$$\frac{\gamma_m}{R_y \gamma_c}\sqrt{\sigma_x^2 - \sigma_x\sigma_y + \sigma_y^2 + 3\tau_{xy}^2} \le 1, \qquad (4)$$

where σ_x and σ_y – normal stresses in two mutually perpendicular directions;
τ_{xy} – tangential stresses at the point of the wall of the shell under consideration;
γ_c – coefficient of working conditions of the structure.

The strongest stress of a shell depending on wall thickness is checked for durability.

5 Conclusions

1. The advantages of metal silos in comparison with reinforced concrete are given.
2. Types of silos depending on a wall design are considered.
3. The design of steel spiral-fold silo is illustrated.
4. The specifics of the construction of spiral-fold silo, which affects their stress-strain state, are analyzed.
5. The normative documents of Ukraine regulating the issues of designing steel silo tanks are analyzed.
6. The algorithm for calculating steel spiral-fold silo is resulted: from load collection to strength testing.

Based on the above material, the authors are planning to conduct an experiment on a full-scale silo to compare theoretical calculations with the experiment results.

Abstract. When performing calculations to assess reliability of hydraulic structures of cascades of hydroschemes on the basis of probabilistic methods, the necessity to simulate random natural-climatic phenomena producing loads and effects on hydraulic structures arises. In particular, statistical series of random quantities of such important natural-climatic phenomena are considered: annual lowest average monthly temperatures, annual maximal amplitudes of average monthly temperatures. Each of the enumerated natural-climatic phenomena is characterized by presence of close correlation connections between random quantities when passing from one hydroscheme of the cascade to another. The necessity to consider correlation connections requires construction (simulation) of joint distribution law of random quantities system. The purpose of the work is simulation of joint distribution law of system of random variables that do not satisfy the normal distributions, taking into account correlation connections between random variables when passing from one hydroscheme of the cascade to another. Methods of the theory of correlation and methods of mathematical statistics with the use of software package MathCad were used in the course of the investigation. Simulation of joint law of distribution of system of random variables that do not satisfy normal distributions, taking into account correlation connections between random variables when passing from one hydroscheme of the cascade to another, and also assessment of accuracy of results, that were performed, have shown advantages of this approach from the viewpoint of accuracy of results obtained by different procedures. The results can be used in probabilistic calculations of reliability of hydraulic structures and cascades of hydroschemes.

1 Introduction

Assessment of safety and reliability of hydraulic structures on the basis of probabilistic methods is regulated by normative documents [1–9]. Taking into account the extremely high potential danger of hydraulic structures, improvement of methods of assessment of their reliability is an important and relevant problem. During performing calculations on assessment of reliability of hydraulic structures of hydroscheme cascades, necessity to simulate distribution laws of random natural-climatic phenomena that create loads and effects on hydraulic structures arises. In this investigation the approaches that allow simulating a joint law of distribution of system of random quantities that do not satisfy the normal distributions in the closed form, and also obtaining the conditional distribution laws of random quantities of natural-climatic phenomena taking into account correlation connections, are realized.

2 Analysis of recent researches

Statistic series of random quantities of such important natural-climatic phenomena, obtained by direct measurements in dam sites of hydroschemes of the Dnieper cascade of hydroelectric stations: annual maximal flood discharges $Q_{max,i}$, annual maximal ice thickness $h_{max,i}$, annual lowest average monthly temperatures $t_{min,i}$, annual maximal amplitudes of average monthly temperatures $\Delta t_{min,i}$ were investigated by methods of probability theory and mathematical statistics with substantiation of the proposed distribution laws in investigations [10–12]. Each of the enumerated natural-climatic phenomena is characterized by presence of close correlation connections between the random quantities when passing from one hydroscheme of the cascade to another. Investigations [11, 13] deal with revealing correlation connections between random quantities of

* Corresponding author: mozgovoyandrey@ukr.net

natural-climatic phenomena in hydroschemes of the Dnieper cascade of hydroelectric stations. The necessity to take into account correlation connections between natural-climatic phenomena requires construction (simulation) of joint distribution law of random quantities system, which is realized in investigation [11]. In the mentioned sources, distribution laws of random variables of natural-climatic phenomena, that enter into the system, do not satisfy the normal distributions, therefore approaches to transform them into the normal laws by way of the use of the corresponding transformations were used. Principles of construction of the joint distribution law of system of random variables that satisfy the normal distributions are widely presented in present-day investigations [14–16]. Investigations of two-dimensional and multidimensional joint distribution laws of systems of discrete and continuous random variables that do not satisfy the normal distributions are proposed in investigations [15–31]. Two-dimensional and multidimensional distributions with multiple correlation connections are presented in investigations [21, 23–26]. Application of non-linear regression models is presented in investigation [22]. Multidimensional distribution laws of random variables simulated with the use of the copula theory are presented in investigations [29, 32–39], in particular, hydrologic mode of hydrosystem in flood period is simulated in investigation [32].

The performed critical analysis of the present-day investigations and publications made it possible to formulate the purpose and determine the objective of the investigation. The objective of the investigation is development of the algorithm of construction of joint distribution law of random variables system taking into account correlation dependences between the natural factors: between annual maximal flood discharges of the watercourse (r. Dnieper); between annual lowest average monthly temperature at hydroschemes of the Dnieper cascade; between annual maximal amplitude of variations of temperature of outdoor air at the hydroschemes of the Dnieper cascade; between annual maximal ice thickness at the hydroschemes of the Dnieper cascade.

The purpose of the work is simulation of joint distribution law of system of random variables that do not satisfy the normal distributions, taking into account correlation connections between random variables when passing from one hydroscheme of the cascade to another.

Methods of the theory of correlation and methods of mathematical statistics with the use of software package MathCad were used in the course of the investigation.

3 Results and discussion

Joint density of distribution of continuous system of random variables (X_1, X_2), that satisfy the lognormal distributions [15, 19, 27, 28, 31] is presented by expression (1):

$$f(\gamma_1,\gamma_2) = \frac{\xi^2}{2\pi\sigma_1\sigma_2\sqrt{1-r^2}\gamma_1\gamma_2} \times$$

$$\times\, exp\left\{-\frac{1}{2(1-r^2)}\begin{bmatrix}\left(\frac{10\,log_{10}\gamma_1-m_1}{\sigma_1}\right)^2+\\ +\left(\frac{10\,log_{10}\gamma_2-m_2}{\sigma_2}\right)^2-\\ -2r\left(\frac{10\,log_{10}\gamma_1-m_1}{\sigma_1}\right)\times\\ \times\left(\frac{10\,log_{10}\gamma_2-m_2}{\sigma_2}\right)\end{bmatrix}\right\}, \quad (1)$$

where $\xi = \frac{10}{ln(10)}$, $\gamma_1 = 10^{\frac{X_1}{10}}$, $\gamma_2 = 10^{\frac{X_2}{10}}$;

σ_1, σ_2 – root-mean-square deviations of random variables X_1, X_2;

m_1, m_2 – mathematical expectations of random variables X_1, X_2;

r – correlation coefficient of random variables X_1, X_2.

Distribution (1) presents lognormal distribution on the plane. In this case each of random variables X_1 or X_2 has density of lognormal distribution:

$$f(\gamma) = \frac{\xi}{\sigma\sqrt{2\pi}\gamma}exp\left\{-\frac{(10\,log_{10}\gamma-m)^2}{2\sigma^2}\right\}. \quad (2)$$

Conditional law of distribution of random variable X_2 at a fixed value of variable X_1 has form [31]:

$$f(\gamma_2|\gamma_1) = \frac{\xi}{\sigma_2\sqrt{2\pi(1-r^2)}\gamma_2}\times$$

$$\times\, exp\left\{-\frac{1}{2(1-r^2)}\begin{bmatrix}\left(\frac{10\,log_{10}\gamma_2-m_2}{\sigma_2}\right)-\\ -2r\left(\frac{10\,log_{10}\gamma_1-m_1}{\sigma_1}\right)\end{bmatrix}^2\right\}. \quad (3)$$

But in practical calculations it is more convenient to use expressions (2–3) in closed form [14]:

$$f(\gamma_1) = \int_{-\infty}^{\infty} f(\gamma_1,\gamma_2)d\gamma_2, \quad (4)$$

$$f(\gamma_2|\gamma_1) = \frac{f(\gamma_1,\gamma_2)}{\int_{-\infty}^{\infty} f(\gamma_1,\gamma_2)d\gamma_2}. \quad (5)$$

Conditional mathematical expectation of random variable X_2 at a fixed value of variable X_1 has form [14]:

$$m(\gamma_2|\gamma_1) = \int_{-\infty}^{\infty}\gamma_2\frac{f(\gamma_1,\gamma_2)}{\int_{-\infty}^{\infty} f(\gamma_1,\gamma_2)d\gamma_2}d\gamma_2, \quad (6)$$

and conditional dispersion and standard deviation of random variable X_1 are determined by expressions:

$$D(\gamma_2|\gamma_1) = \int_{-\infty}^{\infty}(\gamma_2-m_2)^2\frac{f(\gamma_1,\gamma_2)}{\int_{-\infty}^{\infty} f(\gamma_1,\gamma_2)d\gamma_2}d\gamma_2, \quad (7)$$

$$\sigma(\gamma_2|\gamma_1) = \sqrt{D(\gamma_2|\gamma_1)}. \quad (8)$$

Conditional mathematical expectation $m(\gamma_1|\gamma_2)$, dispersion $D(\gamma_1|\gamma_2)$ and standard deviation $\sigma(\gamma_1|\gamma_2)$ of random variable X_1 at a fixed value of variable X_2 are calculated analogously By this means five parameters are determined: $m(\gamma_1|\gamma_2)$, $m(\gamma_2|\gamma_1)$, $\sigma(\gamma_1|\gamma_2)$, $\sigma(\gamma_2|\gamma_1)$, r of density of distribution of continuous system of random variables (X_1, X_2), that satisfy lognormal distributions.

The value of random variable X_2 is determined by conditional law of distribution with parameters $m(\gamma_2|\gamma_1)$, $\sigma(\gamma_2|\gamma_1)$:

$$f_{simulated}(\gamma_2) = \frac{\xi}{\sigma(\gamma_2|\gamma_1)\sqrt{2\pi}\gamma_2} \times \times exp\left\{-\frac{\left(10\, log_{10}\,\gamma_2 - m\cdot(\gamma_2|\gamma_1)\right)^2}{2\sigma^2(\gamma_2|\gamma_1)}\right\}. \quad (9)$$

Let us illustrate the presented approach by an example. We simulate the joint law of distribution of two-dimensional system of random variables (X_1, X_2), that satisfy lognormal distributions. Analysis of statistical data on annual maximal amplitudes of average monthly temperatures at hydroschemes of the Dnieper cascade, and also determination of parameters of their distribution functions is performed in investigation [12]. It is presented in Table 1. Selection of function of distribution has been performed by comparison of deviations of probabilities σp and maximal amplitude of monthly average temperatures $\sigma\Delta t$ of actual values from analytical distribution. It is presented in Table 2.

Table 1. Parameters of distribution functions of probability of annual maximal amplitude of monthly average temperatures at geographical places of location of hydroschemes Dnieper cascade.

Item observation	Logarithmic-normal distribution	
	mathematical expectation	standard deviation
t. Vyshhorod	25.16	1.16
t. Kaniv	24.59	1.16
t. Kremenchuk	25.77	1.17
t. Kamyanske	27.43	1.16
t. Zaporizhzhia	27.00	1.16
t. Nova Kakhovka	26.72	1.16

Table 2. Results of assessment of accuracy of calculations of probability of annual maximal amplitude of monthly average temperatures at geographical places of location of hydroschemes of Dnieper cascade.

Item observation	Logarithmic-normal distribution	
	deviations of probabilities σp, %	deviations of maximal amplitude of monthly average temperatures σΔt, %
t. Vyshhorod	2.8	0.4
t. Kaniv	3.7	0.6
t. Kremenchuk	4.2	0.8
t. Kamyanske	2.8	0.5
t. Zaporizhzhia	6.9	0.9
t. Nova Kakhovka	2.9	0.5

It is found that probabilities of annual maximal amplitudes of average monthly temperatures in t. Kaniv, t. Kremenchuk can be presented by lognormal distribution. Parameters of the distributions for t. Kaniv: mathematical expectation $m_{\Delta t1}$ = 24.59 °C, standard deviation $\sigma_{\Delta t1}$ = 1.16 °C; for t. Kremenchuk: mathematical expectation $m_{\Delta t2}$ = 25.77 °C, standard deviation $\sigma_{\Delta t2}$ = 1.17 °C.

Investigation of correlation connections between annual maximal amplitudes of average monthly temperatures by statistical data of observations at t. Kaniv and t. Kremenchuk, carried out in investigation [13], indicates close correlation dependence between annual maximal amplitudes of average monthly temperatures in dam sites of hydroschemes of the Dnieper cascade.

By results of correlation analysis of statistical samples of maximal amplitude of average monthly temperatures of outdoor air, °C, correlation coefficient of two samples at t. Kaniv and t. Kremenchuk is r = 0.871. It is presented in Fig. 1.

The linear regression equation is taken as

$$y(x) = b_0 + b_1 \times x, \quad (10)$$

where $y(x)$ – regression of pairs of statistical series of annual maximum amplitudes of average monthly temperatures in the alignments in the geographical locations of hydropower plants of the Dnieper cascade;
x – statistical series of the annual maximum amplitude of average monthly temperatures along the X axis;
b_0, b_1 – empirical coefficients.

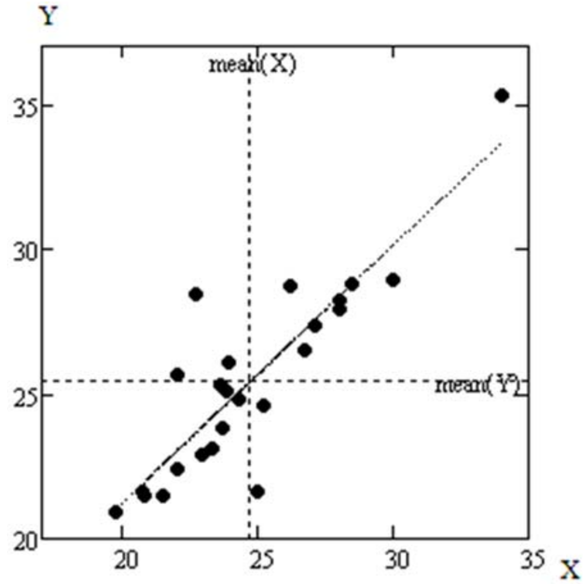

Fig. 1. Graph of the linear regression function of the statistical series of the annual maximum amplitude of the average monthly outdoor air temperatures, °C, observed in t. Kaniv (X axis), for the statistical series of the annual maximum amplitude of the average monthly outdoor air temperatures, °C, observed in t. Kremenchuk (Y axis): - - - – graph of the linear regression function; • • • – statistical series.

Sample correlation coefficients, sample covariance, standard errors are calculated. It is presented in Tables 3, 4, 5.

Using expression (1), we can construct joint density of distribution $f(\gamma_1(\Delta t_1), \gamma_2(\Delta t_2))$ of two-dimensional system of random variables ($X_1 = \Delta t_1$, $X_2 = \Delta t_2$), that satisfy lognormal distributions with parameters for t. Kaniv: $m_{\Delta t1}$ = 24.59 °C, $\sigma_{\Delta t1}$ = 1.16 °C; and t. Kremenchuk: $m_{\Delta t2}$ = 25.77 °C, $\sigma_{\Delta t2}$ = 1.17 °C. It is presented in Fig. 2.

Conditions (11–12), those function of joint density of distribution $f(\gamma_1(\Delta t_1), \gamma_2(\Delta t_2))$ of system of two correlated random variables [14] Δt_1, Δt_2 must obey, – are satisfied

$$f(\gamma_1(\Delta t_1), \gamma_1(\Delta t_1)) \geq 0, \quad (11)$$

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(\gamma_1(\Delta t_1), \gamma_2(\Delta t_2)) d\gamma_1(\Delta t_1) d\gamma_2(\Delta t_2) = 1 . \quad (12)$$

We obtain conditional law of distribution $f(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ of random variable Δt_2 at fixed value of Δt_1 in analytical form by expressions (4–5).

Conditional mathematical expectation $m(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ of random variable Δt_2 at fixed value of Δt_1 is obtained in analytical form by expression (6). Its numerical value is $m(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ = 25.65299 °C. Conditional dispersion $D(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ and standard deviation $\sigma(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ of random variable Δt_2 at fixed value of Δt_1 is obtained in analytical form by expressions (7–8). Their numerical values equal $D(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ = 1.36911 °C^2, $\sigma(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$ = =1.17009 °C.

Random probability of annual maximal amplitudes of average monthly temperatures $p(\Delta t_1) = p(\Delta t_2)$, distributed from 0 to 1 is specified. By known probability of amplitude of average monthly temperatures $p(\Delta t_2)$, using conditional distribution law (9) with parameters $m(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$, $\sigma(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$, we determine the quantile – the value of amplitude of average monthly temperatures $\Delta t_{2\ simulated}$.

The value of random variable Δt_2 is determined by conditional distribution law (9) with parameters $m(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$, $\sigma(\gamma_2(\Delta t_2)|\gamma_1(\Delta t_1))$. It is presented in Fig. 3.

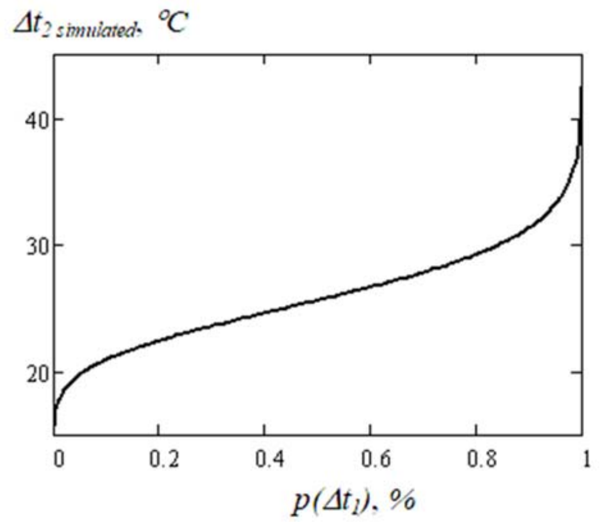

Fig. 3. Probability curve for annual maximal amplitude of average monthly temperatures at dam site of Kremenchuk hydroscheme (t. Kremenchuk) on the coordinates $\Delta t_{2\ simulated}$, °C – annual maximal amplitude of average monthly temperatures, $p(\Delta t_1)$, % – probability.

In investigations [11], substitution of

$$\Delta t_{cond,i} = a \times mean(\Delta t) \left(\frac{\Delta t_i}{mean(\Delta t)}\right)^b, \quad (13)$$

$i = 1 \dots n$, into output statistical series was used to transform laws of distribution of statistical data of annual maximal amplitudes of average monthly temperatures at hydroschemes of the Dnieper cascade into normal distributions, where Δt_i – corresponding members of the output statistical series, $\Delta t_{cond,i}$ – corresponding members of the transformed statistical series; $mean(\Delta t)$ – the average value of annual maximal amplitude of average monthly temperatures of the output statistical series; *a, b* – empirical coefficients. It is presented in Table 6.

Table 6. Parameters of transformation (13) of distribution laws of annual maximal amplitude of monthly average temperatures Δt, °C at geographical sites of location of hydro schemes of Dnieper cascade.

Item observation (reservoir)	*mean*(*Δt*), °C	Coefficients

Kaniv Reservoir (t. Kaniv)	24,733	1,05	0,15
Kremenchuk Reservoir (t. Kremenchuk)	25,458	1,01	0,25
Dnieper Reservoir (t. Zaporizhzhia)	25,975	1,04	0,24

Conditional distribution laws of lowest monthly average temperatures and of maximal amplitudes of monthly average temperatures according to [40] correspond to normal law if values of expression (14) are within the confidence interval:

$$\frac{max(\Delta t_{\mathrm{cond,i}}) - min(\Delta t_{\mathrm{cond,i}})}{\sigma(\Delta t_{\mathrm{cond,i}})}, \quad (14)$$

where $max(\Delta t_{cond,i})$ – maximal values of maximal amplitudes of monthly average temperatures of transformed normal distribution; $min(\Delta t_{cond,i})$ – minimal values of maximal amplitudes of monthly average temperatures of transformed normal distribution; $\sigma(\Delta t_{cond,i})$ – standard deviations of values of maximal amplitudes of monthly average temperatures of transformed normal distribution.

When the number of members of statistical series n = 24 and significance level p = 10%, the lower boundary of the interval is 3.41, the upper boundary of the interval is 4.52. It is presented in Table 7.

Table 7. Confidence intervals (14) of transformation of distribution laws of annual maximal amplitude of monthly average temperatures Δt, °C at geographical sites of location of hydro schemes of Dnieper cascade.

Item observation (reservoir)	**(*max*(*Δt*cond, *i*) – *min*(*Δt*cond, *i*)) / *σ*(*Δt*cond, *i*)**
Kaniv Reservoir (t. Kaniv)	3,41 < **4,20** < 4,52
Kremenchuk Reservoir (t. Kremenchuk)	3,41 < **4,40** < 4,52
Dnieper Reservoir (t. Zaporizhzhia)	3,41 < **4,21** < 4,52

For annual maximal amplitudes of average monthly temperatures $\Delta t_{1\ cond}$ and $\Delta t_{2\ cond}$ at dam sites of two hydroschemes, that are specified by normal distribution law as random correlated variables with the corresponding parameters: mathematical expectations $m_{\Delta t,1\ cond}$, $m_{\Delta t,2\ cond}$, standard deviations $\sigma_{\Delta t,1\ cond}$, $\sigma_{\Delta t,2\ cond}$, correlation coefficient $r_{\Delta t,1\ cond,\Delta t,2\ cond}$, correlation moment $K_{\Delta t,1\ cond,\Delta t,2\ cond}$, variation coefficient C_v; random probability of annual maximal amplitudes of average monthly temperatures $p(\Delta t_{1\ cond})$, distributed from 0 to 1 is specified. By normal distribution law with parameters presented above $m_{\Delta t,1\ cond}$, $\sigma_{\Delta t,1\ cond}$, quantile – the value of annual maximal amplitudes of average monthly temperatures $\Delta t_{1\ cond}$ - is determined by formulas:

$$m_{\Delta t1\ \mathrm{cond},\Delta t2\ \mathrm{cond}} = m_{\Delta t2\ \mathrm{cond}} + r_{\Delta t1\ \mathrm{cond},\Delta t2\ \mathrm{cond}} \times \times \frac{\sigma_{\Delta t2\ \mathrm{cond}}}{\sigma_{\Delta t1\ \mathrm{cond}}} \cdot (\Delta t_{1\ \mathrm{cond}} - m_{\Delta t1\ \mathrm{cond}}), \quad (15)$$

$$\sigma_{\Delta t1\ \mathrm{cond},\Delta t2\ \mathrm{cond}} = \sigma_{\Delta t2\ \mathrm{cond}} \sqrt{1 - r^2_{\Delta t1\ \mathrm{cond},\Delta t2\ \mathrm{cond}}}. \quad (16)$$

Parameters of conditional distribution law $m_{\Delta t1\ cond,\Delta t2\ cond}$, $\sigma_{\Delta t1\ cond,\Delta t2\ cond}$ are being determined. By known probability of the value of annual maximal amplitudes of average monthly temperatures $p(\Delta t_{2\ cond})$, using conditional distribution law, quantile – the value of quantity of annual maximal amplitudes of average monthly temperatures $\Delta t_{2\ cond}$ – is being determined. Recalculation of the value of annual maximal amplitudes of average monthly temperatures $\Delta t_{1\ cond}$, $\Delta t_{2\ cond}$, presented by conditional distribution law with substitution of formula (13), into real annual maximal amplitudes of average monthly temperatures $\Delta t_{1\ real}$, $\Delta t_{2\ real}$ at dam sites of hydroschemes is being performed. It is presented in Fig. 4.

Deviations of the values of amplitudes of average monthly temperatures, obtained by different procedures, from the observed data were assessed by comparison of their standard deviations. It was found that deviation of amplitudes of average monthly temperatures $\Delta t_{2\ real}$, °C, calculated by transformation into conditional normal distribution law [11], from the observed points of annual maximal amplitude of average monthly temperatures is $\sigma(\Delta t_{2\ real})$ = 2.227 °C. Deviation of amplitudes of average monthly temperatures $\Delta t_{2\ simulated}$, °C, calculated by two-dimensional lognormal distribution law, from observed points of annual maximal amplitude of average monthly temperatures is $\sigma(\Delta t_{2\ simulated})$ = 1.682 °C. Difference between $\sigma(\Delta t_{2\ real})$ = 2.227 °C and $\sigma(\Delta t_{2\ simulated})$ = = 1.682 °C is 24.5%.

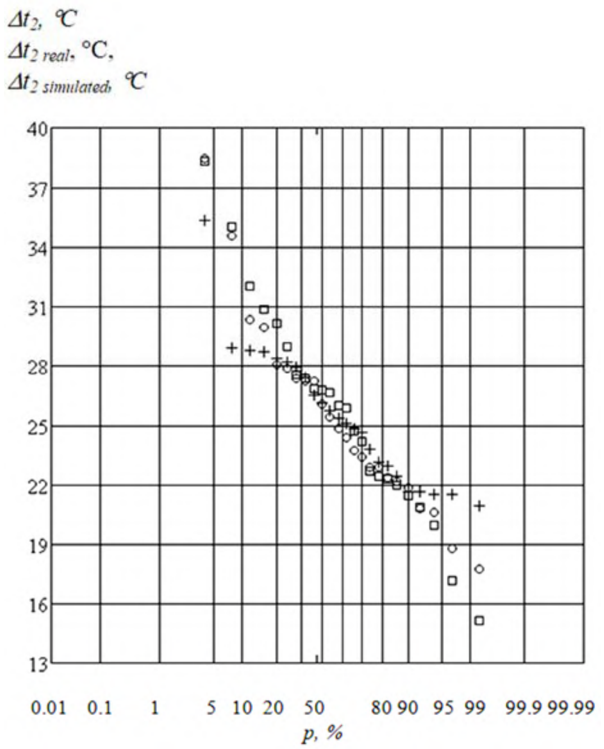

Fig. 4. Points of the probability curve of annual maximal amplitude of average monthly temperatures at dam site of the Kremenchuk hydroscheme (t. Kremenchuk) on the coordinates Δt_2, °C – annual maximal amplitude of average monthly temperatures, p, % – probability: + – observed amplitude of average monthly temperatures Δt_2, °C; – amplitude of average monthly temperatures $\Delta t_{2\ real}$, °C, calculated by transformation into conditional normal distribution law [11]; o – amplitude of average monthly temperatures $\Delta t_{2\ simulated}$, °C, calculated by two-dimensional lognormal distribution law.

Deviation of amplitudes of average monthly temperatures $\Delta t_{2\ simulated}$, °C, calculated by two-dimensional lognormal distribution law, from amplitudes of average monthly temperatures $\Delta t_{2\ real}$, °C, calculated by transformation into conditional normal distribution law, is σ = 2.11 °C.

4 Conclusions

Taking into account the great diversity of distribution laws of random variables of natural-climatic factors connected by correlation dependencies, and mathematical complexity of construction of joint distribution laws, method which is based on transformation of distribution laws into normal form has advantage in the further use. Assessment of accuracy of the results obtained by different procedures is performed. The results can be used in probabilistic calculations of reliability of hydraulic structures and cascades of hydroschemes.

Methods for developing an indoor navigation system

Dimitrina Deliyska[1,*], *Nikolay* Yanev[1], and *Mariana* Trifonova[1]

[1]University of Mining and Geology "St. Ivan Rilski", Department of Math and Informatics, Studenski grad, "Prof. Boyan Kamenov" Str., 1700 Sofia, Bulgaria

Abstract. The report offers methods for developing an indoor navigation system. For this purpose, popular navigation applications have been analysed. We have been strongly motivated by the fact that no universal methods have been established that are applicable with this kind of projects. Very often the case is that new methods are formed in view of a specific process and they are based on a particular technology and on the related organisation, design and other considerations. This is also confirmed by a conducted experiment with a commercial product for indoor navigation. The methods offered include map digitising, determining a user's location, and selecting the shortest path. This is achieved by applying elements of graph theory, databases, XML and QR code. The methods offered are universal and could be applied to any type of building. The methods have been approbated in the building of a mobile application for the needs of the University of Mining and Geology, Sofia.

1 Introduction

With the ever increasing human mobility, the various navigation systems are become more widespread and gain significance. Modern navigation systems (positioning technologies, of location determination technologies) are expected to offer optimised routes taking into consideration the peculiarities of our environment and also, to have a user-friendly, easy, informative and intelligible interface.

The Global Positioning System (GPS) is the most common navigation system used. When localising an object or route indoor, this system does not function well because the signal emitted by its satellites is lost. When navigating indoors, the multitude of objects that reflect signals should be taken into account. These could be the pieces of equipment, the walls, or people [1].

In order to overcome the malfunctions in GPS positioning and to perform accurate positioning in a sophisticated indoor environment, systems called Indoor Positioning Systems (IPSs) are introduced. Some of the most popular technologies of this type are the infrared connection, WI-FI and above all Wi-Fi fingerprinting, which is often employed in the development of smart phone applications [2, 3, 4], Bluetooth, ZigBee, ultrasound, radio frequency identification (RFID), and ultra-wideband (UWB) [5, 6], which offers higher accuracy.

Very generally, the above can be categorised into active and passive. Indoor positioning technologies via radio signal or WI-FI fall into the category of "active" technologies, since their requirement is for the object to move and to be equipped with some sort of a connecting device. In addition, the devices should be able to collect and process the transmitted information. With "passive" systems, a physical device attached to the moving object is not necessary. The concept with this category of technology is to use an available wireless network for data exchange, to detect changes in the environment, and to track the location of objects passively without requiring additional equipment. Only the UWB technology can be used as a passive system as well. The practice of combining several technologies in order to build systems of increased stability and accuracy in location determining has become increasingly popular [7, 8].

The criteria in terms of which wireless technologies can be compared are given in [9].

The areas where such developments are being applied are customer tracking, health and patients' monitoring [10, 11], finding objects, robotics, to name but a few [12].

2 Commercial solutions for indoor positioning

According to IndustryARC [13], the market for applications for indoor positioning and navigation will grow from $ 6.92 billion in 2020 to $ 23.6 billion in 2023.

Various commercial solutions for indoor positioning exist. Among the most popular are: Ekahau RTLS, SpotON – those work on the principle of the radio signal; AT&T Cambridge – it uses UWB; Microsoft Radar, Cisco Prime Infrastructure – these locate objects via WI-FI; SmartSpace – this is a modular, open source location tracking software platform. The commissioning of such a system requires large financial and expert resources.

Mobile applications for indoor positioning exist as well (Navizon, HERE Indoor Radio Mapper,

* Corresponding author: nikolay.yanev@mgu.bg

MapsIndoors, etc.). All of them require a usage fee. They employ different standards to describe the maps used. Some of them (HERE Indoor Radio Mapper) have specific requirements for installation and use. There is no information about the employed methodologies and approaches in the creation of such applications.

In February 2020 with the assistance of *Dundee Precious Metals*, *Chelopech*, a simulation was performed in the Cisco Prime Infrastructure environment in order to determine the location of guests and students in the Laboratory Unit at the University of Mining and Geology.

These are the simulation stages:

To perform the tests, six Cisco Access Points (APs) model 1242 are used; those are positioned in two rooms, each with three APs. The range of one AP of this model is between 60 and 70 m. Each triple AP isconnected to a 12-port switch and the necessary set-ups are made to obtain the IP addresses of APs.

The APs are connected to the Wireless controller (WLC) via the Dynamic Host Configuration Protocol (DHCP). Checks are then made for possible attacks on the transmitted data, called bit-flip attacks, using a Cisco certificate - self-signed certificates (SSC) to the controller. When everything is checked and there is no risk of external interference, the controller returns a request to connect the access point to it. The result is the so-called tunnel between the AP and the WLC. The data is transmitted using the CAPWAP protocol (Control and Provisioning of Wireless Access Points Protocol) for access.

Having performed the required configuration, we proceed to the construction of a map, a building and floors within a system. An approximate location of the building is indicated. The system allows a 2D projection of the map of the building under consideration. It is possible to apply it in any format. For the purposes of the simulation, an evacuation map of the 1st and 2nd floors in the Laboratory Unit at the University of Mining and Geology was used. Three access points (APs) were placed on each floor, equidistant in one direction for both floors.

After applying a map and placing access points, customers are connected to them and their location can be determined. The deviation given by the system is about 2 meters. Access points serve as reference points (or: landmarks). Determining the location of customers across the network is calculated using the RSSI and TDoA methods. For buildings overground, the triangulation method is applied, whereas for underground premises, the trilateration method is applicable.

The tags employed to carry out the simulation are AeroScout T2, and Cisco Prime provides detailed information about the data transfer between the tag and the access point (Fig. 1). A time difference of 2-3 seconds may occur.

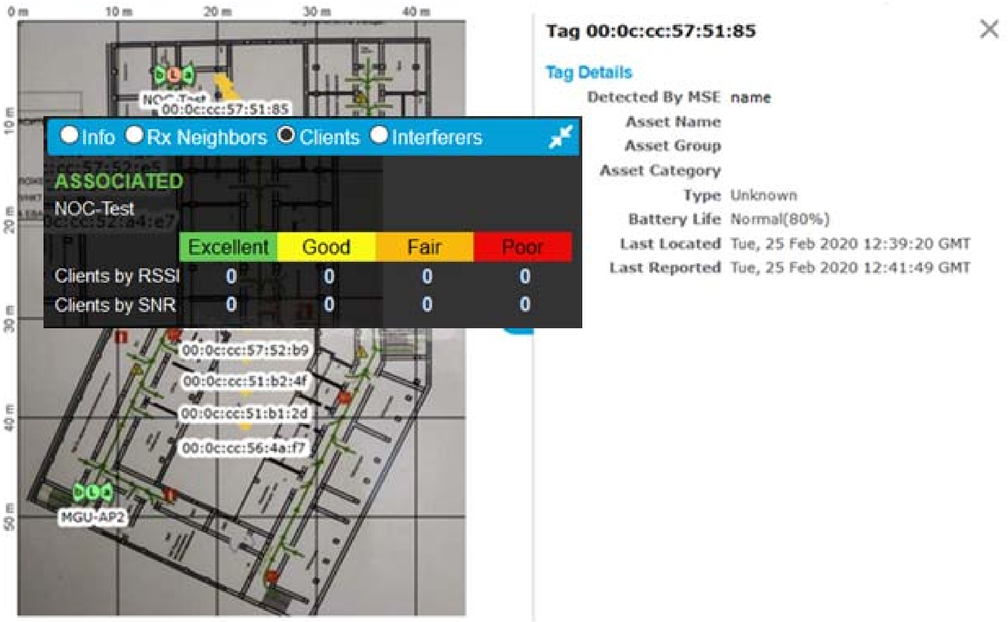

Fig. 1. Detailed information about the clients connected to the map of the building.

After connecting the APs to the wireless controller, a virtual engine (Mobility Services Engine) calculates the location of the objects using mathematical algorithms. The Cisco CEX algorithm is applied for the connection between client and MSE, and the Cisco CMX or DNA spaces algorithms monitor the data over the network. The necessary configuration is required, after which various analyses can be performed. In our case, an analysis of the signal strength between the access points and the RFID tags was performed. At the beginning of the test, no signal interruption was reported. An RSSI analysis was also performed on the day of the tests because the switch used for the simulation was fully configured for the purposes of the simulation and it was not possible to compare the signal strength over a longer period of time. In case signal interference is detected, the Kalman filter algorithm can be applied to determine the cause of the received interference.

The simulation performed with the help of the Cisco's corporate solution has made it possible to visually track objects using the WI-FI wireless technology. The advantage of the system is the provision of a general solution for localising, secure maintenance, and a complete set of tools and the description to it. The disadvantages of this type of systems include the inability to combine various company hardware and software components other than those of the manufacturing company, as well as the lack of ability to use three-dimensional maps. This makes the application too expensive. Additional disadvantages include the lack of a mobile version of the application, as well as the fact that it allows only for localising but not for navigating.

3 Proposing methods and testing them for approval

It is clear, from all that we have stated so far, that the choice of appropriate methods is of particular importance for the construction of NIS. Various computer developments exist that are employed for indoor localising, are commercial solutions, yet the methods wherewith they have been developed are not specified. Universal methods suitable for all types of projects have not been developed yet. As is often the case, new methods are formed for a particular process and they are based on a specific technology and the related organisational, design and other considerations.

Creating an indoor computer application is an elaborate process. Depending on the building, the appropriate navigation technology has to be selected. Then, in relation to this technology, the methods used for calculating the distance and the algorithms for determining the path must be taken into account. However, research has shown that, in the building of a software solution for navigating people indoors where there is no access to a GPS signal, the steps performed can be integrated and presented as methods that are founded on known methods and algorithms.

The structure of the proposed methods for creating computer applications for indoor navigation is presented in Fig. 2.

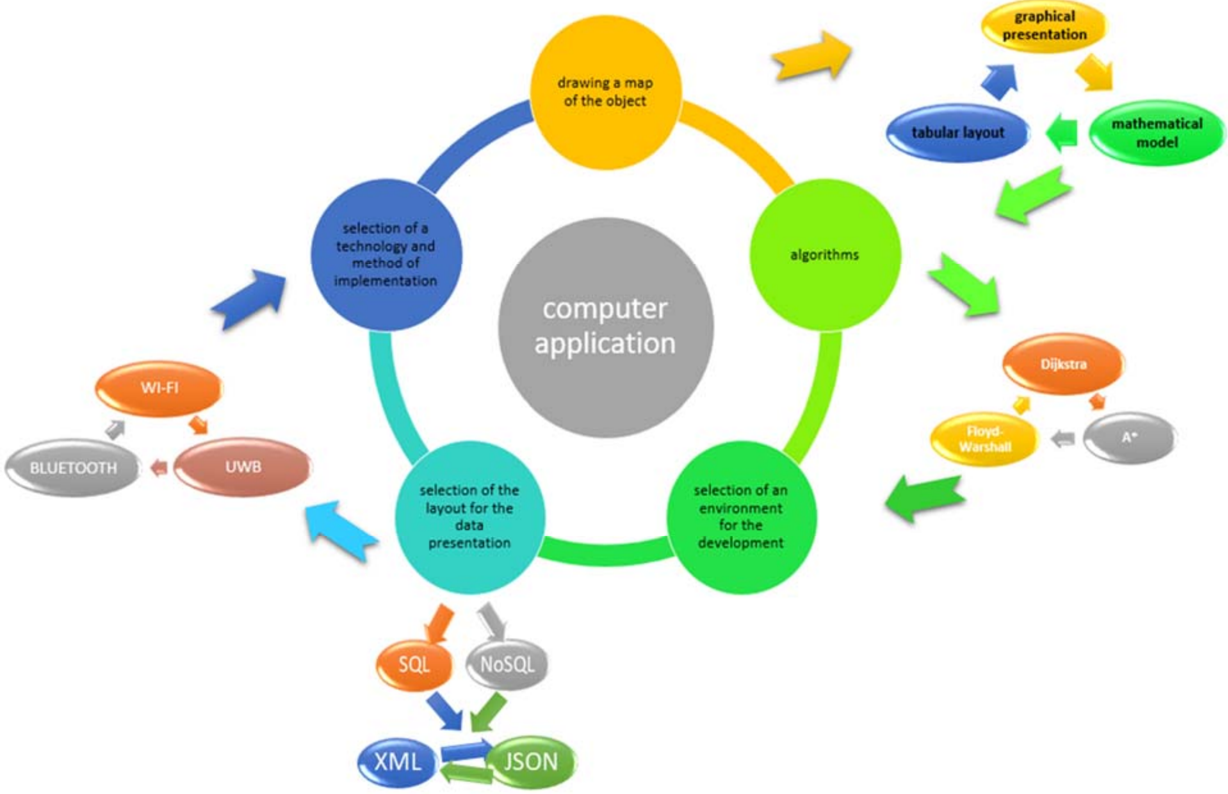

Fig. 2. Structure of the methods for designing computer applications for indoor navigation.

In order to localise an object/site, it is necessary to find its position relative to the surrounding objects. As a rule, when positioning outdoors, cartographic maps of the area in which the object is located are used, whereas a possible solution with indoor objects is maps similar to the Fire Evacuation Plans.

For the implementation of the algorithms in a particular development environment, the appropriate layout for the data presentation needs to be selected. Among the other ways to represent the graph describing the building are the use of such formats as the XML and JSON. These variants are suitable for embedding in systems that use the BigData or NoSQL databases with which the natural evolution of the considered system is associated.

3.1 Digitisation of the map of the building

The object of the current study are the 1st and 2nd floors of the Laboratory Unit at the University of Mining and Geology “St. Ivan Rilski”. The available fire evacuation map has been used as a basis which has been updated with the current hall numeration and the refurbishment of some halls. For a clearer view, the height between the floors on the scheme is extended. Such a map could be applied to any type of building.

https://doi.org/10.1051/e3sconf/202128004001

The map of the building in question can be presented by an undirected graph. The graph considered has 83 nodes and 3403 edges. By properly traversing the graph, a path can be found between each of its two nodes.

In order to determine the shortest path between two vertices of a graph, the algorithms of Dijkstra, A* and Floyd-Warshall were considered. In the long run, Dijkstra's algorithm was chosen due to its popularity, easy implementation, the presence of only positive edge weights, and its speed.

The proposed graph is spatial. It comprises two sub-graphs for each of the floors in the building (Fig. 3). What is checked initially is where the “start” and “end” nodes of the searched route are located; then the search is confined within one of the sub-graphs. But even if the route includes elements from both sub-graphs, the basic search is within each sub-graph separately. Thus, the fast response time of the algorithm increases, since it is not necessary to constantly traverse the entire graph.

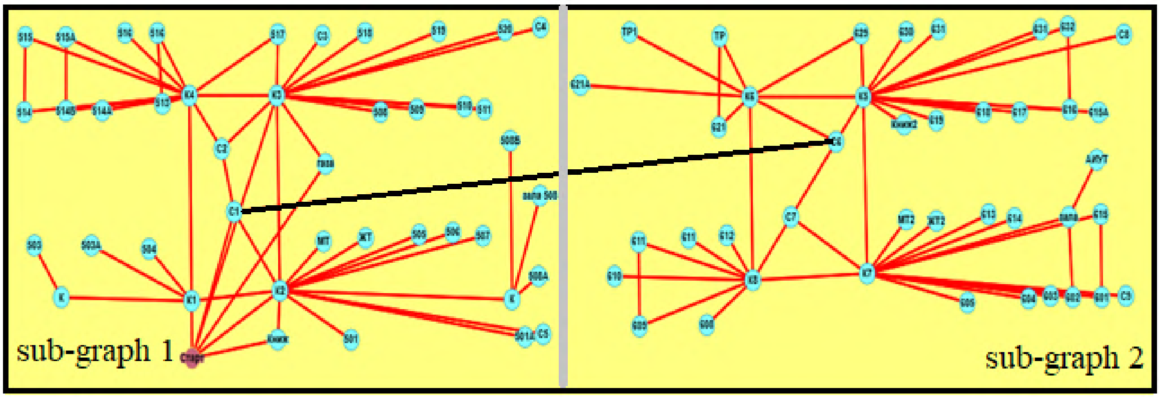

Fig. 3. A map of the 1st and 2nd floors of the Laboratory Unit presented by an undirected graph.

In the application implemented, the structure of the graph is represented by an adjacency matrix. This is one of the most common ways to represent graphs This matrix sets the weight of the edges of the graph

3.2 Mobile application

Using the methods offered, a mobile application for indoor navigation has been implemented.

The developed mobile application is based on the relational data model. The reasons are as follows:

- the rather the static nature of the object described – redistribution of the inner space in order to establish new separate classrooms and offices is rarely done;
- well-developed and accessible means for data import and export from other formats (mostly XML and JSON) are available in the contemporary DBMS - this would facilitate the transition to NoSQL in future addition of information to the database
- intelligible data presentation in the tables;
- a high degree of physical and logical data independence;
- sufficiently rich experience in various relational database management systems (RDBMS).

The mobile application has been developed for the Android operating system. It can be used by registered users and guests. The registered users are allowed to add their own map of a desired building, the information wherewith is included in the database. Guests, in turn, can make use of the services of the application by having only access to the current data – available maps, scanning a QR codes, and entering a hall number. The diagram of the mobile application developed is shown in Fig. 4.

By means of the proposed mobile application, guests and newly-admitted students can easily navigate within the buildings of the university campus without the need for additional guidance and loss of time. The application is offered with a pleasant and lightweight user interface that will eliminate unnecessary “clicks” on the part of its users on their way to the desired goal.

The identification of the starting point is performed by scanning a QR code. For this purpose, a free-of-charge QR code must be generated for each hall (vertex on the graph). It must be positioned at a spot which is convenient for scanning, at the door or in the immediate proximity to it. The choice of QR code scanning was prompted by the fact that more and more cameras on mobile devices support the function of automatic QR code recognition. For devices that lack such an option, an additional installation of an application that reads QR codes is required.

The end point identification can be done in two ways:

1. By entering the number (name) of the required hall. For the user’s convenience, as well as to ensure the selection of a really existing hall, the end point determining is performed through a selection from a menu (Fig. 6).
2. By entering search criteria – the name of the department, laboratory or hall. The end point is selected by clicking on an element (hall) from the result returned.

The mobile application contains one major panel (Figure 5) with the following elements :

1. *Navigation bar* – along with the name of the application, it contains a button with a hidden menu. In order to make it possible to use the application for different buildings and not only for the one under consideration, the feature for adding a new map has been supplemented in the menu as an option. Accordingly, the layout of the map should be in the format proposed by the methods considered. A button for clearing a previous search has also been provided.
2. *Information field (text box)* - it automatically displays the information from the QR code scan.

3. *Scan button* - the application offers its users to scan a QR code as the starting point for determining their location. For this purpose, all halls in the building under consideration have been equipped with additional signs with generated QR codes. The scan information is loaded into the information field.

4. *Editing field (search engine)* – offers the user a possibility to enter the end point of their route. The user can to manually enter the particular hall number they want to reach or search for in the offered list box.

5. *List box* - all of the existing halls, offices and laboratories in the respective building in question are extracted from a database. A filter to the list box has been addedl, whereby, upon entering part of a hall number, the list box shows only the halls containing those numbers.

6. *Floating button* - after scanning the QR code and selecting the final destination, the button visualises the map of the building, calculates the algorithm entered (in this case, Dijkstra's algorithm for find the shortest path), and draws up the route which the user should follow.

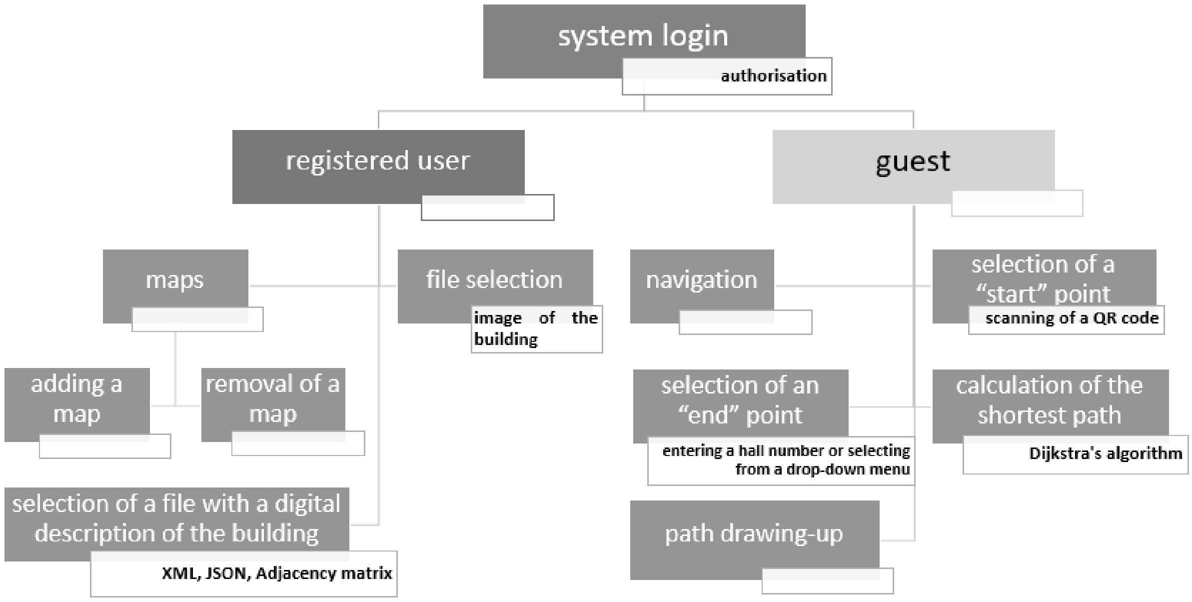

Fig. 4. Diagram of the mobile application.

Fig. 5. Home screen of the mobile application.

Upon pressing the button on the floating bar, the path is visualised in real meters. The result is visualised using a standard Java graphics library for Android (Figure 6)

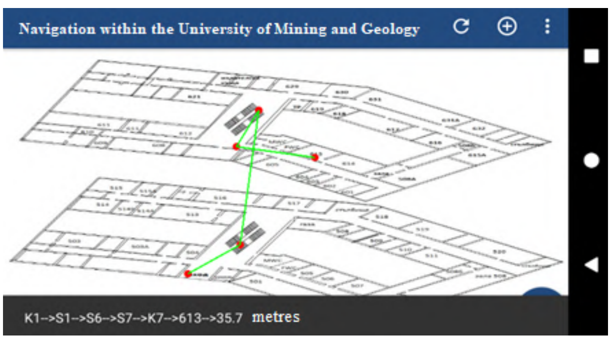

Fig. 6. Visualisation of the shortest route.

4 Conclusion

Systems exist for indoor or outdoor object localising. Globally, indoor positioning systems are currently undergoing a process of active development. This is a relatively new subject matter for professionals. Besides, the information on it is limited. The analysis of existing indoor positioning systems has shown the scarcity of the information available in this area. An even more serious challenge is how to track the position of a moving object, shifting from an outdoor to an indoor environment and/or vice versa.

To date, there is no universal system for indoor navigation, nor is there an approach (methods) for developing such a system.

This report proposes methods for creating an indoor navigation system. For this purpose, a thorough analysis has been performed of existing methods, technologies and algorithms which can be combined in such a manner that the process of navigating an object from one point to another be optimised.

In the methods described, the location of the site is determined by creating a digital map of a building and a graph that describes the connections between the internal sites. The selection of the shortest path is performed by applying Dijkstra's algorithm. In the case of more buildings or multi-floor buildings, separate subgraphs are formed within the overall graph so as to optimise the Dijkstra method. In order to test the methods for approval, a mobile navigation system has been developed. This choice is prompted by the fact that today mobile devices are more popular, affordable and portable than conventional computers. The system is still being developed, and some of the major issues that need to be solved in the near future are the following:

- Enabling users of various operating systems to use the mobile application;
- Ability to navigate in different buildings - outdoors and indoors concurrently;
- Additional modules to the application, according to the specifics of the building;
- Unified representation of a map of the building (e.g. through an XML document validated with a specific XML Schema and transformed into an SVG file);
- Creating Fingerprints based on the object position established via Wi-Fi and comparing those with the results of the current scan by the users for the purposes of neural network training;
- Calculating the approximate duration of movement;
- Navigating handicapped people;
- In order to automate the process of tracking the user's movement from the start to the final point, it would be useful to conduct experiments combining a variety of navigation technologies, such as infrared connection, WI-FI, Bluetooth, ZigBee, ultrasound, radio frequency identification (RFID), and ultra-wideband (UWB).

The evolution of information technologies also requires constant monitoring of new trends in the field, as well as the implementation of new technologies in order to improve the current development.

The participative budget of making a city sustainable: quintuple helix approach

Mykola Petrushenko[1,*], and *Carsten* Grunwaldt[2]

[1]Institute of Market Problems and Economic-Ecological Research of the National Academy of Sciences of Ukraine, Department of Economic Management of Natural Resources, 29 Frantsuz′kyy Blvd., Odesa, 65044, Ukraine
[2]DAAD, 50 Kennedyallee, D-53175 Bonn, Germany

Abstract. For transition economies, urban management processes are also in transition, which also means a situational opportunity to apply an integrated approach to the implementation of innovative projects, in which economic and political, as well as social, socio-cultural and environmental directions of development can receive a positive stimulus. Purpose of the study is to analyze the structure of participatory budgeting projects on the continuum "science and education – environment", in accordance with the methodological approach to justify the innovative development of the city (based on helix-modeling). The paper has outlined an approach to activation the principles of sustainable and inclusive development at the local level, on the example of the participatory budget of Kyiv city in Ukraine. At the methodological level, the stages of the evolution of helix-modeling to the quintuple level have been analyzed in detail, the results of which are proposed to be implemented in accelerating the transformation of the projects structure aimed at the development of economic, social and environmental aspects of citizens life, namely in the fields of education, science, culture, sports, ecology, etc. Analysis of the change in the structure of participatory budgeting in Kyiv for the period 2017-2019 allows us to talk about the optimistic transition scenario of the city and the country in whole to the real pace of achievement the Sustainable Development Goals 2030. Strengthening the current positive changes with the help of state support, as well as ensuring a sufficient responsible investment, allows at a project level to succeed in improving the sustainability of the city.

1 Introduction

Urban sustainability is one of the current areas of research within the concept of sustainable development [1–3]. In the conditions of transformation [4], the specificity of the situation lays not so much in the smart city – the global trend of urban planning and urban ecology of the last decade, but in the constant maintenance of sustainable and innovative urban development.

Contrary to the fact, that scientific sphere in Ukraine as of 2020 is in the situation of waiting for reforms; innovation activity begins exactly in this sphere. And then from here innovations gradually spread to other spheres of society life and development of the country and its cities. From education and science begins all-encompassing progress, in which business and industry, the public and activities related to the environment are involving. It is clear that without state support it is impossible to stabilize the sustainable development of cities and achieve the Global Goals at the international [5] and national [6] levels (especially Goal 11 "Sustainable cities and communities"), given the possible threats and impact of crisis factors.

Along with direct investment, an important tool for provision of sustainable urban development is a participatory budgeting. Since this process is relatively new for Ukraine, it is advisable to theoretically substantiate it on the basis of approaches to innovation modeling, which complement the approaches to modeling the relevant investment processes [7; 8].

It is also advisable to make extensive use of foreign experience in participatory budgeting. At the beginning of the 21st century, Europe adopted this sustainable mechanism from Latin America and, as of 2010, applied it in dozens of cities. The participatory budgeting gained the greatest development in Italy, Portugal, Spain, France, Germany, and the United Kingdom. The most common models of the participatory budgeting development in Western Europe are as follows: participatory democracy (clearly defined rules, good quality deliberation; combining strong participation with social justice), proximity democracy (informal rules, deliberative quality weak or average; combining participation with formal decision-making process) and participatory modernization (rules may be clear, weak deliberative quality; broad political consensus) [9]. In Germany, for almost two decades, participatory budgeting has evolved from a symbolic political instrument to improve communication between citizens and administration [10] to a mechanism for democratic innovation and municipal modernization [11].

2 Methodology

The conceptual basis of the study is an evolutionary approach to innovation development modeling – the helix-modeling (Fig. 1), which includes six types of models (three prototype models and three helix models), as well as five gradual stages of transition from one model to another: from a linear model to a quintuple helix model, which summarizes the following elements of innovation development: science and education, business and industry, government and state support, the civil society, the environment and the social environment.

The proposed approach was used to analyze the dynamics of structural changes in the short term (2017–2019) on the example of the formation and use of participatory budget at the municipal level, namely the example of Kyiv city.

The information base is the online platform [18], on which project data is constantly updated.

The evolutionary approach in the context of changing the forms of descriptive helix-model, when it is transferred to the plane of formation of the participatory budget of the city, allows to identify features of its innovative development and to substantiate expediency of acceleration of transformation of projects structure.

3 Results

The logic of the study consists of, firstly, on the actualization of a set interrelated factors of sustainable development, including reflection in indicators that characterize the social and environmental components of sustainability and inclusiveness, at the level of the economic region of Ukraine, the center of which is Kyiv city; and also, secondly, on the implementation of the analysis of the structure of project directions within the participatory budget of Kyiv city on the basis of an evolutionary approach to helix-modeling of innovation activity.

3.1 Rating analysis of sustainable and inclusive development indicators of the territory

When conducting analysis of sustainable and inclusive development indicators of the Central economic region of Ukraine, their comparison with similar indicators of other economic regions of Ukraine were carried out and, accordingly, the results of the rating assessment were obtained (Table 1). The results (above all, the first place by level of higher education, as well as the second place by level of Internet access) prove the existence of preconditions, and therefore the expediency of innovative modeling of participatory budgeting in Kyiv. Also the composition of the main problems can be seen preliminarily (for example, VII place – overcrowding housing or VI place – the inability to satisfy recreational services), which, on the one hand, reflect the situation in the country, and, on the other hand, indicate bottlenecks in urban development and therefore it should affect the structure of the participatory budget of Kyiv.

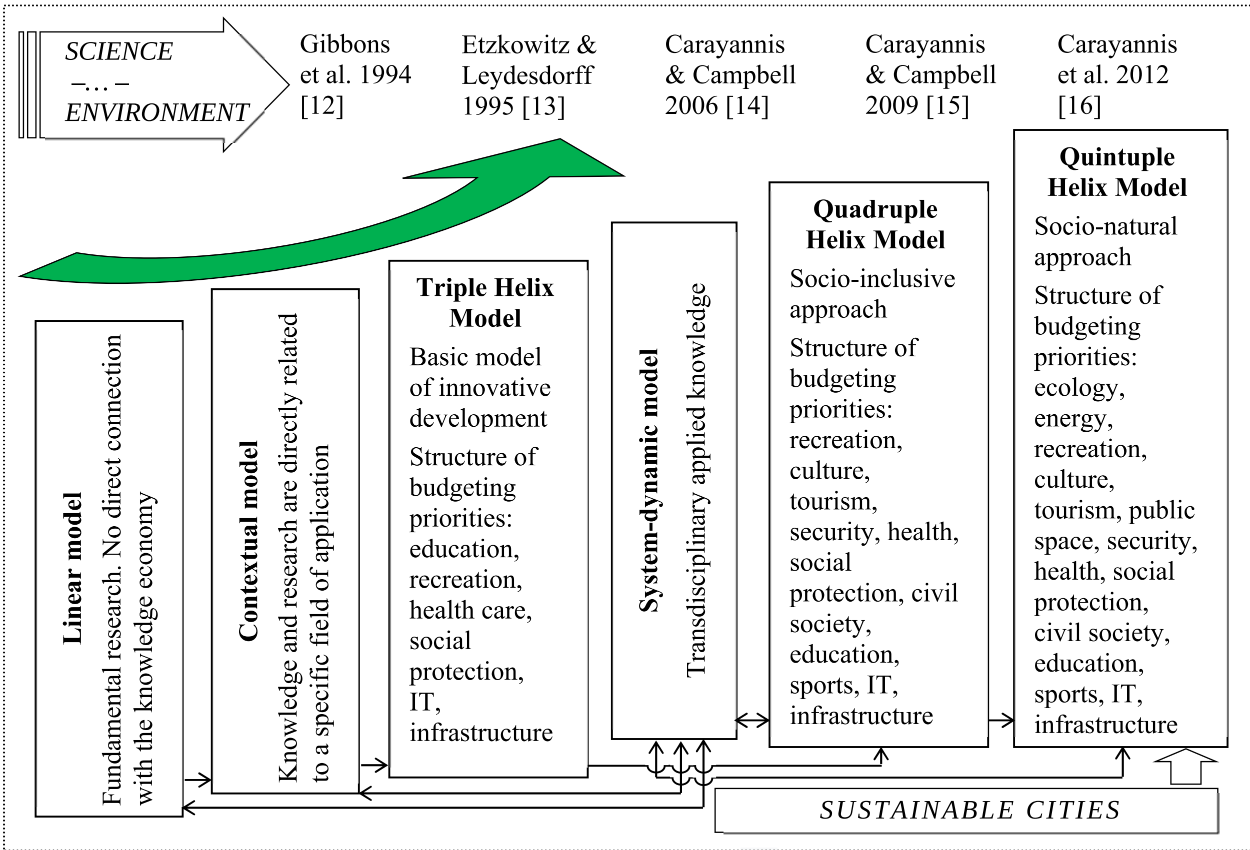

Fig. 1. The evolution of helix-models and its sustainable context (based on [16; 17]).

Table 1. Comparative analysis of sustainable and inclusive development indicators of the Central economic region of Ukraine, 2019 (according to [19; 20]).

Indicators	Value	Ranking
Number of household members who rated their health as good, thousand	3112,25	II
Number of household members who rated their health as bad, thousand	424,49	III
Households whose members constantly denied themselves the most necessary, in addition to food, thousand	654,30	III
Share of persons suffering from 4 or more signs of material deprivation of 9 signs, %	14,90	II
Share of population living in overcrowded housing, %	54,50	VII
Share of households that are (very) dissatisfied with housing conditions, %	13,10	II
Share of households that are (very) satisfied with housing conditions, %	60,60	I
Number of persons who can allow minimum recreational services, thousand	2298,80	VI
Number of persons who reported that they used Internet services at least once a day, thousand	2952,60	II
Number of households with Internet access at home, thousand	1553,00	II
Share of population with complete higher education, %	33,80	I
Number of persons living in households who could not afford unexpected necessary expenses, thousand	2861,50	VI
The average indicator of ecological status	10,00	III
Total	–	I

3.2 Evolution of helix-modeling and its projection into the plane of formation of innovative ecologically oriented, educational and other socially significant projects

That, how helix-modeling evolved is shown in Figures 2-6: from a linear model that reflects the activities of educational and research institutions (Fig. 2, upper left corner) to a model that includes five interconnected components, integrated in the joint innovation process – quintuple helix model (Fig. 6).

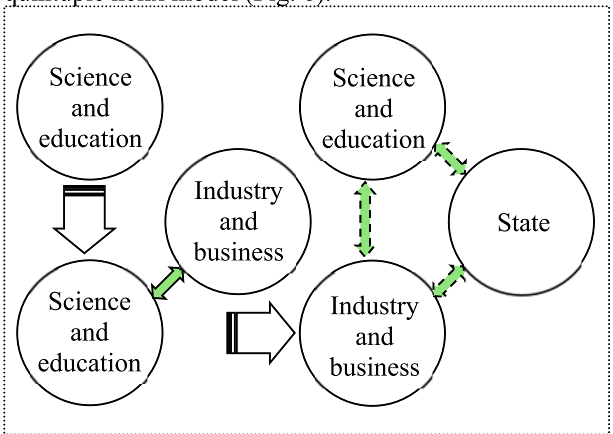

Fig. 2. Triple helix-modeling scheme for innovation activity in emerging countries (based on [21]).

The structure of participatory budgeting in Kyiv is presented in Table 2.

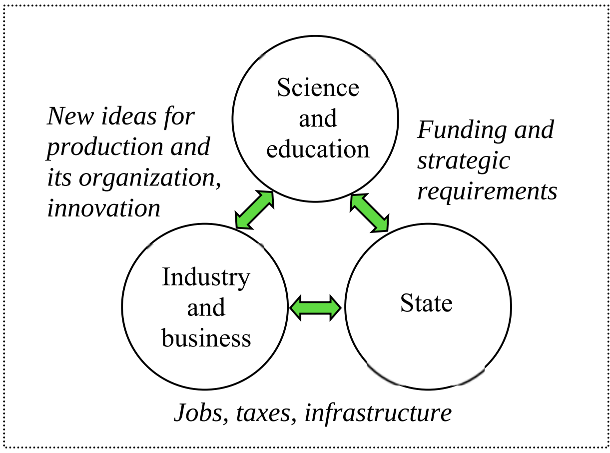

Fig. 3. Triple Helix-modeling scheme for innovation activity in countries with economies in transition (based on [21]).

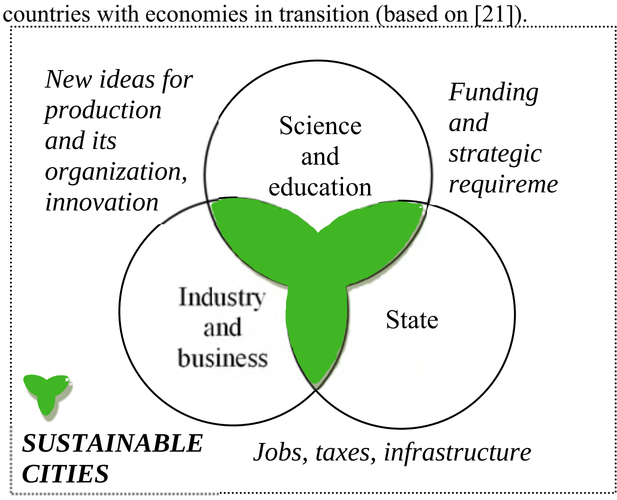

Fig. 4. Triple helix-modeling scheme for innovation activity in developed countries (based on [21]).

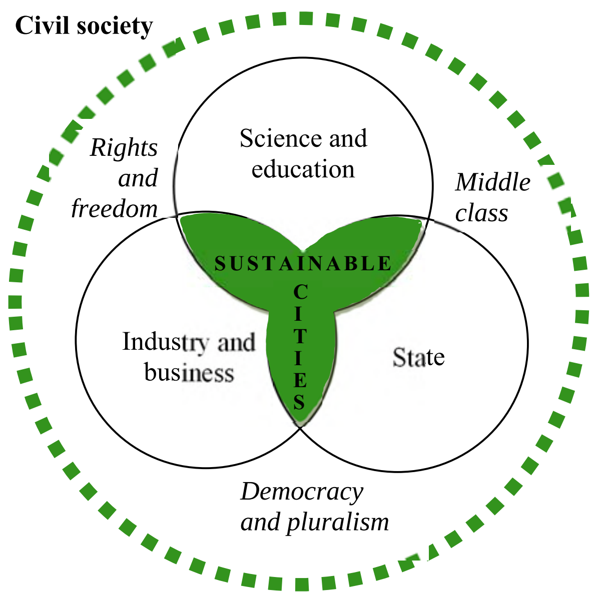

Fig. 5. Quadruple Helix-modeling scheme for innovation activity (based on [15]).

The analysis results of the changeability of the structure of innovative projects directions within the participative budgeting of Kyiv (Table 2) allow to speak about the optimistic scenario of transition of the capital of Ukraine to real rates of achievement of Sustainable

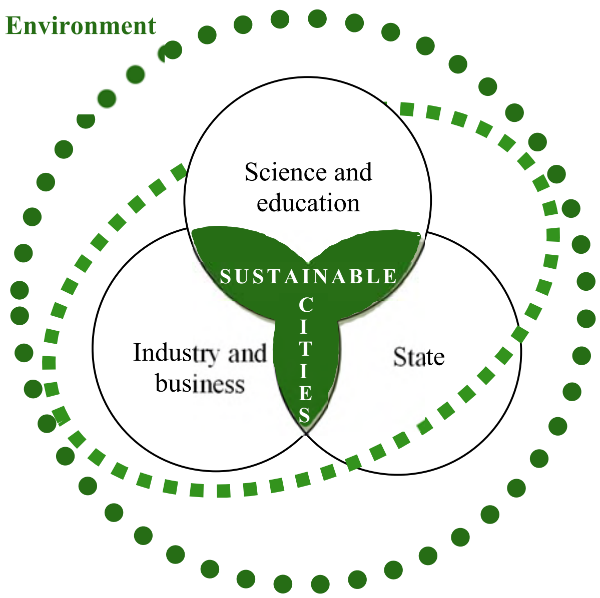

Fig. 6. Quintuple Helix-modeling scheme for innovation activity (based on [16]).

Based on these results and taking into account the experience of Germany [22; 23], as well as recommendations for ecologically oriented recreational development [24; 25] and the introduction of international standards to strengthen the resistance to the coronavirus pandemic [26], an indicative structure as a benchmark for the sustainability of Kyiv city in the medium term is proposed in the paper (Fig. 7).

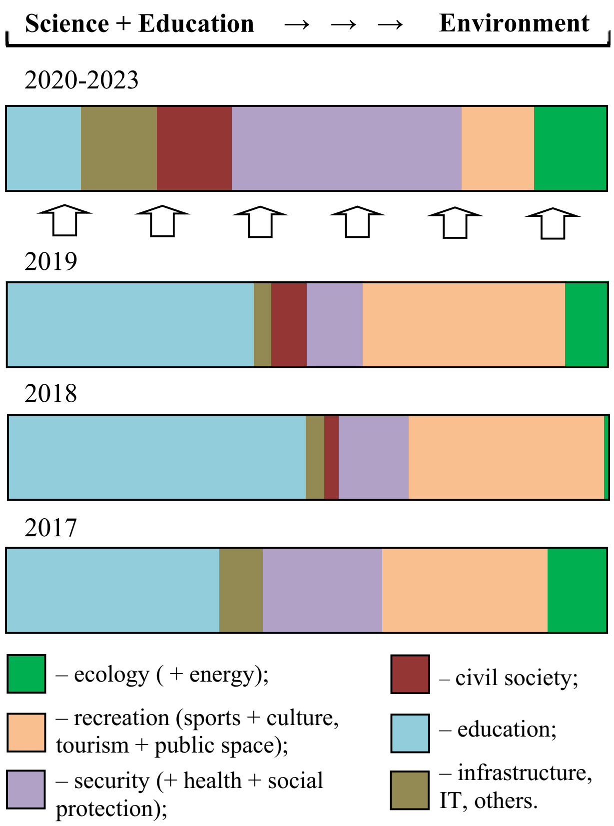

Fig. 7. Structure of project directions (according to the total cost of winning projects) within the participatory budget of Kyiv.

The main share (it is proposed to triple its weight in order to accelerate the response to the pandemic) in the structure belongs to security. Other shares have an approximately equal weight, which corresponds to the principle of balance: the weight of ecology, infrastructure and civil society increases, but the weight of recreation, and education decreases, which is possible in the conditions of distance learning.

4 Discussion

Trends and prospects for the development of educational sector and its support in the side of the state and international organizations, in particular in Germany, which has one of the most progressive and effective systems of education and science [27–33] within participatory budgeting requires a balanced approach to attracting investment. It is necessary to strengthen the role of public-private partnership, which will ensure the guarantee of completion the projects in full of planned costs, as well as control over the quality of their implementation, including in the period after the completion of projects. This provision is principal: the sustainability of cities and, in particular, of educational sector means ensuring the support of realization innovative, especially inclusive, projects over a long period of time, now, as a rule, till 2030. For countries with economies in transition responsible investment is extremely important, especially aimed at the development of inclusive education.

5 Conclusion

The study of the participatory budgeting contribution to the sustainability of the city, on the example of Kyiv in Ukraine, based on the methodological approach of innovative helix-modeling is conducted in the paper. The evolution of helix-models, ranging from the basic model (triple helix model) to the ecologically integrated model (quintuple helix model) demonstrates the importance of not just taking into account the additive principle, but the integration of five components (science and education, business, government, public, environment) in the plane of innovative projects implementation formed on the principles of sustainability and inclusiveness. The analysis of the participatory budgeting structure, aimed at increasing the sustainability of Kyiv city, confirms the positive dynamics relevant to the evolutionary approach of helix-modeling. Given the pandemic crisis, as well as the peculiarities of the Sustainable Development Goals implementation in Ukraine, a benchmark of this structure in the medium term 2021-2023 is proposed in a study, which is based on a balance of six components: ecology, recreation, security, civil society, infrastructure projects and education. Taking into account the specifics of the current situation, security has the largest share, the share of education and recreation should decrease, but the share of the environment, including the recreational environment increases due to the expansion of "green" public space. An increment of the share of civil society to accelerate the development of democracy in the country is also important.

Prospects for further research are related to the analysis of the possibilities of applying the participatory budgeting mechanism within the European Green Deal, in particular such strategies as “A zero pollution ambition for a toxic free environment”, “Accelerating the shift to sustainable and smart mobility”, and “Supplying clean, affordable and secure energy” at the municipal level.

This research is part of the National Academy of Science of Ukraine’s research projects: “Inclusion of the experience economy in the nature management” (No. 0119U000229), “Investment and innovation policy dominants of national economy’s nature management» (No. 0120U100160).

Abstract. The conditions of the origin, development and transformation of the Donetsk and Luhansk regions of Ukraine are considered. There is an irreversible tendency to reduce the industrial potential of the coal and metallurgical industry, the collapse of the urban base. The nature and scale of the impact of the armed conflict in eastern Ukraine on the state of engineering and planning organization in the territory of Luhansk region is studied. Trends of development, circumstances and preconditions of formation of agglomerations of the region are determined. The correspondence of regional typologies on the basis of function in modern conditions of armed conflict is analyzed. The analysis allows us to identify the following important aspects. A gradual but irreversible process of deindustrialization is recorded. The transformation of the engineering and planning organization of the territory of the Luhansk region in the conditions of the armed conflict in the East of Ukraine is a fait accompli. A new political and economic reality is being formed. The Luhansk and Donetsk regions are artificially divided. The internal status of the region has led to the formation of a large number of urban agglomerations, a dense transport network. The analysis of a demographic condition, a territorial, town-planning complex testifies to discrepancy of typological signs of the area in the modern conditions. The Luhansk region is becoming a cross-border region with a dense border. It is expedient to expand the existing classification of regions by introducing certain special functions of the regional typology. In modern conditions in the Luhansk and Donetsk regions the border region is formed. Along this line, the function of cross-border cooperation is complemented by the function of border control. This function aims to limit a certain type – the fixation of the border, the mode of its crossing, strict compliance with statutory procedures. The addition of the functions of the regional typology should be taken into account in the tasks of improving the territorial – planning organization of Luhansk region.

1 Problem statement

The Donetsk and Luhansk regions form the Donbass region, which is characterized by the highest level of urbanization in Ukraine. It is an old industrial region based on the coal and metallurgical complex. The phase of extensive development based on the active exploitation of minerals, primarily coal, has passed. The need for a continuous increase in coal production no longer exists. An irreversible tendency towards a decrease in the industrial potential of the coal and metallurgical industry is forming. Due to a decrease in industrial potential, a reduction of the urban planning base is recorded. In 2014, an armed conflict broke out in the East of Ukraine, inspired from the outside, which significantly worsened the situation, and introduced unforeseen circumstances in the form of alienation of the part of the territories. The strategic directions and tasks of the territorial development of the Luhansk region require updating and adjustment.

The territories of the Luhansk and Donetsk regions are highly urbanized. As of 2014, the percentage of the urban population of the regions reached 80-90%.

The population of the Donetsk region amounted to 4,356,000 people, Lugansk region – 2,256 million people, together more than 6,600,000 people, which in aggregate more than in some small European countries. Of the 47 European states, 27 have a population of less than 6 ml. people. [1] The artificial division of the territories of the two regions radically changed the engineering and planning organization of the region. The task of urban development, territorial planning should take into account the circumstances caused by the armed conflict. Research and analysis of the problems of territorial development of the region are relevant.

2 Purpose, idea and research methodology

The goal of the research – to study the nature and extent of the impact of the armed conflict in the east of Ukraine on the state of the engineering and planning organization of the territory of the Luhansk region. Determine development trends, circumstances and prerequisites for the formation of the agglomerations in the Luhansk region. To investigate the place and role of the Lisichansk-Severodonetsk agglomeration in the system of regional settlement and the Luhansk region, to establish the peculiarities of the formation of the functional spatial structure of the agglomeration, its development trends, the evolution of the regional settlement system, the state and problems of urban development. Analyze the correspondence of the regional typologies on the basis of function in modern conditions of the armed conflict.

The idea. Ukrainian Donbass has unique historical features. In fact, this industrial region instantly emerged and developed. However, the focus on the coal and metallurgical complex, the outdated industrial structure led to a gradual decline in the region. The complex of socio-economic problems has multiplied the complexity of the armed conflict. All development strategies, territorial planning tasks, territorial development management tasks have lost their relevance. The need arose to improve the methodological prerequisites for managing the development of territories.

Methodology. Research is based on systematic analysis, analytical comparison, historical methodology. The paper investigates external and internal factors influencing the functional and planning organization of the region. The information base consists of literary and archival sources, cartographic materials.

3 The research results

In the theory and practice of regional planning, the classification of regions according to the features of function and form is used. By functional purpose, there are the metropolitan, transport and cross-border regions. According to special natural conditions, there are coastal, riverside and regions with minerals. [2] In the Luhansk and Donetsk regions, a border region is formed, which arose and functions in the context of an armed conflict. The border control function aims at a certain type of restriction – fixing the border, the mode of crossing it, strict adherence to legally established procedures. The addition of the functions of the regional typology should be taken into account in the tasks of improving the territorial planning organization of the Luhansk region.

7 agglomerations were formed on the territory of the Luhansk and Donetsk regions of Ukraine (Fig. 1). [1]

The Luhansk region is located in the east of Ukraine and since 2015 is located in the zone of the joint forces operation (JFO), part of the region's territory is not controlled by state authorities. The regional center, Lugansk, was seized by illegal armed groups and lost its administrative and economic significance. The administrative functions of the regional level were transferred to the city of oblast subordination, Severodonetsk.

The region is characterized by a high level of urbanization. By the number of cities, it ranks second in Ukraine. On the territory of the region, it is possible to distinguish the agrarian north, the industrial center, the coal mining south. According to the type of settlement, the following agglomerations can be distinguished: Central-Lugansk (Alchevsk – Kadievka), Severo-Lugansk (Lugansk), Yugo-Lugansk (Khrustalny), Severodonetsk – Lisichansk agglomeration. (Fig. 1). [1]

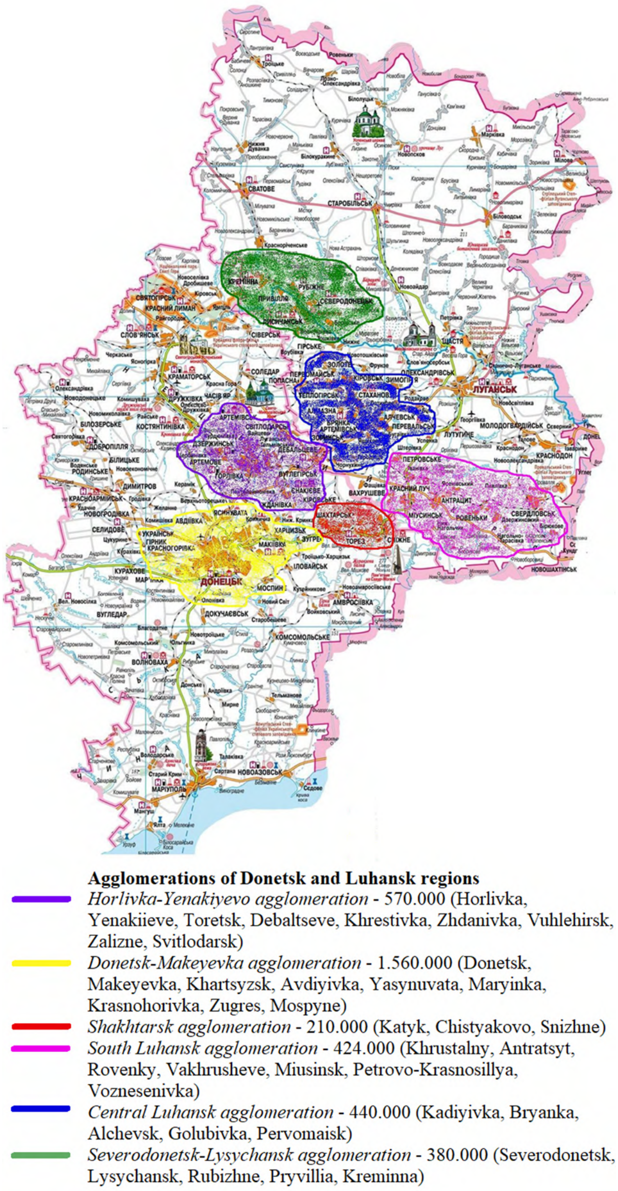

Fig. 1. The agglomerations of the Donbass region.

Donbass arose and developed instantly, by historical standards (Fig. 2, 3). History has not known such cases [3, 4].

Rapid growth of the extensive type threatens the decline of developmental factors. In an industrial economy, excessive urbanization overloads the territory. In conditions of limited natural resources, the maintenance of the vast majority of the working population causes structural distortions of the development. The city's own exports should prevail, then the city has the opportunity to develop. This statement is also true for agglomerations [5]. In the archaic agrarian period, this region is better known as the Wild Field. The Donbass region belongs to the zone of risky farming, when only 2 out of 10 years are usually productive. Thus, from 1799 to 1856, for a period of 57 years, there were 28 non-productive years [3].

There were 1.1% of skilled agricultural workers at the beginning of the twentieth century in the Donetsk region, and correspondingly in the Luhansk region. – 1.3% of the population. Such low indicators show, firstly, an insufficient level of provision of the region with its own food, secondly, the resource of further urbanization is almost exhausted, and thirdly, the lack of agricultural land, however the possibilities of intensifying agricultural production are clearly demonstrated by such states as the Netherlands and Israel.

Fig. 2. The scheme of the main industrial regions of Europe during the Industrial Revolution.

It should be noted – Donbass has always been an internal region. It had transport and geographical advantages and contributed to its development as a powerful industrial hub.

The rapid development of Donbass begins in the 70-80s. of the 19th century, when the action of the several key factors of the industrial revolution coincided:

- The aggression of the Russian Empire in the direction of the Balkans and the Black Sea, which required a large number of weapons, hence metal;
- The emergence and spread of steam engines and steam locomotives – consumers of coal;
- Ukrainian chernozems became safe agricultural economic territories after a series of Crimean and Turkish wars, the partition of Poland.

In 1895–1900 the production of iron and steel in the Donbass equaled the volume of production in the Urals, that is, from this period Donbass can be considered a new industrial center of the Russian Empire. [3]

The events of the XX century, IWW and IIWW affected the territorial development of the region.

Donbass experienced a decline in 1918-1924, which was caused by the civil war and the absence of a central government. In fact, adjusted for the era, the problems were / are of the same nature, and the consequences are generally similar – reduced production, migration of people and workers, widespread gardening to avoid famine, hunger, impoverishment and natural exchange. [6]

For the second time, Donbass was destroyed during the German occupation during World War II. The consequences of the occupation were also exacerbated by the "scorched earth" policy used by the Soviet authorities.

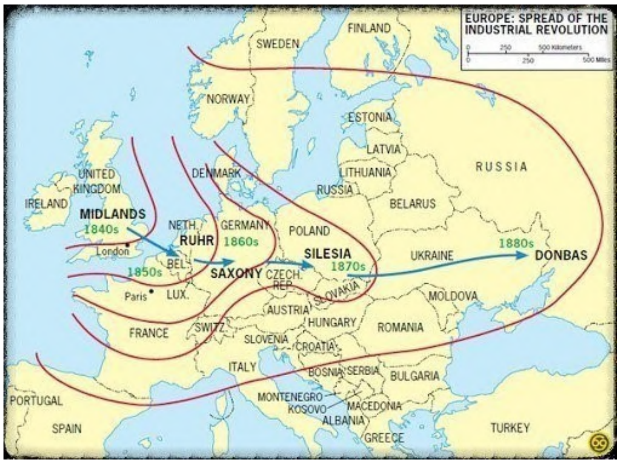

Fig. 3. The speed of the spread of the industrial revolution in Europe [4].

The status of the inland region allowed to quickly restore industrial potential.

After the Second World War, the USSR implemented a large-scale plan to revive Donbass. Metal, energy, and fuel were needed to rebuild the state. However, at that time there were distortions associated with the dominance of the needs of the defense industry. Many companies were focused on the production of military products. [7]

For the period 1950-1980, a strategy for the development of Donbass was laid and partially implemented, which provided for the accelerated urbanization of the region. It is clear that the population growth was mainly due to labor migration, including the use of tough administrative measures.

During the days of independent Ukraine, the coal and metallurgical industry stabilized after the creation of vertically integrated corporations, concentrated in the hands of large oligarchic capital.

Geography does not always take into account state boundaries. Part of the coal deposits are located on the territory of the Russian Federation – in the Rostov region. The Russian part of Donbass still looks ugly, with the only prospect – accelerated degradation, social and demographic. The coal industry practically does not exist in the region. Economic factors, logistics conditions have made the region's coal unprofitable. The mining and metallurgical complex of Russia is concentrated in the Urals. It is necessary to take into account the fact that in this direction the development of the situation in the Russian part of Donbass is ahead of two decades, which means that it indicates the similar consequences in Ukraine for coal-mining cities.

Analysis of the prerequisites for the formation of the Donbass phenomenon, the study of trends that are laid down by statistical data, allows us to determine the following important aspects.

The development of the region was uneven, based on a resource economy. When a natural resource is exhausted, a gradual but irreversible process of de-industrialization begins.

We note once again – the coal has not run out – the need for coal has decreased. As historians testify, J. Hughes, the founder of Yuzovka – Donetsk, counted on the life of his industrial empire for 50-60 years.

Large multidisciplinary cities have developed in an advantageous location, gradually increasing and pulling into their orbit nearby territories and settlements.

History knows cases when majestic capitals disappeared from the map of the world, and cities that had a strategic status and influence have now turned into second-class provincial cities (Carthage, Genoa, Venice).

The Agglomerations of Donbass were formed from settlements at industrial enterprises. Enterprises were grouped near mineral deposits. Socialist cities have their own history, which begins with workers' barracks next to factories.

It can be assumed that the exploitation of the natural resources of Donbass was of a colonial nature. After all, the first investors were foreign capital – the Scots, Belgians, etc. The Soviet government was also more willing to take as much resource as possible from Donbass in a short time. It is impossible to speak seriously about the priority of the development of the urban environment and the quality of life. Among the arguments in favor, opponents give examples of regional development programs for Donbass, but the results of the implementation of these programs speak for themselves:

- The urban development planning proceeded from the needs of the industry in workers. The primary bias is due to the narrow profile orientation of heavy industry. So, during the Soviet era, the question arose of a shortage of jobs for women – after all, mining is a predominantly male profession. Again, they tried to solve the problem in a directive way – they built enterprises focused on women's work. The results have not always been successful;
- the priority for the maximum indicators of industrial production has led to environmental pollution of the territory, which is partly irreversible;
- cases and threats of man-made disasters caused by overexploitation;
- catastrophic pollution of water resources. This fact alone may be enough to make the area uninhabitable;
- unfavorable demographic situation and depopulation, which is actually becoming a fact;
- deindustrialization – and, as a possible consequence, degradation of industrial potential; an excessive number of places of detention, which is typical for the Soviet economy with the use of prison labor.

The deterioration of the ecological situation, the instability of the economic complex, the high proportion of industrial and communal storage areas in the structure of the city have led to the fact that at the present time these "tired" cities are large industrial areas, a significant proportion of the population of which lives in sanitary protection zones. [7]

The consequence of all these distortions, multiplied by the political turbulence of the post-Soviet period, was a significant deterioration in the quality of life of the overwhelming majority of the population. The social, political, economic, and financial crises have deprived the resources necessary for decisive progressive changes. A somewhat deformed structure of employment has taken shape. At the beginning of the 21st century approximately 10% of the population of Donbass was involved in management, 30% of highly skilled workers for non-physical labor, 40% of skilled manual labor, 13% of unskilled professions. [8]

For the first time, Donbass faced a situation when, instead of a recipient of labor resources, it turned into a donor. Objectively, this is a completely natural process. Industrial degradation is causing job losses. The wage arrears crisis is making local jobs unattractive. First of all, young people and highly qualified personnel leave. The deterioration of the situation enters a new circle.

Quote: "The number of workers in the Yekaterinoslav region in 1913 compared to 1861-1870 increased 41 times." In modern conditions, such an increase looks like something extraordinary. [8]

In the society of the region, paternalistic expectations are widespread, the essence of which is briefly described by the thesis "Donbass feeds everyone", "the center is robbing us". The Donetsk and Luhansk regions took the last and penultimate places in terms of the aggregate level of human development in the region. The factors that led to the low rating are due to unsatisfactory indicators of the demographic state, living conditions of the population, the level of education, a very difficult ecological situation, and an inappropriate level of development of the social environment. However, Donetsk region took the third place in terms of material well-being out of 27 regions of Ukraine.

Statistics, however, show that this public belief contradicts economic indicators. The share of GDP of the Donetsk region in 2010 was 12%, and the total share of subsidies and transfers reached 20.9%, and 27% in 2011. The Luhansk region contributed 4% of GDP, while subsidies and transfers in 2010 and 2011 were 7.8% and 11%, respectively. That is, Donbass received 2 – 2.5 times more than it gave. At the same time, the

https://doi.org/10.1051/e3sconf/202128004003

regions recorded the largest volume of wage arrears. [8]

Let us add one more aspect – the economic crisis has entailed humanitarian complications. The number of scientific workers, has decreased. But since the scientific staff had a narrow industry focus, this makes it impossible to use them in other areas.

Deindustrialization, social and humanitarian crises lead to the reproduction of an archaic type of survival – so-called "Copanks" (small illegal coalmine) and the collection of scrap metal. It is becoming the norm and no one is surprised when the trolley wire or cables are stolen.

But a crisis can turn into a disaster. All of the above are prerequisites for the current situation. The armed conflict was inspired, among other things, due to the deformed social and national structure of the region, regional proximity to the border, the lumpenization of the population makes the consequences in the region catastrophic.

At the beginning of the XXI century, the industrial cities of the Lugansk region faced a number of problems caused by the collapse of the industrial base. Such as: ecological overload of territories; outdated technology of the industrial era; curtailment of the urban planning base; decrease in the number of working-age population.

In 2014 this situation was aggravated by the armed conflict. There is a situation of artificial division of the territorial and economic complex, which has been going on for more than 6 years, the time period is comparable to the stage of implementation and planning of the general plan decisions. [9]

Fig. 4. The JFO demarcation line.

The JFO demarcation line separates the two regions of Donbass, blocks a number of highways and a national railway. The north and most of the agricultural land of the Luhansk region are under the control of Ukraine. The south and center are not controlled by the government. The front line runs along the boundaries of the main agglomeration formations and along natural barriers. (Fig. 4). [10]

The situation has certainly negative consequences, the issues of territorial development, improvement of urban planning and planning organization are generally removed from the agenda.

The uniqueness of the situation is that the place of conflict is an urban area. (Fig. 5). [11].

Despite the localization of the front line, the area of the conflict can be compared to a small European state. Ukraine does not control 407 km. state border, 47 000 km^2 or 12% of its territory (including the Crimea), the demarcation line reaches 427 km. (Fig. 6). [10, 12] 1.4 million people are registered as temporarily displaced, and almost 4 million remain in the uncontrolled territory. External military intervention has a hidden hybrid nature. Foreign policy factors dominate in resolving the armed conflict.

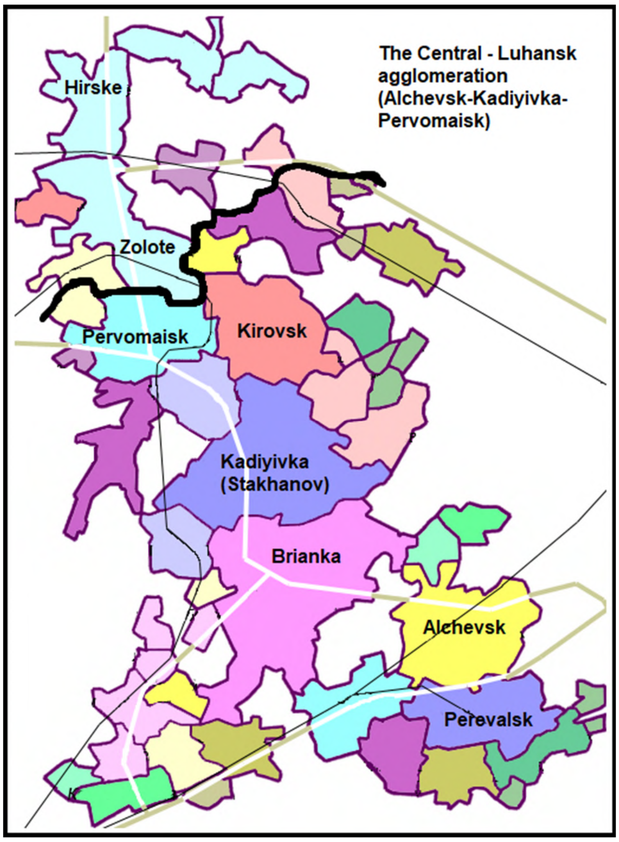

Fig. 5. The scheme of the Central – Luhansk agglomeration. The administrative boundaries of settlements.

Unfortunately, there is still no reason to assert that there is a well-developed, effective and resource-secured scenario for overcoming the crisis.

The political component dominates and makes economic forecasts insignificant.

There may be several basic scenarios:

- Return of control over the temporarily occupied territories in the near future;
- Return of the temporarily occupied territories in the distant perspective.

We will not consider the first scenario in our article, as it will probably involve a number of political agreements that create burdens.

The second scenario makes the territory of the Luhansk region controlled by Ukraine, with the only

 https://doi.org/10.1051/e3sconf/202128004003

large agglomeration – Severodonetsk-Rubezhnoe – Kremennaya, the object of research.

Yu. M. Belokon provides a classification of regions based on function and form. The regions of the first group are divided according to their functional purpose: metropolitan; transport; cross-border.

Regions of the second group, according to special natural conditions, are divided into coastal, riverside and regions with minerals. [7] The author notes that industrial regions with minerals have the same tasks of modernizing the coal industry, providing employment for the population, improving the environment, looking for new incentives for development. Separately, it was noted that cross-border regions should become an actual object of the urban planning. [7]

Fig. 6. The territories of Ukraine occupied by illegal armed group (the temporarily uncontrolled territories of Ukraine).

At the level of scientific discussion, the question arises of an extensive interpretation of the list of individual special functions of the regional typology. Along the demarcation line, along the existing border, which is temporarily uncontrolled by Ukraine, a de facto border region is being formed, within which the concept of "cross-border cooperation" can acquire another function – "border control" – when the state border plays a protective role.

It is advisable to direct further research to drawing up a balance of the available resources of the region. [13, 14] The list of balance groups under consideration should contain: population and its demographic structure; territory including agricultural land; industrial production volumes; available resources of minerals; level of provision (self-sufficiency) with water resources; level of security (self-sufficiency) with energy resources; transport development of the territory; the level of social development of cities and territories; the level of environmental pollution. It is also advisable to perform zoning of the region's territory in modern conditions.

4 Conclusions

The transformation of the engineering and planning organization of the territory of the Luhansk region in the conditions of the armed conflict in the East of Ukraine is a fait accompli. A new political and economic reality is being formed, which cannot be ignored. The Luhansk and Donetsk regions are artificially separated. The industrial region developed as a coal and metallurgical industrial complex. Its status as an inland region has led to the formation of a large number of urban agglomerations and a dense transport network. The analysis of the demographic state, territorial, town-planning complex testifies to the discrepancy between the typological features of the region in modern conditions. The Luhansk region is turning into a cross-border region. The existing classification of regions provides for two groups – by typological features of function and form. There is a need to expand the list of individual special functions of regional typology. In modern conditions, in the Luhansk and Donetsk regions, a border region is formed, consisting of sections of the state border and the JFO demarcation line. On this line, the function of cross-border cooperation, where the dominant is the exchange of goods, services, cultural contacts, is supplemented by the function of border control. This function aims at limiting a certain type – fixing the border, the mode of crossing it, strict adherence to legally established procedures. The addition of the functions of the regional typology should be taken into account in the tasks of improving the territorial planning organization of the Luhansk region.

Abstract. The article deals with the topical problem of economic deprivation of young women and men and alternatives for overcoming it through the introduction of the psycho-correctional practices of positive psychology. The subject of the study is to find out the gender symmetry or its violation in the position of the subjectivity of genders in the choice of life activity strategy. The conceptual model of positive psychology and its components as the indicators of the psychological state of young women and men in personal and professional self-determination are presented. The social and psychological factors that determine the satisfaction of the youth with the choice of a job and its content, the ability to direct and adjust the requests and motivations of young women and men in searching for a more successful professional and social status have been substantiated. It has been found out that overcoming gender inequality in social and economic gender expectations, and a sense of economic deprivation of the youth is possible by internalizing the basic principles of personality self-determination through learning, and involvement in positive psychology. Egalitarian orientations concerning the importance of receiving professional education and developing adequate personality qualities are important for youth but especially for young women's internal subjective well-being experience. Satisfaction with social environment and confidence in the coming day the most common international concepts of economic happiness for group youth psychology.

1 Introduction

COVID-19 affected all layers of the population economically and deepened the level of youth "relative deprivation" as the perception of oneself (family or one's own reference group) as less economically prosperous. Self-esteem, being an indicator of a socially less successful economic personal or group compared to others, has always been much higher for the students and working youth. It is young people entering adulthood who have to face such socio-economic challenges as the need to find the desired professional activity and opportunities to achieve it, pay for vocational education or living separate from the family, look for a job without the necessary level of professional qualifications and work experience, support their own financial needs related to the age interests of the youth and more. Eric Erickson by no coincidence found an all-embracing psychological definition of this age stage in the periodization of personality development: identification versus isolation. The process of creating identity occurs during adolescence, but primarily takes place in early adulthood,in soudens years. Reaching adulthood in modern society is not always a linear or clean transition. As generations continue to adapt new adult markers are created that add different social expectations to what it means to be an adult.

2 Problem statement

Experiencing relative economic deprivation as a psychological source of personal unhappiness due to the un fulfillment of many social and basic needs, ways to correct toxic thoughts and find positive meanings in overcoming internal conflicts is one of the areas of positive psychology, which explores the factors of personal subjective well-being (SWB) [1].

Positive psychology explains why the level of youth aggression (various types of crime), when many young people with their inability to accept socio-economic challenges and implement ways of overcoming them, is higher in authoritarian countries, where the share of the middle economic class is low and there is a significant economic difference in the incomes of the upper, middle and lower classes.

Why do the very youth need special psychological support? Because the youth without a proper professional and educational level create a vicious circle of poverty reflection when young people start families that, due to low economic levels, do not have a sufficient level to meet the material and spiritual needs of their own children who, like their parents, are not able to achieve a sufficient level of education, as well as professional in the near future, which poverty again reproduces a new circle of poverty,

* Corresponding author: okiki77777@gmail.com

so called vicious circle [2, 3, 4, 5]. The results of the researches testify the difference of value attitudes towards material enrichment of the student youth, which underwent socialization within the framework of market and planned socialist economy [6, 7, 8].

Gender-specific problems in young adulthood are observed in double employment of women, their lower economic status, the level of payment. Even in democratic egalitarian societies dominate the ideas of exploiting one-sex responsibility (man is the main breadwinner and the dominative social and personality expectations from women-to stay at the role of mother, children and caregiver for elderly members of the family) [9, 10, 11, 12, 13]. So the main spheres of her subjective well-being in self-realization, working activity and developing personality habits, skills and knowledge is in family settings. Every new generation continues to adapt new adult markers and create that add different social gender expectations to what it means to be a professional and economically sufficient adult.

The experience of European countries is considered to be the most effective regarding implementation of the positive actions on achieving gender equality. Council of Europe Gender Equality Strategy (2018–2023) focus on six strategic areas: 1) to prevent and combat gender stereotypes and sexism; 2) to prevent and combat violence against women and domestic violence; 3) to ensure the equal access of women to justice; 4) to achieve a balanced participation of women and men in political and public decision-making; 5) to protect the rights of migrant, refugee, and asylum-seeking women and girls; 6) to achieve gender mainstreaming in all policies and measures [14].

If the concept of economic culture in the past was mainly characterized in the financial categories such as expenditures, profits, income, etc., today the economic categories are inseparable from the civilizational principles of providing them with certain legal and moral principles. That is why a set of internal and external factors that have caused the frustration of certain social needs is always considered in the process of analyzing the various causes of protest youth economic movements.

Among them, the degree of satisfaction or dissatisfaction with their social and economic status due to the frustration of a ging demands in the psychological theory of economic deprivation [15]. The relative economic deprivation as a source of the frustration occurs in comparison with others, such as the average income of women with average income of men. At the same time, the greater the level of "relative deprivation" is the greater the mass of protest, often aggressive, angry behavior.

Without stopping on the consequences of gender economic deprivation, which are widely presented in the scientific literature [16, 17, 18], we want to draw attention to the ways of overcoming it through the application of the principles of positive psychology, which is capable of activating personal potential of an individual in overcoming traditional gender stereotypes [12, 13, 19, 20, 21, 22]. After all, if the position of women is assessed according to their economic status, both in relatively economically prosperous societies and in those that are just getting on the rails of a market economy, it will occupy the lowest level.

Since the subjective sense of well-being mediates any sphere of human activity, a lot of research in positive psychology is devoted to the problem of the relationship between professional work and a sense of satisfaction with it, including the research of the factors for happiness. Although mindfulness is integrated in many positive psychology manuals as a "positive" technique, they have hardly developed the implications of their use or have investigated the relationship between mindfulness and human well-being [23, 24, 25, 26, 27, 28].

The opinion of the co-founder of the principles of positive psychology M. Seligman referring to the understanding of the significance of the doctrine of roles in young adulthood states that "The positive emotions of confidence hope and trust, for example, serve us best not when life is easy, but when life is difficult. In times of trouble, understanding and building the strengths and virtues like valor, perspective, integrity, equality, loyalty – may become more urgent than in good times" [1, p. 322].

The study aim~~s~~ is to find out the gender symmetry or its violation in the psychological background personality position of the genders SWB in the choice of professional, working life activity strategies.

3 Conceptual models

Progress in psychological measuring of happiness has been made in understanding the components of SWB: there is no gender correlation between estimation material prosperity and possibility to get perfect professional education and happiness of youth the adaptation, goals and meanings, the cultural influences national indicators of happiness [29].

The favor to the gender division of personal self-realization spheres into male (subject-instrumental) and female (guardian-expressive), is inherent in young men and women with traditional orientations, often as an example of parental imitation. The adherents of egalitarian equality have constructed an androgynous, multidimensional concept of building not only a professional career but also a family one on the basis of the interchangeability of family roles and ignoring the role in their construction of gender. Such universalization of family and professional roles of the genders was motivated, among other things, by the factor of the possibility of achieving the fullness of happiness and life satisfaction in equal partnership.

It is important to note that a happy partnership and personal self-realization at work, as an indicator of internal satisfaction of the position of positive psychology, as indicators of a happy life, is the openness to the new experiences and at the same time self-reliance, actualization of self-aspirations, self-sufficiency, self-perception without protective mechanisms, stereotyped expectations, the position of subjectivity in life.

4 Goals and objectives of the research

The object of the study was socio-psychological factors that determine the SWB of the university students as the strivings for the necessity of developing basic professional skills and opportunities future job activities and accepting its demands and personality expectations. The discovering subjective gender differences in meanings, strivings and abilities concerning the requests and motivations for future economic status.

The subject of the study was to find out the gender symmetry or its violation in the position of the students subjectivity in the choice of life activity strategy.

The main hypothesis at the initial stage of the study was the assumption that young people's individual acceptance of patriarchal gender culture which may be observed difference in personality internalized descriptive, indicative or directive-prohibitive sex stereotypes may reduce and limit the level of desirable work positions in developing subjectivity as reflection of professional abilities, career aspirations, demonstration of individual self-presentation. Traditional gender orientations motivate manifestations of polarization of life spheres and self-realization as among female as well as among male students.

The methods of the research included a complex of complementary techniques (theoretical analysis of the achievements of positive psychology; conducting gender-homogeneous, gender-mixed focus groups, content analysis of finishing sentences as short students answers to opened questions connected with the topic: "It's me in 10-15 years" standardized A. Matchak psycho diagnostic test [30].

Gender differences have been noted and compared in the construction of individual scenarios of future socio-economic life in the time perspective in 10-15 years with the dominative content of individual oral narratives fixed in focus groups discussions. The standardized individual interviews have been conducted was with those young women striving for success in professional non-traditional careers, such as police, military, or IT spheres as well for women and males with strict traditional gender orientations. Egalitarian orientations concerning the importance of receiving professional education and developing adequate personality qualities are important for all young people, but especially for young women's internal subjective-being experience. Different kinds of external or internal factors of students function can determine their subjective well-being in chosen professional education or in starting point of practice searching for the desirable economic status. But the quest for youth meaning is a key part of what makes males and females self-assertive in everyday activities coming toward the desirable financially sufficient constant not temporary status.

Satisfaction with social environment and confidence in the coming day are the most common international concepts of happiness on the individual and group youth psychology including gender.

In total, 298 students (180 female students and 118 male students) participated in the research.

5 The results of research

The data obtained in the research study confirm the results of our previous studies, namely the fact of more purposeful development of the image of economic "I" in male students due to higher coherence of affective, cognitive and behavioral components with internalized traditional gender stereotypes concerning the importance for male persons SWB reaching material and financial status and for the women's SBW to have such husband [21, 22, 31, 32]. Female youth more accept emotions connected with subjective working experience with such emotions as fear, sadness, or anxiety as indicators of unhappiness. Male youth are more likely to overcome them.

Female students show a higher level of intimate competence as an important component of social competence (the method "Questionnaire of three types of competence", A. Matchak [30]) (Fig. 1).

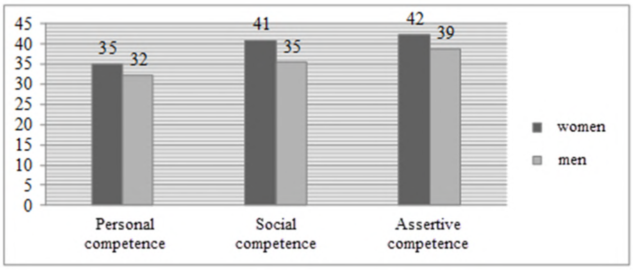

Fig. 1. An average values by "Three types of competence questionnaire" methodology.
Annex to figure1– steins raw results to women and men in**:**
personal competence: females 35–37=3, males 29–33=2;
social competence: females 39–41=5, males 33–35 =3;
assertive competence: females 42–45=5, males, 39–41=4,5.

They are also able to successful presentation their skills and qualities in the social exposition situation compared with the lower men's indicators, which reflecting the ability to be guided by certain standards of presentation of their own professional ability in situations where the person is at the center of attention. Young women are more focused on social interaction than young men; they are characterized through more communicative persistence in the process of doing professional duties. Comparison of the self-determination scale indicators in values of life demonstrates higher results of male selection, reflects their unconditional acceptance of their own life activities, higher self-confidence in successful professional self-actualization.

According to the assessment economic position and "happy human being" turned out to be a significant factor determinates gender difference in economic strivings and professional expectations (Table 1).

The content analysis of the student`s narratives as well as discourses of focus groups discussions (Questions for discussion like "What social environment influence make you more happy?", "What kind of your educational activity make you happier?" etc.) demonstrated the manifestation of gender stereotypes in economic and financial spheres (in youth the design of the concepts of femininity as economic objectivity; masculinity as economic subjectivity and androgynous as gender neutral).

Table 1. The degree of assimilated traditional stereotypes by students (in %).

Varieties (character) of gender prescriptive stereotypes	Percentage of egalitarian stereotypes in the form of women and men *Self*	Percentage of patriarchal stereotypes in the form of women and men *Self*	Varieties (character) of gender prescriptive stereotypes
Descriptive (orienting)	25%	75%	**Descriptive** (orienting)
Prescriptive (evaluating)	10%	90%	**Prescriptive** (evaluating)
Proscriptive	2%	98%	**Proscriptive**

Young women in evaluating SWB in themselves demonstrated a higher level of self-satisfaction in such aspect of it as moral acceptance, coherence of moral views with real behavior, their own ability to manage people than their male counterparts. At the same time, women show a much higher level on the scale of “protective strengthening of self-esteem”, which indicates, on the one hand, a certain degree of acceptance of one’s Self and, on the other, a fear of possible rejection of oneself, rejection of significant others, desire to show oneself in a better way.

In our view, such a gender disparity of results testifies to the greater subordination of a woman's life scenarios, her goal setting and self-realization to the effects of traditional gender stereotypes, which increase a woman's anxiety before expecting to have children, motherhood, a combination of professional and home responsibilities, which affects the corresponding anxious reflection of woman's own meanings of being.

Thus, the dilemma of self-determination in the choice of professional and family roles in the young adulthood demonstrates the negative power of the psychological impact of stereotypes, compliance with which does not allow young people to meet the need for individual choice. On the contrary, the adoption of egalitarian culture, which give~~s~~ them a feeling of happiness through the strengthening of self-confidence, performs an energy-saving function in building family relationships, educational, professional and career growth. It should be noted that the modern female students are more psychologically adapted to functioning in the future “male world”, more successful in mastering political, managerial roles, unusual professions than males, who find it difficult to be involved in the household guardianship and parental roles, teaching professions, family circle~~,~~ etc. However, those women, who are ready to play on the “male field”, still taste androcentric behavior: in the role of leaders they are going to adapt men’s management styles, evaluate economy and career aspirations through the prism of “male” needs and demands, ready take on additional household responsibilities, exacerbating, exasperate the phenomenon of double employment. Nevertheless male financial happiness was related more to being a taker rather than a giver, whereas meaning of women’s economic aspirations were related more to being a giver than a taker.

One of the objectives of the study was to identify alternatives to economic deprivation, including its gender aspect, by applying the psycho correctional personality (individual) approaches.

Positive psychology considers the personality achievement in any kind of self-realization through the prism of adherence to happiness as the intersection between pleasure and meaning. Among set of meanings are the principles of rationality as consciousness and using in practice thought full ways to achieve prosperity, understanding the necessary educational and professional means to achieve it, the consistency of different kinds of economic activity on the legal principles adopted in the nearest social environment. This refers not only to the standards that correspond to the release of some educational product, but also the development of personality features of economic behavior (e.g., frugality, self-assertiveness).

The prestige is the principle of economic activity, which deals not only with the place of work, shopping, but also, above all, with the self: the social status of the profession, working skills and abilities, career economic opportunities, holding a position and career perspectives, the uniqueness of possibility to realize the main meanings of the own Self. The prestige forecast of the chosen profession is an important indicator of the students economic culture, which sometimes have been motivated by “fashionable” professions, such as law or IT, and does not take into account their connection with personality inclinations~~.~~ However, many young people started to notice, that the profession should be in need in far future on the contrary to choosing in soviet times a foreign language translator, which lost its prestige in terms of globalization and open borders.

Altruism is a positive psychology principle that testifies to the extent of the sacrifice for the material support of others: families, elderly parents, orphans, people with special needs. It is not only about charitable activities for the benefit of those who need help, but also about conscious self-sacrifice, self-denial for the economic benefit of others, which brings satisfaction, raises self-esteem. Thus, the key principles of positive psychology of getting satisfaction from economic activity, its pleasure allows not only to be financially supported, but also to have positive emotions to work. Their implementation requires proper psychological counseling of the youth, professional diagnostics and professional selection, which predicts the possibility of satisfaction with the chosen activity as a basic motive for its economic success.

Disclosure of the psychology of gender differences in the economic behavior of the student youth, the ability to be guided by economic principles at different levels of material functioning has a hidden psychological basis such as a positive objective attitude to their personal economic potential and prospects for its application (self-reflection). It is this basis that dictates the different economic behavior of men and women in terms of limited material resources and expanding the range of personal needs. Thus, in addition to the internality of the locuscontrol, the principles that ensure positive thinking play an important role in achieving the desired status of economic well-being and overcoming the psychological pressure of gender stereotypes.

It is known that in positive psychology the feeling of satisfaction, happiness, well-being is divided into two types: hedonistic as situational pleasure, which is usually short-term, sensory according to the external source of pleasure and value, intra-personal. The latter is achieved when a person manages to achieve meaningful goals, objectives, sense of life. That is why this kind of positive experiences is called the result of value-semantic well-being, realization of personal potential.

Discussions about which satisfaction brings more comfort and pleasure hedonistic, situational or value-semantic, show that the latter is the most preferable, because it is able to shift deep emotions, raise self-esteem, prolong the feeling of happiness. The example of one of the student groups, which instead of celebrating the prom, decided to donate the saved money to the orphanage for the needs of local children deprived of parental attention, can be illustrative in this respect. At the same time, proms were quickly erased from the memory of other student groups, but those who organized a holiday for children remembered this for many years and celebrated the memorable event.

Although positive psychology considers both sources of satisfaction equally important and denies personal self-realization as a higher level of satisfaction, its basic postulates are based on the importance of experiencing a state of passion for activity, absorption by its essence, fascination with their achievements. The culture of human economic existence is precisely to maximize the long-term achievements of material support for the realization of vital goals and to minimize situations of the lack of funds. It is no coincidence that poverty is considered the greatest human defect, and material prosperity is a necessary condition for the personal freedom.

If we apply the model of the founder of positive psychology M. Seligman [1, 29] to the economic well-being of a person, then personal achievements according to his theory of well-being depend on the implementation of basic conditions, such as: inclusion in the activity, passion for it, satisfaction with interpersonal relations with people, realization of the sense of their activity and its achievements. Such conditions of the personalized activity can be realized both at the level of microeconomics (household, smallholding, etc.) and at the macro level.

If the proposed conceptual model of life satisfaction of positive psychology is compared with the social situation of student youth development, then its structural components can act as a prognosis and at the same time a diagnosis of psychological states of a young person (well-being or dissatisfaction with life), who masters the basics of their profession, determine their future material status. Indicators of their present and most importantly future psychological well-being can be indicators of the wheel of fortune by M. Seligman, namely confidence in the right choice of professional self-determination and its personal significance, consistency of the chosen path with their own life values, belief in their own ability to fully realize their potential with maximum dedication and in harmonious relationships with others.

The results of research of emotions nature, their impact on a person suggests that the strength of positive and negative emotions are different, that is the well-being of the individual depends on their proportion, the share of both, their ratio in life. According to the research done by representatives of positive psychology, the negative emotions reduce the life satisfaction much more than the same amount of positive ones. The ratio of negative to positive is 3:1, that is bad is much stronger in terms of influence than good.

Theoretical principles of positive psychology prompted us to find the adequate to its conceptual provisions focus groups and training programs with emphasis on the development of the youth ability, regardless of gender, to establish social relations with other people, involve in professional activities in the present and in the future, to realize their views on life, meaningful life orientations, to achieve success.

6 Discussion

According to positive psychology the more people felt their activities were consistent with the core of themselves, the desirable values of their self, the greater meaning they report in their dream about and real professional choice.

According to some male opinion (youth with egalitarian gender orientations in focus-group discussions) scarcity of money in performing some desirable for them “female” professions (teacher, medical nurses, preschool educator, library worker etc.) reduced possibility for self-realization, when possibility for happiness less possible in comparison to meaning. Desirable for youth social-economic status, professional male`s and female`s self-image is formed depending on gender orientations.

Students with egalitarian gender attitudes of both sexes perceive satisfaction with the chosen educational profession as a source of economic activity, which is connected with internal work satisfaction-positive personality traits: the capacity to love chosen vocation, feelings to be proud of it (“we are future teachers”, “psychologists”, “journalists”), independence and creativity in individual performance of working duties, effective interpersonal skills, talent of personality growth in everyday practice and experience.

Prioritize in economic well-being of students with traditional gender orientations are connected mostly with external work satisfaction factors: less strongly with subjective activity, personality determination, mostly with objective circumstances of working duties, the salary level, relations with the colleagues.

The collected empirical data suggest that the social roles of men and women are still largely mediated by gender stereotypes, which serve as a guide in differentiating the areas of their economic self-expression, determining the life scenarios declared by students and views on material obligations. However, the realities of the economic functioning of genders have formed a greater personal potential of women in the development of traditionally male economic space, the trigger for which will be the dominant over patriarchal egalitarian ideas of personal professional self-presentation.

7 Conclusions

Overcoming gender inequality in social and economic status, in particular a sense of economic deprivation is possible by internalizing the basic principles of economic culture through learning, development, involvement in positive psychology.

Pilot testing of a number of questionnaires allowed us to identify the most adequate structural research methods for the identifying feeling of economic youth economic well-being and economic self-deprivation such as the degree of self-reflection and satisfaction by chosen kind of the professional education, as well in the self-analyzing the obtained working experience as skills, abilities and habits which will are in needs for the future professional activities.

Gender difference in the level of self-reflective estimation by students the necessary social and professional abilities have been investigated by the complex methods including A. Matchak psychological test for study the social competences as abilities to perform and be successful in close interpersonal contacts, in actualizing the self in wide social communication and exposition and in social environment demanding assertive behavior. The measurement of such working abilities and skills considered the psychological background of SWB in successful performance any professional job activities and usually considered more often by male population.

The study results exposed higher development of social competences in female students especially among those who are adhered to egalitarian gender culture. Female and male students with traditional attitudes to profession division and household duties, social activities for men's and women's are less optimistic in the individual subjective wellness in reaching the desirable economic status relationships with others, absorption, realization of the Self in a personally significant social activity, its conformity to own system of views, life values.

The realities of gender economic functioning especially among young women oriented on egalitarian sex relationships have shaped their greater personal professional potential and readiness of in intromission to the traditionally masculine economic professions-spheres. The trigger mechanism in striving SWB in economic status is in overcoming patriarchal ideas of bipolar personal professional self-presentation among youth.

Egalitarian attitudes and behavior are more likely help youth to open ourselves up to positive psychology in financial success on the way of their professional education. Gender differences in expected economic well-being and real strivings are best predicted by difference in gender orientations, personal vision on goal attainment and high self-esteem or self-efficacy, but not sex belonging. It is important for youth to feel belongingness in a society and it social care and psychological guardian ship, so they can develop their full working potential and achieve self actualization.

Internalizing egalitarian gender culture can enhance the individual economic activity, increase the motivation for self-development in professional education.

Regional development of enterprises: concept of sustainable development and data mining

Nataliia Maksyshko[1,*], *Sergey* Ivanov[1], and *Serhii* Cheverda[1]

[1]Zaporizhzhia National University, Department of Economic Cybernetics, 66 Zhukovskogo Str., Zaporizhzhia, 69600, Ukraine

Abstract. Ukrainian enterprises are having a goal of get on with the concept of sustainable development. However, in the different regions of Ukraine there are various challenges, which needed to be considered in management of enterprises and organizations. Therefore important question is discovered about the main directions of developing enterprises, which will be relevant for a particular region. This study is highlighting statistic indicators, which characterizing the economic, social and environmental components of sustainable development of Ukrainian enterprises. On the basis of data about 1990-2019 years (2020 isn't used due to the impact of the pandemic, which significantly affected these parameters) cluster analysis of sustainable development enterprises of Ukraine by region is made. In the result of clustering regions were separated in three groups (clusters). Detailed analysis of the features of indicators of each cluster (group of regions) is made. On the basis of results of clustering recommendations about priority directions of increasing the level of sustainable development of Ukraine are discovered. Results of the study can be used in management of local enterprises and organizations in the certain regions to improve the level of achievement of sustainable development goals.

1 Introduction

In modern business conditions, enterprises face the processes of globalization, intensive changes that lead to uneven market development, uncertainty of the environment, inconsistencies in the implementation of the needs and interests of different market participants. It becomes obvious that achieving economic growth alone, even constant, is insufficient, as high rates of production can coexist with low efficiency of economic and social processes, become a threat to the environment. Therefore, it is important to ensure sustainable development of enterprises in the conditions of constant changes [1].

An important role in achieving sustainable development of enterprises is played by the evaluation of its indicators. This allows faster effective decision-making through the choice of appropriate criteria, methods, technologies, models, response mechanisms, interaction [2].

The formation of a system for assessing the sustainable development of Ukrainian enterprises is carried out taking into account the most problematic aspects of management, related to the functioning of ecosystems, ensuring environmental, economic and social needs of society. It should perform not only informational and control functions, but also reflect the desired changes and trends and timely direct efforts to achieve the goal.

Sustainable development has many dimensions, such as improving the social living conditions of the population, improvement of production infrastructure and other. Research in these areas has been carried out in many scientific works [3-4].

