Abstract. This paper presents an overview of the 5th International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters (ICSF 2024), held in May 2024. The conference brought together over 250 researchers, practitioners, and educators from 19 countries to share cutting-edge research and innovative solutions across a wide range of sustainability-related disciplines. The proceedings cover diverse topics, including climate change, disaster risk reduction, sustainable infrastructure, education for sustainability, environmental engineering, and sustainable business practices. Key themes that emerged include the integration of digital technologies in sustainability efforts, the impacts of global crises on sustainable development, and the importance of interdisciplinary approaches. The conference showcased both theoretical advancements and practical applications, with a particular focus on addressing the United Nations Sustainable Development Goals. This overview highlights the conference's role in fostering global dialogue and collaboration to address pressing sustainability challenges and shape a more sustainable future.

In memory of Serhii M. Chukharev, a brilliant researcher and dear friend.

1. Introduction

Welcome to the **International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters** (**ICSF**) proceedings. This conference serves as a cornerstone for global discourse on sustainable development, providing a peer-reviewed international platform where researchers, scientists, engineers, and practitioners converge to share their latest research findings, innovative ideas, and practical applications. As we delve into these proceedings, we embark on a journey across diverse disciplines, united by a common goal of advancing sustainable practices.

Figure 1 showcases the emblem of ICSF 2024, a symbol of our collective commitment to fostering sustainable futures.

Figure 1. ICSF 2024 logo (designed by Andrii M. Striuk).

Since its inception in 2020, ICSF has consistently cultivated a space that encompasses the entire spectrum of sustainable development. With a focus on the intricate intersections of sustainability, environment, and technology, ICSF explores their far-reaching implications for corporations, governments, educational institutions, regions, and societies, both in the present and the future [1–5].

ICSF 2024 is a two-tiered platform comprising pre-conference workshops and the main conference, ensuring an enriched experience for all participants. The pre-conference workshops delve into specific domains of sustainable development.

1.1. Geography for Sustainable Development (GSD-2024)

Geography for Sustainable Development (GSD-2024) serves as a peer-reviewed international workshop, offering a platform for researchers deeply engaged with the challenges of sustainable development within the geographical context. Covering an array of topics, including biogeochemical cycles, climate, natural resources, and more, this workshop is a testament to the expansive scope of geography's role in shaping sustainable futures. Dr. Olha Bondarenko guides these explorations through her leadership.

Workshop URL: https://bondarenkoolga9.wixsite.com/gsd-2024.

1.2. Water for the Future: Management, Use, and Technology (WaterManEnvE-2024)

The *Water for the Future: Management, Use, and Technology* (WaterManEnvE-2024) stands as a peer-reviewed international platform, encapsulating contributions that cover all aspects of water management and environmental engineering, environmental education and modern educational technologies. With a focus on topics including water resources, irrigation, hydraulic engineering, and more, this workshop navigates the complexities of managing our most precious resource sustainably. Dr. Serhii Klimov provides direction for these explorations.

Workshop URL: https://sites.google.com/nuwm.edu.ua/watermanenve-ws2024/home.

1.3. Nuclear Safety and Environmental Protection (IASEI-2024)

Nuclear Safety and Environmental Protection (IASEI-2024) converges as a peer-reviewed international workshop focusing on advancing environmental science research. Covering topics ranging from environmental protection to nuclear safety and technological solutions, this workshop embodies the spirit of pioneering solutions for pressing environmental challenges. Dr. Andrii Iatsyshyn is in charge of cultivating innovative discussions.

Workshop URL: https://iasei.easyscience.education/2024/.

1.4. Infrastructure, Resilience and Sustainable Energy (SEnW-2024)

Infrastructure, Resilience and Sustainable Energy (SEnW-2024) embarks on an exploration of innovative solutions in energy systems. Covering a diverse array of topics, including solar and wind energy, energy policy, climate change, and more, this workshop underlines the essential role of sustainable energy in shaping our resilient future. Guided by Dr. Volodymyr Artemchuk, this workshop paves the way for sustainable energy practices.

Workshop URL: https://ipme.kiev.ua/en/SEnW-2024/.

1.5. Conference sessions

The main conference unfolded through a series of 12 sessions, each shedding light on different facets of sustainable development. These sessions encompassed topics ranging from sustainable mining, materials and technologies to socio-economic development, energy systems, water management, and beyond.

- Session 1. Sustainable mining. Geophysics, geology, mineralogy and petrology, session 1 (May 21, 2024). Chairs: Serhii Chukharev and Andrii Striuk
- Session 2. Technology and materials for sustainability (May 21, 2024). Chair: Serhiy Sakhno
- Session 3. Infrastructure, Resilience and Sustainable Energy (SEnW-2024) (May 21, 2024). Chair: Volodymyr Artemchuk

Session 4. Sustainable use of natural resources. Sustainable transportation (May 21, 2024). Chair: Pavlo Nechypurenko

Session 5. Geography for a Sustainable Future (GSD-2024), session 1 (May 21, 2024). Chair: Olha Bondarenko

Session 6. Green building and sustainable architecture. Sustainable urban planning, cities and society (May 22, 2024). Chair: Serhiy Sakhno

Session 7. Education for sustainability (May 22, 2024). Chair: Tetiana Vakaliuk

Session 8. Sustainable business practices. Environmental policy, economics, and law. Environmental health and sustainable development (May 22, 2024). Chair: Hanna Danylchuk

Session 9. Water for the Future: Management, Use, and Technology (WaterManEnvE-2024) (May 22, 2024). Chair: Serhii Klimov

Session 10. Nuclear Safety and Environmental Protection (IASEI-2024) (May 23, 2024). Chairs: Valeriia Kovach, Andrii Iatsyshyn and Teodoziia Yatsyshyn

Session 11. Sustainable mining. Geophysics, geology, mineralogy and petrology, session 2 (May 23, 2024). Chair: Serhii Chukharev and Andrii Striuk

Session 12. Geography for a Sustainable Future (GSD-2024), session 2 (May 24, 2024). Chair: Olha Bondarenko

This volume is a repository of the scholarly contributions presented at ICSF 2024. With meticulous reviews conducted by a minimum of three program committee members, the selected papers embody the spirit of rigorous exploration and discovery.

Authors were invited to submit full research papers, including surveys, tutorials, and perspective/colloquia articles on conference topics of interest (`https://www.morressier.com/call-for-papers/6501c5b1cd3f7d001924450d`). With meticulous reviews conducted by a minimum of three program committee members, the selected papers embody the spirit of rigorous exploration and discovery. Out of 304 submissions received, 171 papers were accepted after a rigorous peer-review process.

The unfolding events of the ongoing Russian invasion of Ukraine necessitated a hybrid conference format. By embracing both in-person and online modes, ICSF 2024 extended its reach across borders, allowing more than 250 participants from 19 countries to participate through platforms such as Zoom and Google Meet.

The presentation slots were defined as follows:

- invites talks (25 min): 15 min presentation, 10 min question answering and discussion,
- other talks (15 min): 10 min presentation and 5 minutes question answering and discussion.

The full ICSF 2024 program is available at the `https://icsf.easyscience.education/2024/`, where one or more invited presentations usually head details of the sessions. Video records of talks are available at the *Not So Easy Science* YouTube channel:

`https://www.youtube.com/channel/UCH3gego79m-ofCiNEgEzMuA`

As we present these proceedings, we invite readers to explore the diverse range of topics covered, draw inspiration from the innovative approaches discussed, and consider how these findings can be applied to enhance sustainable practices across various contexts and disciplines. We anticipate that the ideas and findings presented will significantly contribute to shaping a more sustainable future.

2. ICSF 2024 program committee

The ICSF 2024 program committee comprised over 100 distinguished researchers from around the world, representing a wide range of disciplines related to sustainable development. Their expertise and dedication were instrumental in ensuring the high quality of the papers presented at the conference.

3. ICSF 2024 organizer

The 5th edition of ICSF was meticulously coordinated by the Academy of Cognitive and Natural Sciences (ACNS, `https://acnsci.org`), a non-governmental organization dedicated to nurturing the growth of researchers' expertise in the cognitive and natural sciences arena. ACNS's mission encompasses enhancing research, safeguarding rights and liberties, and catering to professional, scientific, social, and various other interests.

ACNS is engaged in a spectrum of activities, including:

- Spearheading research initiatives within the cognitive and natural sciences domain and fostering collaborative ties among researchers.
- Orchestrating conferences, workshops, training sessions, internships, and other platforms for the exchange and dissemination of knowledge in the realm of cognitive and natural sciences.
- Publishing scientific journals, conference proceedings, collections of scholarly works, and related materials (`https://acnsci.org/cms/journals/`).

Among ACNS's prominent publications is the Diamond Open Access *Journal of Edge Computing* (JEC) that covers a broad range of topics aligned with the Sustainable Development Goals (SDGs). Here are select articles from *Journal of Edge Computing* categorized by SDG goals:

SDG 3 (Good Health and Wellbeing)

- Non-contact photoplethysmographic sensors for monitoring students' cardiovascular system functional state in an IoT system [396].
- Model of an automated biotechnical system for analyzing pulseograms as a kind of edge devices [397].
- A system for monitoring the microclimate parameters of premises based on the Internet of Things and edge devices [398].
- An IoT system based on open APIs and geolocation for the prevention of human health disorders [399].
- Responding to challenge call for machine learning model development in diagnosing respiratory disease sounds [400].

SDG 4 (Quality Education)

- Design and implementation of an IoT-based educational model for smart homes: a STEM approach [401].
- Investigating the effect of virtual machine migration accounting on reliability using a cluster model [402].

SDG 9 (Industry, Innovation, and Infrastructure)

- Graph theory methods for fog computing: A pseudo-random task graph model for evaluating mobile cloud, fog and edge computing systems [403].
- Analysis and protection of IoT systems: Edge computing and decentralized decision-making [404].
- A new approach for dispatching task flows in GRID systems with inalienable resources [405].
- Introduction to doors Workshops on Edge Computing (2021-2023) [406].
- ImpalaE: Towards an optimal policy for efficient resource management at the edge [407].
- Reliable distributed systems: review of modern approaches [408].
- Empowering the Edge: Research advances from doors 2024 [409].
- Efficient model of PID controller of unmanned aerial vehicle [410].
- Design and implementation of an edge computing-based GPS tracking system [411].
- Telemetry to solve dynamic analysis of a distributed system [412].
- Advancing IoT interoperability: dynamic data serialization using ThingsBoard [413].
- Ambience: an operating system for IoT microservices [414].
- Use of wireless technologies in IoT projects [415].

SDG 11 (Sustainable Cities and Communities)

- Edge computing in environmental science: automated intelligent robotic platform for water quality assessment [416].

SDG 15 (Life on Land)

- Enhanced deep learning model architecture for plant disease detection in Chilli plants [417].

SDG 16 (Peace, Justice, and Strong Institutions)

- A long short-term memory based approach for detecting cyber attacks in IoT using CIC-IoT2023 dataset [418].

4. Proceedings structure

4.1. Atmospheric science, meteorology, and climatology

The papers in this section cover topics related to atmospheric science, meteorology, and climatology. [419] investigates methane degassing within Ukraine using satellite data. [420] analyzes patterns of PM10 particles change in the atmospheric air of Ivano-Frankivsk city. [421] explores the application of remote monitoring tools in the educational process by studying the content of water vapour in the atmosphere. [422] explores the use of FEM technology in analyzing the stability of the design concept of a residential building “Flower of Life” under explosive load conditions.

4.2. Biodiversity conservation and environmental impact

[423] assesses below-ground carbon stock of mangrove stands at a mining site in Hinatuan Island, Philippines. [424] investigates the accumulation of heavy metals by different biota representatives in the operation zone of the Prydniprovska thermal power plant. [425] proposes spatial optimization models of socio-natural interaction as a way to sustainable development.

4.3. Climate change, disaster risk reduction, and environmental policy

Climate change and its impacts are addressed in [426], which proposes ML-ERV, a machine learning-based CO_2 emissions model for rental vehicles. Disaster risk reduction is the focus of [427], a hermeneutic phenomenological study of motivations, challenges, and resilience in a landslide-prone environment in the Philippines. [428] assesses seismic hazard in the Shamkir-Mingachevir reservoir region through ground response analysis. Environmental policy is represented by [429], which explores stakeholders' awareness and perception of bio-economic transformation in Ukraine. [430] evaluates green flood mitigation measures in urban areas within the sustainable city concept. [431] investigates the physical and mechanical properties of burnt-out coal mine waste heaps. [432] assesses the risks for Ukraine's infrastructure under war conditions. [433] focuses on the resilience of systems for public protective actions under wartime.

4.4. Education for sustainability

Several papers address education for sustainability from various angles. [434] models the digital ecophilic tendencies of university students' consciousness. [435] explores the use of digital technologies in education in the context of sustainable development. [436] discusses inclusive culture in Ukrainian higher education institutions for sustainable development. [437] focuses on nanoeducation for a sustainable future and attracting Ukrainian youth to nanotechnological specialities. [438] investigates collaborative learning in training future IT specialists as a strategy for sustainable education. [439] explores transforming education and navigating the human-AI ecosystem in psychological training and beyond. [440] discusses ensuring sustainable development through digital educational hubs for teaching civic education at school. [441] presents a case study of students and plagiarism, focusing on plagiarism checker use at a university in North Sumatra. [442] investigates cultivating intercultural competency and the role of sustainability in pre-service teacher professional development. [443] provides a literature review on the educational dimension of sustainable development from 2019-2023. [444] explores the intersection of artificial intelligence, the labour market, and education for sustainable development. [445] explores the use of ICT by teachers for developing students' critical thinking in the context of sustainable development in Ukraine. [446] investigates transformational leadership in higher education for implementing sustainable development goals, using Ukraine as an example. [447] presents a case study of a school preparing for sustainability management, focusing on the Palau simulation model. [448] explores blended learning, its definition, concept, and relevance to education for sustainability. [449] proposes AI tools for sustainable primary teacher education, focusing on literary-artistic content generation.

4.5. Environmental engineering and green technology

Several papers represent environmental engineering and green technology. [450] evaluates green flood mitigation measures in urban areas within the sustainable city concept. [451] investigates increasing biogas production energy efficiency through vibration activation of heat and mass exchange in the bioreactor. [452] focuses on sustainability and resilience, exploring digital technologies for GHG Scope 3. [453] presents a geoinformation assessment of solar plant potential in the Ivano-Frankivsk region for effective decarbonisation and energy stability. [454] uses canonical correlations to assess the relationship between economic growth and environmental threats. [455] forecasts the development of the circular economy in Ukraine. [456] improves municipal wastewater treatment technology in towns and villages. [457] explores the prospects of using composite preparations based on silica nanosols. [458] provides a review of the current state and prospects of red mud utilization. [459] proposes technological solutions for the population under existing challenges.

4.6. Sustainable infrastructure, mining, transportation, and urban planning
Sustainable infrastructure is the focus of [460], which explores the automated trolleybus park system as part of sustainable city infrastructure. [461] proposes neural network methods for searching additional functions in information-driven permutation operations to increase critical infrastructure sustainability. Sustainable mining is represented by [462], considering multifactorial geomechanical-technological factors in determining rational parameters for site outgassing technology in Western Donbas mines, Ukraine. [463] models the soil erosion process during amber mining. [464] investigates the influence of stress-strain evolution in the immediate floor before and after excavation face on floor heave origin in coal mines roadways. Sustainable transportation is addressed by [465], analyzing prospects and peculiarities of autonomous and cyber-physical systems development for vehicle control at mining enterprises. [466] proposes a strategic approach to sustainable railway transport development and optimizing empty car use in organizing dangerous goods transportation. [467] presents a flight situation advisory system for uninterrupted and efficient air transportation. Sustainable urban planning is the focus of [468], which applies geoinformation systems in developing a city's intelligent transport network. [469] discusses problems in developing urban planning solutions for the restoration of deoccupied cities in eastern Ukraine. [470] explores the sustainable development of the Pirnovo community in the Kyiv region, focusing on problems and perspectives. [471] reviews smart city trends, achievements, and challenges in Ukraine in the context of Sustainable Development Goals. [472] applies geometrization to estimate mineral deposit reserves. [473] investigates the degree indicators of coal metamorphism for predicting hazardous properties of coal seams during mining. [474] explores predictive calculation of blasting quality as a tool for estimating production cost and investment attractiveness of mineral deposit development. [475] proposes a tool for management and planning of the fuel and energy complex, considering the production potential of coal-mining enterprises. [476] investigates the management of resource potential in European countries in the context of "post-coal mining". [477] researches the selection of optimal instrumentation for mine surveying and software for processing field results. [478] presents a methodology for the operative setting of mass crystallization parameters of gas hydrate in reservoir systems. [479] proposes an integrated approach to forecasting and managing emergencies in the working faces of coal mines, focusing on technical, organizational, and safety measures with subsequent assessment of potential consequences. [480] explores the application of prefabricated retaining walls with increased shear resistance to ensure tailings dam stability. [481] develops a method for estimating the carbon footprint when transporting grain by road. [482] predicts CO_2 emissions during multimodal grain transportation. [483] proposes an improvement technique for surveying observations of displacement. [484] analyzes quantitative and qualitative parameters of the gas mixture in thermal processes of mine medium. [485] applies GIS in the retrospective analysis of the territorial organization of the Kryvyi Rih settlement. [486] explores the geography of the COVID-19 pandemic in Ukraine and the world, focusing on similarities and differences. [487] investigates the features of functional zoning of esports arenas, considering the concepts of sustainable development of territories. [488] proposes the FUTURE 5.0 multi-goal decision-making framework for sustainable university governance in the Industry 5.0 era and beyond.

4.7. Agriculture, food systems, and natural resources
Several papers represent sustainable agriculture and food systems. [489] proposes a resource-saving method for extracting cucumber and melon seeds. [490] conducts experimental research on spray opening and closing time in flat and injector nozzles. [491] explores areas of nature reserve fund used in the context of sustainable development. [492] investigates consumer perceptions and determinants of millet milk consumption as a sustainable choice. Natural resources are the focus of [493], assessing changes in forest ecosystem structure using the example of sanitary

woody plantations in the Steppe Dnipro. [494] generates a geospatial database of forest growth using the QGIS software package. [495] explores the peculiarities of using statistical data for the mass valuation of agricultural lands in Ukraine, focusing on the Kharkiv region. [496] investigates the structural and functional content of xerophytic plants of the *Elytrigia repens L.* genus. [497] assesses trends in the functioning of the grain industry of EU countries using ARDL modelling. [498] explores the application of polymer flooding to increase oil recovery. [499] investigates the influence of organic agriculture development processes on Ukraine's economic security components. [500] assesses the bioenergetic efficiency of growing miscanthus with sewage sediment. [501] discusses the prerequisites for improving crop irrigation regimes based on resource optimization.

4.8. Business, economics, and sustainable development

Sustainable business practices and economic aspects of sustainable development are addressed in several papers. [502] proposes a mathematical model of the business process of higher education institutions based on ontological analysis. [503] explores creditworthiness management as a tool for ensuring sustainable, self-sufficient business development in Ukraine. [504] focuses on managing the economic security of food industry enterprises as a direction for ensuring sustainable development. [505] transforms the business ecosystem model into an energy enterprise's strategy. [506] analyzes the motivational profile of personnel directed at achieving sustainable enterprise development. [507] investigates sustainable consumption in times of war, focusing on needs, values, and possibilities. [508] proposes complex socio-economic solutions for the sustainable ecological development of Ukrainian regions. [509] discusses Ukrainian social sector development in contemporary conditions, highlighting problems and areas for their solution. [510] provides a comprehensive review of green accounting practices in India and global perspectives for advancing sustainable development. [511] identifies key competencies for post-war recovery and sustainable development of Ukraine's economy. [512] explores the interconnected roles of human capital, employment, and sustainable development in EU countries. [513] analyzes the income, consumer spending, and well-being of Ukrainian households. [514] explores project sustainability and sustainable project management in times of crisis, focusing on the context of the Russian-Ukrainian war. [515] models the energy security of the country in the context of sustainable development, using Ukraine as a case study.

4.9. Technology, materials, and modelling for sustainability

Various technological and material aspects of sustainability are addressed in the papers. [516] develops a dephosphorization technology for iron ores with high phosphorus content. [517] investigates melamine-doped TiO_2 as a perspective photocatalyst for hydrogen evolution. [518] studies the effect of sodium metasilicate on the early-age hydration and setting behaviour of alkali-activated common cement-containing slag. [519] explores the electrospark method of obtaining metal nanoparticles for creating antifungal drugs (fungicides). [520] designs rapid-hardening cementitious repair mixtures for increasing the sustainability of concrete structures. [521] investigates thermo-responsive hydrogels based on gelatin-alginate composition with humic acids intended for controlled drug delivery. [522] focuses on sustainable web API evolution and forecasting software development efforts. [523] conducts a comparative analysis and models safe variability areas of power for VVER-1000 and AP-1000 power units. [524] calculates electricity losses using neural networks for retrospective data with the presence of anomalous values. [525] forecasts air pollution by leveraging traffic modelling techniques. [526] applies chatbots to support indoor temperature control. [527] investigates the raw material base of crushed stone and rubble stone in the Khmelnytskyi region. [528] studies the influence of deformation degree on the efficiency of thin sheet cold rolling. [529] models cone crusher steady-state operation modes. [530] proposes modelling the process of ensuring the environmental sustainability of the airport as a functional component of socio-technical systems. [531] conducts experimental tests of the over-columned plates of the precast building frame. [532] investigates the effect of electrochemical impact on copper-molybdenum flotation separation. [533] conducts an experimental study of the effect of hydraulic gradient on soil hydraulic conductivity. [534] explores vegetation zone segmentation in multispectral imagery. [535] improves the evaluation of gamma radiation from cylindrical bodies with spatially inhomogeneous source activity distribution. [536] calculates round foundation slabs subjected to non-uniform base deformation under complex loads. [537] researches the effectiveness of using steel reinforcement for strengthening products made of natural stone. [538] investigates reducing the risk of power equipment failure when using information from the information measurement system of vibration diagnosis rotating units of auxiliary engines of power plants. [539] reviews the collapse behaviour of double-layer pipes. [540] proposes a technology for casting restoration by casting alloyed thermite melt onto the surface. [541] investigates changes in the intensity of polished surface glow of natural stone depending on the intensity of its heating. [542] presents a comprehensive approach to calculating operational parameters in hydraulic fracturing. [543] develops the modelling system core for severe plastic deformation processes. [544] explores harmful emissions of welding aerosol during pulse-arc welding of structural aluminium alloy D16. [545] investigates the propagation of elastic waves in cross-sectionally heterogeneous rods. [546] compares the seismic loading of points on the surface of the Earth during a massive explosion in a mine.

4.10. Hydrology, water management, and sustainable tourism

Hydrology and water management are the focus of several papers. [547] assesses the aesthetic and ecological functions of the urbanized part of small watercourses using the indicator of the visual quality of the environment. [548] investigates the issues of technological modelling of physicochemical iron removal from deep groundwater at the rapid filter. [549] explores the influence of war on the content of some components in the rivers of Ukraine. [550] analyzes trends in the variability of particulate organic carbon distribution in the north-western part of the Black Sea. [551] presents geoinformation modelling of the geoecological state of the floodplain-channel complex of rivers in the Turka city community of the Lviv region. [552] assesses the distribution and population characteristics of *Musculium lacustre* in anthropogenically altered aquatic landscapes of the northern right bank of the Dnipro River in Ukraine. [553] investigates the groundwater level dynamics in rice systems under different irrigation and drainage network parameters. [554] focuses on improving the efficiency of saline soil flushing under conditions of water resource scarcity. [555] analyzes the impact of water use and consumption for a nuclear power plant on alterations in the hydrological and temperature regimes of a river through a case study. [556] explores the regulation of water flow on the foothills of Ukrainian Carpathian rivers using flooded groynes. [557] applies numerical modelling for the interpretation of piezometric data on earth dams, considering uncertainties specific to dam operation. [558] analyzes current trends in water runoff of the Sluch River in terms of extraterritorial impacts of hydrotechnical construction. Sustainable tourism is represented by [559], which explores concession as a tool for improving budget and tax incentives for the investment attractiveness of the tourist complex in Ukraine. [560] proposes a new vision for ecological tourism in the industrial environment. [561] investigates sustainable development strategies in the field of tourism and recreation under war conditions in Ukraine. [562] identifies approaches to developing a response plan for potential emergencies caused by external water contamination. [563] investigates the influence of the accident at the Chornobyl nuclear power plant on the condition of pine plantations in Ukrainian forests. [564] designs a variable-structure controller for electric drives with ventilator torque.

4.11. Geology, mineralogy, and petrology

Geological aspects of sustainability are addressed in several papers. [565] proposes a concept for synthesizing the digital twin of a rock massif based on the stability criterion. [566] studies and analyzes amber deposits using ArcGIS techniques. [567] explores the features of mineral composition of garnet-bearing shales of the Kryvyi Rih basin and provides recommendations for further processing. [568] investigates the paleogeomorphological amber traps of the Prypiat amber-bearing basin in Ukraine, focusing on the theory and methodology of searches. [569] applies the geophysical method of NPEMFE for the preliminary geological outline of deposits of technological iron-containing raw materials. [570] studies the impact of low-molecular carboxylic acids on carbon dioxide corrosion of steel in underground gas production equipment in the Dnipro-Donetsk basin fields. [571] assesses the risks of soil foundation stability losses at the Kyiv-Pechersk Lavra Dormition Cathedral due to urban activities.

4.12. Sustainable energy solutions and waste management

Sustainable energy solutions are the focus of several papers. [572] explores the prospects for autonomous low-power renewable energy communities. [573] models and forecasts the production potential of renewable energy sources in the context of sustainable development. [574] proposes an electric drive of coordinated rotation for mechanisms of flow-transport systems. [575] determines the operating parameters of accumulative electric heating systems. [576] studies double short circuits on earth in 10 kV power grids with isolated neutral and high-level penetration of renewable energy sources. [577] discusses the postwar perspective of ammonia production in Ukraine. [578] analyzes the current state and prospects of renewable energy in heating and cooling systems in Ukraine. Waste management is addressed by [579], which focuses on the utilization of vegetative waste from the green infrastructure of cities "in-situ". [580] explores the prospects of recycling metallurgical waste. [581] investigates the natural phytomelioration of coal mine waste heaps in the context of increased radiation background, focusing on the case of the Nadiya mine in the Lviv-Volyn coal basin, Ukraine. [582] proposes increasing the level of an ecologically oriented logistics system in waste management for territorial communities. [583] explores gypsum recycling using an inclined chamber vibrating jaw crusher. [584] explores radioecological monitoring as a critical factor in food quality management. [585] discusses the methodology for improving the concept of maximum security of a nuclear facility at minimum costs. [586] investigates the features of designing systems for the formation of an internal microclimate of a high class of cleanliness in operating rooms of medical institutions. [587] explores climate factors and their role in the development of wind energy in the Lviv region. [588] analyzes the current state and development prospects of the graphite industry in Ukraine. [589] revisits the mathematical model of the process of self-destruction of outburst-prone coals under hydrodynamic effect.

5. Conclusion

The vision driving ICSF 2024 is to establish a paramount interdisciplinary platform, uniting researchers, practitioners, and educators to showcase and deliberate upon the latest innovations, emerging trends, concerns, practical challenges, and adopted solutions in the realm of sustainability.

We extend our sincere gratitude to the authors who submitted their papers and to the delegates for their enthusiastic participation and interest in ICSF as a conduit for sharing ideas and innovation. Our heartfelt appreciation also extends to the program committee members, whose unwavering guidance, dedication, and the invaluable contributions of peer reviewers have elevated the quality of the papers. The constructive critiques, improvements, and corrections they provided have significantly enriched the success of this conference. We also recognize the pivotal role of Morressier's developers, whose robust conference management system facilitated

every stage of the process, from soliciting papers to coordinating peer reviews and crafting the conference proceedings volume.

A special acknowledgement goes to the session chairs, whose steadfast commitment to shaping the conference and its program has been exceptional. Their role has contributed significantly to the cohesive and productive flow of the conference sessions.

Furthermore, we express our gratitude to IOP Publishing for their generosity in waiving the APC payments for corresponding authors based in Ukraine. This initiative enables authors to publish open access without charge in the prestigious *IOP Conference Series: Earth and Environmental Science* journal (`https://iopscience.iop.org/journal/1755-1315`). Additionally, the submission extensions offered by IOP Publishing are a testament to their understanding of researchers' challenges and constraints, underscoring their dedication to fostering a supportive academic environment.

As we move forward, we anticipate exceptional presentations and insightful discussions that will expand our professional horizons. We hope that all participants find immense value in this conference and eagerly anticipate the prospect of reconnecting in a more convivial, light-hearted, and harmonious setting at ICSF 2025. The next instalment in the series, the 6th International Conference on Sustainable Futures: Environmental, Technological, Social, and Economic Matters, is set to take place in May 2025 in Kryvyi Rih, Ukraine (`https://icsf.easyscience.education/2025/`).

Thank you all for being an integral part of ICSF 2024, and here is to a brighter, more sustainable future that we collectively strive to build.

Acknowledgments
We want to acknowledge the contributions of our late colleague, Serhii Mykhailovych Chukharev, a distinguished scholar and dedicated educator who passed away before this work was published.

Figure 2. Prof. Serhii Mykhailovych Chukharev (04/17/1958 – 08/30/2024).

Born on April 17, 1958, in Kropyvnytskyi (formerly Kirovohrad), Serhiy Mykhailovych was a beacon of knowledge and inspiration in the field of mining engineering.

Serhii Mykhailovych graduated from Kryvyi Rih Mining Institute in 1981, earning his degree as a mining engineer-builder. His academic journey continued with the defence of his PhD thesis in 1989, marking the beginning of a prolific career in academia and research. In 1996, he furthered his education by obtaining a second degree in finance and credit, showcasing his versatile intellect and commitment to lifelong learning.

Throughout his career, Serhii Mykhailovych held esteemed positions, including Associate Professor at the Department of Underground Mining of Mineral Deposits at Kryvyi Rih National University and later at the National University of Water and Environmental Engineering. His contributions to the field are immortalized in over 100 scientific and methodological works, including five patents.

Serhii Mykhailovych's research focused on developing innovative technologies and methodologies for the sustainable and efficient extraction of mineral resources. His early works explored the application of vibration mechanisms for forming asymmetric draw figures and the feasibility of this process. He also contributed to the development of a method for mining mineral deposits.

In the 1990s, Serhii Mykhailovych's research expanded to include the development of self-propelled equipment in the mining industry, the technology of extracting under-quarry ore reserves and improving the technology for extracting ore from the underground tier. He also investigated the patterns of formation of the drawing figure for ores with different physical and mechanical properties and the possibility of increasing the stability of the receiving horizon.

In the 2000s, Serhii Mykhailovych's research focused on using communication technologies to improve the efficiency of working with corporate bank clients and applying marketing to the creation and implementation of scientific and technical products.

In recent years, Serhii Mykhailovych's research has centered on the development of resource-saving mining technologies, the enhancement of the stability of mine workings during their excavation and operation in complex mining and geological conditions, and the selective mining of complex-structured ore deposits of the Kryvyi Rih basin.

Serhii Mykhailovych was not only a respected academic but also a mentor and guide to many students and colleagues. His dedication to advancing mining technology and resource-saving methods has left an indelible mark on the industry.

He is survived by his family, friends, and countless students who will remember him for his wisdom, kindness, and unwavering dedication to education and research.

May his soul rest in peace, and may his legacy continue to inspire future generations.

Serhii Mykhailovych was a valuable member of our research team and significantly contributed to this project. We miss him dearly.

Abstract. The article substantiates the concept of degassing the Earth using the example of methane, a gas component of the fluid regime of the lithosphere. According to the analysis of observations from the Sentinel-5P satellite over the territory of Ukraine for the period 2019-2022, data on the distribution of methane (CH_4) in the atmosphere were obtained using the Google Earth Engine (GEE) platform, and a corresponding map was compiled. The distribution of methane content within the main tectonic structures of Ukraine is very complex and is probably not related to the specifics of their development. It has been established that methane is present everywhere in the atmosphere of Ukraine but in different amounts. The relationship between the content of methane in the atmosphere and the content of hydrocarbons within 12 known oil and gas-bearing areas of the Dnieper-Donets Depression (DDD) was established. Two aggregates are distinguished: areas with the largest reserves of hydrocarbons and oil and gas-bearing areas with low reserves of hydrocarbons, which are characterized by a significant range of changes in the content of methane in the atmosphere. This indicates the connection of methane content in the atmosphere with hydrocarbon reserves in oil and gas-bearing areas. That is, the process of degassing is taking place and it can be studied according to the remote sensing (RS) data.

1. Introduction

Global and regional (Ukraine) climate warming, especially in recent years, causes concern in the world community, as the consequences of these changes threaten serious natural disasters (intensification of natural phenomena: increase in droughts, floods, fires, etc.). Therefore, recently, the problem of creating an indication base of global and regional changes in the Earth's climate for their forecast and adaptation to the development of these events in the future is becoming more and more urgent. As many researchers have shown, such a geophysical factor as a change in the gas composition of the atmosphere has a significant impact on the Earth's climate change. The process of degassing the Earth has a decisive influence on the change in the gaseous composition of the atmosphere. Deep degassing of the Earth is a leading planetary process that has occurred throughout the entire history of the planet's development. In this study, we will consider the geophysical factor associated with the processes of degassing from the Earth's interior. In recent decades, more and more attention has been paid by scientists of all countries to the study of the processes of degassing of the Earth, which influenced the geological development of the Earth, as well as its weather and climate conditions [1–10].

Degassing processes play an important role in the formation of deposits of various minerals, not only oil and gas deposits but also ore – endogenous, partly exogenous, and mineral water deposits. In addition, degassing processes, primarily hydrogen degassing, play an important structure-forming role in geodynamic processes. Mechanisms of structure formation in the crystalline basement and sedimentary-volcanogenic shell are associated with dilation processes, which are quite diverse [11].

The composition of the gases released in the degassing process is very diverse, including methane and other hydrocarbon gases, carbon dioxide, sulfur gases, hydrogen, radon, helium, argon, oxygen, mercury vapor, etc. In recent years, researchers have paid considerable attention to the study of hydrogen, which has a significant impact on both climatic and geological processes. In the process of degassing the Earth, there is a simultaneous emission of gases of different compositions. The combination of gases of different compositions within one emission is not accidental, it is probably related to their genetic unity. The impact of degassing on the weather and climate conditions of the planet is evidenced by the fact that the centers of the strongest anomalies in the ozone content of the planet are located above the zones and centers of hydrogen and methane degassing. These are rift and fault zones or nodes of their intersection, as well as centers of modern tholeiitic and alkaline volcanism or ancient ultramafic (kimberlite) volcanism [12].

As a result of the natural degassing of the Earth, the content of hydrogen and methane outside the accumulation of hydrocarbons turns out to be quite strongly interconnected. This allows us to talk about the single depths of their generation [13].

As a result of diffusion and filtration processes, gas aureoles are also formed around not only hydrocarbon deposits but also solid minerals deposits. The size of these aureoles significantly exceeds the size of other geochemical aureoles. During the movement of gases through rocks characterized by different porosity, gas separation occurs. This is best seen from the example of hydrocarbon gases. Lighter and less sorbed components move faster through rocks, overtaking heavy and better-sorbed ones. As the results of the conducted experiments showed, during the movement of hydrocarbon gases, their division into methane, ethane, propane, and butane occurs [11].

The process of degassing the Earth is divided into hot and cold degassing, which differ not so much in temperature as in oxidation-reduction parameters. Cold degassing is characterized by geochemical processes involving reduced (hydrogen-hydrocarbon-based) fluids, while the main factor in hot degassing is hydrogen oxidation under conditions of high temperature gradients. Cold degassing determines the paragenetic associations of hydrocarbons, helium, and hydrogen [11, 14, 15].

It is assumed that the main factor in the processes of degassing are endogenous energy flows of various nature, coming from the depths of the Earth to its surface, which create conditions for the movement of fluids [16]. The most important feature of this process is its unevenness both in time and space. Based on modern observations, the power of gas emissions can spontaneously increase millions of times, and the area of such a gas-dynamic disturbance can reach hundreds of thousands of square kilometers. In addition, a pattern common to the entire planet has been established – increased hydrogen release at the end of the year, when the Earth is at perihelion in its orbit around the sun, while at aphelion the maximum frequency of volcanic eruptions [12].

The volumes of gases released in the process of global degassing of the Earth undoubtedly influenced the component composition of the atmospheric air, especially in the surface layer. Currently, the most significant influence on the composition of the atmosphere is provided by the influx of hydrogen, methane, and carbon dioxide. The introduction of hydrogen into the atmosphere leads to changes in the ozone layer of the atmosphere, which contributes to the emergence of tropical cyclones and climate warming [17].

The indicator in this study will be the gas component of the fluid regime of the lithosphere –

methane. Research of CH_4 emissions began to be conducted already in the early 1930s, when V. O. Sokolov proposed the theoretical and applied principles of gas surveying to find hydrocarbon deposits. In the subsequent study of methane content, along with the solution of search problems, they were also used to study the laws of the Earth's development and to solve environmental problems.

Already the first works on the study of the content of methane in the atmosphere established that many different factors have a significant impact on its content, which are not always possible to take into account. Research was conducted exclusively based on ground observations, which were carried out on relatively small areas, for a relatively small amount of time and only during a certain period of the year. To calculate the effect of various factors, and their quantitative estimates, which affect the methane content, as is known, it is necessary to conduct research for a long time in the monitoring mode. Such an opportunity to quickly and economically conduct such research is provided by the use of only data from space surveys.

Taking into account the significant variability of the Earth's degassing processes, both in time and in space, a long-term series of observations are needed to study this process and assess its impact on climate processes, i.e., work in the monitoring mode. Such an opportunity is provided only by the use of space survey materials. However, as is known, the use of materials from space photography appeared relatively recently, and before that, the only source of studying the gaseous respiration of the Earth was the results of ground measurements of gases. Although such methods provide fairly accurate determinations of the content of various gases, they are very time-consuming and were carried out selectively in small areas. These are primarily the materials of the gas survey, which was carried out only in areas where mineral deposits are located, before all oil and gas deposits. In addition, the materials of the emanation survey, which was carried out during the search for ores of radioactive metals. Therefore, this study, is planned to jointly use these two sources of information about the gaseous respiration of the Earth with a wider use of materials from space image.

2. Materials and methods

Data on the concentration of methane CH_4 in the atmosphere over the territory of Ukraine for the period 2019–2022 were used, which were obtained from the Sentinel-5P satellite, using the Google Earth Engine (GEE) platform.

To interpret the results of remote research data, the results of ground research were used: scheme of the oil and gas geological zoning of the Dnieper–Donetsk oil and gas-bearing region [18] and map of the tectonic zoning [19].

With the use of geoinformation software, the following was done: 1) all geological data are presented in the UTM / WGS 84 zone 36 coordinate system; 2) nine main tectonic structures of Ukraine were vectorized based on the tectonic zoning map (figure 1); 3) according to the oil and gas geological zoning scheme of the Dnipro–Donetsk oil and gas-bearing region, vectorization of twelve oil and gas regions was carried out. This is the most reliable material on the content of hydrocarbons on the territory of Ukraine. The sizes of the districts allow to receive reliable data from the satellite. Each of the districts is marked with a Latin letter from A to O. Methodical approaches were previously tested in the work [20].

3. Results

The relationship between the content of methane in the atmosphere and the content of hydrocarbons within the oil and gas-bearing areas of the DDD, established by drilling data, was analyzed [18]. Distributions of methane content in the atmosphere were compiled for each of the districts and the average value was calculated. Graphs were drawn (figure 2 and figure 3) to establish the relationship between the content of methane in the atmosphere and the content of hydrocarbons within the territory of oil and gas-bearing regions.

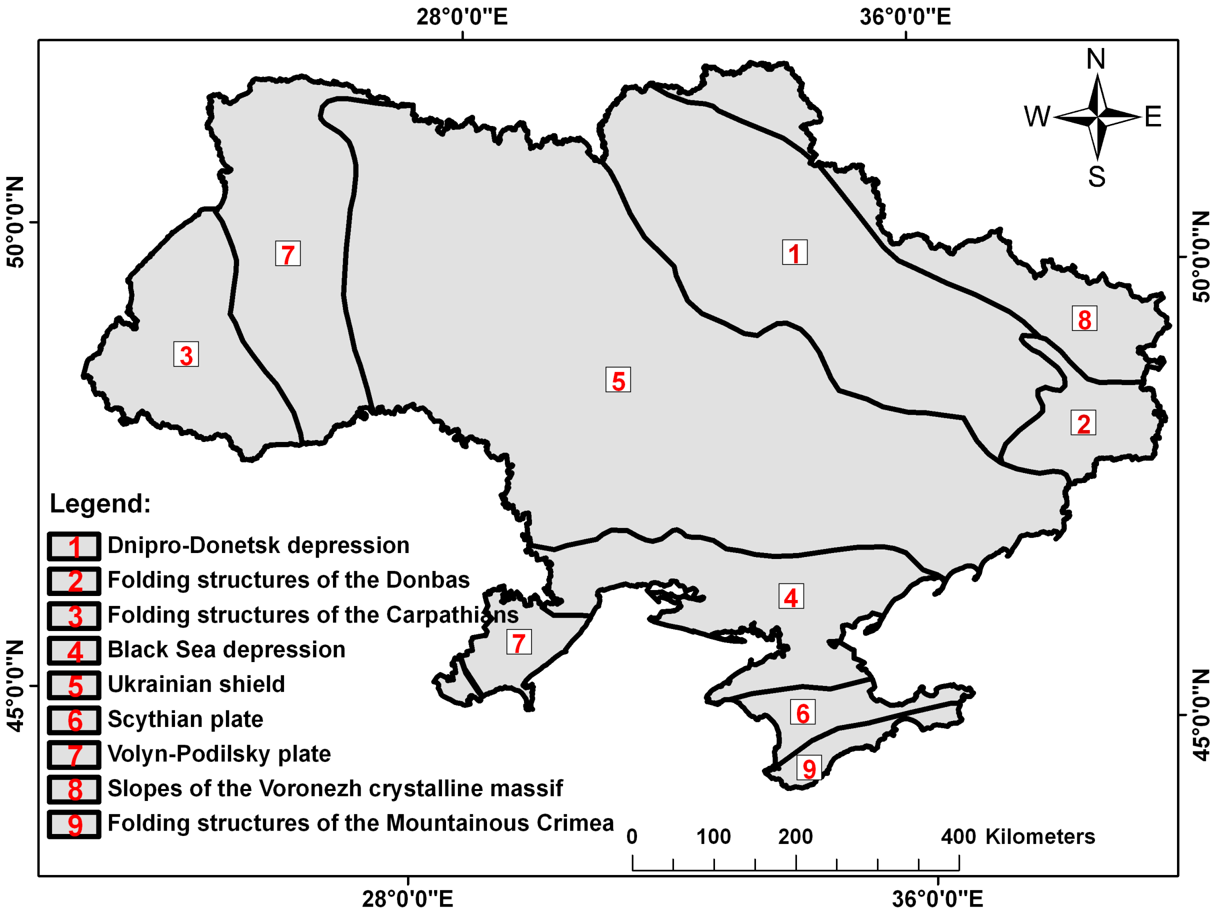

Figure 1. Vectorized contours of nine main tectonic structures of Ukraine according to [19].

The first graph (figure 2) analyzes the dependence of methane content on the size of oil and gas-bearing areas.

The second graph (figure 3) shows the relationship between the specific reserves of hydrocarbons (million tons / km^2) within each oil and gas-bearing region of the DDD and the methane content in the atmosphere above these regions.

The general regularities of the distribution of methane on the territory of Ukraine were evaluated using the Google Earth Engine (GEE) platform based on calculations of the CH_4 methane concentration in the atmosphere for the period 2019-2022. The data were obtained from the Sentinel-5P satellite and combined with the contours of the main tectonic structures of Ukraine (figure 4).

4. Discussion

Analysis of the data received from the Sentinel-5P satellite shows that methane is found in the atmosphere of Ukraine over the entire territory, with the exception of the Carpathian Mountains and Crimea.

The compiled graph (figure 2) shows that the methane content in the atmosphere does not depend on the size of the areas of oil and gas-bearing regions DDD.

The analysis of the compiled graph (figure 3) proved that all Oil and gas-bearing regions DDD are reliably divided into two groups. The first group included 7 districts (I, L, E, K, O1, B, A), and the second group included 5 districts (G, H, F, D, C).

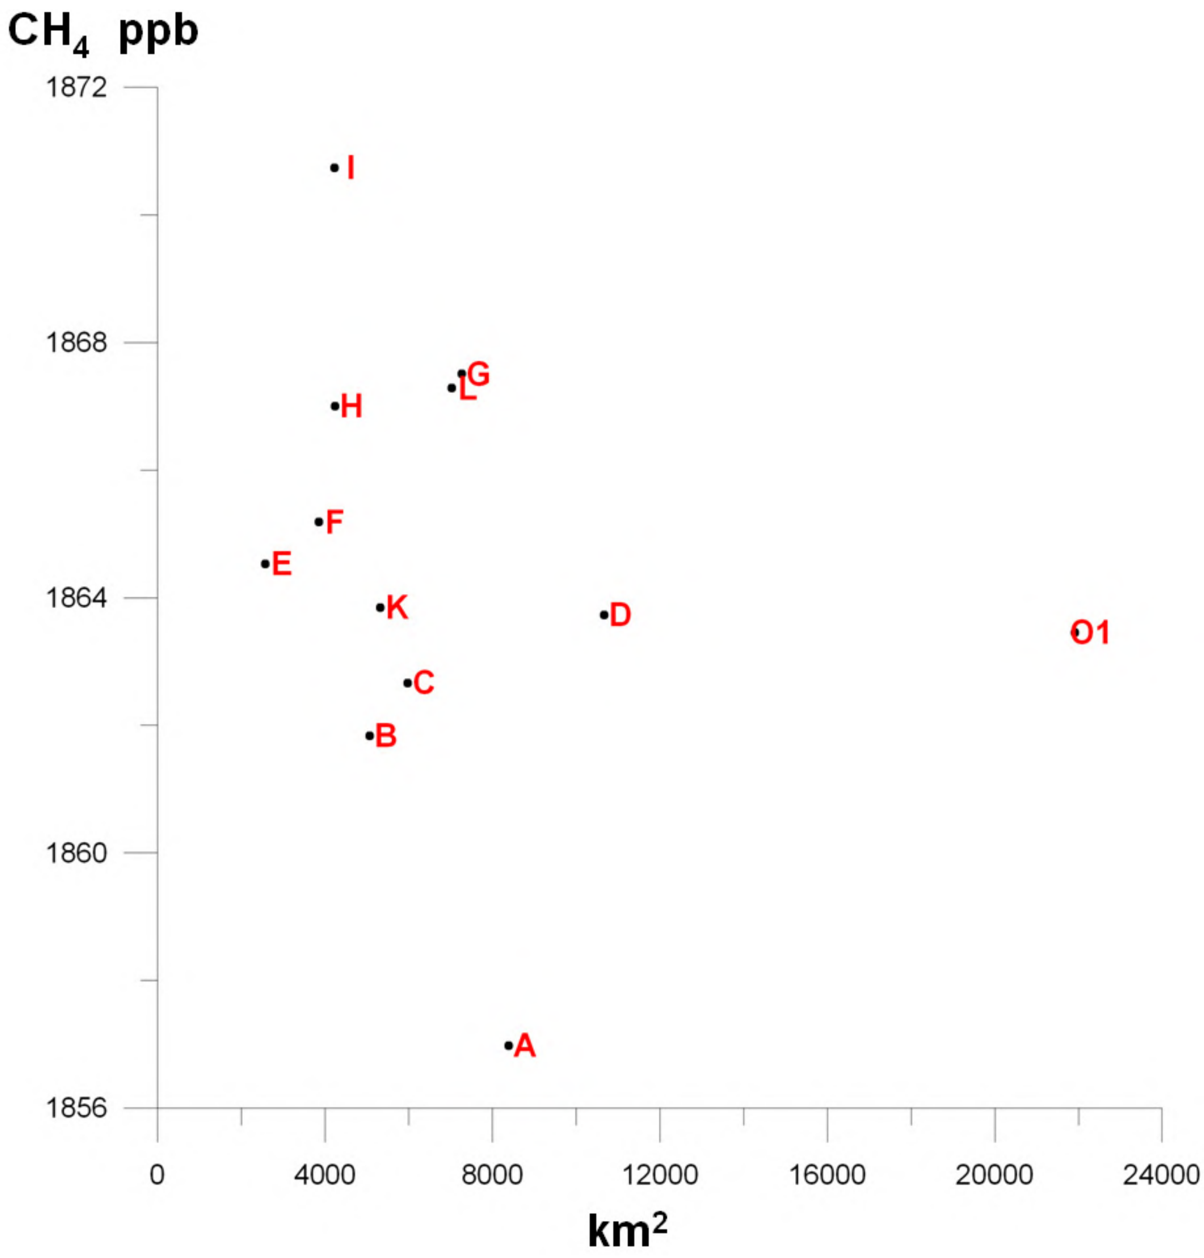

Figure 2. Dependence between the size of the oil and gas-bearing regions of the DDD and the content of methane in the atmosphere. Legend: oil and gas-bearing areas: A – Chernihiv-Braginsky prospective, B – Monastyryshche-Sofiivka oil-bearing, C – Talalaivka-Rybalske oil-and-gas bearing, D – Glynsk-Solokha gas-bearing, E – Antonivka-Bila Tserkva oil-and-gas bearing, F – Ryabukhyne-Northern-Golubivka gas-bearing, G – Mashivka-Shebelynka gas-bearing, H – Rudenky-Proletarske oil-and-gas-bearing, I – Zhovtneve-Lozivka prospective, K – Spivakivka gas-bearing, L – Kalmius-Bakhmut gas-bearing, O – oil and gas-bearing of the northern edge.

