Abstract. The article discusses the prerequisites for improving crop irrigation regimes on the basis of resource optimization. The current approaches to solving the problem of water shortages in irrigation are considered. The results of a machine experiment that reproduces research on the influence of the amount of water resource consumption on the yield of a cultivated crop in relation to the timing of irrigation are given. For the implementation of the machine experiment, a set of optimization, economic, mathematical and forecasting-simulation models was used, including a model of climatic conditions, a model of water regime and water regulation technologies, as well as a model of crop yields on reclaimed land for long-term forecasting. It has been experimentally shown that the impact of water resource shortages is weakened in the second half of the growing season, when crop yield losses are significantly lower than at the beginning of the growing season under similar conditions of water resource consumption. This fact provides prospects for the optimization of crop irrigation regimes as a component of resource optimization. The obtained results and the availability of a set of optimization, economic, mathematical and forecasting-simulation models create prerequisites for improving crop irrigation regimes on the basis of resource optimization.

1. Introduction

The existing global problems associated with climate change, food, water and energy crises pose a need for the world community, including Ukraine, to adapt to existing challenges and threats and to increase the efficiency of all spheres of economic activity, including agricultural production, in the face of modern changing conditions and requirements [1–4].

It is well known that melioration, and especially irrigation, is one of the most effective tools for reducing the negative effects of climate change on agricultural production, and irrigated land yields in 2–3 times higher yields compared to rainfed land. The predominant part of Ukraine's territory is located in the zone, which is characterized by an insufficient level of natural moisture. For the period from 1990 to 2010, the total area of arid and very arid zones, where sustainable agriculture is impossible without irrigation, increased by 8 million hectares. By that time, the restoration of hydrotechnical melioration, taking into account climate-oriented requirements, was already considered at the state level as an important condition for adapting agricultural production to the existing global food, water and energy crises, the threatening nature of which continues to increase in the context of climate change and creates new challenges. According to preliminary estimates, the deterioration of meliorative systems in Ukraine is 85%, and the area of actually irrigated land has been decreasing every year (2020 – 551 thousand hectares, 2021 – 525 thousand hectares, 2022 – 305 thousand hectares), and this is despite the fact that 2/3 of the territory of our country is at risk of agriculture [5]. Restoration of hydrotechnical melioration is a complex and expensive task, but it is necessary to ensure food security in Ukraine.

In order to achieve the goals of restoring hydrotechnical reclamation in 2019 the Cabinet of Ministers of Ukraine approved the Irrigation and Drainage Strategy in Ukraine until 2030 [6], and in 2020 adopted a plan for its implementation. In addition, to identify the existing needs for adaptation of economic sectors to climate change, in October 2021, the Cabinet of Ministers of Ukraine adopted the Strategy on Environmental Security and Climate Change Adaptation until 2030 [7], the first national document that creates a legislative framework for adaptation measures for systematic and long-term work on climate change adaptation.

Since the beginning of the full-scale war, the loss of Ukraine's sown areas caused by the temporary occupation and hostilities has amounted to more than 25% of the total amount, and the main part of these losses are highly productive irrigated lands. After Russia's terrorist attack on the Kakhovka Hydroelectric Power Plant, which led to a further reduction in sown areas, the problem of water shortages for irrigation, which is already relevant at both regional and global levels, reached a critical level [8].

In this regard, ensuring food security in the face of resource scarcity requires increasing the efficiency of irrigation, in particular by developing regime, technological and technical resource-saving measures, and means aimed at reducing the consumption of water and energy resources per unit of agricultural production, i.e. at obtaining the greatest possible effect from "one sown hectare" and "one drop of water".

There are several main approaches to implementing this idea: improving soil properties to increase its water-holding capacity; reducing evaporation from fields; and optimizing the amount of water for irrigation, including by improving irrigation techniques and crop irrigation regimes.

2. Materials and methods

Thus, modern conditions and requirements for conducting agricultural production make it necessary to change approaches to project decision-making in projects of construction, reconstruction and functioning, the purpose of which is to reduce the consumption of water and energy resources, which will ensure an increase in the economic and ecological efficiency of the functioning of irrigation systems in accordance with modern conditions and requirements and the efficiency of agricultural production on irrigated lands as a whole.

In recent years, the trend of targeted reduction of water consumption for irrigation has been gaining ground in the United States, when farmers deliberately reduce crop yields to reduce water consumption [9–11]. Similar practices are applied in China through the introduction of "deficit irrigation" [12–14]. In order to achieve the goal of reducing the values of resources used for agricultural production, the improvement of irrigation techniques and crop irrigation regimes should be based on research on the dependence of these values on the yield of cultivated crops, namely, that in the same year, due to the unequal distribution of the same amount of irrigation water, significantly different yields can be obtained. These provisions can be illustrated by the experimental data of Krafti and Kotov [15]. They studied the effect of different irrigation regimes on the corn yield in the case of a water shortage, when the irrigation rate was 2/3 of the required value.

To apply the entire irrigation rate, three waterings were required with the same watering rate, this option of irrigation was a control variant (№ 1). For the control variant with the full irrigation rate, irrigation was carried out during the periods of panicle ejection–flowering (I), stigma ejection (II) and milk ripeness (III). Different options with two waterings were studied, in which one of the three waterings was cancelled:

- № 2 – irrigation regime with cancellation of watering during period I;

- № 3 – irrigation regime with cancellation of watering during period II;
- № 4 – irrigation regime cancellation of watering during period III (figure 1).

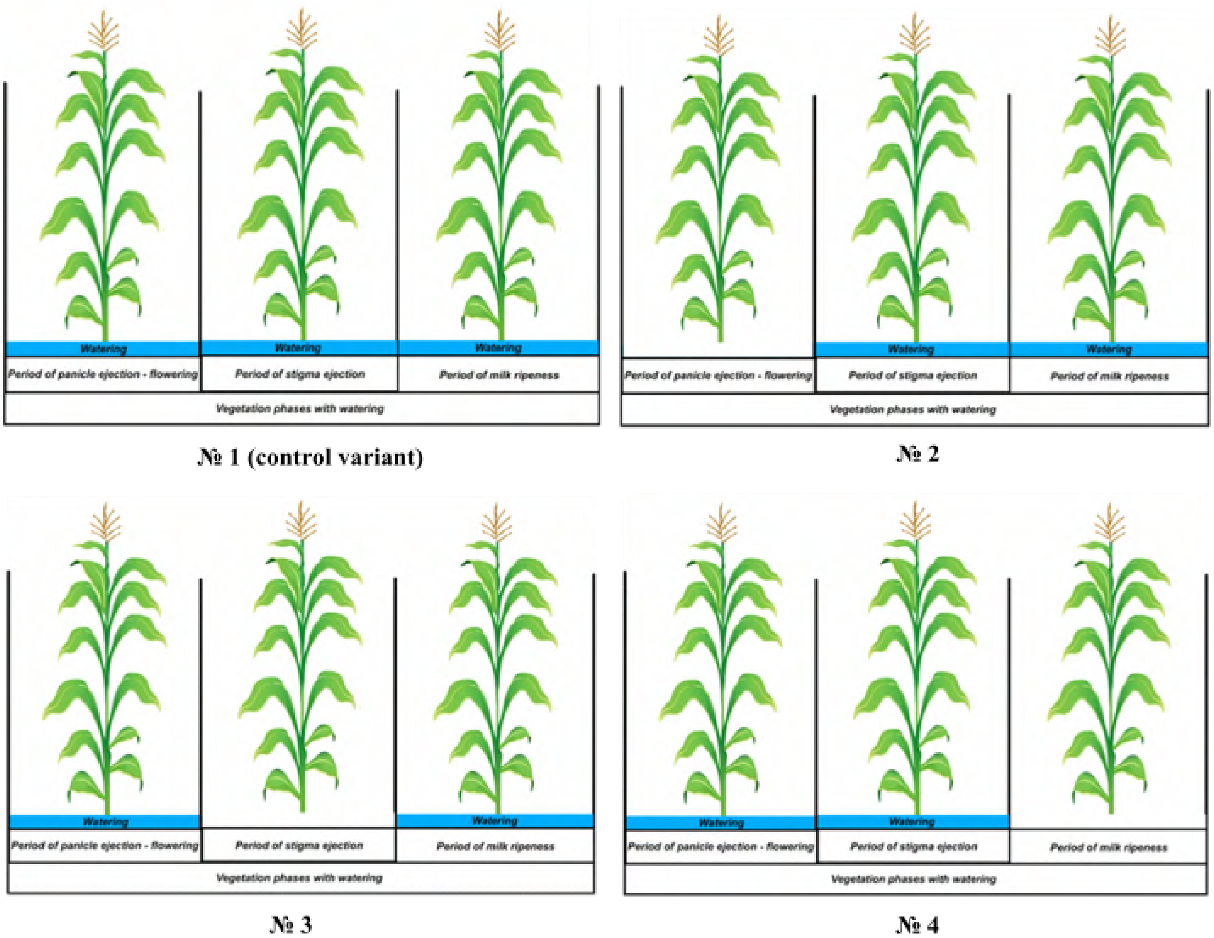

Figure 1. Scheme of options for research the impact of different irrigation regimes on corn yield [15]: № 1 (control variant) – variant with the full irrigation rate, irrigation was carried out during the periods of panicle ejection–flowering (I), stigma ejection (II) and milk ripeness (III); № 2 – irrigation regime with cancellation of watering during period I; № 3 – irrigation regime with cancellation of watering during period II; № 4 – irrigation regime cancellation of watering during period III.

Table 1 summarizes the results of research the impact of different irrigation regimes on corn yield. It shows the ratio of actual yield obtained according to the research options with cancellation of waterings to the yield according to control variant with three waterings. The obtained results are quite indicative: when the first watering is canceled, the ratio of actual yield to the control variant is 0.67; when the second watering is cancelled – 0.78; when the third watering is cancelled – 0.93.

Despite the fact that this research was carried out in the 70s of the last century, this area has not yet gained a sufficient level of study and development, due to the insufficient computer capabilities at that time and the lack of mathematical models capable of describing and reproducing the complex dynamic processes of crop yield formation and the effects of heterogeneous factors of influence. A similar approach was partially implemented in the studies

Table 1. Estimation the impact of different irrigation regimes on corn yield for the case of water shortage [15].

Research options	Vegetation phases with watering			Ratio of actual irrigation rate to control variant	Ratio of actual yield to control variant
	period of panicle ejection–flowering	period of stigma ejection	period of milk ripeness		
№ 1 (control variant)	I	II	III	1.0	1.0
№ 2	–	II	III	0.75	0.67
№ 3	I	–	III	0.75	0.78
№ 4	I	II	–	0.75	0.93

presented in [16, 17]. The results showed that meeting the crop water requirement during the reproductive stage is more important than during the vegetative stage of growing season.

Based on the software complex (computer program) [18] developed in the research laboratory "Optimization and automation of control in water engineering and water technologies" at the Department of Water Engineering and Water Technologies of the National University of Water and Environmental Engineering (Rivne, Ukraine), a machine experiment that actually reproduces the main idea of research described in [15] was conducted. The software complex used for **the machine experiment is based on a set of forecasting-simulation, economic-mathematical and optimisation methods and models**, including a model of climatic conditions, a model of water regime and water regulation technologies, as well as a model of crop yields on reclaimed land for long-term forecasting, the application of which is regulated by the relevant industry regulations of the State Agency of Water Resources of Ukraine.

Thus, the **aim of the research** is to assess the impact of reducing water and energy resources during irrigation on the productivity of cultivated crops in the conditions of increasing shortage of irrigation water due to climate change. The **object of research** is the process of the impact of cancelling crops watering at different periods of the growing season on their productivity.

3. Results and discussions

The purpose of the conducted machine experiment is a predictive-simulation reproducing of the idea of the experiment by Krafti and Kotov [15] for our conditions on the example of growing perennial grasses as a moisture-loving crop of crop rotation in the Kherson region. Using for machine experiment software complex [18] allows to further implement a predictive assessment of the impact of reducing water and energy resources during irrigation on the productivity of cultivated crops in the conditions of increasing shortage of irrigation water due to climate change, as an extremely serious problem of our time in irrigated agriculture. As the main options of research, a set of irrigation regimes that differ in the cancellation of waterings in different periods of the crop's vegetation (watering rate 400 $m^3 \cdot ha^{-1}$) are considered:

- № 1 (control variant) – irrigation regime with six waterings, irrigation rate 2400 $m^3 \cdot ha^{-1}$;
- № 2 – irrigation regime with cancellation of the first watering, irrigation rate 2000 $m^3 \cdot ha^{-1}$;
- № 3 – irrigation regime with cancellation of the second watering, irrigation rate 2000 $m^3 \cdot ha^{-1}$;

Table 2. Evaluation of technological efficiency of perennial grasses irrigation regimes in the conditions of Kherson region.

Research options	Vegetation period, decades													Irrigation rate, $m^3 \cdot ha^{-1}$	Actual yield, $kg \cdot ha^{-1}$	Ratio of actual yield to control variant

- № 7 – irrigation regime with cancellation of the sixth watering, irrigation rate 2000 $m^3 \cdot ha^{-1}$.

The summary results of the implemented machine experiment according to the above research

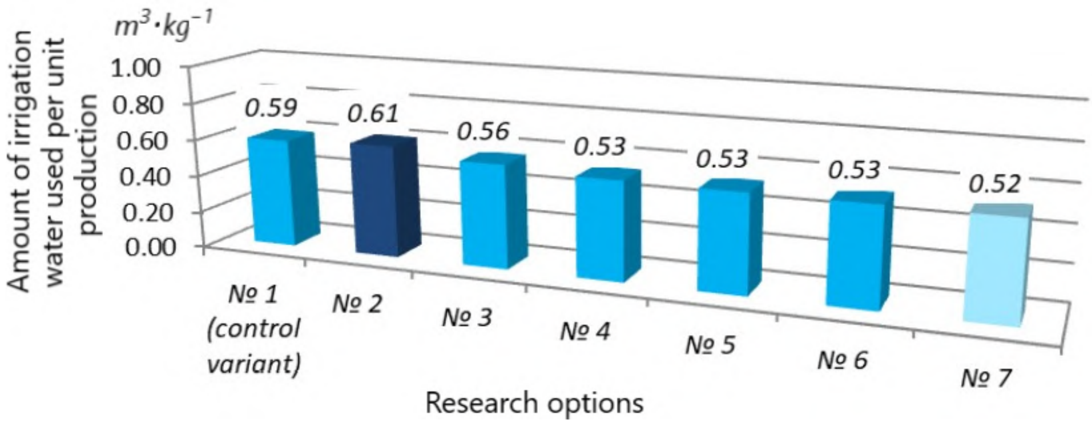

Figure 2. Amount of irrigation water used per unit of plant production of the cultivated crop, $m^3 \cdot kg^{-1}$: № 1 (control variant) – irrigation regime with six watering; № 2 – irrigation regime with cancellation of the first watering; № 3 – irrigation regime with cancellation of the second watering; № 4 – irrigation regime with cancellation of the third watering; № 5 – irrigation regime with cancellation of the fourth watering; № 6 – irrigation regime with cancellation of the fifth watering; № 7 – irrigation regime with cancellation of the sixth watering.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012051 doi:10.1088/1755-1315/1415/1/012051

options are presented in table 2.

These data (table 2) clearly show the nature of the impact of water resource consumption on crop yield in relation to the timing of watering. The impact of water shortages is particularly pronounced in the second half of the growing season, when crop yield losses are significantly lower than at the beginning of the growing season under similar conditions.

According to the obtained results for the research options, an indicator of the productivity of irrigation water use was defined as the amount of irrigation water consumed per unit of plant production (figure 2).

The obtained results and the availability of a set of optimization, economic, mathematical and forecasting-simulation models create prerequisites for optimization of crop irrigation regimes as a component of resource optimization, the basic principles and principles of implementation of which are considered in [19], and optimization of water and energy use of resources in general as a prerequisite for increasing the efficiency of irrigation and agricultural production in relation to modern changing conditions and requirements.

4. Conclusions

1. Modern conditions and requirements for conducting agricultural production make it necessary to change approaches to project decision-making in projects of construction, reconstruction and functioning, the purpose of which is to reduce the consumption of water and energy resources.
2. In order to achieve the goal of reducing the values of resources used for agricultural production, the improvement of irrigation techniques and crop irrigation regimes should be based on research on the dependence of these values on the yield of cultivated crops, namely, that in the same year, due to the unequal distribution of the same amount of irrigation water, significantly different yields can be obtained.
3. In order to research the influence of water consumption on the yield of a cultivated crop in relation to the timing of irrigation, a machine experiment was conducted using a set of optimization, economic, mathematical and forecasting-simulation models, including a model of climatic conditions, a model of water regime and water regulation technologies, as well as a model of crop yields on reclaimed land for long-term forecasting.
4. The machine experiment is based on the experimental data of Bulgarian researchers Krafti G. and Kotov L. concerning the effect of different irrigation regimes on the corn yield in the case of water shortage. Despite the fact that this research was carried out in the 70s of the last century, this area has not yet gained a sufficient level of study and development, due to the insufficient computer capabilities at that time and the lack of mathematical models capable of describing and reproducing the complex dynamic processes of crop yield formation and the effects of heterogeneous factors of influence.
5. The results of the machine experiment proved that the impact of water resource shortages is weakened in the second half of the growing season, when crop yield losses are significantly lower than at the beginning of the growing season under similar conditions. This fact provides prospects for optimization crop irrigation regimes as a component of resource optimization.
6. The obtained results and the availability of a set of optimization, economic, mathematical and forecasting-simulation models create prerequisites for improving crop irrigation regimes on the basis of resource optimization, which will ensure an increase in the economic and ecological efficiency of the functioning of irrigation systems in accordance with modern conditions and requirements and the efficiency of agricultural production on irrigated lands as a whole.

Abstract. In the modern conditions of the ecological crisis, the study of adaptive changes in xerophyte plants, which form natural and cultural phytocenoses, has important theoretical and practical significance. Steppe phytocenoses of the Zaporizhia region, especially the Melitopol city and the Melitopol district, are represented by xerophytic associations. The research aim was to find out the histological and physiological rearrangements of the organs of the genus *Elytrigia L.* to determine adaptation features at the tissue level to water and temperature stresses. The subject of the study was the study of the structural and functional features of plant organs of the genus *Elytrigia repens L.* during adaptation to environmental factors (on the example of the Zaporizhzhia region, in particular the Melitopol city). The theoretical and methodological basis of the work was the synergistic use of a systemic approach, which led to a transparent approach to the choice of research methods, in particular: general scientific (analysis, synthesis, systematization, generalization of literary sources); general biological (experimental method, quantitative-anatomical, physiological and system-structural analysis, methods of mathematical statistics. It was established that the adaptation of xerophytes of the genus *Elytrígia L.* to arid habitats is characterized by structural and functional rearrangements of vegetative organs, in particular, the presence of unicellular trichomes, which ensures a decrease in transpiration, an increase in the share of storage tissues in the leaf and conductive and mechanical elements in the stem, as well as a decrease in intensity photosynthesis under drought conditions. As a result of finding out the functional disturbances in the leaf under the influence of drought, in particular the intensity of photosynthesis and the specificity of the pigment composition of the experimental plant, it was proved that the experimental plants under normal conditions have a parabolic curve of photosynthesis, and under the influence of atmospheric drought these indicators have a hyperbolic shape, and the analysis of the results of daily of the dynamics of photosynthesis established that the most intense photosynthesis occurs in plants under normal conditions, and under the influence of drought in plants there is a decrease and inhibition of the process of photosynthesis.

1. Introduction

The climate aridization and the significant expansion of arid areas due to the global increase in temperature with a simultaneous decrease in precipitation and a decrease in soil moisture attracts the attention of many researchers. In such conditions, the study of adaptive changes in xerophyte plants, which form natural and cultural phytocenoses, has important theoretical and practical significance. The results of quantitative and anatomical researches can be used in systematics, histology and ecology of plants [1–4], as they allow establishing the main adaptive features characteristic of this particular group, which is important for establishing the paths of evolution of the plant world as a whole.

The Melitopol city is a multi-sector industrial center located on the right bank of the once navigable Molochnaya River, but currently, unfortunately, it is temporarily occupied. In 2021, the total area of green areas was 2.2 thousand hectares. About 70% of the city's territory is located on the watershed with average heights of 34-40 m, the rest – on the steep slope of the Molochna River valley. The territory of the city and district is located mainly within the Black Sea Lowland. Its surface is a flat lowland plain, descending from north to south, where it ends with a steep (up to 20 m high) ledge on the shore of the Azov Sea. In the northeast, spurs of the Azov Highlands with absolute height marks from 150 to 250 and more meters above sea level extend into the border [5].

The main feature of the city's climatic conditions is hot summers, moderately cold winters and insufficient humidity. The average monthly air temperature in July is +29°C. The duration of the summer period, when the average daily temperature exceeds +15°C, is 126-138 days. The average monthly temperature in January is -4°C. The absolute minimum reaches -30°C. The average annual amount of precipitation is 400 mm and varies from 350 to 450 mm [6–11].

The soil cover on the territory of the watershed part of the city is represented by sandy and sandy-medium loamy soils of the chernozem type, which are formed on an ancient terrace, on ancient alluvial deposits.

The characteristic xerophytes of the specified region are representatives of the specy *Elytrígia repens L.* – perennial herbaceous plants from the genus *Elytrígia L.*, which belongs to the Poaceae family and includes about 100 species.*Elytrígia L.* is one of the most common and harmful weeds in crops and plantations of cultivated plants, forest areas, and forest clearings. But at the same time *Elytrígia repens L.* acts as a useful medicinal, fodder and food plant. As a medicine, wheatgrass helps to get rid of many diseases not only for humans, but also for animals. On the territory of Ukraine, the most common *Elytrigia repens L.* The name of this plant speaks for itself – this herbaceous plant has a long creeping rhizome, which starts flowering at the end of April and until July, the fruits – grains ripen in July – September. *Elytrigia repens L.* is a medicinal plant, drugs from which are used for metabolic disorders, as a diuretic, diaphoretic, pain reliever, expectorant, and laxative that regulates salt metabolism. The unique ability of *Elytrigia repens L.* is to remove strontium-90 from the body thanks to tannin, which is contained in a sufficient amount; when with increased outflow of water from the body, slags are released, which is manifested primarily in the reduction of skin rashes, fatigue and the state of brokenness are relieved. At the same time, all components work together, both vitamins and minerals [12–16]. *Elytrigia repens L.* as a food plant; it helped people more than once in the most difficult times. *Elytrigia repens L.* rhizome is used for food. It is ground, flour is obtained, which is not inferior to wheat in terms of nutrition, and bread, cakes, gingerbread, and other flour products are baked [16–18]. Therefore, the study of structural and physiological features of representatives of the genus *Elytrigia repens L.* is becoming more and more relevant.

In this regard, the research aim was to find out the histological and functional rearrangements of the organs of the genus *Elytrigia L.* to determine adaptation features at the tissue level under the effects of water and temperature stresses.

The research subject of the study was the study of the structural and physiological features of *Elytrigia repens L.* plant organs during adaptation to environmental factors (on the example of the Zaporizhzhia region, in particular the Melitopol city).

The research object was *Elytrigia repens L.* plants of arid habitats of the Zaporizhzhia region. Systematic position is division Magnoliophyta; class Monocotyledons (*Liliopsida*); order *Poales*; family *Poaceae*; genus *Elytrigia*; specy *Elytrigia repens (L.) Gould*.

Botanical characteristics. Elytrigia repens (L.) Gould) – a perennial plant from the genus

Elytrigia L.; medicinal, fodder and food plant, which grows in areas with steppe vegetation, is found in the steppe regions of Ukraine. A herbaceous plant with a long creeping rhizome, which penetrates the soil in the first year of life by 75 cm, the second – by 195 cm, the third – by 250 cm. The main mass of rhizomes with buds that give rise to a new plant is located no deeper than 20 cm, and on compacted soils up to 8-10 cm. The fruit is a grain. The color is grayish-green. Size – length 6-10 mm, width – 1.25-1.75 cm, thickness 1-1.25 mm. The weight of 1000 grains is 3-4 g. It comes from grains and shoots of underground buds in March-May. It blooms in June-July, fruits in July-August. The stems are erect or ascending, cylindrical, green, with thickened nodes and hollow internodes. Leaves (3-10 mm wide) alternate, sessile, linear, flat, and smooth from below, rough from above, often with thin hairs along the veins. The vagina is bare, smooth, the tongue is short. Inflorescence is an upright complex spike (up to 15 cm long). Spikelets (10-18 mm long) are multi-flowered, lanceolate, sitting on the protrusions of the spike axis. Spike scales (6-12 mm long) are lanceolate, sharp with five to seven veins, smooth or rough. The lower flower scale (7-10 mm long) is lanceolate, glabrous, blunt at the top, pointed or with a short spine. Stamen is three, pistil – one and ovary upper with two pinnate receptacles.

Biological features: maximum fertility – 19 thousand grains. The depth of germination in the freshly reached state – they germinate from a depth of no more than 7-10 cm. Segments of rhizomes 5-15 cm long form shoots from a depth of up to 25 cm. Viability in the soil – more than 5 years.

Environmental requirements: germination temperature – minimum: +2..+4°C and optimal: +20...+30°C. Terrestrial organs are damaged at a temperature of -10...-12°C [19, 20]. *Elytrigia repens L.* grows on wastelands, deposits, forest clearings, along forest edges, near roads, in meadows, arable land, and gardens. It is difficult to eradicate it due to its long, creeping and knotty rhizome, and if you leave pieces of the roots of this plant in the ground, they do not die and give new shoots. But wheatgrass rhizomes dry out quickly outside the soil. This plant also exists well in fields and pastures, including on saline and limestone soils, near roads, houses, throughout the territory of Ukraine [5, 21].

Practical use: in traditional medicine, rhizomes are used for diseases of the respiratory tract and kidneys, as a blood purifier, for nocturnal urinary incontinence, for partial loss of vision, for pulmonary tuberculosis, jaundice, menstrual cycle disorders, rheumatism, for venereal diseases, dropsy, and urinary stones. and bile ducts, rickets, boils, inflammation of the bladder and hemorrhoids; in homeopathy; in animal husbandry – a valuable fodder plant: meadow and fallow hay, mowed before flowering, is characterized by high nutritional properties. On pastures, wheatgrass is eaten by all types of livestock, it is considered a milk-producing agent for cows [7–10]. In the flowering phase, it contains 9% protein, 2.7% fat, 31% fiber, and 47% nitrogen-free extractives. Hay yield on fallow ranges from 6 to 15 t/ha, on flooded meadows – 20-60 t/ha [22, 23]. *Elytrigia repens L.* rhizomes contain polysaccharide tricytin, gum, mucilage, malic and other acids, essential oil, carotene, vitamin C, starch. Ground rhizomes are used to make flour, which can be used to prepare drinks, including beer.

2. Methodology

The theoretical and methodological basis of the work was the synergistic use of a systemic approach, which led to a transparent approach to the choice of research methods, in particular: general scientific (analysis, synthesis, systematization, generalization of literary sources); general biological (experimental method, quantitative-anatomical (using the methods of Pausheva, Baranova, Zakharevich), physiological (Kazakov) [24] and system-structural analysis [18, 25]; methods of mathematical statistics. Statistical analysis of the obtained data was carried out using the general data processing software package Statistica version 10.0. Arithmetic mean (M) and standard error of the mean (SEM) were calculated to compare the samples. A difference of p $\leq$0.05 was considered statistically significant for all indicators. Quantitative and anatomical studies were carried out on material from normally developed plants, collected in the city of Melitopol, Zaporizhzhia region (repetition 3 times).

3. Results

Steppe phytocenoses of Zaporizhzhya region, especially Melitopol and Melitopol district, are represented by xerophytic associations. These are mostly herbaceous plants, which, depending on the degree of dryness of the area, are divided into main groups: succulents, euxerophytes, hemixerophytes, poikiloxerophytes, and ephemera. The main indicators of adaptation to the conditions of minimum water supply are as follows:

1) a reduced, and sometimes completely reduced leaf blade or leaves fall during the greatest drought;
2) the leaves and stem are covered with an epidermis with a well-developed cuticle, leathery, often with a hairy covering or a wax coating;
3) the cells of the epidermis and mesophyll are small in size, and in connection with this, there is a greater number of them per unit surface, including a greater number of stomata;
4) significant development of conductive and mechanical elements, and in connection with this, a large density of veins on the leaves;
5) high concentration of cell juice.

The epidermis study of the *Elytrígia répens L.* leaf according to the Zacharevich method in terms of outlines, projection, and dimensions allowed us to identify the following types of basic cells: type I – cell outlines are tortuous, the projection is rectangular-elongated, the corners are rounded, obtuse, the number per unit area is 125-130 units/cm^2, the short axis is 21.25 μm, the long axis is 38.75 μm, S cell is 823.44 μm^2; II type – outlines of cells are rectilinear and strongly sinuous, the projection is flattened, the corners are sharp, rounded, the number per unit area is 135-140 pcs/cm^2, the short axis is 18.75 μm, the long axis is 41.25 μm, S cells – 773.44 μm^2; type III – cell contours are sharply tortuous, the cell projection is square, the number per unit area is 115-120 pcs/cm^2, the short axis is 21.25 μm, the long axis is 45 μm, cells plane is equal to 956.25 μm^2.

Stomatal complexes on the leaf adaxial side are absent, but on the abaxial side, it is clearly expressed, of the anomocytic type, their number per unit area is 245-250 pcs/mm^2. The height of the cells of the upper epidermis is 41-45 microns. On the upper epidermis, the size of the main cells in comparison with the lower side is 2-3 μm larger, their number decreases: type I – 115-120 pcs/cm^2; II type – 120-125 pcs/cm^2; III type – 110-115 pcs/mm^2.

Endo-structural analysis of the structure of the *Elytrígia répens L.* leaf proved that the leaf is covered with simple, unicellular trichomes. The leaf mesophyll has an isolateral structure and consists of 5-7 layers of palisade-type cells. The length of the cells exceeds the width by 2-2.5 times. The cells of the palisade tissue are closely adjacent to each other; the intercellular spaces are almost invisible. The conducting bundles are collateral, located in the middle layers of the leaf plate. The bundles are surrounded by small, thin-walled parenchymal cells that make up the covering of the conducting bundle. Visual ratio of *Elytrígia répens L.* leaf tissues is shown in figure 1.

Thus, the structural analysis of the primary covering tissue and the internal structure of the *Elytrígia répens L.* leaf showed that the leaf is covered with simple, unicellular hairs; the epidermis is formed by the main cells of three types, which differ from each other in terms of outline, projection, angles, dimensions and quantity per unit surface, whereby the upper epidermis of the leaf makes up 4.53% of the total thickness, the lower epidermis – 3.83%; stomatal complexes of the anomocytic type, their number is 245-250 pcs/cm^2, the location is only on the

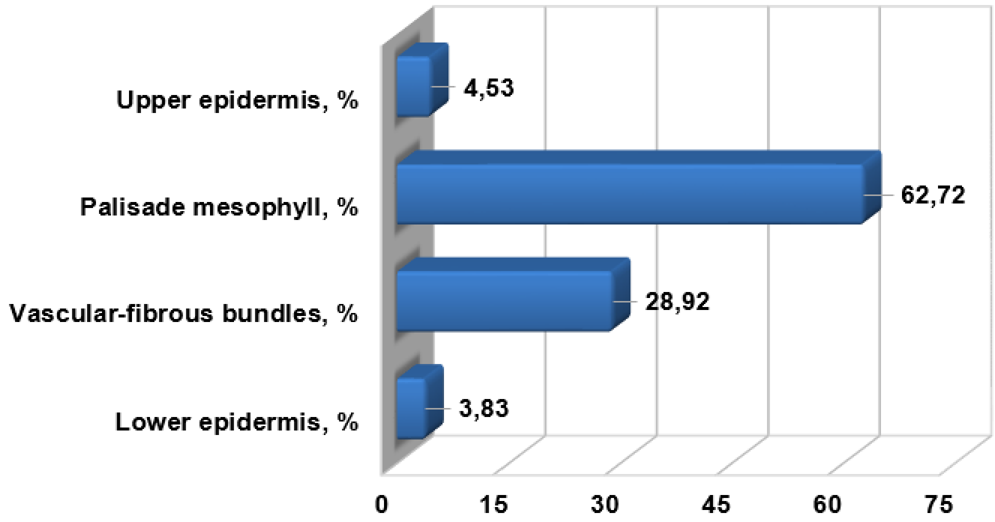

Figure 1. Histological and structural characteristics of *Elytrígia répens L.* leaf (p $\leq$0.05).

lower side of the leaf, i.e. the leaf is hypostomatic. The mesophyll has an isolateral structure, the conductive bundles are collateral, located in the middle layers of the leaf plate, the mesophyll is 62.72% of the total thickness, and the conductive bundle is 28.92%.

The study of the *Elytrígia répens L.* stem in three parts: under the inflorescence, in the middle part and the bottom showed that it has a mixed type of structure and consists of the primary bark, which includes the epidermis, and then two or three layers of angular collenchyma and parenchyma of the bark are placed. It is represented by elongated cells with thin membranes. Cambium is presented in the form of one or two layers of cells, located between the bark and the wood. The xylem in its composition has tracheae of three orders, which are placed in rows, between them are libriform cells. Large vessels are located closer to the phloem. The core consists of multi-angular cells with thin membranes.

The quantitative characteristics analysis of the *Elytrígia répens L.* stem shows that the primary bark occupies from 24 to 27% of the total thickness of the organ in the stem, the bark has the smallest value under the inflorescence, but its size gradually increases due to the growth of the parenchyma of the bark. The cambium layer occupies about 0.14% and throughout the stem, its dimensions almost do not change. The size of the xylem increases when moving from the upper to the lower part of the stem, its part accounts for 17-22%. The core occupies 57% in the upper part, 55% in the middle and 49% in the lower part of the stem (figure 2).

So, our research showed that the *Elytrígia répens L.* stem has a mixed type of structure, consisting of the primary cortex, which is 26.3%, interbundle and bundle cambium – 0.12%, xylem represented by tracheae of three orders – 19.31% and the core, which occupies 54.28% of the total thickness of the stem (figure 3).

Violation of the physiological functions of plants in drought conditions is the first reaction-response of the body to water deficit. Changes in the microstructure appear, as a rule, as a result of functional disorders. According to the degree of sensitivity to phytotoxicants, individual functions of plants can be arranged in the following order in descending order: photosynthesis, respiration, biosynthesis of secondary substances, transpiration, growth and development. The specified sequence is conditional, since the initiated changes of one function entail disturbances in others [13–16]. Carbohydrates are a product of photosynthetic energy storage, serve as a substrate and source of energy for further biosynthetic processes. Violations of the photosynthetic and respiratory functions of plants invariably affect the quantitative content and relatively different forms of carbohydrates.

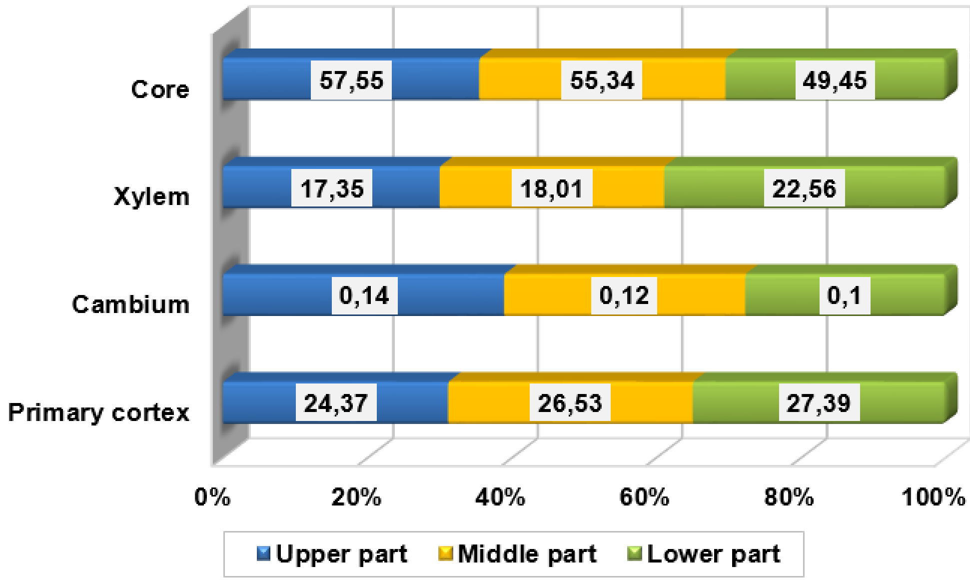

Figure 2. Quantitative and histological characteristics of the *Elytrígia répens L.* stem (in three parts) (p ≤0.05).

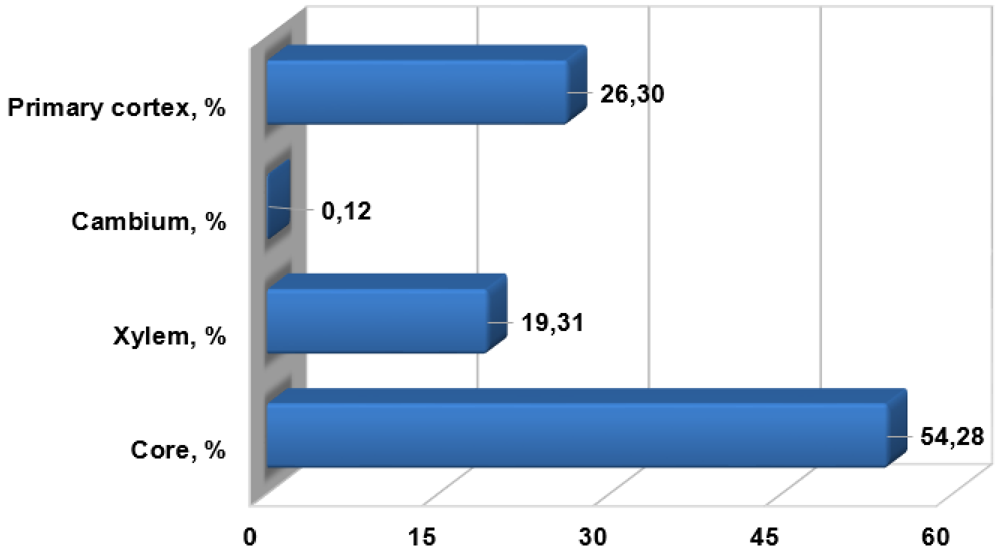

Figure 3. Tissues generalized ratio of a mixed type of *Elytrígia répens L.* stem (p ≤0.05).

Our studies have shown that the daily dynamics of photosynthesis in the studied plants under normal conditions of moisture has a parabola-like shape: with the lowest indicators at 12-1 p.m. of the day, the biggest ones – at 5-6 p.m. days the difference between them is 25% (figure 4).

The photosynthesis daily dynamics of experimental plants under the influence of drought has a hyperbolic shape, with the highest indicators at 9-10 a.m. days, which gradually decrease to 5-6 p.m. The difference between them is 66% (figure 5).

So, the experimental data showed that mainly experimental plants under normal conditions have a parabolic curve of photosynthesis, and under the influence of atmospheric drought these indicators have a hyperbolic shape. Thus, the analysis of the results of the photosynthesis daily dynamics established that the most intensive photosynthesis occurs in plants under normal

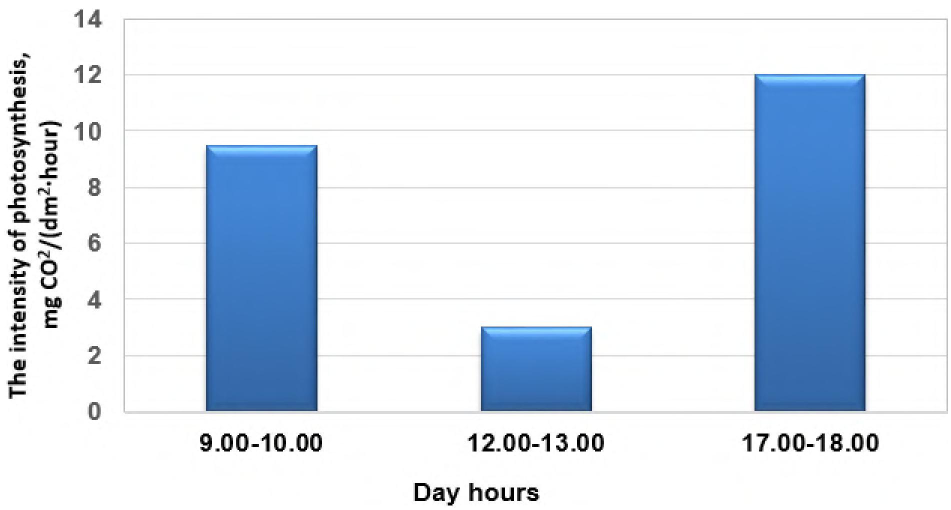

Figure 4. Photosynthesis daily dynamics of plant *Elytrígia répens L.* under normal conditions ($p \leq 0.05$).

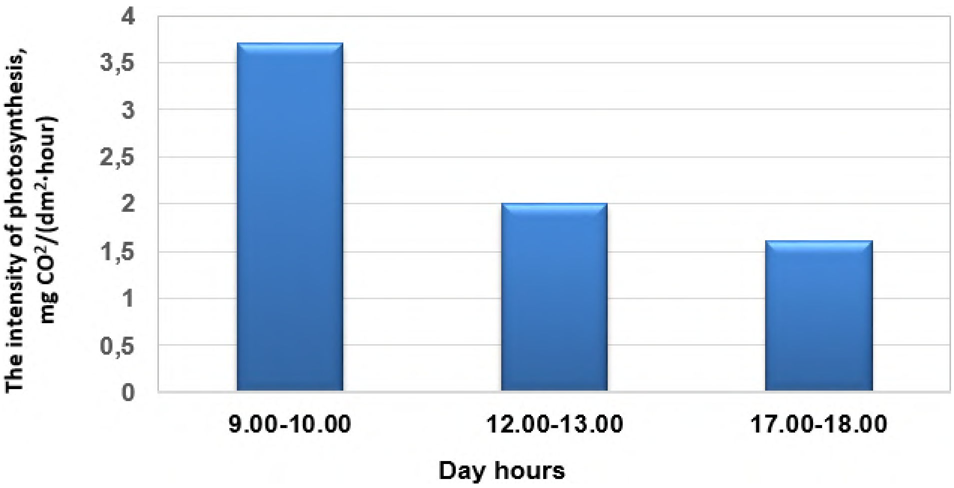

Figure 5. Photosynthesis daily dynamics of experimental plants under the droughts influence ($p \leq 0.05$).

conditions, and under the influence of drought, a decrease in the photosynthesis process is observed in plants.

4. Conclusions

The reseaches of the structural and functional characteristics of *Elytrígia repens L* plants allows us to draw the following conclusions:

1) the study of morpho-anatomical indicators of plant Elytrígia répens L. organs showed that:
   - the *Elytrígia répens L.* leaf is covered with simple, unicellular hairs; the epidermis is formed by the main cells of three types, which differ from each other in outline, projection, angles, sizes and quantity per surface unit, with the upper epidermis of the leaf accounting for 4.53% of the total thickness, the lower epidermis for 3.83%; stomatal complexes of the anomocytic type, their number is 245-250 pcs/cm^2, they are located

only on the lower side of the leaf, i.e. the leaf is hypostomatic, the mesophyll has an isolateral structure, the conducting bundles are collateral, located in the middle layers of the leaf plate, the mesophyll is 62.72% of the total thickness, and the leading beam – 28.92%;

- the *Elytrígia répens L.* stem has a mixed type of structure, consisting of primary bark, which is 26.3%, between bundle and bundle cambium – 0.12%, xylem, represented by tracheae of three orders – 19.31%, and core, which occupies 54.28% of the total thickness of the stem;

2) elucidation of functional disorders in the leaf under the influence of drought, in particular the intensity of photosynthesis and the specificity of the pigment composition of the experimental plant proved that mainly experimental plants under normal conditions have a parabolic curve of photosynthesis, and under the influence of atmospheric drought these indicators have a hyperbolic form, and the analysis of the results of daily dynamics of photosynthesis established that the most intense photosynthesis occurs in plants under normal conditions, and under the influence of drought, a decrease in the photosynthesis process is observed in plants.

In general, we proved that the adaptation of xerophytes of the genus *Elytrígia L.* to arid habitats is characterized by the presence of unicellular trichomes, which ensures a decrease in transpiration, an increase in the share of storage tissues in the leaf and conducting and mechanical elements in the stem, as well as a decrease in the intensity of photosynthesis under drought conditions.The obtained results form a holistic view of the structural and physiological content of the vegetative organs of xerophytic weed plants, which contributes to the development of effective means of control and effective use in the interests of humans.

Abstract. Cultivation of energy crops becomes relevant in areas with a high climatic potential for biomass accumulation. Many studies have established the effectiveness of applying sewage sludge on various types of soil, including under miscanthus and increasing biomass collection of various doses of its application. Field experiments were conducted in the West of our country, namely in the territory of the Ivano-Frankivsk Region, Tsenzhiv Yamnytska united territorial community. Application of growing fertilizers based on compost ($SS-40$ t/ha $+N_{10}P_{14}K_{58}$ and Compost (SS + $straw(3:1))-20$ t/ha $+N_{50}P_{16}K_{67}$) ensures the highest yield of dry biomass of miscanthus (29.8 *and* 27.3 t/ha), as well as the output of gross energy ($547-578$ GJ/ha), which led to an increase in the energy efficiency coefficient from 3.3 to 4.1. Such a relationship describes the regression equation of the linear regression with the coefficients of determination ($R^2 = 0.73$).

1. Introduction

Cultivation of energy crops is gaining relevance in areas with high climatic potential for biomass accumulation [1, 2]. In Ukraine, in order to diversify the supply of energy and increase the share of renewable sources in the state's energy balance, the cultivation of bioenergy crops, in particular miscanthus, is becoming widespread, which is characterized by a number of positive characteristics, one of which is a high level of accumulation of dry mass, which can easily be processed into first and second generation fuel [3, 4].

As a rule, low-productive degraded areas marked by a low level of effective fertility are set aside for planting energy crops, including miscanthus [5–7]. Therefore, it is important to establish effective methods of growing miscanthus with the introduction of various fertilizers. One of the effective sources of replenishment of organic matter in the soil and elements of mineral nutrition is the sewage sludge of the municipal economy, which is characterized by an increased content of nutrients [8, 9].

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012053 doi:10.1088/1755-1315/1415/1/012053

Many studies have established the effectiveness of applying sewage sludge on various types of soil, including under miscanthus, and increasing the biomass collection of various doses of its application [10–12]. However, the issue of bioenergetics of using sewage sludge for miscanthus is insufficiently studied, which led to the implementation of our research.

2. Literature analysis and problem statement

Miscanthus, also known as "silver cane", is an annual herb that is used as an energy crop. It has gained popularity due to its high productivity and the possibility of use as a renewable source of bioenergy. Miscanthus can achieve high yields per hectare, making it an efficient choice for bioenergy production [4, 6, 10].

This plant is characterized by high resistance to various climatic conditions and requires little care, including minimal soil requirements.

Miscanthus has a positive impact on the environment, able to absorb carbon dioxide during its growth, which reduces greenhouse gas emissions.

In addition to the production of bioenergy, miscanthus can be used for the production of paper, bioplastics, and even as a material for construction [9, 13].

With low growing and maintenance costs, miscanthus is an economically viable crop for farmers. Miscanthus can help improve soil structure and prevent erosion.

One planting can produce crops for 15-20 years without the need for annual transplants. Miscanthus can be converted into various forms of energy, including bioethanol, biodiesel and solid fuels [7, 12].

Overall, miscanthus is considered a promising crop for bioenergy production, which can help reduce fossil fuel dependence and promote sustainable development.

The energy efficiency of miscanthus as an energy crop is quite high, making it an attractive choice for bioenergy production.

Miscanthus is characterized by high productivity, the ability to produce significant amounts of biomass per unit area, exceeding many other crops, requiring relatively little energy to grow, harvest and process compared to the energy that can be obtained from its biomass. This makes it energy efficient. The energy crop has low agronomic requirements, in particular the minimal need for fertilizers and pesticides after the establishment of the field, which reduces energy costs for its maintenance. In our research, we used sewage sludge. Miscanthus can be processed into various fuels, including solid biofuels (pellets, briquettes), bioethanol and other biofuel products. In addition to bioenergy production, miscanthus can be used to create bioproducts, which further increases its energy efficiency [10, 11, 14].

Overall, miscanthus is considered one of the most energy-efficient bioenergy crops due to its high yield, low cultivation and maintenance costs, and ability to convert into various forms of energy.

Applying sewage sludge to miscanthus can be agronomically and ecologically beneficial, but it also requires careful consideration and control. Sewage sludge, sometimes called biosludge, can be rich in organic matter and nutrients that are beneficial to plant growth, including miscanthus. However, there are certain aspects to consider [15].

Sewage sludge often contains nitrogen, phosphorus and other trace elements that can promote miscanthus growth. This can help reduce the need for commercial fertilizers.

Adding sediment can improve soil structure, increasing its organic content and helping to retain moisture. It is important to consider the possible content of harmful substances in biosludge, such as heavy metals, pathogens or residues of pharmaceuticals. These substances can be harmful to the environment and human health [3, 16, 17].

Regular soil and plant monitoring may be necessary to ensure that nutrient and potentially harmful constituents are within safe limits.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012053 doi:10.1088/1755-1315/1415/1/012053

3. Purpose and objectives of the study

The use of sewage sludge in agriculture is often regulated by legislation that requires compliance with certain treatment and application standards and procedures. The task of our research is to treat sewage sludge before its introduction to reduce the risk of contamination and ensure its safe use. The purpose of our study is the effect of sewage sludge on miscanthus yield, it can help determine the optimal levels of its application and provide recommendations for the practical use of an energy crop with high energy value with the introduction of a certain dose of fertilizer.

Using sewage sludge as fertilizer for miscanthus can be an effective way to recycle organic waste.

4. Research methods

Field experiments were conducted in the West of our country, namely in the territory of the Ivano-Frankivsk region, village Tsenzhiv Yamnytska Yamnytska united territorial community (figure 1).

Figure 1. The area where field research was carried out.

The scheme of field experiments included the following options (figure 2):

1. Without fertilizers – control;
2. $N_{60}P_{60}K_{60}$;
3. $N_{90}P_{90}K_{90}$;
4. $SS - 20$ t/ha $+ N_{50}P_{52}K_{74}$;
5. $SS - 30$ t/ha $+ N_{30}P_{33}K_{66}$;
6. $SS - 40$ t/ha $+ N_{10}P_{14}K_{58}$;
7. Compost $(SS + straw(3:1)) - 20$ t/ha $+ N_{50}P_{16}K_{67}$;
8. Compost $(SS + straw(3:1)) - 30$ t/ha $+ N_{30}K_{55}$ [6].

Figure 2. Cultivation of miscanthus.

Planting scheme of giant miscanthus – 0.50 x 0.70 m. Planting of rhizomes was carried out by hand, wrapping them in the soil to a depth of 10 – 15 cm. Width of the experimental plot – 5.0 m; length – 7 m. The total area of the experimental site – 63.0 m^2, the accounting area – 35.0 m^2. The number of rows is 10. The number of rhizomes in a row is 10 pcs. [9].

The research results were processed using the methods of mathematical statistics using the programs STATISTICA 12 for Windows, MathCAD 15 and MS Excel 2010. Primary materials included analysis using linear regression equations [9].

In our studies, the efficiency of miscanthus cultivation was determined as the ratio of the gross energy accumulated by the crop to the energy costs for the production of biomass per unit area:

$$Kee = Ei/Ec$$

Kee is the coefficient of energy and efficiency of growing phytoenergy crops. Reflects how efficiently miscanthus plants are grown for energy production. It takes into account the different stages of growing, harvesting and processing biomass. Ei is the energy intensity of the biomass of the grown crop, MJ/ha. Ec – energy costs for growing miscanthus, also measured in MJ/ha. This value describes the energy used to grow crops, including all processes from soil preparation to harvest [6].

The amount of gross energy:

$$GE = Y \cdot Kc \cdot q_{pr}$$

It was used to assess the energy efficiency of growing phytoenergy crops and increase the efficiency of biomass production processes for energy needs.

5. Research results

Miscanthus (Miscanthus x giganteus) is a perennial crop that is grown in America and Western Europe as one of the sources for the production of solid biofuel.

Due to the high yield of dry biomass (up to 25 t/ha), high calorific value (5 $kW/h/kg$ or 18 MJ/kg), low natural humidity of the stems at the time of harvesting (up to 25%), miscanthus is the most effective, compared to others agricultural crops.

The conducted studies show that the biomass of miscanthus grows proportionately during the growing season, starting from May and ending in September.

Accordingly, every year the collection of miscanthus biomass increased and the energy output increased with the harvest. After 4 years of cultivation, the biomass collection was high, therefore, in the control without fertilizers, the energy output was 186 GJ/ha, with the application of mineral fertilizers in a dose of 60-90, the energy output was 193-200 GJ/ha, respectively. In particular, with the application of fresh sewage sludge in combination with mineral fertilizers, the energy output increased and was the highest in the version where SS was applied at a dose of 40 t/ha and mineral fertilizers $N_{10}P_{14}K_{58} - 231$ GJ/ha.

Composting reduced energy output compared to options where fresh sewage sludge was applied, but remained higher compared to the no-fertilizer control. Therefore, the energy yield of miscanthus was the lowest in the control without fertilizers (figure 3).

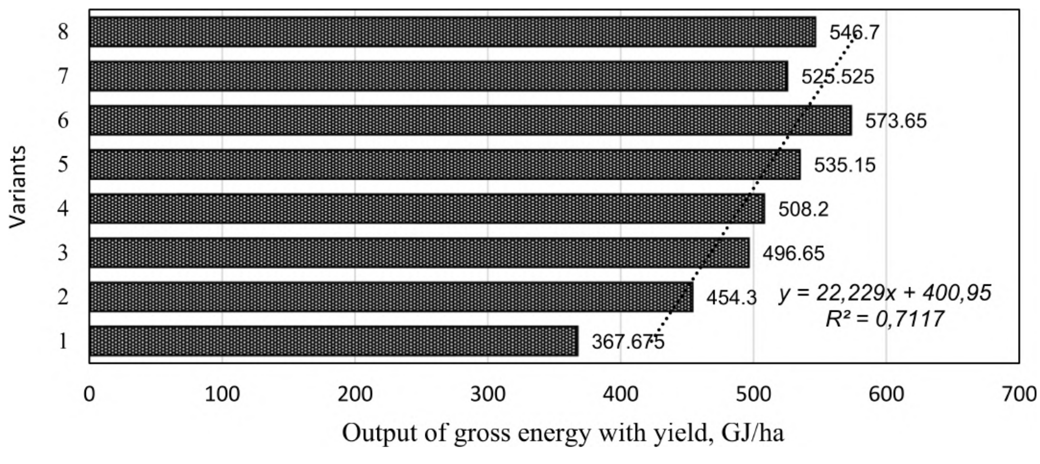

Figure 3. General view of the rod magnetic flaw detector in working condition.

Analyzing the economic efficiency of the production of miscanthus biomass table 1, it should be noted that it is quite profitable at 3805 UAH/ha and profitable at 58.05% at the same time at a low cost of 529 UAH/t, which involves planting the crop on sod-podzolic soils with the application of fertilizer based on SS in a dose of 40 t/ha and mineral fertilizers $N_{10}P_{14}K_{58}$.

Table 1. Output of energy and solid biofuel from obtained miscanthus biomass, average 2020-2022.

Variants	Yield of dry biomass, t/ha	Yield of solid biofuel, t/ha	Output of gross energy with yield, GJ/ha
Control – without fertilizers	19.1	21.01	367.67
$N_{60}P_{60}K_{60}$	23.6	25.96	454.34
$N_{90}P_{90}K_{90}$	25.8	28.38	496.65
SS–20t/ha + $N_{50}P_{52}K_{74}$	26.4	29.04	508.24
SS–30t/ha + $N_{30}P_{33}K_{66}$	27.8	30.58	535.15
SS–40t/ha + $N_{10}P_{14}K_{58}$	29.8	32.78	573.65
Compost(SS + straw(3:1))–20t/ha + $N_{50}P_{16}K_{67}$	27.3	30.03	525.52
Compost(SS + straw(3:1))–30t/ha + $N_{30}P_{55}$	28.4	31.24	546.76

The energy yield decreased with the application of composts compared to the options where fresh SS was applied, but remained higher compared to the no-fertilizer control. Therefore, the energy yield of miscanthus was the lowest in the control without fertilizers.

The Shapiro-Wilk test is equal to 0.97. According to the obtained results, with a probability of 97 percent, the distribution is normal.

At the same time, the p-level in this analysis is greater than 0.05 – (namely, 0.81) – the null hypothesis about the absence of a normal distribution of data can be rejected. The Kolmogorov-Smirnov clarifying (control) criterion confirms the assumption about the normality of the distribution – the p-level of this criterion is greater than 0.2 (figure 4).

Since the options for the introduction of SS directly affected the change in gross energy output with the yield of giant miscanthus, the regression model of gross energy output can be described by the following equation:

$$y = 22.229x + 400.95,$$

where y is the output of gross energy with yield, GJ/ha; x – rules for introduction of SS.

The multiple coefficient of determination was $R^2 = 0.7117$, which indicates a close relationship between the application rates of SS and gross energy output with the yield of giant miscanthus.

6. Discussion of the results

A comparative analysis of the table shows that the application of fertilizers significantly affects the production of dry biomass of miscanthus. The option without fertilizers gives the lowest biomass yield, 19.1 t/ha. The use of mineral fertilizers ($N_{60}P_{60}K_{60}$ and $N_{90}P_{90}K_{90}$) improves this indicator to 23.6 and 25.8 t/ha, respectively. The combination of SS with mineral fertilizers further increases the yield of biomass, reaching a maximum value of 29.8 t/ha at the highest application dose of SS. Variants with compost also show high results, emphasizing the efficiency of using organic waste for growing miscanthus on sod-podzolic soils.

Analysis of dry biomass yield indicators for each research option demonstrates that fertilizer application increases biomass production. Variants with mineral fertilizers ($N_{60}P_{60}K_{60}$ and

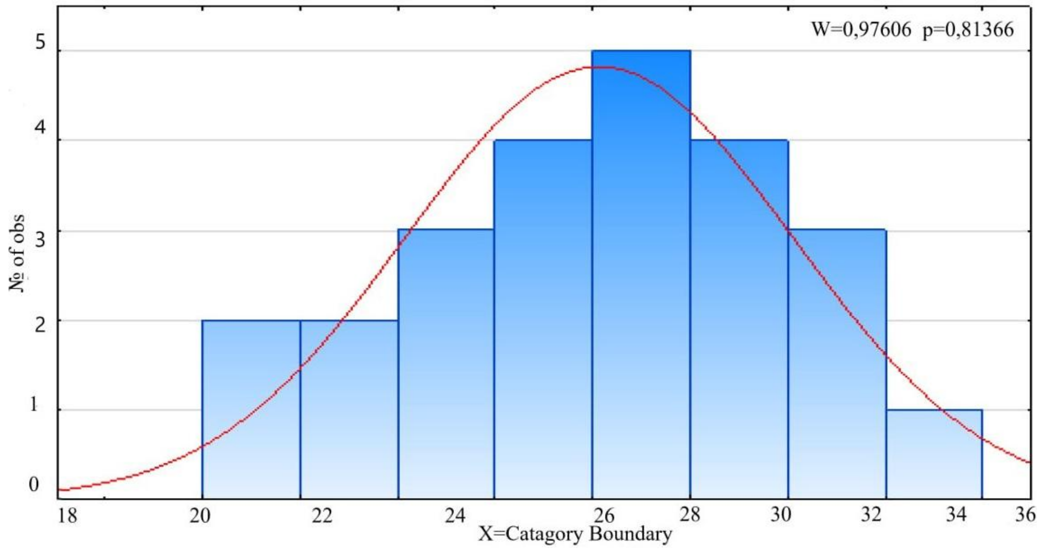

Figure 4. Normal distribution of solid biofuel yield data for miscanthus cultivation.

$N_{90}P_{90}K_{90}$) show moderate growth compared to the unfertilized control. The application of SS further increases biomass yield, with a significant increase in the use of SS doses. Compost combining SS and straw also has an effective effect on biomass production, highlighting the usefulness of integrating organic waste for growing energy crops using the example of miscanthus.

A detailed comparative analysis of the yield of solid biofuel from miscanthus shows that the application of fertilizers contributes to an increase in the yield of dry mass. Without fertilizers, 21.01 t/ha of biofuel is produced. With mineral fertilizers ($N_{60}P_{60}K_{60}$), the yield increases to 25.96 t/ha, and with more mineral fertilizers to 90 t/ha ($N_{90}P_{90}K_{90}$), the yield of solid biofuel is 28.38 t/ha. Variants with SS show even more growth, especially at high doses (SS – 40 t/ha), reaching 32.78 t/ha. Composting with SS also improves yield, from 30.03 t/ha to 31.24 t/ha, depending on the amount of compost and fertilizer.

The relationship between dry biomass output and gross energy of miscanthus can be expressed in the form of a linear regression model as follows:

$$y = 18.2909 + 0.0184x,$$

where y is the content of dry biomass, t/ha; x – gross energy output, GJ/ha.

The study of the relationship between the output of gross energy and the content of dry mass of miscanthus (figure 5) indicates the value of the coefficient of determination ($R^2 = 0.59$). The correlation coefficient $R = 0.71$ indicates a moderately strong positive correlation.

It was established that the coefficient of energy efficiency depends on the yield of dry biomass of miscanthus and the yield of gross energy (figure 6).

Such correlation dependence can be expressed by the regression equation:

$$z = 22.8094 - 1.6169 \cdot x + 0.0099 \cdot y + 0.0224 \cdot x \cdot x + 0.0007 \cdot x \cdot y - 2.7132E - 5 \cdot y \cdot y,$$

where z is the energy efficiency coefficient; x – yield of dry biomass, t/ha; y – gross energy output, GJ/ha.

Taking this into account, it can be argued that the application of SS with a compensatory dose of mineral fertilizers is an extremely effective way of increasing the biomass of energy crops, for example miscanthus.

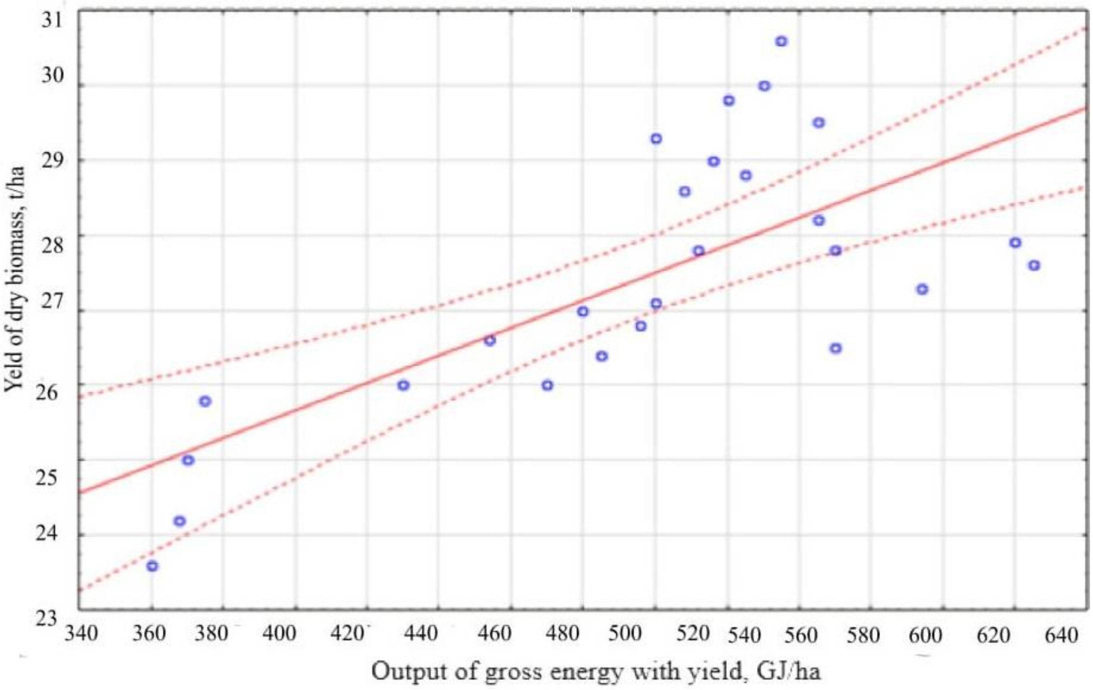

Figure 5. Dependence of the output of gross energy on the output of dry mass of miscanthus.

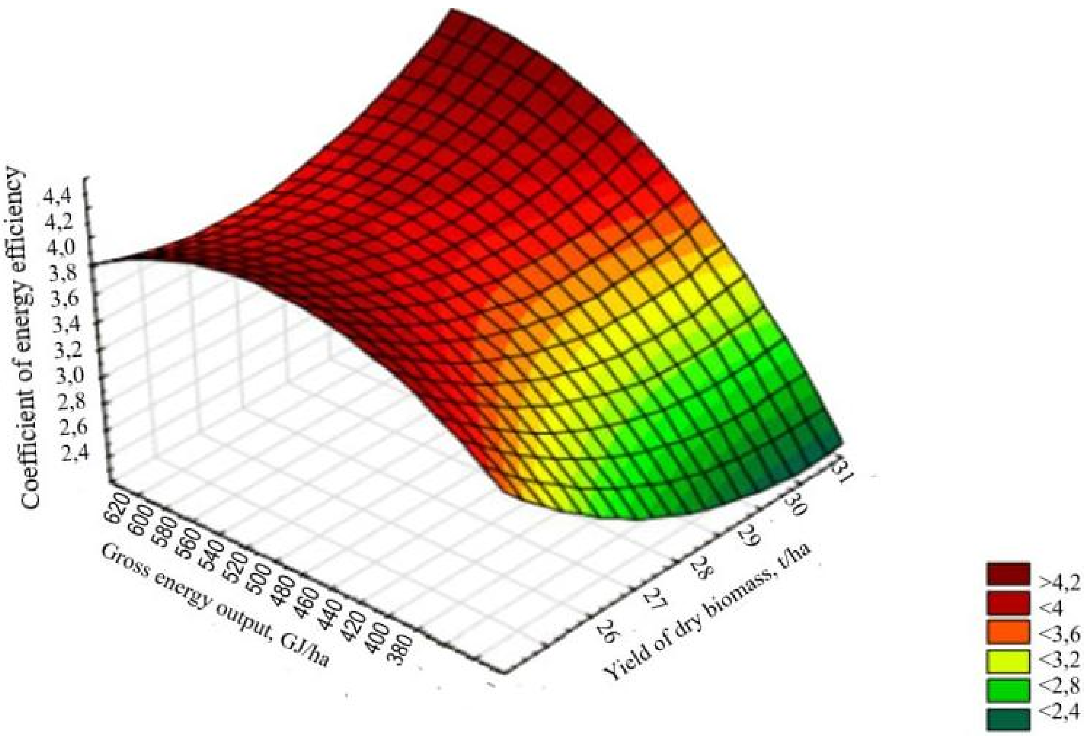

Figure 6. Dependence of the energy efficiency coefficient on the yield of dry biomass of miscanthus and the yield of gross energy.

7. Conclusions

Thus, according to our research, the application of sewage sludge for the cultivation of energy crops, using the example of miscanthus, increases the yield (yield of dry mass) from 19.1 t/ha to 28 – 30 t/ha, depending on the application rates of SS and composts based on SS.

A detailed comparative analysis of the yield of solid biofuel from miscanthus shows that the application of fertilizers contributes to an increase in the yield of dry mass. Without fertilizers, 21.01 t/ha of biofuel is produced. With mineral fertilizers ($N_{60}P_{60}K_{60}$), the yield increases to 25.96 t/ha, and with more mineral fertilizers to 90 t/ha ($N_{90}P_{90}K_{90}$), the yield of solid biofuel is 28.38 t/ha. Variants with SS show even more growth, especially at high doses (SS – 40 t/ha), reaching 32.78 t/ha. Composting with SS also improves yield, from 30.03 t/ha to 31.24 t/ha, depending on the amount of compost and fertilizer.

It is advisable to pay attention to the increase of the energy efficiency coefficient with the application ($SS-40$ t/ha $+N_{10}P_{14}K_{58}$ and Compost $(SS+straw(3:1))-20$ t/ha $+N_{50}P_{16}K_{67}$) from 3.3 to 4.1. It is with the introduction of fertilizer with such a norm of SS 40 t/ha and composts based on SS at a rate of 20 t/ha that increases the output of gross energy to 547 – 578 GJ/ha.

The relationship between the output of gross energy and the content of dry weight of miscanthus was studied, the coefficient of determination ($R^2 = 0.59$) and the correlation coefficient $R = 0.71$, which indicates a moderately strong positive correlation.

Abstract. This article examines the problem of non-uniform oil displacement during the development of multi-layer fields and proposes a promising approach to solve it – polymer flooding. The article outlines the basic principles of polymer flooding, including dissolving polymers in water to increase viscosity and reduce water mobility. Various types of polymers used in this technology and their unique characteristics are considered. The advantages of polymer flooding are highlighted, such as increasing reservoir coverage and increasing oil production efficiency. The illustrations presented in the article compare oil displacement using polymer flooding and traditional methods. In conclusion, a comparative description of various types of polymers in terms of composition and main application parameters is given and the importance of this technology in the context of ensuring sustainable and efficient oil production in multi-layer fields is substantiated.

1. Introduction

The development of multilayer fields is a complex process, which is often accompanied by heterogeneous oil displacement, especially in low-permeability zones. This factor can lead to oil retention in the rocks, which negatively affects production efficiency. To solve this problem, various technologies are used, one of which is polymer flooding (PF).

Polymer flooding is a technology aimed at increasing oil recovery by improving the water sweep factor using polymers. The basic idea is to dissolve polymers in water, which increases the viscosity of the water and reduces its mobility. As a result of the use of polymers, flow-diverting screens are created that promote uniform penetration of water into the rock. There are several types of polymers used for polymer flooding: cross-linked polymer composition (CPC); polymer disperse composition (PDS); polymer-gel system (PGS); cellulose ether (PEC); biopolymers (BP); alkaline-surfactant-polymer flooding (ASP) flooding [1, 2].

Oil that was retained by capillary forces or was not captured remains in the formation. The PF facilitates the recovery of residual oil. The polymer solution penetrates into highly permeable interlayers, as a result of which the dynamic heterogeneity of fluid flows decreases and, accordingly, the coverage of the formation by flooding increases.

If displacement is ineffective, water breaks through to production wells, which contributes to an increase in water cut. In this case, the ratio of oil and water mobilities is unfavorable,

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012054 doi:10.1088/1755-1315/1415/1/012054

so injection of polymer into the reservoir will increase the sweep factor. The causes of breakthroughs can be zonal and layered heterogeneity of the formation, occurrence of bottom water, the presence of highly permeable cracks or channels (especially typical for fractured-porous reservoirs), as well as leakage of the production casing. If the formation has some heterogeneity and a favorable ratio of mobility, then with PF it is possible to extract oil from formations with low permeability [3, 4].

When using PF, greater oil displacement occurs compared to traditional waterflooding, which illustrates (figure 1). PF consists of mixing water and polymer and injecting this solution into the formation. The solution must be injected until the polymer fills 1/3–1/2 of the pore space of the reservoir. Typically solutions consist of 40-50 % polymer components.

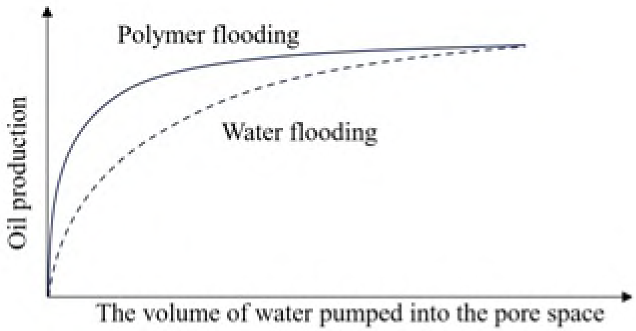

Figure 1. Comparison of polymer and conventional flooding [5].

Water that is injected into the formation tends to take the path of least resistance to neighboring production wells, i.e. get into an area where there is higher permeability and lower pressure. If the viscosity of the injected water is less than the viscosity of the oil, then the water will pass through or bypass the oil. All this leads to a decrease in the reservoir flooding coefficient, and a decrease in oil recovery will also be observed [6].

When choosing a polymer, it is necessary to consider the geological and physical conditions of application for polymer flooding. The range of geological and physical conditions has recently expanded significantly. This is since developments in petrochemicals have made it possible to adapt polymers and make them more resistant to reservoir temperature, formation water salinity and shear factor. Special protective additives are also added to make the polymers more resistant to harsh environments.

New research in the field of PF, considering the specifics of reagent injection into the reservoir, reduces the risk of polymer destruction and increases the efficiency of technology application. Currently, PF is carried out at high temperatures, salinity and in formations with heavy oil. In table 1 an example of polymer flooding parameters is presented.

Reservoir permeability, reservoir temperature and water salinity play an important role when using polymer flooding. Because ions such as calcium Ca^{2+} and magnesium Mg^{2+} are present in carbonate reservoirs, precipitation of the polymer with calcium and magnesium salts occurs in these reservoirs. All this negatively affects the waterflooding process [7].

The permeability of the rock affects the rheological properties of the polymer during filtration in a porous medium. A decrease in permeability entails an increase in the rheological properties of solutions. This has a particularly strong effect on the residual resistance factor. Using this parameter, it is possible to evaluate the effect of the polymer. The resistance factor is associated with the adsorption of the polymer by rocks. Adsorption is the process of rocks absorbing dissolved substances from the environment. The decrease in formation permeability for the polymer solution is much stronger than the change in the viscosity ratio of oil and

Table 1. Example of polymer flooding parameters.

Reservoir characteristics	Current application range
Permeability, μm^2	0.01-2.0
Temperature, $^\circ C$	80-120
Lithological composition	Sandstone
Viscosity of oil in the reservoir, $Pa{\cdot}s$	Less than 10
Oil density, kg/m^3	More than 965.9
Mineralization, g/l	Less than 270
Oil saturation, %	More than 20

water. This is called the resistance factor. The residual resistance factor is a parameter showing that even after complete destruction of the polymer, the permeability of the formation is not completely restored. If the permeability is less than 0.01 μm^2, then the polymer flooding process is practically impossible, since the polymer dimensions are larger than the pore sizes. As a result, clogging of the bottomhole zone occurs – mechanical blocking of cracks and fluid penetration channels [7, 8].

Possessing high viscosity, polymer solutions are capable of displacing oil and bound water from porous media. As a result, interaction occurs with the skeleton of the porous medium (with rock and cementitious substance). This process is called polymer adsorption (figure 2). During the adsorption process, polymer molecules are deposited on the surface of the medium and the channels are clogged, i.e. water filtration deteriorates. The mineralization of water and the mineral composition of the rock affect the amount of adsorption. To reduce adsorption, there is a need to create a freshwater rim.

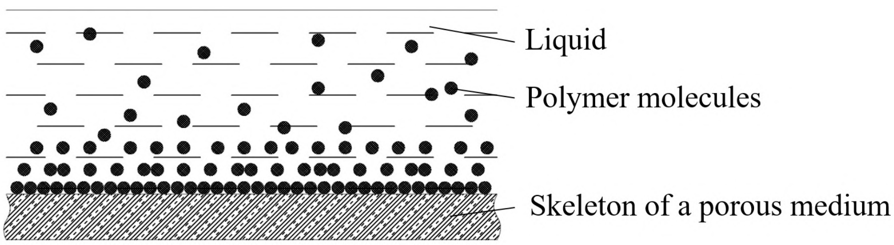

Figure 2. Polymer adsorption.

There is a range of adsorption values at which the flooding process will be most effective. The minimum flooding effect will be observed at zero adsorption, as can be seen from figure 3.

This dependence can be explained by the fact that the polymer solution in the formation is mixed with bound water and destroyed. This leads to a decrease in viscosity. As a result of this process, a zone of inactive water is formed. However, the task of the polymer solution is to increase the viscosity of water and reduce its mobility, as well as to increase the resistance factor at a low filtration rate of the solution, which can ensure the process of polymer adsorption. Thus, a decrease in adsorption reduces the formation resistance factor for water, and reduces the coverage of the formation by waterflooding, which makes the waterflooding process insufficiently effective.

On the other hand, with high adsorption, a decrease in oil recovery is observed. The front of oil displacement by polymer lags the front of displacement by water; accordingly, most of the oil is displaced by inactive water. As a result, oil recovery from the reservoir is reduced. Therefore,

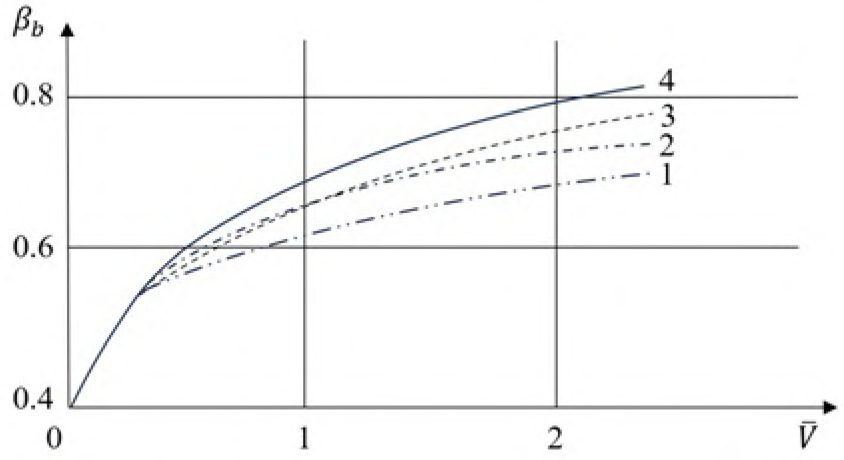

Figure 3. Dependence of displacement coefficient on relative selection at different polymer sorption properties (displacement occurs): 1 – water; 2, 3, 4 – polymer solution with different desorption coefficient 0; 1 and 0.5 respectively.

for the most effective displacement, it is necessary to select the optimal polymer adsorption [9].

The polymer loses stability at high reservoir temperatures, so it is necessary to add stabilizers. These substances can increase the polymer's resistance to temperature and prevent the polymer from precipitating from solution. From figure 4 at the same temperature the viscosity ratio will be lower, the lower the concentration of the solution. This graph also shows that solution concentration and temperature affect the viscosity coefficient.

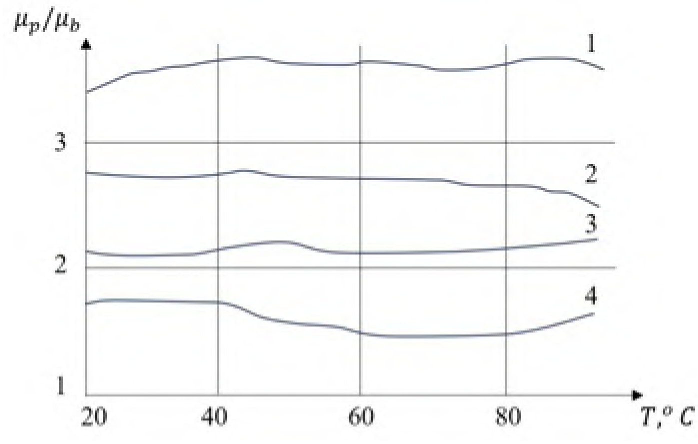

Figure 4. Effect of temperature on the ratio of viscosities of the polymer solution and water at various concentrations. Concentration, %: 1 – 0.1; 2 – 0.05; 3 – 0.03; 4 – 0.015.

The temperature situation in the reservoir can be tracked by the geothermal gradient, i.e. the increase in reservoir temperature per 1 m depth, and the geothermal stage – the reciprocal value of the geothermal gradient. In the subsurface there are not only areas with normal temperatures, but also areas with abnormal temperatures. The magnitude of the geothermal gradient decreases in synclinal zones and increases in anticlinal zones. Thus, synclines are zones of low temperature. This is explained by the fact that in areas of synclinal depressions and troughs, clayey rocks predominate, which, in turn, have lower thermal conductivity. Anticlines are zones of increased temperature. These anomalies are caused by the fact that within the uplifts the sand section predominates, which has increased thermal conductivity. Elevated temperatures are temperatures above 95 °C with a gradient above 4 °C/100m.

Changing the temperature in the formation leads to changes in the volumes of liquid, gas, and host rocks. As a result of increasing temperature, the viscosity of oil and water decreases and the viscosity of gas increases. Reservoir pressure increases with increasing temperature in a closed reservoir. Changes in phase relationships in deposits and the solubility of gases in water and oil, as well as salts in water, are associated with reservoir temperature. A decrease in reservoir temperature entails complications in the production of hydrocarbons and leads to the loss of valuable products (viscous oil, condensate, and paraffin), therefore, the development of oil fields is carried out with an increase in reservoir temperature [10, 11].

The pressure for injecting polymer solutions into the formation must be higher than the pressure of conventional flooding. Accordingly, the optimal pressure should be 20-22 MPa. Such pressure is necessary to maintain reservoir pressure due to an increase in the viscosity of the displacing agent, the appearance of additional resistance of the medium, and due to the manifestation of the apparent viscosity of the solution. For these reasons, PF will be ineffective in low-permeability formations. During filtration through a porous medium, apparent viscosity appears in the solution, as mentioned above. The viscosity turns out to be 10-20 times higher than the viscosity measured by a viscometer. As a result, it is more effective to apply PP for oil with high viscosity to increase the reservoir flooding coefficient [12].

When mixing the polymer and formation water, destruction of molecules is observed and, accordingly, a decrease in viscosity. If formation water has high mineralization, then the polymer concentration should be 2-3 times higher. However, for effective polymer flooding it is better to use low-mineralized water with a low content of calcium and magnesium [13].

The current reservoir pressure maintenance system is in-line waterflooding. It should also be considered that when the water cut of the product is more than 80%, the use of PF becomes ineffective. This is explained by the fact that, under these conditions, the filtration resistance of the porous medium practically does not change when using the polymer [13, 14].

Thus, the choice of polymer and/or polymer protection is an important part of the PF process. The most important parameters that polymers must satisfy are formation temperature, formation permeability and salinity of injected water. It is necessary to pay due attention to such a geological and physical parameter as reservoir temperature. To improve oil recovery, the stability of the reagents determines the duration of the flooding effect; accordingly, the reagent must be resistant to elevated reservoir temperatures [15, 16].

2. Comparative analysis of chemical reagents and formulations

For the greatest efficiency from the use of PF, it is necessary to carefully study the geological and physical conditions and, based on these conditions, select the optimal composition of the reagent. Polymers, like many other reagents, have their own properties. These properties determine the field characteristics of the use of polymers:

1. Viscosity – anionic polyacrylic acid (PAA) have a thickening ability, which is associated with the interaction of macromolecules with high molecular weight. This parameter depends on the concentration and molecular weight of the polymer in solution.
2. Rheological properties – solutions based on PAA are characterized by non-Newtonian behavior, i.e. The viscosity of the solution depends on the applied shear stress. The solution exhibits pseudoplastic behavior in which the viscosity decreases with increasing shear stress.
3. Solubility – problems with solubility and filtration capacity will be observed when using polymers with high (more than 1 million g/mol) or ultra-high (about 18 million g/mol)

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012054 doi:10.1088/1755-1315/1415/1/012054

molecular weights.

Thus, the following requirements are identified when choosing a polymer:

- High viscosity;
- Good solubility;
- Reduced degree of polymer retention in the formation;
- Resistance to mechanical destruction, i.e. shear resistance;
- Resistance to chemical degradation, i.e. use of protective systems to minimize the amount of impurities in water;
- Resistance to thermal degradation, i.e. adding stabilizers to the solution;
- Resistance to biological destruction, use of biocides (substances that can fight harmful organisms);
- Good filterability, i.e. good polymer transfer in a permeable environment.

Polymers entering the formation reduce the permeability of the formation, therefore the optimal polymer concentration is 0.1-0.15% by weight. Using a higher concentration is unprofitable, since a significant decrease in permeability will be observed [17].

Currently, due to the wide variety of reagents in petrochemistry, the following types of polymers are distinguished: cross-linked polymer composition; polymer dispersed composition; polymer-gel system; cellulose ether; biopolymers and ASP flooding [18].

2.1. Cross-linked polymer composition

Cross-linked polymer composition (CPC) is aqueous gels based on water-soluble polymers, which can be used to increase reservoir coverage by flooding. Most often, PAA is used as a water-soluble polymer. CPC is most effective at the third stage of development. At this stage, there is a decrease in oil production and an increase in the water cut of products.

When PAA is injected into the formation, it is possible to reduce the mobility of water and increase its viscosity, and it is also possible to increase the coverage of the formation by flooding. The formation of CPC is the result of chemical crosslinking of polymer macromolecules (crosslinkers) with solvent (water) molecules. Chromium acetate ($Cr(CH_3COO)_3$) or aluminum citrate ($[C_3H_4OH(COO)_3]Al$) are mainly used as a crosslinker. The formation of a gel consisting of cross-linked polymer chains in a solvent occurs during the reaction. The gelation time may be greater than or equal to the time of injection of the composition into the formation. The viscosity of the solution increases during the crosslinking stage [19].

The cross-linked polymer composition is capable of penetrating deep into the formation over significant distances, which contributes to the effective regulation of filtration flows. This composition has high apparent viscosity, as well as viscoelastic and viscoelastic properties. All these properties ensure more effective use of this technology compared to other compositions. Result of applying ATP:

- Redistribution of filtration flows;
- Water inrush containment;
- Introduction of hard-to-recover reserves into development;
- Increased oil production.

2.2. Polymer dispersed composition

Polymer dispersed composition (PDS) is a complex consisting of a polymer solution (usually PAA) and a suspension of mineral particles (clays). This polydisperse complex makes it possible to block water-saturated layers, because of which it is possible to influence low-permeability areas of the formation and involve them in development.

The process of formation of PDS is complex and includes several stages: adsorption of polymer and clay particles on the rock surface, flocculation, and filtration. In this composition, PAA molecules act as both a stabilizer and a flocculant. Polymer molecules enter the formation before the clay particles and are adsorbed and retained on the rock surface, so the concentration of the polymer in the solution decreases. Stabilization of a clay suspension occurs at high concentrations of polymer in solution. As the polymer concentration in the solution increases, the precipitation of particles from the solution slows down. As the polymer concentration decreases, the rate of deposition of clay particles increases. Under the action of PDS, flocculation of a suspension of clay particles occurs, which occurs when mixed with a PAA solution. PAA molecules form flocs, being fixed between clay particles. During these processes, clay particles are retained in the pore space and block highly permeable layers. Thus, with the help of PAA, it is possible to regulate the deposition of the clay suspension in the formation.

The effect of this system is to increase the filtration resistance of flooded zones, increase the coverage of the formation by waterflooding and increase oil production.

Currently, a modified polymer disperse composition (MPDS) is also used. MPDS, which has structural and mechanical properties, consists of a polymer, a cross-linking agent (AMG) and clay particles. This composition makes it possible to increase oil production from heterogeneous formations with large washed out zones.

Injection is carried out by sequential alternation of the PAA slug and the clay suspension. A crosslinking agent is also pumped in at the same time. AMH is introduced into clay and polymer particles. Clay suspension particles interact with PAA [20].

2.3. Polymer-gel system

The polymer-gel system (PGS) consists of a one-component gel system, which is based on PAA; therefore, PGS is based on intramolecular cross-linking of molecules. This system is resistant to mechanical destruction, and the system is also stable in waters with high mineralization and thermal-oxidative stability.

Due to its high viscoelasticity, PGS can reduce the amount of residual oil in the reservoir. Also, because the ASG has small particle sizes, this system can penetrate deep into the formation, thereby increasing the coverage of the formation by waterflooding.

PGS has high thermal stability and salt resistance, which increase the effective time of use of this composition. Due to the possibility of deformation into thin threads from the sphere and vice versa, the use of PGS makes it possible to slow down the movement of the composition slug through the formation [21].

2.4. Cellulose ether

Cellulose ether (CEC) can also be used in conjunction with a polymer to apply PF technology more effectively. This composition can be used at a late stage of development. If a polymer solution with CEC without a crosslinker is used at an early stage of development, thickening of the water will be observed, but without the formation of a gel. Due to a decrease in the mobility of the displacing agent, the displacement front is leveled, i.e. reservoir coverage by flooding increases.

With high water content of the product, which is typical for the late stage of development, the addition of metals entails the formation of a gel. As a result of the formation of the gel, the flow of water into the flushed zones is blocked and the displacing agent is directed to zones that were not previously covered by flooding. When injecting large volumes of CEC polymer solutions (2000 m^3 or more), redistribution of filtration flows occurs not only in the near-wellbore zone, but also in more distant parts of the formation.

For better cross-linking, polyvalent metals (chromium Cr, manganese Mn, iron Fe) are added to the CEC polymer solution. The mobility of the formed gel decreases when reservoir water is pumped into the formation, as well as when the PEC polymer solution is mixed with highly mineralized water [22].

The following cellulose ethers are used for flooding:

- Carboxymethylcellulose (cellulose glycolic acid) – $[C_6H_7O_2(OH)_2(OCH_2COOH)]_n$;
- Methylcellulose – $[C_6H_7O_2(OH)(OCH_3)_2]_n$;
- Ethylcellulose – $[C_6H_7O_2(OH)(OCH_2CH_3)_2]_n$;
- Hydroxyethylcellulose – $[C_6H_7O_2(OH)_2(OCH_2CH_2)OH]_n$ and others.

2.5. Biopolymers
The development of biotechnology has made it possible to use biopolymers (BP) in the oil industry. This type of polymer is polysaccharides of plant and microbial origin.

The possibility of using this type of polymer lies in the fact that at low concentrations the biopolymer can change the rheological properties of aqueous systems, namely: increasing viscosity and forming gels. Biopolymers can be used in harsh environments where the use of synthetic polymers is ineffective.

There are several types of biopolymers: plant and microbial. Plant polysaccharides have a significant drawback – the impossibility of obtaining the reagent in the required volume at different times of the year and in different climatic conditions. Polymers are resistant to different pH environments (acidic and alkaline). Biopolymers have an important property – resistance to destruction. However, biological destruction prevents the effective use of this composition since they can be destroyed by microorganisms during storage and direct use [23].

2.6. ASP flooding
In recent years, alkali-surfactant-polymer stimulation of the formation is often used, which is called ASP flooding. This type of polymer flooding includes several components: polymer, anionic surfactant and soda.

When using this PF, a double effect on the formation occurs: soda and surfactants reduce interfacial tension due to the formation of a microemulsion, while the polymer, in turn, increases oil mobility. Surfactants reduce the capillary forces that hold oil in the small pores of the rock. With the help of a polymer, the coverage of the reservoir by flooding is increased. This type of protection zone is the most effective since each component of the composition has its own effect on the formation. The use of ASP flooding allows the user to increase the amount of oil and reduce the amount of produced water, however, the number of extracted hydrocarbon fluids does not change. The use of this technology will increase oil recovery factor by 10% in the field [24].

3. Conclusions and recommendations
Using polymer flooding, you can increase reservoir coverage and improve oil recovery. In this case, the main parameters influencing the choice of polymer flooding technology are the characteristics of the formation and the high viscosity of the oil.

To achieve the greatest efficiency, an integrated approach to the use of polymer flooding is important. It is necessary to carefully study the geological and physical conditions in which the technology will be applied. The most important formation parameters are temperature (80-120 $°C$), permeability (0.01-2.0 μm^2) and formation water salinity (less than 270 mg/l). The viscosity of the oil also plays an important role – the higher the viscosity of the oil in reservoir conditions, the more effective the impact on the reservoir will be. In carbonate reservoirs, the use of polymer flooding is complicated by the presence of calcium Ca^{2+} and magnesium Mg^{2+} ions in the reservoir. The ions can react with polymers, resulting in the deposition of the polymer on the rock surface.

The variety of research in petrochemistry leads to many compositions for polymer flooding. Developments make it possible to adapt polymers for their use in abnormal reservoir conditions. The following types of polymer compositions are distinguished: cross-linked polymer composition; polymer dispersed composition; polymer-gel system; cellulose ether; biopolymers; ASP flooding. Table 2 a comparative description of various types of polymers is given in terms of composition and main application parameters – temperature and permeability. The features of the use of each composition are also highlighted.

The most effective polymer production technology is copolymerization. The optimal polymer concentration in solution is 0.1-0.15% of mass.

The technological mode of injection of a polymer solution into the formation plays an

Table 2. Comparative table of polymers.

Name	Compound	Temperature, $°C$	Permeability, μm^2	Application	Peculiarities
THX	PAA+ Crosslinker	$\leqslant 80$	0.03-0.5	At a late stage development	1. Penetrates deeply into the formation; 2. High apparent viscosity.
PDS	PAA + Clay solution	$\leqslant 80$	0.2-2.0	Heterogeneous formations in large washed-out zones	Structural-mechanical properties
PGS	PAA+ Crosslinker	$\leqslant 90$	0.03-0.5	Waters with high mineralization	1. Resistance to mechanical destruction; 2. Thermal-oxidative and thermostable stability; 3. Salt resistance; 4. Penetrates deeply into the formation.
PEC	Polymer+ Cellulose ethers	$\leqslant 100$	0.03-0.5	At a late stage development	1. Good binding, wetting and adhesive ability; 2. Redistribution of flows in the reservoir zone and the remote part of the reservoir.
TSA	Polymer+ Alkali+ Surfactant	-	-	High water cut	1. Double impact on the formation; 2. Non-toxic.
BP	Polymers of natural origin (polysaccharides)	$\leqslant 130$	0.01-0.2	Abnormal reservoir conditions	1. Resistance to destruction; 2. Resistance to different pH environments.

important role. It is necessary to deliver the polymer to the desired location in the formation and prevent its destruction. The optimal injection pressure is 20-22 MPa. When the water cut is more than 80%, it is not advisable to use polymer flooding.

A negative process that can accompany polymer flooding is polymer destruction. It is important to prevent the premature onset of this process. To do this, it is necessary to add thermal stabilizers to the polymer solution to prevent the onset of thermal destruction. To prevent chemical degradation, it is necessary to use high-quality water for flooding, i.e. water for flooding must be oxygen-free or with a minimum oxygen content (less than 0.5 mg/l). The risk of mechanical destruction can be minimized by maintaining a fluid flow rate of no more than 5 m/s biological destruction is extremely rare. Also, this type of destruction does not affect the viscosity of the solution.

Currently, polymer solution technologies using ASP flooding or cellulose ether are gaining popularity. Examples of fields where these technologies were applied were considered. The composition for ASP flooding includes 3 components: polymer, alkali, and surfactant. Each component has its own effect on residual oil. This composition is more effective, since because of the composition on the formation, oil production increases and the amount of produced water decreases. Polymer flooding with the addition of cellulose ether is also quite effective. This is explained by the fact that cellulose ether increases viscosity in aqueous solutions, which has a positive effect on the flooding process.

The cross-linked polymer composition has several advantages over other compositions. This composition can also be used at later stages of development. Also, the cross-linked polymer composition is capable of penetrating deep into the formation over long distances. This makes it possible to more effectively influence filtration flows.

Thus, with the help of polymer flooding technology, it is possible to increase the flood coverage of the reservoir and recover residual oil from the reservoir. This technology makes it possible to level the oil displacement front and extend the water-free period of field operation. It is important to choose the correct composition of the polymer solution. It is also necessary to observe the technological regime of injection of the solution into the formation to prevent premature destruction of the polymer and achieve the greatest effect from polymer flooding.

Abstract. The purpose of the article is to characterize the relevance, structure and background of business ecosystem model working out and its implementation at energy companies and to determine the ways of its interconnected and interdependent components transformation into enterprises' strategy. It's proved that formation of a business ecosystem model of energy company is an activity based on combining the efforts of interested parties, which, on the one hand, is aimed to achieve business goals, meet the energy resource needs of various groups of consumers, and on the other hand, on the complying with conditions that ensure the balance of their activities for the realization of the goals of sustainable development and the development of measures to maintain the ability of the business ecosystem to preserve its structure and functionality under the influence of external factors, taking into account global energy trends and energy development strategies. The focus is maid on the business ecosystem model those components integrate business processes, natural ecosystems and people efforts. It is emphasized that the transformation is a process of fundamentally changes based on the application of transformation tools, the choice of which depends on the selected type of transformation: emergency, innovative and evolutionary. Transformation processes require stakeholders' cooperation with, that shifts the traditional orientation of energy companies' activities mainly from economic results and business interests to the taking into account the benefits of an ecosystem approach, which accomplish with the added value by reducing the harm to the environment as well as the creating, in some way the business opportunities. It is justified that consideration of issues of collaboration and communication in transformation acquires special importance, since the achievement ofstrategic goalsinvolvesthe interested participants and the achievement of understanding and interaction in the process of transformation business ecosystem model into strategy.

1. Introduction

The activity of a modern organization takes place in conditions of rapid changes and uncertainty. Taking into account the sources of uncertainty make it possible to improve the management of organizational turbulence. The absence of a preformed path of activity in such conditions complicates the organization's path, creates risks and threats to future activities. Today, there are three main types of dynamism sources that an organization can use to develop in the face of change: technology, business model, and human resources. Each of these types corresponds to a certain limitation: for people – awareness of their needs and desires, for technologies – the possibility of developing and mastering them, for business models – viability and the ability to improve the existing business model. Organizations can manage uncertainty in different ways, focusing on one of these constraints: whether to focus on technological breakthroughs, as well as to study customers and their needs, or sometimes to improve existing business models. All this requires, on the one hand, considering what is happening behind the scenes outside the organization, and on the other hand, whether the organization can or sometimes wants to change its development strategy. Therefore, it is important to understand what challenges today cause the turbulence of the organization and how the organization can ensure its viability in such conditions, what management tools can be used to transform the strengths of the activity into opportunities for development, reducing threats and overcoming weaknesses. The business model itself encompasses the characteristics and properties inherent in the organization, which it transforms into the company's strategy and acts as a regulator of the viability of the strategy formed under the influence of modern challenges and development trends.

2. Literature review

The idea of connecting business and ecosystems dates back to the 1930s, when the English botanist Arthur Tansley coined the term ecosystem to describe a community of organisms interacting with each other and the environment, the components of which co-evolve and co-adapt to external changes. Hence, ecosystem was defined as the concept that in any closed system, its members must work together and around each other to keep the system stable, ideally optimizing the collective benefit [1]. In the natural world, we can observe how a balanced ecosystem benefits all participants, as well as how destructive an imbalance in an ecosystem can be, as we can observe the consequences of global warming. In turn, business strategist James Moore used the biological concept of an ecosystem to compare it to business and drew a parallel between companies operating in an increasingly interconnected world of commerce with a community of organizations that adapt and evolve to survive. Moore proposed to consider the company not as a single firm in the industry, but as a member of a business ecosystem whose members cover different industries [2]. Hence, the functioning of the business ecosystem model falls into the sphere of interaction between society and nature – the noosphere [3] – a concept introduced by W. I. Vernadsky and developed into the law of the noosphere – a provision formulated by the scientist about the transformation of the biosphere, according to which ”at the current level development of human civilization, it inevitably turns into the noosphere, that is, into the sphere where the human mind plays the most important role in the development of nature” [4], within which intelligent human activity becomes a determining factor of development [5]. By remaking nature and the environment, with his mind and the results of intellectual work, man changes the conditions of life on the planet, creating a noosphere, which, unlike the biosphere, does not have its own control mechanisms” [6].

The development of the idea of a business ecosystem fundamentally altering the key success factors for organizations, forcing them to think and act very differently regarding their strategies, business models, leadership, core capabilities, value creation and capture systems, and organizational models [6]. Therefore, taking into account the connection between the functioning of the environment and the activities of organizations, it is important to take into account that such interaction does not occur only between the environment and the organization itself, and the formed business ecosystem is considered as a set of legal entities and individuals of various fields and types of activity, “which functions for development of innovations and entrepreneurial activity by combining the efforts of various groups of stakeholders” [7]. In addition, the formation of the business ecosystem model, in addition to the connection “organization – ecosystem”, takes into account the trends of modern development, determined by the awareness of the need to take into account the conditions of sustainable development, the principles of the “knowledge economy”, the conditions of digitalization and the use of Business Intelligence NEO information and management systems, which allow better understand the goals and solve the problems of further development and implementation of these systems [8]. On the basis of research on the formation of the business ecosystem of an enterprise in the energy sector, it was concluded that this is an activity aimed at combining the efforts of interested parties, which, on the one hand, aim to achieve business goals, meet the needs for energy resources of various groups of consumers [9], and on the other hand, compliance with the conditions that ensure the balance of their activities for the realization of sustainable development goals [10] and the development of measures to maintain the ability of the business ecosystem to preserve its structure and functionality under the influence of external factors [11]. There were substantiated that oil and gas enterprises indicate a readiness for changes in instability of the functioning environment [12,13]. Thus, we define a business ecosystem as a network of organizations, including suppliers, distributors, customers, competitors, government agencies, etc., that participate in the supply of a specific product or service by competing, establishing cooperation, and establishing effective communications between business participants – ecosystems. The idea is that each member of the ecosystem affects others, constantly developing relationships in which each member must be flexible and adaptable to survive as in a biological ecosystem.

However, despite the fact that the idea of a business ecosystem has gained significant development, the issue of the transformation of the content, properties and requirements of the business ecosystem model into the enterprise development strategy has not been given enough attention. Based on the above, the purpose of the article is to characterize the relevance, structure and background of business ecosystem model formation and its implementation into enterprises' strategy taking into consideration the ways and tools forcing the transformation of mentioned model.

3. Methods

19 respondents who are stakeholders of the Ukrainian oil and gas production company, with whom a cooperation agreement has been concluded and who are interested in the results of joint activities, took part in the survey on the role of collaboration in transformational processes. The purpose of the survey was to find out how stakeholders understand the concept of "collaboration" and to determine their readiness for cooperation. The received answers are important for understanding directions and ways of improving interaction, strengthening mutual interest and participation of both the enterprise and its stakeholders in achieving joint results.

4. Results

Modern global energy development trends are determined by the need for energy resources and the problems of transition to low-carbon energy systems to ensure the sustainable development of both individual enterprises and countries and the world in general. Analytical reports predict that in the next 10 years the structure of energy consumption and their energy intensity will not change significantly, and consumption will increase by 2 units of Kj/person [14]. At the same time, experts and scientists note that the increase in the consumption of energy resources is accompanied by an increase in the emission of CO_2 into the environment. The Global Carbon Project estimates that global emissions of CO_2 will remain relatively high at 40.5 Gt CO_2 in 2022, but still below their 2019 peak of 40.9 Gt CO_2 [15]. Of the existing traditional types of energy resources, natural gas has the lowest emission volume of 0.2 kg/Kd CO_2, the largest – peat 0.38 kg/Kd CO_2 and wood 0.39 kg/Kd CO_2. [16]

We note that quantitative data of the business ecosystem development is important for informational support of strategic decisions in the ecosystem's era. The conducted research and the obtained results [17] confirm the relevance and positive dynamics of the creation of added value in various of ecosystems domains. In figure 1 the volumes and dynamics of the creation of added value in certain domains of ecosystems are presented for Europe, NAFTA and the world.

Figure 1. Volumes and dynamics of the creation of added value in certain domains of ecosystems for Europe, NAFTA, and the world [17].

As we cam see from the figure 1, all chosen ecosystem's domain has positive trends in creating of added value as well as in others, mentioned in the analysis [17]. In such conditions, taking into account the potential and capacities for the extraction of energy resources in Ukraine, as well as the need of energy security and energy independent, it is important to take into account the specified trends in the activities of oil and gas production enterprises. The desire to ensure sustainable and stable development of the energy sector led to the adoption of a number of documents that define the strategic directions of development, in particular, of energy enterprises. Modern strategy directions of energy sector development in Ukraine are represented by the following normative documents: Energy strategy of Ukraine for the period until 2035 "Security, energy efficiency, competitiveness", which creates prerequisites for combining business goals and goals of economic development with goals in the field of environmental protection [18]; Low-carbon development strategy of Ukraine until 2050 [19]; Law of Ukraine "On environmental impact assessment" [20], which gives the public the right to submit any comments, objections and proposals, which increases the level of its participation in the process of assessing the environmental impact of the planned activities of the management entity; the unfolding of the Russian-Ukrainian war, which forced a complete reconsideration of the issues of energy supply, energy efficiency and energy security.

Ukraine's accession to the EU and, accordingly, following the regulatory and legal context of integration requirements indicates the need to take into account their basic provisions in modern strategy directions of energy sector development. The national long-term strategies and the EU's strategy have to cover, with a perspective of at least 30 years [21] the next issues: total greenhouse gas emission reductions and enhancements of removals by sinks; emission reductions and enhancements of removals in individual sectors, including electricity, industry, transport, the heating and cooling and buildings sector, agriculture, waste and land use, land-use change and forestry; expected progress on transition to a low greenhouse gas emission economy, including greenhouse gas intensity, CO_2 intensity of gross domestic product, related estimates of long-term investment, and strategies for related research, development and innovation; to the extent feasible, expected socio-economic effect of the decarbonisation measures, including, inter alia, aspects related to macro-economic and social development, health risks and benefits and environmental protection; links to other national long-term objectives, planning and other policies and measures, and investment.

These trends and challenges are reflected in the development of energy companies and influence the formation of their development strategies. Building business models allows

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012055 doi:10.1088/1755-1315/1415/1/012055

determining the criteria, types of activities and processes that support enterprises to achieve their goals and implement a development strategy. The formation of a business ecosystem model of an enterprise in the energy sector demand the unifying the efforts of interested parties. This, on the one hand, will lead to achieve business goals, meet the energy resource needs of various groups of consumers, and on the other hand, will observe conditions that ensure balance between the activities to implement strategic goals and the development of measures of maintaining the ability of the business ecosystem to support its structure and functionality under the influence of external factors, taking into account global development trends and energy development strategies. Thus, we associate the implementation of the strategic goals of the enterprise based on the coordination of business interests with the task of minimizing the negative impact on the environment, with the formation of a business ecosystem model that allows realizing the potential of the enterprise and, if necessary, strengthening it in order to create conditions for implementation enterprise strategy formed under the influence of internal and external environmental factors (figure 2).

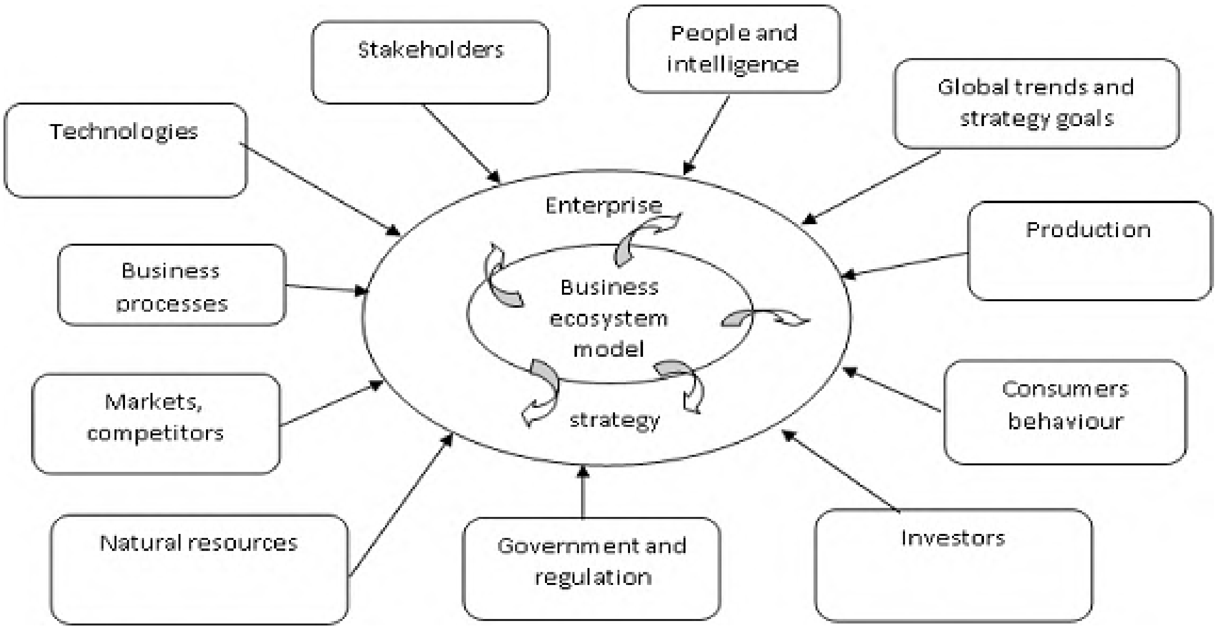

Figure 2. Determinates of enterprises strategy formation and it's connection with enterprise's business eco model.

In turn, the model is a tool for implementing the company's development strategy, takes into account the factors of the internal and external environment that influence the formation of the strategy and covers those components that integrate business processes, natural ecosystems and people involved in this integration process. An important task is the transformation of the model into a strategy as a consistent and systematic solution to the tasks of enterprise development based on the application of transformation tools, the choice of which depends on the selected type of transformation. Transformation processes involve the participation of stakeholders, collaboration with which is also important for transformations of the traditional orientation of energy companies' activities on economic results and business interests accounting the benefits of an ecosystem approach, which adds added value by reducing harm to the environment and people.

We note that the strategic goals of the enterprise must be harmonized with the strategic goals of the enterprise's environmental policy, within which the business model of the enterprise will function and, if necessary, be improved. The idea of a business ecosystem model proposed in this article involves the selection of spheres of activity, business processes, areas of activity that ensure the implementation of the company's tasks while simultaneously complying with the provisions of approved regulatory documents declaring the task of observing environmental policy and environmental responsibility [22].

The search for an integrated approach to the strategic management of a group of internal and external stakeholders at industry enterprises, taking into account the principle of balancing their interests with the highest utility for enterprises, is exactly in line with the idea of a business ecosystem. Achieving the expected results, organizations occupy the appropriate market share, form an image, develop a brand. At the same time, striving to satisfy the needs of consumers, companies use, in particular, natural resources that form the ecosystem of a certain territory. The ecosystem model is a natural environment that exists according to the principle of self-regulation and is aimed at creating conditions for the survival of all participants of this system and is regulated by the laws of nature. Therefore, in the content of the business ecosystem, we include the concept of a business structure that works using the principles of functioning of ecosystems, in particular, self-regulation to maintain its viability.

It should be emphasized that it is precisely for these reasons that in today's business world a company creates its own business ecosystem or invents a way to join an existing ecosystem, finding an advantage that does not currently exist in this ecosystem. Note that, like natural ecosystems, enterprises that are subjects of business ecosystems compete for survival, adapting to business conditions, and sometimes disappearing. The process of moving from the company's existing state to strategic goals occurs through transformation. We recognise business transformation as the process of fundamentally changes of systems, processes, people and technology across a whole business or business unit, to achieve measurable improvements in efficiency, effectiveness and stakeholder satisfaction. According to experts, the transformation process is based on a vision of the need for changes and a clear understanding of them, which is formalized through a portfolio-mix package, in particular, for the energy industry, it includes a low-carbon portfolio, green energy business; optimal portfolio of decarbonized hydrocarbons and green business. The implementation of measures within the list of promising types of activities is based and supported by value drivers such as environmental, social, governmental footprint; trust and confidence of stakeholders; balance between growth and financial flows. All this can be implemented through Business models formed for specific purposes: strategic partnership; low-carbon enterprise and equipment; ecosystem development.

Management practice involves three types of transformation, which depend on the company's readiness for changes, the environment in which the company operates, and management, which considers changes as a necessary condition for the organization's development, namely: evolution as a long-term, planned and well-executed gradual change in resource allocation and business areas; shift as a sudden strategic move that carries massive and abrupt changes to the business models and underlying value creation logic; shock is triggered by outside events or outside pressures that force the company to transform, or at least attempt to transform [23].

We offer to consider the experience of the Ukrainian energy company, which is engaged in gas extraction. The company implements and plans to expand measures that are provided in the field of main and supplementary activities and are aimed at reducing CO_2 emissions, waste management through the implementation of the concept of "green logistics", achieving energy efficiency and energy saving. New challenges that appear as a result of man-made impact on the environment pose new challenges to enterprises of the oil and gas complex. When engaged in the main activity of extraction, production, supply, storage and distribution of energy resources, they must take into account the requirement to carry out their activities with the least harm to the environment, realizing the need for the development of alternative sources of energy resources for the relevant sectors of the economy and various spheres of social life.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012055 doi:10.1088/1755-1315/1415/1/012055

Table 1. Strategic goals and outcomes of business ecosystem model at the oil and gas production company.

№	Elements of business ecosystem model	The main idea	Outcomes
1	Decarbonisation	Decarbonization is the term used for removal or reduction of carbon dioxide (CO_2) output into the atmosphere	Emission reduction goals to mitigate climate change. Decreasing of payments on environment's pollution competitive advantages.
2	Waste management	The aim of waste management is to reduce the dangerous effects of waste on the environment and human health.	Saving money on what you buy. Cutting your waste disposal costs. Meeting your environmental obligations. Finding new sources of revenue.
3	Energy efficiency and energy saving	Energy efficiency and energy saving mean using less energy to perform the same task – that is, eliminating energy waste.	Reducing greenhouse gas emissions, reducing demand for energy imports, and lowering the costs on a household and economy-wide level.

We suggest considering the strategic goals and the results of their achievement on the example of a gas production company table 1. Here is the description of business ecosystem model elements:

1. Decarbonisation transformation tools: related to the reduction of gas emissions during its extraction. One of the possible ways to solve this problem is capture of associated gases during extraction with their further use. The format of the business ecosystem model contains processes that will allow the reduction of CO_2 emissions into the atmosphere due to optimal route planning; reduction of idle time in traffic jams and reduction of fuel consumption, cargo consolidation and use of rail transport.
2. Waste management transformation tools: the company links with Implementation in the business ecosystem model the "green logistics" system in order to establish a system for monitoring the volumes of waste processing and consumption. This logistics system is formed in certain stages according to its functional structure. The first stage is the stage of supply, which is characterized by the formation of a logistics chain, which includes the following functions: collection, transportation and storage of secondary raw materials. The second stage is the sorting stage, which includes the identification, certification and sorting of secondary raw materials and waste and determines their qualitative and quantitative composition, forms a data sheet on waste, conducts an ecological and economic analysis of waste, as a result of which it will be determined whether the given waste is suitable for processing. The next stage – the implementation stage – takes place after waste processing and their promotion to the market as a product, which involves inventory logistics and warehouse logistics. If, after the analysis, it was determined that the waste was unsuitable for processing, the disposal stage is carried out, which includes the development of disposal systems, taking into account the types of waste and the characteristics of the region [24].
3. Energy efficiency and energy saving transformation tools: are implemented through processes that consider thermal insulation of industrial premises as a relatively cheap way

to increase their heat output, thus achieving a reduction in energy costs for heating and reducing the overall load on the environment by reducing the energy intensity of this type of activity; use of alternative energy sources to ensure energy supply of industrial premises.

Taking into account the necessary ecological changes [25] to the business model requires consideration of the preconditions for their transformation into a development strategy, followed by their implementation through the same model. Consideration of issues of collaboration and communications acquires special importance in the process of transformations, since the achievement of strategic goals involves the involvement of all interested participants and the achievement of understanding and interaction in the process of implementing the model for achieving development strategies. The transformation of the model into an enterprise strategy based on the approval of technical measures with the use of appropriate technologies, is accompanied by the study and application of modern management technologies, developing a policy of collaboration and improving communications.

The questionnaire results on collaboration perception by stakeholders could be used in transformation. And the main issues necessary to align with in the collaboration are inherited from the current perception of people, representing the enterprises during the realization of business contracts. And getting results can help to create an environment and conditions for collaboration, namely: 61% of representatives tend to require responsibility in the process of collaboration (figure 3). Team work is leading when interacting with stakeholders. At the same time, 11% of respondents do not have a clear strategy of interaction with stakeholders (figure 4).

On the question how often do you collaborate with stakeholders the most answers indicated the condition when it needed (55%), 11% of respondents indicated the need according the one tine concluded agreement, and 17% of them constantly support relationships with stakeholders. Thus, we can conclude that collaboration isn't considers as continues process but mostly as once time action, and this require appropriate policy of collaboration formation (figure 5).

Evaluating trust in cooperation with other enterprises, it was determined that 50% of respondents are inclined to test previous experience (figure 6). Thus, the results of the survey allow us to identify issues and directions for the future development of the prerequisites for transformation, such as the willingness and ability of stakeholders to support changes and facilitate their implementation.

To succeed in the transformation process, a system of communication needs to be established. Meaning, that the key people/groups and their communication channels must be taken into account – any system consists of objects and relations between them [26]. Moreover, from the perspective of the information theory the people become the nodes of the system and

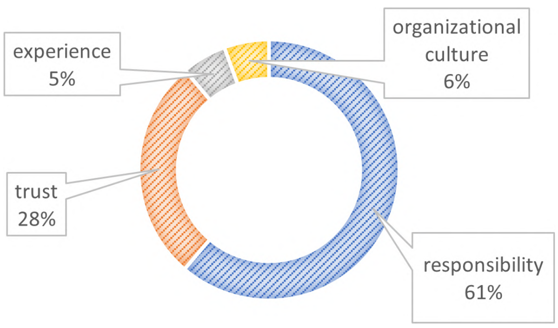

Figure 3. Answers on question "What collaboration does require first of all?".

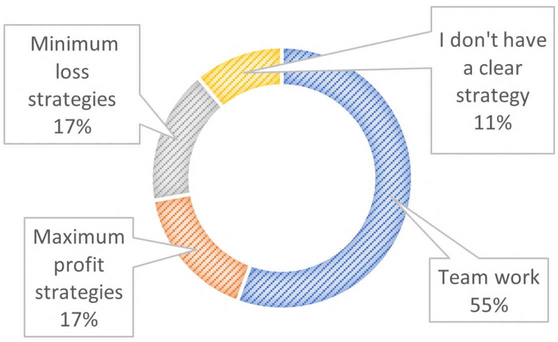

Figure 4. Answers on question "When interacting with stakeholders, what do you adhere to the strategy?".

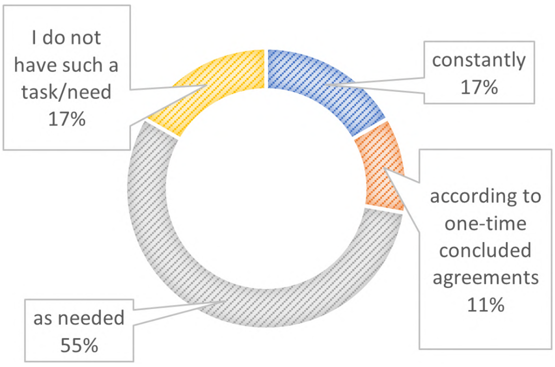

Figure 5. Answers on question "How often do you have to collaborate with stakeholders?".

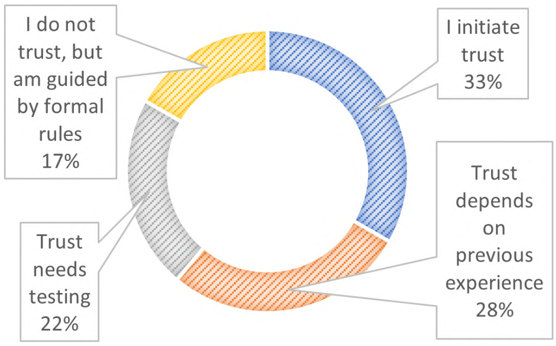

Figure 6. Answers on question "Assess the trust in representatives of other enterprises you work with".

how they communicate becomes its connections between those nodes. So, we must design a communication system, which means creating an effective implementation of the information theory. The most important aspect of creating a communication system is to understand the communication factors that directly affect the priorities and overall behaviour of the system created [27]. The following list defines the most important factors for information system design on improvement: number of nodes; number of connections; information distribution and security; transmission speed and bandwidth; transmission loss; transmission complexity; transmission integration; transmission parallelism; transmission scaling and flexibility.

The complexity of transmission (protocols and tools) is the fifth factor. We would like to present the example of such means at table 4. Even though we design how the nodes are connected, it's impossible to strictly set all of the connections, because the nodes of transmission are people and humans are prone to bringing their features of communication with other humans. So, we should provide the templates of connections, not the exact solutions, and the strict protocols of what's not allowed instead of how to implement the given template – to avoid alienation (a person's feeling of disconnection from a group) and give people the freedom to choose what makes sense in their particular context and situation instead of trying to foresee all potential cases.

Table 2. Communication means (technologies) for transformation process.

Elements of business ecosystem model	Transformation types		
	Shock (Extraordinary events)	Shift (Innovations)	Evolution (Sustainable development)
Decarbonization Waste management Energy efficiency and saving	Mass media Public control Press conferences	Start-up conferences Niche markets Local communities Investment pitching	Strategy meetings Road maps Programs Public Conferences

Taking into account everything said above, the hierarchy of the information transmission factors must be considered due to its direct impact on the contradiction between the factors (i.e. the higher integration the system has, the better its scalability). For example, the successful realization of the complexity factor requires a corresponding material-technical base. Another example is the monitoring of the created system, which provides the evaluation of the overall communication effectiveness. It's crucial to understand that the system runs with the speed of the slowest connection between nodes. So, each node should strive for both being effective at encoding, interpreting, and decoding the information transmitted. In other words, interpretation is the cornerstone of any system where people are the central node, so we must motivate them to explain themselves and understand others to their best ability. Also, way too often there are redundant connections that don't bring any benefits but only slow down the overall bandwidth of communication, so minimization of the connections is another way of optimizing the system structure. It's important to highlight that minimization must be done extra carefully because it leads to an increase in the number of connections each node has, which in turn increases its relative importance – this directly affects how secured the given node must be.

5. Discussion

Today, business practice has formed a significant list of modern business models that use approaches and methods of organizing and managing activities allowing the enterprise to adapt its business processes to the environment due to the modern challenges and development trends. There is a practice of forming business models of leading companies in the world, which ensure their success and competitiveness. Examples of such companies are Amazon, Google, Apple, FedEx, Southwest, Walmart, McDonald's, IKEA, Enterprise, eBay, Dell Computers, Starbucks, Skype, Groupon [28]. We note that the success of the enterprise is ensured by those business models that are based on modern technologies, are oriented towards the consumer, as well as are able to develop human resources, and ultimately provide the enterprise with the uniqueness that allows the realization of strategic goals formed on the basis of a perspective vision of the company role and value. Hence, the formation of the business ecosystem model takes place on the basis of the improvement of existing business models, their reengineering as required, and the mandatory condition of functioning includes the principle of the existence of the ecosystem as the ability to self-regulate and recover [29].

The proposed concept of the business ecosystem model transformation into an enterprise development strategy takes into account the peculiarities of its activity, in particular, for this publication, it is the field of oil and gas production. Actually, the transformation takes place by proposing measures in the areas of activity that correspond to the potential strategic goals of the activities of industry enterprises, which are determined by the prospects of the industry. Note that presented in figure 7 stages of transformation of the business ecosystem model are debatable, because it may appear that the business ecosystem model includes strategy as one of the components of the business model.

However, the enterprise defines a business model that will allow the implementation of a strategy aimed at solving strategic tasks. That is, the processes of the business model describe how the enterprise turns strategic goals into profit, and the strategy focuses on creating opportunities to function in a competitive environment and implement tasks, in particular global development. Despite the emphasis on the specifics of the oil and gas industry, the concept of transformation of the business ecosystem model into an enterprise development strategy has a generalized nature and can be used for enterprises of other industries, however, taking into account that the central point of the transformations is the orientation to the principle of balanced functioning of the business ecosystem derivatives. In addition, such an approach to the orientation of the business model on environmental problems is relevant in the conditions of the post-war recovery of the Ukrainian economy, namely the energy sector. Reconstruction should involve not only the restoration of the physical condition, but also a fundamental rethinking of methods that will allow meeting energy needs with the least harm to people and the environment.

Further research is needed to examine whether the strategies available in enterprises take into account the prospects and trends of the development of the industry based on the consideration

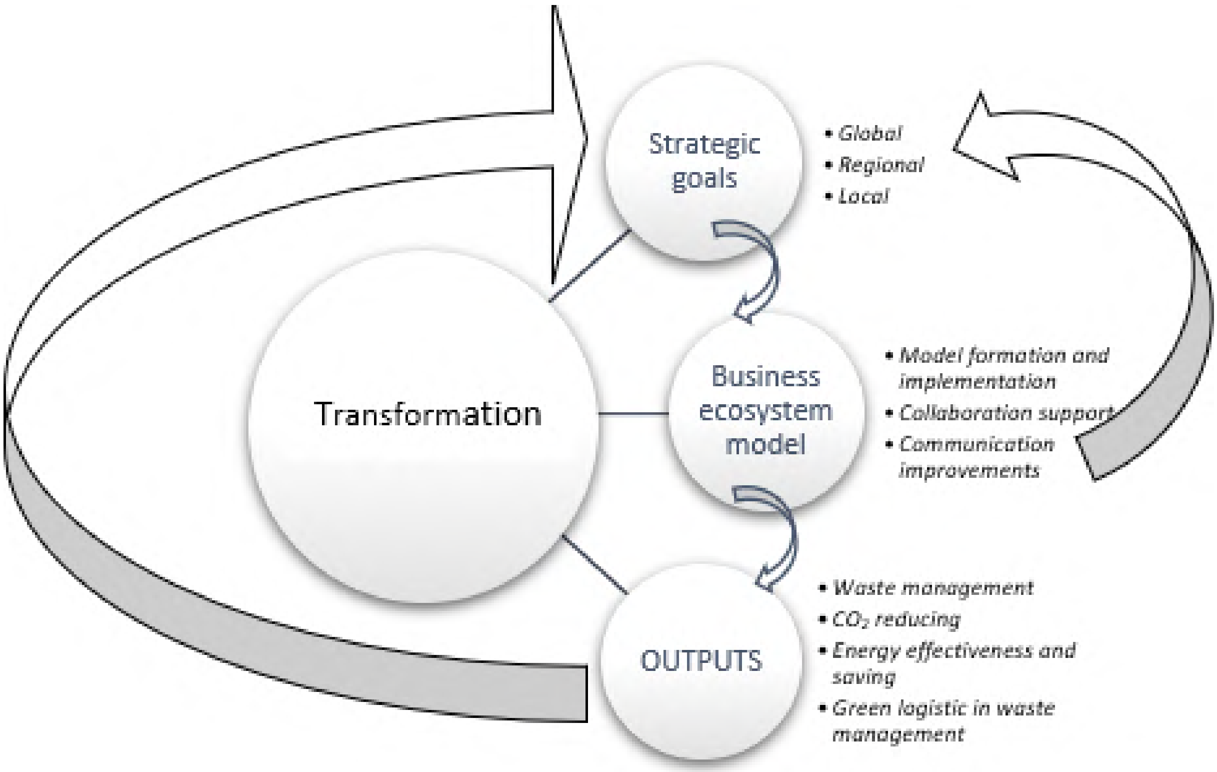

Figure 7. Stages of transformation of the business ecosystem into the strategy of the oil and gas production enterprise.

of international and national legislation and standards, in order to assess the extent to which existing business models are able to realize strategic development goals.

6. Conclusion

The formation of a business ecosystem model of an enterprise in the energy sector is an activity aimed at combining the efforts of interested parties, which, on the one hand, aim to achieve business goals, meet the energy resource needs of various groups of consumers, and on the other hand, comply with conditions that ensure the balance of their activities for the realization of sustainable development goals and the development of measures to maintain the ability of the business ecosystem to preserve its structure and functionality under the influence of external factors, taking into account global development trends and energy development strategies. The model is a tool for the implementation of the energy company's development strategy, takes into account factors of the external environment that influence the formation of the strategy and includes those components that integrate business processes, natural ecosystems and people involved in this integration process.

An important task for enterprises striving to adopt their activity to the global, national, and local trends is the transformation of the model into a strategy as a consistent and systematic solution to the tasks of enterprise development based on the application of transformation tools, the choice of which depends on the selected type of transformation: emergency, innovative and evolutionary. Depend on the transformation type the different approaches could be decided to adopt an enterprise to the challenges and trends. Transformation processes involve the participation of stakeholders, cooperation with which is also important for transformations of the traditional orientation of energy companies' activities on economic results and business interests, considering the benefits of an ecosystem approach, which makes additional value to the business by reducing harm to the environment and people.

Consideration of issues of cooperation and communication acquires special attention in the process of transformations, since the achievement of strategic goals involves the interested of relevant participants and lead to more understanding and interaction due to the collaboration in the process of implementing a business ecosystem model for achieving developed strategies.

The concept of the business ecosystem transformation into the strategy of an oil and gas production company proposed in the article includes and structures the main elements of the functioning of the model, which are related to the company's activities and stem from the strategic goals of global trends, and also include specific characteristics that distinguish the business ecosystem model from traditional business models.

Abstract. The article is dedicated to the study of motivational profiles of employees, identifying dominant motives in conditions of war and uncertainty to develop the proper tools for directing personnel behavior toward reaching the goals of sustainable development. The study was conducted at bakery enterprises in the Sumy region of Ukraine in 2023. The methodological basis of the study is the author's approach to structuring motives, which adapts the classic Martin and Ritchie methodology, sociological research methods (questionnaires, focus group surveys) and statistical analysis to the current conditions in Ukraine. As a result, the hypothesis regarding the dependency of the structure of motives (the image of the motivational profile) of employees on their position within organization and the nature of their work was confirmed. It was shown that management pays little attention to the development of motives directed at achieving sustainable development; at the same time, the very nature of work can serve as the basis for the behavior focused on sustainable development goals (for example, the value of work results for society). At the same time, it is apparent that the war changed the structure of motives: safety in the workplace instead of being just important becomes one of the key motives; the motives of social participation and psychological well-being of personnel acquired a greater weight. Unfortunately, though environmental behavior is understood and accepted as important in the structure of motives of employees, in the real motivational profiles it takes an average level, which indicates the impact of stress and war on the priorities as well as minimal efforts of company management in the development of "environmentally responsible" personnel. The obtained data became the foundation for the recommendations offered to improve staff motivation that include components relevant to the current situation of uncertainty and risks and are aimed at achieving sustainable development goals.

1. Introduction

The modern world is so dynamic and subjected to the influence of social engineering that all business processes have become dependent on non-economic determinants. Thus, reputation can often increase a company's rating overnight or turn the company into a loser [1]. Therefore, the quality of a company's human capital determines how successful and thriving it will be in the world of new social interests. These interests include the goals of sustainable development. According to the studies [2,3], the interest of company managers and ordinary employees in the implementation of sustainable development goals is rising constantly. In addition, in recruitment, one of the criteria for choosing a workplace by a candidate is the implementation of social projects and the company's adherence to sustainable development goals (especially in terms of the green agenda) [4]. The modern financial and economic world is characterized by a reorientation toward sustainable development goals, so considering the development of an enterprise cannot be imagined on a different plane than personnel management based on the principles of green management and corporate social responsibility.

The pivot point of the concept of "green" personnel management is and should be the value structure of human capital. For example, if greater attention is paid to the environmental component during the assessment of the methods of personnel management, this means that achieving the corresponding goals requires that the company's personnel and its top management not only have the necessary competencies but also have internal motivation to achieve such goals. Simply put, it is incorrect to claim that the company is implementing sustainable development goals without the existence of interests and motives among employees toward such goals. Based on the conclusions of scientists who developed a model of business ethics [5], issues of corporate social responsibility, especially in terms of environmental management of an enterprise, are decisive in strategic management. In addition, creating a sustainable business is impossible without the existence of a developed sense of social responsibility, which is defined as the desire to materialize internal and external motives. At the same time, internal motives include concern for nature or the good of society, and external motives include meeting the needs of customers and the willingness to achieve the well-being of employees [6].

In influencing employee behavior through motivation management, companies are often focused on the principles outlined in green HR management, which include developing talent, providing access to new ideas and resources that can help employees become more creative and innovative [7], and fostering well-being, productive social and labor relations, and high-quality communication. Traditional models and methods that take into account the age structure of personnel and the life cycle of the company's development are equally important in motivation directed at achieving sustainable development of a company [8]. At the same time, the very turbulence of the political and socio-economic environment requires constant modification of approaches and tools for motivating personnel, which invariably entails an analysis of the motivational profiles of personnel.

2. Literature review

Personnel management founded on the principles of corporate social responsibility includes all classical processes – from personnel selection and assessment to labor organization, as well as modern ones – digitalization and talent development. Moreover, all processes are in one way or another connected with motivational practices. Considering the increase in the factors of instability of the external situation and changes in personnel values [9], the most acceptable construct for motivation is the "ability-motivation-opportunities" model [10], because it takes into account the values of personnel as much as possible and demonstrates the relationship between motivation for development and behavior of employees, results of their work, and, consequently, increasing productivity of labor, and improving other economic indicators of the company's activities that depend on human capital. This logic is very similar to "green" personnel management. In particular, the goal of motivation will be to achieve sustainable business development, including environmental, by changing employee behavior through additional training.

It is worth noting that motivations are not constant and vary during lifetime with the changes in life conditions. The ongoing war in Ukraine has a catastrophic impact on the economy, human lives, and overall worldview. The priorities and motives are also visibly changing: the motives of safety become paramount [11]. Also, in the innovation sector, the wartime conditions bring forward motives of participating in the work toward the victory [12]. However, low wages and minimal understanding of the importance of work reduce enthusiasm and motivation of employees [13].

Besides, rising uncertainty and risks due to wars, pandemics, and natural as well as man-made disasters are increasingly pushing stakeholders toward the task of ensuring the sustainable development of the company. As Casey and Sieber note, the sustainable development of a company becomes the goal not only of the company itself but also of its employees [14]. Personnel management and motivation (as a component) in the context of sustainable development assumes that both management and all employees are interested in achieving goals and are therefore involved in solving social and environmental problems. Thus, motivation should be focused on a triple result: economic, social, and environmental, which is impossible without influencing the development of a certain motivational profile of an employee. At the same time, the values and interests of each employee must be correlated (harmonized) as much as possible with the goals and strategy of the company. This fully meets the principles of social responsibility and will be implemented through social projects of companies [15].

On the other hand, motivation focused on achieving sustainable development goals can be viewed through the prism of stakeholder (primarily staff) satisfaction. For example, if the content of the work is well-defined and meets the goals and interests of the employee, including social and environmental, then the employee's motivation will be higher. As noted in the study by Shafaei, Nejati and Yusoff [16], such aspects of motivation as involvement, the opportunity for self-realization and participation in social projects, fairness in the appreciation of work, compliance of working conditions with "green" standards, and satisfaction with the content of labor are the basis of "green" personnel management, as one of the goals of sustainable development.. However, the impact of the stress on the motivation of the personnel also becomes evident: the external stress factors (war, devastation) make employees to "accumulate" fatigue and lose productivity of labor [17]. It indicates the difficulties that can arise in motivating people toward reaching the goals of sustainable development.

As we can see, the issue of motivation is very relevant for the sustainable development of a company. However, effective motivation can be achieved by taking into account the values of employees in the selection of motivation tools, i.e. their motivational profile. For the first time, the term "motivational profile" was found in the work by Ritchie and Martin [18], which they understand as individual stimulating factors. Publications devoted to the study of the structure of the motivational profile are most numerous in the pedagogy and psychology of students [19–22], however, there are studies of the motivational profile of workers in various fields of economic activity [23]. In general, all researchers agree that the motivational profile of an employee reflects the dominant motives in work activity and includes the most relevant goals for him. Therefore, an analysis of the motivational profile of the staff will allow us to assess the coincidence of the goals of all employees and the company, the potential and possibilities of their involvement in the implementation of social projects, and other sustainable development goals.

3. Methodology and objectives of the study

The purpose of this research is to study the motivational profiles of personnel to identify dominant motives and, based on this, propose directions for motivating employees of the studied enterprises that contribute to their sustainable development; identify or refute the hypothesis regarding the existence of differences in the structure of motives of different categories of personnel.

Based on the goal, various methods for constructing and analyzing a person's motivational profile were analyzed. The method used by Ritchie and Martin [18] was modified to suit the task of identifying motivation for the sustainable development of an enterprise, the parameters were also semantically clarified. Thus, "acknowledging work results" was redefined as "fairness of labor assessment" because employees would rather know how their work is evaluated by all stakeholders than know it was just acknowledged as existing. The term "Self-improvement" was defined as "Development and training" because this way personnel, as shown by answers of experts, would easier understand the nature and ways of self-improvement. Besides, the term "Interesting and useful work" was clarified and the emphasis was placed on usefulness for society rather than for the employee. Also, there were additions to assess social participation (charity, involvement in social projects) and an environmental component; social contacts and relationships were identified as psychological well-being and social interaction. Thus, the classical methodology has undergone some changes that adapted it to the semantic understanding of the terminology by personnel and expanded the assessment categories setting the focus on motivating personnel to achieve sustainable development goals.

A questionnaire developed according to this method was created in Google Forms, which included questions on self-assessment of the following motives: High earnings and material incentives; Physical working conditions; Structuring (need to establish clear rules for work performance, availability of feedback); Social contacts (the need to communicate with many people); Relationships (the need to form long-term close relationships); Recognition; Striving for achievements; Power and influence; Diversity and change; Creativity; Development and training; Interesting and useful work. The selected scale for assessing each value factor is presented in the range from 0 to 12 points. In this case, 0 is a complete lack of interest in the named factor, and 12 is its maximum representation (impact on behavior), the employee's interest. According to the logic of the study, the employee intuitively determines the characteristic level of one or another proposed factor-motive. Transformation of the results assumes the following scale for assessing motivation: 10.1-12 – Very highly motivated; 8.1-10 – Highly motivated; 6.1-8 – Rather motivated than not motivated; 4.1-6 – Rather unmotivated than motivated; 2.1-4 – Low motivation; less than 2.1 – Lack of motivation or negative motivation.

The study was carried out in March 2023. Unfortunately, 8 people filled out the questionnaire incorrectly. This indicates the complexity of the study for employees. Therefore, to clarify some results and identify links with the goals of sustainable development, the following was conducted: 1) an express survey in a focus group (10 percent of the sample corresponding to the structure of enterprise personnel and participants in the first survey) of enterprises participating in the study in June 2023, which made it possible to formulate the goals of sustainable development for these enterprises; 2) a sociological study in September 2023 among the same respondents (previously, all participants were sent a letter explaining how to fill out the Google form) to determine the link between staff motivations and sustainable development goals.

The survey was attended by 22.5 percent of the general group of bakery enterprise workers in the Sumy region of Ukraine. According to the structure, the respondents are represented by managers (15.6 percent of the entire group of respondents), managers and specialists (22.0 percent of the entire group of respondents), as well as workers (62.4 percent of all respondents). In this study, gender and age aspects were not detailed, because The personnel structure of companies remains unchanged for a long time (there is practically no staff turnover).

4. Analysis of the motivational profile of bakery enterprise personnel and defining priorities in their motivation

The results of the first survey made it possible to determine the significance and integral score of the motives that are inherent in employees of bakery enterprises (table 1).

Table 1. Qualitative evaluations (averaged) of significance and satisfaction by factors for respondents by personnel categories.

Indicator	Factors											
	High salary	Working conditions	Content of work	Social contacts	Psychological well-being	Recognition	Result driven	Power	Changes, innovations	Creativity and ingenuity	Self-refinement	Useful, interesting work
Workers												
Significance of the factor	1	0.9	0.5	0.8	0.8	0.8	0.6	0.2	0.3	0.3	0.6	0.7

Integral meaning of the motive	0.3	0.72	0.5	0.56	0.56	0.48	0.3	0.12	0.24	0.21	0.42	0.56
Specialists												
Significance of the factor	0.89	0.76	0.21	0.71	0.94	0.86	0.87	0.84	0.74	0.63	0.70	0.70
Satisfaction level	0.33	0.89	0.89	0.44	0.21	0.20	0.21	0.69	0.69	0.63	0.64	0.70
Integral meaning of the motive	0.29	0.67	0.19	0.32	0.20	0.17	0.19	0.58	0.51	0.40	0.45	0.49
Managers												
Significance of the factor	0.8	0.3	0.5	0.86	0.84	0.94	0.88	0.78	0.68	0.78	0.88	0.8
Satisfaction level	0.28	0.94	0.9	0.84	0.82	0.46	0.4	0.92	0.52	0.56	0.68	0.6
Integral meaning of the motive	0.224	0.282	0.45	0.72	0.69	0.43	0.35	0.718	0.354	0.437	0.6	0.48

The data in table 1 indicates the following. Firstly, motivation is shown as the sum of integral assessments of motives (according to the degree of its influence and significance):

- for the worker, it shows a value of 4.97, which indicates a fairly low motivation for this category of personnel in general;
- for specialists, it is at the level of 4.46, which indicates low motivation for this category of personnel;
- for managers, the value is 5.735, which demonstrates the average level of motivation and the existence of possible reserves for improving the interest of employees in improving work results.

Secondly, for certain motives, radically different assessments of motives can be seen, which is explained by differences in people's interests. Thus, the motive of "power" has the maximum significance for managers, but the least significance for employees; and the motive of "working conditions," on the contrary, is more important for workers than for managers.

Looking in more detail the resulting motivational profiles of workers (figure 1), specialists (figure 2), and managers (figure 3), the conclusions about the presence of differences in the perception of motives by workers and specialists and managers become obvious; the evident existence of factors that are inherent in the motivation system of enterprises, but do not influence the degree of motivation, and some reserves for improving motivation. In figure 1 1 – High salary; 2 – Working conditions (safety); 3 – The content of the work; 4 – Social contacts; 5 – Psychological well-being; 6 – Recognition; 7 – Result driven; 8 – Power; 9 – Changes, innovations; 10 – Creativity and ingenuity; 12 – Self-refinement; 13 – Useful, interesting work.

Thus, for workers (figure 1), the obvious priority is material well-being and working conditions. At the same time, they acutely feel the little appreciation of their work on the part of management, although there is an understanding of the value of their work on the part of the employees. At the same time, despite the motive "material support (wages)" being prioritized, workers still are not satisfied with its level. While motives related to innovation, creativity and power did not become a priority, therefore workers were satisfied sufficiently with these criteria. The motives of social interaction and psychological support are also important for workers, but the level of satisfaction with them is not high enough, i.e. workers feel a certain discomfort, especially in terms of psychological well-being and assistance, which they expect from management. Therefore, special attention must be paid to non-material motivation of workers. It is important to note that workers are well aware of the social usefulness of their work, which suggests that they are interested in the sustainable development of the enterprise.

It is typical for specialists (figure 2) to focus their motivation on social, psychological, and material factors of well-being. However, employees feel dissatisfaction with their work and its appreciation. They have motivation for development, positively assess the value of work, and the opportunity to participate in innovations, etc. In general, this profile indicates that enterprises have chosen the wrong priorities to motivate this category of employees. Without understanding or seeing a fair recognition of work, such employees are more likely to demonstrate interest than to make efforts to change the situation. The obtained data show that specialists are the least motivated group (the most negative factor is misunderstanding of the work content). One of the reasons for this is the psychological fatigue brought by uncertainties in life and work because of the war and poor management. According to the

						Satisfaction with the defined needs					

Figure 3. Structure of a manager's motivational profile.

The motivational profile of managers (figure 3) shows high motivation for development and recognition of work, however, not understanding the meaning of social capital and the importance of psychological well-being can have a bad impact. Formally, this structure says that managers are sufficiently motivated and remain loyal to the enterprise, however, they are not showing their full potential. Material means of motivation are the least satisfying for managers, and they believe that their work is undervalued. It is noted that in conditions of ongoing war managers are less inclined to innovate although the need to make creative decisions is quite high (and they are aware of this). Managers realize the value of the work of their enterprise and are motivated to work there, which is the positive result, however, motives of achieving power still are their priority. The risks to personal safety negatively affects motivation (since managers are responsible not only for personal safety but also for the safety of all employees, when they can't ensure complete safety they face the dilemma which reduces their motivation; they "transfer" responsibility to the authorities). Thus, managers are quite motivated to solve operational problems but hardly consider achievement of bigger goals in their work.

The results of express surveys in a focus group made it possible to correlate the goals of sustainable development and the motives of employees. Thus, for managers and specialists, sustainable development was a condition of the enterprise when material well-being is beyond doubt, and at the same time, the enterprise has no debts, complies with environmental requirements, participates in social projects (for example, helping the poor, pensioners, orphans, etc.), and ensures a sufficient level of safety in the workplace. Workers understand the achievement of sustainable development goals as the social significance of their work – value for the entire population, arrangement of high labor safety, and social participation (involvement in the lives of employees and their families, assistance to hospitals

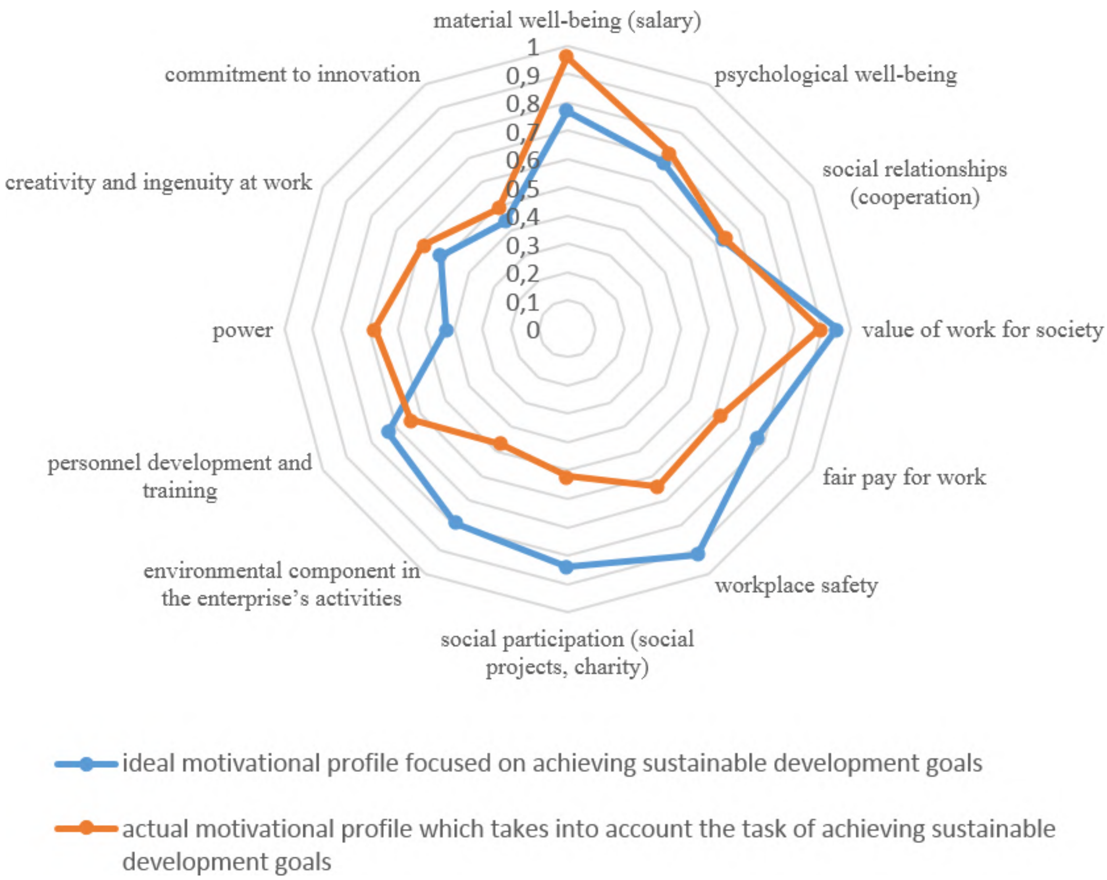

Figure 4. "Ideal" and actual motivational profile of an employee of bakery enterprises (average value), which takes into account the task of achieving sustainable development goals.

and boarding schools). Thus, the logical scheme of compliance of the motivational profile with the goals of sustainable development should include such motives as labor safety, mutual assistance, social participation, and material and psychological well-being.

The second survey, taking into account the updated and more correct formulation of motives designed for the sustainable development goals, showed that there is a difference between the "ideal", required motivational profile (which contributes to the achievement of sustainable development goals) and the actual one, which indicates that personal interests and everyone's vision do not always coincide with the efforts that need to be made to achieve results (figure 4). At the same time, a clear imbalance is observed in the motives of safety, social participation, development and fair recognition of work.

Based on the data obtained (figure 4), the offered model of personnel motivation must necessarily include the following components:

- decent level of remuneration;
- safety in the workplace (shelters, taking into account working conditions when setting work and rest periods, workwear, water, etc.) ;
- recognition of work, bonuses for work results;
- favorable socio-psychological climate ;
- involvement in social projects;
- training, including environmental behavior.

Thus, motivating the staff of bakery enterprises in the Sumy region of Ukraine involves carrying out activities directed at the development of sustainable motives that reflect "green" management, socially responsible behavior, and involvement in the social life of both the enterprise and society.

5. Conclusions and discussion

The scientific and practical values of the current research are the results of the approbation of the developed methods on the analyses of motives that serve the attainment of the behavior directed toward achieving the goals of sustainable development; adapting the methods of studying motivations of personnel to the current conditions in Ukraine and Ukrainian worldview, which would allow redefining personnel motivation and development goals. The hypothesis regarding the dependency of the structure of motivational profiles of employees on their position within organization and the nature of their work was confirmed.

To summarize, it should be noted that the majority of employees of bakery enterprises in the Sumy region of Ukraine have a very vague idea of sustainable development. Therefore, researching this subject required preliminary educational work. The data obtained indicate that employees have motives that directly correlate with those that contribute to the achievement of sustainable development goals, for example, the "work recognition" motive. Employees also agree that the motives for social participation and environmental behavior (for both employees and the enterprise) are very important for achieving sustainable development goals. However, taking into account dissatisfaction with the level of remuneration (level of material well-being and job recognition), the priority of these motives is significantly lower than the potential ("ideal" motivational profile).

In a certain way, such differences between the "ideal" and the actual motivational profile are justified by negative external factors – the risks associated with military operations. At the same time, traditional motives (wages) were and remain, regardless of external factors, the leading motives for the majority of personnel, especially workers. The current situation has rather increased the priority (brought it to dominance) of safety motives and reduced interest in the motives of "green" management. There is also differentiation in the structure of motives by category of personnel, which in general does not reduce the possibility of defining universal motivational components focused on achieving sustainable development goals.

Understanding the influence of force majeure factors (military actions, other disasters), further research will be directed at taking into account and determining the significance of the impact of the war factor (uncertainty and high risks to people's lives) on the structure of the motivational profile and the possibility of motivation to achieve sustainable development goals.

Abstract. The article is devoted to the peculiarities of the economic security management of food industry enterprises as a direction of ensuring sustainable development of economic entities. It was determined that the food industry plays an important role in Ukraine's social and economic system; at the same time, food industry enterprises activity is characterized by the presence of negative trends. The essence and the components of the enterprise economic security were considered. The economic security is defined as a mechanism aimed at confronting threats and overcoming negative trends. The conceptual model of ensuring economic security of enterprises was proposed. In order to determine the key directions for increasing the level of economic security the model of dependence of economic security coefficient was formed using correlation and regression analysis. According to the model, the main factors of influence on food industry enterprises economic security formation are the growth rate of net profit, cash ratio and profitability of economic activity. The key measures for the formation of a constructive influence on the specified factors are proposed in order to increase the level of economic security of food industry enterprises.

1. Introduction

Conditions of functioning of Ukrainian enterprises are characterized by a high level of uncertainty and dynamism, aggravation of competition and crisis tendencies. The mentioned negative phenomena have significantly worsened due to the full-scale invasion of Russian Federation on the territory of Ukraine, which led to emergence of both physical and economic threats, increase in resources prices, in particular energy prices [1]. Thus, today Ukrainian enterprises are being under simultaneous influence of the following crisis factors: war, the consequences of a global pandemic, economic and social disruption, a change in the industrial paradigm, a new model of world perception, etc. [2]. The mentioned factors significantly complicate and threaten the economic entities functioning. Within this context the issues related to ensuring the stability and efficiency of Ukrainian enterprises functioning under martial law conditions and during post-war recovery acquire special relevance. An important place in the system of tasks and instruments of ensuring the stability of economic entities functioning and confronting crisis phenomena belongs to economic security management. Economic security is a comprehensive characteristic of enterprise operation condition which reflects the resilience of economic entity in relation to the action of threats of various genesis. Efficient management of enterprise economic security is a prerequisite of its stability, competitiveness, and is a tool of ensuring sustainable development. The role of economic security is also determined by the fact that it is a key characteristic from the point of view of sustainable functioning and achievement of the necessary development indicators both at the level of individual business entities and at the level of the state [3]. Thus, solving the issue of ensuring the economic security of economic entities is also relevant from the standpoint of the state policy formation.

The food industry, in turn, plays an extremely important role both in the economy of Ukraine and in ensuring the population's food security [4]. In particular, 19.56 % of the total volume of industrial production in Ukraine in January-September 2023 is accounted for the food industry; food industry entities provided 3.62 % of jobs in 2022 [5]. At the same time, the crisis trends that Ukraine is suffering from as a whole have also affected the functioning of food industry enterprises. The presence of negative trends is evidenced by the fact that in 2022, 32.3 % of food industry enterprises suffered a loss, and in the formation of property only 30.0 % of the assets of enterprises were formed at the expense of their own funds (equity) [5]. These indicators reflect the need to develop and implement measures aimed at increasing the stability and economic security of food industry enterprises.

Considering the role of the food industry in the economy of Ukraine and in the sphere of forming food security of the population, ensuring stable and sustainable development of enterprises of the defined industry through the economic security management will contribute to the achievement of the goals of sustainable development, namely SDG 2 "Zero Hunger", SDG 3 "Good Health and Well-being", SDG 8 "Decent Work and Economic Growth" [6]. Thus, the chosen topic of research is relevant and does not raise any doubts in view of the presence of significant crisis trends and the role of the food industry in Ukraine's economy.

2. Literature review

The issues of economic security management acquired special relevance for the post-Soviet countries, that determines the corresponding interest in scientific society. A significant number of publications devoted to issues of economic security have been published by Ukrainian scientists. Thus, Kryshtanovych et al. [7] consider ensuring economic security through the prism of marketing activities in public administration. The authors emphasize the necessity of implementation of marketing approach in the public administration processes due to the advantages provided by such implementation. The study also provides a model of the hierarchy of factors of influence on the implementation of marketing in public administration in the system of ensuring economic security [7]. The mechanism of economic security management is considered in the research of Zachosova, Kutsenko and Koval [2]. Based on the identified shortcomings of traditional approaches to economic security management, the authors propose the key components of the appropriate mechanism, taking into account the existing trends and operating conditions of business entities. The main components of the economic security management mechanism include the following: digitalization, automation, information processing, project management, personnel management, communications, research and innovations, and stakeholders [2].

An important component of the economic security management mechanism is assessment system of its level. Vasyltsiv et al. [8] define the peculiarities of assessment, analysis and ensuring agricultural enterprises' economic and financial security. The authors substantiate the methodical approach to assessment of the level of economic security taking into account the comprehensive nature of the studied characteristic, and propose measures to stabilize economic and financial security of agricultural enterprises based on the calculations [8]. The peculiarities of assessment of economic security level are considered in the research of Onyshchenko et al. [9], the main focus of which is the study of financial and credit institutions. Economic security is proposed to be assessed with the use of a skoring approach. The advantage of the study is the combination of both quantitative and qualitative indicators for assessing the level of economic security of economic entities [9]. Zhytar et al. [10] offers an approach to diagnosing the level of economic security, considering its following components: resource, social, market, and innovation. The specified components are presented through a set of individual indicators, which enables a detailed analysis of the criteria and factors of economic security. Scientists determine group and integral indicators of economic security, which can serve as a basis for the development of managerial decisions in the specified sphere [10].

The issue of the relationship between economic security and information technologies, which is explained by the active processes of digitalization of economic relations, attracted considerable attention of researchers. In particular, Samoilenko et al. [3] focused attention in their research on digital transformation as a driver of changes in approaches to enterprise economic security management. According to researchers, the economic security of an enterprise includes three main components: economic independence, stability, and development. Special attention in the article was paid to issues of ensuring and assessing the level of digital security of the enterprise [3]. Implementing digital technologies in business activities is a powerful tool for ensuring economic security. A special role in this context is played by the spread of IT in product sales, that is, the development of e-commerce. Alazzam et al. [11] propose the formation of the model of e-commerce development, as a perspective direction of economic security ensuring. According to the authors, the implementation of the e-commerce concept in the business activity provides additional options for stabilizing and expanding the economic entity functioning. Thus, to provide a system approach to the e-commerce development Alazzam et al. form a conceptual model of the respective process which includes three functional blocks, such as reorganization of e-commerce, ensuring cybersecurity, and integration of e-commerce into logistics [11]. The important role of information technologies is also emphasized by Zwaid et al. [12]. The research is focused on implementing accounting information systems and information technology to support the economic entity sustainability. In the example of Iraq's economic units, the authors define key challenges to the functioning sustainability: lack of sufficient financing, high level of bureaucracy, which leads to the growth of unofficial illegal activities, inefficient management and marketing activities due to the lack of appropriate knowledge, lack of sufficient data [12]. Thus, rational implementation of IT can potentially benefit in addressing these issues.

One of the important and perspective directions of economic security formation is transition to circular economy foundations. Thus, according to Kuzior et al. [13] implementation of innovations related to energy and resource saving, waste-free production can significantly reduce threats to the functioning of industrial enterprises. The authors determine that implementing the circular economy positively impacts various components of economic security of enterprise: management system and organizational structure, HR-management system, financial and investment systems, production support system, marketing and logistic systems [13].

Issues related to ensuring the economic security of enterprises are thoroughly considered by scientists of both Ukraine and other countries. In particular, these are issues related to ensuring stable, sustainable functioning and managing the financial stability and efficiency of both individual enterprises and countries as a whole.

The importance of issues related to the formation of economic security at the national level determines the presence of a significant number of publications devoted to the formation of economic security / sustainable development of the country and/or region. In particular, Lepers and Serrano [14] study financial instability at the macroeconomic level, adapting the research methodology to emerging economies. Authors provide extensive research of vulnerabilities in emerging economies [14]. Serban and Jianu [15] consider the economic security of the country using five key dimensions: demographic, climate, globalization and ITC adaptation, social, and economic. Authors propose an economic and social security index which provides the opportunity not only to define the positions and perspectives of Euro-Atlantic area countries but also to determine the key factors of influence [15].

Economic security and stability are often analyzed in the dialectical relationship with the energy component. Banna et al. [1] examine the relationship between energy security and economic stability, considering the effects of inflation and war (Russian invasion of Ukraine in particular). The research is based on studying the dataset of 68 countries. The authors define economic stability with the indicator of GDP growth rate, thus performing a macroeconomic approach to the stability issues [1].

The financial component of enterprise economic security is revised in the research of Zwolak [16]. The author analyses the peculiarities of SME functioning in Poland considering the issue of the EU fund support. Financial stability is also reviewed by Pera [17]. The author states that sustainable development of the enterprise is based on its financial stability, which determines the relevance of the research. The formula of the sustainable growth model is provided in the research, based on the financial indicators of the enterprise [17].

The importance of the food industry enterprises efficient functioning determined considerable scientific interest to the issues related to ensuring stable functioning of the respective business subjects. Montenegro and Young [18] provided a literature review on the issues of operational challenges in the food industry during the COVID-19 pandemic using ScienceDirect website. The main challenges were defined by the authors based on the conducted research. The proposed methods for the defined challenges are also generalized in the article [18]. Arenovych [19] considers the basics of socio-economic activity of food industry enterprises activity management. The author necessitates the urge for rational formation and use of resources. The quantitative estimation of the influence of various factors on the efficiency of food industry enterprises functioning is provided [19]. The drivers of economic performance of food industry enterprises are reviewed in the research of Trnková and Žáková Kroupová [20]. On the basis of analysis of 468 companies representing different branches of food industry the scientists provided a detailed analysis of the enterprises performance indicators [20]. Boonklum [21] provided research on key success factors of the food processing industry. The author defined three groups of factors which are crucial to food processing enterprise competitiveness as follows: resources (human, physical, financial), capabilities (marketing, managerial and relationship, innovation), competitive advantage [21].

Sustainable operating of food industry enterprises is considered in research of Sandberg, Alnoor and Tiberius [22], and Venturelly et al. [23]. In particular, Sandberg, Alnoor and Tiberius consider the interrelationship between environmental, social, governance ratings (ESG), and financial performance in European food industry. The authors used least squares regression method for analysis and estimated that higher ESG ratings are related to better financial performance. That conclusion determines the necessity to take into account the necessity of social responsibility concept implementation in the activity of enterprises [22]. Venturell et al. conduct their research through the prism of open innovation. According to the authors, open innovations contribute to the implementation of sustainable practices in the activity of food industry enterprises [23].

While recognizing the significant scientific contribution of these and other scientists, we should note that certain issues related to the management of the economic security of food industry enterprises remain insufficiently covered, and therefore require additional research to ensure the sustainable development of economic entities.

3. Objective of the research

The main objective of the research is to determine the priority directions for increasing the level of economic security of food industry enterprises using internal factors and development drivers. The defined objective involves solving the following tasks: to identify the essence and key components of economic security; to consider the model of ensuring economic security; to analyze the indicators of economic security of food industry enterprises; to define key factors of influence on the formation of the economic security level; to propose the directions of increasing the level of economic security of food industry enterprises.

4. Methodology

The methodological foundation of the research is the system approach, which involves consideration of economic security management as a component of the general management system. In addition, the following methods were used during the research: monographic – to study scientific publications related to the economic security of economic entities; analysis and synthesis – to study the trends in the formation of indicators of economic security of food industry enterprises; correlation and regression analysis – to study the influence of factors on the level of economic security of food industry enterprises; generalization – to form research conclusions; deduction – to substantiate directions for increasing the economic security level of food industry enterprises; graphical and tabular – to visualize the research results.

5. Results of the research

Economic entities of the food industry create a substantial share of Ukraine's GDP, ensure population employment, and form the country's food security. Ukraine has rich potential for the development of the food industry because of available resources, lands, and the development of agriculture, which is a main supplier for food industry enterprises. Taking into account the aforementioned, ensuring sustainable development of food industry enterprises is an important direction of social and economic development of Ukraine. Considering the fact that sustainable development unites three key components, namely economic, ecological, and social, within the framework of this study, we find it appropriate to focus attention on the economic component, namely on the economic security of food industry enterprises.

The main indicators of food industry enterprises' activity are presented in table 1.

Table 1. Indicators of activity of food industry enterprises of Ukraine (according to the data of State Statistical Service of Ukraine [5]).

Indicator	Years					Deviation 2022 to 2018	
	2018	2019	2020	2021	2022	+/-	%
Volumes of sold products, UAH million	547365.7	571914.3	627520.2	769949.9	697233.4	149867.7	27.4
Number of active economic entities, units	14681	15309	15190	15109	13023	-1658.0	-11.3
Number of employees, persons	331261	331339	328475	321814	275009	-56252	-17.0
Net profit (loss), UAH million	9624.4	14705.8	-841.9	14149.6	3101.3	-6523.1	-67.8

According to the data presented in table 1, substantial negative trends are present in the activity of food industry enterprises. In particular, the decline of economic entities number by 11.3 % is observed in 2022 compared to 2018, which led to a decrease of employees by 56252 persons (17 %). The economic entities of the industry have formed net profit during the analyzed period (except for the 2020), however, there is a decline of net profit by UAH 6523.1 million or by 67.8 % in 2022 compared to 2018. The only indicator reflecting a positive increasing trend is sold product volumes (by UAH 149867.7 million or by 27.4 %). At the same time, we should note that one of the factors influencing the increase in volumes of sold products is the inflationary growth of prices for products of food industry enterprises (the inflation index in 2022 was estimated as 26.6 % [24]), so the specified increase is controversial.

Thus, the study of the main indicators of food industry enterprise activity in 2018-2022 provided an opportunity to reveal the presence of significant negative trends, primarily related to the full-scale invasion of the Russian Federation on the territory of Ukraine. According to Arenovych, the key factors of negative impact are the following [19]:

- decrease of raw materials accessibility;
- increase of the costs related to security providing;
- loss of markets;
- logistic processes efficiency decrease;
- personnel loss;
- changes in legal environment;
- consumers demand decrease.

The approach of Montenegro and Young to the definition of key challenges for food industry enterprises can also be applied to the realities of Ukrainian business subjects. The scientists specify the following challenges [18]:

- food safety – this challenge is totally applicable to Ukrainian enterprises as the war risks form a significant impact on both crop and livestock production (e.g., soil contamination, inability to comply with all safety requirements during production, etc.);
- production – is due to decreased resources accessibility, insufficient financial resources, physical threats;
- pricing – such a challenge is due to the decreased level of solvent demand of Ukraine population as well as to the population migration, including refugees to different countries;
- logistics – a lot of logistic chains were disrupted due to the war. Another issue regarding logistic is the essential increase in fuel prices which leads to enterprises costs increase;
- food systems survivability – defines all the risks and threats to the food industry enterprises functioning.

The presence of negative trends indicates the need to develop effective mechanisms for countering crisis phenomena and ensuring the stability and sustainability of the development of economic entities. We believe that one of the key such mechanisms is the management of the economic security of enterprises.

Economic security is a comprehensive characteristic of the enterprise activity, which defines its ability to ensure stable functioning and to confront threats. Economic security is a prerequisite for the development of economic entities, as it ensures the functioning stability and protection of economic interests, resources and rights, as well as the opportunity to confront external and internal threats [9].

The concept of economic security is very dynamic, as it is inextricably linked to the challenges of today [15]. In general, scientists define economic security as a state (a state in which balance and stability are preserved; a state of enterprise development; a state of the most efficient use of resources) or protection (of the business entity from threats, from the negative impact of the external environment).

To counteract the entire set of modern threats and ensure the necessary level of economic security, it is expedient to build a comprehensive system of economic security, for which it is necessary to fully utilize the resources of all structural divisions of the enterprise, as well as the capabilities of external stakeholders, including state authorities and management, subjects of the non-state security system [25]. Sustainable development, especially under modern functioning conditions, is related to the uncertainty of the situation, that is to the risk. Ensuring sustainable development is based on considering and predicting possible changes in the internal and external environment of the enterprise.

Economic security is formed as a condition which is achieved through the following functional goals:

- economic development (extended reproduction of the main business processes, namely innovative modernization of production, implementation of investment activities, development of intellectual potential, increase of competitive advantages in conditions of aggravated competition and uncertainty of the business environment, which ensures the achievement of quantitative and qualitative targets of the enterprise, etc.);
- financial and economic balance (balanced functioning at different stages of enterprise life cycle and in the cyclical conditions of economy, in particular ensuring sufficient financial stability and economic autonomy, maintaining an optimal capital structure, ensuring one's own financial interests and defined goals);
- managerial goal (ensuring the productivity of management, and formation of an effective organizational structure of enterprise management);
- personnel goal (implementing a proactive personnel management policy);
- ecological goal (compliance with the policy of sustainability in the process of minimizing the destructive impact of the results of production and economic activity on the state of the environment);
- harmonious and adaptive goal (flexible and harmonious interaction of the enterprise with the external environment for timely consideration of the influence of external environmental factors in order to maintain the internal balance of the functioning);
- information and security goal (building a legal, information and security environment based on high-quality legal protection, ensuring the protection of the information field, commercial secrets, and achieving a sufficient level of information support for the work of all units of the enterprise; effective organization of the security of the enterprise's personnel, its capital and property, and also commercial interests);
- economic freedom (synergy of economic self-sufficiency and responsibility: formation of high-quality resource potential of the enterprise and control over its rational use to achieve set goals in an unstable business environment).

On the basis of the aforementioned, we propose the following conceptual model of ensuring the economic security of the enterprise (figure 1).

The model of ensuring the economic security of the enterprise is presented by a holistic system through the set of interrelated elements (economic entities, subjects and objects of management, resources, technologies, business operations, innovative objects of activity), the entirety and interaction of which is oriented on achieving the sustainable development with the aim of preventing threats and dangers in the external and internal environments at the micro level (enterprise) and macro level (state).

Modern business functioning conditions characterized by the high level of complexity, volatility and exacerbation of crisis tendencies require adaptation of existing approaches to economic security management. According to Zachosova, Kutsenko and Koval the following characteristics should be inherent to the economic security management system: guarantees and flexibility; utility and rationality; activity and adaptability; resources and results; digitalization; information and innovation; automation and updating; non-linearity and independence [2]. Formation of the economic security management model taking into account the mentioned characteristics is a vital prerequisite for achieving the stability of functioning and sustainability of the development of economic entities.

Economic security significantly depends on the condition and dynamics of both external and internal environment [3]. Considering this, issues related to ensuring interaction with external environment acquire special relevance in the economic security management system. Ensuring interaction with the external environment should be provided through the appropriate mechanism, which includes economic, ecological, and adaptive instruments, which in their

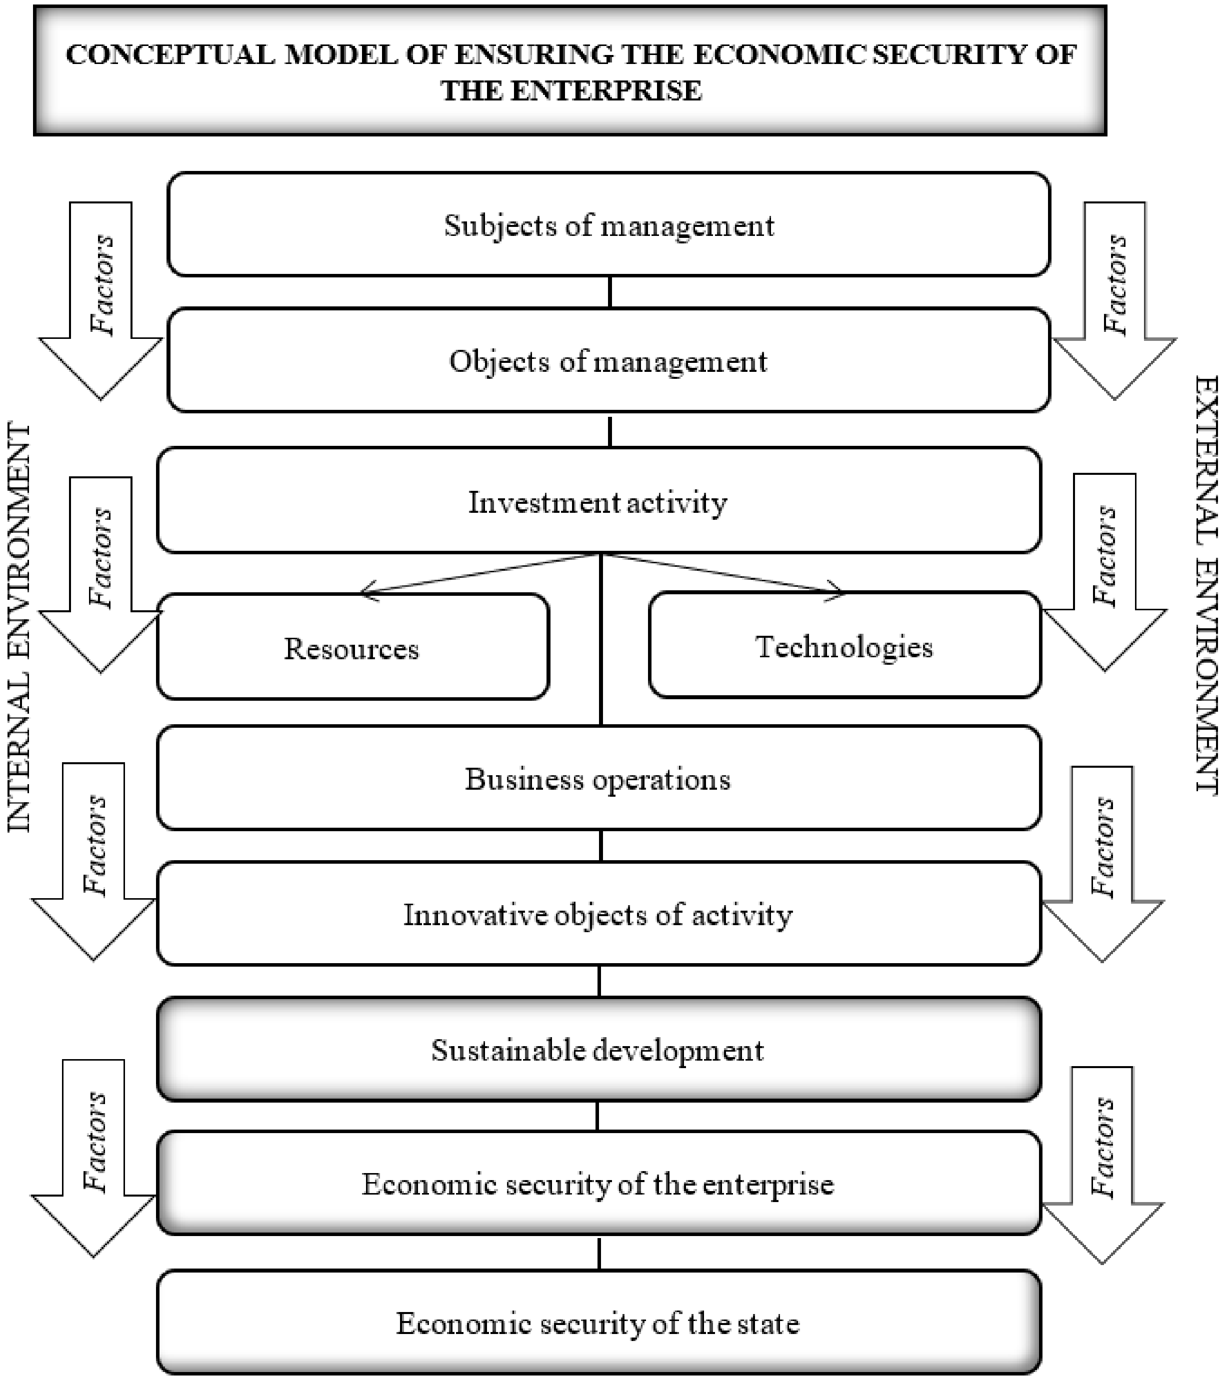

Figure 1. Conceptual model of ensuring the economic security of the enterprise.

entirety contribute to achieving sustainable development and a sufficient level of economic security [26]. Formation of the qualitative new system of interaction with stakeholders is also important in the context of ensuring economic security, that will provide effective communication and further interaction with stakeholders.

An important component for the management is the assessment of economic security level, considering the necessity of understanding the current condition, weaknesses, and potential threats in the enterprise activity. The complexity of the issues related to the assessment of enterprise economic security is due to the fact that the studied category is uncertain, dynamic, and comprehensive from the quantitative estimation standpoint [16]. As of today, there is a significant number of methods of assessment of economic security level. At the macroeconomic level, Lepers and Serrano define financial system stability using the vulnerability index [14]. Vasyltsiv et al. propose composite approach to the estimation of economic security level of agricultural enterprises considering the following elements: resources, investment, money and credit, debt, economy, insurance [8]. Kuzior et al. provide the approach to assessing the level of economic security using 3R model – Resource supply, Recycling, Results (effectiveness), which provides an opportunity for enterprise to define directions of economic security formation [13]. Onyshchenko et al. define economic security through the combination of quantitative (financial component) and qualitative (informational, marketing, personnel components) characteristics. For the assessment the scientists offer use of scoring approach which envisages calculating of points on the basis of assessment of economic entity activity indicators using Harrington scale [9]. An integral approach to the assessment of economic security level is proposed by M. Zhytar et al. The authors consider the following dimensions for determining the integral indicator of economic security of enterprises: resource, social, market, innovative [10].

Thus, we can conclude that today, there is a significant number of different approaches to the assessment of economic security level of economic entities, which is determined by the complexity and multifacetedness of this characteristic. With the aim of defining key factors of impact on the level of economic security and forming the respective propositions, we believe it is expedient to use an express approach to the estimation of conditions and criteria of economic security, which will be based on the limited range of the indicators of financial nature.

For a more detailed study of factors of the formation of food industry enterprises' economic security, we will analyze key indicators of economic security and stability of specific economic entities. Twelve enterprises were chosen for the research, representing different branches of food industry, namely: confectionery industry (PJSC "Vinnytsia Confectionery Factory", JSC "Zhytomyr Lasoshchi", PJSC "Kharkiv Biscuit Factory"), dairy industry (JSC "Zhytomyr Butter Plant", ALC "Yagotynsky Butter Plant", LLC "Loostdorf"), meat processing industry (LLC "Saltivsky Meat Processing Plant", LLC "Hlobyne Meat Processing Plant", ALC "Meat Processing Plant "Yatran"), bakery industry (PJSC "Concern Khlibprom", LLC "Kyivkhlib", LLC "Mykolaiv Bakery № 1"). The choice of the enterprises is determined by the following:

- the enterprises proposed for the study represent the most important branches of the food industry;
- financial reports of the specified enterprises are in public access, which makes it possible to obtain and use data necessary for calculations;
- the enterprises represent different regions of Ukraine, which provides an opportunity to realize a comprehensive approach within the research.

We propose to identify the key factors of the formation of economic security using correlation and regression analysis, which provides an opportunity to determine the relationship between dependent variable and independent variables. The economic security coefficient was chosen as a dependent variable (Y) which in its essence represents the difference between actual and breakeven volumes of enterprise activity. We believe that the choice of this indicator as a dependent variable is substantiated from the standpoint of the necessity to provide enterprise activity profitability, as well as to form a reserve of financial sufficiency for countering crisis phenomena.

We will base the determination of the factors of influence (independent variables) on the level of economic security on financial indicators since the financial component of economic security is one of the most important from the point of view of ensuring sustainable development. Business entities seeking to implement the principles of sustainable development in their activities must be financially stable because financial stability is the basis for ensuring continuous functioning [17].

As the independent variables the following indicators were chosen:

X_1 – net revenue growth rate, coef.;
X_2 – net profit growth rate, coef.;
X_3 – equity growth rate, coef.;
X_4 – autonomy coefficient, coef.;
X_5 – coefficient of financial self-sufficiency, coef.;
X_6 – current ratio, coef.;
X_7 – cash ratio, coef.;
X_8 – return on sales, coef.;
X_9 – economic activity profitability, %;
X_{10} – ratio between receivables and payables, coef.

The choice of the independent variables was determined by the following:

- the chosen indicators reflect the most important characteristics of the financial state of the enterprise, which, in its turn, significantly defines the economic security level;
- the growth rate indicators characterize the enterprise ability to ensure stable development and sustainable functioning;
- utilization of ratios makes it possible to compare enterprises with different scale of activity;
- the defined indicators can be calculated on the basis of public financial statements data which provides accessibility of data for calculations and further analysis.

Calculations for the analysis will be carried out for 2020-2022, which will make it possible to determine the key trends in the functioning of food industry enterprises. The total number of observations is 36, which ensures the representativeness of the raw data for correlation and regression analysis.

The initial data for the analysis are presented in table 2.

In general, based on the results of the analysis of the calculated data, we can draw the following conclusions regarding the trends in the functioning of the food industry enterprises of Ukraine:

- in the activities of a significant number of enterprises (6 out of 12 studied), there is a decrease in the level of economic security in 2022 compared to 2020. Taking into account the fact that in 2020 crisis phenomena related to the COVID-19 pandemic were observed, such trends are extremely threatening from the point of view of ensuring the stability of functioning and sustainable development of economic entities;
- a large part of the enterprises is characterized by a low level of financial stability, which is manifested in a significant share of financing at the expense of liabilities;
- with a mostly sufficient level of general liquidity, a low level of absolute liquidity is observed, which indicates a lack of cash in the activities of food industry enterprises;
- in the activity of a significant number of enterprises from among those studied, there is a decrease in the level of profitability of economic activity in 2022 compared to 2020. Thus, in general, we are talking about a trend towards a significant decrease in the efficiency of food industry enterprises.

Table 2. Initial data for correlation and regression analysis of food industry enterprises (based on public reporting data [27]).

To identify the key factors when building the model, the next step will be an analysis of the presence of relationships between factor characteristics, that is, a multicollinearity test. For calculations, we will use the built-in MS Excel data analysis package. The results of the analysis are given in table 3.

According to the calculations, we should note that the relationships of varying degrees of influence are determined between the dependent variable and independent variables. The most significant is the relationship between the coefficient of economic security (Y) and the profitability of economic activity (X_9), which is quite logical given the peculiarities of calculating the coefficient of economic security. A significant relationship is also observed between the dependent variable and the net profit growth rate (the linear correlation coefficient is 0.62). The relationship with variables X_6 (current ratio) and X_7 (cash ratio) is also significant. At the same time, we should note that factors X_6 and X_7 are multicollinear, i.e. interdependent, therefore, it is not appropriate to include both factors in the model. As the linear correlation coefficient of X_6 factor is 0.46 and the respective coefficient of X_7 factor is 0.5 we can conclude that the relationship of X_7 factor with the dependent variable is more significant. Thus, we should exclude X_6 factor from the consideration. So, for the further construction of the model, we use three factors: X_9 – profitability of economic activity, X_2 – net profit growth rate, X_7 – cash ratio. Based on the results of the regression analysis, the following equation was formed:

$$Y = -0.0065 + 0.0192X_2 + 0.0271X_7 + 0.0418X_9, \quad (1)$$

where Y – economic security coefficient, coef.; X_2 – net profit growth rate, coef.; X_7 – cash ratio, coef.; X_9 – economic activity profitability, %.

According to the regression equation parameters, the determination coefficient $R^2 = 0.84$; that is, 84 % of the variance of the values of the dependent variable (economic security coefficient) is explained by the obtained equation. We believe that the rest of the dependent variable volatility is explained by the impact of external environment factors. According to the results of the F-test (Fisher's test), the constructed model is considered adequate for the sample data because $F_{fact}(55.09) > F_{crit}(2.9)$ (with a probability of error of 0.05).

Thus, based on the conclusion about the adequacy of the built model, we can determine the priority directions for increasing the level of economic security of food industry enterprises:

- ensuring high growth rates of net profit;
- increase in the level of absolute liquidity;
- increase in the level of profitability of economic activity.

It is worth noting that measures aimed at ensuring high growth rates of net profit and increasing the level of profitability are compatible, because net profit is one of the factors in determining the level of profitability of economic activity. Therefore, it is advisable to reduce the key measures for increasing the level of economic security to two directions. Let's consider them in more detail.

1. *Increasing the efficiency of economic activity.* This direction will contribute both to ensuring high growth rates of net profit and to increasing the level of profitability of economic activity. When determining measures to increase the level of the enterprise profit, it is advisable to take into account the factors influencing the formation of the financial result. In particular, Pavlyuk proposes to divide the relevant factors into external, that is, those that have a source of genesis outside the enterprise and are uncontrollable from the point of view of the management of the business entity, and internal, which have a source of origin within the enterprise. In addition, the scientist proposes to divide internal factors into non-productive and productive (extensive and intensive) [28]. Another perspective for increasing the efficiency involves technical and scale efficiency, and technological change [20]. The strategy and individual measures to increase the profit level of food industry enterprises should be formed taking into account the relevant factors in order to achieve the target result.

   Within the framework of this direction, we consider it expedient to propose the following measures:

   1.1. *Search for new sales markets and diversification of activities.* These measures are aimed at increasing the income level of food industry enterprises. The war on the territory of Ukraine has significantly affected the logistics and sales conditions of enterprises, placing special emphasis on the need to review existing and form new economic ties. In particular, reorientation to other segments of the domestic market and/or search for foreign partners is possible. Taking into account the processes of globalization and digitalization, the search for foreign partners is significantly simplified. For example, in June 2017, Ukraine joined the European Enterprises Network [29], a business network that facilitates partnerships and consortia in business. With the help of the appropriate resource, Ukrainian business can search for requests and / or create proposals for foreign business partners.

   Diversification of activities through the introduction of new types of products is also an important component of this measure. Taking into account the above proposal regarding the search for foreign partners, it is expedient for food industry enterprises to consider expanding the assortment with those types of products that, firstly, will meet the requirements and standards not only of Ukraine, but also of other countries, and secondly, will be suitable for long-term storage and transportation.

   1.2. *Expanding the presence of enterprises on the Internet.* Today, the world as a whole and Ukraine in particular have already entered the era of digitalization, which puts forth appropriate demands for digitalization of economic and social relations. Ukraine has significant achievements in this area that contribute to business development, for example, the Diia.Business service, a large-scale national project for the development of entrepreneurship and exports, initiated by the Ministry of Digital Transformation in February 2020 [30]. At the same time, it is worth noting that at the level of individual business entities, the problem of representation in the digital space remains relevant. Positive developments in this area are evidenced by the fact that all 12 studied enterprises have their own websites, where consumers can familiarize themselves with the range of products and key information about business entities. At the same time, only 3 enterprises have online stores: PJSC "Vinnytsia Confectionery Factory"; JSC "Zhytomyr Lasoshchi"; ALC "Meat Processing Plant "Yatran" (delivery only in Kyiv is possible). It is clear that the products of food industry enterprises have their own specifics, which limits the possibilities for their sale through online stores (for example, storage periods, the need to keep the temperature regime during transportation, etc.), however, in our opinion, at least partial use of e-commerce could stimulate sales. Options of such partial use include the geographical localization of product sales (an example is the online store of ALC "Meat Processing Plant "Yatran") or the limited range of products that can be purchased through the online store.

1.3. *Optimization of economic activity costs.* This measure is the most complex and the most difficult at the same time, considering the variety of costs which are formed in the enterprise activity. Thus, the most expedient way of this measure implementation is the conducting an in-depth analysis in order to identify non-productive costs and to direct measures to the relevant specific costs of the enterprise. In the most general form, reducing the costs of economic activity can be achieved with the help of the following steps [31]:
    - control of the amount and processes of cost formation for each element of the value chain;
    - improvement of the value formation chain by elimination of non-productive and excessive costs;
    - economy of scale;
    - effect of experience.

    At the same time, we consider it expedient to emphasize the fact that specific measures to optimize costs depend significantly on what costs they are aimed at (for example, costs for energy supply, raw materials, labor costs, etc.).
1.4. *Implementation of corporate social responsibility (CSR) concept in the enterprises management system.* As Sandberg, Alnoor and Tiberius found in their research, the financial performance of food industry enterprises is under positive impact of ESG (environmental, social, governance) ratings. The companies with high level of CSR development tend to have a better financial performance [22]. Within this context we believe that it is expedient to implement sustainable practices in the activity of food industry enterprises. Such sustainable practices may include the following:
    - to implement open innovations in order to promote sustainability in functioning of the food industry enterprises [23];
    - to increase the food safety management through the implementation of appropriate systems and techniques (e.g., HACCP system);
    - to ensure compliance with the rights of employees and other stakeholders;
    - to implement an effective waste management system which will provide for decrease of pollution and minimize negative impact on environment;
    - to improve resource management in order to optimize the amount of used in the activity resources;
    - to support personnel and local communities with various programs.
1.5. *Increasing the level of enterprise competitiveness.* The enterprise competitiveness reflects its capacities to participate in competition relations, thus, to operate efficiently in the market. So, there is mutual relationship between the efficiency of economic activity and the level of competitiveness. According to N. Boonklum, the key success factors for boosting the competitiveness level are the following: resources (human, physical, financial), capabilities (marketing, managerial and relationship, innovation), competitive advantage [21].

2. *Increasing the level of absolute liquidity.* The cash ratio is important from the point of view of ensuring stability and solvency of any enterprise. In particular, it indicates what share of current liabilities the company is able to repay with the help of available highly

liquid assets. According to the table 2 we should note the negative situation in the field of formation of liquidity indicators of food industry enterprises. In particular, only PJSC "Kharkiv Biscuit Factory" and LLC "Loostdorf" are distinguished by a high level of absolute liquidity during 2020-2022. Two more enterprises (JSC "Zhytomyr Butter Plant" and ALC "Meat Processing Plant "Yatran") achieved a sufficient level of absolute liquidity in 2022. At the same time, the other 8 enterprises throughout the entire period under study are characterized by a low or even zero level of absolute liquidity, which determines the relevance of this direction of increasing the level of economic security. We believe that in order to increase the level of absolute liquidity, it is advisable to implement the following measures:

- optimization of stocks with the aim of freeing up cash to increase the level of absolute liquidity;
- implementation of advanced inventory management systems (for example, ERP systems, just-in-time, lean production, etc.);
- optimization of receivables with the allocation of overdue and bad debts and the application of the factoring procedure to transfer part of the debt into cash;
- improvement of payment discipline in order to avoid the accumulation of a significant amount of receivables;
- optimization of current debt through the maximum possible use of long-term borrowed capital instead of short-term;
- reduction of the duration of the operating cycle. This measure is related to the aforementioned as the duration of the operating cycle depends on the period of turnover of stocks as well as on the period of receivables turnover. Thus, the following steps can be taken in this sphere: implementation of economically substantiated stock norms; compliance with the principle of optimal price-quality ratio when forming stocks; improvement of logistics management and sales policy of enterprises; intensive reproduction of the elements of the enterprise potential; active introduction of aspects of the circular economy; effective management of receivables; building a rational system of interaction with banks regarding the attraction of funds and the implementation of settlements, and the implementation of optimal credit policy; constant monitoring and improvement of the company's settlement system [32].

If to apply the mentioned measures from the proposed approach standpoint to the activity of specific enterprises, we can conclude the following. The priority measures for enterprises with the decline in the level of economic security in our opinion should be the following:

- PJSC "Vinnytsia Confectionery factory" – increasing the efficiency of economic activity, which may include the following measures: optimization of economic activity costs, increasing the level of corporate social responsibility;
- JSC "Zhytomyr Lasoshchi" – increasing the efficiency of economic activity: search for new sales markets, optimization of economic activity costs, increasing the level of corporate social responsibility;
- LLC "Saltivsky Meat Processing Plant" – increasing the efficiency of economic activity and of liquidity: search for new sales markets, expanding the presence on the Internet, optimization of economic activity costs, increasing the level of corporate social responsibility; optimization of stocks, reduction of duration of the operating cycle;
- LLC "Hlobyne Meat Processing Plant" – increasing the efficiency of economic activity: search for new sales markets, expanding the presence on the Internet, optimization of economic activity costs, increasing the level of corporate social responsibility;
- ALC "Meat Processing Plant "Yatran" – increasing the efficiency of economic activity: search for new sales markets, optimization of economic activity costs, increasing the level of corporate social responsibility;

- PJSC "Concern Khlibprom" – increasing the efficiency of economic activity: search for new sales markets, optimization of economic activity costs, increasing the level of corporate social responsibility;
- LLC "Kyivkhlib" – increasing the efficiency of economic activity and of liquidity: search for new sales markets, expanding the presence on the Internet, optimization of economic activity costs, increasing the level of corporate social responsibility; optimization of stocks, reduction of duration of the operating cycle.

As for the enterprises with the increase in economic security level priority steps can vary, but the main stress should also be put on the increasing of efficiency, and liquidity.

The given list of measures is not exhaustive and can and should be specified taking into account the peculiarities of the activity and the structure of the balance sheet of a particular business entity.

6. Conclusions

As a result of the conducted research, we can conclude the following.

1. The food industry plays an extremely important role in the economy of Ukraine, which is explained both by its contribution to the total volume of manufactured industrial products and by its importance from the point of view of food security formation. At the same time, food industry enterprises are characterized by negative trends, which are manifested in the reduction of the number of economic entities, as a result – a decrease in the number of employees and a significant decrease in net profit. The above determines the expediency of finding effective solutions to increase the level of economic security of food industry enterprises as a way to ensure the sustainable development of economic entities.
2. Economic security is a complex characteristic of an enterprise's activity, which determines its capabilities to ensure the stability of functioning and to counter threats. The functional areas of manifestation of economic security include economic development, financial and economic balance, management, personnel, environmental, adaptive, information and security components, and economic freedom.
3. A conceptual model for ensuring the economic security of the enterprise was proposed, which is based on the active implementation of investment activities, covers economic operations, and innovative objects and promotes the sustainable development of the enterprise. The key characteristics that should be inherent in managing the enterprise's economic security were determined.
4. In order to identify factors influencing the formation of food industry enterprises economic security, an analysis of key financial indicators affecting the formation of stability and development prospects of economic entities was carried out. The corresponding analysis was carried out on the basis of data from the financial statements of 12 enterprises representing various branches of the food industry for 2020-2022. As a result of the study, it was found that 6 enterprises out of 12 studied are characterized by a decrease in the level of economic security and profitability, and a significant number of business entities have low levels of financial stability and absolute liquidity.
5. In order to define the influence of the considered indicators on the formation of the level of economic security of food industry enterprises, the factors characterized by the highest influence on the dependent variable (coefficient of economic security), namely the net profit growth rate, the cash ratio, the profitability of economic activity, were identified using correlation analysis. With the help of regression analysis, a linear model of the dependence of the coefficient of economic security on the specified factors was built, which made it possible to propose key measures to increase the level of economic security of food industry enterprises.

6. The practical implementation of the developed approach implies definition of the particular set of measures for food industry enterprises in order to ensure the increase of the economic security level, defined on the basis of the analysis results. It was determined that the main measures to increase the level of economic security should be aimed at increasing the efficiency of economic activity (the search for new sales markets and diversification of activities; expanding the presence of enterprises on the Internet; optimizing the costs of economic activity; implementation of the CSR concept in the management system; increasing the level of enterprise competitiveness) and increasing the level of absolute liquidity (improvement of stocks and receivables management; optimization of current payables). If to specify the measures for the analyzed enterprises, we can propose the following: the priority steps for PJSC "Vinnytsia Confectionery factory", JSC "Zhytomyr Lasoshchi", LLC "Hlobyne Meat Processing Plant", ALC "Meat Processing Plant "Yatran", PJSC "Concern Khlibprom" should be oriented at increasing the efficiency of economic activity. LLC "Saltivsky Meat Processing Plant" and LLC "Kyivkhlib" should also pay massive attention to the measures aimed at increase of liquidity level.
7. Prospects for further research are in the field of substantiating strategies for managing the economic security of food industry enterprises using a matrix approach and forming a specific set of tools for managing the economic security of food industry enterprises.

Abstract. This article is devoted to the refinement of factors determining the structure of Ukrainian households' consumption spending and approaches to interpretation of shifts in such structure in context of population well-being. It contains analysis with using indexes of real volume of consumption, combined with the localization of causes determining fluctuations in relative prices by commodity group. The results of such analysis should create preconditions to clarify the contribution of certain industries and commodity groups in the dynamics of consumer welfare. For estimating the income and price elasticity of consumption by wide aggregated commodity groups the linear modeling was used. Authors have used quite simple linear additive function, the first element of which is close to Working function, and the second – a very simplified replacement of Theil proposed mathematical tools for incorporating relative prices into mentioned model. The elasticity coefficients, calculated on basic our model were compared with coefficients obtained by Seale Jr. and Regmi [1]. For five commodity categories, we also compared the actual indices of real changes in quantity of consumption with similar indicators, which were calculated on basis the elasticity coefficients, obtained in our and mentioned works. Elasticity coefficients are designed by Seale Jr. and Regmi [1] for "Food" and "Furnishings, household equipment and routine maintenance of the house" have demonstrated quite good explanatory power. But estimated figures for both models clearly deviate from the actual values, which were observed for "Clothing and footwear", as well as for "Housing, water, electricity, gas and other fuels". At last, we try to explain the causes determining such deviation of actual scale of consumption comparing with calculated on basis elasticity coefficients and create precondition for better understanding connection of observed change in consumption of such commodity group with level of population's well-being.

1. Introduction

The improvement of analytical tools for the estimation of the population's well-being is a significant precondition for the development of any state policy: it provides feedback and information about how the certain policy implementation affects the living conditions characteristics of the policy's target group. At the same time, the approaches to the quantitative assessment of the well-being aggregate function, or individual components of well-being, remain a promising field of scientific research. In the focus of our article is the connection between shifts in consumption behavior, in the structure of households' spending, and price/income elasticity of certain commodities demand – as factors and economical well-being of the population – as a dependent variable. The aim of this article is to clarify to what extent analytical tools that demonstrate a good explanatory power regarding changes in consumer behavior and well-being in conditions of long-term growth of real incomes of the population remain relevant in conditions of stagnation or even a reduction in the purchasing power of households.

2. Literature analysis

The vast majority of current research in consumer spending of households has considered them as a dependent parameter, reflecting the impact of factors, among which there are almost always two mandatory: income (sometimes – the total expenditure) of households and relative prices by commodity groups. Specificities of the individual studies are largely linked to choice of additional factors, included in the model and structure of mathematical tools, used for the simulation. The similar generalizations is contained in the [2]: "The predominant method used in applied studies of demand has been the demand systems approach, in which a system of equations is used and the dependent variable is household spending on a particular good (usually expressed as a budget share), while the independence variables are the relative prices of other goods, household income (discussed below) and the household's demographic characteristics. The core theory underpinning this approach is based on a view that these expenditures are an outcome of a single, representative household that maximizes its utility in each period by spending on the observed categories according to a linear budget constraint".

Such researches are based mainly on the works of Theil, Slutsky, Working, Hicks, which have been transformed into such prevalent tools as multistage budgeting, model Florida-Preference Independence (PI) and Florida-Slutsky model. Illustrative examples of such tools' application for the study of national consumption patterns and their comparative analysis are given by works [1, 3, 4].

The results of these studies have confirmed that levels of income and relative prices have high explanatory power regarding the differentiation of consumer spending patterns of households around the world. The results obtained have high value in the context of explaining consumer response to fluctuations in relative prices and income (through evaluation the relative prices and income elasticity of demand for different product groups) as well as in the context of predicting potential of growth for each industries, which are determined by patterns of consumer spending (as a significant component of aggregate demand).

However, panel studies which were conducted with using a broad base of national data, have ignored specific of national mechanisms for rationing access to goods, such as the role of governmental suggestion of free goods and services, the national rules and regulations of interaction between producers and consumers and many others. In the most abstract form, our idea may be expressed as: to supplement the panel research with studies of household spending patterns in some national circumstances, taking into account the impact of the free offer of goods and government subsidies to households. In addition, we want to try to estimate the impact of specific national institutions that govern individual or collective (in respect of goods, consumption of which are the result of collective choice mechanisms) consumer behavior.

Proposed research may serve as a complement for global panel models (through defining the mechanisms of manifestation the general laws of consumer behavior in certain national conditions) and clarification of "trajectories", "scripts", under which global patterns of consumer behavior appear in certain national economy. For investigation the connection between changes in consumption patterns and levels of household wealth commonly are using practically only two principles.

The first thesis that households with relatively lower income are characterized by relatively lower diversification of consumer spending, primarily because they spend relatively more of their income on food. This thesis was confirmed by numerous empirical studies since classic Engel's works, to a recent models of consumer behavior: the share of expenditure on food (expressed by proportion of expenditure on food to income) tends to decrease with income growth [2, 3, 5, 6].

A second thesis (in work [2] – basic stylized fact): income growth is accompanied by increasing diversification of consumer spending, and a leading role in this process plays reducing the share of expenditure on food. The most radical expression of this thesis was the "strong" wording of Engel's Law, "doubling the income of a typical (representative) household is accompanied by a decline in the share of household expenditure on food by 10 percentage points" [7].

Such diversification is associated with extension of consumer's choice and enhancement well-being of typical subject of demand. For example, in [5] the proverb is quoted that "variety is the spice of life" and growth of consumer's spending diversity is considered like manifestation of economic opportunities extension in consumers behavior.

We propose to use assessment of the real change in amount of consumption and relative prices to determine the "scenario", under which the changes of spending proportion occurs and refine their impact on public welfare. So increase of expenditure on a commodity group may reflect the result of lower its relative prices, accompanied by elastic expansion of demand, as well as the result of relative price increase, in conditions of price inelastic demand on this commodity group. Clearly, these two scenarios will have different effects on the welfare and conditions of reproduction of the human potential of society. Clearly, these two scenarios will have different effects on the welfare and conditions of reproduction of the human potential of society, similar views can be seen in [8].

In turn, in the context of assessing the contribution of a branch in changing of consumer welfare, the combination of reduction in the relative price with elastic expansion in demand may be a result of increasing production capabilities, which ensured the growth of commodity group availability as well as be caused by substitution of higher quality (and expensive) by goods of less quality (and cheaper). The latter result can be provided by changes in structure of import due to changes in the national currency, or by large-scale government programs to support production that diverted resources away from solving other social issues. It is clear that the assessment of social outcomes from the industry in the first, second and third cases will be different.

That is why we consider it useful to create analytical instruments for deeper understanding of the relationship between changes in the structure of consumer spending – on the one hand, and shifts in the level of welfare; distribution of burden and gain from fluctuations in relative prices between social groups; changes in the availability of various goods and services for the "representative" household – on the other.

For that we propose the following direction of development the common approaches [6, 9] to analyzing the structure of consumer spending.

1. Supplement the analysis and modeling of the structure of consumer spending with using share of commodity groups in the consumer budget by analysis with using indexes of real volume of consumption, combined with the localization causes of fluctuations in relative prices by commodity group. The result should create preconditions to clarify the contribution of certain industries and commodity groups in the dynamics of consumer welfare.
2. For the goods categories, have been produced with a large-scale government supplement of private suggestion, we proposed to study the dynamic of real volume of consumption and relative prices, coupled with changes in the principles, objectives, priorities and levers of government policy in coinciding sectors of economy. It should promote to clarify the evaluation of government programs due taking in account the rate of growth consumption and availability of goods and services for different segments of the population.

This article contains only the first attempt to apply described above approaches to study the structure of household expenditures. Clearly insufficient authors experience in conducting researches under recent methodological frame allowed them to build only initial variant of statistical database and tools for modeling. Our mathematics tools and structure of this database doesn't allow yet obtain a complete solution of formulated above problems. However, we hope that even this issue, made with very simplified analytical tools, may substantiate perspective of the proposed direction, and notice from our more experienced colleagues will help us to improve research tools.

In the article we will try to explain the changes in the consumption pattern of households based on the "canonical" idea about the dominantly influence of two factors: the total level of spending and relative prices. We also try to show the limitations of this explanation and offer first step to specify the causes of fluctuations in real amount of consumption of some goods categories – not only as a result of consumer choice, but in the context of consumer interaction with manufacturers and impact of government programs and regulatory frames.

3. Methods

We proposed for modeling quite simple linear additive function, the first element of which is close to Working function, and the second – a very simplified replacement of Theil proposed mathematical tools for incorporating relative prices into mentioned model [7]. Suggested approaches to modeling are differ by using cumulative rate of growth amount of consumption as the dependent and cumulative rate of growth total spending and relative price as explanatory variables. The dependent variable Y_i – cumulative growth rate of amount of consumption for goods category i; explanatory variables X_1 – cumulative growth rate of real total consumption spending; X_{2i} – cumulative growth rate of relative prices for the goods category i.

This function is expressed as:

$$Y_i = a_0 + a_1 * X_1 + a_2 * X_2, \tag{1}$$

where a_0 – absolute term in function, expresses growth rate of consumption of goods category "i" which are independent from factors involved in function; a_1 – coefficient of variable "cumulative growth rate of real total consumption spending", reflects marginal growth of quantity consumed of goods category "i" in response to growth total spending; a_2 – coefficient of variable "cumulative growth rate of relative prices for the goods category "i", reflects marginal growth of quantity consumed of goods category "i" in response to growth this goods category relative price.

For such database the first order derivative is annual mean growth rate of quantity consumed of goods category "i" during the retrospective period. The partial derivative by first explaining variable is annual mean growth rate of quantity consumed of goods category "i", caused by changing of real total consumption spending. The partial derivative by second explaining variable is annual mean growth rate of quantity consumed of goods category "i", caused by changing of relative price that goods category.

We used growth rate of total consumption expenditures but not their absolute size as the first explanatory variable, then logarithmic (traditional for such models) form of expression aggregate spending in function is not used.

Estimation of model parameters was obtained by first method of least squares (1LSM).

Matrix of estimates of model parameters was determined based on the equation [10]:

$$A = (X^T X)^{-1} X^T Y, \tag{2}$$

where X – matrix of explaining variables; X^T – transposed matrix of explaining variables; Y – matrix of dependent variables.

For estimating the own price elasticity and total consumer spending elasticity we have calculated the corresponding coefficients for all commodity categories.

For this, we used the following formula:

$$E_i = \frac{a_i * x_i}{Y_i},$$

where E_i – explaining variable “i” elasticity of dependent variable; x – average (geometric mean) value of explaining variable; Y – average (geometric mean) value of dependent variable.

The initial data was obtained on the official website of the State Statistics Service of Ukraine [11].

Ukrainian households’ consumption spending were used as an initial characteristic for database formation. Such indicators reflect the average (over the year and across all Ukrainian households) size of consumption spending in monthly dimension per household [12]. So, the one observation (one position in the dynamic series) – is the average monthly expenditures of Ukrainian household for a certain commodity for a certain year. To build the database, all nominal indicators are calculated in real dimension using aggregate consumer price indices (the price indices for each commodity group were used [13]). In the next step, to form the model database, all absolute real indicators were recalculated into base growth rates (2005 was used as the base year). As a result, the dynamics series, used for modeling characterize relative changes, that occurred during the retrospective compared with 2005: 1) the real size of consumption spending on a certain commodity; 2) relative prices of a certain commodity; 3) the total size of consumer expenditures of households;

The retrospective period is limited to 2017 for a number of reasons. First, by striving to ensure the correctness of data comparison with research, which is chosen as a basis for comparison [1]. Secondly, by the necessity to ensure qualitative homogeneity of the series of dynamics. We take into consideration that since 2019 the method of forming sample population for conducting sample surveys of the households’ living conditions, which serve as a source of data for the [12], was updated.

4. Results

The calculation results for the major (by share in consumption spending) goods categories are shown in table 1.

The small number of observation (only 12 for each commodity category) does not allow as consider modeling results as reliable. But if the low reliability is caused only by insufficient number of observations such problem may be simply eliminated in our farther researches.

All calculated functions show relatively high significance of estimated parameters. In particular, the determination coefficients are ranged from 0.616 (for alcohol and tobacco) to 0.978 (for health care), while for five of the eight commodity categories R^2 size exceeds the value of 0.9. For all product categories except one value of Fisher factor is higher than critical (tabulated point).

For example, the determination coefficient of function food real quantity consumed dependence on total spending and relative price indicate that up to 97% variation of dependent variable is determined by the variation of factor variables and the value of Fischer factor (114.84) is much higher than critical, which allow consider the coefficient of determination as not random. Value of Durbin-Watson test (1.8, i.e. in the range from 1.5 to 2.5) allows accept the hypothesis of no autocorrelation of deviations, and the size of t-test for all parameters of model indicates the significance of their differences from zero.

Six of the eight functions have “classic” signs of parameters: positive under the growth rate of real consumption spending and negative – under the growth rate of relative price. Two functions (clothing and footwear and healthcare) have negative coefficients at both explaining variables, and significance of parameter at total spending in function of clothing and footwear quantity consumed is low (the standard deviation exceeds the parameter value more than 17 times – table 1).

This negative sign of coefficient on the variable “growth rate of real total consumption spending” is predetermined by specificity data for 2014 – 2015 years, where the dynamics of real total consumer expenditure has become a pronounced negative, but the quantity of clothing and

Table 1. Parameters estimated and their significance for eight commodity categories which have greatest specific weight in consumption budget of Ukrainian households.

Commodity group	Food	Housing, water, electricity, gas and other fuels	Clothing and footwear	Healthcare*	Alcoholic beverages, tobacco	Transport	Communication	Furnishings, household equipment and routine maintenance of the house

* – Note, that methodology of Ukrainian statistic does not take in account the public spending on health and education, that does not allow to compare domestic Ukrainian data with data ICP.

footwear consumed continued to grow quite steadily. Thus, during 8 years out of 10 included in the database, the size of the real total consumption expenditure and quantity of clothing and footwear consumed showed a kindred trend, and only a sharp distinction in 2014 – 2015 caused the negative sign of coefficient at total spending variable.

The trend in real quantity of consumption commodity category "Healthcare" was mainly formed by events of 2008. In conditions of rising real total consumer spending and a radical increase in the relative price of this commodity group (since 92% of the 2005 level till 822.3%) occurred falling quantity of consumption this goods category since 120% of 2005 till 17.36%. After this the scale of consumption this commodity category remained weakly sensitive to fluctuations in total consumer spending and relative prices.

Such a rapid rise of relative prices and falling of quantity "healthcare" consumed forced us to seek an explanation primarily in the methodology of obtaining source database, particularly in procedures of assessment prices and quantity consumed of medical services. Such searches could be subject to further researches on the structure of Ukrainian households' expenditures.

The high total expenditure and own price elasticity of real quantity food consumed (table 2) indicates that consumption patterns of Ukrainian household are the same with the low-income countries. The first (high spending elasticity) directly indicates a low level of satisfaction even the basic needs of Ukrainian households and as a result – minimal opportunities for households to allocate own resources on consumption of commodity groups, which are more related with improving the educational level and health care quality, increasing of access to modern communications and integration into the mechanisms of social interaction.

Table 2. Spending and own price elasticity for eight prominent commodity categories in total spending of Ukrainian household.

Commodity group	Spending elasticity	Own price elasticity
Food	0.842	-1.202
Clothing and footwear	1.173	-0.623
Furnishings, household equipment and routine maintenance of the house	0.839	-0.376
Housing, water, electricity, gas and other fuels	0.288	-0.395
Health	-0.282	-2.570
Transport	1.254	-0.236
Alcoholic beverages, tobacco	0.737	-0.094
Communication	0.180	-1.074

Second (significant own price elasticity) indicates high households vulnerability on fluctuations in relative prices and incomes. Even minimal adverse changes in market conditions, or deprivation from government programs of social assistance lead to significant threat for an acceptable lifestyle, for ability to improve own social status.

According to the coefficients of income (total spending) elasticity of consumption obtained in our article we have the following classification of commodity categories by the reaction on the growth of consumers' income (table 3).

Table 3. Classification of researched commodity category by total spending elasticity.

Commodity group	Luxuries / essentials / low quality
Food	essentials
Clothing and footwear	luxuries
Furnishings, household equipment and routine maintenance of the house	essentials
Housing, water, electricity, gas and other fuels	essentials
Healthcare	low quality
Transport	luxuries
Alcoholic beverages, tobacco	essentials
Communication	essentials

5. Discussion

We tried to compare our results with estimates of the income and own price elasticity of Ukrainian households demand which were obtained in the survey, which authors have used to model the panel database on ICP data [1]. The elasticity of demand calculated by our model and derived in work are brought together in table 4.

Table 4. Spending and own price elasticity of spending shares (in [1]) and growth rates of quantity consumed (in our work) observed for Ukrainian households.

Commodity group	Our work				Seal and Regmi [1]			
	Spending elasticity		Own price elasticity		Spending elasticity		Own price elasticity	
	Rank by absolute value of coefficient	Coefficient relatively to elasticity for food	Rank by absolute value of coefficient	Coefficient relatively to elasticity for food	Rank by absolute value of coefficient	Coefficient relatively to elasticity for food	Rank by absolute value of coefficient	Coefficient relatively to elasticity for food
Food	3	1.00	2	1.00	7	1.00	7	1.00
Clothing and footwear	2	1.39	4	0.52	6	1.30	6	1.66
Furnishings, household equipment and routine maintenance of the house	4	1.00	6	0.31	5	1.76	2	2.22
Housing, water, electricity, gas and other fuels	6	0.34	5	0.33	2	1.83	5	2.10
Healthcare	8	-0.34	1	2.14	1	2.17	1	2.68
Transport and Communication	6	0.58	4	0.69	3	1.80	3	2.15

It is clear that comparability of coefficients, which we drawn together, is very limited for many reasons. First, the obvious imperfection of mathematical tools of our model and insufficiency of its statistical base (it includes observations only for 11 years).

Second, the differences between expenditure categories used in studies of international consumption patterns and structure of consumption spending using by Ukrainian statistics.

In particular, "alcoholic beverages and tobacco products" included in the commodity category "Food" for the international methodology and highlighted in a separate category for Ukrainian national statistics. As a result, we can expect that the estimate of spending and price elasticity of demand for food by the Ukrainian statistics will be lower than the similar estimate conducted by data, taking into account alcohol and tobacco as part of food. Transport and Communication are accounting separately in inner Ukrainian statistic and united in to one commodity category in database of [1].

Thirdly the differences in the way of accounting spending on education and healthcare make indicators of Ukrainian internal statistic for these commodity categories absolutely no comparability with ICP data (inner Ukrainian statistic does not account individual consumption financed by government, which constitutes the main part of such goods consumed).

Finally, forth, differences of dependent parameters used in the studies: the share of expenditure on a commodity category – in [1] and the growth rate of consumed quantity – in our work.

If the last cause may be eliminated easy (by dividing our elasticity coefficients to growth rate of total expenditures for the retrospective period and multiplying them by index of relative price for each commodity category) the first three reasons are not amenable to correction within available for authors methods.

Taking into account all differences between the databases used for the calculation of the elasticity in our study and in the [1], it seems more correct to compare not the size elasticities, but their ratio (rank of category's elasticity among all calculated and ratio of category's elasticity to food elasticity, which was selected as the basis for comparison). Therefore mentioned figures are showed in the table 4.

Among calculated [1], three types of own price elasticity we consider as closer to our calculations is Slutsky own price elasticity (because they as our reflect the impact of price changes under conditions of fixed real income when Cournot own price elasticity provide a constant nominal income, respectively – on the basis of real is changed).

The spending elasticity of food, estimated by our model not lower as expected, but higher than in the study, which have been using integrated data on the demand for food, alcohol and tobacco and have third rank instead seven in [1].

Such a difference can be explained by the specific dynamics of the Ukrainian households' economic well-being in the period 2009-2014 and, accordingly, by the characteristics of the food demand income elasticity. As shown in [14], the high propensity of Ukrainian households to spend additional income on food is caused by long-term stagnation of economic well-being and even negative dynamics of consumer spending during the crisis (2008-2009) and the first post-crisis years. The authors [15], using the tools of Engel's curves, prove that Ukrainian households are at the initial stage of the evolution of the consumer expenditure structure. And that causes serious problems and limitations regarding the development of the social sphere: as long as the demand for food products remains highly elastic on income, such fields as education and healthcare have minimal chances on the expansion of non-budgetary financing. Accordingly, the development of the policy of reforming the leading branches of the social sphere should be based on analytical support for defining the expected growth of households' consumer spending and an assessment of the prospects for overcoming the exclusive role of budgetary financing of the social sphere. Our and further researches on the dynamics and structure of households' consumer spending can serve to clarify such an assessment.

Consumption of clothing and footwear responses to changing total spending as "luxuries" by our data, instead expected "necessities" – total spending elasticity coefficient is significantly higher than units and have second rank instead sixth in [1].

The spending elasticity of "Furnishings, household equipment and routine maintenance of the house", obtained in our research lead to different classification this commodity category between "luxuries" / "necessities" in comparison the results of study [1].

Assessments of spending elasticity for "Housing, water, electric energy, gas and other fuels" obtained in our study and in [1] also have significant differences: consumption responses to shifts in spending as "necessity" by our results and as "luxury" – by [1].

The spending elasticity of quantity consumed for commodity category "transport and communication" was calculated in our study as weighted by share in overall spending average of two elasticity indicators: for Transport and Communication. And our assessment of spending elasticity for this commodity category indicates that quantity consumed respond to changes in total spending as necessity which is significantly different from [1] results.

Indicators of own price elasticity by our calculations also differ significantly from the parameters calculated in [1]. Only concerning to Housing, water, electricity, gas and other fuels; Healthcare; Transport and Communication the ranks by coefficients of price elasticity, calculated in both studies are close to each other.

For five commodity categories, we also compared the actual indices of real changes in quantity of consumption with similar indicators, which were calculated on basis the elasticity coefficients, obtained in our and [1] models (table 5).

Elasticity coefficients are designed [1] for "Food" and "Furnishings, household equipment and routine maintenance of the house" have demonstrated quite good explanatory power. But estimated figures for both models clearly deviate from the actual values, which were observed for clothing and footwear, as well as for Housing, water, electricity, gas and other fuels.

Namely in explaining such deviations of actual fluctuations in quantity of consumption in comparison of the figures, calculated on basis of formal models, which are accounting impact of

Table 5. Comparing actual and estimated growth rate of quantity consumed for main commodity categories in consumption basket of Ukrainian households.

Commodity group	Growth rate of quantity consumed		
	Actual 2015/2005 ×100-100, (%)	Calculated on basis elasticity coefficients, obtained in our and Seal and Regmi [1] researches	
		Our model	Seal and Regmi
Food	3.952	8.702	3.710
Clothing and footwear	202.329	39.425	42.197
Furnishings, household equipment and routine maintenance of the house	33.974	15.564	35.947
Housing, water, electricity, gas and other fuels	-31.659	-57.288	-123.573
Transport and Communication	183.164	31.712	34.794

total spending and relative price, we see the direction of farther researches.

For example, to explain the actual respond of amount of consumptions to fluctuations in the total costs and relative prices by commodity category “Housing, water, electricity, gas and other fuels” we need to consider the following determinants of the system of interaction between producers and consumers of such goods.

First, majority of consumers housing services (like house heating, water supply and sewage and other) simply have no impact on their consumption (due to lack of maintenance for personal accounting of the quantity of consumption and extremely flawed accounting system of collective consumption).

Second, that the regional monopoly suppliers of these goods, both commercial and public enterprises receive the greater benefits (in the form of official income and informal income, which can reach a large part of the officials), the more consumption is recorded by imperfect system of accounting. Under such enterprises the spreading of individual metering and regulating consumption’s scope is just blocked and transition from collective to individual account of the scale of consumption has faced with strongly sabotage.

Third, the mechanisms of collective consumption in Ukraine is almost absent: Ukrainian consumers are currently unable to identify, formulate and defend their collective interests, both because of the shortcomings of the institutional framework and through the specificity of the technological conditions (e.g. collective consumption of services of gas supply in homes, numbering thousands of apartments where the most number of participants makes coordination extremely difficult) and due to the lack of experience and traditions of activity for upholding the collective interests of consumers.

A calculations made in the [1] and many other studies consist estimating of the demand elasticity by income, which have been conducted on base of panel database (i.e. no aimed to revealing the demand dependence on the dynamics of income over time) or time series, which show clearly dominating trends of increasing consumers’ economic opportunities. Cases where the structure of consumer expenditures is formed in a long-term stagnation or even decline of real income and spending fortunately are rare in today’s world.

However, the mechanisms of consumer behavior adaptation to reduce the real purchasing power of households could not, in our opinion, be considered as symmetric mirroring of the adaptation to revenue growth. We believe that among the commodities, classified to the same group (essentials or luxuries) on the basis of reaction on spending growth we might find goods with radically different reaction to the reduction of income.

Such differences could be caused by a peculiar of "ratchet effect" for different commodities groups: the amount of consumption some goods reduces through a decline in income slower, but some goods – rapidly than increases in response to analogous by absolute size growth of households spending. Motives of consumers could be related with desire to save external features of lifestyle reached in times with higher income, keep the access to sources of social mobility, maintain social identity and ability to communicate with humans who receive higher income.

6. Conclusions

1. Shifts in the structure of households' consumer expenditures in themselves are primary insufficient to definitely assessment of consumers' welfare, caused by such changes (if we don't consider reducing of food share or diversification of consumption spending). To create the conditions for such assessment we propose to complement the data on the dynamics of the structure of households' spending by information about changes in amount of consumption and relative prices for aggregated product categories. It will allow to use the structure of households' spending not only for detection consumer preferences and patterns of demand, but also to assess changes in households' capacity to meet their needs, and for estimating the economic burden, imposed on consumers in the process of interaction with the manufacture of various commodity categories.
2. In today's world, fortunately we not often can found time series of nationwide statistics that demonstrate the dynamics of consumer spending in condition of long-term significant reduction of households' real income. We believe that the patterns, which were confirmed empirically on the basis of databases, covering periods of rising the households' economic opportunities, have little explanatory power for spending structure, formed amidst reduction of consumers' real income. The clarifying of patterns, which determine the national consumption adaptation to reducing the average real households' income, in our opinion, is a promising direction for future research. Empirical basis for such research is provided by statistic on consumption spending of Ukrainian households in 2005 – 20015 years, which was primary analyzed in this paper.
3. Such analysis have shown that even for commodity groups traditionally classified as essentials with a relatively high income elasticity may be observed particular response to the reduction in real income, which cannot be explained by mechanical application of traditional demand models. For example, Ukrainian household expenditures on commodity category "Clothing and footwear" increased by a decline in real incomes, although the opposite reaction is expected by traditional models.
4. We obtain empirical proof in favor of the thesis that the development of the policy of reforming the education and healthcare resource provision should be based on analytical support for defining the expected growth of households' consumer spending and an assessment of the prospects for overcoming the exclusive role of budgetary financing of the social sphere. The further researches on the dynamics and structure of households' consumer spending can serve to clarify such an assessment.

Abstract. The article presents the current state of the ecological and socio-economic development of Ukraine and its regions, the consequences of hostilities on the territory of Ukraine and, as a consequence, the trends of damage to the surface layer of soils, pollution of the atmospheric air, and the subsoil of Ukraine with heavy metals and other harmful substances. The authors emphasize the socio-economic realities and potential trends of social security for internally displaced persons who were forced to leave their place of residence due to hostilities. Based on the analysis of potential total losses in the regions of Ukraine, a complex of socio-economic solutions is provided for strengthening the sustainable economic and ecological development of its regions. Attention was drawn to the fact that the main environmental problem of Ukraine for the coming decades will remain the problem of demining a large part of the territory. On the basis of the factorization of the given trends, the definition of catalysts of ecological development is proposed, which should signal the need for additional specialized research. It is concluded that despite the importance of solving environmental problems and the catastrophic consequences of hostilities for the surrounding environment, the social component and its economic support are fundamental in the processes of "regeneration" of the normal life activity of the regions.

1. Introduction

Sustainable economic and ecological development of Ukraine and its regions depends on Ukraine's natural resources, their economical use, preservation and protection of the environment. However, as of 2023, under conditions of full-scale war and hostilities, about 1.2 million tons of pollutants have already entered the atmosphere, including 430 thousand tons of carbon monoxide, 700 thousand tons of dust, 40 thousand tons of light organic compounds, significant amount of heavy metals and other harmful substances [1]. The consequences of these emissions turned out to be catastrophic and have already reached almost \$ 4.2 billion: 1.8 billion is damage from forest fires, \$ 1.6 billion – from grass fires and \$ 52 million from burning oil and oil products. And these sums do not yet take into account the direct damages caused by the explosion of the Kakhovka Hydroelectric Power Plant in the Kherson region. In addition, due to the damaged objects of the housing stock, communal and transport infrastructure, polluting substances were additionally emitted into the atmospheric air, which brought losses of more than $ 1 billion. In large areas of Ukraine, the surface layer of the soil was significantly damaged as a result of the construction of fortifications, explosions, burning of ammunition, military maneuvers, etc. In other words, 186,000 km^2 of land were contaminated, which is almost 31 % of the territory of Ukraine. Among them more than 20,000 km^2 were damaged more than 75 %. In a full-scale war, Russia makes massive use of so-called dragon's teeth – defensive structures in the form of concrete cones, lined up to stop light vehicles and hinder the advance of infantry, and fills trenches with concrete. Such fortifications appeared in most territories of the temporarily occupied regions of Ukraine [2]. Similar structures were used during the Second World War, so removing the dragon's teeth turned out to be economically impractical at the time. That is, it means that they can remain in their places.

The territories of Donetsk, Kharkiv and Zaporizhzhia regions suffered the most damage, not including the territories of Luhansk region, which is mostly under occupation. In total, total damage from land damage and soil disturbance is estimated at 9.8 billion dollars, endangering the use of damaged land and requiring reclamation, demining, and demining. The estimated amount of damages due to the destruction of the Kakhovka Hydroelectric Power Plant exceeds UAH 55 billion, however, the recording and analysis of direct damages and environmental consequences caused by this tragedy continues, as do the military actions on the territory of Ukraine, and specialists of various Ukrainian and international organizations are involved in this.

In addition to this should be added the losses suffered by the regions and the state from the forced external and internal migration of the population. Millions of Ukrainians left their homes, both in regions where hostilities continued or are continuing, and in those where hostilities did not take place. A significant part left abroad, but accurate statistics on the number, age and gender composition of forced migrants have not been compiled for various objective and subjective reasons. Official statistics claim that only about 2.5 million people were registered as internally displaced persons (IDPs) [3]. And the majority of people who settled with their relatives in other regions quite often do not register as IDPs, hoping for a quick return. However, as international experience shows, the longer the conditions for return are absent, the fewer people will return to their previous place of residence if such conditions arise. Therefore, it can be assumed with high probability that a significant part of those who went abroad or registered as IDPs at their new place of residence may not return to the places from which they left, and this will significantly affect the resettlement system in Ukraine and the placement of productive forces in the regions of Ukraine.

Therefore, it is quite problematic to determine and finally predict the consequences of total losses by region. However, it is already possible to envisage a set of socio-economic solutions to strengthen the sustainable economic and ecological development of Ukraine's regions.

2. Literature review

Decisions made today regarding sustainable economic development are not new for Ukraine. Many scientific works on economic growth and economic development are devoted to this topic [4–6]. These are also topics related to the need for continuous growth and ensuring the scale of consumption of natural resources [7–9] in peacetime and wartime, as well as post-war recovery and use of natural resources [10]. However, the war continues and the situation with planning for sustainable economic development and the use and access to available resources is worsening. Therefore, there is a need to develop complex socio-economic solutions for sustainable ecological development, taking into account all aspects of the restoration of industrial activity and social life in the liberated territories, restoration, relocation, repurposing and diversification of business in all regions of Ukraine.

Therefore, the main goal of the research is the identification of modern environmental challenges and the determination of strategic directions for the implementation of complex socio-economic solutions, taking into account the ecological components of a safe environment.

3. Methodology

The basis of the research methodology is the analysis of the current state of the sustainable development concept implementation in Ukraine and in the world, which originated in the 1970s, developed under the influence of global trends and identified problems, the main of which are environmental challenges, poverty alleviation, food security, equal rights and opportunities for all members of society.

The 17 sustainable development goals that were approved during the 70th anniversary session of the UN General Assembly in 2015 at the Sustainable Development Summit were in the focus of attention within the framework of this concept. According to the resolution of the summit, most of the goals should be implemented by 2030, but the current global cataclysms call this deadline into question. During the research, it was found that depending on the circumstances, the order and priority of goal implementation may not match.

Among the methods of scientific knowledge that were used, it is possible to note: analysis (to identify modern modifications of the concept of sustainable development in the regions of Ukraine), induction (to form conclusions regarding the priority of actions regarding complex socio-economic and environmental solutions); statistical analysis (to highlight quantitative indicators regarding the current situation in the regions of Ukraine); comparison (to compare the goals of sustainable development in Ukraine and in the world).

4. Results

In order to form complex socio-economic solutions, it is necessary to have a complete and sufficiently reliable assessment of the socio-economic and ecological situation in the country. However, none of the existing assessments made by various international and domestic agencies [1–3, 10] can form a sufficiently realistic picture of the ecological situation in the country. Based on this, it is quite difficult to make any predictions for the future. Although, thanks to the conducted research, it is possible to identify the main problems in monitoring the state of the regions, in obtaining certain information about pain points and sensitive zones, as well as priorities in assessing the ecological state.

The main environmental problem of Ukraine for the coming decades, regardless of when the war ends, will remain the problem of demining a large part of the territory. Today, Ukraine is the country whose territory is the most mined in the world. Luhansk, Donetsk, Zaporizhzhia, and Kherson regions are almost completely mined. Mykolaiv, Kharkiv, Sumy, Chernihiv, Kyiv, and Zhytomyr regions remain partially mined. About a fifth of the country's land area is currently considered dangerous. Currently, it is not possible to estimate the amount of mining of the sea coastal areas and the water areas of the Black and Azov seas in general [11].

Environmental problems caused by full-scale hostilities directly affect the socio-economic situation of the regions. In particular, a bright indicator is the export of goods by region of the country. In recent years, before the start of the full-scale invasion, Ukraine was considered an export-oriented country. In 2022, a significant decrease in exports was recorded in 16 regions, compared to 2021 figure 1.

The main reasons for the reduction of export products: inability to carry out production due to the presence of explosive objects; destruction of production facilities; disruption of logistics channels. The largest decrease in exports was recorded in the Donetsk, Luhansk, and Kherson regions, where the decrease over the year took place by 85-95 %.

The impossibility of carrying out economic activities at the pre-war level led to a reduction of income in the budgets of local communities. Donetsk, Luhansk and Kherson regions also suffered the greatest losses. Revenues to the local budgets of these regions in 2022, respectively, amounted to 35.5 %; 50.9 %; 31.2 % of the indicators of 2021. In general, a reduction in local budget revenues was recorded in all regions of the country, with the exception of Zhytomyr and Lviv regions [12] (figure 2).

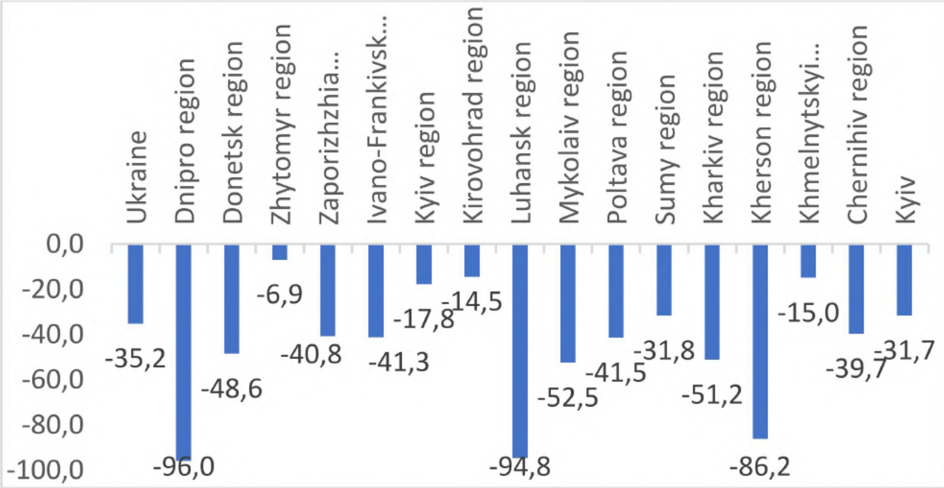

Figure 1. The level of reduction in commodity exports by regions of Ukraine 2022/2021, % [12].

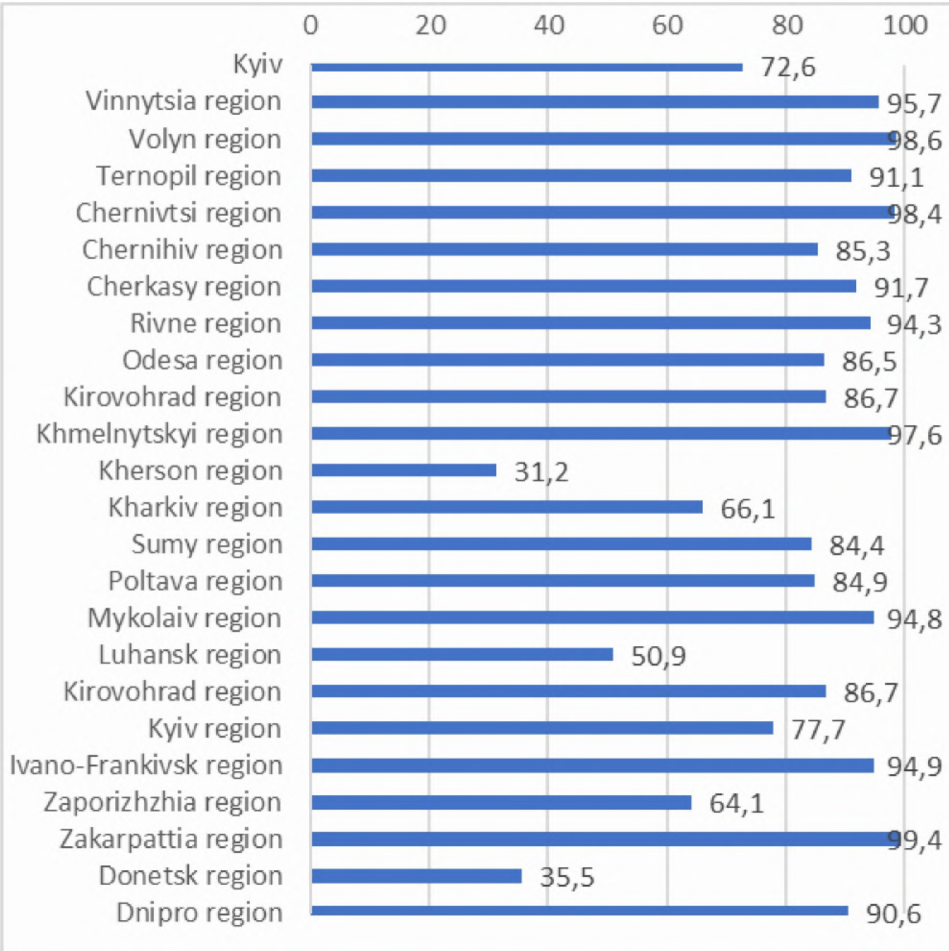

Figure 2. Dynamics of revenues to local budgets of territorial communities 2022/2021, % [12].

Most of these assessments will be very difficult to carry out in the conditions of martial law in some regions of the country, but after the end of hostilities, it will be necessary to make the most complex socio-economic decisions regarding sustainable ecological development, which we must already talk about now, namely:

1. Monitoring of the state of the environment, ecological consequences of individual territories through the prism of the expected post-war restoration and reconstruction of production.
2. Development of forecasts and scenarios for the future development of regions on the basis of cooperation models integrated into the European Union. For this purpose, it is possible to invite authoritative European experts, organizations for assessment and ensuring ecological balance in the regions.
3. Creation of platforms for verification, processing, documentation and identification of a large amount of data on the direct and indirect effects of military actions on the environment based on those regions that received the greatest negative consequences. On the basis of such consolidated information, it is possible to hold various kinds of debates regarding the correction of subsequent decisions at the national, international, including European levels.
4. Determination of the catalysts of ecological development, which should signal the need for additional research, and if necessary, to change, adjust or fundamentally revise the set of socio-economic solutions for the sustainable development of regions.
5. Dissemination and distribution of the received results of the assessment of the state of the environment in order to ensure effective communication with stakeholders and other target audiences.

The identified measures will allow identifying critical gaps in environmental information regarding the sustainable development of regions, implemented socio-economic measures, and the existing capabilities of regions to independently eliminate recognized problems; to find the right priorities in environmental protection and to give answers to the public reaction and various multidimensional connections that arise between the territorial community and the environment.

Today, business remains the backbone of sustainable socio-economic and environmental development in the country. According to the results of a survey [13] of the European Business Association, 96 % of businesses that continue to operate adhere to the goals of sustainable development and strive to implement them. This indicator coincides with the pre-war level recorded in 2021. At the same time, according to the results of an expert study of the level of integration of the UN sustainable development goals into the strategy of business structures and into regional and national strategies, this integral indicator improved by 0.23 points and at the beginning of 2023 amounted to 3.5 points (out of a maximum of 5). The contribution of business to the implementation of the goals of sustainable development was assessed by experts at the level of 3.79 (out of a maximum of 5).

Despite the importance of solving environmental problems and the catastrophic consequences of war for the environment, the social component is fundamental in the processes of regeneration of the normal life activity of the regions. 97 % of working business owners (according to the results of the same survey [12]) note that the main efforts are made to preserve human capital: helping employees and their family members in the process of relocation; timely payment of wages (even in case of temporary downtime of production); financial support for workers and their families affected by hostilities.

This approach is well-founded, because the preservation of human capital will allow the process of ecological and economic recovery of the regions to be launched. Moreover, it is necessary to pay attention to the fact that in each case the priority of tasks of a social, ecological and economic nature will be determined depending on the state of each component of a specific territory (region).

Considering this context, it is possible to present the modern view of the sustainable development concept for the current situation in the Ukraine regions (figure 3).

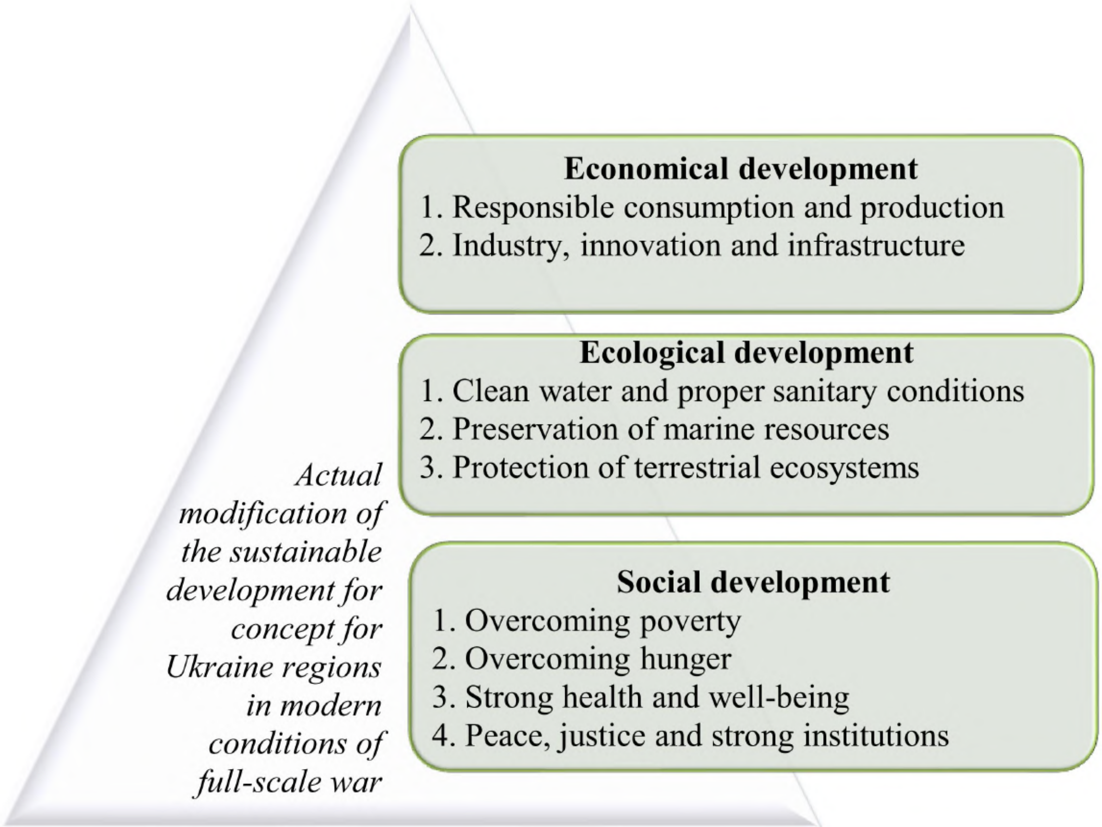

Figure 3. Modern view of the sustainable development concept for the current situation in the Ukraine regions (developed by the authors).

The presented modification of the concept is already being actively implemented in the regions of Ukraine: it is the social component with the main problems that comes first: surviving in war conditions (including evacuation to safer regions), providing all those in need with food and an appropriate level of medical care service. The fourth goal of social development (peace, justice, and strong institutions) is the ideal state that our society strives to achieve. The ecological component is superimposed on the social one: providing the population with proper sanitary living conditions and restoration of territories affected by hostilities (mining, first of all). The economic goals of sustainable development are superimposed as a "third layer", because under the existing conditions, their implementation in the regions of Ukraine is possible only when the goals of social and environmental development are achieved.

Depending on the situation observed in each individual region, the modification of the concept may change. Where the ecological consequences are catastrophic (regions where the evacuation of the population is still ongoing, and the territory has suffered significant losses of natural and recreational resources due to the attacks of the aggressor country), after the end of hostilities, the ecological goals of sustainable development will come to the fore, because in some territories before the return of the local population, it is necessary to carry out a process of complete demining and restoration of critical infrastructure to ensure the minimum household needs of the population.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012059 doi:10.1088/1755-1315/1415/1/012059

A comparison of current goals of regional development in Ukraine and in the world shows discrepancies (figure 4).

Priority goals of sustainable development of Ukraine

Priority goals of sustainable development in the world

Figure 4. Disposition of modern goals of sustainable development for Ukraine at the national and global level, as of 2022 [13, 14].

Based on the identified priority goals of sustainable development (figure 4) and the proposed modification of the sustainable development concept, relevant for Ukraine (figure 3), it is possible to formulate strategic directions of socio-economic development that will contribute to the "reanimation" of the country's ecology during the post-war reconstruction period:

1. Development of renewable energy and implementation of autonomous energy systems based on "green" technologies. Two years of war demonstrated the obsolescence and instability of centralized life support systems. The enemy's targeted strikes on nuclear power plants, hydroelectric power stations, and thermal power plants led to significant losses of capacities at this economy sector and caused "blackouts" of territories under constant shelling. In part, the problem is solved by buying generators for businesses, but most of the existing equipment runs on substances harmful to the environment (gasoline, diesel fuel, etc.).
2. Greening of all economy spheres. Significant losses in the industrial sector set ambitious tasks for the restoration of production, but most large enterprises worked with outdated technologies dangerous for the environment, so the restoration should not take place according to the principle of "modernizing the old" but "building new", safe for workers and the local community, for future consumers of products, etc.
3. Determination (search for new) strategic spheres of ecologically safe economic activity for each region in Ukraine for sustainable socio-economic and neutral ecological development. The most promising is already mentioned the renewable energy sector, which is showing rapid growth at the global level, generating a large number of jobs. Among the most relevant areas, which are already attracting the attention of foreign investors: IT, construction, logistics, the financial sector, medicine.

5. Conclusions

Taking into account the above research results, it can be concluded that the basis for the identification of modern environmental challenges and the determination of strategic directions for the implementation of complex socio-economic solutions for the recovery of Ukraine are:

1) harmonization with the level of global requirements for decision-making regarding the established socio-economic and ecological development of the country and the reconstruction of its regional development;
2) prioritization of the development of the economy of regions and territorial communities, taking into account the ecological factor as a system-forming factor in the concept of sustainable development of the state;
3) audit of effective management and use of natural potentials of regions, on the basis of which it is possible to adopt complex socio-economic decisions regarding sustainable ecological development of regions;

4) implementation of ecological development concepts of the territories of Ukraine to the strategies and development programs of the European community thought the activation of an inclusive consultative process among ecological, economic, demographic, political and economic experts, representatives of the business community, local self-government bodies and other groups of stakeholders who provide geographic, ecological and economic balance of territorial development as well as their careful socio-ecological and economic use.

Thus, the strategic directions of restoration and sustainable development of Ukraine regions proposed in the study, based on ecologically neutral solutions, will make it possible to stop the process of socio-economic and ecological degradation of the regions. The introduction of alternative spheres of economic activity will contribute to the improvement of the life quality for local communities and and support the return of internally displaced persons as well as refugees, who left the country.

Further research will be aimed at forming objective criteria for assessing the level of further established development of socio-economic and ecological regional systems and their level of balance to the requirements of the European Union, taking into account the non-renewability of some natural resources.

Abstract. The article is devoted to the adaptation of social policy's conceptual framework to war conditions, radical growth of defense spending, which, against the background of production infrastructure destruction and declining business activity, lead to critical underfunding of social sector. The authors emphasize the priority of population's quality of life characteristics as a criterion for assessing functioning of social sector's clusters and a basis for updating social policy's principles and priorities. The study identified the main social sector development problems, which primarily include: limited resources in response to the social sector's growing needs, including social protection; reduced access to medical and educational services; insufficiently effective reforms during the period of war; depopulation; increased migration flows, etc. The following priority areas have been identified for their resolution: creation of conditions for increasing the birth rate, and socialization of senior citizens; effective migration policy; reforming the wage system; simplifying access to professional pre-university and higher education; adapting the network of medical institutions to population's growing needs; preserving and restoring social infrastructure, etc. Development and implementation of measures within the mentioned areas will contribute to social sector development and, accordingly, to the improvement of population's quality of life.

1. Introduction

Russia's full-scale military aggression against Ukraine has brought a lot of grief and hardship to the population [1]. Thousands of servicemen and civilians have been killed, and many businesses, homes, communal and social infrastructure facilities have been destroyed [2]. At the same time, Ukraine's struggle for its independence and freedom has prompted the country to realize its personal civilizational choice, which contributes to democratization of society and progressive economic and social transformations.

Under these circumstances, restoration of social sector, which ensures standard of living and quality of life, is of strategic importance for country's social and economic recovery. Social sector recovery under conditions of war, deep social and economic crisis, global economic and technological challenges require development of a concept that provides for coordination in time and space of fundamental areas of certain actors' actions, use of resources required for this purpose, and determination of expected results.

The purpose of this article is to single out the current problems of social sector development and to substantiate directions for their solution. Achievement of this purpose entails formation of the following tasks: to analyze the level of population's quality of life and to argue for the expediency of using it as an indicator of social sector development; to identify current problems of Ukrainian social sector development and to determine priority areas for their solution.

2. Literature review

Studies devoted to the problems of social sector during war mainly proceed from the thesis that social sector's additional needs for resources are formed depending on the scale of losses in population's quality of life and are used to quantify the number of groups that have suffered damage to health or economic well-being; have been deprived of factor income sources or even ability to work; have been forced to stop studying [3–5]. Less widespread are studies that take into account the depth of gap between the existing quality of life characteristics and social norms and standards as a prerequisite for increasing the burden on social sector, and the extent of available resource support for the social sector shortage as a basis for assessing the need for additional resources to ensure its functioning in line with the urgent needs of society. At the same time, these studies consider the level of efficiency of using the available resource potential, firstly, as a given, and secondly, independent of the institutions' quality (policies and procedures used in the process of its implementation) [6]. Accordingly, our study aims to close this gap by taking into account the importance of institutional changes, updating policies and procedures used in the process of their implementation in order to obtain better social results.

3. Methods

The database for analytical component of the study was compiled from statistical sources of the Ministry of Social Policy, the State Statistics Service, the National Bank of Ukraine, the Pension Fund of Ukraine, Eurostat, as well as from news portals and researchers' publications. In order to accomplish the tasks set, methods of comparative analysis and deduction were used to identify development problems, as well as methods of systematization and generalization – to identify priority areas for solving social sector's problems. For quantitative assessment, the study used methods of time series analysis, analytical grouping to assess dynamics of quality of life's individual components and to highlight contribution of individual social sector's clusters to dynamics of meeting basic population needs. Calculation results became the basis for further use of synthesis method to rank the problems of social sector development in Ukraine and to select priority directions for their solution. Generalization method was used in order to formulate conclusions from the study.

4. Results of the study

4.1. Quality of life as an indicator of social sector development

The multidimensionality of human life generates numerous discussions about approaches to determining the level and quality of life. The most popular integral indicator for assessing quality of life in terms of practical application is human development index, which in general is a combination of three components – level of well-being, life expectancy and education. Diversity of visions on the concept of quality of life has stimulated emergence of numerous methods for assessing its level. In particular, Polozhentseva, when studying income inequality, identifies such components of quality of life as life expectancy, efficiency of health care system, level of income and level of education [7]. Eurostat, when assessing quality of life, identifies the following indicators: material surroundings (income, consumption and material conditions); productive or core activities; health, education, leisure and social interaction, economic security and physical security, governance and fundamental rights, natural and living conditions, and general life experience [8]. In Ukraine, the state recognizes an approach that assesses the standard of living based on the level of wages and pensions, their compliance with social guarantees, consumer price and poverty indices. At the same time, scholars have proposed to enrich these indicators with others, such as those characterizing health, education, transport infrastructure, etc. [9]. Thus, when assessing quality of life according to each of the listed approaches, it is necessary to turn to indicators that characterize the state of social sector through the prism of its services accessibility to the population. Therefore, it can be argued that it is reasonable to use quality of life level as an indicator of social sector development. For instance, the level of pensions, the amount of state social standards and guarantees characterize the state of social protection system development, indicators of public access to healthcare and education services – the state of education and healthcare systems development, etc.

The extraordinary events taking place in Ukraine in recent years (pandemic and introduction of quarantine restrictions, war, increased internal and external migration flows, etc.) have led to a deterioration in the standard of living and quality of life, as evidenced by dynamics of average wages and pensions in dollar terms (figure 1), as well as data on the ratio of average wages and pensions to the actual subsistence level for the respective category (figure 2).

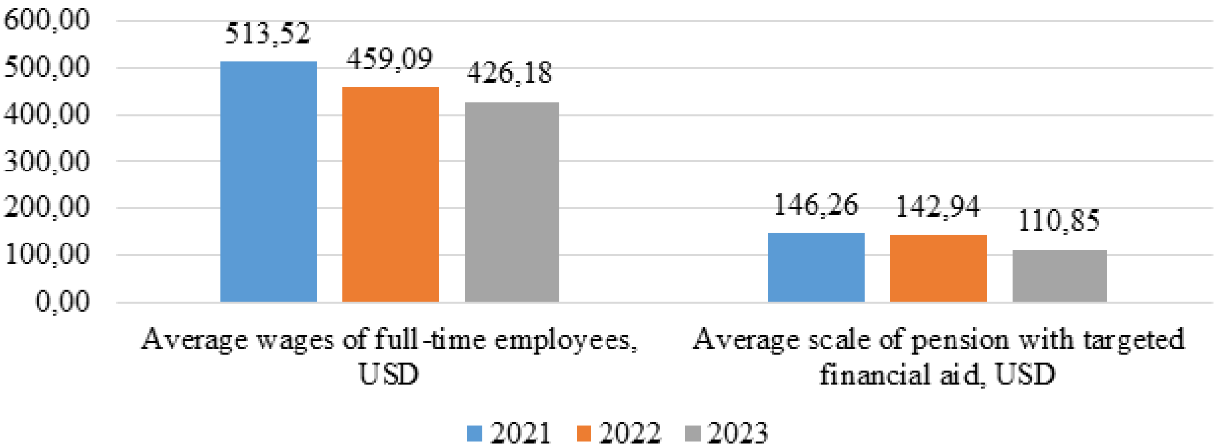

Figure 1. Dynamics of average wages and average scale of pension in 2021-2023, USD (on the basis of [10–13]).

Thus, the average wages of full-time employees during the two years of martial law decreased from \$513.52 in 2021 to \$426.18 in 2023, which means a 17% decrease. The average scale of pension for the same period decreased from \$146.26 to \$110.85, i.e. by 24.2%. The ratio of basic social standards and guarantees is even more revealing. Thus, in 2023, the officially approved subsistence level was only 41.9% of the actual subsistence level, which indicates a significant reduction in all social transfers and wages to budget institution employees. Moreover, this approach practically leads to equalization in labor remuneration: wages from the 1st to the 12th tariff category in the unified tariff net are minimal.

Real wages decreased by 11.4% in 2022. Obviously, the war has significantly deepened pre-existing social problems. According to the World Bank, the level of poverty in Ukraine increased tenfold during the war. All this led to a decrease in population's purchasing power, which directly affected the level of access to educational and medical services.

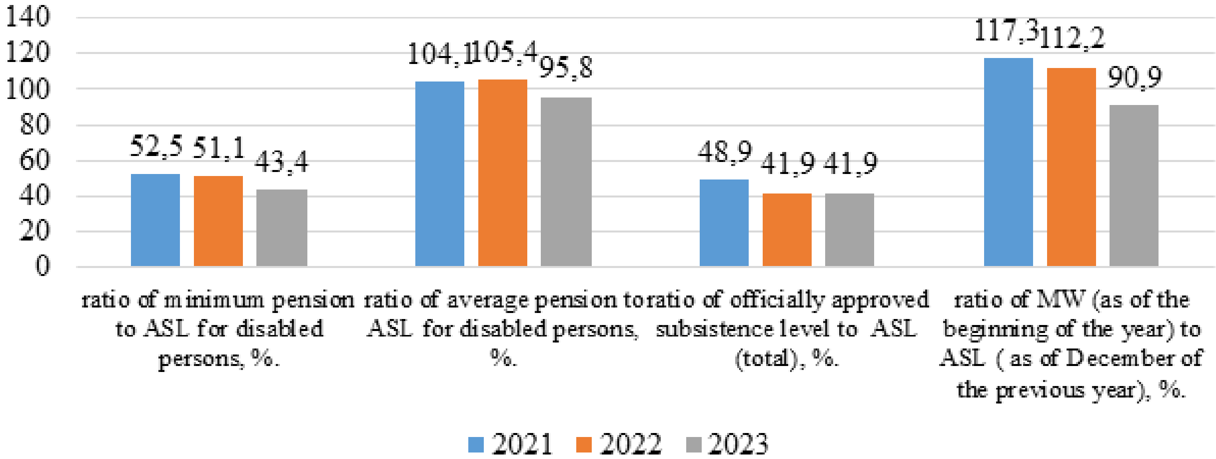

Figure 2. Dynamics of the ratio of certain social standards and guarantees in 2021-2023, USD (on the basis of [14–16]).

At the same time, in nominal terms, there has been a slight increase in incomes (table 1), which in basic indicators is lower than the composite inflation index.

Table 1. Key indicators in the field of household income in Ukraine in 2021-2024 (* for three quarters of 2023, ** composite inflation index for three years) (on the basis of [11–13, 17–19].

Indicators	2021	2022	2023	2024	2024/2021,%
Average wages of full-time employees, UAH	14014	14847	16849,7*	n/a	n/a
Minimum wage as of beginning of the year, UAH	6000	6500	6700	7100	118,33
Average scale of pension with targeted financial aid (as of beginning of the year), UAH	3507,51	3991,53	4622,59	5385,25	153,49
Minimum pension, UAH	1769	1934	2093	2361	133,47
Consumer price index, %	109,4	120,2	112,9	n/a	148,46**

Decline in actual income indicators demonstrates a threatening decline in living standards in Ukraine, which has negative consequences for social sector development.

4.2. Current problems of social sector development in Ukraine

In order to understand current problems in social sector development, it is necessary to note prerequisites for social sector development that formed before the full-scale invasion. These include: high human potential, as evidenced by Ukraine's 77th position in the Human Development Index 2021 and its belonging to the group of countries with a high human development index; an extensive network of social infrastructure facilities (education, culture, healthcare, social security, housing, transport and communications); increased mobility in educational programs; reforming the healthcare sector on the principle "money follows the patient"; increasing housing support programs, etc.

At the same time, social sector development was also affected by unfavorable factors, the negative impact of which deepened with the beginning of Russia's full-scale invasion into Ukraine.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012060 doi:10.1088/1755-1315/1415/1/012060

At the same time, social sector development was also affected by unfavorable factors, the negative impact of which deepened with the beginning of Russia's full-scale invasion into Ukraine. Among them: low GDP per capita ($4,825.4 in 2021, which was only 108.8% compared to 2016; in 2022, this figure deteriorated significantly and amounted to only 77.5%); high level of clandestine employment and "envelope" wages; high level of corruption (in 2021, Ukraine ranked 122nd out of 180 in the Corruption Perceptions Index, scoring only 32 points out of 100); significantly lower life expectancy than in developed countries (69.77 years according to 2021 data, Switzerland – 83.23 years; Canada – 83.80; Japan – 84.83; France – 82.59; Austria – 82.27; Germany 81.51; Poland – 78.76); significant polarization of population by the quality of their life; depopulation; low level of funding for the main components of social sector (in 2021: education – 5.7% of GDP. At the same time, the Law of Ukraine "On Education" stipulates that budget funding should be at least 7% of GDP; healthcare – 3.74%, which is 1.26% less than stipulated by law); dispersion of financial resources and irrational distribution of financial resources (education: there is a practice of placing a state order for 1-2 places, which, in the absence of fee-paying students, leads to unprofitability of the educational program and, accordingly, a decrease in educational services quality), and others.

Social sector functioning has been significantly hampered by military activities. Many social infrastructure facilities have been completely destroyed, and some have been damaged. According to the World Bank [19], the sectors most affected by Russian aggression in Ukraine are housing, transportation, energy, trade and industry. The losses are concentrated in the frontline regions, in particular Donetsk, Kharkiv, Luhansk, Zaporizhzhia, Kherson, Mykolaiv, and in the regions returned to government control, such as Kyiv and Chernihiv regions. Disruptions in economic flows and production, as well as additional war-related costs, are estimated as losses, totaling around USD 290 billion. Ukraine's GDP declined by 29.2 percent in 2022, and poverty increased from 5.5 percent to 24.1 percent in 2022 (based on a poverty threshold of USD 6.85 per person per day).

Educational and healthcare facilities also sustained significant damage. As of November 2023, 365 educational institutions and 193 medical facilities were completely destroyed, and 3428 educational institutions and 1468 medical facilities were damaged [20, 21].

In the context of new challenges emerging during the war, it is worth noting a sharp increase in need for social support for the population while financial resources are limited. In 2022, funding for social protection expenditures increased by 23%, and in 2024, their volume remained almost at the previous year's level. Against the backdrop of high inflation, this increase is offset by a decrease in real funding.

When analyzing social sector's state in times of war, Skipalska [22] notes 4 main problems that are relevant and most significant:

1) *limited resources combined with the growing needs of social sector (due to the increase in the number of IDPs and people in difficult straits).* This problem leads to an increase in the number of challenges social sector has to address. Currently, social services are operating in an under-resourced environment. At the same time, there is a difference in the ability to provide assistance in regions. Additional difficulties arise in occupied and de-occupied territories;
2) *lack of specialists and their experience.* In early 2022, an increase in the number of war refugees led to an outflow of social workers to safer regions or abroad. As a result, many communities are experiencing a shortage of specialists. Unprecedented massive destruction, including houses and civilian infrastructure, has made it impossible in some communities to provide adequate social services at all. Currently, there is an acute need for psychologists. Social workers are only gaining experience in dealing with crisis situations and families who experienced trauma and loss and often require specific assistance or additional forms of training;

3) *further decentralization and reduction of community responsibility.* Currently, communities decide independently how many specialists they need. Under conditions of financial deficit, local authorities neglect the social sector, which leads to the lack of social workers in some communities;
4) *the problem of financing social sector.* Due to large scales, there is an acute problem nowadays, in addition to decentralized centers, of forming a central level structure that would assume funding the most demanded social services at the national level. It is also noted that limited local budgets in wartime complicate this issue.

We cannot fully agree that further decentralization will lead to a slowdown in social sector development. We also do not deem it appropriate to create an additional structure to finance social services.

At the same time, we believe that the following problems in social sector should also be added:

- reduction of healthcare and educational services accessibility due to population's growing needs and insufficiently effective reforms during the war;
- depopulation;
- uneven distribution of labor force by region and with respect to labor market demand;
- destruction of social infrastructure, which will require significant financial and other resources for restoration;
- a significant number of migrants, including children and working-age individuals, most of whom have already adapted in other countries, which will lead to a labor shortage in future should they not return.

All of these and other problems require a more detailed analysis in order to solve them.

4.3. Priority areas for solving social sector problems

Deepening of social sector development problems necessitates revision of areas for their solutions. The main task under current conditions should be overcoming the above-mentioned problems and improving the quality of life of all social groups. The state social policy should be developed in this area, which should become a new policy of social modernization. The social concept of development should focus on the fact that the powerhouse of economic progress is working-age citizens with high labor potential and human capital, significant social activity, mobility, and ability to adapt to the prevailing conditions as quickly as possible and to put their knowledge and skills into practice.

One of the key areas of the abovementioned changes should be creation of conditions for increasing the birth rate and reducing the premature mortality rate. Measures developed in these areas should promote healthy nutrition, careful attitude to one's own health, dissemination of skills for self-preservation behavior during air alerts, etc. In the short term, they will contribute to reducing depopulation rate, and in the long term, to obtaining a positive natural population growth rate, which will contribute to increase in labor force and reduce its shortage in labor market in the postwar period.

In our opinion, the incentive mechanisms to promote appropriate behavioral patterns, both in relation to broad population and companies, are the development of insurance medicine and the introduction of differentiated insurance payment rates. Increasing insurance rates for companies that do not implement measures to reduce morbidity and preserve working capacity (and, accordingly, reducing rates for companies that implement such measures and have evidence of their effectiveness) should become an effective mechanism for stimulating and, at the same time, accumulating financial resources to expand the scope of measures to support families with children.

IOP Conf. Series: Earth and Environmental Science 1415 (2024) 012060 doi:10.1088/1755-1315/1415/1/012060

5. Discussion

Taking into account the shortage of labor, an effective migration policy should be an important area for solving the abovementioned problems, which will include measures aimed at creating favorable conditions for education, development and employment of young people, especially school graduates, as well as for return of forced migrants and those who left Ukraine before the war in search of better jobs.

An equally important area in this context should be optimal deployment of labor in Ukraine. State support for internally displaced persons should be focused on encouraging them to work and adapt to society in the territorial community where they temporarily reside, and in return to their previous place of residence in the postwar period.

Stimulation and economic (resource) support for moving towards an optimal distribution of labor force should, in our opinion, be based on improving efficiency of labor market functioning, primarily by increasing spatial and professional mobility of the economically active population. Expanding state guarantee programs for education loans and including in the requirements for international partners' investment projects the costs of increasing housing affordability in the regions of project implementation should become an effective means of financial support for increasing spatial and professional mobility of the economically active population.

In view of population ageing, it is worth highlighting creation of favorable conditions for active life of the senior citizens as a separate area of solving the abovementioned problems. In the context of this area, measures should be developed to support this category of people's health, their socialization through involvement in labor and other activities under certain employment and cultural recreation programs, as well as acquisition of new skills (drawing, sewing, design, carving, etc.)

The key areas should also address the issues of accessibility and quality of educational services and medical care. First and foremost, it is necessary to simplify access to professional pre-university and higher education during martial law and in the first 5 years of postwar recovery of Ukraine. Combined with an effective employment policy and provision of a first job, this will help young people make decisions about their future residence and life in Ukraine rather than abroad. In addition, all accreditation procedures should be suspended during martial law, while extending the validity of already obtained accreditation certificates. New programs that have not been accredited before and have been created outside the framework of previously accredited specialties should be accredited under a simplified procedure. All saved funds should be used to create shelters with proper working and resting conditions, as well as to strengthen Ukraine's defense capabilities. Given the significant increase in the number of people with disabilities as a result of Russia's military aggression against Ukraine, the network of health care facilities should be adapted to the current and future needs of the population, taking into account its resettlement. This will contribute to increasing medical care accessibility.

Another key area of change should be creation of conditions that will stimulate economic activity and productivity of all working-age individuals. Wages, including minimum wage, assume an extremely important role in these processes, as they determine the extent of poverty, the boundaries of which are defined by the subsistence level. As was mentioned above, in Ukraine it is unreasonably low. Therefore, poor and low-income people have limited access to basic social services that affect the reproduction of human capital in terms of education, culture, and healthcare; they are forced to save on quality medicine and food. Most of the labor force has low wages. In order to change this situation, the eradication of poverty must adhere to new values and principles of social policy based not only on state support but also on creating conditions for increasing the level of remuneration.

It is important that a significant increase in remuneration, combined with an increase in income elasticity of aggregate supply in Ukraine (which will prevent the effect of nominal wage growth from being eroded by inflation), is also accompanied by an increase in the amount of resources accumulated by social insurance funds and budgets, the revenues of which grow proportionally (and in the case of progressive tax rates, even faster) with the growth of wages

An important area for solving social sector problems is restoration of social infrastructure and housing destroyed as a result of the Russian invasion. It is impossible to solve these problems at the expense of the state budget, so participation of business in these processes is extremely relevant. However, when building a dialogue with business regarding its participation in the implementation of social infrastructure restoration projects, the government should understand that a business entity, even if it implements socially responsible practices and upholds generally accepted human values, will be ready to support social projects only in certain cases, when they do not result in unprofitability of its economic activity and ensures its profitability. And also, if it feels public authorities' not just formal but real support, respect, and appreciation of its efforts aimed at rebuilding important social infrastructure facilities [23].

Ukraine should build a future in which cities and villages that have fallen victim to Russian aggression revive and flourish, forming a social and economic ecosystem where people live in decent conditions and have access to modern technologies that promote sustainable social development and ensure well-being. An important condition for the development of such an ecosystem is its tendency to balance, which is achieved by harmonizing relations in labor and social life of population on region, state and world levels [24].

6. Conclusions

Summarizing the abovementioned, we note the deterioration in quality of life as a result of Russia's armed aggression against Ukraine, which evidences the existence of problems that hinder social sector development. The main social sector problems have been identified: limited resources combined with growing social needs; reduced responsibility of territorial communities regarding social sector development; destruction of social infrastructure, which will require significant financial and other resources for restoration; decrease in accessibility of medical and educational services due to population's growing needs and insufficiently effective reforms during the war; depopulation; increase in migration flows and uneven distribution of labor force by region and with respect to labor market demand.

The following priority areas for their solution have been identified: creation of conditions for increasing the birth rate and reducing the premature mortality rate; effective migration policy that will facilitate return of Ukrainians from abroad, including those who left in search of better jobs before the war; reforming the wage system; simplifying access to professional pre-university and higher education during martial law and within five years after it is lifted; adapting the network of medical institutions to population's growing needs; suspension of accreditation procedures for educational programs during martial law and redirection of the saved funds to the construction and equipment of comfortable shelters for study and recreation in educational institutions; optimal placement of labor in Ukraine and creation of conditions for the continuation of active life of senior citizens. Development and implementation of measures within the mentioned areas will contribute to social sector development and, accordingly, to the improvement of population's quality of life.

Abstract. Ukraine's energy industry experienced organizational and territorial challenges, resulting in a coal scarcity and a need for stable and balanced development. Ukraine's unified energy system, which includes a variety of power plants, plays an important role in supplying electricity to other nations. The authors recommend using the multidimensionality principle and a systemic approach to examine the country's energy security, as well as the development of a model based on energy product manufacturing under Ukraine's tough economic and political conditions. Such a theory will show the peculiarities of the production of energy products, which is characterized by a vast collection of qualities and factors that influence it. The factors (or variables) studied in the article are classified as endogenous and exogenous. The E-Views application was used to model the country's energy security in terms of energy product production. The outcomes of the modeling revealed the presence of long-term endogenous and exogenous factors influencing the total volume of energy product production; the existence of a strong relationship between the volume of energy product production and imports, total energy supply, and total final consumption; and opportunities for significant growth in domestic energy product production in the future. The model's practical significance has been demonstrated through reduced reliance on imports, diversification of energy sources, energy independence, energy availability, collaboration in the field of energy security, economic growth, and environmental and sustainable development.The article concentrates the authors' attention on Ukraine's energy sector, which is critical to the country's economy and supply to the EU.

1. Introduction

Faced with global concerns such as climate change, resource depletion, and geopolitical unpredictability, governments throughout the world are being compelled to rethink their energy production capacity, looking for long-term solutions that give both economic prosperity and environmental stewardship. At the intersection of these imperatives is the essential concept of energy security, which encompasses more than just the availability and cost of energy resources, including larger issues of environmental effect, economic sustainability, and social justice. In this paper, the authors investigate the complex relationship between energy security and sustainable development, with a particular emphasis on Ukraine. As a nation at the crossroads of Eastern Europe, Ukraine is dealing with the necessity to ensure a stable and sustainable energy future while matching its trajectory with the principles of sustainable development. Modeling energy security requires a holistic strategy that considers everything from technical progress and the use of renewable energy sources to geopolitical considerations and economic stability. Ukraine, which has a diverse set of energy resources, has traditionally relied on a complex matrix of fossil fuels to supply its energy requirements. However, in recent years, there has been a greater emphasis on diversifying the energy portfolio, improving energy efficiency, and reducing environmental effect. The pressing need to minimize reliance on nonrenewable sources, combined with geopolitical developments affecting traditional energy supply networks, highlights the need and relevance of Ukraine strategically modeling and planning its energy security within the larger context of sustainable development.

2. Literature review

Energy security is defined as the safe and uninterrupted supply of energy resources, which is essential to the operation of the contemporary economy and is linked to national security. The concept of energy security has developed throughout time to include a wide range of concerns. Studies by Abbas and Alqama [1], Popescu [2], and Sutrisno, Nomaler and Alkemade [3] highlight these concerns that include over-reliance on a single source of supply, infrastructure vulnerabilities, and the effects of climate change on energy production. Flaherty and Leal Filho regard them as an economic notion as well as a component of national security, and vulnerabilities in energy infrastructure have both national and international implications [4]. Many countries, as noted by Cherp et al [5], are vulnerable in terms of resource sufficiency, infrastructure reliability, price stability, protection from external threats, and failure resistance. Paleri's study emphasizes energy conservation and sustainable use as crucial aspects of energy security, as excessive energy consumption can harm the ecosystem and deplete resources [6]. Global energy management is critical for addressing energy security concerns and meeting long-term energy demands.

Energy security can be viewed as a component of national security, allowing for an assessment of the vulnerability of the physical infrastructure that transmits energy. Energy security refers to countries' attempts to assure access to a varied range of energy sources, such as oil, natural gas, and renewable energy [4, 7]. Global energy governance is necessary, as is its role in addressing energy security and ensuring long-term energy needs are addressed in a sustainable manner. Misiągiewicz [8], and Paravantis et al. [9] in their research expose the relationship between energy security, economics, and national security, and emphasize the need of a safe and uninterrupted supply of energy resources for the running of modern economies and national security of states.

Energy security in the European Union (EU) is a crucial concern because to its reliance on imports, the Russian invasion of Ukraine, and the post-COVID-19 a pandemic According to Antoniuk and Kulczycka, the EU faced challenges in assuring energy supply from the Persian Gulf region, as well as price instability [10]. The EU's reaction to these difficulties includes a reorientation of energy and security policies, with a focus on eliminating reliance on Russian gas and speeding progress toward the European Green Deal and "Fit for 55" goals [11]. Russia used energy resources as a tool of foreign policy, as emphasized by Yakoviyk and Tsvelikh, resulting in a severe energy crisis in the EU and prompting energy policy adjustments [12]. Streimikiene, Siksnelyte-Butkiene and Lekavičius studied several approaches and instruments to quantify energy supply security and suggested a framework for measuring the dependence and diversification of energy imports in the EU [13]. According to Semenenko et al., the EU responded by implementing steps to strengthen energy security, such as the utilization of renewable energy sources and the diversification of the natural gas market [14].

The authors agree with Vasylyna's study that Ukraine's energy security is a major worry due to its reliance on energy imports, threats of economic and political influence from other nations, and reliance on the global market [15]. The development of vital technologies, such as renewable energy sources, as highlighted by Brych, Putsenteilo and Hunko in their study, is critical for maintaining energy security and enhancing resource efficiency [16]. The war and occupation of

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012061 doi:10.1088/1755-1315/1415/1/012061

a portion of Ukraine's land posed an even greater threat to national energy security, resulting in energy sector losses [17]. The fundamental disadvantage of Ukrainian legislation, as examined by Malinovska and Vysochanska, is the lack of a systematic strategy to ensuring energy security [18]. According to Antoniuk and Kulczycka, Ukraine has a strong energy sector that ranks among the top in Europe in terms of installed power generation capacity and gas production [10]. The usage of renewable energy sources is thought to be good for energy security and the long-term development of Ukraine's energy industry.

3. Materials and methods, starting hypotheses

The authors recommend using the multidimensionality principle and a systemic approach to examine the country's energy security, as well as the development of a model based on energy product manufacturing under Ukraine's tough economic and political conditions. Such a theory will allow us to show the peculiarities of energy product manufacture, which is characterized by a wide range of features and influencing variables. Such factors (or variables) can be classified as either endogenous or exogenous.

The effective use of endogenous elements enables Ukraine to construct a balanced and sustainable energy system, stimulate future economic development, and reduce reliance on imported energy sources. For example, developing renewable energy sources and improving energy efficiency are critical to the energy sector's long-term development. Endogenous elements in Ukraine's energy product production include internal resources and potentials that can be exploited to generate electricity and other energy products. The key endogenous elements in this context include a wide range of energy sources and technologies, including coal, natural gas, nuclear power, renewable energy sources, hydropower, energy efficiency, and the usage of modern technologies. Exogenous factors are vital and necessary for developing a sustainable energy policy in Ukraine, as well as promoting energy security and the country's long-term growth. Exogenous factors affecting Ukrainian energy product production include external influences and events that may have an impact on the country's energy sector. These elements include the geopolitical context (wars), international commitments, technological innovations, raw material costs, and energy demand and consumption.

To model the country's energy security based on energy product production, we will use the E-Views application. The multivariate regression model appears like this:

$$Y = f(X_1, \ldots, X_n) \tag{1}$$

We will investigate the influence of external and endogenous elements, as well as the density of their connections, using the model that has been developed. The use of E-Views comes from the fact that it is one of the most powerful packages for developing econometric models, allowing researchers to simulate an economic process, examine a hypothesis, and generate a forecast.

Based on the statistics data from World Energy Balances Highlights 2023 [19], our model will comprise 12 observations from 2010 to 2021. When selecting the most significant factors, we apply the reliability principle, which adequately reflects the current state of energy product production in Ukraine, the information availability principle, which requires the use of official data, and the representativeness principle, which states that each variable chosen for the sample is the most significant and justified.

The author's hypothesis is that the general production of energy products in Ukraine at the current stage is affected by the political and economic situation, namely the war.

The general appearance of the country's energy security model based on the production of energy products is described by the following linear equation:

$$P = f(I, S, TC), \tag{2}$$

where, P – production of all energy products (coal, peat, oil shale, oil products, natural gas, nuclear, renewables and waste, electricity, heat), I – import of energy resources, S – total energy supply, TC – total final consumption.

4. Results

4.1. Creating a model in line with the hypothesis

We used a variety of parameters in the $f(P)$ research procedure, including energy resource imports and exports, electricity, total final energy consumption, industry, transportation, and power production. The three most important elements influencing the creation of all energy products in Ukraine are energy resource imports (I), total energy supply (S), and total final consumption (TC). So, in the process of analysis according to the Prob. criterion, which reveals the most significant effect on *f*, we produced the following equation:

$$P = C(1) \times I + C(2) \times S + C(3) \times TC + C(4) \tag{3}$$

The module is built on the basis of the data given in table 1.

Table 1. Database for model.

Year	Production (PJ*)	Imports (PJ)	Total energy supply (PJ)	Total final consumption (PJ)
2010	3301	2146	5541	3096
2011	3587	2431	5299	3170
2012	3576	1947	5129	3036
2013	3615	1666	4863	2934
2014	3239	1440	4424	2570
2015	2701	1317	3887	2127
2016	2662	1218	3835	2167
2017	2464	1469	3743	2088
2018	2549	1415	3916	2152
2019	2531	1453	3741	2079
2020	2387	1283	3616	2000
2021	2290	1346	3692	2051

Based on the selected most significant factors, a correlation matrix was constructed that shows the close relationship between the selected factors (table 2).

Table 2. Correlation matrix of selected variables.

	P	I	S	TC
P	1	0.77008	0.91946	0.95773
I	0.77008	1	0.90691	0.89578
S	0.91946	0.90691	1	0.98879
TC	0.95773	0.89578	0.98879	1

The relationship between the selected factors is positive and strong: between P and TC is 95.8%, between P and S – 91.9%, between P and I – 77%.

The results of further regression analysis are given in table 3, which makes it possible to assess the impact of selected variables on the production of all energy products in Ukraine using data for the twelve-year period 2010-2021.

The results of the regression analysis under the conditions of establishing a marginal 5-10% level of significance are:

Table 3. Results of multi-factor regression of P (least squares method, sample 2010–2021, 12 observations).

Variable	Coefficient	Std. Error	t-Statistic	Prob.
I	-0.467249	0.186403	-2.506656	0.0366
S	-0.653663	0.298190	-2.192104	0.0597
TC	2.361913	0.427114	5.529939	0.0006
C	668.3830	259.0415	2.580216	0.0326
R-squared	0.972702	Mean dependent var		2908.500
Adjusted R-squared	0.962465	S.D. dependent var		513.1008
S.E. of regression	99.40758	Akaike info criterion		12.29754
Sum squared resid	79054.93	Schwarz criterion		12.45917
Log likelihood	-69.78521	Hannan-Quinn criter.		12.23769
F-statistic	95.02058	Durbin-Watson stat		1.418393
Prob(F-statistic)	0.000001			

- the analysis of the coefficients of the equation showed that the value of P directly depends on the variables we have chosen;
- the R^2 regression result in this table is 97.3%, indicating how closely the variables in this model we choose are related to the production of all energy products. The regression result indicated that P has a sufficiently strong relationship with the elements we chose to influence it. In addition, the corrected $R_[adj]^2$ is high, at 96.2%. The chance of adopting H_0 is close to zero (F-statistic=0.00), supporting the hypothesis about the equation's overall importance. The relevance of the selected variables in terms of impact on P is confirmed as follows: GFSI: 3.6% energy resource imports; 5.9% total energy supply (within the 10% significance threshold); and 0.6% total final consumption. We chose variables that perfectly conform to the defined level of significance, which is fewer than 5-10%. In general, there are no strict criteria for the constant, although in our instance it is also statistically significant;
- analysis of the DW criterion helps to test our equation for autocorrelation. The value of the DW criterion lies in the range from 0 to 4; in our case, this criterion (DW) is 1.41. Statistics DW helps to determine critical points d_l and d_u. At the level of significance α=1%, we have 0.449<DW<1.373; our value is greater than d_u=1.373, which means there is no autocorrelation of the residuals and we have no reason to reject H_0, that is, we take it as a basis;
- the analysis of information criteria used in building this model showed that Akaike (AIC) and Schwarz (BIC) are 12.3 and 12.5, respectively, which are small acceptable values for the model.

4.2. Testing the autocorrelation model, the presence of heteroscedasticity and the quality of the selected factors in the model

Verifying the model for first-order autocorrelation revealed its absence; we next tested the model for the presence of higher (second) order autocorrelation using the Breusch-Godfrey test (table 4); verifying autocorrelation is reduced to testing the null hypothesis.

Table 4 has strong indications of Prob values. F(2,6) at 45.6% and Prob. Chi-Square(2) at 25.1%, which is greater than the 10% significance level. When using the following lag 3 values of Prob. F(3,5)= 69.2%, and Prob. Chi-Square(3)=42.1%; when using lag 4, the value of indicators is also more than 10%. This allows us to accept H_0 and is evidence that there is no higher (second) order autocorrelation.

Table 4. Breusch-Godfrey serial correlation LM (presample missing value lagged residuals set to zero).

F-statistic	0.897863	Prob. F(2,6)	0.4559
Obs*R-squared	2.764169	Prob. Chi-Square(2)	0.2511
R-squared	0.230347	Mean dependent var	-2.65E-13
Adjusted R-squared	-0.411030	S.D. dependent var	84.77507
S.E. of regression	100.7016	Akaike info criterion	12.36905
Sum squared resid	60844.83	Schwarz criterion	12.61151
Log likelihood	-68.21432	Hannan-Quinn criter.	12.27929
F-statistic	0.359145	Durbin-Watson stat	1.463408
Prob(F-statistic)	0.859537		

The next step is to test this model for heteroskedasticity based on the Breusch-Pagan-Godfrey, Glejser, ARCH, White, Harvey tests (table 5).

Table 5. Results of heteroskedasticity test (least squares method).

Breusch-Pagan-Godfrey test, dependent variable – $\text{RESID}\hat{2}$			
F-statistic	0.575653	Prob. F(3,8)	0.6470
Obs*R-squared	2.130523	Prob. Chi-Square(3)	0.5458
Scaled explained SS	1.228681	Prob. Chi-Square(3)	0.7461
Glejser test, dependent variable – ARESID			
F-statistic	0.690370	Prob. F(3,8)	0.5830
Obs*R-squared	2.467784	Prob. Chi-Square(3)	0.4811
Scaled explained SS	2.104368	Prob. Chi-Square(3)	0.5510
ARCH test, dependent variable – $\text{RESID}\hat{2}$			
F-statistic	0.046743	Prob. F(1,9)	0.8337
Obs*R-squared	0.056835	Prob. Chi-Square(1)	0.8116
White test, dependent variable – $\text{RESID}\hat{2}$			
F-statistic	0.305520	Prob. F(9,2)	0.9145
Obs*R-squared	6.947027	Prob. Chi-Square(9)	0.6426
Scaled explained SS	4.006376	Prob. Chi-Square(9)	0.9110
Harvey test, dependent variable – LRESID2			
F-statistic	0.517768	Prob. F(3,8)	0.6817
Obs*R-squared	1.951120	Prob. Chi-Square(3)	0.5826
Scaled explained SS	3.583219	Prob. Chi-Square(3)	0.3101

The analysis of table 5 proved the probability of accepting H_0 and the absence of heteroscedasticity:

- according to Breusch-Pagan-Godfrey test, Prob. F(3,8)=0.6470 and Prob. Chi-Square(3)=0.5458;
- according to ARCH Prob. F(1,9)= 0.8337 test, Prob. and Chi-Square(1)=0.8116;
- according to White Prob. F(9,2)= 0.9145 test, Prob. and Chi-Square(9)=0.6426;
- according to Harvey test, Prob. F(3,8)= 0.96817 and Prob. Chi-Square(3)=0.5826;
- all tests for heteroscedasticity showed its absence and the probability of accepting H_0>5-10%.

The next step is to check the model for the quality of the selected influencing factors on the production of all energy products based on the Ramsey and Chow tests (table 5 and table 6).

Table 6. Results of Ramsey RESET test (squares of fitted values are omitted).

	Value	df	Probability
t-statistic	0.420552	7	0.6867
F-statistic	0.176864	(1, 7)	0.6867
Likelihood ratio	0.299428	1	0.5842

Table 7. Results of Chow forecast test for observations from 2015 to 2021.

	Value	df	Probability
F-statistic	29.19535	(7, 1)	0.1416
Likelihood ratio	63.89761	7	0.0000

The Ramsey RESET test-based approach for assessing the functional form determines whether any components were mistakenly omitted from the model that have a major impact on the production of all energy products in Ukraine. The F-statistic is 17.7% at df(1.7), which above the 5% significance level. This indicates that the regression is statistically significant, and the linear form of the model we chose is correct.

The Chow forecast test ensures that the regression model's parameters remain stable. The F-statistic is 14.2% at df(7.1), which above the 5% significance level. This means that we accept H_0 in the model, that there are no structural fractures in the sample, and that the model is solid in structure.

4.3. Testing the model for normality of residuals, explanatory power, and predictive quality

The residual normality test (figure 1) is the next stage in ensuring the generated model's accuracy.

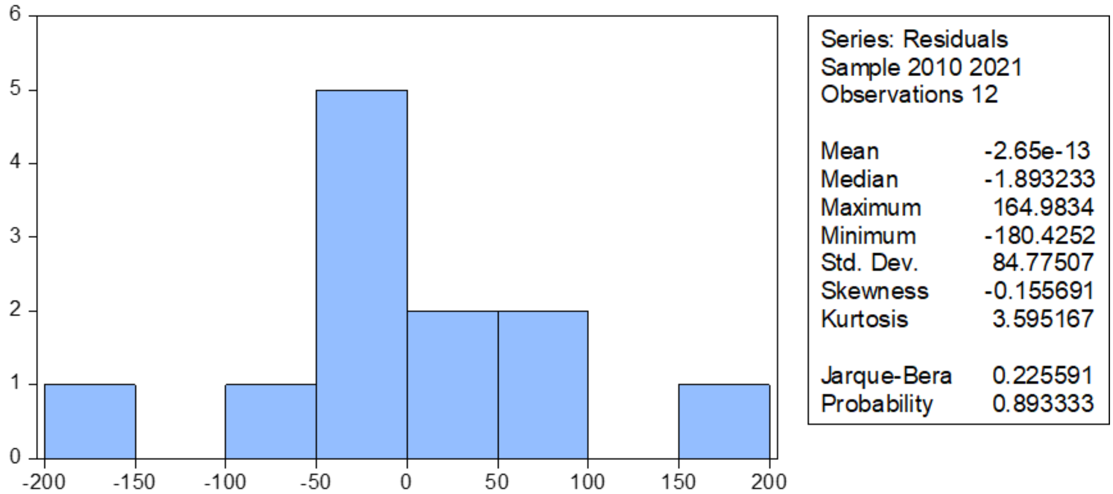

Figure 1. Normality test in $f(P)$.

Figure 1 demonstrated that the model's residual distribution is normal. Kurtosis =3.6, which is larger than zero and implies a steeply peaked distribution; a low value indicates that the distribution is near normal. The average level of production of all energy products was found to be intriguing, with a value of -1.89, indicating the impact of substantial negative factors on the overall volume of production of energy products in Ukraine, which is related to the conduct of the conflict. At the same moment, the probability of accepting H_0 is 89% (high).

The next step in evaluating the developed model is to assess its explanatory power, or how well the selected components arising from changes in the researched variables represent the Ukrainian model of energy product production (figure 2).

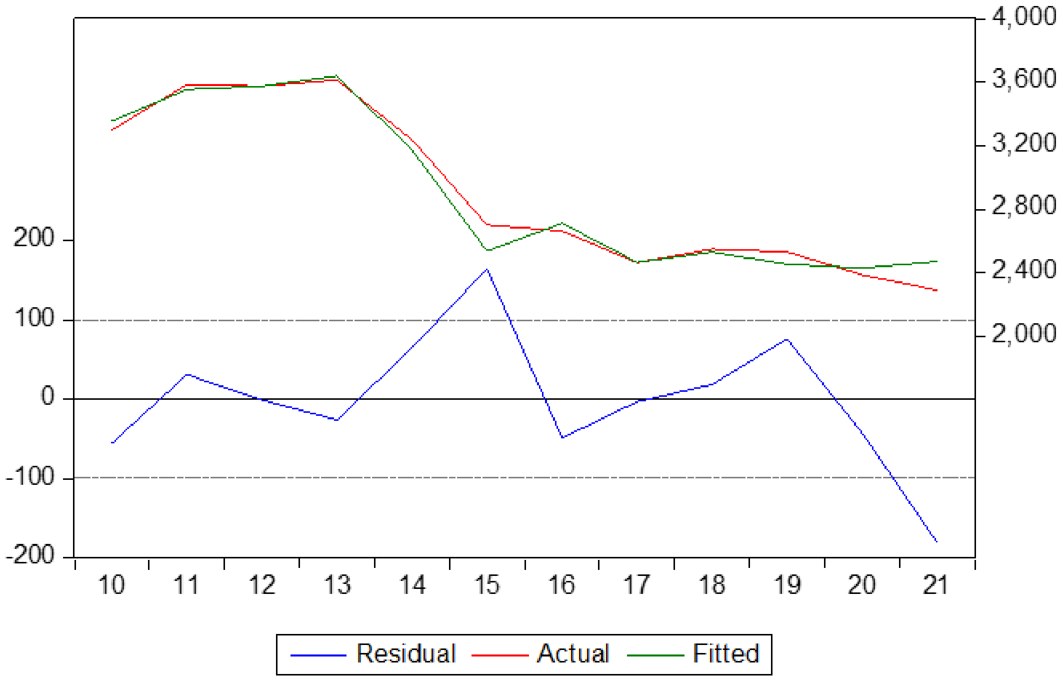

Figure 2. Explanatory ability of the model.

As figure 2 illustrates, the simulated values closely match the actual, true values. This demonstrates that the model we created fits all of the required criteria and is perfectly acceptable. Figure 3 shows the model's predictive quality.

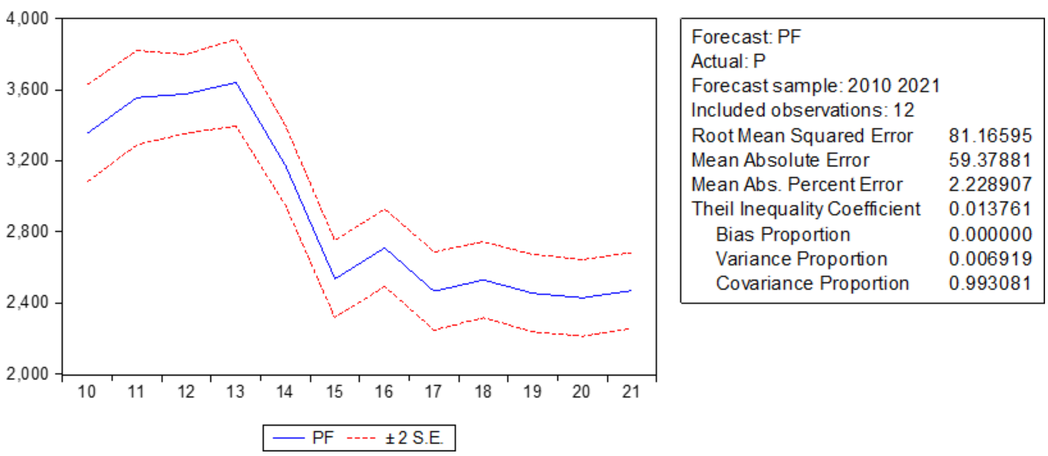

Figure 3. Forecast GFSI.

The forecast, based on data from 2010-2021, as shown in figure 3, implies a reduction in all energy product production in Ukraine after 2014, which is linked to the annexation and occupation of certain of Ukraine's territory. The environment became more stable between 2019 and 2021, and Russia's full-scale invasion of Ukraine had unfavorable implications. The MARE indicator is 2.2%, indicating that the forecast is both accurate and high-quality.

The authors' model completed all relevant tests, including autocorrelation, heteroscedasticity, factor quality, residual normality, explanatory power, and predictive quality. All tests and checks ensure that this model is correct for Ukraine. This means that:

- the equation is statistically significant with a high coefficient of determination;
- the equation represents an economic-mathematical model at a high level of quality;
- the model built by the authors is adequate and fully acceptable for forecasting in the future.

The model's general look is given by the following linear equation:

$$P = -0.4672 \times I - 0.6536 \times S + 2.3619 \times TC + 668.3830 \tag{4}$$

Therefore, the model proposed by the authors based on the selected most significant factors, namely import, total energy supply and final consumption, is developed with an emphasis on domestic energy production. This model of Ukraine's energy security has practical value in the following areas:

- the energy security model is aimed at reducing dependence on imports. By prioritizing domestic energy production, Ukraine is reducing its dependence on external sources. Given the current state of full-scale war in Ukraine, as well as historical tensions and geopolitical difficulties, reducing dependence on external energy suppliers strengthens Ukraine's sovereignty and will help reduce vulnerability to external pressure or manipulation in the future;
- the diversity of energy sources. In order to ensure energy security, Ukraine must prioritize domestic energy production. This allows the state to diversify its energy balance, minimizing vulnerability to supply disruptions or price variations for any given energy source. This diversification may include renewable energy sources such as natural gas, coal, and nuclear power;
- the energy independence, which ensures the energy security of Ukraine. Building a reliable and efficient domestic energy production infrastructure strengthens Ukraine's energy independence. This independence not only strengthens national security, but also provides stability for economic growth and development by ensuring a consistent and reliable supply of energy to industry, business and households;
- the economic growth. Investment in domestic energy generation generates jobs and encourages economic growth in Ukraine, both presently and in the future. This is especially real and noticeable when the expansion of the energy sector is paired with investments in research, innovation, and technology, which contribute to the construction of a trained workforce and the development of local industry;
- the environmental and sustainable development. A paradigm that promotes local production has the potential to provide environmental benefits, depending on the primary energy sources used. Investments in renewable energy sources, for example, can help to reduce greenhouse gas emissions, improve air quality, and support global efforts to battle climate change and achieve the Sustainable Development Goals. Thus, according to Ukraine's environmental strategy, by 2030, 17% of energy will be obtained from renewable sources (now, this figure does not exceed 6%), and the energy intensity of the economy would be halved [20];

- the energy availability. A full-scale war in Ukraine changes the attractiveness of investments, particularly in the energy industry. At the same time, it is worth noting that the initial investment in domestic energy production infrastructure can be substantial, resulting in more stable energy prices in the long run. By reducing its reliance on imported energy sources, Ukraine can limit the impact of external factors on energy costs, providing more stability and affordability for customers;
- the collaboration on energy security, particularly with European countries. A dependable local energy production strategy can promote energy security collaboration with neighbouring countries and international partners. Ukraine can create diplomatic relations and promote regional stability by reaching agreements on energy supply, infrastructure development, and emergency response measures.

The model developed by the authors proposes not only a way to meet energy needs, but also to promote economic development, environmental sustainability and international cooperation.

5. Discussion

When revealing this issue, it is important to acknowledge its intricacy and multifaceted nature. In the process of focusing on Ukraine's energy security in the context of sustainable development, the optimal mix of energy sources to ensure energy security and sustainable development in Ukraine, as well as how to balance the use of renewable and traditional energy sources to ensure sustainable development, are contentious issues that require further investigation. Because many countries rely on imported energy, it is critical to identify future ways to reduce dependence and secure domestic energy security, as well as establish plans for developing local energy sources that can help reduce reliance on other countries.

Technological advances also play an important role in energy security, and can be leveraged to improve energy security and development in Ukraine. Furthermore, its execution will have an impact on both economic development and the environment, in addition to ensuring appropriate energy security.

Further research in this area might include an assessment of the influence of sustainable development goals on total energy production, as well as prospects for Ukraine's EU membership in terms of energy security.

6. Conclusions

The analysis of the country's energy security, taking into account the war in Ukraine and the formulation of a model based on the production of energy goods, revealed:

- the long-term presence of factors of endogenous and exogenous origin that affect the total volume of production of energy products, which is a necessary and sufficient condition for ensuring energy security, the formation of a balanced and sustainable energy system in Ukraine under conditions of sustainable development;
- the existence of a strong connection between the volume of production of energy products and the researched and analyzed factors – import of energy resources, total energy supply, total final consumption, correlation coefficients are 77%, 92% and 96%, respectively;
- a 1% increase in general energy product imports results in a 0.5% drop in total domestic energy product production. With a 1% rise in overall energy supply (Total energy supply = Primary production + Recovered and Recycled products + Imports – Export + Stock changes – International maritime bunkers – International aviation), the total volume of output of domestic energy products decreases by 0.65%. A 1% increase in total final energy consumption (which includes energy consumed by industry, agriculture, and homes) results in a considerable rise in domestic energy product production.

- this model's practical value is exposed, since it is primarily focused at domestic energy generation, which will boost energy security while also contributing to economic development and environmental sustainability. The model's practical value is accomplished through reduced dependency on imports, diversification of energy sources, energy independence, energy availability, and collaboration in energy security, particularly with European countries.