However, it is important to improve the economic efficiency of enterprises in the region subject to the concept of sustainable development. The scientific works of many scientists were devoted to this task [4-7]. These studies help to consider important factors of statistics of key indicators regional development of enterprises.

Modeling of the dynamics of indicators regional development of enterprises can be produced by new methods of Data mining. There are many works dedicated to use these methods to improve quality of management of enterprises on different levels: local, region, country and other [8-10].

Despite the broad theoretical and applied elaboration of sustainable development management in different socio-economic systems and at the level of the country's economy, it should be noted that there is no methodology for integrated management of sustainable development from the standpoint of a holistic approach to modeling the dynamics of such development.

The relevance of the study is based on the questions of sustainable development of enterprises, the analysis of statistic indicators of enterprises in different regions, data mining methods in researching of sustainable development enterprises of Ukraine by region. The purpose, tasks and directions of the research are determined by the insufficient development of the management level of local enterprises and organizations in sustainable development goals reaching.

The purpose of this article is to obtain recommendations for justification for the choice of strategies development of regional enterprises, based on results of data mining with taking into account the concept of sustainable development.

2 Materials and methods

The concept of sustainable development is a new approach that defines new guidelines for the world order. However, significant changes in connection with the transition to sustainable development in all spheres of public life, including political, involve the definition of new complex goals and objectives that require some transformation of this system.

If we consider sustainable development from the point of view of the social component, the agenda of social institutions includes problems related to establishing a balance between the needs of modern generations (namely, the need for global governance, finding effective ways to address pressing issues), on the one hand, and , on the other hand an efficient economic system.

Sustainable development is the process of building a state based on the coordination and harmonization of social, economic and environmental components in order to meet the needs of present and future generations. Harmony in the development of three components of the modern world: man – economy – nature is the basis of sustainable development.

On the way to sustainable development of a country or region, research of indicators that determine this development are important: social (life expectancy, level of education, sanitation, involvement of the working population); ecological (preservation of biodiversity and natural landscapes, waters, atmospheric air, use of household waste); economic (capital investment, remodeling of production, GDP per capita, development of science and technology); institutional (access to information, environmental education, public participation in addressing issues of local and national importance).

The main goal of sustainable development of Ukraine is to ensure dynamic socio-economic growth, preserve the quality of the environment and rational use of natural resource potential, meet the needs of present and future generations by building a highly efficient economic system that stimulates environmental sustainability, productive work, scientific and technological progress. and also has a social orientation.

More and more attention is paid to the practical implementation of the concept of sustainable development in the world. The aggravation of the economic, environmental and social situation requires each state to take measures so that the activities carried out on its territory are not the cause of environmental degradation, which leads to changes in the functions of the state. Hence the modern responsibilities of states:

- to preserve and to use the environment and natural resources in the interests of present and future generations;
- to support the ecosystem and ecological processes necessary for the functioning of the biosphere, to protect biological diversity and to adhere to the principles of maintaining maximum sustainability of productivity during the use of living natural resources and ecosystems;
- to establish appropriate norms of environmental protection, monitor changes in environmental quality, as well as publish all data in this regard.

Thus, the struggle for the preservation of the natural foundations of life should be included among the important state tasks. It is natural that the priority of the environmental function in a global crisis should be quite high – it needs to take place immediately after the economic, to the greatest extent to influence government decision-making.

Since the formation of the system of assessment of sustainable development of enterprises on the basis of criteria and indicators is carried out taking into account the most problematic aspects of management related to the functioning of ecosystems, environmental, economic and social needs of society, it must perform not only informational and control functions. reflect the desired changes and trends and timely direct efforts to achieve the goal.

At the international level, criteria and indicators are a tool to help:

- creation of a single database relating to the state of the economic sector of the world, their ability to perform environmental, economic and socio-cultural functions in order to solve global environmental problems that threaten the existence of mankind, as well as providing basic needs of present and future generations;
- improvement of international cooperation in order to develop common provisions, recommendations and define long-term strategies and, accordingly, to form common approaches and requirements to the system of evaluation of the country's progress towards sustainable enterprise development, including clear and uniform interpretation of terms, methods of collecting, processing, disseminating information, etc. ;
- harmonization of important aspects of international trade related to ensuring compliance with the principles of sustainable development, environmental and socio-economic requirements for the management process.

At the national level, the application of a system of criteria and indicators will be useful for:

- control over the implementation of Ukraine's international obligations related to the decisions of the UN conventions on environment and development, as well as the provisions set out in the Concept of Sustainable Development of Ukraine and other state regulations;
- improvement of national economic, legal framework to take into account the basic requirements for sustainable use of natural resources, national priorities and environmental and economic characteristics of nature, as well as adjusting existing programs, various measures in line with economic trends;
- improvement of the decision-making process regarding the conservation, protection, reproduction and use of natural resource potential.

At the operational level of management include evaluation of the effectiveness of business, which coordinates the management at the operational level, as well as the formation of information base not only for management purposes and objectives, but also to improve all environmental practices in accordance with existing environmental and economic conditions, potential and new capabilities achievements in scientific and technical sphere.

Definitely, using only the system of assessment can`t provide sustainable development without new methods and models. So, to improve the achievement of goals of sustainable development its necessary use data mining.

To solve this problem is recommended to use classification and cluster analyses. Unlike classification tasks, cluster analysis does not require a priori assumptions about the data set, does not impose restrictions on the display of the studied objects, allows you to analyze indicators of different types of data (interval data, frequencies, binary data). Also, chosen variables must be measured on comparable scales.

Cluster analysis allows to reduce the dimensionality of data, to make them clear. Cluster analysis can be applied to sets of time series, here periods of similarity of some indicators can be distinguished and groups of time series with similar dynamics can be determined.

Let's define variables for cluster analysis.

To choose variables for clustering lets analyze indicators of entrepreneurship development (Fig. 1).

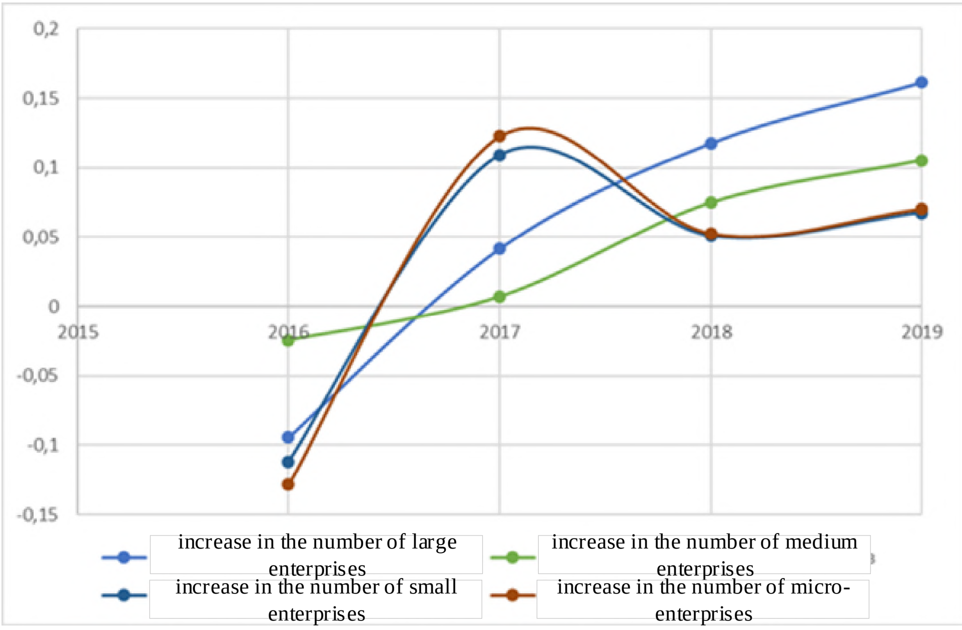

Fig. 1. Increases in the number of enterprises by type in the period from 2015 to 2019 [11].

One of the important indicators of business development, which determines the favorable business environment in particular and the state of the economy as a whole, is the number of small and micro enterprises. A feature of the development of domestic entrepreneurship is a significant jump in the number of small and micro enterprises, caused by the adoption in 2016 of the "Strategy for the development of small and medium enterprises in Ukraine until 2020."

There are 380597 enterprises in Ukraine with net profit about 523778 UAH million according to state statistics service of Ukraine [11]. Due to the analysis of enterprises development, seven variables were chosen for clustering from the full number of 62, which can fully characterize directions of the sustainable development.

In the analysis we will consider the following objects: Vinnytsia, Volyn, Dnipropetrovsk, Zhytomyr, Zakarpattia, Zaporizhzhia, Ivano-Frankivsk, Kyiv, Kirovohrad, Lviv, Mykolaiv, Odessa, Poltava, Rivne, Sumy, Ternopil, Kharkiv, Khmelnytsky, Cherkasy, Chernivtsi, Chernihiv regions.

As variables for clustering we will use the parameters that characterize directions of the sustainable development of the region:

1 – economic direction:
- quantity of sold products by regions;
- the number of employees in business entities by region;

2 – social direction:
- staff costs of enterprises by region;
- capital investments in environmental protection by regions;

3 – ecological direction:
- current costs of environmental protection by region;
- carbon dioxide emissions by region;
- emissions of pollutants into the atmosphere from stationary sources of pollution by region.

The process of ensuring the sustainable development of the enterprise involves the solution of a significant number of complex tasks, among which a lot of space is occupied by the processes of evaluation and implementation. The main task in the study of development is to identify for a particular enterprise all the opportunities that can be used.

To analyze the sustainable development of Ukraine by region, we will use statistics for 2015-2019 (2020 will not be used due to the significant impact of the pandemic, which significantly affected these parameters) [11].

Among the indicators of the dynamics of these parameters we will use the following.

Average time series value:

$$X_{cp} = \frac{\sum_i^n x_i}{n} \quad (1)$$

where X_i is the value of the indicator at period i, n is the total number of periods.

Standard deviation (RMS):

$$X_{CKO} = \sqrt{\frac{\sum_i^n (X_i - \bar{X})}{n}} \quad (2)$$

where $\bar{X}$ is the average value of the indicator.

The value of time series growth for 2015-2019:

$$X_{\text{p}} = X_{2019} - X_{2015} \quad (3)$$

where X_{2019}, X_{2015} values of indicators in the specified periods.

The main point of the study is the choice of distance, this distance depends on the options for the final partition. The most common are two procedures: the method of "nearest neighbor" and the method of "far neighbor".

The criterion for determining the similarities and differences of clusters is the distance between the points on the scattering diagram. This similarity can be "measured", it is equal to the distance between the points on the graph. There are few ways to determine the degree of distance between clusters, which is also called the degree of proximity. The most common way is to calculate the Euclidean distance between two points i and j on a plane when their X and Y coordinates are known. Therefore, in paper there is used Euclidean distance for cluster analysis.

If we need to find the distance between two points in the space of a larger number of measurements, the formula changes to the number of specified measurements.

To perform cluster analysis, we use the MS Excel toolkit add-on Data Mining.

3 Results

We use the tools to search for categories of Analysis Services by the above indicators (Table 1). To search for categories, use the value of the searched categories – 3.

Table 1. The total number of objects in the clusters.

Category name	Row counter
Cluster 1	12
Cluster 2	5
Cluster 3	5

Thus, we obtain three clusters. Cluster 1 has the largest number of facilities, including Volyn, Zhytomyr, Zakarpattia, Kirovohrad, Mykolaiv, Rivne, Sumy, Ternopil, Kherson, Khmelnytsky, Chernivtsi and Chernihiv regions. This cluster is characterized by the following characteristics (Table 2).

According to this analysis, the following conclusions can be drawn: the first category includes regions with low levels of harmful emissions and personnel costs. These are regions without developed industry with moderate costs of enterprises to support workers. Significant changes in the number of employees involved in the enterprise are constantly increasing.

Let's analyze cluster 2. This cluster includes such regions as Dnipropetrovsk, Zaporizhzhia, Kyiv, Poltava, Kharkiv regions.

The second cluster is characterized by the following characteristics (Table 3). According to the results of the cluster analysis, this group includes regions with a moderate level of emissions of toxic substances and an increase in current expenditures on environmental protection. However, the environmental costs themselves in this cluster are higher than in other clusters. This cluster is represented by regions with developed industry.

It can be concluded that with a significant increase in emissions of substances High level of growth of carbon emissions: 11118,3964094464 – 35759,6843737088, the cost of improving the environmental situation is not significant.

Table 2. Characteristics of the cluster 1.

Column	Value	The importance (%)
Standard deviation of carbon emissions	Low:< 652,3916407808	100
Average values of staff	Low:< 8850140,26319299	96
Average values of products	Very low:< 99659768,2879332	82
Average values of emissions of substances	Low:< 59,2431839616	81
Standard deviation of values of staff	Low:< 3912059,98129316	79
Average values of carbon emissions	Low :< 3486,4703696896	62
Growth of investment	Low:< 118108,007038976	61

Table 3. Characteristics of the cluster 2.

Column	Value	The importance (%)
Standard deviation of emissions of substances	Average:33,502394944 – 163,1016636416	35
Growth of environmental costs	Average:739425,918124032 – 1987735,51220654	33
Standard deviation of investment	Average:90005,5426793472 – 676550,476719718	28
Standard deviation of environmental costs	High:>= 516068,619426202	27
Average values of environmental costs	High:636797,562493338 – 2291954,27998597	27
Average values of investment	Average:184307,307380736 – 714445,43874007	27

Let's analyze cluster 3. This cluster includes such regions as Vinnytsia, Ivano-Frankivsk, Lviv, Odessa, Cherkasy regions.

The second cluster is characterized by the following characteristics (table 4).

Table 4. Characteristics of the cluster 3

Column	Value	The importance (%)
Standard deviation of carbon emissions	Average:652,3916407808 – 6697,0645192704	100
Growth of emissions of substances	Very High:>= -4,4394651672	55
Average values of products	Low:99659768,2879332 – 210243602,310234	49
Average values of emissions of substances	Average:59,2431839616 – 629,3593749504	32
Average values of values of staff	Average:8850140,26319299 – 19665719,2475034	31
Growth of values of staff	Average:16272684,5190504 – 26496168,0780296	26

According to clustering data, this class includes regions with average values of harmful emissions and low growth of environmental costs. Unlike other clusters, the objects of this show a very high level of pollution growth with a low value of the products produced by enterprises. These areas are mainly aimed at the recreational sector and tourism without significant industrial facilities. The growth of emissions is largely due to the development of the economy and the emergence of new enterprises during the period under review.

The results of the analysis can be seen in Fig. 2, which shows the ratio of low, medium, high and very high levels of growth in emissions, environmental costs and production by category.

Thus, we can conclude that the regions with developed industry (cluster 2) show the largest increase in the cost of improving the quality of the environment. Also, cluster 3 is characterized by a significant increase in the number of manufactured products and an increase in harmful emissions with a consistently small contribution to the maintenance of the environment.

According to the results of the cluster analysis, three groups of regions have been identified for which it is advisable to apply different types of strategies to implement the concept of sustainable development.

There is no doubt that due to a number of differences in the sustainable development of enterprises in different regions, it is necessary to apply different strategies for the integration of the concept.

In general, based on the resolution of the Verkhovna Rada of Ukraine on the Concept of Sustainable Development in Settlements, it is planned to improve the current state of development in the following areas: coordination of social, economic, urban and environmental aspects of development of settlements and surrounding areas. , creating appropriate conditions for the development of enterprises of all forms of ownership for productive employment, restoration of human and scientific potential, a sufficient number of jobs and others.

To do this, a number of measures are planned to:

- ensuring the rational use of natural resources;
- improving the social living conditions of the population;
- providing the population with housing;
- improvement of production infrastructure;
- development of transport infrastructure;
- development of engineering infrastructure;
- formation of a full-fledged living environment in settlements;
- improvement of sanitary and hygienic conditions;
- protection from adverse natural phenomena;
- prevention of man-made accidents.

However, the funds of local enterprises and organizations of all forms of ownership, capital investments of the state and local budgets are used for the implementation of the measures [12]. Therefore, it is necessary to identify those measures that will bring the greatest benefit within the concept of sustainable development for the region.

Based on the cluster analysis, we offer recommendations for the selection of priority measures by region (Table 5).

These recommendations identify priority actions for areas that need more attention. The application of the stated priorities will allow to carry out actions to achieve the concept of sustainable development more effectively.

The application of the recommendations will allow on the basis of a more efficient allocation of resources to enable the following tasks, which were established in [13]:

– to ensure the annual growth of gross domestic product;

– to promote a change in the structure of exports towards the growth of products and services with a high share of value added;

– to achieve productivity growth in the economy through diversification, technical modernization, creating incentives, including tax incentives, for innovation and increasing the number of jobs.

4 Conclusion

The peculiarity of the functioning of enterprises in the current conditions of a long crisis is their constant dependence on the whole set of industrial and non-industrial entities, which is characterized by increased fierce competition. As a result, it negatively affects the competitiveness and sustainability of domestic enterprises. Therefore, the main task of the enterprise in modern economic conditions is to solve the problem of sustainable development and the ability to withstand adverse situations.

The using of the main socio-economic indicators to get sustainable development in the international, the national and the operational levels was analyzed.

The sustainable development of Ukrainian enterprises is analyzed, on the basis of which the main factors of restoration of the main socio-economic indicators of Ukrainian enterprises are chosen.

A cluster analysis of the dynamics of sustainable development of Ukrainian enterprises by regions is constructed. Based on clustering, the regions were divided into three groups. A detailed analysis of each of the groups of regions was conducted.

On the basis of cluster analysis, recommendations are proposed on priority measures to increase the level of sustainable development of Ukraine, which allows improve quality of citizens' life and reach economic development.

The obtained results can be used in the development of funds of local enterprises and organizations to improve the efficiency of the allocation of resources, which will increase the quality of achieving sustainable development goals.

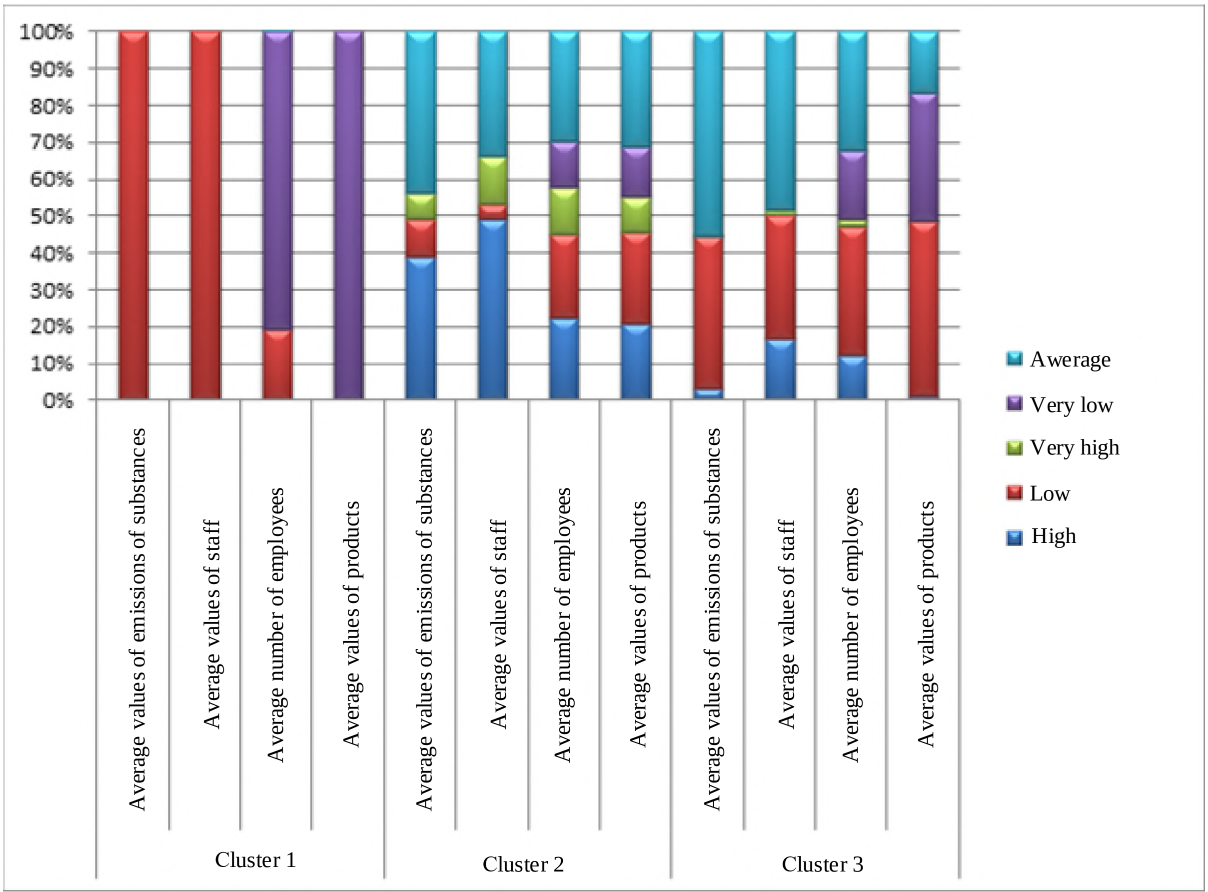

Fig. 2. The results of cluster analysis.

Table 5. Recommendations for measures to achieve the concept of sustainable development by region.

Cluster	Regions included in the cluster	Recommended measures
1	Volyn, Zhytomyr, Zakarpattia, Kirovohrad, Mykolaiv, Rivne, Sumy, Ternopil, Kherson, Khmelnytsky, Chernivtsi and Chernihiv regions	a) ensuring the rational use of natural resources; b) improvement of production infrastructure; c) improving the social living conditions of the population.
2	Dnipropetrovsk, Donetsk, Zaporizhzhia, Kyiv, Luhansk, Poltava, Kharkiv regions	a) improving the social living conditions of the population; b) improvement of sanitary and hygienic conditions; c) prevention of man-made accidents.
3	Vinnytsia, Ivano-Frankivsk, Lviv, Odessa, Cherkasy regions	a) protection against adverse natural phenomena; b) improvement of production infrastructure; c) the formation of a full-fledged living environment in settlements.

Abstract. The article identifies the main types of land valuation – expert monetary valuation for individual evaluation of particular plots and normative monetary valuation for systematic valuation of land for tax purposes. To conduct the last one, a mass assessment of land plots considering geoinformation technologies is used. It is established that at the present stage of normative monetary valuation of non-agricultural land plots in Ukraine two methodologies are used: within the settlement and outside it. The project of the unified methodology of normative monetary valuation of land plots by combining the existing methods submitted for discussion by the Ministry of Economy, Trade and Agriculture of Ukraine is considered. The values of land plots according to the existing and unified methodologies are studied on the example of four land plots under gas stations, which are located in the city of Kharkiv and outside it. It is established that the values of land plots, determined by existing and unified methods, differ both in the direction of increase and decrease, the difference varies from 9 % to 97 %. It is necessary to conduct additional analysis of initial data and indicators, which are the basis for calculating and improve the offer unified methodology.

1 Introduction

Land valuation has recently become a mandatory component in land transactions [1], such as taxation, sale, withdrawal, consolidation [2], as well as in the field of land management, management of land resources [3] and State Land Cadastre management [4]. The value of land depends on physical, economic, social, environmental and legal factors [5]. As in other countries, there are two main concepts of land value - market (expert monetary valuation) and for taxation (regulatory monetary valuation) in Ukraine [6].

Expert monetary valuation of land is performed by an expert appraiser in the case of alienation and insurance, pledge, reorganization, bankruptcy or liquidation of the enterprise that owns the land, it is done by court decision [7]. The following methodological approaches are used [8]:

- capitalization of net operating or rental income (direct and indirect);
- comparison of sale prices of similar land plots;
- taking into account the cost of land improvements.

The expert appraiser uses a methodical approach, which is provided with complete information about the object of evaluation. But determining the exact and optimal approach is a difficult task due to the variation of factors that affect the assessment, so the value of the land is often perceived as contradictory and biased. In addition, there is a human factor that leads to an overestimation or decrease in the real value of the evaluated object. Despite these shortcomings, such a model for determining the value of land may be acceptable for individual assessment of particular plots.

Systematic assessment of all land plots included in the State Land Cadaster [4] is performed for taxation, determination of the amount of rent, alienation, land management and cadaster by conducting an assessment for taxation (in Ukraine analogue to the normative monetary assessment). It requires up-to-date data, clear consistency and transparency [9-11]. Therefore, in most countries of the world mass valuation of land using geoinformation technologies [12-19] is performed, which allows to automate the collection of factors influencing the assessment, to analyze them and the necessary calculations. The use of automatic estimation models has been popular for more than ten years in developed countries such as Sweden, Canada and the United States, and is becoming popular around the world [20].

There is also a tendency to form such automated land valuation systems in Ukraine, but it is only at the stage of creating a regulatory framework and improving the methodology of regulatory monetary valuation of land [21]. Therefore, it is important to study changes in the regulatory monetary valuation of land in Ukraine.

* Corresponding author: atatyanav2017@gmail.com

2 Changes in the regulatory framework for conducting regulatory monetary valuation of land

Nowadays the assessment of agricultural land and non-agricultural land is carried out separately in accordance with the relevant Procedures and Methods [22-27] in Ukraine. At the same time, appraisal works were allocated separately within the settlement [26, 27] and outside it [24, 25] for non-agricultural land plots. The focus will be on non-agricultural land in the future, as they are the most common and their value (especially land for industrial, transport, communications, energy, defense and other) is quite high.

The normative monetary valuation for non-agricultural land plots within a settlement is based on the capitalization of the rent income of the settlement. The main stages of determining the value of non-agricultural land within the settlement are shown in Figure 1 according to the procedure [26].

The cost of one square meter of land of a certain functional use (Cn) is determined taking into account the territorial planning, engineering-geological, historical-cultural, natural-landscape, sanitary-hygienic and engineering-infrastructural features of its location within the economic-planning zone according to the formula (1) [26]:

$$Cn = Cnz \cdot Kf \cdot Km3. \qquad (1)$$

The value of the coefficient Km3 is determined for an individual land plot on the basis of determining the share of the area occupied by the factor on the land plot. The share of the area is established mainly through the use of GIS technologies and electronic digital maps.

Normative monetary valuation of non-agricultural lands within the settlement

↓

The average base cost of one square meter of land of the settlement depending on regional factors of a location (Cnm)

↓

The cost of one square meter of land in settlements by economic planning zones (Cnz)

↓

Local coefficient (Kmz)

↓

The cost of one square meter of land of a certain functional use (Cn)

↓

The cost of land (Czd)

Fig. 1. Stages of determining the value of non-agricultural land within the settlement.

Normative monetary valuation of non-agricultural land outside the settlement is based on the norm of rental income and is determined by formula (2) [24]:

$$Cn = Pd \cdot Rd \cdot Sc \cdot Km \cdot Kv \cdot Kmc \cdot Ki, \qquad (2)$$

where Pd – area of the land plot accepted according to the data of the State Land Cadaster or land management documentation, m^2;

Rd – rental income per m2 of area for the relevant category of land, determined by the standards of rental income for the relevant category of land, UAH / year;

Sc – term of capitalization, years;

Km – coefficient that takes into account the location of the land;

Kv – coefficient that takes into account the type of land use;

Kmc – coefficient that takes into account the affiliation of the land to the lands of environmental, health, recreational, historical and cultural purposes;

Ki – indexation coefficient of the normative monetary valuation of lands.

According to the project of Normative monetary valuation methodology of land plots [21], it is offered to create a single valuation procedure for all land plots, regardless of their purpose and location relative to the settlement. But this takes into account the boundaries of the territorial community.

Normative monetary valuation of land (Cn) is determined by formula (3):

$$Cn = Pd \cdot Nrd \cdot Km1 \cdot Km2 \cdot m3 \cdot Km4 \cdot Kcp \cdot Kmc \cdot Kni, \qquad (3)$$

where Pd – land area, m^2;

Nrd – the rate of capitalized rental income per unit area;

Km1 – coefficient that takes into account the location of the community within the zone of influence of large cities;

Km2 – coefficient that takes into account the resort and recreational value of settlements;

Km3 – coefficient that takes into account the location of the community within the zones of radiation pollution;

Km4 – coefficient that characterizes the zonal factors of the location of the land;

Kcp – coefficient that takes into account the purpose of the land in accordance with the State Land Cadastre;

Kmc – coefficient that takes into account the peculiarities of land use within the category of land for the main purpose;

Kni – the product of the indexation coefficients of the normative monetary valuation of land for the period from the approval of the standard of capitalized rental income to the date of the valuation.

The application of the project Methodology [21] will unify the cadastral information exchange file (XML-file), which is used to enter information in the State Land Cadaster [4], and apply automated methods of calculating the value of land using data from the State Land Cadaster.

3 Investigation of changes in the value of non-agricultural land plots using a unified methodology

To study the change in the value of non-agricultural land plots using a unified method of calculating the normative monetary valuation, land plots with gas stations are selected and information about which is freely available on the Public Cadastral Map of Ukraine [28] (Fig. 2).

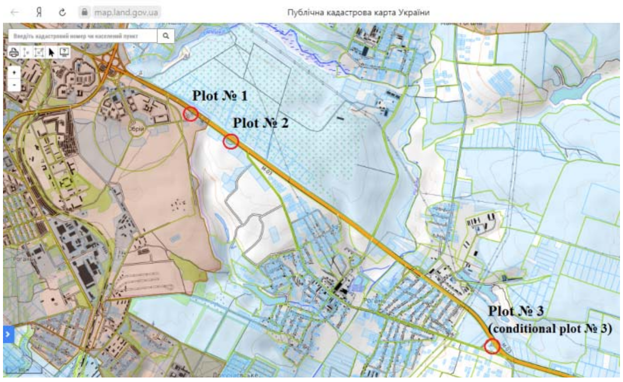

Fig. 2. Layout of land plots (according to the State Land Cadastre) [28].

Land plot № 1 (cadastral number 6310138200:10:015:0003) is located on the outskirts of the regional center – the city of Kharkiv (Fig. 2). The plot has a total area of 2 682 m^2 (0.2682 ha) and is privately owned. It is located along the highway of state importance M-03 Kyiv – Kharkiv – Dovzhansky (to the city of Rostov-on-Don) (Kharkiv – Rostov-on-Don (M19)) at a distance of 250 m from the eastern border of Kharkiv (Fig. 3).

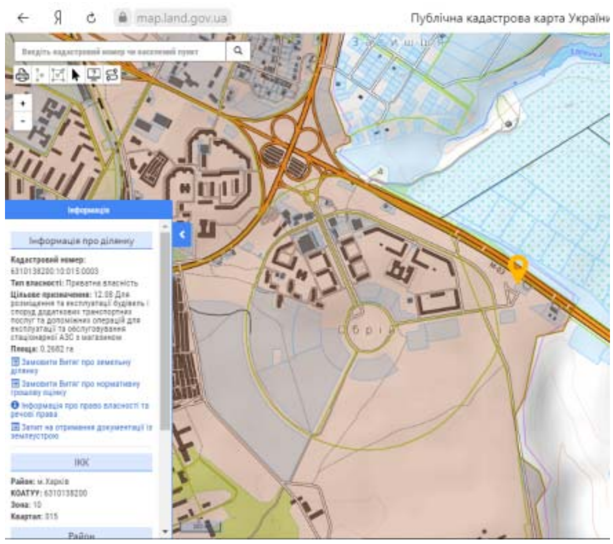

Fig. 3. Information on the land plot № 1 (materials of the State Land Cadaster – data of the Public Cadastral Map of Ukraine) [28].

Land plot № 2 (cadastral number 6325182500:02:005:0005) is located near the border of the regional center – the city of Kharkiv on the territory of Vilkhiv united territorial community within Maloroganska village council, Kharkiv district, Kharkiv region (Fig. 4). The plot with a total area of 10 000 m^2 (1.0000 ha) is state-owned. It is located along the state highway M-03 Kyiv – Kharkiv – Dovzhansky (to the city of Rostov-on-Don) (Kharkiv – Rostov-on-Don (M19)) at a distance of 350 m from the eastern border of Kharkiv. The distance between sections № 1 and № 2 is 560 m on the highway, between sections № 2 and № 3 – 4 600 m on the highway (Fig. 2).

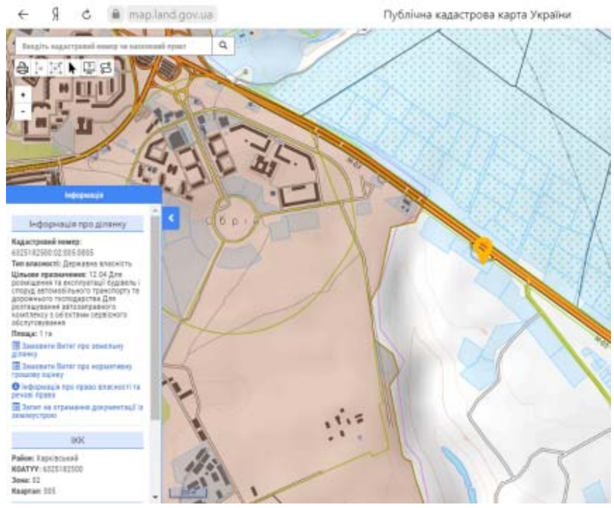

Fig. 4. Information on the land plot № 2 (materials of the State Land Cadaster - data of the Public Cadastral Map of Ukraine) [28].

Land plot № 3 (cadastral number 6325158500:01:041:0005) is located at a distance of km from the eastern border of the regional center – the city of Kharkiv on the territory of Rogan united territorial community within Rogan village council, Kharkiv district, Kharkiv region (Fig. 2). The plot with a total area of 5 270 m^2 (0.5270 ha) is state-owned. Located outside the village of Rogan near its eastern border (in the direction of Chuguev), along the highway of state importance M-03 Kyiv – Kharkiv – Dovzhansky (to the city of Rostov-on-Don) (Kharkiv – Rostov-on-Don) (M19)) (Fig. 5).

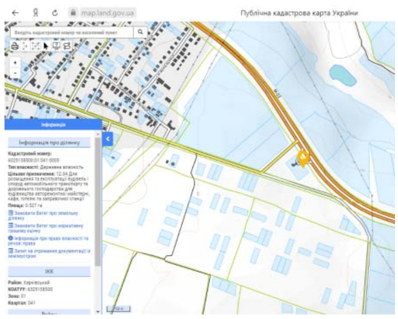

Fig. 5. Information on the land plot № 3 (materials of the tate Land Cadastre – data of the Public Cadastral Map of Ukraine) [20]

For investigation the conditional plot № 3 will be taken, which has the same characteristics as the land plot № 3, but is located within the settlement of Rohan village with the conditional cadastral number 6325158500:00:005:0000 (Fig. 2).

According to the existing regulatory framework and Figure 1, the calculations of the normative monetary valuation of land plots № 1 and № 3 are conditional, as plots are located within the settlements (Table 1). Indicators of the base value of 1 m^2 of land of the respective settlements are taken according to the data posted on the official website of the State Service of Ukraine for Geodesy, Cartography and Cadaster (State Geocadaster of Ukraine) [29]. According to the purpose of further analysis and comparison of indicators of estimation of data reduction we will carry out with base cost of 1 m^2 of land plots of the settlement for 01.01.2020, that's why the indexing factor (Ki) is applied.

According to the calculations of the normative monetary valuation of land plots of same definite purpose, which are located along one highway of state importance on the outskirts of settlements at a distance of about 5 km, the cost of 1 m^2 of land located within the regional center – Kharkiv almost five times more than the cost of 1 m^2 of land located within the neighboring village of Rogan (Table 1).

Land plots № 2 and № 3 are located outside the settlements along one highway of state importance, but on the territory of the neighboring united territorial communities (Vilkhivska and Rohanska). According to formula 2 the normative monetary valuation of land plots № 2 and № 3, which are located outside the settlements (Table 2) can be calculated.

According to the calculations of the normative monetary valuation of land plots of one purpose, which are located along one highway of state importance outside the settlements, the cost of 1 m^2 of land № 2 located closer to the regional center – the city of Kharkiv is almost 13 % higher than the cost of 1 m^2 of land plots № 3, due to the coefficient, which takes into account the location of lands.

The next step is to calculate the normative monetary valuation of four land plots of the same purpose, which are located along one highway of state importance within and outside the settlements according to the draft methodology of normative monetary valuation of land plots [21] (formula 3). In order not to distort the results of the assessment, the coefficient that characterizes the zonal factors of the location of the land plot (Km4) is taken equal to 1 for all land plots. The results of the calculation of the normative monetary valuation of four non-agricultural land plots within and outside the settlements (under the gas station) according to the Project Methodology 2020 [21] are shown in Table 3.

Table 1. Normative monetary valuation of land plots within settlements (under the gas stations).

Indicator	Characteristics	Value	
		plot № 1	Conditional plot № 3
Pd	Land area, m^2	2 682	5 270
Cnm	Base coat 1 m^2, UAH (for 01.01.2020)	639,78	131,63
Km1	Regional location ratio	3	1,5
Kf	Functional utilization coefficient	2,5	2,5
Km2	Coefficient, which concerns the degree of urban value	1	1
Km3	Local coefficients for the location of land	0,87	0,87
Cn	**Monetary value 1 m^2 of land, UAH**	**1 391,52**	**286,30**
Czd	**Monetary value of land plot, UAH**	**3 732 056,64**	**1 508 801,00**

Table 2. Calculation of the normative monetary valuation of non-agricultural land outside settlements (under the gas stations).

Indicator	Characteristics	Value	
		plot № 2	plot № 3
Pd	Land area, m^2	10 000	5 270
Rd	Rent income per 1 m^2 area of relevant land category, UAH/year	0,6637	0,6637
Sk	Capitalization period, years	33	33
Km	Coefficient of land location	5,1708	4,5679
Kv	Coefficient of land usage	2,9750	2,9750
Kmc	Coefficient of land belonging to natural security, recreational, historical, health or cultural objects	1	1
Ki	Indexation coefficient of normative monetary valuation of land	1,8972	1,8972
Cn_1	**Normative monetary value of 1м^2 of land, UAH/m^2**	**639,21**	**564,68**
Cn	**Normative monetary value of land plot, UAH**	**6 392 100,00**	**2 975 863,60**

According to the results of calculations of the normative monetary valuation of four non-agricultural land plots within and outside settlements (under gas stations) according to the Project Methodology 2020 [21], the cost of 1 m^2 of land plot located within the regional center Kharkiv is the highest. The cost of 1 m2 of land № 2, which is located closest to the regional center – the city of Kharkiv (350 m) and at a distance from the site № 1 – 560 m is 4.75 times less than the cost of 1 m^2 of land № 1, and 1,53 times less than the value of 1 m^2 of land № 3 and 1.68 times less than the value of 1 m^2 of conditional plot № 3. The results of comparing the calculations of the normative monetary valuation of four non-agricultural land plots within and outside settlements (under gas stations) according to the current methods [25, 27] and the project Methodology 2020 [21] are shown in Figure 5. According to the results of calculations the regulatory monetary value of land № 1 will increase in 2021 by 15 %.

However, the regulatory monetary value of land № 2 will decrease in 2021 by almost half (47 %). This is due to the value of the capitalized rental income ratio, which is determined depending on the population in the settlement, which is the administrative center of the community. A slight decrease in the regulatory monetary value in 2021 is projected for land plot № 3 – by 9 %. And for the conditional land plot № 3 it is possible to increase the normative monetary assessment in 2021 almost twice (by 97 %), which is partly due to the use when calculating the base value of 1 m^2 of land of the settlement (Rogan village) according to the land valuation settlements held in 2009.

Table 3. Calculation of the normative monetary valuation of non-agricultural land outside settlements (under the gas stations) according to the Project Methodology 2020 [21].

Indicator	Characteristics	Value			
		plot № 1	**plot № 2**	**plot № 3**	**conditional plot № 3**
Pd	Land area, m^2	2 682	10 000	5 270	5 270
Nrd	Rate of capitalized rental income per unit of area	639	87	133	133
Km1	Location coefficient of the community within the area of influence of large cities	1	1,3	1,3	1,3
Km2	Resort and recreational value coefficient of settlements	1	1	1	1
Km3	Location of the community within the areas of radiation pollution coefficient	1	1	1	1
Km4	Zonal factors coefficient of the land location	1,000	1,000	1,000	1,000
Kcp	Land purpose coefficient	2,5	2,5	2,5	2,5
Kmc	Peculiarities of land use coefficient within the category of land for the main purpose	1,001	1,19	1,19	1,304
Kni	Product of coefficients' indexation of normative monetary valuation of lands	1,000	1,000	1,000	1,000
Cn$_1$	Normative monetary value of 1 m^2 of land	**1 599,10**	**336,47**	**514,38**	**563,65**
Cn	Normative monetary value of land	**4 288 786,20**	**3 364 700,00**	**2 710 782,60**	**2 970 435,50**

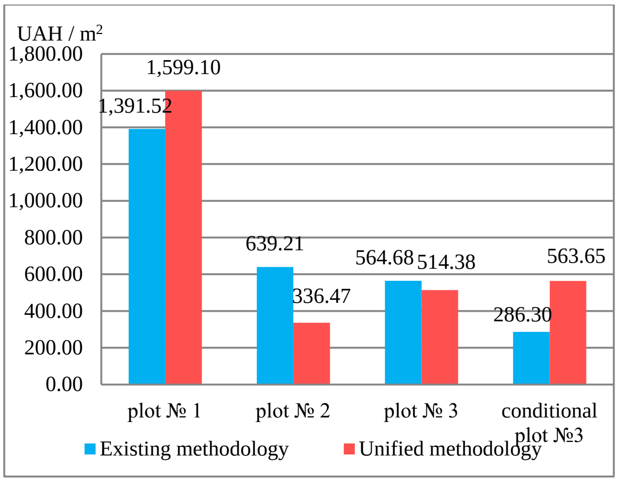

Fig. 5. The results of comparing the calculations of the normative monetary valuation according to the current methods [25, 27] and the project Methodology 2020 [21].

4 Conclusions

1. Works on land valuation do not lose relevance.
2. The use of geographic information technologies in the implementation of land valuation works create preconditions for the development and improvement of both land valuation works and the convenience of using its results by various entities.
3. The unified approach to the normative monetary valuation of land, offered by The Ministry of Economic Development, Trade and Agriculture of Ukraine, increases the convenience and improves the quality of land valuation work as a source of filling the State Land Cadaster with reliable data.
4. These calculations prove the need to analyze the initial data and indicators that underlie the calculations of the normative monetary valuation of land and further improvement of the proposed approach, in order to establish the fair value of all land.

Abstract. The article is devoted to the implementation of sustainable development goals in the training of social employees and military personnel engaged in military and social work. The purpose of the research is to develop a training program “Social work with military staff and military-social work”. There were used such research methods as comparative analysis, theoretical analysis, generalization, survey, modeling, synthesis. The result of the article is the developed program that consist of three modules. Among them there are such modules as “Digital tools for teaching social work”, “Theoretical foundations of social work with servicemen and their families”, and “Practice of social work with servicemen and their families in the community”. The program features are following: a training form and a set of approaches to its content. There are the program prerequisites for the study result implementation such as the mastering by teachers of the tools of media education, the distance technologies and their methods of use, and interaction of community specialists with military component in training. The prospects for further research are the development of specialization disciplines in the higher education institutions on the research issue. The scientific novelty consists of a set of scientific approaches in the program content developing, clarifying the essence of the “military and social work” concept and others.

1 Introduction

We associate the relevance of our research with the fact that:

1. Sustainable development means improving conditions for maintaining health, peace and harmony in countries and communities, ensuring gender equality, overcoming poverty and hunger, reducing inequality, ensuring openness, love of peace, security, resilience and sustainability of cities and towns, high level of education as well as providing decent work and ensuring economic growth, and etc. All these are the social aspects of sustainable development within the competence of social policy. One of the approaches for ensuring sustainable development is social policy, and it solves the social problems of various categories of the population, expresses the interests of various categories of the population, and promotes the realization of human rights. In the context of sustainable development, it is a social policy to preserve humanity and its resources to meet the necessary needs. The social policy is implemented through the social welfare but the social work is implemented through the provision of standardized social services for those in need. Today, the social policy in Ukraine is participatory, and it’s unlike the EU countries. Its resources are not enough to solve the problems of those who has suffered from the military conflict, pandemic, migration and etc. Therefore, there are significant resources in the field of sustainable development policy and social work. The sustainable development policy comprehensively solves the social problems of the population and provides goals as criteria for solving problems. Social work is aimed at solving the[*] people situations with socialization, adaptation, rehabilitation, as well as the people who are in difficult circumstances because of life crises, trauma, and other various external circumstances. So, the sustainable development policy can be implemented through social work with servicemen with particular social problems (socialization, adaptation, rehabilitation, integration, etc.) as a result of the military conflict in Ukraine, the pandemic, or the transformation of society.

At the same time, social work with military personnel in the context of sustainable development of society was not considered in the higher educational institutions educational programs. Although it has significant opportunities for this. The training matters for work with military personnel are included into the program of entrance examinations for a master degree in social work of various institutions of higher education. [1, 2]. In the curriculum of individual higher educational institutions is

[*] Corresponding author: trubavina@gmail.com

included such topic as “Social work with representatives of problem groups, military personnel” [3, 4]. At the same time, the practice reflects that the problems of servicemen and members of their families have increased with their involving into the military conflict in the East of Ukraine and the pandemic. That is why the trained social workers are required today both in the conflict zone and in peaceful communities.

2. The Ukraine's sustainable development strategy should be assessed through the prism of the theory of central places. It has been proven that the theory of central places should be applied in practice not only in relation to the certain settlements, but to the countries. A prime example is the process of human resources formation and development. Conducting statistical analyzing of the initial data of the mentioned process in Ukraine (the dynamics of the population size, its natural movement and the level of unemployment) we have come to the conclusion that real conditions do not correspond to sufficient socio-economic conditions for the formation of the necessary competencies and improvements in people who are suitable for certain activities, as well as the use of the acquired potential of human resources in the process of creating benefits, taking into account the constant changes in the operating conditions. This leads to the migration, which is associated with certain risks to sustainable development [5]. Within the constant changes, in particular, with the emergence of an armed conflict in the East of Ukraine, the spread of COVID-19, we should review the content of training specialists according to the specialty 231 “Social work”, with the stages of implementation of John P. Cotter’s changes [6, 7]. Despite the fact that more than one hundred of Ukraine higher educational institutions are providing such specialists training, more specialists are required according to the listed changes. The solution to this problem is the organization of advanced training for specialists in the field of social work. Considerable emphasis in the content of the relevant program should be paid to social work with such categories as military personnel, of their families’ members, former servicemen, and in particular with those who has become disabled as a result of hostilities. Such advanced training is also advisable for the specialists in the moral and psychological support of military units (deputy commanders in personnel welfare), as they perform social work activities with military personnel within their units. Recently, the discussions regarding the transition from moral and psychological support [8] to psychological support with a method of comparative analysis, focusing on the NATO countries military formations have been taking place in military formations. In our opinion, this is not correct approach [9]. Even before the beginning of the conflict in the East of Ukraine, the sufficient socio-economic conditions for guaranteed recruitment of military posts in the Ukrainian military units were not created [10]. As a result, there is a lack of proper candidates for military service selection. Thus there is a necessity for socio-pedagogical prevention of maladaptation of servicemen [11] and other measures of social work.

3. The social work is necessary for the military personnel, members of their families, and military units in general the at are located on the territory of Ukraine in specific local communities and interact with them and are not isolated from the society. Therefore, a sustainable development in a society or community is an integral part of sustainable development in military units. The communities and the military units’ social services interaction was not traditionally carried out due to the closed nature of military formations. Today, these resources need to be combined, especially in the context of military conflict and pandemic, for their economy and rational use, as well as to achieve the goals 1, 2, 3, 4, 5, 8, 10, 16 in the field of sustainable development. The training of specialists for such interaction has not been conducted before in the interests of servicemen and members of their families.

4. There is a discrete issue of military and social work in military units with servicemen and their families’ members, as they are involved in the military conflict in Eastern Ukraine. There are dead and wounded combatants, received psychological trauma by servicemen family members as well as social and material problems. Ya. Spodar says that today “one of the priorities of the National Guard Command of Ukraine is the implementation of military and social work aimed primarily at ensuring social protection of wounded servicemen, their family members and killed combatants at combat missions [12]. Officers were not trained for military and social work before the military conflict in Eastern Ukraine. Although some issues of military and social work were included in some academic lectures and textbooks of higher military education establishments in Ukraine [13]. The National Academy of the National Guard of Ukraine and the National University of Defense of Ukraine delivers a discipline on military-social work with military personnel and members of their families. There is also a module at the bachelor degree training in this discipline, but the essence of such work is not clearly defined today. The concept of sustainable development as a guideline for such work has not been applied as well as there is no currently advanced training on this issue.

5. Since the 90s of the 20th century, there have been social services consulting centers for young people in Ukraine at the military commissariats, military units and at assembly points. However, these points do not take into account the specifics of our time - the military conflict in the East of Ukraine, its consequences, as well as new social, political and economic realities in Ukraine, and of course the pandemic. Thus, we need to update the content of advanced training of social workers of Ukraine to work with the military personnel and their families in the modern context.

6. Today the State social policy and social work as a direction of its realization through rendering of social services guarantee quality of life of all citizens at the level of the state standards (according to the legislation of Ukraine to all people who are in difficult life circumstances) [14, 15].To-day military personnel and their family members have a number of different problems of socialization, social adaptation and social rehabilitation, associated with military professional activities and its consequences (restriction of certain

human rights, problems with the employment of wives, high-quality education of children in small towns, problems of disability, adaptation of military veterans in civil society, lack of their own housing due to displacement in the country, etc.).The problems of the servicemen necessitated the attention of the leaders of the uniformed services of Ukraine. Their attention is focused on military-social work with their subordinates and members of their families as complementary social assistance and support from the capabilities of their departments. That strengthens the morale of the military. And the servicemen believe that they and their families will not be left without help in the performance of their official duty. These problems are related to health, quality education, decent working conditions, overcoming poverty and poverty in a pandemic and unemployment for family members, gender equality, countering violence, creating conditions for peaceful coexistence in communities, and etc. For example, there are international programs and projects for the Armed Forces of Ukraine personnel social adaptation [15]. In the future, these programs will be implemented only by Ukrainian specialists, who need to be already prepared for this activities. The orientation of Ukraine to the NATO, its social standards for the military today are far from the reality in Ukraine, and if there is no social welfare at this level, there should be, respectively, opportunities for moral and psychological support, military professional activity, that includes military social work.

7. Today we need modern social services of adaptation and rehabilitation in social work with servicemen in the community [17, 18]. A feature of modern social problems of servicemen is the impact of their participation in the military conflict on their future lives and the lives of their families. Among others there are such matters as problems of rehabilitation of combatants in conflicts in Ukraine and peacekeeping forces, psychological trauma due to tasks in the military conflict zone, which affect members of their families, further life of the families of fallen servicemen, peaceful and successful adaptation of the military in civilian life after demobilization due to injury, discharge from military service, etc. These situations are solved by the social services. Solving such new problems is at the same time solving the problems of sustainable development policy of society, and it is necessary to train specialists for this type of job.

8. Legislation on social services that solve social problems of the population and are implemented through social work defines them as “actions aimed at preventing difficult life circumstances, overcoming such circumstances or minimizing their negative consequences for individuals / families in them. Individuals / families can be provided with one or several social services at the same time”[15]. Difficult life circumstances are “circumstances that negatively affect the life, health and development of a person, the functioning of the family, which the person / family cannot overcome on their own. Factors that can cause difficult life circumstances are: a) old age; b) partial or complete loss of motor activity, memory; c) incurable diseases, diseases that require long-term treatment; d) mental and behavioral disorders, including due to the use of psychoactive substances; e) disability; f) unemployment; g) homelessness; h) person poverty; i) behavioral disorders in children due to parental divorce; j) evasion by parents or guardians of their responsibilities for the upbringing of the child; k) loss of social ties, including while in prison; l) child abuse; m) gender-based violence; n) domestic violence, o) getting into a situation of human trafficking; p) damage caused by fire, natural disaster, catastrophe, hostilities, terrorist act, armed conflict, temporary occupation” [15]. This enumeration allows to clarify the list of users of social services. These can be both veterans and active servicemen and their family members, but unfortunately, the resources of the military-social work of military units are not enough to solve most of these problems, and specialists who are to carry out this work have not received appropriate training. In the field of view of specialists who carry out military-social work, is their social and legal protection and socio-economic support in the Armed Forces of Ukraine [13] and social protection in the National Guard of Ukraine [19]. Other existing problems for military personnel and their families require interaction with social workers in the community. So, the training in identifying such problems and overcoming them in cooperation with attracted specialists is needed, as well as a separate management for advanced training, for which we also need to train specialists, both civilian and military.

9. Many social problems arise when people return from the zone of military conflict to peaceful service, families and peaceful cities. This is no longer their own military unit and it may be a different community. And a social employee needs to be able to offer a person necessary social services. This is a difficult to communicate category of people who are not used to being weak and asking for help, they held weapons in their hands, survived the war. Therefore, peaceful people need to be able to talk and work with them, especially women, who are most of all among social workers. There is no theoretical and practical training for future social workers with servicemen in civilian higher education institutions.

10. It should be noted that certain topics of training in higher education institutions still exist, but advanced training still does not exist. This is due to the fact that for social workers for the military it is differ because of different subordination to the Ministry of Social Policy and to Ministry of Defense. Interaction in the interests of servicemen and their family members is absent in the professional development programs, and servicemen today are not subject of the State social standards of social work. Therefore, there is no advanced training on the problem.

Thus, it is necessary to update the advance training for social work with servicemen of different categories and members of their families as the implementation of the state social policy of Ukraine in the context of the policy of sustainable development of the society. Such training should be provided by both civilian and military higher education institutions. This issue requires separate joint programs of disciplines, and not a separate topic in the discipline or an isolated discipline of only a civilian or only a military institution of higher education. Because they need to work in cooperation. Training today should be in a collaborative group for networking and understanding at the community level through the specific people who implement it. The common content is to solve the social problems of servicemen and their families in the context of sustainable development goals, which transfers social work with this category of clients from only social protection, payments, benefits to socialization and social problems through a wider range of social services in interaction with social community workers based on community interaction.

We interviewed thirty-four social workers of social services centers for families, children and youth and non-governmental organizations in Ternopil and Ivano-Frankivsk. They all answered that they did not have enough advanced training in higher educational establishment for such work, and modern approaches and methods of work are needed. Various tried and tested methods of working with servicemen and members of their families are needed too.

We interviewed fifty-six students of the six-year courses of the specialty "Social work" of higher educational establishments in these cities. We asked whether they would be ready to carry out such field of work. Everyone answered that not at all. The reasons for doubting the success of the work were called a young age, lack of experience (professional and life), the complexity of social problems and amount of such problems among servicemen and their families. Although no one said they would refuse to provide social services to this category of clients. This means that the strengthening of such advanced training is obligatory, taking into account gaps and sustainable development ideas. The question arises about the development of such an advanced training program, taking into account the specifics of professional responsibilities and opportunities, state social standards for the providing social services, departmental opportunities, pooling of resources in the community and cooperation in the maintenance of social services, etc. The development of such a program is the purpose of the article.

2 Research methods and methodology

Materials for the study are:

1. Legislation of Ukraine on higher education, military education, social work, social services, sustainable development, social policy of the state. The methodological significance is in the orientation of the program, that we will develop, on the best world models of building the educational process, solving social problems and problems of socialization of servicemen and their families, based on the competence approach in education, ideas of sustainable development in social work and military social work.

2. Regulatory framework for military social work in various law enforcement agencies [19, 20]. Today, the solution to the problem of improving the quality of officers of the security forces of Ukraine service depends on the human factor, moral and psychological support of the service, the microclimate within the military unit and the creation of various conditions for service, including social, economic, material, psychological, medical, etc. The unit commander is unable to solve all the social problems of his subordinates both of an individual and the entire unit. To help them, the positions of deputy commanders in welfare have been implemented. So they are responsible for such areas of work as military social work with personnel. He also carries out morale and welfare work with personnel. There is no definition of the essence of military social work in the legislation today. Therefore, the training of specialists for military social work should be carried out taking into account the regulations of military structures, as well as basic education, science, theory, technology, methodology. Note that the regulations are already based on the idea of sustainable development for goals 1,2,3,4,5,8,10,16. But their implementation at the level of practical social work is absent.

3. Characteristics and list of both general and special social needs and problems of servicemen and members of their families [16, 17, 21-27]. Older people, children with disabilities and others in need of outer support and assistance are particularly vulnerable in pandemics and military conflict, and need more support and assistance in their everyday lives. Thus, goal 10 in the field of sustainable development suggests that, in a pandemic, "Refugees and migrants, as well as the older people, people with disabilities and children, are particularly at risk to be neglected. In addition, hate speech against vulnerable groups is growing" [28]. These are essentially tasks of military social work and social protection, which coincide with the goals of sustainable development. The military conflict in Ukraine has significantly increased the number of social services users. The military themselves have already understood the necessity of social work with their colleagues and members of their families (assessing by modern regulations on the problem of military formations. The list of these problems) [21-27]. Also the military conflict made it possible to determine the current tasks and content of military social work and social work with servicemen and their families such as social adaptation, social prevention, social rehabilitation, social support, management of social services implemented through complexes of social services;

4. Social work with servicemen theoretical and methodological principles developed in the world and in Ukraine to solve their social problems. Thus, Joel F. Handler [29] says about British model of integrated complex family services at the local community level as a rigid set of social services. We believe that they still need some alternative, choice, taking into account the characteristics of customers and their families. But it is valuable to combine the diagnostic model of social work with social policy and management of social services in the community. This combination is not established in Ukraine. The social services are centralized according to standards and categories of clients. In the UK, all social services must comply not only with public social policy, but also be scientifically proved, useful in a particular community. Communication within the community is especially important [30]. The UK uses different approaches to social work, including intervention,

medical social work, group theory and work with them, the idea of group development (which coincides with our idea of family development and organizational development), problem-oriented and environmental approaches to social work [31], and that provides for individualization and differentiation in the provision of social services. But the client cannot determine and choose the set of services. It is the object of services. Since 2001, Ukraine has been working with clients as subjects of social services, only in certain identified crisis cases - as an object ("self-help" and "crisis intervention") [32]. Valuable in the UK is the methodology of working with the families of servicemen who have been involved in military conflicts "FOCUS". This methodology reduces military personnel and their family members' anxiety and depression and provides a long-term positive result. A family-centric approach to socio-pedagogical work with the family is useful for working with servicemen' families. It considers socio-pedagogical services as a subsystem of social services, as the main for learning a new positive model of behavior of family members, and as creating conditions for implementation family rights in society and community and family member rights in the family [32]. This requires considering working with a serviceman, taking into account the integrity and rights. We also relied on Carl Castro and Sanela Dursun's book "Reintegration of the Military Veteran" [33], which reveals the views of experts from all over the world on the problem, offers a methodology for assessing the veteran's needs, and a roadmap for achieving the best social services in the future. Also the description of the program of transition from military service to civilian life, the role of the family, the public, medical institutions in this process is valuable in this study. In the United States, the need for a program-targeted approach to the reintegration and provision of social services has been proven [34]. This is also confirmed by our work as a consultant in the Ukraine central state authority on social work in 2000-2015. We worked on the following state comprehensive and targeted programs for social support of the family: "Social support of the family"; "Social support for disadvantaged families"; "Social support of orphanages and foster families"[32], and implemented them. But there are no separate programs of social work to support servicemen and members of their families in Ukraine. We also relied on approaches to the social services for servicemen and their families in different countries. Among them there are social services and social programs in a peaceful life and in a conflict of Ukraine, the Great Britain, the USA, France and Germany, which use integrated, comprehensive, problem-oriented approaches, the theory of strengths, "self-help" and "crisis intervention"), took into account the results of the analysis of theories of social work in Ukraine [32, 35].

5. World and local experience on the problem. Thus, the goal of the "social service of the Swiss Armed Forces is to reduce social disparities. Assistance takes the form of personal advice on family, financial or legal matters. Topics include labor law (protection against dismissal, continued payment of partial wages), income replacement, health insurance contributions, debt collection and others…. assistance is provided through information, consulting, support, mediation and financial support"[36]. At the same time, the Swiss Armed Forces social service is a specialized agency of the armed forces that provides advice on social issues. It is a military function, not civilian work [38]. In the USA, Canada there are Centers and departments in the Ministries of Defense for work with personnel and veterans, researches of their social rehabilitation, social work with families of combatants are carried out, new approaches and strategies on their social adaptation to civilian life are developed, developed federal programs for the disabled and veterans, conducted research on the psychological and social characteristics of peaceful service and during hostilities [35]. Institutional forms of providing social services to servicemen and members of their families in the world and in Ukraine today are service hubs, integrated support centers, social services and their specialized formations, rehabilitation centers, personnel departments, etc. [39, 32]. Social service centers for families, children and young people have some experience in adapting servicemen to the conditions of service, for example, their psychological boarding on a Ukrainian Navy vessels. The Veterans of Military Conflict Department exists in the Ministry of Internal Affairs of Ukraine. It provides practical social assistance to veterans and members of their families. At the National Guard of Ukraine units, the military social work is carried out essentially as social welfare [19]. All participants in hostilities in Ukraine are provided with social welfare in accordance with the law [40]. It should be noted that military and social work in military units today can be carried out according to normative documents not only by deputy commanders in welfare. The legal acts allows to conduct such type of work with families, children and youth by specialists, such as the authorized bodies engaged in social work with families, children and youth; social work specialists; associations of citizens, charitable, religious organizations; legal entities and individuals that provide social services to families, children and youth; volunteers in the field of social work with families, children and youth (law on social work). Therefore, their experience and resources are appropriate for social work with servicemen. Military and social work is the sphere of activity of the military, but they can interact with other subjects of social work in the interests of solving social problems of the militaries and members of their families, the community in which the military unit is located.

6. Scientific sources on social and military social work, which clarify its essence, purpose, scientific basis. According to the legislation of Ukraine [14], social work is understood as "professional activity aimed at preventing, minimizing negative consequences and overcoming difficult life circumstances of families, children and youth, strengthening their ability to realize their own life potential". This totally applies to officers and their families and is in line with the sustainable development goals 1,2,3,4,5,8,10,16. Savitsky [41] considers that military social work, as well as social work in general, should be considered from such several points of view as: a) it is a kind of human activity - it concerns a person whose life in some way affects the army; b) it is the science of the laws of military social work, its

methods, principles, technologies; c) it is a science that sheds light on practical and transformative charitable practice in the plane of military society; d) it is an academic discipline that, based on the points of the theory of social work, its content shows the peculiarities of the practice of social services in the military social environment.

We agree with this meaning of social work, and it allows us to apply to military and social work all the theoretical principles and methodological developments of social work, to take into account the problems of servicemen and their families as well as methods of training social workers to train officers who practice military and social work. The same researcher defines that "military social work is the science of formation, development, charity in the army, the organization of social services and the providing of appropriate social assistance to servicemen, as well as all those who have or had some relationship to the defense of the Motherland" [41]. Thus, this definition emphasizes the purpose of military and social work, as well as the criteria for defining its objects. They are the active servicemen and those who were involved in military service. There are other points of view on this concept.

Military and social work today is understood in the Russian Federation as "a system of conceptual-theoretical, political-legal and organizational-practical measures of the state and non-state institutions and authorities to meet the needs, interests and benefits of servicemen discharged from military service and their families in the social sphere of life. It serves, on the one hand, as an instrument and conductor of the state's social policy in the military field, and on the other hand, as a concretization and addition of social policy to the activities of civil society institutions to realize specific social needs and interests, rights and freedoms, guarantees and benefits of military society [42]. We do not agree that military and social work is limited to those servicemen who are discharged to the reserve.

Today a number of acting servicemen also need social support and assistance due to the circumstances described above. But the idea of combining in the system the measures of different levels and spheres of activity that implements a systematic and multidisciplinary approach in social work is useful. Today, the Armed Forces of Ukraine interprets social work as "socio-legal, informational and organizational measures regarding promotion of the implementation of the rights, benefits, social assistance and appropriate compensations for servicemen and employees of the Armed Forces and other military formations of Ukraine, for the members of their families, by creating social conditions and guarantees in military and labor collectives which would provide their normal vital activity, conscientious and high-quality performance by servicemen and civilian personnel of the functional and service duties assigned to them" which is established by the legislation of Ukraine and other legal acts, thus military social work is divided into social and material maintenance and socio-legal protection [43].

Sharing the opinion of the authors on the need for social work to create social conditions and guarantees in military social work, we note that social services in Ukraine according to the legal acts are broader than both social welfare and legal protection and social and material security. Moreover, prevention measures are the part of military social work that includes not only educational but also social, psychological, legal content, and so on. Today the spectrum of social problems of servicemen and members of their families is bigger than 7 years ago. Therefore, the content of military social work requires improvement. There is an opinion that in Ukraine "military social work is an integral type of social work and military management, specifically military education, work on humanitarian issues" [41]. And it is true in terms of working with personnel. However, we believe that it should include issues of social management and management of social services, interaction in the community in the interests of servicemen and members of their families. Therefore, it is the way of sustainable development ideas implementation. Families of servicemen also have economic problems today. The Coronavirus pandemic, which has caused many family members of military personnel to lose their jobs, is already a challenge in military camps, where wives often work unprofessionally or are underemployed. Also, there is not much work for young people. A serviceman becomes the only working person in the family, not having the right under the legislation of Ukraine to work part-time anywhere except the scientific and teaching spheres. Therefore, we need to work to support and help family members to prevent impoverishment and create decent living conditions for ourselves and our children. These are goals 1, 2, 3, 4, 8, 10 in the field of sustainable development.

7. The philosophy and sociology studies of war and peace [44-52] determined the socio-philosophical foundations of military and professional activity and the purpose of military service during war and peace, which affects the problems of users of social services, features of their provision, content, technology and methods of social work and military social work in subdivisions and units. The philosophy of war and peace influences the peculiarities of training servicemen for peaceful service and in combat, the peculiarities of social management in military units and social work itself. The philosophy says about number of issues to be solved such as a need to solve a set of problems of servicemen in different conditions, the problems solution, a human factor as the basis of victories and defeats and social conditions for this, a problem-oriented approach in social work in combat, a need to form reliability and resilience of servicemen through competency and activity approaches as well as special training of social workers to provide social services in different conditions to the different categories of servicemen and their families [53, 54].

8. Educational programs of civilian institutions of higher education that train specialists in social work [1-4]. Today these programs almost don't take into account the problems of servicemen and members of their families as subjects and objects of social work. But they provide theoretical and practical foundations for working with different categories of the population, form professional competencies for this purpose.

9. Educational programs of higher military

educational institutions of Ukraine (the National University of Defense of Ukraine (NUDU), the National Academy of the National Guard of Ukraine (NANGU)) and of the world. The analysis of these programs shows the implementation of a competency-based approach in higher military educational establishment. However, there is no interaction with community social workers, sustainable development goals, modern social problems of servicemen and technologies and methods of solving them, world experience on the problem in programs of disciplines related to military social work. In the discipline "Information and propaganda support of military missions and operations", there is a module on military social work, but it does not take into account the issues of interaction with social services of the community and sustainable development. We believe that social work is a separate area of the officer's work, as it includes a range of social services and types of work aimed at solving social problems, of which educational and pedagogical problems are only a small part of the whole range of social problems of servicemen and these problems require a solution with the help of a complex of social services. That is, not educational work should include social work, and military social work can have an educational approach. The reasons for this are that the concept of socialization of the personality in pedagogy is broader than education, and includes it as a purposeful factor in the development of personality, as one of many factors that affect the development of personality and determine it. The Swiss experience of training social workers for the military forces is interesting. It is carried out as advanced training on the basis of education in social work, social sphere and military training (conscript schools). The training course for a military social worker is a fascinating three-week training course (technical course) that prepares for the specifics of social work in the army, as well as for the tasks and activities in favor of social service in the army. After the course an officer is appointed as a specialist. The course is conducted in conjunction with the army pastoral care and the army psychological and pedagogical service" [38]. But this course also did not provide preparation for interaction in the community and there is no focus on the goals of sustainable development. But the Swiss army has great social achievements in terms of social protection of servicemen and at the same time takes care of professional social work in terms of morale and psychological condition of the servicemen. In Germany, the servicemen emerging problems are solved by the social workers from the reserve officers who received the second higher profile education after dismissal at the expense of the Ministry of Defense [55, p. 218].

10. Basics of gender theory in military units. [56] 10% of women took part in hostilities in Eastern Ukraine. Since 2012 there have been female cadet sat higher military educational institutions. There are women who take up military posts. Therefore, it is necessary to take into account their points of view in decisions making concerning of creating social conditions for successful service. In addition, gender-based social work will help prevent family violence, sexual harassment at service, and gender education for men and women. Goal #5 of Sustainable Development states that today, "The coronavirus outbreak exacerbates existing inequalities for women and girls in all areas, from health and economy to security and social protection", "the data show that since the moment of pandemic outbreak beginning violence against women and girls, especially family violence, intensified." Women's economic freedom is the basis of social prevention of family violence. Therefore, a gender approach should be included in the program for the provision of social services.

The methods of our study are following: comparative analysis, theoretical analysis of sources, generalization, survey, observation, modeling and synthesis.

3 Results

In order to develop advanced training programs for working specialists of social services and the servicemen we had to solve several tasks. Among them there are: 1) to clarify the essence of the concept of "military social work"; 2) to determine the users of military social and social work services with servicemen and members of their families; 3) to substantiate and determine the theoretical foundations of such social work and the construction of such programs (in the context of sustainable development); 4) to develop advanced training joint program for social workers of the community and the servicemen who are responsible for this type of job in their units. As there is no legislative definition of this term in Ukraine as well as its unique understanding, we applied to native and international experience in solving the problem. In the United States, military social work has its own organizational structure, regulations, service delivery standards. It provides educational and qualification requirements for military social workers, specific professional training and following certain ethical principles [35, 57]. The military social workers positions were introduced at the United States Department of Defense. At the Department of Veterans' Affairs the positions were established to work with veterans. That is, in the United States, they work both with those servicemen who serve, and with those servicemen who are already retired [57]. At the same time, a profile approach is also interesting. It combines United States civilian social workers and servicemen and defines military social work as "continuous activities, political and administrative measures, and advocacy, including prevention, treatment and rehabilitation services for social clients, veterans, their families and the communities in which they live" [35]. This approach is multilevel and partnership-based to provide services to the military and their families. At the same time, it singles out military social work as a separate area of social work with servicemen. But it does not fully take into account the Ukraine realities and its current problems because it is permanent, and in Ukraine there is an acceptable concept of "help for self-help" in social work [32], which is limited in time and provides a gradual transition from crisis to development. Therefore, we agree with this approach in combination with other approaches that are appropriate in our country.

Today in Ukraine, "the purpose of social work in the context of military service is to restore the physical and mental strength of those who are assisted, to adjust the personal attitudes of clients, teaching them to properly perceive the coercive aspects of their lives; to introduce elements of social justice into the framework of subordinate attitudes which are typical of military service" [58, p. 149-156]. This focuses to social rehabilitation (recovery), social prevention, which are the types of social work, psychological and ethical approaches. But social work is needed by those who are in the conflict zone, veterans and the disabled, their families, and those who are currently serving in peaceful areas. The conflict in Eastern Ukraine leads to the social problems: deaths of servicemen, their injuries, family distance, psychological trauma and mental and behavioral disorders, right up to alcoholism, drug addiction, smoking, etc. At the same time, family members themselves take upon the father burden who performs tasks for a long time in a military conflict zone. This is a long-term stress for the family and each of its members. In addition, the coronavirus pandemic leads to problems with psychological state, anxiety, even suicide, alcoholism and drug addiction. This is a double burden on the family, which requires special psychological and social support and assistance to officers and their families, the promotion of a healthy lifestyle, and so on.

Therefore, Goal #3 in the field of sustainable development says about a need to help maintain the mental health of people during a pandemic and coincides with the goal of social prevention of negative phenomena as a sphere of the social work content. Preventive and rehabilitation approaches are thus important for social work with servicemen and their families. This coincides with the opinion of Yu. V. Brindikov [17], who was engaged in social rehabilitation of ATO soldiers. N. S. Oleksiuk [18] has proved a need for a socio-pedagogical approach in work with the servicemen families. This approach combines social assistance and support along with showing positive patterns of behavior in the family.

The military conflict itself is a threat to sustainable development and requires the social support of those who are affected and involved. "The best form of response will be to neutralize direct threats by actions which are commensurate with those threats, while protecting human rights and the rule of law", the UN Secretary-General claimed [60]. At the same time, human rights must be also ensured in this situation because they preserve human dignity [60]. This means relying on the theory of human rights and a human rights-based approach in social work and makes military social work necessary on this basis to focus on working with those military who are involved in the conflict in Eastern Ukraine. We have proved that socio-pedagogical work as a component of social work is essentially human rights-based like creating conditions for the realization of human rights, showing a new positive model of behavior [32]. In addition, "in relation to a serviceman of service for a fixed period, military social work helps to discharge his/her duty with dignity, for an officer it contributes to family well-being, for a military retiree it provides a dignified existence, etc." [41] This means the differentiation of military social work and targeted provision of social services with different content and methods, technologies. How to implement it in the conditions of a conflict and pandemics, what criteria for providing social services should be guided, how to choose the priority problems to solve in the conflict zone, to find resources and other issues are the problems for many social workers and commanders. They need to be taught this on the basis of a problem-oriented approach and human rights theory. Note that officers often change their place of service, and this requires both their adaptation to new conditions of service and life, and adaptation in the community and micro-environment of their families.

This process is always difficult and long, painful and can be resolved more calmly if you use the services of social workers. Goal #8 of sustainable development says about the necessary socio-economic measures for sustainable development in the conditions of a pandemic: "… helping people to overcome trials through social protection and basic services; promoting social cohesion and investing in community-based resilience and response systems." These are multidisciplinary, organizational and resource-based approaches in social work with the servicemen. Since our advanced training program is designed for adults, not students, it should be developed taking into account an androgynous approach which requires learning from the experience of students, taking into account their views in learning; today a competence approach is the basis of education, and an activity and student-oriented approach and a personality-oriented approach are the basis of all learning, they take into account the views and wishes of learners, learning in activities. All this requires a training form of adult education, the features of which we have explored and taken into account in developing the program. In addition, a digital approach for learning the program material is required, as the presentation of information for learning is the basis of a conscious activity, and the digital form of its presentation better contributes to the implementation of learning principles (clarity, science, connection with life, etc.), accelerates learning.

On the basis of the stated information, we can make such generalizations on the 1st, 2nd and 3rd tasks of the article as a basis for performance of the last task. Military social work is the direction of implementation of social policy with servicemen and the members of their families, which is carried out through the provision of social services on counseling, information, support, assistance, self-help, advocacy, organizational measures, social protection in various types of social work (social prevention, social rehabilitation, social support, social services, social management) and benefits, social guarantees of the state. It should be noted that state standards for the provision of social services in Ukraine also belong to the state social guarantees. Social work is subordinated to social management in the military team, solves social problems of servicemen and is carried out by a unit deputy commander on work with personnel. Its purpose is to create social conditions in the military unit to perform military and professional tasks at the highest level by servicemen, to realize their rights and legitimate interests in everyday life and service, to meet the specific needs of servicemen and their benefits and to solve their special social problems (socialization), adaptation, integration, etc.). Social work with servicemen is a social work, the object of which is the servicemen and the members of their families, it solves their problems of socialization and adaptation, rehabilitation. It is carried out as the provision of social services to people in difficult life circumstances.

The objects of military social work are: servicemen on active service and the members of their families; in reserve servicemen, retired, lost their ability to work; the family members of lost servicemen; all members of military units. The subjects of military social work are: military personnel commanders and military personnel deputy commanders of military units, as well as servicemen and the members of their families. In social work, these are the same objects as in military social work, but only those that are in difficult life circumstances. We consider the objects of both types of social work at the same time as its subjects, except the cases of family violence, child abuse, threats to life and health of family members and children.

Based on the theoretical foundations of the social work in military aspects and the social work with the military, we have identified the following scientific approaches:

1) Philosophical approaches: the persistent development of society, ethical area, philosophy of war and peace, human development;

2) General scientific approaches: the theory of human rights, resources, optimization, multidisciplinary; organizational, systemic, political, comparative and axiological approaches;

3) Specific scientific approaches: the human rights-based approach, social policy, socio-pedagogical (environmental, family-centered, personal), program-target approach, pedagogical (the theory of activation, theory of team, the dialogue of cultures, theory of participation, personality-oriented education, pedagogical support, facilitation);

4) Approaches of social work: the problem-oriented and psychological oriented approaches (humanistic, functional, behavioral and cognitive theories, catalytic and client-centric models of social work), approach of sociological focus (the systemic theory of social work, theory of social roles, theory of stigmatization), complex oriented method (intervention (crisis intervention), a model which is oriented on a task or a problem, a self-help aid); the preventive, rehabilitative, profile and integrated approaches, theory of strong points. Its content is a variety of social services, which are realized in a comprehensive manner at the social prevention, social support, social management, social protection, social services and social rehabilitation.

Of great importance is the consideration of scientific approaches and theoretical foundations: the theory of persistent development; student-centered, informational, digital, competence, androgynous and personality-oriented approaches, theories of educational content, activation of education process. It presents during the development and realization of a professional development program for social workers who help servicemen and members of their families, and the military who work in military units in the context of the military social work.

In view of the foregoing and exploring the professional development programs for social workers and servicemen [1-4,60 and others], we can formulate the purpose and tasks of the professional development programs for social workers to work with the military in the context of persistent development ideas. The purpose is to develop the professional competencies of social workers and officers in military units to occupy the social work with servicemen in coordination in the community. The tasks are to develop the professional competences of social workers and military officers who deliver the social work (the ability to analyze mental properties, states and processes, processes of military personnel socialization, prevention of social risks, difficult life circumstances, prevention and resolving of social conflicts in the military staff, serviceman's family, divorce prevention, ability to understand the organization and functioning of the social protection system and social services in the community and at the military formations, ability to study the social problem of the military and their families, to appreciate their problems, requirements, specifics and resources, ability to develop effective methods and ways to solve problems, ability to give efficient social services to the military, capability to cooperate with community members, capability to adhere to ethical principles of social work, ability to justify, to make professional decisions as regards clients of social work and to take responsibility for their consequences) and general competencies (ability to use the information and communication technologies, ability to be critical and self-critical, ability to work as a team and alone, ability to communicate with members of other professional groups).

Features of the program are the simultaneous training of social workers and the military of the community; focus on social services in the context of persistent development: goals 1,2,3,4,5,8,10,16; focus on the human factor and cooperation, the subjectivity of the individual, human rights and the improving communications in the community, exchange of resources and social services; the theory of social work with the military is combined with exercises, the experience of specialists (ideally as training forms of its realization), the using of media education tools and distance learning technologies, a work in microgroups. This program is developed for professionals of the higher education in social work and military support. The program is designed for 30 hours of classes and 60 hours of individual practice, in total of three credits. It highlights the content of the professional development program for social workers and the military "Social work with the military and the social work in military aspects in the context of the persistent development of society" (See table 1).This development program was discussed at the Departments of Pedagogy and Pedagogical Management; Social work, Special education and socio-cultural management and after approbations it was posted in the website of Ternopil Volodymyr Hnatiuk National Pedagogical University. It was socially advertised among social workers in the region, in the military units. Its content and methodological materials were developed before its implementation and people were interested in. Nowadays there are methodological and organizational studies to introduce the realization of the program using the distance learning tools. Professors (who will realize it) have graduated the distance studding courses of the media education and mastered digital tools of interactive teaching. They have learnt methods of their application during the distance education. The first lessons will be hold after January 14, 2021. It will be based on Ternopil Volodymyr Hnatiuk National Pedagogical in the Ternopil region. The addition of media competence elements as a part of the development course to master tools and the real training by students (use to divide to small groups for discussion, to assume by everyone, to do tasks and etc.) is another successful condition during the pandemic. The curriculum of the program is given in the Table 1 [61].

Table 1. The curriculum of the development program “Social work with the military and the social work in military aspects in the context of the sustainable development of society”.

№	Name and content of training modules	Hours	For		Teacher
			Classes	Independent work	
Module 1 “Digital tools for teaching of social work”					
1	Media education tools and distance technology tools in the educational process	3	1	2	Petryshyn L.Y., Medvid M.M., Trubavina I.M., Meshko H.M.
Module 2 “Theoretical foundations of social work with the military and members of their families”

4 Discussion

Our development program takes into account the purposes of the sustainable development, the main modern problems of the military from the different structures of Ukraine, the foreign and internal experience of social work with them, based on the theoretical foundations of such work. The foundations are determined taking into account the mentality of Ukrainians, the best international experience of the education and the valid legislation about the social work and education in this area, pay attention to thoughts of main stakeholders in this way of educational activities, the experience in developing and realizing such programs in civil and military higher educational establishments in Ukraine.

It should be noted that there is not any social work with the military or the social work in military aspects in the Republic of Poland. But there are the NATO social standards for the military. Seminars for advanced training of the military personnel are conducted in Ukraine by international organizations (UN-women and their partners to introduce a gender approach in the educational process of higher educational establishments). But this is only a separate aspect of our program content. The European University Continuing Education Network held a scientific-practical conference with the simultaneous short-term professional development “Actual Problems of Psychology, Sociology, Social Work and Professional Training of Specialists” [62] in Slovakia. The same event was about the topic “Status and prospects of reforming the security and defense sector of Ukraine”, also the topic “Optimization of training in the context of national and international security” was studied [62].But the issue of training specialists for the social work with servicemen and the social work in military aspects was not considered there. Accordingly, there are not any training programs for the social work with servicemen. According to scientific researches, in the Russian Federation there is a necessity to increase the military and social work, requirements for military and social workers, their education and training in the social work, the studding to improve the cooperation with non-governmental organizations (Committee of Soldiers' Mothers), [63, p. 221]. But our advanced training development program is unique.

Conclusions

The study identifies the possibility of orientation and realization of the social work for the military and members of their families, and the social work in military aspects as a part of the sustainable development ideas and as a direction of realization of sustainable development policy and the governmental social policy. This social development program is topicality, it should be common and simultaneous for all parties. The single program should pay attention to the problems of the military and their families, sustainable development ideas and the social policy, the necessity in the community using the set of scientific approaches for such social work. The program consists of three modules: “Digital tools for teaching of social work”, “Theoretical foundations of social work with the military and members of their families” and “Practice of social work with the military and members of their families in the community”. It is required 30 hours of classwork and 15 hours of independent work. It is based on a set of scientific approaches to professional development of social workers and the military in the social aspects who already have a higher education and a work experience. The conditions for its implementation during a pandemic are the teachers’ development in the area of media tools for education and distance technologies for interactive learning. In this situation they should also accomplish another using method, cooperation in the development community some social services; the social advertising of the program among potential listeners. For students, it is a condition for the successful professional development during the studying of the course about media education tools which will be needed in the developing. Further research into the chosen problems looks promising as the development and implementation of specialization disciplines in higher educational establishments as a choice of studying the social work with the military and members of their families, the social work in military aspects for cadets and students.

Modeling the assessment of investment projects for territorial communities in compliance with the concept of sustainable development

Alyona Polova, *Nataliia* Maksyshko, and *Oksana* Vasylieva

Zaporizhzhia National University, 66 Zhukovskoho Str., Zaporizhzhia, 69600, Ukraine

Abstract. The article is devoted to the problem of evaluation and selection of investment projects aimed at the development of territorial communities (TC) and take into account the need to pursue the goals of sustainable development at the local level. In the context of decentralization reform, attracting investment funds is the leading activity of local self-government. And to ensure the transparency of management and presentation of its results to the governing bodies of TC need new scientific methods to justify the choice of one or more projects from a variety of alternative solutions. Decision-making taking into account the concept of sustainable development determines the evaluation of investment projects in terms of their effectiveness in finding a balance between social, economic and environmental components. The peculiarity of comparative analysis is taking into account the qualitative assessment, so to make optimal investment management decisions, a model is proposed, developed on the basis of fuzzy logic and implemented using tools Fuzzy Logic Toolbox. The article builds and substantiates an improved fuzzy model for evaluating investment projects for TC development. The improved model is based on a system of 15 quantitative and qualitative indicators of achieving goals in the social, economic and environmental components of the concept and allows for a "soft" assessment of the investment project. This model is used to substantiate the decisions of the TC of Zaporizhzhia region and can be used in the development of decision support systems at the level of TC for quantitative justification of decisions, conducting variant calculation.

1 Introduction

In the current conditions of economic development of the territorial communities (TC) in view of the processes of globalization and intensification of competition, the issue of financial security of economic entities of certain regions becomes relevant. Now there is an urgent need for a mechanism of mobilization and optimal management of financial resources of economic entities to protect their investment activities from the consequences of the unstable economic situation in Ukraine and inefficient management.

Ensuring the balanced development of the regions is one of the priority areas of Ukraine's regional policy at the present stage of its transformations. In general, sustainable development is no longer a national or, even more so, a local problem, but encompasses global goals. Significant is the merit of the UN, whose activities are mediated by world summits, declarations, resolutions, final documents of conferences and others. Among the latter are the announced global goals of sustainable development by 2030 [1]. The report presents the results of adaptation of 17 global SDGs taking into account the specifics of national development, 86 national development objectives and 172 indicators for their monitoring, as well as benchmarking benchmarks to be achieved by 2030. This should be considered as a basis for further planning of Ukraine's development and monitoring the state of achievement of SDGs. Therefore, the urgency of the issue of finding ways to achieve the goals of sustainable development is beyond doubt. This also applies to TC in Ukraine.

Among the general approaches to interpreting the essence of the category of sustainable development, we follow the definition proposed by the World Commission on Environment and UN Development in 1987, according to which sustainable development is development that meets the needs of the present, but does not jeopardize the ability of future generations own needs [3].

This concept provides an opportunity to provide comprehensive management of territorial socioeconomic systems, integrates the agreed aspects of economic, environmental and social development of society, creates conditions under which from one generation to the next the quality and safety of human life will not diminish, the environment will not deteriorate and socio – economic progress will be ensured [3]. Each territorial community is tasked with identifying areas and means that will enable sustainable development, both in the long term and at every step of government.

The problem of choosing from possible alternative solutions is usually not easy for decision makers and requires qualified justification. This is especially important in the context of Ukraine's progress towards openness of society, increasing demands for transparency of government actions and their results.

The scientific works of both domestic and foreign scientists [4-8] are devoted to the study of socioecological and economic development of the region, in particular those related to the development of models for assessing its level.

Problems associated with SDGs have been investigated in sources [9, 10]. Methods for determining the degree of achievement of SDGs are considered in the works of Joanna Marszałek-Kawa, Piotr Siemiątkowski [11], Jonathan D. Moyer, Steve Hedden [12]. Foreign direct investment related to SDGs has been considered in the work of Juri Suehrer [13].

However, studies on the quality of investment projects at the regional level [14-17] take into account only certain aspects (environmental, social or economic), indicators of achievement of SDGs are not taken into account. The article [18] proposes a multi-criteria approach to the selection of investment projects. However, there is no analysis of the development of regional systems and integrated territorial communities, especially those that fully take into account the goals and objectives of the concept of sustainable development.

The work [19] of the authors is devoted to solving the problem of evaluation and selection of investment projects aimed at the development of local communities, taking into account the concept of sustainable development. The constructed fuzzy model of evaluation of the investment project gives the chance of "soft" – qualitative estimation of the considered investment project. However, the constructed model is based on selective quantitative and qualitative assessments of the social, economic and environmental components of the concept, but does not take into account the detail of SDGs.

The purpose of this work is to improve and apply a fuzzy model for assessing the quality of investment projects for local communities to take into account the goals and objectives of the concept of sustainable development, recommendations for its application in the strategic decision-making process for the community.

2 Materials and methods

The essence of the problem to which this work is devoted, is the evaluation and comparative analysis of investment projects. These projects are presented to the territorial community (TC) management for selection and influence its further development in the context of the implementation of the sustainable development strategy.

To take into account the concept of sustainable development when choosing investment projects for territorial communities, it is necessary to address two issues:

1) what indicators to take into account when evaluating them;
2) how to take into account the selected indicators.

The last question is equivalent to the choice of a relevant mathematical model, which should be used to build an integrated assessment of the project and develop recommendations for choosing the best project available. The solution of the first question should be based on the use of a system of national indicators of achievement of SDGs, which are used to monitor the degree of implementation of the Concept of Sustainable Development [20].

Sustainable development of territories is ensured by a combination of environmental, economic and social components (spheres), each of which can be assessed by a whole set of relevant indicators. For further modeling of estimation of the level of development of TC as a result of realization of the investment project for each component we will select one measurable indicator, which in the further researches can be replaced by, for example, an integral indicator for a certain area. Each of these marks (indicators) characterizes the effectiveness of an investment project for TC in terms of a specific area. It should be noted that the choice of a measured indicator faces the problem of choosing a measurement scale and methods of its measurement / calculation. If a quantitative indicator can be chosen to estimate the level of economic development, for example, the rate of increase / decrease in community budget revenues resulting from the project implementation, and to estimate the social impact, the number of jobs that will be created during the project implementation, then the environmental component is not always suitable for formal quantitative measurement procedure. Therefore, it is often only expert evaluation that can be used to measure it. However, confidence in such estimates may be different. Thus, the rating system, which characterizes the effectiveness of the implementation of the investment project, can contain both quantitative and qualitative indicators.

With this in mind, we come to the conclusion that in order to solve the problem of evaluating investment projects in the context of the concept of sustainable development and to make management decisions on the development of TC, it is advisable to use data mining tools, namely fuzzy modeling. Its founders – L. Zade [21], D. Dubois and H. Prade [22] devoted their research to problems of the use of a fuzzy logic for the analysis of economic systems. The works of A. Matviychuk [23], A. Nedosekin [24], N. Maksyshko, V. Shapovalova [25], E. Kanaeva [26] and others are devoted to the improvement of decision-making methods in the economy based on the use of a fuzzy modeling methods.

The methodology for constructing a fuzzy model, including to obtain a qualitative assessment of an investment project for the development of TC, taking into account the concept of sustainable development, consists of the following stages:

- formation of a base of a fuzzy model input variables;
- fuzzification of input variables;
- formation of a base of rules of a fuzzy logic;
- accumulation of conclusions based on a fuzzy rules;
- defuzzification of the output variable (see Fig. 1).

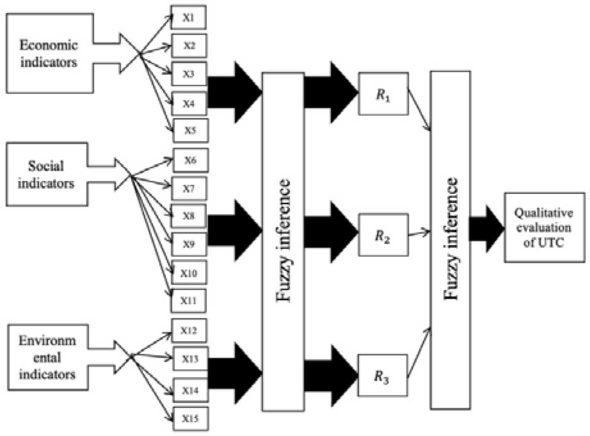

Fig. 1. The general scheme of construction of a fuzzy model of investment project evaluation for the development of TC.

A fuzzy model for evaluating the attractiveness of investment projects will be used to benchmark them on the development of TC in line with the sustainable development concept. The general scheme of the decision-making method for choosing an investment project is presented in Fig. 2.

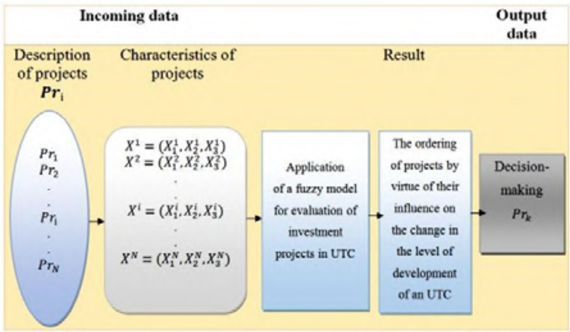

Fig. 2. The general scheme of the method of deciding on the choice of investment project for the development of TC.

To implement the fuzzy TC project evaluation model, the editor uses the Fuzzy Logic Toolbox, which is built into the Mathworks application package.

3 Results

3.1 Assessment of the attractiveness of the project in three areas: economic, social and environmental

The assessment of the investment attractiveness of projects for TC will consist of two parts: first we evaluate each of the three areas, and then we combine the obtained estimates in a generalized model. This approach will allow you to determine the advantages and disadvantages of projects in each area, and choose the best project that will take into account the requirements of all components of sustainable development.

We build a model for assessing the attractiveness of investment projects based on the use of fuzzy logic. Taking into account the three areas of sustainable development for which the assessment and general assessment will be carried out, we are building four models.

To assess the attractiveness of investment projects, taking into account the concept of sustainable development, we will define three assessments R_1 assessment of economic attractiveness of the project, R_2- assessment of social impact, R_3- assessment of environmental impact. The generalized estimate obtained as a result of applying the integrated model is denoted by R.

3.2 Assessment of the economic attractiveness of the project

The first two stages of construction of the fuzzy model (formation of the base of input variables of the fuzzy model and fuzzification of input variables) will be performed in parallel. At the first stage we determine the content of variables, sets of their linguistic evaluations (terms), and at the second stage – fuzzification – we determine the sets of terms of variables and the type of membership functions. To construct a fuzzy model, three types of membership functions are used: triangular, trapezoidal, and Gaussian. The first two of them express a linear relationship between the parameters and the value of its correspondence to the linguistic variable. Moreover, when full correspondence is achieved only with one value of the parameter (for example, 0 with the linguistic variable "neutral influence"), then a triangular function is used, if several values then trapezoidal function is used. The Gaussian membership function expresses a nonlinear dependence that corresponds to the normal distribution and is closest to natural processes. The Gaussian function is used for parameters that contain a significant share of uncertainty or are estimated by experts.

The output variable R_1 means economic impact, and includes 4 input variables:

X_1 – the rate of increase / decrease in community budget revenues;

X_2 – assessment of the impact on productivity growth;

X_3 – the volume of net inflow of direct investment;

X_4 – assessment of the impact of the project implementation on the optimal level of agricultural land use.

Consider each variable in more detail.

Variable X_1 reflects the rate of increase / decrease in community budget revenues. This indicator characterizes relative velocity (%) of changes in budget revenues resulting from project implementation.

The indicator X_1 will be calculated by the formula:

$$X_1 = \frac{F_i}{F_{i-1}} \times 100\%, \tag{1}$$

where X_1 – Economic growth (%);

F_i – the amount of budget receipts after project implementation (at time i);

F_{i-1} – the amount of budget revenues before the implementation of the project (during i-1).

Based on the analysis of existing investment business projects for the set of values of variable X_1 we will select the segment [70; 150] ($X_1 \in [70; 150]$). The 70% limit is explained by the fact that, despite the potential environmental and social benefits of the investment, the project will not be considered if its losses can exceed 30% of the community budget. The upper limit is set at 50% of all budget revenues and is 150 [20].

The next variable X_2 – assessment of the impact on productivity growth, which means comparing output per unit of working time with the previous similar period. X_2 is in the range [-10; 10] and is determined by three Gaussian membership functions.

Variable X_3 means the volume of net inflow of direct investment in total community income, and is measured in percent.

It should be noted that direct investment can have a positive impact on the host, not only through direct cash flows, but also the transfer of technology and management resources, which, in the absence of investment, would be unavailable. Such a transfer of resources can stimulate the economic growth of the local community. The value of the variable X_3 is within $X_3 \in$ [0; 25]. The limit of 25% is explained by the fact that all investments with 25% of income and more are considered absolutely important (membership function $\mu = 1$).

Variable X_4 – assessment of the impact of the project implementation on the optimal level of agricultural land use. According to the Law of Ukraine "On the circulation of agricultural land" [27] the basic principles of state policy in the field of circulation of agricultural land purpose is: rational use of land; priority of land use for its intended purpose; establishment of a special legal regime for the purchase and sale of land; prevention of land monopolization; prevention of speculative transactions. X_4 is in the range [-10; 10] and is determined by three Gaussian membership functions.

Using four input variables that characterize the economic impact, it is necessary to obtain an overall assessment of the economic attractiveness of the project – the output variable R_1, which indicates the level of attractiveness of the investment project to TC (measured in points). R_1 is defined on the interval [0; 100].

The parameters of fuzzification of input and output variables are given in the Table 1.

Stage 3 – building a fuzzy knowledge base and decision-making rules

Decisive rules are based on the following considerations. The leading indicator is X_1, which reflects the level of income generated by the project.

Therefore, if X_1 is increasing and X_2- X_4 are not negative, then the economic effect is considered significant. If X_1 decrease and X_2- X_4 also do not show positive indicators, then the economic effect is slight.

Table 1. Parameters of fuzzification of input variables X_1, X_2, X_3, X_4 and output variable R_1**.**

Linguistic assessment	**View membership function**	**Function options**
	X_1	
Decrease	Trapezoidal	[70;70; 90; 100]
Permanence	Triangular	[93; 100; 107]
Increase	Trapezoidal	[100; 120; 150; 150]
	X_2	
Negative	Gaussian	[3.739; -10]
Neutral	Gaussian	[1; 1.665e-016]
Positive	Gaussian	[3.738; 10]
	X_3	
Low	Triangular	[0; 0; 5]
Middle	Triangular	[2; 10; 15]
High	Trapezoidal	[10; 20; 25; 25]
	X_4	
Negative	Gaussian	[3.539; -10]
Neutral	Gaussian	[1.123; 0]
Positive	Gaussian	[3.538; 10]
	R_1	
Slight	triangular	[0 0 35]
Medium	triangular	[25 50 75]
Significant	triangular	[65 100 100]

For other combinations of input indicators the corresponding rules are developed, in total the model includes 29 rules.

3.3 Assessment of the social attractiveness of the project

Rating R_2 means social impact, and includes 6 input variables:

X_5 – assessment of the degree of compliance of the TC development strategy and the region and action plans for their implementation;

X_6 – the impact of the project on the unemployment rate in the community;

X_7 – assessment of the impact of the project on the state of public health;

X_8 – assessment of the impact of the project implementation on the development of education for the population;

X_9 – assessment of the impact of the project implementation on infrastructure development;

X_{10} – assessment of the impact of the project implementation on the level of public service provision.

Consider each variable in more detail.

Variable X_5 – assessment of the degree of compliance of the TC development strategy and the region and action plans for their implementation. Projects financed from the State Budget of Ukraine must meet the priorities of regional development strategies and action plans for their implementation. In 2015, the order of the Ministry of Regional Development, Construction and Housing of Ukraine on the selection of investment programs and regional development projects for further implementation at the expense of the State Fund for Rural Development was adopted. The order, in particular, states that the project should be aimed at development, and to this end, project applicants are required to determine the problem to be solved, justify the expected quantitative and 11 qualitative results of project implementation and innovation. In turn, the regional commissions that evaluate the project are responsible, among other things, for determining the relevance of the project, as well as the social and economic effect of its implementation [28].

Variable X_6 characterizes the impact of the project on the unemployment rate in the community (calculated as the ratio of the number of jobs created during the implementation of the project to total number of unemployed communities):

$$X_6 = \frac{W}{U} \times 100\%, \quad (2)$$

where X_6 – reduction in the unemployment rate in the community (%);

W – number of new jobs created during the project implementation;

U is total number of unemployed communities [20].

The value of variable X_6 is within $X_6 \in [0; 100]$. Thus, if no new jobs are created during the investment, then X_6=0, if the number of jobs created is equal to the number of unemployed communities, then X_6 = 100 (%). Cases where the number of jobs exceeds the number of unemployed persons should be considered separately and are not the subject of this study, as they cover the issue of changing the social policy of the community regarding labor attraction.

The next variable X_7 is the assessment of the impact of the project on the state of public health. Population health is one of the greatest values, a necessary condition for the socio-economic development of the country. Creating optimal conditions for the realization of the potential of each person throughout life, achieving European standards of quality of life and well-being is one of the main tasks set by the Sustainable Development Strategy "Ukraine – 2020", approved by Presidential Decree of 12 January 2015 № 5, and part of the obligations under the Association Agreement between Ukraine, on the one hand, and the European Union, the European Atomic Energy Community and their Member States, on the other hand [29].

Variable X_8 – assessment of the impact of the project implementation on the development of education for the population. In the field of education, the work is primarily aimed at ensuring the right of all citizens to education, improving the functioning and innovative development of education at the level of all its components, improving quality and competitiveness, creating the necessary conditions for a good modern European education.

Input variable X_9 – assessment of the impact of the project implementation on infrastructure development. Ukraine lags far behind the level of development and efficiency of infrastructure in comparison with developed countries. The main reason for the current state of infrastructure is chronic underfunding from the state budget and inefficient state property management system.

The next variable X_{10} – assessment of the impact of the project implementation on the level of public service provision. Building an efficient and competitive national economy involves a systemic reform of public financial management as part of the public administration system in general, the problems and inconsistencies of which pose a serious risk to the resumption of economic growth. An effective public financial management system is the basis for the implementation of public policy and the achievement of strategic development goals by ensuring compliance with general budget discipline, strategic allocation of budget funds and effective provision of public services.

Using six input variables that characterize the social impact, it is necessary to obtain an integrated assessment – the output variable R_2, which indicates the level of attractiveness of the investment project to TC (measured in points). R_2 is defined on the interval [0; 100].

Given that the variables X_5, X_7, X_8, X_9, X_{10} have a similar nature (determined by experts, are in the same ranges), the same parameters of fuzzification are applied to them (three terms expressed by Gaussian membership functions). The input variable X6 is determined by calculation by formula (2), so for its fuzzing applied triangular and trapezoidal membership function. The main parameters of fuzzification for input and output variable model of social impact assessment of the project R2 are given in the Table 2.

The base of the decision rules of this model consists of only three rules:

1. If at least one of the input variables of the project is Significant – that is, one that significantly affects the improvement of social conditions of the community, the project is important from a social point of view.
2. If the social impact of all six input variables of the project is assessed as weak, then the social impact of the project will also be Slight.
3. In other cases, the social impact of the project is assessed as Medium.

This is due to the fact that the project may not cover all areas of social life of the community, but if it gives a positive result in at least one area, it is considered a socially effective project.

3.4 Assessment of the attractiveness of the project, in terms of the environmental component

Rating R_3 means social impact, and includes 5 input variables:

X_{11} – environmental protection;

X_{12} – assessment of the impact of the project implementation on access to safe drinking water;

X_{13} – assessment of the impact of the project on the management of household and non-household waste;

X_{14} – assessment of the project impact on the increase / decrease of electricity production.

Indicator X_{11} describes the environmental impact of the investment project. The value of X_{11} is determined on the basis of expert judgment, measured in points and is in the range $X_{11} \in [-100; 100]$. That is, at the most destructive value of environmental impact $X_{11} = -100$, at neutral impact $X_{11} = 0$, and at maximum positive 100. The basis for determining the indicator X_{11} can be the results of the report on the environmental impact assessment based on the Law of Ukraine № 2059 -VIII [3] or calculations, for example, by the method [15].

The next variable – X_{12} characterizes the assessment of the impact of the project implementation on access to safe drinking water. The existing inequalities between urban and rural populations in access to quality drinking water and sanitation in Ukraine remain quite significant. According to the National Report on Drinking Water Quality and the Status of Drinking Water Supply, centralized water supply covers more than 99 percent of cities and only 30 percent of villages. Therefore, access to sustainable and safe water supply remains problematic for many Ukrainians.

Variable X_{13} – assessment of the impact of the project on the management of household and non-household waste. The value of X_{13} is determined on the basis of expert judgment, measured in points.

The next variable X_{14} means the assessment of the project impact on the increase / decrease of electricity production. The value of X_{14} is determined on the basis of expert judgment, measured in points.

Using four input variables that characterize the environmental impact, it is necessary to obtain an integrated assessment – the output variable R_3, which indicates the level of attractiveness of the investment project to TC (measured in points). R_3 is defined on the interval [0; 100].

The output variable R_3 means environmental impact, it includes 4 input variables (table 3).

Table 3. Fuzzing of X_{11}, X_{12}, X_{13}, X_{14} variable**.**

Linguistic assessment	View membership function	Function options

Significant	triangular	[65 100 100]

To form a database, we define that the leading (generalizing) indicator is the indicator X_{11}. Indicators X_{12}- X_{14} are ancillary, showing the degree of coverage of environmental problems. And even with one significantly bad indicator X_{12}- X_{14}, the indicator X_{11} can not be good. Therefore, with a negative X_{11}, the project is considered bad from an environmental point of view; when X_{11} is positive, the project is considered good. At neutral values of X_{11}, we turn to the consideration of differentiated indicators for water (X_{12}), waste (X_{13}) and electricity (X_{14}). For such cases the base of rules including 24 rules is formed.

3.5 Integral assessment of the attractiveness of the project in three areas: economic, social and environmental

Thus, we obtain three assessments that characterize the projects in three areas: economic, social and economic. In order to obtain an integrated assessment based on the concept of sustainable development, we will build a generalized model. Its input variables will be R_1, R_2 and R_3. Output: integral estimate R. All input variables have the same interval [0 100] and are given by three Gaussian membership functions. Initial – three triangular functions (Table 4).

The rules of the fuzzy knowledge database will be presented in the form of Table 5.

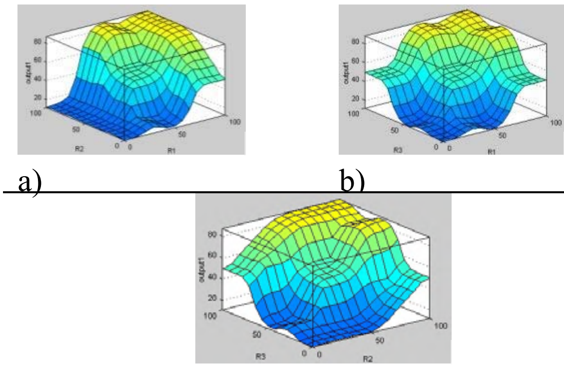
The absence of a statistical sample of quantifiable estimates of the indicators under study and the qualitative nature of the input variables and the output indicator R (investment project estimate), determine the choice of a logical inference using the Mamdani fuzzy inference system mechanism.

As a result of the built model, it is possible to build a surface that gives a graphical idea of the project estimates depending on the values of the input indicators (Fig. 3).

The constructed model can be applied to support decision-making in the development and justification of a strategic plan for the development of Veselivska territorial community [30].

According to the data provided by Veselivska TC, the population (excluding preschool and school age children) is 10,640 people, and the amount of income (according to estimates) of the territorial community is 12.679 million UAH. According to the State Statistics Service of Ukraine, the average unemployment rate in Zaporizhia region is 9.9% among the population aged 15-70 years [31]. Then the number of unemployed Veselovskaya TC is about 1053 people.

Consider two alternative investment projects for the development of the territorial community: the traditional activity for Ukrainian farmers is sunflower cultivation and the construction of a solar power plant.



c)

Fig. 3. The output surface for the variables: a) R1 and R2; b) R1 and R3; c) R2 and R3.

Let's look at project characteristics in more detail.

Project 1 – Sunflower cultivation.

Sunflower growing is a profitable business, it is the most profitable oilseed crop in our country. The basic data for the calculation were obtained from the source [32], in particular, the results of sunflower cultivation of LLC «Dokuchaevsky Chernozem», Karlovsky district of Poltava region.

It is known that the territorial community is considering the use of 20 hectares of land owned by it.

The costs of growing and harvesting in this case amount to 280 thousand UAH, the increase in cash flow from the project is also 280 thousand UAH.

It has been expertly determined that the implementation of the project will not affect labor productivity, and there is no need to attract investment. Since agricultural work does not require a change of purpose or land monopolization, the indicator X_4 is also zero.

Support and development of agricultural production is one of the main strategic directions of the community, but the implementation of the project does not involve significant changes and improvements, so the degree of compliance of the TC development strategy with experts is set at 10 points. The number of jobs created is 10, which is 1% of the unemployment rate. Due to the fact that the implementation of the project does not affect the level of health care, education, infrastructure or public services, the X_7- X_{10}, respectively, will be zero.

The cultivation of sunflower is associated with such negative effects as the depletion and drying of the soil, increased water and wind erosion [33]. Considering that the problem of soil depletion and erosion is solved, and the problem of drying is smoothed by the correct cultivation of land, the expert assessment of environmental impact is -10 points. The impact of the project on access to safe drinking water, on the management of household and non-household waste and on the increase / decrease in electricity production is zero.

So the input variables of the sunflower cultivation project are:

- For R_1: X_1 = 102.2%; X_2 = 0 points; X_3 = 0%; X_4 = 0 points.
- For R_2: X_5 = 10 points; X_6 = 1%; X_7= 0 points; X_8 = 0 points; X_9 = 0 points; X_{10} = 0 points.
- For R_3: X_{11} = -10 points; X_{12} = 0 points; X_{13} = 0 points; X_{14} = 0 points.

As a result of application of the developed models project estimations on three directions of sustainable development were received:

- - economic impact R_1 = 50 points; – - social R_2 = 9.9 points; – - ecological R_3 = 46 points.

This means that Project 1 has average economic and environmental impacts on the development of a TC and low social impact.

Let's calculate the value of the generalized evaluation of the project R.

The result of the evaluation of the project 1 in the defuzzing step is 14.3 points out of 100 possible, which is quite low.

Let's make similar calculations for Project 2 – construction of a solar power plant.

A solar grid power plant is used to sell electricity to the grid at a «green» rate.

Suppose that solar power plant want to build on a plot of 20 ha.

The cost of its construction is $8 million, the profitability of the project will be 25.3%, the payback period of the project – 5 years. As a result, we receive $2.078 million revenues, 25 jobs, and a positive environmental impact assessment at 50 points (used for calculations [34]).

However, it should be noted that the TC doesn't have the financial resources to implement such a large-scale, in terms of initial investment, project, so the implementation of this project is possible only with the participation of the investor. If the community finds an investor and receives only land and taxes, the annual income will be 250,000 UAH. This will increase the community's income to 101.9%.

Increasing labor productivity (X_2) by attracting labor at a solar power plant is estimated by experts at 2 out of 10 possible.

The project will attract $8 million, which is more than 63% of the annual income of the community. Since the maximum value of the input variable is 25, and the value of X3 at which the membership function reaches one is 20% (i.e., all investments greater than 20% of income are considered the most useful), we assume that X_3 is 25%.

Since the implementation of the project involves a change in the purpose of the land, X_4 is estimated at -2.

The assessment of the degree of compliance of the TC development strategy with the region and the action plans for their implementation (X_5) is 40 points. Project 2 does not affect the level of development of health care, education, infrastructure or public services.

The construction of the power plant is associated with waste generation, so the indicator X_{13} is estimated at -10. One effect on the energy component is the most positive X_{14} = 100 points.

Thus, the input variables of a project involving an investor to build a solar power plant are:

- For R_1: X_1 = 101.9%; X_2 = 2 points; X_3 = 25%; X_4 = -2 points.
- For R_2: X_5 = 40 points;X_6 = 2.4%; X_7, X_8, X_9, X_{10} = 0 points;
- For R_3: X_{11} = 50 points; X_{12} = 0 points; X_{13} = -10 points; X_{14} = 100 points.

As a result of the project evaluation by areas, the following were obtained:

- economic impact R_1 = 60.4 points; – social R_2 = 17.4 points; – ecological R_3 = 84.7 points.

That is, Project 2 also has a weak social impact, albeit a larger one than Project 1. The economic impact is above average and the environmental component is high.

The generalizing result of the evaluation of project 2 in the defuzzing step is 62.6 points out of 100, which is better than the project for growing sunflower.

Comparing the two projects, it can be noted that the "weak spot" of both projects is low social impact; project 2 is better than project 1 in all areas, and if the difference is not large for the economic and social component, the environmental positive impact of project 2 is almost twice that of project 1.

As a result of application of the developed two-stage model to two alternative investment projects of the community, the numerical characteristic of projects on separate directions of sustainable development (economic, social and ecological), and the general estimation taking into account all structural components is received.

Thus, when making decisions, it is possible not only to establish which project is more reasonable, but also to identify "weaknesses" and the advantages of each of them.

4 Conclusion

The development of TC is aimed at coordinated and balanced management of its resources, taking into account the concept of sustainable development to ensure social, economic and environmental development of TC, expanding its economic opportunities, creating a full living environment for present and future generations. To achieve this goal, it is necessary to form an effective system of state power, which is facilitated by decentralization reform. The transfer of competencies to TC increases the economic activity of local governments, encourages them to rationally and skillfully use available resources, to make effective decisions when choosing alternatives to increase the competitiveness of TC.

Finding a balance between economic, social and environmental components is one of the main tasks in managing the development of TC, taking into account the concept of sustainable development. To solve these problems, it is necessary to use new digital technologies to optimize and automate decision-making processes, transparency in the activities of local governments and improve connection with community members.

This article develops and describes a fuzzy evaluation model of an investment project for TC development, consisting of two stages. At the first stage, three fuzzy models were created that allow evaluating an investment project in three areas of sustainable development: economic (R1), social (R2) and environmental (R3) impact. For the assessment of the economic in the project, the four most important, according to the authors, input indicators were emphasized: X_1 – the rate of increase / decrease in community budget revenues; X_2 – assessment of the impact on productivity growth; X_3 – the volume of net inflow of direct investment; X_4 – assessment of the impact of the project implementation on the optimal level of agricultural land use. To assess the social impact, the input parameters are X_5 – assessment of the degree of compliance of the TC development strategy and the region and action plans for their implementation; X_6 – the impact of the project on the unemployment rate in the community; X_7 – assessment of the impact of the project on the state of public health; X_8 – assessment of the impact of the project implementation on the development of education for the population; X_9 – assessment of the impact of the project implementation on infrastructure development; X_{10} – assessment of the impact of the project implementation on the level of public service provision. The impact of the project on the environment is determined by the 5 input variables: X_{11} – environmental protection; X_{12} – assessment of the impact of the project implementation on access to safe drinking water; X_{13} – assessment of the impact of the project on the management of household and non-household waste; X_{14} – assessment of the project impact on the increase / decrease of electricity production.

As a result, three diverse indicators that characterize the project were obtained. In addition, using the developed integrated fuzzy model, we obtain an integrated indicator of investment attractiveness of the project, which includes all areas of sustainable development.

The developed models were tested on the data of the Veselivska Territorial Community of Veselivsky District of Zaporizhzhia Region. A comparative analysis was conducted for two investment projects – Sunflower Growing and Solar Power Plant Construction. As a result, the attractiveness assessments were obtained in different areas of each project, weaknesses and strengths were identified, as well as integrated indicators were obtained, which allowed to select the most attractive project for the territorial community.

Application of the proposed models creates opportunities for the formation and development of territorial decision support systems for quantifying decisions, carrying out variant calculations to select the best investment options. The development and improvement of a decision support system is extremely important for TC, as it will help to accumulate and model a database that solves management problems.

Kyiv National University of Construction and Architecture, 31 Povitroflotskyi Ave., Kyiv, 03680, Ukraine

Abstract. The article considers the sustainable development of the city public spaces and the penitentiary complexes problems from the Synergetics and Socionics standpoint. These approaches provide consideration of the opposite processes of public spaces socialization and correctional complexes resocialization, sustainability, and dynamism its organization, and self-organization. The regularities of sustainable development are present in the cyclical nature of historical changes in public spaces and the penitentiary system. Cycles unfold in the alternation order of pairwise polarized processes, on the one hand, dispersion and concentration, and, on the other, – self-organization and adaptation. We have found that the interaction of universal processes and the natural change of cycles stimulates, on the one hand, growth and stabilization, and, on the other, – transformation and metamorphosis, which lead to the emergence of new forms and structures of public spaces and penitentiary complexes. We have proposed to use Socionical methods for increasing tolerance and democracy in the architectural environment of settlements. We have described the methodological tools to achieve the harmonization of the architectural environment of settlements.

1 Introduction

Sustainable development problems, which have become especially relevant and highlighted in international documents, have gradually gained a proper place in architecture and urban planning [1, 2]. The global nature of these problems required large-scale methodological tools for their positive solution. A synergistic approach is one of them. It aims at tolerant Socionic cooperation and self-organization of all participants of the urban environment sustainable development. It involves the study of complex systems, the development of which has signs of sustainability and dynamism.

Sustainable development of architectural and urban planning systems is subject to self-organization laws. They operate in a wide range and determine the formation of diametrically opposite types of architectural environment – socializing (public spaces) and resocializing (penitentiary complexes).

Some scientists have studied the problems of urban self-organization. New areas of research – Urban Synergetics and Architectural Socionics have formed on this basis. The relationship between self-organization and the sustainable development of public spaces and penitentiary complexes, taking into account social relations, has not yet been considered. The solution to these problems is of paramount importance in modern architectural and urban planning theory. The expected results are important for Ukraine, where reforms in urban planning, medicine, education, and other spheres of life continue [3, 4]. New explorations of the features of sustainable development, self-organization and interpersonal relations in urban public spaces, and penitentiary complexes are a direct continuation of our previous research on this topic [5].

Modern cities occupy huge territories and unite various population groups, the interaction between which quite often has polarized and extreme character. This character, on the one hand, testifies to the stability and, on the other, to the dynamism of the urban environment and, in total, determines the boundaries and range of settlements sustainable development. The public spaces are the most actively developing therein that maximally socialize the lives of urban residents. The urban environments of correctional facilities, which aimed at convicts re-socializing and preparing them for regular free life, oppose them. The urgency of the problem lies in the awareness of the need to close the gap between mutually polarized lifestyles.

We need to find ways to organize and self-organize different groups of the population. Then people with different value systems will be able to support each other in a tolerant urban environment. Revealing cyclical order in the historical development of opposite types of architectural environments is the next task. It is associated with the elucidation of differences and similarities in the processes of their self-organization and sustainable development.

2 Sustainable development ranges of the cities architectural environment

2.1 Features of self-organization of the correctional system and urban penitentiary complexes

The architectural environment of the correctional system requires the introduction of sustainable development ideas. Specialists in various fields of knowledge (criminologists, psychologists, sociologists, architects, and designers) are concerned with the problem of the architectural environments' creation, where humanity, justice, and order are harmoniously coordinated and balanced.

Trends in the development of scientific knowledge over the past 30 years provide an opportunity to say confidently that today synergetic concepts are spreading in many areas of scientific, theoretical, and applied activities. The synergetic approach allows us to consider the problems of the penitentiary system development and the architectural environment of correctional facilities from new positions. It provides new opportunities for its harmonious development, improvement, and sustainability.

D. K. Corten has described the conditions for sustainable development of social institutions [6]. Among them is a guarantee of safety and conditions for self-improvement. Penitentiary complexes belong to such institutions. A harmoniously developing dynamic system must maintain a stable mode of operation, despite external interference [7]. Environmental, economic, and social components determine the sustainability of the systems. The system can develop differently in each of these areas. Social systems are less stable than, for example, ecological and biological. Prison riots and rising suicide cases are among the crisis indicators inherent in penitentiaries.

Opposing trends in the development of systems arise due to internal contradictions and external intervention. They can lead to either the destruction of the system or its improvement. O. M. Knyazeva and S. P. Kurdyumov believes that all existing systems are open, that is, have an exchange of energy and information with the environment [8].

We propose to consider the historical development of the penitentiary system from a synergistic standpoint. The cycle of its development begins from the phase of the punishment and detention conceptions emergence and accumulation in correctional facilities. The system is in a state of dispersion. From the chaotic conceptions of punishment, new individual forms of institutions emerge, such as the Zuchthaus in Amsterdam (1595), the prison for beggars in Britain (1563), and the prison for young men of St. Michael in Rome (1735) (Fig. 1).

At the next stage, the approaches to the legal framework formation change. Views on the problem of criminals correcting transform too. Realistic and utopian conceptions of correctional facilities emerge and strengthen their positions. Among them – the penitentiary in Philadelphia (1776), the Panopticon (1791), the Auburn Detention System (1820), and the Irish Progressive System (1850). Selection of optimal technological and spatial solutions of correctional institutions takes place. The most «progressive» options for retention and correction are becoming more common. At this stage, the self-organization processes of the system are occurring.