Oil and gas-bearing regions of the first group (I) are characterized by minimal hydrocarbon reserves and the maximum difference in methane content. Thus, extreme (maximum and minimum) values of methane content are marked by two regions (A, I) within which no

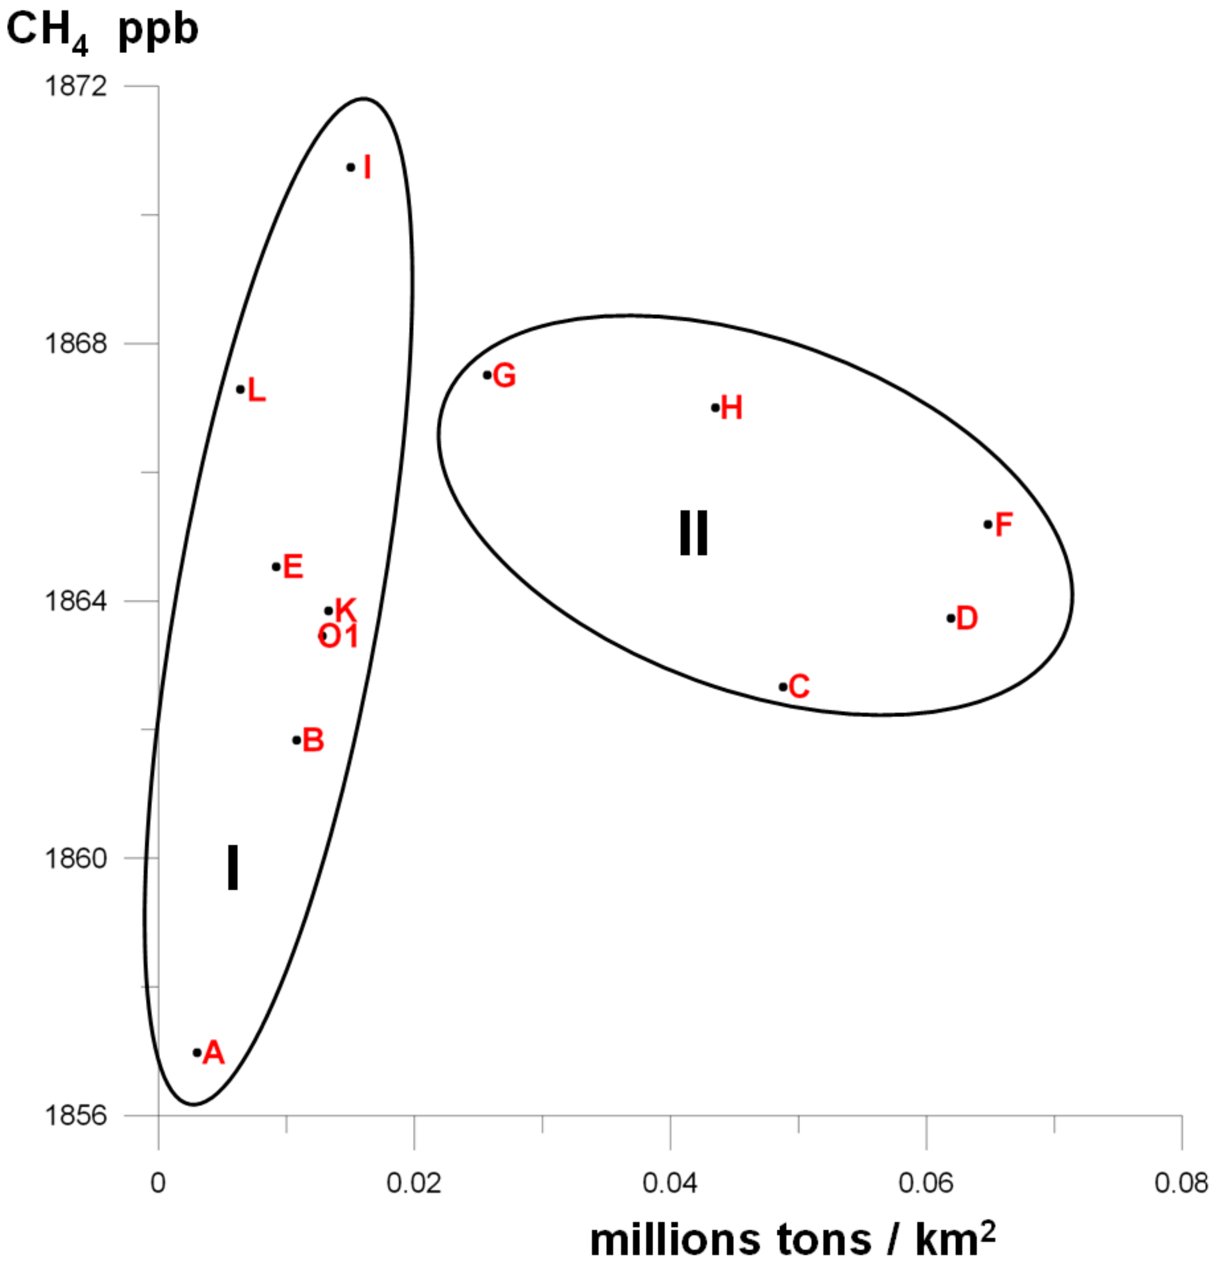

Figure 3. Dependence between the specific reserves of hydrocarbons in the oil and gas-bearing regions of the DDD and the content of methane in the atmosphere.

hydrocarbon deposits have been established. Significant differences in methane content within the regions of the first group are probably caused by corresponding differences in the permeability of the rocks that make up these regions. Thus, in the districts of the first group, there is no dependence between the size of methane reserves within their boundaries and the values of methane content.

Oil and gas-bearing areas of the second group (II) are characterized by the highest values of hydrocarbon reserves within the boundaries. Within their boundaries are also the largest DDD deposits in terms of reserves. At the same time, with an increase in the values of specific reserves of hydrocarbons within the oil and gas-bearing regions, there is a decrease in the content

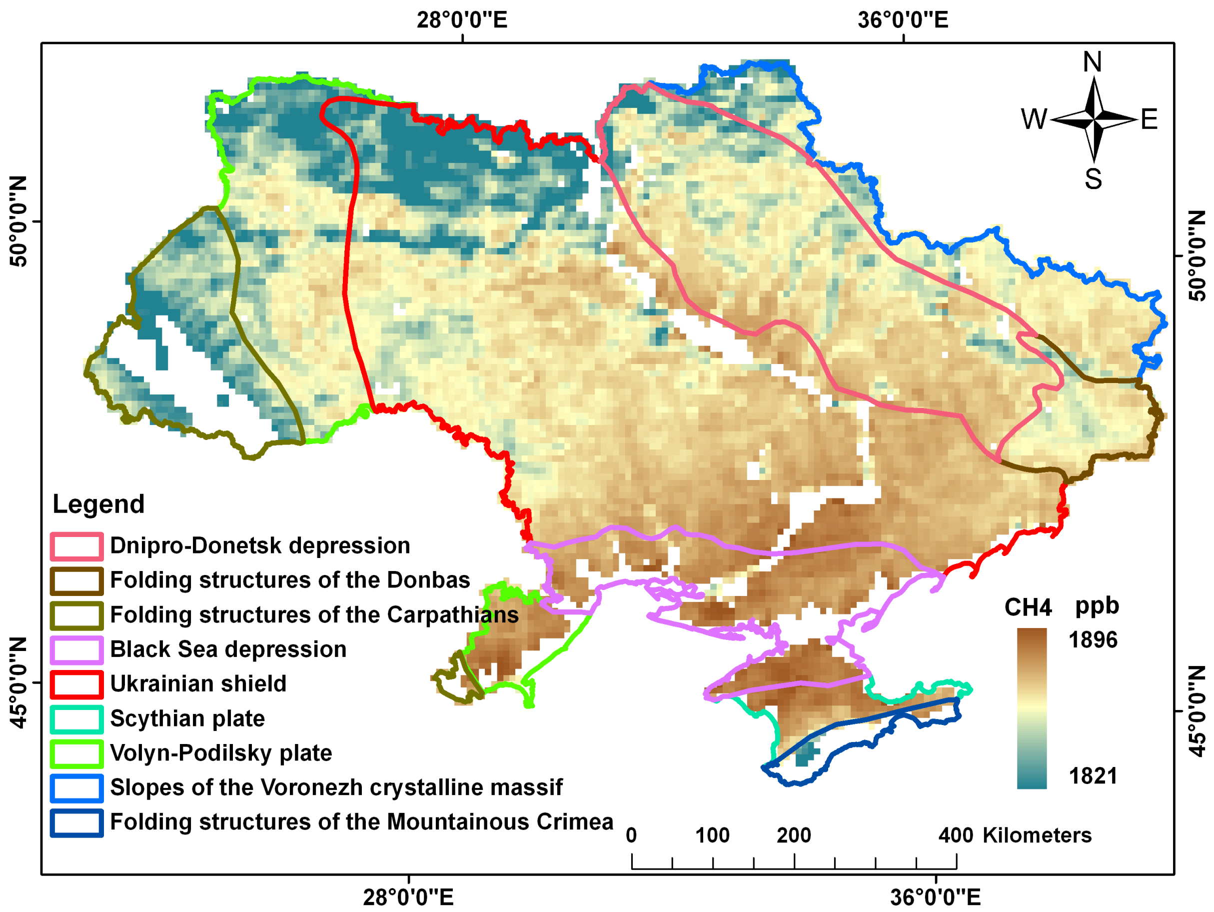

Figure 4. Spatial distribution of methane concentration over the territory of Ukraine according to data from the Sentinel-5P satellite for 2019-2022.

of methane in the atmosphere. Such a dependence is possibly related to the lower permeability of the rocks of the regions and the presence within these oil and gas-bearing regions of the best local structures within which the maximum localization of hydrocarbons migrating in the earth's crust occurs.

Thus, the conducted studies clearly indicate the connection of methane content in the atmosphere with the content of hydrocarbon reserves within oil and gas-bearing regions. This relationship is quite complex. In the future, we consider it expedient, in addition to methane, to investigate the content of other gases associated with hydrocarbon deposits.

A visual analysis of the compiled map (figure 4) proved that methane is found in the atmosphere throughout the territory of Ukraine, there are no areas where methane is absent. The content of methane naturally increases from the north-northwest to the south and southwest. This excludes the influence of vegetation, swamps, and other anthropogenic factors on the recorded content of methane in the atmosphere. Based on the connection established by our predecessors between the presence of methane and the processes taking place in the bowels of the Earth, the influence of the history of the development of individual regions on the content of methane in the atmosphere was analyzed. As a tectonic scheme, the scheme given in [19] was used. The diagram highlights 9 main tectonic structures.

According to the average content of methane and the nature of its distribution, the selected tectonic structures were divided into 3 groups. The first group, with maximum methane values, includes the Black Sea Basin of the Cretaceous-Paleogene age and the Scythian plate of the Epipaleozoic age. The second group with intermediate values of methane content includes the Variscids of the Donbas, the Precambrian Ukrainian Shield, and the Mesozoic Basin DDD. The slopes of the Voronezh crystalline massif of the Precambrian age, the Riphean Volyn-Podilsky plate, the Alpine folded structures of the Carpathians and the Mountain Crimea of the Kimmerian-Alpine age are characterized by the lowest values of methane content. The given data indicate that there is no connection between methane content and the nature of the development of tectonic structures, because one group includes tectonic structures with a completely different history of development. The distribution of methane is probably influenced by other geological factors and, above all, by faults.

A comparative analysis of methane distribution within known oil and gas-bearing areas – western (Carpathian), southern (Scythian Plate), and eastern (DDD) showed significant differences between them. The western area is characterized by the lowest average values of methane content. The southern area is characterized by the highest values of methane content, and the eastern area is characterized by intermediate values of methane content. The established discrepancies are probably related to known peculiarities in the localization of hydrocarbon deposits within these three areas, but this needs to be further analyzed [18].

5. Conclusions

According to the data of measurements of methane content in the atmosphere of Ukraine from the Sentinel-5P satellite, a map of the distribution of methane within the country was compiled.

The existence of a dependence between the content of methane in the atmosphere and the content of hydrocarbons within the oil and gas-bearing regions of DDD has been established. The most productive oil and gas-bearing regions of DDD are characterized by a relatively narrow interval of changes in the methane content in the atmosphere.

The distribution of methane content within the main tectonic structures of Ukraine is very complex and is probably not related to the specifics of their development. This problem needs further research.

Based on the conducted research, it can be confidently stated that there is a rather complex relationship between the reserves of hydrocarbons in the lithosphere and the content of methane in the atmosphere.

In further studies of the processes of degassing of the Earth, it is expedient to study, in addition to methane, other gases that are part of the gases released by the Earth's surface and which are genetically related to each other, as well as the thermal field and other physical fields.

The research of Earth degassing processes provides additional data for understanding problems related to climate change, namely the composition of the atmosphere, as well as established dependencies that can be used as additional information when searching for hydrocarbon deposits.

Abstract. PM is one of the main atmospheric air pollutants causing serious concern for public health. New evidence on health effects of PM has led to the publication of new WHO air quality guidelines. Spatio-temporal patterns of PM10 change are a current topic in atmospheric and environmental sciences. An equally important aspect is the study of the relationship between PM10 concentration and meteorological characteristics. Temperature, humidity, wind and atmospheric pressure can affect the concentration, distribution and transport of PM10. The database for the study included measurements of PM10 concentration, air temperature, atmospheric pressure, and relative humidity for 306 days in 2019 (from March 1 to December 31) every hour, a total of 7,344 for each parameter from the Ecocity public monitoring station in the central part of Ivano-Frankivsk city. There are no significant stationary pollution sources and highways near the observation site. Certain regularities were found in the daily variation of PM10 concentration: sharp increase in concentrations at night with a peak around midnight, decrease during the day (minimum around 16:00). The proposed sinusoidal model fairly well reflects the distribution of data in the morning hours, from 5 to 11 am. Significant fluctuations in daily concentrations (from 0 to 100 μg/m^3) were observed, especially in the cold period of the year. The highest average monthly values of PM10 are in March, the lowest are in July. The current average daily limit value in Ukraine and the EU is 50 μg/m^3 (no more than 35 exceedances per year), 442 instantaneous indicators above the norm. When analyzing the relationship between PM10 concentrations and air temperature, the regularity is observed both during the day and throughout the year (in cold periods, the concentration of particles is higher, which can be explained by lower air temperatures). The patterns identified are related to a number of factors, such as meteorological conditions, pollution sources, and atmospheric chemistry. Multivariate linear regression was used to find the mathematical relationship between the average monthly values of PM10 concentration, humidity and air temperature. The coefficient of determination $R^2 = 0.67$, Fisher's test F = 70.95 and the mean square error MSE = 23.12. On the basis of this, it can be stated that the model is acceptable for estimating and forecasting temporal patterns of the concentration of PM10 particles in the atmospheric air of Ivano-Frankivsk, depending on the average monthly indicators of humidity and atmospheric air temperature.

1. Introduction

Solid particles PM (eng. Particulate matter) belong to the main pollutants of atmospheric air, which cause serious concern for health [1]. These are respirable particles that consist of sulfate, nitrate, ammonia, sodium chloride, carbon black, mineral dust, or water. According to their classification by aerodynamic diameter, PM10 are particles whose diameter does not exceed 10 micrometers. Due to their small size, they are able to penetrate deep into the lungs and enter the blood, causing cardiovascular, cerebrovascular, respiratory and other diseases [2–4].

The sources of PM10 in the atmospheric air can be natural processes, but mainly they are the anthropogenic factors. Despite the EU's 2021 emission reductions, the majority of the urban population was still exposed to key health-damaging air pollutants. Concentrations exceeding the EU daily limit value for PM10 are observed mainly in Italy and some Eastern European countries, in particular due to specific meteorological and geographical conditions that contribute to the accumulation of air pollutants in the atmosphere of densely populated and industrialized areas, the extensive use of solid fuel for heating households, at industrial enterprises and thermal power plants [5].

Many states have their own national or supranational agencies that develop programs, policies, and regulations for air pollution control [6–8]. Given the impact on health, the openness and availability of official data on atmospheric air pollution is a prerequisite. Geoinformation applications such as the European Air Quality Index [9] or the Ambient Air Quality Database Application [2] allow interested parties to get an idea of air quality in individual countries, regions and cities.

The study of spatio-temporal patterns of PM distribution in the atmosphere is an important field of natural sciences. Such research is conducted by scientists, institutes and organizations around the world. NASA [10] and other space agencies, as well as private companies, use satellite data [11] to monitor and study particulate matter in the atmosphere at national and global levels. This includes the study of their sources, processes of transfer and transformation.

It is interesting from a scientific point of view to study the spatio-temporal patterns of PM10 distribution in the atmospheric air, taking into account the patterns of changes in the meteorological characteristics of the atmosphere [12]. Spatio-temporal patterns of particle distribution may differ depending on the region, climatic conditions, local sources of pollution, etc. [13]. Therefore, local research is also of a great importance [14]. This work is dedicated to the partial solution of these problems.

2. Literature review

Most of the scientific works deal with the study of the PM impact on human health. A systematic reviews collection of the latest scientific research concerning the air pollutants effects on health [15] formed the basis for the publication of new WHO air quality guidelines [4]. Regarding the new evidence of PM health effects, it is worth noting the work [16], which conducted a systematic review of 104 cohort studies on the evidence of the relationship between long-term exposure to PM2.5 and PM10 in relation to all-cause mortality and mortality from a specific cause. There was clear evidence that both PM 2.5 and PM 10 were associated with increased mortality from all causes, cardiovascular disease, respiratory disease and lung cancer, with associations at lower concentrations for the limit value of PM 2.5 of 10 $\mu g/m^3$ recommended by WHO until 2021. A study [17], in which a systematic review and meta-analysis of 196 scientific articles was conducted, found evidence of a positive association between short-term exposure to PM10, PM2.5, NO_2, and O_3 and all-cause mortality, as well as between PM10 and PM2.5 and mortality from cardiovascular, respiratory and cerebrovascular diseases.

Spatio-temporal patterns of PM10 change are a current topic in atmospheric and environmental sciences. An analysis of some works is presented below.

Fioravanti et al. [18] illustrates the main results of the process of spatial-temporal interpolation of PM10 concentration with a daily resolution using a set of 410 monitoring locations in Italy for 2015. The result of the model is a set of 365 daily PM10 maps of Italy with a grid (1 km×1 km).

Chu, Huang and Lin [19] investigated spatiotemporal patterns (PM) in Taiwan based on a number of methods (global ordinary least squares regression, geographically weighted regression, and geographically and temporally weighted regression). PM2.5 or PM10 have been found to vary over time and space, depending on weather conditions and the spatial distribution of land use and emission patterns in local areas.

Satellite-based measurements of aerosol optical depth offer the possibility of estimating impacts on populations in locations without monitoring stations, as assessed by Nordio et al. [20], in which scientists extend their previous research by including a model for missing aerosol optical depth data to combat non-randomness of missing data. The use of spatio-temporal hydrometeorological parameters modeling methods is presented in the article by Pernerovska and Arkhypova [14].

An analysis of spatial and temporal pollutants variations and their possible sources in urban areas of Istanbul [21] showed that PM10 concentrations demonstrate significant variations across the city, with current PM10 levels in several traffic hotspots and industrial areas exceeding EU air quality limit. The temporal distribution was characterized by high concentrations in winter and low in summer.

An equally important aspect is the study of the relationship between PM10 concentration and meteorological characteristics. Meteorological conditions such as temperature, humidity, wind and atmospheric pressure can affect the concentration, distribution and transport of PM10.

Huang et al. [22] studied seasonal changes and their impact on aerosol concentrations. The results revealed pronounced seasonal variability in fine particles (aerodynamic diameter less than 2.1 μm), with the highest concentration in summer and the lowest in spring.

Kayes et al. [23] studied the relationships between the average daily temperature, relative humidity, precipitation and concentrations of the main air pollutants in the city of Dhaka according to data from the period 2013-2017. The main results are a negative correlation of PM2.5 and PM10 concentrations with temperature and relative humidity; different effects of meteorological parameters' seasonal fluctuations on the air pollutants concentration; the adequacy of various models application for the solid particles modeling.

3. Materials and methods

Maximum permissible concentrations of PM10 in atmospheric air are established to protect human health and the environment. Air quality standards in the EU regarding PM are determined by Directive 2008/50/EC "On ambient air quality and cleaner air for Europe". In Europe the limit value of the daily PM10 concentration should be 50 $\mu g/m^3$ (no more than 35 excesses per year), and the average annual value should be 40 $\mu g/m^3$. In 2021, based on new evidence of low pollutants concentrations on the health effects, WHO issued new guidelines for air quality [4], with a daily average limit value for PM10 of 45 $\mu g/m^3$ and an annual average limit of 15 $\mu g/m^3$. According to them, the EU standards are currently being revised.

So far, in Ivano-Frankivsk city, which is a regional center with a population of about 250,000 people, there is no systematic state control of PM10 concentration. There is one stationary air quality monitoring post in Ivano-Frankivsk Regional Center for Hydrometeorology of the State Emergency Service of Ukraine. Here, pollutant concentrations are measured four times a day (at 01:00, 07:00, 13:00, 19:00), the content of general dust (undifferentiated by size), SO_2, NO_2, CO is assessed. Also, the state institution "Ivano-Frankivsk Regional Center for Disease Control and Prevention of the Ministry of Health of Ukraine" monitors the atmospheric air pollution condition at 20 route observation points on the border of enterprises sanitary protection zones, within residential buildings, in the influence of highways zone, etc. [24]

In recent years, Ukraine began to bring its legislation into line with European standards, therefore, in the new procedure for state monitoring in the field of atmospheric air protection [25], it implemented Directive 2008/50/EC. According to it, the system of state monitoring is gradually being modernized.

In 2023 Ivano-Frankivsk City Council approved the State Monitoring Program in the field of atmospheric air protection of the Ivano-Frankivsk agglomeration for 2023-2027 [26]. The program provides for the modernization of the atmospheric air quality monitoring system, but this requires significant capital investments, the purchase and installation of a complex of equipment at a stationary observation point for automatic operational fixed measurements.

The aim of our research was to establish spatio-temporal regularities in the distribution of solid particles (PM) and the meteorological parameters of atmospheric air.

Due to the lack of necessary data from official sources, data from public monitoring of atmospheric air quality became a substitute. For this, we used the database of the Ukrainian network of public air quality monitoring – Eco City [24]. Starting in 2019, about ten such online monitoring stations were installed within Ivano-Frankivsk city. Each monitoring station in real time analyzes the content of such pollutants as PM10, PM2.5, CO, SO_2, NO_2, etc., as well as meteorological parameters of atmospheric air.

To achieve the goal of our research, we developed a database for one Eco City public monitoring station for 2019. The station is located in the central part of Ivano-Frankivsk within the historical and architectural protected territory of local importance. There are no significant stationary pollution sources and highways near the observation site (figure 1). The database included hourly measurements of PM10 concentration, air temperature, atmospheric pressure, and relative humidity for 306 days in 2019 (from March 1 to December 31) every hour, with a total of 7,344 measurements for each parameter.

Figure 1. Location of public air quality monitoring station.

4. Results and discussion

Based on the average hourly PM10 concentrations determination for the studied period (306 days), certain regularities in the daily concentration change were established (figure 2). At night (from 00:00 to 05:00) there is a sharp decrease in concentrations, in the morning (from 06:00 to 09:00) concentrations begin to increase and stabilize (from 10:00 to 11:00). During the day (11:00 a.m. to 5:00 p.m.) concentrations continue to decrease, reaching a minimum around 4:00 p.m. In the evening (after 18:00) concentrations increase again, reaching a peak at midnight.

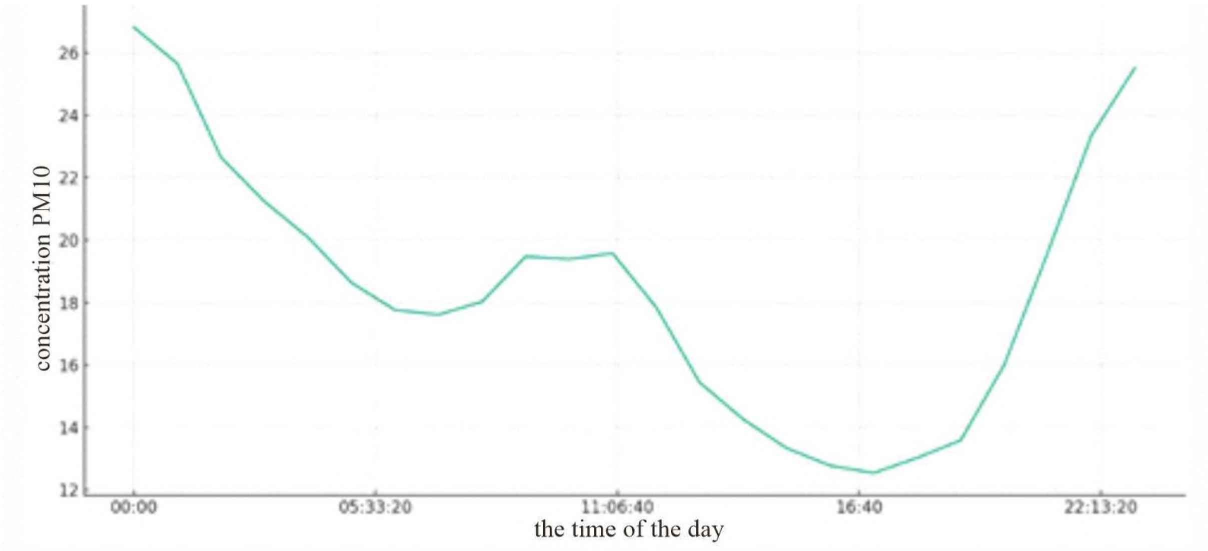

Figure 2. Daily change of PM10 concentration.

These data may indicate certain daily patterns in PM10 distribution, in particular, related to human activity and meteorological conditions. Different approaches can be used to find the mathematical regularity of the PM10 daily distribution, one of the approaches is data modeling functions use. Since the daily distribution is cyclical in nature, the sinusoidal function can serve as one of PM10 daily distribution expressions. Using a sinusoidal function of the form:

$$y(t) = A\sin(B(t + C)) + D \tag{1}$$

where A is amplitude, B is frequency, C is phase shift, D is vertical shift, t is time (h).

The equation that describes the sinusoidal model for the daily distribution of PM-10 dust particles:

$$y(t) = -1.256\sin(1.435(t - 1.610)) + 18.433 \tag{2}$$

where $y(t)$ – concentration of PM10 (μg/m^3), t is time (h).

Figure 3 is a visualization of both actual and predicted PM10 values to see how well our model represents the diurnal distribution. As you can see, the sinusoidal model fairly well reflects the distribution of data in the morning hours, from 5 to 11.

To find the relationship between PM10 concentration values and air humidity, we will try to use linear regression. This will allow us to understand whether there is a direct or inverse relationship between these two quantities. To get an idea of their dependence, we visualize these two values on a scatter plot (figure 4).

The distribution shows that the relationship does not appear to be linear, but there is probably some correlation between these two quantities. The following linear regression model

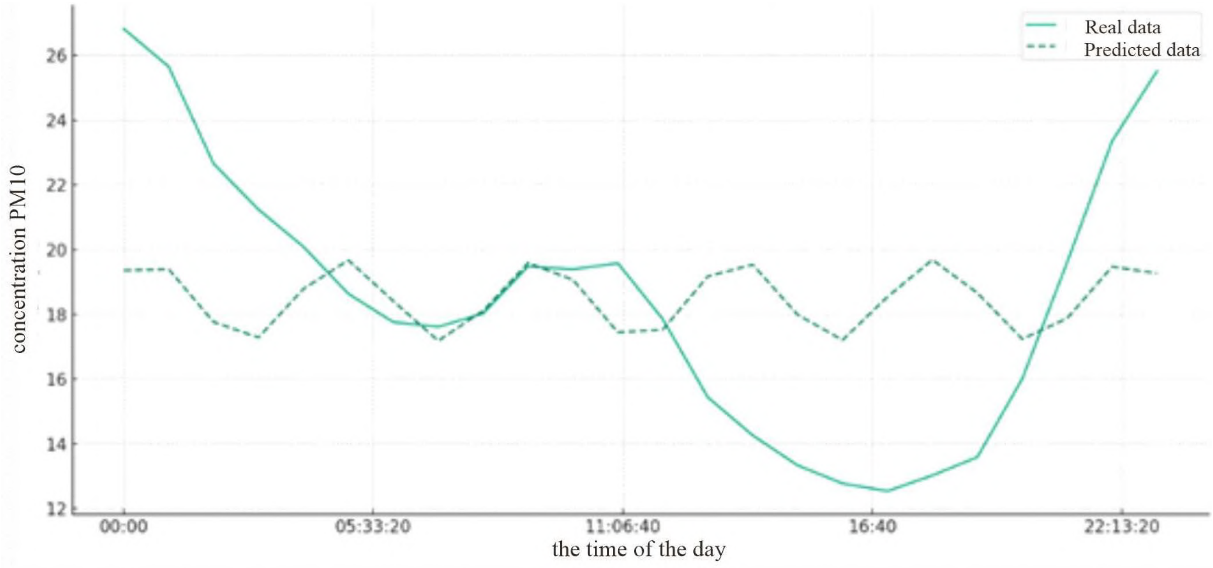

Figure 3. Real and predicted PM10 daily distribution.

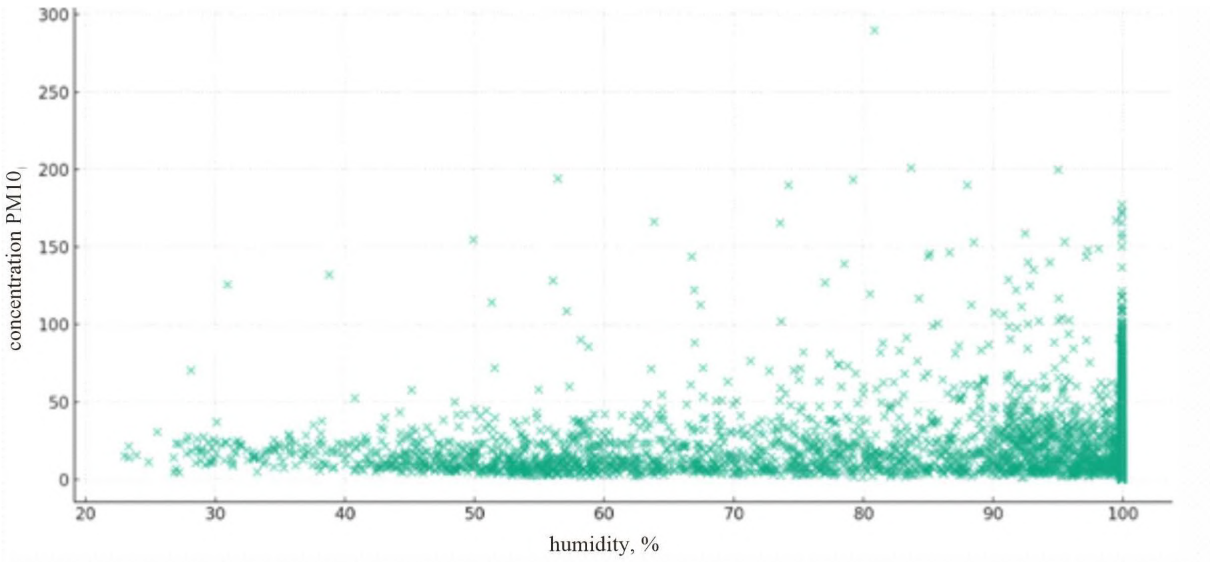

Figure 4. Dependence of PM10 concentration on air humidity.

was obtained:

$$y = -0.0117 \cdot h + 20.32y = -0.0117 \cdot h + 20.32 \tag{3}$$

where y is the PM10 concentration (μg/m^3), h is the relative air humidity (%).

The coefficient of determination R^2 for this model is very small (about $9.23 \cdot 10^{-5}$), which indicates that there is no linear direct or inverse relationship between PM-10 concentration and air humidity

Average daily concentrations were determined in order to obtain regularities in PM10 concentrations distribution on an annual basis. The dynamics of average daily PM10 values in the studied period (March-December) is presented in figure 5. Although the conclusions are somewhat limited due to the lack of values for January-February, there are certain seasonal patterns of changes in the average daily of PM10 concentration values. Hypothesis by analogy with figure 3 – an increase in concentration is associated with a decrease in air temperature, a decrease – with an increase. The regularity can be observed both during the day (temperatures are always lower at night than during the day) and throughout the year (in cold periods, the concentration of particles is higher).

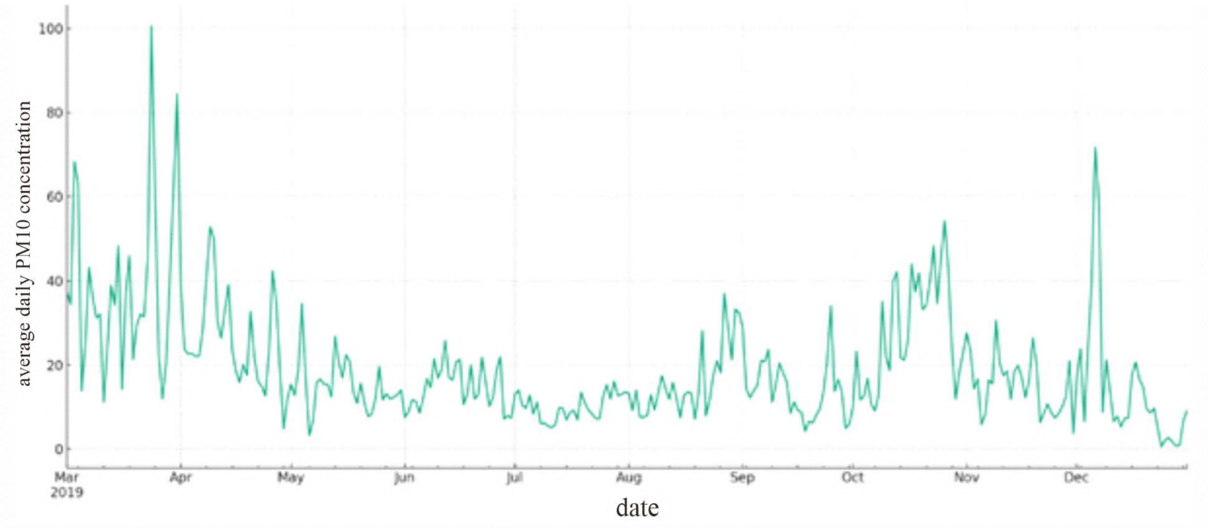

Figure 5. Dynamics of average daily PM10 concentration values.

In figure 5, significant fluctuations in daily concentrations (from 0 to 100 μg/m^3) can be observed, especially in the cold period of the year. The highest average monthly values of PM10 are in March, the lowest are in July. With the average daily limit value of 50 μg/m^3 in force in Ukraine and the EU, the number of exceedances is 442 instantaneous values. According to EU standards, no more than 35 average daily exceedances per year are allowed.

The established patterns are probably related to a number of factors, such as meteorological conditions, sources of pollution or chemical processes in the atmosphere. For example, in the colder months, the use of heat energy increases, in particular by burning solid fuel in the city's boiler houses, which leads to an increase of solid particles concentration. The heating period in Ivano-Frankivsk lasts on average from the second decade of October to the second decade of April. Also, in the cold period, humidity is usually higher and the air can be more stable, which makes it difficult for pollutants to disperse.

To test the hypothesis of the dependence of the solid particles concentration on the air temperature, to establish seasonal features and relationships, the average monthly and average weekly PM10 concentration and the average monthly and average weekly air temperature were calculated. The obtained results are presented in figure 6.

Visually, it can be assumed that there is an inverse correlation between temperature and PM10 concentration, especially in colder months: PM10 concentration is usually higher at lower temperatures.

The mathematical relationship between the average monthly PM10 concentration and the average monthly air temperature is described by the equation:

$$\mathrm{PM10} = -0.5914 \cdot t + 27.6082 \tag{4}$$

where PM10 – PM10 concentration (μg/m^3), t – temperature, $^{\mathrm{o}}$C.

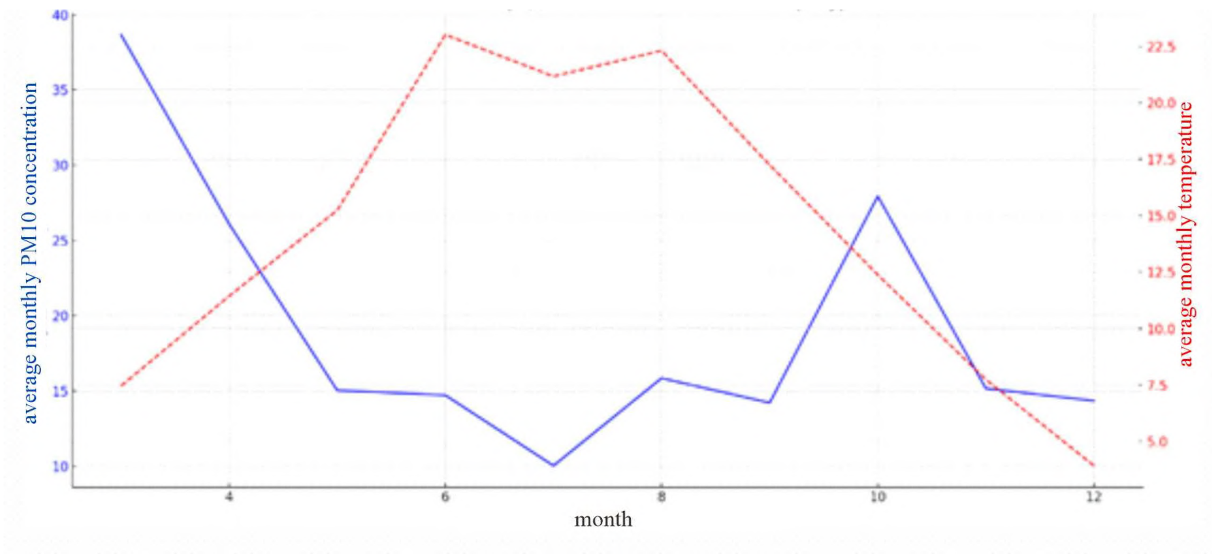

Figure 6. Dynamics of average monthly values of PM10 concentration and air temperature.

The coefficient of determination R^2 for this model is approximately 0.20, which indicates a low degree of connection between temperature and PM10 concentration for average monthly indicators.

Linear regression was also used to find the mathematical relationship between the average monthly values of PM10 concentration and air humidity. The mathematical relationship between values is described by the equation:

$$\mathrm{PM10} = -0.8274 \cdot h + 95.5097 \tag{5}$$

where PM10 is PM10 concentration (μg/m^3), h – relative air humidity (%).

The coefficient of determination R^2 for this model is approximately 0.51, which indicates a moderate relationship between humidity and PM10 concentration for monthly averages.

To test the hypothesis about the joint effect of factors on PM10 concentration, multivariate linear regression was used to find the mathematical relationship between the average monthly values of PM10 concentration, air humidity, and temperature, which is described by the equation:

$$\mathrm{PM10} = -0.7963 \cdot h - 0.5322 \cdot t + 100.1946 \tag{6}$$

where PM10 – PM10 concentration (μg/m^3), t – temperature, $^{\mathrm{o}}$C, h – relative air humidity (%).

The coefficient of determination R^2 for this model is approximately 0.67, which indicates a significant moderate relationship between the specified parameters and PM10 concentration for average monthly indicators.

A higher coefficient of determination compared to previous univariate regressions may indicate that the combined factors (humidity and temperature) together better explain the variability of PM10 concentration.

This confirms the hypothesis that t PM10 concentration in the atmospheric air of Ivano-Frankivsk city depends on a set of meteorological parameters, the main ones of which, as we proved in the conducted research, are the atmospheric air temperature and the air relative humidity.

The 3D image (figure 7) illustrates the dependence of the average monthly PM10 concentration on humidity and air temperature.

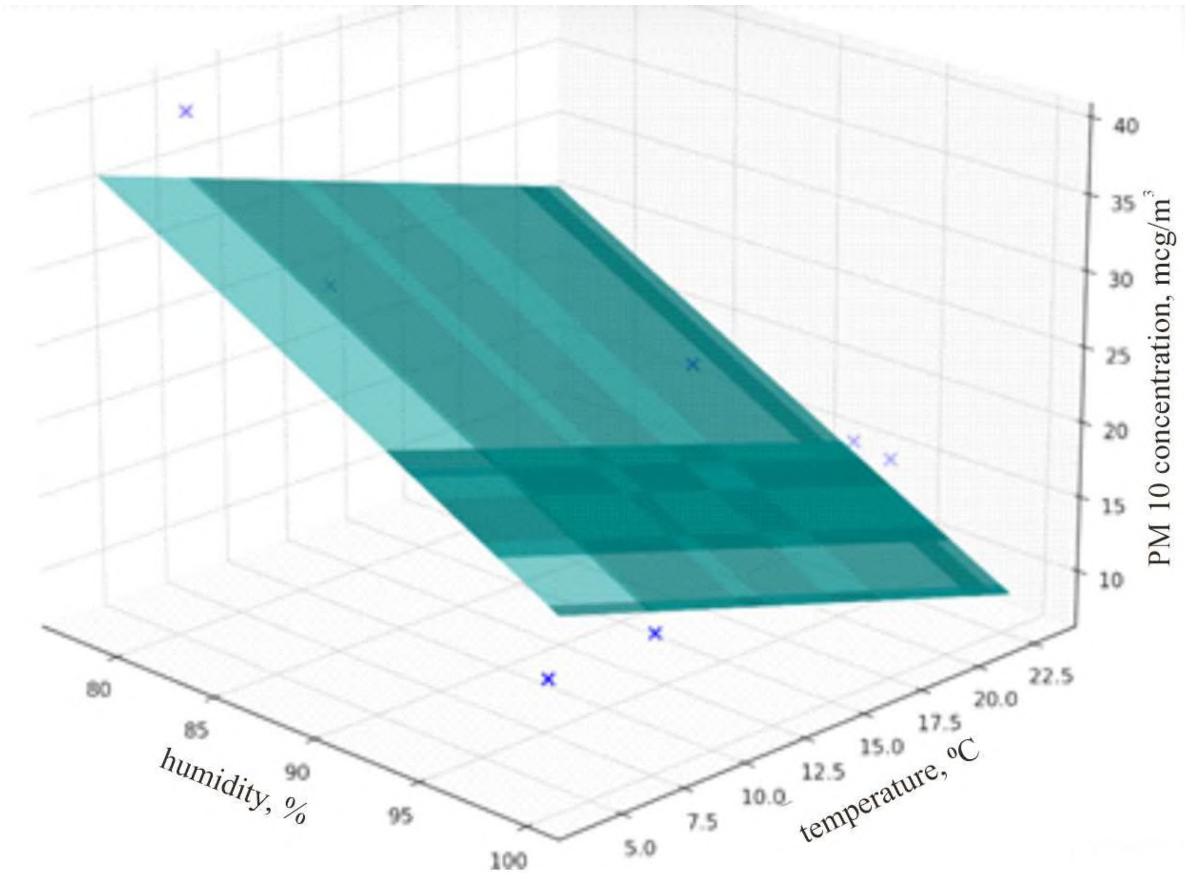

Figure 7. Dependence between average monthly values of PM10 concentration, temperature and air humidity (blue crosses – real data, blue surface – predicted plane based on multivariate linear regression.

To confirm the importance of the coefficient of determination R^2 (0.67), Fisher's test $F = 70.95$ (more than critical) and mean square error MSE = 23.12 were calculated. On the basis of this, it can be stated that the model is acceptable for estimating and forecasting temporal patterns of PM-10 solid particle concentration in the atmospheric air of Ivano-Frankivsk city, depending on the average monthly indicators of humidity and atmospheric air temperature.

5. Conclusions

In the article the database of the public air quality monitoring station in the central part of Ivano-Frankivsk is analyzed and the mathematical dependence for assessing and predicting the time patterns of PM10 particle concentration in the atmospheric air of Ivano-Frankivsk depending on the average monthly humidity and temperature is proposed. The main conclusions are as follows:

1. In the daily variation of PM10 concentration, a decrease in concentration is observed from a maximum of about 0:00 to a minimum of about 16:00 (with an intermediate increase and stabilization at 10:00-11:00). The proposed sinusoidal model reflects the distribution of data in the morning, from 5 to 11, quite well.
2. The seasonal variability of PM10 concentrations is characterized by higher values in the

cold season (the highest monthly average PM10 values are in March, the lowest in July). However, there are significant fluctuations in average daily concentrations (from 0 to 100 μg/m^3), especially in the cold season. 442 instantaneous indicators are above the normal daily average limit value of -50 μg/m^3.

3. There is a relationship between PM10 concentrations and air temperature both during the day (nighttime temperatures are always lower than daytime temperatures) and during the year (higher particle concentrations during cold periods).
4. The assumption of the joint effect of air humidity and air temperature on PM10 concentration is confirmed by the regression equation between the average monthly values of the parameters: $PM10 = -0.7963 \cdot h - 0.5322 \cdot t + 100.1946$. The values of statistical indicators ($R^2 = 0.67, F = 70.95$, MSE $= 23.12$) indicate that the function is acceptable for assessing and predicting the temporal patterns of PM10 particle concentration in the air of Ivano-Frankivsk depending on the average monthly humidity and the atmospheric air temperature.
5. The identified daily and seasonal patterns are likely related to such factors as meteorological conditions, pollution sources, or atmospheric chemistry, which requires further investigation. And the identification of the relationship between the total impact of meteorological factors on the PM10 concentration can be used to adjust management decisions to monitor and improve air quality in the city.