Abstract. Ensuring social stability and environmental sustainability is crucial for implementing the Sustainable Development Goals in European Union (EU) countries. This paper aims to explore the interdependencies among human capital, employment, and resource productivity in these countries, focusing on sustainable development. To comprehensively assess factors influencing sustainable development in the EU countries, the simultaneous model is proposed. The simultaneous equations were derived using a two-step least squares method. The model comprises three endogenous variables (human capital, quantified by students enrolled in tertiary education; employment, in terms of the resident population concept; and resource productivity) and ten exogenous variables. The human capital pillar for the EU countries hinges on public funding for tertiary education, the employment dynamics for tertiary-educated individuals, resource productivity, environmental taxation, and emigration. Employment requires monitoring demographic trends, resource productivity, government funding for tertiary education, and environmental taxation. The environmental pillar depends on employment dynamics, GDP per capita, public funding for environmental protection, material resource extraction, and direct material inputs of fossil energy materials. For Austria, Belgium, and Portugal, from 2013 to 2021, the theoretical values based on the structural model of sustainable development demonstrated good forecast accuracy for human capital, employment, and resource productivity, indicating positive dynamics.

1. Introduction

The integration and cooperation of Ukraine with European Union (EU) countries present a pivotal strategic foundation for the modernization of the national economy, both preceding and amid the full-scale Russian invasion into Ukraine. Furthermore, the collaboration establishes the crucial conditions for attaining the Sustainable Development Goals (SDGs), elevating the standard of human capital, bolstering overall employment rates, and protecting the environment. Given the post-war reconstruction initiatives in Ukraine, elucidating the nuanced dependencies between human capital, employment dynamics, and sustainable development in the EU countries assumes heightened significance.

Within the framework of the global initiative set forth by the United Nations (UN) to effectuate a comprehensive transformation of the world by the year 2030, [1], the EU countries are actively forging national and international partnerships to fulfil the obligations delineated by the SDGs. This implies that each country in the EU has initially customised the set of SDGs to align with the distinctive features of national economic development, social conditions, and environmental status. Consequently, in Poland, the focus on the 4th SDG, "Quality Education", is directed towards fostering an environment conducive to educational development across the entirety of the nation and promoting equal opportunities in education [2, p. 79]. In Germany, the pursuit of this goal is aimed at the ongoing enhancement of both education and vocational training [3, p. 168–169]. In Lithuania, a crucial aspect concerning the "Quality Education" goal involves the acquisition of fundamental and advanced skills at all stages of learning and development. This encompasses the broader and equitable availability of o quality education across various levels, including access to vocational education and training [4]. In other words, at the EU level, the improvement of human capital is ensured by the provision of inclusive and equitable quality education, coupled with the development of opportunities for lifelong learning.

For each EU country, Goal 8, "Decent Work and Economic Growth", encompasses specific objectives and target indicators tailored to the prevailing socio-economic situation and anticipated future changes. For instance, in Poland, a pivotal focus lies in the development of stable employment structures, along with endeavours to augment the labour force participation of young individuals, those aged over 50, long-term unemployed individuals, and those with disabilities [2, p. 95]. In light of this, the EU countries, through the facilitation of employment opportunities, contribute to the heightened efficiency in utilizing human capital and other economic resources. Consequently, this engenders social stability, elevates living standards, and establishes a conductive framework for a productive economic landscape.

At the same time, the EU countries are instituting measures aimed at enhancing the efficiency of natural resource consumption and guaranteeing environmental sustainability. In Germany, the assessment of efficient and economic natural resource employment relies on key indicators such as the productivity of raw material use [3, p. 227–228]. These initiatives are comprehensive in scope and are intricately associated with various SDGs, including Goal 7, "Affordable and Clean Energy", Goal 9, "Industry, Innovation and Infrastructure", and Goal 11, "Sustainable Cities and Communities".

Concurrently, sustainability stands among the foremost priorities of the EU's domestic and foreign policy agendas. EU institutions play a pivotal role in establishing a national framework for the realization of the SDGs and systematically monitor the progress towards achieving these goals [5]. From this perspective, elucidating the complex dependencies between human capital, employment dynamics, and resource productivity in the EU countries becomes imperative for assessing the success of the SDGs and policy decision-making. The utilization of quantitative methods is envisaged to facilitate a nuanced comprehension of the dependencies between these drivers, offering valuable insights for policy aimed at SDG achievement. This approach also holds promise for a deeper understanding of future dimensions related to Ukraine's European integration and post-war recovery.

2. A literature review

Since the publication of Brundtland Report (On our Common Future) [6], discussions on sustainable development of national economies have become a focal point among scholars. Employing non-radical Data Envelopment Analysis (DEA) models, Cyrek and Fura [7] have demonstrated that structural shifts in employment across agriculture, industry, market, and non-market services in highly developed EU countries contribute favourably to the achievement of SDGs. Through the application of panel data regression models with fixed and random effects, as well as the systemic generalized method of moments, scholars [8] have revealed that the total expenditures on R&D, along with the employment rate of recent graduates, play integral roles in fostering sustainable development in the EU countries. Employing qualitative data analysis, methods of comparison and grouping, and the TOPSIS method, Lapinskaitė and Vidžiūnaitė [9] have ranked the G20 countries based on the indicators of SDG 8 "Decent work and economic growth" to assess the peculiarities of economic growth and the creation of a decent working environment in these G20 countries from 2013 to 2018. Given these insights, employment is recognized as a crucial factor that substantially contributes to the attainment of the SDGs.

Certainly, education stands as an equally vital component of sustainable development. Having analyzed the current and future landscape of education, employment and sustainable development in the EU, Gaballah, Dufourg, and Tondeur [10] have substantiated the pivotal role of "lifelong learning" driven by the rapid evolution of technology. Applying the Butterworth filter and correlation analysis, scholars [11] have elucidated the influence of migration on the attainment of the SDGs in Ukraine. Furthermore, they have identified policy measures aimed at ensuring adequate access to education, creating employment opportunities, and fostering intellectual migration to the country. Building on various theoretical approaches, McGrath, Alla-Mensah, and Langthaler [12] have delineated the connection between skills, vocational education, and training in relation to poverty reduction, economic growth, and decent work within the new paradigm of human and sustainable development.

Applying clustering, cross-effectiveness, and contingency assessment, Puertas and Marti [13] have uncovered inequalities in the sustainable development of municipalities in Spain and Italy, with the exception of the dimensions of People (SDGs 1, 2, 3, 4, and 5) and Prosperity (SDGs 7, 8, 9, 10, and 11). Employing a Logit-Probit modelling, Kuzior et al. [14] have demonstrated a positive and statistically significant impact of financial literacy, duration of compulsory education, government spending on education, student-teacher ratio, and secondary school enrolment on sustainable development. Employing vector autoregressive (VAR) methods and Johansen's VEC approach, Marynych [15] has determined that capital related to labour and education has a positive impact on regional sustainable development in Ukraine. Conversely, the lack of macroeconomic stability and unrealized potential of technological progress have a negative impact. Consequently, based on these findings, education in sustainable development and the pursuit of the SDGs serve as catalysts for positive changes in the national economy.

Moreover, various dimensions exist regarding the impact of education on sustainable development. In an empirical assessment of 179 countries aimed at identifying relationships among key SDGs, Sarwar et al. [16] have demonstrated that over the long term, the coefficients of labour and capital exhibit significance and positivity concerning education and carbon emissions. This suggests that reforms associated with the education system and climate change mitigation policies require an extended period to manifest an impact on the economy. Employing multiple regression and correlation analysis, Kichurchak [17] has revealed that within the framework of sustainable development, budget financing of tertiary education in the EU countries was affected by various exogenous factors. These factors include GDP, total annual net earnings of individuals without children, the labour market situation for individuals with tertiary education, and the number of students enrolled in public tertiary education institutions at the bachelor's or equivalent level. Employing a multifactorial analysis to assess the state of implementation of SDGs for quality education across 28 EU countries, Szymańska and Zalewska [18] have underscored that globalization and the establishment of a unified policy framework within the EU necessitate supplementary endeavours at the domestic level. Through modelling the distribution of years of schooling across the country and employing this model to scrutinize educational inequality since 1970, as well as projecting progress towards the 2030 education-related Sustainable Development Goal (SDG) targets, Friedman et al. [19] have identified significant issues with secondary and tertiary completion rates. Hence, it is imperative to persist in prioritizing the improvement of the education sector to elevate human capital and promote the sustainable development of nations.

Alongside this, rationalizing the use of natural resources is also crucial for sustainable development. By employing multiple regression analysis, Taušová, Tauš, and Domaracká [20] have developed a model enabling the assessment of the capability to achieve the goals established by sustainable development and environmental policy within the EU. This model delineates the significance of the impact of the observed variables on the resultant resource productivity of both the EU member states and the Visegrad countries. Meanwhile, Giljum et al. [21] have determined that the EU's sustainable development policy instruments, focusing on enhancing eco-efficiency at the micro level, can contribute to economic growth. This contribution, however, is accompanied by a slight reduction in domestic production across all European countries and a significant increase in resource productivity.

To enhance the measures of Ukraine's sustainable development strategy, Zomchak [22] has proposed a structural (simultaneous) model incorporating GDP, household income and environmental expenditures as endogenous variables, along with seven exogenous variables. Positioning sustainable development as a conceptual framework for the post-war economy of Ukraine, Martynovych, Yemchenko and Kulinich [23] have outlined a procedure for assessing the effectiveness of Ukraine's socio-economic development after the war. They have accomplished this by defining an integral indicator based on the generalized Harrington's desirability function. Employing panel autoregressive distributed lag (ARDL) to examine the correlation between variables, Sadiq et al. [24] have uncovered a positive impact of environmental, social and corporate governance (ESG), and economic growth on the SDGs in ASEAN countries. To assess the progress in achieving the SDGs in the EU countries and understand the interconnections between them, Kuc-Czarnecka, Markowicz and Sompolska-Rzechuła [25] have employed sensitivity analysis, linear ordering of countries, and Spearman's rank correlation coefficient. Their findings indicate there are more potent synergies among the SDGs than trade-offs. Accordingly, the considerations of environmental protection and economic growth in the context of sustainable development for national economies are gaining relevance in policy-making.

Meanwhile, the processes of fostering a diverse and harmonious society have laid the groundwork for evaluating the role of culture in sustainable development and the implementation of the SDGs. By employing the fuzzy set method of qualitative comparative analysis (fsQCA), incorporating the Hofstede approach to cultural dimensions, and utilizing the SDGs index across 82 countries, Sedita, Blasi and Yang [26] have shown that culture significantly influences the strategies employed by countries in attaining sustainable development. Applying the principal components method and econometric modelling, the dependencies of local budget expenditures on culture in Ukraine on the demographic situation, business activity, and well-being of the population were specified to achieve the SDGs [27]. Based on a logistic regression model, Verina et al. [28] have established a connection between employment in the cultural sector, government spending on culture, the number of cultural enterprises, and sustainable development in the EU countries. Applying panel regression methods with random effects and OLS regression based on the first differences of the relevant variables, Sokół, Pangsy-Kania and Biegańska [29] have shown the influence of cultural industries on sustainable development in the EU countries. Additionally, these contributions have demonstrated that the achievement of the SDGs should be guided by the incorporation of cultural considerations and values, aiming to address complex socio-ecological and economic challenges.

Another strand of research focuses on the role of digitalization, information and communication technologies (ICTs) in the attainment of the SDGs. Sorin-Iulian et al. [30] have developed two-panel data regression models to evaluate the influence of crucial ICT indicators at the EU level on SDGs, including economic growth and the reduction of inequality. Their findings indicate that advancements in the implementation of the digital society have the potential to mitigate income inequality. Focusing on a sample of 140 countries over the period 2000-2019, Nchofoung and Asongu [31] have identified the favourable impact of ICTs on sustainable development through fixed effects estimation, Driscoll and Kraay estimation, middle group estimation, system GMM and Tobit fixed effects instrument variable. To elucidate the initiatives of the sectoral national and regional sustainable development policy, Kichurchak [32] has developed a simultaneous model for the information and communication sector by region of Ukraine. In this model, the equations describe the added value of the production costs of business entities, the number of operating business entities and employees, and the structure of service exports in this sector. In the light of sustainable development and the mitigation of the consequences of COVID-19, Polishchuk et al. [33] have examined the factors of digitalization in the national economies of specific countries and categorized the types of trajectories associated with sustainable economic growth. In essence, the sustainable development of national economies, along with the corresponding policy initiatives, necessitates the consideration of factors related to technological change and the advancement of specific sectors and industries.

Overall, scholars have made valuable contributions in elucidating the complex social, economic, and environmental dimensions of sustainable development. They have involved quantitative methodologies for assessing the impact of employment dynamics and education, ecological and rational resources consumption, culture and ICTs on the SDGs in Ukraine, the EU and other countries. However, this paper proposes to employ structural modelling methods to uncover dependencies and assess the relations that delineate the social and environmental dimensions of sustainable development in EU countries.

The purpose of this paper is to explore the dependencies among human capital, employment dynamics, and resource productivity in the EU countries within the framework of sustainable development, employing econometric methods.

The underlying hypotheses are as follows. Firstly, human capital is posited to be linked to the number of students enrolled in tertiary education in the EU countries, potentially influenced by their expectations of employment, the fiscal capacity of the public budget for funding tertiary education, and current approaches to taxation. Secondly, the number of employees may be interconnected with the prevailing demographic situation in the EU countries, resource productivity, budgetary allocations for education, and taxation. Thirdly, it is suggested that resource productivity may be contingent on the state of employment and public expenditures dedicated to environmental protection in the EU countries. This approach seeks to provide a reasonable explanation for the structure of relationships among these parameters and uncover the factors contributing to sustainable development in EU countries.

3. Research methods

The exploration of the dependencies between human capital, employment dynamics, and resource productivity for sustainable development in the EU countries requires careful consideration of their mutual influences on each other. Methodologically, the most suitable approach for this purpose is a framework of simultaneous regression equations involving two or more dependent variables. In a nutshell, the simultaneous model stands out as an approach enabling the identification of complex dependencies within the ecological and social components of countries.

Accordingly, the variables explicable through the structural equation model, and whose values are determined through the simultaneous interplay of the model variables, can be categorized as either endogenous or jointly determined. Moreover, a comprehensive description of the dependencies between human capital, employment dynamics, and resource productivity in the EU countries requires the careful selection of explanatory (exogenous) variables for the simultaneous model. Indeed, the determination of exogenous or endogenous status for variables in the data sample is contingent upon the expertise of the individual constructing the simultaneous regression equations.

Generally, the structural simultaneous model can be expressed as follows:

$$Y_{1t} = b_{12} \cdot Y_{2t} + \cdots + b_{1m} \cdot Y_{mt} + a_{11} \cdot X_{1t} + a_{12} \cdot X_{2t} + \cdots + a_{1n} \cdot X_{nt} + a_{10} + \xi_{1t} \quad (1)$$

$$Y_{2t} = b_{21} \cdot Y_{2t} + \cdots + b_{2m} \cdot Y_{mt} + a_{21} \cdot X_{1t} + a_{22} \cdot X_{2t} + \cdots + a_{2n} \cdot X_{nt} + a_{20} + \xi_{2t} \quad (2)$$

$$Y_{mt} = b_{m1} \cdot Y_{1t} + \cdots + b_{mm-1} \cdot Y_{m-1t} + a_{m1} \cdot X_{1t} + a_{m2} \cdot X_{2t} + \cdots + a_{mn} \cdot X_{nt} + a_{mt} + \xi_{mt} \quad (3)$$

The careful selection of exogenous and endogenous variables is methodologically undertaken to ensure a comprehensive understanding of their roles in the sustainable development of EU countries. Additionally, the correlation between the potential factor variables and the selected resulting indicators is assessed.

The designation of the number of students enrolled in higher education institutions (HEIs) as an endogenous variable for human capital in EU countries is justified by its capacity to quantify advancements in human capital quality. As students acquire valuable knowledge, develop hard and soft skills, and gain practical experience, these educational endeavours contribute to their subsequent engagement in economic activities. In the light of sustainability, such developments exert influence on employment and resource productivity by fostering social stability and instilling a responsible attitude towards the judicious use of limited resources. In other words, an increasing number of students enrolled in HEIs serves as an indicator of growing human capital.

The endogenous variable for the simultaneous regression equations is employment in the EU countries. The selection of this predicted variable is grounded in the perspective that employment dynamics established the conditions for involving human capital in economic activities and serve as a pivotal focal point for the pursuit of the SDGs.

The choice of resource productivity as the explained variable for assessing sustainable development is motivated by the shift towards actively incorporating resource-saving production in EU countries. Additionally, on a macroeconomic scale, resource productivity serves as an indicator reflecting the utilization conditions of available natural resources in the production of various economic goods, as well as the current state of technology and innovation.

4. The structural model of sustainable development in the EU countries

The simultaneous regression equations can be delineated by the following endogenous variables: Y_{1t} – students enrolled in tertiary education in the EU countries, number of individuals; Y_{2t} – total employment in the EU countries (resident population concept – LFS), from 20 to 64 years, thsd. people; Y_{3t} – resource productivity in the EU countries, euro per kilogram. The exogenous variables for the simultaneous model encompass the following: X_{1t} – gross domestic product at market prices in the EU countries, current prices, euro per capita; X_{2t} – average population in the EU countries, people; X_{3t} – total general government expenditures on tertiary education in the EU countries (levels 5–8), mln euro; X_{4t} – total environmental taxes in the EU countries, percent of gross domestic product (GDP); X_{5t} – employment with tertiary education in the EU countries (levels 5–8), from 15 to 64 years, number of individuals; X_{6t} – total environmental taxes, mln euro; X_{7t} – total general government expenditure on environmental protection in the EU countries, mln; X_{8t} – domestic extraction of material resources in the EU countries, tonnes per capita; X_{9t} – direct material inputs of fossil energy materials/carriers, tonnes per capita; X_{10t} – emigration by age in completed years, number of people.

The identified explained and explanatory variables included in the simultaneous model can be characterized through descriptive statistics (table 1). The data have revealed variations among the EU countries in the social and resource dimensions of sustainable development. In other words, this implies that the adoption of policy measures for sustainable development in the EU countries is differentiated and depends on each country's capacity to attain the SDGs.

To construct a set of simultaneous regression equations for human capital, employment dynamics, and resource productivity, statistical data from the Eurostat website [34] were utilized. The data were collected from 2013 to 2021 for the 26 EU countries. Consideration was given to the comprehensiveness of the statistical data provided for both the explained and explanatory variables. Specifically, for the endogenous variable Y_{1t}, statistical data for the year 2022 are not yet available for the sample EU countries. In essence, the simultaneous model comprises three regression equations based on an unbalanced panel dataset. In other words, each equation represents a pooled regression model without effects (fixed or random).

Table 1. Descriptive statistics for covariates of dependent and independent variables (based on [34]).

Variable	Mean	Scope of of variation	Standard deviation	Coefficient variation	Standard error
Y_{1t}	688169.3	3344785	831118.3	1.21	55042.2
Y_{2t}	7233.3	39754	9327.2	1.29	617.7
Y_{3t}	1.88	4.94	1.11	0.59	0.07
X_{1t}	31109.8	107280	21046.3	0.68	1393.8
X_{2t}	17359899	82872314	22158236.8	1.28	1467465
X_{3t}	4067.7	29344.9	5694.06	1.40	377.1
X_{4t}	2.57	2.98	0.65	0.25	0.04
X_{5t}	2477.6	12989.8	3178.8	1.28	210.52
X_{6t}	12203.9	64508.3	16978.9	1.39	1124.5
X_{7t}	4114.8	25950.8	6189.9	1.50	409.94
X_{8t}	17.02	62.35	12.31	0.72	0.824
X_{9t}	6.56	39.58	7.28	0.90	0.48
X_{10t}	97743.58	694438	124200.6	0.79	8225.4

The overall specification of the simultaneous model for the EU countries can be outlined as follows:

$$Y_{1t} = b_{13} \cdot Y_{3t} + a_{13} \cdot X_{3t} + a_{15} \cdot X_{5t} + a_{16n} \cdot X_{6t} + a_{110} \cdot X_{10t} + a_{10} + \xi_{1t} \tag{4}$$

$$Y_{2t} = b_{23} \cdot Y_{3t} + a_{22} \cdot X_{2t} + a_{23} \cdot X_{3t} + a_{24} \cdot X_{4t} + a_{20} + \xi_{2t} \tag{5}$$

$$Y_{3t} = b_{32} \cdot Y_{2t} + a_{31} \cdot X_{1t} + a_{37} \cdot X_{7t} + a_{38} \cdot X_{8t} + a_{39} \cdot X_{9t} + a_{30} + \xi_{3t} \tag{6}$$

In the reduced form, equations (4)–(6) can express in terms of the exogenous variables X_{jt} and the error terms e_{jt} and can write as:

$$Y_{1t} = \pi_{11} \cdot X_{1t} + \pi_{12} \cdot X_{2t} + \pi_{13} \cdot X_{3t} + ... + \pi_{19} \cdot X_{9t} + \pi_{110} \cdot X_{10t} + \pi_{10} + \upsilon_{1t} \tag{7}$$

$$Y_{2t} = \pi_{21} \cdot X_{1t} + \pi_{22} \cdot X_{2t} + \pi_{23} \cdot X_{3t} + ... + \pi_{29} \cdot X_{9t} + \pi_{210} \cdot X_{10t} + \pi_{20} + \upsilon_{2t} \tag{8}$$

$$Y_{3t} = \pi_{31} \cdot X_{1t} + \pi_{32} \cdot X_{2t} + \pi_{33} \cdot X_{3t} + ... + \pi_{39} \cdot X_{9t} + \pi_{310} \cdot X_{10t} + \pi_{30} + \upsilon_{3t} \tag{9}$$

where π_{ij} – reduced form parameters, υ_{ij} – reduced form errors, $i = (\overline{1,3})$, $j = (\overline{1,8})$.

The first equation (4) of the system delineates the number of students in the EU countries enrolled in tertiary education as a function of resource productivity, general budget expenditures on tertiary education, the employment of individuals with tertiary education, the total amount of environmental taxes, and the number of emigrants. The second equation (5) shows the functional dependence of employment in the EU countries on resource productivity, average population, general government expenditures on tertiary education, and environmental taxes by GDP. The third equation (6) in the structural model refers to the factors influencing the functional dependence of the resource productivity in the EU countries, specifically encompassing employment, GDP per capita, general budget expenditures on environmental protection, the volume of domestic extraction of material resources per capita, and direct material inputs of fossil energy materials/carriers per capita.

The structured equations system (4)–(6) can be presented in a tabular form to examine the model for identification criteria (table 2). The order conditions for the simultaneous equations have revealed that each of them is over-identified (table 3). In light of the verification results, it is recommended to employ a two-step least squares method to accurately assess the parameters associated with the over-identified simultaneous regression equations. This approach ensures a rigorous analysis of the model and enhances the reliability of the parameter estimation process.

Table 2. Tabular form of the simultaneous model.

(4)	7	1	Over-identified equation
(5)	6	1	Over-identified equation
(6)	7	1	Over-identified equation

The simultaneous model elucidating dependencies among human capital, employment dynamics and resource productivity is as follows:

$$Y_{1t} = -39574.475Y_{3t} - 17.643X_{3t} + 165.271X_{5t} + 17.351X_{6t} + 1.260X_{10t} + 89829.312 + \xi_{1t} \quad (10)$$

$$Y_{2t} = -318.5286Y_{3t} + 0.000347X_{2t} + 0.3383X_{3t} + 417.0963X_{4t} + 1493.6708 + \xi_{2t} \quad (11)$$

$$Y_{3t} = -0.00004Y_{2t} + 0.000034X_{1t} + 0.000119X_{7t} - 0.0436X_{8t} + 0.0371X_{9t} + 1.1207 + \xi_{3t} \quad (12)$$

The coefficients of determination for each of the structural equations (10)–(12) show the existence of very strong correlations between exogenous and endogenous variables. The simultaneous model exhibits a noteworthy capacity to explain the change in the values of the explained variables, making it well-suited for predictive analysis. Each regression equation within the model satisfies the criteria stipulated by both the Fisher criterion and the Student's t-test, ensuring the adequacy of their representation (table 4). Furthermore, the absence of first-order autocorrelation, as assessed by the Durbin-Watson criterion, substantiates the model's statistical soundness. After delineating the structural parameters of the simultaneous model for human capital, employment dynamics, and resource productivity in EU countries, it is imperative to undertake a judicious interpretation of these equations.

5. The interpretation of the simultaneous model for sustainable development in the EU countries

In line with equation (10) of the simultaneous model, it is posited that the number of students enrolled in tertiary education in the EU countries is influenced by resource productivity, total general government expenditures on tertiary education, the number of employed people with

** – the regression.

tertiary education, and the amount of environmental taxes to the extent of 98.18%. Anticipating changes in these factors provides valuable insights into their impact on the average number of students enrolled in tertiary education (levels 5–8) in the EU countries.

Specifically, an increase of 1 euro/kg in resource productivity in the EU countries is associated with an estimated decrease of 39,574.5 in the average number of students enrolled in tertiary education (levels 5–8). Conversely, a reduction of 1 million euros in the total general government expenditures on tertiary education (levels 5–8) in the EU countries is linked to a decrease of 17.6 in the average number of students enrolled in tertiary education (levels 5–8). Moreover, an increase of 1 person in the number of employed people with tertiary education in the EU countries corresponds to anticipated growth of 165.3 in the average number of students enrolled in tertiary education (levels 5–8). Furthermore, an augmentation of 1 million euros in the volume of environmental taxes is associated with an expected increase of 17.4 in the average number of students enrolled in tertiary education in the EU countries. If the number of emigrants increases by 1 individual, it is expected that the average number of students in the EU countries enrolled in tertiary education may increase by 1.3. These findings provide insights into the complex dynamics governing the enrolment patterns in tertiary education across the EU countries, shedding light on the nuanced influence of key variables within the model.

However, since February 24, 2022, human capital in the EU countries has been affected by the war in Ukraine, resulting in forced migration for temporary protection. Between July 2022 and March 2024, the average monthly growth rate of temporary protection beneficiaries from Ukraine was 102.4%. Of these beneficiaries, 101.4% were under the age of 18, 102.7% were aged 18-34, 103.0% were aged 35-65, and 103.7% were aged over 65 [calculated based on [34]]. Concerning age structure, 34.3% of Ukrainians are under the age of 18, 24.0% are aged 18-34, 35.1% are aged 35-65, and only 5.9% are over 65 [calculated based on [34]]. Essentially, a significant proportion of economically active individuals people and young people under the age of 18 from Ukraine have sought refuge in the EU countries. In the long run, under the most pessimistic possible scenario for Ukraine, the EU countries stand to benefit from the influx of human capital, which could either be enhanced in quality through education or actively participate in the labour market. Nonetheless, determining the relationship between EU human capital, forced migration from Ukraine and other factors is challenging due to Eurostat's recent initiation of compiling statistics on temporary protection beneficiaries from Ukraine.

As indicated by the parameters of equation (11) within the simultaneous model, there is a 99.64% probability that the total employment of the population aged 20–60 in the EU countries, as per the resident population concept is influenced by several factors, including resource productivity, the average population of the country, total general government expenditures on tertiary education (levels 5–8), and the structure of general environmental taxes. These factors collectively account for the variation in total employment to a substantial degree.

The analysis reveals that an increase of 1 euro/kg in resource productivity may result in an estimated decrease of 318.5 thousand people in the average total employment of the population aged 20–60 years in the EU countries, adhering to the resident population concept. Instead, a rise in the average population in the EU countries by 10,000 people is associated with an anticipated increase of 3.5 thousand people in the average total employment of the population aged 20–60 in these countries, considering the resident population concept. Furthermore, an increase of 1 million euros in the total general government expenditures on tertiary education (level 5–8) in the EU countries may lead to a potential increase of 0.3 thousand people in the total employment of the population aged 20–60 in these countries, based on the resident population concept. Additionally, an increase of 1% in the total environmental taxes in the EU countries is linked to an expected decrease of 417.1 thousand people in the average total employment of the population aged 20–60, according to the resident population concept. These findings underscore the intricate dynamics governing the relationship between various factors and total employment within the specified age group in the EU countries, providing nuanced insights for both academic and policy considerations.

On the basis of equation (12) of the simultaneous model, it is posited that resource productivity in the EU countries is significantly influenced by several factors, encompassing 93.5% of the total variance. The determinants include the total employment of the population aged 20–60 years according to the resident population concept, GDP in market prices per capita, total general government expenditure on environmental protection, domestic extraction of material resources per capita, and direct material inputs of fossil energy materials/carriers per capita. Foreseeing alternations in these factors provides valuable insights into their potential impact on the average resource productivity in the EU countries.

In particular, an increase of 10,000 thousand people, according to the resident population concept, is associated with an expected decrease of 0.40 euros/kg in the average resource productivity in the EU countries. Meanwhile, an increase of 10,000 euros per capita in the GDP in market prices may lead to an increase of 0.34 euros/kg in the average resource productivity in the EU countries. Moreover, an increase of 10,000 million euros in the total government budget expenditures on environmental protection in the EU countries is linked to an estimated increase of 1.19 euros/kg in the average resource productivity. Additionally, an increase of 1 tonne per capita in domestic extraction of material resources in the EU countries corresponds to an anticipated decrease of 0.0436 euros/kg in the average resource productivity. If the direct material inputs of fossil energy materials/carriers in the EU countries increased by 1 tonne per capita, the average resource productivity could rise by 0.0371 euros per capita. These findings contribute to a comprehensive understanding of the complex dynamics influencing resource productivity in EU countries, offering insights into the potential impacts of various economic and environmental factors.

By comparing the theoretical and empirical values of endogenous variables within the structural equations system for individual countries of the EU, an examination of the quality of the simultaneous model can be conducted by calculating the forecast accuracy metrics for selected EU countries (table 5). Given this fact, the simultaneous model as represented by regression equations (10)–(12), accurately reflects the dependencies among human capital, employment dynamics, and resource productivity for sustainable development in selected EU countries. The forecast accuracy indicators for variables Y_{1t}, Y_{2t}, and Y_{3t} for all analyzed countries are less than 10%, underscoring the high accuracy of theoretical values. However, for Y_{1t} and Y_{3t} in Austria, the values of MAPE and RMSPE exceed 10%, indicative of a still acceptable but comparatively lower forecast accuracy. Furthermore, the U-statistic values for the endogenous variables Y_{1t}, Y_{2t}, and Y_{3t} are in proximity to 0, affirming the accuracy of the theoretical values calculated for Austria, Belgium, and Portugal. This analysis highlights the robustness of the simultaneous model, implying its effectiveness in capturing and predicting the complex relationships among human capital, employment, and resource productivity in the EU countries, with a specific focus on sustainable development.

Based on the specified parameters outlined in structural equations (10)–(12), the theoretical values of the endogenous variables Y_{1t}, Y_{2t}, and Y_{3t} for selected EU countries, specifically Austria, Belgium, and Portugal can be calculated and subsequently compared with empirical values. Figures 1–3 present the dynamics of both empirical and theoretical values for the endogenous variables Y_{1t}, Y_{2t}, and Y_{3t} in Austria, Belgium, and Portugal. Given this fact, the theoretical values, derived from the simultaneous model, exhibit fluctuations in the number of students, employment and resource productivity, indicating instances where they may surpass or lag behind empirical data. For the attainment of SDGs in the EU countries, it is imperative to sustain the positive dynamics in terms of the number of students, employment, and resource productivity. The disparities between theoretical and empirical values underscore the complexity of these relationships and emphasize the need for ongoing analysis and adaptation of policies to

foster sustainable development.

6. Conclusions

To summarize, the construction of the simultaneous model, comprising three regression equations, provides valuable insight into the complex dependencies among human capital, employment dynamics, and resource productivity in the EU countries from the standpoint of sustainable development. In this model, human capital in the EU countries is conceptualized as a function of the number of students enrolled in tertiary education. This dependence is contingent upon explanatory variables such as resource productivity, general government expenditures on tertiary education, employment of the population with tertiary education, total environmental taxes, and the number of emigrants.

Employment in the EU countries is delineated by the function of the total employment of the population aged 20–64, based on the resident population concept. It is influenced by resource productivity, average population, general government spending on tertiary education, and the share of environmental taxes in GDP. Additionally, the environmental dimension of

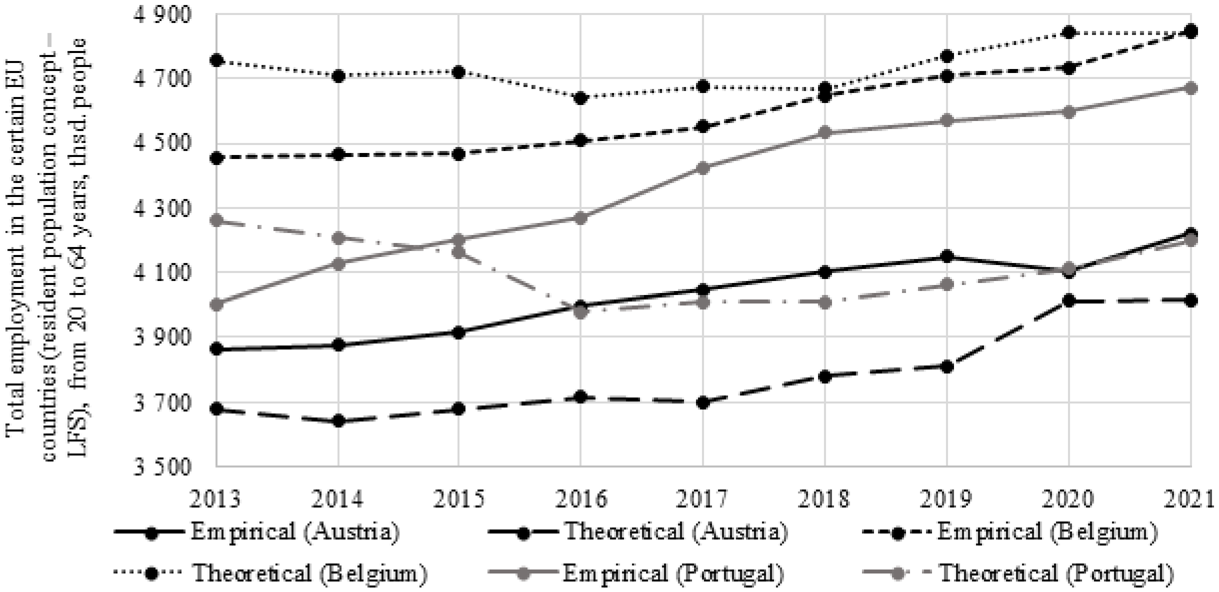

Figure 2. Actual and predicted dynamics of total employment in certain EU countries.

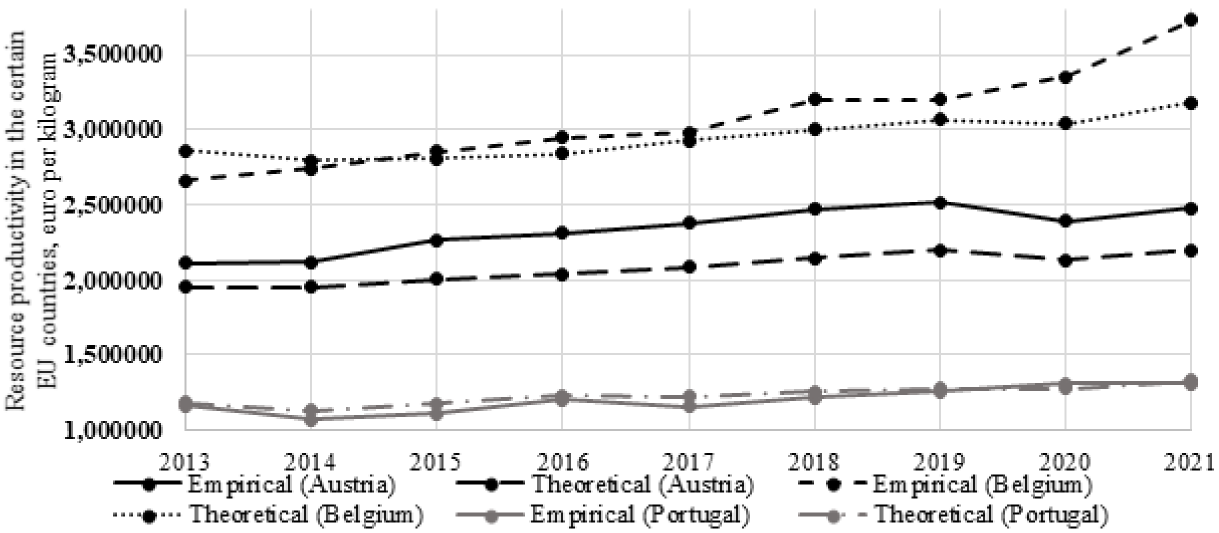

Figure 3. Actual and predicted dynamics of total employment in certain EU countries.

sustainable development is represented through resource productivity in the EU countries. This explained variable functionally depends on the total employment among the population aged 20–64 according to the resident population concept, GDP per capita at market prices, general government expenditures on environmental protection, local extraction of material resources per capita, and the volume of direct material inputs of fossil energy materials/carriers per capita. Additionally, theoretical and empirical figures for the endogenous variables of the simultaneous model were constructed and compared for certain EU countries, providing a basis for evaluating the regression equations' quality. This also confirms the accuracy of the variables selection as well as the description of dependencies among them.

In line with the parameters of the structural equations, the enhancement of human capital for sustainable development in the EU countries hinged upon strategies related to the public funding of tertiary education, the employment scenario for people with tertiary education, determinants of resource productivity, and the volume of environmental taxes. The employment landscape, considered as a crucial dimension of sustainable development in the EU countries, will be shaped by demographic conditions, policy measures aimed at bolstering resource productivity, improvements in the state's capacity to fund tertiary education, and evolving strategies concerning general environmental taxation. The enhancement of the environmental dimension within the EU's sustainable development framework hinged on several factors. These include the features of employment and GDP, government expenditures on environmental protection, the intensity of material resource extraction, and the increase in direct material inputs from fossil energy resources.

Undoubtedly, the war in Ukraine will also exert an impact on the sustainable development in the EU countries. Concerning human capital, this impact will be driven by the integration of forced migrants into recipient countries' economies and the formation of their expectations regarding a potential return to Ukraine following the cessation of hostilities. It is conceivable that some of the forced migrants from Ukraine will engage in educational pursuits, including higher education. Regarding employment in EU countries, this may entail the integration of certain forced migrants from Ukraine into various sectors of the recipient country's economy following an adaptation period. As for the resource productivity in the EU countries, the war in Ukraine may serve as a catalyst for more efficient utilization of local material resources and reduced reliance on fossil energy resources. Additionally, Russian military aggression has had catastrophic repercussions for human capital, the labour market, and the environment in Ukraine, creating substantial barriers to sustainable development.

Abstract. The main methods of removing phosphorus and sulfur from iron ores, as well as magnetite and hematite concentrates, were analyzed. For effective dephosphorization of hematite concentrates, it is necessary to use direct cationic flotation of apatite, with the help of which it is possible to remove more than 74% of phosphorus from the concentrate. As a result of the analysis of the conducted research and the synthesis of the obtained scientific results, a technology was developed for removing phosphorus from iron concentrates. This technology allows for the reduction of the phosphorus content from 0.14% to 0.04%. Chemical methods – alkaline or acid leaching with separation of the leached concentrate – are the most common ways to dephosphorylate metal-containing ores. Research on chemical methods of cleaning ores and iron ore concentrates is carried out in the following directions: leaching with alkali solutions; acid leaching at different temperatures; and leaching of impurities in autoclaves. The conditions of leaching of poor hydrogethite high-phosphorus concentrates at high and low temperatures were investigated. The proposed technology of leaching samples of poor hydrogethite high-phosphorus concentrates at high and low temperatures allows us to claim that the parameters of the firing process allow the recrystallization of iron and therefore contribute to the access of mineral acid to particles containing phosphorus.

1. Introduction

Currently, Ukraine is the seventh largest producer of iron ore raw materials in the world with a state balance of ores in the amount of about 30 billion tons, which are concentrated in 52 deposits, 24 of which are currently being developed [1]. The analysis of the practical experience of beneficiation of magnetite ores at mining and beneficiation factories in Ukraine (more than 70 years) made it possible to establish a clear relationship between the beneficiation indicators of non-oxidized quartzites and their composition by comparing the results of beneficiation of quartzites according to their material composition and structural [2].

Nowadays, 98.5% of iron ore products are used for the needs of ferrous metallurgy, so the requirements for the quality of the mineral-raw material base come from the requirements for steel, and cast iron, as well as from the technological features of steelmaking production [3]. Since the blast furnace is the main technological process in Ukraine and Eastern Europe, the requirements for the quality of iron ore products are primarily focused on it. It should be noted that the requirements for the quality of iron ore products exported to Western Europe are higher since the metallurgical production of industrialized countries is focused primarily on the direct recovery of iron, bypassing the blast furnace process. Therefore, the main task is to provide the iron mining industry with high-quality mineral raw materials suitable for high-quality metallurgy [4, 5]. This is possible due to the improvement of the technology in the development of operational objects [6, 7].

Phosphorus is a harmful impurity in metal, because, being in it, it gives it brittleness and greatly increases the tendency to brittle fracture. Phosphorus also increases the cold-brittleness threshold, that is, the temperature at which the impact viscosity drops sharply. Since phosphorus cannot be easily removed from the flux or melt, the maximum allowable content of phosphorus in steel is limited to a rather low limit, which, taking into account the requirements for the metal and the possibilities of dephosphorization, is up to 0.02-0.04%.

A large amount of damage in the smelting of iron and ferromanganese is caused by an excess of silica. When smelting iron, increasing the silica content by 1% increases the consumption of coke by approximately 3%, fluxes by 4%, and reduces the productivity of the blast furnace by 2-7%. When smelting ferromanganese, silica leads to the formation of strong manganese silicates in the lower part of the furnace, which turns into slag, which, in turn, sharply reduces the extraction of manganese.

In the recovery process of either the ore or the production concentrate, the empty rock contained in the metal pellets is transformed into the final product. In addition, the presence of empty rock in metalized raw materials causes a large slag formation in the steel smelting process. Under these conditions, the consumption of electricity and fluxes increases significantly, and the duration of melting increases. In addition, slag corrodes the lining of furnaces. Therefore, in the metalized raw materials intended for steel smelting, they strive to reduce the content of empty rock as much as possible and to bring the content of acidic rocks (SiO_2) to 4%.

Therefore, the creation of a fairly simple and effective technology for the preparation of magnetite and hematite concentrate, which ensures a reduction in the content of harmful impurities, is a very urgent practical task.

2. Literature review

Depending on the composition of iron ores, technologies for their enrichment and further preparation for metallurgical redistribution are being developed. Preparation of iron ore concentrates for metallurgical redistribution includes calcination, cooling, leaching with mineral acid, separation of the liquid phase from the solid phase, and so on. All this leads to an improvement in the quality of iron ore concentrates, because at the same time unwanted impurities contained in the concentrates, primarily phosphorus, sulfur, and arsenic, are eliminated. Metallurgical methods of phosphorus removal from concentrates are mainly used.

So, the firing process is carried out at a temperature of 800-1000ºC. At the same time, the structure of hydrogethite (FeOOH) is destroyed, and the recrystallization of iron and displacement of phosphorus from grains at the interface of phases (crystals) occurs.

At a temperature below 800ºC, the process proceeds with insufficient completeness. At temperatures above 1000ºC, particles sinter into agglomerates and acid access to phosphorus-containing mineral particles deteriorates, as a result of which the degree of phosphorus extraction decreases.

The firing time within 1 hour ensures a high extraction of phosphorus into the solution during further leaching. An increase in the firing time, of more than one hour, worsens the technical and economic indicators of the entire dephosphorization process. A process combining oxidative calcination-gas reduction and magnetic separation has been developed for iron dephosphorylation at a lower reduction temperature [8].

Studies based on the possibility of redistribution of phosphorus from ore components to slag-forming ones in the process of agglomerate firing have been conducted [8].

Disadvantages of metallurgical methods of dephosphorization include their uneconomical nature, large losses of iron (up to 20%), and environmental problems.

The problem of developing a technology for removing phosphorus by non-metallurgical means and obtaining a phosphorus-conditioned concentrate from these ores is of great practical interest and is of great importance for many countries of the world, such as Australia, Spain, Colombia, the USA, Sweden, France, and others. Part of phosphorus is part of the cement mass, which binds finely dispersed magnetite grains. Therefore, it is impossible to remove it by mechanical means to a mass fraction that meets the requirements of metallurgical redistribution. Fairly limited removal of phosphorus is achieved by grinding and magnetic separation.

The focus of current research and development in the field of flotation is cationic and anionic flotation methods from the point of view of reagent regimes, pulp chemical composition, and particle size, as well as the efficiency of removing major impurities such as silica, alumina, phosphorus, and sulfur [9]. Anionic reagents are usually used to remove phosphorus by flotation methods. Thus, the Aqua Nobel company developed a cationic reagent based on the Lilaflot reagent, the use of which during flotation at a flow rate of about 70 g/t made it possible to remove 90-95% of the phosphorus contained in this concentrate from the magnetite concentrate. At the same time, the loss of iron was about 2%.

A method of direct flotation of phosphate minerals from magnetite concentrates has been developed, in which the pulp is treated with an alkaline agent to pH from 7 to 11 and a depressor of carbonate and silicate minerals. A collector type of succinic acid derivatives is introduced in the amount from 20 to 2000 g/t of the initial product and a foaming agent [10].

Periodic flotation tests of an effective combination of reagents to reduce the content of silica and phosphorus in iron concentrate were carried out. The study aimed to study the influence of dosage, sodium silicate module, and the addition of Ca++ ions on the selectivity of separation of phosphorous and siliceous vein minerals from iron oxides [11].

The disadvantage of flotation methods for cleaning iron ores from phosphorus is the impossibility of their removal from finely dispersed growths. Therefore, in this case, hydrometallurgical methods are used.

Consider the use of hydrometallurgical methods for removing phosphorus from iron ores.

The method of pre-treatment of ore to reduce the content of sulfur and phosphorus in it by washing the ore (essentially iron oxides) with aqueous solutions of soda with a gradual increase in temperature, includes mixing an inorganic base with oxide iron ore, which mainly contains iron oxides at a ratio of approximately $0.1 \div 1.5$ – bases to the weight of iron ore; heating the mixture to 300^{o}C and rinsing the mixture with hot water.

The disadvantages of this method include the fact that the degree of reduction of phosphorus impurities in the ore remains low and, therefore, does not allow obtaining conditioned iron ore concentrates.

Recently, the most common methods of dephosphorylation of metal-containing ores are chemical methods – alkaline or acid leaching with separation of the leached concentrate [12]. In the case of hematite ores, heat treatment is necessary before alkaline or acid leaching to make phosphorus available for chemical separation [9, 13]. The amount of phosphorus removed increases with heating temperature up to 1300°C. Silica, alumina and sulfur are usually removed along with phosphorus. Chemical methods of cleaning ores and iron ore concentrates are used in different versions. Research is mainly carried out in the following areas:

- leaching with alkali solutions;
- acid leaching at different temperatures;
- leaching of impurities in autoclaves.

When choosing a method of chemical enrichment, it is necessary to be guided by the availability of reagents, profitability, and a sufficient degree of purification.

Removal of silicon compounds is possible with alkali solutions. Acids are used to remove calcium and magnesium.

There is a known method of removing phosphorus from Lorraine iron ore, which contains 30% Fe, 20% SiO_2, 7% Al_2O_3 and 1.7% P_2O_5, which involves treating the ore with a 40-50% alkali solution at a temperature of 125-140^oC, duration from 30 min to 3 hours and the amount of solids in the pulp from 50 to 200 g/l. At the same time, up to 60-80% of phosphorus, silica, and other ore minerals were extracted into the solution, while more than 93-95% of iron was extracted into the concentrate.

In this method, the most common is sodium hydroxide. But when it is used, there are non-technological solutions that are poorly defended and filtered. In addition, the discovered optimal leaching regime has several serious drawbacks: a complex scheme of alkali regeneration and significant water consumption for its washing.

A complex method of beneficiation of iron ore using NaOH and magnetic separation has been tested in the USA. It includes the following stages:

(i) mixing ore or ordinary concentrate with a small volume of diluted NaOH solution;
(ii) treatment of the mixture with superheated steam at a temperature of 260-400^oC.

Such processing leads to the fact that the bonds between SiO_2 crystals, as well as between SiO_2 and iron minerals are weakened. There is other evidence that chemical treatment (alkaline or acid) of iron ore concentrates containing quartz and iron silicates alters the surface properties of the minerals, which improves flotation and magnetic re-separation performance. When ordinary hematite concentrates obtained from ores of the Kryvyorizhye deposit were treated with NaOH solution, the silicon content decreased from 8.62 to 0.76%. Phosphorus, sulfur and arsenic were leached to hundredths of a percent. The content of calcium and magnesium increases after alkaline treatment. At the same time, sulfur goes into solution in the form of sulfates according to the equation: $FeS_2 + 16NaOH + 15O_2 \rightarrow 4Fe(OH)_3 + 8Na_2SO_4 + 2H_2O$.

Acid treatment of iron ores is carried out in order to separate impurities of phosphorus, arsenic, sulfur, calcium, and magnesium. According to research, any mineral acid at a temperature of 70^oC removes arsenic from ores from the above-mentioned impurities, such acids as sulfate H_2SO_4 and chlorine HCl are used.

Many studies have been conducted on the purification of iron ores with nitric acid. Most of the works were carried out by Japanese researchers. A method of separating impurities from iron ore with concentrated nitric acid was patented in Japan, which ensured an increase in the iron content from 55 to 65% due to the complete leaching of phosphorus and arsenic and partially – calcium, magnesium, manganese, and sulfur.

In further studies, the concentration of nitric acid was reduced without reducing the leaching efficiency by increasing the temperature adding sulfuric acid to nitric acid, or conducting the leaching process at 200^oC in an autoclave.

Acids, as you know, interact with iron compounds, which leads to additional consumption of acids and a decrease in the yield of the concentrate. But in all patents, these disadvantages of acid enrichment are ignored. It should also be noted that acid regeneration is impossible. After leaching, the alkali can be regenerated by adding lime.

The method of oxidative leaching in an acidic environment of complex iron ores consists of processing the material under such conditions as to promote the oxidation of iron and sulfur, to oxidize sulfur sulfide, at least partially, into sulfate [14,15]. Oxidized iron and impurities go into the solution in the leaching process, which is carried out over a certain period until more than 80% of the sulfide contained in the material is oxidized. At the same time, leaching sediment is formed, which is suitable for the thermometallurgical recovery of iron. This method gives a positive result for sulfur removal but does not provide dephosphorization of iron ore.

The method of leaching phosphorus with sulfuric acid at a temperature of 95-100ºC is also known. The consumption of sulfuric acid to dissolve phosphorus contained in concentrates is 30 kg per 1 kg of leached phosphorus, i.e. much higher than stoichiometry. To avoid re-precipitation of ferric sulfate, it is necessary to operate with pH values in the range of 1.6-1.4, depending on the content of solid particles in the pulp. The ratio of solid to liquid (S÷L) should be 1÷2-1÷3, and the total leaching time should be 50 minutes. Further processing of the concentrate is carried out by the method of pelleting and firing of the obtained pellets. At the same time, the content of sulfur decreases by 95%, and phosphorus – by approximately 80% [15].

The disadvantage of this method is the complexity of the technological design of the leaching process, the high temperature of the process, and the large losses of iron with solutions.

Hydrochloric acid can also be used as a mineral acid during leaching. The essence of the method is that iron ore is first agglomerated, and then leached using hydrochloric acid or gaseous hydrogen chloride. The leaching temperature is 90-105ºC.

The method of selective acid leaching was used to remove phosphorus from iron ores with a high phosphorus content. Hydroxyapatite in iron ores with a high phosphorus content was converted to soluble phosphate in the process of HCl leaching. The effect of reaction time, particle size, concentration of hydrochloric acid, reaction temperature, liquid-solid ratio, and stirring power on the degree of dephosphorylation was studied [16].

The disadvantage of this method is that it uses volatile hydrochloric acid, which is very harmful to service personnel and leads to equipment corrosion due to the presence of hydrogen chloride.

It should be noted that chemical leaching is successful only if it is preceded by heat treatment, which causes recrystallization of iron minerals in L–Fe_2O_3 and concentrated phosphorus between hematite grains. Heat treatment consists of burning the concentrate at a temperature of 500-600ºC for 1-1.5 hours, and for leaching, sulfuric acid is used in an amount of at least 110-150% of the stoichiometric about phosphorus, at a temperature of 60-80ºC, the ratio S÷L = 1÷3-1÷5. The leaching time is 2-3 hours.

A known method of cleaning iron ore from arsenic and phosphorus, in which the ore, crushed to 0.05-0.50 mm, was treated with a 0.5-2% solution of sulfuric acid at a high ratio of liquid to solid phases for 10-20 hours with subsequent ion exchange removal of impurities from the solution.

The disadvantages of this method are the long duration of the process (25 hours) and a significant amount of liquid phase, which requires a large volume of equipment.

The speed of all physicochemical heterogeneous processes increases with increasing temperature. When the leaching of impurities is carried out in autoclaves. At the same time, alkali solutions with concentrations of 40-50% are used in autoclaves at a temperature of 124-140ºC, or sulfuric acid with a concentration of 60-70% at 95-100ºC. The use of autoclaves allows you to maintain the temperature of the process above the boiling point of the solution. This leads to more efficient leaching.

3. Research objectives and approach

The primary objective of this research was to develop effective technologies for dephosphorization of various iron-containing concentrates, including magnetite, hematite, and hydrogethite, to reduce phosphorus content to levels meeting global quality requirements for iron ore products.

Specific aims of the study included:

1. Characterize the mineralogical composition and phosphorus distribution in magnetite-hematite ore samples and concentrates.
2. Evaluate desliming as a method to reduce phosphorus in magnetite concentrates.

3. Investigate direct flotation techniques, both anionic and cationic, for phosphorus removal from hematite concentrates.
4. Examine high and low temperature acid leaching processes for dephosphorization of hydrogethite concentrates.
5. Develop an integrated dephosphorization technology applicable to different types of iron ore concentrates.

The research approach involved detailed mineralogical analysis, laboratory-scale beneficiation and flotation experiments, and leaching tests under various conditions. Multiple dephosphorization techniques were evaluated to determine the most effective methods for different ore types. The ultimate goal was to achieve phosphorus reduction to below 0.05% in the final iron ore products, meeting stringent international quality standards.

4. Results

At the first stage of the research, a sample of magnetite-hematite ore with a mass fraction of iron of 53.8% was received. As a result of magnetic separation, two concentrates were obtained: magnetite (yield 47.7%, Fe_{total} mass fraction 69.509%) and hematite (yield 15.27%, Fe_{total} mass fraction 60.48%). The yield of tails was 37.03%. Iron losses by magnetic technology amounted to 21.2%. As you can see, the concentrates meet the requirements of the metallurgical industry in terms of the mass fraction of iron. However, it should be noted that they have a high mass fraction of phosphorus – 0.071 and 0.343%, respectively, in magnetite and hematite concentrates. Therefore, research on dephosphorylation was carried out precisely on samples of these concentrates. Note that a larger mass fraction of phosphorus is characteristic of hematite concentrate, because it has a smaller size compared to magnetite.

As a result of the study of the mineralogical composition of the concentrates, it was established that calcite is present in all the studied products – a violent reaction with acid. Non-ore minerals are observed in the form of both free fragments and in the form of inclusions with ore minerals. A characteristic feature of the studied magnetite and hematite concentrate is also a sharp dispersion of the dimensions of the fragments. The smallest fragments are mainly represented by iron hydroxides, calcite, and apatite. Apatite is represented by elongated as well as short-prismatic individuals. It most often spatially tends to calcite, but it is emphasized in the form of small inclusions in magnetite. The size varies widely from units of micrometers to tenths of a millimeter (figure 1).

On the basis of the analysis of the results of the study of the material composition, chemical and mineralogical properties of magnetite and hematite concentrates and the properties of apatite, we came to the conclusion about the feasibility of descaling magnetite concentrates and direct flotation of apatite from hematite concentrates.

Descaling was carried out on a sample of magnetite concentrate. The purpose of desliming was to reduce the mass fraction of phosphorus in the sample due to the removal of the minus 0.02 mm grade, where finely divided apatite is mainly concentrated. The results of magnetite concentrate de-slagging are shown in figure 2.

The obtained data confirm the expediency of the de-sludging operation in the technological scheme of beneficiation of rich hematite-magnetite ores. Thus, it was possible to reduce the mass fraction of phosphorus in the concentrate by 2.37 times – from 0.071 to 0.03%, which meets international standards for the quality of magnetite concentrate. which meets international standards for the quality of magnetite concentrate [17]. As a result of the descaling of the magnetite concentrate, the mass fraction of total iron in the concentrate also increased by 0.01%.

In the second stage of research, studies on direct anionic flotation of apatite were conducted on a sample of hematite concentrate. Distilled tall oil soap (DTOS) was used as an anionic

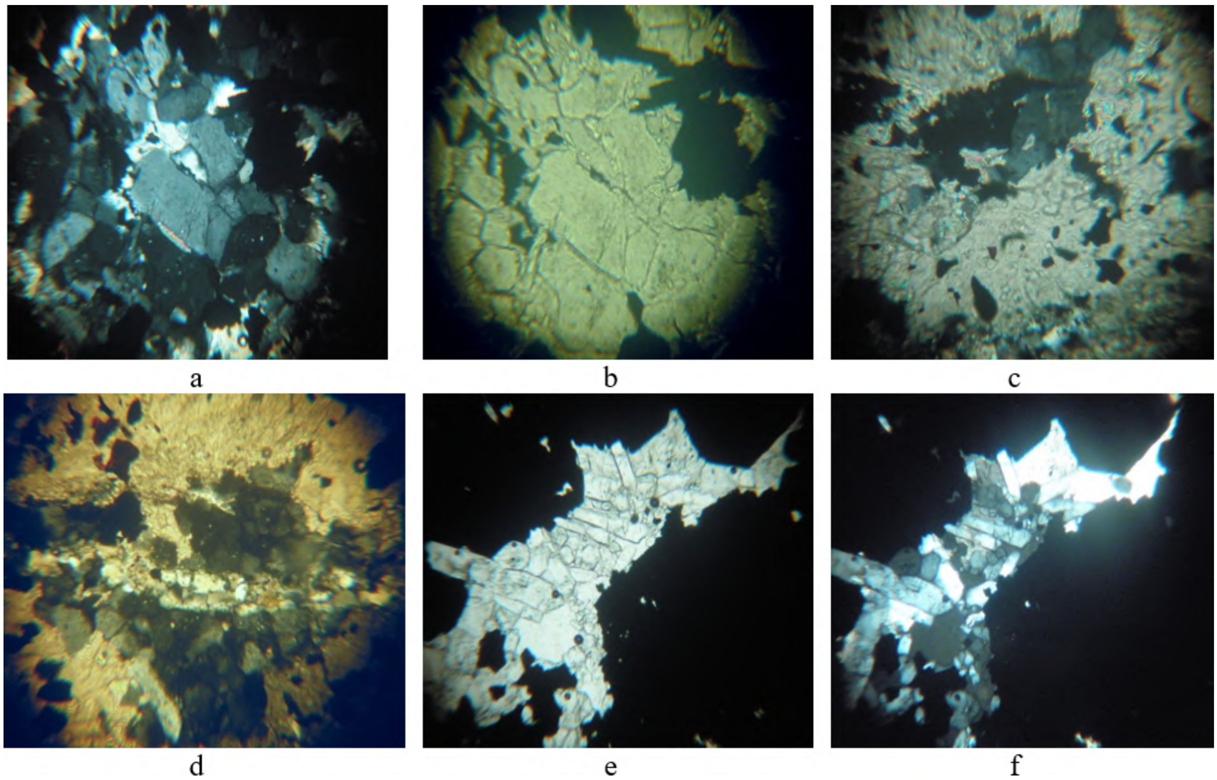

Figure 1. Iron ore raw materials in the light: a, b – nest-shaped aggregate of apatite; c – apatite in calcite mass; d – horizontally oriented quartz vein, apatite-calcite aggregate; e, f – apatite aggregate.

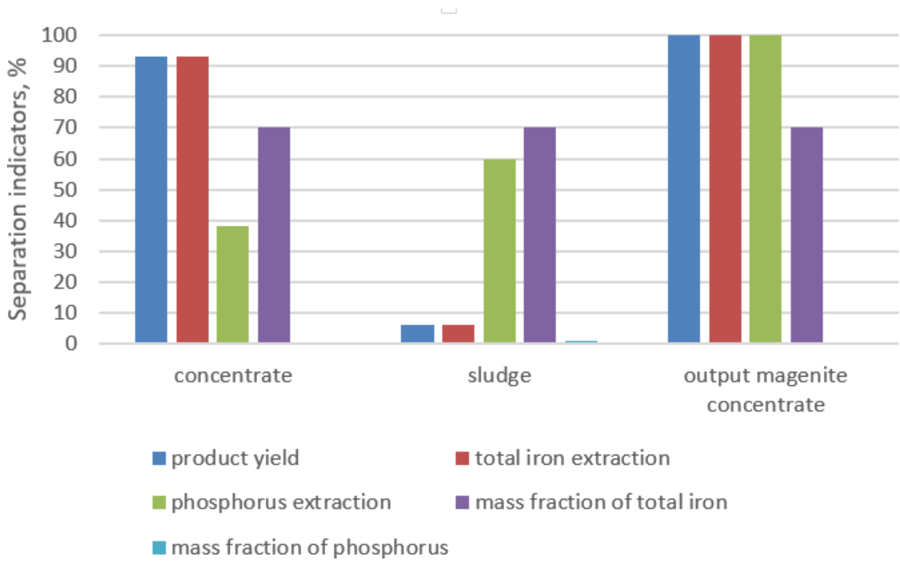

Figure 2. Indicators of magnetite concentrate de-sludging.

oxyhydryl collector during flotation studies. Saponified tallow oil is usually used in practice. DTOS is more selective compared to crude tall oil soap (CTOS). The main part of DTOS is salts (usually sodium) of inorganic fatty acids (oleic, linoleic, and linolenic), and the content of resin acids in it is no more than 10-15%. The increased content of resin acids (up to 30% or more) in CTOS makes it less suitable for obtaining high-quality concentrates due to the deterioration of its collector properties and increased foaming. The choice of such a collector was made, mainly, only empirically and based on the availability and economy of the reagent.

To establish the regularities of the flotation process, several experiments were conducted using the Latin square method, where the variables were the consumption of the regents – the collector, the depressor, the medium regulator, and the contact time with the reagents. The best indicators of dephosphorylation (according to the mass fraction of phosphorus in the concentrate) were obtained at the consumption of reagents (g/t): DTOS – 500 g/t, starch – 2500 g/t, soda – 1000 g/t.

It should be noted that during direct anionic flotation, a large part of hematite aggregates passes into the foam products, which leads to large losses of hematite with a foam product of 75-85%, which indicates the negative results of the conducted research.

Since the desired results were not achieved with direct anionic flotation of apatite, further studies were conducted on direct cationic flotation of apatite. In the study of direct cationic flotation of apatite, amines were used as collector reagents. Lilaflot reagent was used for flotation tests. These reagents are primary amines based on higher fatty acids with 17-21 carbon atoms in the radical. Lilaflot reagent is a mixture consisting of alkyloxypropylamine (60-80%) and alkyloxypropylamine acetate (20-40%). According to the parameters of high toxicity, the product can be classified as a moderately dangerous substance (hazard class 3). It should be noted that it decomposes completely into safe chemical compounds in the air within 24 hours

The use of cationic flotation is because, in comparison with anionic flotation, it does not require softening of water and large consumption of reagent. In addition, the duration of cationic flotation is 2-4 times shorter than that of anionic flotation.

The mechanism of action of amines consists in the hydrophobization of minerals during ion fixation, i.e. chemical interaction of ions and molecules of the collector, as well as their physical adsorption on the surface of the mineral, takes place. The reasons for the adsorption of a surface-active collector ion can be Coulomb attraction of the ion by the electrostatic field of the mineral surface, polarization of the adsorbent by the ion, electrostatic polarization of the ion by the surface field, and nonpolar Van der Waals forces. In turn, the adsorption of amine molecules, the polar group of which has a permanent dipole, depends on the possibility of dipole and dispersion interaction forces, the formation of a hydrogen bond.

A series of tests were conducted in laboratory conditions, which resulted in positive results: it was possible to reduce the mass fraction of phosphorus in the hematite concentrate by 2.87 times from 0.343 to 0.12%. The mass fraction of total iron in the hematite concentrate was 62.88%, which is 2.4% more than in the rough hematite concentrate.

In the third stage, the conditions of leaching of poor hydrogethite high phosphorus concentrate at high and low temperatures were investigated.

High concentration sulfuric acid was used in the research. The firing temperature was maintained at 800°C because at lower temperatures the process of destruction of the mineral structure is not carried out completely.

At a temperature of more than 1000°C, sintering of particles into agglomerates occurs, and access of the acid to the particles of the mineral, which contains phosphorus, deteriorates. As a result, the degree of phosphorus extraction decreases. Therefore, the optimal temperature is 900°C. This is the temperature at which the destruction of the structure of hydrogethite (FeOOH), recrystallization of iron, and displacement of phosphorus grains at the interface of phases (crystals) occurs. At the same time, artificial hematite $2FeOOH \rightarrow Fe_2O_3 + H_2O$ and phosphorus compounds are formed. Thus, access of mineral acid to phosphorus compounds and their transfer into solution is ensured. The firing time is 1 hour. This ensures a high level of phosphorus extraction into the solution during leaching. More time for firing is not required, because it also leads to the sintering of particles into agglomerates.

A weight of iron ore concentrate weighing 100 g was fired in a muffle furnace at a temperature of 900ºC for 1 hour. The cucumber was cooled to a temperature of 25ºC. Leaching was carried out with sulfuric acid with a concentration of 49% for 1 hour. The ratio of the solid to liquid phase was S÷L = 1÷1.5. The suspension was stirred, and after leaching it was filtered. The sediment on the filter was washed with a volume of 50 cm^3 of cold water. The sediment from the filter was dried at a temperature of 105ºC in a drying cabinet for 6 hours to a constant mass, and the content of phosphorus and iron was determined. As a result, a concentrate with a mass fraction of total iron of 55.2% and 1.2% phosphorus was obtained from a concentrate with a mass fraction of total iron of 56.4% and phosphorus – 0.15%.

5. Conclusions

1. The research was conducted on a sample of magnetite-hematite ore with the production of magnetite and hematite concentrate, which have a high mass fraction of phosphorus. As a result of the mineralogical study of the magnetite and hematite concentrate, it was established that the main carrier of phosphorus in the concentrates is apatite, which is found in fine fractions less than 20 μm.
2. To extract phosphorus from magnetite concentrates, it is sufficient to use de-sludging operations in the enrichment technology of rich magnetite-hematite ores, which can remove up to 61% of phosphorus.
3. For effective dephosphorization of hematite concentrates, it is necessary to use direct cationic flotation of apatite, with the help of which it is possible to remove more than 74% of phosphorus from the concentrate.
4. As a result of the analysis of the conducted research and the synthesis of the obtained scientific results, a technology for removing phosphorus from magnetite and hematite concentrates was developed, which allows reducing the mass fraction of phosphorus in the total concentrate from 0.14 to 0.04%.
5. With further improvement of the regime of flotation of hematite concentrates, it is planned to reduce the mass fraction of phosphorus to 0.02%.
6. The proposed technology of leaching of samples of poor hydrogethite high-phosphorus concentrates at high and low temperatures allows us to state that the parameters of the firing process allow the recrystallization of iron and therefore contribute to the access of mineral acid to particles containing phosphorus.

Abstract. The objective of this research is to improve the efficiency of cold rolling of thin steel sheets with a thickness of 1.5 mm by determining efficient deformation degree. Low-carbon steel 20 was used for the research, and reduction patterns under conditions of cold rolling were determined. While maintaining a constant final sheet thickness of 1.5 mm, the deformation degree was observed to vary based on the initial thickness of the semi-finished rolled product. Key parameters, such as the initial temperature and rolling speed, were adjusted at 200°C and 1 m/s, respectively. The strip width was maintained as a constant, and a friction coefficient of 0.01 was adopted. The research delved into the deformation zone formed during longitudinal sheet rolling, defining its coefficients and essential parameters. Additionally, factors influencing the quality of the resulting sheet were identified. The research also explored the influence of the deformation degree on metal stress during the cold rolling process of thin sheets. This involved an analysis of yield strength, metal flow, and overall strength. Furthermore, the study established the rolling force and its variations with changing deformation degrees. An integral aspect of the study was the examination of the impact of the deformation degree on the process productivity of cold-rolled thin sheets. Through comprehensive analysis, a rational deformation degree was pinpointed, ensuring the production of a high-quality product with efficient strength and plasticity. This optimized degree also minimizes the required deformation forces and rolling torques, contributing to maximum process productivity.

1. Introduction

Within the metallurgical industry, considerable emphasis is directed towards the process of rolling production, a process by which sheet products are produced using cold rolling methods. Thin sheet products are used to create a big variety of lightweight welded and pressed structures, extensively contribute to mechanical engineering, aircraft manufacturing, and construction of manufacturing roofs, automotive components, airplane parts and bodies, household appliances, devices, as well as to food and chemical industries, among others. The application of such rolled products extends to the production of roll-formed sections, thereby facilitating a reduction in manufacturing costs. Requirements for thin-sheet rolling include specific criteria associated with wear resistance, strength, operational reliability, material hardness, pressability, and weldability; as well as dimensional accuracy, surface burriness, corrugation, and buckle, among other factors. These properties undergo notable transformations during the course of cold rolling, depending on the selected rolling patterns. To improve the quality of the final product, it is neccessary to develop ways for modifying material strength and hardness by adjusting rolling parameters. The obtaining of a high-quality and reliable product with minimized costs, maximized productivity and reduced power consumption, is achievable using advanced cold metal rolling technologies that shall be seleced based on the extent of metal deformation. Consequently, the research of the influence of deformation degree during the cold rolling of thin sheets on the parameters of process efficiency represents a relevant task. The resolution of this task will contribute to the identification of rational rolling patterns required for the production of high-quality products.

2. Analysis of literature data and problem defnition

Within the framework of the sustainable development program of metallurgical production, scientists from the Department of Ferrous Metallurgy and Foundry at Kryvyi Rih National University address the challenges of improving the quality of industrial products [1], where many issues are related to obtaining high-quality products. Rolling is the final stage of the entire metallurgical production, allowing the production of items due to the capability of metals and their alloys to undergo plastic deformation [2–6]. Hot rolling is applied for large-sized, low deformable products [3, 7, 8], while cold rolling is specifically used for small, highly deformable, and thin sheet products [3, 7–11].

The rolling process applied to sheet material represents a complex and cost-intensive technological proccess consisting of numerous operations with significant resource consumption [11, 12]. Thin sheet, defined as a product with a thickness below 4 mm, manufactured through cold rolling involving specialized operations, equipment, and tools. Within rolling mills, the cold processing technology facilitates the production of sheets with thickness ranging from 0.15 to 1.8 mm and width from 700 to 2300 mm, as well as tin sheets and strips with a thickness of 0.0015 mm. The initial material for cold rolling is hot-rolled sheets, predominantly composed of carbon or alloyed steel with a thickness of 1.6-6 mm [11, 12]. Thin sheets typically serve crucial purposes, finding applications in construction of roofing, and in the manufacturing of essential components and details for devices, automobiles, and aircraft. The physical and mechanical characteristics of thin sheets are subject to specific requirements, encompassing the following properties such as hardness, strength, elasticity, plasticity, reliability, stability, load-bearing capacity without fracture or cracking, and pressability etc., which are influenced by the metal's internal structure [13–15]. Additionally, standards concerning dimensional accuracy, surface burriness, corrugation, and buckle (properties determined by the rolling technology) are applied to thin sheets. Cold rolling significantly affects the mechanical, physical, and chemical properties of the rolled material, which can undergo substantial changes during rolling [15, 16].

As the deformation degree increases, the yield strength, proportionality limit, material plasticity, and electrical resistance increase. Moreover, it results in the increase of the material's strength and hardness, accompanied by a reduction in material density, plastic deformation capacity, elongation during the rolling process, thermal conductivity, and impact strength [17]. The collective occurrence of these phenomena is referred to as material strengthening or hardening, which complicates further material rolling.

During the rolling process, a complex deformation zone is established, wherein the primary transformation processes of the metal occur. Deformation zone is referred to as the volume of the metal alloy undergoing plastic deformation at a given moment [14]. A complex stressed state, requiring a substantial amount of power [18] is formed in the deformation zone during cold rolling. Literature recourses extensively describe the forces arising in the deformation zone [15–18] and the stability of the longitudinal rolling process of sheets. Additionally, considerable attention is given to the modeling processes during sheet rolling [19–21]. In the study [22], a meticulous analysis was conducted on the power consumption associated with temper rolling of thin sheets. Research on the power parameters of the cold rolling process of thin sheets was performed using the computer program DEFORM 3D [23]. This research determined the maximum forces and rolling torques generated during the rolling process. The manufacturing cost of the cold rolling

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012064 doi:10.1088/1755-1315/1415/1/012064

process depends on the efficiency of the process, influenced by the following factors: material hardness and strength, power consumption, quality of the surface layer, equipment productivity, and the intensity of metallurgical equipment wear-out. To ensure high process efficiency, it is crucial to determine the deformation degree that allows achieving maximum process productivity while simultaneously obtaining products with efficient strength and hardness. This shall be done without subjecting the sheet material to plastic deformation during operation, preventing the formation of cracks and microfibers in the metallic alloy.

3. Purpose and tasks of research

Examine the impact of metal deformation degree during the cold rolling on its efficiency, ensuring the achievement of qualitative properties of material in the production of thin sheets with a thickness of 1.5 mm. To accomplish this objective, the following tasks shall be undertaken: investigate the influence deformation degree on the strength and stress characteristics of the material; determine the impact of deformation degree on amount of forces required for the process and on the rolling efficiency for obtaining cold-rolled thin sheets with a thickness of 1.5 mm; determine the efficient deformation degree.

4. Methodology of research

Low-carbon steel – grade 20 was used in the research to manufacture thin sheets with a thickness of 1.5 mm and a width (b) of 1000 mm during cold rolling. The initial rolling speed was 1 m/s, and a friction coefficient of 0.01 was adopted. Hot-rolled strips of variable thickness (ranging from 5 to 7 mm) were used as the initial material, introducing varying deformation degrees. Four experimental rolling patterns involving modifications of the initial stripe and deformation degree were developed for the research. The rolling forces were determined based on the results of prior research, as referenced in the literature source [23].

In the production of a thin sheet from a hot-rolled strip, it is required to determine the efficient reduction patterns that guarantee precise dimensions while minimizing manufacturing cost. During the execution of the research, the deformation zone (figure 1) formed during rolling process was thoroughly analyzed, and its coefficients and parameters were examined. This allowed to identify number of changes in the physical and chemical properties of the material during cold rolling.

In the research, the deformation degree (ε) was determined by the following formula:

$$\varepsilon = \frac{\Delta h}{h_0}, \tag{1}$$

where Δh is the absolute reduction calculated by the following formula:

$$\Delta h = h_0 - h_1. \tag{2}$$

The elongation of metal occurs during the rolling process, which is determined by the elongation coefficient (λ):

$$\lambda = \frac{F_0}{F_1} = \frac{L_0}{L_1}, \tag{3}$$

where F_0 is the cross-sectional area of the initial material; F_1 is the cross-sectional area of the finished product; L_1 is the sheet length after rolling, determined by the following formula:

$$L_1 = \lambda L_0, \tag{4}$$

L_0 was accepted as 10 m in the research.

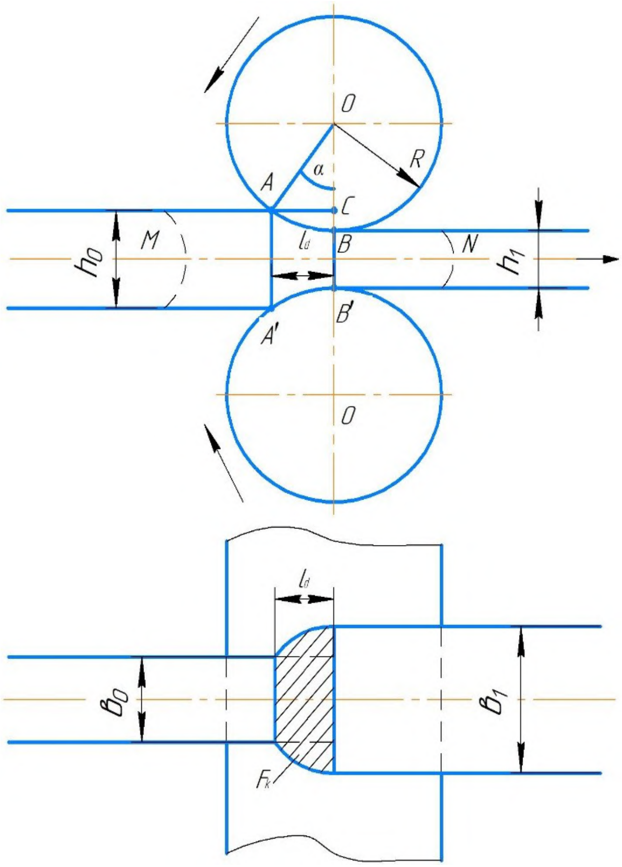

Figure 1. Strip deformation during rolling: $ABB'A'$ is deformation zone, h_0 and h_1 is sheet thickness before and after rolling, respectively, α is angle of strip bite during rolling, R is radius of the roll, F_k is contact area of the roll with the rolled material, l_d is length of the deformation zone, M is movement of metal entering the deformation zone, N is movement of metal exiting the deformation zone.

The theoretical calculation of the rolling force was performed using the formula [23]:

$$P = \sigma n_\sigma b l_d, \tag{5}$$

where σ is the material stress, measured in MPA; n_σ is the stress state coefficient, dependent on the rolling conditions and the size of the deformation zone [11]; b is the average strip width.

The average strip width was calculated using the formula:

$$b = \frac{b_0 + b_1}{2}, \tag{6}$$

where b_0 and b_1 are the strip width before and after rolling, respectively.

The length of the deformation zone depends on the absolute reduction value and the radius of the rolls, and it was determined by the formula:

$$l_d = \sqrt{\Delta h R}. \tag{7}$$

To determine the efficiency of thin sheet production, the process productivity per second was calculated using the following formula:

$$\Pi = \frac{m}{t}, \tag{8}$$

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012064 doi:10.1088/1755-1315/1415/1/012064

where m is the sheet weight measured in kg; t is the rolling time measured in s.

The sheet weight depends on the product dimensions and material density, determined by the following formula:

$$m = l_1 h_1 b_1 g, \tag{9}$$

where g is the material density, which equals $g = 7867$ kg/m^3 for steel products.

The formula for determining the rolling time is the following:

$$t = \frac{L_0}{\upsilon_0}, \tag{10}$$

where υ_0 – initial rolling speed, measured in m/s.

For all cases, it was determined that the rolling time t equals t=10 s.

Changes in rolling forces (table 1) and process productivity (table 2) depending on the deformation degree were calculated using the initial data and the provided formulas. The efficiency of the cold rolling process was determined by the amount of forces and rolling torques for rolling, as well as the process productivity. The quality of the product was assessed based on material stress, yield strength, ductility, and material strength.

5. Results and their explanation

The research enabled to determine changes in the properties of cold-rolled steel. The impact of deformation degree during cold processing on stress is presented in figure 2, allowing the determination of the efficient reduction pattern.

As shown in figure 2, an increase in deformation degree leads to an increase of stress during cold rolling. At low deformation degrees (up to 30%), the material is incapable of plastic deformation, exhibiting elastic deformations. When deformation degree exceeds 40%, the material begins to undergo plastic deformation. With deformation degree surpassing 60%, the material starts to strengthen and gradually reaches the yield strength limit. In cases where the deformation degree exceeds 80%, rolling becomes impractical due to a high probability of crack formation in the solid material and subsequent product destruction. Using a sheet with such defects is impossible. These data shall be considered when developing a technological process to obtain a durable product.

The results of the influence of reduction patterns on material stress during cold rolling and the calculations of the changes of required power consumption for producing cold-rolled thin steel with a thickness of 1.5 mm are presented in table 1.

* σ – yield strength of the material; P – rolling force; ΔP – change in rolling force

The change in rolling force ΔP was determined by the following formula:

$$\Delta P = \frac{P_i - P_1}{P_1} 100\%, \tag{11}$$

where P_i is the rolling force of the respective pattern; i is the pattern number.

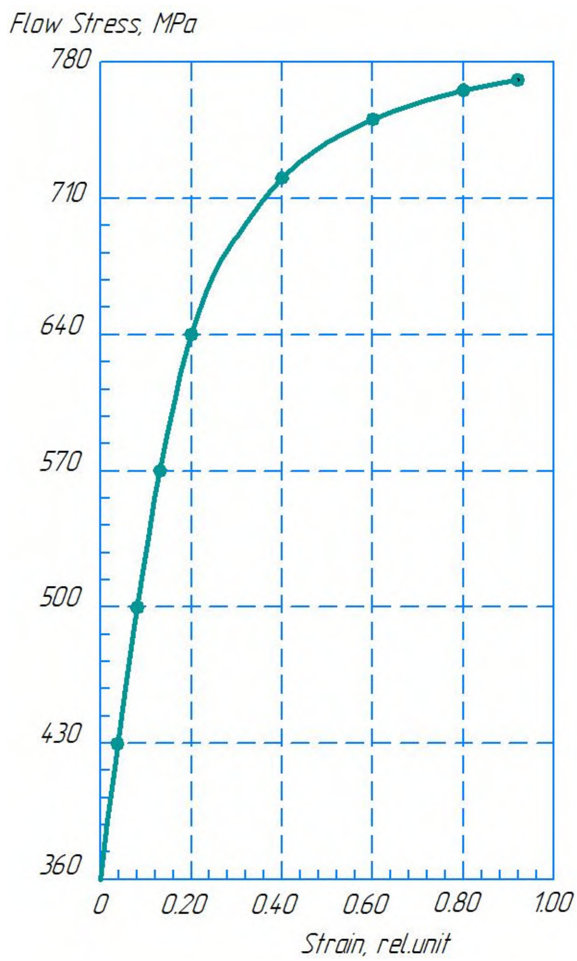

Figure 2. Stress-strain diagram.

The change in productivity $\Delta\Pi$ of the process was determined by the formula:

$$\Delta\Pi = \frac{\Delta\Pi_i - \Delta\Pi_1}{\Delta\Pi_1} 100\%, \tag{12}$$

where $\Delta\Pi_i$ is productivity of the respective pattern.

The strengthening of steel products is characterized by an increase in the hardness of surface layer. The influence of deformation degrees.during cold rolling on the metal strengthening is presented in figure 3.

The data in figure 3 clearly indicates that metal strengthening during cold processing occurs more intensively at lower deformation degrees. With a deformation degree exceeding 70%, the hardness reached its maximum for the given material and demonstrates negligible further changes. Subsequent reduction becomes complicated as steel loses its plastic properties and the capacity for plastic deformation. Therefore, additional reduction will lead to the sheet destruction. The research has shown that material density is also capable of changing during cold rolling (figure 4).

Figure 4 illustrates that the density of Grade 20 steel decreases with an increase of deformation degrees, leading to a decrease of the product mass. However, such a decrease is insignificant, providing a basis to ignore the density decrease in calculations.

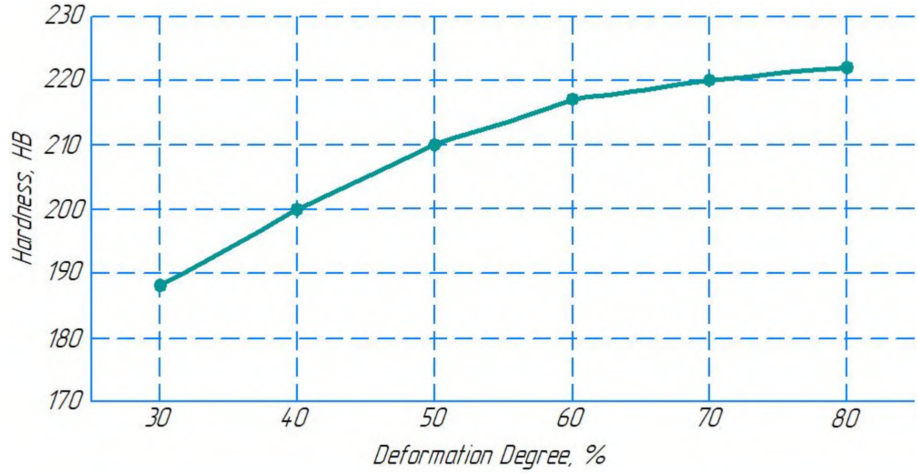

Figure 3. Influence of reduction value on material hardness for grade 20 steel.

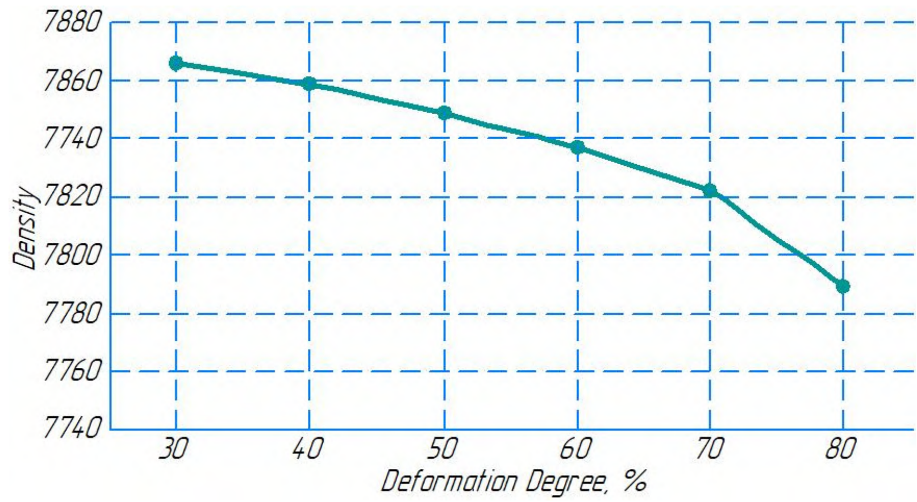

Figure 4. Influence of reduction degree on the density of grade 20 steel.

The results of the influence of the deformation degree on the change of productivity per second of the cold rolling process of thin sheets are presented in table 2.

Table 2. Results of the research on the influence of reduction patterns on the productivity per second of rolling process of thin sheets**.

$Pattern, \#$	$\varepsilon, \%$	m, kg	Π, kg/s	$\Delta\Pi$, %
1	70	3929	392.9	–
2	75	4715	471.5	+20
3	78.6	5501	550.1	+40
4	62.55	3144	314,4	-20

** $\Delta\Pi$, % – change of process productivity

Based on the research results, graphical dependencies were constructed to illustrate the influence of the deformation degree on the rolling force and process productivity (figure 5).

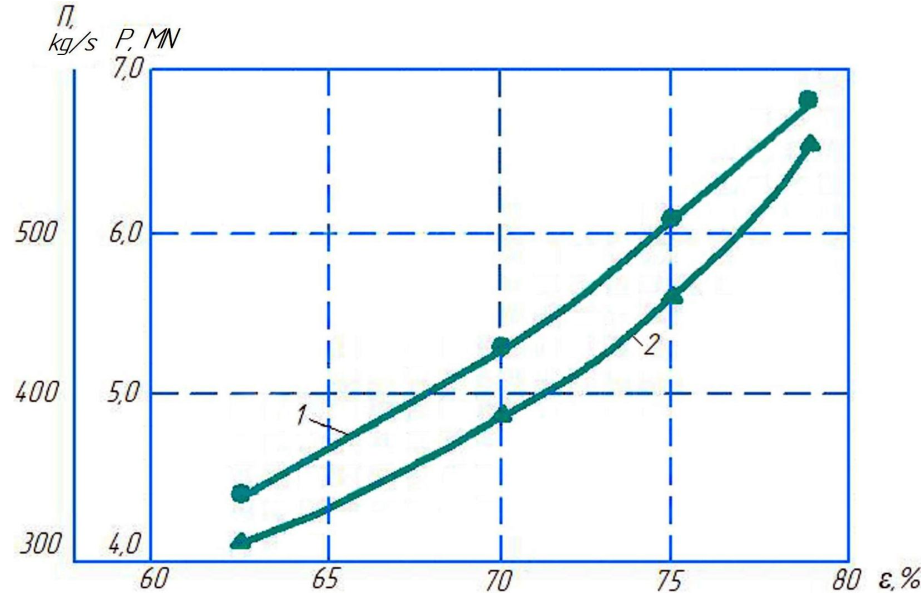

Figure 5. Influence of the deformation degree on the cold rolling force (curve 1) and process productivity (curve 2): P, MN is rolling force; П, kg/s is process productivity per second.

Figure 5 illustrates that an increase in deformation degree leads to an elevation in rolling force and process productivity. The increase of metal deformation force indicates that the cold rolling process of thin sheets becomes more challenging with the growth of deformation degrees. The rise in rolling force contributes to increased stress on the processing tool, leading to more intensive wear-out of the rolls. Additionally, there is an increase of power consumption during the process, resulting in an increase of the production cost of the obtained product, which is a disadvantage. The increase of process productivity indicates an increase in the quantity of manufactured sheets per second, presenting a positive aspect in the manufacturing of rolled products. Following a thorough analysis of the provided data, it has been determined that the most efficient pattern is cold rolling with a deformation degree of 70%. A 5% increase in the deformation degree proves advantageous, resulting in a 20% enhancement in process productivity. However, the rolling force also increases by 18%, leading to higher power consumption. Additionally, it is essential to take into consideration that material stress increases, potentially resulting excessive deformation resistance and the formation of cracks, microcracks, and other defects in the sheets. Furthermore, an increase of deformation degree may lead to elastic displacement of the rolls, negatively impacting the accuracy of dimensions and the quality of the sheet surface layer. When decreasing the deformation degree by 7.5%, a decrease in rolling force by 17% is observed, which is positive in terms of power consumption. However, rolling of the material under such conditions is accompanied by a 20% reduction in process productivity, which is a significant drawback. Moreover, under these conditions, the material does not achieve efficient strength and hardness, which can lead to plastic deformation of the sheet during its operation.

6. Conclusions

The process of manufacturing thin-sheet cold-rolled low-carbon steel 20 with a thickness of 1.5 mm has been studied, and the effect of the deformation degrees on the stress of steel 20, the strength characteristics of the material, the change in rolling force, and the productivity of the process have been determined. This allowed determining the technologically efficient deformation degree. It is reasonable to set the deformation degrees as 70%, ensuring quality indicators of cold rolling. Rise of the deformation degrees increases the productivity of the process, but at the same time, the material significantly strengthens, loses the ability to plastic deformation, making the rolling process impossible. Decreasing the deformation degrees does not allow achieving the required strength of the thin sheet and reduces the productivity of the process.

Abstract. The photocatalysts based on titanium dioxide (TiO_2) doped with melamine were synthesized. The samples of pure and modified TiO_2 were analyzed using X-ray diffraction (XRD) analysis, Brunauer-Emmett-Teller (BET) surface area analysis, and room temperature FT-IR, Raman, and UV-Vis diffuse reflectance spectroscopy. It was established that modifying TiO_2 with melamine leads to a decrease in the crystallite sizes and an increase in the lattice parameters and molecular unit volume. The stoichiometry of modified TiO_2 worsened due to the appearance of additional vacancies of oxygen in the doped samples. The photocatalytic activity of the prepared catalysts in the reaction of hydrogen production from water under light illumination was studied. The melamine-doped TiO_2 samples showed more than two times higher activity than pure titanium dioxide.

1. Introduction

Developing of highly efficient technologies for producing hydrogen from water is relevant and exciting. Hydrogen as a clean energy source has excellent prospects. Getting hydrogen from the photocatalytic decomposition of water under the action of UV and visible light is generally considered the most straightforward and cheapest technology for hydrogen production [1–3]. However, the main problem is finding the most efficient photocatalyst for this process. Among many photocatalysts, TiO_2 is the most efficient and promising [4–6]. TiO_2 is preferred due to its appropriate electronic properties, non-toxicity, chemical inertness, and low cost. Meanwhile, the TiO_2 disadvantage is that it absorbs only a tiny fraction of solar radiation (about 3–5 %). The UV absorption edge (and corresponding optical band gap Eg values) for different polymorphic phases of TiO_2 are somewhat different: about 387 nm ($Eg \sim 3.2$ eV) and 413 nm ($Eg \sim 3.0$ eV) for anatase and rutile, respectively. Many methods are used to increase the photocatalytic efficiency of TiO_2: introduction of metal (Fe, Co, Pt, Nb, Cu, etc.) [6–8] and non-metal (N, S, B, C) elements [9–11], etc.

It has been reported [12–17] that one of the promising ways to increase the photocatalytic activity of TiO_2 is its modification with melamine. Melamine $C_3H_6N_6$ has been shown to be a promising carbon and nitrogen source for the TiO_2 modification. It is known that melamine melts at 345°C with decomposition; when heated to 354°C and above, melamine off-gases ammonia with the formation of melem, which, at temperatures above 360°C, turns into cyanic (or isocyanic) acid. Judging by the literature data, in the high-temperature range of 530–555°C, graphitic carbon nitride g-C_3N_4 can be formed from melem. Recent studies have shown that g-C_3N_4 obtained at 550°C absorbs light in a wide spectral range and shows an increasing photoactivity [18]. However, XPS analysis showed the absence of nitrogen in our samples. Obviously, during the heat treatment of the samples, nitrogen was degassed as ammonium.

Therefore, our work aimed to obtain and characterize melamine-modified TiO_2-based photocatalysts with a further study of photocatalytic activity in the reaction of hydrogen generation from water using solar energy.

2. Experimental methodology

2.1. Samples preparation

The TiO_2 powders were synthesized by the sol-gel method. For the undoped TiO_2 preparation, the titanium(IV)butoxide ($C_{16}H_{36}O_4Ti \geqslant 99.9$ %, Aldrich), citric acid ($C_6H_8O_7$), and glycerol ($C_6H_8O_3$) were mixed to obtain uniform mass at room temperature and further calcinated at 500°C for two hours in the presence of air oxygen. The samples of melamine-doped TiO_2 were obtained using the same mixture but with the additions of melamine (4 and 8 %) before the heat treatment.

After cooling, the powders were triturated until smooth. The 4- and 8-wt.% melamine-doped TiO_2 samples were labeled as 1M/TiO_2 and 2M/TiO_2, respectively. The powder's color ranged from yellow to brown.

2.2. Instruments and methods

The XRD patterns of TiO_2 samples were obtained using a Bruker D8 Advance X-ray diffractometer with monochromatic $Cu_{K\alpha}$ – radiation ($\lambda = 0.154$ nm). The average crystallite size of the TiO_2 samples was evaluated from the A (101) characteristic peaks broadening using the Debye-Scherrer formula: $D = K\lambda/\beta\cos\theta$ where D is an average crystallite size in Angstroms, K is a constant equal to 0.89; λ is the X-ray radiation wavelength, β is the diffraction peak full width at half maximum (FWHM), and θ is a diffraction angle. The measurement errors for the XRD did not exceed ±5 %.

The FT-Raman spectra of the prepared TiO_2 powders were recorded in 80–4000 cm^{-1} spectral range using a Bruker IFS-88 Fourier spectrometer equipped with FRA-106 attachment (Nd:YAG laser, λex=1.064 μm, power 300 mW, backscattering geometry, spectral resolution 2 cm^{-1} and 128 scans accumulated for each spectrum).

The room temperature FT-IR spectra were recorded with a Perkin Elmer Spectrum One spectrometer in the spectral region of 4000-400 cm^{-1} with a spectral resolution of 4 cm^{-1}. For the FT-IR transmission spectra measurements, the samples were ground with KBr powder in a weight ratio of 1:200 and pressed into transparent KBr discs.

The prepared powders UV-Vis diffuse reflectance spectra (DRS) were measured using a Perkin-Elmer Lambda Bio 35 spectrophotometer in the 200–1000 nm wavelength range. The Eg value was estimated by extrapolating the linear part of the graph $(h\nu \cdot \alpha(h\nu))1/n$ vs $h\nu$ towards the energy axis at $\alpha(h\nu) = 0$, where $n = 1/2$ for direct allowed transitions, $n = 2$ for indirect allowed transitions.

The prepared catalysts specific surface area (S_{BET}) and pore size distribution were determined using a Quantachrom Nova Win 2 device. The specific surface area of the samples was determined based on nitrogen adsorption-desorption isotherms using the Brunauer–Emmet–Teller (BET) approach.

Photocatalytic hydrogen evolution was studied in a cylindrical glass temperature-controlled reactor. In the experiment, the prepared photocatalyst (0.03 g) was dispersed in 10.0 ml of an aqueous solution containing 2 mol/l of ethanol (electron donor). The Pd/SiO_2 co-catalyst (0.01 g) was obtained by the reduction of $PdCl_2$ with hydrogen on the surface of commercial silica (1 wt% palladium on SiO_2) and was added into the mixture [19].

The reaction mixture was degassed before the light irradiation using a vacuum pump. The suspension was irradiated using a high-pressure mercury lamp (DRSH 1000; 1000 W; $\lambda_{\max} = 365$ nm; 50 mW/cm^2) under constant stirring with a magnetic stirrer. The gas phase composition above the solution was evaluated chromatographically every 30 min.

3. Results and discussion

The XRD patterns of the undoped and melamine-doped TiO_2 samples show the diffraction peaks at $2\theta = 25.6$; 37.8; 48.1; 54.1; 55.0; 62.9; 69.2; 75.1 corresponding to anatase, and one small peak at $2\theta = 27.4$ that corresponds to the rutile crystal structure (figure 1). The rutile content did not exceed ∼12 % wt.

The overall XRD intensity from M/TiO_2 powders decreases compared with that from undoped TiO_2. Such a decrease may occur due to the TiO_2 lattice deformation or reduction of crystallite size after the modification. Indeed, from the XRD data analysis, the TiO_2 modification with melamine leads to a decrease in the crystallite sizes and some changes in the lattice parameters (table 1).

Table 1. Phase composition and structural characteristics of the prepared photocatalysts.

Sample	Interplanar spacing, d, nm	Lattice parameters, Å	Crystallite size, D_{hkl}, nm	Volume molecular unit TiO_2, V=a^{2}c, Å^3	Axial ratio, c/a
TiO_2	0.348	a = 3.7774 c = 9.2030	10.2	131.32	2.44
$1M/TiO_2$	0.348	a = 3.7894 c = 9.4590	7.6	135.83	2.49
$2M/TiO_2$	0.349	a = 3.7847 c = 9.4681	9.2	135.62	2.5

Modification led to the increasing of lattice parameters and molecular unit volume of TiO_2 and prevent the growth of crystallites during the heat treatment (table 1).

Besides that, the observed increase of the lattice parameters can occur due to the formation of more stoichiometric phase of TiO_2. We used FT-Raman spectroscopy to determine the stoichiometry and the sizes of nanocrystallites in the prepared TiO_2 catalysts (figure 2, table 2, table 3).

It was reported that the positions ($\nu_{\max}$) of the low-frequency phonon mode of TiO_2 crystal lattice Eg=144 cm^{-1} (for anatase) and its half-width ($\Delta\nu_{1/2}$) are very sensitive to the stoichiometric ratio (O/Ti), as well as to the size of TiO_2 nanocrystallites [22].

Based on the $\nu_{\max}$ vs O/Ti and ($\Delta\nu_{1/2}$) vs O/Ti correlation plots [22] it has been found that when TiO_2 samples are doped with melamine, their stoichiometry O/Ti ratio is getting worse (table 3). This is due to the appearance of additional oxygen vacancies in the doped samples. When oxygen vacancies appear in TiO_2, the oxygen environment of the titanium atoms and their valence state undergo changes, and the transition of the titanium atoms from one valence state to another takes place. The presence of oxygen vacancies in the electronic band structure of TiO_2 is associated with Ti^{3+} cations. With the appearance of the oxygen vacancies, the

local electrostatic balance is disturbed, and the transition of titanium atoms from one valence state to another occurs ($Ti^{4+} + e^- \rightarrow Ti^{3+}$). The changes in the oxygen content may be also accompanied by structural transformations. In addition, corresponding decrease in the size of TiO_2 nanocrystallites is observed.

The FT-IR absorption spectra of the TiO_2, $1M/TiO_2$ and $2M/TiO_2$ photocatalysts show the bands around 500–700 cm^{-1} (Ti–O–Ti), 900 cm^{-1} (Ti–O) [23], 1300-1600 cm^{-1} (C-O stretching and OH bending), 2343 cm^{-1}1 (physically adsorbed carbon dioxide [24]) and strong wide band

at 3200 cm^{-1} (absorption of OH stretching vibrations corresponding to stretching vibrations of Ti–OH groups involved in a weak hydrogen bond (~5 kcal/mol [25] with physiosorbed water molecules). Modified samples have additional bands at 2840–2893 cm^{-1} originating from stretching vibrations of the C–H and $–CH_2$ bonds).

The UV–vis absorption spectra of the prepared catalysts were measured to determine the band gap values of M/TiO_2 and un-doped TiO_2. The value of the band gap (Eg) was estimated from the dependence $(\alpha hv)^2 = f(hv)$ by extrapolating the linear region of the spectrum to the intersection with the abscissa axis, i.e., at $(\alpha hv) = 0$ (figure 3). It was revealed that the band gap value of the prepared catalysts changes from 3.27 eV (TiO_2) to 3.14 eV ($1M/TiO_2$) and 3.32 eV ($2M/TiO_2$).

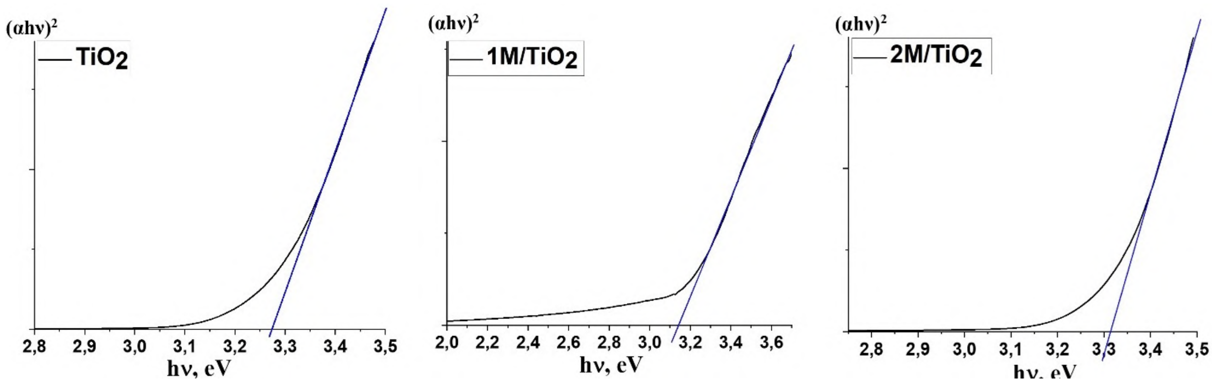

Figure 3. Plots of $(\alpha hv)^2$ versus photon energy ($f(hv)$) of the prepared catalysts.

We investigated the water splitting reaction in the presence of TiO_2 and M/TiO_2 photocatalysts under the light illumination with a power density of 50 mW/cm^2 from a high-pressure mercury lamp. The photocatalytic decomposition of water into hydrogen and oxygen requires the presence of a photocatalyst, an electronically excited semiconductor with a band gap less than the energy of the incident light ($hv > Eg$) [26].

As we have found, the melamine-modified TiO_2 catalysts ($1M/TiO_2$) showed more than two times higher activity (figure 4) than undoped TiO_2.

The $1M/TiO_2$ catalysts appeared to be the most photocatalytically active. Firstly, due to the decrease in the particle size, the rate of volumetric recombination of photoinduced charge carriers also decreased significantly – they reached the surface much faster than the average time of volume recombination. The second reason is the narrowing of the band gap.

4. Conclusions

A set of photocatalysts based on titanium dioxide doped with melamine were successfully synthesized to obtain the highly effective photocatalyst for hydrogen generation. It has been

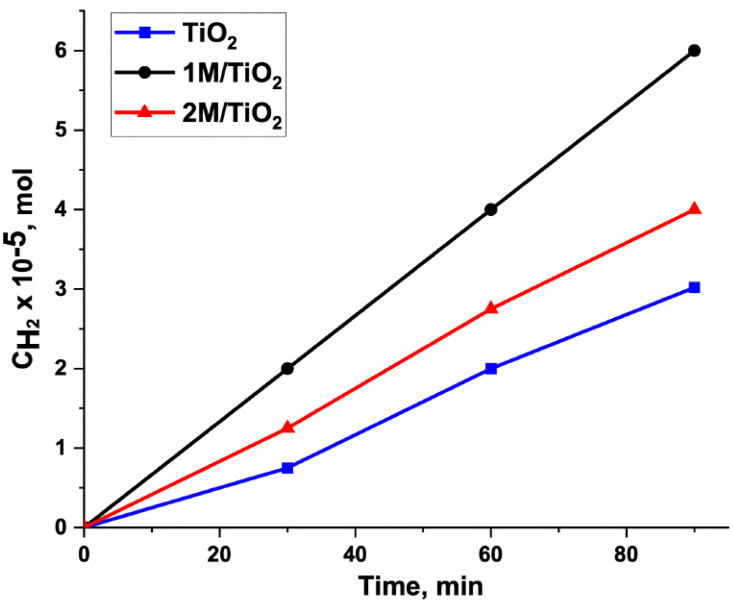

Figure 4. Kinetic curves of the photocatalytic hydrogen evolution from aqueous/ethanol solution.

found that TiO_2 modification with melamine decreases crystallite sizes and changes in the lattice parameters of TiO_2. The stoichiometry of modified samples deteriorates indicating the existence of additional oxygen vacancies in the doped samples. Changes in the oxygen content may be accompanied by the appearance of Ti^{3+} energy levels in the forbidden band of TiO_2.

The enhanced photocatalytic activity of $1M/TiO_2$ towards hydrogen production in the reaction of water splitting, which appeared to be more than twofold higher compared to unmodified TiO_2, is mainly attributed to the narrowing of the band gap, an increased number of surface active sites, and a decrease of photo induced charge carriers recombination rate due to the decreased particle size. This study suggests that the proposed simple way for TiO_2 modification with melamine can be used to obtain new M/TiO_2 materials with improved activity on hydrogen production and industrial wastewater treatment under the action of UV and visible light for creation of green energy and clean environment.

Abstract. Lime is used in the classical copper-molybdenum-pyrite flotation for pyrite depression. Often copper-molybdenum flotation separation is conducted with nitrogen and copper minerals are depressed with the aid of phosphorus- or sulfide-based compounds. The mentioned methods are relatively expensive, difficult for handling, sometimes desired results are not achieved and valuable metals are lost. An electrochemical depression of pyrite, followed by an electrochemical depression of copper minerals is suggested and aimed at increasing the recovery of metals and improving the processes' control. The impact is achieved both by electrodes immersed in the flotation pulp or by using preliminary produced catholyte for pulp preparation. Effective copper-pyrite and copper-molybdenum flotation separation can be achieved under air conditions at significantly reduced amounts of reagents used, latter leading to improved environmental impact.

1. Introduction and brief theoretical basis of copper-molybdenum flotation separation

The present-day industrial technology increasingly needs materials that are operative under high stress, extended temperature ranges, and extremely corrosive environments. Molybdenum (Mo) is used as an alloying component in steel, cast iron, and super-alloys to harden them and enhance their toughness, strength, corrosion and wear resistance. Furthermore, molybdenum is used as a refractory metal in many chemical applications, such as catalysts, lubricants, and pigments. Molybdenum is expected to become an increasingly important factor in environmental protection technology by its use in high-strength steels for automobiles in order to reduce weight at increased safety and advance fuel economy. With the aim to fulfill the requirements for reducing the carbon dioxide emissions from coal-fired power stations, the industry will built plants running at higher temperatures, which will result in greater demand for higher grade molybdenum-bearing steels. Few of molybdenum's uses have acceptable substitutes. Increase in molybdenum use in stainless and specials steels is expected to continue. For example, the estimated apparent consumption in 2022 increased by 96% compared with that in 2021 and the trend is expected to continue [1, 2].

Large part of the molybdenum concentrate production comes as a byproduct from copper-molybdenum (Cu-Mo) sulfide ores [2, 3]. Porphyry copper deposits are among the most important resources of copper and molybdenum. In these ores chalcopyrite and pyrite are most often the dominant minerals and the molybdenite (molybdenum disulfide, MoS_2) is the main molybdenum mineral [4, 5].

Although some oxidation methods have been studied to selectively recover and separate chalcopyrite and molybdenite [6–9], they have not found large industrial application.

In the most widely used flotation flow sheets of these ores in the first stage bulk copper sulfide concentrate, containing molybdenite, is obtained. In the second flotation stage molybdenum and copper concentrates are separated [3, 10, 11] (figure 1).

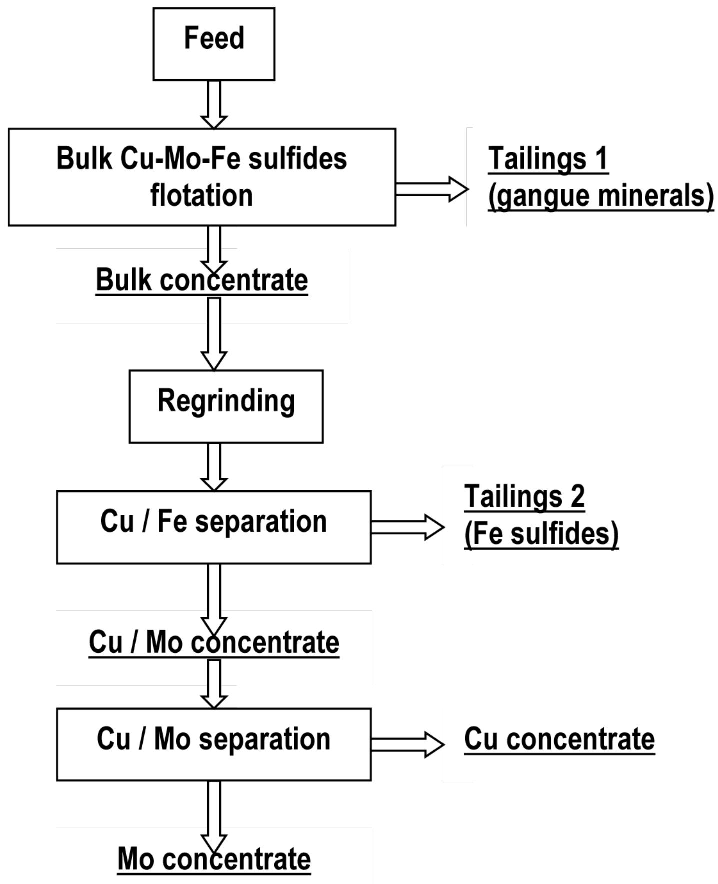

Figure 1. Schematic typical general flow sheet for recovering Cu and Mo from porphyry Cu–Mo ores-adapted from [10].

Usually an alkaline pulp (pH 8.5 - 11) is maintained (most often by lime addition 1 – 4 kg/t), in order to produce a stable froth with good carrying power (when xanthate or/and dithiophosphate collectors are used). A lower pH (i.e. 8.5 – 9.5) is more desirable in the case of chalcopyrite ore, since at a higher pH, the floatability of chalcopyrite is reduced, while chalcosine flotation needs pH > 11.5, [12].

Lime addition also results in pyrite depression in the first stage. Generally, depression of pyrite in the case of porphyry ores, containing chalcopyrite, is at pH about 10.5–11 [12]. Both chalcopyrite and molybdenite are well floating (recovery $> 90\%$) in the pH range 7-10 [13–15].

In the second stage depressants are added in order to decrease the effect of the residual collectors left in the bulk concentrate and to depress (generally, by destroying the copper collector) the flotation of copper sulfides, such as chalcopyrite. Different depressants are used, such as sulfur-containing compounds-sodium sulfide Na_2S, sodium hydrosulfide $NaHS$, Nokes reagent ($P_2S_5 + NaOH$), Na_2SO_3, and $Na_2S_2O_3$ [10, 16]. This method is the most commonly used and involves concentrate dewatering before conditioning with the depressant [12]. Nitrogen-containing compounds ($NaCN$, $Na_4[Fe(CN)_6]$, $Na_3[Fe(CN)_6]$, $NaCN$, KCN, $Zn(CN)_2$, $Ca(CN)_2$, etc.) are the other type of applied Cu depressant [17]. Generally, the depressants are created to react with the uncovered copper and iron ions on chalcopyrite surface and theoretically, the floatability of molybdenite is virtually unaffected, due to the absence of reaction sites [3]. Although the use of inorganic depressants such as $NaHS$ and $NaCN$ effectively depresses copper sulfides and separates Cu and Mo minerals, these reagents have some disadvantages, such as potential release of toxic gases (H_2S and HCN) when pH is out of control, inadequate molybdenite recovery, a possible loss of gold and silver contained in some ores when $NaCN$ is used, and corrosion of storage tanks and pipes [15–17]. Therefore, different organic depressants are studied as eco-friendly and inexpensive reagents [13, 18–20]. Mono- or poly-nuclear complexes are formed by donor atoms (such as nitrogen, sulfur and oxygen) in these compounds with transition metal ions (i.e. Cu and Fe) on chalcopyrite thus depressing it [10]. However, some of these chemicals can cause health problems at working places (such as eye irritation, respiratory irritation, skin irritation [21–23]. Trithiocarbonate may decompose to carbon disulfide that besides above described negative effects causes reproductive toxicity, coronary heart disease, retinal angiopathy, effects on peripheral nerves, psycho-physiological effects, etc [24].

While Cu-minerals are depressed, molybdenite is recovered as a flotation concentrate by using petroleum-based collector and alcohol frothers. Molybdenum oxide is produced by the molybdenite concentrate roasting or acid pressure-oxidation processes [10].

It is established that in plant practice, the correct selection of modifier, frother, collector and operating parameters (i.e. pulp density, mineral particles size, pH, oxidation-reduction potential) ensures an efficient process [12, 25, 26].

When porphyry copper and copper–molybdenum ores are processed the reagent schemes in bulk Cu-Mo concentrate producing stage are relatively simple and usually involve lime as a modifier, xanthate as collector for Cu ores and fuel oil or kerosene – for molybdenite, and frother (most often pine oil, methyl isobutyl carbinol or glycols). However, the lime used as pH modifier, may depress a portion of the molybdenum, causing a decrease in the obtainable recovery of MoS_2 mineral [4, 10, 27, 28].

The reagent scheme used in copper–molybdenum separation stage depends on the type of copper minerals present, type of reagent scheme used in the previous stage and the presence of other impurities in the concentrate. When chalcopyrite is the main Cu mineral or Cu is presented as a mixture of chalcopyrite and bornite, either $NaHS$ or Na_2S is used as depressant in the copper–molybdenum separation [12].

It is considered that $Cu(I)$-xanthate (CuX), formed by reaction (1) is needed for initial flotation of chalcopyrite and adsorbed dixanthogen (X_2), formed by reaction (2) for complete flotation of the same mineral [10, 29].

$$CuFeS_2 + X^- \longrightarrow CuX + FeS_2 + e^-, E^0 = 0.096V; \quad (1)$$

$$2X^- \longrightarrow X_2 + 2e^-, E^0 = 0.009V. \quad (2)$$

The xanthate induced flotation of copper sulfides is influenced by the pulp potential and in the pH region 6 to 10 it requires oxidizing conditions (generally oxidation-reduction potential

Eh, i.e. measured with platinum indicator electrode and presented with respect to SHE, has to be in the range from -100 to 200 mV) [30].

The addition of Cu depressant ($NaHS$ or Na_2S) leads to formation of reducing conditions (a low Eh value) at which chalcopyrite surface oxidation is inhibited [31].

Under these conditions it is impossible for either xanthate or dixanthogen to be adsorbed on Cu mineral surfaces [32]. In addition, Na_2S hydlolyses – reactions (3) and (4):

$$Na_2S + H_2O \longrightarrow HS^- + OH^- + 2Na^+; \tag{3}$$

$$HS^- + H_2O \longleftrightarrow H_2S + OH^-. \tag{4}$$

Produced HS^- ions (when reach a proper concentration) replace X^- ion in copper compounds (i.e. remove the collector from the mineral's surface) – reaction (5), decrease the dixanthogen adsorption by adsorbing on the mineral surface and due to their hydrophilicity increase the hydrophilicity of the mineral thus causing inhibition of its flotation. From the other hand Na_2S (in concentrations $<$ 0.03 mol/L) does not inhibit molybdenite flotation, using petroleum-based collector and alcohol frothers, due to molybdenite good natural floatability [14, 15, 32].

$$2CuX + HS^- \longrightarrow Cu_2S + 2X^- + H^+. \tag{5}$$

Sulfide ions from Na_2S also can replace xanthate ion in CuX and react with dixanthogen (reactions 6, 7) [14, 15]:

$$2CuX + S^{2-} \longrightarrow Cu_2S + 2X^- + H^+; \tag{6}$$

$$X_2 + S^{2-} \longrightarrow S^0 + 2X^-. \tag{7}$$

The pulp potential (Eh) measured revealed that the depression of chalcopyrite occurring at enought available sulfide is due to the strong reducing environment (achieved by the Na_2S addition) leading to the decomposition and desorption of copper xanthate and the dixanthogen respectively. In a different way, the molybdenite shows less sensitivity to Na_2S addition and corresponding changes in Eh and still exhibits a high recovery when chalcopyrite was fully depressed [14].

From the other hand, over-dosage of $NaHS/Na_2S$ may cause molybdenite depressing [33]. The edge surface of molybdenite possesses high energy and electrochemical activity owing to the broken covalent S–Mo bond. At a low $NaHS$ concentration, HS^- could be oxidized as shown in reaction (8):

$$xHS^- + 1/2(x-1)O_2 \longrightarrow S_x^{2-} + H_2O + (x-2)OH^-. \tag{8}$$

Further oxidation may take place on the edge surface of molybdenite as shown by reaction (9):

$$MoS + S_x^{2-} + H_2O + 1/2O_2 \longrightarrow MoS - S_x + 2OH^-, \tag{9}$$

where S_x represents elemental sulfur or polysulfide attached to the edge surface. X-ray Photoelectron Spectroscopy (XPS) analysis confirmed the formation of S_n^{2-}/S_8 species on molybdenite surface. Polysulfide or elemental sulfur on the edge surface renders molybdenite more hydrophobic and this way enhances its flotation recovery. However, when $NaHS/Na_2S$ concentration is high the created reductive environment prevents the formation of elemental sulfur or polysulfide. For such cases, Chen et al. [31] using XPS analysis identified HS^-, S^{2-} and SO_4^{2-} on the surface of molybdenite. As a result, the hydrophobicity of the molybdenite surfaces is decreased, leading to decreased molybdenite flotation recovery.

Molybdenite has to be recovered from a copper concentrate with a high reagent content. It has been found that in order to acheve an effective copper-molybdenum separation the amount of depressant in the pulp must be maintained above certain empirically determined levels. If the depressant available in the flotation pulp is insufficient to be effective, either because an insufficient amount was initially used or because some of the depressant initially present has been consumed or lost, the collector employed to float both sulfide minerals in the initial rough flotation stage will allow the copper minerals to refloat and efficient copper-molybdenum separation will not be achieved [12]. Because of this, the molybdenum copper separation needs a high level of copper depressants and requires a complex multi-stage process, which is costly and may cause lowering of molybdenum recovery.

Instability of sulfide depressants in presence of oxygen in air and dissolved oxygen in water and the depressant adsorption on fine particles of solid phase can increase the consumption of Na_2S about 300 times. The use of nitrogen as the flotation gas in the molybdenite plant ensures stability of the reducing conditions created by the Na_2S addition. This results in about 20% decrease in the consumption of Na_2S owing to the decrease in the undesirable oxidation of Na_2S [32].

Studies carried out in Chuquicamata mine in Chile also showed that the needed depressant ($NaHS$) amount can be decreased by 48% by using N_2 instead of air. A further decrease of 21% was attained when $NaHS$ addition was controlled by potential measurement. Both lab and plant scale test verified that the application of potential measurement and control could significantly decrease the consumption of depressant. For example, laboratory scale flotation tests conducted with a 50:50% mixture of chalcocite and molybdenite showed that electrochemically achieved reducing potential in the range from -600 to -1200 mV (vs. SCE) ensured a good separation of the mentioned minerals [10].

Conducting the flotation separation with air, instead of use of nitrogen, without need of addition of high amounts of depressants of copper will simplify the flotation scheme. Conditions will be created for retention of valuable metals in the produced copper concentrate.

In addition, some problems can be avoided, such as reaction of residual lime with the phosphorus-based flotation reagents to form insoluble compounds that impede the filtration process.

Previous work [34] ensured achievement of needed reducing conditions for Cu-Mo separation by immesring stainless steel electrodes directly into the flotation cell. The study showed that similar oxidation-reduction potentials may be achieved by reagents addition and by the electrochemical impact.

In order to avoid electrodes introduction in the flotation cell and eventual problems with the cell hydrodynamics, another means is searched for ensuring reduction conditions at a decreased use of a reagent depressants. Such means could be use of catholyte of a diaphragm electrolyzer as liquid for pulp preparation in the copper-molybdenum flotation separation stage. The results from such experiments are offered in the present paper.

2. Materials and methods

Bulk copper-molybdenum-pyrite concentrate, taken from a copper flotation factory was used. The metal content was as follows: 17.9% copper, 0.31% molybdenum, and 20.3% iron. Chalcopyrite and molybdenite were the major Cu and Mo minerals, respectively. Chalcocite and bornite were identified as the minor minerals. Experiments were performed in Agitair (2.5 L) flotation cell that was found suitable by a previous study. The flotation time of 4 min was chosen also based on our previous experiments. Pulp density was set at 30% solid, having in mind findings of Zanin et al. [25], particles size was -100 +43 μm. Technical grade reagents were used. Reagents used were potassium ethyl xanthate (40 g/t), pine oil (25 g/t), diesel oil 40 (g/t), n-butanol (10 g/t), Nokes – 0.25 kg/t in the classical experiment, Na_2S in different amounts, slaked lime to reach the desired pH value. Chemical purity nitrogen was supplied by a bottle. The electrochemical impact was realized with the aid of a laboratory stabilized rectifier. The additionally grinded material was subjected to an electrochemical impact with electrodes, made of stainless steel, immersed directly into the flotation cell. The electrodes design is described elsewhere [35]. A home-made diaphragm electrolyzer was used to prepare catholyte from tap water to which some salt is added. Dimensionally stable anode (i.e. titanium covered with metal oxides) and stainless steel cathode were used. The power source was a laboratory stabilized rectifier. Figure 2 presents schematically the experiments carried out.

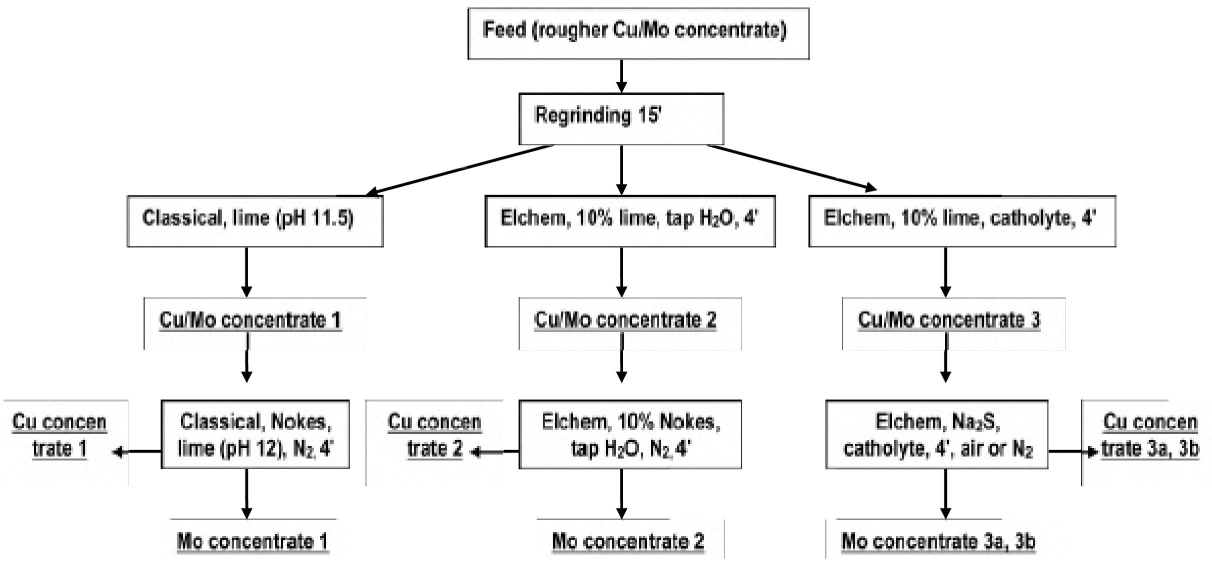

Figure 2. Scheme of the experiments.

The pH value and the oxidation-reduction potential (Eh) value of the pulp were measured with a WTW portable multi parameter 3320 device and combined pH and ORP electrodes (Pt and $Ag, AgCl$). Metals content was determined by ICP720-OES, Agilent Technologies, after proper digestion of samples. Each presented result is an average of 2 parallel experiments. Data were processes with Excel program.

3. Results and discussion

Results on the influence of the electrochemical impact on copper-pyrite selection are presented in table 1. As it can be seen, better results with respect to copper recovery are obtained at decreased lime addition and applied electrochemical impact by electrodes immersed in the pulp. This may be assigned to the fact that the achieved pulp pH value in the range of 10.0 - 10.5 was enough high to ensure the needed foam stability. At the same time, the amount of Ca^{2+} ions that present in the pulp is not too high, so as to decrease the chalcopyrite floatability. It is shown that $CaCl_2$ solutions decrease the floatability of chalcopyrite and molybdenite at pH values higher than 9 [36]. Although a little bit lower, compared to the case with immersed electrodes, copper-pyrite separation is still better in the case of catholyte use, compared to the classical case without an electrochemical impact and with lime addition to reach pH 11.5. The positive aspect of catholyte use is the avoidance of electrodes immersion directly into the flotation cell.

Results on molybdenum recovery and on the recovery of Cu in molybdenum concentrate are presented in figure 3. Figure 4 shows the Eh and pH values measured in the pulp.

As it can be seen in figure 3, when air is the flotation gas, the addition of Na_2S increases molybdenite recovery until reaching particular concentration of 20 kg Na_2S per t and further increase in the amount of added reagent does not practically improve the molybdenite flotation.

This doze of Na_2S ensured the highest depression of Cu minerals, under the given conditions. Carryng the process with N_2 as flotation gas gives best results with respect of both Mo flotation

Table 1. Cu recovery in the Cu/Mo concentrate.

No (according to figure 2)	Cu recovery, %	Fe recovery in tailing, %
1	93.89	79.32
2	96.31	84.94
3	95.44	83.87

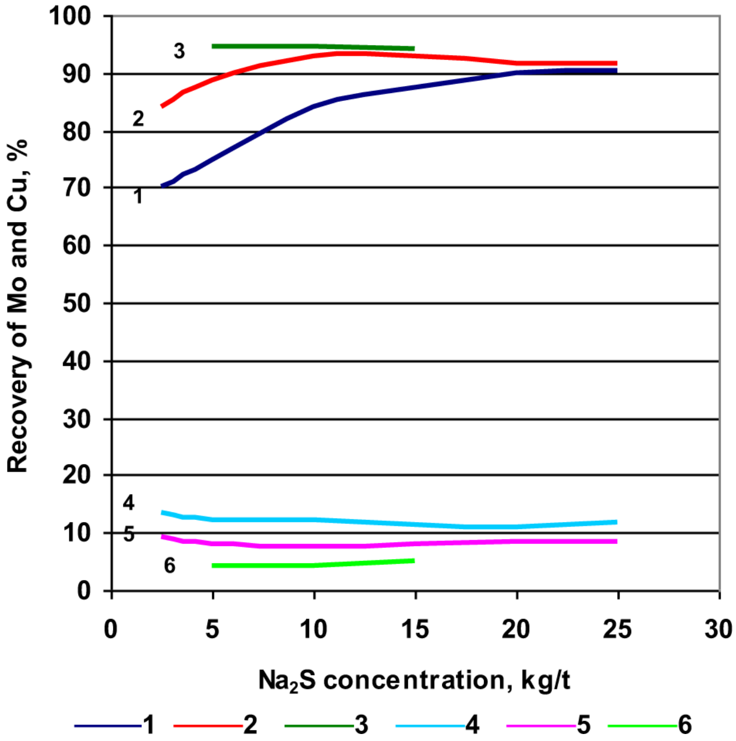

Figure 3. Recovery of Mo (higher values) and Cu (lower values) in Mo concentrate under different concentrations of added Na_2S and different conditions: 1 – Mo, air, pulp with tap water; 2 – Mo, air, pulp with catholyte; 3 – Mo, nitrogen, pulp with tap water; 4 – Cu, air, pulp with tap water, 5 – Cu, air, pulp with catholyte, 6 – Cu, nitrogen, pulp with tap water.

and Cu depression at 3-4 times lower Na_2S doze. When the pulp was prepared with catholyte, instead of tap water, under the air conditions, best results were obtained at half of the Na_2S amount used in the case of tap water. The results can be considered satisfactory both in terms of molybdenite flotation and chalcopyrite depression, although the values obtained when using nitrogen are not reached.

The best results obtained with the use of nitrogen can be explained by achieving and maintaining low values of the oxidation-reduction potential Eh of the pulp at which the molybdenite floats well (figure 4, curve 4). As a result of conducting the process with air as the flotation gas, under stirring conditions, the redox potential of the pulp increases, especially at lower amounts of added reductant. This leads to a deterioration of molybdenite flotation and at the same time a weak chalcopyrite flotation begins, as the low edge of the redox potential of chalcopyrite flotation is reached, at the respective pH values (figure 4, curve 2). Use of catholyte (with reducing properties) in pulp preparation slows the pulp Eh movement to positive values due to the air effect and thus keeps longer the suitable Eh range for molybdenite flotation and

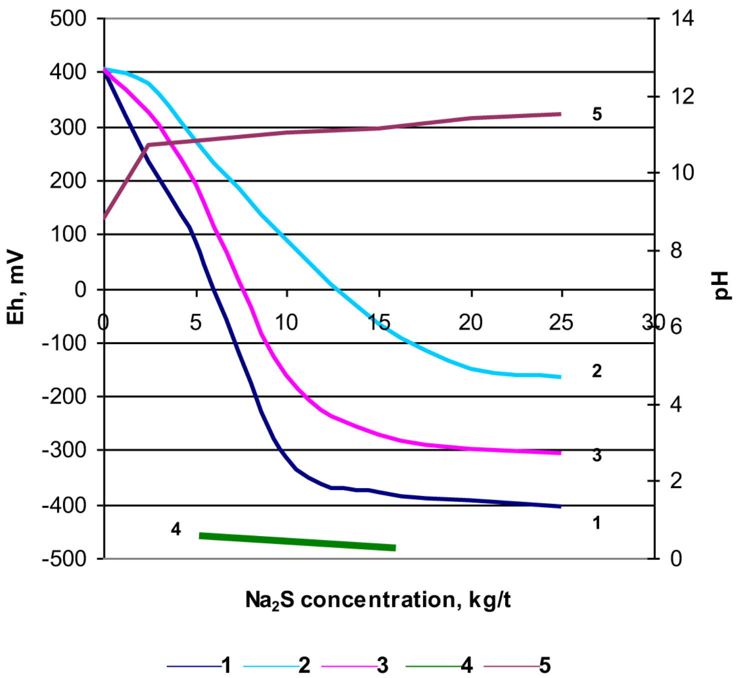

Figure 4. Eh and pH values measured in the Cu-Mo pulp under different concentrations of added Na_2S and different conditions: 1 – air, pulp with tap water, 30" after reagent addition; 2 – air, pulp with tap water, 3rd-4th min after reagent addition; 3 – air, pulp with catholyte, 3rd-4th min after reagent addition; 4 – nitrogen, pulp with tap water, 3rd-4th min after reagent addition; 5 – pH, air, pulp with catholyte, 3rd-4th min after reagent addition.

chalcopyrite depression (figure 4, curve 3).

Studies (with immersed in the pulp electrodes) showed that, at reducing potentials (Eh between -180 and -240 mV), the highest molybdenum recovery of 96-97% and the lowest copper recovery of 4-5% can be achieved [34]. Practically the same range of potentials (Eh from -160 to -270 mV at pH 10-11) has been confirmed as optimal for conducting electrochemically assisted (by immersed electrode or catholyte-assisted) copper-molybdenum selection by the experiments described here.

Potentials in the range of -100 to -200 mV, on hydrogen scale, (obtained by reagents addition) were reported as the optimal for copper-molybdenum separation [37]. Sepalveda-Suarez and Castro studied the effect of Eh on the selective flotation of molybdenite from chalcopyrite by using fresh bulk Cu–Fe–Mo concentrate, taken directly from the "El Salvador" industrial plant, Anamol-D (a Cu depressant), and N_2 as a flotation gas [38]. They found that Cu mineral depression was effective at potentials below -180 to -200 mV. The high effect of Eh on Mo recovery was noticed in the potential range from +20 to -280 mV, with a fast recovery of Mo in concentrate with a high grade in the potential range from -180 to -280 mV.

About 100 mV more reducing potentials (obtained by addition of two types of Na_2S – of mineral origin and of chemical nature) were reported as the range of best copper-molybdenum selection by Kolahdoozan and Noori [39]. The highest achieved molybdenum recovery was 93% and the lowest copper recovery was 4-15%. Addition of extra amounts of Na_2S did not change considerably the potential range reached. At more oxidizing potentials (more positive than about -200 mV), similarly to the found by us, the Cu recovery started and the Mo recovery dropped.

Smith, Davey and Bruckard pointed the potential of -340 mV as the most suitable one for the molybdenum concentrate production [40].

Mehrabani et al. also studied the effect of pulp potential on the flotation separation of chalcopyrite and molybdenite [5]. The potential was changed by the addition of Na_2S and/or by using nitrogen. It is reported that the addition of 16 kg/t Na_2S into the flotation pulp under aeration conditions initially decreased the pulp potential Eh from +450 to -375 mV. Using air as the flotation gas caused gradual increase of the pulp potential to -178 mV. A molybdenum recovery of 91.74% (at only 0.44% recovery of copper minerals) was achieved at a Na_2S consumption of 16 kg/t. The use of N_2 instead of air helped to decrease the consumption of Na_2S to 6 kg/t (pH = 10.5, Eh remained stable in the range of -100 to -200 mV at the end of flotation), where molybdenite recovery of 92.88% was achieved at a separation efficiency of 90.03%.

Bahrami et al. measured the Eh range of -370 to -390 mV in the rougher flotation circuit of the molybdenum plant of the Sungun copper–molybdenum processing-complex [41].

Recoveries of Cu and Mo in final concentrates, obtained under different conditions, are shown in table 2.

Table 2. Recoveries of Cu and Mo in final concentrates obtained under different conditions.

Conditions	Cu recovery in final Cu concentrate*, %	Mo recovery in final Mo concentrate*, %
Classical	No 1 - 93.54	No 1 - 92.75
Electrochemical impact-immersed electrodes, tap water, 10% Nokes, N_2	No 2 – 95.88	No 2 – 94.57
Electrochemical impact-catholyte, Na_2S – 10 kg/t, air	No 3a – 95.03	No 3a – 92.99
Electrochemical impact-catholyte, Na_2S - 5 kg/t, N_2	No 3b – 95.19	No 3b – 94.33

* Numbers – according to figure 2.

The lowest recoveries are obtained under "classical" conditions, with lime and Nokes addition and pH 12 in the Cu-Mo separation stage, although the Eh values were in the suitable Eh range. Flotation with an electrochemical impact gives better results with the best one with electrodes immersed in the pulp. However, the results obtained with use of catholyte are also promising. The electrochemical impact does not ensure achieving as high pH value of the flotation pulp, as the lime addition. This is favorable for Cu minerals depression, besides reaching the suitable Eh ranges. Mehrabani et al. [5] has pointed that Cu minerals flotability increases 3-4 times with the pH increase from 10.5 to 12.5.

Decreased lime use in Cu/Py selection and its avoidance in the Cu/Mo selection most probably lead to better preservation of the molybdenite inherent hydrophobicity. Less Ca-containing precipitation species are expected to be generated. The adsorption of these species is found to cover molybdenite edges. The adsorption of calcium species decreases the contact angle of the molybdenite particles thus reducing their hydrophobicity and leading to a decrease in the floatability of these particles [27,42]. The depression caused by Ca^{2+} ions is proportional to their concentrations [36]. It is found that both copper and molybdenum recoveries were lower in the presence of Ca^{2+} ions in concentrations higher than 10^{-2} M, in particular at pH > 10 [25].

4. Conclusions

1. Effective copper-pyrite and copper-molybdenum flotation selection can be achieved (at significantly reduced amounts of reagents used) with the aid of an electrochemical impact

achieved both by electrodes immersed in the flotation pulp or by using catholyte for pulp preparation.

2. The optimum Eh potential range for the Mo recovery (92-93%) and the lowest copper recovery (7-8%) in molybdenum concentrate is determined as -160 to -270 mV and pH 10-11 under air conditions. Molybdenum flotation separation from copper can be effective by controlling the Eh and pH ranges of the flotation pulp either by reagents addition and/or by the electrochemical impact.
3. Minimization of reagents' use or their replacement by an electrochemical impact exhibits several advantages: easier process control (by the applied electrical energy); a possibility for faster and facilitated response to the changeable minerals that feed the flotation process, including impoverished and complex ores; improved environmental impact.

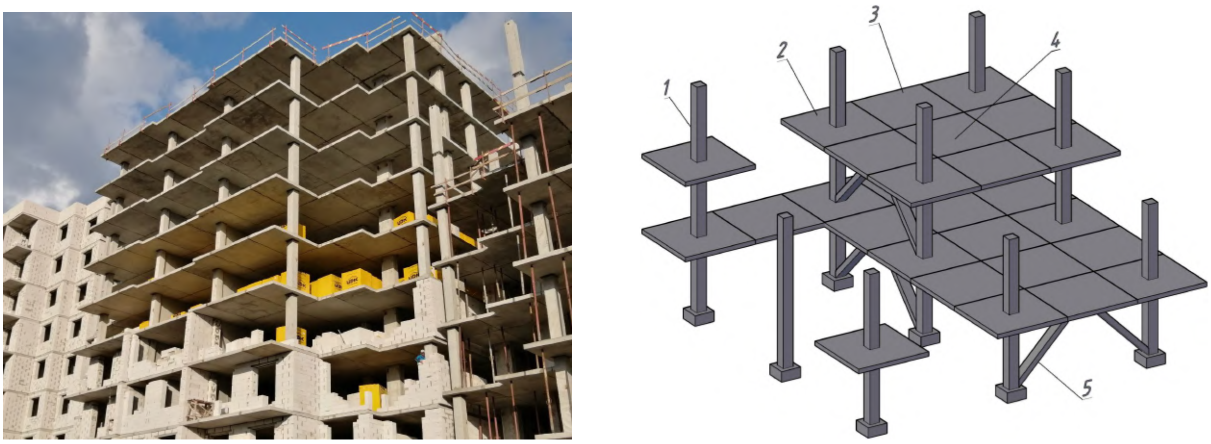
Abstract. The construction of a precast flat plate frame of buildings is considered for its implementation during the restoration of the housing stock of Ukraine. The analysis of the precast flat plate floor system of the frame structural system by using the yield line method showed that in the ultimate state the floor is divided into separate discs along the joints of precast plates. This makes it possible to determine the load-bearing capacity of the floor by considering each plate taking into account their supporting and loading conditions. Based on this, experimental tests of three full-size over-columned plates of a precast flat plate floor system are carried out, according to the diagram closest to the actual scheme of their operation as part of the floor. The general deflections of the plates, moments of crack formation and width of their opening, as well as strains of concrete and reinforcement in characteristic cross-sections of the plates are determined. Based on the experimental tests, the accepted failure scheme of the over-columned plates of the precast flat plate floor system is confirmed and the feasibility of applying the yield line method to the calculation of their bearing capacity is proven.

1. Introduction

To date, renewal of the housing stock of Ukraine has become one of the most urgent tasks in the field of construction. This task can be solved by introducing modern structural systems in the erection of buildings and structures. It is quite possible and expedient to apply the structural system of buildings based on a precast flat plate frame [1] to solve this problem.The benefits of using the named system are proven: construction speed increases by 50% due to the use of industrial precast reinforced concrete structures; installation of reinforced concrete members does not depend on weather conditions and can be carried out throughout the year; starting a production line for the manufacture of precast members is quite simple and can be done in the shortest possible time; the frame has features that allow each building to have unique architectural forms, which makes the urban landscape more attractive and diverse; architectural and planning solutions meet high aesthetic requirements, provide comfort and a high level of microclimate; the cost of 1 square meter of housing is reduced by almost 40% compared to buildings using traditional structural systems.

The precast flat plate frame structural system of buildings is being widely implemented in residential construction (figure 1). The flat plate of the structural system is arranged on columns and is a simple structure consisting of reinforced concrete plates of the same thickness and shape. This composition of floor components simplifies the process of formwork and production and significantly speeds up the construction of objects. The main structural members of the flat plate

Figure 1. One of the new buildings of precast flat plate frame structural system in Poltava.



(a) (b)

Figure 2. Precast flat plate frame structural system of buildings: (a) a building under construction and (b) the general view of the structural system: 1 – column; 2 – over-columned plate; 3 – inter-columned plate; 4 – middle plate; 5 – linear brace.

frame structural system are columns and plates (figure 2). Flat floors are directly connected to columns without the use of protruding members, which provides the opportunity to freely adapt the architectural and planning solutions of buildings for any purpose.

The design of flat plate frame structural systems is usually carried out by dividing them into flat orthogonally located frames [2, 3]. At the same time, the frame is considered as a set of frames with rigid nodes. Over-columned and inter-columned floor plates in the range of each row of columns are considered as continuous crossbars of the frames, and therefore are designed as continuous beams at equalized moments based on consideration of the redistribution of forces in the ultimate limit state. The middle plate is designed as two-way slab according to the limit equilibrium method, taking into account the fastening way in the supporting circuit.

Meanwhile, as practice shows, the work of members in the framework of a precast flat plate structural system differs from that implemented in the mentioned design schemes. In particular,

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012067 doi:10.1088/1755-1315/1415/1/012067

in the precast version of the structural system the destruction scheme of its members is formed depending on the design of the joints of the precast members. At the same time, the schemes of deformation of floor plates are accepted as for plates with special fastening conditions. As evidenced by works [1, 4], for the strength design of plates supported along the contour, it is quite expedient and convenient to use the yield line method, which allows taking into account the actual conditions of fastening, reinforcement and the nature of the destruction of members.

The application of the yield line method [5–9] to the calculation of the bearing capacity of reinforced concrete plates is considered for plates made of fiber concrete [10, 11], plates supported on two adjacent sides [12], plates with an irregular grid of columns [13], plates with the destruction of individual columns [14], as well as in many other cases [15–19]. Data of theoretical calculations in the mentioned works are supported by experimental results. Experimental data [20] for plates of the flat plate frame structural system are scarce today, so there is a need to experimentally investigate the members of this system in order to confirm the proposed fracture schemes [4].

2. Construction of experimental samples of over-columned plates

Three experimental full-scale samples of over-columned floor plates were used for conducting experimental tests. The plate samples had nominal dimensions of 2980×2980×160 mm. The specified geometric characteristics are adopted for the purpose of their compliance with the unified dimensions of precast reinforced concrete members of the flat plate floor system. The design of the test sample and its geometric dimensions are shown in figure 3. The reinforcement scheme of the experimental sample of the over-columned plate is displayed in figure 4. The characteristics of concrete and reinforcing steel used in the manufacture of the samples of the experimental over-columned plates are specified in table 1.

Table 1. Characteristics of materials used in the manufacture of experimental samples of over-columned plates.

Physical and mechanical characteristics of materials	Plate PO-1	sample PO-2	code PO-3
Reinforcement A500C			
Ø18, σ_y, MPa	600	600	600
Ø14, σ_y, MPa	610	610	610
Ø10, σ_y, MPa	620	620	620
Ø8, σ_y, MPa	630	630	630
Concrete C25/30			
f_{cd}, MPa	17	17	17

The production of the tested samples of the over-columned plates is divided into stages: at the first stage, reinforcement products are made for laying in the formwork, at the second stage, concreting is carried out A500C class bars are used as the principal reinforcement of the plates. The over-columned plates are reinforced with a spatial reinforcing cage (figure 4), which includes the upper and lower plane meshes and embedded support structure. The upper mesh was assembled by hand in conjunction with the support structure of the plate in the form of a steel clip and vertical cages welded to it.

The over-columned plates are made of heavy concrete, which has an average density ranging from 2200 kg/m^3 to 2500 kg/m^3. Strength class of concrete is C25/30 [3]. The over-columned

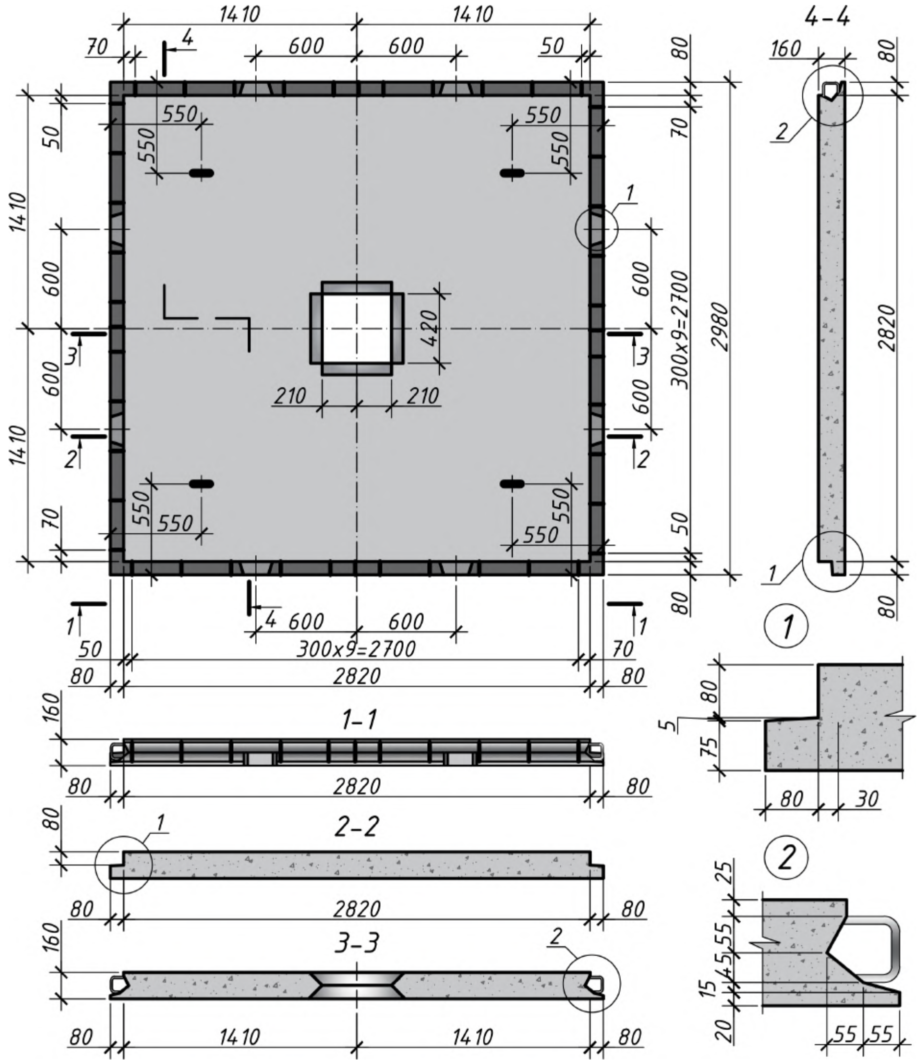

Figure 3. Design of experimental samples of over-columned plates.

plates are reinforced with reinforcing components made of of A500C steel, which included (positions on figure 4):

1 – the plane M-1 mesh made of steel bars of a diameter 14 mm, a length of 2800 mm, connected to an embedded support structure SSE-1, in which 3 outlets of reinforcement with a diameter of 18 mm are arranged on four sides (figure 5);

2 – the plane mesh M-2 made of steel bars with a diameter of 8 mm and a length of 2960 mm;

3 – bent bars B-1 with a diameter of 12 mm, a length of 800 mm, a bending angle of 90°;

4 – the spatial cage CS-1 made of steel bars with a diameter of 12 mm and a length of 850 mm and reinforcing bars with a diameter of 4 mm and a length of 300 mm;

5 – bent bars B-2 with a diameter of 12 mm and a length of 800 mm.

To determine the physical and mechanical characteristics of the reinforcing steel (table 1) the passport data provided by the manufacturer are used.

The production of reinforcing cages, meshes and embedded parts, as well as concreting of over-columned plates was carried out at the plant of reinforced concrete products of "Combinat of industrial enterprises" in the village of Tereshki of Poltava region.

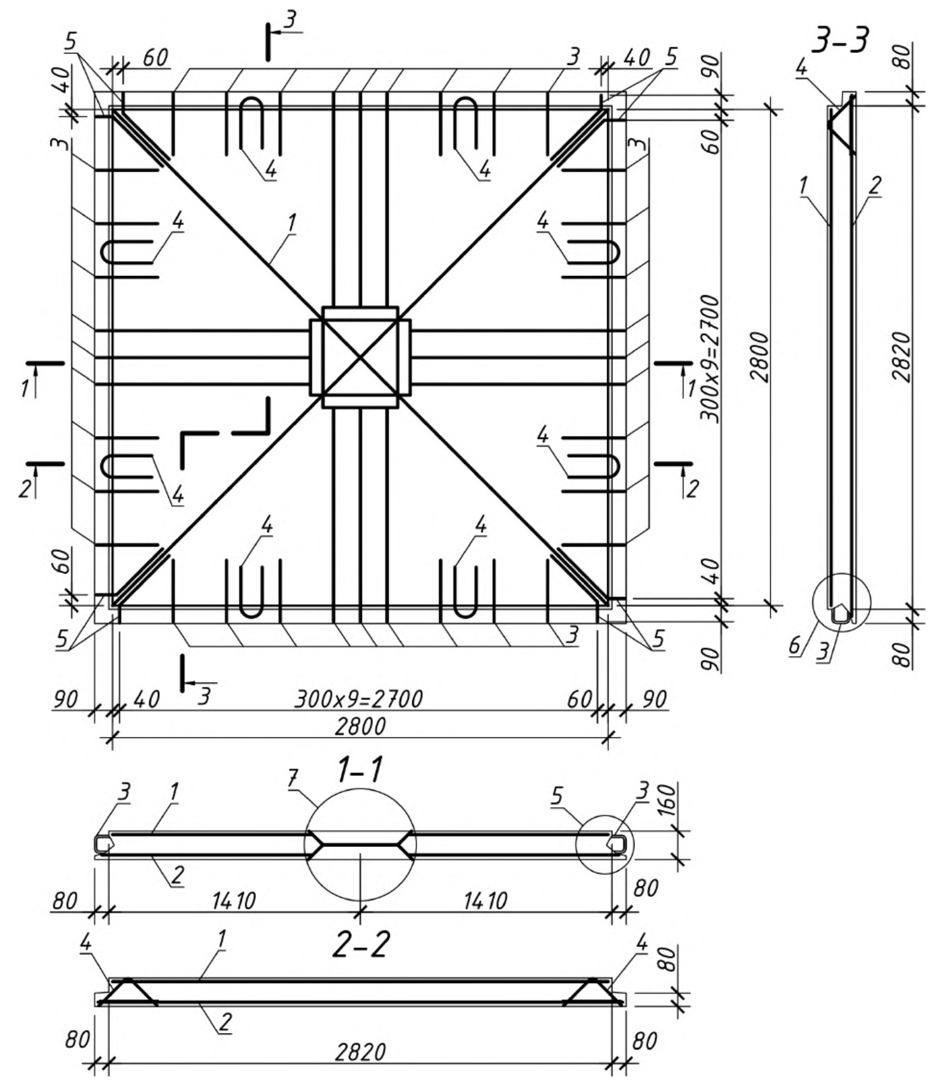

Figure 4. Reinforcing scheme of the experimental sample of the over-columned plate: 1 – mesh M-1; 2 – mesh M-2; 3 – bent bar B-1; 4 – spatial cage CS-1; 5 – bent bar B-2.

The concrete mixture was produced directly at the concrete unit of the enterprise. Dosing of components took place in automatic mode. Laying of the concrete mixture was carried out using a dosing device. After laying the concrete mixture in the metal formwork, it was compacted with deep vibrators. Hardening of the concreted samples took place under the conditions in the steaming chamber. After the concrete reached full strength, the elements were released from the formwork. After that, the tested samples of the over-columned plates were transported to the laboratory of the Department of Building Structures of the National University "Yuri Kondratyuk Poltava Polytechnic" for testing.

In the laboratory, strain gauges with a base of 50 mm and 20 mm, respectively, were pasted on the concrete and on the reinforcing bars of the experimental plate samples in the zones of their possible destruction. Gluing of strain gauges was carried out using BF-2 glue, following all recommendations for performing such works. Previously, the surface of concrete and reinforcing bars in the areas where strain gauges were installed was cleaned, polished, degreased with a solvent and primed with glue.

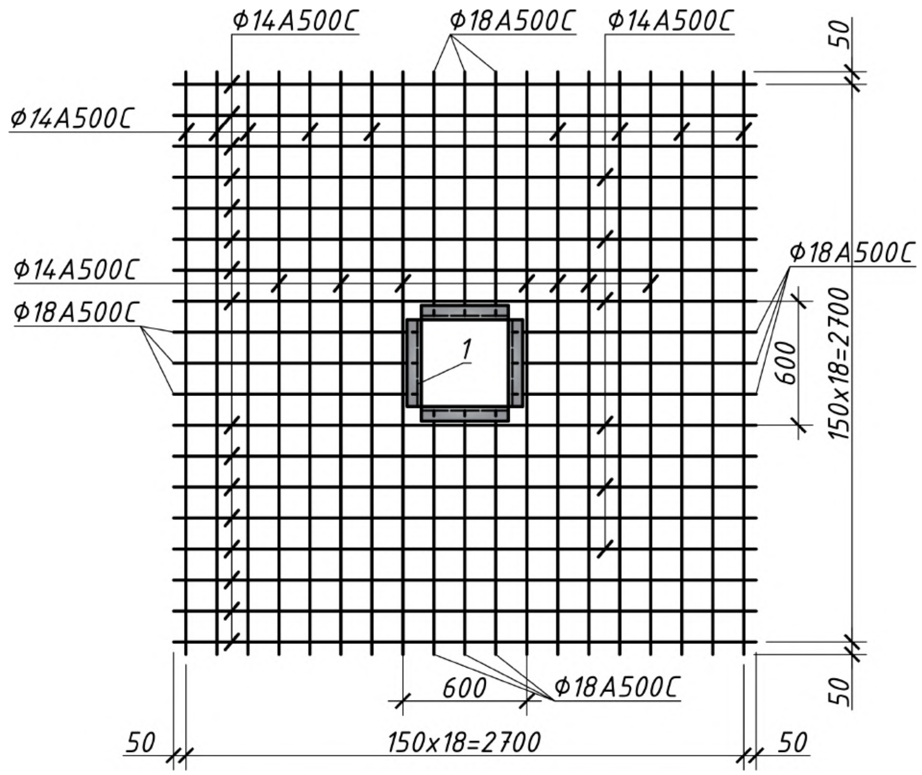

Figure 5. Structure of the reinforcing mesh M-1 of the over-columned plate: 1 – embedded support structure SSE-1.

3. Methodology of over-columned plates tests

Control tests of full-scale samples of over-columned plates is carried out on a specially designed stand according to the developed scheme (figure 6). It is impossible to simulate the supporting and loading scheme of the plate, which would absolutely correspond to the real work of the plate as a member of a precast flat plate floor system. That is why the testing scheme of over-columned plates is adopted in such a way that it allowed implementing the design fracture scheme accepted on the basis of the yield line method, which is realized in the composition of a flat plate floor system [4].

A stand with a hydraulic jack was used to load the experimental samples of the over-columned plates. The pressure in the system was increased using a mobile pumping station. A pressure gauge, which was previously tared, was used to measure the load. When conducting static load tests, the following measuring devices were used: watch-type deflection gauge 6PAO with a division value of 0.01 mm (figure 6) for measuring linear displacements; strain gauges for measuring concrete and reinforcement deformations (figure 7); MPB-2 microscope with a resolution of 0.05 mm for measuring the crack opening width.

The general appearance of the installation during the testing of the over-columned plate samples and the location of all measuring devices is presented in figure 8.

4. Over-columned plates tests results

The testing of the over-columned plates PO-1, PO-2, and PO-3 was carried out to an external load of 320 kN, 360 kN, and 400 kN, respectively. These values of load made up about $0.55F_{Rd}$, $0.6F_{Rd}$, and $0.7F_{Rd}$, respectively, where F_{Rd} = 580 kN – the design value of the destructive load, calculated by the yield line method for the over-columned plate according to [4] taking

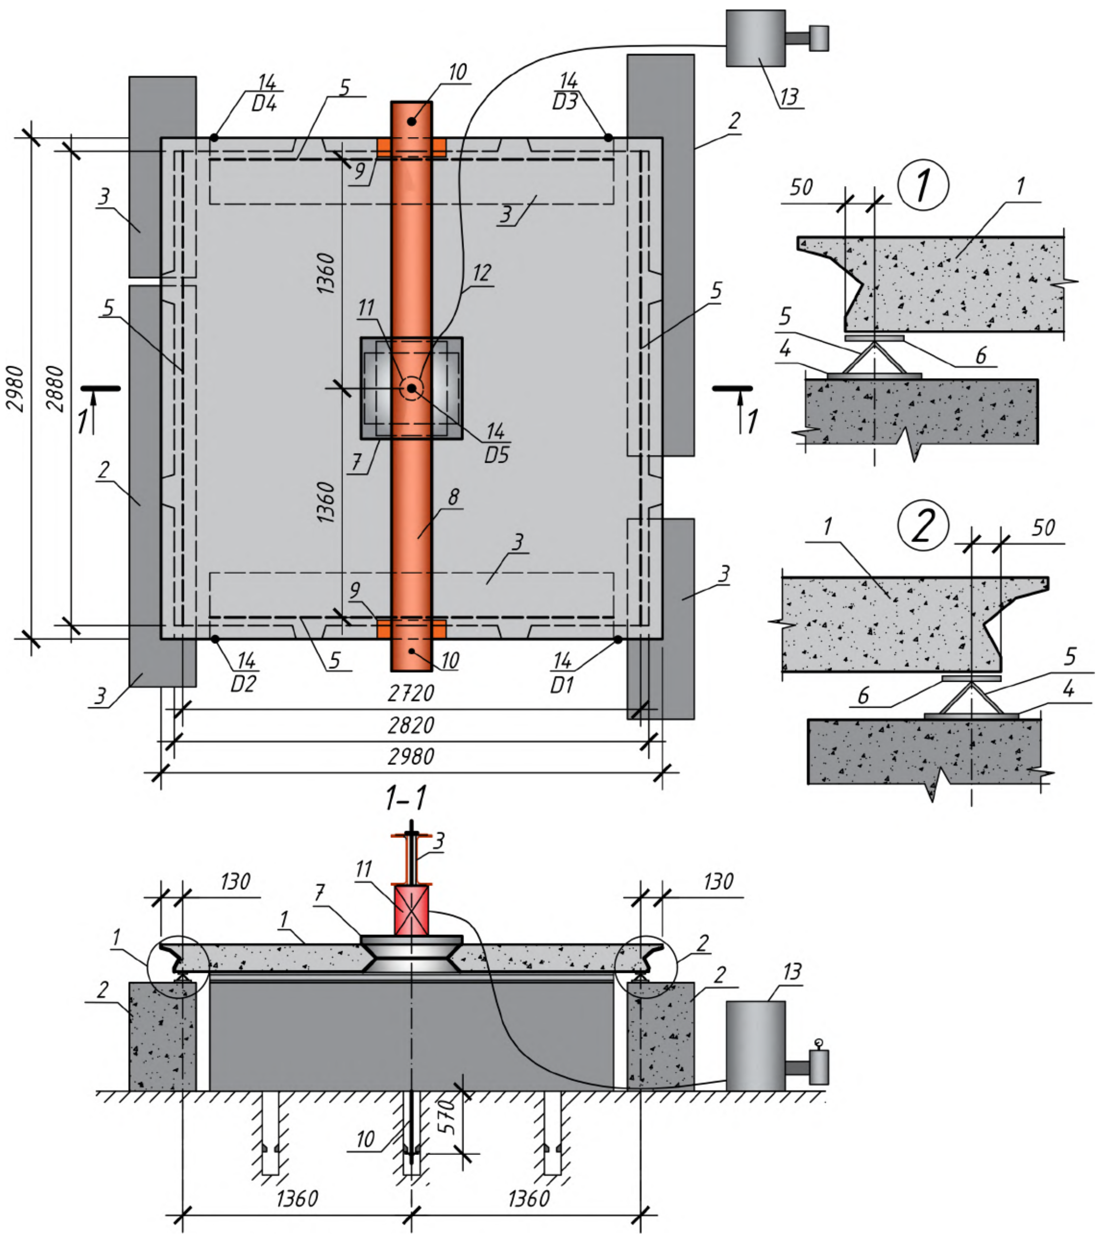

Figure 6. Test scheme of the over-columned plate: 1 – plate PO; 2 – supporting element (concrete block FB 24.6.5); 3 – supporting element (concrete block FB 12.6.5); 4 – steel plate (strip 150×10); 5 – unmovable hinged support (steel angle bar 75×5); 6 – steel plate (strip 100×8); 7 – steel plate (strip 600×5); 8 – traverse (2 channels No. 30); 9 – temporary support for the traverse; 10 – steel bar (Ø30A240); 11 – hydraulic jack F = 500 kN; 12 – oil pipeline; 13 – pumping station; 14 – 6PAO watch-type deflection gauge.

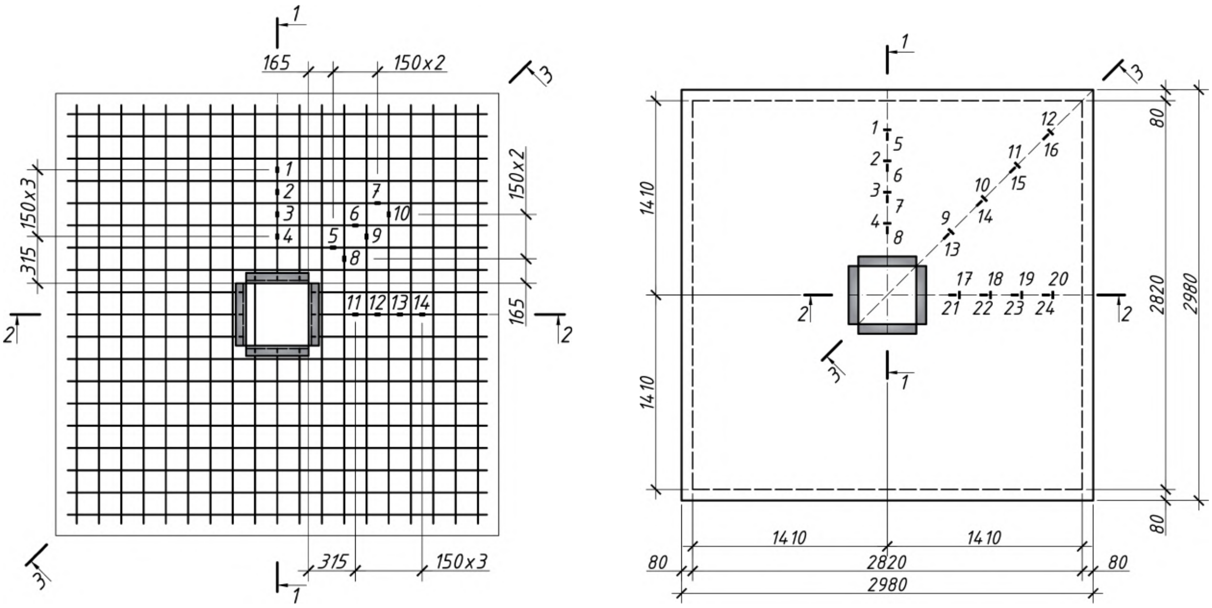
into account calculated values of ultimate strains of concrete in compression.

In the course of the tests, it was noted that the character of the formation of cracks and the deflections growth of various test samples of plates PO-1, PO-2 and PO-3 did not differ significantly, since all the test samples had the same geometric dimensions and were tested according to the same supporting and loading scheme (figure 6).

When testing the PO-1 plate, the first crack was formed near the supporting opening along



(*a*) (*b*)

(*a*) (*b*)

Figure 8. General view of the over-columned plate PO-1 during the test: (*a*) top view and (*b*) side view.

one of the diagonals of the plate under a load of 120 kN ($0.2F_{Rd}$). When the load increased, it began to open, and then another crack was formed along the other diagonal of the plate. During loading, these cracks extended along the diagonals in the direction from the center of the plate to its edges. The opening width of the cracks in the plate under a load of 120 kN was 0.1 mm, under a load of 320 kN ($0.55F_{Rd}$) the width of the crack reached 2 mm.

During the experimental tests of the PO-1, PO-2, and PO-3 the dependence of the deflections on the magnitude of the external load was studied. The readings of the deflection gauges (D1 – D5), the location of which is shown in figure 6, were recorded for all slab samples up to a load value of 320 kN. Graphs of the dependence of deflections of full-scale over-columned plates on

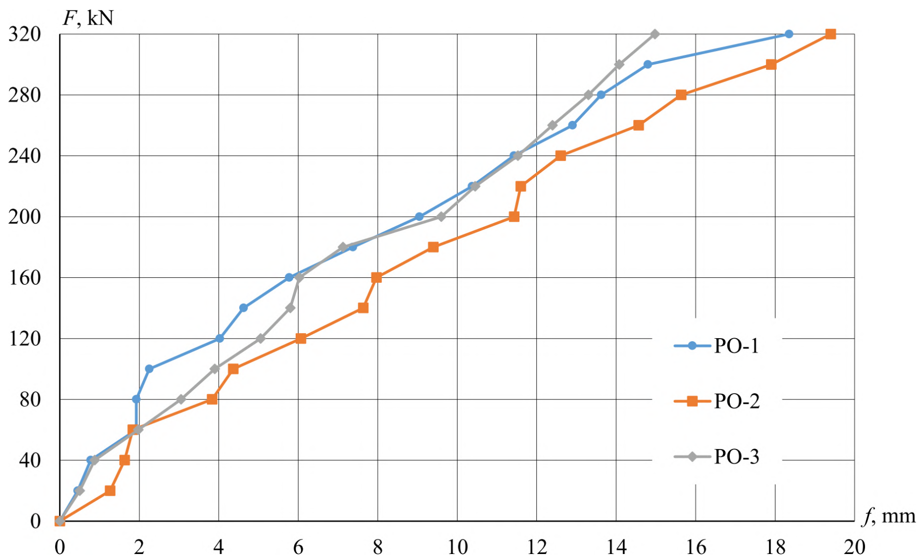

Figure 9. Growth of the total deflection of the over-columned plates during the test.

the value of the external load are shown in figure 9.

It can be seen from the graphs (figure 9), up to a load value of 40 kN ($0.07F_{Rd}$) in PO-1 and PO-3 slabs and 60 kN ($0.1F_{Rd}$) deflections in the plates grew much more slowly than after this level, which is explained by the influence concrete work in the tensile zone of the plate by the amount of its deflections. As long as the concrete in the tensile zone of the plate perceives the tensile forces, the deflections grow more slowly, but as soon as the tensile forces cease to be perceived by the concrete, due to the formation of cracks in it, the deflections begin to grow faster.

The specified load levels can serve as moments of crack formation in the tensile zone of the over-columned plate. In addition, by analyzing the graphs in figure 9, it can be concluded that the dependence of the deflections on the load level is directly proportional. That is, the dependence of the deflections on the load on the graphs is linear, when the principal reinforcement of the plate, located in its tensile zone, works elastically.

The graphs (figure 9) show that at the external load level of 280 kN ($0.5F_{Rd}$) the deflections of all test samples of the over-columned plates are the closest in terms of values. The deflection values for PO-1, PO-2 and PO-3 plates are 13.9 mm (l/209) and 14.9 mm (l/195) and 13.9 mm (l/209), respectively. The maximum measured deflections of plates PO-1, PO-2 and PO-3 under a load of 320 kN ($0.55F_{Rd}$) were 18.2 mm (l/159), 18.4 mm (l/158) and 15.6 mm (l/186) respectively.

When conducting experimental studies, the strains of concrete and reinforcement were measured on one of the four quarters of the plate (figure 7), since the plate is symmetrical with respect to two mutually perpendicular axes of symmetry passing through the center of gravity of the structure. This made it possible to study sufficiently the features of the stress-strain state of the test samples.

The regularity of the distribution of deformations can be traced on the graphs of the dependence of the strains ϵ_s of the tensile reinforcement on the value of the external loading F, constructed based on the results of experimental studies (figure 10, figure 11).

The graphs (figure 10, figure 11) show that the strains of the reinforcement depending on the load had different values in different areas. From the very beginning of loading, the maximum strains were observed in section 3-3, and with further loading, these strains in the diagonal direction (section 3-3) significantly increased and the difference between them and strains in the

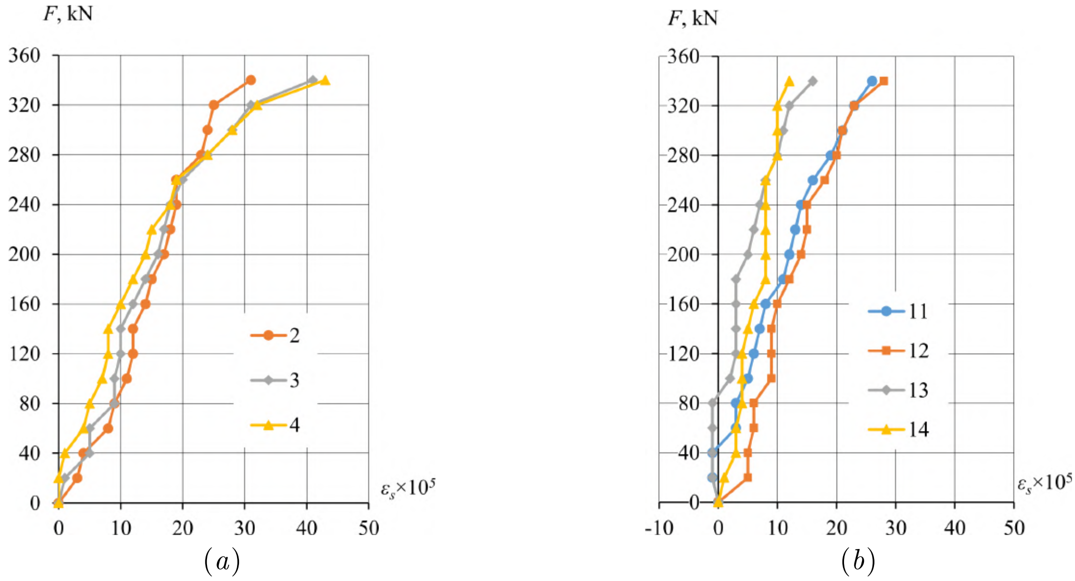

Figure 10. Strains of the principal reinforcement of the over-columned plate PO-1 during loading: (a) in section 1-1 and (b) in section 2-2.

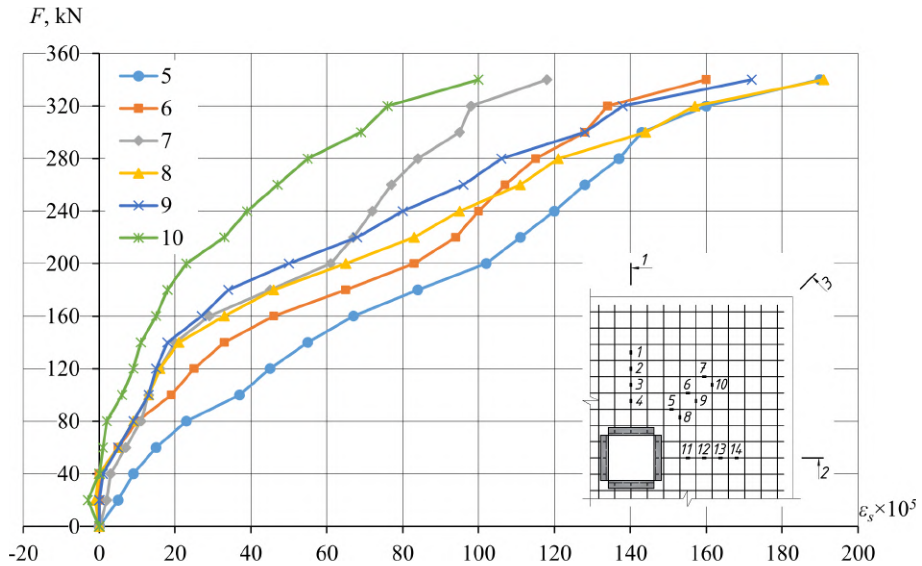

Figure 11. Strains of the principal reinforcement of the over-columned plate PO-1 during loading in section 3-3.

longitudinal and transverse directions (sections 1-1 and 2-2) enlarged considerably.

As it can be seen from graphs in figure 10, in sections 1-1 and 2-2 the bars work proportionally according to the perceived load. At the same time, the values of their strains in the PO-1 slab under a load of 320 kN ($0.55F_{Rd}$) are 10×10^{-5} – 32×10^{-5} ($0.03\epsilon_{s0}$ – $0.1\epsilon_{s0}$), in the PO-2 slab under a load of 360 kN ($0.6F_{Rd}$) – 9×10^{-5} – 37×10^{-5} ($0.03\epsilon_{s0}$ – $0.1\epsilon_{s0}$), in the PO-3 slab under a load of 400 kN ($0.7F_{Rd}$) – 3×10^{-5} – 23×10^{-5} ($0.03\epsilon_{s0}$ – $0.08\epsilon_{s0}$), where $\epsilon_{s0} = \sigma_y/E_s = 600/210000 = 286 \times 10^{-5}$ – strains of reinforcement at the yield point (table 1). Therefore, it is possible to draw a conclusion about the savings reserves of these bars.

Examining the graphs of reinforcement strains in cross-section 1-1 (figure 10, a) at the locations of gauges 1-4, it may be concluded that with the gradual approach to the supporting opening, the strains of the bars in the tensile zone of the plate increase slightly. At that time, in section 3-3 (figure 11), a significant increase in strains is observed as the reinforcing bars approach the opening.

The graphs of the strains of reinforcing bars in the diagonal section 3-3 (figure 11) up to the strain value of 20×10^{-5} $(0.07\epsilon_{s0})$ have a significantly greater angle of inclination to the horizontal axis than after reaching this value. This indicates a more intensive reinforcement deformation in the further range, which is explained by the beginning of the formation of cracks in tensile concrete. At the same time, the reinforcing bars reach the mentioned strain values at different values of the external load from 70 kN to 170 kN. The bars closest to the supporting opening are the first to reach the indicated strain values. Therefore, it can be predicted that the failure of the slab will begin when the yield point is reached, first, in the reinforcing bars that pass around the plate's opening.

The maximum values of tensile strains of the principal reinforcement in the diagonal section 3-3 were 160×10^{-5} $(0.6\epsilon_{s0})$ under a load of 320 kN $(0.55F_{Rd})$ in the plate PO-1, 181×10^{-5} $(0.6\epsilon_{s0})$ at a load of 360 kN $(0.6F_{Rd})$ in the PO-2 slab, 178×10^{-5} $(0.6\epsilon_{s0})$ with a load of 400 kN $(0.7F_{Rd})$ in the PO-3 plate and the minimum values were 76×10^{-5} $(0.3\epsilon_{s0})$, 98×10^{-5} $(0.3\epsilon_{s0})$, 111×10^{-5} $(0.4\epsilon_{s0})$, respectively.

During the experimental studies of full-scale over-columned plates PO-1, PO-2 and PO-3, in addition to strains of reinforcement ϵ_s in the tensile zone of the plate, strains of concrete ϵ_c located in the compressed zone were also studied.

From the very beginning of the experimental research, during the loading of the test samples of the over-columned floor plates, the maximum values of the concrete compressive strains were observed at the locations of the gauges 1–4, 9–12, and 17–20 (figure 13, figure 14), respectively, in sections 1-1, 2-2, 3-3.

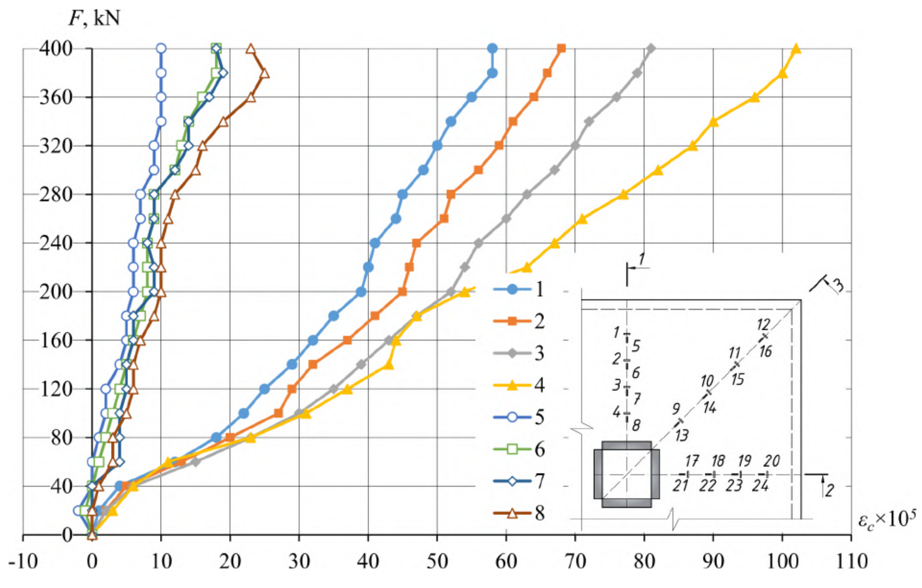

Figure 12. Compressed concrete strains of the PO-3 over-columned slab during loading in section 1-1.

By analyzing the nature of the graphs in figures 12–14, it can be noted that the strains of concrete across sections 1-1, 2-2 and 3-3 occurred more intensively than in the longitudinal direction. The specified difference is typical for all sections. The maximum values of compression strains of concrete in the transverse direction in sections 1-1, 2-2 and 3-3 were:

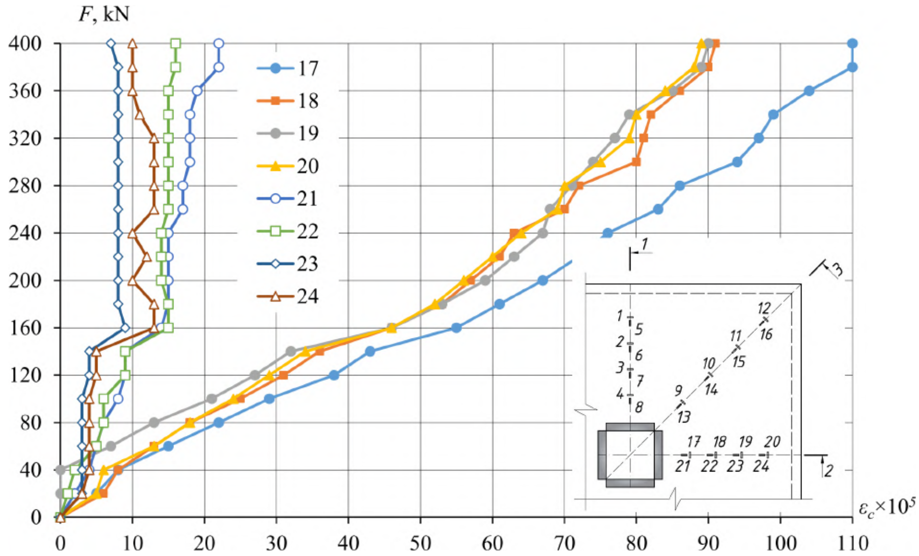

Figure 13. Compressed concrete strains of the PO-3 over-columned slab during loading in section 2-2.

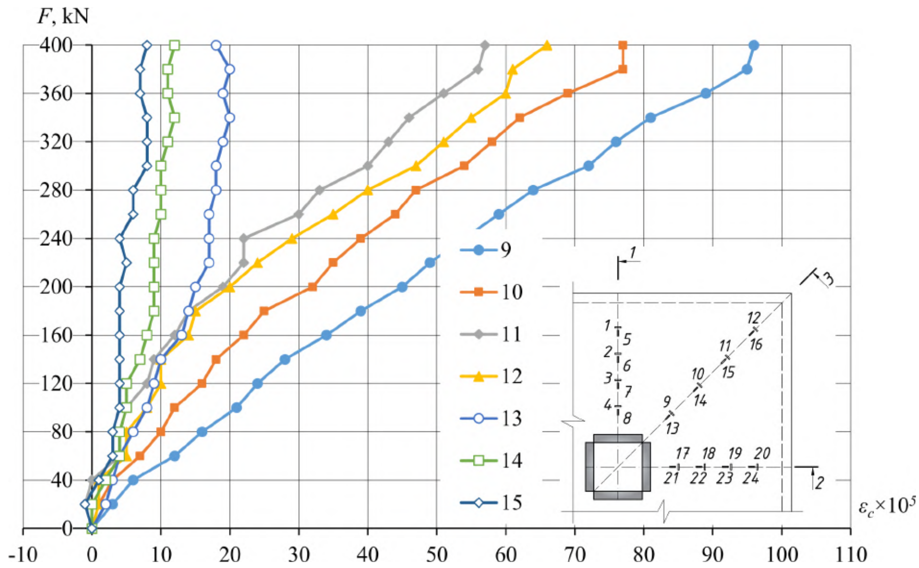

Figure 14. Compressed concrete strains of the PO-3 over-columned slab during loading in section 3-3.

- in the PO-1 plate under a load of 320 kN ($0.55F_{Rd}$), respectively $64 \times 10^{-5}(0.2\epsilon_{cu1})$, $110 \times 10^{-5}(0.3\epsilon_{cu1})$ and $70 \times 10^{-5}(0.2\epsilon_{cu1})$;
- in the PO-2 plate under a load of 360 kN ($0.6F_{Rd}$), respectively $52 \times 10^{-5}(0.1\epsilon_{cu1})$, $89 \times 10^{-5}(0.3\epsilon_{cu1})$ and $84 \times 10^{-5}(0.2\epsilon_{cu1})$;
- in the PO-3 plate under a load of 400 kN ($0.7F_{Rd}$), respectively $102 \times 10^{-5}(0.3\epsilon_{cu1})$, $110 \times 10^{-5}(0.3\epsilon_{cu1})$ and $96 \times 10^{-5}(0.3\epsilon_{cu1})$, where $\epsilon_{cu1} = 350 \times 10^{-5}$ – ultimate value of strains of concrete C25/30 according to [3].

The maximum values of compression strains of concrete in the longitudinal direction in sections 1-1, 2-2 and 3-3 were:

- in the PO-1 plate under a load of 320 kN ($0.55F_{Rd}$), respectively $29 \times 10^{-5}(0.08\epsilon_{cu1})$, $23 \times 10^{-5}(0.07\epsilon_{cu1})$ and $30 \times 10^{-5}(0.08\epsilon_{cu1})$,
- in the PO-2 plate under a load of 360 kN ($0.6F_{Rd}$), respectively $17 \times 10^{-5}(0.05\epsilon_{cu1})$, $10 \times 10^{-5}(0.03\epsilon_{cu1})$ and $9 \times 10^{-5}(0.03\epsilon_{cu1})$,
- in the PO-3 plate under a load of 400 kN ($0.7F_{Rd}$), respectively $23 \times 10^{-5}(0.07\epsilon_{cu1})$, $22 \times 10^{-5}(0.07\epsilon_{cu1})$ and $18 \times 10^{-5}(0.05\epsilon_{cu1})$.

Thus, the difference between strains in the transverse and longitudinal directions for all plates ranged in section 1-1 from 69% to 82%, in section 2-2 from 79% to 93%, in section 3-3 from 64% to 84%.

Examining the graphs of concrete strains by gauges perpendicular to the section, it can be concluded that with the gradual approach to the supporting opening, the values of strains of concrete in the compressed zone of the slab increase significantly. At the same time, in the longitudinal direction (according to the gauges located along the cross-sections), this tendency is much less pronounced. By comparing the graphs of strains of compressed concrete and tensile reinforcement, it should be noted that in concrete the distribution of strains in cross-sections 1-1, 2-2 and 3-3 does not have a considerable difference, in contrast to the reinforcement, in which the strains in cross-section 3-3 are significantly larger in comparison with strains in sections 1-1 and 2-2. The indicated trend is clearly demonstrated in the fields of strain distribution over the area of the experimental plates, built according to the results of experimental studies (figures 15, 16).

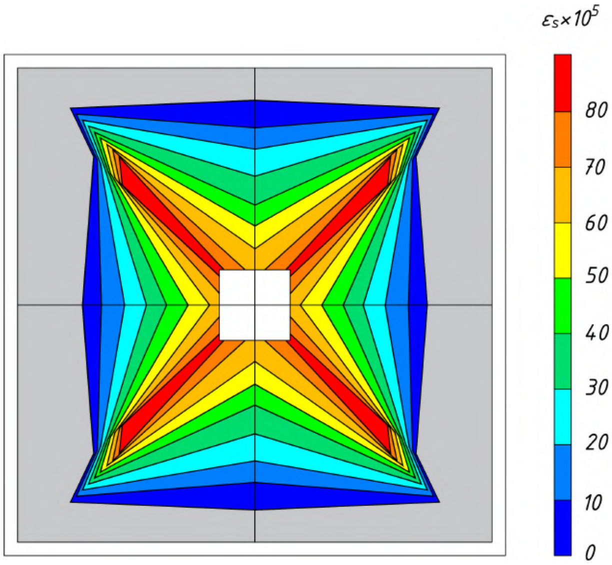

Figure 15. Fields of strains' distribution of the principal tensile reinforcement of the PO-1 plate at the moment of destruction.

Figures 15, 16 illustrate that the over-columned plate when working as part of the floor system has the largest values of strains of tensile reinforcement in diagonal directions. At the time of failure, yield lines will form along the diagonals of the plate, which are characterized by reaching the yield point in the tensile reinforcement.

The yield phenomenon, which begins in the most stressed places of the plate – around the supporting opening – with the load increasing will spread to the entire reinforcement along its diagonals, forming lines along which the bending moment reaches the ultimate value. At the same time, the plate will be divided into separate disks connected by diagonal yield lines, which

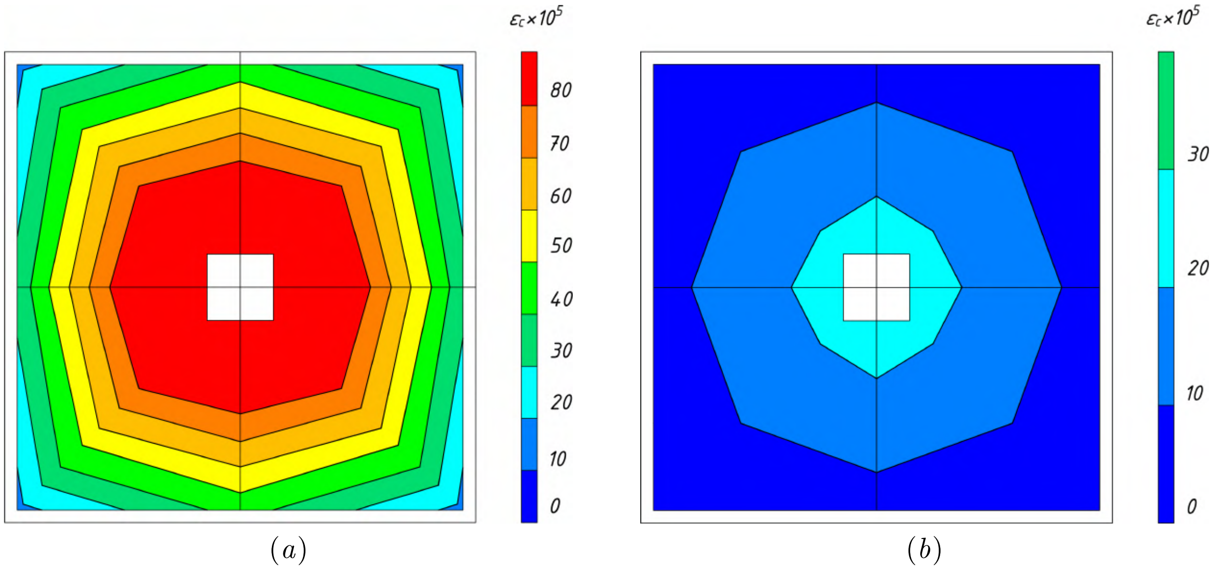

Figure 16. Fields of strains distribution of the compressed concrete of the PO-3 plate at the moment of destruction: (*a*) in the direction transverse to sections 1-1, 2-2, 3-3 and (*b*) in the direction longitudinal to sections 1-1, 2-2, 3-3.

corresponds to the accepted fracture scheme of the over-columned plate [4] when it is designed using the yield line method.

In addition, it should be noted that the plate works in two directions (figure 16), that is, the concrete of the compressed zone undergoes flat biaxial compression. This aspect is not fully taken into account in the calculations of its bearing capacity. Taking into account the actual stress-strain state of the over-columned plate of the precast flat plate floor system will make using principal reinforcement more economical to ensure the strength of the floor structure.

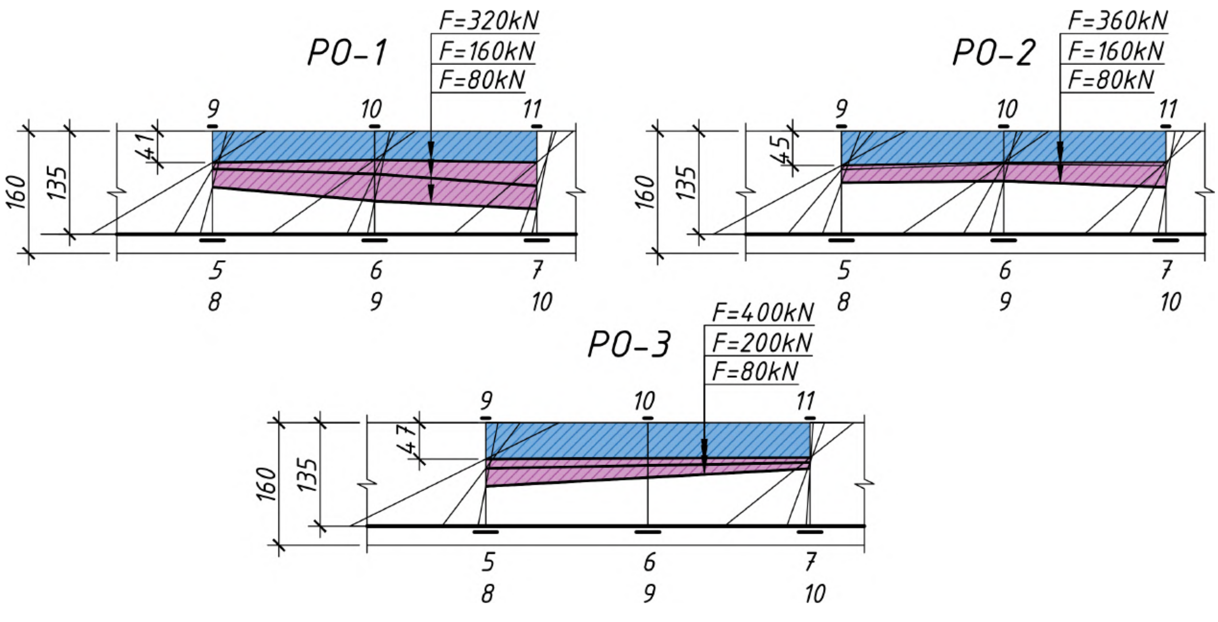

Figure 17. Change in the position of the neutral axis in the diagonal direction of the over-columned plates during loading.

One of the tasks set during the experiment was the task of investigating the change in the position of the neutral axis during the loading of the over-columned plate. This became possible thanks to the graphs in figure 17. To plot the graphs of the neutral axis position changing in the diagonal direction of the plate, the material strains plots were used based on the values of the data from the strain gauges.

As can be seen from figure 17, as the load increased, the compressed zone of concrete decreased, and the neutral axis moved up parallel to the most compressed face. This process occurred most intensively up to the value of the external load of 160 kN ($0.3F_{Rd}$), with a further increase in the load, it significantly slowed down, and after reaching the value of 280 kN ($0.5F_{Rd}$), it almost stopped. Based on the above, it can be concluded that the values of the neutral axis depth obtained from the experiment at loads of $0.55F_{Rd}$, $0.6F_{Rd}$ and $0.7F_{Rd}$ (figure 17) for PO-1, PO-2 and PO-3 plates, respectively, are quite close to the value of the neutral axis depth at the time of failure. At the same time, it should be noted that according to the calculation by the yield line method according to [4], the design neutral axis depth at destruction is $x = 43$ mm.

5. Conclusions

As a result of conducting experimental tests of full-scale samples of the over-columned plates of precast building frames, the following are established:

1. The scheme of supporting and loading of experimental over-columned floor plates during testing is adopted as close as possible to the actual plate operation scheme as part of a precast flat plate floor system during operation.
2. The average value of deflection l/200 is achieved under a load of $0.5F_{Rd}$, where $F_{Rd} = 580$ kN is the design value of the destructive load, calculated by the yield line method for the over-columned plate according to [4].
3. From the very beginning of the experiment, during the loading of the test samples, the maximum deformations of the reinforcement were observed along the characteristic lines located along the diagonal cracking lines of the over-columned plates.
4. It has been experimentally confirmed that the over-columned plate under the ultimate load is divided into four discs due to the formation of diagonal yield lines, which corresponds to the fracture pattern of the plate obtained by the yield line method according to [4].
5. The plate works in two directions, that is, the concrete of the compressed zone is subjected to flat biaxial compression. This aspect is not taken into account at the moment in the calculations of its carrying capacity. Taking into account the actual stress-strain state of the over-columned plate of the precast building frame will make using principal reinforcement more economical to ensure the strength of the floor structure.
6. The neutral axis depth decreases over the entire load period in all test samples of full-scale floor plates. When the load increases above 280 kN ($0.5F_{Rd}$), the decrease in the neutral axis depth is insignificant. Comparison of the estimated neutral axis depth at the moment of destruction by yield line method [4] $x_{teor} = 43$ mm with experimental data at loads of $0.55F_{Rd}$ (PO-1) $x_1 = 41$ mm; $0.6F_{Rd}$ (PO-2) $x_2 = 45$ mm; and $0.7F_{Rd}$ (PO-3) $x_3 = 47$ mm indicates their convergence.

Abstract. In the paper showing A U-Net-type convolutional neural network proposed for vegetation segmentation in multispectral imagery. The architecture of this network has modified and expanded to achieve better results with a smaller training dataset.The use of the network has made it possible to improve the solution to the problem of accurately identifying objects from the background based on existing information without the use of additional means of obtaining data. The processing of images of a corresponding nature is shown for 4-channel multispectral satellite images using a U-Net-shaped network trained on aerial images. Preprocessing showed the need to take into account the image formation model and perform post-training of the network based on the obtained data. A comparison conducted between the results of vegetation zone delineation in multispectral images using a convolutional neural network with a modified U-Net-like architecture and the Normalized Difference Vegetation Index (NDVI). The NDVI vegetation index uses data from various spectral channels and calculated as the ratio between intensities in the red and near-infrared channels of multispectral imagery, displayed as a number from -1 to +1, where a higher index value signifies denser green vegetation. Shown that for acceptable results, it is enough to use 4-channel images (NIR+RGB). The simulation performed in the MATLAB system.

1. Introduction

Semantic segmentation of images using convolutional neural networks allows for the assessment of vegetation areas in multispectral images with high resolution. To improve classification accuracy, multispectral images utilized, providing additional information for each pixel by supplementing color images with near-infrared channels. These channels contribute to clearer class separation and aid in distinguishing classes with similar visual characteristics, such as assigning a specific green pixel to classes like grass, shrubs, or trees.

The issue of the versatility of the models used is practically important. This paper shows the possibility of using U-Net-shaped architecture network, which is trained on a dataset with aerial images, to find vegetation zones in satellite images.

For the validation of results obtained through semantic segmentation, it is essential to obtain a reliable assessment of vegetation cover area independently. To achieve this, the Normalized Difference Vegetation Index (NDVI) proposed as a suitable metric [1]. NDVI is a simple quantitative indicator of the amount of photosynthetically active biomass, commonly referred to as a vegetation index.

The aim of the article it's to consider the implementation of semantic segmentation of a 4-channel multispectral image using a U-Net-shaped network and to assess the quality of segmentation of the vegetation zone using the calculation of the normalized differential vegetation index NDVI.

2. Related work

Numerous modifications of the basic algorithm for calculating NDVI have been developed to reduce the impact of various distortion factors, such as atmospheric aerosol absorption (Atmospheric-Resistant Vegetation Index, ARVI) and reflection from the soil surface (Soil Adjusted Vegetation Index, SAVI), etc. To calculate these indices, formulas are used that consider the relationship between the reflectance properties of various natural objects and vegetation in spectral ranges other than red and infrared, which makes their use more difficult. There are also indices that are based on NDVI and simultaneously correct for several distorting factors, for example, the Enhanced Vegetation Index (EVI) [2, 3].

As mentioned in original paper [4], the main idea of the U-Net architecture is to supplement a conventional convolutional network with a symmetrical part, where the pooling operations (dimensionality reduction) of objects are accordingly replaced by dimensionality increment operators that allow increasing the resolution of the output. In the part in which there is an increase in dimensionality, there are many feature channels that allow the network to spread contextual information to layers of higher resolution. Therefore, the part in which the expansion occurs is symmetrical to the part of the contraction, this gives a U-shaped architecture. Such a network uses only convolutions without any fully connected layers. To predict the value of pixels within an image area, the missing context is extrapolated by additional processing (which looks like a reflection from the point of view of network symmetry) of the input image. This tiling strategy is important for applying the network to large images, as otherwise the resolution will be limited.

The classic network architecture is shown in figure 1. It consists of two parts: compressive (left) and expanding (right), which give it its characteristic U-shape. The compression part follows a typical convolutional network architecture and consists of multiple convolutional layers with 3×3 cores, each followed by a ReLU activation layer (rectified linear unit) and pooling with a maximum function in increments of 2 to reduce the sample.

At each step of sampling, the number of functional features is doubled. Each step of the extension consists of a feature map oversample, followed by a 2×2 convolution that halves the number of features, a merge with a correspondingly cropped feature map from the compression portion, and two 3×3 convolutions, each accompanied by a ReLU. Cropping is necessary because of the loss of boundary pixels in each convolution.

On the final layer, convolution 1×1 is used to map each 64-component feature vector to a given number of classes. In total, the classical U-Net network has 23 convolutional layers [4].

Xie, Sha and Yu [5] discusses various methods for obtaining information about vegetation from remote sensing data, using color and texture information to interpret the images.

Wäldchen and Mäder [6] is one of the first systematic reviews of the literature, where, based on research published in 2005–2015, the results of computer vision studies for the identification of plant species were analyzed and compared.

The use of Convolutional Neural Networks (CNN) to automatically detect and map vegetation

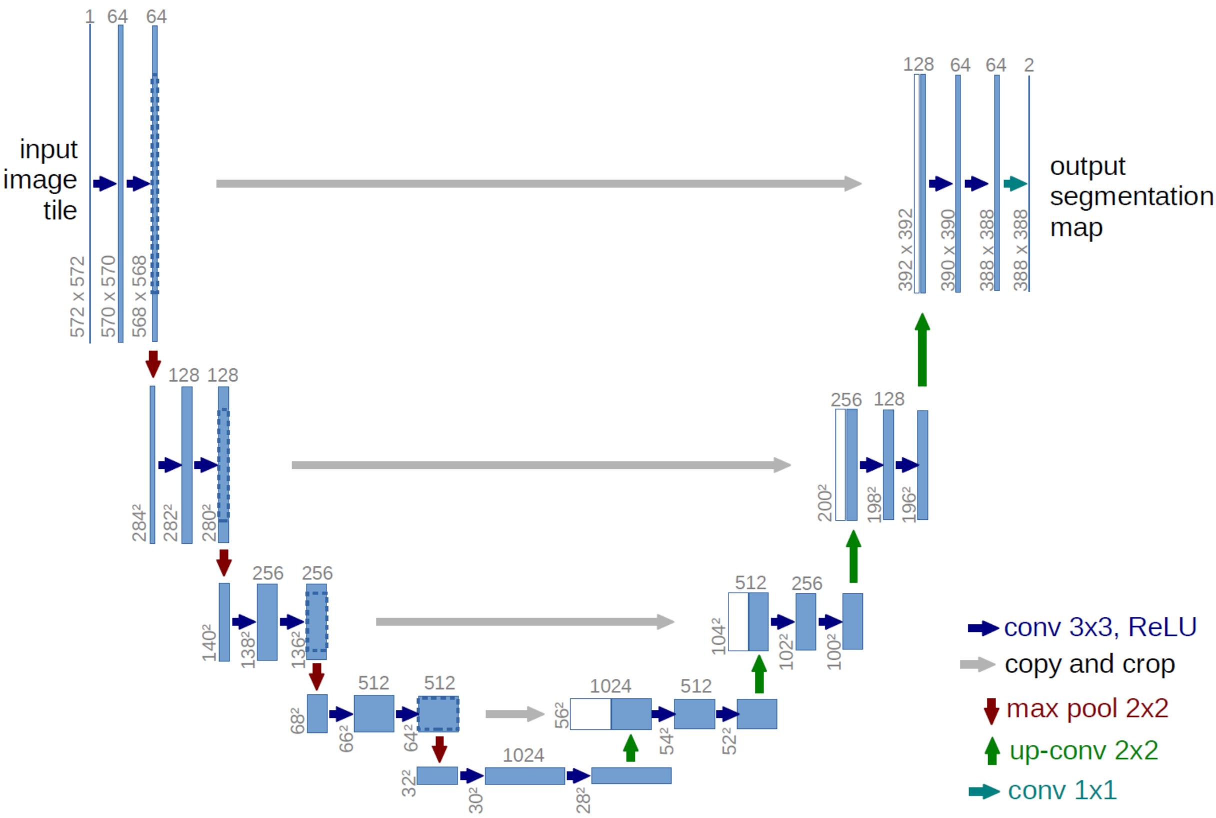

Figure 1. The architecture of the classic U-Net network [4].

using Google Earth imagery is described in [7], where the images are cut into several parts to improve the accuracy and performance of the model.

The effect of the number of channels on segmentation results was also investigated and it was found that the use of other than standard channels in the visible the additional near-infrared (NIR) band improves segmentation accuracy [8].

Kemker, Salvaggio and Kanan [9] explores the application of convolutional deep learning neural networks for semantic segmentation of multispectral view images.

3. Results

In this paper, we propose expanding the number of layers in the U-Net network from 42 to 58, while maintaining the same architecture described in [9]. This modification enables achieving satisfactory results for 4-channel (NIR+RGB) images, instead of requiring 6-channel (3 NIR + RGB) images. A complete list of layers of the proposed convolutional network is given in table 1.

Given that the primary objective is vegetation detection, segmentation into 4 classes is employed instead of 18 as mentioned in [9]:

1) water;
2) vegetation;
3) soil;
4) other.

Table 1: List of layers of the proposed U-Net-like convolutions network.

Table 1 – continued from previous page

#	MATLAB Notation	Layer name	Description
56	'Final-ConvolutionLayer'	Convolution	1×1×64 convolutions with stride [1 1] and padding [0 0 0 0]
57	'Softmax-Layer'	Softmax	Softmax
58	'Segmentation-Layer'	Pixel Classification Layer	Cross-entropy loss

The **Image Input Layer** splits the original image into 256×256×4 (for 4-channel viewports).

Convolution Layers perform convolutions with 3×3 cores for each of the 4 channels, offset step stride=[1 1], completion 0 to prevent edge effects.

ReLU Activation Layers perform a threshold operation on each element, setting the value to zero for negative values.

Max Pooling Reduction Layers reduce dimensionality by dividing into rectangular regions, with the original elements being the maxima for each region.

Dropout Reduction Layers set the output elements to 0 with a given probability.

Transposed Convolution Layers perform convolutions with transposed kernels (sometimes incorrectly referred to as convolution wrap layers).

Depth Concatenation layers combine inputs along the third dimension.

Softmax Activation layers apply to the inputs a *Softmax* function defined as:

$$sofmaxx = \frac{e^x}{\sum e^x} \tag{1}$$

The output **Pixel Classification** Layer makes a final classification of each pixel, minimizing the given loss function. In this paper, the *Cross-entropy* loss function is used as a loss function, which is a measure of error between two continuous random variables. For the forecasted values Y and target values T the weighted cross-entropy is calculated as:

$$L = \frac{1}{N}\sum_{n=1}^{N}\sum_{k=1}^{K} w_k T_{nk} \log Y_{nk} \tag{2}$$

where N is the number of observations, K is the number of classes, and wk is the vector of weighting coefficients for each class k.

To facilitate comparison with the findings in [9], we utilized the identical aerial images sourced from the Hamlin Beach State Park dataset [10] for both training and testing purposes (figure 2).

The proposed network trained using the Stochastic Gradient Descent with Momentum Optimization (SGDM) algorithm. SGDM parameters were set using the *trainingOptions* function (Deep Learning Toolbox).

```
initialLearningRate = 0.05;
maxEpochs = 150;
minibatchSize = 16;
L2reg = 0.0001;

options = trainingOptions(...
'sgdm', ...
'InitialLearnRate', initialLearningRate, ...
'Momentum', 0.9, ...
'L2Regularization', l2reg, ...
```

Since the result of segmentation is noisy, it is advisable to perform post-processing using the median filtering function with a window of size [15,15]. The optimal size of the filtering window depends on the size of the characteristic noise elements, which in turn will depend on the image parameters.

The main indicators of segmentation quality are accuracy, intersection to union ratio (IoU) and assessment of the correspondence of the boundary contour F1 (BF).

For each class, Accuracy is the ratio of correctly classified pixels to the total number of pixels in that class, according to true values, i.e.:

$$Accuracy = TP/(TP + FN) \tag{3}$$

where TP is the number of true-positive classifications, and FN is the number of false-negative classifications.

The intersection to union ratio (IoU), also known as the Jacquard similarity coefficient, is the most used metric. For each class, IoU is the ratio of correctly classified pixels to the total number of true-positive and predictable pixels in that class. In other words

$$IoU = TP/(TP + FP + FN) \tag{4}$$

where FP are false-positive classifications.

The F1 (BF) boundary contour conformity assessment indicates the extent to which the intended boundary of each class is consistent with the true boundary. The BF score is used when there is a need for an indicator to generally be better related to a person's qualitative score than an IoU score.

Now let's define the standard segmentation quality metrics:

1. **Global Accuracy** is the ratio of correctly classified pixels, regardless of class, to the total number of pixels. It is used in cases where a quick and inexpensive estimate of the percentage of correctly classified pixels is required.
2. **Mean** Accuracy is the average of the Accuracy score for all classes in all images, with Accuracy indicating the percentage of correctly identified pixels for each class. Used when you want to read how correctly each class defines pixels.
3. **Mean IoU (average intersection to union ratio) is the average IoU value for all classes in all images.**
4. **Weighted** IoU (weighted intersection to union ratio) is the average IoU value of each class, weighted by the number of pixels in that class. This metric is used if images have disproportionately large classes to reduce the impact of small-class errors on the overall quality score.
5. Mean BFScore is the average of the BFScore score for all classes in all images.

Comparative results of segmentation quality for 6-channel and 4-channel images are shown in table 2.

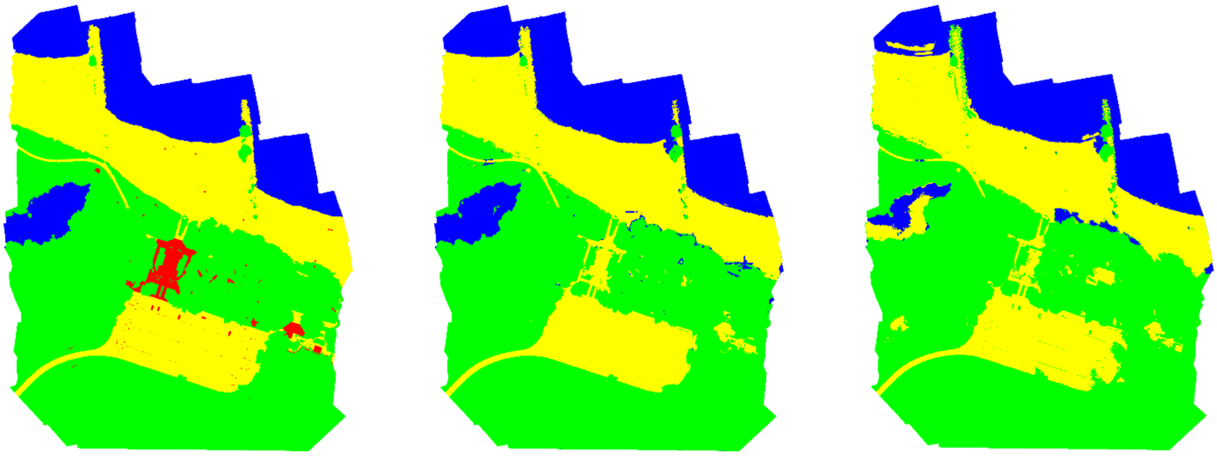
Table 2. Results of segmentation quality comparison.

	Global accuracy	**Mean accuracy**	**Mean IoU**	**Weighted IoU**	**Mean BFScore**
6-channel images	0.96567	0.7363	0.70823	0.93358	0.86183
4-channel images	0.92792	0.69431	0.6484	0.86541	0.76955

The results of segmentation of 4-channel images are expected to be slightly worse than the results of 6-channel images but are quite acceptable for vegetation zone selection tasks.

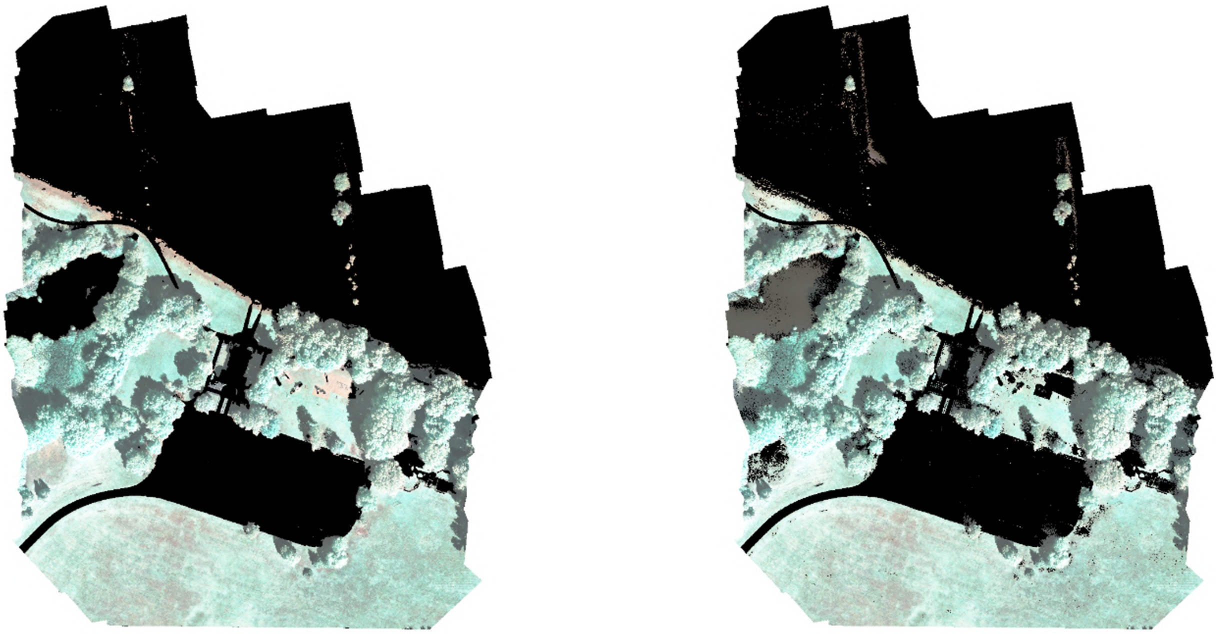
Thus, an additional check is to determine the proportion of the area occupied by vegetation cover. The direct method of determining this number is to calculate the relative area of class corresponding to vegetation.

vegetationClassIds = uint8(2);
vegetationPixels
= ismember(segmentedImage(:),vegetationClassIds);
validPixels = (segmentedImage =0);



a) b) c)

Figure 3. The results of the semantic segmentation: a) ground truth (derived from work [9], combining 18 classes into 4); b) aerial 6-channel image; c) aerial 4-channel image.



a) b)

Figure 4. The result of the selection of vegetation zones for a 6-channel test image: a) using vegetation class; b) using vegetation index.

```
numVegetationPixels = sum(vegetationPixels(:));
numValidPixels = sum(validPixels(:));

percentVegetationCover = (numVegetationPixels / numValidPixels;
```

Another way is through the determination of the vegetation index with its subsequent

Figure 6. Map of the area with marked areas of interest.

binarization. Recall that the value of the $NDVI$ vegetation index is calculated using the formula:

$$NDVI = \frac{NIR - R}{NIR + R} \tag{5}$$

where NIR and R are the near-infrared (800 nm) and red (670 nm) channels of the multispectral image, respectively.

To assess the proportion of area covered by vegetation, we binarized the obtained values of NDVI by applying the Otsu method. This yielded a vegetation cover area fraction of **0.5095** both for 6-channel and for 4-channel images (the values are same because it used the same red

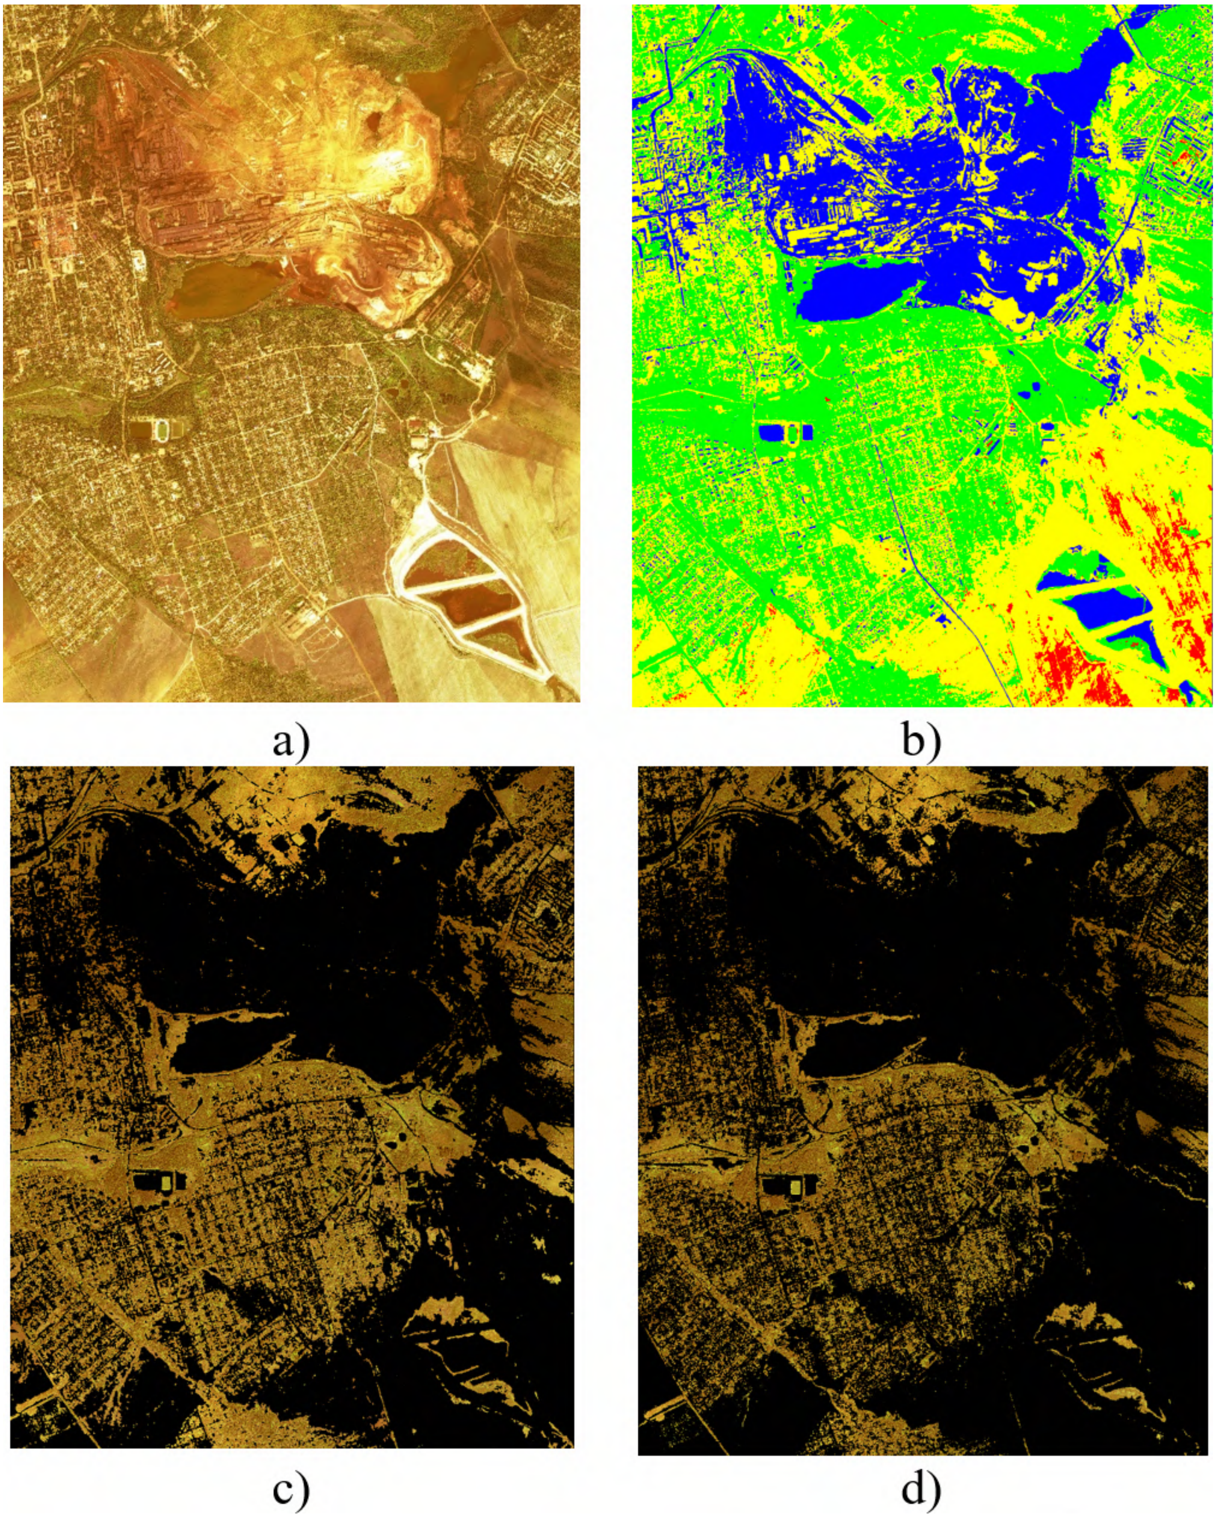

Figure 7. Results of processing for "Fragment 1": a) the original image; b) labeled image; c) selection of vegetation zones using vegetation class; d) selection of vegetation zones using binarized NDVI.

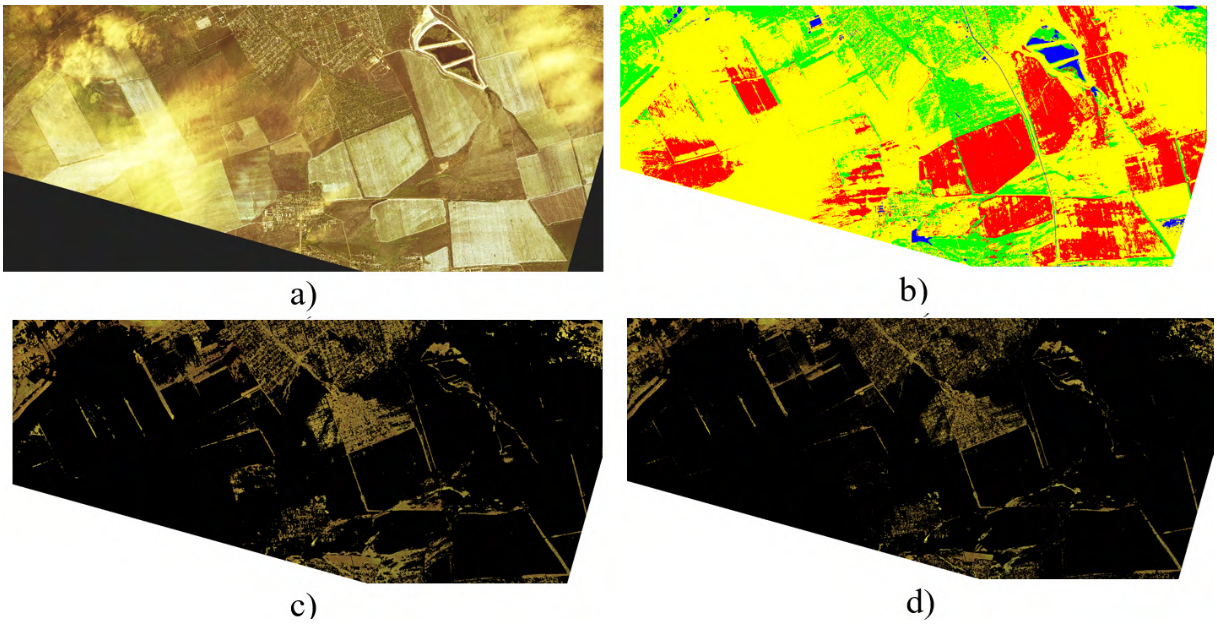

Figure 8. Results of processing for "Fragment 2": a) the original image; b) labeled image; c) selection of vegetation zones using vegetation class; d) selection of vegetation zones using binarized NDVI.

and NIR channels for both cases).

These values align closely with previously calculated values of **0.5185** and **0.5356** for the relative vegetation area, validating the accuracy of semantic segmentation via NDVI method. In the figure 3, figure 4 and figure 5 illustrate the results of vegetation zone selection for the test image, corresponding to 6-channel and 4-channel processing, respectively.

For additional experiments, 4-channel satellite images of the region near Yenakiieve, Donetsk region, denoted as "Fragment 1" and "Fragment 2" (refer to figure 6), were employed.

Note that the image is fed to the network input without any pre-processing, so as not to change its statistics in relation to the images from the dataset that were used for post-training of the network.

In the figure 7 and figure 8 shows the results of processing for "Fragment 1" and "Fragment 2" respectively.

4. Conclusions

This paper demonstrates the process of semantic segmentation using a U-Net-like network, illustrated through the processing of both 6-channel aerial images and 4-channel multispectral satellite images. While the segmentation results of 4-channel images are anticipated to be slightly inferior to those of 6-channel images, they are deemed acceptable for vegetation zone selection tasks. Moreover, utilizing 4-channel images notably reduces processing time. Of particular interest is the ability to train the model with aerial images dataset, allowing its application to satellite images. The quality of vegetation zone segmentation was evaluated in comparison with the normalized differential vegetation index (NDVI). Through analyzing the results obtained, a strong correspondence was observed between the outcomes of semantic segmentation via neural network and NDVI usage.

Abstract. New patterns of determining internal forces for possible conditions of elements of the first and second categories of reinforced concrete slabs subjected to complex loads are established. The introduction into the calculation of a function characterizing the degree of reduction of weakened bases' properties in order to determine the stiffness coefficient with load relief makes it possible to take into account the conditions of contact interaction between the slab and the non-uniformly deformed base. A program is developed to consider the load history of elements using nonlinear diagrams in the whole range of force and deformation effects. The results of simulating the slab's operation on a non-uniformly deformed base under complex loads are obtained. The developed program allows determining the maximum load on the structure with known values of expected deformation effects and solving the opposite problem, i.e. determining the maximum deformation effects with constant external loads caused by structures.

1. Introduction

Slab foundations occupy a significant place among building structures and are widely used in industrial and civil construction. Monolithic reinforced concrete slab foundations of rectangular, polygonal, and round shape are used in construction on natural foundations. They are particularly widely used in complex engineering and geological conditions in the construction of high-rise buildings of various functional purposes, as well as industrial structures such as silos, elevators, flue pipes, etc. The joint operation of these structures with the ground base is conditioned by many factors that should be taken into account when laying foundations, increasing load during construction of buildings and structures and by deformation influences from the base during the operation period [1–4]. Thus, the technical and economic parameters of slab foundations can be determined taking into account their actual operation under real operating conditions, such as loading modes, the nature of force and deformation effects, peculiarities of development of irreversible deformations, settlement of structures, the sequence of formation, opening and closing of cracks, etc.

Their calculation, performed in a linear setting, is associated with the difficulty of obtaining reliable results due to the complexity of the structure of resolving equations, as well as a large number of unknown parameters.

The linear calculation theory with the solution of new problems posed by the construction practice is not universally applicable. This is especially true for calculations of structures designed for complex engineering and geological conditions (swelling, structurally unstable soils, underworked, karsted and landslide areas).

Although the basic patterns of characteristic manifestations in these areas are known, taking into account all the features of the real soil mass is a complex task of soil mechanics. The solution of this problem is possible with the use of numerical calculation methods implemented in simulation programmes [5–8].

By creating soil models, in which there are simultaneously zones of pre-limit and limit states, the non-linear nature of the "load-settling" relationship can be determined, as well as taking into account the variety of physical processes accompanying the deformation of this base.

The behaviour (deformation and depletion of load-bearing capacity) of rectangular and round foundation slabs on the uniformly deformed base has been sufficiently studied [9], but under conditions of non-uniform base deformations, this question still remains understudied, although the types and characteristics of the deformation are known and investigated.

At present, modern calculation methods for buildings and structures operating in complex soil conditions, and, first of all, foundation structures interacting with unevenly deformed base are being developed.

2. Research objectives

The research aims to substantiate and develop a method of calculating round foundation slabs interacting with the non-uniformly deformed base, taking into account inelastic deformations of reinforced concrete and soil under complex loading.

In order to achieve this goal, it is necessary to solve the following tasks:

- to perform an analysis of the available experimental data and theoretical generalizations to select the regularity of deformation of the reinforced concrete slab and the soil base under complex loading;
- to carry out complex experimental and theoretical studies of the stress-deformed state of round-shaped plates in their joint work with the deformable base;
- to develop static methods of calculating round foundation slabs with comprehensive consideration of non-linear and inelastic deformations of reinforced concrete and soil under complex load;
- to develop application programs to calculate round foundation slabs in a non-linear and non-elastic arrangement;
- to identify features and patterns of nonlinear-inelastic deformation of round foundation slabs and bases by simulating their work using the developed methods and calculation programs;
- to introduce the research results into design practice, construction and operation of buildings and structures operating under special conditions.

3. Results

Round foundation slabs are calculated for difficult soil conditions taking into account the infinite stiffness of the slabs. Design and construction practice indicates that, on the one hand, with high slab stiffness there are significant strength reserves, the use of which is hindered by the lack of uniform recommendations for rational slab foundation design. On the other hand, even with sufficient stiffness, the foundation slab bends and gets maximum deflection under load, especially in the non-linear stage of reinforced concrete work, when cracks and fracture lines are formed. It follows that the assumption of infinite stiffness does not reflect the actual work of the structure, and deformation (flexibility) of the slab should be considered in the calculation.

Consideration of non-linear deformation of materials that causes stress redistribution in both components of the foundation-base system makes the contact problem under conditions of non-uniform deformation of the foundation non-linear not only physically but also geometrically, because the locations of the base detachment from the foundation bed are unknown in advance.

Reinforced concrete is known to be an elastic material. If deformation reduces the value of the moment at a cross-section, the load relief curve does not coincide with the load curve. Therefore, slab stiffness should be determined considering the load history. Existing programs for calculating foundation slabs do not take into account specific features of deformation of reinforced concrete during load belief.

Deformations of the base not related to the load of the structure are reflected in the calculation diagram by the corresponding values of the vertical and horizontal shears of the base surface [10]. The calculation of slab foundations with respect to the action of non-uniform deformations of the foundations is performed by considering all possible deformations from the state of the foundation-base joint work, taking into account the most unfavorable combination of the effects.

The most unfavorable options for reactive pressures to be implemented can occur with the following deformation-force combinations (figure 1):

- curvature of the convex surface of the base and the external moment which is perpendicular to the curvature plane;
- curvature of the concave surface of the base and the external moment which is parallel to the curvature plane;
- a ledge or failure at the end of the base and the external moment which is perpendicular to the ledge line.

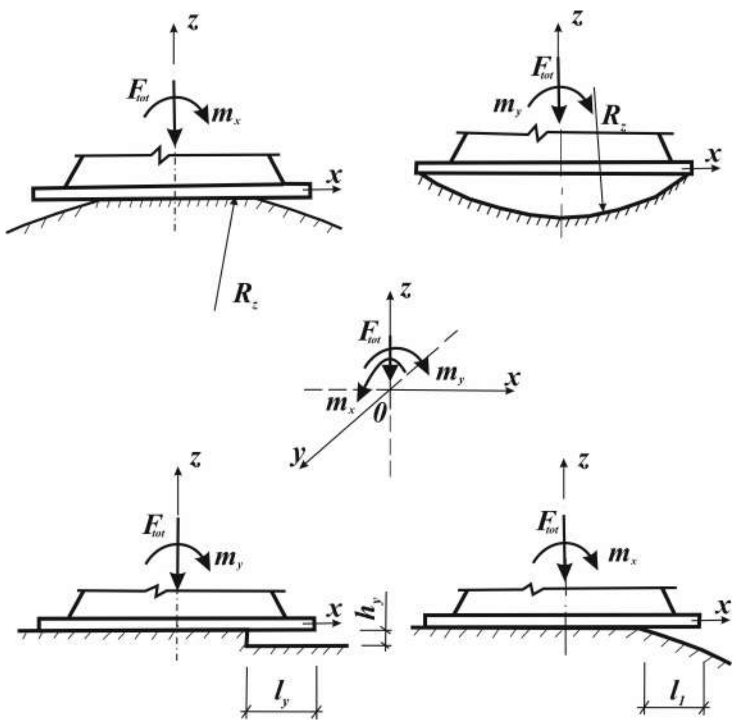

Figure 1. Unfavourable options of the combination of external structure-caused loads and base-caused deformation effects.

There is only one-way connection between the foundation slab and the base, i.e. the base is not capable of preventing the separation of the foundation from the soil, but only prevents the penetration of the slab [10–12].

Further deformation of the base changes physical and mechanical characteristics of the soil, the bearing capacity and the stiffness of the base are reduced [13]. At the same time, the soil deformation curve in the new state do not coincide with the first curve. Therefore, when solving the contact problem for these conditions, it is necessary to take into account the differences in the soil load curves for different points before and after the weakening of the base.

Describe an algorithm that takes into account nonlinear and inelastic properties of the base during complex loads, yet without considering specific features of reinforced concrete deformation [14–17]. In addition, reduction in mechanical properties of the base is considered only for settling soils [14, 16], while in underworking, for example, the change in the soil deformation diagram is neglected [17], although [18] notes that stiffness properties of the base are reduced.

Thus, analysis of existing researches on the behaviour of round foundation slabs interacting with the non-uniformly deformed base shows that there is not yet a generally accepted calculation method that allows simultaneous consideration of the features of deformation of reinforced concrete and soil at complex loading which occurs with additional (independent of external load) deformation of the base in buildings and structures.

The base model is selected according to the design values of contact pressures determined from the sum of the values of vertical load resistance at the interaction of the foundation with the deformed base and horizontal load resistance at the interaction of the slab with the non-deformed base. Frictional forces on the foundation bed due to horizontal deformation of the soil are believed not to affect the bending of the slab, and, therefore distribution of contact pressures [10, 19].

Foundation slab deformations caused by transverse loads and base settling have little effect on horizontal deformation forces. The forces in the foundation slab from vertical shears and horizontal deformations of the foundation are determined separately. At the same time, the forces caused by horizontal deformations are thought to be perceived by the bottom reinforcement.

Solving the problem of determining the load-bearing capacity of foundation slabs operating under non-uniform base deformations requires considering non-linear and inelastic deformations of reinforced concrete and soil. In addition, it is necessary to take into account geometric nonlinearity of the contact problem.

In the case of non-uniform base deformations, it is of practical importance to determine the maximum deformation effects on the slab foundations, i.e. the maximum values of deformation forces that the foundation slab can withstand under constant external loads caused by the structure.

Analysis of real conditions of structures interacting with the non-uniformly deformed base shows that to effectively design structures of foundation slabs in complex soil conditions, it is necessary to consider the following assumptions:

- the foundation slab has a finite stiffness, while the stiffness of each element of the slab depends on a reinforced concrete work stage;
- soils deform non-linearly, so stiffness characteristics of the base should be determined taking into account its interaction with the structure;
- additional deformation of the base occurs during structures' operation. It follows that it is necessary to consider the differences in deformation curves of reinforced concrete and soil during loading and load relief.

On the basis of these provisions, it is possible to correctly solve the following, not sufficiently researched, but important scientific and practical problems:

- specifying the general stress-deformed state picture of foundation slab designs operating under conditions of non-uniform deformation of the base;
- defining the effect of each type of base deformation on foundation slabs;
- determining limit deformation effects on the foundation slab under constant external loads caused by the structure;
- specifying the limit load (caused by the structure) on the foundation slab design, if the value of expected possible deformation effects is previously known.

The operation of round foundation slabs under non-uniform deformations of the base, taking into account deformation characteristics of reinforced concrete and soil, can be studied on mathematical models [13, 20, 21]. For this purpose, consider a round foundation slab under the influence of arbitrary normal to the median plane of the slab external load intensity $q\ (r, \varphi)$ and lying on the soil base, characterized by the stiffness coefficient $k_1(r,\ \varphi)$ (figure 2), where $r,\ \varphi$ are polar coordinates.

The slab has a finite stiffness, but large enough to ignore membrane forces acting on the foundation bed and having little effect on the overall slab operation, especially on its load-bearing capacity. The load from these forces is perceived only by the lower part of the cross-section, so they cannot exhaust the load-bearing capacity of the slab.

The behavior of a reinforced concrete foundation slab at any operation stage is described by systems of resolving equations, combining equilibrium, geometric and physical equations ones.

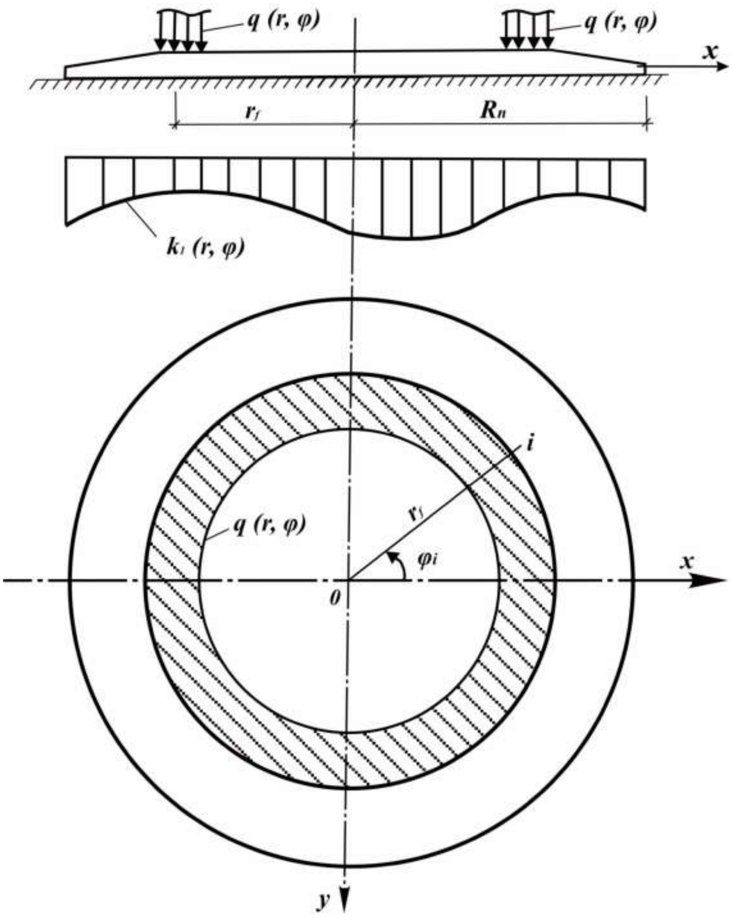

Figure 2. Round foundation slab on the soil base.

The calculation is made under various deformation conditions of the round foundation slab base with the following characteristics:

- geometric dimensions of the slab are shown in figure 3,a;
- curves of the coefficients of reinforcement of the lower and upper slab zones in the radial and annular directions are shown in figure 3,b;
- concrete is class C25/30; as working reinforcement is represented by class A400 steel, radial rods are A400 ∅ 28; ring rods are A400 ∅ 25.

The round foundation slab is reinforced according to the requirements [9, 22–25].

Consider first the operation of the foundation slab under normal soil conditions with the increased total vertical load F_{tot} caused by the structure. For calculation, the soil deformation diagram [17] is taken and the initial stiffness coefficient of the base is $k_i = 58.8\ MN/m^3$.

The simulation results (settling W, reactive pressures P, radial and annular moments M_r and M_φ, crack formation zones) at load F_{tot} equal to 200 MN, 300 MN, 375 MN, and 400 MN are shown in figure 4.

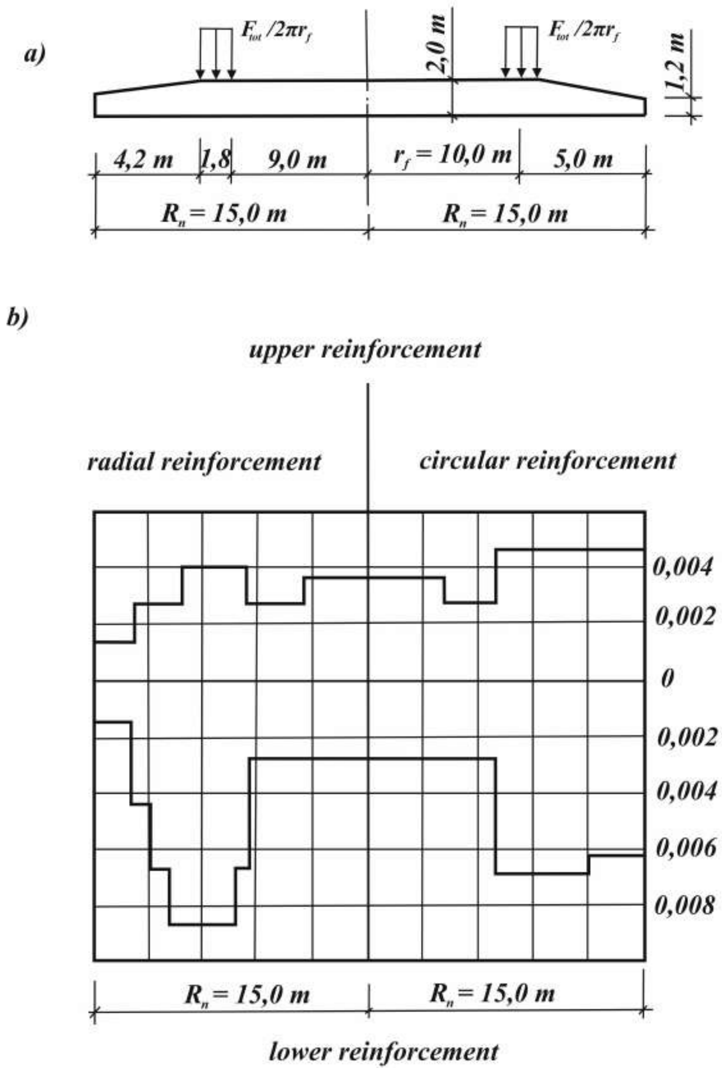

Figure 3. Characteristics of foundation slab: a) geometric dimensions; b) curves of reinforcement coefficients.

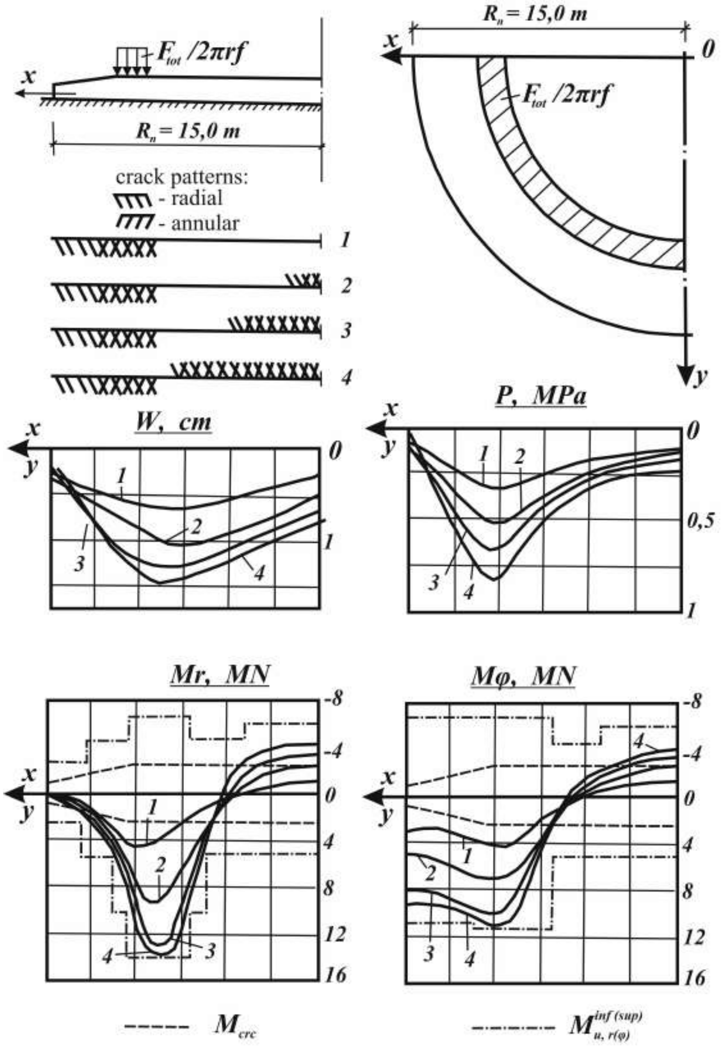

Figure 4. Calculation results under natural soil conditions with the vertical load F_{tot} equal to: 1 – 200 MN; 2 – 300 MN; 3 – 375 MN; 4 – 400 MN.

At $F_{tot} = 400\ MN$, plastic hinges form closed areas, annular and radial fracture lines divide the slab into several separate parts, and thus the load-bearing capacity of the foundation slab is exhausted.

The value $F_{tot,\ u} = 400\ MN$ is the limit load on a given slab under normal soil conditions.

3.1. Simulation of the curvature of the convex base surface

Now consider the behaviour of the round foundation slab with the curvature of the convex surface of the base along the axis Υ (i.e. $\upsilon\,(r,\,\varphi) = \upsilon\,(x)$, figure 5).

The characteristics of the slab are the same. It is subject to a total vertical load $F_{tot,\ 1} = 200\ MN$, which is twice as less than the limit load $F_{tot,\ u}$ ($n_R = F_{tot,u}/F_{tot,1} = 2,0$ is the factor of safety of the foundation slab under normal soil conditions).

It is necessary to determine the stress-deformed state of the round foundation slab when the curvature of the convex base surface is increased. The following values of the curvature radius R_z are used in simulation: 10000 m, 6000 m, 4000 m.

Reduced characteristics of the deformed base are determined according to [18] and [19,26–29].

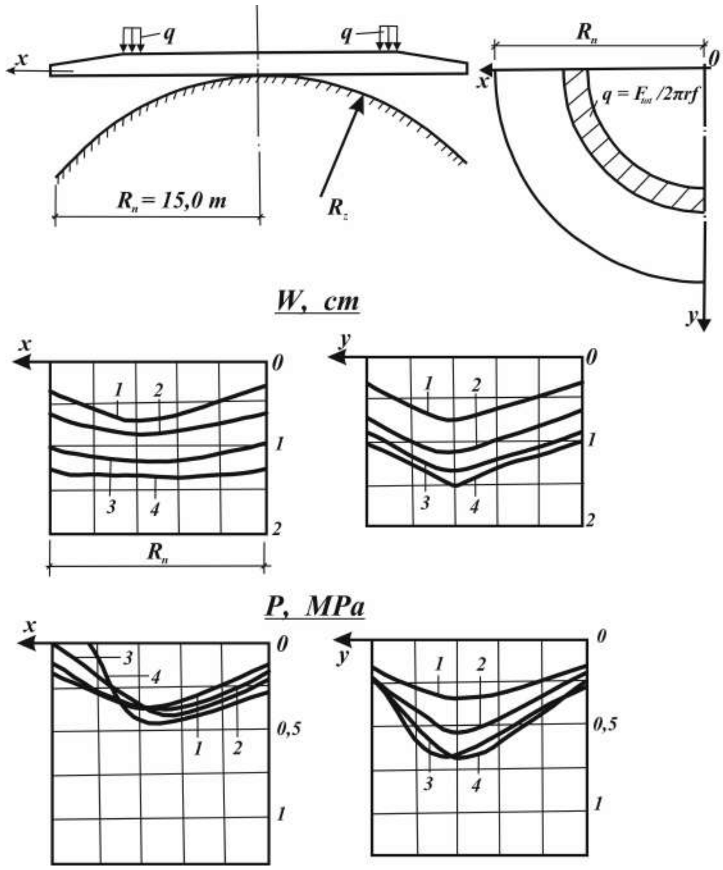

Figure 5. Settling W and contact pressures P along the central axes OX and OY under vertical load $F_{\text{tot}} = 200$MN and the curvature radius of the convex base surface R_z equal to: $1 - \infty$, 2 – 10000 m, 3 – 6000 m, 4 – 4000 m.

Diagrams of the calculated values are shown in figure 5 and figure 6, and in figure 7 shows the process of developing cracks and fracture lines on it and the lower surfaces of the slab when increasing the curvature of the convex base surface.

With the curvature radius $R_{z,\,u_1} = 4000$ m, it is impossible to further increase the effect on the foundation because at the footing support along the Y-axis (the points of maximum values of the soil reactive forces) and fracture lines are formed and develop, dividing the slab into independent parts. Thus, the load-bearing capacity of the foundation slab is exhausted.

Similar simulation is performed with the value of the total vertical load $F_{tot,\ 2} = 300$ MN and the following values of the convex curvature radius R_z: 15000 m, 12000 m, and 9000 m. The load-bearing capacity of the slab is exhausted with the curvature radius $R_{z,\,u_2} = 9000$ m.

The simulation results (design values, development of cracks and fracture lines) are shown in figure 8, figure 9, figure 10.

3.2. Simulation with the curvature of the concave base surface

With the same slab characteristics and total vertical loads $F_{tot,\ 1} = 200$ MN and $F_{tot,\ 2} = 300$ MN, it is necessary to determine the stress-deformed state of the foundation slab by increasing the curvature of the concave base surface along the Y-axis (i.e. $\upsilon\,(r,\,\varphi) = \upsilon\,(x)$, figure 11, figure 12, figure 13).

The following values of the conventional curvature radii of the concave base surface R_z are

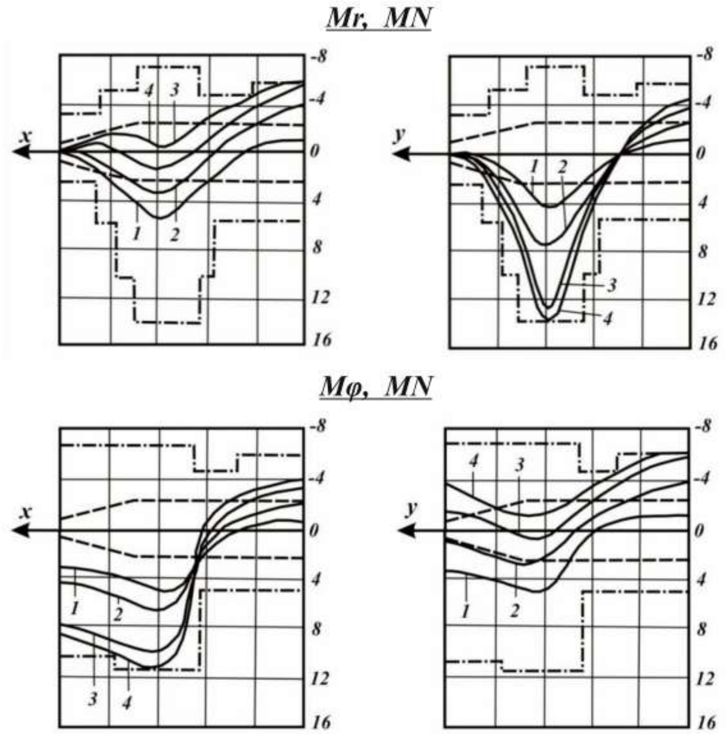

Figure 6. Radial M_r and annular M_φ moments in the foundation slab along the central axes OX and OY with increasing curvature of the convex base surface: 1 – ∞, 2 – 10000 m, 3 – 6000 m, 4 – 4000 m.

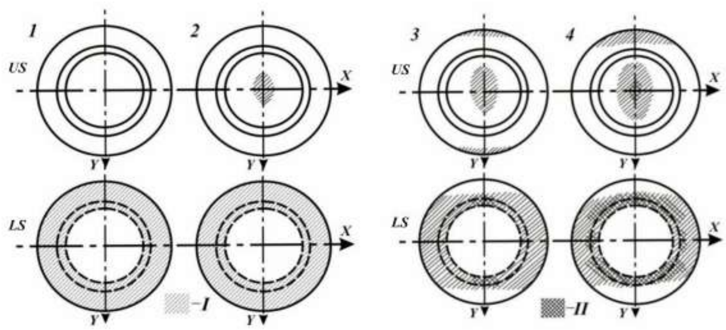

Figure 7. Development of elastic deformation zones in the foundation slab when increasing curvature of the convex base surface: *US, LS* – upper and lower slab surfaces; *I, II* – zones of formation of cracks and plastic hinges; 1 – ∞, 2 – 10000 m, 3 – 6000 m, 4 – 4000 m.

simulated: 10000 m, 6000 m, 5000 m at load $F_{tot,\ 1}$; 15000 m, 12000 m, 10000 m at load $F_{tot},\ _2$.

Reduced characteristics of the deformed base are determined according to [11]. In the first case, i.e. at $F_{tot,\ 1}$, the load-bearing capacity of the structure is exhausted at the value $R_{z,\,u_1}=$ 5000 m, and in the second case (for $F_{tot,\ 2}$), at $R_{z,\,u_2}=$ 10000 m. The simulation results are shown in figure 14, figure 15, figure 16.

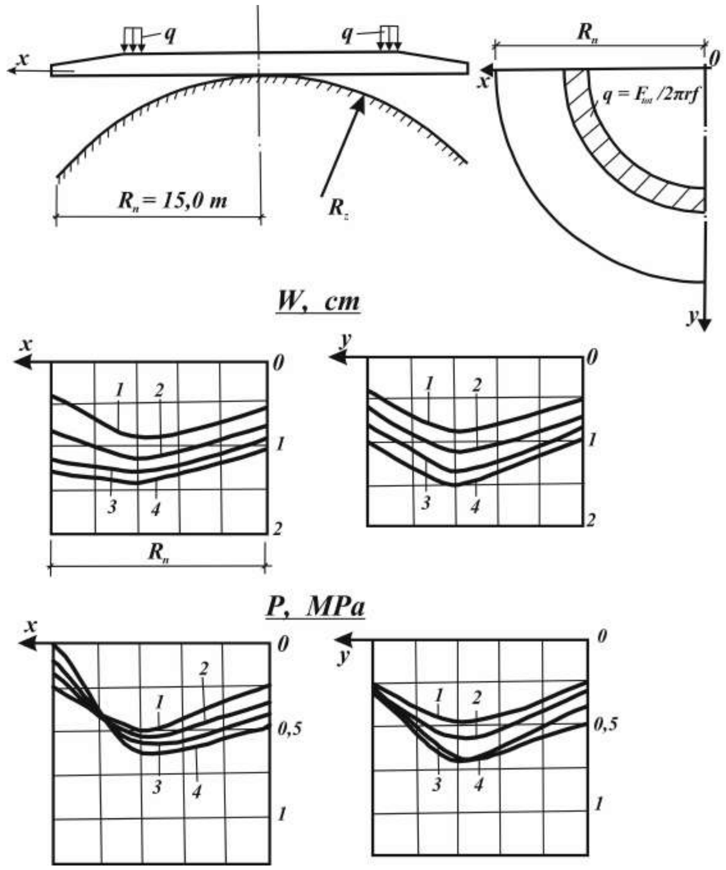

Figure 8. Settling W and contact pressures P along the central axes OX and OY with the vertical load $F_{\text{tot}} = 300\text{MN}$ and the curvature radius of the convex base surface R_z equal to: 1 – ∞, 2 – 15000 m, 3 – 12000 m, 4 – 9000 m

3.3. Simulation with the base settling at the end of the foundation

It is necessary to investigate the behaviour of the round foundation slab with different values of the settling section of the base at the end of the foundation.

The slab undergoes the following loads: the total vertical load $F_{tot} = 200$ MN, the external moment $m_1 = 150\ MNm$. The height of the centre of gravity of the structure relative to the foundation bed $Hc = 75\ m$.

The simulation is carried out with the length of the settling section (ledge) $\ell_y = R_n$ and the height h_y equal to 0.100 m, 0.200 m, and 0.25 m. The characteristics of the settling section are determined according to [30–32].

The simulation results are shown in figure 17, figure 18, figure 19.

With the settling section $\ell_y = R_n$and $h_y = 0.25$ m, the resulting roll begins to increase sharply ($\theta_2 = 0.0120$) and reaches the limit value set by the standards for the structure.

A further increase in the roll leads to a loss of stability of the foundation slab position; therefore, the load-bearing capacity of the structure is exhausted. At the same time, the fracture lines are at the initial stage of development.

3.4. Analysis of simulation results

The simulation results show that the stress-deformed state of the round foundation slab and the patterns of its load-bearing capacity (zones of formation and development of plastic hinges)

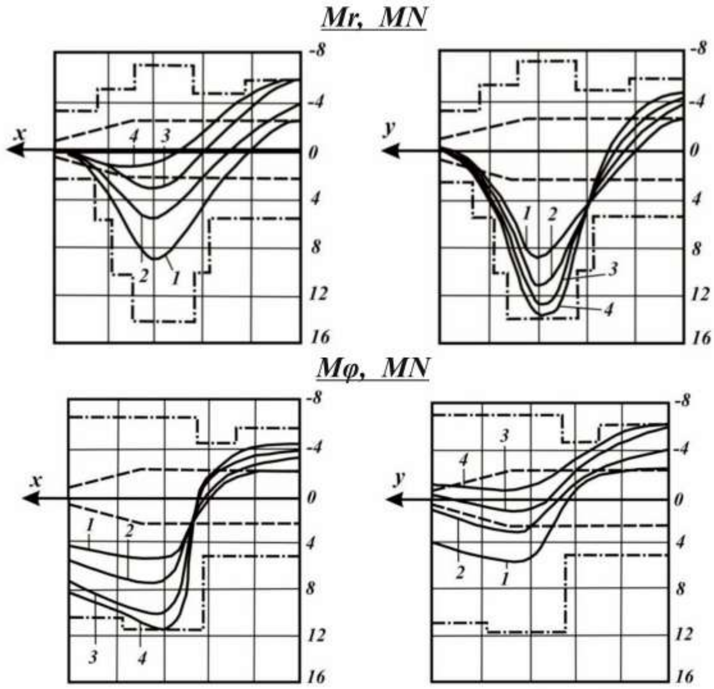

Figure 9. Radial M_r and annular M_φ moments in the foundation slab along the central axes OX and OY with increasing curvature of the convex base surface: 1 – ∞, 2 – 15000 m, 3 – 12000 m, 4 – 9000 m.

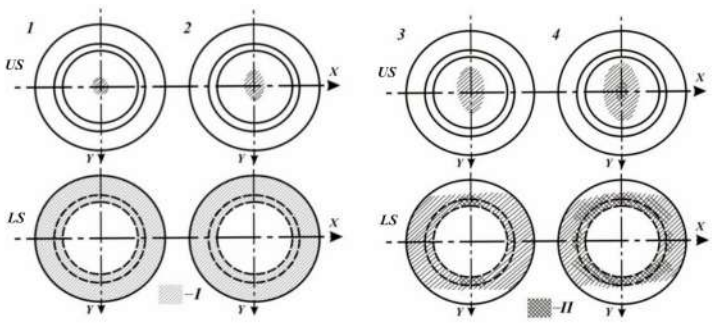

Figure 10. Development of elastic deformation zones in the foundation slab with increasing the curvature of the convex base surface: *US, LS* – upper and lower surfaces of the slab; *I, II* – zones of formation of cracks and plastic hinges; 1 – ∞, 2 – 15000 m, 3 – 12000 m, 4 – 9000 m.

under non-uniform deformation of the base surface are different from the type of change in the shape of the base surface.

The main zones of formation and development of fracture lines in the slab under various deformation conditions of the base are shown in figure 20. Under normal soil conditions, such zones are footing support points (figure 20, *a*). There may also be cracks on the upper surface of the central part of the slab.

When the convex base surface is curved along the Y-axis, the radial bending moments increase along this axis and fracture lines are formed at the footing support points. In the annular direction, the structure is unloaded at these points, and in the central part it is actively deformed and the moments reach the limit values.

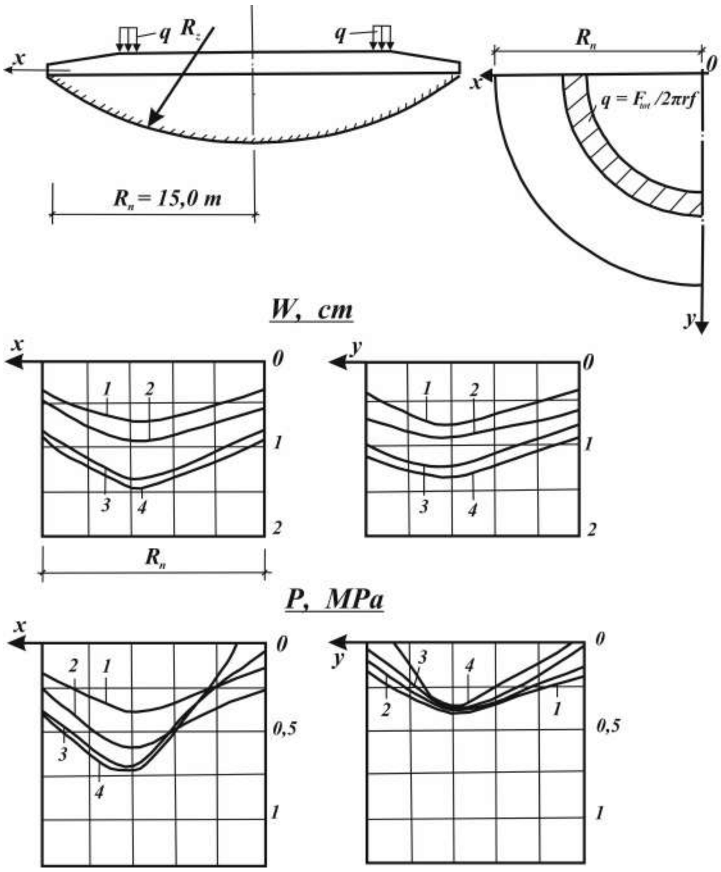

Figure 11. Settling W and contact pressures P along the central axes OX and OY with the vertical load $F_{\text{tot}} = 200$MN and the curvature radius of the concave base surface R_z equal to: $1 - \infty$, $2 - 10000$ m, $3 - 6000$ m, $4 - 5000$ m.

Along the X-axis in the radial direction, there is load release at footing support points and active deformation to the limit states at the centre. As the curvature of the base surface increases, annular moments increase at the points where the load is applied and reach the limit values.

In the central part, they do not change significantly. Note that with the curvature of the convex base surface along the Y-axis, reactive pressures of the soil are concentrated along this axis, resulting in the development of fracture lines and the collapse of the structure (figure 20, b).

Along the X-axis, fracture lines are about to develop from the cantilever part of the slab. It should be noted that with different values of the vertical load F_{tot}, the bearing capacity of the slab is exhausted at different curvature values of the convex base surface. At the same time, the higher the value of the vertical load is, the smaller the value of the curvature becomes.

With the curvature of the concave base surface along the Y-axis, the following patterns of the changed stress-deformed state of the foundation slab can be noted. The reinforced concrete slab is unloaded at the footing support points along the Y-axis in the radial direction and along the X-axis in the annular direction. It is actively deformed along these axes in the corresponding directions at its centre. The radial moments along the X-axis and the annular moments along the Y-axis are maximally increased to the limit values at the footing support points. Fracture lines at these points exhaust the load-bearing capacity of the foundation slab.

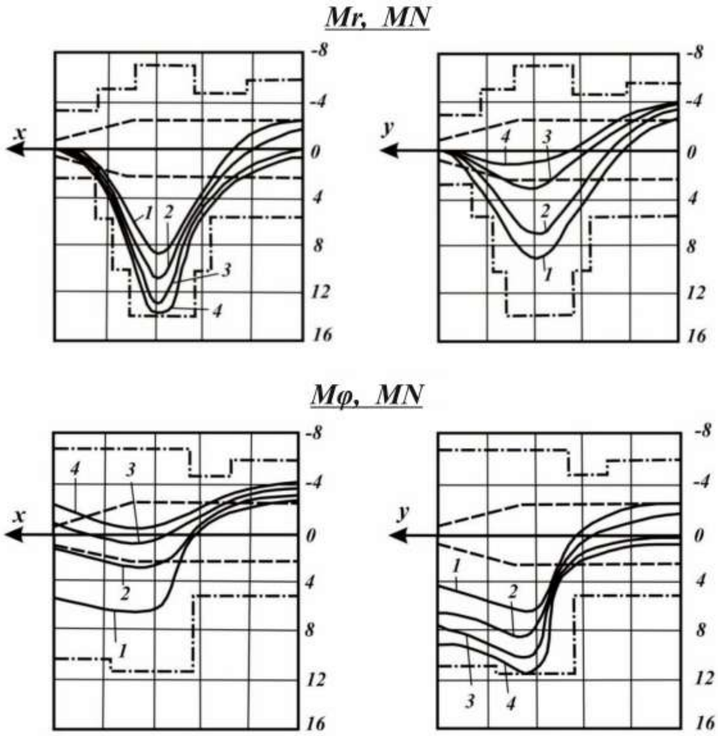

Figure 12. Radial M_r and annular M_φ moments in the foundation slab along the central axes OX and OY with the increased curvature of the concave base surface: 1 – ∞, 2 – 10000 m, 3 – 6000 m, 4 – 5000 m.

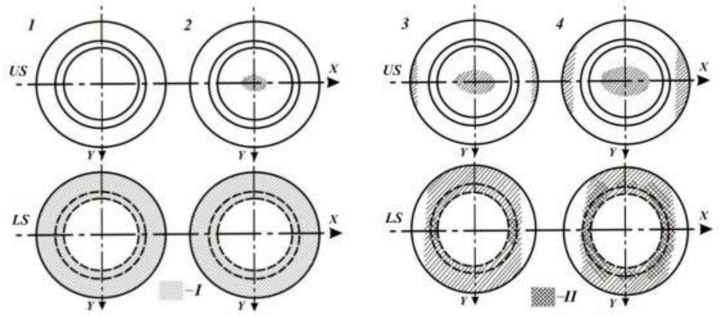

Figure 13. Development of elastic deformation zones in the foundation slab with the increased curvature of the concave base surface: *US, LS* – upper and lower slab surfaces; *I, II* – zones of formation of cracks and plastic hinges; 1 – ∞, 2 – 10000 m, 3 – 6000 m, 4 – 5000 m.

Thus, with the curvature of the concave base surface along the Y-axis, the slab begins to collapse in the perpendicular direction along which the maximum reactive forces from the base side are located (figure 20, *c*). Along the Y-axis from the cantilever part of the slab, radial fracture lines begin to develop simultaneously.

At different values of the vertical load, the load-bearing capacity of the slab is exhausted at different curvature values of the concave base surface. At the same time, the higher the load is, the smaller the curvature value becomes.

It is important to note that with the same values of the vertical load F_{tot}, the load-bearing

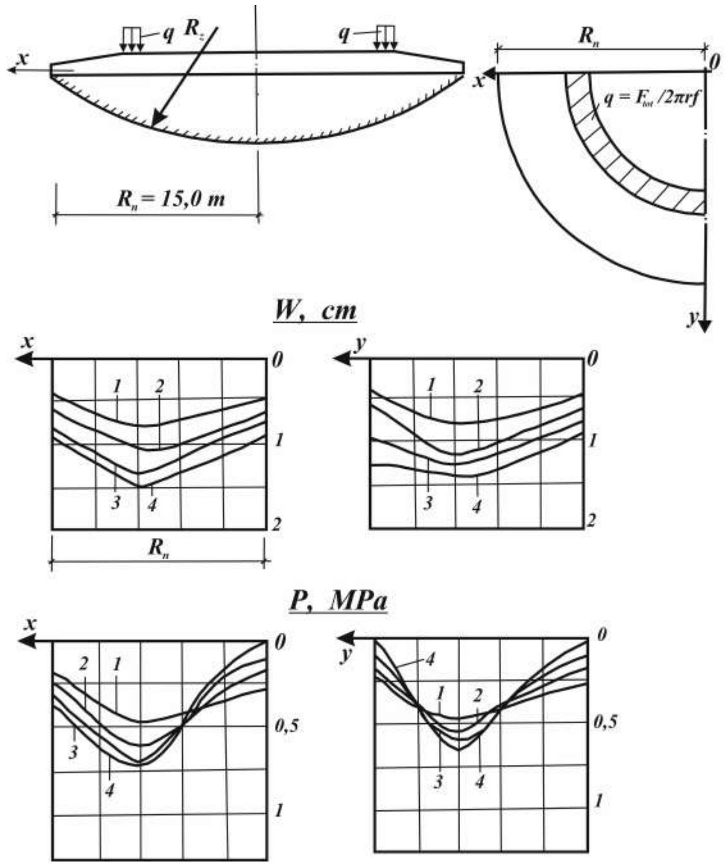

Figure 14. Settling W and contact pressures P along the central axes OX and OY at the vertical load $F_{\text{tot}} = 300\text{MN}$ and the curvature radius of the concave base surface R_z, equal to: $1 - \infty$, $2 - 15000$ m, $3 - 12000$ m, $4 - 10000$ m.

capacity of the foundation slab is exhausted at curvature radii of the convex base surface slightly less than the corresponding concave curvature radii.

If the end of the foundation has a ledge with the line parallel to the Y-axis, the contours of the calculated values are almost unchanged along this axis. The annular bending moments increase significantly in the central part of the foundation, which leads to the formation and development of cracks (further fracture lines) on the upper surface of the slab. In the perpendicular direction at the footing support points, the radial and annular moments increase towards the settling section of the base, and on the opposite side the structure is unloaded. In the central part of the slab, radial moments increase significantly, which causes the formation and development of cracks and fracture lines on the upper surface of the slab (figure 20, d). Fracture lines begin to develop at the places where the load is applied. In this example, the load-bearing capacity of the foundation slab is exhausted not due to destruction, but due to loss of stability. In the general case of an unstable position of the foundation structure, the exhaustion of its load-bearing capacity should be checked for two reasons (destruction and loss of stability).

4. Conclusions

1. New patterns of determination of internal forces for possible conditions of the first and second category elements of the reinforced concrete slab under complex load are established. The characteristic feature of the second category elements in the passive deformation state

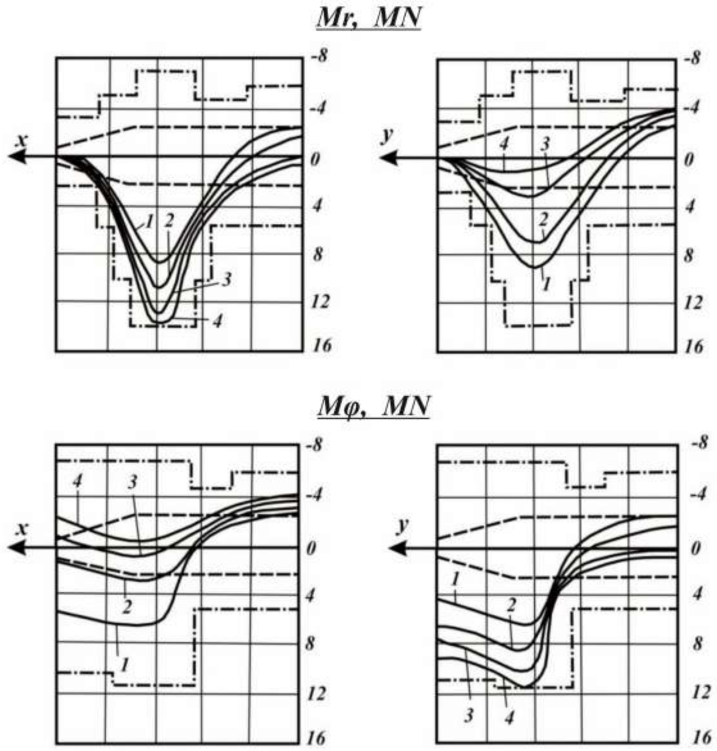

Figure 15. Radial M_r and annular M_φ moments in the foundation slab along the central axes OX and OY with the increased curvature of the concave base surface: 1 – ∞, 2 – 15000 m, 3 – 12000 m, 4 – 10000 m.

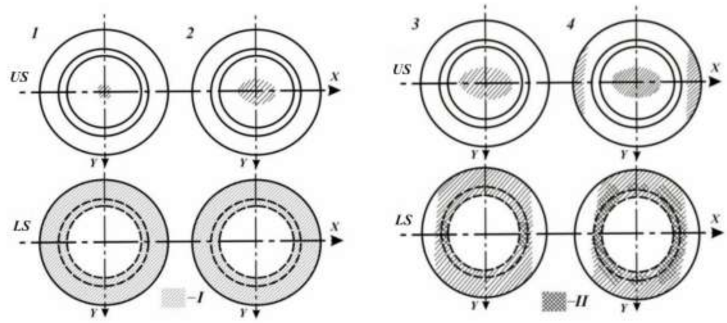

Figure 16. Development of elastic deformation zones in the foundation slab with the increased curvature of the concave base surface: *US, LS* – upper and lower slab surfaces; *I, II* – zones of formation of cracks and plastic hinges; 1 – ∞, 2 – 15000 m, 3 – 12000 m, 4 – 10000 m.

is the determination of the moment corresponding to the curvature of the load-release curve.

2. The introduction into the calculation of the function characterizing the degree of reduction of the weakened base characteristics to determine the variable stiffness coefficient in load release allows taking into account the conditions of contact interaction of the slab and the non-uniformly deformed base. Dependences of the weakened base for collapsible soils, underworked areas, and karsted areas are obtained.
3. The developed programme allows taking into account the load history of elements using

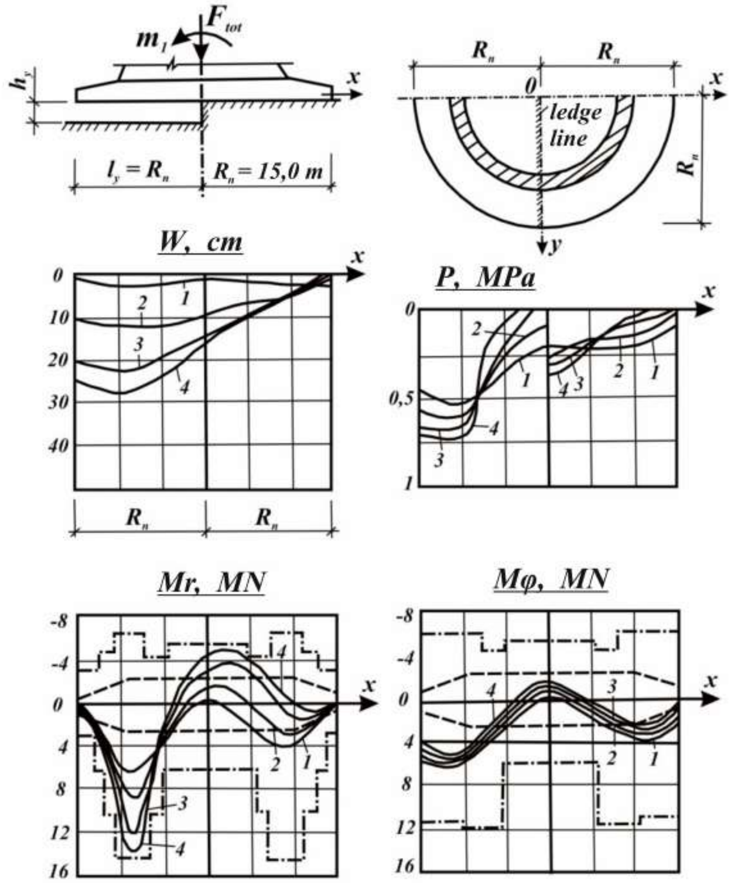

Figure 17. Design values along the OX-axis with the vertical load $F_{\text{tot}} = 200$MN, the external moment $m_1 = 150$MNm, and the settling section of length and height at the end of the foundation equal to: 1 – 0, 2 – 10 cm, 3 – 20 cm, 4 – 25 cm.

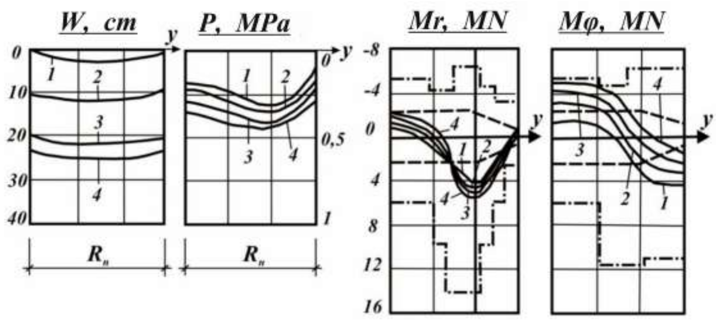

Figure 18. Design values along the OY-axis with the increased settling section: 1 – 0, 2 – 10 cm, 3 – 20 cm, 4 – 25 cm.

non-linear diagrams in the entire range of force and deformation effects.

4. On the basis of the analysis of the obtained simulation results of slab operation on the non-uniformly deformed base under complex loads, the following conclusions can be drawn:
   - at the curvature of the convex base surface along one axis, the maximum plastic deformation zones of the foundation structure are located on both sides of this axis,

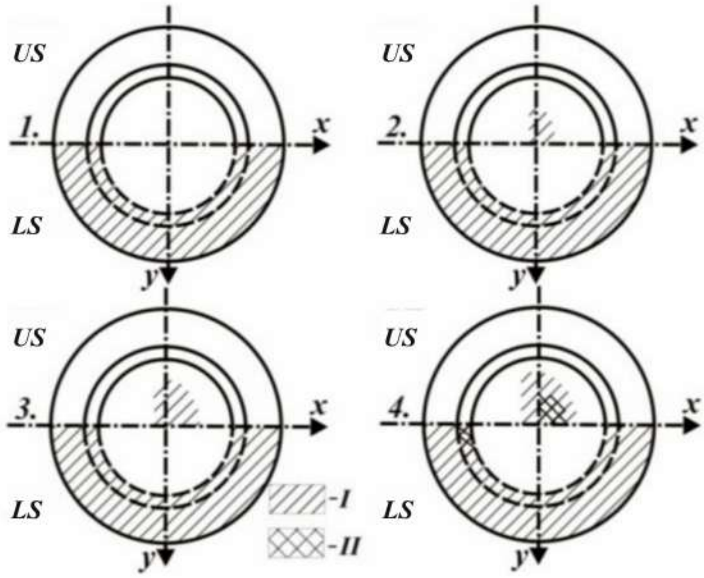

Figure 19. Development of cracks and fracture lines with the increased settling section: *US, LS* – upper and lower surfaces of the slab; *I, II* – areas of formation of cracks and plastic hinges; 1 – 0, 2 – 10 cm, 3 – 20 cm, 4 – 25 cm.

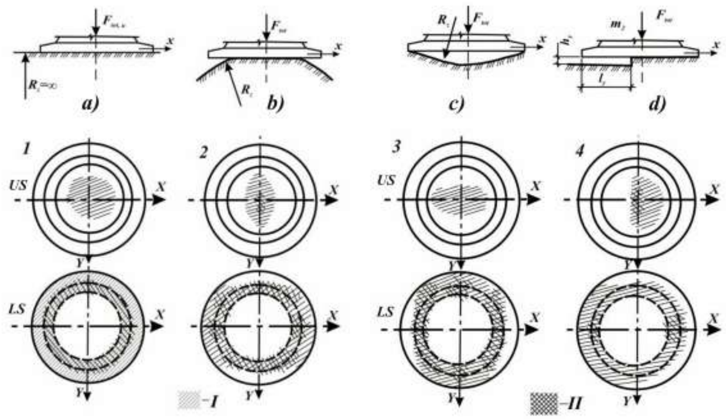

Figure 20. Zones of developed elastic plastic deformations in the round foundation plate under different deformation conditions of the base: *a)* normal soil conditions; *b)* convex surface of the base; *c)* concave surface of the base; *d)* ledged surface of the base; *US, LS* – upper and lower surfaces of the plate; *I, II* – zones of formation of cracks and plastic hinges.

and the slab is destroyed by fracture lines formed and developed in these zones;

- at the curvature of the base surface, the zones of plastic deformations of the structures are located mainly in the places of reactive soil pressures concentration;
- the curvature of the convex base surface, and to a lesser extent the bearing capacity adversely affect the operation of the foundation slab as compared with the curvature of the concave at the same values of the vertical load F_{tot};
- depending on the size of the settling section at the end of the foundation, the load-bearing capacity of the structure may be exhausted either due to destruction caused by the formation of plastic hinges or due to loss of position stability caused by large

inadmissible rolls;

- the value of the limit load on the slab decreases with the increase of deformation effects of the base on it;
- under non-uniform deformations of the base, the main areas of destruction of round foundation slabs are the footing support points, but in some cases (curvature of the base surface, settling of the base at the end of the foundation) such zone may occur in the central part of the slab.

Abstract. The ways to keep under regulation the early-age hydration and setting behavior of the common cements containing slag per EN 197-1:2011 and activated with sodium metasilicate were discovered and the results are discussed. The alkaline activation of these cements using sodium metasilicate is one of the ways to escape the strength loss in the cement systems with blast-furnace slag content of 5…95 %. However, these cements have too short setting times. This requires finding ways to regulate the structure formation. The aggregate states of sodium metasilicate, thesWe were: a liquid state (solution) and a solid state (powder) as well as the admixture-surfactant have been chosen as factors of influence to regulate setting times. The results of the study showed that the use of sodium metasilicate in the liquid state, on contrary to the solid state, provided additional intensification of the structure formation. The acceleration of the structure formation processes was accompanied by the formation of high early (1 day) compressive strength of 43…54 MPa, associated with an extremely quick setting time of 1…8 min. The sodium lignosulphonate admixture could be of help: its addition in a quantity of 4 % can retard the structure formation processes to the required ranges, not depending upon the aggregate state of sodium metasilicate. The resulting alkali-activated common cements containing slag are characteristic of the early (1 day) compressive strength of 33…48 MPa and initial setting time of 38…50 min.

1. Introduction

In recent decades, a lot of concrete structures (highways, pavements of airports, bridge decks, tunnels, tank depots, fortifications, etc.) have undergone degradation under external loads and environmental influences. The damages reduce the durability of such structures as well as cause less functionality during operation [1,2]. The mentioned facts actualize the development of cost-effective and efficient rapid-hardening high strength concretes and mortars of new generation [3], such as concretes for repairing building construction [4,5], shotcretes [6,7], underwater concretes [8–10], reactive powder concretes [11,12], mortars for anchoring [13,14], etc.

Polymers (epoxy resin, acrylic, resin, polyurethane, and acrylamide) are considered effective in some mentioned materials (repair materials, for example) due to high values of compressive strength after 28 d – up to 100 MPa and flexural strength after 28 days – up to 20 MPa [15]. However, limiting factors for the application of such materials are their high cost, reduced durability under the influence of ultraviolet radiation, as well as flammability and smoke release [16–18].

Cements are also widely used in rapid-hardening materials [19–21]. Portland cement [22, 23], magnesium phosphate cements [24, 25], calcium aluminate cements [26, 27], and calcium sulphoaluminate cements [28, 29] are the most commonly used.

The high early strength of rapid Portland cement relies on high percentages of C_3S and C_3A to give rapid hardening and setting [30]. The high early strength of concretes and mortars (≥ 40 MPa at an age of 1 day) can be achieved with a higher specific surface and high OPC content, low water-to-cement ratio (further, W/C), and the use of admixtures-accelerators [31–34].

The magnesium phosphate-based materials and the calcium aluminate-based materials are characterized by high early compressive strength (≥ 20 MPa in 2…3 h) [35, 36]. These cements and concretes based on them are expensive and some of them are not commercially produced in the Ukraine, for example, the calcium aluminate cement, which, above all, has unstable strength at a later age, especially at temperatures over 25 °C.

The perspective direction is the use of alkali-activated cements made using the common cements containing slag per EN 197-1:2011. The alkali-activated cements have high strength and meet the goals of global sustainable development [37–39] due to a comprehensive approach to the saving of natural materials resources and energy and can be considered "environmentally responsible materials".

Depending on the precursor (aluminosilicate component), certain phase ratios are formed in $CaO - Al_2O_3 - SiO_2 - H_2O, R_2O - CaO - Al_2O_3 - SiO_2 - H_2O, and R_2O - Al_2O_3 - SiO_2 - H_2O$ systems [40]. The phase ratio determines the structure of a resulting cement matrix and its properties [37, 41].

Sodium silicates, the anions of which are similar to hydrated initial products of destruction of the alumina-silica-oxygen framework, and serve as their additional reserve [37], are found to be the most effective alkaline activators for rapid hardening alkali-activated cements. The best solution is the use of sodium metasilicate pentahydrate (further, sodium metasilicate) due to its constant composition, market availability in a solid state (powder), and easiness-in-use in the process of cement and concrete manufacture.

The main obstacle in using the alkali-activated cements made with sodium metasilicate is an extremely quick setting [42]. The aggregate state of sodium metasilicate is a factor to be provided high strength of alkali-activated cements but could ensure extremely short setting times [43]. This resulted in a necessity to find ways to regulate the structure formation processes in these cements.

The use of the potassium fluoride admixture as a setting retarder is reported in [44]. However, this admixture can increase the cost of the alkali-activated cements and is classified as toxic compound.

One such setting retarder for the alkali-activated cements is $Na_3PO_4 12H_2O$, however, it could work effectively only with soluble sodium silicate with $M_s \geq 2$ [45].

The use in the alkali-activated cements of traditionally used admixtures-setting retarders was found to be ineffective because of the instability of a molecular structure in a liquid phase of the ones [46]. Sodium lignosuphonates were also found to be highly effective setting retarders for the alkali-activated cements [47].

The use of sodium metasilicate, despite its high potential, is a question from the point of view of setting times, and a choice of ways to keep the structure formation in the alkali-activated cements under regulation and provide acceptable setting times, in this case is an actual task.

The task of the study was to discover an approach to regulate the early-age hydration and setting behavior of the alkali-activated common cements containing slag through alkaline activation with the help of sodium metasilicate.

2. Raw materials and testing techniques

Used as components of the common cements containing slag were :

- Portland cement clinker (further, clinker) (% by mass: CaO – 67.60, SiO_2 – 20.84, Al_2O_3 – 5.12, Fe_2O_3 – 3.99, MgO – 0.78, SO_3 – 0.87, $Na_2O + K_2O$ – 0.80) with specific surface – 390 m^2/kg (by Blaine);
- ground-granulated blast furnace slag (further, GGBFS) (% by mass: CaO – 48.20, SiO_2 – 37.90, Al_2O_3 – 6.80, Fe_2O_3 – 0.30, MgO – 5.21, MnO – 0.11, TiO_2– 0.35, $Na_2O + K_2O$ – 0.35) with a basicity modulus - 1.18, glassy phase - 84.0 %, and specific surface – 400 m^2/kg (by Blaine).

The preparation of cement specimens was done by mixing the above-listed components. Used in the study were three cement systems (No 1, 2, and 3), the compositions of which are given in table 1.

To evaluate the basicity of the cement systems under study, a modulus of basicity, similar to that used in the evaluation of the basicity of GGBFS, namely: $M_b = (CaO + MgO)/(SiO_2 + Al_2O_3)$ – a ratio of masses of oxides, was applied [42].

Table 1. Compositions of three cement systems under study.

Cement system	Modulus of basicity, M_b	Content of clinker, % by mass	Content of GGBFS, % by mass
No 1	2.5	95	5
No 2	1.7	50	50
No 3	1.2	5	95

Used as an alkaline component was sodium metasilicate ($Na_2O \cdot SiO_2 \cdot 5H_2O$) in a solid aggregate state (a non-hygroscopic powder) and in a liquid aggregate state (a solution with a density of 1.24 g/ml). Sodium metasilicate was added in two aggregate states, both in equal quantities – 12 % (calculated on dry matter) or 3.5 % (calculated on Na_2O).

Used as a setting retarder was sodium lignosulphonate (further, LS) in the form of a concentrated solution with density of 1.25 g/ml and concentration of 45 %. The quantity of the admixture was 4 % (calculated on dry matter) (over 100 %).

The cement pastes were prepared in a standard Hobart mixer.

The setting times were measured per EN 196-3:2005 Standard.

The compressive strength of the cements was determined per EN 196-1:2016 Standard with the following amendment: W/C or solution-to-cement ratio (further, S/C) in case of dry state and liquid state of alkaline component accordingly was chosen in such a way that its consistency evaluated by flow would be 106…115 mm per National Standard of Ukraine DSTU B V.2.7-187:2009 (against a standard W/C = 0.5).

Calorimetry was used to study the influence of cement basicity, the aggregate state of the alkaline component, and sodium lignosulphonate admixture.

The heat of hydration of cement pastes was measured using a modified semi-adiabatic calorimetry, the details of which are given in [48]. The initial temperature of the constituents at the moment of mixing was $t = 20 \pm 1$ °C. The frequency of measurements varied from 15 sec and up to 5 min. The W/C in the cement pastes was 0.5. The study of structure formation processes in the cement systems was evaluated under the known criteria [49–51].

3. Results and discussions

3.1. The influence of basicity of the cement systems

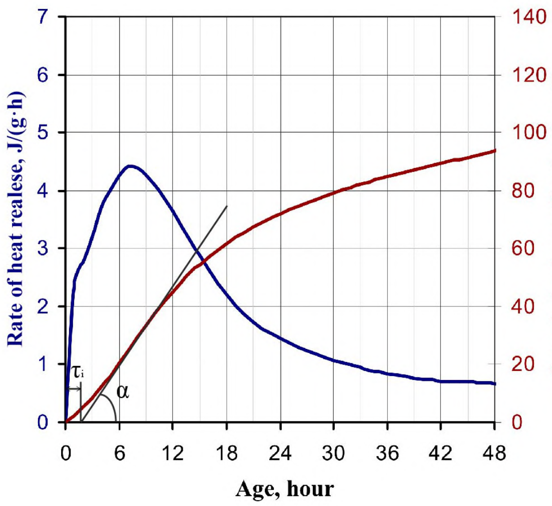
The use of cement systems with various basicities varying from $M_b = 2.5$ to $M_b = 1.2$ with the increase of the slag constituent from 5 to 95 % by mass requires developing a different approach

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012070 doi:10.1088/1755-1315/1415/1/012070

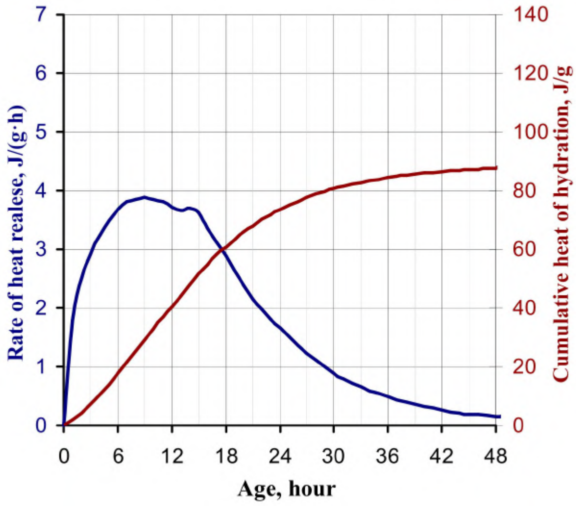
to regulate the structure formation processes.

3.1.1. Heat evolution. The early structure formation processes in the cements made with sodium metasilicate powder, depending upon the cement basicity, were studied.

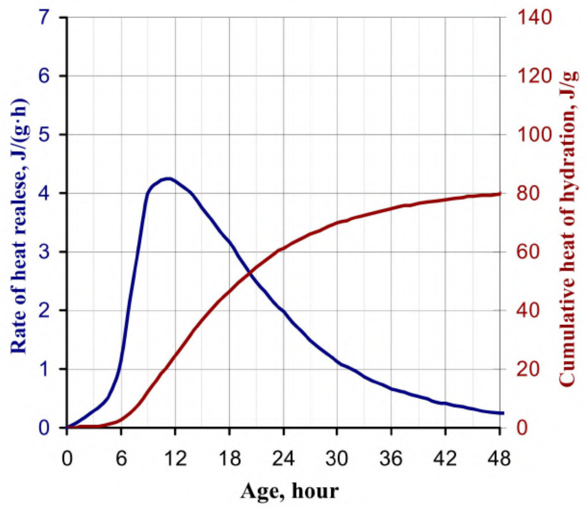
The influence of the basicity on the structure formation processes is shown in figure 1. In all three alkali-activated (AA) cement systems under study made with sodium metasilicate powder, the wetting of active centers of a solid phase took place very quickly, within a few minutes, and a coagulation structure was formed. With increasing the GGBFS content from 5 % to 95 %, the duration of the induction period increased from 50 min (figure 1a) to 6 h (figure 1c). The duration of the induction period (τ_i) was determined using a tangent to a curve of cumulative heat of hydration.



(*a*)



(*b*)



(*c*)

Figure 1. Rate of heat release and cumulative heat of hydration of alkali-activated cement systems No 1 (*a*), No 2 (*b*), and No 3 (*c*) with sodium metasilicate powder vs.age.

The formation of the condensation-crystallization structure of the AA cement systems is accompanied by the increase in the rate of heat release. The rate of hydration was evaluated using a tangent angle (α) to the curve of cumulative heat of hydration [50]. With increasing the GGBFS contents from 5 % up to 95 %, the rate of hydration remained without changes – at a level of 50…52 J/(g·h) (figure 1). At the same time, the degree of hydration (cumulative heat of hydration at an age of 24 h) of the AA cement systems for the above-specified GGBFS contents decreased from 72 J/g (figure 1a) to 60 J/g (figure 1c). The effects in the curves of the rate of heat release of the AA cement systems are caused, chiefly, by condensation of seeds of low-calcium silicate hydrates [37]. The presence of two effects in the case of AA cement system No 2 can be attributed to a joint participation of GGBFS and clinker in the hydration processes.

Above all, with decreasing the AA cement system basicity from M_b= 2.5 to M_b= 1.2, the structure formation processes retarded, and this was supported the shift of the effect on the rate of heat release from 7 h (figure 1a) to 11 h (figure 1c).

3.1.2. Setting times. The initial and final setting times of the AA cement system with 5 % of GGBFS and sodium metasilicate powder were 8 min and 11 min, and those of the AA cement system with 50 % of GGBFS – 19 min and 25 min. These initial setting times cannot be accepted for the alkali-activated cements per National Standard of Ukraine (DSTU B V.2.7-181:2009), under which a value of $\geq$ 30 min is specified. With further increasing of the GGBFS content up to 95 %, the setting times reached the standard-specified values: initial setting time – 100 min, final setting time – 130 min. The obtained results correlate well with the data of the thermokinetic analysis, according to which the higher the content of the slag constituent in the AA cement system, the longer the duration of the induction period.

3.1.3. Compressive strength. With increasing the GGBFS content from 5 % to 95 %, the compressive strength of the AA cement system made with sodium metasilicate powder at an age of 2 days decreased from 39 MPa to 32 MPa while decreasing W/C from 0.35 down to 0.34 (figure 2). The discovered dependence coincided to the results obtained from the thermokinetic analysis, namely: the retarded rate of the structure formation at early ages of hardening (up to 2 days).

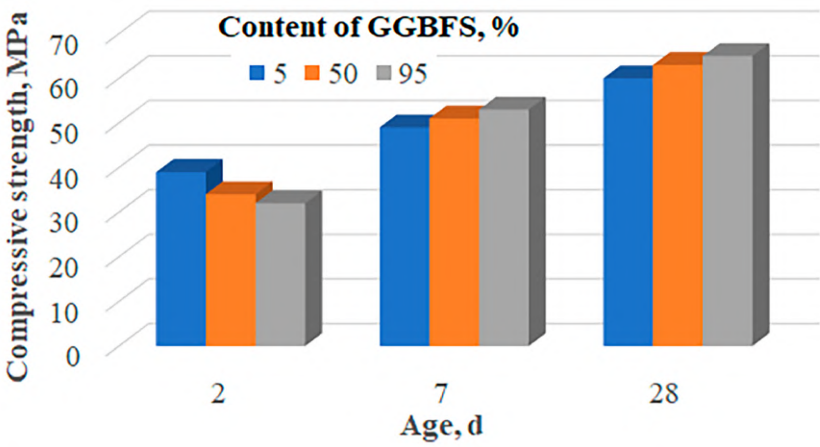


Figure 2. Comparative compressive strength of the alkali-activated cement systems with sodium metasilicate powder vs. content of GGBFS and age.