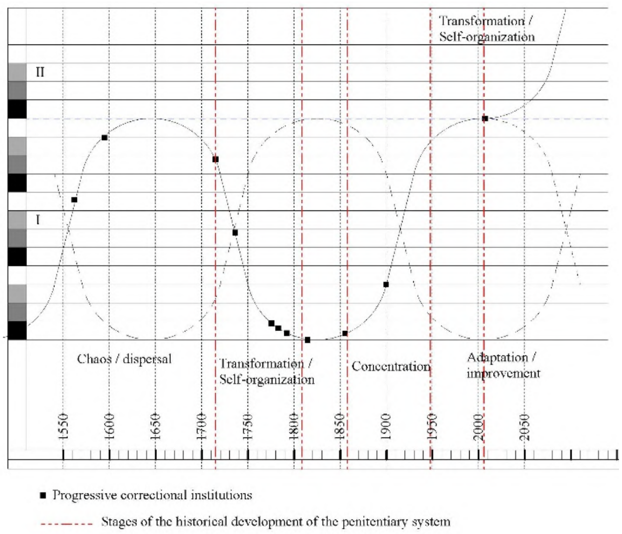

Fig. 1. Scheme of cyclic development of the penitentiary system environment, by Yuliia Tretiak.

Following this, the punishment system is stabilizing. At the stage of concentration, it changes due to the detection of shortcomings. At the same time, awareness of the possibility of returning to past concepts arises. These are the so-called negative feedback loops. For example, the progressive step system of detention of prisoners of the second half of the 19th century acquired the features that operated in the prison of St. Michael in Rome, which functioned since 1735.

For the next almost 100 years, the correctional system was in a stable cumulative state. The Declaration of Human Rights, adopted in 1948, once again changed the socio-humanistic emphasis in the prison sector.

The final phase of the system development cycle is an adaptive one. The results of knowledge accumulation integrate into the paradigm of system modernization at the next hierarchical level. The first period took place in the 1960s and 1970s when the “new wave” penitentiaries appeared in Europe. The second wave followed the prison riots of the 1990s when European countries set out to humanize the correctional environment.

Completely new forms of punishment have rarely emerged in the history of the penitentiary system. The reasons for such system stability were the minimal influence of external factors. The rigid nature of the legislative and regime component of the punishment system restrained this external influence. Thus, the processes of self-organization and adaptation in “closed” systems (prisons, military and labor camps, and towns, psychiatric hospitals) cannot take place fully. Regime restrictions in space and time deprive the process of development of the penitentiary system of extreme conditions. Therefore, completely new forms – architectural complexes and buildings that have no analogs, occur very rarely.

The general cycle of the historical development of the correctional system lasts 120-150 years. Similar processes occur at the level of individual buildings and structures complexes. The life cycle of the building complex of the famous Strangeway prison in Great Britain demonstrates the historical development of its architectural and urban environment for more than 150 years.

A prison for 1,000 men and women opened in 1868 in the park. The plan of the building has the form of a “star” with ten rays. The method of detention and correction in the institution took into account the progressive (Irish) system. The period of “self-organization” of the environment took place until 1963. The transformation into a men's prison took place in 1948 under the influence of the Declaration of Human Rights. From 1964 to 1990, Strangeway experienced a phase of “concentration” when it returned to a harsher detention regime that did not comply with updated and more humane laws.

In April 1990, a series of riots broke out in Strangeway Prison. Damage to the building was one of the reasons for the reconstruction and modernization of the complex. During this adaptive period, the transition to a higher level did not take place in this institution. Reconstruction of the correctional complex could lead to the emergence of new forms. A full-fledged open space could enter the structure of the building. However, the reconstruction of 1994 did not fulfill the corresponding task (Fig. 2). The system returned to the previous stage. To date, regular violations of the detention regime occur in the institution. In 2017, the Independent Oversight Board concluded that Manchester Prison is in urgent need of modernization.

The historical development of penitentiary institutions has shown the pivotal moments of the penitentiary system transformation. It also creates conditions for a rethinking of alternatives.

Synergistic research in economics, sociology, and demography suggests a gradual decline in crime. There are not only objective external but also internal reasons for this. The economic crisis and the stabilization of the population in developed countries are external causes. Tolerance, humanism, and the introduction of alternative means of punishment are internal reasons.

Today, the architectural environment of penitentiary complexes is in a crisis, precarious state. According to the ideas of synergetics, such instability can be a condition for further stabilization and dynamic development of the penitentiary system.

2.2 Architectural Socionics and humanization of the environment of correctional complexes

One of the many possible understandings of the philosophical dilemma of good and evil determines the construction of the penitentiary system in various countries. Each society at each stage of its development chooses the most acceptable ways to achieve a balance between good and evil and appropriate approaches to combating crime. The specific solution to this problem determines the purpose of forcible detention of people who have broken the law.

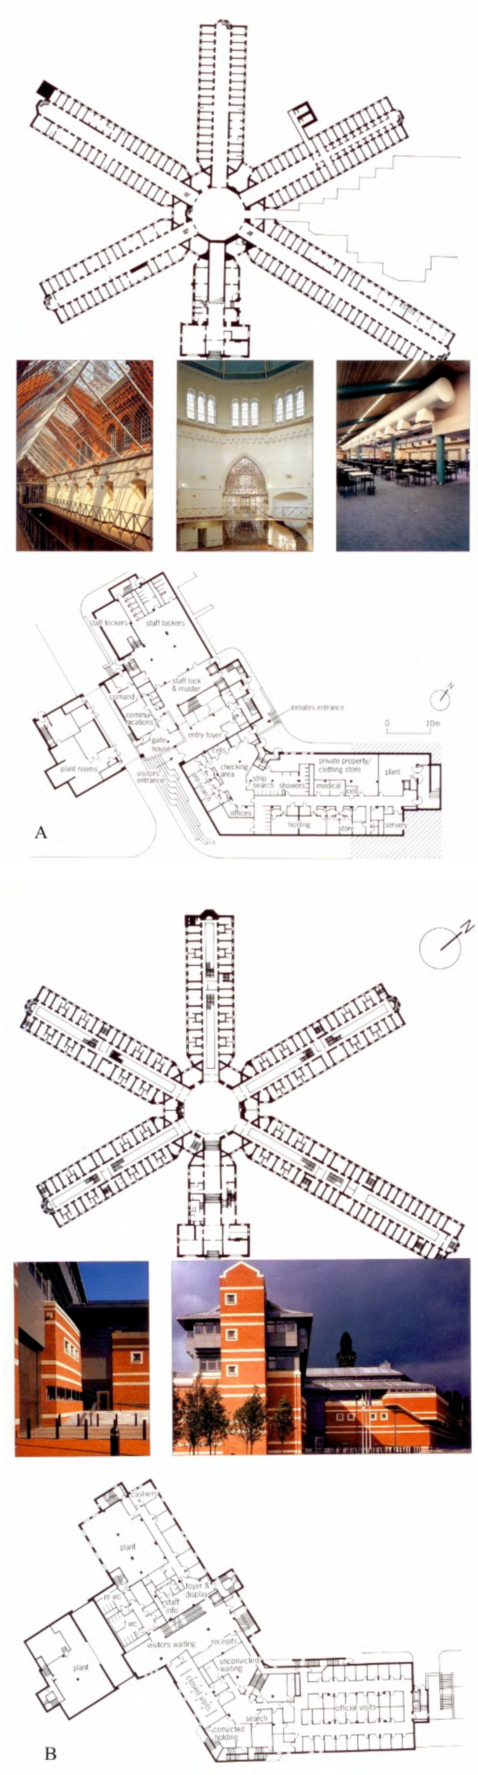

Fig. 2. Strangeway Prison before (A) and after (B) reconstruction. Plan of the building for prisoners (top) and plan of the administrative building (bottom) [9].

Therefore, different penitentiaries solve different and, in essence, opposite problems. Some of them focus on punishing criminals and making it impossible for them to commit atrocities for a certain period. Others try to re-educate people who have committed some offenses for one reason or another.

The architectural environment of detention places is subject to the primary purpose of freedom restricting of these people. Nowadays, therefore, there are prisons with a polar attitude to detainees in different developed countries. Conditions of stay in some of them are intolerable, and in others – similar to sanatoriums. For example, Japan's prison conditions are very harsh (Fig. 3) [10]. Instead, new prisons in Denmark or Norway impress with their humane treatment of detainees (Fig. 4) [11].

Fig. 2. Prohibition of communication even between convicts, Japan, https://novate.ru/blogs/140920/56010/.

Fig. 3. The little play garden for communication of convicts with families in Halden Correctional Facility, Norway https://www.bbc.com/news/stories-48885846

Ironically, both situations do not contradict elementary logic. The first approach appeals to the instinct of self-preservation because the strict order should arouse the desire never to return to prison. In this case, fear should deter criminals from re-offending. The second approach appeals to everyone's innate desire to be better than he is now. The support a person receives during imprisonment will help them achieve what they want. As a result, the former convict will not return deliberately to the wrong path.

Naturally, the question arises – if there are no violations of logic in both cases, why none of both approaches can solve the problem of crime finally. Likely, the matter is not in the architectural and planning solution of the detention places and not in the rules of organizing this process. It may be wrong to use inappropriate methods of influencing different types of people. We believe that a unified attitude towards people is the root cause of many problems occurring in various spheres of social relations. In particular, severe punishment will oppress one person and anger another, encourage one to be cautious, and strengthen the desire for revenge in another. Similarly, the humane treatment of one detainee will encourage spiritual growth, and of the other will allow self-improvement in the criminal craft.

In our opinion, an attentive attitude to each psychological type will significantly alleviate the crime problem, if not solve it. In this way, architects aim at creating the most diverse physical and spatial conditions in buildings and complexes designed for imprisonment. However, it would be good that specialists in Psychology and Socionics work in the penitentiary system. They would be able to determine the type of energy-informational metabolism of each person, committed the offense. Positive experience to the application of Socionics in Pedagogy, Psychology, Business, Politics, artificial intelligence technologies development, and the intelligent systems' formation confirms this hypothesis [12].

Understanding the values system of the appropriate psychological type would allow choosing the optimal detention conditions, both for those who can re-educate and those who have made a life choice quite consciously and are not going to change it. Socionics specialists would provide an invaluable service to convicts if they were involved in the micro collectives` formation in correctional institutions. After all, the compelled long-term stay of people with opposite value systems in the same room causes unnecessary suffering to all participants in such relationships and in no way contributes to the re-education process.

Based on the development of architectural Socionics [13], we propose to supplement the architectural typology of penitentiary institutions by allocating within it at least four types of correctional buildings and complexes. The penitentiary institutions' architectural environment of each proposed types should take into account the value priorities of the relevant Socionic quadra, in other words, – a category of people with a similar worldview, whose psychological types complement each other in pairs. This step will allow architects to offer optimal architectural and planning solutions for correctional buildings and complexes of four types. The first type is for the temporary detention of persons with extraordinary creative abilities (quadra α). The second type is for the temporary detention of persons who support centralized, hierarchical systems, which respect the authorities, focused, primarily, on the strength (quadra β). The third type is for convicts seeking personal self-realization (quadra γ). The fourth type is for individuals who are willing to work on personal self-improvement (quadra δ).

The distribution of offenders in correctional facilities, which architectural environment will correspond to the detainees' psychological types, will not only improve their fate but also create the conditions for the time spent behind bars not to turn into years erased from their lives. On the other hand, such an organization of correctional facilities will facilitate the work of penitentiary staff, increase the effectiveness of the impact on the consciousness of detainees, will improve society's attitude to the penitentiary system. The practical implementation of our proposals, ultimately, will lead to the achievement of a synergistic effect – to the humanization of the penitentiary system as a whole.

2.3 The ways to update the open public spaces of the city

Compared to other fragments of the urban environment, public spaces are more sensitive to settlements' transformations. The natural (undistorted) transformation process of urban centers corresponds to the laws of the evolution of complex open, nonlinear systems. It involves the consistent stages of repetition of dispersion, self-organization, concentration, and adaptation.

At the stages of dispersion, various forms of social activity spontaneously occupy new territories. In the phases of self-organization, the selection of the most acceptable ways of interaction between residents takes place. At the stages of concentration, the number of public functions in the respective urban areas increases, and the structural elements of public spaces become more complicated. The use of material and human resources is increasing. Due to this, the territory of public spaces expand, buildings rebuilt, landscaping is improving. During periods of adaptation, community centers are experiencing a stage of prosperity. At this time, the architectural environment of public spaces reaches its maximum diversity. It becomes able to meet the expectations of different categories of the population. Circumstances, most favorable for the transition of public spaces to a qualitatively new structural development level, are forming in such historical periods. If cities fail to make the necessary efforts at the right time, the quality of public life in their centers declines. The oscillating processes of their transformation continue in a monotonous rhythm in anticipation of the next possibility of an evolutionary leap.

A short digression into the development history of the main square of Ukraine capital allows us to illustrate this process with concrete examples. For centuries, the territory of the modern main square of Kyiv has played a leading role in the development of the city. In the 11-13th centuries, one of the main entrances to the Old Town was there. Public life was bustling in this place. However, in 1240 Kyiv fell under the pressure of the invaders. Any activity in the city froze for almost four centuries. The harmonious development of the settlement was interrupted.

From the 17th century, Kyiv began to return to life. The city gates on the road from the Old City to Pechersk resumed work. The water mill began to operate here. Later, the first residential buildings appeared in this area. Since the 19th century, public space began to function here. Pubs and taverns, dens, and brothels actively received visitors. Until 1818, the detention center functioned next to them. That is, the concentration of functions took place in public space.

In the middle of the century, on weekends, the then Khreshchatyk square performed trade, show, and recreational functions (Fig. 5). In 1843, the first fountain appeared in the square, but, at that time, it mainly satisfied economic needs. The public space was actively operating. Thus, this period testifies to the adaptation of the urban environment to the urgent needs of residents.

Over time, stone houses began to displace wooden houses from the square. In the mid-1850s, paving stones first covered the roadway. In 1866, the first public library began to operate on Khreshchatyk Square. The latest technologies had their origin here. For example, in 1864, the first kerosene lanterns appeared here. In 1872, gas lanterns replaced them [14].

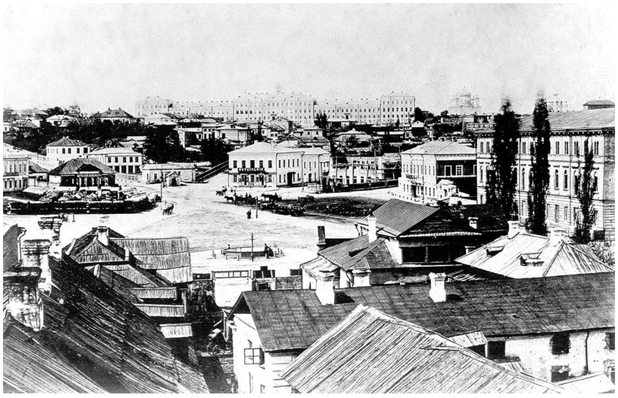

Fig. 5. Panorama of Khreshchatyk Square. Photo of the 1860s, http://archunion.format.com.ua/history/history_004_01.shtml

In 1878, the building of the City Duma appeared on the square. This area has become the administrative center of the city. In 1892, the first trams crossed the then Duma Square. The accumulation of resources to improve the consumer quality of public spaces has reached its maximum at the stage of self-organization.

In 1909, a cozy square with an iron fountain appeared here (Fig. 6). New functions appeared here at the concentration stage – recreation, communication, political meetings, and celebrations.

At the next stage of adaptation, the Second World War interrupted the sustainable development of the main

 https://doi.org/10.1051/e3sconf/202128004009

square of Kyiv. The historic buildings there have almost completely disappeared.

In the third quarter of the twentieth century, a new cycle of the historical development of the central square of the city began with the stage of concentration of functions in the public space. The new buildings have replaced their predecessors. The square with a fountain continued its operation. In 1946, the Christmas tree began to decorate the then Kalinin Square for the New Year holidays. The entertainment function has returned to the public space.

Fig. 6. Kalinin Square. Photo 1954, http://archunion.format.com.ua/history/history_004_04.shtml

In 1964, the first underpass in Kyiv connected two parts of the square, separated by Khreschatyk Street. In addition to the ground, there was an underground level in the central public space. At the beginning of its existence, it provided the transit of pedestrian flows. However, as early as the 1970s, artists and street musicians began to use this space. Authorities struggled with this phenomenon, but not very successfully.

The “finest hour” of the city center began during the last quarter of the 20th century. In 1976, the subway station opened. In 1981, the main square of Ukraine underwent a large-scale reconstruction. Its open space has become more comfortable and grand (Fig. 7). People started spending much more time there. They gladly took part in numerous mass events, when the square turned into a dance floor or a concert hall. Children's holidays and folk festivals raged on the square. A large of events in the personal life of many city residents took place in this space.

A small museum appeared in the underground space below the western part of the square after the reconstruction in 1981. Visitors could see here the original remains of the foundations of the ancient Russian Lyadsky Gate. Anyone could visit this exhibition space at any time. The underground passage under Khreshchatyk Street at that time turned into a real public space, which was popularly called «Trumpet». There, artists demonstrated their skills, representatives of different subcultures met, restaurants, and shops worked [16].

The independence of Ukraine also affected the functioning of Kyiv's main square. It changed its name in honor of this event and became the main square of the country. The external push has moved the central public space of Maydan Nezalezhnosti to a qualitatively new round of urban evolution.

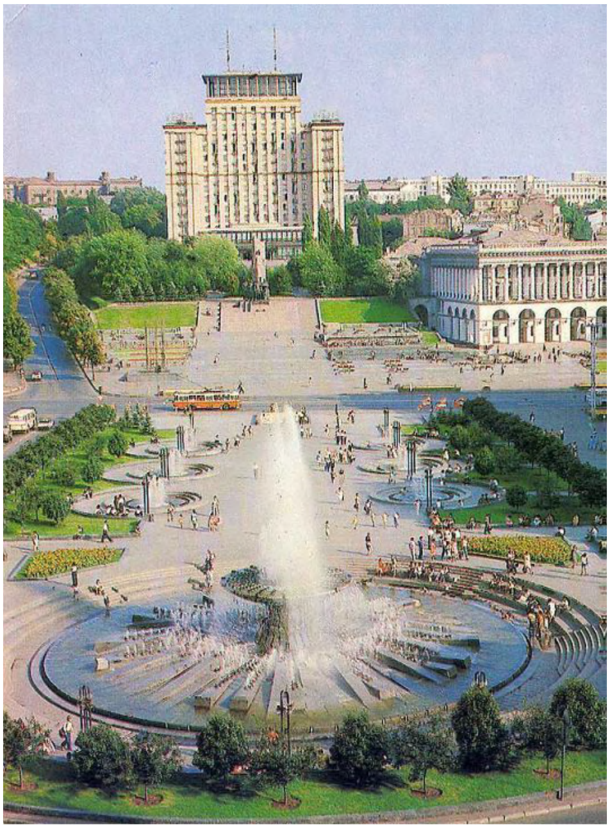

Fig. **7.** October Revolution Square. Photo 1985, http://infoportal.kiev.ua/ploshhad-nezavisimosti-v-kieve-novaya-istoriya-proisxodit-zdes/

The next stage of concentration of public functions has begun in this territory. Reconstruction in 2001 radically changed the area. The underground museum, aboveground recreation areas, and a large fountain have disappeared. Instead, the “Globus” shopping and entertainment complex went under ground level on several floors and rose above its surface (Figs. 8, 9). The main open areas for communication and recreation are at ground level and above ground – in the park near the October Palace and the roof of the third line of the “Globus”. The premises of the shopping and entertainment complex are becoming more popular in the cold season.

Already in the early 1990s, the main square of Kyiv became the primary place of public expression. In 1990, students who made demands to the government lived for a time in a tent camp in the city center. In 2004 and 2013, Independence Square became an arena for political struggle. In 2014, tragic events unfolded there, taking many lives.

The central square of the capital is gradually “healing” the wounds received during the Revolution of Dignity. However, this space will never be the same as before. A memorial was added to the list of his public functions. However, life goes on. A large-scale reconstruction of the underground passage near Khreshchatyk is underway.

The described events testify to the cyclical development of the central public space of Kyiv (Fig. 10).

In this case, the stages of dispersal, self-organization, concentration, and adaptation successively replace one another. Trends in the historical transformations of this space coincide with ideas about the cyclical nature of sustainable development. This opens up prospects for predicting the ways of sustainable and dynamic transformation of public space in the center of Kyiv. They last for about 25 years, which corresponds to the duration of urban activity of one generation.

3 Conclusions

The search for new approaches to solving current problems of sustainable development of cities becomes especially important in the current conditions of reforming the architectural and urban planning industry in Ukraine. We found two opposite trends in sustainable development – the desire for stability and dynamism, rigidity of organization and flexibility of self-organization, tolerance, and hostility. Their mutual coordination is a reliable methodological basis for achieving the goal and solving sustainable development problems. We found that the dynamic component of constancy has a regular cyclical nature that manifested in a kind of genetic code of the alternation of pairwise polarized processes of dispersion and concentration, self-organization, and adaptation. On this basis, we have developed a new method of polarized cyclicity, which differs from existing methods in its dialectical content. It allows identifying important moments when minimal efforts stimulate a new round of sustainable development processes.

Their composition and order of deployment have signs of universality and are distinctive for all types of architectural environments in the city. Therefore, we used Synergetic and Socionic approaches to address sustainable development. Its cyclical nature is in the historical transformations of mutually polarized components of the city – the socializing public space and the resocializing environment of penitentiary complexes. Their diametric opposite outlines the range of tasks for diagnosing the stages of sustainable development and allows them to involve in their solving Socionic methods that contribute to the urban environment humanization.

The revealed patterns of historical and sustainable development and the usage of synergetic and Socionic approaches open new perspectives in architectural studies of transformations and metamorphoses of public spaces and the penitentiary environment. The list of methodological tools includes diagnosing these complex environments, finding out the reasons for their arrhythmic development, coordinating the phases of transformation, and efforts to maintain trends of sustainability and dynamism. They will contribute to achieving the goals, solving the problems of sustainable development of cities, and the humanization of the architectural environment of their various parts.

We propose to use this methodological approach in the architectural and urban planning practice to solve some problems. Among them: tasks of detailed planning of the territory, forecasting the stages of reconstruction and renovation of public spaces, penitentiary complexes, and other types of the urban environment.

Abstract. The article deals with the issues of overcoming poverty, inequality, nutrition improvement, ensuring a healthy way of life, raising education quality, enhancing well-being, and building up a peaceful and open society for internally displaced persons (IDP) and the receiving community by means of the social response strategy. The goal of the research: theoretic substantiation of the response strategy in social work with IDP and the community in the context of the perspective of ensuring their sustainable development. The presented response strategy is for the first time theoretically substantiated and adapted to the Ukrainian realities in the conflict zone and takes into account the peculiarities of the DP and social work in the receiving borderline community and includes standard actions to react to extraordinary situations, activity directions – psychology-and-pedagogic, socio-medical, humanitarian, information-and-cultural assistance. The strategy is based on the principles of integration, multi-sidedness, multidisciplinary connection, resource-orientation, green-aware social work, the advantages theory, partnership, assistance for self-assistance, family-centrism, innovation, synergy, etc.; it takes into account the perspective ensuring of sustainable future for both the displaced families and the receiving community in general. The methods of the research: theoretical analysis, synthesis, systemizing, generalizing, comparison, documentation study, estimation of needs, and mathematic statistics methods. The obtained results of applying the mentioned theory under conditions of the military conflict in the Luhansk oblast (area) of Ukraine confirm its efficiency in qualitative and numerical terms and are supported by mathematic statistics methods.

1 Introduction

Overcoming poverty and hunger, reducing inequality, nutrition improvement, ensuring a healthy way of life, raising education quality, enhancing well-being for various age-groups of population, formation of a peaceful and open society as the goals of sustainable development, proclaimed in the UN General Assembly Resolution for the period till 2030 [1] and adopted by Ukraine [2], are the principal landmarks for working out social projects and programs for improvement of medical, social, and educational services for vulnerable strata of population in the context of securing their sustainable future [3; 4]. Attaining these goals is of special urgency in the east of Ukraine, where the military conflict has affected the population's well-being level, led to the arising of the new for the country vulnerable social group, internally displaced persons (IDP), the number of whom as of 13.04.2020 was 1,446,881 according to the Unified information database on internally displaced persons of the Ministry of Social Policies of Ukraine. These people need support and assistance, including social work concerning a decrease in the conflict's consequences influences on their lives, securing their sustainable development, adaptation to the new communities, and integrating into new conditions of life. On the other hand, the arrival of IDP to new communities has led to the growth of tension therein, due to the need in sharing the existing resources among all the community members, thus making the receiving party poorer as a result of IDP' arrival. It is the border regions of Ukraine where this situation has formed along the demarcation line, where, for instance, in the city of Berdyansk there was registered the ratio of 1:5 between IDP and the local inhabitants which makes 20% of the population. An EU 1.3 mln euros project solved the issue of diminishing social problems, easing tensions between IDP and the receiving community of this city [6], but not all towns in the borderline zone get such financing. Other ways of solving the problems of IDP and local community are needed, like, among other things, activation of people themselves to render self-assistance, granting targeted assistance, and so on. The concepts of social work acting in Ukraine ("assistance for self-assistance", "crisis intervening") are characterized as rendering assistance for adults in the time of peace [7], while the conditions of a military conflict

* Corresponding author: trubavina@gmail.com

attest to peculiar problems of socialization and activities of children, families, and adults [8; 9]. The existing concepts of social work [10–12] insufficiently account for the peculiarities of IDP and the receiving community. Attention should be paid to strengthening and encouragement of communities, to satisfying the needs of all vulnerable families of IDP and local people from the receiving community, which is attained in practice by integrating resources and interdepartmental and multidisciplinary cooperation in rendering social services [6; 13–17]. Nevertheless, the mentioned measures overall do not facilitate the development of IDP and local people or communities. Other approaches are needed, targeted at sustainable development of every person, family, community under conditions of a humanitarian crisis and military conflict.

As to conception and formation of the ideas of sustainable development in social work, it should be noted that accentuation on individual sustainability (a personality sustainability) has existed in social work for a long time and has evolved as a concept, but it was not applied to IDP, particularly to children and their families that prevail among IDP [18]. In its turn, the interconnected vectors of social work and sustainable development of communities, society, of interaction between the personality, the family, and the community are a new direction that has become the reason for activation of research in this sphere to find ways of mobilizing resources of all IDP and the community, for development of strategies which will facilitate ensuring sustainable future [6; 19–24]. Such strategies have not been yet applied to IDP in Ukraine.

Among the researches by foreign scientists devoted to this topic, there are studies representing the theory and practices of social work with vulnerable strata of population, including IDP under conditions of a military conflict. Social work with them is based on eco-social foundations. Military actions are viewed as cause and effect of environment degradation (Aniche Alexander [25], J. Lambert [26], T. John Pardeck [27]; K. van Wormer et al. [28], and others). The impact of a military conflict on internally displaced children and families with the accentuation on their mental health, considering the displacements as a social ecology problem that determines deprivation, poverty, and social rejection, is presented in the works by K. Lai [29], K. Miller [30]. L. Dominelli within the concept of the green social work focuses on the problems of social injustice, social rejection, and segregation of people [31]. Historic development and dilemmas of social work with displaced population are represented in the work by P. Boccagni and E. Righard [32]. The issue of different consequences of internal displacements and IDP integration into receiving communities is elucidated by A. Carrillo [33]. These researches are related to the authors' studies of the IDP's problems [8], their life in the places of compact residence of IDP and social services for them in the receiving community [6] in the context of special problems of socialization and integration of internally displaced children and adults, the need in comprehensive solving their problems. The ecologic perspective in social work with the IDP and the community, according to the world studies, is based on support of a personality and their environment, satisfying their needs, search for and integration of resources for solving personal problems [34; 35]. Currently, social work in the global context of sustainable future is of multidisciplinary character and requires that a social worker perform the role of a coordinator of individual and social sustainability development [31] and is directed at overcoming of poverty, fair distribution of resources, decrease in the risks of negative consequences on the level of an individual, a family, a group, a community and society in general, integration of a personality into a community and accepting them by local people. This highlights the topicality of theoretic substantiation of the new theory of social work with IDP and community with taking into account the country's specifics, its particular region, and practical implementation of the principal guidelines in the activities of various social institutions in the context of the perspective of securing a sustainable future for the mentioned social group and the community.

In the international practice, social work with vulnerable strata of population that suffered as a result of a military conflict began developing after the World War II; it was non-existent in Ukraine. Nowadays, the Ukrainian system of social services appears to be unprepared for timely response to the new social problem, the arrival of IDP. That is why a portion of the work concerning rendering assistance to them was undertaken by international public organizations and volunteers [36]. One of such organizations is the International charity organization "SOS Children's Villages", whose general activity strategy for the period till 2030 is targeted at ensuring the best care of children, innovations introduction, uniting larger numbers of partners to solve the problems of children from the families that found themselves in difficult life situations, as well as to react to changeable needs of communities [37]. Its goals are closely related to the sustainable development goals in such spheres as poverty, inequality, education, healthcare, social protection, decent work, and fostering their achievement with the accentuation on the target group – children and families. This supposes the work of the organization concerning improvement of national social protection systems, combating social inequality, promoting access to quality education, broadening opportunities for youths' employment, eliminating violation to children [38]. These aspects of the organization's activities are of global character because "SOS Children's Villages" operates in 136 countries and territories of the world [39]. They do not reflect the specifics of each state, but lay foundations for working out new theories of social work with children and their families taking into account the circumstances in a particular country, or in a particular region, which determines the expediency in utilizing their experience when developing new theories. This organization applies the responsive strategy of social work which is targeted at working with individuals, groups, and communities that have suffered from extraordinary situations (natural disasters, technogenic catastrophes, wars, etc.), restoring their activities, and access to resources [40]. But this strategy has not been theoretically substantiated and adapted to the realities of Ukraine.

Therefore, there is a need in solving the problems of IDP and community in socially unstable regions. Formation of new communities in such regions and securing for them a perspective of sustainable development is becoming even more acute and calls for substantiation of the new social work theory which the authors have determined to be the response strategy. Therefore, the goal of this article is theoretical substantiation of the response strategy in social work with internally displaced families and the community within the context of the perspective of ensuring their sustainable development.

Attaining the goal supposes solving the following tasks: 1) determining the peculiarities of social work with IDP and the community in Luhansk oblast; 2) substantiation and disclosing the essence of the response strategy in social work with IDP and communities at the areas bordering with the conflict zone in Luhansk oblast; 3) to estimate the efficiency of the response strategy's application on the mentioned theoretical foundations in Luhansk oblast.

2 Methodology

The main methods that ensured attaining the goal and the tasks of this research were theoretical analysis of sources on the studied problem, synthesis, systemizing, generalization, comparison, documentation study, needs estimation, mathematic statistics methods for comparing, evaluation and estimation of the obtained results. The base for the research was the work of the Luhansk area branch of the international charity organization "SOS Children's Villages" in the military conflict zone and the border regions.

The research was conducted within the partnership between the Science-and-research Center of Social Pedagogy Problems and Social Work at the National Academy of Pedagogic Sciences (hereinafter the Center) established on the base of State Institution "Luhansk Taras Shevchenko National University" on the one part, and the Luhansk area branch of the international charity organization "SOS Children's Villages" on the other part. The research was financed from the State budget of Ukraine as part of the fundamental research "Socializing of the school and student youth of the East of Ukraine under the hybrid was in Donbas" (2018–2020) [41] and in the course of participating in the international project on "Strengthening Communities for Ensuring the Children's and Families' Needs in the North of Luhansk Oblast" supported by the UNICEF and Luhansk oblast branch of the international charity organization "SOS Children's Villages International") [41; 42].

In the towns of Starobilsk and Severodonetsk, experimental sites were established to work with IDP, the community, and internally displaced children's villages. The materials of the conducted work have been generalized in this article.

3 The results of the research

3.1 Peculiarities of social work in the conflict border regions

The specifics of the operation of the Center and Luhansk oblast branch of "SOS Children's Villages" is that that the employed specialists' staff is composed of both local specialists and those who are IDP. For this reason, they like no other feel the problems and needs of internally displaced families in a new community. Another peculiarity in the Center's activities is that it takes place in Luhansk region, part of which is temporally occupied. On the territory which is controlled by Ukrainian government, the power is exercised by military-and-civil administrations for securing safety and normalizing population's activity, law order, taking part in counteracting aggression acts, subversive activity and terrorist acts, preventing humanitarian catastrophe [43]. This means the need in coordinating social work, its events with military-and-civil administrations for safety of social workers and the clients. Luhansk oblast is the second in Ukraine after Donetsk oblast by the number of IDP, which amounts to 280,437 people [44] and aggravates the situation considering that the area itself has suffered and is still experiences the consequences of the active conflict. Therefore, the peculiarity of rendering social services is the need in resources in the receiving community and the lack of these resources. At present, an aggravation of conflicts in all spheres of group interaction between IDP and representatives of receiving communities is observed, which is mostly determined by the absence of real public dialogue, ignoring the interests of all parties, taking unjustified decisions concerning socially significant issues [45]. That is why social management is important considering the problem of redistribution of the available resources. In Luhansk and Donetsk oblasts has formed the worst situation in Ukraine as to the state of satisfying the basic needs of people, which is determined by high unemployment level in these areas. In the areas, there is no support of IDP by local authorities who do not develop programs for IDP integration and do not provide for financing their social needs from local budgets. The reason is that IDP have no right to vote at local elections, not being permanent residents. Therefore, the peculiarity of social work is its orientation at those state programs that are limited in an area with military-and-civil administration, as well as at public organizations and citizens' self-assistance.

In the Center's activity and that of "SOS Children's Villages", *resilience* is actively applied, the approach that orientates social work at client's advantages that facilitates avoiding deep traumatizing of children and families that found themselves in dangerous or extreme conditions. Resilience is different from resistance to stress, which changes a person under the impact of outside events and influences. This notion supposes an individual's resistance to such influences, the absence of the result of influencing people. In the context of the research, the authors attempted to compare some peculiarities of social work in terms of applying standard approaches and that of resilience (Table 1).

Table 1. Comparing resilience with standard approaches to understanding a difficult life situation in social work*.

Standard approach – when focusing on deprivation, disorders, a trauma	**Resilience – when orientated at a person's advantages**
Considering a person's problem as a typical case	Orientation at the personality's uniqueness
Focusing attention on the client's problem	Focusing attention at potential opportunities
Needs are determined by social worker	An individual determines their needs independently (or with social worker's assistance)
Difficult life situation is perceived as a risk of negative consequences	Difficult life situation is perceived as activation of a personality's powerful inner resources which had been used before
Inability to resist an extraordinary situation	Ability to overcome difficulties caused by an extraordinary situation, to preserve the balance and stability

* Compiled by the authors as an example based on the exercise "Advantages theory in social work" [46].

Therefore, it is possible to determine the peculiarities of social work in Luhansk oblast: a larger number of clients' social problems compared with other regions, the majority of the clients are IDP, there exist specific problems of IDP and the receiving community, dependence of social work on military-and-civil administrations and the territory status, the need in social management under limited resources, involvement of IDP in social work as specialists, the absence of local assistance programs for IDS, orientation of state social services at state assistance programs for IDP that act on the territory of Ukraine and do not take into account the specifics of the territories in the conflict zone, involvement of public organizations in rendering social services to IDP and the community, orientation at resilience (focusing on the clients' advantages).

3.2 Substantiation of the essence of the response strategy in social work in the military conflict zone

The strategy of social work with clients of different age groups and categories is defined as part of a social worker's skills, which include its basic components connected with his/her ability to select for each presented task the optimal social technologies, methodologies, and tactics that would ensure its successful accomplishment [11]. A strategy's peculiarity is that if the strategy is chosen correctly and is of high quality, it does not need alterations regardless of the changes in environment, for it is in itself a precondition for survival in a constantly changing environment. Only the plan of measures is to be adjusted depending on the chosen strategy. At the same time, the measures should be integrated and mutually connected [47].

The response strategy in social work is meant for work with individuals, groups, and communities who have suffered from extraordinary situations (natural disasters, technogenic catastrophes, wars, etc.), for restoration of their activities and access to resources [40]. It is directed at overcoming the dependency on humanitarian aid, recuperation of work potential, socio-cultural and social relations, efficient self-management and self-assistance [36]. This strategy is maintained on the basis of observing both the legal norms (General Declaration of Human Rights [48], the UN Convention on Children's Rights [49], the UN Guidelines concerning Alternative Childcare [50], the UN Goals of Sustainable Development till 2030 [1] and others) and the developed inner standards in social services provision. Correspondently, the measures of the "SOS Children's Villages" organization and the Center on the issues of readiness for and reacting to extraordinary situations, planning for unforeseen circumstances, joint estimation and development of standards and guidelines, fulfilling of corresponding programs of rendering assistance in extraordinary situations, reacting to consequences of military actions, providing assistance for vulnerable strata of population, particularly to internally displaced children and families reflect the main priorities of the UN activities in this sphere. That is, the measures are oriented at observing the human rights, preserving the integrity of family, safety, and other basic needs of people.

It is stated in the UN Manual on Extraordinary Situations, that "any extraordinary situation is unique, that is why there is no single comprehensive plan to control it. Nevertheless, extraordinary situations usually develop on scenarios that have some common features, which enables specify standard actions in response" [51]. Analysis of the content of the response to extraordinary situations concerning the work with refugees in the UN documents, and in the practices of the "SOS Children's Villages" organization's operation has made it possible to establish the list and the main content of such actions (table 2).

The measures on rendering assistance to IDS as a new category of social services' clients for Ukraine are in many cases similar to those for refugees, although IDP, unlike refugees, remain on the territory of their country, therefore their protection and rights are regulated not so much by particular international legal acts as by national legislation [51]. That is why forming various conditions for their rights implementation and protecting them as the goal of social work enables using scientific approaches of human rights protection, a family-centered approach (of protecting the family, family members and their rights). The peculiarity of the response strategy in social work with IDP and community under conditions of the military conflict and social crisis in Luhansk oblast is that the safety issues are accentuated on, including those of evaluating the family and community's needs for creating a safe life, considering the project initiatives in local development in the context of vision of the perspectives of their sustainable future [52]. This means the need in utilizing all the benefits of the risk-orientated and the project-orientated approaches, of diagnostic social work. They enable solving locally the problems of community, decreasing danger and risks for people's life, and finding additional financing for problems solving.

Table 2. Standard actions within the response strategy to extraordinary situations

Standard actions	Contents of the actions
Estimate the problem, the needs and resources	Initial estimation of the problem and people's needs
Mobilizing resources	Activation and use of potential resources in order to eliminate the threat for people's life and health
Regulating the relations with the donors and the media	Ensuring communication between family members and relatives
Planning operations	Additional estimation of the client's needs, development of the actions plan, determining current tasks and long-term goals and measures to achieve them
Carrying out operations and coordinating the actions	Tasks distribution, making coordination mechanisms of fulfilling individual tasks
Monitoring and estimating the situation constantly	Estimation of the dynamics in changes in the course of solving the problem, comparing the initial, the intermediate, and the final results of social work with the client
Going on to the actions following the termination of an extraordinary situation	Completion of work, defining the perspectives of renewing the work with the client if needed

It should be noted that the response strategy in social work in the "SOS Children's Villages" activity is aimed at work with children and families that found themselves in difficult life situations, at renewal of their viability, access to resources, and integration into the receiving communities [53]. In essence, this strategy relies on the integration and the eco-social approaches, which are based on the foundations of partnership, viability, innovations, and synergy, and can include crisis intervening when a person or a family needs support in difficult and extraordinary situations, which is broader than the social work in difficult life situations conducted by the rest of social workers of Ukraine [not involved in work with IDP]. Due to the fact that such social work can be made by IDP themselves, the participation theory is important for the work with IDP and the community. Partnership in this sense of social work supposes conducting various consultations aimed at well-grounded expectations of the community from power bodies. All the interested parties – representatives of power bodies, scientific and educational institutions, enterprises, and other institutes of civil society – are invited to take part in passing decisions and development of strategic goals. This is the democratic approach in social work. Innovation acts as a kind of indicator of the response strategy projects and for the larger part relates to efficient use of available resources. The synergy approach supposes considering individuals, families, groups, and communities as self-organizing systems, especially in unstable, crisis states.

The idea of application of the integration approach is that social response to the clients' needs supposes not only their adapting to the community, but also the community's adapting to them, community's creating favorable conditions for the utmost implementation of its members' potential, strengthening inter-sectoral cooperation between different social institutions on partnership terms, provision of comprehensive social services [3]. This means the use of the resource approach in a community. An important role in this work is allotted to interdepartmental interaction, which supposes mutually coordinated activity of structural units of the local executive power body and the offices subordinated to them with involvement of other institutions and administrations representatives vested in authorities provided for by legislation if necessary for the best ensuring of the rights of children who reside or stay on their departmental territory, solving their families' problems, forming conditions for children's upbringing by their responsible parents or legal representatives. Interdepartmental interaction on the issues of assistance, support, and guiding a child and their family in the "SOS Children's Villages" operation supposes close cooperation between state organizations, healthcare system institutions, social protection of population, education, non-governmental organizations and institutions. Organizing such interaction in present conditions of development and improvement of social services for families should become the mechanism which facilitates attaining high standards in the sphere of rendering social services [54]. The interdepartmental approach supposes multidisciplinary operation, organizing and coordination of social services provision, systemacy in rendering them, which means integration and cooperation of all structures and specialists, the basis of which may comprise, according to the human rights theory, of the family-centered approach, human rights, and family rights.

The eco-social approach departs from the idea of interconnection and interaction between an individual and the environment. A social worker's actions are directed at assisting a person to overcome a number of problems that are a consequence of this interaction. Social problems are viewed as ecological problems, and corresponding work is aimed at ensuring decent environmental conditions, ecological justice and equal access to natural resources, environment preservation, assistance to population in extraordinary situations [40]. It is access to water, medicines, food, and other essential things that matters most in the so-called "grey zones", in the conflict-bordering areas. That is why socio-economic services are the foundation of satisfying people's basic needs and solving their daily problems. A task-oriented model of social work is needed. In eco-social approach, resilience requires "assistance for self-assistance", as well as training to perform resistance to outer negative influences and circumstances with relying on the positive in the situation and the person.

Thus, the theoretical foundations of the response strategy in the Center's social work with IDP and community in Luhansk oblast are scientific approaches of various levels, namely:

Philosophic approaches: the human rights theory, the sustainable development theory, the pragmatic the democratic, the multidisciplinary approaches, and the participation theory;

General science approaches: the integrated, the innovational, and the synergy approaches;

Specific science approaches: the family-centered, the risk-orientated, the project, and the resource approaches;

Social work approaches: the advantages theory, assistance for self-assistance, crisis intervening, eco-social, diagnostic social work, and task-oriented model.

The principles of social work based on the response strategy in Luhansk oblast are: observing human and family rights, orientation at sustainable development of a person and the community, subjectivity, viability, synergy, integration, cooperation, solving urgent problems, orientation at result, directedness at self-assistance and resilience, innovations introduction in problem solving, removing risks and dangers, their minimization, relying on local projects, joining resources, considering clients as subjects and in case of a crisis as objects of social work, work with environment and in community, problems and needs estimation, responding to problems and needs.

The content of the response measures on this basis should be determined departing from the problems, goals, and principles of work. Thus, the main problems of IDP in the East of Ukraine are the problems of obtaining temporal housing, residence registration, medical examination and treatment, education, food, clothes and hygiene products supply, coordination of procedures to get social assistance, the issues of work and employment, etc., which if not timely attended to will cause instability and loss of control over the situation and one's own life, abrupt decrease in material well-being, fear of being rejected by society, feeling of insecurity, and being unable to foresee one's future [8; 55; 56; 57; 58]. Also, as has been proved, outreach and socio-cultural work is needed [6]. That is why, the main directions in implementation of the response strategy in the Center's social work with IDP and the community are psychology-and-pedagogic, socio-medical, information-and-cultural, and humanitarian assistance. Each of these kinds of work can be performed at different levels of a case: from servicing to rehabilitation, support and intervening. It is these kinds of work that help gradually bring a person out of crisis and lead them to development without negative consequences for their life and health. The chief methods are the following: social, socio-psychological, socio-pedagogical, socio-economic, organization, and diagnostic ones.

Within the authors' experimental research, each of the mentioned kinds of social work became a criterion in evaluating the efficiency of the response strategy application in the "SOS Children's Villages" organization and the Center in Luhansk oblast, and the chief methods of social work mentioned in this connection were indicators of these criteria.

The experiment involved 250 families that found themselves in difficult life situations and were entitled to social support at "SOS Children's Villages" (towns Starobilsk and Severodonetsk) through the response strategy in social work. 80% of these families had the IDP status, while 20% of the families were locals. The answers to the questions concerning the need in these or other kinds of services were given by women as representatives of these families. The experiment supposed comparing the results obtained prior and following the social response actions, i.e. women's independent estimation of needs in obtaining different kinds of services before and after social support. The research was based on the standards of observing ethical principles of conducting research with humans as subjects. The families participated in the interviews on their free will.

At the initial stage of the experiment (October 2018) in the psychology-pedagogic assistance direction, the urgency in satisfying the needs of internally displaced families in logopedist services were estimated and amounted to 12% of the total number of families that agreed to participate in experimental actions concerning the response strategy application in the course of their social support. The needs in psychologist services were 84.4%, in those of a social worker – 81.6%, improvement of their knowledge of English – 25.6%, catching up with the school program – 15.2%. By the socio-medical assistance direction, the needs in covering families' expenditures on medical treatment of children were 31.6%, recovery – 69.2%, By the direction of information-and-cultural assistance, 64.4% of families needed information services, and 89.6% needed help in organization of daily activities and leisure. The families' needs in humanitarian aid were 88.4%. The obtained data match the results of the research concerning the estimation of IDP's needs and employment possibilities in Ukraine (n=2000) conducted in October 2014 – December 2015 by the International Labor Organization, which estimated the unemployment percentage among the IDP due to looking after ill family members and young children to be 31.5% [59] and the research on estimation of IDP and services for them in Ukraine (n=471) conducted by the international NGO "Social Initiatives in Labor Protection and Healthcare" in January 2015, which reported that the number of IDP who had no access to medicines or could not afford them was 27.3%. This research also revealed that the urgent need in humanitarian aid (food and clothes only) was 65.7%, in social assistance – 86.5%, in psychological – 89%, in cultural – 92.7% [60]. It should be noted that the data obtained as to the needs in humanitarian aid differ considerably due to the fact that in the authors' [of this article] research the humanitarian aid services related not only to satisfying the basic needs in food and clothes, but encompassed a somewhat broader range – stationery, hygiene goods, preparing for winter season, etc.

At the main stage of the experiment (November 2018 – October 2019), the response strategy in social work with IDP and the receiving community was applied by the mentioned kinds of social work. By the psychology-and-pedagogic assistance direction, the Center jointly with the "SOS the Children's Villages" cooperated actively with education institutions in order to form a modern, most comfortable for children education environment to assist teachers to cope with the tasks of adaptation of children from vulnerable families to school, to give them an opportunity of overcoming difficulties and develop their abilities to the fullest extent. The following methods and measures were suggested: individual consultations by a psychologist; consultations by a social work specialist; sessions with a logopedist; group classes in art-therapy; group classes in parental potential development; mutual assistance groups; individual psycho-therapeutic sessions for children who experienced a trauma; charity initiatives (for instance “A backpack of kindness” – assistance to children in getting ready for school), additional classes in school subjects, etc. The socio-medical assistance was connected with such aspects as recovery (health improvement) that supposes organizing resting holidays for children from the region that suffered from the conflict, covering a certain sum of expenditures on buying medicines for children if prescribed by a doctor, giving out medicines and vitamins, training children and families in a healthy way of life. The information-and-cultural support supposed organization of joint leisure for parents and children, information support as to a family’s renewal of their social status, family and social ties (information support in paperwork (restoring documents), various kinds of social payments, etc.), development and propagation of information materials for parents and children. Jointly with the “SOS Children’s Villages” the Center provided humanitarian aid in the form of food parcels, hygiene sets, baby-boxes, medicines and vitamins, seasonal clothes and footwear according to the detected needs. It should be noted, that the main programs fulfilled by the Center jointly with the “SOS Children’s Villages” are family forms of upbringing, strengthening families, programs within the projects of responses to extraordinary situations. For covering expenditures on responses to extraordinary situations, the grant financing mechanisms are involved.

The final stage of the experiment (December 2019 – January 2020) included analyzing the efficiency of applying the response strategy in social work with internally displaced families and the receiving community. In Table 3, the work outcomes are presented. The interpretation of the obtained data was made with the use of φ* indicator of Fisher’s angular criterion. The statistical significance levels of different values of Fisher’s φ* criterion were determined from Hubbler’s table [61].

The obtained results attest to a positive dynamics in solving the problems of IDP families and communities in the East of Ukraine because, owing to the use of the response strategy in the course of their social support, the percentage of families who need further satisfying needs in the mentioned kind of services by all kinds of assistance (psychology-and-pedagogic, socio-medical, information-and-cultural, and humanitarian) decreased, which attests to activation of their own resources in overcoming the consequences of the conflict to their lives, restoring their potential and social relations, raising the level of their integration into the receiving community. These data match the authors’ data on IDP’s rehabilitation, integration, and activation within the EU project in the town of Berdyansk [6], when owing to social work with IDP in the places of their compact residence and the community and activation of IDP and local residents’ subjectivity, tension in the local community decreased. Nevertheless, the program was not oriented at resilience development, which told on further IDP’s migration (at present 10% of residents there are IDP instead of 20% at the beginning).

Table 3. Unified actions in the response strategy for emergency situations.

The necessity in satisfying a need in	% of the total number of families to those who needed support	% of the total number of families to those after social support	φ^*_{emp}	p
Psychology-and-pedagogic assistance				
logopedist services	12,0	2,4	4,43	<0,001
psychologist services	84,4	26,8	13,89	<0,001
a social worker’s services	81,6	23,6	13,86	<0,001
improving their English	25,6	17,2	2,3	0,01
catching up with school program	15,2	5,2	3,81	<0,001
Socio-medical assistance				
covering expenditures on medical treatment of a child	31,6	21,2	2,65	<0,003
recovering (health improvement)	69,2	27,2	9,71	<0,001
Information-and-cultural assistance				
information services	64,4	15,6	11,75	<0,001
organizing of daily activities and leisure	89,6	50,4	10,13	<0,001
Humanitarian aid				
non-financial assistance (school stationery, food, hygienic, winter sets, etc.)	88,4	18,0	17,56	<0,001

Therefore, the use of the response strategy in social work with internally displaced families and the receiving community is efficient and forms favorable conditions for achieving the goals of sustainable development on the road to their stable future.

4 Conclusion

The peculiarities of social work with IDP and the community in Luhansk oblast are that this region is characterized by the dependency of social work on military-and-civil administrations and the territory regime; a large number of IDP; the presence of specific problems and the needs of IDP and the receiving community; IDP’s participation in social work as specialists; orientation of local authorities at state assistance programs for IDP acting in Ukraine and not taking into account the peculiarities in the conflict zone; the need in social management under conditions of limited resources; involvement of public organizations to providing social services for IDP; the need in orienting at resilience.

The response strategy in social work with internally displaced families and community is directed at renewal of their viability, access to resources, and integration of internally displaced families in the receiving communities. Its content is connected with such unified actions as the necessity in estimating the problem and needs, resources mobilizing, actions coordination, and permanent monitoring of the situation. Social response of this type is based on scientific approaches of various levels and principles of human rights protection, sustainable development perspectives, ensuring multidisciplinary approach, integration, resource mobilizing, eco-sociality, advantages theory, assistance for self-assistance, innovativeness, partnership, vitality, synergy, etc. It supposes implementation of the technology of social support of vulnerable children and families, holding events, application of forms and methods by the directions of psychology-and-pedagogic, socio-medical, information-and-cultural, humanitarian aid, that are determined by actual problems and needs of IDP and community.

Application of the response strategy in social work with internally displaced families and community under conditions of difficult socio-political situation that has formed in Luhansk oblast is efficient because it activates their resources in overcoming the consequences of the conflict, restores their potential and social ties, raises stability of both the family and the community in the context of vision of the perspective of achieving the goal of sustainable development.

The authors see the perspective of further scientific research in theoretic substantiation of possible tactics of influence in social work with internally displaced families and the community within the application of the response strategy in the context of the perspective of their sustainable development, the role of communities in forming the market of various social services and their accessibility in the eastern Ukraine regions that are characterized as having a difficult socio-political situation.

Thermal comfort analysis in the sustainable educational building

Luiza Dębska[1,*], and *Justyna* Krakowiak[1]

[1]Kielce University of Technology, Faculty of Environmental Geomatic and Energy Engineering, 7 aleja Tysiąclecia Państwa Polskiego, 25-314 Kielce, Poland

Abstract: In the modern world, a person spends most of his life indoors. That is why it is so important to create optimal conditions for the internal environment. Research on thermal comfort and subjective feeling of people inside the building can help in this. The article discusses two methods that are used in research on thermal sensations. This makes it possible to know the thermal assessment of people and then compare this result with the calculated PMV value, which is calculated using the formula from ISO 7730 standard.

1 Introduction

Today, energy consumption is one of the main problems of the modern world. A solution to this problem is sought in energy-efficient construction, which uses various types of renewable energy sources, such as solar collectors, photovoltaic cells, heat pumps, wind turbines, biofuels or hybrid solutions. Moreover, such buildings belong to sustainable construction, whose main goal, apart from the use of devices for the production of renewable energy, is to reduce waste and pollution generated during the construction of ecological buildings in such a way as to minimize interference with the environment. Another advantage is definitely the cost of maintaining such a building, because the building works on itself, it is self-sufficient. In addition, the idea of sustainable construction is to reduce the consumption of water, electricity, heat losses, create appropriate conditions for the internal environment, including air exchange with the help of well-selected ventilation, use containers for waste segregation and create optimal conditions and thermal comfort for people who spend most of their lives indoors [1-6]. At this point, a lot of research into thermal comfort is carried out. An example of such research is a study by Hwang et al. [7] who analyzed 944 people at universities in Taiwan. The respondents definitely determined that the best temperatures in which they feel are in the range of 21.1ºC to 29.8ºC and 24.2ºC to 29.8ºC. In Australia, Dear and others have attempted to forfeit both primary and secondary school students. During the research, 2,850 questionnaires were received. After analyzing the questionnaires, the results were obtained in which the respondents defined their thermal sensations in the range of 19 -26. Later, these studies were extended to include more results. Kim and Dear [8-9] have further decided to forfeit the school environment. From the obtained results, the authors found out that students prefer cooler temperatures, and more of the received questionnaires, students who had the option of using air conditioning during classes were better adapted to it than children who did not have such an opportunity. Zaki et al [10] analyzed three universities – two in Malaysia and one in Japan, over the summer. 1428 surveys were thoroughly analyzed, which showed that in Japan the best temperature was 25.1ºC, while in Malaysia it was 25.6ºC. In Indonesia, Hamzah et al. [11] perished Hasanuddin University in Gowa. The thermal sensations during the research were described by 118 people, from whom it appears that these guards felt comfortable in selected rooms. Liu et al.[12] analyzed naturally ventilated rooms in northwest China, in the city of Xi'an, to see how the students living in these rooms feel thermal. A total of 992 questionnaires were completed, which showed that the most natural temperature was 20.6ºC, and the range in which the students determined their thermal comfort was the temperature from 19.5ºC to 21.8ºC, and the preferred temperature was 22.7ºC. In Brazil, at the University of Goias, Abreu-Harbich et al. [13] investigated classrooms with three air conditioning methods such as natural ventilation, evaporative cooling, and air conditioning. The authors wanted to get to know the students' thermal feelings, because the discomfort in the classrooms might have compromised their knowledge. 200 people were lost. 69.52% of people definitely did not correspond to the creature conditions by natural ventilation. Less, because only 60.67% were dissatisfied with evaporative cooling and 70.18% of the respondents did not accept the conditions of the internal environment created by air conditioning. Moreover, the neutral temperature was set at 25.9ºC. Buonocore et al. [14] at the University of Sao Luis, Brazil, analyzed the subjects' thermal preferences and the feeling of thermal comfort. The rooms covered by the study were air-conditioned and ventilated in a natural way. The authors of these studies wanted to know the appropriate climatic conditions in the internal environment of the room. Therefore, the city of Sao Luis was chosen for its location in an equatorial climate where it is hot and humid. The problem of local students is overcooling associated with the excessive use of air

* Corresponding author: ldebska@tu.kielce.pl

conditioning in the classrooms. From the questionnaires completed by students it was concluded that the best conditions meeting the preferences of the respondents were the temperature range from 23ºC-24ºC. It was in this respect that the students felt thermal comfort. Moreover, they tended to increase the temperature to 26ºC. About 20% of respondents felt discomfort if the temperature was lower than 22, with a clo of 0.3. Guevara et. Al. [15] have taken an analysis of three cities in Ecuador – Quito, Guayaquil, and Tena. From December 2017 to January 2018, the authors of the study received 429 questionnaires completed by volunteers. The aim of this research was to obtain information about the thermal comfort of people living in the tropics, where the weather is very changeable. Neutral temperatures in which the respondents felt best were in turn 21.8ºC, 26.3ºC or 26.9ºC. The respondents from Guayaquil and Tena were directed to cool temperatures because of the hot and humid climate in their areas of residence. In Bangladesh, a study was performed in the summer of 2017 by Talukdar and others [16]. They focused on learning about the thermal preferences of students in naturally ventilated rooms. 579 sheets with respondents' answers were received. The parameters maintained during the test were equal to the temperature – 30.9ºC, humidity – 78.4% and the wind speed – 0.8 m/s. After the analysis, it was found that the best neutral temperature for the feeling of thermal comfort is 27.8ºC. Abdallah [17] conducted research at the Assiut University. The study covered 6 naturally ventilated classrooms. Initially, 331 people participated in the study, but after an in-depth analysis, only 269 questionnaires remained. It was concluded from the responses that the temperature exceeded 28ºC, which was met with discomfort by students in 90%. At the Bahia Federal University in Salvador, Brazil, Costa and others [18] analyzed the students' thermal sensations. Only 53% of the respondents felt thermal comfort. The conclusion of these studies was the incorrect maintenance of the condition of windows and window frames, which prevented the correct flow of air between the external and internal environment. In Thailand, the University tested 3 speeds of the air conditioner – low, medium and high, then the students completed the questionnaires. Puangmalee et al [19] analyzed the results of the surveys which concluded that students would be able to accept a temperature of 28 as long as the air conditioner speed could be regulated. Additionally, the information was obtained that the higher the speed, the higher the neutral temperature.

An educational and laboratory building of Environmental Engineering, Kielce University of Technology, called „Energis" from the year 2012, is such an energy-saving and intelligent building. "Energis" has been designed with sustainable construction in mind. The main and set goal was to monitor the effects of energy saving, the balance of energy gains and losses, maintaining appropriate parameters of the internal environment while using the most modern automation and control solutions for devices such as photovoltaic cells, solar panels, heat pumps, energy storage [20, 21]. Figure 1 presents a photo of the "Energis" building and shows the selected room where the research on thermal comfort of students of Kielce University of Technology was conducted.

Fig. 1. Photo of "Energis" building and selected room where the test was performed.

2 Testing methods

Thermal comfort measurements are divided into two methods, indirect and direct. The indirect method is based on the analysis of completed questionnaires by people in the room covered by the study and direct method aimed at obtaining microclimate parameters using a meter (air temperature, globe temperature probe, air velocity, relative humidity, light intensity). These data, in particular temperature, air velocity and humidity are needed to calculate the PMV (Predicted Mean Vote) from the formula contained in the ISO 7730 standard [22, 23].

The questionnaire included questions about thermal sensations, adequacy of temperature, sensations of humidity, current clothing and physical activity, as assessed by study volunteers. A very important fact when assessing the thermal sensations of test volunteers is to check what physical activity they had before the test. People who did not perform any physical activity, i.e. sat before the test, or walked for no more than 10 minutes, are a reliable source of information about their thermal sensations. If, on the other hand, such people did strength training a moment before the measurement, unfortunately such people may distort the picture of knowing their thermal preferences. Thus, polls must be rejected. Additionally, the actual thermal sensation is also influenced by clothing, otherwise known as the clothing thermal isolation (clo), which for this group was 0,62. Note that if the subject is dressed too warm, he may feel discomfort in the form of heat. Similarly, she will feel bad wearing summer clothes, and the room will be too cold. To measure the internal environment, a Testo 400 meter was used located in the middle of the lecture hall. After 15 minutes, when the values had stabilized, they were collected and recorded. Meanwhile, the volunteers completed the questionnaires. The purpose of using two these methods is to check whether the conditions in the room create thermal comfort for the occupants. Figure 2 and figure 3 below show the meter with a description of the probes collecting the necessary parameters (globe

https://doi.org/10.1051/e3sconf/202128004011

temperature probe, light intensity probe, turbulence probe, CO_2 probe, temperature and humidity probe).

Fig. 2. Location of the measuring station in the lecture hall and probes measuring the conditions in the room.

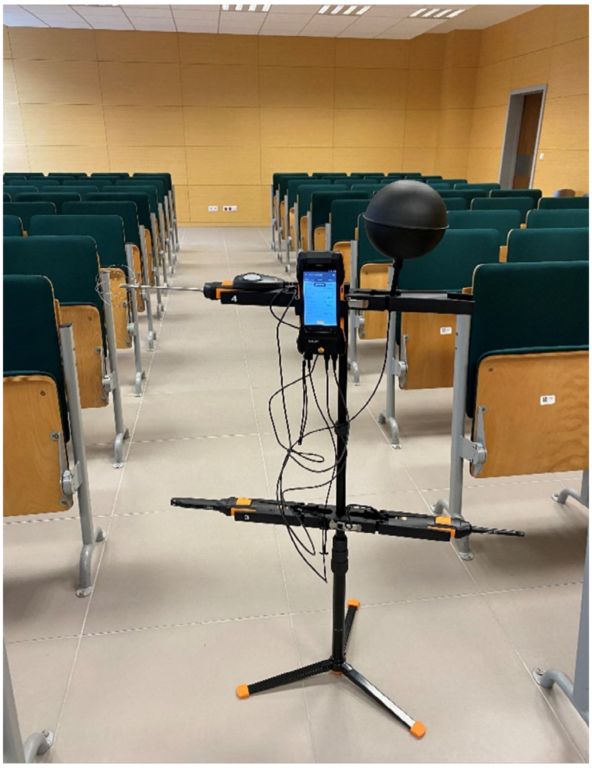

Fig. 3. The meter of Testo 400.

3 Test result

In the selected room where examination was performed, there is mechanical ventilation with adjustable parameters, which was activated during the examination. Table 1 shows the obtained results of the conditions in the tested room with the use of a meter Testo 400.

Table 1. Parameters of the internal environment obtained with the use of the meter.

Air temperature [ºC]	25.7
Black ball temperature [ºC]	25.2
Relative humidity [%]	56,6
Air Velocity [m/s]	0.43

In the study involved 9 people in the age range from 21-24 years. Figure 4 below shows the thermal feelings of the respondents as TSV (thermal sensation votes).

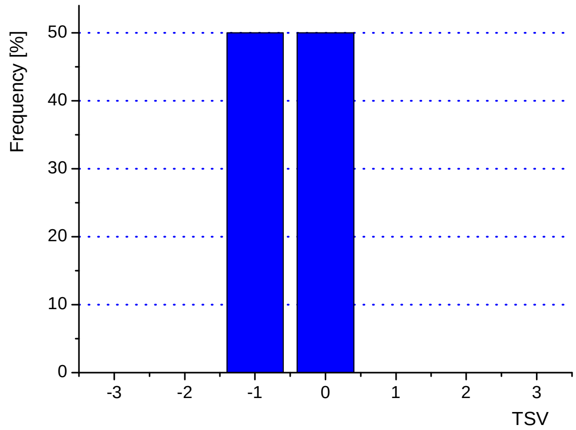

Fig. 4. Voices of the respondents concerning the thermal sensation: -3 – too cold, -2 – too cool, -1 – pleasantly cool, 0 – comfortable, 1 – pleasantly warm, 2 – too warm, 3 – too hot.

50% of respondents consider that the room in pleasantly cool. The other half, i.e. 50% of people described their thermal sensations as comfortable. Figure 5 below shows the group's responses to the feeling of accepting the current temperature in the tested room (TAV – thermal acceptability vote).

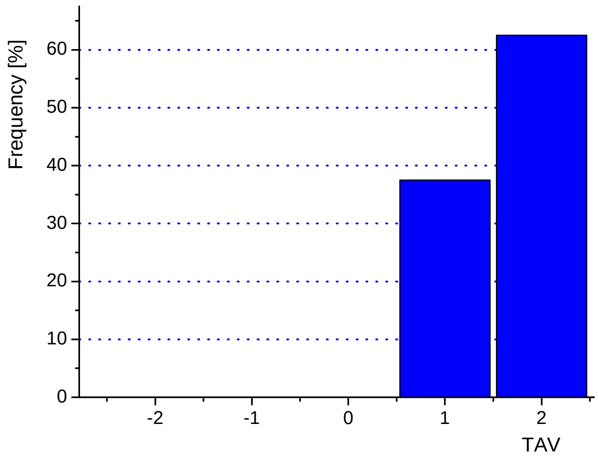

Fig. 5. Acceptance of temperature according to the volunteers: -2 – definitely unpleasant, -1 – unpleasant, 1 – acceptable, 2 – comfortable.

37.5% of people in the study group consider that the temperature is still acceptable, while 62.5% of people described their feelings of temperature as comfortable. Figure 6 shows the responses of individual thermal preferences (TPV – thermal preference vote) in relation to change in air temperature.

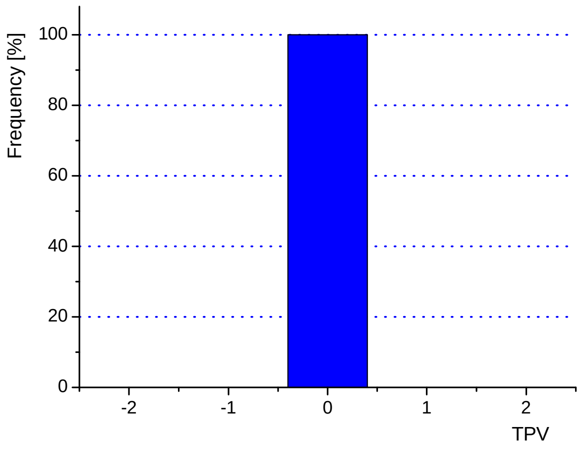

Fig. 6. Thermal preferences vote: -2 – definitely cooler, -1 – cooler, 0 – no change, 1 – warmer, 2-definitely warmer.

100% of people would not want to change the temperature to a cooler or warmer temperature. This proves that the prevailing temperature in the room was so favorable that the whole group of eight felt thermal comfort. Figure 7 below shows the assessment of humidity by the tested group.

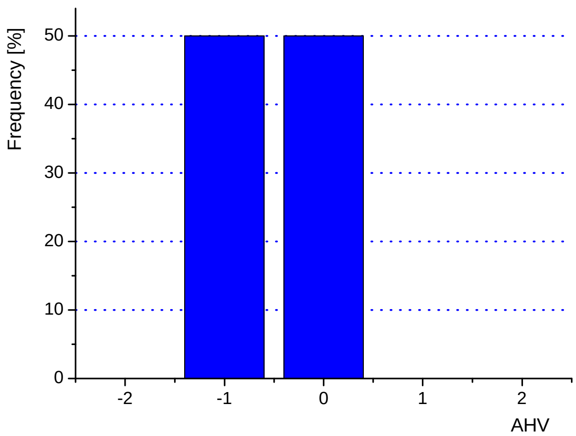

Fig. 7. Assessment of humidity according to the respondents: -2 – too dry, -1 – quite dry, 0 – pleasantly, 1 – quite humid, 2 – too humid

50% of people rated the humidity as pleasant. The other half of the group, i.e. 50% of respondents, think that the room is quite dry. The graph of the humidity preference responses by the volunteers is shown on figure 8.

In the studied group, 75% of people would not like to a change in air humidity, as opposed to 25% of people who would definitely like it to be more humid. Figure 9 shows the relationship between the PMV index and the BMI mass index in order to determine if this parameter had any impact on the obtained results.

According to the figure the higher the BMI index of a person, the warmer they feel. It confirms a generally accepted view and might have a slight impact on the obtained experimental results.

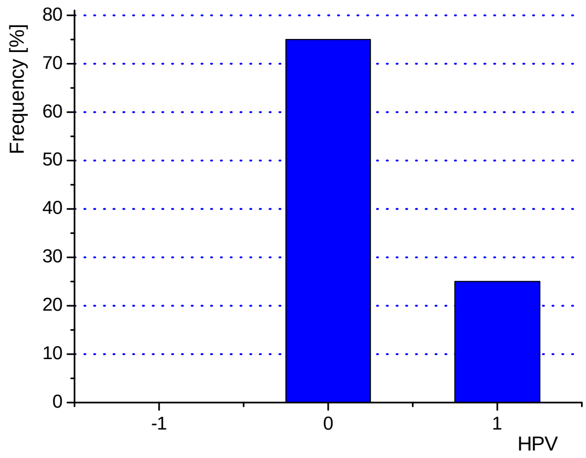

Fig. 8. Frequency of answers humidity preferences vote: -1 – more dry, 0 – no change, 1 – more humid.

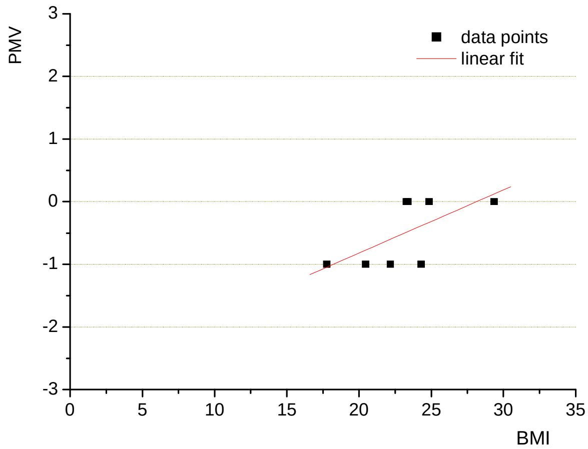

Fig. 9. The relationship between the PMV index and the BMI mass index.

4 Conclusions

To sum up, from the obtained results, it can be concluded that the room meets the expectations of its occupants in the modern “Energis” intelligent building. Thus, such a construction that meets the criteria for the sustainable building is a user – friendly educational building. The temperature there was perceived as comfortable and pleasant, therefore none of the respondents would like to change the prevailing temperature to a warmer or cooler one. Likewise for the humidity where it was found to be pleasant and fairly dry. 75% of the group would not want the humidity settings changed except for the 25% which specified it could be more humid. The conclusion is obvious that the ventilation in this room has well-chosen parameters that ensure well-being in the external environment.

In the future, research on thermal comfort will be carried out in order to better understand the individual thermal preferences of people indoors.

The problems of forming a system of green areas as an ecological framework of a large city (on the example of Kyiv)

Alla Pleshkanovska*

Kyiv National University of Construction and Architecture, Land Management and Cadastre Department, 31 Povitroflotskyi Ave., Kyiv, 03680, Ukraine

Abstract. Each large city is characterized by its own unique model of spatial organization of green areas, which form the ecological framework of the city and act as a condition for its balanced ecological development. The article presents results of an analysis of the actual state and preconditions for the formation of a system of green areas of public use of a large city on the example of the city of Kyiv. The model of the ecological framework of Kyiv, in comparison with the models of other European cities, is characterized. The specificity of the spatial organization of the landscaping system is marked by the presence of a powerful water-green diameter in the central part of the city, formed by the valley of the Dnipro River with islands, and a developed peripheral-ring forest park belt. The central and middle densely developed area of the city suffers from a significant lack of green areas for public use. The article formulates urban planning problems completion of the formation of an integrated ecological network of Kyiv, and outlined areas for improving the city's landscaping system.

1 Introduction

Rapid population growth, human economic activity, and land cover change cause an increase in anthropogenic pressure on the planet's ecosystem, including the depletion of natural resources, global warming and climate change [1]. Awareness of the need to take immediate measures to ensure the preservation of the riches and resources of our world is reflected in the formation of the ideology of sustainable development of mankind. One of the key components of such development is the environmental one. In particular, Goal 15 of the 2030 Agenda for Sustainable Development identifies the need to "Protect, restore and promote the sustainable use of terrestrial ecosystems, sustainable forest management, combating desertification and irreversible land degradation and stopping biodiversity loss".

In turn, global urbanization processes lead to excessive concentration of people in limited areas and the constant expansion of territorial boundaries of urban settlements due to the surrounding natural landscapes. This increases the negative impact on the environment, physical and psychological health [2]. The formation of an ecological network at different hierarchical levels as "… a single territorial system that includes areas of natural landscapes, territories and objects of nature reserves" will help to achieve the goal [1].

At the city level a system of green areas and open water of the city – forests, forest parks, parks, squares, other elements of the system of greenery are an ecological network or ecological framework of the city [3]. The most significant interaction of man and the natural environment is felt it is in cities, due to the high concentration of population (in the world – more than half of humanity, in Ukraine – 69.4 %). One of the ways to ensure sustainable development of settlements, reduce the negative impact of urbanization on the environment, stop the destruction of natural landscapes is the formation of cities' own ecological network, prevention of unjustified destruction of greenery and development of urban green area provision [4, 5].

The natural landscape is an important component of human quality of life [6]. The minimum normatively defined level of green area provision of urban areas is expressed in the area of green areas for 1 person. This figure varies significantly from country to country. Regulatory area of public green area (parks of different functional type and hierarchical planning level, squares and boulevards) ranges from 10 sq.m/person (Ukraine, Russia) to 20-25 sq.m/person (Germany, USA) [7], and the actual area can reach 60-70 sq.m/person [8]. Other types of green areas are subject to separate normative regulation: urban landscape and recreational areas (forests, forest parks, meadows), green areas of limited use (in residential areas, other functional facilities) and areas of special purposes [9, 10].

The subjective perception of the city residents of the adequacy of the greenery level is based not only on the normative and actual indicators of the area of green area per capita [11]. Features of landscape-planning and functional-planning organization of the city territory, specifics of relief, climatic area, presence of significant water objects (part of the sea water area, big river or lake)

* Corresponding author: pleshkanovska.am@knuba.edu.ua

within the city are important. City and district parks and squares, which are located within the built-up area of the city, play an extremely important role for residents. Trees, shrubs, water bodies, open green spaces and clean air embody the elements of the natural environment and create a sense of closeness to nature, contribute to the recovery of physical and moral strength [12]. Convenient location and accessibility of green areas are very important for all residents, and especially for the elderly and parents with young children [13]. The formation of the city system of landscaping as close as possible to the person, his place of residence, is one of the main tasks of balanced development of the city.

2 Materials and methods

The formation of a system of green areas in the conditions of a large developing city is under the pressure of various vector tendencies. On the one hand – the growth of diversity of functions, population and level of motorization, and, accordingly, the growing need for normatively defined areas of green areas for various purposes; on the other hand – increasing the intensity of development, building density and reducing vacant plots for new elements of the city's landscaping system.

The purpose of this study was to identify the existing urban issues of the existing green area provision system of a large city (on the example of the city of Kiev) as a basis for developing further proposals to create the most attractive and balanced green area system. The research was based on the analysis of theoretical bases and normative regulation of formation of a system of green areas of general use; materials of factual information on indicators of green area provision in Kyiv. The cartographic basis was the materials of the general plans of Kyiv [14, 15]. Also uses some results of the author's sociological survey of Kyiv residents regarding their attitude to the actual state of green area provision [11].

3 Results

3.1 The current state of green area provision in Kiev

3.1.1 The actual state of green area provision

According to the current Master Plan of Kyiv [14], the model of spatial planning organization of the territory was based on the development of new, free from construction, territories outside the city within the boundaries of 2001. The area of the city was expected to increase from 83.56 thousand hectares to 143.4 thousand hectares (+74 %) with an actually stable population – 2,637 thousand people (2001) to 2,650 thousand people (for the period up to 2020) [14]. The total area of recreational areas of the city was expected to increase from 34.9 thousand hectares to 48.9 thousand hectares, respectively. At the same time, the area of green public areas was expected to increase from 5,289.4 hectares to 7,608.0 hectares for the period up to 2020, and the provision rate, respectively, from 20.3 sq.m/person. up to 28.7 sq.m/person [14] (see Table 1).

Table 1. The main indicators of development of green areas of Kyiv.

indexes	status 2001	Master plan of Kyiv until 2020	current status (2020)	increase (2020/ 2001)
Population, thousand people	2 637	2 650	2 965	+ 328 (+ 12.4 %)
Total area, ha	83 560	143 400	82 640	- 920 (- 1.1 %)
Developed territories, ha	48 660	94 500	37 610	- 11 050 (- 22.7 %)
Public greenery area, ha	5 289	7 608	5 392	+ 103 (+ 1.9 %)
Landscape and recreational area, ha	34 900	48 900	45 030	+ 10 130 (+ 29.0 %)
Population density, people/ha	31.6	18.5	35.9	+ 4.3 (+ 13.6 %)
Population density in the developed territories, people/ha	54.2	18.5	78.9	+ 24.7 (+ 45.6 %)
Public greenery area, sq.m/person	20.1	28.7	18.2	- 1.9 (- 9.5 %)
Landscape and recreational area, sq.m/person	132.3	184.5	151.9	+ 19.6 (+ 14.8 %)
Total level of landscaping, %	41.8	34.1	54.5	+ 12.7 (+ 30.4 %)

However, the actual territorial development of Kyiv has undergone radical changes in relation to the design decisions of the Master Plan of 2002 (see Fig. 1). The actual territory of the city is 82,640 hectares [15], of which green areas and recreational areas cover 45.03 thousand hectares (or 54.5 %), water surfaces – 6.1 thousand hectares (or 7.3 %) [15].

At the same time, the population increased by 12 % compared to the project and reached 2,965 thousand people as of 01.01.2020 [16]. New construction was carried out mainly not in the projected new territories (former suburban areas, which were envisaged to be included in the project boundaries of Kyiv by the current Master Plan), but in the existing urban areas (see Fig. 1). This has led to a significant increase in population density and urban development density (see Table 1).

The area of the territory within Kyiv, which is covered with greenery of all kinds (including garden and country houses) is 45030 hectares or 54.5 % of the city area. A total of 143 parks in Kyiv with a total area of 4,722 hectares, of which 6 objects are specialized and occupy 611.4 hectares (three botanical gardens, Kyiv Zoological Park, National Museum of Folk Architecture and Life, National Complex “Expocenter of Ukraine”).

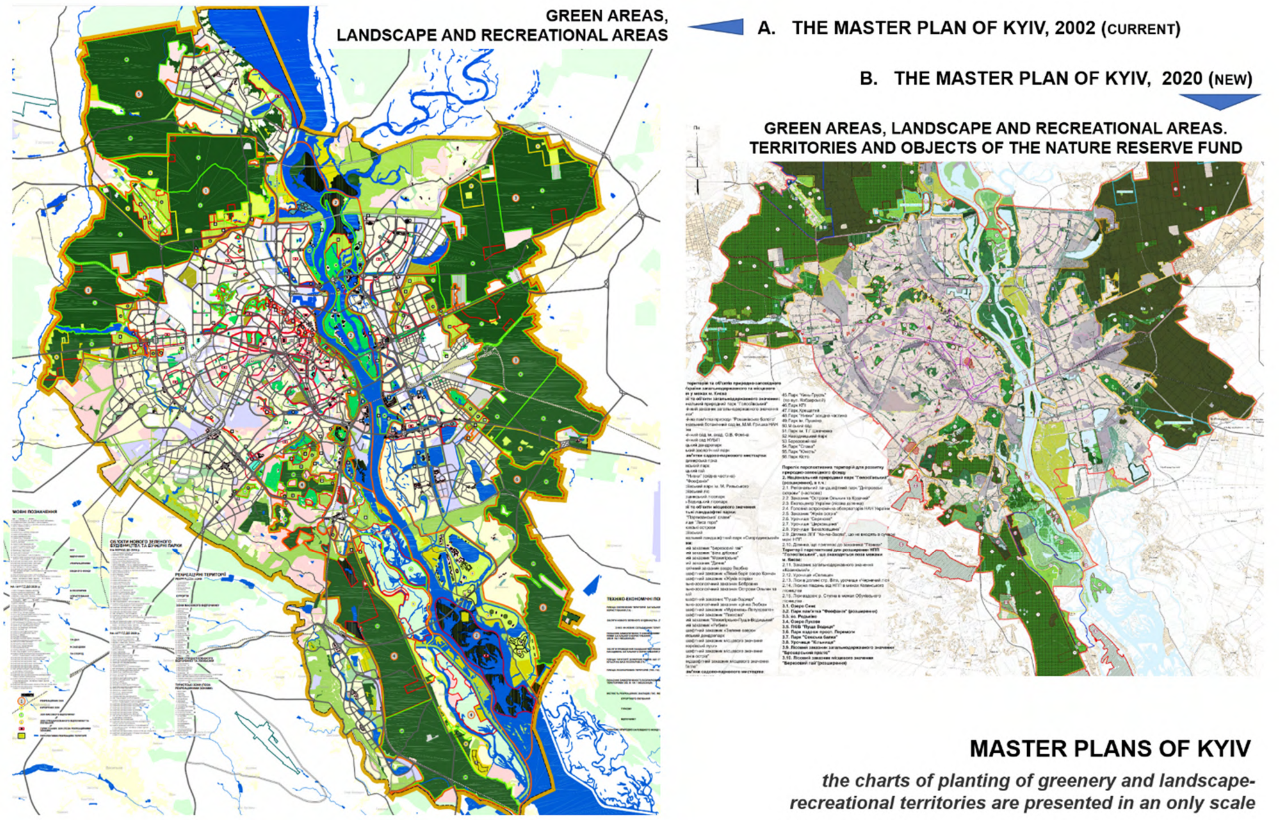

Fig. 1. Schemes of spatial development of green and landscape-recreational territories as a part of general plans of Kyiv. A. General plan of Kyiv, 2002 (current, https://kga.gov.ua/generalnij-plan/genplan2020); B. Master plan of Kyiv, 2020 (draft, https://drive.google.com/drive/folders/1HmqVLp25d4PFL08EuLAQ9O8KEFYbhOo5).

Table 2. Characteristics of the actual state of provision of green areas for public use (by administrative districts of Kyiv).

Administrative districts	Area, ha	Population, persons	Area of public green areas, ha	Level of landscaping, %	Actual landscaping, sq.m/person.
Holosiivsky	15 335	254 331	1069.28	6.88	42.04
Darnytsky	13 160	347 611	473.25	3.60	13.61
Desniansky	14 210	369 155	532.24	3.75	14.42
Dniprovsky	6 170	358 352	1118.35	18.13	31.21
Obolonsky	10 860	318 968	623.41	5.74	19.54
Pechersky	2 555	163 264	367.72	14.51	22.52
Podolsky	3 300	208 449	203.15	5.97	9.75
Svyatoshinsky	10 200	342 544	230.79	2.26	6.74
Solomyansky	4 010	383 387	282.14	7.04	7.36
Shevchenkivsky	2 660	218 952	491.91	18.61	22.47
Kyiv (total)	**82 640**	**2965 013**	**5392.24**	**6.77**	**18.19**

At the same time, 50 % of the park areas are occupied by large parks with an area of over 100 hectares (12 objects). In addition, public recreation areas include squares – 582 objects with a total area of 440.7 hectares and boulevards – 49 objects with a total area of 150.7 hectares [15].

According to the monitoring of the Program of development of the green zone of Kyiv until 2010 and the Concept of formation of green area in the central part of the city [17], within which this study was conducted, as of 01.10.2020 the actual area of green areas is 5 392.24 hectares. The average provision in the city is 18.19 sq.m/person (see Table 2), which meets the regulatory requirements for the city of Kyiv – 16 sq.m/person. However, there is an uneven provision of green public areas in the city districts. The most prosperous are Holosiivskyi and Dniprovskyi, and the least – Sviatoshynskyi, Solomyanskyi, Podilskyi and Darnytskyi districts of the city. The actual state of green area provision in terms of administrative districts of the city of Kyiv is in the Table 2.

3.1.2 Analysis of modern practice of transformation of the green area system of Kyiv

Population growth, the need to increase housing construction, service facilities and places of employment have led to a significant adjustment of the decisions of the current Master plan of Kyiv. Such changes took place by approving of detailed plans of the territory for separate parts of the Master plan. According to the city program of development (updating) of urban planning documentation in Kyiv, approved by the decision of Kyiv City Council dated 13.11.2013 № 518/10006 with changes and additions, 152 drafts of detailed plans of territories, as well as zoning plan of central planning zone and zoning plans of other parts of the territory of Kyiv, are under development now. As of the beginning of 2020, the city has approved 42 detailed plans of territories [18] (see Fig. 2).

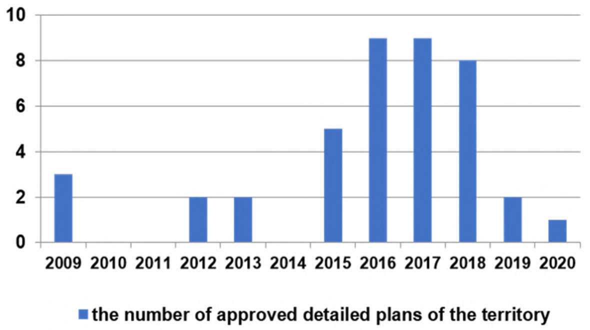

Fig. 2. Dynamics of approval of detailed plans of the territory of Kyiv. Source: data from the Department of Urban Planning and Architecture in Kyiv [18].

There were more than 1,000 changes to the functional purpose of individual land plots taking into account the investment intentions of developers from 2002 to 2011. 1,750 hectares of agricultural land within the city and about 570 hectares of green area have been allocated for construction [15]. Part of the territory really required restructuring due to the suspension of economic activity and degradation of industrial territory and communal warehouses territory. But there is an illegal change of purpose of the land plots of the green area for housing and public building.

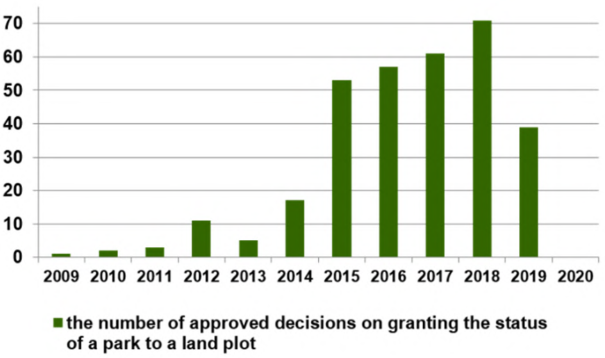

Fig. 3. Dynamics of decision-making on granting the status of a park to a separate green land plot in Kyiv. Source: data of the Kyiv City State Administration [19].

As a compensatory measure and in order to prevent such negative phenomena and excessive compaction of existing housing in the city at the request of deputies of the Kyiv City Council or initiative groups of residents a campaign "to grant the status of a park to land plot" is launched. That is, there is a transfer of green areas of limited use in the category of green areas of public use. There were about 260 such decisions [19] during the period from 2008 to 2020 (see Fig. 3).

However, granting the status of a park to a small land plot within the existing residential building, which is actually part of the adjacent territory of existing residential buildings, leads only to a formal increase in the area of public green areas by reducing the area of adjacent territories and green areas of limited use consequently. In addition, small green areas (0.1-0.5 hectares) do not allow to form an independent element of the system of public greenery - a full-fledged park or square. Such green area remains available only to a limited number of residents of nearby houses.

3.1.3 Assessment by Kyiv residents of the adequacy of the level of landscaping of the city territory

As mentioned above, according to the actual indicators, the level of provision of public green areas in Kyiv is quite sufficient. However, the use of only absolute indicators (area of green area and their share in the total area of the city) or even relative indicators (the level provision of population with green area – sq.m/person.) does not really assess the state of development of landscaping and comfort of the urban environment.

According to the results of a sociological survey conducted by the author [11], the vast majority of respondents in the city (71 %) expressed a lack of green areas, parks and squares. And among the proposed criteria for assessing the attractiveness of the elements of the landscaping system, residents preferred environmental friendliness (over 80 % of respondents) and accessibility of parks (over 67 %) [11].

Dissatisfaction of residents with the level of development of the parks and squares system of Kyiv can be explained by the peculiarities of the spatial organization of the city.

The system of greenery of various functional purposes in Kyiv has been formed for several centuries and has a permanent character. Significant influence on the spatial organization is created by such factors as planning dismemberment into the right-bank and left-bank parts with a large area of the Dnieper River with green islands in the central part. The middle zone of the city is intensively used for residential, public and industrial-warehouse construction and is surrounded by a powerful peripheral forest park belt (see Fig. 1, B). It is the unevenness in the localization of green areas in the planning structure of the city and their proximity to places of concentration of the population (places of residence and places of work) that create the feeling of lack of green areas.

Creating new elements of the system of green areas – parks and squares, which require significant territorial resources, in the conditions of dense urban development and high cost of land in Kyiv is too problematic. Therefore, increasing the attractiveness and level of improvement of existing elements of the city's green area system should be one of the priorities to provide residents with a sense of urban comfort and sufficiency in green areas.

3.2 Specifics of the spatial planning organization of the system of green areas of Kyiv

Spatial planning organization of the system of green areas of any city has its own specific features, due to the peculiarities of the landscape and climate, historical and cultural traditions, the functional orientation of economic activity and regulatory requirements. However, each city, especially a large one, tries to ensure the integrity and continuity of the internal ecological framework, supplementing the existing system of urban green areas with new natural and artificial elements.

Any large city is marked by the unique specificity of the spatial planning organization of the system of green areas. However, the formation of the continuity of the landscaping system with the obligatory connection of individual elements of the landscape into a single network of open spaces (even, including the territories near highways) should be a condition for sustainable ecological development of the city [20]. Consider examples of models of the system of public green areas in some foreign cities [20, 21].

Thus, the municipal project of Milan “Green Rays” in the conditions of dense construction provides for the tracing of pedestrian and bicycle routes, taking into account the available areas of green public areas of different functional types. Complementing them with new planned landscaping – groups of trees along sidewalks, parks - as objects of potential recreation of pedestrians should form a sense of permanence of landscaping in citizens (see Fig. 4, a) [20].

Madrid's ecological system is formed on the basis of suburban natural elements and the restoration of the Manzanares River, forming a continuous connection with large natural areas – the Sierra de Guadarrama, Cuenca Alta del Manzanares, Mount El Pardo, Del Harama Park and Alameda del Tajo. And the main route M30 in some areas was laid underground to open access to the river as the main element of the natural framework of the city [21, 22] (see Fig. 4, b).

The concept of the organization of open spaces in Berlin is to form a system of several groups of green areas. The first – two “green rings” of artificially created in different years elements of urban landscaping: the inner ring around the densely built-up center of Berlin – “Innerer Parkring”; the outer ring is the “Äußere Parkring”, which connects the large residential areas of the 70s and 80s. The second – two “green” diagonals – “Grüne Achsenkreuz”, formed on the basis of the dominant natural elements, green strips about 200 meters wide [23 24] (see Fig. 4, c).

The ecological framework of Krakow includes the most valuable natural areas and cultural landscapes that are subject to protection, and are connected by eco-corridors from individual green areas [25] (see Fig. 4, d). To achieve the goal – the unity of the ecological framework - the Master plan of Krakow provides a change in the purpose of part of the land plots.

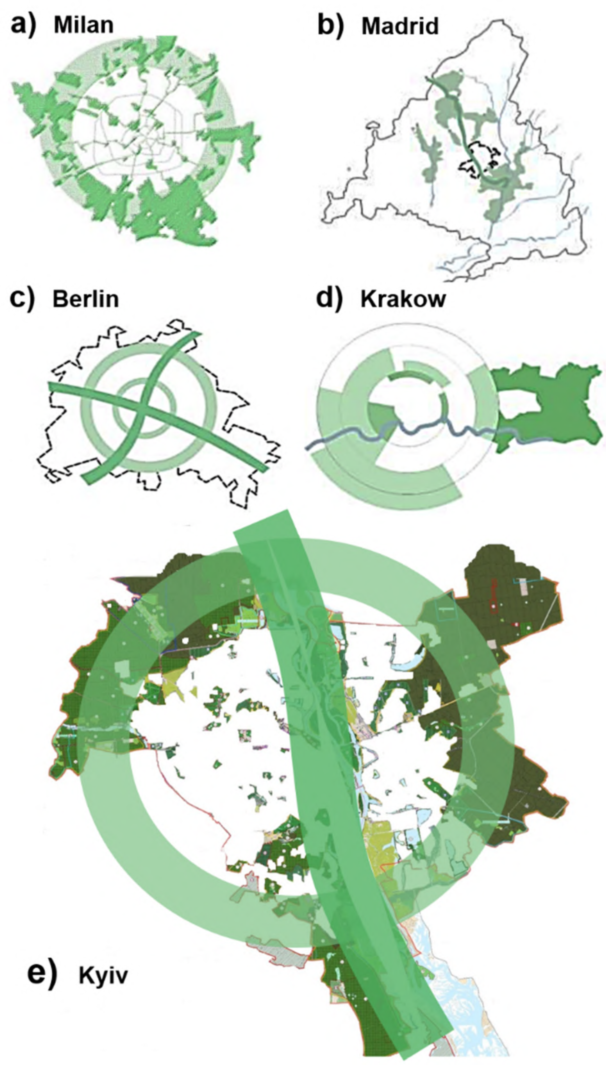

Fig. 4. Examples of ecological framework systems (green and recreational areas) of individual European cities. Sources: a) – [20], b) – [21, 22], c) – [23, 24], d) – [25], e) – own model.

Spatial planning organization of green areas of Kyiv, which has developed over a long period of its development, is also characterized by a unique specificity (see Fig. 4, e). The first characteristic feature is the dismemberment of the city, due to the presence of a powerful water-green diameter in the central part. The Dnieper River with a system of islands and green shores with numerous parks. This diameter runs in the meridional direction from north to south and divides the city into two planning parts – Right Bank and Left Bank.

The second feature is the predominant circular-peripheral model of green areas in the form of a developed system of forests and forest parks around the densely built-up central and middle zones of Kyiv. Within the built-up areas there are a number of separate parks and squares, which creates difficulties in the availability of green spaces for the vast majority of city residents. The modern spatial planning organization of the system of green and recreational areas is shown in Fig. 1, A.

3.3 Urban planning problems of development of the system of green areas of Kyiv

The analysis of the current state of development of the system of green areas of Kyiv allowed to formulate (from the point of view of urban planning) the following main reasons that negatively affect the ecological conditions and the state of green areas:

– anthropogenic congestion of the urban area, which causes the deterioration of the ecological state of the environment and destructive phenomena in the existence of a system of green areas of the city;

– unsatisfactory sanitary and ecological condition of green plantations and insufficient improvement of park territories;

– lack of territorial resources for the creation of additional regulatory areas of public green areas due to the rapid growth of the population of Kyiv (by 328 thousand people or 12.4 % since 2001) in combination with the virtually unchanged area of city territory;

– specificity of spatial planning organization of the city with a clear central-meridional location of a powerful water-green diameter and external ring-peripheral location of the belt of forests, forest parks, meadows and buffer parks, which creates a sense of inadequate landscaping under the conditions of formal normative provision with green areas;

– exceeding the density of the developed (built-up) territory of the city, which occupies only 46 % of the total area of the city, and alternating the location of residential, industrial, utility and transport areas with relatively small interspersed elements of public green areas, which negatively affects the ecological condition of urban areas in general, and green areas in particular;

– uneven distribution of public green areas by administrative districts;

– incorrectness of the practice of increasing the area of green areas of public use due to green areas of limited use by granting the status of parks to certain areas within the adjacent territories of existing buildings;

– improper use of public green areas;

– the need to develop an integrated system of green areas through the creation of new parks and squares in the territories of former industrial and utility facilities to be redeveloped.

4 Conclusions

In conclusion, the strategy of most cities in the world in forming a system of public green areas is to restore, expand and improve the existing network of landscaping, united by creating new elements of green areas into a single ecological framework of the city.

The role of landscape and recreational areas of different origins, nature reserves and green areas of public use in the formation of an integrated system of green areas and the ecological framework of the city differs. If natural objects are the basis of the city's natural planning framework, then objects of artificial origin (parks, squares, boulevards) can complement, optimize or even form the ecological framework of the city.

Completion of the formation of an integral ecological network of Kyiv, general increase of the level of landscaping and comfort, and, accordingly, attractiveness, creation of convenient accessibility of already existing elements of the system of green areas will contribute to the formation of closeness and sufficiency of green areas, providing sustainable environmental development of the city.

Higher education institutions energy efficient methods of functional planning solution

Gelena Kovalska, *Irina* Bulakh, *Margaryta* Didichenko*, *Olena* Kozakova, and *Olena* Chala

Kyiv National University of Construction and Architecture, 31 Povitroflotskyi Ave., Kyiv, 03680, Ukraine

Abstract. The article determines that the priority factor of energy efficiency at the design stage is the optimal functional and planning solution of educational buildings; established architectural and planning techniques aimed at improving energy efficiency of higher education institutions, including compaction of educational institutions, clear zoning, implementation of compact architectural and planning solutions for educational buildings and structures, blocking in one or adjacent areas of several free economic cooperation with cooperative use of engineers increasing the number of storeys of buildings, the use of underground space and landscaping in the architectural and planning solution of buildings.

1 Introduction

In the process of long-term development in the leading cities of Ukraine, an extensive network of higher education institutions (HEIs) of various profiles has been formed, which significantly affects urban planning activities, architectural and compositional qualities of buildings, energy efficiency of buildings [1, 2, 7].

The main trends of energy saving are: introduction of fundamentally new types of building structures, use of effective thermal insulation materials, use of solar, wind, earth energy, use of ground heat for heating and cooling of buildings with heat pumps, energy efficient external enclosing structures [12-17]. However, the priority factor of energy efficiency at the design stage is the optimal functional and planning solution of the educational institutions buildings, as well as the appropriate architectural and planning techniques aimed at improving the energy saving of free economic zones.

2 Results

Analysis of the practice of operation of higher education institutions shows that the development of educational facilities is significantly complicated by the lack of territorial resources and significant energy intensity of educational buildings, especially laboratory and educational purposes. Progressive domestic and foreign experience in forming a network of higher education institutions shows that the most realistic direction for optimizing the development of higher education is the consolidation of educational institutions, clear zoning, implementation of compact architectural and planning solutions for educational buildings and structures [3-5, 7, 8].

According to the pedagogical requirements, the territory of the Free Economic Zone should be built up comprehensively. Educational, research, household, residential and other buildings that provide different directions, forms and methods of educational work should be placed on the allocated area. Buildings need to be functionally connected with each other and with other structural elements of the city. The site should provide conditions for the gradual development of free economic zones and provide an opportunity to develop training areas in the future [4,5, 6, 11].

The main scientifically substantiated and tested by project practice principle of planning decisions of higher education institutions is the functional zoning of the territory. Areas of educational zones should be divided into the following main zones: educational, sports, residential, economic. Each of the marked zones, depending on the profile of HEIs and town-planning conditions, has the features. Thus, the training area may include research units and in this case it grows significantly and requires additional areas. In branch educational establishments of technical, agricultural, medical profile and others in the educational zone, as a rule, a large group of research and educational-production subdivisions is created, and in medical educational establishments - a subzone of treatment-and-prophylactic establishments.

The size of the territory for the construction of educational buildings depends on the size and profile of the free economic zone. Theoretical research has identified, and project construction practice has confirmed that the larger the number of university students, the more efficiently the territory is used.

The second direction of improving the construction of higher education institutions is the blocking of several free economic zones in one or adjacent territories under the condition of cooperative use of engineering communications, some buildings of educational and teaching-auxiliary purpose. Cooperation is especially

* Corresponding author: didichenko.margo@gmail.com, didichenko.mo@knuba.edu.ua

expedient at homogeneity of educational and production functions of the establishments forming a complex. In many cases, this allows for the organization of a single public service system, joint research and production and energy centers.

The main functional requirement of the cooperation is the intensive use of premises and territory, increasing the density of buildings at the maximum allowable load. Particularly effective joint operation of energy-intensive and large-sized training and laboratory equipment, experimental equipment, etc. When cooperating, homogeneous zones should be used as intensively as possible, reducing the total size of the territory compared to the normative ones [7].

Fig. 2. University of Compacted Buildings, Tokyo, Japan.

Fig. 3. Ohlone College Academic Core Buildings in Fremont, USA.

Fig. 4. Ryerson University Daphne Cockwell Health Sciences Comple in Toronto, Canada

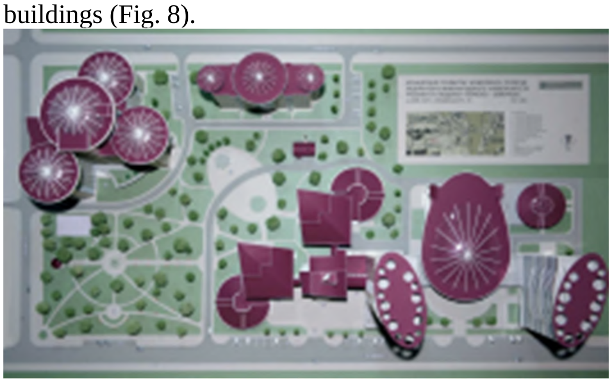
An effective means of compacting the construction of higher education institutions is the use of compact architectural and planning solutions of educational buildings and increasing the number of storeys of buildings, especially student dormitories. In foreign practice, there are many examples of multi-storey buildings of compact structure both in the historical environment (Fig. 1, Fig. 2) and new solutions in developing territories (Fig. 3, Fig. 4) [1, 4, 19, 31, 32].

Fig. 5. 3D model of main buildings of the Kyiv National University of Construction and Architecture, Kyiv, Ukraine.

Fig. 6. Complex of Karazin Kharkiv National University, Kharkiv, Ukraine

In Ukraine, high-rise buildings are built and successfully operate in higher education institutions of Kyiv, Dnipro, Kharkiv, Donetsk, Odessa and other large cities with compacted buildings [1, 2, 21]. Much of the university complexes were built in the second half of the twentieth century, so most of these buildings have a high level of wear, both physical and moral. To increase their comfort and energy efficiency, large-scale reconstruction and renovation works are required (Fig. 5, Fig.6). The main directions of reconstruction should be based on the principles of introduction of resource-saving technologies, ensuring environmental safety. The requirement of compact placement of educational buildings is due not only to the need for rational use of land resources, but also the conditions of effective organization of the educational process, centralized maintenance of teaching aids, more intensive loading of educational premises, reduction of unproductive costs for moving between remote buildings. The total height of educational buildings, the number of floors are accepted depending on the functional requirements and urban conditions. According to the current regulations, educational buildings of higher educational institutions and institutes of advanced training are recommended to provide a height from the ground level, determined at the entrance to the house, to the floor of the top floor within 26.5 m. increasing the number of storeys of buildings [5].

In recent years, the construction and construction of several higher education institutions with high-rise buildings and dormitories have been designed and started. The universities of the new generation include the Open International University of Human Development “Ukraine”, designed in the research and design architectural bureau “LICENZiARCH”. The density of the building led to an increase in the height of educational buildings to 18-21 floors. Increasing the number of storeys did not prevent the creation of all the necessary conditions for effective student learning. This is one of the few higher education institutions in Ukraine that provides comfortable training for professionals with disabilities. Multi-storey educational buildings are blocked with the educational-administrative building and a group of dining room and concert hall. The first floors of the multifunctional volume occupy the premises of general university use. The educational premises of some departments are located on the upper floors. All rooms are connected by stairs and special elevators, which meets the technological needs, fire safety requirements and ensures the movement of people with special needs (Fig. 7). Also, this design bureau made a conceptual proposal for the renovation of the Kyiv National University of Construction and Architecture territory in Kyiv, which provided for the consolidation of the central core and the creation of additional educational and residential buildings (Fig. 8).



a – model of existing complex

b – project proposal

Fig. 7. Open International University of Human Development “Ukraine”, Kyiv, Ukraine.

Fig. 8. Project proposal for Kyiv National University of Construction and Architecture, Kyiv, Ukraine.

The requirement of compact placement of educational buildings is due not only to the need for more rational use of land resources, but also the conditions of effective organization of the educational process, centralized maintenance of technical means of training, intensive loading of educational premises, reducing the length of utilities, heating and electricity. To seal the building, assembly halls, club rooms, libraries, student cafes and canteens are recommended to be blocked on the common territory, thus creating a training and community center. In the conditions of compacted building, if it is impossible to form a public center near educational buildings, part of the club premises, catering establishments, can be located in a residential area [6]. For example, the new campus building at the University of Cincinnati is creating a multi-functional cultural and learning center for collaboration that is not available in older buildings (Fig. 9).

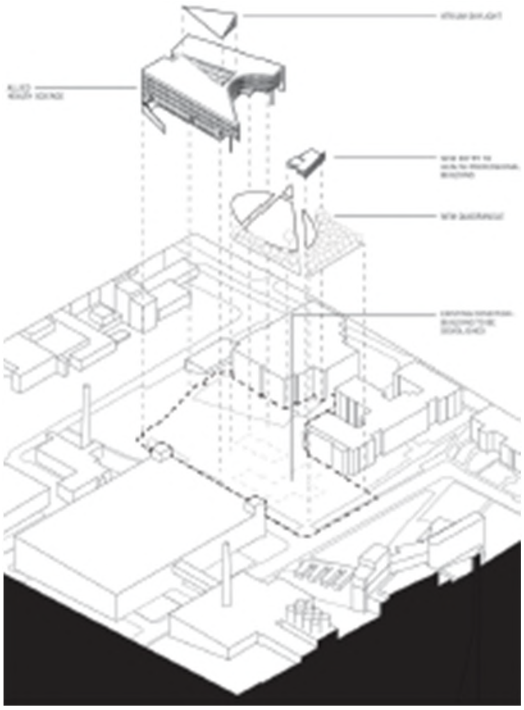


Fig. 9. University of Cincinnati Health Sciences Building, Cincinnati, USA.

Blocks of lecture halls, libraries, assembly halls, dining rooms can be compactly placed in buildings up to 4 floors. In large educational institutions for 5,000 students and more, libraries, club rooms, student canteens should be moved to separate buildings. For a more compact building should also take into account the possibility of using underground space (Fig. 10). In the basement and basement it is allowed to place: TV studios, bookstores, laboratories for the study of individual special projects, part of the premises of catering establishments, warehouses and technical premises. The principle of placement of administrative premises (administration) significantly influences the formation of the educational zone. In educational complexes with a contingent of more than 5,000 students, it is advisable to form a separate administrative and cultural center or block it with a library, assembly hall and other public facilities.

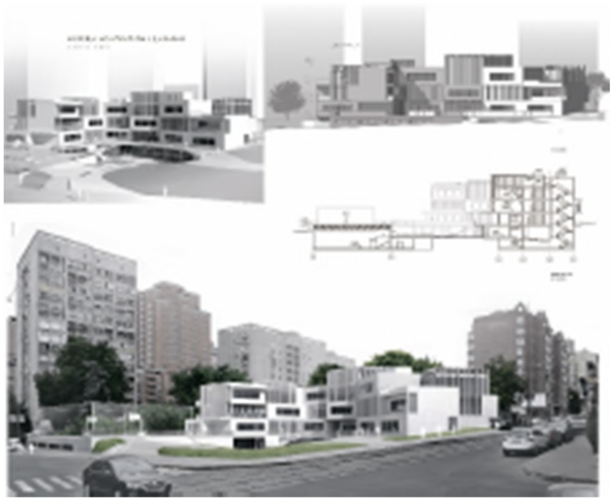

Fig. 10. Bachelor's degree “College of Architecture and Design in Kyiv”, Art. Tolstikov T.O., head – Doctor of Architecture Kovalska G.L.

Energy-efficient methods include the use of landscaping in the architectural and planning solution of buildings. Currently, there are several areas in landscaping of university buildings: landscaping of roofs, landscaping of facades; landscaping due to new ecological materials [22-27]. In this aspect, the interesting building of the non-governmental women's university in Seoul - “Ewha Campus Complex” (Ewha Campus Complex, ECC), arch. Dominic Perrault, 2008 (Fig. 11). The roof of the campus was a garden, which protects the interior from the heat in summer and from the cold in winter. Increases the economy and practical use of rainwater - special tanks have been created for it, from where water is distributed for the operation of bathrooms [10, 12-14, 33]. A similar solution was applied in the design of a social and cultural center in the historic center of Paris (Fig. 12). The building is not only successfully integrated into the existing environment, but also creates an optimal microclimate both inside and outside [34].

Fig. 11. Non-State Women's University (Ewha Campus Complex, ECC) in Seoul, South Korea.

Fig. 12. Modernization of the Lourcine Barracks in the University of Law-Paris I, Paris, France.

The largest area and territory are needed by technical free economic zones due to the need to create auxiliary research units (19-20 square meters per 1 student). When blocking research groups of premises with the relevant departments and faculty blocks, the educational and research process is organized much more efficiently and the energy base is used more rationally. Only specialized research and production units with specific technology are recommended to be allocated and placed in the peripheral areas of the educational institution [2]. Calculations show that due to the compaction of buildings, the introduction of compact architectural and planning solutions can significantly reduce the territory of higher education institutions and reduce energy consumption by 20-30% without deteriorating the conditions of the educational process [8,9].

One of the criteria influencing the energy efficiency of educational complexes is heat loss, which is carried out through the outer walls of the building. Compact architectural solutions, integration of buildings into complexes, blocking of building elements provide reduction of external contours of buildings in comparison with separately placed constructions. As an example, we can calculate the perimeter of the outer walls of two rectangular buildings with sides (a, b) and (c, d), located separately and locked into a single complex (Fig.13). The length of external walls of buildings at a separate arrangement is equal to the sum of their perimeters, namely: 2a + 2b + 2c + 2d. The length of the outer walls of the blocked complex is equal to: 2a + 2c + b + d + (d-b) = 2a + 2c + 2d. These calculations show a reduction in the perimeter of the blocked buildings by 2b and, accordingly, a reduction in heat consumption.

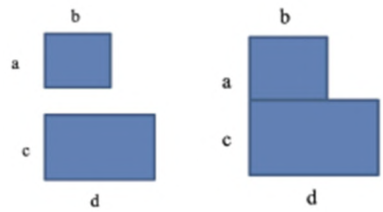

Fig. 13. The scheme of calculation of perimeter at blocking of buildings.

3 Conclusion

Energy efficiency is a necessary measure in the modern architecture of higher education institutions. The architect should think about creating an energy-efficient building at the design stage. The optimal functional and planning solution of buildings, the establishment of appropriate architectural and planning techniques can be called the primary factor in increasing its energy savings.

The article substantiates the importance of a compact architectural and planning solution as one of the important aspects of achieving the overall energy efficiency of the building.

Is the hospital-park future of the sustainable hospital architecture?

Irina Bulakh*, *Margaryta* Didichenko, *Olena* Kozakova, *Olena* Chala, and *Gelena* Kovalska

Kyiv National University of Construction and Architecture, 31 Povitroflotskyi Ave., Kyiv, 03680, Ukraine

Abstract. The article deals with important issues of the ecological approach to the health care facilities design within the general world's attention to the problem of sustainable development of the urban environment. Taking as the example the innovative foreign experience of implemented projects of medical institutions, as well as design, competitive and conceptual proposals revealed the latest idea of coexistence and harmonization of natural and man-made worlds within the medical environment that meets the challenges and needs of the XXI century. It is the concept of the hospital-park, that synthetically combines the architectural environment, natural environment, as well as man-made oasis and creates the basis for emergent results both in the medical field and in the need for a neat attitude to our planet. The article reveals the possibilities of designing a hospital-park of different stories and in different initial conditions: in a dense urban environment with a minimum size of the construction site, in suburban and peripheral areas of the city.

1 Introduction

Architecture is gradually changing along with the society development, its changing perceptions of beauty, strength, usefulness, as well as the growing need for comfort, aesthetics, the ideal environment. For a long time, the architecture of health care facilities was perceived and, accordingly, mechanically designed exclusively as a kind of technically necessary shell to ensure the treatment of the depersonalized population. (Fig. 1).

Fig. 1. "Tysiachka" - hospital №2, Kryvyi Rih, Ukraine. Source: https://krmisto.gov.ua/ua/hospitals/2.html.

This approach appeared due to the acute and rapid need in wast amount of medical institutions widely. In particular, this was the case in the last century in the post-Soviet countries. All over this area there were "cloned" typical projects of medical institutions, integrated into the urban environment with huge industrial and panel arrays without regional, cultural and aesthetic connection with "genius loci" and urban context (Fig. 2).

Fig. 2. City Clinical Maternity Hospital №1, Kryvyi Rih, Ukraine. Source: https://info.1kr.ua/place-4367.html

Do we have the right to condemn this large-scale approach that prevailed in the 20th century? No. At that time, this approach allowed to solve the important medical care issues for the majority of the population of the Soviet Union. Thanks to the mass and economic

https://doi.org/10.1051/e3sconf/202128004014

industrial design and construction approach, Ukraine has received an extensive urban network of various health care facilities, which continue to perform their functions, accepting the harsh challenges and trials of global pandemics and epidemics.

The main issue is that the acquisition of sovereignty in Ukraine provoked political and oligarchic clan "internecine wars", which for decades froze the attention to improving, modernizing, updating and developing the architecture of health care facilities. Many Ukrainian hospitals are in a condition that not only does not meet sanitary and other requirements, but also threatens the health and lives of patients and staff (Fig. 3, Fig. 4, Fig. 5, Fig. 6).

https://doi.org/10.1051/e3sconf/202128004014

Despite the fact of the total ignoring of the problems and issues of compliance of domestic medical architecture with world standards for 30 years already, the powerful and somehow the world's best "machine" continued to work, inertially moving down from its pedestal. Nowadays, in 2021, we are frantically approaching the foot of a new "rock" that embodies all the latest advances in health care and which the world's leading countries have gradually, step by step, overcome with a long-term state plan for medical development and carrying out periodic reforms in the medical field.

2 How the hospitals are designed in the world leading countries?

The architecture of health care facilities needs to be upgraded. Hopefully, this is already happening in developed countries. Today hospitals are more likely five-star hotels with all the services rather than ordinary hospitals, for instance in the United States, Germany, France, England, Singapore, Hong Kong, the United Arab Emirates, and others [1]. The attitude towards a patient, who is now a key figure and not a faceless person for calculating statistical indicators of the beds need, that used to be, has changed. The "hotel" hospitals have various ranges of different restaurants, cafes, bank branches, entertainment, shops, and other public functions, which we use in our everyday life (Fig. 7) [2-4]. A sick person can and should live a full life.

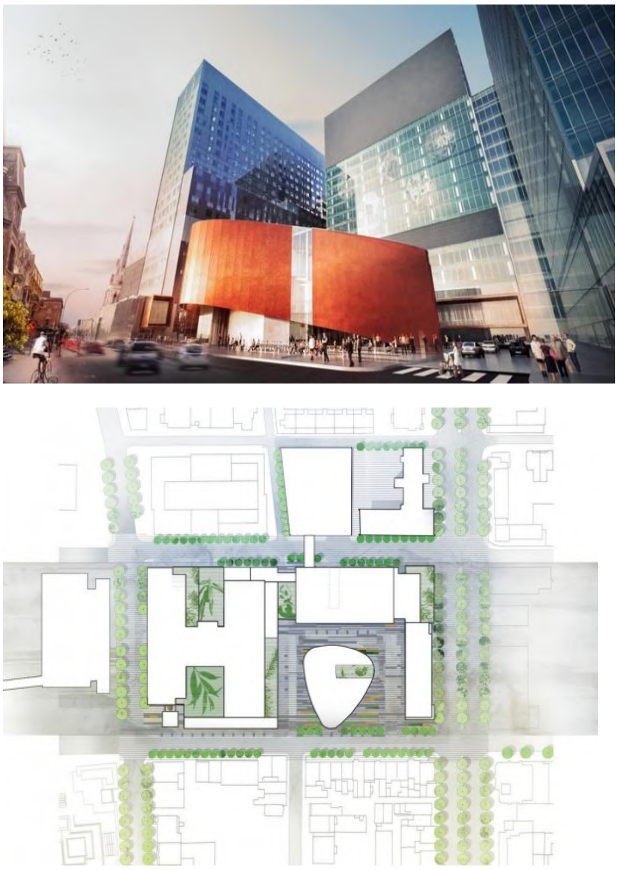

Fig. 7. University of Montreal Hospital Center, Canada. Source: http://healthcare.wsp-pb.com/portfolio/centre-hospitalier-de-luniversite-de-montreal-chum/?portfolioCats=42

Cutting-edge hospitals are megastructural multifunctional medical complexes that have a variety of departments and are usually able to provide all types of medical care services for all age groups of patients. Hospital facilities occupy a large total area, that in some cases can range from 150-300 thousand sq.m. The dense urban environment of megapolises with the lack of free space forces the expansion of existing and historic hospitals significantly in the height dimension. As the result, the new buildings are often difficult to distinguish from the rest of the high-rise public buildings (Fig. 8) [5].

Fig. 8. University Hospital Sant Joan de Reus, Reus, Spain. Source: https://archello.com/project/university-hospital-sant-joan-de-reus

Recently the architectural design of hospital complexes pays significant attention to the organization of public spaces and the interior and adjacent hospital area for the communication between visitors, patients, and staff of the medical institution (Fig. 9) [6]. Architects are actively implementing fascinating multi-story and linear atriums, courtyards, which in addition to public spaces provide natural lighting for the hospital buildings. It should be noted that the patient's ability to independently choose the communication level with society is extremely important. Communicating with others the sick person feels needed, fully-fledged, and not lonely.

3 Future hospitals, which are being developed today

The globe is very contrasting. Simultaneously, many hospitals continue to operate, despite they often do not even have basic living conditions such as sewerage, water supply, and heating. And alongside humanity is working on mega-complex projects of extraterrestrial hospitals. There are many examples of dilapidated buildings with the sign “hospital”. Quite often it’s difficult to name these buildings as “hospitals”. Unfortunately, there are a lot of such destroyed examples all over Ukraine and in rural areas of other post-Soviet states (Fig. 10).

Fig. 10. Rural hospital Voronkiv village, Ukraine.

At the same time, across the planet in the United Arab Emirates a multi-million project and the opening of the world’s first space hospital Emirates Space Hospital, located in Dubai is taking place (Fig. 11, Fig. 12) [7, 8]. The Innovative Hospital of the Future will focus on the UAE Centennial 2071 program and the National Space Program. The hospital will be an example of how telemedicine can be used in the future. Not only in the “Earth” hospitals but also in the space ones. The testing of the first mobile hospital units is planned to be conducted on Mars. The treatment at the Emirates Space Hospital will be carried out using the latest nanorobots, which are able to independently find diseased cells in the astronauts’ bodies and cure them [9].

Fig. 11. Project of Emirates Space Hospital, Dubai, UAE / Mars. Source: https://www.thenationalnews.com/uae/health/space-clinic-being-developed-to-treat-emirati-astronauts-1.700621

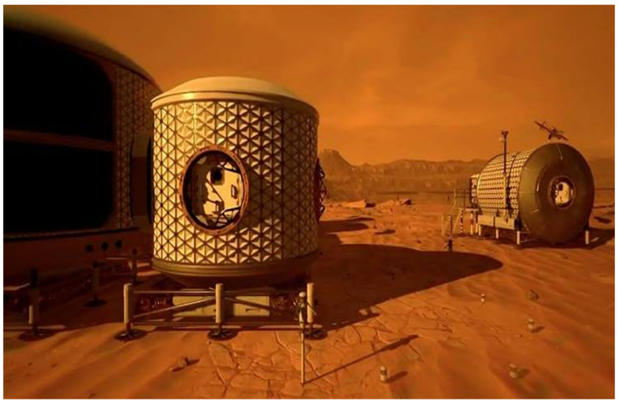

Fig. 11. Medical capsule project to send to Mars, Emirates Space Hospital, Dubai, UAE / Mars. Source: https://dubaiofw.com/mars-science-city-launched/

Besides the project of the future hospital in the UAE, there are already terrestrial and “extraterrestrial” (in terms of architecture and technology) medical facilities that actively use robotization of medical processes, automatic movement of patients and staff, transfer of laboratory materials, and other means by pneumatic pipes, automation of constant control of the main vital signs of patients from mobile devices, etc. (Fig. 12, Fig. 13) [10]. All these and other achievements have allowed bringing the country’s medicine to the world top ten list according to the published rating of the analytical agency Bloomberg [11].