Abstract. The paper shows the advantages of using remote satellite monitoring of the Earth in the educational process for the purposes of sustainable development. Using the example of the study of water vapor content in the atmosphere of Ukraine from 2001 to 2022, calculations of two approaches to obtaining, processing, and interpreting remote sensing data are given. The first approach – complicated – consisted of receiving satellite monitoring data and their further processing (transformation, cutting within the given area, interpretation, and conversion) in the Erdas Imagine program directly on a local computer. The second approach – simplified – consisted of the application of the Giovanni NASA online web application, which allows effective use of remote satellite monitoring data on a remote server based on specific requests and configured parameters, with results displayed on the screen in the form of thematic maps and graphs, that is, requiring their processing to a minimum. The discussion provides a comparison of the obtained results of these two proposed approaches (complicated and simplified) and describes their advantages and disadvantages for more efficiently obtaining the results of scientific research.

1. Introduction

In the last decade, the problem of modernizing the education system and ensuring its high quality was at the center of attention in Ukrainian society. The education of schoolchildren acquires new characteristics thanks to the availability of information technologies, and the emergence of an informational educational space and environment, which is necessary for self-development and self-improvement. A developed intellect, the ability to competently work with any information, and a generally high level of information culture are the most important characteristics of a person adapted to life in modern society.

Modern higher education is characterized by an active transition to the use of new information technologies. In the educational process, informatization programs are implemented, electronic textbooks are developed, and distance learning technologies are developed [1]. All this is due to the fact that a graduate of a higher professional education institution must be ready to work with ICT. Such skills will be needed when solving professional tasks. Adhering to modern trends, employers set higher requirements for future professionals.

Geoinformation technologies are technologies and systems that allow the user to work with spatial data, build models, and solve tasks of spatial and temporal analysis. In the same context, the term geoinformation systems can be formulated – these are systems whose task is the collection, storage, and analysis of spatio-temporal data, as well as their graphic visualization. Today, GIS is used to understand both software and application packages that allow the processing of spatial data [2]. The implementation of these technologies in the system of geographic education is based on the use of GIS – geoinformation systems [3, 4].

The use of information technologies in the natural sciences makes it possible not only to verify information but also, based on the concept of scientific education, to acquire a new, own system of knowledge and ideas about how our planet "works" and how we influence it. Today, anyone can get access to satellite Earth observation data. The space image contains a large array of information, which can be seen and analyzed through the use of a number of special software tools. Currently, there is a large amount of such software in the world, which is created both on a commercial basis and with open-source software. This publication focuses on using Giovanni. It is one of the well-known functional resources that are freely available, dynamically developing and used internationally in academic and professional environments.

The combination of remote sensing with geoinformation systems made it possible to explore the Earth's surface in a new way [5]. The accuracy and information content of remote sensing data is constantly improving due to the increase in the resolution of satellite images and the number of channels, the spectrum of the survey can show detailed information about the level of various objects. Satellite imaging allows not only to obtain images of the Earth's surface and calculate various spectral indices from them but also to obtain maps of geophysical indicators of the state of the environment on a planetary scale using various climatic, hydrological, chemical, and other models in combination with ground data from monitoring stations.

2. Literature review

The practice of using materials of remote sensing in research projects of students of general educational institutions and students in higher education exists and is described in many scientific and methodological works. Namely, as Voss et al. point out [6], the use of remote sensing in school education is reduced to the visual presentation of satellite images to students in lessons, therefore the need to develop educational and methodological literature and didactic teaching aids is necessary to improve the literacy of students and retrain teachers in this direction. The results of an online survey of teachers of geography in Northern Ireland, as stated in [7], indicate that, in general, teachers positively perceive GIS as a tool that can be used in the educational process, express a desire to receive additional materials and undergo training in this direction. In Norway, Rød et al. [8] concluded that the gradual implementation of GIS in school by geography teachers should start with web applications based on GIS or free viewing programs, in particular satellite images. For example, in the publication [9], a broad international view on the pedagogical value of GIS technologies in school was collected and it was demonstrated that GIS is not only a technological tool that should be used in school but also a catalyst for motivation, encouragement and cooperation in understanding and solving global problems. Students should have the opportunity to independently investigate the chosen scientific problem so that their educational experience is real and useful, and the introduction of GIS and remote sensing technologies into the educational process contributes to the performance of such research. Similar reviews were also conducted by Ukrainian scientists, in particular in the work considered the implementation of GIS in the geography course of a specialized school [10, 11]. The analysis of scientific and pedagogical literature showed that in Ukraine, at present, the implementation of GIS and remote sensing technologies in the practice of school education is just beginning.

The educational experience of using materials of remote sensing in higher schools is described in such works. Hejmanowska et al. [12] on the example of the use of satellite images in higher educational institutions, it is assumed that the use of GIS and remote sensing technologies forms a scientific type of thinking in the student. The development of educational electronic materials on the use of remote sensing of the environment is presented in the work [13]. Enhancing visualization techniques with a digital AR application called Satellite Skill 5 helps users conceptualize the theory and technology of remote sensing by demonstrating the potential of datasets such as multispectral imagery, SAR backscatter, drone orthophotography, and bathymetric LIDAR to solve real-world problems, with examples solving many issues of UN sustainable development. The goals (SDGs) are given in the work [14]. Electronic learning of photogrammetry, remote sensing, and spatial informatics is discussed in the paper [15] which emphasizes that GI-Science achievements for the natural and anthropogenic environment help to improve the quality of life. Learning through education must match these achievements. The work deals with training in the field of remote sensing and Internet technologies [16]. The authors of the work present their vision of the application of the geoinformation system in education [17–19]. The importance of teaching geographic information systems at universities in the process of building a European society based on knowledge is shown in the work [20].

A lot of researchers use Giovanni, a web-based application of the NASA Goddard Earth Science Data and Information Services Center (GES DISC) Distributed Active Archive Center (DAAC). Giovanni is a tool for science education. Lecturers at the University of Plymouth (UK), the University of South Carolina (USA), and Bigelow Laboratory for Oceanic Sciences (Maine, USA) have described Giovanni as a very useful tool for their educational activities, and at Plymouth University they call Giovanni a research tool that allows students to explore the regions and processes of their interest with great ease. At the University of South Carolina, training involved generating specific types of Giovanni output for specific regions to illustrate oceanic processes in those regions. In all cases, lecturers noted that the ease of use of the program and the opportunities it provides to students with limited computer experience were an indisputable advantage. The experience of these universities indicates that Giovanni can easily be added as a research tool to oceanographic classrooms. In the early months of 2007, the US Naval Academy (QUSNA) Remote Sensing Class participated in initial pedagogical testing of the use of Giovanni in oceanographic education. First, the students took an oceanographic "knowledge test" consisting of questions that could be answered using Giovanni, and then they were shown an interactive lecture using Giovanni. After the demonstration, the students briefly described their impressions of the system and their expectations from it. After the demonstration, the lecturer created a collaborative research project using Giovanni as a research tool. After the research project presentations, students were shown how to use Giovanni to answer survey questions, and all students answered more survey questions correctly after using Giovanni. At the end of this exercise, students completed a short survey about their use of Giovanni and rated their expectations. All students reported that Giovanni met or exceeded their expectations for ease of use and visualization and analytical capabilities [21]. Acker et al. [21] also describes the benefits of using Giovanni in high school study of environmental science to study regional climate change, compare oceanic regions, and determine how much rain tropical storms contribute to the annual precipitation of a selected region.

Giovanni is a well-known tool for scientific research, since its launch, more than 1700 articles on Giovanni have been published in peer-reviewed scientific journals. In particular, a large number of works highlight the results of the analysis of air quality, the nature of wind for wind energy, the relationship between weather and human health, monitoring the impact of agriculture, the correlation of algae blooms, etc.

Based on the relevance of the study of the use of remote sensing for educational purposes and the analysis of international experience, the **problem** stated in this article is the possibility of using two approaches to the processing of remote sensing data in the educational process.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012003 doi:10.1088/1755-1315/1415/1/012003

The **purpose** of this research is to compare the implementation of two approaches: complicated, which requires downloading and processing data in specialized software, and simplified, automated study of one of the applied problems using remote cloud resources, namely the study of the water vapor content in the atmosphere.

The **object** of the research is complicated and simplified approaches to the processing of data of remote sensing.

The **subject** of the study is the monitoring of the water vapor content in the atmosphere over the territory of Ukraine from 2001 to 2022 using the two approaches.

The **task** of the research – is to assess the skills and abilities of pupils and students necessary for the implementation of two approaches.

3. Methodical approaches

For a deeper understanding of natural processes, we considered two approaches to working with remote sensing data. *I approach (complicated)* is an approach, where the researcher has to: 1) Use the Internet or other primary data, establish which data from which satellites are needed for the research, and 2) find sites with an archive of information on remote sensing data. (Usually, climatic data are never in the same archive with data of high and medium spatial resolution), 3) via the Internet to receive the selected files for the study area on a personal computer, 4) to find software that will be able to open the input files without error and convert them, taking into account the storage features, into a convenient and familiar data format for a scientist. (For example, climate data can be in *nc*, *hdf*, *csv*, or other formats, while optical multichannel data is usually in *tif* format for each channel separately), 5) conducting a direct study with transformed input data and obtaining a result (in the study, an example of using a software product for processing remote sensing data – Erdas Imagine will be shown).

The Erdas Imagine program is one of the well-known software complexes for processing remote sensing data, which allows you to open data in various formats, perform their radiometric and spatial correction, calculate various indices, perform image classification, etc. The program has the ability to create your own models, which can consist of various raster data (satellite images, topographic maps, digital relief models, etc.) and vector data (contours of administrative areas, elevation isolines, etc.), which allows solving various problems facing researchers.

Using the Erdas Imagine program, data processing consists of the following steps: 5.1) Receiving input data in *csv* format and converting it to *grd* format using a developed program that adds additional information about the total number of columns and rows of the image, as well as latitude coordinates and longitude; 5.2) Using the space image processing program Erdas Imagine, input data from *grd* format to *img* format was converted using the *Import* function; 5.3) Multi-channel images containing data from January to December were created for each year using the *Layer Stack* function; 5.4) Using the *Model Marker* function of the Erdas Imagine program, the average values of water vapor for each year were calculated; 5.5) The territory of Ukraine was selected using a vector layer from the "Ukraine 500" map using the *Subset* function; 5.6) The UTM / WGS84 coordinate system was established using the *Reproject* function of the Erdas Imagine program. The validity of using the complicated approach is confirmed in the works of [22–24].

Data from the Terra/MODIS satellite, namely, the MOD07 product, were used as input values for the *I approach* for the diagnostic assessment of the water vapor content over the territory of Ukraine. The study used 264 images of monthly values of water vapor concentration for the years 2001-2022 [25]. The input data processed according to the method made it possible to obtain the averaged distribution for the period 2001–2022 and plot changes in water vapor over 22 years. The ArcGIS program was used for the visual design of the drawings with the addition of geographic coordinates, scale, and legend.

II approach (simplified) – has a significant difference from the first, to achieve the result,

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012003 doi:10.1088/1755-1315/1415/1/012003

the scientist does not need to perform points 1) – 4) of the previous method. The researcher immediately conducts research using a web platform or an online application, which provides him with a simple and intuitive way to visualize, analyze, and access huge volumes of remote sensing data of the Earth, without downloading them directly to a computer for processing (for example, the use of the Giovanni online application is given).

Giovanni (Geospatial Interactive Online Visualization and Analysis Infrastructure) is a web application developed by NASA's Data and Information Services Center (GES DISC). Giovanni is one of the pioneering web services available to the public to analyze NASA Earth data. Since 2003, Giovanni has provided users, both novice and expert, with a way to use remote sensing data and model that data with a minimal investment of time and software. Scientists and educators note the ease of use of Giovanni. This resource provides a way to find data from more than 1600 geoscientific variables (information about weather, climate, atmospheric composition and dynamics, oceanography, hydrological processes and interactions of Earth systems, etc.) of interest to a wide range of research fields, and serves as a reference an environment for finding topics of scientific research. Giovanni consists of the following main elements: an interactive map for selecting the research area; a menu of available data products; a calendar menu for choosing a time period; a visualization options menu; visualization-specific options (color palette, axis values); output options menu.

The data with which the web application allows you to work have a low spatial resolution – from one to tens of kilometers due to the complexity of modeling such data and their significant dependence on the ground observation network. At the same time, the frequency of shooting is usually quite high – once a day, which allows for effective use of this data by services for monitoring natural processes and warning about emergency situations. Giovanni allows researchers to quickly explore data, and most importantly, the data can be analyzed directly online before downloading high-resolution input data.

To use the Giovanni web application, researchers need to take the following steps: 1) Register on the Giovanni website (`https://giovanni.gsfc.nasa.gov/`); 2) Selecting the indicator that we need to investigate, namely Water Vapor, for this on the Select Variables panel, select Atmospheric Chemistry (Chemical components of air); then under the keyword Water Vapor in the new list that will appear in the window, select Precipitable Water Vapor (IR Retrieval) Total Column: Mean of Level-3 QA Weighted Mean (MOD08M3 v6.1); 3) Select the study range (year/month/day), the selected Precipitable Water Vapor data is available from the middle of 2002 to present. In the Select Date Range (UTC) field, select the period for which the program should generate an averaged map, namely from 2003 to 2022; 4) Select the display format of the research result in the Select Plot field. Below are three ways to display Time-Averaged Map data. Area-Averaged Time Series and Time Series, Recurring Averages; 5) Selection of the research area: in the Select Region (Bounding Box or Shape) line, draw a rectangle within Ukraine on the map. The program can process the research territory – within the state borders of the country or any rectangular or square shape specified by the user; 6) Finally, press the Plot Data button to display the data. The obtained results in the form of a map on the graph can be saved to the computer as an Image or downloaded in Microsoft Excel format.

Data from the TERRA/MODIS satellite was used as input values for the II approach for the diagnostic assessment of the water vapor content over the territory of Ukraine, namely, the MOD08 product, which is sorted into cells 1 by 1-degree equiangular grid, which covers 24-hour interval, and then summed worldwide.

4. Results

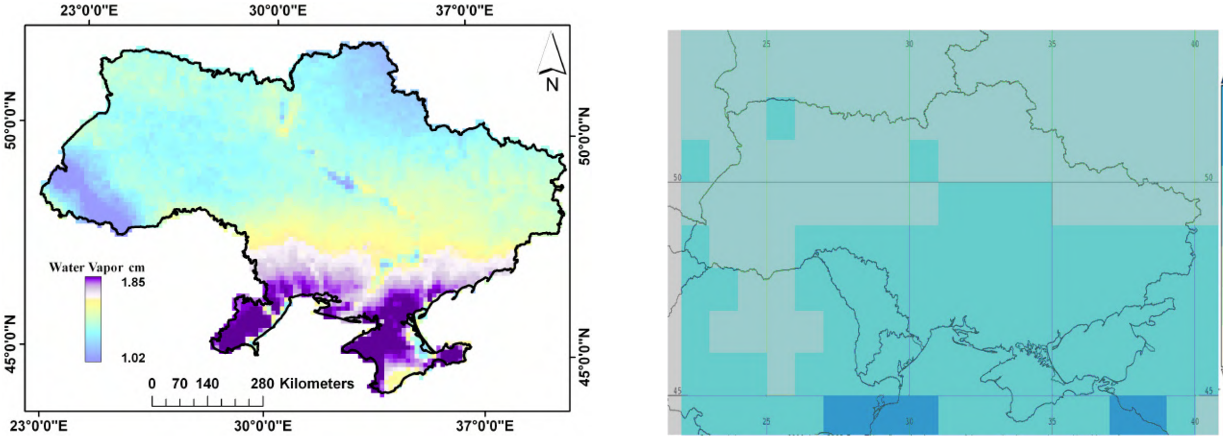
The content of water vapor in the atmosphere over the territory of Ukraine was taken as an example of the study to establish its contribution to the warming process.

In recent years, the increase in surface temperature has been an indisputable fact, but the mechanisms that contribute to global warming remain unclear, and it is becoming increasingly important to explain their respective effects on air temperature rise. Despite the obvious influence of natural mechanisms of climate formation, many researchers (for example, the Intergovernmental Panel on Climate Change) call the increase in the content of greenhouse gases CO_2 and CH_4 the main mechanism of modern warming of the global climate. Although increases in carbon dioxide and methane may be a source of increased greenhouse effect and therefore global warming, the role of the most important molecule in our atmosphere, water, is rarely discussed. Water vapor is not only the main greenhouse gas on Earth. Due to the release of latent heat during condensation, it also plays an active role in the dynamic processes that shape the global atmospheric circulation and thus the climate. Scientific research on the role of water vapor in global and regional weather processes is evidenced by the following studies. The effect of water vapor on climate change depending on altitude is shown in [26]. The researchers discovered the dependence of climate change on water vapor, due to which the temperature trend first increases at low specific humidity, and then decreases with increasing specific humidity. At ground level, the maximum trend of temperature change is manifested in the range of specific humidity of 2.0–3.0 g/kg. This suggests that water vapor is a mediator of climate change and may be responsible for altitude-dependent climate change. The study [27] used the Global Land Data Assimilation System (GLDAS) datasets and the National Oceanic and Atmospheric Monitoring Laboratory (NOAA) (GML) data to investigate the spatiotemporal characteristics of global warming and its driving mechanisms. The effects of water vapor, radiation (total long-wave radiation), and CO_2 on temperature rise are quantified in terms of a coupled land–atmosphere system, and water vapor is characterized by a vapor pressure deficit (difference between saturated and actual water, vapor pressure) to characterize its impact on the global water-heat cycle. The results show the following: Under significant global warming, the vapor pressure deficit (VPD) shows an increasing trend, which is explained by the fact that the rate of increase of actual water vapor is relatively slower than that of saturated water vapor; compared to the significant positive contribution of water vapor to global warming, CO_2 is not, as commonly expected, the most critical greenhouse gas causing global warming; water vapor and total longwave radiation (NLR) have significant mutual feedback on global warming. Changes in projected atmospheric water vapor in Central Asia using several models from CMIP6 are shown in [28]. The response of stratospheric water vapor to climate change caused by various influencing factors is shown in [29–33]. The relationship between extreme precipitation and water vapor in the current climate and the consequences are investigated in [34]. The variability of water vapor in the tropical middle atmosphere, observed from satellites and interpreted using SD-WACCM simulations, is shown in [35].

Based on the analytical review, it can be concluded that water vapor is the dominant greenhouse gas, the most important gaseous source of infrared opacity in the atmosphere. As concentrations of other greenhouse gases, particularly carbon dioxide, increase due to human activity, it is extremely important to predict how this will affect the distribution of water vapor. As the concentration of water vapor increases in a warmer environment, the climatic effects of other greenhouse gases will increase. This is important positive feedback that increases the sensitivity of surface temperature to carbon dioxide by nearly a factor of two when considered in isolation from other feedbacks, and perhaps by a factor of three or more when considered in interaction with other feedbacks [36, 37].

Model projections for future high-emission scenarios show a significant increase in atmospheric water vapor, approximately twice the current value by the end of the 21st century [38]. This is a serious concern for the global and regional climate, as the increase in water vapor volumes will further increase global warming [39, 40]. Thus, significant increases in water vapor in the troposphere at high latitudes and high altitudes may further increase global temperatures and thus accelerate global climate change.

We present the results of calculations of the concentration of water vapor according to the I and II approaches (figures 1 and 2).

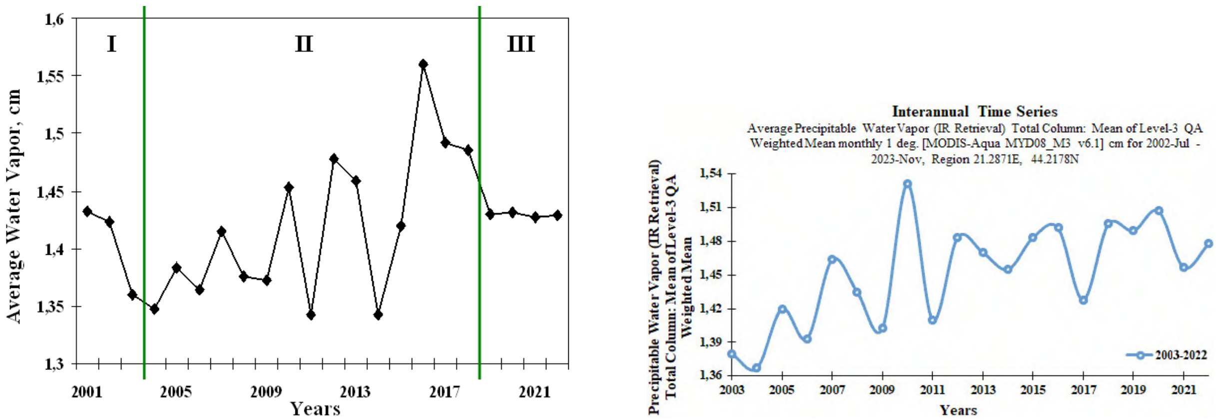


(a) (b)

Figure 1: Average distribution of the amount of water vapor over the territory of Ukraine according to data from the TERRA/MODIS satellite: a) during 2001 – 2022 (*I approach*), b) during 2003 – 2022 (*II approach*).

The analysis of the constructed map of the distribution of water vapor concentration according to the I approach (figure 1.a) showed that within the territory under study, a reduction in the amount of water vapor in the atmosphere in the direction from south to north is evident. The maximum values of water vapor retention were established in the south of Ukraine – in the Crimea, the Black Sea Basin, and adjacent areas. This area is characterized by the highest air temperatures compared to the rest of the area. However, this area directly borders the Black and Azov seas, from the surface of which there is intense evaporation. According to the nature of the distribution of values of the amount of water vapor in the atmosphere on the territory of Ukraine, two large regions, the Northern and the Southern, are confidently distinguished. The border between them is quite clear and runs approximately the width of the city of Kropyvnytskyi, including the Donbas region. In addition, in the west of the territory, there is a relatively small Western region located in the Carpathian region, which differs significantly in values. The northern region is characterized by low variability of the amount of water vapor in the atmosphere, the content of which is characterized mainly by average values. This is in good agreement with the relatively homogeneous natural conditions within this area. Within the Southern region, the water vapor content in the atmosphere varies widely, from minimum to maximum, and the areas occupied by different values of vapor content are relatively small in size. This is due to the influence of the seas and their complex coastline. As you move away from the sea coast, the water vapor content changes significantly less. The western region is characterized by minimum values of water vapor content. At the same time, they vary little by area, this is the most stable area in terms of water vapor content. Perhaps this is because only a relatively small part of this area is located in the territory under study. The highlighted areas differ from each other in terms of the absolute features of the relief and the size of the areas occupied by water basins, that is, those factors that have a decisive influence on the distribution of temperature in the atmosphere. Smaller formations stand out within the Northern and Southern regions. The territory of the Northern region is divided by the Dnipro River valley into the western and eastern halves. This is even though the Dnipro valley is relatively small in size, taking into account the size of the pixels used for observations. In general, the Dnipro River valley differs from the surrounding area both in terms of the intensity of observed water vapor content values and the sharp variability of values within this area. This is probably caused by a much higher moisture content in the river valley than in the surrounding area. As well as the presence of separate significantly watered and drained areas. In the western half of the Northern region, in the northwest of the territory of Ukraine (region of the Ovrutsky uplift), there is a fairly significant area with increased values of water vapor content and an area located to the south with reduced values of water vapor content in the atmosphere. In the eastern half of the Northern region, significant volumes of the area of reduced values of moisture content were recorded, which can be traced far beyond the borders of Ukraine. The southern region differs from the northern region in the less uniform distribution of vapor content. In the north of the region, approximately to the latitude of the Kakhovsky Reservoir, the territory is characterized by relatively high-water vapor content compared to average values. A very colorful picture is observed to the south. This is not surprising; it is caused by the influence of both the land and the Black and Azov seas. The valley of the Dnipro River stands out within the southern region, but, unlike the Northern region, these two territories do not differ from each other.

The analysis of the map of the distribution of water vapor over the territory of Ukraine according to the II (simplified) approach (figure 1.b) is less detailed, according to it, two large Northern and Southern regions are also distinguished, but it is not possible to distinguish local (more detailed) differences within these two regions.



(a) (b)

Figure 2: The schedule of changes in the amount of water vapor over the territory of Ukraine during 2001-2022 according to data from the TERRA/MODIS satellite: a) according to the *I approach*, b) according to the II approach.

The constructed graph of changes in the amount of water vapor over a multi-year period for the I approach (figure 2.a) indicates significant changes in the water vapor content in the atmosphere in different years and at the same time, allows us to identify three cycles of changes in the water vapor content for the territory under investigation. These are the following cycles: the end of the I cycle: 2001 – 2003, where a drop in the amount of water vapor is observed, the II cycle: 2004 – 2018, where a trend of increasing the amount of water vapor is observed, and the beginning of the III cycle: 2019 – 2022, where an almost constant increase is observed the amount of water vapor. Cycle 2, covering the years 2004-2018, was best shown on the available materials. It is characterized by a regular increase in water vapor content. The other two cycles, represented by a limited number of observations, are largely conditional. The greatest interest is cycle 3, which is characterized by an almost constant amount of water vapor in different years, which was not observed in other cycles. In addition, the water vapor content in this cycle is close to the 2001 content.

For the II approach, the constructed graph (figure 2.b) of changes in the water vapor content in the atmosphere of Ukraine is characterized by a constant fluctuation of minimum and maximum values, peak values are less prominent, but a trend toward an increase in the water vapor content in the atmosphere is visible. Although the two graphs have a lot in common, Thus, the years in which the minimum values of water vapor are recorded coincide on both graphs: 2004, 2006, 2009, 2011, and 2014, respectively, the years for the maximum values also coincide: 2005, 2007, 2010, 2012, and 2016.

As a result of the implementation of both approaches to the research of water vapor, we compiled tables of the possibilities of implementing these technologies into the educational process. Based on the obtained results (table 1), it is worth noting that the implementation of the first approach requires a significantly larger number of conditions and criteria, which is why the second approach is more of a priority for secondary education, and the first approach is suitable only for senior students of higher education and expert scientists, as it requires much more knowledge and time for its implementation and interpretation of the results obtained.

Table 1: By comparing the necessary conditions for the implementation of the two approaches.

Conditions or features of implementation of the approach in the educational process)	I approach (complicated) based on desktop software Erdas Imagine	II approach (simplified) based on the remote cloud resource Giovanni
availability of training instructions	−	+
the need for initial knowledge of the basics of remote sensing	+	−
availability of a powerful personal computer	+	−
the need to install specialized software	+	−
the need to download and perform preliminary processing of input data of remote sensing	+	−
using a large amount of time for data selection and process implementation	+	−
obtaining the result in the form of statistical graphs directly in the program	−	+
the possibility of simultaneous comparison of various thematic data	+	+

5. Discussion

It is possible to say that the complicated approach requires the researcher to have a lot of knowledge not only in the field of remote sensing but also in related sciences. The researcher must have full knowledge of satellite survey data, understand what problems can be solved, and have special software tools for processing satellite information. With the development of the latest technologies in the field of remote sensing, there is a shift away from direct processing of primary data and a transition to the use of products created from this data. The owners and developers of the MODIS spectrometer installed on the Terra and Aqua satellites were the first to start this trend. About 80 Terra/MODIS products are currently available, such as subsurface temperature, vegetation index, and others. This allowed researchers to use the indicators they needed without participating in their creation, which greatly expanded the possibility of applying remote sensing data in various fields. But all the same, such products also had to be found, downloaded, and processed on your personal computer.

Therefore, the proposed complicated approach may, due to the complexity of implementation and implementation of the result, be suitable only for students in senior years who have a basic level of knowledge of specialized universities. For pupils of secondary education, it is advisable to use a simplified approach. The great advantage of the simplified approach based on remote web portals is that data from different satellites, processed by the same algorithm, are concentrated in one place. This is a significant breakthrough in the possibility of using remote sensing data not only by information processing specialists but also by the general public of interested persons (schoolchildren, students, etc.). There are many satellite-based algorithms for measuring meteorological parameters, but not all algorithms can easily compare the products or analyze them with other relevant data. But Giovanni's methods illustrate how the data and visualization tools archived in GES DISC (Giovanni is a product of GES DISC) can be effectively combined with cloud computing and cloud-optimized data formats for effective climate analysis.

In general, the two considered approaches complement each other. A simplified approach provides a quick understanding of the process, while a complicated approach allows you to identify more detailed patterns of the process. All this ultimately improves the researcher's scientific results. The use of the Giovanni resource is aimed at the formation of pupils, students, and listeners of knowledge of the basics of remote sensing, skills of working with relevant software, its applications, and analytical tools, and involvement in search and research work.

In accordance with the set goal, the tasks of the program consist of the formation of pupils, students, and listeners of the following competencies:

- cognitive: formation of knowledge on the basics of remote sensing; development of geospatial and analytical thinking in pupils, students, and listeners; the ability to logically present one's thoughts and cartographically argue them;
- practical: formation of skills and abilities to create maps using space images and analytical tools in research activities; independent search and analysis of information; development of spatial thinking;
- creative: use of modern IT in education; formation of creative approaches in research activities and group work experience based on the project method;
- social: formation of a conscious, responsible attitude to the surrounding world, the ability to solve environmental problems; promotion of self-realization and professional self-determination of pupils, students, and listeners by means of GIS and remote sensing.

6. Conclusion

Modern education should be based on the search and application of the latest technologies that contribute to the development of basic competencies that form an independent and creative personality. In the future, this will open up prospects for the purposeful formation of competent specialists in various fields. Such a technology is the application of methods of remote sensing. The advantages of innovative methods of remote sensing are objectivity, reliability, comprehensiveness, detail, efficiency, periodicity, multi-spectral nature of observations, and, most importantly, multi-sectorality (the ability to solve multifaceted tasks in the monitoring mode).

The two methodological approaches considered in the work—complicated (with data processing on a personal computer) and simplified (with data processing on a remote server based on specific requests)—made it possible to conduct a comprehensive study of monitoring the content of water vapor in the atmosphere over the territory of Ukraine over a multi-year period of 22 years. The results of the study of the content of water vapor in the atmosphere showed that the changes are cyclical, and the data for 2022 corresponds to 2001.

As for the educational process, working with remote sensing data will teach them how to use diverse information in the form of space images.

Pupils and students will be able to: carry out operations with remote data, in particular, filter by dates and research area; to be able to search and select the most suitable types of remote sensing data for specific thematic tasks (in the context of climate change); use analytics tools; save the obtained results in the form of graphs and maps; to use the data of remote sensing in research works.

Competences will be formed among pupils and students: to use the materials of remote sensing in their research; use Giovanni software for remote data analysis; analyze the dynamics of changes in the atmosphere, hydrosphere, earth's surface, etc.; identify dependencies between processes (correlation, regression, etc.) based on satellite data.

Abstract. Mangrove ecosystem provides important services such as storing and sequestering large amount of carbon. However, it faces several anthropogenic pressures especially from resource extractive activities that threatened the ecosystem. Hence, huge companies are obliged to make rehabilitation efforts to rehabilitate the mangrove ecosystem that they have caused damage. Our study aims to determine the carbon stock dynamics of a mangrove rehabilitated site which was damaged due to the siltation brought by the nearby mining. We established a study plot in a mangrove rehabilitated site (Lipata) near the mining area and on a nearby natural mangrove forest (cagutsan) as a point of reference. We determine the mean DBH, height and estimated the soil carbon storage capacities. We found out that in both sites of rehabilitated (Lipata) and natural (Cagutsan) mangrove stand the Rhizophora mucronata is the most dominant, both has similar mean dhb of 6 cm and the height is mostly dominated by. The soil C content shows that as the soil gets deeper up to 50-100 cm the higher the soil carbon content. There was no significant variation in terms of the average soil carbon content of the rehabilitated site is 42.63 MgC/Ha and the natural mangrove stand of 53.59 MgC/Ha. Hence the finding supports the effectiveness of the rehabilitation efforts and calls for continuous rehabilitation of damaged mangrove sites in the area.

1. Introduction

The biodiversity of the Philippines is rich in both quantity and proportion. Because of its high endemism rates, varied ecosystems, and geographic isolation, it is recognized as one of the 17 mega biodiversity countries. Maintaining 5% of the world's flora, it ranks sixth internationally in terms of the number of plant species. The nation is home to about 65 species, or at least 50% of all mangrove species worldwide [1].

The diversity of mangroves is relatively high due its geographic location. The country holds at least 50% of the worlds approximately 65 mangrove species [2]. It is also considered as one of the top 15 most mangrove-rich countries in the world [3]. These mangroves are pivotal in supporting diverse marine life and providing essential ecosystem services, including coastal protection and carbon sequestration [2]. Mangroves, a resilient coastal ecosystem lining the interface between land and sea, are invaluable carbon reservoirs, pivotal in global carbon cycling and climate change mitigation [4]. Mangroves have a unique ability to sequester atmospheric carbon in their biomass and sediments, contributing significantly to reducing greenhouse gas concentrations [5, 6]. However, the perpetual and escalating threats posed by anthropogenic activities, particularly mining, cast a shadow over the stability of these ecosystems. As one of the most threatened and undervalued ecosystems globally, mangrove forests face considerable degradation, with estimates indicating a 30-50% decline in their extent. The vulnerability of mangroves to human-induced pressures underscores the urgency of investigating their carbon stock dynamics in regions undergoing mining activities [7].

The scenic Hinatuan Island, located in Taganaan, Surigao del Norte, boasts abundant mangrove forests that are integral to the livelihoods of local communities. However, due to anthropogenic activities as well as natural disturbances, it continues to lose its rich biodiversity resources including mangroves [3, 8]. This ecological wealth coexists with active mining operations, raising critical questions about the potential impacts on the carbon stock of mangrove stands. The delicate balance between economic development and environmental preservation necessitates a comprehensive understanding of how mining pressure influences the carbon sequestration capacity of mangroves in this unique island setting. Mining operations can cause significant alterations in the biophysical characteristics of mangrove ecosystems, such as changes in soil properties, hydrological regimes, and tree composition, which may affect carbon stocks [9]. Therefore, it is crucial to study the impact of mining activities on the carbon stock of mangrove stands to understand the implications for carbon sequestration and storage.

The research investigated the carbon stock dynamics of mangrove stands on Hinatuan Island under the influence of mining activities. This study aims to determine if there is a difference between the mangrove sites near and across the mining site on the belowground carbon storage capacity. We established sampling plots on a mangrove site with a mining operation and in a nearby natural mangrove forest. We determine the heterogeneity in vegetation in both sampling sites and estimated the average soil carbon. We hypothesized a difference in carbon storage between the two sites because the other mangrove sites were not disturbed, contrary to the mangrove in the mining site. Our study supports the broader call for mining site rehabilitation and protection of mangrove forests from further destruction to sustain roles in mitigating the impacts of climate change.

2. Methodology

2.1. The study area

2.1.1. Lipata in Hinatuan Island. Hinatuan Island is located in Barangay Talavera, Municipality of Tagana-an, Surigao del Norte Province, positioned at coordinates 9°46'09" N and 125°39'02" E. The island maintains an average annual temperature of 26.7°C and receives around 320 mm of precipitation annually. Its soil primarily belongs to the Ferralsols category, characterized by clay loam composition. The island's surface features nitrogen levels at 615

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012004 doi:10.1088/1755-1315/1415/1/012004

cg/Kg, soil organic carbon at 1110 dg/kg, and maintains a pH level of 4.7 [10]. Spanning an estimated total area of 1,275 hectares, Hinatuan Island is significantly affected by mining activities, with 60% of its land covered by an approved Mineral Production and Sharing Agreement (MPSA 246-2007-XIII). Nickel mining operations have notably been active on the island since the 1980s.

2.1.2. Barangay Cagutsan. Barangay Cagutsan is situated within the City of Surigao, which is part of Surigao del Norte Province, located at coordinates 9°46'22" N and 125°42'04" E. Currently, the barangay encompasses about 12 hectares of mangrove forests. The prevailing climate in the area corresponds to type II based on the Corona classification system. The soil type in Barangay Cagutsan is classified as Histosols, primarily composed of organic materials. Histosols typically have limited drainage, which slows down the decomposition of plant and animal remains, leading to the accumulation of organic materials over time. The recorded pH level is 4.9, with organic soil carbon measuring 1084 dg/Kg, a bulk density of 68 cg/cm^3, and nitrogen content at 533 cg/Kg [10]. This natural mangrove forest, existing for around a decade, is under the protective oversight of the Department of Environment and Natural Resources (DENR) – Region XIII and the Local Government Unit of Barangay Cagutsan. Approximately ten years ago, the agency initiated the Assisted Natural Regeneration (ANR) program for this mangrove stand.

Five mangrove species were documented in both Lipata and Cagutsan area. Rhizophora apiculata emerged as the most dominant species in both sites accounting for 85.70% and 71.80%. the Lipata site has a total count of 175 individuals while the Cagutsan site has 206 individuals. The second most dominant species in Lipata is the Aegiceras coniculatum and is only recorded in Lipata. While in Cagutsan Rhizophora mucronata ranks second as the greatest number of individuals with Avicennia rumphiana species is found only in Cagutsan [11].

2.2. Field sampling design

In both the Lipata area, situated adjacent to a mining site, and the Cagutsan area, located at a distance from the mining sites, three (3) 150 m transect lines perpendicular to the beach was established, each spaced 50 meters apart. Within each 150 m line transect, two (2) 10 m × 10 m non-destructive quadrats were designated, hereafter referred to as zones, ensuring a 20 m gap between consecutive plots in figure 3.

Three parameters for each field plot were considered to estimate the soil carbon pool: (a) soil depth, (b) dry bulk density, and (c) organic carbon content (% Corg).

2.3. Soil carbon stock determination

Soil samples were randomly taken from the two sampling sites using soil corer of 100 cm high and 6 cm in diameter. Soil samples were partitioned into depth intervals of 0-30 cm, 30-60 cm, and 30-90 cm. Samples representing each depth were collected as subsamples. Collecting subsamples that represent a specific depth is more than adequate for mangroves, as the carbon content changes at a much slower rate with depth, making the collection of the entire range unnecessary [12]. Thus, subsamples obtained from each depth were utilized to analyze the soil carbon content. Soil samples were sent to laboratory for (Corg) using Walkley-Black Method.

The calculation of soil organic carbon per hectare was performed using the equation below [5]:

$$\text{Soil Carbon (Mg/Ha)} = \text{Bulk Density (g/cm}^3\text{)} * \text{Soil Depth Interval (cm)} * \%\ \text{Carbon content}$$

The calculation for the total soil carbon stock across the two entire sampling areas was derived using the equation below:

$$\text{Total Soil Carbon Stock (Mg)} = \text{Total Soil Carbon (Mg/Ha)} \times \text{Area (Ha)}$$

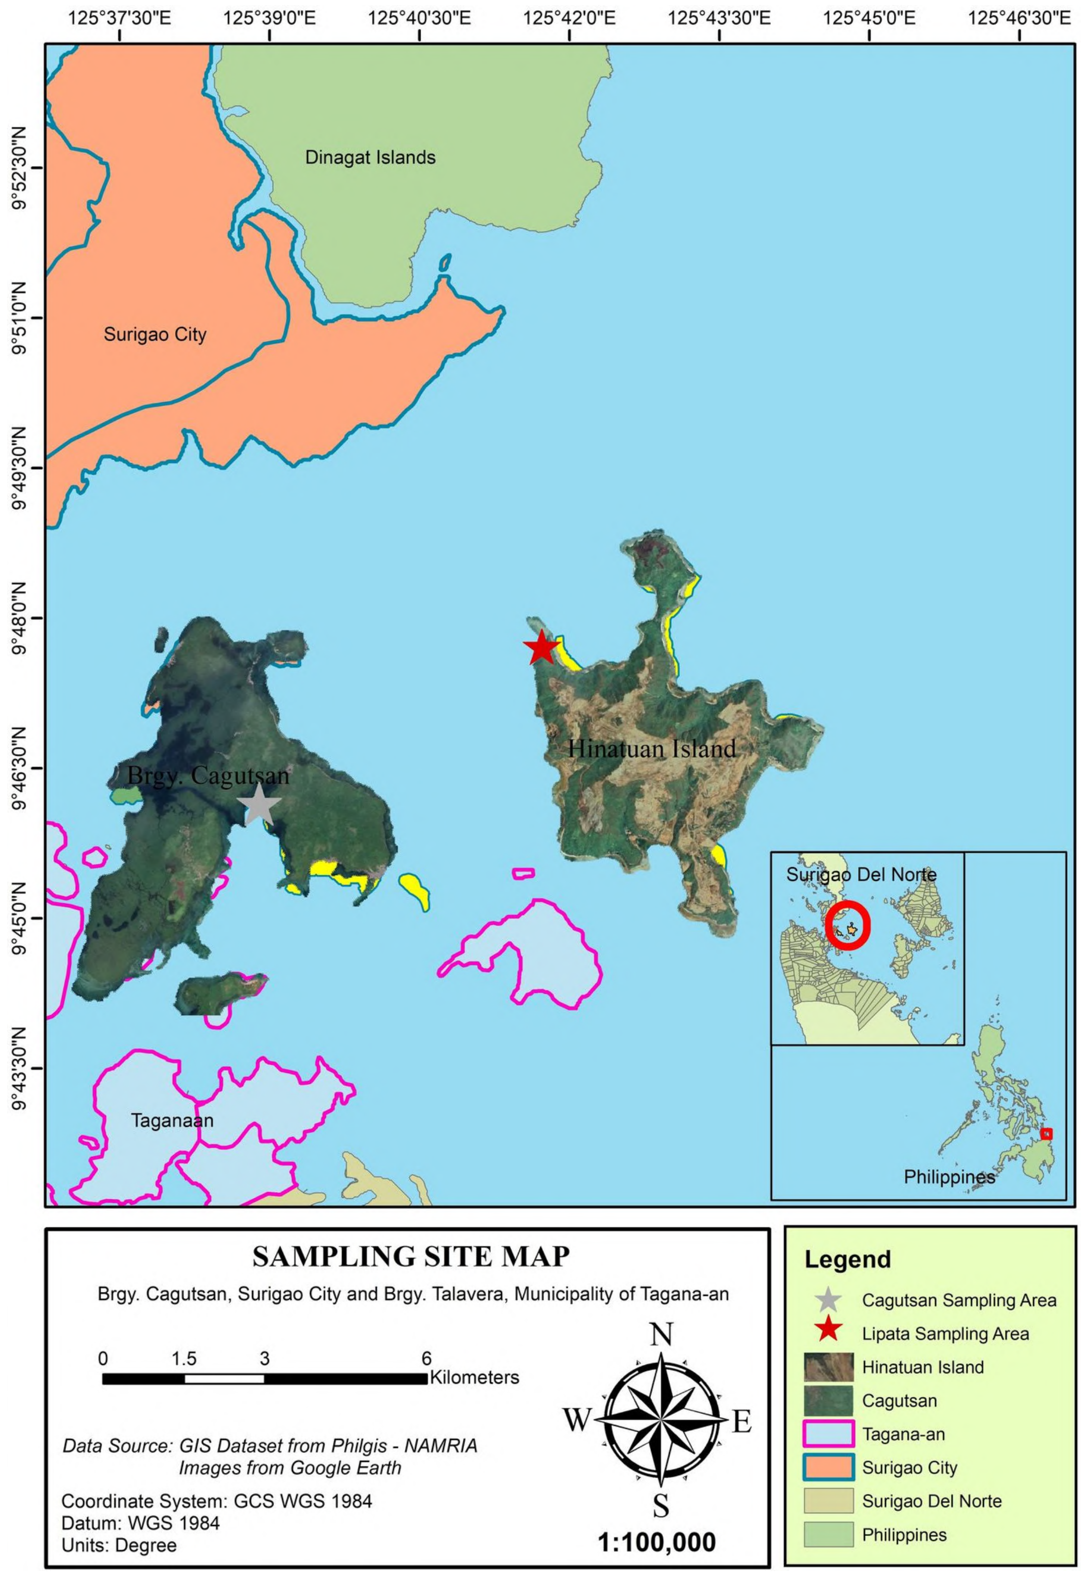

Figure 1. Map of Brgy. Cagutsan and Hinatuan island, Taganaan, Surigao del Norte, Philippines.

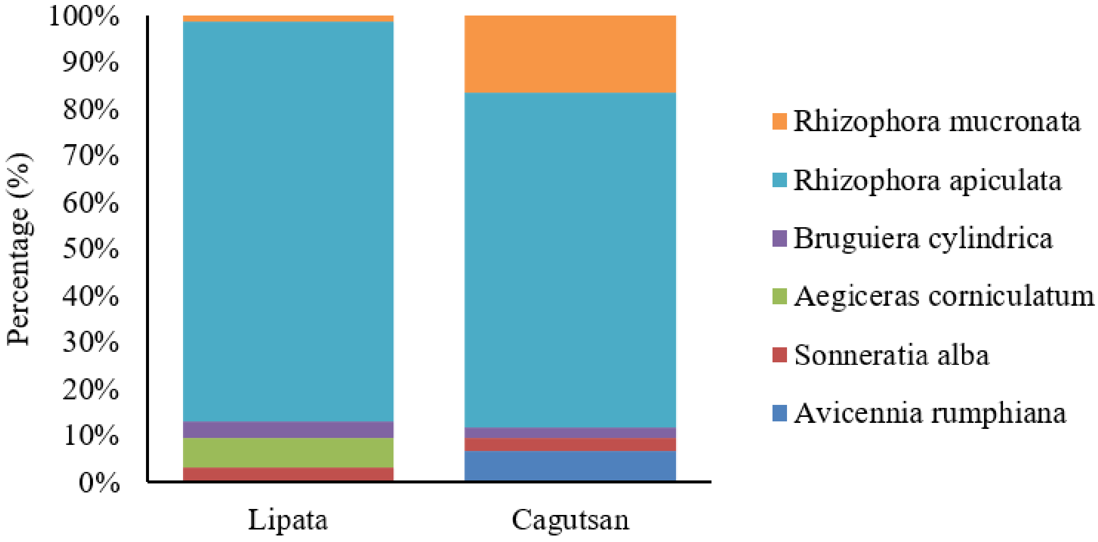

Figure 2. Percentage distribution of species existing in the natural and reforested sites (based on the study of Amparado et al. [11]).

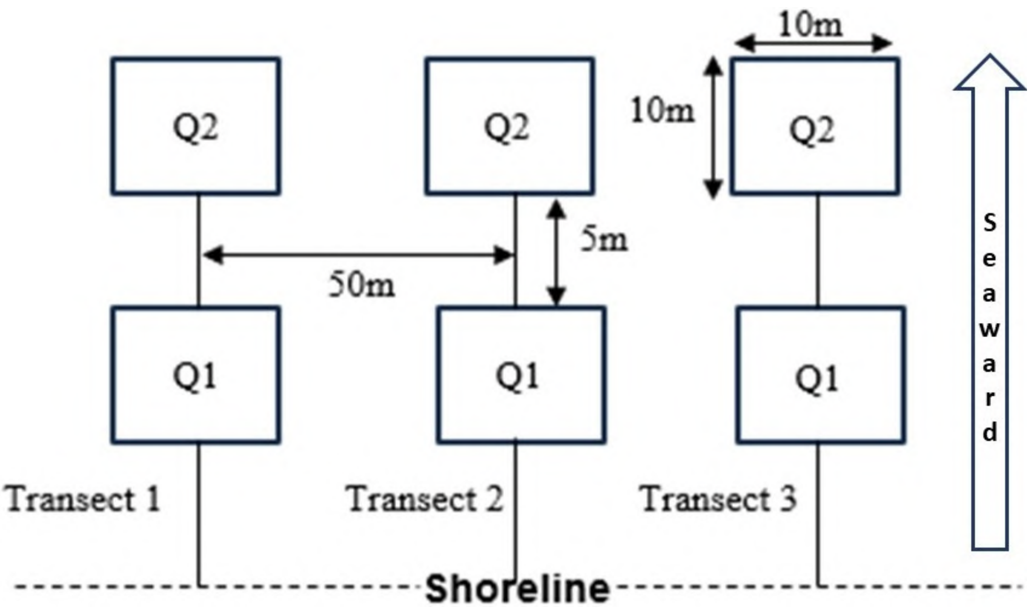

Figure 3. Strip split plot experimental layout used in both mangrove sites in Brgy. Cagutsan and Hinatuan Island, respectively.