At later ages, the rate of strength gain, depending upon the basicity, varied. With increasing the content of the slag constituent from 5 % to 95 %, the compressive strength increased: at an age of 7 days – from 49 MPa to 53 MPa, at an age of 28 days – from 60 MPa to 65 MPa. This result can be attributed to the greater activating effect of sodium metasilicate powder on the clinker constituent at the early stages of hardening compared to that of GGBFS. At that, with time, the activating effect of the alkaline component on the slag constituent prevailed over that of the clinker constituent.

The obtained results testify to the necessity of retarding the early structure formation in the AA cement systems containing slag in quantities of 5. . . 50 % and made with sodium metasilicate powder to obtain the acceptable setting times.

3.2. The influence of the aggregate state of sodium metasilicate

Two aggregate states of sodium metasilicate added to the AA cement systems (powder and solution) require further studying of their effect on the structure formation.

3.2.1. Heat evolution. The effect of the aggregate state of sodium metasilicate was studied using AA cement system No 3 as the best in terms of setting times.

With sodium metasilicate solution compared to that in powder form, the duration of the induction period decreased to 1 h (figure 3) (against 6 h (figure 1c) of the AA cement system with sodium metasilicate powder). This can be attributed to the fact that in the case of powder, a certain time is required for the dissolution of sodium metasilicate in mixing water and its involvement in structure formation processes. In the case of sodium metasilicate solution, these processes occur and start to develop immediately and with a higher intensity. The rate of hydration increased to 59 J/(g·h) (against 52 J/(g·h)), and the degree of hydration to 78 J/g (against 60 J/g).

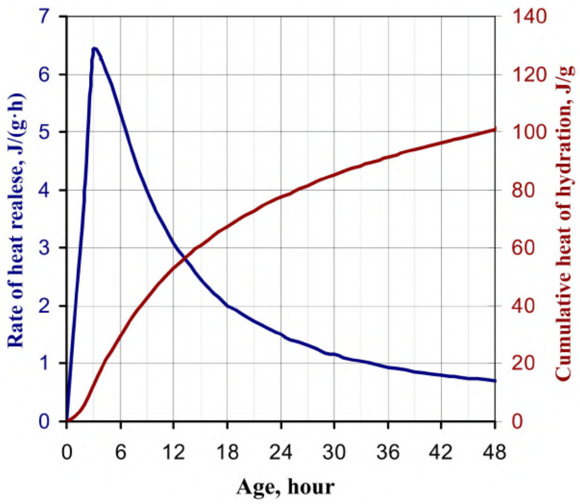

Figure 3. Rate of heat release and cumulative heat of hydration of alkali-activated cement system No 3 made with sodium solution vs.age.

The use of sodium metasilicate solution instead of powder allowed to shift the effect in the curve of the rate of heat release from 11 h to 3 h, thus supporting a conclusion on the intensification of the structure formation processes.

3.2.2. Setting times. The comparison of the setting times of the AA cement systems made with sodium metasilicate solution and with powder showed the quicker initial setting times in the case of solution: AA cement system No 1 (1 min against 8 min), AA cement system No 2

(4 min against 19 min), and AA cement system No 3 (8 min against 100 min) associated with the shorter final setting times – 2 min against 11 min (AA cement system No 1), 6 min against 25 min (AA cement system No 2), and 12 min against 130 min (AA cement system No 3). The obtained results correlated well with the thermokinetic analysis data testifying on the shorter duration of the induction period in the case of sodium metasilicate solution compared to sodium metasilicate powder (figure 3). These initial setting times were too short and could not be accepted for the AA cement systems per DSTU B V.2.7-181.

3.2.3. Compressive strength. In the case of the use of sodium metasilicate solution, the rate of strength gain is similar to that of sodium metasilicate powder, not depending upon the cement basicity. The early (1 day) compressive strength of the AA cement systems made with sodium metasilicate solution within the range of the contents of GGBFS of 5...95 % decreased – 43 MPa with S/C of 0.35 (against 54 MPa with W/C of 0.34) (figure 4). The compressive strength at ages of 7 and 28 days increased: 92 MPa (against 86 MPa) and 115 MPa (against 103 MPa).

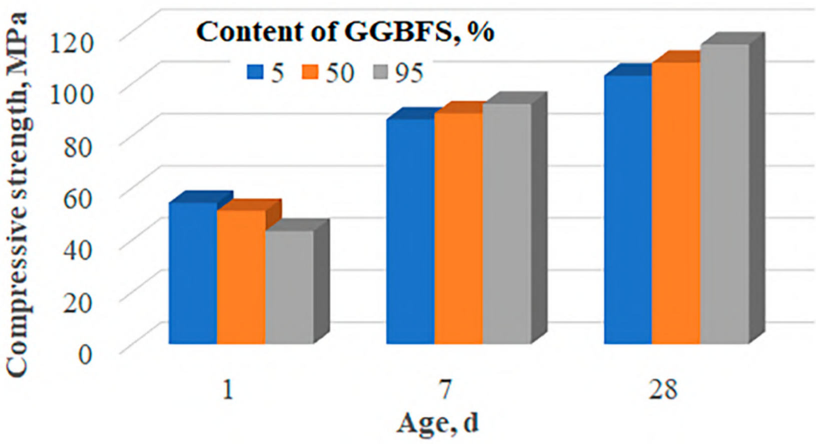

Figure 4. Comparative compressive strength of the alkali-activated cement systems made with sodium metasilicate solution vs. content of GGBFS and age.

The use of sodium metasilicate solution compared to sodium metasilicate powder resulted in a shorter duration of the induction period and, respectively, too quick setting, despite high early (1 day) compressive strength – 43...54 MPa (S/C= 0.33...0.34).

The obtained results testify to a necessity to decelerate the rate of structure formation in the AA cement systems for the whole range of contents of the slag constituent and made with sodium metasilicate solution to provide the standard-specified setting times.

3.3. The influence of the admixture on the structure formation

The influence of the LS admixture was studied using AA cement system No 3 made with sodium metasilicate solution with the account of its quick setting. The quantity of the LS admixture was 4 % of the mass of the cement system.

3.3.1. Heat evolution. The addition of the LS admixture resulted in a longer induction period (from 1 h (figure 3) to 5 h (figure 5)), the rate of hydration decreasing from 59 J/(g·h) to 48 J/(g·h), the degree of hydration – from 78 J/g to 62 J/g. A shift of the effect in the curve of the rate of heat release from 3 h (figure 3) to 13 h (figure 5) was a result of the influence of the admixture.

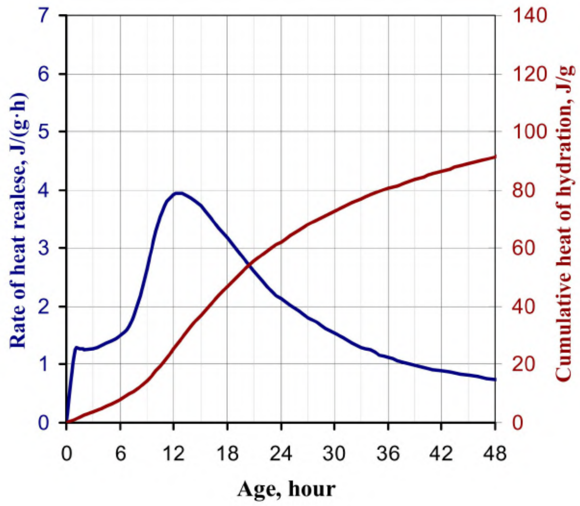

Figure 5. Rate of heat release and cumulative heat of hydration of alkali-activated cement system No 3 made with sodium metasilicate solution and the LS admixture vs. age.

The changes of the thermokinetic characteristics in the case of the LS admixture were reflected in the retarded structure formation processes, thus allowing us to predict the extended setting times.

3.3.2. Setting times. With the use of the LS admixture, the initial setting times of AA cement systems No 1, No 2, and No 3 made with sodium metasilicate solution increase from 1 min to 50 min, 4 min to 38 min, and 8 min to 60 min, respectively. Correspondingly, the final setting times increase from 2 min to 64 min, 6 min to 45 min, and 12 min to 76 min. These setting times comply with the requirements of the National Standard of the Ukraine DSTU B V.2.7-181.

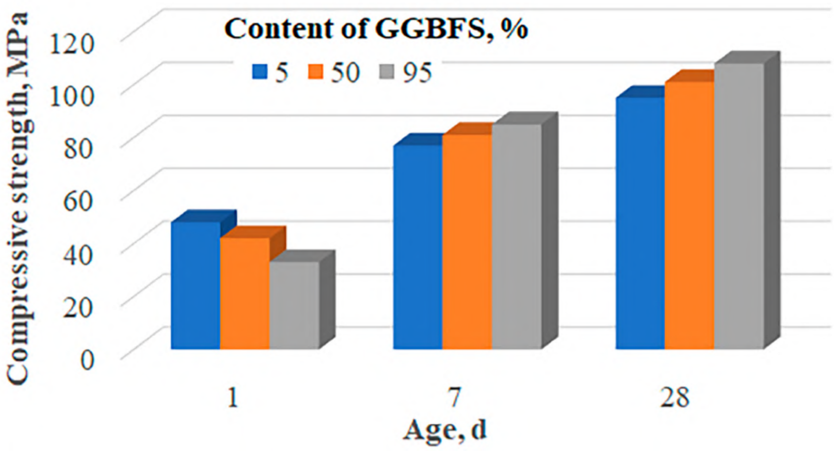

Figure 6. Comparative compressive strength of the alkali-activated cement systems made with sodium metasilicate solution and the LS admixture vs. content of GGBFS and age.

3.3.3. Compressive strength. The addition of the LS admixture to AA cement systems No 1, No 2, and No 3 made with sodium metasilicate solution resulted in some decline of the compressive strength (figure 6) compared to those of the admixture-free cement composition (figure 4): 33...48 MPa (against 43...54 MPa), 77...85 MPa (against 86...92 MPa), and 95...108 MPa (against 103...115 MPa) with S/C of 0.3...0.32 (against S/C of 0.33...0.34) at ages of 1, 7, and 28 days, respectively.

Thus, the use of the LS admixture allowed for quick hardening of the alkali-activated common cements containing slag with the acceptable setting times.

4. Conclusion

1. The basicity and the aggregate state in which sodium metasilicate pentahydrate was added were found to be the main factors determining the early-age hydration and setting behavior of the alkali-activated common cements containing slag.
2. With increasing the cement basicity from M_b= 1.2 to M_b= 2.5 through the increase of the GGBFS content from 5 % to 95 % by mass, the duration of the induction period increased by 7.2 times and was associated with the deceleration of the initial setting times from 8 min to 100 min. At the same time, the retarded processes of early structure formation in the alkali-activated common cements through the higher content of the slag constituent within the above range were accompanied by the lower degree of hydration (by 16.7 %) and the lower 2-day-compressive strength (by 17.9 %).
3. The use of sodium metasilicate in a liquid aggregate state (solution) instead of a solid aggregate state (powder) was accompanied by the acceleration of the structure formation processes in the alkali-activated common cements. This conclusion was supported by the shorter duration of the induction period, and the higher rate and degree of hydration. The more intensive structure formation processes in the alkali-activated common cements made with sodium metasilicate solution resulted in a high (1 day) compressive strength of 43...54 MPa associated with too quick initial setting times (1...8 min).
4. The extension of the setting times of the alkali-activated common cements could be achieved by using the admixtures – surfactants. The admixture-modified alkali-activated common cements had the decelerated structure formation and were accompanied by the longer duration of the induction period, the lower rate and degree of hydration. All this resulted in the production of quick hardening alkali-activated common cements with the compressive strength of 33...48 MPa at an age of 1 day and initial setting times of 38...50 min.

Abstract. The purpose of this work is to create a bioactive "smart" thermo-responsive hydrogel, which, when exposed to the body with a physiological temperature of 37°C, reversibly turns into a sol, which can be used to introduce drugs into hard-to-reach places, for local and long-term delivery of drugs, as well as for reducing doses of delivered drugs. Herein, we developed and studied hydrogel systems containing gelatin, sodium alginate and humic acids. All natural molecular polymers used are low cost and have non-toxic, biocompatible, biodegradable and non-immunogenic properties. In addition, using our own technology, humic acids with antioxidant, antibacterial and anti-inflammatory activity were obtained from lignite, which provided a concrete chance for the technological use of humic acids in accordance with the "waste-to-wealth" approach. Rheological studies confirmed that the hydrogel containing 14 %wt.gelatin and 6.4 %wt. sodium alginate is thermo-reponsive and has a gel-sol transition, manifested in a sharp decrease in its kinematic viscosity at a physiological temperature of 37°C. The FTIR spectra of the gelatin-sodium alginate-H_2O and gelatin-sodium alginate-humic acids-H_2O systems turned out to be similar. The small red and blue shifts in stretching and bending vibration positions occurred due to gelatin-sodium alginate, gelatin-humic acids and sodium alginate-humic acids interactions, and are similar to those observed in the literature, in particular due to a conformational change in the secondary structure of gelatin. The results of a study of the gel-sol transition time at a physiological temperature of 37°C for samples of the developed thermo-responsive bioactive gelatin-alginate hydrogel containing 6.4 %wt. sodium alginate and 14%wt. gelatin, as well as samples of this hydrogel modified with different contents of humic acids, visually showed a sharp increase in the transition time from 6 min to 11 min as a result of adding 2.5 %wt.humic acids. Thus, these studies showed that relatively small concentrations of humic acids can provide a prolonged drug delivery effect through the use of gelatin-sodium alginate hydrogel modified with humic acids on the surface of the human body.

1. Introduction

1.1. Smart hydrogels

The modern sustainable development trend in area of biologically active polymers and materials based on them is the technology that allows creating effective systems for drugs and active substances transdermal delivery into the human body [1].

Currently, a large amount of research is driven by the potential applications of hydrogels based on molecular biopolymers and their composites with various molecular substances of biological origin in various fields such as food, cosmetics, nanoelectronic devices, tissue engineering and drug delivery [2]. The reason is the ability of such "smart" hydrogels to respond to external stimuli by changing their phase state, that is, a reversible transition from sol to gel and back due to the formation/destruction of non-covalent bonds (hydrogen bonds, π-π stacking, Van der Waals etc.) [3]. The literature provides data on hydrogels of molecular biopolymers and their composites that undergo a reversible liquid–viscoelastic hydrogel phase transition depending on temperature, pH, or ionic strength of the medium. Of particular interest are thermo-responsive hydrogels that exhibit a sol-to-gel transformation that is triggered by proper physiological stimuli, such as exposure to body temperature at 37 °C [2]. For example, in [3], a graft copolymer of SA bearing eight poly(N-isopropylacrylamide) side chains enriched with the hydrophobic comonomer N-tertiary-butylacrylamide created in the presence of Ca^2+ a biocompatible self-assembling thermo-responsive hydrogel that behaved as a soft gel at room temperature and a strong gel at a physiological temperature of 37 °C, suitable for potential bio-applications. More typical is the reversible transformation of thermo-responsive gels into sols with increasing temperature, called melting [4]. Such "smart" hydrogels belong to the class of stimulating sensitive hydrogels and have unique advantages, including the possibility of introducing a drug into a hard-to-reach location [5], local and long delivery, and reduction of the dose of the delivered medicine, as well as high adhesion to mucous surfaces. The explanation is that, according to [6], gels are materials consisting of a network of macromolecules in a continuous phase, and when temperature is applied to the gel network, it can be reversibly destroyed at the melting temperature Tm or created at the gelation temperature Tg. Such "smart" gels are usually called thermoreversible [5].

1.2. Thermo-responsive biopolymer hydrogels and their complexes

The use of biomaterials, including biopolymers, to create "smart" hydrogels is a promising area of modern science and technology. The most widely used biopolymers for this purpose are proteins (silk fibroin and gelatin (GN)) and polysaccharides (cellulose, chitosan and SA), the important features of which are low cost, renewability, biocompatibility and biodegradability [7]. GN as a natural peptide macromolecule obtained by partial collagen hydrolysis, during which the regular triple helix structure is broken down to form random coils [8]. It is a natural polyampholyte that has both positively and negatively charged groups, as well as hydroxyl groups and hydrophobic groups [7]. The positive charge of the GN is provided by the residues of arginine (Arg), lysine (Lys), hydroxylysine (Hyl), and histidine (His). The hydroxyl groups arise from the residues of hydroxyproline (Hyp), serine (Ser), threonine (Thr), and tyrosine (Tyr). The negative charge of GN macromolecule is explained by glutamic acid (Glu) and aspartic acid (Asp) residues [7]. GN is one of the most commonly used polymers whose hydrogels are thermoreversible [5]. The availability, low cost, biocompatibility, biodegradability and low antigenicity of GN make it suitable for wide range of applications in nanoelectronics, pharmaceuticals and biomedical fields. Thermoreversible physical gel GN, obtained by cooling aqueous solutions of GN to temperatures below 30 °C, undergoes a sol-gel transition [4]. The gelation temperatures in the pure GN system GN-H_2O containing 2.5 %wt. GN were in the range of 15-18°C. For 5 %wt. GN solutions, the corresponding Tg range was 20-22°C [5]. According to [4], at high concentrations (over 13 %wt.GN) and temperatures below 35°C, the thermodynamic conformation of GN chains is essentially intermolecular; at temperatures below 40 °C, GN chains undergo a progressive conformational change, known as the coil-to-helix transition, producing triple helix networks. According to data [4], at a rate of temperature change of 1 °C/min, the melting temperature Tm in the pure GN gel (GN-H_2O system) is 31°C, and at the ramp rate of 10°C/min, Tm increases to approximately 32.5°C. The Tm of a GN hydrogel with 2.5 %wt.GN is 32.4°C, and at 5 %wt. GN in the GN-H_2O system, the Tm increases to 34°C. Thus, the melting point of pure GN hydrogel is in all cases below the physiological temperature of 37°C. In accordance with [5], the properties of GN can be improved by adding compounds that could interact with GN by creating additive chemical or physical bonds to increase, on the one hand, the rheological and mechanical strength of composite hydrogels or, on the other hand, to impart special properties such as biological activity and thermal stability.

Thus, there is growing interest in finding sustainable and safe cross-linking choices based on natural moieties. For example, it is known [5], that mixtures of proteins with polysaccharides can give variety of phase behavior with synergistic or antagonistic effects creation of soluble or insoluble complexes. One of the most promising materials for this purpose is SA [6]. SA is a water-soluble, neutral and linear polysaccharide with non-toxic, biocompatible, biodegradable and non-immunogenic properties, due to which SA has found use in various biomedical applications, among which the most promising are drug delivery and gene delivery [5], wound dressing [8] and wound healing [9]. According to Cao et al. [10], alginates are natural polysaccharides isolated from brown seaweeds and certain bacteria. SA is an alginic acid derivative consisting of 1,4-β-d-mannuronic (M) and α-l-guluronic (G) acids linked by glycosidic bonds (1$\rightarrow$4), and has the chemical formula $(NaC_6H_7O_6)n$ [9]. The structure of the alginate is formed either by homopolymer (MM or GG) or heteropolymer (MG or GM) blocks. The negative charge of alginate is provided by carboxyl groups (one per monomer) [9]. Pure solutions of SA did not exhibit temperature effects [5]. However, alginates are capable of forming hydrogels through ionotropic gelation with divalent or multivalent cations, and the most studied system is ionotropic gelation with calcium cations, usually described using the “egg box” model [9], which assumes two antiparallel polyuronate chains that form egg-box dimers with Ca^2+ and further aggregate laterally to form multimers. Alginates are also capable of gelation with transition metal cations such as Co^2+, Ni^2+,Cu^2+ and Fe^2+ [8], due to their ionic cross-linking in the presence of divalent cations. Ursini et al. [9] described the formation of metal-free alginate hydrogels in the presence of the free organic amino acid glutamine, when the protonated amino acid causes a shielding effect for electrostatic repulsion of alginate chains, which leads to the formation of chain cross-links and chain–chain stabilization. Disadvantages of SA include its low mechanical strength and cell adhesion, low level of drug loading, hydrophilicity, microbial degradation and burst release [4]. According to Ahmad et al. [4], to overcome such problems, SA should be mixed with various types of synthetic or natural polymers, which would improve its properties.

Recently, many studies have been devoted to the formation of alginate-GN complexes in GN-SA-H_2O systems, which demonstrate the joint synergistic effect of alginate and GN on the rheological and thermo-responsive properties of complex hydrogels [5]. Venezia et al. [5] studied intermolecular electrostatic interactions and hydrogen bonds, as well as, to a lesser extent, hydrophobic interactions between macromolecular chains of GN and SA with the formation of polyelectrolyte complexes in aqueous solutions. Complexation in GN-SA-H_2O systems is accompanied by a change in the secondary structure of GN. As reported by Derkach et al. [7], at a low mass ratio of polysaccharide to GN (up to 0.2), a decrease in the proportion of collagen-like helices and an increase in the share of random coil conformation of GN chains is shown. According to Venezia et al. [5], aqueous solutions of SA with a high content of GN at temperatures below 36°C contained rod-shaped structures that were considered as the initial stage of the helix-coil transition. These gels were prepared at the ratio GN to alginate 2:1; their thermoreversible behavior indicates the absence of covalent cross-linking during gelation in binary mixtures GN-SA-H_2O [5]. As a result of electrostatic interactions, hydrogen bonds and hydrophobic interactions between alginate and GN, the characteristic temperatures of the gel-sol and sol-gel transitions were shifted towards higher values. For example, in thermo-responsive hydrogels of the GN-SA-H_2O system with 5 %wt. GN and 5 %wt. SA, the gelation temperature

Tg increased to 27.3 °C, and the melting temperature Tm increased to 35.9 °C [5].

1.3. Humic acids in thermo-responsive biopolymer hydrogels

In order to increase Tm to a physiological temperature of 37 °C, it was necessary to introduce an additional cross-linking agent into the GN-SA-H_2O system, which, at the same time, did not interfere with the thermoreversibility of the GN-alginate hydrogel [2]. In [5], the addition of humic acids (HAs) was used as a way to tune the gelation of GN hydrogels. Among the bioavailable compounds, HAs are an alkali-soluble fractions obtained as a result of oxidative destruction biomass in natural or biorefinery processes, which contain fragments with different functionality in their main chains including quinone, phenol, carboxyl and hydroxyl groups that give them various properties such as antioxidant, antibacterial and anti-inflammatory activity [11]. De Melo et al. [11] indicate that quinones are responsible for the formation of reactive oxygen species in HAs, which are beneficial for wound healing and have fungicidal/bactericidal properties. Phenols and carboxylic acids are deprotonated in neutral and alkaline environments and are responsible for various other functions, such as the antioxidant and anti-inflammatory properties of HAs. In particular, the presence of phenolic groups in HAs provides antioxidant properties due to their ability to scavenge free radicals. HAs are the most studied group of humic substances, which are natural non-toxic complexing ligands found in nature [12]. In turn, humic substances make up the main part of organic matter [13], since they represent most of the organic materials of soil [14], peat, lignites, brown coals, sewage, natural waters and their sediments [15].

Thus, HAs are biological wastes found in nature in large quantities [5]. The chemical composition and properties of HAs may vary depending on geographic location, origin, age, climate and biological conditions, making it difficult to accurately characterize these substances. In particular, the molecular weights of HAs vary in the range from 2.0 to 1300 kg/mol [15]. According to the currently generally accepted opinion [5], HAs consist of relatively low molecular weight compounds (2-150 kg/mol) that are self-organizing into supramolecular structures held together by weak dispersion forces such as Van der Waals, π-π and CH-π interactions. Moreover, due to the non-covalent nature of the stabilizing interactions, HAs superstructures are not only highly dependent on environmental chemistry, including pH and associated biological molecules, and behave as dynamic systems, but are also subject to self-restructuring in water [5]. Commercial HAs are extracted from peat and lignites in the form of a fraction that is soluble in alkali, but insoluble upon subsequent acidification [5]. The inclusion of HAs in the GN network in [5] influenced viscoelastic properties as well as thermal stability the resulting GN-HAs-H_2O gel. Aldrich HAs was chosen in [5] as a model HAs fragment to study the gelation kinetics and transition temperatures depending on the HAs concentration in thermo-responsive GN-HAs-H_2O hydrogels with HAs/GN concentrations changed in the range 2.67-26.67 wt./wt. Research by Venezia et al. [5] has shown that at lower concentrations of HAs/GN (up to 13.33 wt./wt.). HAs improve the thermal properties of the resulting GN-HAs-H_2O gels due to tight physical interactions of HAs with GN. The melting temperatures Tm of these hydrogels were increased to 33°C at a ramp rate of 1°C/min and to 35°C at a ramp rate of 10°C/min; the corresponding Tg values were 24°C and 16°C, respectively [5]. According to Venezia et al. [5], since HAs are organized into supramolecular soft and permeable clusters exposing hydrophilic groups, while hydrophobic particles are shielded in the interior, these chemical features make HAs highly reactive with proteins. Accordingly, they can interact with GN through non-covalent interactions such as hydrophobic and electrostatic interactions, as well as through H-bonds. Notably, H-bond interactions must be established between the carbonyl groups of HA and the hydroxyl groups of hydroxyproline and proline residues, as well as amino moieties of glycine, which are the most abundant amino acids in GN chains [5]. Thus, up to a maximum concentration of GN and HAS of 13.33 wt./wt., HAs have a beneficial effect on the gelation process, promoting the formation of a denser network. However, higher concentrations of HAs in the GN-HAs-H_2O system led to a disordered structure with a random coil organization of GN, since HAs, due to their high affinity for water, establish preferential bonds with water molecules, preventing them from being coordinated with GN chains [5]. Since water plays a key role in stabilizing the triple helix structure and the resulting gel network, being able to act as a link between GN chains due to H-bonds, at high HAs content the secondary structure of GN lost its triple helix structure. In addition, the content of HAs more than 13.3 %wt. causes swelling phenomena due to water absorption of HAs, which promotes the formation of a weaker gel with reduced thermal stability, and also causes partial coagulation of the protein with the formation of aggregates and precipitation phenomenon, which can prevent the return of GN chains to the ternary structure spirals [5]. Therefore, the melting temperatures Tm of hydrogels in the GN-HAs-H_2O system with HAs/GN concentrations 26.67 wt./wt. were decreased to 26°C at a ramp rate of 1°C/min and to 29°C at a ramp rate of 10°C/min; their Tg values were 17°C at a ramp rate of 1°C/min and 9°C at a ramp rate of 5°C/min [5].

Thus, all thermo-responsive hydrogels based on the GN-SA-H2O and GN-HAs-H_2O systems developed to date have melting points below the physiological temperature of 37°C. Considering the relevance of creating a biocompatible thermo-responsive hydrogels with a physiological melting point based on non-toxic and available biomaterials that have wound-healing properties and are suitable for controlled drug delivery, in this work we developed and studied a more complex GN-SA-HAs-H_2O system. This article has the following objectives. First, it is the optimization of the compositions of thermo-responsive biologically active GN-alginate hydrogels by studying their rheological properties using the viscosimetric method in order to adjust the melting temperature to physiological conditions. Secondly, the aim of this work is to modify thermo-responsive bioactive GN-alginate hydrogels with HAs, which have antioxidant, antibacterial and anti-inflammatory activities, to provide a concrete chance for technological application of HAs in accordance with the "waste-to-wealth" approach. Thirdly, it is assessment of the temporal conditions of the gel-sol transition of thermo-responsive bioactive GN-alginate hydrogels modified by HAs with physiological melting point, and the characterization of these thermo-responsive GN-SA-HAs-H_2O hydrogels using Fourier transform infrared spectroscopy (FTIR).

2. Materials and methods
In this work, food GN brand R-11 was purchased in Ukraine, and SA in the form of sodium salt of alginic acid was purchased in China.

2.1. Preparation of humic acids and thermo-responsive hydrogels
A solution of HAs with a concentration of 8.5 %wt. NaOH in the form of a nanodispersion with a nanoparticle size in the range of 52 – 380 nm was obtained by extraction of lignite with a solution of sodium pyrophosphate, and further extraction with 1%wt. sodium hydroxide and precipitation with mineral acid. To obtain HAs, a 10–15 g sample of lignite was first crushed to a particle size of less than 1 mm. The crushed lignite sample was then extracted with toluene with a density of 0.867 g/cm^3.

After extraction, it was air dried and further ground to a particle size of less than 0.2 mm. Then, the sample weighing 1 g or 2 g in terms of dry ash-free mass was transferred to a conical flask A with a volume of 250 ml, to which 100 ml of an alkaline solution of sodium pyrophosphate was added, and the resulting solution was stirred for 1 hour with a mechanical shaker. The obtained suspension was centrifuged for 15 min at 210 rotate per second. The solution was decanted, collecting in a conical flask B with a capacity of 1000 ml. The residue that did not dissolve was rinsed twice with 100 ml of sodium hydroxide solution. The suspension was centrifuged after each rinse, collecting the rinsing solution in flask B. The rinsed residue was transferred to flask A, 100 ml of sodium hydroxide solution was added and heated for 2 hours in a water bath. After cooling to room temperature, the content of flask A was centrifuged for 15 min at 210 rotate per second. The solution was decanted and collected in flask B. The residue, which did not dissolve, was rinsed twice with the use of 100 ml of sodium hydroxide solution. The suspension was centrifuged after each rinsing, collecting the rinsing solution in flask B. Extraction of HAs was carried out for 7 hours. The contents of flask B were filtered into a 1000 ml flask, and water was added until the whole volume was 1000 ml. Then, 100 ml of the filtrate was collected with a pipette and transferred to a beaker, and 60 ml of 5 % vol. hydrochloric acid was added to precipitate HAs. The suspension was centrifuged. After centrifugation, the solution was separated by decantation and the HAs precipitate was rinsed with water. Rinsing the sediment led to the beginning of peptization of HAs, which was determined by the appearance of a weak yellow color (colloid formation). After that, 5 ml of 5 %vol. hydrochloric acid was added to this colloidal solution for additional precipitation of HAs. The sediment of HAs was filtered through an ash-free filter, which was previously dried to a stable mass in a drying oven at 90±5°C. The filter with the sediment of HAs was placed in an aluminum weighing bottle, previously dried to a stable mass in an oven at 90±5°C, and dried at a temperature of 90±5°C for 1 hour. The bottle with contents was then removed from the drying oven, cooled for 5 minutes in air, and then additionally dried in a desiccator. Control cooling and drying were repeated until the difference in mass of the two subsequent samples was less than 0.001 g.

Subtracting the mass of the weighing bottle and filter, the mass of the HAs-containing sediment was determined. Finally, the dried filter with the HAs-containing sediment was transferred to the pre-frying crucible in a muffle furnace at a temperature of 600±25°C for 1-2 hours until it was solidified and its mass was stabilized. Then the crucible was removed out of the muffle furnace, cooled and dried for 5 hours in air, and then dried in a desiccator with a drying agent. Control frying at the same temperature for 15 minutes, cooling and drying were repeated until the difference in mass between the two subsequent experiments did not exceed 0.001 g. The mass of HAs was determined by subtracting the mass of the crucible.

To obtain thermo-responsive hydrogels GN-SA-H_2O and GN-SA-HAs-H_2O, a certain amount of GN was first placed in distilled water preheated to 90 ± 2°C and stirred on a VEVOR 85-2 magnetic stirrer with a heating plate until a pure GN sol was obtained. To prepare a GN-alginate hydrogel, SA was added to a previously prepared GN sol and stirred with a VEVOR 85-2 magnetic stirrer with a heating plate until a homogeneous sol GN-SA-H_2O was obtained. In this work, we used GN-SA-H_2O systems contained 14 %wt. GN and 3.2 %wt., 6.4 %wt. or 9.6 %wt. SA. To prepare GN-SA-HAs-H_2O systems, HAs were added to the GN-alginate hydrogel, containing 14 w%wt. GN and 6.4 %wt. SA, at concentrations of 2.5 %wt.HAs, 5 %wt. HAs or 7.5 %wt. HAs.

2.2. Characterization

Herein, to optimize the composition of thermo-responsive hydrogels, a standard method for determining kinematic viscosity (mm^2/s) was applied using a glass viscometer VPZh-2 3.35 with a capillary diameter of 3.35 mm and a viscometer constant of 10. Measurement of kinematic viscosity using a viscometer VPZh-2 based on determining the time of flow of a certain volume of sol through a capillary from a measuring container. The gel-sol transition temperature Tm was recorded from the onset of free flow of the sol through a widening in a capillary with a diameter of 3.35 mm.

The technique for studying the gel-sol transition time of thermo-responsive bioactive hydrogels of the GN-SA-H2O and GN-SA-HAs-H2O systems included visual observation and determination of the time of softening and subsequent melting of hydrogel washers 1 cm high and 1.5 cm in diameter, located on glass substrate heated to a physiological temperature of 37°C, which confirmed the gel-sol transition process. Fourier transform infrared spectroscopy FTIR has been used to study non-covalent interactions between GN, SA and HAs in these thermosensitive bioactive hydrogels with a physiological melting point. FTIR spectra were taken using an IR spectrophotometer Nicolet 380 (USA) at 20-25 °C in the 4000-500 cm^{-1} frequency range.

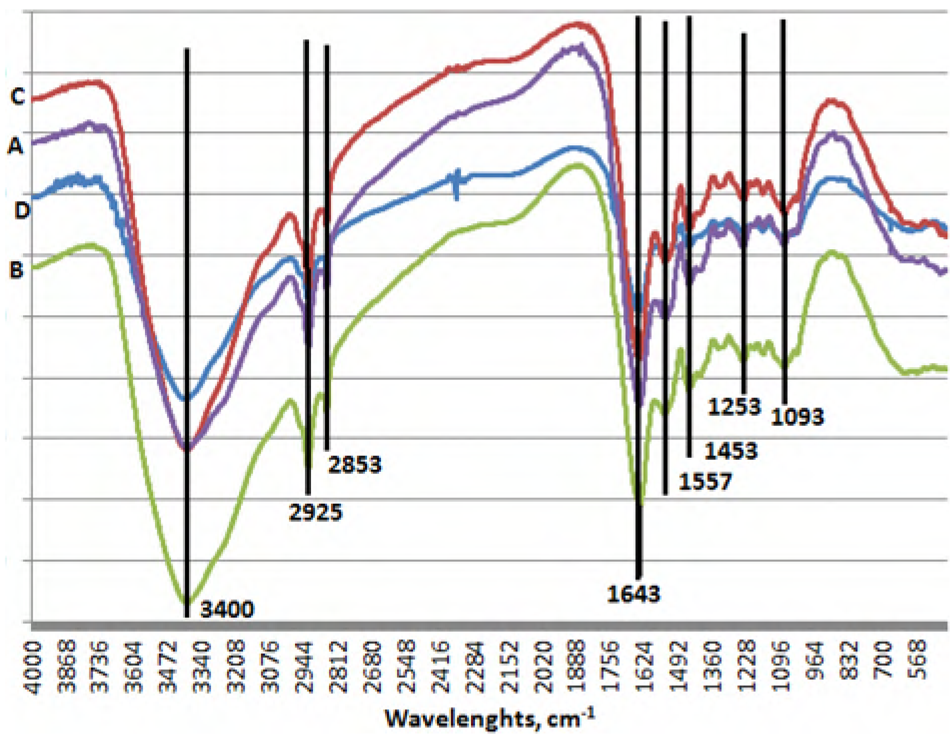

Figure 2. FTIR spectra of the developed thermo-responsive bioactive GN-alginate hydrogel containing 6.4 %wt. SA and 14 %wt. GN (A), and this GN-alginate hydrogel modified with HAs: 2.5 %wt. HAs (B); 5 %wt. HAs (C); 7.5 %wt.HAs (D)

3. Results and discussion

Based on the data by Goudoulas and Germann [6], that in a thermo-responsive hydrogel of the GN-SA-H_2O system with 5 %wt. GN and 5 %wt. SA the melting point Tm is 35.9°C, it was decided to enhance the thermal stability of the GN-alginate hydrogel and thereby bring Tm closer to the physiological level of 37°C by increasing the concentration of its components. When choosing the concentration of GN, we proceeded from the information [6] that at concentrations of more than 13 %wt. GN and temperatures below 40°C, GN chains undergo a progressive conformational change from coil to helix, forming networks of triple helices. Thus, the thermo-responsive hydrogels, the rheological studies of which were carried out, contained 14 %wt. GN and different concentrations of SA: 3.2 %wt., 6.4 %wt. or 9.6 %wt. SA. Experimental studies showed that for a hydrogel containing 14 %wt. GN and 3.2 %wt. SA, the formation of a stable

sol flow was not observed over the entire range of kinematic viscosity studies. A hydrogel with an increased content of SA, containing 14 %wt. GN and 9.6 %wt. SA, had a Tm near 71 $^{\circ}$C, and the formation of its stable sol flow was not observed in kinematic viscosity studies. According to Hernández, Sacristán and Mijangos [8], this behavior can be explained by the presence of a larger number of polymer chains responsible for more entangled bonds, and is typical for chemical gels that are covalently cross-linked and, therefore, do not melt, i.e., they are not thermo-responsive hydrogels. As can be clearly seen from figure 1, according to rheological studies, a hydrogel containing 14 %wt. GN and 6.4 %wt. SA is thermo-responsive and has a gel-sol transition, manifested in a sharp decrease in its kinematic viscosity at a physiological temperature of 37°C.

According to Venezia et al. [5] and based on data from our previous works [16, 17], which showed enhanced mechanical and transdermal characteristics of biopolymer GN hydrogels modified with HAs, in this work we added HAs to the developed thermo-responsive bioactive GN-alginate hydrogel, containing 6.4 %wt. SA and 14 %wt.GN. Analysis of the obtained hydrogels of the GN-SA-H_2O and GN-SA-HAs-H_2O systems by Fourier transform infrared spectroscopy is presented in figure 2. Tables 1, 2 shows their infrared spectral characteristics in comparison with literature data for GN hydrogel [6], for alginate hydrogel [7], and for the GN-HAs-H_2O system [5]. Absorption bands in the FTIR spectra in figure 2 are listed in table 1 to stretching

Photos to visually demonstrate the results of a study of the gel-sol transition time at a physiological temperature of 37°C for samples of the developed thermo-responsive bioactive GN-alginate hydrogel containing 6.4 %wt. SA and 14 %wt. GN (A), and for this hydrogel modified with different contents of HAs: 2.5 %wt. HAs (B); 5 %wt. HAs (C); 7.5 %wt. HAs (D).

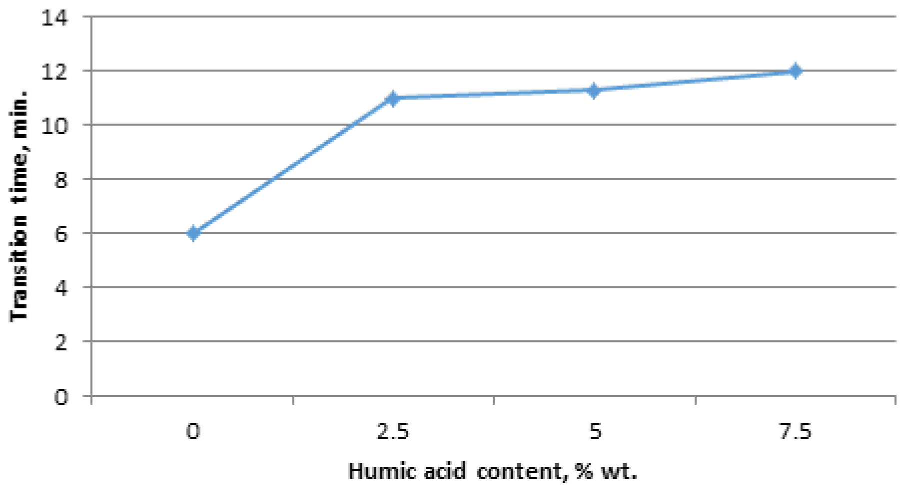

Figure 4. Graph of the gel-sol transition time at a temperature of 37°C in the developed thermo-responsive bioactive GN-alginate hydrogel containing 6.4 %wt. SA and 14 %wt. GN from the concentration of HAs in it.

υ and bending δ vibrations of the corresponding functional groups based on literature data for GN, SA and HAs [12]. It can be seen that the FTIR spectra of the GN-SA-H_2O and GN-SA-HAs-H_2O systems are similar. Small red and blue shifts in the positions of stretching and bending vibrations occurred due to GN-SA, GN-HA and SA-HA interactions similar to those observed in [5], in particular due to a conformational change in the secondary structure of GN.

Figure 3 presents visually results of a study of the gel-sol transition time at a physiological temperature of 37°C for samples of the developed thermo-responsive bioactive GN-alginate hydrogel containing 6.4 %wt. SA and 14 %wt. GN, and also samples of this hydrogel modified with different contents of HAs. Figure 4 shows a graph of the dependence of the gel-sol transition time at a temperature of 37°C on the concentration of HAs in this hydrogel.

A sharp increase in transition time from 6 min to 11 min can be seen as a result of adding 2.5 %wt. HAs to the termo-responsive GN-alginate hydrogel at 37°C. Further increasing the HAs content in the hydrogel to 5 %wt. HAs and 7.5 %wt. HAs led to a slight increase in the gel-sol transition time to 11.5 min and 12 min, respectively. Thus, these studies showed that relatively small concentrations of HAs can provide a prolonged effect of drug delivery through the use of GN-alginate hydrogel on the surface of the human body.

4. Conclusions

In this work, we developed hydrogel systems that synergistically combined the outstanding properties of natural molecular polymers GN and SA, such as low cost, nontoxicity, biocompatibility, biodegradability, and non-immunogenicity. In addition, using our own technology, HAs with antioxidant, antibacterial and anti-inflammatory activity were obtained from lignite and added to GN-alginate hydrogel, which provided a concrete chance for the technological use of HAs in accordance with the "waste-to-wealth" approach. Rheological studies confirmed that the hydrogel containing 14 %wt. GN and 6.4 %wt. SA is thermo-responsive and has a gel-sol transition, manifested in a sharp decrease in its kinematic viscosity at a physiological temperature of 37°C. The FTIR spectra of the GN-SA-H_2O and GN-SA-HAs-H_2O systems are similar. The small red and blue shifts in stretching and bending vibration positions occurred due to GN-SA, GN-GA, and SA-GA interactions are similar to those observed in the literature, in particular due to a conformational change in the secondary structure of GN. The results of a study of the gel-sol transition time at a physiological temperature of 37°C for samples of the developed thermo-responsive bioactive GN-alginate hydrogel containing 6.4 %wt. SA and 14 %wt. GN, as well as samples of this hydrogel modified with different contents of HAs, visually showed a sharp increase in the gel-sol transition time from 6 min to 11 min as a result of adding 2.5 %wt. HAs. Thus, the studies have shown that GN-alginate hydrogel, modified with relatively small concentrations of HAs, is capable of providing a prolonged effect of drug delivery when it is located on the surface of the human body.

Abstract. The research is focused on the development of the structure of the core of the integrated automated modeling system (AMS). The AMS ensures an increase in the functionality of the CAD and CAE systems by combining them with several external independent modules. The AMS modeling technological schemes of severe plastic deformation processes, the behavior of materials in deformation processes, and reducing the cost of choosing the scheme and parameters of the deformation processes. Object-oriented software was developed to analyze the influence of different initial shapes of the billets and the die sets on the changes in the billet's cross-section during deformation. The software is written in C# using the WPF interface and the page structure of the main application window. Using parametric models of processes enables automated calculations in CAE systems and the generation of 3D geometric models of die sets in CAD systems. The design of experiments allows automation research of severe plastic deformation (SPD) processes and reduces the costs of studies. Importing and accumulating calculation results in the CAE system made it possible to find the optimal values of the parameters of SPD technological processes. The parameters of the deformation models obtained based on modeling are the basis for constructing the geometry of the die set in CAD with subsequent integration with CAE to calculate the stress-strain state in the volume of the billet. Ways to expand software functions to support various SPD processes are proposed.

1. Introduction

The processes of severe plastic deformation (SPD) make it possible to obtain materials with a fine-grained structure and improved physical and mechanical properties. SPD processes have been actively developing in recent years, but their research and implementation in industry are more difficult than classical processes of metal forming (MF). Despite the difficulties in obtaining such materials, they are needed in aircraft construction, automobile construction, medicine, and other high-tech industries. Modern integrated AMS (iAMS) systems based on industrial CAD/CAE systems do not allow high-quality modeling of multi-stage technological processes of SPD. This is due to the limited capabilities of integrated AMS, particularly CAE systems, for implementing user models of the behavior of new materials, solving the problems of analyzing the modeling results, and optimizing the SPD processes. When modeling technological processes of MF [1,2], and especially SPD processes, it is necessary to automate the movement of the billet in the space between technological operations and positioning relative to the tool when using their parametric models while preserving the parameters of the stress-strain state between operations, as well as when changing the deforming tool. This is important because when automating tool change, the possibility of structural optimization is realized for the selection of deformation routes using various operations.

Automation of the design of new technological processes includes the stages of developing a conceptual model, a geometric model, and determining process parameters [3–6]. Therefore, in order to automate the formulation of the problem, a method of creating a calculation model template is proposed: to change the corresponding models or calculation parameters in the CAE system using software testing tools (IBM Rational Functional Tester, Unified Functional Testing, TestComplete, etc.) or in manual mode. After entering the parameters of the SPD process modeling in the corresponding CAE system, the user receives the SPD calculation model for the specified geometric model.

Computer-aided engineering (CAE) are used to model physical processes in various branches of mechanical engineering and metallurgy and to significantly speed up the process of designing structures of any complexity without conducting time-consuming experiments. Such systems are widely used in production and scientific research in the field of modeling processes of MF. CAE systems provide opportunities for modeling a wide range of MF processes, starting from sheet forming operations and ending with volumetric stamping or rolling operations, at different temperature modes, with loads, etc. They allow engineers and technologists to see the process of shape change of billets, as well as to investigate the stress-strain state of the processed billets and the tool. Such calculations are performed using universal CAE systems based on the finite element method (FEM) [7, 8], such as Ansys, LS-Dyna, HyperWorks, ABAQUS, QForm 3D [9–14], etc. In such CAE systems, explicit solvers for the calculation of nonlinear processes are implemented [15], which allows modeling the shape change of the billet at large degrees of accumulated deformation and the use of rheological models of the plastic flow of the billet metal. For several MF operations, the obtained shape of the billet is of primary importance, and the stress-strain state is less important. Specialized CAE systems focused only on MF processes are widely used in production.

Currently, various CAD systems have been developed for the design of individual processes (groups of typical processes) of MF, which allow to reduce the time for preparing the calculation in the CAE system. For the SPD equal-channel angular extrusion (ECAE) and twist extrusion (TE) processes, CAD was developed for designing the technological process based on a set of initial data [16, 17]. For less common SPD processes, such CAD does not exist.

2. Development of the designing processes in procurement production

When simulating SPD processes, additional problems arise related to the features of the process itself: the need to simulate various variants of billet loading schemes, large plastic deformations, changes in deformation routing, thermal mode, etc. A feature of SPD processes is that at each subsequent deformation operation, the position of the billet changes due to its rotation around one or two axes in space, which ultimately ensures the uniformity of the distribution of properties over the volume of the billet. Building a model of the SPD process, which includes 4-5 deformation operations with constant movement of the tool and rotations of the billet, requires the construction of a model for the CAE system, which for 1 deformation operation will include 2-3 auxiliary steps in which exactly the rotation of the billet and movement of the tool takes place to new provisions. Thus, the calculation model in the CAE system for the SPD process with 4-5 deformation operations includes 12-15 modeling steps, while deformation in classic MF operations is performed in 1-3 modeling steps. Manual preparation and adjustment of such a complex model takes a lot of the researcher's time. Automating the construction of such models will allow you to get a working model on the first try with little adjustment.

To date, the problems of computational complexity in modeling plastic deformation processes, which are labor-intensive and require significant expenditure of machine time, remain unsolved. The use of parametric models to perform optimization calculations additionally leads to a large number of calculation cycles, which in some cases makes such a modeling scheme inefficient.

The purpose of the research: improve the quality of integration of CAD/CAE systems and develop the functionality of iAMS based on the creation of an object-oriented core for combining external independent modules that provide flexible and adequate modeling of multi-stage SPD processes using parametric models.

3. Structure and functionality of the integrated AMS core

To solve several tasks in the design of SPD processes and the development of iAMS functionality, it is necessary to develop a core that should provide the possibility of modeling multi-stage combined SPD processes; support the integration of external modules with modern CAD (SolidWorks) and CAE (Abaqus, QForm) for modeling stress-strain state of billets during deformation; to provide research into the technological possibilities of new SPD processes based on the parameterization of models of billets and die sets [18].

Based on the analysis of the capabilities of CAD/CAE systems, the functions that should support the core of integrated AMS and the necessary mechanisms for this are highlighted:

- to maintain a data structure for organizing a set of modules;
- to provide a flexible exchange of information between system modules, which can be configured;
- to ensure the preservation of the system state in the form of a collection of objects that contain the parameters of this state;
- the iAMS core should support saving the state parameters for the executed project in (XML) format and restoring the system state parameters for the selected project upon loading. If necessary, store meta-information about modules;
- to ensure the connection of external modules with a low degree of connectivity;
- to provide the possibility of planning experiments in the form of a sequence of calculations with given initial parameters, for example, a List of objects in each module for saving data;
- to ensure the task of sequentially calling modules to perform the necessary sequence of calculations;
- to ensure the execution of optimization procedures, the setting of intervals for the variation of parameters that may change during the optimization process;
- performs general settings for iAMS, including the location paths of components and files necessary for operation.

The physical model of iAMS includes a number of typical external functional modules, which can be conditionally divided into two groups. Modules that solve system problems: connecting modules to organize interoperability, ensuring the selection of processes and routes for the next simulation, and integration with CAD/CAE systems. Modules for planning and carrying out experiments, as well as modules for directly solving the problems of modeling plastic deformation processes using SPD: creating a geometric model in the CAD system, modeling in the CAE system using parameterized scripts, and FEM.

Let's consider the areas of responsibility and functionality of the core classes of integrated AMS. The class diagram of the integrated AMS core is shown in figure 1, which presents the connections between classes of the core, which provides integration with functional modules (Module class) of the design system. This makes it possible to ensure the compatible operation of the system components for simulating the sequence of operations of the technological process specified by the user.

The main task of the kernel is to perform several system operations to ensure the joint operation of the functional modules of the system. The Core class includes a static collection of elements (Element) and thus provides modules access to information common to all. The kernel is also responsible for initializing the necessary modules at the start of the program. The Element

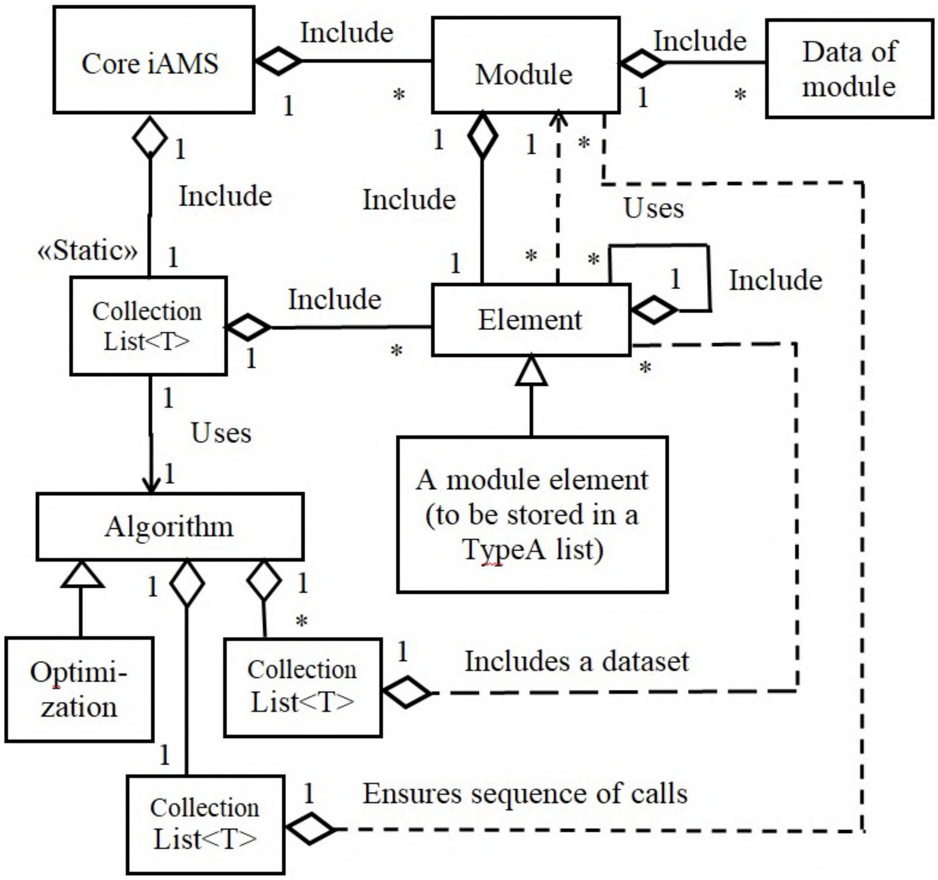

Figure 1. Class diagram of the core of the integrated AMS for designing SPD processes based on the development of a parametric model of billets and die sets.

base class includes a list of base class objects so that it is possible to prepare several options for output parameter tasks for each module, such as billets, fixtures, deformation conditions, etc, and store these settings in a file for later use.

Each module includes elements necessary for it and provides integration and use of external CAD/CAE and other systems. Each module has its own class system to ensure its operation depending on the purpose. For integration with the core, each module includes one inheritor object from the Element class. It contains data that is the result of the module's operation. These results may be necessary for the operation of other modules, as well as for presenting the results of the simulation as a whole. A class can also contain meta-information about the module to which it belongs. Another important responsibility of the system core is to save simulation results and output data to a file implemented in this project. The kernel provides the ability to restore the system state parameters that were saved and thus provides the initial configuration of the modules to continue the simulation. At the same time, a separate module ensures the setting of paths for access to files necessary for the work of other modules (not developed by the author of this work). AMS is implemented in C# in the MS Visual Studio environment using the WPF interface [19]. The main application window is built using a page structure that allows you to build AMS modules independently od them when needed. Each of the AMS modules is associated with its class.

Another responsibility of the system core is to ensure the planning of experiments using connected modules. For this, the Algorithm class was developed, which includes two collections of objects. One of them allows the user to choose the sequence of work performed by the system modules for a specific technological process, the second allows to select and form sets of initial data for each simulation experiment.

During operation, the algorithm sequentially transfers control and output information to the modules in a cycle, which in turn receives sets of output data for each experiment from the basic global list and performs their work.

After calculations in a specific experiment, the modules change the state of the data in a separate global list. After executing a given sequence of module calls, information about the state of the system (simulation results) is stored in a separate XML file, and then the work is repeated for a new set of output data.

4. Discussion

An important issue in conducting research is the planning of experiments. The interface of the module for planning the process of research on the modeling of the SPD process includes two elements of the ListBox type and a dynamically created table, as well as control elements of the Button type.

To plan experiments on the modeling of SPD processes, it is necessary to create lists of objects that contain variants of tasks, for example, several billets with different sizes, parametric models of equipment, etc. (figure 2, figure 3a).

Then, to study a specific technological process, the sequence of work with different modules is set. For this, when the module is activated, the entire set of modules is displayed in the interface. After that, the user selects the sequence that is required for the simulated process. When the Add button is pressed, the name of the modules selected by the user is displayed in the list. These modules are selected from the general list (figure 3a), which is shown in the

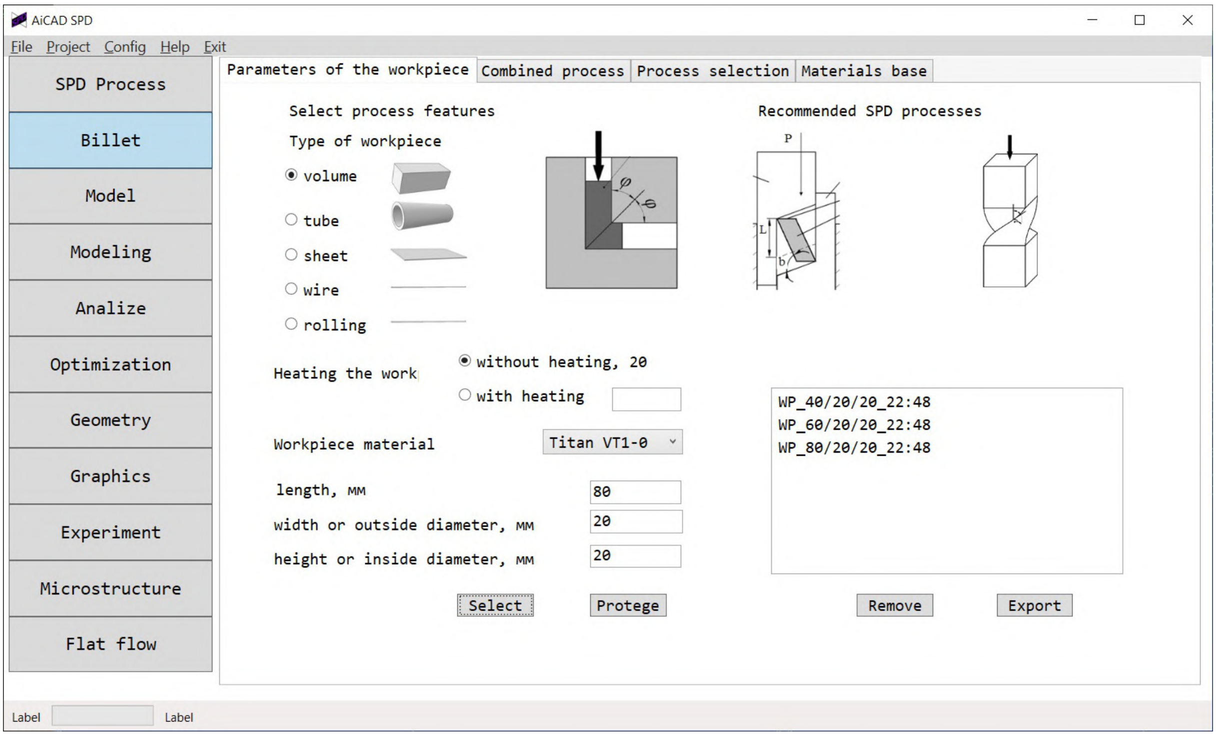

Figure 2. View of the user interface for working with the billet and process type selection module.

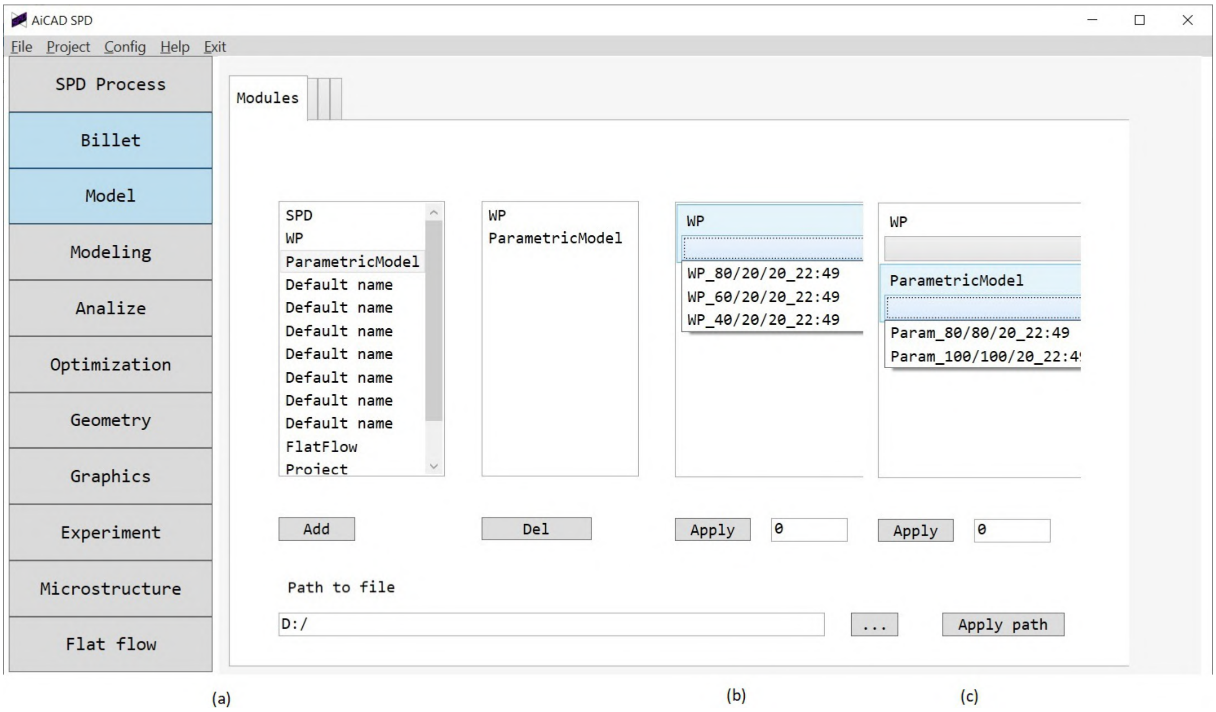

Figure 3. View of the user interface for working with the experiment planning module for the selected process.

left ListBox, and are displayed in the next ListBox (in the center). Lists of options for billets, equipment, and other previously created objects are displayed in the ComboBox included in the ListBox (right).

This list is subject to change. The display of pre-created lists of billets (see figure 3b) and equipment (see figure 3c) is provided in the ComboBox.

After checking the set of selected modules, you need to press the Apply button so that a list of experiment planning is dynamically generated for the applied modules (a table with the required number of terms). The columns of the table create the names of the modules (components) selected for operation.

In the table, each row corresponds to a separate modeling process. In the corresponding cells for each module, object indices are set, which contain the values of the initial parameters for modeling. By specifying objects with pre-prepared data in this way, you can successively fill rows in the table. After the planning of the simulation process is completed, a cycle of sequential activation of modules and execution of calculations takes place. Obtaining additional information from other modules and saving the results of their work is the responsibility of each module.

To simulate the selected technological process, the model is automatically built for the Abaqus CAE system. According to the parametric model of the technological process, a Python script is formed, which includes a set of Abaqus commands [20]. Interaction is implemented through the interface with the CAE Abaqus pre-processor. The Modeling module launches each model from the experiment plan to perform calculations (figure 4). As a result of modeling in Abaqus CAE, a file in .odb format is created for each process model, which is the internal format of Abaqus.

The import of simulation results is implemented in the Analysis module. A Python script is used to connect to the Abaqus post-processor. In the interface of the Analysis module, it is

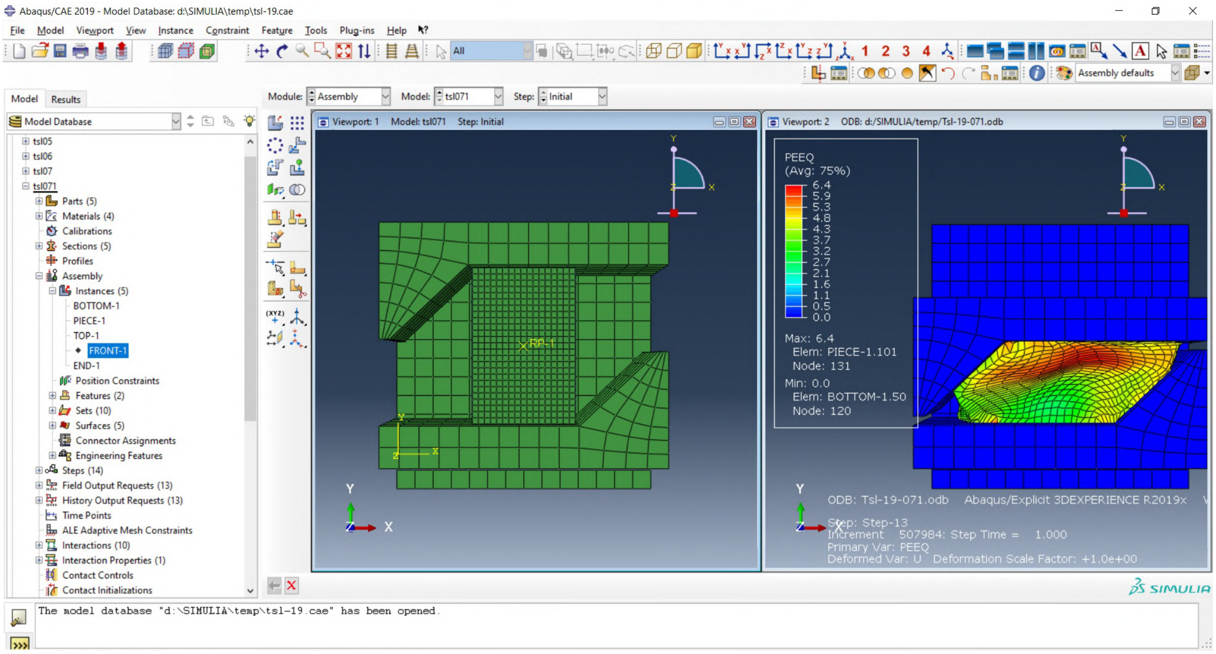

Figure 4. Model of the technological process in the Abaqus CAE system.

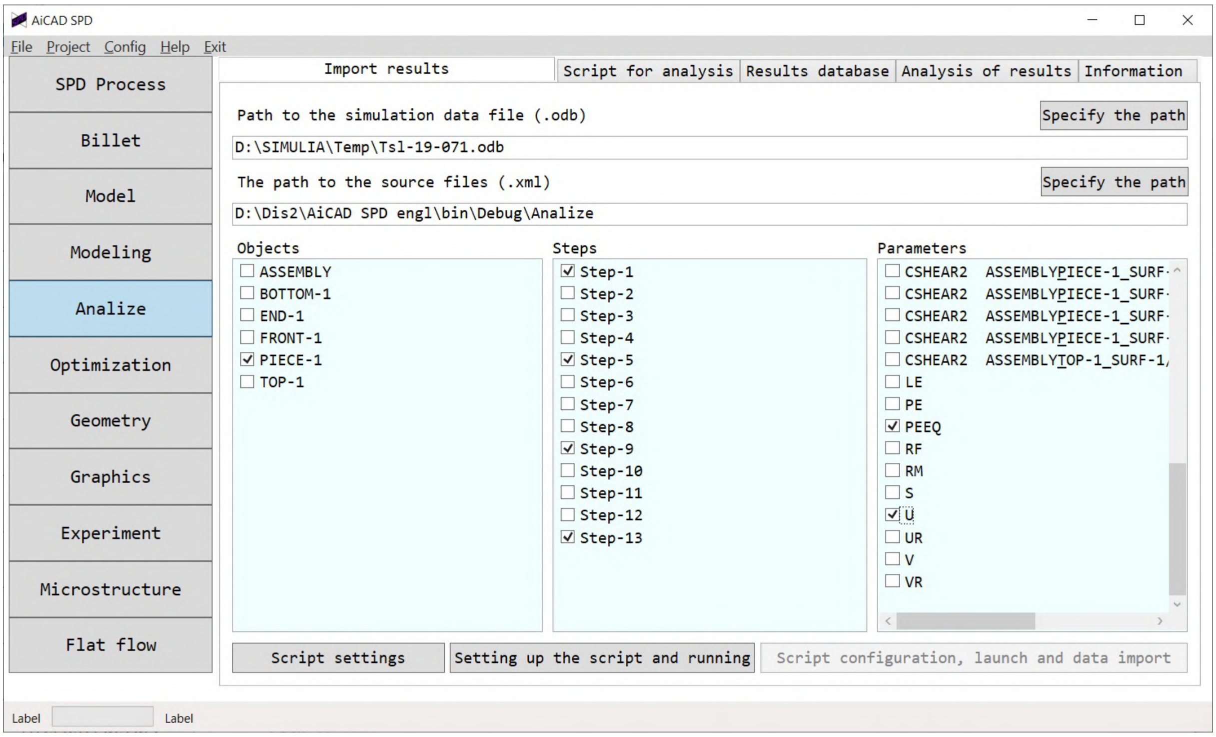

Figure 5. Interface for importing simulation results.

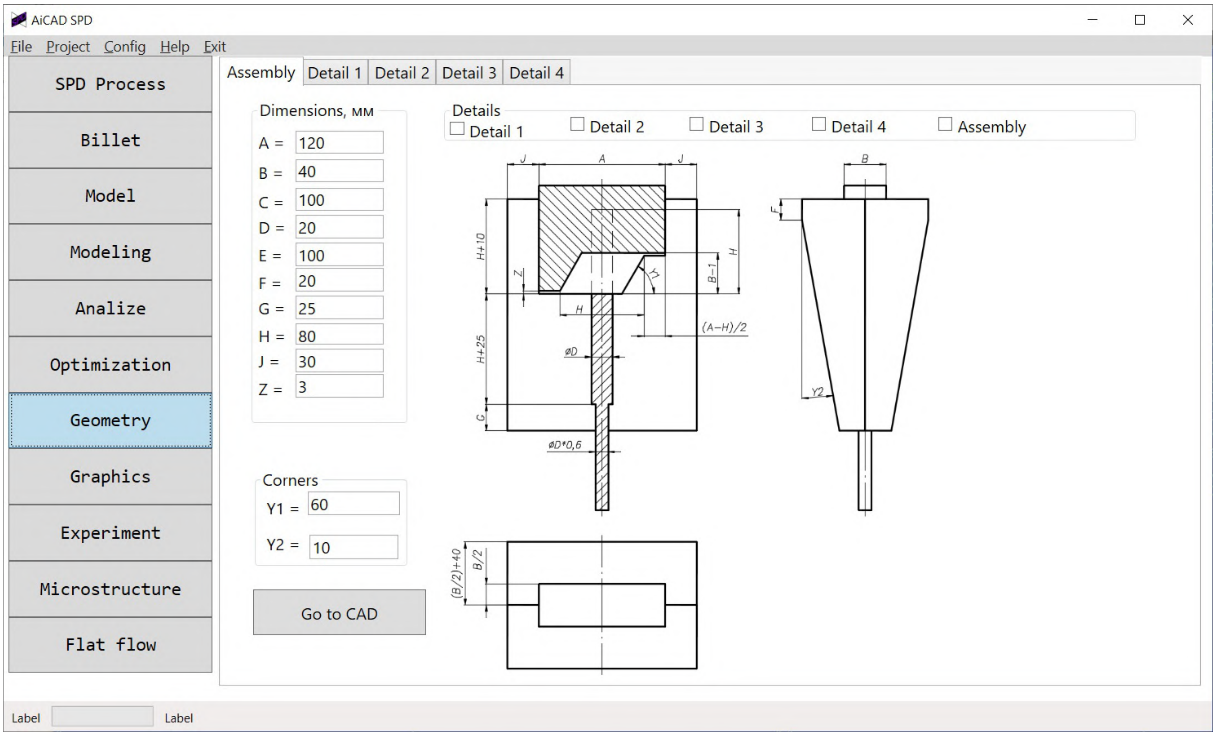

Figure 6. Construction of the geometry based on the parametric equipment model.

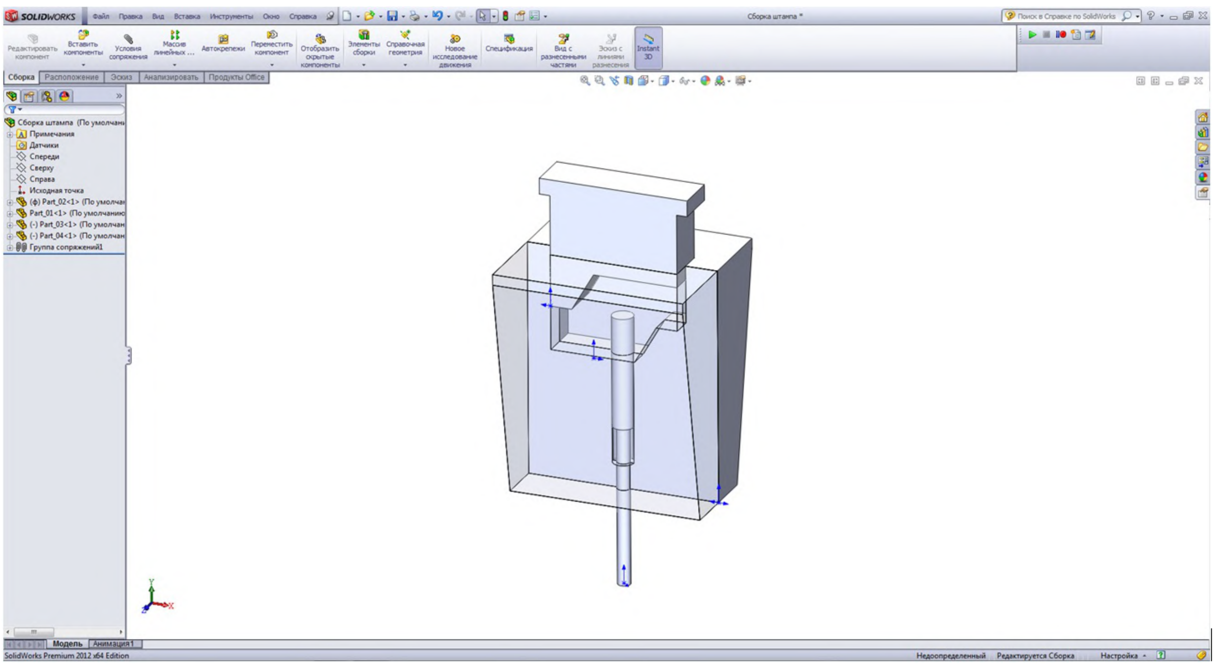

Figure 7. The 3D model of the equipment is generated in SolidWorks CAD.

necessary to select a file with the results of calculations in .odb format. In the Objects field, a list of all parts of the model is displayed. A list of all calculation steps is displayed in the Steps field (figure 5). The Parameters field displays a list of parameters whose values can be imported. The researcher in each field chooses the values he needs for further analysis of the technological process. Next, you need to press one of the buttons in the lower part of the module.

As a result of the simulation cycle, one of the technological process options is selected. The interface of the "Geometry" module (figure 6) displays the parametric model of the selected technological process and allows you to make changes to the dimensions. Clicking on the "Transfer to CAD" button leads to the transfer of a 3D geometric model to the SolidWorks CAD system (figure 7). Interaction with SolidWorks CAD is implemented using the SolidWorks API.

5. Conclusions

The analysis of the state of research in the field of the use of automated design systems made it possible to formulate the problems of creating integrated AMS in the field of processing materials by pressure and to develop typical stages of modeling technological processes for SPD processes. It has been established that a number of problems are solved based on the development of parametric models of billets and die sets used in SPD processes. These models are the basis for choosing a deformation scheme and integrating CAD/CAE systems into a single CAD system. The use of parametric models for the construction of geometry in CAD systems and calculation models for CAE systems increases the degree of automation of the design of technology for processing materials under pressure.

The structure of the object-oriented iAMS core has been developed, which provides an increase in the functionality of iAMS by combining a number of external modules for modeling a number of technological schemes, and adequate modeling of the behavior of materials in deformation processes.

A two-stage approach to modeling the multi-stage SPD process is proposed. In the first stage, preliminary calculations are performed to determine the comparative efficiency of the studied deformation schemes, for which mathematical models and a method of calculating the change in the cross-sectional area of billets in dies of different shapes are developed.

Object-oriented software in the C# programming language was developed to analyze the influence of different initial shapes of the billets and the die sets on the degree of change in the cross-section of the billet during SPD according to the reverse shear scheme of RS-60 and RS-180. Analysis of the influence of the cross-section geometry of the punch showed that increasing the angle of inclination of the punch surface intensifies the process of deformation of the billets. The analysis also showed that the influence of the angle of inclination of the deforming surfaces of the die most significantly affects the degree of change in the shape of the cross-section of the billets. The degree of this influence is most pronounced for billets with a cross-section in the form of a parallelogram.

In the second stage, an analysis is carried out using the CAE system of the stress-strain state of the billet and the stability of the behavior of the billet during deformation, since an increase in the angle of inclination of the deforming surfaces of the punch can lead to the turning of the billet or an unstable passage of the deformation process.

In the course of further improvement of the software, it is planned to develop a common format for storing the description of the SPD process in XML format.

Abstract. The article presents designe of rapid-hardening, non-shrinking cementitious mixtureses, which allows solving the problem of rehabilitation of concrete structures and has a positive effect of environmental sustainability. To ensure the maximum dense packing of the cement mixture, the granulometric composition of the sand was optimized. Mathematical models of physical and technical indicators of repair mixtures based on Portland limestone cement and optimized sand composition were obtained, which quantitatively characterize the action of high-alumina fly ash, sodium hydroaluminate, polycarboxylate ethers with increased rapid hardening, early strength, adhesive strength and reduction of shrinkage deformations. A combination of Portland limestone cement, fly ash, polycarboxylate ethers and alkaline activator ensures the intensification of early structure formation due to the formation of hydrocarboaluminates and alkaline hydroaluminosilicates; larger fractions of limestone particles and fly ash act as a microfiller, which in the complex contributes to increasing the early strength and stability of the cementitious matrix.

1. Introduction

Currently, sustainability is an important issue worldwide [1], particular in the construction [2]. The production of cement and concrete is responsible for the production of 7% of the total CO_2 emissions in the world [3], since concrete is the second most used commodity in the world [4]. That means that it is used a lot and that use costs money, pollution, and energy. Concrete is an excellent construction material (low cost, shapable, fire resistance, low-tech but robust production from widely used raw materials). When done right, concrete is the most environmentally friendly material on the planet. In this case, it is possible to build durable concrete structures that have a service life of 100+ years [5].

At the same time, environmental degradation in the world leads to ecological and other problems. That is why it is necessary to use environmentally friendly materials for the rehabilitation of buildings [6]. In Europe, in recent years, the budget for maintenance and repair has been about half of the cost of construction. In Ukraine, the number of destroyed buildings has increased dramatically as a result of the war. One of the cardinal and most economical ways of rebuilding houses is rehabilitation instead of reconstruction of damaged concrete structures [7].

The sustainability of concrete structures is crucial, especially due to the use of concrete as the main construction material. The problem of concrete repair and rehabilitation is becoming increasingly important due to its positive impact in terms of socio-economic benefits and environmental sustainability. The built environment is responsible for about 40% of global emissions over the entire life cycle of a project [8].

In accordance with the directions of sustainable development, concrete structures must meet technical and functional requirements throughout their life cycle [9]. At the same time, under the influence of external loads and environmental influences, reinforced concrete structures are prone to damage. Cracks in reinforced concrete reduce the durability of structures and lead to their unsuitability during operation. Therefore, the problem of repairing building structures using various types of construction mixtures is currently acute. At the same time, it is necessary to ensure the speed of curing of repair mortars, as well as the durability and reliability of buildings [10, 11].

Special repair mixes are used to repair the original surface quality of concrete structures. The use of such materials in concrete surface repair eliminates the need to completely replace the damaged area. At the same time, a balance should be maintained between the manufacturability of applying thixotropic repair mixtures, the final strength, the rate of strength gain, and the durability of the repaired structure [12]. Therefore, there is a need to find formulation solutions to regulate the properties of repair mixtures based on Portland cement systems, in particular, the rate of hardening and durability. Currently, cement, polymer and polymer-modified mortars are used to repair concrete structures [13].

Cement-based mixtures are widely used materials for the repair of reinforced concrete structures [14]. These materials are compatible with the concrete substrate in terms of their material composition, have adhesion to the substrate and ease of repair work [15]. In addition, in order to improve their durability, active mineral additives, fly ash [16], blast furnace slag [17], and zeolite [18] are often used in the mixtures [19, 20].

At the same time, cement repair mortars usually have problems with high shrinkage [21, 22]. Therefore, a promising direction is to modify cement-based repair materials using new generation superplasticisers [23]. According to Liu et al. [24], During curing, such cements can compensate for the shrinkage of concrete and maintain the required stress state for a long period of operation. In addition, repair mixtures should be characterised by high frost resistance and water resistance, and the main requirement for high-quality repairs and an important condition for the long-term operation of repaired concrete is to ensure the compatibility of repair materials with the damaged base both in the hardened state and during curing [25]. During curing, such cements can compensate for the shrinkage of concrete and maintain the required stress state for a long period of operation. In addition, repair mixtures should be characterised by high frost resistance and water resistance, and the main requirement for high-quality repairs and an important condition for the long-term operation of repaired concrete is to ensure the compatibility of repair materials with the damaged base both in the hardened state and during curing [26].

When using repair mortars, it is often necessary to accelerate their curing kinetics in the early period of hydration. Since rapid setting of cement mixtures is required during repairs, curing accelerators are introduced into their composition [27, 28]. The accelerators used are alkaline accelerators based on alkaline aluminates or alkaline silicates, alkali-free accelerators developed on the basis of mixtures of aluminium sulfate and hydroxide [29, 30].

Alkali-activated materials are environmentally friendly repair materials and they have good potential for use in concrete repair [28,31]. However, the problem with their use is high shrinkage and cracking [32]. The joint effect of dihydrate gypsum and alkali metal salts additives can have a significant impact on the early structure formation of grouting systems [33]. At the same time, carbonates and silicates of alkali metals lead to accelerated cement dough hardening and loss of plastic properties of the system due to their interaction with gypsum dihydrate [34]. Therefore, the expediency of using neutral salts, such as Na_2SO_4, $Na_2S_2O_3$, $Na[Al(OH)_4]$, etc. [35, 36].

Currently, sodium aluminate $Na[Al(OH)_4]$ is an effective alkaline additive that increases the water resistance of concrete and mortars [37]. This alkaline accelerator significantly reduces the shrinkage of mortar and concrete and increases their crack resistance [38]. The principle of operation of such an additive in mixtures is to accelerate the hydration of cement with the formation of submicrocrystalline hydrated phases, which provides high strength [39, 40]. Aluminium accelerator increases the concentration of $Na[Al(OH)_4]$ – in the cement batter. This means that a significant portion of the aluminium coming from the accelerator must be absorbed in the earliest hydration period. Thus, as a result of the reaction with the $Na[Al(OH)_4]$ accelerator, rapid formation of C-A-H phases occurs in the cement batter, which leads to a higher water demand in the cement [41].

Krivenko et al. [42] showed that the introduction of PCE polycarboxylate superplasticizers slows down the setting time, improves the consistency, and reduces the rapid development of the strength of cementing system. Alkali-aluminate nanocomposite with polycarboxylate esters of the C-A-N-H-PCE type belongs to the class of engineering materials. The structure of the nanocomposite consists of layered double hydroxides (CaAl LDH) and organic additives synthesised by sol-gel technology, which makes it possible to produce non-shrinking, fast-hardening cements.

On the other hand, purposeful formation of their mesostructure is important for repair mixtures [43]. Improper design of repair mixtures is a frequent cause of damage and destruction of restored surfaces. Improved operational properties (shrinkage deformations, crack resistance, bond strength with the base, waterproofing, etc.) can be achieved by properly selected granulometric composition of sand, as well as by the introduction of mineral additives [44, 45]. Fly ash is widely used as an additional cementitious material (SCM) for concretes and mortars [46]. The main component of fly ash is a vitreous aluminosilicate phase in the form of spherical particles up to 150 µm in size, which allows increasing the workability of concrete and mortar mixtures [47]. The introduction of fly ash allows reducing heat generation and shrinkage deformations of concrete, providing economic and environmental advantages [48, 49]. The above data show that in order to ensure the rapid restoration and repair of elements of buildings and structures, there is an urgent need to search for prescription solutions for regulating the properties of cement mixtures.

The aim of this article is to design the compositions of rapid-hardening, non-shrinking cementitious mixtures for increasing the sustainablity of concrete structures, to study the processes of their structure formation and the determination of physical and mechanical properties.

2. Raw materials and testing techniques

The samples under study were Portland cements CEM II/A-LL 42.5 R (SSA = 3900 cm^2/g) produced by JSC Ivano-Frankivskcement (Ukraine). Portland cement clinker was characterized by the following mineral composition (mass.%): C_3S – 62.5, C_2S – 13.8, C_3A – 6.7, C_4AF – 12.3; content of alkaline oxides in the clinker (mass.%) was: K_2O – 1.2 and Na_2O – 0.14.

The active mineral aluminum-containing additive fly ash (FA) from Burshtyn TPP was used for research. The specific surface area of the fly ash is $SSA = 4200\,\mathrm{cm}^2/\mathrm{g}$. For fly ash, the content of the fraction up to $1\,\mu$m is 2.21%, the maximum surface activity in the bimodal distribution reaches $K_{\rm isa} = 3.81\mu\mathrm{m}^{-1}$vol.% and $K_{\rm isa} = 2.42\,\mu\mathrm{m}^{-1}$vol.% and is assigned to particles of $0.23\,\mu$m and $3.85\,\mu$m in size.

The alkaline curing activator sodium tetrahydroxoaluminate $Na[Al(OH)_4]$ was used. The mass fraction of sodium aluminate in the additive is 40 mass. %. The pH of the sodium aluminate solution is 13.0 – 13.3. As a superplasticizer based on polycarboxylate ethers (PCE) was used. The complex modifier $Na[Al(OH)_4]$-PCE was used in the development of a rapid-hardening non-shrinkage cementitious repair mixtures. Determination of the effectiveness of additives that accelerate curing, increase the strength of cement mixtures of the basic composition ΔR was carried out in accordance with DSTU B V.2.7-69.

Fine aggregate sands with a fineness modulus of $FM_{1.25}$ (fine sand of the Davydiv deposit, Ukraine) and $FM_{2.76}$ (coarse monofractional sand) were used to design the composition of cement mixtures. The void content of these sands is 46.5% and 47.5%, respectively, and the content of clay and dust particles does not exceed 1.5 mass. %, in particular, for fine sand. Optimization of sands was carried out to obtain a mixture of fine aggregate in the ratio $FM_{2.76} : FM_{1.25} = 100 : 0$; 75 : 25; 50 : 50; 25 : 75; 0 : 100. Fly ash was used to study the characteristics of the optimized composition of the sand mixture.

Tests of granulometric composition, fineness modulus, bulk density, and void content of sands were carried out in accordance with DSTU B V.2.7-232:2010. The workability of the fresh mixtures was measured on a flow table according to EN 1015-3. The compressive and flexural strengths of the cement mixtures were determined on prism specimens measuring $40 \times 40 \times 160$ mm. The strength of the mixtures was measured after 14 h, 24 h, 2 and 28 days under different curing conditions. The shrinkage-expansion deformations of the mixtures were studied on $20 \times 20 \times 160$ mm beam specimens stored in water for 7 days of curing, after which the specimens were cured in air-dry conditions. The adhesion strength of the repair mixture to the substrate was determined by the method of tearing off a metal tear-off with subsequent assessment of damage. The chemical composition of Portland cement clinker was determined using the X-ray spectrometer ARL 9800 XP. The particle size distribution of the fly ash was obtained using a Mastersizer 3000 analyzer by laser diffraction. The phase composition of the initial substances and interaction products was studied using X-ray diffractometry.

3. Results and discussion

To ensure the densest possible packing of the cementitious mixtures, the grain size distribution of sand of different particle size distribution was optimized. It was found that the bulk density of coarse sand with $FM_{2.76}$ and very fine sand $FM_{1.25}$ is 1463 kg/m^3, and when compacted, it reaches 1673 and 1600 kg/m^3, respectively. For a mixture of $FM_{2.76} : FM_{1.25}$ sands in the ratio of 75:25, 50:50, 25:75, the bulk density increases and reaches 1533 kg/m^3, 1522 kg/m^3, 1479 kg/m^3, and when compacted, it increases to 1690 kg/m^3, 1673 kg/m^3, 1655 kg/m^3 compared to sands with $FM_{2.76} : FM_{1.25} = 100 : 0$; 0 : 100. When mixing 25 mass. % coarse sand ($FM_{2.76}$) and 75 mass. % of fine sand ($FM_{1.25}$), the modulus of the mixture increases from 1.25 to 1.57, and the void decreases by 10.7%. For a mixture of sands $FM_{2.76} : FM_{1.25} = 50 : 50$, the fineness modulus increases from 1.25 to 1.85, the void decreases from 46.8% to 42.5%, and the bulk density increases from 1410 kg/m^3 to 1522 kg/m^3. With a decrease in the content of fine sand in the mixture to 25% ($FM_{2.76} : FM_{1.25} = 75 : 25$), the fineness modulus increases to 1.87 ($FM_{1.87}$), and the lowest void in the bulk and compacted states is characteristic, which is 42.2% and 36.2%.

The effect of fly ash on the characteristics of the optimized composition of a mixture of sands with $FM_{1.87}$ was investigated. The ratio of sand with $FM_{1.87}$ and fly ash was changed: $FM_{1.87} : FA = 100 : 0$; 75 : 25; 50 : 50; 25 : 75; 0 : 100. It was found that increasing the amount of fly ash in the mixture to 75 mass. % leads to a decrease in the bulk density to 1150 kg/m^3 and an increase in the void content to 52.1%. At the same time, the composition with a ratio of $FM_{1.87} : FA = 75 : 25$ is characterized by the highest bulk density of 1683 kg/m^3 and the lowest void content of 35.3%.

Based on the obtained results, the design of effective compositions of rapid-hardening non-shrinkage mixtures was carried out using two-factor mathematical planning of the experiment. The optimized sand composition with $FM_{1.87}$ was used in the experiment. The composition of the repair mixture without additives (Cement : Sand = 1 : 2) was taken as a reference. Fly ash ($0-20.0$ mass.% (X_1)) and a complex modifier - Na[Al(OH)$_4$]-PCE($0-5.0$ mass.% (X_2)) were used as variable factors. When changing the formulation levels of the selected factors, the mobility of the cement mixture was stabilized at the Flow $170-180$ mm.

Based on the results of the calculations, isoparametric diagrams of changes in the hardening time, compressive and flexural strength after 14 h; in compression after 28 days under normal conditions and at $T=-5...+5\,°C$ of curing were constructed (figure 1, a-f). For the mixture without additives ($W/C=0.38$), the initial and final settings times are 240 and 285 min, respectively.

The introduction of 2.5 mass.% Na[Al(OH)$_4$]-PCE (X_2) leads to an increase in the water requirement of the repair mixture from 0.38 to 0.40. In this case, the early strength after 14 hour of curing increases from 1.8 to $2.9-3.0$ MPa, after 1 and 28 days it is 18.9 MPa and 63.7 MPa; after 2 days the strength is 34.2 MPa. An increase in $Na[Al(OH)]_4$-PCE to 5.0 mass.% leads to a reduction in the curing time to 90 min. At the same time, the strength decreases by 12 % at the age of the 1 day and by 5.0% after 28 days of curing under normal conditions. The introduction of 10 mass.% fly ash into the mixture, which determines the factor (X_1), offsets the negative impact due to the plasticizing effect, which, depending on the content, leads to a decrease in W/C from 0.43 to 0.41, with the initial settings time of 235 min. Thus, the introduction of 10.0 mass.% fly ash and 5.0 mass.% Na[Al(OH)$_4$]-PCE allows obtaining accelerated settings times - 70 min (initial) and 140 min (final), and high early flexural and compressive strengths - 3.7 MPa and 10.0 MPa, respectively. The highest standard strength (70 MPa) is characterized by the mixture with additives of 2.5 mass.% Na[Al(OH)$_4$]-PCE and 10.0 mass.% fly ash. It is shown that an increase in the fly ash content to 20.0 mass.% leads to a slower hardening time and a decrease in strength. Reducing the fly ash content to $5.0-7.0$ mass.% in the mixture with the simultaneous introduction of 5.0 mass.% Na[Al(OH)$_4$]-PCE will accelerate the hardening time to $30-40$ min and obtain the required strength characteristics.

It was found that for mixtures modified with 2.5 mass.% Na[Al(OH)$_4$]-PCE after 28 days of curing under variable curing conditions ($T=-5...+5\,°C$), the compressive strength is 56.0 MPa. Under conditions at low positive and negative temperatures, the highest strength (57.0 MPa) is characterized by a mixture containing 5.0 mass.% alkaline modifier $Na[Al(OH)_4]$-PCE.

Analysis of the experimental data of mathematical modelling in a given interval of changes in the composition ratio shows that the introduction of an optimal amount of $2.5-5.0$ mass.% Na[Al(OH)$_4$]-PCE and 10.0 mass.% fly ash into the composition of the modified repair mixture and the optimal composition of sand ($FM_{2.76}:FM_{1.25}=75:25$) provides a compressive strength of $66.0-70.9$ MPa after 28 days. It was established that the high technical effect of the repair mixture is achieved after 14 hours ($\Delta R_{c14}=64.0\%$). Thus, the optimal composition of the non-shrinkage repair mixture (2.5 mass.% Na[Al(OH)$_4$]-PCE and 10.0 mass.% fly ash) can be classified as a rapid hardening mixture ($R_{c1}/R_{c28}=31.0\%$; $R_{c2}/R_{c28}=63.0\%$, $R_{c28}=70.9$ MPa).

Studies of the deformations of cement mixtures have shown that during 7 days of curing in water, insignificant expansion deformations are observed for all compositions, varying from 0.10% (0.06 mm/m) to 0.15% (0.25 mm/m). After 28 and 56 days of curing in air-dry conditions, the cement mixture without additives has the highest shrinkage strains (0.78 and 0.81 mm/m). For the developed rapid hardening cement mixture (2.5 mass. $Na[Al(OH)_4]$-PCE and 10.0 mass.% fly ash), the shrinkage deformation is 0.08 mm/m. The adhesion strength to the concrete base after 28 days is 3.2 MPa.

The method of X-ray phase analysis was used to study the hydration characteristics of cement paste modified with the combined alkaline additive Na[Al(OH)$_4$]-PCE after 1 day of hardening. As can be seen from figure 2, the phases of portlandite ($d/n=0.263; 0.492$ nm) and ettringite ($d/n=0.973; 0.560$ nm) are fixed for cement paste without additives after 1 day of hardening. At the addition of 2.5% Fly ash- Na[Al(OH)$_4$]-PCE in 2.7 time decrease of the portlandite line

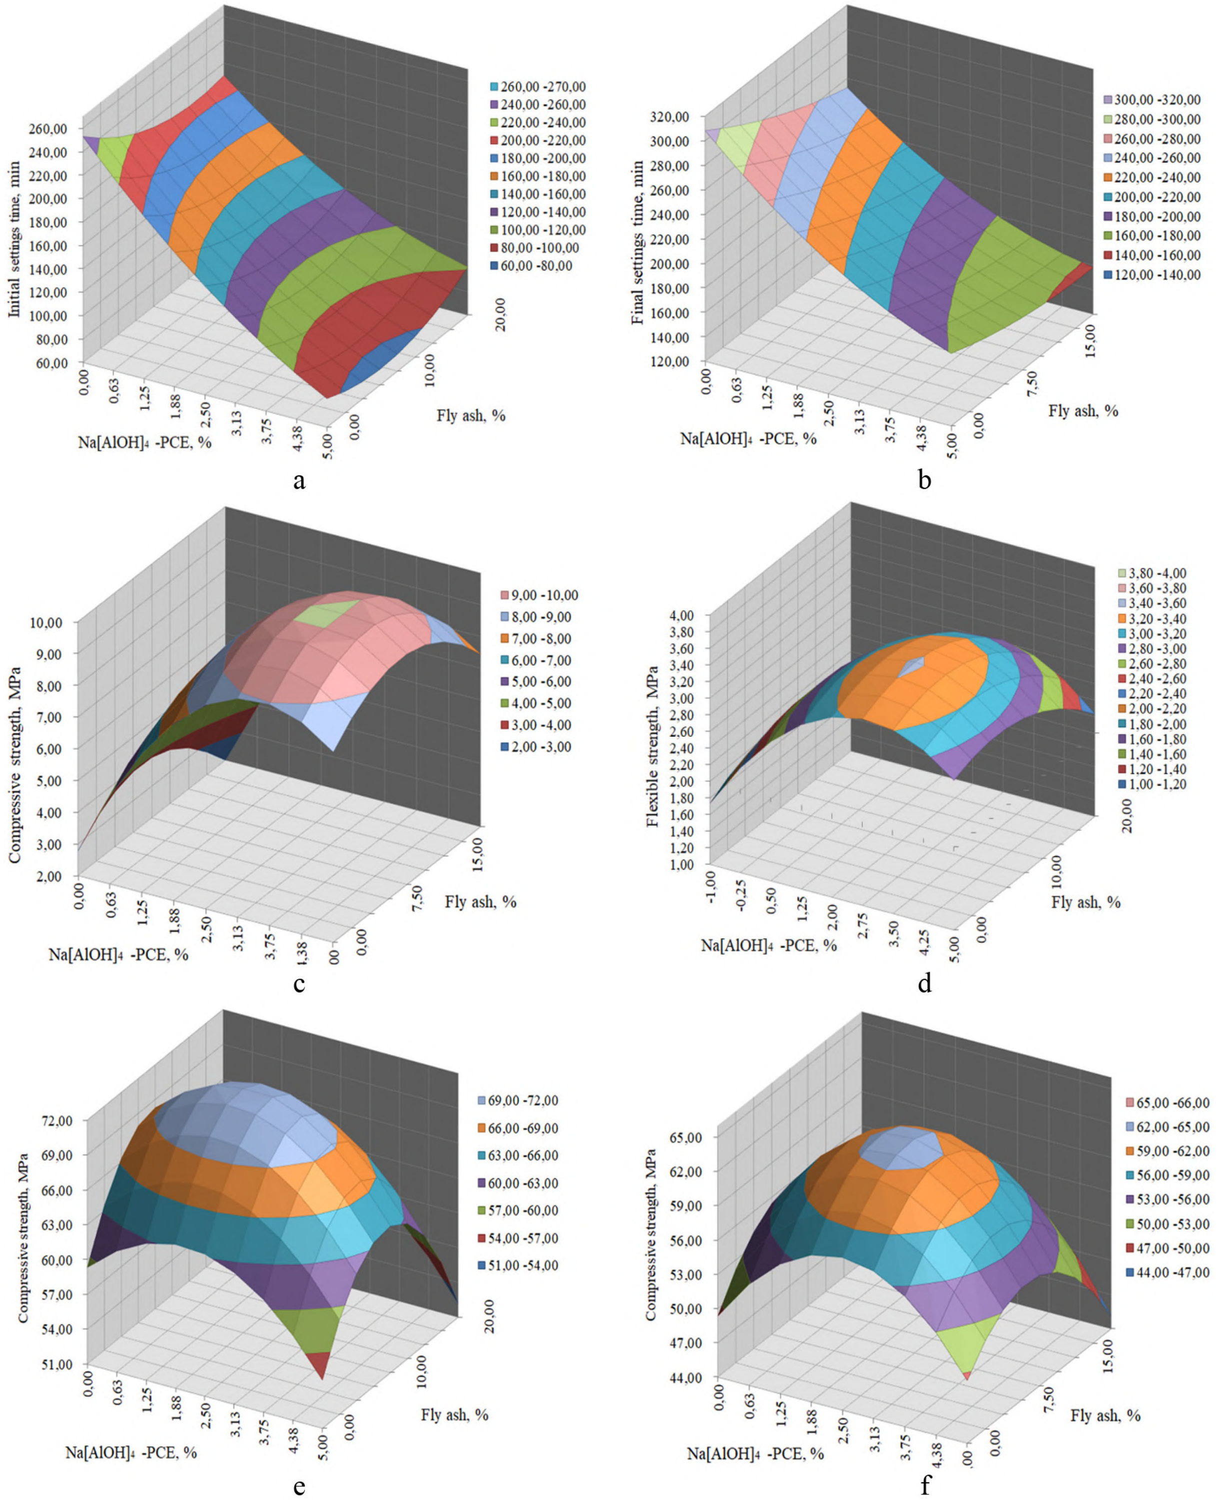

Figure 1. Isoparametric diagrams of changes in the initial (a) and final (b) hardening times, compressive and flexural strengths after 14 hours (c, d), compressive strength after 28 days under normal conditions (e) and at $T = -5 ... +5\,^{\circ}\mathrm{C}$ (f) hardening.

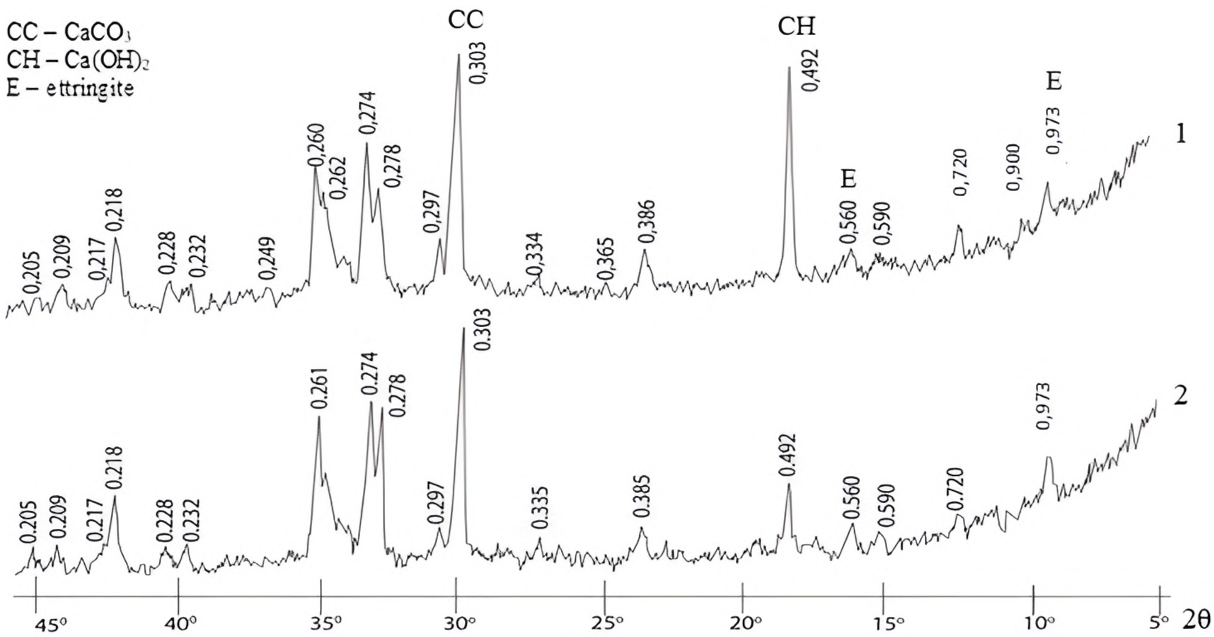

Figure 2. Diffractograms of paste at the age of 1 day: 1 – without additives; 2 – FA-Na[Al(OH)$_4$]-PCE.

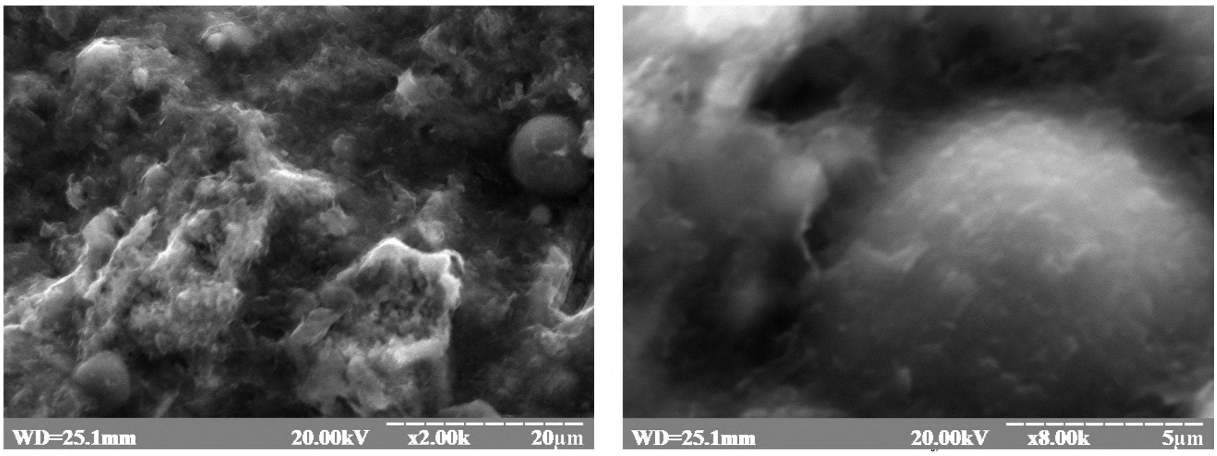
was observed, this indicating an intensive pozzolanic reaction in the modified cement paste.

It was shown by electron microscopy that the cement paste based on CEM II/A-LL with fly ash modified with the combined alkaline additive Na[Al(OH)$_4$]-PCE after 1 day of hardening is characterised by a dense microstructure. Fly ash particles of 6-8 µm in size fill and colmatise the micropore of the modified cement paste (figure 3, a).

The fly ash particles are covered with a densely packed fine crystals, which indicates the passage of the pozzolanic reaction with the formation of low-basic C-S-H phases (figure 3, b). The acceleration of the early structure formation processes is provided by the alkaline activator Na[Al(OH)$_4$] with the formation of zeolite-like hydroaluminosilicates N-C-A-S-H.



a b

Figure 3. Microstructure of modified cement paste with FA-Na[Al(OH)$_4$]-PCE.

When PCE is added to the cement paste, a finely dispersed microstructure is formed due to the phenomenon of adsorption modification of hydrate neoplasms. The complex combination of CEM II/A-LL with the addition of limestone, fly ash, and alkaline activator $Na[Al(OH)_4]$ provides intensification of early structure formation processes through the formation of hydrocarboaluminates and alkaline zeolite-like hydroaluminosilicates; larger particles of limestone and fly ash are used as microfillers, which in combination increase the strength and durability of cementitious matrix.

4. Conclusions

1. The formation of a continuous mesostructure of cement mixtures is achieved by the correct design of the grain composition of fine aggregates, the optimal ratio between their components "sand – fly ash". Replacing part of the sand with fly ash increases the density of the cementing matrix in concrete, which allows to reduce the impact on the environment.
2. The analysis of experimental data from mathematical modeling shows that the introduction of $2.5 - 5.0$ mass.% $Na[Al(OH)_4]$-PCE and 10.0 mass.% fly ash into the modified repair mixture based on the optimized sand composition ($FM_{2.76} : FM_{1.25} = 75 : 25$) provides an accelerated setting time of 60-70 min, compressive strength after 14 h - 8-10 MPa, and 28 days - 66.0-70.9 MPa. The high technical effect is achieved after 14 hours ($\Delta R_{c14h} = 64.0\%$).
3. It was established that in the presence of polycarboxylate ester PCE additives, due to the phenomenon of adsorption modification, the size of the formed crystals decreases, which leads to a significant increase in the density and impermeability of the cement paste; due to the phenomenon of "self-reinforcement" by formation of finely dispersed low-base C-S-H phases and zeolite-like N-C-A-S-H hydroalumino silicates the strength and durability of the repair mixture increase.
4. Complex implementation of the effects of physical optimization and alkaline activation ensures the production of effective rapid-hardening, non-shrinking cementitious mixtures for the repair of concrete structures in accordance with the requirements of sustainability.

Abstract. The research is based on the processes of studying electrospark underwater synthesis of conductive metals in a reaction chamber with low conductivity for the production of metal nanoparticles. Experiment had been carried out using confirmation of silver and copper nanoparticles by electron microscopy. The use of nanoforms of metals, in particular nanosuspensions, is considered as an alternative to acutely toxic chemical preparations in crop production for the protection of field crops. Strains of microorganisms – causative agents of diseases of grain crops were used as objects of research. The ultrafine metal phase of metal nanoparticles (particulate nature of matter – PNM) is considered as an alternative to existing agrochemicals based on metal salts. The obtained colloidal solutions of metals have fungicidal properties and can be used to create plant protection products.

1. Introduction

The issue of the biological impact of nanomaterials remains key in fundamental studies of the interaction between nanoparticles and the biological environment. A new direction of research of solutions based on metal nanoparticles, which exhibit a wide spectrum of biocidal activity, enables their usage as disinfectants, antibacterials, and antifungals. Resulting solutions are not toxic to humans and the environment. Usage of nanoparticles in solutions had been determined very effective not only due to their relative size, but also because of the specific method for obtaining nanoscale objects. Particular attention should be paid to the study of the effect of metal nanoparticles on the causative agents of many human infections and diseases and plant pathogens. These include staphylococci and phytopathogens that cause significant crop losses of *Penicillium sp.* and *Alternaria alternate*. Metals with antifungal action – copper and zinc – are considered as fungicides [1]. Usually, either metal salts (sulfates) or various nanoforms of metal particles and their oxides are used [2–5]. The largest number of studies is devoted to the study of the bactericidal activity of silver. In addition, bactericidal activity was found in gold and some other elements, including carbon nanoforms [6–9].

2. Materials and methods

The use of discharge pulse power generators (DPPG) for the synthesis of metal nanoparticles makes it possible to obtain low-temperature plasma in the discharge channel in a short period of time, which ensures effective erosion of the anode material. A unique feature of the volumetric electrospark dispersion method is the presence of a conductive layer of granules located between the main electrodes. The process takes place in a reaction chamber filled with a weakly conductive liquid, namely: deionized water. Voltage supply to the main electrodes are caused by the passage of current through a chain of freely stacked granules in the stochastic switching mode. The use of low voltages (up to 150 V) and small interelectrode gaps makes it possible to provide modes when up to 85% of all accumulated energy on the capacitor is used for local heating of the surface of the contacting granules. A layer of conductive metal granules with a maximum diameter of 5-10 mm is used to ensure the performance of spark erosion dispersion instead of a single contact gap. With the help of a thyristor generator with capacitive energy storage, discharge pulses were obtained, the amplitude of the voltage of which was regulated in the range of 40 – 150 V, and the current – from 30 to 500 A (figure 1).

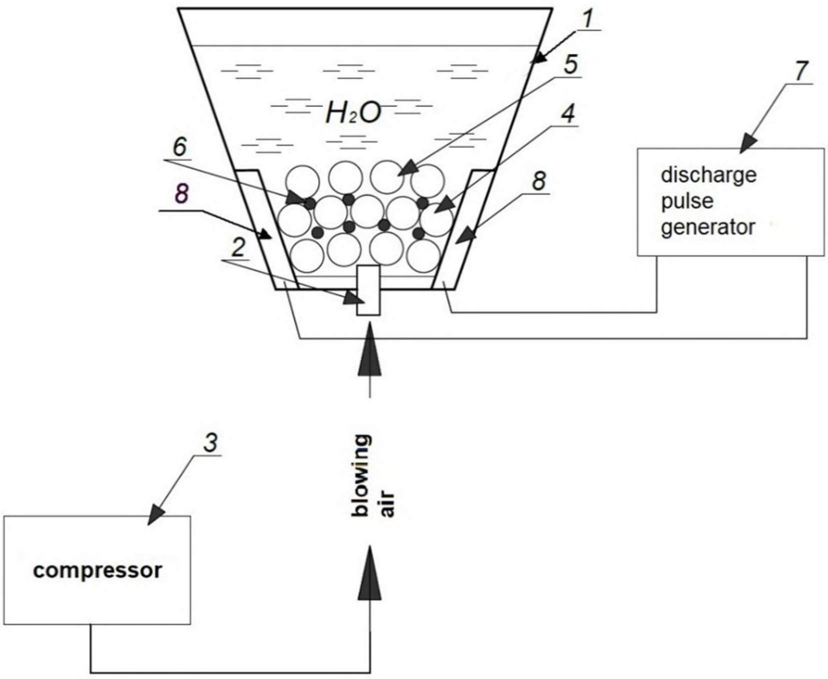

Figure 1. Technological complex for obtaining metal nanoparticles – discharge chamber (1); air sprayer (2); compressor (3); metal granules (4, 5); discharge (plasma) channel (6); discharge pulse generator (7); electrodes- anode and cathode (8).

The system of metal granules and plasma channels immersed in a dielectric liquid and ohmic contacts between them is a complex electrical load. It has a significant nonlinear character and significant parametric dependencies on a number of technological factors: the frequency of discharge pulses, the flow rate and the temperature of the working fluid, etc. In addition, the physical nature of the occurrence of spark discharges in the layer of conductive granules determines the stochastic migration of plasma channels along their surface and switching current flow paths to adjacent pairs of granules. As a result, the instantaneous values of the equivalent electrical resistance of such a medium vary widely: from 0.05 to 100 *ohms*. The frequency of discharge pulses is regulated in the range of 100 – 200 *Hz* and the inductance of the discharge

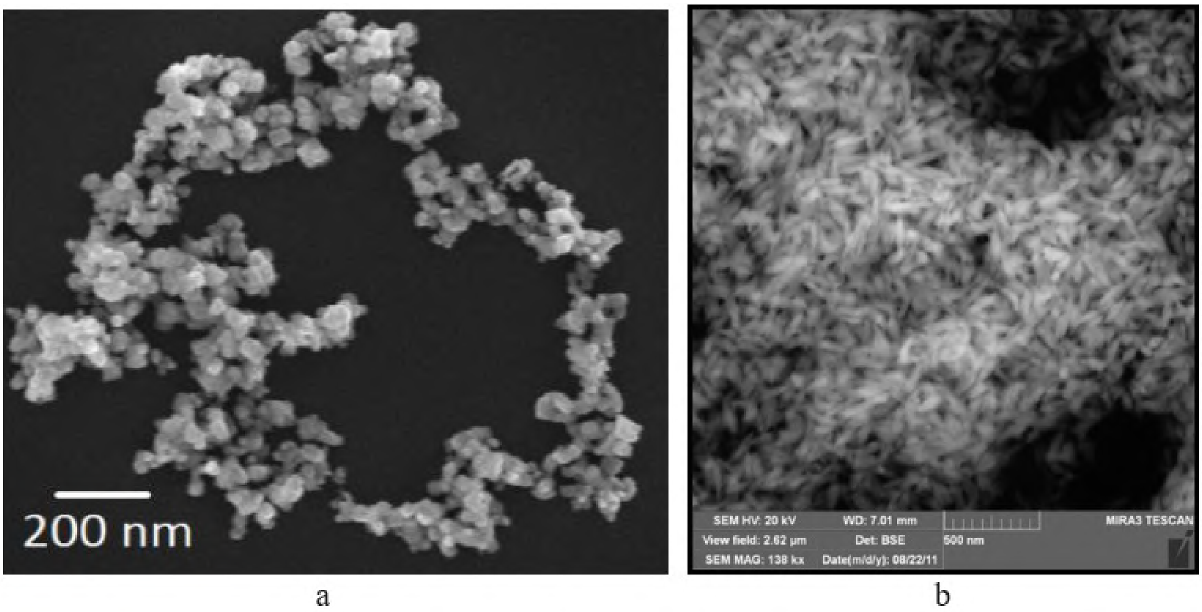

Figure 2. Electron microscopy (SEM) of nanoparticles – Ag (a), Cu (b).

circuit L does not exceed 1 μH.

3. Results and discussion

The result of electrospark treatment of granules is the formation of a nano-sized fraction of the corresponding metals, which are in colloidal form and of sufficient concentration (100-1000 *ppm*) for microbiological research.

Micromycetes of *Penicillium sp.* and *Alternaria alternate* were used as microbiological objects of research. They were obtained from the collection of microbial cultures of the Institute of Microbiology and Virology of the National Academy of Sciences of Ukraine. Nanosuspension of silver and copper with average particle sizes from 20 to 50 *nm* were used as fungicides. For the research we have studied the effect of metal compound solutions on the survival of microorganisms after 30 minutes of incubation at the optimal temperature. The conducted

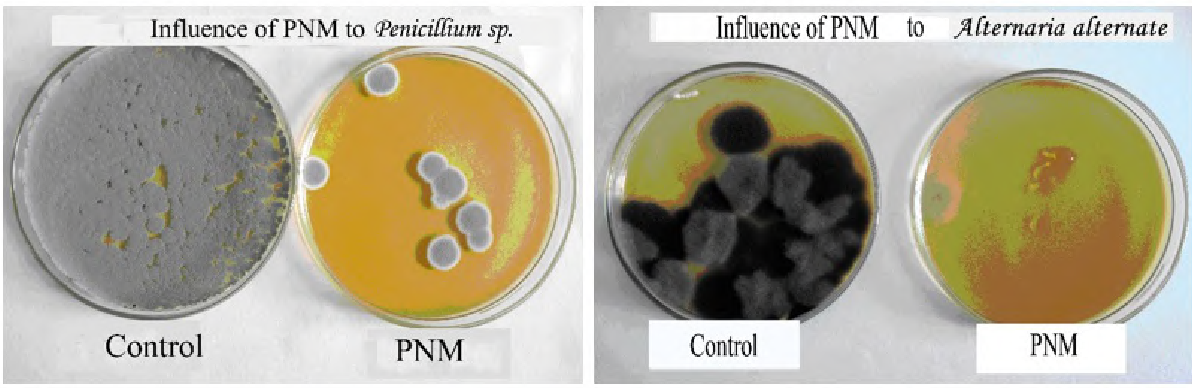

Figure 3. Influence of PNM Ag and Cu on survival microscopic fungi Penicillium sp and Alternaria alternate with.

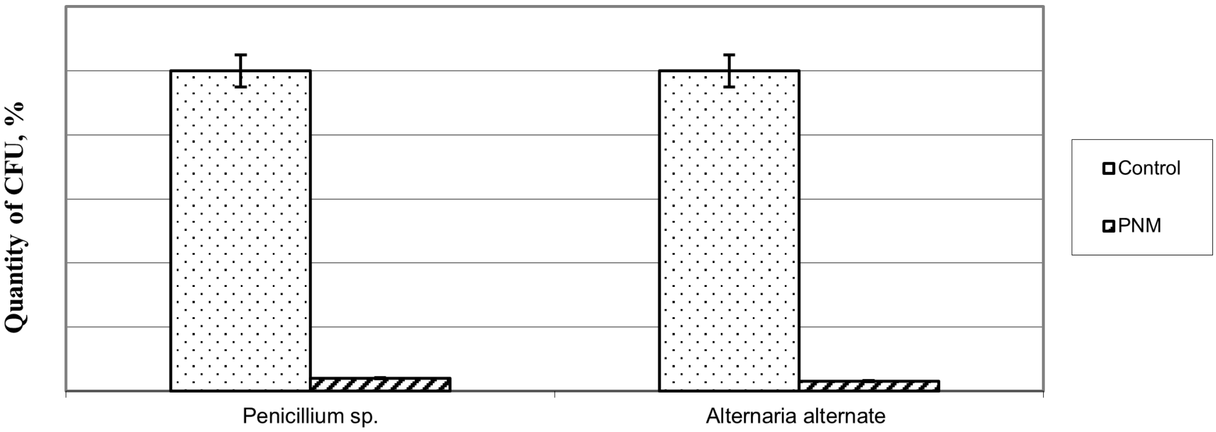

Figure 4. Survival microscopic fungi Botrytis cinerea and Alternaria alternate in action PNM Ag and Cu expressed in percent to control.

test results showed that in the concentration range of 5-50 *ppm*, mixtures of silver and copper compundsolutions have a pronounced fungicidal action on microscopic fungi Penicillium sp. and Alternaria alternate. As a result we found out that the inhibition of germinated conidia of micromycetes was up to 97% in relation to the control. The test results indicate that particulate nature of matter (PNM) solutions prepared based on Ag and Cu at a concentration of 8 *mg/l* are effective fungicidal agents for Penicillium sp. and Alternaria alternate (figure 3 and figure 4).

4. Conclusions

As a result of the study of the bactericidal effect of combined PNM Ag/Cu on microorganisms, pathogens of infectious diseases, it was found that they exhibit a fungicidal effect against the studied strains of microorganisms with a metal in low concentrations, inhibiting the growth of pathogenic microflora by 90-97%. Besides, the study of the effect of PNM data on the micromycetes of *Penicillium sp.* and *Alternaria alternate* indicate that the research solutions can be used as effective fungicidal agents. The use of PNM can solve the problem of using highly toxic chemical fungicides and biocides. The PNM enables solutions to inhibit the growth of pathogenic microorganisms by almost 100%, additionally such solutions are non-toxic to the biological system and have a prolonged effect.

Abstract. The article is dedicated to Internet of Things (IoT) technologies that allow connecting various devices and sensors via the Internet. Effective customer interaction with IoT systems requires smart interfaces that take into account the context and human needs. Chatbots are considered that can provide users with convenient support, process data from sensors, and visualize them. An IoT system consisting of sensors, a cloud platform for data storage and processing, a database, and a chatbot interface for user interaction is considered. The automatic indoor temperature control system uses sensors that transmit data to the cloud, where it is processed and stored. Users can interact with the IoT system through a chatbot that understands commands and responds accordingly. The chatbot has been tested, showing that it can autonomously maintain the optimal temperature, changing it according to user commands, and responding to critical situations. The results of the study demonstrated that the use of a chatbot allows you to create a human-centered automated system.

1. Introduction

The Internet of Things (IoT) is one of the most promising areas of information technology development, which involves communication between various devices and sensors via the Internet [1]. IoT systems can collect, process and analyze large amounts of data generated by these devices and use them to improve people's quality of life, business efficiency and environmental safety [2]. However, in order for customers to be able to easily and conveniently interact with IoT systems, intelligent and natural user interfaces are needed. Chatbots are one such interface that uses artificial intelligence (AI) and natural language processing (NLP) to simulate conversations with people or other chatbots using text or voice messages [3]. Chatbots can provide users with comfortable and efficient assistance by answering their questions, providing them with more interesting answers, directly responding to their problems [4]. This article highlights the ability of chatbots to process the substantial amounts of data generated by sensors and IoT systems, and then present this information in a format that is readily comprehensible and actionable for users [5].

The latest research and publications on this topic testify to the high relevance and perspective of chatbots as a user interface for IoT systems. For example, the authors of the paper [6] propose an interdisciplinary scientific program for the future development of chatbots, in which they distinguish six thematic areas:

- users and consequences;
- user experience and design;
- frameworks and platforms;
- chatbots for cooperation;
- democratization of chatbots;
- ethics and privacy.

For each of these areas, they provide a brief overview of the current state of the art, discuss key scientific challenges, and suggest promising directions for future research.

Maginga et al. [7] consider the use of chatbots to solve complex business problems with the help of AI and IoT. They show how chatbots can provide quick and convenient access to large volumes of data generated by IoT devices and analyze this data to improve performance and service quality. They also describe some use cases for chatbots in smart factories, smart homes, and smart healthcare systems.

In the article [8] the authors describe the history, technology and application of chatbots as natural dialogue systems. They consider the development of chatbots in the context of the development of AI, OPM and human-computer interaction. They also analyze the current types of chatbots based on their functionality and architecture. They show how chatbots can be useful in various industries such as education, healthcare, business and entertainment.

The article aims to examine the functionality of chatbots for indoor temperature management utilizing IoT systems. It analyzes the modern programming languages employed in IoT systems. The study involves testing the chatbot's capabilities, enabling users to set the preferred temperature in rooms, monitor the current status of temperature sensors and air conditioning units, and receive alerts about critical situations and the conditions triggering sensor and air conditioning activation.

2. Results

There are various IoT control systems that can be used for a smart home. Some of them offer ready-made solutions with a variety of functions, such as temperature control, lighting, security, etc. Other systems provide a platform for developing your own solutions, which allows for a more flexible approach to solving specific problems.

One of the platforms for IoT development is the Microsoft Azure IoT Suite, which provides tools for collecting, storing, and analyzing data from IoT devices. For a smart home, We can use various devices such as thermostats, motion sensors, security cameras, etc. and connect them to the Azure IoT Hub. This allows you to collect data from these devices and analyze it using Azure Stream Analytics. Another platform is Google Cloud IoT, which provides tools for connecting, managing, and monitoring IoT devices. With the help of Google Cloud IoT, you can connect various IoT devices to the platform and collect data from them for further processing and analysis.

To implement the temperature monitoring function, we use an IoT temperature sensor that reads the data and sends it to the storage system. To understand user commands, we use natural language processing libraries such as NLTK or spacy. They can be used to recognize commands and determine actions to be performed.

After processing the user command, a temperature control algorithm can be applied, which will change the settings of the temperature control system in the house. For example, if a user asks to raise the temperature by 2 degrees, the bot can use this algorithm to raise the temperature in the house. After performing the action, the bot must update the temperature data in the data storage system and notify the user about the result of the action.

When developing an IoT bot to control the temperature in a smart home, we need to analyze existing natural language understanding methods and choose a programming language to develop the bot.

When choosing programming languages for IoT systems, there are several options available, each with their own advantages and disadvantages and areas of application. Table 1 provides an analysis of popular programming languages used in IoT development

Table 1. Analysis of popular programming languages for IoT.

Programming language	Analysis of the application of the programming language for IoT systems
C/C++	Widely used in IoT due to its efficiency, low management level and compatibility with microcontrollers and embedded systems. It provides direct access to hardware, making it suitable for resource-constrained devices. C/C++ are commonly used in IoT platforms, software development, and device drivers [9]
Python	It is a universal and easy-to-learn language known for its accessibility and readability. It offers extensive libraries and frameworks for IoT development, making it popular for rapid prototyping, data analysis, and cloud integration. Although Python may not be as efficient as C/C++, it is often used for higher-level IoT applications, data processing, and scripting [10]
Java	It is commonly used in IoT gateways, server applications, and Android-based IoT devices. Reliability, security functions and scalability of Java make it suitable for large-scale deployment of IoT and corporate solutions [11]
Rust	It is a systems programming language known for its focus on security, performance, and concurrency. It provides memory safety guarantees and strong typing, making it suitable for low-level programming in IoT devices and firmware. Rust is often used in safety-critical applications or where resource efficiency is critical [12]
Lua	It is a lightweight scripting language often used in embedded systems and IoT devices. It is easy to install and provides good performance. Lua is usually used for programming sensor nodes, Internet of Things gateways and creating special software [13]
Swift	Swift is mainly associated with iOS and macOS development, but it is gaining popularity in the IoT due to its security features, expressiveness and compatibility with the Apple HomeKit infrastructure. Swift is suitable for developing IoT applications that integrate into the Apple ecosystem [14]

Ultimately, the choice of programming language for an IoT system depends on factors such as target hardware, resource constraints, scalability requirements, development speed, and available experience. IoT systems typically use a combination of languages at different levels, such as firmware, gateway, cloud services, and web/mobile interfaces. To implement the project, we use Python, which has many libraries and frameworks for developing chatbots and IoT devices.

This study examines an IoT system comprising sensors, a cloud-based platform for data storage and processing, a database, and a chatbot interface to facilitate user interaction (figure 1).

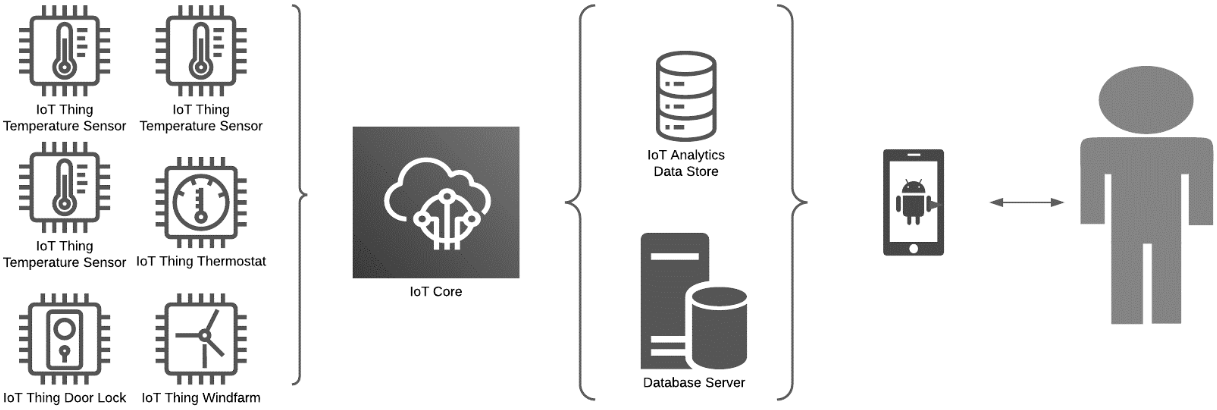

Figure 1. IoT system.

Arduino boards are chosen for IoT devices. The Python development language is used due to its extensive libraries, support for data analysis and ease of integration with IoT devices. PostgreSQL relational database management system is used to store temperature data. This technology provides robust support for SQL queries and can handle large data sets. The psycopg2 library is used to connect to the database from the cloud platform.

The chatbot is written in Python. For the OPM module, the spaCy library is used, which offers advanced functions for tokenization, recognition of named objects, and analysis of syntactic dependencies. Python also provides pre-built models for different languages, which allows for faster application development. spaCy can be used to analyze user queries, extract important objects (eg temperature values, time, location) and understand the context to formulate meaningful answers.

The automated indoor temperature control system operates as follows:

- sensors connected to microcontrollers periodically collect temperature data;
- with the help of special libraries, sensor data are read and stored in the cloud;
- the cloud platform receives temperature data from IoT devices through AWS IoT Core. Python scripts process the input data, perform analysis as needed, and store it in the database;
- a chatbot interface provides users with a conversational interface to interact with an IoT system.

The chatbot understands user commands, retrieves temperature data from the database, and responds accordingly. Users can request current temperature, historical data, set temperature thresholds, or configure other IoT system parameters through the chatbot.

The block diagram in figure 2 illustrates the modules of the presented IoT-based temperature control system.

Let's consider the functions of each block in more detail:

- the chatbot module is an interface between a person and an IoT system. This is software that allows the user to set the desired temperature in each room separately, or to set global parameters for the whole house;

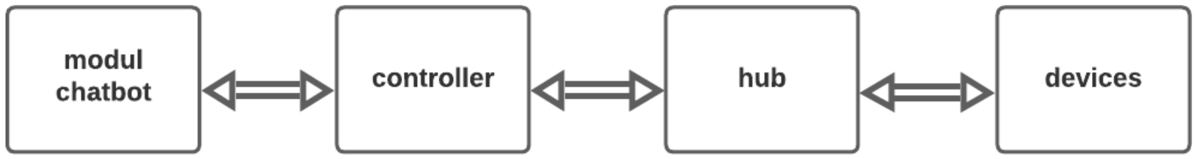

Figure 2. Block structure of IoT-bot modules.

- the controller module analyzes data from the IoT hub and makes decisions about controlling devices to control or change the temperature;
- the IoT hub module collects all data from various sensors and transmits them to the controller module;
- the IoT sensor module includes sensors for measuring temperature, air conditioner operation, open windows, and ventilation grilles. These sensors are connected to the Internet to send data to the IoT hub module.

The system operation algorithm is shown on figure 3.

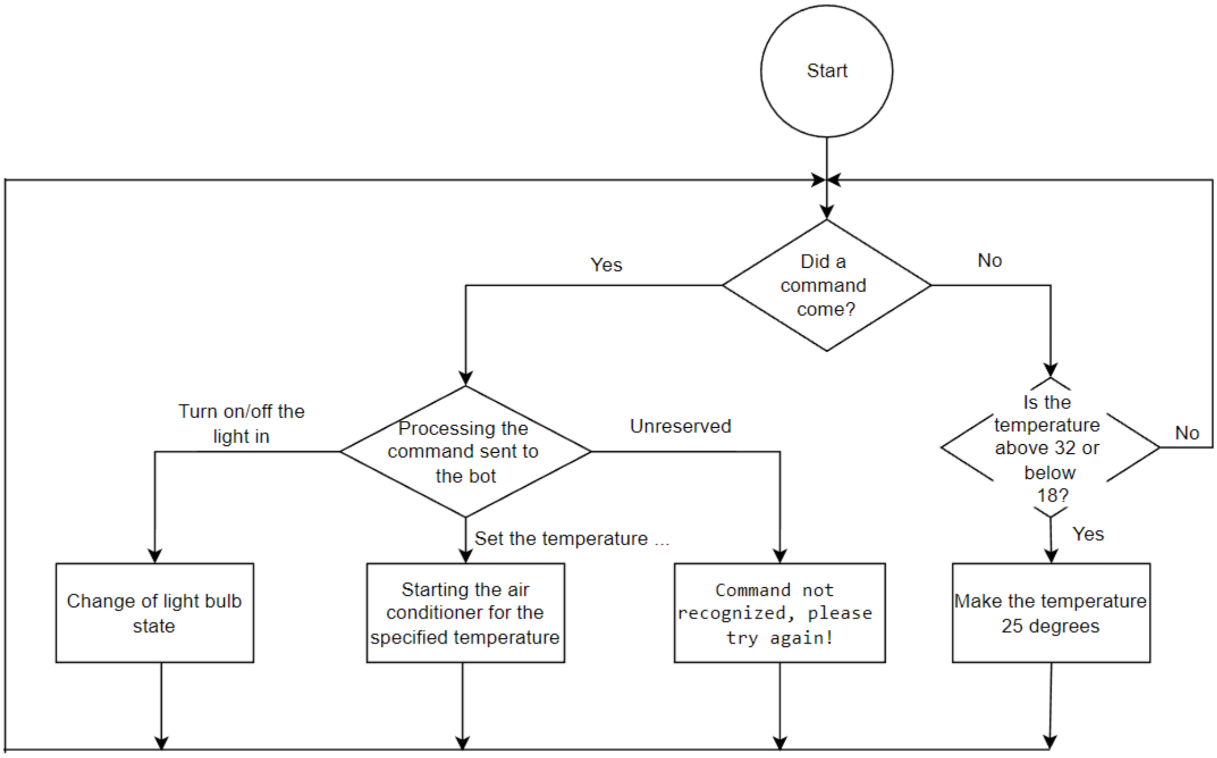

Figure 3. Algorithm of the system.

We can consider the algorithm of chatbot operation with IoT:

- receiving a text command from a user;
- processing a text command using natural language analysis;
- determine the action to be performed based on the processing of a text command;
- interaction with the storage system to obtain information about the temperature in the house;

- application of the temperature control algorithm to change the settings of the thermoregulation system in the house;
- update the temperature data in the storage system;
- sending a response to the user with the results of the action performed.

The chatbot was evaluated in a real-world scenario, tested within a hangar facility spanning 800 square meters. This environment was equipped with a variety of IoT-connected devices, including temperature sensors, air conditioning units, window and door sensors to detect opening/closing, as well as a ventilation system (figure 4). During the testing, the chatbot demonstrated its ability to autonomously maintain the temperature within the hangar, utilizing the air conditioning system to ensure the temperature did not exceed 32 degrees Celsius. The chatbot interface allowed users to interact with the system through text commands, enabling them to adjust the target temperature as desired (figure 5).Crucially, the system incorporates control mechanisms to monitor the status of windows and doors, as well as the ventilation system. Temperature readings were recorded at half-hourly intervals, providing the chatbot with the necessary data to intelligently regulate the environment.The autonomous nature of the chatbot's operation allowed it to proactively manage the temperature without constant human supervision. However, the system was also designed to provide users with a seamless interface to directly manipulate temperature settings, overriding the autonomous control if necessary. This balance of autonomous operation and user interaction represents a key strength of the chatbot-driven IoT solution.Through this real-world evaluation, the chatbot's capabilities were thoroughly tested, demonstrating its ability to effectively maintain optimal environmental conditions within the large hangar space, while also offering intuitive user control capabilities to accommodate specific user preferences and needs.

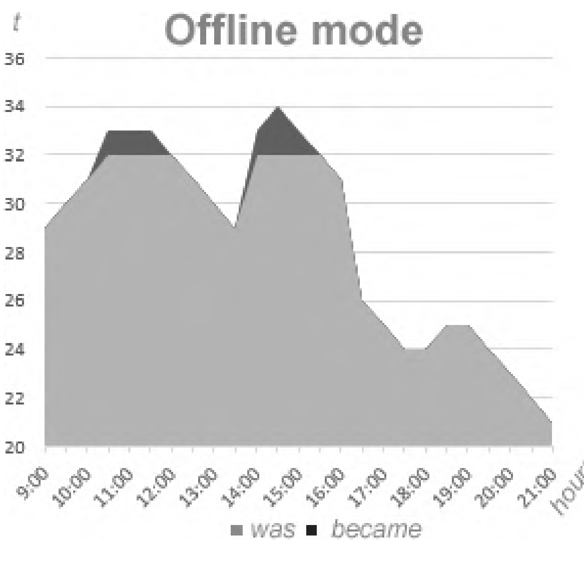

Figure 4. Chatbot operation in offline modes.

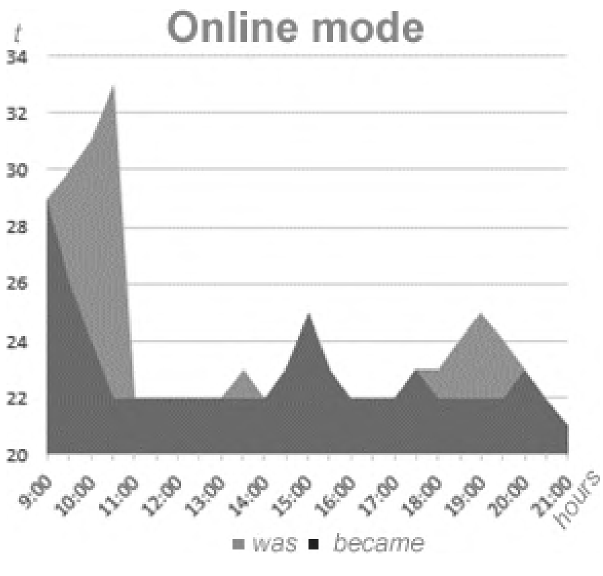

Figure 5. Temperature control according to user commands.

The system provides for critical situations. For example, an IoT temperature sensor failure or an erroneous user command that can lead to a dangerous change in indoor temperature. Therefore, protection mechanisms have been implemented, such as automatic temperature change and notification of the occurrence of a problem.

3. Conclusions

This paper investigated the functionality of chatbots for indoor temperature control using Internet of Things (IoT) systems. The paper analyzed modern programming languages used in IoT systems, and considered the architecture and algorithms of the proposed system.

The system integrates a chatbot driven by natural language processing with temperature sensors, air conditioners, and a database. Users can issue commands through the chatbot to regulate the temperature, monitor the current status, and receive notifications of critical situations. The main components of the system are modules for a chatbot, controller, IoT hub, and IoT sensors. The core of the chatbot is the spaCy library for natural language processing. The system uses the Python programming language, PostgreSQL for the database, and the AWS IoT Core platform. The system has been successfully tested in a real-world environment of a large hangar. The chatbot has demonstrated the ability to autonomously maintain the desired temperature, interact with the air conditioning system, and respond to user commands. The system also has mechanisms to protect against critical situations, such as sensor failures or dangerous commands from users.

The research demonstrates the potential of chatbots as an intelligent user interface for IoT systems, combining automated control and convenient human interaction. The developed system is flexible and scalable, which opens up prospects for its further improvement and implementation in various fields.

Abstract. The study describes the process of forming a functional layer of thermite melts on the surface of castings. The chemical composition of thermite mixtures, technological parameters of various processes of surface alloying of castings, structure and mechanical properties of alloys, and operational properties of castings were examined at various stages of the development of energy-efficient technology for creating a functional surface of a given thickness. The described technology of surface alloying of castings by obtaining functional layers from thermite melts refers to the aluminium-thermite method of obtaining a melt with its subsequent casting on the surface of castings to form a wear-resistant functional layer or direct casting of castings. Characteristic features of the technology are: the use of cheaper internal chemical energy of the interaction of reagents to produce melts, instead of external electrical energy; simplicity and cheapness of the equipment used; obtaining various grades of alloys; high speed of processes in metal synthesis; high productivity of the process of manufacturing or repairing castings.

1. Introduction

The task of improving the wear resistance of chromium cast iron parts includes choosing the chemical composition of a wear-resistant alloy depending on the operating conditions of the casting, the technology of its production, and optimal casting modes.

The choice of materials depends on the manufacturing technology of castings, requirements for mechanical and operational properties, production costs, etc. In conditions of abrasive wear in a neutral environment, chromium-molybdenum cast irons have maximum wear resistance [1,2]. The high cost and scarcity of molybdenum restrain their widespread use.

High chromium cast iron with carbides M_7C_3 is inferior to chromium-molybdenum and chromium-manganese cast iron with a martensitic structure. Nevertheless, chromium-nickel wear-resistant cast iron EN-GJN-HV600(XCr23) DIN EN 12513:2000 is still very widely used to manufacture many fast-wearing processing equipment castings [3]. Under conditions of hydroabrasive wear at small angles of attack, the higher the wear resistance, the more carbides are contained in the alloy.

In the production of a substantial number of cast parts that work in conditions of intense wear, high temperatures and aggressive environments (heat power, metallurgy, mining-processing and chemical industry), their manufacturing technologies using bulk metal alloying [4, 5] are mainly used, which is often not effective since only a tiny thickness of such parts is a working surface and is being worn out. This leads to unjustified costs of expensive high-alloy alloys and an increase in the cost of casting. The production of castings with different properties of individual parts is conducted in different ways: sequential or simultaneous pouring of different melts into a mould, pouring melt on a solid billet, etc [6, 7]. Most of these technologies require the simultaneous melting of alloys of different chemical compositions in separate melting units and additional melt processing operations, complicating the technological process of manufacturing castings with functional layers.

Also, considerable attention of researchers is paid to the development of technological processes for manufacturing castings with surface functional layers, in particular, wear-resistant ones, the properties of which are given by alloying them [8, 9]. Surface alloying of castings by applying alloying coatings to the inner surface of the mould allows obtaining a surface layer with differential properties of no more than 10 mm. Applying a surface alloyed layer to castings by exothermic surfacing in the field of centrifugal forces or electroslag surfacing allows obtaining a functional layer of any size, however, these methods require complex equipment [10–13].

The use of metallothermy methods for the synthesis of melts of a given chemical composition and the production of castings with alloyed functional layers is a promising direction for the development of existing technologies since this ensures a certain autonomy, simplicity and cheapness of technological equipment, high productivity, dismisses the need for powerful sources of electricity, etc [14–19]. However, the problem of predictability of the structures of synthesised alloys and controllability of a substantial part of their physical, mechanical, and service properties limits the use of metallothermal processes in the industrial practice of foundries.

Thus, this study, which is aimed at developing the theoretical and technological foundations of surface alloying of castings by obtaining and casting functional layers from thermite melts, is relevant.

2. Goals and objectives

The purpose of the study is to substantiate the technological parameters of obtaining and casting chromium-alloyed functional layers from thermite melts for the manufacture and reproduction of castings.

Achieving this goal involves solving the following tasks:

- set the parameters for forming the structure of the functional layer and the fusion zone with the casting body (base) depending on the controlled technological parameters;
- develop recommendations for the technological process of surface alloying of castings by forming a functional layer with the specified properties.

3. Materials and methods

Exothermic alloying is the process of obtaining a casting from a liquid thermite metal of a given chemical composition, as a result of an exothermic reaction of a reducing metal with metal oxide.

The standard exothermic reaction proceeds with a substantial release of heat and has the following form:

$$\mathrm{MeO} + \mathrm{R} = \mathrm{Me} + \mathrm{RO} - \mathrm{Q},$$

where MeO – metal oxide; R – reducing metal; Me – metal reduced from the oxide; RO – oxidised reducing metal; Q – thermal energy released during the reaction.

Aluminium has a higher affinity for oxygen than most other metals. It is also relatively cheap and non-deficient, so it is a preferred reducing metal.

As a metal oxide, iron oxides, iron scale, or iron ore are most often used. Scale includes several iron oxides: FeO (iron oxide) – with 22.2% of oxygen, Fe_3O_4 (nitrous oxide-iron oxide) – with 27.58% of oxygen, Fe_2O_3 (ferric oxide) – with 30.0% of oxygen.

During the combustion of the thermite mixture, the following exothermic reactions occur:

$$2Al + 3FeO = 3Fe + A1_2O_3 - 0.835 \cdot 10^6 \text{ J/kg of the mixture},$$

$$8Al + 3Fe_3O_4 = 9Fe + 4Al_2O_3 - 3.239 \cdot 10^6 \text{ J/kg of the mixture},$$

$$2Al + Fe_2O_3 = 2Fe + A1_2O_3 - 0.830 \cdot 10^6 \text{ J/kg of the mixture}.$$

The reaction products are iron reduced from oxides (thermite steel) and aluminium oxide (thermite slag).

When obtaining a melt from thermite mixtures, it is important from a practical standpoint to ensure the necessary chemical and fractional composition, various physical properties, and the maximum yield of a suitable exothermic composition per unit mass. Regulation of the chemical composition of the resulting metal determines the need to use various ferroalloys, ligatures, and carburiser in the composition of thermites, which affect changes in the temperature of reaction products. The more impurity elements contained in the resulting alloy, the more components should be in the thermite composition. This reduces the value of the peak temperature surge of the exothermic process and the residence time of the resulting system at different temperatures. In some cases, when obtaining certain grades of alloys with a low content of impurity elements in the composition, this is positive since the carbon monoxide of the elements decreases, gas release decreases, and the yield of the metal phase increases.

The following components were used to prepare the compositions of thermite mixtures:

- aluminium alloy cuttings of 0.2-0.5 mm fraction with chemical composition: Al = 98.627%; Mn = 0.019%; Si = 0.855%; Cr = 0.016%; Ni = 0.004%; Cu = 0.018%; Fe = 0.462%.
- iron scale powder of 0.2-0.5 mm fraction with chemical composition: C = 0.150%; Mn = 1.188%; Si = 2.960%; S = 0.030%; P = 0.030%; Fe = 71.500%; Al = 0.697%; Ni = 0.188%; Cr = 0.173%; Cu = 0.444%; O_2 = 22.639%.
- ferromanganese powder of fractions up to 0.4 mm with chemical composition: Mn = 78.050%; C = 6.990%; Si = 0.790%; P = 0.500%; S = 0.008%.
- ferrochrome powder up to 1 mm fractions with chemical composition: Cr = 79.500%; C = 0.110%; Si = 1.830%; S = 0.028%; P = 0.030%.
- chrome powder up to 0.3 mm fractions with chemical composition: Cr = 99.0%.
- grits of steel fractions of 1-3 mm with chemical composition: C = 0.180%; Mn = 0.520%; Si = 0.210%; S = 0.021%; P = 0.028%; Ni = 0.010%; Cr =0.110%; Cu = 0.220%.
- powder of graphite electrodes up to 0.063 mm fractions with chemical composition: C = 99.8%; rest – impurities.
- to obtain the reaction initiator consisting of dispersion aluminium and scale, aluminium powder of the PAP-2 brand was used and ground scale of a fraction less than 0.1 mm.

The technology of preparing compositions of thermite mixtures is reduced to the following: scale is calcined to remove lubricants, crushed, subjected to magnetic separation, and separated by fractional composition to obtain an average particle size of 300-400 microns. Powders of aluminium, ferromanganese, ferrosilicon, ferrochrome, chromium, and iron are used for the preparation of metallothermite charges without prior preparation.

When preparing the mixture, no binders are used, which only worsen the combustion process since a thin film appears on the surface of the grains of the components of the thermite mixture, which exacerbates the conditions for redox reactions. One of the main requirements for the initial charge is its uniformity, which determines a uniform combustion front. Therefore, it is necessary to perform high-quality mixing of charge materials. Mixing of thermite charge components was conducted in a drum-type mixer, its application is determined not only by the simplicity of the equipment but also by the high quality of mixing and maximum safety. At a speed of 0.5-0.6 reps, the mixing-pouring mode, in this case, is the most effective. Mixing lasted 5-10 minutes.

The production of castings with functional layers of thermite melts involves compliance with the production process, developed by us, which is shown in figure 1.

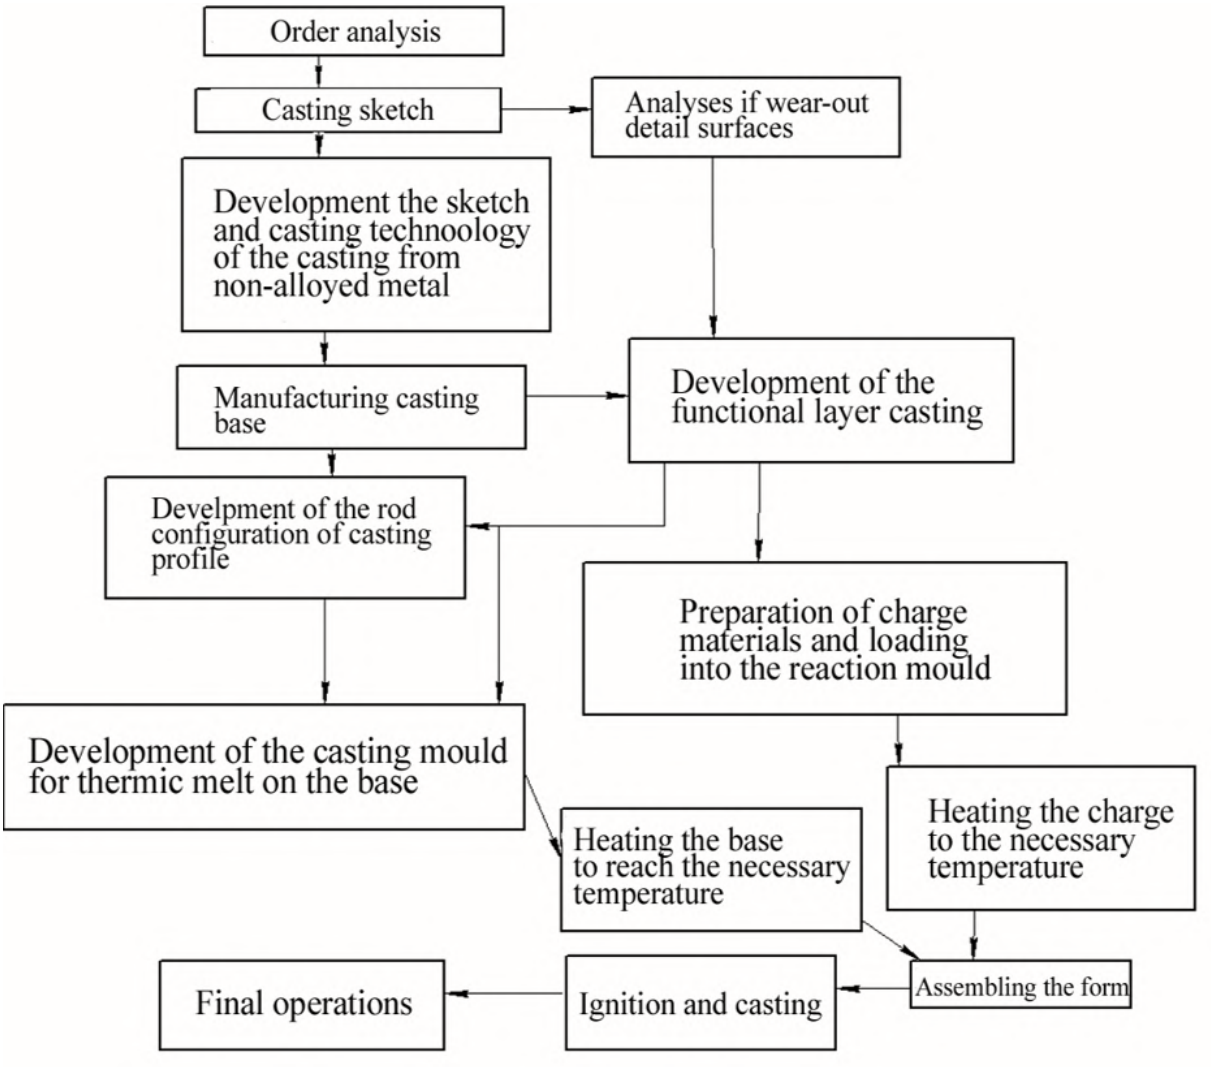

Figure 1. Diagram of the production process for manufacturing castings.

4. Results and discussion

The technology of casting thermite melts provides for the production of both profile castings and planar ones. The assembly mould diagram for surface alloying of profile castings is shown in figure 2, and planar ones – in figure 3. The technology of obtaining planar castings involves loading the charge onto the base, so the casting mould is made without a drain-feed system. After the thermite melt is synthesised, it is deposited on the casting base and forms a functional layer.

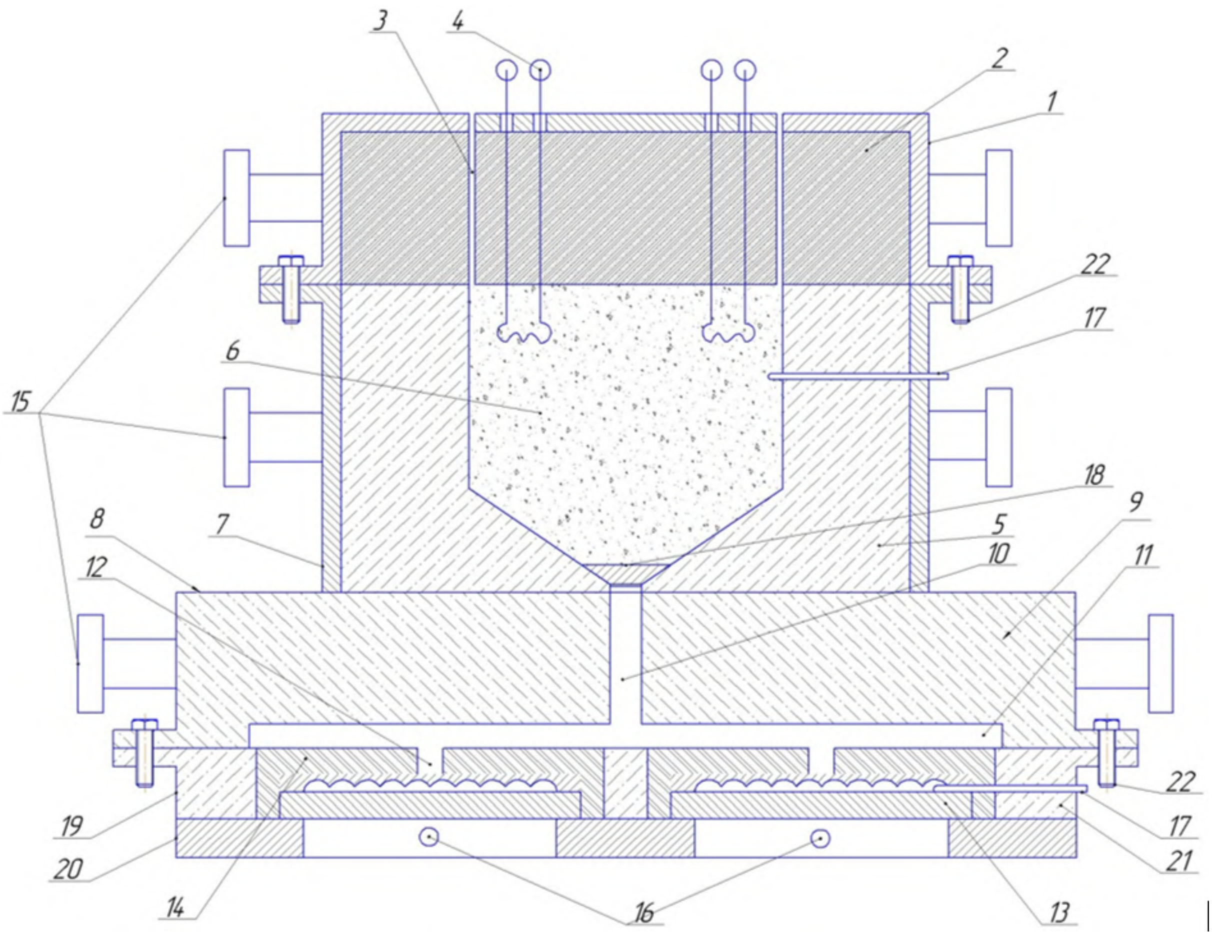

Figure 2. Injection mould assembly: 1 – frame of the top of the reaction mould, 2, 5 – sand-graphite moulding mixture, 3 – vapours, 4 – tungsten spiral, 6 – thermite charge, 7 – frame of the bottom of the reaction mould, 8 – frame of the top of the injection mould, 9 – moulding mixture of the frame of the top, 10 – standpipe, 11 – slag trap, 12 – feeders, 13 – casting base, 14 – rod, 15 – trunnions for transportation, 16 – gas burners, 17 – thermocouple, 18 – aluminium stopper, 19 – frame of the bottom of the mould, 20 – heating plate, 21 – moulding mixture of the frame of the bottom, 22 – centring and guide pins.

In the manufacture of complex-profile castings, a cast base is installed on the heating plate for casting an alloyed functional layer on its surface. The heating plate serves as a submodel plate and is part of the casting base heating system.

Under the influence of high temperature, the aluminium plug that blocks the casting passage melts and the thermite melt is poured through the valve feed system into the cavity between the rod and the casting base, where an alloyed functional layer is formed.

A rod of the appropriate configuration is made to obtain a functional layer of a complex profile. The composition of the core mixture is shown in table 1.

The surfaces of the rods in contact with the melt are painted with a spray gun with graphite-based paint with a layer of 0.2-0.3 mm to ensure stable roughness and prevent burning. The thermite charge is calculated according to the required volume of the cast layer, considering the density of powder shakedown and the yield of a suitable melt. The charge is filled in layers and compacted on the vibrating table for 1–3 min to prevent the formation of hollow arches.

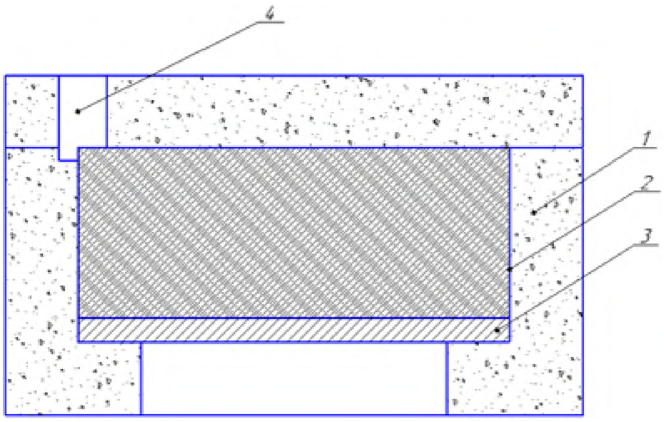

Figure 3. Mould-reactor with an open metal base in the lower part: 1 – moulding mixture; 2 – thermite charge; 3 – metal base; 4 – hole for ignition of thermite charge and gas discharge.

Table 1. Composition of the core mixture.

Name of components	Brand, class	Content in the mixture, %
Quartz sand	2K1O302	11-13
Circulating mixture	–	85
Moulding clay	P1T1K	4-2

The bulk density of aluminium powder is $0.96 \cdot 10^3$ kg/m^3, iron $2.9 \cdot 10^3$ kg/m^3, chrome – $2.5 \cdot 10^3$ kg/m^3, rolling scale $2.1 \cdot 10^3$ kg/m^3. The density of the bulk charge can vary from 1.8 to $2.1 \cdot 10^3$ kg/m^3 depending on the composition, and after the shakedown increases by 22-25%.

The mass of the thermite mixture required to obtain a high-quality casting is based on the total mass of the casting with slug and the drain-feed system, including the mass yield of the thermite alloy during the reaction and is determined by the formula:

$$m_m = \frac{100 \cdot m_c}{W}$$

The volume of this thermite mixture is calculated by the formula:

$$V_m = \frac{100 \cdot m_c}{W \cdot \rho_m}$$

where m_c is a gross mass of castings with slug, kg; W – yield of usable metal, %; ρ_m – bulk density of the thermite mixture kg/m^3.

The resulting compacted mixture is filled in layers into a reactor mould. A tungsten spiral is installed in the upper part of this mould to initiate combustion, and its high-quality contact with the charge is ensured.

After that, the reaction form is fed into a heating furnace to heat the mixture to a temperature of 873 K, which determines satisfactory qualitative and quantitative indicators of the thermite melt [20]. A heated reaction chamber with a thermite charge is installed on top of the mould and fixed above the standpipe, connecting the casting passage and the plug.

Burning of the thermite charge begins from the stage of its ignition with a hot tungsten spiral, the temperature must be at least 1573 K. This heat quickly heats up the surface layer of the charge and excites a rapid exothermic reaction in it. The resulting combustion front extends to the bottom.

Determination of the average volume velocity of the combustion front (kg/m^2·s) was conducted based on calculating the time (t_c) burning of a certain mass of thermite mixture m_m from the beginning of the reaction to its complete completion from a certain area (S_c) by the formula:

$$v_c = \frac{m_m}{S_c \cdot t_c}$$

The temperature of the resulting melt is determined by the composition of the thermite charge and the amount of metal powders – fillers. It is important that the melt has a temperature higher than the melting point of aluminium oxide (corundum, reaction product) since this ensures that there is no layer of slag inclusions in the transition zone between the functional layer and the casting base. The low temperature makes it impossible for the surface of the casting base to alloy since the thermite melt, when it comes into contact with a relatively cold metal, cools quickly. Heating the casting base to a temperature of 873 K using injection burners with a gas/air mixture or induction devices helps to obtain a defect-free strong metal bond in the transition zone. The optimal heating temperature of the casting base is determined by the temperature and time of the melt interacting with it, the maximum thickness of the resulting functional layer, and the wall thickness of the casting.

In addition to obtaining a high-quality fusion zone of the casting base with the thermite melt of the functional layer, the temperature-time regime should ensure that gas bubbles formed during thermite reactions come to the surface. The time t_{min}, required for the gas bubble to escape from the melt of the function layer was determined according to the following scheme. It is assumed that the bubble starts moving from an arbitrary point N in the fusion zone (figure 4) and stops at a point M at a distance r from a point on the surface of the melt mirror that corresponds to the maximum thickness of the resulting layer.

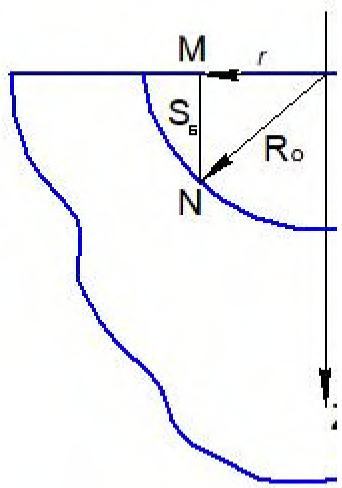

Figure 4. Calculation scheme for the time t_{min} of release of a gas bubble from the thickness of the thermite melt.

A right triangle formed by a segment MN is considered, which is numerically equal to the path S_b that the bubble travels; distance r between M and the center of sphere, inscribed in the heat node of cast layer; radius of this heat node R_0, which limits the local cavern of the defect (wear) at the base. The bubble path is equal to:

$$S_b = \sqrt{R_0^2 - r^2} = R_0\sqrt{1 - \left(\frac{r}{R_0}\right)^2}. \tag{1}$$

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012076 doi:10.1088/1755-1315/1415/1/012076

Then, t_{min} required for the gas bubble to escape:

$$t_{min} = \frac{S_b}{v_b}, \tag{2}$$

where v_b – the speed of the gas bubble.

Substituting expression (1) into formula (2), the following is obtained:

$$t_{min} = \frac{R_0}{v_b}\sqrt{1 - (\frac{r}{R_0})^2} \tag{3}$$

The approximate value of the velocity of a gas bubble with a density of 0.00028 kg/m^3 in a melt with a density of about 7.0 kg/m^3 and a density is 0.0029 kg/m · s, depending on its radius (R), by Stocks equilibria is equal to v_b=4820·R^2.

Then, from equation (3), t_{min} relative to any point on the surface of the casting base and the layer thickness can be determined. Solutions to equations (3) for a bubble with a radius of 0.05 mm were obtained using the MathCAD software in the form of a graph (figure 5).

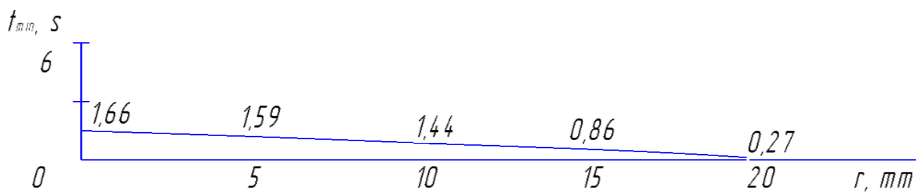

Figure 5. The time t_{min} of exit of a gas bubble with a radius of 0.05 mm at different values of r.

The time of a gas bubble escaping to the melt surface at the deepest point (20 mm) at $r = 0$ is 1.66 s, and when $r = R_0$, is decreased to 0.27 s.

Calculations of the time of movement of gas inclusions of different sizes showed table 2 that in the deepest part of the formed layer (figure 6), all gas bubbles with a diameter of more than 0.03 mm during the melt being in the liquid state (about 20 s [20]) will have time to reach its surface.

Table 2. Time of bubble exit to the surface of the alloyed layer depending on its diameter at different points.

Bubble diameter, D mm	Exit time t_{min} of a bubble at different points of the formed layer, s	
	$r = 0$	$r = R_0$
0.1	1.66	0.11
0.09	2.05	0.13
0.08	2.6	0.16
0.07	3.39	0.21
0.06	4.6	0.41
0.05	6.64	0.66
0.04	10.4	0.98
0.03	18.4	1.43
0.02	41.5	4.5

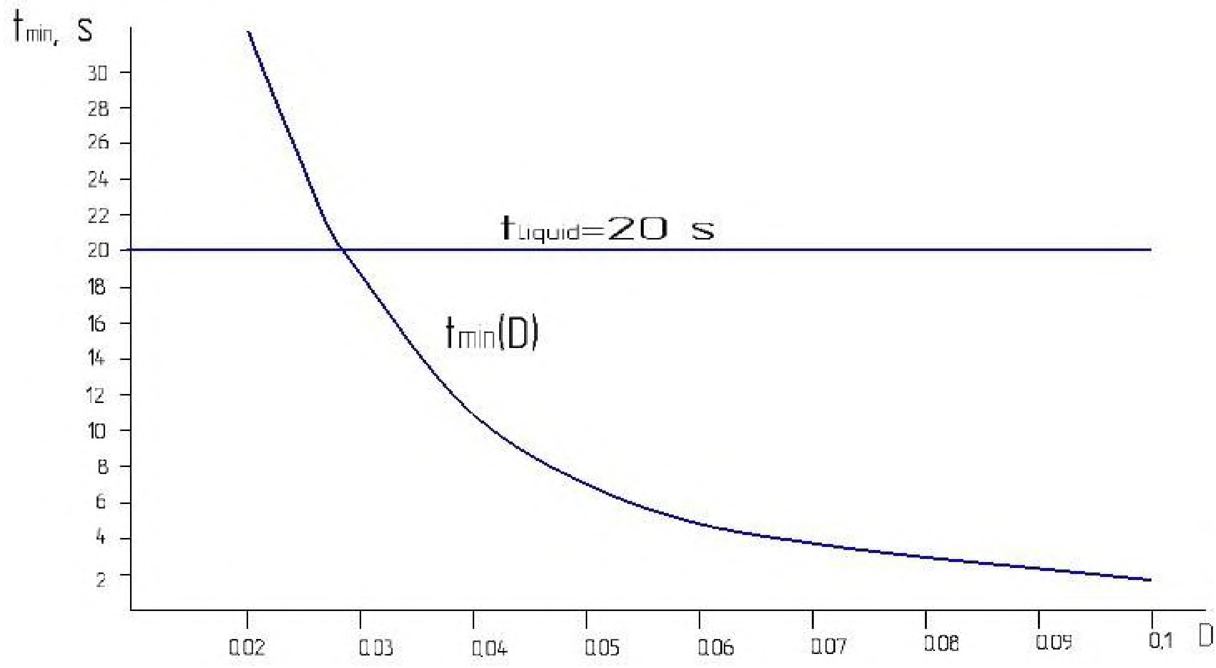

Figure 6. Exit time t_{min} of gas bubbles to the surface from the maximum (20 mm in calculations) depth of the functional layer, depending on the diameter of the bubble.

Near the open interface of the base and the formed alloyed layer at $r = R_0$, all bubbles with a diameter of 0.01 mm or less will exit. Micropores that remain cause a decrease in the density of the functional layer.

Thus, almost all gas bubbles during the time during which the melt is at the solidus temperature, have time to reach its surface. Notably, the above calculations were conducted, provided that the thermite melt is in a stable state and the movement of the gas bubble can be considered laminar. In practice, the formation of a thermite alloyed layer occurs under conditions of strong perturbations, primarily associated with the unstable and turbulent nature of the exothermic reaction. Disturbances that are transmitted to the thermite melt from the reacting components of the charge cause unregulated flows that affect the movement of gas bubbles. This explains the presence of individual pores of small diameter in the functional layer.

Experiments on obtaining a cast with a functional layer were conducted at the Kolbi enterprise (Kryvyi Rih) with a worn-out casting "Front seal disc" (figure 7) – detail of a suction dredge pump 400/40 (8gr-8).

The working surfaces of seal discs wear out due to the contact of solid abrasive particles with the walls of the channels of the flow part.

During the tests, it was attempted to obtain alloyed thermite alloys that are similar in composition to cast iron grades (by ASTM A532) Class 2 type B (C – 1.6-2.4%, Cr – 13-19%) and Class 2 type D (C – 2.4-3.6%, Cr – 19-25%). Based on the results of calculations, the indicators of the melt formation process for various charge compositions (70 kg of scale and 30 kg of aluminium powder) were determined, considering its heating temperature (table 3).

As can be seen from the table 3, reducing the amount of chromium powder for every 10% (relative) and replacing it with iron powder allows increasing the amount of exothermic alloy by 0.9%.

Based on the results of field experiments, it was determined that the highest melt yield (54.77%) can be obtained by heating the charge to 873 K, which was confirmed by the previously

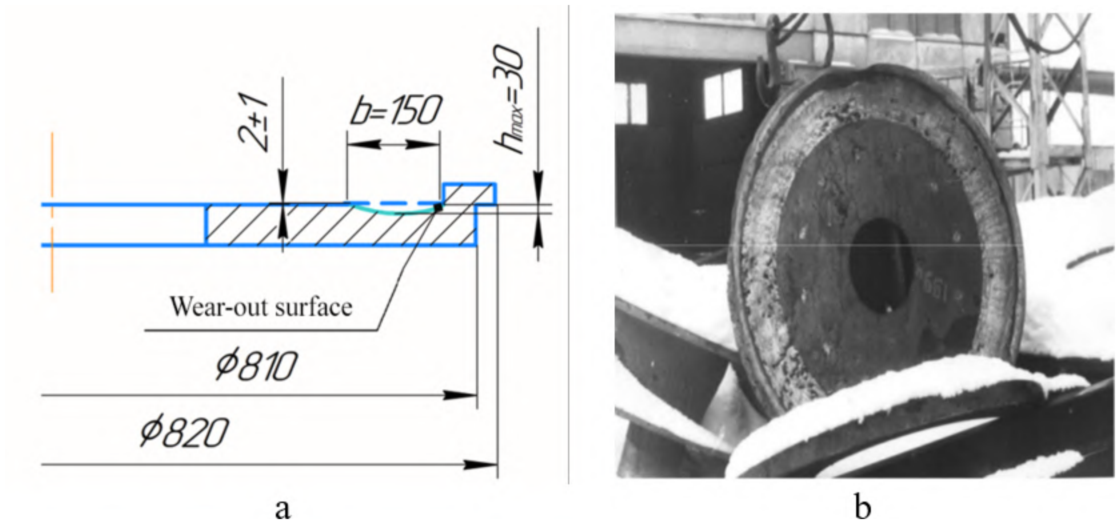

Figure 7. Front seal disc of the 8gr-8 pump: *a* – sketch, *b* – after operation.

identified data [20].

5 dm^3 reactor moulds were installed in five places (considering the charge composition and yield of suitable melt) for obtaining up to 1.6 kg of thermite melt on an area of 150×100 mm with an average layer thickness of 15 mm to recreate the planar working surface of the seal disc. The thermite charge was used with different chromium and carbon content to produce a functional

layer similar in chemical composition to the cast iron grades from Class 1 Type A to Class 2 Type D (ASTM A532).

As noted above, due to the justification of methods for determining the temperature-time and qualitative-quantitative parameters of the melt formation process, it is possible to control the temperature and amount of thermite melt formed, its chemical composition, hardness, and relative wear resistance due to different structural and phase states.

Charge#2 was chosen, the chemical composition of which is close to cast iron Class 2 type D to obtain a wear-resistant layer of the entire damaged surface of the seal disc. A special feature of the surface is uneven wear up to 30 mm thick. According to calculations:

- the area of the damaged surface – 3060 cm^2;
- damaged surface volume – 4600 cm^3;
- thermite melt weight – 32.5 kg;
- thermite charge weight – 70 kg;
- required volume of the reactor mould – 30 dm^3.

The restored casting was formed according to the scheme shown in figure 2. The thermite charge and base were heated to 873 K. After that, surface alloying was conducted by casting a thermite melt on the damaged relief surface. The thickness of the wear layer, depending on the depth of wear, ranged from 1 to 30 mm.

Then the slag phase was separated and the resulting layer was mechanically processed to level its surface.

The resulting seal disc was transferred to the mining enterprise for analysis of its service life in industrial conditions.

It is proposed to replace valuable metal powders with powders prepared from metal waste to reduce the cost of casting, namely by crushing deposits of ferroalloys, cast iron, and aluminium cuttings.

Test results of cut-out samples obtained from experimental charges (table 3) at 873 K are shown in table 4.

Table 4. Chemical composition and mechanical properties of functional layers.

Sample number*	Content of elements in the functional layer, %			Number of strengthening in the functional layers, %			Microhardness of castings, MPa	Wear resistance coefficient

* The sample numbering corresponds to the sample numbers in the table 3

Tests showed the same wear resistance of the thermite functional layer alloyed with Cr 9.52% compared to the base cast iron sample EN-GJN-HV600(XCr23).

The addition of chromium to the charge increases wear resistance by increasing the total number of carbide and oxide phases. The improved wear resistance of the prototypes is also associated with the cooling rate of the functional layers, which reached 83°C/s. A high cooling rate during crystallisation changes structural characteristics such as the size of carbides and the relative position of phases. The increased number of non-metallic phases in the functional layers also increases wear resistance, which is associated with the high physical and mechanical properties of corundum. Since the formation of inclusions takes place during the formation of the structure, they have a high cohesion to the entire metal matrix.

A sample obtained from charge#2 was selected due to high wear resistance and microhardness to examine the quality of the connection of the functional layer with the casting base. The sample was cut into two parts. A conventional cutting abrasive wheel turned was identified to be unsuitable, so cutting was performed with a water-cooled diamond wheel. In cross-section, there are no distinctions in the functional layer, the fusion of casting layers is characterised as a defect-free connection zone.

A metallographic section was made from half of the sample, which was examined using an epiquant metallographic microscope. Against the background of the relief of the microstructure without etching, corundum inclusions inside carbides are observed (figure 8 magnification $\times$ 600).

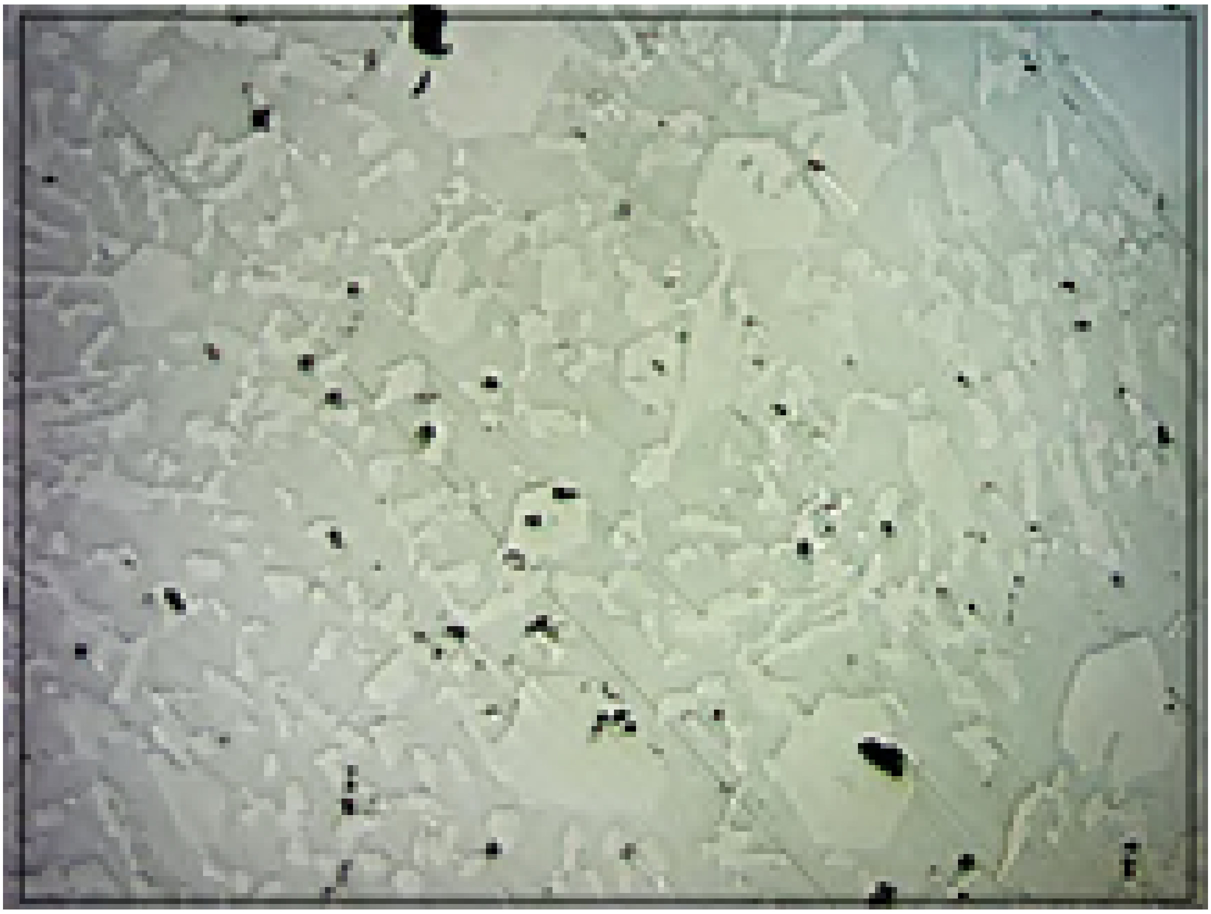

Figure 8. Microstructure of the sample without etching.

Dark inclusions inside carbides are corundum inclusions that provide the effect of modifying the thermite melt. These crystallisation centres contribute to the formation of chromium carbides [21]. The microhardness of individual inclusions is determined by the PMT-3 microhardness meter, which allows accurate measurement of microhardness in the designated zone.

The conducted studies allow concluding that fine-grained chromium carbides are present in the microstructure of the functional layer. Inclusions of chromium carbide with imprints from the diamond pyramid, the microhardness of which is 18540 MPa, are shown in figure 9.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012076 doi:10.1088/1755-1315/1415/1/012076

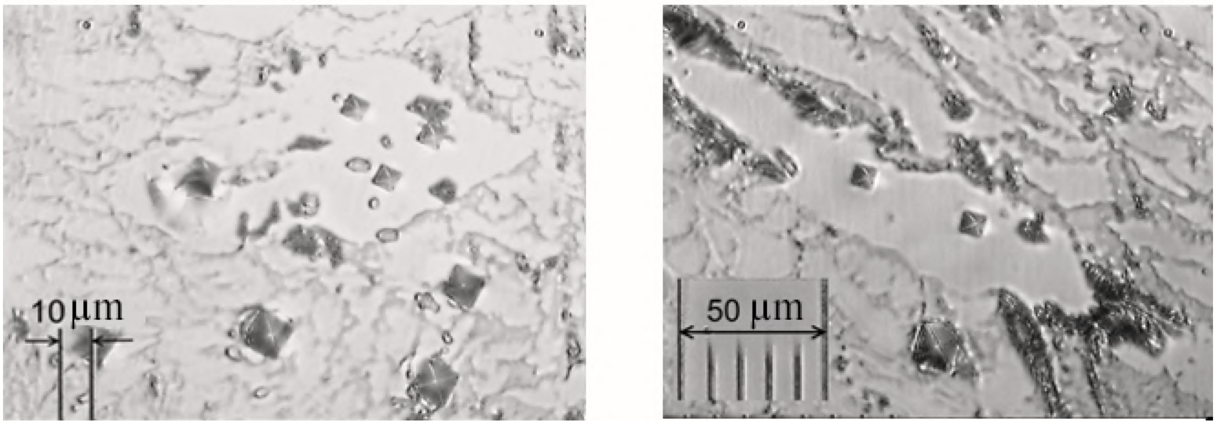

Figure 9. Inclusion of chromium carbide with diamond pyramid imprints.

Examination of the sample after etching in a 4% alcoholic solution of nitric acid showed that the carbide component formed around the corundum prevails against the background of the fragmented relief (figure 10, magnification × 300).

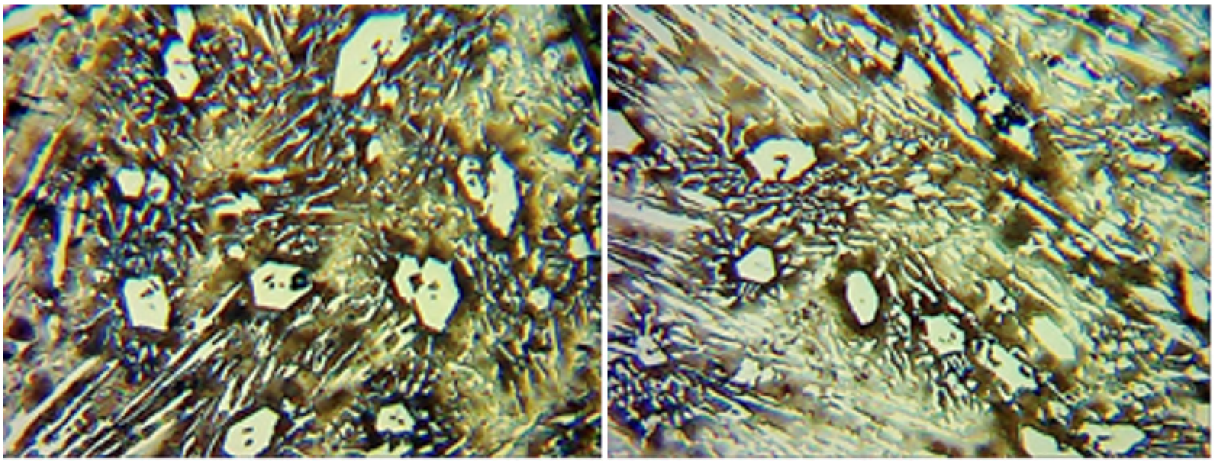

Figure 10. Microstructure of the sample.

5. Conclusions

With a thickness of the formed layer of 20 mm, all gas bubbles with a diameter of more than 0.03 mm during melt being in the liquid state have time to reach its surface. Near the open interface between the main and formed alloyed layers, all gas inclusions with a diameter of up to 0.01 mm will exit its surface.

At a worn-out casting temperature of 873 K and a melt temperature of up to 2500 K, a reliable fusion of a functional layer up to 30 mm thick with a base was observed over the entire surface of the restored disk.

The proposed technology allows the following:

- obtaining a high-quality surface connection zone made of non-alloyed alloy with an alloyed functional layer made of thermite cast iron, close in composition to Class 2 type D (ASTM A532);

- increasing the inter-repair period of casting due to almost 2 times greater wear resistance;
- reducing energy costs in the production of melt by aluminium-thermite method;
- reducing the cost of production.

Abstract. The study delves into the main stages of the life cycle of software systems, emphasizing the integral role of web APIs within this framework. Notably, we focus on analyzing the structural components of development costs associated with these systems. Our findings reveal a considerable portion of the costs dedicated to sustaining the robust development of the software system. This underscores the importance of forecasting the intensity of various types of requests for system changes, enabling the timely fulfillment of customer requirements and accurate estimation of investment costs throughout the software system's life cycle. To address this need, we propose a method for forecasting costs to support the sustainable development of a software system. This method relies on a hierarchical algorithmic clustering approach applied to retrospective weekly schedules of client requests for system changes. The clustering process is executed separately for each type of change, yielding distinct graphs. Representative graphs within the obtained clusters serve as key elements in predictive calculations. Determining a representative graph for each cluster, along with the corresponding cluster size, enables prediction by adding representative graphs in proportion to the cluster size. Maintaining the correct proportionality is achieved through the implementation of a greedy algorithm. The application of the developed forecasting method to support the sustainable development of the software system is illustrated using experimental data. This approach not only caters to current customer requirements but also ensures a comprehensive estimation of investment costs, offering valuable insights for optimizing the software system's life cycle.

1. Introduction

In today's digitally connected world, web application programming interfaces (web APIs) are indispensable in allowing distributed parts of software systems to communicate with one another. Web APIs are exposed over a network and are often referred to as remote APIs to distinguish them from static ones, which are used to connect software components running on the same machine [1]. In a nutshell, web APIs are rules and protocols for building and interacting with software applications. As Andreo and Bosch have put it, "...we can define APIs as a set of requirements that govern how applications can interact and exchange data and how we want to deliver value to the customers" [2]. Due to the rise of containerization and microservices, web APIs are being used even when communicating components are running on the same machine [3].

Web APIs constitute an essential part of services computing, which has evolved from a technology focused on enterprise interoperability to becoming a key driver in developing the web API economy [4]. According to Basole, "The importance of APIs is particularly amplified with the emergence of the idea of the "everything-as-a-service" (XaaS) paradigm, which envisions business capabilities, products, and processes not as discreet vertical offerings operating individually in silos but, rather, as a collection of horizontal services that can be accessed and leveraged across organizational boundaries" [5]. Today's most prominent web API ecosystem fields are online mapping, e-commerce, social, analytics, finance, and health [5]. The availability of such APIs allows companies to explore and enter markets that were previously beyond their consideration [4].

This paper proposes a method of forecasting web API development efforts given historical data on types of web API changes and their frequency. The web API change classification can be based on the motivating factors (new features, simplification, error corrections), the API elements changed (resources, methods, fields), the actions performed (adding, renaming, removing), or the way the clients are affected (breaking vs. non-breaking, syntax vs. behavior) [6]. The proposed method is based on predicting the number of changes of each type. The cost of a change can be obtained with expert judgment per change type or deduced from historical data if such information exists. In addition, each change should be easily identified as belonging to a particular type. Given such requirements, it makes sense to classify changes both by API elements changed and actions performed based on API syntax definition.

The rest of this paper is organized as follows. Section 2 highlights the importance of web APIs for digitalization in the energy sector. Section 3 emphasizes the need to evolve web APIs. Section 4 presents the related work. Section 5 describes the proposed method. Section 6 presents conclusions and future work directions.

2. Web APIs in energetics

In the field of energetics (energy-related systems and technologies), web APIs play a crucial role in facilitating data exchange, communication, and integration among various energy-related applications, services, and platforms. Here are some common uses of web APIs in energetics:

- Energy Data Access:
  - Retrieving real-time or historical energy consumption data.
  - Accessing information about energy production, storage, and distribution.
- Renewable Energy Integration:
  - Integrating with weather APIs to incorporate real-time weather data for better renewable energy production forecasts.
  - Accessing APIs that provide information about solar and wind patterns.
- Grid Management:
  - Interacting with APIs to monitor and manage energy grids efficiently.
  - Accessing grid-related data, such as load balancing, demand response, and outage information.
- Smart Home and Building Automation:
  - Integrating with APIs for smart home devices to optimize energy usage.
  - Connecting with building management systems to enhance energy efficiency.
- Energy Market Information:
  - Accessing APIs to retrieve information about energy prices, market trends, and trading data.
  - Interacting with financial APIs for energy-related investments and transactions.
- Electric Vehicle Integration:
  - Connecting with APIs to monitor and manage electric vehicle charging stations.
  - Accessing data related to electric vehicle battery status, usage, and charging patterns.
- Energy Efficiency and Monitoring:

  - Utilizing APIs for energy monitoring and reporting tools.
  - Integrating with energy analytics platforms to optimize energy consumption.
- Environmental Impact Assessment:
  - Accessing APIs for environmental data to assess the ecological impact of energy production and consumption.
- Policy and Regulation Compliance:
  - Connecting with APIs to stay updated on energy-related policies and regulations.
  - Accessing compliance-related information and reporting tools.
- Collaboration and Research:
  - Sharing data and research findings through APIs for collaborative energy research.
  - Creating interoperability between different energy-related research platforms.

Web services allow interconnecting smart houses, smart grids, and energy service providers [7]. Web APIs are indispensable to a smart city solution in facilitating energy-related data collection, aggregation, and consumption [8]. As a mechanism for handling real-time, online, and historical energy data, web APIs can support interoperability in smart cities, facilitate decision-making for energy sustainability, enhance energy prosumption operations, and improve efficiency in smart grids [9]. A district energy management system can provide APIs that enable energy suppliers and facility managers to continuously oversee and uphold the energy distribution network [10].

For smart cities to achieve a sustainable energy future, using electric vehicles when implementing transportation services is crucial. Web APIs can be instrumental in integrating various mobility solutions provided by different stakeholders in urban transportation, which helps reduce costs and create value-added services [11]. When implementing automation, management, and monitoring of energy consumption for smart homes, web APIs facilitate the exchange of data between smart home services and applications for controlling home devices, efficient energy scheduling, and integration with smart city infrastructure [12]. Household energy consumption can be reduced by building applications powered by web APIs that forecast electricity bills and inform users [13]. By leveraging web APIs, stakeholders in the energetics sector can enhance the interoperability of various systems, improve data accessibility, and foster innovation in the development of energy-related applications and solutions.

3. Web API evolution

Web APIs must be initially developed and continuously improved like any other part of a software system. At first glance, the improvement effort should be insignificant. If an API covers the needs of its clients, there is no reason for it to evolve. Nevertheless, that rarely happens in reality. As demonstrated by a prior study, web APIs are still being updated for a long time after creation [14]. When an API is released for the first time, its developers may still need to obtain all the requirements and gain more knowledge of the domain it addresses. That is the reason why an API is often imperfect at launch. Even an initially adequate API can eventually become insufficient or obsolete as new concepts within the domain emerge, legal regulations change, or clients request additional features. According to previous research, new feature requirements and usability are the most significant reasons static APIs change [15]. Those same reasons are valid for web APIs. In addition, the changes can be made to accommodate technological advancements, address bugs, enhance security, or even unintentionally during code refactoring. So, web APIs constantly evolve to prevent themselves from becoming obsolete.

The need to constantly evolve web APIs matches the conclusions of Zarnekow and Brenner, who have found that most of the life cycle costs for a software system occur after the system has been put into production [16]. According to their research, the life cycle of a software system has four stages: planning, initial development, production, further development, and shut-down. Requirements analysis and design are performed during the planning stage. The initial development consists of building, testing, and deployment. The production stage includes system operation, support, and maintenance (e.g., fixing errors). The purpose of further development is to improve the system functionally. Finally, the system shuts down, often replaced by a newer one. The authors have shown that, given a production time of 5 years, the recurring costs of production and further development were 79% of all the total costs on average [16]. Those results indicate how important it is to predict the cost and schedule of further software development. Such estimation is required for project budgeting, analysis of risks and tradeoffs, planning and controlling the project, and analysis of investments into software improvements [17].

Since web APIs have become an essential part of many software systems, predicting and estimating development efforts to support their sustainable evolution while being in production is getting more relevant than ever. In order to plan months ahead and effectively allocate resources, project managers need to know how often web APIs will change and what development effort will be required to perform such changes, even before the requirements for those changes have been received.

4. Related work

In order to forecast software development efforts for a particular time interval, one needs to predict the distribution of change requests and then estimate the effort for each change. The first part can be solved with a time series forecasting model.

Goulão et al. built an ARIMA model that could predict maintenance and improvement requests in the Eclipse project based on data from its change request tracking system [18]. The model had been trained on seven years of request history and could predict change requests over 12 months. In particular, the model included means to identify seasonal patterns, which helped to provide better accuracy. The independent variable of the model was a timeframe, and the dependent variable was the number of changes, so the model could not differentiate between types of changes.

As an alternative to ARIMA models, Saini and Kaur explored using a computational method based on fuzzy time series to predict the number of commits into source control management repositories in several open-source software projects [19]. The authors used the number of commits per month as a metric to analyze 17 years of evolution for seven projects. The prediction accuracy was better when compared to the one of the ARIMA models. While the method could predict how active a project development was, the commits were not classified in any way.

Kalouptsoglou et al. compared the performance of traditional statistical methods and deep learning models in predicting the number of vulnerabilities in five large software projects [20]. For each project, the monthly number of vulnerabilities was forecasted for 24 months ahead based on previous project vulnerabilities for about 20 years. The authors used single and triple exponential smoothing, an Autoregressive Integrated Moving Average (ARIMA) model, Croston's method, a Multi-Layer Perceptron (MLP) model, a Recurrent Neural Network (RNN) model, and a Convolutional Neural Network (CNN) model. The results showed that all the methods had similar predictive power. However, there were projects for which deep learning models performed better. Vulnerabilities in some projects were more challenging to predict than in others. A notable property of vulnerability time series is that vulnerability occurrences are intermittent, i.e., they fluctuate significantly, and many zero values exist.

An effort has to be estimated for each change predicted by the time series forecasting model. There are many methods for software development effort estimation (SDEE). According to a recent review, they can be based on expert knowledge, size, model, analogy, regression, optimization techniques, fuzzy logic, machine learning (ML), and artificial neural networks (ANN) [21]. Expert-based methods include the Delphi technique, Planning Poker, top-down, bottom-up, and rule-based estimation methods. Size-based methods calculate project size in function, use-case, or story points. Model-based methods (COCOMO, COCOMO II, SLIM, SEER_SEM, WBS) are calibrated on previous projects and rely on such factors as the activities covered and attributes of software, computer, personnel, and project [17]. An advantage of such analogy-based methods as Case-Based Reasoning (CBR) is that it is easy to understand the reasoning behind the result. Many regression methods and related techniques are used for SDEE, e.g., simple and multiple linear regression, stepwise regression, Stochastic Gradient Boosting (SGB), and Support Vector Regression (SVR). Multiple optimization techniques such as genetic algorithms (GA), Particle Swarm Optimization (PSO), and Artificial Bee Colony (ABC) can be employed to obtain more precise estimates. Fuzzy logic methods can deal with imprecise and missing data. The most popular ML methods are support vector machine (SVM) and such tree-based ones as Decision Tree (DT), Classification and Regression Tree (CART), and Random Forest (RF). Artificial neural networks, such as Multi-Layer Perceptron (MLP), General Regression Neural Network (GRNN), Cascade Correlation Neural Network (CCNN), and Radial Basis Function Neural Network (RBFNN), are becoming more popular because they can automatically extract features and capture complex dependencies in data [21].

One of the recent trends is combining several methods in order to obtain better estimates. For example, Case-Based Reasoning (CBR) weights can be optimized using Particle Swarm Optimization (PSO), a method inspired by the social behavior of birds and fish. A study exploring this approach demonstrated that the PSO method outperforms traditional methods in convergence rate and learning efficiency [22]. Another research proposed two architectures of artificial neural networks based on Taguchi's method using such COCOMO attributes as scale factors, cost factors, and software size [23]. According to the paper, clustering projects from different datasets and data fuzzification significantly enhance the efficiency, reliability, and accuracy of SDEE [23]. Even mature methods can provide better results when combined with artificial intelligence approaches. It was reported that integrating a Fuzzy Inference System (FIS) with COCOMO II enhanced model results by introducing fuzziness into estimating size, cost drivers, and scale factors [24]. The authors of another study proposed a heterogeneous ensemble estimation model combining several models such as Use Case Point (UCP), Expert Judgement (EJ), and Artificial Neural Network (ANN) [25]. The study demonstrated that the ensemble technique performed better than separate estimation methods [25].

There is also a challenge of properly integrating effort estimation methods into the practices of agile software development methodologies, which still rely on expert-based effort estimation, despite that ML methods are being used more often than before [26]. An example of such an integration is a model using Bayesian networks to improve effort estimation accuracy for agile teams [27]. In that work, the author identified factors that influenced the effort needed. These were the nodes of a directed acyclic graph and belonged to either teamwork quality or user story characteristics [27].

The papers analyzed consider software development in general without depending on characteristics specific to estimating changes in web APIs. When estimating future changes to web APIs, obtaining the exact number and type of historical changes from API change logs or a version control system storing API definitions may be possible. Having separate data for each type of change should provide better accuracy for predicting changes and estimates of each type of change. The methods used to build a forecasting model need a lot of historical observations for an extended period to predict future changes. That is not the case with web APIs, which usually do not change daily and do not have a history of more than several years. It means another approach to forecasting web API changes must be used. The SDEE methods mainly estimate concrete work when the factors influencing the effort are already known. That makes them of limited use when estimating a typical change that is likely to happen in the future. Nevertheless, most of them can still be used to some extent.

5. Forecasting software development work effort

This research aims to find a way for project managers and stakeholders to predict the effort needed to support web API evolution. In order to manage resources efficiently, it is crucial to estimate the total work for a significant future period and see how the work may be distributed over that period. Since most web APIs do not have to be changed each day, it is impossible to build a predictive model that gives an accurate daily effort estimate for the next quarter or year if the only data available is a list of historical changes. However, building a representative model that captures the underlying patterns and trends is feasible. The proposed method can be used to forecast quarterly or even yearly efforts and understand how future work may be distributed. While that illustrative distribution cannot be used to estimate work effort for a particular day, it will be helpful to assess the expected surges of demand for web API improvements and be ready to invest the time of software engineers into such changes.

In order to demonstrate the proposed method, a representative model based on Stripe API has been built. First, the API changes for three years, from November 18, 2020, to November 17, 2023, were collected from the Stripe API changelog [28]. The distribution of the changes is shown in figure 1.

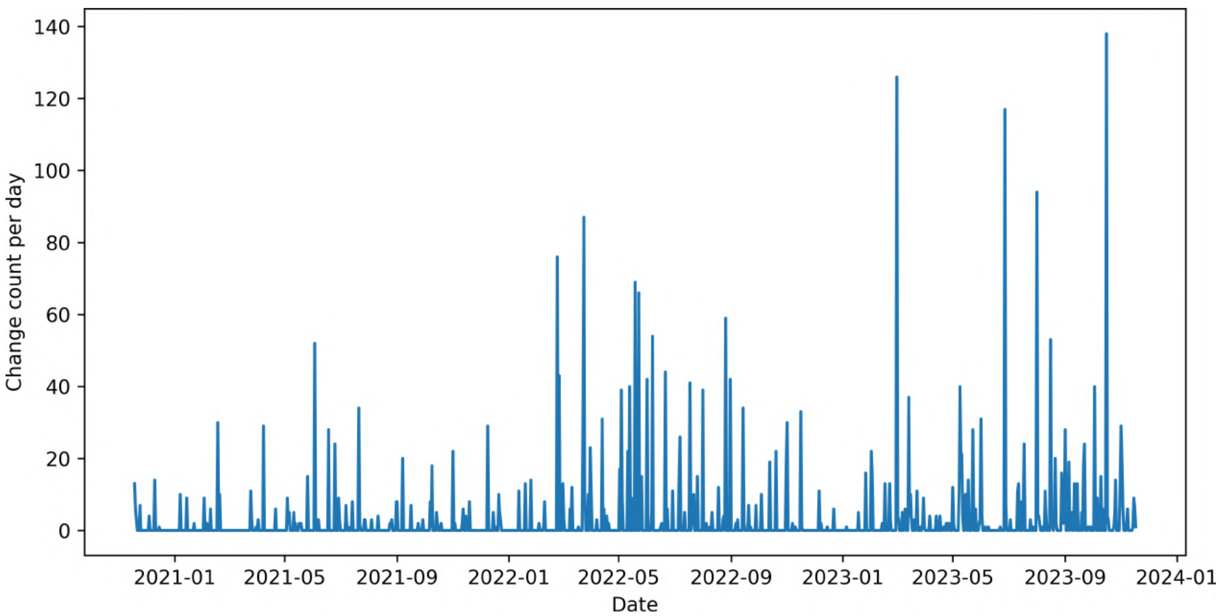

Figure 1. Historical API changes.

In order to demonstrate the proposed method, a representative model based on Stripe API has been built. First, the API changes for three years, from November 18, 2020, to November 17, 2023, were collected from the Stripe API changelog [28]. The distribution of the changes is shown in figure 1.

Second, the changes were classified based on the API elements modified and actions performed. Regardless of whether the method's input or output messages were modified, adding new fields was considered the same type of change because of close semantics and similar implementation complexity. The field removal changes were grouped in the same way. Similar reasoning was applied to the category of field type changes, which includes cases when the actual field type has changed and when field optionality or nullability has changed.

Next, each change type was estimated based on the expert opinion of the authors because the historical data on the work effort spent implementing those changes was unavailable. Any SDEE method can be used to estimate the effort of implementing changes of each type, provided the necessary data related to the project is available. Table 1 lists all the change types discovered, along with the number of changes and effort estimation for implementing a new change of the corresponding type.

Table 1. Change types.

Change type	Historical change count	Effort estimate, person-hours
New resource added	46	100
Resource removed	12	50
New method added	69	20
Method removed	22	10
New field added	1423	10
Field removed	74	5
New enum value added	1338	5
Enum value removed	99	5
Field type changed	343	5

Since historical data can show trends and seasonality, it must be normalized to be useful for forecasting purposes. For example, the demand for web API changes can increase as the number of web API clients grows. However, it is hard to find the exact trends or seasonality in the data collected because, as figure 1 shows, the data is sparse, so three years is insufficient. Because of that, a simple approach was chosen. The changes were counted for each year starting November 18. Also, adjustment factors were calculated as quotients of the change count for the last and each year. The adjustment factors were used in further calculations to normalize historical data by multiplying the change count by the corresponding adjustment factor. Table 2 lists the yearly change counts and adjustment factors.

Table 2. Yearly change counts and adjustment factors.

Year number	Change count	Adjustment factor
1	538	2.7304832713754648
2	1419	1.0352360817477098
3	1469	1

The following steps were made for each change type separately. This paper uses the "new enum value added" change type to illustrate them. The historical distribution of such changes is displayed in figure 2.

After normalization, the 3-year time series containing the change count of a particular type was split into multiple 7-day time series, corresponding to how software developers usually organize their work. For each weekly time series, the mean and standard deviation of the change count were calculated because each day had a different number of changes. The received 2-D data points represent weeks with high demand for changes when the mean is high and low demand when it is low. The standard deviation indicates whether the demand is stable within the same week.

The next step was grouping the weeks the data points represent into several clusters. Each cluster must contain weeks with similar demand patterns for web API changes, leading to similar work efforts for the weeks within the same cluster. The Agglomerative Clustering method was

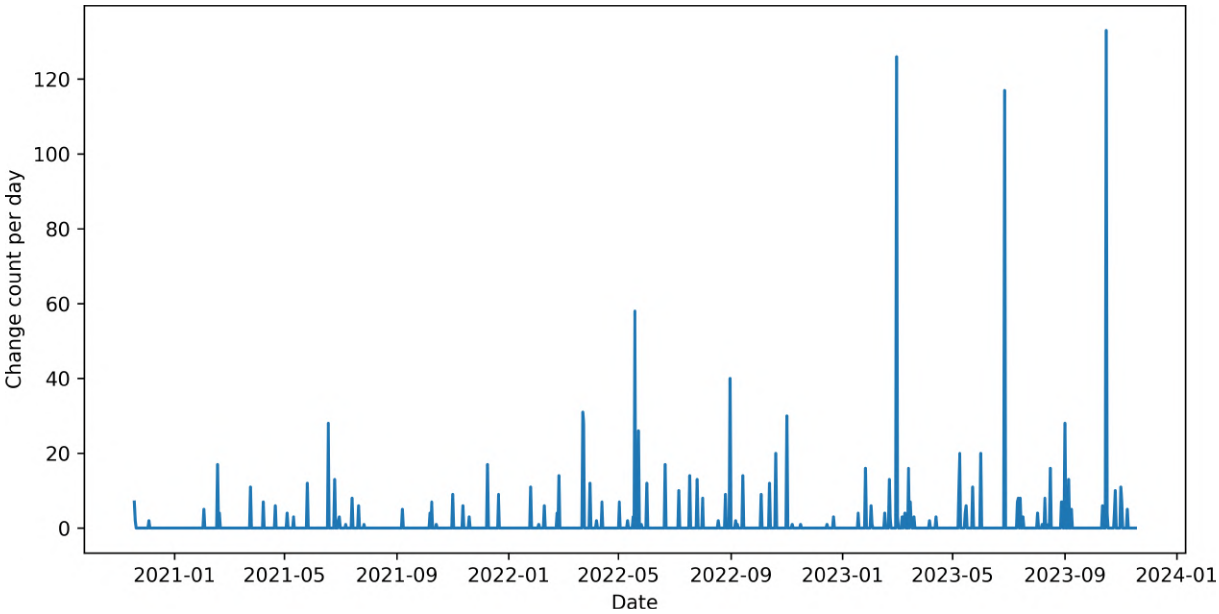

Figure 2. Historical changes of adding new enum values.

used for clustering because it is particularly effective in identifying small clusters and can handle non-spherical shapes better than K-means. The Ward linkage method, which minimizes the total within-cluster variance, was chosen because it tends to create clusters of roughly equal size and works well with quantitative features, like change count, as it uses Euclidean distance. The number of clusters selected was four for all the change types after experimenting with different numbers and visual comparison of the results. For each cluster, a centroid was calculated as the mean of all the data points belonging to the cluster, and a representative data point was found as the one closest to the centroid. Figure 3 illustrates the whole clustering process described above.

The next step was building a forecast of the change number for the next quarter. Since a representative week for each cluster was known, as well as the size of the cluster, a forecast was built by adding representative weeks proportionally to the cluster size, i.e., the number of weeks in the cluster. If the weeks of some kind were rare in the past, their representative had to be rare in the forecast, and vice versa. Keeping the right proportion was achieved with a greedy algorithm. The most underrepresented cluster was selected on each step, and the corresponding representative week was added to the forecast time series until the time series covered the whole quarter. Figure 4 shows a representative graph of the forecasted number of new enum values added and the mean and standard deviation within each week.

After constructing forecasts for each type of change, a representative forecast of the total work effort was built based on the assumption that demand for a change of a particular type requires an effort estimated for that change type. The effort was calculated separately for each day. First, the effort for each change type was calculated by multiplying the predicted number of changes and the estimated effort shown in table 1. Second, the total effort for the day was obtained by adding up the estimates for all the types of changes. Figure 5 presents the resulting representative graph.

The steps above allow for building a representative model for Stripe API that can be used to forecast the work effort necessary to support Stripe API evolution for a quarter. In the same way, a representative model can be built for any web API and any future period, given that an API changelog is available. The proposed method involves collecting and classifying

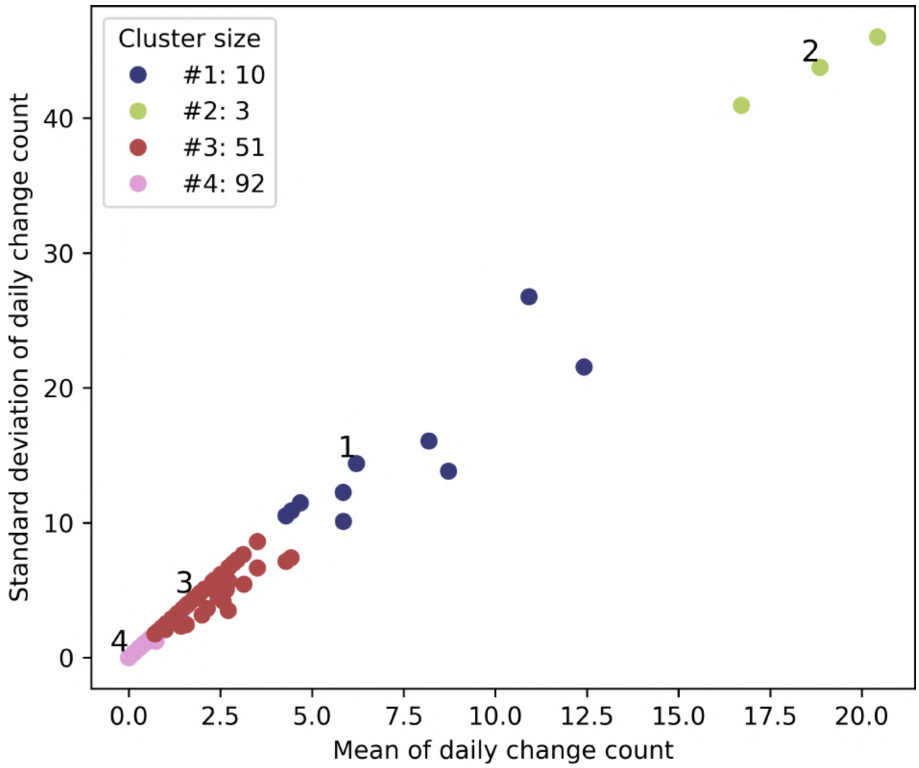

Figure 3. Clusters of similar weeks.

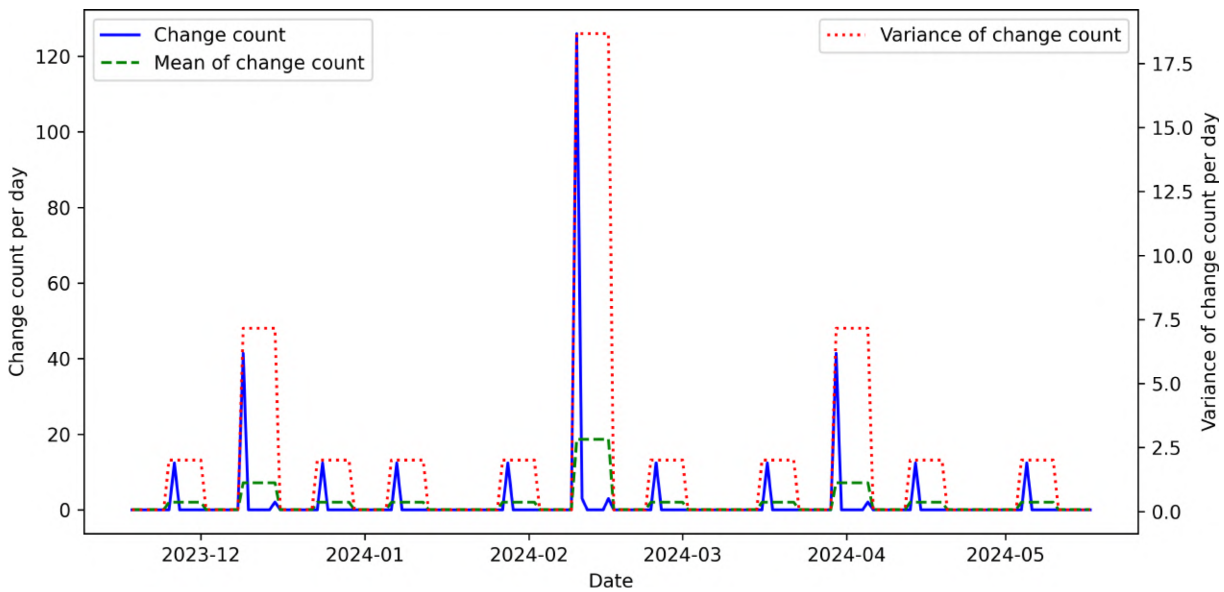

Figure 4. Forecast of adding new enum values.

API changes, estimating the effort for each change type, normalizing the data, and employing clustering to identify patterns in time series. Change demand forecasts are then constructed using a greedy algorithm for each change type, focusing on maintaining the proportion of weeks that follow different demand patterns. Finally, the change demands forecasts are combined to produce a work effort forecast.

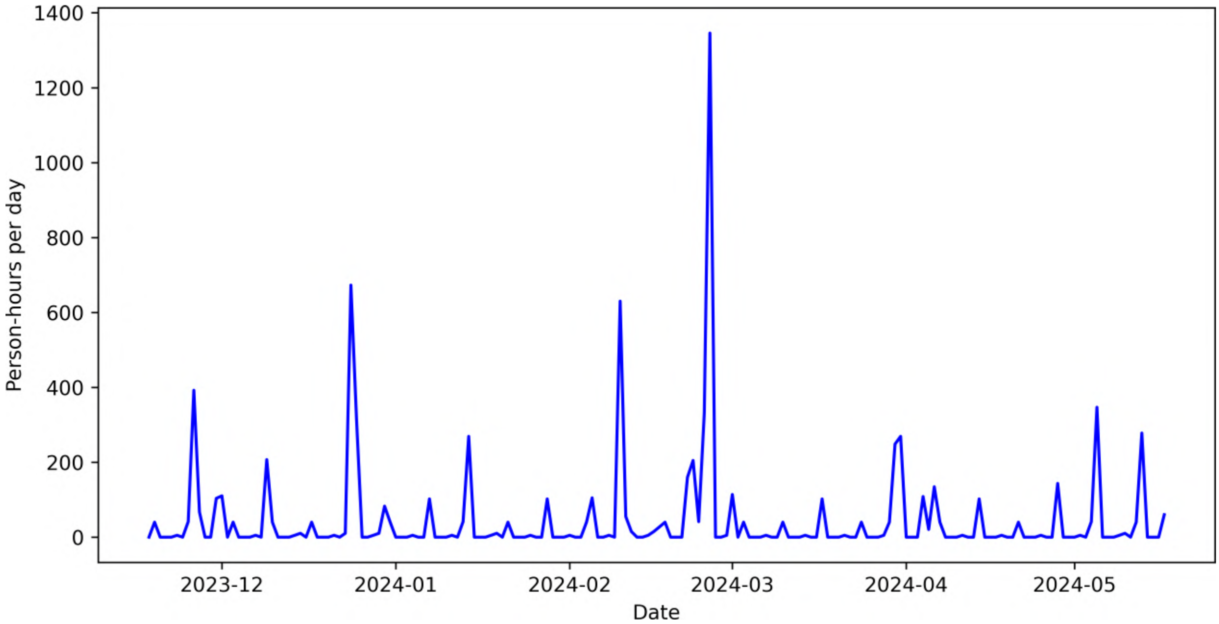

Figure 5. Forecast of work effort.

6. Conclusions

This study introduces a forecasting method designed to predict the work effort required in software development to facilitate the evolution of web APIs. The approach involves constructing a representative model that depicts the anticipated workload over a significant period, such as a quarter or a year. Cluster analysis is utilized to identify common workload patterns from historical data. The method addresses the challenge of staff planning for organizations involved in building and supporting web APIs. Future research aims to enhance forecasting precision by incorporating machine learning techniques, such as the Random Forest ensemble learning method and Multilayer Perceptron artificial neural networks.

Abstract. The design of complex technological processes control systems involves several stages. One of the first is to analyze the steady-state operation modes of the control plant. Ore crushing is one of the most critical processes in mineral processing. The quality of its control determines the level of power consumption not only at this stage of mineral processing, but also at the subsequent ones, especially the grinding processes, which are the most energy-intensive in the entire production. The size and homogeneity of crushed ore significantly affect the power consumption of the mills. Ore is crushed by cone crushers. The crushing process is characterized by a large number of parameters. Depending on the control purpose, any of them can be considered as an input, output or disturbance. As a result, a cone crusher as a control plant is a multi-input multi-output system. The relationships between inputs and outputs are very complex, so it is very important to have an adequate mathematical description of cone crusher steady-state for its quality control. In this article, it has identified second-order polynomials regression models for the dependencies between the most significant parameters for a typical cone crusher with a mantle width 2200 mm. Namely, the dependence of the crusher electric drive power on the closed-side setting and feed capacity; the percentage of the control particle size class in the product on the closed-side setting and product capacity; product capacity on the closed-side setting, lining wear on the product capacity. The least squares method was used to estimate the parameters of the regression models.

1. Introduction

Energy efficiency is currently and will continue to be a key factor in the list of factors that ensure favourable conditions for the recovery and further sustainable development of Ukraine as a whole and its individual economic sectors in particular. At the same time, mining and mineral processing plays a key role due to its high power intensity. Analysing the energy component of mining production costs by individual stages of rock processing, it can be argued that the highest share of energy consumption is accounted for by the technological processes of ore disintegration, such as crushing and grinding. Therefore, energy efficiency improvements can be achieved mainly by improving these technological operations. There are two possible ways to do this. The first is the complete re-equipment of production lines with the latest equipment with a high level of energy efficiency. The second is to improve existing equipment and automated control procedures. The last way is more economically feasible as it does not require large investment.

At the same time, it is implemented if it is possible to identify reserves for improving energy efficiency. This is usually achieved by studying the steady-state operating modes of technological equipment. From the perspective of crushing processes, energy efficiency improvement involves reducing the level of power consumption by the crusher's electric drive while maintaining the product capacity and particle size distribution of the crushed product as regulated by technological requirements, taking into account lining wear.

2. Literature review

A fairly wide range of works is devoted to the study of steady-state operation modes of cone crushers [1–31]. In them, the authors use different modelling approaches. Depending on the type of model used in the analysis, they can be classified as follows.

Most studies use a model that describes the regularities of the crushing process using the functions of selection, breakage and classification, or the so-called Whiten's model [17, 27]. It allows describing the relationship between the particle size distribution of the feed and the product of a cone crusher. Moreover, such a model can be used when the crushing chamber is considered as a continuous object [5,9], i.e. in the form of a model with concentrated parameters, and when the crushing chamber is divided into zones through which the ore moves sequentially from the feed to the exit slot, i.e. in the form of a model with distributed parameters [2, 3, 15]. For example, in [5], the product capacity of a crushing plant is optimised. The authors use the Whiten's model as a single-zone model to determine the particle size distribution of the product at different CSS. In [2], the steady-state characteristics of the Metso GP11M crusher were obtained on the basis of a multi-zone model of a cone crusher. For different CSS, the particle size distribution of the product, the total cone crusher product capacity, and the electric drive power were determined. The mathematical description was used to simulation the secondary crushing process at a real crushing plant.

Given its wide application, this model is quite generalised and versatile, but it requires sufficient computational resources, especially when used as a model with distributed parameters, as well as when the number of classes in the particle size distribution increases.

Another class of models uses the discrete element method (DEM) to describe the crushing process in detail [6–8, 14, 24, 28, 30]. These models are characterised by high accuracy, but are quite complex in algorithmic implementation and have a significant computational burden and are not suitable for use in automated control tasks. They are mostly used in the design, construction, and modernisation of cone crushers.

Empirical models describing the steady-state of the crushing process have also been used [4, 11, 18]. For example, Bengtsson and Evertsson [4] proposes an empirical steady-state model to determine the shape of the crushed product depending on the average feed size and CSS, which is used to optimize the quality of the crushing process.

I would like to highlight the work of Yamashita, Thivierge and Euzébio [29], which is devoted to an overview of the main methods of modeling and controlling cone crushers.

Based on the analysis of steady-state modes of operation, the authors of [1, 6, 12] consider the issues of studying the functioning of cone crushers in dynamics, optimization of their performance [26], as well as the construction of automated control systems [11, 21–23] for both individual crushers and technological stages of crushing. At the same time, there is an approach to crushing control that relies on measured data rather than modeling [13].

The purpose of this article is to obtain a mathematical models of a cone crusher steady-state operation modes, which can be used in the development of a control system for a technological unit to determine the reserve for increasing energy efficiency, as well as its operating point and the limits of change in the main technological parameters.

3. Results and discussion

The main purpose of a cone crusher is to reduce the lumpy material to the required size. Therefore, the main process variables that are controlled are product capacity and a particle size distribution.

During the operation of the crusher, the input variables are the feed capacity, the closed side setting (CSS) and the eccentric rotation speed. The disturbance is represented by a set of parameters that characterise the properties of the ore (percentage of the control particle size class, hardness, fracture, splittability, moisture content, presence of clay inclusions, etc.)

The crushing process, along with the main technological output variables, is also characterised by the power consumed by the unit's electric drive, the wear of the lining plates, and the amount of ore in the crusher.

Thus, there are a lot of input and output variables to control the crusher. The connection between them is shown in the functional diagram of the unit (figure 1).

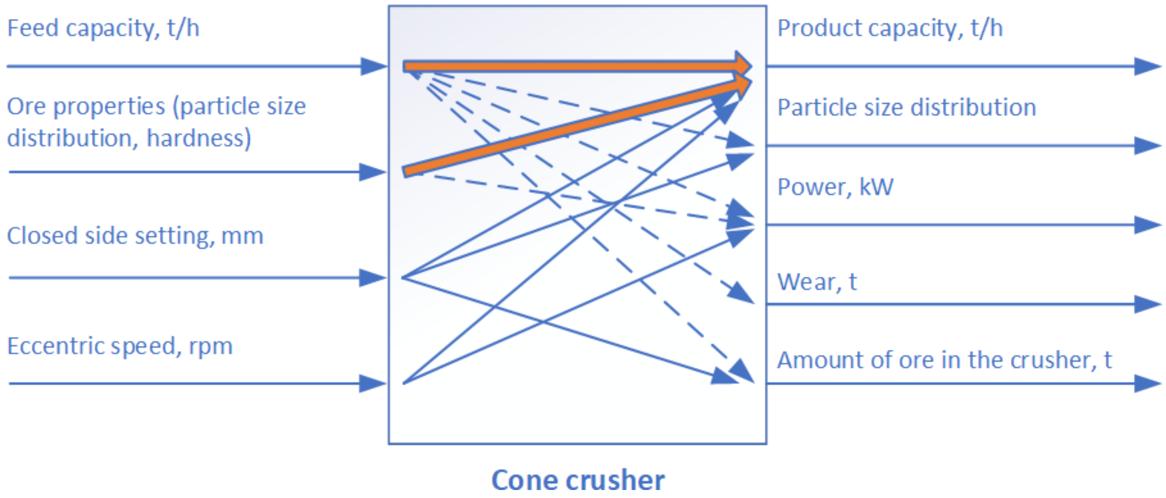

Figure 1. Cone crusher as a multidimensional control plant.

As an target of study of the steady-state properties of crushers, we choose a cone crusher with mantle width 2200 mm, which is in the final stage of crushing at the ore dressing plant No. 1 of PJSC "Pivdennyi GZK".

Let us consider in more detail the relationship between input and output variables that characterise operation modes of the crusher. Taking into account the peculiarities of the technological process at PJSC "Pivdennyi GZK" and based on the technical parameters of the cone crusher with mantle width 2200 mm and the research conducted by scientists, we will build and analyse steady-state models.

Experimental studies [32,33] have shown that at the final stages, the crushing process and the particle size distribution of the product are significantly affected by the physical and mechanical properties (hardness) of the ore. This parameter is the main disturbance. This is because the fluctuations in the cone crushers feed particle size distribution are not significant, and the feed capacity is stabilized by controlling feeders. Also, the CSS is often considered as a disturbance in steady-state modeling, for example, in [19]. It is not taken into account that this value is controllable.

The main condition for ensuring the quality of the crushing process is that crushers should not be idle or overloaded with ore. For a limited period of time, the steady-state model of the relationship between feed capacity and product capacity can be represented by the equation [34]:

$$Q_F = Q_P, \tag{1}$$

where:

Q_F is the crusher feed capacity, t/h;

Q_P is the crusher product capacity, t/h.

The cone crusher product capacity is determined by its technical parameters and ore properties.

The steady-state analysis (figure 2 a) shows that as the ore hardness increases, if the feed is constant, the crusher product capacity decreases. When higher-hardness material enters the crushing zone, the resistance to splitting increases, which leads to a decrease in the mantle rotation speed and, as a result, a sharp decrease in crusher product capacity.

Similarly, the CSS affects product capacity (figure 2 b). Increasing or decreasing the CSS leads to an increase or decrease in product capacity, respectively.

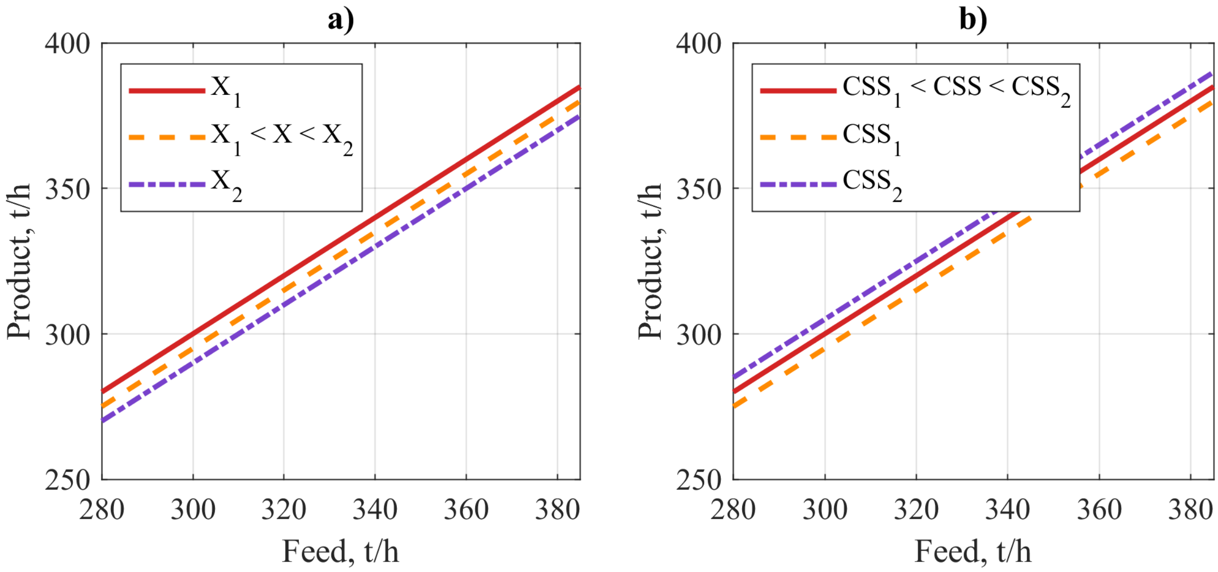

Figure 2. Crusher product capacity as a function of feed capacity: a) variable ore hardness; b) variable CSS.

In general, crusher performance is linearly related to the CSS [17, 19]:

$$\begin{gathered} Q_P\,(CSS) = Q_{P0} \pm K\Delta CSS; \\ \Delta CSS = CSS - CSS_0. \end{gathered} \tag{2}$$

where:

Q_P is the crusher product capacity at the CSS, m^3/h;

Q_{P0} is the crusher product capacity at the CSS_0, m^3/h;

K is the ratio of product capacity to the CSS, $m^3/h \cdot mm$.

Next, we will consider the crusher steady-state model of the relationship between feed capacity (Q_F) and electric drive power (P), taking into account the closed side setting (CSS). In [16], it was determined that the power consumed by the cone crusher electric drive in the operating range increases with increasing feed capacity. As a result of the simulation studies presented in [19], for crushers with a mantle diameter of 2200 mm, it was found that the power consumption has a nonlinear dependence on the crusher product capacity for different values of the closed side setting, $CSS_{\min}$, $CSS_{\min} < CSS < CSS_{\max}$ and $CSS_{\max}$ (figure 3 a). For the crusher, the closed side setting are 5 mm, 10 mm, and 15 mm, respectively.

The initial data used to build steady-state model can be approximated by second-order polynomials:

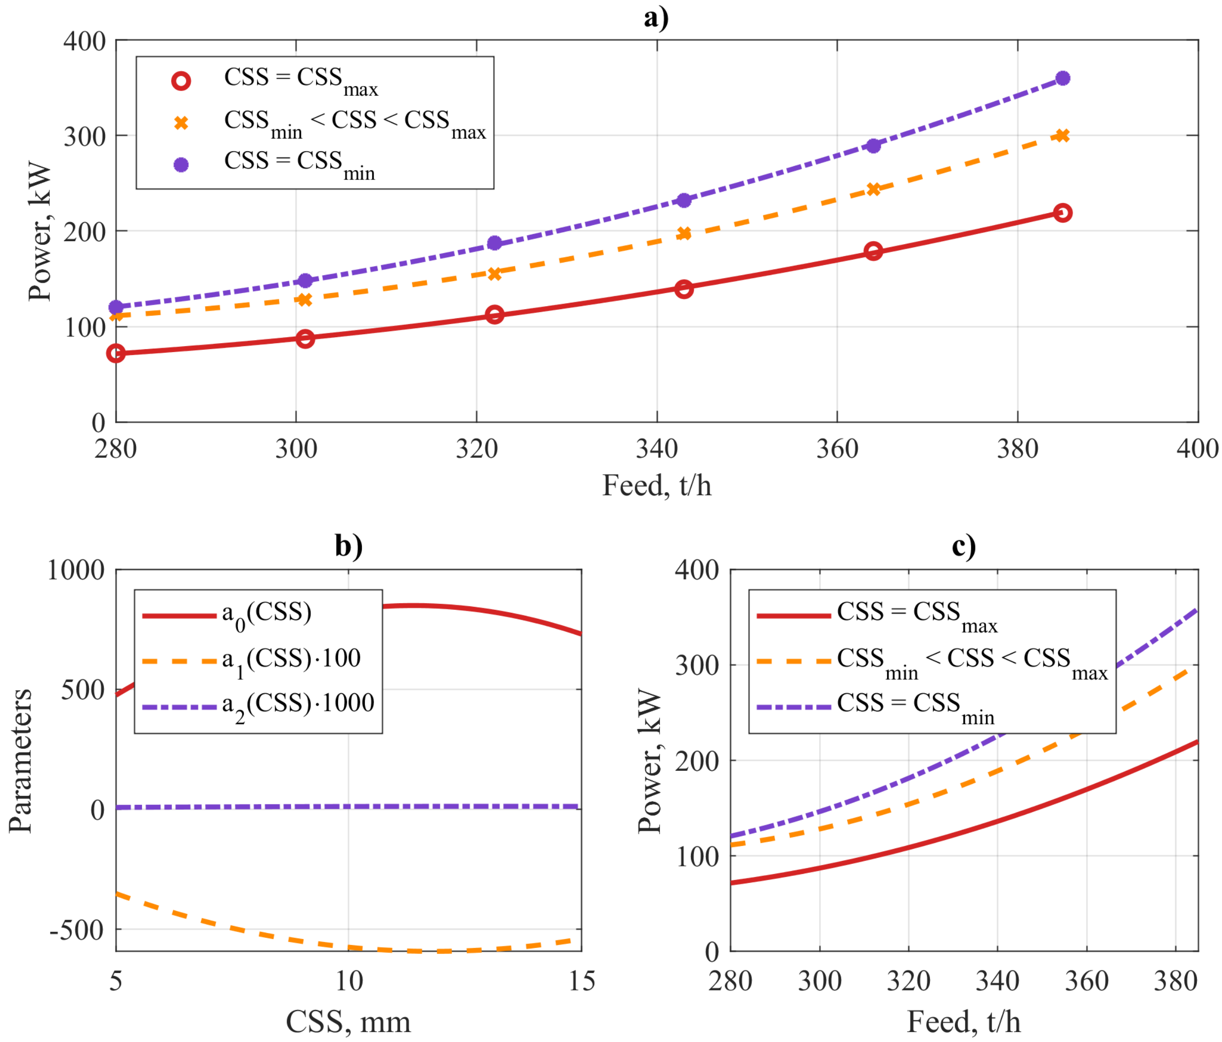

Figure 3. Electric drive power as a function of feed capacity at different values of the CSS: a) experimental data; b) polynomial coefficients; c) model data.

$$
\begin{aligned}
P_1(Q_F) &= 475.1071 - 3.5162 Q_F + 0.0074 Q_F^2; \\
P_2(Q_F) &= 831.2431 - 5.7541 Q_F + 0.0114 Q_F^2; \\
P_3(Q_F) &= 729.4167 - 5.4056 Q_F + 0.0115 Q_F^2.
\end{aligned} \tag{3}
$$

The polynomials coefficients (3) are functions of the cone crusher closed side setting. That is, they can also be approximated by the following equations:

$$
\begin{aligned}
a_0(CSS) &= -338.991071 + 208.615873 \cdot CSS - 9.159245 \cdot CSS^2; \\
a_1(CSS) &= 1.308206 - 1.223515 \cdot CSS + 0.051728 \cdot CSS^2; \\
a_2(CSS) &= -33.406 \cdot 10^{-4} + 0.001927 \cdot CSS - 75.72 \cdot 10^{-5} \cdot CSS^2.
\end{aligned} \tag{4}
$$

The result of the polynomial coefficients approximation as a function of the closed side setting is shown in figure 3 b.

Thus, the polynomial approximating the power consumed by the cone crusher electric drive as a function of two regressors – the closed side setting and the feed capacity has the following form:

$$\begin{aligned} P\left(CSS, Q_F\right) &= a_0\left(CSS\right) + a_1\left(CSS\right)\cdot Q_F + a_2\left(CSS\right)\cdot Q_F^2;\\ P\left(CSS, Q_F\right) &= -338.991071 + 208.615873\cdot CSS - 9.159246\cdot CSS^2 + \\ &+ \left(1.308206 - 1.223515\cdot CSS + 0.051728\cdot CSS^2\right)\cdot Q_F + \\ &+ \left(-33.406\cdot 10^-4 + 0.001927\cdot CSS - 75.72\cdot 10^{-5}\cdot CSS^2\right)\cdot Q_F^2. \end{aligned} \tag{5}$$

The steady-state characteristics based on equations (5) for typical CSS values (5, 10, and 15 mm) are shown in figure 3 c. At low feed capacity, the power consumption decreases with increasing closed side setting. In the case of final crushing stage at Crushing Plant No. 1 of PJSC “Pivdennyi GZK”, the feed capacity is in the range of 320 . . . 350 t/h. Thus, the required product capacity can be achieved under any expected conditions.

Lynch [19] presents steady-state model for the relationship between product capacity and percentage of particle size class +20 mm for certain closed side setting values. Data were obtained during the study of the cone crusher “Hydrocone” operating modes. This crusher has mantle width 2134 mm. Similarly, steady-state characteristics can be determined for the crusher with mantle width 2200 mm, which has similar technical parameters. The percentage of particle size class +20 mm as a function of crusher product capacity is shown in figure 4 a. With increasing product capacity, the percentage of particle size class +20 mm decreases. When the crusher product capacity is constant, the percentage of particle size class +20 mm is growing according to increasing CSS.

The initial data used to build steady-state characteristics can be approximated by second-order polynomials:

$$\begin{aligned} \gamma_1\left(Q_P\right) &= 65.0356 - 0.1827\cdot Q_P + 0.0001\cdot Q_P^2;\\ \gamma_2\left(Q_P\right) &= 82.9514 - 0.2727\cdot Q_P + 0.0002\cdot Q_P^2;\\ \gamma_3\left(Q_P\right) &= 155.5571 - 0.6635\cdot Q_P + 0.0007\cdot Q_P^2. \end{aligned} \tag{6}$$

The polynomials coefficients (6) are functions of the cone crusher closed side setting:

$$\begin{aligned} a_0\left(CSS\right) &= 104.74 - 14.23\cdot CSS + 1.18\cdot CSS^2;\\ a_1\left(CSS\right) &= -0.4167 + 0.0825\cdot CSS - 0.0066\cdot CSS^2;\\ a_2\left(CSS\right) &= 0.4146\cdot 10^{-3} - 0.1192\cdot 10^{-3}\cdot CSS + 0.0093\cdot 10^{-3}\cdot CSS^2. \end{aligned} \tag{7}$$

The result of the approximation is shown in figure 4 b.

An regression equation that approximates the percentage of particle size class +20 mm as a function of two regressors – CSS and the crusher product capacity:

$$\begin{aligned} \gamma\left(CSS, Q_P\right) &= a_0\left(CSS\right) + a_1\left(CSS\right)\cdot Q_P + a_2\left(CSS\right)\cdot Q_P^2;\\ \gamma\left(CSS, Q_P\right) &= 104.74 - 14.23\cdot CSS + 1.18\cdot CSS^2 + \\ &+ \left(-0.4167 + 0.0825\cdot CSS - 0.0066\cdot CSS^2\right)\cdot Q_P + \\ &+ \left(0.4146\cdot 10^{-3} - 0.1192\cdot 10^{-3}\cdot CSS + 0.0093\cdot 10^{-3}\cdot CSS^2\right)\cdot Q_P^2. \end{aligned} \tag{8}$$

The steady-state characteristics plotted according to equations (8) for typical CSS values (5, 10, and 15 mm) are shown in figure 4 c. The graphs show that at a low crusher capacity of 310 t/h, it is impossible to ensure the specified quality of the product. The influence of CSS

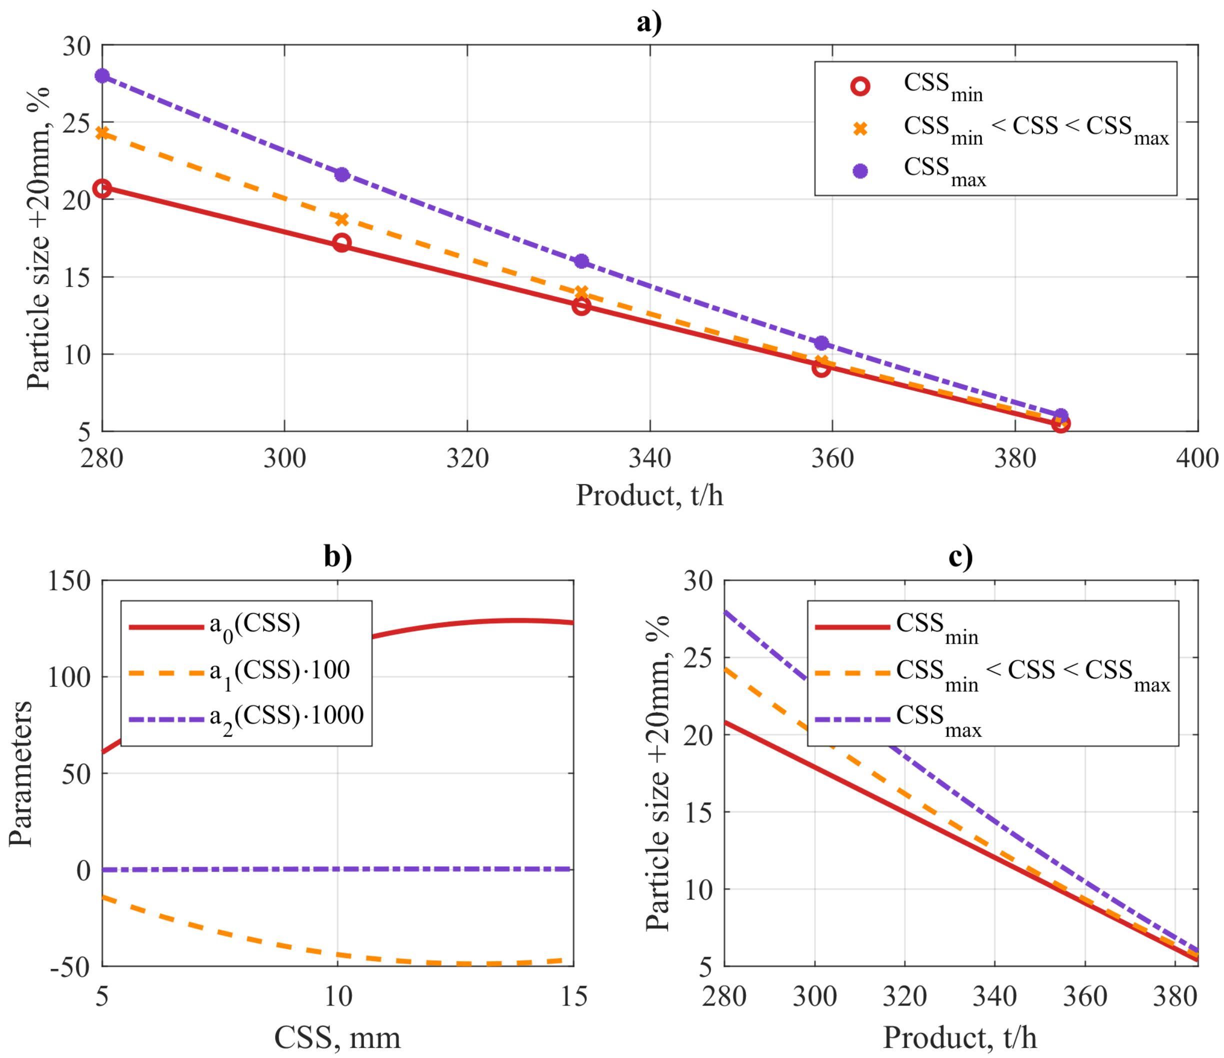

Figure 4. Dependence of the percentage of particle size class +20 mm on crusher product capacity for certain CSS: a) experimental data; b) polynomial coefficients; c) model data.

on the percentage of particle size class +20 mm is not as significant as product capacity, so adjusting CSS in the range (5 ... 10 mm) can provide an acceptable crushed ore size when the product capacity changes in the range from 320 t/h to 330 t/h. At capacity above 330 t/h, the particle size distribution can be controlled by varying the CSS in the full range (5 ... 15 mm).

During the operation of the crusher, the liners of the conecave and mantle, drive shaft bushings, eccentric contact surfaces, gears, eccentric thrust plate and other elements of the unit and electric drive wear out. The wear of the liners is essential to the product particle size distribution and power consumption. Since the liners of the conecave and mantle wears out the fastest, the steel consumption of the plates was chosen as the main parameter characterising the crusher wear.

Figure 5 a shows the steady-state characteristic obtained experimentally in [35] for the crusher with mantle diameter 2200 mm. It demonstrates the dependence of the amount of crushed ore M, thou. t over the service life of the chamber liners depending on the product capacity Q_P, t/h, on the intensity of mineral processing:

$$M\left(Q_P\right) = 3184.23 - 14.2 \cdot Q_P + 0.176 \cdot Q_P^2. \tag{9}$$

The graph shows that with increasing product capacity, the amount of crushed material increases during the period between lining replacements. Therefore, taking into account this fact and based on the data [36] that when using manganese steel lining, its consumption ranges from 0.001 to 0.005 kg per tonne of crushed ore, it can be assumed that with an increase in crusher product capacity, liner wear increases within the specified limits (figure 5 b):

$$w\left(Q_P\right) = 0.02885 - 0.2012 \cdot 10^{-3} \cdot Q_P + 0.3628 \cdot 10^{-6} \cdot Q_P^2. \tag{10}$$

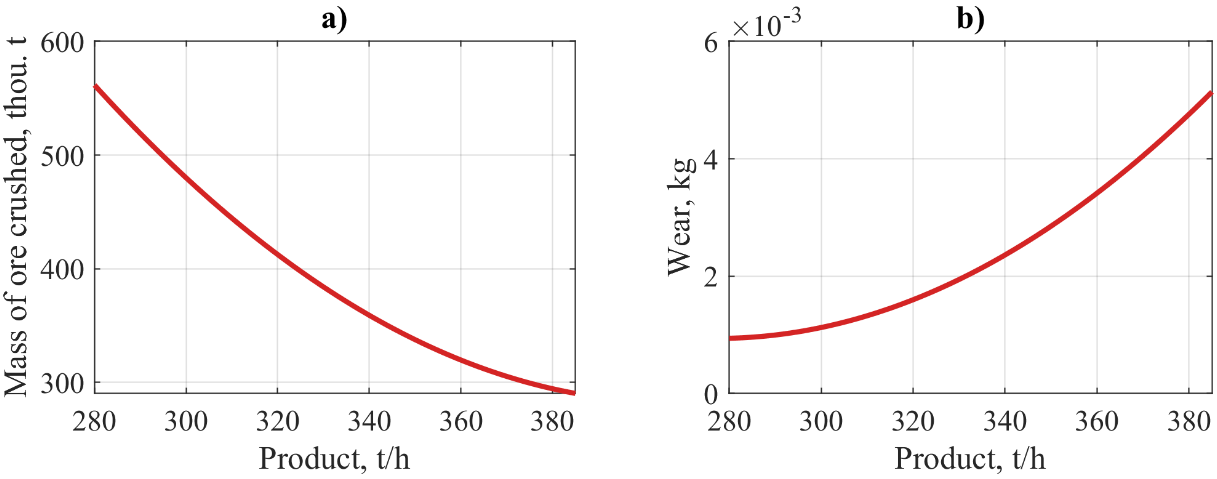

Figure 5. Steady-state wear characteristics of mantle and conecave liners.

The steady-state characteristics of liner wear are discussed in more detail in [20, 25, 31].

During industrial tests at crushing plant No. 2 of PJSC ArcelorMittal Kryvyi Rih, using the ASRi system for the Sandvik Hydrocone cone crusher, time dependencies of liner wear were obtained as shown in figure 6. The analysis of the graphs shows a low level of wear during the first 20 hours of crusher operation. Over the next 45 hours, a linear increase in wear is observed.

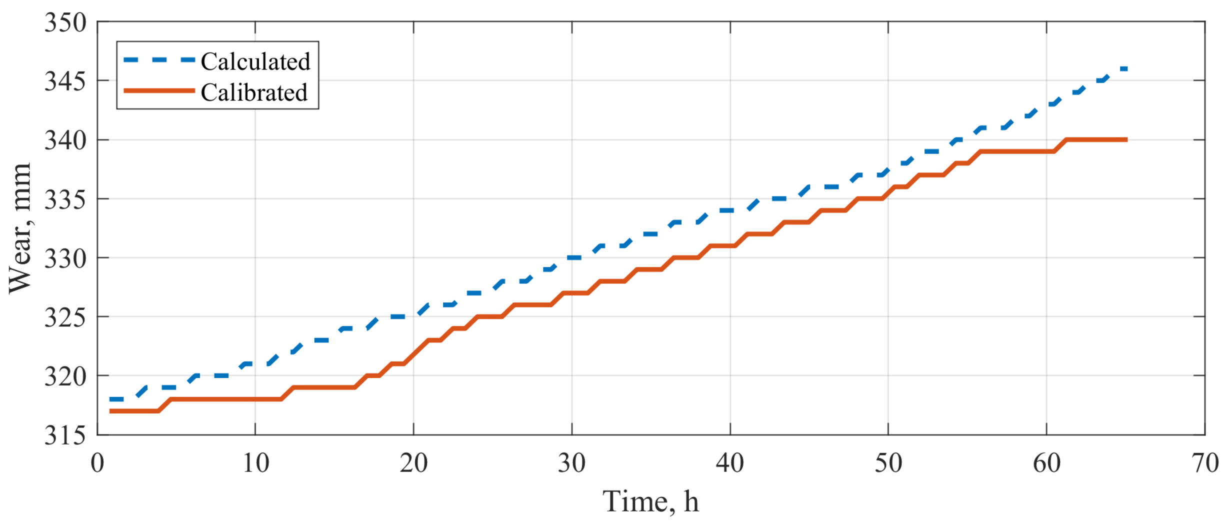

Figure 6. Timeseries of Hydrocone 7800 cone crusher liner wear: calculated and calibrated.

4. Conclusions

Proposed the mathematical description for analyzing the cone crusher steady-state operation modes. Based on experimental data from various sources, multidimensional regression dependencies are determined, which allow us to establish the regularities of the iron ore crushing process. The input variables are the feed capacity and the closed side setting. The output variables characterizing the quality of the process are product capacity, electric drive power, and the percentage of particle size class +20 mm. The model can be used to develop a cone crusher control system to determine the reserve for increasing energy efficiency, as well as its operating point and the limits for changing the main process parameters.

Abstract. We conducted an analysis of the safe loading and power maneuvering areas for both existing VVER-1000 power units and prospective AP-1000 power units. Mathematical models were developed to represent these areas accurately. These proposed models offer a comprehensive assessment of the potential operating conditions for Nuclear Power Plant units within the context of evolving energy systems, which are increasingly reliant on renewable energy sources. By adequately accounting for the limitations and constraints associated with safe power output maneuvering, these models facilitate informed decision-making processes regarding the integration and operation of VVER-1000 and AP-1000 nuclear power units alongside wind and solar power plants in electric power systems. This ensures the safe and efficient operation of NPP units while accommodating the growing penetration of renewable energy sources in the overall energy mix.

1. Introduction

The modern development of many energy systems involves a significant increase in the share of energy production from renewable energy sources (RES), which are characterized by variable and difficult to predict energy production schedules [1–3]. A comparative analysis of the forecast residual load of the electric power system of Ukraine, conducted by the authors under the conditions of an increase in uncontrolled volumes of electricity production by the generating units of wind and solar power plants from 7% in 2021 to 30% in 2050, shows significant changes in the load schedules of controlled generating capacities. The load of the latter increases both in terms of capacity and its variability in the summer and winter seasons, respectively figure 1.

As the share of electricity production from RES gradually increases, there arises a need to explore the potential involvement of Nuclear Power Plant (NPP) units to operate in modes significantly different from the so-called basic mode, while maintaining an almost unchanged level of thermal power output. This becomes particularly relevant for energy systems with a significant proportion of electricity production coming from NPPs.

Given that NPPs in Ukraine accounted for approximately 55% of the total annual electricity production between 2015 and 2023, extensive research has been conducted on licensing the power maneuvering mode of existing VVER-1000 power units. Currently, the future development of Ukraine's energy system until 2050 is being considered under the condition of constructing new power units utilizing AP-1000 technology.

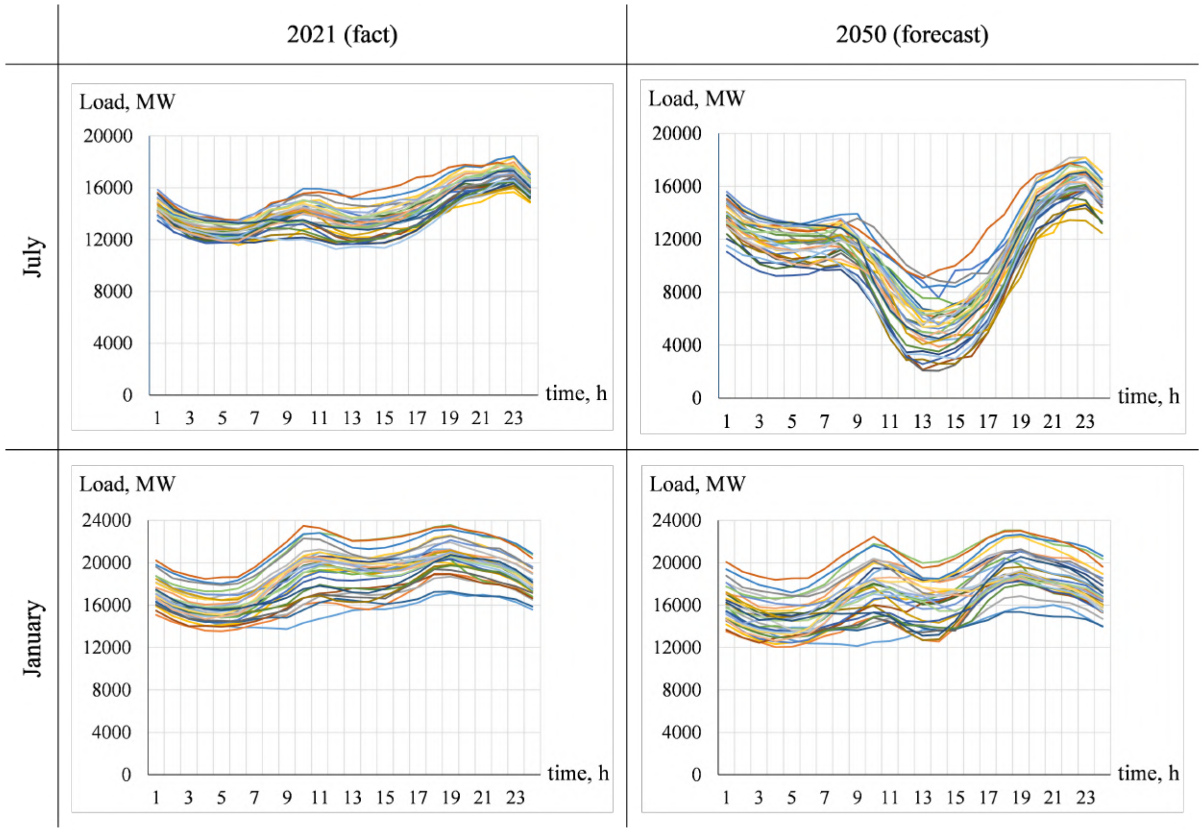

Figure 1. Residual load of Ukraine's energy system under the conditions of increasing electricity production from wind and solar power plants from 7% in 2021 to 30% in 2050, while assuming no changes in the structure of the specified production volumes. The graphs for 2021 are based on the actual data of NEC "Ukrenergo", and the graphs for 2050 correspond to the forecast calculations of the authors.

To address the challenges associated with planning the development of energy systems, it's imperative to consider the safe operation conditions of NPP units under varying thermal power regimes. This task becomes significantly more complex when dealing with energy systems that employ reactors of different types.

In order to ensure the accuracy of mathematical formulations for energy system development planning, it's essential to augment them with a formalized mathematical description of the permissible safe thermal load areas for each reactor design. This description should account for inherent limitations on thermal power levels and the rate at which they can change over time.

2. Design limitations regarding the operating modes of the VVER-1000 and AP-1000 power units

Ensuring the safe operation of NPP under varying loads is contingent upon adhering to predetermined limit values for changes in thermal power, the rate of change of thermal power, and the number of cycles of such changes during the fuel campaign, as specified in the power unit's design. These parameters are crucial for maintaining the structural integrity and operational stability of the power unit, particularly when subjected to fluctuating loads. Exceeding the permitted limit values could lead to undesirable consequences, including potential damage to equipment, decreased operational efficiency, and compromise of safety standards.

Therefore, it is imperative for nuclear power plant operators to monitor and control these parameters within the prescribed limits throughout the operational lifespan of the power unit. This entails implementing robust monitoring systems, adhering to established operational protocols, and conducting regular inspections and maintenance activities to ensure compliance with safety regulations and mitigate operational risks.

According to the "Standard technological regulations for the safe operation of NPP power units with VVER-1000 reactors" RG-B.0.03.179-13, increasing the power of the reactor to the nominal level should be carried out in automatic mode. Increasing the power of the reactor should be carried out while ensuring that the restrictions on the conditions for ensuring the integrity of the nuclear fuel are not exceeded and that the limit changes of the relevant technological parameters are not exceeded. The project stipulates that for VVER-1000 the rate of increase in thermal power of the reactor should not exceed $0.01n_0$ per minute, where n_0 is installed capacity of the reactor. In addition, with significant fluctuations in power, the design requirements for safe operation of the reactor provide for holding for three hours at a power level of $(0.75 - 0.85)n_0$ to ensure relaxation processes in the nuclear fuel and stabilize the fluctuations of the energy release field in the active zone. In the case of a decrease in the thermal power of the reactor, safety conditions can be ensured at a rate of change of power of no more than $0.03n_0$ without other restrictions.

The analysis of the possibility of operation of the NPP power unit in daily power regulation is given in [4], taking into account the classic schedule of changes in thermal power according to the algorithm $(1.0 - 0.75 - 1.0)n_0$ with operation at nominal power for $12 - 18$ hours and at a reduced level capacity for $6 - 12$ hours. At the same time, it is shown the possibility of ensuring safe operating conditions of nuclear fuel and not exceeding the technical limitations established in the reactor design, which allows maneuvering the power of the NPP power unit in a wide, but limited from below, range of changes in its thermal power. Practical confirmation of the possibility of operation of a high-power reactor in a fixed algorithm of changing its load was carried out in 2015 at power unit No. 2 of the Khmelnytsky NPP. According to the results of the experimental operation of the daily power regulation mode, there were no changes in the specific activity of the coolant of the first circuit exceeding the permissible range, violations of the limits and operating conditions established by the technological regulations for the safe operation of the VVER-1000 power unit. The total number of reactor load changes foreseen by the rigid schedule is 200 for the fuel company and 800 for the period of operation of the nuclear fuel in the reactor core. The possibility of operating the reactor in the mode of daily power regulation is confirmed for no more than 2/3 of the fuel campaign.

The power change parameters of the VVER-1000 provided in the technological regulations are justified in the project and regulated, based on the requirements of safe operation of the reactor under the conditions of operation of the power unit in the basic mode at an almost constant level of thermal power. At the same time, the design of the VVER-1000 reactor provides for a list of modes that are currently not used in the operation of NPP power units and are not included in the list of permitted modes in the technological regulations for safe operation, but can potentially be considered acceptable for implementation under the conditions of experimental confirmation. The operation of the reactor under conditions of variable power can be studied for the following load modes:

- Operation of the power unit in the range of thermal power change of $(0.3 - 1.0)n_0$ without limiting the time spent at any power level and power change after long-term operation of the power unit in this range at the permitted speed;
- Daily reduction of power unit capacity to the level of own needs or to the state of "hot stop" for 5-8 hours and further increase of capacity at the permitted speed;
- Reduction of power to the level of own needs or to the state of "hot stop" on non-working days for a period of 24-25 hours and further increase of power at the permitted speed.

But currently, in accordance with the requirements of ensuring the stability of the energy system, the classic algorithm of daily regulation with the power of VVER-1000 in the range of $(1.0 - 0.8)n_0$ is actually being considered. Further development of reactor technologies takes place based on the need to ensure economical and safe operation of power units in conditions of flexibility of energy systems. Based on the analysis conducted, the AP-1000 reactor of the Westinghouse company is considered in Ukraine as the most modern example of the implementation of appropriate technological solutions for electricity generation using nuclear power plants.

AP-1000 is a water-water power reactor with extensive use of safety systems based on the passive principle of action. The operator's influence on reactor control during normal operation and accidents is minimized. AP-1000 allows you to work in the mode of monitoring the load in the power system. When the frequency changes in the power system, the reactor power is automatically increased and vice versa. According to [5], the operation of the power unit in the mode of daily power regulation is ensured for 90% of the duration of the fuel campaign. At the same time, the change in reactor power occurs only due to the use of absorbers in the form of rods without the use of a boron regulation system to reduce neutrons in the active zone, which leads to the minimization of the accumulation of radioactive waste and an increase in the efficiency of operation of the power unit. The logic of the construction of the control system ensures compliance with safety requirements during transient processes in the reactor without reaching the settings of the protection system.

The system of influencing the parameters of the active zone provides for the possibility of changing the thermal power of the reactor and controlling the distribution of thermal power in the reactor itself. The design of the AP-1000 reactor allows for a gradual (sudden) change in thermal power in the range of $\pm 0.1n_0$ without affecting the parameters of fuel and main equipment in a wide range of power regulation:

- From n_0 to $0.25n_0$ when power is reduced;
- From $0.15n_0$ to $0.9n_0$ when increasing the power of the reactor.

Separately, the conditions of safe operation of the power unit are confirmed for deep changes in reactor power up to $0.2n_0$ from the current level at a rate of change of power of no more than $0.02n_0$/min.

The operation of the power unit in the daily power regulation is based on the following algorithm:

- Power reduction from n_0 to $0.5n_0$ for 2 hours;
- Operation at a reduced power level in the range of $(1.0 - 0.5)n_0$ from 2 to 10 hours;
- Power increase to n_0 for 2 hours with further work at the nominal power level;
- Rate of power change up to $0.05n_0$/min.

According to [6], a comparative analysis of AP-1000 and VVER-1000 shows a more flexible algorithm of AP-1000 operation in daily power regulation, which can be described by the scheme (18-2-2-2) instead of (12-3-6-3) for the VVER-1000 during 90% of the fuel campaign and the actual absence of restrictions on the need to ensure the dwell time over the entire range of reactor power changes. Comparison of design characteristics of VVER-1000 and AP-1000 power units are presented in 1.

The analysis of the suitability of the VVER-1000 operation under the conditions of design restrictions regarding the change in the thermal power of the reactor to support the stability of the flexible energy system with a significant presence of renewable energy sources was performed in [1]. Two operating modes of the power unit in daytime supply of peak loads "12-3-6-3" and "15-1-7-1" were considered using the example of high-power AP-1000 power units. For both cases, the power unit unloading depth did not exceed $0.3n_0$. It is shown that the operation of

Table 1. Comparison of design characteristics of VVER-1000 and AP-1000 power units.

	VVER-1000	AP-1000
The range of thermal power change	$(1.0 - 0.5 - 1.0)n_0$	$(1.0 - 0.15 - 1.0)n_0$
The rate of reduction of thermal power	$R_- = 0.03n_0/\text{min}$	$R_- = 0.05n_0/\text{min}$
The rate of increase in thermal power	$R_+ = 0.01n_0/\text{min}$	$R_+ = 0.05n_0/\text{min}$
Exposure time at 80% power level	3 hours	Without limits
The permissible range of sudden changes in thermal power	–	$0.1n_0$

the nuclear power plant in a variable load leads to an increase in the flexibility of the power system in comparison with operation at the nominal power level. It was concluded that the "15-1-7-1" scheme better meets the conditions of variability due to the increase in the rate of change of power of the NPP power unit.

Further analysis of the adequacy of the classic algorithm of NPP operation to ensure the daily balance of electricity was performed in [2]. In addition to [1], the scenario of the optimal operation scheme of the power unit based on the conditions of the power system is considered. It is shown that unlike the algorithm of NPP operation with fixed restrictions on depth and unloading/loading rates, the optimized algorithm can properly organize the sequence of regulation of peak load and power of all units and significantly reduce operating costs, which improves the economy of power system dispatching.

3. Mathematical description of safe region maneuvering the thermal power of the nuclear power plant reactor

Let the function $f(N)$ be defined, representing the dependence of the maximum permissible rate dN/dt of increase in the relative thermal power of the power unit reactor on its current value $N = n/n_0$. Typically, the function $f(N)$ is a piecewise smooth function with I smoothness intervals $\{N_i, i \in I\}$. This function can be represented by the sum of smooth functions $f_i(N)$, denoted as

$$f(N) = \sum_{i \in \mathcal{I}} f_i(N) \mathbf{1}_i(N), \tag{1}$$

where for $\forall i \in \ I$, the function $\mathbf{1}_i(N)$ takes a specific form

$$\mathbf{1}_i(N) = \begin{cases} 1, & N \in N_i \\ 0, & N \notin N_i \end{cases}.$$

Referring to the definition

$$\frac{dN}{dt} = f(N),$$

we obtain a differential equation with separated variables N and t in the form

$$\frac{1}{f(N)} dN = dt$$

or in the equivalent integral form

$$\int\limits_{N}^{N+\Delta N} \frac{1}{f(x)} dx = \int\limits_{t}^{t+\Delta t} dy. \tag{2}$$

The integration is performed over the time interval $(t, t+\Delta T)$ with a duration of ΔT. During this interval, the relative thermal power of the power unit reactor increases at the maximum permissible speed from the initial value of N to the final value of $N + \Delta N$.

Considering expression (1), we express integral equation (2) in the following form:

$$\int_{N}^{N+\Delta N} \sum_{i\in\mathcal{I}} \frac{1}{f_i(x)} \mathbf{1}_i(x)dx = \Delta T. \tag{3}$$

For $\forall i \in I$, suppose that the smooth functions of $1/f_i(x)$ correspond to the original functions of $F_i(x)$. Then, the integral equation (3) can be expressed as the following algebraic equation

$$\sum_{i\in\mathcal{I}} F_i(N+\Delta N)\mathbf{1}_i(N+\Delta N) \;\; - - \sum_{i\in\mathcal{I}} F_i(N)\mathbf{1}_i(N) = \Delta T, \tag{4}$$

and solving it enables the establishment of the dependence of $\Delta N = \Delta N(N, \Delta T)$.

Referring to table 1, for the VVER-1000, we have the value of the upper limit of the rate of increase of its relative thermal power in 1 minute in the form of a set of functions presented in table 2.

Table 2. Functional dependencies of the rate of increase in the relative thermal power of the VVER-1000 power unit reactor on the value of such power.

Smooth function $f_i(N)$	Original function $F_i(N)$ for $f_i^{-1}(N)$	Definition interval $N_i, N \in N_i$
$f_1(N) = 0.01$	$F_1(N) = N/0.01$	$N_1 = (0.50, 0.75)$
$f_2(N) = 1/1800$	$F_2(N) = 1800N$	$N_2 = (0.75, 0.85)$
$f_3(N) = 0.01$	$F_3(N) = N/0.01$	$N_3 = (0.85, 1.00)$

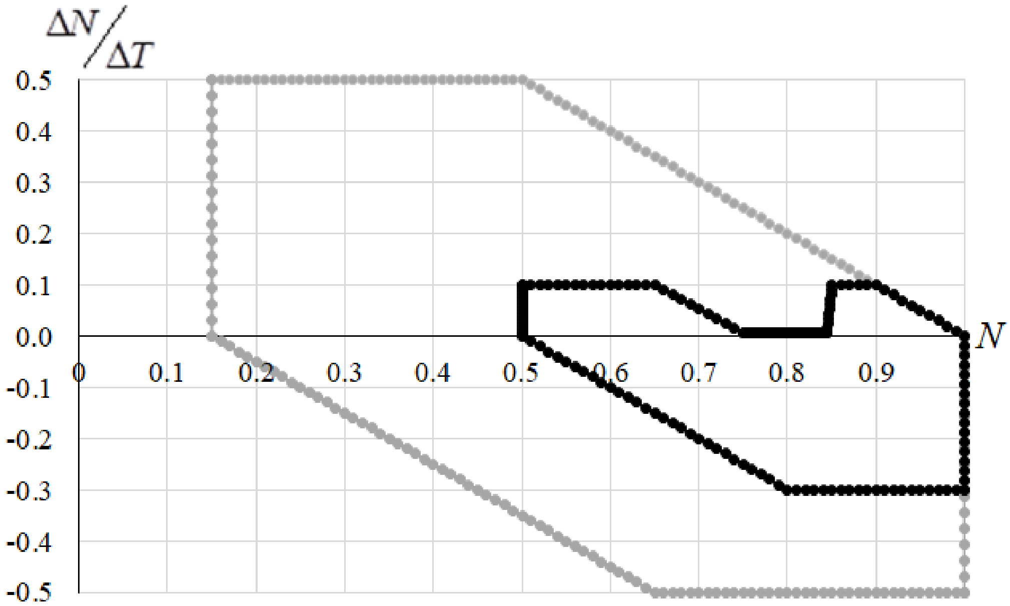
4. Safe regions for maneuvering the thermal power of the VVER-1000 and AP-1000 reactors

Solving equation (4) with respect to ΔN for various values of N and within fixed time intervals ΔT, namely 10 minutes and 1 hour, yields characteristic depicting the maximum rate of increase in thermal power of the VVER-1000 and AP-1000 power unit reactors from its current value. These characteristics are presented in figure 2. The characteristics obtained reflect the power unit's capabilities to operate safely during maneuvering modes.

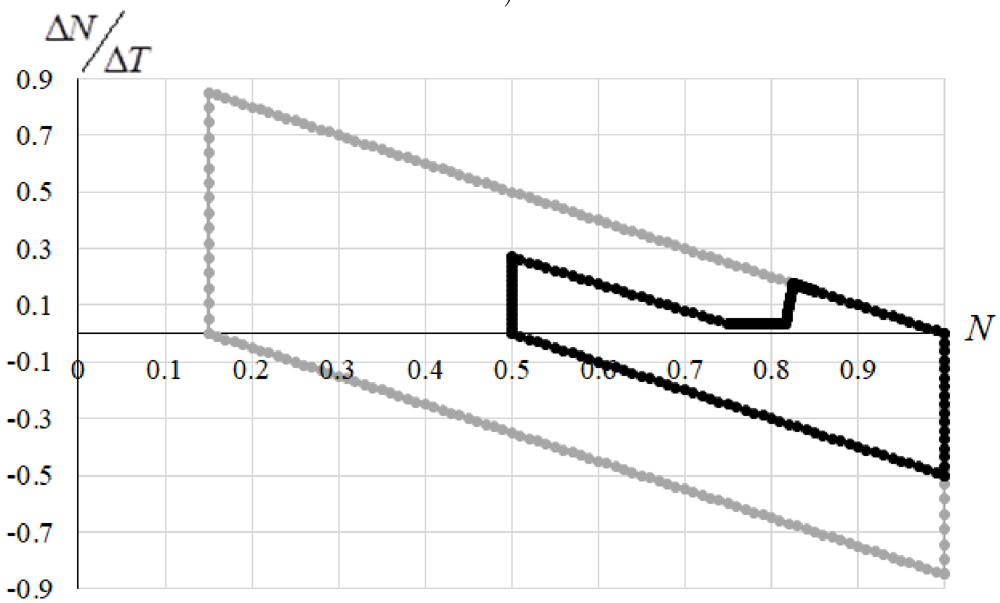
From the characteristics defined, it follows that the reactor units of the VVER-1000 have the largest value of the installed capacity utilization factor in modes close to the nominal load, where power maneuvering is limited enough to increase. Meanwhile the safe load follow operation is technically possible within wider limits of lower thermal power level (less than $0.7n_0$) with low efficiency of the power unit. Furthermore, the transition from the low-load region to loads approaching nominal values is notably extended, necessitating a minimum three-hour residence in load modes $(0.75 - 0.85)n_0$, where maneuvers to increase power are almost impossible.

Instead, the areas of safe maneuvering with the power of the AP-1000 power unit are much wider in a comparatively larger range of its loads.

It is essential to incorporate these conditions of safe loading and power maneuvering for the VVER-1000 and AP-1000 power units into dispatching models of electric power systems and planning tasks for their development.



a)



b)

Figure 2. Safe regions for maneuvering the thermal power of the VVER-1000 (outlined by a black line) and AP-1000 (outlined by a gray line) reactors within ΔT equal 10 minutes (a) and 1 hour (b).

In unit commitment and economic dispatch models [1, 7–9], the value p_t of the load of the generating unit AP-1000 at the current time t depends on the value $p_{t-\Delta T}$ of its load at the previous time $t - \Delta T$ and satisfies the following system of restrictions

$$\begin{cases} 0.15n_0 \le p_t \le n_0 \\ p_t - p_{t-\Delta T} \le R_+\Delta T \\ p_{t-\Delta T} - p_t \le R_-\Delta T \end{cases} . \tag{5}$$

The mathematical description of the area of safe maneuvering by the power of the VVER-1000 power unit is more complex. The upper limit of the rate of increase in power is a piecewise linear function depending on the parameter ΔT. For a fixed value of parameter ΔT, this function has the form

$$\Delta N_a(N,\Delta T) = \sum_{i\in I_a}(\alpha_i + \beta_i N)\mathbf{1}_{ai}(N,\Delta T). \tag{6}$$

The function $\Delta N_a(N,\Delta T)$ is defined on the set $I_a = I_a(\Delta T)$ of linear functions $\{\alpha_i + \beta_i N,\ i \in I_a\}$ with coefficients $\alpha_i = \alpha_i(\Delta T)$ and $\beta_i = \beta_i(\Delta T)$. The unit functions $\{\mathbf{1}_{ai}(N,\Delta T),\ i \in I_a\}$ defined on the intervals $\left\{\underline{N}_i < N < \overline{N}_i,\ i \in I_a\right\}$ (table 3). Using the binary function $u_{i,t}$ and taking expression (6) into account, we obtain the following description of the area of safe maneuvering by the power of the VVER-1000 power unit:

$$\begin{cases} 0.5n_0 \le p_t \le n_0 \\ p_{t-\Delta T} \le n_0 \sum\limits_{i\in I_a} u_{it}\overline{N}_i \\ p_{t-\Delta T} \ge n_0 \sum\limits_{i\in I_a} u_{it}\underline{N}_i \\ \sum\limits_{i\in I_a} u_{it} = 1 \\ 0.15n_0 \le p_t \le n_0 \\ p_t - p_{t-\Delta T} \le n_0 \sum\limits_{i\in I_a} u_{it}(\alpha_i + \beta_i p_t/n_0) \\ p_{t-\Delta T} - p_t \le R_-\Delta T \end{cases}. \tag{7}$$

Table 3. Coefficients of linear functions $\{\alpha_i + \beta_i N,\ i \in I_a\}$ and limits of their definition intervals $\left\{\underline{N}_i < N < \overline{N}_i,\ i \in I_a\right\}$.

The resulting systems of constraints (5) and (7) serve as mathematical models representing safe maneuvering areas for AP-1000 and VVER-1000 power units. These models are specifically designed to accurately capture the characteristics of safe maneuvering regarding the power output of both existing and promising NPP units. They are intended to be utilized in tasks related to planning the development of electric power systems with significant shares of electricity production generated by wind and solar power plants.

These mathematical models provide a framework for assessing and ensuring the safe operation of NPP power units within the context of evolving energy systems characterized by a growing reliance on renewable energy sources. By adequately reflecting the constraints and limitations associated with safe maneuvering of power output, these models contribute to informed decision-making processes regarding the integration and operation of NPP units alongside wind and solar power plants within electric power systems.

5. Conclusion

The operation of electric power systems with a significant proportion of renewable energy sources imposes stringent requirements on the operational conditions of both existing and new Nuclear Power Plant (NPP) units. The ability of a power unit to operate in modes involving daily power regulation with deep unloading, while still meeting other safety requirements, becomes a critical factor when selecting reactor technology for the prospective construction of new nuclear power plants.

The technological solutions employed in the design of the AP-1000 power unit render this reactor technology highly promising in addressing these operational requirements. The presented mathematical models outlining safe power maneuvering areas for both VVER-1000 and AP-1000 reactors ensure the adequacy of their representation in tasks involving the evaluation of economic efficiency. These models are crucial in making decisions regarding the commissioning and operation of reactors of this type within the framework of planning the development of generating capacities for electric power systems.

In summary, the capability of NPP units to operate safely and efficiently in modes involving daily power regulation with deep unloading is a significant consideration in the context of power system operation with a high proportion of renewable energy sources. The technological advancements and mathematical modeling techniques associated with reactors like the AP-1000, VVER-1000, and others play a vital role in ensuring the reliability and sustainability of nuclear power as part of the overall energy mix in the evolving landscape of electric power systems.

Abstract. Hydraulic fracturing (HF) stands as a pivotal method in the development of challenging hydrocarbon reserves, particularly those associated with low-permeability and fractured reservoirs. As these reserves constitute approximately one-third of global hydrocarbon resources, HF has emerged as an indispensable technology for their extraction. The creation of high-conductivity fractures through HF has demonstrated a remarkable capacity to amplify well flow rates, often achieving two to threefold or greater increases. This study seeks to establish robust scientific and methodological foundations for the calculation of operational parameters in HF by synthesizing insights from theoretical research. Emphasizing a comprehensive design approach, the methodology underscores the pivotal role of dynamic parameters such as fluid type, proppant characteristics, and injection rate in optimizing the efficiency of HF operations. To enhance efficiency, an automated algorithm is proposed for the judicious selection of proppants, facilitating expedited calculations and optimization processes. The proposed approach not only streamlines the parameter selection process but also ensures the implementation of the most effective HF scenarios. Additionally, it serves as a foundational framework for the development of automated tools for HF calculations in field applications, thereby advancing the field of hydrocarbon reservoir development.

1. Introduction

Currently, hard-to-recover hydrocarbon reserves confined to low-permeability, poorly drained, heterogeneous, and dissected reservoirs are widely involved in development. Hydraulic fracturing (HF) is one of the most effective methods for increasing the productivity of injection, oil and gas wells that penetrate such formations. Currently, about a third of hydrocarbon reserves can only be recovered using this technology. Highly conductive hydraulic fracturing cracks make it possible to increase well production by 2–3 times or more.

The essence of hydraulic fracturing is the injection of fluid under pressure, which fills microcracks and “weeds” them, and forms new cracks. If you introduce a fixing material (for example, sand) into the formed or widened cracks, then after the pressure is removed the cracks do not close. As a result, the conductivity of the productive formation increases, which leads to the intensification of hydrocarbon production [1, 2].

The highest efficiency of hydraulic fracturing is achieved with an integrated design approach based on factors such as formation conductivity, fracture mechanics, fracturing fluid and proppant characteristics. To implement this approach, in addition to models of fracture formation, it is necessary to create models of filtration in a system of wells with hydraulic fractures and study the characteristics of fluid flow in the vicinity of a fracture, including in heterogeneous and water-logged formations. Therefore, it seems relevant to develop methods for mathematical modeling of hydrodynamic processes in the development of oil and gas fields using hydraulic fracturing based on theoretical research and modern computer technologies.

The purpose of the work is to propose a scientific and methodological basis for calculating the operating parameters of hydraulic fracturing based on generalizing the results of theoretical studies and assessing the technological efficiency of hydraulic fracturing [3, 4].

2. Key parameters in hydraulic fracturing optimization

When hydraulic fracturing is carried out in the near-wellbore zone, cracks of various spatial orientations can form horizontal, vertical, or inclined (figure 1) [5]. To determine the geometry of the created crack, it is necessary to evaluate the mechanical properties of rocks, such as stress, Young's modulus, Poisson's ratio, as well as external parameters: injection rate, pressure, and others.

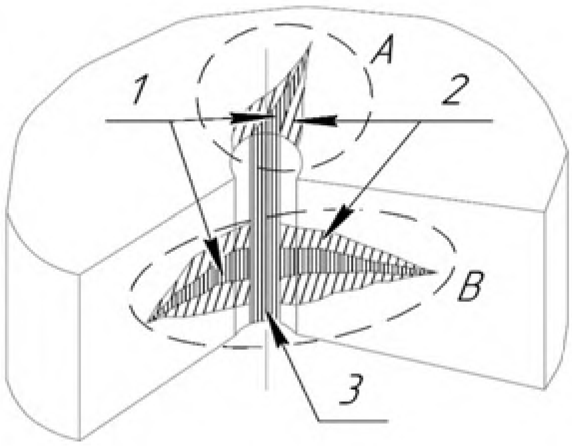

Figure 1. Vertical crack diagram: A – vertical crack; B – horizontal crack; 1 – crack zone; 2 – infiltration zone; 3 – well.

If a filtering fluid is injected into the bottom-hole zone of a well, then filtration begins in the most permeable areas, determined, as a rule, by the presence of cracks. Filtration is possible only at a certain pressure drop: ΔP_f, depending on the pressure difference in the well P_w and the formation P_l [6]:

$$\Delta P_f = P_W - P_l. \tag{1}$$

In this case, the poorly filtered liquid acts as a wedge, increasing the length and opening of the horizontal crack. In this case, a positive result can be obtained only at a certain rate of injection of fracturing fluid. The minimum injection rate of fracturing fluid is determined by the empirical relationship [7]:

$$Q_{min.g} \geqslant 10^6 \frac{\pi R_g \omega_o}{\mu}, \tag{2}$$

where $Q_{min.g}$ is the minimum supply of fracturing fluid by the pumping unit for the formation of a horizontal crack, m^3/s; R_g is the radius of horizontal crack, m; ω_o is the crack width on the well wall, m; μ is the viscosity of the fracturing fluid, mPa·s.

In principle, the formation of a horizontal crack and filtered liquid is possible, which is associated with a significant increase in the rate and pressure of injection.

If a non-filtering fracturing fluid is used, the stress in the rock increases as injection pressure increases. At a certain stress that exceeds the compressive strength of the rock, the rock breaks. Physically, this process proceeds as follows. As the injection pressure increases, the stress in the rock increases and compression occurs. Compression occurs to a certain limit, determined by the compressive strength. Once this limit is exceeded, the rock cannot resist increasing compression and cracks. After the injection pressure is removed, residual cracks (decompaction cracks) appear, usually with a vertical or inclined orientation [8].

The minimum injection rate of fracturing fluid is calculated using the following empirical relationship [9]:

$$Q_{min.v} \geqslant 10^6 \frac{h\omega_o}{\mu}, \tag{3}$$

where $Q_{min.v}$ is the minimum supply of fracturing fluid by the pumping unit for the formation of a vertical crack, m^3/s; h is the formation thickness, m.

Since during the injection process a certain part of the fluid is filtered into the rock ΔQ_f, forming an infiltrate zone along the fractures, the actual rate of injection of the fracturing fluid Q_d must be higher than that calculated using formulas (2) and (3) [10]:

$$Q_d = Q_{min} + \Delta Q_f. \tag{4}$$

On figure 2 the dependence of the hydraulic fracture half-length on the Young's modulus of the rock is shown for different hydraulic fracturing fluid efficiency. Similar graphs for crack height Hydraulic fracturing are presented on figure 3 [11].

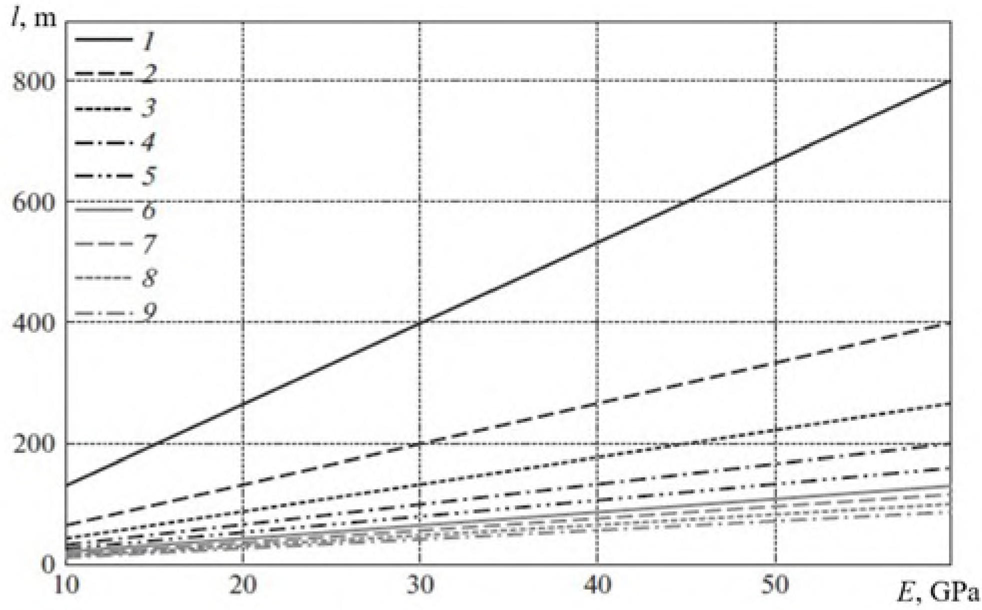

Figure 2. Dependence of the fracture half-length on the Young's modulus of the rock for different hydraulic fracturing fluid efficiency: 1-9 is the h = 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9

High efficiency of hydraulic fracturing fluid means low filtration leakage during hydraulic fracture development. This allows the creation of high fractures because the stress intensity factor for an existing rock fracture is always higher than the critical stress intensity factor due to the high pressure in the fracture. Therefore, in this case, not so extended hydraulic fractures [12].

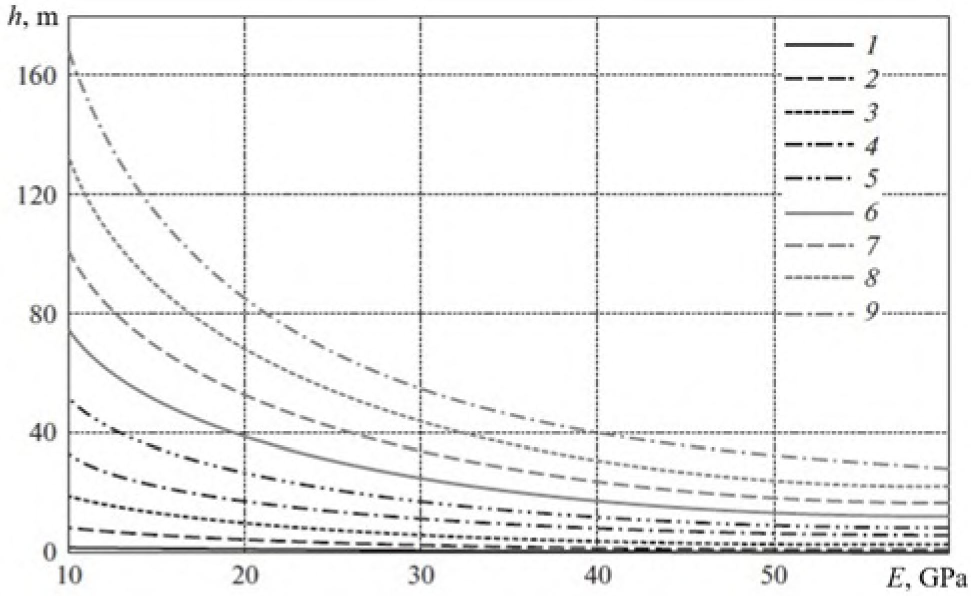

Figure 3. Dependence of fracture height on rock Young's modulus for different hydraulic fracturing fluid efficiency: 1-9 is the h = 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9

Data on the probable fracture geometry obtained during research are necessary to predict subsequent flow rates, as well as the volume of injected proppant.

The geological characteristics of the rock also influence the choice of proppant needed to prevent the well from collapsing when the pressure decreases. There are three main groups of materials from which proppant is produced: sand, resin-coated sand, and synthetic ceramic materials (figure 4) [13, 14].

Figure 4. Types of proppants.

Types of proppants are also classified by no proppants, proppants of various fractions (12/18, 16/20, 20/40, etc.), tarred proppants, tagged proppants, lightweight proppants, weighted proppants, non-standard shaped proppants, elastic proppants, acid-resistant proppants.

Each type of proppant has its own characteristics that are suitable for different types of rocks (figure 5). Choosing the wrong proppant can lead to a significant reduction in the width of the well, or to destruction proppant [15, 16].

To carry out hydraulic fracturing correctly, it is necessary to calculate the pressure. Geological and technological indicators of the reservoir help to calculate the formation rupture pressure.

Proppant type	Density (g/cm^3)	Resistance (psi)
Pure sand	2.65	< 6.000 (~41 MPa)
Resin-coated sand (RCS)	2.55	< 8.000 (~55 MPa)
Intermediate resistance ceramic (IRC)	2.7-3.3	5.000-10,000 (34-69 MPa)
High resistance ceramic (HRC)	3.4	> 10.000 (69 MPa)
Bauxite	2.00	> 7.000 (48 MPa)

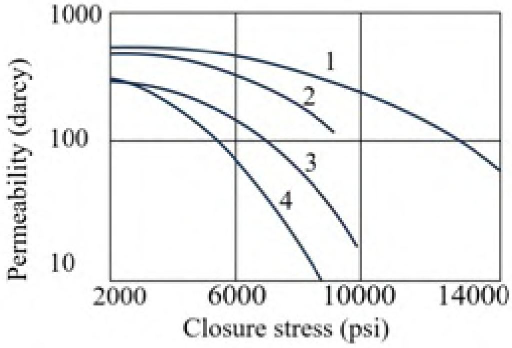

Figure 5. Proppant selection scheme depending on fracture closure stress: 1 – High strength proppant; 2 – Intermediate strength proppant; 3 – Resin-coated sand; 4 – Sand.

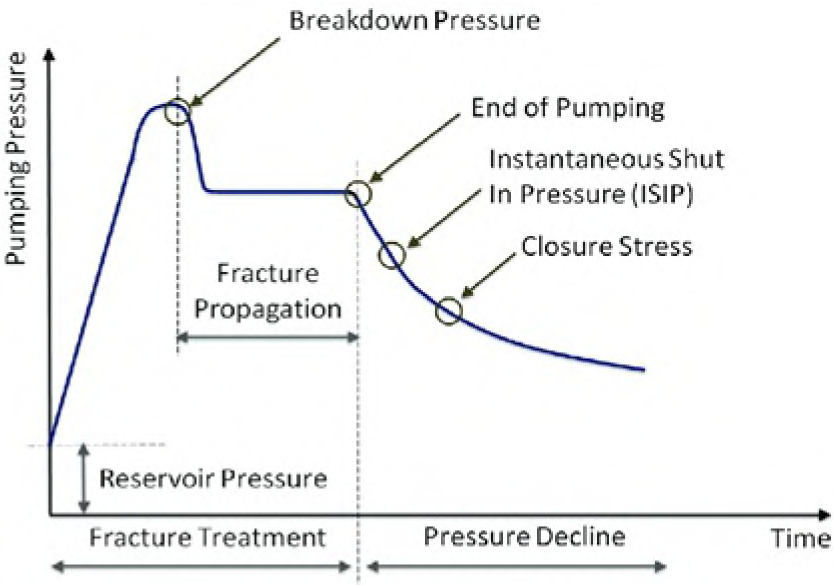

Figure 6. Scheme of pressure changes during a hydraulic fracturing operation.

During the operation, monitoring pressure changes at each stage helps to correctly carry out hydraulic fracturing and identify deviations (figure 6) [17].

An important step is also the selection of hydraulic fracturing fluid. It must satisfy certain physical and chemical properties. The fluid must be compatible with the formation material, could hold the proppant in suspension and transport it deep into the fracture, and must be easily removed from the formation after treatment [18].

Thus, the selection of optimal operating parameters includes the analysis of various parameters, including those that depend on each other. The overall effectiveness of hydraulic fracturing depends on the correct choice of each parameter. During the selection process, it is necessary to process a large amount of information, and therefore optimization of this operation is an important factor [19, 20].

These parameters include the choice of hydraulic fracturing type, selection of the appropriate type of process fluid and type of proppant material. These parameters directly affect the efficiency of hydraulic fracturing. Accordingly, it is necessary to approach the selection of the necessary parameters responsibly and consider all possible options [21].

3. Methodology

Calculation and selection of hydraulic fracturing operating parameters is a complex task. Conventionally, they can be divided into two groups: static and dynamic. Static values include values that are calculated from available geological and technical data. Dynamic parameters include those parameters that can be changed during the hydraulic fracturing process to obtain the most effective result. Dynamic parameters can be selected and optimized considering specific tasks and features of hydraulic fracturing.

Let's consider the methodology for calculating the dynamic parameters of hydraulic fracturing:

1. Calculation of the vertical component of rock pressure:

$$P_{gv} = \rho_p g L_{sv}, \tag{5}$$

where L_{sv} is the well depth, m; ρ_p is the average value of the density of the rock lying from the surface to the bottom of the formation, kg/m^3; g is the free fall acceleration, m^3/s.

2. Calculation of the horizontal component of rock pressure:

$$P_{gg} = P_{gv}\frac{v}{1-v}, \tag{6}$$

where v is the Poisson's ratio of rocks.

3. Calculation of formation rupture pressure when using a non-filtering fluid:

$$P_p = P_{gv} - P_{pl} + G_p, \tag{7}$$

where P_{gv} is the vertical component of rock pressure, MPa; P_{pl} is the reservoir pressure, MPa; G_p is the rock tensile strength, MPa (G_p=1.5...3.0 MPa).

4. Calculation of the required bottomhole pressure:

$$P_{zab} = P_{pl}a, \tag{8}$$

where a is the required excess of bottom hole pressure over the burst pressure (a=1.2...1.4).

5. Calculation of the pressure required for hydraulic fracturing at the wellhead:

$$P_y = P_{zab} - P_{stl} + P_{tr}, \tag{9}$$

where P_{stl} is the static pressure, MPa; P_{tr} is the pressure loss due to friction, MPa.

6. Calculation of static pressure:

$$P_{st} = \rho_{sm} g L_{sv}, \tag{10}$$

where ρ_{sm} is the density of the mixture, kg/m^3.

7. Calculation of pressure loss due to friction:

$$P_{tr} = 1.52\lambda\frac{8Q^2 L'_{sv}\rho_{gp}}{\pi^2 d^2}, \tag{11}$$

where λ is the coefficient of hydraulic resistance; d is the internal diameter of the tubing, m.

8. Calculation of the coefficient of hydraulic resistance:

   - For turbulent mode ($Re > 2300$), the coefficient of hydraulic resistance is calculated using the following formula:

$$\lambda = \frac{0.3164}{Re}, \tag{12}$$

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012080 doi:10.1088/1755-1315/1415/1/012080

- For laminar mode ($Re \leq 2300$), the coefficient of hydraulic resistance is calculated using the following formula:

$$\lambda = \frac{64}{Re}, \tag{13}$$

where Re is the Reynolds number.

9. Calculation of Reynolds number:

$$Re = \frac{4Q\rho_{sm}}{\pi d\mu_{sm}}, \tag{14}$$

where Q is the injection rate, m^3/s; μ_{sm} is the viscosity of the mixture, mPa·s.

10. Calculation of mixture viscosity:

$$\mu_{sm} = \mu e^{(3.18C)}, \tag{15}$$

where μ is the viscosity of the sand-carrying liquid, mPa·s.

11. Calculation of the total volume of injected fluid and the duration of the hydraulic fracturing process:
   (a) The volume of the fracturing fluid is determined by the following formula:

$$V_{gr} = \frac{L_{tr}^2 \left(P_{zab} - P_p\right) h}{E}, \tag{16}$$

   where L_{tr} is the half-length of the fracture, m; P_{zab} is the bottomhole pressure, MPa; P_p is the formation rupture pressure, MPa; h is the thickness of the formation, m; E is Young's modulus, MPa.
   (b) The volume of sand-carrying liquid is determined by the ratio:

$$V_{gp} = \frac{Q_p}{C_p}, \tag{17}$$

   where Q_p is the amount of proppant, kg; C_p is the proppant concentration, kg/m^3.
   (c) The volume of liquid in the pipes is determined by the following formula:

$$V_{pr} = \frac{K\pi d^2 L_{sv}^{'}}{4}, \tag{18}$$

   where K is a coefficient that considers the excess of liquid volume over the total volume of pipes (K= 1.3).

   The total volume of pumped liquid is determined by the following formula:

$$V_k = V_{gr} + V_{gp} + V_{pr}. \tag{19}$$

12. Calculation of vertical crack length:

$$L_t = \sqrt{\frac{V_{gp}E}{5.61\left(1 - v^2\right) h \left(P_r - P_{gg}\right)}}. \tag{20}$$

13. Calculation of the total duration of the hydraulic fracturing process:

$$V_k = \frac{V_g}{Q}. \tag{21}$$

14. Calculation of the technological efficiency of hydraulic fracturing.

(a) Calculation of hydraulic fracture radius:

$$r_{tr} = \sqrt{\frac{V_g E}{5.61\left(1-v^2\right) h \left(P_z - P_r\right)}}. \tag{22}$$

(b) Calculation of hydraulic fracture width:

$$w = \frac{4\left(1-v\right) r'_{tr} \left(P_{zab} - P_p\right)}{E}. \tag{23}$$

(c) Calculation of residual crack width:

$$w_{ost} = \frac{wC}{1-\mu_{tr}}, \tag{24}$$

where μ_{tr} is the fracture porosity (μ_{tr}=0.3).

(d) Calculation of fracture permeability:

$$K_{tr} = \frac{w^2}{12}. \tag{25}$$

(e) Calculation of the permeability of the bottomhole formation zone:

$$K_{pz} = \frac{K_p h + K_{tr} w}{h + w}. \tag{26}$$

(f) Calculation of the expected effect from hydraulic fracturing – oil production after hydraulic fracturing:

$$Q_n = \frac{2\pi K h \Delta P}{\mu_{gp}\left(ln\left(\frac{R_k}{r_c}\right)\right)}. \tag{27}$$

where R_k is the radius of the well supply circuit, m; r_c is the well radius, m.

(g) Calculation of the increase in oil production:

$$Q_e = q - Q_n. \tag{28}$$

where q is the average oil flow rate in the well before hydraulic fracturing, t/day.

4. Results

As can be seen from the calculation methodology, the correct selection of such parameters as the type, properties, concentration of the proppant, the type and properties of the sand carrier fluid, and the rate of injection of the mixture directly affect the efficiency of hydraulic fracturing. Therefore, the selection of the most appropriate operating dynamic parameters for hydraulic fracturing plays an important role. This process can be optimized to obtain better results.