Fig. 13. Robotic operating room. Source: https://www.orlandohealth.com/content-hub/the-wonders-and-benefits-of-robotic-surgery

4 The sustainable development of the health care institutions' architecture

The climate is transforming, and finally, humanity has turned its attention to this issue. At least it's trying to do it. Everyone urges the need for an ecological approach in design, caring attitude to the natural environment, energy-saving, and sustainable development and everywhere [12-23]. In recent decades, the world has held numerous conferences, symposia, international programs, and projects [24]. The problem and the question of the need for sustainable development in architecture affect the whole variety of typological objects of the design activities of architects. Including the segment engaged in the design of health care facilities [25-32].

The current hospitals should not be excluded from the list of energy efficient facilities. They should be designed in accordance with the latest environmental principles and guidelines of sustainable architecture. There are already implemented innovative projects of medical complexes, which should serve as a model for us over the globe. Even in a dense urban environment, on a fairly compact site architects designed and implement a hospital that integrated both the full range of advanced "green" technologies: starting from the full use of regional climate and construction sites (individual aerodynamic spatial and planning structure of the building), ending with the "standard" elements (reuse of rain and used water, solar panels, active and passive insolation, natural ventilation, smart home technology, microclimate through landscaping of roofs and numerous outdoor terraces, as well as many other environmental techniques) (Fig. 14) [33-35].

This design approach has many advantages. Along with the maximum energy autonomy level, compliance with the principles of sustainable development for the future of our planet is achieved by the architects, who managed to create an individual and recognizable artistic icon of the building. This aspect is also very important because the feelings and emotions that the architectural environment evokes significantly affect the process and duration of a sick person's recovery [36]. It should be stated, that the direction of research of the development of their own healing properties of the architectural environment and medical buildings is quite new, but is promising and necessary.

Fig. 14. The hospital complex Ng Teng Fong (NTFGH) & Jurong (JCH) in the urban area, Singapore. Source: https://www.wsp.com/en-MY/projects/ng-teng-fong-general-hospital-singapore

Not fewer than the innovative architectural design approach, which directly affects the development of projects' environmental potential of health care institutions the active integration of the natural environment into the internal and external spaces of medical complexes plays their roles. The latest implemented projects, as well as those that are at the design stage, many competitive and exploratory conceptual developments of hospital buildings allow characterizing this area as the design of the "hospital park".

https://doi.org/10.1051/e3sconf/202128004014

5 "Hospital-park" – a proposal for sustainable development of hospital architecture

The hospital-park is a synthesis of a medical building and the natural environment, which involves the active integration of landscaping both in the interior and in the hospital's area improvement. If we talk about the external environment of hospitals, the considerable attention of foreign architects to landscape design over the past decade should be acknowledged. A striking example of the artificial formation of nature in a rather small hospital area is the Lady Cilento Children's Hospital by Conrad Gargett, South Brisbane, Australia (Fig. 15, Fig. 16) [37, 38].

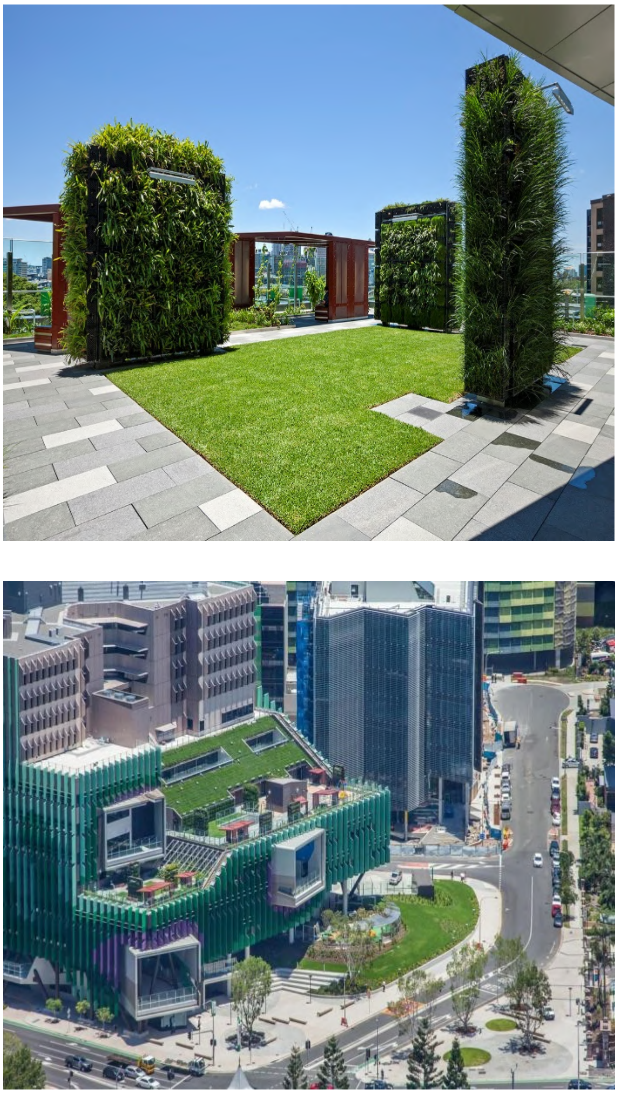

Fig. 15. General view of the Lady Cilento Children's Hospital by Conrad Gargett, South Brisbane, Australia. Source: https://www.archdaily.com/595827/new-lady-cilento-children-s-hospital-lyons-conrad-gargett

In order to maximize the area of the hospital site, the elements of a "man-made nature" were integrated by the architect's decision of plantings and lawns on the terraces, roof, and even used vertical landscaping of the hospital walls. As a result, despite the almost complete absence of its own free territory, the hospital formed a small oasis in the middle of the "stone jungle" of a dense urban environment.

Fig. 16. The Lady Cilento Children's Hospital by Conrad Gargett, South Brisbane, Australia. Source: https://www.archdaily.com/595827/new-lady-cilento-children-s-hospital-lyons-conrad-gargett

Another interesting illustration of the landscape and sustainable design approach of a modern hospital are the finalists of the international competition for the design of the largest hospital in Denmark, namely the architectural offices BIG, Herzog & de Meuron, C. F. Møller submissions. The international competition task was to create a large-scale hospital complex Nyt Hospital Nordsjælland with a total area of about 125,000 sq.m. A picturesque plot of land was proposed for construction, which at the same time served as hunting grounds. Thus, as a context of the environment, the architects received a hilly natural landscape with the largest forest area in the country and many small lakes. Of course, as recognized world-class professionals, each of the finalist teams in their project proposals focused on the integration of nature into the arsenal of the treatment environment.

The team of the Danish office C.F. Møller proposed a project where rather high hospital buildings stand out against the surrounding landscape. The emphasized "functionality" of the project proposal of this variant of the hospital provided the concept according to which the largest hospital of the country should be deployed like the whole city with all necessary functions and structures designed for the needs of patients and staff. The center of the hospital complex is the pubic space with a two round in plan courtyards (Fig. 17, Fig. 18) [39].

Fig. 17. General view of the Nyt Hospital Nordsjælland, C.F. Møller, Denmark. Source: https://www.cfmoller.com/p/-da/Nyt-Hospital-Nordsjaelland-i-Hilleroed-i3067.html

Fig. 18. General view of the Nyt Hospital Nordsjælland, C.F. Møller, Denmark. Source: https://www.e-architect.com/denmark/nyt-hospital-nordsjaelland

The design concept by the BIG architectural office is for the creation of a space capable of "healing"(Fig. 19) [40].

The shape of the hospital complex consists of eight blocks in the form of intersecting rings with courtyards. The architects explained their choice by the fact that it will guarantee a picturesque view from every chamber, the premises will be provided with sunlight, and the opportunity to go for a walk in the public garden will create the conditions for communication. Fresh air, beautiful landscapes, and a positive mood, according to the authors of the project, are true companions of fast and high-quality recovery (Fig. 20, Fig. 21) [40].

Fig. 19. General view of the Nyt Hospital Nordsjælland, BIG, Denmark. Source: https://www.archdaily.com/421002/nyt-hospital-nordsjaelland-shortlisted-proposal-big

Fig. 20. General view of the Nyt Hospital Nordsjælland, BIG, Denmark. Source: https://www.archdaily.com/421002/nyt-hospital-nordsjaelland-shortlisted-proposal-big

Fig. 21. Inner yard view of the Nyt Hospital Nordsjælland, BIG, Denmark. Source: https://www.archdaily.com/421002/nyt-hospital-nordsjaelland-shortlisted-proposal-big

Herzog & de Meuron office offered two- and four-story hospital buildings skillfully integrated into the surrounding natural landscape. The rounded lines of the building plan are more like microorganisms than the traditional shape of a hospital plan. The configuration of the hospital plan is subject to an attempt to provide maximum natural light to the wards. Intersections of hospital buildings with green roofs formed picturesque courtyards. The hospital proposal by the Herzog & de Meuron reflects the close connection between the hospital building and the surrounding landscape, forming an aesthetically pleasing space of a modern hospital park (Fig. 22, Fig. 23) [40-42].

Fig. 22. Inner yard view of the Nyt Hospital Nordsjælland, Herzog & de Meuron, Denmark. Source: https://afasiaarchzine.com/2014/04/herzog-de-meuron_6161/

Fig. 23. Masterplan of the Nyt Hospital Nordsjælland, Herzog & de Meuron, Denmark. Source: https://afasiaarchzine.com/2014/04/herzog-de-meuron_6161/

The idea of a park is obvious in the NTFGH and JCH hospital complex in Singapore. The architects' considerable attention to the integration of sustainable development principles into the architecture of the hospital complex has achieved incredible results. Despite the location of a large hospital in a dense urban environment with almost no free space, the hospital looks like a park with various elements of landscaping. This has significantly improved the views from the windows of hospital rooms and created an atmosphere of psychological peace, relaxation and comfort (Fig. 24, Fig. 25) [33, 34].

The Hughes Medical Institute Hospital in Virginia, USA, designed in 2008 by architect Rafael Vignoli is the best example of how the architecture can reflect the idea of hospital-park using the healing effects of the natural environment, landscape and healing power of water. G. Hughes Medical Complex performs multifunctional tasks, combining state-of-the-art medical laboratory of computational and electrophysiological examinations, robotic and technical research contains conference halls, mini-hotel, spacious public space with registration and recreation area, private offices, medical wards, etc.

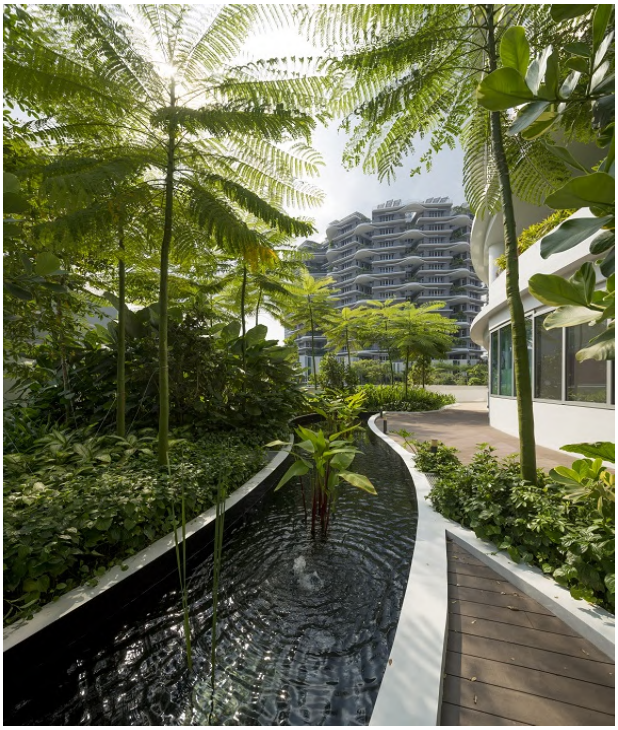

Fig. 24. Exterior and windows from the hospital complex Ng Teng Fong (NTFGH) & Jurong (JCH). Source: https://www.wsp.com/en-MY/projects/ng-teng-fong-general-hospital-singapore

Fig. 25. Active use of landscaping in hospitals Ng Teng Fong (NTFGH) & Jurong (JCH). Source: https://www.wsp.com/en-MY/projects/ng-teng-fong-general-hospital-singapore

The hospital stay provides short-, medium- and long-term medical research courses and programs, so the complex has a hotel for short-term treatment, as well as a building for long-term stay (Fig. 26, Fig. 27) [43-45].

Fig. 26. General view of the Howard Hughes Medical Institute, Virginia, USA. Source: https://www.e-architect.com/america/howard-hughes-medical-institute

Fig. 27. General view of the Howard Hughes Medical Institute, Virginia, USA. Source: https://www.e-architect.com/america/howard-hughes-medical-institute

The next example of the last decade health project, which shows the attention of architects to the integration of the landscape design in medical facilities and thus embodies the ideas and principles of sustainable development, is Seoul National University Hospital Medical Mall, Seoul, South Korea (Fig. 28) [46-48]. The site for the construction of the hospital is located in an urban environment with compacted buildings and has a very limited size. This prompted the bureau of Gresham Smith architects to create an innovative concept, according to which the six-story hospital building was "immersed" in the underground space. Quite a bold idea that does not correspond to the established and traditional architectural approaches to the design of health care facilities! The concept also allowed to develop another unusual tool – the arrangement of a landscape park on the released hospital territory [49].

6 Conclusion

Today in Ukraine there are about 1,793 hospitals with 335,835 hospital beds (78.5 beds per 10,000 inhabitants). Most of these hospitals were built between the 1950s and 1980s. After construction, most of the hospitals received only minimal repairs. And only over the past five years, cosmetic repairs have begun in some hospitals located in large Ukrainian cities. Unfortunately, there is no exact informational data regarding the exact number of hospitals that have already been renovated and those that are currently being renovated.

Fig. 28. General view of the Seoul National University Hospital Medical Mall, Seoul, South Korea.

Nowadays, a number of reforms are undertaken in Ukraine, one of which is to make qualitative and effective changes in the field of health care. From the author's points of view, one of the key issues that need to be addressed immediately is the introduction of ideas and principles of sustainable development in the architecture of medical institutions. From this position, the article analyzes the Ukrainian realities of the state of hospital buildings, as well as advanced foreign design and conceptual experience. Undoubtedly, a huge gap has been identified, which was formed after 30 years of ignoring the needs of modernization and development. But, despite the significant resistance of society against the reformist changes, Ukraine must pass this way. Ukrainian health care facilities must meet world standards of energy-saving and energy efficiency, approaching the zero need for external network engineering systems, making the most of the regional potential of natural properties. It should be noted that it is not possible just to copy the experience of another country. There are always several diverse features (climatic, geographical, relief, hydrological, etc.), which form individual requirements and opportunities. The only invariable potential for the integration of the principles of sustainable development into the architecture of buildings designed for human health, which is appropriate and necessary to implement for all countries of the world, is the active synthesis of the medical and natural environment. One of the possible ways of realization of this idea can be designing a hospital-park, a medical institution that is inserted in a natural environment, and also contains its elements in the internal space. This approach is due to the fact that man is a part of nature, its constituent element and it is natural to assert the harmony of effective and accelerated physical and spiritual renewal in the natural environment.

Modeling of hydrogen sulfide removal under biomethane production in the concept of renewable energy potential growth of Ukraine

Yelizaveta Chernysh[1], *Magdalena* Bálintová[2,*], and *Viktoriia* Chubur[1]

[1]Sumy State University, 2 Rymskoho-Korsakova Str., Sumy, 40007, Ukraine
[2]Technical University of Kosice, Letná 1/9, Kosice, 04200, Slovakia

Abstract. Today, the global trend in the development of renewable energy sources is the implementation of integrated processing of organic waste with the production of biogenic gases such as biomethane. In this case, an essential focus is the study of biogas purification processes to methane. This paper focuses on the process of modeling biochemical purification of biogas from hydrogen sulfide to develop the direction of biomethane production. Simulation of hydrogen sulfide bio-oxidation process with the use of granulated carrier based on phosphogypsum was conducted using experimental data from previous studies to verify the adequacy of the proposed mathematical model. Thus, to implement the process of phosphogypsum utilization in technological systems of biogas purification, it is important to consider the level of bioactivity in the immobilization of bacteria on the loading surface of phosphogypsum and the degree of biotransformation of phosphogypsum components in the oxidation of carbon dioxide and hydrogen sulfide impurities to achieve the highest ecological effect. Also, the use of overlay visualization allowed to form the main clusters of development of research potential in the field of biogas technologies for Ukraine.

1 Introduction

Currently, there is a rapid development of bioenergy worldwide, in particular, the technology of production of biogenic gases for energy purposes [1]. Such countries as Germany and Austria have become the flagships of development in Western Europe, the bioenergy potential is actively developing in the Scandinavian countries (Sweden, Norway) and the United States. Relevant is the problem of the development of renewable energy potential for Ukraine [2, 3] (Fig. 1).

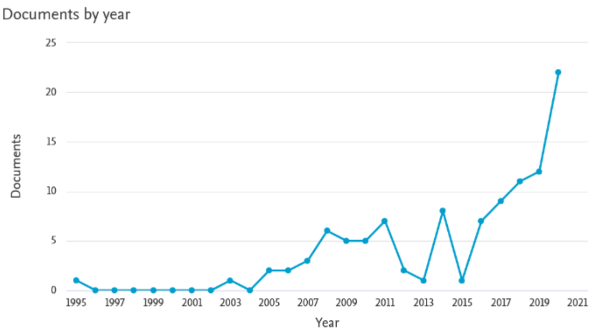

Fig. 1. Publishing trends (number of papers) in the field of biogas technologies research of Ukrainian scientists (using the Scopus database).

When analyzing the publication activity on the query biogas technologies and biomethane production in the Scopus database was highlighted key areas of publications of Ukrainian scientists in highly rated journals, which are associated with bioprocesses of biogas production and waste recycling (Fig. 2 and 3) [4-6]. Thus, the sphere of implementation of scientific research in Ukraine also has significant potential for development and is integrated into the world scientific metrics in the field of bioenergy.

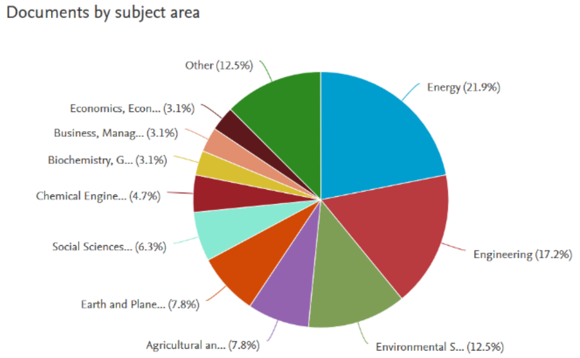

Fig. 2. Directions of publication activity by field of biogas technologies research (using the Scopus database).

The priorities of the new energy strategy of Ukraine until 2035 according to [7] related to bioenergy are as follows:

– promoting the creation of competitive biomass markets;

– support for implementation of cogeneration projects at CHPPs and cogeneration with biofuels;

* Corresponding author: magdalena.balintova@tuke.sk

– creation of conditions for the creation of logistic system and infrastructure for collection of biomass and its further transportation;

– providing centralized heating systems with energy from renewable sources (bio-pellets, household waste, etc.);

– increasing the share of energy exchange in % of domestic consumption, including other fuels, from 10% in 2015 to 60% in 2035.

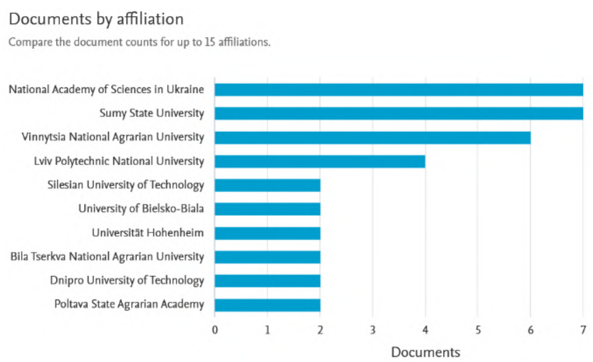

Fig. 3. Affiliation with the leading scientific and educational organizations of Ukraine according to the Scopus database in the field of biogas technology development.

An important direction is also the introduction of integrated processing of organic waste with the production of biogenic gases such as biomethane. In this case, an essential focus is the study of biogas purification processes to methane.

Under our previous studies [8,9] we consider phosphogypsum as an acid-resistant mineral carrier, and besides, it is a source of macro- and microelements for the development of necessary ecological and trophic groups of bacteria. Phosphogypsum entering the environment of life activity of microorganisms becomes a source of nutrition and stimulates metabolic processes of a bacterial cell due to a list of elements necessary for its life activity.

The model of the influence of the main components of phosphogypsum on the vital functions of microorganisms is presented in Fig. 4. For its formation, we used data from previous studies [8,9] and electronic bioinformation databases of the Kyoto Encyclopedia of Genes and Genomes (KEGG) and Metabase of Bacterial Diversity (BacDive).

The annually worldwide production of phosphogypsum is possibly up to 100 million tons [10]. The use of the modified granulated phosphogypsum will make it possible to expand the scope of its use in biochemical purification processes, which is relevant not only for Ukraine, but also throughout the world.

It should be noted, at realization of biogas technologies the special attention is given to quality of biogas and, in particular, to the content of methane, carbon dioxide and other impurities, such as hydrogen sulfide.

Due to the complexity of biochemical reactions, and the presence of inhibitors or hard-to-degrade compounds in the waste, a detailed study of the kinetics is necessary to understand and optimize the process. Vavilov [11] developed mathematical models describing the kinetics of acidogenesis, ethane-degrading acetogenesis, butyrate-degrading acetogenesis, acetoclastic methanogenesis, hydrogenotrophic methanogenesis, bacterial degradation. Gutiérrez Ortiz and Aguilar POllero (2014) provided a methodology for dynamically estimating the total mass transfer coefficient as well as the most appropriate isotherm for a stream containing treated sewage sludge for biogas desulfurization, which requires still evaluating the transition from laboratory studies to industrial applications [12]. The model was verified by comparing the data obtained with experimental data from the literature. Khanongnuch (2019) compared Michaelis-Menten fermentation equations, first- and second-order kinetics of substrate decomposition of cellulose particles of known sizes [13]. The research by Pokorna-Krayzelova et al. (2018) shows that few authors have quantified the kinetics of chemical and biochemical oxidation of sulfides in a single oxygen-limited system. Moreover, the publicly available data are still not consistent, and more specialized measurements are still needed to independently calibrate mathematical models [14].

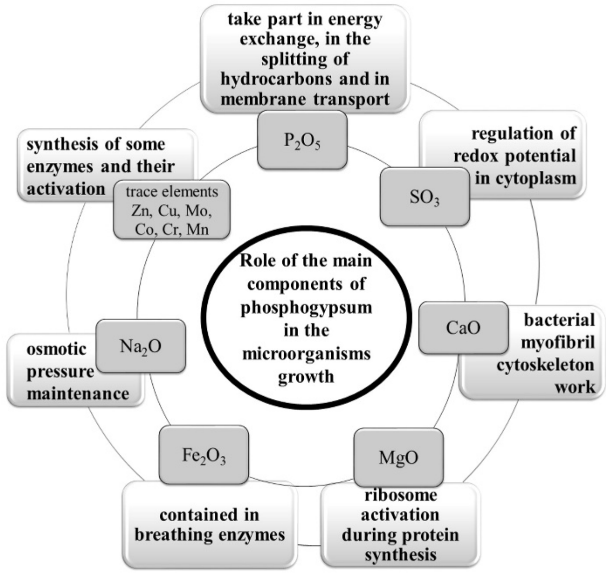

Fig. 4. Role of main phosphogypsum components in microbial activity.

Accordingly, for wide implementation of technologies of biomethane production, it is important to simulate the processes of gas purification with removal of impurities.

However, the growth patterns of bacteria on low-soluble mineral substrate are still practically unstudied. For example, phosphogypsum; in addition, there are practically no data on mathematical modeling and investigation of the biochemical desulfurization process during solid-phase fermentation.Thus, this paper focuses on the process of modeling biochemical purification of biogas from hydrogen sulfide to develop the direction of biomethane production.

This paper focuses on the process of modeling the biochemical purification of biogas from hydrogen sulfide during the biofilm growth on phosphogypsum granules as part of the development of the concept of biomethane production.

2 Materials and methods

Under implementing the mathematical model, we used the values of constants given in Table 1.

Table 1. Constants needed for the software implementation of the mathematical model [15].

Constanta	Value	Unit of measure
$Y_{X/S}$	0.093	mg/mg
μ_m	0.037	d^{-1}
λ	0.031	d^{-1}

Table 2. Symbolic names for program development

Initial designation	Symbolic name	Explanation
F_g	F	input consumption of gas flow containing hydrogen sulfide, dm^3 / min
μ_m	m_max	the specific growth rate of thiobacteria, h^{-1}
V_{gpg}	V	specific layer volume of granulated phosphogypsum, dm^3
C_n	Cn	the minimum value of hydrogen sulfide concentration, ppm
C_k	Ck	the maximum value of hydrogen sulfide concentration, ppm
ΔC	dC	hydrogen sulfide concentration value change, ppm
α_B	*a*	oxidative capacity of biofilm, g / cm^3 h
t	t	contact of the gas flow with the mineral carrier from phosphogypsum, h
ξ_{gph}	L	the biochemical capacity of loading from phosphogypsum, gH_2S / cm^3
C_{H2S}	Chs	the actual concentration of hydrogen sulfide, ppm
λ	l	inactivation rate constant, d^{-1}
e	e	natural constant
$Y_{X/S}$	Y	economic coefficient of thiobacteria biomass yield by substrate - hydrogen sulfide

Fig. 5 shows a simplified algorithm for the simulation process. The computational model was carried out using the C++ programming language in the Borland C++ IDE, which is designed to describe a wide range of tasks and contains mechanisms for controlling the computational process and working with data, optimally suited for the task.

The output data were determined following the biochemical conditions of the biomethane generation process (Table 3).

In this case, the value of C changed in the range, ppm: 250, 400, 550, 700, 850.

Table 3. Initial data for modeling.

Initial condition	Value	Unit of measure
τ	1.5	h.
F_g	0.23	dm^3/min.
V_{gph}	1.8	dm^3

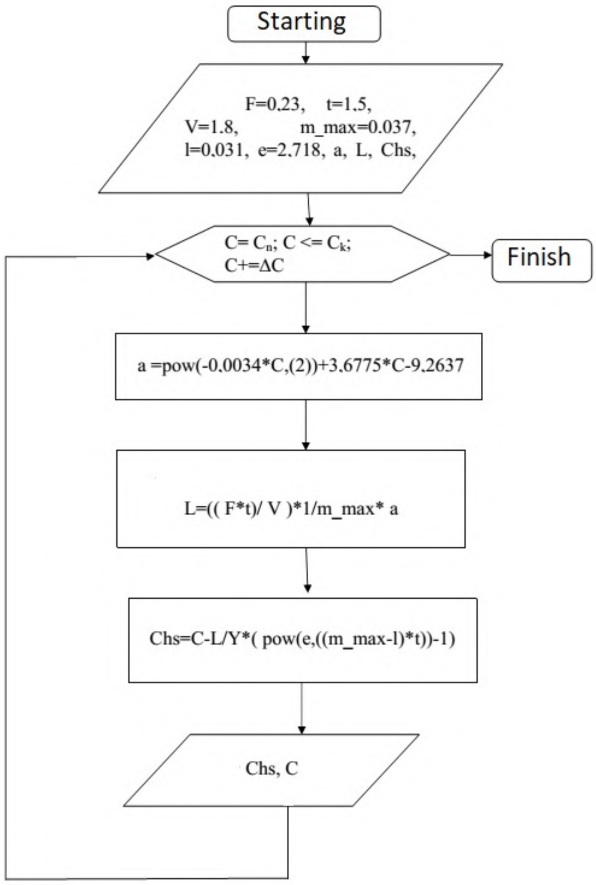

Fig. 5. Simulation algorithm.

To calculate the correlation coefficient between the experimentally determined values of hydrogen sulfide concentration and the values obtained in the simulation, MS Excel program package with the built-in CORREL function was used. Also, special visualization software (VOSViewer v.1.6.15) was used to build a map to visualize the clusters of biogas production in Ukraine.

3 Modeling of hydrogen sulfide removal from biogas for biomethane production

Mathematical modeling of kinetics of hydrogen sulfide conversion by sulfur-oxidizing microorganisms in the process of phosphogypsum utilization assumptions have been put forward: the entire working volume of the biofilter is uniformly filled with phosphogypsum load; concentrations of mineral substrate (phosphogypsum) and biofilm at each point of the biofilter are equal; substrate concentration and the total number of cells are linearly related, the change in hydrogen sulfide concentration (C_{H_2S}) when passing the maximum in the number of viable cells N (at $\mu_m = \frac{1}{N} \cdot \frac{dN}{d\tau}$ = const) gives exponential function and finds dependence on biochemical properties of phosphogypsum load (ξ_{gph}).

The mathematical model of the developed biodesulfurization process using phosphogypsum loading is based on the classical Mono model, widely used in the optimization of biotechnological systems.

 https://doi.org/10.1051/e3sconf/202128005001

Important for analyzing the efficiency of using phosphogypsum as a mineral carrier for immobilization of microorganisms is to evaluate the biochemical capacity of phosphogypsum loading, taking into account the sorption processes on its surface and the uniform distribution of hydrogen sulfide gas flow. Then the behavior of hydrogen sulfide concentration in time and change in the value of biochemical capacity of phosphogypsum loading can be described by the system of ordinary differential equations:

$$\frac{dC_{H_2S}}{d\tau} = \mathrm{C} - \frac{\xi_{gph}}{Y_{X/S}} \times \left(e^{(\mu_m - \lambda)\tau} - 1\right), \qquad (1)$$

$$\frac{d\xi_{gph}}{d\tau} = \frac{F_g \times \tau}{V_{gph}} \times \frac{1}{\mu_m} \times \alpha_B \qquad (2)$$

where ξ_{gph} is the biochemical capacity of loading from phosphogypsum, gH_2S / dm^3; C is the concentration of H_2S in the biogas stream, g / dm^3; $Y_{X/S}$ is economic thiobacteria biomass yield factor by substrate - hydrogen sulfide; μ_m is the specific thiobacteria growth rate, h^{-1}; λ is inactivation rate constant, failure rate, leading to loss of thiobacteria cells' ability to reproduce, h^{-1}; F_g is input gas flow containing hydrogen sulfide, dm^3 / min; τ is contact time, min.; V_{gph} is a specific layer volume of modified phosphogypsum granules in biofilter or bioscrubber, dm^3; α_B is the oxidative capacity of biofilm, g / dm^3 h.

In the process of metabolic activity of sulfur-oxidizing bacteria, there is consumption as a mineral substrate of phosphogypsum. Therefore, when calculating the value of the reduction of hydrogen sulfide concentration in the gas stream in equation (1) was introduced an indicator characterizing the biochemical capacity of phosphogypsum loading.

In expression (2) when describing the biochemical capacity were taken into account parameters affecting the intensity of sorption on the surface of granules, and biochemical activity, which is characterized by the specific growth rate of bacteria and the oxidative capacity of biofilm, which was determined experimentally.

Thus, expression (2) takes into account the most important conversion parameters, without which it is impossible to predict the biochemical component of purification efficiency, since we consider biochemical removal of impurities from biogas as one of the main direction of research on biomethane production. With further development of complex technical solutions, the model can be expanded and optimized for a number of other parameters.

As can be seen from the graph (Fig. 6) the oxidative capacity of biofilm α_B changes with changes in the concentration of hydrogen sulfide in the gas stream.

A curve was obtained (Fig. 7), which corresponded to the theoretical dynamics of hydrogen sulfide reduction and had a good coincidence with the experimental data.

The greatest decrease in hydrogen sulfide concentration occurred in the second half-period of treatment from 0.5 to 1.0 hour, which corresponded to the stabilization of the development of the bacterial film on the surface of modified phosphogypsum granules after the end of the adaptation period. Thus, to implement the process of phosphogypsum utilization in technological systems of biogas purification, it is important to consider the level of bioactivity in the immobilization of bacteria on the loading surface of phosphogypsum and the degree of biotransformation of dihydrate phosphogypsum in the conversion of carbon dioxide and hydrogen sulfide impurities to achieve the highest ecological effect.

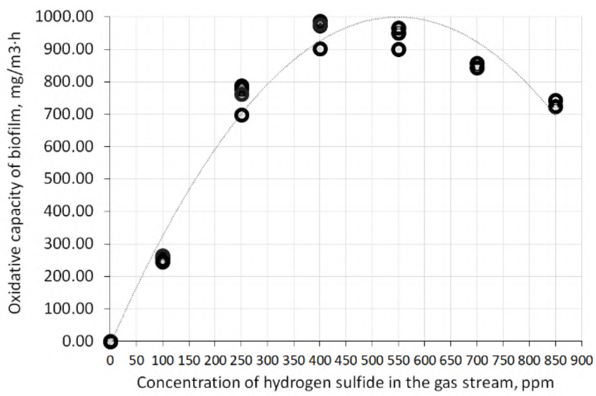

Fig. 6. Biofilm oxidative capacity curve. According to the experimental data from [9].

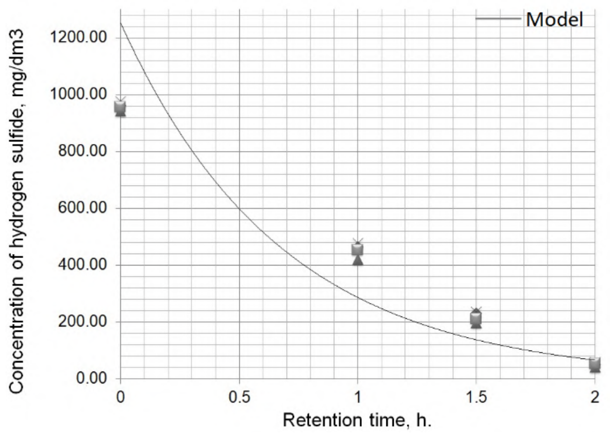

Fig. 7. Change of hydrogen sulfide concentration in biogas with time. Comparative analysis of experimental data and results of mathematical modeling (*r* = 0.923).

Experimental data of dependence of biofilm oxidative capacity (α_B) on the concentration of hydrogen sulfide (C) in biogas can be approximated by regression equation:

$$\alpha_{B=}–0.0034C^2+3.6775C–9.2637 \ (R^2 = 0.9737) \qquad (3)$$

Thus, such species of *Thiobacillus* sp. as *Th. Intermedius* and *Th. Permetabolis* grow under autotrophic conditions, which is associated with the ability of these bacteria to use carbon dioxide to form cell components:

$$CO_2 + H_2O + Enzymen \rightarrow \left[CH_2O\right] + O_2 \qquad (4)$$

Bacterial growth reaches a maximum ($3.5 \cdot 10^{10}$ CFU/g) with maximum removal of H_2S (95.34 %) when supported at pH = 5.0 and contact time of 10 hours [9]. There is a stratification of microbial groups with the development of a zone of facultative aerobiosis and anaerobiosis in the inner bioactive layer of modified phosphogypsum granules.

4 Conclusions

A comprehensive approach to modeling the removal of hydrogen sulfide from biogas and the analysis of the prospects for implementation of biomethanogenesis processes in Ukraine was described.

Simulation of hydrogen sulfide bio-oxidation process with the use of granulated carrier based on phosphogypsum was conducted using experimental data from previous studies to verify the adequacy of the proposed mathematical model.

Further research will focus on the experimental work of the integrated stage-by-stage production of biohydrogen and biomethane with the production of environmentally safe digestate.

This work has been supported by the Slovak Grant Agency for Science (Grant No. 1/0419/19). Research Project was carried out as planned research projects of the Department of Ecology and Environmental Protection Technologies, Sumy State University, connected with subjects “Reduction of technogenic loading on the environment of enterprises of chemical, machine-building industry and heat, and power engineering” according to the scientific and technical program of the Ministry of Education and Science of Ukraine (state registration No 0116U006606).

Development of software control tools for power systems of mining and metallurgical regions

Vladimir Morkun, and *Igor* Kotov

Kryvyi Rih National University, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. There are presented results of developing a conceptual trigger chart of the functioning mechanism of the decision support system. The suggested model of visualizing algorithms as a trigger net of states of the computer decision support system provides for interaction of power objects of mining and metallurgical complexes and regions. The authors introduce new interpretation of components of the network trigger model. The model is interactively connected with both the user-operator's actions and states of power system components. With that, the state of the automatic model is associated with realizing a set of metarules to control the logic output. The authors elaborate a new formalism of representing algorithms of controlling knowledgebases interacting with the outer environment which aggregates primitives of conditions, triggers and transactions of operations and greatly generalizes standard languages of algorithm visualization. It enhances elaboration of standardized smart systems interacting with the external environment. This allows description of functioning algorithms of knowledgebases and the event-driven output to ensure development of reliable standardized smart systems interacting with control objects of power systems in mining and metallurgical regions.

1 Introduction

Advancement of mining and metallurgical complexes and regions is integrally characterized by significant irregularity and effects of some current crisis factors [1,2]. These circumstances call for new approaches to improving efficiency of mining and metallurgical complexes in terms of assessing parameters that define their functioning. As a result, there are developed various transient-free mathematical models and tools of engineering data processing [3, 4].

Large-scale industrial systems of the economy including electric grids of mining regions and metallurgical enterprises are specified by considerable damages associated with emergencies and accidents. In accident elimination, a so-called "human factor" is gaining significance with intensified requirements to managerial personnel. The personnel are under great psychological and physiological pressure in a compressed time frame suffering from high material and social responsibility for their actions. Due to this, managerial personnel are often unable to provide adequate reaction to an emergency and reduce its consequences efficiently [5, 6].

Present-day power system as an integral part of mining and metallurgical complexes is a complicated hierarchical control object characterized by simultaneous power generation, distribution and consumption. With this in mind, the computerized smart support of the managerial operating dispatch personnel's (ODP) decisions is becoming especially urgent. Decision support systems (DSS) are integrated into operating information-control complexes (OICC) of the automated Supervisory Control and Data Acquisition System (SCADA) [7].

Reliability and efficiency of dispatchers' operation is the factor involving reserves to reduce damages caused by accidents and unserved power. Identification of losses and damages in the power system is a complicated and ambiguous task comprising both reliability of power system components and that of dispatch personnel. Basic modern approaches to specifying accident (emergency, crisis) losses resulting from unserved power were analyzed. In general, there are direct losses/damages (lost resources due to breakdowns and accident elimination costs) and lost profits (income deficiency).

2 Problem analysis

Damages can be evaluated by using the following approaches:

– simulation of shutdown scenarios;
– methods of direct analytical calculation;
– market methods (readiness to pay for increased reliability);
– consumers' surveys;
– statistical methods.

To obtain multiple estimates of damages, reliability indices of the power consumption system and management. Meanwhile, specific damage from unserved power can be treated as tripled power costs.

The damage value for a customer is affected by the following parameters:

– the shutdown period;
– the suddenness rate of power interruption;
– depth of limited load;
– the shutdown moment.

Thus, reliability of power supply is a probabilistic index conditioned by a number of the power system's properties.

Analysis of the damage structure and essence in power systems reveals that damage can be reduced due to enhanced automation of emergency management. A decision maker is ODP of power systems [8]. Let us specify the role of dispatch personnel in reducing accident-related damages in power systems. Here, the rate of managerial decision making should correspond to that of accident development. Yet, the decision maker is unable to react in compliance with the set rate of an emergency. Main reasons for that include a great amount of data that require faultless evaluation in the shortest time possible and psychological pressure because of increased responsibility.

Note the generalized information model of technological process management. The model is universal and can be considered invariant in terms of a professional specificity of an enterprise. The given model realizes a cybernetic approach and combines a control object's input and output data with those of a subject. Let us introduce the following symbols: Δt_1 is the period of the information flow passing along the first information arc; Δt_2 is the period of the information flow passing along the second information arc; $\Delta t_{decision\ maker}$ is the period of personnel's decision making; $\Delta t_{Ц}$ is the total time period of the information cycle; S_1 is the control object's state at the moment t_1; S_2 is the control object's state at the moment t_2; t_1 is the moment of the beginning of collecting data on the control object; t_2 is the moment of complete realization of the controlling action on the control object by the control subject.

Thus, we obtain

$$S_1 = S(t_1), \tag{1}$$

$$S_2 = S(t_2).$$

With that,

$$\Delta t_ц = \Delta t_1 + \Delta t_{ЛПР} + \Delta t_2. \tag{2}$$

From (2) it follows that

$$t_2 = t_1 + \Delta t_ц = \Delta t_1 + \Delta t_{ЛПР} + \Delta t_2. \tag{3}$$

For any professional management environment, it is true that

$$t_1 \neq 0, \Delta t_{ЛПР} \neq 0, t_2 \neq 0, \Delta t_ц \neq 0. \tag{4}$$

Then

$$t_2 \neq t_1, S_2 \neq S_1. \tag{5}$$

From (5) provides an important conclusion on the paradox of control: any control is based on the knowledge of an object being in the state S_1 and is realized some time later in relation to another object being in the state S_2. That is why, any control is characterized by some degree of incompleteness, unreliability and ambiguity.

The obvious solution of the control problem is

$$\min \Delta t_ц(X), \tag{6}$$

where $\Delta t_ц(X)$ – is the time period of the control cycle as a function of multiple control factors $X=\{x_i|i=1,n\}$.

As managerial activity is mostly of information-based and cognitive character and the control cycle is based on processing and generation of information flows, solution of problem (6) is related to the IT field. The solution is based on inclusion of the information system into the control cycle. The information system acts as an information 'pump' increasing the speed and volumes of information flows in direct and reverse arcs of the control cycle. The information system nucleus is the data base management system (DBMS), which accumulates and processes information massifs. Application of the DBMS has a considerable time gain, thus enhancing reliability of managerial decisions.

However, reduction of losses calls for new levels of control/management quality. That is why, the information system is complimented with two information mechanisms – the automated process control system (APCS) and the DSS. The APCS is a set of hard- and software modules that ensure production processes. These modules are connected with industrial equipment and their speed of operation cannot be additionally increased to a great extent. On the other hand, expert systems of managerial decision support are predominantly software complexes and are solely associated with the ODP's information activity. Consequently, it is the DSS that is noted for maximum freedom, flexibility, scalability and adaptability in changeable conditions of power system functioning. That is why, the time period for decision-making can be greatly reduced.

Thus, it can be concluded that on the present-day development stage of hard- and software tools of realizing managerial activity in production, reduction of time for managerial decision making ($\Delta t_{decision\ maker}$) is one of the key factors of improving reliability of management and control. Conclusions like that are confirmed by numerous practitioners. This conclusion is gaining more topicality when being applied to managing power systems in emergency and crisis situations under time deficiency. For this reason, within the framework of the given problem, we should consider the issue of the automated dispatcher control system (ADCS) intellectualization.

3 Automation tools of emergency control over power system modes

Let us consider current scientific and practical solutions to automation of emergency control over power system modes. Emergency control of power systems is based on basic principles of emergency control applied to the professional field of power system functioning. Emergency control systems should prevent accidents and provide input of the system parameters into the area of accessible schedule values in the shortest time possible.

Functioning of the control system under the emergency (crisis) mode differs in the fact that emergencies occur unexpectedly and develop fast. Control schedules for stationary modes become inadequate. That is why, emergency control systems should be structurally and functionally different from those in stationary (standard) modes. Comparison of the two system types are in Table 1.

Table 1. Comparison of the control systems.

Conventional control systems	Emergency control systems
Constant functioning mode	Various functioning modes
Inflexible structure and clear distribution of functions for a long period	No inflexible structure and clear distribution of functions for a long period, flexibility
Narrow functional orientation	Wide and partially unpredictable application area
Monostructure	Polystructures
Regulated information flows	Dependency of information flows on a situation
Accurate information	Unreliable information
Excessive information	Insufficient information
Low rate of changes	High rate of changes
Predictability of situations	Unpredictabilityy of situations, past practice orientation, as a rule without any sense
Unanimity of duties and responsibility	Combination of undivided authority, distributed duties and responsibility
Functional potential	Managerial potential
Predominance of social and economic goals and functional criteria	The goal is effciency of elimination of accidents and their consequences; the criteria are reduction of time for goal achivement, minimal losses (victims)

ODP as a tool of operative dispatch emergency control can be considered as both ‘a week link’ of the ADCS and a reserve for increasing efficiency of power system management/control in emergencies.

It is evident that the nucleus of the ADCS is the operating information complex (OIC). The OIC is mostly used for standard modes with such functions as state assessment, reliability analysis and improvement of flow-distribution, which enhance reliable functioning of the power system. The pattern changes greatly if the OIC is to function under unpredictable circumstances or in case of emergencies in any important components of the power system. In these cases, the OIC acts predominantly as a system of data collection and transmission. Complicated applied software created for standard modes can be of no use here. In these conditions, it is mostly dispatch personnel’s responsibility to make decisions about eliminating an accident. The ODP faces the problem of analytical processing of large volumes of operative data which are characterized by considerable incompleteness or unreliability and have to make responsible decisions under severe time constraints. Managerial decision making is difficult to structure and formalize. Correct and efficient decisions are dependent on a dispatcher’s work experience, his/her ability to adequately react to unpredictable stressful situations and psychophysiological characteristics.

In [9], Budovskyi indicates that ‘in each individual case, technological failures are treated as suddenness that makes personnel face a number of various problems. In this case, especially on the initial stage of disturbance when the personnel are not ready to act and the emergency requires taking urgent steps, they are inevitably subject to emotional tension. Here, the personnel’s clear and correct actions are possible only in case of their high-quality readiness to work under given circumstances’. It is evident that there is a problem of improving the ODP’s quality and reliability as responsible part of the ADCS. The problem is solved in many fields including engineering psychology, situational software management, automated knowledge assessment, etc. To improve the ODP’s reliability, there are used multiple methods and approaches: situation evaluation trees, flowcharts and action plans, algorithmization of operative switching plans, observation maps, the business game theory, methods of deduction and expert systems.

The conducted analysis indicates that all the mentioned methods are quite effective and their application enhances reliability of dispatch personnel to some degree. Further increase of the ODP’s reliability is associated with application of training ICT and knowledge assessment – switching training simulators (STSs).

Application of STSs enables a dispatcher to acquire experience of solving operating control problems under standard and emergency modes of power systems. While building the STS, the results of analyzing a dispatcher’s breakdowns (errors) are required to be used. There are two types of dispatchers’ breakdowns – regular and random. Regular breakdowns are those occurring due to dispatchers’ forgetfulness or lack of knowledge as to corresponding sections of normative, directive materials. Random breakdowns are those caused by dispatchers’ mistakes, misses and errors.

To reduce the number of regular breakdowns, the methods of increasing and maintaining personnel’s technical knowledge are used including lectures and exams aimed to provide knowledge and skills of applying the content of normative and technical documents. To reduce the number of random breakdowns, there are used specific instructions, interviews and emergency trainings aimed at increasing personnel’s attention span and accurate responses.

As is mentioned, optimization of obtained knowledge and skills as well as control over the results are provided by simulators including the STSs. The most general features of simulators include:

– a mimic of an electric grid or a substation with indicated symbols and location of commutation equipment;

– simulation of bodies controlling commutation equipment and control indicators for correct accomplishment of operations;

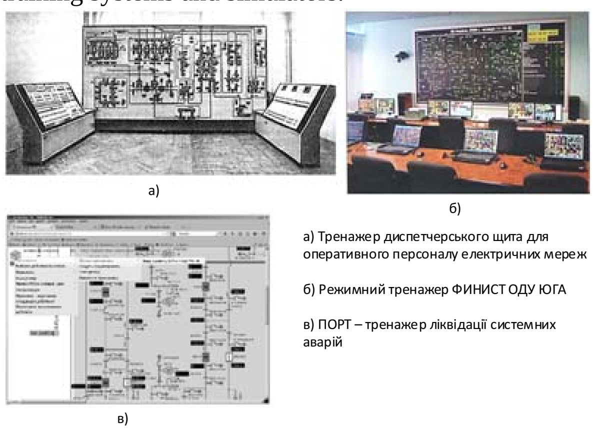
– a logical control block aimed to conduct training according to one or more ‘inflexible’ programmed scenarios – a set of sequences of operations required for a given problem or a given grid.

To acquire required skills for maintaining parameters of the power system mode in a given field under standard and emergency modes associated with sudden imbalances of active power and changes in the grid scheme, there are used mode simulators. They are actively applied to large-scale national power associations and companies of the USA, Canada, Western Europe, Russia and Japan. The mode simulator can be realized on:

– one of the OIC computers removed from the online mode during the training period;

– a computer intended for personnel's training.

In the 1990s, *TE*-2*M* was the most advanced simulator with both relatively simple and complex switching under standard modes with various (standard) schemes of substations as well as problems for dispatchers' independent actions to eliminate accidents. In subsequent years, universal programmed simulators have become popular including *Modus* and *TWR*-12. The simulators include a powerful graphic subsystem which enables reflection of electric grids of limitless sizes with the option of selecting a scheme in the given window. The schemes can be divided into functional blocks comprising separate parts and be united into multilevel hierarchical schemes. Under the supervision of Lyubarskyi, the simulator of the smart grid model *OPTIMAS* was created with multiple applications. The universal mode simulator *FENIKS* (Russia) is worth mentioning as it is widely used by dispatch departments and services of power associations. There are some other simulators used: *RETREN* (Russia), *Finist* (Russia), *KOMPAS-ASDU* (Russia), *EPRI OTS* (the USA), *FAST DTS* (the EU), and *PORT* (Ukraine). Fig 1 contains examples of technical training systems and simulators.



a) The dispatch board simulator for electric grid personnel
b) The mode simulator FINIST of the ODC
c) The accident elimination simulator PORT

Fig. 1. Examples of training systems and the stimulator.

The given analysis reveals that simulators allow increasing efficiency of emergency prevention in power systems. However, current statistics of the human factor impacts represents that 20-25% of all violations of block equipment modes and 30% of all failures in power engineering are caused by personnel's errors. About 90% of those committing a violation had good professional knowledge [10]. Considering the fact that human psychophysiological features have natural constraints to stress resistance, reaction extent, accuracy of big data processing with lack of time, it should be concluded that simulators are to be considered as an intermediate tool for limited improvement of the ODP efficiency. Smart DSSs are higher-level tools with greater reserves of growing efficiency of controlling power systems, i.e. intellectualization tools for power systems.

The research looks into the urgent problem of automatizing control over power grid modes by using software controllers of professional knowledge levels initiated by triggers of the controlled object.

Modern electric grids create a series of specific requirements both to the smart grid itself and to methods of designing it. Let us enumerate some basic requirements: simultaneous functioning with declarative and procedure forms of knowledge representation, identical functioning of the system under the modes of logical input in the knowledgebase and processing of the database, provision of the practical hardware interface with components of power objects and the automated dispatcher control system, implementation of the user visual interface with operating dispatch personnel (ODP), efficient translation into internal system codes and interpretation of controlling meta-rules, realization of the software mechanism of the inductive inference as transactions of meta-rules. The formulated requirements condition the necessity of a new exclusive approach to representing and visualizing structural and functional models of the software complex of the decision-support system (DSS). The model can be applied to solving the following problems: providing identical representation of algorithms of the DSS functioning and algorithms of knowledgebase translation and processing at all representation levels, actual fulfillment of the programme depending on parameters (signals) of conditions of the external surrounding of the smart system.

The research aims to investigate into new formalism of representing control algorithms of knowledgebases interacting with the external environment that aggregates primitives of states, triggers and transactions of operations and generalizes standard languages of algorithm visualization. Each formalism possesses both advantages and disadvantages as well as its preferential application fields. Analysis of their constraints is essential here.

4 Analysis of algorithm representation forms

The formal language of algorithm flowcharts is standardized and well tested. In most cases, based on a designer's talent, a problem can be reduced to visualizing the flowchart of an algorithm.

Dijkstra's flowcharts determine a certain alternative approach to visual modelling of algorithms [11]. Dijkstra introduced principles of structuring flowcharts, i.e. the topology constraint principle, the principle of vertical orientation of inputs and outputs, the single vertical principle, the principle of stringing typical flowcharts into a single vertical.

In order to 'consolidate' algorithm flowcharts and extinguish their complexity, the Nassi-Shneiderman method of visualization is suggested [12]. It ensures absolute observance of structured programming principles and top-down refinement of a problem without binding arrows.

The well-known transient graph is a graphical representation of the machine model. Automation formalisms are expressed by Mealy and Moore machines. Analysis of researches allows admitting the following models in formalizing algorithms – absence of a state hierarchy, generalization of transients.

The SWITCH-technology of designing and Harel's state charts are used as some solutions to the mentioned problems. The SWITCH-technology is based on representation of a programme as a hierarchy of interacting machines. The model enables recording external events.

R-charts are a technology of visualizing system design developed and applied in the Cybernetics Institute of the Academy of Sciences of Ukraine under the supervision of V.M. Hlushkov. Adoption of the standard indicates efficiency of the applied R-charts..

The L-network formalism suggested by M.F. Lekarev is an original solution in the field of modelling computing processes [13].

5 The state flowchart of the trigger DSS

The software current state triggers identify mode parameters at the input and generalize situational codes at the output. This state is associated with a transaction, the fulfillment of which implements operations related to the knowledgebase. Depending on the result of the transaction, the DSS proceeds to another state.

Fig. 2 contains a developed generalized flowchart of the DSS states based on transactions of meta-rules.

$$S = <Q, q_0, F, T, P>,$$

$$S = <s_i \mid s_i = <q_i, t_i, p_i>, q_i \in Q \vee q_i \in F \vee q_i = q_0>. \quad (7)$$

The flowchart conjugates with the chart of data interaction of the DSS with the external environment through hard- and software tools of the automatized dispatcher control system of the electric grid.

Let us introduce interpretation of components of the trigger state grid of the DSS. The series of operation positions (states) of the network is

The series of the network transients is

$$\Delta_\Sigma = \Delta \cup \Delta_t = \{\delta_i \in \Delta \vee \delta_i \in \Delta_i\}, \quad (8)$$

where Δ_Σ is a total series of network transients; Δ is a series of transients between the network states; Δ_t is a series of trigger transients of the network.

The series of the input functions is

$$I(S): S \to <Q_{-1}, V_\Sigma \cup W_\Sigma>, \quad (9)$$

$$I(s_i): s_i \to \{q_{i-1}, v_{i-1} \cup w_{i-1}\},$$

where Q_{-1} is a series of previous states as to the current state.

The series of output functions is

$$a: S \to s_a. \quad (10)$$

Thus, we reduce the machine trigger model to the operational trigger network of states

In the most general form, the example of model (11)

$$N_s = <S, \Delta\Sigma, I(S), O(S) >. \quad (11)$$

can be presented by the following graphical interpretation given in Fig. 3.

In the suggested model, a state is a block of a trigger, an operational transaction, and a result of calculations and output symbols (codes). We denote the state by a vertical line with the state indicator above. Depending on the obtained input codes, the network functioning becomes a branching process as a transient to the next state starts. If the state possesses more than one output, only one transient is chosen. Observance of the given condition guarantees unambiguity and determination of the performed algorithm. The operating cycle of the network is activity of a current state.

The presented considerations enable introducing the notion and the function of marking for the developed model of the operational state network. The presented considerations enable introducing the notion and the function of marking the operational state network for the developed model. The marking function in its essence is an activation function and it realizes choice of an active state out of a whole series of network states

$$a: S \to s_a, \quad (12)$$

where $\#(s_a)=1|s_a \in S$ is the only active state under the given cycle. The rest of the states are non-active − $\#(s_i) = 0 \mid \forall s_i \in S \wedge s_i \neq s_a$.

The marked state network will look like

$$N_s = <S, \Delta_\Sigma, I(S), O(S), a>. \quad (13)$$

On the basis of the developed state model, one can formulate a general principle of the network implementation. The network implementation (the course of implementing the computing algorithm of the software system) is determined by transients between states or state activation and denotes a step-by-step re-marking along some path on the state graph.

6 Algorithm implementation on the trigger state network

By solving the problem on the state network of the software system, we implement an algorithm expressed by a path on the transient graph. According to the structuring theory, the algorithm scheme can be reduced to a basis set of structures – a consequent cycle, branches and backouts (cycles). The trigger state model enables these principles.

The example of a fulfilled algorithm along the state path $s0 \to s2 \to snq \to s0$ of the considered network is reflected by the cycles presented in Fig.4. The trigger t_0 initiates the procedure.

Models enable specifying the model of a state depicted in Fig. 5.

https://doi.org/10.1051/e3sconf/202128005002

We should consider the fact that the programme is a sub-set of a set of paths on the graph of the state network.

$$PROG = B_{prog},$$

$$\forall s_{ik}\, \forall s_{ik+1}\, \forall k|\ s_{ik} \in S_i \wedge s_{ik+1} \in S_i \wedge k=1,2,\ldots,\ n_0{:}\, s_{ik} < s_{ik+1},$$

$$B_{prog} \subseteq N_s,$$

$$B_{prog} = \{b_i \mid I = 1,n_b\},$$

$$b_i = \{s_{i,k},\ s_{i,k+1},\ \ldots,\ s_{i,nbi,}\},$$

where PROG = Bprog is a programme (an algorithm of accomplishing a series of transactions); Bprog=$\{b_i|$i=1,$n_b\}$ is a set of branches (paths) of the algorithm of accomplishing the programme; b_i is the i-th branch of accomplishing the algorithm of the programme set as a strict sequence of states of the trigger network; N_s is a complete network of states.

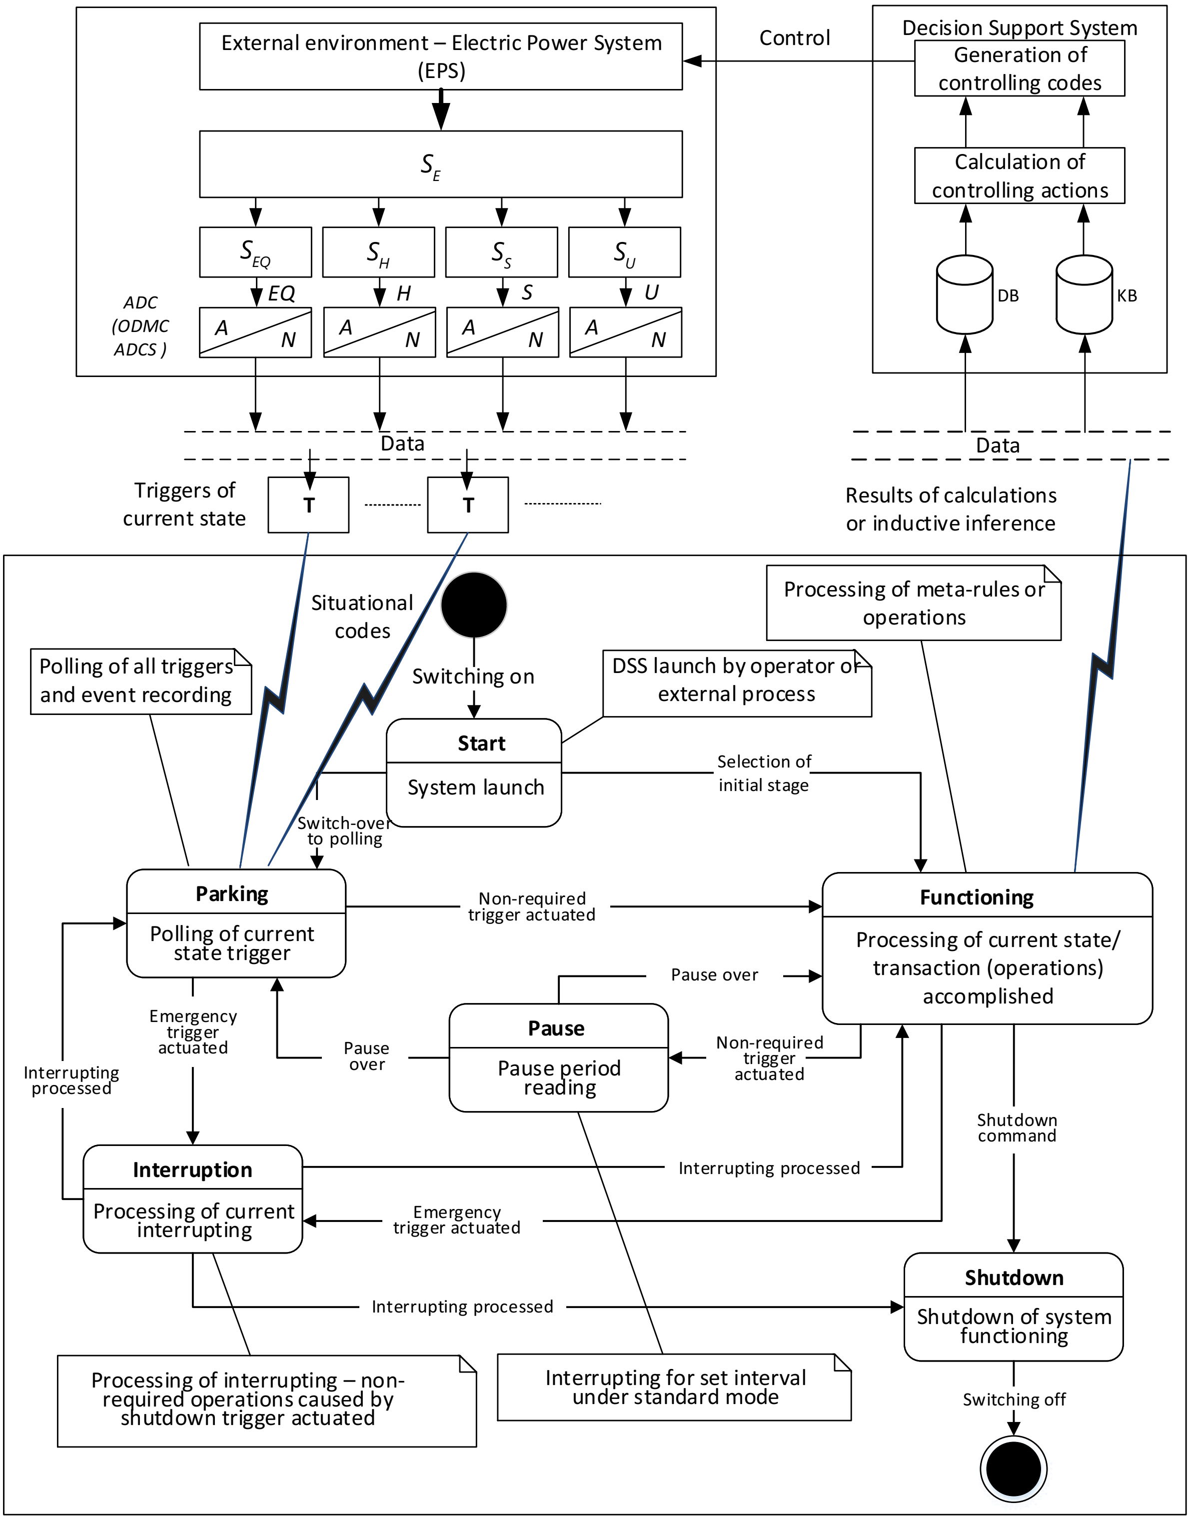


Fig 2. The state flowchart of the trigger DSS.

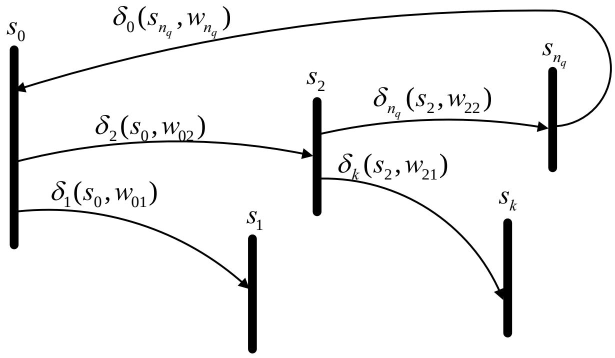

Fig. 3. The state flowchart.

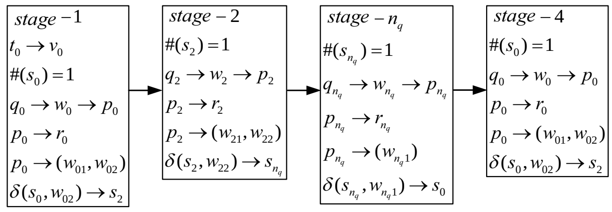

Fig. 4. Frames of step-by-step accomplishment of the algorithm on the trigger state network.

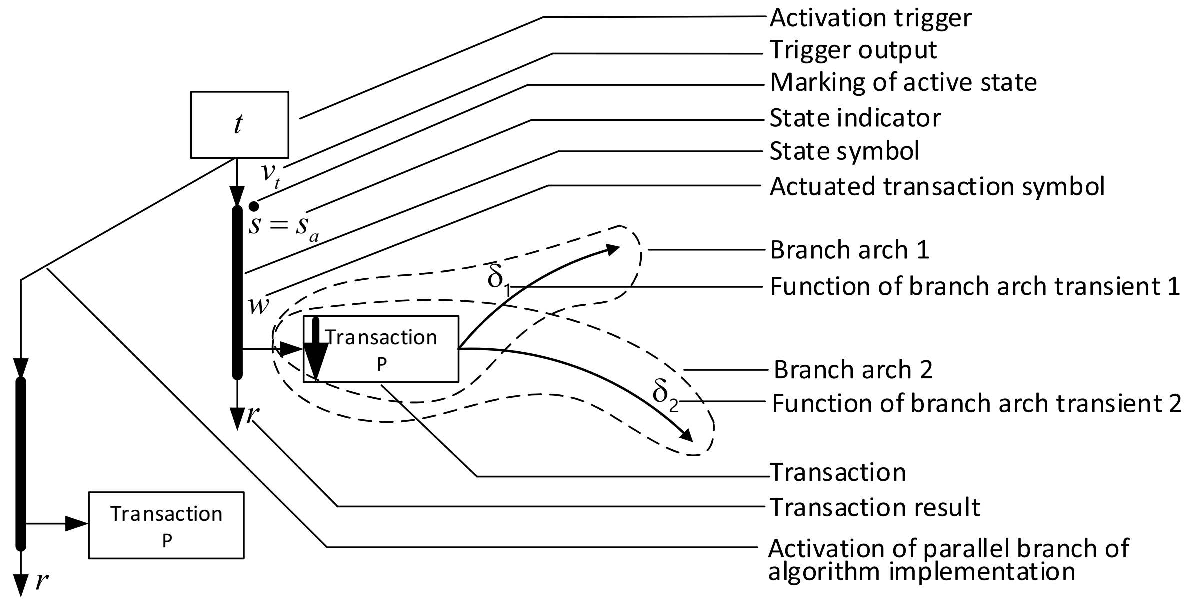

Fig. 5. A state of accomplishing the algorithm of the programme DSS system.

7 Practical software implementation of an automated system

Based on the obtained structural and logical models, a knowledge base was developed and the effectiveness of a professional thesaurus was evaluated.

Fig. 6 illustrates dynamics of relative efficiency of the thesauruses.

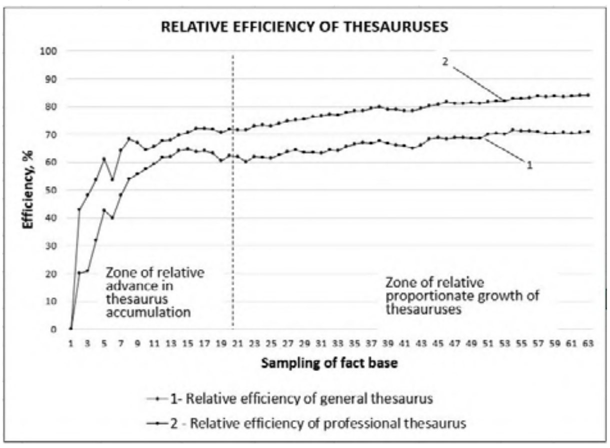

Fig. 6. Dynamics of growing relative efficiency indices of the general and specialized thesauruses.

The diagrams have two distinct zones – that of relative advance in thesaurus accumulation and that of relative proportionate growth of thesauruses. Efficiency of the specific slang and abbreviation thesaurus is higher than that of the general one. The zone of relative advance in thesaurus accumulation is characterized by accumulation of facts in a single terminological and semantic block while the thesaurus is formed rapidly and almost does not grow. The zone of relative proportionate growth of thesauruses indicates the increased volume of the linguistic corpus when new terminological and semantic blocks accumulate. In this case, the thesaurus starts growing again.

Expressions for calculating integral factors of efficiency of corresponding general and professional thesauruses of abbreviations and slang are given in the form of the formulae:

$$K_{ET} = \left(1-\frac{\alpha_T}{\alpha_B}\right)\cdot 100\% = \left(1-\frac{arctg(a_T)}{arctg(a_B)}\right)\cdot 100\%; \qquad (14)$$

$$K_{ETA} = \left(1-\frac{\alpha_{TA}}{\alpha_B}\right)\cdot 100\% = \left(1-\frac{arctg(a_{TA})}{arctg(a_B)}\right)\cdot 100\%,$$

where K_{ET} is an efficiency factor of the general thesaurus; K_{ETA} is an efficiency factor of the abbreviation and slang

 https://doi.org/10.1051/e3sconf/202128005002

thesaurus; α_T is a slope angle of the approximated straight line for the general thesaurus; α_{TA} is inclination of the approximated straight line for the abbreviation and slang thesaurus; α_B is inclination of the approximated straight line for the fact base; a_T is a factor under V_{KB} in the straight line equation for the general thesaurus; a_{TA} is a factor under V_{KB} in the straight line equation for the abbreviations and slang thesaurus; a_B is a factor under V_{KB} in the straight line equation for the fact base.

Graphical results of approximation and explanations of calculations are given in Fig. 7.

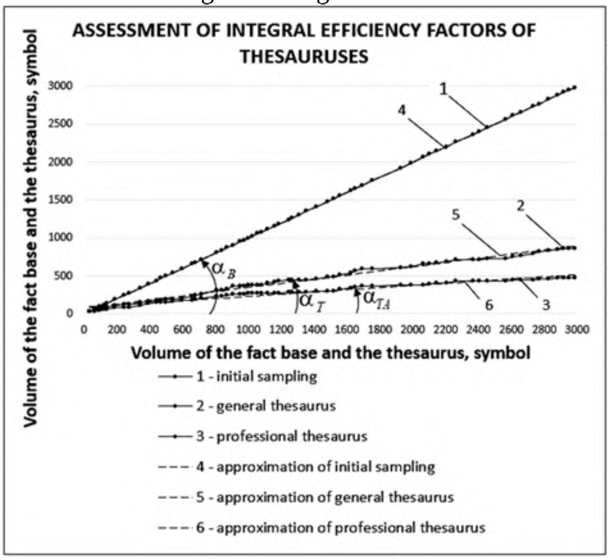

Fig. 7. Calculation of integral factors of thesaurus efficiency.

The physical meaning of the integral factor of thesaurus efficiency is a ratio of inclination of the approximated straight line of the thesaurus growth speed to the inclination of the approximated straight line of the growth speed of the initial base.

Substitution of calculated values provides the following results, %:

$$K_{ET} = \left(1 - \frac{arctg(0{,}2751)}{arctg(1)}\right) \cdot 100\% = 65{,}82;$$

$$K_{ETA} = \left(1 - \frac{arctg(0{,}1439)}{arctg(1)}\right) \cdot 100\% = 81{,}81.$$

Thus, calculations indicate that efficiency of the general thesaurus makes 65.82%, while that of abbreviations and slang is 81.88%. As a result, efficiency of application of knowledge bases increases when the DSS professional area is more specific. The professional area of emergency control over power system modes is highly specific and building its thesaurus is very reasonable.

After building the knowledge base and evaluating its effectiveness, the problems of connecting DSS to ADCS tools are solved. The main form of the developed software package is shown in Fig. 8.

8 Conclusion

There is a model of visualizing algorithms presented as a trigger network of states of a software system ensuring its interaction with the external environment. The trigger flowchart of states and event interaction of the DSS with power objects is developed. The machine model of the DSS functioning with specified semantics of states, transactions and triggers is implemented for the state flowchart. The developed model is generalized in relation to the classical machine model with an output. The model of visualizing a machine formalism as programme system states controlled by triggers is elaborated. Each state implements just one transaction of meta-rules.

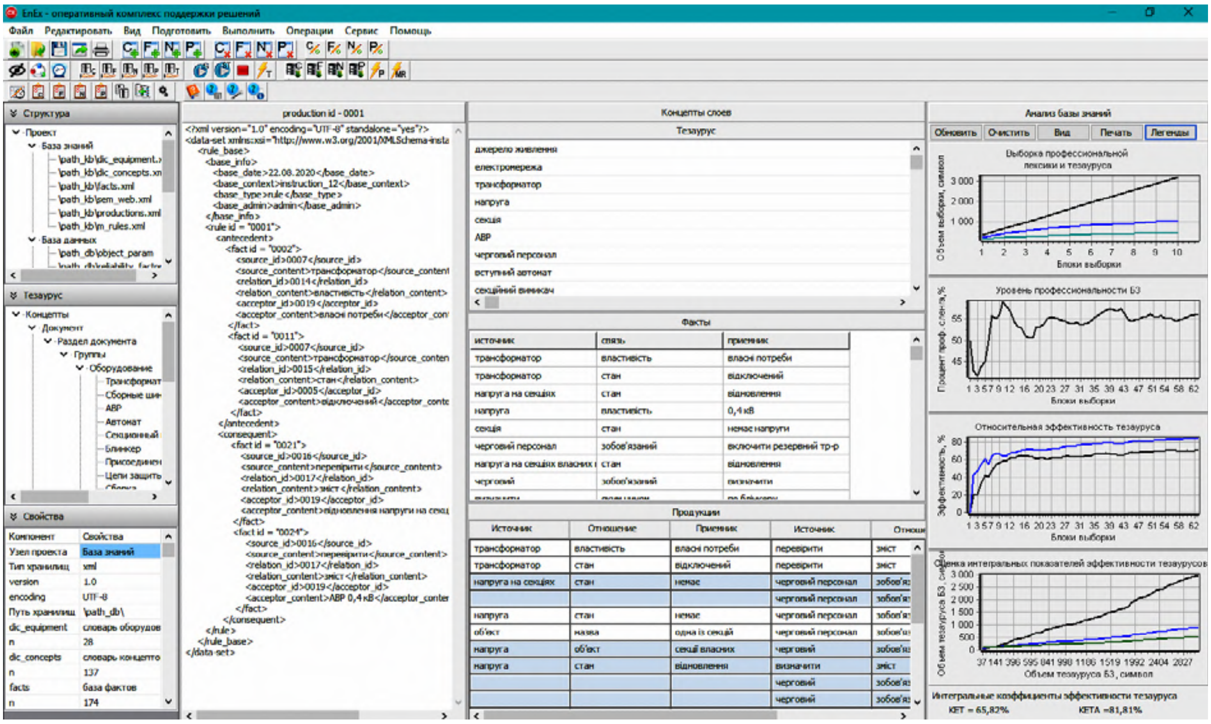

Fig. 8. The main form of the interface of the software package DSS.

https://doi.org/10.1051/e3sconf/202128005002

The research paper gives a developed structure and a fundamental generalized trigger flowchart of the algorithm of the DSS functioning. The suggested model of algorithm visualization presented as a trigger network of system states ensures interaction with the external environment. New interpretation of components of the trigger model is introduced.

Practical applicability, value and significance of the developed models and criteria for assessing efficiency of thesauruses are confirmed.

The assessment of the economic efficiency of the DSS in emergency modes of the power system. Metrics for assessing the quality of the DSS were developed and the quality of the developed DSS was assessed. DSS has shown advantages over analogues in terms of defining criteria. A methodology has been developed and the reliability of a dispatcher watch in emergency mode has been assessed. A quantitative assessment of the effect of increasing the reliability of the DCP from the use of the DSS in the elimination of an emergency violation of the EPS mode has been carried out. The practical increase in the reliability of the ODP from the use of the DSS in the elimination of the accident amounted to 37.2%. The use of the DSS provides an increase in the maximum permissible time of continuous operation of the ODP with a reliable elimination of the accident 1.5 years.

Further research involves developing flowcharts of interpreting the knowledgebase and an inductive inference block, which are functionally overlapped unlike the classical architecture of smart systems. It is suggested to include an ontology level selector into the DSS structure in order to select a form of knowledge and data representation online as well as modules of dynamic formation, verification and ontology replenishment.

Abstract. The paper discusses the influence of low-quality electricity on the temperature modes of operation of an asynchronous motor. In the course of experimental and analytical studies, the heat transfer coefficients and heat capacity of a particular electromechanical converter were determined. Experimental and analytical dependences of temperature changes of an asynchronous motor on time are given when it is connected to a supply voltage with different coefficients of sinusoidal distortion and negative sequence. The resulting model is tested for its adequacy to the real process and can be used as an element in the energy-economic model of an asynchronous motor to assess its uptime. This model that can be useful for simulation of thermal processes in asynchronous motors and optimising these devices for increasing the reliability.

1 Introduction

The presence of low-quality electricity in the shop networks of industrial enterprises leads to a decrease in the main indicators of the operation of asynchronous motors (AM), their accelerated physical aging, and, as a consequence, the occurrence of emergency situations. It is advisable to formulate this problem in the technical and economic plane, and its solution requires a detailed consideration of the system "electrical network - asynchronous motor" with the involvement of methods of mathematical modeling and implementation of computational experiments on a computer [1-3].

The economic assessment of various options for restoring electricity in shop networks to standard quality indicators is the basis proposed in [4-7] for a decision-making method for the operation of electrical equipment, including AM, operating in conditions of poor-quality supply voltage [8].

According to this methodology, according to the current indicators of the quality of electricity in the enterprise network [9-10] and on the basis of energy models [11-13] of the electromechanical converter, its energy indicators are calculated and the time interval of trouble-free operation.

In case of significant deviations of the indicators calculated in this way from the specified ones, various options for technical solutions for restoring the quality of the electric energy supplied to the engine are considered. For each of the options, a cost estimate is performed and a final decision is made on the conditions for its further work.

Wide experience in researching the effect of power quality on the operation of asynchronous motors with a has been accumulated by now [14-16].

Poor power quality in the workshops of industrial enterprises stipulates the increase in direct industrial costs due to the growing power consumption. Moreover, indirect costs related to the reduced operating life of electric machines are increasing as well.

As is known [10, 11], normative operating life of the all-purpose asynchronous motors is about ten years. However, that is true only for the cases when certain conditions are observed. The main condition here is the correspondence of the thermal mode of an electric machine to the insulation class.

Deterioration of the power quality results in the increase of heating losses and insulation temperature respectively. Combined with the overloads, that results in the considerable reduction of the operating life of the electric motors. Practice shows that in terms of 40% of all-purpose AM with nominal voltage of 0.4 kV, the operating life is 1.25-2 years [17].

The aim of the paper is to synthesize a mathematical model of an asynchronous motor, taking into account the influence of changes in the quality indicators of electricity on heating and heat transfer processes, for an economically justified choice of protective equipment.

2 Materials and research results

To study the effect of the operating modes of an electric motor on its thermal conditions, so-called thermal models are applied [18-21]. They are the equivalent circuits where electric losses act as the heat sources; temperatures of structural components are within the nodes; and corresponding heat conductivities and capacities are located between them.

The considered models have different degree of detalization. A single-mass model, in which an electromechanical transducer is represented as a single homogeneous body with the overall temperature, is the simplest one. Although, the real temperature distribution is not uniform: temperature of the AM stator winding may exceed the case temperature by 15-20°C [22, 23].

More detailed models have minor prediction errors; however, that requires having additional data on heat conductivities and capacities of separate structural components of a motor. As a rule, such models are used only at the design stage. Besides, while applying those models, the transient-free thermal conditions are analyzed without consideration of their dynamics.

We consider that during the operation, it is the most expedient solution to use a single-mass thermal model; moreover, it is necessary to analyze the temperature of the AM component, being critical in terms of heating, - stator end winding – as the initial parameter of the model. It is well-known that this component is under the poorest cooling conditions since its thermal efficiency is effected mainly by means of the air.

A single-mass dynamic thermal model of the asynchronous motor is described by the following differential equation:

$$\Delta P = A \cdot \tau + \frac{\Delta\tau}{\Delta t} \cdot C \qquad (1)$$

here ΔP is the power of heating losses generated in the electric motor; τ is the exceedance of the motor temperature over the surrounding temperature; $\Delta\tau$ is the increment of the motor temperature per time Δt; A is the coefficient of thermal efficiency, J/(sec·C) (equal to the radiation heat loss per 1 sec in terms of the difference in the indicated temperatures τ = 1 °C); C is the heat capacity of the motor, J/°C. The indicated heat capacity is equal to the amount of heat required for AM heating by 1°C in terms of the nonavailable radiation heat loss.

As is obvious, equation of thermal balance (1) has two unknown values – A and C, which may be defined with the help of experimental data by composing a system of equations relative to the unknowns. In this context, it is possible to improve the accuracy of determining a coefficient of thermal efficiency and heat capacity of a motor at the expense of the totals of parameters measured in several experiments:

$$\begin{cases} \frac{\sum \Delta P}{N} = A \cdot \sum \tau + \sum \frac{\Delta\tau}{\Delta t} \cdot C \\ \frac{\sum \Delta P \cdot \tau}{N} = A \cdot \sum \tau^2 + \sum \frac{\Delta\tau}{\Delta t} \cdot \tau \cdot C \end{cases} \qquad (2)$$

Corresponding experiments have been carried out in terms of experimental workshop of Ukrspetsservis Ltd. Asynchronous motor of 4АХ80А4У3 type has been analyzed (nominal parameters are as follows: U_n=220/380 V (Δ/Y), P_n=1.1 kW, n_n=1400 rot/min, I_n=4.8/2.8 A, η=75%, cos φ=0.81).

The motor is loaded on a direct-current generator of П31У4 type (nominal parameters are as follows: U_n=230 V, P_n=1.0 kW, n_n=1450 rot/min, I_n=4.3 A, η=75%). During the experiments, AM was heated under the nominal load; the cooling took place in terms of the non-rotating rotor.

A hole was made in the motor cover to determine the temperature of winding faces with the help of laser pyrometer of Fluke 568 type. The hole was open only for a short period for measuring (5 sec); when the electric motor was operating, the hole was closed to prevent the heat exchange between the internal and external air. Currents and voltages were recorded with the help of a mobile measuring and diagnostic complex based on the current sensors of LA 25A type, voltage sensors LV100P (made by LEM, Switzerland), and AD converter E-440 (L-CARD, Russia). Table 1 shows the characteristics of the measuring channels.

Table 1. Characteristics of the measuring channels of a mobile measuring and diagnostic complex

Component	Characteristics
AD converter	
TYPE	E-440
Number of channels	16 differential ones
Digit capacity	12 bits
Conversion time	1.7 mcs
Input range	±5.12V;±2.56V;±1.024V;
Maximum conversion frequency	200 kHz
Zero shift	±0.5LOD; max 1LOD.
Voltage sensor	
TYPE	LV-400
Input range	0 – 500 V
Output range	0 – 10 V
Maximum static error	0.015%
Maximum dynamic error	0.03%
Current sensor	
TYPE	LA-100 C
Input range	0 – 250 A
Output range	0 – 10 V
Maximum static error	0.03%
Maximum dynamic error	0.08%

To eliminate the experiment error stipulated by the increased heating during the starting, the tested electric motor is accelerated with the help of a loading machine operating under the motoring conditions. Only when the facility reaches the idling speed, source voltage is supplied to the asynchronous motor, and a loading machine is placed in the dynamic braking mode (Fig. 1).

Table 2 represents the results of the experiment of test motor heating in terms of ideal supply voltage.

Fig. 2 shows the experimentally obtained curve of test motor heating in terms of ideal supply voltage.

Within the period of 62 minutes, the motor temperature has reached the final value of 76.3°C. The experiment results have made it possible to compose a system of equations (2) and to calculate the parameters of a single-mass thermal model. The parameters are as follows: coefficient of the motor's thermal efficiency while rotating is A=11.2 J/(sec×°C), heat capacity of the electric motor is C – 12.1 kJ/°C.

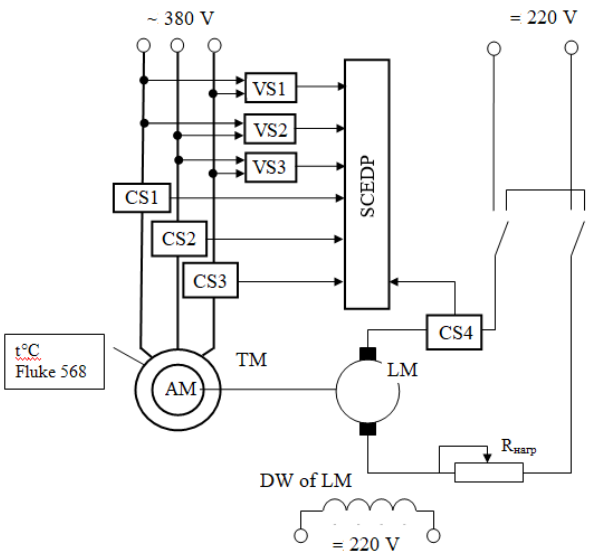

Fig. 1. Schematic of the experience to test adequacy of a thermal model of an asynchronous motor: TM, LM – test machine and loading machine; SCEDP– system to control electric drive parameters (measuring complex); VS – voltage sensor; CS – current sensor ; DW of LM – drive winding of loading machine.

Table 2. Results of experiment #1, ideal supply voltage.

Time, sec	Effective temperature value, °C	Temperature value predicted in terms of the model, °C	Absolute error, °C

1800	50.0	47	-3
1920	50.0	48	-2
Final value	75.7	73	-2

Taking into account the fact that the reference literature contains rather scarce data on thermal parameters of the electric machines (as a rule, there is only the information concerning thermal time constants for motors of certain classes and power ranges), the considered method of their determination while identifying a specific AM model is rather topical.

Further, the heating experiments were carried out in terms of different degrees of distortion of the electric motor supply voltage. The experimental results are represented in Tables 3 and 4.

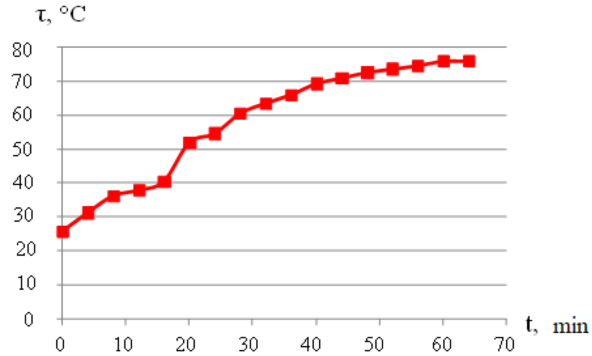

Fig. 2. Curve of motor heating while operating in terms of nominal load and ideal supply voltage.

Table 3. Results of experiment #2, distorted supply voltage.

Further experiments #2-4 were carried out in terms of different degrees of distortion of electric motor power supply. The quality indices of the latter (coefficient of distortion of the sinusoidal voltage curve k_U, coefficient of voltage unsymmetry on the reverse sequence ε_2) are given in Table 5.

Table 5. Power quality indices in the experiments and final temperature values of the AM winding.

Experiment No.	Coefficient of distortion of the sinusoidal voltage curve k_U, %	Coefficient of voltage unsymmetry on the reverse sequence ε_2, %	Final absolute temperature, τ°C
1	0	0	76.3
2	0	4	85.1
3	8	0	92.5
4	13.0	0	117.8

Experience #4 corresponds to the motor operation with the temperature exceeding the admissible one for that insulation class F(105°C); AM may be in such a state only for a short period of time due to the possibility of thermal breakdown of its windings.

The considered experiments have been used to test the adequacy of the proposed AM dynamic thermal model. Figures 3-5 show the comparison of the graphs of temperature exceedance of the motor over the surrounding temperature in those heating experiments with the calculated curves obtained with the help of electrochemical and thermal model of an asynchronous motor [24-26].

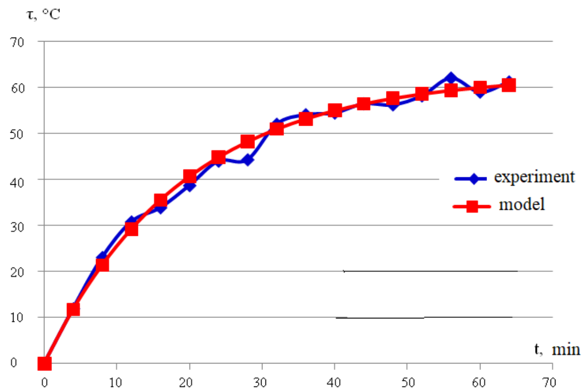

Fig. 3. Curves of motor heating in experiment # 2.

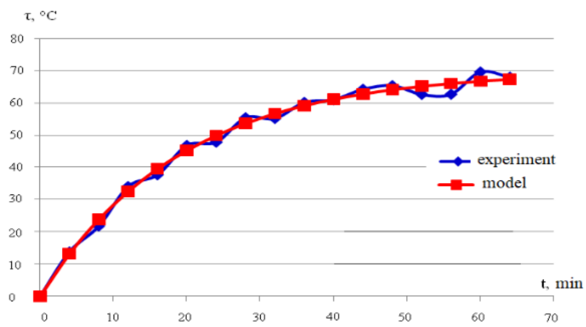

Fig. 4. Curves of motor heating in experiment # 3.

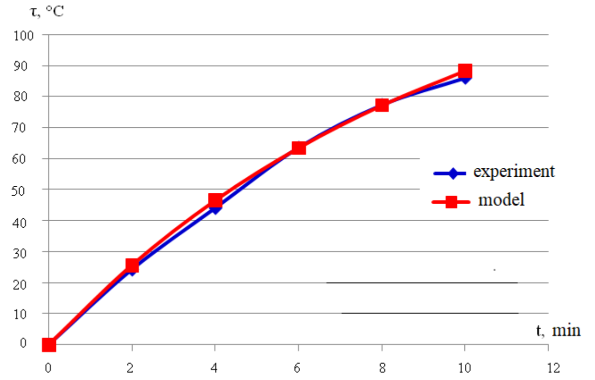

Fig. 5. Curves of motor heating in experiment # 4.

Next, error of the predicted temperature value in the heating dynamics was calculated. Fig. 6 demonstrates the experimental and calculated (predicted) temperature values for all the performed experiments which are used to test the model adequacy according to the method represented in [27-29]. In this context, different format of markers belongs to the corresponding experiments.

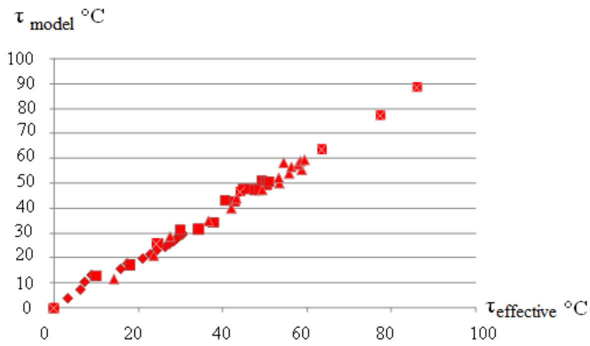

Fig. 6. Relations of the predicted $\tau_м$ and experimental τ_{ef} values of the temperature exceedance of AM winding.

The carried out test for the adequacy supposes obtaining of the following equation of linear regression:

$$Y_n^* = a_0 + a_1 Y_{ef} \qquad (3)$$

where

$$a_0 = \overline{Y_n} - r_{Y_{ef}Y_n} \frac{\sigma_{Y_n}}{\sigma_{Y_{ef}}} \overline{Y_{ef}};\ \ a_1 = r_{Y_{ef}Y_n} \frac{\sigma_{Y_n}}{\sigma_{Y_{ef}}} \qquad (4)$$

Here, $\overline{Y_n}$, $\overline{Y_{ef}}$ are the average values of the predicted and effective values; $r_{Y_{ef}Y_n}$ is the coefficient of correlation between them; $\sigma_{Y_n}, \sigma_{Y_{ef}}$ are the mean square deviations.

The indicated parameters were calculated according to the formulas:

$$r_{Y_{ef}Y_n} = \frac{\sum_1^L (Y_{ef} - \overline{Y_{ef}})(Y_n - \overline{Y_n})}{L\sigma_{Y_{ef}}\sigma_{Y_n}}, \qquad (5)$$

$$\sigma_{Y_{ef}} = \sqrt{\textstyle\sum_1^L \left(Y_{ef} - \overline{Y_{ef}}\right)^2/(L-1)}, \qquad (6)$$

$$\sigma_{Y_n} = \sqrt{\textstyle\sum_1^L \left(Y_n - \overline{Y_n}\right)^2/(L-1)}, \qquad (7)$$

where L=57 is the volume of statistic sampling (number of the temperature measurements in all the experiments).

The mean square absolute error of measurements was determined as:

$$\Delta Y_n = t_p \sigma^*_{Y_n}, \quad (8)$$

where t_p is the Student's coefficient for the given reliability and number of freedom degrees $k = L - 1$. In the case under consideration, reliability was taken as $p = 0.05$. Here, $\sigma^*_{Y_n}$ is the residual mean square deviation calculated according to the formula:

$$\sigma^*_{Y_n} = \sqrt{\sum_1^L (Y_n - Y^*_n)^2/(L-1)}. \quad (9)$$

The mean square relative error of prediction was determined as follows:

$$\delta_{Y_n} = |\Delta Y_n| / Y_{nmax} \quad (10)$$

where $Y_{n\max}$ is the highest value of the predicted one.

Finally, the obtained values are as follows:
σ_{Yef} = 21.2 ºC, $\sigma_{Y\pi}$ = 20.9 ºC, $r_{YefY\pi}$ = 0.99,
σ^*_{Yn} = 2.34 ºC, ΔY_n = 0.28 ºC, δ_{Yn} = 3.2%.

Conclusion

The obtained results show the adequacy of the proposed thermal model of an asynchronous motor operating in the mains with poor quality power. Taking into consideration the fact that in terms of many motor types, reference literature does not contain the required data on the coefficients of thermal efficiency and thermal capacity, and only thermal constants of time are given for certain motor types, values of the specified parameters of the model may be obtained basing on the methodology represented in the paper.

Modeling and simulating dynamics of lithium-ion batteries using block-oriented models with piecewise linear static nonlinearity

Oleksii Mykhailenko[1,*]

[1]Kryvyi Rih National University, Department of Power Systems and Energy Management, 11 Vitalii Matusevysch Str., Kryvyi Rih, 50027, Ukraine

Abstract. The article deals with the research of the efficiency of modelling the dynamics of voltage change in lithium-ion rechargeable batteries in charging/discharging modes using nonlinear block-oriented systems. Drawing on experimental data, a structural and parametric identification of the Hammerstein, Wiener and Hammerstein-Wiener models with a polynomial structure of the linear dynamic block and piecewise linear static nonlinearities was performed. It has been established that the best modelling accuracy was ensured by using the Hammerstein-Wiener system with a linear model having the 6th order of the numerator and denominator polynomials and an input delay of 3 samples. It showed 15.67% and 6.2% higher accuracy compared to the Wiener and Hammerstein systems, respectively. The application of those models in battery management systems will make it possible to improve the control quality for battery assemblies of solar and wind power plants in the context of the variable nature of the charging/discharging processes due to the variability of weather conditions and fluctuations in power consumption during a 24-hour period. This will ensure a wider introduction of renewable power generation into existing power systems, which is currently the leading way to ensure sustainable development of the energy sector.

Introduction

The need to increase generating capacities due to the constant increase in demand for electricity makes the use of traditional energy resources inefficient. This is primarily explained by the rapid depletion of reserves of extractable fuel and energy resources, as well as by high emissions level of harmful substances that is characteristic of processing those resources, and by low enough efficiency of energy conversion.

As a result, designing electricity generation systems that use renewable energy sources and their further integration into existing electric power networks has now become the leading area of the power industry's sustainable development.

Solar and wind energy are by far the main renewable energy sources. One of the features of power plants that use such energy resources is the mismatch (imbalance) between the levels of electric power generation and consumption. This is due to the uneven nature of electric power consumption during the 24-hour period and the variability of weather conditions. In the first case, the efficiency of a power plant is reduced due to the fact that not all electricity produced is fully consumed. In the second case, the power plant does not provide the consumer with electricity, power outages occur, which leads to financial losses of the respective energy company due to non-compliance with contractual terms and conditions.

Thus, for example, at solar power plants, the maximum amount of power is produced during daylight [1] provided that the day is cloudless and the maximum insolation of the working surface of the solar panel is ensured, while the peak of power consumption occurs in the evening and at night. At wind farms, under unfavourable wind conditions, when the wind speed is within the range of the limit value necessary to start the wind turbine, electricity may not be generated at all [2]. Such periods can last for long timespans, sometimes even several days.

In order to reduce fluctuations in output power supply, solar and wind power plants are provided with energy storage facilities. As such facilities, secondary electrochemical sources of electric current that are characterized by the property of multiple recharging are used. In the alternative power engineering, lead-acid rechargeable batteries are the most common, but since some time ago, they have been in the process of being replaced by lithium batteries, in particular, lithium-ion (Li-ion) and lithium-metal-phosphate ($LiFePO_4$) ones. This is due to the fact that lithium batteries have a higher power density, smaller dimensions and a low cost.

The special features of lithium batteries are the operating voltage that ranges from 3.7 to 4.2 V (lithium-ion) or from 3.2 to 3.5 V ($LiFePO_4$), the inadmissibility of overheating, the non-renewable loss of capacity when discharged to a voltage value below 2.7… 3 V, the accelerated degradation when recharged above 4.2 V (lithium-ion) or 3.5 V ($LiFePO_4$), as well as the limited

* Corresponding author: mykhailenko@knu.edu.ua

capacity of an individual battery. In order to create large storage capacities at grid-connected power plants integrated into central power systems, as well as at standalone power plants, lithium batteries must therefore be combined into series-parallel assemblies (battery packs).

The main condition for creating significant storage capacities on the basis of battery packs is the use in those packs of the batteries of the same type and with the same or slightly different parameters. That is, it would be highly ill-advised to incorporate lead-acid and lithium-ion batteries in one energy storage system.

For reliable operation of a battery pack, all connected elements must have the same level of voltage and capacity. The presence of at least one constituent element with different parameters leads either to the premature full discharge of the differing battery below the allowable discharge voltage value during discharging, which causes a non-renewable loss of capacity, or to exceeding the maximum voltage level during charging, which causes overheating of the battery in question and its thermal destruction. As a result, the load on other batteries in the pack increases, which leads to an acceleration of discharging and a decrease in the output voltage of the entire energy storage system of the power plant. This significantly reduces the efficiency of the power plant, because the charging rate of the batteries by the generating equipment may be lower than the intensity of their discharging. The resulting decrease in the output voltage of the energy storage system reduces the energy conversion efficiency by the inverter, through which the consumer receives power. There may also occur a situation where the voltage in the DC link drops below the permissible level, and the energy conversion with the subsequent transfer of the electric power into the network can stop altogether.

In order to eliminate the above situations, the processes of charging/discharging batteries are controlled using protection functions. Battery management systems (BMS) are used for that purpose. The operation efficiency of such a system depends primarily on the accuracy of measuring electrical parameters and predicting on their basis, depending on the mode of operation, the state of an individual battery and the pack as a whole. For predicting purposes, it is necessary to have a model that describes the battery charging/discharging processes with sufficient accuracy. In addition to direct simulation of the operation of a rechargeable battery-based energy storage system for the application as part of the BMS, such a model is also used in the control of generating and converting equipment of power plants that use renewable energy sources [3, 4], and electrical loads connected to battery packs, in particular, electric motors [5]. That makes it possible to improve the quality and reliability of operation.

1 Literature review

A fairly large number of papers deal with the development of rechargeable battery models. That being the case, approaches to simulating the main modes of operation of the principal types of batteries used in energy storage systems of power plants are considered, but special attention is paid to lithium batteries.

All models can be divided into analytical ones, which include electrochemical models [6–11] and models based on electrical replacement circuits [12–19], and data-driven ones [20–31].

Analytical models describe in detail the physical and chemical processes that occur when the battery is charged/discharged. Such models take into account a large number of parameters and use systems of differential equations and partial differential equations. This leads to high accuracy and illustrative nature of such models, but their calculation is accompanied by a high computational load, which reduces their efficiency when used in digital control devices with limited computing resources. Analytical models are convenient to use for studying modes of operation of batteries and establishing new patterns of the ongoing processes.

The research results presented in papers [32–35] show that the most efficient method for estimating the parameters of analytical models made, in particular, on the basis of equivalent replacement circuits is the use of the extended Kalman filter (EKF). Such an approach makes it possible to conduct even quick identification of the parameters of the battery model under the conditions of constantly changing characteristics during operation. However, the peculiarity of such a method lies in reducing the nonlinear model of the plant to a linearized one in the space of states and, as a result, in modelling the operation of the energy storage system in the operating point area. This significantly reduces the accuracy of the model for an essentially nonlinear plant, such as a rechargeable battery.

Data-driven models make it possible to predict the output values of an energy storage system only according to the law of change of input values without taking into account the internal processes of electrochemical transformation. They are characterized by high accuracy at low computational loads upon structural and parametric identification. An important distinctive feature of such models is the possibility, when using certain algorithms, of adapting to changes in the operating conditions of the object. Given the fact that the parameters of batteries, such as their maximum capacity, change with each charging cycle because of degradation processes, the presence of an adaptation mechanism improves the quality of such a model. Data-driven models can be used both when simulating individual batteries and the entire power storage system as a single object. They are therefore convenient to use when handling operational control tasks.

To date, a number of studies have been conducted dealing with the development and investigation of data-driven models of lithium-ion, lithium-polymer and lead-acid batteries used in solar and wind power plants. The main purpose of those studies was to predict such parameters as the battery voltage level during the discharging process, state of charge (SoC) or the depth of discharge (DoD), as well as the remaining useful life (RUL) or the state of health (SoH).

According to the type of response, data-driven models can be divided into linear and nonlinear ones.

Among linear models, polynomial structures are widely used. In papers [20, 21], it was proposed to simulate the modes of operation of lithium-ion batteries using autoregressive models with exogenous input (ARX), whose parameters are estimated by the EKF algorithm, the features of which have been described above. In paper [22], the model based on the equivalent replacement circuit is approximated using the ARX system. A parametric identification of the ARX model is performed based on the full set of experimental data using the least squares method, which reduces the adaptability of the model.

Given the nonlinear nature of the electrochemical processes occurring in a rechargeable battery, it can be argued that the scope of application of linear models is quite limited. Therefore, nonlinear models are normally used.

Machine learning methods are widely used to model and predict the state of rechargeable batteries. The models used for that are nonlinear, have pre-known structure defined at the stage of structural optimization [23], and apply experimentally obtained data for parametric identification. That is, they can be classified as data-driven models.

In papers [24, 25], studies are presented of a classical artificial neural network, a multilayer perceptron, that is a universal approximator, used to predict the RUL of the battery, but it does not always accurately describe the dynamic characteristics of the nonlinear plant. However, parametric identification algorithms for such a model are characterized by high quickness.

The nature of changes in the electrical parameters of the battery is modelled more precisely by recurrent neural networks. In papers [26] studies are presented of a recurrent neural structure based on a nonlinear autoregressive model with an exogenous input (NARX) used to indirectly estimate the RUL and SoC of a lithium-ion rechargeable battery. The studies presented in papers [27, 28] deal with predicting the RUL of a battery using an LSTM network having a recurrent architecture. The results obtained by the authors show that the models in question ensure a low error rate in relation to simulation and experimental data, but create a high computational load during the identification.

In order to predict the SoH and RUL of lithium-ion batteries, deep learning by means of neural network models with many hidden layers is also used [29]. As with recurrent neural networks, these networks can ensure high prediction accuracy, but require a significant amount of time for the structural and parametric identification.

In papers [30, 31], it was proposed to predict the SoC and SoH using an adaptive neuro-fuzzy inference system (ANFIS).

The analysis of literature data has shown that insufficient attention is paid to block-oriented models when simulating the dynamics of a rechargeable battery. At the same time, those models demonstrate high accuracy of simulating nonlinear dynamical systems, which is natural due to a distinctive feature of the configuration, i.e. the presence of a separate dynamic block in the structure of the model. The identification of parameters of such models is efficiently carried out both in off-line and on-line modes based on the algorithms given in [36, 37], which allows those models to be used in digital control systems.

2 Structure of nonlinear block-oriented systems

In order to model and predict the modes of operation of a rechargeable battery, this research proposes to use block-oriented systems. This is due to the fact that these models accurately describe the dynamics of essentially nonlinear plants [38]. Block-oriented systems contain two parts in their structure: a linear dynamic block and a nonlinear static one. Depending on the relative position of these parts when converting an input signal into an output one, the Wiener, Hammerstein, and Hammerstein-Wiener models are distinguished. The structures of those models are shown in Fig. 1.

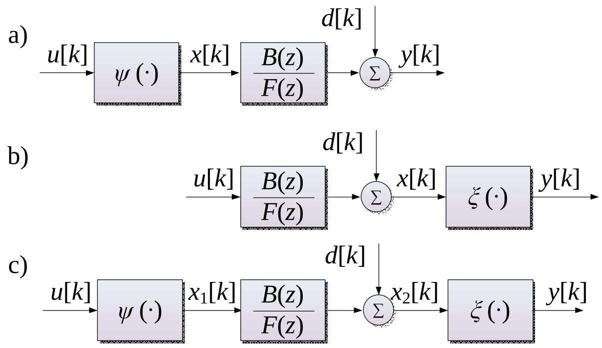

Fig. 1. A function block diagrams of the typical block-oriented systems: a) Hammerstein system, b) Wiener system; c) Hammerstein-Wiener system.

In the Hammerstein model (Fig. 1, a) a dynamic linear block is preceded by a linear static one, while in the Wiener model (Fig. 1, b), the opposite is the case, i.e. a linear block is placed before a nonlinear one. That is, these systems contain one element of each type in their structure. The Hammerstein-Wiener system (Fig. 1, c) consists of two static nonlinear blocks, at the input and output of the model, between which a linear dynamic block is placed.

Mathematically, the above structures are described by the following formulas.

The Hammerstein model:

$$\begin{aligned} x[k] &= \psi\left(u[k]\right); \\ y[k] &= \frac{B(z)}{F(z)} x[k - N_z] + d[k], \end{aligned} \tag{1}$$

where $u[k]$ – model input;

$y[k]$ – model output;

$d[k]$ – disturbance;

$\psi(\cdot)$ – input nonlinearity;

$N_F + 1$ – order of the denominator polynomial $F(z)$;

N_B – order of the numerator polynomial $B(z)$;

N_z – number of input delay samples.

The Wiener model:

$$x[k] = \frac{B(z)}{F(z)} u[k - N_z] + d[k]; \qquad (2)$$
$$y[k] = \xi(x[k]).$$

where $\xi(\cdot)$ – output nonlinearity.

The Hammerstein-Wiener model:

$$x_1[k] = \psi(u[k]);$$
$$x_2[k] = \frac{B(z)}{F(z)} x_1[k - N_z] + d[k]; \qquad (3)$$
$$y[k] = \xi(x_2[k]).$$

The linear part of a block-oriented system can be represented by a transfer function, a state-space model [38], a system of orthogonal basis functions (Laguerre [39], Kautz, Legendre), etc. However, the most widely used polynomial input-output models (BJ, ARX, ARMAX, OE) [38]. According to [40], when modeling dynamic systems, in contrast to prediction, linear polynomial models of the output error (OE) structure are used as part of nonlinear models. In such models, the output depends only on the past values of the input [40], taking into account the disturbances. Since in this paper the problem of modeling the dynamics of lithium-ion batteries is investigated, the OE model is adopted as the structure of the linear part of block-oriented systems.

Piecewise linear functions are used as static nonlinearities $\psi(\cdot)$ and $\xi(\cdot)$. Such an approach ensures flexibility during the identification, since linear functions can be used to approximate a function of any kind. That being the case, the accuracy will depend on the number of linear functions. Also, using a linear function, it is possible to determine the inverse function with low computational load, which simplifies the application of the obtained block-oriented model in digital control systems.

When conducting an analysis of the efficiency of using block-oriented structures for modelling the modes of operation of lithium-ion batteries, it is advisable to apply the following accuracy indicator of the model:

$$e = \left(1 - \frac{\sqrt{\sum_{i=1}^{N} \left(y[i] - \hat{y}[i] \right)^2}}{\sqrt{\sum_{i=1}^{N} \left(y[i] - \bar{y} \right)^2}} \right). \qquad (4)$$

where $y[i]$ – plant output at the i-th sample;

$\hat{y}[i]$ – model output at the i-th sample;

$\bar{y}$ – mean value of the plant's output;

N – number of samples.

This indicator is used due to the clarity and simplicity of calculation. When estimating the accuracy of the plant approximation by data-driven model, it is convenient to use the relative dimensionless errors, rather than errors in units of electrical parameters. This greatly simplifies the analysis and interpretation of experimental results.

3 Simulating dynamics of a lithium-ion rechargeable battery using block-oriented systems

When performing the research, the measurement results for electrical parameters of lithium-ion batteries during charging and discharging conducted and published by NASA were taken as experimental data [41].

The value of the battery voltage during operation, whose dynamic characteristics were approximated by nonlinear models, was assumed as an output variable.

In order to perform a structural and parametric identification of block-oriented systems, Dataset 1 [41] for Battery No. 5 with a nominal capacity of 2000 mAh containing 167 recharging cycles was used. For each recharging cycle, the data was divided into three data frames corresponding to charging, discharging, and impedance measurements. The battery was discharged with a load current of 1C.

Prior to conducting computational experiments, preliminary data preparation for identification was performed as follows. The measured battery voltage in the data frames for charging and discharging during each cycle was combined into one common array. The values of charging and discharging currents were also combined into common arrays, but for the periods that do not correspond to the actual mode of operation some currents were assigned a zero value. That is, the discharging current during charging process and the charging current during discharging have zero value.

At the first stage of the research, a structural and parametric identification of the linear dynamic part of the block-oriented model was carried out (Fig. 2). That being the case, the static nonlinear block had a fixed structure and consisted of 10 linear functions. The parametric identification of the model was carried out using the gradient descent method.

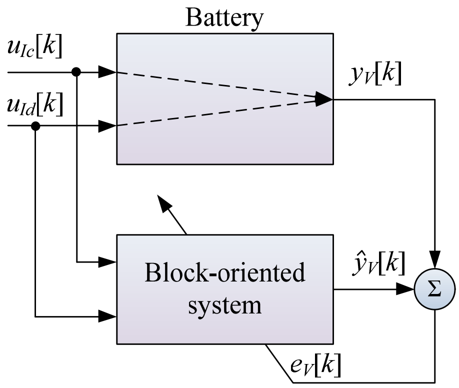

Fig. 2. A function block diagram of the block-oriented model identification process.

For Systems (1) - (3), direct scanning for parameters corresponding to the order of the linear dynamic block's polynomial model's numerator and denominator was performed, as well as that for the value of the input delay in the range from 1 to 6. As a result, 216 structures were obtained for each type of the block-oriented system. The data obtained in the computational experiments for the Wiener, Hammerstein and Hammerstein-Wiener models are shown in Tables 1 to 3. Ten models of the respective type were summarized in each table indicating the parameters of the linear dynamic part that demonstrated the best agreement between the simulation data and the experimental ones.

The analysis of the results for the Wiener system (Table 1) shows that the model, whose polynomial orders for linear blocks $F(z)$ and $B(z)$ are $N_F = 6$ and $N_B = 4$, has the best accuracy, with an input delay standing at $N_z = 4$ samples. The next most accurate model with the $N_F = 3$, $N_B = 3$, $N_z = 1$ structure has 4.35% lower value of the agreement between the simulation and experimental data (4). At the same time, the number of parameters that need to be determined is 2 times lower (7 vs. 14), which leads to a faster parametric identification. Using a personal computer with AMD Athlon II X4 645 3.10 GHz and 8 GB DDR3 RAM configuration, the identification process of Wiener 2 model was performed in 29.56 seconds, while that of Wiener 1 model was done in 33.99 seconds. When using digital control devices with limited computing resources, it is therefore advisable to use Model 2.

Table 1. The results of simulating the dynamic characteristics of the battery using the Wiener model.

No.	N_B	N_F	N_z	e, %
1	4	6	4	77.2154
2	3	3	1	73.8597
3	3	2	5	73.5438
4	5	2	3	73.4139
5	5	4	5	73.3675
6	6	2	6	69.8759
7	4	3	4	69.8349
8	4	3	5	69.5251
9	5	5	3	68.7211
10	4	4	1	68.5545

It should be noted that for structures 2 to 5 and 6 to 10 (cf. Table. 1) the error value differs insignificantly. Thus, the accuracy of Model 5 is only 0.67 % lower than that of Model 2, while the accuracy of Model 10 is 1.89 % lower than that of Model 6.

Models of the following structures that are not shown in Table 1 had the worst quality of simulating the dynamics of the battery voltage changes: $N_F = 4$, $N_B = 6$, $N_z = 4$ ($e = 1.0775$); $N_F = 2$, $N_B = 3$, $N_z = 3$ ($e = 1.7085$); $N_F = 5$, $N_B = 3$, $N_z = 1$ ($e = 1.2831$).

The structural identification of the linear part of the Hammerstein model was carried out next. The results of that identification are shown in Table 2.

A system with the $N_F = 2$, $N_B = 3$, $N_z = 5$ structure showed the best agreement between the model and the plant. The next most accurate model, the Hammerstein one (2, Table 2), has an agreement indicator that is 1.3% lower (4). Given that the number of parameters of the linear block for Structures 1 and 2 is identical, it is advisable to use Model 1 during practical implementation. The identification time for Hammerstein model 1 was 46.59 seconds, while that for Hammerstein model 2 was 46.78 seconds.

Table 2. The results of simulating the dynamic characteristics of the battery using the Hammerstein model.

No.	N_B	N_F	N_z	e, %
1	3	2	5	84.1008
2	3	6	1	82.9962
3	6	5	4	81.8405
4	4	4	2	80.4190
5	6	3	3	77.3667
6	5	4	6	76.2313
7	4	1	6	75.8068
8	3	5	4	74.6718
9	6	5	3	73.6970
10	4	2	6	73.3308

The accuracy of Hammerstein model 1 (Table 2) is 8.92 % higher than that of the Wiener system that has the best quality of simulating the battery dynamics among the models of its type (Table 1). In addition, the number of parameters that need to be estimated is fewer in the Hammerstein system than in the Wiener one, and is 10 versus 14. That is, the computational load of the parametric identification process for such a model is lower.

Let us note that as many as 5 models of the Hammerstein system (1 to 5, Table 2) have a better accuracy than Model 1 of the Wiener structure (Table 1).

A structural identification of the Hammerstein-Wiener model was carried out last at this stage of computational experiments (Table 3). On the whole, this structure demonstrates the best accuracy of modelling the dynamic characteristics of a rechargeable battery. All ten block-oriented systems of this structure have a better agreement with the experimental data compared to the most accurate Wiener and Hammerstein models. Model 1 of the Hammerstein-Wiener system ensures 15.67 % and 6.2 %, while Model 10 does 10.86 % and 1.79 % higher accuracy than Model 1 of the Wiener system (Table 1) and Model 1 of the Hammerstein system (Table 2), respectively.

Table 3. The results of simulating the dynamic characteristics of the battery using the Hammerstein-Wiener model.

No.	N_B	N_F	N_z	e, %
1	6	6	3	89.3127
2	3	4	1	88.0813
3	3	6	3	87.6644
4	5	4	5	86.9817
5	6	3	4	86.7851
6	3	5	5	86.7353
7	6	6	5	86.2524
8	3	5	2	86.0781
9	6	4	3	85.7581
10	3	4	3	85.6027

The agreement index (4) for the two most accurate models of the Hammerstein-Wiener system differs insignificantly. In Model 2, it is only 1.4% lower compared to Model 1. However, for the structure of the linear block of Model 2, it is necessary to determine 7 parameters fewer than for Model 1. The time of the parametric identification for Hammerstein-Wiener 1 model was 55.68 seconds, while that for Hammerstein-Wiener model 2 was 51.56 seconds. That is why it is advisable to use the Hammerstein-Wiener system with the $N_F = 4$, $N_B = 3$, $N_z = 1$ structure of the polynomial dynamic model in a digital control device to ensure a low computational load while providing high quality simulation of the battery dynamics.

A graphical interpretation of the results of the computational experiments is shown in Fig. 3 to 6. For better clarity, two block-oriented systems of each type that had demonstrated the best agreement with the experimental data were depicted in the figures.

Fig. 3 shows the voltage change in a real rechargeable battery and block-oriented models for the first seven recharge cycles. The graphs demonstrate that during the first three cycles, Hammerstein model 2 and Wiener model 1 have a significant error rate when simulating the charging process.

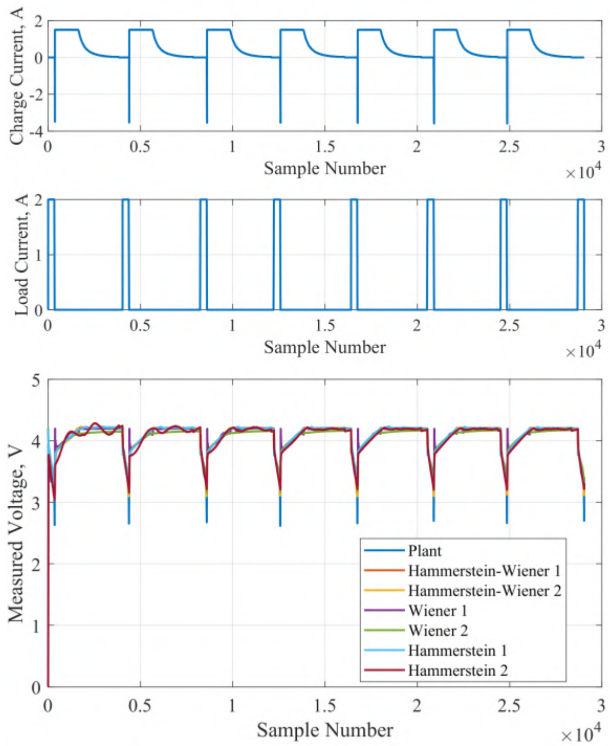

Fig. 3. The results of modelling changes in the battery voltage when using block-oriented systems.

This is corroborated by the detailed graphs shown in Fig. 4 for the first charging cycle. Wiener 1 model poorly describes the initial stage of the charging process, when the charging current is maintained constant (CC mode), while Wiener 2 model, on the contrary, has a high deviation from the experimental data at the stage, when the battery is charged at a constant voltage (CV mode). Hammerstein-Wiener models 1 and 2, as well as Hammerstein model 1, have the best fit.

After the fourth cycle, the accuracy of the models increases. This is evidenced by the graphs shown in Fig. 5.