2.4. Soil bulk density determination

Soil samples were gathered separately for assessing soil bulk density. The top 100 cm of soil was collected, divided into specific depths of 0-15 cm, 15-30 cm, 30-50 cm, and 50-100 cm, respectively. Subsamples were taken at the midpoints of each depth, with depths ranging from 5-10 cm for 0-15 cm depth, 20-25 cm for 15-30 cm depth, 37.5-42.5 cm for 30-50 cm depth, and 77.5-82.5 cm for 50-100 cm depth, to determine bulk density.

The samples underwent oven-drying, the dry mass was then measured to facilitate the calculation of bulk density, employing the adapted formula [12].

Soil Bulk Density was calculated using the equation below:

Bulk Density (g/cm^3) =(oven-dried weight of soil (g))/(volume of soil corer (cm^3))
where volume of the soil $= \pi[r^2h]$.

3. Results and discussion

3.1. Mangrove diameter and height distribution

Based on the diameter at breast height (DBH), both the natural and rehabilitated sites show similar average DBH of 6 cm. in the Lipata site the Bruguiera cylindrica has the biggest (DBH) 23 cm, while the Avicennia rumphiana is the largest in the Cagutsan with a DBH of 54.11 cm. The average height of the Lipata site is 3.4 m while in the Cagutsan site is 3.8 m.

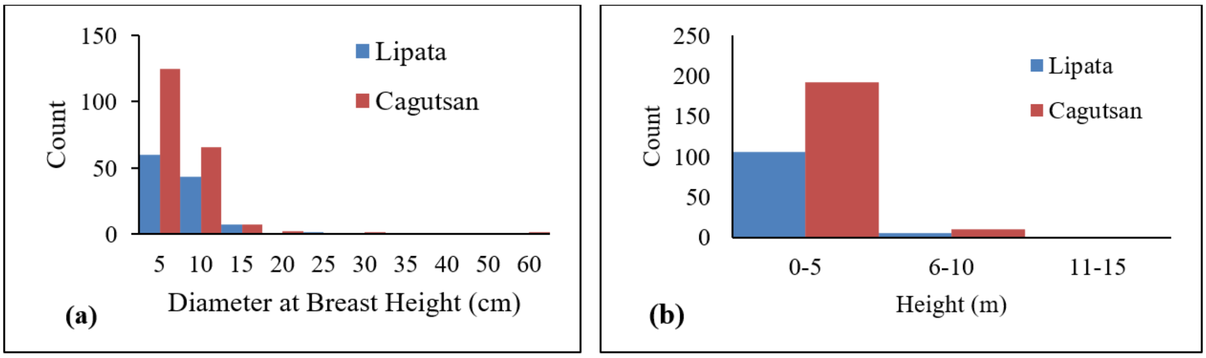

Figure 4. Histogram of (a) diameter at breast height (DBH) and (b) height of tree species in the natural and rehabilitated sites.

In Cagutsan site the Avicennia rumphiana has the largest DBH. Despite not being the most dominant in the area it was able to grow the largest. Cagutsan also has the largest DBH and the highest height compared to the mangroves in Lipata site. The mean DBH of a mangrove stand at Panabo Mangrove Park is 7.67 cm [13] in Zamboanga the mangrove stand has a DBH that range from 5-10 cm [14]. This similarity in mean DBH may indicate a consistent and stable habitat that facilitates similar growth rates among the mangrove species present [14].

Sonneratia alba's emergence as the species with the highest DBH across both sites underscores its adaptability and resilience in different ecological contexts [15]. This species' capacity to attain significant diameters reflects its ability to thrive under varying conditions, making it a vital indicator of the overall health and growth potential of the mangrove ecosystems [16] in Lipata and Cagutsan.

The height further contribute to the differences of these sites. In Lipata, where mangroves predominantly range between 2-4 meters in height, the environment may impose constraints that limit vertical growth. In contrast, the Cagutsan site exhibited a more excellent height distribution, primarily within the 4-6 m range. This discrepancy suggests that environmental factors in Cagutsan, such as nutrient availability or hydrological conditions, may support taller mangrove growth.

The Lipata site is a rehabilitated area hence the DBH of the species found are uniformly similar, compared with Cagutsan site were mangroves are naturally occurring.

3.2. Soil Carbon stock

As the soil got deeper, there was an increasing soil C content. In the rehabilitated site of Lipata the soil C content was 18.76, 24.68, 32.44, and 94.65 MgC/Ha. Post hoc comparison using Tukey HSD test indicates that the soil C content of the rehabilitated site at depth 50-100 cm (M = 94.65; SD = 10.04) is significantly higher compared to the 30-50 cm (M = 32.44; SD = 5.013), 15-30 cm (M = 24.68; SD = 0.73, and 0-15 cm (M = 18.76; SD = 2.59).

In the natural mangrove stand of Cagutsan, the soil C content is also lowest at 0-15 cm with 30.49 MgC/Ha and increased to 32.34MgC/Ha at 15-30 cm, 41.80MgC/Ha at 30-50 cm and up to 109.72 MgC/Ha at 50-100 cm depth. Significant difference was also observed in the soil C content between soil depth $F\ (3,12) = 233.32$, $p < .0000$. Similarly based on the Post hoc Tukeys HSD test 50-100 cm is significantly higher compared to the shallower soil depth. No significant difference was found in the average soil C content across the transect traversing from the landward to the seaward zones within each of the natural mangrove's sites of Cagutsan and the rehabilitated site of Lipata.

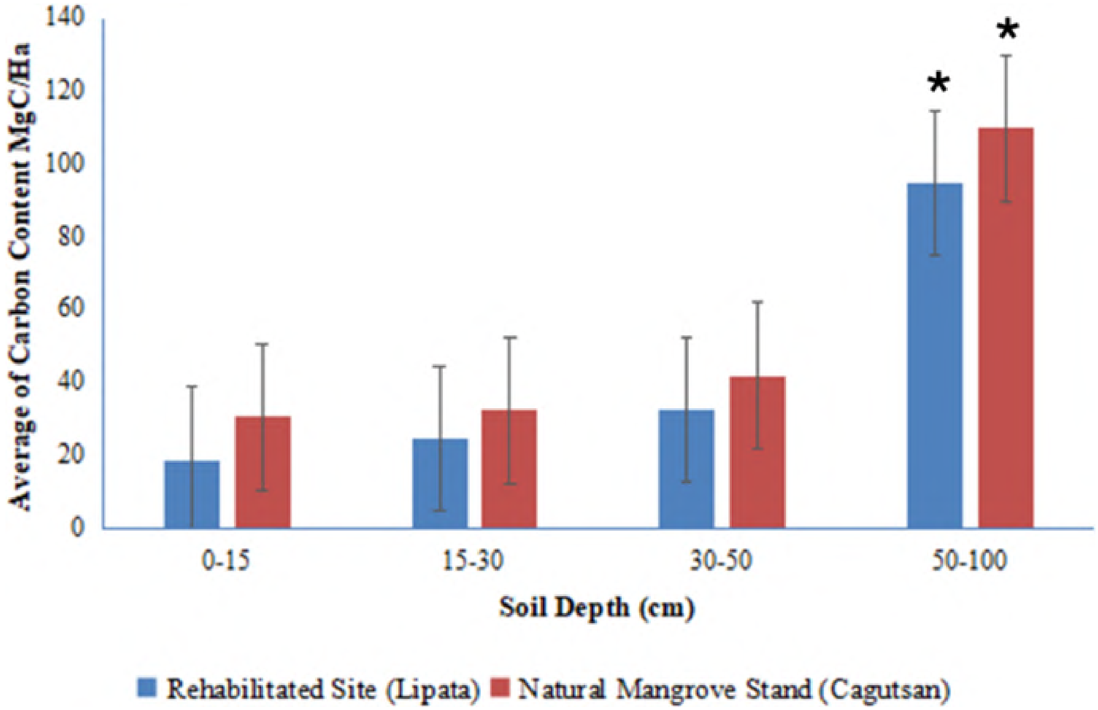

Figure 5. Average soil carbon content at varying soil depths from 0 to 100 cm at the natural mangrove stand and rehabilitated mangrove site. Asterisk above the bars indicate significant difference compared to the other depth at $p < 0.01$ based on Tukey post hoc test.

The higher soil carbon stock in the Cagutsan site suggests that this mangrove ecosystem is particularly effective in sequestering and storing carbon compared to the Lipata site. The average carbon stock is like the carbon stock of the other places in the Philippines where in Honda Bay the average carbon stock is 71.7 MgC/Ha [17].

Understanding the variations in soil carbon stock has broader implications, particularly in the context of climate change mitigation. Recognizing mangrove ecosystems as significant carbon sinks, the differences observed between Cagutsan and Lipata underscore the need for tailored conservation and management strategies. Conservation and protection efforts in areas with higher carbon sequestration potential, like Cagutsan, can contribute to regional and global climate change mitigation goals.

The observed consistent upward trend in soil carbon content with increasing soil depth in both the Cagutsan and Lipata mangrove sites provides valuable insights into the vertical distribution of carbon within these ecosystems. This trend, as illustrated in Figure 5, indicates that deeper soil layers harbor progressively higher concentrations of carbon, highlighting the significance of considering different soil depths when assessing carbon dynamics in mangrove environments [18, 19].

In the Cagutsan site, the specific values of soil carbon content further emphasize the substantial increase with depth. The recorded values of 30.49, 32.34, 41.8, and 109.7 Mg C ha^{-1} for depths ranging from 0-15, 15-30, 30-50, and 50-100 cm, respectively, showcase a notable carbon accumulation as the soil extends deeper into the substrate. This finding aligns with the recognized capacity of mangrove ecosystems to sequester and store substantial amounts of carbon in their soils, particularly in deeper layers.

The depth-dependent variations in soil carbon content reflect the complex interplay of factors influencing carbon dynamics, including root contributions, microbial activities, and organic matter decomposition. Deeper soil layers often serve as repositories for long-term carbon storage, playing a crucial role in the overall carbon budget of mangrove ecosystems. Understanding the vertical distribution of soil carbon has implications for accurately estimating carbon stocks and assessing the potential impacts of environmental changes on carbon sequestration. The observed trend underscores the importance of preserving deeper soil horizons within mangrove habitats to maintain robust carbon storage capacities [20].

The 50-100 cm depth emerges as a critical zone influencing the overall carbon stocks within these mangrove ecosystems. Deeper soil layers often serve as reservoirs for organic matter accumulation, and the observed disparities in this specific depth range suggest that the factors influencing carbon sequestration may differ significantly between shallower and deeper horizons.

The depth-specific disparities in soil carbon content affect our understanding of carbon sequestration processes in mangrove ecosystems.

Understanding the relationship between DBH, height and below-ground carbon stock is important for accurately estimating the carbon sequestration potential of forests. Larger trees, due to their higher biomass and more extensive root systems, can play a significant role in storing carbon [21].

4. Conclusion

Comparing the mean DBH, height and carbon stock of mangroves provides an insight of the mangrove stand carbon sequestration potential. The mangrove rehabilitated site of Lipata has similar mean DBH, height and below ground carbon stock. Hence the rehabilitation efforts of the Lipata site in Hinatuan Island must be continued and should also be implemented in the nearby damaged mangrove ecosystems.

Abstract. Among the consequences of technoecogenic stress caused by the activity of industrial and energy complexes, dust and gas emissions, containing toxic to representatives of biota substances, including heavy metals, have a particularly negative impact on ecosystems. Different types of organisms have different mechanisms to absorb and accumulate heavy metals, that can be used for ecotoxicological studies. The peculiarities of the accumulation of heavy metals in various components of the ecosystem such as soil – plant – animal in the area of operation of the thermal power plant (TPP) of the Dnipro region were investigated. Test samples of soil, sod-forming grasses, and soil-litter invertebrates were collected from artificial plantations of Robinia pseudoacacia L., located in the immediate vicinity of the Prydniprovska TPP in the city of Dnipro, and control samples – at a distance of 30–40 km from the TPP. Determination of the content of heavy metals, which are priority pollutants for the Dnipro region, was carried out by the method of atomic adsorption spectrophotometry according to the standard method. The invertebrates accumulate Fe and Mn in the largest amount at all test sites. From all functional groups, only representatives of saprophages perform the functions of heavy metal accumulators (Fe, Cu, Cd, Mn), contributing to the intensification of the biological cycle (Ni) and the purification of trophic chains (Zn, Pb). The features of the accumulation of heavy metals by the main sod-forming cereals depending on the contamination level in the soil under the influence of the Prydniprovska TPP have been established. The concentration of heavy metals in both the above-ground mass and the underground part of the plants was determined in the experimental and control plots. The different intensity in the elements accumulation by the vegetative organs of the experimental plant species was revealed. The obtained results can be used in bioindication to assess environmental pollution.

1. Introduction

Various types of natural minerals, including hard coal, are intensively used by the industry of Ukraine and its energy complexes. The operation of industrial and energy complexes leads to technogenic stress on natural and artificial ecosystems. Ecosystems are mostly affected negatively by pollution of the air basin with dust and gas emissions [1–3]. The toxic substances found in these emanations include heavy metals. Together with dust emissions, they enter the soil as the habitat of most representatives of the biota [4, 5].

Degradation of natural vegetation begins even during the construction of industrial enterprises. In the future, the state of the environment will worsen. The effect of constant, even one-time, dust emissions can lead to catastrophic consequences. Therefore, those forms of anthropogenic impact on the environment that positively regulate the balance of functioning components, play a significant role [5–7].

Excessive entry of heavy metal ions into cells leads to irreversible changes and disturbances of the vital functions of the plant organism at the morphological, physiological and biochemical level. When accumulating in plant tissues, heavy metal ions displace metals in the active centre of enzymes and thus encourage cells to increase metabolism. There is a gradual dieback of the leaf plate. This process is primarily manifested by necrotic lesions and later leads to its aging and death. In particular, lead in plant cells causes inhibition of ATP production, lipid peroxidation and DNA damage [8, 9]. Each type of plant shows individual characteristics regarding the accumulation of heavy elements. These properties of plants can be used in the biological remediation of areas polluted, particularly by heavy metals [10–14].

Heavy metals are accumulated by plants in the roots and leaves. The processes of their adsorption by roots and leaves are different: in the first case, the ions pass through the cell wall, and in the second – through stomata or through the cuticle of the epidermis. Together with the transport metabolites, a part of the accumulated toxic substances is exported. The cuticle, the thickness and chemical composition of which on the outer surface of the epidermal cells varies greatly depending on the type of plant, its age, systematic position, living conditions, etc., consists of cutin impregnated with wax and is a complex mixture of long-chain alkanes, alcohols, ketones, complex ethers and carboxylic acids, which is a universal adaptation of plants to environmental conditions [15].

Depending on the specific characteristics of the accumulation of heavy metals, plants can be accumulators absorbing metals even with a low amount of them in the environment; indicators, in which the metal content is directly proportional to its content in the environment, and exceptions, in which a low concentration of metals in vegetative organs is maintained regardless of their concentration in the environment. Different indicators of heavy metals accumulation [16] are the result of their selective absorption by living organisms, the quantitative characteristic of which is the coefficient of biological absorption (the ratio of the content of the element in a living object to the content in the substrate). The study of biological absorption coefficients (BAC) allows to distinguish groups of ground cover plants according to the degree of heavy metal absorption. Organisms with BAC>10 refer to energy accumulators. The plant with a BAC 10–1 absorb elements strongly. The plants with BAC <1 are deconcentrators [17, 18].

Local dust emissions lead to the direct introduction of heavy metals into the soil. Soil, plants, and animals are the most important links to the technoecogenic migration of chemical elements. In the soil, the prevalence of trace elements affects the supply of these elements to living organisms. Signs of soil poisoning appear later than air and water [19–21].

The peculiarity of the influence of heavy metals is that when entering the ecosystem, they do not decompose for a long time and accumulate in the tissues of living organisms, in particular in the soil, litter and invertebrates. Invertebrates are litter and soil inhabitants and in terrestrial ecosystems they are represented by such functional groups as phytophages, zoophages, and saprophages. Like plants, they are able to exist in conditions of anthropogenic pressure: during the feeding process, they accumulate various chemical elements, including heavy metals in the zone of technogenic stress [13, 22].

In the body of invertebrates, the concentration of heavy metals depends on the nature of their nutrition and the content of toxicants in their habitat. According to the nature of chemical elements accumulation, terrestrial animals are divided into three geochemical groups:

1) accumulators – the content of trace elements in the animal tissues is higher than in the food object (accumulation coefficient does not exceed 1);
2) scatterers – the trace element content is the same as the power source (accumulation coefficient is about 1). They contribute to the intensification of the biogenic cycle;
3) cleaners – the content of trace elements in the animal is much lower than in the food object (accumulation coefficient is less than 1), contributing to the cleaning of the trophic chain.

The nature of heavy metals migration along the trophic food chains of the animals, namely the invertebrate inhabitants of the soil and litter, and the determination of threshold loads both on individual taxa of animals and for the ecosystem as a whole arouses interest.

The purpose of the study was to establish the features of heavy metals accumulation in various components of the ecosystem: soil-plant-animal in the area of Prydniprovska regional TPP operation.

2. Methodology

Materials of plant and animal origin and soil samples were used for the research. Representatives of soil and litter invertebrates, samples of soil and sod-forming cereals to determine the content of heavy metals were selected in artificial plantations of Robinia pseudoacacia L., located in immediate proximity to the Prydniprovska TPP in Dnipro (figure 1).

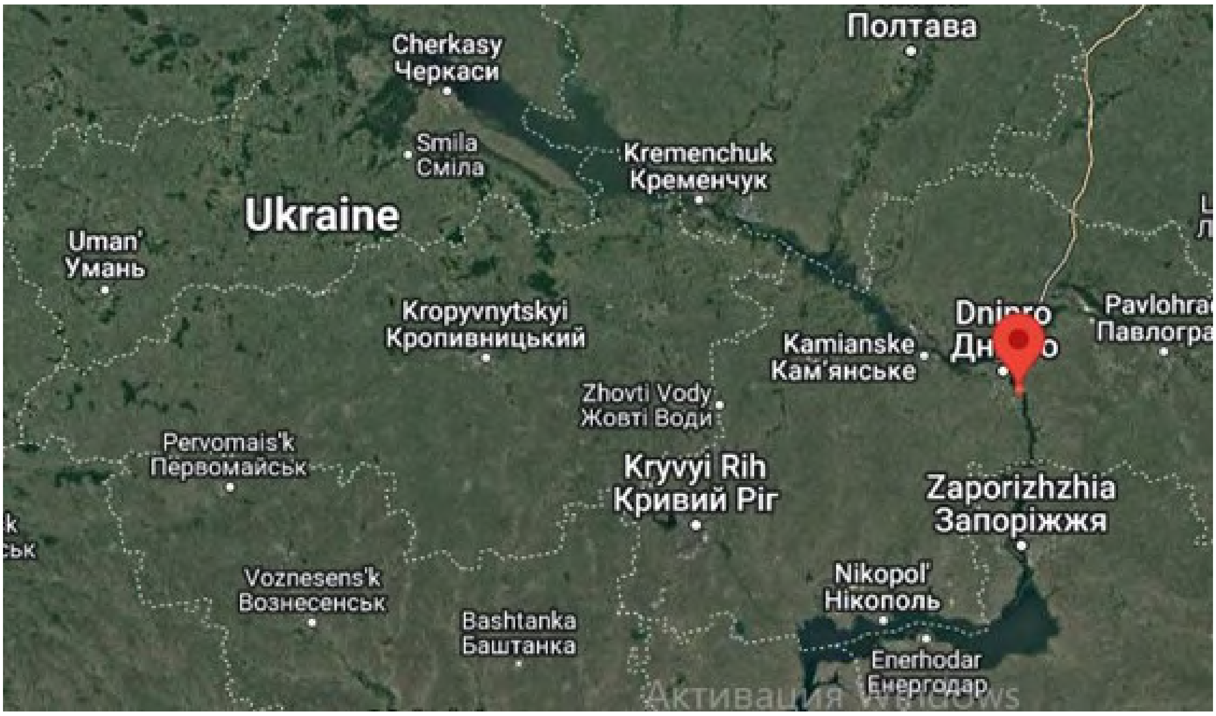

Figure 1. Location of Prydniprovska TPP in Dnipro.

Areas with artificial woody plantations at a distance of 30–40 km from the TPP were used as controls. At the same time, the direction of the winds was taken into account. Soil samples were taken at a depth of 20 cm.

The roots and leaves of the main regional sod-forming grasses – Poa angustifolia L., 1753 and Elytrigia repens (L.) Nevski, 1933 – was used for ecophytoxicological studies.

For the determination of the taxonomic composition of soil and litter invertebrates and the selection of material for animal zooecotoxicological studies Barber's traps were used. Taking into account the functional affiliation of insects, the content of heavy metals was determined only in Histeridae, Carabidae, and Cerambycidae.

The determination of heavy metals content in the invertebrate animals tissues, plant material and soil was carried out by the method of atomic adsorption spectrophotometry according to the standard method using an AAS 30 spectrophotometer [5, 13, 22, 23].

The coefficients of biological absorption (BAC) of heavy metals by the roots and leaves of the experimental plants were calculated.

To detect the presence of a root barrier in the experimental plants, the root barrier coefficient (RBC) was calculated as the ratio of the element content in the roots to its content in the above-ground organs. A RBC value greater than one indicates the presence of a root barrier in the elements absorption by the plants.

The bioaccumulation index (BAI) as the ratio of the heavy metals content in the invertebrates representatives to the heavy metals content in the objects of their nutrition or habitat was calculated. For representatives of saprophages, the ratio of trace elements in the soil (habitat), and for zoophages, the trace elements content in phytophages representatives (Cerambycidae) as potential objects of their nutrition was calculated.

The Statistica software package for statistical processing of the received data was used. The statistical significance was considered at $p<0.05$. [24, 25].

3. Results and discussion

As a result of the research, it was established that the iron ions content in the soil of the research area is fully consistent with the metal content in the lithosphere, soil cover and basic geological rocks [23]. The manganese concentration exceeded the reference indicators but probably did not differ from the indexes of industrially polluted areas. The nickel content slightly exceeded the control metal content. The levels of zinc, copper, cadmium, and lead exceeded the reference values (figure 2, 3).

In the course of the experiment, different intensity of the elements accumulation by vegetative organs of different types of plants was revealed. Thus, in the control area, a significant content of manganese and copper in the roots of Poa angustifolia L., and manganese, zinc, and copper in Elytrigia repens (L.) was noted. In the experimental plants, an accumulation of manganese was observed in the subterranean part (Poa angustifolia L.), copper and zinc (Elytrigia repens (L.)).

In the ground part of Poa angustifolia L. growing in the control and experimental plots, a further increase in the content of copper and cadmium was noted in comparison with their level in the soil and roots. For Elytrigia repens (L.) Nevski, a lower concentration of almost all determined heavy metals was characteristic compared to ones in soils and Poa angustifolia L.. the exception was nickel.

When comparing the absorption intensity of each of the heavy metals of Poa angustifolia L. and Elytrigia repens (L.) Nevski, it was established that in the control plots, the concentration of manganese and iron in the roots of Poa angustifolia L. was lower than the similar indicators of Elytrigia repens (L.) Nevski, by 1.1 times, zinc and nickel by 1.2 times. In the aerial part of the experimental plants, the difference in heavy metal concentrations was 1.5 times for manganese and cadmium.

For plants of the experimental variant, the concentration of manganese and iron in the roots of Elytrigia repens (L.) Nevski exceeded the content in the underground part of Poa angustifolia L. by 2 times. In the experimental variant, a significant excess of copper content in the aerial part of Poa angustifolia L. compared to Elytrigia repens (L.) Nevski was noted. Such a difference in the intensity of the heavy metals absorption at the plants indicates the species specificity of their accumulation.

A different level of heavy metals accumulation was also noted for plants affected by the emissions of thermal power plants growing in forest areas of Europe [26].

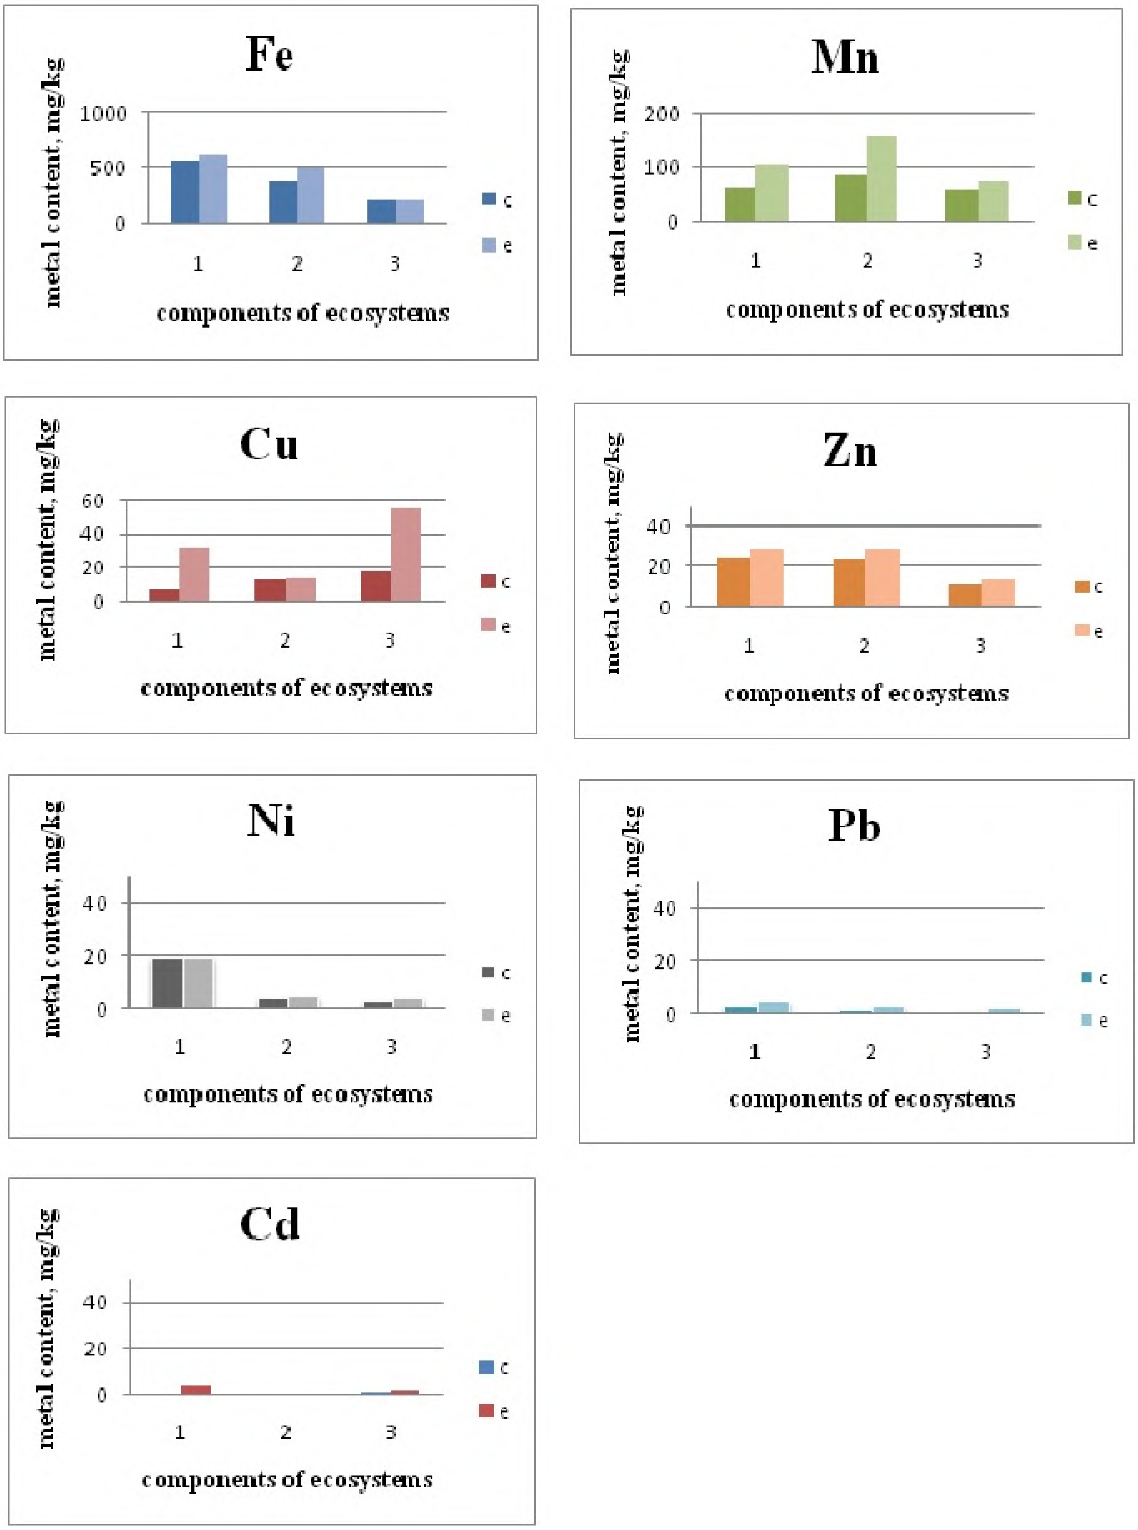

Figure 2. The content of heavy metals in various components of ecosystems under conditions of environmental pollution (Poa angustifolia L.), mg/kg: 1 – soil, 2 – underground part, 3 – above-ground part; k – control, d – experiment.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012005 doi:10.1088/1755-1315/1415/1/012005

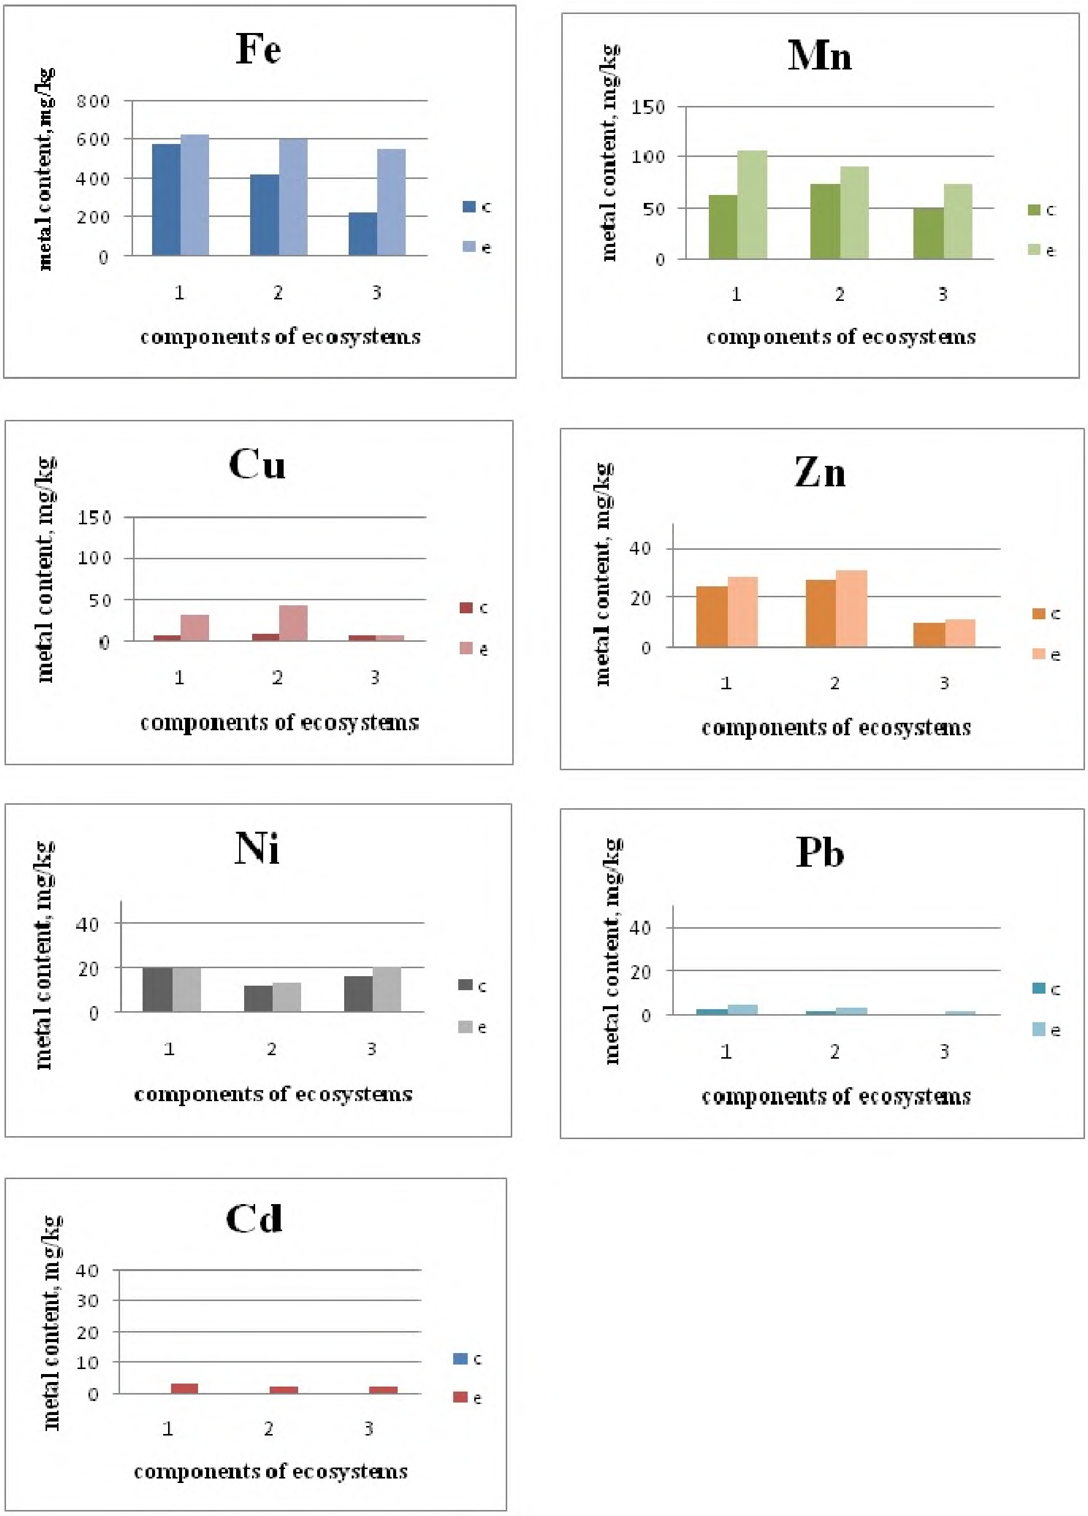

Figure 3. The content of heavy metals in various components of ecosystems under conditions of environmental pollution (Elytrigia repens L..), mg/kg: 1 – soil, 2 – underground part, 3 – above-ground part; k – control, d – experiment.

The conducted studies showed that, as a rule, the highest level of elements accumulated in the roots, which confirms the existence of a physiological protective barrier allowing heavy metals to penetrate into the plant aerial part selectively.

Along with plants, soil invertebrates are an integral part of the biota in artificial plantations of Robinia pseudoacacia L. in the area of Prydniprovska TPS operation. It was found that in artificial plantings of Robinia pseudoacacia L., the population of soil and litter invertebrates is represented by crustaceans, molluscs, arachnids, and insects. They are characterized by high numbers, species richness and diversity of functional groups. In all white acacia plantations, the greatest taxonomic diversity is among representatives of the class Jusecta – Scarabaeidae, Staphylinidae, Carabidae, Silphidae, Tenebrionidae, Histeridae, Cerambycidae. In animals selected in the area of influence of the Prydniprovska TPP and in the control areas Zn content for representatives of Isopoda, Cerambycidae, Carabidae, is almost the same and has the level as 18.1–19.6 mg/kg (figure 4). In the TPP area, soil and litter invertebrates accumulate iron (at the level of 2640.0 – 1450.0 mg/kg) and manganese (at the level of 1480.3 – 960.5 mg/kg) to a greater extent. In the control area, the research objects accumulated 1.2–1.3 times less iron, and 1.3–1.7 times less manganese compared to the contaminated area. Animals accumulate Zn and Ni in the smallest amount at all test sites. Among the highly toxic trace elements present in invertebrates, lead accumulates to a greater extent than cadmium. In the TPP area in representatives of crustaceans, its content is almost two times higher than in animals from control areas. For representatives of arachnids, the Pb content indicators exceed the control by 1.5 times. This shows that heavy metals are present in the dust emissions of Prydniprovska TPP and soil and litter invertebrates accumulate them in the process of life. It can be assumed that the differences in the content of some microelements (Zn and Ni) in the animals studied in TPP operation area compared to the control, are related to the presence of trace elements in the fuel on which the TPP works.

Accumulation of heavy metals by representatives of soil and litter invertebrates occurs in the process of their nutrition. Each animal performs its ecological and geochemical functions, taking part in the cycle of trace elements. Vertebrates feed on invertebrates. In this way, toxic microelements accumulated by invertebrates enter trophic food chains. In the process of research, the features of the heavy metals accumulation by invertebrates, which belong to such functional groups as zoophages and saprophages, were determined. The index of biological accumulation by representatives of individual taxa belonging to certain functional groups was calculated (figure 5).

The object of food of saprophages is leafy plant debris from which litter is formed. The litter is considered as the upper soil horizon. The process of feeding saprophages is closely related to plant material. By crushing dead plant debris, they promote the migration of heavy metals from it into deeper soil horizons. Woodlice (Isopoda sp.) are typical representatives of saprophages. At all test sites, they intensively accumulate Fe, Mn, Cu, Cd. (BAI more than 1). At the same time, they contribute to the purification of trophic food chains from Zn and Pb (BAI less than 1) and intensify the biological cycle of Ni (BAI = 1). Arachnids are typical zoophages. They feed on other invertebrates. In all studied artificial white acacia plantations, both control and in the TPP area, arachnids actively accumulate Fe, Cu, Zn, Ni, Pb, Cd (BAI greater than 1) and contribute to cleaning the trophic chain from Mn.Histeridae. Representatives of zoophages among insects intensively accumulate heavy metals in all investigated test areas (BAI more than 1). Carabidae sp., like Histeridae sp., accumulate Fe, Mn, Cu, Ni, Pb, Cd at all test sites, they contribute to the intensification of Zn circulation (BAI=1). Carabidae sp. is a fairly plastic group of insects with a high number and species richness of representatives. The bioaccumulation index for Fe, Mn, Ni, Pb practically approaches 1 in this objects. Thus, under certain conditions, they can contribute to the intensification of the circulation of these trace elements.

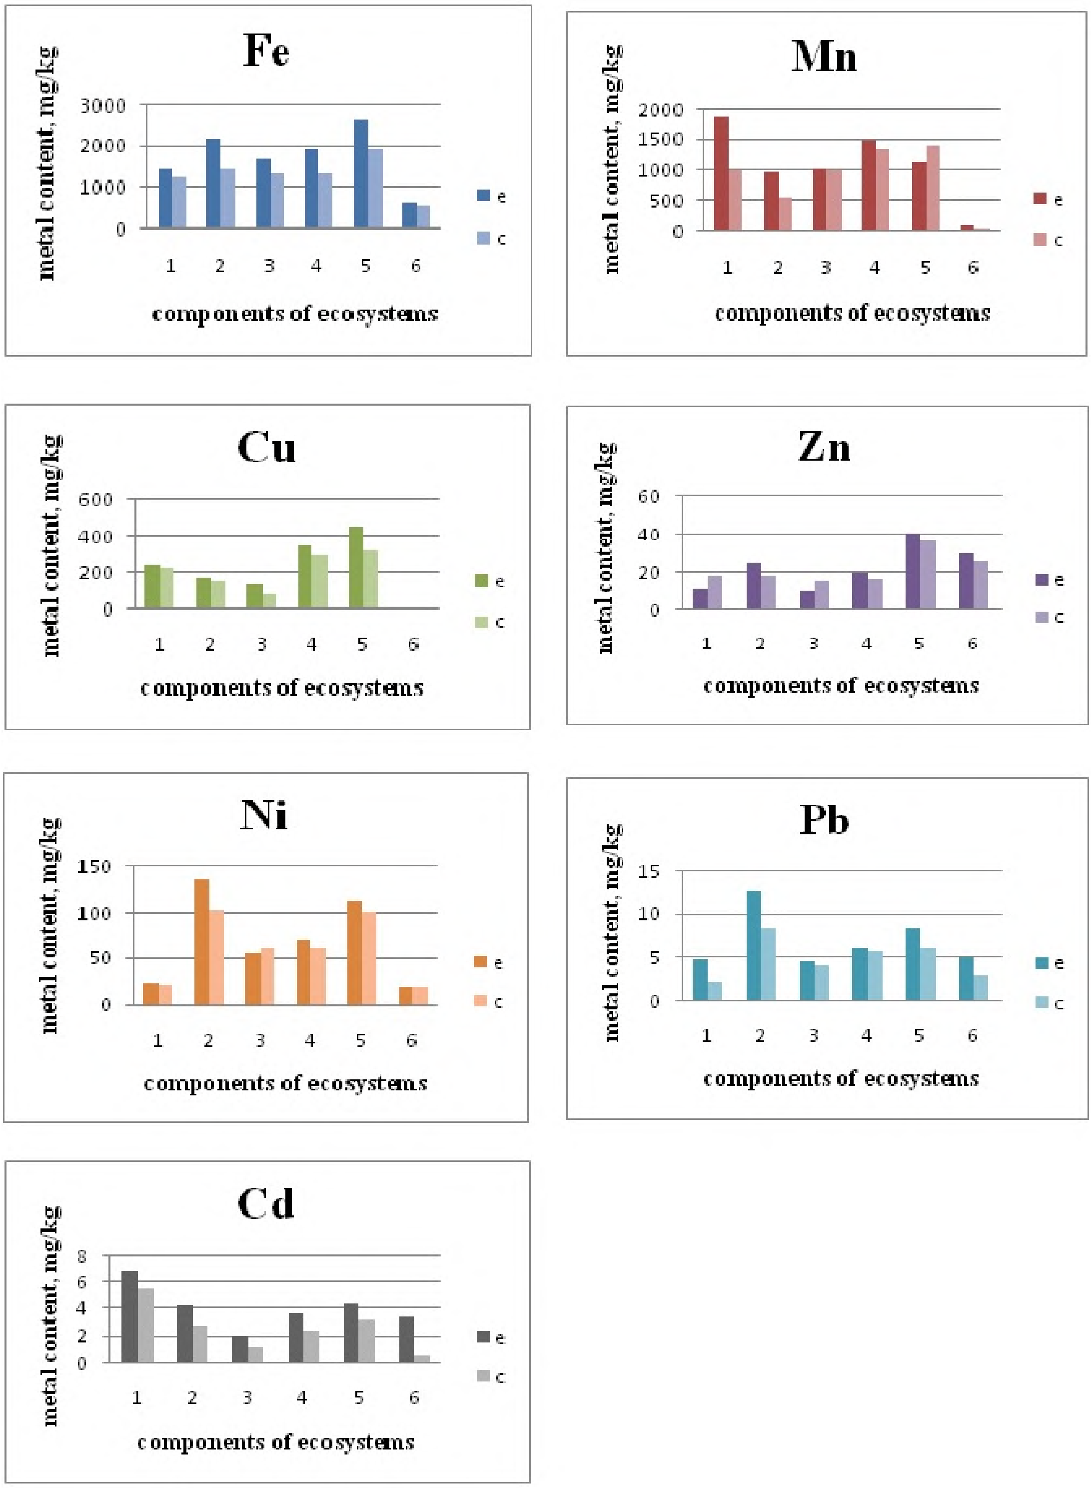

Figure 4. Average statistics of heavy metals accumulation by representatives of soil-litter invertebrates in artificial Robinia pseudoacacia L. stands (white acacia) in the area of Prydniprovska TPP operation; 1 – Isopoda, 2 – Aranei, 3 – Cerambycidae, 4 – Carabidae, 5 – Histeridae, 6 – Soil, d – experiment, k – control.

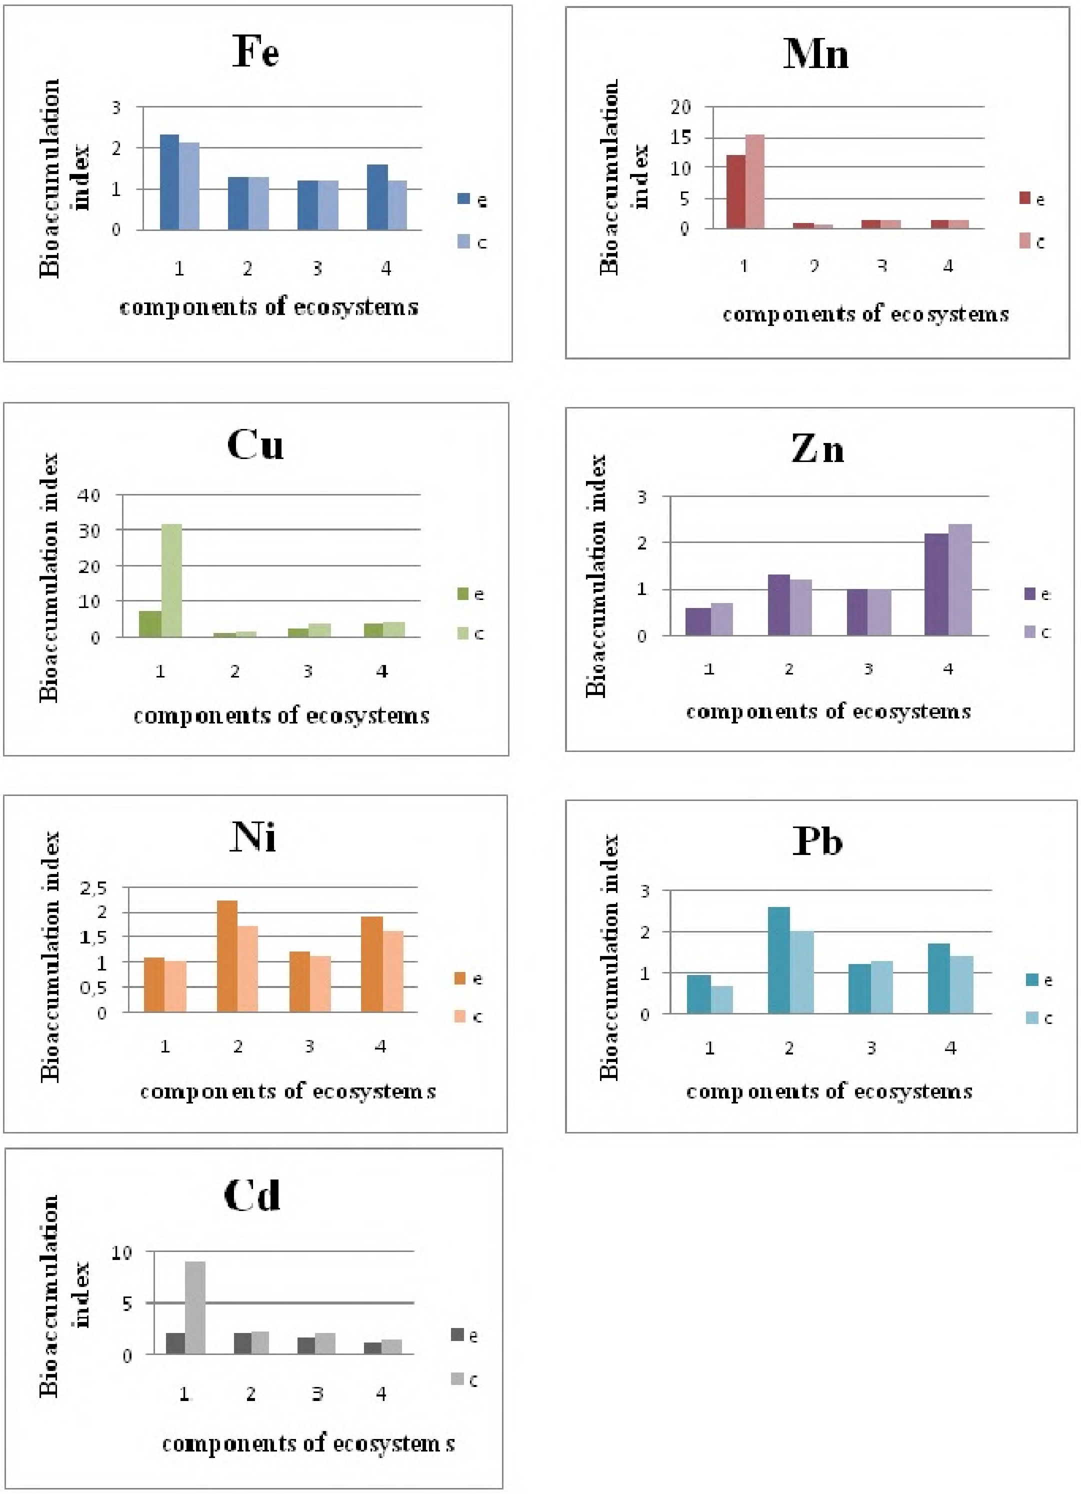

Figure 5. Index of biological accumulation of representatives of soil and litter invertebrates in artificial Robinia pseudoacacia L. (white acacia) plantations in the area of Prydniprovska TPP operation and in control areas; 1 – Isopoda, 2 – Aranei, 3 – Carabidae, 4 – Histeridae, d – experiment, k – control.