To begin with, using the given methodology, calculations are carried out to determine the operating parameters of hydraulic fracturing. After this, the calculation and selection of dynamic hydraulic fracturing parameters begins.

First you need to select the process fluid. The type and concentration of fluid and additives depend on the formation temperature, lithology, and formation fluids.

Next, you need to select the required amount and type of proppant. There are three main proppant parameters that affect fracture conductivity: proppant concentration, proppant size, and proppant strength.

In the process of selecting the appropriate type of proppant, it is necessary to evaluate the magnitude of the closure stress cracks. This value can be calculated using the following formula:

$$P_h = \frac{v}{1-v} - (P_{gv} - P_p) + P_p, \tag{29}$$

where v is Poisson's ratio; P_{gv} is the vertical component of rock pressure, MPa; P_p is the pore pressure, MPa.

On drawing (figure 7) shows the dependence of the proppant type on the fracture closure stress. The proppant size must be selected considering the fracture closure pressure. Different types of proppants with the same granule size also have different effects on fracture permeability depending on the closure pressure [22].

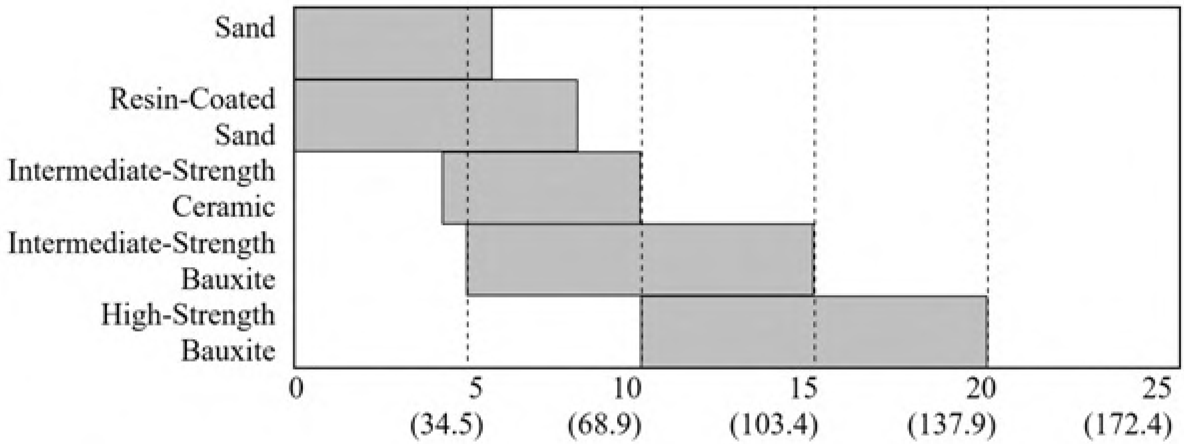

Figure 7. The principle of choosing the type of proppant.

The process of selecting the type of proppant needs to be optimized through automation, since it can be very time-consuming due to the analysis of many factors.

As a result of the analysis of these dependencies, the most effective types of proppants are identified, which are considered in the calculation, and among which the most suitable one is selected. Next, the optimal amount of injected proppant is selected.

The choice of injection rate is based on two principles. Firstly, a low injection rate is unacceptable because the fluid supply rate may be lower than its filtration rate. Secondly, too high an injection rate will lead to the formation of a turbulent regime in the pipes, which will increase pressure loss due to friction.

Substituting the selected parameters into the calculation and having variables in the form of the amount and type of proppant, we select the most effective type of proppant and the mass of injected proppant material [23].

All obtained operating parameters need clarification and can be adjusted after control hydraulic fracturing.

To ensure the accuracy and reliability of geomechanical data on the rock, a calibration test is carried out before the main hydraulic fracturing. Control fracturing is an important stage of on-site testing before the main fracturing operation and involves injection of fluid at a speed close to the main operation, using large volumes of fluid and a small amount of proppant. This allows you to set optimal parameters for further main hydraulic fracturing. Control hydraulic fracturing allows you to obtain the following data: formation closure pressure, closure stress, hydraulic fracturing fluid efficiency, effective pressure, fluid filtration parameters.

5. Conclusions

Considering all the nuances in the hydraulic fracturing process, the following sequence of actions is proposed for calculating and selecting operating parameters when carrying out hydraulic fracturing:

1. Selection, according to the geological features and tasks of the work, of the most suitable type of hydraulic fracturing to be carried out at the well.
2. Selection of the appropriate type and composition of the working fluid, considering the geological and technological features of the well.
3. Selection of the appropriate type of proppant. To optimize this process, it is proposed to use an automated algorithm, which should consider different brands of proppant material, select the most effective one for a specific calculation, and make it possible to quickly reselect the type of proppant when specifying the operating parameters.
4. Selection of the required amount of injected proppant. To optimize this process, it is necessary to consider the dependence of the geometric parameters of the fracture on the volume of injected proppant, based on previously carried out work. Next, you need to select a range of proppant amounts that can provide the required fracture parameters.
5. Calculate hydraulic fracturing, according to the above methodology, for several variants of operating parameters and select the most effective ones that will be used during the work.

This will speed up the process of calculating and selecting hydraulic fracturing operating parameters and carry out optimization, which will eliminate the need to calculate in advance ineffective hydraulic fracturing options. Also, this algorithm can be used as a basis for introducing automatic search and calculation of hydraulic fracturing in the field.

Abstract. The article is devoted to measuring the propagation speed of elastic waves in metal rods of variable cross-section. The paper examines the dependence of the speed measure of propagation of elastic waves on the geometric and physical characteristics of the rods. The research methods are based on the use of known statements of the impact theory during the collision of a ball with the end of a metal rod. Solid rods, stepped rods, and rods with axisymmetric holes of different depths were experimentally studied. A piezo sensor connected to a digital oscilloscope was used to record pressure fluctuations at the end of the rod. The method of least squares was used for processing and further analysis of experimental data. Theoretical and experimental studies proved that there are two characteristic areas in which the speed of propagation of an elastic wave in a non-homogeneous cross-sectional rod differs from the value of the wave speed in a one-dimensional rod. A sinusoidal functional dependence of the propagation speed of the elastic wave on the caliber of the rod was obtained.

1. Introduction

The process of rods colliding with each other or with an obstacle, and also propagation of elastic waves in them is the subject of numerous theoretical and experimental studies. The physics of collisions related to wave propagation in elastic rods has been investigated for more than a century [1]. The number of works in this field is constantly growing, as the issues of modern mechanical engineering, military and mining force researchers to study deeper and deeper the internal regularities of the impact process.

In this regard, it should be admitted that the leading role in the study of phenomena associated with the impact of solid bodies currently belongs to experimental works. Thus, in paper [2] the contact time of metal rods bouncing off a steel plate was measured, the collision of balls and rods was researched in the article [3]. It is concluded that colliding steel rods, unlike steel balls, can lose kinetic energy during collisions. The lost kinetic energy manifests itself in the form of vibrational energy in the rods. But the reasons for which the steel balls collide elastically remained mysterious to the author. In paper [4], analytical and experimental results of experiments with rods were compared. In paper [5], the dependence of the recovery coefficient on the number of repeated hits of the ball on aluminum rods was studied. In paper [6], the results of experiments with bouncing balls, springs, and rods are presented. It was investigated what part of the initial kinetic energy is stored after the collision in the form of vibrational energy in the spring and rod.

The classical theory of the collision of solid bodies, created by a number of researchers, starting with Galileo, considered the collision of bodies as absolutely solid, and the collision process as instantaneous. This theory made it possible to determine only the result of the impact – the change in the speeds of the bodies. The internal regularities of the impact process – its duration (impact time), the amount of contact forces and deformations – remained undisclosed.

Hertz [7] managed to establish by calculation the dependence of the magnitude of the contact force and the duration of the collision of bodies on their masses and velocities before the impact, based on the hypothesis that the relationship between the contact force and the local deformation of bodies upon impact is the same as when they are statically compressed. Along with Hertz's theory, which takes into account only local deformations and does not consider the deformations of bodies far from the contact site, the theory of the impact of elastic bodies has been developed, which takes into account their general deformations and does not consider local deformations in the first moments of impact interaction.

The wave theory of shock, which is adapted to a longitudinal shock on a rod of constant section, was first proposed by Navier. The unsuccessful form of the solution in trigonometric series did not allow Navier to reveal all the features of the longitudinal impact and, above all, excluded the possibility of determining stresses. Later, Saint-Venant and Boussinesq [8] found a solution to the one-dimensional longitudinal impact problem using discontinuous functions, which made it possible to directly trace the propagation of deformation waves along the rod. The experimental verification of the shock wave theory conducted by a number of researchers did not give completely satisfactory results, which caused a critical attitude to the hypothesis of flat cross-sections and the neglect of the transverse movement of the rod particles, as well as the assumption that the collision surfaces are parallel planes. Existing deviations from the hypothesis of flat sections should be especially noticeable near the wave front; the presence of these deviations leads to the fact that the wave front gradually erodes, its steepness decreases. It is obvious that deviations from the hypothesis of flat sections will be more pronounced, the greater the ratio of the diameter of the rod to its length.

The insufficiency of both those theories that take into account only local deformations, but neglect general ones, and those that take into account only general and neglect local deformations, forced to look for a "synthetic" theory of impact, which would consider local and general deformations.

For the longitudinal impact, such a theory was developed by Sears [9]. Considering the collision of rods with spherical ends, Sears suggested that the hypothesis of plane cross-sections is valid for the entire rod, except for a small area near the end of the rod, within which the stress state is sharply inhomogeneous. Deformations of the area near the end of the rod are calculated using Hertz's formulas, and wave theory is used to calculate the rest of the rod. Sears' calculations were confirmed by experiments.

As can be seen from the above, the difficulties associated with the theoretical description of the impact process force us to introduce a number of simplified hypotheses, in most cases they are not sufficiently confirmed by experiments, and all methods of calculating the impact process are approximate.

Thus, in works by Gulidov et al. [10–12], numerical modeling of the rebound process of rods of finite length from an absolutely rigid obstacle, as well as the propagation of elastic waves in round rods in a two-dimensional setting, was carried out. The results of these works confirmed the influence of the rod dimensions on the propagation speed of the elastic wave and the time of contact with the obstacle.

When numerically modeling the rebound of axisymmetric rods from a solid obstacle, it is assumed that the speed of propagation of elastic waves in the rods is equal to twice the length of

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012081 doi:10.1088/1755-1315/1415/1/012081

the rod divided by the contact time. At the same time, it is assumed that the contribution to the kinetic energy of the terms describing the transverse movement of the rod particles is very small. Since tangential stresses are not taken into account, the contribution of shear potential energy is also not considered. One-dimensional theory is used for such rods and the speed of wave propagation c in such rods is defined as $c = \sqrt{E/\rho}$, where E is Young's modulus of elasticity, ρ is the density of the material.

In order to prove the need to take into account transverse unloading waves coming from the side surface of the rod, in our experiments we use stepped rods with a variable step length, as well as rods in the form of a truncated cone with axisymmetric holes of different depths. The results of the experiments need prove the significant dependence of the propagation speed of elastic waves on the shape of the side and inner surface of the rods and thereby prove the fallacy of establishing the limits of calculating the stress-strain state of the rod in a one-dimensional approximation.

2. Research methods

To determine the optimal conditions for conducting experiments, the following was carried out:

a) analysis of the results of numerical modeling of the collision process of a rod of finite length with an absolutely rigid obstacle;
b) analysis of propagation of elastic waves in uniform round rods.

The following were experimentally carried out:

a) measurement of the duration of the impact and the speed of propagation of elastic waves in metal solid rods and rods of round stepped-variable cross-section;
b) measurement of the speed of propagation of elastic waves in metal rods of circular cross-section with axisymmetric holes of different depths.

Two methods of measuring the speed of elastic waves were used:

a) by the time of propagation of the elastic wave in the rod (recorder – piezo sensor);
b) by the time of collision of two rods (electrical contact method).

For this, three types of installations were used:

a) with bifilar suspension of rods;
b) using a guide chute
c) using a guide tube.

A Tektronix TPS2014B oscilloscope was used to simultaneously record the duration of electrical contact of the rods and elastic oscillations.

The purpose of the work was to obtain the dependence of the speed of propagation of elastic waves on the geometric and physical characteristics of the rods.

The research methods are based on the use of known provisions of the impact theory during the collision of a ball with the end of a metal rod. A piezo sensor connected to a digital oscilloscope was used to record pressure fluctuations at the end of the rod. The method of least squares was used for processing and further analysis of experimental data.

3. Results and discussion

Table 1 shows the characteristics of rod materials used in this work (ρ – density, K – volume modulus of elasticity, μ – shear modulus, λ – Lamé's constant, ν – Poisson's ratio, c_e – speed of elastic wave propagation in a one-dimensional rod, c_p – speed of longitudinal waves, c_S – speed of transverse waves, c_λ – speed of waves in a thin layer).

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012081 doi:10.1088/1755-1315/1415/1/012081

When the rod hits a rigid obstacle at the initial moment of time, the end of the rod comes into contact with the obstacle at all points and remains in contact with it for some time, after which it immediately or gradually separates from the obstacle. The time from the moment of contact to the moment when all points of the end of the rod move away from the obstacle is chosen as the contact time.

From the solution of the elastic problem about the contact of a one-dimensional rod with an obstacle upon impact, it is known that the contact time is:

$$t_K = 2L/c_e, \tag{1}$$

where L – the length of the rod.

In the general case, waves of several types with different velocities propagate in the rod as in a solid body. On the basis of equation (1), let us assume that a wave propagates in the rod with an unknown average speed, such that after the wave travels a distance equal to two lengths of the rod, the rod rebounds during the time t_K. Thus, the average wave speed can be found using the equation:

$$c = 2L/t_K. \tag{2}$$

and the contact time will be taken based on the results of work [13], where it was determined using the KRUG software complex, designed for the numerical solution of dynamic problems of mechanics. For certainty, consider the impact of a uniform rod with a diameter of $D = 10mm$ and a caliber of $L/D = 0.1/10.0$ against an absolutely rigid obstacle. There are no transverse stresses in the rod.

Figure 1 shows the calculated dependence of the relative average wave speed on the gauge for uniform aluminum rods [12] (c' – the ratio of the wave speed found by formula (2) to the speed c_e).

Analysis of the data presented in figure 1, allows us to draw the following conclusions:

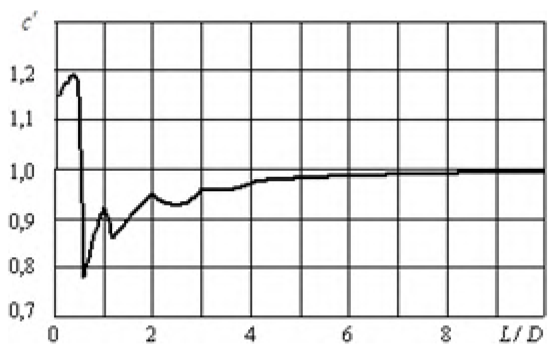

Figure 1. The dependence of the relative average wave speed on the gauge for rod.

a) at small values of the gauge of the rod ($L/D < 1$), the speed of wave propagation is close to the speed of longitudinal waves c_p (this is explained by the fact that slower transverse waves originating at the free cylindrical boundary do not have time to affect the longitudinal wave, the path length the spread of which is insignificant compared to the radius of the rod);

b) when the caliber increases, the average wave speed c goes towards the c_e speed (starting with a rod size equal to three gauges ($L/D = 3$) the ratio $c/c_e = 0.97$, i.e. the difference between the speed of the wave c and the speed of c_e becomes less than 3%);

c) there is such a gauge value ($L/D = 0.6$ for aluminum) at which the average speed of the longitudinal wave is minimal, which is due to the significant effect of transverse vibrations on it.

For each material, the minimum value of the average speed is different according to the caliber of the rod. To estimate the caliber at which the minimum relative average velocity occurs, we use the ratio of transverse and longitudinal velocities c_S/c_p, the value of which is a constant value for the material of the rod.

Figure 2 shows the dependence of the gauge value K_{min}, at which the wave speed reaches a minimum, on the c_S/c_p ratio for rods made of different materials [12]. From figure 2, it follows that the gauge of the rod, at which the minimum value of the wave speed is observed, increases with an increase in the value of c_S/c_p.

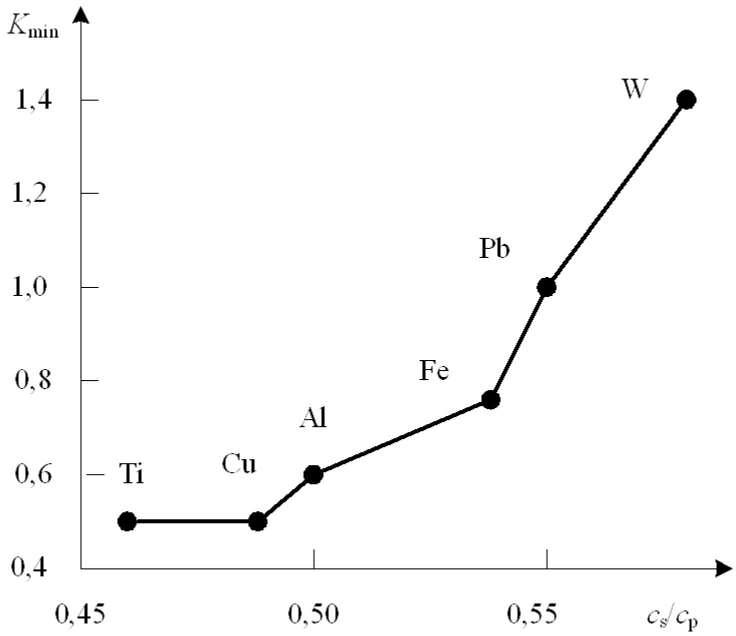

Figure 2. The gauge value at which the relative average speed minimum is observed.

The conducted analysis of the propagation of elastic waves in round rods shows that the value of the average speed of wave propagation in short rods differs from the speed of the wave, which is determined in the one-dimensional theory.

Therefore, when the wave is reflected from the end of the rod, the same processes and regions will appear at the other end of the rod. That is, hitting the other end of the rod will not change the pattern of changes in the speed of the elastic wave along the rod – it will be symmetrical.

These effects can be "manifested" by interfering with the aforementioned processes, for example, by reducing the diameter of the rod in these areas from D to d, forming a stepped rod,

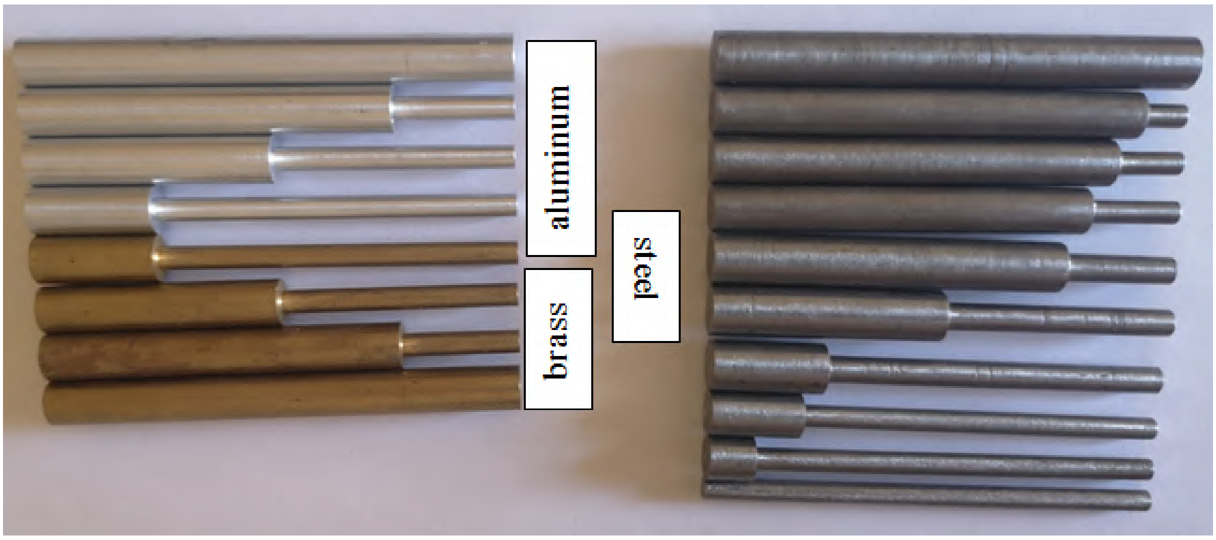

Figure 3. Photo of stepped rods.

or by reducing the cross-sectional area of the rod by making an axisymmetric hole of length l in it figure 3.

As experiments have shown, measuring the speed of an elastic wave on a bifilar type installation is not appropriate because it is impossible to ensure the parallelism of the ends of the rods upon impact and their alignment in most experiments. The error in determining the speed of propagation of an elastic wave by this method is up to 10%. The installation with a guide chute ensures the parallelism of the ends of the rods upon impact and their alignment. The error in determining the speed of an elastic wave in metal rods is up to 7%. The method of measuring the speed of elastic waves using a guide tube turned out to be the most accurate with an error of up to 1%. Therefore, exactly with the help of this method it was determined that the dependence of the speed of the elastic wave on the geometric and physical parameters of uniform and step-shaped rods and rods with axisymmetric holes.

To prove the possibility of controlling the speed of propagation of elastic waves, an experimental setup was made and research was carried out (figure 4).

The results of spectral and oscillographic measurements of the speed of elastic waves in steel are shown in table 2 [14] and graphs in figure 5 for steel, aluminum, brass.

Table 2. Results of oscillographic measurements (St3ps steel, density 7850 kg/m^3).

Caliber l/L	0	0.1	0.15	0.2	0.25	0.5	0.75	0.8	0.9	1.0
$\vartheta, m/s$	4932	5514	5840	5958	5899	4922	3985	4025	4301	4962

The results of oscillographic measurements of the speed of elastic waves in an iron rod with a hole of different depths are shown in the table 3 and figure 6.

4. Conclusions

Experiments proved that the propagation speed of an elastic wave in a rod of finite length depends on the shape of its side and inner surface. For stepped rods, there are two characteristic areas in which the velocity differs from the wave velocity in a one-dimensional rod by $\pm 20\%$.

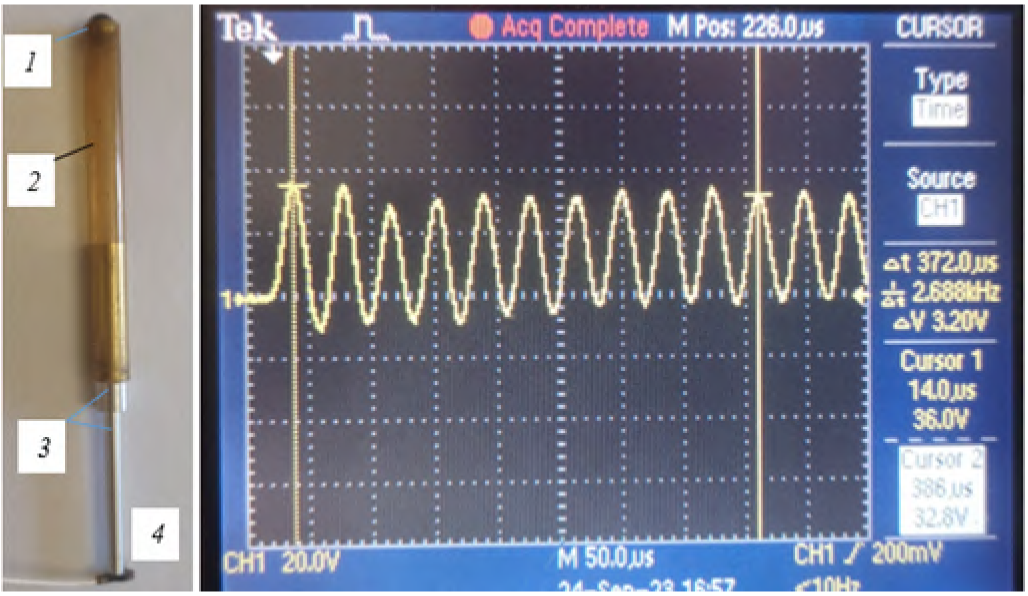

Figure 4. Photo of the research setup and oscillation oscillograms: 1 – metal ball, 2 – guide tube, 3 – rod, 4 – piezo sensor.

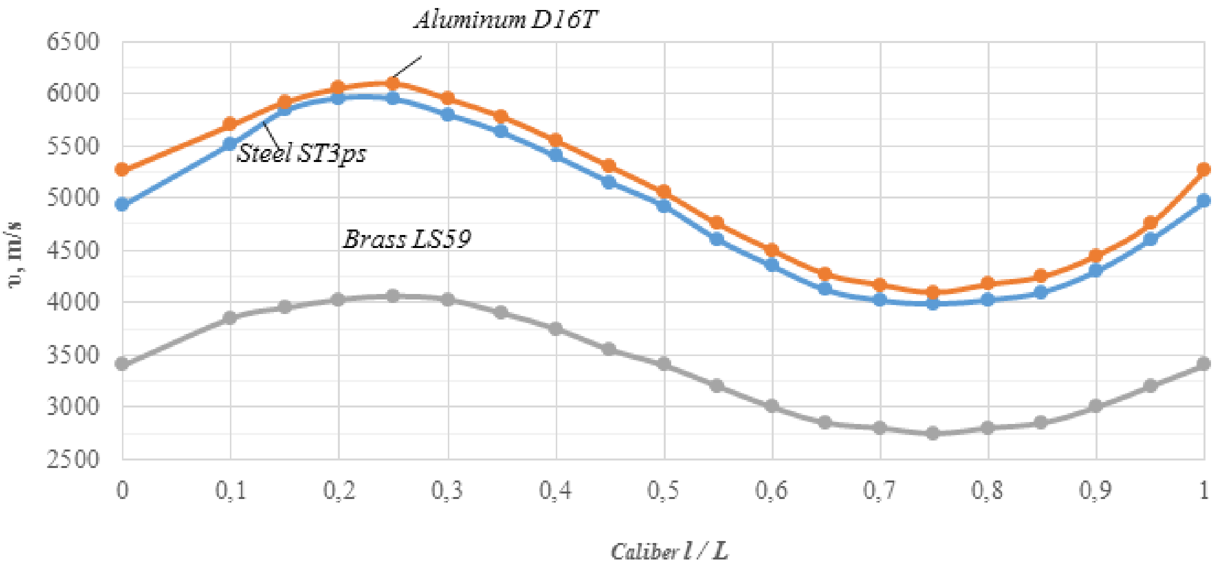

Figure 5. Dependence of the speed of elastic waves on the l/L ratio for a structural carbon steel of ordinary quality (1), aluminum (2), brass (3) rod with a diameter of 10 mm and a length of 100 mm, with a step diameter of 5mm and a length of l.

Table 3. Results of oscillographic measurements of the speed of elastic waves in an iron rod with a hole.

Caliber l/L	0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$\vartheta, m/s$	5208	5319	5376	5376	5319	5208	5076	5025	5025	5076	5208

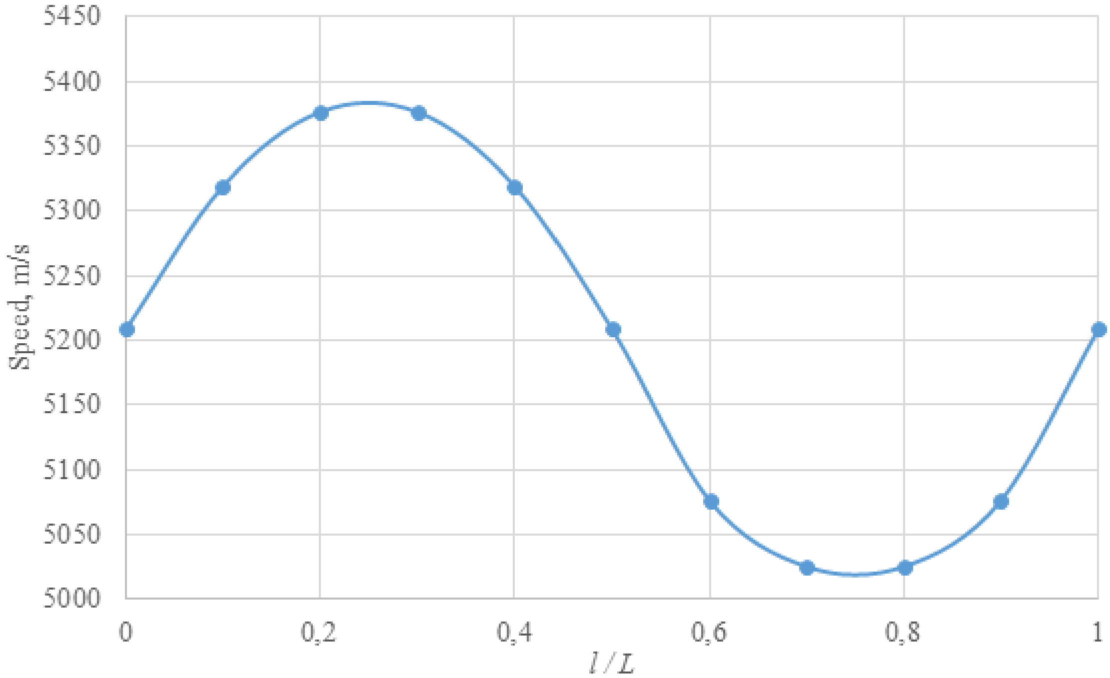

Figure 6. Dependence of the speed of elastic waves on the l/L ratio for an iron rod with a diameter of 10 mm and a length of 100 mm, with a hole diameter of 5 mm and a length of l.

The extreme speed of the wave reaches when the length of the step is about 0.25 and 0.75 of the length of the rod. For steel, the maximum speed was 5958 m/s, aluminum 6098 m/s, brass 4065m/s, the minimum speed was 4000 m/s for steel, 4098 m/s for aluminum, 2747 m/s for brass.

For rods with an axisymmetric hole, there are also two characteristic areas, in which the velocity differs from the value of the wave velocity in a one-dimensional rod by $\pm 3\%$. The extreme speed of the wave reaches when the depth of the hole is about 0.25 and 0.75 of the length of the rod. For iron, the maximum speed was 5376 m/s, the minimum speed was 5025m/s.

The results of these works confirmed the influence of the shape of the variable cross-section of the rod on the speed of propagation of the elastic wave.

Abstract. Geomechanical studies are performed at almost all large mining enterprises in the world. As a result of industrial activity, the Kryvyi Rih region has developed serious environmental problems. The mining of ore in Kryvyi Rih region led to the formation of numerous underground cavities. Hundreds of square kilometers of the Earth's surface were in zones of mass collapse. Therefore, diagnosis and control of the stress state of the massif of rocks are relevant. Along with the processes of movement of underground cavities to the Earth's surface, there is a constant threat of destruction or damage to residential buildings, violation of the integrity of the massif due to mass explosions in quarries and mines. These explosions also affect the rate at which voids emerge. This leads not only to unpredictable exits of funnels and the development of landslides, but also to the threat of rock strikes in mines. The article considers the method of measuring the vector velocity of soil particle oscillations from one source in different directions at the same time.The purpose of this article is to compare the seismic load of points on the Earth's surface during an explosion in a mine with their orthogonal location along the directions under the conditions of destruction of the rock body in a separate area. The main task of the research was to determine the intensity of seismic explosion vibrations near the foundations of residential buildings and industrial buildings in the area of the industrial site of the mine, which were located in opposite directions. The main result of the work is obtaining a set of data related to the amplitude and frequency characteristics of seismic waves that have passed through a half-kilometer layer of rock.

1. Introduction

At the end of 2023, the Laboratory of Explosion Management and Mining Seismics of SRMI of Kryvyi Rih National University (KNU) carried out instrumental measurements of the level of impact of seismic vibrations generated by a massive explosion carried out in a mine on residential buildings. Performed seismic observations are part of the general monitoring of the magnitude of seismic fluctuations during blasting operations at mining enterprises. The purpose of the research was to compare the seismic load of points on the Earth's surface during an explosion in a mine with their orthogonal location along the directions in the conditions of the destruction of the rock body in a separate area. The main task of the research was to determine the intensity of seismic explosion vibrations near the foundations of residential buildings and industrial buildings

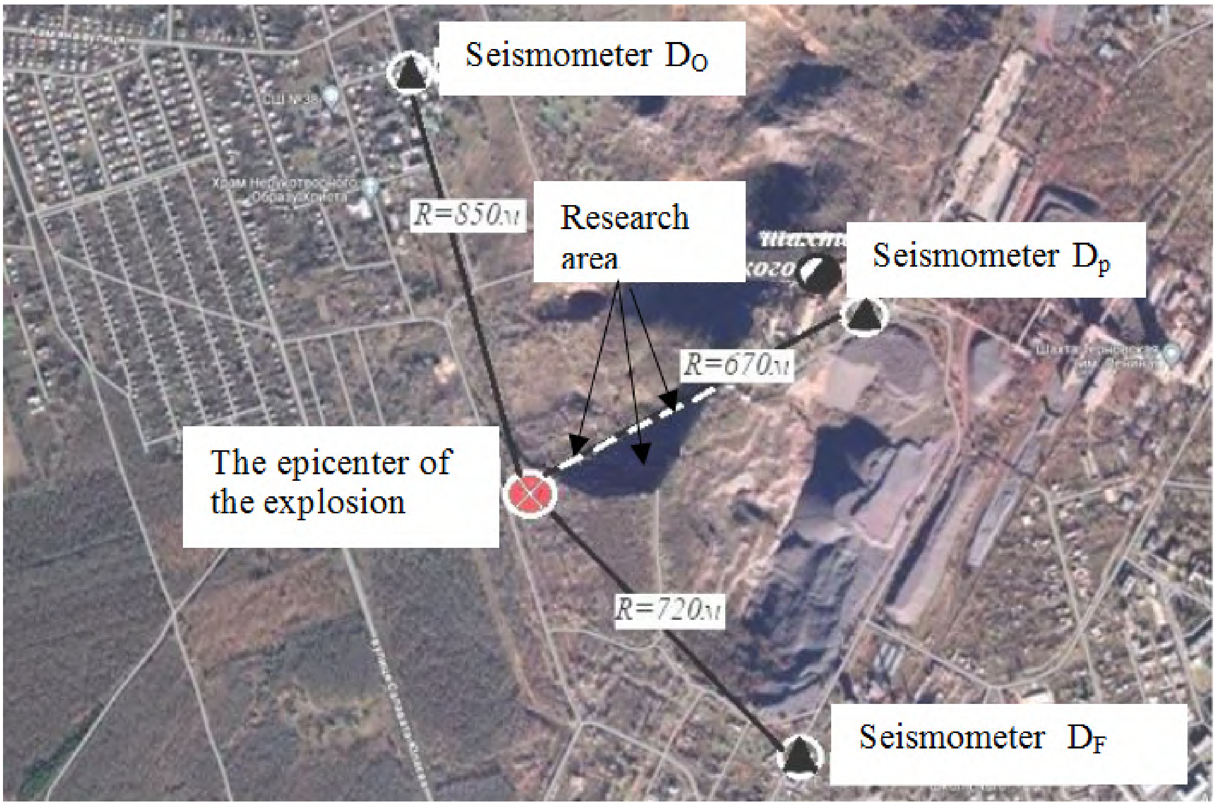

Figure 1. Surface plan of the research area with the location of seismometers on the Earth's surface, the epicenter of the explosion, residential buildings.

in the area of the industrial site of the mine, which were located in almost opposite directions (figure 1).

The intense vibration of residential buildings caused by blasting in mines and quarries is one of the fundamental problems for residents and the environment [1]. The presence of subsurface voids in the areas of ore mining leads to their movement with subsequent collapse of the surface of the Earth (figure 2).

Therefore, reliable forecasting of the state of rock, especially near residential buildings and industrial structures, is an urgent task. It is very important to learn how to control the vibration in such difficult conditions caused by blasting operations in order to mitigate their negative effects. The negative impact of vibration cannot be completely eliminated, but it can be reduced to a safe level.

A massive explosion in a mine generates seismic waves on the Earth's surface with different maximum particle velocities and a wide range of frequencies. This process depends on 1) rock properties, 2) charge parameters and 3) blasting technology. If we want to control the condition of the rock under residential buildings and structures located near the destruction zones, it is necessary to constantly experimentally determine the propagation speed and frequency spectrum of seismic waves from blasting. On the other hand, on the basis of experimentally determined parameters, it is possible to determine the optimal technology of blasting works so that there are no economic losses for the mining enterprise.

Parameters of a mass explosion. The mass explosion at a depth of 387-527 meters was carried out using the technologies of blasting with well charges. The well charges were detonated in short bursts. The number of wells is about 220. The total mass of used granulated and cartridge

Figure 2. Land collapse with the destruction of housing (photo by Archil Svanidze).

explosives was 44 tons. So, on average, the charge of the well was 0.2 t (the estimated specific rate of expansive substance is about 0.41 kg of ES per 1 ton of mining mass).

2. Object and methods of research

It is possible to monitor the development of geomechanical processes by various methods of observation [2, 3]. One of the methods of research is based on the principle of dependence of the properties of rocks and their stress-strained state on the magnitude of the influence of force fields arising in the massif. Therefore, a significant part of research is aimed at evaluating the strength, elastic, rheological, electromagnetic, acoustic and other physical and mechanical properties of rocks. But the problem of operational search for underground cavities can be solved directly by measuring the speed of propagation of seismic waves throughout the rock layer, i.e. instrumentally. As an example of the implementation of this principle, the article considers the method of measuring the vector velocity of soil particle oscillations from one source in different directions at the same time.

During seismometric observations, SM-3 seismographs and Tektronix TPS-2014 oscilloscopes were used. The main environmental criterion of the seismic hazard of an explosion is the intensity of the seismic wave, which can cause damage to the structures of buildings [4–7]. The magnitude of the vector velocity determines the density of the energy flow, therefore, as a characteristic of energy, it is directly related to the conditions of damage to structures. Damage to the protected object occurs if sufficient energy penetrates into it from the seismic wave. Without this energy, damage cannot occur, even if the force characteristics exceed those required for this in the case of statics. Therefore, the measurement of seismic parameters was carried out in this experiment by recording the vector velocity of soil oscillations (figure 3, figure 4).

The formula that determines the vector speed:

$$\vartheta = \sqrt{\vartheta_x^2 + \vartheta_y^2 + \vartheta_z^2} \tag{1}$$

where ϑ_x, ϑ_y, ϑ_z are the maximum instantaneous speeds in the direction of the x, y, z axes: the y axis was directed to the epicenter of the explosion.

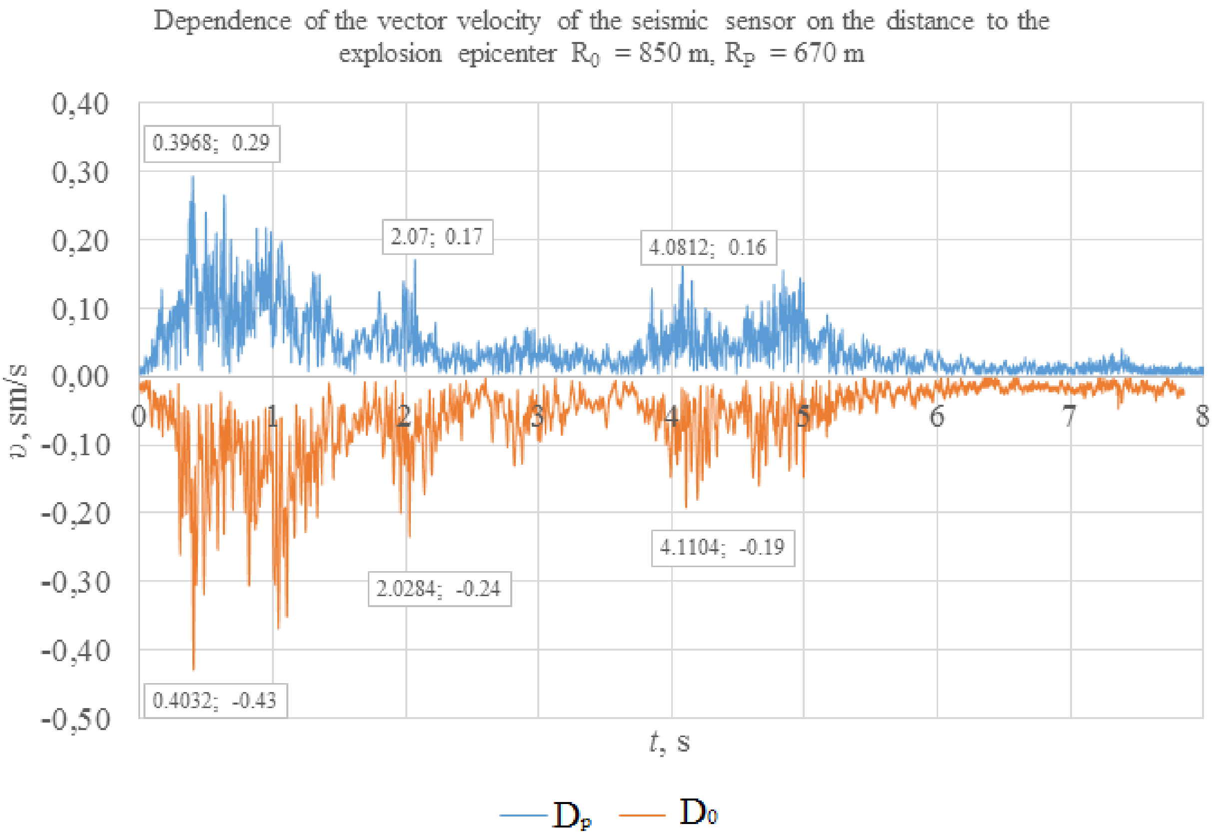

Figure 3. Comparison of seismograms obtained at different observation points: the D_P seismometer was located behind the rock destruction zone at a distance of 670 meters from the epicenter of the explosion, D_0 – at a distance of 850 meters near a residential building.

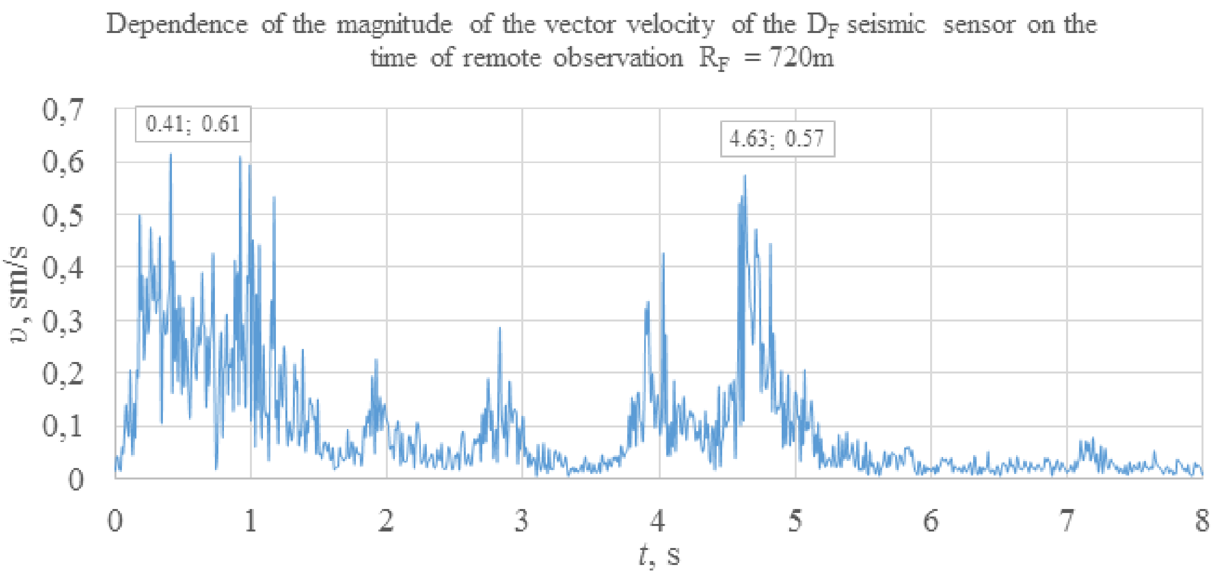

Figure 4. The graph of the change in the vector velocity of the D_F seismic sensor, located at a distance of 720 meters from the epicenter of the explosion near the house.

Since the maximum instantaneous speed is set in different directions not simultaneously, the vector speed does not refer to any common for all moments of time: the moments of reaching the maximum instantaneous speeds and cannot coincide in time in principle.

3. Results and discussion

The duration of ground vibrations was close to 6 seconds. It is noteworthy that the shape of the signals is almost identical (figure 3), but the values of the maximum speed differ: at a shorter distance from the explosion, the amplitude is almost 1.5 times smaller. To explain this phenomenon, it is necessary to obviously recognize that the existing fractured area between the blasting wells and the D_P observation point acts as a screen. It is known that when seismic waves collide with a cavity in rock, a phenomenon called refraction occurs. Part of the energy of the waves is reflected back, and part is refracted and continues to move. This leads to a change in the speed and direction of wave propagation, which is reflected on seismic oscillograms and can be used to monitor the geological structure. The oscillogram obtained from the third seismic sensor of the D_F also confirms this regularity (figure 4, table 1).

Table 1. Measurement results.

	D_O	D_F	D_P
H, m		387-527	
R, m	850	720	670
r, m	994	817	774
ϑ, sm/s	0.43	0.61	0.29

The value of the maximum vector speed registered by the D_F seismometer was 0.61 sm/s, which corresponds to 3 points and almost more than 2.1 times the maximum speed registered by the D_P seismometer and 1.4 times more that registered by the D_0 seismometer. So, we can see the clear influence of the rock structure on the amplitude of oscillations of soil particles near the foundations of residential buildings, the dependence on the direction of seismic wave propagation. The influence of these factors is also observed in the works of other researchers. Thus, in the work [8] as a conclusion is indicated on the the fact that the maximum values of the speed of soil particles depend on a large number of various factors.

Although the distance to the industrial site was the shortest, due to the passage of seismic blast waves through the collapse zone and the loss of explosion energy, the lowest speed of ground vibrations was recorded at this registration point.

To explain the obtained non-trivial results, a frequency examination of the obtained oscillograms was carried out. Their frequency spectrum was studied (figure 5, figure 6, figure 7). The results of spectrogram processing are given in table 2.

Table 2. The results of processing spectrograms.

Seismometer	Frequency, Hz						
D_O	5.7	7.3	10.7				
D_P			10.7	12.5	15.3	19.2	
D_F				13		20	29.5

According to the results of frequency studies, it can be concluded that there is some correlation in the region of more than 10 Hz between the frequency properties of seismic signals

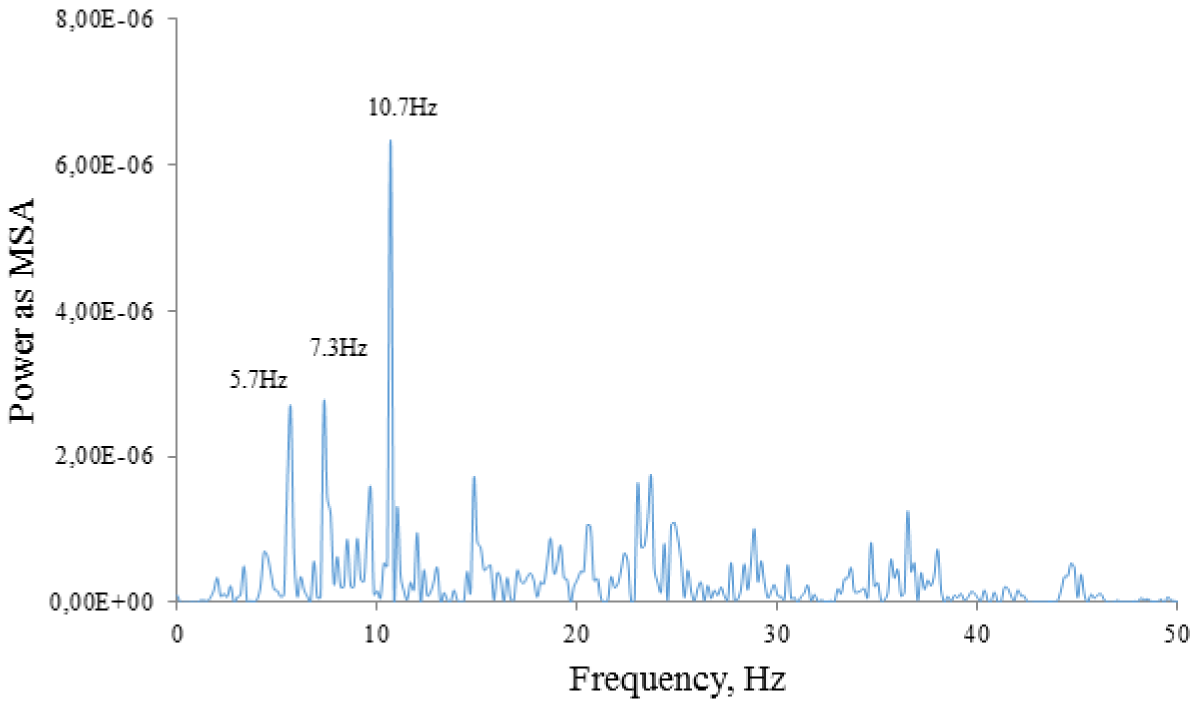

Figure 5. Spectrogram of seismic sensor D_0.

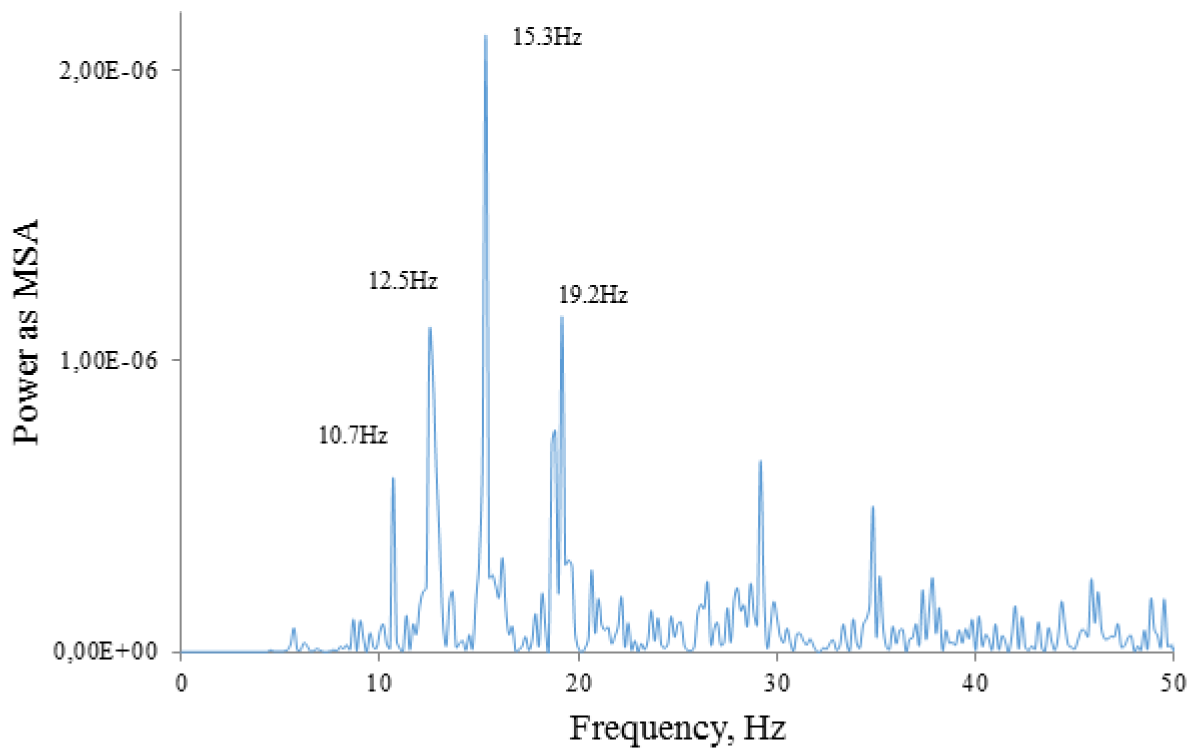

Figure 6. Spectrogram of seismic sensor D_P.

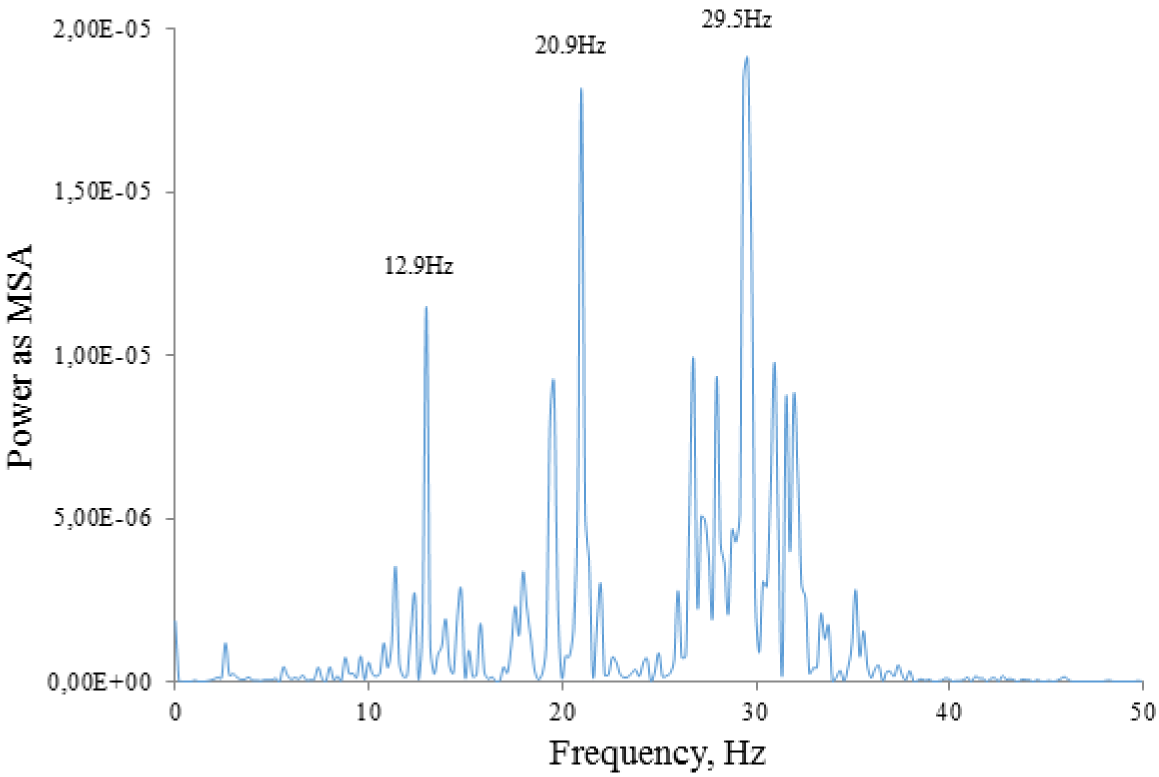

Figure 7. Spectrogram of seismic sensor D_F.

from D_P and D_F sensors installed on different sides of the rock massif destruction zone (figure 1). Such a correlation between the signals of the D_P and D_O sensors is not observed, which indicates a different structure of the massif that the seismic waves from the same source passed through. And this experimental fact provides a method of monitoring the structural changes of the massif.

4. Conclusions

The method of simultaneous measurement of the vector speed of oscillations of soil particles on the daytime surface from one underground source of seismic waves is considered.

A comparison of the seismic load of points on the surface of the Earth during an explosion in a mine with their orthogonal location along the directions in the conditions of the destruction of the rock body in a separate area was performed.

The intensity of seismic explosion vibrations near the foundations of residential buildings and industrial buildings in the area of the industrial site of the mine, which were located in orthogonal directions, was determined.

It has been proven that the intensity of seismic waves that have passed through a half-kilometer layer of rock is not determined by the known laws of their attenuation in a homogeneous environment, but entirely depends on the structure and properties of the rock. Studies of the frequency characteristics of seismic signals have also confirmed this fact.

Abstract. The article addresses the modernization and broadening of the functional capacities of airport infrastructure, focusing on transforming airports into contemporary and ecologically safe spaces within socio-technical systems. This theme is not only pertinent for mitigating the adverse environmental effects of airports but also for enhancing the living conditions and health of the surrounding communities, airport personnel, and waiting passengers. The implementation of the ecologically safe space model yields positive economic outcomes, bolstering the airport's image and competitiveness among investors and the public. The paper introduces an original model for ecologically safe airport spaces, offering new avenues for the development and integration of innovative technologies to optimize environmental safety. The analysis covers economic, political, technological, and environmental factors influencing airport operations and their impact on the country. A range of measures is explored to minimize the negative environmental impact of airports, forming ecologically safe spaces within airports in line with international agreements, including the Airport Carbon Accreditation program. Positive examples of zero carbon emission airports and those evolving as city-airports are examined. The core of the work lies in devising a model for economically safe airport spaces based on a mathematical model of socioium activity within a specific sector of the airport's environmental framework. This dynamic model addresses complex issues such as reducing the airport's negative environmental impact on human within airport confines to prevent accidents, and minimizing the cyclic interaction level among airport stakeholders.

1. Introduction

The demand for air transportation is continuously growing, necessitating the modernization and expansion of the functional capabilities of airport infrastructure. An airport, as a functional component of modern socio-technical systems, is characterized by a "unique" spectrum of transportation services provided to passengers and cargo.

The airport's activities shape an ecological "footprint" in the geographical space of the surrounding environment, characterized by high levels of atmospheric pollution and volumes of "noise pollution". The current situation adversely affects the societal well-being and highlights the existing problem of low environmental safety in airports. Consequently, there is increasing pressure on the operations of airlines and airports to comply with environmental standards.

IOP Conf. Series: Earth and Environmental Science 1415 (2024) 012083 doi:10.1088/1755-1315/1415/1/012083

Regulatory requirements for reducing emissions and improving environmental parameters are becoming increasingly stringent, compelling professionals to seek and implement new solutions to create environmentally safe airport spaces [1].

The establishment of an environmentally safe space will not only reduce the impact on the surrounding environment but also improve living and health conditions for residents around airports, airport personnel, and passengers awaiting their flights.

The strengthening of regulatory requirements for environmental safety necessitates airports to develop and implement models aimed at ensuring both ecological and economic efficiency in their operations [2]. Creating an environmentally safe airport space will enable the implementation of "smart" control over the volume of expenditures on environmental compensations and taxes, contributing to the improvement of the financial stability of airport operations.

Therefore, the modeling of an environmentally safe space for airports becomes crucial, opening new possibilities for the development and implementation of innovative technologies and methods aimed at optimizing the ecological safety of airport operations. It can serve as a tool to enhance public perception of airport activities, a key factor in increasing their competitiveness. As experience shows, airports that adopt an environmentally safe space model enhance their image and competitiveness in the eyes of both passengers and investors and the general public.

Hence, researching the issue of modeling an environmentally safe space for airports as socio-technical systems is relevant and has practical implications.

2. Literature review

Research on various aspects of airports' impact on the environment and the formation of an environmentally safe space is presented in recommendations of the International Civil Aviation Organization (ICAO), European Commission, US Federal Aviation Administration and publications by domestic and foreign scholars.

Among the international requirements and recommendations regulating issues of atmospheric air pollution during operation of aviation transport systems, it is noteworthy to mention:

- ICAO Standards and Recommended Practices: Annex 16, Volume II (2022) [3];
- Doc 10184, Assembly Resolutions in Force (ICAO, 2022) [4];
- ICAO Appendix A: Traffic Forecasts (ICAO, 2021) [5];
- Innovation for a Green Transition/2022 Environmental Report (ICAO, 2022) [6];
- Sustainable and smart mobility strategy: Putting European transport on track for the future (EU, 2021) [7];
- Report from the Commission to the European Parliament and the Council: Updated Analysis of the Non-CO_2 Climate Impacts of Aviation and Potential Policy Measures Pursuant to EU Emissions Trading System Directive Article 30(4) (European Union Aviation Safety Agency, 2020) [8];
- United States: 2021 Aviation Climate Action Plan (Federal Aviation Administration, 2021) [9].

Zaporozhets et al. investigated the impact of aircraft engine emissions on the state of air and the health of residents in the surrounding areas of the airport. They developed approaches to regulate air pollution during operations of aviation transport systems [10].

Kovalchuk examines the issue of preserving the natural environment within airport boundaries, focusing on ways to reduce their negative impact [11].

In the study conducted by Radomska et al., an analysis of soil contamination and phytomass due to the operation of air transport was carried out. Among the primary issues identified, an extremely high level of soil pollution by petroleum products and an elevated content of heavy metals were observed [12].

Omuya and Nkolo [13] analyzed the main spectrum of functional tasks faced by airports (safe landing and takeoff of aircraft; ground handling of aircraft; passenger and airport user management; ground transportation and airport access management; maintenance of buildings, installations, equipment). They also determined the degree of its environmental impact and identified sources of air pollution within airports. The authors emphasize the necessity of implementing effective environmental management through pollution prevention and managing the negative impact.

Xiong et al. [14] analyzes the functions of various institutions regarding the scale and intensity of their impact on airport operations to reduce their pollution potential deserves attention. The authors have developed a concept for modeling institutional causes of external effects on the airport.

The examined works provide a general overview of the environmental "footprint" from airport activities. However, the optimization of expenses for creating an environmentally safe space and ensuring environmental safety for individuals within the society (residents in the vicinity of the airport, airport personnel, passengers) in the geographical space where airports are located has not been adequately addressed in scientific literature, which outlines the problematic nature of this research.

3. Research purpose

In order to solve the problem of ensuring the environmental sustainability of the airport as a functional component of socio-technical systems, the article forms a block of primary tasks that need to be solved:

- analysis of the impact of airports on the basic sectors of the economy of Ukraine with the disclosure of their general characteristics in order to assess the state of the system: "airport-ecological component", using the example of total emissions of carbon dioxide and nitrogen oxides, as chemical elements forming the ecological "footprint" of the activity of airports;
- substantiating the basic priorities for the formation of an environmentally safe space at the airport, as vectors that determine ways to improve its functionality not only as a component of the socio-technical systems of the state, but also from the standpoint: the airport is a complex regional socio-technical system;
- development of a mathematical model for determining the necessary level of costs aimed at ensuring the activity of society's unit in a specific spatial sector of the architectural and spatial framework of the airport itself, taking into account the existing norms of environmental safety.

Based on the formed spectrum of tasks for solving the specified problem, the purpose of the article is the development of conceptual foundations for ensuring the environmental sustainability of the airport as a functional component of socio-technical systems and the mechanism for determining costs aimed at ensuring the activity of society's unit in a specific spatial sector of the architectural and spatial framework of the airport itself with taking into account the existing norms of environmental safety.

4. Results and discussion

The environmentally safe space (ESS) represents an environment where special attention is given to measures for preserving and improving ecological and environmental safety. It encompasses industrial facilities, residential areas, natural resources, and other components where ecological aspects are considered to avoid or minimize negative impacts on nature, human health, and interaction with the natural environment.

The subject of this study is the environmentally safe space of airports. Since airports are a vital component of the modern transportation system and the economy of any country, facilitating rapid and efficient movement of goods and passengers over long distances, contributing to the development of tourism, trade, business, and investments.

The functioning of airports is influenced by economic, political, technological, and ecological factors. Economic factors include the country's economic development, the level of tourism and international trade, fuel costs, etc. Economic growth leads to increased passenger and cargo traffic, requiring the expansion of airport networks and the modernization of their infrastructure, and vice versa. Political factors involve international relations, legislation, aviation-related restrictions linked to military conflicts. Political changes can lead to alterations in aviation routes, airport closures, or even destruction, as witnessed in Ukraine where 11 airports were damaged or completely destroyed due to missile attacks and warfare.

Technological factors encompass advancements in aviation, construction, and other fields. Technological innovations can reduce greenhouse gas emissions and noise from aircraft, expanding their use for cargo and passenger transportation.

Ecological factors include the state of the environment and requirements for its protection. Strengthening ecological standards may lead to additional economic costs but can also ensure a reduction in environmental pollution in airport areas.

If we analyze the impact of airports on the country's economy, we can distinguish the following directions: business and investments; international trade; tourism and the recreational sector; the creation of new jobs (table 1).

Table 1. Impact of airports on the country's economy.

№	Direction of influence	Characteristic
1	Business and investments	Airports, as centers of business activity, provide access to international markets, fostering business development and investments in the country.
2	International trade	Airports ensure a fast and reliable means of transporting goods and cargo between countries. According to the International Air Transport Association, in 2022, over 700 million tons of cargo were transported through airports worldwide, a 15% increase compared to 2021.
3	Tourism and the recreational sector	The presence of airports in a country contributes to the growth of tourist traffic. According to the World Tourism Organization, in 2022, airports worldwide served over 4.5 billion passengers, a 10% increase compared to 2021.
4	The creation of new jobs	The development of airports allows for the creation of new jobs for professionals in various fields, including aviation, infrastructure, construction, trade, and services.

Analyzing airport operations from an environmental impact perspective allows for the identification of both advantages and disadvantages in their functioning. Positive environmental impacts include fuel efficiency and the reduction of air pollution. On the other hand, negative environmental impacts encompass greenhouse gas emissions, noise pollution, and environmental pollution (table 2).

Table 2. Analysis of the ecological impact of the operation of airports.

Positive environmental impact	Negative environmental impact
Fuel efficiency	Greenhouse gas emissions
Air pollution reduction	Noise pollution
	Environmental pollution

The positive environmental impact of aviation lies in the fact that it is currently one of the fastest and most energy-efficient means of transportation. Compared to other modes of transport, airplanes emit less pollution per unit of cargo transported, contributing to a reduction in air pollution, especially when airports are located far from residential areas.

Flying is one of the most carbon-intensive activities – yet it contributes just 2.5% of the world's carbon emissions (figure 1). But air transport has contributed around 4% to global warming to date. Along with emitting CO_2, aircraft also affect the concentration of other atmospheric gases and pollutants (ozone and methane, water vapor, soot, sulfur aerosols, and water contrails) [15].

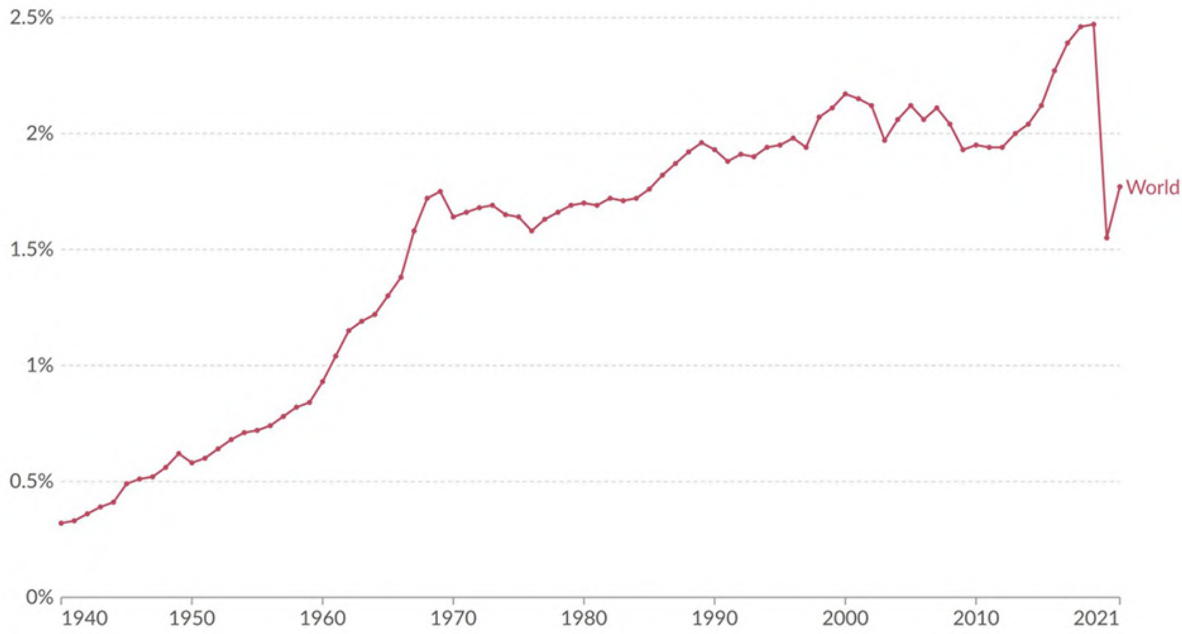

Figure 1. Aviation's share of global CO_2 emissions, 1940 to 2021 [15].

If we analyze the negative environmental impact, aviation is one of the largest sources of greenhouse gas emissions globally. According to the International Air Transport Association, in 2022, airports worldwide accounted for approximately 2.5% of all global greenhouse gas emissions. In turn, due to global warming, the hydrological cycle is changing, which can lead to alterations in precipitation and runoff patterns, affecting water availability. Many regions in Europe are already facing serious water shortages. Water use is typically considered a constraining factor for the growth of many airports [16].

The operation of aircraft generates noise, which can be harmful to human health. Airports can pollute the environment with waste, spent fuel, and other environmentally hazardous substances [13]. The predominant sources of air pollution within the airport are aircraft. The component of emissions from aircraft engines at the local level exceeds 50% of the total mass of pollutant emissions in the airport zone [10]. Soil analysis reveals high contamination with total petroleum hydrocarbons on runways and fuel storage areas. The content of heavy metals is significant, showing a high level of contamination with manganese, copper, lead, zinc, chromium, and iron compared to background soils outside the airport's influence [12].

To mitigate the negative impact of airports on the environment, a comprehensive approach is necessary. This includes improving airport planning and management, transitioning to more environmentally friendly fuel types compared to traditional ones, and developing and refining aircraft manufacturing technology. The possibilities for preserving the natural balance significantly expand when viewing the airport not just as a facility where passengers temporarily stay but as an airport hub. For instance, I Kovalchuk proposes considering the airport hub as a "small city with its 'population', residential and transport infrastructure, administration, and other elements of 'urban' life, where the construction of energy-efficient buildings, emission restrictions, the use of ecological materials in construction, educational activities to increase responsibility for environmental quality, and other initiatives can significantly improve the ecological situation at the airport". Since airport infrastructure consumes a massive amount of energy and water, comparable to the consumption of tens of thousands of households, and generates a large amount of waste, not to mention the scale of the territory it occupies, disrupting the migration paths of animals and birds, the evaluation of the airport's ecological impact is exceptionally important [11].

At the same time, regulatory interventions have always had a significant impact on the transportation industry, and issues related to the environment have been a crucial reason for such interventions. By establishing environmental restrictions, governments can help control/limit the burden of air transport and the harmful impact it may have on human health and the environment [17].

The establishment of an environmentally safe space within the airport boundaries is of paramount importance (figure 2).

In 2009, the Airports Council International (ACI) approved the Airport Carbon Accreditation program, aiming to assess aviation hubs in terms of their environmental impact. The goal was to reduce the negative impact of airports on the environment and transition the maximum number of aviation hubs to a carbon-neutral balance, effectively making them "neutral". In 2015, the Paris Agreement on climate and an international industry-wide Carbon Offset and Reduction Scheme for International Aviation (CORSIA) program were adopted. CORSIA outlines the procedures and opportunities for compensating the negative impact of airports on the eco-environment.

For the certification of buildings and structures according to environmental and energy efficiency requirements, well-known standards such as LEED (USA), BREEAM (UK), and the German standard DGNB exist. New airport terminals can be constructed according to various standards, depending on the country and the choices of designers. Additionally, there are international ISO standards for environmental management (14001), energy management (50001), greenhouse gas emissions (14064), and others, defining the qualitative characteristics of materials and technologies. Concerning airports, the Airport Carbon Accreditation program stands as the sole initiative exclusively focused on them [11].

Currently, there are 49 airports worldwide with a carbon-neutral status, with 40 located in Europe, 1 in the USA, 1 in Latin America, 1 in Australia, and 4 in India. The first international airport to achieve carbon-neutral status in 2009 was Stockholm Arlanda, serving 27 million passengers annually. In Ukraine, there is no such airport. However, it is crucial to initiate progress in this direction, as demonstrated by the management of 270 airports across various countries that have implemented measures for monitoring, assessment, and reduction of their

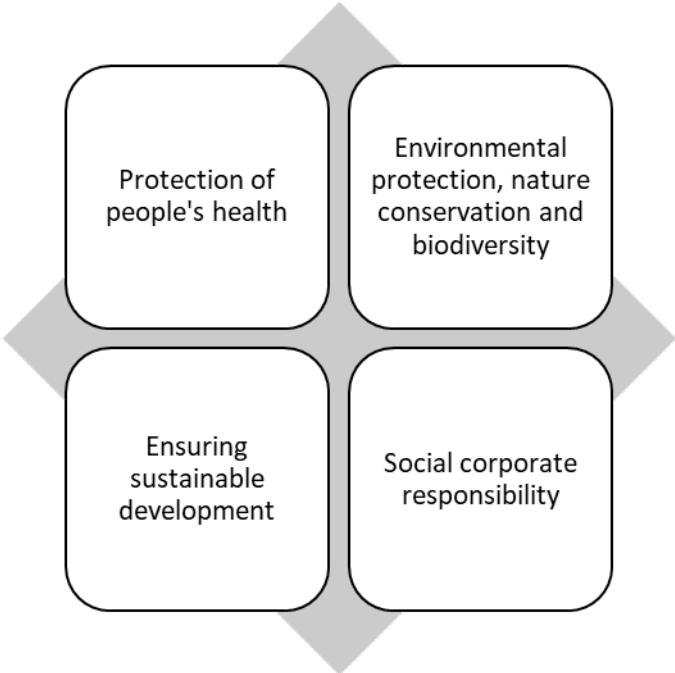

Figure 2. Priorities for the formation of an ecologically safe space at the airport.

environmental impact.

An interesting example is the airport in Helsinki, which is not only carbon-neutral but also follows the city-airport concept known as Aviapolis Vantaa. Therefore, it is essential for the airport to maintain a comfortable environmental setting in the surrounding area. To reduce emissions, the airport employs a range of measures, including the use of renewable energy sources (solar panels, wind turbines), LED lighting, infrastructure construction and reconstruction in line with BREEAM certification, utilization of biofuels, and collaboration with partners. Furthermore, Finavia, the company managing not only Helsinki but also 20 other airports in Finland, plans to completely reduce controlled CO_2 emissions across the entire network by 2020 [11].

It is also worth noting that Budapest Airport becomes the first airport in Central Europe to achieve Level 4+ Transition. It expands its fleet of electric vehicles and develops its e-charging infrastructure; covers 100% of the airport's total electricity consumption by renewable energy sources; has reduced its direct carbon emissions by more than 70% over the last decade and has excelled in waste management, recycling 73% of its municipal and packaging waste in 2023; pays special attention to the materials used for de-icing aircraft, roads, taxiways, and aprons, the fuel consumption of subcontractors during construction and development works, and the management of waste and wastewater to decrease negative environmental impact [18].

Ukraine must consider the impact of international agreements and conventions; therefore, the restoration and reconstruction of Ukrainian airports in the post-war period should occur based on environmentally safe principles, aligning with the principles of sustainable development. Specifically, ensuring an environmentally safe space helps avoid the negative impact of aviation activities on the health of the local population, including the reduction of noise levels and emissions of harmful substances. Protecting the health of airport personnel reduces the incidence of occupational diseases. Modern environmentally safe airports aim to minimize the adverse effects of aviation activities on the natural environment, passengers, and their health.

The restoration of Ukrainian airports with a focus on environmental safety involves the use

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012083 doi:10.1088/1755-1315/1415/1/012083

of energy-efficient technologies and practices. In the long term, this contributes to reducing energy consumption and limiting greenhouse gas emissions. Creating an environmentally safe space involves considering the impact on nature and taking measures to preserve biodiversity and natural resources. Adhering to environmental standards during airport restoration will help preserve and restore local biodiversity. Green zones, the use of environmentally friendly materials, and the creation of natural ecosystems will contribute to the conservation of species diversity. Developing airports on environmental principles includes the application of innovative technologies to reduce environmental impact. This may involve the use of solar panels, the implementation of electric transportation, and other green initiatives.

Environmental standards in airports help create a sustainable space that can easily adapt to changes in regulatory requirements, using modern approaches to reduce environmental impact. The restoration of Ukrainian airports based on environmental principles will attract passengers and investors for whom this is a priority. This will ultimately have a positive impact on shaping the country's tourist image and promoting tourism development.

The formation of an environmentally safe space in Ukrainian airports enhances their image as a responsible corporate player considering the impact of activities on the environment and ready to implement environmentally effective solutions. The result of creating an environmentally safe space at the airport is ensuring the harmonious development of the aviation industry based on principles of safety, sustainability, and environmental responsibility.

An airport, as a socio-technical system, combines a complex of technical, technological, economic, social, and environmental components aimed at ensuring the efficient and safe operation of passenger and cargo aviation services. This system includes:

- Airport infrastructure includes runway systems, terminals, baggage systems, security checkpoints, airport ground transportation systems, and other technical elements that ensure the airport's operation.
- Aviation technologies encompass radio navigation systems, automated air traffic management systems, safety systems, and monitoring systems.
- The social factor involves airport personnel, administration, security services that facilitate the interaction and seamless operation of the airport, and, of course, passengers.
- Financial and economic aspects are related to the management and operation of the airport.
- The system for assessing and reducing the negative impact of aviation activities on the environment, including emissions reduction and resource optimization by the airport.

Thus, an airport is an integrated socio-technical system that operates in a highly dynamic environment, where all elements interact to achieve the main goal – ensuring safe and efficient aviation traffic services.

The safety of the ecological space of the airport represents a state of the environment where there is a balance between the process of ensuring the functionality of the ecological framework architecture and the process of neutralizing all types of negative impact from airport activities on the environment, with the obligatory implementation of the life cycle of all participants in air transportation.

The environmentally safe space for a societal unit within the geographical boundaries of airports can be presented not only by its coordinates in geographical space but also by its location concerning the technogenic component of the environment.

The technogenic component of the ESS in the studied environment is considered not only as a geographical plane occupied by humans but also as a functional sector in society, determined by the ecological potential of humans and dependent on the concept implemented in modern conditions of world development, namely, the concept of a "Healthy City".

The development of the ESS model for airports is based on a mathematical model of the societal unit's activity in a specific sector of the ecological framework architecture of the airport itself [19].

Such a model will help answer various questions, namely: what are the reasons for the decrease in human potential within the airport's existing boundaries, leading to accidents and disasters; reasons for the reduction in the level of cyclical interaction between the components of airport subjects and others.

The functionality of the ESS can be determined by the characteristics of processes aimed at reducing the negative environmental impact of the airport on humans and presented as a dynamic system model (figure 3). Processes aimed at ensuring the functionality of the ESS are presented taking into account the deficit in expenses to ensure the environmental safety of the societal unit's life, synthesized by the operation of transport within airports over a specified time interval.

Factors determining the functionality of the ESS are provided by the permissible range of

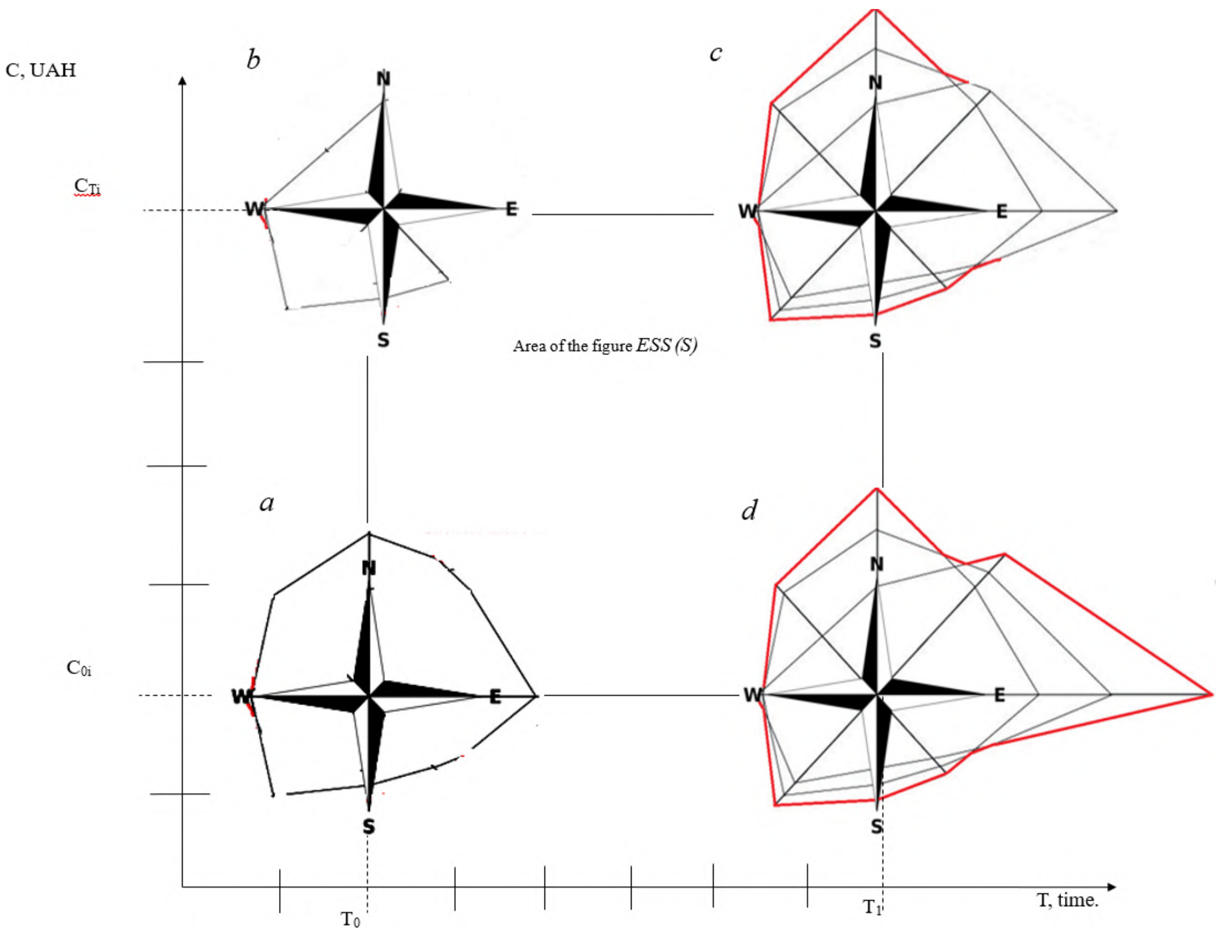

Figure 3. The schematic representation of changes in the ESS indicator $C_{0i} - C_{Ti}$ over time $T_0 - T_1$ in a two-dimensional space by the i-th factor – the level of ESS potential as a component of the ecological framework architecture.
"a-d" – a segment of high functionality of the ESS associated with a low level of deficit in expenses to ensure the environmental safety of the societal unit C's life;
"b-c" – a segment of low functionality of the ESS associated with a high level of deficit in expenses to ensure the environmental safety of the societal unit C's life.

state values (deficit level) $C_{0i} - C_{Ti}$ over the specified time interval $T_0 - T_1$.

Processes aimed at ensuring the functionality of the ESS are presented taking into account the deficit in expenses to ensure the environmental safety of the societal unit's life, synthesized by the operation of transport within airports over a specified time interval.

Factors determining the functionality of the ESS are provided by the permissible range of state values (deficit level) $C_{0i} - C_{Ti}$ over the specified time interval $T_0 - T_1$.

The model development is based on analytical geometry in a two-dimensional coordinate system. Due to the complexity of coordinating dimensions, relative indicators of these quantities in fractions of one unit will be considered in the future, and the magnitude of their changes Δ will be determined by the absolute value.

For simplification of the calculation, the process occurring in the ESS will be characterized by the area of a rectangle (S) formed by segments ΔC and ΔT in the considered two-dimensional coordinate system.

$$S = \Delta C \cdot \Delta T. \tag{1}$$

Based on the mathematical analysis, the area of the rectangle formed by ΔC and ΔT can be determined by the expression:

$$S = \int_{C_0}^{C_1} f(c)dC \tag{2}$$

In this case, we consider that $f(C_0) = T_0$, and $f(C_1) = T_1$. One of the main tasks of minimizing the risk of ESS in airport conditions is to reduce the deficit of the i-th factor (the level of ESS potential) C_{1i} to C_{ni}, i.e., determining $f(C_i) \to C_{ni}$. In the conditions of the ecological framework of airport entities, it can be assumed that $C_{oi} = C_{ni}$ (C_{ni} – the planned indicator set by the budget of the territorial community or other documents for the i-th factor). In this case, the parameter (T) is determined by the working and rest conditions of the employee.

However, for the regulation processes, the parameter is the physiological condition of a person F, which is also functionally related to factors $(C_{0i}, \cdots, C_{1n})$. The efficiency of the regulation process, determined by the level of deficit in expenses to ensure the environmental safety of the societal unit's life (O), will be defined by the magnitude measuring these factors. Changes in ESS factors (ΔC) will be determined by the indicators of expenses (resources) per unit (ΔS) of the "processed" volume of ESS.

The ESS of a person with a system for regulating its factors can be imagined in a three-dimensional coordinate system (figure 4). The volume of a parallelepiped or array formed by the corresponding vectors (C_i, C_d, C_f) will determine the result – compliance with normative requirements for the qualitative indicators (state) (O) of a person's ESS. C_i – the level of assimilation potential; C_d – the assessment of potential; C_f – the volume of consumption of the "dirty resource". The volume of the parallelepiped constructed on vectors is equal to:

$$O = C_i \cdot C_d \cdot C_f = (c_{2f} - c_{1f}) \cdot (c_{2i} - c_{1i}) \cdot (c_{2d} - c_{1d}). \tag{3}$$

The mathematical model, whose functional involves assessing the deficit of economic resources necessary to ensure the environmental safety of the societal unit in ESS as a component of the geographical space of airports, can be formulated in vector form in the algebraic projection of the cube's volume, by moving it to the origin and determining the coordinates of vectors:

$$C_d = \{0, 0, C_{2d}\}, C_i = \{0, C_{2i}, 0\}, C_f = \{C_{2f}, 0, 0\}. \tag{4}$$

The determinant (Δ) of the third order follows from the expression:

$$\Delta = x_1y_2z_3 - x_1y_3z_2 + y_1z_2x_3 - y_1z_3x_2 + z_1x_2y_3 - z_1x_3y_2, \tag{5}$$

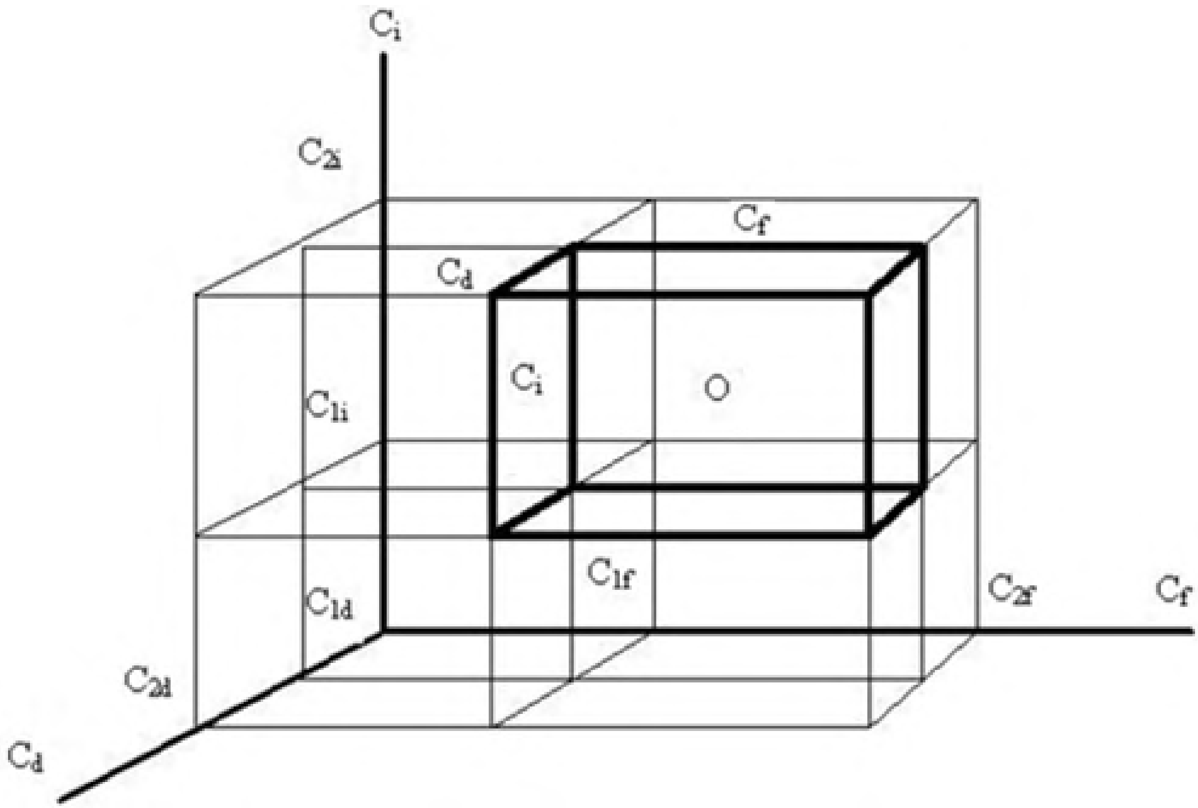

Figure 4. Spatial model of ESS with a system for regulating its ecological factors C_d, C_i, C_f in a three-dimensional coordinate system.

By substituting the corresponding vector values from expressions (4) into expression (5), we obtain the following expression:

$$\Delta = -C_{2i} \cdot C_{2d} \cdot C_{2f}. \tag{6}$$

The spatial domain of a parallelepiped can be determined using the triple integral:

$$O = \int_{C_{1i}}^{C_{2i}} dC_i \cdot \int_{C_{1d}}^{C_{2d}} dC_d \cdot \int_{C_{1f}}^{C_{2f}} f(C_i, C_d, C_d) dT \tag{7}$$

Minimization of the regulation process will be determined by minimizing the deficit of expenditures to ensure the environmental safety of the societal unit (including minimizing ΔC) while meeting the requirements for minimizing environmental hazards (ΔC) after regulating factors in the work sphere, which is determined by the deviation of indicators from the normative value (C_N).

However, the model includes only three factors C_i, C_d, C_f, while in real conditions there are many more of them, and therefore it is necessary to introduce C_j – radiation, waste, noise pollution; C_s – human potential, and others. Introducing these factors requires a transition to a four-dimensional and five-dimensional space. The transition to a four-dimensional space necessitates the construction of a four-dimensional object. Solving the minimization task in four-dimensional space can be done using linear programming.

Minimizing environmental hazards when applying regulation systems for ESS factors in the geographical space of airports will be determined by the following dependence:

$$f(O) \to -O_0 \qquad \text{at} \qquad O \to -O_{\min} \tag{8}$$

That is, the problem of determining the function $y = f(O)$ appears, which has as its limit the number O_0 at O, which goes to $O_{\min}$ for small $\varepsilon > 0$, at which one can find such a number $\delta > 0$ that corresponds to the definition I of the limit of the function. Then:

$$\mid f(O) - O_0 \mid < \varepsilon, \tag{9}$$

once:

$$\mid O - O_{\min} \mid < \delta. \tag{10}$$

This can be written in the following expression:

$$\lim f(O) = O_0 \qquad \text{at} \qquad O \to -O_{\min} \tag{11}$$

When analyzing specific models of ESS factor regulation processes for a three-dimensional coordinate system, it is necessary to determine the values of ε, δ and χ. Expert assessment of these indicators will be the criterion for minimizing the mathematical model of ESS. During the study, the main points that determine the deviations ε, δ and χ can be selected averaged indicators, which are determined by the following expressions:

for C_i:

$$C_{0i} = \frac{C_{2i} - C_{1i}}{2} \tag{12}$$

for C_d:

$$C_{0d} = \frac{C_{2d} - C_{1d}}{2} \tag{13}$$

for C_f:

$$C_{0f} = \frac{C_{2f} - C_{1f}}{2} \tag{14}$$

Thus, you can write:

$$C_{1i} + \varepsilon < C_{0i} < C_{2i} - \varepsilon, \tag{15}$$

$$C_{1d} + \delta < C_{0d} < C_{2d} - \delta, \tag{16}$$

$$C_{1f} + \chi < C_{0f} < C_{2f} - \chi, \tag{17}$$

$$\text{at } \varepsilon, \delta \quad \text{and} \quad \chi \to 0.$$

The main parameters of the spatial model of an environmentally safe space in the conditions of the studied environmental framework of the airport are determined by the existing regulations, which are reflected in the form of a 3D rectangle. By applying the base model as an ideal representation for specific living conditions of the societal unit in the environmental framework of the airport, visually, other geometric figures constructed based on real parameters will have deviations from the vector magnitude of the base model. This deviation of vectors from the real model to the base model defines the violation of normative indicators, which is a characteristic of compliance with normative requirements for environmentally safe living conditions in the investigated environment, both in static and dynamic states. A vector expression for the model of an environmentally safe space has been obtained, formalized at two levels – critically minimal (permissible) and optimal (comfortable). This approach is substantiated by ecological laws of minimum and the law of “stability” regarding existing microclimate parameters in the environmental framework of the airport.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012083 doi:10.1088/1755-1315/1415/1/012083

5. Conclusions

Post-war reconstruction of Ukrainian airports should adhere to international agreements and conventions, taking into account that modern, environmentally safe airports aim to minimize aviation's adverse effects on nature and society (employees, passengers, local residents). Emphasis on ecological safety principles will help mitigate aviation's negative impact on health and the environment. Creating ecologically safe airport space includes: adhering to environmental standards in airport development to preserve and restore local biodiversity; incorporating green spaces, eco-friendly materials, and natural ecosystems; using innovative technologies to reduce environmental impact.

Airports can be considered as integrated socio-technical systems with technical, technological, economic, social, and ecological components. Airport infrastructure, aviation technologies, social factors, as well as financial aspects are crucial components in airport systems. The safety of the airport's ecological space depends on maintaining a balance between ensuring the functionality of the ecological framework's architecture and neutralizing all forms of negative airport activities on the environment.

The development of the ecologically safe space model is based on the mathematical model of societal unit activity within the ecological framework of the airport. The model addresses questions related to minimizing negative environmental impacts. The model focuses on three main factors: assimilation potential, potential assessment, and consumption volume of "dirty resources". Real conditions may involve more factors, necessitating an extension to four-dimensional and five-dimensional spaces. Model involves reducing deficit costs while meeting requirements for minimizing environmental risks. The deviation of vectors from the real model to the base model defines the violation of normative indicators, which is a characteristic of compliance with normative requirements for environmentally safe living conditions in the investigated environment, both in static and dynamic states. The model is based on ecological laws of minimum and the law of "stability" regarding existing microclimate parameters in the environmental framework of the airport.

Abstract. The results of investigations of chemical composition and emission rates of the welding fume (WF), generated during pulse-arc welding of D16 aluminum alloy with ER4043 and 2319 solid-section wires, are presented. It was established that when welding with ER4043 and 2319 wires, such harmful components as aluminum, iron and silicon are present in the WF. It was established that when using ER4043 and 2319 wires, welding fume equally belong to the least harmful "5" class of toxicity and differ in the level of emissions, which varied depending on the welding mode from class "a" to class "b" (in accordance with DSTU ISO 15011). When using ER4043 wire, the level of emissions increases with increasing values of the characteristics of the welding mode. When using wire 2319, the maximum values of the aerosol emission level are at a frequency of 100 Hz.

1. Introduction

Popular metals used on an industrial scale include aluminum. This is due to the excellent resistance of aluminum to negative external influences, good thermal and electrical conductivity. Welding of aluminium through his physical and chemical properties has the features and differences comparatively with steel and other metals and requires the high culture of production [1].

The implementation of measures to improve the working conditions of welding production workers is based on the analysis of data on the chemical composition, emission levels and toxicity of welding fumes. For this, a primary sanitary and hygienic assessment of welding materials is carried out by the method of trapping WF and determining their quantity and chemical composition.

Analysis of existing information on harmful and dangerous factors that occur during arc welding and surfacing of aluminum and its alloys has shown that this area is poorly researched, information on welding fume emissions is very limited, and there is no generalized data.

The purpose of the work is to carry out a sanitary and hygienic assessment of the nature of aerosol emissions during pulse-arc welding of structural aluminum alloy D16

2. Features of welding aluminum and its alloy

An aluminium and his alloys have a considerable sense to superficial oxidization on air, that is why their welding is conducted in the environment of protective gases, inert argon or helium, and their mixtures [2]. The presence of an oxide film increases the complexity of the process of welding aluminum structures, since the melting temperature of aluminum oxide Al_2O_3 is 2015 °C, and the melting temperature of the base metal Al is 650 °C. It follows that at the melting temperature of the surface oxide film, the aluminum under it will already boil and evaporate, so this makes the process of forming a welded joint as such impossible. Another important factor when welding this material is its high thermal conductivity, it is almost 5 times higher than that of steel, which means that in order to melt aluminum and its alloys, a much larger amount of heat must be applied and it must be applied in a highly concentrated manner [3]. To form a high-quality weld when welding aluminum alloys, non-fusible (TIG) and fusible electrode (MIG) welding methods in an inert gas environment are more often used [4]. It is for these methods that specialized powerful welding power sources and corresponding technological processes were developed, which ensure the destruction of the oxide film by a highly concentrated welding arc [5]. Pulse welding power sources are also widely used for aluminum welding, which use the principle of simultaneous combination during welding of the main working welding current and pulse current of adjustable frequency, which has a higher peak value. Due to it, the efficiency of the welding arc and the quality of the transfer of the electrode metal are significantly increased, and the destruction of the oxide film is improved. It also allows you to reduce overheating of the metal, which significantly improves the physical and mechanical qualities of welded joints [6].

3. Normative requirements for air in the working area

Due to the increase in requirements for the quality of the welding seam, welding processes are constantly being improved [7]. In addition, the sanitary and hygienic requirements for welding materials are increasing. Despite the increasing mechanization and automation of welding operations, the role of the welder, as an active and main link in the execution and control of the welding process, will remain decisive for a long time. The creation of workplaces, welding equipment and working conditions that meet the specified requirements allows the welder to perform work movements and control the welding process with high accuracy and reliability under optimal physical stress and nervous tension, maintaining high efficiency during the entire shift. Neutralization of welding fumes is necessary to improve working conditions [8]. For this, data on the chemical composition and emission levels of WF are required. This will make it possible to choose means of local ventilation or more ecological welding materials.

Numerous studies show that accumulating in the body, aluminum:

- acts on brain cells;
- causes anemia, arthritis;
- suppresses the production of gastric and salivary enzymes;
- contributes to the development of osteoporosis and rickets.

A welder can get sick with irreversible aluminosis – pathological changes in the lungs that develop when inhaling aluminum dust [9].

In accordance with the international standard ISO 14000, welding materials are subjected to new requirements for their continuous improvement in order to minimize the harmful effects on the human body, and according to the standards of DSTU ISO 15011 [10], welding materials must be constantly monitored for occupational safety indicators (chemical composition, emission level, toxicity and hygienic class of welding aerosols).

In the countries of the world, sanitary services control harmful substances in the air of the working area of industrial premises. For this, regulatory requirements are used that determine the maximum allowable concentrations (MAC) [11]. These are such concentrations that during daily work do not cause occupational diseases in workers. Their value is regulated by special sanitary regulations, which include data on the maximum concentration of harmful gases and aerosols near the welder's workplace (at breathing level), which is not harmful to health during an eight-hour working day. According to the hygienic regulations of chemicals in the air of the working area, the maximum permissible concentration of aluminum and its alloys in the air of the working area is 2 mg/m^3 and belongs to the 3rd class of danger [12]. The MPC value for neutral dust that does not have poisonous properties is 10 mg/m^3.

4. Processes of welding fume generation during MIG and MAG welding of aluminum and its alloy

A schematic view of the formation process of WF during mechanized welding of non-ferrous metals in a shielding gas environment is shown in figure 1.

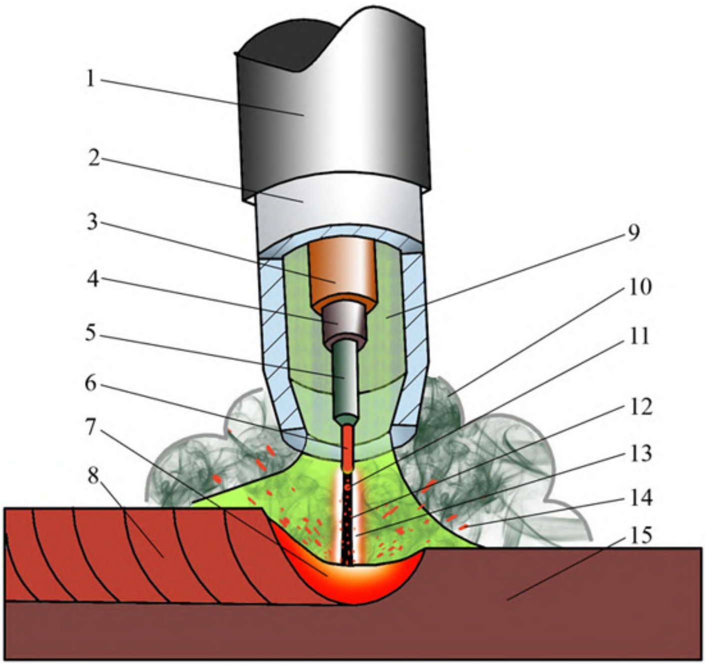

Figure 1. Formation of welding fume during MIG and MAG welding: 1 – torch; 2 – gas nozzle; 3 – insulator; 4 – tip adapter; 5 – contact tip; 6 – welding wire; 7 – welding pool; 8 – weld; 9 – shielding gas; 10 – gases and welding fume; 11 – a drop of molten wire; 12 – arc column; 13 – arc flame; 14 – sparks (splashes) of liquid metal; 15 – base metal.

Under the action of the heat of the arc, a drop of liquid metal is formed and grows on the end of the wire, which is held by the forces of surface tension. Partial evaporation of the metal occurs, as a result of the high boiling temperature of the metal and significant heat of evaporation. Passing through the protective gas supplied to the welding zone, part of the metal vapor condenses into droplets, oxidizes and turns into small solid particles of metal oxides, which form a fume and always surround the welding arc.

5. Procedure of experiments

The scheme of the stand for sampling WF during mechanized welding with aluminum wires in the environment of protective gases is shown in figure 2.

Sampling of WF for their dissolution is carried out in accordance with the standard applying the method of complete capture of the fume, generated during welding with the use of the special bench with the FPP filter installed on a way of movement of WF from a shelter of a welding zone. The following indices of WF formation were determined: intensity of Va emission, g/min; chemical composition of WF, wt.% For each variant at least three experiments were performed.

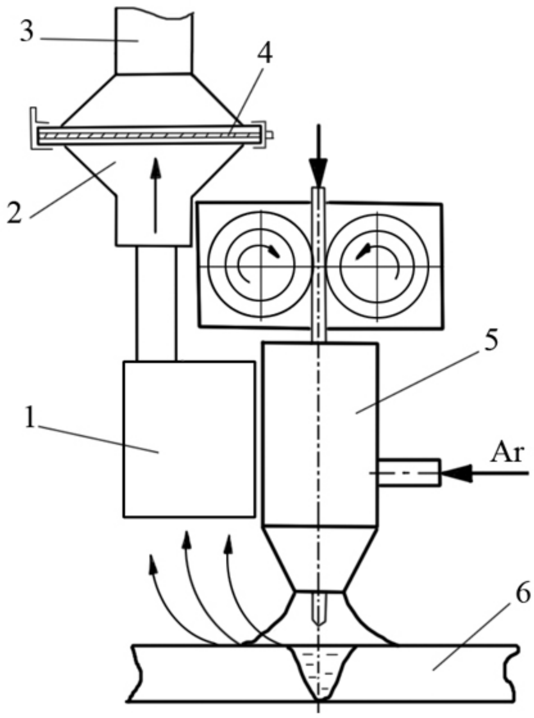

Figure 2. Scheme of the stand for sampling WF during MIG welding with solid wires: 1 – catching nozzle (covering the welding zone); 2 – filter holder chamber (measuring and distribution chamber); 3 – nozzle to the aspirator; 4 – filter for chemical analysis; 5 – burner; 6 – metal to be welded.

The following two indicators are used to determine the final indicators of the hygienic assessment of welding materials by the calculation method in accordance with the DSTU ISO 15011-4:2008 standard:

1. Limit value of welding fume as a measure of toxicity ($LV_{WF(A)}$)
2. Class of welding fume, indicator of the risk of exposure to WF on the human body at a specific workplace.

After the chemical analysis, the obtained results are evaluated.

6. Choice of material and results of investigations

At the E. O. Paton Electric Welding Institute of the NAS of Ukraine conducted a study of the chemical composition, emission levels and toxicity of aerosols formed during mechanized welding of aluminum-based alloys using methodological standards of the ISO 15011 series. To conduct the research, the pulse-arc method of welding D16 aluminum alloy was chosen. Welding was performed with two brands of solid wire ER-4043 and wire 2319 with a diameter of 1.6 mm, which are serial and certified and widely used in industry. The thickness of the D16 plate is 4 mm. The chemical composition of the welding materials used is shown in table 1. The MIG welding process was carried out using an A1431 welding machine and a pulsed power source with a built-in algorithm for regulating the shape of a specialized multi-level current pulse, developed at the E. O. Paton Electric Welding Institute of the NAS of Ukraine for pulse-arc welding with a fusible electrode in shielding gases. Welding was performed with a direct current of reverse polarity with a pulsed current of a set frequency superimposed on it. Argon was used as a shielding gas. Gas consumption (Ar) was 20-25 l/min. The set welding speed is 25 m/h. The current of the welding mode I_{w1}, I_{w2}, I_{w3} indicated the average values of the sum of direct current and pulsed current that flow simultaneously in the welding arc.

Table 1. Chemical composition of plate D16, wires of solid section 2319 and ER4043.

Brand	Chemical composition, wt. %									
	Si	Fe	Cu	Mn	Mg	V	Ni	Zn	Ti	Al
D16T	0.5	0.5	3.8-4.9	0.3-0.9	1.2-1.8	–	0.1	0.3	0.1	the rest
2319	0.2	≤ 0.3	5.6-6.8	0.2-0.4	0.02	0.05-0.15	–	0.1	0.1-0.2	the rest
ER4043	4.5-5.5	≤ 0.8	≤ 0.3	≤ 0.05	–	–	–	–	≤ 0.2	the rest

The welding modes used in pulse-arc welding of D16 aluminum alloy with ER4043 and 2319 solid-section wires are listed in table 2.

Table 2. Welding modes during the research.

Grade of wire:	ER4043			2319		
parameters	Regime 1	Regime 2	Regime 3	Regime 1	Regime 2	Regime 3
f, Hz	70	100	130	70	100	130
I_w, A	120	160	180	110	160	180
U_w, V	20	22	24	22	22	24
V_{feed}, m/min	2.82	4.08	5.1	2.82	4.08	5.1
g, kg/min	0.015333	0.022167	0.027667	0.015333	0.022167	0.027667

The results of the study of the intensity of welding fume emissions during pulse-arc welding of D16 aluminum alloy with ER4043 and 2319 solid-section wires are shown in figure 3.

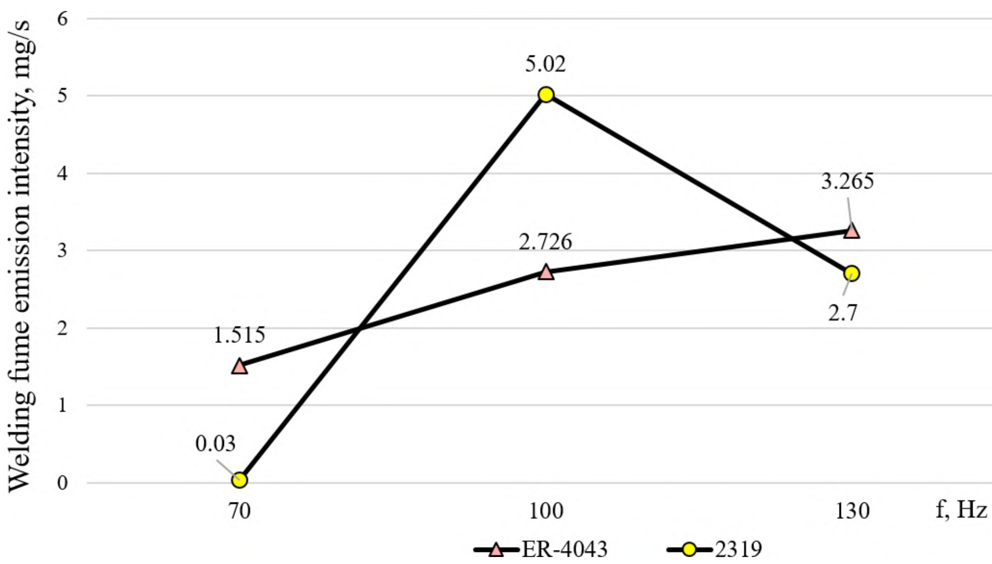

Figure 3. Intensity of welding fume emission during MIG welding with ER-4043 and 2319 aluminum wires with a diameter of 1.6 mm.

As we can see, the intensity of welding fume emissions during MIG welding with ER-4043 aluminum wires is directly dependent on the frequency of the pulsed current superimposed on the main direct current of reverse polarity. Thus, with increasing frequency, the intensity of WF emissions increases. Gross welding fume emissions during MIG welding with 2319 aluminum wire do not have a direct dependence on pulse frequency. The lowest emission values were recorded at the experimental pulse frequency of 70 Hz, and the highest values at the frequency of 100 Hz.

The results of the study of the chemical composition of welding fumes during pulse-arc welding of D16 aluminum alloy with ER4043 and 2319 solid-section wires are shown in table 3.

Table 3. Mass fraction of chemical elements in the welding fume.

Grade of wire	Mass fraction in WF, %			
	Al	Si	Mn	Fe
ER-4043	2.33	1.81	0.127	18.3
2319	2.274	1.4	Not found	19.5

For clarity, graphs of the emission intensity of the i-th component at different welding modes were constructed (figure 4).

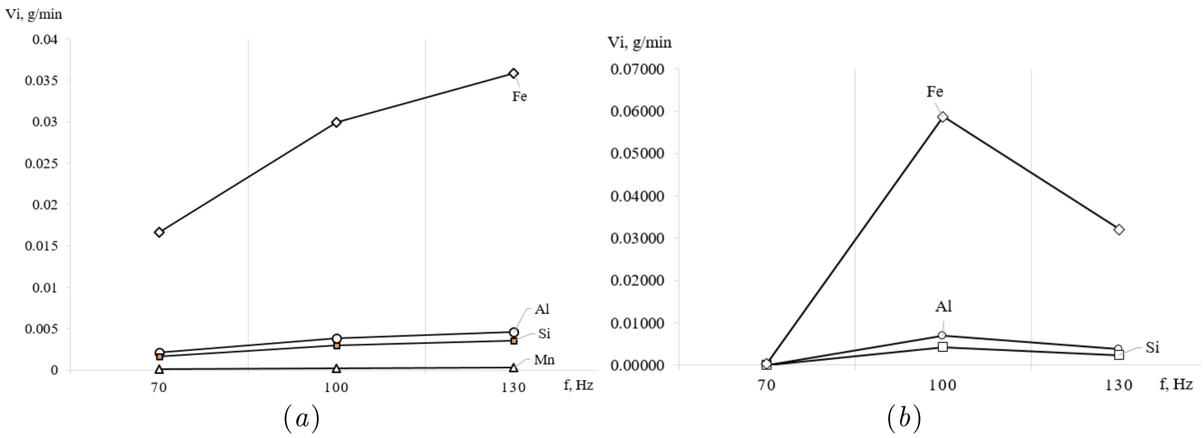

Figure 4. Comparative graph of the intensity of formation of elements in the WF composition during MIG welding with aluminum wire: (a) ER-4043 and (b) 2319.

As we can see, a larger mass of toxic elements in the welding fume during MIG welding with aluminum wires ER-4043 and 2319 consists of such components as aluminum, iron and silicon. The emission intensity of these welding fume components increases with increasing pulse frequency.

To determine the final estimated indices of hygienic evaluation of welding materials in compliance with the standard DSTU ISO 15011-4: 2008, the limit value of the welding fume was determined by the following equation:

$$LV_{WF(A)} = \frac{100}{\sum_{1}^{n} \frac{i}{LV_i} + \frac{100-\sum_{1}^{n} i}{LV_{WF}}}$$

where $LV_{WF(A)}$ is the total limit value of the welding fume, in mg/m^3; n is the number of main components of the welding fume; i is the fraction of i-th main component of the welding fume in %; LV_i is the limit value (MAC) in mg/m^3 for i-th main component of the welding fume; LV_{WF} is the limit value in mg/m^3 for the welding fume, which contains chemicals with a low and medium toxicity, if such a limit was established, or a limit value in mg/m^3 for inhaled dust, if no limit value for the welding fume was established.

Due to the fact that the procedure does not allow determining the content of all components of WF to bring its composition to 100 %, it was assumed that in addition to the revealed components, the residue of WF represents a non-toxic dust with MAC of 10 mg/m^3. The results of the calculation are shown in table 4.

To calculate the toxicity, the data of MAC of toxic components were used in accordance with the hygienic regulations of chemicals in the air of the working area [12].

Table 4. Indices of hygienic evaluation of welding materials determined by the calculation method in accordance with the standard DSTU ISO 15011-4:2008.

Grade of wire	Welding mode	Va, mg/s	$LV_{WF(A)}$, mg/m^3	Category of electrode
ER-4043	Regime 1	1.515	7.665	5a
	Regime 2	2.726	7.665	5a
	Regime 3	3.265	7.665	5b
2319	Regime 1	0.03	8.052	5a
	Regime 2	5.02	8.052	5b
	Regime 3	2.7	8.052	5a

According to the limit value of the welding aerosol, these wires belong equally to the fifth class (“5”), their calculated toxicity values have a slight difference (for wire ER-4043 – $LV_{WF(A)}$ is equal to 8.456 mg/m^3; for wire 2319 – $LV_{WF(A)}$ is equal to 8.993 mg/m^3). According to the DSTU ISO 15011-4:2008 classification, class “5” has the highest MAC values, that is, it is the least harmful. As for the level of welding fume emission, it varies depending on the welding mode and its class varies from “a” to “b”, according to the standard, this designation corresponds to the lowest emission of aerosol mg/s. The highest values of WF intensity were recorded when welding with 2319 wires at a frequency of 100 Hz.

7. Conclusions

In order to ensure the maximum improvement of the hygienic characteristics of the air in the working area, it is necessary to choose the optimal combination of the following technological methods of reducing the level of emissions of harmful substances:

1. Welding materials should be selected according to the classification of DSTU ISO 15011-4:2008, where the limit value of WF (mg/m^3) varies from the most toxic “0” to the least toxic “5”, and the level of emissions (mg/s) is its small values from “a”, and high to “e”.
2. When choosing wires taking into account hygienic characteristics during pulse-arc welding of structural aluminum alloy D16, pay attention to the level of emissions that change depending on the welding mode. Since ER-4043 and 2319 wires equally belong to the “5” class according to the limit value of WF (mg/m^3)
3. The obtained results of the carried out investigations can be used during calculation of the systems for mechanical ventilation: determination of amount of air L (m^3/h) which needs to be supplied or removed from the room. To calculate the ventilation of production

rooms where welding is used, air exchange is required, which is usually determined by the calculation method based on specified data on the amount of harmful substances emissions.

The obtained results are necessary for improving the working conditions of welders and workers in production facilities, which will contribute to reducing of occupational diseases. Work allows you to protect the environment from harmful substances

Abstract. Forecasting of short-term air pollution caused by nitrogen dioxide is valuable for decision making about human health protection. Open real world data collected in Madrid over a period from 2019 to 2022 were used. Trends and patterns in air pollution are presented and analysed. Causation between air pollution by nitrogen dioxide and traffic is investigated. Results of traffic forecasting obtained by corresponding bidirectional Long Short-Term Memory (LSTM) models at the selected stations as well as values of nitrogen dioxide concentration over historic horizon of 6 hours at the same station are used for forecasting of air pollution by nitrogen dioxide as features for LSTM models. Models were created and trained for each air pollution measurement station presented in the corresponding dataset. Forecasting is made for 6 hours ahead. The study confirmed that traffic forecasting results are valuable for models of forecasting air pollution by nitrogen dioxide. It provided increase in forecasting accuracy in comparison with the usage of historical values of traffic as input features. The obtained results improved MAE by 5 % and MSE by 6.37 % comparing to LSTM models with only previous values of air pollution by nitrogen dioxide. It defines an important approach which should be applied for more complex architectures of deep learning models in the following investigations.

1. Introduction

Air pollution has significant negative impact on human health. There are different air pollutants with a main set containing particulate matters (PM2.5 and PM10), nitrogen dioxide, ozone, sulfur dioxide, carbon monoxide.

Nitrogen dioxide is one of the main air pollutants regarding impact on human health particularly in the developed countries. World Health Organization defines recommended levels of nitrogen dioxide. Guidelines [1] contain two indicators:

- long-term (annual) average level set at 25 $\mu g/m^3$;
- short-term (over 24 hours) average level set at 10 $\mu g/m^3$.

Therefore, appropriate decision making about air pollution requires long-term and short-term forecasting models of air pollution caused by nitrogen dioxide. This study is aimed at short-term forecasting of concentration of nitrogen dioxide. Decisions in short term require accurate forecasting, being more sensitive for changes in concentration of nitrogen dioxide. It is known, that not only architecture of forecasting models impacts on accuracy of obtained results, but input feature set as well. At the same time one of the main causes of nitrogen dioxide is traffic. Vehicle emissions increase concentration of nitrogen dioxide in the air. As well as concentration of nitrogen dioxide, traffic does not have static values. So the question is, what period of traffic values should be used in forecasting models?

There is a range of investigations on air pollution, in particular [2–14]. Ivanova et al. [2] apply simple Auto-Regressive Integrated Moving Average model for investigation of nitrogen dioxide concentration. It is followed by seasonal version of this model in the paper by Molina-Cueva et al. [3]. But these models are used for middle or long-term predictions. Time series regression models were developed by Neykov et al. [4]. Li et al. [5] investigates Long Short-Term Memory (LSTM) models for nitrogen dioxide concentration forecasting which are prior to back propagation neural network in terms of forecast accuracy. In the paper by Kristiani et al. [6] LSTM model was proposed to forecast PM2.5 concentration, and the investigation [7] used its aggregated version based on data from different stations. LSTM models had more accurate results compared to support vector machine based regression, gradient boosted tree regression. In the paper by Ding et al. [8] LSTM models were applied for Air Quality Index forecasting with better results as to convolutional neural networks. Papers [9, 10] use LSTM models as well, and papers [11, 12] proposed advanced versions of LSTM.

In the papers [9–11, 13, 14] values of traffic are used as additional input features for forecasting. But in general review of the literature revealed that traffic is fed into existing forecasting models only by its previous values. Some time horizon is used to measure concentration of nitrogen dioxide in the air and traditionally traffic at the place where pollution is measured. This time horizon is a historical one. As short-term forecast is considered, time horizon is defined by a number of hours. Then the measured values are fed into a model to forecast concentration of nitrogen dioxide for the next hours. The next hours are defined as a forecast horizon.

This investigation is an attempt to use values of traffic on forecast horizon instead of historic time horizon as input features for forecasting models. It is necessary to check if it makes forecasting models more accurate.

2. Methodology

Taking into account the results of analysis presented in the first section, different deep learning models should be created. But these models should have the same architecture to investigate impact of traffic on the results of air pollution forecasting. This architecture is presented by LSTM in the paper. It has been chosen because of its wide application for air pollution forecasting in particular and for forecasting in general. The results of studies [2, 5–14] were taken into account as well.

As the problem of forecasting air pollution by nitrogen dioxide is a problem of time series forecasting, it is obvious that values presenting concentration of nitrogen dioxide should be measured on historic time horizon and used as input features for a forecasting model. If a set of measurement stations is given, then a separate model should be created and trained for each station. Each station is defined to measure concentration of nitrogen dioxide in the air at a certain place.

The problem of forecasting air pollution by nitrogen dioxide was considered under constraints. Such an approach allows to apply the proposed models for the cases when a system of measurement stations of traffic and air pollutants does not cover all corresponding city structure. Traffic and air pollution by nitrogen dioxide can be measured at different places. This approach not only creates the possibility, but defines an issue as well. Because different stations at different places can be used to measure traffic and air pollution, it is necessary to define a way to get input features presenting traffic for a forecasting model. In this study it was proposed to use feature selection method based on decision tree ensembles created by Random Forest method. It allows to get the most appropriate traffic measurement stations for each air pollution measurement station. The main idea is to select a subset of traffic measurement stations with the biggest impact on concentration of nitrogen dioxide at certain station based on the historic dataset.

When a subset of traffic measurement stations is selected, corresponding values of traffic should be used as input features for a forecasting model. In this paper it is proposed to use these values on forecast horizon. As values of traffic on forecast horizon are not known for sure at the moment of forecasting air pollution, method for traffic forecasting should be applied. It is proposed to use the method [15], as it is applicable under the constraints defined above. This method creates a bidirectional LSTM model with input features presenting traffic values on historic horizon at forecast station and selected stations as well.

As a result air pollution forecasting model with LSTM architecture is created for a station, using the following input features:

- values of nitrogen dioxide concentration over historic horizon of length H at the same station: $p(0), p(1), \dots, p(H-1)$ for sequential hours with numbers $0, 1, \dots, H$;
- values of traffic, forecasted over a corresponding horizon at the Q selected traffic measurement stations: $t(st(i), H), t(st(i), H+1), \dots, t(st(i), 2H)$ for sequential hours at the i-th selected measurement station with number $st(i)$, where $i = \overline{0, Q-1}$.

So every input data sample is a vector $x^0 =< p(0), p(1), \dots, p(H-1), t(st(i), H), t(st(i), H+1), \dots, t(st(i), 2H) >$, where $i = \overline{0, Q-1}$.

Every i-th LSTM cell consists of state unit s_i^t, forget f_i^t, external input g_i^t and output q_i^t gates for time step t. Biases b_i^f, input weights U_i^f, recurrent weights W_i^f should be defined for forget gates and other gates accordingly. Input vector is defined as x^t. The following computations are used [16]:

$$f_i^t = \sigma(b_i^f + \sum_j U_{i,j}^f x_j^t + \sum_j W_{i,j}^f h_j^{t-1}), \tag{1}$$

$$s_i^t = f_i^t s_i^{t-1} + g_i^t \sigma(b_i + \sum_j U_{i,j}^f x_j^t + \sum_j W_{i,j}^f h_j^{t-1}), \tag{2}$$

$$g_i^t = \sigma(b_i^g + \sum_j U_{i,j}^g x_j^t + \sum_j W_{i,j}^g h_j^{t-1}), \tag{3}$$

$$h_i^t = tanh(s_i^t) q_i^t, \tag{4}$$

$$q_i^t = \sigma(b_i^o + \sum_j U_{i,j}^o x_j^t + \sum_j W_{i,j}^o h_j^{t-1}). \tag{5}$$

3. Results

Experimental investigation was conducted to check if the proposed approach applicable. Real world data were used. The data were collected in Madrid over a period from 1.01.2019 until 30.09.2022 and presented in open access at Open data portal of Madrid City Council [17]. As the proposed methodology includes values of air pollution by nitrogen dioxide and traffic as well, corresponding data presenting nitrogen dioxide concentration [18, 19] at stations [20] and traffic values [21] were used.

At first the data were studied to reveal its structure. Hourly levels of air pollution by nitrogen dioxide at 3 different stations in Madrid over the periods of three days are presented in figure 1 for stations Parque Juan Carlos I, Parque del Retiro, Casa de Campo and in figure 2 for stations El Pardo, Ensanche de Vallecas, Plaza Eliptica. These figures display some time patterns for dynamics of air pollution by nitrogen dioxide. But at the same time these patterns are not static and certain values for different stations could be closer to each other (figure 1) or more distant (figure 2).

Patterns presented in figure 3 display that concentration of nitrogen dioxide at the same station is varied through days and hours. Part (a) of figure 3 presents different days marked

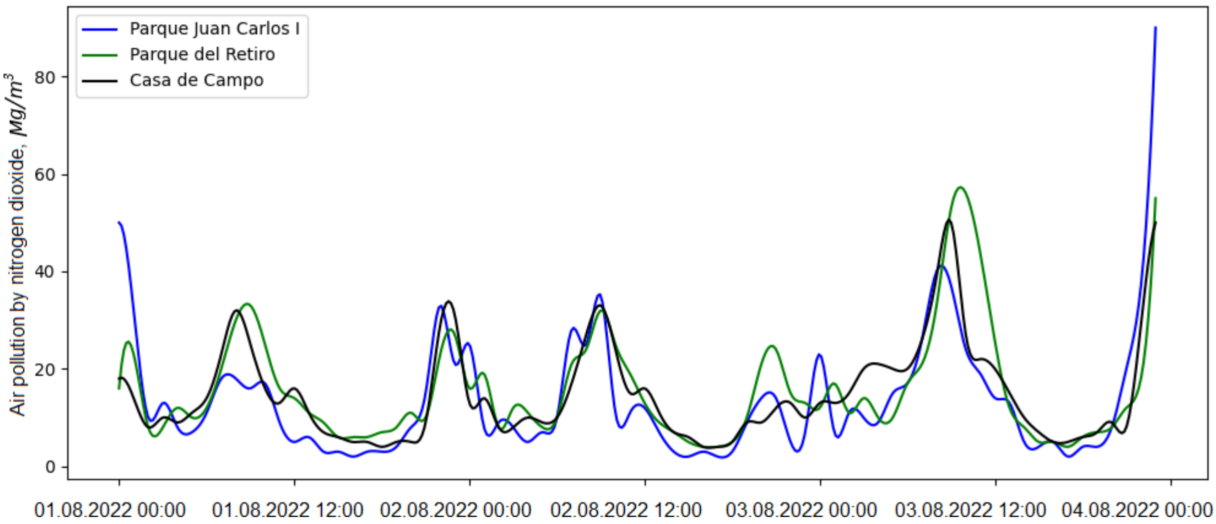

Figure 1. Hourly levels of air pollution by nitrogen dioxide at 3 measurement stations over the period 1-3.08.2022.

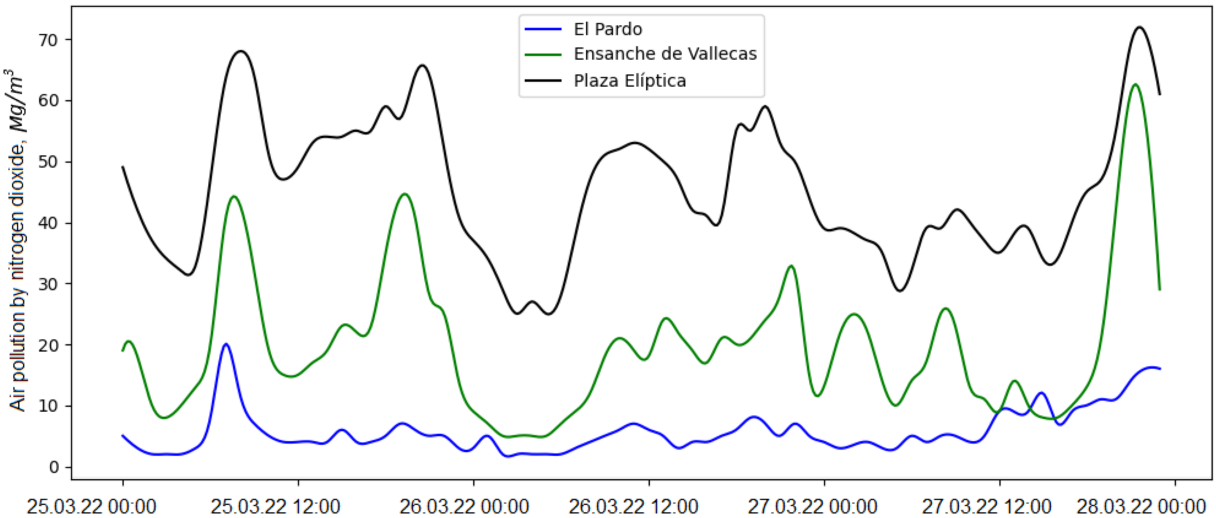

Figure 2. Hourly levels of air pollution by nitrogen dioxide at 3 measurement stations over the period 25-27.03.2022.

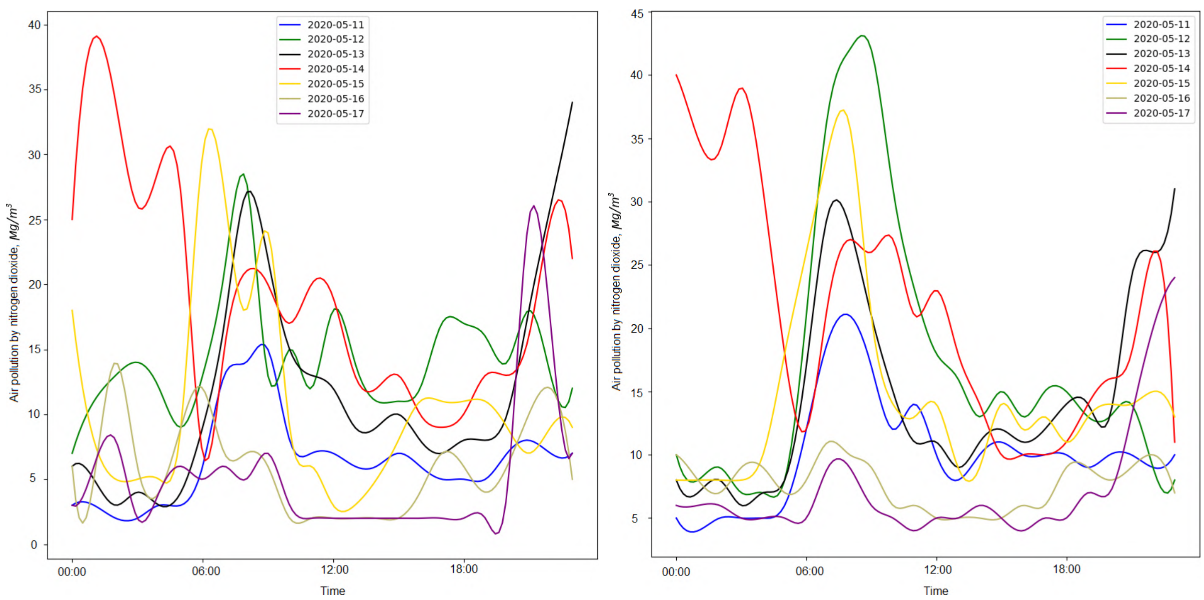
with corresponding colors for Barajas station and part (b) for Villaverde Alto. It clearly shows that concentration of nitrogen dioxide is lower at the weekend, but it is obviously not static through working days as well. At the same time surges of concentration are possible at night (on May 14th, 2020 at both stations), despite general trend for lower values at night.

The figure 4 contains average values of air pollution by nitrogen dioxide at a measurement station for a month. Each part of figure 4 presents a year from 2019 to 2022 and has marks for each month of a year. Different colors at every month mark present corresponding stations (Casa de Campo, Barajas, Vallecas). Annual trends of air pollution by nitrogen dioxide are varied through different measurement stations (figure 4). But at the same time there is a pattern of pollution reduce over a period from March to September. Average monthly values are higher at the beginning of the year and in the end as well. There is a clear trend toward lower concentration of nitrogen dioxide through 2020 when the COVID-19 pandemic happened.



(a) (b)

Figure 3. Hourly levels of air pollution by nitrogen dioxide at the same station (Barajas (a) and Villaverde Alto (b)) during a week.

Every sample has a mark representing verified or non-verified (wrong) value. The data were checked using this information to exclude inappropriate values. Then the data were processed to represent a time series with historic and forecast horizons equal to $H = 6$ hours. Interpolation was used to represent non-verified values. Two datasets representing correspondingly air pollution and traffic as outputs were created.

Experimental investigation was conducted on the presented datasets. Datasets were divided appropriately: 60 % for training, 20 % for validation and 20 % for testing. LSTM models were created and trained for all 24 stations separately. Besides models based on the proposed methodology, two other variants of LSTM models were created:

- with values of air pollution by nitrogen dioxide for 6 previous hours (base models);
- with values of air pollution by nitrogen dioxide for 6 previous hours and traffic for the same previous hours (alternative models).

Two indicators were used for evaluation of results: mean absolute error (MAE) and mean squared error (MSE). As MAE and MSE were calculated for 24 stations individually, final results in table 1 present average obtained values.

Base and alternative models were created as LSTM models with 3 layers of LSTM cells. Each layer has 12 cells. This structure demonstrated the best results. The last layer is a dense one. Adam optimization algorithm was used. Mean squared error was applied as a loss function. Proposed models are differed by its structure: 2 layers with 12 cells in each one. Number of selected traffic measurement stations $Q = 2$.

Experimental results (table 1) demonstrate that the proposed model reduced MAE from 0.04812 to 0.04571 and MSE from 0.00518 to 0.00485. It improved base MAE by 5 %. The proposed approach has the best results with lower levels of both MAE and MSE in comparison with the usage of previous values of traffic as additional input features. On average, the proposed approach improved base MSE (LSTM with only previous values of air pollution) by 6.37 %, which is higher than 1.35 % of alternative model.

Figure 4. Air pollution by nitrogen dioxide through 2019(a), 2020(b), 2021(c), 2022(d).

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012085 doi:10.1088/1755-1315/1415/1/012085

Table 1. Experimental results of forecasting air pollution by nitrogen dioxide using LSTM models with different input features.

LSTM model characteristics	MAE	MSE
Previous values of air pollution by nitrogen dioxide	0.04812	0.00518
Previous values of traffic and previous values of air pollution by nitrogen dioxide	0.04668	0.00511
Forecasted values of traffic and previous values of air pollution by nitrogen dioxide	0.04571	0.00485

4. Conclusions

Forecasting of air pollution is a well known scientific problem. The same is true for traffic forecasting. Air pollution by nitrogen dioxide is connected to traffic activity in urban environments, but only some existing papers consider traffic values as additional features for air pollution forecasting. That is why forecasting of air pollution caused by nitrogen dioxide was investigated in the paper emphasizing the role of traffic data. But new approach was proposed. The idea is to apply results of traffic modeling techniques as inputs to forecast level of air pollution by nitrogen dioxide. These additional inputs are forecasted values instead of historic values used in the known studies.

Deep learning models based on LSTM architecture were created, trained and tested. Data collected in Madrid over a period from 2019 to 2022 were used for experimental investigation. The data were processed and transformed into an appropriate datasets.

Forecasting models with base input features for 6 previous hours were compared to the models with additional features presented by values of traffic. The proposed approach used forecasted values of traffic instead of historical values of traffic as input features. As traffic measurement stations differ from air pollution measurement stations, additional features presented values for 6 hours at selected traffic measurement stations. The selection was made using decision tree ensembles created by Random Forest method. The obtained results improved MAE by 5 % and MSE by 6.37 % on average.

The proposed approach is valuable, as it allows to increase forecast accuracy. At the same time accurate forecasts of air pollution by nitrogen dioxide are critical for decision making. As more complex architectures of deep learning models are promising for air pollution forecasting, it is necessary to apply the results of traffic modeling techniques to such architectures in the following investigations.

Abstract. Radioactivity and radioactive materials are constant companions of our life. Therefore, their studies and utilization are an important part of the development of human society. One of lines of work with radioactivity of various media concerns their gamma ray spectrometry which covers the issues of mineral exploration, ecological monitoring, medicine, security, agriculture, anti-terrorist protection, assessment of the consequences of man-made and natural disasters, etc. The tasks of spectroscopy include the description, survey, and analysis of gamma fields produced by natural environment or artificial objects. To solve these tasks effectively, mathematical modeling based on the fundamental physical laws of radioactivity and modern achievements of mathematics and informatics is used. In particular, in this research, we consider the gamma radiation from the cylindrical body and develop the procedure for assessing the gamma flux intensity when the source activity is inhomogeneously distributed over the body volume. The procedure is a semi-analytic approach and is based on the representation of the source activity function as a linear combination of step functions. Physically it means the approximation of inhomogeneous body by a layered medium. The procedure also allows one to get an analytical expression for the gamma flux intensity which is observed at the axes of symmetry of the cylindrical body. It is performed the comparison of approximate and exact values of intensity for exponential source activity function when analytical integration is possible. We also discuss the procedure application to the case when the source activity function is nonmonotonic and restrictions of procedure use appear.

1. Introduction

Improvement of technologies, methods of nature management, and safety components stimulates the development of economies and human societies. New ideas and their accelerated implementation as a sign of the modern pace of life also affected the gamma spectroscopy methods [1, 2]. Work with radioactive materials that have penetrated essentially into all areas of our life demands the organization of effective control and radiation safety [3, 4]. To achieve this, it is used various tools including stationary observations [5] and remote sensing [3, 6–11], combined with information technologies, mathematical modeling, etc.

Although the introduction of modern methods of data analysis using neural networks [12] and the development of computing capabilities have significantly improved the survey of radioactive objects in all its aspects, the improvement of the description of simple objects and the comprehensive analysis of their radiation fields is still an important task that contributes to the correct understanding of the physics of processes, the development of test and calibration installations, the formation of the theoretical foundations of spectrometry, and also feeds adjacent fields of science with new challenges.

In particular, we are going to use the achievements of mathematical modeling in order to improve the description of gamma radiation field produced by the cylindrical body containing the sources of radioactivity distributed heterogeneously. This problem leads us to the evaluation of the integrals which cannot be represented via analytical expressions, therefore it is hard to conduct the parametric analysis, to apply them to inverse problems, etc. The procedure we develop allows one to get quite simple and highly accurate derivations of complicated integrals appearing in spectrometric problems.

2. Research aim and objectives

This research concerns the analytical description of gamma ray fields produced by radioactive cylindrical bodies (disks), when the disk's source activity depends on the spatial coordinate. In particular, we develop the semi-analytical procedure which is based on the representation of the source activity function via the linear combination of step functions. The results of utilizing this procedure are compared with the exactly solvable classical case when the source activity is described by an exponential function. Moreover, it is considered the nonmonotonic activity function, when the application of the procedure can be complicated.

3. Gamma ray field of a radioactive disk with inhomogeneous source activity

Among the problems accompanying the investigations of gamma field monitoring there are the cases when the structure of gamma ray radiation can be described analytically [13]. Now we are going to consider cylindrical bodies (thick disks). As is known [1], the gamma ray field produced by the homogeneous symmetric disk with constant source activity can be evaluated analytically. When the source activity function is not constant, only partial cases lead to the final analytical relations. Thus, let us develop the procedure to evaluate gamma ray fields for nonconstant source activity functions. Before we start to outline the procedure's stages, a brief theoretical background [1, 2, 14, 15] should be mentioned.

The starting point for evaluating the mono-energetic non-scattered gamma flux emitted from a point source is the following relation for the intensity I:

$$I = \frac{q}{4\pi r^2} \exp\left(-\int_0^r \mu(s)ds\right), \tag{1}$$

where q is the source activity (quants per second), r is the distance from the observation point to a source, μ is the attenuation coefficient along r.

This relation allows one to evaluate the gamma field generated by a plane source in a conventional way, integrating relation (1) over some spatial domain. For instance, when we deal with a *thin* radioactive disk of radius R, then the gamma flux intensity I evaluated at the distance h from its center obeys the following relation

$$I = \frac{q}{2}\left[E_1\left(\sum_{i=1}^{k} h_i\mu_i\right) - E_1\left(\frac{1}{\cos\alpha}\sum_{i=1}^{k} h_i\mu_i\right)\right], \tag{2}$$

where the function $E_1(x) = \int_x^\infty t^{-1}e^{-t}dt$ is exponential integral of the first kind; h_i are the thicknesses of parallel layers lying above the disk ($h = \sum_i^k h_i$); μ_i are the attenuation coefficients for the layers; $\cos\alpha = h/R$.

Here we are interested in the gamma flux of radioactive *thick* disk of radius R and thickness d (figure 1). To evaluate corresponding intensity at a distance H from the top of the disk on its vertical symmetry axis (figure 1), we use the relation (2) and integrate it over the vertical coordinate z. Thus, the general relation

$$I = \int_0^d \frac{q}{2}\left[E_1\left(\mu H + \nu(d-z)\right) - E_1\left(\frac{\mu H + \nu(d-z)}{\cos\alpha(z)}\right)\right]dz, \tag{3}$$

where ν and μ are the coefficients of attenuation for the disk material and medium beyond the disk, respectively. To simplify the theoretical studies, the quantity $\cos\alpha(z)$ is assumed to be constant, although the incorporation of this dependence can be performed with any degree of accuracy [16].

When the source activity q is constant or some elementary function of z, the relation (3) can be presented in an analytical form. For instance, when $q = q_0 = \text{const}$, from (3) it follows

$$I = \frac{q_0}{2\nu}\left[E_2\left(\mu H + \nu(d-z)\right) - \cos\alpha\, E_2\left(\frac{\mu H + \nu(d-z)}{\cos\alpha}\right)\right], \tag{4}$$

where $E_2(x) = x\int_x^\infty t^{-2}e^{-t}dt$ is the exponential integral of the second kind.

Otherwise, alternative methods should be applied.

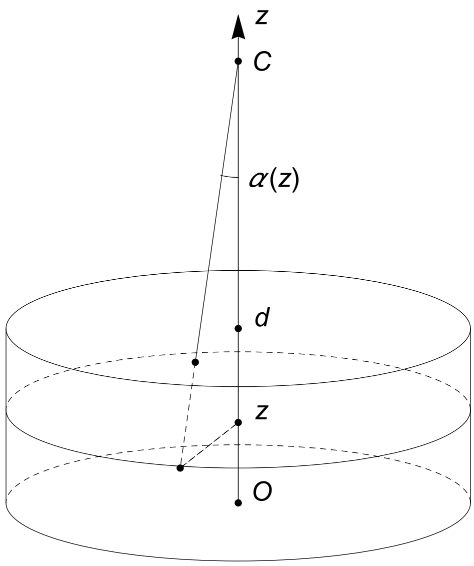

Figure 1. The procedure of evaluation of gamma field for a thick disk. Here d is the disk thickness, O is the origin, $C(0; 0; H + d)$ is the observation point.

In this research, we develop the semi-analytical approach for calculating the integral (3), when q is a function of z. This approach is based on the representation of the function $q(z)$ in the form of the linear combination of step functions. To do this, we use the procedure outlined in [17, 18].

Adopting it to our problem, let us assume that the function $q(z)$ is defined over the range $[0; d]$ and there exist the numbers $\gamma_n = \int_0^d z^n q(z)dz < \infty$. Next, let d_i, $i = 0, 1, \ldots, N$ ($d_0 \equiv 0$, $d_N \equiv d$) be a partition of the domain $[0; d]$. Suppose there exist numbers φ_i such that it is valid the following representation

$$\tilde{q}_N(z) = \varphi_1(\theta(z-d_0)-\theta(z-d_1))+\varphi_2(\theta(z-d_1)-\theta(z-d_2))+\cdots+\varphi_N(\theta(z-d_{N-1})-\theta(z-d_N)), \quad (5)$$

where $\theta(z)$ is the Heaviside function ($\theta(z)$ is 0 for negative z and 1 for positive z).

To get the constraints for the quantities $\varphi_{1,\ldots,N}$ and $d_{1,\ldots,N-1}$ (recall that d_N is fixed), we multiply relation (5) by $(n+1)z^n$, $n = 0, ..., 2N-1$ and each of them integrate over $[0; d]$. The resulting nonlinear algebraic equations can be cast in the form of the following system

$$\begin{gathered}
\varphi_1 d_1 + \varphi_2(d_2 - d_1) + \cdots + \varphi_N(d - d_{N-1}) = \gamma_0, \\
\varphi_1 d_1^2 + \varphi_2(d_2^2 - d_1^2) + \cdots + \varphi_N(d^2 - d_{N-1}^2) = 2\gamma_1, \\
\cdots \\
\varphi_1 d_1^{2N-1} + \varphi_2(d_2^{2N-1} - d_1^{2N-1}) + \cdots + \varphi_N(d^{2N-1} - d_{N-1}^{2N-1}) = (2N-1)\gamma_{2N-2}.
\end{gathered} \quad (6)$$

The solution of this system provides us the partition of interval $[0; d]$ and the weighting factors φ_i for the step functions. Therefore, there is a natural constraint for d_i. They must lay in the interval $[0; d]$, i.e. $0 < d_i < d$. Note also if system (6) possesses the solution $\{d_1, \ldots, d_{N-1}\}$, then any permutation of d_i is the solution as well (φ_i are not preserved).

Considering the subsystems of (6) at small N, it is easy to see that the developed procedure incorporates the approximation (for $N = 1$) of function $q(z)$ by its integral average value γ_0/d on the interval $[0; d]$. The next order of approximation when $N = 2$ leads us to the three equations with respect to $\varphi_{1,2}$ and d_1 which can be evaluated analytically, namely

$$\begin{aligned}
&\varphi_1 = \frac{4\gamma_1^2 - 2\gamma_0\gamma_1 d - 3\gamma_2\gamma_0 + \gamma_0^2 d^2}{2\gamma_1 d^2 - 3\gamma_2 d}, \qquad \varphi_2 = \frac{3\gamma_0\gamma_2 - 4\gamma_1^2}{d(3\gamma_2 - 4\gamma_1 d + \gamma_0 d^2)}, \\
&d_1 = \frac{2\gamma_1 d - 3\gamma_2}{\gamma_0 d - 2\gamma_1}.
\end{aligned} \quad (7)$$

Remark: When $d_1 \to d$, then $\varphi_2 \to \infty$. Indeed, assuming that $d_1 = d$, we arrive at the denominator of φ_2 in (7) is equal to zero.

We have not succeeded in derivating the expressions for the higher orders of approximation yet, since the order of algebraic equations increases quickly. But some simplification still can be made. For instance, for the case $N = 3$, we need to solve five equations with respect to $\varphi_{1,2,3}$ and $d_{1,2}$. Since $\varphi_{1,2,3}$ are included in the system linearly, they are excluded from the system by applying Kramer's rule: $\varphi_k = \Delta_k/\Delta$, $k = 1, 2, 3$, where

$$\Delta = \begin{vmatrix} d_1 & d_2 - d_1 & d - d_2 \\ d_1^2 & d_2^2 - d_1^2 & d^2 - d_2^2 \\ d_1^3 & d_2^3 - d_1^3 & d^3 - d_2^3 \end{vmatrix} = d_1 d_2 d(d_2 - d_1)(d_1 - d)(d_2 - d) \neq 0.$$

Thus, the resulting system consists of two nonlinear equations for $d_{1,2}$. The similar reduction of the number of equations is made for $N > 3$ and the determinant Δ is presented in the appropriate form. Note that it is possible to perform the evaluation of Δ for any N

$$\Delta = \begin{vmatrix} d_1 & d_2-d_1 & \dots & d-d_{N-1} \\ d_1^2 & d_2^2-d_1^2 & \dots & d_N^2-d_{N-1}^2 \\ \dots & \dots & \dots & \dots \\ d_1^N & d_2^N-d_1^N & \dots & d_N^N-d_{N-1}^N \end{vmatrix} = \begin{vmatrix} 1 & 1 & \dots & 1 \\ d_1 & d_2 & \dots & d \\ \dots & \dots & \dots & \dots \\ d_1^{N-1} & d_2^{N-1} & \dots & d^{N-1} \end{vmatrix} \prod_{s=1}^{N} d_s = \prod_{s=1}^{N} d_s \prod_{i>j}(d_i-d_j),$$

where the last determinant is the Vandermonde determinant, $d_N \equiv d$.

Let us apply the developed method to the integral (3), when $q = q_0\, e^{-\beta(d-z)}$ [15] such that the source activity is maximal, q_0, on the disk top and decreases toward the bottom. In this case, the integral (3) can be derived analytically, so that this allows one to compare the results of semi-analytical calculations with exact evaluation. Thus, from (3) it follows [1] that

$$I = \frac{q_0}{2}\int_0^d e^{-\beta(d-z)}\left[E_1\left(\mu H + \nu(d-z)\right) - E_1\left(\frac{\mu H + \nu(d-z)}{\cos\alpha(z)}\right)\right] dz = \\ \frac{q_0}{2\beta}\left[E_1(\mu H) - E_1\left(\frac{\mu H}{\cos\alpha}\right) - e^{-\beta d}\, W_1 + e^{\beta\mu H/\nu}\, W_2\right], \tag{8}$$

where

$$W_1 = E_1(\mu H + \nu d) - E_1\left(\frac{\mu H + \nu d}{\cos\alpha}\right),$$
$$W_2 = E_1\left(\mu H\left\{1+\frac{\beta}{\nu}\right\}\right) - E_1\left((\mu H + \nu d)\left\{1+\frac{\beta}{\nu}\right\}\right) + \\ E_1\left(\mu H\left\{\frac{1}{\cos\alpha}+\frac{\beta}{\nu}\right\}\right) - E_1\left((\mu H + \nu d)\left\{\frac{1}{\cos\alpha}+\frac{\beta}{\nu}\right\}\right).$$

Using the asymptotic expansion $E_1(x) = -\gamma - \ln x - \dots$, ($\gamma = 0.577...$ is the Euler's constant), it is also possible to derive the intencity's value at the disk top, i.e. when $H \to 0$ we have

$$I_0 = \frac{q_0}{2\beta}\Big[\ln\frac{1}{\cos\alpha} - e^{-\beta d}\left(E_1(\nu d) - E_1\left(\frac{\nu d}{\cos\alpha}\right)\right) + \ln\frac{\beta+\nu}{\beta+\nu/\cos\alpha} + \\ E_1\left(\nu d\left\{1+\frac{\beta}{\nu}\right\}\right) - E_1\left(\nu d\left\{\frac{1}{\cos\alpha}+\frac{\beta}{\nu}\right\}\right)\Big]. \tag{9}$$

When $q = \tilde{q}(z)$ defined by (5), integral (3) is transformed into the relation

$$\tilde{I} = \frac{q_0}{2\nu}\sum_{i=1}^{N}\varphi_i\left(E_2(\mu H + \nu(d-z)) - \cos\alpha\, E_2\left(\frac{\mu H + \nu(d-z)}{\cos\alpha}\right)\right)\Big|_{d_{i-1}}^{d_i}, \tag{10}$$

where $d_0 = 0$, $d_N = d$.

Thus, we are going to compare the exact value I derived via (8) and its approximation $\tilde{I}$ evaluated in (10). We do this numerically at the fixed parameters $q_0 = 2$, $\mu = 0.05$, $\nu = 0.005$, and $d = 1$. The studies are conducted for two cases:

(I) $q = q_0 e^{-\beta(d-z)}$, $\beta = 2$, representing the *monotonic* function;

(II) $q = q_0 e^{-\beta(d-z)}(1 + \epsilon(d-z)^4)$, $q_0 = 2$, $\beta = 2$, $\epsilon = 3.5$, which is the *nonmonotonic* function.

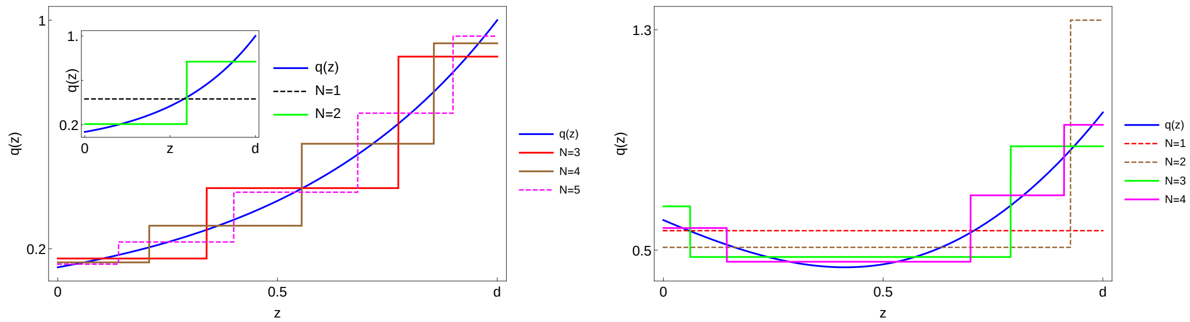
The expressions for the source activity distributions $q(z)$ are chosen in such a way that $q(z)$ is a specified constant at the ground surface $z = d$, i.e., $q(d) = q_0$. These source activity distributions can be related to the depth distributions of radioactive elements such as ^{137}Cs, ^{134}Cs, ^{131}I [19,20], and ^{90}Sr [19] which are typically approximated by exponential-type functions [20, 21].

The angle α is chosen close to $\pi/2$ in order to see the difference between the approximations used. Thus, $\alpha = \pi/2.005$ for the monotonic function q and $\alpha = \pi/2.00005$ for the nonmonotonic one, whereas the parameter H, distance to the disk, is variable in the both cases.

First, we construct the expression (5) for the functions $q(z)$. For case (I), the approximations $\tilde{q}_N$ at $N = 1, 2, 3$ can be derived easily using the elementary integral calculus, formula (7), and the *Mathematica* package command Solve[], respectively. When $N = 4, 5$, the command NSolve[] is used with the initial data for iterations partially taken from the previous step at $(N - 1)$.

The calculations leads us to the following solutions:

$N = 1$: $\varphi = \{0.432\}$;
$N = 2$: $\varphi = \{0.206, 0.768\}$, $\{d_i\} = \{0.597\}$;
$N = 3$: $\varphi = \{0.166, 0.412, 0.872\}$, $\{d_i\} = \{0.339, 0.775\}$;
$N = 4$: $\varphi = \{0.152, 0.281, 0.567, 0.919\}$, $\{d_i\} = \{0.208, 0.555, 0.856\}$;
$N = 5$: $\varphi = \{0.146, 0.224, 0.398, 0.667, 0.944\}$, $\{d_i\} = \{0.138, 0.401, 0.899, 0.683\}$;



(a) (b)

Figure 2. (a): The profiles of monotonic ($q = q_0 e^{-\beta(d-z)}$) (a) and nonmonotonic ($q = q_0 e^{-\beta(d-z)}(1 + \epsilon(d-z)^4)$, $\epsilon = 3.5$) (b) functions and their approximations (5).

The profiles of the function $q(z)$ and its resulting approximations are shown in figure 2a. The quality of approximation can be assessed by analyzing the differences

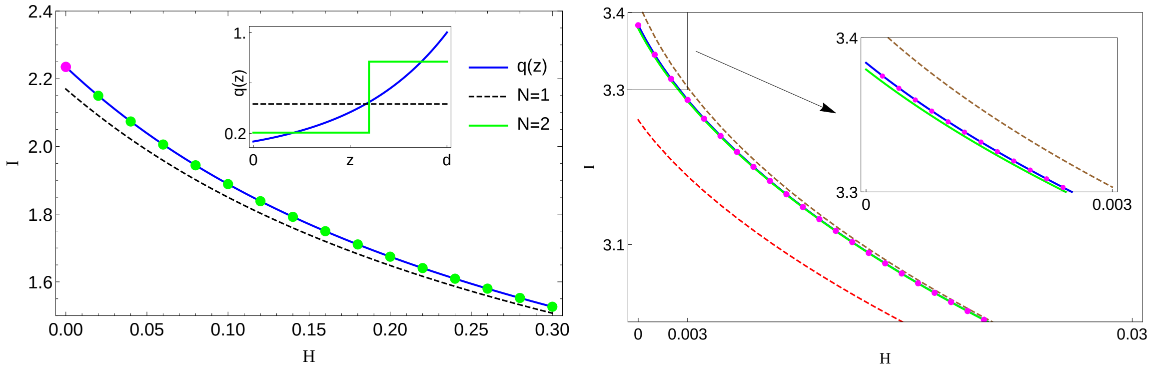
$$\delta_N = \int_0^d (q(z) - \tilde{q}_N(z))^2 dz, \qquad N = 0, \ldots, 4.$$

The corresponding values of δ_N calculated for the exponential function $q(z)$ are given in table 1. It is obvious that as N increases, the δ_N values decrease to zero within the tolerance. This, in turn, means that the approximations $\tilde{q}_N$ approach the function $q(z)$ as N increases.

Table 1. The values of δ_N depending on N.

N	0	1	2	3	4
δ_N	0.0585	0.0194	0.0092	0.0054	0.0036

The same procedure is applied to case (II) and the corresponding approximations are depicted in figure 2b. Here we succeeded in evaluation of $\tilde{q}_N$ only for $N \leq 4$. It can be argued that for a monotonic function the sequence $\tilde{q}_N$, roughly speaking, can be infinite, whereas for a nonmonotonic one only several first elements $\tilde{q}_N$ can be derived properly. For instance, considering the function $q(z)$ from case (II), the number of $\tilde{q}_N$ depends on ϵ, which determines the degree of non-monotonicity. When $N = 2$, we can derive the critical value of ϵ at which $d_1 = d$ in relation (7). From this it follows $\epsilon_{cr} = (2e^2 - 18)/(775 - 105e^2) = 3.786$. Thus, if $\epsilon < \epsilon_{cr}$, then $d_1 < d$ providing the proper solution (7) and in turn $\tilde{q}_N$. If $\epsilon > \epsilon_{cr}$, then $d_1 > d$ and the appropriate approximation does not exist. In other words, we can construct several $\tilde{q}_N$ only for the weakly non-monotonic function q.



(*a*) (*b*)

Figure 3. The dependences of integral (3) when the function $q = q_0 e^{-\beta(d-z)}$ (*a*) and $q = q_0 e^{-\beta(d-z)}(1 + \epsilon(d-z)^4)$, $\epsilon = 3.5$ (see its profile in figure 2b) (*b*).

Next, as soon as the approximation (5) is constructed, the integral (3) is evaluated by the relation (10). Figure 3a shows the dependence (10) on H using the exponential function $q(z)$ (solid curve) and approximations $\tilde{q}_N$ for $N = 1, 2$ (see inset). We see that $\tilde{q}_1$ (dashed curve) is close to the exact curve but the next approximation $\tilde{q}_2$ provides more accurate values depicted with the filled circles. The mostleft point (magenta circle) corresponds to the limiting case when $H \to 0$ and is defined by the relation (9). From the analysis of the figure 3a it follows that the excellent integration results can be achieved starting from the $\tilde{q}_2$ approximation.

The similar calculations are performed for case (II) and are depicted in figure 3b. In this case there are no analytical expressions for the integral (3) calculation, instead, the numerical procedure from the *Mathematica* package (version 7.0 and higher) NIntegrate[] is used. We see that $\tilde{q}_4$ provides the accurate coincidence of numerically evaluated integral (3) and its approximation $\tilde{q}_4$ plotted by filled circles (see inset).

Analyzing figure 3, it is obvious that the most significant difference between exact and approximate integrations is observed near the top of the disk, while this difference decreases as H increases. It is worth noting also that the integration of the parent function $q(z)$ and its approximations for both cases (I) and (II), even at $N = 1$, can provide indistinguishable results when the angle α is not close to $\pi/2$.

4. Concluding remarks

In conclusion, it has been developed the semi-analytical procedure for evaluating the intensity of gamma flux emitted by a cylindrical body with inhomogeneous source activity. In particular, we considered the disk of finite size, the source activity of which depends on the spatial coordinate. According to the procedure developed, the source activity function $q(z)$ is represented as a linear combination of step functions. This allows one to replace the integral, which does not have an analytical representation, by the sum of simpler integrals calculated from their analytical expressions.

We applied the procedure to two cases where the source activity functions were chosen in the form of monotonic and nonmonotonic relations. The former case was represented by the exponential function $q(z)$, while the latter was represented by the product of exponential and polynomial functions. The case with the exponential function $q(z)$ is important since the integral (3) can be derived analytically. This allows one to compare the exact value of the integral and the result of asymptotic evaluation via the procedure.

Experience with the procedure shows that even for a small number of step functions in the representation, the results of calculations are excellent. It is worth to note that the procedure relies essentially on the existence of solutions of nonlinear algebraic system. When the function $q(z)$ is weakly nonmonotonic, the algebraic system is solved successfully. The problem with the system's solving can appear when its dimension is large or the parent function $q(z)$ is essentially nonmonotonic. The description of source activity function with the help of step functions relates to the approximation of disk by the layered medium when the source activity function in each partial layer is constant and coincides with the appropriate weighting factor of step function.

The studies presented above can be interesting for experts in the area of mathematical modeling of gamma fields, as well as for specialists in the organization of environmental monitoring, safety measures, and development of test and calibration installations.

Abstract. Pipes serve as crucial conduits for fluid transportation across diverse industrial sectors, necessitating a thorough understanding of their structural properties and performance under varying conditions. This study explores the resilience of underwater double-layer pipes, comprising inner and outer layers separated by an annulus that usually used in deep water application such as OTEC and gas and oil transport, against collapse induced by bending moment loads or external pressure. The investigation encompasses a comprehensive review of relevant literature and examines different configurations of DLP. The analysis reveals that key factors influencing the buckling capacity under pure bending loads include pipe length, core thickness ratio, and core stiffness. Under hydrostatic pressure, collapse behavior is influenced by the radius-to-thickness ratio and the ratio of the core thickness to outer and inner layer thicknesses. Furthermore, the collapse mechanism of the double layer pipe is analyzed. The study underscores the importance of addressing such structural nuances in design and operational considerations.

1. Introduction

Pipes serve as essential conduits for fluid transportation across diverse industrial sectors especially in marine industry. They are fabricated from a range of materials, such as Fiber-reinforced plastic (FRP) with high specific strengths and excellent corrosion resistance, ideal for subsea applications across multiple sector [1, 2] or HDPE thermoplastic, known for flexibility and low electrical conductivity [3]. Additionally, pipes are available in various configurations, including single-layer and multi-layer designs. Double-layer pipes find widespread use in sectors like the chemical industry, nuclear power, and renewable energy, such as OTEC due to their ability to withstand extreme temperatures and chemical environments while preventing crack propagation. [4]

A double-layer pipe (DLP) structure refers to a pipe within a pipe, or encased in an outer covering, with an annulus (interstitial space) between the two diameters. There are different types of double layer pipes, each with its own unique features and applications. For instance, a double-layer pre-moulded pipe insulation is used when operating temperatures reach 600°F and above. On the other hand, multi-layer composite pipe systems offer a single solution for all potable water and heating supplies for domestic and light commercial projects, as well as industrial applications such as compressed air and cooling water systems. Multi-layer piping is corrosion-resistant, hygienic, and is not liable to oxygen diffusion through the pipe wall, which minimizes the risk of damage by oxygen corrosion elsewhere in the system. Double containment pipe, also known as double wall pipe or dual containment pipe, is commonly used for handling sensitive materials that may be hazardous or costly if leaks occur.

Double-layer pipes are susceptible to instability or buckling because they exhibit an efficient geometrical shape which allows constructing very thin-walled structures. The buckling phenomenon occurs in any slender structure indifferent to the material. The ultimate strength to resist buckling is the critical constraint and focus of development of such thin-walled cylinders [5]. Buckling can occur due to various loads applied to the pipe structure. For example, internal or external pressure, bending, sheer load, etc. In double layer pipe buckling collapse can happen in structure between inner and outer layer, especially in underwater high-pressure environment that usually where double layer pipe is used. Due to the high usability of double-layer pipe, we need to understand how well double-layer pipe withstands hydrostatic pressure and how it is a behavior of collapsing under high pressure applied outside the pipe. The behavior of sandwich pipes, including buckling, can be analyzed using analytical approaches or finite element formulations [6–9]. This article focuses on studying the collapse behavior of the double layer pipe under bending moment load and external pressure by a comparative study of various articles on pipe failure and various double layer pipe configurations that have been studied.

2. Double-layer pipe configuration and application in brief

The double-layer pipe has various configurations that allow the pipe to have thin walls but strong structural integrity. A DLP is a secondary contained piping system that consists of an inner and an outer pipe with an interstitial space between the inner and outer layer. A double layer pipe is a type of composite pipe with a structural configuration that includes an outer composite pipe, inner composite pipe, and a core. One of the core types used is the iso-grid core that is built from a combination of helical and circumferential stiffeners [6]. In figure 1 the geometric double-layer pipe is shown with iso grid core.

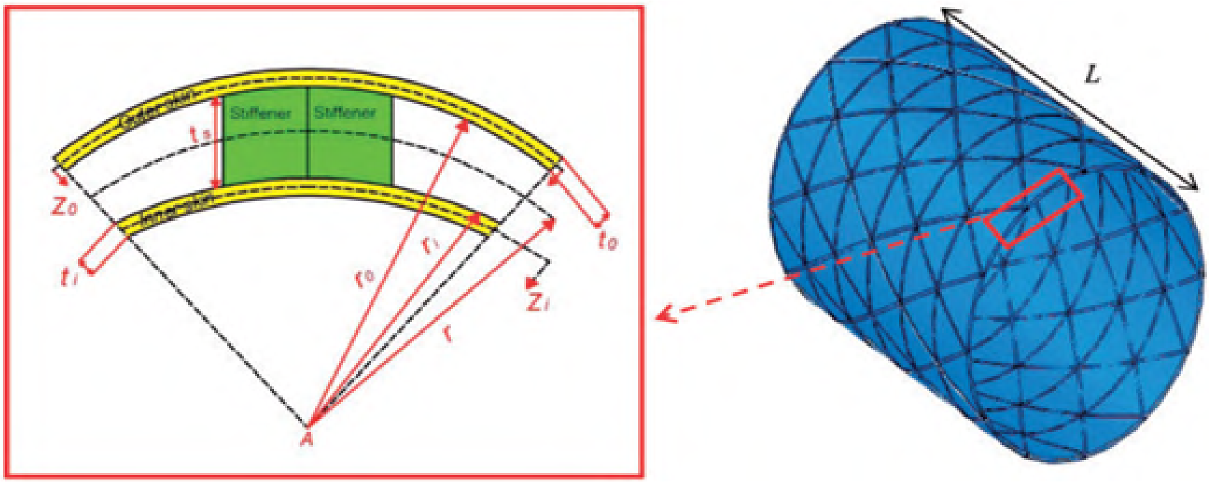

Figure 1. Configuration of the iso-grid sandwich pipe [6].

Figure 1 shows a DLP with a combination of composite outer pipe, composite inner pipe, and isogrid core. The geometric parameter of the pipe are as: L is the pipe length, r is the pipe radius of the middle pipe surface, r_0 is the inner pipe outer radius, r_0 is the outer pipe inner radius, t_0, t_i, and t_s are thickness of the outer pipe, inner pipe, and stiffener. In addition to that, DLP can have many varieties of core material, such as fiber-reinforced cementitious composites, functionally graded interlayers [10], cement annulus [11], compliant core [12], and multiple core pipes [13]. The core material plays a crucial role in the performance of sandwich pipes, and different configurations such as cement annulus or compliance core can be used [11, 12, 14]. In typical DLP structures shown in figure 2. The DLP structure is made up of two layers of plates and a layer of central core. The center core material is thicker and has a lower density than the outer and inner layers, which are thinner panels with greater strength and stiffness. Either glue or welding can be used to join the plates to the core. The moment of inertia of the DLP construction will grow when the thickness is increased for the same mass example. As a result, when compared to a single solid structure made of the same material and weight, the DLP construction has superior bending stiffness and stability.

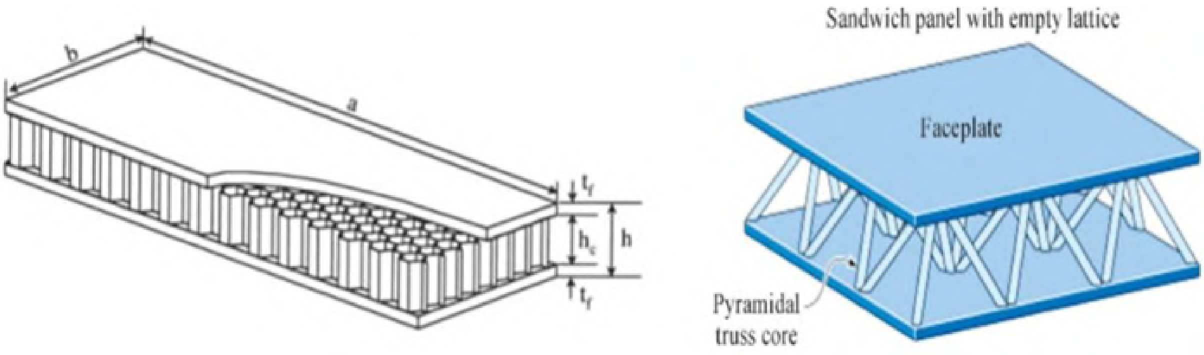

Figure 2. Typical sandwich structure construction [13].

The core structure of a Double Layer Pipe (DLP) can be categorized into various configurations, including I-core, Z-core, O-core, and V-core. Each configuration exhibits distinct core shapes, as depicted in table 1. These configurations are tailored to specific applications, wherein DLPs offer varying characteristics and functionalities. For instance, dual layer external coated pipes find extensive use in the oil and gas industry, providing exceptional resistance against corrosion, cathodic disbondment, as well as abrasion and physical damage. Double wall pipes, also known as dual containment pipes, are prevalent in applications involving sensitive materials, where leakages could pose significant hazards or financial repercussions. Meanwhile, multi-layer composite pipe systems offer versatile solutions for potable water and heating supplies in both residential and commercial settings, alongside industrial applications such as compressed air and cooling water systems. Notably, in ocean thermal energy conversion (OTEC) projects, composite materials are favored for cold-water pipe (CWP) applications due to their high strength and lightweight properties. [15–19].

Table 1. Type of double-layer pipe core configuration [13].

Core type	I	Z	O	V
Illustration				
3. Applied load on double-layer pipe

In an underwater DLP, the predominant load is generated by hydrostatic pressure from the ocean depth crushing and bending moment due to underwater current and its own weight [20]. All that will affect the construction of the DLP itself. Depending on the operational depth of the pipes, it will make a difference in the load received by the pipe, usually the deeper the operational depth of the pipe, the larger it will receive load from its surrounding.

3.1. Bending load

Bending load represents a major load experienced by underwater double-layered pipes (DLP). This load arises the surrounding water's weight, ocean underwater current, and the pipe's own weight. Research on the bending load of DLP is well-documented across numerous publications. Estefen explored the ultimate bending moment for DLP in deepwater contexts [21]. An examined the ultimate bending strength of DLPs reinforced with steel fiber concrete [22]. The buckling and subsequent post-buckling behavior of DLP under a pure bending load were analyzed by Arjomandi and Taheri through the finite element method [23]. Additionally, Cheng and colleagues assessed the ultimate bending strength of DLP, considering the actual behavior between layers [24].

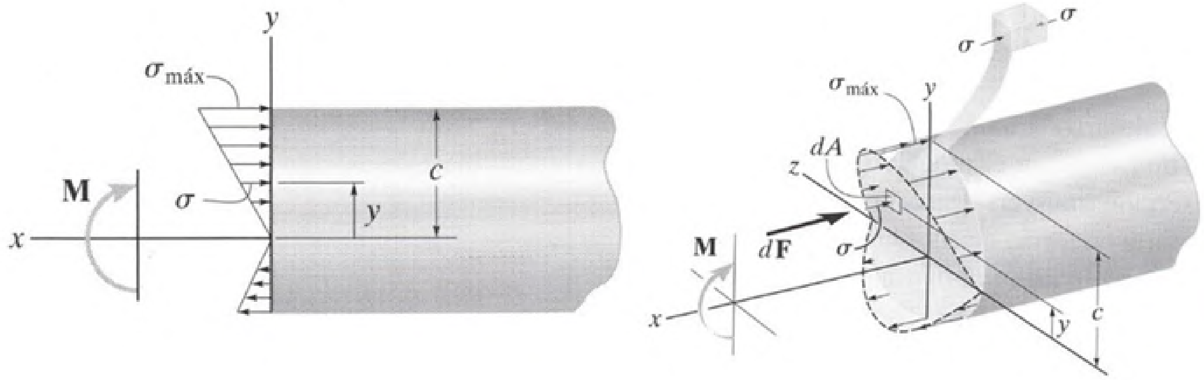

Figure 3. Bending load on DLP [25].

$$\sigma_{Bending} = \frac{M \cdot D}{2I}. \tag{1}$$

According to figure 3, $\sigma_{Bending}$ is the bending stress, M is the bending moment, D is the outer diameter of the pipe, and I is the moment of inertia of the pipe. The distinguishing behavior of pipe under pure bending is the ovalization of the tube's cross-section by the applied called Brazier's effect that reduces the stiffness of the system. This is classified as category I. In this category found that cylinders collapsed when the radially inward deflection reached 2/9 of the cylinder radius [8]. The bending moment that corresponds to the deformation can be calculated by [23]:

$$M_{CR-B} = \frac{2\sqrt{2}}{9} \cdot \frac{E\pi r t^2}{\sqrt{(1-v^2)}}. \tag{2}$$

Referencing equation (2), where M_{CR-B} denotes the critical bending moment, E represents the elastic modulus, r the radius of the pipe, t the thickness of the pipe, and v the Poisson's ratio. In the case of short pipes with a significant $D = t$ value, prone to bending, longitudinal short-wave buckling is observed. With increasing applied moments, the deformation amplitude of the shaft escalates, leading to a catastrophic failure at the critical load. This pipe falls under category II. Consequently, the suggested formula for computing the bending moment is

$$M_{CR} = S\sigma_{CR} = \pi r^2 t \sigma_{CR}, \tag{3}$$

where σ_{CR} is yield stress and can be calculated from

$$\sigma_{CR} = \frac{Et}{r\sqrt{3(1-v^2)}}. \tag{4}$$

3.2. Hydrostatic pressure load

Hydrostatic pressure is pressure exerted by a fluid at rest at a given point within the fluid, due to the force of gravity. It is proportional to the depth measured from the surface, as the weight of the fluid increases when a downward force is applied. That means the deeper a DLP goes the bigger it receives pressure from water outside, The internal pressure of the fluid inside the pipe also plays a role in the hydrostatic pressure that DLP receives so. In OTEC application sandwich pipes used in Cold Water Pipes can reach up to 700 m of ocean depth [26,27]. Castello studied the reeling effect to the strenght of the DLP under external pressure [28] The hydrostatic pressure can be formulated as:

$$P = \rho \cdot g \cdot h. \tag{5}$$

where P is hydrostatic pressure in MPa, ρ is water density at 997 kg/m^3, g is gravity acceleration of 9.87 m/s^2, and h is the water depth in meter.

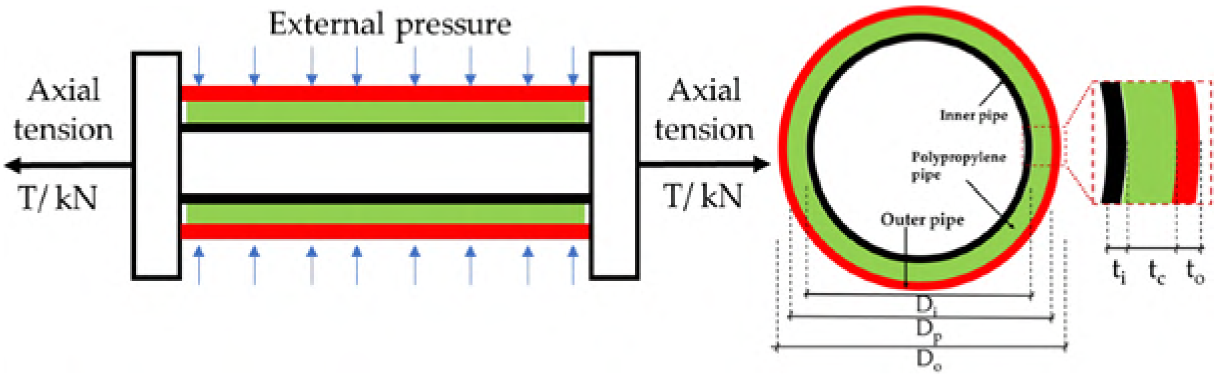

Figure 4. Hydrostatic pressure load on sandwich pipe [29].

As illustrated in figure 4, when hydrostatic pressure is exerted, a pipe may collapse if the disparity between external and internal pressures becomes too large as per the API RP 1111. It is essential that the pipe's collapse pressure surpasses the overall external pressure at all points throughout the pipeline as follows:

$$(P_0 - P_i) \leq f_0 \cdot P_c. \tag{6}$$

Referring to equation (6), P_0 and P_i represent the external and internal pressures respectively. f_0 denotes the collapse factor, and P_C signifies the collapse pressure of the pipe. The equation utilized to approximate the collapse pressure is as follows:

$$P_C = \frac{P_y * P_e}{\sqrt{P_y^2 + P_e^2}}. \tag{7}$$

$$P_y = 2 \cdot S \cdot \frac{t_{min}}{D}. \tag{8}$$

$$P_e = 2 \cdot E \cdot \frac{\frac{t_{min}}{D}}{1 - v^2}. \tag{9}$$

In this equation, P_y represents the collapse pressure at yield, P_e denotes the elastic collapse pressure of the pipe, S signifies the specified minimum yield strength, D stands for the outer diameter, E represents the elastic modulus of the pipe, and v denotes Poisson's ratio.

4. Collapse behaviour

In the previous section, the main load that can be received by DLP consists of bending moment and external pressure. Each of that load will have a different effect of the collapse behaviour of DLP. Usually, it will form a dent in the pipe structure or bending in overall pipe length.

4.1. Collapse behaviour of double-layer pipe under bending load

The buckling behaviour of DLP caused by pure bending load is shown in figure 5. The buckling behaviour and pipe strength are affected by pipe length, core thickness ratio, and core stiffness. The buckling mode shape of the relatively short DLP has short wavelength ripples, meanwhile relatively long DLP does not show any wrinkles along the pipe [23]. As can be seen, the number of wavelengths is changed linearly with respect to the pipe length. This indicates that the buckling moment of longer pipe is smaller than shorter pipe as shown in figure 6a. Core thickness also affects the buckling of DLP. The DLP with thicker core layers show the deformation magnitude of external layer is considerably larger than internal layer, but thinner core thickness show that the deformation profile of internal layer is like external layer in smaller magnitude. Increasing the external layer diameter also increases buckling moment of the system [24]. Core stiffness ratio significantly affects the buckling moment of DLP as well as the buckling mode shape. In this case buckling moment will increase exponentially with the increase of core stiffness ratio as shown in figure 6b.

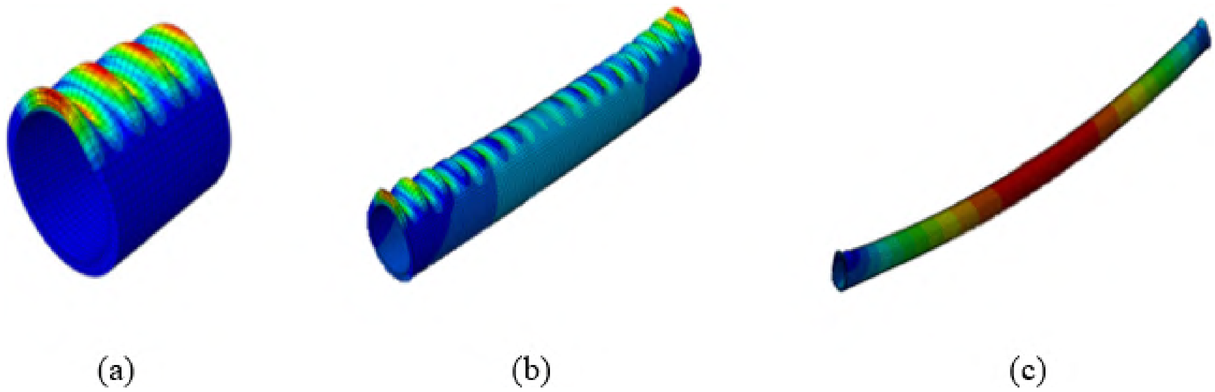

Figure 5. Influence of the pipe length on the collapse behavior of DLP under bending load, (a) L/D=1, (b) L/D=6, and (c) L/D=20 [23].

4.2. Collapse behaviour of double layer pipe under hydrostatics pressure

Numerous research efforts have focused on the stability and post-buckling behavior of DLP when subjected to hydrostatic external pressure. A DLP is sensitive to clearance variations, where minor adjustments in the spacing between layers can significantly affect its maximum strength. Moreover, DLP is prone to imperfections. The outer layer of a DLP possesses greater buckling strength than the inner layer, due to a larger thickness to radius ratio in the outer layer [5]. A linear buckling analysis, depicted in figure 7, illustrates the nodal modes shape of the DLP under external pressure. Generally, the critical buckling pressure diminishes as the radius to thickness ratio increases, as demonstrated in figure 8a. Additionally, the ratio of core to inner

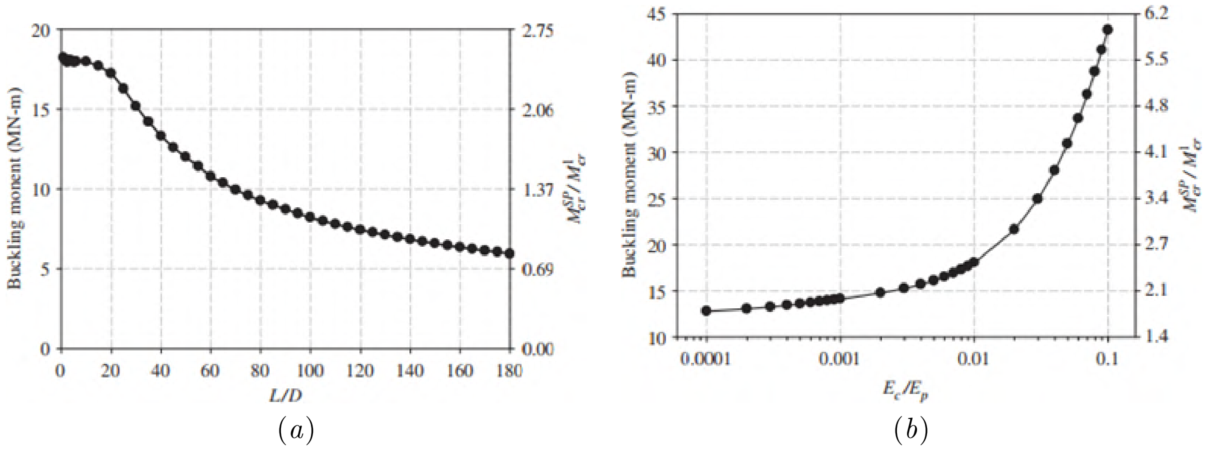

Figure 6. Effect of parameter to buckling moment capacity of sandwich pipe, (a) L/D and (b) core stiffness ratio [23].

and outer thickness influences the buckling pressure of DLP. An increase in this ratio leads to a rise in critical buckling pressure, as indicated infigure 8b [6].

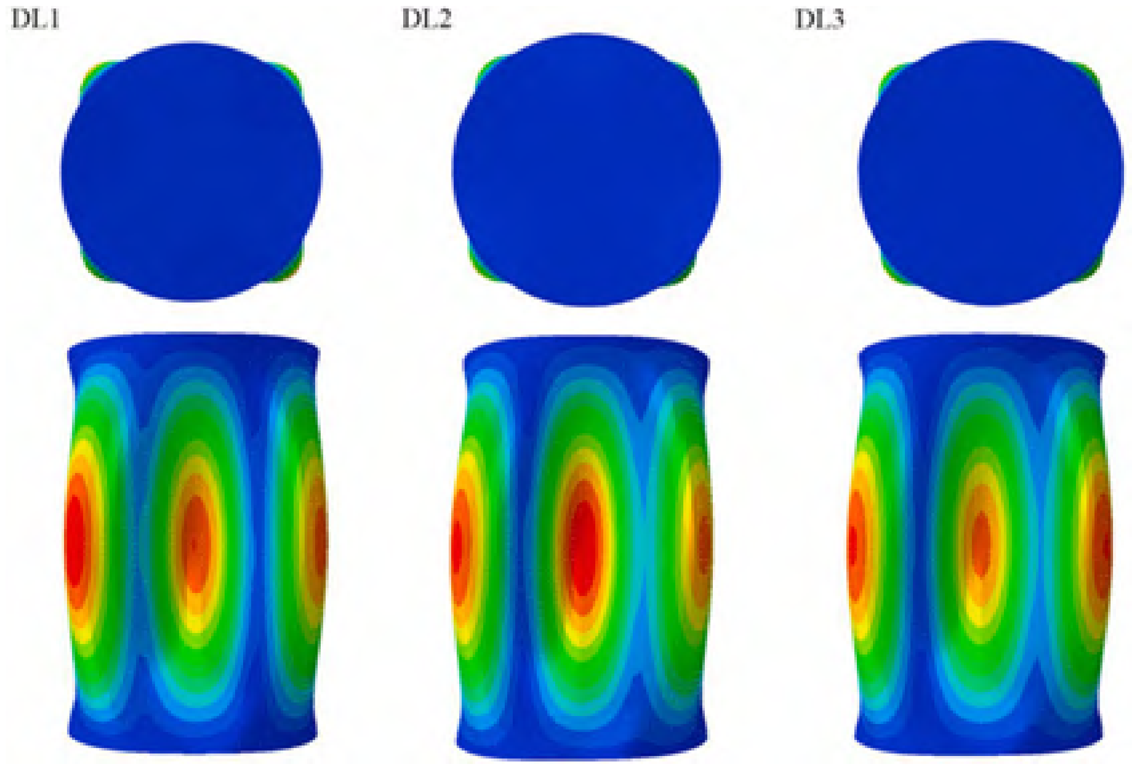

Figure 7. Collapse behavior of DLP under hydrostatic pressure [5].

5. Conclusion

This research explores the buckling characteristics of submerged double-layered pipes when subjected to bending moments and external hydrostatic pressures. The study identifies the primary factors affecting the buckling strength under bending forces are the length of the pipe,

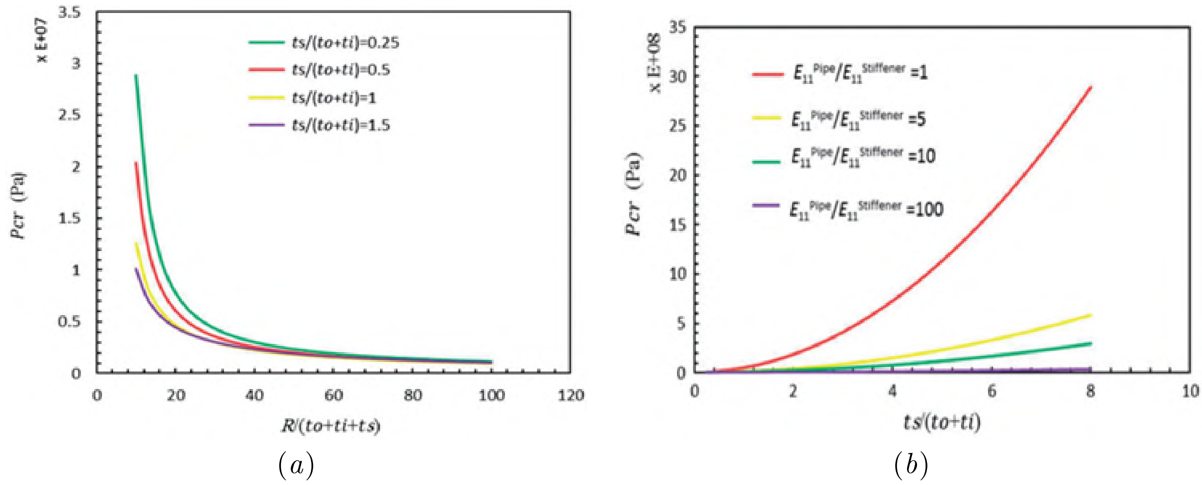

Figure 8. Summarized results, (a) effect of radius to total thickness ratio and (b) core to pipe thickness ratio [6].

the ratio of core thickness, and core stiffness ratio. Pipes with greater lengths have a lower tendency to wrinkle, resulting in a decreased buckling moment. Additionally, an increase in both the core diameter and stiffness enhances the buckling moment. In the presence of hydrostatic pressure, the collapse behavior is determined by the ratio of radius to thickness and the proportion of core thickness relative to the thicknesses of the outer and inner layers. Generally, the critical buckling pressure diminishes as the radius-to-thickness ratio increases, whereas an increase in the ratio of core to outer and inner layer thickness boosts the critical buckling pressures. The research also emphasizes that double-layered pipes are prone to clearances and flaws, underlining the necessity to consider these structural details in both design and operational strategies.

Abstract. The purpose of this reasearch is to investigate the feasibility of using steel reinforcement to improve the strength characteristics of natural stone products. In the course of the research work, recommendations for preparing samples for strength tests are described. Recommendations for the preparation, configuration, and utilization of the main tools and materials employed during the study are provided. The components of conducting an experiment aimed at determining the strength characteristics of samples have been developed and described. Based on the obtained data, the calculation of the values of the main force parameters during the destruction of samples under the action of bending loads has been performed. According to the results of the research on the methodology of using steel reinforcement to enhance the strength characteristics of stone products, it was established that the ultimate strength and load-bearing capacity of the reinforced samples are significantly higher compared to the similar indicators of unreinforced samples.

1. Introduction

The use of stone products is a crucial element in architectural art because this material not only provides a unique natural appearance but also offers excellent physical and mechanical characteristics, ensuring durability. In recent years, there has been a noticeable trend towards an increased utilization of stone products, particularly in the context of sustainable construction and development.

However, Ukraine, with its territory hosting a significant amount of natural stone suitable for the production of architectural and decorative items (granites, granodiorites, gabbro, labradorites, basalt, sandstone, limestone, etc.), holds substantial potential for the development of stone product manufacturing technologies and their utilization in various spheres. National statistics and research enable a better understanding of the volumes of production and sales of stone products, particularly within the territory of Ukraine, which holds significant reserves of natural decorative and facing stone, estimated at over 500 million cubic meters. Currently, approximately 300 deposits of natural facing stone have already been identified and studied in our country (see, e.g., [1]).

According to the data from the State Statistics Service of Ukraine, the production volume of products made from natural stone exhibited steady growth in the years leading up to the start of the full-scale invasion, with an annual increase within the range of 7-10 percent compared to the previous year. Also, according to the results of research conducted by the Ukrainian Geological

Institute, the most common types of stone products are slabs and blocks, stone products for monuments and window sills, as well as products for decorative interior decoration. As a result, the revenue from the sale of stone products also demonstrated positive dynamics, as confirmed by the data from the Ministry of Economic Development and Trade of Ukraine. According to this data, the gross income solely from the export of stone products from Ukraine in 2021 amounted to 120 million USD (0.59 percent).

The widespread use of products made from natural stone in various aspects of human life is indicative of the leading role of this material in the construction industry and design. This is explained by its moderate cost and excellent operational characteristics. While conducting an analysis of the prospects for the use of natural stone products, it is necessary to consider not only their advantages but also their drawbacks. This includes the low strength of certain types of stone or their susceptibility to specific types of loads, such as bending. This drawback significantly limits the range of possible directions of exploitation of products made of natural stone. One way to enhance the strength characteristics of products made of natural stone is by utilizing reinforcement techniques. The essence of this technique lies in the use of reinforcing dowels capable of providing additional rigidity to stone products. Various materials, such as steel reinforcing dowels, composite materials, fiberglass materials, etc., can be used for reinforcement.

2. Literature review

One of the ways to control the strength characteristics of products made of natural stone is the application of reinforcement techniques. Currently, research on this method is quite relevant, as it is one of the most effective ways to strengthen the structure of natural stone products. As a result, there is a considerable amount of work related to this topic.

One of these is the work of Gaevska, who investigates the possibilities of using carbon fiber for reinforcing products made of natural stone [2]. Gaevska showed that the use of carbon fiber significantly increases the strength of natural stone products. In particular, it was established that the tensile strength of natural stone products reinforced with carbon fiber is 2-3 times higher than the tensile strength of unreinforced products.

The possibility of using reinforced steel for reinforcing products made of natural stone is thoroughly discussed in the article by Varshavska [3]. The article establishes that the use of steel reinforcement significantly increases the strength of natural stone products. In particular, it was shown that the tensile strength of natural stone products reinforced with steel inserts is 1.5-2 times higher than that of unreinforced products. The article also examines the impact of various factors on the strength of products made of natural stone reinforced with steel. In particular, it was determined that the strength of the products is influenced by the number of inserts, their diameter, the method of reinforcement, and the type of natural stone.

From the general literature review, it becomes evident that steel is the most common material for reinforcing products made of natural stone. Steel dowels have high strength and durability, but at the same time, they are quite heavy, which increases the final mass of the product. On the other hand, fiberglass is a lightweight and strong material that is resistant to the influence of aggressive environments, such as seawater or acidic atmospheric precipitation. Basalt fiber can be characterized as a strong and durable material that is not susceptible to corrosion. Basalt fiber is often used for reinforcing products made of natural stone that are subjected to high temperatures. According to preliminary assessments, carbon fiber among the presented options is the strongest material used for reinforcing products made of natural stone.

The choice of material for reinforcing products made of natural stone largely depends on the purpose of the product, its size, external influences to which it will be exposed, as well as the financial capabilities of the customer. The use of reinforcement technology allows for a significant increase in the strength of products and their resistance to deformations. This makes natural stone products more durable and reliable.

The relevance, feasibility, and timeliness of applying the methodology of internal reinforcement to products made of natural stone can be explained by several reasons. Firstly, reinforcement allows for the improvement of product strength, significantly expanding the range of possible applications in construction and architecture. Reinforced products are characterized by significantly higher indicators of strength and resistance to loads compared to unreinforced ones.

Secondly, the reinforcement of stone products can increase their durability and reduce the probability of damage or destruction under the influence of external factors, such as vibration, temperature fluctuations, loads, etc. This increases the durability and ensures the reliability of operation of stone products.

In general, the use of methods of reinforcement of products made of natural stone has a significant potential for improving their characteristics and expanding the scope of their application. Research and further development of this technique is an important task that will contribute to improving the efficiency and reliability of stone products in our time.

3. Methods

The main catalyst for ensuring the sustainable development of any industrial sector, including stone processing, is the need to meet a wide range of societal needs [4–8]. For example, in the field of materials science, there is a consistent and prolonged development facilitated by research aimed at finding ways to create new materials that have improved and often unique characteristics compared to already known and used materials. The logical consequence of this is the emergence of new materials that may be more economically advantageous or have superior operational characteristics such as strength, rigidity, resistance to environmental factors (erosive impact, biological influences, influence of alkaline or acidic environments, etc.), and a longer service life. Given the thousand-year experience of using natural stone in construction, it becomes evident that it is one of the earliest materials employed in creating architectural structures. This is demonstrated by a significant number of architectural monuments that have endured through time. Today, construction continues to be the primary sector driving the consumption of stone mining and stone processing products.

For example, according to data from the Information Resources Management Association (IRMA) (table 1), global production volumes of architectural and decorative products increased by 50 percent from 2000 to 2022. The most significant growth was observed in the period from 2000 to 2010, when production volumes increased by 30 percent. In the subsequent years, the growth occurred more slowly, and in 2022, production volumes reached 5250 thousand m^2 [9].

Ukraine is indeed one of the largest producers of architectural and building products made of stone in Europe. According to the approximate calculations of the State Statistics Service

Table 1. World dynamics of production of architectural and construction products made of stone.

Production volumes, thousand m^2	2000	2005	2010	2015	2020	2022
Facing and modular plates	1100	1500	2350	2580	3300	3500
Step plates	500	700	1140	1250	1570	1650
Window sill plates	250	375	500	625	750	875
Countertops	125	187	250	312	375	437
Balusters	62	93	125	156	187	218
Ritual products	31	46	62	78	93	109
Other architectural and construction products	150	225	300	375	450	525

of Ukraine in 2021, around 140,000 square meters of products made of natural stone were manufactured, accounting for approximately 2 percent of global production. Additionally, according to data from the Institute of Geology of the National Academy of Sciences of Ukraine, the volumes of production of architectural and decorative products made of natural stone increased by 130 percent from 2000 to 2021. The most significant growth occurred in the period from 2000 to 2010, with production volumes increasing by 70 percent. The major processing centers for natural stone are in Zhytomyr, Donetsk, Dnipropetrovsk, Kyiv, and Kharkiv regions.

It is worth noting that in the current stage of development of the construction industry, the increase in the use of architectural and building products made of stone is primarily due to a significant increase in the volume of construction and decorative works. At present, the role of natural stone in the construction industry becomes less significant, explained by its displacement by new, more advanced, and user-friendly materials with better strength characteristics, lower weight, providing greater structural rigidity, and possessing several other equally important advantages [10].

The consistently popular materials include granite, marble, quartzite, and others. These materials continue to have the highest demand among architects and designers, which can be explained by:

- the ability to manufacture and use modular elements, which promotes standardization and reduces assembly time;
- a variety of colors, including traditional white, gray, and brown, as well as vibrant shades like blue, green, and red;
- environmental friendliness, as natural stone is an environmentally clean material without harmful substances and toxic fumes;
- the ability to combine with other materials, such as wood, glass, and metal, to create unique interiors and exteriors.

However, like any material, natural stone has its own characteristics, especially regarding strength and resistance to various loads. The loads to which products made of natural stone are subjected can include weight, wind, thermal, and others, which can affect their mechanical strength and stability.

In view of the above, it can be concluded that natural stone remains a popular material in construction, although its role is not as significant as it was in the past. The use of new materials with improved technical characteristics and greater convenience in application leads to a reduction in the use of natural stone for construction structures.

However, natural stone continues to be an indispensable material for the production of architectural and decorative elements due to its aesthetic qualities, environmental friendliness, and the ability to combine with other materials. The frequency of its application can be increased through the improvement of strength characteristics, including through the method of reinforcement.

The technique of reinforcing products made of natural stone is not something new or revolutionary. For example, external reinforcement of products by covering their backside with special meshes fixed with adhesive mortar has been used for several decades. A similar situation applies to the method of internal reinforcement. European Union countries began paying attention to this method in the early 1990s, but its effective use on an industrial scale is only becoming possible now. One of the main catalysts for the spread of this method is the expansion of the range of materials that can be used as reinforcing inserts, including the emergence of entirely new and promising materials from both technological and economic perspectives.

The proposed method of reinforcing natural stone products will consist of a number of the following technological processes:

- manufacturing the product to the required dimensions and shape;
- performing marking along which cuts will be made for placing reinforcing elements;
- making a cut to half the depth of the workpiece, or to the depth necessary to place the reinforcing dowel in the cut;
- cleaning the cut from residual dust (slurry, etc.) and degreasing it using special solutions;
- preparation of fixing mixture and filling the saw cut with it;
- placement of the reinforcement in the saw cut filled with fixing mixture;
- cleaning the surface of the product from excess fixing mixture;
- storage of samples until the fixing material is completely crystallized;
- processing the surface with a polishing wheel to provide flatness to the back side of the processed sample.

As samples, blanks measuring 600×100×30 mm made from Pokostiv granite were used. The main physical and mechanical characteristics of Pokostiv granite are provided in table 2. Pokostiv granite is quite common in the natural stone market in Ukraine. This granite is known for its excellent characteristics, including strength, durability, and decorative appeal. It is used to manufacture a wide range of products such as monuments, countertops, window sills, facing slabs, and more.

Table 2. Physical and mechanical characteristics of the Pokostivskyi deposit granodiorite.

Parameter	Value min.	Value max.	Unit of measurement
Compressive strength	130	190	MPa
Flexural strength	12	18	MPa
Shear strength	15	22	MPa
Density	2.7	2.8	g/cm^3
Water absorption	0.25	0.35	perc.
Coefficient of friction	0.65	0.7	–

The samples used in the study were manufactured and prepared in accordance with the requirements of the National Standard of Ukraine for products made of natural stone (DSTU B EN 12057:2007) [11]. The surfaces of the samples' faces were sawn. For stone with a maximum grain size of less than 25 mm (the investigated granodiorite of the Pokostivskoye deposit meets this condition), the recommended size of blanks is 50×50×300 mm. However, this did not correspond to the task conditions, so samples of different sizes were made, while adhering to the following requirements:

- the thickness h is in the range of 25 to 100 mm, and it is more than twice the size of the largest grain;
- the total length L is greater than the thickness by at least six times;
- the width b is in the range of 50 mm to three times the thickness ($50\,\text{mm} \leq b \leq 3h$) and is not less than the thickness.

Also, based on the requirements established by DSTU B EN13373, control of deviations of linear dimensions of samples was performed. The values of allowable deviations regarding dimensions, flatness, and perpendicularity deviations can significantly affect the results of strength tests. Accordingly, the deviations of the above dimensions of the samples did not exceed the values given in table 3.

Table 3. Permissible deviations of dimensions and shapes of the tested samples.

Characteristic	Permissible deviation values
Dimension l	$\pm 1\%$
Dimension b	$\pm 1\%$
Dimension d	$\pm 1.5\,\mathrm{mm}$
Flatness	0.15%
Deviation from perpendicularity	0.15%

The selection of the type of reinforcing dowel is a crucial task in terms of reinforcement efficiency. A wide range of various materials can be used for reinforcement, but not all of them allow achieving the desired result. For example, the authors investigated the feasibility of using an aluminum profile to reinforce products made of natural stone. As a result of the study, it was found that such a type of dowel does improve the resistance of natural stone products to bending loads, but the increase in stability is very slight, which is explained by insufficient bonding of the dowel surface with the binding material [12, 13].

Another study specifically explores the strength of the adhesive interaction between different types of surfaces of the reinforcing dowel and the binding mixture. The authors investigated the adhesive ability of composite reinforcement with embedded profile, composite reinforcement with a helical winding at angles of 35° and 80°, composite reinforcement with a sand coating, and steel reinforcement. According to the obtained results, the best adhesion indicators are provided by steel reinforcement (Class A600) and composite reinforcement whose surface is coated with a layer of sand. On the other hand, it is not recommended to use composite reinforcement with a spirally wound winding at angles of 35° and 80°, which forms a helical profile, as it gets cut during pulling out, preventing the full realization of the dowel's rod strength [14].

Therefore, based on the information provided above, it can be concluded that the use of steel reinforcing inserts is reasonable to enhance the strength characteristics of products made of natural stone. Steel reinforcement of class A600 with a diameter of 10 mm was used as the reinforcing dowel (DSTU 3760:2006 "Rolled products for reinforced concrete structures. General technical conditions") [15]. The physical and mechanical characteristics of the reinforcement are presented in table 4, and the cross-section is shown in figure 2.

The further preparation of the samples involved cutting longitudinal grooves along the center of the blank to embed reinforcing elements in them. The grooves were cut using an angle grinder, equipped with a solid carbide disc with a diameter of 125 mm and a continuous working edge. An example of a cross-sectional view of a completed groove and the placement of reinforcing

Table 4. Characteristics of steel reinforcement class A600.

Parameter	Value	Unit of measurement
Yield point	600	$\mathrm{N/mm^2}$
Temporary resistance to fracture	800	$\mathrm{N/mm^2}$
Relative elongation after fracture	12	%
Relative uniform elongation after fracture	4	%
Total relative elongation under maximum load	5	%
Bend angle	45	%
Initial modulus of elasticity	19	$\mathrm{N/mm^2}$

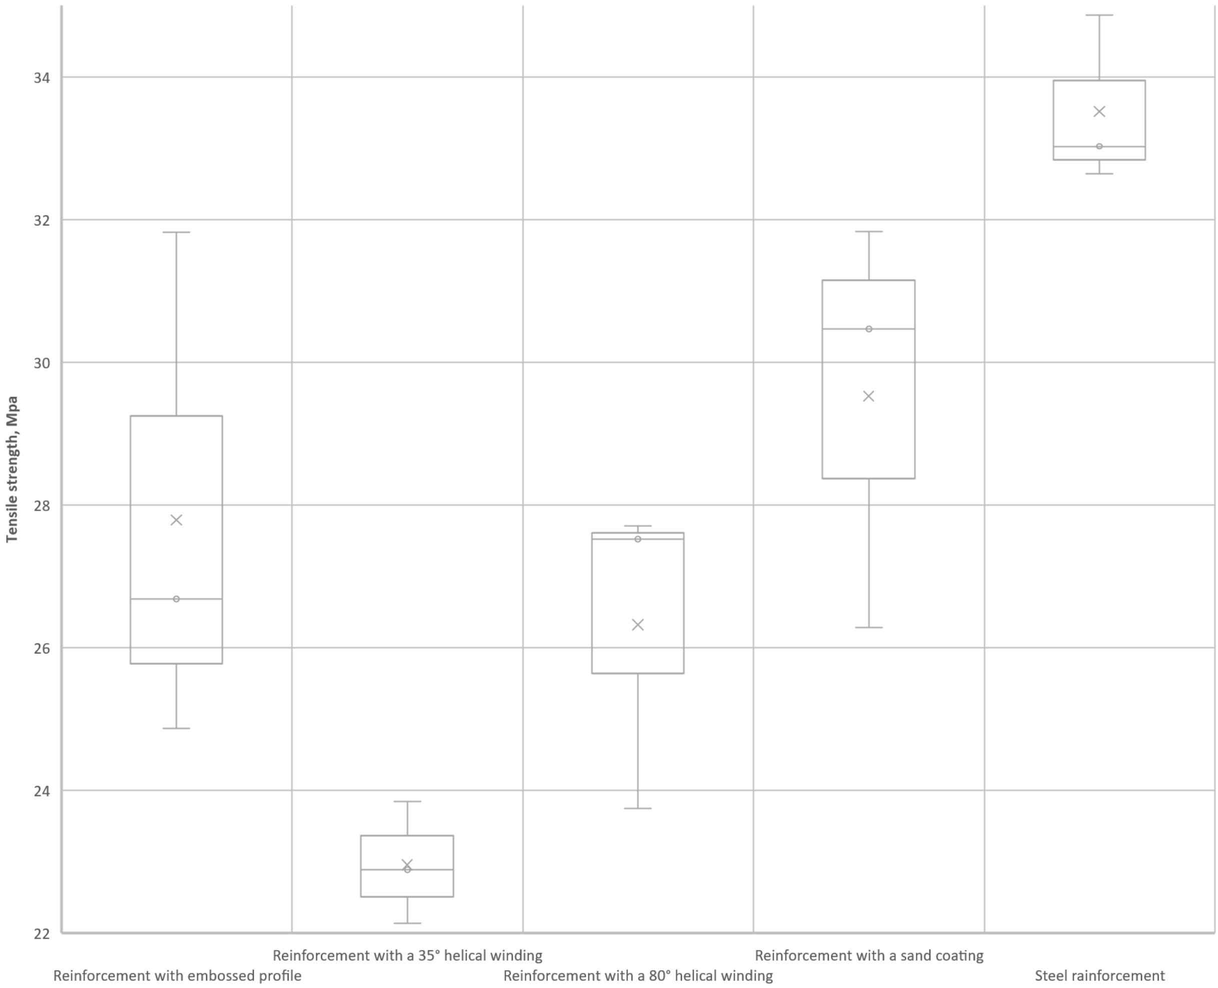

Figure 1. Results of the research of the adhesion interaction magnitude of different types of reinforcing dowels with epoxy binder.

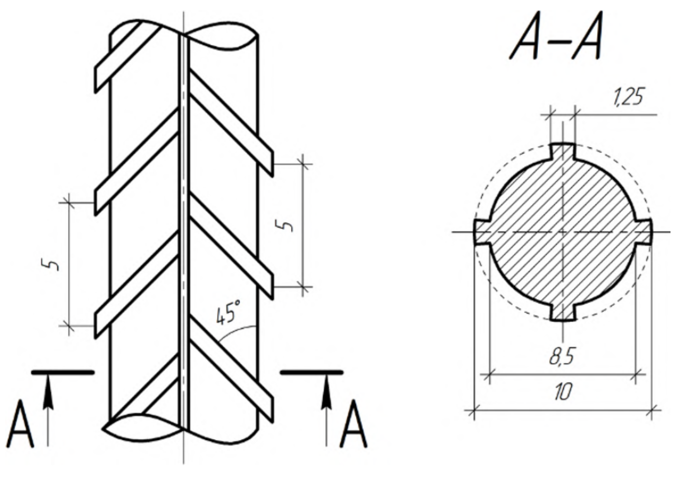

Figure 2. Main linear dimensions of the used steel reinforcement of class A600.

elements in it is shown in figure 3.

For fixing the reinforcing dowel inside the groove in this study, white decorative two-component epoxy resin "Fluid Art" was used, the technical characteristics of which are provided in table 5. Before use, this resin was prepared according to the manufacturer's instructions: first, the hardener was added to the resin in a ratio of 1:8, after which the mixture was vigorously stirred for 5 minutes. The application of the mixture in the groove was done in several stages: initially, the empty groove was filled with resin to a depth of 1/3, then the dowel was placed in it, and it was covered with resin to completely fill the groove (a spatula was used to distribute the resin in the groove and clean up excess). After completing the preparatory work, the blanks were kept for 40 minutes (working time of epoxy resin). After that, the blanks were kept for 28 days. Despite the fact that the resin dries and gains initial strength within 1 day, the manufacturer recommends a storage period of at least 28 days for it to acquire its maximum strength.

An important aspect when working with the "Fluid Art" epoxy mixture is to maintain optimal microclimate conditions, specifically the temperature and air humidity, to ensure the accuracy of the technological process and achieve the highest possible quality for the final product. During the preparation of the epoxy mixture, the air temperature was maintained within the range of +18°C to +25°C, and the relative humidity did not exceed 70%. Similar temperature and humidity conditions were upheld during the aging of the blanks.

The determination of the force parameters of reinforced specimens was carried out according to the recommendations of the National Standard of Ukraine "Determination of the strength limit under bending with concentrated load" DSTU B EN 12372:2011 (EN 12372:2006, IDT). The specimens were placed in the center on support rollers (as shown in figure 4). The roller load was applied in the middle of the specimen. The load applied to the blank was increased

Table 5. Physical-mechanical characteristics of the used epoxy resin Fluid Art.

Parameter	Value min.	Value max.	Unit of measurement
Elastic modulus	2.5	3	GPa
Tensile strength	30	50	MPa
Compressive strength	30	50	MPa
Poisson's ratio	0.3	0.35	-
Temperature resistance	50	60	25°C
Linear expansion coefficient	70	80	μm/(m $\cdot$ K)
Viscosity	300	800	MPa $\cdot$ s

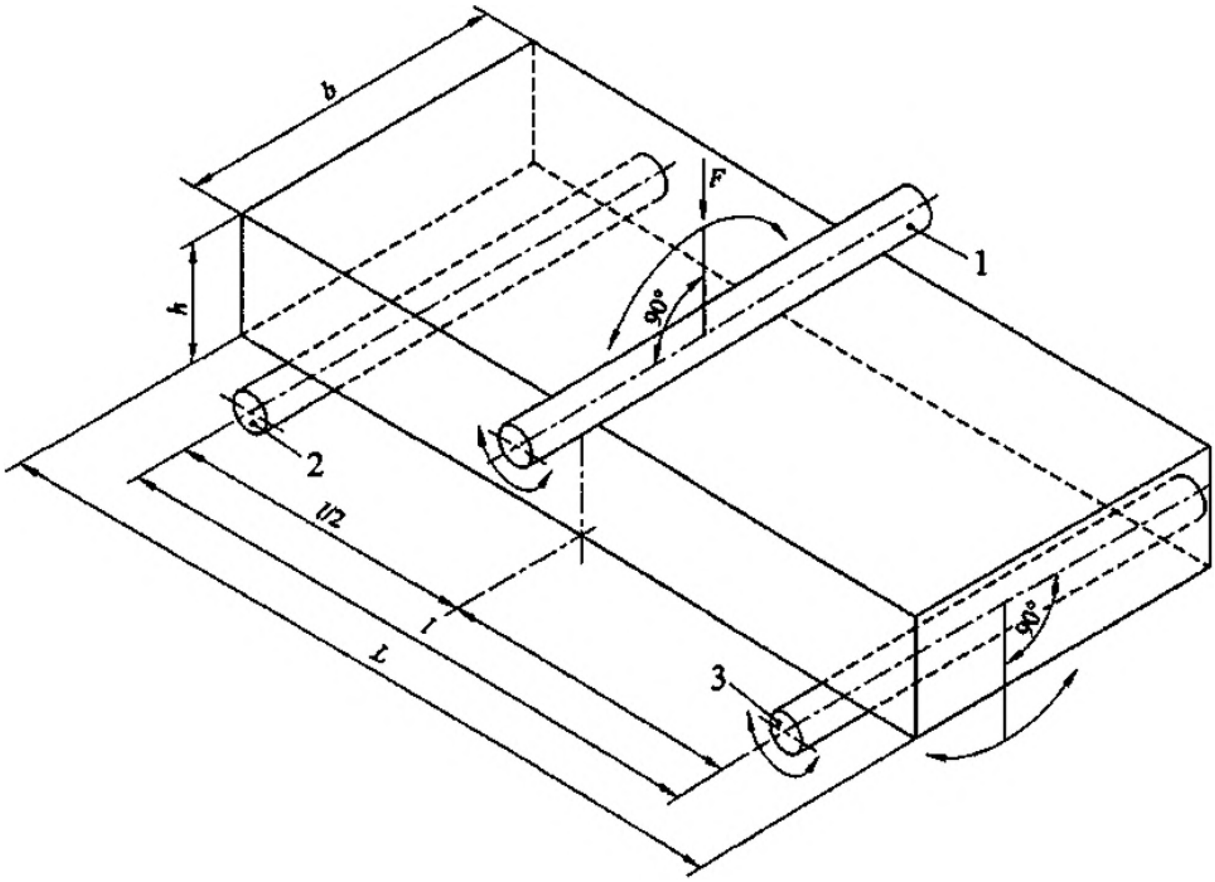

Figure 4. Loading scheme of the test specimen during the determination of the bending strength: 1 – loading roller; 2 and 3 – supporting rollers; b – width of the specimen; h – thickness of the specimen; L – length of the specimen; l – distance between supporting rollers; F – applied force.

uniformly at a rate of (0.25±0.05) MPa/s until the moment of sample failure.

To conduct force experiments, a hydraulic press with a force of 10 tons of the NITRAUM UNY10003 model was utilized. Its initial design did not allow for the necessary research, so a stand was manufactured, consisting of two lower (support) rollers located on a frame made of a rolled beam and one upper (working) roller equidistant from the supports, which actually transmitted the force impact to the specimen (figure 5).

As a measuring device for recording the applied force, a standard pressure gauge installed on the hydraulic press was used and calibrated according to the EN 12390 standard. A Shahe 5306-35 clock-type micrometer with an indicator was employed to measure deformation.

Firstly, unreinforced (control) specimens (figure 6) were studied to establish baseline values and a basis for comparing similar values obtained during the study of reinforced specimens.

From the obtained graph, it can be seen that the unreinforced granite specimen exhibits typical stress-strain behavior, with an initial linear elastic area, followed by a nonlinear plastic area and eventual failure.

The linear elastic area of the stress-strain curve corresponds to the portion where the material behaves elastically, meaning that the deformation is proportional to the applied load. This area is characterized by a constant slope (Young's modulus), which reflects the stiffness of the material.

After reaching a certain point (within the range of 3.8 MPa), the specimen transitions to

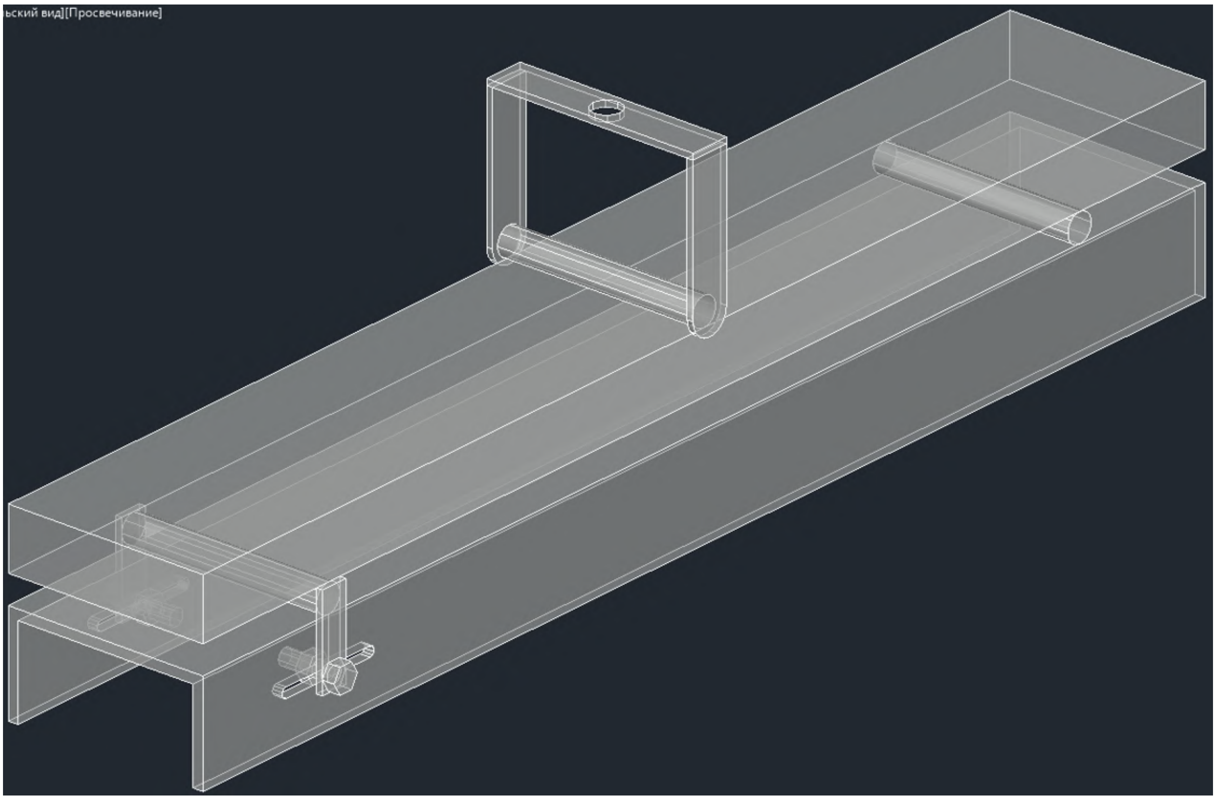

Figure 5. Model of the stand for loading the tested specimens.

a nonlinear plastic deformation area, where the material continues to deform under increased load but at a slower rate. This phenomenon is known as strain hardening, where the material becomes stronger and more resistant to deformation under further loading. In the final stage, unreinforced granite specimens reached their maximum strength and experienced failure in the form of a crack that grew into a fracture (figure 7). The strength of the granite specimen under the given conditions can be determined by analyzing the maximum force achieved during the loading process, which, according to the obtained results, is approximately 4.5 MPa.

The data obtained from the study of specimens reinforced with steel reinforcement was also presented in the form of a graph showing the relationship between the specimen's deformation and the applied load (figure 8).

4. Analysis

The analysis of stress-strain curves for blanks made of natural stone reinforced with steel reinforcement involved identifying typical areas that describe the behavior of the blank. In the initial stage of the stress-strain curves, a linear relationship is observed – the area of elastic behavior of the material. The load within this range increases linearly with the deformation. In this area, specimens retain their original shape after the applied load is removed.

After the elastic area, the stress-strain curve deviates from linearity and demonstrates the yield point. The yield point marks the beginning of plastic deformation, indicating that the material has exceeded the elastic limit. At this point, blanks undergo deformation that will persist even after the load is removed. This specific area of the curve corresponds to plastic deformation, where stone blanks experience significant deformation with a relatively small increase in load.

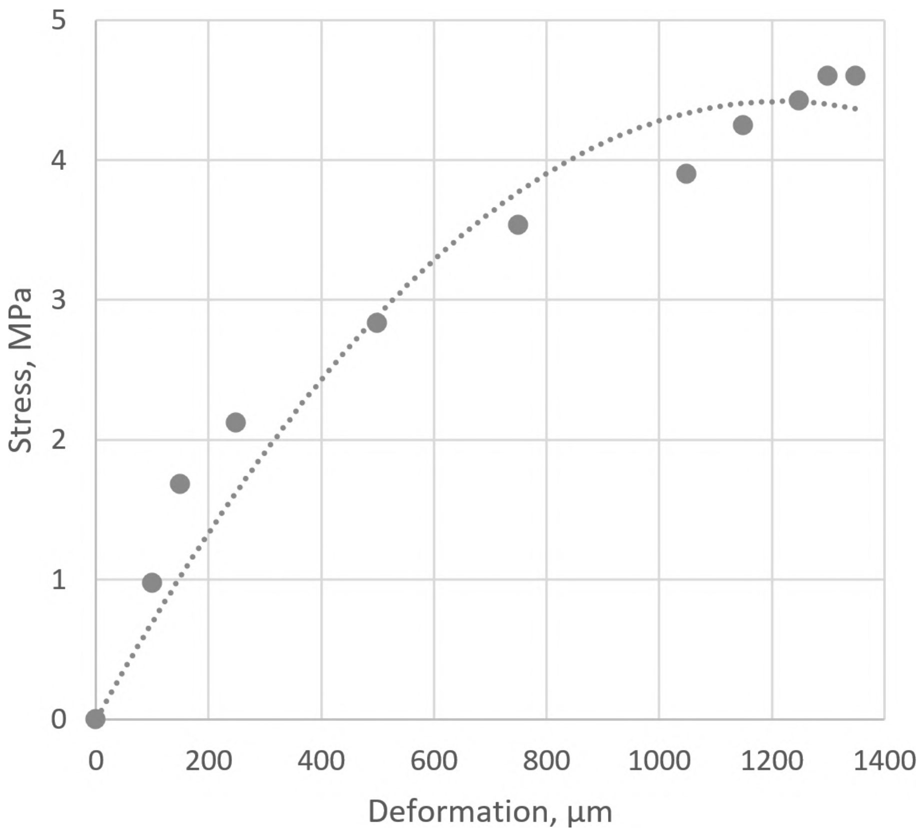

Figure 6. The result of the study of the strength characteristics of unreinforced samples.

Figure 7. Example of failure in unreinforced specimens.

Plastic deformation indicates the material's ability to undergo constant changes in shape without fracturing. The plastic deformation area reaches its peak at the point of maximum stress, which determines the ultimate strength of the specimens.

Beyond the ultimate strength, the curve begins to decline, indicating a decrease in the load-bearing capacity of the blank due to its failure (figure 9).

5. Discussion

The deformation behavior of specimens reinforced with steel reinforcement in all three examined cases follows a common pattern. In the initial stage, the specimens exhibit linear-elastic behavior. With increasing load, they transition into the plastic deformation area, where the

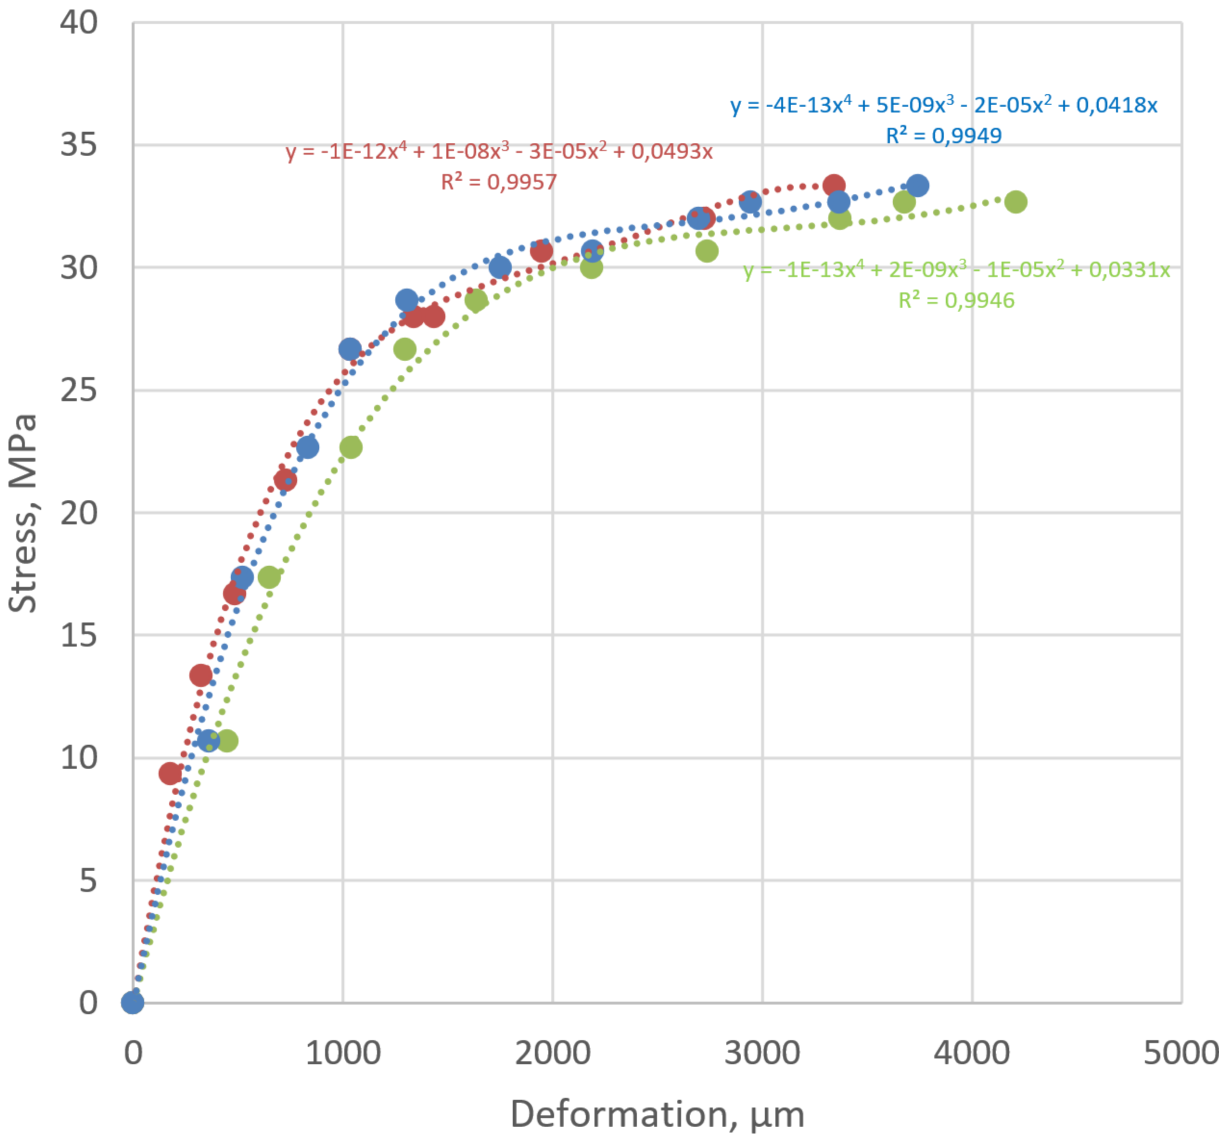

Figure 8. The research results were obtained when testing samples reinforced with steel reinforcement.

stress-strain curve shows a gradual increase in deformation with small increments in load. In the case of the first specimen, the yield strength of 33.3 MPa is reached at a deformation of 3345 µm, after which there is a slight decrease in load, indicating a loss of load-bearing capacity. Similarly, the loading of the third specimen results in a yield strength of 33.3 MPa at a deformation of 3744 µm. The second specimen demonstrates an initial linear-elastic area, but plastic deformation occurs at slightly lower load values, with a maximum of 32.7 MPa. Continuous deformation with slight stress increments is observed until reaching the ultimate strength at a deformation of 4670 µm. The obtained results indicate that specimens reinforced with steel reinforcement exhibit a combination of elastic and plastic characteristics. The steel reinforcement enhances load-bearing capacity and provides plasticity to the specimen.

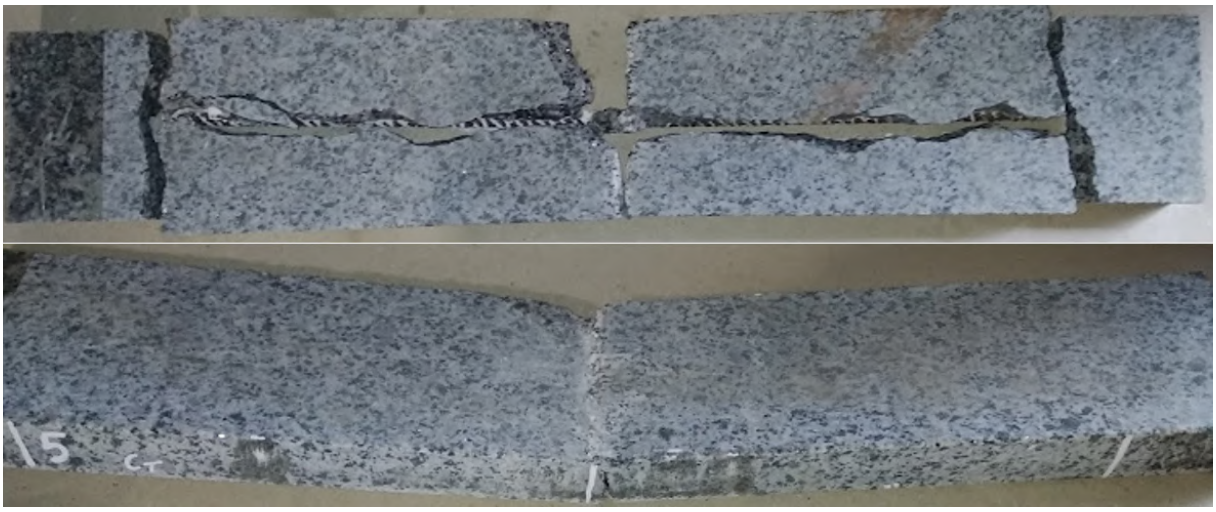

Figure 9. Results of loading specimens reinforced with steel reinforcement feasibility.

6. Conclusions

Comparing the results obtained from the study of specimens made from the granodiorite of the Pokostiv deposit and those reinforced with steel reinforcement, the following conclusions can be drawn:

- the considered type of reinforcing dowel ensures the presence of an initial elastic area;
- the use of steel reinforcement to strengthen stone products ensures a consistent increase in deformation with increasing loads, enhancing the control over the response of plastic deformation;
- the ultimate strength and consequently the load-bearing capacity of specimens reinforced with steel reinforcement are higher than those of unreinforced specimens.

Therefore, reinforcing stone products with steel reinforcement allows for higher ultimate strength, which can be advantageous in cases where maximum load-bearing capacity is required.

In order to improve research results and refine the proposed reinforcement methodology, the following is suggested:

- repeat the experiment using specimens made from other, less robust types of rocks to obtain more diverse data on the strength of different rock types and the feasibility of reinforcing them;
- the textural and structural features of the rock may play a significant role, so investigating the influence of this factor on the effectiveness of reinforcement is also important;
- repeat similar experiments with a larger number of specimens to obtain more statistically significant results and reduce the possibility of random errors;
- in further experiements, examine and measure the impact of various parameters on the strength of specimens, including factors such as loading speed, temperature, etc., as this will provide a more comprehensive understanding of granite characteristics and the possibilities of its reinforcement.

Abstract. Sustained operation of critical infrastructure facilities is an extremely important problem. Power Stations are among these facilities. The reliability of Power Station equipment is closely linked to the effective monitoring and diagnostic systems they are equipped. Such systems are constructed in several stages. Good prioritization is an effective way to address security and risk management issues. It aims to maximize the benefits of available resources by focusing on the most important issues and thereby minimizing inherent security risks. Such decisions may be influenced by an inaccurate interpretation of the system state caused by a forced consensus of judgements on an adverse event. In practice, the process of risk management and assessment involves several technical and organizational factors, not just indicators of the severity of an adverse event. The paradigm of risk analysis in the energy sector is clearly related to the risk paradigm that exists in the development of cybersecurity systems. Such decisions may be influenced by an inaccurate interpretation of the system state caused by a forced consensus of judgements on an adverse event. The paper considers the peculiarities of constructing wireless elements of a multilevel diagnostic system for power plant auxiliary motors and the methodology for assessing the auxiliary motor resistance and their impact on the power plant operation.

1. Introduction

The use of diagnostic systems in the construction and operation of engines of various capacities can significantly improve the reliability of such equipment and increase the economic performance of its use. Taking into account the EU-Ukraine Association Agreement signed by Ukraine, the operation of the engines themselves and their diagnostic systems must comply with European standards.

Diagnostic systems of power equipment are developed in several stages: elaborating or application of mathematical models of the systems such as [1–4], selection the most informative diagnostic features based on the analysis of such models, building of training aggregates and decision rules based on the scientific results obtained [5–8]. Probability theory, random process theory, risk theory, statistical hypothesis theory, pattern recognition theory, etc. are used for the problem solution.

The paper discusses the principles of building systems for technical diagnostics of auxiliary motors using autonomous measuring transducers.

Power plant auxiliaries are understood as a complex that includes mechanisms for servicing or automating the operation of the main units and auxiliary devices of the plant, electric motors for these mechanisms, power supplies, intra-station power grid and switchgear, as well as heating, lighting and domestic needs. An important issue is to provide independent power supply to sensor devices. It is provided greater autonomy and increase the service interval of the devices when the system is developed. The use of rechargeable batteries and optimization of power consumption by the devices themselves can only partially solve the problem. Energy Harvesting technologies are currently being actively developed. The use of these technologies can significantly increase the autonomy of sensor units.

2. Features of the structure of the modern power plants and diagnostic system prototype

Any complex technical facility (including a power plant) can almost always be viewed as a hierarchical structure. Power plants contain a large number of units, machines and structural elements. Individual units and components of a power plant together make up certain functional blocks, the reliability of which to a certain extent depends on the reliability of the equipment included in each block, since defects in the component parts are actually defects in the facility as a whole object [9].

The development of a diagnostic system that covers all possible elements of a power plant is too complex a technical problem. Therefore, when a diagnostic system is developed, it is necessary to determine which elements of the object to be diagnosed are critical for its proper functioning and which are less critical.

It is advisable to divide all possible defects in a given object to be diagnosed into three classes: catastrophic defects, non-catastrophic defects, and partial defects from the point of optimizing the complexity of the diagnostic system.

According to the degree of responsibility of the mechanisms, it is advisable to divide this section as follows: particularly responsible mechanisms, responsible mechanisms, non-responsible mechanisms. The proposed methodology for diagnosing the moving units of auxiliary power plant motors is implemented by means of an information and measurement system (IMS). The system has separate units that provide measurement, conversion and transmission of information (hardware) and units that implement software control of the IMS, statistical processing of measured signals and construction of solving rules for determining the technical condition of the equipment being diagnosed (software).

Principles of modularity of the created system were used to ensure the possibility of modifying the IMS to meet the specific needs of the user when prototype of the IMS for vibration diagnostics of electrical equipment is developed (figure 1).

The analogue signal measured at the unit of the electrical machine under diagnosis at the output of the sensor is a DCM (duty cycle modulated) signal. The ADXL202 accelerometer manufactured by Analog Devices was used as the primary sensor. The frequency of the signal is measured by the ADXL202 accelerometer can be set in the range from 0.01 Hz to 6 KHz. It is sufficient to diagnose the technical condition of parts of electric motors: rotor windings' frontal parts, possible thermal imbalance arising from short circuits of individual turns of the rotor winding, as well as rolling bearings.

The sensor unit used in the developed *prototype* of the vibration diagnostics system consists of the following basic elements: two ADXL202 accelerometers; microcontroller PIC16LF873-041 manufactured by Microchip Technology; Bluetooth module EYMF2CAMM-XX manufactured by TAIYO YUDEN; related elements that ensure the functioning of the unit.

The convenience of the sensors with DCM signals from their outputs is due to the fact that

Figure 1. Vibration analysis of the auxiliary electric motor DKRAI – 4519-4V at Darnytska HPP.

such sensors can be directly connected to the input of the microprocessor counter without the use of analogue-to-digital conversion or binding logic chips. It is simplified the process of processing the measured signal and increases the battery life of the devices. Using the created prototype of the IMS, research of the vibration characteristics of auxiliary engines of the Darnytska Heat and Power Plant (HPP) was carried out. The developed vibration module of the prototype of IMS vibration diagnostics was used to measure and analysis of vibration information signals recorded on the bearing units and rotating shaft of the DKRAI-4519-4V electric motor with parameters $P = 710$ kW; $U = 3000$ B; $I = 156$ A; $n = 1490$ rpm. The motor was made in Germany.

According to the international standard ISO 20816-3:2022 [10], which is in force in Ukraine, the DKRAI-4519-4V electric driver belongs to group 1, which corresponds to the power classification. The sensor on the electric driver was also placed in accordance with ISO 20816-3:2022. The vibration signal was analyzed by using a Bartlett window.

The performed measurements and analysis confirm the possibility of using the developed prototype vibration IMS to diagnose rotating units of the auxiliary motor.

3. Method of resilience estimation of the auxiliary electric drivers of power plant

We used the methodology proposed in [11] to assess the impact of auxiliary motors on the power plant's resilience. According to the definition of the US National Academy of Sciences, the structure as a model of the object of study is modelled as a graph $G(N, L)$ where N is the number of nodes connected by links L. The specification N and L includes characteristics related to resilience, such as capacity, location, and the impact of each node and connection lines on the functioning of the object of research. Let C be a set of temporary decision rules and strategies that will be developed to increase the stability of the system during its operation. From a computational point of view, the parameters and algorithms defined by C depend on the specific model being implemented. Ultimately, the system must maintain its critical functionality K at each time step t, where K maps its states or parameters to a real value between 0 and 1. This mapping, for example, can be linear

$$K(t, N, L, C) = \frac{\sum_{i\in(N,L)} w_i(t; C)\pi_i(t; C)}{\sum_{i\in(N,L)} w_i(t; C)} \tag{1}$$

where $\{N, L\}$ is the set of all nodes and links of the graph; $w_i(t, C) \in [0, 1]$ is a measure of the relative importance of a node or link i at time t, $\pi_i(t, C)$ is the degree to which the node is still active in the presence of an attack. An alternative interpretation $\pi_i(t, C)$ is that it is the probability that a node or an link is fully functional. In a more sophisticated formulation, a non-linear and more detailed definition of the critical functionality mapping is also possible.

The paradigm of risk analysis in the energy sector is certainly related to the risk paradigm that exists in the development of cybersecurity systems [11–14]. According to this paradigm, risks, in accordance with ISO/IEC 27000:2022 [15], information security includes three main dimensions: confidentiality, availability and integrity.

- Confidentiality is the property of information to be inaccessible or closed to unauthorised users, entities or processes.
- Availability is the property of being available and ready for use at the request of an authorised entity.
- Integrity is the property of maintaining the correctness and completeness of assets (information).

The additive risk model of information security can be presented as follows:

$$H_c p_c + H_i p_i + H_a p_a = R \tag{2}$$

where $H_c p_c$ is the risk of confidentiality; $H_i p_i$ is integrity risk; $H_a p_a$ is availability risk; R is overall risk; H is amount of losses; p is probability of losses.

The following paradigms are possible to assess the risks of power unit failure:

- $H_c p_c$ is confidentiality risk will correspond to the risk of unauthorised access to the wireless receiver and the technical condition of such a receiver;
- $H_i p_i$ is integrity risk. It is estimated service life and probability of power unit failure;
- $H_a p_a$ is availability risk, it is the actual service life and probability of failure of a power plant, which depends on the operating mode and technical indicators (for example, vibration, according to ISO 20816-3-2022 is included:
  - Operating modes S1-S10 (according to IEC 60034-1-2022 [16]);
  - Temperature indicators (according to IEC 60034-1-2022 [16]);
  - Load characteristics (according to IEC 60034-1-2022 [16]);
  - Vibration characteristics (according to ISO 20816-3-2014 [10]).

It is clear that if there is no information on the availability risk $H_a p_a$ this value can be assigned 100.

If the system does not have any wireless control or diagnostic systems, then $H_c p_c = 0$.

4. Conclusions

The relevance of the results obtained is due to the fact that in the post-war period, one of the main tasks of the country's reconstruction should be the restoration of its United Energy System, including generating equipment. It is necessary to restore generation at a fundamentally new level with the use of advanced achievements of the world and domestic electrical engineering. Such restoration involves restoring not only the main generating equipment, but also auxiliary equipment, which may not be severely damaged during enemy attacks. But it is necessary to assess the risks of its failure and the impact on the functionality of all power equipment. This assessment can be made using the concept of resilience. The expected results can be achieved by increasing the reliability and safety of electrical equipment operation, extending the service life, reducing maintenance costs, through effective planning of repair work and the use of artificial intelligence elements.

It is necessary to use a multi-level structure of the monitoring and diagnostic system, which includes a significant number of autonomous modules for measuring and processing diagnostic information for technical diagnostics of complex energy facilities, such as power plants. These modules must be able to operate for a long time without the need to replace or recharge their batteries. Optimal algorithms and software are of particular importance for the proper functioning of such modules.

The prototype of IMS of vibration signals of diagnostic of auxiliary motors, algorithms for processing vibration signals, elaboration of decision rules, and technical solutions are proposed for monitoring and diagnosing the technical condition of auxiliary engines at the Darnytska HPP.

Abstract. When operating various hydraulic structures, particularly agricultural drains, during the water movement through soils, various types of suffusion deformations typically occur. Particle reorientation and displacement happen under the influence of various forces, including hydraulic gradients. The movement of fine particles, mechanical suffusion, and colmatage were investigated in the hydro-technical laboratory of the National University of Water and Environmental Engineering (Rivne city). Laboratory experiments on filtration using Darcy's facility reveal patterns of the hydraulic gradient's influence on the hydraulic conductivity in soils with different particle size distributions. The article describes the experimental facility and filtration model, outlines the selection of model soil compositions, and the corresponding experimental constructions, along with the conditions for conducting experiments. Based on the research results for selected model soils, the dependence of the hydraulic conductivity on the magnitude of the hydraulic gradient was established. The hydraulic conductivity increases with an increase in the hydraulic gradient, and upon exceeding a certain value of the gradient, known as the critical hydraulic gradient, when soil particles attain a stable position, deformation processes practically cease. It was also found that with a gradual reduction in hydraulic gradients, the hydraulic conductivity remains constant within a certain interval. Only after reaching specific gradient values does the hydraulic conductivity start to decrease, but it exceeds the initial values significantly (up to 32%). This indicates that deformations in the soil caused by mechanical suffusion and colmatage are irreversible.

1. Introduction

When fluid moves through porous media (soils, granular materials of drainage backfills, etc.), various kinds of suffusion deformations usually occur in them: reorientation of particles in space under the action of various forces, and, in particular, hydraulic gradients; movement of small particles, which are referred to as suffusion particles, within the pores of the soil skeleton formed by larger particles – mechanical suffusion; cessation of suffusion particles brought by filtration flow from – colmatage [1, 2]. The consequence of suffusion deformations is a change in the characteristics of the medium, the most general and indicative of which is the hydraulic conductivity (in Ukrainian terminology – filtration coefficient) [3, 4].

Internal erosion is investigated to consider its effect on the performance of drainage [3], and also because of its destructive nature – it is the main cause of failure of many hydraulic structures, in such as dams and levees [1,5,6]. Internal erosion includes four mechanisms, namely, erosion in concentrated leaks, backward erosion, contact erosion, and suffusion [4–6]. Suffusion is a process in which finer soil particles are transported through constrictions between larger soil particles under the influence of filtration forces [7], leading to changes in the physical and geo-mechanical properties of the soils (e.g., permeability, volume change, compressive strength, and soil grain gradation) [1, 8].

The water-regulating capacity of the drain also significantly depends on the permeability of the soil adjacent to the drain [9], which is especially important when working on poorly water-permeable clay soils [10]. With regard to agricultural drainage, wells, and drainage devices in hydraulic structures, suffusion deformations, under certain hydromechanical conditions, are the most influential, especially in the initial period of their operation [3, 11, 12].

In recent years, mathematical modelling of hydraulic processes has been carried out both in general drainage [13] and in particular sufosion phenomena. For such calculations, modelling systems have been created that take into account the influence of a number of factors, including soil gradation on internal erosion, without modelling each particle separately, and the particle parameters are introduced as an additional dimension [14].

When the filtration forces (hydraulic gradients) reach certain critical values, the soil begins to suffusion (i.e., particle transport and changes in the internal structure of the soil). These conditions and critical values make a crucial role in assessing the risks of damage to hydraulic structures and the nature of water inflow to drains and wells. A common criterion for assessing critical suffusion conditions is the gradient, in particular the critical hydraulic gradient (CHG) [1]. CHG is related to internal soil properties and some external factors. During the last decades, the influence of internal properties such as particle size distribution (PSD), gradation, porosity and particle shape has been widely studied using analytical and experimental approaches [1, 7, 8, 15, 16].

Our theoretical studies of filtration in environments where soil deformations occur under the influence of hydraulic gradient and, as a result, changes in its hydraulic conductivity, have established the following. To describe such processes, in addition to the traditional characteristics of the soil (particle size distribution, porosity, hydraulic conductivity, etc.), it is necessary to know additional parameters that determine the property of the soil to change the hydraulic conductivity under the influence of forces from the filtration flow [3]. Such characteristics can be determined using Darcy's facilities if, during soil studies, changes in their hydraulic conductivity are recorded when the hydraulic gradient changes.

2. Materials and methods

To determine the dependencies for filtration flow rates, head functions and their gradients, it is necessary to have reliable systematic research data that reveal the picture of the phenomena that occur around drains in the process of filtration. These data are most expediently obtained using physical filtration models, which, unlike field studies, allow controlling all influencing factors and are built according to the boundary conditions of the filtration problems under consideration. It is practically impossible and impractical to achieve this in the field.

In the series of experiments on filtration models presented in this article, the water flow rate and gradients in the filtration area were determined depending on the change in head at its boundaries. Based on the obtained flow rate q and the head distribution function $h(r)$ (or $h(x, y)$), the following derivatives were calculated: functions of hydraulic gradient distribution $I(r)$, hydraulic conductivity $k(r)$ (respectively $I(x, y), k(x, y)$), additional filtration resistances of the experimental facilities and others.

2.1. Description of the experimental facility

Experiments on the study of filtration flow were performed in the hydrotechnical laboratory of the National University of Water and Environmental Engineering (Rivne) using a special installation (figure 1) [17].

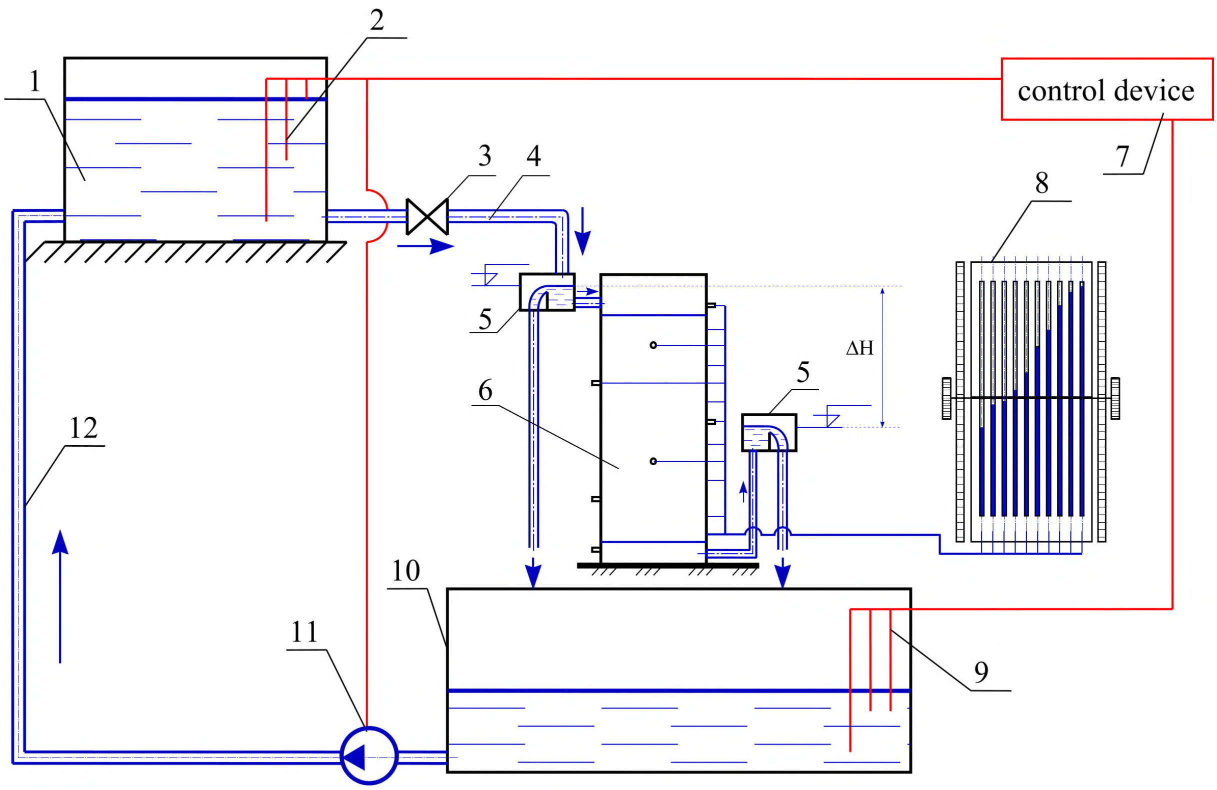

Figure 1. Schematic of the experimental facility: 1 – pressure tank; 2 – level sensor in the pressure tank; 3 – valve; 4 – supply pipeline; 5 – special water overflow; 6 – filtration model (Darcy's facility); 7 – control device; 8 – micromanometer block; 9 – level sensor in the discharge tank; 10 – discharge tank; 11 – pump; 12 – pipeline.

Water from the pressure tank 1 (figure 1) with a volume of $1.0\,m^3$ flows through the pipeline 4 to the filtration model (Darcy‘s facility) 6, from which it is discharged into the drain tank 10 with a volume of $1.0\,m^3$. The flow rate to the model is regulated by the valve 3, and the steady flow rate and pressure are regulated by a special water overflow 5. With the pump 11, water from the drain tank is periodically pumped through the pipeline 12 to the pressure tank 1. Automatic switching on of the pump is provided by the control device 7 and water level sensors 2 and 9.

Such a circular system made it possible to use settled and filtered water in the experiments, the temperature of which was almost constant, which stabilised the effect of air dissolved in water on filtration. The use of water from the centralised water supply system in filtration experiments is unacceptable due to the significant obstruction of the filtration flow of dissolved air, which is concentrated in the small pores of soil from the water [18, 19].

To study the one-dimensional filtration flow, a Darcy's facility was used (figure 2) [17].

The casing of the facility 7 is made of a plastic cylinder with an internal diameter of 23.8 cm and a height of 75 cm. A supporting grid 3 with a layer of filter material (fabric) 2 is attached to the bottom of the cylinder.

Methodological studies of the filtration flow rates at the contact of the experimental soil with the casing and their comparison with the averaged rates in the array have established that contact filtration for the studied soils does not affect the results of the experiments [20].

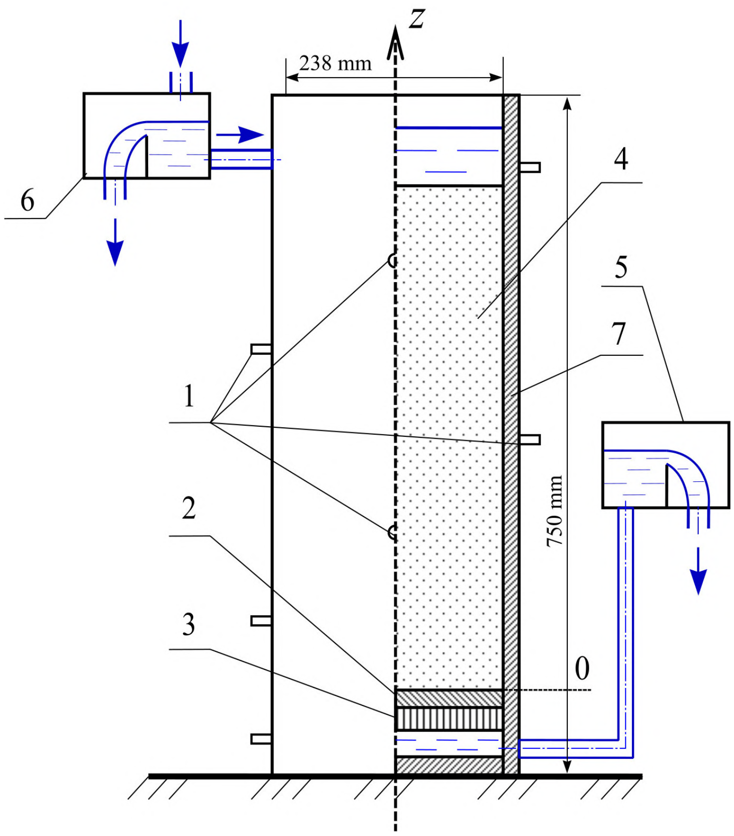

Figure 2. Scheme of the Darcy's facility: 1 – piezometers; 2 – filter fabric; 3 – supporting grid; 4 – test soil; 5; 6 – movable water overflows; 7 – facility casing.

2.2. Model soils and experimental conditions

The soil models used were thoroughly washed homogeneous sands (fractions) with different average diameters and hydraulic conductivity (soils No. 1 to No. 4, No. 6, No. 8 to No. 10), a suffusion soil (No. 7) and natural soil from the experimental site (No. 5), the characteristics of which are given in table 1 and table 2.

The soil hydraulic conductivity given in table 2 are baseline, i.e. those determined in the Darcy's facility at gradients well below the critical gradient.

The formation of the suffusion soil was carried out according to the methodology of G. Pravedny [21]. Initially, a sandy fraction, the characteristics of which are given in table 1 (soil No. 10), was selected to form the skeleton of the suffusion soil.

The calculated diameter of the filtration pores for the particles forming the skeleton was determined by the formula [21]

$$d_0 = 0.455\eta^{1/6}\frac{n}{1-n}d_{17}, \tag{1}$$

where η – is the coefficient of grain size distribution; n – porosity; d_{17} – is the diameter of soil particles less than 17 % by weight.

For example, for model soil No. 10, d_0 is 0.347 mm. The diameters of particles d_{ci} that are capable of moving in the soil and can be taken outside the filtration area at an unprotected outlet are determined by the following relationship

$$d_{ci} \leq 0.77d_0^{max}, \tag{2}$$

where $d_0^{max} = kd_0$ is the diameter of the maximum filtration stroke; $k = 1 + 0,05\eta$ – coefficient of unevenness of particle distribution in the soil or coefficient of localised suffusion (for $\eta \leq 25$).

The calculation according to dependence (2) established that $d_{ci} < 0.29$ mm. Therefore, to obtain a suffusion soil, were added to the skeleton fraction 5 % of particles with diameters in the range of 0.10...0.16 mm. Fine-sandy loamy soils with the content of loamy particles of about 5 % are the most common in the Polissya zone of Ukraine and are the most dangerous in terms of the development of suffusion processes.

Loading of soils into Darcy's facility was performed in layers, with a height of 7...10 cm into water (homogeneous soil) or in a dry state with a gradual increase in the water level (suffusion soil). Each soil layer was flattened, and the removal of air bubbles was carried out.

At the Darcy's facility, the surface of drainage structures with perforation degrees of 0.08% and 0.6% was simulated, corresponding to different plastic drainage pipes. The conditions of the experiments are provided in table 3.

2.3. Measuring equipment

Brass piezometers (figure 3) were utilized for measuring pressures in the Darcy's facility, with their intake section protected by a filter fabric.

Table 3. The conditions of the experiments.

Characteristics of the experiment	Soil No. 3	Soils 1, 2, 4-5, etc.
Height of soil fills, cm	25; 37; 49.5; 60	60
Degree of perforation of structures, %.	0.08; 0.6	0.08; 0.6
Number of layers of the filter fabric	1; 2; 3	1
Number of set pressures	14	14
Number of repeated tests	3-5	3

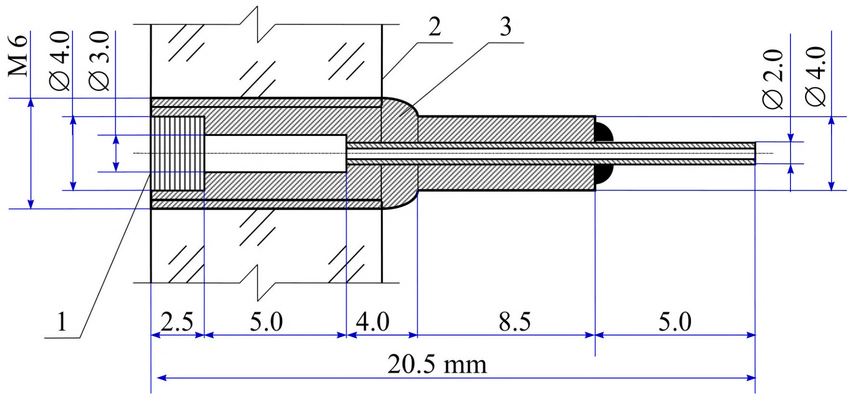

Figure 3. Construction of the piezometer: 1 – the receiving part is protected by a filter fabric; 2 – the wall of the filtration model; 3 – the piezometer body.

At the Darcy's facility, piezometers were mounted on the lateral surface along a screw line, allowing for the averaging of the influence of soil compaction heterogeneity uniformly across the height. The step along the height was 5 cm, with a displacement angle of 30^0 degrees (figure 2, position 1).

Filtration rate was determined using a volumetric method. The water volume was measured with a measuring cylinder of 10 liters capacity for flow rates (Q) greater than 50 cm^3/s, 1-liter graduated cylinders for $Q = 25...50\, cm^3/s$, 0.5 liters for $Q = 5...25\, cm^3/s$, and 0.1 liters for $Q < 5\, cm^3/s$. The filling time of the measuring vessels was measured with a stopwatch with an accuracy of 0.1 s. The water temperature during the experiments was monitored using a mercury thermometer with a division of $0.5\,^0C$.

2.4. Planning and methodology of experiments

Experiments at the Darcy's facility were conducted according to the developed experimental design matrix. The boundary levels and intervals of the investigated factors were established based on prior information obtained from literature sources and hydraulic practice. To compensate for the impact of random errors, simplify mathematical processing, and enhance the accuracy of experimental data, tests were conducted with a uniform triple replication of experiments [22].

The range of variation of ΔH_k was divided into $N = 8$ levels – 0.5; 1.0; 1.5; 2.0; 2.5; 3.0; 3.5; and $4.0cm$. Table 4 provides the experimental plan and the sequence of conducting experiments. The results of the experiments are presented in table 5.

In the table 5 $\overline{V}_j$ – average (arithmetic mean) of the density of the filtration flow; $s_j^2\,(V)\cdot 10^6$ – the average absolute deviation of the experiment; $s_j\,(V)\cdot 10^3$ – standard deviation of the filtration flow.

The methodology for conducting the experiment with non-suffusion sand was as follows.

Table 4. Experiment design matrix with uniform replication.

Number of the experiment	The value ΔH_k, cm							
	0.5	1.0	1.5	2.0	2.5	3.0	3.5	4.0

4.0	55.8	56.5	57.9	56.73	1.14	1.07
					$\sum 31.19$	$\sum 13.43$

Fixed levels (head) were set using movable special water overflow with micrometric screws. After stabilizing the piezometer readings (25-30 minutes), the flow was measured three times with subsequent averaging. To eliminate the influence of uncontrolled boundary effects, the hydraulic conductivity was determined for the middle layer of soil with a thickness of 12 cm. Then, the effective head was increased, and similar measurements were taken under steady conditions. After reaching the maximum head specified by the planning matrix (table 5), the changes were made in the direction of reduction. Water passed through the soil from top to bottom (downward filtration – the direction of filtration force coincides with the direction of the force from the weight of the soil). The temperature of the water was monitored at the beginning and end of each experiment. The methodology for conducting the experiment with suffusion sand is similar. The difference lies in determining the change in the hydraulic conductivity over time for the entire soil fill. After reaching the maximum head specified by the planning matrix and conducting the corresponding measurements, the experiment was completed. The quantity of suffusion particles was controlled layer by layer at the beginning and end of each experiment by determining the particle size distribution of the soil [17].

2.5. Processing of research results

In processing the research results and their generalization, methods of mathematical statistics were used: variance and regression analyses, least squares methods, interpolation, and extrapolation [23–25].

The choice of the experimental area was made based on the density of the filtration flow, which was determined by the formula

$$V = Q/S, \tag{3}$$

where Q – is the filtration rate and S – is the cross-sectional area.

The density of the filtration flow V varied from 0 to 0.064 cm/s for experimental soil No. 3 with a soil fill thickness of 60 cm. Through methodical investigations, the maximum value of head loss H_k on the drainage structure being modeled was determined. The value of H_k was found using the (3):

$$\Delta H_k = \Delta H - \Delta H_0 = \Delta H - V\frac{b_{sf}}{k_0}, \tag{4}$$

where ΔH_k – is the experimental head difference, b_{sf} – is the thickness of the soil fill, k_0 is the soil hydraulic conductivity, determined directly from the experiment at small values of hydraulic gradients.

3. Results and discussion

The void space of granular soils is considered by researchers as a system of deformed tubes, namely capillaries [4, 7, 14, 16, 26]. It is known that laminar flow in capillaries of any Newtonian fluid, including water, follows the Hagen-Poiseuille law, according to which the flow rate is directly proportional to the hydraulic gradient. Therefore, considering non-deformable soil, for the conditions of experiments on the Darcy's facility, we can express it as

$$V = k_0\frac{\Delta H}{L}, \tag{5}$$

where V – is the filtration velocity (which can be regarded as the density of the soil flow [3]); k_0 – is the soil hydraulic conductivity; ΔH – is the pressure difference at the boundary surfaces; L – is the length of the sample of soil.

If the test soil is homogeneous and does not change its properties (cemented sands, solid-porous materials, etc.), the hydraulic conductivity can be determined from (5), the pressure distribution function $h(z)$ is linear, and the density of the soil flow V will increase directly proportional to the increase in pressure difference ΔH.

However, if there is a uniform change in the hydraulic conductivity k throughout the soil under the influence of pressure gradients, the linearity of the function $V(\Delta H)$ is disrupted. In the case of non-uniform changes in k across the filtration area, the linearity of the function $h(z)$ is also disrupted. In this scenario, the Darcy's law can be applied in the form:

$$V = -k\left(I_d\right)\frac{dh}{dz}, \tag{6}$$

where $k\left(I_d\right)$ – is the hydraulic conductivity, which depends on the value of the effective gradient at which deformation processes occur; $h = h(z)$ – is the head function; z – is the coordinate that coincides with the direction of filtration (figure 2).

At the same time, a check was carried out on the water flow regime for all soils. According to various recommendations [3, 27–29], the critical velocity $V_k r$ was determined, and for all test soils, it exceeded the velocity in the experimental facility V_d. In other words, in the experiments, the limit of laminar flow was not exceeded.

Based on the results of laboratory filtration studies in different soils using Darcy's facility, it was established that hydraulic gradients influence the soil hydraulic conductivity, and the linear dependence of $V(\Delta H)$ is disrupted. The hydraulic conductivity is affected both by the overall increase in hydraulic gradients, determined by the pressure difference in the experiments, and their local variation, which can be caused by the resistance of the filtration flow to the supporting grid. Therefore, for further research, we present the values of the hydraulic conductivity k determined for the layer $z = 15...27$ cm, where there is no influence of perforation, in table 6. Figure 4 shows the data processing results of 3 series of experiments on the Darcy's facility with soil No. 10, a fill height of 27 cm, and downward filtration.

The functional relationship $k = k\left(I_d\right)$ will be sought in the form

$$k = k_0\left(1 + b_f I_d\right), \tag{7}$$

Using the least squares method, the unknown equation parameters were calculated, which for soil model No. 10 are $k_0 = 0.85\,\text{cm/s}$, $b_i = -0.28$. With the known values of k_0 and b_i, points were calculated using (7) and plotted on the graph (figure 4, position 3). They correspond to the gradients of experimental points 2, with a correlation coefficient $R^2 = 0.964$.

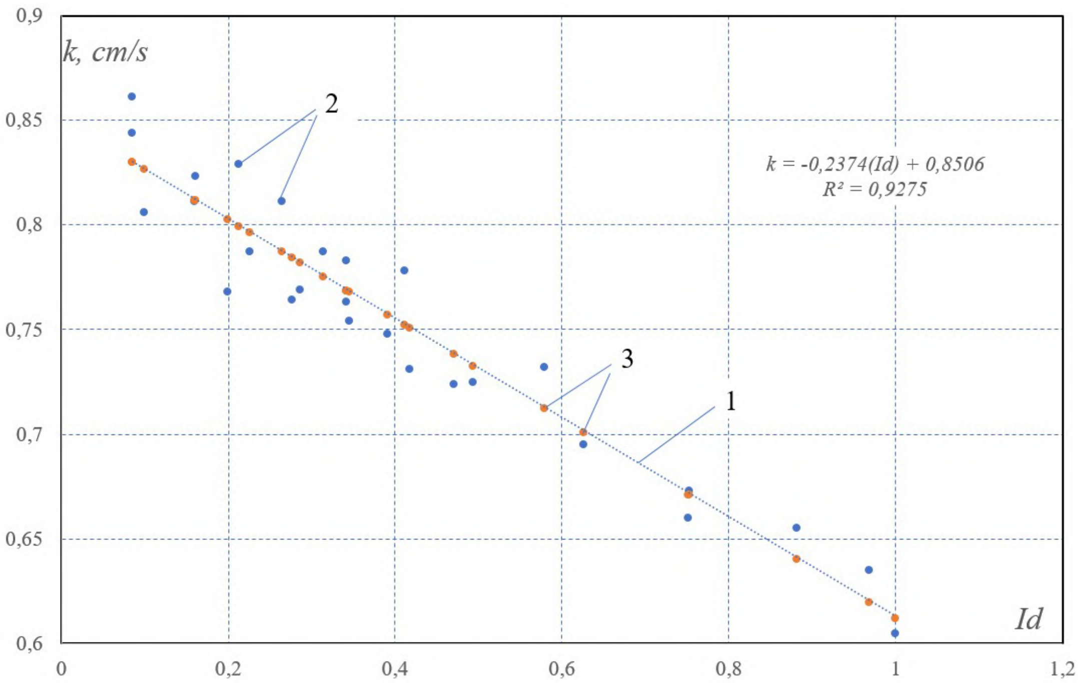

Figure 4. Graphs of the dependence $k = k\,(I_d)$ for soil model No. 10: 1 – theoretical line; 2 – experimental points, 3 – calculated points using (7).

Therefore, for soil No. 10, the average hydraulic conductivity is described by the relationship $k = k_0(1 - 0.28I_d)$, where $k_0 = 0.85$ cm/s. If we substitute the values of $k(I_d)$ into equation (6), we get

$$V = k_0 I_d(1 - 0.28I_d). \tag{8}$$

Figure 5 depicts the graph of the dependence $V(I_d)$ constructed according to (6) – line 1.

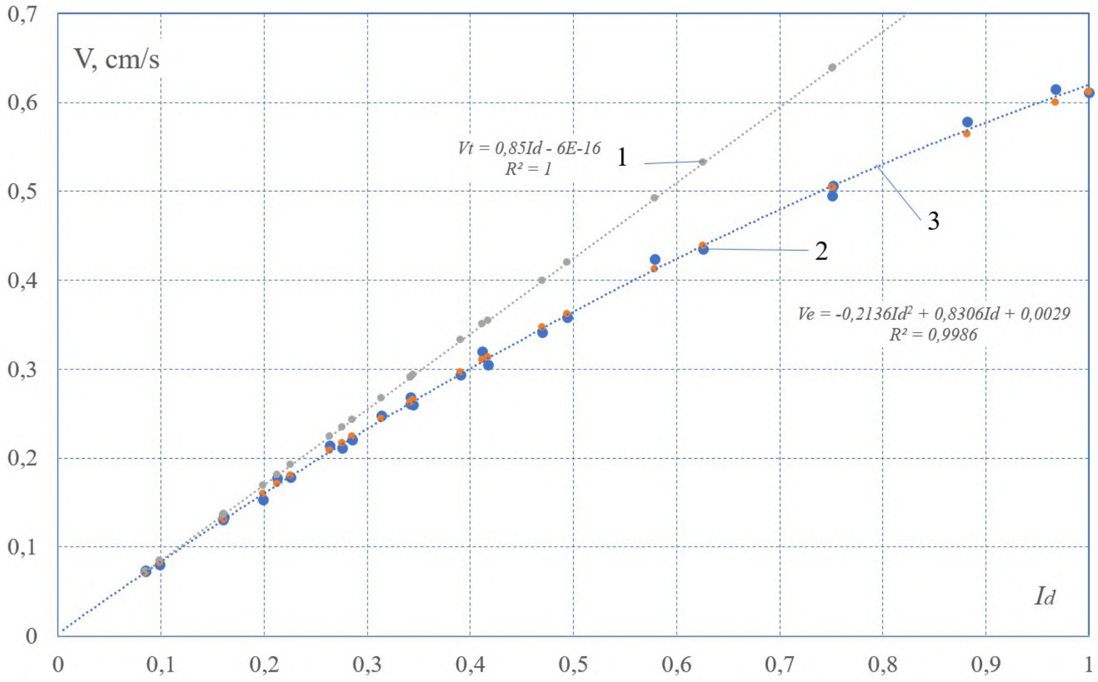

Figure 5. Graphs of $V = V(I_d)$ for soil model No. 10: 1 – theoretical curve, $V = k_0 I_d$; 2 – experimental points; 3 – function $V(I_d)$ according to (8) with $k = k_0 = const$.

Adequacy of the theoretical curve to the experimental points 2 (figure 5) is confirmed by the Fisher criterion. From the graphs (figure 5), it can be seen that when the hydraulic conductivity of soil remains constant $k = k_0$ (assuming no deformations occur), the function $V(I)$ is linear. However, in the presence of deformations, which indeed occur, it becomes nonlinear.

Let's present the results of experiments on the Darcy's facility with soil model No. 6, where the hydraulic conductivity of soil increases with the growth of effective hydraulic gradients. The results of these experiments, conducted according to the conditions in table 3 and where the hydraulic conductivity was determined for the soil layer without the influence of the supporting grid, are shown in figure 6.

Comparing the average values of the hydraulic conductivity $\overline{k_j}$, determined at different effective gradients I_d, allows us to identify the significant changes in the hydraulic conductivity at specific I_d values. The calculation results are presented in table 7, where $\overline{k}$ – represents the average value of $\overline{k_j}$ for the corresponding range of gradient variation.

As we can see from table 7, the soil hydraulic conductivity intensively increases with the elevation of gradients up to a certain value, equal to the experiment for soil model No. 6 $I_d = 2.0$. Further increase in I_d practically does not affect k. This implies that under the influence of the hydraulic gradient, there is a gradual reorientation of particles leading to an increase in the hydraulic conductivity in the direction of the filtration flow. Upon reaching a critical value of gradients (for this case $I_{cr} = 2.0$), particle reorientation has reached its limit, so further increase in I_d does not lead to a change in k. In the range of effective gradients from $I_d = 0$ to $I_d = I_{cr}$, the change in the hydraulic conductivity can be described by (7). Based on the research results, $k_0 = 0.015$ cm/s, $\Delta k_0 = \pm 0.003$ cm/s, $b_f = 0.22$, $\Delta b_f = \pm 0.04$ are determined, and the adequacy of (7) to experimental data with these hydraulic conductivity values is confirmed by the Fisher criterion (calculated value $F_c = 1.72$ is less than the tabulated $F_t = 2.70$ at a 5% significance level).

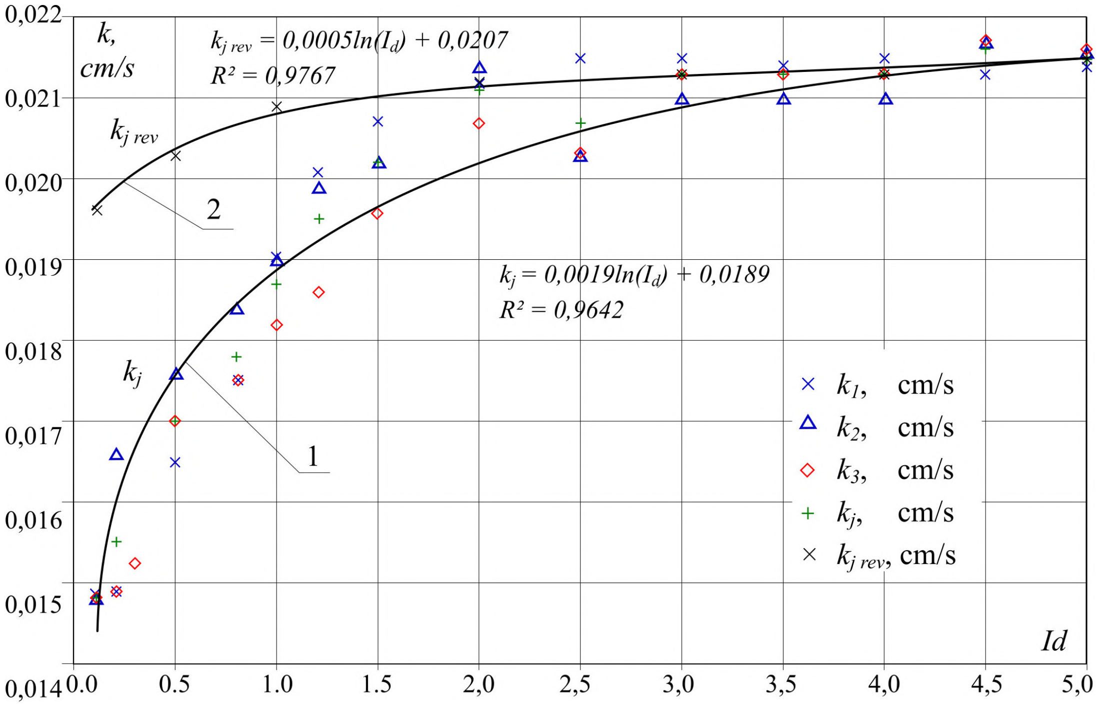

Figure 6. Results of the investigation of the hydraulic conductivity of soil model No. 7 under gradually increasing (pos. 1) and decreasing (pos. 2) gradients.

Table 7. Results of statistical calculations for the average values of the hydraulic conductivity for non-suffosive soil No. 6.

I_d	N	$\overline{k_j}$, cm/s	$\bar{k}$, cm/s	f	s^2, (cm/s)^2	$\overline{s^2}$, (cm/s)^2	F_c	F_t	Conclusions
0.1–2.0	8	0.0148 0.0155 0.0170 0.0178 0.0187 0.0195 0.0202 0.0211	0.0181	16	3.55×10^{-7}	1.49×10^{-5}	41.9	2.7	The changes are significant
2.0–5.0	7	0.0211 0.0207 0.0213 0.0213 0.0213 0.0215 0.0216	0.0213	14	1.24×10^{-7}	2.59×10^{-7}	2.1	2.9	The changes are not significant

For this particular case, when there is actually an upper critical gradient at which deformations cease (unlike the traditional critical value where deformations displacement of colloidal particles begin), it is expedient to express (7) in the form:

$$k(I_d) = k_2(1 + b_f(I_d - I_{cr})), \quad 0 < I_d < I_{cr}, \tag{9}$$

where k_2 – is the stabilized value of the soil hydraulic conductivity for $I_d > I_{cr}$; b_f =

$(k_2 - k_0)/I_{cr}$ – is the coefficient characterizing the intensity of the soil hydraulic conductivity change in the soil with a change in the effective hydraulic gradient.

After reaching the maximum gradient, according to the experimental design matrix, there was a gradual stepwise decrease. The average values of the soil hydraulic conductivity for this case are presented in figure 6, item $k_{j\,rev}$, curve 2.

4. Conclusions

- During the research, it was established that deformation processes occur in the soil around drains, significantly affecting filtration rates.
- It was found that the variation in the soil hydraulic conductivity is influenced by the magnitude of the hydraulic gradient. The hydraulic conductivity increases with an increase in the hydraulic gradient (soil model No. 6), and upon exceeding a certain value of the gradient (for soil model No. 6, $I_{\mathrm{cr}} = 2.0$), soil particles attain a stable position, and deformation processes practically cease (figure 6).
- When reducing hydraulic gradients from maximum values to $I_{\mathrm{cr\ rev}} < I_{\mathrm{cr}}$ (for soil model No. 6, $I_{\mathrm{cr\ rev}} = 1.5$), the soil hydraulic conductivity remains constant. With further reduction, it starts to decrease but does not return to its initial value, exceeding k_0 by 32% at $I_d \to 0$. This indicates that deformations in the soil are irreversible.
- In the course of the research, it was revealed that the major soil deformations occur in the lower zone of the Darcy's facility, i.e., above the filtration device (item 2, 3, figure 2). This zone, due to soil deformations caused by the suffusion processes, has become significantly different from the soil above it. Therefore, in further investigations, we will more closely examine this zone and, overall, the distribution of changes resulting from suffusion and colmatage in soils along the height.

Abstract. In this publication, the authors consider the influence of high temperatures on the change in the intensity of the gloss of the front surface of products made of acidic and basic rocks of natural stone. Changes in gloss intensity were analyzed for each of the control points of heating for the front surface of samples of acidic and basic rocks of natural stone. The main factors affecting the change in the intensity of the gloss of the front surface of products made of acidic and basic natural stone are determined. It has been established that when heated (exposure to high temperatures), acidic rocks of natural stone lose their luster less intensively than rocks with a basic composition. The greatest loss of luster upon heating (exposure to high temperatures) is characteristic of labradorite. On the basis of the obtained values, it is possible to predict the change in the intensity of the gloss of the front polished surface of products from basic and acidic natural stone after exposure to high temperatures, as well as to control the quality of the front surface of natural stone products to obtain products with specified parameters for restoration or restoration work.

1. Introduction

Natural facing and decorative stone today is recognized as a high-quality and durable natural building material widely used for decorative purposes in the embellishment of many buildings and structures. Therefore, in addition to its physical and mechanical indicators, its aesthetic and decorative characteristics play a crucial role in selecting its application locations.

The decorative features of natural stone are determined by such factors as color, pattern texture, structure, translucency, and the degree of surface polishing, precisely defined by the gloss intensity indicator [1, 2].

Various aggressive environmental factors affect the facing surface of products made from natural stone, leading to changes in their decorative and aesthetic properties. One such factor is high temperatures, resulting from fires caused by both human activities and aggression from the Russian Federation. Hence, it is essential to predict how the decorative properties of the facing surface of products made from natural stone will change and accordingly develop recommendations for the use of different varieties of natural stone, as well as restoration guidelines.

Furthermore, the research has practical implications. Firstly, based on the obtained values, it is possible to predict changes in the intensity of gloss on the facing polished surface of products made from basic and acidic varieties of natural stone after exposure to high temperatures.

Secondly, scientifically grounded recommendations can be developed for quality control of the facing surface of products made from natural stone to achieve products with specified parameters for restoration or repair work.

2. Related work

A considerable number of publications have been dedicated to studying the impact of high temperatures on the facing surface of natural stone. For instance, in the study [3], a methodology is described that allows for the control of iron oxidation intensity in products made from labradorite using temperature values. The findings of this research enable the development of a comprehensive set of recommendations for modifying the aesthetic and decorative characteristics of labradorite products. However, these studies primarily focus on color changes and the analysis of the appearance of defects such as red and brown spots [4–13], with little consideration given to the alteration of gloss intensity during these processes.

Most of the preceding research involved heating samples to specified temperature levels, followed by testing them at room temperature. Studies on testing granites [4, 5], limestones, marbles, and gabbros [6, 7] indicate that at temperatures up to 300 °C, stone samples undergo minimal damage. However, in the temperature range of 400–600 °C, microstructural changes and irreversible thermally induced microcracks occur due to differential thermal expansion of minerals. In labradorites, microcracks between minerals are visually observed at a temperature of 600 °C. Nevertheless, less attention has been given to determining the intensity of gloss change on the facing surface of natural stone under the influence of high temperatures.

3. Results

The objective of this research was to establish the fundamental dependencies characterizing the change in gloss intensity of the polished surface of acidic and basic variants of natural stone samples based on the intensity of their heating. Measurement of the reflective (gloss intensity) capability of the polished surface is based on comparing the obtained values with a gloss meter against the benchmark of an etalon surface. Gloss intensity depends on the mineral composition of different variants of natural stone, the processing methods, and changes under the influence of aggressive external factors. To establish the fundamental dependencies characterizing the change in gloss intensity of the polished surface of acidic and basic variants of natural stone samples based on the intensity of their heating, 20 samples were selected from four natural stone deposits (5 samples from each deposit).

The chosen samples include acidic variants from the Leznikivsky and Maslavsky granite deposits and basic variants from the Katerinivsky labradorite and Irshynsky gabbro deposits. The sample dimensions were 15x15 cm.

The polishing process was carried out on a column-lever machine using diamond tools. Gloss was measured with a photometric gloss meter BF5-45/0/45. Heating was performed in an electric furnace at a rate of 1°C/min. The samples were held at temperatures of 200, 400, 600, and 800 °C for one hour, followed by cooling to 20 °C at a rate of 1 °C/min. Before measuring gloss, the device was calibrated on a black-colored sample included with the instrument, having a gloss value of 97 units. Gloss was measured at five points on each natural stone sample, and measurements were conducted for five samples from each deposit. The obtained results were averaged.

Upon analyzing the data on the initial gloss measurements (zero point) in control samples, it was found that the highest gloss value is present on the polished surface of samples from the Irshynsky gabbro deposit, while the lowest gloss value is observed on samples from the Leznikivsky granite deposit (figure 1).

After measuring and statistically processing the measurement data, graphical dependencies were obtained, characterizing the change in the intensity of gloss on the polished surface of acidic

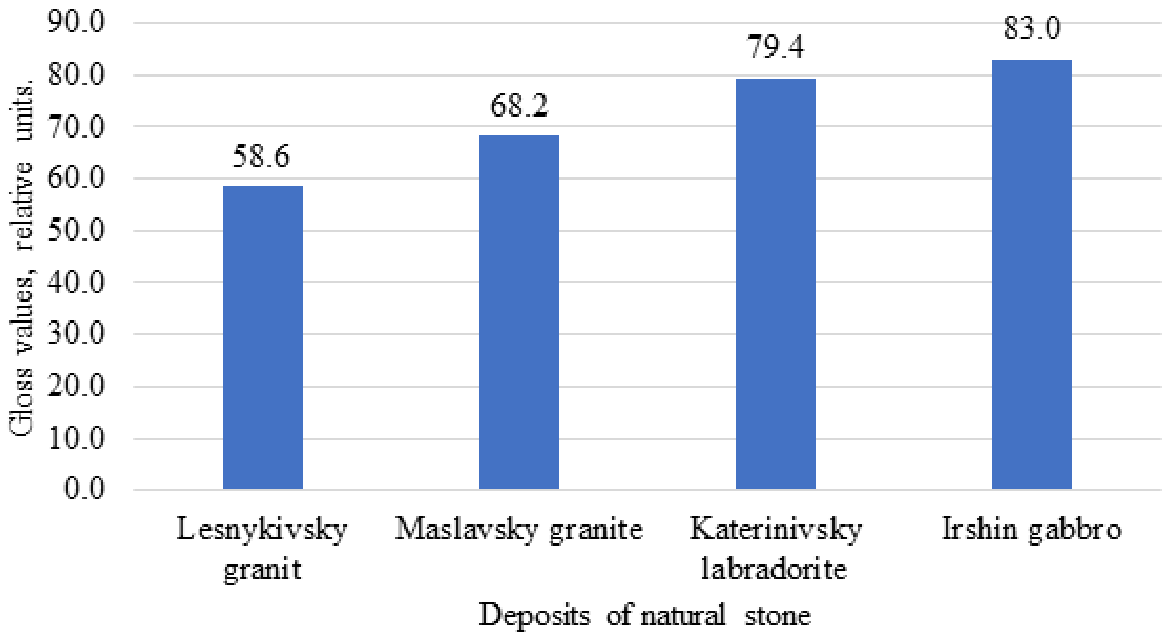

Figure 1. The gloss values of polished facing surfaces of samples of natural stone that have not been subjected to heating (zero point).

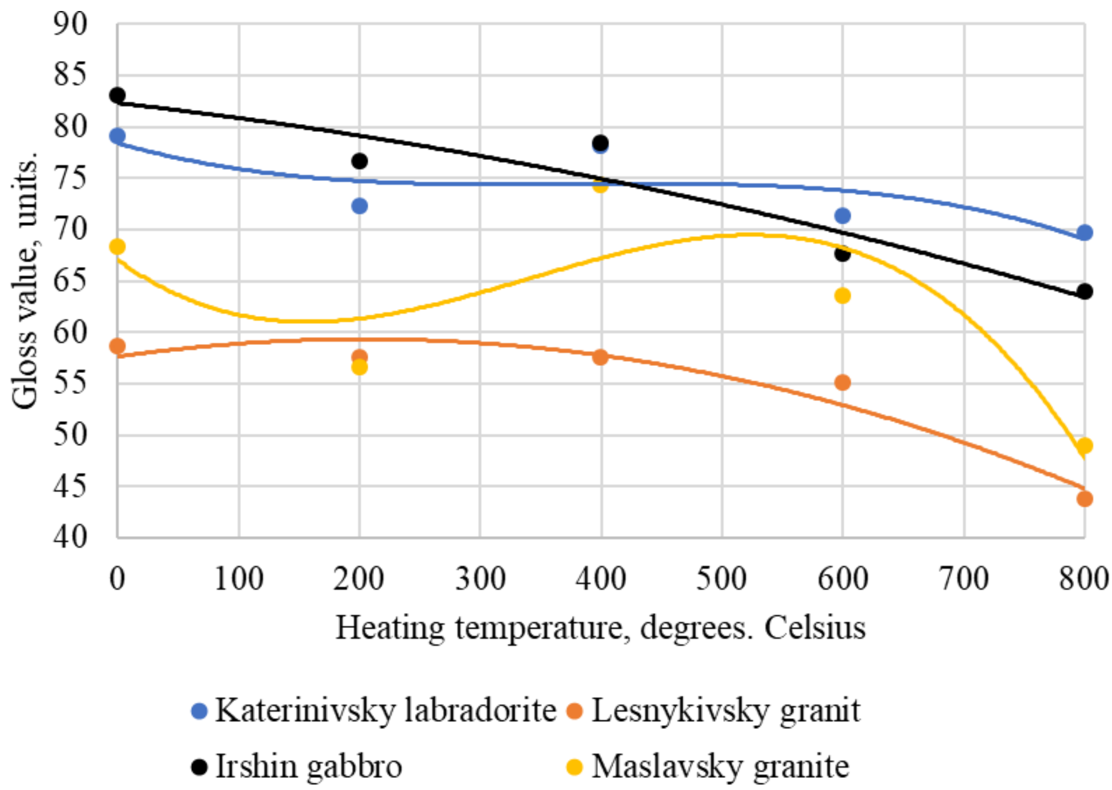

Figure 2. The dependence of the change in shine of the polished surface of natural stone on the heating temperature.

and basic types of natural stone samples depending on the intensity of their heating (figure 2).

The analytically derived relationships are described by polynomial dependencies of the 2nd and 3rd order.

Leznakyivsky granite:

$$S = -4 \times 10^{-5}t^2 + 0.0166t + 57.64, \quad (1)$$

where S is the surface luster value of the natural stone, unitless; t is the temperature of heating the natural stone, degrees Celsius.

Maslavsky granite:

$$S = -3 \times 10^{-7}t^3 + 0.0004t^2 + 0.0851t + 67.045. \quad (2)$$

Katerinivsky labradorite:

$$S = -8 \times 10^{-8}t^3 + 9 \times 10^{-5}t^2 + 0.033t + 78.389. \quad (3)$$

Irshynske gabbro:

$$S = -1 \times 10^{-5}t^2 + 0.0133t + 82.31. \quad (4)$$

During the investigation of the luster of polished surfaces of Labradorite samples, it was observed that at a temperature of 200 °C, there is a decrease in luster values in samples from the Katerynivske deposit of Labradorite (figure 2). At a temperature of 400 °C, there is an increase in luster values, followed by further decrease, and this process continues until a temperature of 800 °C. A similar trend is observed in samples of Irshynske gabbro.

The decrease in luster values of the polished surface of Labradorite samples at a temperature of 200 °C is explained by the onset of the breakdown of the mineral composition of Labradorite. Heating minerals induces the diffusion of atoms and molecules, leading to a change in their crystalline structure. In Labradorite and gabbro, the main minerals are plagioclase and Labradorite. Upon heating, plagioclases begin to decompose into orthoclase and anorthite. This process is accompanied by the release of free liquid, which disturbs the surface of the sample and reduces its luster.

The increase in luster values at a temperature of 400 °C is explained by the restoration of the crystalline structure of Labradorite. With further heating, the breakdown of the mineral composition continues, leading to a decrease in luster values.

Detailed explanation of each stage:

- 0 °C – Initial state of the sample, the crystalline structure of minerals is not disturbed, high luster.
- 200 °C – Initiation of the breakdown of the mineral composition, liquid is released, disturbing the surface of the sample, luster decreases.
- 400 °C – Restoration of the crystalline structure of minerals, increased luster.
- 600 °C – Continued breakdown of the mineral composition, luster decreases.
- 800 °C – Maximum level of breakdown of the mineral composition, minimal luster.

When heating Leznakyivsky granite to 200 °C, the luster decreased from 58.6 units to 57.5 units. Upon heating to 400 °C, the luster value almost did not change and remained at 57.4 units. Heating the granite samples to 600 °C resulted in a decrease in luster to 55.1 units, and at 800 °C, the luster value became 44 units.

The decrease in luster values of the polished surface of Leznakyivsky granite samples at 200 °C is explained by the initiation of the breakdown of the granite's mineral composition. Heating minerals induces the diffusion of atoms and molecules, leading to a change in their crystalline structure. In granite, the main minerals are feldspar, quartz, biotite, and amphibole.

Upon heating, feldspar begins to decompose into orthoclase and anorthite. This process is accompanied by the release of free liquid, which disturbs the surface of the sample and reduces its luster.

The almost unchanged luster value at 400 °C (57.4 units) may indicate that at this temperature, chemical and physical changes in the granite do not significantly affect its optical properties.

The decrease in luster at 600 °C (55.1 units) and 800 °C (44 units) may be associated with changes in the crystalline structure of minerals, such as deformation, decomposition, or phase transformation.

It is worth noting separately that Leznakyivsky granite contains a significant amount of feldspar, which is the most heat-resistant mineral. Therefore, the decrease in the granite's luster occurs more slowly than in Labradorite, where the main mineral is plagioclase, which is more prone to breakdown when heated.

When heating Maslavsky granite to 200 °C, the luster decreased from 68.2 units to 56.6 units. Upon further heating to 400 °C, the luster, on the contrary, increased and even exceeded the initial values of the unheated sample, reaching 74 units. With further heating, the luster decreased at 600 °C (63.5 units) and 800 °C (49 units).

The decrease in luster values of the polished surface of Maslavsky granite samples at 200 °C is explained by the initiation of the breakdown of the granite's mineral composition. Heating minerals induces the diffusion of atoms and molecules, leading to a change in their crystalline structure. In granite, the main minerals are microcline, plagioclase, quartz, biotite, and hornblende. Upon heating, microcline begins to decompose into microcline and albite. This process is accompanied by the release of free liquid, which disturbs the surface of the sample and reduces its luster.

The increase in luster values at 400 °C is explained by the restoration of the crystalline structure of granite. At this temperature, there is also some removal of free liquid from the sample surface, contributing to the increase in luster. Crystallization of microcline into more stable forms occurs at this temperature, improving the surface structure of the sample and increasing its luster.

The decrease in luster values at 600 °C and above is explained by further breakdown of the mineral composition of granite. This leads to the destruction of quartz, biotite, and hornblende, resulting in a deterioration of the surface structure of the sample and a decrease in its luster.

In conclusion, the changes in the luster of the polished surface of Maslavsky granite samples during heating can be explained by the following factors:

- Decomposition of microcline into albite and liquid at 200 °C.
- Restoration of the crystalline structure of microcline at 400 °C.
- Crystallization of microcline into more stable forms at 400 °C.
- Breakdown of quartz, biotite, and hornblende at 600 °C and above.

When heating natural stone to 800 °C, the greatest decrease in the luster of the polished surface of natural stone occurred in Irshynske gabbro – 23.7% (figure 3), and the least in Katerinivsky labradorite – 12.1%. Labradorite showed little change in its luster when heated. The average reduction in luster values was observed in Leznakyivsky and Maslavsky granites, at 21.3% and 18.5%, respectively.

The greatest decrease in luster on the polished surface of natural stone when heated to 800 °C in Irshynske gabbro is explained by the fact that the main mineral in gabbro is pyroxene, which is the most susceptible to breakdown when heated. At a temperature of 200 °C, pyroxene begins to melt, and at temperatures of 600 °C and above, it completely breaks down. This leads to a deterioration of the surface structure of the sample and a decrease in its luster.

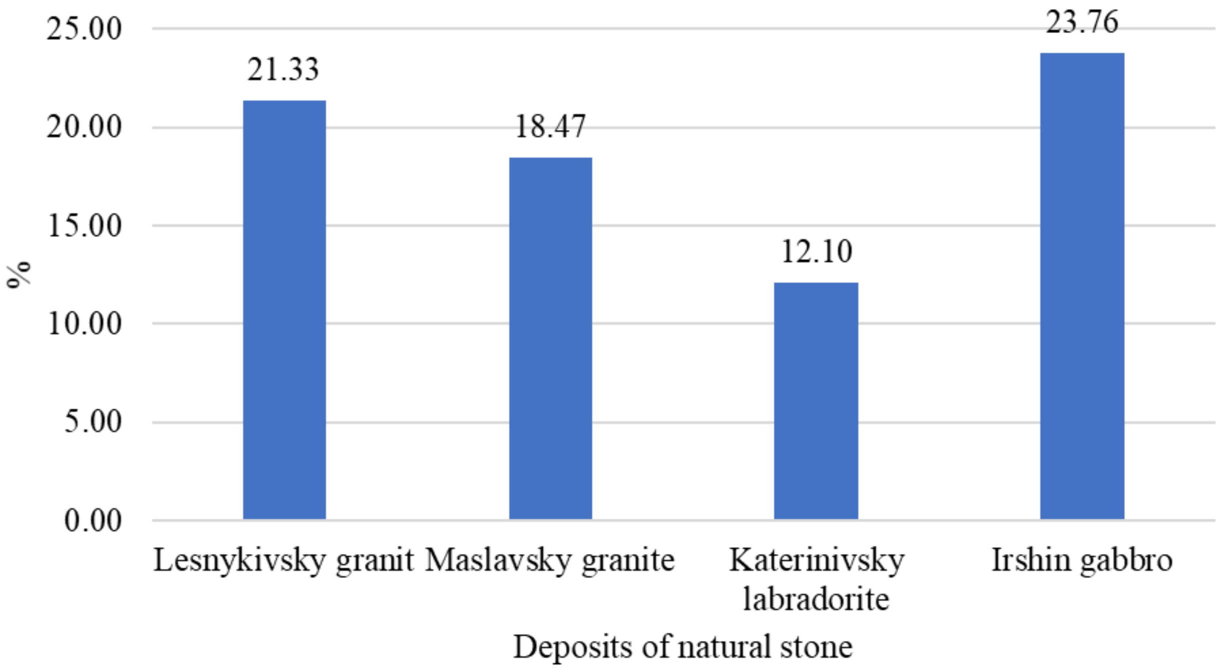

Figure 3. The magnitude of the decrease in the intensity of luster on the polished surface of natural stone after heating to 800 °C.