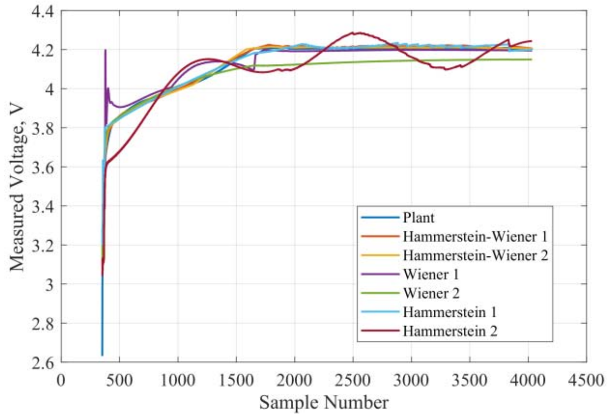

Fig. 4. The results of modelling changes in the battery voltage during the first cycle charging

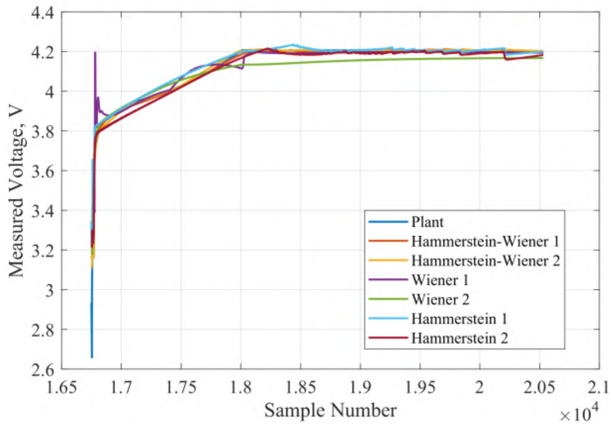

Fig. 5. The results of modelling changes in the battery voltage during the fifth cycle charging

The discharging process (Fig. 6) is best described by Hammerstein-Wiener 1 and Wiener 1 models, but the latter shows a delay at the beginning of discharging. In Hammerstein-Wiener 2 systems, as well as in Hammerstein 1 and 2 ones, periodic fluctuations occur, which generally reduces their accuracy. All the models considered do not make it possible to simulate a sharp drop in battery voltage during the final stage of the discharging process that begins at sample 4350.

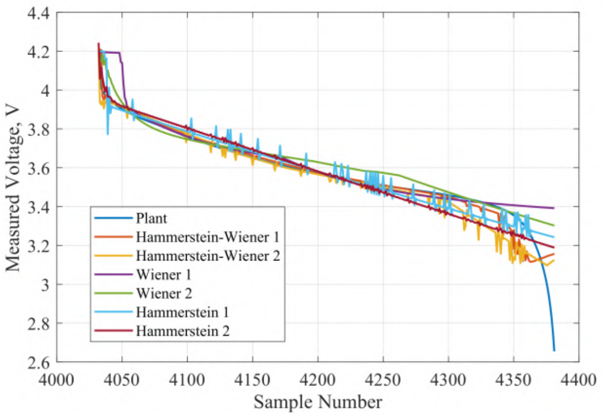

Fig. 6. The results of modelling changes in the battery voltage during the first cycle discharging

After the structural and parametric identification of the linear part of the block-oriented system containing a static nonlinear block, with a constant number of piecewise linear functions, computational experiments of the quality of modelling the change in the battery voltage when changing the configuration of the nonlinear part were performed. For that purpose, the number of piecewise linear functions was changed from 7 to 19 in increments of 3 units for the block-oriented systems of each type with the highest accuracy indices (cf. Tables 1 to 3) obtained at the previous stage of the research. The calculated data are summarized in Tables 4 to 6.

Table 4. The results of simulating the dynamic characteristics of the battery using the Wiener model $N_F = 6$, $N_B = 4$, $N_z = 4$.

Number of piecewise linear functions	**e, %**
7	75.226
10	77.21.54
13	71.6213
16	76.3325
19	64.9123

Table 5. The results of simulating the dynamic characteristics of the battery using the Hammerstein model $N_F = 2$, $N_B = 3$, $N_z = 5$.

Number of piecewise linear functions	**e, %**
7	44.6968
10	84.1008
13	71.8778
16	20.5270
19	35.4378

Table 6. The results of simulating the dynamic characteristics of the battery using the Hammerstein-Wiener model $N_F = 6$, $N_B = 6$, $N_z = 3$.

Number of piecewise linear functions	**e, %**
7	60.6098
10	80.0813
13	35.3615
16	48.195
19	40.5924

The analysis of the results obtained shows that setting the number of piecewise linear functions to a value other than 10 leads to a decrease in the accuracy of block-oriented systems in all three cases. It is therefore advisable to leave the structure of the nonlinear block unchanged.

Conclusions

In this paper, a research done has been presented of the efficiency of modelling the dynamic characteristics of lithium-ion rechargeable batteries and, in particular, the voltage change at the unit during charging and discharging processes using block-oriented systems with static nonlinearities on the basis of piecewise linear functions.

The Hammerstein-Wiener structures have been found to have the best accuracy. They adequately describe the process of charging the battery in the modes of constant current (CC) and constant voltage (CV), as well as the discharging process. At the same time, only the Hammerstein-Wiener systems with high orders of the linear model's polynomial components generally describe the discharging process in a quality way. Output fluctuations are observed in the low-order systems, which reduces their accuracy. However, such models ensure a low computational load on the digital control device.

The Hammerstein systems with high order polynomials of the linear model have demonstrated a simulation quality comparable to that of the low order Hammerstein-Wiener systems.

The Wiener models provide low agreement with a real nonlinear plant when describing the processes of charging a lithium-ion battery in the CC and CV modes, as well as discharging it at the rated loading current. When using them, an unstable nature of modelling the charging process was observed, viz. the accuracy at different cycles differed significantly. However, the Wiener systems did not have output fluctuations at the discharging stage unlike the Hammerstein systems.

All the block-oriented systems considered do not make it possible to describe a rapid decrease in the rechargeable battery voltage at the final stage of the discharging process.

Consequently, taking into account the high accuracy of individual structures of the block-oriented systems, they can be used in simulating and predicting the state of lithium-ion rechargeable batteries in control systems for both storage devices and generating and converting equipment of power plants that use renewable energy sources. An efficient control of energy storage systems will make it possible to improve the quality and reliability of solar and wind power plants in the context of changing weather conditions and fluctuations in electricity consumption during a 24-hour period. This will contribute to their wider implementation in energy systems of various levels and promote the sustainable development of the energy sector.

Further research will be devoted to the analysis of the efficiency of lithium-ion batteries electrical parameters prediction using block-oriented systems. The application of these models in nonlinear model predictive control systems of energy storage equipment of renewable-energy power plants will also be investigated.

Abstract. This paper aimed at studying the current state of development of liquid biofuels' world market. The authors considered the theoretical bases of liquid biofuels production, their types, disadvantages and advantages. The world experience of introducing stimulation mechanisms of development and their influence on the sectors' growth is analyzed. In this study's frame, there is outlined the world leaders in the production of liquid biofuels. The findings represent the peculiarities of state regulation in implementing mandates for creating transport fuels with bioliquids. The current state of investment in the production of liquid biofuels was investigated. The obtained results contribute to the prospects for promoting world production of liquid biofuels to achieve the Paris Agreement's goals by 2030 under the sustainable development scenario.

1 Introduction

At the present stage of human development, most countries' main driver of economic growth is fossil energy resources. In turn, it negatively impacts the ecosystem. Therefore, the world community faces the problem to find energy resources, which will compromise the rate of economic growth and its impact on the environment. One of the promising areas aimed at reducing the anthropogenic impact is developing biomass potential for energy purposes. As the transport sector is one of the largest emitters of greenhouse gases, greening the industry is becoming increasingly crucial for the world. Given the current state of development of technologies related to the transport sector, the most promising direction to increase transport decarbonization may be liquid biofuels.

For Ukraine, the problem of liquid biofuels development has a special place because, despite the significant development of the agro-industrial sector, the market of liquid biofuels is in its infancy. Therefore, for implementing effective mechanisms to stimulate the growth of liquid biofuel production in the country, it is necessary to study current trends in the global biofuel market and analyze the experience of public policy created in countries that occupy leading positions in the market.

The article aims to study the main aspects of the world biofuel market development, determine the world leaders in biofuel production, and analyze the experience in creating a state biofuel policy. The paper provides an investigation on the development trend of world production of liquid biofuels.

Besides, there is an assessment of the prospects for achieving the Paris Agreement's goals by 2030 under the SDS (sustainable development scenario).

2 Theoretical bases of producing liquid biofuels from biomass

The modern branch of bioenergy offers the production of fuel for internal combustion engines based on raw materials of plant origin (liquid biofuel) [1,2], animal origin [2,3], organic waste (biogas) [3,4]. However, the use of liquid biofuels by the transport sector has become the most popular among the various types of renewable energy sources due to the convenience of the production process and higher energy density [5]. It stands to mention that liquid biofuels are usually producing by fermenting sugars (corn grains, sugar cane, etc.). That results in ethanol or by processing oilseeds such as rapeseed, soybean or palm oil into biodiesel.

Replacing biofuel, a traditional petroleum-based transport fuel, has several advantages. First, the production of biofuels helps to increase the country's energy security, reducing oil imports. Second, the use of bioliquids for transport helps reduce greenhouse gas (GHG) emissions [6]. Third, the production and use of liquid motor biofuels contribute to agricultural development, job creation and the filling of local budgets.

Note, the economic feasibility of liquid biofuel production directly depends on the choice of raw materials. When choosing a raw material base, it is necessary to consider the following [7]:

1. Crop capacity. This indicator is significant because the land resources used to grow energy crops are limited. For example, the yield of ethanol per acre is 462 gallons

* Corresponding author: ye.hyrchenko@uabs.sumdu.edu.ua

per acre of 165 bushels of corn. Approximately 35 tons of crop or about 560 gallons of ethanol can be obtained from a sugar cane hectare [8]. Therefore, it is advisable to use land resources efficiently and prefer raw materials with the highest yields.

2. The need for nutrients. Growing raw materials for the production of liquid biofuels should not require large amounts of fertilizers. In addition to nutrients, there is a need for water resources. Indeed, nowadays, water is a valuable and scarce resource, so growing plants must require a moderate amount of water.

3. Growing conditions. Finding useful raw materials is closely related to the country's climatic conditions. Thus, it is advisable to grow energy crops that are best adapted to a particular country's climatic conditions.

It worth noting that nowadays, there are three generations of liquid biofuels as follows:

1. Biofuel of the 1st generation. This category includes fuels such as bioethanol, biodiesel, etc. First-generation biofuel production technologies are not new in the modern world. Approximately 2% of the world's arable land is used to produce such biofuels. However, the commercial competitiveness of the 1st generation biofuels remains low compared to fossil fuels generally. The main difference characterizing the first generation of biofuels lies in the fact that it is producing from sugar and starch-rich plants, oilseeds and animal fats. Alternatively, the raw material could be used for food purposes [9].

2. Biofuel of the 2nd generation. This category includes biofuels made from non-edible raw materials and lignocellulosic biomass. Biofuel of the 2nd generation is considered to be advanced technology in the modern world. The development of second-generation biofuels could address using land for growing bioenergy crops [9].

3. Biofuel of the 3rd generation. This category includes biofuels produced from algae. The main advantage of this technology is the lack of need to attract agricultural land and use raw materials that could be used for food purposes. However, this technology is quite expensive. Therefore, it would not be able to compete commercially with other technologies for biofuels soon [10].

It stands to mention that the use of liquid biofuels has both advantages and disadvantages. Table 1 systematized the main of them.

Table 1. The main advantages and disadvantages of using liquid motor biofuels (based on [10,11,12]).

	Advantages	Disadvantages
Ethanol	The use of bioethanol reduces the emissions of carbon monoxide released by the vehicle's exhaust gases. Besides, bioethanol impurities to gasoline allow obtaining a fuel mixture with an increased octane number, which reduces fuel consumption.	The consumption of bioethanol in the engine power supply is by 51% higher than gasoline consumption. For using bioethanol in higher concentrations, modifications have to be made to the internal combustion engine.
Biobutanol	Compared to ethanol, butanol can be mixed in higher proportions with gasoline. Besides, biobutanol has the property of less solubility in water, less volatility and more excellent safety. Thus, it allows for transporting fuel through existing piping systems. The use of biobutanol in its pure form does not require additional modifications to the engine.	The process of biobutanol production is quite complicated and lengthy. Moreover, the production of biobutanol is low profitable and requires significant investment.
Biomethanol	Biomethanol production has significant economic advantages over the production of other liquid biofuels. In comparison with gasoline use, powering of the engine with fuel from a gasoline mix with impurity of methanol reduces emissions of harmful substances in the atmosphere.	The consumption of biomethanol in the engine power supply is greater than the consumption of gasoline. Besides, the use of biomethanol by the vehicle contributes to corrosion processes in the fuel system. Biomethanol requires special attention from the car owner because it is toxic. Moreover, it poses a potential danger to the human body.
Biodiesel (FAME)	The use of biodiesel fatty acid methyl ester (FAME) allows significantly reduce emissions of harmful compounds and particulate matter during engine operation compared to traditional diesel. At the same time, biodiesel has good lubricating properties, which allows increasing the engine's service life.	The use of biodiesel to power the engine in winter requires additional compounds because the fuel begins to thicken at low temperatures. Biodiesel is more aggressive against polymer and rubber engine parts than gasoline.
Bio-diesel	The use of HVO (hydrotreated vegetable oil) biodiesel reduces NOx, PM and CO2 emissions compared to traditional diesel fuel. Compared to biodiesel, FAME has a longer shelf life and higher energy content.	The price of fuel is relatively high. Therefore, it is impossible to compete with traditional diesel fuel. Limited feedstock when using only vegetable oil.
Dime-thyl	Proportional performance and efficiency with diesel fuel while having a high cetane number and low particulate emissions.	Compared to diesel fuel, it has less heat of combustion and kinematic viscosity. Besides, DME is a strong solvent, so it destroys rubber products

3 The world trends in the liquid biofuels sector development

Nowadays, the liquid biofuel sector is showing high growth rates. Currently, a large number of countries declare strategic goals for the development of the biofuel sector.

However, despite increased energy efficiency, an increase in the number of electric vehicles, and a steady increase in biofuel consumption persists transport as the industry with the lowest share of renewable energy sources [1, 13]. Thus, liquid biofuels provide only about

3%) of the world's fuel needs in the transport sector (Fig. 1).

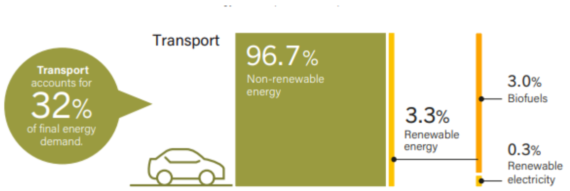

Fig. 1. The share of renewable energy in the total final energy consumption of the transport sector (based on [15]).

Nowadays, the production and use of biofuels such as biodiesel and bioethanol are the most widespread in of liquid biofuels market. Besides, approximately 65% of total world production is ethanol, and almost 35% – biodiesel [14].

Nowadays, the United States, Brazil, the EU and Asia-Pacific are the world leaders in liquid biofuels production (Fig. 2). However, the undisputed leaders who provide more than half of liquid biofuels' world production are the United States and Brazil.

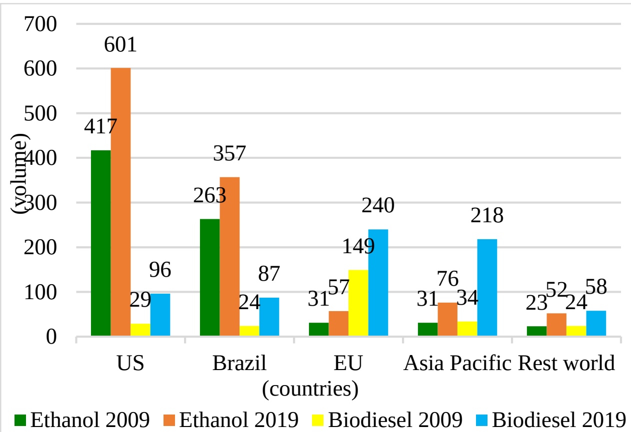

Fig. 2. Biofuels production (thousand barrels of oil equivalent per day) (based on [14]).

The United States and Brazil provided more than 80% of world bioethanol production in 2019. It worth noting that these countries had been holding their leading positions in the bioethanol market for more than ten years. In turn, biodiesel production technology has gained the most popularity in the EU. Herewith, the EU had been in the lead for over ten years. It stands to mention that the rapid growth in biodiesel production occurred in Asia-Pacific, where production increased by six times over the past decade [14].

The world market for liquid biofuels has an annual growth rate of 3% (54 thousand barrels of oil equivalent per day), while in the last decade, the growth rate was two times higher [14].

In general, biodiesel production is experiencing higher industry growth than ethanol (13% vs 2% relatively). Thus, Indonesia demonstrated a rapid increase in biodiesel production (7%) [14].

It could be assumed that the global liquid biofuels sector has been growing for more than a decade. However, the growth rate has slowed significantly. Besides, biodiesel production, which is confidently increasing its share in the global fuel and energy sector structure, is gaining popularity. In turn, the Asia-Pacific countries show a significant contribution to the worldwide growth of liquid biofuels. These countries consider the industry as an effective mechanism for disposing of agricultural residues and increasing energy sovereignty.

4 Energy policies to promote sector of liquid biofuels development

Figure 3 demonstrates that implementing an effective strategy for developing the industry at the national level results in the liquid biofuel sector's positive effect. However, there is still a lack of a comprehensive strategy for decarbonizing transport in many countries. Besides, policies to promote renewable energy in the transport sector continue to focus mainly on road transport, which accounts for the vast majority of energy use in the transport sector, while ignoring aviation and shipping.

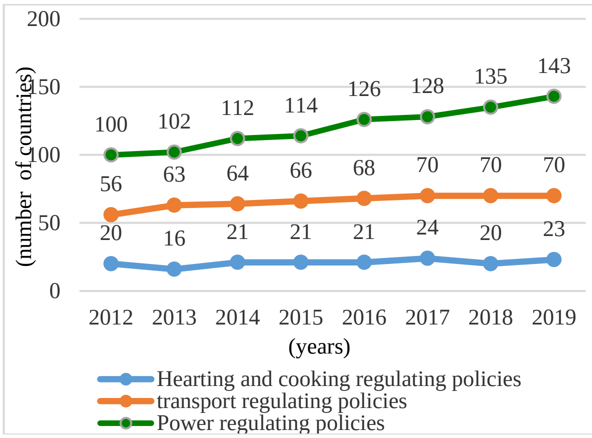

Fig. 3. Number of countries implementing Renewable Energy Policies (2012–2019) (based on [15]).

Policies for support biofuels' production and using include blending mandates, financial incentives, public procurement, and infrastructure support for refuelling and blending. Herewith, mandates for blending biofuels are the most widely accepted type of policy to increase renewable fuels in the transport sector, common in all regions and countries

Table 2 demonstrates that the number of countries with the authority to mix biofuels has recently remained stable (70 countries in 2019). However, mandates for blending are not always fulfilled.

The trend of stimulating the development of liquid biofuels' production and using the mandate to create fuel mixtures has recently gained popularity in many countries due to the increase in the mandate to create fuel mixtures. However, the most significant changes took place in Indonesia (from B20 in 2018 to B30 in 2019), Brazil (where the blending standard increased from B10 to B11 in 2019; besides, the country approved the sale and use of B15) and France (where agreed with an increase in the mandate for mixing bioliquids from 7.9 to 8.2 in 2020) [15].

According to Ren 21, the global biofuel market demonstrates the growing popularity of advanced biofuels. In 2019, the EU and eight other countries had mandates to mix advanced biofuels, while 24 countries were preparing to introduce such mechanisms [15].

Table 2. Biofuels Global Production in 2019 (Top-10 countries and EU-28) (based on [15,16]).

Country	Ethanol	Biodiesel (Fame)	Blend Mandate		
	Billion litres		Ethanol	Biodiesel	Advanced biofuel
USA	59,7	4,0	E2-E20	B2-B10	-
Brazil	35,3	5,9	E27	B11	-
Indonesia	0	7,9	E3	B30	-
China	4,0	0,6	E10	-	-
Germany	0,8	3,8	-	-	0.05% from 2020 (for fuel suppliers supplying at least 20 PJ/a).
France	0,9	2,8	7.9% biofuels in motor fuel		2.3% of diesel and 3.4% of petrol from advanced biofuels by 2023
Argentina	1,1	2,5	E12	B10	-
Thailand	1,6	1,7	E5	B7	25 million litres per day by 2022
Spain	0,5	2	Overall 6		0.1% from 2020
EU-28	4,7	12,4	-	-	0.2% by 2022, 1% by 2025; 3.5% by 2030

Table 2 shows the leaders of world production of liquid biofuels. The assessment of the structure of national policies of mandates for mixing reflects the industry trend and the prospect of further changes in the construction of fuel consumption by the transport sector. However, liquid biofuel producers' success is due to the introduction and other individual mechanisms to stimulate the production and consumption of liquid biofuels, consider the most significant of them, for individual leaders in the global biofuel market (Table 3).

The total amount of investment in liquid biofuels production decreased in the last decade, while RE's investment income almost doubled (Fig. 4). This fact explains the slowdown in sectoral growth in biofuel production and the shallow renewable energy level used in the global transport sector.

Despite the low level of investment support in the industry, there is still a significant increase in investment activity for some types of biofuels. Recently, increasing investor attention has focused on advanced biofuels technology, including HVO.

Table 3. The policy of the state stimulating the development of liquid biofuel production and its efficiency (based on [17,18]).

Co-unt-ry	Public policy	Efficiency
USA	The loan guarantee program is designed to support new innovative bioenergy facilities. Several programs have been created at the federal level that encourage increased production, biofuels, and the development of biomass supply logistics.	The United States provides 50% of world production of ethanol and 14% of biodiesel. Over the last decade, many experimental, demonstration, and commercial projects of 2nd generation biofuels have emerged.
Brazil	Tax benefits for producers and users of liquid biofuels. The quota for duty-free imports of ethanol is 600 million litres per year. Providing subsidies for producers of raw materials used in the process of biofuel production. Financial incentives for the development of 2nd generation biofuel production.	Brazil provides 26% of the world production of ethanol and 12% of biodiesel. Two commercial and one demonstration plant for cellulose ethanol production has been established. The possibility of joint processing of crude oil and vegetable oils is actively studied.
China	Producers of ethanol from non-food crops have the opportunity to receive tax benefits in the form of exemption from excise duty and VAT. Discounts on VAT for exporters of ethanol and biodiesel. The government provides a subsidy of \$ 0.07 per litre for cellulosic ethanol producers. China focuses on ethanol production.	In 2019, China produced 4 bln litres of ethanol and ranked third in the world in terms of ethanol production and consumption. The ethanol producers' support scheme often depends on the country's grain stocks. The use and production of biodiesel in the country is 0.2% of diesel fuel volume.
Germany	Various types of funding programs focus primarily on stimulating the production of advanced biofuels and, to a lesser extent, conventional biofuels. For example, “energy transition in the transport sector” no longer any unique counting of biofuels mechanism included in the national legislation.	In average, since 2007, ethanol's total production and use have grown annually by 10-12%, while annual biodiesel production remains relatively unchanged. Several demonstration research projects aimed at the production of advanced biofuels have been created.
India	The import of biofuels is banned. However, it is allowed for importing raw materials for biofuel production. State support aimed at stimulating the production of 2nd generation biofuels. Biofuel policy provides permission for foreign direct investment in the biofuel facility's equity in the amount of 100%.	The current share of biofuels in India's transport sector is approximately 1.2%. The percentage of mixing ethanol with gasoline is 2%, biodiesel – 0.1%. The effectiveness of state policy on the development of liquid biofuels is low. The main limiting factor in developing the liquid biofuels market is the lack of the required volume of raw materials.

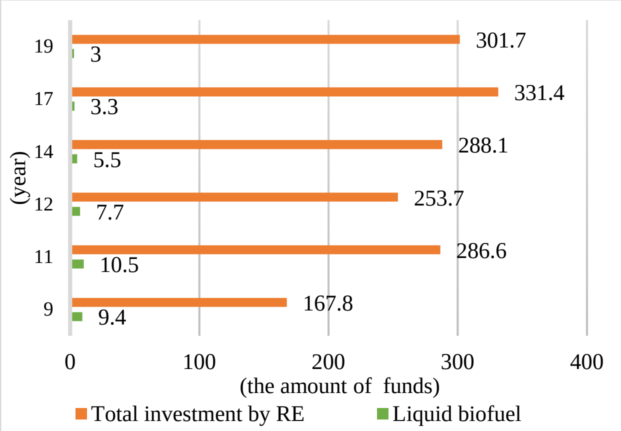

Fig. 4. New Investments by Technology, bln USD, (2009-2019) (based on [11]).

The growth of investment attention to the HVO is primarily due to a significant increase in demand for biofuels from heavy goods vehicles and aviation. According to REN 21, if the planned HVO projects are successfully implemented, the industry's global production capacity will triple to 22 bln litres annually.

It is worth noting that despite the prevalence of investor attention to HVO technology, this industry provides only 6% of biofuels, while biodiesel FAME 35%.

5 Paris Agreement and perspectives biofuels

The modern world market of liquid biofuels characterized by the dominant role of production and consumption of 1st generation biofuels; however, the need to produce new generation liquid biofuels are multiplying.

According to the International Energy Agency (IEA) forecasts, liquid biofuel production's growth rate would be 3% in the next five years. Simultaneously, to achieve the Paris Agreement's goals, the minimum amount of sectoral growth should be 10% by 2030. To comply with the SDS (sustainable development scenario aimed at achieving the goals set out in the Paris Agreement), world production and consumption of liquid biofuels should increase by three times by 2030 (to 298 Mtoe). However, given the current pace of biofuel production, most countries would not reach the required level provided for in the SDS (Fig. 5). It is also necessary to increase the pace of development of advanced biofuel consumption and the adoption of biofuels in aviation and marine transport to achieve these goals. Only sustainable biofuels have a place in the SDS [20].

The main limiting factor that slows down the global transport sector's greening is the lack of strong political support and insufficient development of technological innovations that would help reduce the cost of production of advanced biofuel.

Biofuel production in the US and EU countries lags far behind SDS rates. The increase in demand for biofuels in these countries is due to fuel mixtures containing bioliquids. Therefore, given the tendency to increase the efficiency of vehicles, and as a consequence, the decrease in fuel demand, the rate of increase in biofuel production does not change significantly. However, if countries change their market regulation policies to increase mandatory mandates for blending fuels, the share of liquid biofuels in the country's fuel and energy sector could grow[20].

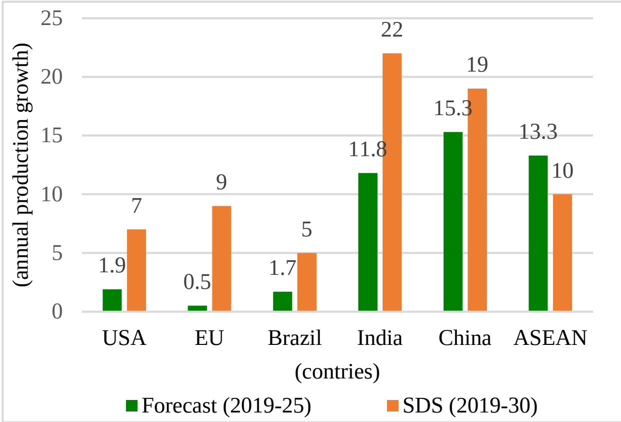

Figure 5. Prospect for key biofuel markets (% of growth) (based on [18])

In turn, Brazil is already one of the leading producers of biofuels. The country is also increasing its mandate for blending fuel mixtures and is actively increasing production capacity for ethanol production. However, according to IEA forecasts, the government would not achieve a pace of sectoral growth to meet the SDS goals [20].

Given the current state of biofuel production in India, the country would not achieve the SDS goals. However, recently the production of biofuels in the country is actively growing. The government also introduced a new regulatory policy in 2018. This policy expanded the authorization to use different types of raw materials that could be used for ethanol production. Moreover, it provided subsidies aimed at expanding production capacity for ethanol production. However, it stands to mention that the country focuses only on ethanol production[20].

In turn, China and the ASEAN countries could reach the SDS level while maintaining the current growth rate. China is actively increasing new production capacity for ethanol production and plans to introduce the E10 standard in 10-15 provinces.

It worth emphasizing that the main barrier that slows down the global transport sector's greening is the lack of strong political support and insufficient development of technological innovations that would help reduce the cost of production of advanced biofuel [20].

Recently, researchers have paid more attention to the introduction of Euro 7 (for cars) and VII (for heavy). The new Euro 7 emission standard is to enter into force in the EU in 2025. The planned Euro-7 standard provides for clear emission standards for vehicles from 2025. Thus, new vehicles will emit only 30 mg of NOx (nitrous oxide) per kilometre, and in the second scenario - only 10 mg per kilometre. The current limit is 60 mg for gasoline and 80 mg for diesel cars. Besides, CO2 limits should be sharply reduced to 300 or 100 mg, depending on the car category

[21]. The adoption of relevant legislation is expected to increase the transport sector's transition rate to the use of low-carbon and sustainable renewable fuels [22]. New realities open up great opportunities for the liquid biofuel industry, in particular new generation biofuels.

Conclusion

Several advantages of liquid motor biofuels produced from bioenergy raw materials testify to the prospect of their production against the background of depletion of oil reserves and global environmental challenges.

World production of liquid biofuels is growing every year, gaining more and more supporters among different countries. The global biofuel market is competitive and fragmented, with several well-known international players. The last trends of the leading countries in the organizational and economic mechanisms on stimulating the liquid biofuel industry indicate the prevalence of state support, namely in the production of advanced biofuels.

By regional segmentation, the global biofuel market can grow in North and South America, Europe, Asia Pacific (APAC), the Middle East and Africa (MEA). According to forecasts, North America will hold a leading position in the global market for liquid biofuels. Besides, high growth rates of liquid biofuel production will be observed in the EU, China, the United States and Brazil.

The obtained results showed that the level of investment in biofuel production remains relatively low. Therefore, it makes the transport sector one of the largest greenhouse gas emitters. The forecast on the industry's development and the assessment of the possibility to achieve the Paris Agreement goals indicates that most countries would not achieve the required levels of liquid biofuels production by 2030.

Predictive control of induction motor drive

Ihor Kozakevych[1,*], and *Kyrylo* Budnikov[1]

[1]Kryvyi Rih National University, Automatic Electromechanical Systems in Industry and Vehicles Department, 11 Vitalii Matusevych Str., Kryvyi Rih, 50027, Ukraine

Abstract. The work is devoted to the study of the possibilities of using the predictive torque control system instead of the currently widely used direct torque control system. Aspects of using the system of direct torque control of an induction motor are considered and it is found that its significant disadvantage is the variable frequency of semiconductor switches. As a further development of the direct torque control system, a predictive torque control system is analyzed, which contains blocks for estimating unmeasured state variables, as well as predicting the state of a dynamic system when applying possible control signals. The systems were compared by mathematical modeling in Matlab / Simulink.

1 Introduction

Recently, the vector control system and the direct torque control system have proved to be the main control systems for AC electric drives [1, 2]. The advantages of the latter include the ability to work without an angular velocity sensor on the shaft, simple structure and high dynamic quality control. At the same time, the main disadvantages of this system are the high level of torque ripple, which becomes especially sensitive when working at low angular velocity, as well as the presence of a variable switching frequency of power switches. A number of researchers' works in the field of automated electric drive are devoted to solving these problems. In [3], a modification of the direct torque control system was proposed, which is aimed at achieving a low level of torque ripples and ensuring a constant switching frequency of the power switches. In [4] the system of direct torque control with the involvement of neuro-phase technologies to achieve a low level of distortions of the motor current and its pulsations is investigated. In [5], a sliding mode system was used to implement sensorless control at very low angular velocities. In [6], the direct torque control system was supplemented by space-vector pulse-width modulation to obtain a constant switching frequency of the inverter switches. At the same time, it is easy to see that the further development of such systems requires more precision in controlling the values of stator flux coupling and torque. Therefore, currently predictive control systems for converters and electric drives are being actively developed [7].

Among such systems, the system of predictive torque control deserves special attention, which can be considered as an alternative to the system of direct torque control for electric drives with induction motors. To use such a system, it is necessary to use discrete models of the power converter and induction motor, and the values of stator flux and torque are considered as control variables of the system. The use of the mentioned discrete models allows to estimate and predict the values of stator flux linkage and torque, and further on the basis of these predictions the cost function is calculated, which allows to select the optimal control effect for the next discrete interval of the system. The synthesis of the cost function is carried out using weight coefficients that allow you to combine different sizes with each other and set priorities regarding their importance to achieve the desired control goal. Therefore, the quality of control of such systems depends very much on the choice of weight coefficients. Despite the fact that a number of publications have been devoted to the choice of weight coefficients [8, 9], this problem still remains relevant, as this step is important at the stage of synthesis of the electric drive control system.

2 Direct torque control system

The structure of the electric drive using the direct torque control system is shown in Fig. 1. In such a system, the induction motor is powered by a voltage-fed inverter. The task of the system is to provide the ability to independently control the values of the stator flux and motor torque by selecting the appropriate states of the inverter. As you know, a voltage-fed inverter is able to create 6 non-zero space voltage vectors, shifted by 60 degrees, as well as 2 zero voltage vectors. The system uses relay hysteresis torque and flux regulators, which allows to provide high dynamic control of the electric drive system, and expanding the width of the hysteresis allows to reduce the switching frequency of the inverter switches and, consequently, the power of losses in it.

The principle of direct torque control can be explained by considering the mathematical expression for the electromagnetic torque in the following notation:

$$T_e = \frac{3}{2} p \frac{L_m}{L_s L_r} |\boldsymbol{\psi}_s| \cdot |\boldsymbol{\psi}_r| \sin(\theta), \qquad (1)$$

* Corresponding author: aepigor@gmail.com

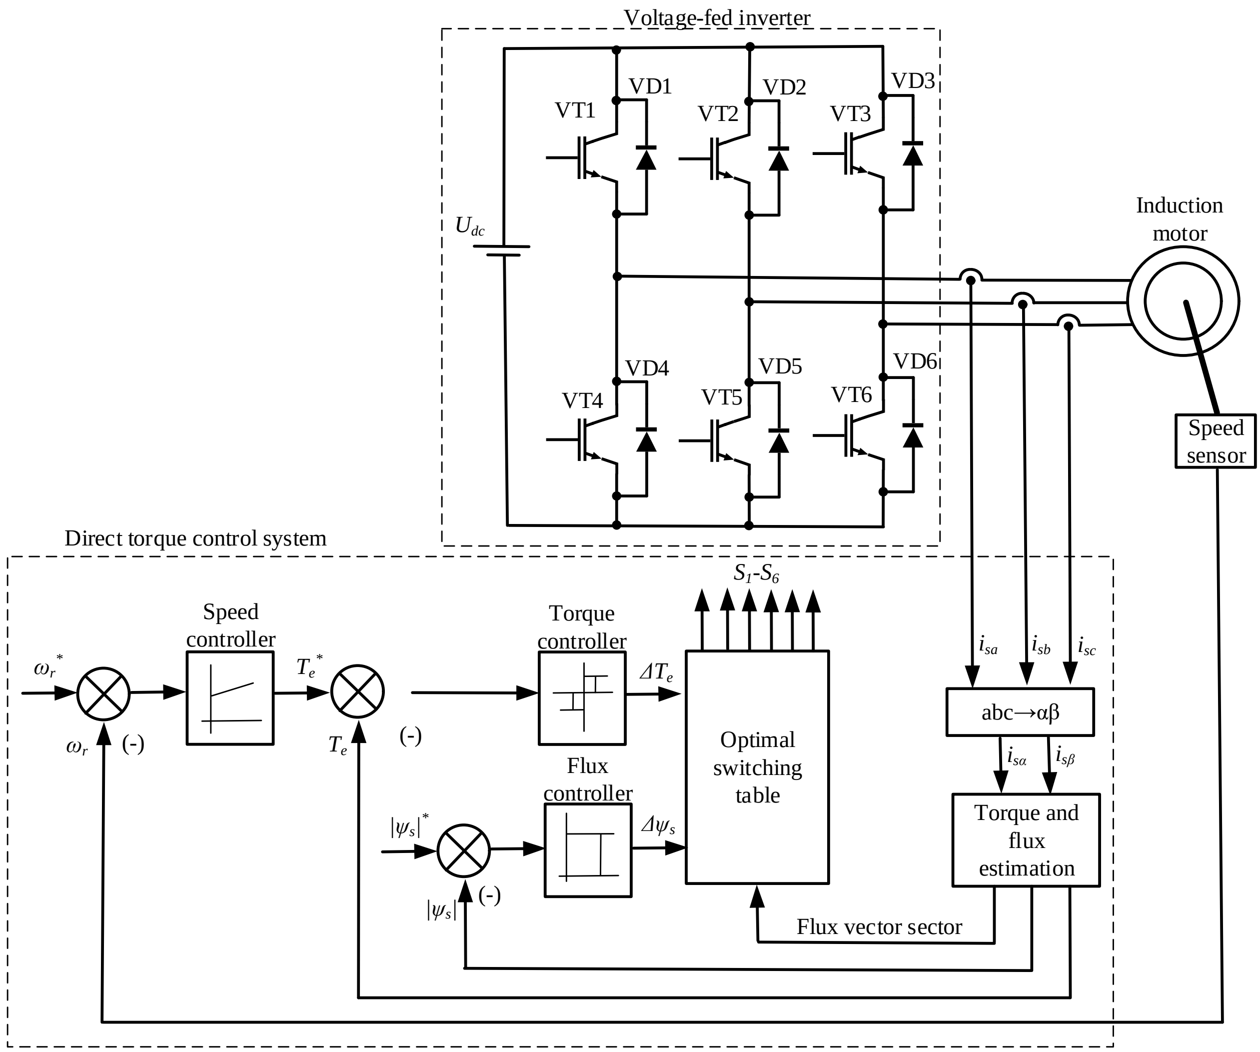

Fig. 1. Structure of direct torque control system.

where p – the number of pole pairs; L_s and L_r – inductance of the stator and rotor windings of the motor, respectively; L_m – mutual inductance of stator and rotor windings; $\boldsymbol{\psi}_s$ – flux linkage vector of the motor's stator windings; $\boldsymbol{\psi}_r$ – flux linkage vector of the motor's rotor winding; θ – angle between the flux linkage vectors of the stator and rotor.

It is believed that the stator flux vector reacts less inertially to the voltage applied to the motor windings, because the rotor time constant is significant. For simplicity, it is assumed that at one discrete interval of the system, the vector of flux linkage of the rotor is stationary. Therefore, the rotation of the stator flux vector in the direction of rotation leads to an increase in the value of the angle θ and increases the amount of torque. If the space voltage vector applied by the inverter causes the flux vector to rotate in the direction of convergence with the rotor flux vector, which will reduce the angle θ, the torque generated by the motor will decrease. Since the stator flux linkage, when the value of the active resistance of the motor stator windings is small, can be found by integrating the voltage applied to the motor, the selection of the appropriate inverter voltage vector also allows to control the stator flux value. Thus, the use of a direct torque control system allows independent control of torque and stator flux linkage. The selection of the appropriate voltage vector and the state of the inverter switches is carried out using the table of optimal switching, which is presented in Table. 1.

Table 1. Switching table of direct torque control system of induction motor drive.

$\Delta\psi_s$	ΔT_e	Sectors					
		1	2	3	4	5	6
1	1	U_2	U_3	U_4	U_5	U_6	U_1
	0	U_0	U_7	U_0	U_7	U_0	U_7
	-1	U_6	U_1	U_2	U_3	U_4	U_5
0	1	U_3	U_4	U_5	U_6	U_1	U_2
	0	U_7	U_0	U_7	U_0	U_7	U_0
	-1	U_5	U_6	U_1	U_2	U_3	U_4

3 Predictive torque control system

Predictive control systems for converters and electric drives are currently being actively developed. The principle of predictive control is to predict further changes in system state variables using a mathematical model of the system. In the next step, a certain optimization principle is used to compare possible options for changing the state of the system with each other in order to identify the most profitable in terms of achieving the ultimate goal of control. It is necessary to use a discrete model of the control object, which will allow you to predict changes in the state variable values.

The equations of electrical equilibrium of the stator circuits of the motor in a stationary frame of reference αβ have the following form:

$$\frac{d\psi_{s\alpha}}{dt} = U_{s\alpha} - R_s i_{s\alpha}; \quad (2)$$

$$\frac{d\psi_{s\beta}}{dt} = U_{s\beta} - R_s i_{s\beta}, \quad (3)$$

where $U_{s\alpha}$, $U_{s\beta}$ – projections of the stator voltage vector on the axis of the stationary coordinate system αβ; $i_{s\alpha}$, $i_{s\beta}$ – projections of the stator current vector on the axis of the stationary coordinate system αβ; R_s – active resistance of the motor stator winding; $\psi_{s\alpha}$, $\psi_{s\beta}$ – projections of the stator flux vector on the axis of the stationary coordinate system αβ.

Convert equations (2) and (3) into a discrete form using Euler's method:

$$\psi_{s\alpha}[n+1] = \psi_{s\alpha}[n] + U_{s\alpha}[n] \cdot \Delta t - R_s \cdot i_{s\alpha} \cdot \Delta t; \quad (4)$$

$$\psi_{s\beta}[n+1] = \psi_{s\beta}[n] + U_{s\beta}[n] \cdot \Delta t - R_s \cdot i_{s\beta} \cdot \Delta t, \quad (5)$$

where Δt is the discrete time of the system.

The obtained equation allows to calculate the flux linkage of the stator $\psi_{s\alpha}[n+1]$, which refers to the discrete step $n+1$, based on the value of the flux linkage of the stator $\psi_{s\alpha}[n]$, which refers to the previous discrete step n.

The components of the flux vectors of the stator and rotor can be recorded through the appropriate inductances and currents:

$$\psi_{s\alpha} = L_s i_{s\alpha} + L_m i_{r\alpha}; \quad (6)$$

$$\psi_{s\beta} = L_s i_{s\beta} + L_m i_{r\beta}; \quad (7)$$

$$\psi_{r\alpha} = L_r i_{r\alpha} + L_m i_{s\alpha}; \quad (8)$$

$$\psi_{r\beta} = L_r i_{r\beta} + L_m i_{s\beta}, \quad (9)$$

where $i_{r\alpha}$, $i_{r\beta}$ – projections of the rotor current vector on the axis of the stationary coordinate system αβ.

Since the rotor current is not a measurable value for motors with a short-circuited rotor, we get rid of its use through the combined use of equations (6) - (9):

$$\psi_{s\alpha} = \left(L_s - \frac{L_m^2}{L_r}\right) i_{s\alpha} + \frac{L_m}{L_r}\psi_{r\alpha}; \quad (10)$$

$$\psi_{s\beta} = \left(L_s - \frac{L_m^2}{L_r}\right) i_{s\beta} + \frac{L_m}{L_r}\psi_{r\beta}. \quad (11)$$

The dynamics of change of the components of the flux coupling vector of the rotor can be described by the following dependences:

$$\frac{d\psi_{r\alpha}}{dt} = -\frac{R_r}{L_r}\psi_{r\alpha} + \frac{L_m R_r}{L_r} i_{s\alpha} - \omega_r \psi_{r\beta}; \quad (12)$$

$$\frac{d\psi_{r\beta}}{dt} = -\frac{R_r}{L_r}\psi_{r\beta} + \frac{L_m R_r}{L_r} i_{s\beta} + \omega_r \psi_{r\alpha}. \quad (13)$$

where R_r – the active resistance of the motor rotor winding, ω – the angular velocity of rotation of the rotor.

Using the Euler method, the prediction of the stator current can be performed in accordance with the following dependencies:

$$i_{s\alpha}[n+1] = \left(1 - \frac{\Delta t(R_s L_r^2 + R_r L_m^2)}{L_r(L_s L_r - L_m^2)}\right) \cdot i_{s\alpha}[n] +$$

$$+ \frac{\Delta t(R_s L_r^2 + R_r L_m^2)}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} u_{s\alpha}[n] +$$

$$+ \frac{\Delta t L_m R_r}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} \psi_{s\alpha}[n] +$$

$$+ \frac{\Delta t L_m L_r \omega}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} \psi_{s\beta}[n]; \quad (14)$$

$$i_{s\beta}[n+1] = \left(1 - \frac{\Delta t(R_s L_r^2 + R_r L_m^2)}{L_r(L_s L_r - L_m^2)}\right) \cdot i_{s\beta}[n] +$$

$$+ \frac{\Delta t(R_s L_r^2 + R_r L_m^2)}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} u_{s\beta}[n] +$$

$$+ \frac{\Delta t L_m R_r}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} \psi_{s\beta}[n] -$$

$$- \frac{\Delta t L_m L_r \omega}{\Delta t(R_s L_r^2 + R_r L_m^2) + L_r(L_s L_r - L_m^2)} \psi_{s\alpha}[n]; \quad (15)$$

Prediction of the value of the electromagnetic torque can be obtained using the predicted values of the stator flux and stator current:

$$T_e[n+1] = \frac{3}{2} p \times$$

$$\times \left(\psi_{s\alpha}[n+1] i_{s\beta}[n+1] - \psi_{s\beta}[n+1] i_{s\alpha}[n+1]\right), \quad (16)$$

where p is the number of pole pairs.

The cost function is composed using the deviations of the torque value from the specified value and the deviation of the modulus of the flux linkage vector from the corresponding rated level:

$$c = |T_e[n+1] - T_e^*| +$$

$$+ w_\psi \left| \sqrt{\psi_{s\alpha}^2[n+1] + \psi_{s\beta}^2[n+1]} - |\boldsymbol{\psi}_s|^* \right|. \quad (17)$$

where w_ψ – a weighting factor that reflects the relative importance of flux control in relation to torque control. As the initial setting of this parameter it is advisable to use the following value:

$$w_\psi = \frac{T_{rated}}{\psi_{srated}}, \quad (18)$$

where T_{rated} – the value of the rated torque of the motor; ψ_{srated} – rated value of stator flux linkage.

The structure of the system of predictive torque control of an induction motor is presented in Fig. 2. By analogy with the previous system, the torque reference signal is formed by the PI controller, and the magnitude of the stator flux linkage when operating at a speed lower than the rated, usually set at the nominal level and attenuated when switching to higher nominal. Based on the measured values of motor current and voltage, the values of the torque and flux linkage of the stator are estimated, because the direct measurement of these values is difficult to implement. Based on the obtained equations, the values of motor torque and stator flux coupling are predicted by applying each of the eight possible voltage vectors generated by the voltage inverter. In accordance with equation (17) get eight values of the objective function, from which the minimum value is selected and in the next interval of discreteness of the system, the inverter applies to the motor a vector with a number corresponding to the obtained minimum value of the objective function.

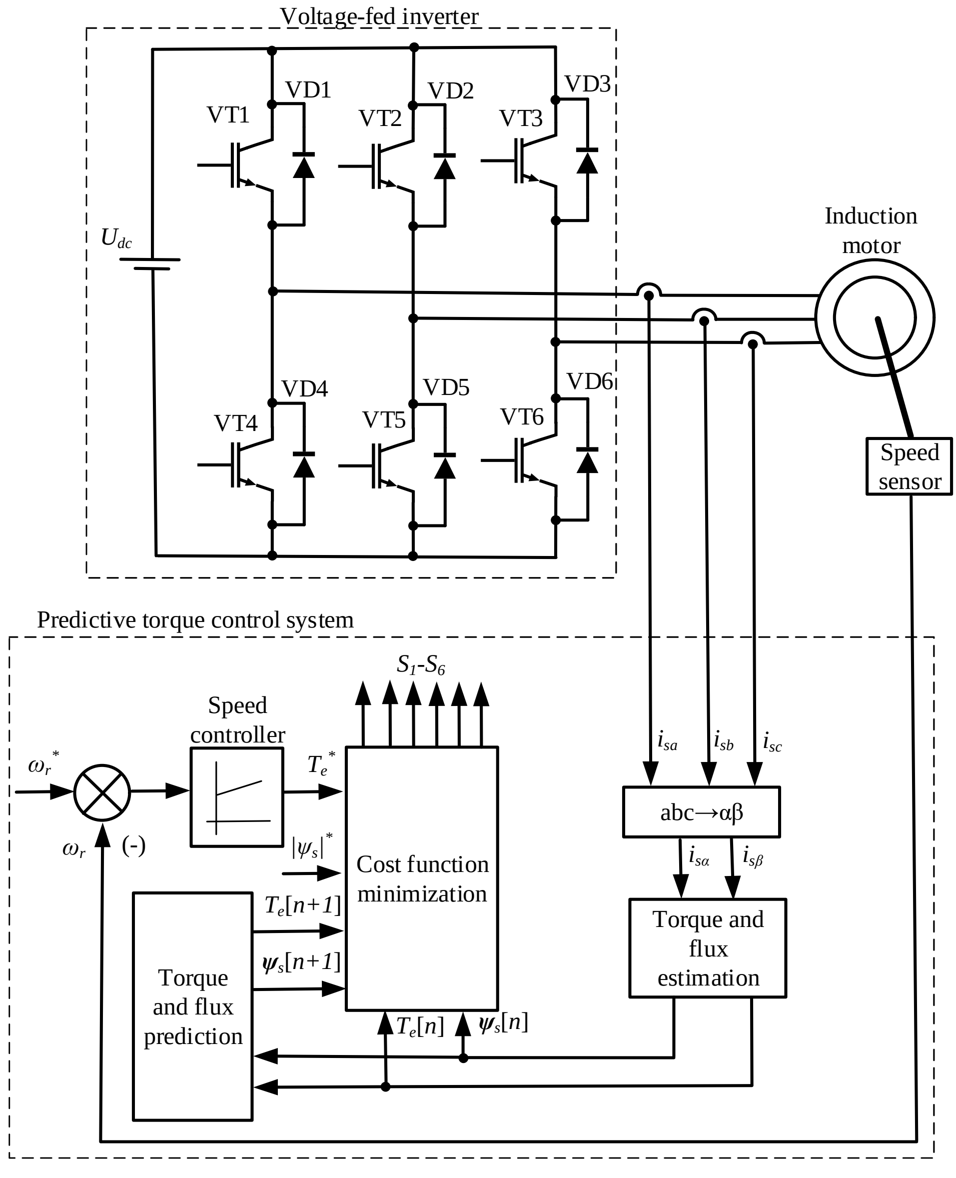

Fig. 2. Structure of predictive torque control system.

4 Simulation results

A mathematical model in the Matlab / Simulink environment was developed to analyze the predictive torque control system of an induction motor. The parameters of the engine used in the simulation are given in Table 2.

Fig. 3 shows a comparison of motor torques when using direct torque control and predictive torque control in steady state operation. The graphs show that the use of predictive control reduces the level of torque ripple.

Table 2. Switching table of direct torque control system of induction motor drive.

Parameter name	Parameter value
Rated power P_{rated}	75 kW
Number of pole pairs, p	2
Active resistance of the stator winding, R_s	0.035 Ohm
Active resistance of the rotor winding, R_r	0.021 Ohm
Leakage inductance of the stator winding, $L_{\sigma s}$	330 mH
Leakage inductance of the rotor winding, $L_{\sigma r}$	330 mH
Mutual inductance of stator and rotor windings, L_m	0.015 H

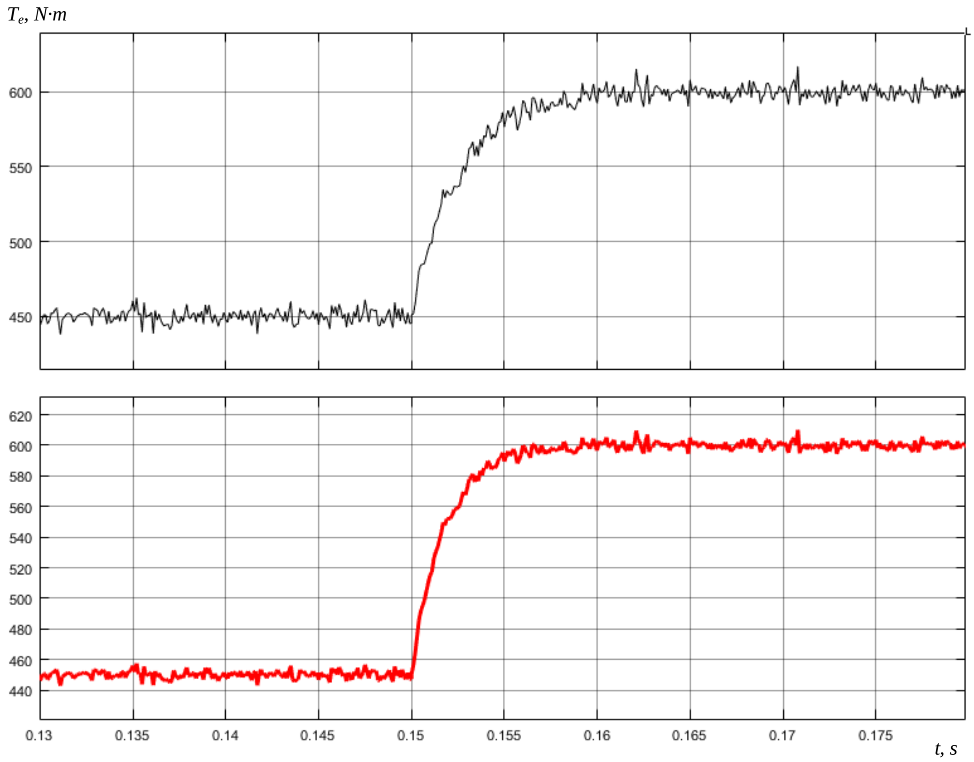

Fig. 5. Motor torque when load torque changes with direct torque control system (top) and predictive torque control system (bottom).

Conclusions

The paper considers the system of direct torque control and the predictive torque control system of an induction motor. The direct torque control system selects the voltage vector based on pre-calculated rules that allow to take into account the sector to which the stator flux vector currently falls, as well as the output signals of two relay hysteresis regulators - stator flux regulator and motor torque regulator. This structure allows this system to have a simpler structure compared to the vector control system, eliminating the need to use coordinate transducers. However, a significant disadvantage of the direct torque control system is the variable switching frequency of the keys and the presence of a noticeable torque ripple. A variant of predictive torque control of an induction motor is considered, which contains a discrete mathematical model for calculating the predicted values of stator current, stator flux and torque for the next step of the system discreteness. Since the number of voltage vectors generated by the voltage inverter is limited, it is possible to calculate the value of the objective function for each variant of the control effect. In the future, the choice of option that corresponds to the minimum value of this function. To compare the two systems, mathematical modeling was performed in the Matlab / Simulink environment, which showed that the use of predictive control reduces the level of torque ripple and improves the dynamic control of the electric drive. In the subsequent stages of research it is necessary to carry out the analysis of influence of deviations of parameters of the engine on indicators of system of predictive control.

Abstract. The paper deals with the problems of balancing the United Energy System of Ukraine caused by high renewable energy penetration and the impact of the COVID-19 pandemic on the energy sector. The paper analyses the trends in renewable energy development, the dynamics and structure of electricity consumption and export in pre-epidemic and epidemic periods and identifies the main challenges to operational security of the United Energy System of Ukraine. The methodical approach to improve the methodology for estimation of country's energy security level by considering the index of developing capacities for balancing the United Energy System of Ukraine is suggested. In addition, proposals have been made to reduce threats to the stable work of the United Energy System of Ukraine by putting into operation of energy storage capacities, promoting the development of мaneuvering renewable energy capacities, and implementation of other appropriate measures in this field.

Introduction

One of the important indicators that affects the energy security of any country is the stable operation of the energy system. The peculiarity of the United Energy System of Ukraine is deficit of мaneuvering energy capacities, as nuclear power plants cover about 50% of electricity demand in the country [1]. In recent years, this problem has been enhanced by putting into operation of renewable power plants, especially solar and wind ones, electricity generation based on which is unstable, as it is directly dependent on the season, time of day and weather conditions.

This issue has developed into the energy crisis in 2020. During the quarantine restrictions caused by the COVID-19 pandemic, the rapid growth of green electricity generation was compounded by the problem of declining domestic demand for electricity and limiting opportunities for its export [2]. This, in turn, has caused technical difficulties with integrating renewable electricity into the United Energy System of Ukraine and its balancing.

The purpose of this paper is to: 1) study of the main challenges for the operational security of the United Energy System of Ukraine caused by high renewable energy penetration and the impact of the COVID-19 pandemic on the country's energy sector; 2) improve the methodology for assessing the energy security of Ukraine by taking into account the level of development of capacities for balancing the United Energy System of Ukraine; 3) develop the recommendations on effective balancing the United Energy System of Ukraine taking into account the priorities for the transition to a carbon-free economy.

1 Features of Ukraine's United Energy System operation

The United Energy System of Ukraine is a set of power plants operating on conventional and renewable energy resources, main and distribution networks, which are united by a common way of production, transmission, and distribution of electricity [1].

The mode of the United Energy System of Ukraine is determined based on the balance of generation and consumption of electricity, repairs of power grids and generating equipment, as well as the possibility of emergency response in case of disconnection of generating equipment at power plants and main power lines. The balance between generation and consumption of electricity provided through the process of scheduling. The main dispatcher of the United Energy System of Ukraine is the National Power Company "Ukrenergo", which takes the necessary measures to prevent violations of its mode of operation.

Peaks in electricity consumption occur during the day and evening. Maneuvering capacities of thermal power

* Corresponding author: t.kurbatova@macro.sumdu.edu.ua

plants, hydropower plants, including pump storage power plants, are used for regulation and passage of peak loads.

Part of the capacities of hydropower plants is in the "hot reserve" – on idle, but heated steam generators and turbines are maintained nominal operating parameters, so they can be started in minutes. Today, the capacity of the "hot reserve" in the electricity generation of Ukraine is about 300-400 MW [1].

The balance between мaneuvering generating capacities and power plants that cannot maneuver quickly is one of the conditions for the stable functioning the United Energy System of Ukraine.

2 Challenges to the United Energy System of Ukraine caused by high renewable energy penetration and the COVID-19 pandemic

In recent years, the balance between мaneuvering and non-мaneuvering generating capacities in the United Energy System of Ukraine has been disturbed due to the dynamic putting into operation of renewable power plants, especially solar and wind ones, the generation of electricity based on which is difficult to predict (Table 1).

Table 1. Number and structure of renewable power plants put into operation in Ukraine in 2017-2019 [3, 4, 5].

Renewable power plants	2017	2018	2019
Solar power plants	3203	7806	22548
including solar power plants of private households	*3010*	*7450*	*21969*
Wind power plants	20	31	69
Biomass power plants	27	43	64
Small hydropower plants	137	149	157
Total	3387	8029	23111

As shown in Table 1, the number of renewable power plants in 2019 increased 6.8 times compared to 2017. The largest growth was shown by solar power plants, both in the business sector and the private households. The increase in the number of renewable power plants, therefore, contributed to the increase in the amount of electricity generated on their basis (Table 2).

Table 2. Dynamics and structure of electricity generation by renewable power plants in Ukraine in 2017-2019, million kWh [3, 4, 5].

Renewable power plants	2017	2018	2019
Solar power plants	737.4	1172	3235
including solar power plants of private households	*22.7*	*92*	*303*
Wind power plants	973.5	1180.2	2022
Biomass power plants	194.8	275.4	309
Small hydropower plants	212.5	241.6	242
Total	2118.2	2869.2	5808

According to Table 2, it can be concluded that the amount of electricity generated by renewable power plants in 2019 increased 2.7 times compared to 2017 and 2 times compared to 2018.

The predominance in the structure of generation of solar and wind energy is due to the maturity of these technologies. Global experience shows that most investors prefer to invest in these technologies. Thus, in 2018, solar energy accounted for 48.9%, wind energy – 47.2% of total new investments [6]. However, other countries, along with promoting these technologies development, pay considerable attention to the effective integration of such electricity into the national energy systems, but in Ukraine such measures have not been taken.

In 2020, this problem was exacerbated by the impact of quarantine restrictions caused by the COVID-19 pandemic, which contributed to significant reduction in domestic demand for electricity (Table 3).

Table 3. Dynamics and structure of electricity consumption in Ukraine for 9 months of 2017-2020, million kWh [7].

Consumer groups	9 months 2018	9 months 2019	9 months 2020
Total	89659.8	89553.9	86238.6
including:			
1. Industry	38655.3	38550.9	36493.5
including:			
Energy sector	2623.8	2533.4	2378.9
Metallurgical sector	22117.2	22063.4	20366.7
Chemical and petrochemical sector	2395.4	2702.2	3099.9
Machine-building sector	2972.0	2734.2	2256.6
Building materials sector	1681.1	1668.5	1676.9
Food and processing sector	3259.9	3294.6	3152.0
Other sectors	3606.0	3554.6	3562.4
2. Agricultural sector	2864.9	2778.0	2798.4
3. Transport sector	5090.7	4856.4	4117.0
4. Construction	691.1	711.1	669.9
5. Utility consumers sector	11357.5	11276.5	10289.1
6. Other non-industrial consumers	4975.3	5444.4	5264.6
7. Population	26024.9	25936.6	26606.1

As shown in Table 2, electricity supply to final consumers for 9 months of 2020 decreased by 3315.3 million kWh compared with 9 months of 2019. The decrease in consumption was observed in almost all consumer groups. The exception were the chemical and petrochemical sector, agricultural sector, and households. Adding to the above problems it was the reduction in electricity exports, as quarantine measures caused by the COVID-19 pandemic led to the reduction in electricity demand in importing countries, namely Hungary, Romania, Poland, and Belarus (Figure 1).

As can be seen from Fig. 1, starting from March 2020, the period of implementation of the lockdown due to the COVID-19 pandemic, electricity export declined sharply, and only in July began to show growth with positive dynamics. However, in September it was still 1.6 times less than in March 2020 [5].

The above trends have caused the problem of effective balancing the United Energy Systems of Ukraine, violating the equality of electricity supply and demand. To solve this problem, the government has decided to shut down several power units of nuclear power plants in the country [8]. This choice was caused the fact that nuclear power plants cannot maneuver their capacity, and the dynamic growth of renewable energy requires the flexibility of the energy system. The decision to limit the green electricity generation was not made because according to Ukrainian law, the state has obligations to: 1) purchase the total amount of green electricity by feed-in tariff until 2030 [9]; 2) increase the share of green electricity in the total energy mix, in the framework Ukraine’s membership in the European Energy Community; 3) achieve strategic goals for renewable energy development, specified in the Energy Strategy of Ukraine until 2035 [10].

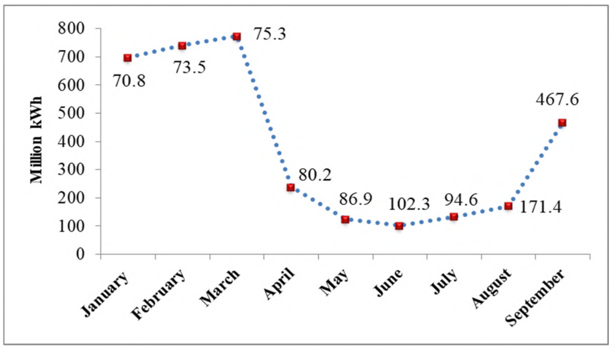

Fig. 1. Dynamics of electricity exports for 9 months of 2020, million kWh [11].

It should be noted that nuclear power plants generate the cheapest electricity in country (580 UAH / MWh), while electricity from renewable energy sources is purchased at the feed in tariff that is one of the highest in Europe (the average feed-in tariff for all renewable energy technologies represented on the Ukrainian market is 4705 UAH / MWh) [12]. It has led to a significant increase in the weighted average unit cost of electricity and, as result, to increasing in electricity prices for households and industry. To partially reduce the effects of rising electricity prices, the government has decided to reduce the feed-in tariff by 7.5% for wind farms and 15% for solar power plants. It is predicted that it will provide savings of about 6 bln UAH each year until the end of the period to support scheme for renewable energy promotion based on feed-in tariff in 2030 [13]; however, at the same time, it will worsen the investment climate in the renewable energy sector.

3 Improving the methodology for assessing the energy security of Ukraine

Unstable functioning the United Energy System of Ukraine is a direct threat to both energy and economic security of the country, so the indicator of development of capacities for balancing the energy system should be included in the calculation of the integrated indicator of energy security.

Today, the level of energy security of Ukraine is determined based on the Guidelines for calculating the level of economic security of Ukraine, approved by the order of the Ministry of Economic Development and Trade of Ukraine No 1277, 29.10.2013 [14]. According to [14] the integrated indicator of energy security is calculated based on 10 indicators, namely:

− the share of own sources in the balance of fuel and energy resources of the state, %;

− the level of import dependence on the dominant resource in the total supply of primary energy, %;

− the share of fuel import from one country (company) in the total amount of its import, %;

− depreciation of fixed assets of the fuel and energy complex, %;

− the ratio of investment in the fuel and energy sector to gross domestic product, %;

− energy intensity of gross domestic product, kg of fuel equivalent / UAH;

− natural gas reserves, months of consumption;

− coal reserves, months of consumption;

− the share of renewable energy resources in the total supply of primary energy, %;

− the share of losses in the transportation and distribution of energy, %.

It is worth noting that the capacities for balancing the United Energy System of Ukraine include maneuvering power plants and energy storage systems.

Thus, the indicator of development of capacities for balancing the United Energy System of Ukraine can be calculated by the formula:

$$I_b = \frac{\sum MP_i + ES}{\sum PP_i}, \qquad (1)$$

where I_b – index of development of capacities for balancing the United Energy System of Ukraine; MP_i – installed capacity of the *i*-type of maneuvering power plants, *ES* – installed capacity of the *i*-type of energy storage systems, MW; EP_i – installed capacity of the *i*-type of power plants in the United Energy System of Ukraine, MW.

The optimal value of the above index is reached at values close to unity. In this case, the maximum level of development of energy capacities for balancing the United Energy System of Ukraine is provided, which has a positive effect on increasing the level of energy security of the country.

It should be noted that at present balancing the United Energy System of Ukraine is carried out by thermal power plants and hydropower plants (including pump storage power plants). For this purpose, it also can be used combined heat and power plants and biopower plants. At the same time nuclear, solar, and wind power plants are not flexible and can be used for balancing energy system. The dynamics of the installed capacity of power plants in the United Energy System of Ukraine in 2017 - 9 months of 2020 are shown in Table 4.

The data presented in Table 4 show significant increase in the installed capacity of solar and wind power plants that worsens the balance between flexible and non-flexible power plants and threatens the stable functioning the United Energy System of Ukraine. These risks can be reduced by implementing several measures, which are discussed in more detail in the next section.

Table 4. Installed capacity of power plants in the United Energy System of Ukraine in 2017 - 9 months of 2020, MW [15, 16, 17, 18].

Power plants in the United Energy System of Ukraine	Installed capacity, MW			
	2017	2018	2019	9 months 2020
Thermal power plants	24565	21842	21842	21842
Combined heat and power plants	5972.3	6099.5	6097	6070
Hydropower plants (including pump storage power plants)	6228.7	6170.2	6520	6300
Biopower plants	96.9	97.5	170	177
Nuclear power plants	13835	13835	13835	13835
Solar power plants	758.4	1388.3	4925	4938
Wind power plants	328.4	532.8	1170	1071

4 Measures for effective balancing the United Energy System of Ukraine

A few measures can be used for effective balancing the United Energy System of Ukraine, namely: introduction of additional flexible capacities of conventional power plants, promotion of development of flexible renewable power plants, installation of energy storage systems, import of electricity from other countries, introduction of more accurate forecasting methods, responsibility for imbalance, electricity demand management, etc. [19].

Balancing energy system by existing fossil fuels power plants and construction of new ones is the least appropriate in terms of considering the priorities for the transition to a carbon-free economy.

In should be noted that currently Ukraine holds the leading position in the world for energy intensity of gross domestic product and it is included to 30 world countries, which are the largest polluters with CO_2 emissions due to burning fossil fuels [20]. It is an energy sector takes the first place for CO_2 emissions among other sectors of national economy in Ukraine: its share was about 76% of total CO_2 emissions during the last years.

Besides, Ukraine has a commitment to reduce greenhouse gas emissions by 40% from 1990 level by 2030 and by 70% by 2050 under the Paris Climate Agreement (Figure 2) [21].

The construction of new power plants based on fossil fuels for this purpose is impractical not only from environmental point of view, but also from economic one. Thus, the costs of electricity generation by solar photovoltaic plants and onshore wind plants decreased by 82% and 39%, respectively, compared to 2010. More than half of the renewable power plants put into operation in 2019 achieved lower electricity generation costs than fossil fuel power plants [22].

Partly improve the situation with balancing the United Energy Systems of Ukraine it is possibly by regulation of construction of new renewable power plants under the new support scheme for renewable energy promotion – the green auctions.

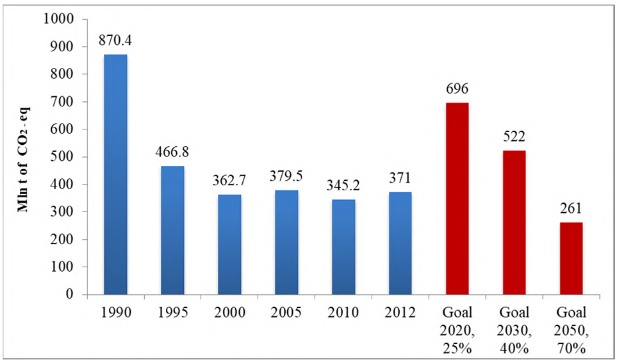

Fig. 2. Greenhouse gas emissions in Ukraine in 1990-2012 (million tonnes of CO_2 eq) and targets for 2020-2050 (%) [22].

This mechanism is designed to identify renewable power projects that will receive state support for electricity generation. Green auctions based on following: the winner is the investor who offers the lowest price for green electricity. The starting price of bidding is the rate of the feed-in tariff established by the Ukrainian legislation. The winner gets the opportunity to build new renewable power plant and sell electricity at a price determined at the auction for 20 years from the date of commissioning of the power plants [23].

Under this mechanism, the government sets annual support quotas for the next five years. The size of quotas determines how many new renewable power capacities the state is ready to support. Quotas will be calculated in accordance with Ukraine's international obligations, Energy strategy of Ukraine, conformity assessment of generating capacities, etc.

The total support quota is divided into three lots – solar, wind and other renewable energy sources. Competition at green auctions takes place between projects in one category. The share of quotas for each category cannot be less than 15%. It should be noted that the legislation also provides for the possibility of conduction of technology-neutral auctions [25].

Green auctions are a market mechanism; this is its main advantage over the feed-in tariff. Competition allows to determine a fair price for green electricity, that will be more beneficial for the state and final consumers.

The start of green auctions, which would legally limit the number of renewable power plants, was planned in 2020, but was postponed due to the lack of annual quotas determining the total capacity of renewable energy projects that claims the feed-in tariff [24].

It should be noted that within the framework of this mechanism it is reasonable to introduce additional incentives aimed at promoting the development of hydropower and biopower plants. In addition to the advantages associated with the stability of electricity generation based on them, the ability to maneuver capacity, the electricity generation cost based on such power plants is much lower compared to solar and wind ones that, in turn, will put less pressure on the final consumers.

Financial liability for electricity imbalances, when producers and consumers pay for an inaccurate forecast, can partially improve the situation with balancing the energy system. Although its introduction does not increase the flexibility of the energy system, it encourages market participants to build balancing capacities or use more accurate systems to forecast electricity generation.

This approach is already provided for by the amendments to the Law of Ukraine "On the Electricity Market" [25]. Thus, according to [25] producers are obliged to bear financial responsibility for the imbalance of electricity, in case of non-compliance with the hourly schedules of its transmission. For producers of electricity from renewable energy resources, this legislative norm will take effect from January 1, 2021 – for power plants put into operation after April 2017, which are part of the balancing group of producers at the feed-in tariff. It is 10% of the cost of settling the imbalance and will grow by 10% annually.

Another requirement regarding reimbursing the cost of the imbalance to 31 December 2029 is the occurrence of conditions when the deviation of the actual hourly electricity supply from the hourly schedule exceeds 20% for wind farms, 5% – for small hydropower plants, and 10% – for solar power plants [26].

The most promising option for balancing the energy system in the conditions of rapid development of renewable energy and instability of electricity demand is the development of energy storage facilities.

Energy storage systems have several advantages because they allow [27]:

– to regulate the generation and consumption of electricity, accumulating its surplus in the least necessary time for consumers and giving it to the network when demand exceeds supply;

– to avoid financial responsibility for imbalances in case of non-fulfillment of hourly schedules of electricity transmission;

– increase the security of electricity supply in case of emergencies. when the electricity generation at power plants is impossible. In such cases, energy storage systems will be able to provide an uninterrupted supply of electricity for a certain period.

To date, no energy storage system has been installed in Ukraine. The first projects to build a network of energy storage facilities with capacity of 220 MW are planned to be implemented by the National Power Company "Ukrenergo" together with the European Bank for Reconstruction and Development and the International Finance Corporation within the framework of the signed memorandum in 2019 [28]. However, large-scale implementation of energy storage systems requires the formation of a legal framework and the introduction of motivational mechanisms under new or existing schemes supporting the renewable energy development.

It should be noted that above measures should be considered in conjunction with other ones that may have a positive impact on the effective integration of green electricity into the United Energy System of Ukraine. Such measures include: connection of Ukraine's energy system to the grid of the European Union with a permit to import electricity [29]; introduction of demand management mechanisms, when consumers are actively involved in balancing the grid, for example, charging electric cars in moments of excess electricity [29]; development of decentralized energy systems based on renewable energy resources [30, 31], as a large number of geographically spaced renewable power plants will reduce the unevenness of the electricity production schedule and increase the flexibility of the grid.

Conclusions

The COVID-19 pandemic has become a global determinant that has had a significant negative impact on Ukraine's energy market. One of the consequences of the quarantine restrictions caused by the COVID-19 pandemic for the Ukrainian energy market was a decrease in domestic demand for electricity and a reduction in electricity export. Against the background of the growing share of green electricity in final energy consumption, these problems have escalated into an energy crisis and created challenges to the operational security of the United Energy System of Ukraine. This leads a revision of the state policy on the renewable energy development, implementation of appropriate measures to increase the flexibility of the energy system and on their basis improving the current methodology for calculating the country's energy security. The main such measures include the development of мaneuvering energy capacities and electricity storage systems. These measures can be strengthened by the implementation of a number of secondary measures, which are described in this paper.

The research has been supported by the National Research Foundation of Ukraine under the projects "Formation of economic mechanisms for sustainable development of renewable energy in the conditions of global and local threats to energy security of Ukraine" (No. 2020.01/0135) and "Stochastic modelling of road map for harmonizing national and European standards for energy market regulation in the transition to a circular and carbon-free economy" (No. 2020.02/0231).

Abstract. The principal of identification of isolation workability in relation to a ground was proposed. It is based on the electrosafety criteria usage and a minimum current flow to a ground. The conditions of workability of isolation of distribution network is calculated in look of changes of isolation workability restrictions in relation to regulations and standards. A mathematical model for the calculation of isolation workability in a look of a relation of workability indicators to the isolation parameters according to a ground. By analyzing the adequacy it as set that introduced formed models assumptions result in the appearance of a method error to 3,5 %.

1 Introduction

For the workability conditions determination of any object or system two ways can be used the first way for the object diagnostics (OD / DO) wish mostly overhead homogeneous structure of elements, that have a small amount of parameters that can be directly calculated first are theoretically researched for the selection of items of a technical condition (TC). Based on certain criteria's that should be necessarily previously noted, the analysis of possible of OD should be held by its control. Data that forms a diagnostic model of OD forms the workability conditions of OD. The checking of informative evaluation of a chosen complex of controlled items should be done.

According to another approach the previously chosen controlled items are used, that can describe TC of diagnostic object. Then for the DO the amount of experimental researches is made for the setting of sensitivity impact on a chosen complex of items on a technical condition of an object. The next stage contains she mathematical model of a change description of TC and then statistical reference of data basis being formed or neuron network that gives the opportunity of identify object TC according to the result of chosen items control. Given method is used in cases, that theoretically can`t explain the ability of controlled items to show TC through the difficulty of DO. Specifically, the workability conditions of DO can be formulated on the basis of analysis of theoretically formulated model or can be get experimentally [1].

The most unreliable part of network distribution is a overhead power lines (OPL) [2-4] where in a from of isolation the glass, porcelain and recently polymeric isolators are used. Isolators OPL are by direct impact of aggressive environment, which reveals in a look of a contamination of isolators top by dust, salt compounds that while hydrated cause the formation of leading on the top of isolator in accordance with current flow to the ground [5-10].

The determination of isolation workability in conditions of exploitation is more complicated because of the absence of precise quantitative methods of impact factors evaluation that worsen the isolation condition. That factors are the aging isolation process, hydration, contamination, mechanical impact, overstrain, corrosion etc. That`s why for the TC isolation control is practically used by average electrical items: neutral bias voltage, the tangent of the dielectric loss angle, common active resistance in relation to a ground, current and resistance zero sequence, phase conductivity according to a ground. [11-12].

To solve the calculation problem of isolation workability IW it is proposed to take precise and understandable for the isolation workability IW calculation. As such criteria safety operation conditions of isolation equipment from current flow to the ground that that form through the defects of isolation damages should be used as such criteria.

The aim of the study is the determinations of conditions of isolation workability of network distribution in relation to a ground by the technical conditions evaluation of isolation through the safety criteria`s and a minimum loss of electrical current from the current flow to the ground.

2 Research result

To gainthe set goal the following algorithms is proposed. The first step is to explain the criteria`s for the isolation workability conditions determination that should the multiple TC isolation divide into two submultiples of workable condition and unworkable condition.

* Corresponding author: vmkytin@gmail.com

The second stage is to determine the workability conditions. DN isolation to a ground should be looked upon as a whole integral object of technical condition that is described as the group parameter change-active phase conductance DN in relation to a ground. The item selection of technical isolation condition should be ground on correspondence analysis the whole items complex, that in one way or another characterize the processes of isolation technical conditions change through the chosen criteria`s of TC isolation evaluation: safe usage DN and economical functioning. [13].

The main reason of isolation DN TC change is from isolated neutral is damage in relation to a ground, that`s why it is known that technical condition of sub phases isolation does not largely influence on its common TC. And its influence can be unnoticed. The phase unity in relation so a ground (C_a, $C_в$, C_c) depends on constructive network parameters and that's why their numbers are considered as constants. Small increase of common volume is observed only by isolator top hydration. Active isolation conductance in relation to a ground (q_a, q_b, q_c) can be changed in a rather wide range of significations. These changes characterize the process of formation of isolation damages. It`s main reason is the formation of shunting connections within network phases and ground.

Two boundary processes of TC are isolation change determined:

1. Symmetrical increase of active conductance's of isolation phases in relation to a ground, as a result of hydration and contamination of isolators top.
2. Non-symmetrical major increase of active conductance of certain phases in relation to a ground, as a result of appearance of shunting connections in them with the ground.

As we know [14] there is a standard in Ukraine in accordance with which current that can flow through a human body is restricted by the number 50 Hz, a magnitude no more than 6MA within the continuous protection work from the single-phase earth closure that is no more than 1s.by calculating the voltage and current though a human body it is modeled in electrical chain by a resistor with the resistance in a continuous protection act from SPEC to 1s - kOhm, more 1s – 6 kOhm. So, for the explanation of safety criteria of operation, indicator of isolation damage, that has a connection with the isolation damaging process and current through a human body that appears in the process should be introduced. Such an indicator can be current in shunting connection, created by a person with his touch to a current conducting part of electro setting. For the explanation of the choice of a taken indicator a special model of appearance of isolation damages should be built and considered. [15].

According to another criteria, it`s obvious that, the main way of economical functioning of network distributions is losses in the process of transmission of electroenergy. The instant characteristic is active power of electroenergy loss of the current flow to the ground (ΔP_{iz}). It can be considered as a way of economical functioning of isolation DN and according to the indicators of workability in a use of this criteria.

As an explanation of electrosafety criteria let`s look at the case when human touch appears in grounded parts of electrosetting (body, carcass, metallic construction). (Fig. 1),

where r_a, r_b, r_c,- active isolation phase resistance DN;

C_a, C_b, C_c - volumes of certain phases in relation to a ground;

r_1, L_1 – parameters of transformer substitute scheme of voltage (TV), isolation control;

Z_N– equivalent resistance load ;

r_l –human body resistance, (r_h *=6 kOhm*[16]),

R_g – grounded equipment resistance,

r_d– additional transitional resistance.

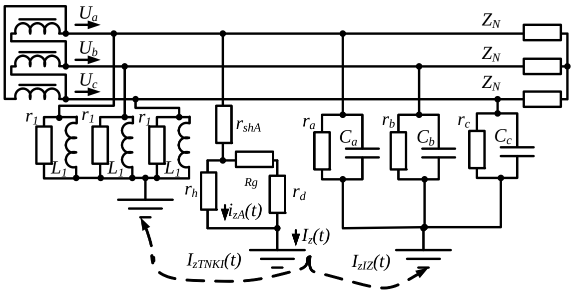

Fig. 1. Backup scheme for the description of a process of shunting connection appearance and human touch to the grounded elements electrosetting.

For the modelling of the most unfavorable case let`s consider that isolation damage happens in electrosetting with the simplest way of grounding. And additional transitive resistance of current flow to the ground is approximately the same as the wire that fell on the ground [17]and thus in the place of spread on the ground it approximately eques 100 Ohm for the raw soil. For the most unfavorable case let`s consider that the damage appears simultaneously in 2 different phases and human touch happens in a most damaged place of an isolation and current (i_{zA}), flows in a human body and it should not be more than 6 mA.

For that conditions limit values of workability conditions of an isolation can be calculated as:

$$\begin{cases} I_{z\mathrm{A}} = U_A \dfrac{g_{sh\mathrm{A}} \cdot g_h}{g_{sh\mathrm{A}} + g_h + g_g} \le 6 \cdot 10^{-3}\mathrm{A}; \\ I_{zB} = U_B \dfrac{g_{shB} \cdot g_h}{g_{shB} + g_h + g_g} \le 6 \cdot 10^{-3}\mathrm{A}; \\ I_{zC} = U_C \dfrac{g_{shC} \cdot g_h}{g_{shC} + g_h + g_g} \le 6 \cdot 10^{-3}\mathrm{A}. \end{cases} \quad (1)$$

where U_A, U_B, U_C – voltage phase A, B,C in relation to a ground (active items);

g_{shA}, g_{shB}, g_{shC} – shunting connection transmission appeared damages in certain phase;

g_l- human body transmission that equally ($g_h = 1/ r_h – 1/(6{\cdot}10^3)$) ;

g_3 = ground transmission that is calculate das ($g_g = 1/ R_g +1/ r_a$, where R_g – nominal resistance of grounded gear, that should not be more than 10 Ohm; r_d– additional transmission resistance of a ground).

Shunting connection transmission if for different can be calculated in a way of measuring in active phases in relation to a ground in the primary time moment (r_{a0}, $r_{в0}$, r_{c0}), for example, after putting to a work of electrosetting and its current repairmen and also these resistances calculation in any time moment (r_a, $r_в$, r_c) and their further comparison with the primary numbers and formulas:

$$\begin{cases} g_{shA} = 1/r_a - 1/r_{a0} - 1/r_S\,; \\ g_{shB} = 1/r_b - 1/r_{b0} - 1/r_S\,; \\ g_{shC} = 1/r_c - 1/r_{c0} - 1/r_S\,, \end{cases} \quad (2)$$

where r_s – symmetric reduce of isolation resistance in relation to a ground as a result of hydration of isolators top in a time of atmospheric precipitations that can be calculated as:

$$r_s = Min(r_{a0} - r_a); (r_{b0} - r_b); (r_{c0} - r_c)\,. \quad (3)$$

Stream usage in shunting connecting in a way of technical condition isolation item and a formation on a basic of these conditions of isolation workability (1) lets restrict the isolation workability condition multiples, based on equipment usage conditions.

Voltage in phases in a relation to a ground also depends on the isolation parameters

$$\begin{cases} U_A = I''\sqrt{\left[g_b + g_c + \frac{\omega}{\sqrt{3}}(C_c - C_b)\right]^2 + N}; \\ U_B = I''\sqrt{\left[g_a + g_c + \frac{\omega}{\sqrt{3}}(C_a - C_c)\right]^2 + M}; \\ U_C = I''\sqrt{\left[g_b + g_a + \frac{\omega}{\sqrt{3}}(C_b - C_a)\right]^2 + K}; \\ I'' = \frac{1{,}5\ \cdot U_f}{\sqrt{(g_a + g_b + g_c)^2 + (\omega(C_a + C_b + C_c) - B_L)^2}}; \\ N = \left[\frac{g_b - g_c}{\sqrt{3}} + \omega(C_b + C_c) - \frac{2B_L}{3}\right]^2; \\ M = \left[\frac{g_c - g_a}{\sqrt{3}} + \omega(C_a + C_c) - \frac{2B_L}{3}\right]^2; \\ K = \left[\frac{g_a - g_b}{\sqrt{3}} + \omega(C_b + C_a) - \frac{2B_L}{3}\right]^2, \end{cases} \quad (4)$$

where U_f – network distribution phase voltage;

ω- angle frequency DN;

C_A, C_B, C_C – volumes of certain phases in relation to a ground;

g_A, g_B, g_C– active transmission network phases in a relation to a ground;

B_L – sum reactive transmission of all inductive elements set to DN in a relation to a ground (transformer volume winding to the isolation control ZNOM , NTMI type and also arc extinguishing reactors and resonant grounding neutral devices): ($B_L = 3/\omega(L_{TNKI\sum 1} + L_{DGR} + L_{PRZN})$), thus, the winding induction TNKI is considered as linear items (for the state work regimes in a network).

Take (4) in an equation (1) we get mathematical model for the workability calculation using mentioned above criteria's.

Using safety criteria's of usage of mathematical model for the isolation workability calculation looks as:

$$\begin{cases} I_{gA} = I'' \cdot g_{shA} \cdot g_h / (g_{shA} + g_h + g_g) \cdot \sqrt{G_{A'} + G_{A''}}; \\ I_{gB} = I'' \cdot \frac{g_{shB} \cdot g_h}{g_{shB} + g_h + g_g} \cdot \sqrt{G_{B'} + G_{B''}}; \\ I_{gC} = I'' \cdot \frac{g_{shC} \cdot g_h}{g_{shC} + g_h + g_g} \cdot \sqrt{G_{C'} + G_{C''}}; \\ G_{A'} = \left[g_b + g_c + \frac{\omega}{\sqrt{3}}(C_c - C_b)\right]^2; \\ G_{A''} = \left[\frac{g_b - g_c}{\sqrt{3}} + \omega(C_b + C_c) - \frac{2B_L}{3}\right]^2; \\ G_{B'} = \left[g_a + g_c + \frac{\omega}{\sqrt{3}}(C_a - C_c)\right]^2; \\ G_{B''} = \left[\frac{g_c - g_a}{\sqrt{3}} + \omega(C_a + C_c) - \frac{2B_L}{3}\right]^2; \\ G_{C'} = \left[g_b + g_a + \frac{\omega}{\sqrt{3}}(C_b - C_a)\right]^2; \\ G_{C''} = \left[\frac{g_a - g_b}{\sqrt{3}} + \omega(C_b + C_a) - \frac{2B_L}{3}\right]^2. \end{cases} \quad (5)$$

The power of electroenergy loss from the current flow to the ground can be calculated using the information about power and active transmission network phases in a relation to a ground

$$\begin{cases} \Delta P_{iz\sum} = \Delta P_{izA} + \Delta P_{izB} + \Delta P_{izC}; \\ \Delta P_{iz\sum} = U_A^2 \cdot g_a + U_B^2 \cdot g_b + +U_C^2 \cdot g_c. \end{cases} \quad (6)$$

A gotten number of power loss in isolation ($\Delta P_{iz\sum}$) is compared to normative (ΔP_{iz}^{norm}), that can be calculated, having such technical data about a network as a type (OL or CL) common length L, nominal volume and cable type preferable, according to a described method in [18]:

$$\Delta P_{iz\sum} \leq \Delta P_{iz}^{norm}. \quad (7)$$

Thus, over normative power isolation can be calculated as restriction on its number for the formation of the workability conditions. Thus, the taken restrictions can be separated for different phases:

$$\Delta P_{izA} \leq \Delta P_{iz}^{norm}/3\,;$$
$$\Delta P_{izB} \leq \Delta P_{iz}^{norm}/3\,;$$
$$\Delta P_{izC} \leq \Delta P_{iz}^{norm}/3.$$

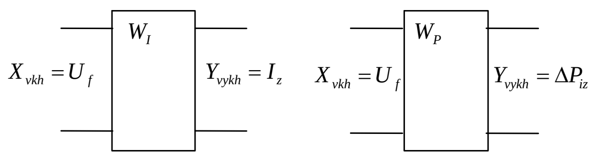
According to a method [18], there are few states of environment, where the researches has been alone (LvivORG-RES) and has been got the normative isolation power loss numbers. They are: 1) rain, wet snow, drizzle; 2) fog; 3) dew, no precipitation. So, for the calculation of isolation workability DN calculation should first calculated normative power loss in isolation for those three states of environment and only after that compare the factial number of power loss in isolation with the normatives for the certain hydration level of environment that should be controlled. Using the economical criteria's of mathematical model functioning for the isolation workability calculation looks:

 https://doi.org/10.1051/e3sconf/202128005008

$$\begin{cases} \Delta P_{iz\mathrm{A}} = I'''(N' + M'); \\ \Delta \mathrm{P}_{\mathrm{iz}B} = I'''(N'' + M''); \\ \Delta \mathrm{P}_{\mathrm{izA}} = I'''(N''' + M'''); \\ I''' = \dfrac{2{,}25 \cdot U_f^2 \cdot g_a}{(g_a + g_b + g_c)^2 + (\omega(C_a + C_b + C_c) - B_L)^2}; \\ N' = \left[g_b + g_c + \dfrac{\omega}{\sqrt{3}}(C_c - C_b\right]^2; \\ M' = \left[\dfrac{g_b - g_c}{\sqrt{3}} + \omega(C_b + C_c) - \dfrac{2B_L}{3}\right]^2; \\ N'' = \left[g_b + g_c + \dfrac{\omega}{\sqrt{3}}(C_a - C_c\right]^2; \\ M'' = \left[\dfrac{g_c - g_a}{\sqrt{3}} + \omega(C_b + C_c) - \dfrac{2B_L}{3}\right]^2; \\ N''' = \left[g_b + g_c + \dfrac{\omega}{\sqrt{3}}(C_b - C_a\right]^2; \\ M''' = \left[\dfrac{g_a - g_b}{\sqrt{3}} + \omega(C_b + C_c) - \dfrac{2B_L}{3}\right]^2. \end{cases} \tag{8}$$

As we see, the main part in describing the change process of isolation DN technical phase are the active transmission network phases in a relation to a ground (g_a, g_b, g_c). They are the only numbers in correlations (7) and (8), that change in a developing damaging process, because later we will consider them as diagnostical items for the isolation workability calculation.

Given the above, the diagnostic model for the method of determining the efficiency of insulation can be represented as a four-pole network with the input signal – phase voltages of the distribution network, and output: in the first case (using the criterion of operational safety) – currents flowing to ground through the shunt connection (Fig. 2.a); in the second case (when applying the criterion of economy of functioning) – the power of electricity losses from currents flowing to ground (Fig.2.b).



a) б)

Fig. 2. Diagnostic model for determining the efficiency of insulation.

a) – when applying the criterion of operational safety; b) – when applying the criterion of economy of functioning; in the diagram (W_I) is the transfer function when used as an output signal of the current in the shunt connection, (W_P) – is the transfer function when used as an output signal of the power of electricity losses from currents flowing to ground.

Determination of operability can be obtained from the relationship between the transfer functions (W_I) and (W_P), since both the currents in the shunt and the power of electricity losses from currents flowing to ground depend on the phase voltages of the network relative to ground:

$$W_I = |W(i\omega)| \cdot \frac{g_{shX} \cdot g_l}{g_{shX} + g_l + g_z}; \quad Wp = |W(i\omega)|^2 \cdot g_x \tag{9}$$

Where (x) is the index of the corresponding phase of the network; ($W(i\omega)$) is a complex of the transfer function, when the phase voltage (x) of the network relative to ground is used as the output signal.

As can be seen, both transfer functions have a common component: a complex of transfer functions ($W(i\omega)$). To simplify the problem of constructing a characteristic equation, we will further use it as a diagnostic model.

Let's define the transfer function for the received diagnostic model and the characteristic equation for carrying out check of correctness of a choice of indicators of efficiency of isolation.

Complexes of transfer functions at consideration of various phases of a network is going to be identified by the formula:

$$W_X(i\omega) = \frac{\dot{U}_X}{U_f}.$$

To simplify the calculations in further research, we will consider only networks with isolated neutral, in which there are no inductive elements that have a connection to ground, ie. ($B_L=0$).

$$W_A(i\omega) = \\ = \frac{\sqrt{3}\left[(g_b + i\omega C_b)e^{i30^0} + (g_c + i\omega C_c)e^{-i30^0}\right]}{(g_a + g_b + g_c) + i\omega(C_a + C_b + C_c)};$$

$$W_B(i\omega) = \\ = \frac{\sqrt{3}\left[(g_c + i\omega C_c)e^{i30^0} + (g_a + i\omega C_a)e^{-i30^0}\right]}{(g_a + g_b + g_c) + i\omega(C_a + C_b + C_c)};$$

$$W_C(i\omega) = \\ = \frac{\sqrt{3}\left[(g_a + i\omega C_a)e^{i30^0} + (g_b + i\omega C_b)e^{-i30^0}\right]}{(g_a + g_b + g_c) + i\omega(C_a + C_b + C_c)}. \tag{10}$$

In ratios (10) the expressions for the complexes of the voltages of the network phases relative to the ground were obtained by using the formula for the bias voltage of the neutral (U_0) in complex form.

To move from a complex to the operator form of the record (operational method is used: ($i\omega \to p$)) open the complexes in the numerator of expressions (10) and multiply the numerator and denominator on the conjugate denominator complex. As a result, we get:

$$W(p) = \frac{\sqrt{3}(a_3p^3 + a_2p^2 + a_1p + a_0)}{(g_a + g_b + g_c)^2 + \omega^2(C_a + C_b + C_c)^2}, \tag{11}$$

where a_0, a_1, a_2, a_3 - coefficients of the characteristic equation.

For getting the characteristic equation, it is necessary to equate the numerator of expression (11) to zero.

$$a_3 \cdot p^3 + a_2 \cdot p^2 + a_1 \cdot p + a_0 = 0 \quad (12)$$

For phase A the coefficients of the characteristic level

$$\begin{cases} a_3 = -\left[\frac{1}{2 \cdot w} \cdot (C_b - C_c) \cdot (C_a + C_b + C_c)\right]; \\ a_2 = \frac{1}{2 \cdot w} \cdot (C_b - C_c) \cdot (g_a + g_b + g_c) - \\ -\left[\frac{1}{2 \cdot w}(g_b - g_c) + \frac{1.5}{\sqrt{3}}(C_b + C_c)\right](C_a + C_b + C_c); \\ a_1 = -\frac{1.5}{\sqrt{3}} \cdot (g_b - g_c)(C_a + C_b + C_c) - \\ -\left[\frac{1}{2 \cdot w}(g_b - g_c) + \frac{1.5}{\sqrt{3}}(C_b + C_c)\right](g_a + g_b + g_c); \\ a_0 = \frac{1.5}{\sqrt{3}}(g_b + g_c)(g_a + g_b + g_c); \end{cases} \quad (13)$$

For phases B and C the coefficients of the characteristic equation are similar to expressions (13) with the only difference that instead of the factors ($g_b \pm g_c$) and ($C_b \pm C_c$) for phase B there will be factors ($g_c \pm g_a$) and ($C_c \pm C_a$), and for phase C – ($g_a \pm g_b$) and ($C_a \pm C_b$).

To check the correctness of the choice of insulation performance indicators (diagnostic indicators) we will study the sensitivity of the roots (poles) of the characteristic equation (13) to change of diagnostic indicators (parameters of isolation of phases – active conductivities of isolation of the distributive network concerning the ground). With the help of this study, you can qualitatively assess the degree of influence of the selected diagnostic indicators on the technical condition of the object of diagnosis, namely the isolation of the distribution network concerning the ground. In the final result we should receive confirmation of correctness of a choice of set of diagnostic indicators and the information for their ordering according to degree of influence. For the convenience of research, a real distribution network of overhead power lines with a voltage of 10 kV with a total length of 70 km was taken.

Based on its technical data, the normative power of insulation losses for all three environmental conditions was determined according to the method [18] by the formula:

$$\Delta P_{iz\_i}^{norm} = I_{iz}^2 \cdot R_i \cdot T_i \cdot \frac{L}{100},$$

where I_{iz} - specific square value of the ground fault current (given in tabular form in [18] for air distribution networks of different voltage classes) for the corresponding i-th level of ambient humidity, A/ 100km;

R_i - the specific value of the equivalent active resistance of the insulation relative to the ground for the i-th level of humidity, Ohm 100km;

T_i - duration for a year of weather with the i-th level of humidity, hours (from the reference of the hydrometeorological center);

L – is the total length of the distribution network.

For given distribution network: $\Delta P_{iz_{100\%}}^{norm} = 23377\ W$; $\Delta P_{iz_{80-100\%}}^{norm} = 17910\ W$; $\Delta P_{iz\_<80\%}^{norm} = 6643\ W$.

Initial conditions of the study:

1. At the initial moment of time, the active insulation of the network phases relative to the ground is symmetrical ($r_{A0}=r_{B0}=r_{C0}=100\ kOmh$). Accordingly, we introduce the concept of the normal value of the active conductivity of the phase insulation relative to ground, which is equal to ($g_n=10^{-5}\ Sm$). Any current value of active conductivity, the effect of which on the poles is investigated, can be represented as the sum of the normal value and the current value of its deviation ($g_i=g_n+\lambda_i$).

2. Capacities of isolation of phases concerning the ground are symmetrical, are ($C_a=C_b=C_c=C_f=0.5\ mcF$) and remain unchanged.

3. When studying the effect of a diagnostic indicator on the poles, it is believed that all other indicators remain unchanged.

4. The extreme change of the diagnostic index is considered to be the permissible deviation of the active conductivity (λ_i), in which the active conductivity in the phase of shunting (phase A) is equal to the active conductivity of the phase whose change is investigated (phase B or C), at critical performance of working conditions (6) and (7) It is believed that the damage occurred simultaneously in two phases and gained maximum development, up to the limit of the efficiency of the insulation.

5. For working conditions (6) and (7) the simulation is carried out and the limits of change of active conductivities are determined for the given initial conditions:

– for performance conditions (7) in the study of the effect of active conductivity of phase B – ($\lambda_B=5.39\cdot10^{-5}$); of phase C – ($\lambda_C=6.692\cdot10^{-5}$);

– for performance conditions (6) in the study of the effect of active conductivity of phase B: ($\lambda_{B\ 100\%}=4.118\cdot10^{-4}$, $\lambda_{B\ 80\text{-}100\%}=2.992\cdot10^{-4}$, $\lambda_{B<80\%}=8.766\cdot10^{-5}$) ; of phase C: ($\lambda_{C\_100\%}=4.118\cdot10^{-4}$, $\lambda_{C\_80\text{-}100\%}=2.992\cdot10^{-4}$, $\lambda_{C\_<80\%}=8.766\cdot10^{-5}$);

With a symmetrical increase in the conductivities of all three phases simultaneously: ($\lambda_{sym\_100\%}=2,238\cdot10^{-4}$, $\lambda_{sym\_80\text{-}100\%}=1,691\cdot10^{-4}$ $\lambda_{sym\_<80\%}=5,644\cdot10^{-5}$);

Since the capacitances of the phases are symmetric, the characteristic equation will be quadratic and will have the following roots:

$$x_1 = \frac{g_a + g_b + g_c}{C_a + C_b + C_c} = \frac{g_n}{C_f};$$
$$x_2 = \frac{-\frac{1,5}{\sqrt{3}} \cdot (g_b + g_c)}{-\frac{1,5}{\sqrt{3}} \cdot (g_b + g_c) + -\frac{1,5}{\sqrt{3}} \cdot (C_b + C_c)} = -\frac{g_n}{C_f}. \quad (14)$$

Given the above initial conditions, we write the expressions of the characteristic equation for three cases:

1. In the study of the impact g_a:

$$-3\sqrt{3}C_f^2x^2 + \sqrt{3}\lambda C_f x + 3\sqrt{3}g_n^2 + \sqrt{3}\lambda g_n = 0. \quad (15)$$

2. In the study of the impact (g_b):

$$\left(3\sqrt{3}C_f^2 - \frac{3C_f}{2w}\lambda\right)\left[\frac{\lambda^2}{2w} + \left(\sqrt{3}C_f + \frac{3g_n}{2w} - \frac{3\sqrt{3}C_f}{2}\right)\lambda\right]x + \\ +3\sqrt{3}g_n^2 + \frac{5\sqrt{3}g_n}{2}\cdot\lambda + \lambda^2 = 0. \quad (16)$$

3. In the study of the impact (g_c);

$$\left(\frac{3\lambda C_f}{2w} - 3\sqrt{3}C_f^2\right)x^2 + \left[\left(\frac{-\lambda^2}{2w}\right) + \left(\sqrt{3}C_f - \frac{3g_n}{2w} - \frac{3\sqrt{3}C_f}{2}\right)\lambda\right]x + 3\sqrt{3}g_n^2 + \frac{5\sqrt{3}g_n\lambda}{2} + \lambda^2 = 0 \quad (17)$$

To assess the sensitivity of the poles to diagnostic indicators and to organize them according to the degree of influence, we will use the method of determining the norm of the vector of relative sensitivities [1]. In general, the norms of the vectors of relative sensitivities of the poles (in the form of dependence on the deviation λ) to change the relevant diagnostic parameters will take the form:
in the study of the impact (g_a):

$$\mathrm{Ta}(\lambda) = \mathrm{const} = \\ = \sqrt{\left[\frac{\sqrt{3}C_f\cdot x_1 + \sqrt{3}g_n}{6\sqrt{3}C_f\cdot g_n\cdot x_1}\right]^2 + \left[\frac{\sqrt{3}C_f\cdot x_2 + \sqrt{3}g_n}{6\sqrt{3}C_f\cdot g_n\cdot x_2}\right]^2}, \quad (18)$$

in the study of the impact (g_b):

$$\mathrm{Tb}(\lambda) = \\ = \sqrt{\frac{\left[\left(\frac{-3C_f}{2w}\right)\cdot x_1^2 + \left(\frac{\lambda}{w} + \frac{3g_n}{2w} - \frac{\sqrt{3}C_f}{2}\right)\cdot x_1 + 2\lambda + \frac{5\sqrt{3}g_n}{2}\right]^2}{-6\sqrt{3}C_f\cdot g_n\cdot x_1} + \frac{\left[\left(\frac{-3C_f}{2w}\right)\cdot x_2^2 + \left(\frac{\lambda}{w} + \frac{3g_n}{2w} - \frac{\sqrt{3}C_f}{2}\right)\cdot x_2 + 2\lambda + \frac{5\sqrt{3}g_n}{2}\right]^2}{6\sqrt{3}C_f\cdot g_n\cdot x_2}}, \quad (19)$$

in the study of the impact (g_c):

$$\mathrm{Tc}(\lambda) = \\ = \sqrt{\frac{\left[\left(\frac{3C_f}{2w}\right)\cdot x_1^2 + \left(\frac{-\lambda}{w} - \frac{3g_n}{2w} - \frac{\sqrt{3}C_f}{2}\right)\cdot x_1 + 2\lambda + \frac{5\sqrt{3}g_n}{2}\right]^2}{-6\sqrt{3}C_f\cdot g_n\cdot x_1} + \frac{\left[\left(\frac{3C_f}{2w}\right)\cdot x_2^2 + \left(\frac{-\lambda}{w} - \frac{3g_n}{2w} - \frac{\sqrt{3}C_f}{2}\right)\cdot x_2 + 2\lambda + \frac{5\sqrt{3}g_n}{2}\right]^2}{6\sqrt{3}C_f\cdot g_n\cdot x_2}} \quad (20)$$

The norm of the vector of relative sensitivity to change (g_a) is a constant value, and is equal to (T_a=$3.333\cdot10^{-4}$). This is explained by the fact that the dependence of the roots of the characteristic equation from (g_a) has a linear character (compiled to consider the possibility of damage in phase A), and therefore at differentiation for definition (T_a) as a result a constant will be received. The norms of the vectors of relative sensitivities to the change of (g_b) and (g_c) are functions of the deviation (λ). Graphs of dependencies are going to be built for a visual assessment of sensitivity for each diagnostic indicator, Figure 3.Thus, as a result of the conducted researches it is established that influence of all three conductivities of phases on poles (roots of the characteristic equation) has approximately one order of magnitude, and influences (g_c) and (g_b) are almost identical that it is possible to observe in fig. 3 (curves of the dependence of the norm of the sensitivity vector on the deviation for phases B and C are almost coincide). Therefore, the set of diagnostic indicators was chosen correctly and the diagnostic model is appropriate.

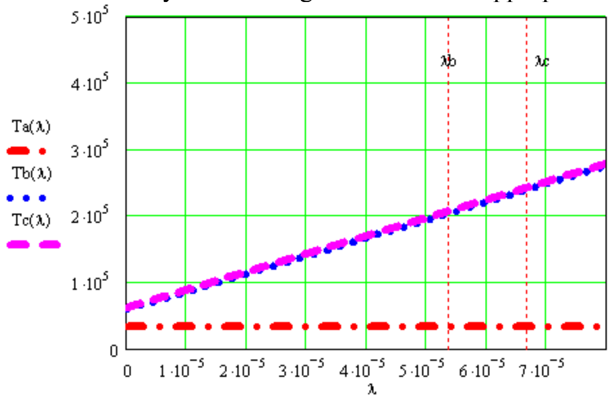


Fig. 3. Dependences of norms of vectors of relative sensitivities on deviation: a – is general schedule of dependencies.

3 Conclusion

The main reason isolation damage is appearance of shunting connecting's within conductive part and a ground in electrical distribution network with the voltage 6-35 kV. In this case there are 2 processes-smooth symmetrical reduce of active isolation resistance of isolation phases as a result of hydration work on the isolator top and non-symmetrical harsh reduce of isolation active resistance of separated phase in a relation to a ground as a result of shunting connecting appearance. Isolation workability conditions calculation of distribution network in a look of restriction of isolation workability items change in relation to a ground, based on official documents and standards should carry out the current reduce through shunting connection with the electrosafety criteria's and active power loss in isolation from current flow to a ground with the economical criteria of minimum electroenergy loss.

Research of modular multilevel converter with phase-shifted pulse-width modulation

Ihor Kozakevych[1,*], and *Roman* Siyanko[1]

[1]Kryvyi Rih National University, Automatic Electromechanical Systems in Industry and Vehicles Department, 11 Vitalii Matusevych Str., 50027, Kryvyi Rih, Ukraine

Abstract. The work is devoted to the study of performance of a multilevel electric energy converter using phase-shifted pulse-width modulation. Equations describing the state of a dynamic system multilevel converter - load are investigated and a mathematical model of the system in Matlab / Simulink environment has been constructed. Variants of implementation of phase-shifted pulse-width modulation systems from the point of view of influence on harmonics of output voltage and magnitude of circulating current in the converter are investigated.

1 Introduction

The introduction of an adjustable frequency electric drive for low-voltage AC motors over the last decade has proven to be an effective method of improving energy efficiency in industry and utilities [1–3]. The uncontrolled rectifier- voltage-source inverter circuit has become a kind of industry standard for low- and medium-power AC drives [4]. However, high-power electric drives using medium-voltage motors also have significant energy saving potential. There is no single approach to the construction of power converters of such systems [5]. Another area of use of high-power converters is distributed generation systems, which provide for the integration of renewable energy sources into power supply systems. Therefore, the development of means of converting electricity in systems with a medium level of rated voltage is an important area.

Cases of using direct converters in systems with a medium level of rated voltage are isolated, specific industrial models that are mass-produced are absent [6], and therefore it is advisable to focus on converters with intermediate DC link, which, in turn, are divided into converters based on voltage-source inverters and converters based on current-source inverter depending on the configuration of passive elements of the DC link. The advantage of converters based on current-source inverters is the ability for the electric drive to work in four quadrants without the use of additional hardware or software. However, their main parts must have a controlled rectifier, which leads to an increase in reactive power consumption levels. In addition, this type of converter is able to switch the inverter switches only when operating on active-capacitive load, and therefore its use without additional capacitive elements is possible only when used as a motor synchronous motor with excitation that is greater than the rated one. Therefore, more promising now is the use of circuits based on voltage-source inverters [7 – 9]. These circuits, in turn, are divided into two-level converters and multilevel converters. However, due to the fact that the operation of a two-level converter in a system with a medium level of rated voltage will lead to significant values of du / dt, their use in this case is not possible [10]. The use of multi-level converters allows to reduce the du / dt, as well as the total harmonic distortion ratio (THD), which reduces the size of the filters on the AC side [11]. Multi-level converters based on a circuit with cascaded H-bridges, circuits with "flying" capacitors, with a diode-clamped converters and modular multi-level converters are currently being mass-produced [12]. In addition, scientists are constantly developing new schemes that are certain combinations of existing options. The main disadvantage of the circuit with cascaded H-bridges [13] is the need to use a phase-shift transformer to obtain several galvanically isolated DC sources. The disadvantages of circuits with "flying" capacitors and clamped diodes are the difficulty of balancing the voltages on the capacitor dividers. The scheme of a modular multilevel converter does not require a complex transformer, and therefore its use is more appropriate for reasons of economy and reliability.

2 Analysis of the modular multilevel inverter and mathematical dependences describing its state

The generalized structure of the modular multilevel inverter is shown in fig. 1. It consists of three legs designed to power the load phases and connected to a common DC link. A three-phase symmetrical load is connected to the midpoints of the inverter legs through an inductor L.

Each arm consists of a number of semiconductor (SM) cells connected in series. Inductors L are designed to limit

* Corresponding author: aepigor@gmail.com

the intensity of the current rise in the circuit on the DC and AC side, as well as to compensate for the difference between phase voltage and voltage in the DC link caused by voltage changes on cell capacitors or other reasons. However, the active component of the resistance of these inductors leads to an increase in the overall level of losses in the converter. A significant advantage of such a circuit is the ability to build it using the same type of circuit modules, which provides the ability to replace them quickly in case of failure of semiconductor elements. In this case, there are a significant number of options for constructing circuits of individual cells, which allows you to modify the general characteristics of the converters and the number of output voltage levels.

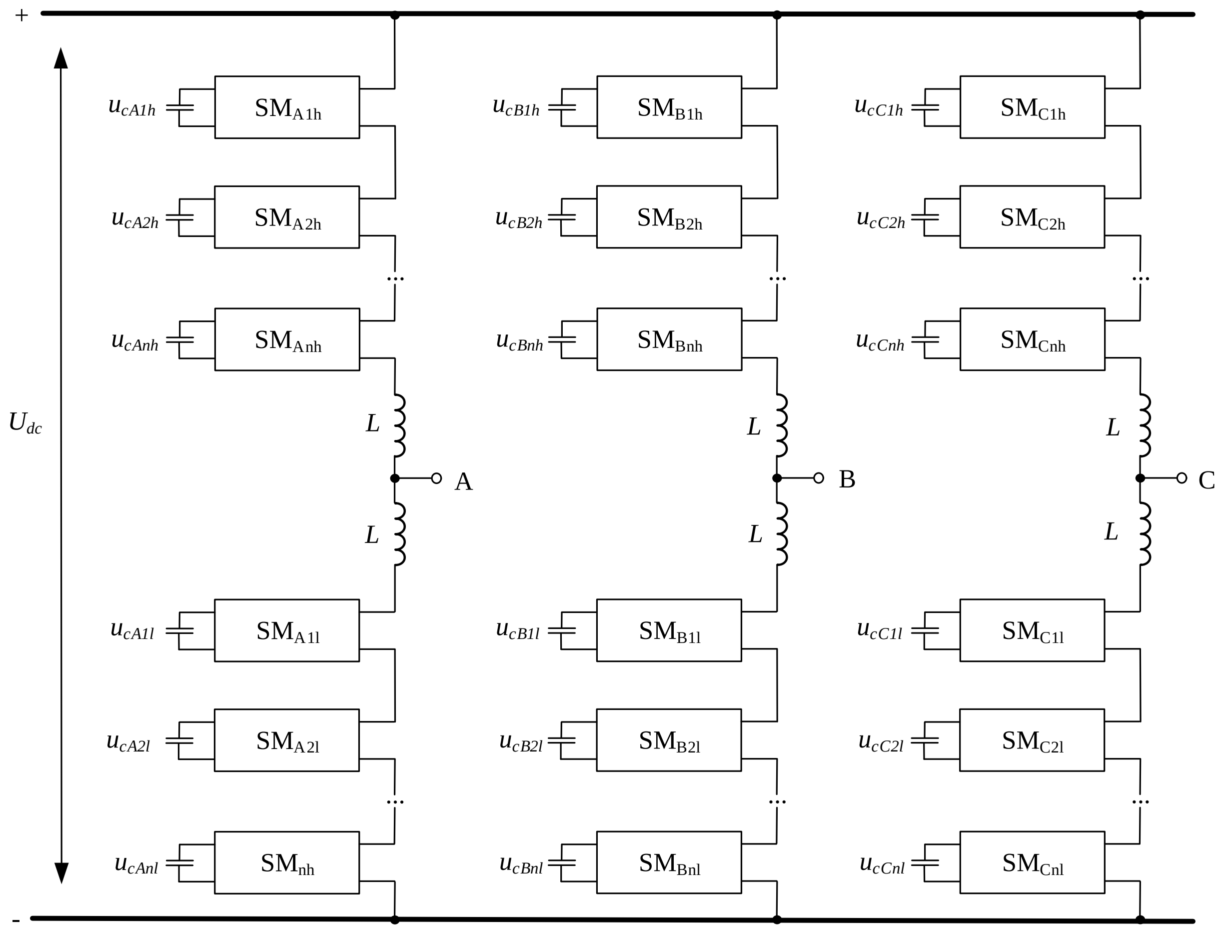

Fig. 1. The structure of a modular multilevel converter.

The most popular is the scheme of half-bridge modules, which is shown in Fig. 2a. It contains two switches operating in inverse mode and provides two levels of output voltage - zero voltage and a voltage equal to the voltage on the capacitor u_c. This scheme is able to provide a low level of energy loss and high reliability. The use of more complex schemes of converter modules is explained by the need and expediency to have more levels of output voltage, which reduces the total number of semiconductor elements used and the overall dimensions of the modular multilevel converter. As such modules their full-bridge variant which is shown in fig. 2b. This scheme allows to obtain a bipolar output voltage, which is useful both in terms of increasing the flexibility of voltage balancing on capacitors, and in terms of the possibility of reducing the magnitude of the emergency current. The use of circuits with a fixed zero point (Fig. 2c) and with "flying" capacitors (Fig. 2d) allows to significantly expand the number of switching states, and therefore requires more complex control methods with the ability to maintain voltage balance on capacitors.

Consider the equivalent scheme of one phase of a modular multilevel inverter (Fig. 3). The voltage in the DC link is divided into two sources with voltages of $\frac{1}{2}U_{dc}$ to obtain an artificial zero point. The output voltage of phase j is denoted by u_{jout}, and the output current is denoted by i_{jout} $(j \epsilon \{a, b, c\})$. In the upper and lower arms, switching of the semiconductor switches of the modules leads to the sequential turning-on of a certain number of capacitors and the emergence of voltages u_{jh} and u_{jl}, respectively. The currents i_{jh} and i_{jl}, respectively, flow in the upper and lower arms.

Using Kirchhoff's second law for the contour of the upper and lower arms, the following equations can be obtained:

$$\frac{1}{2}U_{dc} - u_{jh} - u_{jout} = i_{jh}R + L\frac{di_{jh}}{dt}; \quad (1)$$

$$\frac{1}{2}U_{dc} - u_{jl} + u_{jout} = i_{jl}R + L\frac{di_{jl}}{dt}. \quad (2)$$

As a rule, in order to reduce the overall dimensions of inductive elements, conditions are created for the occurrence of mutual inductance between them. If we

https://doi.org/10.1051/e3sconf/202128005009

denote the mutual inductance of inductive elements M, then equations (1), (2) can be written as:

$$\frac{1}{2}U_{dc} - u_{jh} - u_{jout} = i_{jh}R + L\frac{di_{jh}}{dt} + M\frac{di_{jl}}{dt}; \quad (3)$$

$$\frac{1}{2}U_{dc} - u_{jl} + u_{jout} = i_{jl}R + L\frac{di_{jh}}{dt} + M\frac{di_{jh}}{dt}. \quad (4)$$

The voltage on the inductive elements of the invertor's leg can be determined as follows:

$$u_{jL} = L\frac{di_{jh}}{dt} + M\frac{di_{jl}}{dt} + L\frac{di_{jh}}{dt} + M\frac{di_{jh}}{dt}. \quad (5)$$

With a unit coefficient of mutual inductance $L = M$, then:

$$u_{jL} = 4L\frac{di_{jc}}{dt} = U_{dc} - u_{jh} - u_{jl}, \quad (6)$$

where i_{jc} – the circulating current of the converter's arm that feeds the load phase j and flows in the upper and lower converter's arms, which can be defined as:

$$i_{jc} = \frac{1}{2}(i_{jh} + i_{jl}). \quad (7)$$

Ideally, the phase load current i_{jout} is divided equally between the upper and lower arms, then the arm currents can be defined as follows:

$$i_{jh} = \frac{1}{2}i_{jout} + i_{jc}. \quad (8)$$

$$i_{jl} = \frac{1}{2}i_{jout} + i_{jc}. \quad (9)$$

The output voltage of the converter through the voltages of the upper and lower arms of the previously obtained dependences can be expressed as:

$$u_{jout} = \frac{1}{2}(u_{jl} - u_{jh}). \quad (10)$$

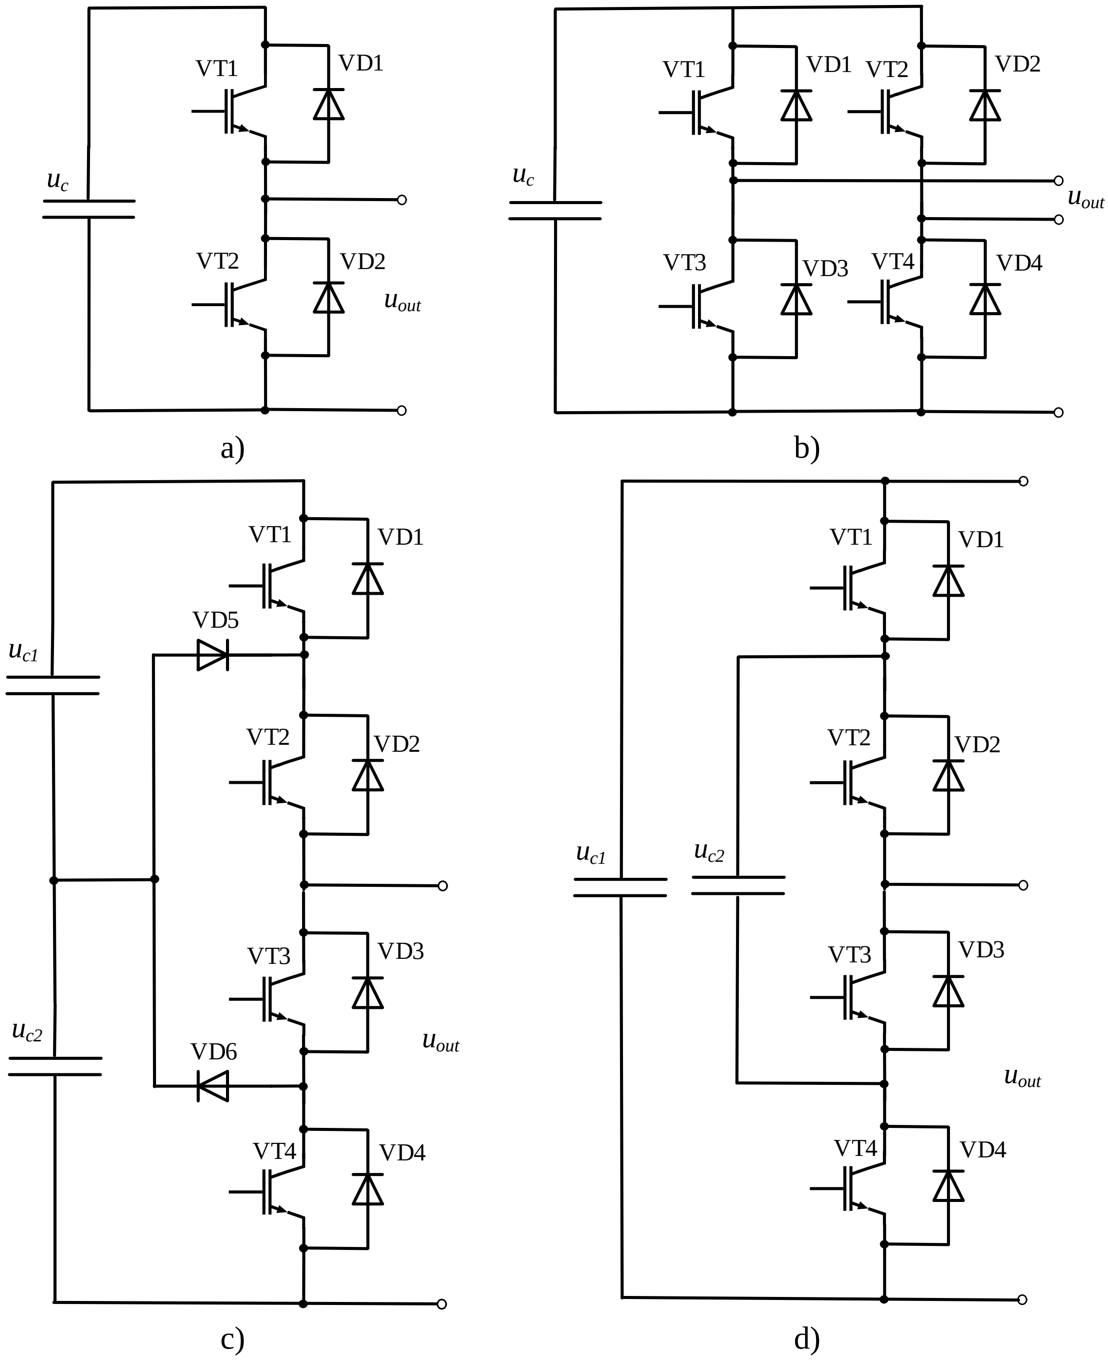

Fig. 2. Some cell diagrams that are suitable for use in a modular multi-level converter circuit.

 https://doi.org/10.1051/e3sconf/202128005009

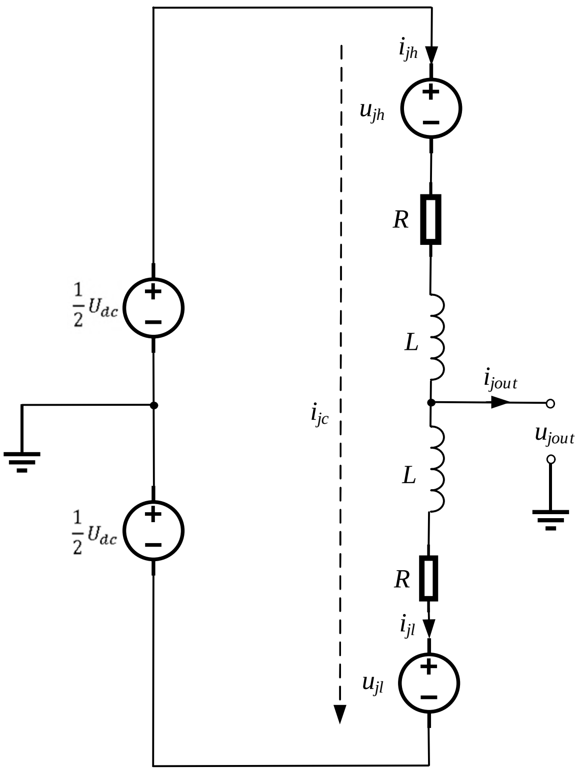

Fig. 3. Equivalent scheme of one leg of the converter.