4. Conclusions

Based on the conducted research, it was established peculiarities in the accumulation of heavy metals by the main sod-forming cereals, depending on the level of soil pollution in the plantings of Robinia pseudoacacia L. in the area of the Prydniprovska TPP operation. It was found that in the soil of the experimental site, the content of zinc, copper, cadmium, and lead exceeded the reference indicators, and the excess was significant for manganese and nickel. The peculiarities of the heavy metals accumulation in the above-ground and underground parts of the main sod-forming grasses growing on the TPP territory were revealed.

Soil-litter invertebrates living in Robinia pseudoacacia L. plantations in the area of Prydniprovska TPP operation and control sites accumulate heavy metals Fe, Cu, Zn, Ni, Mn, including highly toxic Pb and Cd. In the control and experimental areas indicators of Zn accumulation by invertebrates do not differ significantly. At all test sites, invertebrates accumulate Fe and Mn in the largest amount. Of all the functional groups, only representatives of saprophages perform the functions of the heavy metals accumulators (Fe, Cu, Cd, Mn), contribute to the intensification of the biological cycle (Ni) and the purification of trophic chains (Zn, Pb). The obtained results can be used for conducting monitoring ecotoxicological studies. Certain taxa of soil and litter invertebrates (Carabidae sp., Cerambycidae sp.) can be used as bioindicators of the state of the environment.

E-mail: `aola@carbookr.com`

Abstract. On-road carbon dioxide (CO_2) emissions from rental vehicles are very much affected by vehicle category, types of vehicle transmission, fuel type and traveled distance. In this paper, four machine learning models (decision trees, random forest, AdaBoost and XGBoost) were used to predict CO_2 emissions from rental vehicles. The models were trained and tested on Carbookr's bookings dataset. The results show that the traveled distance, the included mileage, the ACRISS code, the rental duration, the driver's home country, the country where the driver works and the country where he pickups up the vehicle as well as the country where he returns the vehicle had clear impacts on the transient CO_2 emission rates. There was a positive correlation between these features and CO_2 emission rates. The findings also indicate that XGBoost achieves the best accuracy performance when compared to other machine learning algorithms in terms of the Root Mean Squared Error (RMSE), the Mean Absolute Error (MAE), the Mean Absolute Percentage Error (MAPE) and the Coefficient of Determination (R^2). The results show that the machine learning-based CO_2 emission model ML-ERV trained using XGBoost algorithm outperforms the state-of-the-art CO_2 emissions calculators.

1. Introduction

Carbon dioxide (CO_2) emissions from the transportation sector are one of the largest contributors to greenhouse gas emissions [1]. These emissions are a result of fossil fuel combustion in various types of transportation such as road transportation, maritime transportation, aviation, public transit, and rail transportation. The percentage of CO_2 emissions per transportation type can change over time due to many factors including advancements and shifts in transportation habits [2]. However, according to [3–5], nowadays, road transportation, which includes rental vehicles and individually owned vehicles, releases a significant amount of CO_2. It accounts for a substantial portion of total greenhouse gas emissions. Rental vehicles, which might be cars, trucks, vans, and buses, contribute to CO_2 emissions in the same way as individually owned vehicles. In what follows, we will focus on CO_2 emissions from rental vehicles.

France has various environmental regulations and policies in place related to CO_2 emissions from rental vehicles. These regulations aim to reduce greenhouse gas emissions which do not only have environmental benefits but also wide-ranging positive impacts on both public health and economic well-being. Indeed, decreasing CO_2 emissions from rental vehicles will mitigate climate change, protect ecosystems, ensure cleaner air, improve physical and mental health, reduce healthcare costs associated with treating pollution-related illnesses, lower fuel consumption which leads to cost savings for both consumers and businesses, and encourage companies to become more innovative and competitive.

Environmentally friendly vehicles, including electric vehicles (EVs) and hybrids, are nowadays being promoted by rental vehicle companies as a vital solution to effectively tackle climate change [6]. However, transitioning to environmentally friendly vehicles for rental vehicle companies can be challenging for various reasons. The following are some of the common challenges associated with making this switch: limited charging stations or repair facilities, higher purchase price compared to traditional gasoline-powered vehicles, limited driving ranges which can be an issue for individuals who travel long distances without regular charging options, lack of variety compared to traditional vehicles, and charging a vehicle takes much more time than filling up a gasoline tank.

Calculating and reporting CO_2 emissions from rental vehicles can contribute significantly to reducing CO_2 emissions. Here are some common ways that help mitigate CO_2 emissions given CO_2 emissions reports: it serves as a reference point for understanding the current environmental impact of rental vehicles, which helps identify sources with high CO_2 emissions and thus come up with solutions to help reduce these emissions, it brings more awareness to eco-driving practices, customers make a more sustainable choice when selecting a rental vehicle (opt for lower-emission vehicles), it enhances the company's brand image by promoting sustainability, it assists companies to better comply with regulations and avoid penalties related to CO_2 emissions, and it helps companies manage their fleets by offering vehicles with varying emissions based on customer preferences and local regulations.

Valuable as it is, developing a machine learning model to predict CO_2 emissions from rental vehicles is complicated as it faces numerous challenges, which includes lack of rental vehicle bookings datasets, often unavailable data about the traveled distance, missing information about the customer's driving style (aggressive braking, gentle braking, etc.), missing information about the places the driver will visit (cities, rural areas, highway, mountains, etc.), lack of information about the number of passengers and baggage, unavailable information about the weather and traffic conditions, etc.

In this paper, we introduce an unprecedented machine learning-based CO_2 emissions model designed for rental vehicles (ML-ERV). ML-ERV was built using a dataset from Carbookr's bookings. Carbookr (`https://www.carbookr.com/`) is a car booking platform for business travels. The key idea of ML-ERV is to predict CO_2 emissions from a vehicle prior to renting it. ML-ERV is an innovative and environmentally responsible solution for both rental vehicle companies and consumers. We make the following contributions:

- Introduce a new machine learning-based CO_2 emission model, ML-ERV, designed for rental vehicles and trained using XGBoost algorithm.
- Provide a CO_2 emission calculating solution that takes into consideration information closely related to the rental vehicle domain.
- Develop a CO_2 emission model with a high accuracy and a very low percent error.
- Make better predictions than existing CO_2 emissions calculators.

The rest of this paper is organized as follows. Section 2 reviews the state-of-the-art CO_2 emissions calculators, and then presents their key limitations. Section 3 describes ML-ERV, and compares it against current CO_2 emissions calculators. Section 5 concludes this paper and discusses future research directions.

2. Literature review
Plenty of research work has been conducted on calculating CO_2 emissions from vehicles. However, to our knowledge, none has been designed for tracking and managing CO_2 emissions generated by vehicles in a rental fleet. In the following, we will review the state-of-the-art calculation methods of CO_2 emissions from vehicles. We grouped them into four major categories, each using a different set of information about the vehicle and the travel specifics.

2.1. Calculators using distance

Numerous research works [7] have defined CO_2 emission factors for a specific city; however, these factors cannot be used in other locations because the emission factor depends on the type of the vehicle, the passenger load factor, and the engine size. Furthermore, the number of vehicles on the road during peak hours differs for different study locations. Given all that, Wei and Pan [8] introduces equation (1) to calculate CO_2 emissions, such that M_i refers to CO_2 emissions, D_i is the distance, and E_i is the CO_2 emission factor.

$$M_i = D_i \cdot E_i \tag{1}$$

2.2. Calculators based on vehicle type

Aksoy et al. [9] introduces a CO_2 emission calculating method that uses vehicle type. This method uses the vehicle weight, the vehicle technical data as well as the distance traveled. Researchers found that CO_2 emissions are directly correlated with vehicle type and distance traveled, where higher fuel consumption leads to higher CO_2 emissions. The formula (2) presents their contribution where C refers to CO_2 emissions (kg), FC is the vehicle fuel consumption (L/100 km) and f is the fuel-based emission factor (kg/L).

$$C = FC \cdot f \tag{2}$$

2.3. Calculators based on fuel consumption

According to Zahoor et al. [10], CO_2 emissions from vehicles are calculated based on the combustion of different types of fossil fuels (petrol, gas, diesel, kerosene-oil, etc.). Zahoor et al. [10] indicates how to calculate these emissions, such that $Fuel_i$ is the mass of fuel type i, HC_i is the heat capacity of fuel type i, C_i is the carbon content of fuel type i, FO_i is the oxidized fraction of fuel type i, CO_2(m,w) is the molecular weight of CO_2, $C(m, w)$ is the molecular weight of carbon. The equation is defined as follows:

$$Emission = \sum_{k=0}^{n} \mathrm{Fuel}_i \times \mathrm{HC}_i \times C_i \times \mathrm{FO}_i \left(\frac{\mathrm{CO}_2(m, w)}{\mathrm{C}(m, w)} \right) \tag{3}$$

Weigel, Southworth and Meyer [11] introduces an improved equation (4) of the previous measure. (4) uses the volume of fuel, the measured carbon content of the fuel per unit of energy (or per unit of volume or mass) and the measured heat content (or density) of the fuel used. F refers to the fuel consumption, R is the thermal capacity or density of the fuel and K is the carbon content.

$$E = F \cdot R \cdot K \cdot \left(\frac{11}{3} \right) \tag{4}$$

2.4. Calculator using the average vehicle speed

Gharineiat and Khalfan [12] presents an average vehicle speed-based measure. It calculates CO_2 emissions $f(x)$ as showed in equation (5) presented below, where v_s is the average speed in km/h, f_i is the fuel consumption rate in mL/h, c is a derived regression coefficient, K is the adjustment factor and the constant term cK takes into account inertia and effect of slope on fuel.

$$f(x) = f_i \cdot v_s + c \cdot K \tag{5}$$

Table 1 presents the key features each of the aforementioned CO_2 emissions calculators takes into consideration.

Current vehicle emission models are either overly simple not using enough information, resulting in low estimation accuracy, or they are too complicated requiring excessive inputs,

Table 1. State-of-the-art CO_2 emissions calculators.

CO_2 calculators	Distance	Fuel type	Fuel consumption	Speed	Vehicle type	Manufacturer	Model	Year
Equation (1)	✓	✗	✗	✗	✓	✗	✗	✗
Equation (2)	✓	✗	✓	✗	✓	✗	✗	✗
Equation (3)	✗	✓	✓	✗	✗	✗	✗	✗
Equation (4)	✗	✓	✓	✗	✗	✗	✗	✗
Equation (5)	✗	✗	✓	✓	✓	✗	✗	✗

relying on too much prior knowledge [13–16]. Each calculating method described above has its own pros and cons (table 1), but one thing that all these calculators have in common is that they were not defined to fit rental vehicle needs. Thus, they do not meet the unique requirements and challenges a calculator of CO_2 emissions from rental vehicles should comply with. Below we will present these requirements:

- Predicting CO_2 emissions prior to renting the vehicle.
- Using the distance traveled during the rental duration.
- Profiling drivers.
- Using precise information about the vehicle (category, type, transmission, fuel, etc.).
- Using the driver's place of work, vehicle pickup station, vehicle return station and home address.

In the next section, we will present thoroughly ML-ERV, our solution to the problem described above.

3. Machine learning-based rental vehicle model

In this section, we will present ML-ERV, our machine learning model designed to estimate CO_2 emissions generated by vehicles in a rental fleet. This model aims at predicting CO_2 emissions prior to renting the vehicle. This section is organized as follows. First, it will describe the dataset used to build our model. Second, it will study the correlation between rental vehicle CO_2 emissions and the predictor variables. Third, it presents the machine learning algorithms used to build ML-ERV.

3.1. Data collection

We developed ML-ERV using Carbookr's bookings dataset (table 2). This dataset includes 26770 samples, and it contains input features and a corresponding output target. It consists of rental vehicle bookings made through Carbookr's platform in the period 2016-2023 and handled in accordance with privacy policies. Each record contains data regarding client identification (client refers to the company the driver works for), driver identification, user identification (user refers to the person who made the booking, it can be the driver himself or it can be someone working for the client company), vehicle information, travel information, invoice information, supplier information and invoice data. Table 2 shows the total number of variables contained in the dataset provided, along with the percentage of missing data and invalid data.

The records of bookings provided by Carbookr were subject to data cleaning. The criteria followed for data cleaning are the following. Eliminate variables that are not considered of interest for this study, get rid of variables with a high proportion of missing values, eliminate variables that make the analysis difficult, remove those that provide duplicate information, and

Table 2. Dataset description.

Dataset	Total number of records	Total number of variables	Percentage of missing values	Percentage of invalid records
Carbookr's bookings	26770	114	15%	32%

eliminate those used for the generation of new variables. Table 3 shows the descriptive statistics of the independent variables used to predict CO_2 emissions.

Table 3. Predictive variables of CO_2 emissions.

Variables	Description	Min	Max	Mean	Standard deviation
ACRISS (acriss)	Vehicle classification code	NA	NA	NA	NA
Mileage (mileage)	Traveled kilometers	0	40056	516.26	946.91
Duration (duration)	Rental duration (in half days)	2 (1 day)	300 (150 days)	8.1	10.2
Included mileage (incl)	Kilometers he can drive without incurring additional charges	0	23976	876.2	1121.83
Driver's country (dr_country)	Where he lives	NA	NA	NA	NA
Client's country (clt_country)	Where he works	NA	NA	NA	NA
Pickup country (pu_pl_country)	Where he took the vehicle	NA	NA	NA	NA
Return country (r_pl_country)	Where he returned the vehicle	NA	NA	NA	NA

Note that ACRISS (`https://www.acriss.org/car-codes/`) is short for Association of Car Rental Industry Systems and Standards. It assigns a code of four characters to each vehicle. The first character denotes the vehicle category. The second character defines the vehicle type and chassis type (van, SUV, wagon, convertible, etc.). The third character defines the transmission and drive – automatic / manual and 2WD / 4WD / AWD. And the fourth character defines the fuel type (petrol, diesel, hybrid, electric, etc.) and whether air conditioned or not.

Next, we will study the correlation between CO_2 emissions and the independent variables listed in table 3.

3.2. Correlation of rental vehicle CO_2 emissions and independent variables

Let's examine the correlation between the target variable (CO_2 emissions), which is a continuous variable, and the continuous predictors by measuring the Pearson's correlation coefficient; and between the target variable (CO_2 emissions) and the categorical predictors by means of the ANOVA test.

Table 4 summarizes the relationship between CO_2 emissions and continuous features. The results indicate a high positive correlation between the traveled distance and CO_2 emissions, and a moderate positive correlation between the included mileage and CO_2 emissions. The findings also show a low positive correlation between the rental duration and CO_2 emissions.

Table 4. Correlation values (continuous variables vs CO_2 emissions).

	Traveled distance	**Duration**	**Included mileage**
CO_2 emissions	0.73	0.45	0.6

Table 5 summarizes the relationship between CO_2 emissions and categorical features. The results indicate that the p-value for all categorical variables is less than the chosen significance level 0.05 which rejects the null hypothesis.

Table 5. Correlation values (categorical variables vs CO_2 emissions).

	ACRISS code	**Driver's country**	**Client's country**	**Pickup station country**	**Return station country**
CO_2 emissions	$1.34 \cdot 10^{-38}$	0.01	$9.69 \cdot 10^{-6}$	$7.389 \cdot 10^{-5}$	$1.2 \cdot 10^{-5}$

Traveled distance, included mileage and duration have a strong relationship with CO_2 emissions. Furthermore, the ACRISS code, the driver's country, the client's country, the pickup station country and the return station country have a great impact on CO_2 emissions. In this respect, the selected features are the traveled distance, the included mileage, the duration, the ACRISS code, the driver's country, the client's country, the pickup station country and the return station country.

3.3. Machine learning models

Decision trees, random forest, AdaBoost and XGBoost were fitted on the training dataset. The four models were compared based on performance metrics of predictive accuracy: coefficient of determination (R^2), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE). Table 6 summarizes the hyper-parameters used in the execution of each model.

In subsequent section, we will first describe the results obtained by each model, analyze and compare the findings. Then, we will compare ML-ERV to the state-of-the-art calculators.

4. Results and discussion

We will start with presenting the results of training and testing decision trees, random forest, AdaBoost and XGBoost on Carbookr's dataset. Then, we will describe the impact of each factor on the final predictions. Next, we will compare the results obtained by our model to the results obtained by the state-of-the-art calculators described in section 2.

4.1. Training and testing ML-ERV

The dataset was divided into two sets: one is the training data, which the machine learning algorithm uses for learning, and the other is the testing data, which is used to measure and compare the accuracy of the machine learning models. To identify the best split strategy, two proportions were used (70-30% and 80-20%). The training data and the testing data were defined

Table 6. Hyperparameters used in the execution of the models.

Model	Hyper-parameters description	Value
Decision trees	*max_depth*: the maximum depth of the tree	10
Random forest	*max_depth*: the maximum depth of the tree	10
	n_estimators: the number of trees in the forest	100
AdaBoost	*n_estimators*: the maximum number of estimators at which boosting is terminated	100
	base_estimator: the base estimator from which the boosted ensemble is built	Decision trees
	learning_rate: weight applied to each regressor at each boosting iteration	0.01
XGBoost	*max_depth*: maximum depth of a tree	10
	learning_rate : step size shrinkage in boosting	0.1
	n_estimators: the maximum number of estimators at which boosting is terminated	100
	objective: the learning task and the corresponding objective function	Squared error

by stratified sampling in order to help the response variable reach a balanced distribution in both sets. All four models are executed 20 times each, and the findings show consistency. The comparison in terms of the performance of the regression models were carried out using R^2, RMSE, MAE and MAPE. Table 7 presents the average results.

Table 7. Comparison of regression models.

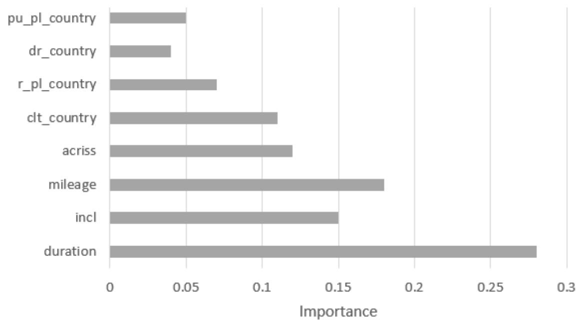
Model	80–20%				70–30%			
	RMSE	MAE	$\mathbf{R^2}$	MAPE	RMSE	MAE	$\mathbf{R^2}$	MAPE
Decision trees	1331.951	1177.816	0.497	0.088	1332.881	1178.511	0.496	0.088
Random forest	1200.741	1049.324	0.581	0.076	1202.445	1050.874	0.579	0.076
AdaBoost	1145.361	978.369	0.711	0.067	1147.256	979.185	0.71	0.067
XGBoost	1136.231	958.125	0.753	0.065	1137.587	956.224	0.752	0.065

The evaluation results show that there are no big differences with different training and test data proportions. The findings also indicate that the 80–20% proportion achieves better results than 70-30%. Therefore, the XGBoost has the better performance prediction compared to other models, which is clearly confirmed when the values of the evaluation metrics between the different models are compared in table 7, where the XGBoost has the highest R^2 value (0.753) and the lowest MAE (958.125), RSME (1136.231), and MAPE (0.065) values.

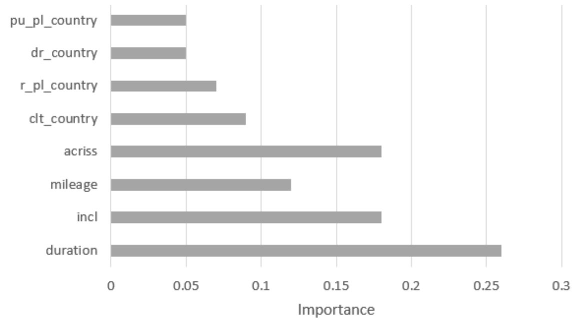
In the next section, we will show features importance for each single model through bar charts.

4.2. Variables importance

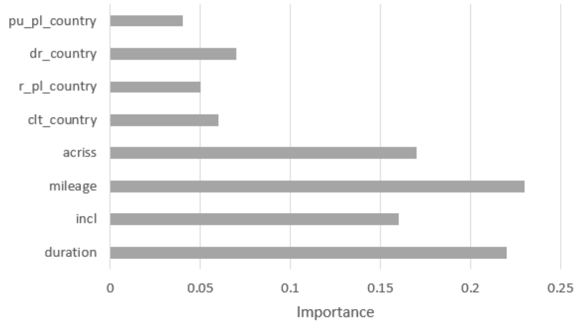
It is important to assess the variables' importance for each model through the permutation method in order to better understand how each model processes these variables to make predictions. This method determines the impact of features by measuring how much the model's performance decreases when the feature's values are randomly shuffled. Figure 1 illustrates the variable importance for each model.



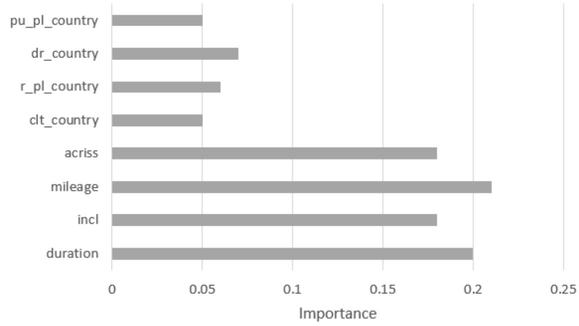
(a) Decision trees model



(b) Random forest model



(c) AdaBoost model



(d) XGBoost model

Figure 1. Features importance.

The four models select the features duration, mileage, included mileage and ACRISS code as very important variables, followed by driver's country, work country, country of the pickup station and country of the return station.

Next, we will compare the results obtained by ML-ERV against the existing calculators.

4.3. Comparing ML-ERV to the state-of-the-art calculators

Table 8 presents the results of applying each of the existing calculators shown in section 2 to the bookings dataset. The results (table 7 and table 8) indicate that ML-ERV achieves better results in terms of the evaluation metrics than existing calculators.

Table 8. Results obtained by the state-of-the-art CO_2 emissions calculators.

$\mathbf{CO_2}$ emissions calculators	RMSE	MAE	R^2
Equation (1)	1564.127	1487.457	0.37
Equation (2)	1678.118	1601.327	0.27
Equation (3)	1400.397	1315.742	0.39
Equation (4)	1497.738	1481.225	0.38
Equation (5)	1332.102	1228.575	0.4

In the next section, we will conclude this paper and present potential future research directions.

5. Conclusions and future research directions

This paper has critically reviewed the state-of-the-art CO_2 emissions calculators and showcased their key limitations in the rental vehicles industry. It then introduced ML-ERV, a new machine learning-based solution, to predict CO_2 released from rental vehicles prior to their usage. ML-ERV is designed to align with the rental vehicles' unique requirements.

ML-ERV was developed based on Carbookr's extensive booking dataset. Through an analytical exploration of the dataset, some correlations were identified between CO_2 emissions and the following variables ACRISS code, traveled distance, included mileage, duration, country of the pickup station, country of the return station, driver's home country and the country where the driver works. This research study used four machine learning models: decision trees, random forest, AdaBoost and XGBoost. The models were optimized by determining the best values for different hyper-parameters. The evaluation of the models via the metrics R^2, RMSE, MAE and MAPE indicates that XGBoost has the best prediction performance, and that our model ML-ERV trained using XGBoost reaches better accuracy than the existing calculators.

While our findings present a substantial leap forward, there remain avenues for further exploration and improvement. Future research work includes the development of user profiling models based on the booking dataset along with external data sources, leveraging such insights to enhance both ML-ERV's accuracy and adaptability to diverse user needs. Furthermore, incorporating additional rental vehicle-related features such as the vehicle model and the registration number holds promise for refining CO_2 emission predictions and ensuring the continued relevance of ML-ERV in a rapidly evolving industry landscape.

Beyond its immediate implications for CO_2 emissions monitoring in rental vehicles, our research work contributes to broader discussions surrounding sustainability efforts, technological innovation, and the optimization of transportation systems. By continually refining and expanding upon ML-ERV's capabilities, we aim to catalyze positive change within the rental vehicle industry and advance towards a more sustainable future.

Abstract. This research addresses the imperative task of effective disaster mitigation planning for significant earthquakes, specifically focusing on the Shamkir-Mingachevir reservoir region. The complexities of seismic risk assessment involve the intricate interplay of geological, geotechnical, and environmental factors. The character of propagation of seismic waves is influenced significantly by local site conditions, shaping the observed intensity of ground motions at the surface. The term "site effects" is central to this research, signifying the amplification of seismic waves influenced by distinctive geological conditions. The results indicate that soils with lower shear wave velocities exhibit lower peak ground accelerations at the surface. However, the study highlights the susceptibility of softer soils to nonlinear effects, emphasizing the need to consider the composition of local soils in developing seismic safety measures. The separate study of resonant frequencies of the soil-structure system is crucial to mitigate resonant effects during earthquakes. This approach facilitates the development of accurate and tailored building standards aimed at safeguarding infrastructure and ensuring safety in seismic zones.

1. Introduction

To effectively address disaster mitigation planning for significant earthquakes, it is crucial to conduct thorough assessments of ground motion intensities and potential building damage resulting from hypothetical seismic events. The complexities of seismic risk assessment involve not only the magnitude and depth of earthquakes but also the intricate interplay of geological, geotechnical, and environmental factors. The observed intensity of ground motions at the surface is influenced by source effects, path effects, and, notably, site effects [1, 2]. Evaluating site effects is crucial because surface soil characteristics can lead to significant amplification of ground motion during seismic events, posing a heightened risk of severe damage to buildings, infrastructure [3], and potential loss of lives.

The recognition that local site conditions play a pivotal role in the propagation of seismic waves has been consistently affirmed through extensive earthquake studies, has found broad application in practical engineering [2, 4–12], and has stimulated comprehensive theoretical investigatins [1, 13–15].

Seismic waves undergo modifications influenced by local geological conditions. Seismic site effects are intricately linked to the amplification of seismic waves in superficial geological layers. In a broader context, the term "site effects" encompasses the amplification of seismic waves resulting from specific geological conditions. Site effects stem from various physical phenomena, including multiple reflections, diffraction, focusing, and resonance, all of which impact the incoming wave front.

A notable illustration of this phenomenon occurred during the 1985 Michoacan earthquake in Mexico City [16]. Surprisingly, peak ground accelerations (PGAs) were more pronounced at 400 km from the epicenter than at the epicenter itself (figure 1).

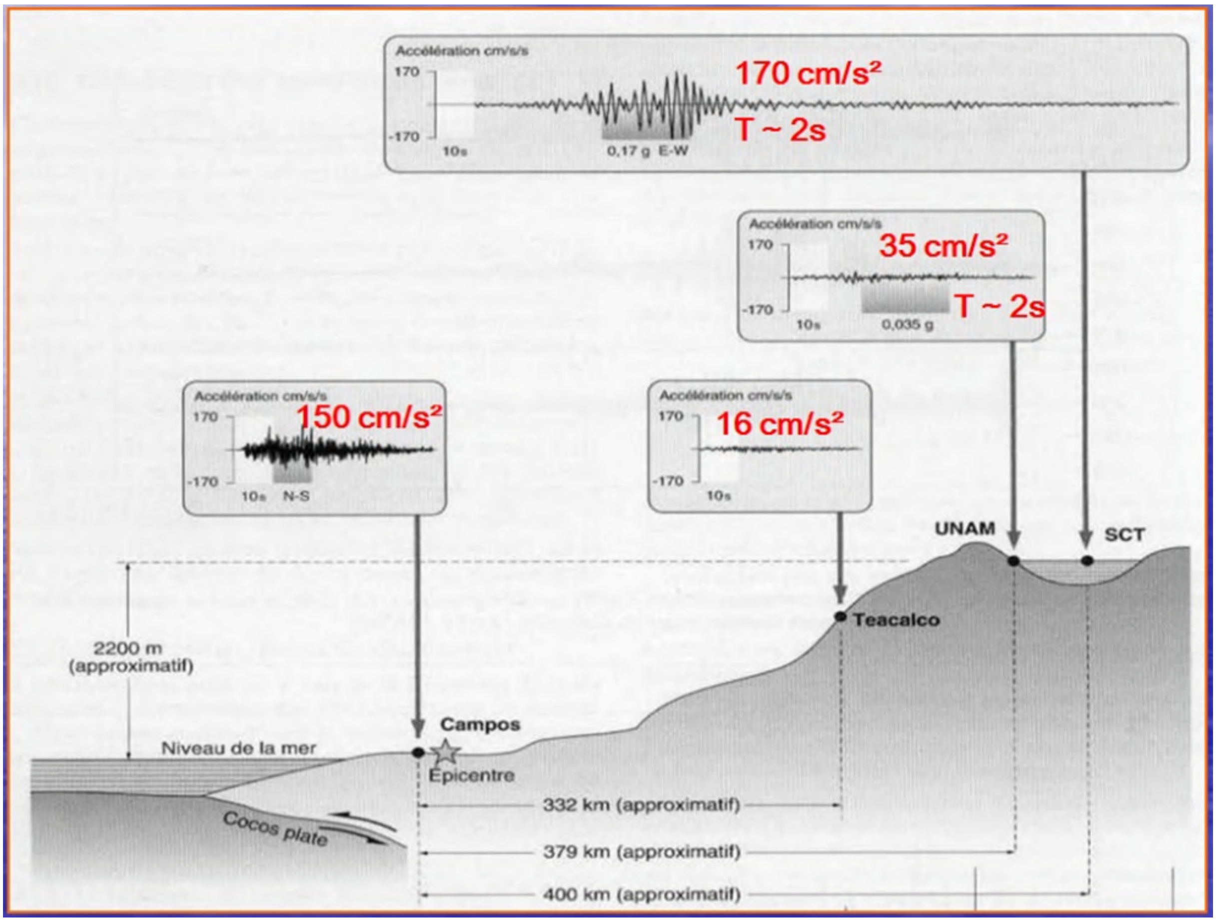

Figure 1. Example of seismic site effects [3, 16].

This unusual occurrence was attributed to the amplifying effect of the soft sediments underlying the region. Despite the earthquake's epicenter being approximately 400 km away, the seismic motions experienced in Mexico City were significantly intensified. The amplification reached a factor of 60 compared to the bedrock, primarily due to the presence of soft clay deposits beneath the city [9]. This case underscores the critical role of local geological conditions in shaping ground motion intensities during seismic events.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012007 doi:10.1088/1755-1315/1415/1/012007

2. Research aim and objectives

These studies deal with advanced examination of seismic hazards within the Shamkir-Mingachevir reservoir region, which is a critical area where significant hydroelectric infrastructure is located. The investigation is prompted by the imperative need to understand the seismic dynamics of this region, particularly due to the presence of essential hydroelectric power stations (HPSs). The term "site effects" is key to our research, signifying the amplification of seismic waves influenced by distinctive geological conditions. The intricate relationship between seismicity, the response of local soil conditions, and the crucial hydroelectric infrastructure in this region underscores the importance of this study in contributing to effective disaster preparedness and risk mitigation strategies.

3. Seismicity in Azerbaijan and the Shamkir-Mingachevir reservoir region

The Azerbaijan territory, as a part of the Alpine folded system, is characterized by very high seismic activity. Throughout history, the region has experienced strong and catastrophic earthquakes leading to significant human losses and widespread destruction.

Among the areas heavily affected, it is worth noting the Shamakhi and Ganja regions, where some of the most powerful earthquakes were occurred [17, 18]. The earthquake in Shamakhi in 1668, with a magnitude of 7.0 and an intensity of 9-10 points, is considered one of the strongest earthquakes in the Caucasus. Historical records indicate that this event triggered landslides resulting in the tragic loss of over 80,000 lives.

Shamakhi continued to experience seismic activity with intensities reaching up to 8 according to MSK-64 in the years 1828, 1859, 1869, and 1872. The last catastrophic earthquake in this region, with a magnitude of 6.9 and an intensity of 9 points, occurred in 1902.

Another region affected by destructive earthquakes is Ganja, where significant seismic events took place in 427 (magnitude 6.7, intensity 9 points), 1139 (magnitude 6.8, intensity 9 points), and 1235 (magnitude 5.7, intensity 8 points). The earthquake in 1139 led to the creation of Goy-gol Lake due to landslides.

Various other regions of the republic have also recorded numerous strong earthquakes, with intensities ranging up to 6-7 points. While the intensity may not have been as extreme, these seismic events often resulted in substantial destruction. The historical seismicity of Azerbaijan underscores the importance of ongoing seismic risk assessment and disaster preparedness efforts in the region.

In this research, we examine the seismic activity in Azerbaijan spanning the years 1973 to 2023 utilizing data sourced from the US Geological Survey (USGS) [19]. Figure 2 displays the locations of earthquakes with magnitudes exceeding 3 that occurred during this period providing a visual representation of the seismic events in the region.

Considering the statistical properties of these earthquakes, we evaluate the histograms for earthquake magnitudes and depths. In particular, figure 3a shows the earthquake magnitudes histogram approximating the corresponding *unimodal* distribution of earthquake magnitudes.

The earthquake magnitude distribution indicates that most events in Azerbaijan occur with a magnitude of 4-4.5 (almost 42%). Earthquakes with a magnitude greater than 5 are less than 17%, and those greater than 6 are less than 1%.

Doing in the similar manner, the histogram for earthquake depths is evaluated and depicted in figure 3b. It is worth to note that, in contrast to the magnitude histogram, the histogram for depths quite confidently tends to a *multimodal* depth distribution of earthquakes. The depth distribution analysis underscores a predominantly crustal nature of seismic events in Azerbaijan. Almost all earthquakes are concentrated at depths of less than 50 km, with the majority occurring at depths of up to 25 km. This pattern suggests that the seismic activity in the region is primarily associated with crustal tectonic processes.

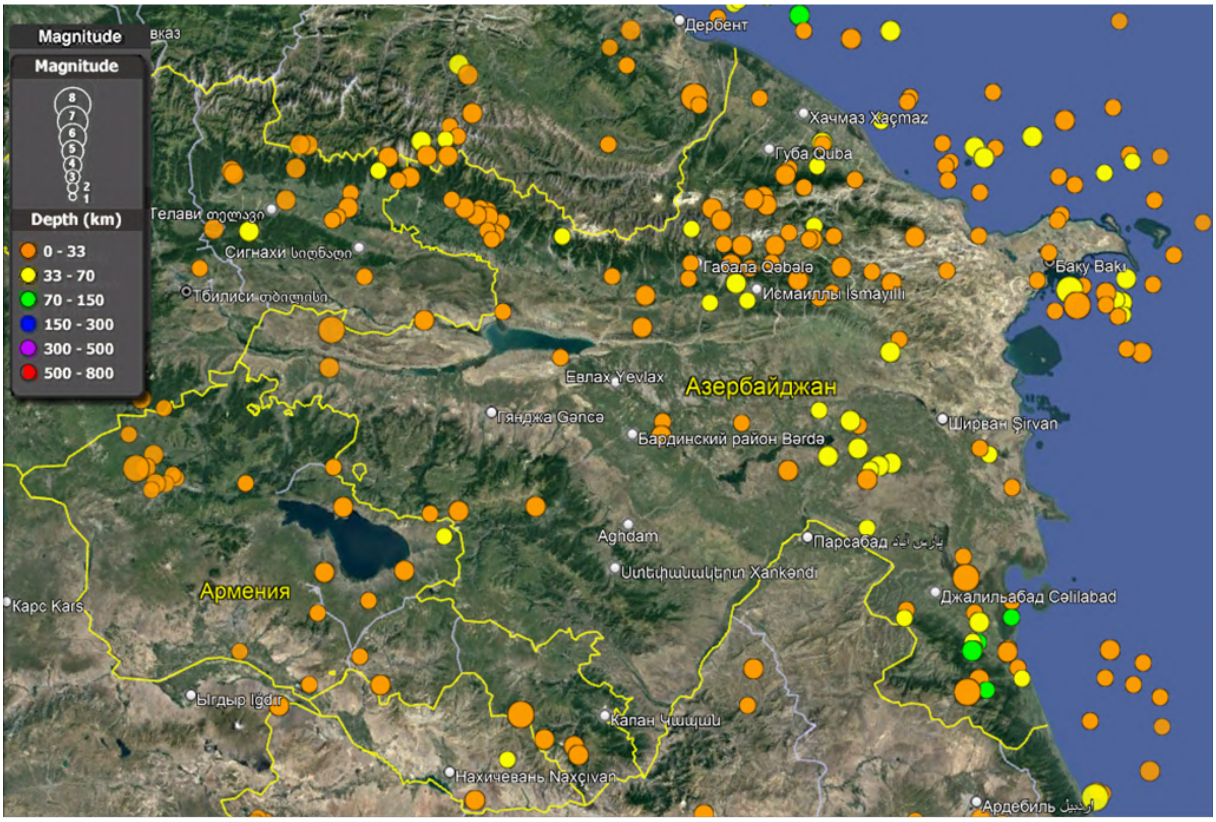

Figure 2. Earthquakes with magnitudes exceeding 3 observed in Azerbaijan from 1973 to 2023.

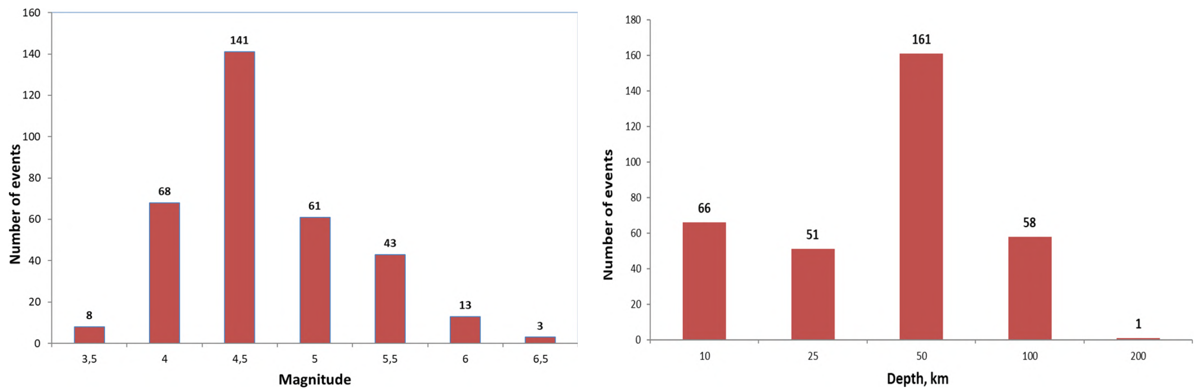

(*a*) (*b*)

Figure 3. Magnitude and depth distributions of earthquakes exceeding 3 occurred in Azerbaijan from 1973 to 2023.

Analyzing data mentioned above, we also reveal a notable trend – earthquakes tend to occur with higher frequency in proximity to HPS in Mingachevir compared to the Shamkir HPS. Most earthquake epicenters, as recorded by the USGS, are situated within the 25-150 km range from the Mingachevir HPS. In contrast, over 50% of seismic events occurred at distances exceeding 150 km from the Shamkir HPS. On average, the distance from the Mingachevir HPS to earthquake epicenters is approximately 150 km, while for the Shamkir HPS, this distance extends to 225-250 km.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012007 doi:10.1088/1755-1315/1415/1/012007

4. Seismic site effects of the Shamkir-Mingachevir reservoir region

We conducted an in-depth examination of the seismic activity in the Shamkir-Mingachevir reservoir region, with a particular focus on the response of surface soils at the Mingachevir and Shamkir HPSs during seismic events. Recognizing the crucial role of near-surface soils in amplifying the propagation of earthquake waves from bedrock to ground level, our study delved into the intricate details of this phenomenon. Our analysis utilized seismic data from USGS and applied ground response analysis techniques to comprehensively assess the potential impact of seismic motions on these vital infrastructures.

Seismic site response analysis is used to assess the effect of site-specific soil conditions on expected earthquake ground shaking. Our research focused on modeling the impact of the upper 30 meters of local soils at the Mingachevir and Shamkir HPSs in response to seismic impacts of different amplitudes. We used accelerogram records on bedrock with maximum amplitudes ranging from 0.05g to 0.33g as seismic impacts. These amplitude values correspond to the expected levels of seismic activity that could affect the territory of the Mingachevir and Shamkir HPSs, in accordance with preliminary studies of seismicity in Azerbaijan.

In our initial examination of seismic activity in Azerbaijan, we have concluded that earthquakes with a magnitude of approximately 4.5 are the most prevalent in the region. However, establishing a direct correlation between earthquake magnitude and the amplitude of surface vibrations proves elusive. The amplitudes of seismic motions at the surface are influenced by various factors such as the distance from the earthquake source to the site, the orientation and direction of fault rupture, site-specific conditions, and more.

Recognizing the multifaceted nature of these influences, we have adopted a comprehensive approach by considering a broad spectrum of potential maximum amplitudes of seismic vibrations on bedrock. This inclusive strategy aims to account for the diverse array of factors that can impact seismic activity and ensures a thorough assessment of the associated risks. We applied the one-dimensional equivalent linear method to assess the effect of the upper 30 meters of soil conditions at the Mingachevir and Shamkir hydroelectric power stations on changes in the amplitude-frequency composition of seismic vibrations during an earthquake.

Site response analyses utilizing the equivalent-linear approach incorporates nonlinearity in soil behavior by employing curves for modulus reduction and damping that are dependent on strain. The calculations for the equivalent-linear approach were conducted using the ProShake program [20].

The part of the map presented in figure 4 illustrates the V_s^{30} distribution, i.e., the distribution of average shear wave velocity for the upper 30 meters of soil in the specified area. This data is extracted from the USGS resource [21] and visualized with the help of tools offered by [22]. In addition, the data serves as crucial input for modeling seismic site response analysis. Signifying its paramount importance, this parameter stands as the key input for evaluating the seismic response.

From the analysis of V_s^{30} values it follows that the regions neighboring Mingachevir HPS exhibit lower velocities compared to those in proximity to Shamkir HPS. This observation suggests that, from a seismic standpoint, the soil conditions at Mingachevir HPS are less favorable than those at Shamkir HPS. The presence of a low-velocity upper 30-meter soil layer at Mingachevir HPS implies a higher susceptibility to nonlinear effects and potential stability issues during seismic events.

5. Results and Discussion

Figures 5(a)-(d) illustrate the computed variations in bedrock motion peak ground accelerations at the Mingachevir and Shamkir HPSs' surfaces. These variations are associated with soil effects within the upper 30 meters, considering maximum amplitudes of 0.05g, 0.1g, 0.19g, and 0.33g.

Figures 5(a)-(d) highlight a noticeable rise in PGA at the surface compared to the initial

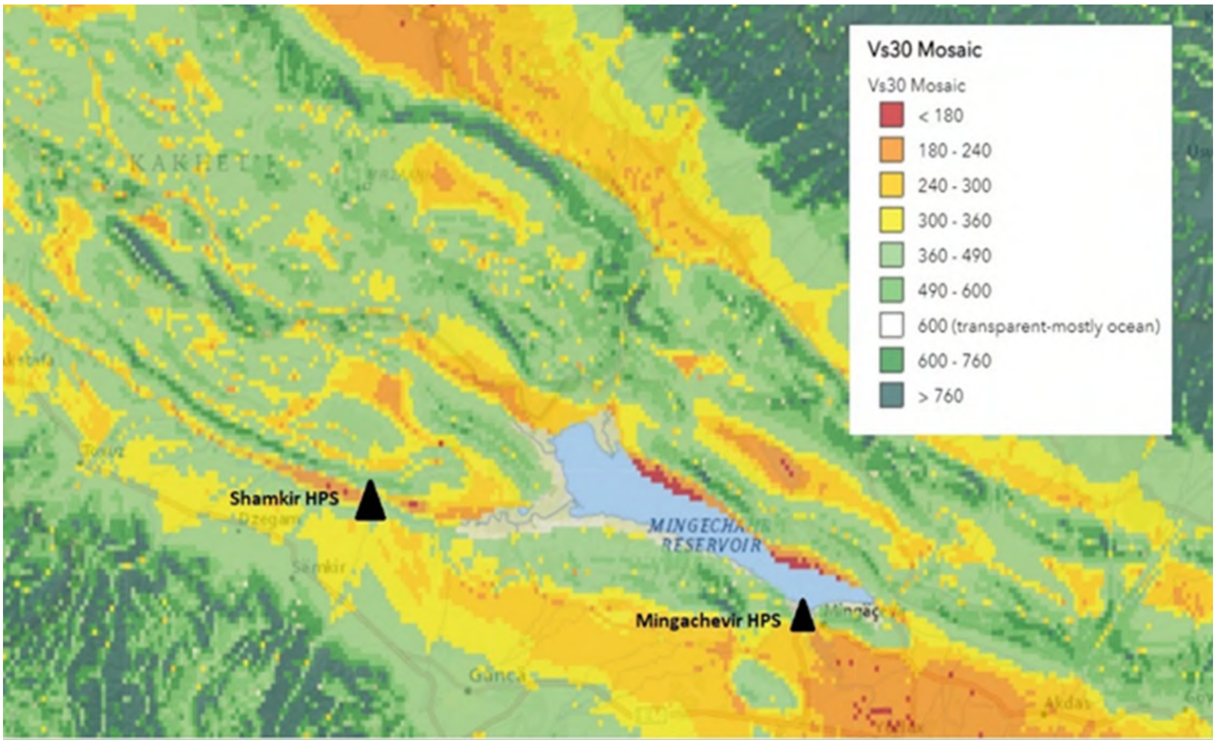

Figure 4. The V_s^{30} map of Shamkir and Mingachevir HPSs and adjacent areas.