The least decrease in luster on the polished surface of natural stone when heated to 800 °C in Katerinivsky labradorite can be explained by the fact that the main mineral in labradorite is plagioclase, which is more resistant to heating than pyroxene. At a temperature of 200 °C, plagioclase begins to decompose into feldspar and anorthite, but this process is not accompanied by the release of liquid that would disturb the surface of the sample. At a temperature of 400 °C, there is some restoration of the crystalline structure of plagioclase, which also contributes to the increase in luster.

The average reduction in luster in Lesnykivsky and Maslavsky granites is explained by the fact that these granites primarily consist of feldspar and quartz, which have moderate resistance to heating. At a temperature of 200 °C, feldspar begins to decompose into feldspar and anorthite, while quartz may partially melt. At temperatures of 600 °C and above, the breakdown of quartz and feldspar occurs, leading to a reduction in luster.

During the heating of labradorite under atmospheric pressure, chemical reactions and transformations of the internal structure of minerals take place. The main processes include phase transition and oxidation of minerals, especially those containing iron. For example, in study [5], changes in the physical characteristics of granite under the influence of temperature due to the phase transition of quartz, which occurs at 573 °C under atmospheric pressure, are discussed. Unlike granite, labradorite does not contain quartz, so the oxidation of Fe in pyroxenes is the main source of changes in the physical and mechanical properties of labradorites at temperatures above 600 °C. Microscopic studies [3] confirm that high temperatures promote oxidation of gabbro specimens. It turns out that 600 °C is a threshold for the onset of mineral oxidation under atmospheric pressure, starting with a thin coating around pyroxenes.

With increasing temperature, oxidation develops on other crystals. At a temperature of about 800 °C, minerals containing $Fe2+$ inclusions undergo oxidation. Oxidized plagioclases appear as reddish spots on the surface. Gabbro and labradorites are among the primary rocks and contain 55–98% plagioclase. Therefore, similar processes are observed in labradorite specimens during heating. However, studies show that the oxidation of minerals, visually observed on all labradorite specimens, begins at a temperature of 300 °C.

4. Conclusion

The decrease in the luster indices of the polished surface of labradorite specimens at a temperature of 200 °C is explained by the initiation of the breakdown of the mineral composition of labradorite.

The increase in luster indices at a temperature of 400 °C is explained by the restoration of the crystalline structure of natural stone specimens.

The decrease in luster at 600 °C (55.1 units) and 800 °C (44 units) may be associated with changes in the crystalline structure of minerals, such as deformation, decomposition, or phase transformation.

The most significant reduction in luster of the polished surface of natural stone at 800 °C in Irshynsky gabbro is explained by the fact that the primary mineral in gabbro is pyroxene, which is the most susceptible to degradation when heated.

The least reduction in luster of the polished surface of natural stone at 800 °C in Katerynivsky labradorite can be explained by the fact that the primary mineral in labradorite is plagioclase, which is more resistant to heating than pyroxene.

At a temperature of about 800 °C, minerals containing $Fe2+$ inclusions undergo oxidation. Oxidized plagioclases appear as reddish spots on the surface. Gabbro and labradorites are among the primary rocks and contain 55–98% plagioclase. Therefore, similar processes are observed in labradorite specimens during heating. However, studies show that the oxidation of minerals, visually observed on all labradorite specimens, begins at a temperature of 300 °C.

Based on the obtained values, it is possible to predict changes in the luster intensity of the polished front surface of products made of basic and acidic natural stone after exposure to high temperatures. It also enables quality control of the front surface of natural stone products to obtain products with specified parameters for restoration or refurbishment works.

Abstract. The article highlights the importance of protection and preservation of small rivers in the conditions of global urbanization, in the context of the study of the aesthetic value of the territory within urban and suburban landscapes. Since the preservation of small rivers is the primary goal for ensuring quality ecosystem services for the purpose of: recreation, functioning of the hydro-complex of the urban system, aesthetic purposes, such a study will allow to identify, at the initial stage, areas that have been significantly changed as a result of anthropogenic activity. One of the approaches to such a study is the assessment of the indicator of visual quality of the environment, which is the result of the summation of visual effects (visual pollution) inherent in urbanized areas within the shoreline of small watercourses. The study was conducted on the example of the small rivers Radchanka and Mlynivka within the limits of the Ivano-Frankivsk urban united territorial community. The main focus of the research was on identifying objects and factors that create visual pollution, according to 30 main criteria based on the proposed methodology, taking into account the elements of expert evaluation. To determine the contribution of each of the three groups of evaluated criteria – natural objects, anthropogenic and man-made objects, physiognomic characteristics of the territory, the method of calculating the relative indicator of the visual quality of the environment was applied. The result of the assessment was the identification of areas with high aesthetic value and areas that need to be restored to preserve natural aesthetic and ecological functions. The article contains proposals and solutions that can be recommended to communities to improve the visual quality of the territories within the shoreline of the mentioned watercourses.

1. Introduction

The protection and preservation of small watercourses is actualized in connection with global climate changes on a planetary scale. For Ukraine, in the conditions of war, such a task is complicated not only by the issues of revitalization and protection of rivers, but also by those issues that urgently arise before territorial communities in connection with the rapid pace of urbanization of territories that were not directly affected by military actions.

In such realities, urban planning solutions must be balanced in such a way that the natural conditions of the territories, in particular within the coastal lines of watercourses, are as close as possible to the original state, and natural river landscapes can provide aesthetic and ecological functions, within the limits of possible ecosystem services [1].

Among the scientific community in the field of environmental economics, urban planning, and experts in environmental protection, scientific research in the field of the potential of ecosystem services of small watercourses, rivers, and streams is being updated. Ecosystem services are defined as a set of functions and resources of ecosystems that ensure the preservation of the environment, create conditions for maintaining and improving human life.

Such an approach leads us away from the strict implementation of engineering and technical solutions and control of physico-chemical parameters of surface waters to a multifunctional approach, which aims to restore and preserve the river ecosystem, in particular, its aesthetic and ecological features and functions.

In order to increase the importance of protection and preservation of small rivers in the conditions of global urbanization, it is necessary to study the aesthetic value of the territory, one of the approaches to such a study is the assessment of the indicator of visual quality of the environment. This study reveals the importance of ecosystem services of small rivers and watercourses within urban and suburban landscapes.

2. Literature analysis and problem statement

In the Law of Ukraine "On the Nature Reserve Fund of Ukraine", Chapter 1, Art. 6 [2], the need to protect territories and objects of special aesthetic value, in addition to ecological or scientific value, is clearly highlighted. Instead, within urbanized territories, the Law of Ukraine "On the Improvement of Settlements" [3] Article 22 defines the need to improve the aesthetic appearance of the territories of cities or towns.

The legislation of Ukraine has a number of by-laws that determine the quality of the urban environment in terms of visual pollution and visual quality of the environment, in particular, DBN B.2.2-12:2019, DBN B.2.2-5:2011 with amendments, DBN B.2.2-41: 2019, DSP 173-96 with changes, DSP-145, where the need to apply planning decisions in harmony with natural landscapes and selection of dominant natural objects is indicated.

In the context of our research, the requirement prescribed in DBN B.2.4-3:2010, which determines the need to apply aesthetic requirements to structures located on the banks of watercourses in populated areas, is important [4].

There is significant progress in the scientific analysis of methodical approaches to solving the issue of assessing the aesthetic value of natural landscapes/complexes. In our opinion, approaches based on the methodology of Eringis and Budryunas [5] are extremely valuable, as well as Wöbse [6] and Kane [7].

In the studies [8–12] has accumulated sufficient theoretical and methodological experience for conducting such studies, which can be used to justify granting the status of a protected (reserved) territory depending on the aesthetic value and visual quality. Today, especially in conditions of altered natural landscapes as a result of military operations, such a value is extremely important.

The evaluation of the visual quality of the urbanized environment has a number of developments in the works [13–17], where various methods are applied, from surveying local residents to calculating coefficient of video-ecological receptivity of the territory. The assessment of the visual environment has already been carried out for some cities of Ukraine, in particular Lutsk, Rivne, Vinnytsia, Ivano-Frankivsk, Kharkiv, Dnipro, some districts of Kyiv [18–22].

From the analysis of the publications, we can see that the majority of research is focused either on the assessment of the visual (aesthetic) quality of natural landscapes or only on rural areas complicated by urbanization. Therefore, the question arises of the need to apply such an assessment for the suburban territory, which has aspects of both a natural and territorial complex, and an urban development of urban settlements with transport junctions, elements of improvement and engineering and technical construction solutions.

3. Purpose and objectives of the study

The purpose of the study was to assess the visual impacts inherent in urbanized areas within the shoreline of small watercourses, using the example of the small rivers Radchanka and Mlynivka within the limits of the Ivano-Frankivsk urban united territorial community. Since the preservation of small rivers within cities is the primary goal for ensuring quality ecosystem services for the purpose of: recreation, functioning of the urban water complex, aesthetic purposes, such an assessment will allow identifying, at the initial stage of research, areas that have been significantly changed due to anthropogenic activity and areas, where natural factors do not have a sufficient compensatory effect.

The authors of the study set the following tasks:

(i) Conduct an assessment of visual impacts in the urbanized area within the coastal line of small water streams, using the example of the small rivers Radchanka and Mlynivka within the Ivano-Frankivsk city united territorial community.

(ii) Identify, at the primary stage of the studies, areas that are significantly altered due to anthropogenic activity and areas where natural factors do not have sufficient compensatory impact, namely objects and factors that create visual pollution within the natural coastal line of the watercourse ecosystems.

(iii) Determine which groups of criteria (included in the list of assessment methodologies) have the most significant contribution to the visual quality indicator of the environment of Radchanka river and Mlynivka river and, accordingly, which zones along the coastal line have the most favorable conditions for restoration and recreation.

(iv) Provide suggestions regarding decisions that can be recommended to the communities for improving the visual quality of the territories within the coastal line of the mentioned small water streams.

4. Research methods

As part of the scientific project “Revival of the aesthetic and ecological functions of small watercourses of the Mlynivka (Stebnytska) and Radchanka rivers on the territory of the Ivano-Frankivsk City United Territorial Community”, an assessment of the visual effects along the shoreline of these watercourses was carried out. The assessment was carried out according to the protected scoring method [22] using the author’s software product “VisualEcoSafety” [23]. The formation of the matrix of points for statistical processing of data by groups of criteria was carried out in the Microsoft Excel environment, the elements of expert assessment were also used, the markings of observation points and images of watercourses were given using remote images in the Google Earth Pro program.

The visual impact evaluation scale contained 30 criteria, for a separate criterion the maximum score was 2 points, respectively, the observation point that is evaluated and is the most naturally and aesthetically attractive can receive 60 points. The gradation of the scale is distributed as follows: 0-20 points – we assess the visual impact as “satisfactory”, 21-40 points – “moderate” impact, 41-60 – visual impact is “acceptable”.

To assess the visual quality of the environment, 15 observation points were determined, which are evenly located on the research territory along the coastline of watercourses (figure 1).

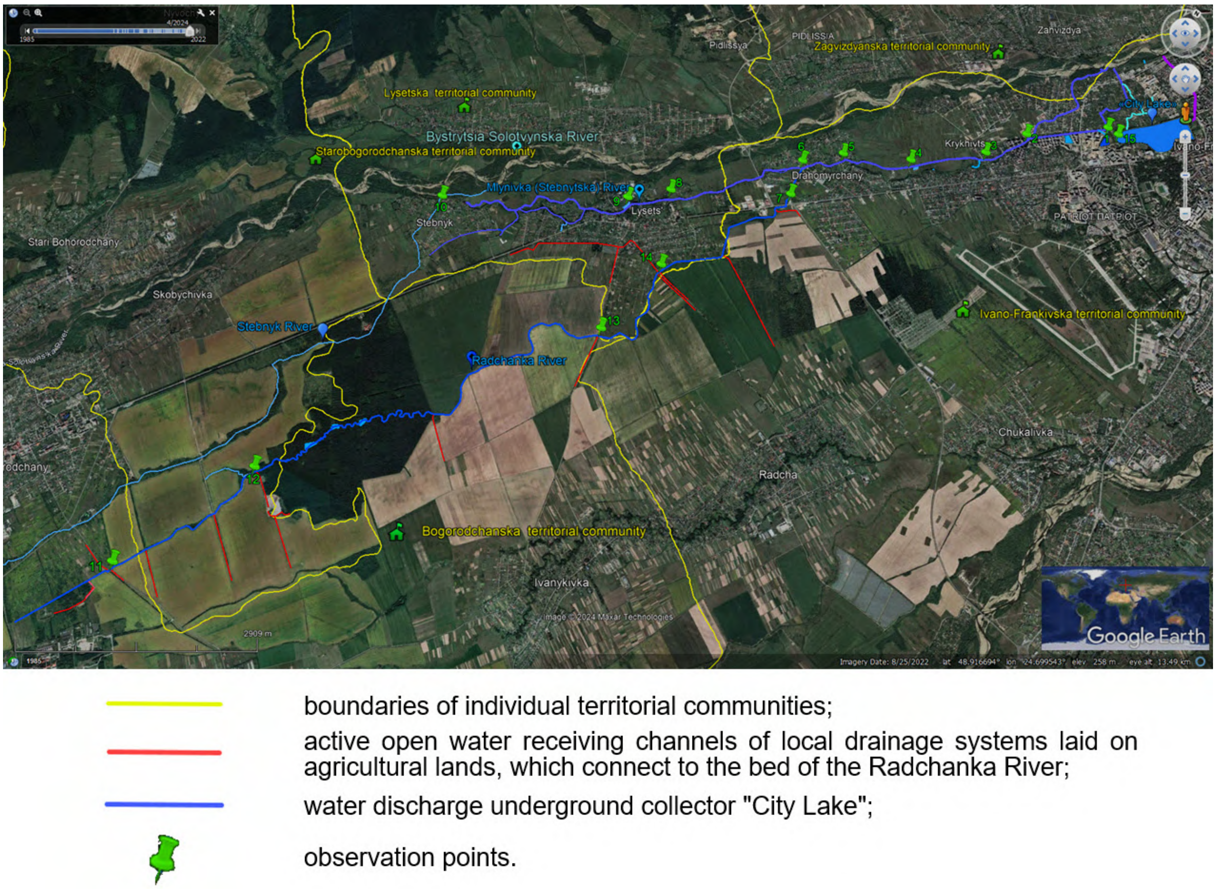

Figure 1. Location of visual impact assessment observation points along the coastline of the Mlynivka and Radchanka rivers.

4 experts were involved in the implementation of the project tasks, who conducted an impact assessment at the research site, this element of the expert assessment was used to avoid subjectivity. In order to obtain the evaluation results, the point evaluation was summed up for each criterion for each point for four experts separately, later the final result was averaged, in case the final score of one of the experts differed significantly (by more than 5 points) from the opinion of other experts, such final score was not the results of three or two experts were taken into account and averaged. The final final score can be identified as an indicator of the visual quality of the environment.

5. Research results

In the conditions of significant urbanization of agricultural areas, development with the creation of residential towns, “grabbing” of green zones and water protection zones of small watercourses for the arrangement of parking lots, expansion of the infrastructure of shopping areas, playgrounds, access roads, public transport stops, gas stations and solid waste storage areas , the use of advertising banners, pulsed lighting sources and electrical engineering objects, cellular communication objects, the visual environment of the city and suburban areas undergoes significant destruction.

We define the visual environment as the entire visible space of the environment perceived by the human eye, which is part of the environment. Accordingly, we consider visual pollution to be such pollution of the surrounding visible environment that distorts its natural (naturalistic) perception. The main elements of pollution include homogeneous and aggressive visual fields, man-made objects, as well as objects that increase elemental and destructive chaotic accumulation: solid waste, construction waste, power lines, lack of landscaping elements, green spaces, solid buildings and lack of open spaces , overpopulation of small areas, as well as the mass of objects that are not inherent in the natural environment. Visual pollution has the greatest negative impact on the state of a person's visual apparatus, nervous system and mental health. The human visual apparatus is significantly affected due to the uniformity of information (homogeneous visual fields) that enters the brain during binocular vision, as there are no dominant, natural and pleasant objects for perception, which in turn leads to discomfort and physiological disorders of visual functions, visual memory.

For example, the presence in the field of vision of the same gray buildings, a darkened environment with insufficient sunlight, in particular due to the closedness of spaces, especially in the non-vegetation period, since the vast majority of tree and shrub vegetation in cities belongs to November, causes a depressed and depressive mood, which identified as autumn or seasonal depression [24].

The overwhelming number of "visual pictures" that we observe outside our own home are advertising banners, gray buildings and an artificial environment that suppresses the emotional state and the nervous system. In particular, in the study [16], it is stated that visual pollution has such consequences for human health as: constant distraction, attention deficit syndrome, eye fatigue, reduction of diversity of thoughts, loss of goals and personal identity, stressogenicity and anxiety due to artificial landscapes, exhaustion, depression, rheumatic diseases, chaotic images reduce the ability of the brain to make clear and balanced decisions, especially in children. Dark, gray, subdued color combinations of the environment change the perception and psychological mood of a person.Currently, modern urban planning is faced with the problem of reducing the number of open green spaces, such as urban green zones and oases, in the form of parks, squares, coastal areas of rivers and lakes, urban botanical gardens, mini green spaces and local vertical gardening. The public and progressive representatives of city improvement departments are acutely concerned about the expansion of such green zones, the creation of green corridors between city districts and remote recreational facilities, the qualitative indicators of the visual environment of which are high. In addition, in the spring and summer, and with climate changes in the autumn periods, the need of citizens for the so-called recreational and rest green areas, which provide maximum visual contact with the natural objects of the environment, increases sharply.

Today, we observe a tendency towards a sharp increase and concentration of citizens in recreation parks and embankments of water bodies, especially on weekends. The recreational load is increasing sharply, accordingly, green areas cannot accommodate such a large number of people, the quality of the visual environment is sharply decreasing due to the excessive number of people.

Also, there is a problem of expanding access to aesthetically attractive natural territories that can provide a recreational function for residents of remote areas of the city, that is, to the possibility of ecological use of local territories in order to reduce the impact of visual pollution on citizens within the urban system, since a comfortable visual environment promotes health a person's health, his work capacity, improving his psychological state.

Since riverbed sections are not only located on the territory of the Ivano-Frankivsk City United Territorial Community, the research was expanded to include settlements located on the lands of Bogorodchanska, Starobogorodchanska, and Lysetska territorial communities. A detailed list of observation points, settlements, object links and coordinates are given in (table 1)
.

Table 1: List of observation points for assessment of the visual quality of the environment

No. of points	Name of the settlement	Street name	Object reference within the observation point	Name of the watercourse	Coordinates of the point
1	city Ivano-Frankivsk	Pryozerna Stefanyka Chornovola Tsentralna O. Girnyka Technical road Ivanikivska Radchanska-Poleva Mazepa	"Ozero" residential complex, sump, water inlet channel	Mlynivka river	48.912006^0 24.682422^0
2	city Ivano-Frankivsk	August 24	"Kalynova Sloboda" settlement, arch, pond	Mlynivka river	48.905830^0 24.669126^0
3	village Krykhivtsi	Vyvizna-Misyachna	Source, bridge	Mlynivka river	48.900705^0 24.663748^0
4	village Krykhivtsi	Sonyachna	"Bagno" tract, bridge made of connected pipes	Mlynivka river	48.894933^0 24.651787^0
5	Dragomyrchany village	Starotserkovna	Source, bridge	Mlynivka river	48.891447^0 24.639832^0
6	Dragomyrchany village	Shkilna-Nadrichna	Bridge, public transport stop	The mouth of the Radchanka River (confluence with the Mlynivka River)	48.887900^0 24.633667^0
7	Dragomyrchany village	Shkilna	Kolyba "Knaipa"	Radchanka river	48.882827^0 24.634903^0
8	Lysets urban-type settlement	Stefanyka	Wooden bridge	Mlynivka river	48.875849^0 24.614591^0
9	Lysets urban-type settlement	Chornovola	Pond on the river, stadium	Mlynivka river	48.872211^0 24.608244^0
10	Stebnyk village	Tsentralna	Object Bridge, Church of the Nativity of the Blessed Virgin Mary	Stebnyk river	48.860692^0 24.577381^0
11	Pohivka village	O. Girnyka	The river passes through a road pipe, agricultural fields, Bohorodchany LFGD in the distance	Radchanka river	48.804330^0 24.566940^0
12	Lands of Staro-Bohorodchansk	Technical road	Mochary tract, landfill, hydraulic fracturing	Radchanka river	48.820868^0 24.577906^0
13	Lysets urban-type settlement	Ivanikivska	Reclamation fields	Radchanka river	48.855331^0 24.617179^0

No. of points	Name of the settlement	Street name	Object reference within the observation point	Name of the watercourse	Coordinates of the point
14	Lysets urban-type settlement	Radchanska-Polova	Bridge near the hospital	Radchanka river	48.866231^0 24.620559^0
15	city Ivano-Frankivsk	Mazepy	City lake, canal outlet to the city lake	City lake	48.911703^0 24.684721^0

The results of the evaluation of the visual effects of the above observation points are distributed as follows (figure 2). Point 12, located on the lands of the Starobogorodchansk Territorial Community, received the lowest visual quality of the environment (figure 3). The territory is designated for a solid waste landfill, contains a gas distribution station, the access roads are complicated and eroded, the designated communications are covered with corrosion, the physiognomic characteristics of the territory are mainly of anthropogenic origin, the visual impact is satisfactory.

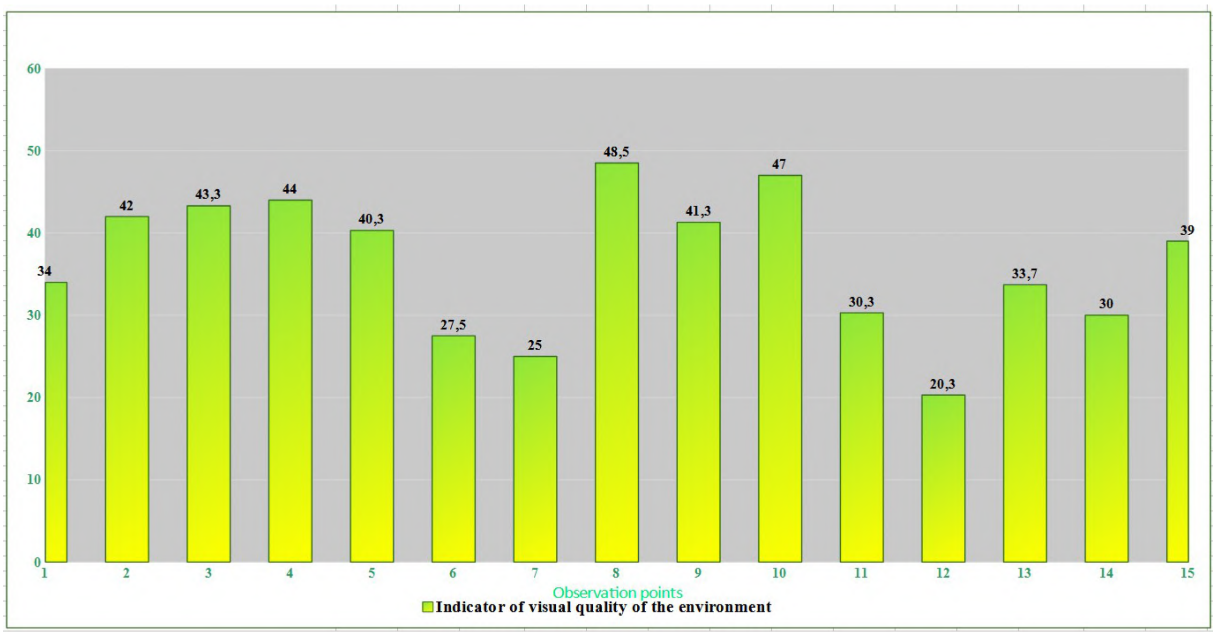

Figure 2. The results of the assessment of the indicator of visual quality of the environment along the coastline of the Mlynivka and Radchanka rivers.

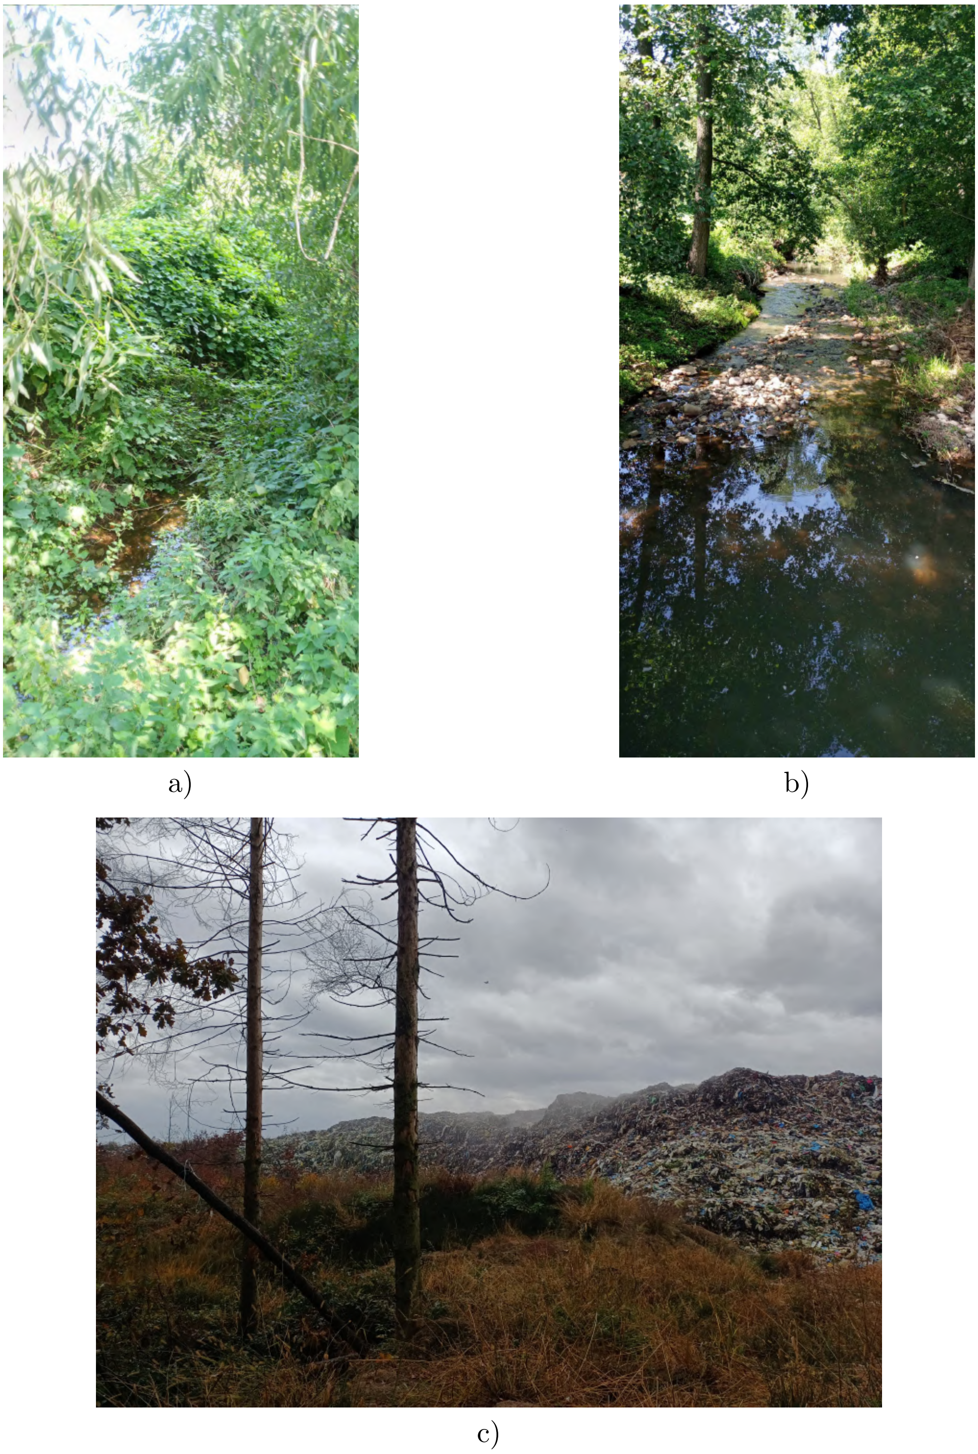
Research points 6 and 7 are located within the village. Dragomyr residents received 27.5 and 25 points, which corresponds to a moderate visual impact. Despite the presence of a small watercourse, the coastline is overloaded with anthropogenic objects – the extreme proximity of an asphalt road to the watercourse, an unfortunate combination of a children's playground and a public transport stop, which can cause lubricants and gasoline to flow into the riverbed during rainy periods, the location of a commercial trailer with external storage of construction materials materials, the location of the bio-toilet opposite the site of the public catering establishment (kolyba), etc.

The highest points of the visual quality of the environment were obtained by 8 and 10 observation points (figure 3), located in the village of Lysets et al. Stem respectively. The extremely high potential for the development of ecological and aesthetic functions of the research area is reflected in the dominant objects in the village. Lysets on the Mlynivka River, the



a) b)

c)

Figure 3. Photo-fixation of observation points with the highest and minimum points of the indicator of visual quality of the environment (a) – 8 observation point, territory of the village. Lysets, Mlynivka River; b) – 10 observation point, territory of the village. Stebnyk, river Stebnyk; c) – 12 observation point, land of Starobogorodchansk Territorial Community, solid waste landfill near the Radchanka River).

natural coastline with its inherent ecosystem of vegetation is perfectly preserved, perennial woody vegetation was present in the study area, the meandering of the channel flow was clearly expressed, visually assessed water quality indicators were high, the territory was equipped with small architectural forms made of natural materials – trees yan motyk, cult buildings are present as objects of cultural and historical value, the territory has not changed much, the physiognomic characteristics of the territory are of natural origin.

Research points 2, 3, 4, 9 are located in the city of Ivano-Frankivsk, the village of Kryhivka and the village of Foxes also correspond, according to the results of the assessment, to an acceptable visual impact, and have the potential of high visual quality of the environment.

Moderate visual impact corresponds to points 1, 5, 6, 7, 11, 13, 14, 15 of the shoreline of the Mlynivka River and the Radchanka River with the outlet of the water flow to the city lake in the city of Ivano-Frankivsk.

To determine the contribution of each of the three groups of evaluated criteria – natural objects, anthropogenic and man-made objects, physiognomic characteristics of the territory, the method of calculating the relative indicator of the visual quality of the environment was applied. For this purpose, the points assigned by the experts, received in each of the criteria groups, were summed up, averaged and divided by the number of criteria contained in the group. As a result, we received an indicator reflected by a certain group of criteria. Since the maximum relative indicator can correspond only to the 2nd, we can analyze according to the given diagram (figure 4) which of the groups of criteria makes the greatest contribution to the indicator of the visual quality of the environment and in which territories the visual quality can be improved relative to the point area of observations.

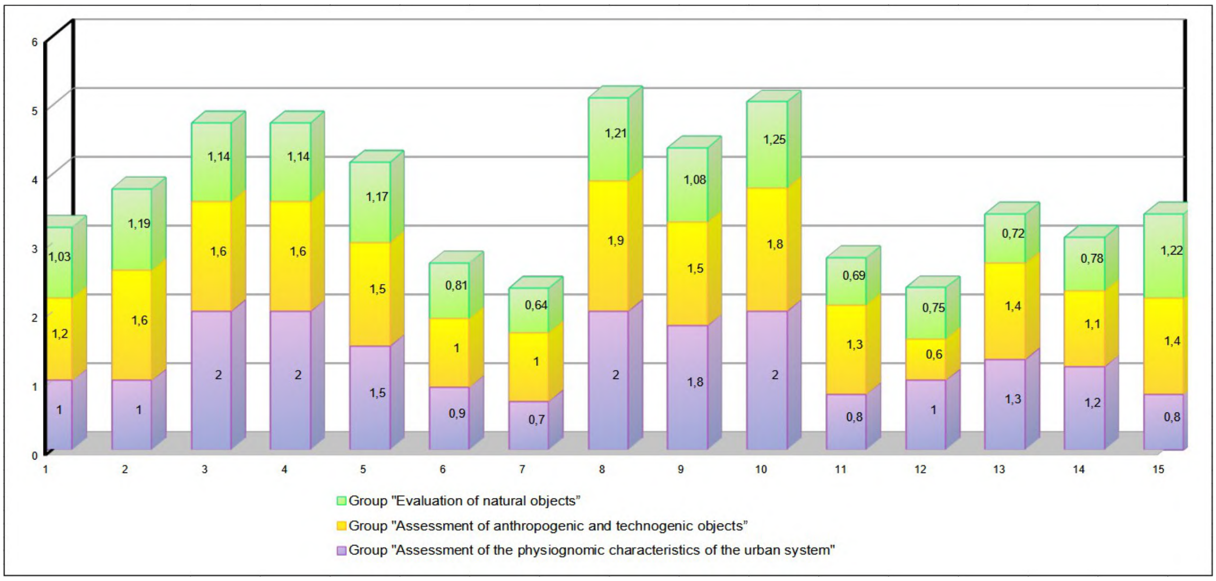


Figure 4. General distribution of the relative indicator of the visual quality of the environment by groups of criteria at observation points.

According to the group "Evaluation of natural objects (general impression of the territory being evaluated)", more than half of the criteria in this group are clearly reflected in the research territory, in particular – the color of the territory, the formed coastal zone, the presence and meandering of rivers, the mixture and diversity of the state of forest stands, striking dominants of natural origin stand out, the naturalness of the territory is ensured at 1, 2, 3, 4, 5, 8, 9, 10, 15 observation points. The maximum naturalness among the specified points is presented in 10 and 15 points, although the highest overall score of visual quality was 8 point.

According to the group "Assessment of anthropogenic and technogenic objects (diversity and expediency of anthropogenic objects)", more than half of the criteria in this group are absent and not reflected in the research area, in particular – urbanization, chaos, the presence of advertising banners, places for collecting solid waste, which is in sight, the territory is little changed by human activity, combined with natural objects, agricultural fields are absent or combined with one-story residential buildings, large-scale engineering structures are not visually noticeable, there is a sufficient number of visually pleasing objects with a variety of elements. This visual situation is reflected in 1, 2, 3, 4, 5, 8, 9, 10, 11, 13, 14, 15 observation points. Observation points 6 and 7 were overloaded with anthropogenic objects, which was analyzed above, at observation point 12 there is a garbage dump, which sharply worsens the indicators of the visual quality of the environment, despite the presence of a forest strip and a watercourse in the field of vision.According to the group "Assessment of the physiognomic characteristics of the urban system", the maximum naturalness of smells and sounds of nature is reflected in points 3, 4, 8, 10, which also have the highest indicators of the visual quality of the environment (figure 2).

In points 1, 2, 5, 9, 12, 13, 14, more than half of the criteria reflect a combination of smells of natural and anthropogenic origin and quiet single sounds of technogenic origin. The moderate situation in this group of criteria is reflected in points 6, 7 located in the village. Dragomyrchany is near the road, which worsens the acoustic and physiognomic situation of the territory. At point 11 in the village In the course of the investigation, a spill of lubricants was recorded near the dirt road, which caused a strong toxic smell over a large area. Point 15, this area of the Ivano-Frankivsk city lake is oversaturated with the number of vacationers who create noise of anthropogenic origin, there is also a skate park nearby, a parking lot of the "Reinkarts" hotel with active car parking, which causes sharp sounds and smells from the operation of car engines.

6. Discussion of the results

In order to reduce visual pollution and increase the visual quality of the environment on the territory of the channel sections of the Mlynivka (Stebnytska) and Radchanka rivers within the To the Ivano-Frankivsk City United Territorial Community, Bogorodchanska, Starobogorodchanska, Lysetska territorial communities, it is necessary to implement specific planning decisions regarding urbanized territories, and within the boundaries of natural (unspoiled) areas, the principle of non-interference should be observed as much as possible, which will correspond to the preservation of the aesthetic value and visual comfort of the environment.

The analysis of literary and scientific sources showed sufficient experience from developments in domestic and foreign practice, the support of such decisions is substantiated by the application of a number of legislative acts and state building regulations. We hope that soon the domestic environmental protection legislation will be adapted to the legislation of the European Union and will contribute to the approval of the Law of Ukraine "On the territories of the Emerald Network", which would outline the value of such territories not only in terms of biodiversity, but would also be supplemented by the criterion of visual/aesthetic quality of the set of natural factors, that form the territories and corridors of the Emerald Network. In our opinion, such an addition would be a clear argument for the introduction of protective status.

7. Conclusions

(i) Based on studies of visual impacts along the riverbanks of Mlynivka and Radchanka, it has been found that the lowest level of visual quality of the environment is observed at point 12 in the Starobohorodchanska community. The highest indicators of visual quality were recorded at points 8 and 10, located in Lysets and Stebnyk respectively. Specifically, in Lysets, there is a high potential for the development of ecological and aesthetic functions with a beautifully preserved natural shoreline, well-expressed meandering of the channel, and high water quality. Other points are characterized by moderate visual impact.

(ii) Analysis of visual pollution of natural riverbanks in the Starobohorodchanska territorial community and the village of Dragomyrchany revealed significant anthropogenic interference. The presence of a solid household waste landfill, eroded paths, corroded communications, and the proximity of asphalt roads to the water streams increase the risks of pollution and negatively affect the visual attractiveness of these landscapes.

(iii) Research on visual, anthropogenic, and physiognomic characteristics of urban systems along the rivers Mlynivka and Radchanka demonstrates significant differences between selected points. Evaluation of natural objects showed high naturalness at points 10 and 15, but the overall score for visual quality is highest at point 8. In the context of anthropogenic objects, points 6 and 7 were found to be overloaded, while at point 12, the presence of a landfill negatively affects visual quality. Physiognomic characteristics of the urban system revealed maximum naturalness of smells and sounds of nature at several points, however, point 15 suffers from noise of anthropogenic origin due to a large number of vacationers and cars. Overall, the results of the study will contribute to the expansion of natural zones and revitalization of rivers, enhancing ecological safety and the role of ecosystem functions in local communities.

(iv) To improve the visual quality of the environment within the studied areas, we can provide the following suggestions:

- Make changes to the local normative acts regulating the implementation of measures for the improvement of the territories of Ivano-Frankivsk, Lysets, and Starobogorodchansk communities, emphasizing the need to minimally change the natural river landscape complexes, thus improving the visual natural environment.
- Inform the public of the specified territories about the causes of visual pollution and its possible consequences for the environment and the health of the population, especially children. Formation of the importance of the habit of a healthy visual (visual) environment.
- To recommend local communities to carry out regular measures to clean and organize the coastline of Mlynivka, Radchanka, and Stebnyk watercourses, combining them with eco-educational actions.
- To the Ivano-Frankivsk City United Territorial Community to recommend the expansion of recreational areas due to the development of ecological trails, historical reconstructions along the Radchanka and Mlynivka rivers, to equip sources of drinking water that come to the surface on the territory of Krykhivtsi and Dragomyrchany villages. Such solutions will reduce the recreational load on the city lake and recreation park on weekends and holidays.
- The Starobohorodchansk community to initiate design decisions regarding the possibility of reducing the area of the solid waste landfill, using modern approaches to the household waste management system in accordance with the provisions of the Law of Ukraine "On Waste Management" No. 2320-IX dated March 31, 2023.
- Reduce the use of advertising banners, set up container sites for the collection of solid waste, in specially designated places, with the limitation of getting into the field of vision in open spaces, change the color of painting large-scale electrical engineering objects (power lines, distribution stations) from black to gray-blue, as an example of the application of such practice in the territory of the Republic of Poland.
- Reducing the influence of aggressive and homogeneous visual fields due to the use of environmentally acceptable solutions: changes in color scheme, visual separation of territorially large-scale objects using the principles of landscape design. Although the degree of natural areas and green spaces within the research area is sufficient, it is recommended

to use vertical and horizontal greening within the population centers of the city of Ivano-Frankivsk (town "Kalynova Sloboda", housing complex "Ozero", "Millennium") and suburban territory with Krykhivtsi, Dragomyrchany village. Such solutions will form dominant, natural, visually pleasing greening centers, especially during the growing season.

The analysis of scientific interest and research in this area shows the need to create a separate regulatory document that would highlight standardized methodological approaches to the assessment of visual pollution and permissible levels of impact, would regulate the application of regulatory decisions in the territories of communities, since the issue of assessing the impact of visual pollution in the field of environmental safety is no less important than the assessment of the effects of other polluting factors.

Abstract. An exact solution to the task of physicochemical iron removal from natural water containing excess iron ferric form at the rapid filters is presented in the article. The principles of applied optimization of filters for iron removal are formulated based on technical and economic calculations. Three filter control algorithms are described and technological modeling of its operation is performed throughout the service life of the filter medium when implementing a regular algorithm. The impact of the main design parameter on the economic indicators and, first of all, the reduced costs is analyzed. The possibility of minimizing the cost of water treatment through a reasonable choice of the packed bed height has been demonstrated.

1. Introduction

The existence of humanity is directly related to the use of water resources, and the key to the progressive development of society is their frugal use [1, 2]. Human health is largely determined by the quality of consumed water [3, 4]. The natural water sources are recommended to use that most closely meet the requirements for drinking water [5,6]. The ground interlayer waters belong primarily to such sources [7,8]. Quite often, the deep groundwater contains a high concentration of iron and requires special treatment [9]. Different methods of iron removal from water have been developed, which have their own technical and economic limits of use [10–14]. The method of contact iron removal from groundwater has become widespread in Ukraine [5,15]. It provides the previous degassing and aeration preparation and filtration at rapid filters.

The assessment of the functionality of specialized filters for iron removal and their treatment potential, is more difficult than that of clarifier filters, since it is necessary to monitor the development of the physicochemical situation in their medium throughout a numerous sequence of filter runs [5, 16]. These conditions are unique during each filter run due to the inevitable increase in the amount of non-washable deposit based on iron hydroxide [15,17,18]. Not only the quality of the treatment, the losses of mechanical energy but also the composition of the solid phase have to be constantly monitored in practice now. It is much easier and cheaper to carry out such control using mathematical modeling methods [19, 20]. Therefore, a special approach is required to calculate the filtration of water with a high concentration of iron compounds, providing for a quantitative analysis of the complex of processes in the filter medium throughout both a separate operating period and the entire time of its effective operation.

The technological optimization procedure usually used at rapid filters is based on two efficiency criteria when separating aqueous suspensions for different rate modes [21]. In relation to the filtration mode with a constant rate, the specified criteria are formalized in the form of relationships between the contamination concentration of in the filtrate, head losses in the packed bed and their standard values. These criteria express the restrictions in symbolic form that must be imposed on the function of filters as clarifiers. Their compliance should be constantly monitored.

However, such an approach is insufficient for technological optimization of physicochemical iron removal, since it helps to reduce only operating costs. Indeed, capital costs while playing a special role in the economic analysis of the filter operation are not actually taken into consideration. As a result, it is necessary to conduct full-scale mathematical and technological modeling of the operation of such filters in order to minimize the cost of deep groundwater treatment. So, it is necessary to analyse in detail changes in filtration characteristics (output concentration of total iron C_e, head losses in the operation bed Δh, filtration rate V) over at least the entire service life of the packed bed (total time of productive operation of the filter with one change of medium T_f).

2. Theoretical analysis of physicochemical iron removal

The fundamental mathematical model of the physicochemical iron removal from deep groundwater using a rapid filter was developed based on the results of our own experimental studies of the technological process in laboratory and industrial conditions and the conceptual model [15]. Its formulation as a system of three interconnected compartments (ferrous iron, ferric iron, and hydraulic), as well as a rigorous solution in a complex integral form, are presented in [22]. In the article, the variables and parameters with a dash above are dimensionless. The dependencies shown below make it possible to predict spatiotemporal changes in the most important filtration characteristics for the particular case when the processes of removing ferrous iron and ferric iron Fe substances occur independently of each other for the relative volumetric concentrations of iron oxide in dissolved $(\overline{C}_h)$ and deposited $(\overline{S}_h)$ forms

$$\overline{C}_h\left(\overline{z},\overline{t}\right)=\frac{\overline{C}_{h0}\overline{C}_h^0\left(\overline{z}\right)}{\overline{C}_h^0\left(\overline{z}\right)+\left[\overline{C}_{h0}-\overline{C}_h^0\left(\overline{z}\right)\right]e^{-\overline{k}_h\overline{C}_{h0}\overline{t}}},\tag{1}$$

$$\overline{S}_h\left(\overline{z},\overline{t}\right)=1-\frac{\overline{C}_{h0}\left(1-\overline{S}_h^0\right)e^{-\overline{k}_h\overline{C}_{h0}\overline{t}}}{\overline{C}_h^0\left(\overline{z}\right)+\left[\overline{C}_{h0}-\overline{C}_h^0(\overline{z})\right]e^{-\overline{k}_h\overline{C}_{h0}\overline{t}}}.\tag{2}$$

Where $\overline{C}_{h0}$ is the inlet volumetric concentration of iron oxide; $\overline{S}_h^0$ is the constant regardless of height (due to intensive mixing of the filtering material during washout) relative initial volumetric concentration of the deposited iron hydroxide; $\overline{k}_h$ is the relative reduced rate coefficient of the deposition of hydroxide particles; $\overline{t}$ is the filtration time; $\overline{C}_h^0\left(\overline{z}\right)$ is the relative distribution of dissolved hydroxide along the height of the packed bed after the first portion of water passes through it, which is described in the absence of ferrous iron by the expression

$$\overline{C}_h^0\left(\overline{z}\right)=\overline{C}_{h0}e^{1-\overline{k}_h\psi\left(\overline{S}_h^0\right)},\tag{3}$$

where $\psi=S_{mh}/\left(n_0C_0\right)$, $\overline{S}_h^0=S_h^0/S_{mh}$; S_{mh} is the dirt-holding capacity of the filter medium in relation to hydroxide particles; n_0 is the clean bed porosity; C_0 is the initial concentration of total iron in water. Then representations (1), (2) are transformed to the form

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012093 doi:10.1088/1755-1315/1415/1/012093

$$\overline{C}_h\left(\overline{z},\overline{t}\right)=\frac{\overline{C}_{h0}}{1+\left(e^{\psi\overline{k}_h\overline{z}}-1\right)e^{-\overline{k}_h\overline{C}_{h0}\overline{t}}},\tag{4}$$

$$\overline{S}_h\left(\overline{z},\overline{t}\right)=1-\frac{1-\overline{S}_h^0}{1+\overline{C}_h^0\left(\overline{z}\right)\left(e^{\overline{k}_h\overline{C}_{h0}\overline{t}}-1\right)},\tag{5}$$

If the relative initial concentration of ferrous iron is $\overline{S}_f^0>0$, then the general expression is valid

$$\overline{C}_h^0\left(\overline{z}\right)=\overline{C}_{h0}e^{-\psi\overline{k}_h\left(1-\overline{S}_h^0\right)\overline{z}}+\frac{\overline{K}_d\overline{S}_f^0}{\psi\overline{k}_h\left(1-\overline{S}_h^0\right)}\left(1-e^{-\psi\overline{k}_h\left(1-\overline{S}_h^0\right)\overline{z}}\right).\tag{6}$$

The expression for $\overline{S}_h$, in particular (2), make it possible, if there is an empirical relationship between the specified concentration and the current hydraulic conductivity k, simply determine the relative head losses in the bed in case $V=$ "$const$". The corresponding formula is derived as a result of solving the hydraulic compartment [22]

$$\triangle\overline{h}\left(\overline{t}\right)=\frac{h\left(0,\overline{t}\right)-H_d}{H^0-H_d}=\int_0^1\frac{\mathrm{d}\overline{z}}{f_k\left(\overline{S}_h\left(\overline{z},\overline{t}\right)\right)},\tag{7}$$

where h is the piezometric head, H_d is the head at the bed outlet; f_k is the symbol of the normalized hydraulic conductivity function; H^0 is the head at the inlet to the clean filter medium at the constant filtration rate V.

3. Technical and economic analysis and choice of filter control algorithm

We set the control time T for a generalized economic analysis of filtration costs. It includes both productive (directly work of the filter) and non-productive (spent on all washouts) times. The basic equation for technical and economic analysis was taken in the following general form [23]

$$CC+CO=VT\Omega_fP_W,\tag{8}$$

where CC, OC are the capital and operating costs; Ω_f is the filter medium surface area; P_W is the cost per unit volume of the treated water.

$$\frac{LP_F}{VT_f}+\frac{N_T}{T}\frac{P_{BW}}{V\Omega_F}=P_W-\frac{\Delta CC+\Delta OC}{VT\Omega_F},\tag{9}$$

where L is the bed layer height; P_F is the cost of a unit volume of filtering material and the cost of its replacement; T_f is the service life of the bed material; N_T is the number of filter runs in the specified period; P_{BW} is the cost of one washout; ΔCC, ΔCC are all items of capital and operating costs with the exception of the costs of filtering material (automation equipment, pumps, aerators, etc.) and washout. The relative time is introduced to generalize the results of subsequent calculations, so that $\overline{T}_f=VT_f/\left(n_0L\right)$, $\overline{T}=VT/\left(n_0L\right)$. Then equation (9) will be

$$\frac{P_F}{\overline{T}_f}+\frac{N_T}{\overline{T}}\frac{P_{BW}}{L\Omega_F}=n_0\left(P_W-\frac{\Delta CC+\Delta OC}{\overline{T}L\Omega_F}\right),\tag{10}$$

In the case of the second (regular) algorithm ($t_{fj}=t_f$), equation (10) is transformed to

$$\frac{P_F}{\overline{T}_f}+\frac{P_{BW}}{L\Omega_F\overline{t}_f}=RC=n_0\left(P_W-\frac{\Delta CC+\Delta OC}{\overline{T}L\Omega_F}\right),\tag{11}$$

where RC is the reduced costs of the treated water. The main goal of a large extent of technical and economic calculations was a comparative analysis of three filter control algorithms, namely, irregular I (decreasing durations of filter runs t_{fj}, $j = 1, 2...N$), regular II (with a uniform calculation step, so that $t_{fj} = t_f$) and combined III (with sequences of filter runs I, II of identical durations, respectively t_{fI} and t_{fII} and besides $t_{fI} > t_{fII}$).

Particular attention was paid to algorithm II, which is widely used in practice due to its simple automation. In order to clearly establish the optimal interval t_f at which the reduced costs will be minimal when controlling the filter in accordance with algorithm II, it is necessary to calculate the dependence $RC\left(\bar{t}_f\right)$. Three graphs of this relationship, which correspond to the basic values Ψ_0 (the ratio of the contents of ferric iron and total iron in the initial water) and moderate contamination of the water supplied to the filter ($\overline{C}_0 = 1$), are shown in figure 1.

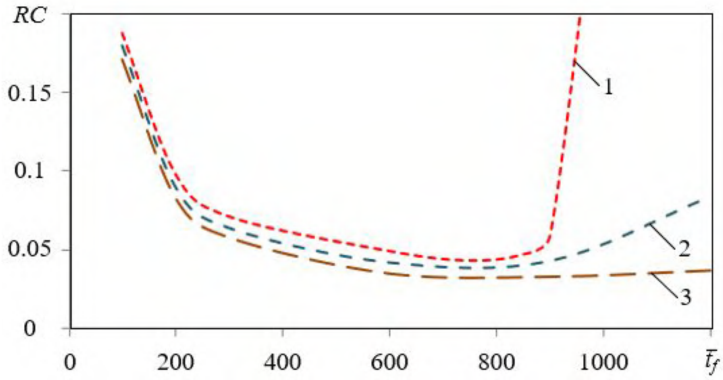

Figure 1. Dependence $RC\left(\bar{t}_f\right)$ at $\overline{C}_0 = 1$: $1 - \Psi_0 = 0$; $2 - \Psi_0 = 0.5$; $3 - \Psi_0 = 1$.

Based on that it is clear that the optimal relative value $\bar{t}_f$ is uniquely related to Ψ_0. Thus, in order to reduce the cost of the treated water to a minimum when using algorithm II, it is enough to specify the curve of the function $RC\left(\bar{t}_f\right)$ for a given initial ratio between the forms of iron. Approximate values of the required optima for $\bar{t}_f$ and RC correspond to the lowest point on this curve. In the case under consideration, three values $\bar{t}_f$ corresponding to the condition $RC = min$ were obtained, namely, $\bar{t}_f = 800$ at $\Psi_0 = 1$, $\bar{t}_f = 700$ at $\Psi_0 = 0.5$, $\bar{t}_f = 630$ at $\Psi_0 = 0$.

Logically, as $\overline{C}$ increases and Ψ_0 decreases, the range of practically acceptable values of $\bar{t}_f$ decreases. Finally, such a procedure for applied optimization of a technological process no longer makes sense if $\overline{C}_0 \geq 2.5$ and $\Psi_0 = 0$, since the filter here is generally not able to cope with such heavy contamination.

4. Applied optimization of design parameters

One of the effective ways to increase the efficiency of rapid filters for iron removal is a scientifically substantiated choice of their design parameters. The fundamental importance among them for the duration of filter runs and service life of filter medium, and as a result for the economics of iron removal are the height of the medium layer L and (equivalent) diameter of filter media grains d_g.

Particular attention in theoretical studies of the significance of the main design parameter was paid to the more unfavorable from the technological point of view limiting case, namely, the initial water (when fed directly to the filter) contains an excessive amount of iron only in the oxide form. Such type of groundwater contamination is real after its forced aeration, which, however, significantly increases the cost of water treatment. But the results of mathematical modeling obtained in this case allow us to get a clear idea of the greatest complications that can be encountered during physical-chemical iron removal in practice.

The recommendations on the rational control of the filter under such conditions, developed on their basis, will guarantee its effective work and, first of all, high quality of the filtrate in any situations encountered in practice, when iron is initially contained either only in the oxide form, or in both forms at an arbitrary ratio between them. Moreover, the value of such analysis also consists in the fact that it is easy to foresee and technically realize in the filter design the operative change of the bed height and thus to correct the filter operation at any stage.

Finally, the subject of the calculations was the evaluation of the sensitivity of the reduced costs in relation to the height L. The calculation interval for the argument L was limited to a minimum possible value (L_{min}) and a maximum value of 2 m. In fact, in this way the range of values L occured in existing filtration plants was fully covered. Then a new variable $\overline{L} = L/L_{min}$ was introduced and the calculation dependencies were transformed to single it out as an argument of the required functions. In particular, the formula for the relative output concentration of dissolved iron took the following form

$$\overline{C}_{he}\left(\widetilde{t}, \overline{L}\right) = \frac{\overline{C}_{h0}}{1 + \left(e^{\psi \overline{k}_h \overline{L}} - 1\right) e^{-\widetilde{k}_h \overline{C}_{h0} \widetilde{t}}}, \tag{12}$$

where $\widetilde{t} = \overline{L}\overline{t}$, $\widetilde{k}_h = \overline{k}_h/\overline{L}$.

The regular filter control algorithm was chosen as the most promising in practical terms (minimum automation costs), i.e. the duration of all filter runs during the bed service life was assumed to be the same. The most representative data of calculations are shown in the form of two sets of curves in figure 2 and figure 3. Figure 2 illustrates the dependencies $RC\left(L\right)$ at duration $t_f = 8$ hours and discretely varying water contamination C_0. All curves have a distinct minimum, which indicates the importance of a reasonable choice of L.

A similar conclusion follows from figure 3, where the above curves correspond to a single value C_0 and different durations of t_f. The indicated curves have similar features. First of all, we should note the existence of extremely small values of RC at strictly defined values of L. Moreover, the corresponding values L_{min} differ markedly at different values of t_f and C_0 (figure 2).

For this reason, it is very important for the preliminary selection of L to be based on the specific conditions and, above all, on the assumed value C_0 and the intended duration of t_f. Also noteworthy is the behavior of the calculated curves at low bed heights. Their asymptotic

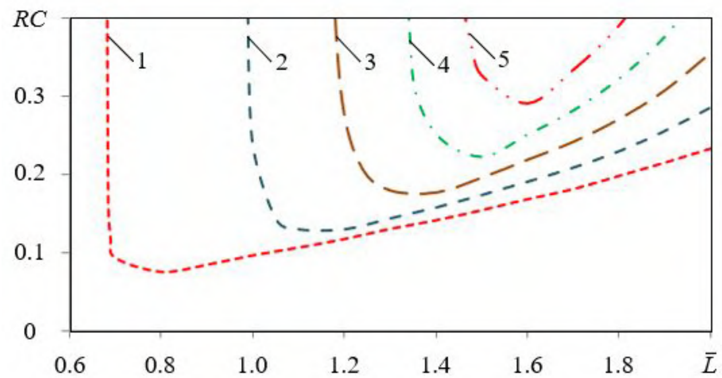

Figure 2. Dependence of reduced costs on packed bed height $\left(\overline{t}_f = 100\right)$: 1 – $\overline{C}_0 = 1$; 2 – $\overline{C}_0 = 2$; 3 – $\overline{C}_0 = 3$; 4 – $\overline{C}_0 = 4$; 5 – $\overline{C}_0 = 5$.

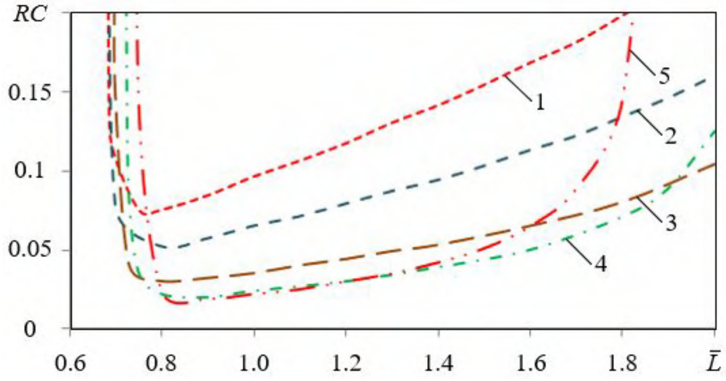

Figure 3. Dependence of reduced costs on packed bed height $\left(\overline{C}_0 = 1\right)$: $1 - \bar{t}_f = 100$; $2 - \bar{t}_f = 200$; $3 - \bar{t}_f = 300$; $4 - \bar{t}_f = 600$; $5 - \bar{t}_f = 900$.

character indicates the existence of extremely low values of L_{min}, at which the filter is able to operate only during the first run for a given value t_f.

Similar analysis for irregular algorithm and arbitrary composition of iron contamination is supposed to be carried out at the next stage of our research. In the near future, it is planned to generalize the available materials on the reaction of the filtration characteristics and economic indicators on the second key design parameter – the size of filter medium elements (effective grain diameter).

5. Conclusions

Based on the results of technical and economic analysis of physical and chemical iron removal at different bed layer heights and levels of iron contamination of water, effective algorithms for long-term control of the filter are developed and tested. It is possible to minimize the reduced costs and the cost of water treatment due to the practical application of these algorithms.

The high sensitivity of economic indicators and, first of all, of the reduced costs in relation to the main design parameter has been revealed. It is shown on the basis of technological modeling of iron hydroxide removal during the service life of the rapid filter medium it is realistic to achieve a significant reduction in the cost of water treatment due to a reasonable choice of the bed layer height taking into account the initial water contamination.

Abstract. As a result of hostilities, the surface waters of Ukraine may be polluted by various components. This can significantly affect the safety of drinking water supply and the ability of water bodies to self-clean. The article is devoted to the calculation of modified water pollution indices and the assessment of water pollution for some Ukrainian rivers that may have been affected by the war. We calculated the modified water pollution index and assessed water pollution for 7 points of 5 Ukrainian rivers (Desna, Dnipro, Styr, Siversky Donets and Oskil) that may have been affected by the war. The modified water pollution index also included nitrates and polyphosphates, unlike the conventional water pollution index. River conditions were assessed from 2018 to 2023 in order to compare water quality in these rivers before and after active hostilities began in February 2022. The most significant effect of military operations on water quality in 2022 was seen at the Siversky Donets and Oskil rivers in the Kharkiv and Donetsk regions, where there were numerous ongoing hostilities. Pollution by biogenic components did not exceed the self-cleaning capacity of these rivers, but bioremediation methods can be used to accelerate the return to normal conditions. Despite being in a conflict zone in the spring of 2022, this had minimal impact on the water quality of the Desna and Dnipro rivers near Kyiv in the summer of 2022. The water quality of the Styr river was improved due to absence of active military actions near the river and significant decrease in tourism and agricultural use of territories.

1. Introduction

During hostilities, the safety of using tap water depends not only on possible cases of sabotage on drinking water treatment plants or plants and pipes destruction due to explosions, but also on unpredictable changes in the quality of natural waters [1]. Military actions can cause damage to the environment in many ways. As a result, natural water, soil and air can be significantly polluted. Pollution of rivers and farmland is of particular concern, as it can lead to poor quality drinking water and food. In most Ukrainian cities, treated water from rivers is used as tap water. Thus, the pollution of rivers can significantly affect the health of the population, if the water cannot be purified to the standard quality [2]. Currently, in warfare, water weaponization has a place to achieve strategic or tactical advantages. Water weaponization is the use of water as physical arms to harm and gain leverage over an adversary by limiting access to water, degrading water quality and creating a shortage of safe drinking water [3].

The ways of military actions influence on water quality in rivers can be divided into direct and indirect (figure 1). Direct ways of influence can include drowning of military vehicles equipment and shells and also decomposition of dead organisms. Rivers are frequently targeted for the deployment of explosives, such as aerial bombing or minelaying, either due to their proximity to settlements, their importance as transportation routes, or the strategic significance of associated structures, such as bridges, irrigation canals, jetties, hydroelectric dams, etc. [4]. Heavy metals can leach from military vehicles, weapons and ammunition. According to analysis of bottom sediments from the lake in Bucha district (Kyiv region, Ukraine) [5], iron content increased from 360.5 mg/kg in 2022 to 1722.0 mg/kg in 2023, manganese level rose from 10.5 to 50.0 mg/kg, copper and aluminium contents grew up from 0.9 and 237.0 mg/kg to 2.0 and 691.0 mg/kg, respectively. A significant increase in the concentrations of heavy metals was also observed in the Molochna River (Zaporizhia region, Ukraine) as a result of hostilities [6]. Significant excesses were observed for Cu, Pb, Cr and Ni (950, 20.7, 4.8 and 10.6 times higher than the maximum permissible concentrations). In addition, the drowning of vehicles can lead to the pollution of water bodies with various petroleum products, which are part of fuel and grease, as well as products of thermal decomposition and incomplete combustion. Drowning ammunition can lead to the leaching of explosives from them, which are often highly toxic. As a result of the decomposition of dead organisms, water is not only polluted with decomposition products, but also the level of dissolved oxygen decreases in water, which can lead to the death of aquatic organisms.

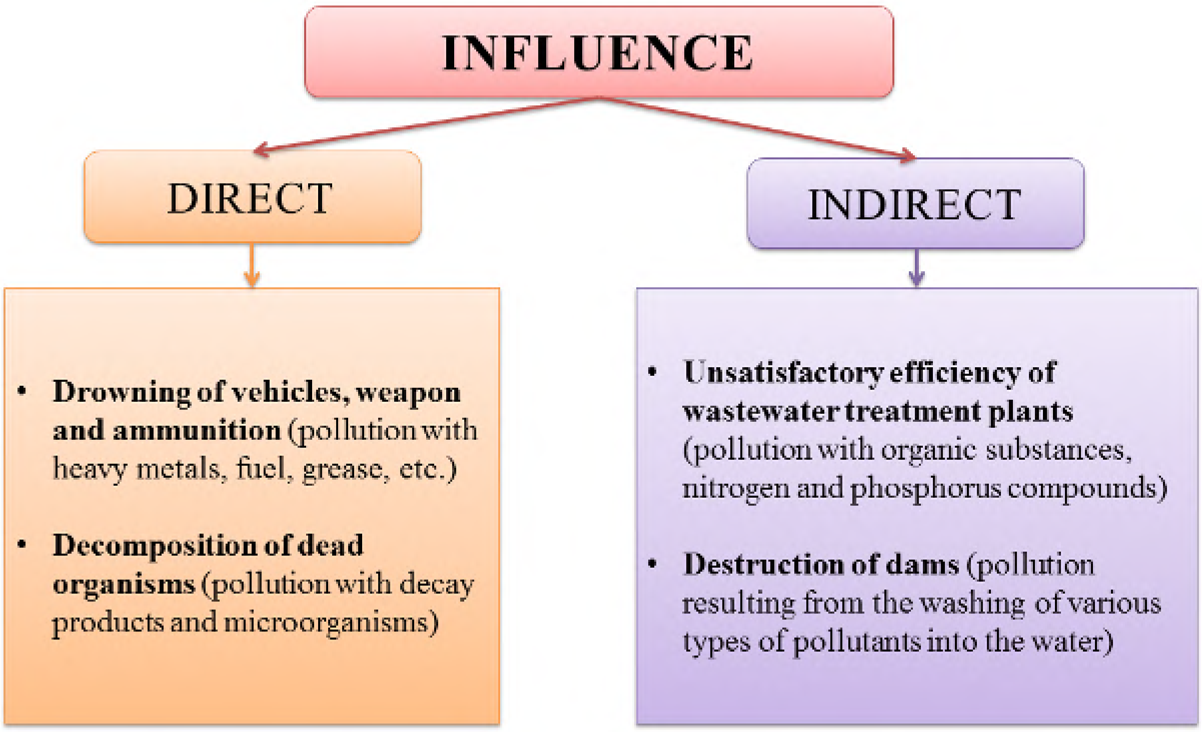

Figure 1. Military actions influence on water quality in rivers.

In addition to direct effects, water quality in rivers can deteriorate as a result of various cases that arise as a result of war. Destruction of dams causes washing of various types of pollutants into the water especially due to flooding of landfills. Wastewater treatment plants can function inefficiently due to blackouts, shortage of reagents for wastewater treatment, partial damage of the plant. As a result, significant amounts of nitrogen compounds, including ammonium nitrogen, nitrites and nitrates, as well as organic matter and phosphorus compounds, including polyphosphates, can enter the river.

Currently, the impact of the war on the state of the rivers of Ukraine is not yet sufficiently studied, since most of the pollution cases occurred in 2022 and 2023. In addition, the main part of research concerns pollution with heavy metals, while pollution with biogenic elements is almost not investigated. Although, unlike heavy metals, biogenic elements cannot lead to extremely long-term pollution of the ecosystem, but such pollution can lead to substantial disturbances in the ecosystem and significant deterioration of water quality due to unbalanced eutrophication.

Identifying rivers whose water quality has deteriorated as a result of direct or indirect effects of war is critical for timely remediation and remediation method selection, as different methods, including biological [7] and chemical [8, 9] approaches, are used for different pollutants.

2. Methods

Water quality monitoring data were obtained from the State Agency of Water Resources of Ukraine [10]. 7 points on 5 rivers of Ukraine, which could be polluted as a result of military operations, were selected for assessment:

1) Desna river, 3 km, drinking water intake in Kyiv (Dnipro river basin, data from Basin water monitoring laboratory);
2) Styr river, 48 km, village Zarichne near the border with Belarus (Dnipro river basin, data from Laboratory of water and soil monitoring in the Rivne region);
3) Dnipro river, 897 km, Vyshhorod, lower beif of the Kyiv hydroelectric station, drinking water intake (Dnipro river basin, data from Basin water monitoring laboratory);
4) Siversky Donets river, 522 km, Raigorod Dam in Slovyansk, drinking water intake into the Siverskyi Donets-Donbas canal (Don river basin, data from Basin water monitoring laboratory);
5) Siversky Donets river, 527 km, drinking water intake of the utility company "Company Water of Donbass" (Don river basin, data from Basin water monitoring laboratory);
6) Siversky Donets river, 540 km, Slovyansk drinking water intake (Don river basin, data from Basin water monitoring laboratory);
7) Oskil river, 112 km, downstream Kupyansk (Don river basin, data from Water and soil monitoring laboratory).

River conditions were assessed from 2018 to 2023 in order to compare water quality in these rivers before and after active hostilities began in February 2022. Water pollution index is usable method to evaluate of water quality of natural water, especially in the cases of using water bodies for drinking water production or fishering [11, 12]:

$$WPI = \frac{1}{n} \cdot \sum_{i=1}^{n} \frac{C_i}{MPC_i},$$

where C was concentration of the component in river water, mg/L; MPC was maximum permissible concentration of the component in river water, mg/L.

To assess the quality of river waters, we used a modified water pollution index, which, unlike the conventional water pollution index [12], also included nitrates and polyphosphates, which allowed for a more accurate assessment of pollution by biogenic components.

Formula for calculation of a modified water pollution index:

$$WPI_m = \frac{1}{6}\Big(\frac{C(NH_4^+)}{MPC(NH_4^+)} + \frac{C(NO_2^-)}{MPC(NO_2^-)} + \frac{C(NO_3^-)}{MPC(NO_3^-)} + \frac{C(BOD)}{MPC(BOD)} + \frac{MPC(O_2)}{C(O_2)} + \frac{C(PolyPO_4^{3-})}{MPC(PolyPO_4^{3-})}\Big).$$

In this article, the water quality is assessed only point by point, but differential equations [13] can be used for a generalized assessment of the state of the river or its part.

3. Results and discussion

After the start of active hostilities in February 2022, the modified water pollution index increased rapidly for most of the studied points (figure 2). In 2022, among the studied points, the greatest impact of military actions on water quality was in the case of the Siversky Donets and Oskil rivers, the basins of which are located in the Kharkiv and Donetsk regions, where at that time there were many active hostilities.

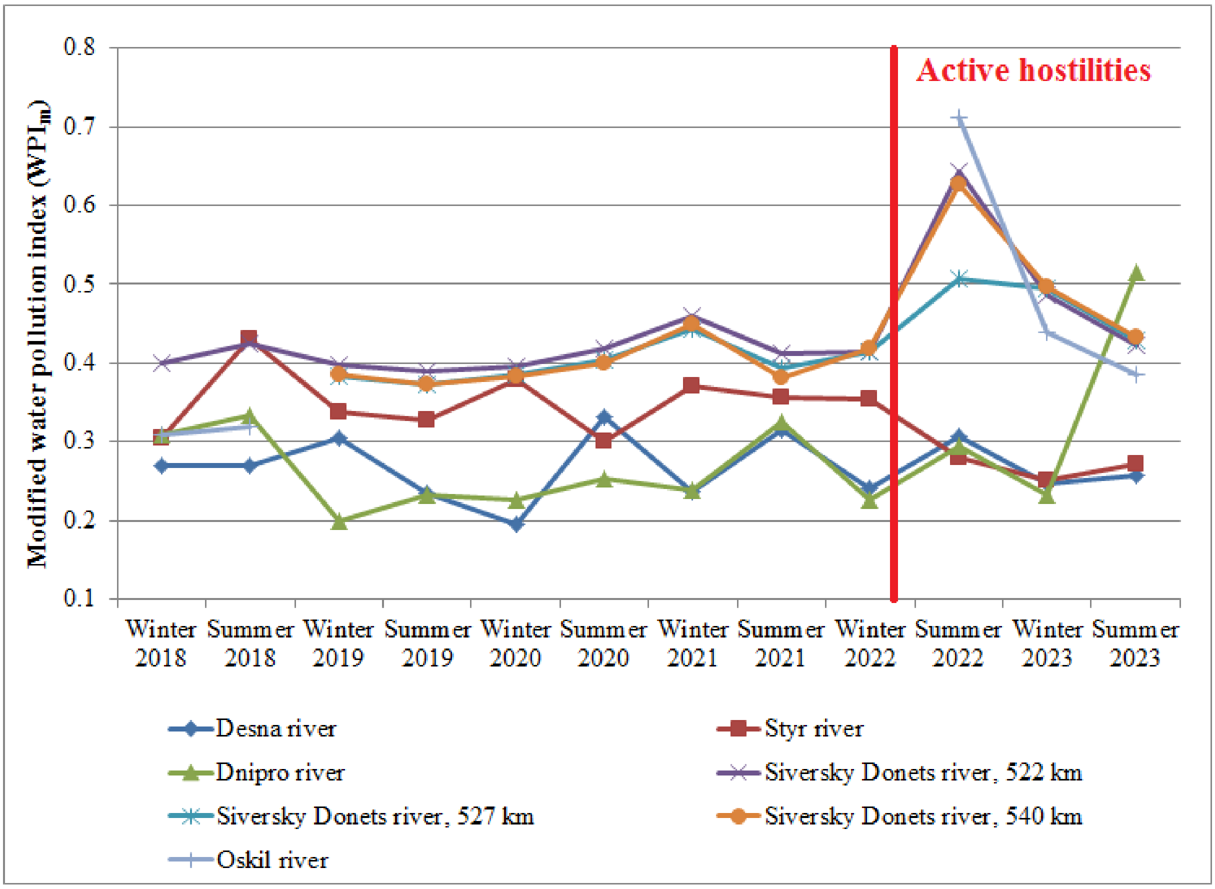

Figure 2. Influence of active hostilities on the modified water pollution index.

Although during the spring of 2022, a significant part of the Kyiv region was a zone of active warfare, this did not significantly affect the quality of water in the Desna and Dnipro rivers near Kyiv in the summer of 2022. In the case of the Dnipro river, significant changes in the modified water pollution index were observed only in the summer of 2023, which may be related to the shelling of the infrastructure. Such a rapid increase could not be caused by seasonal natural phenomena, since in the case of the Desna river located nearby, there was not notable deviations from the reproduced seasonal changes.

In the case of the Styr river, after the start of the active war, the water quality did not deteriorate and even improved. The basin of this river did not belong to the zone of active warfare, and the war led to a significant decrease in the presence of civilians near the border with the Republic of Belarus, and therefore to a decrease in anthropogenic water pollution.

Although the modified water pollution index did not change significantly for the Dnipro river after the start of active hostilities, an increase in ammonium levels (in the range of 0.89-1.09 mg/L) was observed from the summer of 2022 to the summer of 2023 (figure 3). This could be caused by the inefficient operation of wastewater treatment plants and the decomposition of organic matter.

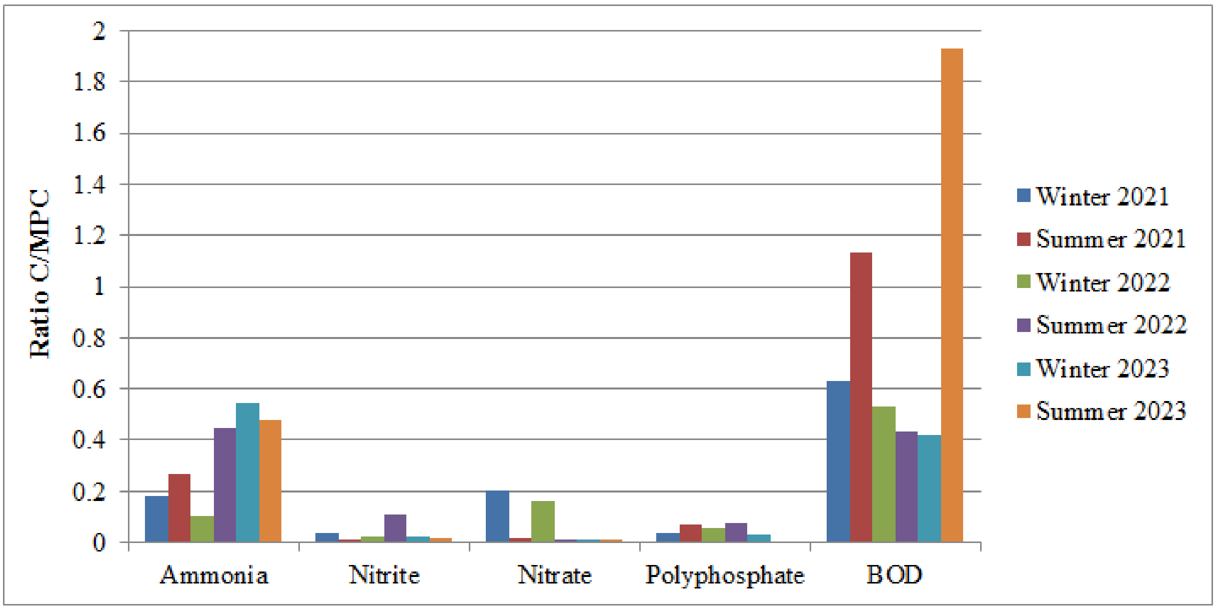

Figure 3. Influence of active hostilities on the water quality of the Dnipro river near Vyshhorod.

A sharp increase in the modified water pollution index in the summer of 2023 is caused by a strong increase in BOD (figure 3), i.e. the content of easily degradable organic substances. The rise and suspension of bottom sediments as a result of shelling could be the reason of such growth.

In the summer of 2022, a significant increase in the concentrations of ammonium (1.63 mg/L), nitrites (0.49 mg/L), polyphosphates (3.01 mg/L) and easily degradable organic substances (BOD 3.86 mg O2/L) were observed in the water of the Siversky Donets river (figure 4).

As a result of active hostilities in the Kharkiv and Donetsk regions, the agricultural use of these areas at that time practically did not take place, so such rise in levels could not be due to leaching of fertilizers from the soils. Thus, the inefficient operation of wastewater treatment plants and the decomposition of organic matter were also the most likely reasons.

4. Conclusions

The pollution of rivers and farmland is a major concern due to its potential to result in low-quality drinking water and food. Heavy metals, petroleum products, microorganisms, products of incomplete combustion, as well as biogenic components can be pollutants of water. Unlike

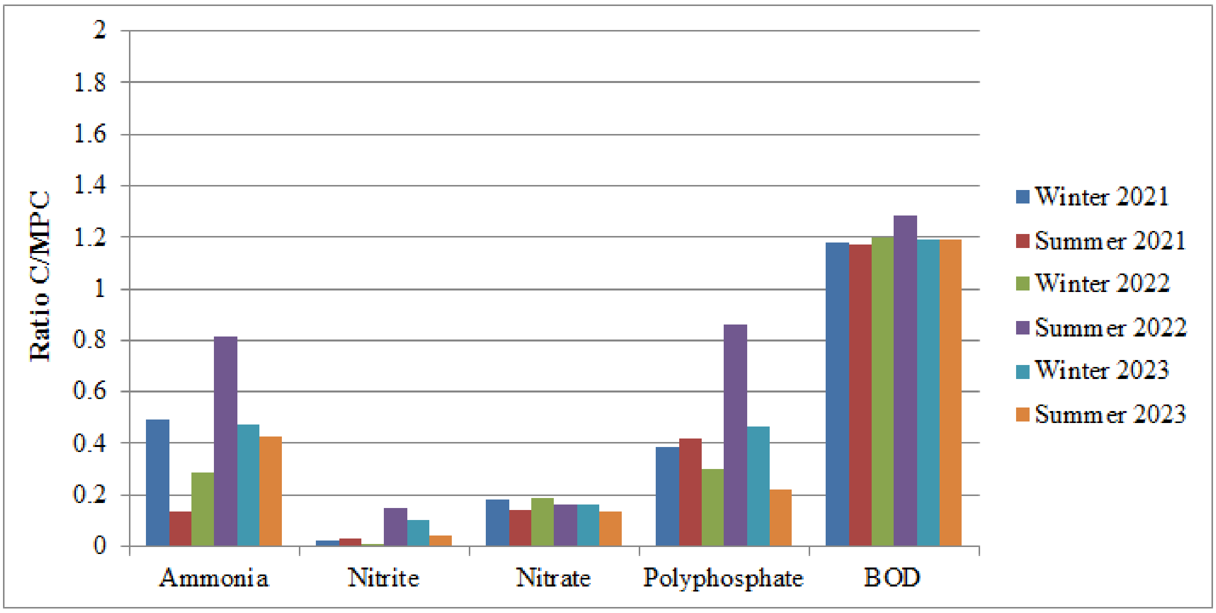

Figure 4. Influence of active hostilities on the water quality of the Siversky Donets river near Slovyansk.

heavy metals, biogenic elements may not cause long-term pollution of the ecosystem, but they can still lead to significant disruptions and deteriorate water quality due to unbalanced eutrophication.

We calculated the modified water pollution index and assessed water pollution for 7 points of 5 Ukrainian rivers (Desna, Dnipro, Styr, Siversky Donets and Oskil) that may have been affected by the war. The modified water pollution index also included nitrates and polyphosphates, unlike the conventional water pollution index. It is suitable for a more accurate assessment of pollution by biogenic components. River conditions were assessed from 2018 to 2023 in order to compare water quality in these rivers before and after active warfare began in February 2022.

The onset of active hostilities in February 2022 resulted in a rapid increase in the modified water pollution index at most of the surveyed points. The largest impact of military actions on water quality in 2022 was observed at the Siversky Donets and Oskil rivers, located in the Kharkiv and Donetsk regions, where there were numerous active hostilities. The inefficient operation of wastewater treatment plants and the decomposition of organic matter were the most likely reasons of such pollution. These plants may operate ineffectively as a result of power outages, a lack of reagents for wastewater treatment, or partial damage to the facility.

Despite being a zone of active hostilities during the spring of 2022, this had a little impact on the water quality of the Desna and Dnipro rivers near Kyiv in the summer of 2022. Following the outbreak of active warfare, the water quality of the Styr river did not worsen and in fact, improved. This was due to the fact that the river basin was not within the active conflict zone, and the war resulted in a significant reduction of civilian presence near the border with the Republic of Belarus, leading to a decrease in anthropogenic water pollution.

Pollution by biogenic components did not exceed the self-cleaning capacity of the considered rivers, but bioremediation methods can be used to accelerate the return to normal conditions. These pollutants can be easily consumed by plants in the process of bioremediation.

Abstract. The dynamics of groundwater level formation on two types of rice irrigation plot were studied: "rice irrigation plot with an irrigator-discharge in a notch and with drainage channels CCD" and "rice irrigation plot with an irrigation channel in an embankment and with drainage-discharge channels (KTC)" with various design parameters of the drainage network. On the basis of long-term field observations of the groundwater level (GWL) lowering on the CCD and KTC with use a network of observation wells, differences in the intensity and uniformity of drying of these types of rice irrigation plots in the pre-harvest and inter-vegetation periods have been established. It has been established that a more favourable water-air regime takes place in the rice irrigation plots CCD with different parameters of the drainage network compared to the rice irrigation plots KTC. At CCD, due to the draining effect of the irrigator-discharge, the field dries out more intensively after the water discharge process. This allows the rice harvest to be carried out in an optimal and rather short time. The presence of the irrigator-discharge as the element of the CCD allows to supply and divert water in a short period of time, evenly over the entire area as well as to perform the role of shallow drain and contribute to intensive drying and desalination of soils. It has been established that the yield of rice on CCD higher than on KTC with the corresponding parameters (on average 400–500 kg$\cdot$ha^{-1}). It has been established that due to these advantages, the rice yield on the CCC the inter-drainage distance 200 m and 250 m is on average 5–7 centner$\cdot$ha^{-1} higher than on the KTC with the same parameters, and higher than on the CCD with the inter-drainage distance 500 m on 17 centner$\cdot$ha^{-1}.

1. Introduction

The modern rice irrigation system (RIS) is a complex set of water supply, drainage, regulating and other elements interconnected by a single technological process in combination with rice fields, on which the leading crop of flooded rice and accompanying agricultural crops are grown.

The main element of any engineering rice irrigation system is the rice irrigation plot. How successfully the design of the rice irrigation plot was chosen and its parameters were selected depends on how successfully it will perform its functions, which are creating an optimal salt, water and air regimes for flooded rice and accompanying crops in the rice irrigation plot. The creation of a favorable salt, water and air regimes determines the conditions for the formation of the ecological and amelioration states on the lands of the RIS and, accordingly, the yield of both flooded rice and accompanying agricultural crops [1–7].

In addition, the productivity of agricultural machinery during the performance of various agrotechnical operations, the productivity of irrigators, and the rational use of irrigation water depend on the design features of the rice irrigation plot and its main parameters.

The composition and construction of the rice systems of the Danube region during their construction were determined by various factors, in particular, climate conditions [8], the fact that they are all located in territories with complex hydrogeological and soil-forming conditions, characterized by the close occurrence of mainly highly mineralized low-flow groundwater [1, 3, 4, 9–11]. This in itself presupposed the presence of a powerful drainage network in the construction of rice systems, which also combined the functions of a discharge system and was called a drainage-discharge network.

Drainage on the RIS is the main means of maintaining a favorable ecological and amelioration state, without which it is impossible to obtain high yields of flooded rice and accompanying agricultural crops.

One of the main tasks of drainage is to ensure the necessary level regime of groundwater in different periods of vegetation, especially in the pre-harvest and inter-vegetation periods of both flooded rice and accompanying agricultural crops [3, 4].

One of the main issues that have been studied throughout the existence of the RIS is the determination of the optimal inter-drainage distances and depth of the drainage-discharge network [9–11]. They must ensure the following functions: compliance with the optimal terms and norms of rice field drainage before harvesting and in the inter-vegetation period; ensuring optimal depths of groundwater level during growing of accompanying agricultural crops; maintaining uniform desalinization of soils both in terms of area and depth; preventing secondary salinization of soils. According to these authors, the optimal inter-drainage distances in the case of saline soils with heavy granulometric composition, both in terms of land reclamation and economic points are within 150–200 m. For soils with a light granulometric composition, depending on the degree of their salinity, depth and mineralization of groundwater, it is recommended to take the value of inter-drainage distances within fairly wide limits – from 200 to 500 m.

As for the design features of rice irrigation plots of the RIS, only certain ameliorative aspects of their operation and efficiency have been sufficiently studied [12–15]. Today, there are practically no results of research on the peculiarities of the formation of groundwater regimes in rice fields with different design parameters.

2. Materials and methods

The aim of research is to study the dynamics of groundwater level formation on the lands of the RIS depending on the design features of rice irrigation plots, as well as the influence of intensity and direction of filtration processes on the ecological and amelioration states on the lands of the RIS and the yield of the leading crop of flooded rice. Therefore, the article aim is comparison of effectiveness of two types of rice irrigation plots design, evaluation their influence on the formation of the water and salt regimes and yield of the leading crop of flooded rice.

The research was carried out during 2011–2016 on three experimental rice fields with various parameters and designs on the Danube RIS located in the Odessa region (Danube Delta) within the framework of a comprehensive program to improve the overall efficiency of the operation of the rice systems in the Danube Delta (figure 1).

The first experimental rice field consisted of two rise irrigation plots, which we call for better understanding “rice irrigation plot with an irrigator-discharge in a notch and with drainage channels (CCD)”. In this type of irrigated areas, the irrigator-discharge performs the role of irrigation channel (supplies water to the rice field) and discharge channel (removes water from the rice field). The average depth of such channel was only 0.7–1.0 m. The inter-drainage distance distance which drain filtration water from the rice field, amounted 200 m. As a control

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012095 doi:10.1088/1755-1315/1415/1/012095

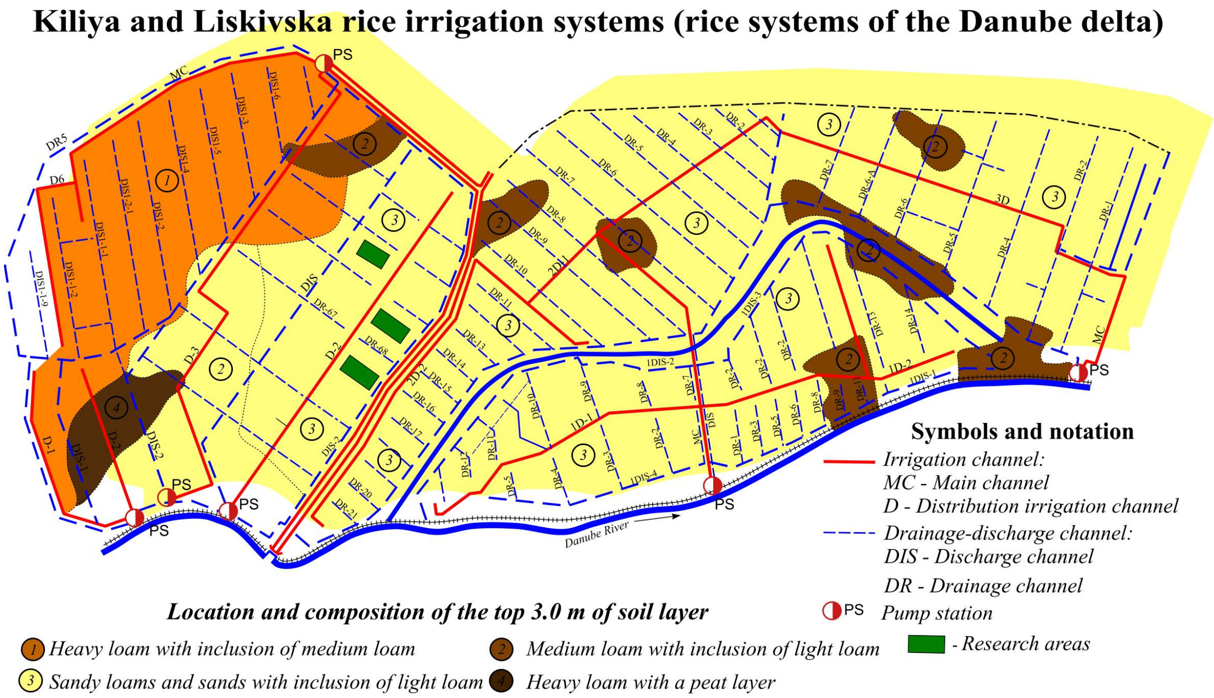

Figure 1. The map of rice systems under research.

plot was chosen the rise irrigation plot of Krasnodar type, which we call "rice irrigation plot with an irrigation channel in the embankment and with drainage-discharge channels (KTC)". In this case, the irrigation channel was used to supply water to the rice field, and the drainage-discharge channels were used to remove filtration and discharge water. The distance between drainage-discharge channels was also 200 m.

The second experimental rice field also consisted of two rice irrigation plots (CCD) and the control irrigation plot of Krasnodar type (KTC), but the inter-drainage distance on the CCD and the drainage-discharge channels on the KTC of both rice irrigation plots was 250 m.

The third experimental rice field consisted of two rice irrigation plots CCD with the inter-drainage distance 250 m for the first plot and 500 m for the second plot.

Schemes of two types of rice irrigation plot – CCD and KTC are presented in figure 2.

The study of the dynamics of the groundwater level was carried out using a network of boreholes that formed longitudinal and transverse cross-sections. On each of the experimental plots, three transverse and one longitudinal borehole-lines with five boreholes in each were arranged. With the inter-drainage distance 200 m, the boreholes in the transverse borehole-lines were placed on both the KTC and the CCD with the distance of 15 m, 25 m, 50 m, 75 m and 90 m from the drain (figure 3), on the CCD at 250 m – at the distances of 15 m, 30 m, 60 m, 90 m and 115 m, and at 500 m – at the distances of 15 m, 60 m, 125 m, 190 m and 240 m (figure 4).

On the basis of long-term observational data processing, it was possible to get an idea of the intensity of the lowering of the groundwater level on the area of rice fields with different design parameters both after the final discharge of water from them and about the dynamics of the groundwater level in rice fields during the inter-vegetation period and during cultivation of flooded rice and accompanying agricultural crops.

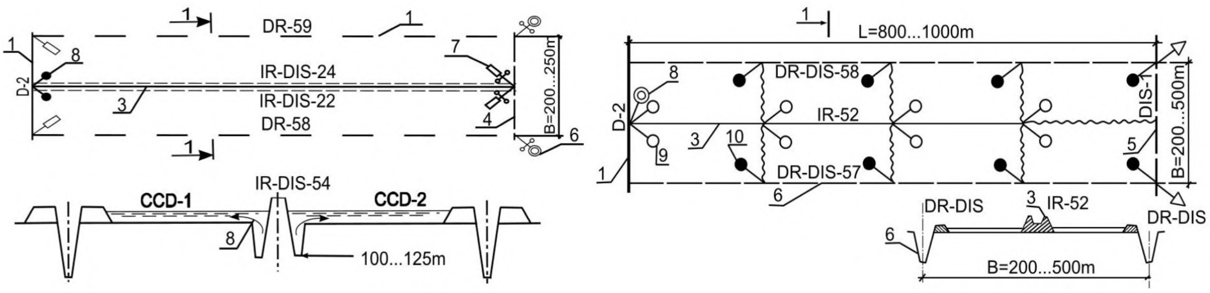

Figure 2. Schemes of two types of rice irrigation plot (CCD and KTC) on the Danube rice irrigation systems: 1 – distribution irrigation channel (D2); 2 – discharge channel (DIS-1); 3 – drainage channel on CCD (DR-58; DR-59), or drainage-discharge channel on KTC (DR-DIS-57; DR-DIS-58); 4 – irrigator-discharge of unilateral command (IR-DIS-22; IR-DIS-24; IR-DIS-54); 5 – water outlet from the distribution channel to the irrigator-discharge; 6 – water outlet from the irrigator-discharge to the discharge channel; 7 – water outlet from the drainage channel to the discharge channel; 8 – water outlet from the distribution channel to the irrigation channel in the embankment; 9 – irrigation channel in the embankment (IR-52); 10 – water outlet from the field to the drainage-discharge channel; 11 – water outlet from the irrigation channel to the field.

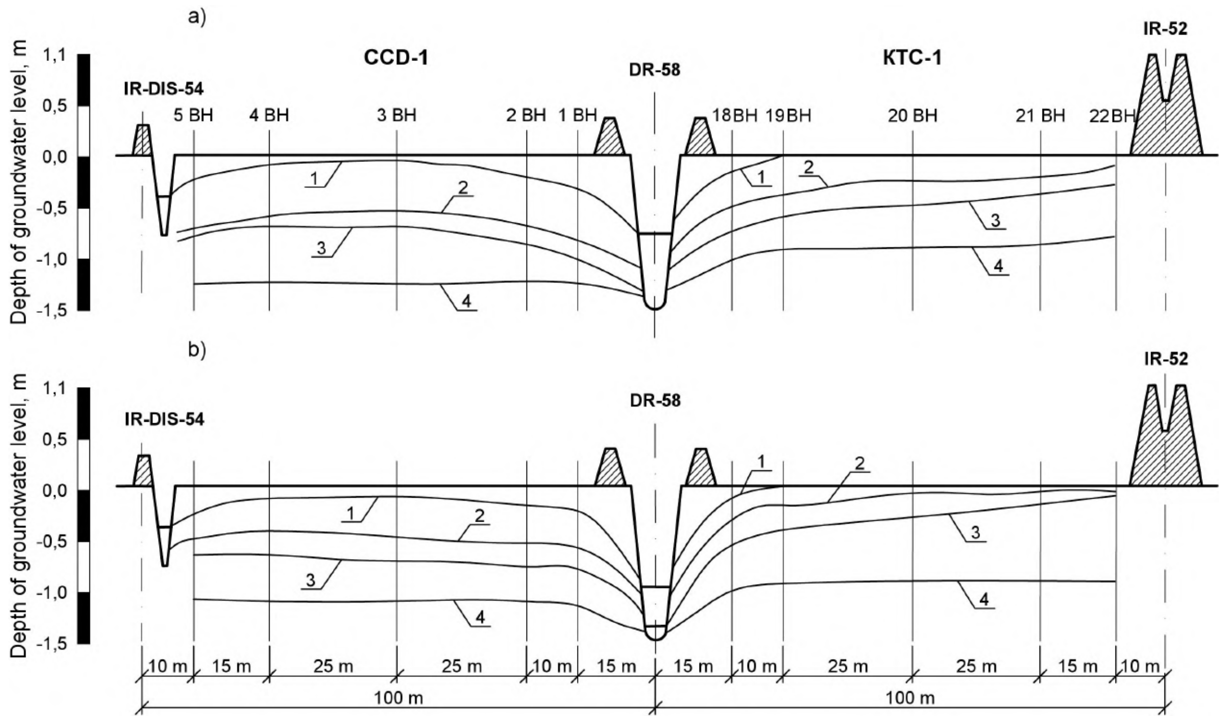

Figure 3. The dynamics of the groundwater level lowering on CCD and KTC after discharging water from rice fields for the 4th (a) and 5th (b) years of the rice irrigation plot No. 1 (inter-drainage distance of 200 m): 1 – after 1 day; 2 – after 5 days; 3 – after 10 days; 4 – after 30 days; 1 BH, 2 BH – 22 BH – observation boreholes.

3. Results and discussion

The duration of the pre-harvest drying of rice fields is one of the most important indicators of the operation of the rice system and its drainage, especially in conditions of saline soils. The terms

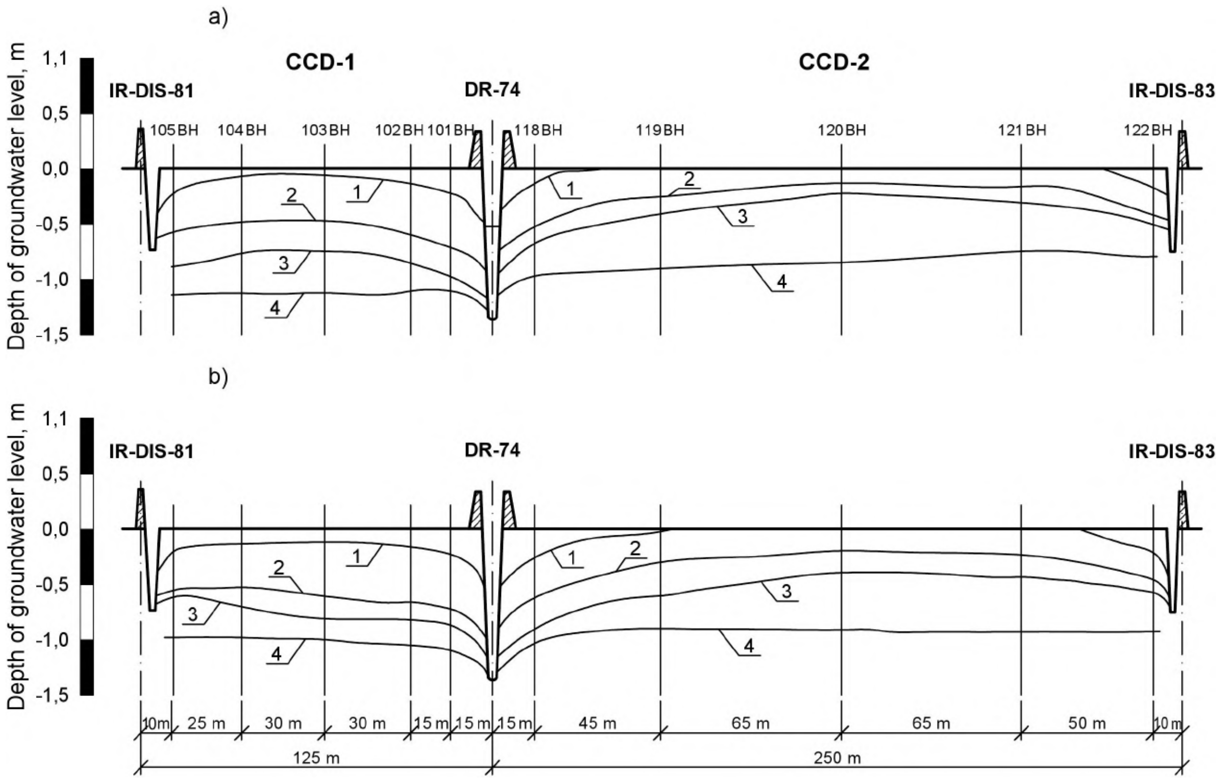

Figure 4. The dynamics of the groundwater level lowering on CCD after discharging water from rice fields for the 4th (a) and 5th (b) years of the rice irrigation plot No. 3 (inter-drainage distances of 200 m and 500 m): 1 – after 1 day; 2 – after 5 days; 3 – after 10 days; 4 – after 30 days.

of harvesting and carrying out autumn field work depend on the duration of the pre-harvest drying [9].

The inability of the drainage network to maintain the necessary rate of drainage and, accordingly, sufficient aeration of the root-containing soil layer in the inter-irrigation period and the related intensity and directionality of oxidation-reduction processes in the soil, as well as to ensure their washing under the influence of filtration flows, are the main reasons for the occurrence of unfavorable soil processes on the RIS (formation of gravelly soils, secondary salinization and waterlogging, etc.), reducing soil fertility and, accordingly, the yield of rice and related crops.

The results of the groundwater level observations on CCD and KTC by using the network of boreholes indicated the existence of differences in the intensity and uniformity of the drying process in these types of rice irrigation plots.

As can be seen from figure 3 and figure 4, on CCD in the first 10 days of drying, the depression curve has a well-defined slope in two directions – to the open drain and to the irrigator-discharge, which indicates the operation of the irrigator-discharge during this period as a shallow drain. Precisely due to the draining effect of the irrigator-discharge the process of the groundwater level lowering in the rice field during the pre-harvest drying occurs much faster on the CCD than on the KTC.

Evaluating the intensity of the pre-harvest drying on the area of the rice fields, it can be noted that in the first 10 days after the discharge of water from the fields, in the conditions of CCD the intensity is the highest within the lanes adjacent to the open drain and to the irrigator-discharge, and the lowest – in the central part of the field (figure 3 and figure 4). On the KTC the groundwater level also decreases, with the highest intensity – in the lanes along the open drain, and the lowest intensity – in the lanes along the irrigation channel in the embankment (figure 4).

The intensity of the groundwater level lowering on the area of rice fields, regardless of the type of construction, for all studied inter-drainage distance (200, 250 and 500 m) is the highest within the zones adjacent to both the discharge channel, the open drain and the irrigator-discharge, and the lowest – in the central part of the fields (figures 5-7).

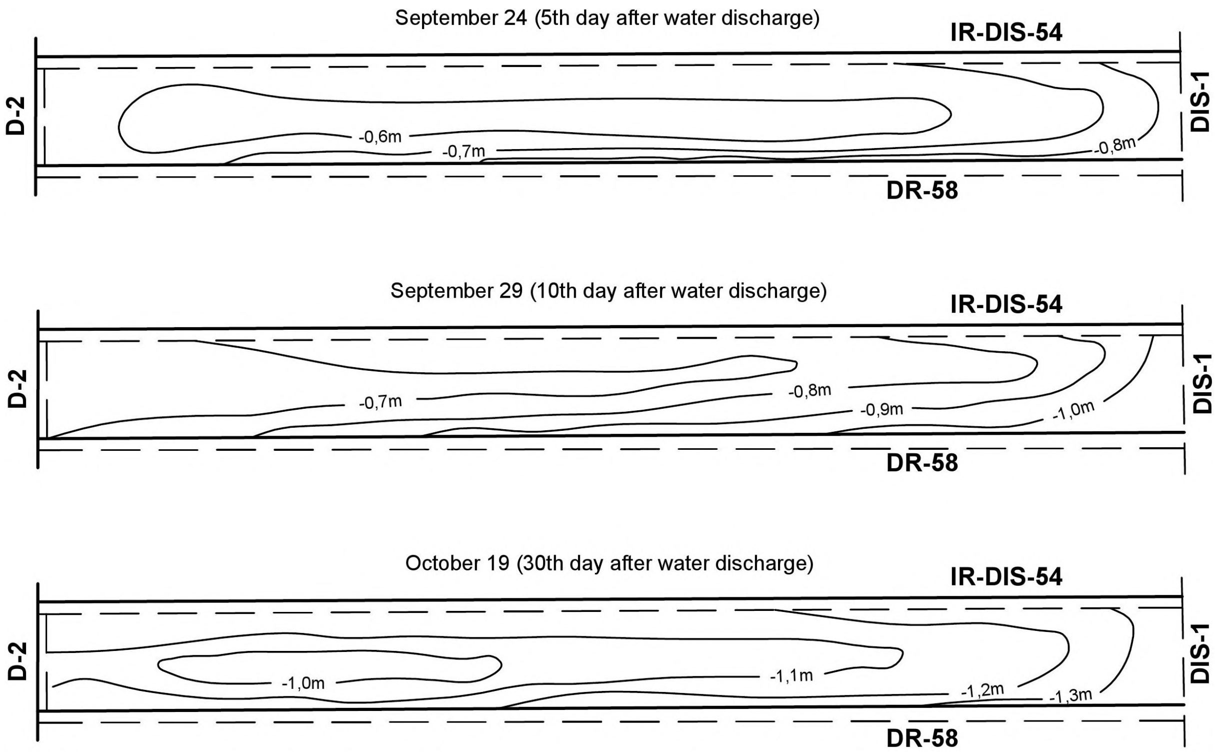

Figure 5. Drying of CCD of the rice irrigation plot No. 1 (inter-drainage distance of 200 m).

In the central part of the fields with the inter-drainage distance 200 m during the first five days after the discharge of water, the depth of lowering the groundwater level (GWL) is about 60 cm, and with 500 m it is only 20 cm (figures 5-7). A similar situation observes on the 10th day after the discharge of water, for example, with the inter-drainage distance 200 m and 250 m the GWL decreases by 70–80 cm, then with the inter-drainage distance 500 m – only by 40–50 cm.

Therefore, the most difficult conditions for the operation of grain-harvesting equipment and other agricultural machines during the harvest period will arise precisely in the central part of the rice fields. Precisely for this zone of rice fields, according to the data from measurements of the position of groundwater in the central boreholes, correlations between the depth of groundwater level in the experimental rice irrigation plots and the duration of their drainage were established. These correlations are expressed by the following regression equations:

a) for CCD with inter-drainage distance of 200 m

$$H = 8.15 + 65.49 \cdot LgT, \tag{1}$$

b) for CCD with inter-drainage distance of 250 m

$$H = 2.24 + 69.36 \cdot LgT, \tag{2}$$

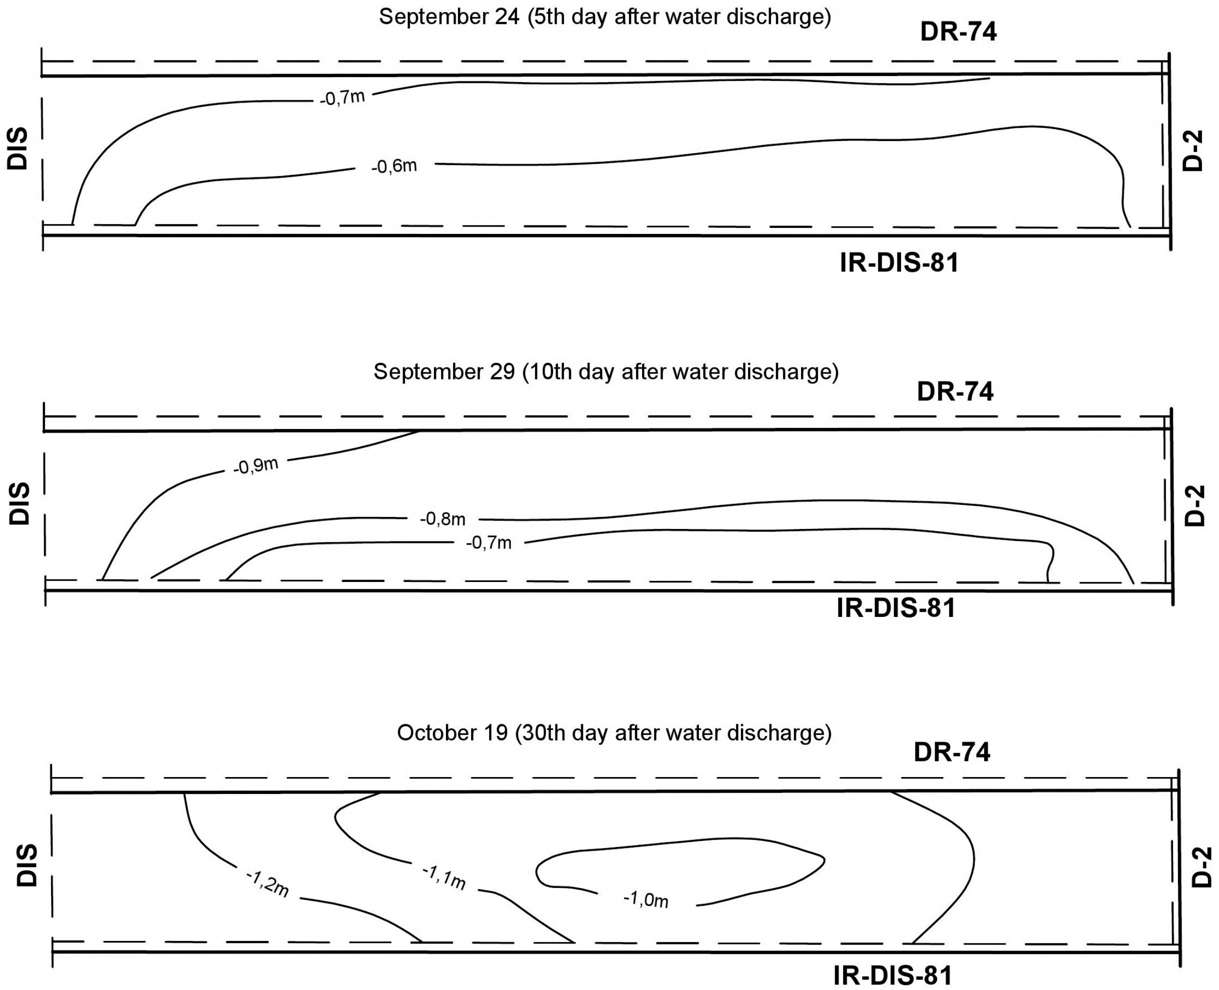

Figure 6. Drying of CCD of the rice irrigation plot No. 3 (inter-drainage distance of 250 m).

c) for CCD with inter-drainage distance of 500 m

$$H = 2.78 \cdot T - 1.13, \tag{3}$$

d) for KTC with inter-drainage distance of 200 m

$$H = 3.07 \cdot T + 3.82, \tag{4}$$

e) for CCD with inter-drainage distance of 250 m

$$H = 3.06 \cdot T + 0.28, \tag{5}$$

where H – the depth of the groundwater level from the field surface at a certain moment in time, cm; T – duration of field drying, days.

For regression equations (1) and (2), the correlation coefficients are 0.95 and 0.91, respectively, and for regression equations (3), (4) and (5), the correlation coefficients are 0.98, 0.99 and 0.97 respectively. Such high values of the correlation coefficients testify to a close relationship between the correlated values and show that climatic factors do not have a determining influence on the intensity of the groundwater level lowering in the rice fields. The intensity of the groundwater level lowering is mainly determined by the design features of the drainage and discharge network.

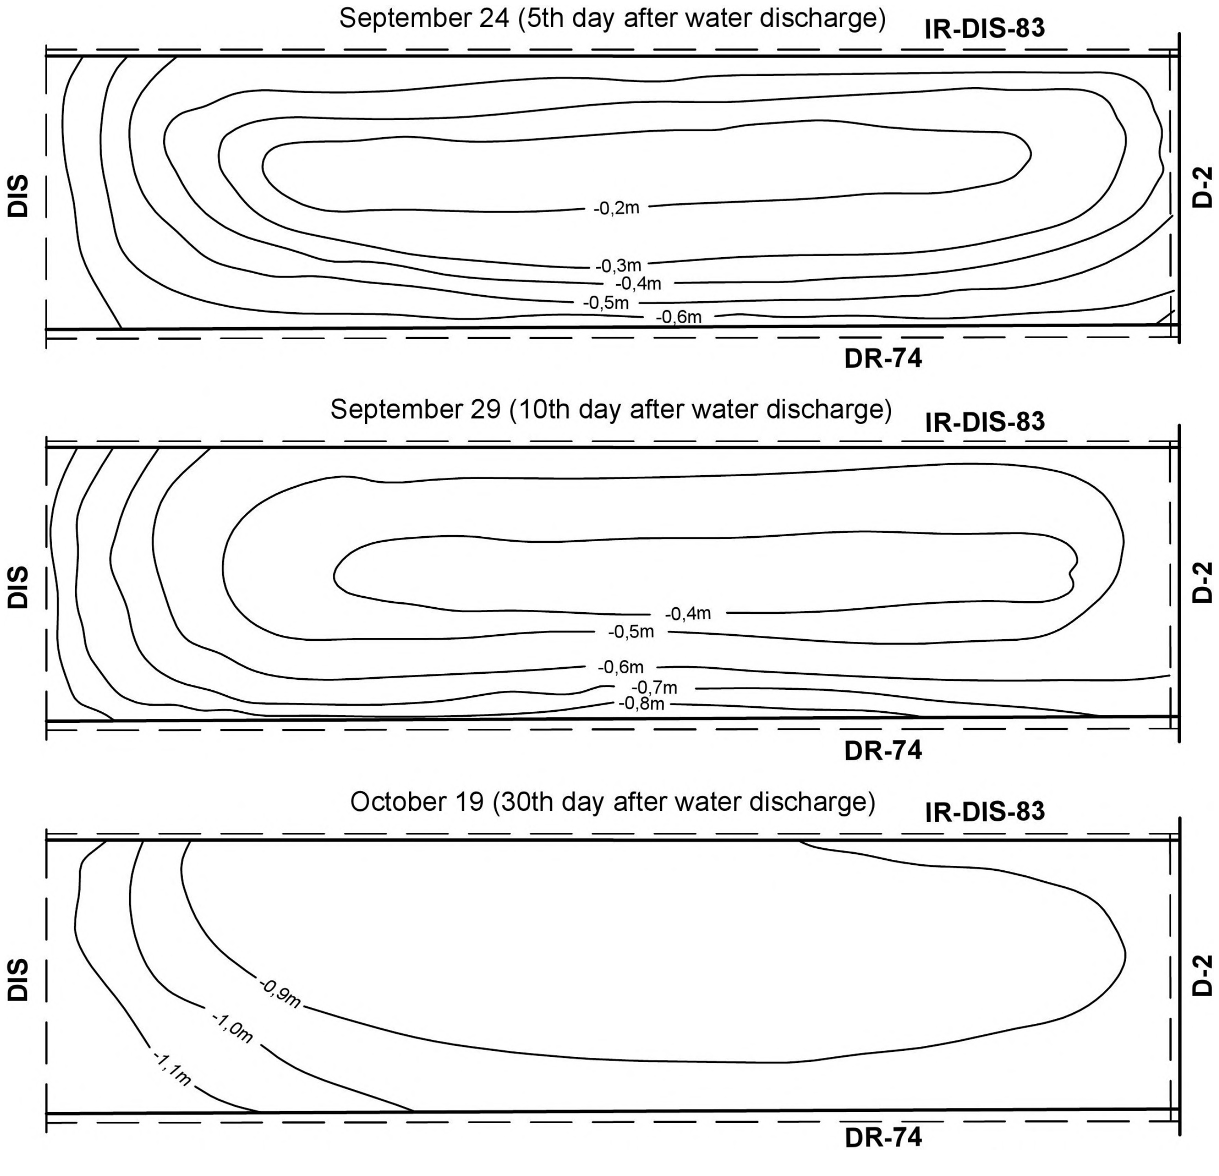

Figure 7. Drying of CCD of the rice irrigation plot No. 3 (inter-drainage distance of 500 m).

The graphs of the groundwater level lowering during the pre-harvest drying on the area of the rice fields, which were obtained according to regression equations (1–5), are shown in figure 8. They can be used to forecast the duration of the pre-harvest drying on the area of the rice fields with different parameters of the drainage network for the Danube RIS. With their help, it is possible to establish the terms of the groundwater level lowering in the rice fields to the depths under which a highly productive and high-quality harvesting of the rice crop will be possible

For the rice systems of the Danube delta, these depths are 0.6 m or more [2,9]. For conditions of CCD with inter-drainage distances of 200 and 250 m, the groundwater level lowering to the required depths is 6–7 days after discharge of water from them (figure 8). It takes 18–20 days for conditions of KTC with the same inter-drainage distances and 22–23 days for conditions of CCD with inter-drainage distance of 500 m. At the same time, the intensity of the groundwater lowering at a distance of 25 m from the drainage channel in the first day after water discharge is 0.2–0.12 m/day, and in the 20th day after water discharge, it decreases to 0.03–0.02 m/day.

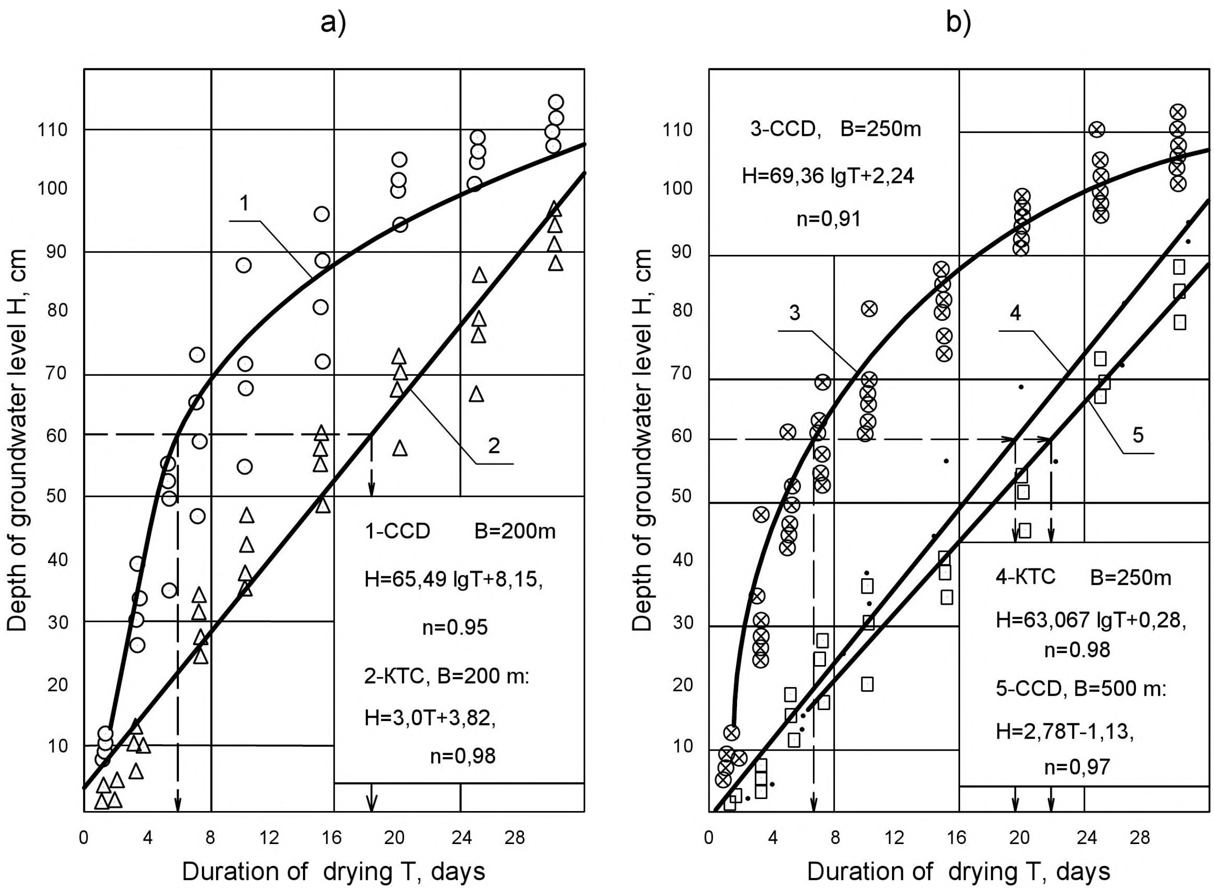

Figure 8. Intensity of the groundwater level lowering in conditions of KTC and CCD with inter-drainage distances of 200 m (a), 250 m and 500 m (b).

At a distance of 100 m from the drainage channel, the intensity of the groundwater lowering is 0.04–0.03 m/day in the first day after discharge and 0.005–0.01 m/day in the 20th day after water discharge (figure 9).

Due to the fact that rice fields of the CCD type with inter-drainage distances of 200 and 250 m dry three times faster than fields of the KTC type with the same parameters, as well as rice fields of the CCD type with inter-drainage distance of 500 m. Accordingly, the harvesting of the rice crop can be started earlier and done in a fairly short period of time. At the same time, harvesting equipment will be used more rationally, and crop losses associated with grain shedding will be minimized, which will positively affect the amount of the gross harvest.

Not only the timing of harvesting depends on the duration of pre-harvest drying but also the timing of autumn field work, namely, tillage (autumn plowing). Autumn plowing has a number of advantages over spring plowing, especially if it is carried out in September or at the beginning of October, since later times of its implementation reduce the yield of the crop [3, 4]. For conditions in the rice systems of the Danube Delta, autumn plowing of soils can be carried out when the groundwater level in the rice fields is reduced to a depth of at least 0.8 m. It takes 12–14 days to reduce the groundwater level to such depths on fields of the CCD type with inter-drainage distances of 200 and 250 m, 25–27 days for fields of the KTC type with the same parameters, and about 30 days for fields of the CCD type with inter-drainage distance of 500 m (figure 8).

Since the discharge of water from rice fields in the Danube RIS is carried out mainly in the

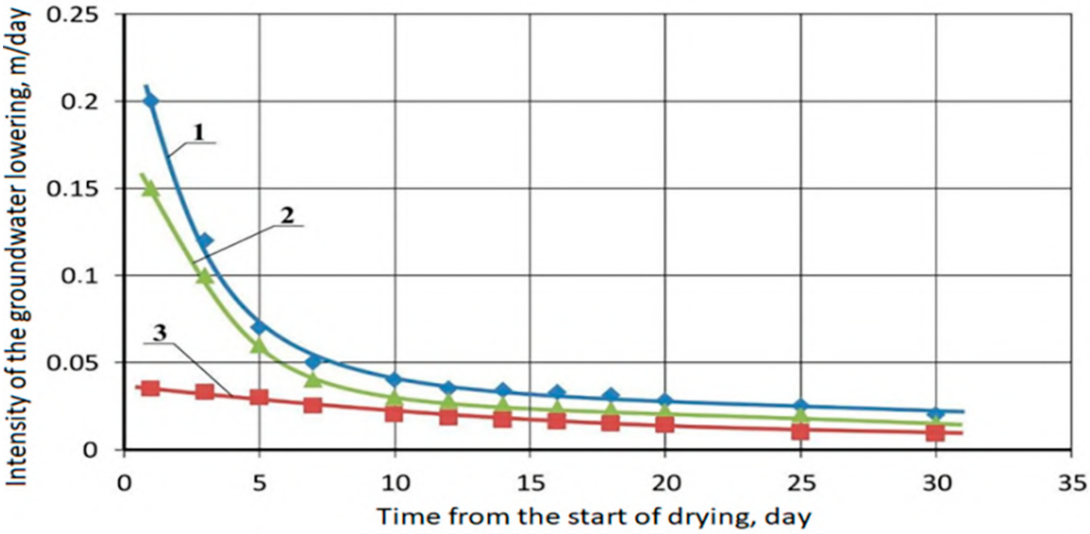

Figure 9. The graph of the groundwater lowering intensity change after water discharge from the rice fields for conditions of CCD with inter-drainage distance of 200 m (1 – at a distance of 25 m from the drainage channel, 2 – at a distance of 50 m from the drainage channel, and 3 – at a distance of 100 m from the drainage channel).

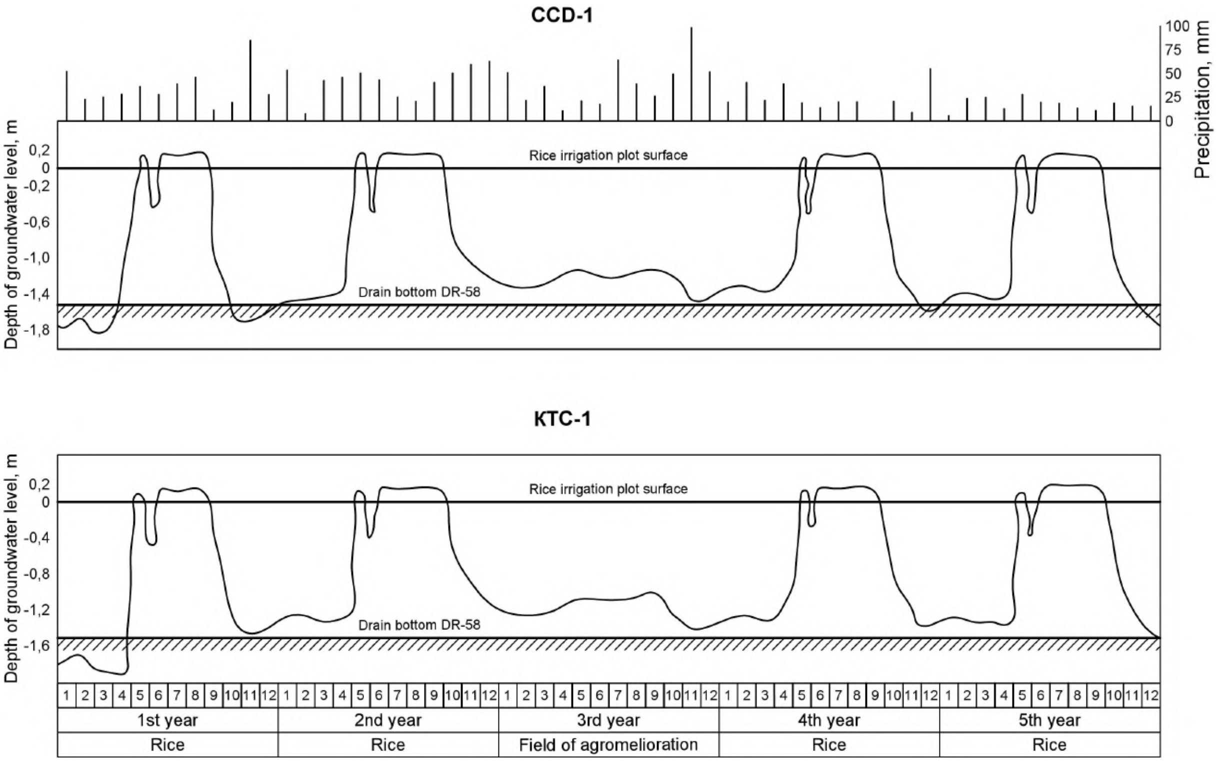

Figure 10. Change of groundwater level position in the rice irrigation plot No. 1 (for CCD and KTC with inter-drainage distance of 200 m).

second half of September, taking into account the terms of drying of the fields, it is possible to carry out autumn plowing at the optimal time only on the CCD type with a gap of up to

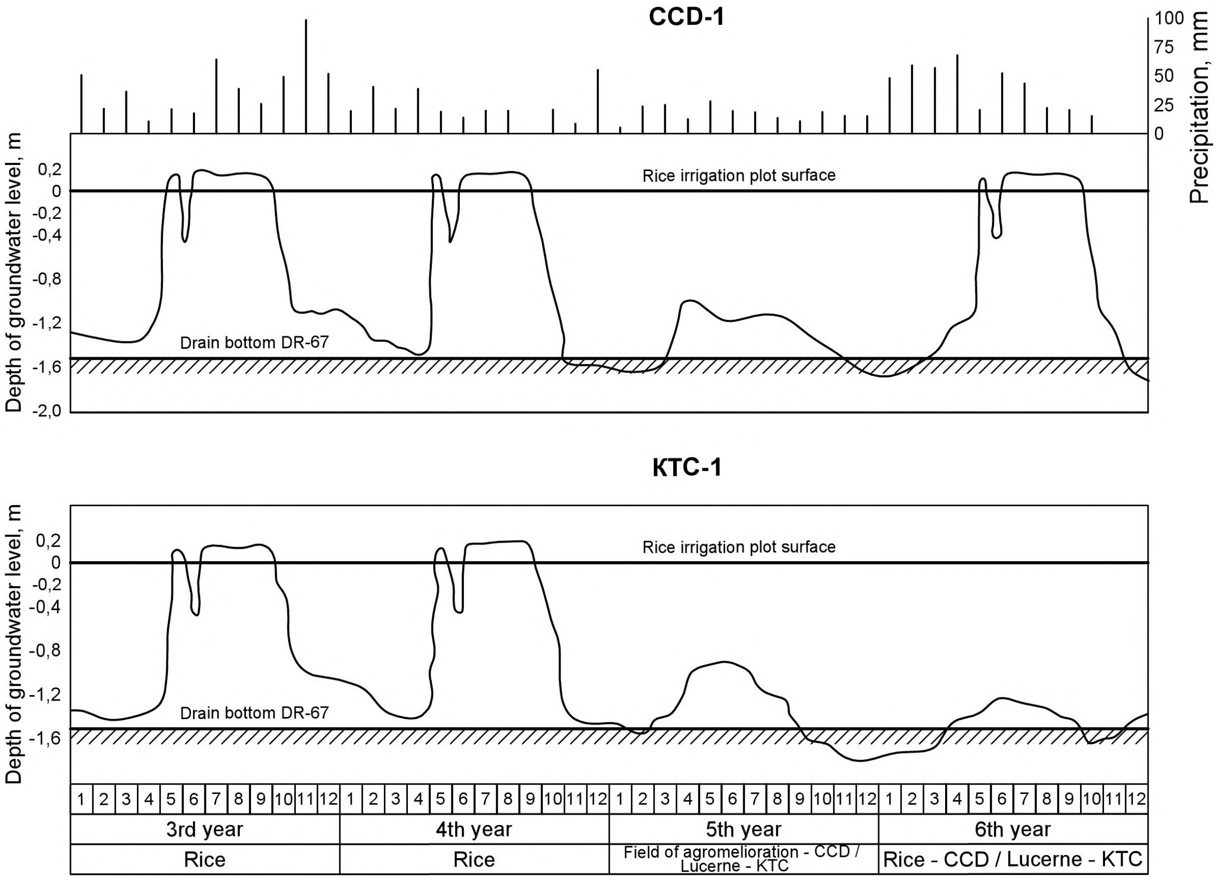

Figure 11. Change of groundwater level position in the rice irrigation plot No. 2 (for CCD and KTC with inter-drainage distance of 250 m).

250 m. It is almost impossible to carry out this measure in the optimal time on fields of the KTC type with inter-drainage distances of 200 and 250 m and on fields of the CCD type with inter-drainage distance of 500 m. In some cases, due to the large amount of precipitation that fell in November, it becomes impossible to carry out autumn plowing at all, as we observed in some fields of the KTC type.

An important indicator of the effective operation of the drainage and discharge network in rice fields is the maintenance of groundwater level within optimal during the inter-vegetation period. In [12] it was established for the conditions of researchers in other areas of rice sowing that obtaining high rice yields is possible when the groundwater level occurs during the inter-irrigation period at depths of more than 1.5–2.0 m [14–17]. With such depths of groundwater level in rice fields, aeration conditions are improved and salinization of the root layer of soils is prevented.

In the areas with a close occurrence of the groundwater level (0.5–0.6 m), reduction processes are intensified in the upper horizon, which leads to the accumulation of divalent forms of iron (Fe^{2+}), hydrogen sulfide, mobile manganese, and ammonia nitrogen, the pH value increases, and the content of nitrate nitrogen decreases. At the time of sowing rice, the soil does not have time to oxidize well, which causes poor crop germination and, as a result, a drop in the rice crop harvest.

Since the highest level of groundwater is typical for the central parts of rice fields, graphs of changes in the groundwater level were constructed for boreholes located in the center of

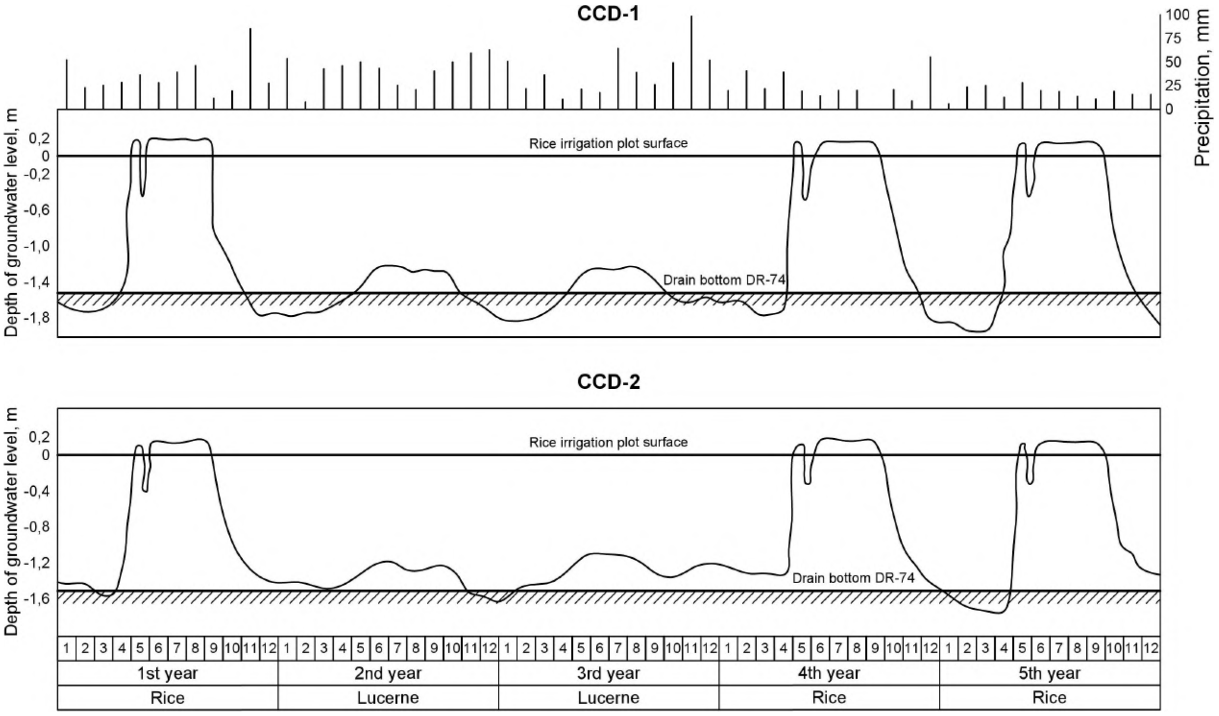

Figure 12. Change of groundwater level position in the rice irrigation plot No. 3 (for CCD with inter-drainage distance of 250 m and for KTC with inter-drainage distance of 500 m).

experimental plots CCD and KTC (figures 10–12).

According to the received data, it was determined that after 30–60 days after the discharge of water from the fields of the CCD and KTC types with inter-drainage distances of 200 and 250 m, approximately the same level of groundwater remains, which, before the beginning of the next irrigation season, changes within, close to 1.5 m from the surface of the rice fields. In this case, the level of groundwater practically did not depend on the type of rice irrigation plots but was mainly determined by the depths of the drainage and discharge network and the amount of precipitation in the inter-irrigation period. In some cases, for example, in the autumn of the 1st and 3rd year of the research at the experimental rice irrigation plot No. 1 (CCD), the groundwater level was somewhat lower than at the KTC (figure 10). This is explained by the more intensive drying of fields of this type in the first 15–20 days of pre-harvest drying.

On fields of the CCD type with inter-drainage distances of 500 m, the levels of groundwater during the inter-irrigation period were mainly 0.4–0.6 m higher than in the neighboring fields of the CCD type with inter-drainage distances of 250. Groundwater levels practically did not decrease below a depth of 1.5 m in relation to the surface of the rice fields (figure 11 and figure 12). This was one of the main reasons for the rather low yield of rice on this type of field.

Due to the fact that on the CCD it is possible to create a water regime that best meets the physiological needs of rice culture, as well as due to the uniform and more intensive desalination of filds, a higher rice yield was recorded on them, on average by 5–7 centner·ha^{-1} than on control KTC with the same parameters and by 17 centner·ha^{-1} higher than on the CCD with the distance between drainage channels 500 m.

4. Conclusions

Thus, evaluating the efficiency of operation of the drainage and discharge network of rice fields on the experimental rice irrigation plots in the period of pre-harvest drying and in the inter-vegetation period, the following conclusions can be obtained:

- due to the more intensive and uniform drying of rice fields of the CCD type with inter-drainage distances of 200 and 250 m, they have the most favorable conditions for high-quality and highly productive performance of rice harvesting and autumn field work;
- fields of the KTC type with inter-drainage distances of 200 and 250 m and fields of the CCD type with inter-drainage distances of 500 m dry slowly, as a result, harvesting and tillage are often carried out late. The terms of performance of these works are significantly extended, and in some cases, it becomes impossible to perform autumn plowing of soils;
- during the inter-vegetation period, in all experimental rice irrigation plots, groundwater was observed at depths of 0.2–0.5 m above the optimal limit, and in the fields of the CCD type with inter-drainage distances of 500 m, the groundwater level was almost constantly above the optimal limit;
- in order for the groundwater level to be at the required depth (more than 1.5 m from the field surface) during the inter-irrigation period, regardless of climatic factors, the open drainage and discharge network must have a depth of at least 1.8–2.5 m.

Abstract. The Water Strategy of Ukraine for the period up to 2050 [1] identified the main areas for improving water resources management through the creation of automated information systems for eight river basin districts. Conducting geoecological studies using GIS technologies to assess the state of river-basin systems at the level of an individual community in order to optimize water use and water protection is an urgent scientific task. The creation of geographic information models and the formation of the database took place in the environment of software packages: Google Earth Pro, SAGA, QGIS 3.28 Firenze and ArcGIS 10.8. To assess the geoecological state of the floodplain-channel complex of rivers within the territory of the Turka territorial community (TC), the methodology of Khimko et al. [2,3] was chosen, which is modified in accordance with the purpose of the research and specific water bodies. The created geoinformation models of the gynaecological state of the floodplain-channel complex of rivers indicate the need to make effective management decisions to optimize the use of natural resources within the basin and floodplain-channel systems and control over the use and protection of water.

1. Introduction

The Water Strategy of Ukraine for the period up to 2050 [1] outlines the vectors for the development of water management and water resources management, which includes the introduction of eight automated information systems in the relevant areas of river basins by 2032. They will be involved in making management decisions in the field of environmental protection to ensure management, control over the use, protection of water and reproduction of water resources at the national level. At the same time, the administrative reform of 2020 [4] opens up wide opportunities for local communities to dispose of the natural resource (including water resource) potential of the territory of their residence. Therefore, the *urgent* scientific task of today is the analysis of the geoecological state of water bodies at the regional and local levels and the creation of appropriate geoinformation databases that will be used in the development of a water protection strategy for the development of a separate territorial community and the assessment of the investment attractiveness of the territory. The *object* of the study was the Turka community (with an area of 398.8 km^2) as a newly formed administrative-territorial unit within the Sambir district of the Lviv region (Ukraine). Part of the Main European Watershed, which separates the waters of the Baltic and Black Seas, passes through the territory of the Turka urban community. The second important watershed within the community is the Verkhovyna watershed range, which separates the waters of the Dniester and Danube basins [5]. This is the place of origin (source), formation of the flow of many small rivers. Within the study area there is also the Stryi River, which is classified as medium according to the Water Code of Ukraine, and the upper reaches of the large Dniester River. The analysis of the hydrological regime of water bodies and the quality of river waters has been carried out by many scientists and the results of regional comprehensive geoecological studies have been published in monographs [6–12].

Detailed studies of the geoecological state of the upper part of the Dniester basin were conducted by Pylypovych [12]. The state of the environment of the study area is also analyzed in [10, 11].

Among the world's best practices, it is worth mentioning the study by Grizzetti [6], which indicates that the ecological status of rivers in the European Union is influenced by multiple natural and anthropogenic factors at the local and regional levels. This indicates the need for an integrated approach when implementing measures to improve the ecological quality of rivers. Similar conclusions can be traced in [7, 13–18]. Noteworthy is Xu et al. [9], who has developed a new system for assessing environmental parameters for small rivers in Shanghai, using 17 indicators to assess water quality, ecological system, and ecological landscape.

However, detailed large-scale hydroecological studies at the level of a separate territorial community using modern GIS technologies have not been carried out in order to create an information database of geodata and optimize water resources management and water protection.

The analysis of the water resource potential of the territory of the Turka community was carried out by assessing the geoecological state of the floodplain-channel complex of rivers, carried out using GIS technologies and field research materials.

2. Method

Geoinformation modelling of the geo-environmental state of the community territory involved the following research stages: collection of existing information, its processing; conducting own research (field, geoinformation, laboratory and other methods); generalisation of the collected geo-environmental information and formulation of general conclusions.

In the course of the research, a series of large-scale topographic maps, as well as Google satellite images of 2022, open-source OpenStreetMap data, and land cadastre materials were processed [19]. The following software packages were used to create geoinformation models and create the database: Google Earth Pro, SAGA, QGIS 3.28 Firenze and ArcGIS 10.8 [20].

The algorithm for creating geoinformation models included:

1. Search and selection of cartographic sources and satellite images.
2. Preparation of images and satellite images for processing in the geographic information software environment.
3. Coordinate referencing of geospatial data and selection of a coordinate system.
4. Create feature layers in shapefile formats with a geometric element (point, line, or polygon).
5. Digitization of data and addition of information from state cartographic databases.
6. Filling in attributive data taking into account the types of objects, their quantitative, qualitative and spatio-temporal parameters.

7. Carrying out cartometric, analytical, overlay operations to obtain new analytical data on the state of each of the analyzed components of the environment using optimal visualization and presentation techniques.

A method for assessing the geoecological state of the floodplain-channel complex of rivers (test) was proposed by Khimko [2,3,21,22]. It involves determining the state of the channel and floodplain by visual indicators based on their comparison, inspection and comparison, as well as determining changes based on the results of a survey of old-timers in this area. The assessment is carried out by assigning appropriate points. According to this scheme, a river in good condition should receive the highest marks (points); Accordingly, the river in poor condition is not high. The scheme allows the provision, if necessary, of intermediate estimates. There are 5 gradations of the sum of points (5 quality classes), and 23 parameters are analyzed to determine them. These parameters are grouped into three categories: the first is the assessment of the river; the second is an assessment of the state of the floodplain; the third is information from a survey of the population (changes over a period of 10-40 years) about the depth and nature of the changes that have occurred with the river, in comparison with the state that old-timers recall (the use of comparative characteristics – before/after) [21,22].

After summing up the points, according to this methodology, an act of survey and determination of the general geoecological state of the river is drawn up.

3. Results and discussion

The *Turka community* is a territorial community in the Sambir district of the Lviv region (figure 1).

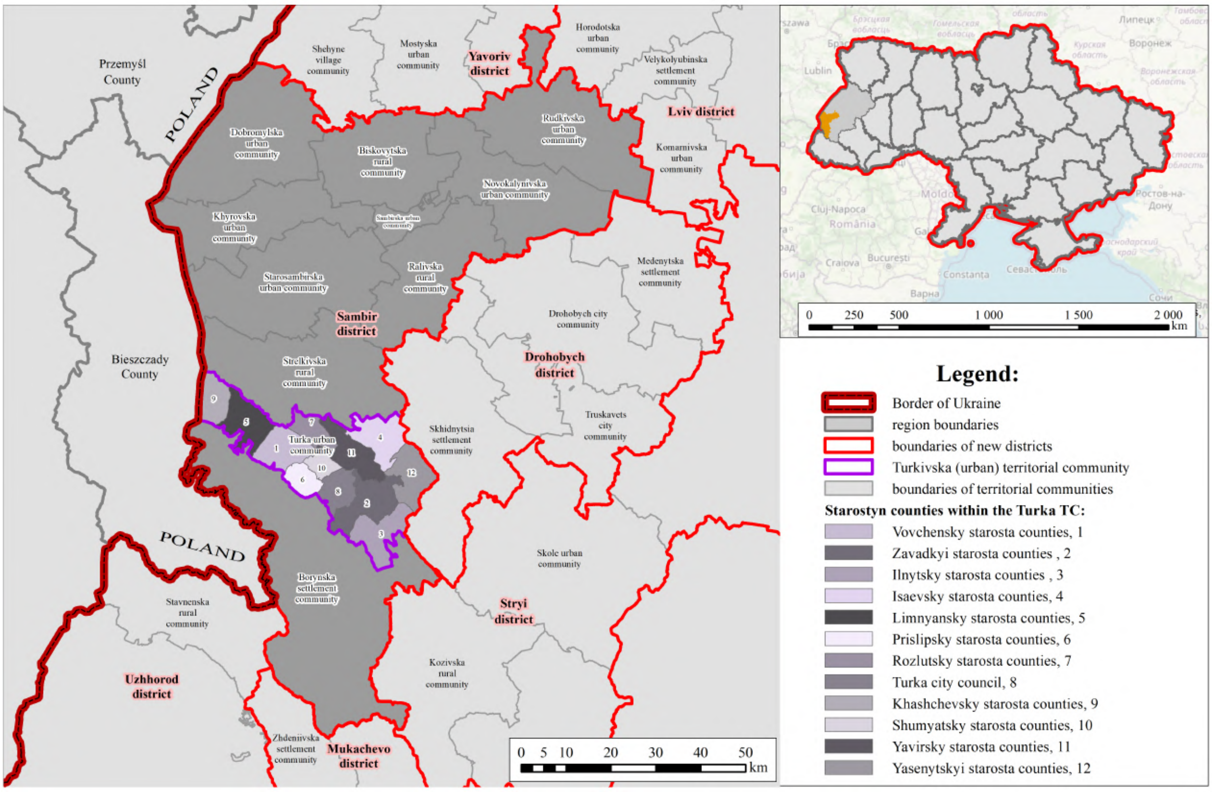

Figure 1. Location of Turka territorial community (complied on the basis of OSM).

Its administrative center is the city of Turka. The area of the community is 398.8 km^2, the population is 23.6 thousand people. people (as of 2022). The population density is 59.17 people/km^2. In the north, the Turka community borders on the Strilky TC of the Sambir district, in the east with the Skhidnytska TC of the Drohobych district, in the south – the Borynska TC of the Sambir district, and in the west – with the Republic of Poland [23, 24].

The hromada consists of 1 city (Turka) and 24 villages, which in turn are united into 11 starosta districts (created on the basis of village councils of the same name).

The total length of watercourses within the territory of Turka TC is 1,282.95 km (obtained from the QGIS statistical report layer). It is worth noting that these are permanent watercourses that do not dry up in summer, but only change the water regime. The river network is formed by: the Dniester River, the Stryi River, the Zavadka River, the Yasenytsia River, the Yablunka River, the Litmyr River, the Kindrativka River, the Zvir River, the Yavirka River, the Yasenychanka River, the Khashchivka River and their tributaries.

The average density of watercourses is 2.21 km/km^2) The data are obtained on the basis of GIS analysis of the river network. This indicator ranges from 0.04 to 6.64 km/km^2) and is characterized as high (figure 2). The highest density of watercourses is concentrated near the village of Vovche – at the headwaters of the Dniester River; in the village of Shumyach, where the Zvir River flows into the Litmyr River; in the village of Ilnyk – near the mouth of the Zavadka River; in the village of Yavora – the confluence of the Yavirka River with the Stryi River; in the catchment area of the Kindrativka River near the villages of Kindrativ and Yasenytsia. Accordingly, the lowest values of the density of watercourses were determined at the community boundary.

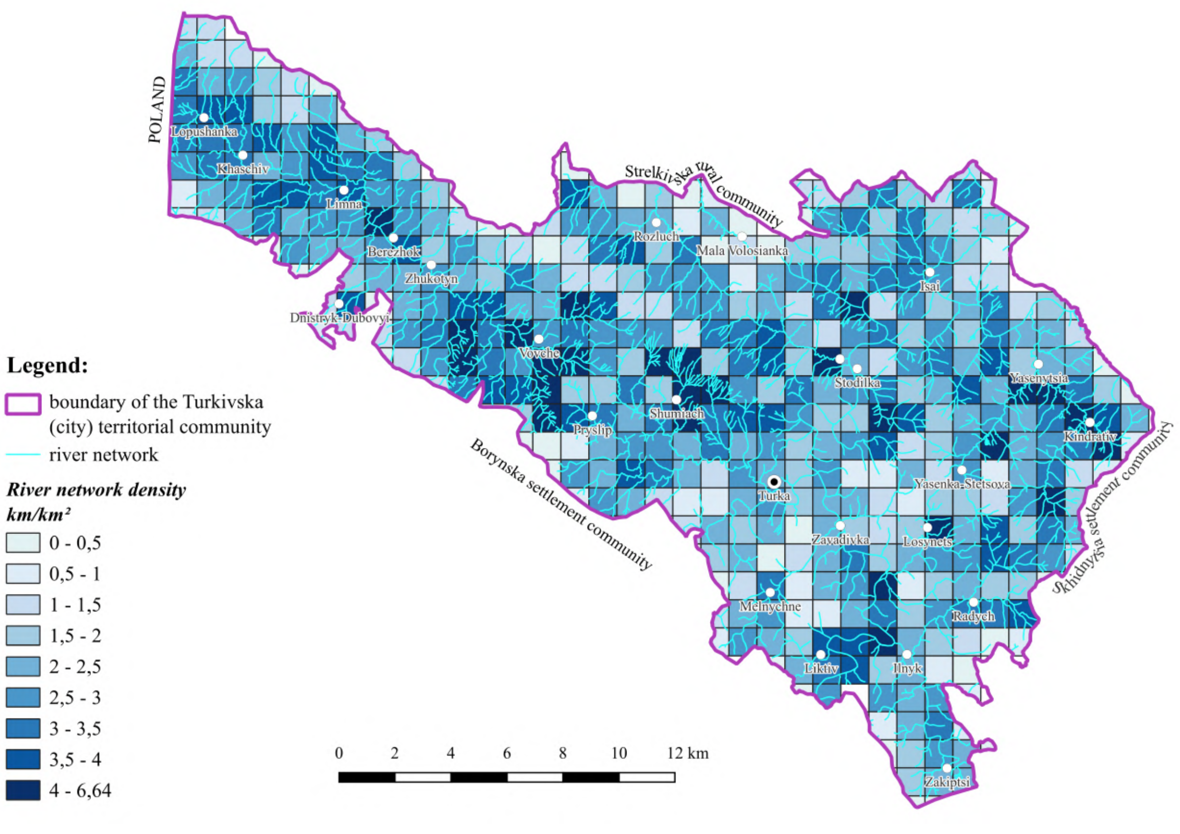

Figure 2. Density of the river network within the study area.

The study of the state of the floodplain-channel complex within the territory of the Turka community was carried out in three standard stages: preparatory, field surveys and office processing of the collected materials by summarizing the results of the assessment of the geo-ecological state of the river according to the test performed.

The preparatory stage consisted in the study of natural conditions and economic factors that affect the formation of the geo-ecological state of the community. Based on these results, it was determined which components of the environment are most affected. It was found that water resources are the most vulnerable within the community, and the impact on other components of the environment is minimal or absent (due to the lack of sources of impact), so our research was further aimed at assessing the state of water bodies [2, 3, 21].

To assess the geoecological state of the floodplain-channel complex of rivers within the territory of the Turka community, the methodology of Khimko et al. was chosen [2, 3, 22], which was modified in accordance with the purpose of the research and adapted to specific water bodies [25]. According to this methodology, a set of parameters (23 indicators in total) was determined, which were interpreted in the form of a point scale, and then, on the basis of their summation, an assessment of the geoecological state of the floodplain-channel complex was given.

At the *preparatory stage*, the following was also developed: routes for field surveys of the state of rivers and their floodplain-channel complexes were developed (on the basis of cartographic studies); key areas of riverbeds and floodplains were selected as priorities for detailed research; evaluation forms (figure 3) and forms of reporting materials are formed; measuring equipment (pre-calibrated and other inventory) has been selected.

Field geoecological studies were carried out according to the plan:

- departure to the study area, inspection of the floodplain-channel complex of rivers when moving along its banks;
- along the main route (at key points) the states of the channel and floodplain were described

Observation point No. 12

Geographical coordinates: 49.112725° N, 23.075748° E

Description of the area

The right bank of the Stryi River, the beginning of Ilnyk village, next to the road. The riverbed is natural - it has all its inherent elements: shallows and deep sections, meandering, with sections with fast and slow flow. The bottom is of a natural rocky type with soft sediment. There are accumulations of objects of unnatural origin. Landscapes within the valley are heavily disturbed, as a large area is used for economic purposes, including buildings. Natural phytocoenoses are heavily modified. Non-compliance with the boundaries of coastal protection zones. There are a significant number of sources of small volumes of runoff. The river and surrounding landscape have changed over the years, but they are still attractive.

Indexes	value
Загальний вміст солей (TDS)	95 mg/dm³
The pH level	7 (l. t. - 7)
Water temperature	13,9 °C
Electrical conductivity (EC)	304 μS/cm
Salinity	0,01 ‰
Specific density (S.G)	1,000 g/l
Redox potential	-42 mV
Flow rate	0,9 - 1,2 m/s
Maximum depth	211 m/s

Identification of organoleptic properties of water		
Indicator	Water colour	Yellowish colour, shade - light yellow.
	Water smell	Subtle, fishy - score 2 points. The comparison was carried out: at collection; 6 hours after collection, where the water was heated to 60 °C; after settling for 24 hours. The smell did not change.
	Transparency	When using the Secchi disc, the water transparency is 40 cm, at a depth of 50-55 cm the transparency is minimal. According to the water column method, the height of the water column is 43 cm.
	Turbidity	The water at this site is classified as slightly opalescent.
	Precipitate	The sediment is noticeable. The quality is of silty-clumpy nature. It is black-brown in colour. During shaking, the precipitate is noticeable.

Methodology (test) for assessing the geo-ecological state of the floodplain and channel complex according to Khimko R.V. et al.

Parameters	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	sum

Figure 3. Survey form of floodplain-channel complex conditions.

and their scores were given in accordance with the described methodology;

- a survey of local residents about changes in the state of the riverbed and floodplain was carried out and estimates in the form of "before/after" were recorded;
- point and diffuse sources of environmental pollution were linked and fixed on the map;
- photographing and mapping of the study area was carried out;
- water quality was assessed by organoleptic indicators;
- search for sites or intermediate points for additional studies was carried out.

The *stage of generalization* of the research results consists in the processing and systematization of the collected information, summing up the results of field work, determining the geoecological state by summing up the scores and their visualization and interpretation in the form of maps.

Based on the results of the test, both general conclusions about the geoecological state of the floodplain-channel complex of rivers and local ones for individual sections (of the same type and representative) were formed.

To assess the geoecological state of the floodplain-channel complex of rivers (GSFCCR), the Stryi and Dniester rivers were surveyed within the territory of the Turka urban community (figure 4).

The following indicators were studied: *I. Assessment of the river:* (flow rate; condition of the riverbed; regulation of the river by dams, ponds or other regulatory structures; nature of the bottom, its siltation; nature of river water; water temperature; clogging of the riverbed; nature of aquatic vegetation; overgrowth of the riverbed; presence of ichthyofauna; state of banks and

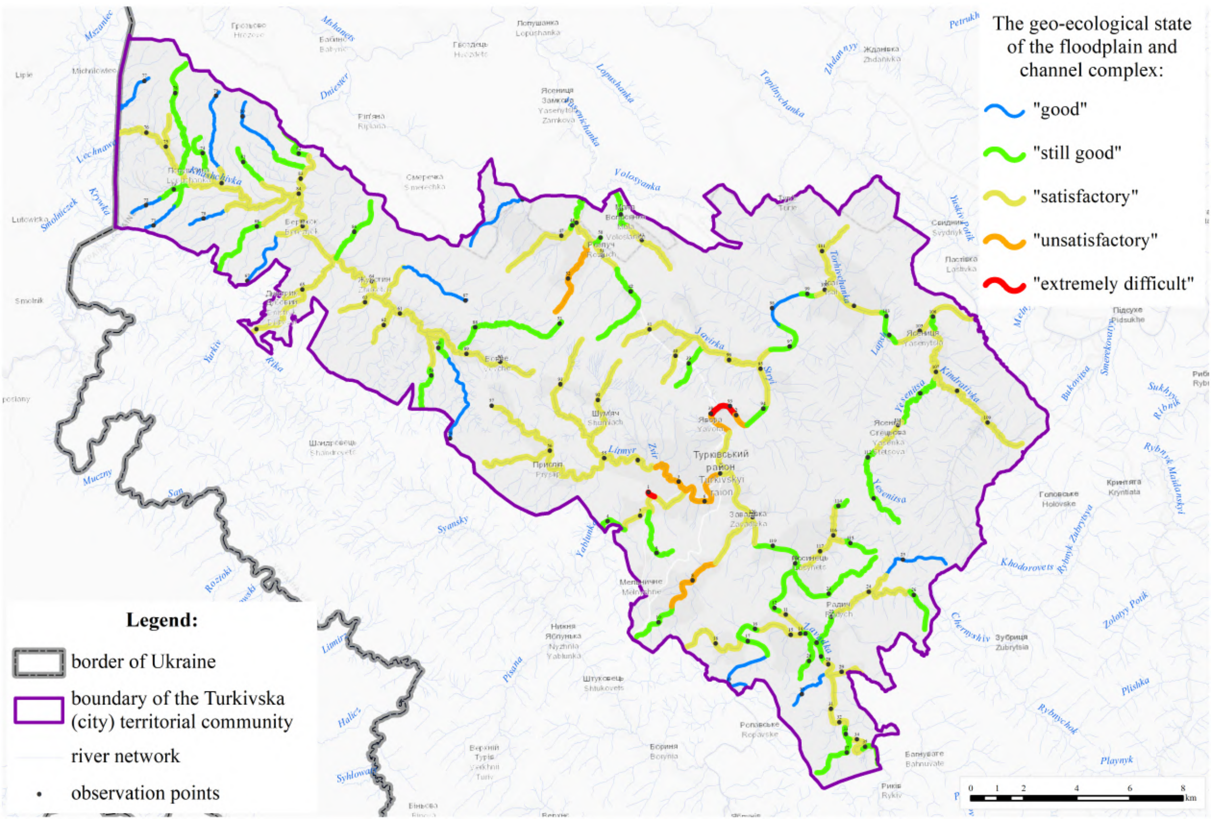

Figure 4. GSFCCR within the territory of the Turka urban community (built for [2, 3, 22]).

coastal protective strip (CPS)); *II. Assessment of the state of the floodplain* (the ratio of natural elements of the floodplain to the transformed ones; the width of the undisturbed part of the floodplain with natural or close to it biocenotic (vegetative) cover, the degree of disturbance of the natural landscapes of the river valley; the degree of degradation of natural phytocenoses of the floodplain; traces of water plane erosion; the level of recreational load; contamination of the coastal protective strip; the nature of the economic use of the floodplain; the presence of residential buildings or other buildings in the floodplain Structures; use of river water, the presence of direct effluents into the river); *III. Information from the population survey* (changes that occurred over a period of 10-40 years).

The total number of key points where we measured the main parameters and mapped the territory is 120 pcs. For their initial display, a Google map was created with free access (for viewing), where the coordinates of these points and other information are indicated [26].

It was found that the general indicator of the geoecological state of the floodplain-channel complex of rivers on the territory of the Turka TC ranges ***from 59 to 253 score***. Of the total:

- 14 points received more than 230 score, where the condition can be assessed as *"good"*;
- 47 points (in the range of 230-170 score), where the condition of the river is *"still good"*;
- 51 points (in the range of 170-120 score), where the condition of the river is *"satisfactory"*;
- 6 points (in the range of 120-65 score) where the condition of the river is *"unsatisfactory"*;
- 2 points (less than 65 score), where the state of the river is *"in extremely serious condition"*.

According to the calculations based on the methodology [2,3,22] the average score is ***172.65 score*** (within the range of 230-170). The general condition of the rivers can be assessed as *"still good"*, but there is a possibility of degradation processes. This should cause concern among local residents and the need to implement a set of preventive measures to preserve and protect rivers; among them, educational and informational activities are particularly important.

As can be seen from (figure 4), the condition of large sections (42.5 percent) of the floodplain-channel complex of rivers (mainly the valleys of the Dniester and Stryi) is assessed as *"satisfactory"*. Negative changes are actively taking place in the river. It is necessary to implement water protection measures for its recovery. It is also expedient to develop and gradually implement a local environmental action plan to reduce the anthropogenic load on multi-rank basin systems within the territorial community.

Sections of watercourses with an indicator of more than 230 score (11.6 percent) were singled out separately, where the state of the river can be assessed as *"good"* and limited only to preventive measures for its preservation, in particular, compliance with the conditions of nature management within the coastal protection zones – restriction of grazing, prevention of regulation of flow and construction of economic structures within the floodplain, as well as clogging of the floodplain and riverbed, etc.

4. Conclusions

The study of the state of the floodplain-channel complex at the level of an individual territorial community using modern GIS technologies and detailed field surveys allows obtaining an information base as a tool for implementing an environmental action plan for the conservation of water bodies at the local level.

Within the territory of the Turka community, only half (50.8 percent) of the studied river-basin systems received an indicator of the state of the river as *"good"* and *"still good"*. These are generally small watercourses – tributaries of the upper Dniester (figure 4). About 7 percent of the sections are characterized by the condition of the river as *"unsatisfactory"* and *"in extremely serious condition"*.

The obtained cartographic materials reflecting the geoecological state of the floodplain-channel complex of rivers on the territory of the Turka community indicate the need to make effective management decisions to optimize nature management within the basin and floodplain-channel systems and control over the use and protection of water.

In particular, ensuring the functioning of the system of coastal protection zones significantly reduces the load on the channel complex due to the prohibition of: plowing land (except for preparing the soil for tinning and afforestation), as well as gardening and horticulture; storage and application of pesticides and fertilizers; arrangement of summer camps for livestock; construction of any structures (except for hydrotechnical, navigational, hydrometric and linear), including recreation centers, summer cottages, garages and parking lots; arrangement of garbage dumps, manure storages, accumulators of liquid and solid production waste, cemeteries, cattle burial grounds, filtration fields, etc.; washing and maintenance of vehicles and equipment.

Acknowledgments
The research was carried out within the framework of the topic “Problems of transformation of natural and anthropogenic geosystems of the western region of Ukraine in the context of European integration” (state registration number: 0123U102092) of the Department of Constructive Geography and Cartography of Ivan Franko National University of Lviv and cooperation with the Department of Geodesy and Cartography of the National University of Life and Environmental Sciences of Ukraine.

Abstract. Today, the rapid disappearance of bivalves in European water bodies is a matter of serious concern. The state of study of mollusks of the family Sphaeriidae in Europe, including Ukraine, is considered insufficient, which does not allow to assess their resources, develop measures for protection and restoration of their numbers. The paper assesses the distribution and frequency of occurrence of the small bivalve *Musculium lacustre* Müller, 1774 (Mollusca, Bivalvia, Sphaeriidae) in the anthropogenically altered aquatic landscapes of the northern right bank of the Dnipro River of Ukraine. This species is considered to be quite eutopian, but in the surveyed region it shows a clear tendency to decrease the frequency of occurrence and population density of individuals. The reason for this situation is the disappearance of typical habitats due to the transformation of rivers into a system of ponds and reservoirs as a result of dam construction and pollution. Out of 232 sites analyzed, *M. lacustre* was found in the Pripyat sub-basin in only 5 sites, and in the Teteriv basin (Middle Dnipro sub-basin) in only 2 sites (the frequency of occurrence in these sub-basins is 4% each, and the overall figure for the sampling area is 3%. The maximum population density was 21 in the Hnylopyat River, 11 in the Gusak River, and 1-3 ind./m^2 in other sampling sites, although according to literature data, in the last century it could reach several thousand per m^2 in Ukraine. Found in rivers and streams, it prefers flowing areas.

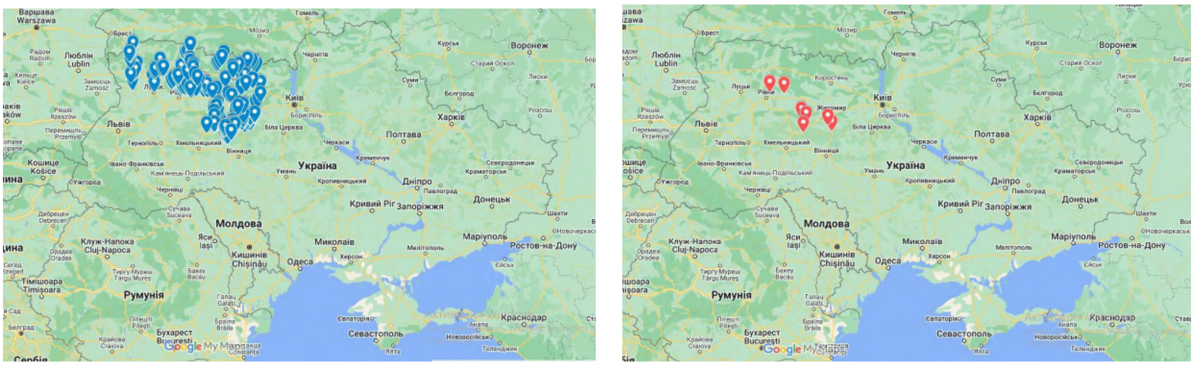
1. Introduction

Freshwater bivalves are important components of hydroecosystems because they provide an important ecosystem service by filtering water and shaping its quality. No freshwater ecosystem can exist without filtering species. Ukraine's integration into the European scientific space, the implementation of the Water Framework Directive [1, 2], and the realization of the Sustainable Development Goals [3, 4] require that information about this group of aquatic organisms in Ukraine be presented on the scientific map of Europe, which will further allow for the planning of joint conservation measures and the inclusion of bivalves in Ukraine in the state water quality monitoring programs for natural water bodies. The issue of water conservation is an acute one in Ukraine. Freshwater bodies, especially rivers, have undergone significant anthropogenic transformation as a result of human activity. Their condition has been affected by damming, land reclamation, discharge of untreated wastewater, unregulated fertilization in areas of intensive agricultural development, pesticide ingress, deforestation, etc. As a result, many groups of aquatic organisms, including bivalves, have seen their numbers in freshwater bodies sharply reduced and often disappear from them due to changes in habitat conditions. The problem of revitalizing rivers, especially small ones, and restoring important and typical groups of aquatic organisms is becoming increasingly acute. Today, 77.3% of freshwater mollusks of the Unionidae family in Europe are already in need of protection and have a protected status, but due to insufficient study, only 8.3% of Sphaeriidae representatives have such a status (Red List). For this purpose, first of all, according to the International Union for Conservation of Nature and Natural Resources (IUCN) Red List criteria (Criterion A and B), it is necessary to estimate the number of their populations and the current area. In total, there are 39 species of mollusks of the family Sphaeriidae in the Western Palaearctic, including two North American invasive species, *Sphaerium transversum* and *Euglesa compressa*, whose invasion aggressiveness has not yet been recorded. The systematics of the group of bivalves Sphaeriidae is one of the most controversial. There is no consensus among malacologists on the number of species that exist in Europe, and in Ukraine, and on the number of genera to which they belong. According to the previously prevailing systematic views, from 21 to 73 species were recorded for the territory of Ukraine at different times. Of the representatives of the genus Musculium, 6 species were recorded for Ukraine. Thus, the only currently recognized species *Musculium lacustre* Müller, 1774, was divided into the following: *M. terverianum* (Dupuy, 1849), *M. hungaricum* (Hazay, 1881), *M. mucronulatum* (Moquin-Tandon, 1855), *M. creplini* (Dunker, 1845), *M. ryckholti* (Normand, 1844), *M. clessini* (Clessin, 1880). Today, according to recent studies [5], all these species are considered to be one species of *M. lacustre* (Marsh Musculium), which belongs to the genus *Musculium*, although French malacologists include it in the genus Sphaerium. The species is distributed in the Palaearctic, in North America it was found from the northern states of the United States to Alaska, and introduced to Australia [6]. It is considered resistant to pollution, oxygen deficiency, and is the only species among the closely related ones present in degraded habitats [5, 6]. It is capable of settling in marshes, and due to their drainage, it has become rare in areas subjected to reclamation. Among European countries, it has a protected status in Ireland (Vulnerable species, VU) [7] and the Czech Republic (Near Threatened, NT) [8]. In general, according to the IUCN Red List 2022, it has the LC status, i.e. the least in need of protection [9].

Currently, Ukraine is home to eighteen species of Sphaeriidae belonging to three genera, namely Musculium, Sphaerium, and Pisidium. Freshwater bivalves are one of the most important components of hydroecosystems, acting as "ecosystem engineers", acting as natural filters and shaping the quality of water in reservoirs. Of course, the main attention of scientists has traditionally been drawn to the largest and therefore most convenient mollusks of the Unionidae family. Some of them can reach up to 250 mm in length, although they usually do not exceed 100 mm. It is known that one individual of this family can filter 200-400 ml of water per hour. Mollusks of the Sphaeriidae family are small (from 1.5 to 22 mm), so they are inferior in their filtration activity. However, since they can have population densities of up to several thousand per square meter, they undoubtedly play an important role in purifying water from particles of biological and mineral origin. They can also serve as food for fish, waterfowl, and aquatic insects. It is important to note that these mollusks, unlike the closely related Unionidae, are hermaphrodites, so they do not need a partner for reproduction and can quickly restore their numbers. At present, we can talk about the catastrophic disappearance of Sphaeriidae species from Ukrainian water bodies and watercourses. In our opinion, this is due to anthropogenic impact and the reduction and disappearance of habitats suitable for these species. The analysis of data on the detection of species of the family Sphaeriidae and their habitat in Ukrainian water bodies allows us to understand the causes of their extinction.

2. Material and methods

The material was based on our own collections of mollusks of the family Sphaeriidae, conducted in 2019-2023 within the northern right bank of the Dnipro River of Ukraine (mainly Zhytomyr-Volyn Polissya) (figure 1, table 1). Information on the collected material was entered into the database [5]. In total, we examined 232 typical habitats. We surveyed large, medium, and small rivers, streams, reservoirs, and ponds. Species affiliation was determined by analyzing



(*a*) (*b*)

The Khomora River, Polonne	50.09864, 27.68014	1	*U. tumidus*, *U. pictorum*, *A. anatina*, *A. cygnea*, *S. nucleus*

qualitative and quantitative morphological characters [10]. During the collection of material, a 50-100 meter long section of the water body was examined by the route method, habitats typical for the species were selected, where the material was searched for by cleaning the bottom sediments using hydrobiological sieves.

2.1. Ethical compliance

Throughout the experiments, we strictly adhered to ethical norms and principles governing research involving living organisms, in full compliance with the current laws of Ukraine. As part of our ethical commitment, we emphasize the following: the experimental mollusks in our study belong to the category of invertebrates, and we ensured that ethical considerations for their welfare were upheld; compliance with Ukrainian laws: we affirm that our research is fully compliant with the prevailing laws and regulations of Ukraine, including those governing the ethical treatment of research subjects.

3. Results and discussion

The analysis of literary and museum data from the malacological collections of the State Museum of Natural History (Lviv) and the Zoological Museum (Kyiv) allows us to conclude that in the twentieth century M. lacustre was quite widespread in Ukraine (figure 2). Analysis of museum materials allows us to conclude that it was also found in Galicia in the nineteenth century. The species was discovered in the basins of the Dniester, Dnipro, Western Bug, Prypiat, Prut, and was found in the rivers of Crimea and the Azov Sea [5, 11]. According to O. Korniushyn, the species is common to water bodies throughout Ukraine [5]. However, in recent years, there have been increasing reports of the disappearance of this group of aquatic organisms from reservoirs and watercourses due to their anthropogenic transformation and reduction of their

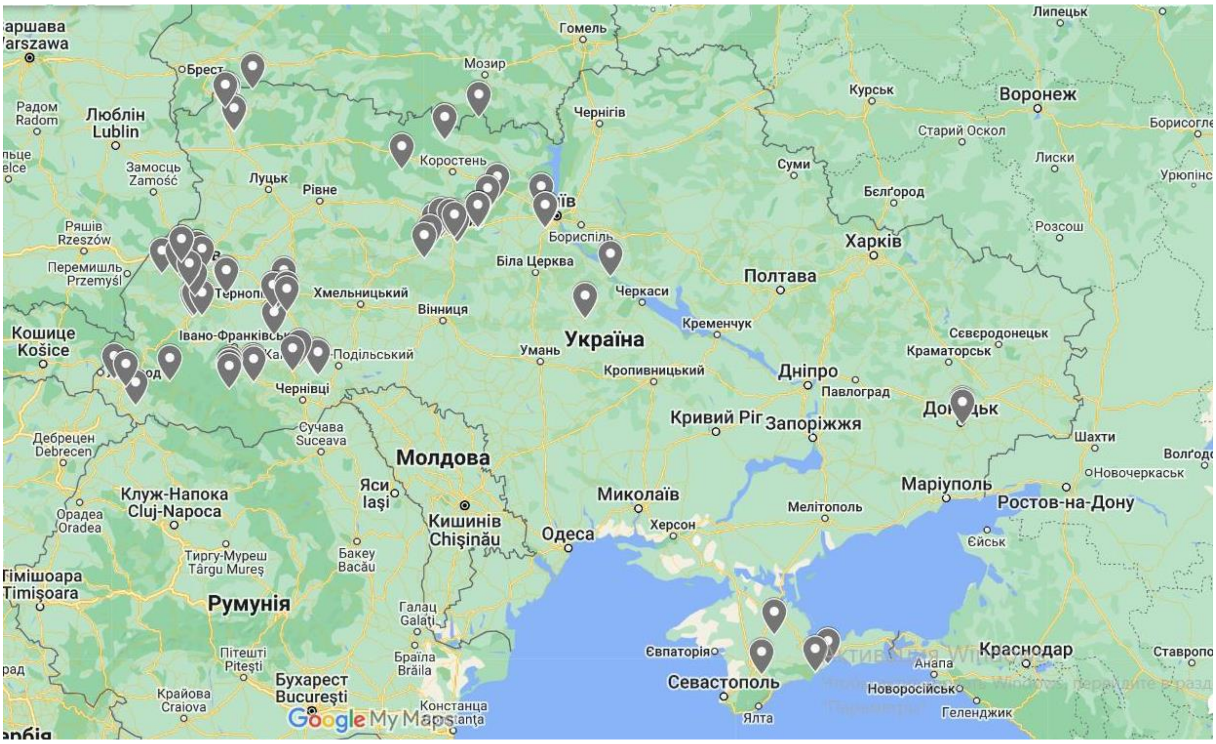

Figure 2. Locations of *M. lacustre* in the nineteenth and twentieth centuries in the river basins of Ukraine according to literature and museum data.

typical habitats [5, 10]. The landscapes of the area under study have also been significantly affected by human activity.

The analysis of the collected materials showed that out of 232 analyzed sampling sites, *M. lacustre* was found in the Pripyat subbasin in only 5 sites, and in the Teteriv basin (Middle Dnipro subbasin) in only 2 sites (table 1, figure 1, figure 3), i.e. its frequency of occurrence in these subbasins is 4% in each, and in general this figure is 3% for the study area. In its habitats, the species was found together with *Sphaerium rivicola* Lamarck, 1818, *S. nusleus* Studer, 1820, *P. obtusale* Lamarck, 1818, *Anodonta anatina* Linnaeus, 1758, *A. cygnea* Linnaeus, 1758, *Unio pictorum* Linnaeus, 1758, *U. tumidus* Philipsson, 1788 (table 1).

Typical sampling sites of *M. lacustre*: The Sluch River, Nova Chortorya village (*a*); The Hnylopyatka River, Khazhyn village (*b*); The Husak River, Levkivka village (*c*); The Horyn River, Oleksandriia village (*d*); The Hnylopyatka River, Raiky village (*e*); The Stavy River, Shchekichyn village (*f*); The Khomora River, Polonne town (*g*).

The analysis of the collected material allows us to conclude that *M. lacustre* has average size among the species of the family. According to our data, the sizes of the studied individuals are: convexity up to 4.7 mm, height 9.5 mm, length up to 11 mm (table 2). The shell is trapezoidal or rounded-oval, angular, moderately convex, thin-walled, fragile, whitish-yellowish (figure 4). The embryonic part of the shell is separated in the form of a cap (nipple-like elongated), which allows to distinguish this species from other species of the family. At the same time, the shape and

location of this part of the shell varies somewhat in different populations, which is emphasized by other researchers. The surface is smooth and has thin, not evenly spaced spherical arcs. Hinge piates are narrow. The teeth are well defined.

Considered to be a rather eutopian species [11, 12]. We found it in rivers, streams, prefers flowing areas. Avoids heavily silted areas of water bodies. It has never been found in water bodies that are blocked by dams. It has been repeatedly noted as settling in ponds, puddles,

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012097 doi:10.1088/1755-1315/1415/1/012097

canals, swamps [11, 12], but we have not found it there. It is concentrated in slightly silted areas, sandy-silt and rocky-silt. It also occurred in areas with more silt (up to about 10 cm), but was concentrated on its surface. It is able to bury itself in silt when water bodies dry out and survive even prolonged (almost up to a year) drying out of the reservoir. It was found exclusively among macrophyte thickets. According to some researchers, it is able to crawl along the stems of macrophytes. The maximum population density was 21 in the Gnylopyat River, 11 in the Gusak River, and 1-3 ind./m^2 in other sampling sites, although according to literature data, in the last century it could reach several thousand per m2 in Ukraine. In total, only 35 individuals of the species were collected and studied.

4. Conclusions

The survey of reservoirs and watercourses in the northern right bank of the Dnipro River in Ukraine in 2019-2023 suggests a significant decrease in the frequency of occurrence and population density of *M. lacustre*. The maximum population density of individuals of the species was 21 in the Hnylopyat River, 11 in the Gusak River, and 1-3 ind./m^2 in other sampling sites. The overall frequency of occurrence in the study area is very low and amounts to only 3%. According to the Red List of European freshwater bivalves, the main reasons for the extinction of these animals are the loss of typical habitats due to anthropogenic transformation of hydroecosystems and pollution. Such changes are caused by the construction of numerous dams, changes in flow velocity and siltation, as well as pollution with wastewater and pesticides. Bivalves are sedentary and require stable habitat conditions. Our analysis of the autecological characteristics of M. lacustre allows us to confirm the information that it is the transformation of watercourses into low-flowing or non-flowing reservoirs that makes it impossible for the species to exist in them. In no case were individuals of the species found in reservoirs, ponds, or dammed river sections characterized by the absence of flow and significant development of muddy bottom sediments; in all cases, the animals were concentrated exclusively in flowing areas.The impact of pollutants on individuals of the species requires further investigation. Further anthropogenic transformation of water bodies can lead to the complete extinction of this species and bivalves in general. There is a need to revitalize rivers, especially small ones, and to develop and implement environmental protection measures.

Abstract. Dam monitoring is an effective method of the management of risk associated with dam operation. Interpretation of monitoring data is an essential part of the monitoring procedure. The main purpose of data interpretation in dams is the well-timed detection of hazardous conditions. Since numerical modelling such as finite element modelling method (FEM) is based on physical equations, it can provide results that can be converted into diagnosis. The application of the numerical modelling for monitoring data interpretation in earth dams in the view of uncertainties specific for dam operation and monitoring is studied with the purpose of obtaining the interpretation results that will be practically valuable for intervention planning. In this study the application of one of the techniques of numerical model calibration for the series of alternative diagnoses for real dam monitoring data interpretation is presented. For reducing the uncertainty, the probabilistic estimations of the alternative diagnoses were inferred with the use of Bayes' rule. The technique applied provides a visually clear representation of the possible diagnosis for the practical decision making.

1. Introduction

As water retaining structures earth dams have application to many industries and serve many purposes from water accumulation to protection from flooding. Due to their specific purpose to resist a big volume of water, dams are a hazard potential. Dam collapse can cause enormous human, economic and environmental losses as it can affect huge territories [1–3].

Seepage is an inherent process constantly present in earth dam body, foundation and abutments. Major part of earth dam failures has been associated with development of seepage related defects [1–5]. Seepage barriers such as impervious core, cutoff wall, diaphragm wall are intended to prevent or slow down seepage. Besides, filters and drainage as "seepage control" measures are implemented. The performance of seepage control components can change over time due to seepage action and aging defects [5, 6].

Monitoring is an effective strategy of providing the dam safety [7–10]. The purpose of monitoring is to provide qualitative and quantitative information for dam performance analysis. Monitoring of the structures covers parameters that technically can be regularly and continuously controlled. In earth dams the traditional controlled performance parameters are piezometric water levels, seepage quantities and settlement. The purpose of the performance analysis in relation to seepage is to assess whether actual seepage situation can ensure the safe operation of the dam. In terms of planning the intervention measures the seepage analysis should also entail the assessment of the effectiveness of seepage barriers and seepage control devices. As far as the assessment of the performance of seepage control devices cannot be concluded directly from the monitoring device readings the proper interpretation of the monitoring data acquires importance.

The application of the methods and techniques of monitoring data interpretation in earth dams in the view of uncertainties specific for dam monitoring and dam behavior are studied. Obtaining the practically valuable interpretation results are in the focus.

2. Overview of the issues in monitoring data interpretation with numerical modelling

2.1. Literature review

Monitoring data analysis, interpretation and consistent explanation of dam behavior is an indispensable step of the structure monitoring [9–12]. In terms of technical diagnostics which is targeted on the practical outputs the interpretation of monitoring data can be also considered as the identification and localization of faults and failures [13, 14]. With the parameters usually controlled in dams the judgement regarding the technical condition of the components cannot be inferred directly from the readings. The aim of the interpretation in this insight is to derive from the monitoring data the estimation of the effectiveness of the performance of the structure components [13]. For dam seepage analysis the structure components are: seepage control members, drainage, soil massifs in dam body and foundation. In this sense interpretation can be considered as diagnosing the technical condition of the separate dam components [10–12].

There are different methods that can serve for data interpretation: deterministic, statistical, artificial neural network approach, probabilistic [7–9]. Since deterministic methods are based on physical governing equations, they provide results that can be easily converted into diagnosis. Among deterministic methods finite element modelling method (FEM) is a useful tool for monitoring data interpretation. It has been gaining more and more practical utility because of the development of high-performance computer hardware as well as software. It is widely used for seepage analysis of earth dams as well [8, 11].

FEM modelling for seepage analysis is based on the Laplace equation. Basic components of the numerical model with FEM incorporate seepage domain geometry, material properties and boundary conditions [6, 8, 11]. In seepage analysis FEM simulates hydraulic heads within the seepage domain including the position of zero pressure line (phreatic line). The zero pressure line corresponds to piezometric water levels that are traditionally monitored on earth dams. In a single simulation the static conditions are considered.

Mismatching of the theoretical groundwater levels provided with FEM and the field piezometric heads can be explained with the fact that actual soil properties differ from design values, spatial properties variance, anisotropy, specifics of boundary conditions, 3D flow effects etc. In the view of the interpretation purpose the deviation (or changing) of material properties that may provide adverse effects for structure performance are also implied. As a means of interpretation FEM modelling enables stepped adjustment of the model with intended changing of the numerical model inputs. This procedure is also known as model calibration [6, 8].

Intrinsically, by its statement and tasks the interpretation is an inverse analysis or inverse problem which in mathematics refers to ill-posed problems [15]. With the multi factor problem, as in the case of seepage analysis, the more factors (or inputs) are involved the more possible solutions are out there. In regards to dams, multiple solutions include numerous combinations of the material properties of dam elements (hydraulic conductivity in terms of seepage analysis) as well as their dimensions that if put together could induce the observed readings.

At the same time, the major disadvantage of the deterministic methods that limits their applicability and reduces the veracity of its simulations for diagnostic purposes is that deterministic methods require the numerous input data which are usually only partially known or have significant spatial variance [6, 11]. Uncertainties from different sources are present in deterministic analysis [9, 10] such as material properties, loading environment, geological and hydrogeological conditions, stochastic uncertainties in monitoring procedures etc. Multiple possible solutions provided during FEM model calibration also increase the uncertainty.

For reducing uncertainties involving the probabilistic approach to results interpretation is required [9].

2.2. Specifics of the monitoring data interpretation in earth dams

Interpretation of the monitoring data with numerical modelling implies model calibration procedure namely the model inputs adjustment so it can reproduce the observed readings. The FEM model calibration procedure can be intricate and ambiguous, and differ according to the considerations behind the purposes. In the insight of diagnostics being aimed at the identification of malfunctioned elements and zones, calibration of the numerical model can be considered as a directed search of the material properties and dimension of dam key elements.

Besides the issue of soils properties variance, the additional complications connected to the particularities of the objects under study (dam and processes) and monitoring methods can be pointed out from the experience of the data processing in earth dams, which are as follows.

Monitoring procedure is based on measurements which are characterized with stochastic variance. Both variance provided by measurement equipment and variance of material properties determining seepage situation bring to the need to not search for the inputs set giving the precise match but to the desired degree of the fit of outputs.

For earth dams commonly hydraulic heads are used as targeted outputs for calibration. Under static conditions the single set of the observed piezometric heads is implemented as targeted outputs of the simulation.

Due to technical limitations with arrangement of monitoring systems in dams there are sections with no measurement equipment that are the monitoring “blind” zones of the dam body with unknown values of performance parameters. For piezometric heads the monitoring “blind” zones usually include the upper shell of the dam body where there are no field data for calibration. Within the upper shell there is often impervious members located as inclined core, concrete protective slabs, other impervious layers that can induce a sharp drop of hydraulic head behind them. The actual position of the phreatic line in such a zone can be predicted through extrapolation or from other considerations. However, the results of the calibration adjustments within such zones can be considered as highly subjective.

On the other hand, the presurmise in the background of the selection of the monitoring data set as the calibration targets can have its impact on the results on calibration. As an example, regarding to the time frame piezometric water levels in all piezometers are observed simultaneously. But then, with deterministic insight, whereas seepage velocities in earth dam are low, changing of piezometric heads doesn’t proceed immediately but with a delay. The presence of the time lag effects in monitoring data also increases the solution uncertainty [16, 17].

In this study we are focused on the investigation of the approaches to FEM model calibration from the view of obtaining the interpretation results that can be used for intervention measures planning in practical decision making. Along with it the implementation of probabilistic estimations to the modelling outputs is considered.

There are different methods of the numerical model adjustment (or calibration of the model) such as iterative adjustment with the use of manual trial-and-error or automated algorithms and sensitivity analysis approach to define the most significant tuning constitutive parameters [8] etc.

The iterative calibration procedure comprises updating of the model inputs in order the model simulations reproduce observed values. Under this approach the single set of monitoring readings (for example, the observed piezometric levels in the given cross section at a certain date) is considered as targeted outputs in all iterations. According to this approach the number of alternative diagnoses comprising different combinations of inputs (or different diagnoses) can be defined that are corresponding to some single position of the observed phreatic line. Since they are producing same outputs, consequently same probabilities of occurrence can be assigned to each of the alternative diagnoses.

One more variation of the iterative approach which can be useful for interpretation purpose implies providing the series of the simulations with different model inputs that refer to the several preliminary defined alternative diagnoses regarding the condition of the dam's key elements [9, 18]. Consequently, there are several simulated phreatic lines as outputs of the modelling which corresponding to several assumed diagnosis.

Fluctuations of the field piezometric water levels define the domain of the possible position of the phreatic line in the range from the upper to lower observed values for reference period. The superposition of the set of the simulated phreatic lines with the domain of observed piezometric water levels provides the visual identification of the possible diagnosis and enables geometric evaluation of the probability of the diagnosis [18]. The set of inputs that brings the phreatic line positioned within the observed interval can be considered as corresponding to the most probable diagnosis. However, as several sets of inputs are simulated, more than one simulated phreatic lines can be located within the observed interval of performance parameter that requires to attribute each of them with the probability of occurrence.

With this approach the issue of time lag effect as well as the issue of the appropriate set of monitoring data selection can be neglected as far as the whole range of observed data is involved in the analysis.

In this study the application of numerical modelling for the series of given diagnoses for real dam monitoring data interpretation is presented. For the probabilistic estimation the Bayesian interpretation of probability can be considered as the most adequate basis for the consistent representation of uncertainties, independently of their sources [6, 9]. With the Bayesian method the a priori probabilities of the structure safety levels provided by experts are combined with the likelihood probability of the monitoring information [19–21].

3. Principles, materials and methods

The real monitoring data is used for the presentation of the interpretation techniques of the monitoring data. The dam under study is located in western Ukraine. The dam is in operation for more than 30 years. The earth dam is 14.7 m high, 7.1 km long with reservoir capacity over 0.1 km^3. It has exposed inclined concrete core and impervious blanket as seepage barriers and the sloped drainage and the drainage ditch with filter layers as seepage control measures. There are sands in the foundation with the local thin layers of peat. Seepage monitoring is provided by operational services on a regular basis. Piezometric water levels and seepage quantities measurements are performed manually in several cross sections of the dam. Monitoring data are provided as time series for the period 2000-2009. The piezometric heads in one cross section are considered for illustration the dam monitoring data interpretation.

FEM seepage modelling was used for piezometric data interpretation. Rocscience RS2 software was used for providing analysis. Since 2D seepage analysis is employed the piezometric heads are used as the outputs.

Considering the structural arrangement of the dam the simulated scenarios include the condition of the key dam's components such as seepage control elements [22]. As tune parameters hydraulic conductivity of the materials and the extent of the seepage control members are used that intended to simulate the presence of the mechanical defects (cracks, unsealed joints etc.) as in the case of impervious structural members or clogging of the filter layers as in the case of drainage zones. For concrete inclined core failure, it is assumed that the possible failure mechanisms may include cracking from uneven settlement and/ or suffusion in filter layers. Reduction of filtering capability of the drainage also relates to seepage. Due to the specific features of the drainage operation mechanical or biological clogging of the exposed parts of the drainage is possible.

For the analysis the following combinations of the effectiveness of the dam components (simulated scenarios) were specified (table 1). Further the simulated scenarios are deemed as diagnosis.

Table 1. Simulated scenarios according to the condition of the key dam's components.

Inclined core condition	Drainage condition	
	Normal	Poor
Normal	Diagnosis 1	Diagnosis 4
Limited effectiveness	Diagnosis 2	Diagnosis 5
Poor	Diagnosis 3	Diagnosis 6

The simulated phreatic lines for the alternative diagnoses are presented on the (figure 1).

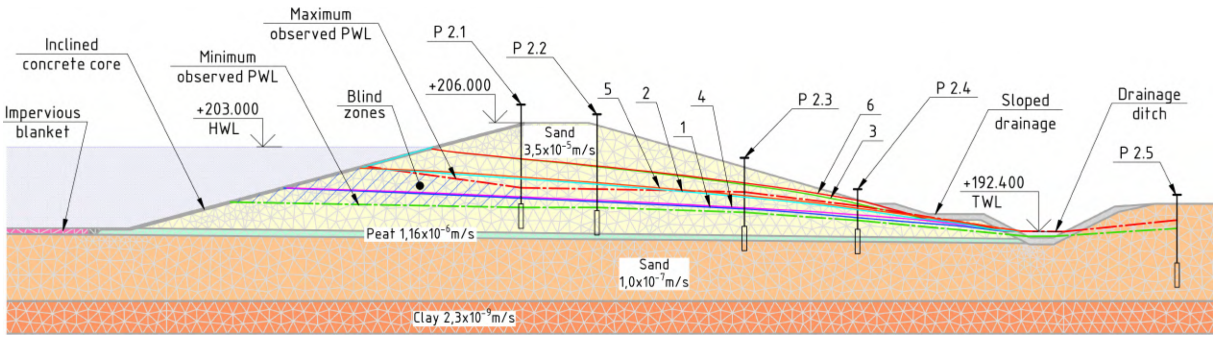

Figure 1. The simulated phreatic lines for the alternative diagnosis.

Since the simulated scenarios are potential, in FEM seepage simulations for all scenarios the normal reservoir water level is assumed as boundary conditions.

The probability of each diagnosis can be defined with two main considerations. The geometric probability implies that the observed value of the piezometric level can be theoretically explained based on material properties and dam zones dimensions. Another consideration is the statistical significance of theoretical explanation based on the historic performance or other knowledge of dam behavior.

The probability of each diagnosis is defined as [18]

$$P(R_i) = P(G_i) \cdot P(D_i)\,. \tag{1}$$

$P(G_i)$ is geometric probability of the location of the simulated phreatic line within the observed domain of piezometric water levels for i-th diagnosis; $P(D_i)$ is probability of the occurrence of the simulated event (i-th diagnosis).

The boundaries of the domain of observed piezometric water levels are based on the data from 4 sensors installed in the same control cross section for the period 2000-2009.

The frequency-based statistics can be used for the assessment of the occurrence probability of the simulated events [1,2,6,18]. For the dams aged from 20 to 50 years the annual probability of failure is estimated to be 0.0038 [1].

Bayesian method of adjustment of the frequency data for site-specific factors is used for this analysis.

The additional considerations like a presence of the symptoms (indirect, visual or instrumental readings) associated with some or other diagnosis can be used for assessment the probability of the diagnosis $P(D_i)$. Two possible symptoms of the diagnoses were considered: the reducing the seepage quantities (symptom k_1) and the cracking of the protective concrete on the upstream face (symptom k_2). Therefore, the conditional probability of the diagnosis with the involvement of the additional statistic information is considered instead namely for the cases of occurrence $P\left(D_i \mid k_j\right)$ or absence $P\left(D_i \mid \overline{k_j}\right)$ of the symptoms k_1 and k_2.

The probability of the diagnosis is computed then with the Bayes' rule for conditional probabilities [9, 21]

$$P\left(D_i \mid k_j\right) = \frac{P\left(D_i\right) \prod\limits_{j=1}^{l} P\left(k_j \mid D_i\right)}{\sum\limits_{i=1}^{n} P\left(D_i\right) \prod\limits_{j=1}^{l} P\left(k_j \mid D_i\right)}. \tag{2}$$

$P\left(D_i\right)$ is prior probability of the diagnosis; $P\left(k_j \mid D_i\right)$ is conditional probability of the occurrence the symptom k_j on objects with diagnosis D_i.

4. Results and discussions

With the use of FEM seepage modelling simulated phreatic lines for the preliminary defined alternative diagnoses were obtained. Simulated phreatic lines for the diagnoses from table 1 are shown on figure 1. Furthermore, the array of the observed piezometric levels for the reference period 2000-2009 is drawn as a domain with boundaries attributed to their maximum and minimum observed values.

The value of the geometric probability is assigned equal to 1 for the simulated phreatic line when it is fully located within the observed domain of piezometric water levels and equal to 0 when it is fully out of the domain. Taking into account the presence of "blind" monitoring zone geometric probability should be reduced according to the "blind" zone extent.

As malfunctioning of two structural members of the dam is assumed with simulated cases (table 1) the prior probability of the diagnosis was computed with the multiplication law as the malfunctioning of the core $\left(P\left(D\left(c\right)_i\right)\right)$ and the drainage $\left(P\left(D\left(d\right)_i\right)\right)$ can be considered independently (table 2).

Table 2. The prior probability of the diagnoses.

Simulated diagnoses	$P\left(D\left(c\right)_i\right)$	$P\left(D\left(d\right)_i\right)$	$P(D_i)$	$P\left(k_1 \mid D_i\right)$	$P\left(k_2 \mid D_i\right)$
D_1	0.85	0.95	0.8075	0.05	0.05
D_2	0.10	0.95	0.0950	0.05	0.10
D_3	0.05	0.95	0.0475	0.05	0.80
D_4	0.85	0.05	0.0425	0.80	0.05
D_5	0.10	0.05	0.0050	0.80	0.10
D_6	0.05	0.05	0.0025	0.80	0.80

With the Bayes' rule (2) the probabilities of each of diagnosis at various combinations of the symptoms are as follows (table 3).

Table 3. The probabilities of the diagnosis at the symptoms.

Simulated diagnoses	$P(D_i \mid k_1, k_2)$	$P(D_i \mid \overline{k_1}, k_2)$	$P(D_i \mid k_1\overline{k_2})$	$PP(D_i \mid \overline{k_1}\overline{k_2})$
D_1	0.249	0.454	0.483	0.880
D_2	0.059	0.107	0.054	0.098
D_3	0.235	0.428	0.006	0.011
D_4	0.210	0.005	0.407	0.010
D_5	0.049	0.001	0.045	0.001
D_6	0.198	0.005	0.005	0.0001

Finally, the probabilities of the diagnosis according to (1) with the geometric considerations are as follows (table 4). As the diagnosis D_3 and D_6 have geometrical probability constituent equal to 0, those diagnosis were not included to the final results table.

Table 4. The probabilities of the diagnosis by equation (1) at the symptoms k_1, k_2 based on monitoring data.

Simulated diagnoses	$P(D_i \mid k_1, k_2)$	$P(D_i \mid \overline{k_1}, k_2)$	$P(D_i \mid k_1\overline{k_2})$	$PP(D_i \mid \overline{k_1}\overline{k_2})$
D_1	0.249	0.454	0.483	0.880
D_2	0.021	0.037	0.019	0.034
D_3	0.210	0.005	0.407	0.010
D_4	0.017	0.000	0.016	0.0004

From the figure 1 two diagnoses could be concluded with almost same geometrical probability. With the involvement of the conditional probability based on statistical information and knowledge of dam behavior the Diagnosis 1 (normal dam condition) can be concluded as the most probable according to the monitoring data for the reference period (table 4). With the inclusion of more site-specific symptoms this technique can become more sound.

The most advantage of the interpretation technique under discussion is that it allows the examination of several diagnoses for data interpretation. Furthermore, it provides the visually clear representation of the possible diagnoses for the researcher or the dam owner, as well as the physical insight of the possible causes of the changes in performance parameters (for this case study the increasing or decreasing of the piezometric water levels). The technique considered is quite illustrative in regards to physical insight of the changing in elements performance to seepage situation that gives the insight of the practical intervention planning. Consideration and graphical representation of the phreatic lines for several alternative diagnoses corresponding to alternative conditions of key dam's elements can serve as visualization of sensitivity analysis for the dam operation personnel.

Along with it, one cannot exclude that the mismatching of the simulated values and field measurements may be not necessarily induced only by deviations or changes of the material properties or dimensions of the key members that was considered in this study as malfunctioning. Changes of the permeability within zones of the dam body can take place both because reducing permeability with clogging and increasing the permeability due to erosion. Those changes not necessarily can cause adverse effects. Nevertheless, they induce the performance changing. Still 3D flow effects can cause the deviation from simulated 2D seepage pattern. The researcher should provide a careful examination regarding what to include in the analysis. The involvment of the historic data and other heuristic approaches can be helpful.

Generally, the main shortcoming of the inverse analysis provided by any calibration method is that the veracity of the results depends on the knowledge of the dam and foundation specific features and understanding of the dam behavior. The experience of the engineers is essential for the inverse analysis.

5. Conclusions

The interpretation of monitoring data is quite challenging as it implicates the inverse analysis with many uncertainties that are an unavoidable feature of earth dam engineering. As a means of interpretation FEM modelling enables calibration of the model with intended changing of the numerical model inputs. However multiple possible solutions provided during FEM model calibration also increase the uncertainty. The numerous uncertainties bring to the need of involving the probabilistic approach into the interpretation problem. The additional uncertainties connected to the particularities of the dam monitoring such as presence of "blind" zones, time lag effects and choice of the required level of accuracy during calibration should also be considered as complications of the interpretation problem.

The application of the techniques of numerical modelling for seepage analysis in real earth dam based on monitoring data is presented. The numerical modelling was performed for several preliminary defined diagnoses. The probabilistic estimations of the alternative diagnoses were inferred based on real dam monitoring data and with the involvement of expert probabilities with the use of Bayes' rule. The obtained estimations enable clearly distinguishing the most probable diagnosis among the alternative ones.

The technique presented can be useful for intervention measures planning in practical decision making for the researchers or the dam owners as it is a quite illustrative in regards to physical insight of the changing in elements performance to seepage situation.

Abstract. Based on the results of extensive laboratory studies of regulatory and protective structures – groynes, carried out in the hydrotechnical laboratory of National University of Water and Environmental Engineering (NUWEE), recommendations for the design, construction, and operation of structures have been developed. The method of hydraulic calculation of groynes is presented. According to these recommendations, a system of structures with experimental types of groynes on the foothills of the rivers of the Ukrainian Carpathians was designed and built. Surveys were carried out on objects of various types of groynes after the passage of floods on the rivers of the specified region. The causes of deformations of buildings and their destruction have been established. The influence of the existing groynes on the channel process has been studied. Conclusions were drawn on the further use of groynes structures as regulatory and protective structures in the foothills of rivers.

1. Introduction

Every year, the problem of the water element becomes more and more urgent, and the need to carry out work on regulating the flow of water on rivers and protecting territories, rivers, and river banks from flooding and erosion is increasing. It should be noted that, usually, floods provoke and intensify other natural disasters, such as landslides, mudslides, tornadoes, possible pollution and contamination of water supply sources, and others [1, 2]. Therefore, damage from inundation by floods ranks second after damage from earthquakes [3].

This topic is especially relevant to the mountain rivers of the Carpathian region. The issue of improving the ecological condition of small and medium-sized rivers in various regions is also relevant. At the same time, it is known that the regulation of rivers is the cheapest and most rational means of influencing natural hydromorphological processes.

On the foothills of rivers, there is a support, which is formed in the channel by random obstacles located in front of the water flow. They change the direction of the flow in this place and cause storm currents to the river bank or to the slope of the protective dam. They are characterized by significant specific flows and slopes of the water surface and erosive flow velocities. Papers [4, 5] describe flow currents associated with a sharp approach to the dynamic axis of the transit flow to the riverbank or the slope of the dam.

Regulation of water flows to protect against natural phenomena can be carried out with the help of low floodable semi-gates located at an angle to the direction of flow.

According to the terminology given in the construction regulations, structures built on the rivers of the Ukrainian Carpathians and designed to protect territories, objects, riverbanks, dam slopes from erosion are called: shore strengthening, protective and regulatory structures. By their majority, they perform protective and regulatory functions for individual local objects of the national economy or territories that need such protection, by regulating the water flow near them.

This paper details the experience of using and operating groynes built from various materials, as such structures are the most common structures among those used as protective and regulatory structures on the rivers of the Ukrainian Carpathians.

As noted by Pysklyvets [6], destructive floods in the Ukrainian Carpathians can be prevented only with the help of systematic hydrotechnical measures (implementing complex regulation), which Austria, Switzerland, and the USA have experience in using. Groynes are one of the main structural elements of the complex regulation of water flows to protect river banks and the slopes of enclosing dams from local erosion.

2. Materials and methods

When performing theoretical and experimental research, we used methods of theoretical and experimental modeling. To confirm the adequacy of the obtained analytical models, generally accepted methods of statistical processing of experimental results were used. In the hydrotechnical laboratory of NUWEE (National University of Water and Environmental Engineering) for a long time, laboratory hydraulic studies of single groynes and their systems were carried out, the methods of which and the results of experiments are given and described in works [7]. Based on theoretical and experimental methods, a methodology for calculating groynes on the rivers of the Ukrainian Carpathians was developed. These methods were improved based on taking into account the main active factors.

The ultimate goal of the experimental research was to write recommendations for the design of coastal protection structures (groynes) designed to protect the bulk banks of rivers and the slopes of longitudinal enclosing and jet-directing dams, which undergo deformations during the passage of floods [7]. The study of the elements of the kinematic structure of the flow near the shore without the installation of groynes and with their presence, as well as the values of the depths of local washouts near the banks of rivers, was the task of this study.

The experiments were carried out on rigid and erosion models of artificial straight and curved channels, and the relative curvature of the channel varied within $R/B=3...5$, where R is the radius of rounding of the channel, and B is the channel width (width between cuts). Model hydraulic studies of built (real-life) regulation objects were also carried out using groynes.

At the same time, the field of actual and averaged velocities was studied on the rigid model, and the erosion capacity of the stream was studied on the erosion model for variants of the channel without structures and with groynes of various structures and parameters.

3. Results

Low groynes refer to active transverse control structures that are designed to protect dams or riverbanks from local erosion by regulating the internal structure of the flow near the structures. Such structures reduce or move erosion away from the bank or levee and reduce the intensity of adverse transverse circulation or change its direction. The choice of the type of the specified structures is carried out based on a technical and economic comparison of the construction options.

Low groynes, if they are placed at an acute angle to the water flow, cause circulation currents in it. Currents lead to a reduction in the danger of flooding and the negative effect of the flow on the shore. In addition, in the bottom area behind the structures, a powerful stationary helix current appears, which captures bottom sediments from the transit flow near the groynes and transports them to the shore. It is such currents that have an increased transport ability to move bottom sediments. The deposition of sediments and their gradual accumulation in the river section near the shore between neighbouring groynes, caused by helical currents, contributes to the sprouting of bushes, trees, and other vegetation, as well as more reliable anchoring of the shore. When using such groynes, the principle of using the flow's internal energy to control the movement of sediments in the desired direction is implemented. An example of such an application of groynes is shown (figure 1).

Figure 1. System of three groynes (gabion structures) to protect the base of the left bank of the Limnytsia River at the approach to the bridge and channel slope of the barrier dam on the Limnytsia River.

The mechanism of interaction of an obliquely located groyne with a water flow is characterized by the following two simultaneous processes that are observed:

- first of all, the peculiarity of the work of the obliquely located groynes is the emergence of a helical current in the form of a vortex roller (local transverse circulation). The vortex originates near the head of the structure, having the greatest intensity of rotation here, and further spreads with the transport of sediments and the gradual attenuation of the circulation. Due to the hydrodynamic structure of the flow in this zone, the current transports an extremely large amount of bottom sediments to the shore. It preliminarily captures them from the transit flow and the erosion pit that forms near the head of the structure. Thus, over time, there is a gradual accumulation of sediments near the beginning of the structure and in the area between the adjacent groynes, which contributes to the provision of reliable protection of the river bank or the slope of the dam from erosion by the water flow (figure 1);

- secondly, the work of an obliquely located groyne consists of creating secondary currents (general transverse circulation), which organize the movement of the flow in the desired direction over the entire width of the groyne. Such a circulation arises and manifests as a result of the deflection of surface currents, which flow from above over the groyne and try to get into the lower part of the building normal to its longitudinal axis. They (surface currents) receive and keep trajectories directed from the shore in the direction of the transit part of the water flow. As a result of the interaction of the surface and bottom currents flowing around the groyne, a pressure gradient appears in the compressed part of the channel, which directs and organizes the movement of bottom currents over the entire width of the groyne toward the shore. It is the bottom currents that transport the sediments to the river bank or the slope of the dam.

The direction of average vertical velocities must be known in the design of the structure, which, in the absence of data, can be determined by constructing a flow plan. Taking this plan into account, they carry out the optimal arrangement of groynes.

Based on the conducted experimental studies, a methodology was developed for the calculation of obliquely located groynes to protect river banks and dam slopes from erosion.

The parameters of low and obliquely located groynes can be determined as follows:

- The angle of the location of the groynes. The location of individual groynes in the plan is characterized by the angle between the axis of the groynes and the direction of the river flow near the structure α. Groynes should be placed upstream in such a way that the angle α is within 50-60^0.
- The height of the groynes. The average longitudinal height of the groynes P for the foothill sections of the rivers, calculated from the limit water level with a probability of exceeding 95%, should be taken equal to $P = (0.5 - 0.6)H$, where H – the average depth of the water flow, m.

Then the mark of the top of the groynes in the middle of the structure will be $\downarrow TG$=$\downarrow TQ$(95%)+ P. The mark of the crest of the groynes near the head and root is determined taking into account the slope of the crest of the structure, the value of which is recommended to be taken within $i_s = 0.01 - 0.02$.

In areas of rivers with severe ice conditions, the height of the groynes must satisfy the requirements that during the ice retreat, the thickness of the ice t_i passes over the groynes. That is $P < H_i - t_i$, where H_i is the depth of the water flow during the ice advance.

Taking this into account, the height of continuously flooded groynes for the conditions of foothill sections of mountain rivers should be no more than 1.0 m. Recommendations for the design of groynes are given in [6,14,15,18].

The length of the groyne, l, should be determined so that the planned compression of the river flows with a width of B is within $lsin\alpha/B = 0.2...0.4$, $l'/B = 0.2...0.4$, and the ratio of the projection of the groyne l' to the height of the groyne P is within $l'/P = 21...35$. Here there are B – this is the width of the river flow in the area where the structures will be installed. The length of the structure is recommended to be within $0.1 - 0.3$ of the width of the stream – $l' < 0.3B$, while its length should be $7 - 15$ of its height. Its minimum length should meet condition $l(min) > m_1 h_p + a_0$, where $m_1 = 1.2...2.0$ is the coefficient of laying the slope of the erosion gap near the head of the groyne; h_p – the depth of the erosion gap near the head of the groyne; $a_0 = 2..3$ m – margin in the length of the structure; l' – projection of the length of the groyne on the normal to the direction of the flow near the groyne.

The distance between adjacent groynes on straight sections, as well as on slightly curved sections, is taken to be 200 m – for medium and large rivers, and 70-150 – for small rivers. The recommendations of I. L. Rozovskyi [8] should be used for determining the bottom velocities and their direction when locating groynes on a meandering riverbed.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012099 doi:10.1088/1755-1315/1415/1/012099

Determining the planned position of groynes, their sizes, types, and sizes of bottom and bank (slope) fastenings is carried out by using experimental data on the fields of instantaneous bottom velocities and specific flows. They determine the erosion capacity of the river flow near the groynes. The calculation of the fastening of the bank of the river bottom or the slope of the dam near the structure can be performed in the following order.

First, the value of the maximum specific flow is determined near the head of the groyne

$$\left(\frac{q_{\max}}{q_0}\right) = [1.44 - 0.353\,(\alpha - 90)]^2 \left(0.82 + 0.46\frac{P}{h} + 4.65\frac{\Delta}{h}\right), \tag{1}$$

where q_0 and $q_{\max}$ – the specific consumption of domestic sewage in the area of the groyne and the maximum at its head; $\frac{\Delta}{h}$ is the relative height of roughness protrusions.

In the case of erosion of non-homogeneous non-cohesive soils, flow velocities are allowed, taking into account the formation of self-wetting. In this case, the permissible non-eroding speeds are approximately equal to 75% of the permissible non-eroding speed for large soil particles, which should be no more than 10%. Based on the known values of the maximum specific flow and the permissible non-eroding speed, the maximum depth of the flow when washing the bottom is established.

$$H_B = \frac{q_{\max}}{v_H}, \tag{2}$$

where v_H is the non-washable speed.

Then the depth of the erosion gap itself will be equal

$$h_b = H_B - h. \tag{3}$$

The distance from the intersection of the axis of the groyne with the end face of the head of the groyne to the place of maximum erosion of the bottom a is determined by the formula

$$\frac{a}{P} = \left[4 + 5.56(\alpha - 90)^2\right] \left(2.7A\frac{B}{45^\circ} + 1\right) \left(1.61 - 1.53\frac{P}{H}\right). \tag{4}$$

The maximum width of the flexible mattress is determined from the considerations of its coverage of the slope of the erosion gap with some margin according to the formula

$$b_T = \sqrt{\left(a - \frac{\tilde{b}}{2}\right)^2 + P^2 + K}, \tag{5}$$

where $\tilde{b}$ is the width of the head groynes along the bottom; $K = 1...2m$ – margin in the width of the mattress attachment of the bottom is set depending on the value of the maximum bottom instantaneous velocities of one-percent coverage near the head of the groynes, which are determined by the formula

$$\frac{v_{1\%}}{v} = \left[0.85 - 0.115\frac{l'}{l - l'} + \left(0.0182\frac{l'}{P} - 0.1\right)\frac{\alpha}{\pi - \alpha}\right] \sqrt[6]{\frac{h}{P}} \left(1 - \frac{a}{P}\right) + 1.215\left(1 - \frac{\Delta}{h}\right)\frac{a}{P} \tag{6}$$

The size of the upper layer of stone of the bottom mattress is determined by the formula of M. M. Biliashevskyi $d_k = 0.0067v_{1\%}^2$ [9]. To obtain a stable fastening, the found diameter of the stone should be multiplied by the stock factor of 1.2÷1.4. If the size of individual stones in the overburden is too large at high flow speeds near the groyne, then the upper layer of the bottom mattress outside the structure should be made of interconnected concrete slabs. Unenforced groynes can be more reliable and easier to operate than mattress-rigged groynes if their soles are sunk below the mark of expected bottom erosion. The expediency of such a design is greater, the smaller the expected erosion of the bottom.

The type of mattress reinforcement of the shore near the groyne can be selected according to the value of the instantaneous (actual) speed of one-percent security within the shore or slope along the groyne, which is determined by formula

$$\frac{v_{\max}}{U_O} = \left(\sqrt{\frac{\alpha - 13}{408}} + 1\right)(0.74 + Fr)\left(0.72 + 0.61\frac{P}{h} + \frac{1}{0.115}\frac{\Delta}{h}\right)\left(1 - \frac{a}{P}\right) + 0.342\left(1 - \frac{\Delta}{h}\right)^{0.7}. \quad (7)$$

4. Analysis of the operation of groynes on the rivers of the Ukrainian Carpathians based on the results of field studies

Starting in 1957, a significant number of groynes of different designs were built on the rivers of the Ukrainian Carpathians. According to the design features and functional purpose, the most common types of groynes are: type 1 – deaf high (non-flooded) groynes; type 2 – low flooding groynes; type 3 – combined groynes (consisting of a deaf and lowered part); type 4 – through groynes.

Different types of groynes can be made of different materials, namely: concrete blocks, gabions (figure 2), reinforced concrete blocks, stone, soil (temporary structures). Such structures are arranged to protect the slopes of enclosing dams and the ground surface of mountain highways, river banks and the foundations of dams. They reduce the speed of the water flow, reduce or change the intensity of adverse transverse circulation, ensure the accumulation of sediments near the banks or slopes and, thereby, protect the main regulatory structures or river banks from erosion.

Low, continuous flooded groynes, compared to blind groynes, have proven themselves well in work, because they interact "softer" with the water flow, which leads to less erosion of the bottom near the structure. They also reduce the possibility of erosion of the opposite bank or slope and are less affected by the ice flow. Even when they are located against the flow, they can regulate the regime of sediments, accelerating the introduction of sediments and siltation of the space between neighbouring structures. Thus, at the same time, they strengthen and protect the river bank (dam slope) from possible erosion and damage. Currently, the following types of low flooded groynes are used in the foothills of the rivers of the Ukrainian Carpathians: groynes made of massive reinforced concrete blocks measuring (2.0x1.0x0.5) m or gabions, which are placed on brushwood and stone mattresses with a thickness of 0.35...0.5 m; tuff-free cellular groynes; groynes made of massive shaped blocks with metal (hinged) joints.

In recent times, groynes made of oversized stone are more often practiced, which justify themselves in work, and work reliably, thanks to the significant weight of each stone, they can resist the erosion ability of the stream. Therefore, they perform a protective function. During the operation of low submersible groynes, during their operation in a submerged state during the passage of floods, regardless of their design (and material), the following modes of operation can be distinguished: 1) flow around a single groyne, located facing the water flow; 2) flow around the system of groynes, also located upstream.

The following conclusions can be made based on the results of field observations of the operation of low groynes made of concrete reinforcement blocks or gabions:

- the operation of such groynes is effective at the initial stage of their operation until the metal elements of the connection are not broken;
- the groynes works effectively as long as its design (plan and height) position in the structure is preserved;

Figure 2. System of short fortifications of the river Siret, Storozhynets district, Chernivtsi region.

- in the most difficult hydraulic conditions, the first groyne located in the system, which first meets the water flow, and the last groyne in the system, which does not have additional water support, work; as a result of this arrangement, these two demigods experience the greatest disturbance or destruction;
- an erosion is formed near the head of each groyne, the depth of which must be determined at the design stage;
- after the passage of the next flood, the condition of each groyne should be examined and, if necessary, the necessary repairs should be carried out.

5. Conclusions

On the rivers of the Ukrainian Carpathians, various regulatory and protective structures are used: barrier and flow-directing dams, dams, groynes, traverses, longitudinal shore fortifications, etc. Based on the theoretical and experimental methods, a methodology for calculating reefs on the rivers of the Ukrainian Carpathians was developed. These methods were improved based on taking into account the main active factors. Also, the advantages and disadvantages of these structures were determined based on the results of multi-year field surveys of their operation. The problematic elements of the construction, which require further laboratory research, have been identified. Surveys were carried out on objects of various types of groynes after the passage of floods on the rivers of the specified region. The causes of deformations of buildings and their destruction have been established. It was determined that the first and last groynes of the system are subjected to the greatest load in the system, which includes several groynes, so they need periodic repair. During the repair of groynes (restoration of the main parts, extension, and formation of the groynes, etc.), it is necessary, first of all, to identify the cause that led to the destruction of the main structure, and then carry out repairs.

Abstract. Hydrological indicators are important in shaping the ecological status and economic potential of surface water bodies. Industrial facilities that consume water can change the hydrological and temperature regimes of water bodies. The purpose of this study was to investigate the impact of water use and consumption for the Rivne Nuclear Power Plant (RNPP) on alterations of indicators of the hydrological and temperature regimes of the Styr River. The study revealed patterns of changes and analyzed the hydrological indicators of the Styr River under water use and consumption by the RNPP, and the temperature regime of the Styr River in the RNPP impact zone, revealed patterns of dynamics of water use and consumption for the RNPP, determined the correlation between the Styr River discharge and the RNPP water discharge in the hydrological regime of the Styr River. The range of variability approach was used to assess of the Styr River hydrological alteration in the RNPP impact zone. During the warm seasons of 2019 and 2020, the Styr River experienced periods of low water flow. A strong positive correlation ($r = 0.7 - 0.9, R^2 = 0.7623, p < 0.0001$) was found between water use and consumption at RNPP and the temperature of Styr River water. Additionally, a very strong positive correlation ($r = 0.9934, R^2 = 0.9869$) was found between the temperature of Styr River water before and after discharge. Furthermore, it is observed that during the warm season, there is an increase in water consumption and discharge costs for RNPP. Thus, the results of the study indicate that there is no impact of RNPP water discharge, and therefore no measures to improve the condition of the Styr River are required.

1. Introduction

The implementation of the Water Framework Directive (WFD) [1] provides a legal framework for the sustainable management and protection of freshwater resources. The WFD states that the "good" ecological status of surface water bodies should be achieved. To determine the ecological status of surface water bodies, hydrological, chemical and physico-chemical indicators should be taken into account. Chemical and physico-chemical indicators of surface water bodies can be determined using actual concentrations of pollutants [2]. Hydrological indicators represent the established hydrological regime, the good ecological status of which is achieved when the quantity and dynamics of runoff are in balance, reflecting undisturbed conditions [3]. Thus, improvement actions are required where hydrological indicators affect the ecological status of surface water bodies and impede the achievement of WFD objectives. According to the WFD Reporting Guidance [4] , hydrological alteration is considered as an impact on habitat change, i.e. indicators of the current hydrological regime. Therefore, determining the actual hydrological regime is important in terms of establishing a baseline for further assessment of anthropogenic pressure on water bodies. Changes in the hydrological regime can lead to erosion or deposition of sediments, potentially affecting the riverbed and the habitats of aquatic organisms. The basis for the alteration of the hydrological regime is to determine changes in the current hydrological indicators of water bodies. In particular, the most commonly used hydrological indicators for assessment of hydrological alteration are: the average annual flow – Q_a, the average daily flow – Q_d, the average monthly flow – Q_m, the average annual low flow – Q_{al}, the average annual maximum flow – Q_{dl} [5]. However, the assessment of hydrological alteration is carried out by the range of variability approach (RVA). The RVA requires an assessment based on differences in the characteristics of the flow between two defined periods. The RVA approach uses a simple three-class system of equal range of hydrologic alteration: low 0–33%, moderate 33–67%, and high 67–100% [5, 6].

The assessment of hydrological alteration is important for the river basin, as it solves the problem of identifying loads and minimizing the impact of human activity on the environment. Thus, in order to minimize the anthropogenic impact on hydrological alteration, it is necessary to understand the mechanisms of its consequences, in particular, the flow of significant volumes of industrial water discharges into the river. The operation of an open recirculating power plant is connected with the use of large quantities of water that is intake and discharged into a water body. Continuous withdrawal of water can reduce a water body, potentially affecting aquatic ecosystems and water quality. Water discharge from an open recirculating power plant can reach up to 1.0 m^3/s per 1000 MWh of electricity generated, containing residual heat removal and chemical compounds [7]. Additionally, the combination of temperature effects with a large quantity of water flow can affect the hydrological indicators of a water body. Continuous discharge of treated but potentially contaminated water from an open recirculating power plant can contribute to water quality issues, affecting downstream water users and ecosystems. Thus, the assessment of hydrological alteration of a water body under industrial water discharge requires an integrated approach, taking into account operational and environmental aspects. In summary, the water use and consumption associated with nuclear power plants can have considerable impacts on the hydrological and temperature regimes of rivers. Careful consideration, monitoring, and implementation of mitigation measures are crucial to balance the need for energy production with the preservation of aquatic ecosystems and water quality. The practical significance of the study is that the results obtained can be used for planning and implementing WFD in the area of non-radioactive influence of nuclear power plants. It is worth noting that while there have been no recent systematic studies investigating the impact of NPP water usage on the hydrological regime of water bodies, including rivers, we can confidently state that this is an area of ongoing research. It is important to approach this topic, acknowledging the need for investigation.

The purpose of this study was to investigate the impact of water use and consumption for the Rivne Nuclear Power Plant (RNPP) on changes indices of the hydrological and temperature regimes of the Styr River.

2. Methodology and methods of research

The object of research is the hydrological alteration and water temperature of the river in the zone of water use and consumption of the RNPP under the influence of discharge of return water from an open recirculating system. The methodology of this study was to determine the flow of water use and consumption for RNPP and the Styr River water flow in the RNPP impact zone. This study used the daily flow monitoring results for the period 2018-2022, carried out by the RNPP hydrological post on the Styr River below the RNPP intake, located within the urban area of Varash figure 1. Water flow measurements were carried out using standard measurement methods (ultrasonic meters and diaphragm-type instruments). The flow velocity was measured using an acoustic flow meter, and the flow was calculated as the product of the cross-sectional area (m^2) and the average flow velocity (m/s). The temperature of natural and processed waters was measured according to [8]. Statistical processing of the study results involved determining the range of data series (min-max), arithmetic mean (M), standard deviation (± SD), and coefficient of variation (CV) of the corresponding sample using the BioEstar software package (Version 5.3, MLM). The analysis of the data set to assess the relationship between the variables of the control results was performed using the Pearson correlation coefficient (r) and the significant influence (p) and the coefficient of determination (R^2) [9]. The hydrological alteration (G, %) in the Styr River study area was calculated for hydrological indicators: $Q_a, Q_d, Q_m, Q_{al}, Q_{dl}$, according to formula.

$$Gn = (Q_n - Q_{n+1}) \cdot 100/Q_n \tag{1}$$

were Q_n – the flow for the previous year (2018, 2019, 2020, 2021) or month (January-December) depending on the hydrological indicator, m^3/s; Q_{n+1} – the flow for the following years of the study (2019, 2020, 2021, 2022) or month (February-December) depending on the hydrological indicators, m^3/s.

3. Results

The RNPP has four power units with a water-powered energy reactor with a total capacity of 2835 MWh, built in the 1980s. The RNPP has an open recirculating system with cooling towers, and water is constantly being intake and discharged into the Styr River (right tributary

Figure 1. The scheme Styr River water intake and discharge for the RNPP (1 – site of the RNPP; 2 – Styr River; 3, 4 – water intake; 5 – return water discharge; 6 – hydrological post).

of Pripyat (Dnieper basin). The Styr River basin is located in the north-west of Ukraine, within the Lviv, Volyn and Rivne regions. The river is 494 km long and covers an area of 13100 km^2, with an average annual water flow of 49.5 m^3/s at the mouth, narrowing to 10-20 m in the upper reaches and widening to 30-50 m in the middle and lower reaches. The bottom of the riverbed is composed of sandstones and shales of Cretaceous and Paleogene age, and in the lower reaches – Miocene clay deposits. However, according to the surface water typology, the Styr River is a lowland, sandy loamy river [10].

In particular, the Styr River water flow (D) during monitoring at RNPP hydrological post varied in the range (min-max) from 10 to 63 m^3/s, M = 27 m^3/s, SD = ± 18 m^3/s, CV = 51.36 %. In addition, the water temperature of the Styr River (T) during monitoring at RNPP hydrological post varied in the range (min-max) from 0.3 to 24.6 °C, M = 12.6 °C, SD = ± 8.7 °C, CV = 77.12 %. Thus, before and after the RNPP discharge, the Styr River water temperature has increased by up to 1.11 °C in the summer season and by up to 2.07 °C in the winter season. The established limit for the increase in water temperature, according to the terms of the RNPP special water use permit [11], should not exceed 3 °C. Therefore, the actual difference in water temperature of the Styr River before intake (T intake) and after discharge (T discharge) for 2018-2022 does not exceed the established limit and is an average value of 1.07 °C, SD = ± 0.64 °C, CV = 73.55 %.

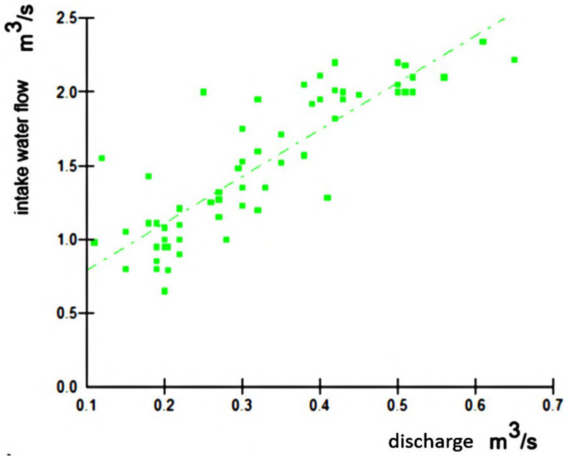
In particular, the flow water intake (MU) RNPP varied in the range (min-max) from 0.8 to 2.4 m^3/s, M = 1.48 m^3/s, SD = ± 0.51 m^3/s, CV = 27.92 %. In addition, the flow discharge return water RNPP (BD) varied in the range (min-max) from 0.15 to 0.67 m^3/s, M = 0.31 m^3/s, SD = ± 0.22 m^3/s, CV = 45.63 %. The correlation between the Styr River water temperature values before and after the discharge is positively significant ($p < 0.0001$) at the very strong level ($r = 0.9934$) and is determined by $R^2 = 0.9869$ (figure 2, table 1).

The magnitude of Styr River discharge does not correlate significantly with temperature (figure 2, table 1), while the maximum Styr River discharge formed either from meltwater during spring high water or as a result of extensive rainfall. Indeed, the water temperature of the Styr River is influenced by the flow intake and discharge of RNPP water, because it is observed a positively significant ($p < 0.0001$) at a strong level ($r = 0.7 - 0.9$) correlation between the flow intake and discharge RNPP water and the water temperature of the Styr River(figure 2, table 1).

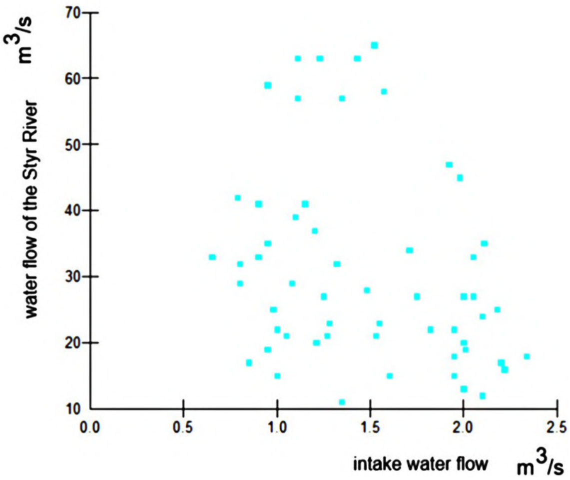
The decrease in the river flow with the increase in the amount of water discharged to the river by the RNPP (figure 2 e) is not related, as the discharge is only 10 per cent of the river flow. The higher water discharged and discharged (figure 2 e,f) to the river is due to the technological mode of operation of the open recirculating power plant and is observed during the warm season, when the river flow is minimal.

The magnitude of the hydrological alteration of the Styr River by $Q_a, Q_{al}, andQ_{dl}$ using RVA in 2018-2022 are characterized as low and moderate (table 2), and by Q_d, Q_m in 2018-2022 are characterised as low (table 3). This suggests that the alterations in the Styr River's hydrology for components Q_a, Q_{al}, and Q_{dl} are within a range considered acceptable or moderate. However, the term "low" suggests that the impact might be minimal for some components, while "moderate" indicates a more noticeable but still manageable level of alteration. For Q_d and Q_m, the characterization is consistently low. This implies that alterations in these components are minimal and likely have a limited impact on the hydrological regime of the Styr River.

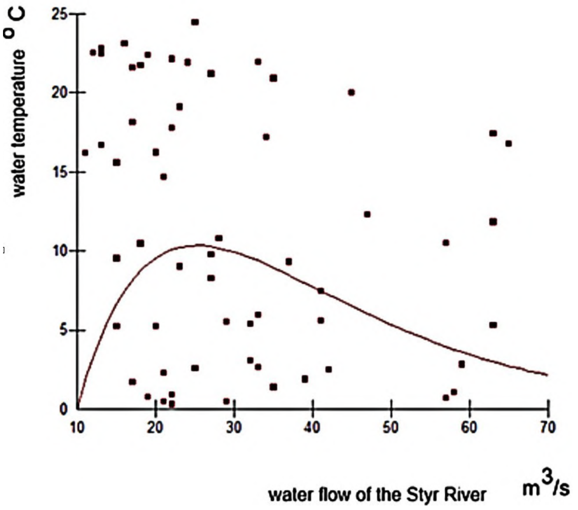
In particular, $G(Q_a)$ by module for the Styr River in the RNPP impact zone varied in the range (min-max) from 3.7 to 16.2 %, $G(Q_{al})$ min-max from 8.3 to 31.5 %, $G(Q_{dl})$ min-max from 9.5 to 46.1 %, $G(Q_d)$ min-max from 2.2 to 28.6 %, $G(Q_m)$ min-max from 2.2 to 32.4 % (table 2, table 3). Statistical indicators by module of hydrological alterations for the Styr River in the RNPP impact zone (figure 3) show the largest variations for the maximum values of the flow (Q_{dl}), the smallest variations are observed for the annual flow (Q_a). Therefore, this suggests



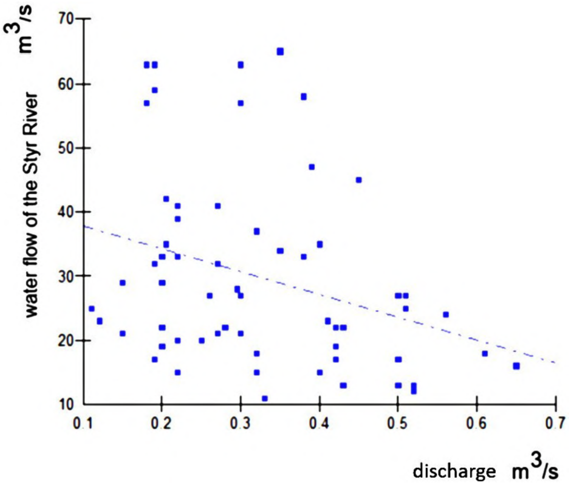
(a) – RNPP intake and discharge flow



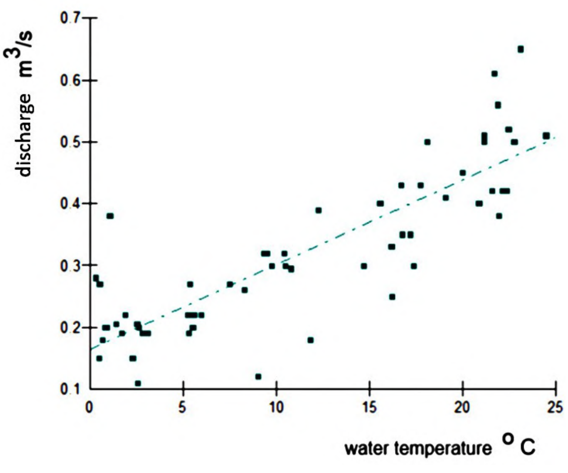
(b) – Styr River and RNPP intake flows



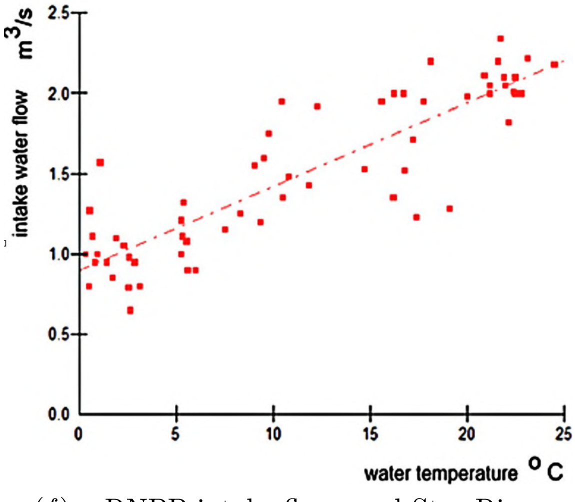
(c) – Styr River and RNPP discharge flows



(d) – Styr River temperature and flows



(e) – RNPP discharge flows and Styr River temperature



(f) – RNPP intake flows and Styr River temperature

Figure 2. Correlation of observed flow data of the Styr River and RNPP sites.

Table 2. Calculation results of the hydrological alteration of the Styr River (breakdown of years).

Year	Hydrologic indicators, m^3			Hydrological alteration, %		
	Q_a	Q_{al}	Q_{dl}	$G(Q_a)$	$G(Q_{al})$	$G(Q_{dl})$
2018	804168000	504576000	1829088000	–	–	–
2019	834470000	426666555	1586768000	-3.7	-22.9	-43.7
2020	748980000	346896000	1103760000	10.2	8.3	46.1
2021	870393600	378432000	2049840000	-16.2	25.0	-12.1
2022	963740160	409968000	1797552000	-10.7	31.5	9.5

that, among the hydrological parameters studied, the maximum flow Q_{dl} exhibits the greatest variability over the analyzed period and Q_a over the analyzed period, the overall yearly flow pattern remains relatively stable. Minimum values by module for $G(Q_a)$ and $G(Q_{al})$: 3.7 and 8.3 for the Styr River in the RNPP impact did not follow the normal distribution of the data (figure 3).

The discharge of return water with a pH level of 8.3-8.7 of the Rivne NPP does not affect the pH values of water in Styr River and compliance with the requirements of national standards of Ukraine. The data of pH control of the Styr River given in the figure show that the indicator is subject to seasonal fluctuations throughout the year. Thus, in winter, the pH at 25 °C level decreases to 7.5-8.0 units, and in summer it increases up to 7.8-8.5 units and are determined by the equilibrium of the carbonate water system [12].

4. Discussion

The analysis of the dynamics of the Styr River hydrological regime shows a characteristic phase of increasing flow in the spring flood every year, which confirms the historical data on the Styr River water flow [10]. Considering that the river is nourished by both melting snows and rains, it is not unexpected. Nevertheless, the low water flow can lead to serious consequences of limiting

Table 3. Calculation results of the hydrological alteration Styr River (breakdown of months).

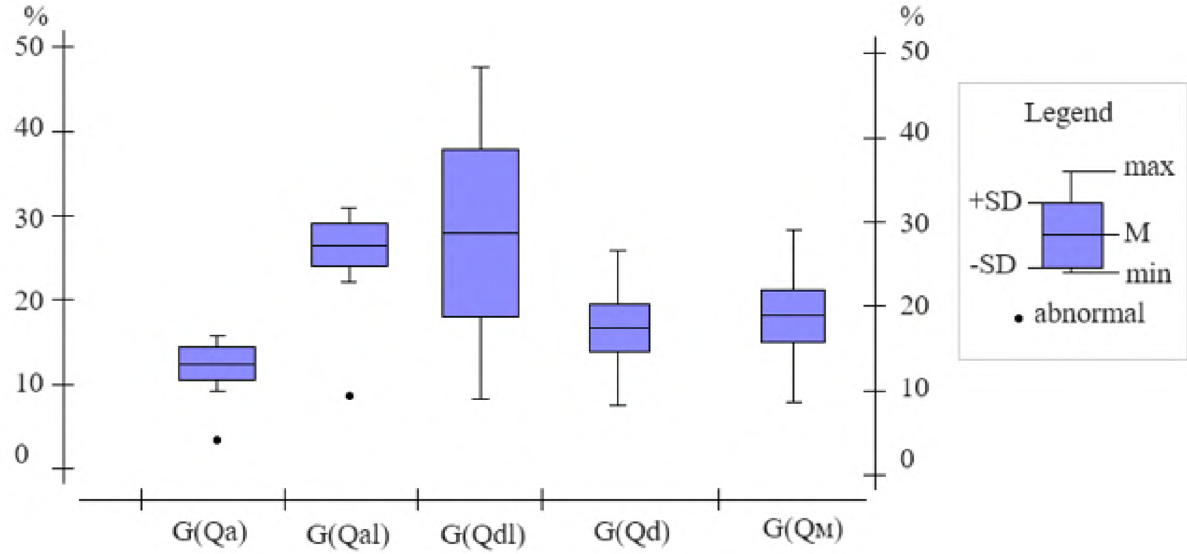

Figure 3. Statistical indicators by module of hydrological alterations for the Styr River in the RNPP impact zone.

the water supply to the power plant and negative environmental impact on aquatic ecosystems. Under the terms of the RNPP special water use permit [11], the flow limit is 8 m^3/s, below which it is prohibited to withdraw water from the Styr River. The actual Styr River water flow for 2018-2022 in the RNPP impact zone did not decrease below the normalised limit flow. Therefore, the recorded moderate hydrological alterations of the Styr River according to $G(Q_{dl})$ obtained in 2019 and 2020 may be associated with natural factors, namely an increase in the Styr River flow in spring floods and a decrease in the flow in the warm season. The water temperature dynamics in the Styr River are expected to show a seasonal increase during summer and a decrease during winter, as hypothesized by the authors. In the controlled areas before the water intake and after the RNPP water discharge, an increase in the temperature of the Styr River water due to the

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012100 doi:10.1088/1755-1315/1415/1/012100

RNPP water discharge is observed, and the temperature effect of the return water discharge does not exceed the limit according to [11].

Heat removal in a power plant's open recirculating system leads to evaporation and requires constant addition of make-up water and discharge of return water [10]. However, the water intake flow for RNPP needs, according to the terms of the RNPP special water use permit [11], should not exceed the intake flow limit of 2.79 m^3/s, and the return water discharge should not exceed the flow limit of 0.7 m^3/s. In practice, the actual water intake and discharge flows of the RNPP open recirculating system for 2018-2022 did not exceed the limits. Thus, an increase in water consumption of cooling systems is observed in the warm season, which is associated with an increase in ambient temperature and, accordingly, greater evaporation of water [7], as evidenced by the correlation dependencies obtained figure 2.

The moderate hydrological alteration ($G = 33-67\%$) for the Styr River was recorded in 2019 and 2020. In general, the significance of Qd and Qm for the Styr River in the RNPP impact zone for 2018-2022 is characterised as low, since the obtained RVA values do not exceed 33 % table 3. Thus, the values of $G(Q_m) = 32.4$ and 31.3 % of the Styr River recorded in March and August table 3 and the hydrological alteration are approaching the threshold values of RVA, which defines the hydrological alteration as moderate. However, the classification of low and moderate alterations suggests that the changes observed fall within an expected or acceptable range based on historical variability. The comparison of statistical indicators hydrological alteration by module provides valuable insights into the temporal variability of different hydrological parameters [13, 14]. The fact that maximum flow exhibits larger variations can be of particular interest, as extreme flow events can have significant ecological and infrastructure implications [15,16]. Further research will confidently compare the design values of RNPP water intake before and during operation. This will assess the impact and identify natural and man-made factors that may influence any alterations. It is important to acknowledge the potential complexity of this task to ensure all factors are considered.

5. Conclusions

To determine the ecological status of surface water bodies, hydrological indicators should be taken into account, as industrial objects that consume water can change the hydrological and temperature regimes. The Styr River water flow has a seasonal variation. It is thus established that an increase in RNPP water use occurs during the warm season, which is associated with higher temperatures and, consequently, greater evaporation of water in an open recirculating system. In 2019 and 2020, minimum Styr River flows were recorded during the warm season (August, September), these can be identified as periods of low water in the Styr River. Consequently, a positive significant ($p < 0.0001$) correlation was found at level strong ($r = 0.7 - 0.9$) with $R^2 = 0.7623$ between water use and consumption at RNPP and Styr River water temperature; and a positive significant correlation was found at level very strong ($r = 0.9934$) with $R^2 = 0.9869$ between Styr River water temperature before and after discharge. The RVA revealed low hydrological alteration of the Styr River (0-33%) in the RNPP impact zone. Thus, moderate hydrological alterations of the Styr River (33-67%) were recorded once for $G(Q_{dl})$ in 2019 and 2020. In general, the results of the study indicate that the RNPP does not affect the Styr River hydrological alteration, and therefore does not require optimization, as hydrological indicators and their changes do not affect the ecological status of the river and do not impede the achievement of the WFD goals.

Abstract. The paper describes the results of a study of the variability in the distribution of particulate organic carbon (POC) concentrations in the north-western part of the Black Sea. The initial data for the calculations were satellite data on the concentration of particulate organic carbon particles. In the process of research, such tasks as the formation of relevant POC databases, built maps of the spatial distribution of POC in the north-western part of the Black Sea in different seasons, the analysis of the intra-annual and inter-annual distribution of POC, and the identification of trends were solved. It was established that the concentration of POC in the north-western part of the Black Sea has a seasonal character with an annual periodicity, with the cyclonic movement of POC along the coast. The maximum concentration of POCs is generally concentrated in wetlands of international importance, indicating that they perform much broader ecosystem functions than filtering and purifying water. These wetlands store blue carbon, occupying a certain link in the marine carbon cycle. This confirms the important role of these coastal ecosystems within the transition of the blue economy of the studied area to sustainable development, namely increasing the contribution to solving climate and biodiversity problems, in accordance with the SDGs: Goal 13 - Climate action, Goal 14 - Life below water, Goal 15 - Life on land. Insufficient consideration of this role in the relevant decisions, in particular according to the Ramsar Convention on Wetlands, will lead not only to a decrease in biodiversity, but also to a deterioration of the climate within the territory of the Northern Black Sea.

1. Introduction

The development of industry and technology over the past centuries has gradually led to an increase in the level of environmental pollution. Today, the seas and oceans contain almost 40 % of carbon dioxide obtained from the atmosphere. This leads to deregulation and negative consequences for the ocean's natural capital and ecosystem services. Oceans absorb and store emissions and sources of pollution, playing a vital role in regulating the global carbon cycle. It is undeniable that the protection and preservation of the ocean environment and biodiversity must be complemented by the goal of reducing emissions and pollution that negatively impact the oceans. This goal fully coincides with the tasks of achieving the goals of sustainable development and blue growth and, accordingly, the sustainability of the blue economy [1–3].

To date, no generally accepted definition of the blue economy has been precisely established. The World Bank defines the blue economy as the sustainable use of ocean resources for economic growth, improving living conditions and jobs while preserving the health of the ocean ecosystem [4]. According to the definition of the European Commission, the blue economy is all economic activity related to oceans, seas and coasts. The blue economy covers a wide range of interconnected existing and emerging sectors [5]. Also, the European Commission defined the working title of a sustainable blue economy – a sustainable blue economy promotes economic growth, social integration and improved livelihoods, while ensuring the environmental sustainability of the natural capital of the oceans and seas. The blue economy encompasses all sectoral and cross-sectoral economic activities related to oceans, seas and coasts. It includes new sectors and economic value based on natural capital and non-market goods and services through the conservation of marine habitats and ecosystem services [6]. Also, according to the definition of the EU [6], the natural capital of the ocean is the stock of natural assets of the ocean with its biotic and abiotic components and services. That is, the natural capital of the ocean provides ecosystem services, which according to the Common International Classification of Ecosystem Services (CICES) can be divided into provisioning services (food, water, energy), regulating services (climate and weather regulation) and cultural services (e.g. recreational benefits). These ecosystem services are the basis for the activity of the blue economy and the associated socio-economic development of the region. The authors [6] note that the ocean's natural capital and associated services are fragile to (cumulative) pressure from human activities. Coastal ecosystems are among the most productive on Earth. They provide essential ecosystem services such as coastal protection from storms and fish feeding grounds. They are also known to provide another essential service – the sequestration and preservation of Blue Carbon from the atmosphere and oceans and are therefore an important part of solving the problem of global climate change [7].

In the natural global carbon cycle, a dynamic equilibrium exists in the global carbon cycle between the surface ocean, the terrestrial biosphere, and the atmosphere. This balance is disrupted not only by fossil-fuel emissions, but also by direct human disturbance of land use and indirect climate warming of the biosphere, especially the permafrost, soils, and the ocean. The global carbon cycle consists of four main subcomponents, or carbon pools, such as: the atmosphere; oceans; terrestrial biosphere (which usually includes freshwater ecosystems and non-living organic material such as carbon in soil), sediments (ocean sediments, plus carbonaceous rocks and fossil fuels) [8]. In marine ecosystems, carbon occurs widely in the form of dissolved organic carbon (DOC), solid organic carbon (POC), dissolved inorganic carbon (DIC), and solid inorganic carbon (PIC). In the active layer of the ocean, DIC, together with nutrients, can be used to produce POC through phytoplankton photosynthesis [9]. Oceans and seas, especially their open areas, because of their vast water areas, are the most important sinks of atmospheric carbon dioxide (CO_2). The high productivity phytoplankton biomass and water carbonate chemistry result in significant uptake of CO_2, the products of which are precipitated into the oceanic carbon sink [8]. Carbon-containing compounds such as Blue Carbon are valuable on Earth. The blue economy is developing due to the huge demand for the synthesis of materials and their application in various fields, such as the food industry, medicine, cosmetology, etc. Blue Carbon obtained from ocean resources also contributes to socio-economic development, which is a reflection of the non-living resource sector components of the blue economy. Blue Carbon refers to organic carbon derived from ocean flora such as seagrass, seaweed, mangroves, and marshes (seaside grasslands). Marine resources derived from carbon sequestration and storage help to boost the economy. Seaweeds are macroscopic and adapted to different conditions of the marine environment. Algae (marine), which are formed by carbon sequestration and the accumulation of many products, are considered a Blue Carbon generator for the development of the blue economy [10].

The dynamics of the particulate organic carbon (POC) pool in the ocean is central to the marine carbon cycle. POC is the link between surface primary production, the deep ocean, and sediments. It is known that the rate of POC decomposition in the dark ocean can influence atmospheric CO_2 concentrations [11]. POC are related to the content of organic carbon in suspended matter, which includes various autotrophic and heterotrophic organisms (phytoplankton, bacteria, zooplankton), as well as organic detrital (inanimate) particles. Compared to the dissolved carbon pools in the ocean, standing stocks of POC are relatively small, but they are important to the marine food chain. These POC stocks are also responsible for relatively large carbon fluxes, including the export of carbon from the surface to the deep ocean via sinking particles as part of a "biological pump" that provides a mechanism for carbon sequestration in the deep ocean and sediments [12].

Determining trends in the variability of the distribution of particulate organic carbon concentrations in the north-western part of the Black Sea was the aim of the research.

2. Related work

Scientists around the world have been conducting research related to climate change for many decades. European standards, based on economic, ecological and social components and aimed at limiting harmful emissions into the environment and its pollution, are introduced into international legal documents. This, in turn, contributes to climate mitigation.

The International Union for Conservation of Nature (IUCN) together with Conservation International (CI) has prepared recommendations for the coordination of actions within the framework of international political processes for the conservation and restoration of coastal blue carbon ecosystems [13] and their implementation in the United Nations Framework Convention on Climate Change (UNFCCC) [14], the Convention on biological diversity (CBD) [15], the Ramsar Convention on Wetlands of International Importance (Ramsar Convention) [16], as well as the Sustainable Development Goals (SDGs) [1]. It is known [7] that according to the definition of Conservation International, Intergovernmental Oceanographic Commission of UNESCO, International Union for Conservation of Nature: Blue Carbon is carbon stored in coastal and marine ecosystems. Created by these organizations, the Blue Carbon Initiative now focuses on carbon in coastal ecosystems – mangroves, wetlands and seaweed. These ecosystems sequester and store large amounts of Blue Carbon in both the plants and the sediment below.

The international carbon market began to develop in the second half of the last century. As a result, carbon prices are set, carbon credits are introduced, carbon trading and carbon taxation are introduced, penalties for emissions committed without a certain quota (cap and trade), etc [17, 18].

Ecosystems that contain Blue Carbon are disappearing so quickly that they have begun to be classified as one of the most vulnerable ecosystems on Earth. This problem is not ignored. Measures to restore and protect these ecosystems are increasingly being developed. They are mainly based on the same three component dimensions of benefit that support the blue economy, namely: economic, social and environmental. The benefit is an increase in carbon sequestration, as well as an opportunity to significantly reduce the negative impact of factors that destroy ecosystems and, as a result, benefits are also provided for the society that depends on these ecosystems. Blue Carbon recovery and protection measures also open up the potential to develop market-based mechanisms that leverage existing carbon offset mechanisms (known as carbon credits) [19]. The development of reliable and accurate non-market estimates is also accelerating as a result of improved understanding of carbon stocks and flows. These financial incentives for Blue Carbon can also help protect and benefit from other ecosystem services provided by these ecosystems, such as healthy fisheries, improved water quality, and coastal protection from floods and storms. This, in turn, will bring additional benefits beyond the direct benefits of carbon sequestration. The authors [19] claim that Blue Carbon meets all three main elements of sustainable development – economic, environmental and social. Based on this, Blue Carbon should be considered as the most important component of the blue economy.

Together with the renewable energy sector and the carbon sequestration and storage industries, Blue Carbon is emerging as an industry in its own right, helping the global transition to a "low carbon" economy. This, in turn, contributes to the creation of economic opportunities, which are very important for both developing countries and developed countries or developed industries.

The European Commission has developed criteria and indicators for assessing the sustainability of the blue economy [6]. They are based on four dimensions of sustainability: environmental, economic, social and governance. According to the European Commission, the subsector "Storage of CO_2/Carbon sequestration" of the blue economy sector "Non-Living Resources" is an actively developing subsector today. Therefore, a consolidated list of relevant criteria and indicators for this subsector has not been fully formed. Today, the EU proposes to focus on the following areas of the components of sustainability measurements in this specific subsector [6]:

- Carbon dynamics (e.g. carbon burial rate; change in the amount of carbon gained or lost over time; amount of carbon stored per unit area (carbon density) are used to describe the carbon sequestration / Blue Carbon sector – Environmental);
- Carbon valuation (e.g. the economic value of blue carbon ecosystems per hectare (Ecosystem service value per hectare (US$); carbon price – Economic / Governance);
- Climate change (mitigation – Governance).

3. Materials and methods

Global observations of ocean color from space have been ongoing since the late 1990s and will continue for the foreseeable future thanks to a multitude of satellite missions. This observational approach provides a unique opportunity to monitor long-term trends in satellite data products characterizing biogeochemical components and processes in the upper ocean at regional, basin, and global scales. One such data product of significant interest for the study of ocean carbon cycles is the concentration of particulate organic carbon (POC) in surface ocean waters [12]. Today, despite many researches the identification and analysis of trends and anomalies in the long-term variability of characteristics in the marine environment are under the major focus [20].

The research process was based on the following stages:

1. Formation of POC databases
2. Build of POC spatial distribution maps.
3. Analysis of the variability of the spatial distribution of POCs by season between 2000 and 2023 and their overall distribution over the entire period.
4. Identifying trends.

The initial information for the research was satellite data of particulate organic carbon (POC) in the period from 2000 to 2023 [21]. These data were measured by NASA's Tera (MODIS) satellite. Processing of raw data was carried out using MatLab software. Verification of POC satellite data processing was performed using specialized NASA software – SeaDAS. SeaDAS (SeaWiFS Data Analysis System) is a comprehensive software package for processing, displaying, analyzing and quality control of Earth remote sensing data. NASA is the official distributor of SeaDAS science software [22]. Maps of the spatial distribution of POC in the north-western part of the Black Sea were built using ODV (Ocean Data View) software. The ODV software is designed for interactive exploration and graphical display of oceanographic profiles, trajectories or time series data [23].

The statistical characteristic (β_{poc}) characterizing the variability of POC concentration per year was calculated using a well-known equation [24, 25]:

$$\beta_{poc} = \frac{n\sum x_i y_i - \sum x_i \sum y_i}{n\sum x_i^2 - (\sum x_i)^2} \quad (1)$$

where y_i – the value of POC concentration in a long-terms series of observations, x_i – a unit of time in a long-term series of observations, n – the number of members of long-terms series.

Identification of trends in POC variability was carried out on the basis of graphical material built using averaged satellite data in the period 2000–2023.

4. Results and discussion

Studies of POC variability have been concentrated in the north-western part of the Black Sea. After all, it is known that in this part of the Black Sea there are ecosystems that with a high probably contain blue carbon – this is the world's largest colony of red algae – the Zernov's Phyllophora Field, the condition of which has improved from "poor" to "moderate" according to the results of a joint EU and UNDP project [26]. There are also 7 wetlands of international importance along the coast, namely: Kyliiske Mouth, Sasyk Lake, Shagany-Alibei-Burnas Lakes System, Dnipro River Delta, Yagorlytska Bay, Tendrivska Bay, Karkinitska and Dzharylgatska Bays [27]. In addition, on the basis of the UN Convention on the Law of the Sea [28], which was ratified by the legislation of Ukraine in 1999 [29], the shallow northwestern part of the Black Sea includes the territorial waters, contiguous zone and exclusive economic zone of Ukraine. According to Article 4 of the Law of Ukraine "On Exclusive (Maritime) Economic Zone of Ukraine" [30]: "In its exclusive (maritime) economic zone, Ukraine has sovereign rights to explore, exploit and conserve natural resources, both living and mineral, in the waters covering the seabed, at the seabed and under seabed, as well as rights to manage these resources and rights to conduct other activities of economic exploration and development of the said zone, including the production of energy by means of using of water, currents and wind".

4.1. Formation of POC concentration databases for conducting research in the north-western part of the Black Sea

Satellite observation data from 2000 to 2023 were used to build maps of the spatial distribution of POC concentration by season and in general for the entire period. The number of averaged data for the studied period was about 9500 measurements for the seasonal distribution of POC, and about 2400 measurements for determining the spatial distribution of POC in general for the entire period.

To analyze the intra-annual distribution of POC concentration, a database of average monthly values for the period from 2000 to 2023 was formed. The number of averaged data was about 28000 measurements.

A database of average annual values for the period from 2000 to 2022 was created to identify trends in the POC concentration distribution. The number of these data was about 54500 measurements.

4.2. Analysis of the variability of the spatial distribution of POC concentration in the north-western part of the Black Sea

Maps of POC distribution in different seasons were built to analyze the variability of the spatial distribution of POC concentrations in the north-western part of the Black Sea. Averaged POC data for the period 2000 – 2023, which were formed into the appropriate database, served as initial data for building maps. Built maps are shown in figure 1.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012101 doi:10.1088/1755-1315/1415/1/012101

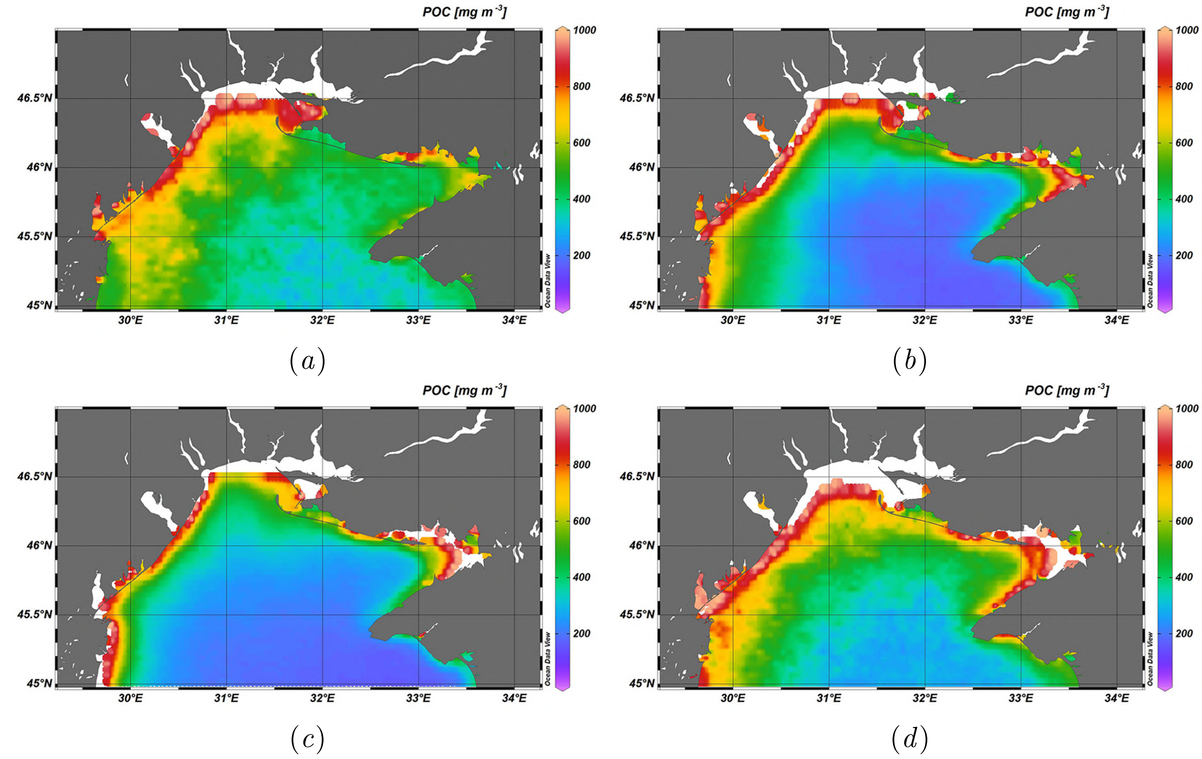

Figure 1. Maps of the spatial distribution of POC concentration in the north-western part of the Black Sea by seasons: (a) – winter, (b) – spring, (c) – summer, (d) – autumn.

In figure 1 (a), the maximum concentration of POC is observed along the coast from the Yagorlytska Bay to the Kyliiske Mouth, as well as in the area of the Dzharylgatska Bay. From these areas with the maximum concentration of POC, its decrease spreads to the south of the north-western part of the Black Sea.

In spring (figure 1 (b)), the maximum concentration of POC along the coast increases in the southern direction and reaches the end of the Danube Delta. In the east of the north-western part of the Black Sea, an increase in the concentration of POC is also observed along the coast in the southern direction from the Dzharylgatska Bay to almost the entire water area of the Karkinitska Bay. The minimum concentration of POC is observed in the central, southern and eastern (region of the western part of Crimea) parts of the studied area of the sea.

In summer (figure 1 (c)), in general, the POC concentration decreases in the water area of the north-western part of the Black Sea. Areas with maximum POC concentration remained the same as in spring except for the northern part of the study area. A decrease in POC concentration is observed in this area. In contrast to figure 1 (b), the minimum values of POC concentration extend to the west of the central part of the studied area.

Figure 1 (d) shows that in autumn there is a clear increase in the concentration of POC throughout the water area of the north-western part of the Black Sea. Small areas with minimal POC concentration are observed in the southern part of the water area of the studied area.

To visualize the general spatial distribution of POC concentration in the north-western part of the Black Sea in the period from 2000 to 2023, a corresponding map was built (figure 2).

Figure 2 shows that the maximum concentration of POC extends behind the cyclonic movement along the coast from the Yagorlytska Bay and the Tendrivska Bay to the Danube Delta, as well as in the water area of the Karkinitska and Dzharylgatska bays. The minimum concentration of POC is observed in the central, southern and eastern (region of the western

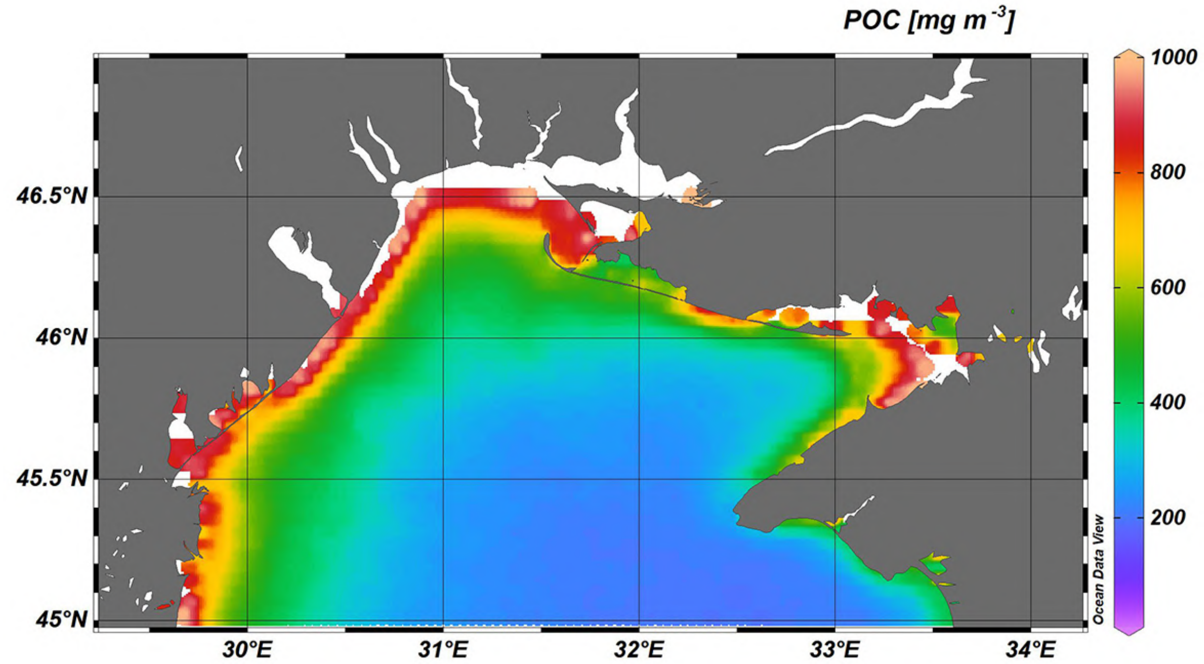

Figure 2. Map of the spatial distribution of POC concentration in the north-western part of the Black Sea as a whole for the period from 2000 to 2023.

part of Crimea) parts of the studied area of the sea.

Thus, based on the maps built (figure 1 and figure 2), we can conclude that the maximum concentration of POC in the north-western part of the Black Sea is generally concentrated in the areas of wetlands of international importance. Its movement has a cyclonic character along the coast and is caused by the general circulation of waters in this area. The width of the maximum POC concentration band depends on the season. The minimum width is observed in summer and increases until winter.

4.3. Identification of POC concentration distribution trends in the north-western part of the Black Sea

To analyze the intra-annual distribution of POC concentration in the north-western part of the Black Sea, a corresponding graph was built (figure 3). The initial data were satellite data of POC concentrations averaged for each month in the period 2000–2023.

From figure 3 it can be seen that the maximum concentration of POC is observed in December/January and is about 647 mg/m^3. The minimum concentration of POC occurs in July and is about 327 mg/m^3. In general, the annual periodicity can be observed in figure 3.

To identify trends in the distribution of POC concentration in the north-western part of the Black Sea, a graph of its interannual variability was built (figure 4). Satellite data of POC concentration averaged for each year in the period 2000-2022 served as initial data.

Figure 4 shows the maximum interannual variability of POC concentration in 2000, 2004-2005, 2007, 2009 and 2017. Clear minimums can be singled out in 2003, 2008, 2014 and 2018. Overall, figure 4 illustrates to us a clear downward trend in the time series of POC concentration variability with an absolute maximum in 2000 of about 518 mg/m^3 and an absolute minimum in 2014 of about 344 mg/m^3. In the fifteen years from 2000 to 2014, the POC concentration in the north-western part of the Black Sea decreased by 1.5 times. In 2022, the concentration of POC

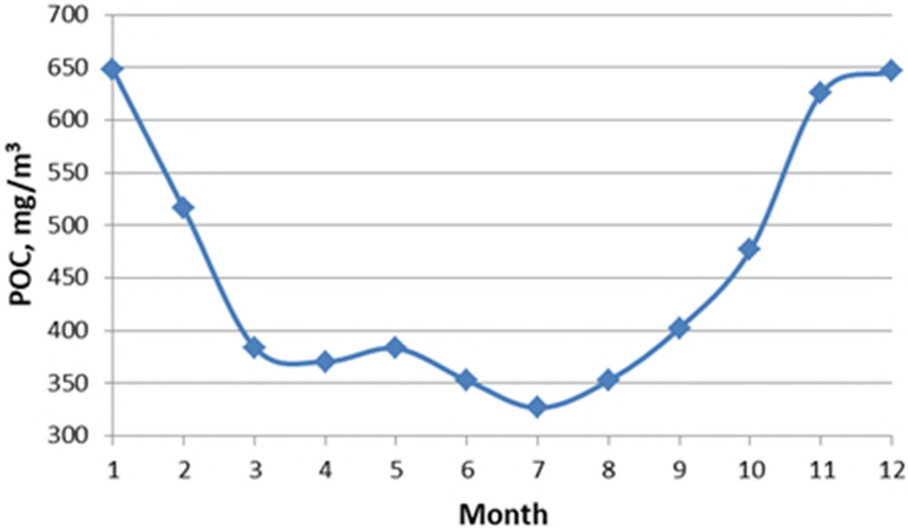

Figure 3. Graph of intra-annual distribution of POC concentrations in the north-western part of the Black Sea based on average monthly data in the period from 2000 to 2023.

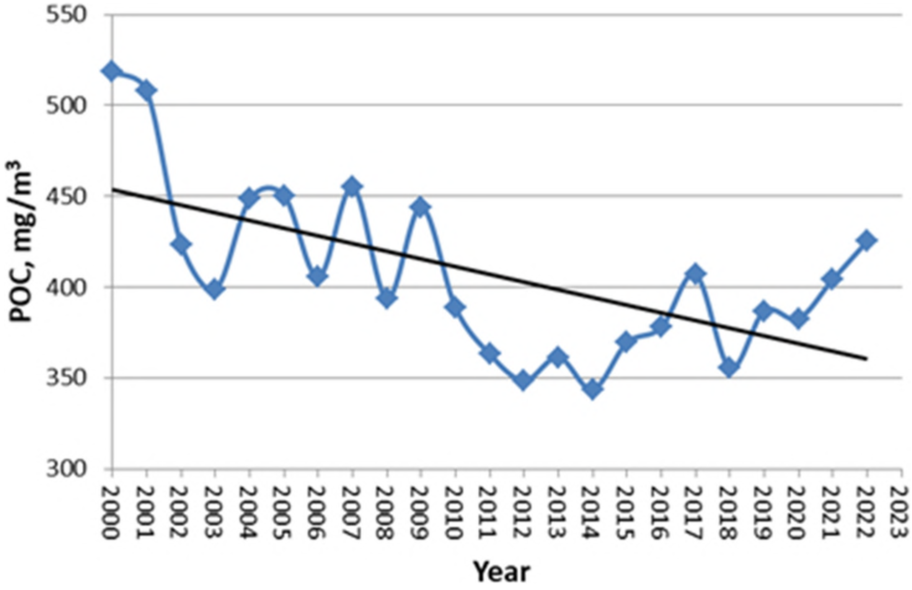

Figure 4. Graph of interannual variability of POC concentration in the north-western part of the Black Sea based on data averaged for each year in the period from 2000 to 2022.

was already about 425 mg/m^3, which increased almost 1.2 times compared to the indicators of 2014.

Statistical assessment of the variability of the downward trend of POC concentration per year (β_{poc}), which was calculated according to the well-known equation (1), was β_{poc} = -4.22 mg/m^3 per year. This indicator shows that over a total of 23 years, the concentration of POC in the surface layer of the north-western part of the Black Sea decreased by 4.22 mg/m^{-3} per year. Based on the result of the β_{poc} indicator, it can be stated that the amount of POC in the surface one-meter layer of the north-western part of the Black Sea decreases by approximately 200 tons per year.

5. Conclusions

Based on the obtained calculation results, it can be asserted that the variability of the concentration of POC in the north-western part of the Black Sea has a seasonal character with an annual periodicity, with the cyclonic movement of POC along the coast. The maximum concentration of POCs is generally concentrated in wetlands of international importance, indicating that they perform much broader ecosystem functions than filtering and purifying water. These wetlands store blue carbon, occupying a certain link in the marine carbon cycle. This confirms the important role of these coastal ecosystems within the transition of the blue economy of the studied area to sustainable development, namely increasing the contribution to solving climate and biodiversity problems, in accordance with the SDGs: Goal 13 – Climate action, Goal 14 – Life below water, Goal 15 – Life on land. Insufficient consideration of this role in the relevant decisions, in particular according to the Ramsar Convention on Wetlands, will lead not only to a decrease in biodiversity, but also to a deterioration of the climate within the territory of the Northern Black Sea. Considering the fact that a large part of these territories has suffered damage as a result of military operations and / or is under Russian occupation, the situation is very difficult.

The task in the wartime is to preserve the health of the studied ecosystems as much as possible, with the involvement of specialists and observers of regional and national, as well as international levels. The post-war period will require the restoration of wetlands, as well as the development of a national blue carbon strategy within the coastal ecosystems of Ukraine. This strategy will provide for a range of nature-based solutions within the scope of area expansion and regeneration of wetlands of international and national importance. The basis of financing the implementation of this strategy should be state regional support with the addition of international financial instruments, primarily through Ukraine joining the World Bank's Blue Economy Program (PROBLUE) and other international environmental programs. This will allow the country to systematically receive targeted financial assistance and become a full participant in the blue bond market. It is also expected to expand the range of ecosystem services of wetlands, in particular recreational fishing and ecological tourism, thereby increasing the contribution to the sustainability of other sectors of the blue economy.

Abstract. The aim of the conducted research was to uncover current trends in the variability of the Sluch River's flow in the context of potential depletion of its water resources due to climate change and anthropogenic activity in its catchment area. The research methodology relied on the analysis of time series data from hydrological observations of average annual, maximum, and minimum water flows. Modern trends in the variability of the river flow were determined using data collected from three operational hydrological posts located at different sections of its course: "Hromada" in the upper part of the river basin, "Zviahel" within the middle course, and "Sarny" in the lower course. The total monitoring period for establishing modern trends in the variability of the river flow spanned 27 years, from 1989 to 2015. The research revealed that the minimum flow of the river underwent the most significant negative changes in the context of water resource depletion during this period. This finding was particularly evident at the Zviahel hydrological station.

1. Introduction

According to the well-known forecast by Rodda [1], made by him at the end of the last century, by 2035-2045, the consumption of fresh water in the world may equal its available stored resources. The UN report "Water Resource Management in Conditions of Uncertainty and Risk" [2] on the state of global freshwater resources noted that in case of unfavorable circumstances, already within the 21st century, 7 billion people on Earth from 60 countries will face a real problem of drinking water shortage; under favorable conditions, this problem will still exist in 48 countries worldwide, where 2 billion people reside. The final conclusion is disheartening: if the situation does not change, by 2030, the global water resource deficit on the planet will reach 40% [3].

It is expected that over time, the water resource deficit, particularly in the context of river runoff resources, which is the main source of drinking and industrial water supply in most countries worldwide, will only intensify [4,5]. This is already a global water management problem, which, despite the efforts of the global community, becomes more acute with each passing year, and for several countries worldwide, the deficit of water resources poses a threat to their very existence. Its essence lies not only in the fact that the water resource potential of humanity for ensuring river runoff is quantitatively limited, but also in the highly uneven geography of its distribution globally, which is significantly inversely proportional to the needs of the main consumers of freshwater – the population and participants in economic activities [6].

The fact that water resources can become one of the limiting factors for socio-economic development, both for Ukraine as individual sectors of its economy and entire regions, was noted by scientists [7] as far back as the 1970s. However, despite the large-scale hydrotechnical construction within the country in the 1950s-1980s, involving the creation of large reservoirs on the Dnieper, Dnister, Southern Buh, and other rivers capable of accumulating significant water volumes and redistributing them throughout the year according to needs, as well as numerous calls from scientists for the rational use and protection of water resources, especially river runoff resources, the issue of depletion and deficit of water resources in the country has not only remained relevant but continues to intensify over time [8, 9].

Among the main issues of water use in Ukraine, the following are prominent: a general deficit of water resources in the country, uneven territorial distribution, and peculiarities of international integration (not in favour of Ukraine). Alongside this, there is a high water demand in the domestic economy, irrational use, and excessive pollution of water resources, leading to the unsatisfactory state of exploited water bodies [9].

Indeed, in terms of internal reserves of freshwater per capita, Ukraine ranks 111th globally out of 152 countries and territories (according to World Bank statistics) [9] and is one of the least water-supplied countries in Europe. The reserves of local resources of river flow in Ukraine amount to about 1.0 thousand m^3 per year per person. For comparison, in European countries, this indicator is as follows: Norway – 96.9 thousand m^3 per year; Sweden – 24.1; Finland – 22.5; France – 4.6; Italy – 3.9; Great Britain – 2.7; Poland – 1.7; Germany – 1.3 thousand m^3 per year [10]. While the western regions of the country are the most endowed with river runoff resources, ranging from 2 to 7 thousand m^3 per year per inhabitant, the least endowed with surface water resources are the most industrially developed southeastern regions: Kherson, Donetsk, Dnipropetrovsk, Zaporizhia, Luhansk – from 0.1 to 0.5 thousand m^3 of water per year. At the same time, only 25% of the volume of potential river flow resources of Ukraine is formed within its territory; the rest comes from the Russian Federation, Belarus, Poland, Hungary, Moldova, and Romania [10, 11].

Extensive anthropogenic transformation of landscapes within river basins due to agricultural production in watersheds, excessive involvement of river waters in economic circulation, their pollution, and irreversible losses (up to 12% of water intake [10]), and, simultaneously, a high level of river flow regulation thanks to hydrotechnical construction and hydromelioration – all these significantly disturbed the natural balance of most river ecosystems, changed the hydrological regime of rivers, and led to the depletion of water resources in many regions of Ukraine [8]. All these phenomena also take place in the basin of the Sluch River, one of the important rivers for the economy of three regions, the flow of which is completely formed within the borders of Ukraine. This makes it possible to analyse modern trends in changes in its flow regardless of cross-border anthropogenic influences.

Climate changes, which have intensified since the middle of the last century, have impacted the water regime of rivers, including those flowing within the territory of Ukraine. Alongside climatic changes, significant contributions to alterations in river discharge have been made by anthropogenic pressures on their watersheds [11–14].

According to the results of recent studies by Ukrainian hydrologists, the onset of the period of modern changes in the hydrological regime of rivers in Ukraine, including those in the Pripyat River basin, can be traced back to 1989 [11–14]. For convenience, this year has been chosen as a reference point for analyzing the contemporary trends in the variability of the Sluch River's

runoff.

2. Description of the research area

The objective of the study was to identify current patterns in the fluctuation of the Sluch River's flow, considering the potential depletion of its water reserves attributed to both climate change and human activities within its watershed. The main tasks include analyzing general flow trends separately for warm and cold periods, processing maximum and minimum annual runoff. Additionally, for a clearer understanding of the factors influencing flow conditions, we present and analyze a geoinformation model of the catchment area.

The Sluch River belongs to the Dnieper River basin, it is the right and largest tributary of the Horyn River. Originating from a small lake in the Podolian Upland near the village of Chervony Sluch in the Teofipol district of the Khmelnytskyi region of Ukraine, it flows through three regions: Khmelnytskyi, Zhytomyr, and Rivne.

The total length of the Sluch River is 451 km, ranking as the 18th longest river in Ukraine. In terms of the watershed area (13.8 thousand km^2), it occupies a position in the third decade. However, the Sluch is the longest fourth-order river in Ukraine (its waters initially flow into the Horyn River and then into the Pripyat River before reaching the Dnieper). Its primary source of nourishment is mainly snowmelt and rainfall.

The width of the river valley ranges from 0.2-0.8 km in the upper reaches to 5 km in the lower reaches, where it traverses the Polissya Lowland. The riverbed varies from 5 to 50 m, with the maximum width reaching 110 m. The average gradient of the river is 0.4 m/km. Within the Volyn-Podolian Plateau, from the town of Starokostiantyniv (Khmelnytskyi region) to the town of Sosnove (Rivne region), the river flows through an area of crystalline massif. Here, it runs through crystalline rocks (granites, gneisses) with rocky banks and numerous rapids. The river freezes in December and thaws in March.

The Sluch River receives the inflow of 1643 small rivers with a total length of 6136 km. Major tributaries include Ikopot, Derevichka, Khomora, Smilka, Tserem, Korchyk, Stavy, Serehivka, Yazvinka (left); Tnia, Tyukelivka, Popivka, Bober (right).

Several towns and significant settlements, such as Baranivka, Zviahel, Kuzmin, Voronkivtsi, Starokostiantyniv, Hromada, Liubar, Polonne, Myropil, Rohachiv, Chyzhivka, Horodnytsia, Korets, Sosnove, Berezne, Sarny, and numerous villages, are situated along the banks of the Sluch River and its tributaries. The river basin is home to more than 200 ponds and 17 reservoirs, including 39 directly on the Sluch River.

Partially, the water resources of the river and its tributaries are utilized for water supply. In particular, the Zviahel Reservoir on the Sluch River serves as the sole source of municipal and industrial water supply for the city of Zviahel, for which there is currently no alternative. Additionally, six mini hydroelectric power stations (MHPS) operate on the river: Myropilska (with a capacity of 500 kW) and Pedynkivska (600 kW), which have been in operation for more than 50 years since 1957 and 1959, respectively; Korzhivska (320 kW), built in 1953 and restored in 2004; Liubarska (200 kW), constructed in 1950 and restored in 2006; Chyzhivska (600 kW), built in 1951 and restored in 2015; and Baranivska (382 kW), constructed in 2017.

Artificial water bodies (reservoirs, ponds) are important infrastructure objects in the economy of Ukraine and many other countries [15]. Alongside performing vital water management functions (municipal and technical water supply, irrigation, hydroelectric power,fish farming, flow regulation, flood control, recreation, etc.), they significantly alter river flow [16], including the minimum flow. And these changes, including those concerning minimum flow, are not always positive, including, as practice shows, for certain participants and objects of the water management complex [17, 18], which provide for the livelihoods of the population or perform functions critical to the functioning of the national economy and, accordingly, may be considered as critical infrastructure objects.

Jurik et al. [17] categorize reservoirs into three distinct groups, identify hydromelioration structures, watercourses and substantial water reserves, health and water management structures, which play a vital role in managing water resources within municipalities, towns, and industrial facilities. All of that types presented within Slych River basin, including reservoirs for water supply and small hydropower, numerous ponds and reservoirs. The Kuzminsky Pond in the upper reaches of the river (village of Kuzmin, Krasylivskyi district, Khmelnytskyi region), with its first documented mention dating back to 1480, and the Nemovytske Reservoir downstream (Rivne region), are also renowned ornithological reserves. All of this results in significant anthropogenic pressure on the river. Currently, there is no small river or stream in the Sluch River basin that remains untouched by human activity.

The state of the water resources of the Sluch River is significantly influenced by the negative impacts it undergoes during water use and economic activities within its basin. The primary pollutants entering the river come from discharges of wastewater from residential and municipal areas (Lyubarsky, Baranivsky, Novohrad-Volynsky, Sarnensky), as well as discharges from the Myropil and Mokva paper mills, the Horodnytske porcelain factory, and others. Agriculture, which is also one of the sources of persistent water pollution, is the main land user in the Sluch River basin. In recent years, the largest left tributary of the Sluch, the Khomora River, has been particularly affected by pollution from discharges of the Poninky paper and cardboard factory. The anthropogenic impact on the Sluch is increasing annually, partly due to recreational activities and increased water consumption.

Throughout its length, the river has undergone significant hydro-morphological changes, especially evident in the lower reaches (figure 1), which may be associated with the regulation of flow and the operation of numerous hydrotechnical structures in its basin.

Despite clear signs of degradation based on hydrobiological, hydrochemical, and hydromorphological indicators, the ecological status of the Sluch River, according to basin principles, is still classified by domestic scientists as 'satisfactory'. However, there is a risk that the hydro-morphological and hydrobiological changes that have occurred are already so profound and extensive that, according to international standards, the Sluch River may be categorized as a waterbody significantly altered. The assessment of the structure of individual watersheds was carried out using Landsat data, and the results are presented in table 1.

Table 1. Primary types of land in the context of separate catchments.

Main types of land and land use	Hromada	Hromada-Zviahel	Zviahel-Sarny
total area, km^2	2480	4982	3358
including:			
1. Agricultural land	2313.7 93%	3918.7 79%	1306.1 39%
2. Forests and other forested areas, marshy lands	137.7 6%	887.6 18%	2029.5 60%
3. Built-up lands, surfaces of water bodies	19.2 1%	22.4 0.45%	7.2 0.2%
5. Bare lands without vegetation cover or with minimal vegetation cover	9.4 0.4%	153.3 3%	15.2 0.5%

3. Results and discussion

In figure 2, a geoinformational hydrological model of the Sluch River watershed is presented, highlighting the catchment areas that contribute to the discharge at the three operational hydrological stations along the river: "Hromada" – in the upper part of the river basin; "Zviahel" – in its middle course; "Sarny" – in the lower course of the river, not far from its confluence with the Horyn River.

The hydrological station "Hromada" (station code 79543) is situated 312 km from the river mouth near the village of Hromada in the Lyubarsky district of the Zhytomyr region, bordering the Khmelnytsky region. The catchment area controlled by this hydrological station, as indicated in the water cadastre, covers 2480 km^2 (approximately 18% of the total catchment area).

The hydrological station "Zviahel" (station code 79545) is located 199 km from the river mouth in the city of Zviahel, in the Zhytomyr region. The catchment area controlled by this hydrological station, as indicated in the water cadastre, encompasses 7460 km^2 (about 54% of the total catchment area).

Hydrological station "Sarny" (station code 79549) is situated near the town of Sarny in the Rivne region. The watershed area controlled by this hydrological station, as indicated in the water cadastre, covers 13,300 km^2 (over 96% of the total watershed area of the Sluch River).

To establish the contemporary trends in the variability of the Sluch River discharge, existing time series data for annual, maximum, and minimum water flows during both 'warm' and 'cold' periods were investigated over the interval from 1989 to 2015. The total duration of the hydrological observations period was 27 years, providing a sufficiently lengthy dataset for relevant trend analysis.

General trends in the change of warm and cold period annual, maximum, and minimum flows were assessed based on exponential trends for uniform comparison across different hydrological stations and different flow periods. The results of trend modeling are presented in figure 3, and their analysis revealed the following.

Overall, from 1989 to 2015, the Sluch River exhibited the smallest changes in annual and maximum flows, while its minimum flows experienced relatively greater changes.

Notably, there are virtually 'zero' trends in annual and maximum flows for the Sluch River from 1989 to 2015 at the hydrological stations "Zviahel" and "Sarny".

Significant differences in trends for different flow periods throughout the year were observed between the hydrological station "Hromada" and the stations "Zviahel" and "Sarny" over the period from 1989 to 2015.

In contrast to the "Zviahel" and "Sarny" stations, the "Hromada" station, during this time interval, shows moderate negative trends (tendencies to decrease) in both annual flows (trend determination coefficient $R^2 = 0.106$) and maximum flows ($R^2 = 0.138$). Simultaneously, despite the practical absence of a trend for the time series of 'warm' period minimum flows at the "Hromada" station, there is a noticeable positive trend (tendency to increase over time) for the corresponding time series of 'cold' period minimum flows ($R^2 = 0.247$). This increase in flows, specifically the 'cold' period minimum flows at the "Hromada" station, represents the only such case among the analyzed hydrological time series (figure 3) characterizing the water flow of the Sluch River based on the available hydrological observations.

At the same time, for the "Zviahel" station, located downstream from "Hromada", pronounced negative trends (tendencies to decrease over time) are already evident for minimum flows during both 'warm' ($R^2 = 0.281$) and 'cold' periods ($R^2 = 0.134$). The least changes in flow characteristics for the designated period are observed at the "Sarny" hydrological station. Here, a negative trend is present only for the 'warm' period minimum flows ($R^2 = 0.18$).

As of today, effective methodologies have been developed for assessing hydro-morphological changes in river channels using remote sensing data [19, 20]. To ensure efficient river basin management [21, 22], traditional and community monitoring should complement satellite

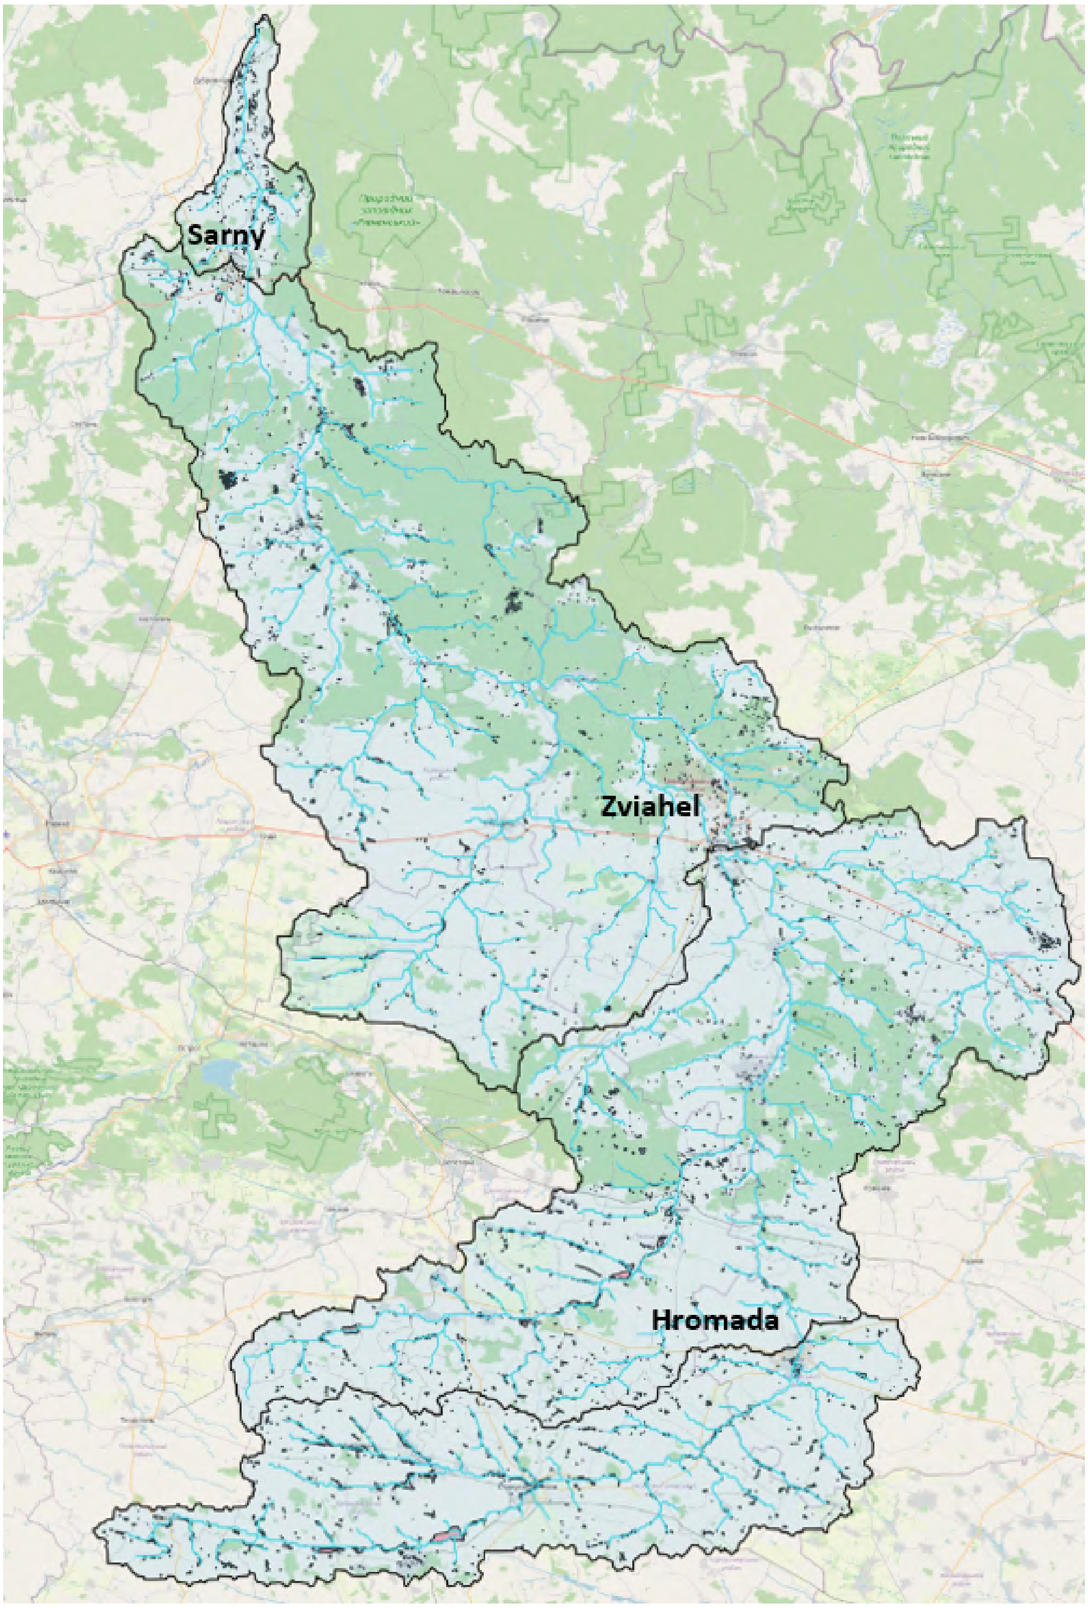

Figure 2. Hydrological model of the Sluch River catchments.

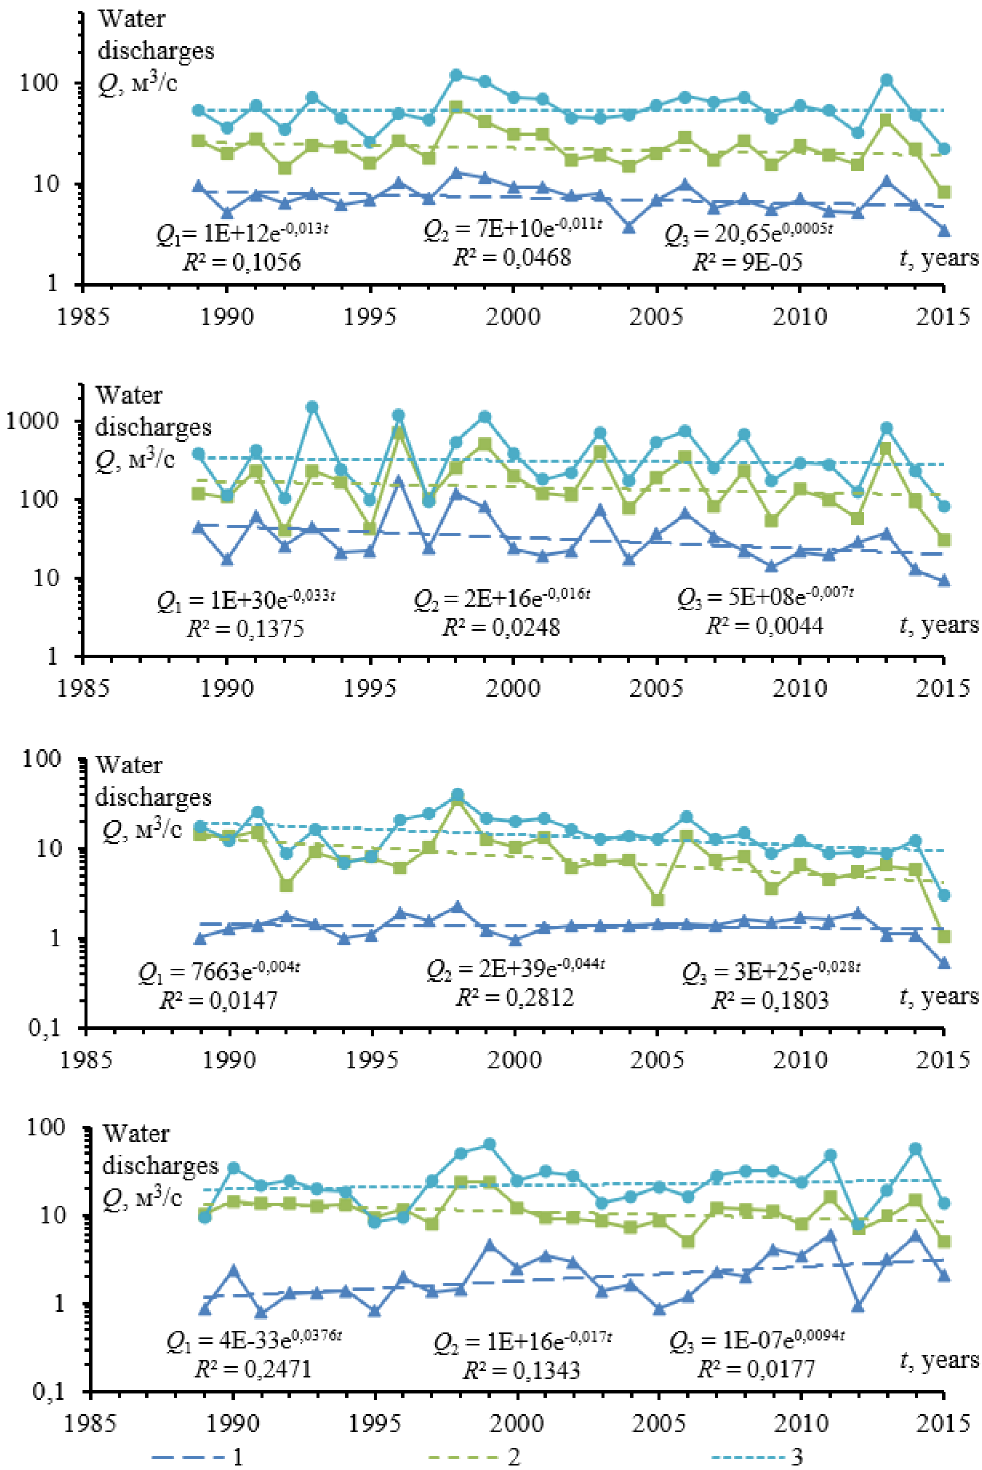

Figure 3. Trends of changes during the period from 1989 to 2015 in the average (a) and maximum (b) water discharges; minimum discharges during the 'warm' period (c), and minimum discharges during the 'cold' period (d) of the Sluch River at the hydrological stations “Hromada” (1), “Zviahel” (2), and “Sarny” (3).

technologies. The synthesis of modern and retrospective data should provide an answer to the genesis of changes in the river system – whether it is the result of climate change or perhaps inexpert decisions regarding land management and construction on the rivers.