From equation (6) the circulating current of the converter can be determined as follows:

$$i_{jc} = \frac{1}{4L}\int_0^t u_{jL}dt + I_{jcDC}, \tag{11}$$

where I_{jcDC} is a constant component of the circulating current.

3 Phase-shifted pulse-width modulation

The principle of pulse-width modulation with phase shift of the carrier signals is presented in Fig. 4. To obtain the switching signals of the switches of the converter modules containing N modules in one arm, N phase-shifted triangular carrier signals are generated to control the upper half of the circuit and N the same signals to control the switches of the lower half of the circuit. The frequency of the triangular signal carriers is selected depending on the required switching frequency of the semiconductor elements. Subsequently, the sinusoidal reference signal of each phase is compared with a number of triangular carrier signals and the corresponding control signals of the circuit switches are obtained. To improve the coefficient of total harmonic distortion between the triangular carrier signals, a phase shift of θ = 2π / N is set. Thus, it is expedient to investigate the influence of the magnitude of this shift on the performance of a modular multilevel converter.

A mathematical model in Matlab / Simulink environment has been developed to study the influence of the carrier shift angle on the operation of a modular multilevel converter. The parameters of the simulated converter are given in Table. 1.

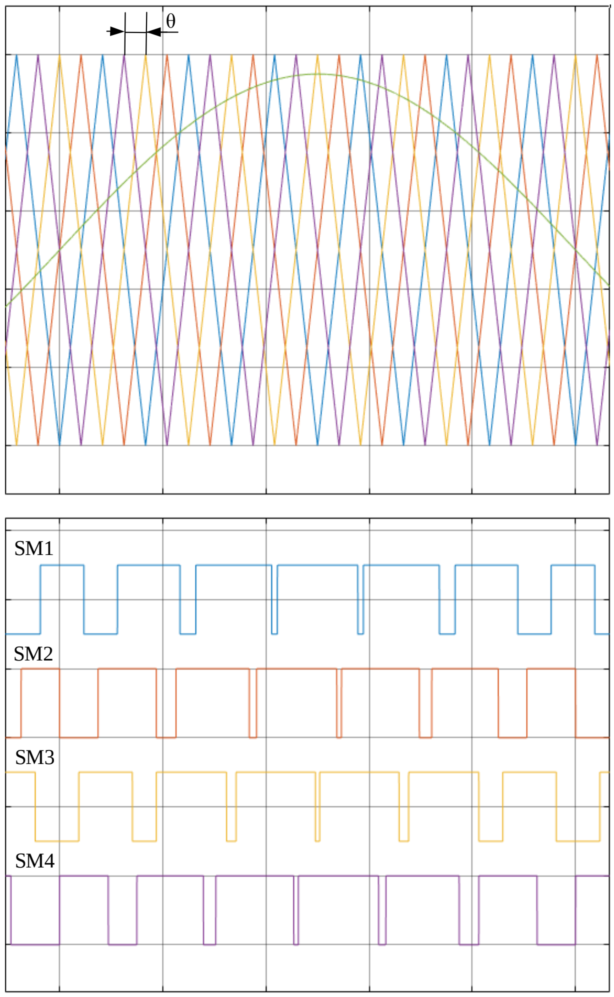

Fig. 4. The principle of phase-shifted pulse-width modulation.

Table 1. The parameters of the simulated converter

Parameter name	**Parameter value**
Number of converter modules per arm	4
The scheme of the module of the converter	half-bridge
Voltage in the DC link U_{dc}	4000 V
The capacitor capacity of each converter module	750 μF
The inductance of the arm of the converter	0.02 H
Modulation factor	0.9
Frequency of carrier signals	500 Hz
The frequency of the reference signal	50 Hz
Active load resistance	85 Ohm
Load inductance	0.167 H

Fig. 5 represents the simulation results of a modular multilevel inverter with a shift of carrier signals by θ = 2π / N. The shape of the output voltage (Fig. 5a) has a clearly visible number of levels, which corresponds to the number of modules in each arm of the converter, circulating current (Fig. 5b) has a frequency, which corresponds to the frequency of the output voltage of the converter, and its root mean square value for this case is 6.157 A. A positive property of this method of modulation is the ability to balance voltages on capacitors (Fig. 5c) without the use of additional hardware or software. The

* Corresponding author: aepigor@gmail.com

amplitude of voltage ripple on the capacitors in steady state does not exceed ± 40 V, which is quite satisfactory. Analysis of the output voltage spectrum of the converter (Fig. 5d) shows the presence of significant harmonic components in the vicinity of 2000 Hz, and the total coefficient of nonlinear distortion (THD) was 26.99%.

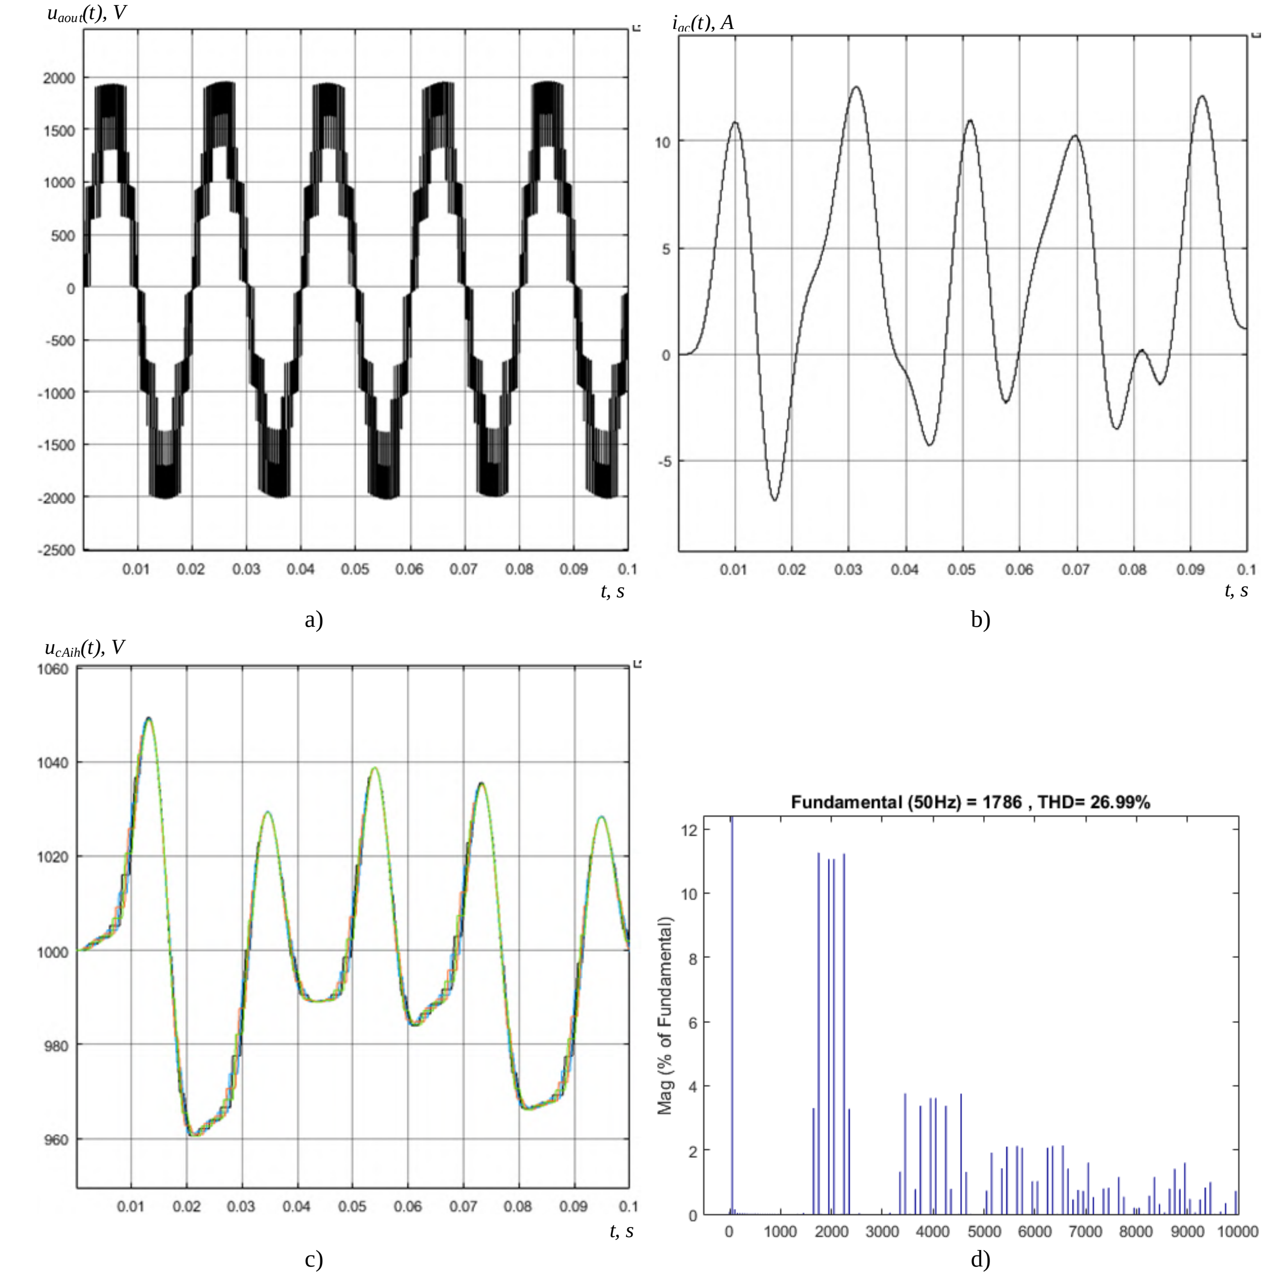

Fig. 5. The results of modeling the operation of a modular multilevel converter when the carrier signals are shifted by 2π / N: a – change in the output voltage of the converter; b – change in the magnitude of the circulating current; c – voltage change on the capacitors of the upper arm of the circuit; d – the spectrum of the output voltage of the converter.

Fig. 6 represents the results of modeling a modular multilevel inverter when reducing the values of the shift of the carrier signals to the level of 2/3 of the previous case. The graph of the output voltage (Fig. 6a) shows a visually greater sinusoidality than in the previous case. The frequency of pulsations of the circulating current (Fig. 6b) has become much higher than the frequency of the output voltage of the converter, although the fundamental harmonic, which corresponds to the frequency of the output voltage, is visually noticeable. However, the rms value of the circulating current increases almost twice to 11.8 A, which leads to an increase in losses in the converter. Another significant disadvantage of this method of modulation is the loss of the ability to balance the voltages on the capacitors of the modules (Fig. 6c), which during observation (0.1 s) are significantly unbalanced, which allows us to conclude that such a system is unsuitable for practical implementation without developing additional measures to reduce imbalance voltage. The positive effect of using such a system is the reduction of the total harmonic distortion to 21.71%, which confirms the previously described conclusions about the greater sinusoidality of output voltage of the converter. Therefore, in the future it is advisable to perform a search for the shift angle, which minimizes the coefficient of total harmonic distortion without losing the ability to self-balance the voltages on the capacitors of the modules.

 https://doi.org/10.1051/e3sconf/202128005009

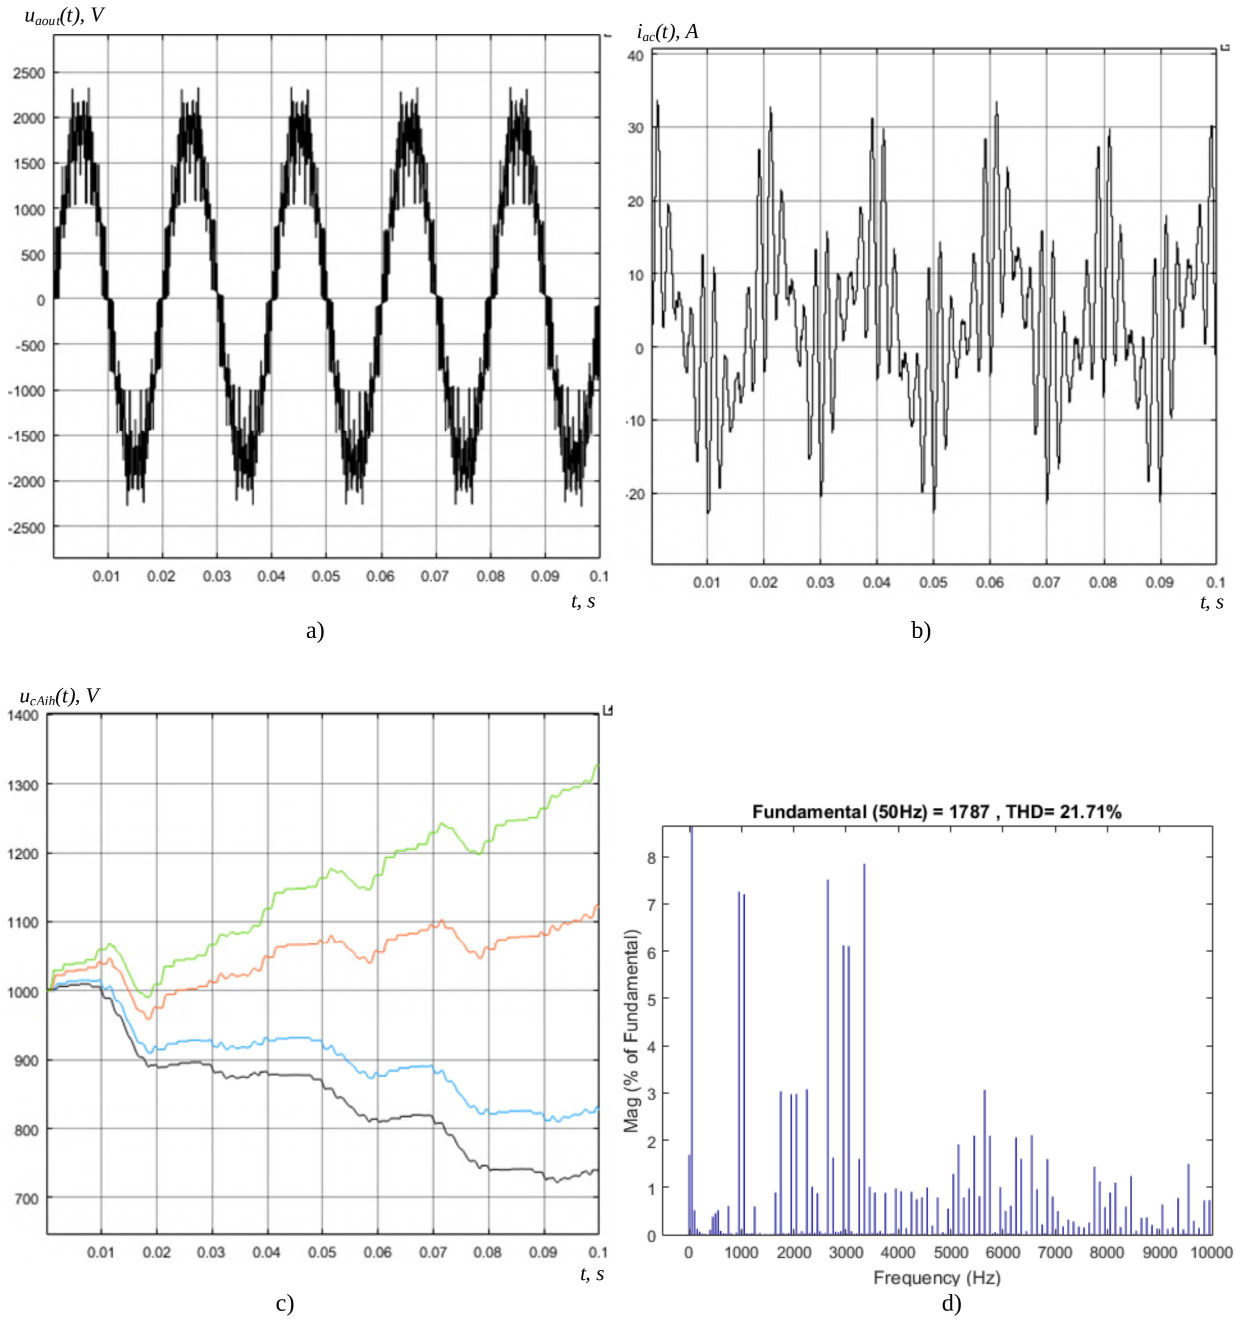

Fig. 6. The results of modeling the operation of a modular multilevel converter when the carrier signals are shifted by $4\pi / 3N$: a – change in the output voltage of the converter; b – change in the magnitude of the circulating current; c – voltage change on the capacitors of the upper arm of the circuit; d – the spectrum of the output voltage of the converter.

Fig. 7 represents the results of modeling a modular multilevel inverter when reducing the values of the shift of the carrier signals to the level of 1/2 from the previous case. The graph of the output voltage (Fig. 7a) visually shows even greater sinusoidality than in the previous case, the presence of individual discrete voltage levels is almost invisible. The nature of the pulsations of the circulating current (Fig. 7b) corresponds to the previous case, but the current value increases significantly to the level of 19.52 A. The ability to balance voltages on capacitors modules is lost (Fig. 7c), as in the previous case, showing a significant difference with time. The coefficient of total harmonic distortions of the output voltage (Fig. 7d) remains lower than when using modulation with a shift of $\theta = 2\pi / N$, and is equal to 21.81%. In the demonstrated spectrum, harmonic components with a frequency equal to twice the switching frequency of the converter's switches are clearly distinguished, which are lower frequency compared to the dominant harmonic components of the previous cases, and therefore easily eliminated from the output current due to load inductance.

Let's analyze the operation of a modular multilevel inverter using pulse-width modulation with in-phase carrier signals, i.e. in the absence of phase shifts between them. The results of modeling such a system are presented in Fig. 8. The output voltage graph (Fig. 8a) shows a significant decrease in output voltage levels, which is a negative phenomenon, because in this case it is necessary to use more cumbersome passive output filters to bring the output voltage in line with current standards. The current

* Corresponding author: aepigor@gmail.com

value of the circulating current (Fig. 8b) almost corresponds to the previous case and is 19.36 A, which leads to the need to increase the value of the inductance in the arms of the converter to reduce the level of losses due to the influence of this current. A positive characteristic of such modulation is the ability to balance the voltages on the capacitors of the converter modules (Fig. 8c), the average deviation of these voltages does not exceed ± 30 V, which is the best result among the analyzed options. The decrease in the output voltage levels leads to a significant increase in the coefficient of total harmonic distortion to the level of 50.49%, which is the worst result among the options analyzed.

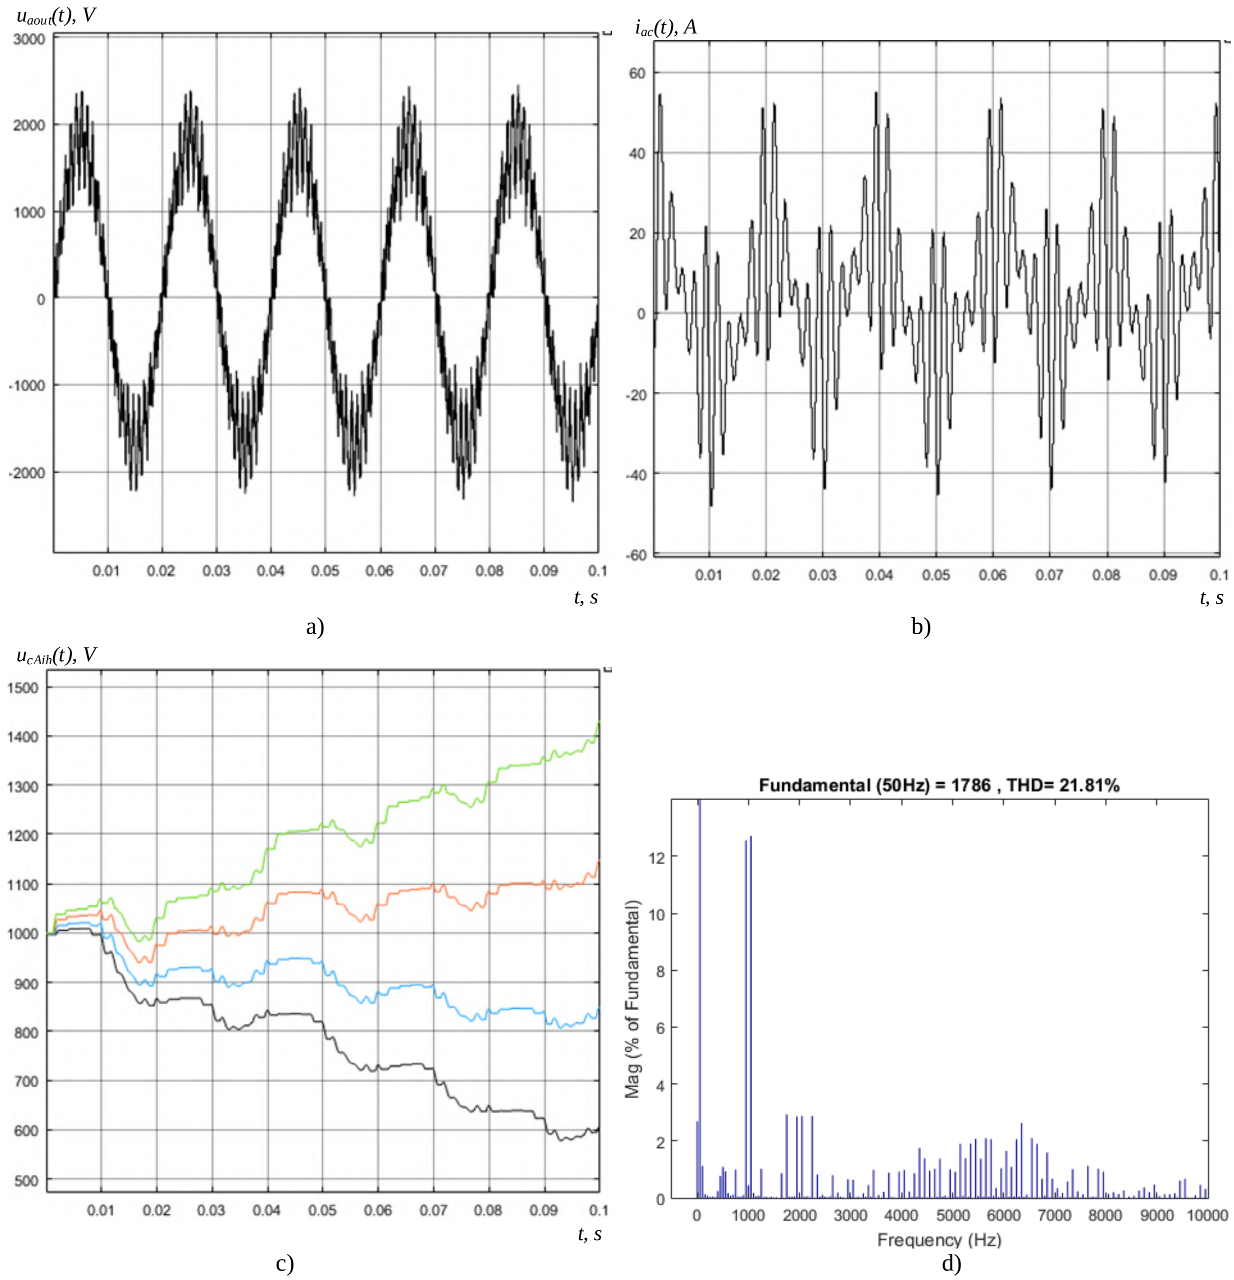

Fig. 7. The results of modeling the operation of a modular multilevel converter when the carrier signals are shifted by $2\pi / 3N$: a – change in the output voltage of the converter; b – change in the magnitude of the circulating current; c – voltage change on the capacitors of the upper arm of the circuit; d – the spectrum of the output voltage of the converter.

Conclusions

The aspects of functioning of the modular multilevel converter at use of pulse-width modulation with shift of carrier signals on a phase are analyzed in the work. The general structure of such converter is considered, and also the most widespread circuit decisions concerning construction of modules. The general analytical dependences describing the relationship between the main variables of the state of the converter are analyzed. A mathematical model in the Matlab / Simulink environment is compiled and the behavior of a modular multilevel converter at different values of the phase shift between the carrier signals of pulse-width modulation is analyzed. It is proved that the absence of this shift shows

 https://doi.org/10.1051/e3sconf/202128005009

the worst indicators in terms of the coefficient of total harmonic distortion of the output voltage of the converter, but the best in terms of accuracy of voltage balancing on the capacitors of the circuit modules. The presented analysis of shift values proves the compromise of the choice of the shift angle in terms of the total harmonic distortions of the output voltage, the magnitude of the circulating current in the converter arm and the ability to balance voltages on the capacitors of the circuit.

Abstract. Widespread use of semiconductor radiation sources in optoelectronic devices for various purposes requires further study of the mechanisms of formation of photometric characteristics of the integrated device in the near illumination zone, where the law of inverted squares is violated. A mathematical model of the multicomponent beam-diode module is proposed. On its basis the analysis of influence of the parameters of separate beam sources on the deformation of the indicatrix of radiant intensity at transition from the far zone to the near one is carried out. It is shown that the determining parameter of the indicatrix change in longitude and polar distance is the distribution in the plane of the modulus of the product of the radiant intensity of a single diode on its polar radius vector. The displacement of the polar angle of the maximum of the vector of the diode radiant intensity is more significant for wide radiation patterns than for concentrated ones. For specific parameters of diodes and geometry of their location the suitability of the proposed model for a priori modeling of beam-diode modules is illustrated.

1 Introduction

Successful development of unmanned aerial vehicles encourages the development and improvement of optoelectronic devices (OED) for light signals and reconnaissance purposes. They are mainly implemented by introduction of new element base of higher quality where not the last place belongs to artificial sources of infrared (IR) radiation. Increasing the range of security and reconnaissance OEDs is achieved by their transition to active mode, increasing the power of sources, the use of longer wavelengths of the IR range of electromagnetic waves (EMW). Among the artificial sources of spontaneous radiation, undoubtedly, the most promising are the semiconductor sources of injection electroluminescence of p-n junctions – light-emitting diodes (LEDs) (visible area of EMW) and beam diodes (ultraviolet and infrared areas of EMW). Beam-signal and other devices of active action of the IR range have significant operational advantages at the working lengths of the EMW, which correspond to the "windows" of the transparency of the atmosphere in the middle range of the IR spectrum: (3.3 – 4.2) μm, (4.5 – 5. 1) μm, (8–13) μm. Modern technological advances in the production of ultra-bright p-n-emitters in these parts of the spectrum require further study of the mechanisms of formation of the basic physical and technical characteristics of multicomponent beam-diode sources of directional action.

Due to the topicality of replacing traditional light sources with more efficient ones in many respects, a large number of scientific papers are devoted to the development and design of LED-based lighting devices. Most of the papers are limited to offering a mathematical model for calculating the lighting characteristics of the LED module and computer software for these calculations. This is enough to perform practical tasks and the problem consists only in choosing the most rational model. From a theoretical point of view, it is important to study the peculiarities of the formation of light intensity curves (LIC) for the development of light intensity algebra. The non-triviality of these questions lies in the specific use of the category of light intensity for non-point sources. By definition, the intensity of light is a characteristic of a point source located at the apex of the solid angle and to arithmetically add vectors of light intensity from several sources is valid only for vectors of one direction when the source is at one point [1, 2, 3]. The method of virtual transfer of radiating components to one point to obtain a diagram of the direction of light intensity of the integrated device can be approximated only in the far illumination zone. The transition to the near zone raises the question of the legitimacy of the use of the light intensity characteristic.

Obviously, the pattern of light intensity or LIC of the integrated lighting device depends on the lighting characteristics of individual LEDs and the geometry of their placement. In principle, the LIC of any LED, even with secondary optics, can be calculated by considering the course of the beams in a semiconductor crystal [4, 5, 6]. However, in practice a less costly approach is used. A simplified parametric model is selected for the empirically obtained data set. Such analytical models are the basis for the classification of the main types of LIC for sources of any radiation mechanism [7, 8, 9]. Together with the idealized diagram $f(\theta)=\cos^{-3}\cdot\theta$ (θ –a

* Corresponding author: klk.nauka@gmail.com

polar distance) there are 8 such types. Using the specified classification or point-discrete representation of empirical data for LIC diodes, the coordinate distribution of illumination from the multicomponent module E(x, y) is determined as follows:

$$E(x,y)=\sum_i\sum_j(I(x,y,i,j)\cdot cos[\theta(x,y,i,j)])/((x-i\Delta x)^2+(y-j\Delta y)^2+l^2), \quad (1)$$

where *i* – the number of LEDs along axis x with distance Δx between them; *j* – the number of LEDs along axis *y* with distance Δy between them; $I(x,y,i,j)$ – the intensity of light of the LED; *l* – the distance from the LED module to the lighting plane; $\theta(x,y,i,j)$ – the angle of incidence of light from a single LED.

Due to the cumbersomeness of formulas and the specificity of simulation modeling, the identification of physical patterns of formation of integrated characteristics is complicated. Numerical results do not reflect the functional relationships of the characteristics of the isolated LED with the characteristics of the module. Therefore, the patterns of formation of integrated parameters of LED modules, determined at present, are the result of the analysis of graphical dependencies and are expressed verbally.

Basically, they are as follows:

1. The most uniform illumination can be provided by [10, 11, 12]:

– modules of the cluster variant with a large number of low-power LEDs;

– placement of powerful LEDs in groups with non-concentrated LIC;

– turns of LED, which is convenient in this case because of small occupied area and storage of a light flow.

2. When the module size is compared with the observation range, the illuminance with a change in distance changes insignificantly for non-turned diodes and for turned diodes with LIC with large radiation angles [14–18].

3. The anomalous coordinate dependence of the deviation coefficient on the law of inverse squares $K(r)$ is manifested when the beams are focused. Maximum values $K(r)$ increase as the angles of radiation of the LED decrease. With anomalous $K(r)$, value $E(r)$ sharply changes in the near illumination zone [13,14, 17–19].

4. Normal dependences of $K(r)$ are observed when using unturned LEDs with cosine-type LIC, as well as when defocusing the module [14, 16, 15, 19, 20-22].

5. The more gently sloping dependences $K(r)$ are the less the decrease of $E(r)$ is [13, 18, 19, 23–24].

6. Dependences of relative uniformity of light distribution (RULD) are non-monotonic with minima in the near zone. For the near zone, defocusing results in higher RULD values than focusing [16–19].

7. High RULDs are achieved by reducing the maximum illuminance [16–22].

Purpose of the paper – to analytically research the peculiarities of the formation of the spatial distribution of the radiant intensity of the integrated beam-diode module, depending on the parameters of its components.

2 Results

For p-n-diode emitters with a spectrum outside the visible range the term "beam diode" is more correct than the term "LED". Suppose we have an integrated planar module assembled from *N* beam-diode point sources. The irradiance at the observation point *A* of the parallel plane (Fig. 1) is determined as follows:

$$E(r,\theta,\varphi)=\sum_{k=1}^{N}(I_k(\theta_k,\alpha_k,\rho_k,\varphi_k))/(L_k^2(r,\theta,\varphi,\rho_k,\varphi_k))\cdot cos\theta_k, \quad (2)$$

where L_k $(r,\theta,\varphi,\rho_k,\varphi_k)$ – the distance from the *k*-th source to the point of observation; θ_k – polar distance of spherical coordinates with the pole at the location of the *k*-th source; r,θ,φ – radius vector, polar distance, longitude of spherical coordinates with pole at selected point of module plane; ρ_k,φ_k – the polar coordinates of the *k*-th source; αk – half the width of the radiation pattern of the *k*-th source; $I_k(\theta_k,\alpha_k,\rho_k,\varphi_k)$ – radiant intensity (light intensity) of the *k*-th source.

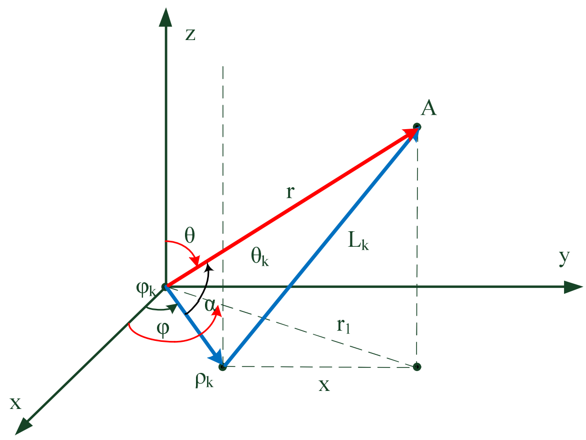

Fig. 1. The geometry of the analysis of illumination at point A from a point source with polar coordinates ρ_k, φ_k.

Taking into account that (Fig. 1):

$$L_k(r,\theta,\varphi,\rho_k,\varphi_k)=r\cdot\sqrt{(1-2r_k\cdot sin\theta\cdot cos\Delta\varphi_k+r_k^2)}$$

and

$$\theta_k\ (r_k,\theta,\varphi)=arccos(cos\theta/\sqrt{(1-2r_k\cdot sin\theta\cdot cos\Delta\varphi_k+r_k^2)}),$$

where $r_k=\rho_k/r;\ \Delta\varphi_k=\varphi-\varphi_k$.

Expression (2) can be presented as follows:

$$E(r,\theta,\varphi)=cos\theta/r^2\cdot\sum_{k=1}^{N}(I_k\ (r,\theta,\Delta\varphi_k,\alpha_k,\rho_k))/[1-2r_k\cdot sin\theta\cdot cos\Delta\varphi_k+r_k^2]^{3/2}. \quad (3)$$

With $r_k\to0$ irradiation $E(r,\theta,\varphi_k)\to cos\theta/r_2\cdot\sum_{k=1}^{N}I_k$ (θ,α_k), describing the irradiance of the module as a point source with radiant intensity $\sum_{k=1}^{N}I_k\ (\theta,\alpha_k)$. Based on this and the form of expression (3), the value

$$I_m(r,\theta,\varphi)=\sum_{k=1}^{N}[I_k(r,\theta,\Delta\varphi_k,\alpha_k,\rho_k)]/[1-2r_k\cdot sin\theta\cdot cos\Delta\varphi k+r_k^2]^{3/2}, \quad (4)$$

where $r_k^2-2r_k\cdot sin\theta\cdot cos\Delta\varphi_k\neq1$ can be conditionally interpreted as radiant intensity of the module at $r\gg\rho_k$, i.e.

for far illumination. In the near zone, where the coefficient of deviation of the irradiance from the law of inverse squares $K(r)$ <0.95, such an interpretation of expression (4) is problematic, because at such distances from the module it is far from point one and for it the classical definition of radiant intensity cannot be applied.

Multiplier $\psi k(r,\theta,\varphi)=[1\text{-}2r_k\cdot sin\theta\cdot cos\Delta\varphi_k+r_k^2]^{-3/2}$ takes into account the influence of a single source on the radiant intensity of the module depending on its location, or, on the other hand, takes into account its contribution to the "non-point nature" of the module. For the ease of analysis, we present ψ_k as a power series. So, provided $|2r_k\cdot sin\theta\cdot cos\Delta\varphi_k\text{-}r_k^2|<1$, which corresponds to the variation of r from $r\gtrsim\rho_k/2.4$ at $sin\theta\cdot cos\Delta\varphi_k=1$ to $r\gtrsim\rho_k$ at $sin\theta\cdot cos\Delta\varphi_k=0$, we have [10]:

$$\psi_k\ (r,\theta,\varphi)=1/\Gamma(3/2)\cdot\sum_{n=0}^{\infty}\Gamma(n+3/2)/n!\cdot (2r_k\cdot sin\theta\cdot cos\Delta\varphi_k\text{-}r_k^2)n, \qquad (5)$$

where $\Gamma(x)=\int_0^{\infty}t^{x\text{-}1}\cdot e^{\text{-}t}\cdot dt$, $(Re\ x>0)$ – gamma function [25, 26].

Condition $r>\rho_k$ is sufficient for the legitimacy of the representation of ψ_k by expression (5) with arbitrary values of θ and $\Delta\varphi_k$. Satisfied with the approximation at $max\ n$=1, we have:

$$\psi_k(r,\theta,\varphi)\cong 1+3r_k\cdot sin\theta\cdot cos\Delta\varphi_k\text{-}3/2\ r_k^2. \qquad (6)$$

Then the radiation pattern of the modulus of radiation taking into account (4) and (6) can be represented in the following way:

$$f(r,\theta,\varphi)\cong\sum_{k=1}^{N}(Ik/I_0)+(3sin\theta/r)\sum_{k=1}^{N}[Ik\ (I_k\cdot\rho_k)/I_0]\ cos\Delta\varphi_k\text{-}3/(2r^2)\sum_{k=1}^{N}(I_k\ \rho_k^2)/I_0\ , \qquad (7)$$

where $I_0=\lim_{\top}(r\to\infty)\sum_{k=1}^{N}I_k\ (r,\theta_k,\alpha k,\rho_k,\varphi_k)$.

(To simplify expression (7), the record of the functional dependence $I_k\ (r,\theta_k,\alpha_k,\rho_k,\varphi_k)$) is omitted.

The first term in (7) describes the pattern of the algebraic sum of the radiation intensity of all point sources that are components of the module virtually located in the spherical coordinate pole.

The second term characterizes the deformation of the diagram in the meridional and azimuthal planes and is determined by the weighted average radial size and azimuthal arrangement of sources $\bar{r}=\sum_k(I_k\cdot\rho_k\cdot cos\Delta\varphi_k)/I_0$.

The third term describes the effect on the axial value of the diagram θ=0 of the average radiation-weighted square of radial size $\bar{r}^2=\sum_k(I_k\cdot\rho_k^2)/I_0$.

With $r\gg\bar{r},\bar{r}^2$, corresponding to the far illumination zone, the pattern is determined by the first term (7). Experimental measurements of LIC or radiation patterns describe the dependence that corresponds to the first term (7) because the measurements are made in the far zone at the length of photometry where the radiant intensity does not depend on the distance from the source. It is obvious that dependences (4) and (7) can be used to interpret empirical data obtained in the near illumination zone with a large approximation.

The radiation pattern of the module is fixed relative to the selected pole of the spherical coordinates and the shape of the diagram in the near zone depends on this choice. It is most effective to choose the pole at the point of the plane of the module with the largest statistical contribution of the radiation of the diodes to the total radiant intensity or in the center of the weighted average radiation size of the module [27, 28].

The configuration of the radiation pattern of the isolated beam-diode is fixed relative to the pole located at the point of placement of the diode at a time when in the integrated device it is measured relative to the selected center of the spherical coordinates. However, in the integrated device, a large number of diodes are located outside the center of the spherical coordinates. Let us analyze the influence of the distance of the isolated diode from the center of registration of radiation force.

Based on a Lambert emitter with polar coordinates (ρ_k,φ_k) and axial symmetry of its own diagram, the diagram of its radiation intensity in the module can be represented as follows:

$$f_k(r,\theta,\varphi)=[cos(P_k\cdot\theta_k)\cdot R(\theta_k,\alpha_k)]/ [1\text{-}2r_k\cdot sin\theta\cdot cos\Delta\varphi_k+r_k^2]^{3/2}, \qquad (8)$$

where $P_k=\pi/(3\alpha_k)$ – the concentration parameter of the Lambert pattern [29];

$R(\theta_k,\alpha_k)=H(\theta_k)\text{-}H(\theta_k\text{-}(3\cdot\alpha_k)/2)$ – limiting function for polar distance θ_k;

$H(z)$ – asymmetric unit function.

Fig. 2 (a, b) contains the change of the shape of the meridional section $(\Delta\varphi_k=\varphi\text{-}\varphi k=0)$ of the indicatrix of the radiation intensity of a single diode when the position of the diode shifts relative to the pole of the spherical coordinates of the module. With the diode distance $\rho_k=0.2\cdot r$ the maximum length of the radiation force vector θ_{max} shifts by a certain value depending on α_k and makes 45° for $\alpha_k=\pi/3$ and 15° for $\alpha_k=\pi/12$. Displacement θ_{max} in plane $\Delta\varphi_k$=0 may theoretically reach 90°, in other meridional planes with $\Delta\varphi_k\neq 0$ it will be less significant. Comparison of dependences of the coefficient of illumination deviation from the law of inverted squares (LIS) $K_r(r_k)$ and $\theta_{max}(r_k)$ (Fig. 2 e) shows that at the boundary of the near and far zones of illumination $(K_r\cong 0.95)$ displacement θ_{max} for the Lambert source is ~30°.

The deformation of the indicatrix in the azimuthal plane occurs in the direction of displacement of the diode relative to the pole and is more significant for diodes with smaller α_k.

For the axial force of the beam, taking into account (8), we obtain:

$$I_{м.о}(r)=\sum_{k=1}^{N}\{I_{0k}\cdot cos[P_k\cdot arccos1/\sqrt{(1+r_k^2)}]\cdot R(r,\alpha_k)\}/ (1+r_k^2)^{3/2}, \qquad (9)$$

where $R(r_k,\alpha_k)=H(r_k)\cdot H(r_k\text{-}tg\ 3/2\ \alpha_k)$;

$$I_{0k}=I_k(\theta_k=0).$$

For the Lambert emitters P_k=1 axial radiant intensity $I_{м.о.л}$ of the module with the Lambert components takes the form:

$$I_{м.о.л}(r)=\sum_{k=1}^{N}I_{0k}/(1+r_k^2)^2 \qquad (10)$$

Fig. 2. Deformation of radiation patterns of diodes with $\alpha_k=\pi/3$ (a, c) and $\alpha_k=\pi/12$ (b, d) on frontal plane $\Delta\varphi_k=0$ (a, b) and azimuthal plane (c, d), curves: 1, 3 – $r_k=0$; 2, 4 – $r_k=0.2$; e) dependence θ_{max} (1) and coefficient LIS (2) for the Lambert diode on $r_k=\rho_k/r$.

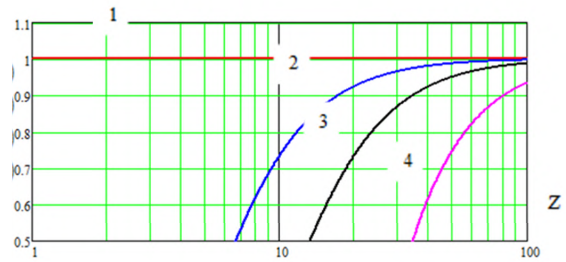

Fig. 3. Dependence of the normalized axial force of the diode radiation on the distance to the observation point Z, curves: 1 – $r_k=0$, $\alpha_k=\pi/6$; 2 – $r_k=0.1$, $\alpha_k=\pi/6$; 3 – $r_k=0.2$, $\alpha_k=\pi/6$; 4 – $r_k=0.1$, $\alpha_k=\pi/36$.

From expression (10) it follows: if N identical beam-diodes are placed radially symmetrically with respect to the pole (geometric center of the circle) then the total axial radiation intensity of the module $I^*_{м.о.л}(r)$ is:

$$I^*_{м.о.л}(r)=N\cdot I_{0k}/(1+r_k^2)^2 \qquad (11)$$

Fig. 4 (a, b) contains the radiation patterns of the radiation of the module according to formula:

$$f(r,\theta,\varphi)=1/I_0\sum_{k=1}^{N}\{I_{0k}\cos[P_k\cdot\theta_k(r_k,\theta,\varphi)]\cdot R[\theta_k(r,\theta,\varphi),\alpha_k]\}/(1-2r_k\cdot\sin\theta\cdot\cos\Delta\varphi_k+r_k^2)^{3/2} \qquad (12)$$

It should be noted that the radiation pattern for the axial radiant intensity expresses the coefficient of deviation of irradiation (illuminance) from the law of inverse squares $K(r)$:

$$f(r,\theta=0)=K(r)=[J_м\,(r,\theta=0)]/I_0\,. \qquad (14)$$

3Conclusions

1. The proposed analytical model of a multicomponent beam module is suitable for a priori modeling of light intensity curves (radiant intensity curves).

2. The proposed model includes:

a) the synthesis of radiant intensity and its indicatrix of the module integrated from point sources is performed according to the formulas (4), (12);

b) in the far illumination zone (K_k>0.95) the indicatrix of the radiant intensity of the module does no

* Corresponding author: klk.nauka@gmail.com

depend on the nature of the placement of the diodes and is determined by the first term of expression (7);

c) the deformation of the indicatrix of the radiant intensity of a multicomponent module during the transition from the far illumination zone to the near one depends on the geometry of the diodes relative to the pole of the spherical coordinates of the module and is determined by statistical values $\bar{r}$ and $\overline{(r^2)}$.

d) the displacement of the longitude of the maximum of the radiant intensity vector of a single diode depending on the distance to the coordinate pole is more significant for beam diodes with a wide pattern than with a concentrated one. The nature of the displacement of the azimuthal projection of the maximum of the vector is exactly the opposite.

Abstract. The article is devoted to the problem of increasing the efficiency of using energy resources of enterprises of the pulp and paper industry in Ukraine. It has been determined that the pulp and paper industry belongs to energy-intensive types of economic activity. Based on the results of the correlation and regression analysis, a connection was revealed and an economic and mathematical model was formed of the dependence of energy costs for the production of 1 ton of paper on the productivity of paper machines, equipment wear and the volume of investments in energy saving measures. Application of the proposed model will improve information support for the analysis of the effectiveness of energy saving measures, forecasting energy costs and strategic energy management in general. It was carried out at pulp and paper mills, the main obstacles to replacing fossil fuels with biomass in heat production were identified. This made it possible to develop a scientific and organizational model for the energy modernization of enterprises in the pulp and paper industry. It includes financial, organizational, environmental, regulatory, technological, scientific and educational tools. Their application at management will help improve the infrastructure of enterprises in terms of the use of renewable energy resources.

1 Introduction

The pulp and paper industry plays an important role in the economy, in meeting social needs and in the implementation of low carbon energy systems, but it is an energy intensive activity. According to the Technological Map of the European Strategic Plan for Energy Technologies, the average energy costs in the pulp and paper industry of the European Union countries are from 16 to 30%, and in Ukraine they measure up to 40% [25]. In 2018, in the production of paper and cardboard in Ukraine, they used 65,8 million m^3 of water, emitted 256 million tons of carbon dioxide into the atmosphere, and discharged 254 million m^3 of wastewater [20].
Reduction of energy costs in the pulp and paper industry of Ukraine, bringing them to the average European level are especially relevant in the context of adaptation to environmental changes caused by the global pandemic Covid-19. In particular, energy efficiency is an important reserve for reducing operating costs, which, in turn, can to be directed for maintenance of financial stability in the conditions of decrease in demand for production, disturbance of supply chains, growth of logistic expenses. Therefore, increasing the efficiency of the use of energy resources is a priority task to ensure sustainable development, maintain market positions, increase the competitiveness of pulp and paper enterprises in the context of the introduction of European environmental, technical and energy standards.

2 Literature review

Scientists of various fields of scientific activity are engaged in solving the problem of increasing the efficiency of the use of energy resources. Talita Mariane Cristino, Antonio Faria Neto and Antonio Fernando Branco Costa [1] have compiled and systematized scientific publications on energy efficiency in buildings. In their opinion, the greatest contributions were made by scientists from the United States, China and the United Kingdom, namely from the Lawrence Berkeley National Laboratory, the Hong Kong Polytechnic University and City University of Hong Kong.

Honggang Zhang, Andreas Gladisch, Mario Pickavet, Zhifeng Tao and Werner Mohr [2] substantiated that the current stage in the development of the information society is accompanied by a rapid growth in energy demand and consumption. This entails certain difficulties in terms of energy supply. In particular, the unprecedented expansion of wired and wireless networks has led to significant increases in energy consumption and a significant environmental footprint. Therefore, the energy costs of mobile service providers (operators) can reach half of the annual operating costs. In these conditions the introduction of energy management system and development of innovative solutions in the field of energy efficiency is especially important. Technologies for efficient energy distribution are being actively developed in the introduction of a sound DLT and IoT system, which

* Corresponding author: nota7sha@ukr.net

in the future will lead to increased energy efficiency. Therefore, it is important to combine the development of technological innovations with energy efficient technologies.

Khan et al [3] argue that the quality of the environment in the long run depends on the consumption of natural resources and renewable energy. Researchers have proposed policies that control the overuse of natural resources, promote sustainable living and set an environmental budget to ensure the country's sustainable development.

António Cardoso Marques, José Alberto Fuinhas, Carla Tomás [4] formulated a hypothesis that investments and organizational measures in the field of energy efficiency contribute to the sustainable development of the country's economy in general and the energy sector in particular. To prove the hypothesis, scientists have applied the ARDL model, which allows analyzing short- and long-term relationships for upward and downward movements of variables. For the analysis, indicators of the development of the industrial sector of 11 countries of the European Union from 1997 to 2015 were used. The results obtained indicate that investments increase energy efficiency in industrial enterprises, while reducing greenhouse gas emissions. At the same time, economic growth, in turn, directs the economy towards greater energy efficiency.

Saffet Akdag and Hakan Yıldırım studied the relationship between energy efficiency and greenhouse gas emissions through panel cointegration, panel causation, and FMOLS and DOLS analysis [5]. Using data from the European Union for 1995-2016, the authors also concluded that there is a close relationship between energy efficiency and greenhouse gas emissions. In particular, greenhouse gas emissions decrease with increasing energy efficiency. Maozhi Chen, Avik Sinha, Kexiang, Hu Muhammad, Ibrahim Shah [6] studied the impact of technological innovation on energy efficiency and sustainable development in the context of the "Fourth Industrial Revolution". Scientists claim that in the era of Industry 4.0, energy efficiency issues can be crucial in terms of sustainable development. The authors analyzed the dependence of the above economic factors on the example of the Middle East and North Africa (North African Republic of the Middle East) during 1990-2016.

Shuaiyin Ma, Yingfeng Zhang Yang Liu, Haidong Yang, Jingxiang Lv and Shan Ren [7] argue that the circular economy plays an important role in energy-intensive industries, since it is aimed at sustainable development of society. Scientists believe that in the context of Industry 4.0, advanced technologies (e.g., cloud computing, Internet of things, cyber-physical system, digital twin and big data analytics) provide numerous opportunities for implementing cleaner production strategies and developing smart manufacturing.

Burlov et al. [8] developed a mathematical model for managing the energy sector of the region, which was based on three main system-forming indicators describing the social, economic and ecological systems. Cosmi et al. [9] suggested using the R-MARKAL model to study the possibility of using renewable sources for the production of electricity and heat. Beyzanur Cayir Ervural, Selim Zaim and Dursun Delen [10] proposed a two-stage analytical methodology for assessing energy efficiency (a combination of different energy sources, mainly based on renewable sources) in Turkey.

Incekara and Ogulata [11] show that the main goal of optimal energy distribution is to reduce the cost of energy production, create a minimum impact on the ecosystem and use uninterrupted, clean energy sources under the light of the UNFCCC and the Kyoto Protocol. Ukrainian scientists [12, 13] have proposed models for providing the Ukrainian economy with energy resources, in particular, electricity and natural gas. At the same time, many scientists [14, 15] are exploring the issue of the relationship between the policy of reliable energy supply and environmental safety and sustainable development. Yemelyanov et al. [16] and Andrusiv et al. [17] argue that the economic growth of the national economy directly depends on the efficient consumption of energy resources. Conditions are modeled under which economic growth is accompanied by a decrease in the level of dependence of the economy on energy imports. Semerikov et al. [18] in their work consider the impact of the COVID-19 pandemic on the sustainable development of the national economy.

Despite the previous scientific results, energy efficiency and energy modernization of production remain relevant for most sectors of the economy and are of particular importance for Ukraine in connection with the proclaimed European Green Deal.

Therefore, the purpose of the article is to develop theoretical foundations and practical recommendations for increasing the efficiency of energy resources use at the pulp and paper industry in the context of environmental modernization of production and the introduction of alternative energy sources at enterprises.

3 Research methods

To achieve the goal of the study, traditional methods of economic analysis were used, in particular, statistical, mathematical, sociological. Thus, the volume and trends in the use of energy resources in the pulp and paper industry of the countries of the European Union and Ukraine were studied using the series of dynamics, comparison, average values and groupings. The methods of correlation and regression analysis made it possible to identify factors affecting the efficiency of energy resource use, to establish a relationship between energy costs per 1 ton of paper and the productivity of paper machines, equipment wear and the level of investment in energy saving measures. To identify obstacles to the use of biomass for the production of heat energy at the pulp and paper industry, a SWOT analysis and an expert survey of industry specialists were carried out. The experts were 26 top and middle managers in the field of energy management (chief engineers –18 people, heat and power engineers – 3 people, specialists in the field of energy management – 5 people) who work at the pulp and paper industry. The modelling method was used in the development of a scientific and organizational model of energy production modernization aimed at increasing the efficiency of energy resources use.

4 Results and discussion

4.1 The state and dynamics of energy consumption at the enterprises of the pulp and paper industry

The pulp and paper industry is an energy-intensive sector of the economy. Consumption of energy resources in this area in 2017 was 2.4% in Ukraine, 5.6% in the EU, 6.8% in the United States and Canada, and 9.4% in China of their total industrial consumption [19].

The dynamics of consumption of energy resources in the pulp and paper industry of individual countries of the European Union and Ukraine is different. In 2018, among the countries of the European Union, Finland consumed more energy resources in the pulp and paper industry – 6245.8 thousand tonnes of oil equivalent (toe), Germany – 5691.6 thousand toe, France – 2398.4 thousand toe and Great Britain – 1817.6 thousand toe. During 2010-2017, the average annual growth rate of energy consumption in the pulp and paper industry in Hungary amounted to 14.2 thousand toe, or 7.0%, Poland – 46.1 thousand toe or 2.82%, Portugal – 0.9 thousand toe or 0.1%, Belgium – 6.3 thousand toe or 0.9%, Great Britain – 46.9 thousand toe or 2.8%. At the same time, the average annual consumption of energy resources in the pulp and paper industry decreased in Denmark – by 190.0 thousand toe or 1.5%, in Germany – by 32.8 thousand toe or 0.6%. France – by 86.7 thousand toe or 3.3%, Spain – by 28.2 thousand toe or 3.6%. In the pulp and paper industry of Ukraine, the consumption of energy resources in the period under review decreased by 36 thousand toe or 12.9% (Table 1).

Table 1. Dynamics of consumption of energy resources by enterprises of the pulp and paper industry in Ukraine and some EU countries, 2014-2018, thousand toe ([19, 20]).

Country	2014	2015	2016	2017	2018	on average for 2014-2018		
						absolute increase	growth rate, %	rate of increase, %
Finland	5886	5936	5881	6060	6245,8	90.0	101.5	1.5
Germany	5823	5821	5672	5542	5691,6	-67.2	99.4	-0.6
France	2745	2384	2310	2369	2398,4	-86.7	96.7	-3.3
UK	1630	1629	1624	2082	1817,6	46.9	102.8	2.8
Spain	2052	1800	1681	1645	1764,9	-71.8	96.3	-3.7
Poland	1571	1552	1568	1637	1755,2	46.1	102.8	2.8
Portugal	1405	1311	1351	1367	1408,7	0.9	100.1	0.1
Belgium	715	707	737	708	740,3	6.3	100.9	0.9
Hungary	182	196	190	205	238,9	14.2	107.0	7.0
Ukraine [1/]	280	240	221	214	243,0	1.0[2/]	100.4[2/]	0.4[2/]
Denmark	169	76	75	74	74,0	90.0	101.5	1.5

In 2018, Ukraine the most energy resources has used in ferrous metallurgy - 8608 thousand toe (tons of oil equivalent), food and tobacco industry - 1484 thousand toe, mining - 1463 thousand toe. The pulp and paper industry together with the printing industry consumed 264 thousand toe. It should be noted that in other industries, similar in terms of average annual gross output, this indicator was significantly lower (construction – 197 thousand toe, transport equipment – 159 thousand toe, textile and leather industries – 62 thousand toe). Thermal energy prevails in the structure of consumption of energy resources of domestic enterprises of the pulp and paper industry.

It accounts for more than 57.2% of the total consumption of energy resources, while electricity accounts for more than a third and natural gas – 7%. Over the past five years, the consumption of all types of these resources has increased (on average by 2.4% per year), except for renewable sources, the volume of which is insignificant – 0.3 thousand toe, which does not correspond to global trends.

The energy intensity of paper and cardboard production by the pulp and paper industry in 2018 was 0.335 toe/t (Table 2).

Table 2. Level and dynamics of energy intensity of paper and cardboard production in Ukraine and some countries of the European Union, 2010-2017, kgoe/t ([21-22]).

Country	2010	2014	2016	2017	2018	2018 to 2010	
						kgoe/t	%
Portugal	1279,0	942,8	869,3	931,3	960,6	-318,4	75,1
Finland	746,3	793,9	801,7	853,8	868,0	121,7	116,3
Sweden	661,5	709,6	797,9	798,4	796,5	135,1	120,4
UK	740,5	1009,4	2267,9	808,9	673,6	-66,9	91,0
Norway	654,0	677,9	563,3	552,5	600,2	-53,8	91,8
Austria	409,3	502,1	467,6	481,9	532,4	123,2	130,1
Poland	480,3	546,7	603,0	504,3	524,7	44,3	109,2
Ukraine	518,2	555,0	473,9	426,8	480,4	-37,8	92,7
France	322,8	487,7	413,4	423,9	427,2	104,4	132,3
Italy	353,1	-	383,3	453,9	406,8	53,7	115,2
Spain	340,7	464,4	387,6	377,9	405,5	64,8	119,0
Germany	372,6	371,4	358,5	349,9	354,6	-18,0	95,2
Netherlands	351,8	356,9	302,7	306,5	282,4	-69,4	80,3

Thus, in comparison with the developed EU countries, Ukraine has a high energy intensity of production in the studied area. Therefore, in 2017, 480.4 kgoe/t was spent on the production of paper and cardboard, while in Italy and Spain – 406-407 kgoe/t, which is 15-16% less, Germany – 354.6 kgoe/t (26.2% less) and in the Netherlands – 282.4 kgoe/t (41.2% less).

In world practice, in order to improve energy efficiency and ensure energy independence, pulp and paper industry enterprises are increasing the use of renewable energy resources. According to the Technology Map of the European Strategic Energy Technology Plan, the average energy consumption in the pulp and paper industry of the European Union countries is between 16 and 30%. At the same time, 55% of the energy used comes from the combustion of biomass, 38% – from natural gas [21].

Despite the large reserves of biomass in the agricultural sector and forestry, the pulp and paper industry in Ukraine uses very little renewable resources and lags far behind foreign countries. In 2017, the share of used renewable energy sources in total energy consumption was only 0.1%, while in Austria – 45.1%, Poland – 46.1, Finland – 57.6, Portugal – 60.7 and Sweden – 65.5 % (Table 3).

Table 3. The share of renewable energy resources in total energy consumption in the production of paper and cardboard in Ukraine and individual EU countries, 2013-2018, % (according to data [23-25]).

Country	2013	2014	2015	2016	2017	2018	2018 to 2013, p.p.
Sweden	62.1	64.2	95.5	66.6	66.8	65.5	3.4
Portugal	64.7	65.8	63.3	60.8	63.2	60.7	-4.0
Finland	48.9	51.5	52.9	54.7	56.1	57.6	8.7
Poland	35.8	41.4	41.7	1.9	44.5	46.1	10.3
Austria	36.5	39.5	39.1	37.1	43.9	45.1	8.6
France	28.1	22.0	2.3	26.3	31.5	35.0	6.9
Spain	23.0	29.6	17.4	31.0	40.2	32.6	9.6
UK	0.0	0.0	0.0	0.0	19.9	24.0	24.0
Norway	34.3	32.0	15.4	16.6	16.2	20.5	-13.8
Germany	10.7	10.9	11.5	10.9	10.8	12.7	2.0
Netherlands	0.6	0.6	0.9	0.7	0.9	0.9	0.3
Ukraine	0.0	0.0	0.0	0.9	0.0	0.1	0.1
Italy	0.0	0.0	0.0	0.0	1.8	0.0	0.0

The general trend in 2013-2018 was the increase in the share of renewable energy resources in the total energy consumption of the pulp and paper industry, most of countries shown in Table 3. In particular, high growth rates for this indicator are observed in the UK – 24 p.p. and Poland – 10.3 p.p. At the same time, the UK pulp and paper industry began to use renewable energy resources only in 2016. The share of Spain increased by almost 10 p.p. (9.6%). Austria and France are next with 8.6 p.p. and 6.9 p.p. respectively. In Ukraine, the share of renewable energy sources in 2018 was only 0.1%. Domestic pulp and paper mills began to use renewable energy resources only in 2015.

4.2 Factor analysis of energy efficiency in enterprises

The efficiency of energy resources use in pulp and paper enterprises is influenced by a combination of internal and external factors. Mathematically, the dependence of the efficiency of energy resources in enterprises on organizational, production, energy and other factors should be reflected as a function

$$f\ (x_1, x_2 \dots \dots \dots x_n\ )\ , (1)$$

where f is a dependent variable, an indicator of energy efficiency,

$x_1, x_2 \dots \dots \dots x_n$ – factors influencing the efficiency of energy resources.

For a more detailed analysis of the influence of factors on the efficiency of the use of energy resources in the pulp and paper industry, production, economic, environmental, energy and personnel indicators are systematized and grouped by the authors (Table 4).

Table 4. Groups of indicators for factor analysis of the efficiency of using energy resources of enterprises of the pulp and paper industry.

Group of indicators	Indicator	Unit
Organizational and production	Paper machine productivity	t / day
	Efficiency of production equipment	%
	Wear and tear of production equipment	%
	Heat losses in production facilities	Gcal
	Heat losses during energy transportation	Gcal
Economic	The price of electricity	UAH / kW · hour
	The cost of thermal energy	UAH / Gcal
	Capital investments in energy saving measures	UAH
	Environmental tax rate per 1 ton of CO_2 emissions into the atmosphere	UAH / t
	The share of energy costs in the cost of paper or cardboard	%
	Costs for the operation of the energy management system	UAH
	The share of investment resources attracted through state and local targeted energy saving programs	UAH
Energy	Electrical capacity of products	kW · hour / t
	Heat capacity of products	Gcal / t
	Fuel capacity of products	m^3 / t
	Heat losses in networks	%
	Share of renewable energy costs	%
Ecological	The volume of CO_2 emissions, per 1 toe of fuel consumption	t
	Water intensity of production of 1 Gcal of thermal energy	thousand m^3 / 1 Gcal
	Share of recycled waste	%
Personnel	The amount of remuneration to employees for saving energy resources	UAH
	Expenses for measures to improve the qualifications of employees	UAH

4.3 Modeling the impact of factors on energy efficiency of enterprises

Based on the results of the preliminary study, it is possible to formulate a hypothesis about the existence of a relationship between the level of energy costs for the production of 1 ton of paper (cardboard) (resultant sign) and the following indicators (factor signs): paper machines productivity, the share of heat recovery, the share of renewable energy resources, equipment wear and tear, investments in energy saving measures. To confirm the hypothesis, let us group 27 pulp and paper enterprises in Ukraine according to the above performance indicator (Table 5).

Table 5. Dependence of the level of energy consumption for the production of paper (cardboard) on organizational and production, energy and environmental factors at pulp and paper enterprises of Ukraine, 2016-2018.

Indicator	Groups of enterprises in terms of energy consumption per 1 ton of paper, UAH / t			On average (total)	The ratio of indicators of group I to group III, %
	I	II	III		
	below 3600	3600-4000	above 4000		
Average energy consumption in the group, UAH	3450	3820	4220	3835	81.8
Number of enterprise years, units	8	11	7	26	114.3
Productivity of paper processing machines, t / day	232.6	196.8	156.7	194.7	148.4
The share of heat recovery, %	36.2	28.4	22.6	29.4	13.6 p.p.
Share of renewable energy resources, %	56	33	8	32	48.0 p.p.
Equipment wear, %	52	68	72	62	-20 p.p.
Investments in energy saving measures, UAH / t	125	95	52	88.5	240.4
CO_2 emissions, thousand tons	18560	18756	15692	17126	118.3
Share of recycled waste, %	14	17	12	13	-2.0 p.p.

Thus, group I includes enterprises with the lowest energy costs per 1 ton of products – below UAH 3600. In them, the productivity of paper machines is 232.6 t/day, the share of heat recovery is 36.2%, the share of renewable energy resources is 56%, equipment wear is 52%, investments in energy saving measures are 125 UAH/t.

Group II includes pulp and paper enterprises, in which energy costs per 1 ton of products range from UAH 3,600 to 4,000. Here, the productivity of paper machines is 196.8 tons / day, the share of heat recovery is 28.4%, the share of renewable energy resources is 33%, equipment wear is 68%, investments in energy saving measures are 955 UAH / ton.

The enterprises of group III have the highest expenses – more than 4000 UAH. In such enterprises, the productivity of paper machines is the lowest in comparison with other groups – 156.7 tons / day, investments in energy saving measures – 52 UAH / ton, as well as high wear and tear of production equipment – 72%.

In order to identify the direction and closeness of the relationship, we will perform a correlation-regression analysis based on data from 27 enterprise-years of the pulp and paper industry of Ukraine. Taking into account the previously obtained data for the formation of a multivariate regression model, the following main factors are included:

performance indicator – Y – energy costs per 1 ton of paper or other products, UAH/t;

factor features:

x_1 – productivity of paper machines, t/day;

x_2 – equipment wear, %.

x_3 – investments in energy saving measures, UAH/1 t

Using the specialized program of statistical data processing Statistica 10, the primary statistical analysis of the initial data was carried out (Table 6).

Table 6. Numerical characteristics of variables.

	Y	X_1	X_2
Average	3835	84,5	326.5
Standard error	28	12,5	34.8
Median	3674	86,5	315.4
Mode	2158	83.5	301.4
Standard deviation	25	16	41
Sample variance	326,4	36.2	47.5
Excess	174	47	65
Asymmetry	21	12	11
Interval	374	165	465
Maximum	3985	96.8	578.1
Minimum	3145	47.2	112.4
Sum	148759	165871	2165846

According to the results of regression analysis, the following multifactor regression equation is obtained

$$Y_{x_1} = 3860 - 428_{x_1} - 365_{x_2} + 65_{x_3} \qquad (2)$$

Multiple correlation coefficient r=0.728 indicates a strong relationship, and the coefficient of determination R^2 = 0.5298 shows that almost 53% of the energy consumption of paper and other paper products is formed under the influence of the above factors included in the model.

Of course, many more factors (social, managerial, environmental, etc.) influence on energy costs. They require further in-depth research. Thus, Tatenda Taodzera, Bhekisipho Twala, Johnson Carroll [26] developed an econometric model in which factors determine almost 90% of the change in performance.

Bazylevych et al determined that the profitability of organic production by more than 80% is determined by such indicators as profitability of fixed assets, the share of agricultural land engaged in organic farming and energy consumption. 10 tons of organic wheat [27].

To increase the energy efficiency of the pulp and paper industry, it is advisable to implement the following measures:

– technical re-equipment, modernization of production equipment, in particular, paper machines in order to increase their productivity;

– increase in investments in energy efficient technologies, reconstruction of the heat supply system, use of renewable energy sources, introduction of energy management systems, reduction of anthropogenic impact.

4.4 Model of energy modernization of enterprises

In the context of decreasing reserves of fossil fuels, the introduction of sustainable development principles, the priority task of increasing the energy efficiency of enterprises in the pulp and paper industry is the use of renewable energy resources. Given the natural and climatic conditions, a promising source is the production of heat energy from biomass. The most common types of biomass in Ukraine are:

– agricultural waste – straw, stalks and rods of corn, stalks and husks of sunflower;

– forestry waste – bark, wood chips;

– energy crops – willow, poplar, miscanthus.

In the pulp and paper industry, successful projects for the production of thermal energy from biomass have been implemented. In 2016, a new boiler house with a boiler for burning wood fuel with a moisture content of up to 60% was put into operation at PJSC "Kokhavian Paper Factory". The average annual heat production is 24 thousand Gcal. Annual consumption of wood chips is about 14 thousand tons / year (40 tons / day at maximum load). As a result of the energy modernization, the enterprise completely abandoned the use of natural gas (over 3 million m3 / year) and reduced the volume of greenhouse gas emissions.

Despite the obvious advantages, the use of renewable energy resources in the pulp and paper industry is accompanied by a number of risks (Table 7).

To identify the most significant barriers to the use of biomass for heat production at the pulp and paper industry in 2019, the authors conducted an expert survey of industry experts. According to the results of an expert survey, it was found that the use of renewable energy resources in the pulp and paper industry of Ukraine is constrained by the following reasons: lack of funds for capital investments, insufficient development of infrastructure for storing and transporting biomass, low supply of processed biomass, the need to re-equip the internal energy supply system (Table 8).

Thus, 26.9% of respondents indicated a lack of funds for the re-equipment of heat production, 19.2% highlighted the problems of the biomass market (weak development of infrastructure for transportation and storage of biomass, low supply in the biomass market), 15.4% stated the complexity of the technical re-equipment of the main production.

Table 7. SWOT-analysis of the use of renewable energy resources in the pulp and paper industry.

Environment	Positive influence	Negative influence
Internal environment	Opportunity to use waste of own production. Cost reduction of 1 Gcal of thermal energy. Reducing the cost of 1 ton of paper.	Increased energy costs. The need to ensure a stable supply of energy resources. The need to re-equip the energy supply system.
External environment	Introduction of state incentive instruments (tax benefits). Great potential of biomass in the agricultural and forestry sectors of Ukraine.	Rising prices for fossil energy resources (coal, natural gas). Strengthening the regulation of the anthropogenic impact of enterprises. The need to establish conditions for the supply of biomass. Underdevelopment of the biomass market in Ukraine.

Table 8. Distribution of answers of specialists of pulp and paper enterprises to the question "What are the obstacles to the use of renewable energy resources?"

Obstacle	**Number of answers**	
	people	**%**
Lack of funds for capital investments	7	26.9
Weak development of infrastructure for transportation and storage of biomass	5	19.2
Low supply in the biomass market	5	19.2
The need for technical re-equipment of basic production	4	15.4
High costs for biomass transportation	3	11.5
The need to stop production	1	3.8
The complexity of the operation of the equipment	1	3.8
Total	26	100.0

To increase the efficiency of energy resources use, we propose a scientific and organizational model of energy modernization of the pulp and paper industry. It aims to replace fossil and fuel energy resources with thermal energy from biomass. It contains a set of economic and organizational tools that are systematically implemented at the regional and local levels and are aimed at the formation of intersectoral logistics, marketing, financial, scientific and information flows (Fig. 4).

The implementation of the proposed scientific and organizational model will contribute to the technical and energy modernization of thermal energy production of the pulp and paper industry, in particular through the combustion of biomass of various types.

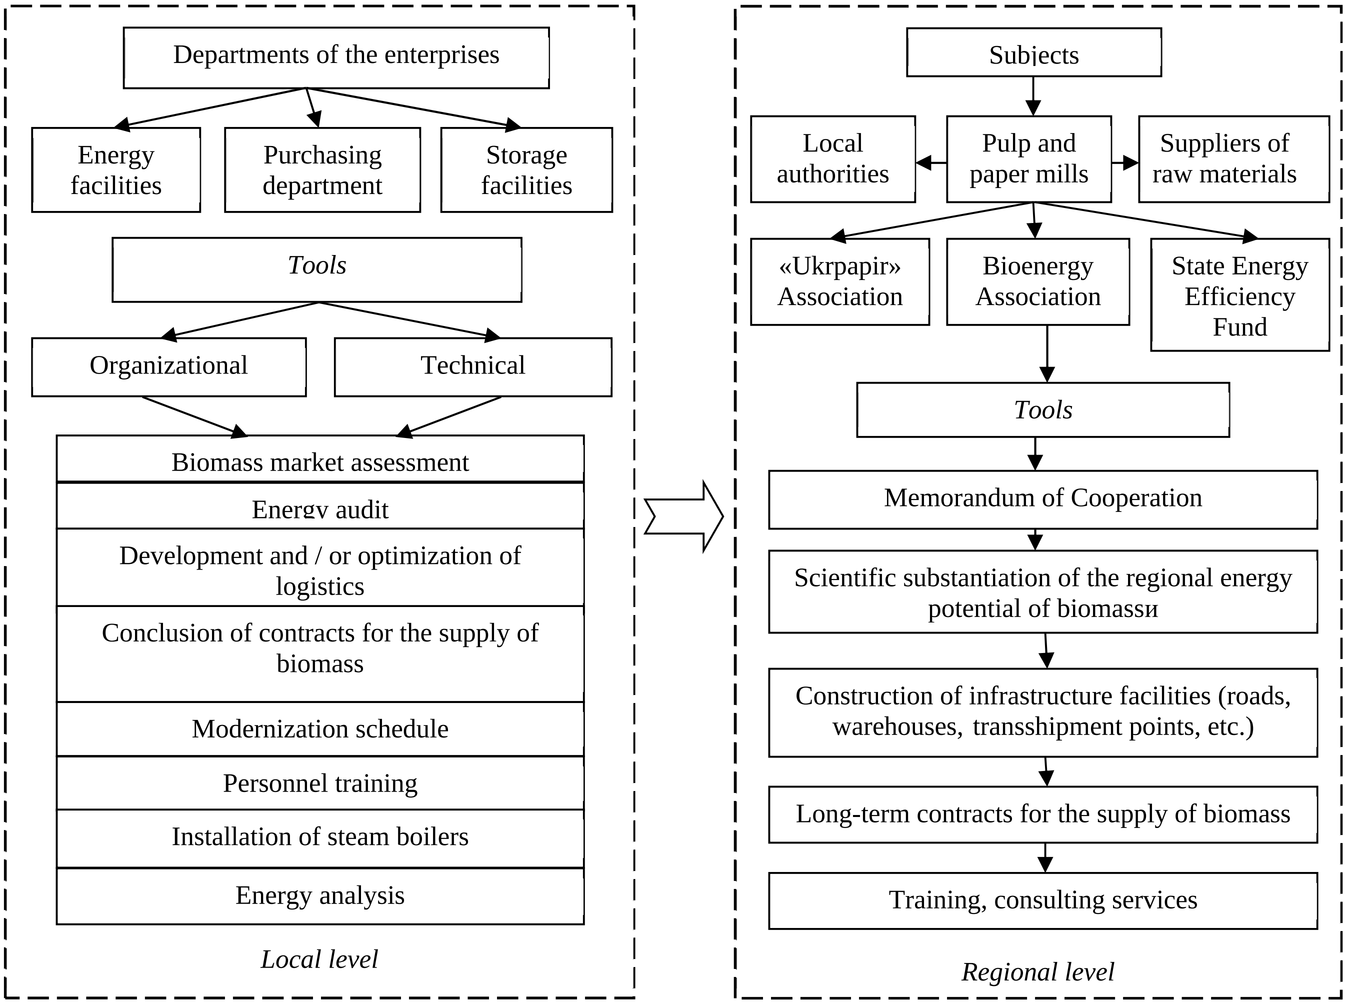

Fig. 4. Scientific and organizational model of energy modernization of the enterprises of the pulp and paper industry of Ukraine for the production of thermal energy from biomass.

5 Conclusion

In the context of reforming the energy sector of Ukraine, the introduction of a new model of energy markets, the harmonization of national legislation in accordance with European standards, an urgent requirement of the time is to increase the efficiency of using traditional and renewable energy sources in the production activities of business entities, in particular in the pulp and paper industry. In this industry, energy resources play a decisive technological and economic role in the production of paper and cardboard. Rational, scientifically grounded use of such resources will help reduce energy intensity, production costs, as well as the level of anthropogenic impact on air, water and land resources.

In recent years, at the enterprises of the studied industry, there has been a tendency towards an increase in the volume of consumption of energy resources. In 2018, compared to 2014, the volume of energy consumption here increased by 244 thousand toe, or 12%, including electricity – by 14 thousand toe or 20.5%. At the same time, in the past two years, the growth rate of energy resources consumption exceeded the rate of increase in the volume of production. As a result of rising prices, the share of energy costs in the structure of the cost of paper and cardboard has almost doubled, which has made the enterprises in the industry unprofitable.

To improve the information base for the analysis and assessment of energy consumption, the implementation of innovative measures for energy conservation, and the forecasting of energy costs, it is proposed to apply the developed multivariate correlation-regression model. It describes the dependence (multiple correlation coefficient = 0.728 – strong relationship) of the level of energy costs for the production of 1 ton of paper or cardboard (effective indicator) on the impact of production (productivity of paper machines, equipment wear) and environmental and economic factors (investments in energy saving measures, share of renewable sources).

To stimulate pulp and paper enterprises for energy modernization using renewable energy resources, it is necessary to implement a set of measures aimed at accumulating financial resources, forming and developing institutional and organizational ties between biomass producers and consumers, and strengthening information and educational training of engineering and management personnel. A scientific and organizational model of energy modernization of enterprises of the pulp and paper industry of Ukraine is proposed. It includes financial and economic, organizational, environmental, regulatory, technological, scientific and educational (personnel) and other tools for implementation at various levels of management, in particular, at the regional (biomass exchange, cross-industry research projects for assessing the biomass market, energy efficiency standards, mandatory energy audit and certification of the energy management system) and local (cooperation of producers and consumers of biomass) levels.

Abstract. The article investigates into the level of energy efficiency of main water pump stations of iron ore underground mines in case of time-of-day electricity rate. There are developed and suggested methods of analyzing the influence of pump electric capacity on electricity cost based on multifactor regressive models. The data on power consumption of iron ore mines indicates a complex character of analyzing the results obtained. However, application of information technologies enables using static materials in a new way including indices of power consumption, costs, water intake, mining depth, the number of pumps and their capacity by synthesizing mathematical models as complicated objects through in-depth procession of static materials and substantiation of the obtained results. For the first time, there are used multifactor regressive models considering multicollinearity and non-linearity of pump capacity in order to study its influence on power costs by using the elasticity factor. Analysis of mathematical simulation results relevant to static materials and applying the algorithm of studying dependency of the consumed power costs on pumps' capacity reveals some critical values resulting in corresponding effects. The authors recommend to apply the elaborated algorithm to conducting corresponding calculations by for mining enterprises to monitor formation of the strategy of providing energy efficiency under time-of-day electricity rates.

1 Introduction

Mining enterprises are considered energy-intensive or, to be exact, electric power-intensive [1-4]. The fact that power makes about 90% of the whole energy consumption and over 30% of the cost forms the basic component of the current level and constantly increasing power-intensity of mineral mining, thus negatively affecting mining enterprises' economy and their competitive character on the international market of raw materials [3-5].

The characteristic of the research object. The problem of controlling power supply and consumption in terms of some technological factors is challenging and real-life among other issues of reducing energy-intensity of mineral mining [6-7]. To do this, there are some positive steps taken at mining enterprises including ore underground mines. Among those, are a limited number of energy-intensive consumers consuming about 90% of the total power (Fig. 1) [8, 9]. Facts like these a priori are highlighting the vector-related character of developing the strategy of researching into control over power-supply/consumption of such enterprises by transforming energy-intensive consumers into power regulators [8-10]. Besides, this process is stimulated by the *Law on power in Ukraine* which has actually intensified the 'power load' on mining enterprises, thus enhancing this process [8].

2 Research materials

Analysis of distributing power consumption levels among energy-intensive consumers of iron ore underground mines enables or rather testifies to the individual character of each enterprise (Fig. 1).

Without generalizing solutions to the energy-efficiency problem of all energy-intensive consumers of iron ore underground mines, from all the mentioned issues (Fig. 1), we focus on investigating into power consumption and control levels of major pump stations.

According to Fig. 1, Batkivshchina mine has the highest power consumption level, while Hvardiiska – the lowest. It should be noted that besides typical conditions of pump stations, unlike other power consumers, they are noted for functioning not only in periods of enterprises' active operation, but also after their full or partial conservation (closure) [3-5].

It is essential to accentuate that power consumption of pump stations at non-operating underground mines is actually higher than that of operating ones (Fig. 2-3) [9-

* Corresponding author: ol.dozorenko2017@gmail.com

12]. At some underground mines, systems of underground water pumping are often combined into a single power complex. This causes some additional aspects affecting the choice of a pumping scheme design and operation modes of corresponding equipment.

Fig. 1. Variations of power consumption levels by types of mine consumers: a – Zhovtneva, b – Batkivshchina, c – Hvardiiska, d – Ternivska.

Yet, the basic component forms the foundation for the pumping structure of an individual underground mine and remains as given in Table 1.

According to Fig. 2-3, power consumption levels do not change greatly form year to year and tend to be stable.

Energy efficiency of underground mining enterprises' pump stations can be enhanced by:

- improving the technology of their 24-hour functioning and transferring them from the maximum pumping to a more economical mode of power consumption;
- creating return-water pump stations.

The latter will allow mining enterprises to generate their own electric power. The algorithm of major pump stations functioning is as follows: during 'economical time periods' water is pumped from the mine into the surface to corresponding water storage ponds, while during 'non-economical' ones, part of water from those ponds is pumped to the mine and pump motors start generating power [11-14].

Table 1. Established capacity of motors at Kryvyi Rih underground mines.

Mine	Motors		
	Capacity, kW	Number	Total capacity, kW
Ternivska	800	9	7200
	315	4	1260
	250	4	1000
			Total 9460
Hvardiiska	800	9	7200
	630	3	1890
	500	1	500
	315	3	945
			Total 10535
Zhovtneva	800	8	6400
	400	8	3200
			Total 9600
Batkivshchina	800	20	16000
	560	6	3360
			Total 19360

In other words, the power supply complex structure is transformed into the distributed power generation pattern [8].

With that, it is also necessary to develop (elaborate) the structure of pump stations' functioning under the power generation mode and upgrade the pump stations themselves both under the pumping mode and the power generation one.

To analyze the given process, one should develop mathematical models to analyze and elaborate trends of implementing theoretical results.

It is possible by introducing modern system-based approaches and mathematical and statistical methods.

By analyzing power consumption of pump stations, we can identify basic impact factors for individual iron ore underground mines (Table 2) [15-19].

While treating a power-consuming object (an underground mine) as a structural scheme, we can single out some input changes with controlling and disturbing actions of a corresponding energy-intensive unit, while the total electricity load of a mine is an output value.

In its general form, the mathematical model of the iron ore underground mine's consumption can be set by the function of input variables [6]:

$$P_{\Sigma} = F(\nu, n_i, Q_j, Q_\omega, q_j, R_j) \qquad (1)$$

where P_{Σ} is the total electric load of a mine, kW/year; v is intensity of the skip hoister functioning, t/year; n_i is the number of operating pumps at the j-th pumping stage, units; Q_j is efficiency of the j-th mine fan, (m^3/*sec*); Q_ω is total efficiency of underground mining

 https://doi.org/10.1051/e3sconf/202128005012

sites, (t/year); q_j is water inflow for the *j-th* pumping stage, (m^3/sec); R_j is resistance of the fan network of the *j*-th main mine fan. For model (1) variables ν, n_j, Q_j are controlling, while Q_w, q_j, R_j are disturbing.

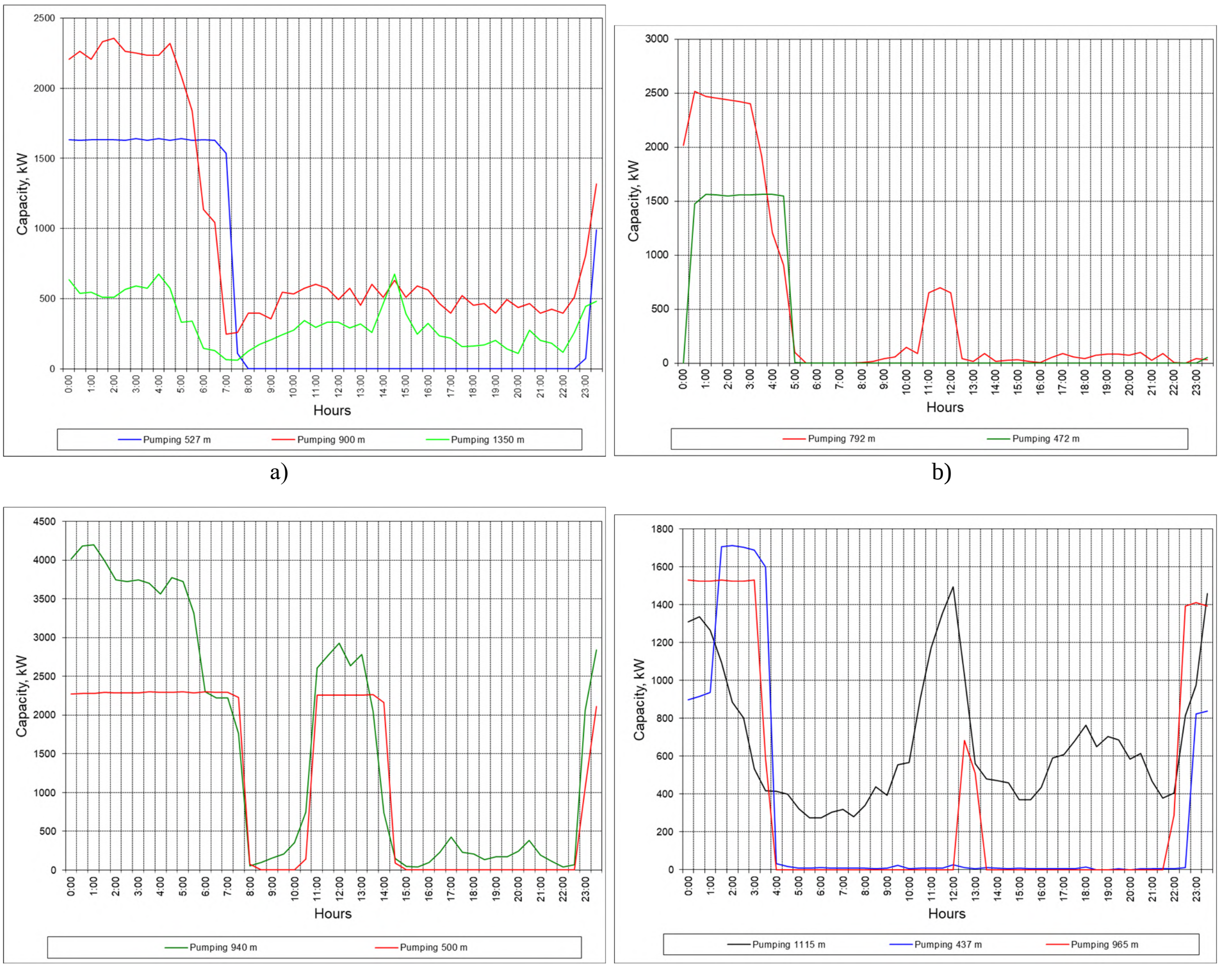

Fig. 2. Power consumption levels at major pump stations of some Kryvyi Rih iron ore mines in May 7, 2012: a – Ternivska, b – Hvardiiska, c – Batkivshchina, d – Zhovtneva.

Table 2. Basic factors impacting Kryvyi Rih iron ore mines' power consumption.

Power consumption of pump stations, kW/year			**Mining depth, m**	**Water inflow, m^3**			**Number of pumps, units**	**Capacity, kW**
2014	2015	2016		2014	2015	2016		
Ternivska								
11307677	10742330	8984057	1350	1585407	1494432	1211279	4	315
Hvardiiska								
9888508	8258434	6556150	1350	1310352	1136586	844396	3	315
Zhovtneva								
1037486	9293986	8482342	1265	1466460	1273886	1167783	1	400
Batkivshchina								
25801367	26878130	25583364	1465	4416601	4619121	4394257	4	800

According to established formalization, power consumption of pump stations can be set as:

$$P_\Sigma = F(\nu_1, n_i, q_j, R_j) \qquad (2)$$

where P_Σ is total power load of corresponding pump stations, kW/year; ν_1 is a level, m; n_i is the number of operating pumps at the *j*-th pumping stage, units; q_j is water inflow for the *j*-th pumping stage, (m^3/sec); R_j is capacity, kW.

For (2), variables ν_1, n_i, Q_i are controlling, while R_j is disturbing.

After considering the diagram of total power load realization of various combinations of input variables and recognizing dependency of power consumption of corresponding pump stations on controlling and disturbing actions, we can control functioning of the energy-intensive station according to the set criterion.

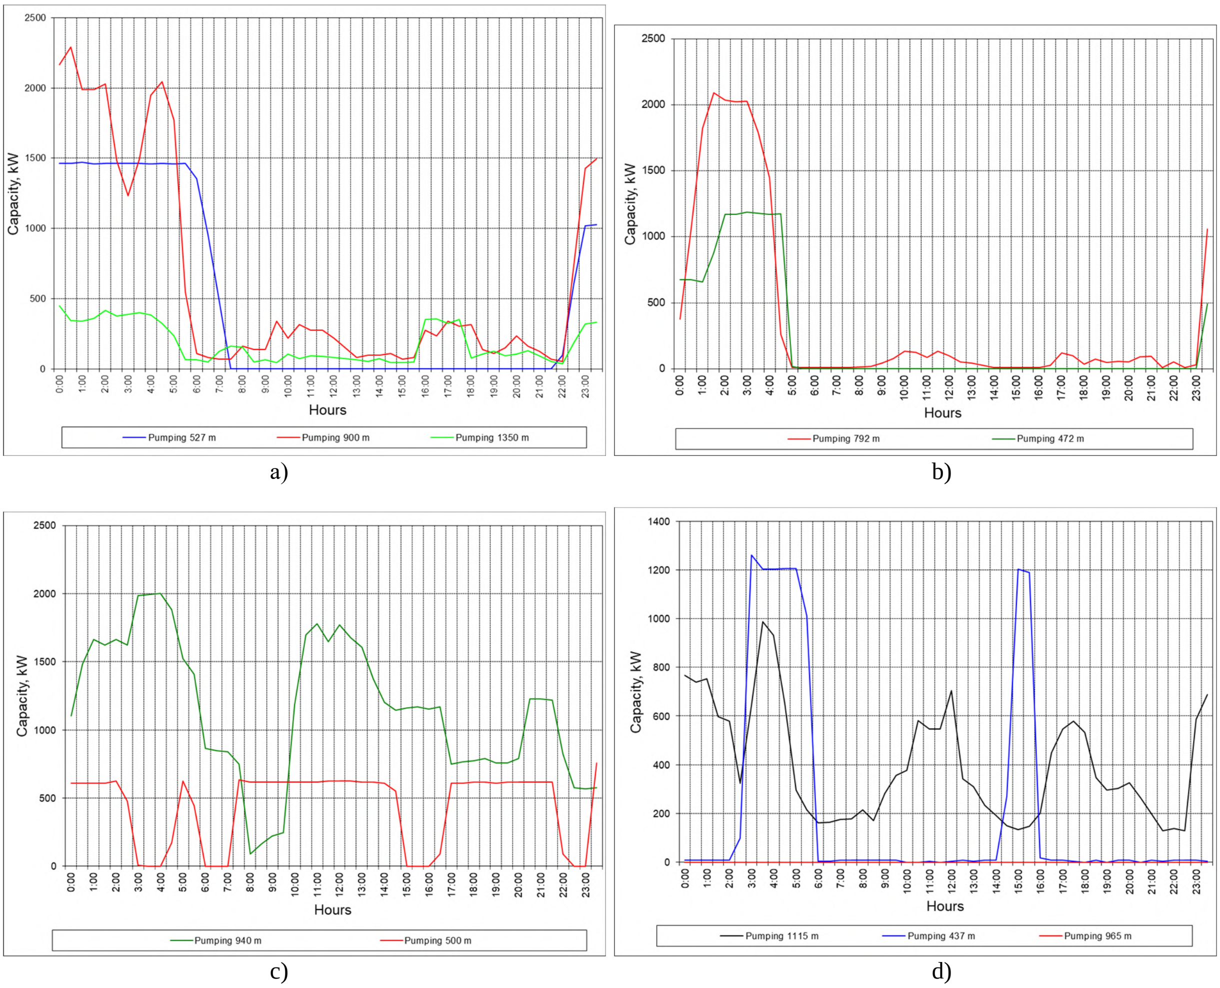

Fig. 3. Power consumption levels at major pump stations of some Kryvyi Rih iron ore mines in February 15, 2019: a – Ternivska, b – Hvardiiska, c –Batkivshchina, d – Zhovtneva.

The simplified two-area time-of-day rate can be written as:

$$C_{\Sigma} = C_{\partial} + C_{н} \tag{3}$$

where C_{∂}, $C_{н}$ are expenditures considering two-area (day, night) rates, *UAH*.

Besides, we can write:

$$C_{\Sigma} = C_1 \cdot W_{\Sigma}, C_{н} + C_2 \cdot W_{\Sigma},$$

where C_1, C_2 are area rates, *UAH/kW*.

According to [9], the maximum effect of controlling consumption is achieved by reducing loads in peak hours of the power system. In this case, the formula for expenditures required to minimize loads for pump stations can be set as the criterion:

$$C = \frac{C_1}{T_1}\int_0^{T_1} P_{\Sigma}\,(t)dt + \frac{C_2}{T_2}\int_0^{T_2} P_{\Sigma}\,(t)dt \rightarrow min \tag{4}$$

where T_1, T_2 are selected intervals of day and night hours, *hours*.

Thus, the problem involves finding values controlling variables$v_1(t)$; $n_i(t)$; $g_i(t)$ which, with set values of disturbing actions R_j will form the diagram of power consumption $P_{\Sigma}(t)$ that will have the criterion at least (4). The choice of values of controlling actions should consider some technological constraints associated with continuity of the process and provision of standard working conditions at an underground mine. The conditions include:

- keeping the accumulating underground bunker unfilled:

$$\int_0^T Q_{ш}(t)dt = \int_0^T v(t)dt, \tag{5}$$

- keeping the water level in water storage ponds stable:

$$\sum_{j=1}^{n}\int_0^T q_j(t)dt = \sum_{j=1}^{n}\int_0^T Q_{nj}\cdot n_j(t)dt, \tag{6}$$

where Q_{nj} is efficiency of a pump of the *j*-th pumping rate, m^3/sec; n is the number of pumping stages.

Real-time solution to the given problem with constraints (5) and (6) calls for application of calculation controlling devices and industrial programming controllers. On the first stage, they should forecast power consumption of an underground mine and provide a controller with recommendations for taking relevant controlling actions.

Meanwhile, reduction of criterion (4) in a general form is quite a complicated task even when applying computers. To simplify this problem, it is expedient to divide total target function (4) into local target functions.

The solution provides for in-depth preliminary analysis of the factor research.

For comparative analysis, we use Z-scaling to obtain a single interpretation system for indices equaling from 0 to N.

By way of illustration, we accentuate the research conducted at Batkivshchina mine with the largest water inflow among underground mines of Kryvyi Rih iron ore basin. Thus, we obtain the following diagram:

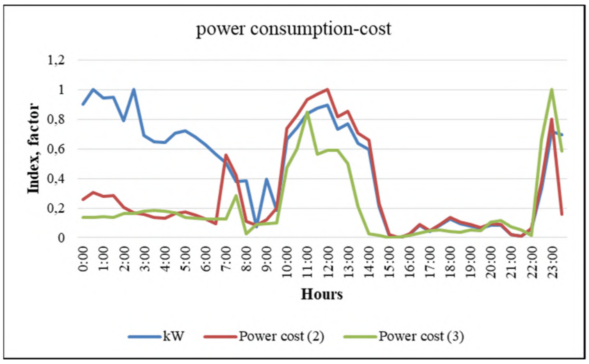

Fig. 4. Dependency of power consumption and its cost on the time of the day.

Visual analysis of the diagram enables stating some correlation of power costs and time-of-day power rates (Fig. 4). Yet, after totaling the output data, we observe excessive power costs for area power rates in comparison with the two-area one. In other words, it is expedient to conduct a multifactor research into power consumption. In a general case, the form of the multifactor regressive model is indefinite. Yet, while investigating into efficiency of power consumption, it is reasonable to use a linear form of a model structure representing it in an additive manner. On the basis of Batkivshchina mine data, $\hat{Y}$ is the consumed power cost (UAH), x_1 is water inflow (m^3/year), x_2 is mining depth (m), x_3 is the number of pumps (units), x_4 is motor capacity (kW) [9-12],

$$\hat{Y} = a + a_1 x_1 + a_2 x_2 + a_3 x_3 + b x_4^2 + \varepsilon \;, \qquad (7)$$

where a, a_1, a_2, a_3, b are parameters; ε is uncontrolled disturbance.

The next step of building the model involves identification of parameters through determining their values that are included into (7).

Processing output data in MS Excel enables identifying these parameters by the least-square method.

The multifactor regressive model results in the following (7).

To identify multicollinearity, according to the output data, we build a correlation matrix of input variables.

$$R = \begin{pmatrix} 1 & 0,886 & 0,702 & 0,572 \\ 0,886 & 1 & 0,665 & 0,611 \\ 0,702 & 0,665 & 1 & 0,420 \\ 0,572 & 0,611 & 0,420 & 1 \end{pmatrix} \qquad (8)$$

Analysis of correlation table (8) reveals that there is a close correlation between variables x_1 and x_2 which indicates multicollinearity. As the variable x_1 can be expressed by x_2, the variable x_1 can be excluded from input variables. The correlation matrix of input variables results in the following:

$$R_1 = \begin{pmatrix} 1 & 0,665 & 0,611 \\ 0,665 & 1 & 0,420 \\ 0,611 & 0,420 & 1 \end{pmatrix} \qquad (9)$$

Analysis of correlation matrix (9) indicates no close correlation between input variables, i.e. there is no multicollinearity.

In the given research, it is reasonable to apply a linear model representing it in an additive form.

Identification of model parameters by processing the corresponding statistic materials enables finding these parameters by means of the least-square method. Multifactor regressive model (9) results in:

$$Y = -0,391x_2 + 2,728x_3 + 33,23x_4 \qquad (10)$$

With that, the determination factor makes R^2 = 0.824, while the Fischer criterion is F = 14.1. The table value of the Fischer criterion is $F_T\left(0,05;3;8\right) = 4,07$. As $F = 14,1 > F_T\left(0,05;3;8\right) = 4,07$, equation (10) is statistically significant.

Absence of the nonlinear member for pump capacity indicates a monotonous character of dependency of power costs on pump capacity.

Thus, on the basis of the simulation results for Batkivshchina mine, it is expedient to conclude that the influence of pump capacity on power costs is positive, i.e. it increases this value. With that, elasticity of power costs in compliance with pump capacity is calculated by:

$$E_{Y/x_4} = \frac{33,23x_4}{-0,391\overline{x}_2 + 2,728\overline{x}_3 + 33,23\overline{x}_4}, \qquad (11)$$

Fig. 5 shows the diagram of function (11).

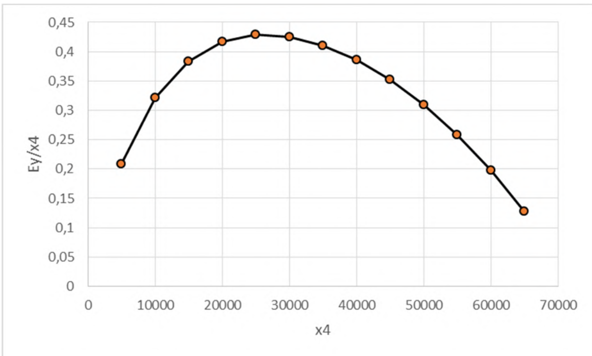

Fig. 5. Elasticity of power costs by pump capacity at Batkivshchina underground mine.

Analysis of Fig. 4 reveals that elasticity depends on power costs in compliance with motor capacity of Batkivshchina mine being positive and increases monotonously. Thus, there are developed methods of economic and statistical analysis that enable obtaining high-quality evaluation by using critical power costs depending on motor capacity as well as assessing its influence on power costs.

3 Conclusions

1. The suggested methods involve innovative approaches to evaluating power costs for operating pump stations of iron ore underground mines.
2. Application of modern IT enables digital methods of processing statistic data of power consumption indices including consumed electricity costs, the water inflow

level, the mining depth, the number of pumps and capacity of motors.

3. After synthesizing mathematical models as complex objects, the authors assess the influence of pump capacity on power consumption and conduct numerical analysis by using the elasticity factor to determine dependency of power costs on the capacity index of pump motors. This approach is worth applying in practice to forming the strategy of providing energy efficiency with time-of-date electricity rates.

Abstract. The bucket positioning of the excavator in three-dimensions (3-D) is the precondition of the robotic excavator starting automatized works. The electric excavator is one of the most widely used machinery in the mining industry, mainly due to its versatility and portability. Among the tasks performed by the excavator, there is a significant number of repetitive movements associated with moving the bucket to the unloading point and back to the face. Using automated functions to perform such repetitive tasks will not only significantly increase overall productivity, but also reduce energy consumption. This research is carried out to create a method of coordinate control of electric drives of the boom, dipper stick, and bucket of an electric excavator to perform accurate and efficient work. On the basis of the kinematic analysis of the excavator's attachment system, the trajectory of the end of the working body can be determined from the point of view of the coordinated movement of the electric drives of the main mechanisms of the excavator. Thus, the complex algorithm of the excavator bucket 3-D position control can be carried out by coordinated control of the movement of three separate electric drives. This coordinate control algorithm was tested on the example of the EKG-8I excavator, and the results of the verification showed that this developed control method can satisfactorily perform the function of automatic control of the bucket position in three-dimensional space. Optimization of control will be further carried out based on the analysis of the energy efficiency of various possible trajectories.

1 Introduction

The excavator is an earth-moving machine designed for excavation of soil with lifting, moving it and unloading it into a dump or onto vehicles. Excavators play an important role in opencast mining of ore deposits, are used in land reclamation and road construction, dredging and port work, and the building of defensive constructions.

The most powerful excavators are used in open pit mining both for stripping operations and for reloading the rock mass and forming dumps. Discontinuous single-bucket excavators are most widely used in these production conditions. Discontinuous (cyclic) excavators perform work operations in a specific sequence, forming a full working cycle; the movement of the machine itself is carried out after performing several cycles.

They are made with various types of interchangeable working equipment (Fig. 1), but in any case, the working body has rigid connections with the machine mechanisms, which limits its degrees of freedom.

In the mining industry, the production of new generation equipment is characterized by a functional and constructive combination of electromechanical converters with energy and information components with a high level of organization of control processes, i.e., the creation of mechatronic complexes. A modern excavator is a complex of interconnected electrical, mechanical, electromechanical and electronic systems of high complexity [1]. This allows us to consider the technological units of the excavator as mechatronic modules, combined into a complex mechatronic complex [2].

For mechatronic complexes of mining machines, due to their significant installed capacity, the energy efficiency of their functioning is of great importance. Increasing the efficiency of using electrical energy in industry and, consequently, mechatronic systems of mining machines is a determining factor in the development of technical systems in the near future [3].

In this regard, the study and modeling of energy processes is of decisive importance in the design of mechatronic systems for mining machines.

2 Literature review

At present, this task is becoming extremely urgent due to the fundamental renewal of both the power equipment of the excavator electric drives and the technical means of control. Energy calculation remains the most difficult and critical stage in the design of mechatronic systems. At present, it is carried out using separate methods [4], which do not take into account the settings of regulating devices and the features of power converters.

Analysis of modern scientific and technical literature indicates that at present there is no general theoretical approach to the analysis and synthesis of control systems that ensure the rational use of electricity in mechatronic systems, and effective models of energy processes for the study and design of mechatronic systems. Modern methods of designing mechatronic systems make it possible to synthesize the structure with a given quality of transient processes [5, 7]. Standard methods for adjusting the regulators of slave circuits of electric drive systems – modular and symmetric optima [6, 7], do not take into account not only energy losses and the influence of power supplies, but also the different physical essence of control processes in a mechatronic system. For electric drive systems with thyristor and transistor energy converters, the operation of which is characterized by harmonic distortions of the shape of currents and voltages, both calculations and measurements of energy characteristics turn out to be difficult, since specialized measuring instruments for these purposes are not produced, and models and estimates of the parameters of electric power processes for nonlinear systems do not have unambiguous and generally accepted definitions [8, 9]. The synthesis of control systems that are optimal in terms of the minimum energy consumption is a complex problem, which in many cases does not have an unambiguous solution [10]. In addition, as shown in [11], the minimum energy consumption is not identical to the increase in the energy efficiency of technical systems.

The synthesis of control systems optimal in terms of energy efficiency is significantly hampered by the lack of scientific papers devoted to a comprehensive analysis of the interrelated movements of excavator mechanisms to implement the desired trajectories of the bucket movement during the working cycle. A significant part of well-known scientific works is devoted to the study of individual excavator mechanisms, isolated from the general complex. The interconnected operation of the electric drives for lifting and head during the digging process is considered in articles [12, 13], but the operation of the same mechanisms in other sections of the trajectory is not considered.

Thus, there is a contradiction between the practical need to increase the energy efficiency of industrial mechatronic systems, on the one hand, and the limited capabilities of modern methods of analysis and synthesis and control algorithms for solving this problem. An important distinguishing feature of mechatronic devices is the presence of a perfect system for monitoring and controlling the position of the working bodies [14]. But it should be noted that the modern equipment of mining excavators does not contain a system for controlling the position of the working body. These functions are performed by the excavator operator by the joint or separate movement of individual elements of the kinematic chain with visual control of the result, which significantly reduces the possibility of automatic optimization of productivity, energy consumption, increases the requirements for the operator's qualifications.

The solution to this problem is possible only with the correct formulation of a complex of interrelated scientific and practical problems: the formation of indicators of the energy efficiency of mechatronic systems of mining machines, taking into account both energy costs and changes in productivity when implementing various control laws; automating the development of optimal trajectories for moving the working bodies of mechatronic systems in space; implementation of high-quality positional control systems that ensure the development of these trajectories; verification of the obtained technical solutions and their approbation in industry.

The formulated range of tasks cannot be considered in detail within one publication. The aim of this work is to develop a mathematical model of the mechanical part of open-pit excavators, which provides a solution to the inverse kinematics problem, i.e. establishing the required law of motion of individual mechanisms of a mining excavator to ensure a given trajectory of movement of the working body, which will further determine and optimize energy and technical and economic indicators when performing a working cycle.

3 Excavator design features. Excavator-related coordinate systems

The most common type of powerful mining excavators in the conditions of Ukrainian mining enterprises are shovel excavators – EKG-5, EKG-8, EKG-10, EKG-12.5, EKG-20. These excavators have a similar design of the main mechanisms, differing in geometric dimensions and minor structural elements.

The further presentation will be carried out in relation to the EKG-8I excavator, in our opinion, the most common model of a mining excavator in the conditions of the Kryvyi Rih iron ore basin. In fig. 2 shows the layout of the equipment on the platform of the EKG-8I excavator.

The main movements of the excavator, performed during the execution of the working cycle – lifting / lowering the bucket when digging and unloading (hoisting mechanism); a linear movement of the dipper stick during digging and unloading (crowd mechanism) and rotation of the platform to the place of unloading and digging (swing mechanism). We do not mention the mechanism of the excavator's travel, since the movement of the excavator is carried out separately from the working cycle.

The formulation of the problem of controlling the movement of the working bodies of an excavator requires the solution of kinematic problems typical for mechatronic systems: determining the position of the bucket in space for the given values of the positions of the crowd, hoisting and swing mechanisms (the direct problem of the kinematics of the mechanical subsystem) and determining the positions of the crowd, hoisting and swing mechanisms for a given position bucket in space (the inverse problem of the kinematics of the mechanical subsystem). The main difficulty in determining the position of the working bodies in space is that individual mechanisms perform different types of movements, and the axes of rotation of individual mechanisms do not coincide with each other.

Figure 3 a simplified kinematic diagram of the mechanisms of a power shovel excavator is presented. The position in space of the excavator bucket is fully described by the three-dimensional coordinates of the digging point K .

The lift of the bucket is carried out by changing the angle of rotation around the axis passing through point 1, perpendicular to the plane of the figure.

The extension and retraction of the bucket occur with linear movement in the saddle bearing located at point 1 and is carried out by the linear movement of the dipper stick L_N . The platform rotates around a vertical axis passing through its center of mass and is carried out by changing the rotation angle φ_R . Figure 4 illustrates the relative position of the boom and bucket of an excavator at various limiting values of the angle φ_P of the bucket and the linear movement of the dipper stick.

Thus, the controls action can be represented by the vector $u = [L_N \ \varphi_R \ \varphi_P]$, the state vector, that describing the position of the bucket, is given by the Cartesian coordinates of the digging point $s = [X \ Y \ Z]$.

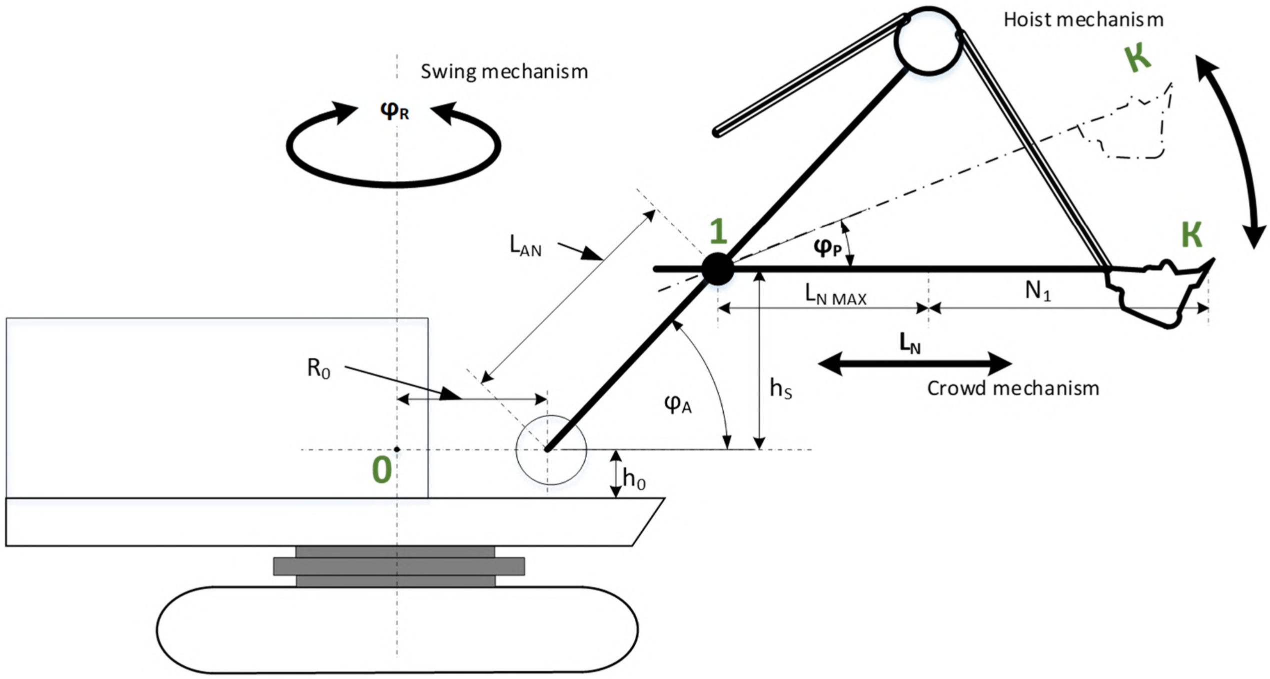

Fig. 3. Simplified kinematic diagram of the mechanisms of a power shovel excavator.

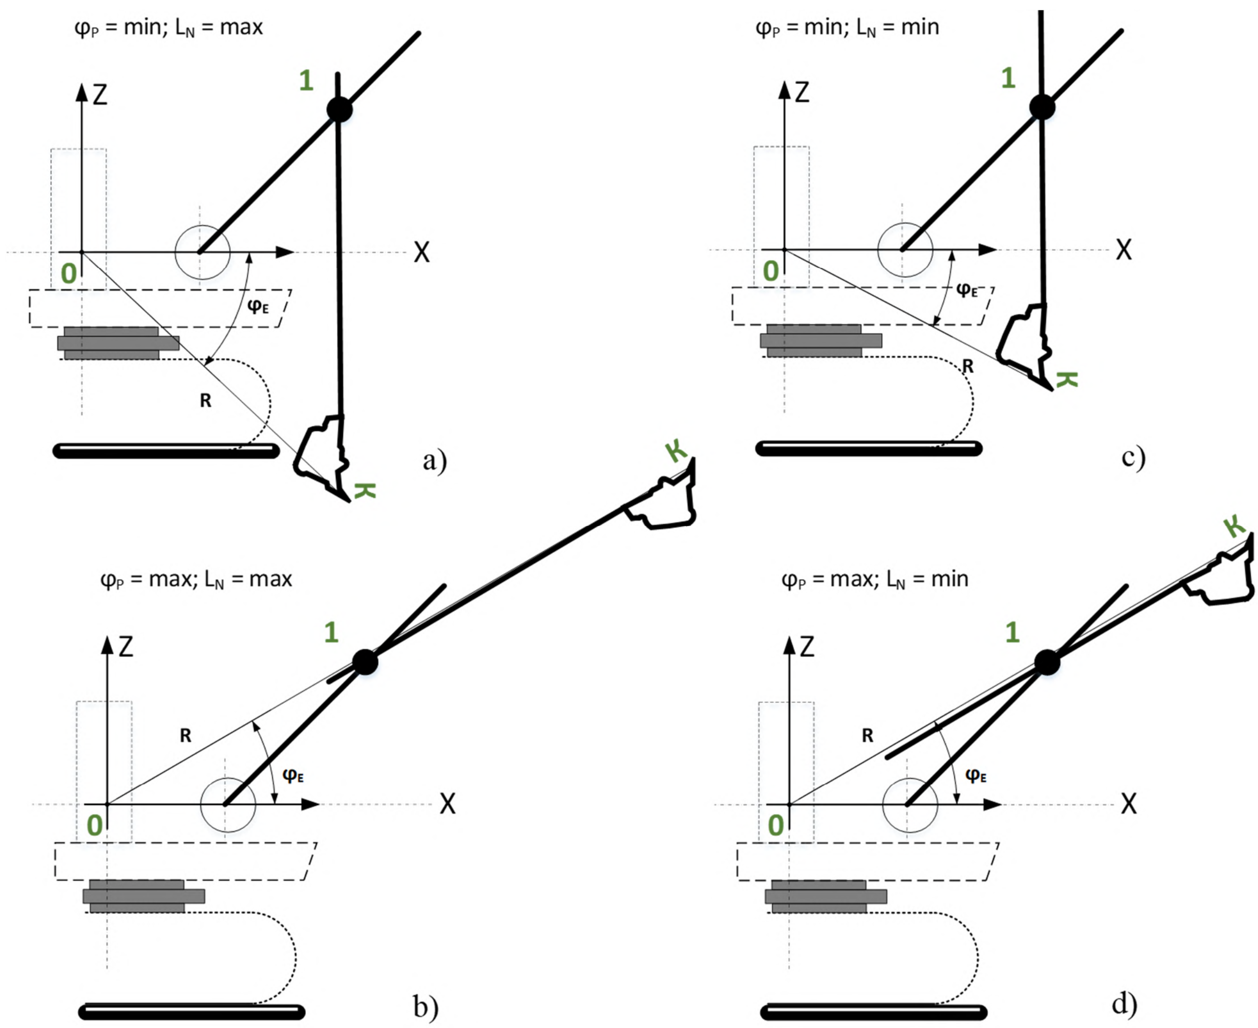

Fig. 4. Diagram of the mutual arrangement of the boom and dipper stick of an power shovel at various limiting values of the ascent angle of the dipper stick φ_P and linear movement of the dipper stick L_N : a) $\varphi_P = min$; $L_N = max$; b) $\varphi_P = max$; $L_N = max$; c) $\varphi_P = min$; $L_N = min$; d) $\varphi_P = max$; $L_N = min$.

Since the working bodies of the excavator make two different rotational movements, it is most natural to consider the movement of the working bodies of the excavator in a spherical coordinate system. The center of the spherical coordinate system of the excavator is located at point O on the platform rotation axis at a height equal to the height of the boom heel attachment, Fig. 5, Fig. 2.