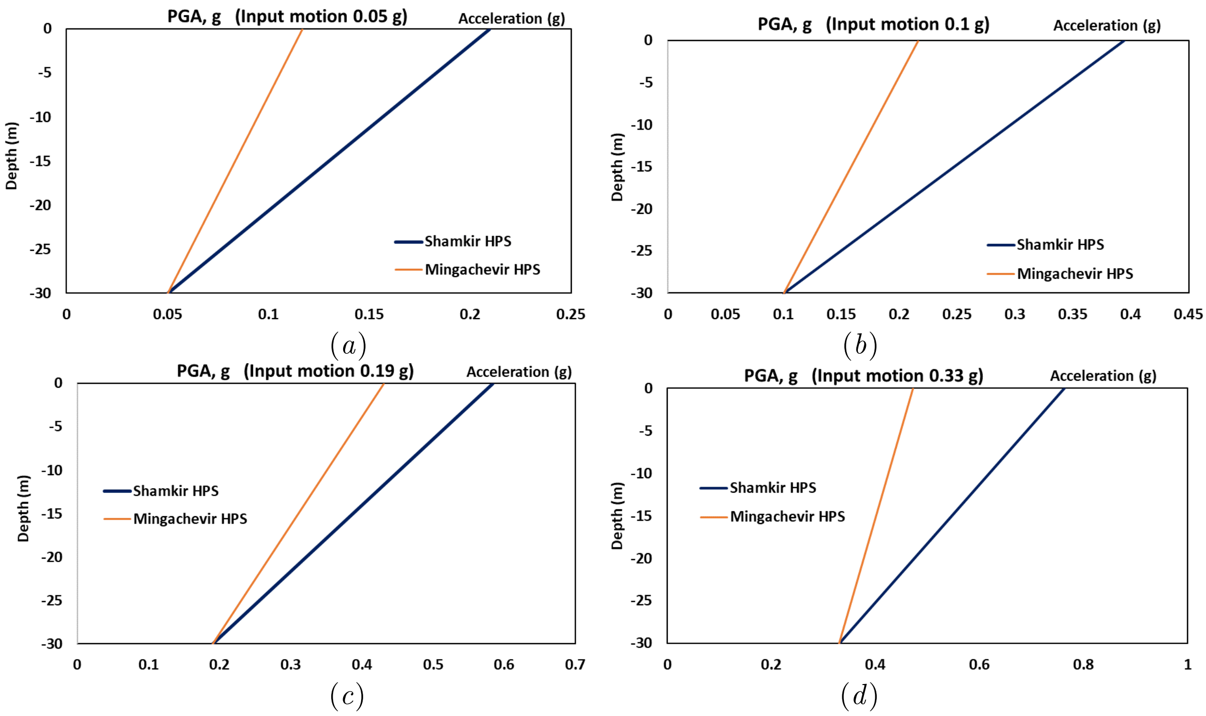

Figure 5. Variation in PGA from the bedrock to the surface along the top 30 m of soil for different input motion amplitudes: 0.05g (a); 0.1g (b); 0.19g (c); 0.33g (d).

PGA from the bedrock motion. More deep examination of these dependencies allows us to conclude that in all cases the PGA of seismic vibrations increases within the upper 30 meters of the soil. Notably, the Shamkir HPS site exhibits a more pronounced surge in PGA compared to the Mingachevir HPS site when a seismic wave passes through the upper 30-meter soil layer. This observed effect is presumably linked to a greater increase in the seismic energy absorption coefficient within the lower-velocity soil layer at the Mingachevir HPS site, as opposed to the case of the Shamkir HPS site.

Figure 6 displays the calculated transfer functions for the upper 30 meters of soil at the Mingachevir and Shamkir HPSs. The transfer function, a crucial parameter in soil response analysis, essentially dictates how each frequency in the bedrock motion (input) is either amplified or attenuated by the soil sediments [1]. Conceptually, a transfer function can be likened to a filter, influencing an input signal to generate a corresponding output signal.

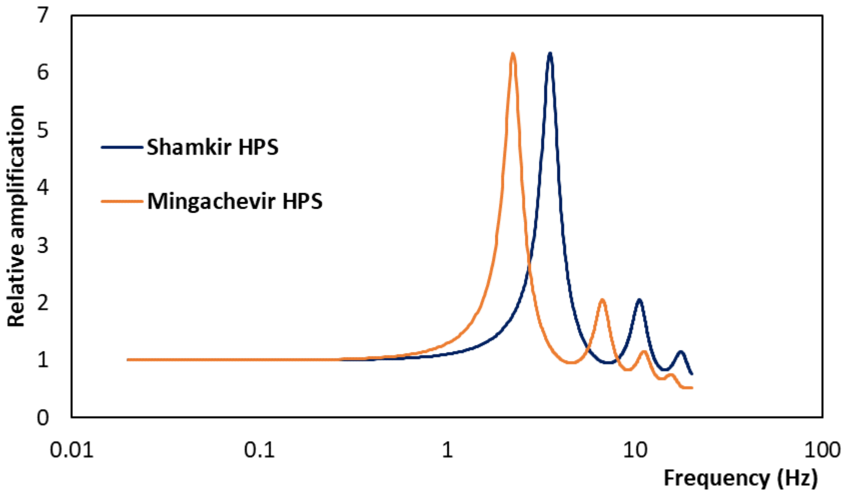

Figure 6. The transfer functions for 30 m deep soil profiles at the Mingachevir and Shamkir HPSs.

As illustrated in figure 6, both sites prominently exhibit amplified seismic motion owing to their near-surface geology. While the transfer functions generally align, distinctive peaks emerge at varying frequencies, signifying the potential for resonant amplification of seismic motions, nearly reaching a factor of 7. However, upon closer inspection, a nuanced analysis unveils unique resonant amplifications occurring in different frequency ranges, emphasizing the diverse seismic characteristics inherent to each location.

Examining the Mingachevir HPS site, the soil predominantly amplifies seismic motions at lower frequencies, manifesting resonant amplifications within the frequency range of 1.8-2.68 Hz. A particularly noteworthy peak occurs at 2.28 Hz. In contrast, the soils at the Shamkir HPS site exhibit a tendency to amplify seismic motions at higher frequencies, displaying resonant amplification within the frequency range of 2.84-4.22 Hz. The pinnacle of resonant amplification at this site is observed at 3.56 Hz.

Thus, the study's findings underscore a divergence in the seismic behavior of surface soils between the Mingachevir HPS and Shamkir HPS areas. Specifically, at the Mingachevir HPS site, worst-case scenarios are projected to be associated with low-frequency seismic motions. Conversely, in the Shamkir HPS section, a predisposition for more adverse scenarios linked to higher-frequency seismic motions is anticipated compared to the Mingachevir HPS site. This distinction emphasizes the imperative need to tailor seismic risk mitigation strategies based on the unique characteristics of each site.

6. Conclusions

The conducted studies highlight the crucial influence of upper near-surface soils on the dynamics of seismic motions during their propagation from bedrock to the free surface. The results indicate that soils with lower shear wave velocities, due to greater seismic energy absorption, exhibit lower PGA at the surface. However, it is imperative to acknowledge that softer soils are susceptible to nonlinear effects, and despite the observed decrease in PGA values, this does not imply seismic stability of the soil. On the contrary, with an increase in the absorbing properties of the soil, the probability of nonlinear deformation of the soil increases, which, in turn, depends on the amplitude of seismic loading. Thus, the nonlinearity of the soil, during seismic impact on the site, mainly leads to a decrease in the resonant frequency of the site and a decrease in the amplification at high frequencies (for instance, PGA) but an increase in the amplification of vibrations at low frequencies.

The soils of the Mingachevir HPS, initially characterized by lower values of V_s^{30} compared to the soils of the Shamkir HPS, exhibit resonant maxima at lower frequencies as a result of a comparative analysis of transfer functions. It is important to note that as soil softness increases, high frequencies are damped while low frequencies are enhanced. Given that most above-ground buildings have a resonant frequency in the range of 2-10 Hz, soils with a tendency to amplify lower frequencies (10 Hz or less) may have a more significant impact and cause serious vibration damage.

In summary, to enhance our understanding of the seismic impact and to develop effective seismic safety measures, it is advisable to consider not only the overall amplitudes of vibrations but also the specific characteristics of the soil, which selectively amplifies seismic vibrations at certain frequencies. Furthermore, a crucial aspect involves individually studying the resonant frequencies of the soil-structure system to mitigate resonant effects during an earthquake. We also believe that this approach will allow one to develop more accurate and tailored building standards aimed at protecting infrastructure and ensuring safety in seismic zones.

Abstract. The flood protection problem has always existed for the Ukrainian Carpathians. The floods that caused damage to urban areas occurred 10 times during the past 20 years in the basin of the Uzh River, ones were the cold period floods in most cases. The Uzh River passes through the central part of the Uzhhorod city, the river is crossed by five bridges, the embankment consists of "grey" flood protection structures: dams, concrete and stone walls. The central embankment was flooded by extreme floods only. At the same time auxiliary buildings and greenhouse in the Botanic Garden and the Bozdos Park area are flooded almost every two-three years. The purpose of the work is to update hydrological calculations, to calculate the flood water surface curve and assessment of the "green" flood mitigation measures in the central part of the city. Flood flow rate of 1% probability was calculated by processing continuous observations data for 72 years. Flood water levels of 1% probability were calculated using a 1D HEC-RAS model. Retention reservoirs, old river bed, mobile flood protection systems for local areas and buildings were considered as "green" flood control measures. Relocating embankments to make "room" for river within the existing buildings is not possible, but some stream widening has been preserved within the Botanic Garden by local flood protection of the single buildings and the central part of the garden. Calculation showed that the central part of the city is protected from flooding by the existing dykes, except for a few areas that would be protected by local mobile barriers. It is not possible to create an exclusively "green" flood control measures in the urban area, but the further development of flood risks management must be directed to the concept of a sustainable city development with minimization of the negative environment impact.

1. Introduction

The problem of hazard floods has always existed for the Ukrainian Carpathians. The frequency and flow rate of floods has been increasing over the past 20 years. The both natural phenomena associated with climate change [1] and the population economic activity, which mercilessly exploited nature and the water environment in the last century, became the reason for the flood risks increasing. Mountain areas are particularly sensitive to climate change, as research shows, these areas will be subject to extreme floods in the future and the amount of flood flow rate tends to increase [2]. Therefore, the problem of protecting settlements from extreme floods remains relevant and is an integral part of the concept of a sustainable city.

The history of flood control management includes different periods and corresponding approaches to flood protection. In the past, the population that settled along the river banks tried to choose elevated area. Population growth led to the building on the floodplains, people settled closer to the water and periodically suffered from flooding. In the article [3] is indicated the development of urban infrastructure, solid waterproof coverings, storm sewers lead to the temperature and flood flow rate increasing on the urban territory. Flood protection traditional method is dyke and walls construction that narrow the floodplain and channelize the river bed. Canalization of the river leads to the water speed increasing, erosion and increasing the flood flow downstream [4].

Sustainable Development Goals (SDGs) require other approaches to protect against extreme floods, which have received the term "green" measures in the literature. The modern approach requires the floodplain restoration and usage of its retention capacity [5], an expansion of the room for overflowing the flood flow, which leads to a lag time in reaching the river bed due to the natural cover, and peak flow reduction. Restoration of the floodplain in some catchments allows to significantly reduce the peak flow [6]. At the same time, the territories in the countryside are occupied by agriculture and it is not always possible to create conditions for the free flood flowing along the floodplain. Increasing the roughness of the river bed contributes to a lag time when the flood flow is running downstream. Calculations in the work [7] showed that vegetation cover with and creating berms on the river banks allows to reduce the water speed and erosion of the banks and decrease the flood flow downstream.

In the conditions of the existing infrastructure, agricultural fields and housing, it is not always possible to allow the river bed to freely meander and overflow. In work [8], instead of strengthening the banks of the main channel, it was proposed to use the old channels of the Czarny Dunajec River, Polish Carpathians. Environment-friendly measures allowed enhanced ecological functions of the multithread channel and the natural variability.

The most significant flood flow reduction is possible due to the retention capacity of the floodplain. In work [9], analysis of flood mitigation measures using dry and wet retention reservoirs on the Glinscica River catchment (Slovenia) were carried out. Calculations using HEC-RAS showed that retention reservoirs can provide a significant decrease in peak flow, but the decrease in water levels during a flood is local and reservoir effects quickly reduce with scale. The cost of building retention reservoirs is quite high and may exceed the potential benefits. It is obvious that the implementation of flood reservoirs requires their multifunctional use. At the same time, Bezak et al. [9] notes that afforestation as a sole flood protection measure is not effective for larger flood flow.

In a mountainous area, the formation of floods is fast and the peak flow are significant, so the use of retention reservoir is an effective method, if there are the natural depressions of sufficient volume to located near the protected settlement. But there are not always favourable conditions for the construction of such reservoir. Pudar et al. [10, 11] analysed the improvement of the existing "grey" infrastructure (dykes) with the possibility of introducing "green" measures (retention reservoirs) on the upper watershed of the river Tamnava and its tributaries Gracica and Ub, in central Serbia in rural and urban areas and offered a holistic, integrative approach that includes both types of infrastructure.

Green measures for sustainable development of cities are developed in the direction of increasing the time of rainwater runoff into the river and the spread of green zones due to the creation of roofs with vegetation, vertical vegetation (green facades), vegetation elements in the area, trees and tree lines, artificial wetlands, permeable and semi-permeable grassed land cover [12]. Bezak et al. [9] assessed the possibility of using Permeable Concrete as a road cover, which transfers surface rainwater runoff into the underground, due to which the lag time increases. The article also notes that, unfortunately, the implementation of such an initiative is quite expensive and can be used in new construction, and it is also noted that the use of retention reservoir is much more efficient. Hamin and Usman [13] studying the green infrastructure noted that increasing the area of parks and green spaces, arranging 30 m and 100 m free bank area reduces the flood flow, but not significantly, up to 2.5 %. Also, works [14, 15] note the positive effect of the introduction of “green” infrastructure as rainwater harvesting and the increase of green areas in the city, but these measures cannot solve the problem of protection against extreme floods, because the flood flow of the river basin significantly exceeds the local flow of rainwater.

Mobile flood control systems do not belong to “green” measures and “green” infrastructure, they manage water, but do not contribute to the restoration of natural ecosystems. On the other hand, these systems are installed temporarily during extreme floods, so they do not have a negative impact on the ecosystem in other periods [16–18]. Mobile flood control systems can be classified as flood measures that helps to achieve sustainable development goals.

The aim of the work is to update hydrological calculations, to assess flood risks on the urban territory and to develop an environmentally friendly “green” flood mitigation measure.

2. Materials and methods

2.1. Study area

The Uzh River is a left tributary of the Laborets River (Slovakia) and belongs to the Danube basin. The length of the river is 128 km, the catchment area is 2750 km^2 (within Ukraine, respectively, 107 km and 2010 km^2), the total level drop is 775 m, the average slope is 0.0072.

Floods in the river basin are observed both in the summer and in the cold period, the height of the water rise is 1.5-2.0 m and 2.5-3.0 m in years of high water with the intensity of the water rise of 2.2-3.0 m/day. The rain floods of warm period are observed with maximum flows significantly lower than cold period floods. In total, the Uzh River basin is monitored at 7 gauging stations with duration of up to 20 years and 5 gauging stations with observation period of more than 50 years (figure 1). The cold floods are of mixed origin, i.e. formed as a result of intense snowmelt and torrential rainfall. Extreme floods were observed in 1926, 1955, 1957, 1968, 1992, 1998, 2001, 2005, 2008, 2010, 2015, 2016, 2017, 2019, 2023. The highest flood occurred on December 14, 1957, the flow reached 1680 m^3/s, the extreme flood of the last 20 years occurred on November 17, 1992 with a flow rate of 1280 m^3/s.

Study area is central part of the Uzhhorod city between gauging station and bridge along Babyak street (figure 1). The riverbed has a trapezoidal shape with a berm in the form of a footpath and is covered with grass, near the bridges the banks are strengthen by stone walls. The Uzh River floodplain is limited on both sides by dykes (figure 1), designed for flood of 1% probability, except the dyke along Bozdos Park, which is built at the level of 10% flood flow and has several damages. There are five bridges across the river. During floods, the territory of Bozdos Park is flooded almost every two-three years: November 2016, December 2017, December 2020, January 2023.

2.2. Study methods

In this research, the analysis procedures involve following steps: hydrological analysis, hydraulic analysis and environmentally friendly “green” flood control measure.

To determine the main characteristics of the flood runoff of the Uzh River, the materials of long-term observations of the city of Uzhhorod gauging station (the beginning of observations is 1947) were used. The catchment area calculated by QGIS and SAGA GIS is 1976 km^2. The estimation of the statistical parameters of the analytical flow duration curve was performed by the grapho-analytical method [19], the following equation were used:

$$S = \frac{Q_5 + Q_{95} - 2Q_{50}}{Q_5 - Q_{95}}, \tag{1}$$

$$\sigma = \frac{Q_5 - Q_{95}}{\Phi_5 - \Phi_{95}}, \tag{2}$$

$$\overline{Q} = Q_{50} - \Phi_{50} \cdot \sigma, \tag{3}$$

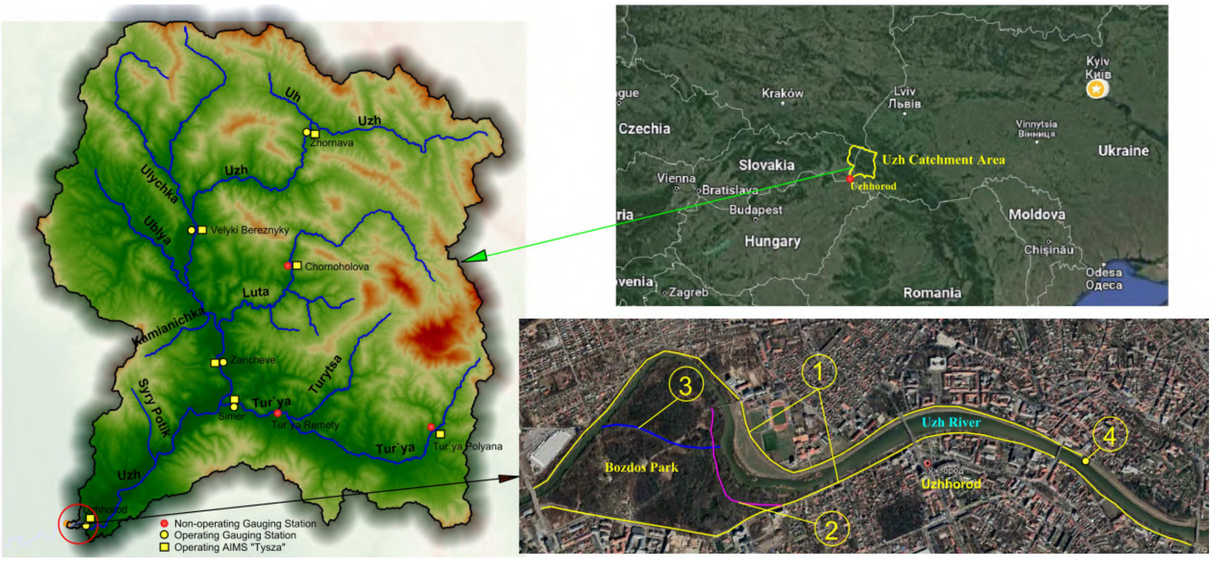

Figure 1. Study area: 1 – dyke 1% probability; 2 – dyke 10% probability; 3 – old river bed; 4 – gauging station Uzhhorod; yellow circle – operating gauging station; red circle – non-operating gauging station; yellow square – operating AIMS "Tysza".

$$C_v = \frac{\sigma}{\overline{Q}}, \tag{4}$$

where S – skew coefficient of the flow duration curve; Q_5, Q_{50}, Q_{95} – flow rate of probability, respectively, 5%, 50%, 95%, m^3/s; Φ_5, Φ_{50}, Φ_{95} – standard deviation from the mean value of the ordinates of the log-normal distribution of the flow duration curve; σ – mean square deviation; $\overline{Q}$ – mean flow rate, m^3/s; C_v – coefficient of variation.

The values of the statistical parameters of the cold flood on the Uzh River on the base of the observation of the Uzhhorod gauging station are given in table 1.

Table 1. Statistical parameters of the cold flood in the site of the Uzhhorod gauging station.

Catchment area, km^2	Flow rate of 1%, m^3/s	Flow rate of 50%, m^3/s	C_v
1976	1844	461	0.55

As the model of the hydrograph of the flood 1% probability was taken the flood hydrograph with mean daily flow of the flood dated on November 16-24, 1992 (figure 2).

The calculation of the flood hydrograph of 1% probability was carried out using transition coefficient [19]:

$$K_Q = \frac{Q_1}{Q_M}, \tag{5}$$

$$K_t = \frac{q_M}{h_M} \cdot \frac{h_1}{q_1}, \tag{6}$$

where Q_M, Q_1 – the peak flow of flood, respectively, of the model hydrograph and the hydrograph of 1% probability, m^3/s; q_M, q_1 – specific flow, respectively, of the model hydrograph and the hydrograph of 1%, $m^3/s{\cdot}km^2$; h_M, h_1 – runoff layers of the model hydrograph and the hydrograph of 1%, mm.

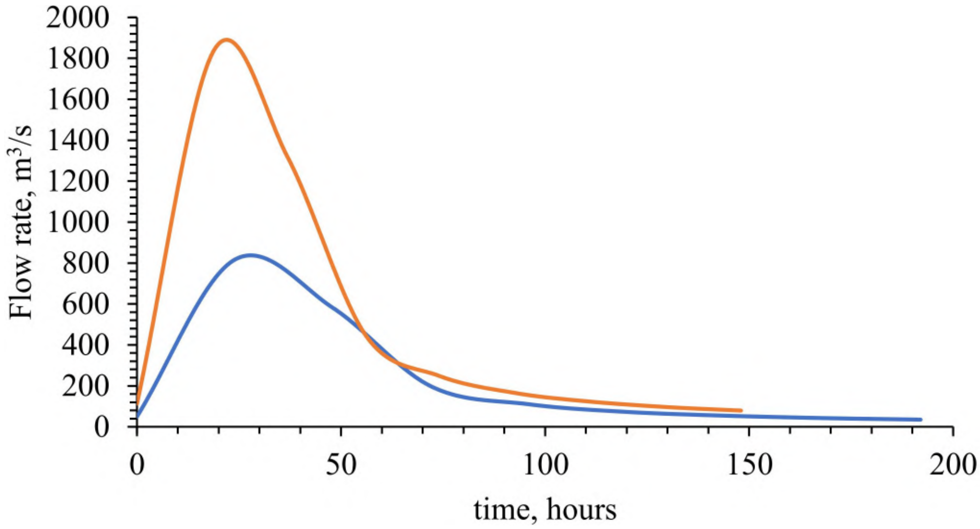

Figure 2. Hydrograph of extreme flood in 1992 and flood 1% probability: blue line – flood hydrograph of 1992; red line – flood hydrograph of 1% probability.

The coordinates of the hydrographs of 1% are calculated according to the equation:

$$Q_i = Q_{i,M} \cdot K_Q, \tag{7}$$

$$t_i = t_{i,M} \cdot K_t, \tag{8}$$

where $Q_{i,M}$, Q_i – peak flow at i-th time, respectively, for the model hydrograph and the hydrograph of 1% probability, m^3/s; $t_{i,M}$, t_i – time, respectively, for the model hydrograph and the hydrograph of 1% probability, hours.

Hydraulic calculations of the flood level of the 1% probability were carried out using HEC-RAS software complex for the 1D flow model. The basis of the calculation is the digital model of the area in the form of cross-sections, which are tied along the length of the river channel (figure 3) and bridges. The cross-sections were made instrumentally, as the cross-sections that can be obtained from free-access satellite images with a resolution of 30 m do not reflect the surface under water and often incorrectly reflect the position of the embankment (figure 4). Since the distance between the sections affects the calculation results [20], the sections are located perpendicular to the channel line at an average distance of 150-200 m.

The surface roughness data for the model were taken according to the analysis of land cover in the channel and banks of the Uzh River (figure 3). The bottom of the Uzh river is uneven, with large stones and pebbles. The channel in the central part of the city is channelized, limited by dikes with grass vegetation. The dyke crests are embankments with pavements, trees and bushes are planted on the edges, there are no parapets. Buildings located near the pedestrian zone.

The 1D flood simulations based on St. Venants continuity equation, which describes the preservation of mass in a given control volume. The upstream boundary condition is 1% flood flow rate, downstream model boundary is a normal depth-type condition with the hydraulic slope calculated from the average slope of the historical flood in 1992.

The calibration of the model and the determination of the calculated values of the Manning's values took place according to the flow curve at the Uzhhorod gauging station and using the historical flood in 1992 with flow rate of 1280 m^3/s.

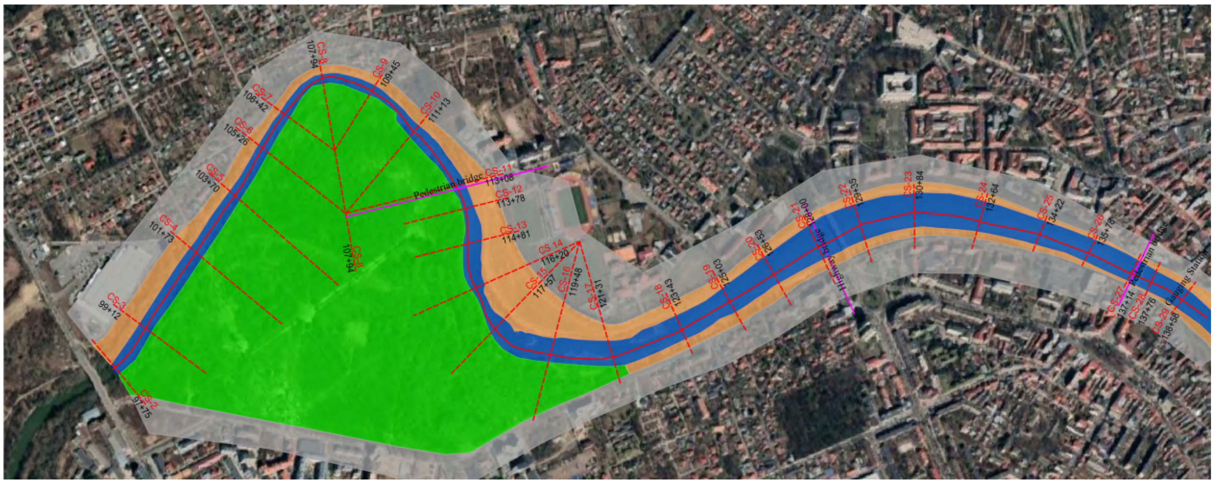

Figure 3. Land cover: blue – water; yellow – flooded vegetation; green – trees; grey – built-up area.

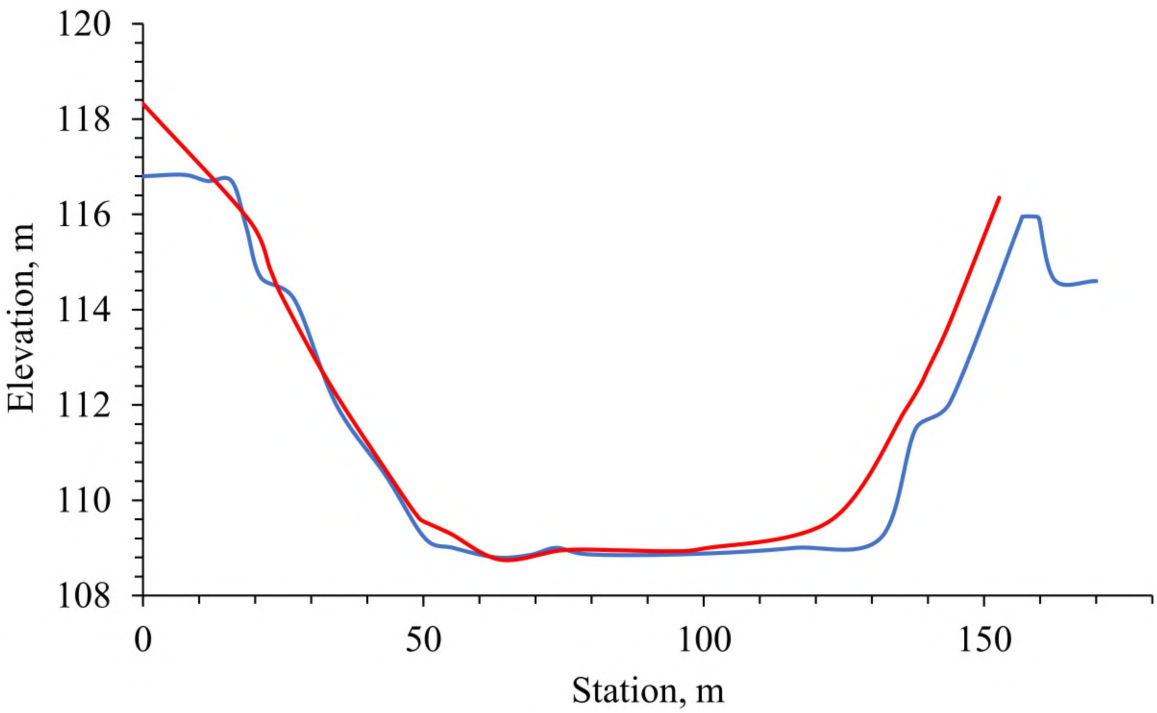

Figure 4. Comparison of cross sections: blue line – topo-geodetic survey; red line – from DEM resolution 30 m.

3. Results and discussion

Flood control measures is carried out for flood flow of 1% probability according to Ukrainian standards for urban areas. Monitoring of water levels and calculation of discharge has been carried out continuously for more than 70 years at the Uzhhorod gauging station. The observations are representative and the flood discharge of 1844 m^3/s was taken for calculation as 1% probability flood flow.

The purpose of calculating using the 1D flow model on the HEC-RAS was to determine the position of the flood surface, to compare the flood level with the embankment elevation and, in case of overflow, propose flood control measures, trying as much as possible not to affect the architectural ensemble of the central part of the city. We used the 1D HEC-RAS modelling because it gives good results in cases of flood propagation along the main river [21] and we didn't have DEM of high resolution to simulate 2D flow accurately. 1D HEC-RAS modelling allows to receive results in the form of a profile with water levels and data in the form of tables for further processing. It is also possible to plot inundation zones, but for data analysis it is more convenient to use a profile for overflow assessment in riverbed limited by dykes.

To assess the reliability of the embankments, we plotted the results of the calculated flood flow of 1% probability, the top of the left and right banks of the river, historical flood in 1992 according to the data of high-water marks on the profile (figure 5). It can be seen from the figure that the flood flow of 1% probability passes free under the bridges, the suspension bridge near the park area has the smallest free room, but it is quite sufficient. The central part of the city from the gauging station to the Babyak's bridge on the right bank of the river are protected by dykes from the overflow of the flood flow. A short site has a slight 15cm decrease and flood risk in front of the Masaryk's bridge from CS-22 to CS-23 on the right bank. The area near CS-17 has a local lowering of the right-bank dyke approximately 70m long, through which an overflow may occur. The left bank of the Uzh River is reliably protected from flooding from the gauging station to the beginning of Bozdos Park CS-16. The left bank with the old dyke is significantly lower on the site below CS-16 to the Babyak's bridge, which is confirmed by periodic flooding of the lower part of the park. The dyke ends above the gauging station on the right bank, so the children's railway and buildings in the Botanic Garden will flood, the privet houses have high concrete retaining wall in this part of the city and will not be flooded.

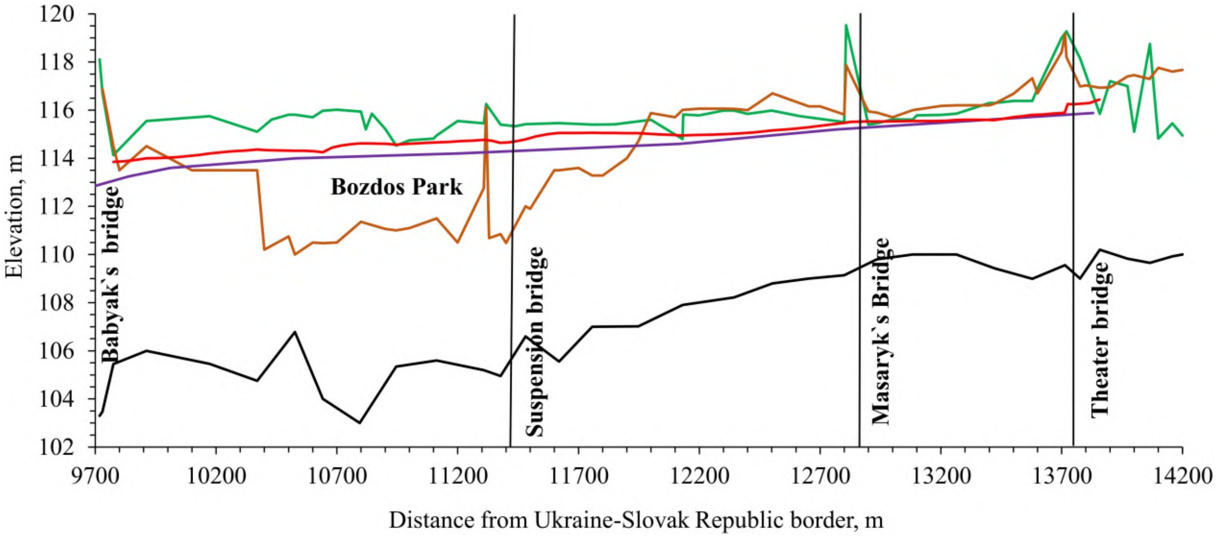

Figure 5. The flood of 1% probability elevation, calculated on the 1D flow model: black line – bottom of the river; green line – right bank; brown line – left bank; violet line – high water marks of the flood in 1992; red line – flood of 1% probability.

The calculation of the extreme flood levels shows that some parts of the central embankment are not sufficiently protected. There are dykes in the city, which generally fulfil their function. Therefore, the flood protection will have combined measures, which include both the "grey" existing system and additional "green" measures that will strengthen the reliability flood control measures. Environmentally friendly measures, as shown by the analysis in the introduction, include retention reservoirs, floodplain expansion, and the use of old river bed.

According to studies [9–11], an effective method of mitigation flood measures is the accumulation of flood runoff in dry mountain reservoirs and polders. The volume of flood flow of 1% probability on the site of the Uzhhorod gauging station is 294 million m^3, the accumulation of even a tenth of the flow requires a reservoir with a significant volume. According to the Program of Flood Protection of the Tisza River Basin, several possible locations for the retention reservoirs construction were proposed in the Uzh River basin (figure 6): 1 – dry retention reservoir of 10.44 million m^3 on the Ulychka river, 2 – dry retention reservoir of 9.3 million m^3 on the Luta river, 3 – polder with volume of 9.44 million m^3 on the Tur'ya river. The retention reservoirs are located at a considerable distance from the city of Uzhhorod, and as study [9] shows, their impact on long distance down will be very insignificant. There are silted lakes on the territory of Bozdos Park, which, after cleaning, can retain a small volume of water, 170,000 m^3.

It is not possible to carry out measures to expand the floodplain within the city limits. The Uzh River floods the Botanic Garden and the children's railway above the gauging station during extreme flood. The construction of dyke will change the landscape, significantly narrow the floodplain and raise water levels in the central part of the city, which is undesirable. At the same time, it is possible to allow the flood flow to spread within the green zones (Botanic Garden, lower part of Bozdos Park), protecting buildings with local mobile barriers. Mobile flood barriers will allow not to narrow the floodplain in green zones and use their retention capacity. The local lowering on short sites along the embankments will be protected by mobile barriers, the foundation of which is located in the underground part of the embankment, and the upper barrier is installed only during the extreme flood, the required number of people to assemble a 100m barrier is 6-8 people, assembly time 1 hour [16].

The old river bed of the Uzh River is located on the territory of the Bozdos Park (figure 6), which, after clearing and strengthening, can be used to discharge part of the runoff and lower the flood levels in front of the suspension bridge.

Figure 6. Flood mitigation measures: 1, 2 – dry retention reservoirs; 3 – polder; 4 – dyke 1% probability; 5 – dyke 10% probability; 6 – old river bed; 7 – oxbow lake; 8 – mobile barrier; 9 – retaining wall; 10 – mobile protection of single building.

4. Conclusions

1. Calculations of the flood level of 1% probability using the 1D HEC-RAS model showed that the central part of the city is protected from flooding by the existing dykes, except for few areas that can be protected by local mobile barriers.
2. It is not possible to create "green" flood infrastructure in the existing city. But we can try to achieve a holistic approach, trying as much as possible to use environmentally friendly measures approaching the concept of sustainable city.

3. Since the backwater by flap gates is planned near the suspension bridge and Bozdos Park, it is necessary to carry out a more accurate 2D modelling of the combined operation of the river, old river bed and oxbow lake during the extreme flood to assess the impact of the structures on the flood levels.

Abstract. Currently, the issue of finding new ways to process, utilize and reuse burnt-out waste heaps in order to reduce their technogenic impact on the environment becomes relevant. The presence of a porous structure in combination with undissolved properties opens up the possibility of using the burnt-out mine rock to make composite fertilizers to improve the quality of agricultural and technogenically degraded soils. The widespread use of burnt-out mine rock for the manufacture of composite soils requires the study of their physical and chemical properties and deformation characteristics. In laboratory conditions, the physical and mechanical properties of samples of burnt-out rock masses ranging in size from 1.25 to 10 mm with and without the addition of powdered soil under a load of up to 110 kN were studied. For the first time, a certain increase in load resistance was found when soil powder was added in the initial period of compression of the tested material. It was determined that the destruction of particles of burnt-out material occurs in two waves. These results indicate the presence of two strength limits in the burnt-out medium composed of two initial petrotypes.

1. Introduction

The coal industry of Ukraine is one of the most important branches of the mining industry, since it is the main supplier of raw materials for domestic power and metallurgical enterprises, as well as an exporter of extracted products to world markets [1]. Despite the trend towards popularization of alternative energy sources, it is expected that the intensity of coal mining will increase annually due to the demand for energy raw materials in the world [2], which is associated with the energy crisis, rapid industrialization, and population growth [3].

Underground coal mining causes various environmental problems that cause significant damage to the environment and natural biocenoses. These problems include exogenous and endogenous fires [4], methane emissions [5], water pollution by mine wastewater, surface subsidence, destruction of biodiversity [6], and soil degradation [7]. A special part is played by the problem of solid mining waste management, which often contains substances that are harmful and hazardous for the environment [8], and their deposition contributes to dust and toxic gas emissions, as well as toxic solution washing-off.

The practice of coal mining enterprises has shown that one ton of coal produces about 0.4-0.5 tons of waste rock. This figure is an average and may vary depending on the quality and strength of the coal seam. Thus, for coal basins in Ukraine, this figure is in the range of 0.12-0.39 tons, and 0.4-0.5 tons in Poland [9].

Modern mining technologies used in different coal-producing countries are mainly aimed at the fullest possible extraction of coal from the longwall [10] and accumulation of waste rock in the mine working space without recovering it to the surface [11]. This method minimizes the amount of solid waste generated during coal mining and reduces the technogenic impact on the environment. However, just like 20-40 years ago, most coal mines in Ukraine continue to operate according to the old scheme: the bulk of the waste rock is not utilized but is placed near coal mines, forming waste heaps of various configurations. This has led to the accumulation of more than 25 billion tons of solid mining waste in the country's coal mining regions [12], which is stored in more than 1,000 waste heaps [13].

Waste heaps cause significant environmental damage. Being under the constant influence of climatic factors, their surface is subject to wind and water erosion, as a result of which dust, as well as oxidized compounds of sulphur, iron, carbon and other harmful elements, enter water bodies [14] and adjacent agricultural soils, thereby contaminating them [15].

However, the greatest danger of waste heaps is their fire and explosion hazard. This is especially true for old heaps. This is due to the fact that chemical and biological processes in the waste mass, involving pyrite and coal, have been occurring for many years with the release of elevated temperatures and are often accompanied by smouldering, burning [16], and sometimes explosions [17]. Such fires are a source of dust and gaseous substances emitted into the atmosphere, and the high temperatures [18] accompanying the fires pose a threat to the population within the radius of the waste heaps [19]. Therefore, the issue of finding new ways to process, utilize and reuse burnt-out waste heaps in order to reduce their technogenic impact on the environment becomes relevant.

2. Literature review

Waste heaps in the coal basins of Ukraine mostly consist of a coarse mixture of mudstones, siltstones, sandstones, pyritized and other types of rocks with a number of components, such as aluminium, zinc, sulphur, titanium, molybdenum, which is why they can be considered as valuable secondary deposits. The direction of possible reuse of waste heaps is determined by the physical and chemical characteristics of the waste mass. However, during prolonged burning, under the influence of high temperatures ($1000...1200\,^{\circ}C$), changes occur in the structural characteristics of the original rock, which leads to the formation of new material from the waste mass of varying degrees of burning-out: from sintered to slightly burnt, with different strength, water permeability and porosity. These indicators should be taken into account when determining promising areas for further use of burnt-out mine rock.

Burnt-out waste from coal enterprises has great potential for use in the construction sector [20]. Thus, studies have shown the prospects of using burnt-out mass for the manufacture of porcelain stoneware [21], cement mixtures, modified building insulation materials, and materials for backfilling mine workings [22].

It is recommended to use burnt-out mine rock in a concentration of 50% for the manufacture of modified foundations. Due to the use of modified material from burnt-out solid waste, which has stable characteristics, the bearing capacity and strength of foundations constructed on loess soils increases [23]. For buildings constructed in areas that are prone to surface subsidence, such as over mine shafts, it is recommended to use a three-layer slab foundation, in which one layer is made using burnt-out rock. In this case, the use of burnt-out waste rock will not only increase the reliability of buildings but also improve the environmental situation in the coal mining region.

Given the shortage of local natural stone raw materials, the use of burnt-out waste heaps in coal mining regions for the construction of structural layers in the construction of pavement is of particular relevance [24], or for the creation of subgrade in the levelling of sites [25]. This minimizes the costs associated with the extraction and transportation of stone raw materials.

The presence of a porous structure in combination with undissolved properties opens up the possibility of using both burnt-out and common mine rock to make composite fertilizers to improve the quality of agricultural and technogenically degraded soils. To do this, the rock is mixed with an organic component, which can be municipal sewage sludge or water body silt. Studies have shown that the addition of coal industry waste and its mixtures with municipal sewage sludge and rock wool waste improves soil pH and its occlusion properties [26]. Laboratory studies have confirmed that the creation of a nutrient mixture based on 25% burnt-out mine rock, 25% river silt, and 50% degraded loamy black soil treated with red California worms allows for 100% germination of tomatoes, unlike other substrates that did not contain burnt-out rock [27].

However, the widespread use of burnt-out mine rock for the manufacture of composite soils requires the study of their physical and chemical properties and deformation characteristics.

The purpose of this paper is to evaluate the effect of particle size distribution on the physical and mechanical properties of burnt-out waste rock.

3. Research methods

The study of the physical and mechanical properties of experimental samples of burnt-out rock mass was based on DSTU BV.2.1-4-96 "Soils. Methods of laboratory determination of strength and deformation characteristics" [28].

The process of deformation of the mixture of burnt-out waste mass and soil was studied. Samples for the study of rock properties were taken from the non-operational heap of mine No. 5/6 of the Myrnohradvuhillya Production Association (Myrnohrad). The rock was sampled at five points from a depth of up to 10 cm using the "envelope" method. The sampling site had no signs of intense oxidation, burnt zones, etc. The initial waste mass was represented by interspersed layers of siltstones and mudstones (sand shales) with sandstones. In the burnt-out state, their residues were: dark – siltstones, light grey – mudstones and sandstones. The gradual burning-out of rocks occurred slowly over several decades under the influence of atmospheric processes: oxygen, moisture, wind, bacteria, temperature changes, etc. The largest of the selected pieces were crushed mechanically. After crushing the rock, the resulting particles were separated using laboratory sieves into fractions, *mm*: 10...5; 5...3; 3...1.25. Preliminary laboratory studies have shown that the burnt-out mine rock of larger fractions have characteristics which not suitable manufacture of composite soils. Therefore, physical and chemical properties and deformation characteristics was carried out only for fractions 10...5; 5...3; 3...1.25.

Each rock fraction was microscopically examined using a monocular microscope XSP – 128 and a camera Levenhuk M1000 PLUS. The magnification of the images was the same. To compare the geometric dimensions of the inclusions and the parameters of irregularities and pores, a 0.02 *mm* Momoi Hameleon Extreme fishing line was included in the image composition as a geometric reference.

For both petrotypes, namely dark and light, the particle shape, the nature of its edges, the presence of visual porosity, cracks and faults were assessed for each fraction.

To determine the deformation characteristics of the rock in each fraction, 4 samples were prepared: a reference, without additives, and three samples each with the addition of loamy soil typical for the area with mass concentrations of 10, 20, and 30 percent. The soil additives in powder form were thoroughly mixed with the dried rock. The weight m (g) of the samples and their bulk density ρ_{pb} (g/cm^3) were determined by the weight method (table 1). The table shows that the addition of soil powder led to an increase in the density of the mixture compared to the 'pure' (0 percent additive) rock by 0.03...0.15 (g/cm^3). However, the difference in this indicator, when adding 10...30 percent (wt.) of soil, was within the measurement error.

Table 1. Data of laboratory studies for determining the bulk density and weight of the studied samples of burnt-out mine rock.

Percentage of soil in the mixture, %	Fraction size, *mm*					
	5...10		3...5		1.25...3	
	$m,\ g$	$\rho_{pb}, g/cm^3$	$m,\ g$	$\rho_{pb}, g/cm^3$	$m,\ g$	$\rho_{pb}, g/cm^3$
0	290	1.08	281	1.04	301	1.12
10	300	1.11	320	1.19	326	1.21
20	300	1.11	320	1.19	326	1.21
30	300	1.11	320	1.19	320	1.19

The prepared samples were placed in a steel cylinder (figure 1) with a diameter of *d=7.5 cm* and a height of *h=6.1 cm*. The steel cylinder with samples of burnt-out mine rock was covered with a massive metal plunger and placed between parallel press plates and subjected to loading.