4. Conclusions

The contemporary trends of flow variability in the Sluch River have been identified and assessed in the context of the depletion of its water resources due to climate change and anthropogenic activities in the watershed. The assessment was based on time series data of observations on average annual, minimum (for two distinct periods – warm and cold), and maximum water flows, measured at three hydrological stations situated along different sections of the river: "Hromada" – in the upper part of the river basin; "Zviahel" – within the middle course; "Sarny" – in the lower course. The overall duration of the monitoring period for flow rates was 27 years: from 1989 to 2015. It was found that the most significant negative changes in the context of water resource depletion during this period occurred in the minimum flow of the Sluch River at the "Zviahel" hydrological station.

The transformation of the Sluch River's minimum flow has led to its degradation and further deterioration of its condition. The restructuring of the river regime exhibits a certain inertia from the moment the destabilizing factor begins to act. Therefore, without spatial-temporal analysis, it is difficult to ascertain the reasons for changes in water bodies, as the action combines both global and local factors. However, land management can be aimed at reducing water deficits and their impact on the quality of water bodies and the necessary minimum conditions for preserving biodiversity. Among the priority measures may be the development of plans for the use of local runoff with minimal losses, especially during low-water periods, as well as maintaining such flow and velocity regimes in river sections that do not hinder their restoration. To achieve this, it is necessary to abandon the perception of the river solely as an industrial resource intended to address local economic issues. Ultimately, this not only imposes significant economic losses on water users throughout the river basin but also put in risk the functioning of critical infrastructure elements.

Abstract. The requirements are analysed and the basic principles of developing a Response Plan for emergencies caused by water contamination are defined. Under martial law, the problem of drinking water safety and quality should be considered from the perspective of a possible threat of enemy use of chemical, biological and radiation-nuclear weapons to damage water management facilities, water supply and sewage systems. Monitoring of water quality at water supply facilities should be carried out on a continuous basis using indicator physical and chemical parameters without the constant presence of personnel. In the event of a sharp change in any of the defined indicators, an operational system for detecting hazardous substances in water should be connected. The paper develops the basic principles of organization, technical, methodological and financial support for water contamination monitoring.

1. Introduction

One of the principles of the state policy of Ukraine in the field of drinking water and drinking water supply is the priority of drinking water supply over other types of special water use and, at the same time, the preventive nature of measures to protect sources and systems of drinking water supply [1].

But the reality is that water resources have been a source of contention and have been weaponized in various political and armed conflicts throughout history. The control and manipulation of water sources can be a strategic tool to exert influence, create vulnerabilities, and achieve political or military objectives. In [2–5] the multifaceted nature of how water resources and related infrastructure can be weaponized in conflicts is emphasized. This involves not only the direct manipulation of water systems for strategic purposes but also the intentional or incidental targeting of these resources and the people associated with them.

Under martial law, when it is obvious that the aggressor is trying to destroy critical infrastructure in Ukraine, it is necessary, in particular, to assess the situation with centralized water supply from the standpoint of a possible threat of the enemy's use of chemical, biological and radiation-nuclear weapons to destroy water sources, water treatment facilities, water networks, other water supply and sewage facilities and deterioration of tap water quality.

The possibility of such actions is confirmed by the explosion of the Kakhovka Hydroelectric power plant (HPP) and the destruction of the Kakhovka reservoir, which negatively affected the water quality of the Dnipro River, in particular in the area of drinking water intakes.

Among the main factors that led to the deterioration of the Dnipro River water quality are the following [6–12]:

- destruction of the Kakhovka reservoir;
- a sudden runoff of more than 10 billion cubic meters of water from the Kakhovka reservoir;
- significant changes in the hydrological regime throughout the Dnipro River catchment area;
- washing downstream of the Dnipro River of the bottom sediments of the Kakhovka Reservoir;
- flooding and possible washout of fuels and lubricants, a wide range of chemicals, including acids, alkalis, organic solvents, paints, mineral fertilizers, pesticides, etc. from the territories of industrial and agricultural enterprises;
- flushing from the territories of cemeteries, unauthorized burials of people and animals, cesspools, septic tanks, cattle cemeteries, and landfills.

In addition, the destruction of the Kakhovka reservoir led to the following phenomena [11,12]:

- massive fish kills and death of aquatic life after the water runoff;
- the formation of large areas of bare bottom, from which inorganic and organic chemicals of various compositions will be released into the Dnipro River for a long time.

Our conclusions regarding the possible risks of a threatening deterioration in water quality are comparable to those set out in the report of the international organization OXFAM [13] "Hydrogeological Remote Desk Study – Kakhovka Reservoir Area – Ukraine", prepared after the destruction of the Kakhovka HPP. In addition to the damage to wastewater management systems, this report identifies the following causes of deterioration in natural water quality due to military operations:

- pollution of surface waters by sunken military objects (which in turn can contaminate any interconnected aquifer systems);
- release of chemicals due to shelling;
- overflooding of mines and minewaters due to damage to dewatering pumping equipment casing increased salt content, mineralization and heavy metal concentrations;
- bacteriological pollution due to mass poultry deaths;
- flooding associated with the bombing of reservoirs and dams e.g. the recent Kakhovka dam attack.

Further potential threats to water quality that have also been identified within the same study include:

- damage to nuclear power plants by low-flying missiles which can potentially damage cooling ponds, spread radioactive dust and materials into environment etc;
- explosions of containers containing chemicals at industrial sites or wastewater plants releasing large volumes of toxic chemicals into the environment which can infiltrate into groundwater systems (e.g. chlorine, fertilizer (ammonium, nitrate), hydrocarbons, potash);

- underwater decomposition of ammunition leading to release of heavy metals and toxic explosive compounds, which will be incredibly critical in the study area due to vast irrigation channel networks being in existence.

Deterioration of water quality in the area of drinking water intakes can lead to a decrease in the efficiency of existing drinking water treatment facilities. This may result in a situation where the quality of drinking tap water does not meet the current hygienic requirements in Ukraine [14], which threatens human health and life.

Considering the urgency of solving the problems of drinking water supply to the population, in particular, the safety and quality of drinking water, it is necessary to provide water utilities with an effective system of timely and adequate response to chemical, biological and radiation-nuclear (CBRN) water contamination.

This paper identifies the basic principles for developing a Response Plan for chemical, biological and radiation-nuclear emergencies caused by water pollution and organizing CBRN monitoring of water contamination.

2. Basic principles for developing a Response Plan for CBRN water contamination

When assessing and countering the consequences of emergency situations related to chemical, biological, radiation and nuclear water contamination, it is necessary to take into account that it is a potentially fatal chemical poisoning, bacterial contamination or radioactive / nuclear water contamination [15, 16].

The general flowchart of the Response Plan for CBRN water contamination emergencies is shown in figure 1.

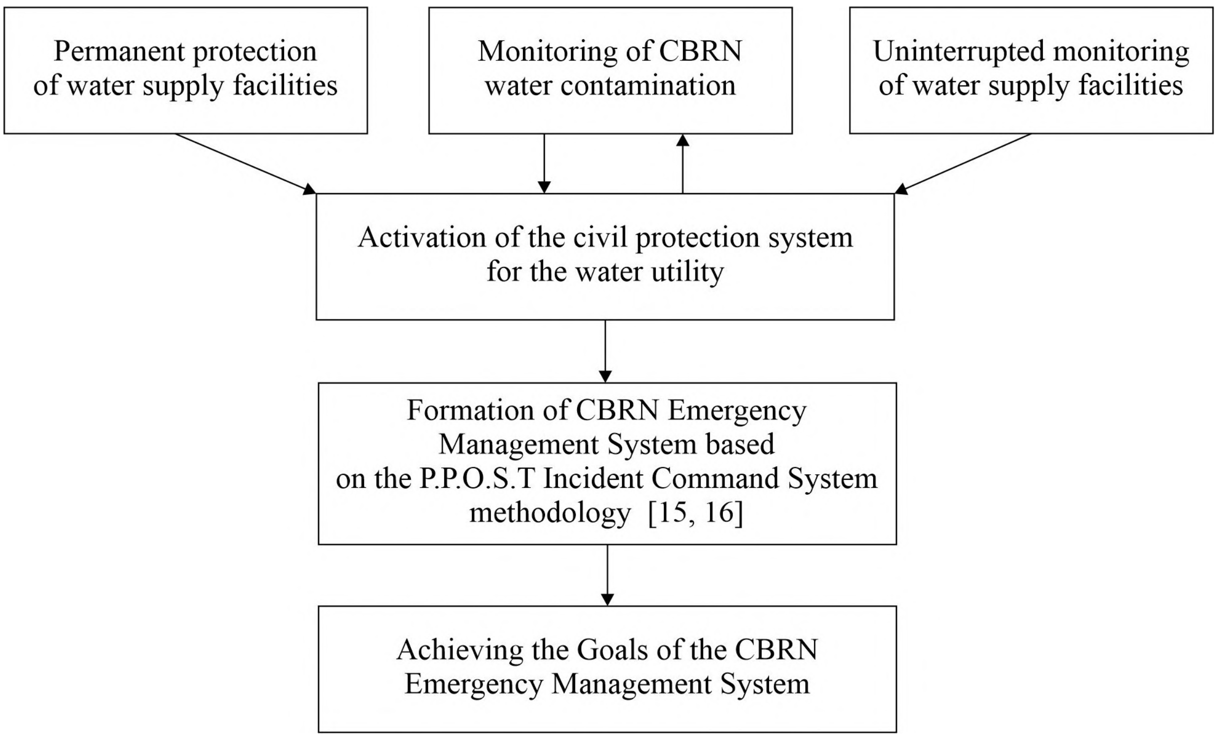

Figure 1. Flowchart of the Response Plan for CBRN water contamination emergencies.

The proposed structure of the Response Plan for CBRN water contamination emergencies provides for:

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012103 doi:10.1088/1755-1315/1415/1/012103

1. Permanent protection of water supply system facilities.
2. Continuous monitoring of probable sites of possible CBRN contamination of water.
3. Monitoring of CBRN contamination of water in places where it is likely to enter the drinking water supply system.
4. Activation of the water utility's civil defence system in the event of unauthorized entry into the water supply system and/or detection of CBRN contamination of water.
5. Formation of the CBRN Water Contamination Emergency Management System [17,18] and achievement of the set goals.

The first task is directly related to the organization and functioning of the system of physical protection of water supply facilities. This system operates continuously and is not exclusive to emergencies involving CBRN water contamination. However, in case of a probable CBRN threat, this system should be guided by the following basic rule: any unauthorized access to a water supply facility, including sources of drinking water supply, must be evaluated from the point of view of possible entry of CBRN contamination into drinking water.

The difficulty of solving this task lies in the fact that the water utilities are not able to independently effectively counter the enemy's intentions to use CBRN-based weapons of mass destruction (WMD) against the water utility.

Therefore, the main attention should be paid to the third element – monitoring of CBRN water contamination, which should be carried out on the basis of a national operational system of laboratory control of water quality, in which the role and tasks of water utilities should correspond to their real technical capabilities. A general flowchart of CBRN water contamination monitoring is shown in figure 2.

First of all, water utilities must carry out on-line monitoring of water quality at water supply system facilities according to the main indicator parameters, which can be measured by hardware, without the constant presence of personnel. In the case of a sudden change in any of the indicators, the system issues an alarm signal about a possible threat of CBRN water contamination.

When confirming the reliability of the alarm signal from the on-line water quality monitoring system, the entire operational system for determining CBRN should be connected.

Since there is no such operational system in Ukraine, one of the tasks of this work is to develop the basic principles of its organization and technical and methodological support.

The following was taken into account during the development of the system of operational identification of CBRN water contamination:

1. It is impossible to work with CBRN-based WMD in the departmental laboratories of water utilities, as this will lead to the presence in the laboratories of a significant number of WMD elements in the form of standard samples of toxic substances, reference strains of pathogenic microorganisms, calibration sources of ionizing radiation, which are necessary for metrological support of the measurement process.
2. The list of toxic chemicals hazardous to humans, which, if released into water, can disrupt the water supply system, is so extensive that it is impossible to organize comprehensive laboratory monitoring on the basis of a single water utility.
3. To work with the most dangerous microorganisms of the I-II groups of pathogenicity in Ukraine, it is necessary to comply with the requirements of the DSP No. 9.9.5.035-99 [19]. It is practically impossible for the laboratories of the water utilities to completely fulfill these requirements, therefore they do not have the right to work with the biological component of weapons of mass destruction.
4. Radiological control of water quality after the accident at the Chernobyl NPP at water utilities corresponds to possible nuclear threats.

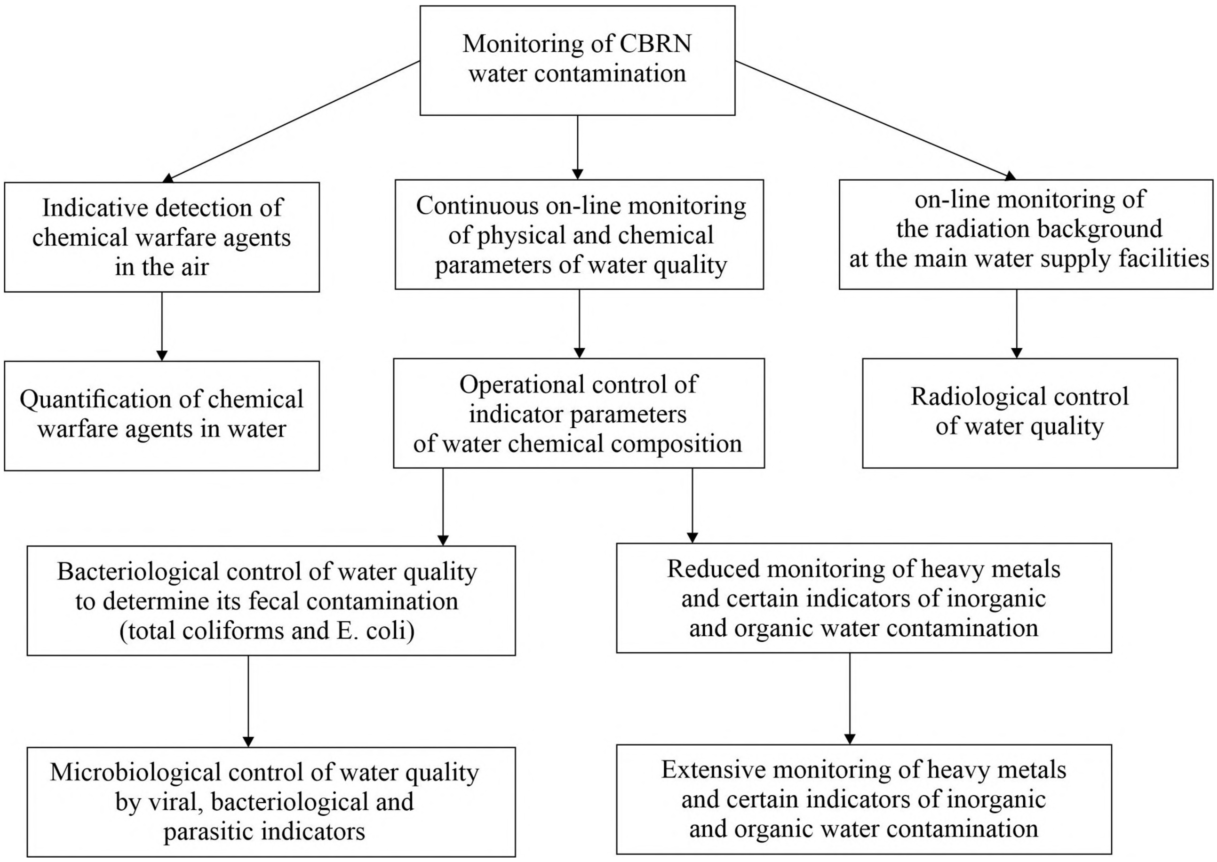

Figure 2. Flowchart of CBRN water contamination monitoring.

5. CBRN water pollution can be carried out both as a result of direct use of WMD, and through destroyed industrial, agricultural and private facilities, on which CBRN elements were concentrated.

3. Technical and methodological support for CBRN water contamination monitoring

Radiation monitoring of water quality after the accident at the Chernobyl NPP at the Ukrainian water utilities is organized at an appropriate level and corresponds to possible radiation threats to the quality of drinking water.

It is only necessary to pay special attention to the need to organize monitoring of the radiation situation, in particular, in the area of water intakes and at water treatment facilities by means of continuous measurement of the level of gamma radiation in the environment.

Radiation monitoring is also a mandatory component when conducting radiation and chemical reconnaissance of the territory that is critical for centralized water supply, affected by weapons of mass destruction or particularly dangerous non-combat substances, about which the water utility must receive information from the relevant authorized and competent services (SES, Armed Forces, etc.).

Biological monitoring of water quality involves the determination of biological pathogenic agents (BPA). In DSP 9.9.5-080-02 [20] it is indicated that "BPA are microorganisms pathogenic to humans (bacteria, viruses, chlamydia, rickettsia, protozoa, fungi, mycoplasma), genetically engineered microorganisms, poisons of biological origin (toxins), helminths that can cause disease, intoxication or death of a person or animal, as well as material (including blood, other biological fluids and body excreta) suspected of containing the listed agents".

Centre for Disease Control and Prevention of the United States defines four levels of classification of laboratories that act in the event of a threat of bioterrorist attacks [21–23]. These levels are classified from 1 to 4 (depending on the level of danger of the microorganisms that are studied in the laboratory), and they determine the necessary level of biological safety of the laboratory (BSL), that is a series of measures designed to protect the personnel of the laboratory, as well as the environment and the population [22].

A BSL-1 (lowest biosafety level) laboratory is a basic laboratory specializing in the study of non-lethal microorganisms that pose a minimal potential threat to laboratory workers and the environment.

A specialized research laboratory dealing with potentially deadly infectious agents such as the Ebola virus is defined as BSL-4 (the highest and most stringent level).

Knowledge of the difference in levels of biosafety laboratories and the corresponding safety requirements for them is mandatory for anyone who works with microorganisms in a laboratory setting.

Laboratories of Ukrainian water utilities belong to the lowest level of biosafety, so they have the right to determine only opportunistic microorganisms, for example, Escherichia coli, which is an indicator of fecal contamination of water. Approved in April 2022, the State Sanitary Rules and Regulations for Drinking Water Quality [14] recommend using Colilert-18 tests manufactured by IDEXX (USA), which several dozen water utilities have experience with.

Chemical monitoring of water quality should be organized both for the quick determination of the presence of combat toxic substances and for the constant monitoring of chemicals of "peaceful" (industrial, agricultural, household) origin.

The need to determine combat toxic substances is established on the basis of information received from the competent authorities - the State Emergency Service or the Armed Forces. Like radiation monitoring, such determination is also a mandatory component of radiation and chemical reconnaissance of the territory that is critical for centralized water supply.

In order to establish the fact of the enemy's use of combat toxic substances and their possible contamination of drinking water, [14] indicate the possibility of using a military chemical intelligence kit of the VKHR type. The kit includes indicator tubes through which air is pumped from the affected area. In the case of the presence of poisonous substances in the air, the colour of the tube filler changes, which roughly determines the concentration of these substances. The codes of the indicator tubes for determination of chemical warfare agents are given in table 1.

Table 1. VKHR indicator tube codes for determination of chemical warfare agents.

№	Code of the indicator tube	Type of chemical warfare agent	Sensitivity, mg/m^3
1	DT-11	GB, GD, VX (sarin gas, soman, V-gases)	0.05
2	DT-12	CG, CK, AC, DP (phosgene, diphosgene, hydrocyanic acid, chloroacetic acid)	5.0
3	DT-15	HD (mustard gas)	1.0

It is clear that the determination of combat toxic substances in the air is not a confirmation of their contamination of drinking water but indicates the possibility of such contamination. In any case, if the use of chemical warfare agents is confirmed, for example, in the water intake area, this will mean that water intake will have to be suspended until the situation with water contamination is clarified.

The VKHR kit can also be equipped with indicator tubes for detecting non-combat (industrial, agricultural, etc.) hazardous chemicals in the air (table 2).

Table 2. VKHR indicator tube codes for identifying industrial hazardous substances.

№	Code of the indicator tube	Type of chemical warfare agent	Sensitivity, mg/m^3
1	DT-001	Phosgene	0.5
2	DT-002	Hydrocyanic acid	3.0
3	DT-003	Chlorine	3.0
4	DT-004	Sodium oxide	2.0
5	DT-005	Sulfur dioxide	1.0
6	DT-006	Sulfonamide	5.0
7	DT-007	Sulfur dioxide	20.0
8	DT-008	Ammonia	50.0
9	DT-009	Hydrogen chloride	10.0
10	DT-010	Formaldehyde	0.5
11	DT-011	Carbon monoxide	30.0

Continuous monitoring of non-combat hazardous chemicals in water is proposed to be organized in four stages.

Stage 1. Continuous on-line monitoring of physical and chemical parameters that can change when water quality deteriorates, such as electrical conductivity, pH value, redox potential, turbidity, colour, and free chlorine concentration.

Since the World Health Organization (WHO) recommends [24] to establish continuous on-line monitoring of the indicated parameters at the main water supply facilities, it is planned to measure them also for all water samples that are examined at the next stages of monitoring.

This stage of monitoring is crucial for deciding whether to deploy more detailed water quality analysis.

It is recommended to consider a reliably established change of one of the indicated parameters by 15% during a time of less than 15 minutes as a basis for strengthening monitoring. For example, if the pH value was 7.5, but quickly began to change and in less than 15 minutes went beyond the interval of 6.5-8.5, then this is a reason for expanding monitoring. It is also necessary to pay attention to the possible change of other online indicators, even if they did not go beyond the 15% interval.

To increase the effectiveness of on-line monitoring, it is necessary to establish at least 2-3 consecutive control points at one water supply facility, and a sharp change in any of the indicators at several points should be considered a sufficient reason for deploying monitoring and finding the reason for the change in the parameter.

The dispatch service and management of the water utility are immediately informed about the confirmed operation of the on-line monitoring system and the need to deploy operational monitoring.

Stage 2. Operational monitoring of indicator parameters of the chemical composition of water (table 3), which are determined by the EU Drinking Water Quality Directive [25] and supplemented by the indicators specified in [14].

Table 3. Indicator parameters of operational water quality monitoring.

№	Parameter	Unit	Parametric value
1	Taste		Acceptable to consumers and no abnormal change
2	Colour		Acceptable to consumers and no abnormal change
3	Odour		Acceptable to consumers and no abnormal change
4	Turbidity		Acceptable to consumers and no abnormal change
5	Hydrogen ion concentration	pH units	6.5-9.5
6	Conductivity	µS/cm at 20°C	2500
7	Total hardness	mmol/l	7.0
8	Total alkalinity	mmol/l	6.5
9	Aluminium	µg/l	200
10	Ammonium	mg/l	0.5
11	Chloride	mg/l	250
12	Iron	µg/l	200
13	Manganese	µg/l	50
14	Sulphate	mg/l	250
15	Sodium	mg/l	200
16	Oxidisability	mg/l O_2	5
17	Chemical oxygen demand	mg/l O_2	no abnormal change
18	Total organic carbon		no abnormal change

Also at this stage, bacteriological control of water quality is carried out to determine fecal contamination (total coliforms and E. coli), for which [14] recommends using Colilert-18 IDEXX tests.

It is possible to carry out daily operational monitoring of the quality of natural, drinking and waste water in all settlements of Ukraine, including in emergency situations, with the help of a mobile chemical and bacteriological laboratory [26], which is equipped on the basis of a 7500 Palintest photometer (England) and bacteriological equipment IDEXX (USA).

Such mobile laboratories should be located in places where, no later than 30 minutes after establishing the fact of a sharp change in the on-line indicator, it is possible to start water quality monitoring based on indicator parameters for water samples taken at on-line monitoring points.

It is recommended to keep one mobile laboratory ready at water treatment facilities and to have at least one laboratory for traveling to water supply facilities.

The list of indicator parameters that are measured first is determined by which of the on-line indicators has changed dramatically and which indicators have also changed.

For example, if there is a sudden change in the concentration of residual free chlorine, it is imperative to check the indicators of organic contamination of water, as well as the concentration of ammonium and iron. In case of changes in electrical conductivity, it is necessary to check the salt composition of the water. If the redox potential decreases, it is necessary to check the ammonium concentration as an indicator of drinking water contamination by wastewater.

Stage 3. Shortened monitoring of the content of heavy metals and individual indicators of inorganic and organic water pollution [14] (table 4).

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012103 doi:10.1088/1755-1315/1415/1/012103

Table 4. Parameters of shortened water quality monitoring [14].

№	Parameter	Unit	Parametric value
1	Nitrate	mg/l	50
2	Nitrite	mg/l	0.5
3	Fluoride	mg/l	1.5
4	Cyanide	µg/l	50
5	Copper	mg/l	1.0
6	Zinc	mg/l	1.0
7	Volatile phenols	µg/l	1.0
8	Chloroform	µg/l	60
9	Trihalomethane (sum)	µg/l	100
10	Oil products	µg/l	100
11	Surfactants anionic	µg/l	500

To determine the indicators specified in tables 3 and 4, the water utility laboratory should be equipped with the following analytical equipment: spectrophotometer, fluorometer, gas chromatograph, AAS analyzer and TOC analyzer.

Stage 4. Expanded monitoring of the chemical, microbiological and radiological composition of water – the content of heavy metals and certain indicators of inorganic and organic water pollution (table 5), microbiological indicators and radioisotope composition – are determined.

The first three stages of water quality monitoring, as well as the determination of some heavy metals included in the Stage 4, can be carried out by the water utility's laboratory with proper technical, methodological and personnel support. The fourth stage of monitoring is carried out on the basis of state specialized toxicological, microbiological and radiological laboratories supplied with the necessary analytical equipment and methodological support and authorized to work with particularly hazardous substances, biopathogens and radioisotopes.

The cost of laboratory equipment for determining water composition at this stage is several million euros, and therefore it makes no sense to equip water utility laboratories with it. It should also be kept in mind that water utility laboratories do not have the financial capacity to hire highly qualified specialists capable of working with such equipment.

Water samples for analysis at all 4 stages are collected with the participation of specialists from the water utility's laboratory, but at the Stage 4, they must be instructed on the rules of sampling by a representative of a specialized laboratory, depending on the type of analysis.

The main characteristics of the stages of CBRN water contamination monitoring are presented in table 6. The general algorithm for CBRN water contamination monitoring is shown in figure 3.

To implement CBRN water contamination monitoring within the first three stages, a list of additional analytical and auxiliary laboratory equipment, consumables and reagents was compiled in the laboratory of the water supply and sewerage enterprise.

The calculation was made for one year of laboratory operation, assuming that the on-line monitoring system is activated on average once a week. The estimated cost of organizing such monitoring is 893 thousand euros.

Also, based on this list, a preliminary estimate was made of the operating costs for organizing and conducting CBRN water contamination monitoring, which amount to about 464 thousand euros.

Table 5. Parameters of expanded water quality monitoring.

№	Parameter	Unit	Parametric value
1	Boron	mg/l	1.5
2	Bromate	µg/l	10
3	Lead	µg/l	5
4	Mercury	µg/l	1
5	Nickel	µg/l	20
6	Antimony	µg/l	10
7	Arsenic	µg/l	10
8	Cadmium	µg/l	5
9	Chromium	µg/l	25
10	Selenium	µg/l	20
11	Acrylamide	µg/l	0.1
12	Benzo(a)pyrene	µg/l	0.005
13	Pesticides	µg/l	0.1
14	Chlorophenols	µg/l	0.3
15	Pesticides Total	µg/l	0.5
16	Benzene	µg/l	1
17	Carbon tetrachloride	µg/l	2
18	1,2-dichloroethane	µg/l	3
19	Dibromochloromethane	µg/l	10
20	Tetrachloroethene and Trichloroethene	µg/l	10
21	Formaldehyde	µg/l	50
22	Polycyclic aromatic hydrocarbons	µg/l	0.1
23	PFAS Total	µg/l	0.5
24	Sum of PFAS	µg/l	0.1
25	Epichlorohydrin	µg/l	0.1
26	Microcystin-LR	µg/l	1
27	Haloacetic acids (HAAs)	µg/l	up to 60
28	Bisphenol A	µg/l	up to 2.5

4. Conclusions

Ensuring the safety and quality of drinking water is a crucial task, especially in the context of martial law and the possibility of damage to water sources, water treatment facilities, water networks, and other water supply and sewerage facilities and deterioration of tap water quality. To ensure an effective system of timely and adequate response to various types of water contamination, several measures should be taken:

- develop emergency response plans in the event of chemical or radiation releases, as well as biological contamination. These plans should identify procedures, responsible personnel, and use advanced technology to quickly identify and correct problems;
- as part of the implementation of the Response Plan for CBRN water contamination emergencies, monitor water quality in water supply sources and water networks to detect any changes in the level of chemical, biological, radiation and nuclear contamination;
- use modern technologies, such as automated monitoring systems, sensors, and rapid pollution detection systems, which allows for prompt detection of problems and real-time response.

Table 6. Main characteristics of the stages of CBRN water contamination monitoring.

No. of stage	Stage name	Indicators to be determined	Control points	Sample collection	Location of the analysis
	Radiation and chemical reconnaissance	Environmental radiation background, chemical warfare agents, particularly hazardous non-combatants	Determined on the basis of information on WMD from competent state services	Specialists of the competent services with the participation of the water utility laboratory	At control points
1	Continuous on-line monitoring of physical and chemical parameters	Electrical conductivity, pH value, redox potential, turbidity, colour, free chlorine	Key facilities of centralized water supply (water intake, clean water tank, water supply network, etc.)	Automatically	On-site installation of on-line monitoring systems
2	Operational control of indicator parameters of water chemical composition	Table 3, total coliforms and E. coli and on-line monitoring indicators (Stage 1)	First, at the on-line monitoring points from which the alarm came, then according to the situation	Water utility laboratory	On-site installation of on-line monitoring systems and / or in the water utility's laboratory
3	Reduced control of water chemistry	Table 4 and on-line monitoring indicators (Stage 1)	Based on the results of the previous stage	Water utility laboratory	In the water utility's laboratory
4	Extensive control of the chemical, microbiological and radiological composition of water	Chemical warfare agents, toxic compounds that pose a potential threat to water quality, biological warfare agents, table 5, on-line monitoring indicators (Stage 1), radioisotopes	Based on the results of the previous stage and radiation and chemical reconnaissance	Specialized toxicological, microbiological and radiological laboratories with the participation of the water utility's laboratory	In a specialized laboratory

It is also necessary to ensure effective crisis management through training of water utility personnel, cooperation with authorities, scientific institutions and local residents to identify potential threats and jointly address water supply problems.

These measures will contribute to the creation of a system that will ensure an effective and adequate response to chemical, biological, radiation-nuclear water contamination, which is important for ensuring the safety and quality of drinking water for the population.

Abstract. The article analyzes the distribution of trees according to the main ecological indicators that characterize the viability of artificial pine stands, in which forestry activities were stopped due to significant radioactive contamination, 35 years after the accident at the Chernobyl nuclear power plant. In intensively polluted areas and control trial areas in fresh forests, the following distribution of trees by categories of sanitary condition was noted: healthy pine trees (category I) make up 29–33 percent and 47–53 percent of the total number of trees, respectively, weakened (category II) – 29–33% and 29–37%, very weakened (III category) – 13–17% and 6–12%, the share of dying and dead trees (IV–VI status categories) is 22–24% and 9–12%. It can be emphasized that in the same studied types of forest vegetation conditions, where the levels of radioactive pollution allowed to carry out forestry activities, a much better sanitary condition of pine stands was noted. Analyzing the indicators of the general index of the sanitary condition of pine plantations in the zone of unconditional resettlement, it can be noted that all stands belong to very weakened ones, the index is in the range from 2.45 to 2.55. In the control test areas, where forestry measures for the care of stands were carried out in a timely manner, this indicator was lower – by 13-26%. The study of the process of formation of waste and drying of pine stands shows that the share of trees of IV-VI categories of sanitary condition in fresh forests is 22-24%, and this is almost a third of trees that, as a rule, will die within a few years. In addition, trees of category III (13–17%) pose a significant threat, which will move into lower status categories without forest management measures. Research results show that after the cessation of forestry activities in the zone of unconditional resettlement, there is an intensive accumulation of dryness and a significant weakening of tree stands. In the radioactively contaminated territories, almost 58 to 70% of the trees are belonging to the II and III categories of technical suitability, and in the control areas the share of trees of the I category ranges from 45 to 64%.

1. Introduction

The forest massifs of the Ukrainian Polissia are represented, in the vast majority, by forest crops of Scots pine (Pinus sylvestris L.) [1, 2]. Growth characteristics and productivity of such plantations depends on the biological characteristics of the species and resistance to environmental conditions of growth, which, in turn, is directly related to the implementation of timely and highly qualified forestry measures. All forestry enterprises of the Zhytomyr region are characterized by the proper implementation of forestry measures, which contributed to the maintenance of the optimal state of forests and the formation of high-quality stands [3, 4]. However, as a result of the accident at the Chernobyl nuclear power plant, part of these forest areas were exposed to radioactive contamination and were withdrawn from forestry use. Pine plantations of different age groups were left unattended for a long time. In connection with this, negative changes began to be traced in them. Favorable conditions for the development of pests and diseases were created, the fire hazard increased, the quality of wood decreased, the processes of self-liquefaction of stands accelerated, accumulation of dry matter and the formation of litter increased. In general, the processes of degradation of artificial pine plantations have begun.

For tree stands in the area of radioactive fallout, an increase in the share of stands with disturbed stability was noted, and the intensity of growth of pine stands increased significantly [5–7]. Researchers [8–10] noted that in the forest vegetation conditions of a fresh forest, the tendency to the deterioration of the state of plantations was more pronounced than in the conditions of a wet forest, fresh and wet forest. The processes of self-liquefaction and accumulation of waste accelerated. The rates of accumulation of waste are higher in high-quality young animals and medieval cultures and depend on the conditions of local growth [11]. As a result of the transition of stands to older age groups, there is a decrease in the number of trees per unit area, which causes accumulation of dryness. This leads to an increase in the cluttering of plantations, roads and canals, as a result of which a 1.5-2 times increase in the density of pine plantations was noted [7]. Under the forest canopy, stocks of forest litter increase, dead needles, leaves, small branches, bark accumulate, which slowly decompose, but burn very well, and create an additional fire hazard [12]. As a result of the restriction of economic activity in radioactively contaminated pine plantations, productivity decreased, the sanitary condition worsened, the number of trees of IV–VI status categories increased, and the number of trees of I–III categories decreased [5, 9, 13]. In radioactively contaminated territories, the sanitary condition of young trees and medieval stands is the most threatening. A natural, significant deterioration of the condition index of pine stands is observed, starting from 81–100-year-old to 1–20-year-old young trees and to stagnant stands [14]. The phytosanitary situation has significantly deteriorated, favorable conditions for the spread of pests and diseases have been created [15].

It is known that after entering the components of forest ecosystems, radionuclides gradually moved from the upper to the lower layers of vegetation and the soil surface. Directly under the influence of precipitation and wind, as well as due to the fall of leaves, needles, branches and bark, their vertical and horizontal migration took place [16, 17]. The duration of vertical migration in the crown-litter-soil-root chain, during which up to 95% of radionuclides move from the crown to the forest floor, is approximately one year in deciduous stands, and up to 3 years in conifers [16], and according to others estimates – from 3 to 7 years [18]. After the movement of radionuclides to the forest floor and depending on the type of forest vegetation conditions and the composition of the tree layer, the migration of radionuclides of different intensity began in the genetic horizons of forest soils [19–25].

Scots pine (Pinus sylvestris L.) is the most common species in forests that have experienced significant radioactive contamination and belongs to wood species that are quite plastic in terms of ecological requirements. The researchers noted that coniferous tree species are 5–10 times more sensitive to radiation exposure than hardwoods [16], and accumulate radionuclides 2–3 times more [18] compared to them. That is why pine plantations can be used as an indicator of contamination of the ecosystem with radionuclides in the process of assessing and forecasting the sanitary condition of forest areas in radioactively contaminated territories.

More than 35 years have passed since the accident at the Chernobyl nuclear power plant, and the radiation situation in forest areas has changed. That is why it is necessary to carry out a modern assessment of the sanitary state of pine plantations in radioactively contaminated territories. The obtained results will provide an opportunity to consider ways of optimizing forestry management in radioactively contaminated territories, which will contribute to improving the condition of stands on these lands.

2. Methodology

In order to assess the sanitary condition of pine plantations, test plots were laid out in the fresh forests of the Narodychi Forestry of the State Enterprise (SE) "Narodychi Specialized Forestry", where forestry activities were completely stopped due to high levels of radioactive soil contamination, and in the Malyn Forestry of the SE "Malyn Forestry", where timely forestry measures for forest care (figure 1). Test areas were established according to generally accepted methods in forestry and ecology. The research is based on the classical method of comparative forest ecology with its detailing according to individual ecological and forestry areas.

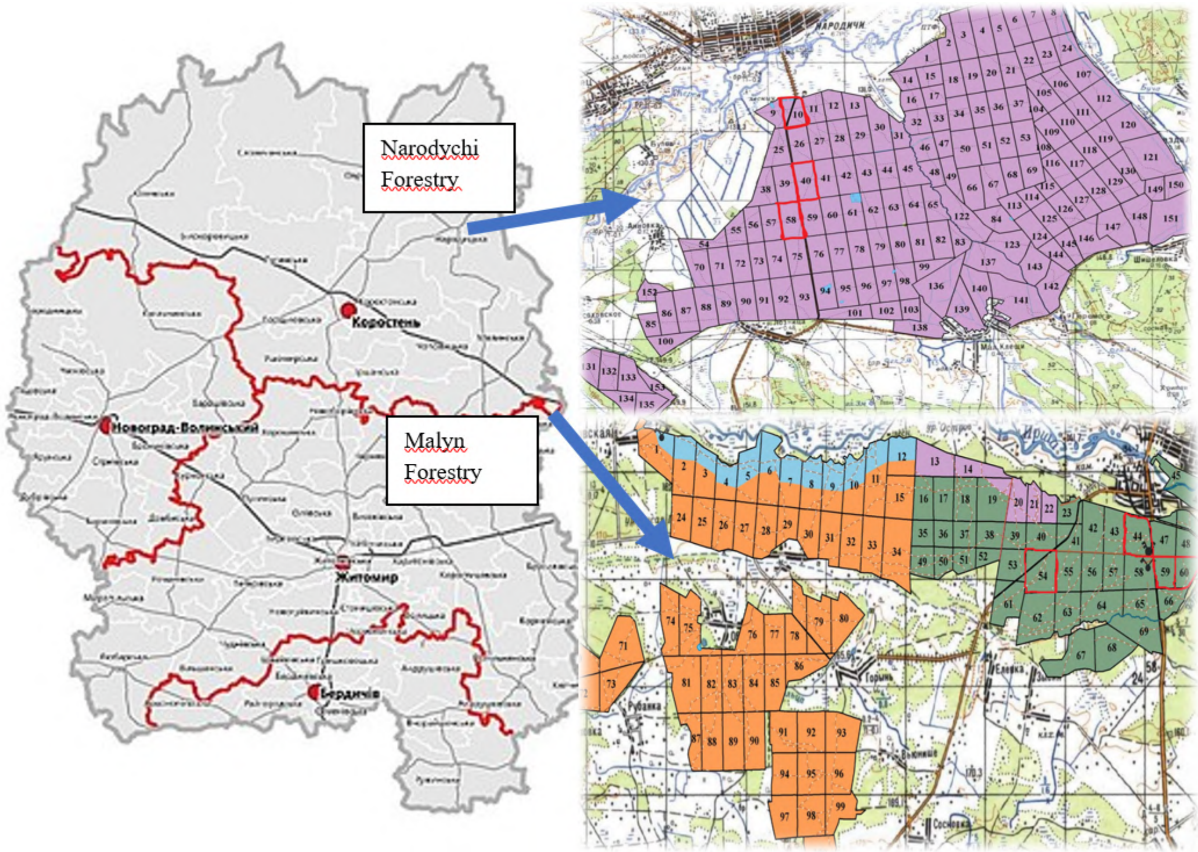

Figure 1. The studied region.

Assessment of the sanitary condition of pine stands on radioactively contaminated and control trial plots of the studied type of forest vegetation conditions, the actual taxing indicators of the plantations were determined using standard methods. Thus, after laying out the trial areas, a full description of tax indicators was carried out, which includes the following indicators: origin of plantations, shape, composition, average height, age, elements of the forest, bonity, fullness, average diameter, reserve, marketability class, type of forest. Each plot consisted of 100 trees. Recalculation of trees was carried out by measuring their diameters at a height of 1.3 m from the neck of the root. The minimum diameter of the trees that were included in the recalculation was more than 8 cm. The height measurement was based on the measurement of the heights of 30 trees, which were distributed according to the degrees of change in the diameter of the plantations (the measurement of the trees with the most frequently repeated diameter, in the direction of increase and decrease), i.e. stepwise. Determining the age of the main element of the forest is determined by counting the annual rings on the cores. For this, cores were taken to determine the age of the trial area with the help of an age drill. The origin of plantations was determined by forest tax records, in which it was indicated which plantation it was: natural or artificial, seed or sprout. The composition of the plantations is determined by the list of tree species that make up the stand, with an indication of the share of each species in the total stock. The quality of a forest can be determined by the total stock of wood or by its average growth, but the most widely used indicator of forest productivity is the average height of the trees of the first tier of the forest stand at a certain age. Knowing the average height and age of the trees, they can find the standing's standing according to the tables of standing classes. The completeness and stock of plantations was obtained by the calculation method, after the analysis of the tax indicators listed above. An assessment was also carried out according to the marketability class of wood according to categories of technical suitability. Clutter was taken into account separately, dividing it into liquid and non-liquid wood.

The sanitary condition of pine plantations was assessed according to the condition index (I) of the first tier of stands, which was calculated according to the methodology of the Ukrainian Research Institute of Forestry and Agroforestry named after G. M. Vysotskiy on a 6-point scale [26, 27]:

$$I = \frac{(i_1 n_i) + (i_2 n_i) + (i_3 n_i) + (i_4 n_i) + (i_5 n_i) + (i_6 n_i)}{N}$$

where: I – forest condition index, $i_1 - i_6$ – tree condition categories (from I to VI), n_i – the number of trees of the same state category, individuals, N – total number of assessed trees on the trial area, individuals.

Stands with an index of 1.00–1.50 are considered healthy (no damage); weakened – 1.51–2.50 (damage is weak); severely weakened – 2.51–3.50 (damage is average); those that dry out – 3.51–4.50 (severe damage); dead – 4.51–6.00 (the damage is very strong).

This technique most accurately characterizes the current state of pine plantations in the forest areas of Ukraine.

3. Results

The decline in the viability of pine stands in the zone of unconditional resettlement is largely characterized by the distribution of trees by categories of sanitary condition. In the Narodychi Forestry, where the level of radioactive contamination of the soil did not allow any forestry activities to be carried out, the range of variation of the specific weight of individual categories of trees fluctuated significantly. Healthy pine trees (category I) accounted for 29 to 33%, weakened pines (category II) – 29–33%, very weakened (category III) – 13–17%, drying and withered (categories IV–VI) – 22– 24% of the total number of trees. In the Malyn Forestry, where the level of radioactive contamination is low and full-fledged forestry work was carried out in a timely manner, the sanitary condition of trees is much better: I category – 47-53%, II – 29-37%, III – 6-12%, IV-VI – 9 -12% of the total number of trees.

When analyzing the distribution of trees by status categories in medieval pine plantations (figure 2), it was noted that on permanent trial area (PTA) No. 4K the number of pine stands without signs of weakening (category I) is 1.2 times more than on PTA No. 4, and weakened (category II) – 1.1 times, respectively. Regarding the distribution of tree stands according to the III category, no significant difference was noted, however, the share of very weakened trees is 13% on PTA No. 4, and 12% on PTA No. 4K.

When comparing the percentage distribution of the following categories of sanitary condition, it can be noted that there are 1.7 times more dying stands of IV category on PTA No. 4 than on the control (PTA No. 4K), fresh dry ones (V category) – 3 times more, and old dryness (VI category) – 1.2 times. Therefore, according to the obtained results, it can be stated that

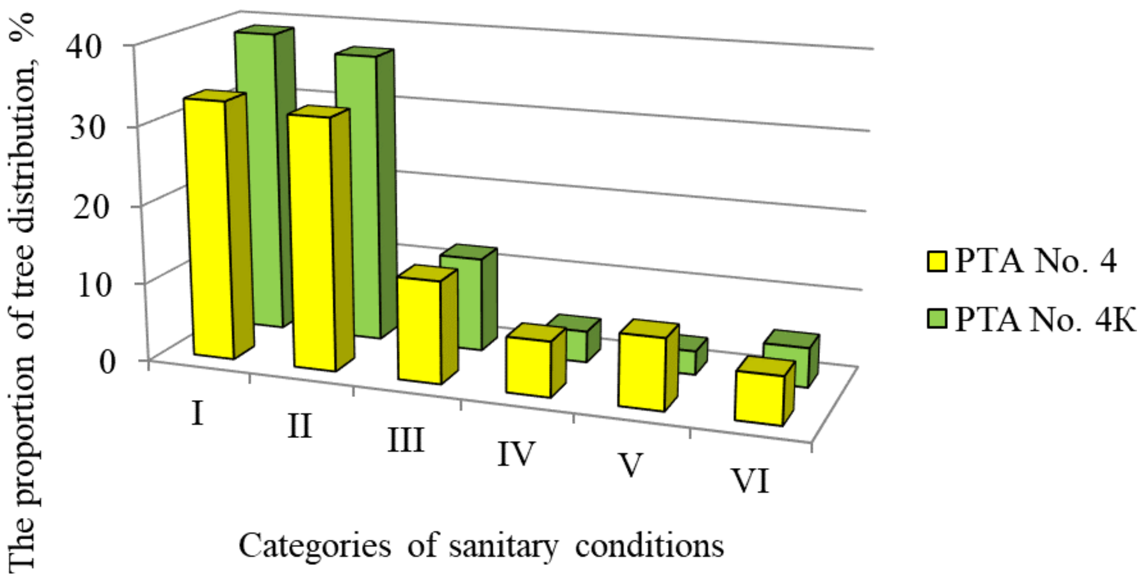

Figure 2. Distribution of trees in medieval pine stands by categories of sanitary condition in conditions of fresh pine.

in the 60-year-old forest plantations of the Narodychi Forestry, the distribution of stands by status categories is much worse than in the Malyn Forestry. Although, conducting a one-factor variance analysis of the distribution of trees by category of sanitary condition, no significant difference in mean values was found – $F_{fact.} = 3.0 < F_{(1;199;0.95)} = 3.9$.

The distribution of pine stands by status categories in the incoming plantations of fresh pine of the Ukrainian Polissia shows that there are 1.8 times more pine stands with no signs of weakening on PTA No. 5K than on PTA No. 5 (figure 3). However, the total percentage of weakened stands of the II category was the same and amounted to 29%. Analyzing the further distribution of stands, significantly higher indicators of deterioration of the state of plantations in Narodychi Forestry compared to the control were noted. Thus, the number of very weakened stands (category III) is 2.8 times greater on PTA No. 5 than on PTA No. 5K.

With regard to the distribution by other categories, a similar difference is observed, and the excess of the number of trees on PTA No. 5 in comparison with PTA No. 5K is: for IV category – 2.2 times, V category – 2.0 times, and old drywood (VI category) – 1.7 times. When conducting a one-factor variance analysis of the distribution of categories of the sanitary state of the arriving plantations, the existence of a reliable difference in the average values at the 95% confidence level was established: $F_{fact.} = 11.2 > F_{(1;199;0.95)} = 3.9$.

Analyzing the distribution of trees by categories of sanitary condition in mature pine stands, it was found that on the PTA No. 6 healthy stands (I category) are 1.6 times less than on the PTA No. 6K, and weakened ones (II category) are 1.1 times less, respectively (figure 4). The share of very weakened stands on PTA No. 6 is 14%, which is 2 times more than on PTA No. 6K. The analysis of the distribution of trees according to IV, V and VI categories is very important, because it makes it possible to reflect the processes of self-liquefaction of plantations. Thus, on PTA No. 6K, the distribution of trees by category was characterized by the following values: for IV – 3%, V – 1% and VI – 5%; while at PTA No. 6 these indicators are 3.3, 6.0, and 1.6 times higher, respectively. The obtained results of the difference between the categories of the condition of mature pine plantations are confirmed by the results of one-factor variance analysis: $F_{fact.} = 12.6 > F_{(1;199;0.95)} = 3.9$.

The general distribution of the studied stands shows that in radionuclide-contaminated

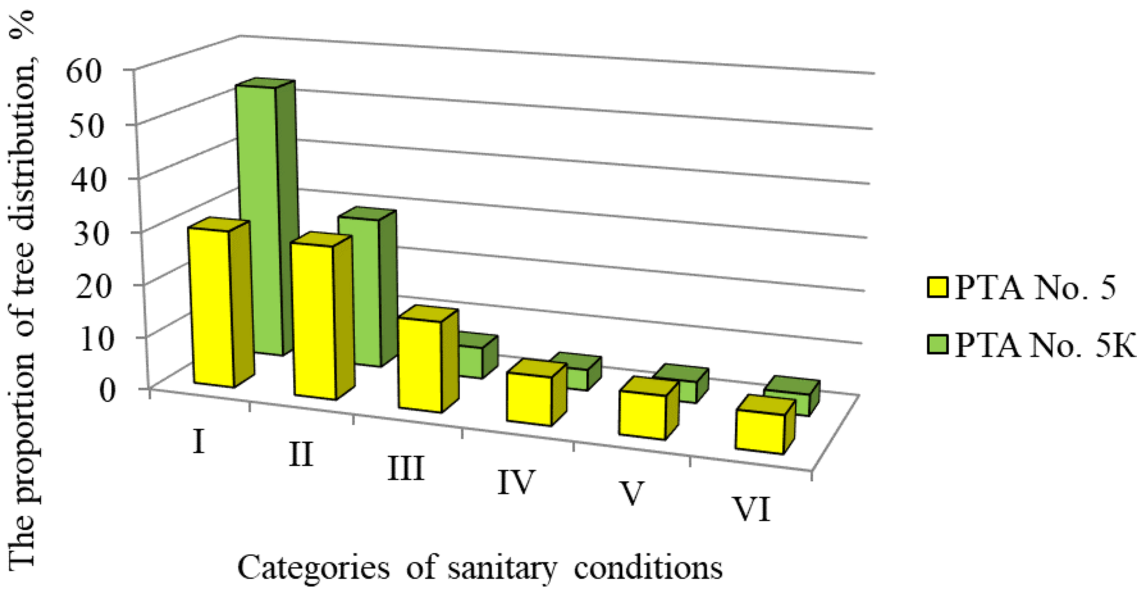

Figure 3. Distribution of trees in incoming pine stands by categories of sanitary condition in conditions of fresh pine.

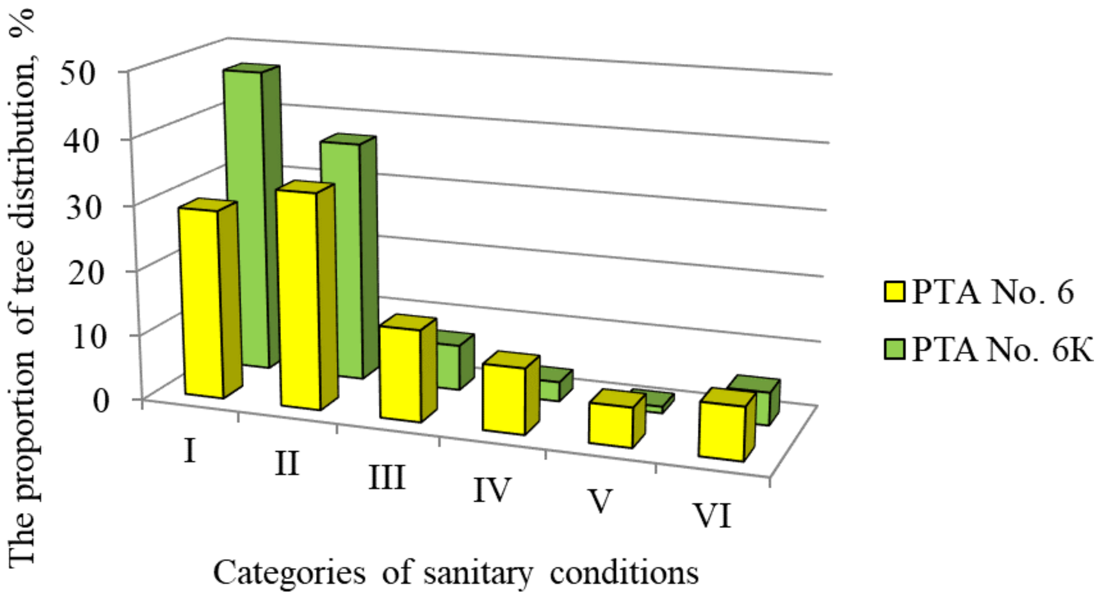

Figure 4. Distribution of trees in mature pine stands by categories of sanitary condition in conditions of fresh pine.

plantations of all age groups, the specific gravity of healthy pines is lower, and weakened and very weakened ones are much higher than in plantations outside the zone of radiation contamination. The obtained results are confirmed by the index of sanitary condition, which in the Malyn Forestry, where economic activity was carried out in a timely manner, ranged from 1.89 to 2.13, and in the Narodychi Forestry, it is in the range from 2.45 to 2.55.

In addition, the distribution of stands by marketability classes in the experimental plots was analyzed. It has been established that there are 1.2 times fewer trees belonging to the I class (business wood) on PTA No. 4 than on PTA No. 4K. The distribution by class II (semi-finished wood) is almost the same and amounts to 43 and 42%, respectively. However, during the analysis of the IIIrd class of marketability, it was noted that there is 1.7 times less firewood on PTA No. 4K than on PTA No. 4.

Similar patterns were observed on other test plots. Thus, the share of distribution of trees of the IIIrd class of marketability on PTA No. 5K and PTA No. 6K is 1.5 and 1.4 times less than on PTA No. 5 and PTA No. 6, respectively. On the control plots, the share of class I forest stands was 42% in PTA No. 5K and PTA No. 6K – 48%, while in PTA No. 5 and PTA No. 6 it was 1.5 times less. Analyzing the distribution of stands by marketability class, it can be assumed that the distribution of trees according to this indicator depends on the quality and timeliness of forestry activities.

The analysis of the obtained data shows that the specific activity of 137Cs in the components of the forest ecosystem differs significantly in fresh pines. The minimum values of the studied indicator were noted in the soil, and the maximum values were recorded in the forest floor and individual representatives of the grass-shrub and moss cover (figure 5).

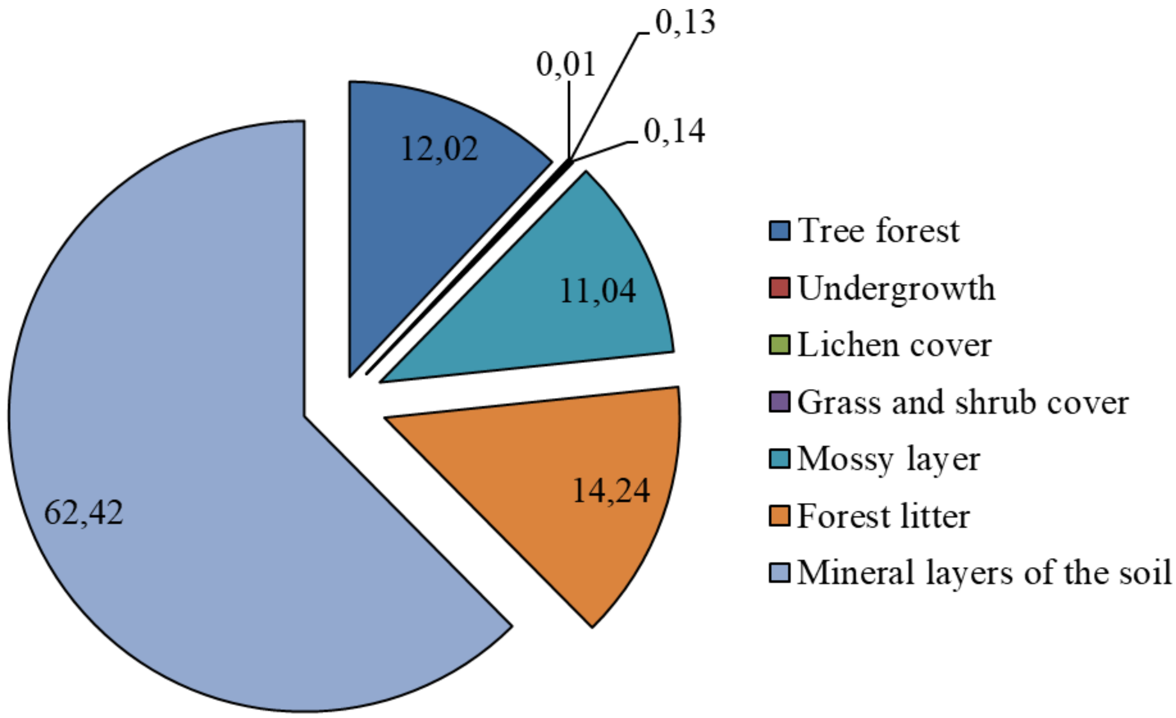

Figure 5. Share of the total activity of ^{137}Cs in the forest ecosystem of a pine forest under conditions of fresh boron, %.

During the analysis of the values of the specific activity of the radionuclide in pine, the usual highest indicator was noted in the inner bark, which is 2.0 times more than in the outer one, and the wood is characterized by the lowest values of ^{137}Cs content. According to the increase in the specific activity of the radionuclide in the morphological parts of the tree, the following ranked order can be established: $wood < thickbranches < thinbranches < outerbark < pins < innerbark < shoots$.

4. Conclusions

The following conclusions can be drawn on the basis of the conducted research:

1. The distribution of stands by categories of sanitary condition shows that in the Narodychi Forestry healthy pine trees (category I) accounted for 29 to 33%, weakened pines (category

II) – 29–33%, very weakened (category III) – 13–17%, drying and dry (IV–VI categories) – 22–24%. In the Malyn Forestry, I category stands account for 47–53%, II – 29–37%, III – 6–12%, IV–VI – 9–12% of the total number of trees.

2. The index of the sanitary state of pine plantations in the Malyn Forestry ranges from 1.89 to 2.13, which refers to the plantations as weakened, and in the Narodychi Forestry this index ranges from 2.45 to 2.57 and indicates a very weakened state of the plantations.
3. The obtained indicators of the distribution of stands by the class of wood marketability indicate that the proportion of category I trees in the Malyn Forestry is significantly higher compared to the Narodychi Forestry (PTA No. 4 – 38%, PTA No. 4K – 45%, PTA No. 5 – 28%, PTA No. 5K – 42%, PTA No. 6 – 32%, PTA No. 6K – 48%). At the same time, in radioactively contaminated territories, the share of II and III class stands is growing significantly.
4. The distribution of the radionuclide among the components of the artificial scots pine ecosystem in fresh pine shows that the main content of ^{137}Cs is concentrated in the forest soil – 76.66%, and the share of the total activity of the radionuclide in the phytocenosis is 23.34%. It has been established that the main role in keeping the radionuclide is played by the tree and moss layer. Yes, the above components contain ^{137}Cs: in fresh pines – 51.49% and 47.32%, respectively.
5. In order to preserve pine plantations, it is necessary to consider the possibility of resuming forestry activities in forest divisions in which they were prohibited, taking into account the current density of radioactive soil contamination. This requires an examination of forests for radioactive contamination based on an updated methodology using modern data on the study of the migration of radionuclides in forest soils.
6. The distribution of the radionuclide by the components of the artificial ecosystems of scots pine, wet undergrowth and fresh pine shows that the main content of ^{137}Cs is concentrated in forest soils – 74.06% and 76.66%, and the share of the total activity of the radionuclide in the phytocenosis is 25.94% and 23.34%, respectively. It has been established that the main role in keeping the radionuclide is played by the tree and moss layer. Thus, the above-mentioned components contain ^{137}Cs: 49.47% and 46.06% in wet pines, and 51.49% and 47.32% in fresh pines, respectively.

Abstract. The paper is devoted to the design of a framework to study uncertain nonlinear dynamical plants. We use the results of this study to design a variable-structure control system for the considered plants. Our studies are based on the use of interval methods to take into account possible plant parameters variations and perform a piecewise linear approximation of the plant's nonlinearity. We offer to replace a nonlinear function, which is used to define a plant's dynamic with a phase space domain where this function is localized. This allows us to rewrite the initial nonlinear differential equation into piecewise linear form and apply the Laplace-Carson transformation for the considered differential equation to define the generalized transfer function which gives us the possibility to study and design system dynamics. We use a determined piecewise linear interval transfer function to solve the inverse dynamic problem and define the controller's transfer function which allows for reaching the desired motion trajectories. We show the use of our approach and its benefits by designing a controller for a ventilator electric drive. Comparison of the designed control system with the known one allows us to claim its high accuracy and energy efficiency.

1. Introduction

The efficient control of electric drives [1], plays a pivotal role in various industrial applications [2, 3], contributing to advancements in automation [4–6] and energy management [7–9]. One particularly critical area is the integration of electric drives with ventilator loads [10], which finds extensive application in fields ranging from heating, ventilation, and air conditioning systems to industrial ventilation. The ability to regulate and optimize the performance of electric drives in conjunction with ventilator loads is essential for achieving energy efficiency, precise control, and system reliability [11].

The unique characteristics of ventilator loads, characterized by dynamic airflow demands and variable load conditions, present intricate challenges for control systems [12]. Addressing these challenges requires advanced control strategies that can adapt to the dynamic nature of ventilator-driven systems [13, 14]. Moreover, the pursuit of energy-efficient solutions aligns with the broader global initiative towards sustainable practices [15], making the study of electric drive control with ventilator loads both timely and significant.

Recent advancements in the field of electric drives with ventilator loads have been shaped by a multitude of studies focusing on control strategies, system optimization, and the integration of innovative technologies. The literature in this domain reflects a diverse range of approaches and methodologies, showcasing the ongoing efforts to address the challenges posed by the dynamic nature of ventilator-driven systems.

In this paper, we consider design of robust control system for elecctric drive with ventlator load by using interval methods to define electric drive model and take into account its nonlinearities and uncertainties. When we use this model to solve inverse dynamic problem and define robust controller transfer function. At last, we consider some example to show usage of our approach.

2. Interval model for electric drive with ventilator torque

Let us consider the use of our approach to design controller for electric drive with ventilator load. We continue our previous studies [16] and think that ventilator torque depends not only electric drive speed but operational and environmental conditions

$$\tau = T_0 + k_T \omega^a, \tag{1}$$

here T_0 is a constant, which defines an idling torque, k_T is a weight factor, ω is a drive speed, and a is a power factor, which is depend from electric drive operational conditions. It is known that this factor is defined in the interval $[1.5, 2.5]$ and its conventional value equals to 2.

We consider dynamic of an electric drive in the simplified way by assuming that its electromagnetic inertia is compensated by using internal currents and/or flux controllers

$$T_m \dot{\omega} = -\omega + k_d u - k_d^2 R \tau, \tag{2}$$

here T_m is an electromechanical constant, k_d is a drive gain, and R is a drive resistance.

Since the above-given motion equations is considered as equation in a normal form, we transform (2) into normal form by taking into account (1)

$$\dot{\omega} = -\frac{1}{Tm}\omega - \frac{k_d^2 k_T R}{T_m}\omega^a + \frac{k_d}{T_m}u - \frac{k_d^2 R}{T_m}T_0. \tag{3}$$

It is clear that dynamical plant (3) is a nonlinear plant with uncertain nonlinearity. That is why to simplify its studies we offer to take into account following relative units

$$w = \frac{\omega}{\omega_0},\ v = \frac{u}{u_m} = \frac{k_d u}{\omega_0},\ t_0 = \frac{T_0}{T_{max}} = \frac{k_d^2 T_0 R}{\omega_0}, \tag{4}$$

where ω_0 is an drive's idle speed, u_m is a maximal drive supplied voltage, T_{max} is a maximal drive torque
and rewrite (3) into dimensionless form

$$\dot{w} = b_1 w + b_{1a} w^a + m_1 v + m_0 t_0, \tag{5}$$

here

$$b_1 = -\frac{1}{T_m};\ b_{1a} = -\frac{k_d^2 k_T R \omega_0^{a-1}}{T_m};\ m_1 = \frac{1}{T_m};\ m_0 = -\frac{1}{T_m}. \tag{6}$$

The study drive's dynamic in a relative units allows us to consider its state variable w, control signal v, and idle torque t_0 in range $[0, 1]$ instead of their real values. It is clear that such approach gives us the possibility to make dynamic representation and comparison more clear.

It is necessary to say that the values of drive's parameters is not exactly known or they can change during the operation time because of heating, supplier's voltage variations and other environmental effects. We take into account possible parameters' variations by considering intervals of their possible values. In the mathematical way this assumption can be taking into account by following intervals

$$\mathbf{T_m} = [T_{m\ low}, T_{m\ up}];\ \mathbf{k_d} = [k_{d\ low}, k_{d\ up}];\ \mathbf{k_T} = [k_{T\ low}, k_{T\ up}];\ \mathbf{R} = [R_{low}, R_{up}]. \tag{7}$$

The usage of intervals (7) allows us to rewrite factors (6) in the interval compact

$$\mathbf{b_1} = -\frac{1}{\mathbf{T_m}};\ \mathbf{b_{1a}} = -\frac{\mathbf{k_d}^2\mathbf{k_T}\mathbf{R}\omega_0^{\mathbf{a}-1}}{\mathbf{T_m}};\ \mathbf{m_1} = \frac{1}{\mathbf{T_m}};\ \mathbf{m_0} = -\frac{1}{\mathbf{T_m}} \tag{8}$$

and extended

$$\begin{gathered}\mathbf{b_1} = \mathbf{m_0} = \left[-\frac{1}{T_{m\ min}}, -\frac{1}{T_{m\ max}}\right];\ \mathbf{m_1} = \left[\frac{1}{T_{m\ max}}, \frac{1}{T_{m\ min}}\right];\\ \mathbf{b_{1a}} = \left[-\frac{{k_{d\ max}}^2 k_{T\ max} R_{max}\omega_0^{a_{max}-1}}{T_{m\ min}}, -\frac{{k_{d\ min}}^2 k_{T\ min} R_{min}\omega_0^{a_{min}-1}}{T_{m\ max}}\right]\end{gathered} \tag{9}$$

forms.

Now we design the interval piecewise linear model for the uncertain plant's nonlinearity (figure 1). Here we define upper piecewise linear boundary for the nonlinear torque with factors $a = 1.5$ and lower one for the case when $a = 2.5$. In this and others figures we show results of our studies for dimensionless electric drive model. In this case we assume that 1 in figure means maximal possible value of electric drive state variables.

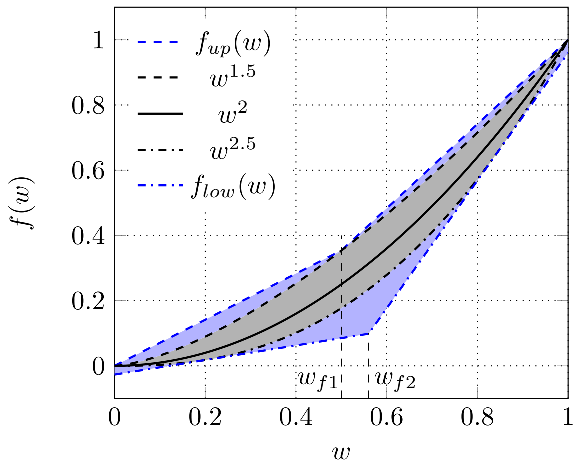

Figure 1. Domain of the nonlinearities possible values.

The solution of minimization problem for piecewise linear bounded area in (figure 1)

$$I = \sum_{i=1}^{n}\int_0^{y_{fi}} (f(y)^2_{iup} - f(y)^2)dt + \sum_{i=1}^{m}\int_0^{y_{fi}} (f(y)^2 - f(y)^2_{ilow})dt \rightarrow min \tag{10}$$

for functions

$$f_1(w) = w^{1.5};\ f_2(w) = w^{2.5} \tag{11}$$

gives us the possibility to define fracture points $w_{f1} = 0.5$ and $w_{f2} = 0.56$ in upper and lower boundaries and appropriate piecewise linear functions are determined in such a way

$$f_{up}(w) = \begin{cases} 0.701w & if \quad 0 \leq w \leq 0.5; \\ 1.293w - 0.293 & if \quad 0.5 < w \leq 1, \end{cases}$$
$$f_{low}(w) = \begin{cases} 0.223w - 0.027 & if \quad 0 \leq w \leq 0.56; \\ 1.959w - 1.0 & if \quad 0.56 < w \leq 1. \end{cases} \tag{12}$$

Function (12) can be rewritten in the interval form

$$\mathbf{f}(w) = \begin{cases} \mathbf{k_{11}}w + \mathbf{k_{01}} & if \quad w \in \mathbf{w_{f1}}; \\ \mathbf{k_{12}}w + \mathbf{k_{02}} & if \quad w \in \mathbf{w_{f12}}; \\ \mathbf{k_{13}}w + \mathbf{k_{03}} & if \quad w \in \mathbf{w_{f2}}, \end{cases} \tag{13}$$

if one assumes following intervals for its factors

$$\begin{aligned} &\mathbf{k_{11}} = [0.701, 0.223];\ \mathbf{k_{12}} = [1.293, 0.223];\ \mathbf{k_{13}} = [1.293, 1.959]; \\ &\mathbf{k_{01}} = [0.0, -0.027];\ \mathbf{k_{02}} = [-0.293, -0.027];\ \mathbf{k_{03}} = [-0.293, -1.0]; \\ &\mathbf{w_{f1}} = [0, w_{f1}];\ \mathbf{w_{f12}} = [w_{f1}, w_{f2}];\ \mathbf{w_{f2}} = [w_{f2}, 1]. \end{aligned} \tag{14}$$

Substitution (13) into (5) allows us to write down interval model for the considered electric drive

$$\dot{\mathbf{w}} = \begin{cases} (\mathbf{b_1} + \mathbf{k_{11}}\mathbf{b_{1a}})\mathbf{w} + \mathbf{m_1}v + \mathbf{m_0}t_0 + \mathbf{k_{01}}\mathbf{b_{1a}} & if \quad w \in \mathbf{w_{f1}}; \\ (\mathbf{b_1} + \mathbf{k_{12}}\mathbf{b_{1a}})\mathbf{w} + \mathbf{m_1}v + \mathbf{m_0}t_0 + \mathbf{k_{02}}\mathbf{b_{1a}} & if \quad w \in \mathbf{w_{f12}}; \\ (\mathbf{b_1} + \mathbf{k_{13}}\mathbf{b_{1a}})\mathbf{w} + \mathbf{m_1}v + \mathbf{m_0}t_0 + \mathbf{k_{03}}\mathbf{b_{1a}} & if \quad w \in \mathbf{w_{f2}}. \end{cases} \tag{15}$$

We call (15) as piecewise linear interval model of electric drive with ventilator load.

3. Interval model in the operator form

Let us assume that before control signal is supplied to the electric drive, it has already operates with speed near 5% from idle speed because of environment affects. This fact defines non-zero initial condition

$$W(0) = 0.05, \tag{16}$$

which makes it possible to rewrite (15) into the operator form

$$\begin{cases} s\mathbf{W}(s) - sw(0) = \mathbf{a_{11}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{01}} & if \quad w \in \mathbf{w_{f1}} and sw > 0; \\ s\mathbf{W}(s) - sw_{f1}(0) = \mathbf{a_{11}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{01}} & if \quad w \in \mathbf{w_{f1}} \ and \ sw < 0; \\ s\mathbf{W}(s) - sw_{f1}(0) = \mathbf{a_{12}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{02}} & if \quad w \in \mathbf{w_{f12}} \ and \ sw > 0; \\ s\mathbf{W}(s) - sw_{f2}(0) = \mathbf{a_{12}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{02}} & if \quad w \in \mathbf{w_{f12}} \ and \ sw < 0; \\ s\mathbf{W}(s) - sw_{f2}(0) = \mathbf{a_{13}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{03}} & if \quad w \in \mathbf{w_{f2}} \ and \ sw > 0; \\ s\mathbf{W}(s) - sw_0 = \mathbf{a_{13}}\mathbf{W}(s) + \mathbf{m_1}V(s) + \mathbf{m_0}T_0(s) + \mathbf{a_{03}} & if \quad w \in \mathbf{w_{f2}} \ and \ sw < 0; \end{cases} \tag{17}$$

here

$$\begin{aligned} &\mathbf{a_{11}} = \mathbf{b_1} + \mathbf{k_{11}}\mathbf{b_{1a}};\ \mathbf{a_{01}} = \mathbf{k_{01}}\mathbf{b_{1a}}; \\ &\mathbf{a_{12}} = \mathbf{b_1} + \mathbf{k_{12}}\mathbf{b_{1a}};\ \mathbf{a_{02}} = \mathbf{k_{02}}\mathbf{b_{1a}}; \\ &\mathbf{a_{13}} = \mathbf{b_1} + \mathbf{k_{13}}\mathbf{b_{1a}};\ \mathbf{a_{03}} = \mathbf{k_{03}}\mathbf{b_{1a}}; \end{aligned} \tag{18}$$

Applying trivial algebraic transformations for (17) makes it possible to rewrite (17) into matrix form

$$\mathbf{W}(s) = \mathbf{K}(s) \cdot \mathbf{X}(s) \tag{19}$$

by using piecewise interval matrix transfer function

$$\mathbf{K}(s)=\begin{cases}\begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{11}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{11}}} & \frac{sw(0)+\mathbf{a_{01}}}{s-\mathbf{a_{11}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f1}}\ and\ sw>0;\\ \begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{11}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{11}}} & \frac{sw_{f1}(0)+\mathbf{a_{01}}}{s-\mathbf{a_{11}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f1}}\ and\ sw<0;\\ \begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{12}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{12}}} & \frac{sw_{f1}(0)+\mathbf{a_{02}}}{s-\mathbf{a_{12}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f12}}\ and\ sw>0;\\ \begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{12}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{12}}} & \frac{sw_{f2}(0)+\mathbf{a_{02}}}{s-\mathbf{a_{12}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f12}}\ and\ sw<0;\\ \begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{13}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{13}}} & \frac{sw_{f2}(0)+\mathbf{a_{03}}}{s-\mathbf{a_{13}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f2}}\ and\ sw>0;\\ \begin{pmatrix}\frac{\mathbf{m_1}}{s-\mathbf{a_{13}}} & \frac{\mathbf{m_0}}{s-\mathbf{a_{13}}} & \frac{sw_0+\mathbf{a_{03}}}{s-\mathbf{a_{13}}}\end{pmatrix} & if \quad w\in\mathbf{w_{f2}}\ and\ sw<0;\end{cases} \tag{20}$$

and the generalized inputs vector

$$\mathbf{X}(s)=\begin{pmatrix} V(s) & T_0(s) & 1(s)\end{pmatrix}. \tag{21}$$

Results of numerical solution of (19) are shown in figure 2. Also, to compare both interval and exact solutions, we show in this figure results of numerical solution of (5) with conventional value of a factor.

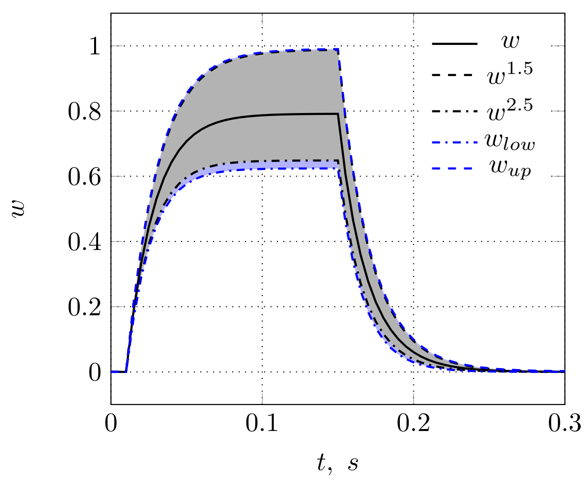

Figure 2. Simulation results of electric drive start, steady state, and stop.

Analysis of obtained simulation results shows that exact solution is localized in the area which is bounded by interval solutions for upper and lower boundaries. If one analyzes figure 2, he finds what the main uncertainty in the model is made by uncertainty of electric drive's parameters and factor a values (grey area in figure 2) and only minor one is caused by using piecewise linear boundaries (blue area in figure 2).

4. Interval piecewise controller design

The use of above-shown approach to define controller transfer function requires to determine the desired transfer function and transfer function of feedback channel. Here we assume that feedback channel has non-inertial dynamic. Also, we think that asymptotic motions are energy-efficient ones and that is why define the desired transfer function of closed-loop system in such a way

$$\Phi^*(s) = \frac{k^*}{T^*s + 1}, \tag{22}$$

where k^* is a desired system gain and T^* is its time constant.

We use (22) and (20) to define controller interval transfer function as follows

$$\mathbf{K_c}(s) = \begin{cases} \left(\frac{k^*(s - \mathbf{a_{11}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw(0) + \mathbf{a_{01}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f1}} \\ and\ sw > 0; \end{matrix} \\ \left(\frac{k^*(s - \mathbf{a_{11}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw_{f1}(0) + \mathbf{a_{01}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f1}} \\ and\ sw < 0; \end{matrix} \\ \left(\frac{k^*(s - \mathbf{a_{12}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw_{f1}(0) + \mathbf{a_{02}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f12}} \\ and\ sw > 0; \end{matrix} \\ \left(\frac{k^*(s - \mathbf{a_{12}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw_{f2}(0) + \mathbf{a_{02}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f12}} \\ and\ sw < 0; \end{matrix} \\ \left(\frac{k^*(s - \mathbf{a_{13}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw_{f2}(0) + \mathbf{a_{03}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f2}} \\ and\ sw > 0; \end{matrix} \\ \left(\frac{k^*(s - \mathbf{a_{13}})}{\mathbf{m_1}(T^*s - \mathbf{k_f}k^* + 1)} \quad -\frac{\mathbf{m_0}}{\mathbf{m_1}} \quad -\frac{sw_0 + \mathbf{a_{03}}}{\mathbf{m_1}} \right) & if \quad \begin{matrix} w \in \mathbf{w_{f2}} \\ and\ sw < 0. \end{matrix} \end{cases} \tag{23}$$

One can use defined in such a way the generalized interval controller transfer function to write down interval control law for the considered electric drive

$$\mathbf{V(s)} = \mathbf{K_c}(s) \cdot \mathbf{X_c}(s), \tag{24}$$

here $\mathbf{X_c}(s)$ is a vector of closed-loop system's inputs

$$\mathbf{X_c}(s) = \begin{pmatrix} W^*(s) - W(s) & T_0(s) & 1(s) \end{pmatrix}. \tag{25}$$

Analysis of (25) shows that to control the considered electric drive it is necessary to have informations about control error, idle torque, and drive's initiial conditions which are caused by its variable structure.

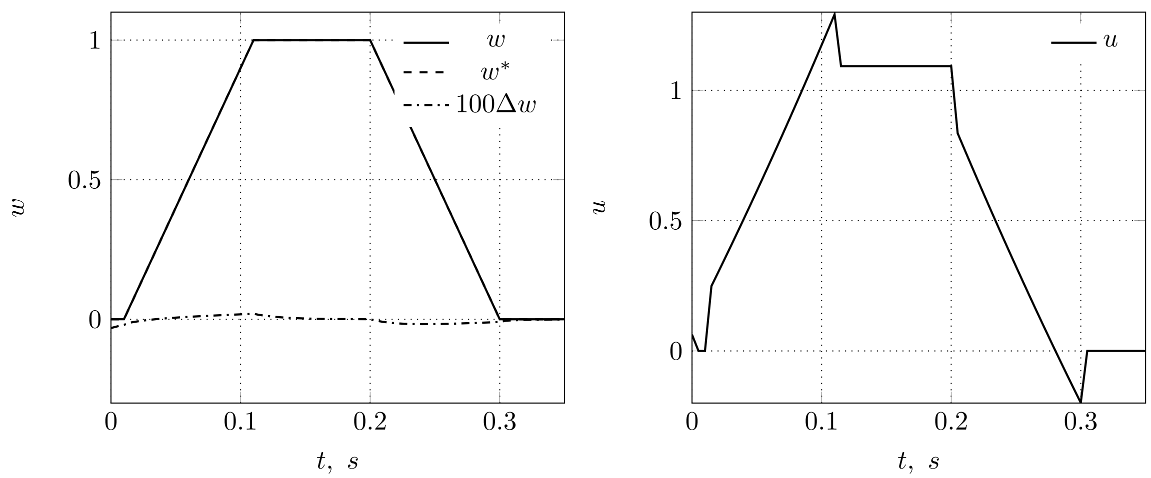

Figure 3. Simulation results for the designed closed-loop control system.

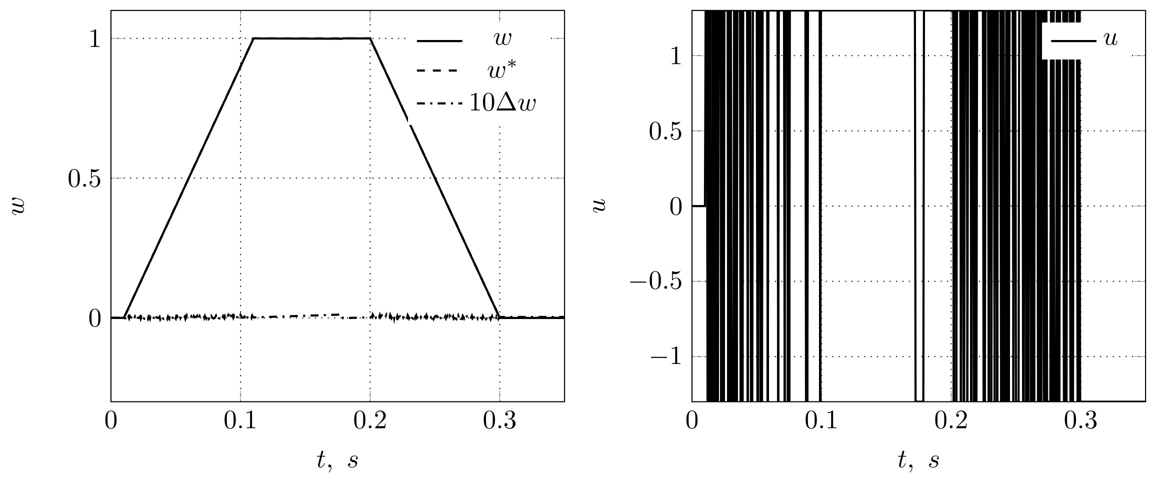

Figure 4. Simulation results for the sliding mode control system.

Control law (24) defines lower

$$V_{low}(s)=\begin{cases} \dfrac{k^*(s-a_{11up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw(0)+a_{01up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f1}} \text{ } and\ sw>0; \\ \dfrac{k^*(s-a_{11up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw_{f1}+a_{01up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f1}} \text{ } and\ sw<0; \\ \dfrac{k^*(s-a_{12up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw_{f1}+a_{02up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f12}} \text{ } and\ sw>0; \\ \dfrac{k^*(s-a_{12up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw_{f2}+a_{02up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f12}} \text{ } and\ sw<0; \\ \dfrac{k^*(s-a_{13up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw_{f2}+a_{03up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f2}} \text{ } and\ sw>0; \\ \dfrac{k^*(s-a_{13up})}{m_{1up}(T^*s-k_{flow}k^*+1)}(W^*(s)-W(s))- \\ \quad -\dfrac{m_{0up}}{m_{1low}}T_0(s)-\dfrac{sw_0+a_{03up}}{m_{1low}}\cdot 1(s) & if \quad w\in \mathbf{w_{f2}} \text{ } and\ sw<0. \end{cases} \tag{26}$$

and upper

$$V_{up}(s) = \begin{cases} \dfrac{k^*(s-a_{11low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw(0)+a_{01low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f1}} \\ and\ sw>0; \end{matrix} \\ \dfrac{k^*(s-a_{11low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw_{f1}+a_{01low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f1}} \\ and\ sw<0; \end{matrix} \\ \dfrac{k^*(s-a_{12low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw_{f1}+a_{02low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f12}} \\ and\ sw>0; \end{matrix} \\ \dfrac{k^*(s-a_{12low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw_{f2}+a_{02low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f12}} \\ and\ sw<0; \end{matrix} \\ \dfrac{k^*(s-a_{13low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw_{f2}+a_{03low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f2}} \\ and\ sw>0; \end{matrix} \\ \dfrac{k^*(s-a_{13low})}{m_{1low}(T^*s-k_{fup}k^*+1)}(W^*(s)-W(s))- & \\ -\dfrac{m_{0low}}{m_{1up}}T_0(s)-\dfrac{sw_0+a_{03low}}{m_{1up}}\cdot 1(s) & if \quad \begin{matrix} w\in \mathbf{w_{f2}} \\ and\ sw<0. \end{matrix} \end{cases} \tag{27}$$

boundary of control signal, which should be supplied to the considered electric drive.

Simulation results of the designed control system are shown in figure 3.

Analysis of the above-given simulation results shows that designed system has zero control error in the steady state and near zero dynamical error while drive starts and stops. Voltage which is supplied to drive is continuous and physicaly-implemented one.

Now we show the benifits of our system from energy viewpoint by comparing it with a classical sliding mode control system which allows to get zero control error in system's dynamic and steady state.

We consider closed-loop control system with controller which implements folowing control law

$$U(s) = U_{max}\cdot sign(W^*(s)-W(s)). \tag{28}$$

As one can see the use of sliding mode controller allows drammaticaly reduce control error. At the same time sliding mode control system consumes much more energy than other control systems (figure 5). As an indicator of system energy efficiency we use following integral which shows all control energy

$$I = \int_0^\infty u^2 dt \tag{29}$$

Comparison of graphics in figure 5 proves the benifit of our approach because of its allows to reduce energy consuming near three times due to using continuous control signal which contrary to discontinuous sliding mode control can have zero value.

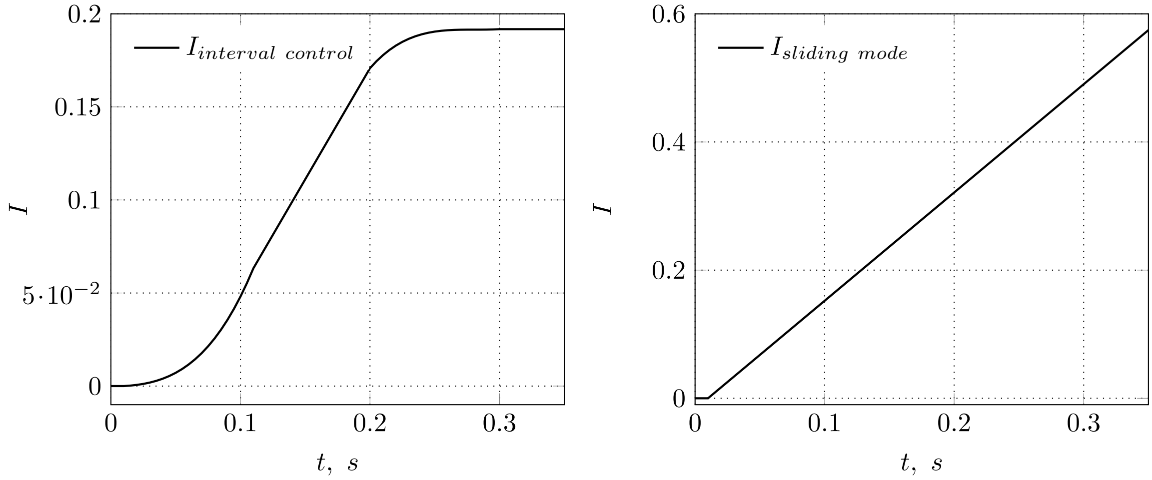

Figure 5. Energy characteristics of studied systems.

5. Conclusion

The use of inerval methods to define dynamical systems motions allows us to take into account possible uncertainies and nonlinearities of the considered plant and gives possibility to write down differential equations in piecewise linear form. These equations allows to define the generalized transfer function which for the nonlinear uncertain plant can be considered as piecewise matrix anisotropic differential operator. The use of this operator make it possible to design variable-structure controller which can be implemented in both anaolg and digital ways. The control system with such a controller has performance and control error similar to sliding mode system but consumes three times less energy what should be useful to design energy-eficient industrial processes based on the turbomachinery usage.

Since a lot of industrial processes and equipments are defined by the second and third order differential equations, we see future development of our approach in considering high order dynamical system and design optimal energy-efficient controllers for them.

Abstract. The argumentation of the use of concession of historical and architectural objects in Ukraine as a tool for improving the budget and tax incentives for investment attractiveness of the tourist complex has been carried out. A scientific approach to budgetary and tax incentives for investment attractiveness of tourist facilities has been formed using an optimization model for calculating concession payments, which ensures the flexibility of incentives, takes into account the interests of investors, based on indicators for assessing the effectiveness of an investment project with a simultaneous focus on maximizing budget revenues. It is substantiated that the budgetary and tax incentives for investment attractiveness of tourist complexes through the introduction of public-private partnership in the form of a concession of historical and architectural objects will allow private business to invest in attractive tourist sites and ensure higher profitability of the hotel and restaurant business, since the interests of the investor are taken into account, and will also reduce budget expenditures and increase tax revenues to the budgets from servicing tourist flows.

1. Introduction

Today, the problem of preserving the historical and architectural component of the tourism industry [1, 2] has arisen quite sharply in Ukraine. Since, having a rich tourist potential, the Ukrainian economy not only does not use it to the full, while not maintaining revenues from tourist flows, moreover, objects of historical and architectural heritage every day, waiting for financing and repairs, are destroyed and lose tourist attractiveness, and often simply disappear from the tourist map of Ukraine [3, 4].

Foreign and domestic practice has proved that the most effective form of protection of historical cities is the allocation of areas with a special regime of development and reconstruction on their territory, the organization of reserves. In Ukraine, the transition to comprehensive protection of the cultural heritage of cities began in 1975 with a historical and cultural reserve that covered the historical center of the city of Lviv. Then similar reserves were created in Kamianets-Podilskyi (1977), Chernihiv and Novhorod-Siverskyi (1978), Pereiaslav-Khmelnytskyi (1979). Ostrozi (1981), Lutsk (1985), Putivli (1986), Kerch and Kyiv (1987), Bakhchysarai (1990), Baturyn and Dubna (1992), Hlukhiv, Zbarazhi, Halychy, Odesa, Korsun-

Shevchenkivskyi (1994), etc. In total, out of 38 reserves of the historical and cultural profile, 18 areassociated with the protection of heritage in cities.

All reserves should be managed by a single state body for the protection of cultural heritage. In the meantime, the next management system has been formed. The Ministry of Culture and Information Policy of Ukraine manages seven nature reserves, the State Committee for Urban Development manages four. The National Academy of Sciences – only one. The remaining reserves are subordinate to regional or district administrations.

Currently, the state program for the development of historical and cultural reserves of Ukraine is being developed, which would identify the whole range of problems – from the criteria for assessing heritage to the principles of financing activities and insurance of risks arising in this case, in particular:

1) reservation of leading historical and cultural complexes for the next organization of reserves.
2) creation of new reserves in the system of the unified state body for the protection of historical and cultural heritage;
3) financing of reserves in a separate line in the state budget, as has already been done for biosphere and nature reserves, as well as national parks;
4) development of master plans for development and comprehensive regeneration programs for all reserves.

Despite all the current difficulties and uncertainty of the legislative framework, reserves now and in the future remain the optimal form of comprehensive protection of the historical and cultural environment.

The search for ways to solve the outlined problem, as the practice of managing tourist facilities in Ukraine shows, is rather limited. On the one hand, most of the objects are state property and belong to monuments of national and local importance, but on the other hand, it is the protection of architectural authenticity that makes the process of their restoration and reconstruction extremely difficult. Budget financing is usually aimed at preserving these objects from further destruction, and not always successful. And the access of a private investor to historical buildings is limited by the lack of commercial motives and the complexity of the mechanism of investing in state-owned objects [5].

Analysis of possible sources of investment in tourist facilities showed that the most optimal is the development of public-private partnership (PPP) in the tourism sector, namely the concession agreement, which is popular both in Ukraine and abroad. A public-private partnership is a long-term cooperation between public and private organizations aimed at fulfilling public responsibilities and allocating risks, rewards and responsibilities to the partner (government or contractor) that is best able to manage them [6]. Public-private partnerships usually include various contractual agreements, which may differ depending on the sector they relate to and the national legislation of each country. Among the various financial arrangements, a concession is usually considered to be a "design-build-finance-operate-maintain" PPP instrument [7]. In this case, the contractor designs, builds, finances and operates the cultural heritage site. Given that governments typically use different procurement and contracts for each of the above-mentioned stages of the process, concessions allow contractors to be more involved not only in decision-making but also in the subsequent management of cultural heritage sites. Concessions are a particularly attractive way to implement projects in the public interest when state or local authorities need to mobilize private capital and know-how to supplement limited public resources. They are the basis of a significant share of EU economic activity and are especially common in network industries and for the provision of services of general economic interest [8]. However, almost all concession projects in Ukraine are insignificant and are implemented in the field of housing and communal services, construction of roads and seaport facilities of the seaport industry.

Thus, the purpose of the study is to deepen the theoretical and methodological provisions and develop practical recommendations for fiscal stimulation of the investment attractiveness of the tourism complex by forming an effective public-private partnership in the field of preservation of historical and architectural objects. The objectives of the study include:

- analysis of foreign and domestic experience in the field of concession in general and tourism facilities in particular;
- establishing the conditions necessary for the transfer of cultural heritage sites into concession;
- analysis of the advantages and disadvantages of concession of historical and architectural objects; determination of the optimal rate of concession payment through the optimization problem of mathematical programming;
- substantiation of the elements of the optimization model for determining concession payments;
- calculation of the budgetary and tax effect of the implementation of the optimization model for determining concession payments.

2. Literature review

It should be noted that the vast majority of scientists believe that the development of public-private partnerships, in particular the concession agreement, is a particularly attractive way to implement various projects in the public interest, when state or local authorities need to mobilize private capital to supplement limited public resources. Thus, Carpintero analyzes the competitive advantages enjoyed by Spanish companies in the international toll road industry and how profitable such concessions are [9]. Bogunović and Kukurin substantiated the positive impact of land concessions on the camping business in the coastal areas of Croatia [10]. Fujiwara reflected the benefits of public-private partnerships in Japan's sustainable public sewage industry [11]. Łapniewska substantiates the advantages of concession on the Berlin electricity grid (the largest in Germany) [12]. Khmurova et al. substantiate the strategy for the development of public-private partnership in the context of global changes [13].

The use of such a tool as a concession in the tourism sector is widely used in many countries around the world. Therefore, Pizzanelli compares the legal aspects of national and European law in the process of regulating state maritime concessions for tourist and recreational use and procedures related to their purpose [14].

Dinica substantiates the use of concessions for tourism business in protected areas, including national parks in New Zealand, with special reference to their financial and in-kind contributions to conservation work [15].

Rodrigues and Abrucio [16], Brumatti and Rozendo [8] consider partnerships and concessions as an alternative for tourism management, a priority for the federal government and for the development of tourism in Brazilian parks, as well as the creation of institutional arrangements with the private sector through concessions to provide tourism alternatives and recreational services.

Wyman et al. [17] analyzed the best practices of tourism concessions through private sector partnerships in tourism in 22 countries. They identified environmental and empowerment commitments and social commitments as the strengths of the best practices of tourism concessions, with these components being most represented in Colombia, Costa Rica, Botswana and South Africa. The analysis of government documents and case studies showed that the biggest gaps in best practices relate to qualification requirements for concessionaires, legal and financial obligations. Canada, New Zealand, Costa Rica, and Botswana demonstrated a higher representation of agreements with these components.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012106 doi:10.1088/1755-1315/1415/1/012106

At the same time, despite the significant revenue potential of managing protected areas through private tourism concessions, there are also situations where it is necessary to refrain from approving concessions. Paying for a concession may not be an effective option for some sites, especially if demand for services is limited. In some cases, demand may exist, but the potential concessionaire may not be sufficiently capitalized, interested, or willing to take financial risks. Examples from South Africa and Colombia confirm these problems [18].

It should be noted that there are a number of works that criticize the use of concessions, but such criticism mainly concerns the ability of local authorities to transparently and fairly manage the process of obtaining economic and social benefits, as well as achieving the main goal of protected areas – environmental protection [15, 17–19].

A strong point of concessions in the tourism sector is the support of environmentally responsible tourism practices. Thus, concession agreements increasingly include measures to minimize environmental impact. Depending on the type of concession activity, contracts may require management plans in areas such as waste disposal, infrastructure development, water use and management, and waste recycling measures [20].

The concession of cultural heritage occupies a special place in scientific research and the practice of applying public-private partnership agreements in many countries. Boniotti describes the useful role of research in investment analysis for concessions for Italian state-owned cultural heritage sites [21, 22]. The main examples of public-private partnerships in Italy include the wing of the Royal Villa in Monza, which is currently under concession to a private firm [23]; the 16th-century Villa del Bene, located in Dolce (Verona Province), is now managed by the Regional Directorate of Museums in cooperation with the local agency Pro Loco (local promotion agency). It has become a museum, educational center, contemporary art gallery, and a venue for conferences and weddings [24]; acquisition of the Castle of Pergine (Trento Province) by the CastelPergine Foundation through public underwriting [25].

Lee [26] focuses on the study of the impact of the private sector on the preservation of cultural heritage in China on the example of the Xinhepu Conservation Area in the old residential district of Yuexiu in Guangzhou [25].

Negussie explores the impact of neoliberal conventions and practices on institutional and ownership structures in cultural heritage management using the experience of Ireland and Sweden [27]. Hofmeister and Borchert put forward proposals for improving public-private partnerships in Switzerland [28].

It should be noted that the study of the issue of concession of tourist facilities in Ukraine is urgent, because if these processes are not activated in the coming years, then historical and architectural monuments will completely lose their investment attractiveness.

Returning to the analysis of the Law of Ukraine "On Concessions" [29], in the context of our study, we see that the objects that can be granted a concession include those that carry out activities in such areas of economic activity as the construction and operation of hotels, tourist complexes, campsites and other relevant objects of the tourism industry. According to the European Commission, concessionaires can, for example, build and operate motorways, provide airport services or operate water distribution networks, etc. [30].

The legislator is rather unclear on the issue of whether the concession object includes, for example: fortifications, castle complexes, towers and other architectural monuments. However, practice shows that they act as such objects, but not without a question from the public about the legality of such a concession agreement.

Thus, in 2010, the Lviv Regional State Administration for the first time in Ukrainian practice transferred two old emergency buildings to a concession for 49 years – a palace in Tartakiv (Sokal district) and the ruins of a castle in the Old Village (Pustomyty) district. The first monument was planned to be used as a cultural and recreational complex, and the second – as a platform for festivals and mass events. Despite the obligation to immediately carry out emergency work and bring the monuments to proper condition in a few years, so far none of the concessionaires even has ready design documentation [31]. Accordingly, during the years of inactivity of the concessionaires, the condition of the facilities deteriorated. To better understand the depth of the problem of concession agreements for castle tourism facilities, we will analyze the appeal of the head of the RSA to the Cabinet of Ministers of Ukraine with a request to allow the transfer of Pidhirtsi Castle to concession and grant the right to determine the concessionaire to the regional state administration. However, the draft resolution of the Cabinet of Ministers, according to which all the requests of the RSA were satisfied, was never signed. The initiatives of the concession regarding the Svirzh Castle (the initiative of the RSA in 2005) and the creation of a recreation complex on the site of the archaeological monument "Novobogoroditska Fortress" in Dnipro did not advance. The concession of the castle "Palanok" in Mukachevo was rejected by the decision of the Verkhovna Rada.

One of the problems that stands in the way of concession agreements is the uncertainty of ownership of objects, for example, Pidhirtsi Castle is absent from the General Register of State Property. Today, there are about 300 castles and about 5 thousand objects of defense architecture on the state register, while only 10%, according to experts, are in satisfactory condition [32]. And now, it is necessary to take into account that the priority restoration work is estimated at UAH 30-35 million in Svirzh Castle, and more than UAH 350 million in Pidhirtsi Castle.

Obviously, in the scale of tourist sites, only a small proportion of them have a chance to receive budget financing, and only after the stabilization of the situation in Ukraine. On the other hand, it is the presence of legislative conflicts that makes it impossible to attract private investment capital to restoration work. It is necessary to fill the legislative gap and add cultural heritage objects to the list of concession objects [33, p. 361].

Restoration of abandoned architectural monuments by private investors has a widespread and successful world practice. For example, the Chateau de Chantilly (France), owned by the Institut de France, under the terms of the concession is at the disposal of billionaire and philanthropist Karim Aga Khan IV and is open to tourist flows, international events and world championships. Similarly, the royal castle of Chenonceau has been privately owned by the Meunier family of entrepreneurs since the late nineteenth century, but is open to the public. The experience of Great Britain, the Czech Republic and neighboring Poland demonstrates that the concession and the leasing of monuments are perceived and popularized. There are dozens of Polish examples where the castle is simultaneously used as a hotel, museum, nature reserve and restaurant. In the Czech Republic, in addition to the concession of Konopiste, Karlštejn, Miroshnik, Sternberk castles, there is also an experience of selling castles into private hands, while historical palaces, fortresses and castles were sold at quite reasonable prices [34].

In turn, it is impossible to ignore the fact that in Ukraine for quite a long time they were extremely cautious about such concession agreements, fearing that the object of national importance would be privately owned. However, in conditions when since 2008, funding for castles from the state budget is practically not allocated, the question is not in whose ownership the object will be, but how to preserve it in general. Unfortunately, thecollapse of the tower at Chervonogorodsky Castle in 2013, the Gate Tower of the unique fortification and hydraulic structure of the Polish Gate (2009), the "New West Tower" on the territory of the Kamianets Historical and Architectural Reserve (2011) indicate that time is running out to find an investor. In addition, the Resolution of the Cabinet of Ministers of Ukraine "On the Effective Use of Public Funds" [35], which regulates the termination of the preparation of drafts of new state target programs or amendments to approved target programs that require additional funding from the state budget.

Although the concession issue is not limited to the concession permit, the question of how to make is limited to the concession permit, the question of how to make the facility attractive to the investor, while the investor has more incentives to invest in quick-recovery industries, with a higher rate of return, without fulfilling the obligation to the state and society to preserve the facility in good condition, its reconstruction in accordance with a whole set of rules and restoration requirements. The main problem is finding a concessionaire who will be willing to invest in the tourism industry in Ukraine [33, p. 362].

Article 6 of the Law of Ukraine "On Concessions" regulates that proposals on the list of specific objects of state ownership that can be granted in concession are made by the relevant central executive bodies. Approval of the object-by-object list is carried out by the Cabinet of Ministers of Ukraine [29]. It should be envisaged that the initiators of the preparation of concession proposals may include not only executive authorities, local self-government, but also investors (both residents and non-residents), which will allow them to independently initiate investment projects that interest them.

When transferring objects of cultural heritage to concession, it is necessary to comply with the following conditions [33, p. 362]:

- correct conduct of restoration work;
- work schedule and strict adherence to it;
- 70-80% of the use of the object for tourist (cultural) purposes and only partially for other functions, such as a hotel, museum, restaurant, gift shop, workshop, etc.;
- monuments of national importance must be accessible to visitors;
- compulsory insurance by the concessionaire of concession objects;
- granting concession payments privileges, including in the form of installments, deferrals, full or partial exemption from concession payments for a certain period of time to concessionaires of unprofitable and low-profitable concession facilities of social importance;
- the concessionaire may provide in the contract for the provision of subsidies, compensations and benefits, but only within the limits and in accordance with the procedure provided for by law;
- it is mandatory to carry out entrepreneurial activities on the basis of the operation of the concession facility (not to use the castle as an example for living);
- create jobs and conclude employment contracts, as a rule, with citizens of Ukraine;
- to use technologies, materials, and equipment of domestic production at the concession object, unless otherwise provided for by the terms of the agreement; to keep the concession object in proper technical condition;
- to transfer the concession object in proper technical condition to the concessor under the conditions of the agreement after the expiry of the concession agreement;
- providing the concessionaire with a land plot for the implementation of the relevant project.

The Law of Ukraine "On Concessions" actually does not provide benefits for the investor, according to which the concessionaire pays duty, VAT and excise tax when importing tangible assets under a concession agreement on a general basis. In addition, regardless of the consequences of economic activity, the concessionaire must pay a concession payment to the budget. Given this, both Ukrainian and foreign investors have no incentives to invest in infrastructure facilities. One of the tasks of forming investment attractiveness should be to ensure the flexibility of tax policy. So far, analyzing the legislation, it is quite difficult to name the signs of the attractiveness of the Ukrainian concession and distinguish its sectoral aspects. Despite this, the development and improvement of relations between business entities and the state, based on concession principles, is an important element of the approval of truly market methods of organizing the national economy. In addition, such aspects of tax policy in Ukraine regarding concession activities contradict the essence of the concession as a special business regime that establishes incentives for business entities [29]. It should be noted that the procedure for determining concession facilities, as well as the conditions for granting subsidies, compensations and benefits are established by the Cabinet of Ministers of Ukraine, but this significantly complicates the procedure, especially for small local tourist facilities. Therefore, it would be advisable to provide for the possibility of establishing the budget and tax incentives within the powers of local self-government bodies. Ukraine should also study the experience of collecting concession payments from countries where concession facilities are exempt from taxes. For example, Germany and France. It is necessary to think about certain preferences for taxpayers; alternatively, it is necessary to provide for the possibility of state aid. For example, in France, state grants for conservation and restoration of monuments are practiced, even if they are privately owned. But at the same time, the status of the monument and the accessibility mode are very clearly prescribed [32].

Returning to the cost of reconstruction of historical heritage sites, in compliance with all restoration requirements, the concession of tourist facilities requires significantly more investment resources than investment in other industries.

Therefore, preferences in concession activities should be sectoral in nature and accordingly increase the tools of benefits and incentives in accordance with the complexity of the investment process and the volume of investment.

Let us consider in more detail the concession of historical and architectural objects, and its advantages in comparison with other forms of management. However, along with the advantages, the concession also has a number of disadvantages that must be taken into account when looking for potential investors.

A distinctive feature of the concession in tourism is that the state, as one of the parties to the concession, has a monopoly on tourist resources (castles, museums, historical and architectural reserves, estates, defense structures, etc.). The most optimal type of concession agreement for tourist facilities, in our opinion, is: ROT – "Rehabilitate – Operate– Transfer". This scheme is similar to BOT – "Build – Operate – Transfer", only instead of the building of a new facility, the reconstruction of the existing one is provided [36, p. 42].

Thus, the concessionaire carries out the reconstruction of the historical and architectural object, and then operates it within the established period, after which the object is transferred to the state. Typically, BOT concession schemes are used during the construction of highways, pipelines, power plants, airports, tunnels, stadiums, and other facilities that require significant investment, but must remain state-owned. Among the shortcomings of this concession scheme, it should be noted that such projects are very complex in terms of technical and financial issues and require the involvement of professional experts and consultants in the field of restoration, archaeology, history, art history, etc. This, in turn, leads to an increase in investor costs and a conflict of interest between the benefits of the private and public sectors.

At the same time, a concession is much more profitable for the state as a tool for managing state property than, for example, a lease. The concession eliminates the possibility of so-called "hidden privatization", when the tenant of state property legally formalizes the ownership of inseparable improvements and actually requires the state to compensate for the cost of these improvements, or does not return the object under the control of the state. In the case of a concession, this option is excluded – here all investments belong to the state [37, p. 310].

It is impossible to ignore the fact that concession agreements are subject to all types of state guarantees for investments made by private investors. Thus, part 1 of Article 18 of the Law of Ukraine guarantees investors the stability of legislation and regulation of investment relations by the norms that were in force at the time of investment (except for tax, customs and currency legislation and legislation on licensing certain types of economic activity). The Law of Ukraine "On the Foreign Investment Regime", in turn, states that a foreign investor may require the application of the legislation in force at the time of investment for ten years".

Table 1. Advantages and disadvantages of concession of historical and architectural objects.

Advantages	Disadvantages
By attracting investments for the modernization or reconstruction of tourist facilities, the problems of their accident rate and destruction are solved, the national historical and cultural wealth is preserved.	Lack of a clear and sufficiently tested procedure for the use of state and municipal facilities and their assets (competitive selection procedure, distribution of concession payments, public control).
Creation of sources of revenues of concession payments to budgets of different levels.	Transferring the financial burden for reimbursement of the costs of restoration of the concession agreement object to visitors by raising prices.
For the concessionaire, the conditions for increasing the overall profitability of the business at the expense of significant economic freedom compared to the lease.	Legal support regarding the rights, obligations of the concessionaire, especially regarding tourist facilities, is not sufficiently regulated.
The formation of a competitive environment in the market of state and communal property, in fact, the absence of any competition explains the practical absence of progressive changes in the attractiveness of tourist facilities.	Direction of revenues from the use of the object of the concession agreement to finance projects not related to its operation, for example, the concession of the castle will provide for the construction of a hotel or restaurant in it.
The increase in tourist flows to objects, for example, castle tourism, will inevitably lead to the synchronous development of other enterprises of the tourism industry, as well as related industries (transport, catering, souvenirs, etc.), each of which is a source of tax revenues and new jobs.	There is a risk that raising prices will make it impossible for boarding school students, pensioners, and other socially vulnerable groups of the population who currently enjoy preferential tariffs to visit tourist facilities.
They make it possible to interrupt the concession agreement in case of violations by the concessionaire of its terms and conditions and return the object to state or municipal ownership.	Possibility of appropriation of the concession facility after the expiration of the concession agreement through illegal actions or amendments to the legislation.
They ensure partnership between the state and private business in solving priority tasks, in particular, during the concession of historical and architectural monuments, a number of tasks are solved, from stimulating tourist flows to preserving the national heritage of Ukraine.	They require significant tax and credit preferences in the conditions, since the object of concession agreements is characterized by low investment attractiveness and a high payback period of the project.
Ensuring significant cooperative and cumulative effects due to the economic growth of the tourist facility.	The risk of poor-quality restoration and reconstruction, which violates the historical and architectural value of the object.
Strengthening the competitiveness of castle tourism, strengthening its domestic and international positions.	The financial risks of the concessionaire grow into financial risks for the state property (the possibility of freezing construction and restoration works, as evidenced by two previous concessions of castles in Ukraine).

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012106 doi:10.1088/1755-1315/1415/1/012106

The same regulatory act stipulates that foreign investments in Ukraine are not subject to nationalization, requisition and confiscation. However, the legislator provides for the forced termination of investment activities in case of violation of architectural norms, which should be clearly understood by the concessionaire who invests in historical and architectural objects, in particular palaces, castles, towers, estates, etc. This norm also significantly affects the level of investment attractiveness of tourist facilities, since it increases, in this case, the level of intervention in the activities of the investor by state bodies and carries the risk of termination of the concession agreement. In general, negative aspects of this kind should be compensated to the investor by other fiscal instruments to equalize the investment attractiveness at the intersectoral level.

3. Methodology

The concession payment based on the results of the concession tender or direct negotiations is calculated:

1) as a share (in percent) of the net income received by the concessionaire from concession activities according to the following formula:

$$CP = NI \times CPR \tag{1}$$

where CP is the amount of the concession payment, UAH; NI – net income for the relevant reporting period (month/quarter/six months/year) from concession activities (sale of products (goods, works, services) carried out in accordance with the terms of the concession agreement, UAH; CPR – concession payment rate, interest;

2) as a share (as a percentage) of the value of the granted concession facility, determined based on the results of its market valuation. For such a calculation, the estimated amount of the concession payment is determined according to the following formula:

$$CPe = (MV \times CPR) \div n \tag{2}$$

where CPe is the estimated amount of the concession payment, UAH; MV – market value of the granted concession object based on the results of its independent appraisal as of the date of appraisal of the concession object, carried out in the manner prescribed by the legislation on the appraisal of property, property rights and professional appraisal activities (excluding value added tax), UAH; CPR – concession payment rate, interest; n is the frequency of payment of the concession payment (determined in the concession agreement (month (12), quarter (4), six months (2), year (1).

The estimated amount of the concession payment is subject to mandatory indexation to the consumer price index.

In order to determine the concession payment in the concession agreement for the first reporting period, the amount of the concession payment for the base calculation period is determined by the following formula:

$$CPb = CPe \times CPI \tag{3}$$

where CPb is the amount of the concession payment for the base settlement period, UAH; CPe is the estimated amount of the concession payment, UAH; CPI is the consumer price index from the date of evaluation of the granted concession facility until the beginning of the first reporting period for which the concession payment is made.

The amount of the concession payment is determined by adjusting the amount of the concession payment for the previous period by the consumer price index for the relevant reporting period. If the concessionaire provides new concession facilities to the concessionaire during the term of the concession agreement, in accordance with the terms of such agreement, the concession payment may be increased in the manner prescribed by the concession agreement.

3) as a fixed payment, which may depend on the volume of goods, works or services provided by the concessionaire. A fixed payment is defined in monetary form as the product of payment for a unit of goods, work or service (hereinafter referred to as the payment) and the total number of units of goods, work or services. The amount of payment may decrease in the event of an increase in the volume of goods, works or services. The minimum thresholds for increasing the volume of goods, works or services that give grounds for reducing the amount of payment, as well as the maximum amount of such reduction, are determined in the tender documentation. The fixed payment determined in UAH is subject to indexation to the consumer price index in the manner and on the terms specified in the concession agreement.

The amount of the concession payment rate is determined based on the results of:

- concession tender and consists of the minimum concession payment rate specified in the tender documentation and the additional concession payment rate proposed by the winner of the concession tender;
- conducting direct negotiations, taking into account the conclusion on the expediency of making a decision on the implementation of a public-private partnership in the form of a concession.

Having considered all the above methods of concession payment, we can say that they all have certain shortcomings.

1) when finding the concession payment as a share (in percent) of the net income received by the concessionaire from concession activities, there are a number of risks:
   First of all, it is difficult to predict the amount of net income for, for example, a brewery in the Kushnirska tower of the city of Kamianets-Podilskyi, since the demand, commercial risks and features of the cost of the future business are not known in advance. Another disadvantage is that if the payment is paid upon receipt of net income, it may be shadowed by the concessionaire;
2) with the second method of concession payment as a share (in percent) of the value of the granted concession object, determined by the results of its market valuation, there are problems of market valuation of historical and architectural development. As an example, to estimate the market value of the Old Fortress of the city, if there are no analogues in the market, the object is unique, and the historical and architectural value has a very wide range of probable valuation. Here, the subjectivity of the appraiser is possible and there are potential risks of corruption agreements to underestimate the value of the concession object.
3) when calculating the concession payment as a fixed payment, which may depend on the volume of goods, works or services provided by the concessionaire, it is also difficult to avoid potential risks. For example, during a pandemic, when delivery is not carried out or during production downtime. After all, factors independent of the concessionaire interfere here. The possibility of preliminary agreements on the creation of favorable minimum thresholds for increasing the volume of goods, works or services is not excluded.

We, in turn, propose an alternative method of calculating concession payments, which will allow the most profitable public-private partnership for both parties to the concession agreement.

The proposed approach is based on the optimization problem of mathematical programming. The task of this optimization task is to determine the optimal concession payment rate, which will ensure, on the one hand, the target profit from the concession of the historical development object, and on the other hand, it will meet the interests of the concessionaire and serve as a guarantee that after the payment of concession payments, the entrepreneur will still have a profit, which is not always guaranteed by existing methods.

However, a very important point is that in this aspect we are talking primarily about the concession of historical and architectural objects. It is those castles, palaces, fortifications that are in disrepair that require significant budget investments (in their absence) and concession is the only way to preserve historical buildings.

The main requirement for this method is the preservation of profitability for the investor, while maximizing concession payments for the entity that concessions the facility, taking into account the costs of reconstruction and restoration ofthe facility.

Then the mathematical model of the problem will look like this:

$$Z = (NPV - Vr) \cdot x_i \to \max$$

$$\begin{cases} IRR\% \geq x_i < R\%; \\ x_i \geq i \times V_b; \\ (NPV - Vr) \times x_i \leq Wk. \end{cases}$$

where x_i is the concession payment rate; NPV is the net present value of the investment project; Vr – the cost of reconstruction, restoration, conservation (determined before the approval of the investment project); i – the interest is provided by law as the starting rent; V_b – book value of the object; R – discount rate in the market; Wk – is the market value of a long-term lease of a commercial facility similar in area; IRR – internal rate of return (reduces the risk of the investor to incur losses in the process of execution of the concession agreement); R is the cost of capital (discount) in the market or the rate of return on the investment project.

4. Results

Let's analyze investment projects in the tourism sector on the example of the city of Kamianets-Podilskyi [38]. All proposed investment projects fall under the direction of public-private partnership, which is an effective way to solve the problem of destruction of tourist facilities. In general, there are thousands of historical and architectural objects in Ukraine that need to attract investment resources. This is also confirmed by tourism projects submitted for funding from the State Fund for Regional Development. The vast majority of them relate specifically to repair and restoration works. Analyzing the objects of investment proposals in the field of tourism in Kamianets-Podilskyi, we see at first glance, quite attractive objects for public-private partnership. However, despite the very advantageous location in a picturesque canyon or in the historical part of the Old Town, we have a situation where for many years these investment projects remain offers and are not in demand. The main problems of the situation are:

- imperfect investment proposals, where there are no other data in addition to the above information
- the investor's need to work with historical and architectural objects and fulfill the requirement to preserve the authenticity of the object, to preserve its historical material and technical structure and form and the original architectural design together with valuable historical layers and allows to consider the object as a document of history and a work of architecture;
- the need for strict compliance by the investor with repair and restoration, construction, finishing standards;

Table 2. Justification of elements of the optimization model for determining concession payments.

Element of the optimization model	Argumentation of application
IRR Limitations	the internal rate of return reduces the investor's risk of incurring losses in the course of fulfilling the concession agreement.
Restrictions on the discount rate R (cost of capital in the market)	creates an automatic advantage of doing business over placing capital in order to obtain passive income.
Restrictions on the rate of return of the investment project	protects the investor's profit in the event of an economic crisis and does not allow the price of the concession agreement to exceed the profitability of the investment project.
Determination of the net present value of the investment project minus the cost of reconstruction, restoration, etc.	reduces, on the one hand, the costs of the concessionaire, at the same time allows the authorities to control the cost of performing these works and prevent violations of the historical and architectural ensemble of the city and destroy the uniqueness of the tourist site.
IRR Limitations	the internal rate of return reduces the investor's risk of incurring losses in the course of fulfilling the concession agreement.

- the high cost of not only renting tourist facilities, but also their restoration and design compared to the construction of a similar object built independently in the medieval style.
- lack of engineering communications (sewerage, water supply, gasification, electrification, Internetconnection), difficulties with establishing communications in historical monuments.

In fact, we have a situation where it is easier for a restaurateur to build a restaurant and give it an exterior design in the appropriate architectural style than to deal with numerous checks, architectural supervision, control by various state institutions. On the other hand, there are unacceptable problems similar to the situation with the Gonchar Tower (1583) and the adjacent synagogue (19th century), in which the Stara Fortetsia restaurant operates, where modern repairs have been carried out instead of authentic decoration.

It is obvious that despite the existence of legislative prerequisites for the conclusion of concession agreements in the tourism sector, the investment attractiveness of such facilities remains low.

We will calculate the cost of the concession agreement for one of the facilities that is in disrepair and requires significant budgetary investments. As an example, the object of the concession agreement is the Kushnir Tower. This object is presented among the investment proposals on the website of the Kamianets-Podilskyi city territorial community [39]. The monument is provided with a complex of buildings: “Furrier Tower”; “Wind Gate”; “North Gate”, the total area of the buildings is 433.8 sq.m., its detailed description and initial data to confirm the reliability of the calculations are given in the presentation materials [38]. The facility is in municipal ownership, which simplifies the procedure for transferring it to a concession.

An option for an investment project, taking into account the location, area and movement of tourist flows, can be a restaurant made in a medieval style with a suitable kitchen. Let's take as a basis the typical indicators of the development of the restaurant business in Ukraine, adjusted for the volume of the tourist flow of the National Historical and Architectural Reserve in Kamianets-Podilskyi in 2019. As a result, we will obtain the following indicators of the investment project.

Table 3. Output data for solving the problem of optimization of concession payments.

Output parameters	**Parameter value**
Object area, sq.m.	433.8
The cost of reconstruction and restoration (according to the approved amount of budget expenditures), UAH	3393632
Initial investment, UAH	8393632
Total discounted cash flow for 5 years), UAH	5,000,000
Profitability index (PI);	11822175.96
Net present value (NPV) (excluding reconstruction costs), UAH	(1746724.89 + 3051047.84 + 2664670.61 + 2327223.24 + 2032509.38)
Discount rate, %	2.36
Concession payment accrual base, UAH $\rightarrow$ max	6,822,175.96
IRR	14.5
Wk is the market value of a long-term lease of a commercial facility similar in area.	3428543.96

The mathematical model of the concession payment optimization problem will be as follows:

$$Z = (6,822,175.96 - 3393632) \times x_i \rightarrow \max$$

$$12,43\% \geq x_i \leq 14,5\%$$

$$x_i \geq 1\% \times Vb; (6,822,175.96 - 3393632) \times x_i \leq 1558800$$

where x_i is the concession payment rate.

The obtained results of the optimization model calculated by the simplex method are presented in table 4.

The proposed model will avoid a situation that has already been repeated twice in the city, when the Gate Tower collapsed under the weight of wet snow and due to an emergency condition, and due to improper restoration work, the New West Tower was destroyed, which, incidentally, proves the inefficiency of spending budget funds.

And taking into account the interests of the investor through the introduction into the optimization model of such indicators as the net present value of the investment project; the cost of reconstruction costs; the discount rate in the market; the market value of a long-term lease of a commercial object similar in area; the internal rate of return; the cost of capital, will not only reduce the investor's risk, but also guarantee the profitability of the project.

This, in turn, will avoid a repetition of the situation that occurred in 2013 in the Lviv region, when the experiment with the transfer of two castles (Tartakiv and Stare Selo) to the concession failed and none of the concessionaires began even emergency work. Kamianets-Podilskyi also has enough examples of violation of the authenticity of historical and architectural buildings, which can be observed in the results of repair and restoration work on Dovha Street and insulation of

Table 4. Budgetary and tax effect from the implementation of the optimization model for determining concession payments [40, 41].

Indicator	Value
x_i is the concession payment rate	0,476
The cost of the concession payment per 1 sq. m.	62.79
The cost of fulfilling the terms of the concession agreement for the concessionaire, per 1 sq. m, UAH	193.42
Annual cost of concession, UAH	326269.1
Budget effect	
The amount of revenues to the city budget from the delivery of the object to concession, UAH	1631345
Reduction of expenditures of the State Budget, UAH	3393632
Total budget effect, UAH	5024977
Tax effect	
Projected amount of tax liabilities:	
Value added tax, UAH	3 600 000
Profit tax	1,080,000
Single social contribution	2376000
Personal income tax	1944000
Social effect	
For residents: improving the historical and architectural ensemble of the city, reducing the risk of failure of the object, preserving historical and cultural monuments. For tourists: creation of tourist infrastructure facilities, increasing the tourist attractiveness of catering establishments.	

the facade of the ancient building of the Church of Peter and Paul with foam plastic. Another potential concession object may be the Tower on the ford (Art. 16), for the restoration of its roof, the Ministry of Culture and Information Policy of Ukraine allocated funds in the amount of UAH 1,232,000 in 2020 [42].

5. Conclusions

In the context of a shortage of budget funds for the maintenance and restoration of tourist infrastructure, in particular large-scale historical and architectural monuments, such as castles, fortresses, an alternative to a radical institutional shift is such a form of PPP as a concession that allows attracting private sector assets, but keeping economic objects in state ownership. For the tourism sector, which is characterized by both significant funding needs and a large number offacilities, this is most relevant. The concession regime eliminates the investment deficit and, based on positive foreign experience, will increase the fiscal return of attracting architectural monuments to active entrepreneurial activity.

The analysis of the search for alternative options for budgetary and tax incentives for investment attractiveness of historical and architectural objects is their transfer to concession. The most optimal form of the concession agreement for tourist facilities is determined by the ROT – "Rehabilitate – Operate – Transfer". However, the current methods of calculating concession payments allow possible neglect of the interests of the state or the investor. The application of the optimization model for determining concession payments to strengthen the budget and tax incentives for investment attractiveness of historical and architectural objects is proposed. Approbation of the optimization model at the historical and architectural site of Kamianets-Podilskyi showed budgetary and tax effects of UAH 5.025 million and UAH 8.028 million, respectively, and a social effect, which confirms the need for its use.

Along with this, further research and testing are needed to improve the legal regulation of the concession agreement and the mechanism for its implementation in the area under study, to guarantee the fulfillment of financial obligations by the investor and to expand the instruments of state participation in public-private partnerships in order to stimulate the investment attractiveness of the tourism industry.

Abstract. Ecologization of thinking and hedonization of life are processes that have greatly influenced motives behind ways to spend free time in recent decades. Ecotourism has become a way of exploring unique and exotic natural landscapes and a tool for their preservation Such an interpretation of ecotourism deprives residents of large industrial cities located far from such environmental sites of the opportunity to join the process of ecological cognition. The available sources analyzed by the authors interprete the concept of ecotourism merely through the environmental prism, the prism of the value of natural areas. The concept of ecological tours, which reveal only one aspect of ecology – the problem of protecting natural landscapes within specially protected natural areas/water bodies, is not yet developed either and is only interpreted as nature protection. The authors' interpretation of ecotourism and excursions as a type of industrial and sustainable tourism in the industrial environment is broader. Ways to settle environmental issues can only be found through understanding their essence. During eco-excursions, visitors can understand the nature and causes of the environmental crisis, emergence of global and local environmental problems and their consequences directly through observation, study, understanding, and experiment under the guidance of a qualified guide. Only real environmental emotional experience gained in the field can act as a driver for forming environmental behavior. The authors set out to interpret ecological tourism and ecological tours through familiarizing visitors with negative consequences of human impact on the environment; to reveal the content, methodological features of preparing and conducting ecological excursions; to perform a statistical analysis of ecological tours and excursions. Based on their own many years' experience in tour activities, the authors substantiate and characterize their own vision of ecological tourism and ecological excursions in the industrial environment, and establish the specifics of the excursion process related to ecological education and nurturing. The present research highlights problematic aspects of the classical concept of ecological tourism (its main limitation – by merely natural areas), the ecological excursions available in the world tour practice (merely nature-oriented or educational for schoolchildren/students), analyzes the methodological features of organizing and giving ecological excursions (identifies specific features of each stage of developing an ecological excursion, provides examples of methods from their own experience of excursion activities), and summarizes the authors' experience of ecological excursion activities at the theoretical and practical levels.

1. Introduction

The modern urbanized world, the world of technology and large information flows, the world of hard work, makes people look for various ways to fully recover their physical and mental strength, ways to learn and develop themselves during their leisure time. More and more people are considering the potential of eco-tourism when planning their free time. The concept of ecotourism emerged in the last century with recognition of the fragility of natural ecosystems, their rapid transformation due to human impact that could lead to extinction of both individual species of animals and plants and entire ecosystems. Several other factors have also contributed to the development of this type of tourism:

- realization of the value of natural landscapes in restoring human vitality as it is a well-known fact that from the time of Ancient Greece to the present, the ideal landscape for recreation is a natural landscape;
- saturation of the tourist market with mainstream cultural travels or "All inclusive" vacations;
- a desire to see, learn, and in some cases explore unknown natural corners of the planet;
- a desire to spend time actively, etc.

According to Cambridge Dictionary, ecotourism is the business of organizing holidays to places of natural beauty in a way that helps local people and does not damage the environment [1].

Ceballos-Lascurain, who formulated the leading principles of ecotourism, is considered the founder of this type of tourism William P. Stewart and Soehartini Sekartjakrarini [2,3]. However, as tourist demand for natural areas has changed, tourists' attitude to the value of natural ecosystems has changes as well, and negative alterations have occurred in the ecosystems themselves. In particular, Wang et al. note that conflicts of stakeholders' interests concerning development of ecotourism in environmentally fragile areas often negatively affect efficiency and effectiveness of ecotourism implementation [4].

Mondino and Beery also emphasize the fact that no matter how satisfactory the definition of ecotourism is, it does not qualitatively define the impact that this form of tourism can have on the cultural and ecological environment of the destination [5].

Thus, ecotourism is no longer inherently ecological or the one that ensures sustainable development of a tourist destination and especially a natural ecosystem. Therefore, there emerges a challenge of forming a new vision of ecotourism and possibilities of implementing its principles. This issue is particularly acute in industrial areas, such as Kryvyi Rih, where a large number of industrial enterprises engaged in iron ore mining, enrichment and processing are concentrated in a relatively small area. According to the authors, traveling to such industrial areas and landscapes radically altered by human activity and technology may be of ecological and educational value. These trips can then be called ecological excursions.

2. Publication overview

A thorough analysis of various sources of information reveals that different authors have diffenent understanding of ecological tourism and ecological excursions.

The relevance of the research is confirmed in [6] which shows that ecotourism has been developing rapidly in recent years, and the number of published articles is growing annually. The field of ecotourism research spans many disciplines and is a complex interdisciplinary subject. Ecotourism is also attracting the attention of many developed and developing countries. The United States, China, Australia, and South Africa are relative leaders in ecotourism research and development.

According to the UNWTO, ecotourism is defined as all nature-based forms of tourism in which the main motivation of the tourists is the observation and appreciation of nature as well as the traditional cultures prevailing in natural areas. It contains educational and interpretation features. It is generally, but not exclusively organised by specialised tour operators for small groups. Service provider partners at the destinations tend to be small, locally owned businesses. It supports the maintenance of natural areas which are used as ecotourism attractions [7].

Regarding the regulatory framework for the development of ecotourism in Ukraine, according to the current Law of Ukraine "On Tourism", Article 4 lists ecological tourism among a cohort of other types of tourism, and Article 6 lists ecological and rural tourism as priority tourism directions for Ukraine. At the same time, the Law does not define the concept of ecotourism [8]. The new Draft Law of Ukraine "On Tourism" provides a definition of ecotourism, but it is rather simplified. This type of tourism is interpreted as organization of recreation or obtaining natural or practical ecological knowledge and experience that does not harm the environment [9].

The authors of the article understand ecotourism as a type of industrial and sustainable tourism associated with visiting places the ecology of which is altered by man to this or that degree for the purpose of ecological education, awareness and nurturing. These are diverse landscapes that have undergone negative anthropogenic changes, recovered from such changes on their own, and have been reclaimed; or operating industrial facilities with a distinct ecological function (e.g. aeration plants that treat municipal waste water, waste sorting plants, solid waste landfills, etc.) [10, 11].

In the vast majority of sources, ecological excursions are considered a type of educational excursions into nature. Accordingly, their goal is to form an individual ecological worldview in order to prevent undesirable actions (aggression towards nature objects, cruelty) and provide targeted assistance to the child in the process of science education [12, 13]. The practice of Ukrainian and foreign educational institutions on organizing educational ecological excursions shows that they aim to highlight environmental problems and familiarize students with ways to solve them. Examples of these include excursions to waste management and recycling facilities (Ukrainian cities: Lviv, Khmelnytsky, Kyiv; German cities: Augsburg, Aachen, Zwentherdorf), a visit to the gasmeter in Oberhausen (Ruhr) for environmental education purposes, an environmental quest to collect garbage in Lviv parks, etc. Excursions to the waste water treatment plant Dresden-Kaditz are also conducted. However, the excursions that are offered in Europe to make people aware of global environmental issues are not visual observations of the sites of their manifistations. These excursions just introduce the problems and use modern technologies to demonstrate their consequences. The analysis of known practices shows that such excursions are not systematic, and the authors cannot find any scientific publications that would reveal the essence, features of organizing and conducting such ecological excursions and tours, or describe the ecological objects visited.

In the authors' opinion, the environmental responsible behavior is more likely to be shaped through direct observation and analysis of environmental objects and processes, e.g. observation of deforestation or landscapes transformed by accumulation of highly mineralized mine waters. Ecological excursions and tours should also be addressed not only to schoolchildren and students, but also to a wide range of visitors and ordinary people in order to broaden their general worldview, make them aware of modern technologies of solving local and global environmental problems, and build environmental culture and environmental behavior skills.

The analysis of various sources on organizing and conducting ecological excursions shows that they are understood as organized short trips to landscapes of special value in terms of nature, usually to specially protected territories and water areas of various conservation ranks [14]. In the English-language literature, the concept of excursion is usually interpreted as a short-term tour, and the term ecological excursion is extremely rare. The view of ecological tourism is traditional for this field and understood as "responsible travel to natural areas that conserve the environment, sustains the well-being of the local people, and involves interpretation and education" [14]. According to the authors of the article, this understanding of ecological excursions and ecological tourism omits an important fragment: there is no explanation, demonstration or clarification of the causes of biological diversity reduction (at all its levels), other environmental problems, the causes and consequences of the environmental crisis in general, i.e. only the result of environmental processes is shown without disclosing their causes. After all, the environment of modern man is created by not only natural conditionally undisturbed areas, but also by anthropogenic modifications of various shapes and depths industrial landscapes, mining areas, cultural landscapes, bad lands, etc.

As a result of their research, the authors found a concept of staycations which are ecological excursions similar to their own concept of ecotourism just like ecotourism, "staycation" is also a term representing an idea with a reduced ecological impact. Staycation, i.e., vacations spent at home or near home rather than traveling to distant places, have the potential to cause less environmental harm as less fuel (or no fuel at all if we consider electric vehicles) is spent. It also means more money spent at a local or national level and this consumption helps strengthen the economy, supports existing or new jobs and increases local resilience. A staycation is a form of alternative tourism that is fully in line with the slow tourism trend. Slow tourism invites you to live in the present moment. It encourages you to take your time, discover nearby landscapes, reconnect and spend more time outdoors in nature with the people you enjoy. Discovering or rediscovering the beauty of your city or region, which we often forget to notice due to stress and the power of habit is another potential benefit of staycation [15]. It should be noted that the concept of "ecological excursion" is intermediate between "ecotourism" and "staycation" as it is based on the principles of ecotourism and involves short trips aimed at exploring the nearby environment.

The authors of this work are practicing guides with many years of experience in the tourism business and are members of the All-Ukrainian Association of Guides and the National Tourist Organization of Ukraine. In 2015, for the first time, the authors developed and conducted the first ecological excursion for residents and guests of Kryvyi Rih to the local solid waste landfill. Later, several other routes discussed in more detail in this article, were introduced into practice.

Based on their own practice of organizing and conducting tours and excursions around Kryvyi Rih, communicating with tourists from different countries and regions of Ukraine, teaching ecological disciplines at Kryvyi Rih Pedagogical University, and conducting ecological learning practices, the authors have accumulated experience and understanding of ecological tours and their popularity with the general public.

3. Methodology

Objective. The article aims to interpret eco-tourism and excursions through the prism of familiarizing visitors with negative consequences of human impact on the environment; to reveal the content, methodological features of preparing and conducting ecological excursions; to perform a statistical analysis of the ecological tours and excursions conducted.

The research is based on systemic and dialectical approaches and the simultaneous use of theoretical and empirical methods.

The theoretical research is carried out using the methods of comparison, analysis, abstraction, concretization and generalization. The theoretical methods are used to study the concept of ecotourism and sustainable tourism, identify their similarities and specifics; analyze the concepts "ecological excursion", "excursion into nature", compare different approaches to understanding the essence, organization and guidance of excursions, specify the authors' interpretation of the concepts "ecotourism" and "ecological excursion". The theoretical methods are also applied when assessing the tourist potential of ecotourism objects, selecting elements of research to be performed by tourists during the excursion.

The empirical methods are aimed at both finding and confirming theoretical conclusions while identifying ecological processes and their negative consequences; collecting information about them; analyzing the geographical location, structure, dynamics, and accessibility of selected objects. Selecting and using various methods and forms of ecological education, preparing, organizing and conducting ecological excursions and tours are empirical processes as well.

The research methodology involves a combination of theoretical and empirical studies through a number of successive stages:

1. **Exploration of the territory.** In the course of field research and fulfillment of the tasks of ecological educational practices during 2000–2023, potential objects of ecological excursions and tours were identified.
2. **Development and testing of the authors' ecological excursions** lasted from 2010 to 2015, when theoretical foundations of the research were partially formulated and possibilities of using the selected forms and methods of excursion work with different target groups of visitors were tested out. Working versions of the authors' ecological excursions were actually developed.
3. **Implementation of the authors' ecological excursions and tours in the practice of tourism activities of the Public organization "Kryvbastur" (director – V. L. Kazakov).** Since 2015, the authors of the research have introduced ecological tours of Kryvyi Rih and ecological aspects into tours to Kryvyi Rih. At this stage, regular ecological excursions were launched and their elements were introduced in tour programs for the general public. This made it possible to confirm attractiveness of tourist objects for a wide range of visitors and non-ecology specialists, effectiveness of the forms and methods of excursion work used, to form an assessment of the tourist attractiveness of the developed ecological excursions and tours to Kryvyi Rih and, all in all, confirm correctness of the theoretical conclusions and formulate the authors' interpretation of ecotourism.
4. **The authors' interpretation of ecotourism.** For the first time, the research comprehensively substantiates the essence of ecological tourism and excursions as a type of industrial and sustainable tourism at the theoretical, empirical and methodological levels.

4. Results

Since the authors did not find any similar understanding of the definition of ecotourism and excursions in the analyzed sources, they made an attempt to generate such a definition using artificial intelligence (in order to confirm correctness of the direction of the theoretical research in a certain sense). When requested to define ecological sustainability tours, ChatGPT responded "They are organized trips or tours designed to educate and raise awareness about environmentally friendly practices, conservation initiatives, and sustainable lifestyle principles. These tours typically involve visits to sites, places or projects that exemplify and promote environmentally sustainable practices The main objectives include promoting understanding of the interdependence between human activities and the environment, showcasing innovative environmental technologies, and inspiring participants to adopt environmentally friendly behaviors. Such excursions can include a wide range of activities, from tours of renewable energy facilities and organic farms to visits to protected areas and seminars on eco-friendly living. The main goal is to encourage people to make environmentally conscious choices in their daily lives and to help preserve the natural world" [16]. Thus, the authors realize specificity of their own views of the issue and the importance of interpreting ecotourism and ecological excursions from the perspective of industrial and sustainable tourism.

The research has revealed the following important functions that ecological excursions perform :

1. They have a significant educational potential in shaping knowledge about the concept of sustainable development for the general public. The educational role of ecological tours is mentioned in many sources, e.g. [17] touching upon methods of forming environmental knowledge and knowledge of sustainable tourism development. The authors have established the importance of experimental and problem-based learning and case studies. These

methods are widely used by the authors of this article during outdoor classes (when teaching the educational components "Ecology and Ecotourism", "Industrial Tourism", and identifying the effect of Barry Commoner's laws of ecology through the local example of a solid waste landfill). Moreover, these teaching and learning methods prove to be useful, especially when dealing with environmental issues and gaining experience from local perspectives. It is also important to develop skills of systemic thinking, empirical learning, techniques and methods of raising ecological awareness, and scientific research skills during ecological excursions (for students and the general public).

2. They are an active form of leisure time, involving considerable physical activity, as ecological objects are usually within a walking rather than transport distance.
3. They create social value because they unite tourists with ecological ideas into a group of like-minded people and direct the community as a whole to possible solutions to environmental problems.
4. They have a significant economic effect (especially for single-profile cities like Kryvyi Rih) – they contribute to economic diversification through development of new sectors: tourism in general, and such types as industrial and ecological tourism.
5. In terms of sustainable tourism, they help to disperse tourist flows and do not create an excessive burden on popular tourist centers.

In addition, through demonstration of local environmental problems, concepts and even ecological skills are formed. Ecological tours promote ecological education and advocate for the sustainable development of the nature-society-economy system.

The analysis of information sources, personal observations of excursions, and self-analysis of excursion activities enable identifying certain problematic aspects in the traditional interpretation of the concepts "ecological tourism" and "ecological excursion":

1) there is no comprehensive definition of the concept "ecological excursion" that would correspond to the content of excursion activities for all segments of the population (not just schoolchildren and students) and objects to be visiteds (especially protected natural areas, parks, public gardens, etc.);
2) development and conducting of ecological excursions into nature are the responsibility of individual professionals (secondary school teachers and specialists of particularly protected areas), which significantly narrows the possibilities of interpreting environmental problems for all the public and does not form a comprehensive vision of the essence of nvironmental processes and phenomena;
3) there are no clear methodological recommendations on the specifics of preparing, organizing and conducting ecological excursions to "real" ecological objects, such as a solid waste landfill or a mine water sump;
4) the tourist market lacks ecological tours that would reveal the genesis and show the consequences of environmental problems (there are few examples of tours to waste processing plants and a few "pseudo-ecological" tours);
5) the niche in tourism and the concept of ecological excursions are not defined, as they are considered in the vast majority of sources as educational tours into nature, and in terms of content and essence are a type of ecological tourism.

The authors propose to understand ecological excursions as a focused demonstrable process of learning ecological objects, which takes place under the guidance of a qualified guide and aims to: form ecological knowledge, skills and abilities, observe ecosystems and processes, familiarize with environmental problems and negative consequences of human economic activity, form economical

use of natural conditions and resources in everyday life, expand the ecological worldview.

In the authors's opinion, this understanding of ecological excursions is quite broad and comprehensive, allowing formation of an ecological worldview not only by visiting concervation areas, but also by showing such territories/water areas that are in an unsatisfactory ecological condition, or show the consequences of unsustainable use of natural conditions and resources, and introduce "environmentally friendly" technologies and industrial enterprises.

The purpose of ecological excursions should consist in:

- revealing the essence of many global environmental problems and consequences of their manifestation on local examples;
- forming basic ecological knowledge (e.g., ecosystem, anthropogenic and cultural landscape, reclamation, solid waste landfill, B. Commoner's laws of ecology, etc;)
- developing the basics of research activities (when visitors are involved in an interactive ecological research analyzing the impact of a solid waste landfill on individual components and landscapes as a whole, drawing up an ecological assessment report on the state of surface waters, determining ways to treat wastewater, etc;)
- developing ecological skills (e.g., household waste sorting, better use of water, fuel, and other natural resources);
- broadening the worldview;
- forming an active way of spending recreational / leisure time.

Ecological excursions have a significant educational potential in shaping knowledge about the concept of sustainable development for the general public. They are an active form of leisure time, involving considerable physical activity, as ecological objects are usually within a walking rather than transport distance.

In view of the above issues, the authors of the article propose to analyze the essence, methodological and organizational features of conducting ecological excursions based on the their own practical experience.

Ecological excursions can be classified by content and objects (figure 1) into thematic ecological excursions to:

1) operating industrial enterprises that employ ecological and innovative practices:
   - solid waste landfills and waste sorting stations, waste processing plants;
   - enterprises producing environmentally friendly energy (solar, hydrothermal plants, etc.);
   - wastewater treatment plants;
   - heavy and chemical industry enterprises with modernized production (e.g. coke oven batteries No 5 and No 6 at ArcelorMittal Kryvyi Rih).
2) landscapes altered due to unsustainable use of natural conditions and resources:
   - mine water sumps;
   - facilities for production waste;
   - open pits and waste dumps;
   - mine failure zones;
   - altered riverbeds.

Elements of ecological tours can also be organically woven into sightseeing tours, especially in industrial cities (figure 2). In particular, the basic program of the sightseeing tour of Kryvyi Rih includes visits to the following objects that demonstrate landscapes formed by anthropogenic activity: coke production of the ArcelorMittal Kryvyi Rih metallurgical plant, iron ore open pits of the Southern Mining Plant, Red Lake – a mine water sump, failure zones of the Kozatska

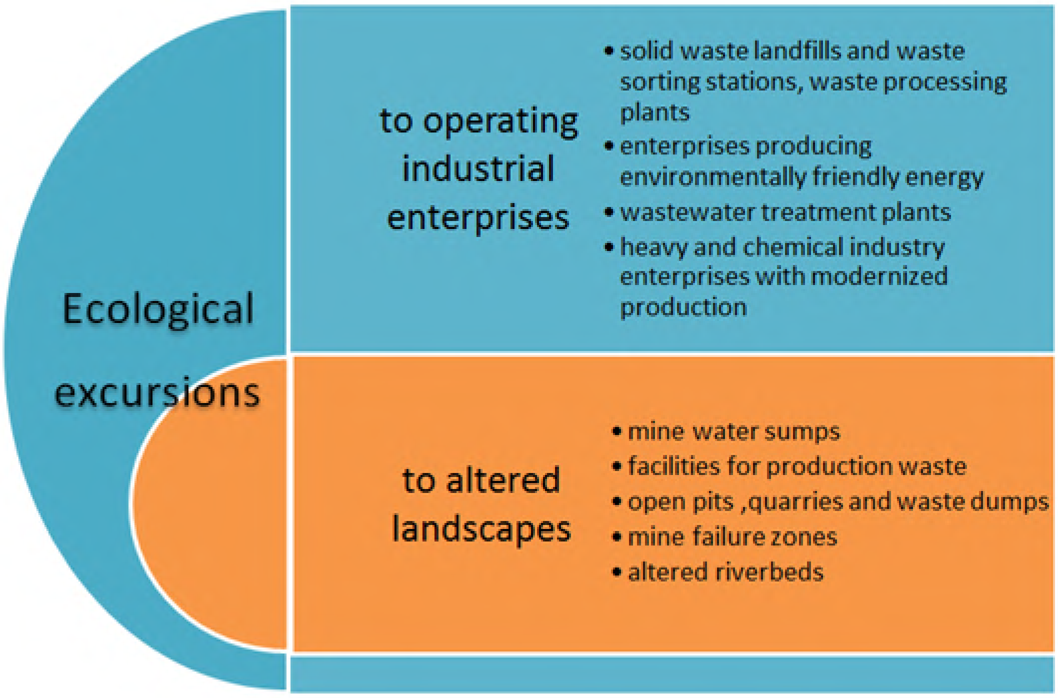

Figure 1. Types of thematic excursions by content and objects.

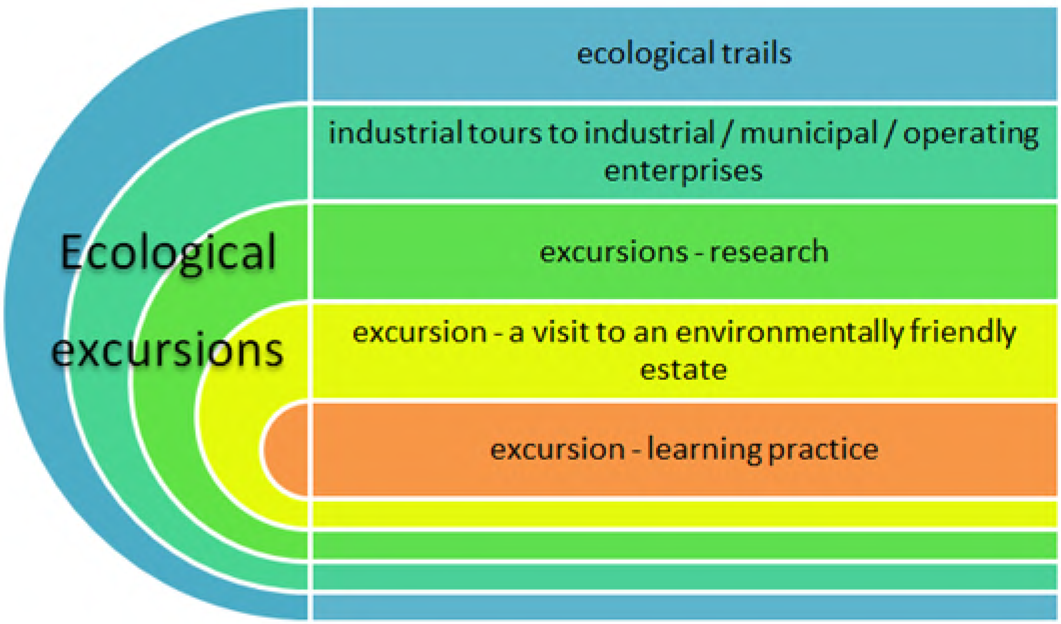

Figure 2. Organizational forms of ecological excursions.

mine, etc. When talking about Kryvyi Rih during a sightseeing tour, it is impossible to avoid environmental issues.

The experience of conducting ecological excursions allows distinguishing several organizational forms:

1) "ecological trails" – excursions in attractive and unique areas including demonstrations of ecological objects that are the result of the unsustainable use of natural conditions and resources (a mine water sump, altered ecosystems of the small Saksagan River, a dead pit, etc.), combining educational and recreational elements;
2) industrial excursions to industrial / municipal and other operating enterprises, where the raw material of production is usually the waste of another enterprise (examples in Kryvyi Rih include the waste sorting station, the waste processing plant, the procurement company "Clean City", the Central Aeration Station of the municipal enterprise "Kryvbasvodokanal", etc.), familiarize with specifics of technological processes, form knowledge of the environmental consequences of human activity for landscapes, create a positive image of enterprises, and build consumers' trust of these companies' services, make visitors aware of operation of environmental laws in real time;
3) excursions – researches, or scientific ecological excursions that aim to form elementary ecological knowledge and skills, when tourists have the opportunity to conduct a short scientific ecological investigation (excursions to the solid waste landfill involve preparation of an ecological passport and analysis of ecological links between various altered natural components, excursions along the Saksagan River involve surveying tourists regarding the attractiveness of the landscapes seen, etc.);
4) excursions – visits to an environmentally friendly estate, which familiarize a wide range of visitors with possibilities and efficiency of equipping a private house with solar panels, applying the principles of a closed cycle of resource use, waste sorting, etc.
5) excursions – learning practices conducted for schoolchildren and students and aimed at consolidating theoretical knowledge of ecological disciplines through practical experience, teaching ecological research methods and developing skills in their use, familiarizing with the city, etc.

The above organizational forms can be used altogether on the routes of ecological excursions, or fragmentally, combining several of them. For example, the ecological trail "Contrasts of the Saksahan River" combines the form of a trail and a research tour, as visitors are involved in collecting information about the attractiveness of Kryvyi Rih's industrial landscapes and fill out an assessment report on the state of surface water (using templates prepared by the guide).

The theme, purpose and objectives of an ecological excursion reflect its essence and purpose. The theme of the excursion is always underlain by basic ecological objects and phenomena. The theme defines the essence of the guide's story on the route. The name of the excursion should clearly reflect the theme and be formulated in such a way as to attract visitors. The name distinguishes the travel product from others on the market. For example, the authors called a series of thematic ecological tours of Kryvyi Rih "Breaking Conventions", in particular, an excursion to the mine water sump at the Hihant Hlyboka mine and the mine administration of the ArcelorMittal Kryvyi Rih metallurgical plant, thematically dedicated to the problem of utilizing highly mineralized mine water, was succinctly named "Breaking Conventions: Red Lake of Kryvbas", and vivid photos were selected accordingly when forming the market offer (figure 3). The purpose of ecological excursions is to develop elementary ecological competencies, broaden the worldview, and foster the economical use of natural conditions and resources.

Selection, study and assessment of ecological excursion objects. Ecological excursion objectss are often unique, sometimes exotic landscapes (even those located on the territory of industrial enterprises, such as aerotanks or wastewater lagoons), which, most importantly, demonstrate and explain the specificity of environmental problems and their solutions. Objects of ecological excursions are multifaceted, as there is no component of the landscape that is not affected by human activity: altered riverbeds, reservoirs, lakes in dead pits, mine water

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012107 doi:10.1088/1755-1315/1415/1/012107

Figure 3. An advertisement for social networks (created by the authors in Canva).

Figure 4. Examples of ecological excursion objects (Red Lake, Solid Waste Landfill) (photos by the authors).

sumps, reclaimed areas of dumps, pits and tailings ponds; functioning solid waste landfills, anthropogenic and cultural landscapes (figure 4).

While developing any excursion, including an ecological one, the route developer must carefully assess available ecological objects according to several criteria: ecological character, safety of the visit, cognitive value and popularity of the object, its exoticism and uniqueness, expressiveness and preservation of the object, location and accessibility, and viewability. When developing an excursion, basic and additional objects must be identified; for ecological excursions, basic objects always include those demonstrating environmental issues, revealing the essence of the formation/solution of environmental problems. Additional objects can have both environmental and local history features.

The excursion route and its preliminary testing. Routes of ecological excursions are as diverse as the ecological objects. Depending on the travel mode, ecological excurcions can be walking and bus and walking tours. The route can be the same as on all other excursions: linear, circular or combined. The developer should arrange the selected excursion objects in accordance with the logistics of the visit, excluding: passing the same path more than 1–2 times, long journeys / transits between objects, etc.

Before implementing a new route for an ecological excursion, the guide must "walk/drive" along it in the field. the same is necessary in the case of a clear seasonality of the route: before the start of the new season, the route should be inspected for obstacles, emergence of new objects, changes in landscapes, development of the territory, etc.

The text of an ecological excursion should be scientific, based on reliable, verified facts, clearly and logically reveal the essence of the environmental objects shown to visitors, reveal environmental problems, and arouse visitors' reflection and suggestions for their solution. However, *delivery of the material and demonstration of objects during the ecological excursion should be easy, not burdened with complex terms and incomprehensible concepts.* The specificity of ecological excursions, especially to operating enterprises, implies the use of highly specialized technical terminology, so the guide of such routes must be professional in explaining complex terms in simple words when describing processes and phenomena (e.g. an aerotanks is a "jacuzzi for active sludge", "rock weathering" is the destruction of rocks, "solid waste landfill is a garbage dump"). The guide should always have additional information, as this provides good knowledge of the subject; texts of excursions are usually not fully reproduced during these excursions. At operating enterprises, the text of the ecological excursion is approved by their management.

"Guide's portfolio" and logistics of the ecological excursion. The "guide's portfolio" usually consists of the printed matter that complements the main content of the excursion and reflect the specifics of the objects shown (e.g., an enlarged photo of a blue bacillus on a tour of treatment facilities or a map of the route of the tour "Contrasts of the Saksaghan River" with the altered sections of the riverbed depicted, etc.). It is a good idea for the guide to have the opportunity to create a convenient electronic format of the "portfolio" using a tablet or laptop to allow additional use of video fragments or audio recordings, historical maps, chronologically arranged photos of a particular place, animation of the spread of pollution from its source during ecological excursions.

Ecological excursions are quite specific, so the guide shold have prepared templates for scientific research for certain routes (forms for filling out the environmental passport of the landfill, a sample of documents of the State Construction Standards for the construction of landfills, a form of the Surface Water Assessment Act, questionnaires for assessing the attractiveness of landscapes, etc.) If the excursion program provides for the study of physical and chemical properties of geocomponents, the necessary equipment should be available (e.g. a transparent glass flask for visual assessment of water clarity and impurity).

Certain routes may require additional equipment, e.g. a laptop (TV in the bus) to show a short video about the Kryvbasvodokanal enterprise and the specifics of the applied wastewater treatment methods for the tour "Revival of Kryvyi Rih Water" (to the Central Aeration Station). The guide should be ready to comment on the video and ask visitors questions about it.

Selection of techniques for showing and narrating on an ecological excursion. The showing and narrating methods are typical for all tours, but they reflect the level of the guide's professional skills. The distinguishing feature of ecological excursions is the use of generalization and abstraction techniques when telling about local environmental problems and the globalized character of their consequences. The narrative should employ specialized ecological and technological terms.

The technique of conducting an ecological excursion is characterized by the need to distinguish the ecological aspects of surrounding areas', landscapes' and objects' functioning. Since most of these excursions are walking tours, it is necessary to take into account field and weather conditions to choose proper clothing and footwear (figure 5). Ecological excursions to operating enterprises necessarily include an introductory safety briefing; in particular, when visiting the Central Aeration Station of Kryvbasvodokanal, heeled footware is prohibited. When giving ecological excursions, it is imperative to take into account all the requirements for walking tours (do not narrate until the whole group has gathered, choose areas for stops depending on the weather, provide for alternating active movement and rest along the route, etc.) The guide must have a first aid kit and be able to provide first aid.

The passport of an ecological excursion is drawn up according to a typical tabular scheme.

A trial ecological excursion is a mandatory stage in the development of an excursion route of any subject and it is aimed at walking around the route, making sure that the selected objects are correct and accessible for viewing, specifying paths, timing the excursion, selecting places for photography and rest. It is advisable to invite an experienced guide for a trial excursion. At the production facilities, the control excursion is tested by representatives and specialists of the enterprise itself.

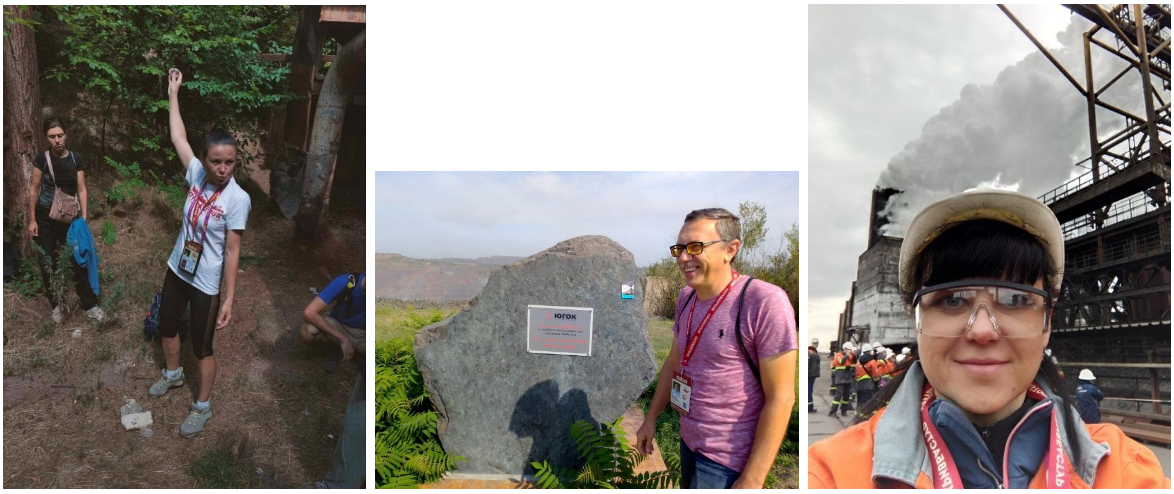

Figure 5. Fragments of ecological excursions guided by the authors of the article (photos by the authors).

There are certain requirements for professional skills of an ecological excursion guide: mastery of the conceptual and terminological apparatus of ecology and branch sciences (geography, biology, engineering, treatment technologies, mining, etc.), the ability to present information about operation of ecological objects, the system of relationships between landscape components and complex anthropogenic impacts in clear and simple terms are mandatory. The information presented should not be dry and the story should not be like in a textbook. The guide should present information in the form of a dialogue, discussion with visitors, use a variety of showing and narrative techniques, and control his/her voice. To dilute the scientific information, interesting facts and funny stories should be used (e.g. when visiting the Central Aeration Station in Kryvyi Rih, the guide asks visitors what the well-known abbreviation WC means. After hearing all the options, he/she says that it is a "water closet" – a toilet with a water flush of a modern form invented and patented in 1775 by the Scotsman O. Cumming). To enhance the "immersion" effect, interactive activities, including ecological games, quizes with valuable prizes (certificates for free participation in other excursions, samples of rocks and minerals from Kryvyi Rih basin, etc.) can be introduced.

The guide on ecological excursions does not have to have an ecological education, but he/she should possess relevant information on a high-level, experience in practical ecological research, a guide's qualification, and the ability to work with people regardless of their individual, age or other characteristics. Thus, to give ecological excursions at a high professional level, a specialist must undergo basic training in tourist skills and possess scientific ecological knowledge, skills, and abilities, have experience in practical ecological activities, and be able to present the excursion material in an easy, relaxed manner.

According to the authors, ecological excursions aim to create a proper image of landscapes and objects altered by human activity; reveal prospects for their functional content and further use; form an ecological worldview; transform consumer behavior. So, inherently, such excursions have a social value.

Take a closer look at the authors' ecological excursions.

The ecological excursion "Breaking Conventions – Kryvyi Rih Solid Waste Landfill" provides the opportunity to feel like an ecologist-researcher, as it involves the study and description of ecological processes that occur during the operation of solid waste landfills. The tour follows the route shown in Fig. 6, is a walking one and lasts up to 5 hours. It aims to introduce the problem of household waste disposal in Kryvyi Rih, environmental laws, develop waste sorting skills, teach visitors to identify environmental processes of the landfill's impact on the urban environment through simple observations and experiments, provide environmental education and develop skills in the economical use of natural conditions and resources.

During the excursion, the guide provides information on sanitary, hygienic, construction and environmental requirements and standards for the construction of a landfill, gives examples of more rational waste disposal, and tourists create an environmental passport for the landfill. Thus, a number of ecological concepts and ideas are being formed to foster a responsible attitude to waste sorting and recycling.

While observing the processes occuring at the landfill, the guide reveals the essence of the Laws of Ecology (by American ecologist B. Commoner): "Everything is connected to everything else", "Everything has to go somewhere", "Nature knows best", "There is no such thing as a free lunch" [18].

The excursion route passes along a road with heavy traffic of dump trucks loaded with oxidized ores that are dumped nearby into the pit. Due to this the road is bright red. In addition to ecological objects, the tour includes a look at industrial heritage objects (the pit of the Shmakivskyi mine, 1886; remains of a miners' village, early 1907; an old mine cemetery, 1900; a culvert under a railway line, 1893).

During the excursion, tourists can make an almost mountain climbing to the rocky waste dump consisting of various rocks and minerals, which brings elements of extreme, shows the possibilities of optimizing landscapes, allows the tourists to see the panorama of the southern part of the city and take many exciting photos. Also, the tourists can select individual mineral samples for their home collection as souvenirs.

As a result, the tourists get great impressions, master the skills of ecological culture, and some of them start sorting garbage after the excursion.

The ecological excursion "Breaking Conventions – Contrasts of the Saksahan River" is a walking tour along the Saksahan River, a second-order tributary of the Dnipro (figure 7). Its goal is to shape ecological knowledge of the process of forming the ecological state of water bodies (on the example of the Saksahan River) and the consequences of surface water pollution, to provide practical experience in identifying features of attractiveness of industrial landscapes, and to contribute to ecological nurturing. The program of the excursion includes

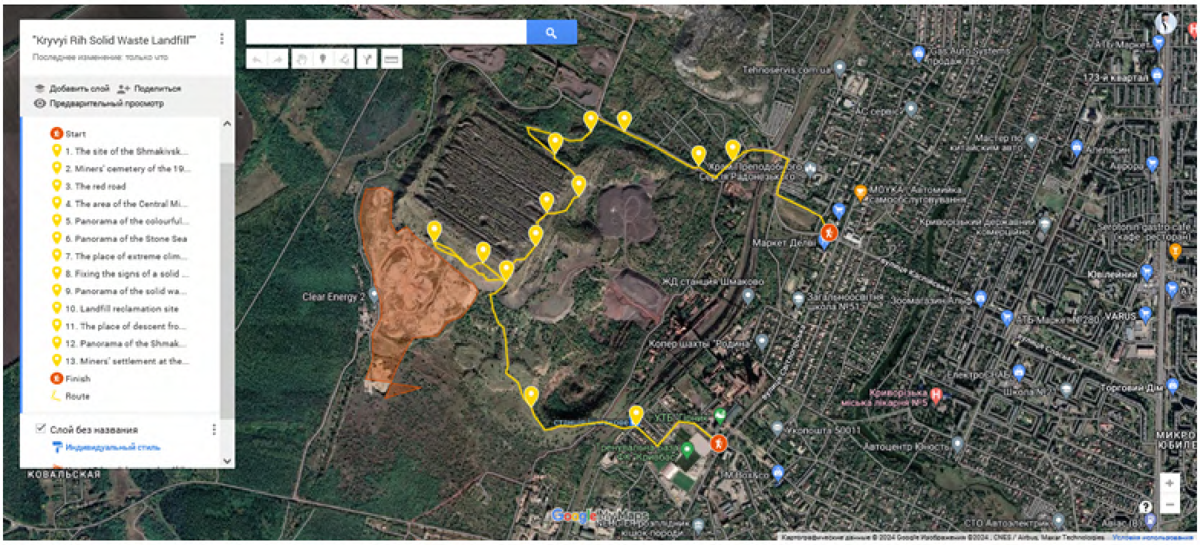

Figure 6. The route of the ecological excursion "Breaking Conventions – Kryvyi Rih Solid Waste Landfill" (compiled by I. Ostapchuk on Google).

a research: tourists under the guidance of the guide draw up an "Act of Environmental Assessment of the River", which characterizes the ecological state of the reservoir and the river valley, and familiarizes the tourists with the standards for changes in water quality and the state of the bank landscapes. After the Act is drawn up, the general ecological condition of the river and river valley is determined. The results of the research conducted during the excursion usually show their satisfactory condition. During the tour, the guide demonstrates natural and anthropogenically altered areas of the riverbed and river valley. The Saksagan riverbed underwent significant changes: – during 1929 – 1948, the KRES valley-type reservoir was constructed; – in 1960, the riverbed was straightened (the river meander Bazhanivskyi Kut was cut off); – in 1960, the river was diverted into an artificial rock canyon (the river meander Vechirnyi Kut was cut off), simultaneously discovering unique rocks of the Skeliuvata Formation of the Proterozoic, represented by quartz metasandstones, metagravelites, and metaconglomerates [19]. All these alterations are observed on just a 5 km long section of the river!

During the excursion, tourists are encouraged to pay attention to their own subjective feelings and impressions of the landscapes they see.

At the end of the trip, in one of the picturesque places, the guide offers to fill out an aesthetic valuation questionnaire. According to the results of visitors' assessments of the excursions, the landscapes of the lake in the KRES granite quarry and the landscapes of the Saksahan Canyon are identified as the most attractive.

Thus, the excursion of this kind is aimed at forming ecological, geographical and geological knowledge, showing positive and negative aspects of human impact on the global cycle of substances, revealing historical features of the area, including unique locations of Kryvyi Rih, and allowing tourists to capture their own impressions in vivid photographs.

The environmental excursion "Red Lake of Kryvbas" aims to show the features and some aspects of the environmental consequences of iron ore mining in Kryvyi Rih basin, to familiarize with the history of the Saksahan Reservoir, the Saksahan branch of Catherine's Railway, and the history of settling the area. The excursion is a walking one, lasts up to 4 hours, and is designed for a wide range of visitors. The main object of the excursion is a settling

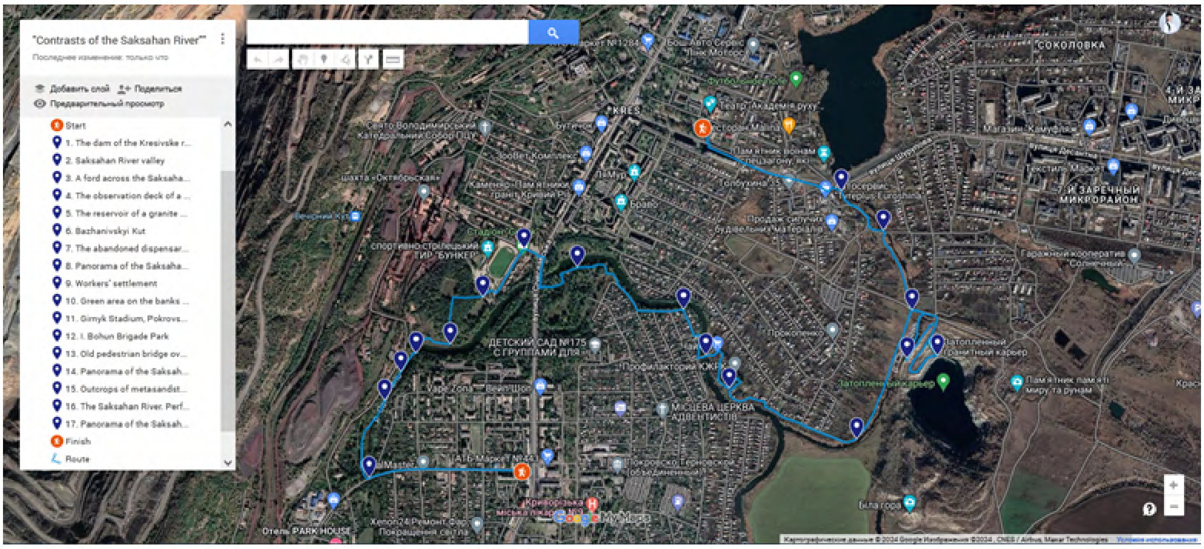

Figure 7. An excursion route "Breaking Conventions: Contrasts of the Saksahan River" (compiled by I. Ostapchuk on Google).

pond of highly mineralized mine water from the mines of ArcelorMittal Kryvyi Rih and Hihant-Gluboka, which is called Red Lake. There are many similar lakes in Kryvyi Rih, but this lake stands out among them: – it is easily accessible within the city; – it has "natural" shores; – it is partially reclaimed; – it has free of water areas with specific types of vegetation and wildlife; – scientists have substantiated that the chemical composition and genesis of waters are remnants of ancient seas (figure 8).

On the shores of Red Lake, the guide introduces visitors to the specifics of iron ore mining, the need to pump out groundwater (12–14 million m^3 annually, salinity of 35‰) and its primary treatment in such sumps. The narative is complemented by vivid examples and illustrations of how to avoid negative environmental consequences of such water treatment, possible alternatives are considered, and tourists' suggestions are listened to [10].

It is striking that the chemical composition of salts in these waters is alien to the water-bearing rocks; the chlorine-bromine coefficient testifies that the lake's salty waters are of marine origin. From Red Lake, a panorama of the nearest operating and mothballed mines opens up; tourists can see Kryvyi Rih TV tower, the Mudriona railway station, Kryvyi Rih Metrotram route, the unique Saksahan Reservoir, the history of which is connected with the construction of the Saksahan Derivation Tunnel (1957), etc.

Red Lake is located in a historical place where in the late 19th century there was landowner Halkovskyi's rich iron ore mine. Later, a dam was built, the Saksahans branch of Catherine's railway ran nearby and the Mudriona residential area was built (as a station settlement). There were always vegetable gardens and orchards in the Saksahan valley because of the 4-meter-thick layer of black soil, and daphnias were caught in the waters of the reservoir. The route then runs parallel to the high-speed tram line, enters the Mudriona railway station built in 1951, and ends near another building of the same station built in 1893, which is currently used as a warehouse.

This excursoin impresses foreign guests with its environmental friendliness and uniqueness.

The 4-hour bus and walking ecological excursion "Revival of Kryvyi Rih Water" (figure 9) aims to familiarize tourists with peculiarities of sewage treatment before it is discharged into surface water bodies in order to provide sanitary and hygienic safety in the region. The excursion provides environmental education and nurturing, and develops skills of the rational use

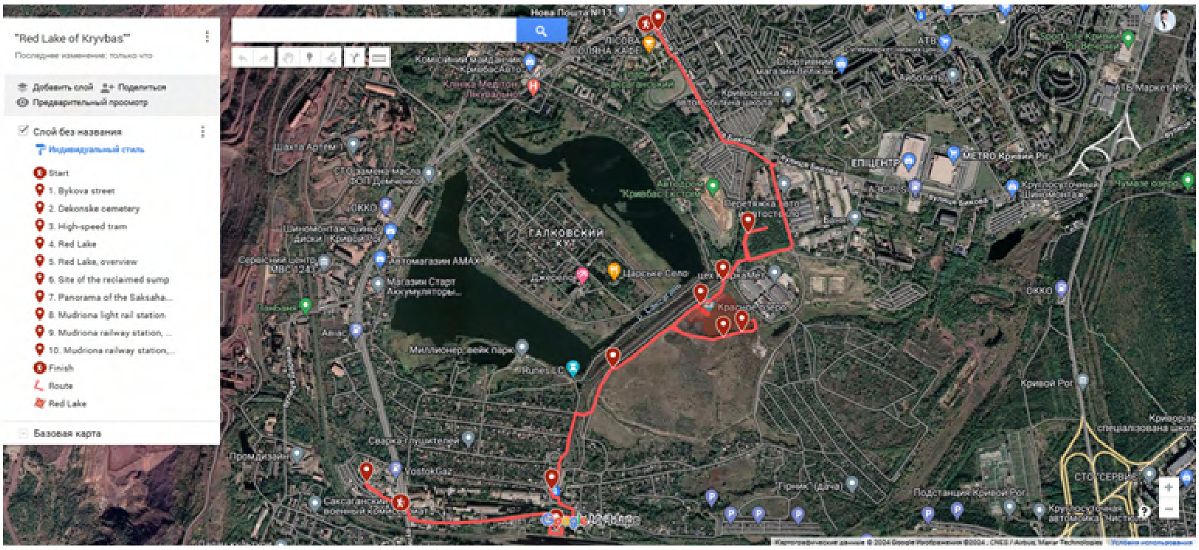

Figure 8. The route of the ecological excursion "Red Lake of Kryvbas" (compiled by I. Ostapchuk on Google).

Figure 9. The route of the ecological excursion "Revival of Kryvyi Rih Water" and the aerotank.

of fresh water. This is an excursion to an operating industrial enterprise – the Central Aeration Station (CAS) of the Kryvbasvodokanal utility enterprise, so a safety briefing is mandatory.

During the excursion, visitors get acquainted with the peculiarities of Kryvbasvodokanal's operation (since 1928), which helps to strengthen the company's image; learn the history of sewage treatment technology invention and creation of a water supply system in the city and the world.

The excursion of the Central Aeration Station is conducted by a guide and an employee of the company and covers the entire technological chain of water treatment: sewage – mechanical treatment at sand traps; biological treatment in aerotanks and methane digesters; water settling in primary and secondary settling tanks; chemical and/or physical decontamination; discharge into surface water bodies through a buffer pond.

The enterprise provides the opportunity to observe the operation of the units (air blower, cooling tower, primary and secondary settling tanks, aerotanks), walk across the bridge over the aerotanks, and talk to employees. During the narative, the guide draws attention to the systematic control of water quality, its compliance with the standards and current legislation of Ukraine.

The excursion ends with a visit to a buffer pond and a wastewater disperser, where the guide summarizes the information, verbally presents the technological chain and methods of water treatment, and reminds tourists of the need to use water economically in everyday life and during recreation near water bodies.

Ecological excursions – environmental learning practices. The authors have experience in giving similar excursions for students of Kryvyi Rih colleges (Mining Professional College and Inhulets College of Kryvyi Rih National University). This type of excursions is aimed at consolidating the previously studied theoretical material on ecology during the college course and developing practical competencies. Programs of such excursions are usually developed individually depending on the customers' requests. Most of them are bus and walking tours lasting up to 4 hours. The basic objects for the ecological practice excursions include Red Lake, the waste dump of the Central Mining and Processing Plant, the solid waste landfill, and other options:

Hannivka iron ore pit of the Northern Mining and Processing Plant, the mining equipment skansen of the same enterprise, Pershotravnevyi mine and the Obiednanna underground mine, the KRES granite quarry, and failure zones in the Kozatska underground mine area.

In contrast to ecological excursions that are conducted for the general public and taking into account the specifics of the order, the program of this excursion contains more information on theoretical ecology (the effect of environmental laws, environmental factors, ecosystems, etc.), iron ore mining and processing technologies, environmental problems of the city and methods of their solving.

Much more attention is paid to development of research skills and practical ecological competencies, e.g. investigation of the ore dust spread depending on the topography and distance from the source of pollution; identification and description of existing and possible ways to reclaim post-industrial landscapes; preparation of an environmental and sanitary passport for a solid waste landfill, drafting an ecological assessment report for surface water or developing ways to utilize highly mineralized mine waters, etc.

Ecological excursions-practices necessarily contain elements of local history, as when moving between sites, the guide tells not only about environmental issues, but also provides interesting facts from the historical past of different parts of the city and mines, reveals the specifics of forming an industrial city from ancient times to the present, guides students by the names of certain objects, and reveals the role of famous figures in the development of the city, shapes certain geographical knowledge.

Participants of excursions-practices are better prepared to perceive scientific information (due to their studies in specialized institutions) and learn certain practical skills. This type of excursion is in demand among the educational institutions of the city.

The authors began offering ecological excursions on the tourist market of Kryvyi Rih in 2016. The intensification of this excursion activity was due to the implementation of measures adopted in the municipal programme for the development of industrial tourism [20, 21]. Figure 10 shows the dynamics of thematic ecological excursions in the city. The exceptions were 2021 due to the authors' participation in other projects, and 2022, when no tours were conducted at all due to military operations. As a result, one can see the largest total number of ecological excursions (21) in 2017. The lowest number was recorded in 2020 (5) due to the COVID-19 pandemic, and in 2023 (6) due to the city's frontline position. Currently, holding mass events is also aggravated. At the same time, there was no significant dominance of excursions on specific themes during the period under review. Excursions to the Central Aeration Station "Revival of Kryvyi Rih Water" attracted quite a steady interest of visitors, but they have not been held since the beginning of the quarantine and subsequent military operations. There are fewer excursions in the format of learning practices due to the narrow target audience.

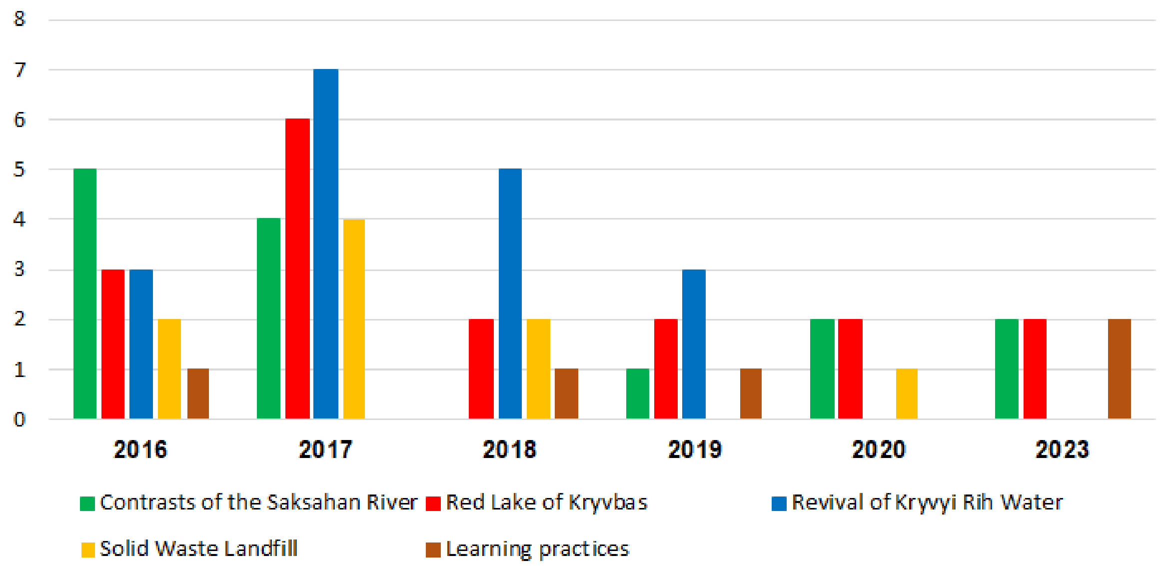

Figure 10. Dynamics of ecological excursions in Kryvyi Rih in 2016–2023.

In total, the authors organized 63 ecological excursions during this period. This relatively small number is due to the fact that the authors are scientists and organize tours not for commercial purposes, but to popularize their ideas and test certain hypotheses. The generalized data for the entire period of these excursions (figure 11) shows that "Revival of Kryvyi Rih Water" was the most popular one which dominated in terms of the total number of excursions conducted (18), the number of visitors (362), and the average group size (20.1 persons). "Red Lake of Kryvbas" and "Contrasts of the Saksahan River" were somewhat less popular. A smaller number of excursions were organized to the solid waste landfill due to the specifics of this subject. However, the average group size (19.8 persons) was also quite large. The lowest number of excursions (5) and visitors (72) was recorded among the learning practices with an average group size of 14.4 persons. This was because of the distance learning of students and the fact that some young people have left the country due to the war, and others can only be involved in excursions if they comply with all safety requirements, which is quite difficult in today's reality.

In addition to purely ecological excursions, the authors of the article are involved in development and implementation of other city excursions and tours of various duration to Kryvyi Rih. The environmental and social aspects of these tours cannot be avoided.

Thus, the main, basic objects during a one-day tour to Kryvyi Rih ("Technogenic Fiction in Kryvyi Rih" from the tour operator Krayina UA) include the following: iron ore pit of the Southern Mining and Processing Plant, coke production of the ArcelorMittal Kryvyi Rih metallurgical plant, the monument to Kozak Kryvyi Rih, the Flower Clock, Kryvyi Rih Metro – a high-speed tram, Red Lake, the KRES granite quarry, Kozatska mine sinkholes, Kochubeyivski

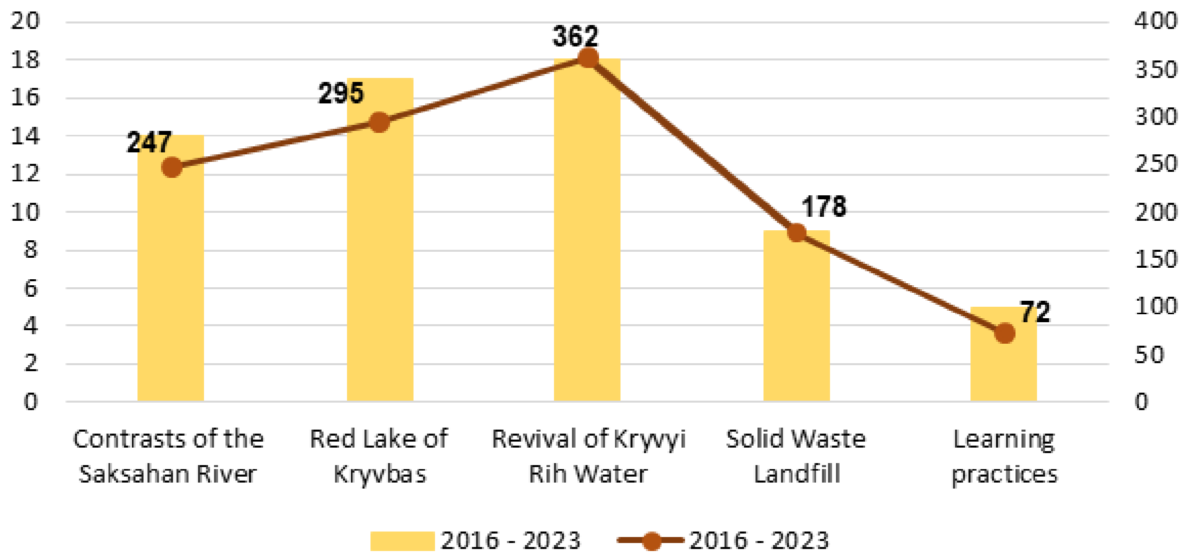

Figure 11. Analysis of ecological excursions in Kryvyi Rih and tourists coverage in 2016–2023.

adits. When visiting industrial enterprises, environmental issues inevitably arise, ranging from the "environmental friendliness" of blasting operations in the pit, safety of coke production gases emisstions, environmental problems of utilizing and recycling pumped-out highly mineralized mine waters, to safety of working conditions for employees and approaches to landscaping the city.

Table 1 presents details of the environmental aspects of visiting some tourist objects in Kryvyi Rih.

Table 1: An example of the environmental content of tourist objects in Kryvyi Rih

No.	Name	Main technological process	Environmental phenomena and processes, problems that are objects of observation
1	Iron ore pit at the Southern Mining and Processing Plant (430 m deep, 3 km in diameter).	Extraction of magnetite quartzite, drilling and blasting operations, transportation of extracted raw materials (iron ore and waste rock), groundwater pumping.	Earth's crust disturbances, groundwater disturbance, landslide processes on pit walls, air pollution with dust and gases, man-made earthquakes, destruction of soil and biota, formation of new landforms, formation of anthropogenic landscapes, production waste disposal and recycling.
2	Coke production at ArcelorMittal Kryvyi Rih	Production of coke for blast furnaces of the metallurgical plant.	Air pollution with harmful substances: solid aerosols, water vapor, carbon dioxide, hydrogen sulfide, nitrogen oxides, ammonia, benzopyrene, etc. Thermal air pollution, participation of the production in formation of an urban heat island and global climate warming. Formation of a typical industrial factory landscape instead of that of natural steppe.

Table 1 – continued from previous page

No.	Name	Main technological process	Environmental phenomena and processes, problems that are objects of observation
3	Red Lake	Logistical intermediate storage of highly mineralized groundwater pumped out of the underground mine, hematite sludge settling and pumping of water to the main mine water storage pond in Svystunov gully.	Movement of deep groundwaters (from a depth of 1–1.3 km) to the surface. Mine waters with high mineralization is not utilized, but transported further to a large pond for discharge into the Inhulets River. Pollution of surface waters by highly mineralized mine waters. Air pollution with red hematite dust in summer due to dust storms. Formation of atypical halophytic vegetation communities. Ways of solving the problem of mine water treatment and utilization (current and prospective).
4	KRES granite quarry	Granite extraction, waste rock storage in a nearby dump, granite crushing.	Air pollution by dust and gas emissions, destruction of natural topography, soil, vegetation, landscapes, etc. Formation of the ‘second” nature – industrial landscapes of the pit and waste dump, emergence of a lake in the dead pit, emergence of derivative natural phenomena – landslides, crumbling and collapse of granite mass. The problem of anthropogenic impact on the processes of rock destruction and the impact on the global biogeochemical cycle of substances.
5	Sinkholes of Kozatska mine	Mining of minerals – rich iron ore and extraction of associated rocks – shale and quartzite. Reclamation of sinkholes by backfilling with crushed waste rock.	Deep and planar deformations of the geological structure, formation of gigantic depressions above the mined-out space (voids), landslides, collapses, washouts, destruction of residential settlements, fatalities and destruction of the city’s mine infrastructure resulted from natural manifestation of sinkholes. Possible ways of reclamation of the areas disturbed by sinkholes.
6	Kochubeyivski adits	Iron ore mining in the early XX century.	Deformations of geological structure, formation of underground cavities (adits, vertical passages, underground mining rooms), emergence of industrial landscapes of the pit and dump.

Table 1 – continued from previous page

No.	Name	Main technological process	Environmental phenomena and processes, problems that are objects of observation
7	Sludge storage facilities – Obiednane, Voikivske, Hrushovatske – of Inhulets, Central and Northern mining and processing plants.	Storage of sludge, a waste product from processing poor iron ores, using pipes (slurry pipelines).	Air pollution by dust, destruction of soil and vegetation, flooding of land by infiltration and condensation water, formation of new landforms, drainage of infiltration water, reclamation, the risk of man-made mudflows, accidents on slurry pipelines and pollution.

5. Conclusions

Ecotourism in its classical interpretation involves the study of natural landscapes in their natural state (mainly within specially protected areas), but not all regions of the world have high natural resource potential. For example, industrial regions, such as the city of Kryvyi Rih, which have been heavily transformed by human activity and technology, are characterized by a new industrial artificially created environment. However, this does not mean that there are no eco-tourism facilities in such ares. In the authors' opinion, the situation is quite the opposite – observations, study, and analysis of industrial landscapes, environmental situations of varying degrees of severity, formation of environmental problems and methods of solving them, etc. are perhaps the best option for ecotourism objects.

Ecotourism, in the authors' interpretation, is a type of industrial and sustainable tourism. It is aimed at traveling to ecological tourist objects (not necessarily natural) that demonstrate manifestations of various environmental problems and their consequences in order to carry out ecological education and nurturing. These include various landscapes that have undergone negative anthropogenic changes, have recovered from such changes on their own or have been reclaimed, and operating industrial facilities with a clear ecological function (for example, an aeration plant where municipal wastewater is treated, waste sorting plants, solid waste landfills, etc.)

Ecological objects in the industrial environment are the ones of both eco-tourism and ecological excursions.

Ecological excursions aim to create a proper image of industrial landscapes and objects altered by human activity; reveal the prospects for their functional content and further use; shape an ecological worldview and personal responsibility for global environmental issues; transform consumer behavior into a responsible attitude towards the use of natural conditions and resources; implement sustainable development goals in everyday life.

The authors of the research are practicing guides who have developed and conducted ecological tours and excursions in Kryvyi Rih. The specificity of the developed ecological excursions consists in the fact that they are available to a wide range of visitors: both schoolchidren and students, as well as city residents, domestic and international tourists, and are aimed at visualizing global and local environmental problems and learning about the industrial environment through interactive participation in a simple scientific ecological investigation, identifying local environmental problems and clarifying their personal role and responsibility in emergence of global problems of humankind.

The authors have created four routes of thematic ecological excursions, which aim to form an understanding of global problems of humanity through local examples of unsustainable use of natural conditions and resources, through personal experience of observing, analyzing and assessing various ecological situations in the industrial environment. These excursions with an enhanced research component are used to conduct ecological training practices for students of Ukrainian educational institutions.

During testing, some ecological objects proved to be so attractive that the authors included them in the programs of tours around Kryvyi Rih. In general, a visit to our city cannot do without touching upon environmental issues even during a sightseeing tour. The basic objects in the program of a one-day tour to Kryvyi Rih (e.g. "Technogenic Fiction in Kryvyi Rih" from the tour operator Krayina UA) include the following: iron ore pit of the Southern Mining and Processing Plant, coke production of the ArcelorMittal Kryvyi Rih metallurgical plant, the monument to Kozak Kryvyi Rih, the Flower Clock, Kryvyi Rih Metro – a high-speed tram, Red Lake, the KRES granite quarry, the Kozatska mine sinkholes, Kochubeyivski adits. During the tours, visitors most often ask environmental questions ranging from the "environmental friendliness" of blasting operations in the pit, safety of coke production gases emisstions, environmental problems of utilizing and recycling pumped-out highly mineralized mine waters, to safety of working conditions for employees and approaches to landscaping the city.

During 2016–2023. (excluding 2021, 2022 – pandemic and martial law), the authors of the research conducted about 80 ecological excursions (excluding sightseeing tours) for 1500 tourists. "Revival of Kryvyi Rih Water" was the most popular excursion before martial law, but now its objects are strategic facilities of the city's infrastructure). "Breaking Conventins – Kryvyi Rih Solid Waste Landfill" was the least popular route.

In general, the ecological excursions developed and introduced in excursion activities by the authors of the research are relevant for the whole world, and while in some countries such excursions are conducted for schoolchildren and students, in Kryvyi Rih ecological excursions have been tested and are available for a wide range of visitors.

Thus, ecotourism in the industrial environment is a new interpretation of the traditional concept. The authors' interpretation of ecotourism and excursions, in contrast to the existing concepts and approaches implemented in the world practice of excursion and tour operator activities, expands the possibilities of forming ecological competencies, implementing ecological education, broadening the worldview, forming an active way of spending leisure time, economical use of natural conditions and resources in everyday life for all segments of the population regardless of age, social affiliation, etc. As a result of direct observation of real ecological objects and functioning industrial enterprises, and personal investigations of environmental processes, visitors gain their own experience of learning about environmental problems in the industrial environment, which effectively directs further human behavior and life towards the mode of "sustainability" and "environmental friendliness". If the guide uses carefully selected environmental objects and interactive methods and techniques of ecological education and nurturing, the visitor gets a positive experience and emotional trace after the excursion, and an actually formed skill of environmental behavior. These and other aspects of ecotourism in the authors' interpretation are of particular importance for achieving the goals of sustainable development.

A new look at ecotourism in the industrial environment can be a way of rethinking the essence of classical concepts. The involvement of industrial and post-industrial landscapes (not only as industrial tourism objects), functioning industrial enterprises, reclaimed and revitalized spaces in the ecotourism sector will significantly expand the possibilities of achieving the goals of ecological education and nurturing and shaping the ecological worldview of all residents of the planet Earth. Within Kryvyi Rih, it would be advisable to create an ecological park on the territory of non-functioning production areas or facilities, which would present expositions on the ecosystems of the region/Ukraine, anthropogenic landscapes depending on the direction of use, and the possibilities of waste-free technologies. This park could be filled with interactive elements that would allow visitors to simulate the effects of technogenesis. This interpretation of eco-tourism allows understanding the nature, causes of global environmental problems and possible methods of solving them through understanding the participation and responsibility of everyone. For example, unsorted garbage accumulated in a solid waste landfill today will result in pollution and deterioration of drinking water quality, or inavailability of a favorable recreational environment, or contamination of soil and food grown on it, or all of these consequences together. Real-time visual observation of the entire cause and effect chain is perhaps the best way to shape environmentally sound human behavior. Just watching a movie about global environmental issues can have an ecological and educational impact, but it is quite clear that once visiting a sewage treatment plant, the visitor will definitely understand the rules for using sanitary appliances in everyday life, join in saving water, not clogging sewage systems with garbage, etc. Similarly, it is more effective to develop waste sorting skills through visits to waste processing plants when the consumer understands possibilities of saving natural resources through implementation of recycling and reuse technologies.

These examples confirm the timeliness of the authors' theoretical research and its practical results; the environmental, economic, and social significance of ecological excursions and tours implemented in excursion activities; opportunities for further theoretical and empirical research on ecotourism in the industrial environment.

Abstract. For Ukraine, the question is very acute today: will Ukrainian business be able to continue its activities in war conditions and support the state's economy. In the conditions of war, it is extremely difficult to solve many practical issues related to the problems of forming a business strategy based on the principles of sustainable development. The basis of which are ecological interests of society, eco-oriented development of companies, constant consumption and production. The article examines the peculiarities of the operation of tourist companies in the conditions of war, conducts a basic STEEPLE analysis, presents five illustrative cases of the experience of the operation of tourist companies during the war, defines the main components of strategies based on the principles of sustainable development and new formats of Ukrainian tourism in the realities of war. The purpose of the research is to study the practical experience of conducting activities in the field of tourism during the war in Ukraine and to develop recommendations for the formation of a strategy for the ecologically oriented development of tourist companies during the war.

1. Introduction

1.1. Research question

For Ukraine today, the question is very acute: will Ukrainian business be able to continue its activities in war conditions and support the state's economy. It is impossible to win a war without the proper functioning of a business. This means that businesses must operate, provide jobs, pay taxes, and provide the country with an important resource to defeat the enemy. To do this, it is necessary to create appropriate conditions and an appropriate institutional environment, using all available capabilities and reserves. In war conditions, it is extremely difficult to solve many practical issues related to the formation and implementation of an appropriate business strategy. This is especially relevant for industries whose functioning depends on the level of safety and stable rates of economic development, in particular for enterprises in the tourism and recreation sector. Enterprises of these industries, due to the specifics of their activities, have an anthropogenic impact on the environment and are capable of causing destructive environmental phenomena. Further development and restoration of tourism and recreational facilities will require the use of new views and approaches to the development of business strategies, as well as proactive entrepreneurial decisions on the part of market participants, since

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012108 doi:10.1088/1755-1315/1415/1/012108

the state, given the continuation of the war, will have other financial priorities. Such strategies must necessarily be environmentally oriented. In modern conditions, debate continues among scientists on theoretical and methodological approaches to the formation of environmentally-oriented development strategies [1].

The research question in this article consists in the analysis of methods of improving strategies in the field of tourism and recreation in Ukraine, based on the adaptation of strategic management methods and attention to sustainable development. The use of proactive strategies for the sustainable development of enterprises in the field of tourism and recreation will allow market participants to make strategic decisions necessary to increase competitiveness, including in the ecological vector.

1.2. Related work

The issue of forming an activity strategy is important for the successful functioning of a business [2]. Whittington et al. define strategy as the long-term direction of an organization [3]. Porter [4] noted that strategy determines a company's specific approach to competition and the competitive advantage on which it will be based. Mintzberg [5] emphasizes that strategy is a certain pattern in the flow of decisions. However, in war conditions, the company must take into account the rapidly changing situation in the external environment and count on its own potential. Therefore, in our research, we proceed from the fact that strategy is the determination of promising guidelines for the company's activities based on an assessment of its potential capabilities and forecasting the development of the external environment.

Companies operating in turbulent market conditions usually implement several main stages in the formation and implementation of a strategy. This is primarily the development of a strategic vision, setting goals, developing a strategy for achieving goals, implementing a strategy, monitoring development, evaluating results and making adjustments depending on the situation in the environment. However, in war conditions the situation with making strategic decisions is different. Firstly, the time frame for strategic planning is short, since war can destroy all plans quite quickly. Secondly, because of the war, entrepreneurs must decide for themselves to function at the moment or not, or to change the direction of activity, or to offer a new product depending on the situation that develops from the outside. Thirdly, when developing a strategy, it is important to take into account the social component of the strategy. The last component plays an important role during the war. We believe that every business during this period should be socially oriented. This concerns the provision of jobs, environmental protection, corporate volunteering, etc.

1.3. Problem statement

The scientific problem is the use of strategic management and planning tools to increase the effectiveness of enterprises operating in the field of tourism and recreation in the conditions of war on the territory of Ukraine. In the public discourse of Ukraine in pre-war times, more attention was traditionally paid to the development of state and regional programs to support the sphere of tourism. However, during a war, the state has other priorities related to security, economic and social issues. Therefore, the study of the state of the external environment, the structuring of the factors of action, the study of the best practices of the development of companies in the field of tourism and recreation during the war represents significant enthusiasm.

The hypothesis of the article has both a theoretical and an applied basis and concerns the need to strengthen the level of strategic management at the micro level, taking into account the destructive influence of military actions and changing the priorities of state policy.

The purpose of the article is to study the practical experience of making strategic decisions for enterprises in the field of tourism and recreation in the context of sustainable development in the conditions of war in Ukraine. Based on surveys of business representatives, consumers, industry experts, and the use of information in open sources and social media, a study of best practices was conducted and recommendations were developed on the specifics of forming strategies based on sustainable development in war conditions. The object of the study is the strategies of enterprises in the sphere of tourism and recreation in Ukraine.

1.4. The research methodology

The study is based on data from Ukrainian analytical organizations on the role and potential of the tourism industry in the economy, expert assessments of the impact of military operations on tourism and recreation, as well as data from qualitative and quantitative research collected directly from market participants and processed by statistical methods. In addition, in preparing the article, open data was used on successful projects that have been implemented in Ukraine over recent years, including the period of hostilities.

The analysis of the state of the tourism and recreation sector covers 2019-2023, with details on individual important characteristics. The period chosen to conduct an anonymous survey of market participants was November-December 2023.

The scientific novelty of the methodology is as follows: the study of best practices and generalization of successful strategies in combination with desk research made it possible to formulate conclusions about the strategic decisions of tourism companies based on sustainable development

The study found that environmental, social and economic considerations should be seen as a driver of innovation and a source of competitive advantage.

1.5. Paper structure

The current study consists of the following parts:

- firstly, a theoretical basis is provided regarding the formation of strategies in the context of sustainable development;
- secondly, the potential of the tourism and recreation sector in Ukraine is described; analyzed the impact of military operations on the sphere of tourism and recreation; to summarize the impact results, the STEEPLE matrix of external environment analysis was used, quantitative assessments of the influence of individual factors and sub-factors were given; a case analysis of successful practices in the field of tourism and recreation was conducted.
- thirdly, the study of macro environmental factors in combination with the results of case analysis made it possible to highlight the author's recommendations for the development of strategies based on sustainable development, containing a list of possible strategic decisions of tourism market participants, a description of new forms of tourism, as well as the most common digital tools.
- the following are the conclusions of the study on the peculiarities of the formation of strategies in the field of tourism and recreation based on sustainable development in war conditions.

The practical result of the study is that the results can be used as part of the development of strategies by individual market participants to increase their own competitiveness, improve economic and social results, and develop environmental awareness. Researching best practices and disseminating information on the specifics of developing strategies for tourism organizations during the war will allow us to pay focused attention to issues of sustainable development and develop support and recovery programs, including in the post-war period.

2. Theoretical background

In war conditions, when forming a company's strategy, it is necessary to focus on its environmental orientation. Since war destroys the environment, disrupts the natural balance, and negatively affects people's health, the state and enterprises must act to preserve nature and the environment for the future of Ukraine. Environmental orientation in strategy is a set of principles, means and prospects for an enterprise's activities in the natural environment with the aim of preserving it and thereby ensuring its own sustainability.

Ardente et al. [1] note that the main environmental benefits of implementing a green development strategy are the reduction of resource depletion, air emissions and landfilled waste. The proposed strategies are economically viable and reduce costs for the company and have a positive impact on its sustainability.

Beloborodova's [6] proposals regarding the formation and implementation of an environmentally oriented development strategy are worthy of attention. To do this, certain criteria are formed by which the level of environmental responsibility is determined. All criteria are divided into two groups: those that relate to environmental responsibility (i.e., are regulated by law), and those that relate to the enterprise's own environmental initiative and are determined voluntary. The group of criteria for its environmental initiative includes two subgroups of characteristics: environmental management of production and the effectiveness of communications with stakeholders. Forming a strategy for environmentally-oriented development based on these criteria will allow achieving positive changes in the qualitative state of the external environment, improving the quality of final products (services) and the main indicator of the success of this strategy should be the stability of the functioning of the ecosystem.

The priorities for forming a strategy for environmentally-oriented development should be the preservation (restoration) of natural elements of the ecosystem, identifying negative factors that destroy the ecosystem and reducing their influence; restoration and protection of natural resources.

3. Results

3.1. Tourism and recreation in Ukraine

Tourism is considered one of the most profitable sectors of the economy around the world; the tourism industry produces approximately 10-11% of the GDP of countries around the world [7].

Having a favorable geopolitical location, Ukraine has significant recreational potential: favorable climatic conditions, varied terrain, transport networks, cultural heritage. In this context, Ukraine is a rich country bordering the Black and Azov seas, the mountain peaks of the Carpathians and steppe regions inhabited by wild birds and animals. In pre-war times, in 2021, Ukraine entered the ranking of the best tourist countries in Europe.

During the coronavirus pandemic and full-scale invasion, the tourism sector accounted for 2.3% of Ukraine's GDP and provided about 375 thousand jobs [8]. However, the real contribution of tourism to the quality of life and well-being of Ukrainians was greater, because its multiplier effect stimulates spending in related industries: transport, trade, food establishments, etc. This indirect result of the same 2019 amounted to 7% of GDP and 1.2 million jobs [8].

During the COVID-19 pandemic, domestic tourism in Ukraine became more popular. In the post-COVID period, the main destinations for domestic tourism in Ukraine (in percentage) were trips to spas – 44.4, mountain recreation – 29, ski destinations – 19.5, and seaside destinations – 4.1 [9]. It is worth noting that the growing popularity of domestic tourism among the population contributes to an increase in tourist flows, the development of new road routes, the opening of new tourist and hotel complexes and the development of local infrastructure and an increase in local budget revenues, which is particularly important for small towns in Ukraine. In particular, the visibility of local cultural communities is growing.

In February 2022, the war with Russia paralyzed the tourism industry and came to a virtual standstill. The eastern and southern regions of Ukraine have become inaccessible to tourists due to active hostilities, danger to human life, destruction of historical and cultural heritage, systematic shelling and mining of resort areas in the Mykolaiv, Kherson and Odesa regions [10].

3.2. The impact of military operations on tourism and recreation

The scale of the impact of military operations on Ukrainian tourism is still difficult to fully assess, because a full-scale war continues. However, it is already known that in 2023 tourism enterprises decreased by 36% compared to 2021 [8]. Russian occupation, military operations and constant shelling of different regions lead to the destruction of infrastructure: hotels, recreation centers, airports, railway connections, as well as museums, historical attractions, nature, that is, what people travel for (if we are not talking about work trips). Significant territories in the east, south and north of Ukraine are mined. According to foreign experts, this is about 30% [8] of the entire area of the country. It is even more difficult to assess the long-term impact of the war on the country's tourism potential, because while the world will associate Ukraine with destruction and grief, the challenge will be to convince the international community of its safety and reliability for tourism and investment.

According to the Ministry of Environmental Protection and Natural Resources, according to preliminary estimates, as of March 1, 2022, the aggressor was conducting military operations on the territory of 900 objects of the natural reserve fund with an area of 12,406.6 square kilometers, which is about a third of the area of the natural reserve fund of Ukraine [11]. About 200 Emerald Network sites covering 2.9 million hectares are under threat of destruction. The Emerald Network is a network of protected areas created to conserve species and habitats that are in need of protection at the European level but are located in non-EU countries. These are habitats for thousands of species of plants and animals. These areas play an important role in protecting biodiversity and preserving the climate. The habitats of some rare and endemic species and habitats have been affected by the active hostilities, which threatens their existence, such as virgin, uncultivated steppes, chalk slopes in Donetsk region, coastal habitats in the southern regions, and marshes in the north. As a result of the hostilities, part of the forests in Luhansk, Donetsk, Zaporizhzhia and Kherson regions are currently under the control of the occupiers [11].

The fact that Ukraine is in a state of war presents new challenges for the development of tourism, which are complicated by a number of problems, namely: zones of occupation and active military operations are dangerous for tourists; loss of a significant part of the natural, historical and cultural potential of tourist areas; destruction of tourism infrastructure; decreasing savings for vacations; violation of logistics within Ukraine; departure of the working population abroad, etc [10].

Tourism in Ukraine is losing a very significant amount of finance. Firstly, this is due to a decrease in the total number of tourists. There were about 4 million foreign tourists in 2020, almost 90 thousand of them used the services of Ukrainian travel agencies. In 2022-2023, this figure decreased fourfold. The situation is quite similar with domestic tourism. Due to active hostilities, threats of missile strikes and mined tourist areas, 13 of 24 regions were left largely without tourism [12].

As of June 2023, the share of direct damage caused to the infrastructure of the spheres of culture, religion and tourism is $2.4 billion. In total, since the beginning of the war, at least 1,804 cultural sites, 348 religious buildings, 343 sports sites, and 164 tourism sites have been damaged or destroyed. Total indirect losses in the spheres of culture, tourism and sports as of June 2023 amount to $10.8 billion, of which $6.4 billion are culture and sports, $4.4 billion are tourism [12].

3.3. Recommendations for developing strategies based on sustainable development

3.3.1. STEEPLE analysis of the external environment. An important stage in the formation of a strategy is to determine the state of the external environment of the company's functioning. The STEEPLE analysis method allows one to describe the components of the external environment, have a positive and negative impact of these factors on the development of companies in the industry being studied, and determine the strength of this influence using expert advice. Table 1 shows the results of the STEEPLE analysis of factors influencing the activities of companies in the tourism sector. The analysis methodology involved the authors formulating the content and characteristics of individual subfactors and their subsequent assessment by market participants. The survey was conducted in November 2023 and included 33 respondents representing companies operating in the tourism and recreation sector. Research has shown that the greatest influence is exerted by economic factors of the external environment (table 1).

Table 1: Factors of the external environment according to the STEEPLE analysis matrix.

Group of factors	Manifestation of the factor	Nature of the influence	Strength of influence
Economical	Reduction in market capacity as a result of a significant number of the population (citizens) leaving abroad, changing priorities, falling solvency and general instability.	−	9.7
	Infrastructure in many regions has been destroyed and damaged: airports, roads, bridges, hotels and other recreational and tourism facilities.	−	8.0
	Many accommodation establishments were forced to close due to safety concerns, lack of demand, and technical reasons.	−	8.0
	The current situation has resulted in a change in the quality of tourist flows.	+	5.7
	Changes in tourist routes as a result of military operations, especially in border areas.	−	5.7
	Transformation of international business tourism into volunteer and solidarity tourism.	+	5.7
	Reorganization and change in business strategies of market participants.	+	7.3
	Development of the tourism potential of regions of Ukraine remote from the combat zone.	+	9.0
	Development of new forms of financing socially important and environmental projects.	+	6.3
Political	The hostilities have led to increased instability and security threats, which has influenced tourists' decisions to visit the country.	−	9.7
	Occupation and replacement of part of the territory of Ukraine, threats of missile attacks and airstrikes.	−	9.3

Continued on next page

Table 1 – continued from previous page

Group of factors	Manifestation of the factor	Nature of the influence	Strength of influence
Social	Boarding houses and hostels were used as temporary shelter for displaced people forced to leave their homes due to fighting.	+	6.3
	The war stimulated the development of domestic tourism in Ukraine. Numerous Ukrainians decided to visit and support the country during this difficult time.	+	7.7
	In some regions, tourism is also facing an outflow of personnel. Due to the difficult situation, employees are looking for work in safer areas or near the border.	–	6.0
	Development of cooperation with local authorities, partnerships at the regional level to better take into account the characteristics of the territory.	+	5.7
	Development of volunteerism, mutual support, civic consciousness, implementation of donation-based restoration projects, acquisition of social connections, improvement of the level of interaction between the state and citizens.	+	6.3
Technological	Development of virtual tourism in Ukraine. Inviting tourists to virtual excursions or online tours.	+	5.7
	Using digital tools to promote projects and services: extensive data analytics, geoanalytics, targeted advertising, development of online services, special services and applications.	+	5.0
Legal	Since the full-scale invasion, Ukraine has been subject to a wartime legal regime and associated risks, such as curfews, restrictions on visiting certain locations, filming bans, etc.	–	7.7
	The war stimulated the development of domestic tourism in Ukraine. Numerous Ukrainians decided to visit and support the country during this difficult time.	+	7.7
Ethical	The massive media campaign on the war in Ukraine is reflected in the image of the country.	–	5.3
	The ethics of competition acquires specific features: as a result of destruction, environmental disasters, and the loss of specialists, some travel companies disappeared from the market.	+–	5.0
Environmental	Changing the landscape of tourist sites. The military conflict led to the destruction, occupation or change of territorial affiliation of many popular tourist sites.	–	5.0

Continued on next page

Table 1 – continued from previous page

Group of factors	Manifestation of the factor	Nature of the influence	Strength of influence
	Direct harm to the environment caused by the physical destruction of objects, the appearance of additional garbage, emissions, etc.	–	6.3
	Growing environmental consciousness of tourists. They have become more aware of the environmental impact of their travel and are looking for ways to travel more sustainably.	+	6.7

The most influential economic factor of negative impact is the reduction in market capacity as a result of the departure of a significant number of the population (citizens) abroad, changes in priorities, a drop in solvency and general instability. In general, for the group of economic factors, the impact is estimated at 65.4 points. The overall influence of political factors is determined at 19 points, social – 32 points.

The generalized influence of macroenvironmental factors is presented in figure 1.

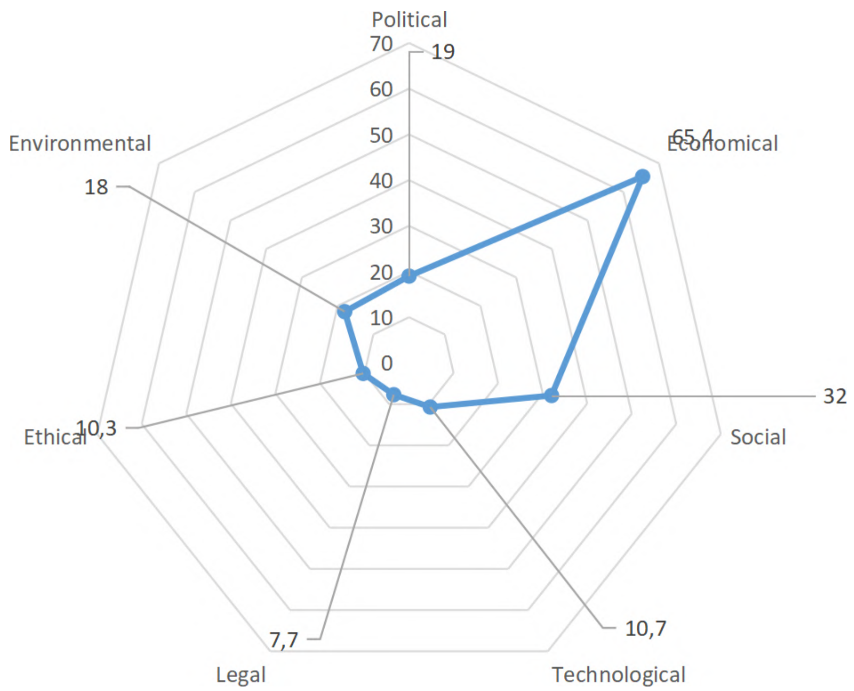

Figure 1. STEEPL analysis of marcoenviromental factors.

The resulting diagram shows the greatest influence on the activities of travel companies by economic, social, political and environmental factors. Accordingly, when forming a company's development strategy, they should be taken into account first.

3.3.2. Case analysis of successful practices in the field of tourism and recreation. In our study, we analyzed five tourism projects and described the unique experience of these companies in successfully operating during war.

The Potter's House is a family business run by Olha and Oleh Pavlik, which has been operating in the Ethnoselo cultural and tourist complex in Zaporizhzhia Oblast since 2015. They organize pottery masterclasses, welcome guests and conduct excursions. When the war broke out, Olha became the coordinator of the complex and provided shelter to 600 people fleeing the war from the Zaporizhzhia region. The Ethnoselo also helps people with disabilities by employing them and developing a park where young people recycle waste. There is a special swing for people in wheelchairs. At the beginning of the full-scale war, the Potter's House won a grant to support people with disabilities and developed the brand "Fitochai". The project involves people with disabilities collecting medicinal herbs, drying them, packaging them and selling them as tea from the Zaporizhzhia steppes. Now the Potter's House already has a small plantation and a greenhouse with medicinal plants. The highlight of the complex is the upcycling park, where garbage is recycled, and new items are made from used items. Most often, we work with beverage bottles and plastic sets, reducing them to make them easier to transport to collection points. This is also a social project involving people with disabilities. Since children in wheelchairs often came to the complex, we created a swing that a child can use to swing in a wheelchair [13].

When Oleg Pavlik returned home with a wound, it became clear how important rehabilitation is for the military. Therefore, it was decided to create a rehabilitation center to support military personnel and family members. Now Oleg Pavlik is interested in beekeeping, so the company plans to make a house for apitherapy, which will help military personnel after injury and veterans improve their emotional state [13].

The Shelter Project is the largest service aimed at finding free housing for Ukrainian refugees and internally displaced persons who suffered losses as a result of the full-scale war in Ukraine, both within the country and abroad. This government project is run on a volunteer basis and aims to promote connections between those in need of shelter and those who are willing and able to provide it. Participants in the program providing shelter to internally displaced persons (IDPs) receive compensation from the state, observing the main condition – to provide housing free of charge. As of January 2023, approximately 16 thousand advertisements are available on the web platform, of which 13 thousand are located in different regions of Ukraine, and 3 thousand are located abroad. The site offers translation of texts into 40 languages [14].

The Flat Planet [15] project is an innovative travel app whose main goal is to provide excursions around the world, particularly as an alternative to traditional tour guides. The concept of this startup, according to its founder Dmitry Dubilet, arose during the global COVID-19 pandemic, when restrictive measures were introduced, but it is noted that today this project is quite relevant for Ukrainian users. The app's audio content plays based on geographic coordinates and is available in different languages. Flat Planet also offers collaborations with cultural institutions and tour guides to produce content for visitors. In this case, identified users can determine whether to make the content paid or free, and the resulting income in the amount of 100 % is transferred to the museum. Flat Planet's plans include launching online excursions both within Ukraine and abroad.

The pandemic became a decisive factor for the launch of the tourist and recreational complex ULIS, founded by Ukrainian businessmen Evgeniy Lavrenyuk and Igor Farberov with the aim of providing ecological recreation in the middle of the forest, without any territory restrictions or fences. A special feature of this project is the absence of a single investor, allowing everyone who shares these values to join its development and become an investor.

During the full-scale war, the ULIS project consisted of 27 permanent houses in the Kyiv region. However, during the invasion of Russian troops in February 2022, the community where the houses are located found itself under occupation. Although properties are intact, confidence in investing in the region has dropped significantly. The founders of the ULIS project solved this issue by developing cabins – portable ecological houses that can be moved.

The main goal of the ULIS project is to develop environmental consciousness and support the society where it is implemented. Ten percent of the profits from ULIS are allocated to social initiatives within the local community, such as creating walking paths in the forest adjacent to the hotel location, repairing roads damaged during the occupation, financing social infrastructure and sorting waste. The founders of the ULIS project are also developing a social complex in the city of Khust in the Transcarpathian region, aimed at providing housing for internally displaced persons based on the reconstruction of a mothballed hotel building. The main goal of this project is to provide housing for internally displaced persons. When booking for a long time, hostel rooms were given at cost, but in the end they settled on a model in which housing is provided free of charge thanks to donations from philanthropists [16].

Volunteer tourism became an important component of tourism activities during the war. Public organizations (such as "Brave to Restore" and "BUR-Camp") are active participants in volunteer initiatives aimed at restoration and rehabilitation in de-occupied territories. The work is carried out through donations from Ukraine and abroad. Foreign volunteers also show interest in restoration, most of whom are visiting Ukraine for the first time [17].

The "BUR-Camp" project is a volunteer construction camp operating in different cities and villages of Ukraine, attracting young people from all over the country to volunteer. Here, volunteer participants repair houses for people who have lost their homes due to war, restore buildings damaged during shelling, and contribute to the creation or improvement of youth centers. In addition, volunteers can discover a new area, gain new knowledge, have fun and establish social connections [18].

In addition to the above-mentioned cases, it should also be noted that in Ukraine for a long time there have been various veterans' institutions, the basis of which is the reintegration of former military personnel into civilian life. However, with the beginning of the full-scale invasion, tourism institutions also became involved in this process. One of these projects was the city program for the socio-cultural rehabilitation of military personnel who are being treated or undergoing rehabilitation in medical institutions located on the territory of the Lviv city territorial community. The essence of the project is to organize excursions for veterans and injured military personnel. For the military, such measures are a way of adapting to civilian life after hostilities [19].

3.3.3. Strategic development toolkit. The study of successful practices and cases of domestic entrepreneurs made it possible to formulate a list of possible strategic decisions of tourism market participants, formed on the basis of the components of sustainable development (table 2).

Table 2 presents strategic decisions that travel companies can make depending on the situation in the business environment and taking into account the entrepreneurial potential of a particular travel company.

3.3.4. New formats of Ukrainian tourism that emerged or spread during the war. During the war, new functions arose in Ukraine: volunteer assistance and humanitarian support; "solidarity tourism", there has been a shift in emphasis – from entertainment to restoration; investing efforts in the integration of temporarily displaced persons, searching and developing common values

The inclusion of these types of services in the activities of tourism and recreation enterprises can bring additional value to consumers and thus increase the competitiveness of market participants. It should also be noted that the above services correlate with the ideology of sustainable development, since they are focused on ethical and social phenomena. Taking into account the needs of Ukrainian citizens for such new types of services in war conditions will allow us to develop public values of mutual support and respect for new requests from consumers (table 3).

Table 2. Strategic decisions (efforts) of tourism companies based on sustainable development.

Economic	Social	Environmental
• Job creation • Investing in security: availability of shelter, backup power sources, water, communications • Development of online services, virtual tourism, digital platforms, innovative applications • Entering international markets	• Creation of rehabilitation conditions for military personnel, members of their families and other citizens of Ukraine • Support for inclusion • Development of volunteer, memorial and solidarity tourism • Implementation of projects to preserve the cultural heritage of Ukraine	• Initiation of waste processing and disposal projects • Development of environmental consciousness, ecological and cultural tourism

Table 3. Types of services related to sustainable tourism.

No.	Types of services	Description
1	Memorial tourism	Documenting the consequences of Russia's armed aggression against Ukraine
2	Solidarity and volunteer tourism	Combination of tourism and volunteering to support and quickly restore de-occupied territories
3	Inclusive and recreational tourism	Providing tourist services for military personnel and their families, as well as other categories of people affected by hostilities
4	Ecological tourism in Ukraine	Preference for quiet places where you can enjoy nature and take a break from the bustle of the city

3.3.5. Elements of digital strategies. Analysis of the strategies of market participants showed that they widely use innovative digital tools, the main ones of which are presented in the table 4.

In general, tourism in Ukraine today is effectively adapting to new conditions. Despite the war, Ukrainians continue to discover its natural and cultural diversity.

The environmental consciousness of tourists has increased significantly. They have become more aware of the environmental impact of their travel and are looking for ways to travel more sustainably. Businesses offering environmentally friendly goods, services or eco-tours have become more popular and attractive to tourists.

4. Conclusions

In general, tourism is an important sector of the Ukrainian economy. It is a source of cash income and also actively contributes to the creation of new jobs. The tourism and hotel sectors are one of the most dynamic sectors of the Ukrainian economy, which, despite all the difficulties and challenges that Ukrainians have to face, continue to develop in an amazing way.

The Ukrainian tourism industry needs flexibility, creativity and cooperation of all participants in this market to ensure its stability and development. Tourism in Ukraine faces many obstacles,

Table 4. Digitalization tools in tourism.

No.	Digitalization tools	Description
1	Big Data analytics	Organizations use this technology in the areas of customer service, operational efficiency, and risk management.
2	Geoanalytics	For the successful development of this business, it is important to understand where the flows of tourists are coming from and where they are going. And geo-analytics is key to understanding trends.
3	Targeted travel offers	Thanks to modern technologies, tourism has received a number of effective tools to attract audiences. So, let's say, it is possible to offer services based on an analysis of preferences, habits, and experience.
4	Virtual tourism	Tourist requests for virtual excursions or online tournaments could be an alternative for those who are not ready to alienate the country especially.
5	Expansion of online services	Booking tours, hotels, purchasing tickets, obtaining a green card and health insurance, 24-hour support for tourists who need help. Providing MTPL and health insurance.
6	New travel apps	With excursions around the world, which are designed to become an alternative to guides. The audio content of the application is played in relation to geocoordinates and is available in many languages.
7	Online platforms	For volunteering, mutual assistance, finding partners, financing, information exchanges, popularizing projects.
8	Cultural Digitalization	Digitization and cataloging of museum and cultural exhibits to preserve cultural heritage and make online exhibitions available to the public.

but it has already demonstrated incredible resilience and enormous potential. And despite external and internal obstacles, the tourism business continues to look for ways to adapt and innovate. At the same time, the development of tourism in Ukraine requires joint efforts from the government, business and the public. Indeed, with the right approach and strategy, Ukraine will be able not only to restore its tourism potential, but also to strengthen it, attracting tourists from all over the world with its unique culture, nature and hospitality. Moreover, tourism in Ukraine after the war is predicted to become a promising niche for small and medium-sized businesses.

Abstract. The proposed concept of synthesizing the digital twin of a rock massif is based on the application of a developed method for determining stability coefficients. This method involves measuring the intensity of electromagnetic pulse (EMP) in rock formations and application of Intelligent AutoRegressive Moving Average with Bumpiness and Sparsity regularization (ARMABiS) system. ARMABiS is a modification of the Wang-Mendel fuzzy neural network designed for field processing of primary information regarding the transient process of EMP intensity before, during, and after a mass explosion in a quarry. The reconstruction of the spatial field of stability criteria for the rock massif along the quarry perimeter is also considered. The uniqueness of the method lies in the prior determination of the frequency range corresponding to the specified depth of the rock massif to assess the stability reserve coefficient. Explosions during rock blasting are used as an external influence on the massif. The method involves measuring the parameters of the transient process through electromagnetic pulse impulses during mass explosions and until the restoration of the background EMP level. The stability reserve coefficient of the massif is determined by a formula that considers the internal friction angle of rock formations, the maximum value of EMP induced by the explosion, and the duration of damping to the background EMP level

1. Introduction

Ensuring the stability of quarry slopes is one of the key challenges in mining engineering and geomechanics. Over the past decades, with the increase in depth and intensity of excavation in quarries, the importance of a reliable assessment of slope stability has significantly grown. A crucial indicator in this context is the safety factor of the rock mass, defined as the ratio of the actual strength of the rocks to the applied loads. The relevance of this problem is emphasized in the works of many scientists and researchers, such as Toderaş and Filatiev [1], where particular attention is given to the development and adaptation of stability assessment methods to the specific conditions of quarries in different regions.

Modern methods for assessing the stability of quarry slopes are based on a comprehensive approach to analyzing the geomechanical characteristics of rock formations and their spatial arrangements. As indicated by Adriansyah et al. [2], important factors in this process include the geological structure of the massif, the physico-mechanical properties of rocks, the presence, and characteristics of fractures, as well as hydrogeological conditions.

One of the most widespread and traditionally used approaches to stability assessment is the limit equilibrium method, detailed in [3]. This method allows for evaluating the conditions for potential slope failure based on the analysis of force equilibrium in the rock mass. However, as noted by [4], this method has its limitations, especially in conditions of complex geological settings.

In recent years, numerical methods such as the finite element method and the discrete element method have gained popularity. These methods, discussed in [5, 6] enable a more accurate and detailed analysis of the stress-strain state of rock formations, considering their heterogeneity and anisotropy. The assessment of quarry slope stability and the determination of the safety factor of the rock mass are fundamental tasks in mining engineering [7], aimed at ensuring the safety and efficiency of mining operations. The significance of these studies is justified by the potential risk of collapses, which can lead to significant economic losses and, more importantly, pose a threat to human life.

The safety factor, a key indicator in the assessment of the stability of rock masses, is determined as the ratio of the actual strength of the rock to the loads acting on it. This indicator helps experts assess the potential danger of slope failure and develop appropriate measures to reinforce quarry slopes. Major methods for slope stability assessment include the limit equilibrium method, finite element method, finite difference method, and discrete element method, each having its advantages and application areas depending on the specific conditions and characteristics of the quarry.

Currently, there is a known seismic-acoustic method for predicting massif stability, involving the registration and analysis of acoustic emission impulses. However, a drawback of this method is its limited application, as the use of piezoelectric geophones does not account for geomechanical processes accompanied by compression or extension of the rock mass, determining its deformation.

Applying the borehole methodology for determining the stability of rock mass sections requires drilling boreholes in the research areas, which is not always technically feasible [8]. This complicates the measurement of acoustic emission, considering which stability assessment of the massif is conducted.

The most technically relevant and results-oriented approach to the developed methodology is the method for determining the safety factor of the massif based on the magnitude and frequency of acoustic emission impulses. This method is based on the registration of acoustic emission impulses occurring in the investigated massif during the drilling process and determination. A disadvantage of monitoring acoustic emission impulses is that, in this method, it is possible to measure acoustic emission only in the immediate vicinity of the drilling site, negatively affecting the relevance of determining the safety factor reserve of the rock mass [9].

The aim of this research is to increase the accuracy of determining massif stability by measuring electromagnetic pulse impulses simultaneously over significant areas. This is achieved by considering the time of the transient process until the restoration of the natural EMP background, allowing for the consideration of stress concentration in rock mass locations with different types of heterogeneity, such as fractures, inclusions, etc.

2. Methodology

The goal is achieved in the developed methodology for determining the safety factor of rock mass stability, involving the measurement of EMP magnitudes in the massif of rocks arising from natural stresses in the massif and additional loads added to it. Explosions during ore blasting are used as additional loads to excite EMP in the massif. The time of EMP damping after ore blasting until returning to the background EMP level is measured, and the safety factor of massif stability can be determined by the formula [10]:

$$Y_c = \tan^2 \phi \left[\left(e^{-0.01m} + e^{-0.02m} + e^{-0.03m} \right) + \left(e^{-0.01t} + e^{-0.02t} + e^{-0.03t} \right) \right] \tag{1}$$

where ϕ is the internal friction angle of rock formations, degrees; m is the maximum EMP intensity induced by the explosion, impulses per second; t is the duration of damping to the background EMP level, seconds.

Measurements of acoustic emission intensity arising from natural stresses in the rock massif and additional loads are conducted in the rock mass. The stability of the massif is assessed based on the parameters of acoustic emission impulses, and the coefficient of friction of rock formations is preliminarily determined. Explosions during ore blasting are used as additional loads to excite EMP in the massif. The time of EMP damping after ore blasting until returning to the background EMP level is measured, and the safety factor of massif stability can be determined by the formula (1).

During the first stage, the background EMP value is measured before ore blasting. Then, measurements and recording of EMP magnitude are carried out directly during the explosion and throughout the transient process after the explosion of rock formations [11]. Simultaneously, the time from the moment of the explosion to the restoration of the natural EMP magnitude background is measured and recorded for depths of 300-400 meters in the frequency range of 0-1 kHz, and for depths up to 80 meters in the frequency range of 1-2 kHz.

In the initial period after the explosion, the EMP magnitude will be significantly higher than the natural background before the explosion. Over time, EMP will decrease and reach a constant value of the natural background. The natural EMP background after the explosion in a stable rock massif will be lower after some time, due to the redistribution of stress in the massif. In an unstable massif, EMP will generally be higher, as explosions in unstable rocks induce intensive stress redistribution in the massif.

Based on the conducted measurements, the maximum intensity of EMP (m) is obtained, and the time of damping of peak EMP values to the background level (t) is determined. The safety factor of rock mass stability is calculated using the formula:

$$\text{If } Y_c > 1, \text{ the massif is stable.}$$
$$\text{If } Y_c < 1, \text{ the massif is unstable.}$$

Thus, by combining new and known features, the reliability of determining massif stability is increased by the ability to measure electromagnetic pulse impulses simultaneously over large areas and by selecting the frequency range for different depths of the rock mass when determining the safety factor of stability.

3. Results and discussion

The chosen object of study is the Velyka Hleyuvatka deposit located in the Kryvyi Rih iron ore basin. In this basin, three structural-tectonic zones are distinguished: Southern, Saksahansky (Central), and Northern.

The Velyka Hleyuvatka deposit is associated with the Southern part of the Saksahansky zone and is located in its thrust part. The characteristic feature of the rocks of the Kryvyi Rih series, which constitute the deposit, is the monoclinal steep bedding with a western dip at an angle of 40-55º and a north-northeast strike at an angle of 20-25º.

The most significant tectonic disturbance in the Velyka Hleyuvatka deposit is the Saksahansky thrust, which extends throughout the Saksahansky belt and is represented by several zones of complexly foliated structure. The thrust plane dips at an angle ranging from 9º to 32º to the south-west on the north-east [12].

Within the deposit, several diagonal faults are traced, branching off from the Saksahansky thrust. These faults are of the strike-slip type with a variable azimuth ranging from 20-30º to 300-310º. The dip of displacement planes, typically, is to the east at an angle of 30-45º, but with depth, the dip angle increases to 65-80º.

In the southern part of the deposit, several sub-latitudinal faults of the strike and strike-slip type are observed. The dip of displacement planes is towards the east at an angle of 65-90º [13].

At the boundary of the quarry's sanitary protection zone (figure 1), the natural background EMP of the rock massif was measured at the first stage (points 1, 2). It amounted to m1 = 10-14 impulses per second. In the next stage, measurements were taken immediately after the explosion of the rock formations until the restoration of the natural background (figures 2, 3).

Figure 1. Layout of measuring equipment stations in the plan of the area adjacent to the quarry.

After the explosion on August 3, 2023, the maximum intensity of EMP was $m_2 = 140$ pulses per second. The natural background was restored after $T = 37.200$ seconds. The internal friction angle of the rocks in this area was $\phi = 41^\circ$. According to the expression [1], the stability reserve coefficient of the massif was determined, which equaled 0.241. The calculated stability reserve coefficient is less than one, indicating instability of the massif. The advantages of the developed

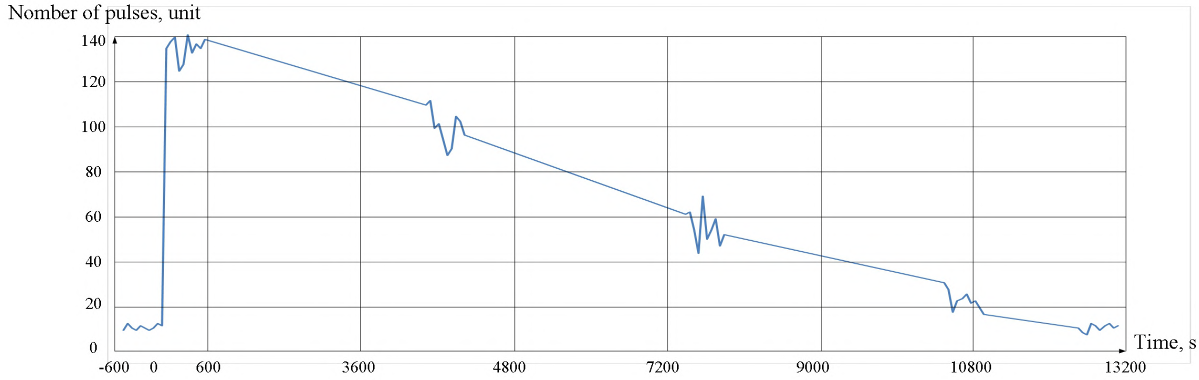

Figure 2. Results of EMP pulse measurements before the restoration of the normal EMP background at measurement point 1.

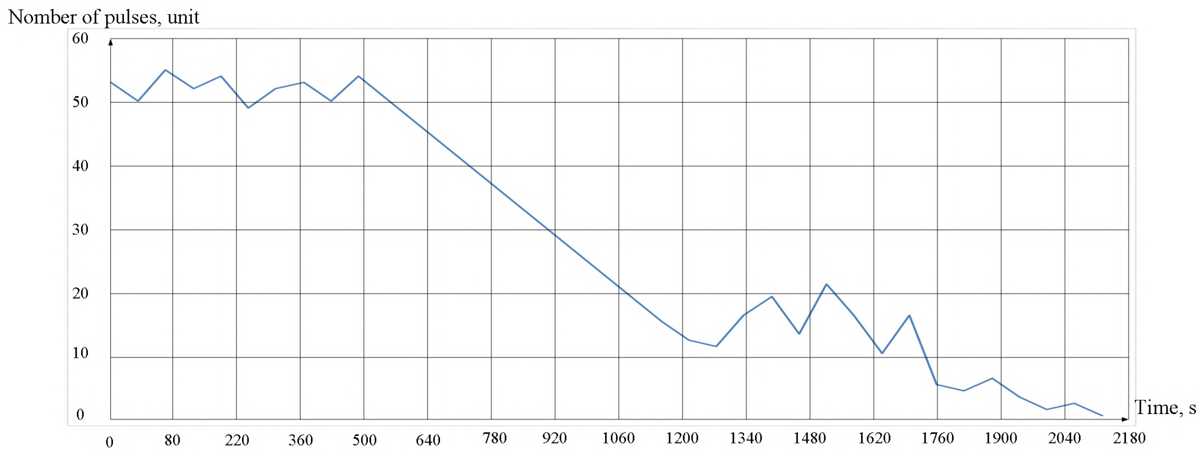

Figure 3. Results of EMP pulse measurements before the restoration of the normal EMP background at measurement point 2.

methodology lie in the increased reliability and accuracy of determining the stability reserve coefficient of rock mass areas. This allows for a more reliable assessment of the likelihood of sudden rock mass collapses, evaluation of the results of measures aimed at increasing the stability of massifs, and more accurate determination of mining operation regimes. This is crucial for ensuring safe working conditions and preventing injuries.

After the explosion on March 30, 2023, the maximum intensity of EMP was $m_2 = 55$ pulses per second. The natural background was restored after $T = 2.100$ seconds. The internal friction angle of the rocks in this area was $\phi = 45°$. According to the expression (1), the stability reserve coefficient of the massif was determined, which equaled 1.102. The calculated stability reserve coefficient is greater than one, indicating stability of the massif.

4. Mathematical foundation for the synthesis of the digital twin of a mining massif (ARMABiS) based on stability criteria

Considering that the measured Electromagnetic Pulses (EMPs) are derivatives of natural stresses in the massif and additional loads induced by mass explosions, the creation of a digital twin for a mining massif based on stability criteria involves conceptualizing the synthesis of this intelligent autoregressive structure with regularization. In this context, the overall adaptation process of the digital twin will be implemented as a function of several variables, in which one or more variables have predefined stability criteria for the mining massif.

In accordance with the foregoing, the dynamic model for the digital twin of a mining massif will employ the developed structure of the adaptive AutoRegressive Moving Average (ARMA) model with distributed lag [14] The model is dynamic, where criterion lags are utilized as regressors.

The general form of the model with distributed lag (ADL(p,q) – Autoregressive Distributed Lag) is presented below:

$$y_i = \alpha + \sum_{k=1}^{\rho} \beta_k Y_{i-k} + \sum_{j=0}^{q} \gamma_j X_{i-j} + \varepsilon \tag{2}$$

where α is the model constant; β is the autoregressive coefficient; y is the distributed lag coefficient; ε is the model error.

The first sum represents the AutoRegressive (AR) component in the form of a distributed lag of the criterion variable, and the second sum represents the distributed lag of the regressor. In the operator form, the ADL(p,q) model takes the following expression:

$$y_i = \alpha + Bf(B)y_i + g(B)x_i + \varepsilon \tag{3}$$

where $f(B)$ and $g(B)$ are polynomials.

The difference equation (3) characterizes autoregressive processes (AR(p) model with a distributed lag of the criterion parameter) with a moving average (MA(q) model with a distributed lag of the regressor), or ARMA processes. Let's express the discrete ARMA model with a distributed lag of order (0,q) (MA(q)) for the reference stability criterion (desired):

$$y^*[i] = \alpha + \sum_{j=0}^{q} \gamma_j x[i-j] + \varepsilon \tag{4}$$

At the same time, the final difference of the second order of the output coordinate will have the form:

$$\Delta^2 y[i] = 1 - 2B + B^2 = \mu(y^*[i] - 2y[i-1] + y[i-2]) \tag{5}$$

where μ is the adjustment speed.

By excluding the measured quantity (EMP) from the last equation, we obtain the discrete ADL(2,2) model characterizing the ARMA process:

$$y[i] = \mu y_0 x[i] + \mu y_1 x[i-1] + \mu y_2 x[i-2] + (1-\mu)2y(t-1) + (\mu - 1)y[i-2] + \mu\varepsilon \tag{6}$$

In order to imbue intelligent properties to the ADL models, an adaptation method for weight coefficients $y_0, y_1, y_2 ... y_n$ has been developed based on a modified gradient method for minimizing the quadratic functional. This method serves as the foundation for adjusting the weights of the Wang-Mendel fuzzy neural network [15].

$$J(\varepsilon_u) = 0.5\varepsilon_u^T \varepsilon_u \tag{7}$$

As there is no explicit dependency of the vector (as per components (6)) and the function $J(\varepsilon_u)$ on the weight coefficients $y_0..y_l$, the error ε_u in the adaptation procedure of the fuzzy neural network (5) is recalculated into generalized errors , which explicitly depend on the values of $y_0..y_l$. In this case, the adaptation of the weight coefficients of the digital twin of the rock mass (5) at the step $[i+1]$ is carried out according to the following pattern:

$$\gamma_j[i+1] = \gamma_j[i] - \lambda q^{(i-j)}[i]\Lambda^{(j)}[i] \tag{8}$$

where $q^{(i-j)}$ is the distributed lag of the regressor or the criterion parameter.

$$\Lambda^{(j)}[i] = \mathrm{col}\left(\frac{\partial J}{\partial q_1^{(i-j)}}, \ldots, \frac{\partial J}{\partial q_{n_j}^{(i-j)}}\right) = -\varepsilon_u[i] \tag{9}$$

Therefore,

$$\gamma_j[i] = \gamma_j[i-1] + \lambda \cdot \varepsilon_u[i] \cdot q[i-j-1] \quad \text{for } j = 0, 1, \ldots, \ell, \lambda > 0 \tag{10}$$

The adaptation error $\varepsilon_u[i]$ is defined as the difference between the measured stability coefficient and the actual output of the digital model (stability coefficient of the rock mass) at the i-th iteration.

It is necessary to note that the task of determining the lag structure of ADL(p,q) models (2) is solved according to the developed method [16] for estimating the value of the maximum lag, which is based on the analysis of finite differences of the transient function of the digital model of the rock mass.

5. Conclusion

As a result of industrial research conducted at the quarry of Joint-Stock Company Yuzhniy GOK dependencies of the frequency ranges of the Earth's electromagnetic field on corresponding depths of rock stability studies have been confirmed. Specifically, for depths of 300-400 m, the informative frequency range is 0-1 kHz, while for depths up to 80 m, it is the frequency range of 1-2 kHz. Scientific conclusions have experimentally confirmed that the intensity of electromagnetic pulses is derived from natural stresses in the array and external disturbing influences in the form of mass explosions from rock rebounds.

Additionally, it has been experimentally verified that the portrait (parameters) of the transient process for EMP from a mass explosion allows for the determination of the stability margin coefficient of the rock mass.

The results of the study on the possibility of synthesizing a digital twin of a rock mass based on the stability coefficient, through the development of an intelligent autoregressive system with regularization, which is a modification of the fuzzy neural network of Wang-Mendel, led to the following conclusions:

- the proposed method for constructing a digital twin of a rock mass allows solving problems related to determining the stability of quarry walls when EMP is measured at only one control point within the calculation sector;
- the proposed system operates under conditions of previously designed measurement sectors for EMP;
- the proposed synthesis method allows for the creation of digital models for quarries without a mathematical description of the distribution of the stability coefficient along the quarry walls;
- the structure and algorithm of operation of the developed system are oriented towards functioning in conditions of errors in determining the parameters of the EMP transient process, which are not subject to operational control;
- the formation of basic transformation laws of the model can be carried out taking into account the availability of a priori information;
- the process of primary adaptation of the parameters of the digital twin of the rock mass takes place over two periods of primary EMP measurements at each control point in the sector.

In the presence of significant errors in EMP measurements, the developed intelligent system requires 3-4 periods to stabilize an adequate level of system error based on the stability criterion throughout the rock massif. This can be explained by the functional features of fuzzy reasoning technology.

Abstract. Amber deposits are located within the Baltic-Dnipro province and cover vast land areas and coastal seas. In the regional dimension, the formation of amber deposits is determined by the climatic, facial and tectonic features, so it is important to link their occurrence to specific structures, especially on platform areas where morphostructures are linked to the tectonic structure. Amber deposits on the territory of Ukraine are considered to be non-commercial due to their low technical and economic indicators and limited geological exploration. The evaluation of amber deposits is proving to be an important task that affects the country's economy. The question of the origin of known placers, including intermediate collectors, remains unresolved. Numerous researchers studied amber placers, however, the question of the origin of placers, methods of their detection and evaluation is still relevant at the present stage, since the solution of this issue will largely allow to revise their resource potential. This article examines the prospects of utilising the ArcGIS geographic information system to analyse the geological and economic potential of amber resources in Ukraine. Geological and economic modelling using ArcGIS tools makes it possible to determine the industrial value of exploration of amber deposits. The calculation of the geological and economic indicators of the deposit is based on the most relevant data under current conditions.

1. Introduction

Amber placers belong to deposits of a very complex geological structure with variable quantitative or qualitative parameters of deposits and extremely uneven nested distribution of amber in terms of sediment thickness and area of their development [1]. Their boundaries are defined only on the basis of sampling data. Placers are controlled by palaeogeographical factors and the possibility of predicting and extrapolating the placer is complex.

On the territory of Ukraine, amber deposits are represented by placers associated with the Carpatian province and the sediments of the Prypiat and Dnipro basins of the Baltic-Dnipro Amber Province. Commercial amber deposits in the Prypiat basin are associated with sediments of coastal and marine lagoon-deltaic facies [1]. Marine lagoon-deltaic deposits, which are widespread, are the main geological and industrial type of fossil resin deposits not only in Ukraine, but also in the USA, Canada, Burma, etc.

Geological exploration of amber deposits is directed towards determining the material composition, quantity, quality and processing properties of amber, geological structure, hydrogeology, mining and other conditions of deposits, for further substantiation of engineering solutions on the method and system of extraction and the scheme of integrated processing of ore materials. The techno-economic study of amber deposits is aimed at establishing, in ever-increasing detail, the mining engineering, geographical-economic, socio-economic, economic and other conditions for the industrial development of the discovered ore deposits, suitable extraction methods and technological schemes of mining [2].

These tasks are successfully solved by GIS. As for the distribution of geological, mining and economic indicators for amber deposits, Polish researchers have developed considerable experience [5]. However, an important aspect of research here is the development of a geological and genetic model of the deposit, since amber is characterised by complex patterns of accumulation in traps due to its low density and ability to move in different ways: by saltation, floating on the water surface, in suspension, depending on many factors. That is why the patterns of amber placer formation differ from those of heavy minerals. Hence the complex distribution of amber concentrations in deposits.

According to Czuryłowicz and Sałaciński [3], amber is transported mainly in a suspended state, with only large pieces being subject to drag. In flowing aquatic environments, amber is deposited in places where the near-wall layer of the current is detached from the substrate, i.e. in various depressions in the riverbed over which the current is slowed down, for example, in depressions on the underside of ledges. In other words, we are dealing with geomorphological and sedimentary traps. Amber deposition in deltaic sediments occurs in the subaquatic part, within the sedimentary strata of the prodelta and adjacent embankments of distribution channels. Wave action, the nature of the currents, the distribution of wave divergence and convergence zones, and the shape of the coastline are decisive factors for the placement of amber deposits, so it is reasonable to analyse the directional sedimentary structures and the reconstruction of paleocurrents as important factors affecting amber deposition in the coastal zone.

Observations related to the experimental model of amber deposition in the coastal zone show a close substantive connection with the hypothesis that amber deposits should be associated not with areas of deltaic hollows, but with the extreme distal parts of the delta, the sediments of which were subsequently processed by wave action and became part of the barrier facies. The authors of the article emphasise that these regularities should be taken into account when setting up prospecting and appraisal works for amber. These ideas were further developed by Czuryłowicz [4]. The resource potential of the "Gurka Liubartovska"(Poland, Lublin region) deposit was illustrated by a map describing the probability that the percentage of amber will reach a value higher than the established threshold. Taking into account that the best way to exploit the deposit is through open pit mining, the analysis included layers describing the thickness of the overburden and a series of deposits developed at the stage of building the stratigraphic model. In papers by Nieć et al. [5, 6], models of amber deposits are presented and, on this basis, the choice of a method for their exploitation is proposed, taking into account mining and geological conditions.

Ukraine also has experience in developing models of amber deposits. Lustyuk, Dyakon and Rachkovsky [7] employs the method of continuous kriging, which means that the mass of each sample is assigned to the content of each sample, which ensures the minimum variance of the average content estimate. The mass of samples is determined by geostatistical methods, taking into account the geometric shapes, sizes and relative positioning of the samples of the block being evaluated. In general, the more distant the sample is from the centre of the block, the lower the weight assigned to it. The estimation of reserves by this method was based on the commercial implementation of the complex of mechanical and hydraulic testing of the Klesiv amber deposit in Rivne region.

The considered mathematical model allows to obtain an estimate of the average content in the blocks explored by the systems of excavation chambers, passed by the method of mechanohydraulic extraction. The considered mathematical model allows to obtain an estimate of the average content in blocks explored by systems of excavation chambers, passed by the method of mechanohydraulic extraction of large diameter wells (exploration wells), and also refines the estimates of average block content of useful components. This methodology allows to exclude systematic errors in the estimation of average grades in rich blocks, which are closely related to the problem of hurricane samples, which often arises in the exploration of amber deposits in Ukraine. The authors of the article present a flowchart of amber reserves estimation using the proposed method. This scheme allows establishing the upper and lower boundaries of the "sands" layer, as well as determining the volume of "peat" to be excavated and the volume of "sands" to be processed.

That is, an important aspect of model building is the representation of the space within which the parameters of the geological environment are studied. It should also be noted that spatial dependencies play a significant role in the construction of field models. Currently, a researcher has many possibilities for representing space. On the one hand, it is necessary to determine the dimensionality of the space (one-, two- or three-dimensional space), and on the other hand, to resolve the issue of representing the space in a continuous or discrete form. In the latter case, it can be a series of columns representing a certain topographic element.

Surfaces can also be described in an approximate discrete form using a series of prismatic rectangular sections of different heights. The heights of the prisms form a sequence of numbers, each of which is characterised by two coordinate values corresponding to a geographical location. Various options for the grid basis are given in [8]. The practical implementation of the space representation in a discrete form is the construction of block models, where blocks with different levels of mineral content are shown in the volume of the geological body. They are based on mathematical models and 3D modelling algorithms developed by various research centres: American, French, Norwegian, etc. There are many commercial software programs for this purpose, many of which have been used in petroleum geology [9]. An example of such modelling for nickel laterite deposits is given in [10]. Such models, in their computer implementation, make it possible to identify the most investment-attractive areas of deposits – areas of priority development. Mining parameters and geological and economic indicators are added to geological indicators.

Similar approaches have been used in Ukraine for ilmenite and other heavy minerals [11–13], as well as amber [14, 15]. However, the identification of investment-attractive sites requires the use and analysis of a set of geological and economic indicators. This approach was best developed on the example of the Torchynske ilmenite deposit, where an integral indicator was calculated to identify blocks with optimal economic and geological parameters, which is calculated as the difference between the notional value of the ilmenite concentrate and the cost of stripping and processing of the productive formation [12]. Such models have not been developed sufficiently for amber deposits.

In this article, we provide a method for the rapid assessment of geological and economic indicators of amber deposits (content and value of amber, costs of overburden excavation and extraction of "ore" with its subsequent processing, etc.) using integrated approaches to create technical and economic parameters of the deposit, in this case, using the ArcGIS geographic information system. Geological data helps determine the location of minerals and other geological aspects, while technical and economic parameters determine the efficiency of resource extraction. This interaction of geological data and technical and economic parameters of the deposit provides the necessary information to form a complete understanding of the subsoil potential, providing a basis for developing strategic management decisions.

The capabilities of ArcGIS geographic information system tools for geological research are virtually unlimited. With the acquisition of experience and an increase in the level of expertise, the functionality of the software environment and the possibilities of creating a working database are expanded. Understanding the principles of operation of various tools allows their effective combination to achieve new opportunities for data processing and interpretation.

The most important geological characteristics of any mineral deposit are a consequence of the process during the formation. Therefore, high-quality genetic modelling is the best basis for a complete geological definition of a mineral deposit, and with it safer conditions for the development of the deposit and greater profit in the overall complex. Many of the elements obtained through genetic modelling are directly applicable in the relevant submodels of geological and economic models. This is especially true for the metallogenic and geological submodels, and partially for the mining and technological, geo-environmental, and other submodels. The combination of genetic studies of conditions and pathways of formation is the basis on which the superstructure is given through the adjustment of some segments in the geological and economic model, especially for the technical and economy elements [16].

The object of modelling is the Zalissia amber deposit located in Sarny district of Rivne region (figure 1). In geostructural terms, the site is located within the northern part of the Volyn-Podolsk plate. According to the mineralogical zoning, it is located in the Dubrovytsia amber-bearing district of the Volodymyrets-Dubrovytsia amber-bearing zone of the western part of the Prypiat amber basin.

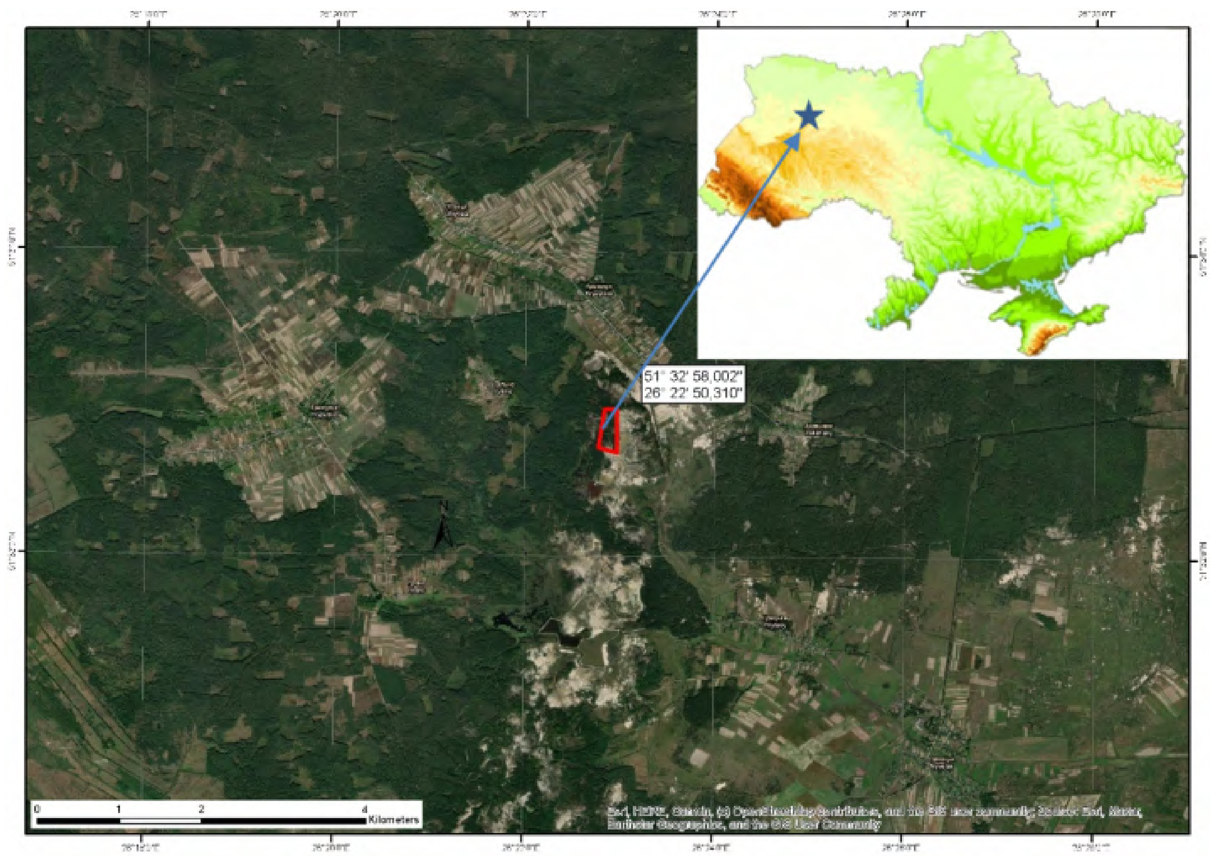

Figure 1. Location map of the Zalishke amber deposit, Sarny district, Rivne region.

According to the results of a detailed geological and economic evaluation, the site contained sediments of the Paleogene, Neogene and Quaternary systems in the borehole sections. The Paleogene system within the area is represented by the Obukhiv formation of the Eocene and Mezhyhirska formation of the Oligocene.

The amber-bearing sediments at the site are those of the Mezhyhirska Formation, which overlie the sands and siltstones of the Obukhiv Formation. The strata are represented by quartz sands, fine-medium grained with gravelly quartz grains and flakes of dark-coloured minerals. The sands are of medium to good coarseness, with rare grains of glauconite and small fragments of lignified wood. There are also occurrences of pyrite, pebbles of flints and quartz and crystalline rocks. In addition to sand and gravel deposits, the Mezhyhirska Formation is represented by nests of multi-coloured clays, dark grey-green, with mica flakes, inclusions and layers of lignified wood and some pieces of amber. Sedimentation of the Mezhyhirya Formation occurred in lagoonal-deltaic conditions.

2. Methodology

In this study, the method of modelling in a geographic information system using the ArcGIS computer program was applied. This programme is a system that allows collecting, organising, managing and analysing spatial information. The feature of using this method is the ability to work with vector and raster data that have a spatial reference to perform mathematical, statistical and spatial operations with data and to present them in the form of graphical depictions or data arrays.

During mining operations, technical and economic parameters are not stable (such as overburden excavation cost, processing cost, cost of raw materials) and even changes in the cost of fuel and lubricants can significantly affect the profitability of a deposit. This model allows us to make strategic decisions on the most efficient, productive, and rational development of a deposit.

The initial materials for the work were the data of exploration drilling of the Zalissia amber deposit, which underwent a detailed geological and economic evaluation. To build the model, the following parameters were set: boreholes (with geological parameters specified in the attribute plate: overburden thickness, productive rocks and amber content), corner points and the outline of the special permit boundaries.

3. Modelling process and results

The modelling study consisted of the following stages:

The first stage is the extrapolation of the edge boreholes beyond the boundaries of the special permit. This is done to ensure that the model fully covers the area of the site during interpolation.

The second stage is interpolation of the values of overburden thickness, productive rocks and amber content in the rock within the special permit. For this purpose, the Topo to Raster tool is used to create hydrologically correct models that are closer to the natural geological situation [17]. To interpolate the amber content, the Kriging tool was used (figure 2).

The key role in this model is played by the raster cell size. This parameter is crucial for this model because the raster cell size determines the area of the segment. Depending on the size of the field and the width of the working area, the cell size may vary. For example, in this model, the cell size is 20 m, so the cell area is 20x20=400 m^2.

The third stage is the display of economic data based on geological information using the Raster Calculator tool. During the geological and economic assessment of any stage, the following indicators are set for the deposit: the cost of removing 1 m^3 of overburden and processing 1 m^3 of amber-bearing ore. The following values for these indicators will be used for the model: the cost of overburden excavation – 25 UAH/m^3, the cost of amber-bearing rocks processing – 100 UAH/m^3.

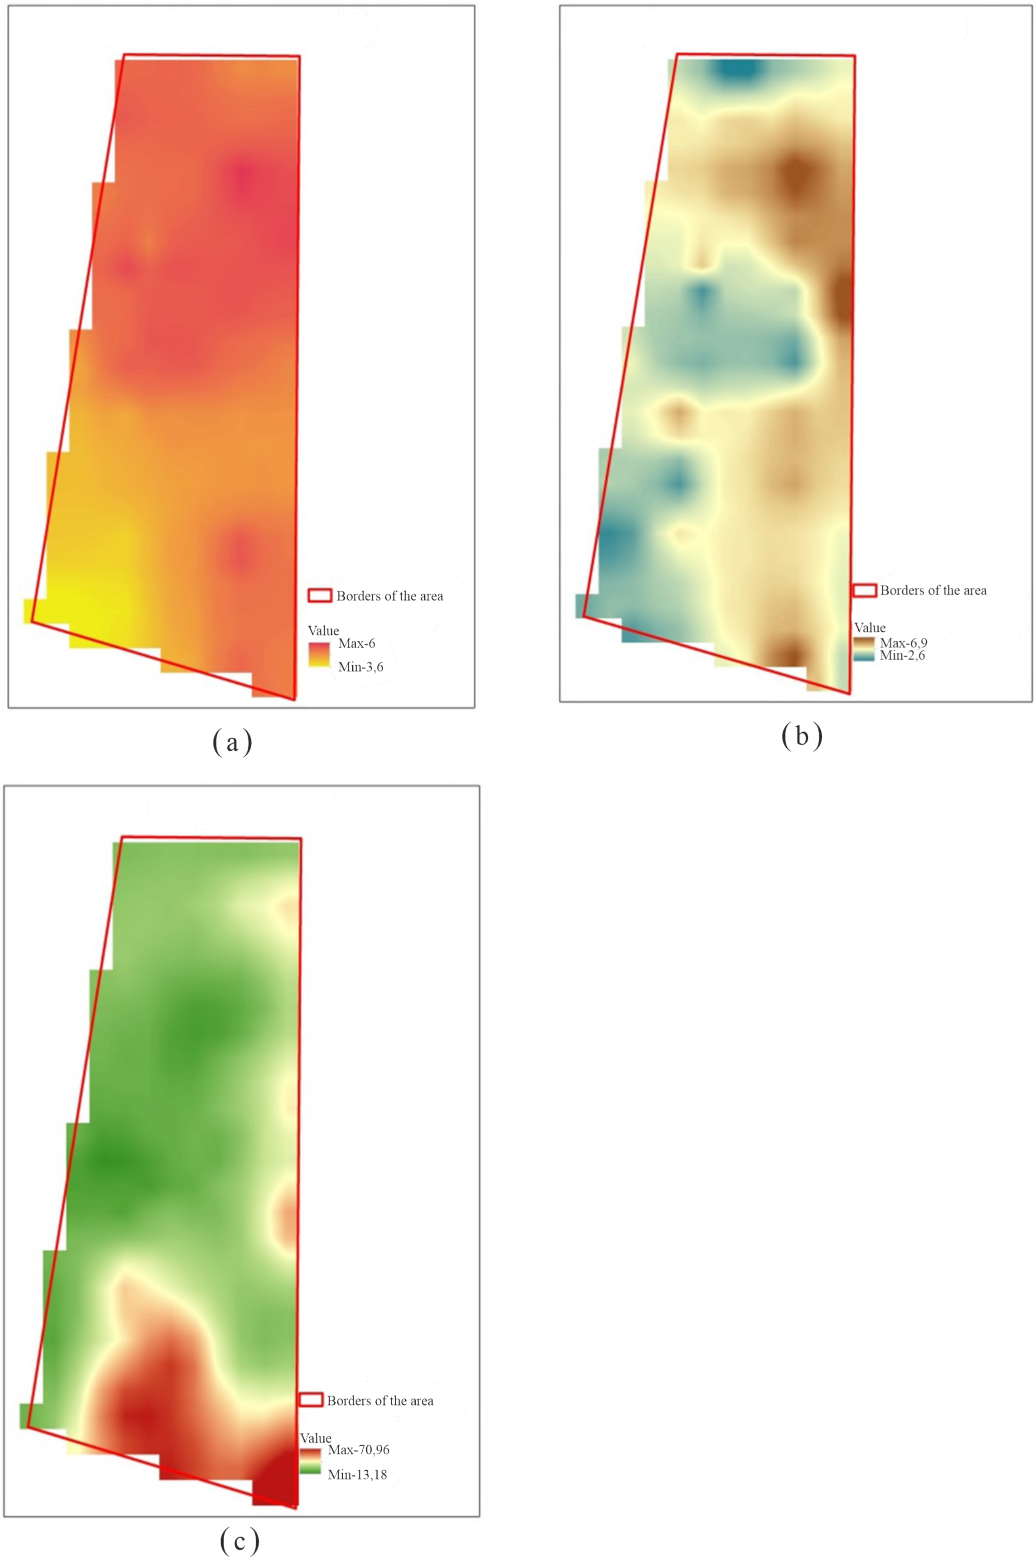

Figure 2. Interpolation of deposit parameters, (a) the thickness of the stripping rocks, (b) the thickness of productive rocks, (c) amber concentration.

In the Map algebra expression window, the following formulas were entered:

- For overburden – “Overburden thickness” (raster obtained by interpolation) x 25 (cost per unit of overburden excavation) x 400 (raster cell area)
- For ore deposit – “Ore deposit thickness” x 100 (cost per unit of ore processing) x 400 (raster cell area)
- To calculate the amount of amber in the subsoil -(“Ore deposit thickness” x “Amber content” x 400 (raster cell area)) / 1000 (to convert grams to kilograms)

For calculation the value of amber in the subsoil – (“Amount of amber in the subsoil” x 10735 (UAH, amber value) [18]. To display values in segments, the raster must be converted to points using the Raster to Point tool [19], which will create a point with raster attributes in the centre of each cell. The resulting maps are shown in figure 3.

The fourth step is to use the Raster Calculator tool to calculate the profitability of each segment based on the previous rasters. In the Map algebra expression window, we use the following formula: - “Cost of amber in the segment” – “Cost of overburden excavation” – “Cost of amber-bearing ore processing”. The resulting raster is a graphical representation of the financial results of the development of the deposit segments (figure 4).

Additionally, you can select the cells that will generate higher than average income, for example, for this model this value is 350453 UAH. The first year of operation of a mining company requires more capital investment, and therefore it is advisable to start development in those parts of the deposit that will bring the most profit at the initial stage. To identify such parts of the field, we will select all segments that are greater than or equal to the average. To do this, use the Create Fishnet tool to create a polygon network similar to the size of the raster cell and compare it with the raster. Select the necessary cell points using the Select by attributes tool and copy the selected points. Using the Select by location tool, select the polygons that correspond to the points and select them in the Switch selection attribute table, create a new column with an arbitrary name and assign a value of 1 to all selected polygons using the Field Calculator and display these polygons with a solid fill in the Display tab. The field segments highlighted in this way represent those areas that will generate above-average revenues and serve as a marker for identifying areas for priority commercial development.

The model is flexible, and when operating costs change, such as fuel prices or obtaining additional exploration data, the model is quickly recalculated to take into account such changes and their impact on future mining operations. Additionally, royalties, deforestation, stumpage, reclamation, etc. can be taken into account.

When modelling other deposits, segments with negative profitability may appear, which will serve as a warning to the subsoil user that it is unreasonable to develop part of the deposit or that it is necessary to change equipment or production methods.

4. Conclusions

The presented research and the developed method can be the basis for the development of an integrated geological and economic digital model and information and analytical support that can be used at all stages of research and development work on the study of amber content, resource development and objective assessment of mineral deposits, which is determined by the need to invest in further development. The main task is to determine whether the expected revenues from the operation of the deposit will be large enough to compensate for the costs and provide investors with an adequate level of profitability. Successful field development also has a significant impact on the overall economic and social development of the region and the country. The development of a new methodology for defining a mineral deposit is critical to attracting investment and developing regions, especially in depressed areas such as Polissya.

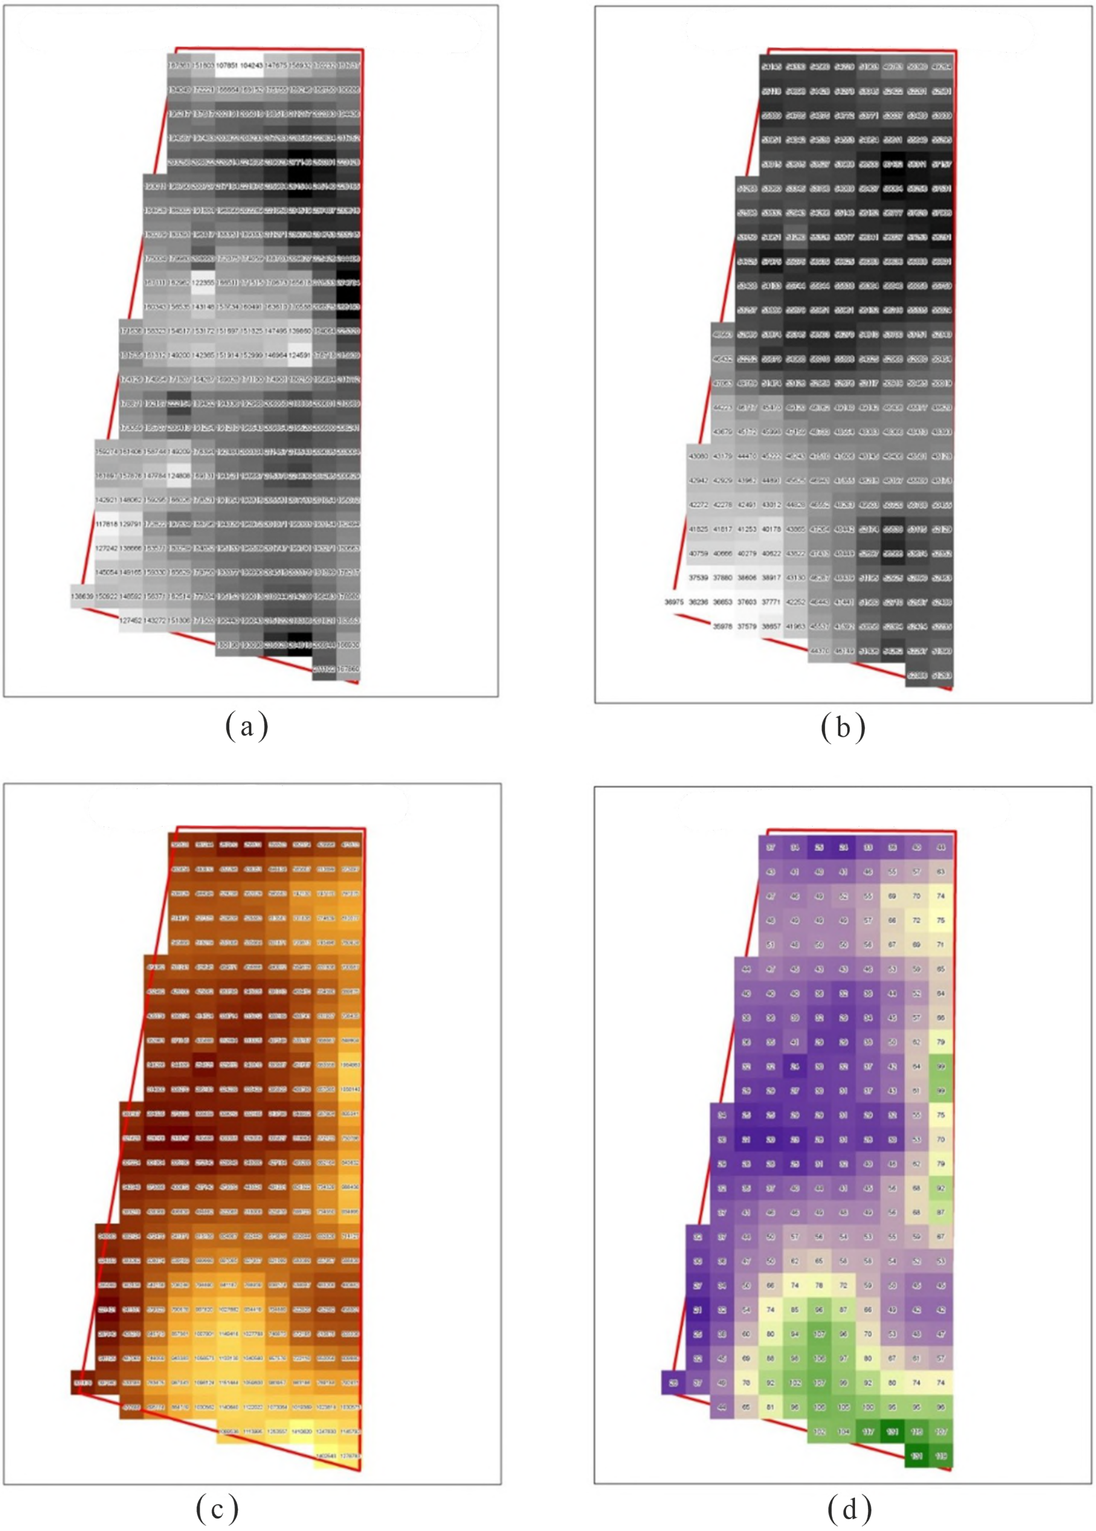

Figure 3. The resulting maps created using the Raster Calculator tool, (a) – costs of amber-bearing rock processing, (b) – costs of stripping operations, (c) – the cost of amber in the segment, (d) – amber weight in the segment (kg).

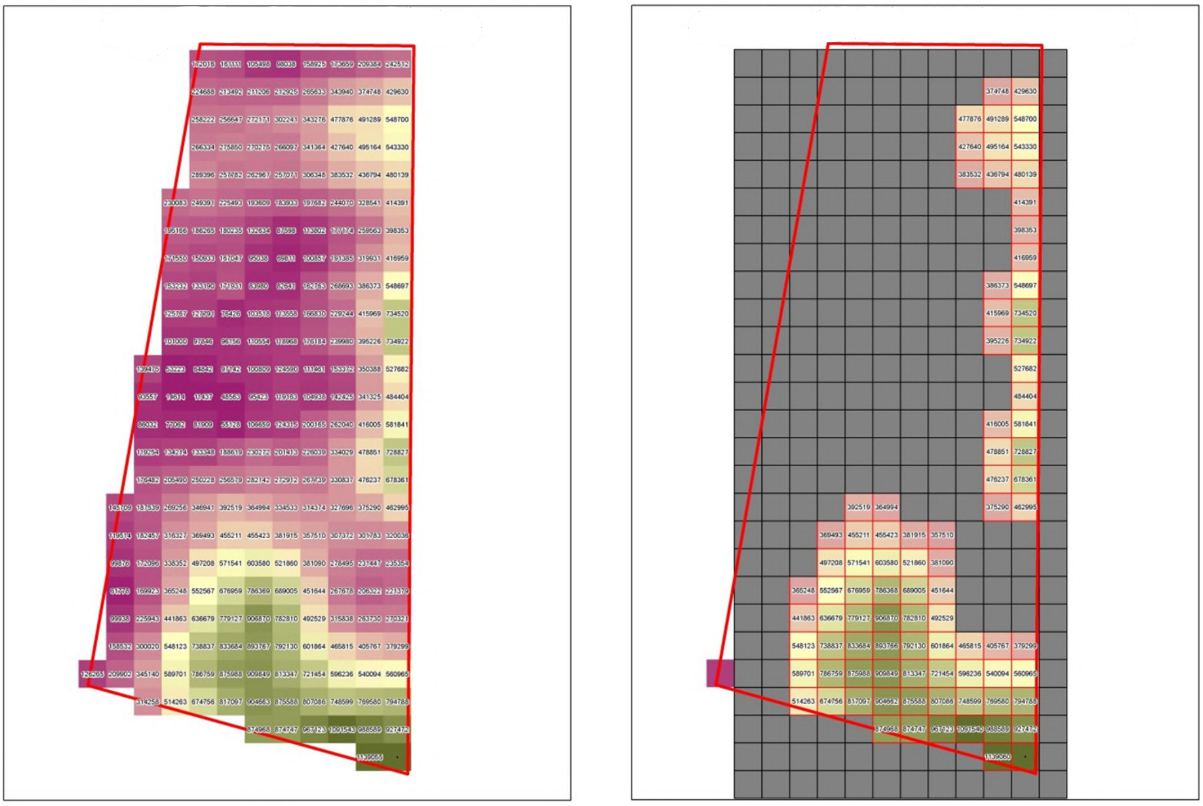

(a) (b)

Figure 4. Two-dimensional models of technical and economic indicators of field development, (a) – projected profit from the segment, (b) – segments with above-average profitability.

The study uses segment modeling – small (400 m^2) areas of one large deposit (for example, the area of the Zalissya deposit is 98,000 m^2), taking into account various attributes such as the cost of stripping, the cost of beneficiation, and the cost and quantity of raw materials in the subsoil. Based on these parameters, it is possible to predict the profitability/loss of each segment and determine the sequence of site development, risks and financial component of industrial development. The authors have highlighted the cells with segments with income that exceeds the average (for the Zalissia field, it is UAH 350,453). The selected segments with the highest income determine the areas of priority field development, which helps to maximize profits at the initial stage of development.

For a more efficient study of new deposits and assessment of their economic potential, the authors propose to use the tools of the ArcGIS program. This allows comparing the expected revenues from production with the corresponding expected costs of further exploration, development and production, objectively determining the suitability of the field for investment. ArcGIS provides the ability to store, process and analyze graphical and attribute data, which allows for a comprehensive assessment of the economic potential of a field. ArcGIS provides a comprehensive analysis of graphical and attribute data, helping to make management decisions.

The model of using simple mathematical methods in the design and geological and economic evaluation of an amber deposit emphasizes the accessibility and efficiency of the approach. The authors point out that such a model can be applied to other mineral deposits with simple mining conditions. This approach can be important for the sustainable economic and social development of regions and the country as a whole.

Abstract. In the research, the use of numerical analysis of the soil foundations stability losses of Dormition Cathedral, where in the interiors of the II tier northern part, deformations of structural elements have been recorded since 2016, probably caused by uneven settlement of the foundations due to overmoistening. The initial data were the results of constant monitoring of the technical condition of the building, engineering and geological investigations, etc. To determine (confirm) the deformation factors and forecast their activation stabilization, a numerical calculation of the stress-deformation state of the cathedral soil foundations was performed for soils in their natural state and water-saturated state. The calculations of the stress-strain state of the cathedral foundations and the determination of plastic deformation zones were done using the PLAXIS software complex. They showed an increase in deformations in its northeastern part, under the basement premises, in particular for the scenario of flooding of the underground part. According to calculations, the plastic deformations of the base soil and, as a result, the deformations of structural elements are still in the stage of incomplete stabilization in the northern part of the cathedral, in the area where the basement part is located. The deformations extend the entire pile field under the construction of the cathedral, but do not reach the extreme minimum values in 8 cm. The main factor in the activation of deformations is the overmoistening of the soil massif, the impact of blast waves is not excluded (confirmation of which requires vibration monitoring). The direction of improving protection management measures for Dormition Cathedral is proposed.

1. Introduction

The territory of the Kyiv Pechersk Lavra National Reserve, the architectural ensemble of which is included in the UNESCO World Heritage List (no. 527), occupies a significant area and covers various geomorphological elements of the Dnieper slopes in Kyiv. Taking into account the complexity of the relief and the engineering-geological structure of the territory (the presence of soils with different physical and mechanical properties at the base of the monuments, erosional dissection of the relief, high groundwater levels, etc.), hazardous geological processes have become widespread, significantly affecting the technical condition and preservation architecture [1, 2].

The stability and preservation of the Lavra's objects are ensured by a system of special retaining and water-regulating engineering protection structures, controlled by constant monitoring, operating since 2009. However, in the context of growing urbanization impacts – building development within protected zones, accidents on water-carrying mains, etc., in recent decades the development of deformation processes is recorded on the monuments of the Reserve.

One of the attractions of the ensemble of the Reserve is the Dormition Cathedral – a unique building of ancient Russian architecture, partially preserved in authentic condition, and rebuilt in the forms of the 18th century [3–5]. The building was undermined in 1942. The restoration of the Cathedral began after 1996, when a decree on priority measures to revive St. Michael's Golden-Domed and Dormition Cathedral was signed. In 1981, a program for the revival of the Dormition Cathedral was approved. The project was developed by the UkrNIIproektrestavratsiya Institute [6]. The authentic strip foundations were strengthened with micropiles. Interior finishing work has not yet been completed.

Today, in the interiors of the northern part of the second tier of the Cathedral, horizontal cracks are recorded on the walls along the perimeter, at a height of about 2 m (the installed beacons are intact); vertical structural cracks of spalling of the brick mass of pilaster masonry from the plane of the load-bearing wall, with an opening of up to 1.5 cm (control gypsum beacons have been replaced since 2016 every 1-1.5 years) (figure 1); structural cracks around the spring-loaded arch and under the vault with an opening of up to 0.5 cm at the junction of the northern aisle with the main volume of the cathedral.

On the walls of the basement there are numerous traces of old wetting as a result of repeated flooding (destruction of the paint and plaster layers, formation of efflorescence); remains of suffusion soil removal on the floor (figure 2).

The deterioration of the technical condition of the building is probably caused by uneven settlement of the foundations due to waterlogging due to repeated basement flooding. One of

Figure 1. Structural cracks in the spalling of pilasters from the supporting (bearing) pillar, northwestern part of the 2nd tier (Preobrazhensky chapel).

Figure 2. Traces of flooding and soaking in the basements (red line – flood level).

these floods occurred on February 8, 2014. Near the northern apse of the eastern facade of the Dormition Cathedral, a fire hydrant was torn off in the inspection well, and flooding of the basement was recorded with suffosion removal of soil [7]. The waterlogging of the northern wall of the basement was probably caused by emergency leaks from the water supply in October 2021 (a rise in groundwater levels was recorded in GSS-101) and August 2022 (inspection wells were flooded throughout the Cathedral Square).

Flooding of the basements occurred repeatedly as a result of surface runoff entering the cathedral due to an imperfect drainage system from the adjacent territory, in particular due to abnormal rainfall. Further infiltration of water into the soil mass led to waterlogging of the loess soil layer, its subsidence and, as a consequence, to uneven settlement of the foundations. Also, the compaction of the loess soils at the base was caused by an increase in groundwater levels as a result of emergency leaks from networks (2016, 2017, the rise in groundwater levels was about 1 m). The rupture of plaster control beacons and stickers confirms this assumption.

With the beginning of full-scale hostilities as a result of the armed aggression of the Russian Federation, new technogenic influences of a military nature appeared on the reserve's monuments – the spread of blast waves when air targets were fired or hit by missiles, which could manifest itself in the deterioration of their technical condition, conditions of preservation and operation.

Monitoring of architectural elements in the interior of the cathedral indicates a deterioration in the technical condition of the monument in its northern part. The formation of horizontal cracks and spalling of pilasters probably entails uneven settlement of foundation piles; different pile depths; the piles are based on soils with different physical and mechanical properties; the unfinished process of initial subsidence of foundation soils should continue according to the project – 20-30 years after restoration [6].

Deformations that occur in the structural elements of monuments as a result of the action of certain processes require additional detailed and comprehensive analysis and development of solutions (protection management) to eliminate impact factors, preservation taking, into account the uniqueness of objects. It should be noted that the uniqueness of the historical objects of the Lavra makes it impossible to apply standard (destructive) research methods and approaches to strengthening and restoration work to them.

The purpose of the work is to calculate the stress-strain state of the soil foundations of the Dormition Cathedral and determine zones of plastic deformation and strain growth to determine the factors of deformation of structural elements and predict their activation/stabilization shortly and develop optimal (effective) restoration measures.

2. Materials and methods

The scheme of engineering protection of the territory (scale 1:1000); the plan of the current state of the Reserve (scale 1:1000); data of engineering-geological surveys [3, 5–7], geodetic plan (scale 1:500); data of engineering and geological investigations, the results of constant monitoring of the technical condition of the building materials are used.

The authentic strip foundations of the Dormition Cathedral were strengthened with micropiles with a diameter of 15-20 cm, which were deepened by 16-17 m. The load from the cathedral is transferred to the clayey soils of the Novopetrovskaya suite and moraine deposits. The height of the temple reaches 51.7 m, the thickness of the walls is 120-170 cm [3, 5, 6].

The natural basis of the Assumption Cathedral, as well as other monuments on Cathedral Square, is a layer of Upper Quaternary eluvial and aeolian-deluvial undifferentiated sediments (Priluki, Uday, Vitovsky, Bug, Dofinovsky and Black Sea horizons). The geological structure [6] distinguishes 10 engineering geological elements (IGE). IGE-1 bulk soils with a thickness of 1.9-3.5 m lie on the surface. Further down the section:

- loess-like sandy loam IGE-2 with a thickness of 11-13 m;
- loess-like loam IGE-3 with a thickness of 2-3 m;
- sand layer with gravel IGE-4, thickness 1.5-2 m;
- fine quartz sand IGE-5;
- semi-solid loam (moraine) IGE-6;
- fine sand, medium density IGE-7;
- plastic sandy loam, with layers of sand IGE-8;
- hard, brown clay IGE-9.

The basis of the existing strip foundations of the Assumption Cathedral are loess-like sandy loams (IGE-2). The consistency of soils in their natural state is solid.

Compression tests using the one- and two-curve method show a slight tendency of soils to subsidence (relative subsidence ϵ_{sl} <0.01), which gave grounds to consider soils as non-subsidence when designing foundations [6].

Calculation of the stress-strain state of the soil foundations of the Dormition Cathedral and determination of zones of plastic deformation was carried out using a numerical method using

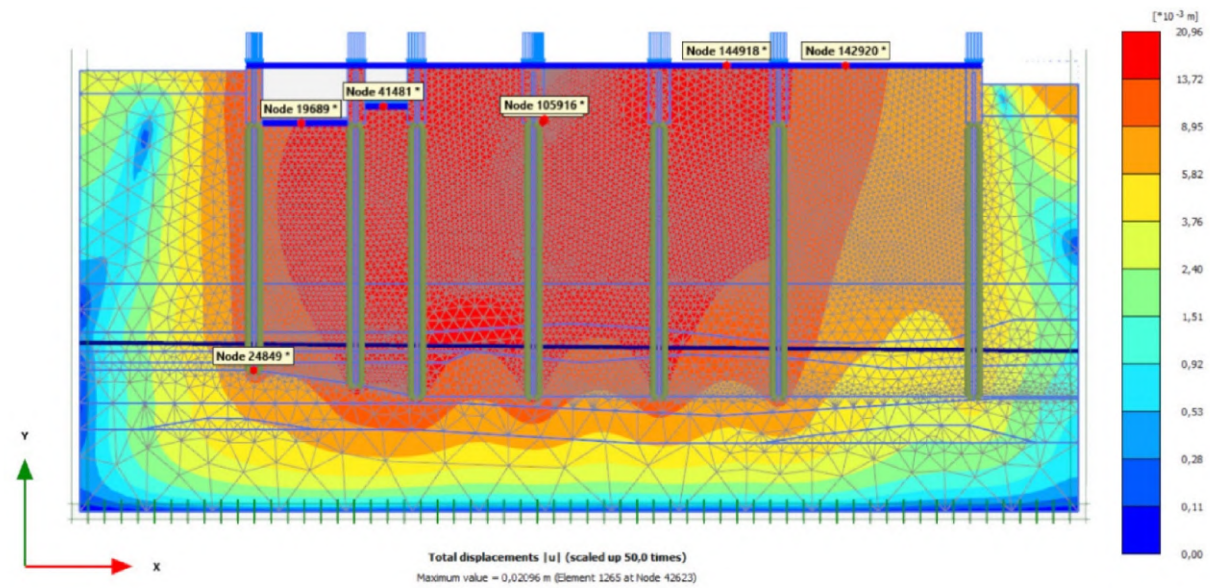
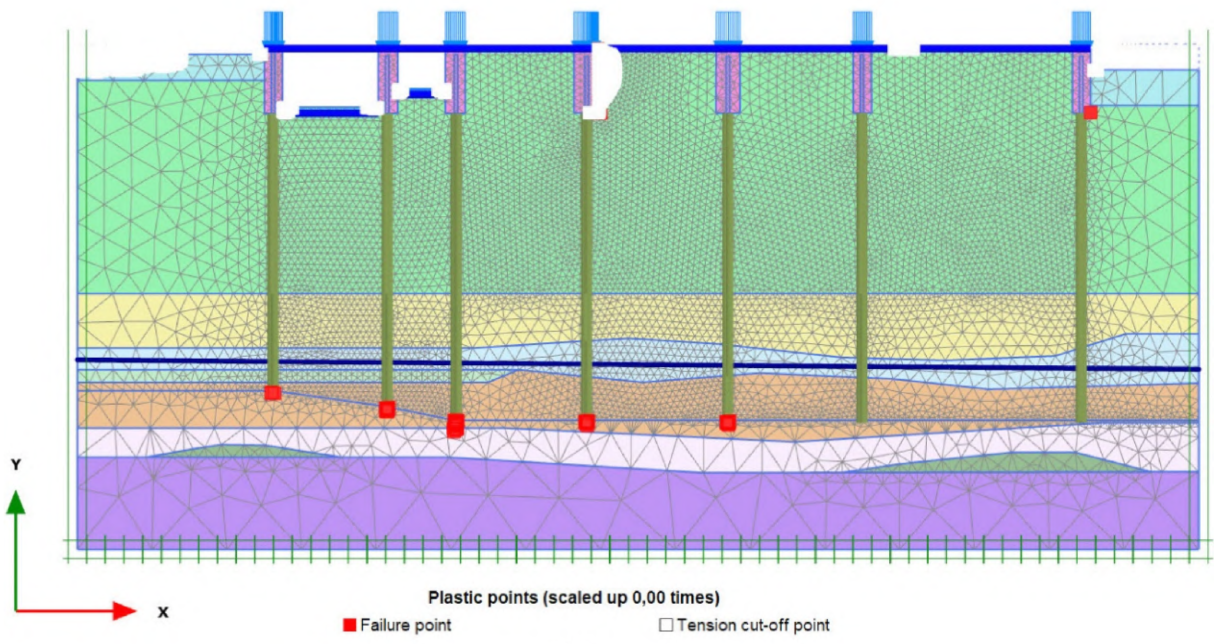
the finite element analysis package PLAXIS [8,9]. The physical and mechanical properties of the IGE isolated in the foundations of the cathedral are summarized in table 1. The Mohr-Coulomb model was applied for all IGEs.

The geological section diagram shown in figure 3 was used for the calculation. When constructing the model, slabs were used to specify the overlap of foundations, interfaces were used to model contact surfaces between piles and soils. The load on the foundations of the cathedral is specified by a distributed type of effort for slab and strip foundation types. The geometric model of soil clusters was imported in *.DXF format from a computer-aided design software environment, where it was created at an internal scale of 1:1000. The absolute elevation of the surface on the right corner of the model is 186.2 m, at the point (0.0; 0.0) – 159.8 m. Pore pressure and external water pressure are generated based on the groundwater level – 172.4 m.

A plane problem was considered. Using the finite element method, the computational domain



a)



b)

Figure 5. General deformations (a), formation of plastic zones (b).

was discretized into 63,690 15-nodal triangular elements of small and medium size. The nonlinear deformation process is modeled stepwise according to the load parameter.

The calculation was carried out in stages reflecting the sequence of events from the natural state, construction, load from the weight of the cathedral and up to the emergency situation – flooding of the basement on the left side (figure 3). The conditions of each stage were set by activating/deactivating the corresponding model elements (soil clusters, engineering structures, loads).

3. Results

At the first stage, the soil mass is under the influence of loads from its own weight and from groundwater. The calculation type used is Gravity loading. The second stage took into account the construction of foundations, first strip foundations, then micropiles. At the same time, the stress state in the soil mass, calculated at the first stage, was taken into account, and the deformations were set to zero, which corresponded to the natural state of the massif at the time of construction. The type of calculation at this stage and subsequent ones is Plastic. As a result, the stress state in the massif was obtained from the own weight of the soil, groundwater and the load from engineering structures, and the deformations were determined from the load of the structures.

At the third stage, the load from the cathedral on the strip foundation elements was introduced into the calculation – 294 kN/m^2.

The fourth stage is modeling the flooding situation of the basement by specifying a band-distributed load on the foundation slab from the weight of the water column (50 kN/m^2).

The displacements of the finite elements of the design scheme are taken into account only after the fourth stage (figure 4).

In figure 5a, the diagram of total displacements is shown. The maximum values acquire a value of 0.02096 m after the fourth stage. The deformations cover the entire pile field under the cathedral building, but do not reach the maximum minimum values – 8 cm by [10–15]. The

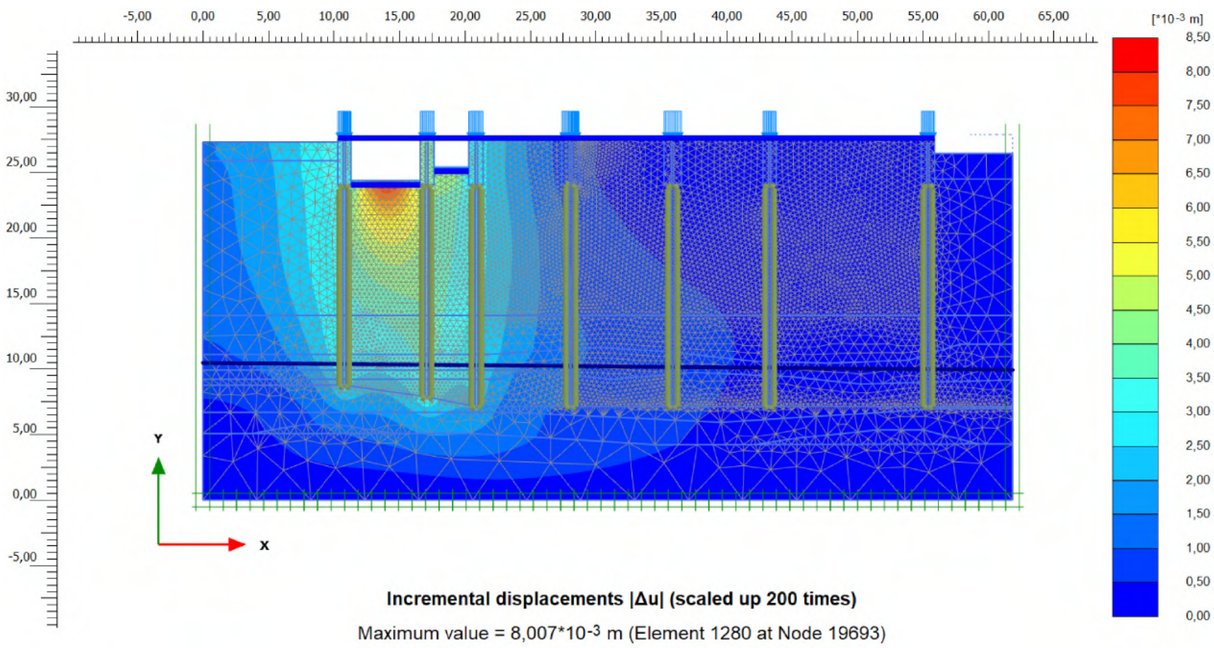


Figure 6. Increase in deformation after flooding of the cathedral basement part.

diagram of the formation of plastic zones in the massif is shown in figure 5b. Areas of possible displacements (red squares) are clearly visible. Clusters of white squares indicate plastic zones formed during tension.

Additional displacements are generated in a separate calculation step. General displacements have no physical significance, but additional displacements at the last stage (during flooding) provide an indication of the likely mechanism and locations of imbalance in the soil mass and, accordingly, places in the structural elements of the structure where cracks should be expected to appear.

Each stage of modeling shows an increase in deformations in the left part of the model under the basements of the cathedral, in particular after the flooding of the underground part, as shown in figure 6.

Curves in figure 7 shows all four simulation stages for control points. For each stage, the Mstage parameter varies from 0.0 to 1.0. A decrease in the slope of the curve in the last stage indicates an increase in the magnitude of plastic deformations. The calculation results show, however, that the soil mass remains stable at the end of the last stage.