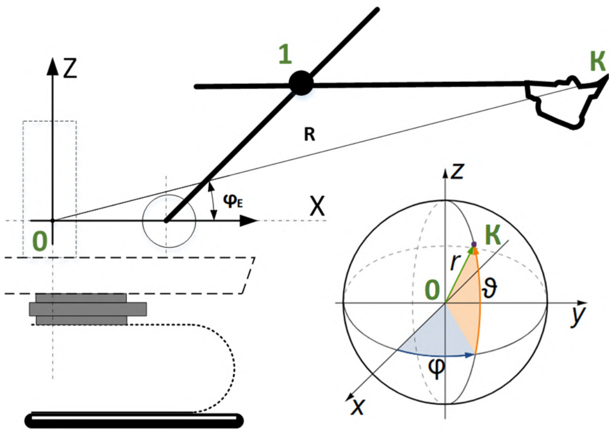

Fig. 5. Spherical coordinate system associated with the power shovel.

In this case, the spherical coordinate φ will be equal to the angle of rotation of the power shovel revolving deck φ_R, the spherical coordinate r will be equal to the length of the segment $0K$, the spherical coordinate ϑ will be equal to the angle $K0X$ (angle φ_E).

The traditional way to derive kinematic equations for backhoe/excavator or generic robots is to start with Denavit-Hartenberg parameters and transformation matrices [15]. In this paper, a less traditional approach will be used to take advantage of the fact that the stick and bucket move in a plane that is rotated by the swing joint (see Fig. 4). Taking advantage of this fact, the position vectors can first be derived using spherical coordinates and then converted into Cartesian coordinates (Fig. 5). With this location of the center of the coordinate system and the accepted direction of the coordinate axes of the orthogonal Cartesian coordinate system, the level of the excavator is characterized by a negative value of the coordinate Z.

4 Solving the direct problem of power shovel kinematics

It is necessary to determine the Cartesian coordinates of the position of the digging point K $(X, Y,\ Z)$ according to the specified values of the control coordinates of the excavator – the linear movement of the shovel L_N, the angle of the boom φ_P, the angle of rotation of the platform φ_R.

Consider how the coordinates r and ϑ of the spherical coordinate system are related to the lift angle φ_P and linear movement of the shovel L_N.

Let's define the coordinates of the point K K in the coordinate system $Z0Y$.

$$\begin{cases} K_X = R_0 + L_{AN}\,cos(\varphi_A) + (L_N + N_1)\,cos(\varphi_P) \\ K_Z = L_{AN}\,sin(\varphi_A) + (L_N + N_1)\,sin(\varphi_P) \end{cases} \quad (1)$$

Then the spherical coordinates of the point K can be determined as follows:

$$\begin{aligned} r &= \sqrt{K_X^2 + K_Z^2} \\ \vartheta &= \arctan\left(K_Z / K_X\right) \end{aligned} \quad (2)$$

The transition from a spherical coordinate system to three-dimensional Cartesian coordinates is carried out using the well-known expressions:

$$\begin{cases} X = r\,cos(\vartheta)\,cos(\varphi_R) \\ Y = r\,cos(\vartheta)\,sin(\varphi_R) \\ Z = r\,sin(\vartheta) \end{cases} \quad (3)$$

Formulas (1-3) give us a closed solution to the direct problem of excavator kinematics and determine the equations for the transformation of the excavator control coordinates $(L_N,\ \varphi_R,\ \varphi_P)$ to the Cartesian coordinates of the digging point $(X, Y,\ Z)$.

5 Solution of the inverse problem of power shovel kinematics

It is necessary to determine the excavator control coordinates $(L_N,\ \varphi_R,\ \varphi_P)$ using the specified Cartesian coordinates of the position of the digging point .

The transition to spherical coordinates from Cartesian coordinates is carried out using the well-known expressions:

$$\begin{cases} \varphi_R = arctan\frac{Y}{X} \\ \vartheta = arctan\frac{Z}{\sqrt{X^2+Y^2}} \\ r = \sqrt{X^2 + Y^2 + Z^2} \end{cases} \quad (4)$$

Using equations (2), we obtain the following relations:

$$\begin{cases} K_X = \frac{1}{\sqrt{1+tan^2(\vartheta)}} \\ K_Z = \frac{tan(\vartheta)}{\sqrt{1+tan^2(\vartheta)}} \end{cases} \quad (5)$$

And finally, based on equations (1), we get the follows:

$$\begin{aligned} \varphi_P &= \arctan\frac{K_Z - L_{AN}\sin(\varphi_A)}{K_X - R_0 - L_{AN}\cos(\varphi_A)} \\ L_N &= \frac{K_X - R_0 - L_{AN}\cos(\varphi_A)}{\cos(\varphi_P)} - N_1 \\ \varphi_R &= \arctan\frac{Y}{X} \end{aligned} \quad (6)$$

When solving the inverse problem of power shovel kinematics, it is necessary to take into account that not all points in space $(X, Y,\ Z)$ are reachable, which is associated with the existence of design constraints on the control coordinates of the excavator.

Therefore, equations (4–6) must be supplemented with the following restrictions:

https://doi.org/10.1051/e3sconf/202128005013

$$\begin{cases} L_{N\min} \le L_N \le L_{N\max} \\ \varphi_{P\min} \le \varphi_P \le \varphi_{P\max} \\ \varphi_{R\min} \le \varphi_R \le \varphi_{R\max} \end{cases} \quad (7)$$

Equations (4–6) subject to constraints (7) gives us a closed solution for the inverse problem of excavator kinematics.

6 Computational experiment

To validate the obtained expressions, a number of calculations were performed using the example of the EKG-8I excavator. The overall dimensions of this excavator used in the calculations are shown in Table 1. Fig. 6 shows the results of calculations of the working area of the EKG-8I excavator, which shows the entire area of space reachable by the excavator bucket under the constraints indicated in Table 1. The working area of the EKG-8I excavator has a complex spatial shape, limited in the front and rear by areas of the sphere.

Using the obtained expressions, a number of trajectories were calculated for moving the bucket after the end of digging from point 1 to point of unloading the bucket 2 (Fig. 7).

Trajectory 1 is obtained with the uniform motion of all excavator mechanisms. The Trajectory 2 was obtained by implementing a rectilinear movement from point 1 to point 2. Since a part of this trajectory went beyond the limits of the excavator's working area, a curvilinear section was formed in its middle part, corresponding to movement along the border of the working area.

Table 1. Dimensions of the power shovel EKG-8I

Parameter	Value
Boom length, m	13.35
φ_A – Tilt angle of boom, deg	47
Dipper stick length, m	11.425
Dipper stick stroke, m	4.3
R_0 – Distance from the revolving deck rotation axis to the boom heel attachment point, m

φ_{Tmax} – The maximum value of the swing angle of the power shovel revolving deck, deg (determined by the parameters of the power shovel working area)	120

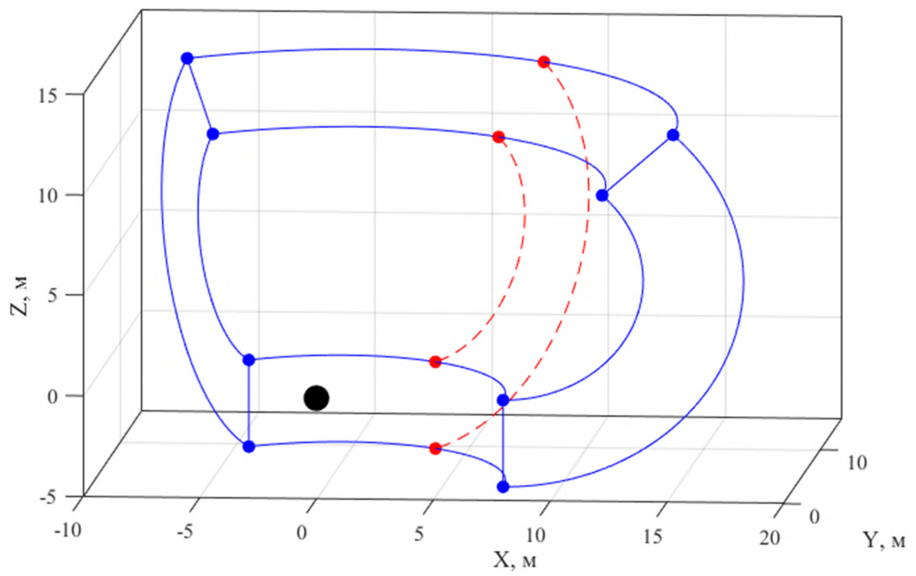

Fig. 6. Working area of the power shovel EKG-8I.

Trajectory 3 was obtained by sequentially turning the platform and then lowering the bucket to point of unloading 2.

The implementation of Trajectory 1 and Trajectory 2 requires the simultaneous coordinated operation of the electric drives of all the main mechanisms of the excavator, which may require high qualifications of the operator. Trajectory 3 is ensured by the sequential operation of the electric drives of the main mechanisms of the excavator.

The calculations showed that the length of these trajectories differs significantly: from 25 m (Trajectory 2) to 33 m (Trajectory 3), which is 32%.

Conclusion

The analysis of the mechanical structure of a mining bucket excavator was carried out, which made it possible to solve the inverse problem – according to a given trajectory of movement of the working body, taking into account technological limitations, at each point, the coordinates of individual actuators were calculated. The obtained trajectories of movement show the available possibilities for optimizing the operation of mining excavators, in particular, for minimizing the length of trajectories. However, it should be borne in mind that only the length of the trajectory cannot serve as an optimization criterion, since it does not take into account the speed of movement of the bucket along the trajectory and the associated energy costs of individual mechanisms, in which not only the speeds and accelerations but also the equivalent moments of inertia change during the movement.

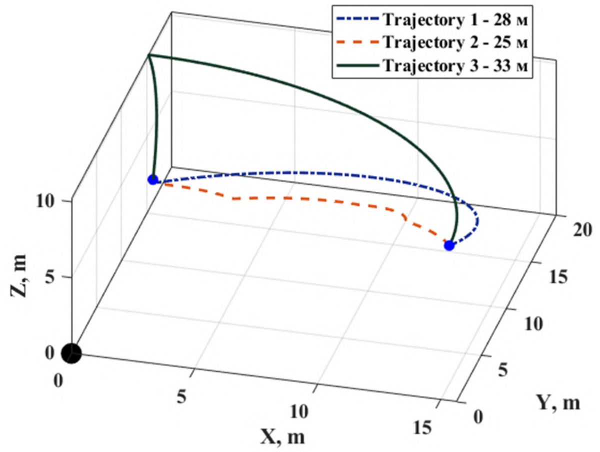

Fig. 7. Trajectories for moving the bucket after digging to the point of bucket unloading

The analysis of the energy costs of individual mechanisms, which is planned in the future, depending on the specified trajectory of the working body, will serve as the basis for optimizing the energy consumption and productivity of mining excavators when performing a full working cycle and can automate the processes of controlling the position of its individual mechanisms.

Abstract. The research deals with analyzing peculiarities of using active rectifiers in frequency controlled electric drives of underground mine hoists. There are developed MATLAB models aimed at comparing two types of control systems – hysteresis-based and the one with pulse-width modulation. The research aims to analyze power modes and parameters of active rectifiers, quality of voltage control, current and power of active rectifiers and to determine ways of improving power indices of electric equipment of hoists as well as provide power compatibility of electric equipment and underground mines' grids. Main attention is paid to analyzing circuitry of control systems of active rectifiers, parameters of power transformers and reactor equipment at underground mines' substations, frequency converters and synchronous slow-speed motors. There are also analyzed statistic data on power consumption at underground mines equipped with automated systems of commercial and technical power meters and specific consumption of power. The research results reveal advantages of the pulse-width modulation control system as compared with the hysteresis one by using such indices as speed-performance, quality of control, potential of controlling reactive power and the power factor. Application of the research results will enable determining structures and methods of adjusting control over the active rectifier in the frequency-controlled drive of underground mine hoists.

1 Introduction

Kryvyi Rih iron ore basin is a large producer of iron ore and raw materials for metallurgical enterprises (pellets, sinter) not only in Ukraine, but also in post-Soviet countries. Kryvyi Rih houses the largest metallurgical works, ArcelorMittal Kryvyi Rih, four mining and concentration plants (InGZK, PivdGZK, Central GZK, PivnGZK) with open pit ore mining and Kryvyi Rih iron ore works with underground ore mining.

At Kryvyi Rih underground mines, iron ore mined possesses a higher iron content than that from open pits of the mining and concentration plants. Power consumption of ore mining and haulage from underground levels of 1300m-1500m is higher than that at 200m-300m.

Four underground mines of Kryvyi Rih iron ore works (Rodina, Zaria, Hvardiiska and Ternovska), Yuvileina (Sukha Balka deposit) and the underground mine named after Artem (ArcelorMittal Kryvyi Rih) mine and hoist iron ore in Kryvyi Rih basin. Skip hoists with automated DC/AC drives perform these operations [1-3].

In the1960s-1970s, skip hoists primarily used DC drives with the Ward-Leonard drive system. This system enables required power of DC motors, smooth adjustment of mined mineral hoisting and minimal impacts of an electric drive on the main. The drawbacks of this drive system include necessity to install extra powerful large machines – a synchronous motor (SM) and a DC generator. This also involves additional maintenance expenses, increased power losses for idle performance of the generator and the DC motor, etc.

In the 1980s, there appeared powerful thyristor machines produced by Kharkiv electric-mechanical plant and Zaporizhzhia production association *Preobrazovatel*. This arouse the issue of applying these machines to replacing Ward-Leonard drives to increase electric drive capacity because of increased mining depth. The research institute *Kryvbasproekt* developed a design of modernizing some underground mines using a thyristor drive-motor (TD-M) system (Pervomaiska, the underground mine named after Lenin (Ternovska now), Yuvileina).

Practice of exploiting these drives has revealed both their efficiency and drawbacks. When reducing power consumption per a ton of mined ore, weight-size indices of electric equipment and maintenance costs, it is determined that the TD-M system impacts power quality in 6kV transmission grids of underground mines, their sub-consumers (municipal mains, electric transport, water treatment, etc.). This impact is revealed through voltage slumps and sinusoidal wave

[*] Corresponding author: mila.baranovskaya@gmail.com

https://doi.org/10.1051/e3sconf/202128005014

deformation when starting hoist drives, resonant phenomena when changing parameters of the supply main because of consumer switching, etc. The measures provided on the stage of electric drive designing and implementing (installation of harmonic filters) enabled partial reduction of this impact. With condensers of harmonic filters getting obsolete and broken, there appeared a problem of replacing TD-M drives of hoists by more effective ones [4-6].

AC electric drives with the FC-SM (frequency convertor-synchronous motor) and FC-AM (frequency convertor-asynchronous motor) systems came into use worldwide in the 2000s. These drive systems use AC motors which are more efficient as compared to the DC ones (smaller sizes, inertia moments, copper consumption for winding, no collector and costs for its maintenance, etc.) [7,8].

Besides, application of IGBT-transistors in frequency convertors of these drive systems allows developing and improving their control algorithms aimed at ensuring the higher-order harmonic, reactive power and the power factor.

The world-leading producers of powerful frequency convertors (ABB, General Electric, Siemens, Danfoss) are engaged in improving their power indices, quality of electric power in the main, reducing weight-size indices, providing better maintenance and service, etc.

In 2011, the skip hoist drive at Ternivska underground mine was modernized in order to increase its hoist capacity from 25t to 35t and mining depth up to 1800m. That included replacement of the TD-M system by the FC-SM one with the frequency convertor produced by ABB. Instead of two DC motors of the ПБК – 120/60 type, the AC motor AMZ 2500 LL 16 was installed. To supply this motor, there was installed a frequency convertor ACS 6000 with the microprocessor system of direct torque control in the main circuit of which ARU is an active rectifier, CBU is a unit of condensers; INU is an invertor unit.

Main advantages of the ACS 600 drive include:

- high operational characteristics;
- fast and accurate control combined with low power consumption ensures the best operational characteristics;
- control over the motor by the ACS 6000 through applying the highly effective direct torque control (DTC) method developed by ABB;
- the DTC method ensures the best dependency between torque and speed ever achieved in medium-voltage drives, thus providing fast and smooth control in any condition;
- the ACS 6000 drive uses the latest semiconductor switch contacts IGCT (gate turnoff thyristors with control units) developed by ABB on the basis of their own researches;
- the network power unit for the two-quadrant work with the constant power factor of 0.96 within the whole speed range;
- the active rectifier unit for the four-quadrant work with reduced harmonic content and controlled power factor;
- the DC bus for working with one or more motors and power recuperation;
- breaking energy generated in a single motor can be conveyed to other invertors along the DC bus without feeding from the main;
- recuperation of rotation energy;
- low noise and vibrations.

Operation of the hoist drive with the frequency convertor ACS 6000 at Ternovska underground mine during 12 years has revealed efficiency of electric equipment and minimal impact on the main.

In 2016, the skip hoist of Zaria underground mine was modernized with the TD-M system replaced by the FC-SM with the frequency convertor made by ABB and two AC motors AMZ 2500 LL 16. To supply these motors with power, two frequency convertors ACS 6000 with the microprocessor system of direct torque control were installed. Installation of the two motors and the two convertors was caused by greater hoisting capacity (50t) and the need to increase ore mining depth.

Greater driving power deteriorated quality of electric power in grids. At the 6kV section of 150/6kV Oktiabrska substation, there are much more significant deviations of voltage than those at Leninska substation with the FC-SM of the skip hoist (Fig. 1).

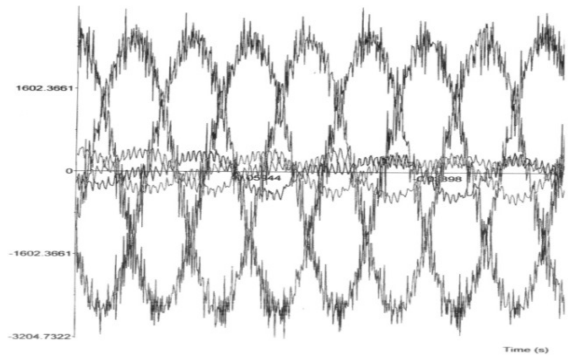

Fig. 1. Diagrams of voltage and current in the 6kV section.

Besides increased driving power of the skip hoist, some other factors also affect the grid including different standard capacities of power transformers at the substations (Oktiabrska - TDTN-40, Ternovska – TDTN-32), the structure of power supply diagrams, presence of shunt reactors, condenser units, etc.

The single-line diagram of power supply of Kryvyi Rih iron ore works' mines includes a power transformer of the step-down substation 154/6kV, a shunt reactor harmonizing the 6/3.1kV frequency convertor and a synchronous motor.

Hvardiiska underground mine is the next to upgrade its skip hoist drive. The 154/6kV substation contains two TDTN-63 transformers. Thus, in our opinion, while designing technical tasks to upgrade the drives, one should analyze their possible influence on the mains and quality of power. This analysis should consider technical potentials of active rectifiers of frequency converters. To do this, the research simulates electromagnetic processes and analyzes power quality control indices in the grid.

2 Characteristic of the control object

Table 1 contains data on power transformers and reactors of mine substations (1 – Ternovska, 2 – Zaria, 3 – Hvardiiska, 4 – Rodina).

Table 1. Parameters of power transformers of mine substations.

The three-phase active rectifier and the self-commutated voltage inverter invertor with high power indices are used in the frequency convertor. This diagram enables the power factor close to one, the DC mode and recuperation of power flow, i.e. the potential to transmit power to the mains.

3 Simulation of operational modes

This convertor type is similar to the self-commutated voltage inverter with the only exception that the diagram works in the rectifier mode and ensures the power factor close to one [9-16]. The key switches of the active rectifier can be controlled by the pulse-width modulation system or the hysteresis control system. Fig. 2 presents the diagram of the active rectifier model with the pulse-width control system. The control system has feedback signals along the input voltage U_1 and input current I_1.

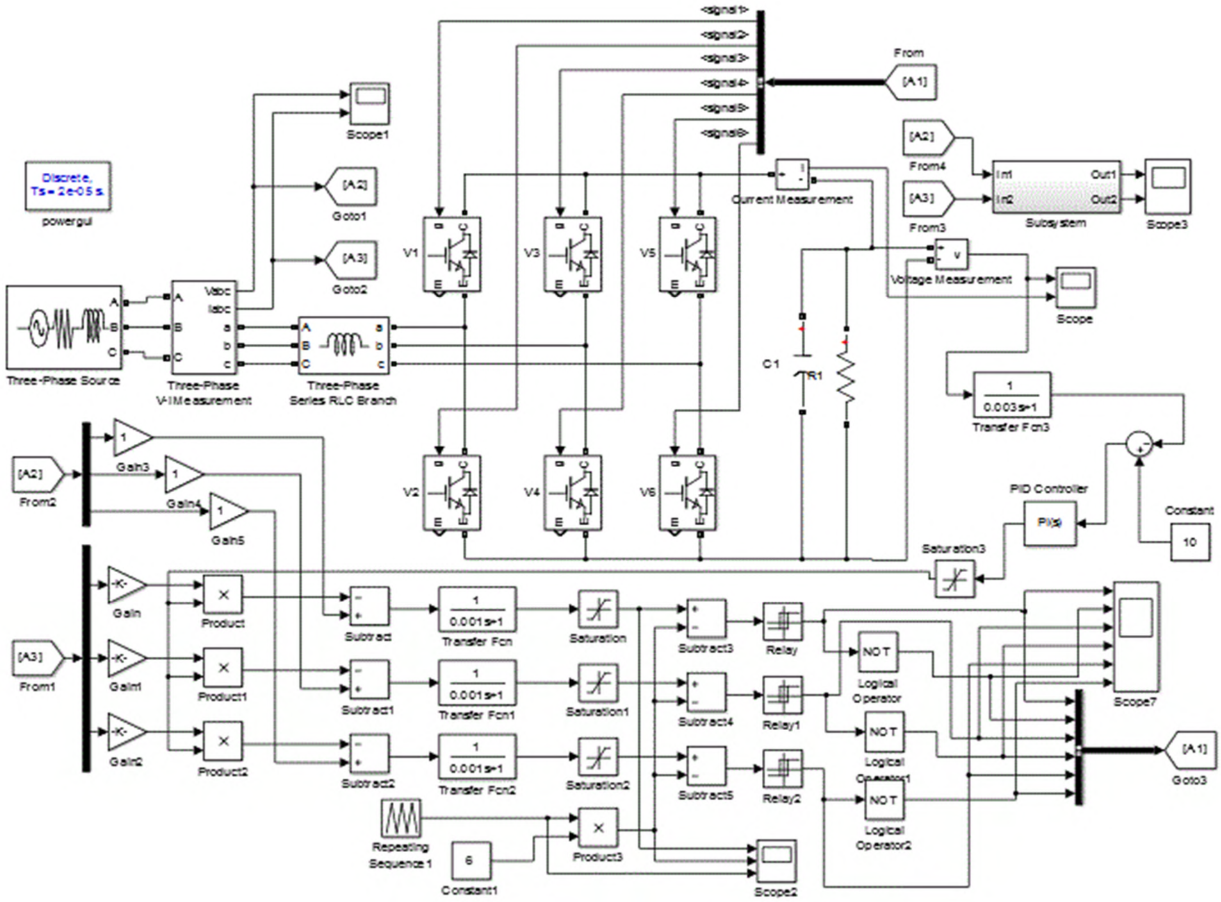

Fig. 2. Diagram of the active rectifier model with the pulse-width control system.

Pulse-width modulation is provided by comparing the controlling signal with that of the triangle waves. There is also a proportional-integral controller of input voltage U_d and a unit calculating consumed active and reactive power (Fig. 3).

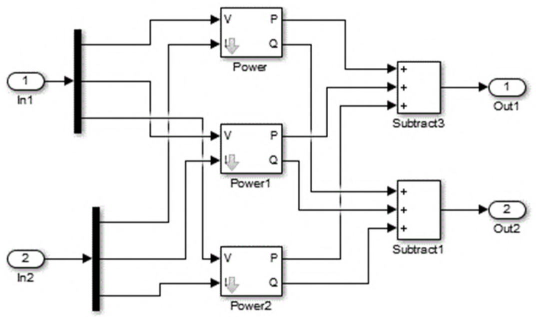

Fig. 3. Diagram of the model of calculating active and reactive power.

In simulating, dynamics of electric parameters of the active rectifier is under study. Fig. 4 shows an oscillogramme of the output current and voltage of the active rectifier.

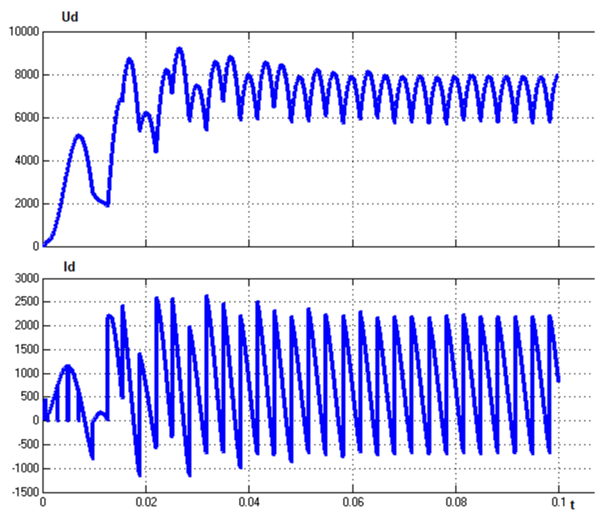

Fig. 4. Oscillogramme of the output current and voltage of the active rectifier with pulse-width modulation.

As is seen in the given diagrams, the control system enhances high-speed performance of voltage control (t_h=0.05÷0.06 c). Fig. 5 contains diagrams of the input current and voltage of the active rectifier. As is seen, the current curve coincides in phase with that of voltage, thus providing the power factor of 1.0.

The form of the current curve is determined by the two-level active rectifier and ratio of active and inductive resistance of the power transformer of the mine substation. The time of the output voltage increase to reach the set value makes 0.02sec, the pulse number is m=6.

Fig. 6 shows the diagram of the active rectifier model with the hysteresis control system.

Fig. 7 contains the oscillogramme of the output current and voltage of the active rectifier, while Fig. 8 presents oscillogrammes of the input current and voltage.

As is seen from the given oscillogrammes, the voltage and current curves of the same phases are cophased, that indicating the power factor being close to one. The primary current curve of the active rectifier differs from a sinusoid and can be improved by making the rectifier diagram more complex to increase its levels.

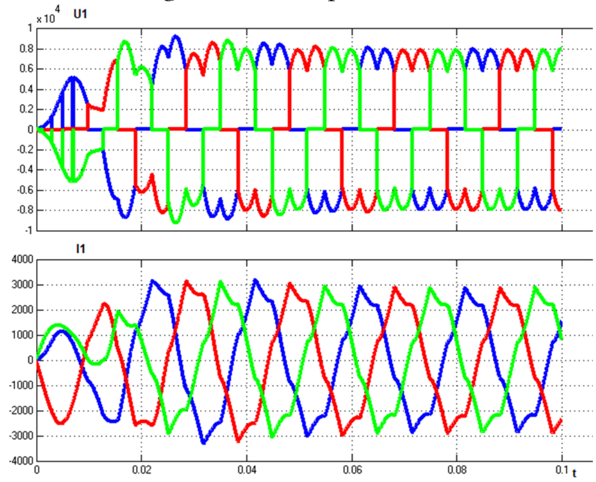

Fig. 5. Oscillogramme of the output current and voltage of the active rectifier with pulse-width modulation.

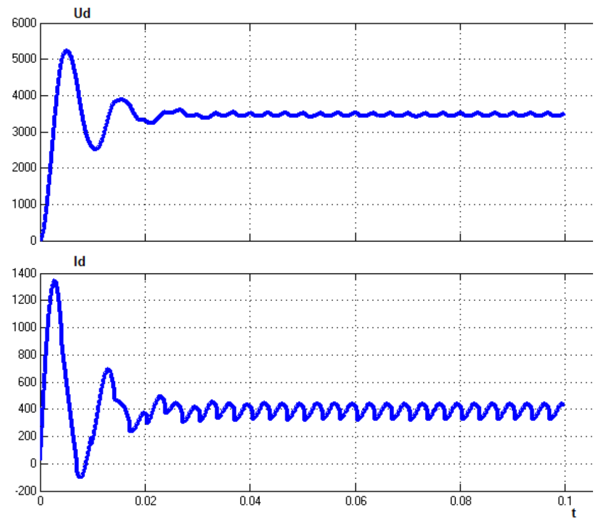

Fig. 7. Oscillogramme of the output current and voltage of the active rectifier with hysteresis control system.

The form of the input voltage and current can be improved by increasing inductance of the input filter of the active rectifier. As is seen, the diagrams of the output voltage and current of the active rectifier with the same parameters of the model elements indicate overcontrol of these parameters as absence of pulse-width modulation reduces speed-performance of control over output voltage of the self-commutated rectifier.

To reduce voltage overcontrol, the control system and the output voltage controller are to be readjusted. The time of the output voltage increase to reach the set value makes 0.02 sec, the pulse number of the rectifier scheme is m=6.

The curves of input currents of the active rectifier with the hysteresis control system have significant deviations as compared with the active rectifier with the pulse-width modulation control system. The form of these parameters can be improved by changing parameters of the input filter of the active rectifier.

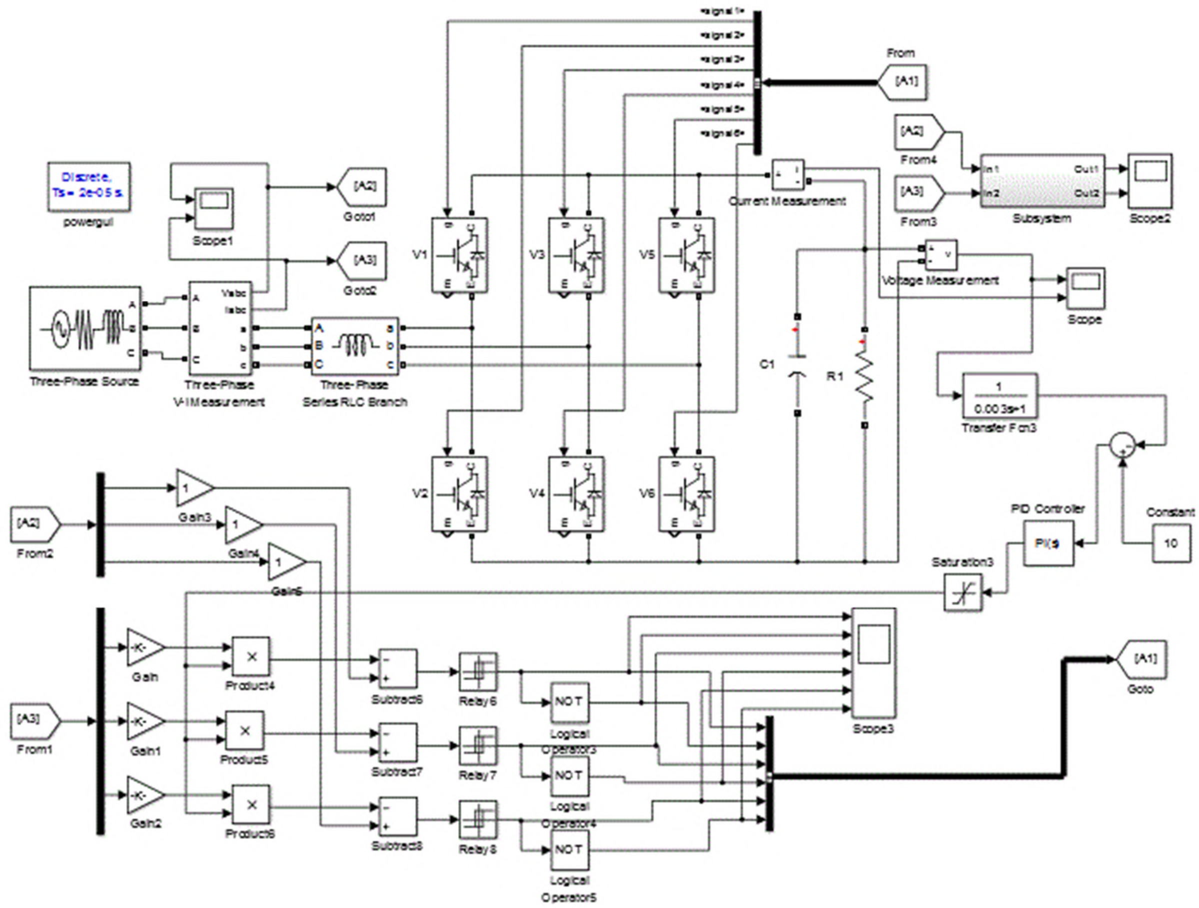

Fig. 6. Diagram of the active rectifier model with the hysteresis control system.

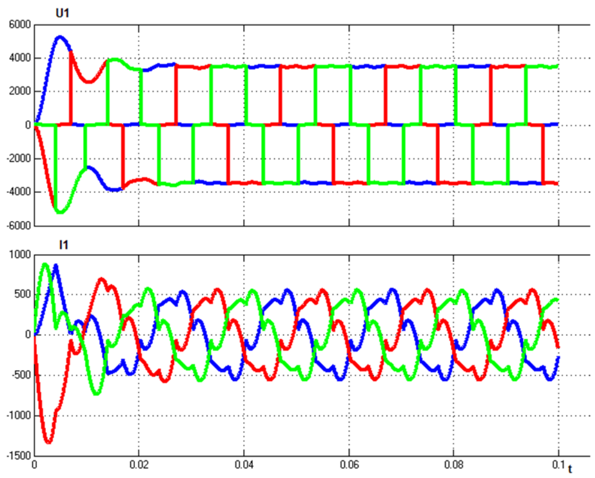

Fig. 8. Oscillogramme of the output current and voltage of the active rectifier with the hysteresis control system.

Fig. 9 shows oscillogrames of active and reactive power of the active rectifier.

Pulsations of signals of active and reactive power are conditioned by pulsations of the input voltage and current. To use these signals as feedbacks, it is necessary to set corresponding filters.

There are MATLAB researches into the drive model of the FC-SM system with the active rectifier. Fig. 10 presents a drive model with the active rectifier.

This model has units of the three-phase voltage source, the three-phase voltage and current meter, the self-commutated synchronous motor with subsystems of the synchronous motor, the rectifier, the DC chain, the invertor, the speed controller, the rectifier controller and the vector controller, the demultiplexor of motor parameters and the calculator of active and reactive power from the grid.

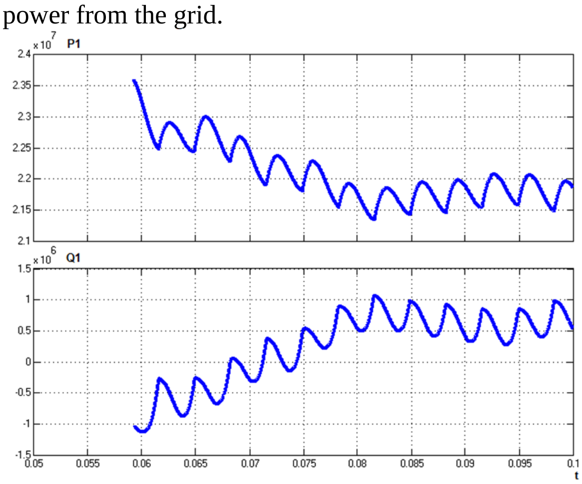

Fig. 9. Oscillogramme of active and reactive power of the active rectifier.

Fig. 11 contains diagrams of the rotor speed of the synchronous motor, electromagnetic torque, active and reactive power. This model reduces reactive power from the grid. The reaction of the drive to load surge and changes of consumed active and reactive power are studied. As is seen from the speed diagram the astatic control system after the load surge reacts to dynamic speed slumps and monitors the signal by the speed. The diagram of consumed active power is determined by the motor speed and torque. Reactive power is minimal and

https://doi.org/10.1051/e3sconf/202128005014

provides the power factor close to one. The system is also able to generate reactive power. The system has four control channels – by the input reactive current of the active invertor, by the set output voltage of the active rectifier, by frequency and the pulse ratio of the invertor voltage.

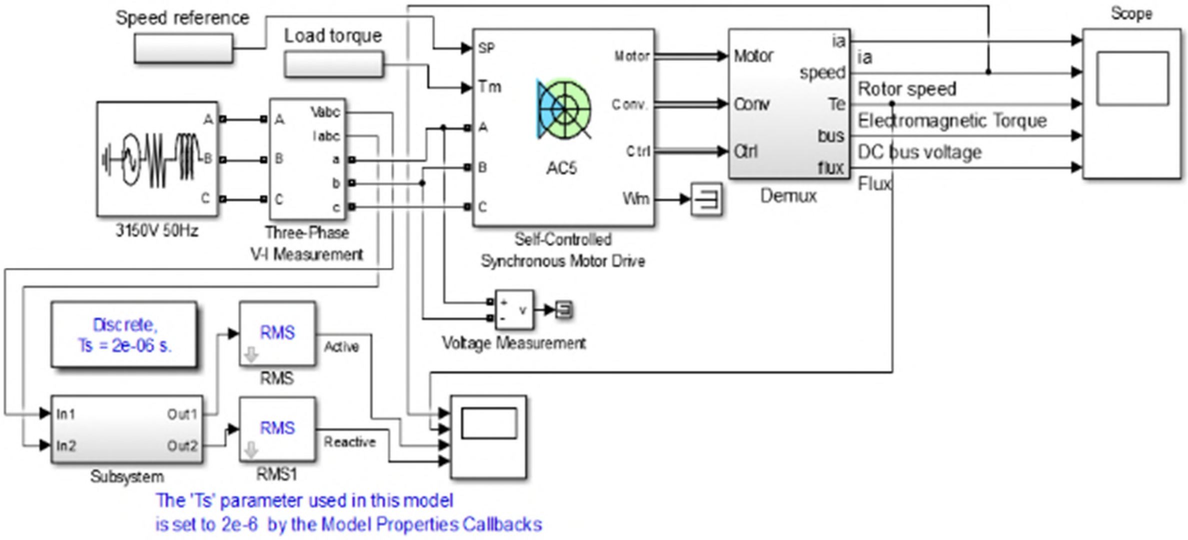

Fig. 10. Diagram of the drive model with the FC-SM.

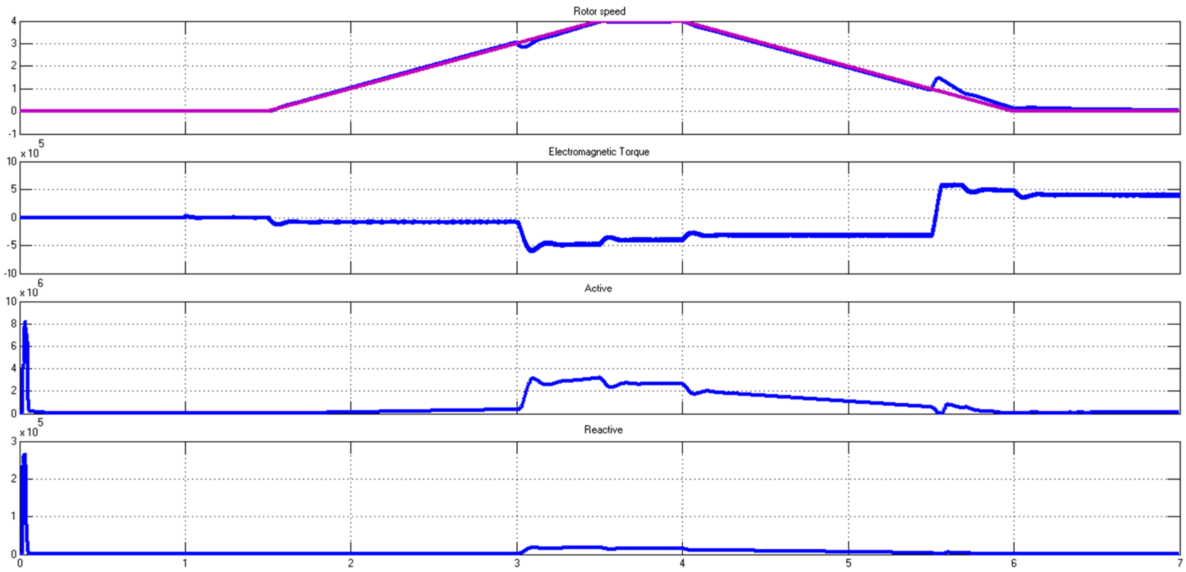

Fig. 11. Oscillogramme of rotation speed, active and reactive power of the FC-SM.

4 Conclusions

The research investigates into specific features of applying active rectifiers to frequency-controlled drives of underground mine hoists. Corresponding models are developed and studied to compare and analyze two types of control over transistor switches of the active rectifier. Analysis of the active rectifier mode enables determining advantages and disadvantages of these control systems and formulating requirements to improving parameters of the active rectifier. The structure of the control system of the frequency convertor is also analyzed, this indicating a potential control over torque controllers, the motor flux, the level of consumed reactive power and the power factor value.

Application of the research results will allow determining structures and methods of adjustment of control systems of the active rectifier in the frequency-controlled drive of underground mine hoists. The scope of further research will involve improvement of energy efficiency of active rectifiers and reduction of their impact on the grid.

Abstract. The active and reactive power sharing of distributed generation sources (DGs) connected to isolated microgrids with a single point of common coupling (mono-PCC) to which the loads are also connected has already been the subject of several studies. A high penetration rate of DGs based on renewable energies has as a logical consequence the development and implementation of mesh and more complex multi-PCC microgrids. In this paper, a developed droop control method for synchronization and power sharing between different DGs connected to a mesh islanded multi-PCC microgrid with many distributed generation sources (DGs) and different type of loads (including active load (CPL)) randomly connected to different PCCs is applied. Then, a state model of the entire mesh microgrid is developed integrating the generators with their controllers, power lines, droop algorithms and dynamic loads. This model is then used to study the asymptotic stability and robustness properties of the system. The simulation results confirm the effectiveness of the applied strategies for the synchronization of the different DGs to the microgrid while ensuring an efficient active and reactive power sharing. also, they confirm the validity of the developed state space model of the system.

1 Introduction

Microgrids powered by clean renewable energy through distributed power generation units are one of many solutions to reduce greenhouse gas emissions [1]. The intermittency of renewable energies can lead to some serious microgrid instability problems. therefore, one of the challenges is to synchronize and connect all distributed generators to an isolated microgrid while ensuring "plug and play" functionality and respecting the active and reactive power sharing between the different distributed generation units [2-4].

Strategies based on Droop control is currently the most used methods for power sharing and synchronization in literature strategy [5-9]. Those strategies were proven to be effective in microgrids with a single point of common coupling (mono-PCC) like in [10].

Unlike in mono-PCC microgrids those strategies for synchronization and power sharing are less efficient when they are applied on a mesh multi-PCC microgrids, with many distributed generation sources (DGs) and different type of loads randomly connected to different PCCs. And that's firstly because of the strong couplings between active and reactive powers injected by the DGs in different microgrid PCCs introduced by the line feeders and also due to the complex nature of the mesh microgrid.

Limited researches have focused on solutions that concern the active and reactive power sharing in mesh microgrids [10-12]. In [10] the authors propose the use of bi-directional communication. In [11] a variable Droop control strategy with virtual impedance correction loop and [12] using a modified Droop control strategy by adding a decoupling term in order to remove the coupling phenomenon between active and reactive power.

Another problem is the possible unstable behavior of the microgrid due to the interaction between the DGs and loads, especially the ones supplied trough tightly regulated power converters. These loads behave as constant power loads (CPL) and may cause the system instability [13-15].

In this paper, a mesh microgrid constituted by several PCCs to which are connected multiple DGs and different type of loads including an active load CPL is considered. The different PCCs are interconnected with power supply lines, modeled by RLC circuits inspired by an IEEE 9-bus test feeder Fig. 2. Like as in [12], a modified droop control and synchronization strategies, adapted to the considered multi-PCC mesh microgrid is applied in order to ensure an accurate power sharing and to provide the "plug and play" function. The microgrid voltage and frequency are imposed by the first DG connected. For other DGs an adapted synchronization strategy is proposed and applied before its interconnection to the microgrid.

To study the stability of the mesh microgrid and the robustness of its control, a state model of the entire mesh microgrid is developed considering the generators with their decentralized controllers integrating modified droop

* Corresponding author: youssefhennane@gmail.com

algorithms, power lines and several loads including a CPL.

The simulation results confirm the effectiveness of the applied strategies and the validity of the developed mathematical model.

2 Power sharing strategies in mesh multi-PCC islanded microgrids

Classical Droop control strategy in (1) and (2) can be efficient for power sharing in mono-PCC microgrids in Fig.1 if and only if the microgrid lines impedances were ignored. Therefore, a developed Droop control strategy in (3) and (4) from [11] that was proven efficient for power sharing in mono-PCC microgrids is applied on the mesh multi-PCC islanded microgrid in Fig.2.

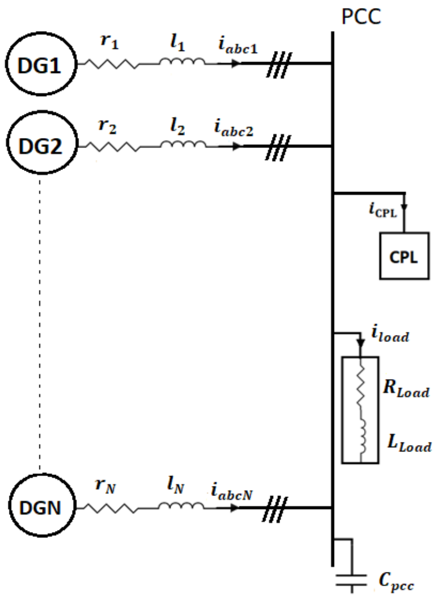

Fig. 1. Mono-PCC microgrid.

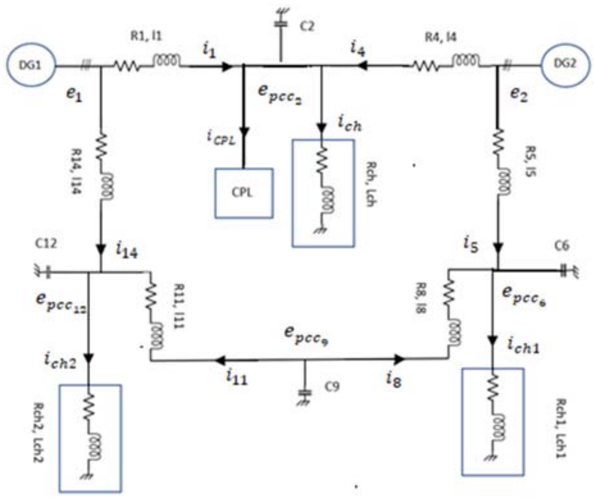

Fig. 2. Mesh multi-PCC microgrid.

$$\omega_i = \omega_n - m_i(P_i - P_{in}) \quad (1)$$
$$V_i = V_n - n_i(Q_i - Q_{in}) \quad (2)$$

$$With: \quad m_i = \frac{\Delta_\omega}{P_{in}}, \quad n_i = \frac{\Delta_V}{Q_{in}}$$

Classical Droop control in (1) and (2) sets for each DG, the frequency and the voltage amplitude at the associated PCC. Where P_i and Q_i are the measured values of the active and reactive power of the i^{th} DG, P_{in} and Q_{in} are their nominal values, ωn and V_n are the nominal values of the pulse and voltage of the i^{th} DG, Δ_ω and Δ_V are the permissible variations of the pulse and voltage, and m_i and n_i are the droop control coefficients.

$$\delta_i = \int \big(K_a(\delta_{in} - \delta_L) - m_i(P_i - P_{in})\big).dt \quad (3)$$
$$V_i = \int \big(K_e(V_{in} - V_L) - n_i(Q_i - Q_{in})\big).dt \quad (4)$$

The proposed angular droop aims to indirectly control the voltage at the PCC and its phase to be equal to the nominal values (i.e. V_{in} and δ_{in}). The added integrators can minimize the static error between the return signal and the corresponding nominal values. By choosing identical K_a and K_e for each generator, a precise active and reactive power sharing is achieved that no longer depends on the system impedance

It can be observed in Fig.3 that the proposed strategy in (3) and (4) ensure a perfect active power sharing while Fig.4 prove that the applied strategy does not guarantee an efficient reactive power sharing due to the complexity of the microgrid.

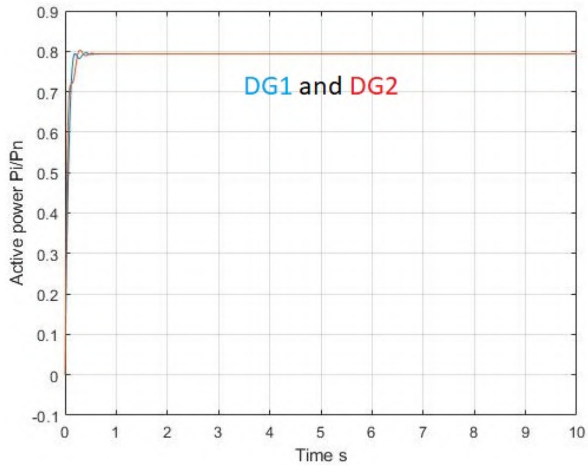

Fig. 3. Evolution of the DGs active powers (both DGs are connected to the microgrid at 0s).

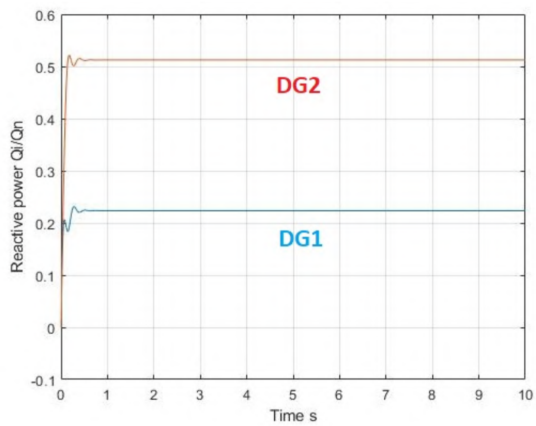

Fig. 4. Evolution of the DGs reactive powers (both DGs are connected to the microgrid at 0s).

In multi-PCC microgrids, each line connecting the i[th] PCC to the j[th] PCC has a non-negligible inductance $\lambda_{i,j}$ and a resistor $\rho_{i,j}$. Due to this phenomenon, the line voltage drop between these two PCCs creates a coupling between the active ($P_{i,j}$) and reactive ($Q_{i,j}$) powers exchanged [12], according to the following formula (5):

$$\Delta V = \rho_{i,j} I_{i,j} \cos\varphi + j\lambda_{i,j}\omega I_{i,j} \sin\varphi = \frac{\rho_{i,j}P_{i,j} + j\lambda_{i,j}Q_{i,j}}{V_i} \quad (5)$$

With φ the phase shift between the voltage V_i and the current $I_{i,j}$.

Based on the strategies developed in [12] to obtain an efficient reactive power sharing in this type of multi-PCC microgrids, the voltage equation is modified by adding a decoupling term (see equation (7)) removing the coupling phenomenon between active and reactive power. This non-linear coefficient, called J_i, is estimated using a PI regulator, forcing the cancellation of the ε_i error defined in (8).

In steady state, when the error ε_i tends towards zero, the reactive power is shared between the DGs.

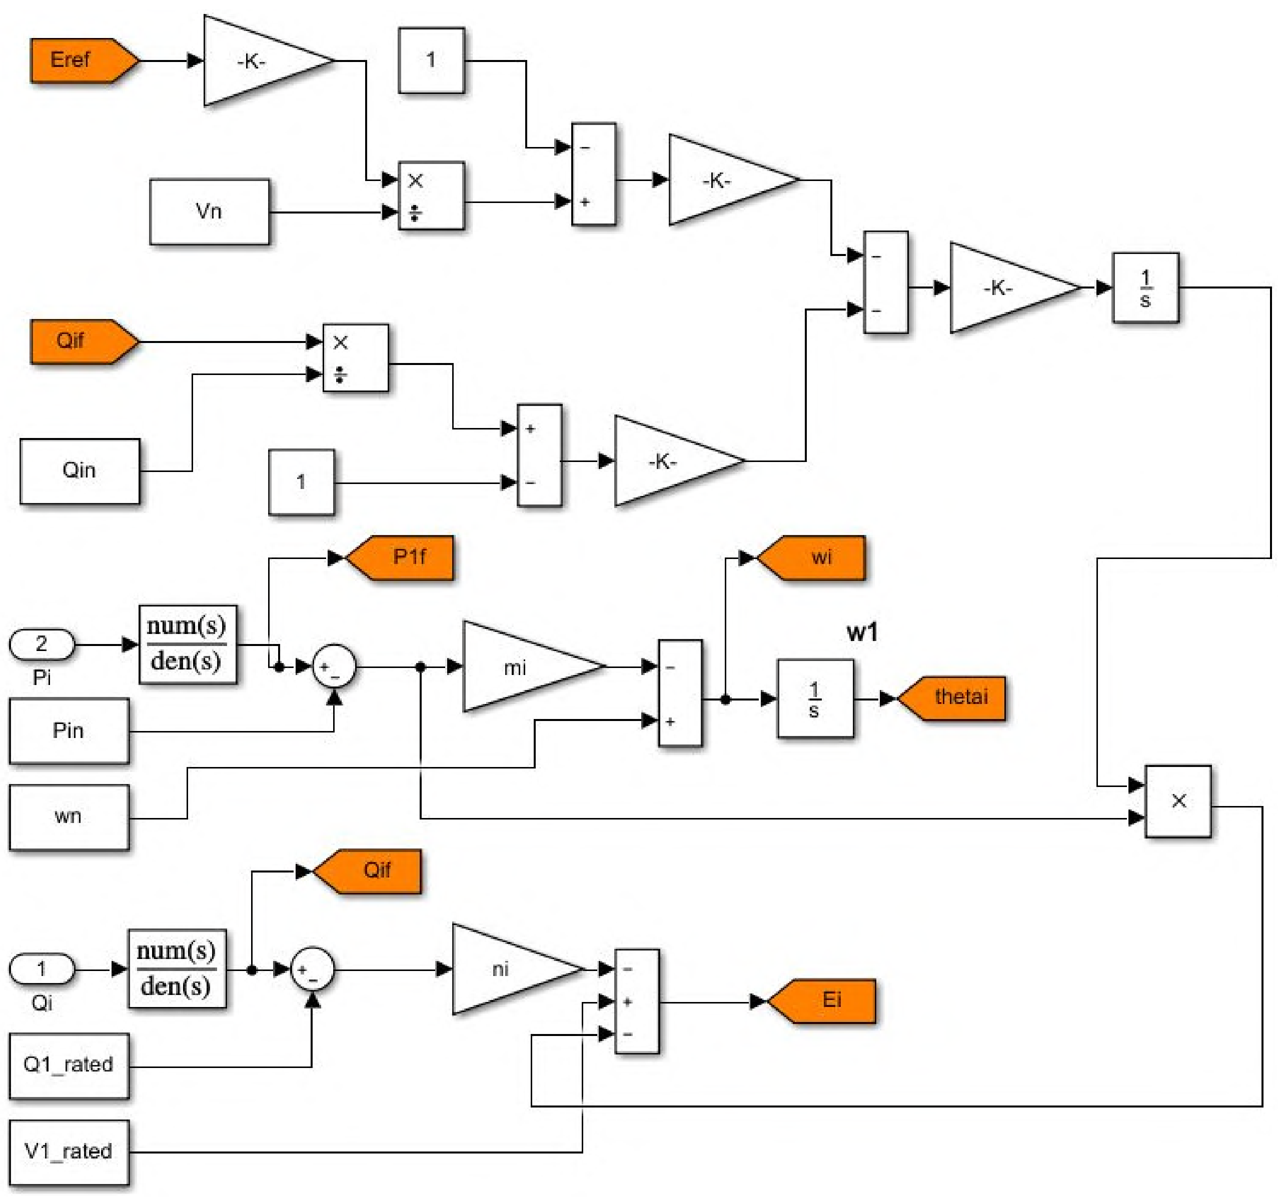

Fig. 5. Primary control.

This approach allows the primary control of the voltage of the i[th] DG Fig.5, regardless of the operating point of the loads. It should be noted that V_{ref} in Fig.5 and equation (7) is a reference potential corresponding to one of the PCC voltages in the studied mesh Microgrid serving as a pilot node and its nominal voltage is called V_n.

$$\omega_i = \omega_0 - m_i(P_i - P_{in}) \quad (6)$$
$$V_i = V_0 - n_i(Q_i - Q_{in}) - J_i(P_i - P_{in}) \quad (7)$$

With: $J_i = K_P\varepsilon_i + K_I \int \varepsilon_i dt$

$$\varepsilon_i = [-\left(\frac{V_{ref}}{V_n} - 1\right) - \left(\frac{Q_i}{Q_{in}} - 1\right)] \quad (8)$$

In the absence of information on V_{ref} the coefficient J is set to 0 and we return to the classical droop in (1) and (2).

3 Synchronization strategy in mesh multi-PCC islanded microgrids

Due to the complexity of the mesh multi-PCC microgrid and the intermittency of renewable energy, DGs frequently connect and disconnect from the microgrid which make the integration of a fast and an efficient synchronization strategy an obligation. The big challenge here is to propose a synchronization strategy that is at the same time efficient and doesn't affect the power sharing between the DGs already connected to the microgrid.

To show the effect of the lack of synchronization in mesh multi-PCC islanded microgrid, modified droop control in (3) and (4) is applied to the mesh microgrid.

It can be seen in Fig.6 that the strategy in (3) and (4) as explained in section 2 does ensure a perfect active power sharing but at 5s it can be remarked that an unacceptable disturbing active power peak occur due to the lack of synchronization.

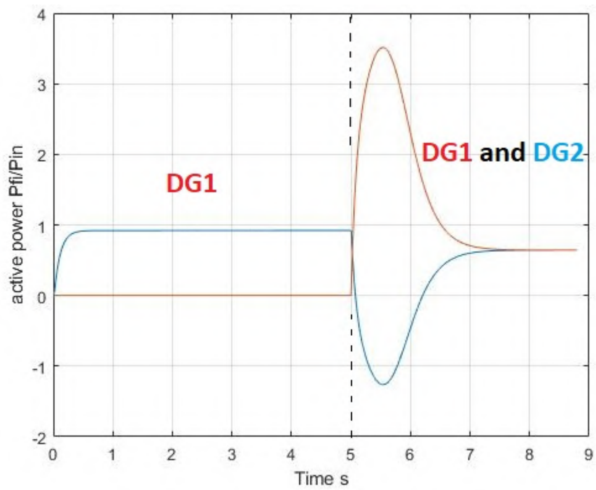

Fig. 6. Evolution of the DG active powers (first DG supplies the microgrid up to 5s, the second DG is connected to the microgrid at 5s).

The same power peak occurs in the DG's reactive powers.

To remove those unacceptable power peaks, a fast and an efficient synchronization of the i^th DG to the i^th PCC should be applied before their interconnection. Therefore, the voltage amplitude V_{pcci}, pulsation ω_{pcci} and phase θ_{pcci} of the i^th PCC must be approximately equal to those of the i^th DG ($V_{DGi}, \omega_{DGi}, \theta_{DGi}$). To achieve this objective, the errors between the amplitudes, pulsations and phases of both sides (the i^th DG and the i^th PCC) are forced to zero by adding only during the synchronization interval pure integral controllers to the i^th DG Droop control as shown in equations (9) and (10) [12]

$$\omega_i = \omega_0 - m_i(P_i - P_{in}) + K_{ai}\int(\omega_{pcci} - \omega_{DGi}) - K_{bi}\int(\theta_{DGi} - \theta_{pcci}) \quad (9)$$

$$V_i = V_0 - n_i(Q_i - Q_{in}) - J_i(P_i - P_{in}) - K_{ei}\int(V_{DGi} - V_{pcci}) \quad (10)$$

4 System modeling

Due to the dynamic interaction between the DGs and the loads, the stability of the microgrids is strongly influenced. Therefore, for a future study of system stability and robustness, a complete mathematical modeling of the system is provided in this section.

4.1 State-space model of a distributed generator (DG)

In order to formulate the equations describing a DGi, an equivalent synoptic diagram is shown in Fig. 7.

- Power calculation

As shown in Figure 7, the measured output voltages and currents are used to calculate the instantaneous active and reactive powers using the equations (11):

$$\begin{cases} P_i = e_{di} * i_{di} + e_{qi} i_{qi} \\ Q_i = e_{qi} * i_{di} - e_{di} * i_{qi} \end{cases} \quad (11)$$

- Low-pass filter

To obtain the average values P_{fi} and Qf_i The instantaneous powers P_i and Q_i pass through a first order low-pass filter in (12), with ω_f representing its filter cut-off frequency.

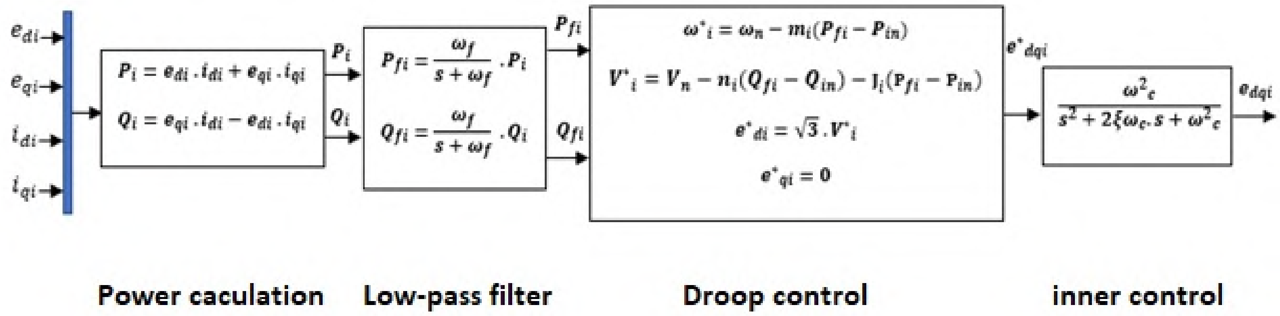

Fig. 7. Equivalent synoptic diagram describing a Droop controlled DGi.

$$\begin{cases} \frac{d}{dt} P_{fi} = \omega_f \left(P_i - P_{fi} \right) \\ \frac{d}{dt} Q_{fi} = \omega_f \left(Q_i - Q_{fi} \right) \end{cases} \quad (12)$$

- Droop control

The third bloc applies the modified Droop control strategy in (6) and (7)

- Inner control

The fourth bloc models the delay imposed by the Voltage Source Inverter (VSI) controlling the ith DG output voltages by means of a second-order filter. This filter which has a faster dynamic compared to the external droop control loop allows the output voltages ith DG ($e^{*}{}_{i_{dq}}$) following their voltage references ($e_{i_{dq}}$). The transfer function of this forth bloc is defined in (13):

$$\frac{e_{i_{dq}}}{e^{*}{}_{i_{dq}}} = \frac{\omega^2{}_c}{s^2 + 2\xi\omega_c . s + \omega^2{}_c} \quad (13)$$

4.2 Microgrid structure and modelling

In this section the microgrid used for modelling is the one presented in section 2. The considered Microgrid is composed of two DGs powering three classical inductive loads, modeled by serial R-L circuits, and a CPL load. They are interconnected by RLC power lines to present a mesh multi-PCC microgrid.

In order to study the considered microgrid having 2 DGs, the state equations are given using a common reference frame for expressing the different variables. The used d-q reference frame is defined in a way that its d-axis is oriented toward the first DG voltage vector V_1 (Fig.8). In steady state, the frequencies of the system are the same (i.e. $\omega_i = \omega_j = \omega_{com}$).

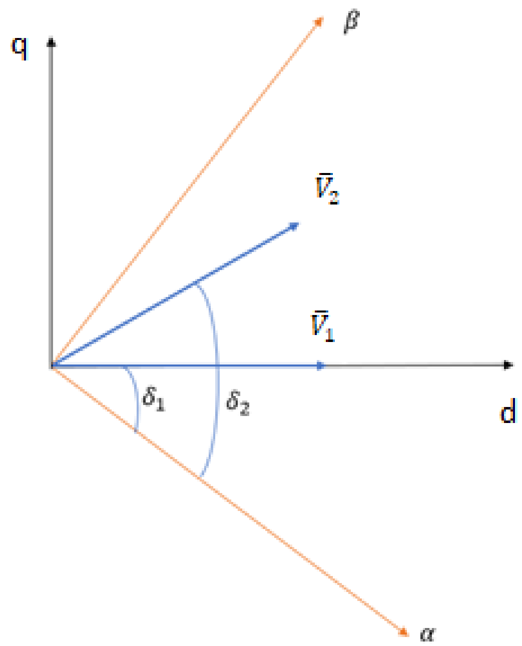

Fig. 8. Reference Frames $\alpha - \beta$ and $d - q$.

Knowing that the phase voltages of DG1 and DG2 (connected to PCC1 and PCC2) have the RMS values of $\boldsymbol{V_1}$ and $\boldsymbol{V_2}$, the $\boldsymbol{\alpha - \beta}$ components of $\bar{\boldsymbol{V}}_{\boldsymbol{1}}$ and $\bar{\boldsymbol{V}}_{\boldsymbol{2}}$ are obtained using Concordia transformation $\boldsymbol{T^t_{32}}$:

With: $T^t_{32} = \sqrt{\frac{2}{3}} . \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \end{bmatrix}$

$$\text{DG1}: \begin{cases} \begin{pmatrix} e_{d1} \\ e_{q1} \end{pmatrix} = P(-\delta_1) . \begin{pmatrix} V_{\alpha 1} \\ V_{\beta 1} \end{pmatrix} \\ \begin{pmatrix} e_{d1} \\ e_{q1} \end{pmatrix} = \begin{pmatrix} \cos\delta_1 & \sin\delta_1 \\ -\sin\delta_1 & \cos\delta_1 \end{pmatrix} . \begin{pmatrix} \sqrt{3}. V_1 . \cos\delta_1 \\ \sqrt{3}. V_1 . \sin\delta_1 \end{pmatrix} \\ \begin{pmatrix} e_{d1} \\ e_{q1} \end{pmatrix} = \begin{pmatrix} \sqrt{3}. V_1 \\ 0 \end{pmatrix} \end{cases} \quad (14)$$

$$\text{DG2}: \begin{cases} \begin{pmatrix} e_{d2} \\ e_{q2} \end{pmatrix} = P(-\delta_1) . \begin{pmatrix} V_{\alpha 2} \\ V_{\beta 2} \end{pmatrix} \\ \begin{pmatrix} e_{d2} \\ e_{q2} \end{pmatrix} = \begin{pmatrix} \cos\delta_1 & \sin\delta_1 \\ -\sin\delta_1 & \cos\delta_1 \end{pmatrix} . \begin{pmatrix} \sqrt{3}. V_2 . \cos\delta_2 \\ \sqrt{3}. V_2 . \sin\delta_2 \end{pmatrix} \\ \begin{pmatrix} e_{d2} \\ e_{q2} \end{pmatrix} = \begin{pmatrix} \sqrt{3}. V_2 . \cos(\delta_2 - \delta_1) \\ \sqrt{3}. V_2 . \sin(\delta_2 - \delta_1) \end{pmatrix} \end{cases} \quad (15)$$

- Network model

Equations (16) present a network model of N supply lines, connecting N DGs to N randomly placed common coupling points (PCC) of a microgrid.

$$\begin{cases} \frac{d}{dt} i_{d_i} = \frac{1}{L_i} \Delta e_{d_{jk}} - \frac{r_i}{L_i} i_{d_i} + \omega_{com} i_{q_i} \\ \frac{d}{dt} i_{q_i} = \frac{1}{L_i} \Delta e_{q_{jk}} - \frac{r_i}{L_i} i_{q_i} - \omega_{com} i_{d_i} \end{cases} \quad (16)$$

With:

$$\Delta e_{d,q_{jk}} = \left(e^{*}{}_{d,q_j} - e^{*}{}_{d,q_k} \right), \; e^{*}{}_{d,q_j} \in \left\{ e_{d,q_j}, e_{pcc}{}_{d,q_j} \right\}$$

- Load model

The loads considered in this work are serial passive R-L loads and an active CPL (Fig. 2). The next equations (17) are written for all PCCs except the ones connected to the DGs for which the voltages are imposed by their droop controllers.

$$\begin{cases} \frac{d}{dt} e_{pccd_i} = \frac{1}{C_{pcci}} \left(\sum i_{Di} - i_{CHdi} - i_{CPLqi} \right) + +\omega_{com} . e_{pccq_i} \\ \frac{d}{dt} e_{pccq_i} = \frac{1}{C_{pcci}} \left(\sum i_{Qi} - i_{CHqi} - i_{CPLdi} \right) - \omega_{com} . e_{pccd_i} \end{cases} \quad (17)$$

$$\begin{cases} \frac{d}{dt} i_{CHdi} = \frac{1}{L_{CHi}} \left(e_{pccd_i} - Rch_i . i_{CHdi} \right) + \omega_{com} . i_{CHqi} \\ \frac{d}{dt} i_{CHqi} = \frac{1}{L_{CHi}} \left(e_{pccq_i} - Rch_i . i_{CHqi} \right) - \omega_{com} . i_{CHdi} \end{cases} \quad (18)$$

With Rch_i and Lch_i representing the resistance and inductance of the RL load. i_{CPLdi} and i_{CPLqi} are the input current of the CPL load.

The active CPL_i connected to PCC_i is supposed to absorb the active and reactive powers P_{CPLi} and Q_{CPLi}. They are related to the d-q components of the current absorbed by CPL_i (i_{CPLid} and i_{CPLiq}) by the next relation:

$$\begin{cases} e_{CPL_{DQi}} = \begin{pmatrix} e_{pccd_i} & e_{pccq_i} \\ e_{pccq_i} & -e_{pccd_i} \end{pmatrix} \\ i_{CPL_{DQi}} = (e_{CPL_{DQi}})^{-1} . \begin{pmatrix} P_{ci} \\ Q_{ci} \end{pmatrix} \end{cases} \tag{19}$$

5 Simulations results

To validate the efficiency of the strategies proposed in sections 2 and 3 for power sharing and synchronization, the multi-PCC mesh microgrid (Fig. 2) is modeled using the Simscape toolbox of Matlab/Simulation. DG1 and DG2 are formed with two controllable voltage sources Fig. 9, connected to PCC1 and PCC2 and controlled with the modified droop strategies described by equations (9) and (10). The main parameters of different element of the microgrid and its control are listed in table 1.

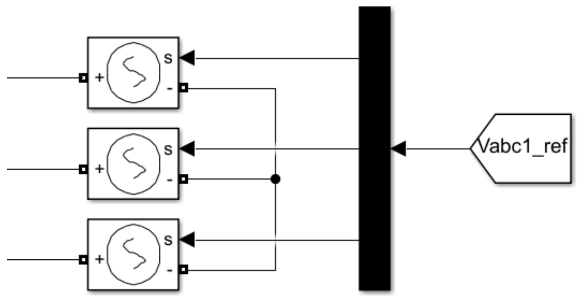

Fig. 9. Controllable voltage source.

Table 1. Parameters of the considered microgrid.

Lines	Resistance (Ω)	Inductance (mH)	capacitance (µF)	Points of connections
Line 1	0.63	7.14	205	Bus 8- Bus 7
Line 2	2.55	11.4	230	Bus 5- Bus 7
Line 3	0.63	7.14	205	Bus 8- Bus 9
Line 4	2	7	180	Bus 9- Bus 6
Line 5	1.7	7.6	153.4	Bus 4- Bus 5
Line 6	1.7	7.6	153.4	Bus 4- Bus 6
Sources and loads	Active power (MW)	Reactive power (Mvar)	Phase to pahse voltage (kV)	Point of connection
Source 1	3	0.9	20	Bus 7
Source 2	2	0.9	20	Bus 9
Load 1	1.5	0.35	20	Bus 5
Load 2	1.2	0.25	20	Bus 6
Load 3	1	0.25	20	Bus 8

These simulations are performed to validate the efficiency of the synchronization and power sharing strategies proposed in relations (9) and (10). The first DG imposes at 0 s the frequency of the microgrid as well as the voltages of the different PCCs. The second DG is synchronized during the interval [4 s ~ 5 s], and connected to the microgrid at 5 s. Fig.10 and Fig.11 show the evolution of voltage amplitude and phase angle of both the ith PCC $(V_{pcci}, \theta_{pcci})$ and the ith DG (V_{DGi}, θ_{DGi}) before and during the synchronization and after the interconnection of the ith DG. It can be seen that the synchronization is fast and it can be achieved in less than 1s.

To prove that it is efficient and doesn't affect the power sharing Fig.12 and Fig.13 show the evolutions of active and reactive powers. It can be remarked in Fig.12 and Fig.13 that the active and reactive power sharing are ensured in steady state without being affected by the synchronization procedure. In addition, power peaks are cancelled during the transient state following the interconnection of the second DG to the microgrid. It should be noted that these performances are maintained with a higher number of DGs, even if the results are not presented.

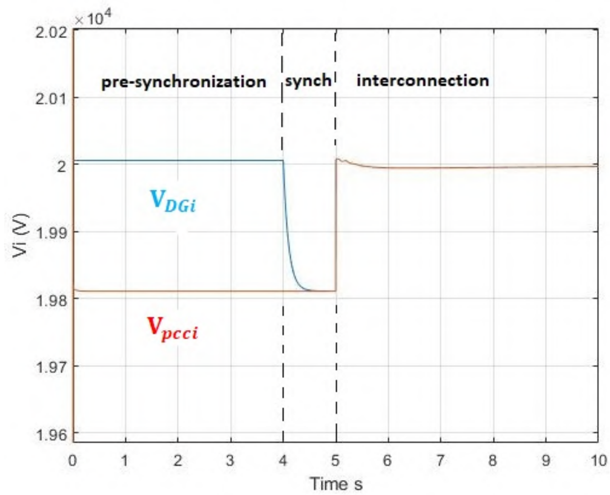

Fig. 10. Evolution of DG2 and PCC2 voltage amplitudes.

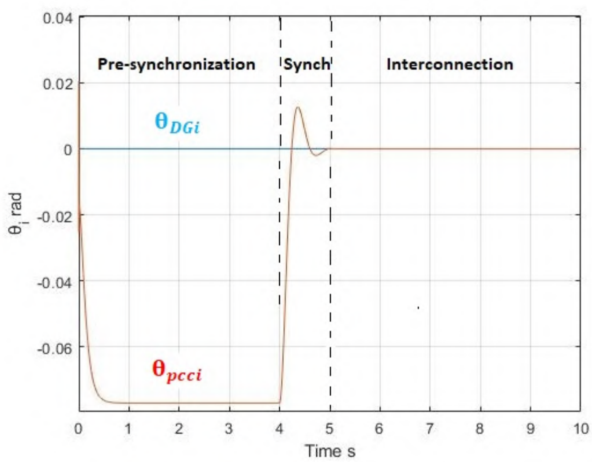

Fig. 11. Evolution of DG2 and PCC2 phase angles

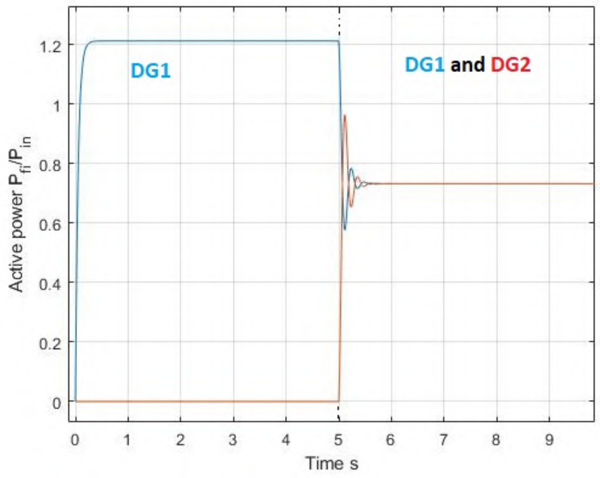

Fig. 12. Evolution of the DG active powers (first DG supplies the microgrid up to 5s, the second DG is connected to the microgrid at 5s).

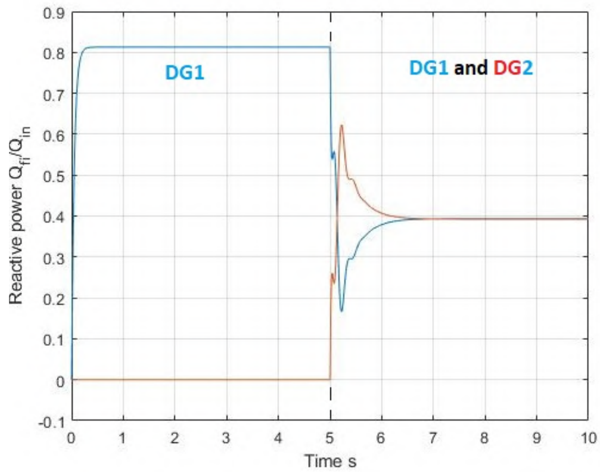

Fig. 13. Evolution of the DG reactive powers (first DG supplies the microgrid up to 5s, the second DG is connected to the microgrid at 5s).

To validate the developed model in section 4. A simulation is performed by applying the modified droop in (9) and (10) at the same time and under the same conditions on the Simscape model and the mathematical model in Matlab.

Figs. 14 and 15 show the evolution of the active and reactive powers of the two models on the same figure at the same time.

It can be seen that the evolutions of active and reactive powers in the two models are the same, which shows the validity of the model proposed in section 4.

5 Conclusion

An improved Droop control strategy is proposed to ensure a controlled active and reactive power sharing in an islanded multi-PCC meshed microgrid. Only the RMS voltage measurement at a pilot node of the microgrid is necessary for its implementation. A synchronization technique is also introduced for the connection of the DGs to the microgrid. The proposed technique allows a correct connection without important power overflow during transient states. Moreover, the proposed droop control strategy with its synchronization technique is compliant with a "plug and play" function and does not require a priori knowledge of the microgrid structure and parameters. A mathematical model of the complete system has been proposed in order to perform stability and robustness studies. The developed modified droop control strategy can be adapted and used for power sharing in grid-connected mesh microgrids. The developed and validated state-space model can be the base for many future studies in mesh microgrids.

Economic feasibility of wind and photovoltaic energy in Kuwait

Waleed K. Al-Nassar[1,*], *S.* Neelamani[2], and *Teena Sara* William[2]

[1]Energy and Building Research Centre, Kuwait Institute for Scientific Research, P.O. Box: 24885, Safat 13109, Kuwait
[2]Environment and Life Sciences Research Centre, Kuwait Institute for Scientific Research, P.O. Box: 24885, Safat 13109, Kuwait

Abstract. The worldwide environmental concern and awareness created a way towards the generation of pollution-free wind and solar renewable energies. Wind and Photovoltaic (PV) power plants of each 10 MW capacity located in the Shagaya area, west of Kuwait, were compared after one year of operation. The wind power plants recorded high capacity factors resulting in a yearly power production of 42.59 GWh, 21% higher than expected (contractual 31.160 GWh). It will reduce the emission of CO_2 throughout the projected lifetime of 25 years by 118,303 tons. CAPEX (capital Expenditure) and OPEX (operation expenditure) were taken into consideration throughout the life of the plants along with investment costs resulting in a levelized cost of electricity (LCOE) for wind of 0.015 KWD/kWh or 0.046 USD/kWh, compared to 0.027 KWD/kWh or 0.082 USD/kWh for solar PV (44% lower than PV). Offshore, Boubyan Island, Northern Kuwait territorial waters, were found to be the foremost appropriate for wind energy generation, with Wind Power Density of more than 500 Watt/m^2 in summer which is ideal for the high energy demanding season in Kuwait. The LCOE for offshore wind energy was 27.6 fils/kWh, compared to 39.3 fils/kWh for thermal power plants.

1 Introduction

A move towards pollution-free renewable energy, particularly wind power and solar energy generation, has generated global concern and environmental awareness. Wind energy potential analysis requires thorough statistical evaluation of wind characteristics such as mean wind speed and frequency distribution [1-2].

The Shagaya area, west of Kuwait, hosts the first renewable energy power plant that combines three different technologies in the Arabian Gulf area. Wind energy, photovoltaic and consecrated solar power (CSP). Dust storms play a big role in renewable energy technology performance and efficiency. Depending on the area and the climate, some areas have more sand storms than others. In the Shagaya location, wind is fairly high. As this location is an open desert location, sand storms are very common and have different effects on the two technologies in question, wind and photovoltaic. The wind turbines in the Shagaya power station were optioned with a high temperature package that allows more air flow to pass through the nacelle, ultimately allowing the dissipation of heat, however, this means more dust in the air filters of the nacelle, which in turn could cause blockage of the air flow and hence increasing the nacelles components (gearbox and hydraulic systems etc.) temperature. This may affect the operation availability and allowable down time where energy may not be produced.

When it comes to photovoltaic (PV) cells, dust may cause calcification on the top surface of cells. This may reduce the cell's efficiency if not immediately cleaned. Water in the desert is also scares and very hard to come by. With all the above mentioned effects on the performance of renewable energy technologies in question in open desert climates, economic feasibility of the technologies may determine the choice of renewable energy technology that would be more favourable for such climates [3].

The main aim of this paper is to compare the economic feasibility of wind and Photovoltaic (PV) power plants, each of 10 MW capacity located in the Shagaya area, west of Kuwait, after one year of operation. The annual power production, CAPEX (capital Expenditure) and OPEX (operation expenditure) were taken into consideration for the designed life span of these plants along with Investment costs resulting in one figure, known as LCOE (levelized electricity cost). From this analysis, it is possible to understand which one is better (wind power or PV based power production) for country like Kuwait with high annual temperature variation (5 to 52 degree C) and with high suspended dust concentration in air.

1.1 Mean monthly wind speed and expected annual power production

The Shagaya area is situated on the western side of Kuwait with 280 meters above mean sea level. This is causing airstream over the location to be compressed. This area is exposed year round to higher wind velocities than the urban areas of Kuwait. Based on the meteorological data in Shagaya Wind Farm, the average monthly wind speed is around 7.8 m/s, as shown in Table 1.

This 10 MW wind power plant consists of 5 turbines, each of 2.0 MW capacity. It has recorded an annual power production of 42.59 GWh gross total power (contractual 31.160 GWh) which is 21% higher than expected. As for the PV of 10 MW capacity, expected annual energy production is estimated to be 18.85 GWh gross total.

1.2 Wind farm capacity factor

Fig. 1 below shows the monthly calculated capacity factor obtained during the first year of operation for the wind farm. June and July of 2018 are near record numbers ever recorded worldwide by industry standards, 68%-70%. The wind speed is comparatively high and it is sustained during these months. This has resulted in high capacity factor. In this figure, the five different colors for each month indicate the capacity factor of each 2 MW wind turbines.

Based on the capacity factor evolution observed, the Capacity Factor for the Shagaya wind farm is expected to be above 40%. Note that the standard capacity factor for on-shore wind farms are, on average, 25-35%. Comparing the first month of operation, July of last year with July of this year (2018), Fig. 2, there is a great difference in performance as that first 6 months are dedicated to adjust and improve wind farm performance. Therefore, availability was low (below the contractual, 95%) during the first few month as can be seen in Fig. 2. With these information, the aim of this paper is to reveal the economics of wind and PV power generation based on one year power production from the wind mills and PV plants of 10 MW capacity in Kuwait.

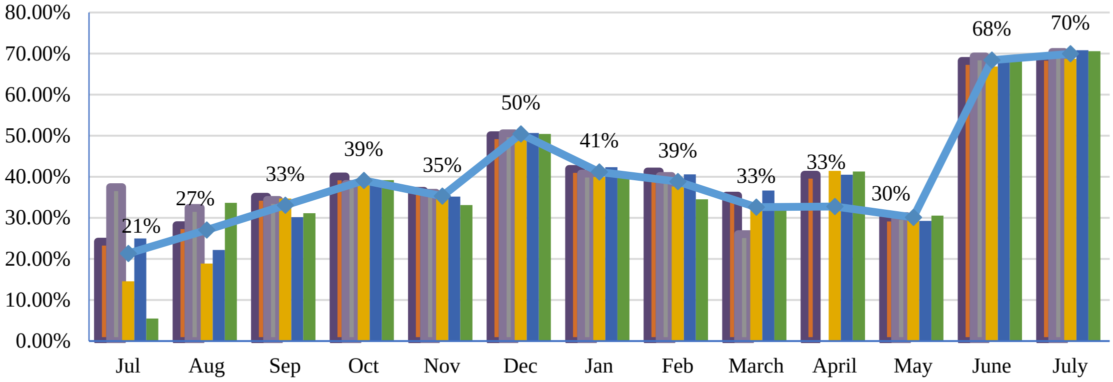

Fig. 1. Monthly Capacity Factor.

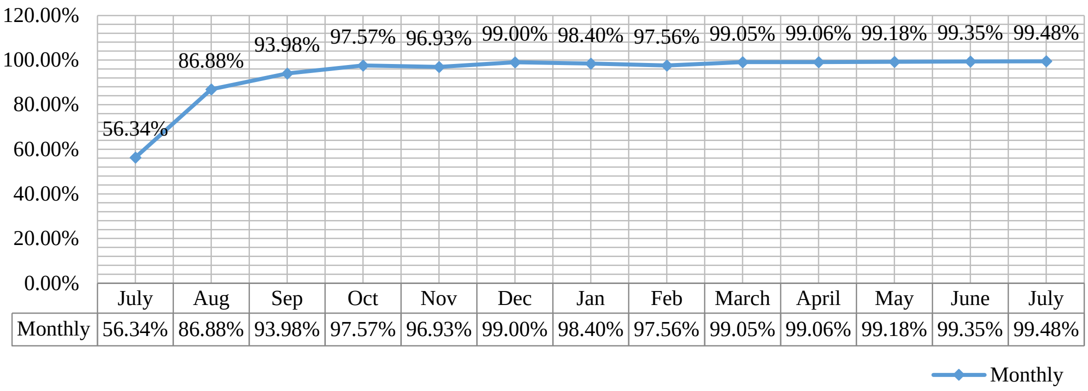

Fig. 2. Kuwaiti 10 MW Wind Farm - Monthly Average Availability.

2 Methods

The present work is focused on the economic analysis based on actual power generation for 1 year from wind and PV plants of each 10 MW installed in Kuwait. The economic analysis results are projected based on Levelized Cost of Electricity (LCOE). The purpose of this is to encourage investment in projects, which promote the most efficient use of a nation's resources. As the economic analysis is done from the point of view of the national economy, inflation, customs, duties, and other factors, which distort market prices are not taken into consideration. The objective of the economic analysis is to calculate the cost of electricity supply of these options for the Kuwaiti national economy.

2.1 Economic analysis approach

LCOE is derived by dividing the present value of the project costs at economic prices by the present value of the quantity of power generation. It thus represents the specific energy generation cost over the entire project life cycle. Mathematically, the LCOE is described as follows:

$$LCOE = \frac{\sum_{t=0}^{n} \frac{C_t}{(1+i)^t}}{\sum_{t=0}^{n} \frac{E_t}{(1+i)^t}} \quad (1)$$

Where:
- C_t is the project costs incurred in year t
- E_t is the power generation in year t
- i is the economic discount rate
- n is the number of years in the period under consideration.

After calculating the LCOE, a subsequent step will assess the financial feasibility of the WTG project. In the future situation with these projects, wind or PV energy replaces energy that in the absence of these projects would otherwise have to be generated by conventional (thermal) power plants. The energy produced by the projects thus serve to avoid the costs of thermal generation of the equivalent amount of energy. The benefit derived from this avoided cost consists solely of the energy benefit, which comprises the avoided operating costs of the alternative, i.e., fuel costs and variable operation and maintenance costs. Furthermore, CO_2 emissions are foregone as a consequence of this avoided fuel consumption. The benefit through capacity replacement is evaluated with the average specific CAPEX of the Ministry of Electricity and Water (MEW) planned thermal power plants to be built until 2023 and counts for USD 1,650/kW (1,146 EUR/kW). The benefits accruing to the project include the following:

- Inescapable fuel utilization
- Foregone variable operation and maintenance costs
- Environmental benefits (CO_2 savings)
- Replacement of conventional generation capacity.

These benefits materialize because the implementation of these projects effectively offset energy that would otherwise have to be produced by thermal power plants.

Within the context of the economic analysis, the generation in thermal power plants would be calculated with the following assumptions:

- Average electrical efficiency: 42%. This corresponds to the average electrical efficiency of the planned conventional power plants in the medium term in Kuwait.
- Fuel price: USD 13.59 2010/GJth. Average annual increase: 1.8%.
- Fuel specific CO_2 content: 15.3 kg CO_2 /GJth, according to IPCC.
- Price of CO_2 emissions: USD 10/t CO_2. This price reflects current market prices for emission allowances in international carbon stock markets.

2.2 Project costs

In general the investment costs for wind farms comprise the following items:

- Purchase price for wind turbines (WTGs) and PV cells, ex-works.
- In the case of wind energy, purchase price for WTG towers, in case it is excluded from the aforementioned item.
- Purchase price for MV (step-up) transformer, in case it is excluded to the aforementioned items.
- International and local transportation.
- Supervisory Control and Data Acquisition System (SCADA), in case it is excluded from the aforementioned items.
- Civil works (control room and substation building, administration, workshop and other buildings).
- Access roads (in most cases a width of 8 m) and cable trenches.
- Foundation works (in case it is excluded in the turbine price and PV price).
- Electrical works (grounding, cabling, substation, transformers).
- Engineering and installation supervision (consultancy services, construction supervision, as well as project management).
- Miscellaneous (computer and network, working table and accessories, printers, fax, phone lines, security, purchase of land, etc.).

2.3 Operation and maintenance costs

Operational expenditures for the wind and therefore the PV farms arise from the following:

- Fees for O&M Contract
- Spare Components
- Insurances
- Administration

2.4 Net present value

The Net Present Value Approach (NPV) is a decision tool generally used to measure the long-term financial costs and benefits of a project by considering the money's time value. The time value of money essentially indicates that at some point in the future, a dollar earned today is worth more than a dollar earned, since the dollar received today can be spent to gain interest. The potential net cash flows of a project are discounted by a rate called discount rate to measure the time value of a project, which is a percentage representation of how much more a dollar is worth to the project funded today than next year, which may indicate other variables such as the project's perceived danger which expected escalation variables over the estimated NPV era. The time value of cash depends on a variety of variables, including net cash flows, the period of estimation of the NPV and the discount rate[5]. NPV

 https://doi.org/10.1051/e3sconf/202128005016

estimates find the current value of the potential net cash flow of a project in today's dollars, enabling that amount to be compared with the amount of money needed to execute the project. Cash Flow is a project 's income minus the project's expense for a given year.

$$NPV = C_0 = -I_0 + \frac{CF_1}{1+i} + \frac{CF_2}{(1+i)^2} + ... + \frac{CF_t}{(1+i)^t} = -I_0 + \sum_{t=1}^{n} \frac{CF_t}{(1+i)^t} \qquad (2)$$

Where,

- I_0 is the Investment in time t=0
- CF_t is the cash out - flow in t
- t is the period (year)
- $0 \leq t \leq n$
- i is the discount rate

2.4 Future value of money

The financial ROR is an indicator to measure the financial return on investment of an income generation project. It is obtained by simply rearranging the time value of money equation,

$$FV = PV\ (1+i)^t \qquad (3)$$

Where,

- FV is the future value of money
- PV is the present value of money
- t is the period (year)
- $0 \leq t \leq n$
- i is the discount rate and effectively in this case ROR

2.5 Payback period

The payback period is simply the time required to recover the initial investment at the beginning of the project.

3 Economic analysis results

The economic output of the wind project was focused on MEW's reference fuel price scenario. The Net Present Value (ENPV) is positive because of the relatively low CAPEX and OPEX of the WTG project and the relatively high energy production, indicating that the investment is profitable for the Kuwaiti economy. This can also be seen in the Rate of Return (ROR), which is 8.5 percent and thus greater than the 7.0 percent basic discount rate.

4 Solar photovoltaic (PV) vs wind energy

The current Shagaya wind farm powers 450 houses, at the current annual household consumption of 94,500 kW/h/yr compared to 199 homes for PV. Reducing local and global emissions throughout the projected lifetime of 25 years by 118,303tons of CO_2, 2.3 times higher than that of PV. As for potential power producing companies, the Shagaya wind energy power plant provides investors with 8.5% rate of return with a 5.36 year payback period. A comparison between the Levelized Electricity Cost (LCOE) of wind energy generation with the LCOE of photovoltaic power plants is essential. Fig. 3 below compares PV to On-shore wind energy. For the Shagaya wind energy power plant, Simplified LCOE obtained for Shagaya wind farm is 0,015 KWD/kWh, that represents an LCOE of 0,046 USD/kWh(1), compared to 0,027 KWD/kWh or 0,082 USD/kWh(1) for solar PV. Thus the LCOE value for wind energy is 44% less than that of PV.

Exchange rate considered: 1 KWD=3.2988 USD.

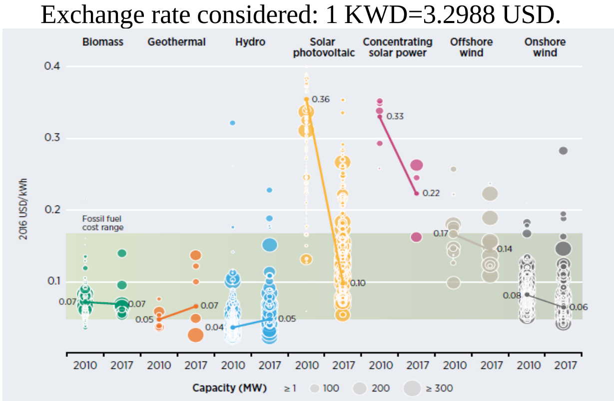

Fig. 3. Comparison of LCOE according to the technology implemented. Renewable power generation costs in 2017, [6].

Table 2. Depositional rates of dust fallout within major dust storm trajectories in the world from upwind to downwind.

Zone-Location	Country	Ref.	Tons.km^{-2}.yr^{1}
A long Niger River	Mali	7[7]	913-10446
Northern Diarnena	Chad	[8]	142
Kano	Nigeria	9[9]	137-181
Southern Chad	Chad	[10]	109
Nouadhibou	Mauritania	[11]	80
Smara	Western Sahara	[12]	111
Agadir	Morocco	[13]	114
Sidi Ifni	Morocco	[14]	145
Tan Tan	Morocco	[15]	175
Dakhla	Mauritania	[16]	191
Boujdour	Western Sahara	[17]	219
Libya	Libya	[18] [16]	155
Negev Desert	Palestine	[19]	57-217
Crete	Greece	20	10-100
Fahal	Oman	[21]	89
Riyadh	Saudi Arabia	[22]	392
Dead Sea	Palestine	[23]	45
Khur Al-Zubir	Iraq	[24]	75.92
Um Qasr	Iraq	[24]	193.47
Kuwait	Kuwait	[26]	370
Xilingele	Mongolia	[24]	292
Shapotou	China	[25]	372
Tokyo	Japan	[26]	3.5
Adelaide	Australia	[27]	5-10
Namoi valley	Australia	[27]	16.9-58.2

The Fig. 3 below compares the LCOE of various renewable energy technologies worldwide. It can clearly been seen that the simplified LCOE of wind energy is approximately 50% lower than expected LCOE values for solar photovoltaic, PV plants. For decision makers, a comparison between the Levelized Electricity Cost

(LCOE) of wind energy generation with the LCOE of photovoltaic power plants is essential. Also, table 2 shows that deposited dust in Kuwait is one of the highest compared to regional and global scales. These amounts of deposited dust will surely act as a major challenge for the solar energy. Therefore, wind energy is the alternative and proper solution for future power generation in Kuwait.

From table 2, it is found that the dust deposit arte in Kuwait is about 370 Tons.km^{-2}.yr^{1}. This dust deposits on PV surface is found to reduce the efficiency of PV power generation. It is also found that the calcification is as hard as the PV surface itself. This makes the surface cleaning difficult.

4 Conclusion

Wind and Photovoltaic (PV) power plants of each 10 MW capacity was installed in the Shagaya area, west of Kuwait. This wind power plants recorded high capacity factors and has resulted in a yearly power production of 42.59 GWh, 21% higher than the contractual value of 31.160 GWh. A detailed economic analysis is carried out based on the actual capital Expenditure, operation expenditure and is taken for the complete life time of these installed plants. Based o this analysis, it is found that the levelized cost of electricity (LCOE) for wind is 0.015 KWD/kWh (0.046 USD/kWh), compared to 0.027 KWD/kWh (0.082 USD/kWh) for solar PV (44% lower than PV).

Kuwait Foundation for the Advancement of Sciences (Project No. P315-34SE-02) is thankfully acknowledged for its financial support. The authors are grateful to the Kuwait Institute for Scientific Research (KISR) senior management for the use of infrastructure facilities in carrying out this work.

[2]University of Zilina, Department of Transport and Handling Machines, 8215/1 Univerzitná, 010 26 Žilina, Slovakia

Abstract. The article considers the issues of determining the main technical and economic indicators of the shunting locomotive during its modernization by a hybrid power plant. The analysis of scientific and practical works on the impact of railway transport on the environment and increase the efficiency of shunting locomotives due to design changes, which are aimed at reducing emissions. A model has been developed to determine the rational ecological and energy characteristics of a shunting locomotive, which has been modernized by technical means for energy saving taking into account the ecological component. A procedure, algorithm and program for calculating locomotive parameters have been developed. The main parameters of the shunting locomotive of the ChME3 type at modernization by its hybrid power plant taking into account an ecological component are defined and the estimation of expediency of such modernization is given.

1 Introduction

With the growing trend of human mobility and increasing freight traffic, vehicles face the problem of shortage of primary energy resources. To date, the analysis of the locomotive fleet of Ukraine has shown the urgent need to update it, which can be done in two ways: the purchase of new locomotives, the price of which is very high, or the modernization of the existing rolling stock.

In recent years, active work has been carried out to modernize locomotives on railways and industrial enterprises of Ukraine. The need to increase the efficiency of rolling stock operation motivates the search for innovative solutions during the modernization process. Diesel locomotives need to be more efficient and better adapted to alternative energy sources, the use of which solves the issue of shortage of primary energy resources and increases the environmental performance of diesel traction.

2 Literature review and problem statement

The issue of ecology in transport is given much attention in the works of scientists [1-7]. Thus, in [3] an analysis of various aspects of the impact of rail transport on the environment was conducted, in addition, examples of the negative impact of rail transport on the environment and human health are given.

Studies [4] on reducing the environmental load have shown the need to create a new comprehensive scheme for the treatment of waste oils and technological sludge of railways, the implementation of which will increase the efficiency of recovery and resource conservation, increase the environmental friendliness of oil circulation.

The authors in [5] considered the impact of rail transport on the environment. Ways to reduce the eco-destructive load of transport on the environment are given, the necessity of transition of railway transport to electric traction is also conditioned. As a result, the procedure for calculating the economic damage from the impact of railway transport on the environment is proposed, thus necessitating the introduction of an indicator that takes into account the mode of operation of locomotives at different power, which affects the mass of emissions.

The analysis conducted in [6] showed the relevance of improving the environment and improving the efficiency of natural resources. Thus, the preconditions for the development of "green" logistics in railway transport are identified, in addition, environmental issues in Ukraine are considered, which are the most relevant at present in the existence of problems that hinder the development of "green" logistics.

In [7] the results of researches of determination of bacteria of group of Escherichia coli in ballast of a railway track are published. As a result of which, conclusions were made about the level of pollution of railway ballast and described ways to radically solve this problem.

The issues of modernization of shunting locomotives with hybrid power plants were considered by scientists of the Ukrainian State University of Railway Transport in [8-10]. They provide methods for determining the main characteristics of a locomotive with a hybrid power plant,

[*] Corresponding author: gurao@ukr.net

but the environmental component is not sufficiently taken into account.

According to research by scientists and transport workers, shunting locomotives run idle for more than 50% of the time. The specific emissions of pollutants are the largest. Therefore, the introduction of modern power plants, especially those that have the technical means to save energy, in the modernization of locomotives, is a topical issue in terms of ecology.

But, unfortunately, some scientific issues of the use of hybrid transmissions in the modernization of locomotives, taking into account the environmental component, the choice of energy storage and the region of operation of these scientists or not considered at all, or were not fully considered. Therefore, based on the analysis, the purpose of the study was formulated and tasks were set to achieve it.

3. Objective and tasks

The purpose of the work is to increase the efficiency of modernized shunting locomotives by improving their design with modern technical means and technologies for energy saving and improving environmental performance. To achieve the goal of the work it is necessary to solve the following tasks:

- - to analyze scientific and practical works on the impact of railway transport on the environment and increase the efficiency of shunting locomotives due to design changes that are aimed at reducing emissions;
- - to develop a model for determining the rational ecological and energy characteristics of the shunting locomotive, which is modernized by technical means for energy saving
- - to determine the main parameters of the shunting locomotive type ChME3 during the modernization of its hybrid power plant taking into account the environmental component and to assess the feasibility of such modernization.

4 Equations and mathematics

As a result of the analysis of different types of schemes of hybrid power plants taking into account features of shunting locomotives and conditions of their operation for shunting work the scheme which power chain is presented in figure 1 was chosen.

In General, the power of the hybrid power plant *Nгеу* is presented as follows,

$$Nгеу = f(Ndg, Nne, Ene, limi,j, Mpred, Vpred, Kzav, Uzag\ I, Kvzr) \qquad (1)$$

where *Ndg* - diesel power, kW; *Nne* - energy storage capacity, kW; *Ene* - energy consumption of the energy storage, kJ; *limi* - restrictions on the length of the energy storage, m; *j* - the number of elements of energy storage; *Kzav* - locomotive load factor.

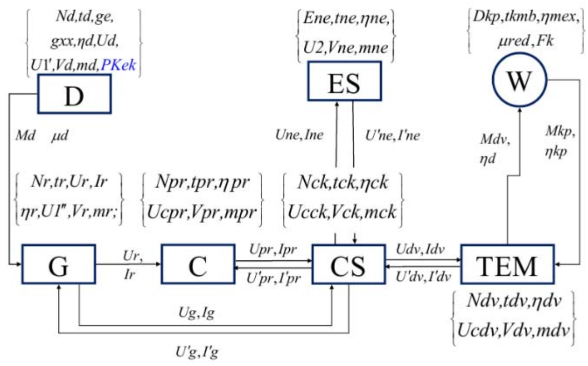

Fig. 1. Functional diagram of the power circuit of a shunting locomotive with a hybrid transmission.

Based on the European experience of environmental taxation, the target function for determining the technical and economic indicators of the locomotive included compensation for environmental losses, in addition to those previously taken into account, the cost of energy storage and maintenance and repair costs. It should also be borne in mind that the parameters of the energy storage can be affected by its limitations in terms of mass and size parameters. In General, the objective function is described as follows:

$$\begin{cases} Czag=f(C0,\ C1,\ C2,\ C3,\ C4,\ C5) \rightarrow min, \\ \Delta Vlim= f(Ene,\ l_{ne},\ b_{ne},\ h_{ne},\ j) \rightarrow min. \end{cases} \qquad (2)$$

where C0 – the cost of an old diesel generator, UAH.; *C1* – cost of a diesel generator, UAH.; *C2* – cost of energy storage devices, UAH; *C3* – fuel costs after modernization, UAH.; *C4* – maintenance and repair costs, UAH; *C5* – costs of environmental penalties, UAH; *ΔVlim* – underutilized free space of the locomotive to be engaged in energy storage, m^3; - respectively the length, width and height of one element of the energy storage, m. The costs of environmental penalties are determined by the formula, UAH:

$$C5 = \sum(C5i \cdot \sum gik \cdot \tau k \cdot T10pm \cdot Kf \cdot KT), \qquad (3)$$

where $T^{10}_{рт}$ – total operating time of the locomotive for 10 years, hours.

The target function, taking into account the constraints on energy storage, power plant and environmental emissions, will be explicitly presented as follows,

$$\begin{cases} Czag \ = \ C0 \ + \ A{\cdot}Nд2 + B{\cdot}Nд + C \ + \\ +\left[\sum_{i=1}^{n}\left(Nf_i \cdot ge0 \cdot \Delta\tau/3600\right) - \sum_{i=1}^{n} G_{i,j}\right] \cdot \mathrm{ct}- \\ -(1-k(Neng_j))Cб + \\ + \ \sum(C_{5i} \cdot \ \sum g_{ik} {\cdot} \tau_k {\cdot} T^{10}{}_{pm} {\cdot} Kf \cdot K_T) \rightarrow \ min, \\ \Delta Vlim = \ kv{\cdot}Ene \ \rightarrow \ min \end{cases} \qquad (4)$$

where *A, B, C* – coefficients that characterize the diesel power plant; Nд – power of a diesel power plant, kW;

u2 – specific cost of energy storage, UAH / kWh; *ct* – fuel cost, UAH / kg; *ge0* – specific fuel consumption by diesel of the base locomotive, kg / kW·h; *Gi,j* – fuel consumption by hybrid locomotive, kg; where *Cб* – costs for maintenance and repair of the base locomotive, UAH.; *k(Nengj)* – the ratio of expenditure on maintenance and repair of the hybrid locomotive to the base, depending on the selected power diesel generator set; k_v – coefficient of underutilization of free space of the locomotive to be engaged in energy storage, m^3 / MWh. The coefficient is chosen depending on the type of locomotive, the overall dimensions of the elements of the energy storage and its required energy consumption.

Parameter limits were set for the model: $Nf_j \in [0 \ldots Nf_{max}]$, $Neng_j \in [0 \ldots Nf_{max}]$, $Nust_j \in [0 \ldots Nf_{max}]$, $E_{1,j}=Eo=0$, $Ene \in [0 \ldots Em_{max}]$, $Ene \in [0 \ldots Ev_{max}]$, де Em_{max}, Ev_{max} – maximum values of energy consumption by mass and volume for a certain shunting locomotive.

To determine the technical and economic characteristics of the shunting locomotive with a hybrid power plant, an appropriate procedure was developed (Figure 2), which consists of seven stages.

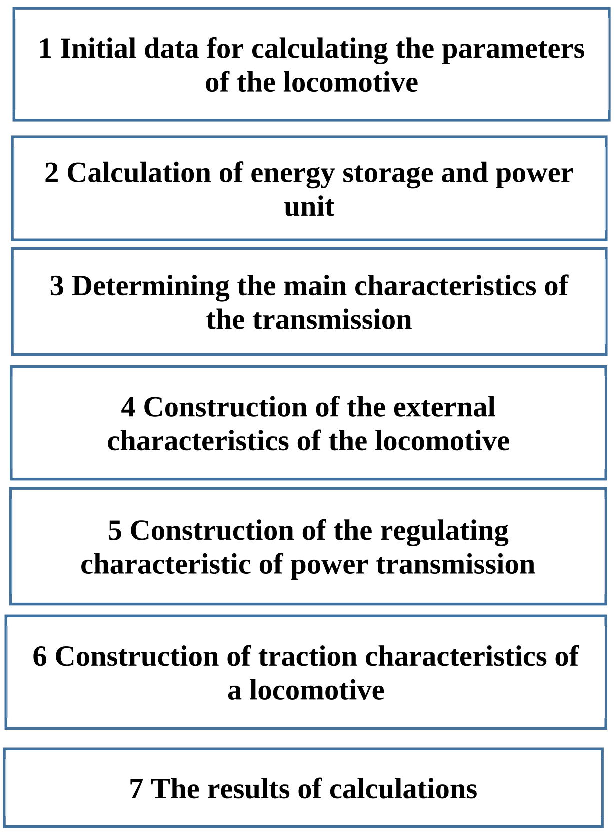

Fig. 2. Procedure for determining the technical and economic performance of shunting locomotive with hybrid power transmission.

At the first stage the values of necessary parameters for calculation are defined. Then the calculation of the energy storage is performed. In the third stage, the main parameters of the hybrid transmission are determined. After that, the construction of the external characteristics of the traction generator, the characteristics of the electric transmission and the traction characteristics are performed.

On the basis of the developed procedure the algorithm of the program of calculation of technical and economic indicators of the shunting locomotive with hybrid transfer of power was made.

To determine the main parameters of power transmission of a shunting locomotive with a hybrid power plant for operation in shunting motion, the model described in [11] was improved.

The initial data for determining the parameters of the energy storage and power plant of the locomotive, taking into account the works [12-14] are: power of the power plant Nf_i, кВт, which is determined during the time interval $\Delta\tau$, c, and a matrix of energy storage parameters is introduced in the form of a matrix *kne* and mass storage limits *Mpred*, kg; and volume *Vpred*, m^3, provided they are placed on the locomotive.

The proposed model differs from the existing ones in that when using an energy storage device, its power *Nne* is used for traction of engines to 3 the position of the driver's controller. Charging it is performed, if necessary, at 6 the position of the driver's controller. When using a power of more than 4 the position of the driver's controller, the shunting locomotive begins to operate according to the usual scheme. If necessary, the power of the energy storage *Nne* added to the power of the diesel generator *Ndg* and total power *Ntey* supplied to traction engines, kW,

$$Ntey = Nne + Ndg. \qquad (5)$$

As a result of calculation of this block we receive: dependence *Ene(Neng)* the required energy consumption of the energy storage, MWh, and the power of the locomotive power plant, kW, as well as the limit parameters of the energy consumption of these storage in the form of a matrix *Enelim*, MJ, and the optimal power values of the diesel generator *Nopt*, kW and energy consumption of the energy storage *Eopt*, MWh.

As a result of the analysis of works [2; 15-20] the initial data for definition of the basic parameters of electric transfer of the locomotive are expressed through an array *Mpoch*:

$$Mpoch = \{Ne\ , kdod, \eta g, Ps, \psi kr, \eta vu, \eta ed, \eta sl, c\}, \qquad (6)$$

where *Ne* – locomotive power, kW;
kdod – percentage of costs for ancillary needs, %;
ηg – efficiency of the generator;
Ps – coupling weight of the locomotive, kN;
ψkr – thrust coefficient on the calculated lift;
ηvu – efficiency of the rectifier;
ηed – efficiency of the electric motor;
ηsl – efficiency, taking into account losses in the power circuit;
c – number of traction motors, pcs.

The result of the calculation of this block is the mass *Mrzr*:

$$Mrzr = \{\Delta N, Nd, Pg, \eta en, Fkr, vp, Ped, Pde\}, \qquad (7)$$

where ΔN – power auxiliary needs, kW;

Nd – потужність дизеля, яка віддається на тягу, кВт;
Pg – diesel power, which is given to traction, kW;
ηen – efficiency of power transmission;
Fkr – the calculated thrust force determined from the condition of realization of the thrust coefficient on the calculated lift, kN;
vp – speed on the calculated rise, km / h;
Ped – power at the terminals of the traction motor, kW;
Pde – power on the shaft of the traction motor beforehand, kW.
An array of parameters was used to construct the external characteristics of the traction generator:

$$M_{TT} = \{Ugmax, Cgu, CgI\}, \tag{8}$$

where *Ugmax* – maximum voltage of the traction generator, kW;
Cgu – voltage control factor of the traction generator;
CgI – current control coefficient of the traction generator.
The result of the construction of this unit is the construction of the external characteristics of the traction generator *U(I)* with all restrictions.

To build the control characteristic of the power transmission is also added *vmax* – maximum speed of the locomotive, km / h. The result of the calculation of this block is the construction of graphs and dependence *Ig(v)* and *Ug(v)* generator current and voltage from the speed of movement.

To construct the traction characteristics of the locomotive, the dependence of the efficiency of the electric transmission on the current is introduced. As a result, dependence is built *F(v)* with limitation on current and coupling.

Based on the proposed algorithm, a program for calculating the technical and economic characteristics of a shunting locomotive with a hybrid power transmission using a software package was developed Mathcad,

The verification of the developed model for adequacy was performed on the basis of the choice of parameters of the locomotive ChME3.

The parameters of the locomotive were calculated and its characteristics were constructed. In Figure 3.5. shows the traction characteristics of the locomotive ChME3: real and built on the model. Current and clutch restrictions are also applied to the characteristics.

Figure 3 shows that the characteristics are almost identical. But there is a need to determine the difference between them. For this purpose, the absolute error of the traction characteristic according to the formula was determined:

$$\Delta(v) = \left|Fp(v) - F(v)\right|, \tag{9}$$

where *Fp(v)* – traction characteristics of the locomotive ChME3, built on the model;
F(v) – real traction characteristic of the ChME3 locomotive.

From the analysis of which it turns out that the maximum error is about 6.3%, which is satisfactory for calculations.

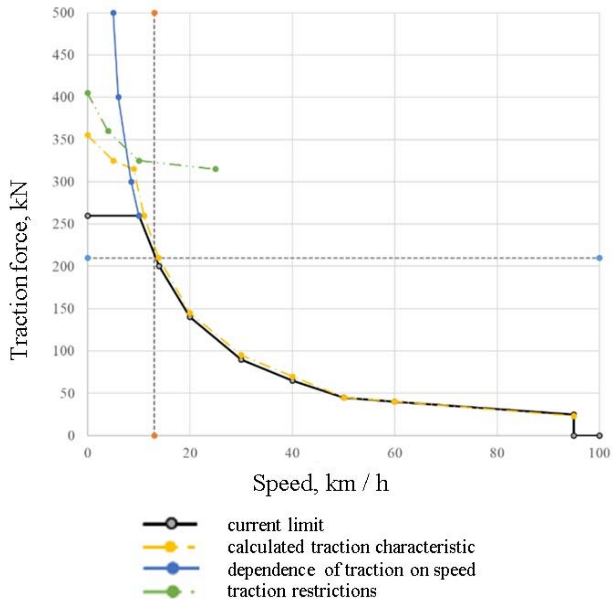

Fig. 3. Traction characteristics of the locomotive ChME3 basic and calculated and its limitations.

Based on the absolute error, the relative error of the traction characteristic is calculated by the formula,

$$\delta(v) = \frac{\Delta(v)}{F(v)} \cdot 100\%. \tag{10}$$

Figure 4 shows the change in the absolute and relative errors of traction from velocity in the construction of the traction characteristics of the locomotive ChME3.

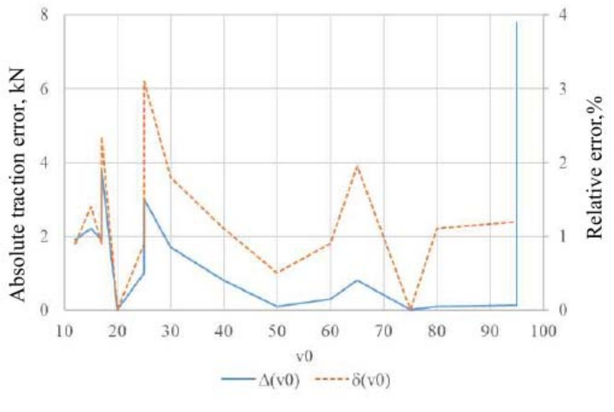

Fig. 4. Dependences of absolute and relative error in determining the thrust force as a function of speed

Based on the developed model, the main technical and economic parameters for a six-axle shunting locomotive are determined, taking into account the selected modern energy-saving technologies.

According to scientific research and operation of serial six-axle shunting locomotives, taking into account the limitations (mass and dimensions and provided that the free space of the locomotive is limited), the maximum energy consumption of various energy storage devices was calculated. The capacity of the energy storage is selected so that it is sufficient for the operation of the locomotive, which is equivalent to its operation at 1 to 3 positions of the driver's controller. The power dependences of the hybrid locomotive power plant for each position of the locomotive driver's controller are constructed.

The total costs associated with the upgrade are calculated *Czag*, UAN. It is determined that taking into account the restrictions imposed on the energy storage device, the minimum modernization costs are observed for the power of the diesel generator of 360 kW and the energy consumption of the energy storage device of about 600 kWh. Calculations of parameters of the modernized shunting locomotive with the hybrid power plant for performance of shunting works by the locomotive are executed.

The calculations of life cycle costs of modernized locomotives by a hybrid power plant (two options) and the base locomotive ChME3 showed the following. The costs of emission fines in the base locomotive ChME3 are more than 40% higher than in the locomotive with the base engine and energy storage and almost 75% higher than in the modernized locomotive with a new power plant and energy storage.

Similarly, the life cycle costs for modernized locomotives have shown that it is advisable to perform a deep modernization of the shunting locomotive with a new diesel and energy storage. But at lower costs, ie the installation of only energy storage and repair of the base diesel, there will also be a positive effect, the costs will be lower by 12%.

According to the results of calculations, the appropriate parameters of the modernized shunting locomotives at the energy capacity of the energy storage of 600 kWh are selected, the optimal power of the diesel generator will be within: for shunting operation 250 kW; for export - 800 kW; for work on a hill - 300 kW. According to the results of traction calculations for export work, fuel consumption of the hybrid locomotive was reduced to 30% compared to the base.

The life cycle of a hybrid locomotive based on ChME3 and a basic locomotive for a period of 20 years - the time from modernization (or overhaul) of the locomotive to its complete decommissioning. Thus, when using a hybrid locomotive based on ChME3, during operation the total economic effect of one locomotive will be UAH 3.5 million.

The efficiency of the shunting locomotive is proposed to be determined taking into account the technical, economic and environmental components according to the formula

$$K_{ef} = K_1 \cdot \sum_{i=1}^{i=s} k_n \varphi(i) \Big/ \sum_{i=1}^{i=s} \varphi(i) + K_2 \cdot LLC_{TB} / LLC_{TG} + \\ + K_3 \cdot \sum_{z=1}^{n} A'_z m_{бz} \Big/ \sum_{z=1}^{n} A'_z m_{гz} \qquad (11)$$

where *kn* – the ratio of numerical parameters of the new development to the parameters of existing objects for rational categories and irrational categories; $\varphi(i)$ – function that normalizes the weight of the parameters in the ranked sequence; i – shunting locomotive parameter number; LLC_{TB}, LLC_{TG} – life cycle cost of the basic *locomotive* and the modernized, respectively, UAH.; $A'z$ – indicator of the relative activity of impurities of the z-th type; $m_{бz}$, $m_{гz}$ – average annual masses of pollutant of the z-th type, which enter the atmosphere in year t during operation, respectively, of the basic locomotive and modernized, kg / h per section; K_1, K_2, K_3 – weights of efficiency components. At the same time $\sum_{i=1}^{3} \mathrm{Ki} = 1$. The weights of the components of efficiency are determined by the expert method depending on the presented tasks. This factor when using a locomotive in shunting operation for the base locomotive is equal to K_e=1, for an upgraded diesel locomotive with a basic diesel engine and an energy storage capacity of 600 kWh equal to K_e=1,13, and for the upgraded new diesel with a capacity of 250 kW and this energy storage equal to K_e=1,4. This confirms the efficiency of modernization of six-axle shunting locomotives with a hybrid power plant of the proposed type.

Conclusions

Based on the results of theoretical and experimental studies, the following conclusions were made.

1. Analysis of the directions of work of scientific organizations, rolling stock manufacturers and works of scientists shows that to solve the problem of determining the technical and economic indicators of locomotives with hybrid power plant requires a comprehensive approach that should link the technical parameters of the locomotive, performance and cost indicators taking into account the environmental component. To substantiate the choice of technical and economic indicators of locomotives with hybrid transmission, an approach based on mathematical modeling was taken. He allowed to justify the choice of the main technical and economic indicators of the modernized locomotive at the lowest cost of the life cycle when using it in shunting work.
2. The functional scheme of the power circuit of a shunting locomotive with a hybrid power plant is proposed, which allowed to determine the functional connections between the elements of power transmission with a hybrid drive.
3. A model has been developed to determine the rational design and energy characteristics of an upgraded shunting locomotive with a hybrid power plant. The functional dependences of the power of the diesel generator set on the energy consumption of the energy storage for shunting operation of the locomotive are obtained.
4. It is proposed to determine the efficiency of shunting locomotive modernization by an appropriate coefficient, which takes into account the technical level of the locomotive, life cycle costs and environmental component with the appropriate weights. This factor when using a locomotive in shunting operation for the base locomotive is equal to K_e=1, for an upgraded diesel locomotive with a basic diesel engine and an energy storage capacity of 600 kWh equal to K_e=1,13, and for the upgraded new diesel with a capacity of 250 kW and this energy storage equal to K_e=1,4. This confirms the efficiency of modernization of six-axle shunting

locomotives with a hybrid power plant of the proposed type.