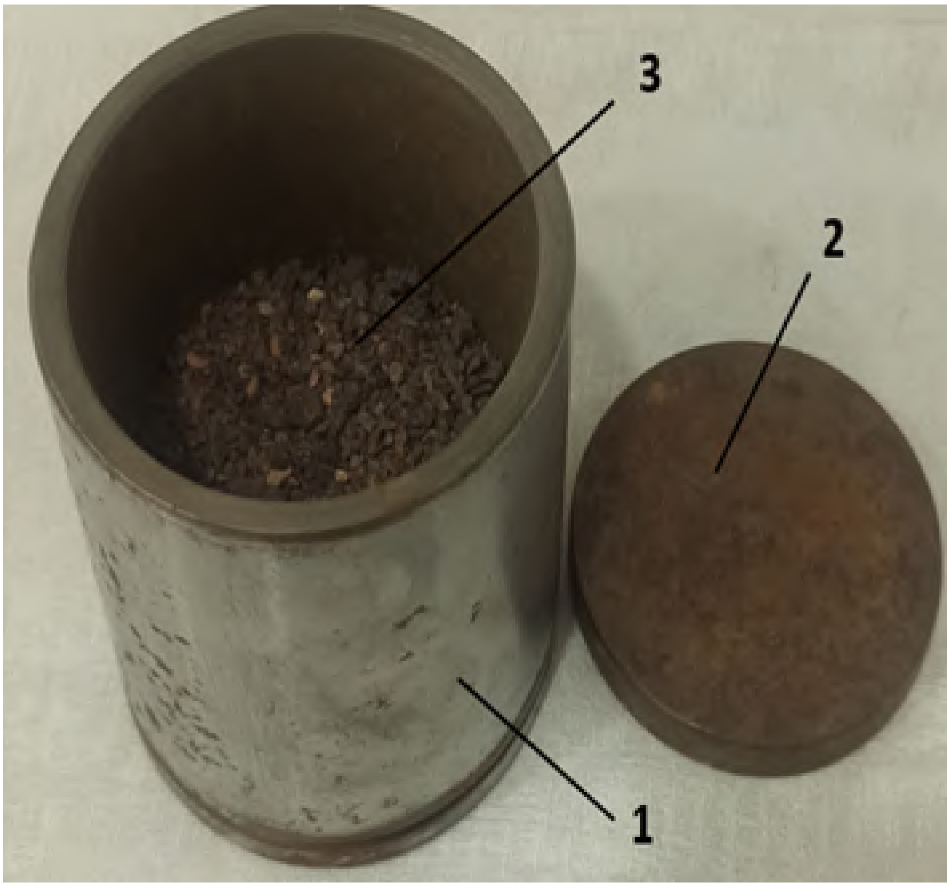

Figure 1. Device for experimental determination of deformation characteristics of burnt-out mine rock: 1 – steel cylinder, 2 – plunger, 3 – experiment sample.

The deformation characteristics were determined using a press P-50 (figure 2, *a*). The loading speed was automatically adjusted to 0.21 *m/s*, and the loading force of the samples was increased

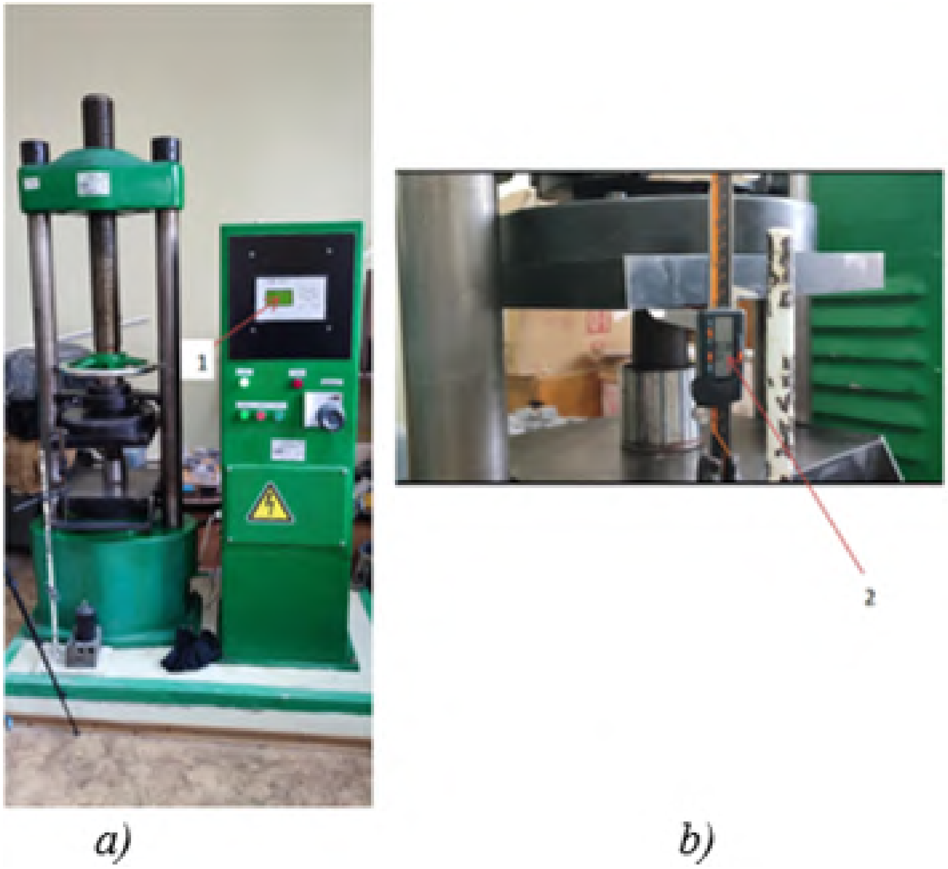

Figure 2. Laboratory setup for measuring the deformation properties of soils: *a)* – general view of the P-50 hydraulic press, 1 – indication of the compression force, F, N; *b)* – strain measurement unit, 2 – indication of plate convergence Δh, m.

from 0 to 110 kN. At the same time, the convergence of the press plates was recorded (figure 2, b), which corresponded to the deformation of the sample. The experiment was timed using a laboratory stopwatch.

The task of the observations was to record the dynamics of changes in the height of the sample Δh, m, which corresponded to the action of a certain value of the compressive force F, kN.

The test results were processed using the following formulas. Relative vertical deformation of the sample ε:

$$\varepsilon = \frac{\triangle h}{h} \tag{1}$$

where Δh is the value of the vertical absolute deformation of the sample under load, m; h is the initial height of the sample, m.

Energy E, J, which was spent on compressing the sample to a value of Δh:

$$E = F \cdot \Delta h, J, \tag{2}$$

where F is the sample compression force, N.

Pressure in the rock sample P, Pa:

$$P = \frac{F}{S}, Pa, \tag{3}$$

where S is the cross-sectional area of the cylinder, m^2.

Power W, W, of compression of the sample:

$$W = \frac{E}{t}, W, \tag{4}$$

where t is the duration of the loading process, s.

4. Research results

The results of microscopic examination of particles of different fractions are shown in figure 3 and table 2.

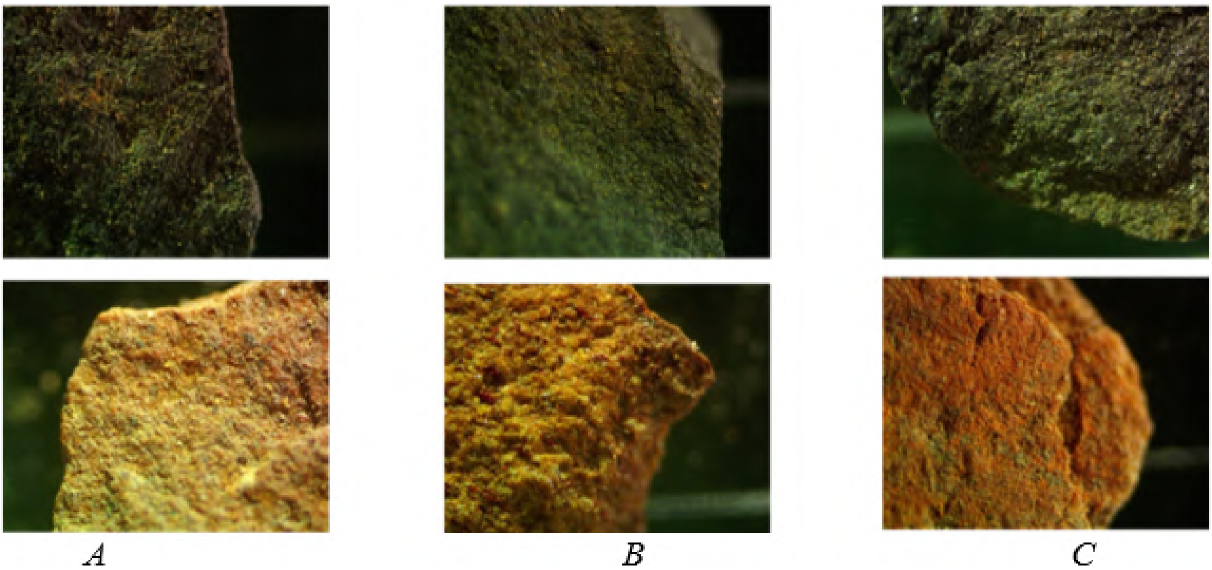

Figure 3. Microscopic images of rock samples, dark: mudstones, light: siltstones and sandstones: A, B, C – respectively, fractions (mm), 10...5, 5...3, 3...1.25.

The particles of the 10...5 mm fraction (figure 3, A) of the rock have a pronounced flat shape with a diverse geometric structure. The edges of the particles are rounded with uneven protrusions. The surface is porous with a small number of depressions, there is a significant number of inclusions of yellow colour, a smaller amount of orange and black; no cracks are observed. The relatively uniform nature of the surfaces indicates a low probability of air bubbles accumulation on them, and air retention is possible mainly in the space between rock particles.

The rock particles of the 5...3 mm fraction (figure 3, B) have both flat and three-dimensional shapes, resembling pyramids and parallelepipeds. The edges of the particles have the shape of sharp angles, and the protrusions of inclusions are pronounced. The porosity of the rock surface is increased, there is a large number of mineral inclusions of yellow, orange and white colour; no cracks are observed. The light-coloured particles are characterized by a pore-like texture, which may contribute to the retention of air bubbles covered with suspension.

The particles of the 3...1.5 mm fraction (figure 3, C) have three-dimensional shapes, the vast majority resembling grains and pyramids. The edges of the particles are rounded with faults, and inclusion protrusions are pronounced. The porosity of the rock surface is increased. A large number of inclusions: yellow, orange, white, black and transparent. Cracks and faults are observed on both dark and light-coloured particles, which can serve as air collectors.

Table 2. Characteristics of the fractions of the studied samples of burnt-out mudstones and siltstones.

Particle characteristics	Fraction, *mm*					
	10...5		5...3		3...1.5	
Initial rock	mudstone	siltstone	mudstone	siltstone	mudstone	siltstone
Shape	flat		flat and three-dimensional		three-dimensional	
Shape edge	rounded	sharp corners	pronounced sharp corners		rounded	
Porosity	porous	porous	increased porosity		increased porosity	
Cracks	–	–	–	–	+	+
Faults	+	–	–	+	+	+
Inclusions of a certain colour*, %						
Yellow	22	38	18	42	28	34
Orange	2	5	–	16	5	8
White	–	–	6	8	4	9
Black	–	11	–	–	–	8
Transparent	11	–	10	–	9	18

* Inclusions are calculated in % of the total area of the studied rock surface of a certain fraction.

From the results presented in table 2, it follows that particles with a size of 10 to 3 *mm* are characterized by a flat (scaly) shape, they are porous, there are no cracks, and there are stepwise faults.

Smaller particles are characterized by a rounded shape, greater porosity, and a higher frequency of cracks and faults. Unlike others, the 5...3 *mm* fraction is characterized by sharp edges, which may affect the nature of the deformation process. In the larger fraction, the presence of sharp protrusions is less pronounced.

According to the results of force tests, it was found that there is a parabolic relationship between the energy expended on the compression of the rock sample and its deformation (figure 4). It is valid for all types of the tested samples. At the beginning of loading, deformation occurs at a high rate. Thus, 50 J was sufficient to achieve a vertical deformation of Δh= (0.014...0.018) m. However, at a level of more than 50 J, a sharp increase in the energy required to reduce the height of the sample is observed. At a load in the range from 50 to 250 J, the level of additional deformation was only about Δh=0.01 m.

The addition of soil to the fraction of 1.25...3 *mm* in the amount of 10% did not significantly affect the deformation pattern of the sample (figure 4, A), which did not differ from the deformation of pure rock. An increase in the soil additive to 20...30% led to an increase in the value of Δh by about 0.005 m at the initial stage, with a load of up to 50 J. With further loading, the deformation dynamics was the same for all samples.

All samples of the 3...5 *mm* fraction were compressed in a single movement (figure 4, B) as a whole. A similar pattern is also characteristic of samples of 0, 10, 20% of the 5...10 *mm* fraction (figure 4, C). At the initial period of loading (up to 50 J), a close to Δh=0.002 m increase in deformation is inherent in the sample with the addition of 30% soil.

For almost all tested samples, the final deformation was about Δh=0.02...0.025 m at a loading energy of 250 J. The exceptions were samples of 0 and 10% of the 1.25...3 *mm* fraction, where this indicator was Δh=0.016...0.018 m (figure 4, A).

It should be noted that the 'power-deformation' diagrams reflect the reaction of the samples to the force impact of the loading setup. Of interest are the dependencies between the load and the power spent at this pressure in the test material. Such dependencies show the dynamics of deformation of the dispersed medium under uniaxial vertical loading with a horizontal

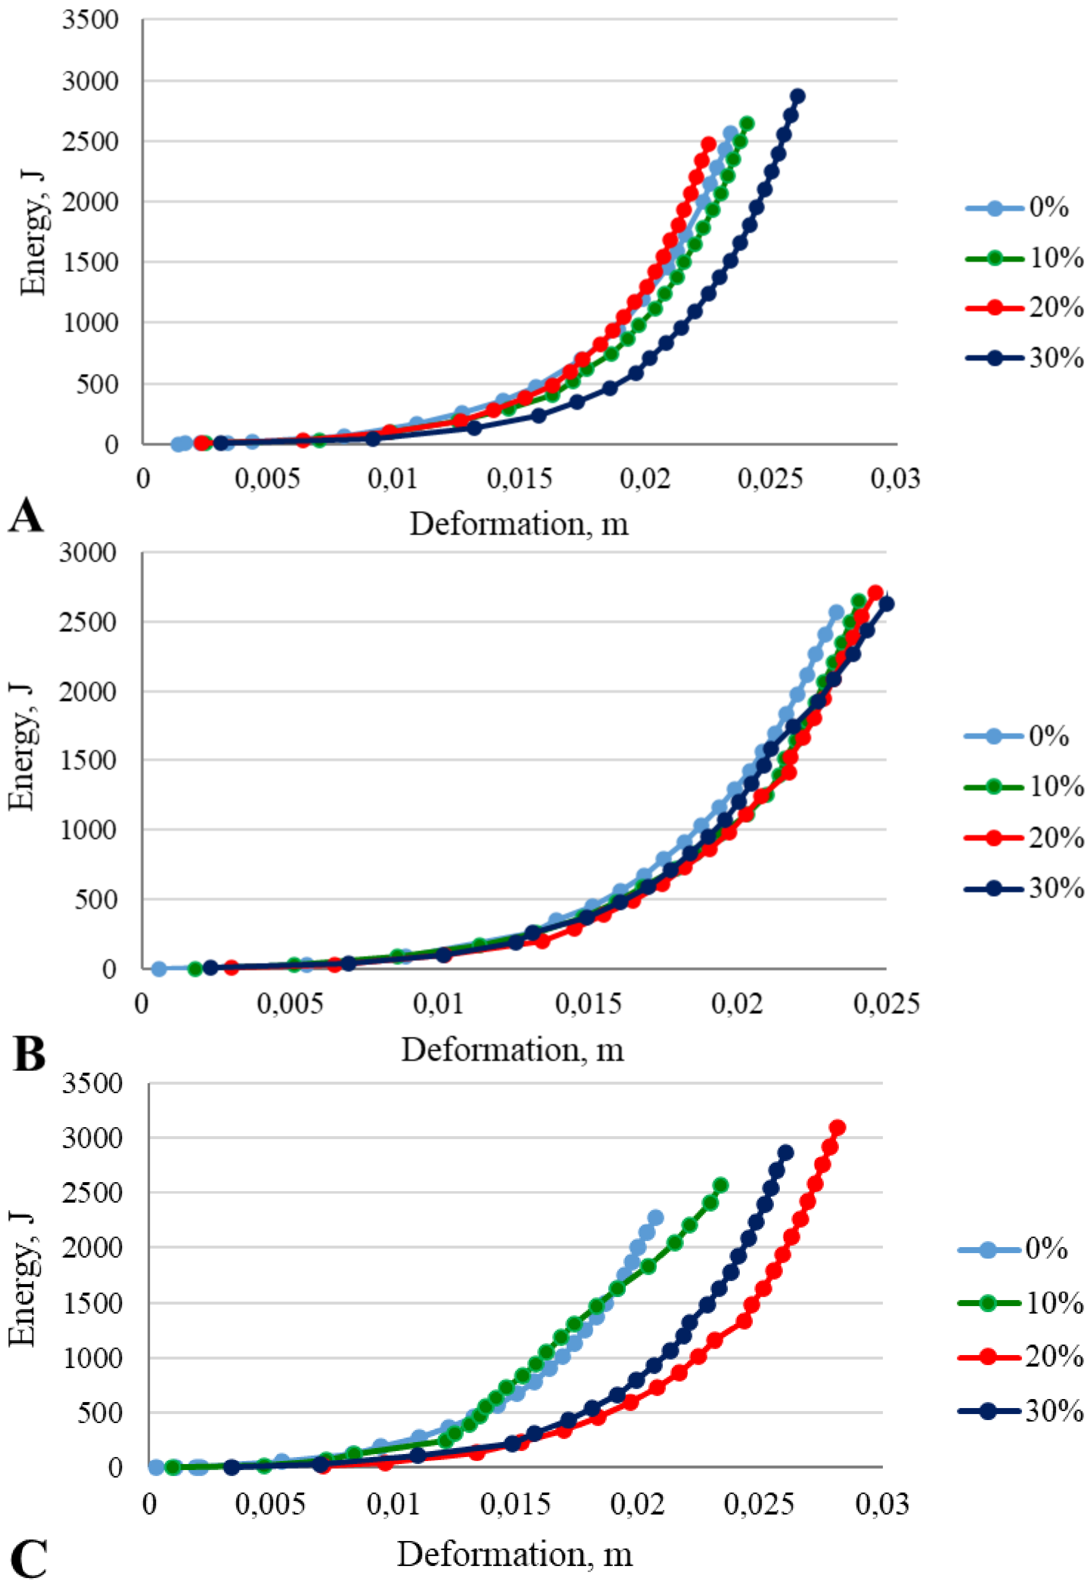

Figure 4. Energy (J) spent on deformation (Δh, m) of the samples: A, B, C – respectively, fractions (mm), 1.25-3; 3-5; 5-10.

displacement limit. The results of the study in the form of 'power-pressure' diagrams are shown in figure 5. The results obtained are visually strikingly different from those shown above. There are no smooth lines, and their synchronous location. The graphs illustrating the dependence of the power required to compress the sample are characterized by a broken form, and in many cases, there are extremes. It is known that line bends, and especially the presence of extreme points, indicate a qualitative change in the nature of the process under study.

It can be assumed that the change in the deformation mode of the sample is caused by the accumulation of potential energy in the rock particles and the mutual sliding of the particles of the discrete medium, as well as the transition of the potential energy accumulated in the particles to kinetic energy by breaking the particles and subsequent movement. Particle breaking can occur by separating sharp edges, separating rounded particles, etc. Due to the chaotic arrangement of particles in the steel cylinder (figure 1), individual elements of the process of rock particle movement and breaking are not clearly reflected in the graphs, but when a common phenomenon characteristic of the sample scale occurs, it manifests itself in the form of bends or extremes.

The analysis of the results of loading rock samples without the addition of soil powder is indicative. The power increase in the largest (5...10 mm) fraction (figure 5, A, item 1) was observed linearly with an approximately uniform rate up to the level of 7 W and a pressure of about 3800 kPa, after which the power increase rate decreased until the end of the experiment (W=9 W, P=5800 kPa). It can be assumed that at the initial stage, the energy of rock particles was accumulated, accompanied by simultaneous particle breaking and the appearance of small particles. Subsequently, after reaching a high pressure level comparable to the tensile strength of the material, the process of breaking with particle movement has intensified, but the required power increase has decreased.

It should be noted that the absence of powder provided a high level of contact stresses between the particles, which contributed to their intensive breaking. This is indirectly confirmed by the test graphs of samples of 5...10 mm fraction with the addition of powder; all lines (figure 5, A, items 2, 3, 4) are above the line of pure rock. In the samples with the addition of soil, due to the increase in the contact areas of energy accumulation, an intensive increase in power occurred at the initial stage without significant crushing and sliding of particles.

When loading the samples of clean rock of 3...5 mm fraction (figure 5, B, item 1), an intensive power increase occurred to a level of about 7 W and a pressure of up to 1800 kPa, after which there was a slight decrease to 6 W at 2000 kPa. It should be noted that the number and area of contacts between the particles in this fraction is much smaller than in the previous one, so the difference between the pure rock and the one with additives is not so significant. This indicates that up to a certain level of load, the particle crushing was of a small scale, and after reaching a certain limit, breaking and sliding occurred. The power level of such a limit was 6...8 W, i.e., close to that when loading a larger fraction at 1500...2000 kPa (figure 5, B, items 1, 3).

The deformation pattern of the sample of the 1.25...3 mm fraction was close to that of the coarse fraction, the graph curve (figure 5, C, item 1) is similar to (figure 5, A, item 1), only the bend point had the coordinates W=10 W, P=4000 kPa, which can be explained by a larger number of contacts between small particles and, therefore, a lower level of contact stresses at the same pressure level.

The presence of powder in the mixtures reduced the destructive role of contact stresses, which sometimes required higher power levels for loading at relatively low stresses (figure 5, A, item 3, figure 5, B, item 2, figure 5, C, item 4).

In the process of loading, more than half of the samples of the three fractions showed a rapid increase in pressure to a level of about P=1500...1800 kPa and power to W=7...11 W, followed by an increase in pressure to P=2000...2200 kPa accompanied by a decrease in power level by 2...3 W, sometimes more. Subsequently, the increase in power and pressure occurred at

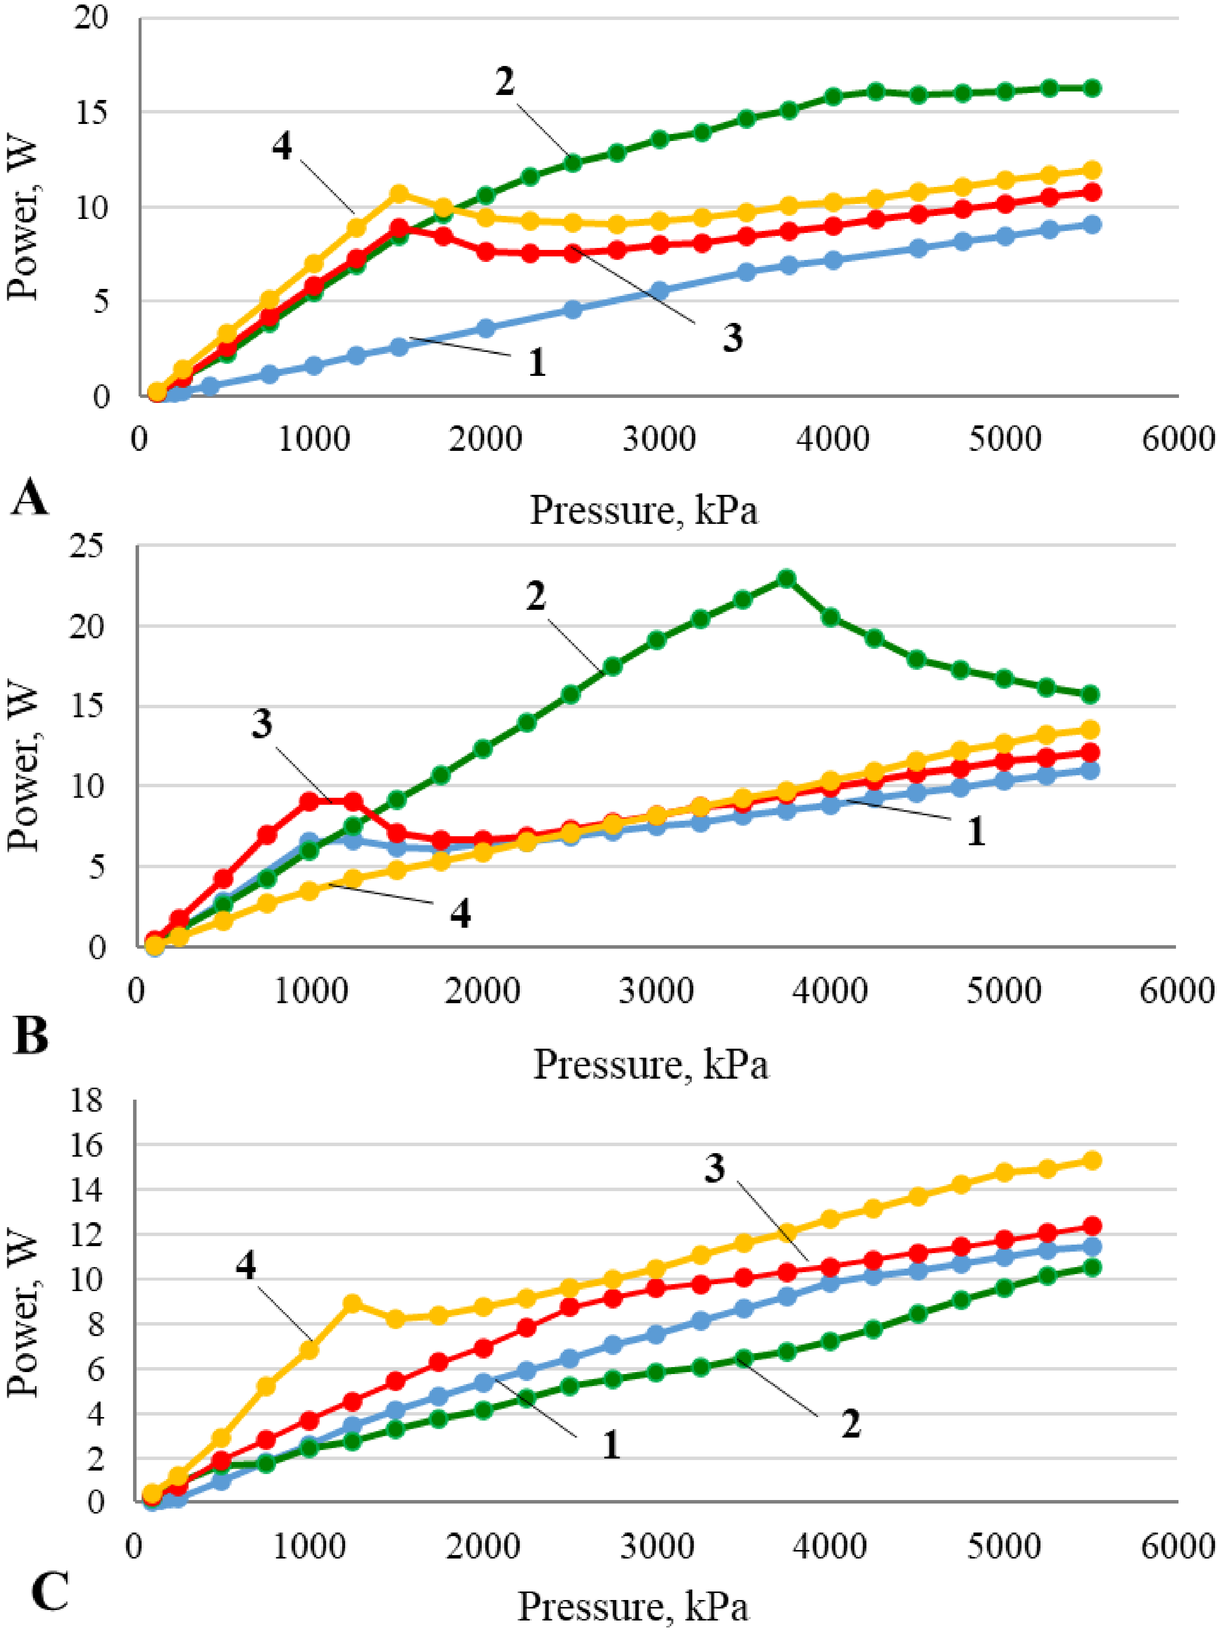

Figure 5. Power W (W) consumed to compress rocks to a pressure P (kPa): rock without additives; 2,3,4 – respectively, 10, 20, 30% of soil powder added: A, B, C – respectively, fractions (mm), 5-10; 3-5; 1.25-3.

a constant rate for all samples.

The reference rock samples of each fraction, after loading up to 110 *kN*, were sieved and the percentage of rock that was crushed was determined (table 3). These data showed that a significant portion of the energy used to compress the rocks was spent on crushing the rock particles, and the rest on compacting the sample. The largest percentage of crushing is inherent in the larger fraction. Particle breaking occurs at the points of contact with neighbouring particles, when the level of contact stress exceeds the tensile strength. Such conditions are more likely to occur when larger particles interact due to a smaller number of contacts and a corresponding increase in contact forces. Such processes can be manifested in the form of an abrupt change in the Δh indicator. Moreover, the deformation of small fractions should be almost twice as smooth as that of large ones.

Table 3. Percentage of rock crushed after loading of the reference samples.

Fraction size, *mm*	Fraction weight, *g*		Proportion of crushed rocks, %
	before	after	
5-10	290	96.76	66.63
3-5	281	174.04	38.06
1.25-3	301	209.31	30.46

5. Discussion of the results

The study of the deformation properties of mixtures of rocks and powdered additives is necessary, e.g., for the construction of road bases using burnt-out rocks. The addition of a sufficient amount of powders that swell under the influence of water, such as montmorillonite, to gravel or crushed stone allows for creating a waterproofing 'jacket' that prevents water from penetrating the road body and deforming it during freezing and thawing. The availability of deformation data sheets for the mixture allows for establishing a consensus between the bearing capacity of the mixture and its waterproofing properties.

The results obtained revealed a certain increase in load resistance when soil powder was added during the initial compression period (figure 5). Almost all the lines of the graphs characterizing the power required for compression located above the line are characteristic of pure (0% soil additive) rock. This can be explained by the contact stress levelling effect due to the filling of voids with powder and, therefore, an increase in the interaction areas of rock particles. The destruction of rock particles was observed, in most cases, at a pressure of 1500...1800 *kPa*, which is typical for burnt-out mudstones. After crushing such particles, their mutual sliding occurred with a slight decrease in the power required for further deformation. The next wave of particle crushing was observed when the pressure increased to an index approximately equal to 3800...4000 *kPa* (figure 5, *A*, items 1, 3; figure 5, *B*, item 2; figure 5, *C*, items 1 and 3), which is typical for siltstones and sandstones. Subsequently, the rate of pressure growth slowed down. After the active destruction of rock particles was completed, the material consolidated and deformation of the samples occurred at almost the same rate. These results indicate the presence of two strength limits in the burnt-out medium composed of two initial petrotypes.

The methodology of the experiment did not provide for the registration of the process of rock breaking, only its results were reported (table 3). In the future, it would be advisable to observe mechanical and acoustic phenomena in the samples in parallel with the compression of the samples to clarify the periods of intense rock destruction. An additional disadvantage of the conducted research should be considered the limited scope of the experiments both in terms of the number of samples and the number of experimental objects, only one waste heap was considered. This can be explained by the difficulty of working under martial law, and the shortcomings will be eliminated in the future.

Microscopic studies have shown the presence of various types of mineral components that make up burnt-out rocks. The photographs (figure 3) clearly distinguish inclusions of yellow, orange, white, black, and transparent colours (table 2). No mineral analysis of these inclusions was performed. However, based on the literature data, it is possible to provide a rough estimate that red and orange inclusions are typical for iron oxides, yellow – for sulphur compounds, white and transparent are quartzite, black are carbon compounds. This approach is very approximate and should be further refined. However, different types of minerals have different attitudes towards water, namely, they can be hydrophilic or hydrophobic. This is an important characteristic of the material in its practical use, so was evaluated the occlusion capacity of the burnt-out waste rocks of mine No. 5/6 [29]. Laboratory studies have shown that burnt-out rocks are able to retain a certain amount of liquid on their surface, the so-called film water (W_f), as well as capillary water, which is retained in pores and cracks (W_C). The latter indicator was defined as an increase in the moisture capacity of the rock (W_{RC}=W_f+W_C) after prolonged (up to 24 hours) saturation with water that penetrated into cracks and capillaries in the rock particles (table 4).

Table 4. Fractional indicators of the capacity of film occluded and capillary water in burnt-out rocks.

Fraction, *mm*	W_{RC},%	W_f, %	W_f/W_{RC}, particle
5-10	8.08	6.96	0.86
3-5	12.58	11.36	0.90
1.25-3	13.60	12.96	0.95

The total moisture capacity W_{RC} increased from 8.08 to 13.6% relative to the mass of dry rock with decreasing fraction size. The occluding surface of larger particles (5-10 *mm*) was the smallest with the same weight of the experimental samples, so the film water indicator was the lowest. Experimentally, it was found that for a geometrically smaller fraction (1.25-3 *mm*), which is three to four times smaller, the W_{RC} indicator was about 40% higher.

The data obtained are also needed in the future to reveal the mechanism of deformation of a mixture of rocks with wet bottom sediments [30]. The thing is that in addition to solid and liquid components that are almost incompressible, the mixture may contain air. It is an elastic substance and affects the results of the experiment. When wet materials placed in a test vessel are loaded, the gases are not completely displaced, but migrate to pores, cracks, etc. When testing dry samples, this phenomenon is not observed, instead, moisture isolates the gaps between the particles and seals air bubbles, which change their volume during loading and unloading, which affects the deformation of the material. The test methodology does not provide for control of the presence of air in the test medium.

To assess the impact on the deformation of a mixture of rock and wet sediments, it is necessary to consider the possibility of air in the pores, cracks, and gaps between the particles. Visual observations and research show that in the process of burning-out, the waste masses become close in properties to ceramics; their particles do not increase in volume when wet.

6. Conclusions

In laboratory conditions, the physical and mechanical properties of samples of burnt-out rock masses ranging in size from 1.25 to 10 *mm* with and without the addition of powdered soil under a load of up to 110 *kN* were studied. For the first time, a certain increase in load resistance was found when soil powder was added in the initial period of compression of the tested material.

It was determined that the destruction of particles of burnt-out material occurs in two waves. The first wave was observed at a pressure of 1500...1800 kPa, followed by material sliding with a slight decrease in the power required for further deformation. The second wave was observed at a pressure increase of approximately 3800...4000 kPa.

It was also determined that after the active destruction of rock particles was completed, the material consolidation and deformation of the samples occurred at almost the same rate. These results indicate the presence of two strength limits in the burnt-out medium composed of two initial petrotypes.

Abstract. Existing bio-economic strategies are complex political documents that affect all spheres of human life, nature, and the economy and require broad social perception. Despite Ukraine's high bio-economic potential, this term has yet to enter the everyday lives of both politicians and ordinary citizens. The vision of what positive or negative consequences this concept generates and what conflicts and political demands may be associated with it has yet to be accurately formed. The article explores the micro-level perception of bio-economic transformation by critical stakeholders to support policy and strategy development at all decision-making levels. We used quantitative data from surveys in three target groups of respondents (scientific and innovation sector, business and industry, government and non-government organizations) to form an approximate picture of the bio-economic transformation perception from scientific, public, and business perspectives. According to the results, bio-energy and agriculture are considered the sectors of the bio-economy with the highest potential for growth in Ukraine. Respondents of all target groups are united in the understanding that the state bears greater responsibility for communicating and promoting the bio-economy among a broader audience, which is not sufficiently informed about potential advantages and problematic issues. The advantages of bio-economic transformation for the environment are perceived as undeniable. Potential risks are minimized or not perceived as such. The understanding of the role of bio-economic transformation in economic growth, job creation, innovation development, and digitalization is less visible. Almost 20 percent of respondents believe that the problem of insufficient biomass for bio-economic transformation is the most critical risk. Biomass as a raw material of sufficient quality may have other options for creating products with high added value before being used in bioenergy at the end of its life cycle. The risks of insufficient biomass can be partially reduced due to the widespread implementation of the cascade use of biomass and the principles of the circularity of the bio-economy. Thus, it is vital to include circularity, cascading use of biomass, and aspects of the rational resources used in the communication policy of bio-economic transformation, as well as its synergy with the main bio-economic sectors regarding the use of biomaterials and innovative knowledge and technologies with their undeniable positive impact on mitigation climate change. The results of the bio-economy perception survey can be used by stakeholders when developing or revising communication strategies and plans and fill a scientific gap in the perception of bio-economic transformation by various stakeholders in Ukraine.

1. Introduction

There are many definitions of the bio-economy. According to the definition of the European Commission from 2018, "Bio-economy covers all sectors and systems that consist of biological resources (animals, plants, microorganisms and derived biomass, including organic waste), their functions and principles. It includes and interconnects terrestrial and marine ecosystems

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012010 doi:10.1088/1755-1315/1415/1/012010

and the services they provide; all primary industries that want and the sector produces biological resources (agriculture, forestry, fishing, and aquaculture); and all economic and industrial sectors that require biological resources and processes to produce food, feed, bio-products, energy, and services. For the successful implementation of the bio-economic strategy, the European bio-economy is based on the principles of sustainability and circularity. According to the European Commission, it will help renew our industries, modernize our primary production systems, protect the environment, and enhance biodiversity" [1]. In this understanding of the concept of bio-economy, we conducted research. The method of bio-economic transformation of socio-economic systems is the transition to an innovative economy with low CO2 emissions, anticipation of development requirements for sustainable agricultural production and fishing, ensuring food security and sustainable use of regenerated biological resources for industrial purposes while ensuring the preservation of biodiversity and environmental protection environment. Traditionally, the bio-economy sector includes agriculture and forestry, fishing, and the food industry, along with traditional industries related to the use of biomass, such as the paper and pulp industry, as well as part of the chemical, biotechnology, and energy industries [2]. To date, more than 40 countries of the world have included the bio-economic concept in the agenda of sustainable development, which is underlined in EC report [3], and indicates the global trends of the transition to a sustainable bio-economy [4]. As one of the largest agricultural countries of the European continent, Ukraine has a high potential for bio-economic transformation. This becomes an even more urgent issue in the context of the risks that the country faces in the war for its raw resources against the Russian Federation, since military actions are taking place in the most mineral-rich territories. The agro-industrial complex remains the main resource for the further development of the country's economy in the near future, and its innovative and sustainable development should become a priority.

At the beginning of its emergence, the term bio-economy was primarily used by scientists who studied the industrial application of evolutionary biology processes. Still, over time it became mainstream in the EU, due to the possible expansion of the scope of application in sustainable economic development. To date, bio-economy has become an interdisciplinary and interdisciplinary field with a large number of identified development vectors.

Bran and Dobre note that the bio-economy's interdisciplinary characteristics make it possible to solve certain environmental and socio-economic problems [5]. Biology, biotechnology, environmental and engineering sciences, economics, management and information technologies are the main fields of knowledge formulating the bio-economy concept defined by Bugge [6]. Falcone and Imbert defined that new promising opportunities for bio-economic transformation are formed due to demand growth and rapid development of bioproducts and bioproduct markets [7]. Development of markets and increasing demand for bio-products opens up new business opportunities, as well as the creation of sustainable chains of added value for biomass and bio-products, bio-energy, and related services, creating economic advantages and demonstrating the positive impact of the bio-economy on sustainable development [8]. The economic benefits of implementing bio-economic models are not always obvious, as they are challenging to measure due to the interdisciplinary nature of the bio-economy, different measurements of direct and indirect results at the micro and macro levels are sufficient, or even simply because of reliable statistical data [9]. The complexity of assessment and forecasting creates additional obstacles to implementing integrated bio-economy policies, management, and strategies at the national, regional, and local levels.

From the above, it was evident that developing an action, a comprehensive strategy for bio-economic transformation, is an extremely difficult. While there is already enough research in the academic community that addresses the concept of the bio-economy, other stakeholders, such as businesses and the public, often need more information and act intuitively, and their opinion is often leveled. One, perceptions, interests, and beliefs are altered depending on the sector the stakeholders belong to (e.g., agriculture or the technology sector).

In Ukraine, a bio-economic strategy has not yet been approved at the national level, although it is long overdue. The development of bio-economic policy and strategy is largely influenced by the perception of bio-economic transformation by key stakeholders: representatives of government bodies and academic/research institutions, as well as representatives of business and the non-governmental sector. The identified stakeholders have their roles; the state representatives involve decision-makers and can adapt the legislative framework, all directives, and policies, while the academic community conducts research and promotes the development of technology and innovation and is the main source of knowledge dissemination about sustainable development. The opinion of businesses and entrepreneurs cannot be neglected either, since they are the ones who implement the concept of bio-economy in life, in the real sector of the economy. In contrast, the public sector is responsible for the advocacy and dissemination of knowledge and informal education of citizens. Both categories of interesting pages contribute to the development of the business department and support the transition of citizens and consumers to sustainable consumption in the processes of bio-economic transformation.

In the world's scientific practice, there are many works [10] dedicated to the concept of bio-economy, from the beginning of its formation to its improvement as one of the concepts aimed at achieving the goals of sustainable development [11] and circularity [12]. At the research level, the bio-economy relies entirely on the development of science and technology. According to many researchers, all developed bio-economic strategies involve a technological innovation transition to the bio-economy [13]. In addition, bio-economy is also considered a driver of dynamic social transformation [14] and regional local development, especially for rural depressed areas [15], which requires consideration of the political aspects of bio-economic transformation. At the global level, the process of bio-economic transformation is held up by the desperate resistance of the world's giants engaged in the extraction of minerals [4]. Therefore, among other things, bio-economic transformation requires strong political will and well-formed dynamic initiatives [16]. For this, it is necessary to educate a new generation of politicians who will possess the appropriate in-depth knowledge necessary to initiate and support the bio-economic transformation at all levels [17]. Over the last decade, Ukrainian scientific thought has been significantly enriched by scientific works in the field of bio-economy: starting from the definition of the main components and advantages of bio-economy [18], its strategic priorities and institutional support for development in Ukraine [19], in particular in agriculture, to its development in the management system natural resources using advanced European experience [20].

The purpose of the article is to form a generalized vision of bio-economic transformation by the main stakeholders at the micro level based on the study of the perception of the concept of bio-economy for further consideration in the formation of policies and strategies at all levels of decision-making, development of curricula and disciplines, conducting scientific research in the context of Ukraine.

To achieve the research goal, we conducted an online survey to determine the level of bio-economic perception, its advantages, problems, and prospects by various stakeholders in the academic environment, industry, business, civil society, and the public sector. The survey was conducted through different target groups, including business and industry representatives, governmental and non-governmental organizations, and research, innovation, and educational institutions, to understand their perception of the bio-economy and its benefits and threats. In particular, the survey aimed to achieve six target results: to understand how business, science, and political actors perceive the bio-economy; review value chain priorities and related communication activities; identify obstacles and conditions for supporting bio-economic transformation; assess the "willingness to cooperate" with the bio-economy; get information on how to improve cooperation between government, science, and industry; find critical points of influence on the development of the bio-economy by identifying overlaps with other areas of state policy.

To achieve the research goals, we have developed a scientific and methodological approach that can be used as a basis for socio-economic justification and development of strategies for the bio-economic transformation of socio-economic systems in Ukraine and further prospects for their implementation. The scientific and methodological approach we propose involves using a mixed research design. In the first stage, we used a qualitative method of research, which is not the subject of this study, the results of which formed the basis of the second, quantitative stage of the study, during which the conclusions obtained from the qualitative part were further investigated and transformed into a quantitative expression. The qualitative research method used in the first stage is focus group moderated sessions held in an expert environment of representatives of Ukrainian science, business, state and public sectors, and companies in selected industries. At the stage of implementation of the second quantitative part of the research, the method of surveying a wide range of interested persons was used, and questionnaires were formed based on the results of the qualitative stage of the research. In our study, focus group experts are managers of certain strategic areas of development of the organizations under study. The selected respondents for the online survey are employees of organizations related to business, educational and scientific institutions, and the state and non-state sectors, who are directly related to the general processes of transformation of organizations through management decision-making. From a managerial point of view, an expert at this level possesses information that allows for certain conclusions regarding the organization's perception of strategic aspects of bio-economic transformation and related risks and opportunities.

A multi-stage stratified sample was used to select organizations based on the sub-industry's characteristics and the organization's size. The selection of respondents was carried out randomly within each stratification group. The number of respondents for the survey is determined separately for three groups: business, research and educational organizations, and public and non-governmental organizations. The selection of the number of respondents from the general list is mainly carried out using a random number generator. As a result, a list of respondents to be surveyed has been formed. The research task did not involve the determination of any mathematical dependencies but only quantitative testing and visualization of trends determined in focus group studies, within which assumptions about the qualitative patterns of the process were determined. When processing the questionnaire survey results, we used graphic representation methods. Graphic representation gives the most visual presentation of the obtained results, allows to understand better the physical essence of the perception of bio-economy by various stakeholders, to reveal the general nature of the functional dependence of the studied variables, to establish connections between trends.

This research structure and concept provided an opportunity to test and quantify the results of qualitative research. The advantages of the proposed methodological approach are the improvement of the perception of qualitative parameters of the parameters of the researched topic by its quantitative addition, as well as in the ease of its implementation and interpretation. The shortcomings of the proposed research are insufficient consideration of the regional context because the perception of bio-economic transformation and its main directions often depends on the natural resource potential of the respondents' region of origin and the relatively small sample of respondents. However, considering the sufficiently high expert background of the surveyed respondents, the obtained research results can be useful for a wide range of interested parties, and the developed methodology is used for conducting additional regional, larger-scale studies.

2. Perception of bio-economy in business, politics and science

A total of 131 people took part in the survey, 63 respondents of which classified themselves as "scientific research, innovative, educational institutions" (48.1 percent), 36 respondents – from the category "government (the relevant public sector) or non-governmental organizations" (27.5 percent), 32 people from "industry and business" (related private sector) (24.4 percent). 33.6 percent of respondents were men, 65.6 percent were women, and others preferred not to answer. The respondents were representatives of all age groups except for those 65+ years. The majority of respondents belong to the age group of 35-44 years (41 percent of respondents) and 45-54 years (22 percent). The majority of respondents live in urban areas (78 percent), compared to those who live in rural (12 percent) or semi-rural/suburban areas (10 percent). Most respondents answered that they are very familiar with the bio-economy concept, with 13.7 percent indicating a high level of awareness and 60 percent meaning that they have an average knowledge of the bio-economy. 26 percent of respondents reported that they know absolutely nothing about the bio-economy. In the first part of the survey, respondents were asked questions about the concepts and sectors that, in their opinion, can be considered as part of the bio-economy, what are the main advantages and risks of the bio-economy in their region, and what is the level of awareness of the bio-economy among the population. Circular use of biomass (76 percent of respondents), use of biomass for different purposes (70 percent), ecosystem services (62 percent), sustainable land management (59 percent) and sustainable consumption (53 percent) are the main concepts that are most often considered as part of bio-economy (figure 1).

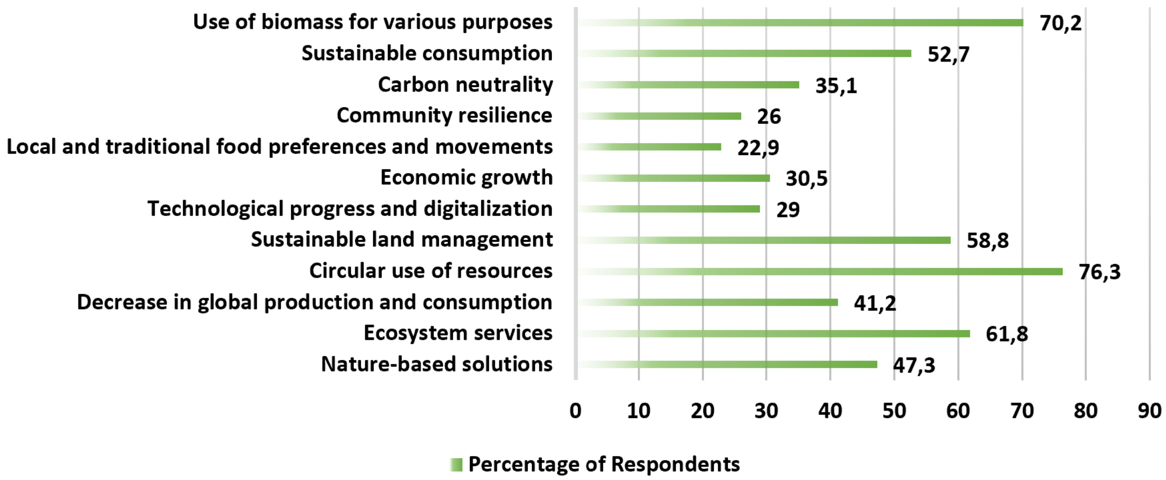

Figure 1. Sectors of the national economy, as a component of the bio-economy, percentage of respondents.