The modeling carried out indicates that plastic deformations of the foundation soils are still in the stage of incomplete stabilization; the main risk of intensifying deformations at the present stage is waterlogging of the soil mass, both as a result of a natural rise in groundwater levels (overmoistening of soils at the base of the piles), and as a result of emergency leaks (waterlogging

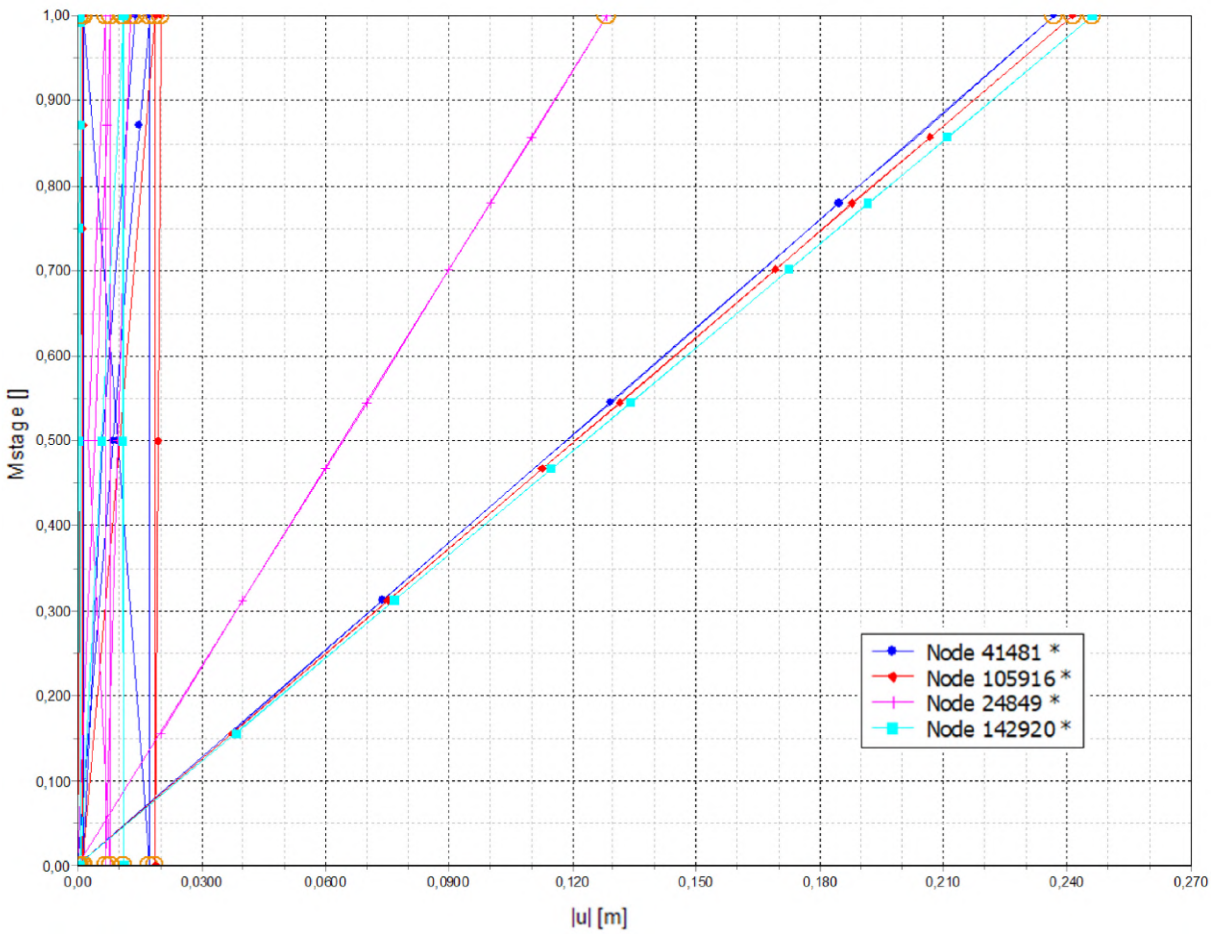

Figure 7. Load-displacement curve for observation points (Node).

of soils at the base of the cathedral's strip foundations).

4. Conclusions

Calculation of the stress-strain state of the soil foundations of the Dormition Cathedral and determination of zones of plastic deformation using the PLAXIS software package showed an increase in deformations in the northeastern part, under the basements, in particular for the scenario of flooding of the underground part. This is confirmed by field observations – it is in this place that deformations were recorded (vertical structural cracks of the brick mass of the pilaster masonry from the plane of the load-bearing wall, structural cracks around the spring arch and under the vault with an opening of up to 0.5 cm in the place of the cathedral).

Plastic deformations of foundation soils and, as a consequence, deformations of structural elements are still in the stage of incomplete stabilization; the main risk of intensification of deformations may be the processes of overmoistening of the soil mass, both as a result of a natural rise in groundwater levels and as a result of emergency leaks from networks, in incl. caused by damage to backbone networks as a result of military operations.

However, the calculation results show that at the end of the last stage, the soil mass remains stable and should provide the bearing capacity for the construction of the Cathedral. However, reliable operation and prevention of cracks and deformations in structural elements must be ensured by improving the management of protection measures according to research and norms [16–18].

Measures to minimize the impact of man-made leaks should be aimed at the following:

1. Reconstruction of water supply networks.
2. Current repairs with crack injection.
3. Modeling the stress-strain state of the structure.
4. Constant monitoring, incl. geophysical research.
5. Consolidation of loose soils.

Complex engineering and geological conditions caused by the presence of subsidence soils, excessive overmoistening of the soil base, which, among other things, causes the deterioration of the technical condition of unique structures, require the implementation of a comprehensive system of tools for instrumental "Structural Health Monitoring" (SHM) [19–21] of the objects of the Reserve into the existing monitoring system in the Reserve and the use methods of mathematical analysis of the received data streams. This will make it possible to track man-made, military (during missile attacks, UAVs) and other influences on structural changes in monument structures – the accumulation of microcracks, changes in the parameters of the spectral model of monument structures that cannot be reliably detected by visual surveys.

The preservation of the unique UNESCO World Heritage Sites of the Reserve requires further improvement of the comprehensive monitoring system (simultaneous observations of the microclimate of buildings, humidity of building materials, hazardous exogenous geological processes, etc.), using modern non-destructive monitoring methods and mathematical modeling. In particular, to determine the response to external influences, including those of a military nature, seismometric (vibrometric) equipment must be installed on the cathedral structures in its northern part. In order to determine (confirm the zones of soil decompression (plastic deformation) obtained by calculations (modeling), it is recommended to perform geophysical studies using electrical tomography).

Abstract. In addition to iron ore, the deposits of the Kryvyi Rih basin contain about 50 types of metallic and non-metallic minerals, which are simultaneously extracted from the subsoil during the exploitation of the deposits and can be used in the national economy of Ukraine. An important place among them is occupied by garnets, which are rock-forming minerals of some types of granitoids, gneisses and crystalline shales. Garnet-bearing shales are widely distributed within the Kryvyi Rih basin. In this paper, we investigated garnet-bearing shales of the Hannivske field from the Northern region of the Kryvyi Rih basin. Based on the results of detailed studies, the mineral composition was established, their varieties were identified, and mineralogical recommendations for further processing technology were given.

1. Introduction

In addition to iron ore, the deposits of the Kryvyi Rih basin contain about 50 types of metallic and non-metallic minerals, which are simultaneously extracted from the subsoil during the exploitation of the deposits and can be used in the national economy of Ukraine [1]. An important place among them is occupied by garnets, which are rock-forming minerals of some types of granitoids, gneisses and crystalline shales [2, 3].

The Hannivske ferruginous quartzite deposit is located in the Northern Iron Ore District of the Kryvyi Rih Basin and is currently being developed by Northern Mining and Processing Plant, which uses poor magnetite ores as its raw material base. The deposit is located within the East-Hannivska metamorphic rock band, which is a northern extension of the Saksagansk iron ore band. The structure of the East Hannivska band includes rocks of all world Paleoproterozoic and Cenozoic series of Kryvyi Rih [4]. Syngenetic and epigenetic processes of ore formation led to the formation of the productive and host strata of the deposit, mineral and chemical composition of ores and rocks [5]. Dynamothermal metamorphism, sodium metasomatism, hydrothermal phenomena, and hypergenesis in the process of transformations of primary sediments caused the presence of poor magnetite ores and a number of associated minerals in the productive and host strata of the deposit: abrasive garnet, muscovite, facing and paving stones, amphiboles and pyroxenes as ceramic raw materials, mineral dyes, artistic pigments, manifestations of collectible and industrial raw materials: dispersed goethite, dispersed hematite jasper, crystals and aggregates of quartz, chalcedony, goethite and other minerals, etc. [4, 6]. Among the minerals of the deposit, a special place is occupied by garnet-bearing shales, which can be used to produce both high-quality garnet concentrate and high-quality collecting raw materials [7–9]. Garnet-bearing shales occupy a special place among the deposit's minerals. Garnet of the Hannivske deposit is a rock-forming mineral of the zero (40-80 m thick) and first (50-200 m thick) shale horizons. The formation of garnet is caused by dynamothermal metamorphism of primary alumina-iron-siliceous sediments in the epidote-amphibolite facies [4, 10]. The multi-stage formation of the Saksahanske and host strata of the Hannivske deposit, the diversity and activity of syngenetic and epigenetic geological processes have led to a variety of petrographic and mineralogical composition of the productive and host strata of the deposit. There are several mineral types of garnet-bearing shales. The most common within the deposit are garnet-quartz-biotite, cummingtonite-garnet-quartz-biotite, and garnet-biotite-quartz-cummingtonite. The average garnet content in shales varies from 5-7 to 20-25 vol.% [11].

Within the mining allotment of the Hannivske deposit, the resources of garnet-bearing shales amount to about 1 billion tonnes.

The purpose of this work was to conduct detailed mineralogical studies of garnet-bearing shales, identify their mineral varieties, and provide mineralogical justification for the possibility of producing garnet concentrate from garnet-bearing shales during further technological tests.

2. Methodology

In the framework of this work, the authors selected 25 initial samples of garnet-bearing shales in the faces of the Hannivske quarry, and 26 initial samples from the lithic collections of the Kryvyi Rih National University were added to the selected samples. The garnet-bearing shale samples are equally represented by the zero and first shale horizons of the Saksagan Formation of the deposit. Transparent and polished grinds were made from the material of all selected samples.

The authors carried out detailed geological and mineralogical studies of the garnet-bearing shales of the Hannivske deposit. All mineralogical studies were carried out using macroscopic and microscopic methods. Macroscopic studies were carried out visually and with the help of a binocular microscope, microscopic studies – using serial petrographic and mineralogical microscopes. Microhardness studies were carried out using a PMT-3 microhardness tester. From 30 to 34 garnet individuals were analysed in samples from certain types of shale of the Hannivske deposit – three micro-pressures in each. A load of 100 g was used. The total number of microhardness measurements was 507. The studies focused on the mineral composition of garnet-bearing schists, morphology and anatomy of garnet individuals, their fracture, and the nature of inclusions of ore and nonmetallic minerals. Geological, mineralogical, petrographic, and statistical methods of geological data processing were applied.

As a result of the studies, the existing knowledge about the localisation of garnet-bearing shales was clarified. The garnet-bearing shales of the Hannivske deposit were mineralogically characterised and their mineral varieties were identified. Mineralogical recommendations for their further processing were provided.

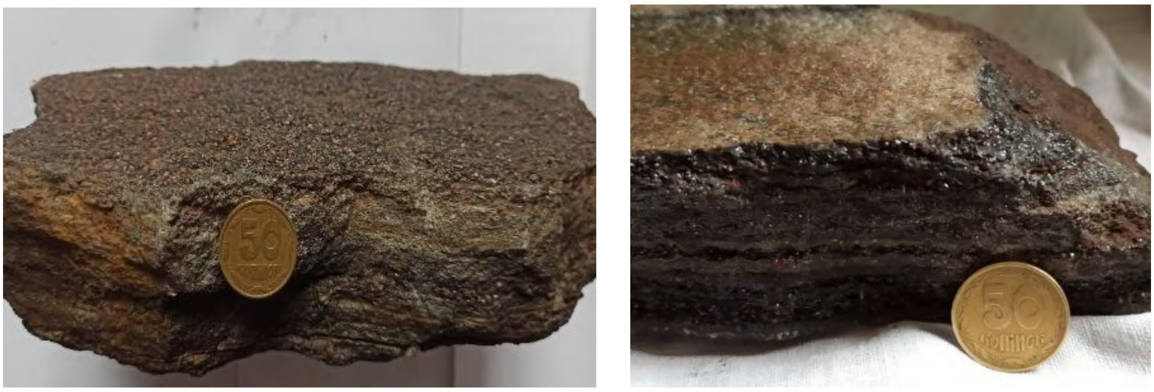
3. Results

Garnet-bearing shales are found in the shale horizons of the underlying strata of the Hannivske deposit, which are represented by the zero and first shale horizons. The basal position is occupied by the zero shale horizon. It, as well as the first shale horizon located above the section, is characterised by the most perfect mineralogical zonation among all shale horizons of the field. Its character is determined by the ratio of alumina content (increasing from the periphery of the horizon to its central part) and iron oxides (decreasing in the same direction) [5]. Thus, it can be concluded that the central zones of both (zero and first) shale horizons are composed of high-alumina shale, the intermediate zones – alumina-iron shale, and the peripheral zones – low-alumina, high-iron shale.

Garnet of the Hannivske deposit is a rock-forming mineral of the zero and first shale horizons. The most common rocks in the deposit are garnet-quartz-biotite, cummingtonite-garnet-quartz-biotite, and biotite-garnet-quartz-cummingtonite. The average garnet content in the shales varies from 5-7 to 20-25 vol.%.

Detailed mineralogical studies of the composition, structure, texture, morphology and anatomy of garnet individuals, their fracturing, and the nature of inclusions of ore and nonore minerals in garnet-bearing schists were carried out by the authors.

The rock texture of garnet-bearing schists is schistose, schistose-laminated, layered, and disseminated. The most common textures for garnet-bearing shales are shale and shale-laminated (figure 1).



(*a*) (*b*)

Figure 1. The most common textures of the original samples of garnet-bearing shales of the Hannivske field: (*a*) shale (*b*) shale-laminated texture.

Rock structure: granulopodoblast, porphyroblast. Based on the results of detailed microscopic studies of the initial samples, their quantitative mineralogical calculations and taking into account the results of previous studies, the authors identified five mineral varieties of garnet-bearing shales of the Hannivske field:

- type 1 – staurolite-biotite-quartz-muscovite shales with garnet;
- type 2 – garnet-muscovite-quartz-biotite shales;
- type 3 – garnet-quartz-biotite shales;
- type 4 – cummingtonite-garnet-quartz-biotite shales;
- type 5 – garnet-quartz-biotite-cummingtonite.

The results of determining their average mineral composition are shown in (table 1).

The data shows that the highest garnet content is characteristic of mineral type 4 (cumingtonite-garnet-quartz-biotite shale), with a garnet content of 18.23 vol.% in rocks of this type. The lowest garnet content is observed in the composition of type 1 (staurolite-biotite-quartz-muscovite schist with garnet), the average garnet content in this type does not exceed 1.35 vol.%. For mineral type 5 (garnet-quartz-biotite-cummingtonite schist), the garnet content is also significantly increased and amounts to 12.26 vol.%. For mineral types 2 and 3 (garnet-muscovite-quartz-biotite schist and garnet-quartz-biotite schist), the average garnet content is 5.45 and 9.86 vol.%, respectively.

Table 1. Average mineral composition of mineral varieties of garnet-bearing shales of the Hannivske deposit.

Note: mineral varieties type 1 – 9 samples; type 2 – 11 samples; type 3 – 12 samples; type 4 – 10 samples; type 5 – 9 samples.

Due to the fact that garnet-bearing shales of the Hannivske deposit are considered as a promising raw material for the production of garnet concentrate, the authors conducted mineralogical studies to investigate in detail the morphology and anatomy of garnet individuals, the nature of inclusions of ore and nonore minerals in their composition, and the fracture of garnet.

Crystallomorphological studies of garnets from the initial samples allowed the authors to identify two main habit forms of garnet crystals: tetragon-trioctahedron {211} and rhombododecahedron {110}. No other forms were found during mineralogical studies.

The habit forms for garnet crystals of different sizes were also determined. Figure 2 shows the frequency of occurrence of habitual forms of garnet individuals of the Hannivske deposit depending on their size.

According to the data obtained, it can be said that the process of crystal growth was accompanied by a gradual evolution of their shapes from rhombododecahedron to tetragon-trioctahedron. This can be explained by the accelerated growth of the rhombododecahedron faces and the associated gradual degeneration of the vertices.

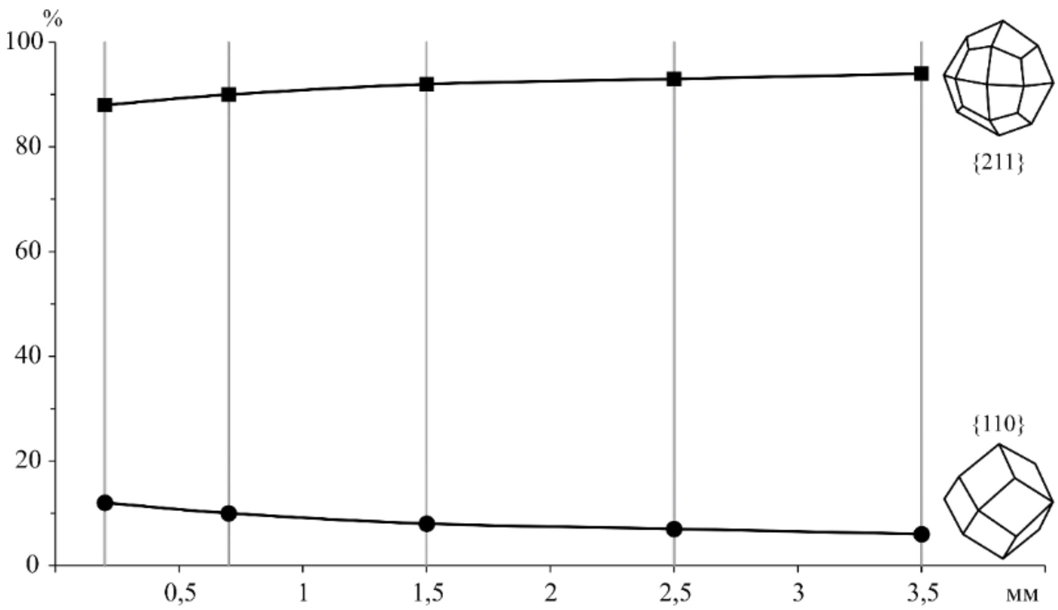

Figure 2. Occurrence of habitus forms of garnet crystals of the Hannivske deposit depending on their size.

The combination of the rhombododecahedron and tetragon-trioctahedron shapes gives garnet crystals an isometric appearance that is close to spherical. During mineralogical observations, considerable attention was also paid to the correctness (idiomorphism) of the shape of garnet individuals. It was found that the shape of garnet grains in the studied initial samples is diverse. Most often, garnet crystals are found in the isometric form of hypidiomorphic (figure 3a, b), xenomorphic with rounded outlines (figure 3c) and xenomorphic with "torn" edges ((figure 3d).

Correct habitual forms are typical for garnet crystals whose size does not exceed 2.5-3.0 mm. With the increase in the size of crystals, distortion of their shapes is observed, as well as the appearance of complex fusions with individuals and aggregates of cummingtonite, biotite, and quartz. Thus, the increase in the size of garnet crystals is accompanied by a decrease in their perfection, which will significantly impair the enrichment of garnet-bearing shales.

The crystals of the main rock-forming minerals (cummingtonite, biotite, quartz) in the shale have completely opposite shapes – cummingtonite is characterised by a columnar appearance, muscovite and biotite by a lamellar appearance, quartz most often forms irregularly shaped xenomorphic formations in the main fabric of the shale.

Individuals of garnet from the Hanna deposit are characterised by a predominant crystal size of 1-2 to 5-10 (sometimes 15-20) mm. The authors have measured the average size of garnet individuals for all the identified mineral varieties of garnet-bearing shales. The measurements were made in transparent and polished grinds and cuts of the original samples using an eyepiece micrometer with a ruler. The average value of the determinations was taken as the mean value crystals in the rock of each mineral type. The results of the determinations are shown in (table 2).

It was found that the average size of garnet crystals naturally increases from staurolite-muscovite-quartz-biotite shales (mineral type 1), which occupy a central position in the shale horizon, with the average size of garnet individuals in shales of this type being 0.92 mm, to garnet-quartz-biotite-cummingtonite (mineral type 5), which are located in the peripheral parts of the shale horizons. The average size of garnet crystals in them is 3-4 times higher than the average size of garnet crystals from the central parts of shale horizons and reaches 3.68 mm. This is due to an increase in the activity of metamorphogenic mineral formation processes

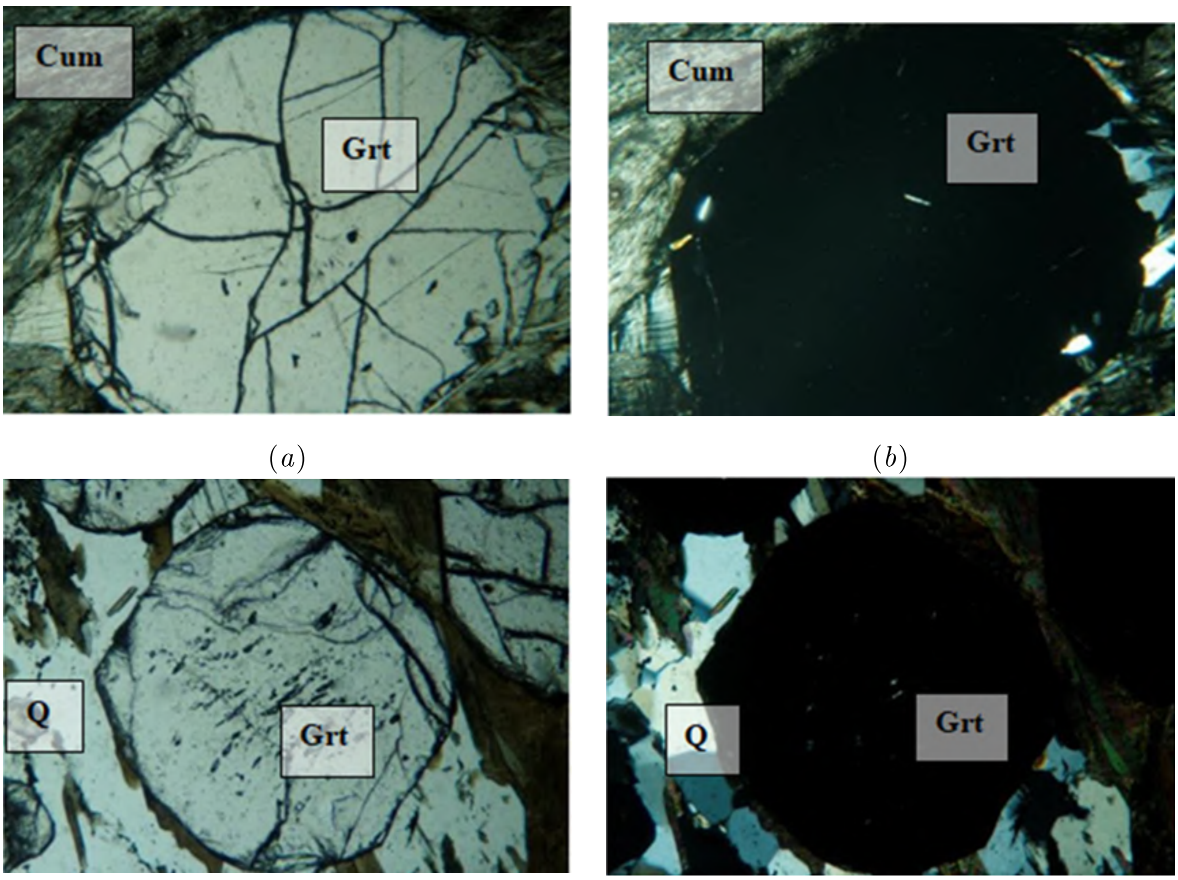
from the centre of the shale horizon to the periphery (its contact with the ferruginous horizon). In the parts of the shale horizon in contact with the ferruginous horizon, metamorphism was accompanied by an active exchange phenomenon – bimetasomatism [4, 5], which contributed to the growth of large garnet crystals. For cummingtonite-garnet-quartz-biotite and garnet-quartz-biotite-cummingtonite schists located in the contact zones, large (15-20 mm) xenomorphic fractured crystals are often found, which most often form granoblast aggregates.

Differentiation of garnet individuals by size is observed in shale layers of different mineral composition. Microscopic studies have also shown that quartz layers are characterised by much smaller garnet crystals than the adjacent biotite and muscovite-biotite layers. This is due to different growth kinetics of garnet crystals. In the apopiskovik or apoaleurolytic quartz layers, the growth of garnet crystals was difficult compared to the apopelitic silicate layers, within which the nutrient solutions and mineral formation conditions were more optimal for garnet crystals. This tendency is observed for all the identified mineral varieties of garnet-bearing shales of the Hannivske deposit.

The composition of mineral aggregates surrounding garnet individuals will have a different impact on the further processing technology of garnet-bearing shales of the Hanna deposit [7]]. Based on the results of detailed microscopic determinations, it was found that the most common minerals surrounding garnets are biotite, cummingtonite, muscovite and quartz and their combinations (figure 4).

In the further processing technology, the environment of biotite and muscovite will be the most favourable due to the fact that garnet grains will be easily leached from the mica matrix



(*a*) (*b*)

(*c*) (*d*)

Figure 4. Inclusions of garnet individuals surrounded by various minerals from the garnet-bearing shales of the Gannisky deposit: transmitted light; without the analyser (*a, c*) and with the analyser (*b, d*); 35x magnification. Grt – garnet; Cum – cummingtonite; Q – quartz.

during crushing and grinding. In the environment of cummingtonite, garnet individuals are more difficult to remove. Fine-grained quartz aggregates will reliably retain garnet individuals during ore preparation operations.

Anatomy of garnet crystals. Microscopic examination of garnet-bearing shales from the Hannivske deposit in reflected and transmitted light revealed that garnet individuals have different levels of defectiveness (fracture). Along with whole, non-cracked crystals, the bulk of the crystals in the rock of all mineral varieties are cracked to some extent (figure 5). 23% of garnet individuals are non-cracked, 27.6% are slightly cracked, 14.0% are moderately cracked, 13.7% are heavily cracked and 21.7% are very heavily cracked. Thus, about 50% of garnet crystals are non-cracked and slightly cracked.

Microscopic studies also revealed that a significant number of garnet individuals contain small (0.01-0.25 mm in size) inclusions of ore and nonmetallic minerals. The ore minerals are most often represented by magnetite (figure 6), non-metallic quartz (figure 7), cummingtonite and biotite (figure 8).

Magnetite most often forms single xenomorphic inclusions 0.01-0.1 mm in size in the middle

of garnet individuals; quartz, similar to magnetite, occurs as separate inclusions, sometimes forming thin veins (figure 7c, d); biotite and cumingtonite – as personified individuals (figure 8). During mineralogical studies of garnet-bearing schists, it was found that in garnet individuals, the most common non-metallic inclusions are quartz. Some garnet individuals are found almost without inclusions of ore and nonmetallic minerals.

The colour of garnet grains depends on the fluctuations in the shade of individual garnet individuals in the range from black to pink, as well as on the inclusions of other minerals (polychrome and uniformity of colour) [9, 12]. The polychromaticity of individual garnet individuals in the garnet-bearing schists of the Hanna deposit is mainly due to inclusions of other minerals. As a result of macroscopic and microscopic studies of shales, it was found that black and dark green colour within individual garnet individuals is due to inclusions of

Figure 8. Inclusion of non-metallic minerals (biotite and cummingtonite) in garnet individuals from garnet-bearing shales of the Gannisky deposit; transmitted light; without analyser (*a, c*) and with analyser (*b, d*); 35x magnification. Grt – garnet; Cum – cummingtonite; Bt – biotite.

magnetite, biotite and cumingtonite. The identified individuals and quartz vein aggregates do not significantly affect the colour of garnet individuals.

According to the results of previous studies [10], the chemical composition of garnet was determined, which is similar in composition to almandine with impurities of pyrrhotite and spessartine minerals. The content of pyralspethite mineral (the total molecular content of almandine, pyrrhotite and spessartine) in garnet from the Hanna deposit varies from 87 mol% to 99 mol%. According to the technical specifications, the content of pyralspeth mineral should be at least 80-90%. Therefore, the garnets from the studied garnet-bearing shales significantly exceed this indicator.

The microhardness of garnets is an important characteristic that determines their technological application. Highly ferruginous garnets with a high proportion of almandine mineral, whose microhardness value is more than 1400 kgf/mm^2, are suitable as abrasive raw materials [13]. The microhardness values of garnet individuals from the studied shales range from 1477 to 1597 kgf/mm^2 (table 3). The highest values of microhardness were found for garnets of the fourth type of shale, and the lowest – for the first type.

Table 3. Average microhardness values of garnets from different shales of the Hannsvka deposit.

Mineral varieties of garnet-containing shales	Interval of values, kgf/mm^2	Average, kgf/mm^2
Type 1	1411-1496	1477
Type 2	1438-1507	1489
Type 3	1519-1592	1563
Type 4	1523-1617	1597
Type 5	1495-1527	1514

In terms of microhardness, the studied garnets meet the technical requirements for abrasive raw materials.

4. Conclusions

1. Garnet-bearing shales are part of the rocks of the first and zero shale horizons that underlie the productive iron ore strata of the Gannivske deposit. Garnet is similar in composition to almandine with impurities of pyrope, andradite, and spessartine minerals.
2. The garnet-bearing shales of the Gannivske deposit are considered as a possible promising raw material for the production of garnet concentrate.
3. In the early 80s of the twentieth century, the reserves of garnet-bearing shales within the project contour of the Hannivskyi open pit were estimated at 150 million tonnes, and currently the resources of garnet-bearing shales are about 1 billion tonnes.
4. The garnet-bearing shale horizons, which were metamorphosed in the epidote-amphibolite facies, are characterised by mineralogical zonation. There are several mineral varieties of garnet-bearing shales, the average garnet content in them varies from 1-2 to 15-25 vol.
5. Depending on the position in the horizon, garnet-bearing shales of the zero and first shale horizons contain garnet crystals that differ sharply in morphology and anatomy, composition, and properties.
6. The average size of garnet crystals naturally increases from staurolite-muscovite-quartz-biotite schist (mineral type 1), with the average size of garnet individuals being 0.92 mm, to garnet-quartz-biotite-cummingtonite schist (mineral type 5), with the average size of garnet crystals reaching 3.68 mm.
7. Crystallomorphological studies of garnets from the material of the initial samples allowed us to distinguish two main habit forms: tetragon-trioctahedron and rhombododecahedron. The tetragon-trioctahedron habit form prevails. The combination of the rhombododecahedron and tetragon-trioctahedron shapes gives garnet crystals an isometric appearance that is close to spherical. This should be taken into account when developing the technology for the production of pomegranate concentrate.
8. The crystals of the main rock-forming minerals (cumingtonite, biotite, quartz) in shale have completely opposite shapes – cumingtonite is characterised by a columnar appearance, muscovite and biotite by a lamellar appearance, quartz often forms irregular xenomorphic formations in the main shale fabric.
9. The majority of garnet individuals (77%) are fractured. Increased fracturing will cause crystals to be reworked during ore preparation operations and a significant part of garnet crystal fragments to become a fine-grained fraction. This factor will significantly impair the recoverability of shale and cause an increase in the content of the garnet component in the beneficiation waste.

10. The most common minerals surrounding garnet individuals are biotite, cummingtonite, muscovite and quartz. When developing a technology for the beneficiation of garnet-containing shales, it is necessary to provide for their removal from intermediate products.
11. Based on the results of detailed mineralogical studies, it is possible to predict the possibility of producing garnet concentrate from garnet-bearing shales. Technological indicators of beneficiation can be determined after special studies.
12. The study of pomegranate-bearing shales of the Hannivske deposit is due to the possibility of producing pomegranate concentrate. It is used in many industries due to its high hardness (7.5-8 Mohs), abrasiveness, density (4000-4500 kg/m3), physical and chemical homogeneity and stability, non-toxicity and inertness in a wide pH range, and the ability to split into particles with sharp cutting edges during grinding. The following applications are possible for garnet concentrate, which can be obtained from garnet-bearing shales of the Hannivske deposit
    – as an abrasive (powders, bars, skins, material for sandblasting surfaces);
    – for waterjet cutting of various materials;
    – as a powder coating;
    – as a material for water filtration;
13. In order to consider the possibility of introducing the processing of garnet shale during the development of the Hanna quarry in the north-eastern direction, the following can be recommended: detailed exploration of garnet shale deposits, calculation of their reserves, economic assessment of the feasibility of their extraction, obtaining a development permit, and conducting pre-project studies.

Further areas of research include technological studies of pomegranate concentrate extracted from the garnet-bearing shales of the Hannivske deposit in the Kryvyi Rih iron ore basin.

Abstract. Ukraine's amber industry requires expansion of its mineral resource base. The territory of the Prypiat amber basin (PAB) is considered to be the most promising for this purpose. Here, a prognosis and search system for amber (PSSA) has been created that is capable of solving current problems of the industry and its development on a scientific basis, including the concept of the amber-bearing formation (AF) and its practical implementation – the search for the amber-bearing objects (AOs) – traps of various genesis. Currently, it is believed that the main increase in amber production in the territory of the PAB will occur due to paleogeomorphological traps (PTs). This task is solved by the morphochronodynamic concept, the information and methodological basis of which is paleogeomorphology. The morphochronodynamic concept uses the methodology of systems theory, presents its own research method and determines the content of subject cartographic models that reflect the results of the research. These are maps of: paleogeomorphological cycles of development of the geomorphosystem of the time of the AF formation; statics and dynamics of its materialised space-time – the geomorpholithosphere. On their basis, the paleogeomorphological traps of the PAB territory were typified by rank and their general assessment was made to identify increased, primarily industrial, concentrations of amber. The first rank is the geomorpholithosphere of the time of the AF formation, the second rank is its structural elements and, at the same time, forecasting and prospecting units – historically-dynamic basin geomorphosystems. The third rank includes morpholithohorizons of the geomorpholithosphere (elements of its vertical structure) and morpholithocomplexes (elements of its horizontal structure) that are promising for amber deposits. A comprehensive analysis of paleogeomorphological maps of the cycles of geomorphosystem development and formation of the AF allows to distinguish the fourth and fifth ranked PTs in the territory of the PAB. The fourth rank includes some forms of palaeo-relief of perspective cycles (ancient valleys, coastal zones, uplands). The fifth rank includes parts of large forms – depressions in paleodolines, beaches, benches, etc.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012113 doi:10.1088/1755-1315/1415/1/012113

1. Introduction

The Prypiat Amber Basin (PAB) is the only operating industrial basin in Ukraine, the development of which allows us to expand the mineral resource base of the amber industry. The prognosis and search system for amber (PSSA) allows us to solve current problems and develop the industry. The theoretical basis of the PSSA is the idea of a geological amber-bearing formation (AF). Practically, the most important elements of the AF are amber-bearing objects (AOs) or traps. There are genetic types of amber traps: stratigraphic, lithological, tectonic, geomorphological, paleogeomorphological, and combined [1–3]. A significant increase in amber production in the PAB is possible due to the discovery of paleogeomorphological traps (PTs). This allows for a comprehensive analysis of large-scale paleogeomorphological maps of the AF formation cycles, as well as maps of the statics and dynamics of the geomorpholithosphere of the PAB territory.

2. Methods and materials

The methodology of the general theory of systems, a set of geological, geomorphological, paleogeographical, paleogeomorphological methods, and the results of laboratory amber study were used in the work. The obtained results were presented in tables, displayed on graphs, general and special maps, geological and geomorphological sections. Traditional paleogeomorphological maps of reconstructed paleoreliefs of Cenozoic cycles of development of the geomorphosystem of the time of the AF formation, special maps of statics and dynamics of the geomorpholithosphere were also studied. Maps of statics – composition, complexity, structure; maps of dynamics – evolutionary-dynamic zones, functional-dynamic zones, which show the correlation of processes of initial (destruction), transit, terminal (accumulation), restructuring of the geomorphosystem during the Mesozoic-Cenozoic and its individual segments. The results of the authors' own research, obtained in the course of research work amber in Ukraine on, as well as the implementation of international projects (in particular, joint projects with the Republic of Poland: "Amber Roads: Formation of deposits – extraction. Scientific and methodological foundations, rational use"; "Amber deposits and their characteristics"). Materials of "Geoinform" and geological expeditions of the Ukrainian geological company were used.

3. Paleogeomorphological reconstructions and results

The searches for the PP are carried out on the basis of the morphochronodynamic concept of geomorphology, the information and methodological basis of which is paleogeomorphology [4, 5]. The morphochronodynamic concept is based on its own comprehensive research method that combines geological, geophysical, geomorphological, paleogeographic, cartographic, mathematical and other methods. Paleogeomorphology studies the ancient stages of development of the Earth's morphosystem, the results of which are shown on paleogeomorphological maps. There are 2 types of paleogeomorphological maps: ancient buried relief, which exists in real time; paleogeomorphological maps of the restored reliefs of ancient cycles (stages) of geomorphosystem development. The morphochronodynamic concept allows to create special maps (statics, dynamics) of the geomorpholithosphere and to carry out on their basis a cross-cutting forecast of material movements, energy transformations, information transfers in the geomorpholithosphere of the past (retrospective forecasting), present (actual forecasting), and future (prospective forecasting). The developed methodological algorithm for the use of both types of paleogeomorphological maps allows for more efficient and rational prospecting for various minerals (including amber). This made it possible to distinguish different types of PTs, which form a certain hierarchy (ranks), and to make predictions about the detection of increased concentrations of amber (and industrial value) in them. When typing the traps, we took into account works [6–9].

The *first rank* of the PTs is a part of the geomorpholithosphere of the time of formation of the AF of the PAB territory.

The *second rank* is historically-dynamic basin geomorphosystems – structural elements of the geomorphosystem (geomorpholithosphere), which are also the forecast and search units of the PSSA of the PAB territory.

The *third rank* is the morpholithic horizons of the geomorpholithosphere of the time of the AF formation, as well as elements of its vertical structure. This rank can also include morpholithocomplexes – elements of the horizontal structure of the geomorpholithosphere that are "filled" with morpholithohorizons. In this case, morpholithohorizons and morpholithocomplexes are important, as they are promising for the discovery of amber deposits. First of all, these are Paleogene morpholithohorizons. The Neogene and Quaternary morpholithohorizons may also contain amber deposits, but they are repeated (redeposited) and inferior to the primary deposits of the Paleogene morpholithohorizons.

The following ranks (fourth and fifth) are identified using traditional paleogeomorphological maps of restored paleoreliefs, prospective for amber deposits, stages of geomorphosystem development, and maps of the geomorpholithosphere statics and dynamics.

The *fourth rank* is formed by large forms of palaeorelief – ancient buried valleys, uplands, plateaus, deltas, and cones of deposition.

The *fifth rank* of the PTs can be independent or have a historical and genetic connection (be part of) large palaeorelief forms (within the PAB these are cones of deposition, abrasion-accumulative benches and beaches).

The PAB is crossed by 12 historically-dynamic basin geomorphosystems located on the Ukrainian shield, Volyno-Podolskya plate and directed to the Prypiatskaya depression and the Luginskaya historically-dynamic basin geomorphosystem, which opens into the Dniprovsko-Donetskaya depression.

Within the PBB, the Nihovyshchenska, Khmelnytsko-Stepanska, Zvyahilsko-Dubrovytska, Snovydovytska, Kupilska, Olevska, Horodetska, Luchenkivska, Zhelonska, Rudnenska, Vystupovichska, Denysovychska geomorphosystems are located from west to east (figure 1).

We studied the area, configuration in plan, exposed surface (orohydrography, topography), position, lower buried surface (relief, composition and age of rocks), thickness and shape (symmetry, anisotropy) of the morpholithobodies of the basin geomorphosystem, neighbourhood,

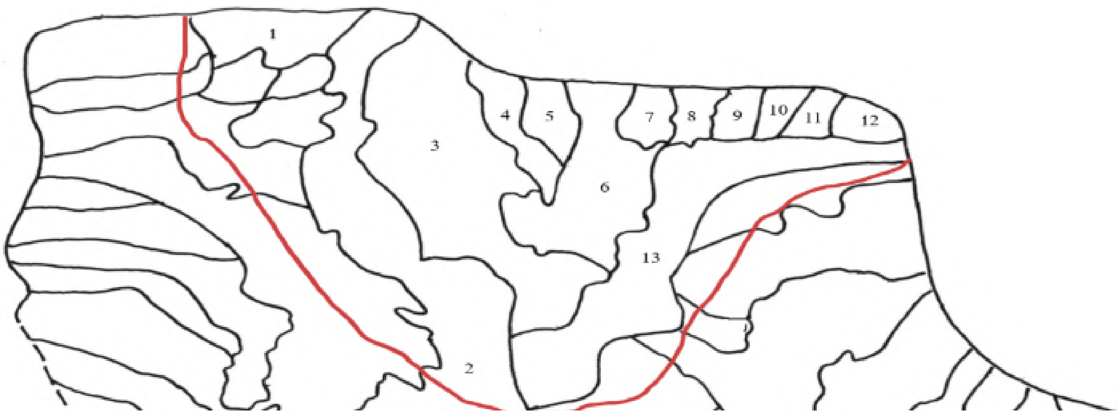

Figure 1. Prypiat amber basin. Historically and dynamic basin geomorphological systems: 1. Nihovyshchenska, 2. Khmelnytsko-Stepanska, 3. Novohrad-Volynsko-Dubrovytska, 4. Snovydovytska, 5. boundaries, vertical (distribution, thickness, lithology of morphological zones) and horizontal (composition, complexity, areas of morphological complexes) structure, conformity of exposed and buried surfaces, valley formation of historically-dynamic basin geomorphosystems. Their quantitative and qualitative characteristics (coefficients) were calculated, which together show their positionality, metrics, composition, structure, historical, evolutionary, and functional dynamics.

Historically-dynamic basin geomorphosystems differ in various metrics: area size; length; width; power; symmetry, anisotropy, volumetric shape, external shape of their morpholithobodies; nature of neighbourhood, system boundaries; height differences of the exterior surface, lower boundary and interior surfaces. In terms of plan, the form of historically-dynamic basin geomorphosystems is characterised by the coefficients of elongation (ratio of the average width and length), proportionality (ratio of the actual lengths of thalweg and interfluve lines) and tortuosity (ratio of the directed length of the interfluve to the actual length).

The composition of the systems is characterized by morpholithohorizons. Historically-dynamic basin geomorphosystems differ in composition, interrelationship and spatial differences of morpholithohorizons, which characterize their structure. In the vertical structure of the geomorpholithosphere of the territory of the PAB, there are 9 morpholithohorizons (2 – Jurassic, 2 – Cretaceous, 2 – Paleogene, 2 – Neogene and Quaternary), which occupy different areas. Their spatial relationship is characterized by interbeddedness, thrusting and nesting. Overlaps are widespread, while nesting and adjacency are less common. The horizontal structure of the systems is characterized by morpholithocomplexes that differ in complexity (number of morpholithohorizons). The complexity is always maintained or increases in the direction of the mouth. An indicator of the structure is the plasticity of the surfaces of morpholithohorizons, which is determined by the combination of concave, convex and straight sections. The total information content of the plasticity of buried surfaces relative to the exposed one is expressed by the integral indicator, which characterizes the internal shape, which can be straight (the plasticity of the majority of surfaces is the same), inverted (the plasticity of most of the exposed surfaces is opposite to the exposed one) and semi-inverted (the plasticity of the exposed and exposed surfaces are equally the same).

The structure of historically-dynamic basin geomorphosystems can be expressed by volumetric-planers (morpholithocomplexes) and linear-pointer elements. According to the ability to transmit material and energy flows, morpholithocomplexes are divided into through (composed of bedrock with vertical water movement in them) closed (composed of hard rocks and no water movement in them) and transitory (composed of permeable and hard sediments and predominantly horizontal water movement in them). This is complemented by data from the valley formation in historic-dynamic zones: active, less active, and free of movement. In historically- dynamic basin geomorphosystems, the most active are functionally valley formations, which are characterized by different valley coefficients – general (ratio of the length of all valleys to the basin area) and more than 20 partial (ratio of the length of valleys of individual cycles to the basin area). The total coefficient of valley formation of the historically-dynamic basin geomorphosystems of the PAB is 0.01-0.4.

Statics reflects the current dynamics – the currentness of functional, historical and the historically-dynamic basin geomorphosystems. The dynamic analysis of statics indicators is carried out using the methods of systematic analysis, analogies (extrapolations), and correlation analysis. The directions, intensity, and nature of the movement of the matter-energy are reflected in the following indicators of symmetry, anisotropy, and the volumetric shape of the morpholithobodies. Larger deviations from symmetry (partial symmetry, asymmetry) also indicate a greater dynamical potential of the system, while pronounced anisotropy indicates directions. The opposite is evidenced by the developed symmetry, not pronounced anisotropy, flat and complex forms. The planer form of the themes is expressed by the coefficients of elongation, prominence, and sinuosity. Their widening towards the mouth and straightness enhance transit, sounding, tortuosity and vectors – the accumulation of matter and energy. Predicting the current (and past) vertical and lateral changes of matter and energy in systems allows us to make a comparative analysis of internal and external shape maps. Complex neighbourhoods, interconnections of morpholithobodies of systems show changes in the directions of flows, isolated areas, and places of accumulation of potential energy. The overlapping of morpholithohorizons and their straight plastic bounding surfaces indicate a displacement, while nesting and sheltering, concave and convex surfaces indicate accelerated movement, as well as the accumulation of matter and energy. A symmetry analysis of the long-term distribution of morpholithocomplexes by complexity and composition indicates trends in their development, and their metrics, positionality and permeability of morpholithocomplexes to matter and energy flows (through, transit, closed) – the current functional dynamics of historically-dynamic basin geomorphosystems. The linear-pointer structural elements of the systems directly show their modern and historical functional dynamics, intensity and directions of movement of matter and energy. Figures 2, 3, and 4 show the maps of statics and dynamics of the geomorpholithosphere of the PAB territory.

The analysis of paleogeomorphological maps of the PAB area shows that at the end of the Cretaceous, the seas transgressed and the area rose sharply. In the early Eocene, new

depressions occurred: 50-80% of the area is occupied by denudation-accumulation plains and 15-25% by denudation plains. After a slight uplift in the early Eocene-Oligocene cycle (P2-3), marine transgression gradually expanded into the PAB. Large terminals appeared everywhere. At the beginning of the Miocene cycle (N1), the area was dominated by a denudation-accumulation plain. In the Miocene-Pliocene cycle (N1-2), the area of the coastal-marine and mixed accumulative plains changed. In the Quaternary cycle (Q), active differential tectonic movements, emergence of large areas of denudation and accumulation, intensification of transit processes, emergence of new flow directions, river bifurcations, lake and marsh transgressions, and glaciation are observed in the PAB (figure 5, 6).

Paleogeomorphological map of the Paleocene-Middle Eocene stage of the development of the territory: 1 – denudation relief, 2 – denudation-accumulative and accumulative-denudation relief, 3 – accumulative relief of the coastal plain, 4 – abrasive-accumulative relief of the shallow sea with islands and raised seabed areas, 5 – accumulative relief of the relatively deep sea with islands and elevated seabed areas, 6 – thalwegs of continental and submarine paleodolines, 7 – watershed lines, 8 – boundaries of historical and dynamic basin geomorphosystems, 9 – boundaries of the Prypiat amber basin.

Figure 6. Paleogeomorphological map of the Late Eocene-Middle Oligocene stage of the development of the territory: 1 – denudation relief, 2 – denudation-accumulative and accumulative-denudation relief, 3 – accumulative relief of the coastal plain, 4 – abrasive-accumulative relief of the shallow sea with islands and raised seabed areas, 5 – accumulative relief of the relatively deep sea with islands and elevated seabed areas, 6 – thalwegs of continental and submarine paleodolines, 7 – watershed lines, 8 – boundaries of historical and dynamic basin geomorphosystems, 9 – boundaries of the Prypiat amber basin.

In the historically-dynamic basin geomorphosystems, during the stages of formation of the AF, the boundaries and integrity were violated, the conditions, types of exogenous morpholithogenesis, and the correlation of denudation, transformation and accretion processes changed. They, especially the adjacent ones, are developing simultaneously. According to the peculiarities of evolutionary dynamics, relatively stable and unstable systems are distinguished within the PAB. Their central element is the zone of consolidated negative forms, which occupies 10-40% of the area. In plan, it has an elongated (straight, arcuate, sinuous) and isometric configuration. The zone of internal basement alterations (20-70% of the area) is of a planer distribution and is more common in the internal part of the systems. The zone of inter-basin alterations (15-65% of the area) is represented by straight, arc, circle, often sinuous strips that coincide with the boundaries, cross them and divide the systems.

Most systems have a certain percentage of newly formed boundaries, which are primarily of tectonic nature. Distributions of denudation, transit and accumulative landforms reflect the distributions of the initial, transit and terminal functions of the systems. Denudation forms, which are found everywhere and occupy 10-25% of their area, indicate the initial nature of the systems. The places of increased density of morpholthohorizons are terminal. They are sub-parallel, intersecting, and multi-story. Terminality can be quantified on statics maps. In geomorphosystems, terminals often occupy more than half of the area. The absolute measure of transitivity is the total mass of sediments. The transitivity expresses the composition of the morpholithocomplexes, and for the whole system, the development of the valley formation, which expresses the valley coefficient.

Functional dynamics in historically-dynamic basin geomorphosystems is carried out due to stable groupings of morpholithocomplexes, through which the substance moves from and to them. During the Mesozoic-Cenozoic, historically-dynamic basin geomorphosystems determined the established directions and channels of substance movement. According to the ratio of dissipative functions in the systems, they are divided into groups. The following groups are

characteristic of the PAB: 1) intensive, directional transit, subordinate terminal development, no significant changes (5 systems); 2) uneven in intensity directional transit, well-developed terminals, no significant changes (5 systems); 3) intensive but unrestricted transit in directions, different terminal development, significant changes (3 systems).

Table 1 presents the most important information from the paleogeomorphological maps of the cycles (stages) of the geomorphosystem development during the formation of the AF and maps of the statics and dynamics of the geomorpholithosphere (first rank of PTs) of 13 historical and dynamic basin geomorphosystems (second rank of PTs) in relation to PTs of the third, fourth and fifth ranks. On the basis of these and direct prospecting data, their amber bearing capacity was estimated on a relative scale (h-high, m-middle, l-low). The geomorphosystems may be dominated by the 1 or 2 and 3 variants of amber bearing capacity.

4. Conclusions

The amber industry of Ukraine requires expansion of the mineral resource base. The most promising for this purpose is the territory of the PAB. For this purpose, a forecasting and prospecting system for amber has been created, the practically important elements of which are the AOs or traps of various genesis. The main increase in amber production will take place in the territory of the PAB due to the use of Pts. The search for the PT should be carried out at the modern scientific level, which is provided by the morphochronodynamic concept of geomorphology, the main methodological and informational-methodical element of which is paleogeomorphology. A methodical algorithm for the combined use of cartographic models of the geomorphosystem (paleogeomorphological maps of certain cycles of its development, statics and dynamics of its materialized space-time – geomorpholithosphere) has been developed, which allowed typifying the PTs by rank. The first rank is the geomorpholithosphere, the second rank is the historically-dynamic basin geomorphosystems as the main regional units of prognostic and prospecting works for amber and other sedimentary minerals, the third rank is morpholithohorizons, which are located in the geomorpholithosphere and are promising for amber placers; the fourth rank is paleorelief forms (ancient buried valleys, plateaus, uplands adjacent to the coastline, large river deltas); fifth rank – parts of large paleorelief forms (elements): thalweg and depressions of ancient valleys; places of confluence and confluence of tributaries – “twins”, “tees”; cones of ravine outflow from plateaus and uplands; abrasive-accumulative beaches (bench). On the basis of the developed typification of paleogeomorphological amber traps, a prognostic and exploratory assessment of 13 historically-dynamic basin geomorphosystems of the PAB territory was made.

Abstract. The work carried out a set of experimental studies to reduce the activity of corrosion processes in underground well equipment. Corrosion of downhole equipment is a complex heterogeneous process. In the complex of factors influencing both magnitude and intensity of corrosion damage, low molecular weight water-soluble carboxylic acids play a significant role. The features of metal-carbon dioxide corrosion (CO_2 corrosion) in production well fluid have been established depending on low molecular weight carboxylic acids. It has been revealed that the influence of carboxylic acids in field wells in the initial period of development is reduced to the destruction of protective carbonate films formed as a result of carbon dioxide corrosion of the metal surface. The highest corrosion rate is at the beginning of droplet water condensation since the main factors influencing the corrosion rate (acid concentration and temperature) are greatest at this point. It has been established that the interaction of organic acids with metal occurs in the Dnipro-Donetsk basin fields at the temperature range of 90-110 °C and a depth of 3000-3500 m. The interval of action of organic acids on the metal of tubing pipes depends on the regime constancy and operating time of the well. In constant mode, the effect of organic acids is limited to 100-150 m. The effect of corrosion under the influence of organic acids is especially pronounced in wells where the carbon dioxide content is insignificant. The influence of corrosion products on the process speed has been determined. Iron salts of carboxylic acids, formed as a result of corrosion during condensation of aqueous fluid in a well, are subsequently inhibitors of carbon dioxide corrosion of gas industry equipment.

1. Introduction

One of the main reasons affecting the stability of hydrocarbon raw materials production and transportation is gas industry equipment corrosion [1–4]. The service life of pumping and compressor pipes in some cases is 0.5-1.5 years instead of the planned 10 years. More than 3000 hydrocarbon collection system pipeline failures due to internal corrosion are recorded annually. The accident rate of hydrocarbon collection systems pipelines leads to significant losses in hydrocarbon production and environmental pollution [4, 5].

The introduction of advanced technologies for operational equipment protection helps to reduce labor costs and material consumption and to decrease repair and restoration work carried out at industrial enterprises [6–8].

Downhole equipment corrosion is a complex heterogeneous process. In the complex of factors influencing both magnitude and intensity of corrosion damage, low molecular weight water-soluble carboxylic acids play a significant role [5, 9–11].

2. Problem statement

The mechanism of carbon dioxide corrosion has been studied quite deeply and comprehensively [1–4, 9, 10, 12–14]. The intensity of equipment corrosion destruction in fields where gas contains CO_2 is determined both by the partial pressure of carbon dioxide (with a low content of organic acids) and the temperature at which the corrosion process occurs [2, 14].

As the gas moves through the wellbore, a liquid phase is released. As a result, a three-phase gas flow of gas-water-hydrocarbon is created inside the pipes. The corrosion rate in a three-phase system is mainly determined by the structure and flow regime. The corrosive activity of the medium in a well depends on the ratio of hydrocarbons to water. Intensive corrosion of equipment, according to some researchers, begins when the water content in the well is 0.1%, and then the corrosion rate remains constant, although the water content increases [2, 3, 9].

The presence of the hydrocarbon fraction in aqueous electrolytes has a significant impact on the corrosion process kinetics and nature. The hydrocarbon phase of a heterogeneous medium, practically inert to metal, accumulates an increased amount of H_2S, O_2, and CO_2 compared to the aqueous phase. As a result, thin layers of electrolyte appear on the surface of the corroding metal, where the corrosion process under conditions of free depolarization proceeds at a higher speed than in the volume of the deposit [2, 9, 15].

However, other studies have noted that the presence of a hydrocarbon phase reduces the gas-liquid flow aggressiveness [3].

Corrosive destruction of equipment surface and underground caused by CO_2 and low molecular weight water-soluble carboxylic acids are usually local and have the form of pittings. They are detected in those elements of equipment where there is water accumulation (coupling and flange connections, fittings). Straight sections of pipes outside these connections, as a rule, corrode very little [10, 11, 13, 16]. In addition to corrosion, erosion-corrosion destruction is observed, caused by powerful speeds of the movement of aggressive environments containing mechanical impurities (iron sulfide, sand) [2].

In the wells located at the gas condensate fields, a certain pattern of corrosion and erosion-corrosion destruction distribution is observed. There is virtually no corrosion at the bottom of tubing hangers (TBG). At a certain depth for each deposit, pitting corrosion appears at the lower ends of the pipes. Their intensity, when moving upward, first increases quite sharply, and then remains approximately constant. In the upper part of the pipes, these damages are almost always the most significant [17].

Corrosion processes in a borehole are affected by temperature: high temperatures shift the limit of corrosion damage to the well mouth, and TBG hangers are intensively destroyed [4].

Carbon dioxide corrosion of both pipes and well equipment is predominantly an electrochemical process with the metal anodic dissolution and hydrogen ions reduction at the cathode sections [2–4].

The corrosion forecast helps to select the optimal methods of anti-corrosion protection of wells at different stages of field development, which in turn helps to increase the effectiveness of protective measures, reduce operating costs, decrease the time of both repairs and downtime of wells, and increase the hydrocarbon production volume [5, 9, 13].

Purpose of the study is to identify the effect of low molecular weight water-soluble carboxylic acids on carbon dioxide corrosion of metal in gas production equipment of wells

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012114 doi:10.1088/1755-1315/1415/1/012114

in the North-Eastern region of the Dnipro-Donetsk basin.

3. Materials and methods

The rate of both surface and underground well equipment corrosion depends on various factors, the main of which should be considered the aggressive components CO_2 and low molecular weight water-soluble carboxylic acids contained in natural gas. So natural gas, hydrocarbon condensate, formation water and pipe steel have been chosen as the object of the study. In the low molecular weight water-soluble carboxylic acids mixture, the main component is acetic acid, which, therefore, has been taken further for laboratory studies (table 1).

The main component contained in the formation waters of fields of the North-Eastern Ukraine is sodium chloride. Cation content Na^+ reaches 42 equiv.%. Since the concentration of salts in formation and condensation waters varies over a wide range [2, 3, 5], solutions NaCl and CH_3COOH in distilled water of different concentrations (NaCl from 0.0017 to 2 M, CH_3COOH from 0.00083 to 0.5 M) were chosen for model environments of experimental studies.

Table 1. Composition of water-soluble carboxylic acids in the products of wells of gas industry management fields “PoltavaGasVydobuvannya”.

Yablunivske	2.0	88	3.8	6.2

Similar to the real operating conditions of gas industrial equipment, the experiments were carried out in the temperature range from 293 to 373°K. Since the corrosion of gas industrial equipment with the participation of CO_2 and low-molecular carboxylic acids is local with obvious foci of corrosion characterized by pittings, the study of corrosion processes in model environments was carried out mainly by the gravimetric method, namely with the help of witness samples.

The study of the effect of low molecular weight water-soluble carboxylic acids on carbon dioxide corrosion of downhole equipment was carried out on samples of pipe steel grade D in the gas phase, simulating the interval at which the condensation of aqueous fluid began, and in a liquid single-phase electrolyte-hydrocarbon system, simulating the installation (figure 1 [5]). It is a glass vessel into which the test solution was poured and a fluoroplastic cylinder with witness samples and a propeller stirrer was placed.

The cell was connected to an electric motor, which rotated the stirrer. When the stirrer rotated in a fluoroplastic cylinder, circular movements of the liquid were created in laminar mode with a flow speed of 0.3-0.5 m/s. When the stirrer propeller was installed under the bottom of the cylinder, while rotating it at a speed of 1400 rpm. there was a circular motion of the liquid in a turbulent regime. In this case, the flow speed in the area where the witness samples were placed was 7-8 m/s. In addition to the circular motion, there was also a circulation of liquid through the small cylinder due to the creation of irritation when the stirrer rotated.

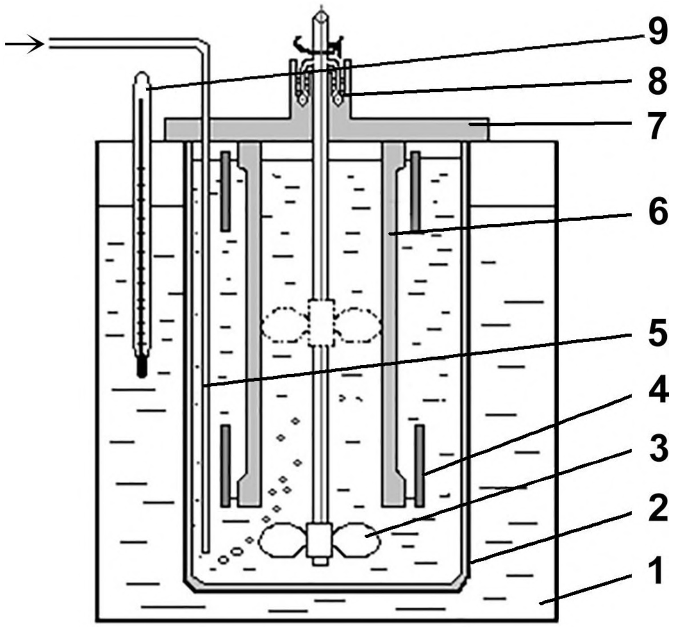

Figure 1. Installation diagram for corrosion research: 1 – thermostat; 2 – glass chamber; 3 – stirrer; 4 – samples; 5 – gas supply tube; 6 – fluoroplastic cylinder; 7 – cover; 8 – hydraulic hole; 9 – mercury thermometer.

The corrosion rate was determined by the loss of metal mass of witness samples placed in the test environment per unit time according to the formula (1) [5]:

$$v = \frac{\Delta m}{S\tau} \tag{1}$$

where v – the corrosion rate of a sample, g/(m^2·h); Δm – weight loss during the study, g; S – sample surface area, m^2; τ – research time, h.

The protective effect of surfactants (Z) was calculated using the formula (2) [5]:

$$Z = \frac{v_0 - v_1}{v_0} 100, \% \tag{2}$$

where v_0 – corrosion rate of the sample without corrosion inhibitor, g/(m^2·h); v_1 – corrosion rate of the sample with corrosion inhibitor, g/(m^2·h).

The measurement results were analyzed using mathematical statistics methods GOST 9.905-82.

Some corrosion studies were carried out in gas fields directly at the wellhead using several methods: gravimetric and iron ion content.

4. Research results

It has been established that the corrosion rate of pipe steel over solutions of acetic acid in CO_2 is the highest 0.35-1.2 g/(m^2·h), in a CO_2 atmosphere over distilled water is the smallest 0.2-0.6 g(m^2·h) (figure 2). No corrosion of steel in an N_2 atmosphere over distilled water was detected during the experiment.

Stabilization of the corrosion rate in the gas phase in the atmosphere CO_2 after a N_2 atmosphere occurs twice as fast (≈12 min.) than in a N_2 atmosphere after CO_2 (≈24 min.) (figure 3).

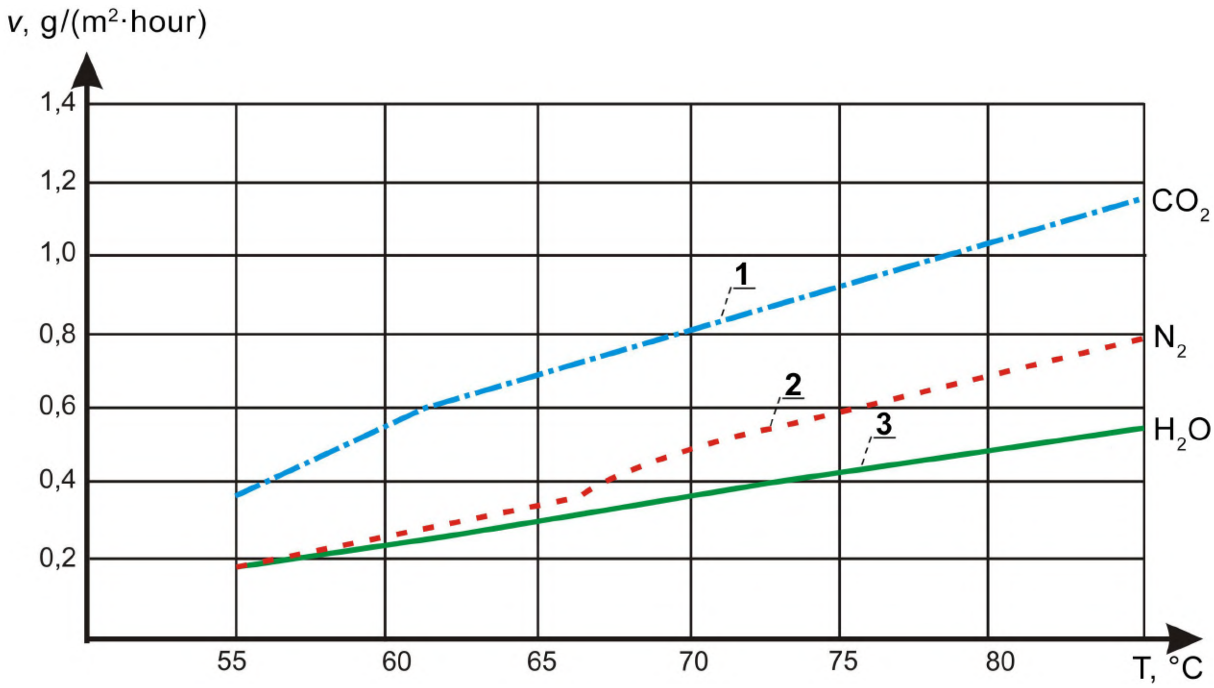

Figure 2. Dependence of the corrosion rate of pipe steel on temperature in a solution that contains 0.5 mol/l NaCl and mol/l CH_3COOH: 1 – in a CO_2 atmosphere; 2 – in a N_2 atmosphere; 3 – in a CO_2 atmosphere over distilled water.

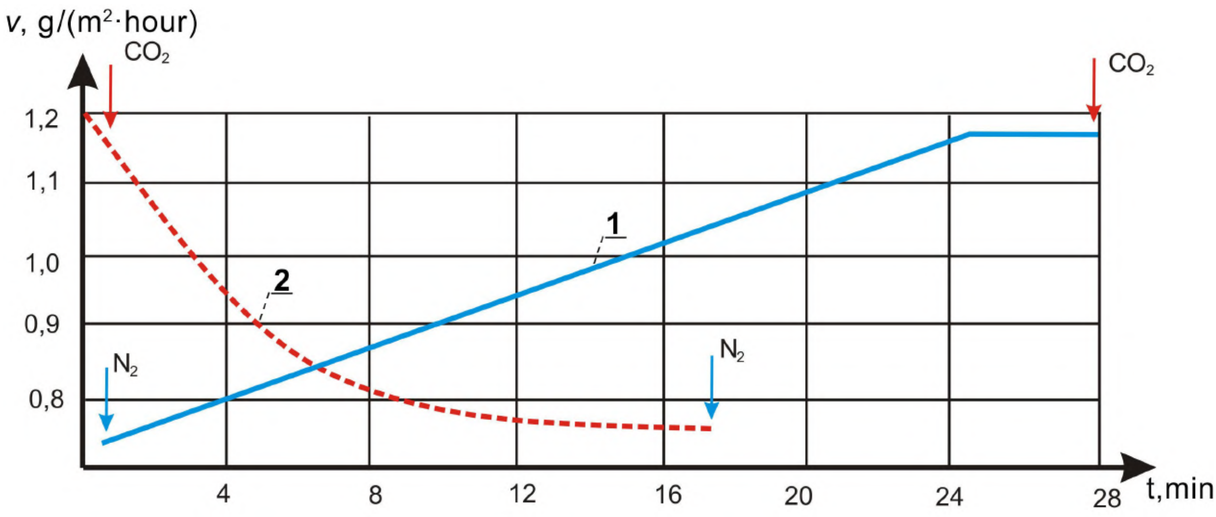

Figure 3. Kinetics of formation of protective carbonate films in a CO_2 atmosphere (1) and their destruction in a N_2 atmosphere (2) at temperature 80°C over solvent 0.5 mol/l CH_3COOH, 0.5 mol/l NaCl.

From the given temperature and kinetic dependencies it follows that acetic acid vapor increases carbon dioxide corrosion. However, the combined action of CO_2 and CH_3COOH causes less corrosion than acetic acid vapor.

According to V. P. Kuznetsov [2], insoluble products of carbon dioxide corrosion located on the metal surface consist of oxide and carbonate compounds of iron.

It can be assumed that with the concentration of water vapor and acetic acid in the well, the destruction of protective oxide films occurs according to the scheme:

$$FeCO_3 + 2\ CH_3COOH \rightarrow Fe(CH_3COO)_2 + H_2O + CO_2;$$
$$FeO + 2\ CH_3COOH \rightarrow Fe(CH_3COO)_2 + H_2O.$$

In an atmosphere of inert nitrogen gas, protective films do not form; corrosion in this case occurs under the electrolyte films by an electrochemical mechanism without the formation of insoluble compounds [2]:

$$Fe + 2\ CH_3COOH \rightarrow Fe(CH_3COO)_2 + H_2.$$

Thus, the influence of carboxylic acids in field wells in the initial period of development is reduced to the destruction of protective carbonate films formed as a result of carbon dioxide corrosion of the metal surface. The highest corrosion rate is at the beginning of droplet water condensation, since the main factors influencing the corrosion rate (acid concentration and temperature) are greatest at this point. The presence of carboxylic acids in condensation water shifts the interval for the beginning of the aqueous fluid condensation in the well towards higher temperatures and depths compared to pure carbon dioxide corrosion.

The intensity of corrosion in the wellbore was determined by the gravimetric method on witness samples installed in the tubing and visually on the tubing raised during repair. At these deposits, there is a correlation between the concentration of iron ions and the concentration of organic acids in the condensation water (table 2).

Table 2. Characteristics of gas condensate wells at the Dnipro-Donetsk basin fields.

Kotelevske	450-700	2.0	up to 130	300-500
Novotroitske	300-700	0.3-0.5	3-50	240-400
Raspashnivske	900-1200	0.1-0.6	0,5-25	300-600
Mashivske	200-900	0.2-0.5	1-25	150-500
Yablunivske	250-500	4-8	0.2-3	300-1000

It has been established that the interaction of organic acids with metal occurs in the Dnipro-Donetsk basin fields in the temperature range of 90-110 °C and at a depth of 3000-3500 m. The interval of action of organic acids on metal tubing depends on the constancy of the regime and the operating time of the well. In constant mode, the effect of organic acids is limited to 100-150 g. The effect of corrosion under the influence of organic acids is especially pronounced in wells where the carbon dioxide content is insignificant $P_{CO_2} < 0.02$MPa (figure 4).

The corrosion rate of ground-based equipment was determined to be 0.002-0.5 g/(m^2·h). It should be noted that the corrosion rate of above-ground equipment is tens of times less than that of underground equipment and 5-15 times less than the calculated rate for carbon dioxide

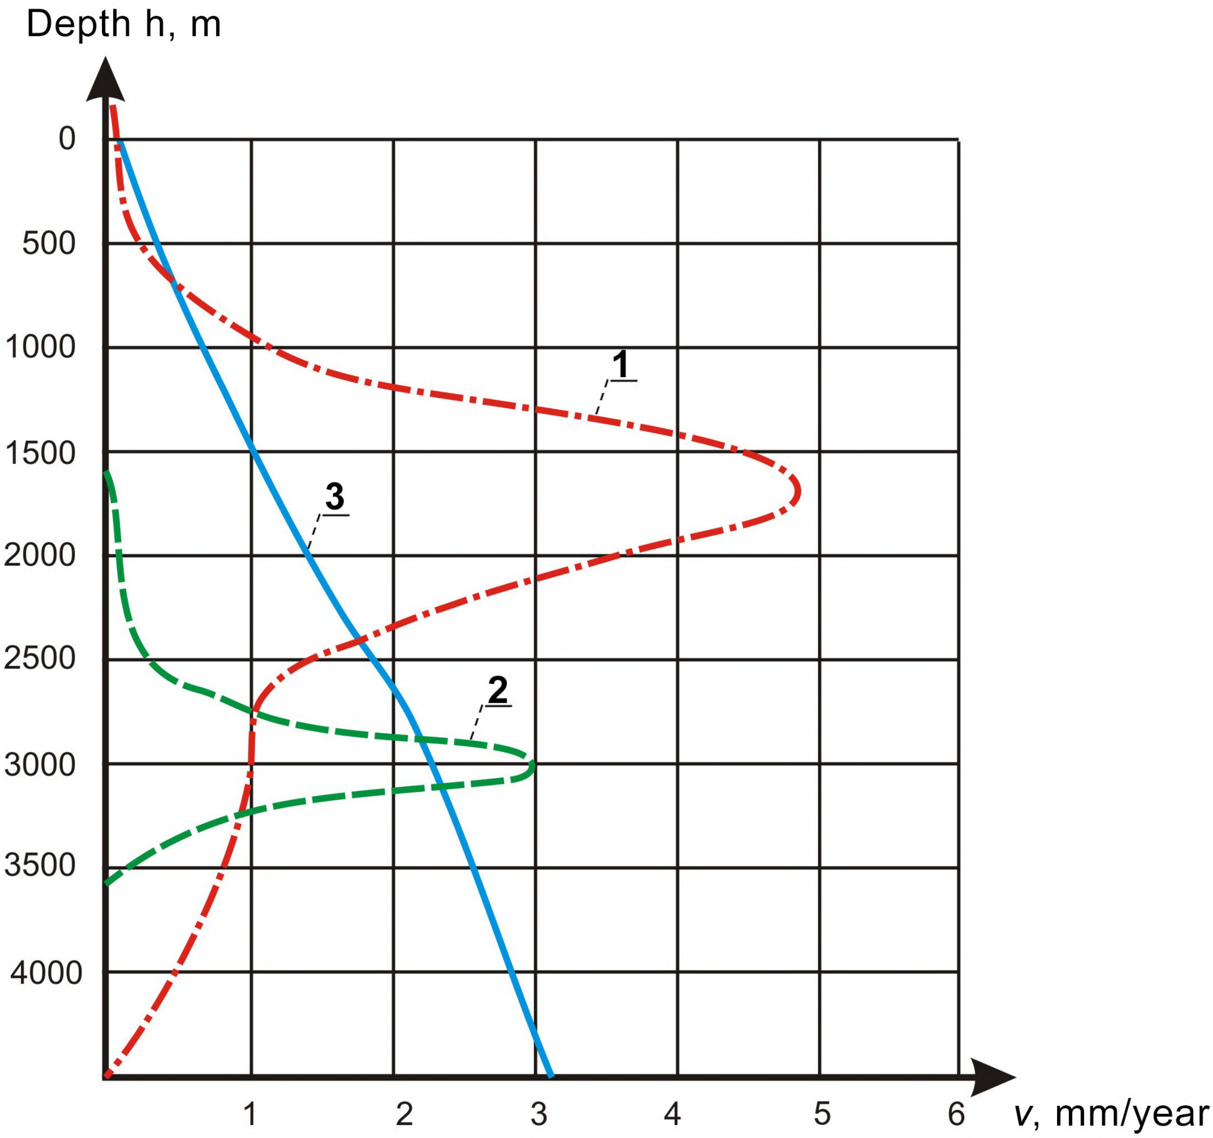

Figure 4. Distribution of corrosion intensity in the wellbore: 1 – corrosion is caused by the general effect of CO_2 and low molecular weight carboxylic acids at the initial stage of field development; 2 – corrosion caused by the action of low molecular weight carboxylic acids at the initial stage of field development; 3 – corrosion caused by the presence of CO_2 and low molecular weight carboxylic acids at the final stage of field development.

corrosion, determined by the V. P. Kuznetsov's equation [2]:

$$lgv = 0.7493 \cdot lgP_{\mathrm{CO}_2} - 0.0095t, \tag{3}$$

where v – corrosion rate; P_{CO_2} – partial pressure of carbon dioxide, Pa; t – temperature, ℃.

The actual rate of corrosion of the surface equipment of the wells of the Yablunivske deposit is 0.3-0.5 g/(m^2·h), while according to equation 1, it is 8-5 g/(m^2·h). The reason for this difference was the inhibitory effect of iron salts of organic acids on carbon dioxide corrosion.

This assumption has been confirmed by laboratory studies. It has been established that the corrosion rate in the medium taken from the well is 0.05-0.2 g/(m^2·h), in the model medium under similar conditions it is 3 g/(m^2·h). After treatment of the selected reservoir water with oxygen to decompose iron salts and remove iron oxides, the aggressiveness of the water condensate increases 10-15 times. For example, the corrosion rate of steel tested under the same conditions in water taken from the mouth of well No. 61 of the Yablunivske deposit, after removal of iron ions, increased to 14 g/(m^2·h).

Thus, iron salts of carboxylic acids – corrosion products during condensation of aqueous fluid in a well, are subsequently inhibitors of carbon dioxide corrosion of gas industry equipment.

5. Conclusion

1. The corrosive effect of organic acids entering the well along with water vapor is to stimulate carbon dioxide corrosion due to the destruction of oxide protective films.
2. In wells with products containing $P_{CO_2} < 0.02$MPa, the equipment corrosion intensity is determined by the concentration of carboxylic acids in the gas, temperature and flow rate. Maximum corrosion damage in wells is in the range of the beginning of carboxylic acid condensation.
3. Iron salts formed as a result of corrosion, during further movement in the wellbore, in plumes, and communications of complex gas treatment plants, are inhibitors of carbon dioxide corrosion.

Abstract. The frequency method is currently recognized as the most technically and economically feasible approach for controlling alternating current electric drives. However, systems employing frequency-controlled electromechanical setups with stator circuits, while offering extensive capabilities, present a more intricate challenge for voltage frequency regulation compared to systems utilizing rotor circuits. This complexity arises from the fact that the power of a thyristor frequency converter is comparable to that of electric motors. Consequently, there is a pressing need in contemporary electromechanics for the development of innovative circuit solutions to regulate the performance of flow transport systems. This study aims to design a two-motor electric drive for the mechanisms of flow transport systems with medium to high power, aiming for improved energy efficiency. As a result of this study, it was found that utilizing a cascade circuit in a dual-motor electric drive, along with an additional power source in the rectified rotor current circuit, enables the synchronized rotation of two motors. This synchronization can be achieved not only with identical nominal parameters but also with differing power and synchronous frequency of rotation. The primary advantages of this coordinated rotation approach in a twin-motor electric drive using a cascade scheme include the ability to adjust the power factor of the machines and reduce the power transferred to the control circuit by the thyristor frequency converter, thereby enhancing the reliability of the electric drive's power components. Furthermore, by regulating the rotation frequency of two AC motors, it becomes feasible to enhance overall energy efficiency.

1. Introduction

Presently, energy conservation stands as a primary focus of innovative development in the Republic of Kazakhstan, reflected in the inclusion of energy-saving initiatives in nearly all significant strategic documents [1].

The integration of energy-efficient technologies is evident across six key sectors of innovative and industrial advancement: metallurgy, chemistry, petrochemistry, mechanical engineering, construction materials, and the food industry [2].

Notably, the industrial sector alone accounts for approximately 70% of total electricity consumption, with electric drives of flow-transport systems (FTS) contributing an average of 20% [3].

Flow transport systems in electricity refer to a network of interconnected conveyors or transport mechanisms within industrial settings that facilitate the continuous movement of goods or materials along production lines. These systems are integral to various industries such as manufacturing, mining, and logistics, where the efficient and seamless transfer of materials between different stages of production or processing is essential.

FTS typically consist of a series of conveyors, each designed for specific functions such as loading, transporting, sorting, and unloading. These conveyors may include belt conveyors, roller conveyors, screw conveyors, or pneumatic conveyors, depending on the nature of the materials being transported and the layout of the production facility.

Understanding the operational dynamics of FTS has become increasingly pertinent, given that the interconnected transport and technological lines within enterprises constitute a unified system. Moreover, the contemporary approach of flow production relies heavily on conveyor systems to facilitate the seamless transfer of goods between different stages of production [4]. Belt conveyors play a vital role in this process, maintaining production rhythm, enhancing labor efficiency, and bolstering output. Furthermore, they serve as primary tools for comprehensive mechanization and automation across both primary and ancillary production processes [5].

Typically, the automation system for a network of conveyor lines within an industrial facility must be capable of activating and deactivating different conveyors in a specific sequence, aligning closely with the production process. It ensures the precise speed of cargo transportation and, when needed, synchronizes the speed of various conveyors. Additionally, it manages the blocking of technological and emergency equipment as required [6].

Presently, the majority of FTS utilize adjustable direct current (DC) electric drives to power conveyor actuators [7]. Thyristor converters are employed to control the speed of DC machines within a relatively limited range, typically ranging from 500 to 1900 rpm of the motor shaft [8].

Regarding the electric drive, the FTS can be viewed as a load with static torque unaffected by speed variations. Operating continuously over extended periods, it experiences infrequent starts and stops. There are no stringent demands on the dynamics of the electric drive, and no limitations are placed on the characteristics of transient processes during start-up, braking, or speed transitions [9].

Based on the general attributes, it is evident that the operational demands on the electric drive under normal conditions are relatively modest. However, intermittent instances of sudden load spikes during operation, potentially leading to a substantial increase in static torque, up to the point of actuator jamming, cannot be discounted [10]. Moreover, electric machines operate within an environment laden with dust from construction materials. Hence, in the modernization of such electric drives, the primary focus lies in enhancing their reliability and performance characteristics. In such scenarios, transitioning to asynchronous electric drives with frequency regulation is proposed as a solution. These drives, in terms of functionality and performance, align with the technical requisites and operational conditions of the task at hand [11]. Nonetheless, in making decisions regarding modernization, it is imperative to accurately evaluate the associated costs and, more significantly, compare them with the resultant benefits.

As commonly acknowledged, the frequency method stands out today as the most technically and economically viable control method for alternating current (AC) electric drives [12]. Nevertheless, research indicates that frequency-controlled electromechanical systems utilizing stator circuits, while offering extensive functionalities, pose a technically more intricate challenge for voltage frequency regulation compared to regulation through rotor circuits. This complexity arises from the fact that the power of a thyristor frequency converter (TFC) is comparable to that of electric motors [13].

Consequently, the advancement of novel circuit solutions for regulating the performance of FTS emerges as a pressing task within contemporary electromechanics.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012115 doi:10.1088/1755-1315/1415/1/012115

2. Circuit design for cascade connection of two asynchronous motors

Figure 1 illustrates a functional schematic of a dual-motor electric drive of coordinated rotation featuring a cascade arrangement of two asynchronous motors. In this configuration, the rotor windings of the asynchronous motors are linked in series via a controlled rectifier (CR) within the rotor circuit of the first motor (AM1) and an inverter (I) within the rotor circuit of the second motor (AM2), collectively referred to as a thyristor frequency converter.

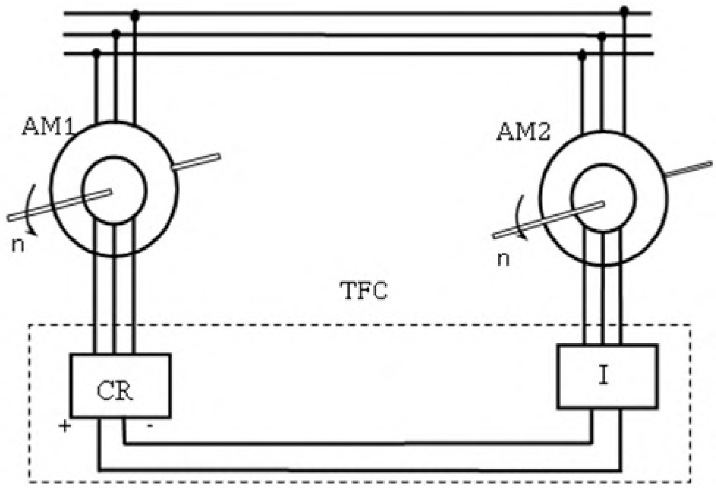

Figure 1. Functional diagram of a double-motor electric drive.

An inherent characteristic of this system is its notable energy efficiency, achieved by harnessing the regenerative energy from the first asynchronous motor to power the thyristor frequency converter within the rotor circuit of the second motor [14].

Consequently, the efficiency of the dual-motor electric drive experiences a substantial boost, particularly as the installed power of the motors increases, further enhancing the system's overall efficiency [15].

For investigating the dynamic characteristics of the coordinated rotation electromechanical system in FTS mechanisms, we conduct computer simulations of a two-motor electric drive setup. This configuration comprises two asynchronous motors with wound rotors, with one motor connected via an asynchronous valve cascade (AVC) circuit and the other connected through a dual-fed machine (DFM) circuit [16, 17].

Figure 2 shows a simulation model of a two-motor electric drive corresponding to the functional diagram shown in figure 1.

3. Results

3.1. Computer simulation results

Computer simulation of a dual-motor electric drive was carried out in the MatLab system. Dynamic characteristics of a two-motor electric drive obtained at various values β (opening angles of the thyristors of the rectifier group) are shown in figure 3 and figure 4.

Examination of the dynamic traits reveals a distinction between the second motor, linked via the dual-power circuit, and the first motor, connected through the valve cascade circuit. Despite identical parameters in the equivalent circuits of both motors, the sliding power directed to the rotor windings of the second asynchronous motor proves inadequate to replicate the characteristics of the first motor [18]. Consequently, an additional power source in the rectified current circuit of the motor rotor is deemed necessary [19].

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012115 doi:10.1088/1755-1315/1415/1/012115

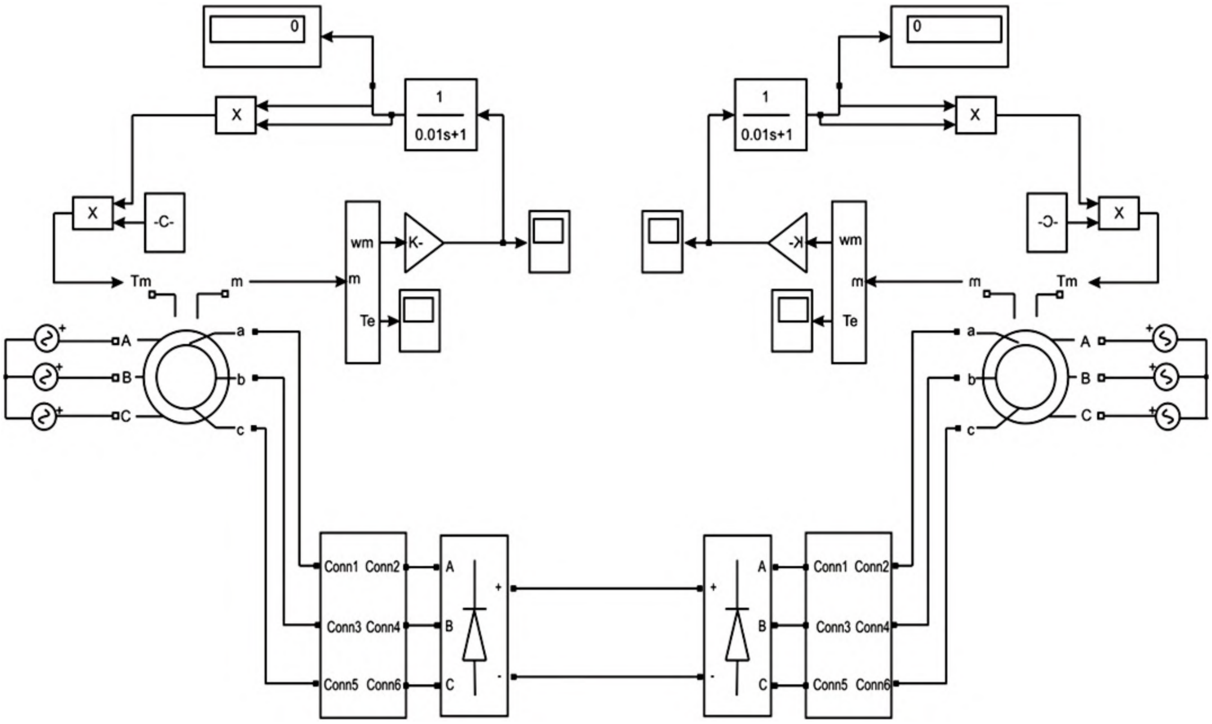

Figure 2. Simulation model of a control circuit for two asynchronous motors in the MatLab environment.

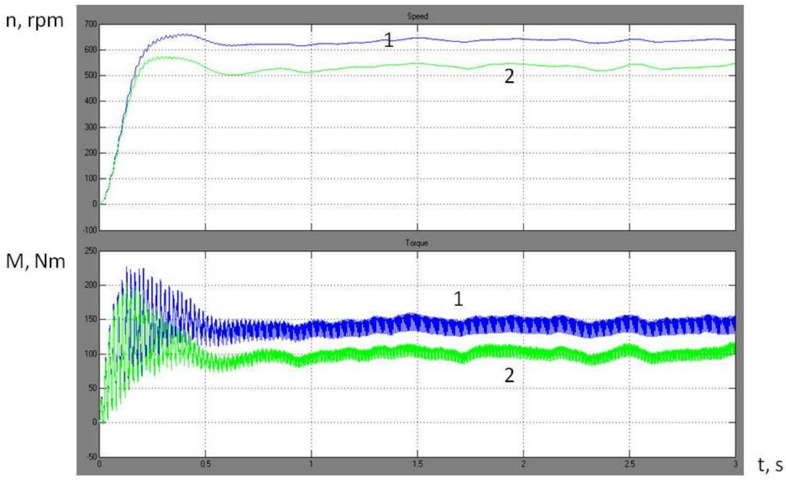

Figure 3. Dynamic characteristics of a two-motor electric drive at $\beta = 30°$: 1 – characteristics of the first motor; 2 – characteristics of the second motor.

3.2. Circuit design with an additional source in the rotor rectified current circuit

A functional diagram of a two-motor electric drive with an additional power source in the rectified current circuit of the rotors of two asynchronous motors is shown in figure 5.

Then, when determining the value of the current in the rotor windings of the second motor, one must proceed from the condition [20]:

$$I_2 = k_i I_{dp} = k_i \left(I_d + I_{ad}\right) \leq I_2, \tag{1}$$

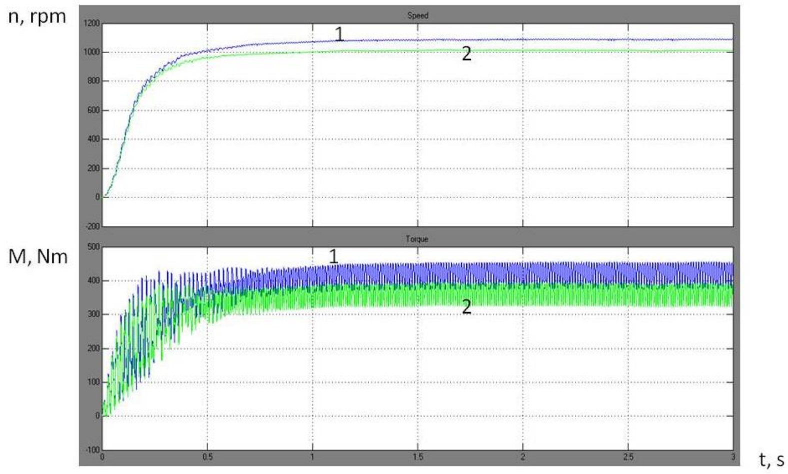

Figure 4. Dynamic characteristics of a two-motor electric drive at $\beta = 60°$: 1 – characteristics of the first motor; 2 – characteristics of the second motor.

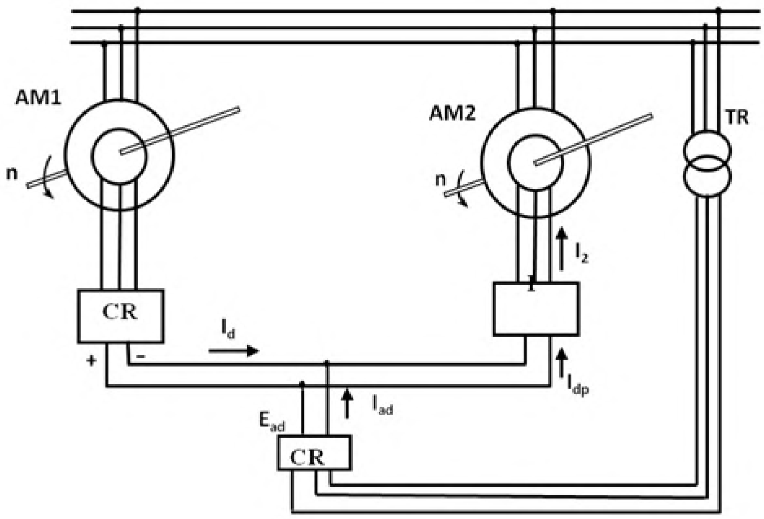

Figure 5. Functional diagram of a double-motor electric drive with an additional power source in the rotor rectified current circuit.

where $I_{dp} = (I_d + I_{ad})$ is rectified current with an additional source, $k_i = 0.815$ is coefficient for current in a three-phase bridge circuit [21].

Additional current [22]:

$$I_{ad} = \frac{E_{ad}}{R_{ad}} = \frac{k_3 U_{tr} cos\alpha}{R_{ad}}, \tag{2}$$

where $R_{ad} = \frac{3x_{p2}s_2}{\pi} + 2r_{p2} + r_{cd}$ is additional resistance [23].

To determine U_{tr} we assume that $cos\alpha = 1$, $cos\beta = 0$, then:

$$I_{ad} = \frac{k_3 U_{tr}}{R_{ad}}. \tag{3}$$

The rated value of the rectified current with an additional power source is determined from

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012115 doi:10.1088/1755-1315/1415/1/012115

the condition [24]:

$$I_{dp} = k_i\left(I_{dnom} + I_{ad}\right) \leq I_{2nom}, \tag{4}$$

where I_{2nom} is rated current in the rotor windings of the second motor.

Then:

$$\frac{k_3 U_{tr}}{R_{ad}} + I_{dnom} \leq \frac{I_{2nom}}{k_i}, \tag{5}$$

where $I_{dnom} = I_d$, at $cos\beta = 0$, $s_{1nom} = s_1$, $I_{dnom} = \frac{\pi k_1 E_{p1}}{3x_{p1}} \frac{s_{1nom}-\lambda}{(s_{1nom}(1+k_s q)+\rho)}$ [25].

From here:

$$k_3 U_{tr} = \left(\frac{I_{2nom}}{k_i} - I_{dnom}\right) R_{ad}, \tag{6}$$

where $k_3 = 0.9$ for a three-phase bridge circuit [26, 27].

After conversion:

$$U_{tr} = \frac{R_{ad}}{k_3}\left(\frac{I_{2nom}}{k_i} - I_{dnom}\right). \tag{7}$$

Thus, at low slip values, in order to ensure synchronous rotation of two motors in a cascade circuit, an additional power source must be provided in the rotor rectified current circuit I_{ad}, the output of which changes according to the above law [28].

Figure 6 shows a simulation model of a two-motor electric drive corresponding to the functional diagram shown in figure 5.

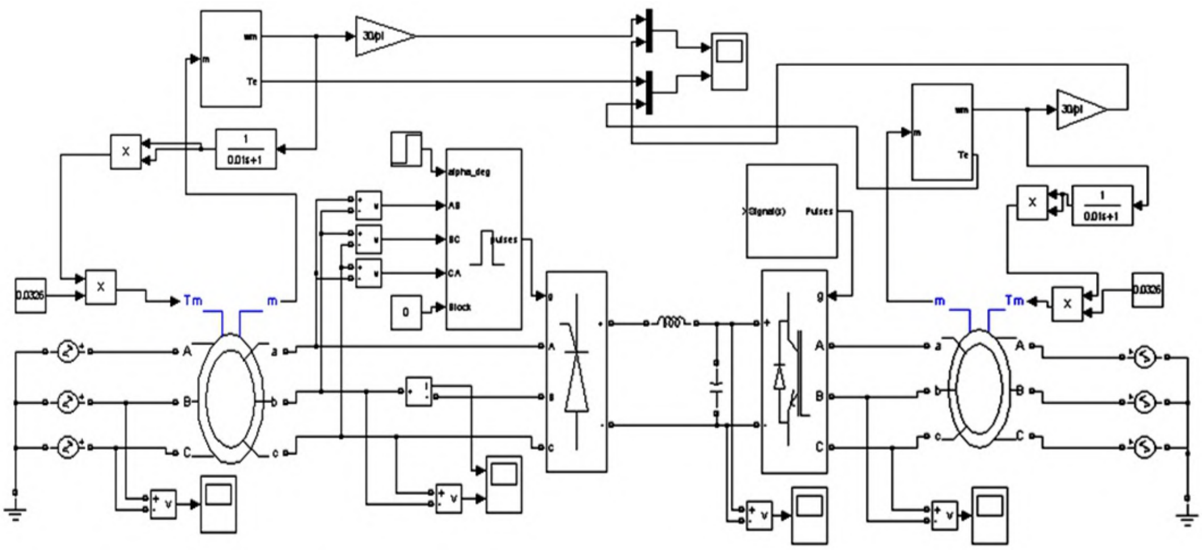

Figure 6. Simulation model of a control circuit for two asynchronous motors in the MatLab environment with an additional power source.

As can be seen from the last figure 7 and figure 8, after connecting an additional power source to the rectified rotor current circuit, the dynamic characteristics of the two motors coincide.

For computer simulation, we utilized the technical specifications of 200 kW motors of type AKN355S6U3 with a rotation frequency of 1000 rpm. The simulation was conducted using MATLAB software, simulating start-up under rated load conditions and assuming even distribution of load on the motor shaft.

To assess the energy-saving and resource-efficient characteristics of the proposed coordinated rotation electric drive scheme, we will compare various systems of double-motor electric drives (DMED) by analyzing technical and economic parameters.

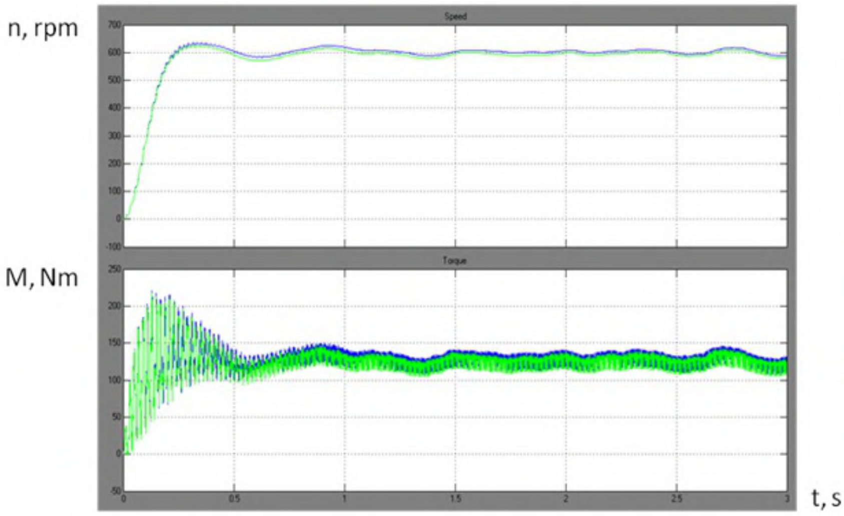

Figure 7. Dynamic characteristics of a two-motor electric drive at $\beta = 30°$.

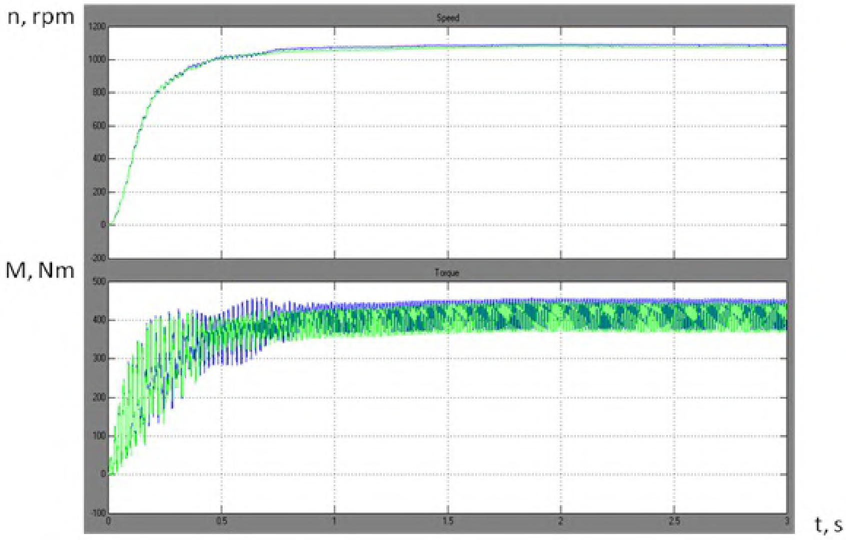

Figure 8. Dynamic characteristics of a two-motor electric drive at $\beta = 60°$.

The installed power of electric motors and power thyristors or TFCs play a significant role in determining the weight, size, and cost of DMED systems. These factors are crucial indicators of DMED performance and largely hinge on the structural diagram of the DMED, the types of TFCs and electrical machines employed, as well as their operational modes. Consequently, these indicators serve as key criteria for comparing different DMED configurations.

As the weight, size, and cost of DMED are primarily influenced by power, rotation frequency, as well as the types of electrical machines and thyristor (or transistor) frequency converters, we derived dependencies of specific cost and mass of these components based on power.

The assessment of cost and weight-size indicators for electrical machines and TFCs relies on specific statistical data concerning commercially available standard sizes of these devices. Analyzing the cost of AC electric machines suggests that evaluating the unit cost as the ratio of the machine's cost to its power is a more practical approach, i.e.

$$C_m = \frac{C_e}{P} = \frac{K_s}{\sqrt[4]{P}}, \tag{8}$$

where C_e is the cost of an electric machine, in conventional units (cu); P is machine power, kW; K_s is specific cost indicator at a given rotation frequency and $f = 50$ Hz. If we take an asynchronous motor with a power of 100 kW as the base machine, then at $n_s = 750$ rpm, $K_s = 60$; at $n_s = 1000$ rpm, $K_s = 48$; at $n_s = 1500$ rpm, $K_s = 35$.

It's important to highlight that the specific cost of an asynchronous motor with a wound rotor is typically 10–12% higher than that of an asynchronous motor with a squirrel-cage rotor, given the same power and speed.

Figure 9 illustrates the relationship between the specific cost of an asynchronous machine with a wound rotor and power at different rotation frequencies. From the graph, it's evident that the specific cost of the machine increases as the synchronous rotation frequency decreases. This indicates that high-speed electric machines are more cost-effective than their low-speed counterparts.

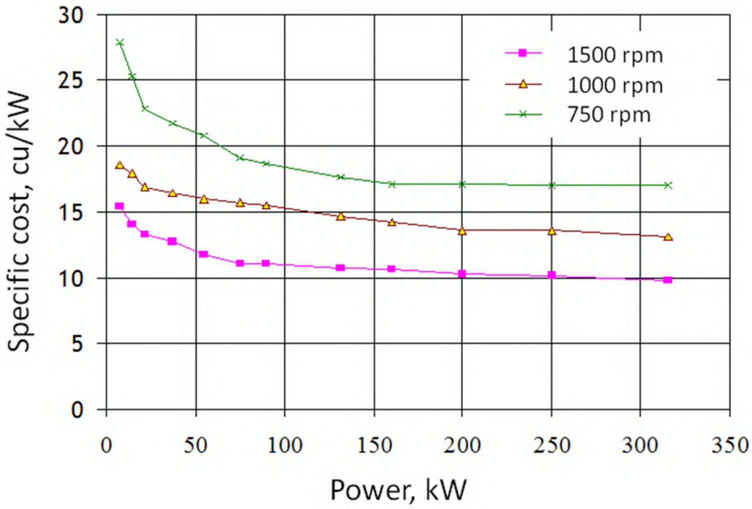

Figure 9. Dependence of the unit cost of an asynchronous machine on power at various rotation frequencies.

A similar dependence would be applicable for TFCs, indicating that

$$C_{TFC} = \frac{C_{TF}}{P_{TFC}} = \frac{K_{TF}}{\sqrt[4]{P_{TFC}}}, \tag{9}$$

where C_{TF} and P_{TFC} are the cost in USD and power in kW TFC; K_{TFC} is specific indicator of TFC power; $K_{TFC} = 510$ and K = 0.333 for a transistor frequency converter.

To conduct a technical and economic evaluation of DMED, we examined the following systems:

1. Frequency-controlled dual-motor electric drive (with TFC situated in the stator circuit of each motor).
2. Double-motor electric drive utilizing a dual-power machine (with TFC positioned in the rotor circuit of each motor).

3. Two-motor electric drive incorporating an asynchronous valve cascade and a dual-power machine (with one TFC situated in the rotor circuit of two motors).

The specific cost of a frequency-controlled DMED, with TFC located in the stator circuit, is determined by the following expression:

$$C_{1DMED} = 2\left(C_{as} + C_{TFC}\right), \tag{10}$$

where C_{as} is the specific cost of one asynchronous motor; C_{TFC} is cost of TFC.

The specific cost of DMED based on dual-fed machines (figure 1), when the TFC is in the circuit of each rotor, is determined by the following expression

$$C_{2DMED} = 2\left(C_{as} + C_{CTFC}\right), \tag{11}$$

where C_{CTFC} is cost of the TFC in the rotor circuit.

The specific cost of DMED based on AVC–DFM, when there is one TFC in the rotor chain of two engines, is determined by the following equality

$$C_{3DMED} = 2C_{as} + C_{CTFC}. \tag{12}$$

It's worth mentioning that the power rating of the TFC in the stator circuit closely matches that of asynchronous motors. Consequently, the variable frequency electric drive system along the stator circuit is more costly compared to the electric drive utilizing the dual-power machine circuit.

The TFC power in the rotor circuit will be equal to

$$P_{TFC} = sP_1, \tag{13}$$

where s is slip, the maximum value of which depends on the control range (for most general industrial motors $s_{max} = 0.3$); P_1 is the power of an asynchronous motor with a wound rotor.

Figure 10 illustrates the relationship between the specific cost of different DDPS systems and the power of the primary engines. It's evident from the graph that this indicator remains relatively constant across a wide power range. The DMED system following the AVC–DFM scheme proves to be more economical compared to DMED systems employing the TFC scheme in both the stator and rotor circuits of each engine. An examination of the weight and size parameters of electric machines can be conducted based on specific static data regarding commercially manufactured motors.

As is known, for an alternating current machine the following equality is true:

$$G_{em} = \frac{G}{P} = \frac{K_g}{\sqrt[4]{P}}, \tag{14}$$

where G is the mass of the electric machine, kg; P is machine power, kW; K_g is specific mass indicator at a given rotational speed and $f = 50$ Hz. If we take an asynchronous machine with a power of 100 kW as the base machine, then at $n_s = 750$ rpm, $K_g = 24$; at $n_s = 1000$ rpm, $K_g = 19.8$; at $n_s = 1500$ rpm, $K_g = 16$.

As demonstrated, a comparative assessment of DMED systems concerning cost, weight, and size indicators reveals that the DMED system following the AVC–DFM scheme is considerably more economical across the entire power spectrum compared to DMED systems adopting the TFC–AM and DFM schemes. Moreover, it does not compromise on weight and size indicators.

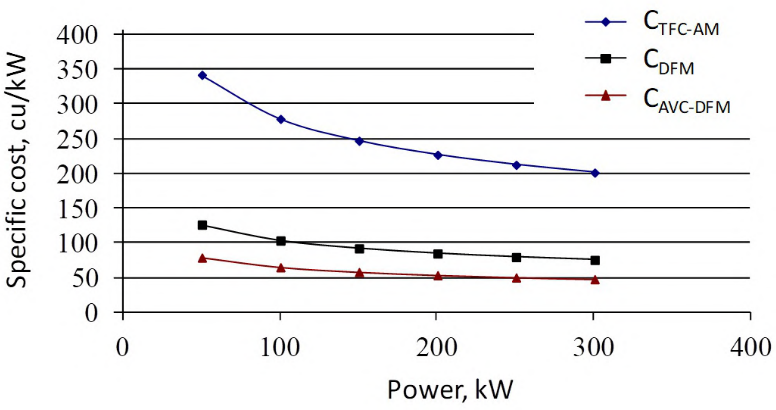

Figure 10. Dependence of the unit cost of an asynchronous machine on power at various rotation frequencies.

4. Conclusions
Therefore, employing a cascade circuit in a dual-motor electric drive, supplemented by an additional power source in the rectified rotor current circuit, enables the synchronized rotation of two motors. This synchronization can be achieved not only with identical nominal parameters but also with differing power and synchronous frequency of rotation.

The primary advantages of this approach to coordinated rotation in a twin-motor electric drive using a cascade scheme include the capacity to adjust the power factor of the machines. Moreover, it reduces the power transferred to the control circuit by the thyristor frequency converter, thus enhancing the reliability of the electric drive's power components. By regulating the rotation frequency of two AC motors, it becomes feasible to enhance energy efficiency [29,30].

Abstract. The Ukrainian energy sector is experiencing a crisis. The necessity for sustainable development in Ukraine's regions, as well as energy independence, stems from the destruction of infrastructure and the consequences of dependency on Russian resources. The current trend is to develop renewable energy sources at the regional level, resulting in a more decentralized model. The article examines the empirical relationship between the causality of production, the potential of renewable energy, and the factors that influence the country's economic growth, such as export, electricity, total final consumption, and total energy supply. The authors propose applying the system approach principle to the study of renewable energy source production in order to ensure the country's energy security, contribute to increasing competitiveness on the international market, and develop a model based on the production of renewable energy sources and waste in Ukraine's difficult economic development conditions. To model the production of renewable energy sources, which is one of the vectors ensuring energy security, the authors used the software product E-Views, which allows for making informed decisions based on statistical analysis and forecasting. During the research process, the authors demonstrated that more effective achievement of sustainable development goals will be facilitated by the formation of a reasonable approach to renewable energy production and the development of a sustainable development policy for Ukraine's regions, which should have significant differences based on the region's specifics.

1. Introduction

The relevance of renewable energy is due to a number of significant factors that affect modern society and the near future. The use of renewable energy helps reduce the negative influence on the environment because, at the moment, the increase in greenhouse gas emissions and other types of pollution causes severe problems such as global warming, rising sea levels, and other bad consequences. Renewable energy provides an opportunity to diversify and decrease our dependency on finite resources, as we observe today that reliance on traditional energy sources, particularly coal and oil, endangers economies and geopolitical stability, potentially leading to war. To prevent wars and other future conflicts over energy supplies, the potential of renewable energy should be chosen, reducing dependence on imported energy carriers.

Additionally, several countries are implementing policies to limit greenhouse gas emissions, with renewable energy serving as an effective tool to achieve these objectives. As a result, renewable energy is acknowledged as a critical component of current sustainable development and resource management strategies, and its importance grows in the face of global environmental and energy issues.

2. Literature review

Renewable energy sources are becoming increasingly significant in the context of the geopolitical crises. The financial market is undergoing a change, with a primary focus on increasing corporate sustainability and its impact on business strategies [1]. This can be explained by the Paris Agreement, which places huge corporations in the forefront of the fight against climate change. Aluchna et al. highlights the role of institutional investors in driving companies to publish social information and corporate transparency in the renewable energy sector [2]. The development of the green economy should begin at the local level, as indicated in the papers by Afroz and Muhibbullah [3], and Dmuchowski et al. [4], because the dynamic linkages between non-renewable and renewable energy sources and economic growth are studied. This nonlinear methodology provides a methodological perspective that may be used to evaluate Ukraine's economic growth potential through the implementation of renewable energy. Ahmad, Zhang and [5], and Saqib et al. [6] conduct a comprehensive review of renewable energy sources (RES) and electricity demand forecasting models, with a focus on smart grid applications and buildings, to ensure the development of technological innovations for environmental sustainability.

According to Stern and Valero, innovation is at the nexus of growth and zero-emissions transition [7]. Understanding forecasting models is critical for strategic planning and policy formation as Ukraine pursues energy security through renewable energy sources. Such an understanding is critical to Ukraine's long-term energy security plan. The role of the government and macroeconomic stability continue to be important considerations in determining strategy and maintaining long-term development. The escalation of environmental issues necessitates the search for an adequate system and resources to address them without compromising economic growth. This demands a shift from resource-based to green economic development [8, 9].

Understanding the policy consequences is crucial for coordinating modeling efforts with national energy security objectives. Countries are creating collaborative energy initiatives and are always looking for sustainable energy alternatives. This may be seen in the post-pandemic cases for EU energy and climate policies, particularly following Russia's invasion of Ukraine. The studies by Miík and Nosko [10], and Barbier [11] examine the impact of geopolitical events on energy policy and ecological revival in democratic countries.

Furthermore, Europe actively refuses to cooperate with Russian energy resources, sparking debate within the community about geopolitical considerations, policy implications, and the challenges faced by EU member states, particularly Hungary, in implementing sanctions against Russian oil [12–15]. Global energy consumption is rising, with policy implications. It is vital to understand the causes contributing to the growth of energy demand and to explore appropriate policy actions to address the issues connected with energy consumption trends. Much of the renewable energy can be generated locally, reducing the requirement for huge energy infrastructure and fuel transportation. This helps to system stability and reduces the risks associated with international energy commerce, particularly in times of geopolitical or economic uncertainty that may limit access to traditional sources.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012116 doi:10.1088/1755-1315/1415/1/012116

3. Materials and methods, starting hypotheses

Various factors influence renewable energy production, development, and potential, including economic, technological, infrastructural, resource, and other considerations. The majority of published studies in the present literature investigate theoretical and empirical correlations. Despite the relationship, there have been very few empirical studies that investigate the relationship between the causality of production and the potential of renewable energy and the factors that determine a country's economic growth, such as E – export, EI – electricity, TC – total final consumption, and TS – total energy supply.

The authors propose applying the system approach principle to the study of renewable energy source production in order to ensure the country's energy security, increase its competitiveness on the international market, and develop a model based on the production of renewable energy sources and waste in Ukraine's difficult economic conditions. This principle is founded on the idea of viewing the system as a whole, with components interacting with one another and the external environment. According to the authors, this method allows us to think of the energy system as an interconnected complex of many aspects, such as renewable energy production and waste management, which will help to ensure energy security. The chosen approach includes system integrity, which is not limited to individual components; component interaction – verification of the cause-and-effect relationship between the selected variables; and an emphasis on system management to achieve goals, such as optimizing energy production, efficient resource use, waste minimization, and ensuring sustainable development. A systems approach to modeling renewable energy and waste management enables a more thorough and integrated knowledge of energy-ecological systems, as well as the development of effective solutions for resource sustainability.

We are using the E-Views application to model renewable energy production, which is one of the vectors for assuring energy security. The multivariate regression model appears like this:

$$Y = f(X_1, \ldots, X_n) \tag{1}$$

We examine the influence of the selected most significant variables and the density of their link using the model we have developed. The E-Views application is used because it allows for the creation of an econometric model, forecasting, and drawing conclusions to assure the country's energy security. As a result, the selection of the specified software product is relevant in terms of instrumental capabilities to the tasks addressed in this study. The statistical data used in the analysis were collected between 2010 and 2021, hence the model has 12 observations. The equation below describes the model's general appearance:

$$P = f(TC, E, TS) \tag{2}$$

where P – Production (PJ); TC – Total final consumption (PJ); E – Exports (PJ); TS – Total energy supply (PJ); PJ is petajoules.

When selecting the most significant factors, we apply the reliability principle, which adequately reflects the current state of renewable energy production, the information availability principle, which involves the use of official World Energy Balances Highlights 2023 data [16], and the representative principle, which states that each variable chosen for the sample is the most significant and justified.

4. Results and discussion

4.1. Renewable energy as a vector for the country's energy security and sustainable energy future

Renewable energy is a crucial component of ensuring energy security. The use of renewable energy sources allows the country to diversify its energy mix. Instead of relying on scarce resources such as coal or natural gas, which a country may lack or have in limited supply, solar, wind, hydropower, and other renewable sources can be employed. This decreases the risk of energy crises and helps to provide a more sustainable energy supply. In addition, renewable energy is a key strategic method to ensuring the sustainability and security of the country's energy system. The benefits of diversifying energy sources include:

- reduction of energy risks associated with possible fluctuations in the cost of raw materials, changes in the world markets of energy resources, political and economic turbulence;
- reducing dependence on energy imports, in particular oil, gas, and coal, which collectively reduces vulnerability to economic or political changes in exporting countries;
- support for sustainable development, which contributes to achieving environmental goals and reducing the negative impact on the environment;
- ensuring the stability and reliability of the energy system thanks to renewable energy through the placement of various sources. The diversity of renewable sources allows to ensure the stability of the energy system in case of emergency situations, such as natural disasters or geopolitical conflicts, and reduces the risk of interruptions in the supply of energy;
- the possibility of using the latest innovative technologies, as well as solar panels, wind turbines, hydropower, biomass, etc. The launch and development of renewable technologies stimulates the domestic market, promotes the attraction of investments in the energy sector and the development of the innovative sector. This can lead to the creation of new jobs, support for small and medium-sized enterprises and increase the country's competitiveness in the global energy market. This enables countries to choose technologies that best suit their conditions and needs.

In general, renewable energy is not only a source of clean energy, but also a strategic component in enhancing the country's energy security and establishing a secure, sustainable energy future.

4.2. Econometric modeling of renewable energy production, hypothesis testing, correlation analysis and causality analysis

Globalization has put the world's economies in a new economic context that is linked to the growth of renewable energy sources. However, how specifically and forcefully do the factors influence the output of renewable energy sources as a vector of Ukraine's energy security? The answer to this issue can be reached by examining the functional relationship between renewable energy production and the variables being researched. For this purpose, the authors utilized the software product E-Views, which enables the generation of results in the form of tables, graphs, and charts. Among the econometric methods available in E-Views, we employed Descriptive Statistics, Hypothesis Testing, Correlation and Covariance Analysis, Regression Analysis, Forecasting, and Pairwise Granger Causality test.

To identify the relationship between the production of renewable energy sources and the selected variables, we will use the multivariate regression method. The general form of the regression equation is as follows:

$$P = C(1) \times TC + C(2) \times E + C(3) \times TS + \epsilon \tag{3}$$

where $C(1, 2, \ldots, n)$ – the regression coefficients for the selected variables, ϵ – the vector of random deviations.

The correlation matrix built by the authors allows establishing the relationship between the selected variables (table 1).

Table 1. Correlation matrix of selected variables.

	P	TC	E	TS
P	1	0.9570	-0.5629	0.9859
TC	0.9570	1	-0.6380	0.9157
E	-0.5629	-0.6380	1	-0.4229
TS	0.9859	0.9157	-0.4229	1

The relationship between the selected factors is positive and strong for P and TC is 95.7%, for positive P and TC is 98.6%, and the inverse relationship between P and E is 56.3%. The positive relationship between the production of renewable energy sources and the total final energy consumption and supply indicates their close interdependence.

It should be noted that the inverse relationship between renewable energy production and exports can benefit the country not only economically through market opportunities, but also in terms of sustainable development, job creation, and environmental impact reduction. Countries that actively develop and produce renewable technology might gain a competitive advantage in the global market and export their innovations. This might involve exporting solar panels, wind turbines, energy storage technologies, and other components of green systems. As a result, the inverse relationship between the selected factors can reveal new challenges and opportunities for the energy industry, helping to transition to a more sustainable and efficient energy future.

The cause-and-effect relationship between the selected variables (TC, E, TS) and P – the production of renewable sources is investigated using the Granger causality test. The idea behind the test is whether past values of one variable can be used to predict another. Granger causality test results are interpreted based on F-statistics and p-value ("Prob." in table 2). If the p-value is less than the specified level of significance (usually 0.05), then the null hypothesis is rejected, which indicates the existence of a causal relationship between the variables. If two coefficients are simultaneously statistically significant, then the relationship is two-way or inverse. The presence of a two-way relationship may indicate the existence of a third variable that is the real cause of changes in the two variables represented in the equation. The tests were carried out for lags 2 and 3. The test results are presented in table 2. The null hypothesis of the test claims that there is no causal relationship.

The pairwise Granger Causality test was run on all variables with lags 2 and 3, allowing the

Table 2. Pairwise Granger Causality test on all the variables, 2010-2021.

E does not Granger Cause TS	2.30734	0.1950	accept	1.29792	0.4630

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012116 doi:10.1088/1755-1315/1415/1/012116

study to incorporate the long-term interaction of all indicators chosen for examination. The table displays this information. Two data points suggest that there is a causal relationship between the selected variables. Note that the test revealed that "E does not Granger Cause TC", which means: the historical values of the E – export variable cannot be used as an effective prognostic indicator for changes in the TC – total final consumption variable, i.e., exports have no effect on and do not determine the total final consumption of renewable energy in the country, whereas exports determine renewable energy production volumes. As a result, the historical correlations between these two variables may not be obvious enough to foresee.

The pairwise Granger Causality test demonstrated that all selected variables can be used to model and anticipate P – production from renewable sources.

Table 3 shows the results of additional regression analysis, allowing us to examine the impact of chosen variables on renewable energy generation in Ukraine over the twelve-year period 2010-2021.

Table 3. The results of multi-factor regression of P (least squares method, sample 2010–2021, 12 observations).

Log likelihood	-21.03753	Hannan-Quinn criter.		4.113079
F-statistic	3157.184	Durbin-Watson statistic		2.056079
Prob(F-statistic)	0.000000			

We define the model's requirements for the qualitative parameters of the factors, using a marginal 5% level of significance. Table 3 shows the following results:

- The export variable's coefficient has a negative impact on renewable energy production, whereas the total final consumption and energy reserve coefficients have a favorable impact.
- The value of the regression R^2 indicates how strongly the specified variables are related to renewable energy generation. According to regression calculations, 99% of the increase in P depends on the selected variables (correlation coefficient is 0.99). This indicates the presence of a sufficiently strong connection. The probability of accepting the null hypothesis is close to zero (F-statistic=0.00), which confirms the alternative hypothesis, which indicates the significance of the equation as a whole. The selected variables are significant in terms of impact on P: total final consumption – 1.26%; export – 0.00%; the total energy reserve is 0.00%, and this meets the threshold of less than 5%. As a rule, there are no strict requirements for the constant, but in our case, it is also statistically significant, because it is less than 1%, that is, all indicators are statistically significant. We use the Durbin-Watson (DW) test to determine whether the equation has first-order autocorrelations. The DW criteria has a value ranging from 0 to 4; zones are separated into zones with no autocorrelation, zones with positive and negative autocorrelation, and zones of uncertainty (critical zones). Table 3 shows that the criterion (DW) is 2.056. We use Durbin-Watson statistics to calculate the significant (critical) points d_l and d_u. For the number of observations of 12 and 4 variables at the level of significance α=5%,

0.658<DW<1.864; at the level of significance $\alpha 1 = \%$, 0.449<DW<1.373. This means that there is no autocorrelation of the residuals and we have no reason to reject H_0, that is, we take it as a basis.

- We also use the Breusch-Godfrey test (table 4) to determine the presence of higher (second) order autocorrelation. Second-order autocorrelation testing is equivalent to testing the null hypothesis: it determines whether there is dependency in the model's residual terms at different remote time steps. The Breusch-Godfrey test aims to discover autocorrelation in the regression model's residual terms. That is, we check again to see if the null hypothesis is accepted or rejected. Prob. $F(2,6) = 25.7\%$, and Prob. $\chi^2(2) = 11.24\%$, beyond the 5-10% threshold of significance. This test demonstrates the absence of higher (second) order autocorrelation and the feasibility of accepting H_0.
- The analysis of the information criteria used in the development of this model revealed that Akaike (AIC) = 4.17 and Schwarz (BIC) = 4.11 are small, acceptable values for the model.

Table 4. Breusch-Godfrey serial correlation LM of P (Presample missing value lagged residuals set to zero).

Prob(F-statistic)	0.651059			

The next step is to evaluate the autocorrelation of the model's remaining members (table 5). A residual term correlogram is used to investigate the structure of residual terms and uncover potential patterns or connections among them.

The "prob" value reflects the probability that the chosen statistical model has a null hypothesis of no residual autocorrelation. If "prob" is less than a predetermined significance level (such as 0.05), the null hypothesis is rejected, indicating a statistically significant autocorrelation. All "prob" values in the created model are greater than the significance threshold, implying that the model can continue in its current form without further analysis to account for the identified autocorrelation in the remaining terms.

4.3. Testing the model for the presence of heteroscedasticity and the quality of the selected variables in the model and forecasting

The next step is to test the model for heteroscedasticity, which allows us to evaluate whether the remaining members of the model have uneven dispersion, i.e., whether the error variance changes

Table 6. The results of heteroskedasticity test of P.

Test: White	Obs*R-squared	5.25508	Prob. Chi-Square(9)	0.7670
Test: Breusch-Pagan-Godfrey	Obs*R-squared	3.377655	Prob. Chi-Square(3)	0.3370
Test: Harvey	Obs*R-squared	2.705518	Prob. Chi-Square(3)	0.4393
Test: Glejser	Obs*R-squared	2.253159	Prob. Chi-Square(3)	0.5216
Test: ARCH	Obs*R-squared	2.575876	Prob. Chi-Square(1)	0.1085

in relation to the independent variable values. Heteroskedasticity can impair the efficiency and consistency of model parameter estimates. We do this check using tests (table 6).

If the p-value obtained from the test is less than a specified significance level (for example, 0.05), then there is statistically significant evidence of heteroskedasticity and the null hypothesis is rejected. Analysis of table 5 showed that the p-value in all tests is greater than 5%, so it is possible to accept H_0.

The next step is to evaluate the model for explanatory power, which indicates how well the model represents the variation in the dependent variable (the variable the model is trying to explain) based on the input independent variables. This is an important aspect of evaluating the effectiveness of the model and its ability to adequately describe the data (table 7).

Next, we compared P to variables (with a focus on regressors), which implied a partial analysis of the relationship between P and other variables while accounting for the influence of regressors or independent variables. In this instance, "partial" refers to the analysis that takes into consideration the effects of the given regressors, effectively eliminating their influence to investigate the net link between renewable energy output and the remaining variables (figure 1).

This analysis shows how P evolves as the effects of regressors are taken into account. Figure 1 depicts a partial correlation that measures the strength and direction of the relationship between two variables $P - TC, P - E$, and density. A strong relationship is observed for $P - TS$, while taking into account the influence of other regressors, and allows to isolate the net effect between P and other variables, regardless of the influence of regressors.

Figure 2 depicts the normality test for the residuals. Figure 2 demonstrated the normality of the model's residual distribution, with a Kurtosis value of 2.51, which is more than zero and suggests a strongly peaked distribution; this indicator indicates that the distribution is near normal. However, 2.51 does not indicate a deviation from normality on its own, but it may be one indicator to consider in conjunction with other statistical features and graphs when assessing the normality of the residual distribution.

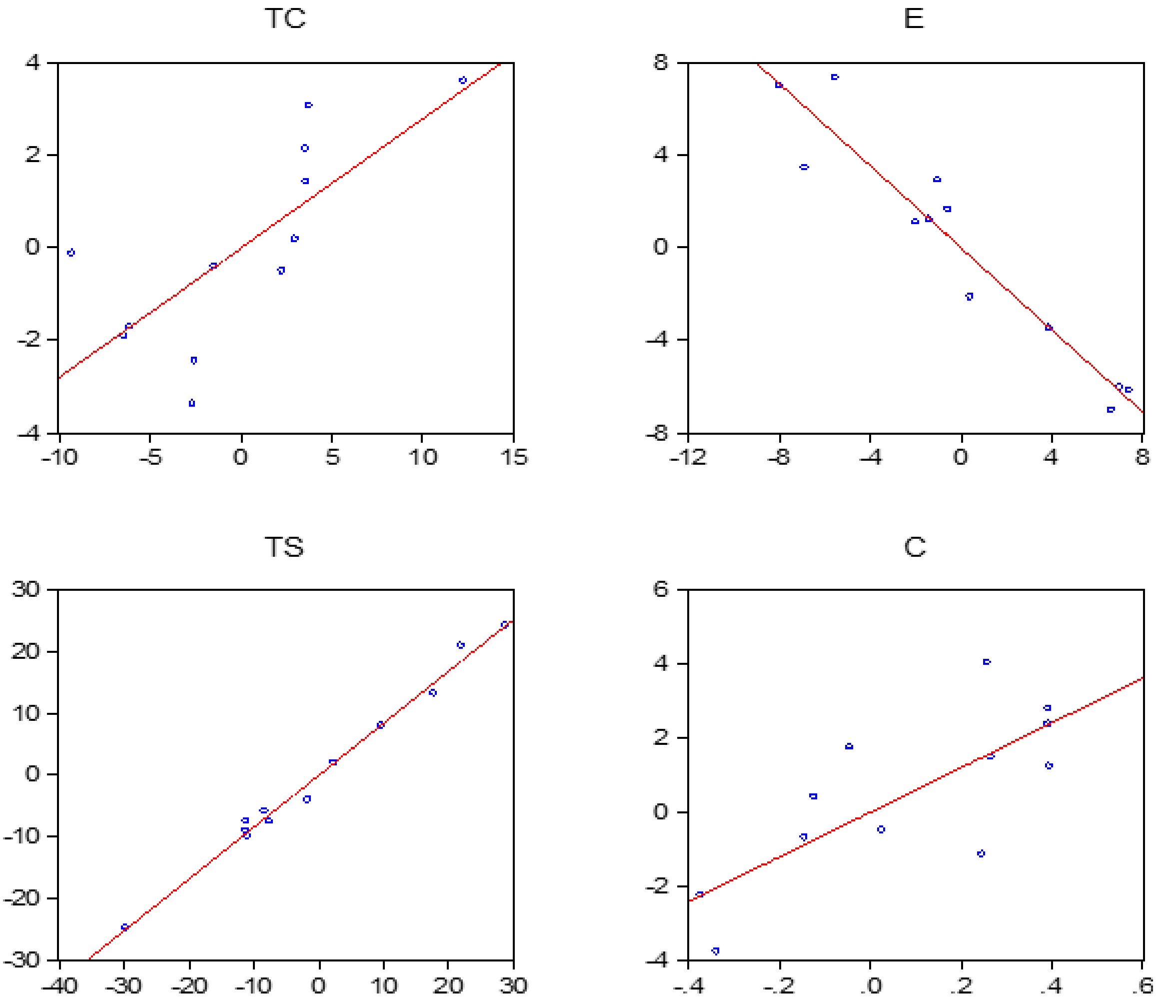

Figure 1. Production vs variables (partialled on regressors).

Table 7. Explanatory ability of the model.

obs	Actual	Fitted	Residual
2010	117	116.9901	0.0098
2011	114	113.5748	0.4251
2012	113	114.1370	-1.1370
2013	146	143.5267	2.4732
2014	137	137.1059	-0.1059
2015	134	136.6305	-2.6305
2016	173	173.6434	-0.6434
2017	188	185.9822	2.0177
2018	202	200.8461	1.1538
2019	200	199.8168	0.1831
2020	246	247.7437	-1.7437
2021	257	257.0021	-0.00217

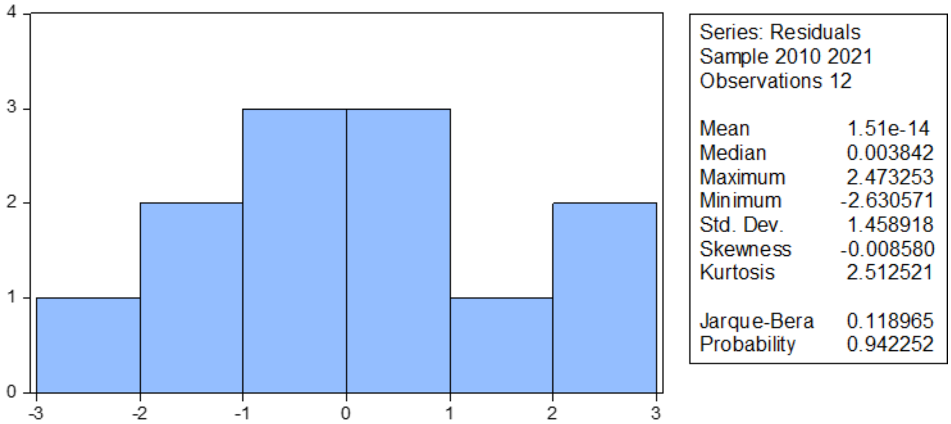

Figure 2. Normality test in $f(P)$.

The skewness indicator value of -0.0085 is a measure of the asymmetry of the value distribution in our model, indicating that it is skewed to the left (negative) and symmetric (skewness is close to zero). That is, skewness shows that the residual distribution deviates slightly from symmetry, close to zero, and does not pose any significant concerns in terms of residual distribution normality.

Figure 2 shows the probability of acceptance of H_0 at a high level and it is 94.2%.

Figure 3 shows the forecasting trend, which has a positive growing trend demonstrating the relevance and value of renewable energy production.

In our model, MAPE = 0.66, indicating that the average percentage error between predicted and actual values is 0.66% This means that, on average, predictions differ by 0.66% from actual values. The lower the value, the better, because MAPE implies great forecast accuracy.

So, we have a statistically significant equation with a high coefficient of determination:

$$P = 0.2794 \times TC - 0.8868 \times E + 6.0362 \tag{4}$$

The multiple regression model predicting the development of renewable energy output based on independent factors was successfully tested. All examinations and testing have confirmed the

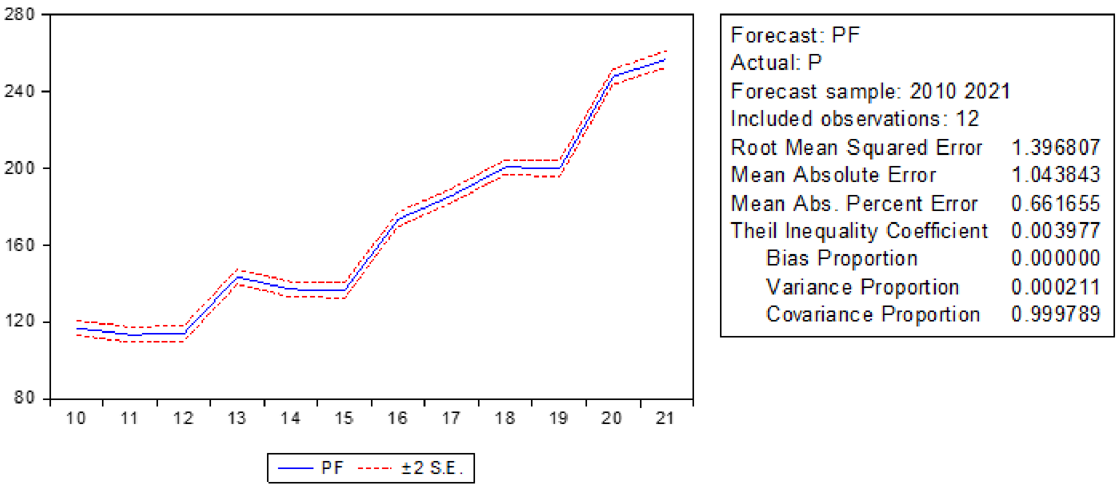

Figure 3. Forecast of P.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012116 doi:10.1088/1755-1315/1415/1/012116

accuracy of this model for Ukraine. This means that:

- the equation is statistically significant with a high coefficient of determination;
- the equation represents an economic-mathematical model at a high level of quality;
- the model built by the authors is adequate and fully acceptable for forecasting in the future with a deviation of 0.66% from the actual values.

5. Discussion

Further discussion of the selected problem is important for the future of all countries throughout the world. The authors revealed this issue by utilizing Ukraine as an example, taking into account the country's unique economic development and political environment. Certainly, while dealing with the situation, alternative econometric models might be utilized for predicting. Furthermore, our attention was focused on three variables: total final consumption, exports, and total energy supply; however, the impact of other factors, particularly those affecting renewable energy production, such as climatic conditions, technological innovations, economic factors, and regulation, should be investigated in the future.

It would be useful to evaluate the economic aspects of renewable energy generation, such as the cost of installing and maintaining equipment, efficiency in comparison to conventional energy sources, and the growth of countries' energy markets. These components can be used to broaden and deepen the conversation, encompassing various areas of renewable energy modeling and forecasting for energy security.

The author's multi-regression model of the dependence of renewable energy production growth was constructed and analyzed based on statistical data spanning from 2010 to 2021. However, starting in 2022, the full-scale invasion of Russia into Ukraine began. Therefore, it will be pertinent to examine the repercussions of the war for Ukraine's energy security, as well as the potential impact on the implementation of renewable energy initiatives in future research.

6. Conclusions

The authors conducted study on renewable energy sources as one of the energy security vectors of Ukraine, modeling and projecting their production. They identified:

- the presence in the long-term period of factors that affect the total volume of production of renewable sources, which is one of the vectors/directions of ensuring energy security, the formation of a balanced and sustainable energy system of Ukraine in conditions of sustainable development;
- the existence of a strong relationship between the amount of renewable energy production and the total final consumption and the total energy reserve, and the correlation coefficients are quite high;
- the analysis of the coefficients in equation (4) showed that an increase in the value of the TC variable by 1% should lead to a positive contribution to the production of renewable energy by 0.3%; if the value of TS increases by 1%, then the value of P will increase by 0.8%; if the value of variable E increases by 1%, it will lead to a negative contribution to P by 0.9%;
- the modeling and forecasting of renewable energy generation demonstrated a good trend in the context of modern energy security difficulties and a general increase in awareness of environmental pollution problems. This trend, based on Ukraine's experience, demonstrates the active deployment and development of modern renewable energy technology. Increased output of renewable energy sources, including solar, wind, and hydropower, is a significant positive element. This contributes to the diversification of the country's energy mix, reduces dependence on traditional sources, and contributes to the creation of a sustainable and

environmentally friendly energy sector. An additional factor of the positive trend today and for the future is the active participation of Ukraine in the implementation of international programs and agreements aimed at supporting renewable energy. This will allow the country to receive technical and financial support for the modernization and development of renewable energy, especially after the end of the war (because statistical data were analyzed before the start of the full-scale Russian invasion of Ukraine). The overall favorable trend in Ukraine's renewable energy production helps to reduce dangerous substance emissions and encourages sustainable energy development. Supporting and developing this trend is crucial for Ukraine's energy security, including achieving energy independence and addressing environmental concerns in the modern world;

- to more effectively achieve the goals of sustainable development, countries, including Ukraine, should encourage the formation of a reasonable approach to the production of renewable energy sources as well as the development of sustainable development policies for Ukraine's regions, which should differ significantly based on regional characteristics. The current geopolitical scenario, as well as the war in Ukraine, have demonstrated the implications and problems confronting European countries and Ukraine, demonstrating the benefits of renewable energy sources in maintaining Ukraine's energy security.

Abstract. The article presents the results of research aimed at determining the parameters and characteristics of storage heating systems, justifying the possibility of using heat accumulators to increase the efficient use of energy that is generated, including from renewable sources. The virtuality, frequency and significant dependence on natural conditions and climate of renewable energy sources, as well as the need to optimize their installed capacity, leads to the need to use energy storage installations. The presence of efficient energy batteries is a prerequisite for modern efficient energy and heat supply systems. The methodology of the work is based on our own theoretical and experimental studies, which provide practical recommendations for the arrangement of energy accumulators obtained using renewable heat sources. This is especially relevant for Ukraine during the period of active military operations on its territory, the destruction of traditional energy sources and a shortage of generating capacity. Recommendations have been developed for the design of heat accumulators for heating systems of residential and public buildings. Their effectiveness has been assessed under conditions of limited use of fossil fuels and the use of hybrid energy sources. Scientific and practical results of the work make it possible to carry out low-cost reconstruction of heating systems for the introduction of storage systems using electrical energy, the source of which is wind and solar energy. Such developments are becoming particularly relevant in Ukraine, taking into account the requirements for ensuring the stability and efficiency of infrastructure facilities in war conditions.

1. Introduction

Thermal batteries are one of the important elements when addressing the issue of replacing fossil fuels, such as natural gas, with renewable energy sources, as well as when using low-potential energy sources. The use of energy batteries when installing hybrid systems is also mandatory [1]. Accumulation makes it possible to solve important tasks set in the updated energy efficiency directive [2].

The use of thermal accumulators in thermal power systems with renewable sources, including the generation of electrical energy from biogas, helps reduce CO_2 emissions into the atmosphere and reduce the greenhouse effect [3].

Renewable energy sources generate energy that is variable in both time and quantity. For example, the use of solar or wind energy for heating purposes is practically impossible without the use of heat storage. In addition, heat accumulation can be considered as a means of leveling the energy consumption schedule. When using two and three-rate tariffs, heat accumulators make it possible to obtain a significant economic effect associated with the possibility of obtaining energy during periods of the lowest tariffs.

An additional challenge is charging for the installed power of the power generator. The use of heat accumulators makes it possible to reduce the installed capacity of consumer heat and power systems by leveling the load and covering peak loads using accumulated heat. In addition, heat accumulation allows for more efficient use of renewable energy sources with variable generation capacity.

There are two types of such batteries. The first type includes those whose temperature increases as a result of the supply of heat, the second – those in which the supplied heat is spent on some kind of phase transition – most often melting. In the first case, the specific energy of the battery is determined by the heat capacity of the storage substance and the permissible change in its temperature, and in the second – by the latent heat of phase transition.

The article discusses the issues of determining the operating parameters of water batteries without a phase transition.

The developed methodology for determining the characteristics of thermal accumulators can be applied not only when using electrical energy, but also for any other energy sources in heating systems. It is also possible to use the technique when using hybrid energy sources.

Algorithm for researching the given problem:

- work with literary sources on the topic of using electrical energy in heating systems [4–6];
- analysis of the issue of using heat accumulators in electric heating systems [7–9];
- full-scale studies of operating modes of heating systems in residential and public buildings;
- construction of a mathematical model to determine the operating parameters of heat accumulators;
- determination of the main parameters of the heat accumulation system;
- experimental verification of the obtained dependencies to determine the operating parameters of the accumulation system.

2. Methodology

The design and installation of storage heat supply is facilitated by the continuous increase in the price of natural gas and other types of fossil fuels. This, in turn, leads to an increase in tariffs for thermal energy received in centralized and other heat supply systems.

Thus, renewable energy can be considered as a useful alternative to energy obtained by burning fossil fuels (such as natural gas).

However, the use of electrical energy for heating needs helps solve the problems of power engineers themselves. Namely, the problem of a shortage of shunting capacity to regulate the daily load schedule of the energy system against the backdrop of a surplus of electrical energy generation. The use of electrical energy for heating buildings at night can be a good way to level out the unevenness of electrical energy consumption in the power supply system. Especially when using electrical energy generators using renewable and alternative energy sources. And also in conditions of military threats to infrastructure facilities.

The advantage of using electrical energy as an energy carrier is also the ability to maintain the temperature regime of heating water in boilers with high accuracy.

The use of electric heating systems makes the task of assessing the efficiency of storage systems extremely relevant. From a thermodynamic point of view, from 1 m^3 of natural gas of group L or E according to the classification [10,11] with a calorific value of up to 40 MJ/m^3 it is theoretically possible to obtain (provided that the process is 100% efficient) up to 11 $kW{\cdot}hour/m^3$ of electrical energy.

However, the low efficiency of condensing thermal power plants leads to the fact that the amount of generated electrical energy does not exceed 3-4 kW·hour/m^3, which immediately affects electricity tariffs.

Let's perform a thermodynamic analysis of the use of various types of energy.

The advantage of electric heating boilers, without a doubt, is their high thermal efficiency of converting electrical energy into heat, which is close to 99%.

For comparison, when using the best hydrocarbon fuel – natural gas – in non-condensing boilers, the thermal efficiency does not exceed only 91-92%. It cannot be large due to the fear of condensation of water in the composition of fuel combustion products. In condensing heat generators, the efficiency of fuel use can be increased to 95-96% [12].

However, the difference in the efficiency of heating gas and electric boilers for municipal energy is easily compensated by the extremely low efficiency of the steam power cycle for generating electrical energy at condensing power plants.

The situation may change if renewable sources are used to generate electricity. However, the potential of such energy sources in the cold season, as a rule, decreases, and the virtuality of obtaining energy from renewable sources, on the one hand, and the high requirements for the reliability of heating systems, on the other, transform this task into a multi-variant one. This conclusion may also be valid when comparing the cost of energy, unless the cost of electrical energy is subject to any preferences, such as a "night tariff".

A significant reduction in the cost of electrical energy occurs when switching to a two-part (or three-rate) tariff for electrical energy. This method of payment for electrical energy makes it possible to implement such a method of electric heating as electric storage heating.

During the night period of the day, during the period of preferential tariff for electrical energy, the electric storage system takes electrical energy from the network for the purpose of heating water and accumulates hot water in the storage tank. The volume of accumulation must be sufficient for full operation of the heating system during the daytime period, when the selection of electrical energy from the network at an increased tariff is impractical. During this period of the day, coolant will be withdrawn from the storage tank.

A schematic diagram of the arrangement of such a system is shown in figure 1.

It is possible to determine the main parameters of such a system and performance indicators of its operation.

Initial data for calculation:

M_o – the flow rate of water that circulates in the heating system of the building is determined according to the relationship:

$$M_o = \frac{Q_o}{(t_1 - t_2)c_w}, \tag{1}$$

where Q_o is the heat flow for heating the building, depends on the heat-protective characteristics of the building envelope, kW; c_w – heat capacity of water, kJ/(kg·°C);

M_b – the mass of water in the accumulation tank (kg) which can be written as:

$$M_b = V_b \rho_w, \tag{2}$$

where V_b is the volume of the accumulation tank, m^3; ρ_w – density of water in the container, kg/m^3.

Let us introduce other factors that influence the solution of the problem.

N is the power of the electric heater, which should ensure heating of water with a flow rate of M_o to a temperature t_1 sufficient to ensure comfortable conditions for people to stay in the building during periods of both supply and accumulation, and consumption of thermal energy.

τ_n – duration of night supply of electrical energy and accumulation of heat throughout the day, at a reduced tariff, per hour, for example $\tau_n = 7$ hours (from 23:00 to 6:00) – time of supply and accumulation of energy.

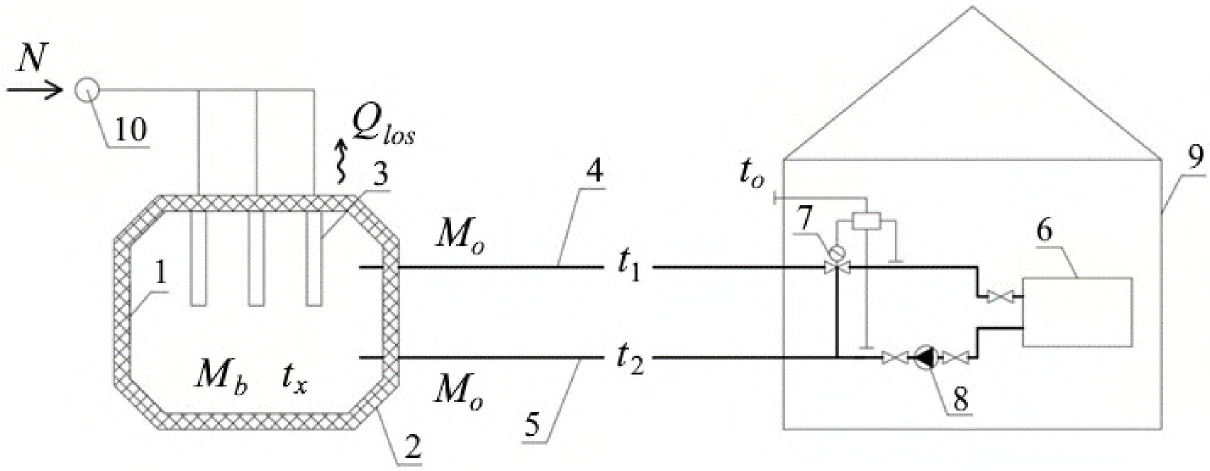

Figure 1. Schematic diagram of the arrangement of an electric storage system with a water storage tank: 1 – water storage tank; 2 – thermal insulation of the tank; 3 – electric heater; 4 – hot water supply pipeline with coolant temperature t_1; 5 – return pipeline with temperature t_2; 6 – heating devices for building heating systems; 7 – three-way control valve; 8 – circulation pump; 9 – heated building; 10 – multi-tariff electric meter; Q_{los} – heat loss from the electric storage tank.

$\tau_u = (24 - \tau_n)$ – daily duration of energy use without external replenishment. During this period of the day, the use of electrical energy to heat the coolant is not economically justified, since the daily tariff for electrical energy exceeds the night tariff.

η_l is a coefficient that takes into account heat loss from the battery tank to the environment. Provided effective thermal insulation of the tank $\eta_l = 0.93 \div 0.95$ (heat loss to the environment is $5 \div 7\%$).

$n' = Q'_o/Q_o$ is a coefficient that takes into account the presence in the system of buildings and structures for which it is possible to partially or completely reduce the amount of heat released for heating during the period of energy supply and accumulation (for example, due to the accumulation of heat in building envelopes or a temporary decrease in temperature in the room).

$n'' = Q''_o/Q_o$ is a coefficient that takes into account the share of buildings in which it is impossible to temporarily reduce the supply of heat for heating during the period of energy accumulation.

Q'_o is a heat flow for heating that part of buildings in which it is possible to reduce the amount of heat supplied for heating during the period of energy supply and accumulation, kW.

Q''_o is the heat flow for heating that part of the buildings in which it is not possible to reduce the amount of heat released for heating during the accumulation period, kW.

Thus, the total amount of heat (kW·hour) supplied for heating needs for a group of buildings and structures can be written as an equation:

$$Q = Q_o \cdot n' \cdot (24 - \tau_n) + Q_o \cdot n'' \cdot 24. \tag{3}$$

If the coefficient $n' = 0$, then this means that there are no buildings in which a temporary reduction in heat supply at night at the subsidized tariff is possible. If during the night period there is a possibility of disconnecting all buildings from the heat source, then $n' = 1$, and the coefficient $n'' = 0$. If it is possible to reduce the heat consumption for heating at night by half, the values of the above coefficients will have the values $n' = 0.5$ and $n'' = 0.5$.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012117 doi:10.1088/1755-1315/1415/1/012117

3. Results and discussion

The main design parameters of electric storage heating systems include the following:

- required electric power of the heater – N;
- capacity of the hot water storage tank – V_b.

Such a tank, under conditions of periodic supply of energy to water, must provide the required temperature of the coolant in the supply line of the heating system throughout the entire period of energy use. This temperature, in addition, depends on the temperature of the external air and is determined in accordance with the temperature schedule for the release of the coolant.

We determine the required power of the electric heater from the system heat balance equation:

$$\eta_l \cdot N \cdot \tau_n = Q_o \cdot n' \cdot (24 - \tau_n) + Q_o \cdot n'' \cdot 24. \tag{4}$$

After some mathematical transformations we get:

$$\eta_l \cdot N \cdot \tau_n = Q_o \cdot (24 \cdot n' - \tau_n \cdot n' + 24 \cdot n''). \tag{5}$$

Or the required electrical power of the heater should be:

$$N = \frac{Q_o \cdot (n' \cdot (24 - \tau_n) + 24 \cdot n'')}{\eta_l \cdot \tau_n}. \tag{6}$$

The results of calculations of the required thermal power of the electric heater of the system depending on the outdoor temperature, up to which the accumulation mode of operation will be ensured, are shown in figures 2, 3 and 4.

In order to make the calculation results universal and possible for use in the conditions of any building with an arbitrary value of Q_o, the ordinate axis of the graph shows not the absolute, but the relative value of the required power of the electric heater k, which is defined as the ratio of the absolute power N to the calculated value of heat consumption for heating.

$$k = \frac{N}{Q_o}. \tag{7}$$

This coefficient shows how many times the power of the electric heater must exceed the calculated heat flow for heating in order for the heat accumulation system to operate with comfortable microclimate parameters.

For example, in accordance with figure 2, to ensure the functionality of an electric storage heating system for buildings with complete heat extraction ($n' = 0$) during the energy storage period, the required power of the electric heater must exceed the calculated heat requirement for heating by 4 times.

Calculations were made for operating conditions over the entire range of outside air temperatures. For example, provided that the storage system operates at a temperature not lower than -10°C (87% of the time of the total duration of the heating period), an electric heater power at the level $N = (2.5 \div 2.6) Q_o$.

Provided that the duration of the energy supply and accumulation cycle increases from seven to ten hours, the power of the electric heater can be reduced to $N = (1.8 \div 1.9) Q_o$.

However, in this case, the economic attractiveness of the system is significantly reduced. In addition, the question of how to provide consumers with heat for heating during the period when the external air temperature reaches values from -10°C to a standard value of -23°C becomes relevant. And this is about 600 hours of work for the climatic conditions of the city with a standard outdoor temperature about $t_o = -23$°C.

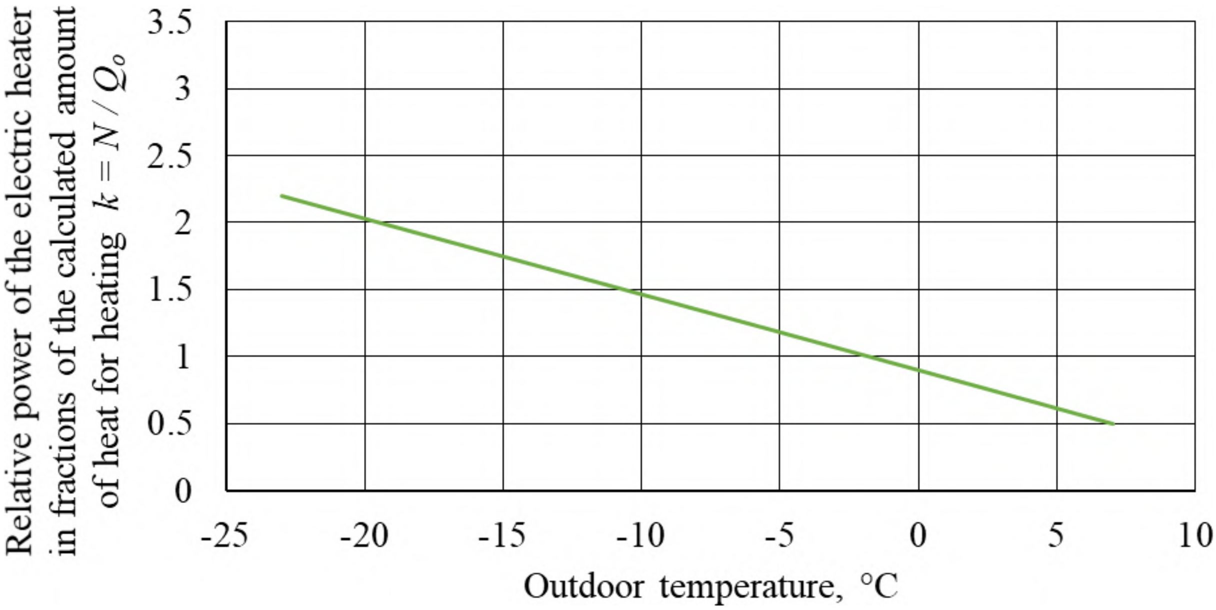

Figure 2. Dependence of the required power of electric heaters of an electric storage heating system on the outside air temperature, up to which the system can operate in storage mode without additional heat supply. $n' = 1, n'' = 0$ (during the night charging period, all buildings do not consume thermal energy for heating).

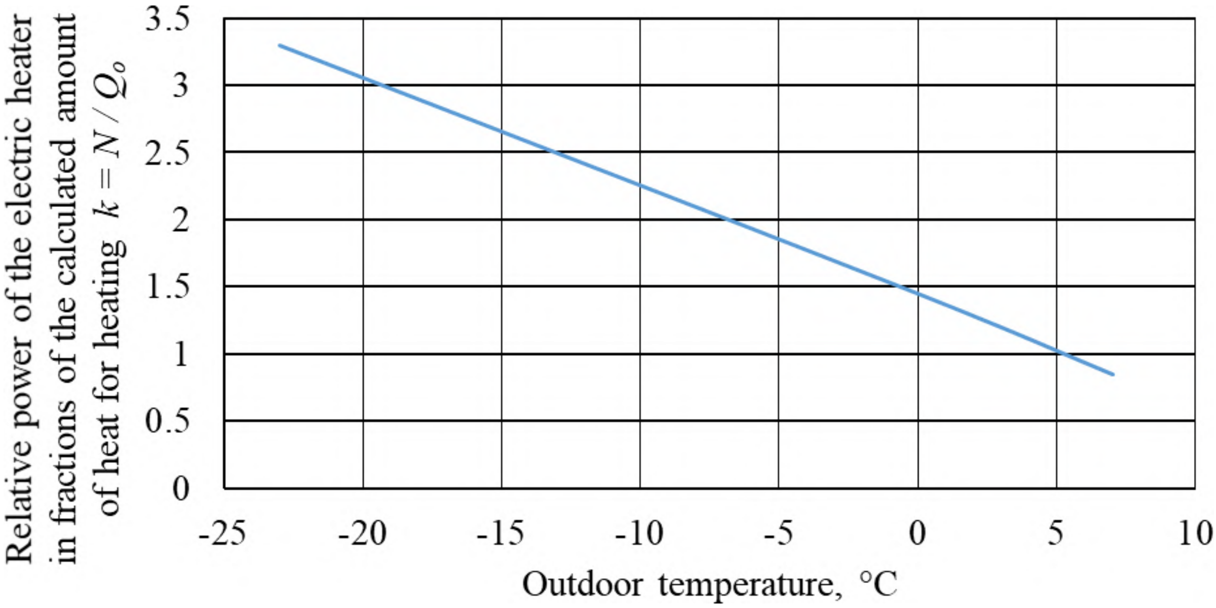

Figure 3. Dependence of the required power of electric heaters of an electric storage heating system on the outside air temperature, up to which the system can operate in storage mode without additional heat supply. $n' = 0, n'' = 1$ (during the night charging period, all buildings consume thermal energy for heating in full, depending on the outside temperature).

In the absence of a heat source using fossil fuels, the only alternative to supplying heat during this period is the selection of electrical power during the daytime period at an increased tariff, which is economically unprofitable.

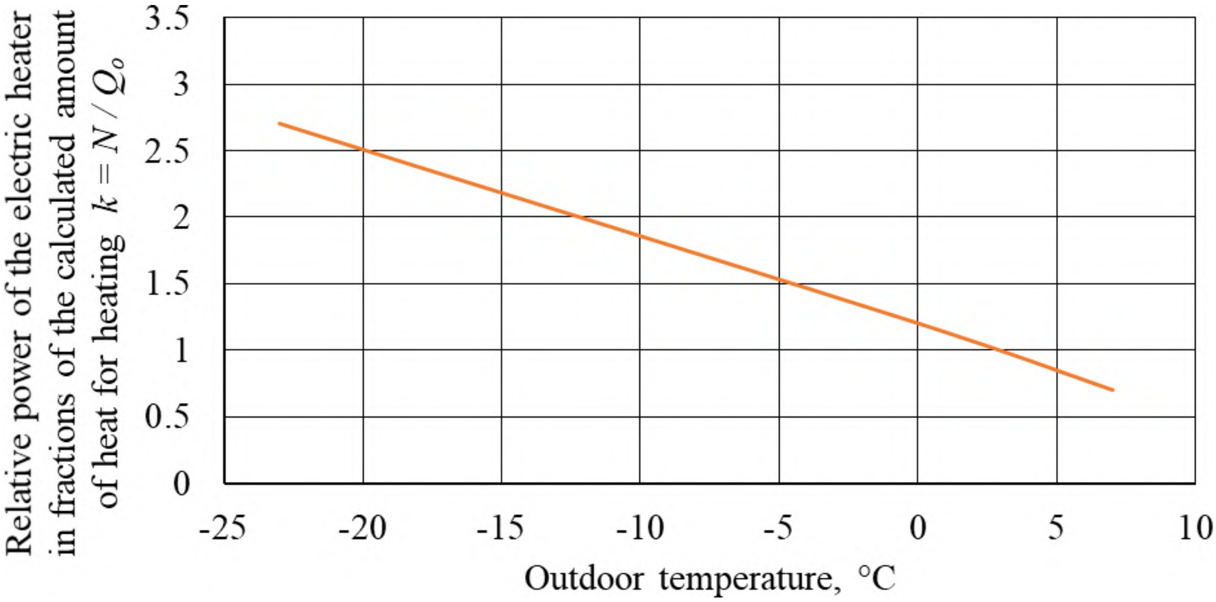

Figure 4. Dependence of the required power of electric heaters of an electric storage heating system on the outside air temperature, up to which the system can operate in storage mode without additional heat supply. $n' = 0.5, n'' = 0.5$ (at night, 50% of buildings do not consume thermal energy for heating, and the remaining 50% consume energy in full, depending on the outside temperature.

Thus, reducing the consumption of primary fuel (for example natural gas), which is usually the main goal of using electric storage heating systems, will lead to an increase in the cost of heating buildings. For hybrid heat supply systems that use several energy sources, including renewable types of energy, the choice of power of the heating source determines the feasibility, cost-effectiveness and possibility of switching from one energy source to another.

A significant problem with the use of electric storage heating systems is the need to modernize external electrical networks, due to the inability of electrical networks to withstand the additional loads that arise during electric heating. Thus, when introducing an accumulative electric heating system in an 80-apartment residential building with an estimated heat requirement for heating of 250 kW, the power of the electric heater, in accordance with the graph in figure 2, should be about 900 kW. Connecting such a heater to the existing electrical networks of the house seems problematic.

Another important design parameter of the system is the volume of the water storage tank.

The capacity of such a tank must ensure the required temperature of the coolant throughout the entire period of its circulation in the system without replenishing energy during the period of increased tariff.

Let us denote by t_x the current values of the coolant temperature in the tank. And through n – the relative capacity of the tank, which we will express through the calculated value of the hourly water consumption in the heating system, M_o':

$$n = \frac{M_b}{M_o'}, \tag{8}$$

where M_o' (t/hour) is the estimated flow rate of network water in the heating system, determined in accordance with the relationship:

$$M_o' = \frac{Q_0}{\Delta t \cdot c_w} \cdot 3.6, \tag{9}$$

where Q_o the heat flow for heating buildings, kW; $\Delta t = t_1 - t_2$ – calculated temperature difference in the heating system (for example $\Delta t = 90 - 70 = 20$°C); $c_w = 4.2$ kJ/(kg·°C) – heat capacity of water.

Let us write the heat balance equation for the period of water withdrawal from the tank in the form:

$$c_w \cdot M_b \cdot t_1 - c_w \cdot M_o' \cdot t_1 + c_w \cdot M_o' \cdot t_2 = c_w \cdot M_b \cdot t_x. \tag{10}$$

From (10) we obtain the value of the current temperature of hot water during its selection from the tank – t_x:

$$t_x = \frac{M_b \cdot t_1 - M_o' \cdot (t_1 - t_2)}{M_b} = \frac{k \cdot M_o' \cdot t_1 - M_o' \cdot (t_1 - t_2)}{k \cdot M_o'} = \frac{t_1 \cdot (n-1) + t_2}{n}. \tag{11}$$

In accordance with the calculations on dependence (11), after the end of the first cycle of the coolant circulation, provided that $M_b = 10M_o'$ the water temperature in the tank will decrease from the initial 95°C to 93°C. If the volume of the tank is lied to $M_b = 5M_o'$, then the water temperature after the first circle of circulation will be set at a level of 91°C with a further continuous decrease in temperature in the tank during the subsequent circulation.

Thus, it is possible to create a graph of the dependence of the necessary capacity of the tank-accumulator on the temperature of the outdoor air, provided that the installed schedule

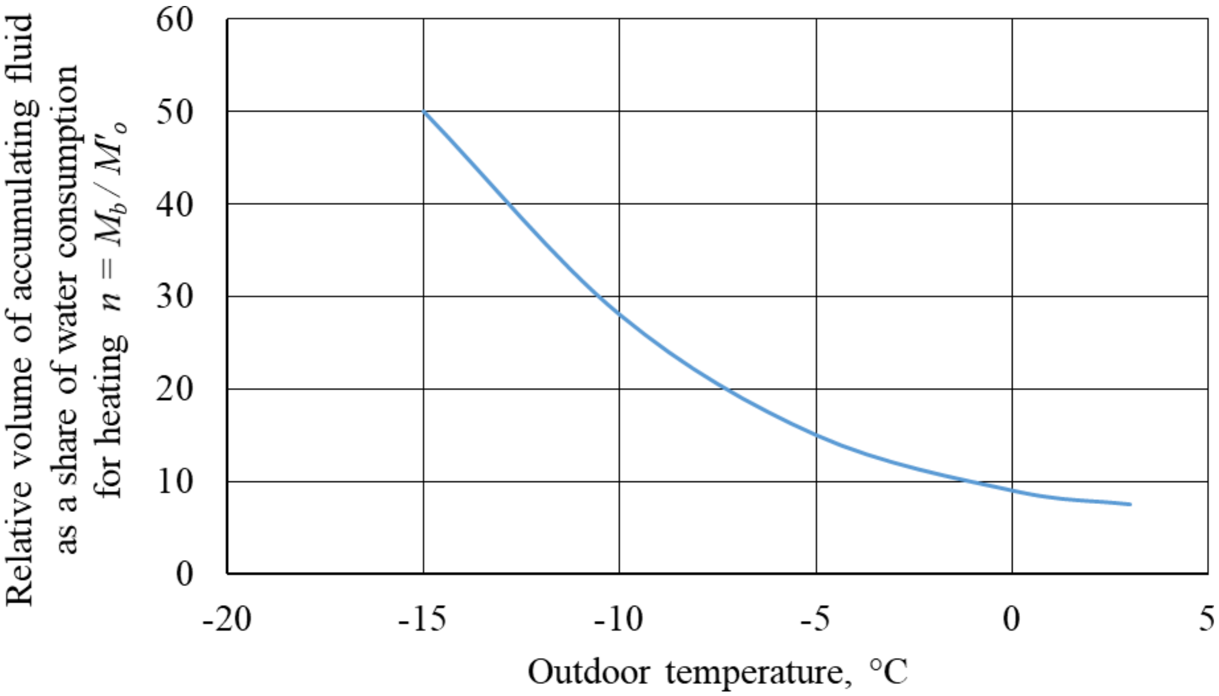

Figure 5. Dependence of the relative capacity of the accumulator tank “n” of the electric storage system on the outside air temperature, to which it is possible to operate the heating system to ensure comfortable microclimate parameters without additional consumption of electrical energy in the heating system during the daytime hours at an increased tariff.

of heat flow and maintain the optimal microclimate parameters in the premises. The condition for constructing the graph is also that continuous selection of the coolant from the tank is made without replenishment of energy from the outside in the daytime period of the day for an increased tariff for electric energy.

Figure 5 shows such a graph, which was obtained during the experimental stage of the research. It is built for a calculated temperature difference in the supply and return lines of the heating system $\Delta t = 20°\text{C}$.

The studies were carried out for an accumulation heating system of a residential building with a calculated heat consumption for heating of 250 kW without replenishing energy up to an outside air temperature of -10°C. The required capacity of the accumulation tank in accordance with the obtained schedule was no less than $V_b = 25V_b'$ or 134 m^3. Figure 6 shows a photo of such a tank for an accumulation heating system.

Placing a tank of this size in a building caused understandable problems. Therefore, it was placed outside and was carefully insulated. The heat supply system provided heat to the building of a sanatorium in the city of Mirgorod, Poltava region (Ukraine). A significant reduction in the size of the storage tank is possible by performing thermal modernization of the building and reducing the need for heat for heating. So, for example, for the estimated heating requirement of a building of about 40 kW, the volume of the tank is reduced to 34 m^3.

To reduce the building's need for heat, it is necessary to carry out a set of works on thermal

Figure 6. Storage capacity for a heating system with an estimated heat demand (thermal power) of 250 kW.

modernization of the building – increase the thermal resistance of external fences from 1 m^2g/W to 5 m^2g/W, use energy-efficient translucent fences, introduce a ventilation system with heat recovery, install an automated individual weather control system in the building heating point.

Experimental studies on the arrangement of a heating system with water storage tanks confirmed the obtained research results. However, it is noted that placing accumulation tanks of significant size in the premises of a building will require some structural work and significant costs.

4. Conclusions

The paper presents a methodology for determining the main design parameters of an electric storage heating system with water storage tanks.

Dependencies were obtained to determine the required volume of storage tanks and the required power of electric heaters of the electric storage heating system depending on the outside air temperature.

The results of calculations based on the given methodology indicate the possibilities of using electric storage heating systems and give an idea of the limitations that occur when implementing such systems.

As a result of the studies performed, it was shown that the tank capacity and the power of the system's electric heaters depend on the magnitude of the building's heating needs. In this regard, one of the conditions for the successful implementation of electric storage heating systems is the thermal modernization of buildings to a level that meets modern requirements for thermal protection of buildings. Carrying out work on thermal modernization of heat supply facilities and reducing the need for heat for heating significantly increases the efficiency of electric storage systems.

Abstract. Proposed study described positive influence of high level penetration of renewable energy sources in distributed electrical networks for power system in total in war conditions. Faults in transmission power lines are analysed and shown depend on level voltage. The paper presents the results of studies of double earth faults in 10 kV networks with an isolated neutral in the MATLAB program package.

1. Introduction

Reliability indicators of power supply systems as a whole are largely determined by the level of reliability of distribution electrical networks voltage of 6-35 kV. In previous work was indicated problem of 0.4 kV power grids [1]. According to various literary sources, the emergency in networks voltage of 6-35 kV, operating in the mode with an isolated or resonance-grounded neutral, is largely connected with the shorting of the phases of the lines between themselves and to the ground [2].

The analysis of damage and experience of operation of 6-35 kV networks [3–5] allow us to made the following conclusions:

- finding and eliminating places with weakened insulation is a complex process, as it requires multiple disconnections of the same network elements;
- a significant share of damage in networks is damage to support and through insulators and switching devices [6, 7];
- specific damage of switching devices from internal overvoltages is quite high and only 3 times lower than from lightning overvoltages [8].

In three-phase electrical networks with an input switch and lines fed from 10 kV substation busbars, during different single-phase short-circuits on two lines, there are cases of non-selective operation of the input switch protection, in the event that the current of the input switch exceeds the tripping set point of the current protection that acts on this switch. At the same time, such an excess occurs before the conditions for tripping of current protections are met, which act to disconnect the circuit breakers connected to the buses and the input circuit breaker. Therefore, the serviceable line will be turned off by the input switch.

2. Importance of distributed sources of generation in times of war

RES were implemented in distributed power grids last few years. Also, the green energy market is developing rapidly because more and more people understand and want to pass on our world to their descendants in at least as good a condition as we received from our parents and distributed power plant can be more safety, then nuclear power plants or condensing heating plants. Other reasons, that see from global surveys that equipment used in green energy is becoming cheaper and more affordable every year. More windmills and solar panels appearing on our streets and in our homes, because energy communities is developing. But it is imported to note that at the current level of development, green generation alone will not be able to meet the full demand for electricity. A lot of RES and distributed power grids were damaged under war attacks also (figure 1 and figure 2).

Figure 1. Damaged photo-voltaic power station.

In blog materials of Yurii Kasich for Energy Club was noted, that small sources of energy are able to provide electricity to settlements close to them, the enemy will of course be able to damage them, but in most cases thermal power plants, hydroelectric power plants, distribution substations are under attack. The lower the voltage class of power lines or substations, the greater their number and the less known to the aggressor. It is there, in those networks, that the distributed small generation of Ukraine (solar power plants, wind power plants, bio-fuel

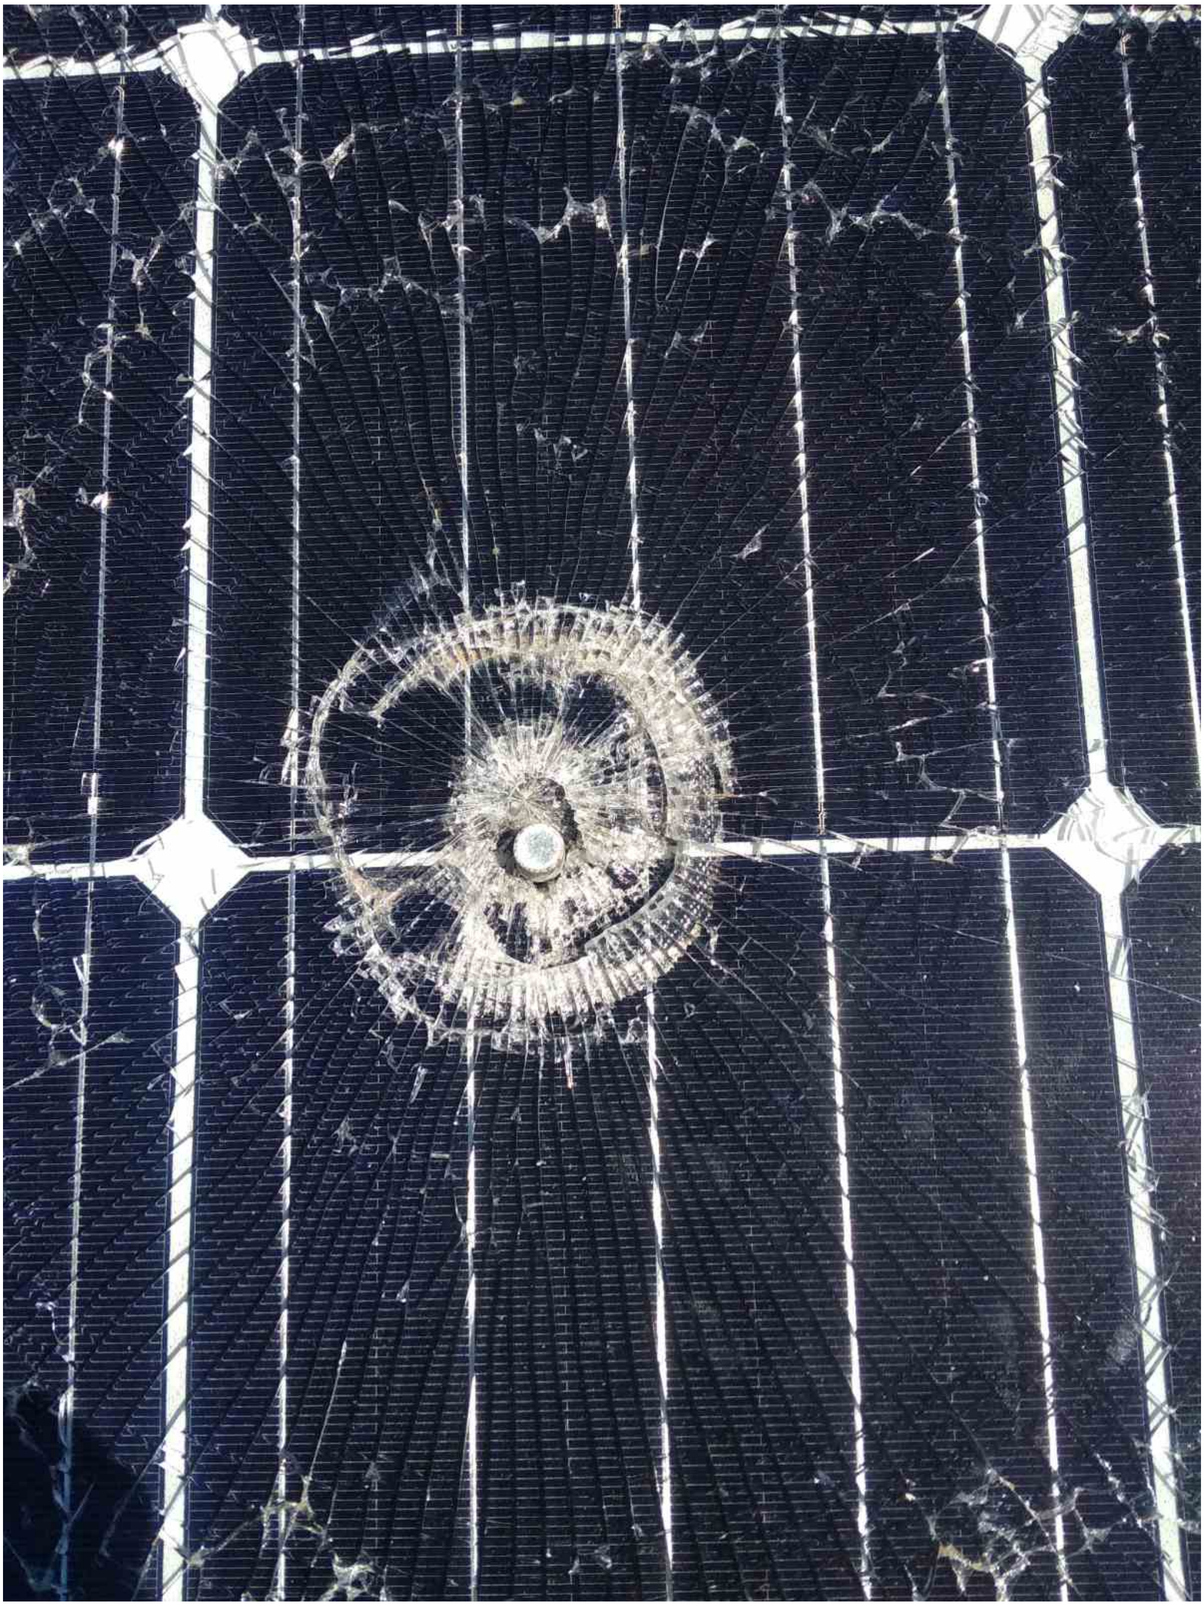

Figure 2. Damaged solar module.

installations, small hydroelectric power plants) is located, which should not be forgotten in today's conditions. These sources, in most cases, do not require the use of fossil fuels and the entire infrastructure associated with fuel supply. RES can work in off-grid mode. Dispersion of distributed energy sources of electrical energy is a valuable indicator – it is impossible to damage them at the same time, and in practice it is impractical (the costs far exceed the cost and benefits). Each individual distributed source of electrical energy does not represent "systemic, or national" value, but the whole point is that all of them (small sources) together are valuable as a general source of energy in Ukraine. Such sources are able to provide electricity to nearby settlements with all infrastructure (hospitals, communications, etc.) for an almost unlimited time [9]. High penetration of RES in distributed power grid forces up to development of effective means of researching reasons of over-voltages in these networks and find approach to decrease over-voltages.

3. Analysis of 10 kV network damage data

The main causes of damage to 10 kV transmission lines are

- in overhead networks: damage to line poles, overlapping and damage to insulation on poles, damage to cable couplings during the transition of overhead lines to cable lines;
- in cable networks: damage to insulation at substations, damage to terminal and connecting couplings, damage during excavation works in the vicinity of the cable route, damage to cables.

The most vulnerable element of the power grid to internal overvoltages are cables, in particular, the places where they are connected to each other and to other elements of the grid. Therefore, a significant proportion of damage is associated with overvoltages during single-phase earth faults in cable networks (according to data, 77 percents of the number of damages [8]).

The analysis shows that the causes of damage to cable lines in most cases are: mechanical damage, factory defects, defects in the installation of couplings, violations of the technology of laying cable lines, and extreme operating conditions. Single-phase short circuits occur, as a rule, in places of defects in the insulation of cable lines and substation equipment due to aging of the insulation, failure to comply with the technology of manufacturing insulating structures at factories, standards and instructions for the installation and operation of equipment, as well as mechanical damage, which at the time of their occurrence leads to only a partial reduction in electrical strength.

Internal overvoltages often occur during transients from an intermittent arc and are dangerous for the insulation of electrical installations due to their duration and the breadth of coverage of the network associated with the damage site.

The process of insulation aging is greatly influenced by technological and operational factors. Technological factors include hidden defects in manufacturing and installation; the use of materials that do not meet the requirements for them; changes in the modes of thermal vacuum treatment of insulation after manufacturing; and crimping defects. Operational factors, if we exclude accidents caused by human error, include, first of all, overloads: short-circuit currents, switching and lightning surges. Overloads lead to the emergence of various kinds of defects, which then develop in the operating mode. The complex organic insulation of cables, connecting and termination cable couplings tends to accumulate defects. The effect of over-voltage on such insulation is accompanied by a decrease in electrical strength, which is not restored to its original state after the over-voltage ceases. After the over-voltage action, the cumulative development of weaknesses (defects) occurs, and a breakdown may occur with further accidental over voltages. An inter-phase short circuit occurs, as a rule, after multiple accidental actions. In a complex set of locations with weakened insulation, a network disturbance occurs when at least one location with the most weakened insulation (with the largest defect) finally loses its electrical strength.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012118 doi:10.1088/1755-1315/1415/1/012118

To ensure sufficiently high operational reliability, measures must be taken to strengthen the insulation and limit over-voltages. The second way, as less costly, is more profitable.

The most frequent type of internal over-voltage in 6-35 kV networks is over-voltage associated with single-phase earth faults, accounting for up to 80 percents of all types of accidents (figure 3). In recent years, the average specific rate of damage to grids due to electrical causes has increased by about an order of magnitude and, according to operational experience, taking into account the equipment of power grids that was broken during tests, is more than 100 damages for every 100 km of the grid per year. In the overwhelming majority of cases (up to 90 percents of the number of disruptions to the normal operation of the network), the damage begins with an insulation breakdown to the ground, and then more than half of them (up to 70 percents under the circumstances) develop into inter-phase short circuits or multi-location insulation breakdowns with group failure of electrical equipment.

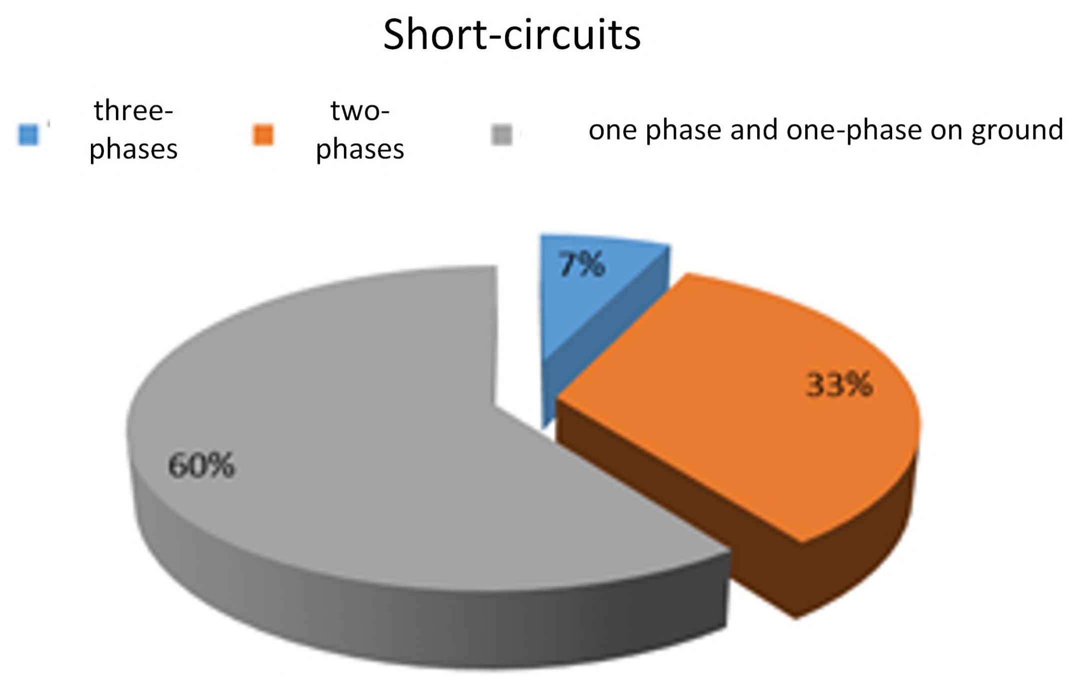

Figure 3. Diagram of damage to power lines with a voltage of 6-10 kV.

The biggest danger is posed by arc over-voltages that occur in the network when the arc burns in an intermittent manner at the point of breakdown of phase insulation to earth, as the arc can damage the insulation and cause a two- or three-phase short circuit. According to some reports, about 60 percents of earth faults in these electrical networks are of this nature. The extinguishing and ignition of an intermittent arc causes complex transients, the intensity of which, as operating experience shows, depends on such factors as arc characteristics, capacity, inductance, circuit resistance, etc. In networks with a predominance of cable lines, outages due to the transition of a single-phase fault to an inter-phase fault reach 70 percents of the number of outages. An increase in earth fault current leads to an increase in the probability of single-phase fault to inter-phase fault directly at the point of arc burning.

From the experience of operating 6-10 kV cable networks, there are repeated cases of multi-location insulation breakdowns under operating voltage. There are cases of simultaneous breakdowns in 4-5 points of the lines. First, the presence of insulation breakdowns under operating voltage indicates an insufficiently high level of insulation. Secondly, the presence of multiple breakdowns indicates the existence of over-voltages. Thus, despite significant insulation reserves, the accident rate of 6-35 kV networks due to internal over-voltages is quite high. Therefore, the development of effective means of studying over-voltages in these networks and means of reducing them is currently relevant [10].

The goal of the research is to investigate the causes of false activations of relay protection of 10 kV power transmission lines during double earth faults using MATLAB. Therefore, the purpose of research is relevant.

Data on the features of operation, damage and damage protection of 10 kV lines are given in [8]. Features of the protection of equipment of electric power systems are considered in [11]. The processes of changing currents and voltages in lines with an isolated neutral and protection against their damage during earth faults are discussed in [7, 12].

Relay protection in 6–10 kV power grids s with an isolated neutral (including a neutral grounded through an arc extinguishing reactor) must be provided with relay protection devices against multi-phase circuits and single-phase circuits to the ground). Protection against multi-phase short-circuits should be provided in a two-phase version and connected to the same phases throughout the network of a given voltage to ensure that in most cases of double earth-faults, only one point of damage is turned off. Protection should be performed with one, two or three relays depending on the requirements of sensitivity and reliability. As a rule, two-stage current protection should be installed on single lines with single-sided power supply from multi-phase circuits, the first stage of which is made in the form of current cut-off, and the second – in the form of maximum current protection with an independent or dependent time delay characteristic.

On non-reactor cable lines with one-way power, departing from the busbars of power plants, current cut-offs must be performed without time delay and the area of their effect must be determined from the condition of short-circuit shutdown, accompanied by residual voltage on the busbars of the specified power plants below 0.5–0, 6 nominal. To fulfill the specified condition, it is allowed to perform non-selective protection in combination with Automatic Transfer Switch (ATS) or automatic circuit reclosers (ACRs) devices, which fully or partially correct the non-selective effect of protection. It is allowed to install the specified cut-offs also on the lines departing from the busbars of substations and feeding large synchronous electric motors. Current cut-offs are not allowed on lines whose switches are not designed to turn off the short-circuit to the reactor. On double-fed single lines with or without bypass connections, as well as on lines forming part of a ring network with a single point of supply, it is recommended to use the same protections as on single-sided fed lines, performing them directional if necessary. In order to simplify protections and ensure their selective action, it is allowed to use automatic division of the network into radial sections at the time of damage with subsequent automatic restoration.

4. Simulation of the mode of a three-phase 110/10 kV network in MATLAB

A model of a three-phase 110/10 kV network was built using Matlab. Three lines are connected to the 10 kV bus, on which switches Q1, Q2, Q3 are installed. The input switch is marked QBB. The load of the lines is 600, 500, 400 kW, according to lines 1-3. The model simulates single-phase short circuits on lines with the first (line 1) and second breaker (line 2). During the simulation of a short-circuit at a given time, a transient process occurs, the model allows analyzing the parameters of this process, considering the processes in a certain period of time. With the help of models of measuring devices and the “Scope” element, we can study the graph of current and voltage at the desired moment in time in the examined node of the circuit. For example, by installing, after the input switch, a three-phase measuring device connected to the “Scope” element, the model allows you to obtain a current oscillogram (figure 4). The network diagram is shown inlabelThe diagram of the studied network Consider figure 4, “Scope” built an oscillogram of three-phase current: yellow line – phase A, blue – phase B, orange – phase C.

In the study was simulated the short circuit of phase A of the first line and the short circuit of phase B of the second line at a time of 0.2 s. The maximum value in phase A, the first line,

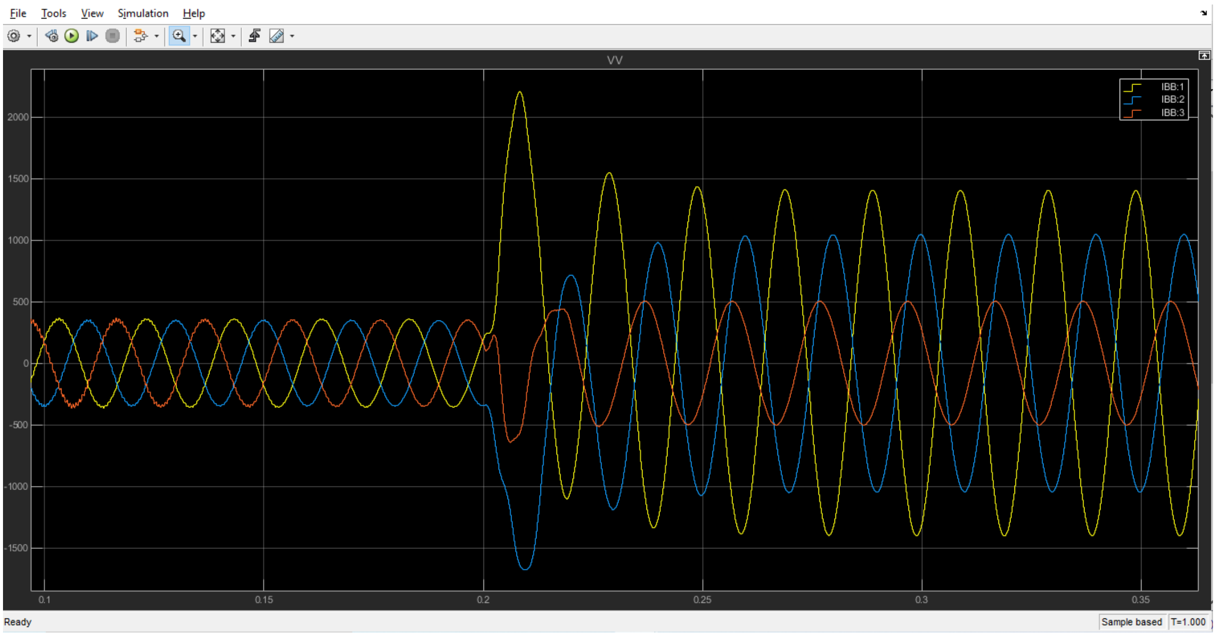

Figure 4. Current oscillogram obtained using "Scope".

is 2300 A, and in phase B, the second line, 1905 A. On the input switch, the same values were equal to 2206 A and 1680 A, respectively. Values in short-circuit mode have increased by 30 – 40 times.

The calculated values of the maximum current protection settings for phase A of the first line, phase B of the second line and for the input switch are shown in table 1.

Table 1. The calculated values of the maximum current protection settings for phase A of the first line, phase B of the second line and for the input switch.

Name	The calculated values of the maximum current protection
A	300.3
B	264.5
Input	1322.75

For clarity, a graph of the K coefficients is plotted (figure 6), showing how many times the short-circuit current is greater than the short-circuit current.

The graph shows that the excess of the current in the damaged overhead line over the over-current protection set-point of this overhead line, during double faults, can occur earlier, by 0.004 s, than the increase in the current in the input switch for certain values of the overhead line and short-circuit parameters. Therefore, it is necessary to set a delay in the operation of the input circuit breaker so that it does not trip the undamaged lines. The graph shows what value of the delay time in the operation of the recloser should be set (taking into account the time of the selectivity degree, to ensure error-free operation of the protection. The time selectivity degree of the recloser takes into account the operating time of the circuit breakers and the errors of the time relay. According to the graph, the delay time is 0.05 s, as the transient process ends and the steady-state short-circuit mode begins.

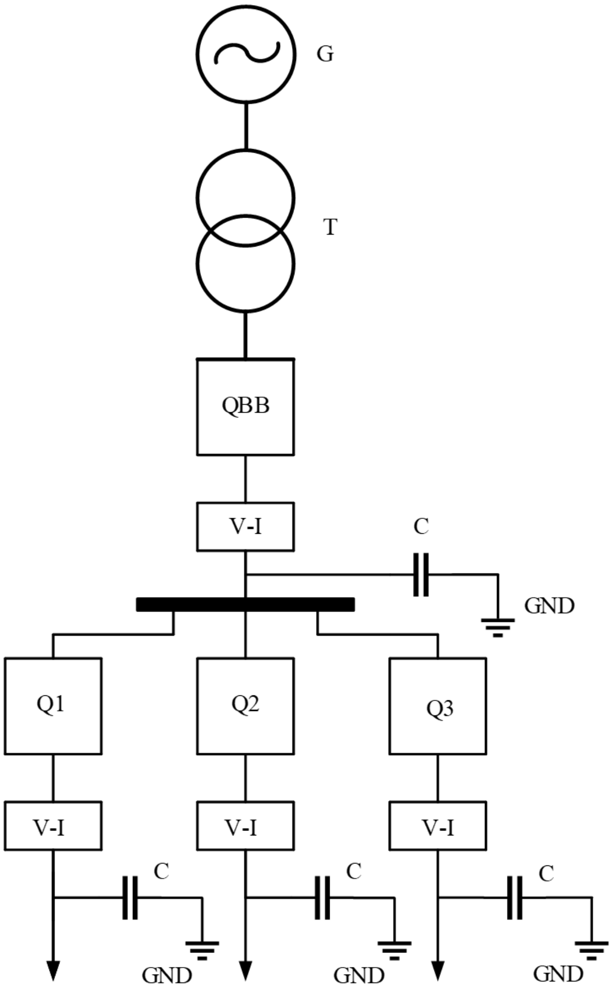

Figure 5. The diagram of the studied network.

5. Conclusions

According to the results of the analysis of double short circuits in the power line, the current in the damaged power line exceeds the set point of the relay protection system of this power line, during double short circuits, may occur earlier, by 0.004 s. Than the current increases in the input circuit breaker for certain values of the power line and short-circuit parameters. Based on the results of calculations of the parameters of the 10 kV power transmission line considered in the work, it was determined that the tripping current is equal to 300 A, and the power supply acting on the input switch of the substation to which the 10 kV power line is connected is equal to 1323 A. For the considered examples of operation of the power transmission line in the first case will happen selectively, and in the second case, the protection will not work correctly. First, the input switch will turn off, and then the feeder switch. Turning off the input switch de-energizes not only damaged lines, but also healthy lines. Therefore, the conditions for ensuring the selective operation of the power transmission system for the investigated variant of the power transmission line are not always provided. In order to reduce false disconnections of 10 kV power lines, it is necessary to increase the operating time of the relay protection acting on the input circuit breaker at the substations on the 10 kV side so that the 10 kV input circuit breaker operates later than any of the feeder circuit breakers of the investigated substation.

E-mail: ivan_na@i.ua, Stanytsina_VV@nas.gov.ua

Abstract. After the war, a favorable situation may arise in Ukraine not only for the restoration of ammonia production but also for its increase and the implementation of new state-of-the-art technologies that make it possible to improve energy efficiency and reduce CO_2 emissions. The authors have identified the prerequisites for the post-war ammonia production development in Ukraine. The authors have presented the optimization model to minimize primary investments for reaching given ammonia production and specific CO_2 emissions. The sharp increase in required investments is observed when new production capacities are needed. For existing capacities that will be undamaged after wartime the most effective mitigation measure both economically and environmentally is carbon storage and capture. The main directions of further study were outlined. The paper aims to analyze the prerequisites for post-war ammonia production in Ukraine and develop an optimization model to minimize primary investments in the quantitative and qualitative development of ammonia production in Ukraine.

1. Introduction

Ammonia production is a highly energy-intensive process consuming around 1.8% of global energy output and producing as a result about 500 million tonnes of carbon dioxide (about 1.8% of global carbon dioxide emissions) [1]. Ammonia synthesis is significantly the largest carbon dioxide emitting chemical industry process. Along with cement, steel, and ethylene production, it is one of the 'big four' industrial processes where a decarbonization plan must be developed and implemented to meet the net-zero carbon emissions target by 2050. About 70% of ammonia is used for fertilizers, while the remainder is used for various industrial applications, such as plastics, explosives, and synthetic fibers. While the use of ammonia as a fuel shows promise in the context of clean energy transitions, this application currently remains nascent.

International Energy Agency has developed Ammonia Technology Roadmap which presented three scenarios of ammonia production till 2050 [2]: the Stated Policies Scenario (STEPS), Sustainable Development Scenario (SDS) and Net Zero Emissions by 2050 Scenario (NZE). Table 1 presents the main characteristics of these scenarios.

After the war, a favorable situation may arise in Ukraine not only for the restoration of ammonia production but also for its increase and the implementation of new state-of-the-art technologies that make it possible to improve energy efficiency and reduce CO_2 emissions. The paper aims to analyze the prerequisites for post-war ammonia production in Ukraine and develop an optimization model to minimize primary investments in the quantitative and qualitative development of ammonia production in Ukraine.

Table 1. The characteristics of Scenarios from [2] (% in 2050 relative to 2020).

Scenarios	Description	Ammonia	CO_2 emissions
STEPS	Reflects the sector's current trajectory, influenced by existing and announced policies. All regions are on track to reach current BAT energy performance levels soon after 2050, as plants are upgraded and replaced to meet stringent energy performance standards in several regions and to maintain competitiveness in others. Continued improvements in process energy efficiency are outweighed by increasing demand for ammonia, pushing up overall energy consumption.	40%	14%
SDS	Presents a pathway with regional detail that puts the energy system as a whole on a trajectory compatible with the goals of the Paris Agreement. The main shifts in energy consumption stem from the deployment of innovative near-zero-emission technologies. In this scenario 83% of the total electricity demand for ammonia production in 2050 is used to produce hydrogen via electrolysis, with the remainder appying ancillary units (e.g. air separation units) and carbon capture equipment.	25%	73%
NZE	The faster pace of emissions decline is achieved primarily through more rapid deployment of innovative near-zero-emission technologies. By 2050, 41% of ammonia is produced via electrolytic hydrogen. CO_2 capture for permanent storage from ammonia production would rise to 100 Mt CO_2 by 2050, with almost 50% of the fossil-based capacity equipped with CCS.	23%	96%

2. The current state of ammonia production in Ukraine

Five big industrial plants could produce ammonia in Ukraine (table 2). Only two are in operation now due to wartime, the high price of natural gas, etc. The annual ammonia production capacity totals approximately 5.7 mln tonnes.

All plants use steam methane recovery technology for ammonia production in Ukraine. Ammonia production, corresponding CO_2 emissions and CO_2 emission factor are presented at the figure 1 [6, 7].

At the figure 1 CO_2 emission factor was estimated at the national level. Recently, it has become possible to obtain data on natural gas consumption and CO_2 emissions at the installation level. In view of the future entry of Ukraine to the EU and accession to the EU Emission trading system the Law of Ukraine dated 12.12.2019 No. 377-IX "On Principles of Monitoring, Reporting and Verification of Greenhouse Gas Emissions" (hereinafter referred to as the Law on MRV) have entered into force from January 1, 2021 [8]. The Resolution of the Cabinet of Ministers of Ukraine dated 23.09.2020 No. 880 [9] set the requirements for the operators to register in the Unified MRV Register if they are subject to monitoring, reporting, and verification. All installations of ammonia production are included in the list of activities under this Resolution.

Table 2. The big industrial plants of ammonia production (t per year).

Plant	Owner	Capacity	Comments
PJSC "Odesa Portside Plant" [3]	State Property Fund of Ukraine	1240000	In September 2021, the PJSC stopped the production of chemical products due to the high natural gas price in Ukraine and the low price of ammonia on the world market
PJSC "Azot" (Cherkasy) [4]	OSTCHEM Group DF	963000	In operation
PJSC "Rivneazot" [4]	OSTCHEM Group DF	420000	In operation
PrJSC "Severodonetsk Azot Association" [4]	OSTCHEM Group DF	1020000	The activity was blocked due to hostilities
JSC "Dniproazot" [5]	State Property Fund of Ukraine	584000	The JSC stopped the production of chemical products due to the high natural gas price in Ukraine
PJSC "Concern Stirol" [4]	OSTCHEM Group DF	1470000	From 2014 "Concern Stirol" is located in the temporarily occupied territory and does not produce ammonia

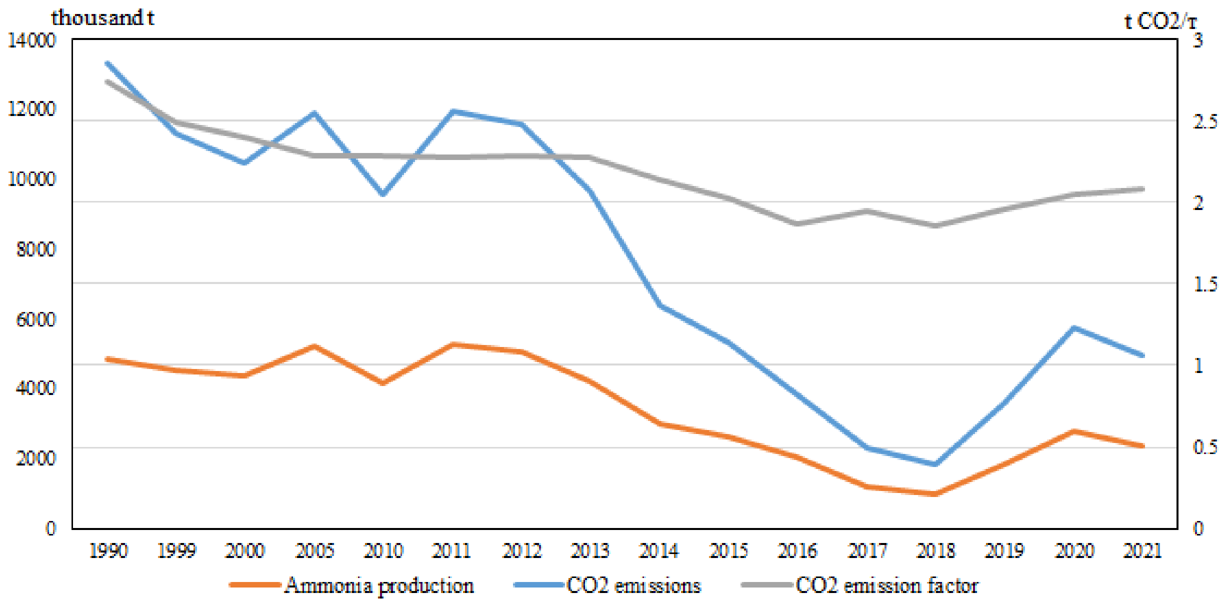

Figure 1. Ammonia production and corresponding CO_2 emissions in Ukraine.

Operators should carry out monitoring and reporting following the requirements specified in the Procedure for Monitoring and Reporting on Greenhouse Gas Emissions, approved by Resolution No. 960 of the Cabinet of Ministers of Ukraine dated September 23, 2020 [10].

According to Article 16 of the Law on MRV information on quantitative and qualitative indicators of greenhouse gas emissions is open and access to it cannot be restricted.

Operators of installations had to report their emissions starting in 2021. Unfortunately, due to the martial law, the Ukrainian government adopted the Law of Ukraine dated 03.03.2022 No. 2115-IX "On the Protection of the Interests of Subjects Submitting Reports and other Documents during the Period of Martial Law or the State of War" [11].

According to Article 1.1 of this Law legal entities submit accounting, financial, audit reports and any other documents, the submission of which is required following the norms of current legislation in the documentary and/or in electronic form, within three months after the termination or cancellation of martial law or the state of war for the entire period of failure to submit reports or the obligation to submit documents.

Therefore many installation do not report their emissions during wartime. After the war ends plant-specific information will become available.

3. The prerequisites for post-war ammonia production in Ukraine

Ukraine would have significant advantages from ammonia production in both the existing conditions and given the appropriate CO_2 emission factors.

The previous section states that the ammonia production capacities in Ukraine totaled 5.7 mln t before the wartime. It should be mentioned that ammonia fertilizer production facilities also exist in Ukraine. The shortage of fertilizers on world markets leads to an increase in their cost, reaching the highest levels since 2012 in 2021 [2].

Another advantage for Ukraine is the presence of a large branched system of gas pipelines and preserved wells, that is, there is the necessary infrastructure for carbon storage and capture. Ukraine has an 800-kilometer ammonia pipeline "Horlivka – Odesa" with a capacity of up to 2.5 million tons per year and a significant fleet of railway and road tankers for transporting ammonia.

Ukraine is one of the largest exporters of food. In 2021, the largest percentage of Ukraine's exports was accounted for by agricultural and food products, namely 40.7%. The leaders of this industry are oil as a processed product, cereals (wheat, corn, etc.), sugar, confectionery, vegetables and fruits, and flour products. During the wartime food and agricultural products remained the largest part of Ukrainian exports, accounting for 53% in 2022. After the wartime Ukraine will need fertilizers to provide intensified agriculture development.

Appropriate legislation has already been implemented in Ukraine, which creates a normative and regulatory field for the commercial circulation of ammonia.

Ukraine would have an advantage from the participation in the EU Emissions trading system and a significant benefit from the export of ammonia given the appropriate CO_2 emission factors.

In present the Carbon Border Adjustment Mechanism (CBAM) holds substantial implications for ammonia production, particularly in the context of the European Union's ambitious decarbonization strategies. CBAM, as a carbon pricing framework, seeks to establish a fair competition landscape between EU producers and their global counterparts by attaching a price tag to carbon emissions associated with imports, including ammonia. The overarching objective is to incentivize international trading partners to curtail their manufacturing emissions. For ammonia producers, CBAM ushers in specific stipulations. Under the preliminary CBAM proposal, European ammonia producers continue to benefit from free carbon credit allowances, in line with the benchmarks outlined in the EU Emissions Trading System. This approach encourages EU-based ammonia producers to maintain their emissions below benchmark levels, thereby shielding them from carbon leakage risks, where competitively priced imports from less regulated nations could undermine the competitiveness of EU producers. Furthermore, CBAM enforces comparable carbon costs on ammonia importers as those faced by EU-based producers. Importers are obliged to procure and surrender CBAM certificates for emissions exceeding benchmark levels. This policy provides advantages to importers, if their emissions fall below the benchmarks, allowing them to evade additional costs associated with CBAM certificates. This arrangement proves advantageous for European ammonia producers, guaranteeing a level

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012119 doi:10.1088/1755-1315/1415/1/012119

playing field and the opportunity to capitalize on their "free" allowances, contingent upon their emissions remaining beneath the benchmark [12].

In the broader economic spectrum, industries affected by CBAM, such as ammonia in the fertilizer production sector, confront challenges stemming from elevated energy prices and inflationary pressures. These factors culminate in diminished production capacities and escalated production expenses. These circumstances underscore the necessity for policies that bolster corporate investments and mitigate excessive short- to medium-term outlays.

In summation, while CBAM aspires to cultivate a sustainable and equitable trading milieu, it simultaneously introduces an array of challenges and ramifications for ammonia producers, both within and outside the EU. The mechanism serves as a catalyst for the reduction of carbon emissions in ammonia production but introduces intricacies into market dynamics, exerting an impact on both EU producers and importers.

4. Results and discussion

General Energy Institute of National Academy of Sciences of Ukraine has long been conducting research related to the reduction of greenhouse gas emissions in the energy [13,14], industrial [15], coal [16, 17], oil and gas [18] and transport [19] sectors, etc.

The authors have been developing a set of optimization models with different objective functions (primary investments, cost of ammonia production, CO_2 emissions, etc.), different levels (national, plant), periods (implementation stage, life cycle period), etc.

The authors have been developing a database of ammonia production technologies. At the present stage, this database includes the following technologies: steam methane recovery (SMR), auto-thermal reforming (ATR); carbon capture and storage (CCS), and electrolysis. Techno-economic indicators of ammonia production technologies are presented at the table 2 [2, 7, 20].

Table 3. Techno-economic indicators of ammonia production technologies.

Indicators	Units	SMR	CCS	ATR+CCS	Electrolysis
Typical plant capacity	thous. t/year	220-1205	220-1205	220-1205	10-510
Capital investments	thous \$/t	1.91	0.14	2.11	2.36
O&M cost	mln \$/year	50	10	55	65
CO_2 emissions	t/t	1.81	0.12	0.19	0.00

Below the authors consider the optimization model to minimize primary investments for reaching given ammonia production and specific CO_2 emissions.

The objective function is as follows:

$$Investments = \sum_{i=1}^{5} InvRest_i + \sum_{i=1}^{5} \sum_{j} Prod_{ij} * Inv_{ij} + \sum_{k=1}^{new} Prod_k * Inv_k \rightarrow \min.$$

A set of constraints are as follows:

$$TotalProduction = \sum_{i=1}^{5} \sum_{j} Prod_{ij} + \sum_{k=1}^{new} Prod_k,$$

$$EmissionFactor = \frac{\sum_{i=1}^{5} \sum_{j} Prod_{ij} * Emission_j + \sum_{k=1}^{new} Prod_k * Emission_k}{Production}.$$

For each i:

$$\sum_j Prod_{ij} \leq ProductionCapacity_i,$$

where $Investments$ – primary investments for existing and new (if any) ammonia production plants, i – index for existing plants, j – index for production technology at the existing plants, $InvRest$ – investments needed to restore existing plants (at present these values cannot be estimated), $Prod_{ij}$ – ammonia production at the existing plant i by production technology j, Inv_{ij} – matrix of specific investments for transition from production technology i to production technology j, $Prod_k$ – ammonia production at the new plant k, Inv_k – specific investments to implement production technology k, $TotalProduction$ – the given value of total ammonia production at the existing and new (if any) plants, $Emission_j$ – specific CO_2 emissions for production technology j at the existing plants, $Emission_k$ – specific CO_2 emissions for production technology k at the new plants (if any), $ProductionCapacity_j$ – ammonia production capacity at the existing plant i (table 2).

The results of the calculation for different production volumes (restoring before the war, two times increase and three times increase) and specific CO_2 emissions (the average in EU and the benchmark for CBAM) are given at the table 4.

Table 4. Preliminary estimation of primary investments to ammonia production.

Ammonia production, thous t	Specific CO_2 emissions, t/t	Primary investments, mln $
2000	1.85	24.00
2000	1.57	57.60
4000	1.85	48.00
4000	1.57	115.20
6000	1.85	69.03
6000	1.57	164.79

The sharp increase in required investments is observed when new production capacities are needed. For existing capacities that will be undamaged after wartime the most effective mitigation measure both economically and environmentally is carbon storage and capture.

For existing plants that will be damaged after the war, it is necessary to estimate the level of destruction of each plant and make a decision about the expediency of restoring previous production technology or implementing new state-of-the-art technology.

The authors are planning the following research:

- The further development and clarification of the technology database is needed. For instance, ammonia is produced from nitrogen (N_2) and hydrogen (H_2), not only synthetically but also naturally. Whilst the synthetic ammonia production routes have developed over the past century, some organisms in nature fix nitrogen in the form of ammonia with nitrogenase [21–24]. Other sources of fixed nitrogen are atmospheric deposition, recycling of crop residues, and animal manures such as guano. The authors are planning to estimate the availability of nitrogen-fixed products in Ukraine and corresponding technologies.
- The authors are looking for installation reports under MRV system. The use of plant-specific data on energy consumption and emission factors gives a possibility to obtain more accurate results from the optimization model at the national level.
- The authors are planning to develop a set of optimization models. For example, after the war ends it is of primary importance to minimize the levelized cost of ammonia production at the national level.

5. Conclusions

After the war, a favorable situation may arise in Ukraine not only for the restoration of ammonia production but also for its increase and the implementation of new state-of-the-art technologies that make it possible to improve energy efficiency and reduce CO_2 emissions.

The authors have identified the following prerequisites for the post-war ammonia production development in Ukraine.

- The ammonia production capacities totaled 5.7 mln t before the wartime.
- the presence of a large branched system of gas pipelines and preserved wells, that is, there is the necessary infrastructure for carbon storage and capture.
- Ukraine has an 800-kilometer ammonia pipeline "Horlivka – Odesa" with a capacity of up to 2.5 million tons per year and a significant fleet of railway and road tankers for transporting ammonia.
- Ukraine is one of the largest exporters of food. After the wartime Ukraine will need fertilizers to provide intensified agriculture development.
- Ukraine has nitrogen fertilizer facilities while the shortage of fertilizers on world markets is observed.
- Appropriate legislation has already been implemented in Ukraine, which creates a normative and regulatory field for the commercial circulation of ammonia.
- Ukraine would have a significant benefit from the export of ammonia given the appropriate CO_2 emission factors.
- Ukraine would have an advantage from the participation in EU Emissions trading system given the appropriate CO_2 emission factors.

The authors have presented the optimization model to minimize primary investments for reaching given ammonia production and specific CO_2 emissions. The sharp increase in required investments is observed when new production capacities are needed. For existing capacities that will be undamaged after wartime the most effective mitigation measure both economically and environmentally is carbon storage and capture.

The authors have outlined the main directions of further study: development and clarification of the technology database, use of plant-specific data on energy consumption and emission factors, development of new optimization models, in particular minimizing the levelized cost of ammonia production at the national level.

Abstract. This article explores strategies for ensuring the autonomous operation of Renewable Energy Communities (RECs) in Ukraine, aligning with the ongoing reform in the country's energy sector. The reform emphasizes the implementation of promising autonomous decentralized systems, potentially leading to the establishment of RECs. These initiatives aim to incorporate low-capacity sources in providing electricity during autonomous conditions or outages. Examining data on small electricity producers reveals the prevalence of solar power plants, the emergence of micro-hydro plants, and limited representation of wind power. The article also underscores the increasing significance of biogas in electricity production. Furthermore, it explores the formation of RECs as a contemporary decentralized solution, requiring a thorough analysis of sustainability for autonomous operation. The utilization of various generation types in the structure of RES (renewable energy sources) communities enables the adaptation of electricity generation to dynamic conditions, ensuring system resilience in the face of failures or challenges associated with a predominant generation source. The core focus shifts towards optimizing existing hybrid systems encompassing different renewable energy sources. This involves analyzing load and capacity distribution, technological profiles, and integration strategies for RECs into the power grid, ultimately contributing to the enhancement of Ukraine's energy security. The proposed approach involves mathematical modeling of low-power hybrid renewable systems that derive electricity from RECs. This modeling incorporates generation characteristics, objective functions, and constraints to facilitate multi-criteria decision-making. The results underscore the significance of exploring diverse scenarios and combinations of generating sources, taking into account resource potential, electricity generation variability, operating costs, and other factors. This holistic approach allows for the optimization of the RES community structure, striking a balance between reliability and cost considerations.

1. Introduction

In the contemporary Ukrainian energy landscape, there is a discernible trend towards augmenting the role of RES. The primary emphasis lies in advancing solar and hydropower, particularly through the establishment of mini- and micro-hydroelectric power plants (HPPs). Conversely, wind energy exhibits limited representation, attributed to its elevated capital requirements and the intricacies associated with implementation in smaller facilities. Solar power plants (SPPs) within the 10–50 MW range claim a substantial market share due to their

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012120 doi:10.1088/1755-1315/1415/1/012120

scalability, accounting for 3.135 MW of installed capacity. Following closely are plants with capacities between 5 and 10 MW, contributing 1.192 MW to the installed capacity (table 1) [1].

Table 1. RES market segmentation based on power plant capacities.

Power MW	< 1	1–5	5–10	10–50	50–100	100–200	> 200
Number of plants, pcs.	492	337	168	188	15	2	2
Total capacity, MW	184.8	846.3	1 191.7	3 134.6	1 102.8	362.8	569.4

In the realm of RES technologies employed by small-scale electricity producers, a notable divergence emerges compared to the broader market landscape. Analogous to the overall electricity market structure, SPP) dominate among small RES power plants, boasting a total installed capacity of 121.991 MW. This contrasts with the larger market, where wind farms rank second in installed capacity. In the domain of small electricity producers, however, wind farms hold the penultimate position, with a total installed capacity of 1.7 MW. Conversely, the second position among small RES power plants is claimed by small and micro-hydroelectric power plants, amassing a total installed capacity of 47 MW.

A discernible pattern emerges when examining the technological composition of the small RES market categorized by capacity:

- SPPs predominate across all capacity categories;
- mini- and micro- HPPs secure the second position across all capacity categories;
- Wind Power Plants (WPPs) are notably absent in categories up to 300 kW, attributable to technical and economic considerations, such as the relatively high cost of turbines and substantial maintenance efforts.

These outcomes align with various factors:

- photovoltaic technology's high standardization and minimal spatial requirements facilitate diverse installations on the ground, roofs, or building facades.
- the prevalence of small and micro-hydroelectric power plants results from the refurbishment of Soviet-era hydroelectric facilities on small rivers.
- the capital-intensive nature of wind power generation technologies renders them economically unviable on a smaller scale.

As of 2020, table 2 delineates regional leadership in total capacity for RES power plants with an installed capacity of less than 1 MW, with Vinnytsia, Khmelnytskyi, Ivano-Frankivsk, Kyiv, and Zakarpattia regions emerging as frontrunners. While other Ukrainian regions contribute noteworthy capacities of small-scale RES, their collective total remains below 7 MW.

In addition to advancing solar energy, the utilization of biogas for electricity production is gaining traction in Ukraine [2]. As of 2022, several noteworthy developments have transpired in the bioenergy sector:

- bioenergy plants boast an installed capacity of 140 MW, encompassing facilities ranging from 125 kW to 26 MW.
- the aggregate electricity generation in 2022 amounts to 505.4 GWh.
- the count of operational biogas plants stands at 83.

Table 2. Technological composition of small renewable energy power plants: regional installation structures.

Region	Regional installed capacity in megawatts (MW)			
	WPP	Mini-micro HPP's	SPPs	Total
Vinnytsia	0	4.83	17.33	22.16
Dnipropetrovska	0	0.13	11.34	11.47
Transcarpathian	0	6.71	6.01	12.72
Ivano-Frankivsk	0.6	2.44	12.19	15.23
Kyiv	0.45	2.02	9.37	11.84
Lviv	0	0.62	8.59	9.21
Ternopil	0.66	2.64	8.9	12.19
Khmelnytsky	0	7.55	8.29	15.85
Cherkasy	0	3.15	6.55	9.7

These bioenergy initiatives contribute to regional energy autonomy, with many projects generating electricity primarily for internal consumption. The progression of renewable energy sources enhances supply chain reliability, bolsters overall energy security, and fosters local economic growth, thereby fortifying community resilience.

Against the backdrop of ongoing energy sector reforms in Ukraine, there exists a compelling imperative to cultivate distributed generation and align with the tenets of the 4th Energy Package [3]. Concurrently, European nations, guided by the National Energy and Climate Plan and various directives (e.g., Renewable Energy Directive 2018/2001/EU, Directive on common rules for the internal market in electricity EU/2019/944, Energy Performance of Buildings Directive 2018/844), are instituting decentralized structures in their energy systems and markets. The emergence of RECs [4], contingent upon the renewable sources within specific territories [5], epitomizes a contemporary solution. The operation of these communities forms decentralized autonomous energy systems, a subject of growing relevance in recent years [6, 7].

In the present context, the vitality and evolution of our country's energy sector necessitate a more profound analysis. This entails not only scrutinizing the prospects of autonomous decentralized systems with the potential formation of RECs but also delving into the sustainability of these systems, particularly in conditions of autonomy or blackouts [8].

Hence, a pressing imperative is to investigate the optimization of existing hybrid power systems [9]. These systems, incorporating diverse RES types, respond to challenges such as power supply instability induced by natural disasters, aging infrastructure, and damage during conflicts. The paramount goal is to enhance the reliability and autonomy of energy systems. This becomes especially pivotal after severe damage to energy infrastructure and amid significant uncertainties in regional energy supply, particularly in areas directly impacted by hostilities.

This study addresses the optimization of small RES power plant load and capacity distribution, technological profiling, and their potential integration into resilient hybrid systems. The overarching objective is to devise strategies for optimizing their operation, thereby fortifying the country's energy security. Subsequent research will strive to identify the most effective methodologies and approaches to modernize and heighten the level of autonomous operation in energy systems, minimizing dependence on centralized networks and maximizing RES potential, with significant societal and economic implications.

2. Definition of objectives, constraints, and solution methodology

Following research on hybrid renewable systems [10–13], a mathematical model (figure 1) was developed by the authors. This model encapsulates the operational dynamics of low-power hybrid renewable energy systems, considering mode characteristics of generation sources, a set of objective functions, and technical and economic constraints. The model facilitates optimal load distribution among system components. Specific optimization methods are employed to address the challenge of achieving optimal load distribution among generation sources. The model's response to changes in objective functions and constraints illuminates its behavioral variations.

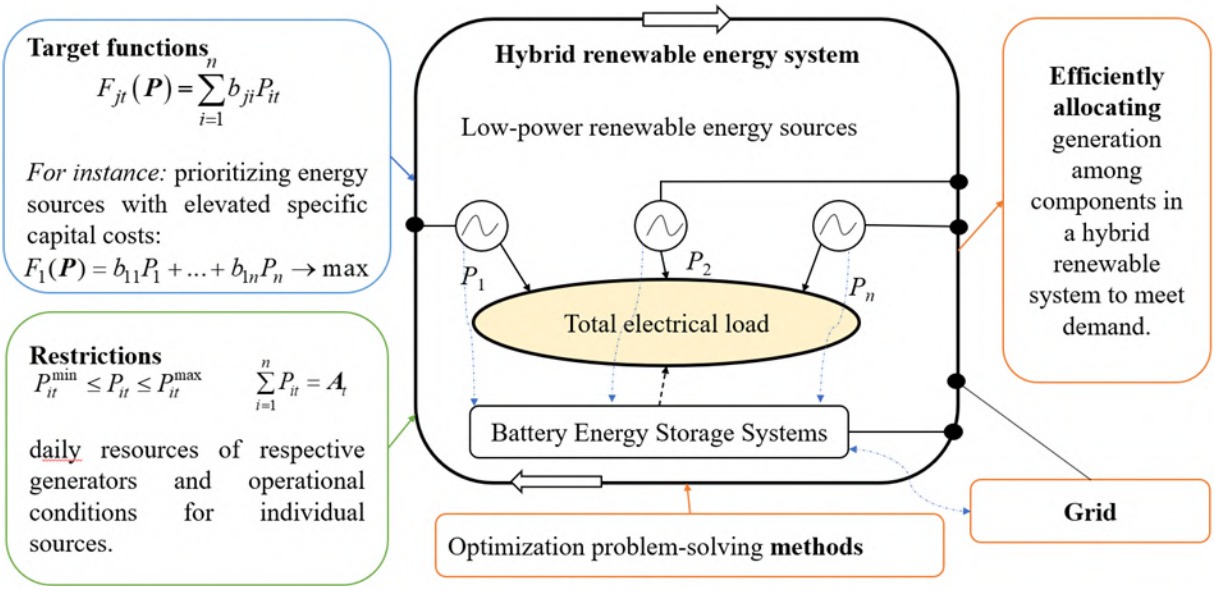

Figure 1. Mathematical model for the operation of a RES.

In addressing the challenge of optimizing the utilization of energy resources, a set of objective functions is initially defined, and the problem constraints are identified. When deliberating on optimal decision-making under the specified conditions, priority is given to the economic considerations associated with the operation of a low-capacity RES. This encompasses the proximity of RES, technical specifications of community components, and the environmental implications of employing various controlled or uncontrolled electricity generation sources. The functions defining the optimal efficiency of a small-scale RES community are articulated in user-friendly language.

It is evident that, in specific contexts, the roster of target functions may be subject to limitation or expansion. The objective is to formulate a list of target functions that effectively characterize various participants in the electricity market, including suppliers and operators. Hence, the list remains open-ended. The structure of each objective function is as follows:

$$F_{jt}(P)=\sum_{i=1}^{n} b_{ji}P_{it}, P=\{P_1,\ \ldots,\ P_i,\ \ldots,\ P_n\}, \tag{1}$$

where, b_{ji} represents the coefficients of respective additional objective functions; P_{it} denotes the proportional contribution of the i-th renewable energy source to the electric load during each time period t; $j=1$, ..., m – the total number of objective functions; n represents the number of factors (i.e., generating energy sources); and t signifies a specific time period (e.g., a particular hour of the day).

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012120 doi:10.1088/1755-1315/1415/1/012120

In certain objective functions, the coefficient, for instance, may assume values such as: 1) the specific operating costs; 2) the number of hours of maximum utilization; 3) the level of harmful emissions into the atmosphere, etc.

During the optimization problem-solving process, some of the aforementioned objective functions necessitate minimization, while others require maximization. Mathematically, the formulation of the problem for the objective functions is as follows, aiming to determine for individual periods t.

$$F_{jt}\left(P\right) \rightarrow \underset{P\in L}{\operatorname{extr}}, j = 1, , m, P = \left\{P_1,\ ...,\ P_i,\ ...,\ P_n\right\}, \tag{2}$$

where m – number of objective functions; on condition if

$$L = \left\{P \in R^n\right\}, L \subseteq \Omega, \tag{3}$$

where Ω – Pareto optimal solution space [14–16].

Practically, most multicriteria optimization problems are inherently heuristic. Therefore, in the development of methods for solving such problems, several pivotal issues must be considered [14–16]. Firstly, the optimality principle in these problems should elucidate the context in which the optimal solution surpasses all other valid options and provide guidelines for discovering this optimal solution. Secondly, local criteria in these tasks often exhibit different physical natures and are measured on distinct scales, complicating direct comparisons of results for each criterion. Consequently, normalization is necessary to standardize the dimensionality of local criteria to a unified, dimensionless measurement scale. Thirdly, the analysis of numerous practical tasks underscores those different local criteria carry varying levels of importance in achieving the final result. Hence, when defining the optimality principle and the solution space, consideration should be given to the fact that certain local criteria hold higher priority and necessitate the incorporation of a degree of their 'importance'. Insufficient clarity in defining optimal solutions poses a key methodological challenge in addressing multicriteria optimization tasks. The practical application of multicriteria decision-making procedures across a broad spectrum of problems [16] has demonstrated the effectiveness of the Bellman-Zadeh method, grounded in the mathematical principles of fuzzy set theory. Advantages of this method include: 1) the simultaneous consideration of quantitative and qualitative factors, with the ability to distinguish their levels of importance; 2) a clear and logical definition of the optimality criterion in terms of maximizing the achievement of all target functions; 3) automatic attainment of a solution guaranteed to belong to the Pareto region, making it the definitive resolution to the problem.

The application of the Bellman-Zadeh method in a fuzzy environment for making optimal decisions aligns with the principle of reliable outcomes and provides a constructive approach to achieving harmonious solutions. The Bellman-Zadeh method stands as an efficient, computationally sound, yet demanding method in obtaining solutions from the Pareto region in the analysis of multicriteria models [14, 16].

According to this approach, each evaluated objective function $F_j(X), j = 1, , m$ is replaced by a fuzzy objective function or a fuzzy set of the form

$$A_k = \left[A,\ \mu_{A_k}\left(X\right)\right], \tag{4}$$

where $\mu_{A_k}\left(X\right)$ is the membership function of the fuzzy function A_k [14, 16]; L represents the trade-off domain.

The membership function of a fuzzy set is an extension of the characteristic (indicator) function of a conventional set. In fuzzy logic, this function quantifies the extent to which each element in the space belongs to a specific fuzzy set. The membership function serves as a subjective measure of fuzziness, as assessed by experts through a survey, indicating the degree of correspondence of an element X to the concept formalized by the fuzzy set A_k.

The fuzzy solution to problem D is derived as outlined in [10,12] $D = \bigcap_{k=1}^{m} A_k$, yielding the following membership function:

$$\mu_D(X) = \min_{k=1,\ \dots,\ m} \mu_{A_k}(X), X \in L. \tag{5}$$

This decision may be construed as an ambiguous directive, introducing uncertainty regarding the selection of a specific alternative. Consequently, there arises a necessity to address and resolve this ambiguity. Multiple methods and techniques exist for mitigating this uncertainty. A prevalent approach, proposed in [16], involves selecting the alternative with the highest degree of membership in the fuzzy decision. In essence, the alternative is identified based on the following condition:

$$\max \mu_D(X) = \max_{X \in L} \min_{k=1,\ \dots,\ m} \mu_{A_k}(X). \tag{6}$$

These alternatives are referred to as maximizing alternatives.

The final decision in the optimization process is determined by the point corresponding to the maximum value of the membership function.

$$X^0 = \arg \max_{X \in L} \min_{k=1,\ \dots,\ m} \mu_{A_k}(X). \tag{7}$$

When addressing an optimization decision-making problem using the aforementioned approach, the formation of the membership function holds significance. These objective functions should aptly capture the essence of the respective evaluation objectives.

Specifically, the following membership functions can fulfill these conditions, structured as follows:

- For the objective functions to be minimized:

$$\mu_{A_k}(X) = \left[\frac{\max\limits_{X \in L} F_j(X) - F_j(X)}{\max\limits_{X \in L} F_j(X) - \min\limits_{X \in L} F_j(X)} \right]^{\lambda_j}. \tag{8}$$

  For optimization problems involving minimization of the objective function, the membership function attains large values at smaller evaluation function values. At the point of minimum, it reaches its maximum value of one.

- For objective functions to be maximized:

$$\mu_{A_k}(X) = \left[\frac{F_j(X) - \min\limits_{X \in L} F_j(X)}{\max\limits_{X \in L} F_j(X) - \min\limits_{X \in L} F_j(X)} \right]^{\lambda_j}. \tag{9}$$

  In optimization problems involving maximization, the membership function is expected to assume a value of one at the maximum value of the estimated objective function, where λ_j – is an indicator reflecting the importance of the k-th evaluation function, often determined through experimental or expert means.

Figure 2 illustrates the implementation of these concepts in the multi-criteria load balancing method for generating energy sources within the RES community.

The multi-criteria resource allocation algorithm encompasses multiple stages executed for each designated time period t, as detailed in [14, 15].

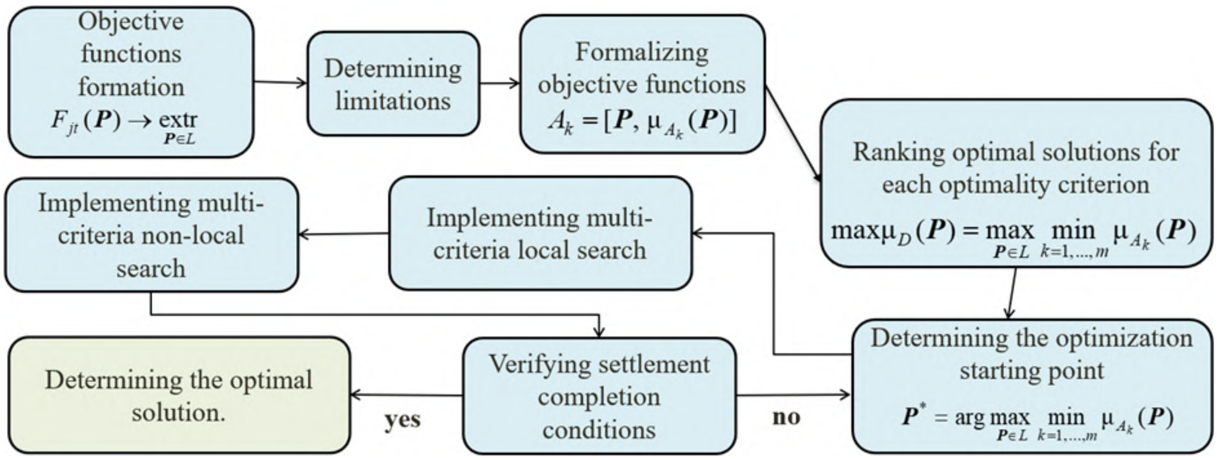

Figure 2. Modified resource allocation method.

3. Results

To simulate the autonomous operation of the RES community, we employed data on electricity consumption [17] by consumers in a specific region of Ukraine over a 24-hour period. The consumer load profile utilized for modeling is depicted in figure 3.

The autonomy of the analyzed RES community is achieved by eliminating power flows with the external power system. This requires that all consumed electricity be generated exclusively from its own facilities, necessitating an increase in their installed capacity.

The problem at hand involves determining the minimum installed capacity for each type of generator, aiming to minimize energy intake from the external grid for each hour of the billing day. To address this, we simulate the optimal loading mode of various generators, seeking the total daily generation while considering the overall power flow with the external power system. The simulation involves varying the installed capacity of generators within a predefined range as a percentage of the current capacity. The minimum value of installed capacity resulting in the minimum power flow with the external power system is selected from the obtained results.

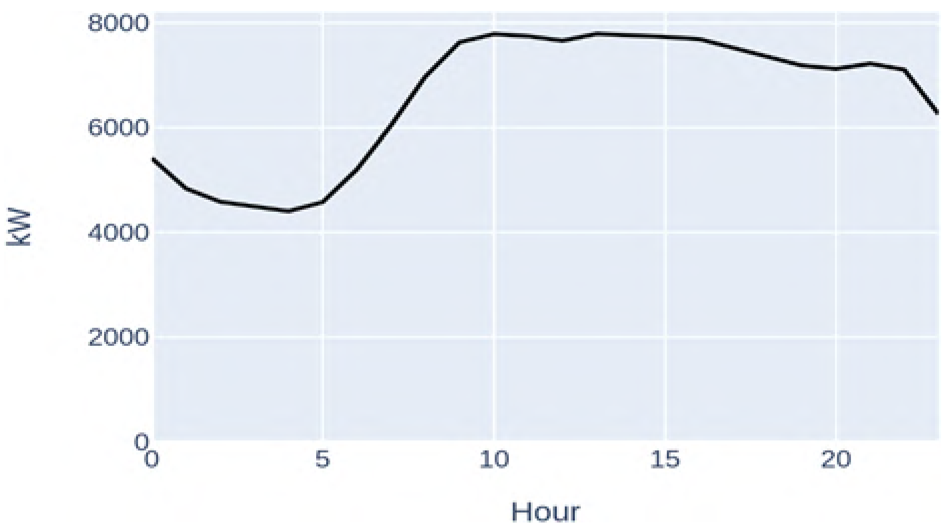

Figure 3. Electricity consumption graph in the RES Community.

Table 3. Capacity ratios among different RES types in RES community structures.

Proposed RES community structures	biogas plants	SPPs	micro-HPPs
Structure 1	44 %	27 %	29 %
Structure 2	33 %	32 %	35 %
Structure 3	38 %	23 %	39 %
Structure 4	28 %	27 %	45 %

In experimental calculations, we assessed an electric power system, comprising low-capacity RES in close territorial proximity, providing electricity to a specific community. Potential generation sources include SPPs, micro-HPPs, and biogas plants.

Modeling was conducted for four distinct RES community structures, delineated by the ratio of installed capacities among different types of generation (SPPs, micro-HPPs, biogas plants). The ratios employed in the modeling are outlined in table 3.

Initially, let's examine the autonomy scenario for the RES community by augmenting the installed capacity of biogas generators. We will conduct simulations with variations in the installed capacity of the plants within the range of 50-200% of the current capacity. The results of the modeling figure 4.

As evident from the graph, achieving autonomy in a type 1 power system structure necessitates a 175% increase in the installed capacity of biogas generators. For a type 3 structure,

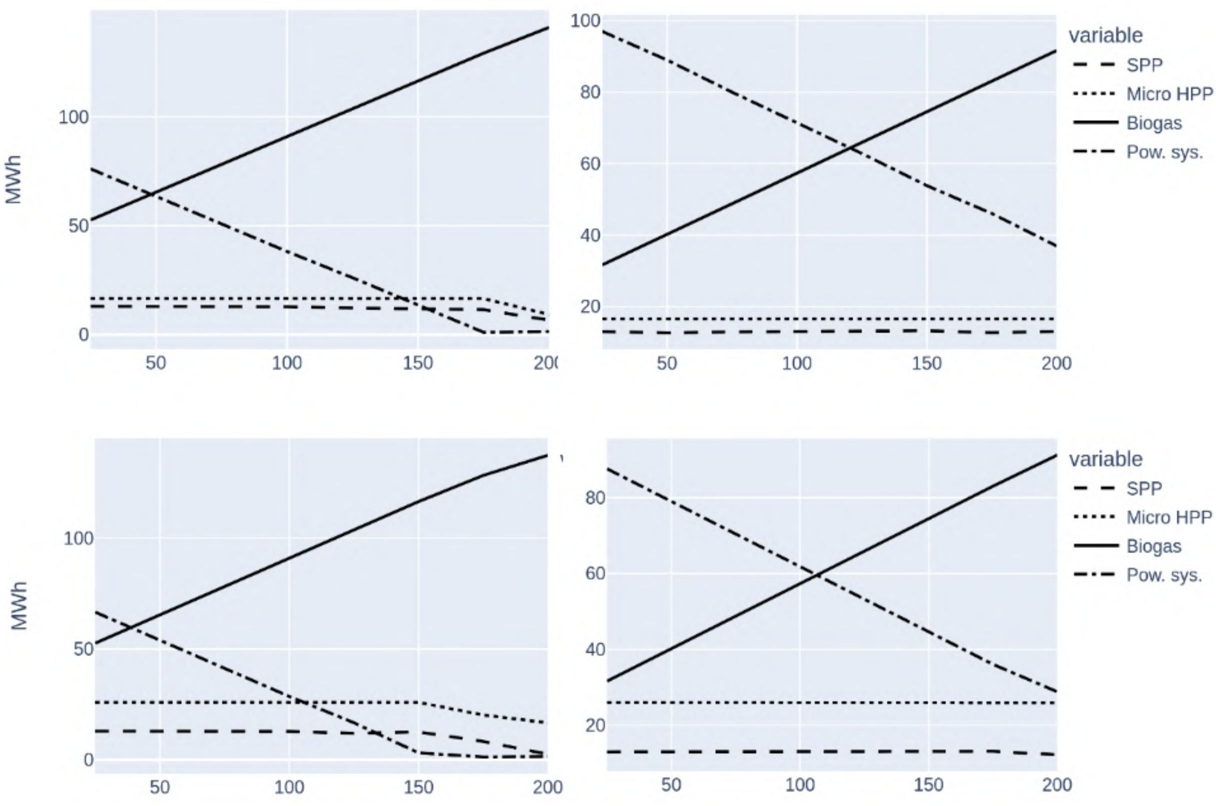

Figure 4. Relationship between the total daily electricity generation and the percentage increase in biogas generator installed capacity.

a 150% increase is required. However, autonomy remains unattainable for structures with types 2 and 4, even with a 200% increase in the installed capacity of biogas generators.

Figure 5 illustrates the results of optimizing the operation mode of a RES community with a type 1 structure under initial conditions (figure 5*a*) and the conditions of achieving autonomy through an increased installed capacity of biogas generation (figure 5*b*).

Next, let's explore the autonomy scenario for the RES community by augmenting the installed capacity of SPPs. Simulations will be conducted with variations in the installed capacity of the plants within the range of 150-500% of the current capacity. The modeling results are presented in figure 6.

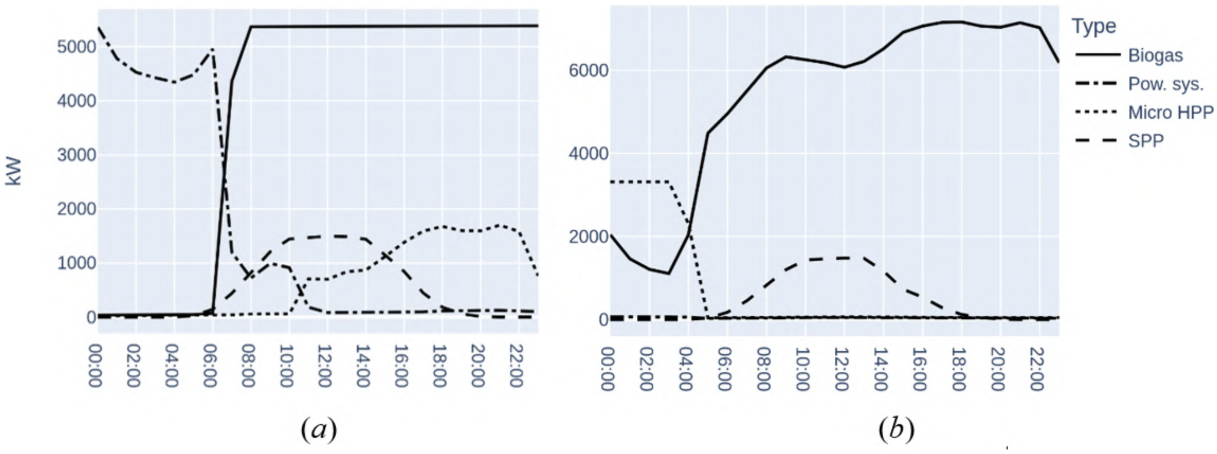

Figure 5. Optimization results for the operation mode of RES community structure type 1.

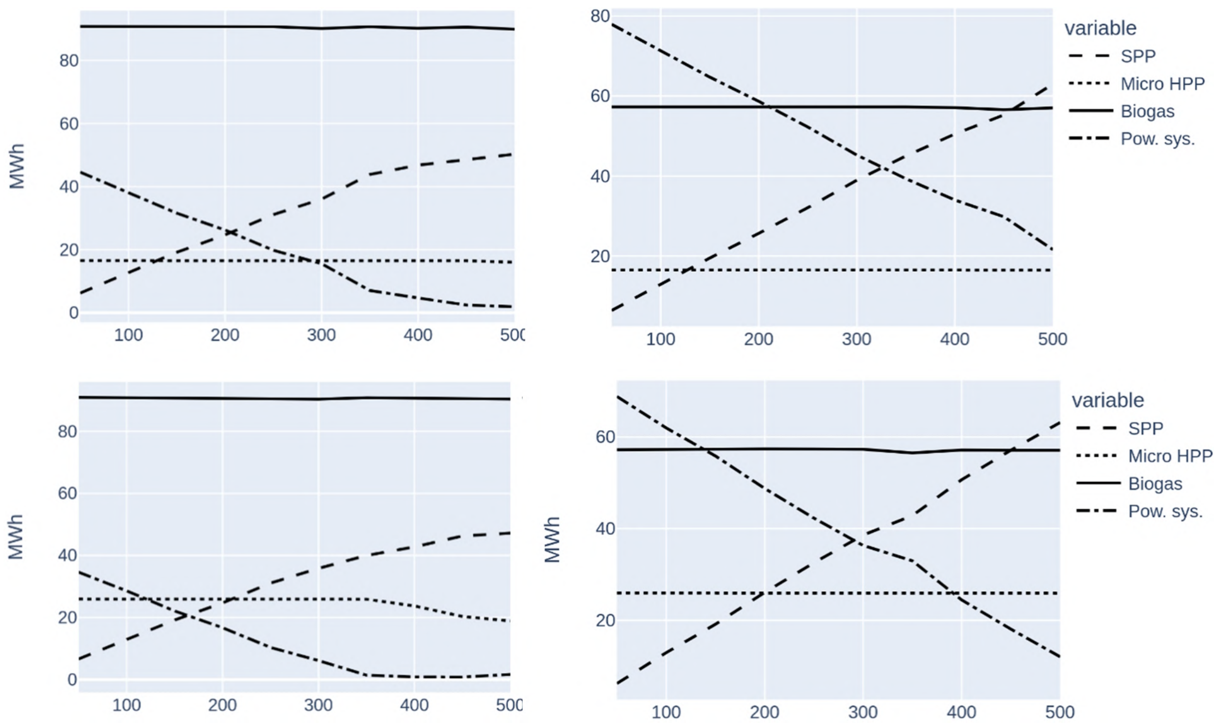

Figure 6. Relationship between the total daily electricity generation and the percentage increase in SPP installed capacity.

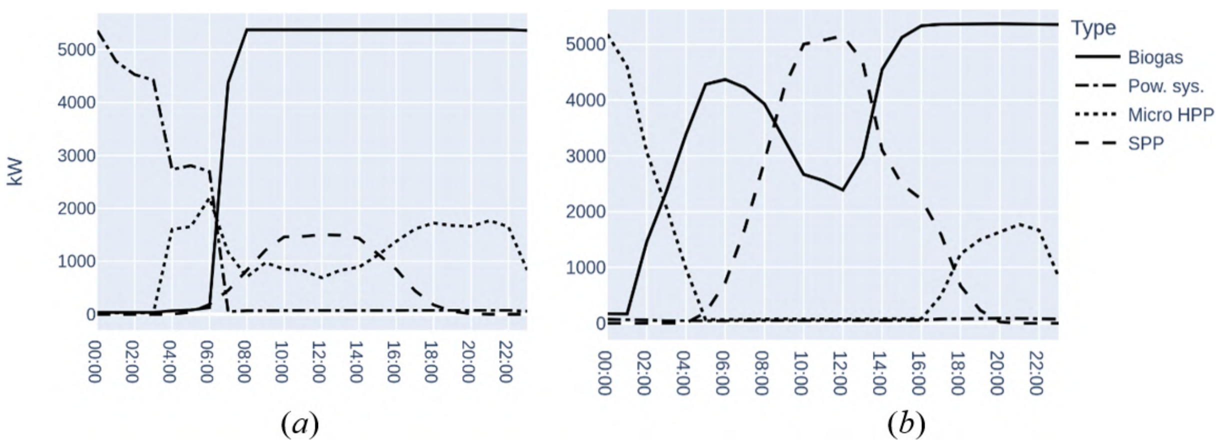

Figure 7. Optimization results for the operation mode of RES community structure type 3.

As evident from the graph, achieving autonomy in a type 1 power system structure requires a 450% increase in the installed capacity of SPPs. For a type 3 structure, a 350% increase is needed. However, autonomy remains unattainable for structures with types 2 and 4, even with a 500% increase in the installed capacity of the SPP.

Figure 7 illustrates the results of optimizing the operation mode of a RES community with a type 3 structure under initial conditions (figure 7*a*) and the conditions of achieving autonomy through an increased installed capacity of SPPs (figure 7*b*).

Several uncertainties impact the optimal outcomes, encompassing natural components, grid configuration, load fluctuations, and other factors. Despite these variables, the use of generation and consumption profiles enables the execution of simulations, facilitating the derivation of optimal solutions.

4. Conclusions

To ensure the autonomous operation of the RES community in the considered region of Ukraine, it is imperative to augment the installed capacity of generating facilities to meet peak loads, eliminating the need for external grid energy. Simulation across four types of RES community structures reveals autonomy feasibility for the first and third structures, requiring substantial increases in biogas generator capacity (up to 175% for the first structure and up to 150% for the third).

For structures with types 2 and 4, autonomy remains unattainable even with a 200% increase in biogas generator capacity, prompting the exploration of alternative measures for energy independence or the integration of additional generation sources. A similar trend emerges with an increased installed capacity of SPPs. Autonomy is achieved for the first structure with up to a 450% increase and for the third structure with up to a 350% increase. However, structures with types 2 and 4 fail to achieve autonomy, even with a 500% increase in SPP capacity.

The optimal pathway to autonomy involves adapting the RES community with a predominant share of biogas generation in the first structure and SPPs in the third structure. Nevertheless, these substantial capacity increases necessitate significant investments and may encounter limitations due to technical, economic, or environmental constraints.

The modeling results underscore the importance of exploring diverse scenarios and combinations of generating sources, considering their resource potential, electricity generation variability, and operating costs. This approach facilitates the optimization of the RES community structure, achieving a balance between reliability, cost, and environmental considerations.

Abstract. One of the options of self-destruction process model of outburst-hazardous coal seams under hydrodynamic impact (HDI) in the conditions of mines in the Donbas central region is considered. The model is based on the results of a comprehensive study of the parameters of the HDI process: mass and coal recovery factor; flow rate of technological boreholes and volume of extracted gas; the calculated degree of the massif degassing and the HDI degassing index from the coal hardness and the natural gas content of outburst-hazardous coal seams. The solution to this problem is connected with the lack of a model for coal destruction during HDI, which leads to an avalanche-like self-destruction of outburst-hazardous coals with the generation of methane. The phenomenon of methane generation is considered in the "coal-gas" system, which is a complex globular organization of macromolecules of outburst-hazardous coals. The model allows to consider the process of development of additional stresses around new formations and theoretically substantiate the presence of an additional source of gas release. To determine the stress-strain state, a solution to the spatial problem of elasticity theory is proposed for n successively arranged cylindrical cavities under the internal pressure action in an isotropic and homogeneous infinite medium is proposed. The dynamic component of the process is determined by the component of the stressed state of the elastic medium under the action of variable load and inertia forces in stressed gas-filled media. The research results are used in the development of technology of active degassing and coalbed methane production by hydrodynamic impact method.

1. Introduction

One of the types of catastrophic man-made natural phenomena is sudden release of coal and gas during mining operations at great depths. The solution to this problem is related to the study of the relationship between methane and coal matter. The results of such studies are sufficiently presented in the scientific and technical literature and do not require explanation. Herewith, it is known that the results of laboratory studies of outburst-hazardous coals do not always correspond to the truth, as they are carried out on transformed coal samples. This discrepancy is especially evident during hydrodynamic impact (HDI) on outburst-hazardous coal seams [1,2]. Some features of HDI and the self-destruction process were considered in paper [3].

The structure of outburst-hazardous coals, and these are grades of coal "K" and "Zh" *(Medium volatile bituminous and Hight volatile bituminous A)*, unlike other grades, have a globular supramolecular assembly (SMA) of the coal substance and are considered as a coal-gas medium formed by nature, or a "coal-gas" system [2, 4]. Transformation processes in such systems are accompanied by new formations with the generation of gases, mainly methane. It is practically impossible to create an analogue of coal-gas medium for its study in laboratory conditions. Therefore, the results of mine experiments are of particular importance in presenting this natural phenomenon.

Hydrodynamic impact (HDI) on outburst-hazardous coal seams through boreholes is one of the methods for initiating such a transformation process. The effective use of HDI in order to prevent gas dynamic phenomena (GDP) during the opening of outburst-hazardous seams, during degassing of abutment pressure zones (APZ), during the extraction of methane from a coal rock massif through boreholes drilled from the surface, and the subsequent analysis of study results made it possible to establish a number of new, previously unknown features of the destruction of outburst-hazardous coals. In the process of study, the following were established: the phenomenon of the occurrence of dynamic loading of a gas-saturated rock massif: the phenomenon of spontaneous destruction of an outburst-hazardous coal seam; the pattern of destruction of porous medium [1].

It is known from solid mechanics that the cause of layer-by-layer destruction of solid bodies is the manifestation of tensile stresses at the boundary of the plastic and elastic zones [5]. In this case, it does not really matter how the plastic state of the borehole contour rocks is achieved. It is important that the unloading process occurs relatively quickly. The manifestation of tensile stresses at the boundary of the plastic and elastic zones is confirmed by the appearance of ring cracks on models made of homogeneous isotropic materials. However, when studying such models, the question of the presence of any gaseous media in the system was not considered.

When solving problems of hydrodynamics in a rock massif, when the brittle, plastic and elastic properties of bodies manifest themselves in the studied medium (rock layers), different models of the processes are considered. Thus, the mathematical description of the processes and phenomena that occur during HDI is based on the model of layer-by-layer destruction of coal [6]. When developing this model, liquid filtration processes were considered, on the basis of which the parameters and modes of the method were established. In the process of mining operations, HDI modes were improved, the gas-dynamic state of coal seams and the stress-strain state of the coal rock massif were studied, new methods and their technological schemes were developed, and the results of studies [1, 6, 7], were analyzed. Herewith, the models of liquid filtration and layer-by-layer destruction of coal during HDI have not changed. As a result, the processes established during HDI are: spontaneous destruction of the coal seam; gas emissions in volumes that exceed the calculated values by an order of magnitude or more; self-supported destruction of coal; the formation of the zone of the near-borehole gas reservoir and the active degassing of the massif have not received scientific justification.

Solving problems of this level is possible using numerical methods. For example, in the paper [8] the processes of fluid filtration and deformation of a porous medium are considered in the finite element packages ABAQUS and MSCMarc. The authors [9] use the numerical modeling method to solve unsteady hydrodynamic equations. The paper [10] discusses the features of conducting a computational experiment using the finite element method when calculating a multi-parameter system "rock massif – combined bracing". In paper [11], problems related to coal gasification in underground conditions are solved.

The search for a mathematical model that can explain the process of avalanche-like self-destruction of the coal-gas system is also related to studies of the parameters of wave and resonance phenomena that manifest themselves during HDI. In this regard, the article [12] is of interest, in which the problem of propagation of acoustic waves in a pre-deformed elastic half-space that interacts with a layer of viscous fluid is considered. Since the problem is solved in an analytical form, the media models have a classical character, i.e. they are based on the application of both the theory of elasticity and the Navier-Stokes equations. However, it should be taken into account that when applying such a solution to the conditions of the rock massif, some of its provisions should be simplified.

2. Problem statement

In order to describe the processes occurring in the massif around the borehole during HDI, it is necessary to find a model that will scientifically substantiate the process of self-destruction of the coal-gas system and methane generation.

The necessity of solving this problem is associated with the high efficiency and reliability of the HDI method, as well as the lack of a model for coal destruction during HDI, which leads to an avalanche-like self-destruction of outburst-hazardous coals with the generation of methane. The phenomenon of methane generation is considered in the "coal-gas" system, which is a complex globular assembly of macromolecules of outburst-hazardous coals. Therefore, the model should reflect the processes of new formations and the development of additional stresses around defects on the coal surface, which theoretically justify the presence of additional sources of gas release.

The purpose of the paper is to study the hypothesis of justification of additional gas release from the borehole by creating additional stress concentrators in its vicinity. Development of an adequate mathematical model to describe the process of initiating and maintaining self-destruction of outburst-hazardous coals under hydrodynamic impact through boreholes.

3. Methods

When considering models of the process of self-destruction of outburst-hazardous coal seams during HDI, analytical and experimental study methods were used. To describe the processes of additional methane generation from a coal massif in the borehole vicinity by organizing stress concentrators, the numerical solution of a spatial axisymmetric problem of elasticity theory is considered by applying the Papkovich-Neuber functions.

4. Results

4.1. Problem solution

From the conclusions formulated in paper [3] we highlight that the lack of theoretically based solutions in determining the components of dynamic loading of a coal-gas medium during HDI does not allow us to substantiate the mechanism of its self-destruction process. At the same time, the effect of initiating self-destruction of coal in a stressed-strained coal-gas system and its maintenance by the HDI method is widely used in the mines of the Central region of Donbas [1, 6, 7].

The high efficiency and reliability of HDI, established in practice, are confirmed by the results of scientific study and their reliability. The established patterns of process development are based on the results of studies of the coal recovery coefficient (C_R), the flow rate of technological boreholes (Q), the volume of extracted gas (V), the degree of degassing of the massif (k), the coal hardness (f) and the natural gas content (X) of outburst-hazardous coal seams. The correlation between the parameters C_R, f, X and k_p, f, X is confirmed by the determination coefficient R^2 from 0.95 to 0.98.

This gives grounds for the development of a mathematical model of the process of self-destruction of outburst-hazardous coals under hydrodynamic impact.

4.2. Solving the problem with stress concentrators in cracks

The intensity of the destruction process can be controlled either by changing the pressure gradient or by changing the length of the working chamber. The influence of pressure drop in the borehole cavity was studied in a practical way. To obtain answers to the questions posed, it is necessary to present the results of solving the dynamic problem of a pressure pulse impact on the borehole vicinity. In this paper such a problem was not considered due to the complexity of its solution. It is proposed to consider changes in the parameters of the working chamber by solving the following analytical model [13].

It is known that increasing the cavity length leads to an increase in the front of liquid action and a decrease in the destruction process intensity. Reducing the length, on the contrary, leads to intensification of deformation processes in the disturbance zone. The use of several sequentially located chambers will increase the efficiency of the process and the emergence of additional stress gradients in the surrounding space.

For a significant length of the working chamber, the Lamé solution is usually used [14]. In case of short chambers, it is not advisable to use it due to the large error. Therefore, at the first stage, a cylindrical cavity was considered, which is divided into short chambers of the same length equal $2l$ with a distance between them equal $2d$ (figure 1).

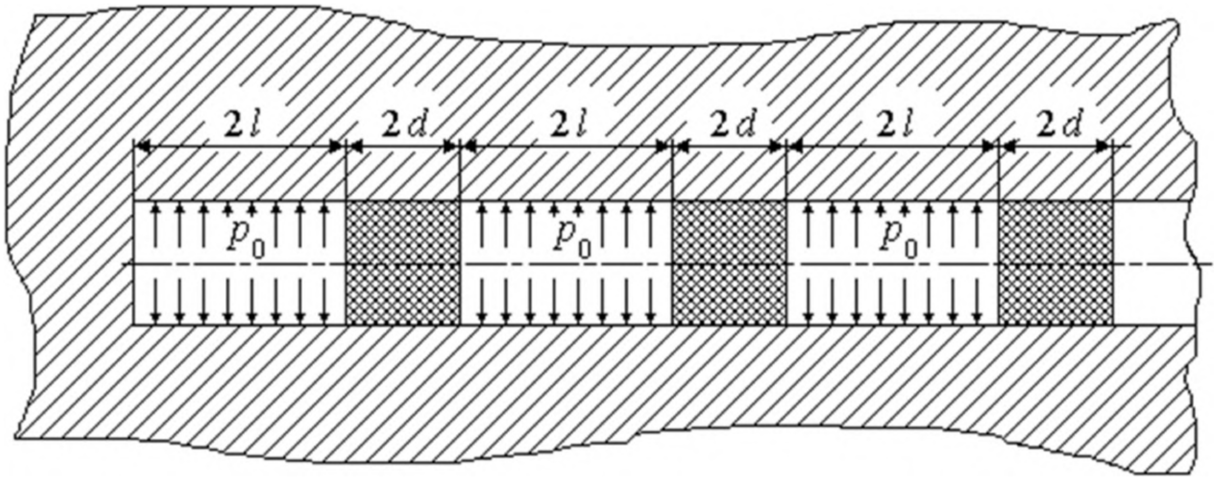

Figure 1. Layout of cylindrical chambers.

Pressure p_0 acts on the side surface of the chambers from the inside. The problem in this formulation is axisymmetric with cylindrical coordinates r, ϕ, z and is solved using the Papkovich-Neuber functions in the form [14, 15]

$$\begin{aligned} u &= 4(1-v)B_r - \frac{d}{dr}(rB_r + zB_z + B_0), \\ w &= 4(1-v)B_z - \frac{d}{dz}(rB_r + zB_z + B_0), \end{aligned} \tag{1}$$

where u, w – radial and axial displacement components; r, z – radial and axial coordinates; B_r, B_z – projections of the harmonic vector B onto the corresponding coordinate directions; B_0 – harmonic scalar; v – Poisson's ratio.

The algorithm for finding the functions B_r (r, z) and B_0 (r, z) can be found in [16]. In this case, after some transformations we get

$$\begin{aligned} u &= [(4(1-\nu)K_1(\beta\rho) + \beta\rho K_o(\beta\rho))C_2 + \beta K_1(\beta p)D_2]\cos\beta\zeta, \\ w &= [pK_1(\beta p)C_2 + K_o(\beta\rho)D_2]\beta\sin\beta\zeta, \end{aligned} \tag{2}$$

The constants C_2 and D_2 are determined from the boundary conditions and can be formulated as follows for an even number of cavities

$$\sigma_r(\zeta)\Big|_{\rho=1} = \begin{cases} p_0 \quad \text{at } (2k-1)(b+\delta)-b<|\zeta| \\ |\xi| < (2k-1)(b+\delta)+b, \quad k=1,\ldots,n/2; \\ 0 \quad \text{in other cases} \end{cases} \tag{3a}$$

for an odd number of cavities

$$\sigma_r(\zeta)\Big|_{\rho=1} = \begin{cases} -p_0 \quad \text{at} \quad 2k(b+\delta)-b<\zeta<2k(b+\delta)+b, \\ k=0,\pm1,\ldots,\pm(n-1)/2; \\ 0 \quad \text{in other cases} \end{cases} \tag{3b}$$

where $d = d/r_0$; $b = l/r_0$.

Another condition for any number of cavities will be the condition that the tangential stresses on the surface of the cylindrical cavities are equal to zero:

$$\tau_{rz}\Big|_{\rho=1} = 0 \tag{4}$$

After performing a number of operations, partial solutions will have the form

$$\begin{aligned} \sigma_r &= -\frac{2G}{r_0}\left[\left((3-2\nu)\beta K_0(\beta\rho) + \left(4(1-\nu)\frac{1}{\rho}+\beta^2\rho\right)K_1(\beta\rho)\right)C_2\right. \\ &\qquad\qquad\qquad\left. +\beta\left(\beta K_0(\beta\rho)+\frac{1}{\rho}K_1(\beta\rho)\right)D_2\right]\cos\beta\zeta, \\ \sigma_z &= \frac{2G}{r_0}\left[\left(\beta^2\rho K_1(\beta\rho)-2\nu\beta K_0(\beta\rho)\right)C_2+\beta^2K_0(\beta\rho)D_2\right]\cos\beta\zeta, \\ \sigma_\phi &= \frac{2G}{r_0}\left[\left((1-2\nu)\rho K_0(\beta\rho)+4(1-\nu)\frac{1}{\rho}K_1(\beta\rho)\right)C_2+\frac{\beta}{\rho}K_1(\beta\rho)D_2\right]\cos\beta\zeta, \\ \tau_{rz} &= -\frac{2G}{r_0}\left[\left(\beta\rho K_0(\beta\rho)+2(1-\nu)K_1(\beta\rho)\right)C_2+\beta K_1(\beta\rho)D_2\right]\beta\sin\beta\zeta. \end{aligned} \tag{5}$$

General solutions can be found in the form of Fourier integrals of the form

$$\int_0^\infty \sigma_i(\rho,\zeta,\beta)P(\beta)\,d\beta, \quad i=\overline{1,4} \tag{6}$$

where $\sigma_1 = \sigma_r$, $\sigma_2 = \sigma_z$, $\sigma_3 = \sigma_\phi$, $\sigma_4 = t_{rz}$,

$$P(\beta) = \frac{2}{\pi}\int_0^\infty \sigma_r(\zeta)|_{(\rho=1)}\cos(\beta\zeta)d\zeta =$$

$$= \begin{cases} \frac{4p_0}{\pi}\sum\limits_{k=1}^{n/2}\cos\left[(2k-1)(b+\delta)\beta\right]\frac{\sin b\beta}{\beta}\cos\zeta\beta, & \text{for } n \text{ even;} \\ \frac{2p_0}{\pi}\left(1+\sum\limits_{k=1}^{(n-1)/2}\cos[2k(b+\delta)\beta]\right)\frac{\sin b\beta}{\beta}\cos\zeta\beta, & \text{for } n \text{ odd.} \end{cases} \tag{7}$$

Boundary conditions (3a, b) will be rewritten in the form

$$\sigma_r(\zeta)|_{\rho=1} = \begin{cases} \frac{4p_0}{\pi} \int\limits_0^\infty \sum\limits_{k=1}^{n/2} \cos[(2k-1)(b+\delta)\beta] \frac{\sin}{\beta}\beta \cos(\zeta\beta)\, d\beta, & \text{for } n \text{ even;} \\ \frac{2p_0}{\pi} \int\limits_0^\infty 1 + \sum\limits_{k=1}^{(n-1)/2} \cos[2k(b+\delta)\beta]\beta \frac{\sin}{b}\beta \cos(\zeta\beta)\, d\beta, & \text{for } n \text{ odd.} \end{cases} \tag{8}$$

Substituting the boundary conditions (4), (8) into the general solution (6) at $r = 1$, we obtain a system from which we will find the constants C_2, D_2

$$C_2 = \frac{p_0 r_0}{\pi G} \frac{K_1(\beta)}{\psi(\beta)}, \quad D_2 = -\frac{p_0 r_0}{\pi G} \frac{K_0(\beta) + 2(1-\nu)K_1(\beta)}{\beta\psi(\beta)} \tag{9}$$

where $\psi(\beta) = (2(1-\nu) + \beta^2)K_1^2(\beta) - \beta^2 K_0^2(\beta)$.

Finally, the expressions for stresses will have the form

$$\sigma_r = -\frac{2p_0}{\pi} \int\limits_0^\infty \left[\left((3-2\nu)K_0(\beta\rho) + \left(4(1-\nu)\frac{1}{\beta\rho} + \beta\rho \right) K_1(\beta\rho) \right) C + \left(\beta K_0(\beta\rho) + \frac{1}{\rho} K_1(\beta\rho) \right) D \right] P(\beta) \sin(\beta b) \cos(\beta\zeta) d\beta,$$

$$\sigma_z = \frac{2p_0}{\pi} \int\limits_0^\infty \left[(\beta\rho K_1(\beta\rho) - 2\nu K_0(\beta\rho))\, C + \beta K_0(\beta\rho) D \right] P(\beta) \sin(\beta b) \cos(\beta\zeta) d\beta,$$

$$\sigma_\phi = \frac{2p_0}{\pi} \int\limits_0^\infty \left[\left((1-2\nu)\frac{\rho}{\beta} K_0(\beta\rho) + 4(1-\nu)\frac{1}{\beta\rho} K_1(\beta\rho) \right) C + \frac{1}{\rho} K_1(\beta\rho) D \right] P(\beta) \sin(\beta b) \cos(\beta\zeta) d\beta,$$

$$\tau_{rz} = -\frac{2p_0}{\pi} \int\limits_0^\infty \left[(\beta\rho K_0(\beta\rho) + 2(1-\nu)K_1(\beta\rho))\, C + \beta K_1(\beta\rho) D \right] P(\beta) \sin(\beta b) \sin(\beta\zeta) d\beta$$

where the function $P(b)$ is determined by formula (8), and the constants C, D are given by the relations

$$C = \frac{\pi G}{p_0 r_0} C_2, \quad D = \frac{\pi G}{p_0 r_0} D_2$$

Figure figure 2 (a, b, c) shows the axial stresses distribution for three consecutive chambers.

Analysis of the obtained solutions shows that the presence of several successively located chambers reduces compressive stresses around the cavity and simultaneously leads to a significant increase in tensile stresses between them.

Thus, the results of scientific and industrial experiments and the solution of the analytical problem of stress distribution around one or several successively located cavities allow to formulate the following.

1 When applying the hydrodynamic destruction mode in the near-borehole zone of a coal-gas massif, both due to partial extraction of coal and the development of cracking, many cavities are formed. The sequence of their development and location in space is determined by the nature and intensity of the pressure gradient (destruction) manifestation of the reverse impulse. As a result of a decrease in compressive stresses and an increase in tensile stresses, a complex stress-strain state is formed around the cavities in the massif. An additional

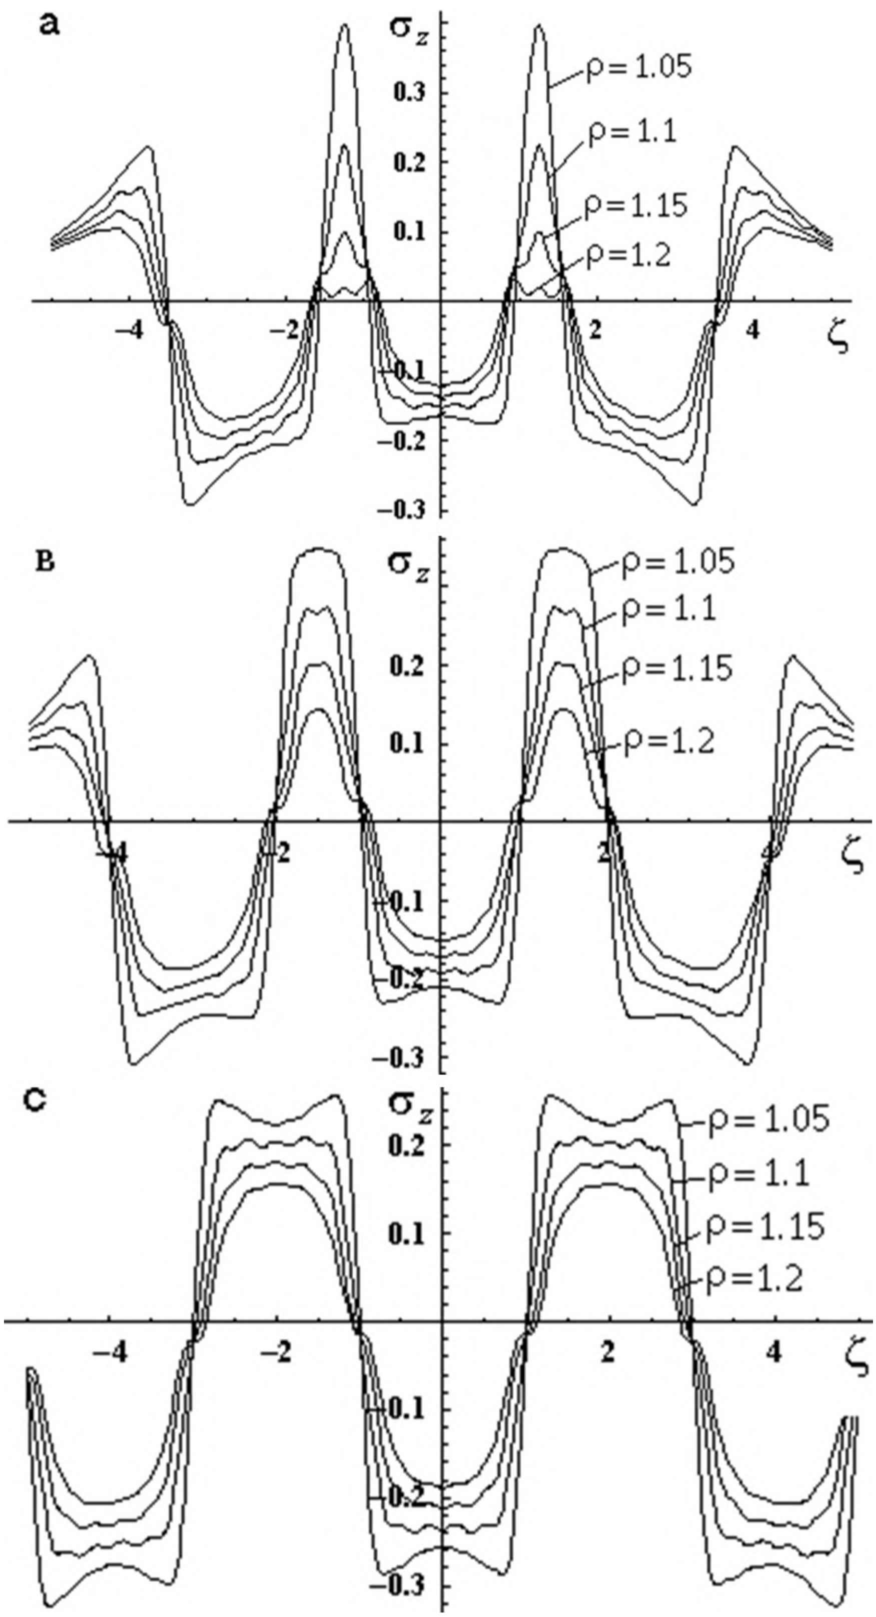

Figure 2. Distribution of axial stresses around the chambers.

increase in stress gradients provokes self-destruction of the massif, which is supported by the transition to the next stage of the HDI mode.

2 The discrete mode of hydrodynamic destruction leads to the intensive formation and development of new open surfaces (cavities), which is a fundamental factor in the intensification of the desorption process during the man-made methane generation by coal-gas medium.

4.3. Dynamic problem solution

Determine the components of the stress state of an elastic medium under the action of a variable internal load. Its peculiarity was the wide use of inertial forces for the dynamic unloading of stressed gas-filled media. The purpose of the approach was to promote development of cracking and degassing in medium. The dynamic parameters of the process of elastic deformation of the medium were determined from the solution of the wave equation in the one-dimensional formulation:

$$r^2 \frac{\partial^2 u_r}{\partial r^2} + r \frac{\partial u_r}{\partial r} - u_r = \frac{r^2}{\nu_p^2} \frac{\partial^2 u_r}{\partial r^2} \tag{10}$$

where u_r (r, t) – radial displacement of an elastic medium, m; t – time of the deformation process, s; ν_p – elastic wave velocity, m/sec.

Boundary conditions on the inner and outer surfaces of the borehole were determined as

$$\sigma_r \Big|_{r=r_0} = -\psi(t); \quad \sigma_r \Big|_{r=r_N} = 0 \tag{11}$$

where r_0 – inner radius; r_N – outer radius.

Despite the large number of options for solving this equation, no simple solutions have yet been found. The found solutions are complex in form and can be obtained using complex numerical algorithms.

The solution given in [17] directly uses widely approved integration methods. For the case of plane strain, the radial σ_r and annular σ_θ stresses can be calculated using formulas (12), (13).

Using the direct Fourier transform in time t to equations (10), (11), we obtain a second-order ordinary differential equation with respect to the displacement transform $\overline{u}_r$ and the transformation parameter ω, which is a Bessel equation, whose general solution is known:

$$r^2 \frac{d^2 \overline{u}_r}{dr^2} + r \frac{d\overline{u}_r}{dr} + \left(\frac{r^2}{\nu_p^2} \omega^2 - 1 \right) \overline{u}_r = 0 \tag{12}$$

$$\overline{\sigma}_r|_{r=r_0} = -\overline{\psi}(\omega), \quad \overline{\sigma}_r|_{r=r_N} = 0 \tag{13}$$

$$\bar{u}_r = A \cdot J_1 \left(\frac{\omega \cdot r}{\nu_p} \right) + B \cdot Y_1 \left(\frac{\omega \cdot r}{\nu_p} \right) \tag{14}$$

where $A(\omega)$, $B(\omega)$ – arbitrary constants determined from the boundary conditions (12); ω – transformation parameter, 1/s; ν – Poisson's ratio; J_1, Y_1 – Bessel functions of the first and second order; $\overline{u}_r$ – displacement transform, m; $\overline{\psi}(\omega)$ – load transform; $\overline{\sigma}_r$ – transform of radial stresses, Pa.

Using the formulas for the case of plane strain for radial and tangential stresses in displacements and using the direct integral Fourier transform in time, we obtain:

$$\overline{\sigma}_r = \frac{E}{1-\nu^2} \left(\frac{d\bar{u}_r}{dr} + \nu \frac{\bar{u}_r}{r} \right); \quad \overline{\sigma}_\theta = \frac{E}{1-\nu^2} \left(\frac{\bar{u}_r}{r} + \nu \frac{d\bar{u}_r}{dr} \right) \tag{15}$$

where E – modulus of elasticity, Pa; $\overline{\sigma}_\theta$ – transform of tangential stresses, Pa.

Substituting the expression for the transform of displacements (13) into equation (14) and using the formulas for differentiating Bessel functions of the first and second order, we obtain the following formulas for transforms of radial and tangential stresses, taking into account the notations $\xi = \omega \cdot r_0/\nu_p$:

$$\frac{\overline{\sigma}_r}{2G} = A\left(\frac{1}{1-\nu}\frac{\xi}{r_0}J_0\left(\frac{\xi r}{r_0}\right) - \frac{1}{r}J_1\left(\frac{\xi r}{r_0}\right)\right) + B\left(\frac{1}{1-\nu}\frac{\xi}{r_0}Y_0\left(\frac{\xi r}{r_0}\right) - \frac{1}{r}Y_1\left(\frac{\xi r}{r_0}\right)\right) \tag{16}$$

$$\frac{\overline{\sigma}_\theta}{2G} = A\left(\frac{\nu}{1-\nu}\frac{\xi}{r_0}J_0\left(\frac{\xi r}{r_0}\right) + \frac{1}{r}J_1\left(\frac{\xi r}{r_0}\right)\right) + B\left(\frac{\nu}{1-\nu}\frac{\xi}{r_0}Y_0\left(\frac{\xi r}{r_0}\right) + \frac{1}{r}Y_1\left(\frac{\xi r}{r_0}\right)\right) \tag{17}$$

where J_0, Y_0 – Bessel functions of the first and second type of zero order; G – displacement modulus, Pa; $\bar{t} = v_p t/r_0$ – dimensionless process time; r – current radius; $t_c = t_2 - t_1$– valid load rejection time, s; q_0 – internal load, Pa; t_1, t_2 – respectively, the time of increase and the time of load rejection, counting from the origin of the coordinates, sec.

As can be seen (16), (17), the initial expressions for determining stresses and displacements are cumbersome and inconvenient for practical use.

The main parameters influencing the process of non-stationary deformation of the elastic medium include: the inner radius of the borehole r_0, the magnitude of the load on the inner surface q_0, the elastic wave velocity v_p and the time of the internal load rejection t_c. Estimating the degree of influence of each parameter is not a simple task, since they are under the integral. From a practical point of view, the dependence of the change in the radial tensile stresses occurring on the inner surface of the cylindrical cavity on the above-mentioned parameters is of great interest. Since most methods of stimulating the destruction of gas-content medium (coal) and degassing are based on the use of inertial forces, we will consider the procedure for obtaining these dependencies in the area of their action. The graphical dependences of stress (displacement) changes in time after the end of the force action have the form of a damped sinusoid. All calculations and transformations are determined in relation to the maximum value of the radial tensile stresses in the first half-wave of stress change in the area of inertial forces action (figure 3).

The presented solutions to problems (16) and (17) in the form of simple engineering formulas convenient for calculating stresses or displacements of an elastic medium during short-term unloading using the method of successive approximation are given in [17].

As a representation function, we will take the value of the maximum tensile stress in the first half-wave of its change related to the value of the maximum amplitude of the internal load q_0 :

$$\bar{\sigma}_r = \frac{\sigma_r}{q_0} = \sigma(t_c^{\alpha_1} \cdot \upsilon_p^{\alpha_2} \cdot r_0^{\alpha_3}) \tag{18}$$

where α_1, α_2, α_3 – indicators of the functions degree of the parameters under studying. The domain of the function definition is set by the parameters change intervals: the interval of the inner radius change of the cylindrical cavity r_0 = 0.05-0.5 m; elastic wave velocity υ_p = 100-2000 m/sec.; load rejection time t_c = 0.001-0.1 sec.

Reference point $M{=}M(x_1^0, x_2^0, ..., x_n^0)$ $M \in \overline{D}$ is set by the values of the parameters: load rejection time t_1^0= 0.01 sec.; elastic wave velocity υ_p^0 = 600 m/sec.; inner radius $r_0^0 = 0.1$ m.

Using the stages of the sequential approximation method algorithm, we obtained:

$$\sigma_r = 0.917\frac{q_0^{1.0} \cdot r_0^{1.01}}{\upsilon_p^{0.957} \cdot t_c^{0.944}} \tag{19}$$

Taking into account the closeness of the exponents parameters to unity, we will obtain a more convenient formula for calculating the tensile stresses on the inner contour of the cylindrical cavity at the first half-wave of the stress change in the form:

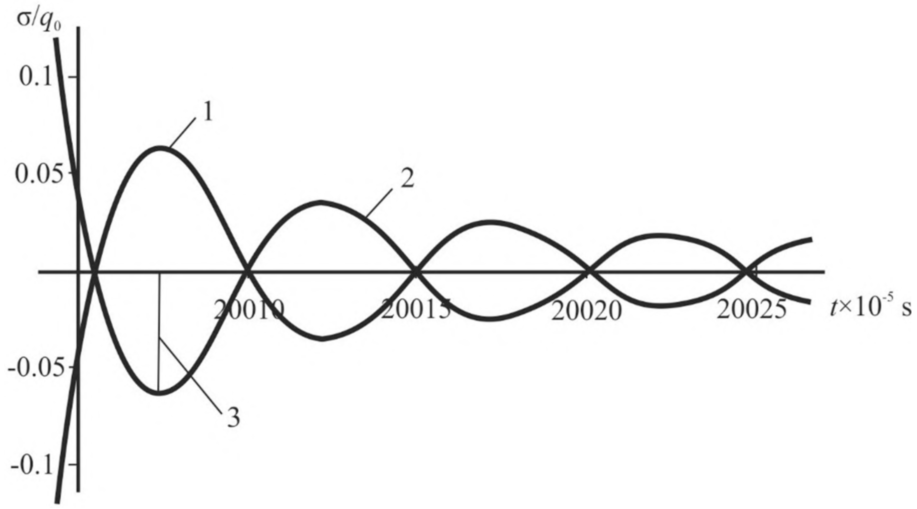

Figure 3. Change of radial and annular stresses with time in the area of inertial forces action at u_p = 400 m/sec.; t_c = 0.001 sec.; $r = r_0$ = 0.1 m; r_N = 1000 m. 1 – annular dimensionless stresses; 2 – radial dimensionless stresses; 3 – maximum radial tensile stresses in the first half-wave.

$$\sigma_r = 0.9\frac{q_0 \cdot r_0}{\upsilon_p \cdot t_c} \tag{20}$$

A comparison of the relative stress errors determined by formulas (19) and (20) was made with the exact one obtained by the Fourier integral transformation method. The analysis of solution errors (19) showed: the average error for the load rejection time does not exceed 3.8%, for the velocity of the elastic wave – 2.0%, for the inner radius – 4.3%.

The analysis of the results of comparing the relative errors of the stresses calculated by formula (20) with the exact one obtained by the method of integral Fourier transformation showed that the average relative error for the load rejection time does not exceed 2.7%, for the velocity of the elastic wave – 2.2%, and for the inner radius – 4%.

Regarding to the usefulness of formula (20) for regulating the rock layer that will separate from the massif under the tensile stresses action, it can be argued that for different types of rocks the rate of load rejection should be correspondingly different. Reducing the rejection time can significantly increase the tensile stress and, accordingly, increase the layer of rocks that will be separated. The risk of reducing the power of the layer that separates is associated with a decrease in the load on the cavity walls or an increase in the time of its discharge.

5. Conclusion

1 Hydrodynamic impact on the coal and gas massif through boreholes with a diameter of 0.1 m due to partial extraction of coal up to 7% of the volume of the treatment zone; cracking and degassing, leads to the formation of many open defects in the form of cavities. The sequence of their development and location in space is determined by the nature and intensity of the pressure gradient (destruction) manifestation by the reverse impulse at an elastic wave velocity of 600 m/s. As a result of a decrease in compressive stresses and an increase in tensile stresses, a complex stress-strain state is formed around the cavities. An additional increase in the stress gradient leads to the development of the process of self-destruction of coal and new formations on its surface. The process of self-destruction

is supported by gas release from the massif and partial extraction of destroyed coal during the change of the pressure set-relief cycle.

2 The discreteness of the hydrodynamic destruction mode leads to the intensive formation and development of new open surfaces (cavities), which is the main factor in the intensification of the desorption process during man-made methane generation by coal medium.

3 The process of self-destruction of coal and its intensity depend on changes in the dynamic components of the process over time. The change of compressive stresses by tensile stresses under the action of variable load and inertial forces leads to the destruction of the coal layer and changes in the stress-strain state of the gas-filled medium. A decrease in pressure relief time leads to an increase in tensile stresses and more effective failure.

4 The average relative error in the calculation of the proposed model parameters calculated by formula (20), for the load rejection time up to 0.1 s does not exceed 2.7 %, for the elastic wave velocity – 2.2 %, and for the internal radius of cylindrical cavities – 4 %.

Abstract. The article is devoted to establishing the current state of graphite deposits development in Ukraine and the prospects of supplying industry with this critical raw material. The countries with the largest production of natural graphite and Ukraine's share of the world market have been determined. Global trends in graphite consumption in industry and its impact on market value have been established. The mining and geological conditions of typical graphite deposits occurrence have been determined, which indicates the expediency of surface mining. The geological characteristics of the largest graphite deposits of Ukraine have been studied, which allows further research to determine directions for increasing the efficiency of beneficiation of graphite raw materials and to increase the greening of production. The main areas of graphite use in high-tech sectors of the economy are given, which confirms the critical role of this raw material in the creation of renewable energy chains. Estimated reserves of graphite have been established in the most significant graphite deposits of Ukraine, which include Zavallivske, Petrivske, Troitske, Mariupolske, Balakhivske and Burtynske. The estimated content of graphite in the ore of the main deposits has been determined, which makes it possible to forecast the country's resource availability with this critical raw material in the future.

1. Introduction

Graphite is a critical mineral raw material with a specific set of characteristics that make it optimal and practically unchanged in various fields of industry, production and scientific research. Even without being a metal, it exhibits unique properties as a metal and a non-metal at the same time, having a unique set of characteristics arising from its molecular structure [1]. If at the beginning of graphite mining, it was used mainly for the metallurgical industry, then later the scope of use expanded significantly.

Graphite has been mined in the world for several centuries, and now the main exporters of this material are China, Mexico, Canada, Brazil and Madagascar [2]. At the same time, the largest producer of graphite in the world is China with an average production level of 700,000 tons per year. This country accounts for 65% of world graphite production and 35% of consumption. The second place in terms of development was occupied by India with 170,000 tons and production of graphite in Mozambique in 2019 amounted to 100,000 tons. The fourth place in terms of graphite production is occupied by Brazil with an annual production of 95,000 tons.

In this ranking, Ukraine was ranked 7th with an annual production of 20,000 tons. The most dominant enterprise in Ukraine for the production of this critical raw material is "Zavallivsky

Graphite", the development of which is carried out by the surface mining.

The analysis of information open sources made it possible to establish that world prices for graphite have significantly increased in recent years, and taking into account the projected increase in the production of electric vehicles, the demand for this raw material will increase in the future. The previous sharp increase in price was recorded in 2011-2012, which was associated with significant demand from manufacturers of lithium-ion batteries, but in 2013, prices decreased significantly due to the decline in the development of the Chinese economy and the insufficient development of Western economies [3].

Starting from 2020, there is a sharp increase in the price of natural graphite, which is due to increased demand in the moderate of an increase in the volume of offers. According to open sources of information, from 2020 to 2022, the price of graphite on the world market increased 3 times and reached 2281 $/t [4], which brought it closer to the indicators of 2012 (figure 1).

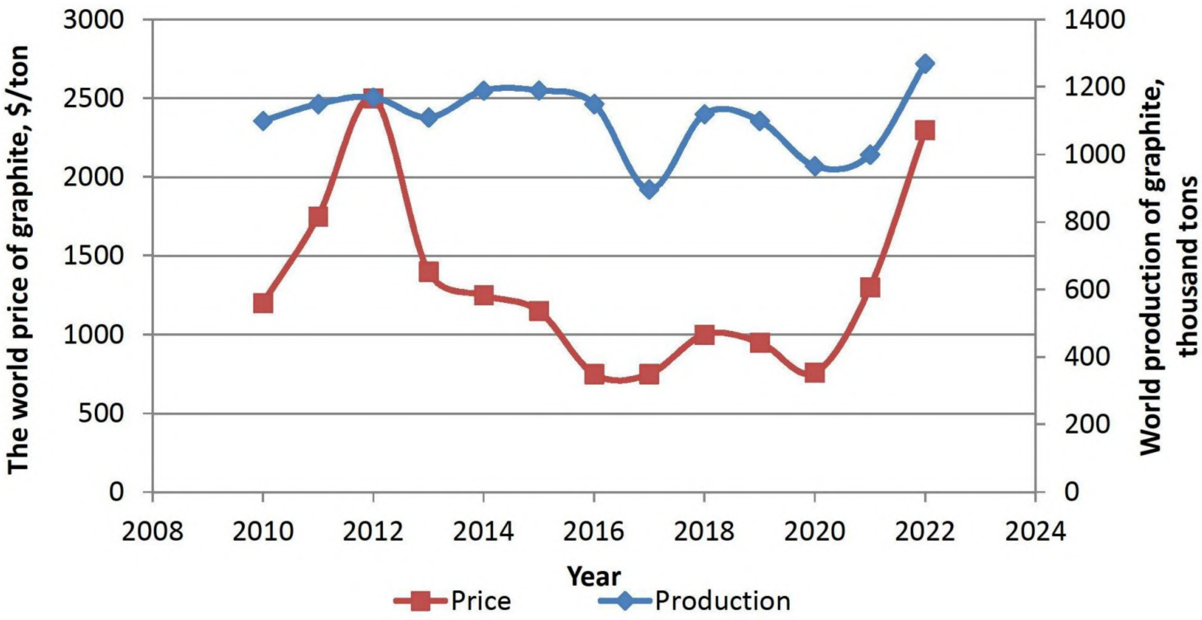

Figure 1. World production and value of graphite in the period 2010-2022.

The indicators displayed on the graph (figure 1) allow establishing that the annual volumes of world graphite production were in the range of 850-1270 thousand tons, and in recent years the value has increased considerably with an insignificant decrease in production volumes.

In connection with the growing global demand for graphite raw materials, determining the state of graphite deposits development of Ukraine and studying the issue of using this critical raw material in various industries are urgent scientific and practical tasks.

The aim of the research is the analysis of technological schemes for the mining and extraction of graphite in Ukraine to meet the needs of the industry of the European Union with critical raw materials.

To achieve the goal, the following research tasks should be solved: analyze the mining and geological conditions of graphite deposits in Ukraine; to investigate the directions of using graphite for high-tech production processes; to establish approximate reserves of graphite raw materials in the most promising deposits of the country.

2. Analysis of mining and geological conditions of graphite deposits

Ukraine has important deposits of graphite, confined to the Ukrainian crystalline shield with a content of valuable components of 2.5 – 20%. In general, there are four graphite-bearing regions in the country: Berdychiv, Priazovsky, Kryvorizky, Pobuzky, where there are approximately 100 deposits and zones with crystalline graphite, which genetically belong to the metamorphic type [5]. Graphite is found in places of contact between hard coal and igneous rocks, in crystalline slates and marbles. It is also found in the form of inclusions of acidic, medium and basic igneous rocks with limestones.

There are 6 graphite deposits on the state balance of mineral reserves (figure 2). One of the main ones is the Zavallivske deposit, which is located on the left bank of the South Bug River and is the largest in Europe with confirmed graphite reserves of 96.6 million tons (6.1 million tons of ordinary graphite).

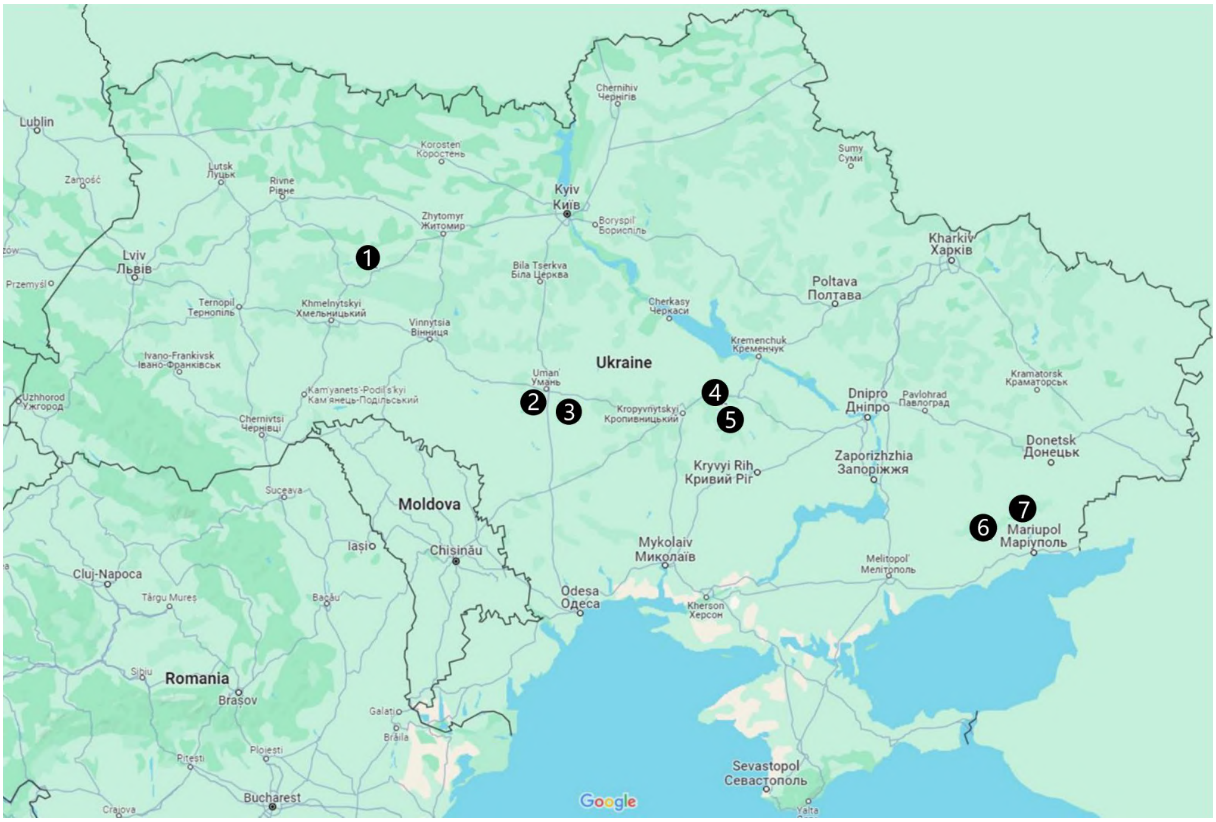

Figure 2. Map of the graphite ore deposits location (Data according to the annual publication of State research and production enterprise "GeoInform of Ukraine" for 2021): 1 – Burtynske; 2 – Zavallivske; 3 – Zarichna; 4 – Balakhivske; 5 – Petrivske; 6 – Troitske; 7 – Mariupolske.

The Zavallivske deposit is located in the fault zone that separates the northern and southern blocks. The northern block is composed of rocks of the Gaivron complex (enderbites), and the southern block is composed of the Khashuvato-Zavalliv rocks of the Buzka series (marbles, calciphyres, magnesian skarns), between the blocks there is an intensely dislocated stratum of graphite-containing crystalline schists and gneisses. This zone of intensely dislocated rocks determines the morphology, structure and mineral composition of ores and graphite is in paragenesis with pyrrhotite and magnetite. Zoning in the distribution of pyrrhotite and magnetite in the central zone was also established, indicating the presence of a geochemical barrier between the blocks. According to the research results, graphite on this barrier was formed as a result of mixing two fluids of different composition.

Recently, two promising deposits of Balakhivske (Kirovohrad region) and Burtynske (Khmelnytska region) have been explored, which are not low-grade to Zavallivske in terms of quality characteristics, so they can become a raw material base for the creation of new mining enterprises.

Graphite is distinguished by its structure – flaky, dense-crystalline and hidden-crystalline types, there are also corresponding grades depending on the use.

Of greatest interest are ores containing flake graphite, where it is placed in the form of individual crystals that form flakes up to several millimetres in size. Coarse-flaky (for example, Madagascar, India), medium-flaky and fine-flaky (Germany) graphites are distinguished by the size of the scales and morphological features. At the same time, the amount of graphite flakes is not constant within one deposit, it depends on the type of host rock. For example, coarse-luxated graphite is found mainly in the Zavallivskyi, Velikovodyanskyi, Bebenkivskyi deposits, and medium-flaky graphite – in the White Horby, Volyanskyi, Starokrymskyi, and Troitskyi deposits. Other known deposits of graphite are classified as fine-flaky type [6].

Quite often, for example, in the Zavallivske and Bebenkivske deposits, separate veins and strips of amorphous graphite are found in cracks. This graphite is a secondary formation that arose as a result of the destruction and removal of graphite flakes in cracks. The occurrence of graphite in the form of separate and equal-sized scales and its clusters forms graphite ore. With contents that meet the condition standards, such ore has industrial value, but these are separate values for each deposit.

Six types of graphite ores are distinguished in the Ukrainian graphite deposits. Four of them are of no industrial importance and are represented by scattered individual fine flakes, liquid accumulation of graphite of various sizes in the form of bushes and nests, dense uniform saturation of rocks with graphite flakes, and accumulation of amorphous graphite. The fifth type in the form of continuous accumulations of graphite flakes of different sizes in the form of lenses, veins and veins (Zavallivske, Starokrymske, Bebenkivske deposits) already forms industrial reserves. The sixth type of graphite ores is industrial and is represented by a dense uniform saturation of rocks with an accumulation of scales in the form of nests and bushes (Zavallivske, Troitske, Starokrymske deposits, etc.). This type, unlike the rest, is well enriched.

Considering the above, four significant deposits of graphite can be distinguished in Ukraine: Zavallivske, Petrivske, Burtynske and Starokrymske deposits. Zavallivske represents a single raw material base for the production of graphite. The Balakhivske field in the Kirovohrad region is promising, the reserves of the license area of which up to a depth of 150 m amounted to 43 million tons, the total reserves are 185 million tons, and the estimated resources are 500 million tons.