5. The procedure for the designation of technical and environmental indicators of locomotives for a specific core structure can be used for similar applications in other types of transport.

Abstract. The paper considers models of optimal distribution of fertilizers and vehicles in grain production. To ensure the delivery of fertilizer to the destination for the chemical treatment agriculture, the optimal distribution of fertilizers in grain production was solved. On the basis of optimal models, the needs of vehicles for servicing these works are determined. As calculations show, the cost of acquiring machines and operating costs can be reduced by 20-30% due to the correct selection and use of equipment. This made it possible to distribute mineral fertilizers between farms in accordance with the characteristics of their soils. With the help of ground equipment, mineral fertilizers are applied, chemical pest and plant disease control is carried out, weed vegetation is destroyed in grain crops. The optimal plan for the use of machine and tractor fleet can only be determined using optimization methods, since the composition of machines and tractors and their possible use have such a large number of options that it is almost impossible to simply sort them out and select the best. Further, the algorithm and the solution to the problem of optimal distribution of vehicles in grain production are considered.

1 Introduction

One of the most important works in the transport system of the grain processing industry is to ensure the delivery of fertilizers to the destination for the chemicalization of agriculture. In this regard, in determining the transportation of fertilizers, it is necessary to solve the problem of optimal distribution of fertilizers between grain crops, individual farms, as well as districts, oblasts.

The need for mineral fertilizers considerably exceeds the possibilities of their production, therefore the problem of developing methods for their most rational use is of extremely great not only sectoral, but also national economic importance. The increase in yield and the amount of net income in agriculture largely depend on the rational distribution of organic and mineral fertilizers between crops and farms.

All currently known methods for solving the problem of fertilizer distribution, taking into account computer-aided implementation programs, can be divided into two groups: 1) based on iterative models; 2) optimization. In the first case, the algorithm of the preferred saturation method is used, in the second – the simplex method. Iterative models make it possible to select the most rational of them through targeted analysis and evaluation of plan variants; the use of optimal methods ensures the selection of the best solution for the given conditions of the problem. Despite the differences in the methods of solution, the formulation of the problem has much in common. In both cases, a plan for distributing a limited fertilizer pool is sought, ensuring maximum efficiency in their use.

The effectiveness of fertilizers is expressed in yield increase, which can be measured in physical and monetary terms. Moreover, the increase in value terms can be commensurate with the costs associated with its receipt, that is, with the costs of purchasing, transporting, storing and applying fertilizers. Based on these indicators, net (conditional) income per 1 ha of sowing from mineral fertilizers is calculated.

The optimization criterion for the distribution of fertilizers is taken as the maximum gross yield of grain crops obtained through their use, or the maximum conditional net income obtained as the difference between the value of the gross yield increase from mineral fertilizers and the costs associated with their use.

In the previously described models for the optimal distribution of mineral fertilizers, practically the same indicators are used as constraints: size of sown areas, limits of mineral fertilizer funds, planned production volumes (increase) of production, doses of mineral fertilizers, increase in yield of grain crops as a result of using mineral fertilizers. However, these models do not always take into account the presence of local fertilizers, soil types, agrochemical characteristics, the effect of fertilizers, as well as the conditions for the preservation and improvement of soil fertility. These factors are taken

* Corresponding author: sad171@mail.ru

https://doi.org/10.1051/e3sconf/202128006002

into account when solving the problem of determining the rational distribution of mineral fertilizers.

Consequently, the statement of the problem can be formulated as follows: determine a plan for the distribution of mineral fertilizers between grain crops and farms, which would provide the maximum conditional net income.

The optimal distribution plan for fertilizers should take into account: the presence of fertilizers on the farm; the area of fields of crop rotations (areas) with different agrochemical characteristics; the priority of fertilizing for the main crops and crops grown on land-reclamation lands. It follows that the constraints of the problem are:

– balances on the use and availability of mineral fertilizers;

– conditions on the areas of grain crops in the context of individual areas that differ in agrochemical characteristics;

– conditions for ensuring the planned production volumes;

– conditions for the preservation and improvement of soil fertility in the farms;

– conditions for ensuring the priority of crops grown on land-reclamation lands.

Currently, insufficient knowledge of soils and agroecosystems as objects of modeling creates the greatest difficulty in developing complex mathematical models of renal fertility. Therefore, the creation of models of soil fertility is still at the stage of modeling the dynamics of its elements.

In the work of Z.O. Zhadlun [1] developed economic and mathematical models of the vital nutrition of plants.

When constructing and studying mathematical models of the optimal distribution of fertilizers, the following objective conditions are taken into account that affect the yield of grain crops:

soil type and agrochemical characteristics (acidity, provision of mobile phosphorus and potassium compounds);

weather conditions are average for 5 years;

predecessors based on the data of production experiments, based on the structure of the sown area;

level of agrotechnology, which took place in the production experiments. It is accepted as advanced and accessible to all households.

At present, a large number of economic and mathematical models in agricultural production have been developed [2-6], in which there are three main areas:

– development and solution of economic and mathematical problems of on-farm analysis;

– development and solution of economic and mathematical problems at the level of agro-industrial associations and individual units of agricultural production;

– development and solution of economic and mathematical problems of industry analysis.

At present, the tasks of the first direction are the most developed and implemented, since the information necessary for them is more accessible and reliable. The objectives of this direction include: optimization of the use of mineral and organic fertilizers; optimization of crop development plan; optimization of the production structure of the grain enterprise, etc.

The second direction, which has arisen in connection with the organization of agro-industrial associations, includes the tasks of optimizing not only the production of grain production, but also its industrial processing within the associations.

The third direction is connected with the development and solution of problems of development of individual links of the grain processing industry at the level of the oblast, krai and republic. The main objective of this direction is the optimal placement and specialization of grain production by regions, as well as the optimization of purchases of grain products by farms, regions, regions and republics [6].

2 Material and methods

Taking into account the above features, a mathematical model of the optimal distribution of fertilizers can be formulated as follows:

Find the maximum net income

$$\left(\sum_{e\in E}\sum_{j\in J}\sum_{q\in Q}G_{ejq}X_{ejq}+\sum_{e\in E}\sum_{j\in J}\sum_{q\in Q}G^{1}_{ejq}Y_{ejq}\right)- \quad (1)$$

$$-\left(\sum_{e\in E}\sum_{j\in J}\sum_{q\in Q}C_{ejq}X_{ejq}+\sum_{e\in E}\sum_{j\in J}\sum_{q\in Q}C^{1}_{ejq}Y_{ejq}\right)\rightarrow \max$$

under restrictions

on the distributed fund of mineral and organic fertilizers

$$\sum_{e\in E}\sum_{j\in J}h_{eju}X_{ejq}+\sum_{e\in E}\sum_{j\in J}h^{1}_{eju}Y_{ejq}\le F_{qu}, q\in Q, u\in U \quad (2)$$

on conservation and improvement of soil fertility in farms

$$\left(\sum_{e\in E}\sum_{j\in J}h_{eju}X_{ejq}+\sum_{e\in E}\sum_{j\in J}h^{1}_{eju}Y_{ejq}\right)- \quad (3)$$

$$-\left(\sum_{e\in E}\sum_{j\in J}h_{eju}X_{ejq}+\sum_{e\in E}\sum_{j\in J}h^{1}_{eju}Y_{ejq}\right)\ge B_{qu}, q\in Q, u\in U$$

to fulfill the minimum required volume of gross production of grain products by farms

$$a_{ejq}X_{ejq}+Y_{ejq}\ge P_{ejq} \quad (4)$$

to the maximum possible amount of increase in production

$$Y_{ejq}\le M_{ejq} \quad (5)$$

on fertilized crop areas by crops

$$X_{ejq}\le S_{ejq} \quad (6)$$

on non negativeness of variables

$$X_{ejq}\ge 0,\ Y_{ejq}\ge X_{ejq}\ge 0,\quad Y_{ejq}\ge 0,\ e\in E;\quad j\in J;\quad q\in Q; \quad (7)$$

Where, E - many types of soil, fields;

e – soil type, field e $\in$E ;

J – a variety of crops;

j – grain crop index, j $\in$J ;

Q – a set of farms - grain production;

q – farm index, q $\in$Q ;

U – many types of fertilizers;

u is the type of fertilizer, u $\in$U ;

a $_{ejq}$ – average yield (base) *j*-th culture on th *e*-th soil of the *q*-th farm;

h_{eju} – the rate of application of the u-th type of fertilizer per unit area under the j-th crop on j-ts soil;
h^1_{eju}– the rate of application of the *u*-th type of fertilizer per unit of yield increase under the *j*-th crop on the *e*-th soil;
Z_{eju} – removal of the u- th type of nutrient (fertilizer) per unit area at the baseline yield of the j- th crop on the *e*-th soil;
Z^1_{eju} – removal of the u- th type of nutrient with the unit of the prefix of the harvest of the j- th crop on the *e*-th soil
F_{qu} – the fund of fertilizers allocated for the q-th farm containing u-th nutrient;
B_{qu} – the value characterizing the preservation of the balance of the u-th nutrients in the q-th household:

$$B_{qu} = \sum_{ujq} \left(B^{(1)}_{ujq} + B^{(2)}_{ujq} + B^{(3)}_{ujq} \right), \qquad q \in Q,\ u \in U,$$

$B^{(1)}_{ujq}$ – the number of u-th fertilizers delivered by the j-th crop with the gross q-th farm gain obtained due to other factors, except fertilizers;
$B^{(2)}_{ujq}$ – the number of u-th fertilizers, which characterizes the difference in the effect of organic and mineral fertilizers of the j-th crop in the q-th farm;
$B^{(3)}_{ujq}$ – the amount of biological nitrogen entering the soil (it is included in the calculation of the nutrient balance only for nitrogen);
S_{ejq} is the allowable sown area of the j-th crop on the e-th soil in the q-th farm;
P_{ejq} – the minimum required for the planned task of the production of j-th culture on the e-th soil in the q-th economy;
M_{ejq} – the maximum amount of the gross increment of the j-th crop on the e-th soil of the q-th farm;
G_{ejq} is the assessment of the production of the j-th crop on the *e*-th soil in the q-th farm per unit of sown area (in purchase prices);
G^1_{ejq}– evaluation of the unit of yield increase of the j-th crop on the *e*-th soil in the q-th farm (purchasing systems);
C_{ejq} is the cost per unit area for the j-th crop on the *e*-th soil in the q-th farm, associated with the use of fertilizers;
C^1_{ejq} – costs per unit of yield increase from the use of fertilizers for the j-th crop on the *e*-th soil in the q-th farm;
X_{ejq} – the size of the used area under the j- th crop on the soil on the q-th economy;
Y_{ejq} – the value of the increase in gross output for the j-th crop on the e-th soil in the q-th farm from the entire area.

The model of the problem (1) – (7) reminds one of the most frequently encountered generalizations of the transportation problem – the so-called distribution problem. In [2-6] provides an overview of methods for solving such problems. Recently, at the Institute of Cybernetics named after V.M. Glushko. NAS of Ukraine developed a number of new more efficient gradient type algorithms [7], which can be applied to the solution of distribution problems.

Recommended rates of application of mineral fertilizers for crops and yield, obtained at each site when applying the recommended dose of fertilizers are determined according to the zonal agrochemical station. Application rates are determined based on the use of organic fertilizers. For example, the doses of mineral fertilizers can be determined by calculation using the formulas [8]:

for phosphate and potash fertilizers

$$D = (100 * B - P * K_{P} - P' * K_{r}) / K_{y}$$

for nitrogen fertilizers

$$D = (100 * B - P * K_{r}) / K_{y}.$$

Where D – the dose of fertilizer, kg dv;

B – removal of nutrients with the planned yield, kg ae.;

P – the content of mobile compounds of phosphorus and potassium in the soil, kg dv per 1 ha (determined by multiplying their amount in milligrams per 100 g of soil by 30, since 1 mg of phosphorus and potassium per 100 g of soil corresponds to 30 kg per 1 ha);

P' is the nutrient content of organic fertilizers applied per 1 ha, kg;

K_p – the utilization of mobile substances of phosphorus and potassium from the soil, %;

K_y – the utilization of nutrients from fertilizers in the first year, %;

K_r – the utilization of nutrients from the manure in the year of application, %.

The implementation of the model (1) – (7) on a computer technique will be considered using a specific example.

3 Results and discussion

Distribute the fund of mineral fertilizers for applying them to grain crops in such a way as to obtain the maximum conditional net income. The total sown area is 2750 hectares. It is planned to cultivate winter wheat, corn for grain, sunflower, corn for green fodder. Funds of mineral fertilizers (in kg of active ingredient) were allocated for these areas: nitrogen – 167400, phosphate – 196200, potash – 136200. Planned to produce 12000 centner grains, sunflower – 10600 centner, green mass of corn – 170000 centner.

The optimal distribution of mineral fertilizer funds by crop is given in Table 1.

In the obtained optimal plan, the fertilized areas with basic yield were: winter wheat – 1000 hectares, corn for grain – 700 hectares, sunflower – 220 hectares, corn for green fodder – 439 hectares. The increase in corn yield was 3,500 c.

Table 1. Optimal distribution of mineral fertilizer by crop.

Fertilizers	Dedicated fertilizer and active substance funds	Distribution of mineral fertilizers and active ingredients by crop				
		Winter wheat	Corn for grain	Sunflower	Corn for green fodder	Total
Nitrogen	1674	400	588	354	332	1674
Phosphoric	1962	450	704	432	376	1962
Potash	1362	400	385	279	288	1362

An economic analysis of the use of fertilizers showed that the mineral fertilizers available on the farm, with their optimal distribution, make it possible to increase the net income of crop production by 14,6%.

Thus, in solving the optimization problem, factors describing the effect on yield were more fully taken into account than in traditional planning. This made it possible to distribute mineral fertilizers between farms in accordance with the characteristics of their soils.

Receiving sufficiently high and stable yields of grain crops is impossible without the use of chemical agents, the introduction of which can be carried out using the machine-tractor fleet. In this case, there is a need for a coordinated solution of the tasks of the machine-tractor park and the achievement of maximum efficiency from its use in grain farming.

With the help of ground equipment, mineral fertilizers are applied, chemical pest and plant disease control is carried out, weed vegetation is destroyed in grain crops.

Each chemical work (technological operation) can be performed using different types of machine and tractor fleet. To perform the same operation, an unequal number of ground equipment with different performance and operating costs will be required. Therefore, it is necessary to choose the best option for the use of machine and tractor fleet, which will ensure the implementation of a given amount of chemical work in a timely manner at the lowest cost.

The optimal plan for the use of machine and tractor fleet can only be determined using optimization methods, since the composition of machines and tractors and their possible use have such a large number of options that it is almost impossible to simply sort them out and select the best.

Consider the problem of optimal use of machine and tractor fleet.

The mathematical model of the problem has the following form [8].

Find a solution that minimizes total costs.

$$\sum_{i=1}^{m}\sum_{j=1}^{n}\sum_{k=1}^{k} C_{ijk} t_k x_{ijk} + \sum_{i=1}^{m}\left(\max_k \sum_{j=1}^{n} x_{ijk}\right)\alpha_i \qquad (8)$$

under restrictions

$$\sum_{i=1}^{m} P_{ijk}\, x_{ijk} = d_{jk} \quad j=\overline{1,n}; \qquad k=\overline{1,K}, \qquad (9)$$

$$x_{ijk} \geq 0,\ i=\overline{1,m};\ j=\overline{1,n}; \qquad k=\overline{1,K}, \qquad (10)$$

Where i is the index of the type of ground equipment, $i=\overline{1,m}$;

j is the index of the type of chemical works, $j=\overline{1,n}$;

k – the index of the type of the calendar period, $k=\overline{1,K}$;

d_{jk} – changeable amount of chemical work of the j-th species, which must be performed in the calendar period k, ha;

P_{ijk} – replaceable productivity of ground equipment of type i performing the j-th type of work in the *k*-th calendar period, ha / h

C_{ijk} – replaceable costs for performing work of the j-th type by the i-th type of ground-based equipment in the k-th calendar period, independent of the annual load of machines, tenge;

α_1 – the coefficient of annual deductions of the i-th type of ground equipment;

t_k – the duration of the k-th calendar period;

x_{ijk} is the number of the used ground equipment of type i, the j-th type of work in the k-th calendar period.

In the more general case, the model (8) – (10) can be supplemented with an inequality of the form

$$\sum_{j=1}^{n} x_{ij} + x_{m+1} = b_i,\ i=\overline{1,m},$$

where x_{m+1} – underused power of ground equipment; b_i – the total power of the ground equipment of the i -th type (in terms of reference hectares)

That is, the total power of ground equipment should be sufficient to perform all types of work. However, the mathematical content of the model will not change.

The first component of the objective function (8) takes into account the costs associated with the operation of ground equipment; This includes the cost of fuel and lubricants, salary, the cost of repairs, maintenance and storage of ground equipment.

The second term takes into account the deductions associated with the specified payback period of the machines. Equation (9) reflects the requirement that all chemical works were carried out in agrochemical terms, inequality (10) requires non-negativity of variables.

Thus, the task is described using a convex non-differentiable (piecewise linear) objective function (8) and linear constraints (9), (10).

In the model (8) – (10) it is assumed that the values C_{ijk}, P_{ijk}, d_{jk} are deterministic, however, studies show that these values cannot be considered as predetermined, since they can vary significantly under different conditions. Therefore, the model (8) – (10) does not reflect the conditions associated with the random nature of the quantities, and it becomes necessary to consider models of stochastic programming that take into account the probabilistic nature of the initial information.

We construct a mathematical model of the problem, assuming random variables d_{jk}, i.e. the amount of work that due to fluctuations in natural and climatic conditions in advance cannot be accurately predicted.

Assume that plan X is taken before actual values d_{jk} become known. After they become known, equality (9) is corrected by values y^+_{jk}, y^-_{jk} determined as follows:

$$y^+_{jk} = d_{jk} - \sum_{i=1}^{m} P_{ijk}\cdot x_{ijk};\ y^-_{jk} = 0,$$

if $\quad d_{jk} \geq \sum_{i=1}^{m} P_{ijk}\cdot x_{ijk};$

$$y^+_{jk} = 0;\quad y^-_{jk} = \sum_{i=1}^{m} P_{ijk}\cdot x_{ijk} - d_{jk};$$

if $\quad d_{jk} \langle \sum_{i=1}^{m} P_{ijk}\cdot x_{ijk}.$

Where y^{+}_{jk} – the amount by which the actual volume is more than planned, if we denote by h^{+}_{jk} additional costs per unit of work, then the total cost of additional work is

$$\sum_{j=1}^{n}\sum_{k=1}^{k} t_k h^{+}_{jk} y^{+}_{jk};$$

y^{-}_{jk} – the amount by which the actual amount of work was less than planned; set a penalty for unused equipment per unit of work by h^{-}_{jk}, then the total losses will actually be

$$\sum_{j=1}^{n}\sum_{k=1}^{k} t_k h^{-}_{jk} y^{-}_{jk}$$

$\sum_{j=1}^{n}\sum_{k=1}^{k} t_k \left(h^{+}_{jk} y^{+}_{jk} + h^{-}_{jk} y^{-}_{jk}\right)$ on average were minimal.

Then we come to the problem of stochastic programming.

Find a plan X that minimizes total costs,

$$\min F(x) = \sum_{i=1}^{m}\sum_{j=1}^{n}\sum_{k=1}^{k} C_{ijk} x_{ijk} t_k + \sum_{i=1}^{m}\left(\max_k \sum_{j=1}^{n} x_{ijk}\right)\alpha_i + M\left\{\min \sum_{j=1}^{n}\sum_{k=1}^{k} t_k \left(h^{+}_{jk} y^{+}_{jk} + h^{-}_{jk} y^{-}_{jk}\right)\right\} \tag{11}$$

under restrictions

$$y^{+}_{jk} - y^{-}_{jk} = d_{jk}(W) - \sum_{i=1}^{m} P_{ijk} x_{ijk}, \tag{12}$$

$$y^{+}_{jk} \ge 0; \quad y^{-}_{jk} \ge 0, \tag{13}$$

$$x_{ijk} \ge 0,\ i = \overline{1,m}; \quad j = \overline{1,n}; k = \overline{1,K}. \tag{14}$$

where $d_{jk}(W)$ is a random realization of d_{jk}.

This is a non-linear two-stage stochastic programming problem.

To solve this problem, we use the iterative random search method proposed in [9].

According to this method, at each iteration for fixed X_{ijk} and $d_{jk}(W)$, we solve the problem dual to the following problem of the second stage:

$$\Phi(x, d(w)) = \min \sum_{j=1}^{n}\sum_{k=1}^{k} t_k (h^{+}_{jk} y^{+}_{jk} + h^{-}_{jk} y^{-}_{jk}) \tag{15}$$

under conditions

$$y^{+}_{jk} - y^{-}_{jk} = d_{jk}(W) - \sum_{i=1}^{m} P_{ijk} x_{ijk} \tag{16}$$

$$y^{+}_{jk} \ge 0,\ y^{-}_{jk} \ge 0, \quad j = \overline{1,n};\ k = \overline{1,K}. \tag{17}$$

The dual problem has the form: to find

$$G(x, d(w)) = \max \sum_{j=1}^{n}\sum_{k=1}^{k} \lambda_{jk}(x, d(w)) \cdot (d_{jk}(w) - \sum_{i=1}^{m}\{P_{ijk} x_{ijk}) \tag{18}$$

under conditions

$$\lambda_{jk}(x, d(w)) \le h^{+}_{jk} t_k \tag{19}$$

$$-\lambda_{jk}(x, d(w)) \le h^{-}_{jk} t_k \tag{20}$$

Require that the relation be satisfied

$$h^{+}_{jk} + h^{-}_{jk} \ge 0.$$

Then the solution of the effective problem (18) – (20) is simply:

$\lambda_{jk}(x, d(w)) \le h^{+}_{jk} t_k$ if $d_{jk}(w) - \sum_{i=1}^{m} P_{ijk} x_{ijk} \rangle 0,$

$\lambda_{jk}(x, d(w)) = -h^{-}_{jk} t_k$ if $d_{jk}(w) - \sum_{i=1}^{m} P_{ijk} x_{ijk} \langle 0,$

$\lambda_{jk}(x, d(w))$ – any number on the segment (h^{-}_{jk}, h^{+}_{jk}), if

$$d_{jk}(w) - \sum_{i=1}^{m} P_{ijk} x_{ijk} = 0$$

Consider a random vector with components

$$\xi_{ijk} = C_{ijk} t_k + F_x(x) - P_{ijk} \lambda_{jk}(X, d(w)) t_k,$$

where $F_x(x)$ is the gradient of $\sum_{i=1}^{m}(\max_k \sum_{j=1}^{n} x_{ijk})\alpha$ function expression (11).

As shown in [10], the expectation of the vector ξ coincides with the vector of the generalized gradient of function (11), and the sequence $\{x^{(s)}\}$, whose components

$$X^{(s+1)}_{ijk} + \max\left\{0, x^{(s)}_{ijk} - \rho_s \left[C_{ijk} t_k + F_x(x) - P_{ijk} \lambda_{jk}(x, d(w)) t_k\right]\right\}$$

(ρ_s is a step size, $d(w^{(s)})$ is an arbitrary realization of the vector $d(w)$ in the s-th iteration), converges with probability 1 to the minimum of function (11) with

$$\rho_s \rangle 0, \sum_{s=0}^{\infty} \rho_s = \infty, \sum_{s=0}^{\infty} \rho_s^2 \langle \infty.$$

Thus, we propose the following algorithm for solving problem (11) - (14) by the method of random search. Let the value be obtained at the s-th step $X_{ijk}^{(s)}$ (the initial plan $X_{ijk}^{(0)}$ is specified).

1. Choose a random implementation $d_{jk}(w^{(s)})$ in accordance with the given distribution law.

2. Calculate the value

$$L^{(s)} = d_{jk}(w^{(s)}) - \sum_{i=1}^{m} P_{ijk} x^{(s)}_{ijk}$$

3. At $L^{(s)} \rangle 0,\ \lambda^{(s)}_{jk} = h^{+}_{jk} t_k$;

at $L^{(s)} \langle 0,\ \lambda^{(s)}_{jk} = h^{-}_{jk} t_k$;

at $L^{(s)} = 0,\ \lambda^{(s)}_{jk} = h^{+}_{jk} t_k$;

4.Find

$$X^{(s+1)}_{ijk} = \max\left\{0, x^{(s)}_{ijk} - \rho_s \left[C_{ijk} t_k + F_x(x) - P_{ijk} \lambda_{jk} t_k\right]\right\}.$$

4 Conclusion

To ensure the delivery of fertilizers to the destination for the chemicalization of agriculture, the problem of optimal distribution of fertilizers in grain production has been solved. Based on optimal models, the needs of vehicles for servicing these works are determined. As the obtained calculations show, the cost of purchasing machines and operating costs can be reduced by 20-30% due to the correct choice and use of equipment.

We have developed a complex of economic and mathematical models for the use of vehicles (machine and tractor fleet and agricultural aviation) in the chemicalization of grain crops in a deterministic and stochastic setting. The developed models, in contrast to the previously known ones, are built in accordance with the principles of targeting and taking into account the peculiarities of the development of regions.

The method of determining the need for a machine-tractor park of the economy involves the following main steps:

– identification of typical farms in a given zone or area;

– development of technological maps of crop cultivation and the determination of the optimal composition of the machine-tractor park for typical farms of the zone or area;

– development of standards requirements in the technique for groups of farms characterized by selected typical farms;

– determination of the composition of the machine and tractor fleet of any agricultural object, characterized by this typical farm.

Abstract. Nanosized semiconductor sensor materials based on SnO_2 with different palladium contents were obtained via zol-gel technology with the use of ethylene glycol and hydrate of tin (VI) chloride as precursors. Morphology and phase composition of nanosized sensor materials were studied by X-ray diffraction and TEM methods. Catalytic activities of the Pd/SnO_2 nanomaterials in the reaction of H_2 and CO oxidation were investigated. Adsorption semiconductor sensors based on Pd/SnO_2 nanomaterials were made by their calcination up to 620 ^{0}C in air and the sensors were found to be highly sensitive to presence of CO and CH_4 in air ambient. Higher responses to CO of Pd-containing sensors in comparison with their responses to CH_4 were confirmed by higher reaction activity of CO in catalytic oxidation reaction. Differences in sensitive properties of the sensors to methane and carbon monoxide were explained by features of the catalytic reactions of methane and carbon monoxide oxidation occurring on surfaces of the gas sensitive layers of the sensors.

1 Introduction

Nowadays, a significant degradation of environment due to an increase in harmful substances emissions from industry, multiple technogenic accidents and uncontrolled usage of the existing resources of the planet is one of the global problems of humanity. It should be noted that such ecological situation is due to the pollution of almost all components of the environment (air, water reservoirs and soils). In particular, such gases as CO, CH_4, H_2S, NO_2, CO_2, NH_3, SO_2 etc. presented in air can lead not only to local significant air pollution by toxic gases, but also to climate change throughout the planet. Therefore, control over the emission of such gases in the air is one of the necessary challenges, the solution of which will prevent further deterioration of the environment.

Among harmful gases presented in air control of natural gas and carbon monoxide is crucially needed. Natural gas is widely used in chemical industry and is one of the main energy sources. On the other hand, natural gas can combine with air explosively that leads to human's deaths and economical loses. Since methane is the main component of the natural gas detection of CH_4 allows to monitor the natural gas leakages. Besides, methane is also known to be one of the most dangerous greenhouse gases (Fig.1) and, thus, control of the methane emission in atmosphere is important for reduction of global warming.

Carbon monoxide is widely used in industry also, e.g. in synthesis of aldehydes, methanol, phosgene, in oil industry, in metallurgy etc. But the main part of carbon monoxide emission falls on incomplete combustion of carbonaceous substances. In particular, vehicles, coal and wood burning, portable and back-up generators emit large amount of CO in environment (Table 1).

Table 1. Sources of CO emissions.

Concentration	**Source**
5–15 ppm	Near properly-adjusted gas stoves in homes, modern vehicle exhaust emissions
<1000 ppm	Car exhaust fumes after passing through catalytic converter
5000 ppm ppm	Exhaust from a home wood fire
30000–100000ppm	Undiluted warm car exhaust without a catalytic converter

Carbon monoxide emission hazard is attributed mainly to ability of CO molecules almost irreversibly bounded with iron in human blood (with hemoglobin cells) that leads to decrease in its ability to transport oxygen. Deficit of oxygen leads to different symptoms including headache and dizziness (Table 2). If the CO concentration is high enough human death can be occurred. Carbon monoxide is colorless and odorless gas that make detection of its presence in air crucially needed, especially in household where burning of different organic or carbon-reached compounds is present.

It is known that gas analytical devices based on sensors are promosing to determine the content of

* Corresponding author: georgf@ukr.net

methane and carbon monoxide in air. It should be noted that nowadays a variety of the sensors are being widely developed [1], and they are intended for usage in various branches of science, technology and industrial production. The main areas of the sensors application are [2-8]: control over volatile combustion products in industry, analysis of exhaust gases from automobile transport, quality control of food products, diagnostics of some diseases, studies of cell transformations of living organisms, determination of drugs purity in pharmacology and environmental monitoring.

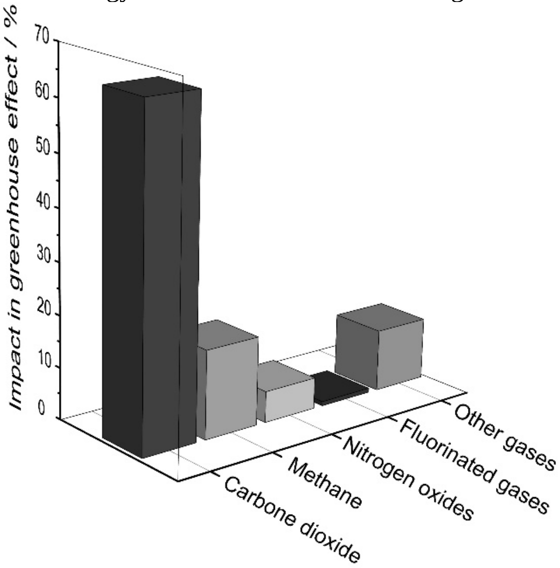

Fig. 1. Impact of different gasses in greenhouse effect.

Table 2. Influence of different CO concentrations on human.

Concentration	Effect
35 ppm	Headache and dizziness within six to eight hours of exposure
400 ppm	Frontal headache within one to two hours
800 ppm	Dizziness, nausea, and convulsions within 45 min; insensible within 2 hours
1600 ppm	Headache, increased heart rate, dizziness, and nausea within 20 min; death in less than 2 hours
6400 ppm	Headache and dizziness in one to two minutes. Convulsions, respiratory arrest, and death in less than 20 minutes.
12800 ppm	Unconsciousness after 2–3 breaths. Death in less than three minutes.

The gas sensors are widely used to detect leakages of toxic and explosive gases and monitor their content in air of both domestic premises and industrial production [9]. Cheap and reliable, with low power consumption, such sensors are widely used. Requirements for them are growing and, in particular, the main characteristics of the sensors - sensitivity, selectivity, response time, relaxation, gas measurement range, stability etc. should be improved [10]. The adsorption semiconductor sensors are perspective to determine presence of both carbon monoxide and methane in air due to combination of their high sensitivity to reducing gases and operational characteristics [11-13]. But the adsorption semiconductor sensors have poor sensitivity to methane and carbon monooxide [14] because of their chemical inertness and thus low oxidation rates of CH_4 and CO by oxygen, chemisorbed on the gas sensitive layer of the sensor.

To create highly sensitive adsorption semiconductor sensors intended to detect toxic and explosive gases leakages it is very important to develop new more sensitive functional nanomaterials [9, 15]. It is known that the main semiconductor material of a sensitive layer of such sensor is tin dioxide due to its chemical and thermal stability [16, 17]. However, it has low sensitivities to gases [18]. One of the effective ways to improve variety functional properties of materials, including their sensitivity, is to use them in a nanosized state [19-21]. In particular, the usage of nanosized semiconductor as the gas sensitive material can lead to increase in the sensor response to reducing gases (such as carbon monoxide and methane) through increase in contribution of surface processes into bulk properties (conductivity) of the semiconductor [14, 22].

Another way to increase the sensor responses to carbon monoxide and methane is introduction of catalytically active additives into the gas sensitive layer of the sensors [23]. Palladium, platinum, gold, oxides of transition and rare earth metals can be such active components [24, 25]. Among the known catalysts for oxidation of carbon monoxide and methane, palladium is one of the most effective [26].

Therefore, development of new nanosized semiconductor gas sensitive materials based on tin dioxide containing catalytically active components, in particular, palladium, should be considered as promising in order to obtain highly sensitive adsorption semiconductor sensors intended to detect carbon monoxide and methane.

The aim of this work is creation of palladium-containing nanosized materials based on tin dioxide for development of the adsorption semiconductor sensors to carbon monoxide and methane.

2 Experimental techniques

Initial SnO_2 was synthesized by a sol-gel technique. The reagents ($SnCl_4 \times 5H_2O$ and ethylene glycol) were mixed under stirring and excess of ethylene glycol was evaporated in two steps corresponding to a gel formation (120 ^oC) and xerogel formation (150 ^oC). The crystalline SnO_2 was obtained after high temperature treatment (up to 600 ^oC) of the xerogel [12].

For the sensors creation the initial powder of SnO_2 was mixed with a binder (10% carboxymethylcellulose solution in water) to form a paste that was applied on a ceramic sensor plate between platinum measuring electrodes [13]. Palladium was introduced into a gas sensitive layer by a wet impregnation technique using water solutions of $PdCl_2$. After impregnation the plates were dried at 90 ^oC and then calcinated up to 620 ^oC in

https://doi.org/10.1051/e3sconf/202128006003

air. Gas sensitive materials and catalysts were prepared by the same procedure as the sensors.

In the sensor materials added palladium content were determined by X-ray fluorescence analysis with the energy dispersion X-ray spectrometer ElvaX EXS - 01.

Morphology of the gas sensitive materials was studied by transmission electron microscopy (TEM) using the SELMI PEM-125K electron microscope (accelerating voltage was equal to 100 kV).

X-ray diffraction (XRD) analysis of the materials was conducted by using a Bruker D8 Advance with CuKα radiation. Estimation of the XRD particle sizes was performed by a Scherrer equation: [27]:

$$D = k{\cdot}\lambda \,/\, \beta{\cdot}cos\theta \,, \qquad (1)$$

where D is the XRD particle size; k is a constant close to unity (for our calculation value 0.9 was taken); λ is the wavelength of CuKα radiation (λ= 1,5418 Å); β is a true broadening of a diffraction peak ($\beta = \Delta - b$, where Δ is an experimental broadening and b is an instrumental broadening); θ is a Bragg angle.

For stabilization of the electric characteristics of the sensors they were periodically treated by 930 ppm CH_4 for 30 seconds per 1 hour. During the procedure the temperature of the gas sensitive layer was 405 ^oC. A ratios R_0/R_{CO} and R_0/R_{CH4} were taken as measures of the sensor responses to CO and CH_4, correspondingly, where R_0 is a value of the sensor electric resistance in air, R_{CO} is a value of the sensor electric resistance in the presence of 1000 ppm CO and R_{CH4} is a value of the sensor electric resistance in the presence of 930 ppm CH_4. The used gas mixtures were certified at the Ukrainian Center of Certification and Metrology. Carbon monoxide- air and methane–air mixtures with lower CO and CH_4 concentrations (less than 1000 and 930 ppm, correspondingly) were obtained through dilution generators.

The values of the sensor signals in air and in the presence of carbon monoxide or methane were measured in a special electric stand [13]. The sensors were sequentially connected to load resistors. The sensor electric resistance was calculated according to the Ohm's law by the next formula:

$$R_s = R{\cdot}(U_{p.s.} - U_r) \,/\, U_r \qquad (2)$$

where $U_{p.s.}$ is a value of voltage supplying by power source at the gas sensitive layer (V); U_r is a value of voltage at the load resistor (V) that depends on the gas composition surrounding the sensor (CO or CH_4 content); R is a known value of electric resistance of the load resistor (Ohm); R_s is a value of the sensor electric resistance (Ohm) in air (R_0) and in the analyzed gas mixture (R_{CO} or R_{CH4}).

Catalytic activities of the Pd/SnO_2 nanomaterials were studied in flow-type reactors using gaseous mixtures 1000 ppm CO or 930 ppm CH_4 with air. Analysis of the gas mixture components was carried out by a chromatographic method using a chromatograph Shimadzu GC-14. The weight of the analyzed catalyst was 200 mg. The temperature of 100% CO or CH_4 conversion (T_{100}) was taken as a measure of the catalytic activity of the samples.

3 Results and discussion

3.1 Morphologies of the sensor materials

It was shown that the initial tin dioxide consists of particles with predominantly spherical shape with an average size 10-11 nm estimated by TEM (Table3). High temperature treatment of the sensor material based on the initial SnO_2 without any dopants results in an increase in its particle size up to 19-20 nm (Table3). Introduction into the sensor material a low amount of palladium is enough to prevent the semiconductor particles enlargement during sintering up to 620 °C. Therefore, for all studied gas sensitive materials with palladium additives the average particle size observed by TEM was 14-15 nm (Table3).

Table 3. Particles sizes calculated from TEM and XRD data for initial SnO_2 and different sensor materials (s.m.).

Materials	TEM size / nm	XRD size / nm
Initial SnO_2	10 – 11	6.7
SnO_2 (s.m.)	19 – 20	20.1
0.31 wt.% Pd/SnO_2 (s.m.)	14 – 15	12.8
1.41 wt.% Pd/SnO_2 (s.m.)	14 – 15	12.4

TEM observation of semiconductor gas sensitive materials revealed their nanoscale nature (Fig. 2). The semiconductor nanoparticles for Pd/SnO_2 are spherical shaped with particle distribution range from 6 to *c.a.* 30 nm (Fig. 3). It should be noted that particles size in sensor materials are larger in comparison with initial SnO_2 (Table 3). This fact can be explained by particles agglomeration and enlargement during high temperature treatment during formation of gas sensitive layer of the sensors [28].

According to the XRD data the cassiterite phase (Fig.4) was detected for Pd-containing sensor materials (ICDD PDF-2 Version 2.0602 (2006), card no. 00-041-1445). Calculated parameter of SnO_2 unit cell (Fig.4) was: a=b= 4.7382 Å, c= 3.1882 Å. For Pd doped materials no phases corresponded to palladium compounds were found even for materials contained up to 3.31 wt.% Pd. No electron diffraction attributed to palladium containing spices also was observed for all studied Pd/SnO_2 materials. The absence of diffraction from Pd-containing particles (metallic Pd, PdO, etc.) for both XRD and electron diffraction methods can be explained by high palladium dispersion on tin dioxide surface and/or probably due to large number of defects in palladium species [27].

Calculation by the Scherrer equation shows different SnO_2 particle sizes for the sensor materials without any additives and the Pd-containing samples (Table 3). The XRD sizes for them are quite smaller than corresponding TEM sizes (12-13 and 14-15 nm respectively). This may be caused by additional defects on the tin dioxide surface [29].

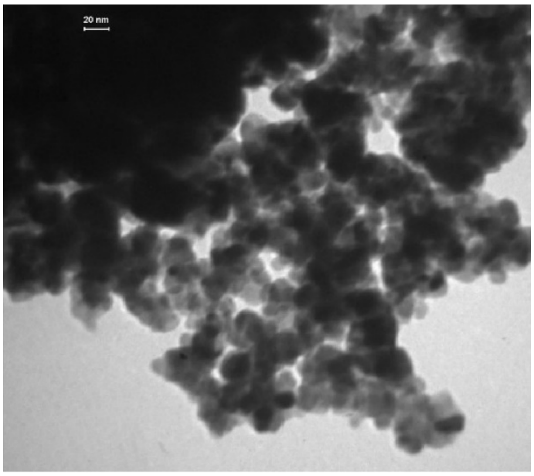

Fig. 2. TEM image of the 1.41 wt.% Pd/SnO_2.

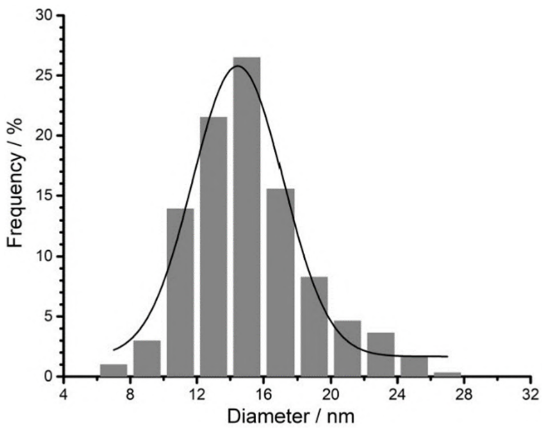

Fig. 3. Histogram of the particles distribution calculated through analysis of TEM data for the samples 1.41 wt.% Pd/SnO_2.

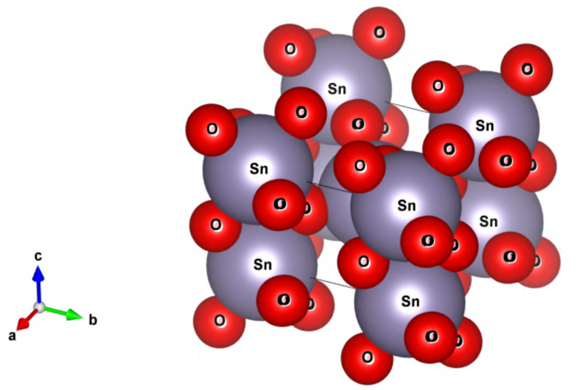

Fig. 4. Crystal structure of tin dioxide calculated by using the XRD data.

3.2 Gas sensitive properties of the sensors

The changes of the values of the sensor electrical resistances in air on the dopant content have an extreme character for both Pd-containing sensors (Table 4). The initial decrease in the electrical resistances in air for the sensors with a low Pd content (0.09-0.23 wt.%) can be attributed to formation of more quantity of oxygen vacancies in tin dioxide crystal structure due to palladium introduction. Such changes can occur at the high temperature treatment process of the sensor formation. It leads to increasing surface charge carriers concentration.

Further increase in dopant content leads to increasing the electrical resistance (Table 4) that can be caused by formation of an interface between the palladium particles and tin dioxide support. The interface consists of active centers for the oxygen chemisorption [30]. Therefore, the increase in the electrical resistance with an increase in the palladium content (from 0.23 wt.% to 1.41 wt.%) is caused by the increase in amount of oxygen chemisorbed on the longer interface between the catalytically active additive and tin dioxide. Further increase in the palladium content leads to the enlargement of the particles of the catalytically active additives and to their aggregation. As a result, the length of the interface begins to decrease and the amount of chemisorbed oxygen decreases too. This leads to decrease in the electrical resistances of the sensors with a large content of the catalytically active Pd additives (Table 4).

Table 4. Electrical resistance in air of the sensors based on Pd/SnO_2 at different operation temperatures.

Sensor resistance / kOhm							
T / °C	**Pd content / wt.%**						
	0.09	**0.31**	**0.62**	**1.41**	**2.28**	**2.42**	**3.31**
405	206	296	392	416	469	395	271
380	218	357	625	681	739	569	399
350	217	372	852	963	1005	720	507
325	211	354	1001	1243	1311	809	542
295	192	290	977	1428	1355	828	523
260	152	200	790	1276	928	592	434
225	106	99	397	660	609	377	240

For the sensors based on Pd/SnO_2 a change in the responses to CH_4 on palladium content correlate with the change in the electrical resistances at the various sensor operation temperatures (Table 5). The highest responses to methane and the highest values of the electrical resistances in air are observed for the same sensor composition (based on 1.41 wt.% Pd/SnO_2) (Table 4). Such correspondence indicates to a common reason that determines both the value of R_0 and γ to methane. This reason is the amount of oxygen chemisorbed on the interface Pd-SnO_2. The electrical resistance in air depends on the number of electrons localized on the chemisorbed oxygen. On the other hand, the response of the sensor is determined by the rate of the reaction that also depends on the amount of chemisorbed oxygen [14].

It was established that the dependences of the Pd-containing sensor responses (γ) to 1000 ppm CO on palladium content are extremal (with maximum at 0.228 wt.% Pd) for all studied operation temperatures (Fig. 5). The highest response was observed at 380 °C ($\gamma = 13.5$ for the sensor based on 0.228 wt.% Pd/SnO_2). The shift of maximal CO response value in comparison with response to methane for the sensors with lower Pd loading can be explained by differences in catalytic activities of Pd/SnO_2 gas sensitive nanomaterials in oxidation reactions of CO and CH_4.

It was found that introduction of Pd into SnO_2 materials leads to increase in their catalytic activities in both CO and CH_4 oxidation reactions. Maximal differences of temperatures of CO and CH_4 total conversions (ΔT_{100}) for nanomaterials Pd/SnO_2 in comparison with nanosized SnO_2 are equal to 240 and 185^0C, respectively. It was found that Pd/SnO_2 materials are much more active in CO oxidation reaction in comparison with CH_4. For the catalyst 2.3wt.% Pd/SnO_2 temperature of total conversion is equal to 110 ^0C in CO oxidation reaction and 415 ^0C in CH_4 oxidation reaction. Such difference in catalytic activity may be due to the chemical inertness of methane molecules. Since the optimal operating temperatures of the sensors (when their significant response values are observed) are quite high. It should be noted that optimal operation temperatures are much higher than the temperature of 100% CO conversion on the corresponding Pd/SnO_2 materials, it can be assumed that a significant amount of products of the CO oxidation reaction occurred on the surface of palladium clusters will prevent access of reagents (CO and O_2) to the interface Pd-SnO_2, that is responsible for the formation of the responses of the sensors. This leads to the shift of the maximal response of the sensors to CO in the area of the sensors with the lower palladium content. For these sensors, due to the higher rate of CO oxidation, the effect of blocking the interface of Pd-SnO_2 interface by CO oxidation products is much greater compared to sensors based on Pd/SnO_2 materials with palladium content higher than 0.228 wt.%, though the additional introduction of palladium increases the interface as evidenced by the increase in the electrical resistance of the sensors (Table 4). It should be noted that the final exclusion of oxygen chemisorbed at the interface Pd - SnO_2 from the formation of the sensor response to CO occurred probably for the sensors with Pd concentration > 1 wt.%. This leads do decrease in response of such sensors to the level of the sensors based on undoped tin dioxide (Fig. 5).

Table 5. Response to 930 ppm CH_4 in air of the sensors based on Pd/SnO_2 at different operation temperatures.

T / °C	Sensor response						
	Pd content / wt.%						
	0.09	**0.31**	**0.62**	**1.41**	**2.28**	**2.42**	**3.31**
405	3.0	9.2	10.1	9.7	9.0	8.9	6.1
380	2.2	8.1	11.5	12.0	11.3	10.7	7.8
350	1.6	6.4	11.1	12.4	11.1	10.5	7.8
325	1.3	4.6	8.4	10.1	8.7	8.4	6.4
295	1.0	3.0	5.3	7.0	5.7	5.4	4.2
260	1.0	1.7	2.7	3.6	2.5	2.4	2.5
225	1.0	1.2	1.3	1.6	1.6	1.3	1.4

The temperatures of CH_4 total conversion are higher in comparison with the sensor operation temperatures. This results in include of the full interface Pd-SnO_2 length in the formation of the sensor responses to methane. This assumption is in consistent with the fact that the maximal responses to methane and values of electrical resistances in air are observed for the sensors with the same palladium content (Tables 4, 5).

The response time and relaxation time of the optimal CO and CH_4 sensors based on Pd/SnO_2 obtained in this work and characteristics of the sensors known in the literature are presented in Table 6. As it can be seen, the dynamic characteristics and response values of the sensors with 0.228 wt.% Pd to CO and 1.41wt.% to CH_4 obtained in this work are better than literature data.

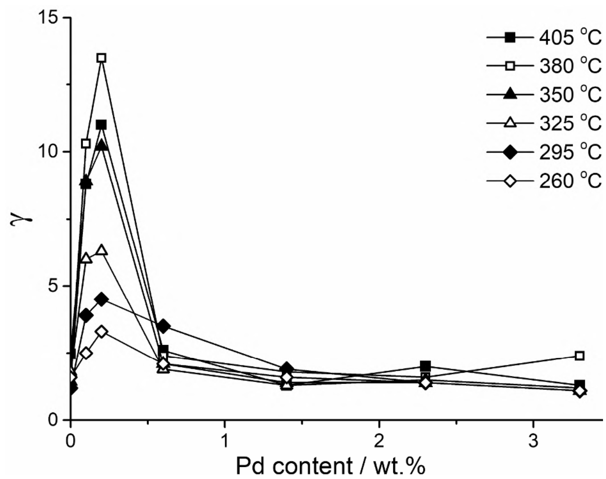

Fig. 5. Responses to 1000 ppm CO of the sensors based on Pd/SnO_2 on palladium content at different operation temperatures of the sensors.

For the sensors with maximum responses that based on the materials 0.228% Pd/SnO_2 for CO and 1.41% Pd/SnO_2 for CH_4, the dependences of their signal values in the presence of different CO and CH_4 concentrations in air correspondingly were studied. It was found that the sensors can measure CO in the range of 20 -1000 ppm and CH_4 in the range of 50 - 930 ppm. It should be noted that the studied dependences are practically linear in these ranges of measured concentration. These results indicate to possibility of using the obtained sensors to measure with good dynamic characteristics presence of CO and CH_4 in a wide concentration range in air.

4 Conclusions

The synthesized nanosized material based on SnO_2 with palladium additives allowed to create adsorption semiconductor sensors with enhanced response intended to measure different concentrations of CO and CH_4 in air. The sensors containing 1.41 wt.% palladium demonstrate the highest response to CH_4 at 350 °C and the sensors containing 0.228wt.% palladium exhibit the maximum response to CO at 380^0C. The higher sensitivities of the sensors to CO compared to CH_4 is explained by the mechanism of the sensor response formation, which is based on the occurring the catalytic oxidation reaction of gases on the surface of the sensors with involving of chemisorbed oxygen adsorbed from air on the semiconductor surface. The sensors obtained in the work have good dynamic properties and a wide range of carbon monooxide and methane detection, that is necessary to provide fast analysis of the environment using sensor gas analyzers based on the created sensors.

Abstract. The intensification of crop production coupled with current declining soil fertility needs proper plant nutrition management and improved effectiveness of fertilizer use. Sustainable practices providing new soil amendments could be a useful tool to improve soil fertility and crop productivity causing economic benefits. The technology of processing local raw materials (leonardite, bentonite, and molasses) was developed to produce new soil amendments with optimal physical and chemical properties and to meet the needs of a particular crop in the nutrients. The best ratio of components was proved in a model experiment with an estimation of the full cost of final organic and organo-mineral soil amendments. In a field experiment, the effect of new soil amendments on available nutrients in Chernozem Podzolic and corn yield was studied. Two doses and methods of application (banding and broadcasting) of new soil amendments were compared taking into account its economic efficiency. Development of technologies to improve fertilizing properties of local organic materials, compliance to recommended doses, and methods of soil inputs application could increase the efficiency of crop production emerging environmental and economic benefits.

1 Introduction

With a growing world population food security has become a global concern. Soil protection in response to increasing food demand is a great challenge, which, in turn, may contribute lasting benefits for climate change mitigation and biodiversity conservation [1, 2]. The importance of fertilizers in raising soil fertility and food production is undoubtedly high. International Fertilizer Association declares that fertilizers play an important role in achieving several of the Goals of the 2030 Sustainable Development Agenda and contribute to Goals: 1 (No Poverty); 2 (No Hunger); 9 (Sustainable Industrialization); 13 (Climate Change); and 15 (Life on Land). Fertilization is essential element of all quality systems in primary production, such as Integrated Production, Good Agriculture Practice or Sustainable Agriculture Initiative [3]. On the one hand, our modern society would not exist without the invention of the Haber–Bosch process and synthetic nitrogen (N) fertilizers, which have become significant factor for increasing agricultural productivity worldwide [4]. On the other hand, the high rate application of synthetic nitrogen requires strategies to mitigate associated environmental damage, such as eutrophication of waters, greenhouse gases emission, soil degradation [5].

To minimize these environmental problems related to the use of chemical fertilizers, organic fertilizers are of increased interest as an alternative source of nutrients for crops. Organic fertilizers have long since been known to increase the organic matter content of the soil, therefore stimulating flourishing of beneficial soil organisms, which, in turn, improves nutrient mobilization and decomposition of toxic substances. They release nutrients slowly and contribute to the residual pool of organic N and phosphorous (P) in the soil, improving the exchange capacity of nutrients [6, 7].

Organic fertilizers serve as both fertilizers and soil amendments. It is known that application of organic amendments is an effective tool to improve soil structure, increase soil water retention as well as to buffer the soil against acidity, alkalinity, salinity, pesticides and heavy metals. Organic amendments have an increasing impact on aggregate stability and organic carbon content in macro- and micro-aggregate scale [8].

Locally available organic materials are an essential source of carbon and nutrients for arable soils. The most

* Corresponding author: vg.issar@gmail.com

common soil organic amendments are animal manure and compost, but also peat moss, wood chips, straw, sewage sludge, sawdust *etc.* Meanwhile, several organic by-products coming from manufacturing processes such as residues from sugar extraction, biochar, distillery waste, biosolids from paper mill can be applied to soil [9].

Sound organic materials management contributes to environmental, economic and social benefits [10]. A socially inclusive and low-carbon economy is achieved by tapping into waste as a resource and increasing the use of secondary materials. Organic amendments are gaining popularity on the market within the European Union, if they come from approved or registered enterprises or plants [11]. The significance of production new soil amendments has become even clearer considering the escalating prices of chemical fertilizers. Involvement of local raw materials for the production of fertilizers is an important issue in agriculture today.

Integrated use of organic materials and chemical fertilizers is beneficial in increasing available nutrients content and organic carbon content in soil [12, 13]. Scientifically based application of organo-mineral amendments stimulates biological activity, improves soil structure, water retention and preserves soil fertility. Organo-mineral amendments provide essential nutrients [14], enhance soil physicochemical properties [15] and re-establish microbial populations [16].

Weak market and low application rate of organic amendments lead to a gap between the actual and potential crop yields. The lack of policy and institutional support in a changing technological environment may lead to negation of organic amendments efficiency by farmers before any economic or environmental benefits would appear. Increasing interest arises in production of organic amendments that can improve soil fertility, stabilize soil organic carbon and allow a sufficient release of mineral nutrients to sustain crop yields.

2 Materials and methods

There is an insufficient availability of organic materials in Ukraine connected with decreasing livestock production (in three times since 1992). That is why the role of alternative soil amendments is constantly increasing in Ukraine. As the main component of new soil amendments, a leonardite was chosen. Leonardite moisture content is 55.8 %, ash content 9.0 %, content of total nitrogen 0.06 %, phosphorus 0.001 %, potassium 0.02 % in dry matter, pH 5.3. To assess the role of organic fertilizer as source of humus, the data on its organic matter composition is necessary. Leonardite contains 48.3 % of carbon, while in pyrophosphate extract was determined carbon content 5.7 %.

To increase the degree of humification of leonardite and to improve its agrochemical characteristics different materials were used: bentonite, $FeSO_4$ and molasses. Model experiment was conducted to determine the best ratio of these components for production high-quality soil amendment with optimal physical and chemical properties.

The effectiveness of new soil amendments was studied in field experiment (table 1). Research was conducted on the experimental field «The impact of different levels of biologization of agriculture on soil fertility» (at State Enterprise «Experimental Farm Grakivske» NSC ISSAR, Kharkiv oblast, v. Novy Korotich). Geographic coordinate: 49°58'12.4"N 36°01'31.7"E. Natural-climatic zone – Forest-Steppe. Climate – temperate continental, sum of positive temperatures about 2400-2900 °C. The average annual precipitation is 465-680 mm. Soil of the experimental field - Chernozem Podzolic, low-humus heavy loamy formed on loess loam with humus content by the Tyurin method 4.1%; total nitrogen content - 0,21%; phosphorus by the method of Chirikov - 111 mg kg^{-1}; potassium by the method of Chirikov - 90 mg kg^{-1}.

Table 1. Field experiment design.

Treatment	Abbreviation	Total N fertilization (kg N ha^{-1})	Method of application
Without fertilizer	WF	0	-
Mineral fertilizer	MF	30	Banding
		60	Broadcasting
Organic amendment	OA	30	Banding
		60	Broadcasting
Organo-mineral amendment	OMA	30	Banding
		60	Broadcasting

The three-replicate trials was set up according to the randomized complete-block design. The elementary plot size was 4 sq. m. Maize (Zea mays) was cultivated. Soil samples were collected after harvest.

Analytical research was carried out in the certified laboratories. Total nitrogen content was determined by Kjeldahl method. Phosphorus and potassium content in soil amendments were determined by sample mineralization during heating with sulfuric acid followed by photometric determination. Mineral nitrogen (NH_4-N + NO_3-N) in soil was determined by modification of the method of NSC ISSAR named after O. N. Sokolovsky: nitrogen extraction from the soil using potassium sulfate then nitrates determined photometrically with disulfophenol acid, and ammonium with Nessler's reagent. Available phosphorus and potassium in soil was determined by the Chirikov method, extracting P_2O_5 and K_2O by 0.5M acetic acid with a ratio of soil to a solution 1:25 followed by photometric determination. All measurements were performed in triplicate. Analysis of variance was performed using Statistica 10 software.

Calculation of cost of soil amendments production to assess the economic efficiency of their use was carried out taking into account the methodological approach and standards given in papers [17-19]. Evaluation of the economic efficiency of soil amendments and mineral

 https://doi.org/10.1051/e3sconf/202128006004

fertilizers was carried out using the author's scientific and methodological approach, which provides an assessment of the impact on effective fertility (crop yield) and profitability of agricultural production [20]. In the calculations were used the following: the average cost of NPK 16% fertilizer - 11440 UAH/t; the average cost of organic soil amendment – 2984 UAH/t; the average cost of organo-mineral soil amendment – 5243 UAH/t; average costs NPK 16% fertilizer application – 1350 UAH/t; average costs of soil amendments application – 125 UAH/t.

3 Analysis and discussion

3.1 Production of new organic and organo-mineral amendments

Leonardite is an oxidized lignite, which has not completed process of coalification. It has high content of carbon (about 50 %) and considerable aromaticity. Leonardite and humic substances derived from leonardite used in many sectors agriculture [21, 22].

To increase humic substances content in leonardite and to improve its agrochemical characteristics were used different components (figure 1). Catalysts of the process of humic substances synthesis can serve variable-valent metals, such as iron; a bentonite was used as matrice to their synthesis. Bentonite is a complex mineral ($Si_8Al_4O_2(OH)_4 \times nH_2O$) and it include amorphous silicon which is an center for the formation of organo-mineral complexes due to the polyvalence of this element. It is also used to improve soil quality and to prevent leaching of fertilizers from a soil [23]. Molasses (sugar refinery waste) were used as the binder during granulation of new soil amendments.

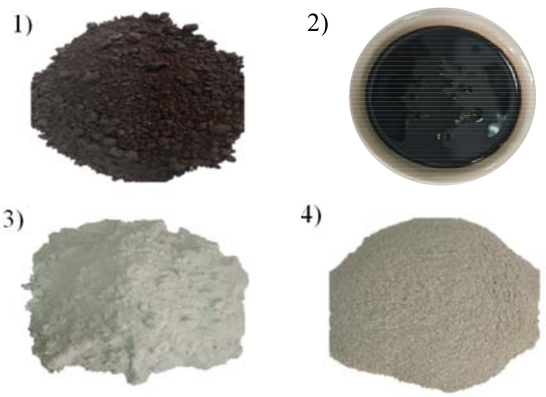

Fig. 1. The initial components for new soil amendments production: 1) leonardite; 2) molasses; 3) $FeSO_4$; 4) bentonite.

Bentonite increases the strength of granules and as well as molasses make the granules denser. In addition, due to high hydrophilicity of bentonite its particles intensively absorb moisture that leonardite contains. The following technological scheme of production of soil amendment was developed (figure 2).

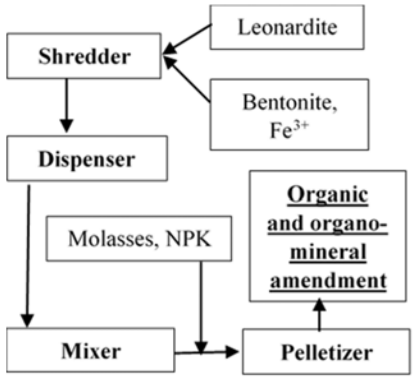

Fig. 2. The scheme of technological process of production of organic and organo-mineral amendments.

Granulation of amendments allows obtaining homogeneous granules of spherical forms, reducing consolidation of a product and preventing the destruction of a product during transportation. The technological solution for production organo-mineral amendment (OMA) involves the combination of organic compounds and mineral fertilizers in organo-mineral form (figure 3). The period of nutrients releasing from organo-mineral mixtures into a soil is longer compared to organic materials. The organo-mineral amendment production could be adapted to meet different specific needs (soil type, particular crop requirements for nutrients *etc.*).

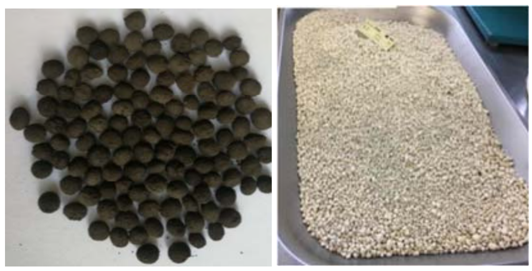

Fig. 3. Final organic soil amendment (left side of figure) and organo-mineral soil amendments (right side of figure).

In model experiment, it was proved that the best ratio of components for production of organic amendment with optimal physical and chemical properties is leonardite:bentonite:molasses:$FeSO_4$ in the mass ratio 1:0.5:0.5:0.01; to produce organo-mineral amendment the best mass ratio of components is leonardite:bentonite:molasses:$FeSO_4$:NPK 16 % fertilizer - 1:0,5:0,7:0,01:0,7.

Nutrients ratio in finished organic amendment (OA) is N:P:K = 1:0.1:2.7, while organo-mineral amendment have a balanced composition for particular crop and soil and promote a balanced crop nutrient uptake. OMA contents nutrients in ratio – N:P:K = 1:0.86:0.95 (according to the corn need).

Expert calculation showed that the estimated cost of 1 ton of organic soil amendment is 3134 UAH, and organo-mineral amendment - 5393 UAH (table 2).

Table 2. Calculation of the estimated cost of organic and organo-mineral amendment, 2020.

Cost	Cost per 1,000 tons, thousand UAH		Structure of production costs, %	
	OA	OMA	OA	OMA
The cost of raw materials	2876.5	5135.2	96.4	97.9
Remuneration	8.8	8.8	0.3	0.2
Fuel	17.2	17.2	0.6	0.3
Amortization	29.2	29.2	1.0	0.6
Current repairment	41.9	41.9	1.4	0.8
Other expenses	10.4	10.4	0.3	0.2
Production cost	2984.0	5242.7	X	X
Selling expenses	150	150	X	X
Total cost	3134.0	5392.7	X	X
Full cost of 1 ton, UAH	3134	5393	X	X

3.2 The effect of new organic and organo-mineral amendments on soil chemical indicators and crop yield

Soil pH plays a central role in many chemical properties and biological soil processes including solubility and availability of nutrients and trace metals. Soil pH value under different types and methods of application of organic and organo-mineral amendments do not change compared to the control, where no amendments was ever applied. Only high dose of organic soil amendment led to an increase in pH value of Chernozem Podzolic (table 3).

Nutrients in synthetic fertilizer are soluble and immediately available to the plants. Therefore, the effect of mineral fertilizer is fast, while from soil amendments nutrients slowly released into soil that makes them have prolong effect. Nutrients are easily lost from soils through fixation, leaching or gas emission and can lead to reduced fertilizer efficiency.

Nitrogen is one of the most important inputs in crop production and the main limiting factor for productivity in agroecosystems. It was found that the application of soil amendments significantly affects the nitrogen regime of chernozem podzolic with both broadcasting and band application, promotes the accumulation of mineral nitrogen (NH_4-N + NO_3-N) in the soil that increases proportionately with the application doses. The broadcasting application of organic and organo-mineral amendments increases the mineral nitrogen content by 0.7 mg/100 g (7 % compared to the control) and 2.0 mg/100 g (19 % compared to the control). Ammonium-nitrogen is accumulated in 1.2–1.4 times more intensive under broadcasting application of soil amendments than under banding. The amount of NO_3-N provided by new soil amendments was less than the amount provided by mineral fertilizer.

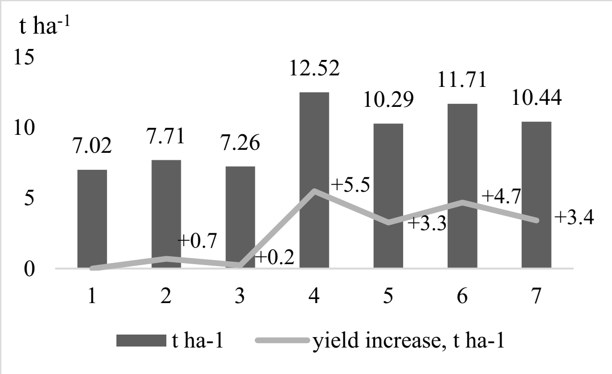
Table 3. Effect of new soil amendments on available nutrients content in the 0-20 cm layer of chernozem podzolic.

Treatment	pH	NH_4-N, mg kg^{-1}	NO_3-N, mg kg^{-1}	P_2O_5, mg kg^{-1}	K_2O, mg kg^{-1}
Without fertilizer	6.1	59.0	45.0	70.0	120.0
MF banding	6.1	57.7	75.4	67.5	112.5
MF broadcasting	6.1	86.3	74.7	72.5	130.0
OA banding	6.1	56.1	43.5	67.5	117.5
OMA broadcasting	6.2	59.4	51.5	70.0	125.0
OA banding	6.1	55.8	46.5	67.5	120.0
OMA broadcasting	6.1	59.2	64.5	67.0	127.5
LCD_{05}	0.1	3.2	5.8	3.1	6.7

Phosphorus is the second most limiting nutrient in crop production. Unfortunately, the reserves of phosphate rock are finite; estimates of the reserve suggest that at the current rate of use this resource will become exhausted within some hundreds of years [24]. Phosphorus is abundant in soil; however, the concentration of plant available P in the soil solution is generally low [25]. New soil amendments do not have significantly effect on the content of available phosphorus in the soil. However, the application of new soil amendments (organic amendment as well as organo-mineral one) caused an increase in the content of available potassium in Chernozem Podzolic compared to the control.

Potassium is also an essential and unsubstitutable nutrient for plants. Although most soils are rich in K minerals, its availability to plants is relatively little. Hence, the demand for K fertilizer is increasing worldwide [26]. After broadcasting application of organic and organo-mineral amendment, the potassium content was increased by 0.5 mg/100 g (4%) and 0.8 mg /100 g (7%) compared to the control. Meanwhile, another study found the effects of leonardite applications on nutrient contents in soil were statistically significant [22].

With a growing world population, food security require appropriate management greater demand of fertilizers to increase yield per unit land. Corn is one of the most important food crops in the world and demand for maize is constantly increasing. Studies showed the increase of corn yield under the band application of organic and organo-mineral amendments by 5.5 and 4.69 t ha^{-1} compared to the control, respectively (LSD_{05} = 2.09) (figure 4).



Note. 1 – without fertilizer; 2 – mineral fertilizer (banding); 3 – mineral fertilizer (broadcasting); 4 – organic amendment (banding); 5 – organic amendment (broadcasting); 6 – organo-mineral amendment (banding); 7 – organo-mineral amendment (broadcasting)

Fig. 4. Effect of new organic and organo-mineral amendments on corn yield.

3.3 Economic efficiency of new organic and organo-mineral amendments

The results of calculation of economic efficiency of application of organic and organo-mineral amendment showed (table 4) that the total cost of band application of organic soil amendment was 15545 UAH/ha, meanwhile the cost of broadcasting method of their application - 31090 UAH/ha; for organo-mineral soil amendment these indicators were equal to 4026 and 8052 UAH/ha, respectively.

Table 4. Model calculation of cost indicators of application of new soil amendments, 2020.

Treatment	The rate on 1 ha, t physical mass	The cost of fertilizers, UAH/ha	Application costs, UAH / ha	Total costs, UAH / ha
MF broadcasting	0.375	4290	506	4796
MF banding	0.188	2151	254	2405
OA broadcasting	10.000	29840	1250	31090
OA banding	5.000	14920	625	15545
OMA broadcasting	1.500	7864	188	8052
OMA banding	0.750	3932	94	4026

Respectively, 96 and 97 % of the total costs for the use of both soil amendments belong to their value. Differences in costs are due to different application rates as well as different production costs of soil amendments. The use of soil amendments is much more expensive compared to the total cost of NPK 16% fertilizer.

Conditional additional income from band application of organic soil amendment was 23580 UAH/ha, while broadcasting application of OA characterized by conditional additional loss of 6950 UAH per hectare (table 5). At the same time, band application of organo-mineral soil amendment can provide conditional additional income 28898 UAH/ha, and broadcasting application of OMA - 16076 UAH/ha. Therefore, the conditional level of profitability of band application of organic amendment can reach 158% and band application of organo-mineral amendment - 204.4-734.9%, while the broadcasting application of organic soil amendment was unprofitable (as well as the application of NPK 16%).

Table 5. Model calculation of indicators of economic efficiency of application of new soil amendments, 2020.

Treatment	Cost of additional income, UAH/ha	Additional profit (loss), UAH/ha	Level of profitability (loss), %
Without fertilizer	-	-	-
MF broadcasting	1680	-2610	-60.8
MF banding	4830	2679	124.5
OA broadcasting	22890	-6950	-23.3
OA banding	38500	23580	158.0
OMA broadcasting	23940	16076	204.4
OMA banding	32830	28898	734.9

Note. The calculations take the average realization price of corn (October 2020) at the level 7000 UAH/t.

As a result, it was defined a higher economic efficiency of the application of organo-mineral soil amendment, compared to organic one, because application of OMA characterizes by the conditional additional income and the level of profitability which is significantly higher than similar indicators for OA. Moreover, the application of organic soil amendment was found to be economically inefficient.

It should be noted that the calculations are based on one-year data and need to be clarified on the basis of at least three-year field experiments. It is clear that in case of other price of harvested corn, as well as in case of cultivation of another crop, the economic efficiency may be completely different. Therefore, future research would be related to an effectiveness of new soil amendments for production of various crops.

4 Conclusions

1. Large use of synthetic inputs and soil fertility decline have emerged as major impediments to sustainable

agricultural production causing a large pressure on the environment. Soil amendments are an environmentally friendly alternative to recover soil fertility and they might offer the potential for sustainable agriculture through adaptation against climate change and lifting farmers out of poverty. Proposed technological scheme makes the production of soil amendments more efficient and effective. New soil amendments based on local raw materials and their efficient use is an option of maintaining soil quality and increasing crop production per unit of land from economic and environmental perspectives.

2. In model experiment on production of new soil amendments from local raw materials, it was proved that the best ratio of components is leonardite:bentonite:molasses:$FeSO_4$ in the mass ratio 1:0.5:0.5:0.01 to produce organic amendment with optimal physical and chemical properties. Moreover, soil amendments could be produced to meet the needs of particular crop in the nutrients though addition of NPK in calculated doses.

3. Correct dose and method of fertilizer application plays an important role in its efficient use. The results of field trial indicated that the application of new soil amendments can provide significant benefits for crop yield and provide an impact on accumulation of main nutrients in a soil. Band application of organo-mineral amendment increased corn yield, available N content in soil but had no effect on P_2O_5 and K_2O. Meanwhile, broadcasting application of organo-mineral amendment enhanced available potassium content in a soil. The plot with the broadcasting application of mineral fertilizer showed the highest nutrients concentrations; while it had the smallest yield increase compared the control plot, where no amendment was applied.

3. The higher economic efficiency of application of organo-mineral soil amendment in comparison with organic soil amendment is established. Thus, conditional additional profit of band application of organo-mineral soil amendment is by 22.6 % higher compared with organic soil amendment. Estimated level of profitability of organo-mineral amendment band application is in 4.7 times higher than profitability of organic amendment.

This small research project is framed within the activities of the Eurasian Soil Partnership Implementation Plan. We acknowledge the GSP Secretariat, the Intergovernmental Technical Panel on Soils (ITPS) and the Eurasian Centre for Food Safety (ECFS), members of the Scientific Committee, for the technical and scientific support provided in the preparation and implementation phases of this project.

Abstract. The relevance of our research is determined by the need to find practical measures that will be aimed of the sustainable development formation and maintenance at mining and metallurgical areas by used of artificial woody plantation. The main objective of this work was on the standpoint of the ecosystem approach to consider the artificial woody plantations as a significant factor for sustainable development paradigm implementation at Kryvyi Rih mining and metallurgical district (Central Ukraine). During 2015-2020, by classical methods were studied the natural forest ecosystems and the artificial forest plantations, which are located in contrast ecological and environmental conditions. Numerous scientific papers about sustainable development have also served as materials for our work. At Kryvyi Rih mining and metallurgical district the leading characteristics of artificial woody plantations have a clear ecological and environmental conditionality. It is proved that in artificial woody plantations of this district tree species are in a state of stress. Therefore, these species lose stability due to the constant influence of adverse environmental factors of natural and anthropogenic genesis. The authors assume that the biogeochemical parameters of trees fallen can be considered one of the promising markers that determine the vitality / healthy of tree species and forecast the development of artificial woody plantations. It has been suggested that the artificial woody plantations at Kryvyi Rih mining and metallurgical area should acquire the status of one of the key factors that determine the sustainable development of this district and Ukraine as a whole. In practice, to achieve this goal, the following steps must be taken: (i) artificial woody plantation assessment, (ii) ecological and environment conditionality of artificial woody plantation current state ascertainment, (iii) sustainable model of artificial woody plantation development, (iv) sustainable management of artificial woody plantation, (v) sustainable development of artificial woody plantation. In the near future, it is recommended to optimize the Kryvyi Rih forest cover by 8-10%. The first step in streamlining and preliminary assessment of the artificial forest ecosystems sustainability is the use of biogeochemical indicators of the chemical circulation system relationship "Leaf precipitation - soil" as markers and predictors of the artificial forest current state in Kryvyi Rih District.

1 Introduction

Practices of the natural forest ecosystems and artificial forest plantations sustainable management are implemented in the World already over century. The international experience history of their service is changing as a result of growing interest to traditional paradigms forest resources policy. The greatest achievements are among the countries of the European Union [13]. Thus, currently in Europe the activities of many institutes are aimed at the most efficient forest use for both present and future generations. Ministerial Conference on the Protection of Forests in Europe is pan-European political tool for forest management [4, 26].

Since 1990, the cooperation of European countries has intensified their policies. These activities were aimed at: (i) consolidating funds for modern forest use, (ii) combating illegal logging, (iii) developing an approach to the assessment of ecosystem services and (iv) increasing attention to the social aspects of forestry and to the role of forests in a green economy [3, 5, 6, 8].

However, in most cases, current environmental activities are aimed primarily at sustainable development and to solving the problems of forest ecosystems and woody plantations. Meanwhile, forest stands can be very factors for sustainable development at industrial areas. This is most relevant for such areas where there is a strong anthropic impact on the environment, including mining and metallurgical areas [9, 12, 14, 17].

Last years the scientific community is actively searching for ways to implement the paradigm of sustainable development in practical measures. Scientists propose: (i) improving the optimal conditions for land use planning and conservation, (ii) developing strategic steps for sustainable development, (iii) calculating the amount of environmental compensation and (iv) community development planning [28, 30,31]. In our opinion, the change for approaches in achieving sustainable development in certain industrial areas (including mining and metallurgical areas) should be aimed at measures involving the use of natural forest ecosystems and artificial tree plantations [19, 21].

It should be noted that in many countries around the world (at the national / regional / local level) various institutions (scientific / public, state / municipal / private) are actively researching natural forest ecosystems and artificial woody plantations. In particular, the scientific field of these studies is: (i) assessment of the natural artificial forests resilience, (ii) elucidation of their cultural and aesthetic value, (iii) establishment of compensation mechanisms for damage. Also analyzed: (i) the state of forest ecosystems, as a complex of trees, shrubs, grasses, bacteria, fungi, protozoa, arthropods and other invertebrates, (ii) parameters of geochemical cycles of oxygen, carbon dioxide, water, minerals and dead organic matter. At the same time, researchers claim that in forest ecosystems the natural changes can never reach equilibrium, but is constantly changing in time and space [10, 11, 13, 23].

In general, natural forest ecosystems and artificial woody plantations have recently been well analyzed in numerous scientific publications. There are also numerous ones on various aspects of sustainable development. However, practical measures to implement sustainable development in a separate industrial area (for example, in the mining and metallurgical district) have in fact been left out of the attention of researchers.

The objective of this paper was to considered the artificial woody plantations as a significant factor for sustainable development paradigm implementation at Kryvyi Rih mining and metallurgical district.

2 Materials and methods

This study was conducted in the artificial woody plantations, which are located at Kryvyi Rih mining and metallurgical district (Central Ukraine). The study area is located between 47°53'54" and 48°8'52" north latitude and 33°19'52" and 33°33'38" west longitude (Figure 1).

During 2015-2020, we studied the natural forest ecosystems and the artificial forest plantations, which are located in contrast environmental conditions.

We studied all types of artificial woody plantations: (i) woody stands of city parks, (ii) woody stand of health protection zones, (iii) woody stands of city protection forest and (iv) woody stands of river protection forest. The natural forest ecosystems from of Gurivsky forest were used as control.

A forest woodland inventory was made a random sampling scheme. The 34 research plots (25*25 m) were established in natural forest ecosystems and in artificial woody plantations. Field data were collected through direct enumeration and measurement of all trees in every plot. In each plot, all woody stems of diameter at breast height (dbh) > 10 cm were recorded and: (i) their diameter at 1,3 m above ground (in two perpendicular directions by a caliper); (ii) their height (by a hypsometer) and (iii) their vitality were measured [16, 29].

For each research plot the following dendrometric parameters were computed: tree-density of the stand, basal area of the tree and volume of the tree [16, 29]. For each research plot the vitality of stand also was computed [1].

All data were submitted to descriptive statistics and analysis of variance (ANOVA). The statistical analysis was performed using the program SPSS for Windows. For all statistical analysis, significance was considered $P < 0,05$ [20].

Numerous scientific papers about sustainable development have also served as materials for our work. In their study, classical scientific methods were used: analysis and synthesis, induction and deduction, analogy and formalization, abstraction and concretization, classification and modeling.

3 Results and discussions

3.1 Current state of artificial woody plantations

The artificial woody plantations in the Kryvyi Rih mining and metallurgical district were planted in the 30-60s of the 20th century. In that historical period, afforestation was carried out as part of Soviet government state program to transform nature. For this purpose, significant financial and human resources were used.

In Kryvyi Rih district the artificial forests are characterized by significant variances in their structural and functional organization. It should also be noted that these artificial forests are located in areas with contrasting ecological & environmental condition.

Summing up the soil factors actions (fertility and moisture) and the air pollution actions, four ecological locations were identified: 1) environmentally friendly area (Background), 2) relative environmentally friendly area (Buffer 1), 3) relative environmentally not friendly area (Buffer 2) and 4) environmentally not friendly area (Impact).

Natural forest ecosystems of Gurivsky forest are located in environmentally friendly area. These ecosystems have a natural origin and are 110-160 years old (table 1). In their floristic composition, the dominant species are English oak, Norway maple and European ash. The natural origin of the Gurivsky forest ecosystem led to the presence of a full complete vertical structure. In this composition were detected Emergent, Canopy Understory Shrub and Herb layers. It was established that at Natural forest ecosystems of Gurivsky forest the values of stand density varied from 1100 to 1300 trees * ha^{-1}, stem heights were 17-19 m, stem

https://doi.org/10.1051/e3sconf/202128006005

diameters were from 19 to 21 cm, stand basal area were from 44 to 48 $m^{2*}ha^{-1}$, stand volume were from 500 to 550 m^3*ha^{-1}. It should be noted, that the vitality of the stand were very high and indicated to healthy forests of these ecosystems. In general, the characteristics of the Gurivsky forest were typical for the floodplain forests of Ukraine [15, 18, 25].

Dendrometric parameters of the stand				
Density, trees/ha	1100-1300	800-900	1400-1500	1400-1500
Height, m	17-19	15-17	12-14	10-12
Diameter, cm	19-21	24-26	16-18	14-16
Basal area, m^2/ha	44-48	34-38	30-34	26-32
Volume, m^3/ha	500-550	300-350	200-250	150-250
Vitality of the stand				
Levels of the vitality	High (healthy forests)	High (healthy forests)	Moderate (partially healthy forests)	Moderate (partially healthy forests)

Artificial woody plantations of the Veseloternivsky arboretum, river protection forests (Karachuny and Dubki forest tracts) are located in relative environmentally friendly area (Buffer 1). These plant communities grow on fertile and moist soils under low level of air pollution (table). In these woody plantations the dominant species are English oak, European ash, European white elm and Ashleaf maple. The age of these plantations is 50-120 years. It is important to note that the vertical structure of these plantations was not formed at all locations. On some forest sites understory and shrub layers were absent. In Buffer 1 area the dendrometric parameters of artificial woody plantations were slightly different from the control (F>Fcritical, p<0,05). Thus, the values of stand density varied from 800 to 900 trees $*ha^{-1}$, stem heights were 15-17 m, stem diameters were from 24 to 26 cm, stand basal area were from 34 to 38 $m^{2*}ha^{-1}$, stand volume were from 300 to 350 m^3*ha^{-1}. In relative environmentally friendly area the vitality of the stand was high and indicated to healthy forests of these woody plantations. In general, biological and dendrological characteristics of artificial woody plantations from Buffer 1 are typical for other artificial forests of Ukraine [15, 18, 25].

Artificial woody plantations of Dovgintsivsky arboretum and River protection forests (Karachuny forest tract (partially)) are located in relative environmentally not friendly area (Buffer 2). These plantations develop on relatively fertile soils with insufficient moisture under moderate level of air pollution (table). The age of the plantation varies from 40 to 80 years. English oak, Red oak, European ash, Ashleaf maple, Scots pine and Littleleaf linden are Dominant species. There is also an insufficiently formed vertical structure: trees of the emergent layer, with partially identified canopy and understory layers, shrub and herb layers is weakly expressed (table).

In these artificial woody plantation, the values of stand density varied were 1400-1500 trees $*ha^{-1}$, stem heights were 12-14 m, stem diameters were 16-18 cm, stand basal area were 30-34 $m^{2*}ha^{-1}$, stand volume were 200-250 m^3*ha^{-1}. These values differ significantly from the control measurements in the natural ecosystems of the Gurivsky forest (F>Fcritical, p<0,05). The vitality of the stand was not high and indicated to partially healthy forests of these woody plantations.

Health protection zones (protection zones of PJSC "ArcelorMittal Kryvyi Rih") and city protection forests (Lisove and Sotsmisto forest tracts) are located in environmentally not friendly area (Impact). These woody plantations develop mainly on relatively fertile soils with little moisture under high level of air pollution (table). The age of these plantations is 50-90 years. English oak, European ash, Ashleaf maple, Norway maple and Black cottonwood are dominant species (table).

In artificial woody plantation from environmentally not friendly area there is no complete vertical structure. Only emergent and canopy layers are present in all forest sites. While other layers (understory, shrubs and herb) are absent in forest sites. It was established that at these woody plantation the values of stand density varied from 1400 to 1500 trees $*ha^{-1}$, stem heights varied from 10 to 12 m, stem diameters varied from 14 to 16 cm, stand basal area varied from 26 to 32 $m^{2*}ha^{-1}$ and stand volume varied from 150 to 250 trees m^3*ha^{-1}. These values are very different from the control (F>Fcritical, p<0,05). The vitality of the stand was very low and indicated to partially healthy forests of these woody plantations.

In general, at Kryvyi Rih mining and metallurgical district the leading characteristics of artificial woody plantations have a clear ecological and environmental conditionality.

It is known that in all industrial regions, which are located in the steppe zone of Ukraine, tree species in artificial woody plantations grow and develop under the combined stress of moisture deficiency and anthropic pollution. In such negative ecological conditions, tree species are characterized by (i) inhibited growth (ii) suppressed physiological state, (iii) accelerated old aging processes and (iv) reduced environmental efficiency. Analysis of recent papers shows that the real vitality of the stand and healthy of trees in artificial woody plantations is unknown, due to their botanical features. That is why the development of rapid methods of early diagnosis of the vitality / healthy of tree species in artificial woody plantations in the steppes of Ukraine and the industrial area is becoming very important.

In our opinion, the biogeochemical parameters of trees fallen can be considered one of the promising markers that determine the vitality / healthy of tree species and forecast the development of artificial woody plantations [7].

At one time, even V.I. Vernadsky [27] taught that trees fallen leaves are "thin, the uppermost layer of soil, full of life". But it is still unclear what chemical elements in fallen leaves can be considered the most informative for diagnosing vitality / healthy of tree species at artificial woody plantations.

Our research proves the reliable 29 correlation coefficients (from possible 70 ones) of the alkaline earth metals content in trees fallen leaves and the vitality of the stand from artificial woody plantations. In 15 cases these correlation coefficients confirm the presence of a direct relationship ($r^2 > 0$). That is, in the case of increasing values of alkaline earth metal content in fallen leaves, there is an increase level of the stand vitality.

In contrast, for the other 14 cases, an inverse correlation was observed ($r^2 < 0$). Based on the correlation strength assessment between the alkaline earth metals content in fallen leaves and stand vitality at the artificial woody plantations certain patterns have been established. At the same time various communications between the certain indicators were followed: (i) in 15 cases there was a weak connection ($0.3 < |r^2| < 0.5$), (ii) in 12 cases there was a medium connection ($0.5 < |r^2| < 0.7$), (iii) in 2 cases there was a strong connection ($0.7 < |r^2| < 0.9$). No cases of strong correlation were found within the calculation matrix ($|r^2| > 0.9$). This phenomenon requires additional reflection.

The obtained results confirm the hypothesis that the stand vitality of the emergent and canopy layers is the most sensitive to the alkaline earthmetals content in trees fallen leaves.

In general, at Kryvyi Rih mining and metallurgical district for 30-60 years numerous and large artificial woody plantations were created. At present, these plantations have reached their peak of development. Their leading biological and dendometric characteristics have a clear ecological conditionality. For woody plant species, soil moisture deficiency and atmospheric repetition pollution are significant environmental factors. In some cases, negative phenomena in artificial woody plantations are observed. At the same time, these plantations can become a "green framework" for future sustainable development Kryvyi Rih mining and metallurgical district.

3.2 Artificial woody plantations and sustainable development of the Kryvyi Rih district

For the last 40 years, the concept of sustainable development has been considered the only possible strategy for further interaction between man and his natural environment. Currently, there are more than 60 different definitions of the "sustainable development" concept. However, in our opinion, the most successful is the definition that was voiced in 1992 in Rio de Janeiro. According to him, "sustainable development of mankind" is understood as such a development that allows satisfying the needs of the present generation and does not jeopardize the ability of future generations to meet their needs.

In the practice of the sustainable development concept implementing, two main directions can be distinguished: resource-economic and socio-philosophical. In the first case, attention is focused on economics and ordering of natural resource consumption. The second direction involves the further development of the sustainable development concept, substantiation of the philosophical basis of this idea, as well as the search for ways and methods of forming an environmental ("ecological") culture for mankind.

Over the past 20-25 years, a significant number of recommendations for the implementation of sustainable development have been developed. Without diminishing the importance of all the aforementioned directions of sustainable development implementation ideas in modern realities, it should be noted that until now, the biosphere aspect of this concept has not been fully considered. Although it is generally accepted that the biosphere, as a phenomenon of our planet, forms unique conditions where only humanity can exist. At the same time, the existence of the biosphere and its stability are determined by natural forest ecosystems and artificial woody plantations.

In general, the concept of sustainable development is considered as the fundamental paradigm and the dominant vector for the further development of modern forestry. However, in the overwhelming majority of cases, the theoretical aspects of this concept development in relation to the forest were considered in scientific papers. The issues of sustainable development of forests and forestry are also actively discussed. While the applied aspects concerned exclusively the "greening" of forestry and grasslanding, optimization of land use systems, conservation of biodiversity, the study of ecological forest services, etc.

In our opinion, artificial woody plantations can be an important factor for the further sustainable development of the Kryvyi Rih area. In practice, to achieve this goal, the following steps must be taken: (i) artificial woody plantation assessment, (ii) ecological and environment conditionality of artificial woody plantation current state ascertainment, (iii) sustainable model of artificial woody plantation development, (iv) sustainable management of artificial woody plantation, (v) sustainable development of artificial woody plantation (Fig. 2).

<u>Artificial woody plantation assessment</u> intends consistent analyze of the plantation area and the plantation stand. Plantation area assessment has a purpose to study soil characteristics and to analyze the levels of soil and air pollution. Plantation stand assessment has a purpose to get a comprehensive understanding of stand with a vision of biology, dendrology and ecology. Moreover, special attention should be paid to the dendrometric characteristics of the stand and the viability of the stand. These parameters manifest the environmental prospects of the stand at natural forest ecosystems and artificial woody plantations. It should also be noted that the biogeochemical indicators of leaf litter are promising indicators of the forest stand.

<u>Current state of artificial woody plantation</u> is ecologically environmentally conditioned. Therefore, it is so important to identify this conditionality and also develop a model for this conditionality. Moreover, in this model, ecological markers and ecological predictors will be the "active center". In our understanding, ecological markers will manifest the current state of the stand, and ecological predictors will manifest the future state of the stand.

<u>Sustainable model of artificial woody plantation</u> should reflect the optimal floristic composition and spatial structure of future artificial woody plantations. We believe that by choosing adapted tree species and rationally placing tree species on the ground, it is possible to create very promising woody plantations. Such woody plantations will be maximally adapted to the climate, soil and environment of the area. Such tree plantations will be maximally adapted to the climate, soil and environment of the Kryvyi Rih area.

<u>Sustainable management of artificial woody plantation</u> has two directions. The first direction involves the improvement of already existing artificial woody plantations. The second direction involves the creation of new artificial tree plants. By our opinion, these two directions should be based on sustainable model of artificial woody plantation. In this case, the improved plantings and the created plantations will be as stable and efficient as possible.

In the leading countries of the world Issues of ensuring the stable development of natural forest ecosystems and artificial tree plantations are considered in conjunction with ensuring the balanced implementation of environmental and natural resource relations. In this case, the criteria and indicators of sustainable use of forests are a combination of simultaneous: 1) conservation of biological diversity; 2) maintaining the economic potential of forest ecosystems as a source of resources; 3) maintaining the viability of ecosystems that are affected by anthropogenic impacts, man-made pollution, changes in climatic conditions; 4) conservation and maintenance of soil and water resources on the territory of forest ecosystems; 5) ensuring the implementation of functionalities in the prevention of regional climate change in the region; 6) support and strengthening of long-term multiple socio-economic benefits from natural and artificial forests to meet the needs of society, strengthening the recreational and tourist potential of forests, as well as opportunities to meet cultural, social and spiritual needs in the process of forest use; 7) legal, organizational and economic framework for forest conservation and sustainable management in the relevant field. Ukraine is one of the least forested countries in Europe. At the same time, Ukraine has the smallest specific area of forests, both natural and artificial, per 1 ha of its territory compared to other European countries (only 0.178 ha per 1 ha).

In general, an important measure to achieve sustainable development in the Kryvyi Rih mining and metallurgical area is the streamlining of a few existing natural forest ecosystems and the creation of new artificial tree plantations. As is known, artificial tree plantations are able to improve the microclimate of certain areas due to the positive impact of trees on the environment. Due to the influence of tree plantations, the amount of precipitation increases by 5-25%, and the total river runoff increases by 15-20%. Such results are extremely relevant for water-deficient conditions. In addition, natural and artificial forests reduce levels of

https://doi.org/10.1051/e3sconf/202128006005

soil and groundwater pollution, prevent the spread of water and wind erosion. When creating artificial woody plantations at Kryvyi Rih area taking into account the levels of soil pollution by heavy metals and their biogeochemical features is very important [2, 7, 22, 24].

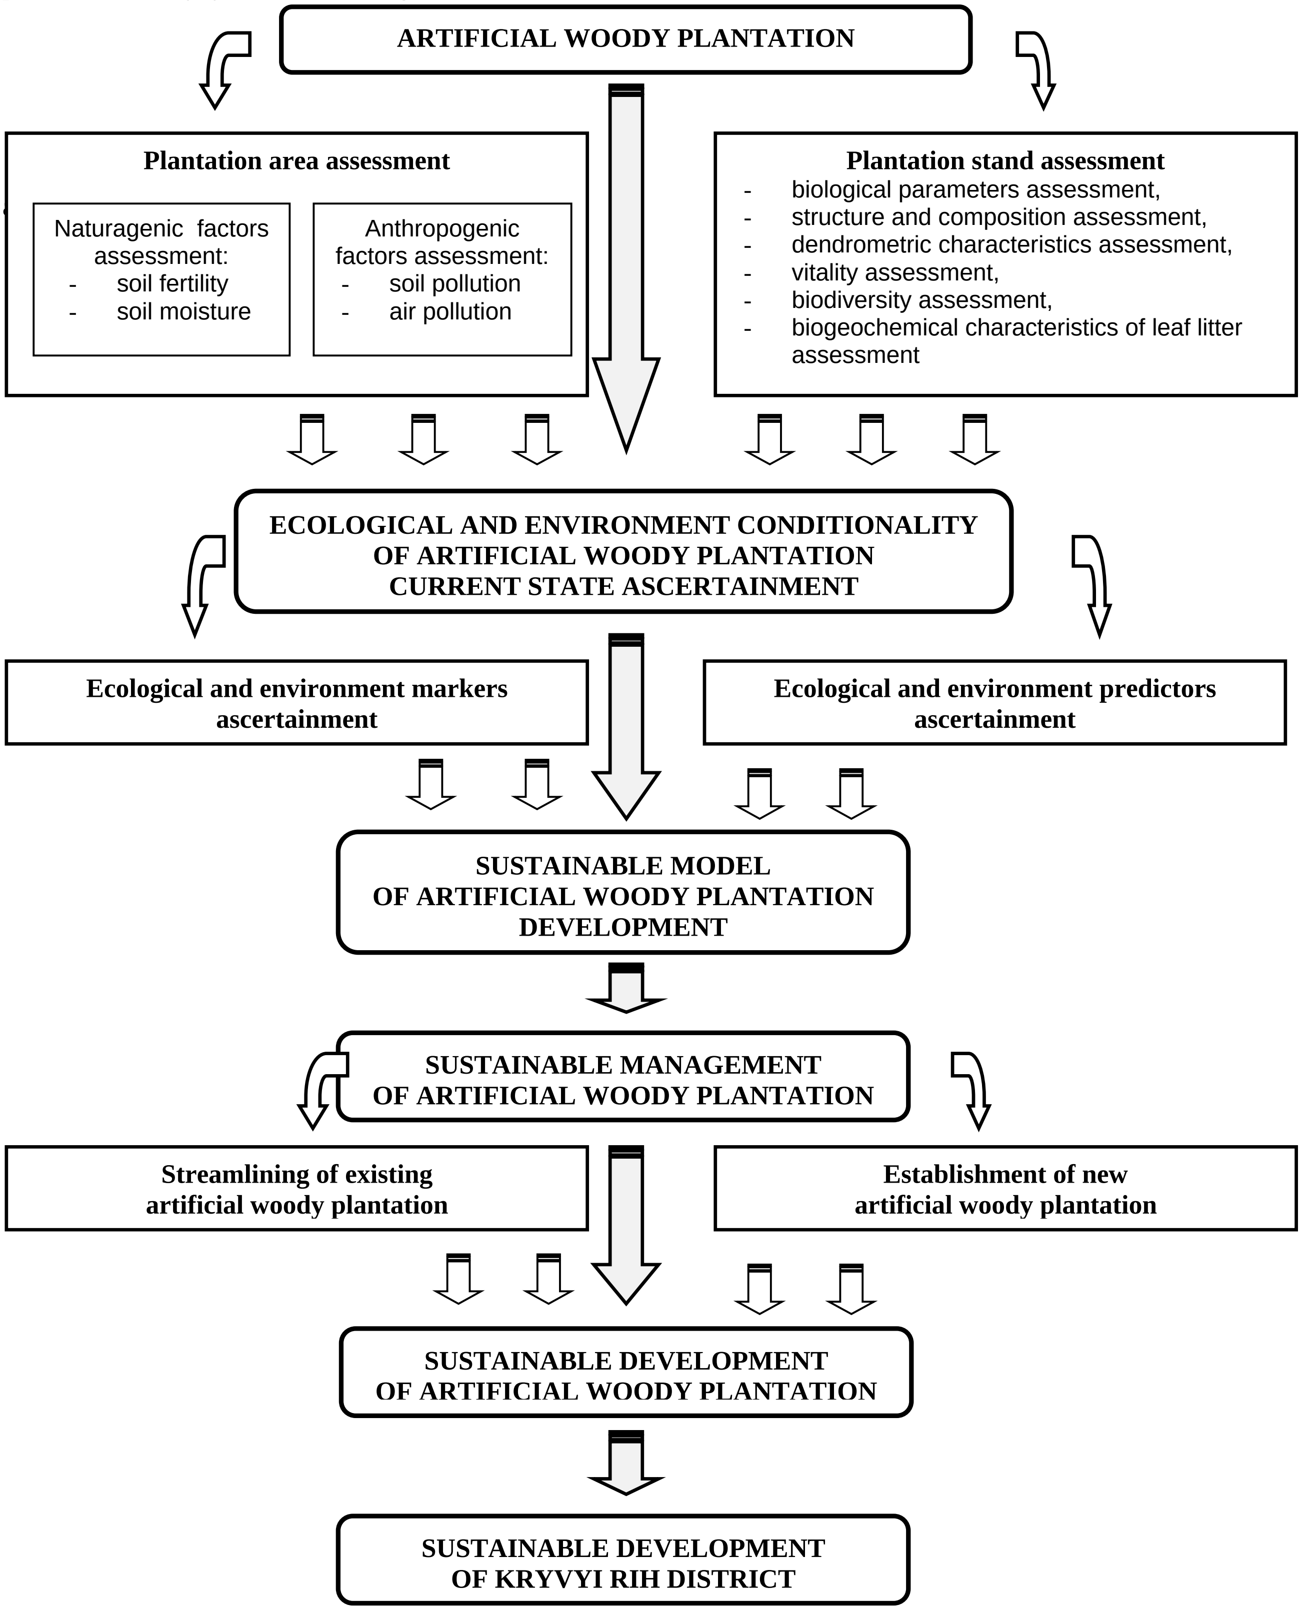

Fig. 2. Conceptual model of artificial woody plantations implementation in sustainable development at Kryvyi Rih district.

4 Conclusions

At Kryvyi Rih mining and metallurgical district for 30-60 years numerous and large artificial woody plantations were created. These plantations have reached their peak of development. Their leading characteristics have a clear ecological conditionality. For woody plant species, soil moisture deficiency and atmospheric repetition pollution are significant environmental factors. In some cases, negative phenomena in artificial woody plantations are observed. At the same time, these plantations can become a "green framework" for future sustainable development Kryvyi Rih mining and metallurgical district.

Artificial woody plantations can be an important factor for the further sustainable development of the Kryvyi Rih area. In practice, to achieve this goal, the following steps must be taken: (i) artificial woody plantation assessment, (ii) ecological and environment conditionality of artificial woody plantation current state ascertainment, (iii) sustainable model of artificial woody plantation development, (iv) sustainable management of artificial woody plantation, (v) sustainable development of artificial woody plantation.

Population structure and symbiotic relationships of the invasive species *Sinanodonta woodiana* (Lea, 1834) in water bodies of Ukraine

Tetiana Yermoshyna[1,*], and *Olesia* Pavliuchenko[1]

[1]Zhytomyr Ivan Franko State University, Department of Zoology, Biological Monitoring and Nature Conservation, 40 Velyka Berdychivska Str., Zhytomyr, 10008, Ukraine

Abstract. Understanding the process of penetration and distribution of the invasive species *Sinanodonta woodiana* is important for predicting associated changes in biodiversity and the structure of freshwater communities. The biomass, density, age and sex structure of mollusk populations were analyzed. An increase in the size of Chinese pond mussels was noted after the introduction: the shell length of individuals from a pond (Romanivka village, 2017) was 24,2% more than of mollusks from the Velyka Repida river (Matroska village, 2004), and in 2019 it increased by another 14,7% (by 42,5% compared to the shell length of the mollusks from the Velyka Repida river). The body weight of *S. woodiana* from the river was 125,3 g, while in the pond there was a 2,13-fold increase in body weight in 2017, with a further increase in this indicator by another 23,6% in 2019 and another 37,7% in 2020. The relative number of *S. woodiana* and native species *Unio pictorum* and *Anodonta anatina* in 2017 was 26,3%, 47,4% and 26,3%, in 2020 – 64,0%, 16,0% and 20,0% respectively. Ciliates of the genus *Conchophthirus* and *Trichodina*, *Aspidogaster conchicola*, *Helobdella stagnalis*, larvae of *Chironomus* sp. are in a symbiotic relationship with *S. woodiana*. The most common *Conchophthirus* sp. – in 21,6% of individuals. Further spread of *S. woodiana* to the cold regions of Ukraine and the formation of new populations in the already developed regions should be expected.

1 Introduction

There is a problem of colonization of territories by invasive species in many countries these days. This is one of the largest environmental problems of our time, which is associated with active processes of biotic globalization.

Invasive species in new habitats, as a rule, do not have natural enemies to control their numbers, which contribute to their rapid spread and a sharp increase in numbers in the newly populated area. Invaders, directly and indirectly, affect native species in natural ecosystems. An invasive species has a direct impact, entering into a relationship of interspecific competition with local species for resources of the same type. As a result, it can suppress or completely displace native species, which leads to a simplification of the structure of the community and a decrease in its resistance to external influences. An indirect influence is associated with a change in the system of evolutionarily formed complex relationships of local organisms with the habitat. The spread of an invasive species in new habitats leads to the disruption of the established biocenotic relationships between native species. An invasive species can bring its symbionts from their native range, where they were originally distributed, and can also acquire local symbionts in a new range [1–5]. Penetrating new regions, it enters into relationships with local species, negatively affecting the size and structure of their populations, resulting in a reduction in natural biodiversity.

The bivalve freshwater mollusk *Sinanodonta woodiana* (Lea, 1834) is an invasive species that was introduced into freshwater bodies of Europe in the middle of the last century and continues to colonize new territories. Its original range is in East Asia. However, from the second half of the twentieth century, a rapid expansion of the range of *S. woodiana* began. Due to its ecological features and wide morphological variability [6], this species of unionid mollusks is actively spreading further, as indicated by the constantly growing number of new sites in which *S. woodiana* is found [7–9]. Although this mollusk was previously considered a thermophilic species, it is found both in reservoirs with a changed (due to the discharge of heated waters) and with a constant water temperature. Depending on the temperature of the aquatic environment, only the density of the settlement and the biomass of this species change. Thus, the population density of *S. woodiana* in favorable conditions of existence usually ranges from several to tens of individuals per square meter. In fish ponds, which do not receive heated waters, the population density of the Chinese pond mussel is relatively low – about 4 individuals per m^2 [10].

Understanding the process of penetration and distribution of an invasive species is important in

* Corresponding author: yermoshyna.t@gmail.com

predicting the associated changes in biodiversity and biocenosis structure. However, at present, information on the symbiotic relationship of *S. woodiana* in the biocenoses of European freshwater bodies, where the mollusk enters, is scarce [11–14].

Our study aimed to study the structure of populations of the species *S. woodiana* introduced into the water bodies of Ukraine and its symbiotic relationship with local species of freshwater fauna of Ukraine.

2 Material and methods

2.1 Study area and sampling

The material was the authors' collections from the Velyka Repida river (Matroska village, Izmail Raion, Odessa Oblast) (geographic coordinates – N 45°33'43"; E 28°77'70") in July 2004. Also, the collection of material was carried out in July–August 2017, 2019 and 2020 from a pond in Romanivka village (Berdychivsky Raion, Zhytomyr Oblast) (geographic coordinates – N 49°89'22"; E 28°48'80"). A total of 94 specimens of *S. woodiana* were examined.

The mollusks were collected by hand at a depth of 0,7–2,5 m. The density of their settlement was determined by the site method. The biomass was calculated by weighing live mollusks together with the liquid of the mantle cavity, followed by recalculating the mass per unit of bottom area. The species identification of mollusks was carried out according to generally accepted literary sources [15; 16]. The age of the animals was determined according to the lines of winter growth arrest. The sex of the mollusks was determined by a smear made from the gonad fluid after its opening. Statistical analysis of the data was performed using descriptive statistics and independent samples t-test.

2.2 Symbiont detection

The mollusks underwent a complete parasitological dissection with the preparation of temporary preparations of symbionts. The animals inhabiting *S. woodiana* were initially searched for on the surface of the mantle, oral lobes, gills, in the mantle fluid, and then inside internal organs such as the gonads, pericardium, and kidneys.

The prevalence of symbionts was determined as the percentage of infected hosts with a specific species or group of symbionts. The intensity of invasion is an arithmetic mean of the number of parasites per one infected individual of the host. Abundance index – the average number of a particular species or group of parasites in all host individuals (including uninfected ones).

Determination of the systematic affiliation of symbionts was carried out using keys and scientific articles devoted to the taxonomy of the corresponding groups [17–20].

The study of the morphological organization of local species of freshwater fauna was carried out visually by the movement of objects in a drop of water, at magnifications of 40–400 times based on a biological microscope ULAB XY-B2. The observation was accompanied by photographing using an IS Capture digital camera designed for observation, photographing and video projection of transparent objects in transmitted ordinary light.

3 Results and discussion

3.1 Population structure of *S. woodiana*

For the first time in the Ukrainian part of the Danube river basin, the Chinese pond mussel was recorded in 1999 [21], where the species probably entered from Romania, spreading downstream of the Danube. The Velyka Repida river is a left tributary of the Danube, where the collection of mollusks was carried out in 2004 and 2005 (Matroska village, Izmail Raion, Odessa Oblast).

The entry of *S. woodiana* into a pond in the Romanivka village (Berdychivsky Raion, Zhytomyr Oblast), most likely, occurred in 2005 as a result of the release of mollusks glochidia during their temporary maintenance (for two summer months in special cages-baskets) under conditions natural reservoir. Chinese pond mussels, collected from the Velyka Repida river, got into the pond.

The population density of *S. woodiana* in the Velyka Repida river was 1,8 ind./m^2, the biomass was 227,1 g/m^2 (Table 1). In the pond, the density of this mollusk during the study ranged from 0,3 to 4,0 ind./m^2, and the biomass – from 133,5 to 1354,8 g/m^2.

Table 1. Changes in quantitative indicators of *S. woodiana* and its populations

Year	Shell length, mm (M±SD)	Weight, g (M±SD)	Median age	Population density, ind./m^2	Biomass, g/m^2
Velyka Repida river, Matroska village					
2004	106,2± 8,9	125,3± 25,7	4,3	1,8	227,1
Pond, Romanivka village					
2017	131,9± 6,8	267,0± 41,6	3,6	0,5	133,5
2019	151,3± 4,2	330,1± 35,1	3,9	4	1354,8
2020	158,6± 4,2	454,4± 35,3	3,9	0,3	145,4

The lower values of these indicators for mollusks from the pond in Romanivka village in 2017 and 2020 may be associated with more severe winter conditions in the north of Ukraine since the water temperature has a direct effect on the growth rate, reproduction and distribution of this species. However, in 2019, we saw a surge in the number of Chinese pond mussels in the local population from a pond in the Pyatygirka river.

Like any invasive species at the stage of conquering new territories, individuals of *S. woodiana* actively reproduce, spread, and, easily winning interspecific competition with native bivalve mollusks for environmental resources, grow rapidly from year to year.

The average shell length of individuals living in the Velyka Repida river was 106,2 mm, whereas, after introduction into the pond, mollusks significantly increased in length. Thus, the average shell length of individuals collected in 2017 was 24,2% more ($p<0,01$) than that of mollusks from the Velyka Repida river, and in 2019 increased by another 14,7% (by 42,5% compared with the length of the shell of the Chinese pond mussels from the Velyka Repida). The average shell length of specimens collected in 2020 remained almost unchanged, but the average mass (with shell) continued to grow. Thus, the mass of *S. woodiana* from the river was 125,3 g, while in the pond, a 2,13-fold increase in body weight was noted in 2017 ($p<0,01$). In 2019, in mollusks collected from the same local population, this indicator increased by another 23,6% (Table 1), and in 2020, Chinese pond mussels also increased their body weight by another 37,7%. Although the average age of individuals in this local population in 2019 and 2020 increased slightly to 3,9 years compared to 3,6 years in 2017, the increase in shell length and body weight was faster. This process is especially noticeable when studying the growth of these parameters in age groups. So, if 2-year-old individuals collected in 2017 and 2019 weigh the same, then by the age of 6 year the body weight gain is more noticeable in individuals collected in 2019 (5,6 times) compared to 2017 (3,9 times). These data indicate that the Chinese pond mussel, thanks to its modification variability, is adapting better and better to new conditions of existence every year.

The age structure of *S. woodiana* populations was studied according to the ratio of age groups – young individuals (1–3 years): average age (4–6 years): older group (7 years and older). In populations from two areas, individuals aged from 2 to 8 years were found, in particular, from the Velyka Repida river, 3–8-year-old mollusks were found, and from a pond in Romanivka village – 2–7-year-olds. The age structure consists of representatives of all age groups: the ratio of age groups is 0,8 : 1 : 0,2 for mollusks from the Velyka Repida river and 0,9 : 1 : 0,04 for Chinese pond mussels from the pond. In both populations of mollusks, the most numerous is the middle age group (from 4 to 6 years old). Young individuals account for a slightly smaller percentage of the total collection. Thus, in the river, 3-year-old mollusks represent 39,5% of the population of the studied group (Fig. 1), and in the pond, 2- and 3-year-old individuals – 45,1%. The smallest is the older group (2,0–9,3%). We did not find 1-year-old individuals in two local populations, and 2-year-olds were found only in the Velyka Repida river. The presence of a large number of young individuals in the studied populations of *S. woodiana* indicates its active reproduction.

In the sex-age structure of *S. woodiana* from the Velyka Repida river, the most numerous group among all age groups are 3-year-old males, from the pond – an equally large number of 3- and 4-year-old males and females (Fig. 2). The number of females and males of other age groups is much less.

The sex-age structure in the Velyka Repida river more reflects the invasive nature of the *S. woodiana* species. The presence of a large group of 3-year-old males suggests a growing population in this collection site. In the pond, all age groups are represented relatively evenly, which indicates the sufficient viability of this population and the transition of the Chinese pond mussels from conquering the territory to stable existence in this water body.

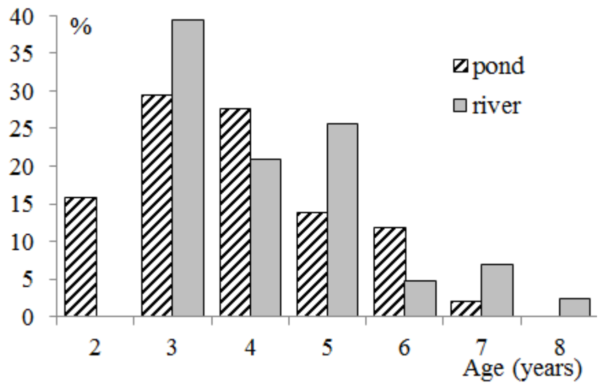

Fig. 1. Age structure of *S. woodiana* population from surveyed biotopes (the ratio of individual age categories to the total number of individuals, %).

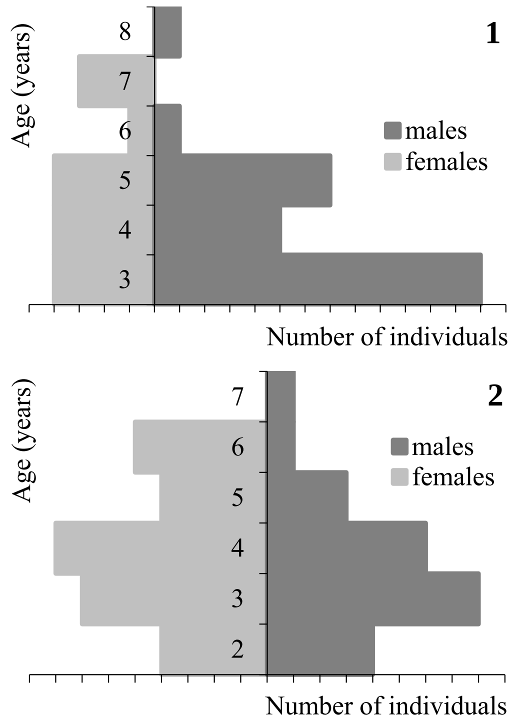

Fig. 2. Sex-age structure of *S. woodiana* population from the studied water bodies: 1 – Velyka Repida river, Matroska village; 2 – pond, Romanivka village.

The sex structure of the population from the Velyka Repida river was dominated by males (female : male ratio is 0,6 : 1). Whereas in the sex structure of the studied group from the pond, females quantitatively prevailed over males (1,2 : 1). This may indicate active reproduction of the invasive species in a new place. Also, almost all females from the pond during the period of collecting the material had a gill pregnancy (85,7%), that is, all age groups of mollusks, including 2-year-old individuals, participated in reproduction. The smallest female with glochidia in the gills had a shell length of

9,3 cm. That is, even with a slow growth rate of mollusks at the beginning of their life in a reservoir with a natural temperature regime in northern Ukraine, they are capable of reproduction at 2 years of age.

It is known that individuals of *S. woodiana* reach sexual maturity already in the first year of life with a shell length of about 30 mm [22], while the native *Anodonta* species reach maturity at 2 years or later [23]. This feature of the reproductive biology of the Chinese pond mussel gives a significant competitive advantage over the local unionid mollusks.

3.2 Advantages of *S. woodiana* in freshwater biocenoses and its impact on their biodiversity

One of the key factors in the success of a species invasion is its tolerance to environmental stress. There is ample empirical evidence that invasive species can better tolerate adverse conditions than native species. Thus, researchers have studied the resistance of *S. woodiana* to thermal stress and trace metallic zinc pollution stress. The higher tolerance of this mollusk in stress tests was associated with a significant decrease Rhodamine B accumulation, indicating more efficient multixenobiotic resistance mechanism; with significantly higher INT reduction capacity; with less pronounced changes in the activity of stress-related enzymes (glutathione-S-transferase, catalase) and neurotoxicity biomarker (cholinesterase) [24].

We noted a high variability in the shape and color of shells in *S. woodiana* from the two studied biotopes. The shape of the shells of individuals of the initial population from the Velyka Repida river is most often rounded (the shape of the lower edge of the shell corresponds to a regular semicircle), however, it can be elliptical and irregularly rhombic (the lower edge of the shell forms an obtuse angle). The mollusks from the pond in Romanivka village do not have a rounded shell. The specimens here are usually elliptical, although a third of the specimens have an irregular rhombic shape. An egg-shaped form is occasionally found.

The color of the periostracum of 2/3 of the mollusks of the progenitor population (the Velyka Repida river) is bright green. The rest of the individuals are olive-colored with a small amount of yellow or brown. All individuals from this biotope have pink stripes along the growth lines and vertical green rays. The general background of the periostracum of half of the mollusks from the pond is yellow-green, the second half of the Chinese pond mussels have a darker olive-brown color. The latter variants, as a rule, have a proportion of gray color against the general background of the shell. In all specimens, areas of the periostracum along the growth lines, especially in the lower part, are colored red, and vertical green rays are visible on the shell.

So, the color of shells from the Velyka Repida river is light, bright, while the color of the mollusks from the pond is dominated by a dark general background, which is probably associated with living in very turbid water. Specimens from the Velyka Repida river are more similar in shape and color to typical *S. woodiana*, while specimens from the pond in Romanivka village resemble mollusks of the genus *Anodonta*. Such a wide morphological variability of individuals of the Chinese pond mussel is its specific feature, which allows *S. woodiana* to adapt better to different habitats.

Since an invasive species readily adapts to new living conditions, it can rapidly increase the density of the newly formed population and, as a result, threaten native species. We observed such relationships in the investigated pond between *S. woodiana* and two other species of unionid – *Unio pictorum* Linnaeus, 1758 and *Anodonta anatina* Linnaeus, 1758, which form joint malacofauna. The relative number of *S. woodiana* and native species *U. pictorum* and *A. anatina* in 2017 was 26,3%, 47,4%, and 26,3%, respectively. In 2020, the ratio of these species in the malacofauna changed and amounted to 64,0%, 16,0% and 20,0%, respectively. However, much earlier, before the Chinese pond mussel appeared in the pond, there were more other mollusks of the Unionidae family: the population density of *U. pictorum* was 2,1 ind./m^2, and *A. anatina* – 1,5 ind./m^2. That is, after the introduction of the Chinese pond mussel, the number of local species of unionid mollusks significantly decreased: from 3,6 ind./m^2 (in 2005) to 0,2 ind./m^2 (in 2020).

Thus, *S. woodiana* is a large species of bivalve mollusks, which actively assimilates the environment in a new habitat, multiplies intensively, and rapidly increases in size and weight. Due to these features, it can be an attractive settlement site (microbiota) for various freshwater symbionts.

3.3 Symbiotic relationship of *S. woodiana* in new biocenoses

Among the wide variety of interconnections of living organisms in ecosystems, such a type of interspecific relations as symbiosis is distinguished. A symbiotic relationship is a type of close interspecies relationship in which at least one of the species benefits from it. The forms of symbiosis are quite diverse [25]. So, one of the forms is commensalism, in which one of the partners (commensal) imposes on the other (the owner) the regulation of his relations with the external environment and thus receives a certain benefit, without bringing the owner either harm or benefit. Also, a form of symbiosis is parasitism – a form of interspecific relations in which one organism (parasite) exists at the expense of another (the host), repeatedly using it: feeding on its blood, tissues or digested food, and also using it as a temporary or permanent habitat.

Various forms of biological connections between species serve as regulators of the number of living things in a community, determining its stability.

Among the organisms found in association with *S. woodiana*, one can distinguish the group of truly symbiotic organisms for which association with the host is obligatory throughout the life cycle (ciliates of the genus *Conchophthirus* and *Trichodina*, *Aspidogaster conchicola* Baer, 1827) and the group of free-living organisms, which, as a rule, accidentally enter the mantle cavity of the mollusk, but can live there permanently

(*Helobdella stagnalis* Linnaeus, 1758, larvae of *Chironomus* sp.).

Thus, we found the genus *Conchophthirus* (Oligohymenophorea: Conchophthiridae) typical ciliates to unionid, which are found in aboriginal species from similar biotopes. These ciliates are widespread and occur exclusively in freshwater bivalve mollusks [26]. Ciliates were identified on the gills and in the mantle fluid from the mantle cavity of the *S. woodiana*, where they live and actively move. The prevalence of *Conchophthirus* sp. in the mantle cavity of the Chinese pond mussels was 21,6%. The body of these ciliates is flat, elliptical, with a mouth near the middle of the body. They have dense cilia over the entire surface and an average length of about 100 microns. Sometimes it can attach to host tissues, especially gills and oral lobes, without causing harmful effects on these tissues. Host age has no effect on invasion by the ciliate *Conchophthirus* sp. Individuals of age categories from 2 to 6 years old were infected.

We found a parasitic ciliate of the genus *Trichodina* (Oligohymenophorea: Trichodinidae) on the gills of *S. woodiana* (Fig. 3). The prevalence is insignificant – 5,9%. The intensity of the invasion of the Chinese pond mussels was 3,7 specimens per individual. Ciliates of the genus *Trichodina* from the mantle cavity of mollusks *S. woodiana* have also been identified and described by Chinese researchers [27].