The depth of graphite ores mainly ranges from 10 to 80 meters. Graphite-bearing rocks form layered and lenticular structures up to 300 m thick and 500 to 1500 m long, sometimes reaching 3.5 to 5.0 km. Graphite is characterized by flaking and is found in ores in amounts from 2.5 to 20%, rarely up to 30%. Estimated reserves of graphite ore in Ukraine amount to approximately 230 million tons. There is also the potential to increase these reserves by another 100 million tons [7].

Most deposits of Ukraine are characterized by a layered form of graphite ore occurrence in the form of elongated bands, the length of which is several times greater than the width. The saturation of these bands with graphite is uniform and maintained along the extension. The layered type refers exclusively to gneiss rocks. There are also cases when the graphite-bearing strip consists of several types of graphite-bearing rocks, separated by layers of empty or low-productivity rocks, which complicates further mining (common in the Azov region, less so in Kryvorizha and Pobuzhha) [6, 7].

In addition to layered deposits, forms of occurrence in the form of lenses, xenoliths, inclusions, nests and inclusions have been recorded, but they do not form industrial reserves. Vein forms of graphite deposits are also present in separate areas of many graphite deposits. It is also worth noting that of all the listed deposits, only strata deposits are of industrial importance.

3. Use of graphite in high-tech production processes

Today, graphite is necessary for the production of lithium-ion batteries, diamonds, composite and lubricating materials of various types, fuel cells, nanotechnologies and many other renewable energy technologies. The main attention in the world today is given to it because it is a critical material in the manufacture of lithium-ion batteries. Despite its considerable geographical distribution, preference is given to raw materials with a minimum content of impurities obtained by synthesizing petroleum coke. Since the development of modern technology is highly dependent on the supply of this raw material, EU countries are making a lot of efforts to diversify the supply of graphite materials.

Significant demand for graphite in the world has recently been increasing, as it is a critical raw material in the production of lithium-ion batteries for electric vehicles. The rapid development of this market requires large volumes of attraction of natural graphite [2]. For example, up to 54 kg of graphite must be used to make one Tesla S electric vehicle.

The study of possible directions for the use of graphite in high-tech production processes also made it possible to establish a wide range of its use. Among the most common final goods, graphite is used in the production of lithium-ion batteries, carbon steel, crucibles, friction and lubricants, pencils, insulation and composites, flame retardants, seals and foils, refractory materials (figure 3). It is also used as a recarbonizer, fuel cell and metal forming [8].

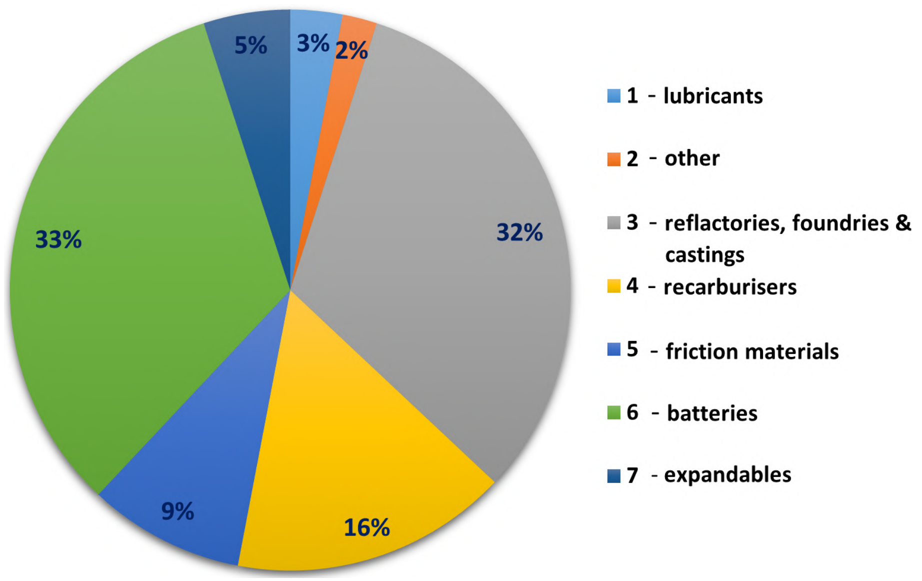

Figure 3. Natural graphite demand by application as of 2022.

One of the main areas of graphite consumption in world industry is the metallurgical industry. Due to its high heat resistance (in an oxygen-free environment) and chemical resistance to molten metals, graphite is used for the manufacture of melting crucibles and lining plates.

Natural and synthetic graphite are increasingly used as anode materials in the production of battery electrodes. This is possible due to their high electrical conductivity and chemical resistance to almost any aggressive aqueous solutions, even higher than that of noble metals [9].

Graphite is also widely used as a tool for processing casting molds. This is a water-based paint that contains amorphous or finely dispersed flaky graphite. After applying this paint to the inner surface of the mold and drying, a thin graphite layer is created. This layer makes it easier to separate the cast object after the hot metal has cooled. Graphite lubricants are used in conditions of high and low temperatures: for lubrication of dies during forging, as anti-seize lubricants, and also for lubrication of gears of mining equipment.

In Ukraine, extraction and beneficiation of graphite ores is mainly carried out at the Zavallivske graphite plant. The company produces grades of graphite for various sectors of industry, such as crucible, elemental, foundry, electric coal, battery, pencil, friction metal-ceramic, powder, special low-ash and others. The main products are foundry, crucible and elemental graphite. Production of graphite products by Ukrainian enterprises meets world quality standards and is exported to other EU countries [5].

4. Development of graphite deposits in Ukraine

The dynamics of natural graphite production in Ukraine shows its significant influence in terms of supply to EU countries. So, in 2020, 5.2 thousand tons of graphite were produced, which was about 0.5% of world production. It should be noted that according to the annual report on the evaluation of critical raw materials, graphite is not only a critical, but also a strategic raw material [9]. The development of graphite deposits has certain difficulties, which is due, first of all, to economic reasons. The main deposits of Ukraine with a high level of graphite reserves include: Zavallivske, Petrivske, Troitske, Mariupolske, Balakhivske and Burtynske (figure 4).

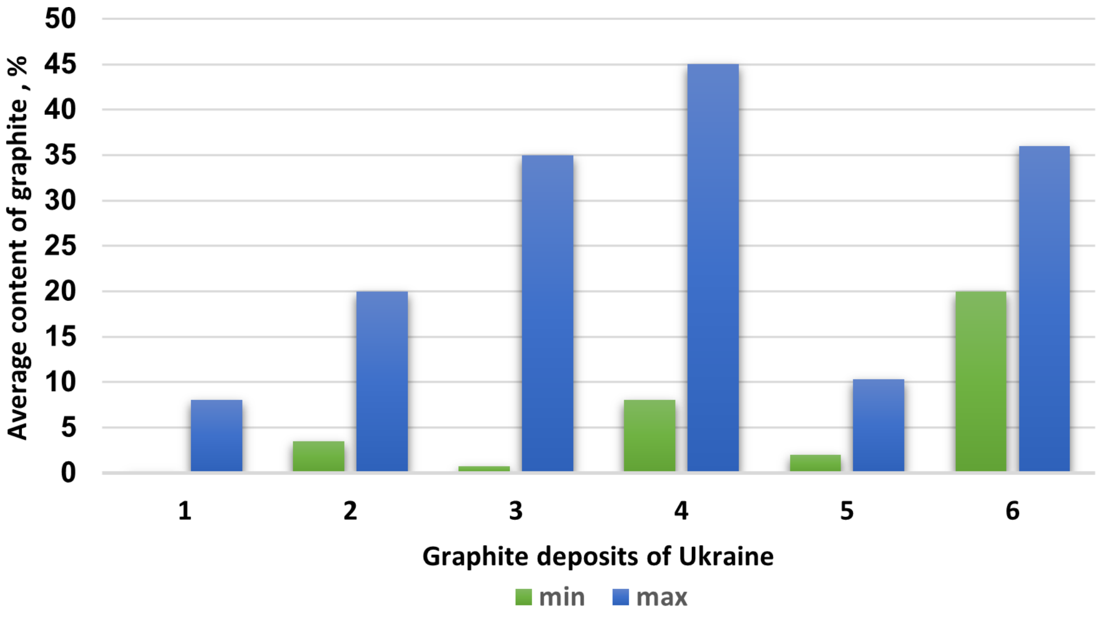

Figure 4. The average content of graphite in ore by deposits : 1 – Troitske; 2 – Petrivske; 3 – Mariupolske; 4 – Zavallivske; 5 – Balakhivske; 6 – Burtynske.

Pobuzky ore district the most attention a graphite-bearing area composed of igneous and to a lesser extent, metamorphic rocks of the Archaean age. This area includes the Zavallivske deposit, which is unique in its size and structure.

This deposit is the largest in Europe and the second in the world. Extraction is carried out by surface mining method [10] using well charges and hydromechanization [11]. The deposit's ores are enriched by flotation (and chemical methods), resulting in a concentrate that contains high-quality graphite in the amount of 85 to 99.5% and has an ash content of no more than 10-15%.

The deposit belongs to the stratimorphic type, where the formation of graphite is characterized by metamorphic or organogenic-syngenetic hypotheses [6]. The high industrial ores value of the Zavallivske deposit allows for the production of a wide range of graphite commercial grades, among which the most valuable is crucible graphite. A number of sulphide and oxide minerals were found in the rocks of graphite deposit, which may also provide grounds for a more thorough study of the genesis, taking into account the changing views on the deposits formation in the world. A good example is the deposits of the USA (Black Hills) or Sri Lanka, which were previously considered metamorphosed, but now hydrothermal in origin.

Graphite mining is carried out only in the south-eastern part of Zavallivske deposit by a surface mining [12] of critical raw materials. The depth of the pit reaches 250 m. The design capacity of the beneficiation plant is 800,000 tons/year of ore, and the design term of operation is 110 years. The products are exported to the countries of the European Union, Asia, the USA, etc.

The Petrivskoe deposit is also typical, where graphite is mainly found in the lower parts of the metamorphosed layer of rocks. It can occur as small clusters and plates in crystalline limestones, graphitic quartzites and gneisses. A significant amount of graphite is found in graphite shales, but they cannot be used as an ore for mining because they are not suitable for beneficiation. Biotite-plagioclase gneisses contain more crystalline graphite, where its concentrations increase with depth. Also, graphite rocks directly, in most cases, do not form a continuous ore body. The presence of migmatized of diopside hornblendes and graphite-coal slates, along the graphite contours near the pegmatite veins, indicates the genesis of the deposit through metamorphic processes and assimilation of limestones by granites [6].

The Balakhivske deposit of the Kirovohrad region with estimated resources of 500 million tons is also promising for development. The reserves of the license area of which up to a depth of 150 m amounted to 43 million tons, and the total reserves – 185 million tons.

Based on the analysis of the study [13], it was established that the deposits of graphite deposits of Ukraine belong to category B, that is, the reserves of mineral raw materials are explored, but mined in limited quantities. The dynamics of the extraction of this raw material in the countries of the world has been established, which shows that countries with smaller reserves extract significant volumes of graphite. While countries with large reserves extract this critical raw material in minimal volumes. This indicates the different economic importance of graphite raw materials for each region separately.

5. Conclusions

It was determined that since 2020, the world market has a sharp increase in the price of natural graphite, which is due to the moderate of an increase in the offers volume. According to open sources of information, from 2020 to 2022, the price of graphite on the world market increased 3 times and reached 2,281 $/t with moderate growth indicators of the global production of this raw material from 850 to 1,270 thousand tons.

It has been established that Ukraine has a high level of resource provision with graphite, a critical raw material, which allows it to become a reliable supplier to the countries of the European Union. In addition, the establishment of graphite exports will lead to the development of the goods production with added value. For this, it is necessary to consider the prospects of expanding the raw material base of graphite by conducting research involving areas with a high content of this critical raw material in ore.

The conducted research made it possible to establish the main characteristics of the graphite deposits of Ukraine, including the capacity of the ore deposit, the complexity group of the geological structure, the average content of graphite in the ore, the amount of reserves, etc. It was determined that the highest average content of graphite in the ore is observed in the Zavallivske deposit and varies from 8 to 45%, while the lowest concentration is observed in the

Troitske deposit, where the graphite content in the ore does not exceed 8%.

The most promising direction of further research is technological solutions for modernization of production and improvement of environmental protection of the processes at the existing Zavallivske graphite plant, which will allow to expand the existing list of commercial products, for example, electro carbon graphite for use in the manufacture of lithium-ion batteries.

Abstract. Given work describe proposals concerning Pampuro method use for improvement of the maximum security concept of nuclear facility at minimum costs. The main provisions of the maximum security concept ensuring for nuclear facility at minimum cost are analyzed. The meaning of the terms threat and risk in relation to critical infrastructure objects is considered. One of the directions for optimal management concept implementing of protected critical infrastructure object using the Pampuro method is proposed. The mathematical model was developed to ensure security of protected nuclear facility at minimum of costs. It takes into account different intensities of terrorist influence. It was concluded that software implementation of the developed mathematical apparatus can be used as a unified software product by security services or physical protection services of various protected objects.

1. Introduction

State's ability to ensure security and protection of critical infrastructure objects from terrorist influence [1–3] is one of the key factors determining the independence of the state. It includes nuclear power plants (NPP), plants on uranium ore enrichment, factories for production and storage of nuclear fuel. They are strategic nuclear facilities [4, 5]. Security management of these protected objects is an urgent problem [6]. Traditionally, its solution is carried out using the concept of deep echelon protection. It is based on an expert approach to ensure security of NPP [7] and international regulations on NPP safety [8–11]. This concept is reduced to security due to creation of protection system from physical barriers. They are built according to the principle of preventing all possible catastrophic events and in their occurrence case – minimizing possible consequences. Engineering and organizational measures are used to create barriers. They should provide at least five levels (barriers) of protection.

NPP safety methods were developed based on the concept of deeply echeloned protection. Some of them are described in works [12–14]. However, these methods do not allow optimal security management – they are associated with methodological limitations of the concept of deeply echeloned protection.

Methodologically important case requires accounting for unlikely events such as an earthquake or a plane crash. For example, periodicity of an earthquake is assumed to be equal one in 10^6 years. It is not possible to assert constancy of the earthquake frequency over a limited interval τ if the service life of the object $\tau \ll 10^6$ years (for NPP $\tau \ll 100$ years). In other words, such cases should be considered as statistically unstable in relation to the accident case at potentially dangerous object and in particular at nuclear power plant. Thus, consequence of the methodological error of postulating probabilistic essence of potentially possible serious accidents (such as the melting of the active zone) is transfer of hypothetically possible accidents to the category of statistically regular and therefore theoretically inevitable. Then the deep defense concept becomes theoretically futile because an accident is inevitable with any defenses according to the probabilistic hypothesis.

The work aim is to consider proposals for the Pampuro method use to implement improvement of maximum security concept of nuclear facility at minimum costs. It is necessary to consistently solve number of tasks to achieve the set aim:

(i) analyze the basic provisions of the ensuring maximum security concept of nuclear facility at minimum costs;
(ii) consider meaning of the terms “threat” and “risk” in relation to critical infrastructure objects;
(iii) propose one of the directions of the concept improvement of optimal management of the protected critical infrastructure facility using the Pampuro method.

2. Basic provisions of maximum security ensuring concept of nuclear facility at minimum costs

Optimal security management of the protected object (maximum effect at minimum costs) is the main principle of optimal security management. At the same time security of protected nuclear strategic object should be considered as a combination of all types of security and physical protection of the object. They are defined as degree of its stability and ability to resist threats. A “thret” is a potentially possible case, action, process or phenomenon that can lead to harm. For nuclear strategic object it is ability to resist military, terrorist, political, social, legal and organizational threats. This is ability to counteract man-made and informational, environmental and criminal threats caused by the action of the forces of nature. Ensuring maximum security is achieved through its practical implementation. At the same time implementation should be carried out with the maximum possible economic efficiency, with minimum amount of all security costs and their optimal distribution [15, 16].

Essence of the optimal security management concept of protected nuclear strategic facility is to ensure maximum security of nuclear facility at minimum costs. It is shown in figure 1 [17].

The abscissa axis shows the risk value R. It determines probability of catastrophic event. Accordingly, it is measured as a fractional number or as a percentage. It cannot exceed a maximum value equal to one or 100%. The value indicators of C calculated in hryvnias or conventional units (usually in thousands or millions of value units) are plotted along the ordinate axis.

The diagram shows cost curves for two technologies implemented at nuclear facility. The first is costs for preventing a hypothetical catastrophic case. Higher costs lead to the lower risk of catastrophic event and vice versa. The second is costs of the consequences eliminating of hypothetical catastrophic case. In some cases, this technology is called insurance costs. Here, the higher risk leads to the higher costs. The third curve shows the total costs of both technologies. The situation determined by the point of intersection of the first and second curves is the

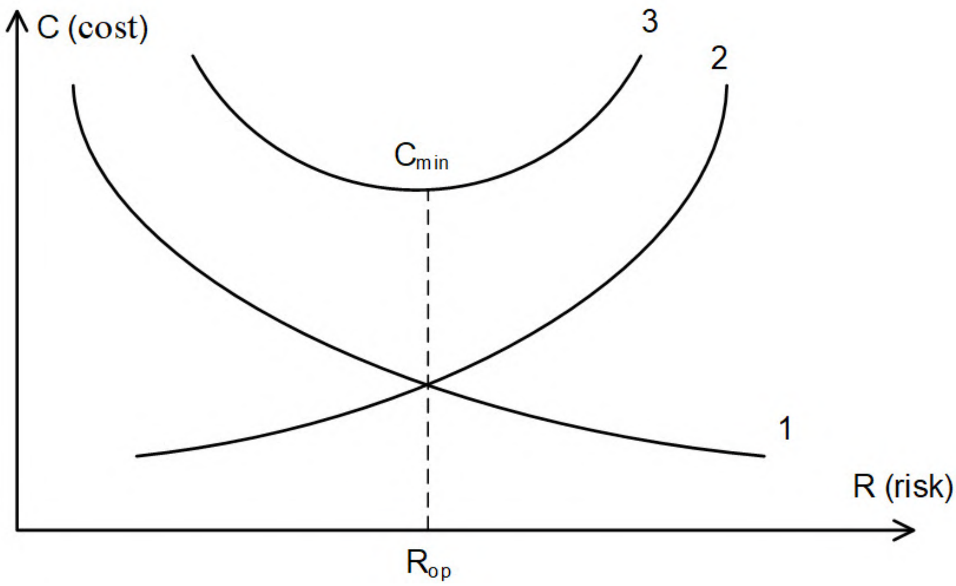

Figure 1. Dependence of security costs on the risk of catastrophic event: 1 – Costs for preventing a hypothetical catastrophic case; 2 – Costs of the consequences eliminating of hypothetical catastrophic case; 3 – Total costs of both technologies.

situation of optimal security management of protected nuclear facility. Under this situation, the optimal (acceptable) value of the occurrence risk of the hypothetical catastrophic case is ensured. It requires minimal total costs.

The concept itself is based on the following eight postulates [17]:

1) optimal security management of the protected object (maximum effect at minimum costs);
2) possibility of occurrence of any hypothetical (virtual) catastrophic case, both at the protected object and in its immediate vicinity;
3) need to use all possible technical means, technologies, laws and knowledge to prevent occurrence of hypothetical catastrophic cases at the protected object and in its immediate vicinity;
4) presence of margin of security control of the protected object;
5) determination of the upper limits of development of hypothetical catastrophe which can cause loss of control both for protected object security and the object itself (its main technological cycle);
6) prediction of options for extreme management of protected object when the upper limits of the development of hypothetical catastrophe is occured;
7) calculation of the total costs for security ensuring of the protected object;
8) compliance with the system in managing protected object and ensuring its safety.

Their practical implementation faces two key concepts – “threat” and “risk” despite the apparent simplicity of the stated principles.

3. Meaning of the terms “threat” and “risk” in relation to critical infrastructure objects

A threat is an opportunity. In turn, opportunity is a direction of development available in every phenomenon of our life. It acts as a future and as an explanation. It has a categorical nature from a philosophical point of view. The concept of opportunity is not fully understood in a rational way because in every opportunity there is a possible impossibility (or possibility of the impossible). Furthermore, possibility is not defined by knowledge of what can be.

In other words, the term threat is reffered to any phenomenon with the potential to harm interests of the state or society. This phenomenon can be natural (tindependent of human activity or can be caused by an entity endowed with will and intention, represented by an individual, group, organization or state).

Currently, it is customary to separate such types of threats at the state level [18]. These are military, terrorist, political, economic, social, environmental and threats caused by the action of natural forces.

Military threats include domestic and international conflicts that are resolved with the use of armed forces. This group also includes threats arising in the case of a military conflict in other countries, if the conflict consequences of the (political, economic, migration, and others) affect the interests of the defending community or the state.

Terrorist threats are threats to commit violent crime or to cause any harm in order to achieve declared goal or obtain a certain benefit in political, religious, criminal and other spheres.

Political threats – are threats of political pressure and promotion of other people's interests. They are the most often observed on the part of dictatorial regimes.

Economic threats are manifested in the growth of inflation, reduction of gross domestic product, closure of enterprises, reduction of the banking or stock exchange sector and others.

Social threats are mainly reduction of social guarantees, for example, provision of work, housing, medical care, inflow of immigrants, rise in prices for basic necessities and others.

Environmental threats are occurrence of industrial accidents and man-made disasters that lead to pollution of the natural environment: atmosphere, water basins and groundwater, the earth's surface, flora, fauna, etc.

Threats caused by the action of natural forces are called natural phenomena. These are floods and droughts, hurricanes and landslides, epidemics and pandemics, epizootics (wide spread of an infectious disease among animals) and epiphytotia (spread of infectious plant disease over the large areas).

Risk is a situation that has uncertain outcome with the mandatory presence of adverse consequences [19]. The situation is characterized as a one-act and unrepeatable occurrence of many events, coincidence of life circumstances and conditions that are revealed by human perception and activity. In other words, the situation is a deviation from the ideal picture. On the other hand it is a compulsion to make a decision. It is to have in mind a possible danger or to act at random in the hope of a happy outcome.

The word "risk" according to [20] is borrowed from the ancient Greek word meaning a rock or the foot of a mountain. Hence, the term "to risk" is translated from French and Italian as "to maneuver between rocks".

Some authors apply the term "risk" to real phenomenon (risk of a fire, risk of a car accident) and others authors apply it to a model of a real phenomenon built with the help of certain mathematical tools. It can be, for example, apparatus of probability theory and mathematical statistics, theory of fuzzy sets, interval mathematics.

Risk is an undesirable opportunity. Here, the term risk is used to describe an actual event. Risk is the probability of loss or failure to receive income compared to the predicted option [21]. In this case the term risk is used in the process of modeling of a real case using probability theory. Sometimes it creates confusion.

Therefore, the most comprehensive definition of risk [22] was initially used in the development of automated systems for forecasting and preventing events in aviation transport. Risk is a measure of quantitative multi-component measurement of danger, including amount of damage from exposure to security threats, probability of occurrence of these threats and uncertainty in the amount of damage and probability.

This definition of risk includes three components. Risk is (first of all) a measure of quantitative multi-component measure of danger, including amount of damage caused by the impact of security threats. Risk is (secondly) the probability of occurrence of these threats. And thirdly there are probabilities (or uncertainties) in the amount of damages. The authors of this article note that they choose their most acceptable risk description at each stage during the implementation of the project.

In addition, it should be noted that even after deciding on the interpretation of the terms threat and risk [23], practical implementation turns out to be quite difficult and time-consuming. It requires priority development of specialized mathematical apparatus used by large-scale (for example, a nuclear power plant) and individual (such as an experimental reactor) nuclear facilities.

4. Characteristic of the concept improvement areas of the optimal management of protected critical infrastructure object using the Pampuro method

The idea of the new concept implementation of optimal management of protected critical infrastructure object using the Pampuro method provides following five provisions.

The first provision is protected object selection.

This object can be any object of the state's critical infrastructure – from municipal gas distribution station which provides gas supply to domestic residential premises and enterprises (boiler plants, chemical plants, etc.) to the nuclear power plant which provides tens of percent of all electricity produced in Ukraine.

The second provision is determination of the security ensuring means of the object and the solved tasks.

Security of protected strategic object is assessed by the risk of any (the most incredible, hypothetical, sometimes bordering on fantasy) catastrophic event. General or total costs to ensure protected object security consist of two components. The first one is the preventing costs of catastrophic event. The second one is the liquidating cost of the consequences in the case of this catastrophic event. The given work shows that there is a certain (optimal) value of the risk of the occurrence of catastrophic event for each hypothetical catastrophic event. It corresponds to the minimum total costs. This minimum total costs is usually called limit of allocated funds to ensure security of protected object. It in turn provides a real (numerical) characteristic N_0 which takes into account all means involved in the object security.

In the general case the finite set consists of three subsets

$$N_0 = N_{01} + N_{02} + N_{03} \tag{1}$$

The first subset is danger detection tools. The second is means of prevention of danger. The third is means of consequences elimination in the case of danger.

Almost two years of the current war shows that the main danger to strategic protected objects located throughout Ukraine are air weapons – missiles and unmanned aerial vehicles (UAVs).

Based on this, the first subset of means of security ensuring of protected object includes means of detecting missiles and UAVs. It can be the widest range of stationary, mobile and portable radio equipment for detecting air targets. They can implement electromagnetic (radar), infrared (thermal), acoustic, optoelectronic, optical and other active and passive detection methods. This is not only technically sound electronic system, but also calculation that ensures its use for its intended purpose. This calculation should have several changes so that this technical system can function for a long enough time (hundreds of hours). This subset solves three main tasks:

- detection of danger (missiles and UAVs) approaching the protected object;
- recognition or identification of the detected danger;

- issuance of data for interception (destruction) of danger by the means of the second subset.

The second subset are means of preventing (destroying) danger. These can be various stationary, mobile and portable anti-aircraft missile systems (AAMS) designed to destroy various aerial targets. These can be: large-caliber and small-caliber anti-aircraft guns; stationary and mobile positions equipped with anti-aircraft small arms (large-caliber machine guns); means of radio-electronic warfare (REW) and camouflage. This subset solves one task: destroy or disable the means of air attack before they approach protected object. As in the case of the first subset, the components of the second subset are both technically servicable fire systems and their crew which ensure intended use. These crew should have several changes so that this technical system can work for a long time.

The third subset is means of consequences elimination in the case of danger. Even in the general case this subset consists of three groups. The first is fire and rescue crew with their technical means. These are fire, special engineering vehicles and special equipment designed for the disposal of unexploded ordnance and other explosive substances. These calculations should also be in constant readiness and with ability to eliminate consequences of catastrophic events for a long period of time. The second group is engineering technique used to dismantle rubble and extract (rescue) people from under rubble. As a rule these are mobile excavators, cranes, lifts and others. The third group is ambulances with medical teams. They are intended for providing first aid to victims on the spot and for evacuating wounded to medical facilities.

The third provision is the Pampuro method use.

Pampuro's method allows you to consider technological object from the point of security ensuring as an abstract hypothetical object. Its structure consists of elementary elements as an example of electronic circuit. This allows a single protected critical infrastructure object to be considered as a quadripole.

The input of the quadrupole receives information flow from all means of ensuring security of protected object N_0 which can be interpreted as accepted multi-frequency combinations of pulsed electromagnetic reflections from a radar target. Such sound combinations form meaningful phrase, full or partial spectrum that allows recognition of thermal or sound image. Of course, such reception of useful information flow cannot be without reception of informational interference (informational noise). The incoming mixture is considered additive. So, the flow of useful information is integrated with information noise and is further considered from spectral positions.

The fourth provision is definition of research goals of the abstract quadripole.

The following research goals of the abstract quadripole can be proposed taking into account material presented above.

The first goal of the study is to find frequency characteristic of abstract quadrupole. It will show how useful information is transformed with given parameters of the input information flow and information noise entering the input of the abstract quadripole.

The second goal of the study is to find optimal characteristic of the abstract quadrupole. It is determined by the Pampuro method as product of the optimal risk value (R_{op}) by the amount of the minimum cost (C_{min})

$$T_0 = R_{op} C_{\min} \tag{2}$$

This characteristic is primarily determined by the number of all means of ensuring security of protected object. Secondly, it should minimize the mean square of the error during the abstract quadripole functioning.

The fifth position is development of mathematical apparatus for solving problem of optimal management.

Mathematical apparatus is necessary to solve separate tasks to ensure safety of protected critical infrastructure object when the conditions for solving the problem are changed. For example, when security measures are increased or decreased, the operating conditions of technical means ensuring the main production process are changed.

5. Development of mathematical apparatus for different intensities of terrorist influence on nuclear facility

For example, let's consider a situation where the intensity of terrorist influence on nuclear facility grows exponentially over a limited period of time.

Let's introduce the following notation:

K_0 – coupling coefficient of an abstract quadrupole;

T_0 – characteristic of an abstract quadripole determined by the Pampuro method;

t_0 – initial countdown;

ω – circular frequency (ω_0 – initial circular frequency);

α– coefficient which shows the ratio of the information effect result on the abstract quadrupole to the square of the minimum transformation error of the entire information flow passing through the quadrupole;

σ_S^2– root mean square error;

H_0 – intensity of informational noise;

β – value determined by the information flow entering the system input;

Δ – shift in time determined by the operation time of the abstract quadrupole;

K(jω) – frequency characteristic of an abstract quadrupole that is physically realized;

A – intensity of influence;

t_ν – duration of exposure.

$$x\,(t) = s\,(t) + n\,(t) \tag{3}$$

where *n(t)* – informational noise in the form of stationary normal white noise with spectral density

$$S_n\,(w) = \frac{H_0}{2} \tag{4}$$

and *s(t)* – information flow from useful information, statistically independent of *n(t)*, which grows exponentially over a limited period of time (5) as shown in figure 2.

$$s\,(t) = \begin{cases} Ae^{\alpha(t-t_0)}, at \to t \le t_0 \\ 0, at \to t \succ t_0 \end{cases} \tag{5}$$

So, it is necessary to find complex frequency characteristic of abstract quadrupole which minimizes mean square error when the intensity of the input information flow increases according to the exponential law during a limited period of time. Its maximum will be determined by the intensity of exposure to A and its duration:

$$[s_v\,(t)]_{\max} = K_0 A^2 t_v \tag{6}$$

The square of the error in the operation of the abstract quadrupole will be equal to

$$E_{\min}^2 = \sigma_s^2 = \frac{1}{2\pi}\int_{-\infty}^{\infty} S_{s+n}\,(w)\,K_0\,(jw)\,dw = \frac{K_0 N_0}{2}\int_{-\infty}^{\infty}\frac{2}{w}\,(1-\cos wt_v)\,dw = \frac{K_0 N_0 A}{2} \tag{7}$$

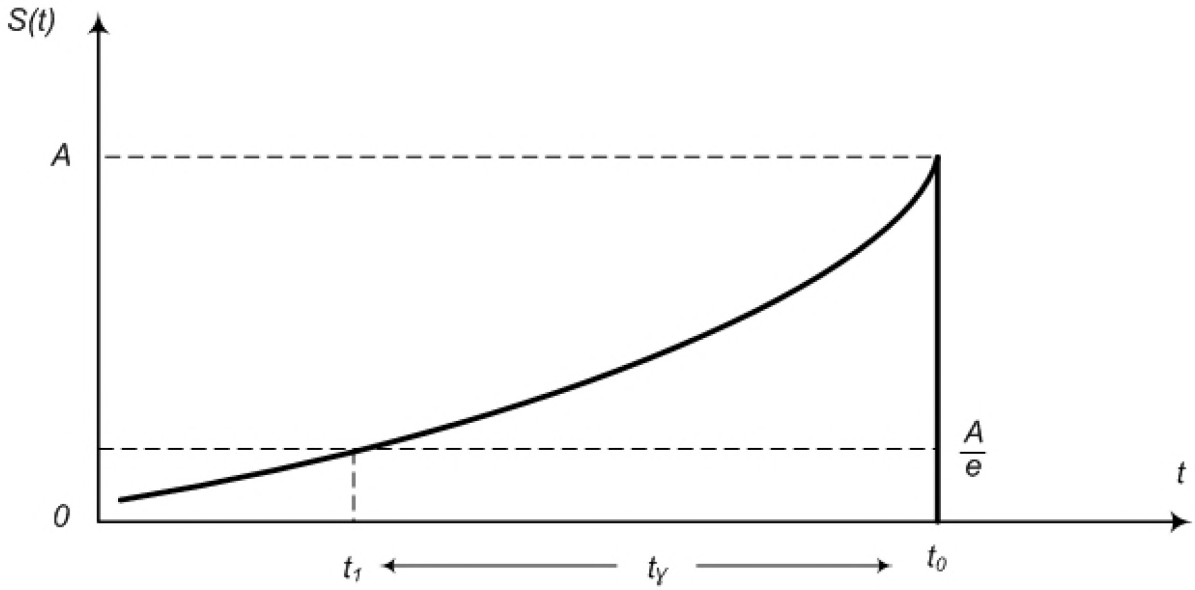

Figure 2. Scheme of flow growth according to the exponential law.

The relation (8) is defined according based on the fact that the optimal characteristic of the abstract quadripole, determined by the Pampuro method

$$T_0 = \frac{1}{\alpha} \tag{8}$$

coefficient α is defined as the result ratio of the information effect on the abstract quadrupole (7) to the square of minimum transformation error of the entire information flow passing through the quadrupole (8), i.e.

$$T_0 = \frac{N_0}{2At_v} \tag{9}$$

The frequency characteristic of abstract quadripole under the influence of an information flow grows according to the exponential law. In the conditions of white information noise it is described by

$$K_0\,(jw) = \frac{A}{jw}\exp\,(jwt_v) \tag{10}$$

Let's consider another case when the intensity of terrorist influence on a nuclear facility is maximum and persists for a limited period of time.

For the given case *s(t)* – information flow from useful information statistically independent *n(t)*, which in the moment t_1 for a limited period of time t_ν will have maximum to the moment t_2 (11), as it shown by figure 3.

$$s\,(t) = \begin{cases} A, at \to t_1 \le t \le t_2 \\ O, at \to t \prec t_1, t \succ t_2 \end{cases} \tag{11}$$

The final form of the frequency characteristic of abstract quadrupole under the maximum influence of information flow during a limited period in the conditions of white information noise is described:

$$K_0\,(jw) = A\exp\,(jwt_v) \tag{12}$$

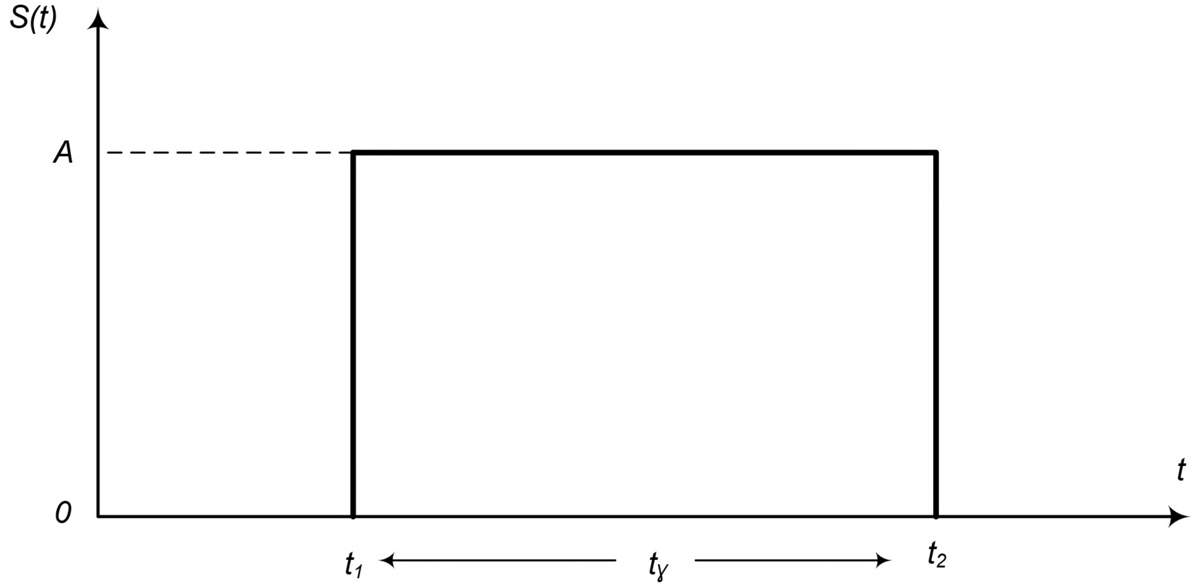

Figure 3. Scheme of maximum intensity maintaining of the incoming information flow during a limited period of time.

its maximum will be determined by the intensity of the impact A and its duration,

$$[s_v(t)]_{\max} = K_0 A^2 t_v \tag{13}$$

Square of the error in the abstract quadrupole operation will be equal to:

$$E^2_{\min} = \sigma^2_s = \frac{1}{2\pi}\int_{-\infty}^{\infty} S_{s+n}(w)\, K_0(jw)\, dw = \frac{K_0 N_0 A}{2e} \tag{14}$$

Based on the fact that optimal characteristic of abstract quadrupole is determined by the Pampuro method (8):

$$T_0 = \frac{N_0}{2eAt_v} \tag{15}$$

So, we obtain frequency characteristic of abstract quadrupole under the influence of n information flow. Its maximum intensity is maintained for a limited period in the conditions of white information noise (12) and optimal characteristic of an abstract quadrupole is determined by the Pampuro method (15). Combination of these dependencies into system (16) will give the optimal characteristics of an abstract quadripole. It will be realized protected object with minimized mean square error at the maximum intensity of the incoming information flow. This is maintained for a limited period of time in the conditions of white information noise

$$\left.\begin{array}{c} K_0(jw) = A\exp(jwt_v) \\ T_0 = \frac{N_0}{2eAt_v} \end{array}\right\} \tag{16}$$

The developed mathematical software can be used as a unified software product by security services or physical protection services of various protected objects.

6. Conclusions

Security methods developed based on the concept of deeply echeloned protection do not provide optimal security management of nuclear strategic objects – ensuring maximum security at minimum costs. Their practical implementation requires the development of a specialized mathematical apparatus despite the apparent simplicity of the eight principles of optimal management. It is applied to large-scale (for example, nuclear power plant) and to single (such as a research reactor) nuclear facilities.

One of the implementation areas of optimal security management is use of the Pampuro method. It provides following five provisions: selection of the protected object; determination of the ensuring security means and tasks solved by it; application of the Pampuro method; determination of research goals of the abstract quadrupole; development of mathematical apparatus to solve task of optimal management. The mathematical apparatus was developed using the Pampuro method to ensure security of the protected nuclear facility at minimum cost. It takes into account different intensities of terrorist influence. The software implementation of the developed mathematical apparatus can be used as a unified software product by security services or physical protection services of various protected objects.

Abstract. This publication is devoted to the study of the peculiarities of designing systems for forming an internal microclimate of a high cleanliness class in the operating rooms of medical institutions. The article presents an analysis of the requirements for microclimate hygiene and air environment of operating rooms of medical institutions, cleanliness classes of premises to be implemented with permissible air components and microclimate parameters for operating rooms of medical institutions, analysis of methods of microclimate regulation, analysis of the features of the construction of ventilation and air conditioning systems of high cleanliness class; analysis of air preparation systems for premises. The article identifies the features of ventilation and air conditioning systems and substantiates the need to use multi-stage filtration; installation of air conditioners with air recirculation and central air conditioning for fresh air preparation; creation of overpressure about neighbouring rooms; use of CAV and VAV systems to regulate airflow parameters and provide overpressure. Conceptual design solutions are presented, and typical block diagrams for the formation of an internal microclimate of a high class of cleanliness in operating rooms in a medical institution are developed, which can be used as standard ones in the development of design solutions. The necessity of developing an automation system is substantiated. A typical structural diagram of an automated air conditioning control system has been developed and substantiated. A generalising algorithm for subsystem functioning has been developed, which can be widely used in the design and construction of such systems.

1. Introduction

Modern treatment methods require specific microclimate conditions in wards, operating theatres, intensive care units, and the prevention of the spread of viruses and harmful bacteria between wards due to environmental pollution in healthcare facilities. Creating comfortable and appropriate environmental conditions in healthcare facilities is essential for successful surgeries and patient recovery.

Creating an internal microclimate of a high class of cleanliness is particularly relevant in operating rooms, where a mismatch in microclimate parameters can have several negative consequences, including unsuccessful surgery. Failure to meet the requirements of temperature conditions, especially during transplantation, can lead to infection and, subsequently, inflammation in the postoperative period and organ rejection. Clean rooms are mandatory for modern medical facilities, especially cell and tissue technology centres, to produce medicines, medical devices, etc.

The development of modern science and technology and changes in regulatory and legal support require finding new solutions for constructing premises, especially high-cleanliness operating theatres in healthcare facilities.

When constructing indoor climate systems, special attention is paid to using energy-efficient technologies to minimise the company's costs and environmental impact. Given Russia's full-scale invasion of Ukraine, it is essential to conserve energy resources and find new and effective energy-saving technologies. Therefore, research on improving the systems and equipment for creating an internal microclimate of high cleanliness in operating premises is relevant.

The **aim** of the work is to design systems for the formation of an internal microclimate of high cleanliness in the operating rooms of medical institutions.

2. Theoretical background

2.1. Analysis of the requirements for microclimate hygiene and air environment in the operating rooms of medical institutions

In modern medicine, the cleanliness of the premises plays an essential role in the adequate performance of operations and the recovery of patients [1–3]. Therefore, in the construction of medical facilities, great attention is paid to the,materials used to decorate walls, floors, ceilings, furniture and plumbing fixtures (heating appliances, plumbing fixtures, etc.). Ventilation and air conditioning systems (VAC) ensure clean premises [3, 4].

According to research by the World Health Organization (WHO), purulent inflammatory diseases have increased significantly over the past ten years abroad and in Ukraine. An analysis of HAIs has shown that their duration and frequency depend on the state of the ambient air environment in healthcare facilities. Medical personnel are the primary source of the "release" of various bacterial particles and microorganisms while moving around the room. The intensity of the appearance of new particles and microorganisms in the airspace is influenced by temperature, the degree of mobility of people, and the speed of air movement. They move with air currents, which creates the possibility of them getting into a patient's open wound on the operating table. It is impossible to influence the movement of healthcare workers, so maintaining the desired temperature, air flow rate, and air exchange is a priority to minimise the likelihood of "infection". Therefore, operating theatres have special requirements for creating suitable microclimate parameters.

Multi-stage air purification and unidirectional air distributors ensure the required microclimate parameters in operating theatres. The need to ensure the boundary's shape and the straightness of air movement over the area selected for protection, in which the surgical table is located, has been identified [3, 5]. The airflow in the room should maintain the microclimate parameters [6,7] and assimilate harmful factors (heat, odour, humidity, toxic substances), protect the selected areas from possible infections and ensure the air purity required in the operating room.

The approaches and concepts of building such systems are covered in [8, 9].

2.2. Analysis of ways to regulate the microclimate of a high purity class

Filtration methods based on airflow displacement are widely used to prevent the ingress of bacterial contamination into critical areas. For this purpose, laminar air distributors of various designs have been developed [3], which are built into the ceiling structure above the area of the room requiring aseptic conditions.

The flow of displacement air moves slowly in small sections from top to bottom so that the sterile areas of the operating theatre and the areas where sterile materials are handled are separated from the environment. The air is removed simultaneously from the lower and upper areas of the room to be protected [3].

Designers usually use unidirectional ultra-fine airflow air distributors in operating theatres with built-in ceiling filters. A large volume of airflow slowly moves down the room, separating the area to be protected from the ambient air. However, many experts need to pay more attention to the fact that such solutions are insufficient to maintain the required level of air purification during surgery.

The high air exchange rate keeps the supply airflow close to isothermal. Due to the large surface area, laminar flow systems with high air exchange rates provide a low initial flow rate. Controlling changes in room air pressure and the operation of the exhaust system minimise air recirculation zones. To ensure an acceptable level of bacteriological cleanliness of the air environment, the operating frequency of air exchange is approximately 25 times per hour, and in some cases, even less. The air is removed through exhaust vents symmetrically placed on the walls of the lower zones. Smaller laminar flow units distribute smaller amounts of air. They are installed directly above critical areas of the room in islands in the centre of the room rather than occupying a large part of the ceiling area.

The observations made it possible to establish that laminar air distributors sometimes provide unidirectional flow due to the difference between the temperature in the air jet and the temperature of the ambient air environment. The vertical low-temperature laminar flow velocity will increase as you descend towards the floor. The flow acceleration increases as the supply air volume increases and the temperature decreases relative to the room air. The "unidirectionality" is not maintained at higher flow rates. As the air moves from the starting point, the flow lines run parallel and then the flow boundary changes and narrows towards the floor, thus not protecting the area defined by the size of the laminar flow unit. The airflow at a speed of 0.46 m/s draws inert air from the room. In addition, bacteria are constantly entering the room, which means that contaminated particles will be introduced into the airflow coming out of the air intake. The air recirculation facilitates this due to the air pressure in the room.

To maintain cleanliness in the operating room, it is necessary to ensure air imbalance by increasing the air supply by 10% more than the exhaust. Excess air gets into neighbouring unclean rooms. In modern operating theatres, sealed sliding doors are often used, so excess air circulates the room without going outside and then is drawn back into the supply system with the help of a built-in fan, where it is filtered, cleaned and reintroduced to the room. The circulating air flow collects all the pollutants from the room air. If the flow boundaries are breached, air from the interior space will inevitably enter the flow, and harmful particles will enter the sterile area that needs to be protected.

Increased air mobility leads to the detachment of dead skin particles from the exposed skin of the healthcare professional, which subsequently enters the incision. On the other hand, infections during the postoperative rehabilitation period result from hypothermia, which is exacerbated by the moving flow of cold air. Therefore, conventional laminar air distributors that work well in clean production environments can be beneficial and detrimental during surgery in conventional operating theatres.

Proper air circulation and distribution in a room requires the selection of an air inlet panel of sufficient size, as well as a standard flow rate and temperature of the supplied air. However,

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012124 doi:10.1088/1755-1315/1415/1/012124

more is needed to solve the issue of air disinfection [4, 5, 10–13]. Properly designed ventilation and air conditioning systems (VAC) prevent the accumulation and spread of infectious diseases, which can minimise the spread of viruses, fungal spores, bacteria and other biological pollutants through the air. When designing a VAC for operating rooms, it should be taken into account that the design of the air supply system should be aimed at minimising the entry of HAIs into clean areas through the air and ensuring the highest possible level of cleanliness in the rest of the operating room. In addition, it is necessary to conduct epidemiological monitoring of the air in the operating room. However, the complexity of such measurements during operations and the need for an approved methodology for collecting and counting microorganisms to assess the level of air purity would require more than such monitoring.

Particular attention should be paid to the location of supply and exhaust devices to ensure the required air conditions in the operating theatres. When designing, it should be noted that using the entire ceiling and floor area is impossible, and the location of exhaust devices on the floor needs to be more hygienic needs to be more hygienic (challenging to clean, quickly contaminated). The analysis of customer requirements and completed projects has shown that the most common are the "island" placement of laminate panels above the protection zone, especially in small operating rooms and the placement of exhaust holes in the lower part of the room's walls.

To prevent contaminated ambient air from entering the laminar flow, air curtains are used, which are constantly working on the exhaust, creating a protective barrier in the form of a narrow "shell" of air with a higher velocity, which is created around the perimeter of the ceiling. To prevent the effect of narrowing the laminar flow and stabilise the required velocity, the exhaust slots of air curtains should be placed along the perimeter of the laminar flow. This will stretch the airflow, expanding and filling the entire area under the air curtain. Design errors or improper installation of the air curtain will have negative consequences – the functioning of the air curtain as a laminar system, without providing the required functionality; high air suction rate at which the airflow does not reach the operating table, which can lead to the threat of leakage of LBW into the operating area from the floor level; curtains with insufficient suction rate may not completely block the airflow and be sucked into it. The need to install an air curtain is determined by the purpose of the operating room and the cleanliness class.

2.3. Analysis of the features of the construction of a high purity class's ventilation and air conditioning systems

The research and analysis of regulatory and legal support made it possible to identify the specifics of the VAC:

- presidential air conditioners are used to ensure and maintain precise temperature and humidity parameters;
- only supply air conditioners are allowed in clean and medical premises;
- split systems are allowed in administrative premises of healthcare facilities and laboratories;
- materials and structural elements of air ducts and filtration chambers must be adapted for regular washing and disinfection;
- it is necessary to install a multi-stage filtration system (at least two filters of different degrees of purification) and use HEPA (High-Efficiency Particular Airfilters) as final filters;
- ensure the required level of air exchange by creating an overpressure relative to neighbouring rooms.

To summarise the above, let us define the main tasks set for cleanroom air handling systems: supplying the required volume of supply air and distributing it throughout the room; preparing the supply air according to the specified parameters (humidity, temperature, purification); organising the required direction of air movement throughout the room.

If there are several cleanrooms, each of them uses a different class of filter or requires a different supply air velocity, the resistance of the branches with these filters will change unequally. This means that the airflow rate during the cleanroom operation will gradually differ from the required one, even with initially balanced network branches. Special measures must be taken to compensate for this effect, one of which is frequency regulation. However, frequency-controlled power supplies in variable-impedance networks are only effective for one room, as they can only support the total air flow rate. CAV (Const Air Volume) flow controllers convert a VAV (Variable AIR Volume) system to a CAV system to address this situation. The basic idea is to keep the resistance of the CAV system constant when operating together with the HEPA filter. That is, as the HEPA filter's resistance increases, the CAV controller's resistance should decrease proportionally. This algorithm ensures that a constant airflow is maintained in rooms with a high class of cleanliness and guarantees automatic stabilisation of several clean rooms during operation, even in the absence of frequency control.

In order to meet the acoustic requirements when using the H14 filter, not only must a duct sound attenuator be used, but the CAV controller must also be factory-coated with a sound attenuating coating. The air ducts before and after the CAV regulator must also have a noise-absorbing coating. It is worth noting that using duct sound attenuators requires increased pressure developed by the air handling unit. A distinctive design feature of CAV controllers is the impossibility of its complete closure, i.e. the CAV controller cannot act as a shut-off valve. For "dirty" rooms, the ability to cut off the branch when changing the filter is a prerequisite. The CAV controller must be retrofitted for these rooms with a shut-off valve. In order to reduce the installation space required for the CAV valve and the shut-off valve, a VAV controller with a constant flow function can be used. Depending on the application, the VAV controller can act as a CAV controller with the ability to maintain constant or multiple air flow rates and act as a shut-off valve. If the VAV is equipped with a differential pressure sensor, it can maintain an overpressure in rooms with a high cleanliness class or create a negative pressure in dirty rooms.

The cost of an air circulation system is proportional to the airflow rate. A creative approach to the design of a cleanroom requires keeping airflow to a minimum. This can be done, for example, by:

- Careful consideration of the air purity requirements, including analysing risk criteria to avoid imposing excessively high air purity requirements;
- using turbulent flows wherever possible;
- providing a high degree of protection only for those stages of the process where the risk analysis requires it;
- Reducing the area with unidirectional airflow to an absolute minimum, taking into account the risk factor;
- minimising the speed of unidirectional airflow, taking into account the process geometry, the instability caused by it and the upward heat flows from heat sources;
- Limiting critical areas with unidirectional airflow by using partitions or plastic curtains.

To achieve a compromise between quality and flexibility of solutions on the one hand and capital and operating costs on the other, open cooperation between the designer, supplier and cleanroom user is essential.

2.4. Analysis of air treatment systems for high-cleanliness premises

Among such systems, we should note systems with indoor air recirculation, integrated air conditioning systems for clean rooms with non-directional (turbulent) flow, and integrated air conditioning systems for high-cleanliness rooms with unidirectional flow. Let us make a brief analysis of these systems.

Room air recirculation systems protect a small area, such as a research laboratory. Such work areas are autonomous installations connected to the network and use the room's air. The HVAC system controls the temperature and relative humidity in the room. Due to the difficulties with temperature and humidity control and maintaining an appropriate noise level, dense installation of such devices in one room is undesirable.

Integrated air conditioning systems for cleanrooms with non-directional (turbulent) flow combine air circulation and outside air in a typical circuit. When using turbulent airflow, the final stage with HEPA filters is added to the air supply system and fed directly into the air distributors, where the HEPA filter and diffuser are combined in one housing.

To minimise the risk of cross-contamination, the same air conditioner is only used in rooms with the same purpose. If several individual air conditioners are used, a unique air conditioner must be provided for the outdoor air preparation of the central air conditioner. Each supply air conditioner serves a separate zone of the building, consisting of rooms that can use the same air.

To prevent pollution of the natural environment caused by the presence of highly active or toxic pollutants from the process, a separate exhaust is provided to the atmosphere after proper air purification through air filtration. Air circulation is the most efficient approach in terms of energy saving. However, in cases where the risk of cross-contamination is high, air circulation is not possible even with HEPA filters, and all ventilation and air conditioning systems must be operated with outside air.

In order to reduce heating and cooling costs, a water/glycol heat exchanger is used to exchange energy between the outside air and the exhaust air. In winter, the outside air is heated by the energy in the exhaust air. In summer, the outside air is cooled by the exhaust air.

Integrated air conditioning systems for high-cleanliness rooms with unidirectional flow are used to achieve maximum protection with minimum effort. Such systems allow for a wide range of combinations to meet design needs. There are three main principles of protection: local, linear and zone.

The following algorithm is proposed for the preparatory stage of designing ICS for operating rooms of medical institutions:

(i) To analyse the requirements for microclimate hygiene and air environment of medical institutions' operating rooms to determine the cleanliness classes of the premises to be implemented with permissible air components and microclimate parameters.

(ii) To analyse how to regulate the microclimate of a high cleanliness class to determine the acceptable way of implementing design solutions.

(iii) Analyse the features of the construction of ventilation and air conditioning systems of a high purity class to determine the need for multi-stage filtration; installation of air conditioners with air recirculation and a central air conditioner for fresh air preparation; creation of overpressure about neighbouring rooms; use of CAV and VAV systems to regulate airflow parameters and provide overpressure.

(iv) Analyse the air preparation systems for high-cleanliness rooms to determine the feasibility of using recirculating air ventilation and air conditioning systems, an integrated air conditioning system for clean rooms with turbulent flow, or an integrated air conditioning system for high-clean rooms with unidirectional flow.

3. Results

3.1. Design

It is necessary to analyse the premises for the implementation of design solutions, analysis of design tasks, architectural and construction drawings of the project, applicable regulations and state standards. Based on the analysis of the source above documents for the design and considering the location of the facility, it is necessary to determine the characteristics of the construction area.

The next step is to analyse the location of the premises, investigate the building's features, get to know the functional purpose of the premises, and determine the cleanliness classes. For example, let us consider premises on two floors requiring appropriate solutions to create an internal microclimate of a high cleanliness class for operating rooms in a medical facility. We classify clean rooms and areas. When determining the cleanliness class, we consider the location of the premises and the technological features of air ducts in the building. The defined cleanliness classes for all rooms of the design object are the initial data for calculating the supply air flow rate and making conceptual decisions on forming an internal microclimate of a high cleanliness class of operating rooms and further system design.

We carry out the necessary calculations of the supply air flow rate. The air supply in a room of a given cleanliness class is determined by a calculation method that considers the requirements for excess heat and humidity, carbon dioxide emissions and permissible concentrations of colony-forming units (CFU). The calculation of the air exchange rate in terms of harmfulness is carried out according to the methodology given in the designer's manual. The external supply air is pretreated before being supplied to the high-cleanliness class premises to comply with the set temperature and humidity parameters and to remove contamination. Pre-treatment is costly, so the design should minimise the outside air used for energy efficiency. The results of the calculations are presented in the form of tables. Having calculated the total amount of supply air and the amount of air to be removed from the intensive care unit, we obtain the following data: supply air – 10030 m3/h; exhaust air – 10330 m3/h. The air that needs to be more for the exhaust systems of the bathrooms is supplied from the hall and corridors that are not part of the clean area. The calculations are used to develop conceptual design solutions.

3.2. Development of conceptual design solutions

Based on the calculations performed, it is proposed to use a ventilation and air conditioning system with air recirculation and outdoor air preparation in the central air conditioner to provide the operating premises with a microclimate, which is proposed to be improved with a recuperator with an intermediate heat carrier (glycol) to recover the heat of the exhaust air, a constant air flow valve on the supply to each room, and a variable flow valve on the exhaust branch from each room to maintain the pressure drop between the rooms. For rooms not used 24/7, we use constant air flow valves with an electric drive to select a mode of 100% capacity or 50% and the ability to turn off the air supply, i.e. 100/50/0% operation.

The use of separate supply and exhaust systems is recommended. Separate mechanically driven supply and exhaust systems should be provided to ensure standardised temperature, humidity, and air purity parameters that meet sanitary, hygienic, comfort, and technological requirements, with air exchange for clean rooms. Air handling units for clean rooms should be implemented in a hygienic design with backup fans.

As a rule, ventilation equipment is located in specially designated rooms (ventilation chambers) on the roof. The air exchange in the room should be calculated based on the assimilation of hazards and taking into account the requirement to prevent the movement of air from more polluted areas to less polluted ones. This ensures sanitary and hygienic conditions for different cleanliness classes of premises. Air distribution and exhaust will be carried out using diffusers and ventilation grilles located in the plane of the suspended ceiling and connected to the supply and exhaust units by air ducts. If the premises of the operating and intensive care units are located on two floors, it is recommended to divide them into separate groups of rooms, each of which will be served by separate supply and exhaust ventilation systems. The temperature in the premises is assumed to be 22°C, and the humidity – 55-60%. The relevant parameters are maintained automatically. Maintaining humidity at 55-60% also protects against electrostatic effects.

The temperature and humidity in the room will be monitored by sensors that will be installed in the recirculation air duct as close as possible to the room to be served. Appropriate sensors will monitor the temperature and humidity of the supplied air, and a maximum humidity hygrostat is proposed to be installed in the supply air duct within the room, close to the laminate panel.

According to the technological task, indoor air cleanliness class is ISO7 in operating rooms and ISO8 for intensive care, anaesthesia, preoperative and other clean rooms. For outdoor air and for systems serving clean rooms, we offer 4-stage air purification in filters. The air will be supplied to the upper zone and removed from the two zones of the room with a distribution of 40% from the upper zone and 60% from the lower zone.

In operating theatres, automatic maintenance of the set pressure drop is recommended. For this, a constant airflow regulator should be installed on the supply line and a variable airflow regulator on the exhaust line. The variable airflow regulator will be triggered by a signal from a pressure sensor installed in the room.

The ventilation of the premises should be organised in such a way as to prevent the flow of air masses from "dirty" zones (rooms) to "clean" ones. Airflow regulators should maintain the required pressure drop with high-speed drives, which are recommended to be installed on exhaust air ducts. They should be controlled by a signal from differential pressure sensors, which should be installed in the room to be served. Supply air treatment units should include steam humidifiers to maintain the relative humidity in their rooms. Steam humidifiers should be installed on the technical floor to be "fed" with water from the building water supply system. The steam from them will be fed through a steam distributor into the air duct.

Ventilation systems for operating theatres and intensive care units should have 100% redundancy to ensure uninterrupted operation. Outside air intake for ventilation systems should be organised in a clean area. Exhaust air should be discharged at a height above the roof. Air handling units should be equipped with water and electric heaters to heat the air in the winter. With this approach, during the warm period, the standard air parameters will be ensured by cooling the air in water heat exchangers. Refrigeration machines, which are recommended to be installed on the roof, should be used as a source of cold.

The selection of air distributors in all premises is proposed to be based on the estimated air flow rate on the premises and take into account the regulatory requirements for speed and temperature difference in the working area of the premises. Air ducts laid outside the building should be insulated with mineral wool products with a thickness of at least 50 mm and covered with a casing. Air supply ducts inside the building are proposed to be insulated with foamed rubber insulation. It is proposed to install shut-off and control valves on all branches of air ducts to air distribution and air intake devices.

The following measures are proposed for more efficient use of energy resources: automation of air conditioners will allow programming a reduction in the temperature in the premises at night or after hours; use of equipment of a high energy efficiency class; installation of check and air valves; use of external enclosing structures with thermal performance that meets the latest regulatory requirements; installation of recuperators with an intermediate heat carrier to utilise heat from the exhaust.

The next design stage is the development of block diagrams for indoor climate control systems. We make design decisions, taking into account the architectural layout of the premises on the floors and the possibility of laying air ducts. For example, we decided to divide the ventilation and air conditioning systems into two systems to reduce the cross-sectional area of the air ducts and, accordingly, the height to which the false ceiling will drop.

The next design stage is the development of block diagrams for indoor climate control systems. Considering the architectural layout of the premises on the floors and the possibility of laying air ducts, we make design decisions. For example, the decision to divide the ventilation and air conditioning systems into two systems to reduce the cross-sectional area of the air ducts and, accordingly, the height to which the false ceiling will drop.

To prepare the air supplied to the operating rooms serving the operating rooms and provide the rooms that are part of the clean area but not related to the operating rooms, with supply and exhaust air, a ventilation and air conditioning system with a central air conditioner is proposed. To ensure the multiplicity of air exchange and a given microclimate, it is proposed to use a separate air conditioner with recirculation and fresh air mixing to ensure sanitary standards for each operating room. Excess air should be pushed out into rooms not part of the clean area. The following design stage is the final equipment selection and laying of air ducts on architectural plans.

Structural control model for distributed ventilation systems. As a result of the study of medical centre operating rooms and construction approaches, it is recommended to develop an automated control system for air conditioning systems that provide a microclimate directly in operating rooms and supply and exhaust systems that prepare air for these systems and provide ventilation to other cleanroom areas to ensure proper air quality and quantity. The ventilation system for intensive care units is recommended to provide heating and cooling of the air, while other systems should provide for heating only. A centralised control system should be used.

The analysis of approaches to automation, the subject area of research, and the requirements for cleanroom ventilation allowed us to form a block diagram of the automated air conditioning control system, which is shown in figure 1. It can be widely used at design facilities with minimal adaptation. An automated system of three modules, M1-M3, should be built. Module M1 is an input unit responsible for reading data from the measuring equipment necessary for decision-making. Module 2 is an information processing and decision-making unit. This unit is the central unit that processes the information from the measuring equipment and makes the appropriate decision on the necessary actions in the system. The M3 module is an output unit that controls mechanical devices (actuators). The number of control subsystems and actuator units can be adapted to a specific medical facility, but the construction concept will remain the same.

This example shows that the M1 module includes six sensor units responsible for monitoring the corresponding subsystem. Let us consider the example of an air conditioning automation system for one operating room, which is typical:

- room air temperature sensor, Troom (T5);
- supply air temperature sensor, Tsa (T3);
- fan pressure difference sensor, Pfp (PDI);
- differential pressure sensor on the filter, Pf (PDI);
- air flow sensor, DPS;
- overheating thermostat of the electric heater, Th;
- control panel for the PKM subsystem.

Assuming that subsystems 1-3 have the same structure, the sensor units and actuators of these subsystems will be the same, figure 2 and figure 3.

The analysis of implemented systems and our own experience suggest that the M2 module usually includes a programmable logic controller (PLC), which is used to automate the control of actuators of such systems. The PLC processes information from the devices of the M1 module

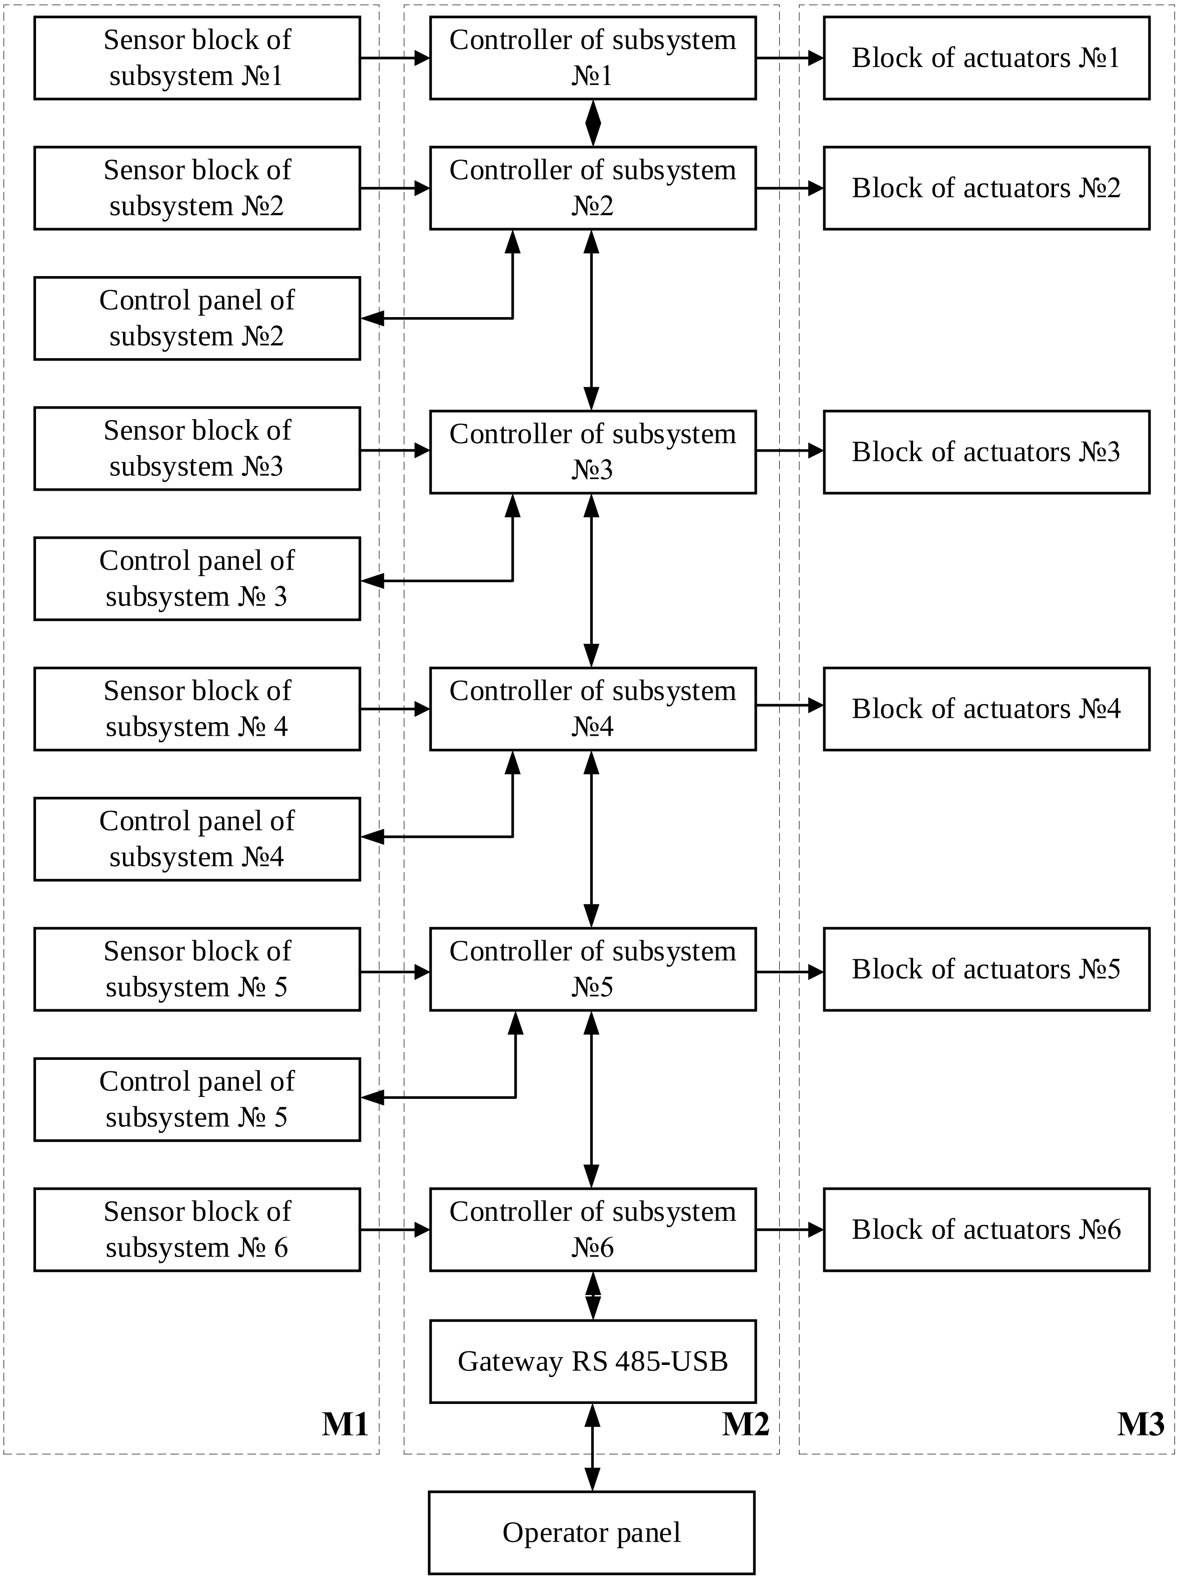

Figure 1. Block diagram of the automated air conditioning control system.

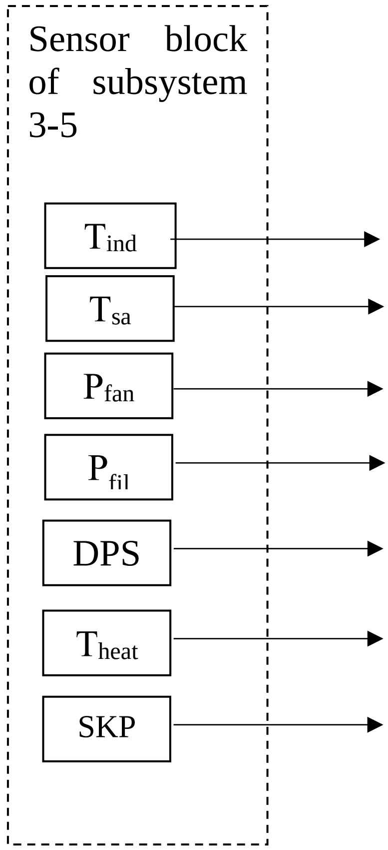

Figure 2. Block diagram of the sensor unit of subsystem 3.

and, based on the processing of the received information, makes decisions on the control of the actuators of the M3 module.

A typical actuator unit includes: relay units, RB1 – RB3; variable airflow device, VAFD; supply air fan, Fsa; electric heater, K; coolant pump H; three-way valve of the water cooler; alarm indication device, Ia; frequency converter of the supply fan, FC.

In modern conditions of building automated control systems, it is proposed that remote control of the developed system be used. A typical model of interaction between system components is shown in figure 4. The model provides for the organisation of data transmission via twisted-pair cable using the RS-485 interface and the Modbus-RTU protocol.

The central control panel allows you to continuously receive and archive all data on the operation of the automatic control system of air conditioning units, in particular:

- View the current parameters of the engineering system and make adjustments to its operation (switch on/off equipment, change the values of control parameters, set time schedules for equipment operation, etc.;
- analyse data from the archive and event logs and, based on the analysis, make adjustments to the operation of the equipment.

Using the Internet and a mobile device (tablet, laptop, smartphone) or a desktop PC that must have an Internet browser with HTML5 support, you can use the WEB server to remotely control or switch systems on/off. No additional software installation is required. The central control panel (CCP) must have a static IP address on the Internet. The data from the measuring

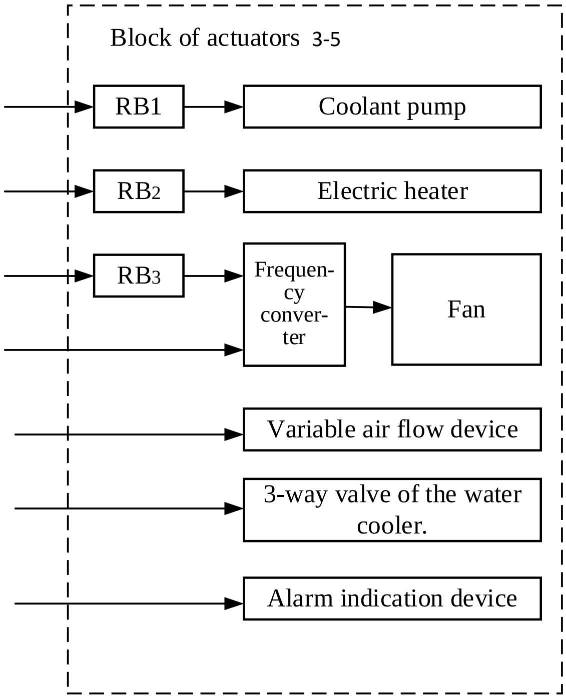

Figure 3. Block diagram of the actuator unit of subsystem 3.

equipment is read from the controller and displayed on the control panel screen in the software interface in real time. If necessary, it is possible to make changes to the operation of air conditioning units in real-time.

Analysing the purpose and tasks of each structural module of the system allows for determining the requirements for the subsystem functions and selecting equipment. The developed system is an integrated system. It can operate in both automatic and manual modes. In the automatic mode, the system reads sensor data, processes it and controls actuators to maintain the set indoor climate parameters. On the other hand, its operation requires human intervention to clear an alarm, adjust operation, set parameters, and switch it on and off. The power supply of module 2 consists of step-down transformers from 220 V to 24 V for each subsystem.

3.3. Development of a functional air conditioning control scheme for the operating unit

A functional diagram is developed based on the structural diagram of the system's functional modules and a thorough analysis of the requirements for the system and the installation site. The functional diagram shows the connection of actuators and measuring equipment to the controller of the respective system, indicating the type of inputs/outputs. In addition, this diagram should show the assignment of measuring equipment and actuators to subsystems. Typical control objects are a servo drive of a variable airflow device, a servo drive of a three-way valve of a water cooler, a coolant pump motor, an electric motor of a supply fan that supplies air to the room, and electric heaters that heat the air if necessary. In addition, the subsystems can provide for smooth control of the supply fan motor speed using a frequency converter (FC) to maintain a constant airflow rate on the HEPA filters. In the next stage, selecting the element base to draw up the electrical schematic diagram of the system and ensure the specified functionality is necessary.

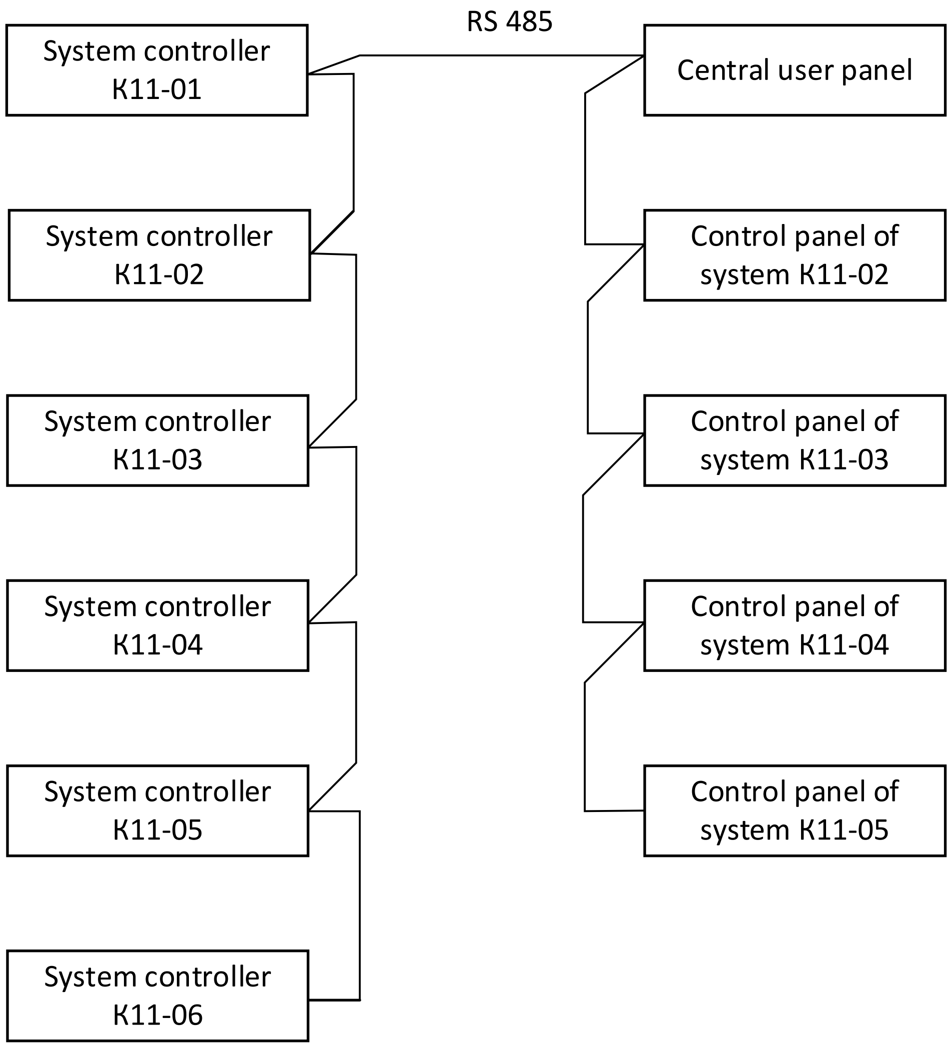

Figure 4. Interaction model of a centralised remote control system.

3.4. Block diagram of the subsystem operation algorithm

The generalised algorithm of the subsystem operation is shown in figure 5. This algorithm shows the system's generalised operation that provides the operating room's microclimate. As can be seen from figure 5, operations related to the removal of the emergency (blocks 17, 18), switching on (block 5) and switching off the system (block 23) are performed by a person, except in cases provided for by the emergency shutdown of the system.

The system starts to operate when it is switched on by a person (operator) through the operator panel or on the control panel using the power button. The system is at rest until it receives a signal to switch on the system (block 5). Next, the fans are switched on (block 7), and the fan switch-on is checked (block 8) using data from the PDI pressure difference sensor. The next step is to read the data from the airflow sensor (block 9). Next, the data received from the supply air flow sensor DPS is checked against the system setpoints (block 10).

Depending on the results obtained, the system proceeds to read the temperature sensors (block 11) if the air flow rate is equal to the setpoint. Otherwise, it checks whether the air flow rate exceeds the setpoint (block 1). If the airflow rate is higher than the set value, the frequency converter reduces the frequency of the supply fan (block 2). If the airflow rate does not meet

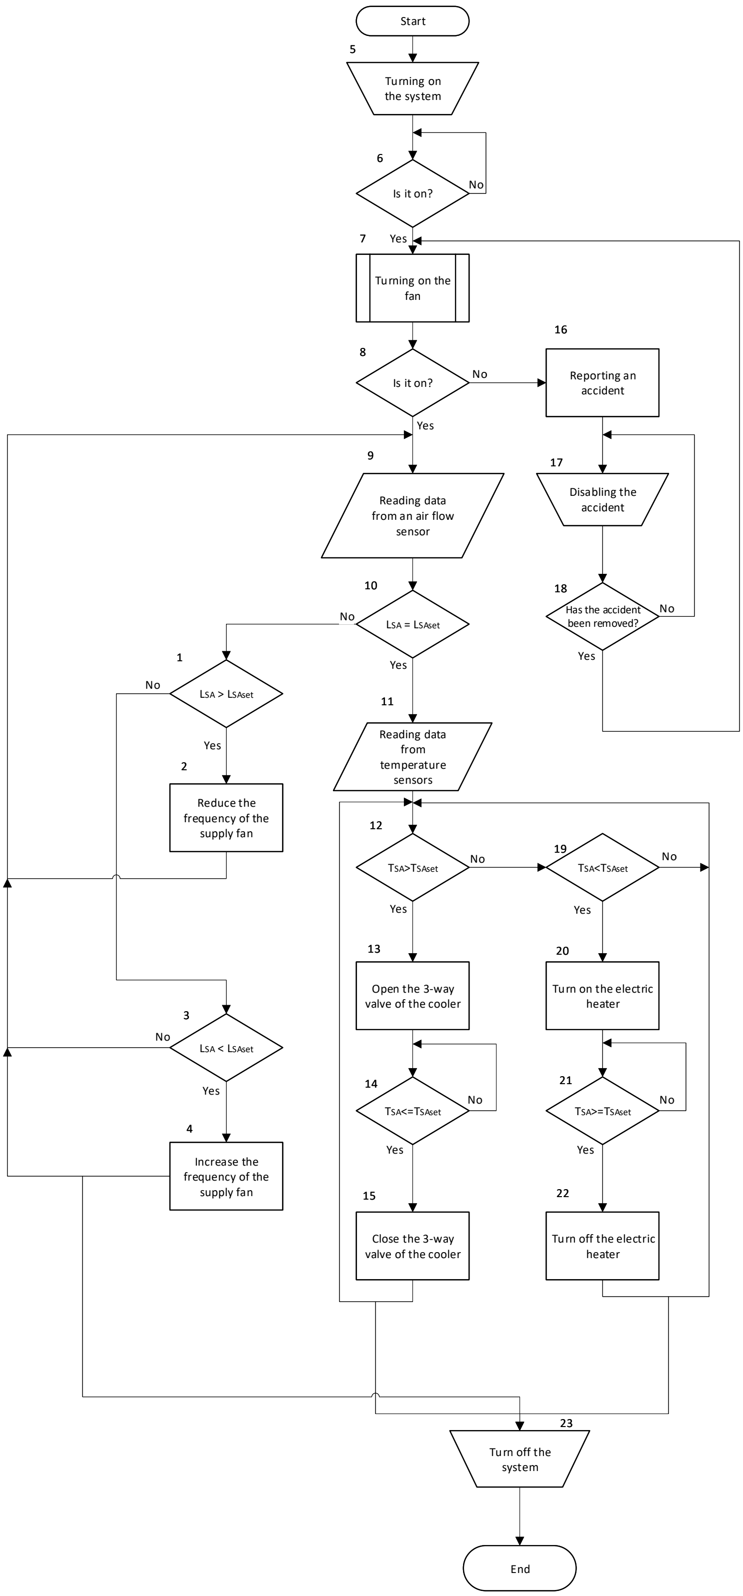

Figure 5. Generalised algorithm of subsystem 4 (K1) functioning.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012124 doi:10.1088/1755-1315/1415/1/012124

the condition, check whether the air flow rate is not less than the set value (block 3). The fan speed increases if the flow rate is lower (block 4). Then, the flow rate is rechecked to ensure it equals the set value (block 9). Moving on to reading the data from the temperature sensors (block 11), we check Tpp>Tppz (block 12).

If the temperature is higher, the three-way coolant supply valve to the air cooler is opened, and then the condition Tpp≤Tppback is checked (block 14); if Tpp meets the condition, the three-way cooler drip trap is closed (block 15), and then we return to checking the condition Tpp>Tppback (block 12).

If the Tpp>Tppz (block 12) is not valid, the condition Tpp<Tppz (block 19) is checked for compliance. If the condition is met, the electric heater is switched on (block 20). Next, the condition Tpp≥Tppz (block 21) is checked. If the condition is proper, the electric heater is switched off (block 22), and we return to checking the condition Tpp>Tppz (block 12). If not, we wait until the condition is fulfilled.

Optionally, at any stage, the system can be switched off (block 23).

4. Conclusions

As a result of the analysis of the requirements for microclimate hygiene and air environment of the operating rooms of medical institutions, the cleanliness classes of the premises for implementation with permissible air components and microclimate parameters for the operating rooms of a medical institution were determined. The analysis of methods for regulating the microclimate of a high cleanliness class made it possible to determine an acceptable way to implement design solutions, namely using airflow displacement due to laminar and turbulent air flows.

The analysis of the features of the construction of ventilation and air conditioning systems of a high class of purity made it possible to highlight the features of ventilation and air conditioning systems, which made it possible to determine the need to use multi-stage filtration, installation of air conditioners with air recirculation and a central air conditioner for fresh air preparation; creation of overpressure about neighbouring rooms; use of CAV and VAV systems to regulate airflow parameters and provide overpressure. It is established that the design and materials of air ducts, filter chambers and their elements should be adapted for regular cleaning and disinfection. The analysis of air treatment systems for high-cleanliness premises has made it possible to establish that it is advisable to use ventilation and air conditioning systems with air recirculation for operating rooms.

As a result of the research, approaches to the design of systems for the formation of an internal microclimate of a high class of cleanliness of operating rooms of medical institutions, which are typical and can be used as a reference, have been proposed. Several recommendations have been developed to improve methods and approaches to constructing such systems.

A typical flowchart for forming an internal microclimate of a high class of cleanliness of operating rooms in medical institutions has been developed. The peculiarity of these solutions is the introduction of a central air conditioner to ensure the system's functioning. To ensure the multiplicity of air exchange and a given microclimate in each operating room, it is proposed to use a separate air handling unit with recirculation and fresh air mixing to ensure sanitary standards. Separate exhaust systems are recommended to remove air from the bathrooms and showers of the male and female sanitary checkpoints. Excess air should be pushed out into rooms not part of the clean area.

As a result of the study of one of the operating units of the medical centre, which is located on the second floor and the ventilation system scheme for this room, it was decided that in order to ensure the proper quality and quantity of air, it is necessary to develop an automation system for four air conditioning systems that provide a microclimate directly in the operating rooms, and two supply and exhaust systems that prepare air for these systems and provide ventilation for other rooms of the clean area. The analysis of automation approaches, the subject area of the study, and the requirements for cleanroom ventilation allowed us to form a block diagram of an automated air conditioning control system, which includes an input module responsible for reading data from measuring equipment necessary for decision-making; an information processing and decision-making module; and an output unit designed to control actuators. As a result of the conducted research and based on the developed structural diagram of functional modules, the functional diagram of the system was developed, and the system element base was selected. A generalising algorithm for the functioning of subsystems has been developed.

The results of this study can be used as methodological materials in the design and construction of systems for the formation of an internal microclimate of a high class of cleanliness of operating rooms of medical institutions. It contains generalised recommendations for the design of such systems, the main algorithmic and functional actions.

Abstract. Currently, there is significant focus on the transition to green energy, particularly in achieving climate neutrality. The European Green Deal outlines one of the main approaches in this field, which is being implemented in the EU. As Ukraine aims to become an EU member, it would be beneficial to consider adopting renewable energy solutions, especially in heating and cooling systems, in order to align with the EU's efforts towards sustainability. The statistical analysis of the field shows that Ukraine's share of renewable energy is two and a half times less than that of the EU, but it still exceeds that of three EU member states. It is worth noting that the majority of renewable energy for heating in Ukraine is generated by biomass, which is considered less economical and ecological compared to heat pumps. At present, there is a notable interest in increasing the proportion of renewable energy used for heating and cooling, with heat pumps being the primary focus. Various methods are being investigated to facilitate the adoption of heat pumps, including government assistance to reduce system costs and step-to-step realisation in cases of limited financial resources.

1. Introduction

At present, there is considerable attention being given to the topic of a green transition, especially with regards to the move towards renewable energy sources as a substitute for conventional fossil fuels. However, there is a number of different understandings on how to value and define the topic of green energy transition [1].

One of the approaches being considered is the European Green Deal [2]. This set of policy initiatives was first presented in 2019 by the European Commission with the aim of achieving climate neutrality for the European Union (EU) by 2050 [3]. Any new member of the EU is expected to be in line with this [4], so it is crucial for Ukraine to adopt the same policy.

Defining climate neutrality is a crucial aspect of this topic. The term 'climate neutrality' generally refers to achieving net zero emissions of all greenhouse gases or solely carbon dioxide, depending on the context. This necessitates balancing emissions in and removal from the atmosphere during a specific period of time [5]. According to the International Energy Agency's (IEA) annual report for 2023 [6], further progress is required to achieve the goal of net zero emissions by 2050, as outlined in its 2050 Net Zero Emission Scenario. The report identifies a lack of state regulation and clear goals as major obstacles to achieving this target. The scenario aims to limit the temperature increase to 1.5 °C above pre-industrial levels, as outlined in the Paris Climate Agreement [7].

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012125 doi:10.1088/1755-1315/1415/1/012125

When it comes to the direction of green energy transition in energy supply, there are three main directions:

(i) electricity;
(ii) heating and cooling demands;
(iii) transport.

Traditionally, it has been observed that a significant amount of attention has been directed towards the transition to green energy in the field of electricity production. For instance, the article [8] that analyzed the demand for personnel in renewable energy development was primarily focused on renewable electricity production. However, it is noteworthy that heating and cooling account for almost 50% of the EU's total gross final energy consumption [9]. Therefore, it may be beneficial to conduct additional analysis to determine the current trend in the EU and Ukraine for renewable share in heating and cooling as well as to explore potential strategies for increasing the proportion of renewable energy sources in Ukraine.

2. Comparison of the share of renewable energy in heating and cooling in EU and Ukraine

To examine the share of renewable energy in Ukraine and the EU, it is crucial to carefully review statistical data. However, it can be difficult to obtain such data due to the current Russian war against Ukraine. That war began with the Russian aggression and occupation of Ukrainian territories since 2014 and escalated with Russia's full-scale invasion against Ukraine in 2022, has made it challenging to access up-to-date information on the energy sector as it is not shown due to the martial status. Therefore, the analysis is based on the latest data provided in the source [10], which pertains to the conditions of 2020.

Figure 1 shows the share of renewable energy used in heating and cooling systems in Ukraine, the EU, and its members. Based on this data, it can be observed that:

(i) Ukraine's share (9.28%) was almost two and half times lower than the EU's share (22.98%).
(ii) Ukraine had a higher share than three EU member countries: Belgium (8.45%), the Netherlands (8.05%), and Ireland (6.26%);
(iii) the three largest economies in the EU have a share of either less than (Germany at 14.48% and Italy at 19.95%) or only slightly higher (France at 23.27%) than the EU.

3. Analysis of the share of renewable energy in heating and cooling in Ukraine

The following analysis presents the types of renewable energy sources used for heating and cooling in Ukraine from 2014 to 2020. The data is displayed in table 1. Based on this data, it can be observed that:

(i) the majority of renewable energy used for heating and cooling is generated by biomass, with other energy sources accounting for no more than 2.5% as shown in figure 2;
(ii) biomass energy is primarily derived from solid biomass, while biogas makes up less than 1%;
(iii) biomass is mainly consumed by private households. However, there has been a decrease in the share of private households from almost three-quarters to two-thirds of that consumption during the selected period from 2014 to 2022, as shown in figure 3;
(iv) heat pumps are the only other type of renewable energy with a share of more than 1% of the total share of renewable energy. The share of air heat pumps among all types of heat pumps is always much higher than 50%, as shown in figure 4. It should be noted that the potential for heat pump implementation is considered a way above the current level of its current implementation, especially in the district heating system [12];

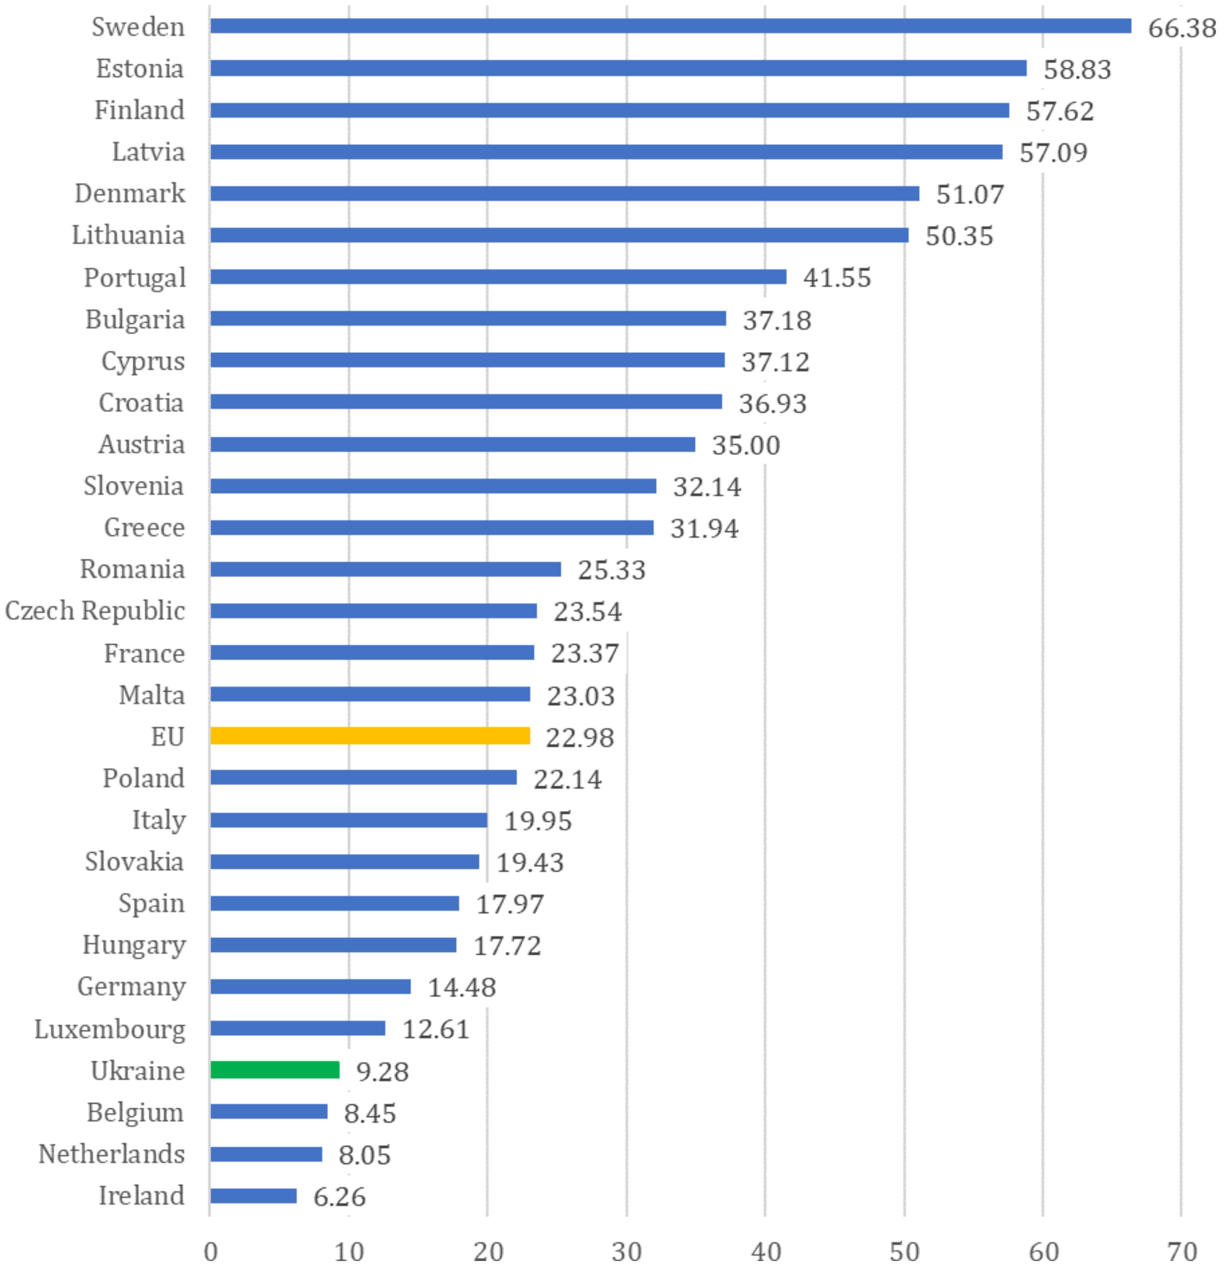

Figure 1. The share of renewable energy used for heating and cooling in Ukraine and the EU and its members, %.
Note that the data for Ukraine is taken from [10], while the data for the EU is taken from [11].

(v) the share of other renewable energy sources is either negligible, as in the case of solar energy, or not reported at all, as in the case of geothermal energy (except for heat pumps).

(vi) data suggests that district heating and cooling systems are not currently utilizing renewable energy.

Table 1. Amount of energy produced from different types of energy sources for heating and cooling in Ukraine, ktoe, based on data from [10]

Type of renewable energy	Amount of energy generated, ktoe

biomass for private households	1069.2	1096.1	1505.7	1677.4	1812.2	1857.1	1891.6

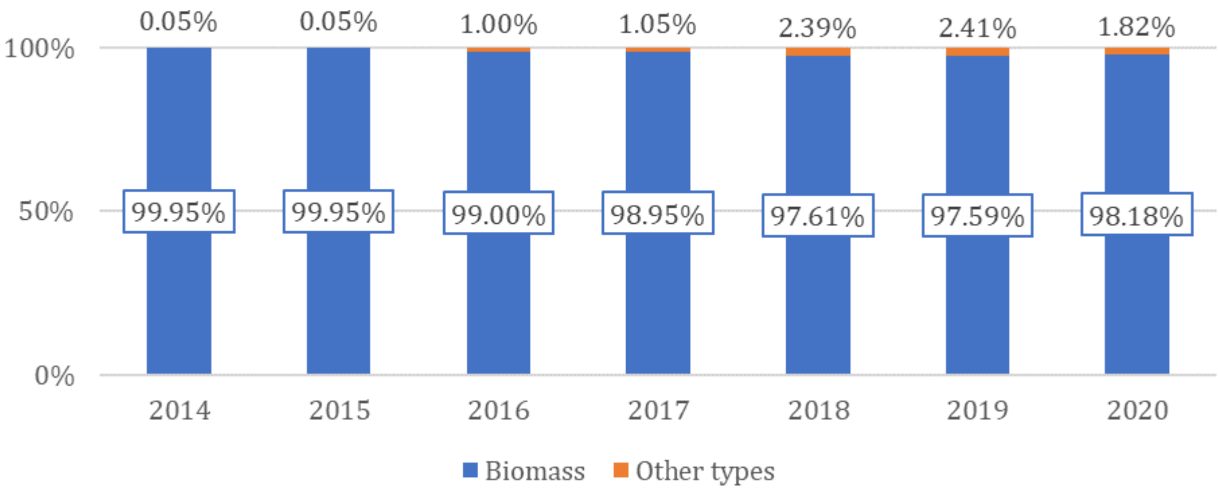

Figure 2. The share of biomass in heating and cooling for Ukraine in relation to the total share of renewable energy in heating and cooling, %, based on data from [10].

4. The future of biomass and heat pumps in Ukraine

In relation to biomass, it is worth noting that there are differing opinions on which types of biomass should be classified as a renewable energy resource [13] or a green energy source due to their environmental impact [14]. For example, a comparison between a biomass boiler and a heat pump revealed that the biomass boiler system emitted air pollutants, including greenhouse gases, at a significantly higher rate than the heat pump [15].

When considering the economic aspects of biomass boilers and heat pumps, it is important to

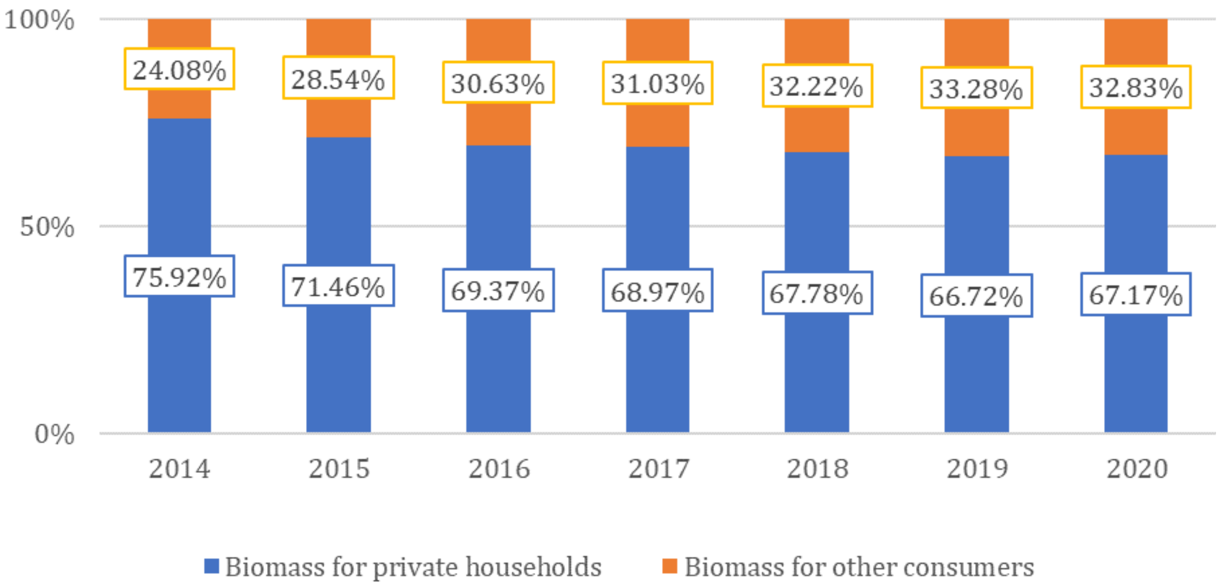

Figure 3. The share of biomass in the heating and cooling of private households in Ukraine in relation to the total share of biomass in the heating and cooling, %, based on data from [10].

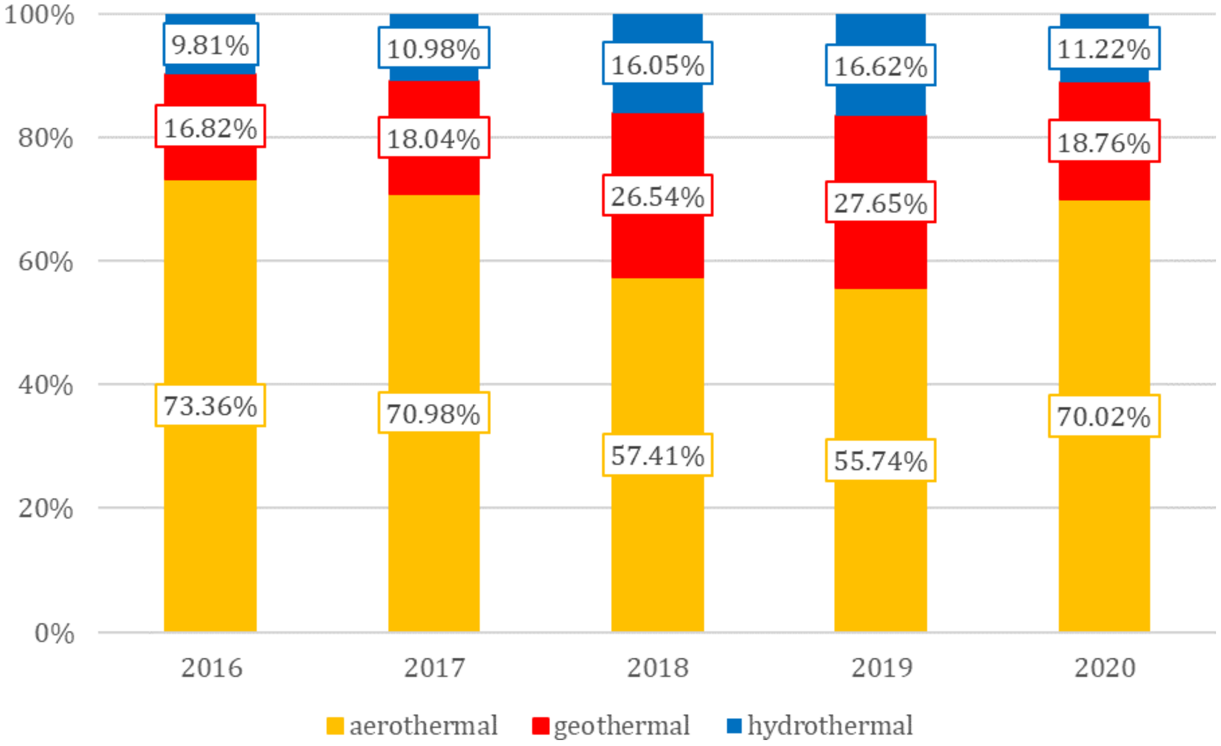

Figure 4. The share of different types of heat pumps, %, [10].

take into account the method of comparison. When comparing the energy efficiency of different heating systems, the concept of levelized cost of energy (LCOE) is commonly used. In this particular case, it is also referred to as levelized cost of heat (LCOH) since the cost of heat is being analyzed. The LCOH value is determined using the following formula [16, 17]:

$$LCOH = \frac{\sum_{t=1}^{n} \frac{(C_t + M_t + F_t + T_t)}{(1+r)^t}}{\sum_{t=1}^{n} \frac{Q_t}{(1+r)^t}}, \ \$/\mathrm{MWh_t}\ , \tag{1}$$

where C_t is the capital expenditure of the system in the year t, \$; M_t is the operation and maintenance expenses in the year t, \$; F_t is the fuel cost in the year t, \$; T_t is the carbon tax cost in the year t, \$; $(1 + r)^t$ is the discount factor in the year t with the discount rate r (%) for that year t; Q_t is the heat generated in the year t, $\mathrm{MWh_t}$; n is a heating system lifetime, year. It is worth noting that the price of conventional fossil fuel F_t, \$, in the European region has increased significantly due to the full-scale Russian invasion against Ukraine. As a result, measures have been introduced to conserve these resources, making renewable energy sources a more cost-effective option [18].

When calculating LCOH, it is important to take into account the specific context of the system, including its temporal, spatial, and scale-related aspects. As noted in [19], the LCOH of the natural gas boiler was comparatively lower (30%) than that of ground-source heat pumps for individual heating, based on data from the United Kingdom in 2018. In 2021, just three years later, data from IEA revealed that the levelized cost of energy (LCOE) for ground-source heat pumps in the UK had become equivalent to that of gas boilers [20]. Furthermore, based on the data [20], it appears that the LCOH of pellet boilers is notably higher than that of heat pumps.

As previously mentioned, it is important to take into account the scale of the system. This involves considering not only the potential decrease in LCOH with increased capacity, but also the possibility of utilizing other cost-reducing technologies. For example, exploring the potential of seasonal thermal energy storage systems [21] and optimizing the use of wind or solar energy to power heat pumps [22]. Therefore, district heating with heat pumps may be a more financially competitive option, especially in densely populated areas.

In summary, it can be observed that there are both economic and financial reasons for the increase in the use of heat pumps for heating and cooling. As of 2021, heat pumps have covered approximately 10% of global space heating needs, and this figure is on the rise due to various state programs aimed at promoting their use [23].

In Ukraine, the level of heat pump usage is relatively low due to limited financial resources. To address this issue, a step-to-step realisation to implementing district heating pump projects was proposed in [24]. This realisation considers not only the implementation of the heat pumps themselves, but also the thermal insulation and the retrofitting of a heating system inside the buildings. The choice of which part of the system to modernise first is based on the sequential selection of parts of the system based on the shortest of their payback periods in the case of modernisation. A similar approach was proposed in [25].

5. The prediction of future heat pump share in renewable heating in Ukraine

It is of great importance to assess the future share of heat pumps in overall heating and cooling consumption in order to facilitate the transition to renewable energy. This evaluation helps to track progress and determine the pace and timing of reaching milestones in this area. The aforementioned pace can be influenced by a number of factors, including legislation and the availability of funding [26].

There has been a degree of criticism regarding the predicted share of heat pumps in Ukraine being significantly higher than what may actually occur. This criticism was highlighted in the market study [27] which provided a rather conservative evaluation of the possible future share of heat pumps (and the number of heat pumps) in household building in Ukraine. For the year 2040, there were two scenarios: the higher share level was that 8% of households could be provided by heat pumps, while the lower one was approximately 4%. The primary rationale for this assumption was the annual average growth rate of the EU's heat pump market, which was estimated to be approximately 10% between 2009 and 2018.

It is worth noting that the growth rate of the heat pump market was significantly affected by the full-scale Russian invasion against Ukraine. According to a report by the European Heat Pump Association [28], annual sales of heat pumps in 15 European countries increased by 37.6% in 2022 compared to 2021, but then decreased by 5% in 2023 compared to 2022. This decrease can be attributed to several factors, such as the stabilisation of energy prices in Europe, consumers delaying purchases in 2023 to take advantage of expected higher subsidies in 2024, or the removal of government subsidies in some countries.

An alternative approach to forecasting this share was presented in [26], which also drew on information from [29]. In contrast to the previous source [27], this information focused on providing data on the amount of heat generated by heat pumps. As indicated in [29], by 2040 in Ukraine, the annual amount of heat Q_{el+b}^{2040} generated by electrical heat pumps and electrical boilers is expected to reach 192.2 million Gcal, while the general annual heat generation $Q_{heating}$ is expected to reach 359 million Gcal. Furthermore, in [26] it is stated that the proportion of heat pumps in heating η_{el}, in combined heat generation by heat pumps and electrical boilers, is expected to be 0.92. Consequently, the ratio of heat provided by heat pumps in 2040 is anticipated to be:

$$\eta_{el} \times \frac{Q_{el+b}^{2040}}{Q_{heating}^{2040}} \times 100\% = 0.92 \times \frac{192.2}{359} \times 100\% = 49\%. \tag{2}$$

This value is considerably higher than that predicted in the previous forecast: 49% vs. 8%. Despite the differing areas addressed (all consumers and residential only) and characteristics employed (amount of energy produced and total number of heat pumps installed), this fluctuation highlights the pressing necessity for a more comprehensive evaluation of the optimal methodology for forecasting the growth of the heat pump market in Ukraine.

Some of the ideas presented in [30] can be utilised as a basis for future research in this field. In particular, while the analysis of future heat pump share was done in [26] using the average value of the coefficient of performance of heat pumps, it was proposed in [30] to create several scenarios with different proportion of air-source and ground-source heat pumps. It should be noted that the classification of heat pumps in [30] is different from the classification of heat pumps shown here.

Conclusion

In conclusion, the results of this analysis show that:

(i) the data from 2020 indicates that Ukraine's share of renewable energy in heating and cooling is 9.28%, in comparison to the EU's share of 22.98%. Ukraine's share is higher than that of three EU countries (Belgium, the Netherlands, and Ireland) but lower than that of the largest EU economies (Germany, Italy, and France), whose shares are either less or only slightly higher than the EU's share.

(ii) the data from 2020 indicates that biomass is currently used almost exclusively (over 97.5%) as a renewable energy source for heating in Ukraine. Over 99% of this consumption is solid biomass. Private households account for the majority of this consumption, but that share declined from almost three-quarters to two-thirds during the period from 2014 to 2022.

(iii) although the proportion of heat pumps in renewable heating and cooling is currently relatively small, it is anticipated that this will increase. However, in order for the models used to forecast the growth of the share of heat pumps in renewable heating and cooling systems to be accurate, they must align with the actual market conditions. Currently, the methods used to calculate the growth forecast of the heat pump share are quite disparate, and the expected share of heat pumps in providing renewable heating and cooling can differ by several times. This necessitates the undertaking of further work to enhance the proposed methodologies, which would be founded upon the actual market and forecast not only the share of heat pumps in general, but also individual types.

Abstract. The construction of new buildings and the demolition of obsolete and war-damaged buildings generate hundreds of thousands of tonnes of drywall waste. Gypsum waste, harmless in an isolated state, when thrown into a landfill causes environmental problems by polluting groundwater, emitting hydrogen sulphide and greenhouse gases. The solution of such an urgent problem, coinciding with the purpose of this work, is possible through the development of effective technological schemes and equipment for processing waste into secondary raw materials. The research on the selection of the lining plate of the jaws of the vibratory jaw crusher has been carried out on the impact bench. The dependence of effective destruction of gypsum layer of drywall on the profile of lining plates is shown. Drywall was crushed in a laboratory crusher. The innovative technological process allowed to separate the initial composite material into three constituent parts converted into secondary raw materials. The obtained results substantiate the feasibility of processing drywall waste in a vibratory jaw crusher at the place of its formation and obtaining at the same time marketable products, reducing transport costs, improving the environment and preserving mineral resources.

1. Introduction

Gypsum, according to Protodyakonov scale, belongs to rather soft materials and is widely used in construction, agriculture, art models, pharmaceutical, chemical, food and other industries. The density of gypsum is 2.3 – 2.8 g/cm^3, hardness on the Mohs scale is 2, and the texture is massive. Gypsum mining is carried out by underground or open-pit methods. In this case gypsum quarries occupy huge areas of the earth surface suitable for agricultural and industrial production. The general view of known gypsum quarries is shown in figure 1.

USMining forecasts that global demand for gypsum will grow at a rate of 2.5% over the next few years. It is estimated that by 2030 the global demand for gypsum will reach 300 million tonnes. The largest volume of gypsum is mined in the USA, Iran, and Canada. In Ukraine, the first place in the number of reserves and production of gypsum and anhydride is occupied by the Donetsk basin, where a significant part of the explored deposits are located in the Bakhmut district. A large number of enterprises are located in the Lugansk region and Crimea [1, 2]. All these enterprises are located in the temporarily occupied territory and in the war zone, so the main production of gypsum is carried out in the Carpathian region. The decrease in production can be partially covered by processing industrial and construction waste gypsum

materials. In construction, gypsum powder is used in building finishes, gypsum blocks, as a binding component in concrete to improve its properties.

However, the predominant use of gypsum is for the production of drywall [1]. The boards are two sheets of specially made paper (cardboard) between which a dense gypsum filler is placed. The finished gypsum board includes 92...93 % of gypsum 6...7 % of cardboard and 1 % of additives. The standard length of plasterboard is taken as 2, 2.5 or 3 metres, the width of sheets is mainly 1.2 metres, thickness varies from 6.5 to 24 mm. [3]. The global drywall market is growing at a high rate. This is fuelled by the growth in residential construction, renovation and modernisation of old buildings. A huge amount of drywall will be required in the reconstruction of war-ravaged cities in Ukraine. The global drywall market is expected to grow from 15.08 billion square metres in 2023 to 20.37 billion square metres by 2028 at a compound annual growth rate of 6.19% during the forecast period (2023-2028) [4].

The increase in the production of drywall predetermines an increase in construction waste, which can be generated from several sources [5]. In the construction of new residential buildings, supermarkets, shopping and office centres, warehouses, industrial workshops, etc., waste (trimmings) is generated in the process of cutting drywall sheets to the required dimensions (figure 2, a) and discarding sheets or their individual parts that have mechanical damage. This group of waste is relatively easy to sort, clean and store. As a result of crushing, gypsum is obtained, the purity of which is sufficient for its use in the production of new drywall panels. Similar conditions occur in the production of new gypsum drywall. For example, from the drywall produced at the Powered plant in 2019, approximately 5,700 tonnes (internal and external scrap) were sent to landfill [6].

When demolishing and renovating obsolete buildings and structures, drywall waste can be sorted and stored in the process of dismantling the panels. This rational technology greatly simplifies the recycling process, but it is not always used and the construction waste is taken to the landfill [7].

The most labour-intensive is the preparation of drywall waste obtained from completely destroyed buildings and structures as a result of natural disasters or military operations. In this case, the required material categories are separated from the total mass of construction waste by manual disassembly. The drywall thus obtained (figure 2, b) can have a high degree of contamination in the form of nails, screws, wires, insulation, glue, wall coverings, etc., and can be analysed for harmful impurities. Waste drywall is disposed of in two main ways: landfill and recycling. Landfill is the most common and easiest method in most countries, but there are significant problems with it. Although gypsum is a small proportion of the total waste, its disposal usually results in hydrogen sulphide emissions and higher greenhouse gas emissions [8].

Due to the huge amount of drywall waste, much research is being conducted on the rational use of gypsum isolated from it. At the Czech Technical University in Prague, the effectiveness of using drywall waste in mixtures for the production of gypsum blocks was studied [6]. Gypsum isolated from drywall, containing more than 95% $CaSO_4$, was calcined at a temperature of 1200 °C. Taking into account water coefficient, amount of foam, polypropylene microfibres and density of gypsum mixture, its thermal and strength properties were investigated. The obtained results confirmed the prospectivity of the considered direction of utilisation of drywall waste. The possibility of using such waste in the production of new gypsum drywall sheets is considered in [9, 10].

The use of powdered recycled gypsum in concrete mixes reduces carbon dioxide emissions by reducing the amount of cement. A study [11] used recycled gypsum powder to introduce more sustainable and environmentally friendly concrete production while maintaining adequate strength and durability. Studies have shown positive results for the use of gypsum powder in the agricultural industry [12].

The current drywall recycling technologies do not have any noticeable differences. They are

(*a*)

(*b*)

Figure 2. Sorted drywall: a – during construction of new buildings; b – during demolition of demolished buildings.

based on the method in which the initial drywall is sorted and loaded into a receiving hopper from where it is fed to the shredding plants. The method provides for the conversion of the entire mass of drywall into a fine-grained product by means of successive coarse, medium, fine crushing and further separation in a drum separator into gypsum component and paper.

In particular, the Turkish company Parget Makina [13] at the first stage of drywall processing uses a shredder of drywall sheets in the working chamber of which there are two shafts with disk toothed knives. The resulting mass of fragments is fed into a separator for processing drywall waste with a capacity of up to 20 t/h. The separator is made in the form of a cylindrical chamber with an inner shaft on which radially fixed destructive elements in the form of rods, blades, plates and others. The lower part of the chamber has a perforated surface for the output of the product of a given fraction.

In a number of design schemes of drywall waste recycling plants, roll crushers are used. At the first stage of coarse crushing [14], the rolls of the double-roll crusher are made with spikes that break the panel into pieces. In the next stage, the pieces are conveyed by a conveyor belt to the double roll crusher for fine crushing. A magnetic catcher can be installed along the transportation path. The crushed mass enters the drum separator, where the gypsum component is further crushed and discharged through the perforated bottom with holes of 4...25 mm. To grind waste in one stage, multi-roll crushers are installed [15], and the efficiency of grinding can be increased by giving the paired rolls different speed of rotation. Similar designs take place in [16, 17], etc.

The processing of drywall into a mixed fine-grained product is a common disadvantage of the currently used crushing and grinding equipment. The multistage processing process increases the metal intensity of the processing line, its overall dimensions, requires a significant number of handling devices. It becomes problematic qualitative separation of components, especially in the processing of contaminated boards.

A promising direction for the development of drywall processing technology is proposed to use small crushers, as well as mobile units directly on the construction site [18, 19].

The current technology is used in processing plants [20], but the urgency of the problem requires research and development of new technological schemes and small-sized efficient equipment.

Research aim is to determine the efficiency of innovative technological process of recycling of construction waste drywall into secondary raw materials with the use of small-sized vibratory jaw crusher.

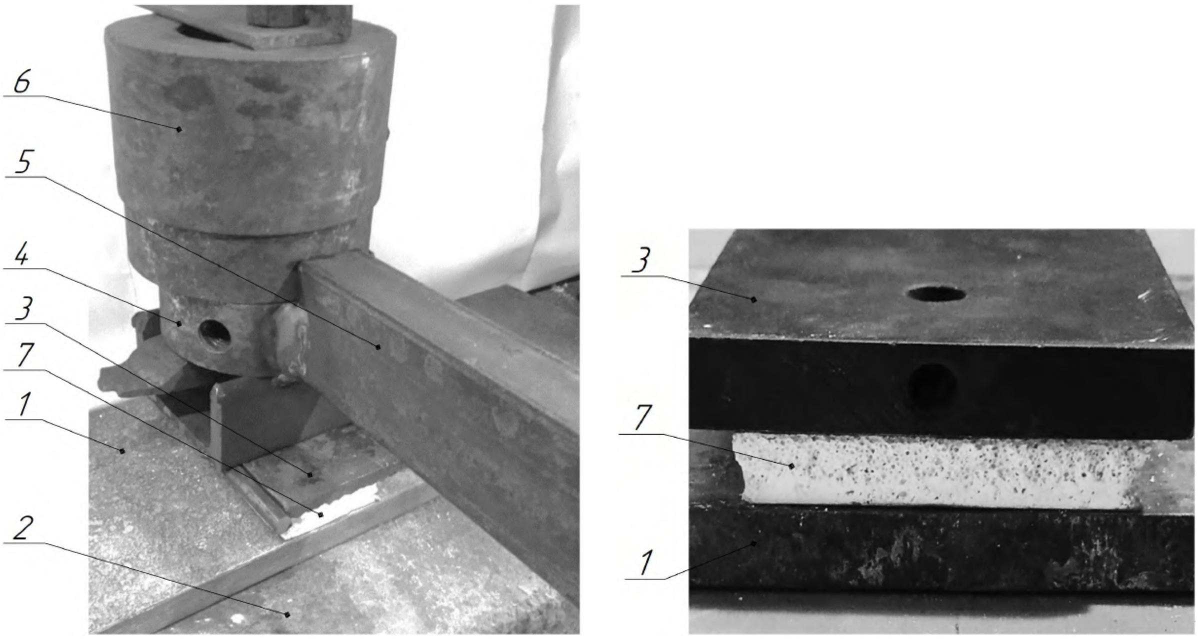
2. Results

When disintegrating composite materials, one of the significant factors affecting the quality of separation of the component parts is the working surface of the executive body, interacting with the object being processed. Research on the selection of the lining surface of the jaws of a vibratory jaw crusher was carried out on a laboratory impact bench, the design and operating principle of which are described in [21].

The transformed impact unit (figure 3, a) includes the lower 1 lining plate, rigidly fixed on a massive base 2 and the upper 3 lining plate, fixed on the mounting disk 4 of the pendulum 5. A replaceable load 6 is attached to the top of the disk. The test sample of drywall 7 (figure 3, b) is placed on the lower lining plate 1. The working plane of the upper lining plate 3, by means of rotating mechanisms (not shown in the figures), is installed parallel to the opposite surface of the drywall sample. This ensures contact of interacting elements over the entire area of the connector at the moment of impact. The impact energy for all studied samples was assumed to be 35; 55 and 75 J.

The effectiveness of the lining plate was assessed by the percentage of destroyed gypsum in the test drywall sample per blow.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012126 doi:10.1088/1755-1315/1415/1/012126



(*a*) (*b*)

Figure 3. Arrangement of elements of the impact unit in statics: a – impact unit; b – initial installation of drywall sample.

When impacted by the smooth surface of the lining plate (figure 3, b), the sample practically retains its original shape. Minor damage to the gypsum layer occurs at the ends and increases with increasing impact energy (figure 4, curve 1), however, the central part of the layer opens extremely slowly. The use of such a surface when crushing drywall is impractical.

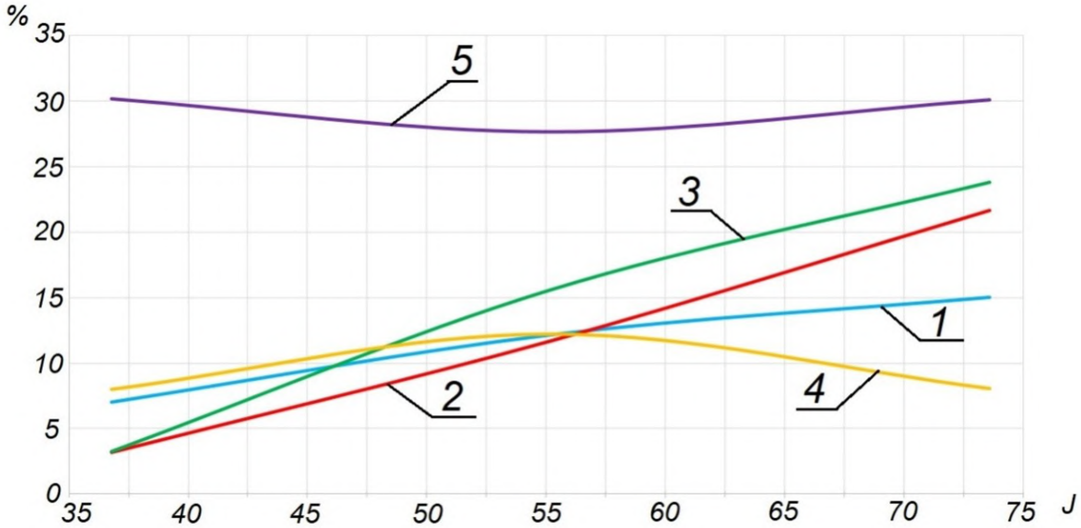


Figure 4. Dependence of the destruction of the gypsum layer on the impact energy for the shape of the working surface of the lining plates: 1 – smooth top/smooth bottom; 2 – pyramidal upper/smooth bottom; 3 – prismatic top/smooth bottom; 4 – wavy top/smooth bottom; 5 – wavy top/wavy bottom.

In order to influence the crushing process of pinpoint impacts, the working surface of the lining plate (figure 5) is made in the form of pyramidal protrusions with a height of 2 mm and a pitch of 5 mm.

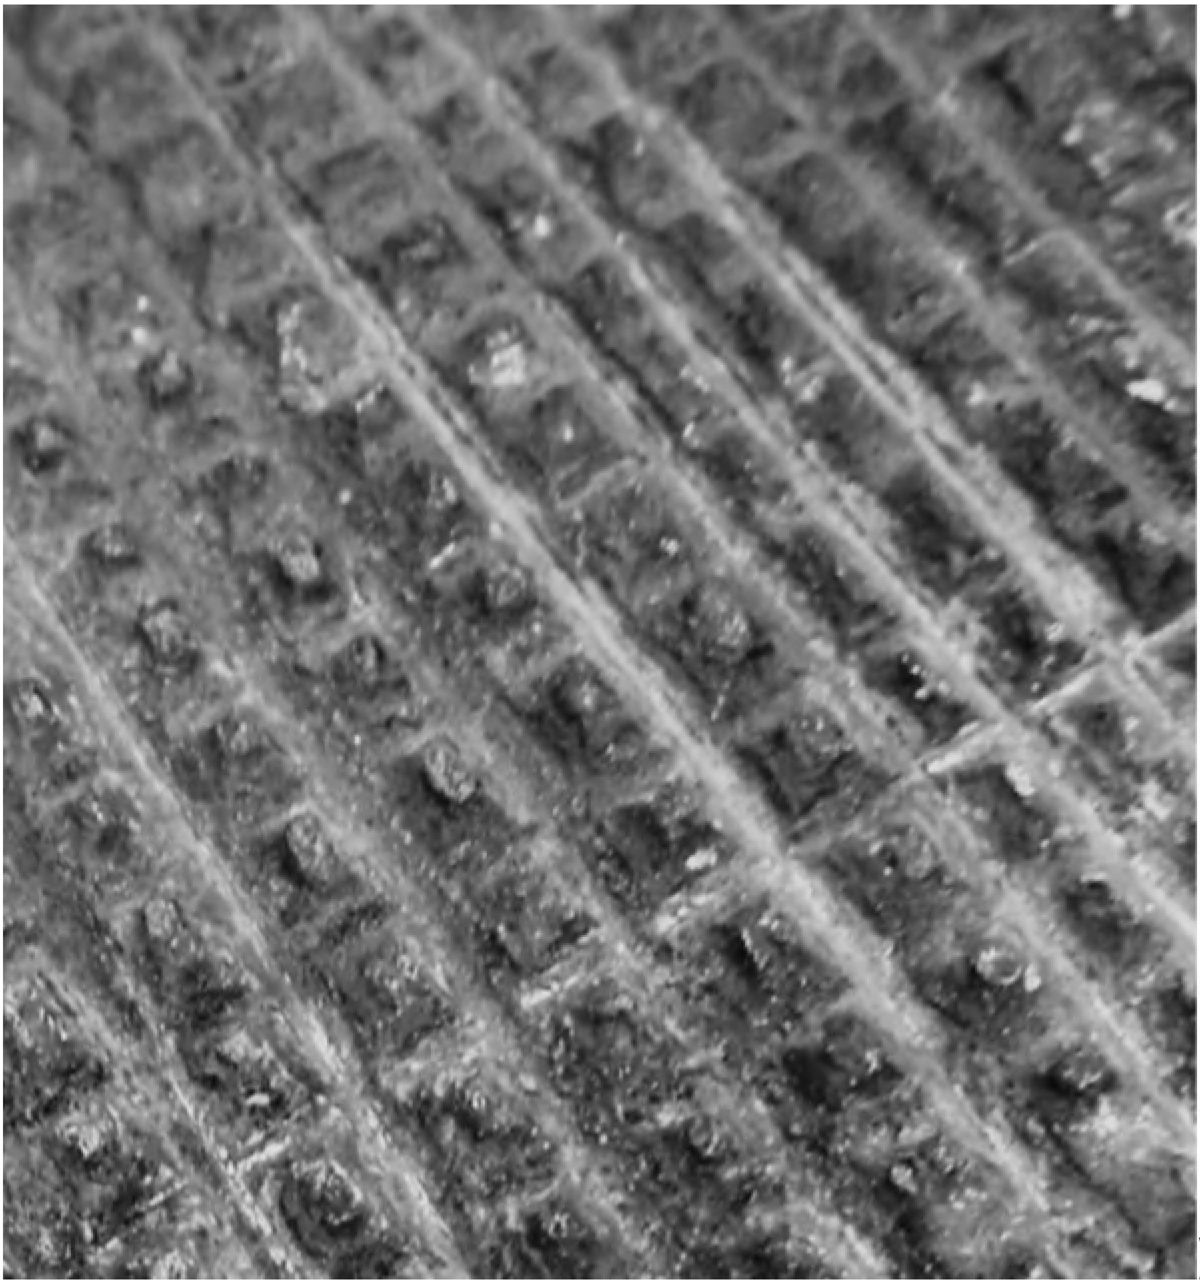

Figure 5. Pyramid surface of the lining plate.

Analysis of the obtained results shows that for all accepted values of the impact load, the qualitative picture of the destruction of the samples is preserved. With increasing impact energy, the yield of destroyed gypsum fractions increases (figure 4, curve 2). The top plate of cardboard (figure 6) is separated and the top plane of the gypsum layer is exposed, loosened by the protrusions of the lining plate, which can significantly improve the process of gypsum separation in the subsequent crushing stage.

Figure 6. Crushed drywall: 1 – gypsum; 2 – cardboard.

During the research, the force impact on drywall by a lining surface made by a set of triangular prisms was considered (figure 7).

The side ribs of the prisms can practically be located at any angle to the direction of movement of the material in the crushing chamber. At the impact stand, we limited ourselves to installing lining plates with the side ribs of the prism directed perpendicular to the longitudinal side surface of the drywall sample.

The process of interaction of the lining surface with the sample can be divided into several phases. Initially, at the moment of contact, the cardboard stretches between the penetrating side edges and simultaneous compression of the gypsum located in this gap occurs. As a result of the relative displacement, there is a lack of rigid connection between the components of the drywall and the formation of individual elements. The subsequent impact of the lining on the sample leads to rupture of the cardboard along the length of the side ribs (figure 8) and the formation of cardboard strips, the width of which corresponds to the distance between adjacent side ribs. The upper surface of the gypsum layer becomes free and displays the profile of the lining plate, has areas of compaction under the side ribs and loosening under the side edges. With a single impact, the prismatic lining in combination with the smooth surface of the lower lining showed (figure 4, curve 3) the highest yield of the destroyed fraction. However, many relatively small

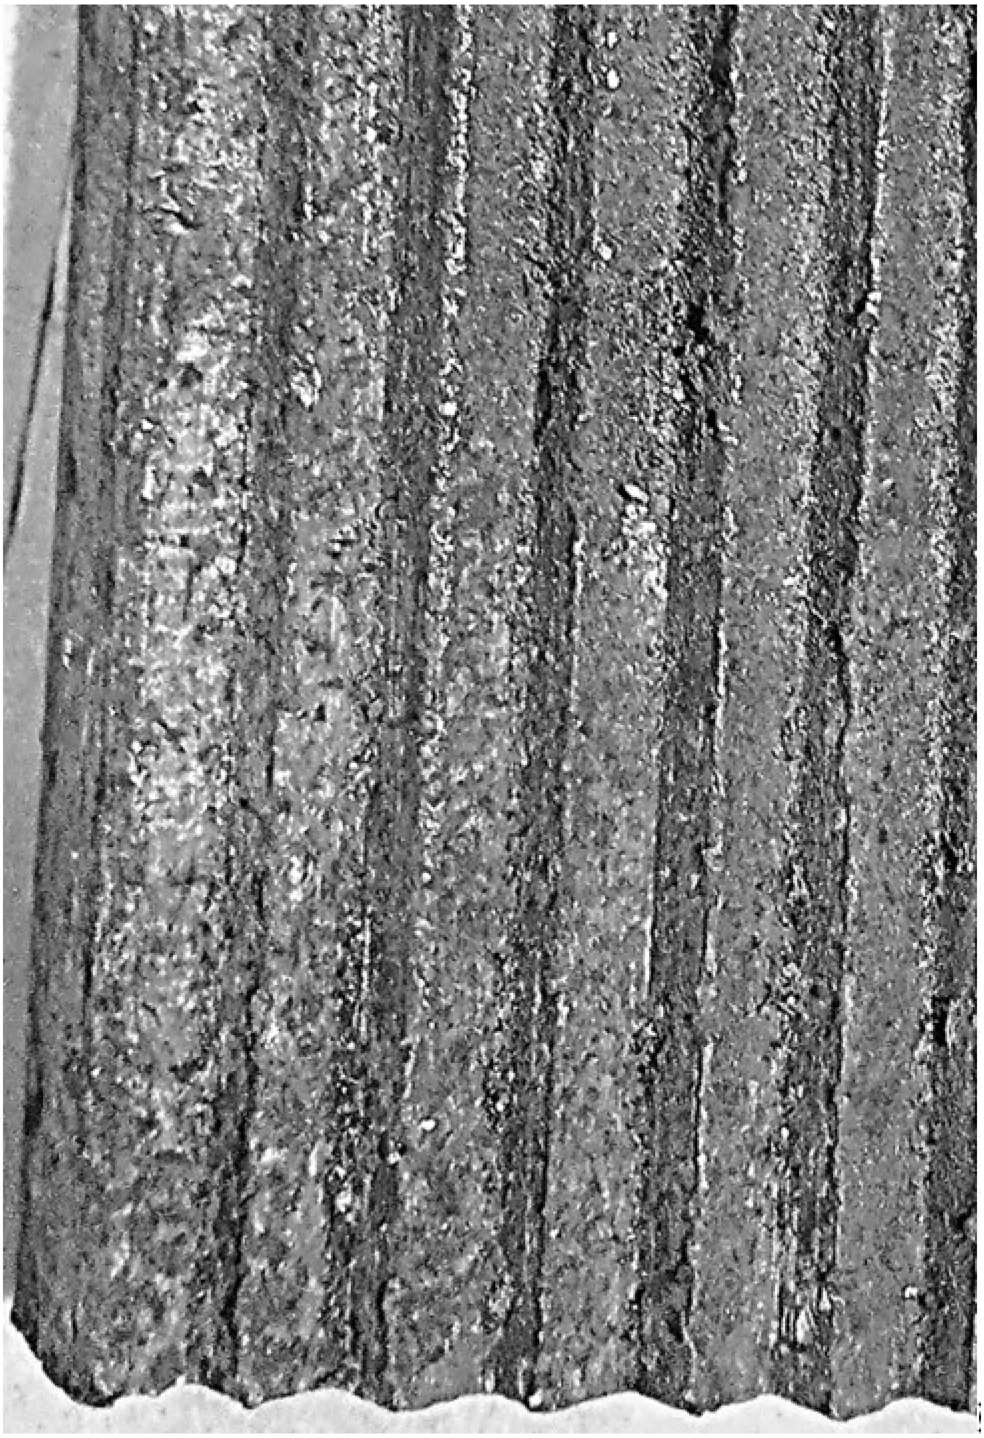

Figure 7. Prismatic surface profile of the lining plate.

cardboard strips under high-frequency impact loading will transform into a fine-grained material and create a problem in separating it from the gypsum component.

The oval surface profile of the lining plate (figure 9) was considered for several options. When installing a sample of drywall on a flat base, an ambiguous result was obtained. The curve (figure 4, curve 4), describing the amount of destroyed gypsum, has a maximum. This is

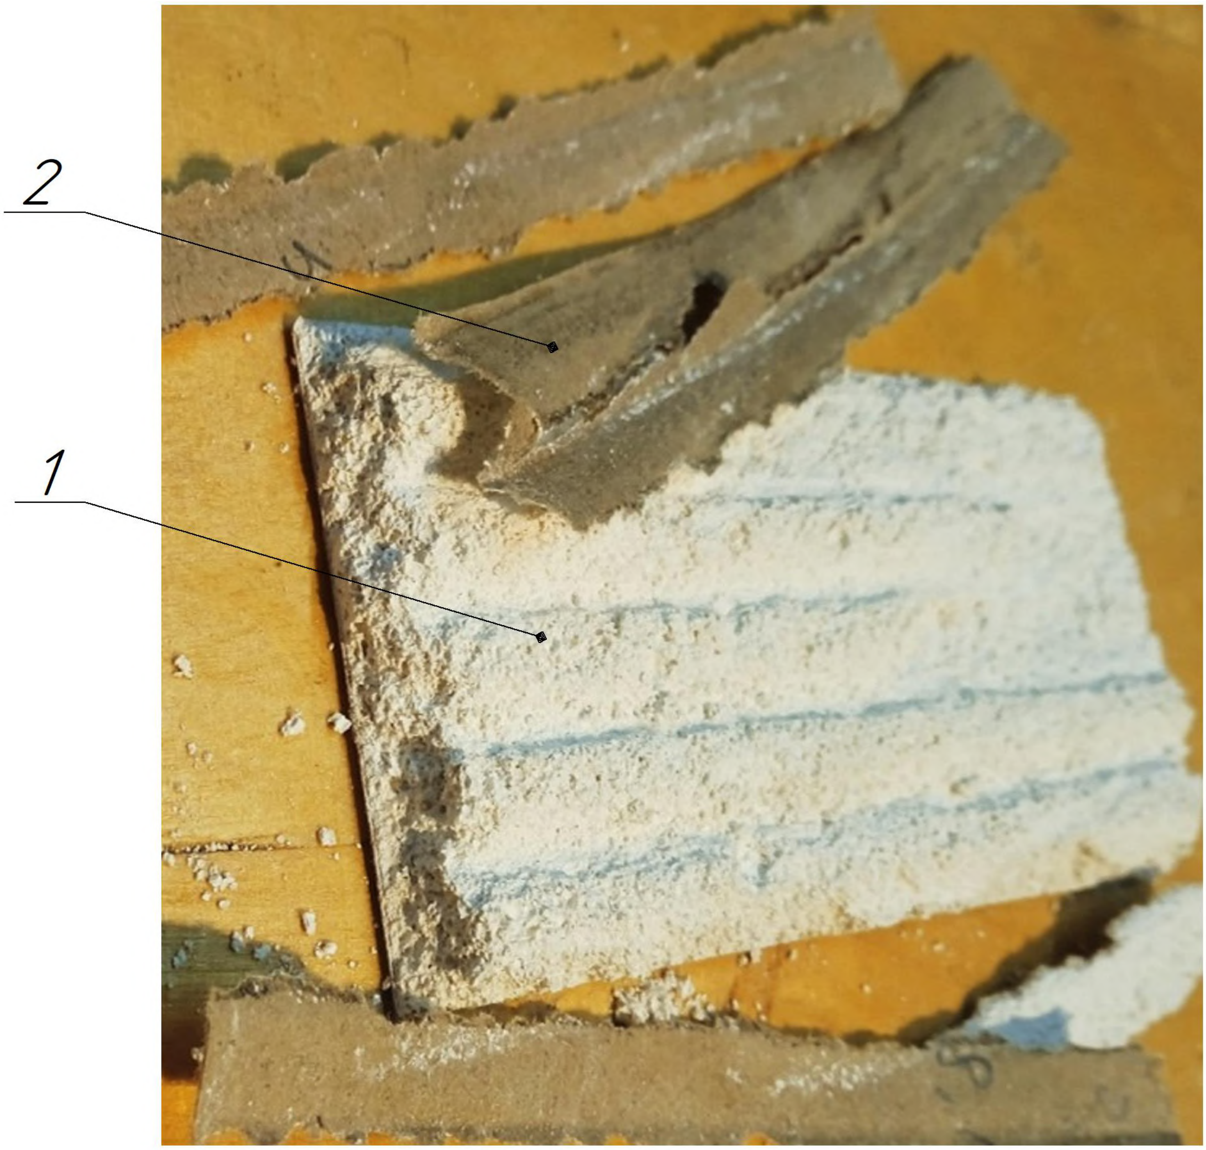

Figure 8. Crushed drywall: 1 – gypsum; 2 – cardboard.

probably due to the rather large contact area of the lining plate with the surface of the sample and the formation of compressed gypsum sections.

The working surface of the lower jaw of a vibratory jaw crusher can be equipped with a different profile. One of the combinations, the mutually perpendicular arrangement of ovals (figure 10), gave a significant increase in the amount of destroyed gypsum (figure 4, curve 5).

The results obtained on the impact stand show a significant dependence of the effective destruction of the gypsum layer of drywall on the profile of the lining plates.

Crushing of drywall was carried out on a laboratory sample of a vibratory jaw crusher with an inclined chamber [22]. This type of crusher has a pronounced impact nature of the application of load to the crushed material, and has the advantages of jaw and rotary crushers. Having a large set of adjustable parameters (frequency, amplitude of vibrations and mass of the jaws, size of the unloading gap, profile of the working surface of the jaws, grip angle, etc.), the process of destruction of the material is effectively controlled. In general, the design diagram of the

Figure 9. Oval surface profile of the lining plate.

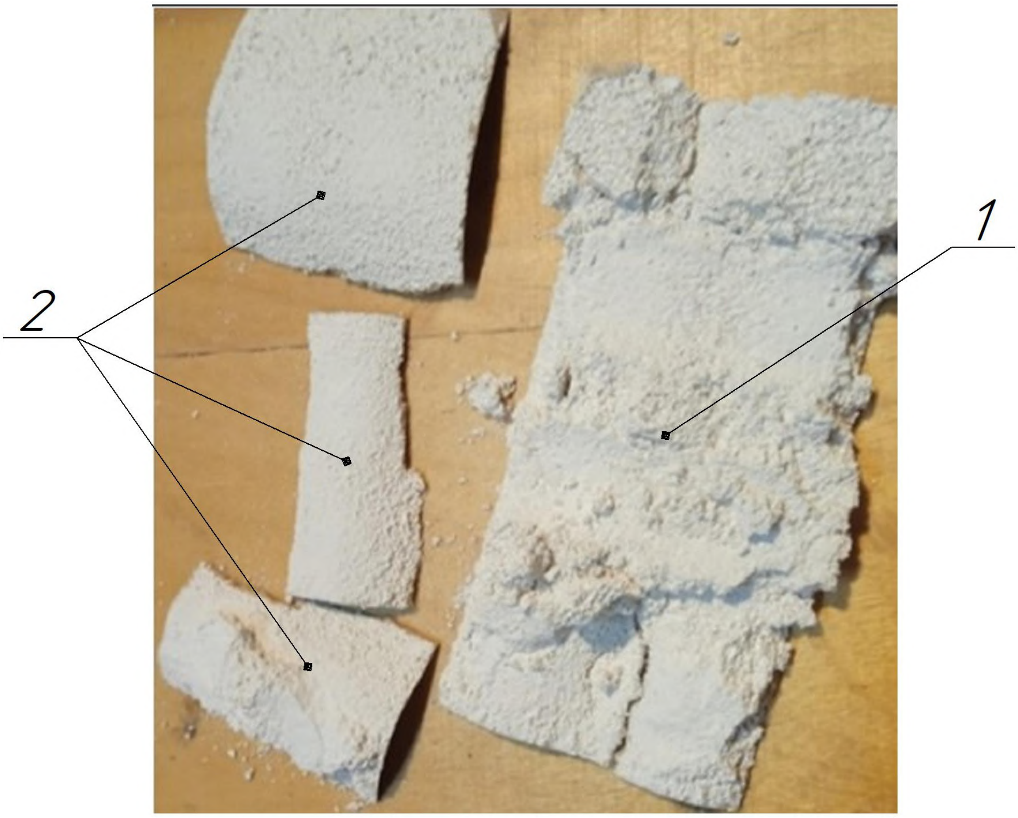

Figure 10. Crushed drywall: 1 – gypsum; 2 – cardboard.

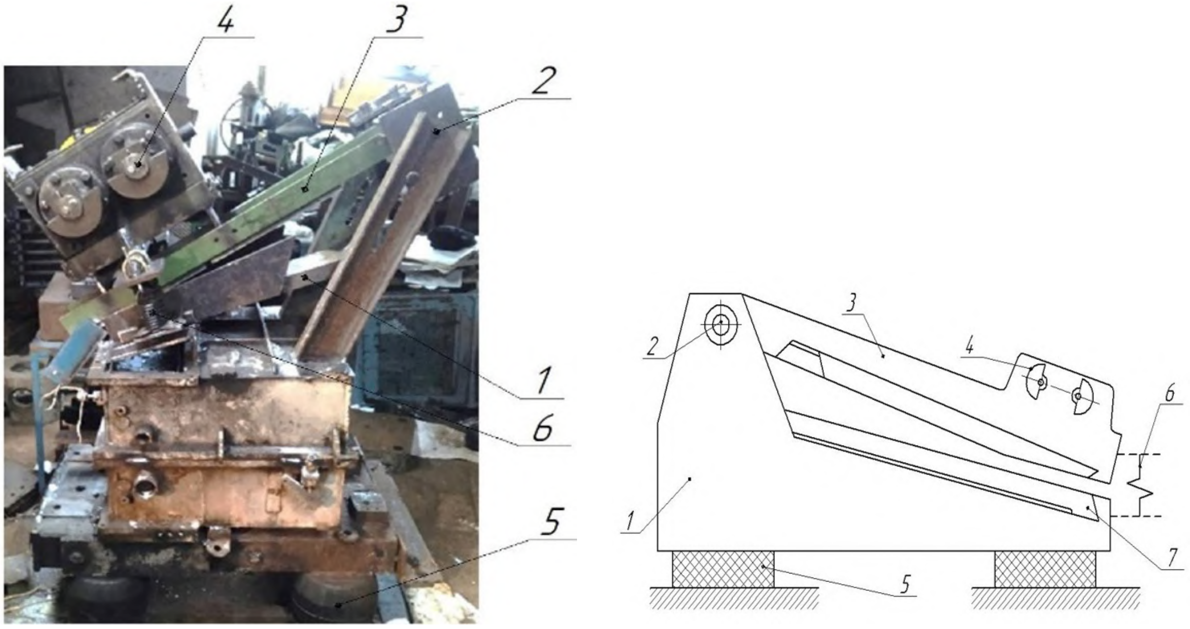
vibratory crusher represents an oscillatory system in which vibrations with a frequency of 16 – 32 Hz are transmitted to the jaws.

A vibratory jaw crusher with an inclined crushing chamber (figure 11) includes a passive (lower) crushing jaw 1 with a liner plate 7, mounted on elastic elements 5 and simultaneously serving as a housing. The active jaw 3 is installed in the racks of the passive jaw by means of the suspension axis 2, relative to which it can perform rotational oscillations. The vibrations of the jaws are generated by a two-shaft inertial vibration exciter 4. The destruction of the material occurs in the crushing chamber formed by the working surfaces of the passive 1 and active 2 jaws. The design feature of the crusher allows loading of the source material and unloading of the crushed product in a horizontal plane, which is especially important when processing sheet material. The working surface of the lower jaw is made smooth, the surface of the upper jaw is oval with the longitudinal axis of the ovals located perpendicular to the movement of the strip. The vibration frequency of the jaws was 16.7 Hz, the width of the unloading gap was set to 0 mm and 10 mm.



(a) (b)

Figure 11. Vibrating jaw crusher with an inclined crushing chamber: a – general view of the crusher, b – structural diagram.

Strips of Knauf Blue drywall, 12.5 mm thick and 130 mm wide, identical to those studied on the impact stand, were crushed. Figure 12 shows a typical view of drywall coming out of the crushing chamber. There is a slight residual gypsum deposit on the inside of unbroken cardboard plates, and the gypsum core has a fairly high degree of crushing. Thus, the original composite material is divided into three components, which represent secondary raw materials.

The resulting form of the crushed product allows for fairly simple separation on the sieving surface. The qualitative characteristics of the material after sieving are presented in figure 13, the quantitative characteristics – in figure 14.

Fraction 0 – 200 (figure 14) after calcination restores the properties of gypsum and can be used in the production of drywall, building materials, etc. Larger fractions, as finished commercial products, are used in agriculture, cement production, landscape design, etc. This indicates on the feasibility of recycling drywall waste at the site of its generation, which will make it possible

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012126 doi:10.1088/1755-1315/1415/1/012126

Figure 13. Crushed gypsum component of drywall.

to both obtain marketable products and reduce transportation costs, relieve garbage dump, improve the environment and preserve mineral resources.

The graphical dependence (figure 14) demonstrates the qualitative similarity of the granulometric curves at different widths of the unloading gap. In quantitative terms, the output of individual classes differs from each other. This indicates the possibility of changing the content

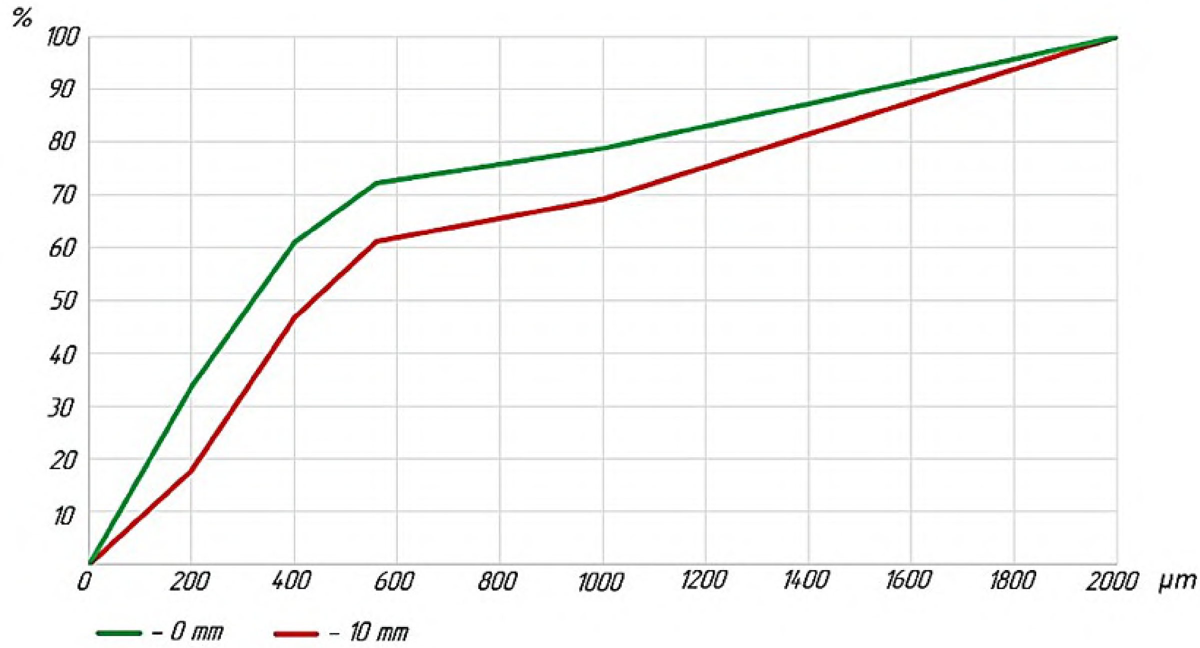

Figure 14. Characteristics of crushed gypsum size.

of the required size class in the finished product and preparing the material with the specified parameters.

The process of crushing contaminated drywall is similar to that outlined above. When using a vibratory jaw crusher with an inclined crushing chamber, most of the crushed gypsum component located inside the panel is clean material. Contaminated material is generated from the end surfaces of the panel and from the outer planes of the cardboard plates. The main part of plate contamination (paint, glue, wallpaper, varnish, etc.) remains almost unchanged in the considered crushing method. In this connection, in comparison with existing methods of drywall processing, the insignificant percentage of contamination allows direct use of the obtained gypsum component in agrarian and some other industries.

3. Conclusion

1. The analysis of literature sources indicates the rapid growth of drywall waste, environmental hazard when throwing it to the landfill and the possibility of recycling, which substantiates the relevance and necessity of research, development of innovative technologies implemented in the created efficient equipment.
2. A huge number of destroyed buildings is associated with the need to create landfills for storage of construction waste and its subsequent processing. The conducted research has shown that a significant part of waste, in particular drywall, can be successfully processed in a small-sized vibratory jaw crusher with an inclined crushing chamber. Insignificant dimensions and small occupied area predetermine the installation of the crusher directly at the place of formation of construction waste drywall in the process of its sorting. Obtaining a marketable product reduces the load on landfills, reduces transportation costs, improves the environment and conserves mineral resources.
3. In the process of researches on drywall crushing on vibratory jaw crusher with an inclined crushing chamber the modes at which separation of components for one pass of drywall through the crushing chamber is carried out are received, that allows to create lines on

processing of drywall with one stage of crushing and reduction of their metal consumption and dimensions.

4. On the impact stand the research on force impact on the flat surface of drywall was carried out by the impactor having a flank in the form of: pyramidal protrusions, a set of three-sided prisms, a set of oval protrusions and a plane. The obtained results show a significant dependence of the effective destruction of the gypsum layer of drywall on the profile of lining boards, with the greatest effect observed with oval protrusions, the least with a flat impactor.
5. The vibratory jaw crusher has a sufficient number of parameters that control the crushing process: frequency and amplitude of vibrations of the jaws, the magnitude and direction of the disturbing force, the mass of the jaws, the size of the unloading gap, the rigidity of the elastic elements, the profile of the working surface of the jaws, the grip angle, the angle of inclination of the transporting surface, which allows you to significantly increase the obtained indicators based on additional research.

Abstract. Taking into account the need to provide the city's population with green areas in accordance with the European program "Green City", there is a problem of the formation of large volumes of plant residues that need to be utilized. At the same time, the cultivation of green infrastructure elements on urban soils requires of fertilizer. The analysis of existing systems for the management of fallen leaves in different countries, including Ukraine, was carried out and the creation of a municipal infrastructure for the disposal of in-situ organic waste of plant origin in the context of the circular economy was proposed. The author's technology for the creation of municipal infrastructure for the disposal of organic waste of plant origin for different urban landscapes. The effectiveness of using plant waste to form the initial substrate for the creation of composts and vermicomposts was investigated. The volumes of phytomass formation from fallen leaves in the green zones of administrative districts and the city as a whole, as well as in household plots with different vegetation composition were calculated. On the basis of the data obtained, a SWOT analysis was made of the implementation of the program utilization of plant waste.

1. Introduction

The relevance of the study is due to the need for ecosystem management in the disposal of urban organic waste as an important cluster of the Smart City concept and Green City. Ukrainian cities are gradually moving towards the implementation of the principles underlying the EBRD Green City program [1]. The program provides for the creation of new and revitalization of existing green areas in cities, bringing the provision of urban green spaces to 50 m^2 /1 person. This is the rate of urban greening recommended by the World Health Organization. During the growing season of green spaces and especially at the end of it in autumn, a large amount of plant organic phytomass is created, which needs to be utilized. Thus, the collected leaves in most cases fall into containers with household waste and are taken to landfills or burned in places of accumulation.

Burning of vegetative organic waste is a violation of Ukrainian legislation, namely: Article 50 of the Constitution of Ukraine; Articles 9, 12 of the Law of Ukraine "On Protection of the Natural Environment"; Article 16 of the Law of Ukraine "On Protection of Atmospheric

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012127 doi:10.1088/1755-1315/1415/1/012127

Air"; paragraphs 3.6.14, 3.7.4 "Rules for the maintenance of residential buildings and adjacent territories"; paragraphs 3.6, 6.4.2 "Rules for the maintenance of green spaces in cities and other settlements"; the Law of Ukraine "On landscaping in settlements".

It is inexpedient to dispose of plant organic waste to landfills, thus significantly increasing the burden on public utilities and the area allocated for waste disposal.

As an alternative to these methods of disposal of fallen leaves and other plant residues is composting, vermicomposting or biodynamics. Our study is devoted to these issues. Its purpose is to assess the opportunities and risks of using composting and vermicomposting for the disposal of plant waste in urban landscapes.

2. Literature review

According to the UNEP, important areas of green economy development are, in particular, the utilization and recycling of domestic and industrial waste, greening of the urban environment. On the one hand, cities are the main polluters of the environment, and on the other hand, they have a powerful potential for implementing the green growth model.

Among the leaders in the development and implementation of new policies is the European Union, where environmental policy is one of the development priorities. This direction is enshrined in the following EU strategic documents: "Europe 2020: A Strategy for Smart, Sustainable and Inclusive Growth" and the Resource Efficiency Roadmap [2]. The EU Sustainable Development Strategy "Europe 2020" aims to promote sustainable growth by developing a more resource efficient, green and competitive economy. In 2011, the Roadmap for the transition to a low carbon EU Society by 2050 was adopted [3, 4].

In its publication "Sustainable Financing and Policy Models for Municipal Composting", the World Bank considers composting as a strategy for organic waste management and states that organic waste management is a growing global concern as cities experience increasing waste generation and the associated climate impact. Composting is a sustainable solution for managing organics that has the potential to be inexpensive and require less technical capacity than alternative treatment methods. Composting potentially reduces waste management costs as it avoids landfill fees, extends the life of the waste and reduces transportation costs. World Bank experts emphasize that there is no single model that can be applied to all cities. There is a need to develop several models that will differ in approaches to waste collection, composting technologies, scaling, and distribution depending on the characteristics of the city [5].

The European Bank for Reconstruction and Development, within the framework of the project to support investments in sustainable municipal solid waste management and recycling in Ukraine, has developed a Solid Waste Management Strategy called "Changing our Behaviour" for the period 2017-2030. The approach of the Strategy "Changing our Behaviour" means transforming the attitude in Ukraine towards waste in favour of considering it as a valuable resource to be managed, rather than a problem to be solved [6].

The difference between the situation with waste in Ukraine compared to other developed countries is the large volumes of waste generation and the lack of waste management infrastructure. At the same time, the availability of such infrastructure is an indispensable feature of all economies of developed countries [7].

The total area of green spaces in the built-up part of Kyiv is 16.8 thousand hectares. On average, 260 trees grow on one hectare. When shedding, the weight of 1 square meter of leaf ball in the moistened state is 100 g. The weight of leaves of one middle-aged tree is 35 kg, young – about 10 kg (young trees occupy 40 % of the total area of green spaces – Obolon, Troyeshchyna, Teremky and other residential areas). The weight of 1 cubic meter of wet leaves is 300 kg. The total weight of leaf mass in medieval plantations per 1 hectare is 9.1 tons; young plantations – 2.6 tons. The total weight of all leaf mass of the capital is about 100-110 thousand tons [8].

Nutritious compost substrate has a higher (2-3 times or more) content of organic matter, macro- and microelements, mineral and organic colloids in comparison with soil. Its application allows to improve the agronomic properties of the topsoil for 5-6 years, optimizes the agrophysical and agrochemical parameters of the soil, improves the use of nutrients by plants, optimizes water consumption.

The purpose of the work is to substantiate the creation of municipal infrastructure for the utilization of organic waste of plant origin "in-sity" for various urban landscapes.

3. Methods

An analysis of the methods presented in several specialized publications [9–13] made it possible to determine the most optimal one, since it takes into account the entry of carbon into the soil, fixed in the form of humus from the organic matter of plant residues.

The estimated calculation of plant residues was carried out according to the method of calculating the balance of humus and organic fertilizer rates to ensure its deficit-free content in chernozem soils, which was developed by Chesnyak and Zinchenko at the ESC "O.N. Sokolovsky Institute of Soil Science and Agrochemistry". According to this method, the profitable item of the humus balance includes the inflow of carbon into the soil, fixed in the form of humus from organic matter of plant residues and organic fertilizers. Other sources of humus replenishment in the soil, such as seeds and atmospheric carbon dioxide sequestered by blue-green algae, are not large and are not taken into account [14].

The mass of plant residues is determined by means of regression equations on the yield of the main product (c/ha) as the sum of surface and root plant residues. In particular, the mass of surface plant residues of potatoes, vegetables and melons is determined by the following regression equation:

$$Z = 0.068Y + 0.5X, \tag{1}$$

mass of root plant residues is determined by the regression equation:

$$X = 0.07Y + 8.0 \tag{2}$$

When calculating the amount of newly created humus from plant residues, the corresponding humification coefficients are used. They show how much newly created humus is obtained from decomposing plant residues. In particular, the humification coefficient of plant residues for potatoes, vegetables and melons is 0.13.

4. Results and discussion

Among the modern methods of utilization of plant organic residues, in particular processing into fuel briquettes and pellets, biogas production, composting to obtain a nutrient substrate, utilization by composting and vermicomposting of organic plant waste is the most environmentally friendly and economically feasible approach.

At the same time, the dominant way of handling household waste in Ukraine remains its removal and disposal in landfills and dumps. In 2016, only 0.003 % of organic waste was composted in Ukraine [7].

In addition, spontaneous dumps of plant residues and fallen leaves are often formed in local areas of public territories in rural urban and suburban areas. The reason for this situation is that local residents in response to the ban on burning leaves generally refuse to further dispose of them. Of course, a significant drawback in working with the population is the lack of environmental education and the formation of basic environmental knowledge.

A survey of residents of settlements in Kharkiv oblast revealed an insufficiently high level of competence among owners of private estates in the field of environmental management. In particular, every second respondent could not give the correct answer to the question about the definition of the terms “humus”, “soil pH”, “nutrients” [15].

The main organizing role in changes related to waste management in Ukraine belongs to local authorities. They are obliged to ensure the continuous improvement of the physical and social environment in which their communities live. Therefore, it is advisable for land management departments, departments of communal property and ecology of city (settlement, village) councils to actively implement measures with the participation of ecologists, agronomists to teach composting technologies, etc.

Monitoring and control of measures to implement the National Waste Management Strategy in Ukraine until 2030 is carried out, in particular, by such an indicator as “the number of composting points in households” [7]. It is necessary to stimulate the introduction of composting technologies by owners of private estates, in particular by providing compost boxes for rent or free of charge at the expense of local budgets. The problem of illegal waste disposal can be solved by establishing financial sanctions. The funds received from compensations paid for the deterioration of the ecological condition of soils by unscrupulous land users can serve as a source of funding for incentive measures.

The Program of in-situ municipal utilization of plant waste developed by the authors aims to adjust the strategy of organic waste management in public urban, settlement, rural areas, as well as to focus on the formation of a culture of environmental management among owners of private estates who use their land for horticulture and gardening. The practical value of the Program lies in the use of ecosystem management in the disposal of urban organic waste in the context of the implementation of the circular economy concept for the Smart City green cluster. The novelty of the program is the development of in-situ recycling technology, i.e. on-site recycling of plant organic waste (plant residues, branches, leaves, grass), without their transportation by composting or vermicomposting.

Currently, there are no completed projects in Ukraine to create municipal infrastructure for in-situ disposal of organic waste of plant origin. The proposed technology belongs to one of the eight clusters of critical factors, namely, the green cluster, which form the content of smart city initiatives. The program has clear and realistic goals. The strength of the program is high environmental and economic efficiency, a wide range of stakeholders interested in the project results, involvement of the end user (city residents) in the project.

Disposal by composting and vermicomposting of organic plant waste is the most environmentally friendly and economically feasible approach. Composting is one of the models of waste management at the municipal level. The estimated calculation carried out by the authors according to the methodology of Chesnyak and Zinchenko [14] shows that in household plots where potatoes, vegetables, melons are grown, 4.0-4.5 t/ha of plant residues that need composting accumulate during the growing season.

Within the framework of research conducted by the Department of Environmental Monitoring and Conservation in households in Kharkiv and Kirovohrad regions, whose household plots were occupied not only by a vegetable garden, but also by a productive fruit-bearing garden, mixborders with perennial plants, lawn, formed hedges, the mass of plant residues during the growing season reached 10 t/ha.

In Ukraine, within the family-individual household sector of rural areas, the land use of household plots and personal peasant farms prevails, in particular, household plots of citizens in rural areas alone account for about 10 million households with a total area of almost 1.5 million hectares [6]. The average size of such plots is: width – 10-40 m, length – 20-100 m [7].

That is, composting as a strategy of organic waste management for balanced nature management on household plots with the cultivation of fruit, vegetable, ornamental crops have the potential to create up to 2 million tons of humus only at the expense of households in rural areas.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012127 doi:10.1088/1755-1315/1415/1/012127

An important factor affecting the intensity of the composting process is the ratio of carbon and nitrogen. The most favorable C:N ratio for intensive microbiological processes is 25:1. It is generally accepted that if crop residues have a high carbon content, the nitrogen content can be compensated with a nitrogen fertilizer of 0.5 to 1 %, which accelerates the composting process.

If only nitrogen fertilizers are used, crop residues become a place for the development of all indigenous microflora, including pathogens. This means that they also activate pathogenic organisms, Fusarium, rot, mold, etc. When the destructor is added, the soil is populated with saprophytic microorganisms in high concentration, which displace pathogens. This happens both through direct competition for habitat and nutrients, and through the synthesis of antibiotic compounds that inhibit the development of pathogens.

Modern microbiological destructors of Ukrainian production for the controlled decomposition of plant residues contain strains of *Bacillus, Paenibacillus polymyxa, Azotobacter, Enterobacter, Enterococcus, Agrobacterium*, strains of fungi of the genus Trichoderma. These preparations for accelerated decomposition of fallen leaves directly on the territory of the garden, park: it is enough to treat with a working solution in a concentration of 2.0 l/ha during the leaf fall, the cost of one liter of the preparation is 4.3 €.

Expected effect: effective decomposition of leaves, reduction of soil toxicity, improvement of soil structure, increased availability of nutrients, biocontrol of pathogens. The latter function is especially important for improving the conditions of growth and development of the main tree species of urban landscaping, in particular, maples, lindens, chestnuts, which have a high level of infection with phytopathogenic fungi.

The use of such effective microbiological preparations is safe for human and animal health, solves the problem of creating high-quality composts both in rural and urban areas. They activate the natural forces of plants, help plants survive adverse biotic and abiotic conditions, preserve their decorative qualities and the natural beauty of a small garden or a large park.

Previous studies have found that such species as *Fraxinus excelsior L., Tilia cordata, Tilia platyphyllos*, representatives of the genera *Populus L., Betula L., Sambucus nigra L., Hedera helix L., Parthenocissus quinquefolia (L.)* Planch, species and varieties of *Vitis L.* respond well to the improvement of nitrogen nutrition in urban ecosystems by the state of morphological organs and crown habitat [16].That is, these species actively accumulate nitrogen compounds.

Therefore, it is appropriate to form the green infrastructure of the city using plant species and cultivars with high nitrogen content in the leaves, which will contribute to intensive microbiological processes during composting. According to the authors, such cultivars as *Catalpa bignonioides, Catalpa ovata, Morus alba, Malus niedzwetzkyana, Malus x floribunda, Malus hybridus, Crataegus laevigata* meet such requirements.

Vermicomposting is a system of organizational and technological measures with the use of vermiculture – populations of dung worms together with accompanying heterotrophic organisms in a specific organic substrate, Vermicomposts – products of processing of organic mass by earthworms and microorganisms. The processing of organic waste produces a valuable organic fertilizer – vermicompost. The production of biohumus is based on the ability of earthworms to use organic residues, transform them in the intestines and excrete them in the form of coprolites.

The best samples of vermicompost contain several billion cells of microorganisms in 1 g, which is much more than in manure samples (about 150-360 million cells). Biohumus has a high enzymatic activity. Its organic matter contains a significant amount of humic acids (Chc = 31.7-41.2 %) and less fulvic acids (Cfc = 22.3-34.85). In humic acids the most valuable fraction prevails – calcium humates (43.3-47.6 %). The presence in vermicompost of fulvate-humate type of humus (Cgc: Cfc = 1.18-1.42) contributes to the formation of agronomically valuable soil structure [17, 18]. Nutrients in the process of interaction with organic acids form complex complex compounds, so they are reliably preserved from leaching, slowly dissolve in water and provide plant nutrition for a long time (at least 2-3 years).

Biohumus has a multifaceted positive effect on agrochemical, physicochemical and biological properties of the soil. It contains a complex of nutrients and therefore can be used for all crops, but is especially useful for those that require nutrients in concentrated form, balanced in chemical composition.

Worms release calcium from the substrate and thereby reduce the acidity of the environment. The coefficient of substrate humification is 15-25 %, while for manure it is about 10 %. As a result of intensive fermentation, biohumus is enriched with a large number of biologically active substances (auxins, heteroauxins, etc.), which significantly reduce the stress of plants, especially seedlings when planting in the soil, increase its survival rate, accelerate seed germination, increase plant resistance to diseases, affect their growth, development and thereby contribute to obtaining early products of high biological quality suitable for long-term storage. Biohumus also has other valuable properties: high moisture capacity, moisture resistance, hydrophilicity, mechanical strength, does not contain weed seeds. It is able to retain up to 70 % of water and is 15-20 times more effective than any organic fertilizer [17, 18].

The agrochemical properties of the average sample of vermicompost are as follows acidity (pH) – 6.5-7.2, dry organic matter content – 40-60 %, humus – 10-12 %, total nitrogen – 0.9-3.0%, phosphorus (P_2O_5) – 1.3-2.5 %, potassium (K_20) – 1.5-2.5 %, calcium – 4.5-8.0 %, magnesium – 0.5-2.3 %; iron – 0.2-2.5 %, copper – 3.5-5.1 mg/kg; manganese – 60-80 mg/kg; zinc – 28-35 mg/kg; humidity – 40-50 %; bacterial form – up to 20 trillion colonies in 1 g of vermicompost [17, 18].

Nutrients are in organic form, so they are reliably preserved from leaching. Due to the decomposition of vermicompost by microorganisms, macro- and microelements are released, plants are provided with carbohydrates necessary for photosynthesis. When applying vermicompost, which is characterized by high buffering capacity, an excessive concentration of salts is not formed in the soil solution, which can be traced in the case of high doses of mineral fertilizers.

Vermicomposts are especially valuable due to humic acids, the content of which ranges from 5.6 to 17.5 % in terms of dry matter. In addition to decomposed waste, vermicomposts also contain a certain amount of dead worms, which also increases their value.

The quality of biohumus is assessed according to the international standard, which sets the following requirements: humidity – 30-40 %; organic matter – 20-30 %; water-soluble salts – 0.5 %; pH – 6.5-7.5; total nitrogen – not less than 1.6 %; P_2O_5 – 1.2-1.5 %; K_2O – 11-12 %; Cu – 1 %; Mg – 1 %; Ca – 4 % [17]. Biohumus should not contain substances that are not biologically processed (polymers, stone, glass), plants capable of reproduction. The nutrients of vermicompost dissolve slowly in water, and therefore can nourish plants for a long time. In granular humus fertilizers, the humus content is 4-8 times higher than in manure and compost.

To obtain biohumus from fallen leaves, a population of special worms is used. The optimal density of worms in one bed is 50-100 thousand adults and young individuals, as well as cocoons with eggs. It is established that the productivity of vermiculture depends on the density of the bed. If the density is excessive, the excitement of worms increases and stress caused by overpopulation occurs, which negatively affects their reproduction. At low density, the productivity of worms and the yield of vermicompost also decreases. For breeding queen worms, standard beds are used, the population density of which ranges from 1.5-2.0 to 10-12 thousand individuals/m^2 [17].

Knowing the number of beds, the approximate number of worms in them, the average composition of the population by age groups (young – 60.1 %, adults – 21.8, cocoons – 18.1%), in each case it is possible to calculate the mass of the required feed (or feeding). The substrate for worms is fed with organic matter, including household and other waste, to which solid organic components – fillers – are added in various proportions to create a loose structure. They can be tree bark, leaves (except fresh needles), etc. About 1000 kg/year of substrate is required per

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012127 doi:10.1088/1755-1315/1415/1/012127

100 thousand worms [17].

There are special requirements to the structure of the substrate and its chemical parameters: its humidity should be 70-80 %, it should not contain non-decomposable objects (stones, metal, glass, etc.), have a neutral reaction of the medium (optimal pH 6.8-7.2) and the content of iron oxides should not exceed 10 %.

The nutrient substrate should be of semi-liquid consistency, well crushed, as the largest particles that can be swallowed by the Californian worm are up to 1 mm in size. It is believed that the worms eat food in an amount equal to their body weight (about 1 g); 40 % of the food is absorbed, and 60 % is excreted as coprolites.

The prepared substrate undergoes a fermentation stage, during which eggs and larvae of helminths, as well as weed seeds are killed. Fermentation can be carried out both in natural and accelerated mode. In natural mode, the process lasts 6-7 months depending on the type of organic waste, and in accelerated mode – 1-3 months. To ensure the accelerated mode of fermentation, organic waste is piled in heaps, which are then supplied with hot steam at a temperature of 60 °C through pipes.

The substrate, which does not self-heat, is laid out in a layer 20-30 cm thick and 1-1.6 m wide, moistened to 70-80 % of the total moisture capacity and kept for 10-15 days. After that, it is populated with worms at the rate of 1.5-2.5 thousand individuals/m^2 [17, 18]. To preserve moisture, the substrate is covered with chopped straw or burlap. In winter, it is desirable to keep the worms in a closed warm room at a temperature not lower than +10 °C, because at a temperature of +7 °C they fall into a state of anabiosis. The best feed for them in winter is manure containing at least 20 % straw.

The vermicomposting method can be successfully used for processing organic waste on individual plots. To do this, the waste is collected in a pile, moistened and left to rot. After 1-1.5 months, when the self-heating process is over, the accumulated mass is populated with worms (at the rate of about 1 thousand individuals/m^2). After 3-4 months (depending on the quality of the substrate and climatic conditions) the compost is ready. Organic matter to be vermicultured should contain easily digestible carbohydrates and fiber in an amount of at least 20-25 %.

At the experimental site of the Uman National University of Horticulture, the suitability of fallen leaves (on the example of hazel tree) as a filler for vermicompost was evaluated, because one of the areas of work on the utilization of fallen leaves is its use as an integral part of the nutrient medium for vermiculture [19].

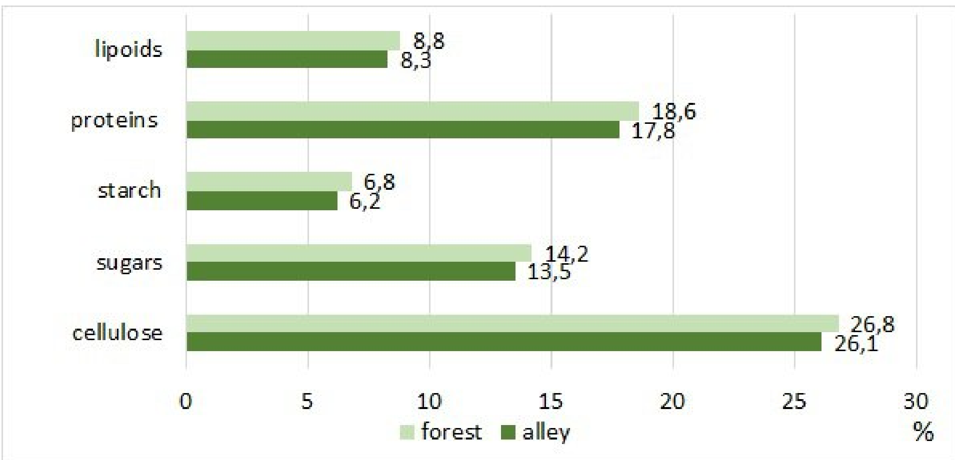

Figure 1. The proportion of organic substances in the absolutely dry mass of tree hazel leaves.

Table 1. Accumulation of fallen leaves in the administrative districts of the Kharkiv city.

Administrative district	Area, ha	Area of GI, ha	The area from which fallen leaves are collected, ha	Mass of fallen leaves,tons
Shevchenkivskyi	4418.44	2241.45	159.3	1449.2
Kyivskyi	4569.45	1001.7	53.7	488.2
Slobidskyi	2434.24	169.4	21.3	193.8
Kholodnohirskyi	3211.32	181.5	29.7	270.3
Saltivskyi	2401.24	68.3	49.9	454.1
Nemyshlainskyi	2229.22	32.1	32.1	292.1
Novobavarskyi	3471.34	75.1	49.4	449.5
Industrialnyi	3339.33	84.9	38.1	346.7
Osnov'yanskyi	4532.45	223.35	15.6	142.0
Total	30607.03	4077.8	449.0	4085.9

It was found that the fallen leaves of the tree hazel contain fiber from 26.1 to 26.8 %, easily fermentable carbohydrates from 13.5 to 14.2 %, starch from 6.2 to 6.8 %, proteins from 17.8 to 18.6 % and lipoids from 8.3 to 8.8 % of the absolutely dry weight of the leaves (figure 1).

At the experimental sites of the Department of Ecology and Life Safety of the Uman National University of Life Sciences, the effectiveness of the use of plant waste to form the initial substrate for vermicomposts was investigated [19].

Based on the results obtained, we propose to develop an environmentally friendly technology for the utilization of urban tree litter, taking into account the peculiarities of the structure of the tree stands of the green zone of Kharkiv. The dominant species in it are sharp-leaved maple (Ácer platanoídes), common chestnut (Aesculus hippocastanum), broad-leaved linden (Tilia platyphyllos) and others. The positive effect of vermicomposting is still expected in relation to

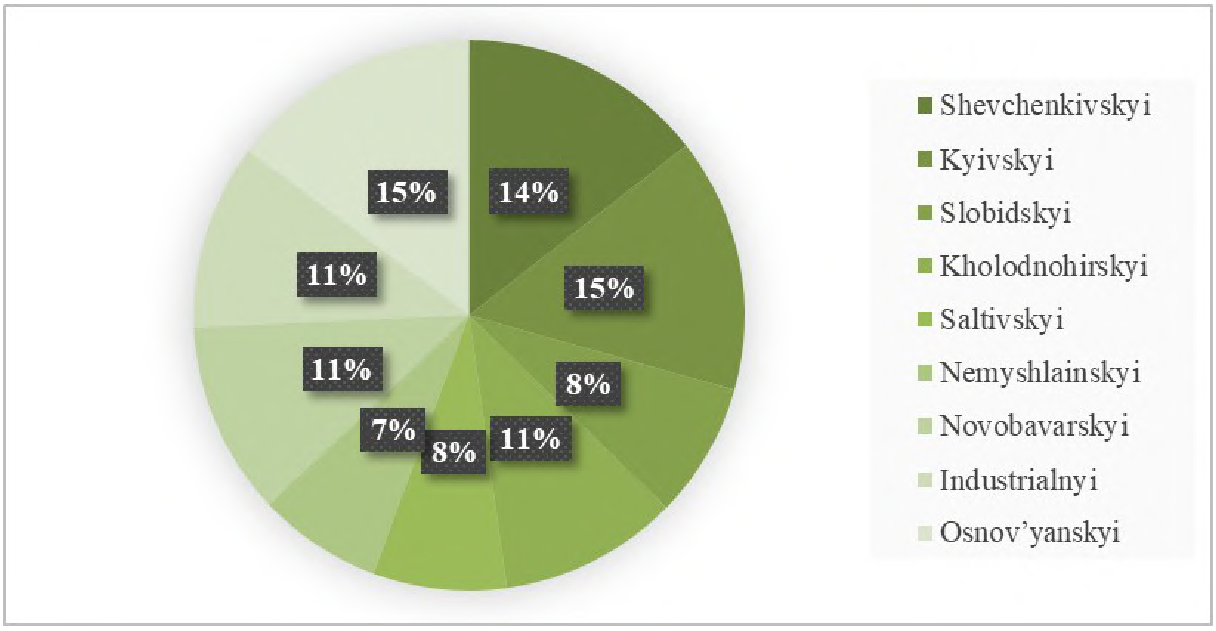

Figure 2. Area of administrative districts of the Kharkiv city, %.

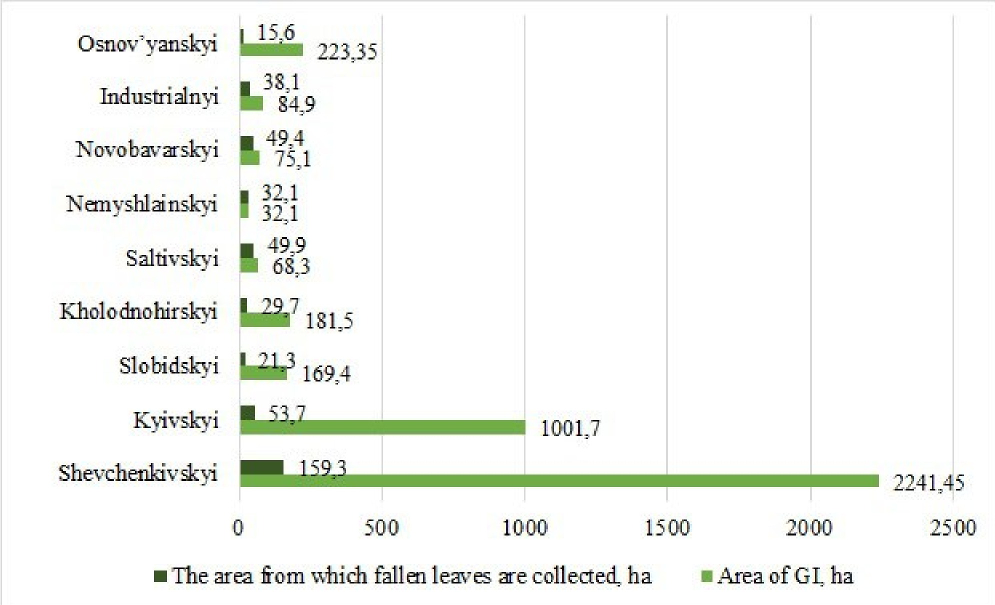

Figure 3. Area of Green Infrustructure in administrative districts of the Kharkiv city and the area from which fallen leaves are collected, ha.

the control of such a pest as chestnut moth, which has become critically widespread in urban plantations.

To estimate the amount of plant waste that can be processed into vermicompost, the following calculations and their analysis were made (table 1).

Kharkiv is a city with a total area of 30607.03 ha, consisting of 9 administrative districts. The largest areas are Kyivskyi (15 %), Osnov'yanskyi (15 %) and Shevchenkivskyi (14 %) (figure 2).

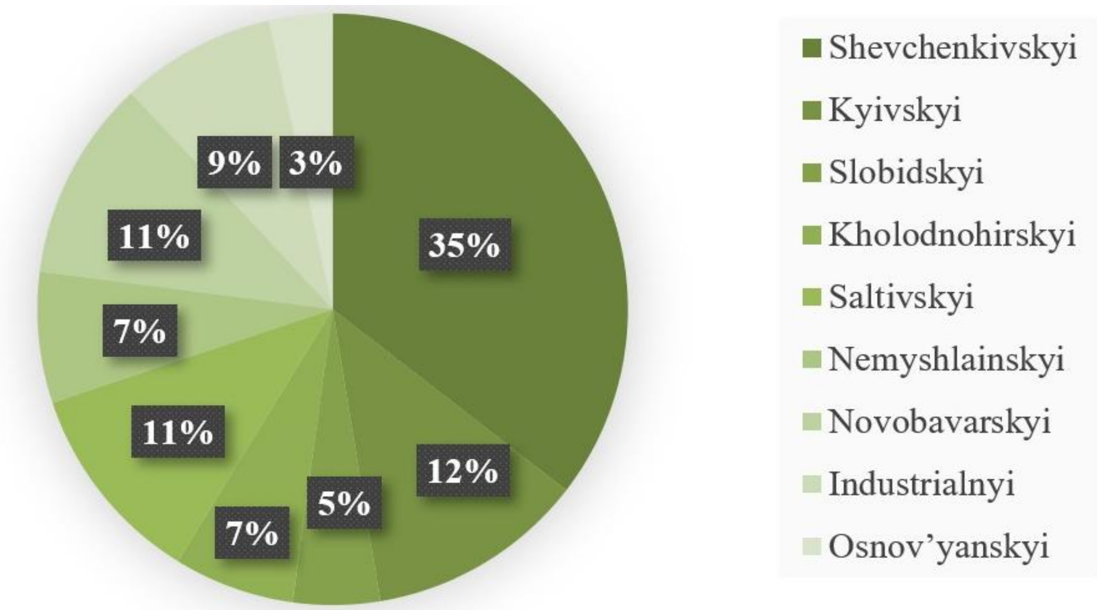

Figure 4. Mass of fallen leaves in administrative districts of the Kharkiv city, %.

Table 2. SWOT analysis of municipal program in-situ utilization of plant waste.

Strengths	**Opportunities**
• Development of environmental principles for the development of green infrastructure of the city on the principles of circular economy • Composting potentially reduces waste management costs, as it avoids waste disposal fees, extends the life of waste and reduces transportation costs. • Nutritious compost substrate compared to soil has a higher (2-3 times or more) content of organic matter, macro- and microelements, mineral and organic colloids. • Its application allows to improve the agronomic properties of the topsoil for 5-6 years, optimizes agrophysical and agrochemical parameters of the soil, improves the use of nutrients by plants, optimizes water consumption. Nutrients are in organic form, so they are reliably preserved from leaching.	• Formation of a culture of nature management among owners of private estates who use their land plots for gardening and horticulture. • Development of in-situ utilization technology, i.e. in-situ utilization of plant organic waste without the need to transport it. • Vermicomposting biohumus has the following valuable properties: high moisture capacity, moisture resistance, hydrophilicity, mechanical strength, does not contain weed seeds. It is able to retain up to 70% of water and is 15-20 times more effective than organic fertilizers. • When applying vermicompost, which is characterized by high buffering capacity, an excessive concentration of salts is not formed in the soil solution, which can be traced in the case of high doses of mineral fertilizers. • For large volumes of plant waste of the city it is advisable to replace vermiculture with a special preparation – organic destructor.
Weaknesses	**Threats**
• There is a need to develop several models that will differ in approaches to waste collection, composting technologies, depending on the characteristics of the city • Generation of large volumes of vegetable waste and lack of infrastructure for their processing. • The dominant way of handling household waste in Ukraine disposal at landfills and dumps. • Lack of environmental education work with the population and the formation of basic environmental knowledge.	• Vermicomposting uses worms for the disposal of plant residues, which do not have any protective organs, so they can be attacked by any animals: rats, mice, snakes, frogs, birds. Necessary to have additional equipment to avoid this. • The processes take place only in warm humid conditions and therefore additional humidification and heating or warm season is required. In winter, it is desirable to keep the worms in a closed warm room at a temperature of up to +10 °C, because at a temperature of +7 °C they go into a state of anabiosis. • The method is difficult to implement for large volumes of waste.

Each district has elements of green infrastructure: parks, forest parks, meadow parks, squares, boulevards, alleys, gardens, forests, etc.

The largest area of organized green infrastructure elements is in Shevchenkivskyi (2241.45 ha) and Kyivskyi (1001.7 ha) districts (figure 3). However, it includes a Forest park, a Hidropark and a Meadow park, which are not the objects of our calculations, since they, as well as forests, nature reserves and some other elements of green infrastructure do not practice the collection of fallen leaves. Therefore, only the part of the green infrastructure where leaf collection is organized in autumn was taken to calculate the amount of plant waste.

The districts with the largest area where leaves are collected include Shevchenkivskyi, Kyivskyi, Saltivskyi and Novobavarskyi (figure 3). Of course, in each of the districts there are intra-quarter plantings and adjacent vegetation, but it is not taken into account in this calculation.

Proceeding from the fact that medieval plantations of broad-leaved species in autumn produce about 9.1 t/ha of fallen leaves, we made the corresponding calculations and obtained the results (table 1), which show the potential of plant residues that can become biohumus and be used for fertilizing urban soils. Comparison of the districts by the volume of plant waste generation showed that almost a third of all residues are produced by Shevchenkivskyi district (35 %), as it is on its territory that the Taras Shevchenko Garden, the Central Recreation Park named after M. Gorky, Sarzhyn Yar, the Botanical Garden and other green infrastructure facilities where fallen leaves are collected are located (figure 4). Kyivskyi, Saltivskyi and Novobavarskyi rayons (11-12 %), with significant differences in the total area and greenery area, have the same percentage of the territory that is maintained and requires organized leaf disposal.

Complex processing of a particular type of plant raw materials is due to the peculiarity of their technological properties and biochemical composition. According to the experience of biotechnology specialists, it is known that organic matter to be vermicultured should contain easily digestible carbohydrates and fiber in an amount of at least 20-25 % [19].

Skip et al. [20] has shown that fallen leaves of broad-leaved linden, sharp-leaved maple, common bitter chestnut trees contain a significant amount of biopolymers, in particular carbohydrates (fiber from 16.3 to 24.6 %, easily fermentable carbohydrates from 6.9 to 12.4 %, starch from 2.5 to 5.8 % of absolutely dry weight of leaves) and other biologically active substances that can serve as a nutrient medium for vermiculture.

Thus, we conclude that the composition of the phytomass of green areas of the city. Kharkiv fully meets the requirements of composting. The use of plant waste processing products as fertilizers using vermiculture significantly reduces the cost of soil enrichment with nutrients, increases the possibility of obtaining environmentally safe products. And what is very important – conditions are created for the utilization (with great benefit) of significant volumes of organic waste.

5. Conclusions

To summarize the collected information, we use the SWOT analysis method, identifying the strengths and weaknesses of the creation of a municipal program for the collection and utilization of plant waste in-sity, opportunities and threats to its implementation (table 2).

The study allowed to draw a number of conclusions that will contribute to improving the quality of ecosystem management of organic residues utilization in urban landscapes. Several environmentally-oriented methods of processing fallen leaves directly on the territory of formation on the principle of in-sity and further use of the resulting product – vermicompost.

Abstract. The article focuses on the peculiarities of waste management of the mining and metallurgical complex. As a result of growing environmental awareness, iron and steel slag is highly valued as a recycled material that can reduce environmental impact due to its resource conservation and energy conservation. The key factors contributing to increasing the attractiveness of investments in the processing of metallurgical waste are: 1. limitation of supplies of primary metal in case of expected growth of demand in the conditions of energy transition; 2. carbon emissions: steel and aluminum together account for almost 10 percent of global emissions, in turn secondary aluminum production creates 5-25 times less carbon emissions; 3. geopolitical instability and dependence on imports from China increase the need to increase the security of supply of primary metals. One of the promising directions of reuse of metals is the production of building materials. Slag is an improved and more ecological alternative to traditional building materials. It can be used in various applications such as filler for concrete and asphalt mixtures, railway ballast, cement, etc. It has been established that the use of slag cement not only provides high-quality concrete, but also prevents global warming, contributes to the conservation of natural resources and minimizes pollution in landfills.

1. Introduction

Metal waste constitutes a significant part of industrial and consumer waste worldwide. Proper handling of them is not only important for reducing the impact on the environment, but also for more rational use and recovery of very valuable resources. Solving the problem of waste disposal has been a priority issue for many years from the point of view of restoring and preserving the state of the environment. The issue of the possibility of circulation of products produced by industrial enterprises is raised immediately before the determination of measures to improve the state of atmospheric air, water bodies, and protect the diversity of flora and fauna. Currently, in terms of industries, the attention of the world community is directed to the waste of the mining and metallurgical complex, in particular to the metallurgical industry, the waste of which is sent to artificially created landfills to a greater extent. Many works are devoted to the study of methods of handling metallurgical residues [1–4].

In Ukraine, metallurgy has been a fundamental branch of the national economy for many decades. Metallurgical plants and steel plants have been the largest tax payers to the budgets of all levels for many years and constantly create new jobs. Ukraine's provision of large amounts of natural resources for many years made it possible not to consider waste as a production material. This has led to the fact that the reuse of metallurgical slag as industrial waste from metal smelting processes is only 40-50 percent, on the other hand, in European countries, up to 90 percent of industrial slag from the total annual volume of formation is processed as components of mixtures for construction, asphalting of roads etc. (in Ukraine, only approximately 20 percent of slag waste is used in mixtures for road construction).

Slags, as industrial waste, according to standard approaches, need to be transported to designated waste storage sites, which causes additional extremely high transport costs, fuel costs, and for giant enterprises – costs for the construction of transport routes.

Currently, due to the military actions on the territory of Ukraine, there is also the problem of disruption of many logistics supply chains, which has a negative impact on the supply of construction material, in particular, stone and other raw materials for the production of concrete mixtures. Therefore, the search for and substantiation of ways to use industrial slag at metallurgical enterprises of Ukraine in order to increase the economic effect for the enterprise itself and for the general ecological effect as a whole is gaining relevance.

2. Results

In terms of environmental security, global organizations and leaders are raising the issue of finding new ways of processing waste. This problem is especially acute in the countries of Europe and the East, because due to the lack of natural resources and the relatively small size of the countries, which does not make it possible to find additional places for landfills and landfills, they are constantly in search of ways to process materials.

During the last decade, the global production of crude steel shows quite high indicators with a mostly positive trend, which, accordingly, causes the aggravation of the problem of handling waste from metallurgical production (figure 1).

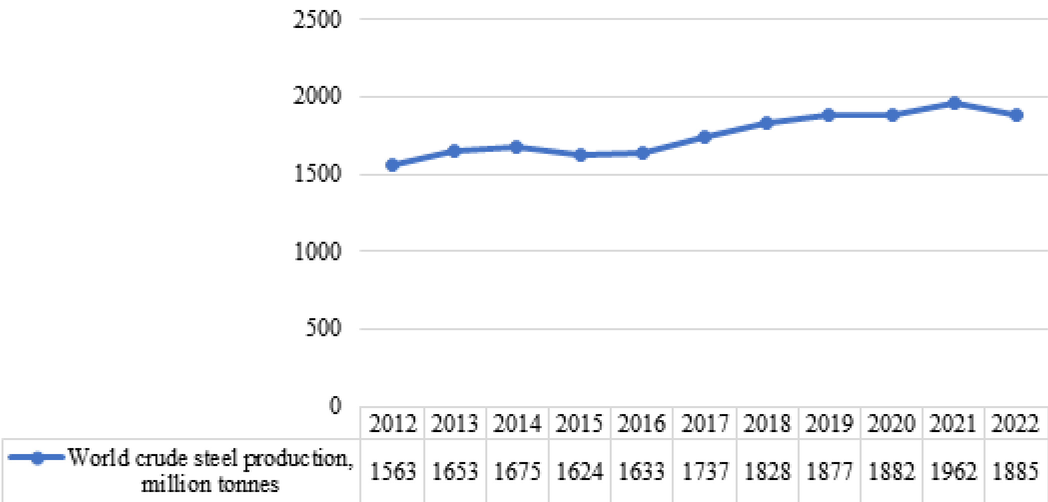

Figure 1. Dynamics of world production of crude steel, million tons (based on the data of World Steel Association [5]).

For a long time, China has remained the key exporter on the world steel market, and the main importer is the United States of America (table 1).

Among the production of basic materials used today, steel production has one of the lowest levels of carbon dioxide emissions per ton of material. However, due to the scale of steel use, the industry is exploring a number of decarbonisation pathways. At the same time, the adoption of

Table 1. Key exporters and importers of steel in the world market [5].

cyclical principles is an integral part of industrial and social transformation and is an important contribution to achieving the goals of the Paris Agreement.

As a permanent material that can be recycled again and again without losing its properties, steel is a fundamental material for the circular economy. As a result of growing environmental awareness, iron and steel slag is highly valued as a recycled material that can reduce environmental impact due to its resource conservation and energy conservation.

Analysts of the Worldsteel Association in their report Net Zero Steel Pathway Methodology Project list the types of steel production waste and the most diverse ways of their application, including not only road construction, but also the use of carbon and the restoration of biodiversity in water bodies (figure 2) [1].

At the same time, it is noted that waste that has already been used in other sectors is recognized as an effective means of reducing greenhouse gas emissions. In order to achieve the target indicators of sustainable development and reduce the burden on the environment, it is advisable to use metallurgical slag in industrial, road construction and repair, in the production of crushed stone, slag-steel products, use in agriculture as a soil deoxidizer, and the creation of artificial islands like the Japanese ones.

Slag is an improved and more ecological alternative to traditional building materials. It can be used in various applications such as filler for concrete and asphalt mixtures, railway ballast, cement, etc. (figure 3). Historic Roman roads in the county of Sussex in England were built using discarded furnace slag. Since the early 19th century, the United States has used slag in pavement construction as a base and in asphalt mixes, railroads, and cement [6].

The reduction of electricity consumption for the production of cement, lime and metal is also important. Thus, with a comprehensive approach to the processing of solid waste of metallurgical enterprises, it will be possible to significantly reduce the anthropogenic burden on the environment, save scarce building materials and fuel and energy resources for their production.

As governments around the world favor low-carbon concrete in new construction projects, the search for suitable replacements for cement in the concrete mix is at the forefront of new developments in infrastructure technology. Although cement only makes up about 10 percent of the weight of the concrete mix, its production is responsible for 90 percent of the emissions associated with concrete production. The growing demand for low-carbon concrete, combined with the need to meet the growing demand for new infrastructure amid global reconstruction following the COVID-19 pandemic, has made reduced-cement concrete a particularly desirable option [2, 7].

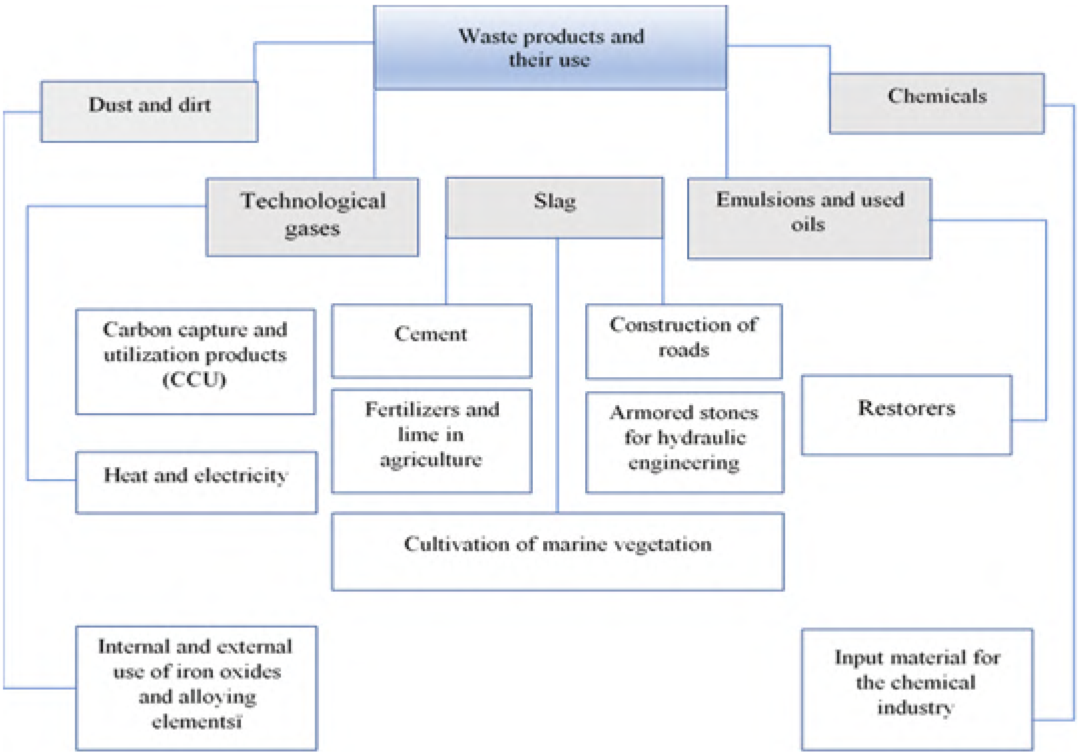

Figure 2. Waste products of metallurgical production (based on the data of World Steel Association [5]).

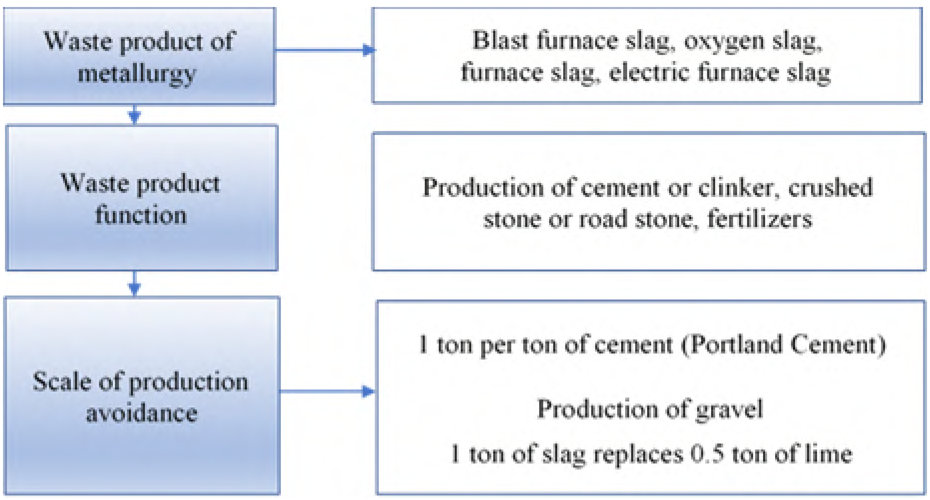

Figure 3. Application of slag waste products of metallurgy (based on the data of World Steel Association [5]).

Slag cement, also known as ground granulated blast furnace slag (GGBFS), is a cement that enhances the strength and durability benefits of traditional concrete while reducing waste, energy consumption and greenhouse gas (GHG) emissions. It is used in construction in combination with traditional Portland cement, as part of a cement mixture or as a separate cement [7, 8].

One of the most important aspects of slag cement is its ability to reduce emissions into the environment, as its production requires less clinker consumption, resulting in lower greenhouse gas and carbon dioxide emissions. Slag cement also reduces the burden on landfills and reduces emissions from the steel industry compared to the traditional process. In addition, the production of slag cement requires 50 percent less energy. Thus, the use of slag cement not only provides high-quality concrete, but also prevents global warming, preserves natural resources, and minimizes landfill pollution [8–10].

3. Conclusions

Leading European countries, in the face of resource scarcity and climate change, are constantly working on finding ways to use waste for re-processing. The countries of the European Union pay considerable attention to the issue of metallurgical waste processing in order to reduce dependence on the shortage of primary raw materials and minimize the impact on the environment. Among the European leaders in the processing of metallurgical waste, Germany, Sweden, the Netherlands and Belgium should be singled out.

- Germany recycling systems are among the most efficient in Europe. Germany has created an effective waste management system that ensures the collection and processing of various materials, including metals.
- Sweden has introduced an innovative system of incentives for the collection and recycling of metal waste, as well as an active company for working with the community.
- The Netherlands shows the best results on the continent regarding the processing of metallurgical waste, and is a leader in the implementation of modern waste management systems.
- Belgium has the most serious and strict metal waste management policy in Europe. Today, we can note the successful use of industrial waste in industrial and road construction, chemical and energy industries, as well as in the agricultural and environmental spheres.

To a large extent, environmental and economic goals can be achieved by finding the use of metallurgical production waste – slag. The use of metallurgical slag as a full or partial substitute for a binding substance (crushed stone) creates a positive economic effect for the enterprise, by reducing waste transportation costs, saving on building materials for the construction and repair of commercial buildings and individual workshops, obtaining profit from the sale of concrete mixture and building materials from it, and the overall ecological effect, making it possible to reduce the burden on the environment by reducing the volume of emissions at artificially created landfills and reducing emissions into the atmosphere during waste transportation.

Abstract. The effective functioning of radioecological monitoring of food is a crucial task for all countries worldwide as it directly impacts public health. This article confidently describes the migration of radiocesium (Cs) in the environment and its pathways into the human body. The article analyses the data of radionuclide content in food products across France, Spain, Great Britain, Germany, China, and Ukraine. This text confidently compares the regulatory frameworks for food quality management and radioecological monitoring in the mentioned countries. It also provides clear and decisive recommendations for visualising the obtained information on a public portal for scientific research, public awareness, and general use.

1. Introduction

Increased use of nuclear power plants (NPPs), nuclear waste disposal, and radiation technologies in various sectors of the economy inevitably leads to the release of artificial radionuclides into the environment. After nuclear weapons testing and technogenic accidents, more and more citizens around the world began to worry about the quality of food (content of heavy metals, radionuclides, etc.).

Radionuclides that are dangerous to humans, including isotopes of uranium, plutonium, iodine-131, cesium-134, cesium-137, and strontium-90, were dispersed globally through atmospheric circulation and ocean currents following the Chornobyl NPP (ChNPP) and Fukushima accidents.

As these radionuclides share some chemical properties with nutrients, plants and animals absorb them along with necessary nutrients for growth. Several factors influence the radioactivity level of radionuclides in food, such as the radioactivity content of the source environments (soil, water); the availability of nutrients and other substances contained in soil and water; and other environmental conditions affecting animals and plants.

As shown in figure 1, artificial radionuclides migrate through the food chain. Radioactive cesium (Cs) is washed out through atmospheric precipitation and enters the soil, substituted potassium in plants. This process is particularly significant for potassium-rich crops, which can result in radiocesium entering the human body through trophic chains.

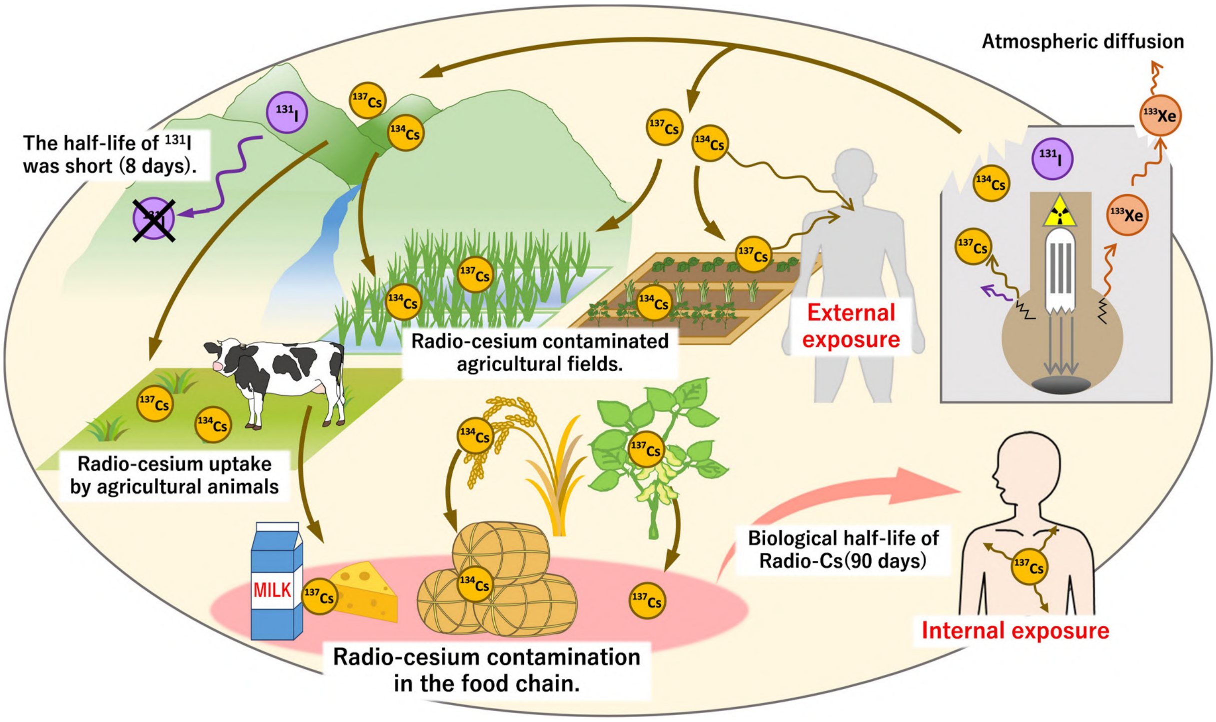

Figure 1. Migration of radiocesium (Cs) in the environment [1].

One of the ways of radionuclides incorporation into biological and food chains may be ingesting of soil particles containing radionuclides during grazing by animals with food. The gastrointestinal tract, kidneys, and mammary glands in lactating animals are the main channels for excreting radionuclides from the mammalian body. Part of the fission products that entered the body of lactating animals excreted with milk.

After cesium-137 and strontium-90 enter the human body, they replace potassium (in muscle tissue) and calcium (in cysts), leading to disease-causing mutations and cancers.

Therefore, to eliminate public doubts and ensure food safety, it is necessary to conduct and implement high-quality radioecological monitoring of natural and artificial isotopes in food to the extent possible.

2. Related work

The study has resulted from an in-depth analysis of wide range of legislation, scientific publications, and information sources. The result of the analysis showed that the problem we outlined is considered and described in the following areas:

- development and use of equipment for radioecological monitoring [2–4];
- use of monitoring data to solve problems of management of radiation-contaminated areas [5–7];
- study of radionuclide migration through trophic chains [8–11];
- peculiarities of functioning and regulatory and legal support of radioecological monitoring of food products [12–14].

The article [15] examines the peculiarities of food control in the member states of the European Union. These states are obliged to carry out radioecological monitoring of food products and environmental components from the moment of signing the Euratom Treaty. However, we would like to note that there is no newer information on radioecological monitoring (at the time of writing this article) since there is no published information on radio-ecological monitoring in the information access (official websites of the organizations conducting this monitoring, as well as the International Atomic Energy Agency (IAEA) monitoring, methods and methods of determining the level of radioactivity in various components of the environment, according to which certain indicators were determined. Therefore, the authors refer to the generally accepted methods of determining the radioactivity of radionuclides in food products.

Máté, Sobiech-Matura and Altzitzoglou [16] note that to carry out monitoring, it is necessary that the procedures for responding to emergency situations with a radiation factor be implemented and well known to all participants in the process, both from a legal and from a regulatory point of view. For this purpose, a database of environmental radioactivity monitoring was created in the European Union in 1988, with the help of which you can view information that is available to the public [17,18]. However, we would like to note that this database contains information until 2020. That is, generalized information on radioecological monitoring of food products of all EU countries for 2024 is not available.

Monitoring data is crucial in detecting any increase in radiation levels in food products and the environment. This information is used to take appropriate response measures. In the absence of measurement data, scientists rely on mathematical models to predict radiation exposure, which requires monitoring data for identification and verification. You can find more information on this at [19].

Radioecological monitoring of food products is crucial, as demonstrated in the work mentioned in [20]. In response to the Fukushima Daiichi accident in 2011, Japanese authorities established temporary regulatory values for radionuclides in food. A year later, current regulatory values were set and regularly monitored by checking radionuclides in food. Any food item that exceeded the standard limits was not distributed due to Japan's rigorous food management system.

After the accident at the Chornobyl Nuclear Power Plant in 1986, a similar situation arose. Radionuclides spread in the territories of Ukraine, leading to the establishment of temporary regulatory values for food products. It was only in 1997 that radiation safety standards were approved in Ukraine, specifying the permissible levels of radiation.

Thus, effective functioning of radioecological monitoring of food is a crucial task for every country worldwide as it directly impacts public health.

Objective: to analyse the data and compare the regulatory framework for food quality management within the framework of radioecological monitoring.

3. Results of the study

Radioecological monitoring is the collection pf primary information (measurement of the dose rate absorbed in the air, determination of the content of radionuclides in environmental objects, food, drinking water, etc.) for the purpose of its further use for radiation-hygienic and domestic monitoring. The control of food for radionuclide content is a crucial component of radioecological monitoring [2].

Internal exposure resulting from the ingestion of radioactive substances present in crops and livestock products in the primary cause of radiation dose in individuals living in areas contaminated with radionuclides.

The following section will analyse data on the radionuclide content in food, allowing us to identify the specificities of radioecological monitoring in different countries worldwide.

3.1. France

Monitoring of radioactivity in food in France at the national level is carried out by the Direction générale de l'alimentation (DGAL) in cooperation with the Institut de radioprotection et de sûreté nucléaire (IRSN) [21]. This includes:

- monitoring of foods exposed to potential sources of radioactive contamination (areas close to the nuclear base);
- light departmental monitoring: characterisation of the radiological quality of food (in particular, mil) outside the direct influence of the most important nuclear facilities;
- monitoring in areas affected by radioactive residues (zones de remanence);
- coastal monitoring.

The most important radionuclides tested are ^{134}Cs and ^{137}Cs. The IRSN carries out additional analyses on the samples submitted to check for several natural and artificial radioactive elements. To ensure that samples are representative for certain types of analysis (especially considering seasonal random factors), milk sampling may distribute over the year. In these cases, a sample is taken from the following the same producer for each quarterly or half-yearly sample. In addition to collecting milk samples from farms located near nuclear facilities, samples from cooperatives or dairies allow representative reference values to be obtained for the total production of cow's, sheep's, and goat's milk in the region and for health monitoring at national level. This monitoring also allows the maintenance of a network of competent laboratories [21]. This network is vital in the event of a crisis. The sampling frequency (in most cases annual) can increase in case of a radiological event. At the Orano La Hague site, there are three sampling points in Digulleville where the Ministry of Agriculture takes a milk sample every quarter and sends it to the IRSN. There is analysis for free tritium, ^{129}I, ^{14}C, ^{90}Sr and gamma emitters. One meat sampling point is selected annually to analyse bound tritium, ^{14}C, ^{90}Sr and gamma. As part of the coastal monitoring, three sampling points located in the municipalities of Barfleur, Goury and Saint-Georges-de-la-Riviere, where fish are sampled annually for bound tritium,^{14}C, ^{90}Sr, plutonium isotopes, ^{241}Am and gamma emitters.

3.2. Spain

The Spanish Nuclear Safety Council (CSN) manages the National Radiological Surveillance Network, consisting of automatic and sampling stations. This network provides information on the levels of radioactivity in air, water, soil and basic foodstuffs [22].

Let us consider how the radioecological monitoring of food is carried out in the city of Palomares. The main economic activity of this town is intensive agriculture, namely animal products such as milk, honey, and fish. Intensive radioecological monitoring has been carried out in this region for about 50 years due to the release of plutonium and other radioactive materials following the crash of North American military aircraft, one of which was carrying thermonuclear bobs [9].

Cultivated vegetables are collecting at 16 stations in different farms. Intensive agriculture is carried out both in open ground and in greenhouses. The main products harvested are lettuce, peppers, cucumbers, peas, lima beans, watermelons, tomatoes, zucchini, green beats, broccoli, oranges, olives, etc. The type of vegetables accepted at each station may vary in different seasons, depending on the choice of the owner who grows them. Edible animal products such as honey, goat's milk and fish are collecting near Palomares. All these foods are analysing for $^{239+240}$Pu and ^{241}Am at the RERA laboratories in Madrid [22, 23].

3.3. The United Kingdom

In England and Wales, the Food Standards Agency and the Environment Agency monitor food and non-food (including seawater, sediments, and dose rates). The Scottish Environment

Protection Agency and the Northen Ireland Environment Agency monitor food and non-food products in Scotland and Northern Ireland respectively. Food monitoring includes the collection and analysis of cow's milk. The Food Standards Agency and the Scottish Environment Protection Agency also monitor milk and table food remotely collected from nuclear-licensed sites in the UK [24].

The Northern Ireland Environment Agency monitors the long-range impact of liquid discharges from the UK's largest nuclear complex, Sellafield, into the Irish Sea. It is sampling fish, shellfish and indicator materials from several locations along the coastline (figure 2).

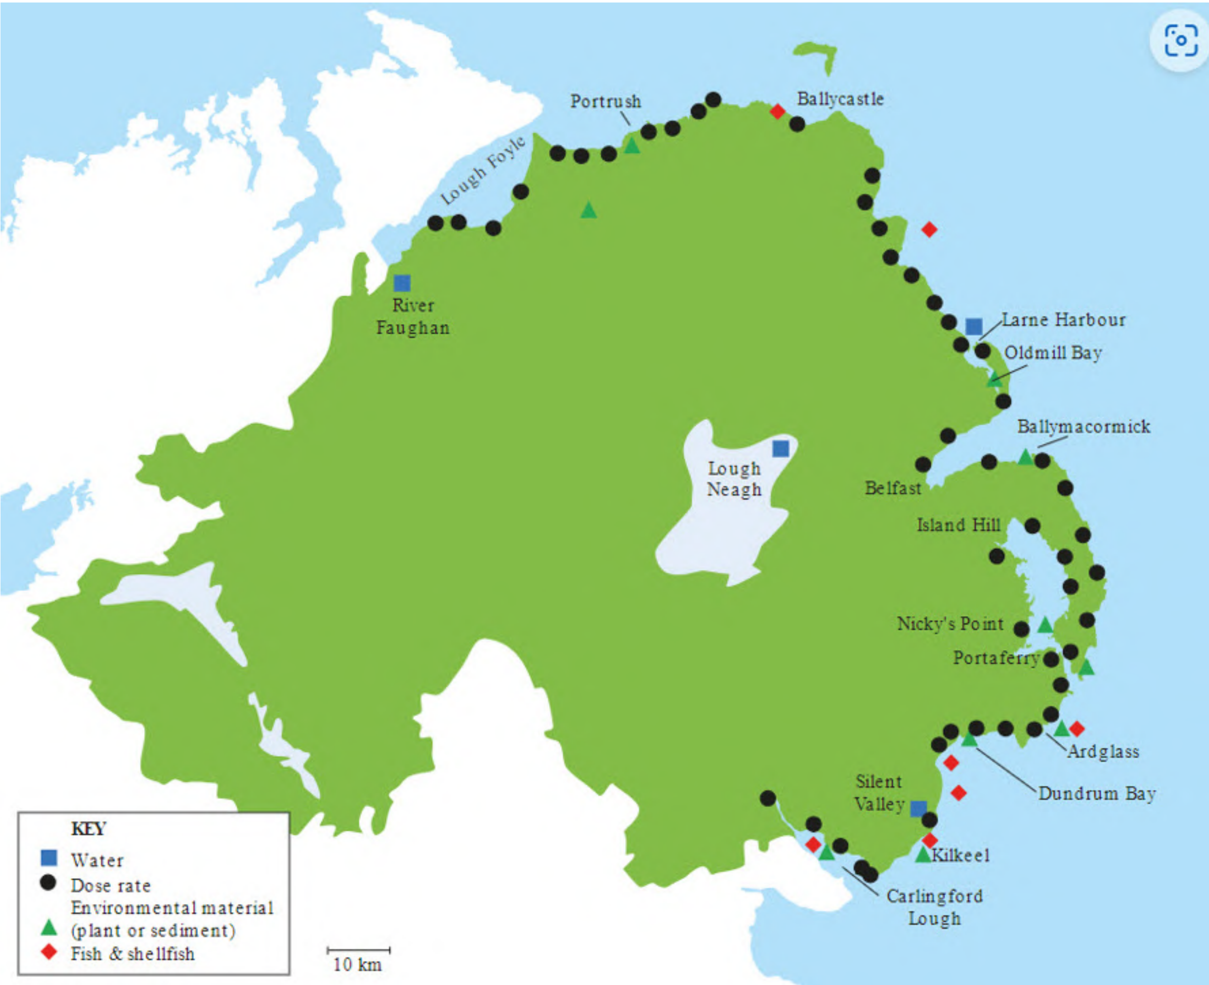

Figure 2. Monitoring sampling locations in Northern Ireland [24].

In 2022, the main effect of Sellafield releases was observed in technetium-99 concentrations in shellfish and seaweed samples. Concentrations of cesium-137 were low and generally similar to those observed in 2021. Low levels of transuranic radionuclides have also been detected in 2022. Table 1 shows the concentrations of radionuclides activities in seafood from Northen Ireland [25].

In 2022, a programme was implemented to sample at UK dairies for radionuclides. This programme provides helpful information that can be used to compare data from farms located near nuclear-licensed facilities and other establishments that may increase values above background concentrations of radionuclide activity [24].

The results of milk monitoring in 2022 were similar to those of previous years, Average carbon-14 concentrations in England, Northern Ireland, Wales and Scotland were close to the expected

Table 1. Concentration of radionuclides in seafood in Northern Ireland.

background concentration in milk. The maximum carbon-14 concentrations in milk for England (Dorset and Kent), Northern Ireland (Co. Tyrone), Wales (Clwyd) and Scotland (Dumfriesshire and Nairnshire) were 22, 25, 43 and less than 16 Bq/L, respectively. As in previous years, tritium concentrations were below the limit at all remote sites. Strontium-90 concentrations were below (or slightly above) the values in 2022, with the UK average concentration being less than 0.033 Bq/L in 2022 (0.037 Bq/L in 2021). In the past, the highest concentrations of radiocesium in milk were in the regions that received the highest amount of radioactive fallout from Chornobyl. However, now the concentrations are very low, and it is impossible to distinguish this trend [25, 26].

The programme to monitor natural and artificial radionuclides in crops (in England, Wales, and the Channel Islands) as a check on general food contamination (away from nuclear facilities) was discontinued in 2014 [25].

3.4. Germany

Radioecological monitoring of food in Germany carried out by the Bundesamt für Strahlenschutz. In the past, artificial radionuclides from the atmosphere have been deposited on plant and animal food in Germany following the Chornobyl accident and atmospheric nuclear weapons testing. Southern Germany was particularly affected by the Chornobyl accident. Today, food produced in Germany has cesium-137 levels of a few becquerels per kilogram fresh weight or less. However, some types of edible wild mushrooms and game such as wild boar, may have significantly higher levels of contamination [27].

As part of the Integrated Measuring and Information System for the Surveillance of Environmental Radioactivity, samples of agricultural products and drinking water produced in Germany are regularly [28].

In modern laboratories in Berlin, the raw milk from farms in the suburbs of Berlin was analysed for ^{90}Sr. Milk samples were subjected to gamma spectrometric analysis.

Plants, food, and feed are analysed based on the National Metrological Institute's nuclide library, which is constantly updated with the latest available information. Data on the following nuclides are provided regularly: ^{40}K, ^{60}Co, ^{103}Ru, ^{131}I, ^{132}Te, ^{134}Cs, ^{137}Cs, ^{144}Ce. Reporting obligations for monitoring programmes under the REI Guidelines are limited ^{40}K, ^{60}Co, ^{134}Cs and ^{137}Cs. Any additional nuclides detected during analyses (e.g. ^{7}Be) are also reported [28].

Other foodstuff (meat of cows, calves, pigs and poultry) is also subject to gamma spectrometric analysis as foodstuffs of animal origin. About 20 measurements are carried out each year. Samples (approximately 1.5 to 2.5 kg each) are purchased from regional farms or slaughterhouses [28].

Regular official monitoring of imported foodstuff does not include measures to detect potential radioactive contamination. However, imported goods may be inspected for the Fukushima and Chornobyl accidents. Samples are taken at the veterinary border inspection post at Berlin-Tegel airport. Samples are tested at the radiation monitoring station of the Berlin-Brandenburg State Laboratory in [27, 28].

3.5. China

National Nuclear Safety Administration (NNSA) is improving the management of the national environmental radiation monitoring network. The NNSA is providing recommendations to environmental protection authorities in all provinces, autonomous regions, and municipalities. The NNSA is also strengthening radioecological monitoring of the marine environmental in connection with the release of treated wastewater from the Fukushima NPP in 2023. A programme has been confidently developed to create comprehensive plans or monitoring radioactivity in the marine environment. Ongoing and decisive work is being done to ensure the highest quality of radiation monitoring [29].

Figure 3 displays the activity concentrations of ^{90}Sr (A) and ^{137}Cs (B) in various food samples collected around different NPPs in China from 2012 to 2019. The presented figure demonstrates that the radionuclides concentrations found in rice, salsa, muller, and crucian carp are well below the regulatory limit for general-purpose food in China. Therefore, we can confidently conclude that during the specified period, the food in the vicinity of the NPP was within the normal range [30].

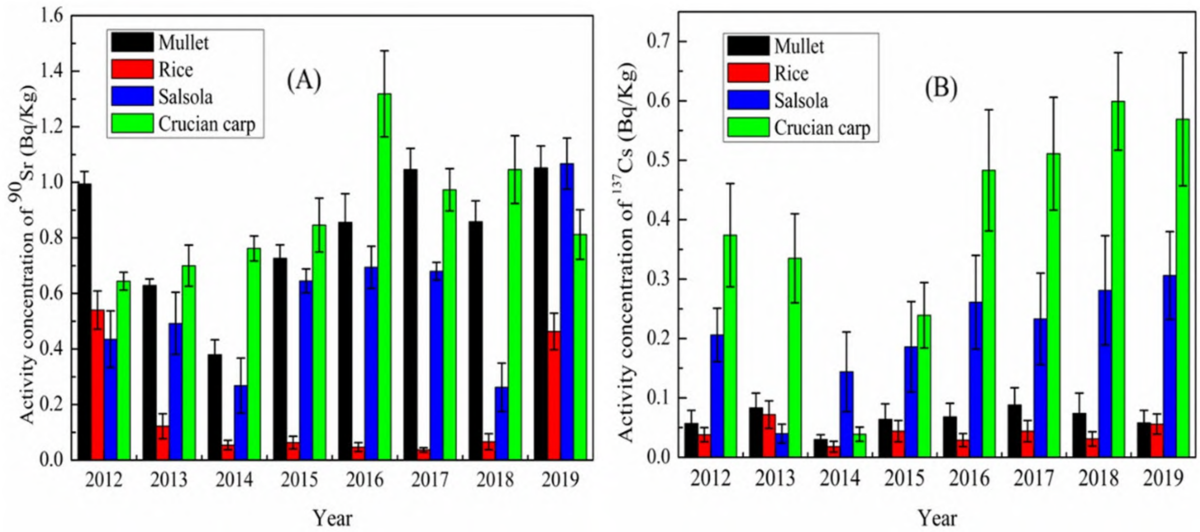

Figure 3. Radionuclide activity concentrations in different food samples [30].

According to [31], hairtail had relatively high concentrations of ^{137}Cs, with the maximum value (0.13 ± 0.01 Bq/kg) observed in 2015. All samples of milk, kelp, and crucian carp had concentrations of ^{137}Cs below the respective minimum detectable activity concentrations. Most samples of rice and salsola also had concentrations below the minimum detectable activity. The measured activity concentrations of ^{90}Sr from 2012-2019 in milk, rice, salsa, kelp, grass carp and crucian carp fall within the ranges of (0.11 ± 0.06) -(0.30 ± 0.04) Bq/l, (0.029 ± 0.009)-(0.16 ± 0.08) Bq/kg, (0.081 ± 0.008)-(0.64 ± 0.06) Bq/kg, (0.067 ± 0. 023)-(1.3 ± 0.4) Bq/kg, (0.18 ± 0.06) -(0.74 ± 0.10) Bq/kg, (0.33 ± 0.08) -(1.10 ± 0.05) Bq/kg, respectively. It was noted that the concentration of ^{90}Sr varied significantly depending on the type of food. Elevated mean ^{90}Sr

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012129 doi:10.1088/1755-1315/1415/1/012129

levels were observed in rice, salsola, and crucian carp from the vicinity (Haiyan/Haining) of the Qinshan NPP from 2012 to 2019 when compared to food from Hangzhou. This is a probably due of the impact of radioactive releases from the Quinshan NPP [31].

3.6. Ukraine

The State Service of Ukraine on Food Safety and Consumer Protection carries out radiation monitoring of the level of radioactive contamination of agricultural products and food by the legislation of Ukraine (`https://zakon.rada.gov.ua/laws/show/667-2015-%D0%BF#n9`). All information on the level of activity of radionuclides in food in different regions of Ukraine is available on the website of this institution (`https://dpss.gov.ua/`). The monitoring laboratories of the Ministry of Agrarian Policy and Food of Ukraine also carry out monitoring in place of concentration of radioactive substances in soil and food. The Ukrainian Research Institute of Agricultural Radiology (a structural unit of the NULES of Ukraine) deals with radiation monitoring of agrobiocenoses, including radiation monitoring of products in contaminated areas. For information on ^{137}Cs contamination in food, please visit `http://uiar.org.ua/Ukr/index.htm`.

In paper [32] describes the results of a study of ^{137}Cs and ^{90}Sr radioactivity in vegetable crops grown in the Kyiv region in 2015-2018. The study found that the lowest ^{137}Cs activity was in potatoes, onions, and cucumbers. It was twice as high in zucchini and bell peppers, almost four time higher in carrots and tomatoes, almost eight times higher in beets and radishes, and 11 times higher in beans. The activity of ^{90}Sr in vegetable crops varied significantly across different types of vegetables. Onions had the lowest activity, while tomatoes and cucumbers had twice as much activity. Sweet peppers had four times higher activity, potatoes and cabbage had almost ten times higher activity, and zucchini had twenty times higher activity. Table beets, carrots, radish, and beans had the highest activity, with thirty times higher activity compared to onions.

The study [33] investigated the content of certain pollutants, such as heavy metals and radionuclides, in meat from various types of industrial production animals sold in retail chains in the Kyiv region. The analysis of radionuclide accumulation in the studied meat products confirms that their contamination level was well below the national maximum permissible levels of radionuclides in food products regulated by the state hygiene standards.

4. Discussion

Although radionuclides occur naturally in the environment, their presence can have negative impacts on living organisms. Accidents at nuclear power plants like ChNPP in Ukraine and Fukushima-1 NPP in Japan, as well as nuclear weapons testing, have released artificial radionuclides into the environment, increasing the level of radiation in various parts of the world. Given the continued growth of the nuclear industry and the potential for accidents at nuclear facilities, it is essential to regularly monitor the presence of radionuclides in various settings, including food products, water samples, and the air we breathe. This is a critical task for organizations at all levels to ensure a safe and comfortable life for society.

The IAEA is responsible for regulating the use of nuclear energy and weapons throughout the world. This agency establishes safety and environmental standards related to nuclear activities. All countries that utilize nuclear installations for scientific or civil purposes must provide detailed reports on their operation, including information on the nuclear fuel cycle and environmental pollution control measures.

Various emergencies with a radioactive damage factor inevitably have a certain impact on food and drinking water. To provide the population with high-quality food products, it is necessary to constantly carry out radioecological monitoring of food products and visualize (make public) the relevant information obtained for the public's awareness.

The authors of this study gathered and analysed data from open sources to determine the level of radionuclides in food products in different countries. They compared the content of the two most common artificial radionuclides, strontium-90 and cesium-137, which can be life-threatening as they can replace potassium and calcium in the body. The study also examined how the levels of these radionuclides compare with the national standards of different countries. These radionuclides are formed during the decay of uranium and are present in most parts of the world as pollutants. Table 2 shows the permissible levels of ^{137}Cs and ^{90}Sr radionuclides in different food products in Ukraine, the European Union, China, and South Korea.

Table 2. Radioactivity levels of 137-cesium and 90-strontium in food products in different countries according to their legislation (Bq/l, Bq/kg) [34–37].

№	Material	Ukraine		The European Union		China		South Korea	
		^{137}Cs	^{90}Sr	^{137}Cs	^{90}Sr	^{137}Cs	^{90}Sr	^{137}Cs	^{90}Sr
1	Milk and dairy products	100	20	1000	125	330	33	50	10
2	Meat and meat products	200	20	1250	750	290	800	100	1000
3	Fish and fish products	150	35	1250	750	290	800	100	1000
4	Baby food products	40	5	400	75	300	41	50	10
5	Vegetables	40	20	12500	7500	210	77	100	500
6	Potato	60	20	12500	7500	90	33	100	500
7	Grain	50	20	12500	7500	260	96	100	500

From the above limit requirements (norms) for radioactive substances in food in different countries for the sake of human health, each country/region has formulated limit requirements for radioactive elements based on national conditions and food safety perspectives. Given the constant attention to various emergencies with a radioactive damage factor and to reduce the circulation of food with a high content of radionuclides during import, each country ensures strict compliance with the relevant regulations.

Based on table 3, we can conclude that Ukraine has the most stringent regulations on the maximum content of radionuclides in food. After analyzing the IAEA publications, we have compiled table 3 that shows the permissible levels of radionuclides in food products in Ukraine following the accident at the Chornobyl nuclear power plant. It is worth noting that monitoring the migration of radionuclides and their impact on the population has enabled us to determine the maximum level of radionuclide contamination in food products and take appropriate measures. This has helped in reducing the mortality rate among the population and livestock, ensuring a safer life for all.

5. Conclusions

According to the Euratom Treaty and several IAEA treaties, countries that possess nuclear technology must perform radioecological monitoring of the environment and food products.

Table 3. Temporary permissible levels (TPL) of the content of radionuclides in food products (according to IAEA data) (Bq/l, Bq/kg).

№	Material	The date of approval of the TPL after the accident at the ChNPP				
		06.05.1986	30.05.1986	15.12.1987	06.10.1988	22.01.1991
1	Milk and dairy products	3700	370	20	20	20
2	Meat and meat products	-	3700	1850	1850	740
3	Fish and fish products	37000	3700	1850	-	740
4	Baby food products	-	-	370	370	185
5	Vegetables	-	3700	740	740	600
6	Potato	-	3700	740	740	600
7	Grain	-	370	370	370	370

This is necessary to ensure a swift response in case of an emergency that involves radiation damage and to guarantee a secure life for society. All relevant information regarding the level of radioactivity in the environment should be made available for public access by the above-mentioned documents.

This work has compiled and analysed information from open sources around the world concerning the monitoring of radioactivity in food products. This allows for the dissemination of information to the population regarding the levels of radioactivity in their food, as well as the points where raw materials are selected and laboratories that conduct analyses to determine radioactivity.

The comparison of the maximum allowable levels of radionuclides in food products according to the legislation of different countries revealed that Ukraine has the most stringent standards for the maximum content of 137-cesium and 90-strontium.

The authors of a publication suggest that due to the significant delay (usually 3-4 years) in updating data on radioecological monitoring of food products, it would be beneficial to have a single portal where information on the contamination of food products with radionuclides can be published. The European Radiological Data Exchange Platform (EURDEP) could be utilized for atmospheric air radiological monitoring data, making the information readily available for public use, scientific research, and public awareness. This approach would enhance the effectiveness of radioecological monitoring efforts.

Author contributions

The following research results presented in the publication are the joint contribution of individual authors:

- **Andrii V. Iatsyshyn**: idea generation, research relevance substantiation, and preparation of the draft article. Also, analysis of literary sources regarding monitoring of food products, monitoring and regulatory framework in Ukraine, and identification of monitoring subjects.
- **Valeriia O. Kovach**: analysis of literary sources regarding the regulatory framework of the European Union, works related to the monitoring of food products in France, and

maximum permissible levels of 137-cesium and 90-strontium in food products in different countries according to their legislation.

- **Anastasiia M. Lahoiko**: justification of the research relevance, analysis of literary sources regarding food monitoring in Great Britain, availability of various reports on permissible levels of radionuclides concentration in food, impact of ChNPP and Fukushima-1 accidents on the quality of food products, and comparison of the regulatory framework of the studied countries regarding the concentration of radionuclides.
- **Viktor O. Gurieiev**: analysis of literary sources regarding the regulatory framework for the concentration of radionuclides in food products in Asian countries and peculiarities of the functioning of food monitoring in China.
- **Anna A Humeniuk**: analysis of the availability of different reports on permissible levels of radionuclides in food in Germany and Spain.
- **Inna A. Semenets-Orlova**: analysis of literary sources regarding the monitoring of food products and temporary permissible levels of radionuclide content in food products.
- **Roman Shevchuk**: functions and role of food quality management in the aspect of radioecological monitoring.

Abstract. At the United Nations Climate Change Conference (COP26) in Glasgow in autumn 2021, world leaders and participants decided to phase out coal power. Ukraine is committed to shutting down its state-owned coal-fired power plants by 2035. Natural and technical geosystems in coal mining areas have a significant impact on environmental and anthropogenic environmental safety and require comprehensive researchThis scientific article delves into the thorough examination of the impact of augmented radiation levels in the waste piles of the Nadiya mine in the Lviv-Volyn coal basin. The exploitation of the Lviv-Volyn coal basin has led to many negative changes in the flora and fauna, atmosphere, hydrosphere and biosphere, and has significantly affected the life and health of the Ukrainian population. The Nadiya mine waste heaps are located on the outskirts of the town of Sosnivka, Chervonohrad district, Lviv region (Ukraine) on fluvioglacial sands, partially on alluvial sediments of the Western Bug River. The height of the waste heaps is over 42 m and the area is 12 hectares. The spoil heap is bounded by woody vegetation on both sides and agricultural land on the other. The spoil heap is composed of burnt and unburnt rocks with sulfuric acid zones on the burnt pieces. Spontaneous combustion is observed on the spoil heap, in particular at the top, where the radiation background was investigated. The radiation power at the top of the spoil heap was found to be significantly higher than in other areas. The investigations of the radiation background of the Nadiia mine spoil heap showed the equivalent dose rate at the top of the heap, which is 0.42 μSv/h, exceeding the permissible standards of 0.3 μSv/h. It should be noted that the excess radiation background is due to the combustion of rock.

1. Introduction

The coal industryis the basis for sustainable development of the national economy and energy security. Coal mining areas are often plagued with an array of environmental and socio-economic issues, such as land deformations, flooding, salinization, underground and surface water pollution, and depressed zones, all of which pose significant challenges. Coal mines in Ukraine are developed with old and dilapidated coal equipment in challenging mining and geological environments. Chronic underfunding of coal mine environmentalization projects has led to serious changes in the environmental state of the affected areas [1, 2]. The depletion of balance sheet reserves, unprofitability of most mines, difficult geological conditions of mining, and unstable economic situation have led to large-scaleliquidation of mining enterprises. The heightened danger of surface subsidence, flooding of lands, drastic alterations in ground and surface water quality, and impairment of structures and facilities is a direct consequence [3]. Coal mining destroys the landscape and also causes large amounts of wastewater entering mine workings. The treatment of mine water in closed mine reservoirs remains unresolved, and standards governing its discharge into the hydrological network remain to be defined. Mine water contaminated with mineral salts, suspended solids, sulfates and other pollutants causes contamination of aquifers and disruption of their hydrology [4].

The geographical location of the Lviv-Volyn coal basin corresponds to the Lesser Polissya area, whose climate is influenced by Atlantic air masses. Since the Chervonohrad mining district of the Lviv-Volyn coal basin was the first to be developed, its waste heaps contain the largest amount of rock. One of the largest mines in the district is the Nadiya mine, with a waste heap volume of over 2869.4 thousand m^3. The ash content in the rock is over 83.1% and sulfur is 2.4%The density of the rock is over 2.25 kg/m^3. The base area of the waste heap is 120 thousand m^2, the height is 53 m, the angle of rock dumping along the contour is 36°, and the annual rock supply to the heap is more than 9.8 thousand m^3 (according to the Passport of the waste heap No. 1 of the Nadiya mine, as adjusted in September 2021). In general, rock dumping began in August 1962, and rock combustion began in September 1963 and continues in several locations to this day. Intensive rock combustion took place from 1975 to 1979 [5]. Currently, the surface of the waste heap is inhabited by pioneer species, including the moss *Campylopus introflexus*. Within a relatively short period of time, *Campylopus introflexus* has significantly increased the projective cover on the waste heap, additionally, the species contributes to the accumulation of organic carbon and the formation of a humus layer of the substrate. It was noted that a decrease in the chlorophyll *a/b* ratio, and an increase in the content of chlorophylls versus carotenoids under conditions of inhibition of chlorophyll photochemical activity play an important role in protecting the photosynthetic system of C. *introflexus* [6, 7].

Considering the numerous scientific studies of [8–10] related to the assessment of the environmental hazard of coal mine waste heaps, it should be noted that the problem is extremely relevant today. Technogenic and environmental safety of coal mines directly depends on the state of financing and timeliness of environmental protection measures. Identifying and eliminating the root causes of an environmental issue is usually a more cost-effective strategy than the present expenses incurred in battling the aftermath of the same issue. Mining activities lead to a number of phenomena and processes that have a negative environmental and technological impact. These phenomena and their consequences are currently poorly understood, unpredictable and mostly uncontrollable. The potential danger posed by a waste dump to the environment is influenced by various factors, including the chemical and mineral makeup of the rocks, physical and chemical properties of internal and external transformation along with climatic and hydrogeological conditions, sensitivity of degradation processes, and heightened radiation levels [11]. Each waste heap has certain characteristics and a specific negative impact on the environment, flora and fauna, and human health, depending on its location [12]. The degree and scope of the impact caused by a human-made hazard is determined by its geographical placement and the individual who is affected by its adverse effects [13, 14].

Thus, factors such as the age of the dumping and the processes of combustion of waste rock prompted us to investigate the technogenic hazard of the Nadiya mine dump in the Lviv-Volyn coal basin [15].

2. Material and methods

2.1. Edaphic and climatic conditions of the research

Chervonohrad is situated in the northern region of Lviv oblast, at a distance of 80 km from the oblast's center and 70 km from the border with the Republic of Poland. The area of the region is 21 km^2 (Chervonohrad – 17.8 km^2; Sosnivka – 2 km^2; Hirnyk – 1.2 km^2). The study area is characterized by the dominant processing and mining industry. The city of Chervonohrad is located in the Western Ukrainian forest-steppe zone and Lesser Polissia, at the confluence of the Solokia and Rata tributaries into the Western Bug River. Chervonohrad is located in a humid, moderately warm agroclimatic zone with sufficient soil moisture. The climate is temperate continental, characterized by mildness and high humidity. Main natural resources: Zabuzhske and Mezhyrychanske coal deposits. The region has over 2097 hectares in use, including 1779 hectares in Chervonohrad, 198 hectares in Sosnivka, and 120 hectares in Hirnyk. The Nadiya mine is located on the outskirts of Sosnivka on fluvio-glacial sands, partly on alluvial deposits of the Western Bug River, and has been in operation since 1962. The height is over 42 m, the base area is over 12 hectares. The spoil heap is bounded by woody vegetation on both sides and agricultural land on the other [16]. The elevated section comprises embankments, depressions, and overgrown regions. The spoil heap is formed by burnt and unburnt rocks with sulfuric acid zones on the burnt pieces. Linear erosion is present on the side surfaces [17]. In some places, the slopes of the waste heap are quite steep and abrupt and form vertical walls. The southeastern side of the spoil heap and the western part of the spoil heap are covered with mine rock, making the topography of the spoil heap even more complicated [18–20].

2.2. Edaphic and climatic conditions of the research

We chose 7 different sites near the Nadiya mine to analyze the environmental situation and take substrate samples for radiation background analysis. The samples were taken from depths of 0-15 cm and 0-20 cm, as well as from an anthropogenic reservoir which accumulated the waste formed from anthropogenic activities (figure 1).

Seven study areas of the Nadiya mine were selected to study the radiation background of the waste heap, since the combustion process was observed there: 1 – at the foot of the spoil heap in relatively favorable growth conditions; 2 – on the slope, where intensive water-erosion outcrops 1-2 m wide and 0.5-1 m deep are present; 3 – on the terraced slope, with numerous places of water-erosion outcrops (1-1.5 m wide, 0.5-1 m in width, 0.5-1 m in depth), deflation (wind erosion), places of fire, discharge of fuels and lubricants, household waste, as well as increased soil cover density, and as a result, almost complete absence of above-ground grass cover; 4 – at the foot of the spoil heap of the forest area, in some places there are traces of soil washout and exposure of tree root systems (danger of tree fall); 5 – on the top of the waste heap, mostly flat with small hilly areas and minor relief depressions; 6 – control, at a distance of 3 km from the waste heap in the forest area with practically no anthropogenic impact (there are natural forest roads); 7 – from an anthropogenic reservoir, at a distance of 2 km from the western side of the waste heap.

2.3. Research devices

The radiation levels of the waste heaps were measured with the SOEKS environmental tester (shown in figure 2) in compliance with the guidelines of Ukraine's Radiation Safety Standards (NRBU-93) [21]. Modeling of radiation background is carried out using computer program Surfer. The intensity of illumination was determined using a digital luxmeter with a remote sensor (model LX1010BS, measuring range 1-100000 Lx), measurement accuracy ± 4% operating temperature of the environment -10°C...+50°C. Humidity and air temperature were determined using a UNI-T UT333 digital thermo-hygrometer (humidity 0-100% temperature: -10°C...+60°C), error ±1°C/±5%. The wind speed was measured using a mini-anemometer HT-383, measurement accuracy ±1.5 m/s, measurement range 0...30 m/s. The substrate temperature was measured using an AMT-300 analyzer, temperature error ±1°C, measuring range from +9°C to +50°C.

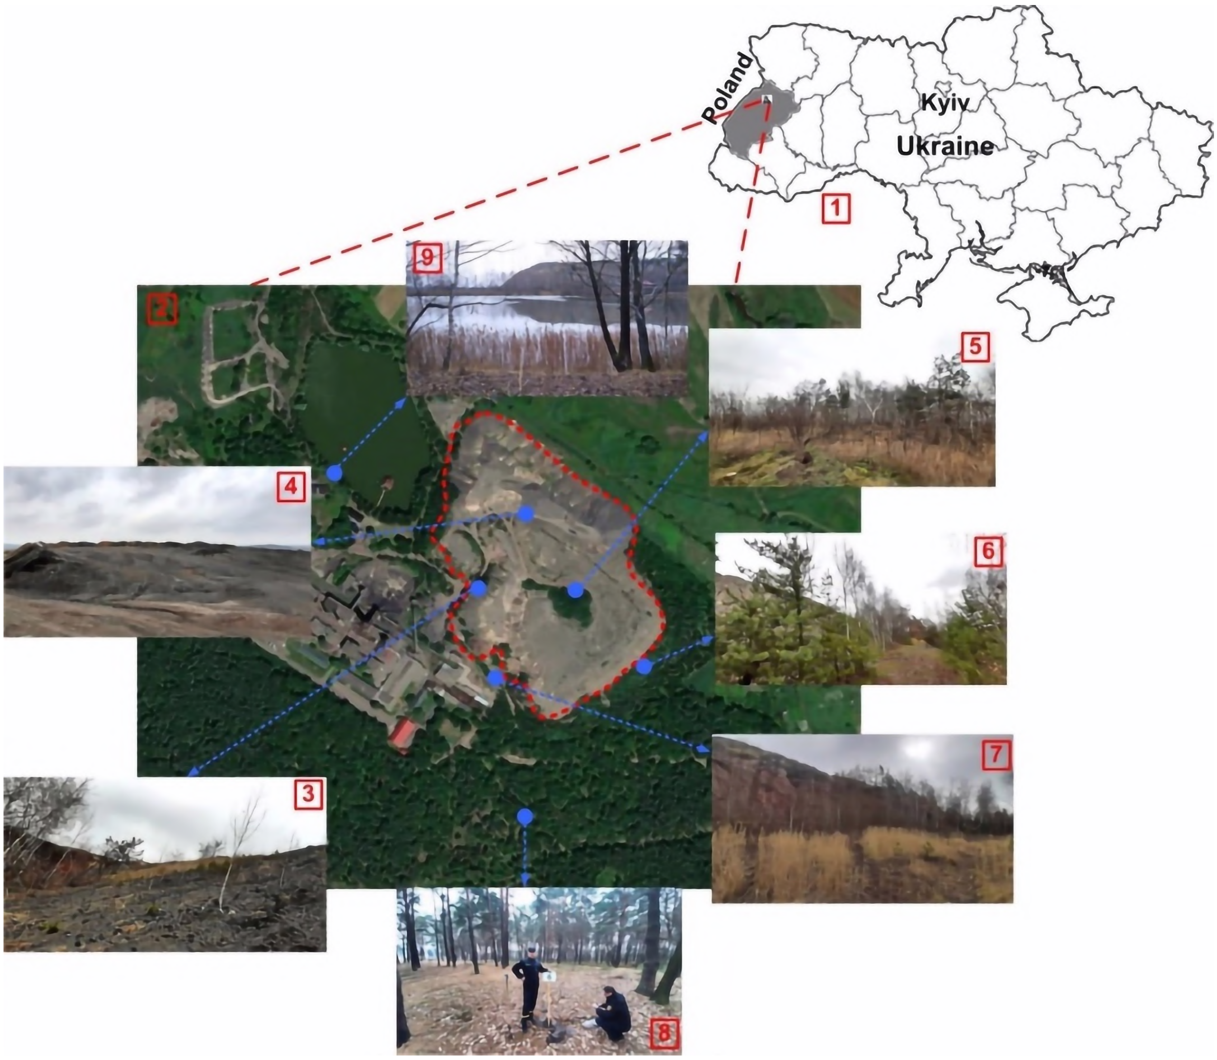

Figure 1. Location of the study site: 1 – map of Ukraine with the designation of the Nadiya mine; 2 – image of the waste heap of the Nadiya mine using GoogleMaps; 3-9 – sampling points.

3. Results and discussion

3.1. Radiation background research

The radiation background with distance from the waste heap was measured to study the impact of waste heaps on natural phytomelioration. The general characteristics of the studied areas are shown in table 1.

According to the radiation background studies of the Nadiya mine waste heap, it was found that at the level of 10 m from the foot of the heap and on the terraced slope (where there are numerous places of water erosion outlets, places of waste heap fire, fuel and lubricants drainage, household waste), the radiation power is significantly higher than in other areas, except for the top of the heap. Studies of the radiation background of the Nadiya mine spoil heap showed that the equivalent dose rate of photon ionizing radiation on the surface of the decaying heap is 0.42 μSv/h, which exceeds the permissible radiation background values established by the radiation safety standards of Ukraine (0.3 μSv/h). In addition to exceeding the permissible standards, the radiation background at the top of the waste heap at Nadiya mine also exceeds the background values for Sosnivka (0.12 μSv/h). It should be noted that the highest values of the equivalent

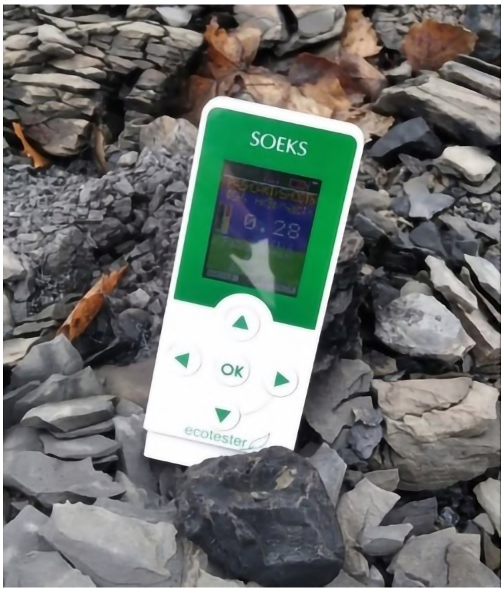

Figure 2. SOEKS environmental tester operation.

Table 1. Characteristics of the studied areas of the Nadiya mine waste heap.

Location	Radiation background, μSv/h	Lighting intensity, lux	Air humidity, %	Wind rate, m/s	Substrate temperature, °C
The foot of the heap	0.25	28350	82	3.6	5
Slope	0.18	30170	80	3.9	6
Terraced slope	0.29	32100	79	4.1	6
The foot of a terraced forest plot	0.21	25390	84	2.5	4
Top of the heap	0.42	34630	72	4.5	6
Control point 3 km from the waste heap	0.12	22480	83	1.6	5
Reservoir	0.17	–	–	–	–

dose rate were observed near the burning areas of certain parts of the waste heap and amounted to 0.21, 0.25, 0.29 and 0.42 μSv/h (figure 3). The lowest values were recorded in the forest area 3 km from the waste heap and near the man-made reservoir 2 km from the waste heap, which amounted to 0.12 and 0.17 μSv/h.

3.2. Modeling the spread of radiation background

Researchers say that burning waste rock can lead to an increase in the radiation background [22]. According to the studies, it was confirmed that the radiation power on the top and slopes of the Nadiya mine spoil heap, where the heap is burned, is much higher than in other areas [23]. The study of the radiation background of the investigated waste heap showed an average equivalent dose rate on the surface of the decaying waste heap of 0.27 μSv/h, which does not exceed the radiation safety standards but exceeds the background values for the region [24, 25]. The modeling of radiation background propagation in the edaphic horizons of the Nadiya mine waste heap is shown in (figure 4).

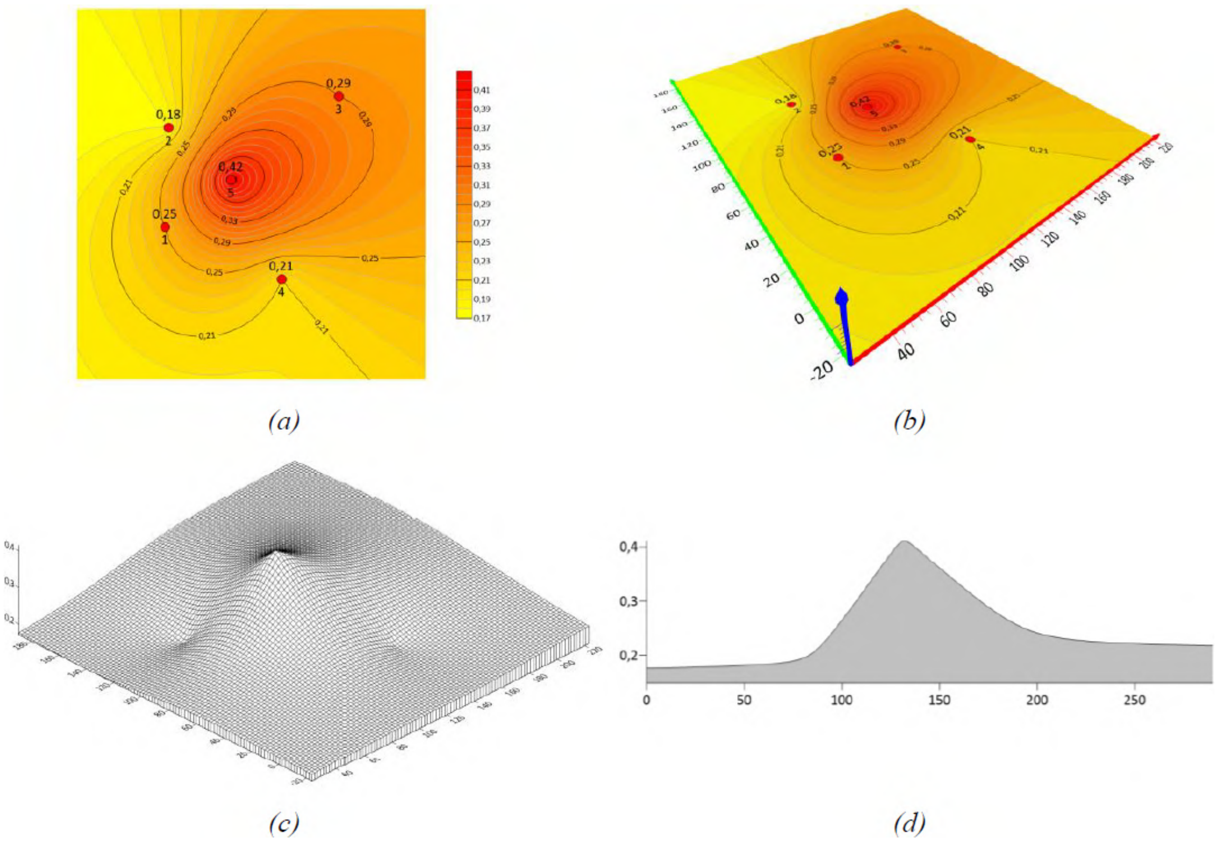

Figure 4. Radiation background propagation in the edaphic horizons of the Nadiya mine waste heap, μSv/h ((a), (b) – spread of the highest equivalent dose rate of photon ionizing radiation; (c), (d) – mine waste heap horizon 0-0.5 m).

The results of modeling the spread of radiation background are consistent with the data of phytocoenological studies. The slopes exhibit a multitude of instances of erosion caused by wind and water, fire-prone areas, release of household waste, fuel and lubricants, and high-intensity water erosion.

3.3. Influence of radiation background on the development of vegetation species composition in a coal mine

During the study of the spread of radiation background in the edaphic horizons of the Nadiia mine waste heap, a variety of species composition of the grass cover was observed, which was greater. Only single groups of Canada bluegrass (*Poa compressa* L.) are found in the grass cover. The smallest distance from the control site with virtually no anthropogenic impact

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012130 doi:10.1088/1755-1315/1415/1/012130

(natural forest plantation with significant forest litter and Scots pine *Pinus sylvestris* L.) is characterized by the foot of the waste heap of the forest site. There are quite favorable growing conditions here. The projected cover of the grass cover is more than 65% and of the tree species more than 60%İn addition to the Canada bluegrass (*Poa compressa* L.), there are such plants as dandelion (*Taraxacum officinale* Webb. ex Wigg.), narrowleaf plantain (*Plantago lanceolata* L.) and other species. Narrow-leaved lupine (*Lupinus angustifolius* L.) and common broom (*Cytisus scoparius* (L.) Link.) also occur on the top and slopes of the waste heap. As for the tree species, silver birch (*Betula pendula* Roth.) 7-9 m high, Scots pine (*Pinus sylvestris* L.) 1-2 m high (up the slope and at the foot (forest zone) of the waste heap can reach 6-7 m high), and *Robinia pseudoacacia* L. – 3-6 m high. The following species grow sporadically: common hawthorn (*Crataegus monogyna* Jacq.), common dog rose (*Rosa canina* L.), goat willow (*Salix caprea* L.) – over 2-5 m high and pedunculate oak (*Quercus robur* L.) – 2-4 m high.

Thus, the models of dynamic or spatial distribution of vegetation, the relationship between vegetation and tree species and the impact of the radiation background, and the assessment of the human impact of the waste heaps at the Nadiia mine can be explained in terms of categories of directions and distances in the multidimensional feature space. However, to reduce the radiation background on waste heaps (especially where it reaches 0.27 μSv/h and above), we recommend planting vegetation and tree species (protective afforestation that reduces the spread of radionuclides) in the ecological and technogenic areas of the waste heap, because radiation has no borders.

4. Conclusions

Thus, the coal industry contributes pollutants to the soil, underground and surface water bodies, air and biota, creating a huge anthropogenic load on subsystems of natural objects. Coal mining and processing waste contains a large number of useful components. In accordance with the requirements of environmental safety and rational nature management, the most efficient way to deal with waste heaps is their complete elimination, but in modern society this way has almost no prospects of realisation, which is due to many economic reasons. That is why the development of new technologies related to environmentally safe and cost-effective disposal of waste heaps is of great importance today.

As mentioned earlier, the coal sector is a major problem for the coal industry and, consequently, for environmental protection. Taking into account the large number and high heterogeneity of waste heaps, as well as excessive radiation background values inherent in areas where rock combustion processes occur (0.21-0.42 μSv/h), any rational decision-making process, despite numerous studies of waste heaps, would not require more information about their composition, structure and location, but much more about appropriate solutions, namely closure of state-owned coal-fired power plants in Ukraine by 2035 (in accordance with the decision at the UN Climate Change Conference to phase out coal-fired power and gradually subsidize fossil fuels, reduce methane emissions by 30% by 2030, and stop deforestation), succession of the vegetation cover of waste heaps, and gradual introduction of natural phytomelioration on coal mine spoil heaps. Environmental safety studies of the natural and technological system of a mining district should be systematic and use a large number of methods and equipment, as their significant impact on the environmental safety of the region is obvious. The prospects for using the research results open up practical bases for the application of methods of the biological stage of reclamation (the so-called natural and artificial phytomelioration), which can reduce radiation and man-made pollution. Thus, continued research in mining areas will expand the range of methods needed to clean the atmosphere, soil, and water bodies from coal mine spoil heaps, while improving the environmental condition of the region. Studying and researching the process of restoring the natural vegetation cover of disturbed lands in the vicinity of coal mines and developing methods for restoring devastated landscapes is extremely important for all coal regions of Ukraine.

We believe that today (in difficult times for Ukraine), it is necessary to carry out reclamation and greening of waste heaps (spoil heaps) and reduce its anthropogenic impact on the urban environment in order to improve the environmental and technological safety of the area. By carrying out these projects, we can not only make rational use of the land damaged by mining, but also dramatically diminish the environmental harm caused by human activity in the state.

Abstract. The characteristic features of nature protection policy in Ukraine are established. The significance of the solutions ecological logistics development for of municipal solid waste in order to reduce the negative impact on the environment has been confirmed. The significance of logistics for reducing the amount of waste and achieving its financial social and environmental goals is presented. The importance of environmental protection information and ecological knowledge as a special resource in innovative activity is emphasized. The characteristic qualities of the ecological approach in the field of logistics have been revealed.

1. Introduction

Given the increasing ecological challenges, it is imperative to examine the critical function ecologically aligned logistics systems have in improving waste management within local communities.

From an environmental perspective, logistics covers the entire life cycle of a product, including the possibility of recycling, the need to dispose of waste in various ways, and the choice of the most environmentally friendly transportation. Waste management logistics systems should include an analysis of the movement of waste from its generation in any production process to its transformation into marketable products or further disposal and safe storage in the environment. The formation of a waste logistics system requires the improvement of economic relations, involves the development of domestic production, state support for enterprises participating in the processes of implementing eco-friendly innovations in economic activities; revitalization of the commercial component and strengthening of the material and technical base.

This examination aims to explore the complex relationship between environmental policies, logistics innovations, and legislative conditions in Ukraine, emphasizing the paramount significance of this topic in today's ecological discussions. The goal is to perform a comprehensive analysis of the current waste management approach, illuminating sustainable practices that harmonize economic development with environmental protection. The results intend to furnish applicable understandings for policymakers, industry players, and the academic field, energizing the dialog towards viable environmental solutions.

2. Literature analysis and problem statement

Effective waste management in local communities involves a variety of strategies and processes that are complex and determined by unique local conditions such as geography, population density, and applicable regulations. This review synthesizes key insights from recent research to illustrate the challenges and solutions in this area.

Kartava, Kartavyi and Khrutba [1] draw attention to the importance of integrating environmental logistics into regional waste management programs, especially emphasizing the need to adapt European experience. They outline the key areas for implementing environmental logistics business strategies, including efficient use of resources, development of safe methods of waste disposal, and development of infrastructure to reduce their negative impact on the environment.

Popovych, Malyovanyi and Popovych [2] focus on the environmental challenges of rural areas, in particular the lack of necessary infrastructure for proper waste management. They emphasize the need to establish waste processing plants and develop a common logistics system to reduce environmental risks through integrated approaches to waste management.

Current research emphasizes the importance of taking into account local territorial characteristics, such as waste generation patterns and sorting dynamics, which critically affect the sustainability and working conditions at waste management facilities. In addition, a study conducted by Passarini et al. [3] in Emilia Romagna, Italy, found that rural areas demonstrate better environmental performance, which is explained by higher rates of separate waste collection and lower total waste generation compared to urban areas.

Predictive modeling is becoming a vital tool to inform the development of municipal waste management policies. By integrating socio-economic and demographic factors, such models allow for the development of tailored policy measures that reflect the diverse needs of different territorial levels [4].

Optimizing waste collection routes in communities not only reduces operational costs but also improves environmental outcomes. Bihun, Lytvyn and Oleksiv [5] demonstrate how strategic route planning significantly contributes to more efficient waste management. The introduction of smart technologies is playing a transformative role in waste management systems. Veloz-Cherrez et al. [6] discuss how systems equipped to monitor waste decomposition can optimize collection schedules and reduce environmental impact by providing real-time data.

Modern international experience offers many effective solutions to address the problem of accumulation of solid waste and the introduction of modern technologies for their implementation. The application of modern management methods involves the introduction of a logistics approach in the development of local waste management programs, which ensures the effective implementation of these programs and reduces the negative impact of waste on the environment. The implementation of the programs involves a wide range of stakeholders, which requires the use of new innovative management methods, such as crowdsourcing networks, as a mechanism for realizing the potential of the public.

The novelty of this study is the introduction of a conceptual model of an environmentally friendly innovative logistics system of waste management, which is integrated and comprehensive for territorial communities. The study focuses on three levels of management: strategic, tactical, and operational. This ensures the development and implementation of programs that include the regulation of production, processing, sorting and collection of waste. The key aspect of novelty is the change of priorities in the interrelationships of municipal solid waste management, the inclusion of environmental awareness and waste management culture of all stakeholders. This approach helps to reduce the negative impact on the environment, optimize waste management processes and efficiently use resources, which opens up new opportunities for creating sustainable and effective waste management systems.

3. Results and discussion

The implementation of a conceptual model of an environmentally safe innovative logistics system of waste management, as an integrated complex system of waste management for united territorial communities (here and after – UTC) (figure 1), is based on three levels of regional management – strategic, tactical, operational.

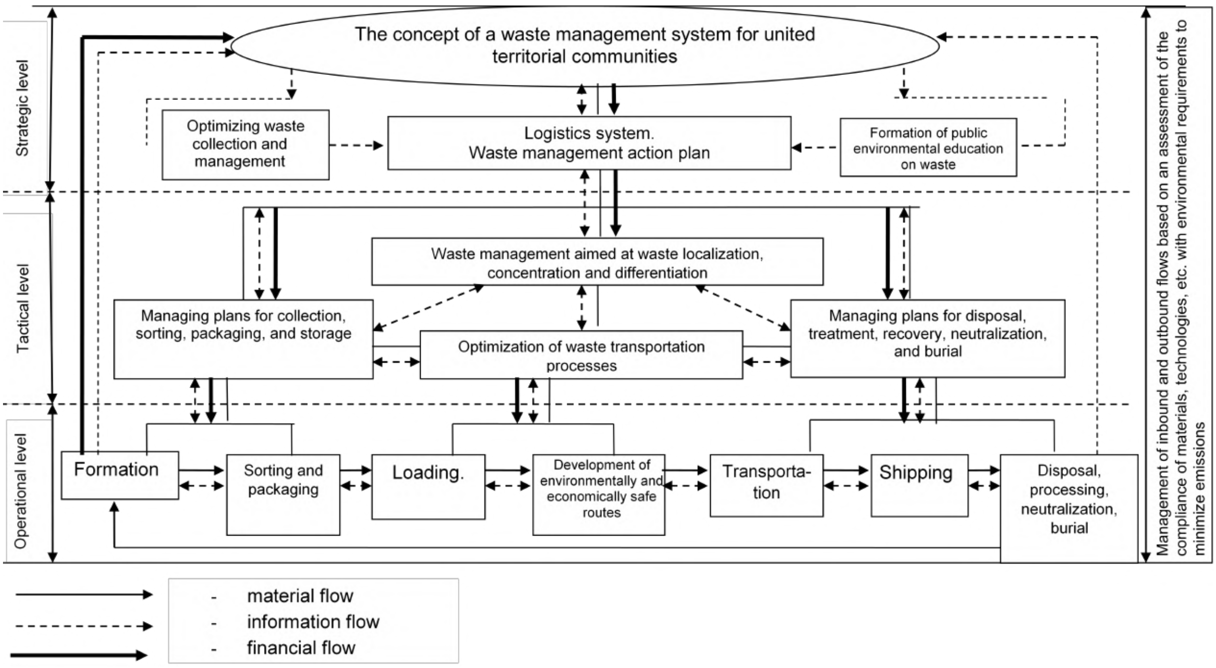

Figure 1. Components of the logistic approach to the waste management system concept for united territorial communities.

The strategic level is determined by compliance with the legislation of Ukraine. The Verkhovna Rada of Ukraine adopted the law "On Waste Management" [7], which will establish new transparent rules for the industry and allow the construction of a modern waste management infrastructure. This bill was developed on the basis of three EU directives – on waste, on waste disposal, and on industrial emissions.

The law provides for:

- introduction of the waste management hierarchy;
- introduction of the "polluter pays" principle;
- introduction of a system of extended producer responsibility, which establishes a requirement for packaging manufacturers to bear responsibility for the full life cycle of created packaging, batteries, accumulators, electrical and electronic equipment, etc.;
- creating an opportunity to attract investments in the construction of waste processing plants;
- introduction of strict European environmental standards for incineration and waste disposal operations in order to prevent harm to human health and the environment;
- the legal basis for short-term and long-term waste management planning;
- introduction of an electronic waste management information system to ensure transparency in the industry and avoid corruption risks, which will consist of open registers, modules for providing administrative services (issuance of documents online), reporting and analysis of static information [8, 9].

The law proposes to solve such problems as uncontrolled disposal of waste at landfills that do not meet environmental standards; fictitious waste processing, when in fact they are processed only according to documents; carrying out operations with waste without permit documentation.

The implementation of this law at the tactical level is possible due to the development and implementation of logistic systems of waste management with minimization of the impact on the environment. The main problems of the existing organization of waste management in the Zhytomyr region include:

- overestimation of costs for transportation due to the fact that the volume of waste to be removed is determined on the basis of theoretical norms of waste generation;
- a decrease in the quality of sanitary cleaning and an increase in the cost of services due to the fact that most often garbage trucks drive half-empty, since the payment for services for the transportation of solid waste is carried out in terms of volume;
- the increase in the number of unauthorized landfills due to the lack of centralized control over the process of transporting solid waste in cities contributes to the increase in the cost of maintaining the necessary sanitary and ecological standards of living in the city.

The advantages of using reverse logistics are protecting the environment from pollution, reducing the amount of household waste, minimizing costs and saving raw materials, materials, fuel and energy, increasing the environmental rating of the enterprise, forming recommendations and services for the purpose of making administrative decisions [10].

The final goal of implementing a logistics approach is the rapid collection of logistics data for the systematic operation of services.

The novelty of the concept of the logistic approach in the management of the waste management system consists in the change of priorities in the distribution of relationships in the management of waste management and includes the formation of environmental awareness and the culture of waste management of all stakeholders. The scheme of the proposed logistic system of functioning of the regional waste management plan for territorial communities with the inclusion of a coordinating agent for waste management is shown in figure 2.

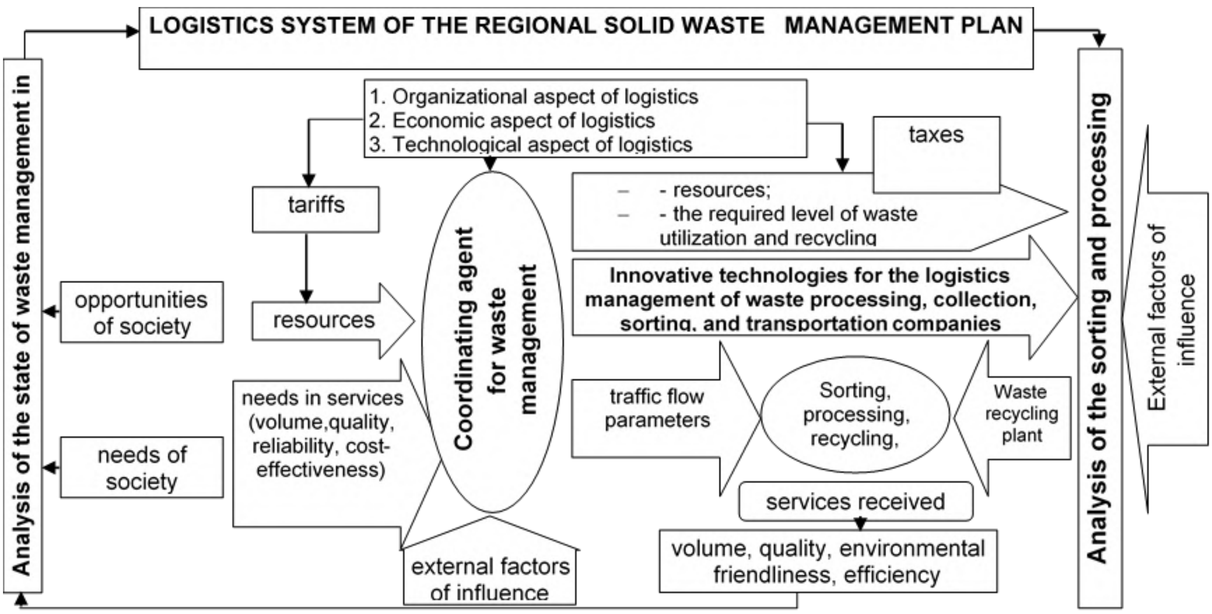

Figure 2. Diagram of the logistics system of the waste management process for territorial communities.

The logistics concept in waste management involves the presence of a coordinating agent and involves the management of knowledge that is applied to new business lines implemented in certain program plans. The coordination agent provides management of all logistics flows of solid waste – financial, material, informational (figure 3). The operation of the system on the scale of this model is focused on stability and duration.

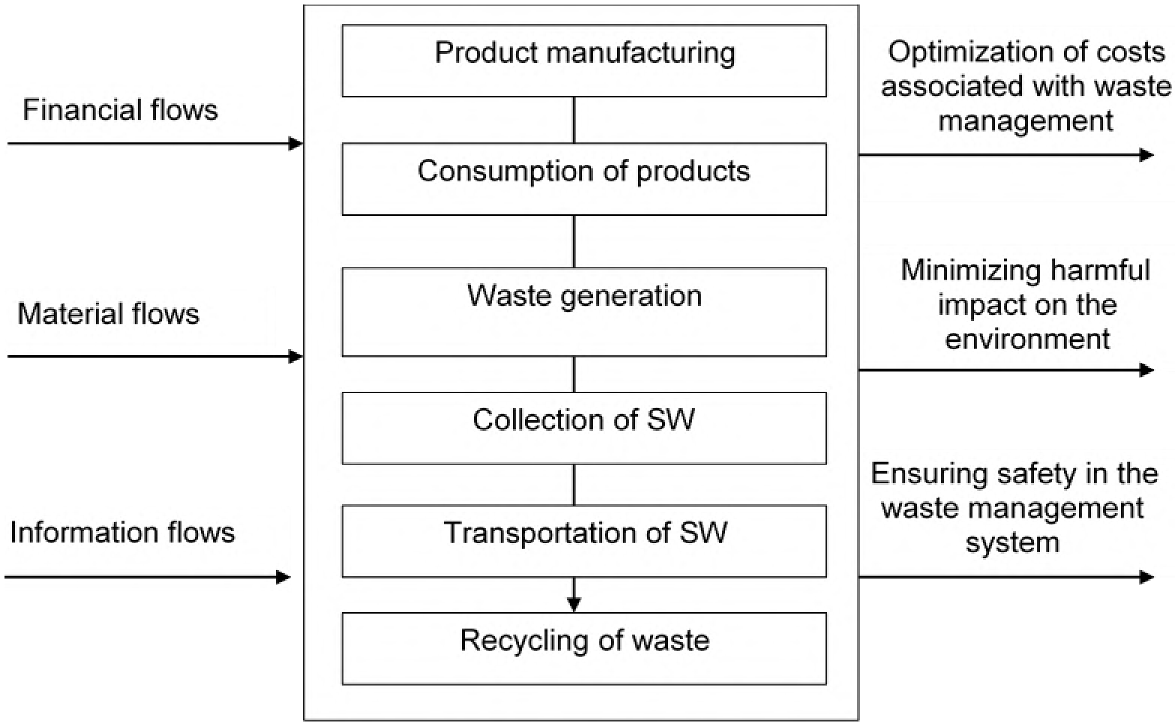

Figure 3. Flows of solid waste in the management of logistics.

The implementation of an ecological logistics business strategy to reduce overall emissions in the management of regional waste management programs for each territorial community should go through four stages:

1) strategic decisions, which are made based on the results of the analysis of the amount of waste, the location and assessment of the potential of waste transport enterprises, waste enterprises, waste storage and disposal sites;
2) the tactical level of planning communal and commercial decisions regarding the production of secondary waste processing products, waste recycling and distribution of finished products, creation of a structure of partnership relations between the processing company and its suppliers, distributors and customers;
3) operative decisions on coordination of the terms of implementation of planned decisions regarding production from resource-valuable raw materials and distribution, redistribution of links to separate material flows of waste and determination of the speed of rotation of the inventory in places of storage or sorting of waste;
4) functional solutions related to the management of material and technical resources during the implementation of planned solutions of the waste management program.

The logistics concept of waste management combines the management of the waste life cycle from generation and accumulation to transformation into a marketable product or safe storage in the environment. The logistics of waste management is influenced by the following factors: the amount of waste generation; basic professional ideas; prevailing scientific and technical concepts; regulatory framework; attitude of the state; attitude of the community and its economic opportunities. The Coordinating Center is assigned for the organization of the waste accounting system created as a result of product consumption, namely: waste accounting; analysis of their morphological state at all stages of their life cycle; collection of solid waste in eco-containers or at points of reception of secondary raw materials; transporting them for processing with subsequent transformation into a finished useful product.

The formation of the material flow of waste is shown in figure 4.

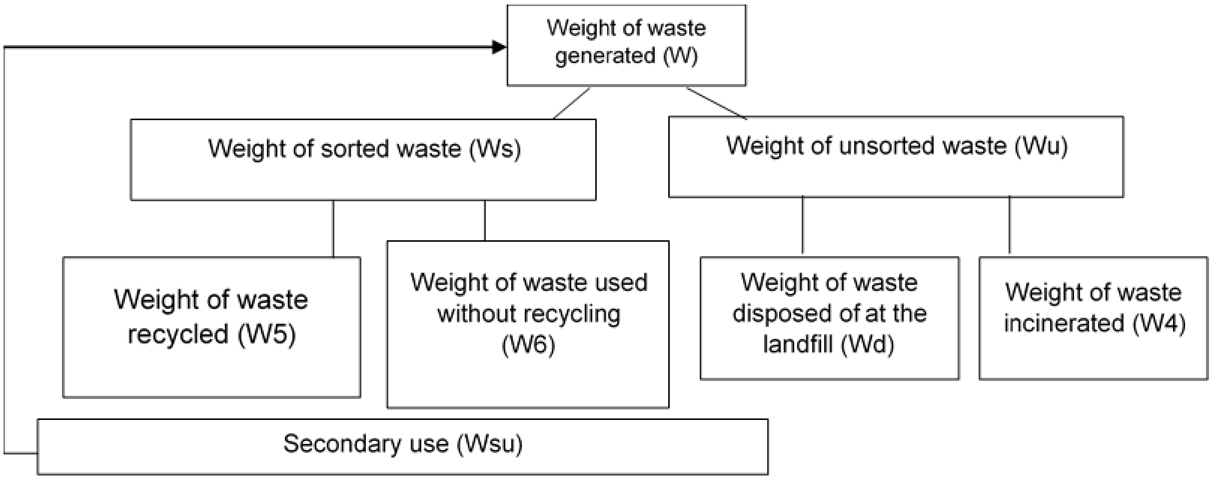

Figure 4. Flows of solid waste in the management of logistics.

Material flows of solid waste can be represented by corresponding sets:

$$W_{SW} = (W_{met}, W_{glass}, W_{other\,waste}, W_{PET\,plastic products}, W_{paper}), \tag{1}$$

where W_{met} is material flows of waste metal products, which have the form of a set:

$$W_{met} = (W_{tin\,cans}, W_{cans}, W_{metal\,covers}), \tag{2}$$

where $W_{tin\,cans}$ is material flows of tin can waste, W_{cans} is material flows of canning can waste, $W_{metal\,covers}$ is material flows of metal lid waste; W_{glass} is material flows of glass waste, which have the form of a set:

$$W_{glass} = (W_{glass\,bottles}, W_{glass\,products}), \tag{3}$$

where $W_{glass\,bottles}$ is material flows of glass bottle waste, $W_{glass\,products}$ is material flows of waste glass products.

$W_{other\,waste}$ is material flows of waste of other waste, which have the form of a set:

$$W_{other\,wastes} = (W_{organic\,species}, W_{debris}, W_{wood}, W_{leaf}, W_{textile}), \tag{4}$$

where $W_{organic\,species}$ is material flows of waste organic waste, W_{debris} is material flows of construction waste, W_{wood} is material flows of wood waste, W_{leaf} is material flows of leaf waste, $W_{textile}$ is material flows of textile waste.

$W_{PET\,plastic products}$ is material flows of waste plastic products, which have the form of a set:

$$W_{PET\,plastic products} = (W_{containers}, W_{bottles}, W_{container}, W_{bottles}, W_{plastic\,covers}, W_{caps}), \tag{5}$$

where $W_{containers}$ is material flows of waste packaging materials, $W_{bottles}$ is material flows of bottle waste, $W_{container}$ is material flows of container waste, $W_{bottles}$ is material flows of bottle waste (cosmetic and household chemicals), $W_{plastic\,covers}$ is material flows of waste plastic covers, W_{caps} is material flows of waste caps.

W_{paper} is material flows of paper waste , which have the form of a set:

$$W_{paper} = (W_{newspapers,magazines}, W_{cardboard\,boxes}, W_{paper\,packaging}, W_{wastepaper}), \tag{6}$$

where $W_{newspapers,magazines}$ is material flows of newspaper, magazine waste, $W_{cardboard\,boxes}$ is material flows of cardboard box waste, $W_{paper\,packaging}$ is material flows of paper packaging waste, $W_{wastepaper}$ is material flows of paper waste.

Management of material flows of waste includes:

- ensuring effective collection of waste in places of their greatest concentration;
- determination of the optimal transportation route, taking into account the possibilities of their sorting.

The movement of the material flow of waste in the logistic scheme of handling waste is depicted in figure 5.

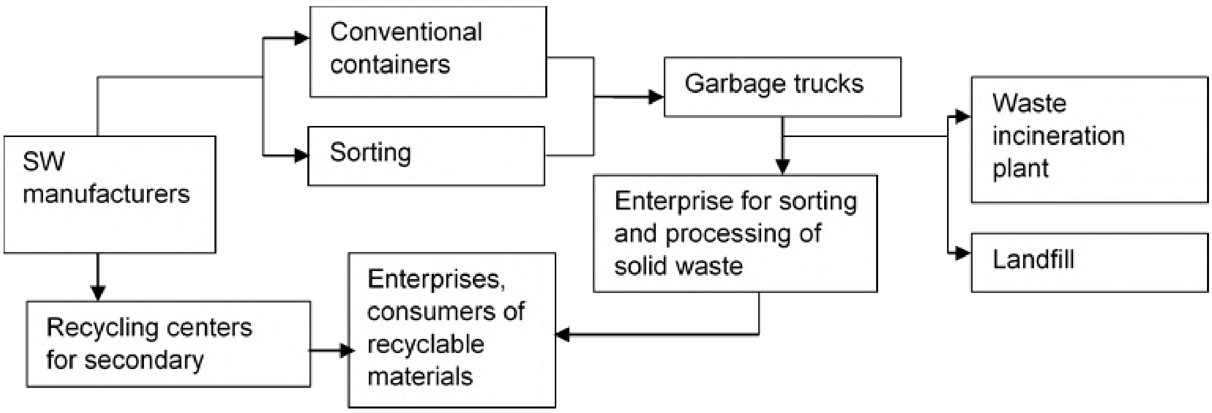

Figure 5. The movement of the material flow of waste in the logistic scheme of the management of solid waste.

The experience of implementing logistics concepts in the regional management of mechanisms of secondary resources to optimize the interests of suppliers and consumers and the ways of applying logistics chains for the organization of the movement of secondary raw materials are discussed in publications [11, 12].

The logistics system in waste management programs consists of two logistics subsystems. The first is the logistics system of direct waste mass movement, which includes the processes of generation, collection, transportation, utilization, and disposal. The second is a logistical program management system, which includes the processes of agreement, selection and implementation of program projects.

The tasks of the logistics system in waste management programs include management of material flows of waste and resources of the program, consulting of financial flows and management of information flows.

The logistics chain of solid waste management is implemented in the integrated logistics concept of the settlement of UTC and includes the following links: primary sorting of municipal solid waste, waste collection, transportation of solid waste, secondary sorting of waste, burial of waste at a landfill and its incineration, processing of solid waste to obtain secondary raw materials and its implementation. The task of optimizing the logistics system is to redistribute material flows in such a way as to reduce waste flows for landfill or incineration and increase flows of secondary use or recycling.

During the operation of logistics systems in the waste management of the region to reduce the total emission of waste, it is important to take initiatives at the lower level of the decision-making hierarchy determined by both economic and environmental benefits. Functional-level solutions focus on increasing fuel efficiency for waste transportation, optimizing vehicle routing, and saving energy at waste collection and sorting sites. The main task is to integrate environmental principles into the strategic planning of logistics and coordination of environmental management at all four levels of decision-making, which will allow achieving the mission of the program at every step of its implementation.

To enhance the management of waste material flows across different territorial areas, we need to address the challenge of uncertain future costs. These costs are related to waste management processes and the utilization of production resources. It's crucial to consider the unique aspects of technological processes and the production resources available to economic entities. Our goal is to develop a production program that minimizes environmental damage during the operation of the waste management system. To build economic-mathematical models, we introduce the following notation [11].

Known quantities:

- n – the volume of solid waste that can be formed in UTC;
- j – number of a separate type of solid waste $j = \overline{(1, n)}$;
- m – the number of types of production resources of business entities in the waste management system;
- i – number of a separate type of production resources $i = \overline{(1, m)}$;
- a_{ij} – regulatory costs ith of the production resource for collection, sorting, transportation, processing, disposal of the unit of the jth type of solid waste;
- b_i – available volumes of production resources of the ith type of business entities in the waste management system;
- c_j – the variable part of the cost of the processes of handling the solid waste unit of the jth type of waste, without taking into account the cost of consumed production resources;
- x_j^{min}, x_j^{max} – respectively, the lower and upper limits of the amount of waste of the jth type, which are generated in a separate territorial community;
- y_i^{min}, y_i^{max} – respectively, the lower and upper limits of the volume of production use of the ith resource of business entities in the waste management system;
- v_i^{min}, v_i^{max} – respectively, the lower and upper limits of the volume of acquisition of additional production resources of the ith type of business entities in the waste management system;
- w_i^{min}, w_i^{max} – respectively, the lower and upper limits of the volume of realization of surplus production resources of the ith type of business entities in the waste management system.

Unknown quantities (controlled variables):

- x_j – the amount of waste of the jth type, generated in a separate territorial community;
- y_i – volume of production consumption of the ith resource of business entities in the waste management system;
- v_i – volume of procurement of additional production resources of the ith type of business entities in the waste management system;
- w_i – the amount of excess production resources of the ith type of economic entities in the waste management system;

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012131 doi:10.1088/1755-1315/1415/1/012131

- z – total costs of business entities in the waste management system in its variable part.

Uncontrolled parameters:

- p_j – market price of a unit of the jth type of solid waste;
- q_i – the market price of a unit of the ith production resource of business entities in the waste management system.

In deterministic conditions, the values of uncontrollable parameters at the moment of decision-making are considered known. If there are risks, they are considered as random variables with known statistical characteristics.

Dependencies between known, unknown quantities, and uncontrollable parameters:

- volumes of generated waste, as well as volumes of production use, acquisition of additional, or sale of surplus production resources of business entities in the waste management system, must meet predetermined limits:

$$x_j^{(min_j,max_j(1,n))}; \quad y_i^{(min_i,max_i(1,m))}; v_i^{(min_i,max_i(1,m))}; \quad w_i^{(min_i,max_i(1,m))};, \tag{7}$$

- the production use of resources of business entities in the waste management system is determined by the features of the technological processes of collection, sorting, transportation, processing, disposal of solid waste:

$$y_i = \sum_{j=1}^{n} a_{ij} x_j, \quad i = \overline{1,m};, \tag{8}$$

- a balance must be maintained between the formation of solid waste and the use of production resources of economic entities for the processes of collection, sorting, transportation, processing, and disposal of solid waste:

$$b_i + v_i = y_i + w_i, \quad i = \overline{1,m};, \tag{9}$$

- the costs of economic entities in the waste management system are determined by the sum of the losses of territorial communities caused by the amount of generated waste and the costs of economic entities for the use of production resources:

$$\begin{aligned} z = \sum_{j=1}^{n}(p_j + c_j)x_j + \sum_{i=1}^{m} q_i y_i + \sum_{i=1}^{m} q_i w_i \to \min, \\ \sum_{j=1}^{n} a_{ij}x_j - y_i = 0, \quad i = \overline{1,m}, \\ y_i - v_i + w_i = b_i, \quad i = \overline{1,m}, \\ x_j^{\min} \le x_j \le x_j^{\max}, \quad j = \overline{1,n}, \\ y_i^{\min} \le y_i \le y_i^{\max}, \quad i = \overline{1,m}, \\ v_i^{\min} \le v_i \le v_i^{\max}, \quad i = \overline{1,m}, \\ w_i^{\min} \le w_i \le w_i^{\max}, \quad i = \overline{1,m}. \end{aligned} \tag{10}$$

The model is a linear programming problem, and the widely used MS Excel package can be used to find its solution.

To implement the production program of the UTC for the implementation of a logistics system for waste management, it is advisable to form a system for managing information logistics flows according to the service model presented in figure 6. The information system ensures the collection, transmission and processing of information received by business entities in the waste

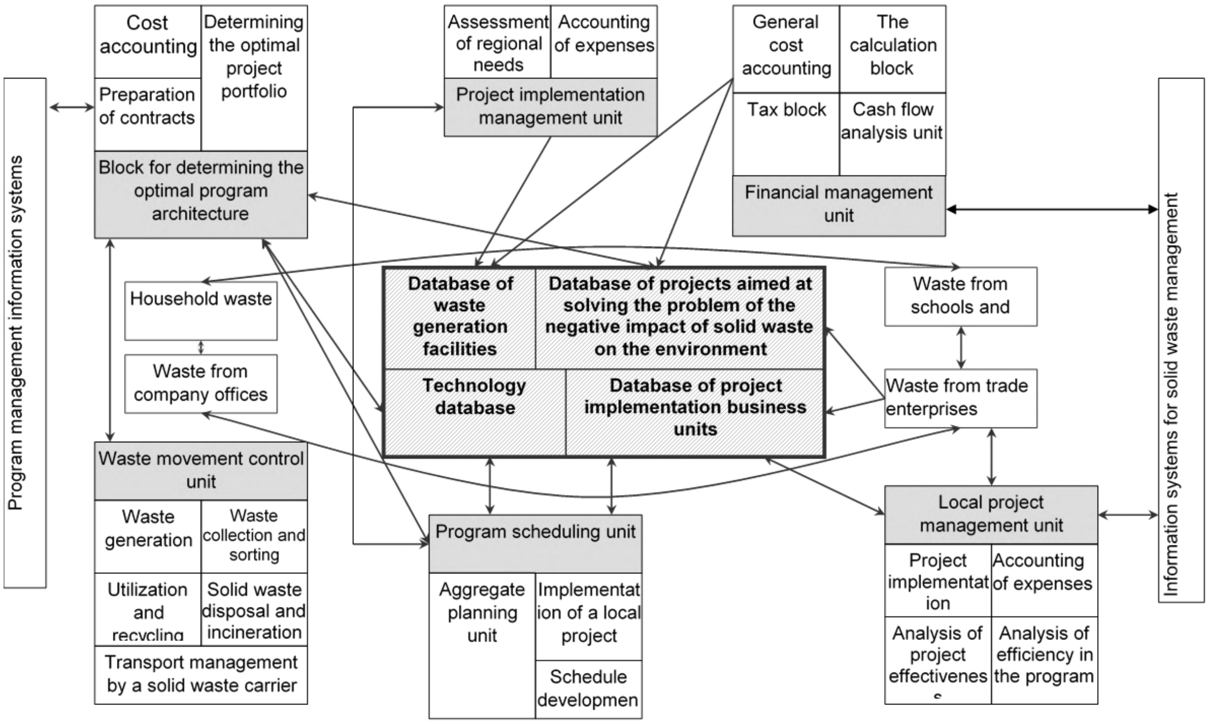

Figure 6. Service model of electronic waste management information system for territorial communities.

management system. In the system, information processing tools are placed inside information flows to achieve the greatest efficiency of its use. At the same time, the process includes the search for ensuring the level of logistics activity, at which the costs for the implementation of the technological processes of collection, sorting, transportation, processing, disposal of solid waste are minimal.

Management of information flows includes the exchange of information about the composition and structure of the material flow of waste, the value of emissions during certain processes related to the formation, storage, transportation and disposal of waste. Exchange of information between the heads of the UTC during the implementation of the production program and project managers, between the formation of the solid waste and their management processes, between all interested parties, including residents of the community and region [13].

Information has quantitative and qualitative characteristics and, as a rule, is related to material and financial flows and can follow them synchronously, or can be separated. Using the model will increase the flexibility of the logistics system, improve its scalability and stability, and reduce the time to respond to changes [14, 15].

This logistics system allows to improve the functioning of organizational business processes of interaction of the community, authorities and communal enterprises in the removal, transportation, collection of waste and to implement logistics technologies in practical activities. The result of the interaction of all interested parties is the creation of an effective system of collection, sorting, transportation and disposal of waste, characterized by the achieved level of ecological and economic efficiency and environmental safety. Therefore, comparing the parameters of the actual volume of services with the required parameters, determine the logistical effect of the waste management system and the use of secondary resources.

4. Conclusion

A systematic model of solid waste management for territorial communities was developed, taking into account the interests of stakeholders and a morphological model of a regional waste management program. The model allows to identify ways of waste management (prevention of generation, reduction of waste, optimization of waste flows by restoring their value, reuse, recycling, disposal and control over waste disposal facilities) for territorial communities to prevent the harmful effects of waste on the environment and public health.

Methods and tools for implementing a regional waste management program based on a logistics approach have been developed, which involves the formation of an environmentally oriented logistics system for managing waste management programs and the development of logistics models for municipal waste transportation processes.

The results include:

- a business strategy for the implementation of environmental logistics to reduce overall emissions for the management of regional waste management programs for a particular UTC, which provides for the sequential implementation of stages – strategic decision-making, formation of the tactical level, implementation of operational and functional solutions;
- a schematic model of the logistics system for the functioning of the regional waste management plan for the UTC with the inclusion of a coordinating agent for waste management to ensure the management of all logistics flows of the solid waste – financial, material, information. and allows the formation of projects, technologies and measures to reduce the amount of waste, its recovery, recycling or disposal in a complementary manner;
- an economic and mathematical model for determining the production program of the UTC for the implementation of the logistics system of waste management, the optimization of which allows redistributing material flows of solid waste in individual UTCs in the implementation of waste management processes and production resources, based on the characteristics of technological processes and available production resources of business entities while minimizing environmental damage;
- a service model of an electronic information system for managing logistics waste flows to implement the production program of an UTC. Information flow management includes the exchange of information on the composition and structure of the material flow of waste, the value of emissions from certain processes related to the generation, storage, transportation and disposal of waste. Information exchange between UTC managers in the implementation of the production program and project managers, between the formation of solid waste and its management processes, between all stakeholders, including community residents;
- a set of criteria for a comprehensive assessment of the impact of the system of transportation, disposal and processing of solid waste is proposed for a comprehensive assessment of the impact of the system of transportation, disposal and processing of solid waste is proposed, which includes material and technical criteria, criteria of professional requirements, financial and economic criteria, environmental criteria and social criteria. Each group of criteria is characterized by a set of local criteria, which allows the choice of the business structure of the carrier for the transportation of solid waste while optimizing the logistics system of waste management;
- the conceptual model of a regional waste management program based on the logistics approach includes sets of relevant sets: strategic goal (M_i), resources (R_i), finance (F_i) and information (I_i) and involves the involvement of a coordinating agent as a separate business entity to manage the waste management system, which manages all waste generated in a certain territory and allows the formation of projects, technologies and measures to reduce the amount of waste, its recovery, recycling or disposal with the addition of one or more

of the following Implementation of the model for UTCs involves increasing the efficiency of waste collection, transportation and storage.