Interestingly, less than 50 percent of respondents associate the bio-economy with the implementation of nature-based solutions (47 percent), the reduction of global production and consumption (41 percent) and economic growth (30.5 percent), technological progress and digitalization (29 percent), carbon neutrality (35 percent), local and traditional preferences and movements, and community sustainability have the lowest affiliation (23 and 26 percent, respectively).

It can be concluded that the respondents associate the increase in the use of biomass for various purposes, the implementation of circular economy principles, the growth of ecosystem services, and the sustainable management of land resources with the bio-economic transformation. On the other hand, bio-economic transformation is considered less relevant for economic development, technological progress, digitalization, and the sustainability of local communities. In terms of primary production, the bio-economy is more associated with agriculture (85 percent) than with forestry (76 percent), fisheries, and aquaculture (56 percent) (figure 2). A significant proportion of respondents consider waste processing, biotechnology, and pharmacology as part of the bio-economy (66 percent each).

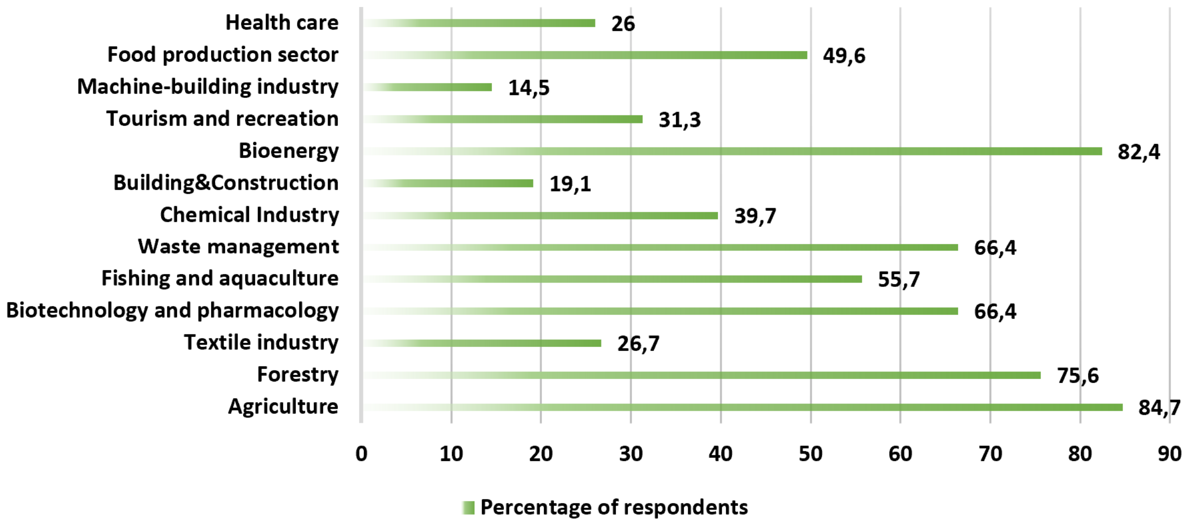

Figure 2. Sectors of the national economy, as a component of the bio-economy, percent of respondents.

Among the sectors of the processing complex, the most attention is paid to bioenergy (82 percent), the food industry, and gastronomy (50 percent). Chemicals (40 percent), tourism and recreation (31 percent) are other secondary industries that more than a third of respondents consider to be part of the bio-economy, followed by the textile industry (27 percent) and healthcare (26 percent). The construction and mechanical engineering sectors (19 and 14.5 percent, respectively) are the least correlated with the bio-economy. In addition, almost 3 percent of respondents determined that all the listed sectors are part of the bio-economy – everything depends on technology. As shown in Figure 3 below, based on the level of correctness of relevant statements characterizing the bio-economy, the vast majority of respondents (85 percent) agreed with the positive impact of the bio-economy, such as that the bio-economy provides opportunities for business and innovation, contributes to sustainable economic development, provides advantages for the development of rural areas, helps mitigate climate change, creates new jobs. More than 95 percent of respondents agree that the bio-economy offers opportunities for business and innovation, promotes sustainable economic growth, and helps mitigate the effects of climate change.

On the other hand, about 25 percent of respondents note some risks of the bio-economy, namely increasing the load on natural systems and causing deforestation. Slightly less than 50 percent of respondents note that there is not enough biomass for bioeconomic transformation.

When evaluating the most important benefits of the bio-economy, the most frequent answer is the reduction of raw materials and waste usage, the promotion of reuse and recycling (47 percent), followed by the reduction of the preservation of biodiversity and ecosystem services (19 percent), renewable energy to replace fossil fuels (12 percent), renewable alternatives to non-renewable materials (10 percent), transition to a low-carbon economy (6 percent). The lowest indicators received such benefits as creating jobs and economic growth (2 percent), ensuring people's well-being (3 percent) or promoting technological innovation (2 percent).

When assessing the risks of the bio-economy, the most common answer is "Insufficient biomass to support the bio-economy" (19 percent). 17.6 percent of respondents indicated that the most critical risk is the increase in the cost of essential goods (for example, food, water, housing, etc.) and the negative impact on ecosystem services (16 percent). Fewer respondents considered the impact of biomass imports from Europe (11.5 percent) and the increase in biomass costs (10.7 percent) significant. The smallest number of respondents noted the possible negative impact of the bio-economy on poverty or food sovereignty (6 percent). A significant proportion of respondents (18 percent) indicated that none of the predefined risks was the most critical risk.

3. Improving communication strategy and prioritization for values

The questions of this section related to the extent to which Ukraine is ready for the transition from a traditional economy to a circular bio-economy, the identification of bio-economy sectors with the highest potential for development, and to what extent different sectors can replace fossil raw materials with biological materials in the region by 2050. The answers we received allow us to review value chain priorities and related communication activities and compare them with existing bio-economy sectors and development strategies.

When respondents were asked how they assess Ukraine's readiness to transition from a traditional economy to a circular bio-economy, the majority of respondents answered that it is medium readiness (44 percent of respondents), high readiness, and very high readiness (5 percent, and 2 percent of respondents, respectively) and low readiness and very low readiness (31 percent and 16 percent, respectively) (figure 3).

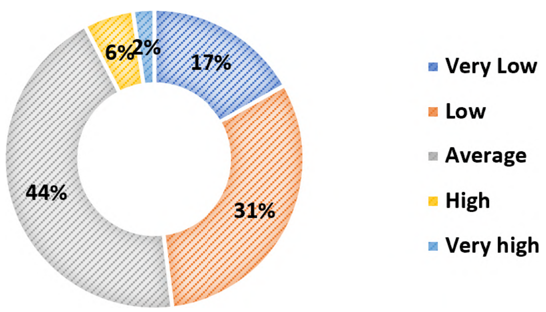

Figure 3. Perception of Ukraine's readiness to transition from a traditional economy to a circular bio-economy.

According to the respondents, bioenergy has the most significant potential in Ukraine's bio-economy (72 percent), corresponding to the region's vision of energy transformation. The agri-food sector (60 percent), green tourism (43 percent), bioplastics (36 percent), new advanced biomaterials (34 percent), green chemistry (24 percent), and the food sector (28 percent) were noted by respondents as having medium potential. The sectors with the lowest potential in Ukraine include pulp and paper (11 percent), textile industry (5 percent), wood products and furniture (8 percent), and non-wood forest products (for example, mushrooms, resins, etc.) (14 percent). Also, one of the respondents added a category that he considers the most promising sector – the development of green hydrogen in Ukraine. In this section, respondents were asked to predict how much six selected sectors of the economy can replace fossil raw materials with biomaterials by 2050 in Ukraine. Table 1 shows that more than 40 percent of respondents believe that the sectors of "Energy", "Textile industry", "Manufacturing industry" and "Food processing and packaging" can replace with biomaterials more than 50 percent of fossil materials/raw materials (50-70 percent, 70-90 percent, and 90-100 percent) by 2050 in Ukraine (figure 4).

As for agro-processing, trade, and food packaging, more than 60 percent of respondents think so – that is, the most potentially likely option.

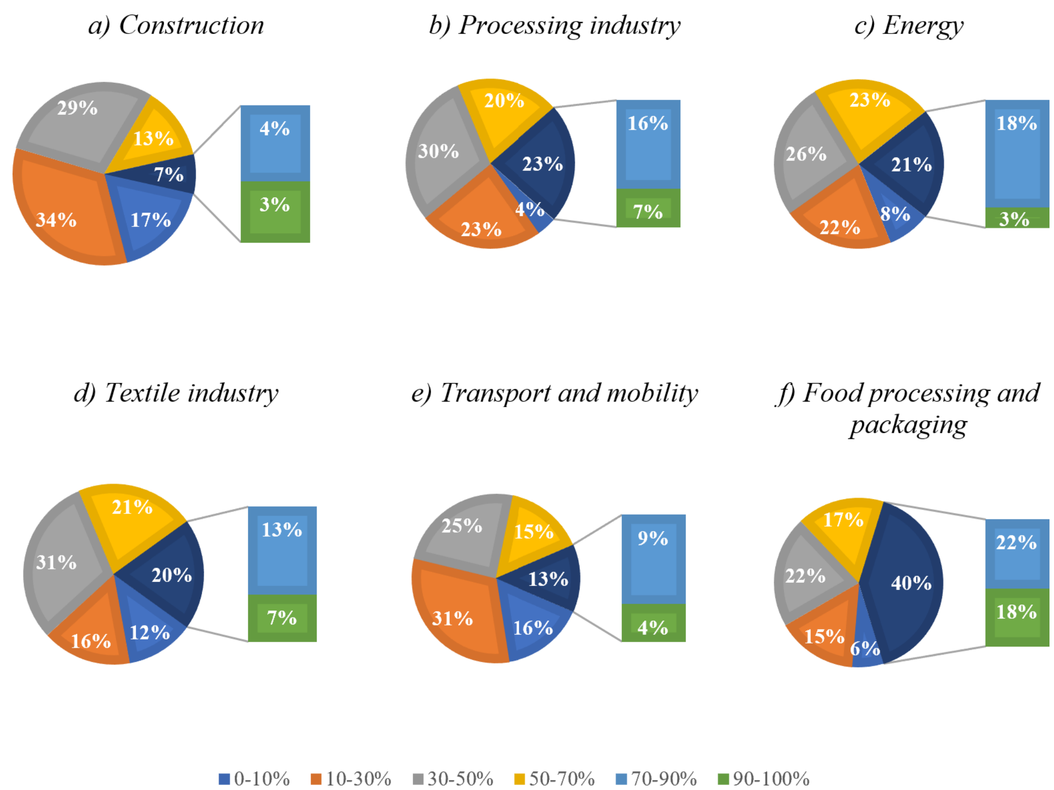

Figure 4. Perception of the prospects of replacing fossil raw materials with biomaterials in selected sectors of Ukraine's economy by 2050.

Using averages over a range of predefined proportions (e.g., assuming that respondents who chose 10-30 percent on average believe that about 20 percent of conventional materials are replaceable), we can estimate the average proportion of fossil raw materials/materials that can be replaced with biomaterials. The result of this study is that the agro-food sector is, on average, estimated to be the sector with the highest potential for replacing fossil raw materials with bioresources in Ukraine by 2050. Namely, 57 percent of resources are estimated as replaceable. The second sector with the largest share of replaceable resources is the manufacturing sector, with 48 percent. In third place is the energy sector, with 46 percent, and the textile industry, with 45.6 percent.

4. Analysis of potential obstacles and mechanisms for supporting bio-economic transformation

The issues of this survey section are related to the definition of favorable conditions and possible obstacles to developing the bio-economy in Ukraine. The information obtained allows you to ensure compliance with the most important conditions of support and to develop strategic decisions to overcome barriers to bio-economic transformation.

The most important factor supporting bio-economic transformation in Ukraine is the availability of information for the scientific justification of political decisions, investment in innovation, and adequate state regulation to overcome possible negative consequences for the ecosystem and local communities. These factors were rated as important and very important by more than 86 percent, 85 percent, and 84 percent of the surveyed respondents, respectively (figure 5). Public procurement and carbon tax programs were rated as important and very important by more than 70 percent of respondents.

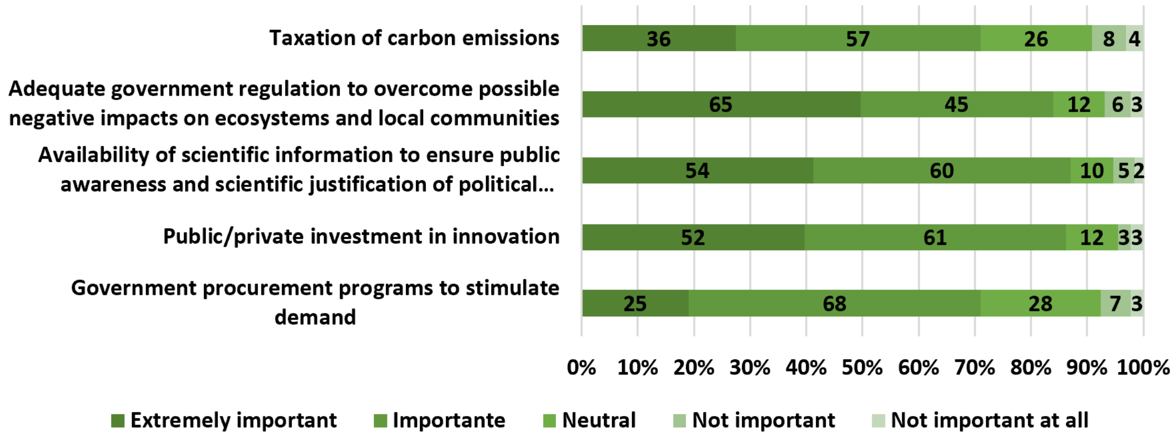

Figure 5. Perception of factors supporting bioeconomic transformation in Ukraine.

Regarding the perception of obstacles to bio-economic transformation, one of the most important obstacles noted by the largest number of respondents is the lack of favorable state policy and legislative support adapted to regional needs. More than 85 percent of respondents have this opinion. A little more than 80 percent of respondents consider the lack of cooperation between various interested parties (for example, politicians, business, and scientific environment) as a very important or important factor (figure 5).

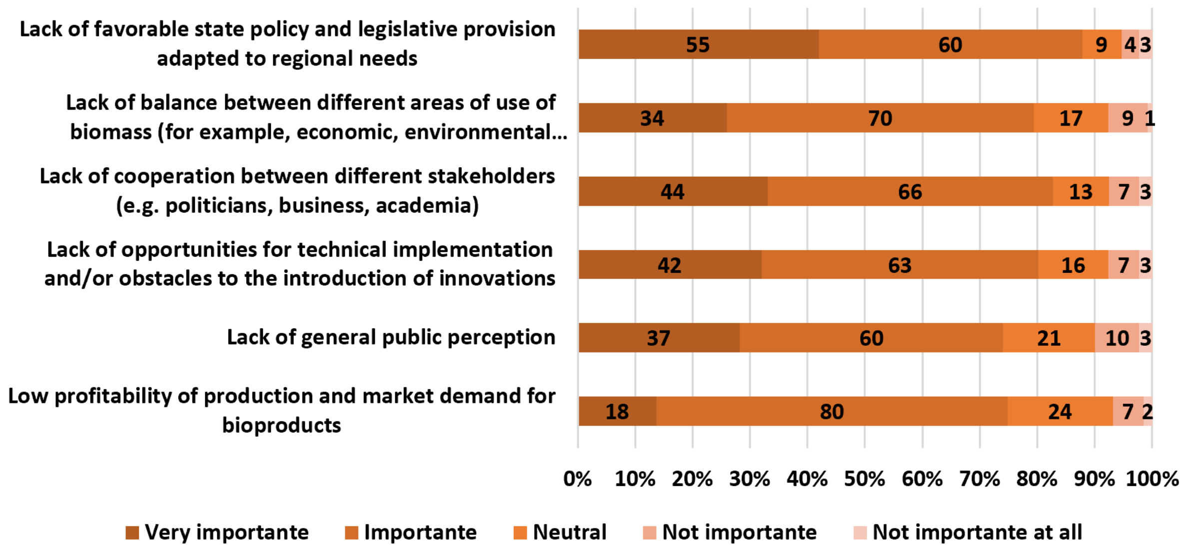

Figure 6. Perception of factors hindering the development of the bio-economy in Ukraine.

Two other obstacles, the lack of balance between different areas of biomaterial use (for example, economic, environmental protection, carbon absorption, etc.) and the lack of opportunities for technical implementation and/or obstacles to the introduction of innovations, were supported by 80 percent of respondents. Low profitability of production and market demand for organic products and the lack of general public perception are recognized by more than 75 percent of respondents as important or very important. However, suppose the lack of public perception is considered a very important factor for more than 25 percent of respondents. In that case, low profitability is only for a little more than 10 percent of respondents.

5. Analysis of readiness for active implementation of bio-economic vectors of development

In this section, respondents answered questions about the readiness of a scientific institution, industrial enterprise, government agency, or state institution to develop the bio-economy; the involvement of the organizations they represent in the implementation of any investment projects, regulation or initiatives related to the bio-economy, as well as the main reasons for their participation in such projects. Below are the results for the three surveyed categories of respondents (figure 7).

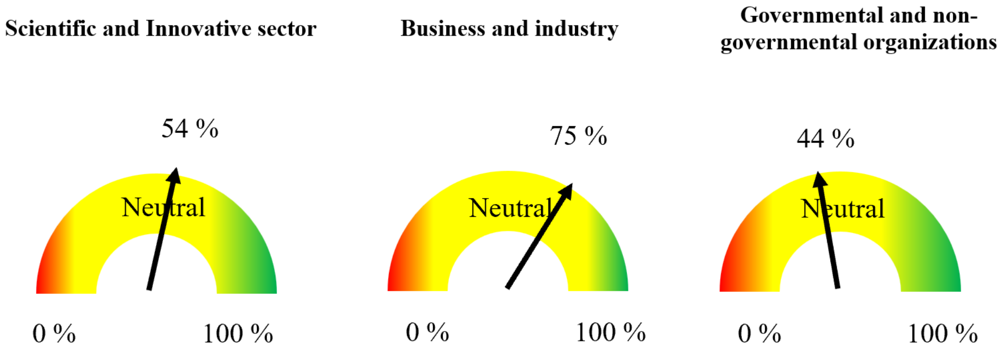

Figure 7. Perception of factors hindering the development of the bio-economy in Ukraine.

The representatives of the scientific and innovative sectors were asked a question regarding their sense of readiness of their sector for the development of the bio-economy. About 29 percent of respondents declared 100 percent readiness, 16 percent of respondents noted that their sector is not at all ready to develop the bio-economy, while the largest part (54 percent of respondents) expressed an opinion about an average level of readiness. 20 percent of respondents testified to the fact that their organizations implement, or have implemented in the past, investment bio-economic projects. The main reasons for their implementation were the following factors in descending order: to use state support mechanisms, to use existing market opportunities, and to obtain competitive advantages in the market. 50 percent of respondents named the lack of technical capabilities as the main obstacle on the way to the implementation of bio-economic projects. In second place is high uncertainty in bio-economic projects and the immaturity of the market (27 and 22 percent, respectively). Low expected profitability defined about 11 percent of respondents from implementing bio-economic projects in science. The fact that conducting research and development in the bio-economy has some state support is obvious, and the negative side of innovative bio-economic development is also observed – the lack of technical capabilities for implementing investment bio-economic projects in the scientific and innovative sector. According to the survey research results, the largest number of respondents from business and industry attest to an average level of readiness for bio-economic transformation – 75 percent – which means that respondents from business and industry are more likely to develop the bio-economy. However, only 7 percent of those consider themselves 100 percent ready for this, while 19 percent of respondents were not ready at all for bio-economic transformation, which is probably related to a specific field of industry. 28 percent of respondents from business and industry stated that they had implemented investment projects in the bio-economy in the past.

The main reasons for the implementation of investment projects in the bio-economy by representatives of business and industry are the use of existing market opportunities (100 percent of respondents from business and industry who implemented projects in the field of bio-economy), to obtain competitive advantages in the market (67 percent), the use of state support mechanisms (33 percent), several respondents noted such incentives as saving resources and reducing the cost of goods and services. The main reasons for dealing with bio-economy projects were immaturity of the market (40 percent), followed by high uncertainty of bio-economy projects (34 percent), low expected profitability, and lack of technical capabilities noted by 30 percent of respondents. Respondents had the opportunity to choose several possible reasons and incentives. Summarizing, we can emphasize the fact that most representatives of business and industry do not have information about any mechanisms of state support for bio-economic projects, and all of them implement such projects to use existing market opportunities. The respondents of this group were asked how ready they were to develop the bio-economy on a scale from zero (I have no desire) to one hundred (I really want to). The average level of expressed desire was confirmed by 44 percent of respondents from the governmental and non-governmental (public organizations) sectors, which means that the position is more neutral than that of the two previous groups of respondents. However, 100 percent readiness to support the development of the bio-economy was shown by 33 percent of respondents (half of whom are from the public sector), 22 percent were not ready for bio-economic transformation at all, of which only one respondent belonged to the public sector, the rest to the non-governmental organizations. In addition, only 19 percent of respondents from the governmental and non-governmental sectors confirmed participation in investment projects in the bio-economy, most of which are, however, representatives of the public sector.

The main incentives for the development of investment bio-economic projects are considered to be the use of state support mechanisms (almost 50 percent of the respondents who participated in the implementation of such projects), 46 percent and 38 percent, respectively, attributed them to the incentives of obtaining competitive advantages and using existing market opportunities. The lack of technical capabilities and the immaturity of the market are the main restraining factors (36 and 28 percent of the surveyed respondents share this opinion), a slightly smaller number of respondents (17 and 19 percent, respectively) consider high uncertainty in bio-economic projects and low expected profitability as important factors.

However, when we ask the question from a different angle to all three groups of respondents, namely: to what extent is the public sector ready to develop the bio-economy? We have somewhat more pessimistic predictions, especially regarding the perception by business and industry of the public sector's readiness to develop the bio-economy. 50 percent of respondents consider the public sector not ready to implement bioeconomic transformations, while the other half assesses the level of readiness as average. In this block of questions, a high level of government readiness for bio-economy development was not confirmed by any group. In particular, in the groups of science and innovation and the governmental and non-governmental sectors, there were 2 such respondents from each group. In contrast, in the business and industry group, no respondent voted. However, only a third of the industry and governmental/non-governmental groups of respondents are aware of any developed regulations or initiatives related to the development of the bio-economy. More than 63 percent of respondents of all groups do not know anything about the developed regulatory and legislative initiatives related to bio-economic transformation.

Ensuring sustainability or social justice (60 percent of respondents), creating markets and social acceptance of bio-economy products (50.8 percent), as well as improving provision and access to biological resources (38 percent) are defined as the main goals of developing relevant regulatory acts or initiatives regarding bio-economic transformation. In addition to the proposed goals, the respondents identified the implementation of the European Green Course and the declarative nature of individual draft laws as two of the goals.

Among the main obstacles of the bio-economic transformation initiatives, the most common opinion is the lack of financial opportunities (52.7 percent) and the lack of such goals on the agenda of local strategies and policies (48.4 percent), 43 percent of respondents also noted the lack of a request from society for such initiatives, and 30 percent noted that regional development plans do not contribute to the development of the bio-economy. Instead, some of the respondents indicated additional negative factors restraining the development of the bio-economy, namely, lack of systemic vision, planning and forecasting, corruption of officials, and attempts to open the land market in Ukraine.

We have summarized six key statements about the perception of the bio-economy in Ukraine.

1. The bio-economy is considered to have great potential for business development and innovation, promotes sustainable economic development, benefits rural development, helps mitigate climate change, and creates new jobs. Still, its potential for economic and innovative growth appears to be less visible.
2. Among the respondents, there is a firm belief that the public needs to be sufficiently informed about the bio-economy and its development prospects in Ukraine.
3. The most promising sector from the point of view of bio-economic transformation is agriculture – in the primary sector and bioenergy – in the processing sector of Ukraine.
4. Readiness for the bio-economic transformation of industry sectors by 2050 in Ukraine remains average, with the most promising areas in agro-processing and retail trade (food packaging).
5. Most of the proposed favorable conditions are considered key factors for the development of the bio-economy. In contrast, the main negative factor remains the lack of favorable state policy, and legislative support adapted to regional needs.
6. The scientific and innovative sector and the business environment show a higher readiness for the development of the bio-economy than the public sector. Still, all areas are quite consistent in their understanding of the areas of responsibility.

The results of the online survey indicate that the bio-economy, as the next wave of economic growth, is perceived quite positively by all groups of stakeholders involved. Among the respondents, there is an understanding of the potential opportunities that the bio-economy transformation opens up, such as the creation of new jobs, the opening of new markets, and increased competitiveness. A significant part of respondents confirm the importance of the role of bio-economy in the sustainable development of socio-economic systems in Ukraine. The economy of scale, networking, reuse, and processing of bioresources and their waste, combined with appropriate financing mechanisms, are considered important elements of an effective transition to bio-economic business models and in forming new strategic competitive advantages for organizations. It is important to note that some statements were obvious to academics in specific fields. At the same time, respondents from business and government organizations had different views, so it is important to conduct deeper analysis and further research, considering all stakeholders' perspectives. It can be concluded that most categories of stakeholders work in isolation, which prevents the achievement of synergy effects and the possibility of uniting around the intended perspectives and desired results. According to the perception of the interviewed stakeholders, Ukraine's bio-economy is closely related to the use of biomass and the sustainable and efficient use of natural resources. Expanding information, knowledge, and government support are critical elements of policy development in conjunction with technological and industrial development. According to the results obtained, the Ukrainian adapted version of bio-economic transformation (in a broad sense – sustainable, circular bio-economy) can be implemented by overcoming isolation and ensuring multilateral cooperation between various scientific fields, technologies, institutions and organizations using a synergistic approach. Such initiatives should be supported by appropriate public and private funding mechanisms and be based on science-based strategies and plans, as creating innovative and sustainable value-added chains requires significant investment, research support, innovation development, and compliance with the principles of circularity and resource efficiency. The results of the study demonstrate the urgent need for the creation of interdisciplinary and interdisciplinary working groups for the formation of a national strategy for bio-economic transformation in Ukraine, the development of specific policies that may relate to the improvement of interdisciplinary and intersectoral communication, and the promotion of the concept of bio-economy, its potential advantages and the analysis of necessary transformations at the entrepreneurial, technological, and legislative levels. Determinants of development and the identified risks of bio-economic transformation give the possibility to formulate the following recommendations for the development of a national bio-economy strategy in Ukraine:

1. Consistent development of the political background and comprehensive cross-sectoral vision of bio-economic transformation with the involvement of a wide range of interested parties.
2. Effective coordination with regional, national, and European policies.
3. Investing in stimulating the acquisition of new knowledge and the implementation of modern approaches, the introduction of innovations at all levels of the bio-economy, the reduction of interdisciplinary and intersectoral isolation and the formation of heterogeneous working groups of experts for decision-making and policy development to expand the strategic vision and form the mechanisms of bioeconomic transformation.

Such an approach will provide an opportunity to eliminate inconsistencies between fields of science, priorities of scientific research, political vision, practical initiatives, and legislative support. A coordinated interdisciplinary and interdisciplinary approach can contribute to the comprehensive development of the bio-economy based on sustainable development by ensuring the development and implementation of new technologies by the local characteristics of the region. The development of strategies in this way will enable the conscious movement of production and economic activity from “sectors” to “socio-economic systems” or “sustainable value-added chains” due to the establishment of constructive network ties of the relevant economic and production sectors to ensure a closed cycle of deep processing bioresources.

6. Conclusions

The cross-cutting nature of new bio-economy models determines various stakeholders’ excellent perception of bio-economic transformation. On the other hand, the perception of the bio-economy by key stakeholders has a significant impact on the development and implementation of relevant transformational mechanisms. The survey results provide an opportunity to analyze the level of perception of the bio-economy in Ukraine, its advantages, and the challenges associated with the bio-economic transformation by representatives of the academic community, public sector, and civil society at the local level, and business. The results of the conducted research on the perception of bio-economic transformation by various interested groups of stakeholders will be important for determining the priorities of regional bio-economic strategies for policy development and communications to maximize the effectiveness of their impact. We have summarized six key statements about the perception of the bio-economy in Ukraine. Empirical results indicate the need to develop a coherent cross-sectoral and interdisciplinary approach to knowledge, skills and competencies for the proper bio-economic development on the basis of sustainability, the development and use of innovative technologies, taking into account national and regional characteristics. The study contributes to the expansion of the discussion on the need to implement the concept of bio-economy in Ukraine and fills the scientific gap in the perception of bio-economic transformation by various stakeholders at the micro level.

Abstract. This article explores the dynamic impact of artificial intelligence (AI) on education, with a focus on its integration into the field of psychology. The study analyzes the dichotomous nature of AI in educational settings, highlighting both its potential for innovation and the challenges it presents, particularly in terms of academic integrity and the quality of training. Utilizing the concept of self-organization of systems, the article examines AI as a transformative factor in education, necessitating a new order of collective interaction among educational participants. Empirical research is presented, comparing the content, structure, and style of texts generated by AI (specifically Claude 2.1 and ChatGPT 4) and psychology students. This comparison establishes criteria for differentiating between "human" and "artificial" texts, underscoring the unique aspects of human creativity and critical thinking that AI currently cannot replicate. The study also reveals the evolving role of educators as facilitators within a hybrid ecosystem of human and AI participants. The article proposes future research directions, including the exploration of collaborative interactions between individuals and AI and the development of accelerated learning methodologies within the human-AI ecosystem. It emphasizes the necessity of balancing the strengths of human creativity with AI's computational efficiency, aiming to enhance student motivation and expand cognitive capabilities in educational settings. Furthermore, the article discusses the emergence of new professional roles such as AI user facilitators, and AI facilitators, highlighting the growing complexity of human-AI interactions. These roles are crucial for effective and ethical utilization of AI in education, especially in psychology. The article presents AI as a catalyst for significant paradigm shifts in education and professional training, particularly in socionomic fields. It advocates for a synergistic approach to education, where AI complements human abilities, leading to enriched learning experiences and the development of a more adaptive, personalized, and efficient educational landscape.

1. Introduction

The integration of artificial intelligence (AI) in education, particularly in psychology, is crucial for shaping a sustainable future. By enhancing the training of future psychologists, AI can equip them with the skills and knowledge needed to address complex sustainability challenges. As psychologists play a vital role in promoting sustainable behaviors and well-being, the responsible incorporation of AI in their education can better prepare them to contribute to sustainable development. Moreover, the ethical integration of AI in psychology education serves as a model for other disciplines, demonstrating how technology can support sustainability goals without compromising essential human elements in the learning process.

2. Literature review: AI and emerging trends in education

The integration of AI in education, a field historically advocating for more authentic and individualized teaching and assessment methods [1], has introduced both exacerbation of existing challenges and new opportunities. Recent literature highlights several emerging trends in this domain, centering on attitudes towards AI, its potential impacts on individuals and society, and the dynamics of its development, along with necessary actions at various levels ranging from international to organizational [2–7].

A prominent trend is the academic community's concern regarding the potential for fraud and violation of academic integrity, triggered by the use of AI technologies in writing educational and scientific papers [8]. Another trend is the reformation of learning and assessment methodologies through AI technologies [9], though their effectiveness for technical specialty students is debated [10]. Moreover, the adaptation of various professions, including teaching and research, to the evolving AI landscape is actively being explored [11–13].

A further trend involves the automation of routine educational tasks, such as test checking and content preparation, through AI tools like chatbots. This aims to strike a balance between automation, human capabilities, and AI, ultimately freeing up time for creativity and personalized learning [14–16]. Additionally, the development of AI regulatory policies in general [17], particularly in science [18], and education [19], is being closely examined. However, there is a caution against over-regulation from innovation advocates like Roose [20], who argue it could stifle AI development and limit educational prospects. Soft regulatory mechanisms, such as ethical principles and self-regulation by educational and scientific organizations, are also under consideration [21, 22].

3. Theoretical substantiation: from AI chaos to a new order in education

The advent of AI in the educational landscape has disrupted the traditional linear progression of educational system evolution. This disruption is evident in the emergence of both long-maturing and entirely novel trends. This non-linear development process, when viewed as a self-organization of education, underscores the infeasibility of maintaining the status quo. The future shape of the education system remains indistinct, with its contours likely to emerge retrospectively upon the completion of this transition. This break in gradualness signifies a rhythm of self-organization in the education system, transitioning from the former SPOD (Stable-Predictable-Orderly-Definite) model to a VUCA (Volatile, Uncertain, Complex, Ambiguous) educational environment. This shift, often perceived as chaotic and unpredictable, leaves students, educators, and educational administrators without a clear trajectory for immediate educational development.

In the context of Vygotsky's developmental zones theory, these phenomena align with the concept of a 'buffer development zone', characterized by high energy and potential for exploring new self-organization forms [23]. The emergence of a new order in education represents a synthesis of foundational elements for the system's existence, following a developmental model of thesis-antithesis-synthesis, indicative of a robust self-organizational process.

Analogous to the healthcare and education system transformations during the COVID-19 pandemic, AI, similar to the virus, has acted as an agent of chaos, catalyzing fundamental changes in treatment, education, and management approaches. We are currently witnessing these transformations.

Presently, the educational system is likely in a phase analogous to producing "antibodies" against the "AI virus", transforming it into a positive entity or "enhanced immunity of the social education system" [24]. At this stage, any attempts to inhibit the actions of teachers and students are seen as slowing down development. However, paradoxically, these actions also contribute to system evolution under the principle of "preservation innovation", which posits that innovations don't obliterate the past but rather reaffirm it in new forms.

The rapid proliferation of AI, exemplified by tools like ChatGPT 4 and Claude 2.1, has facilitated a non-linear management approach in educational and pedagogical processes, characterized as eco-centered psychological facilitation (ECPF). Given the necessity for students, teachers, and researchers to significantly adjust their methodologies, this situation presents an opportunity not only to assess the potential of a natural experiment in all aspects but also to expedite the learning process by embracing these changes.

The primary research objective is to investigate the potential of AI technologies in the training of psychology students and to explore the possibility of integrating these technologies into the educational process to enhance the quality of training for modern specialists. To achieve this objective, the following research questions were addressed: What are the distinguishing characteristics of essays written by psychology students compared to those generated by AI chatbots like Claude 2.1 and ChatGPT 4? What criteria can be used to differentiate between human-written and AI-generated texts in the context of psychology education? How can AI technologies be effectively integrated into the educational process to augment the training of future psychologists?

This integration aims to enhance the quality of training for modern specialists, aligning with the evolving educational landscape. The focus is on understanding how AI can be optimally utilized to foster a more efficient, adaptive, and individualized educational environment, responsive to the dynamic needs of students and educators alike. This exploration into AI's role in education represents a critical step towards navigating and shaping the future trajectory of educational development and innovation.

4. Methodology

In addressing the challenge of self-organization within the education system, triggered by the advent and rapid proliferation of artificial intelligence, a dynamic methodology was adopted. This approach acknowledges the dialectical relationship between AI and human intelligence, recognizing the emergent tension and potential crisis. Resolving this crisis is seen as an opportunity for the integration of AI and the holistic development of the educational ecosystem.

This study observes the spontaneous formation of new problem-oriented groups across various disciplines, including psychology and pedagogy. These groups are characterized by their non-linear approach to transitioning towards a higher level of self-organization and functioning, embodying the concept of 'order through chaos'.

Participants in the study: included a diverse mix of human and artificial intelligences: master's degree students in psychology (31 individuals, average age 31±4.6 years, 16.1% male, 83.9% female), two chatbots (GPT 4 and Claude 2.1, chosen for their proficiency in creating text-based content and their widespread use), independent experts (2 psychology professors, 2 practicing psychologists, 2 Ph.D. psychology students) and research facilitators. All participants were aware of the capabilities of the GPT 4 and Claude 2.1 chatbots.

Procedure and tools. Participants were tasked with writing a creative essay on one of 100 proposed topics, without size limitations. The chatbots received prompts in Ukrainian, instructed to simulate a psychology student composing a creative essay. The essays' potential was assessed by independent experts, who conducted a "blind" analysis, focusing on content, structure, and style, to differentiate characteristics inherent in human-versus AI-generated works. This analysis facilitated the establishment of criteria for distinguishing between "human" and "artificial" texts and aided in developing a list of collaborative tasks suitable for the training of future psychologists.

Statistical processing: includes descriptives, frequency and carried out using the SPSS statistical package.

Research ethics. Informed consent was obtained from all participants for their involvement and the publication of the study's results, adhering to norms of anonymity and confidentiality. The personal data of the participants are not disclosed and will remain inaccessible in any publications or dissemination of the study's findings.

Using large language models (LLM). Language translation, text editing and implementation of a prompt developed by us, which distinguishes the roles and functions of the professionals (table 3), was carried out in collaboration with the Claude 2.1 chatbot, ensuring linguistic precision and coherence. This methodology provides a comprehensive framework for exploring the integration of AI in educational contexts, particularly in the training of psychology students, with a focus on ethical and effective utilization of AI technologies.

5. Comparative analysis of students' essays and Claude 2.1, ChatGPT 4

In response to the task, students selected 17 topics from the provided 100. Both chatbots, Claude 2.1 and ChatGPT 4, generated essays on these same topics, albeit shorter in length. The essays were then analyzed by experts and the chatbots themselves to identify authorship. Surprisingly, neither the experts nor the chatbots could accurately determine the chatbots' authorship. False identifications related to student essays were not further analyzed due to the inherent ambiguity in ascertaining their authenticity (table 1).

Table 1. Quantitative analysis of students' creative essays and chatbots.

Analyzed essay parameters	**Students**	**Claude 2.1**	**ChatGPT 4**
Number of essays	31	17	17
Number of topics	17	17	17
Average word count	352	186	104
Standard deviation	257	118	36
Mininimum word Count	82	163	37
Maximum word count	1071	201	149
Erroneous elections of experts, %	–	16.7	19.6
False picks Claude 2.1, %	–	29.4	17.6
False ChatGPT elections, %	–	17.6	29.4

Content analysis revealed that ChatGPT 4 essays were impersonal, relayed well-known academic knowledge, and provided stereotypical answers with general advice. These essays were deemed simple in terms of semantic, syntactic, and stylistic complexity, lacking originality, thesis, and antithesis. Claude 2.1's essays were more personalized, sometimes using first-person narratives, including appeals to experience, arguments from academic psychology, alternative judgments, generalized advice, conclusions, and rhetorical flourishes. In contrast, the future psychologists' essays varied greatly in content and length, but most exhibited elements of creativity, metaphor, unique style, emotional personal coloring, reflection, and a strong personal perspective.

The task of discerning the authorship of the texts proved straightforward in some instances and challenging in others for the experts. It was later determined that the presence of originality, multi-dimensionality of meanings, creative elements, and pronounced linguistic stylistics were convincing indicators of human authorship. A notable characteristic of human-written essays was the ability to present a detailed psychological portrait of the author.

This study demonstrates that while it is currently challenging to unequivocally determine the authorship of texts, certain criteria can be identified to make educated guesses. The presence of multiple relevant features in an essay increases the likelihood of accurately predicting its authorship (table 2). The criteria listed in table 2 for distinguishing between human-written and AI-generated essays were derived from a comprehensive content analysis conducted by a panel of experts.

Table 2. Criterion features of a human and AI essay.

Criterion	**Signs of an essay: man**	**Signs of an essay: Claude 2.1, ChatGPT 4**
Psychological portrait of the author	Holistic, convincing, imaginable	Difficult or impossible to imagine the author, dubious
Critical thinking	Deep understanding, correlation of data, subjective opinions with reasoning, marking ambiguous aspects	Surface-level, known facts, unambiguous interpretations
Linguistic complexity	Varied semantic, syntactic, stylistic complexity	Simple, repetitive, predictable
Structure of the text	Flexible, original	Template-based
Style and form of presentation	Variable, individual; personal appeals, reflections	Uniform, formal; impersonal, abstracted
Vocabulary	Rich, imaginative, unique speech patterns	Modest, standard, lacks stylistic uniqueness
Originality of content	Creative, original, personal reflections and judgments	Standard, known knowledge, lacks personal attitude
Creativity of ideas, argumentation	Original, creative, use of metaphors and figurative comparisons	Standard reasoning, limited creativity, minimal figurative language
Emotionality, attitude	Emotional, personal opinions and attitudes, topic significance	Emotionless, neutral, non-judgmental
Errors	Possible stylistic, grammatical errors, inconsistent logic	Substantive errors, generally consistent logic

The findings highlight the nuances in AI-generated versus human-written texts, especially in fields that require personal insight and creativity like psychology. This has implications for the role of AI in educational settings, particularly in tasks requiring personal expression and critical thinking. The study underscores the importance of developing and recognizing these unique human elements in education, even in an age increasingly influenced by artificial intelligence.

The results underscore the vast potential of the "human-AI" dynamic ecosystem in educational interaction. It suggests that the system of evaluation should shift focus from the end product (the essay text) to the process of its creation. This aligns with emerging professions such as prompt engineers or hybrid roles like prompt psychologists or facilitators, reflecting the intermingling world of human and AI interactions.

These professionals are envisioned to guide the creation of individual educational trajectories and foster self-help. The role of a human AI facilitator is envisaged as one who not only understands AI but also possesses expertise in the relevant subject area. For instance, in psychology, this would include knowledge of psychological counseling or psychotherapy basics, developing AI training exercises, and engaging in effective dialogue with AI. This role is about mastering a unique modality of psychological guidance, where the facilitator creates and adjusts AI assistants or agents to suit specific needs.

An AI facilitator is characterized by the ability to listen and understand both the capabilities and limitations of AI, without imposing their own decisions. They bear the responsibility for establishing a mutually comprehensible dialogue between humans and AI. The primary objective isn't to provide direct assistance to clients but to configure an AI assistant for mastering relevant psychological counseling skills. As the AI agent evolves, the facilitator must continually analyze and guide its development and self-improvement pathways, even to the point of "self-destruction" to lay new foundations for AI functioning.

This concept extends to non-linear management of learning processes and professional self-organization. In this context, we prompted ChatGPT 4 to differentiate the roles and functions of various professionals such as prompt engineers, AI user facilitators (specialists in user interaction with AI), and AI facilitators (specialists in AI development and adaptation to human needs) (table 3). This exercise aims to clarify and distinguish these emerging roles, highlighting the diverse skill sets and responsibilities required in a world where AI and human interactions are increasingly intertwined and complex.

The differentiation of roles in AI interaction and facilitation underscores the evolving landscape of AI integration in various fields, including education.

The distinction between professionals with and without psychological education becomes particularly significant. It emphasizes the need to perceive AI as a collaborative partner rather than merely a tool. This view shifts the perception of AI from an agent with dominating capabilities to an agent that understands and empathizes with human needs while maintaining its technological advantages. Such a perspective fosters a collective approach to civilization and bolsters social-psychological immunity.

In the realm of education, especially in the field of Educational Psychology, there arises a need to teach students to work not only with clients but also with AI. This emerging branch of study involves more than just employing AI in educational and assistance settings. It encompasses learning how to interact with AI, leveraging its capabilities to aid people. This approach is crucial for preparing future professionals to navigate an increasingly AI-integrated world.

Through this lens, AI is viewed as a collaborator in problem-solving processes, enhancing human capabilities rather than supplanting them. This collaboration marks a significant shift in educational practices and professional development, reflecting a holistic understanding of AI as an integral component of modern educational systems and psychological practices. This shift highlights the importance of fostering AI literacy and competency among students and professionals, ensuring they are equipped to effectively utilize AI in their respective fields.

6. Discussion of the results

The findings of this study align with other research on AI's capabilities in content generation and its limitations and advantages in science and creativity compared to human output [22, 25]. Our focus on humanitarian, psychological, and philosophical texts offer a different perspective compared to Tsidylo and and Esteve Sendra [26], who examined AI's potential in design. The observed specifics in ChatGPT text generation, such as lower creativity levels and limited logic, resonate with the findings of Lucey and Dowling [13], who noted ChatGPT's adequacy in generating scientific articles for journals.

Table 3. Roles and responsibilities in AI interaction and facilitation.

Aspect in AI interaction and facilitation	**Prompt engineer**	**AI user facilitator**	**AI facilitator**
Primary role	Designs and optimizes prompts for AI interaction	Assists and guides users in effective AI usage	Guides the integration and application of AI in specific contexts
Focus	Technical structuring of prompts	Enhancing user experience and engagement with AI	Ensuring effective use of AI in operational settings
Skills required	AI language models expertise, programming skills	Communication, user engagement strategies	Management skills, AI operational knowledge, problem-solving
Objective	Accurate AI understanding and response	User clarity and proficiency in AI interaction	Optimal AI usage in specific operational environments
Outcome	Efficient AI responses	Improved user-AI interaction and satisfaction	Effective and seamless AI integration
User interaction	With the AI system	With users, providing guidance and support	With operational teams using AI
Problem-solving	Technical (e.g., refining prompts)	User-focused (e.g., resolving usage challenges)	Operational (e.g., adapting AI to specific needs)
Knowledge base	AI systems, language processing	AI capabilities, user experience principles	AI applications in specific industries or sectors
Industry role	AI development or research	User support, training, education	AI integration in business or operational settings

AI and chatbots show promise for innovative learning forms, especially in student collaborations [12], and in the development of critical thinking skills [5, 20, 27]. This study further explores AI's role in analytical tasks for psychology students, contributing to the effective realization of AI's positive potential in education and training. This includes process optimization [28, 29] and the development of emotional artificial intelligence in future specialists [30].

The general potential of AI and chatbots in education, as outlined by sources like [14, 31], underscores the importance of our research in finding optimal ways to implement chatbots in the professional training of psychologists.

Despite AI's limitations in creativity and critical thinking, there is a consensus among researchers about AI's significant potential in education, enhancing the training system for specialists, and the need for further exploration of the educational potential of different AI models. Our study contributes to this body of research, particularly in the context of training psychologists, and suggests that the educational potential of various AI models for psychologists and other professionals warrants further investigation.

This discussion indicates a growing recognition of AI as a versatile tool in the educational sector, capable of complementing human efforts, especially in areas requiring high cognitive and emotional skills. It points to a future where AI is seamlessly integrated into educational practices, enhancing learning experiences while also addressing its limitations through ongoing research and development. The integration of AI in educational settings, particularly in psychology, offers an opportunity to revolutionize traditional pedagogical approaches, making education more adaptive, personalized, and efficient.

The study highlights the necessity for educational institutions and educators to adapt to these technological advancements. This adaptation includes not only the integration of AI tools into the curriculum but also the development of new pedagogical strategies that leverage AI's strengths while mitigating its limitations. It also underscores the importance of preparing students to interact effectively with AI, equipping them with the necessary skills to utilize these technologies in their future professional practices.

In summary, the role of AI in education, specifically in the field of psychology, is multifaceted and evolving. While AI can augment the educational process, its limitations in areas like creativity and critical thinking must be acknowledged and addressed. This balance between leveraging AI's strengths and compensating for its weaknesses is critical for the effective integration of AI in educational contexts. The future of educational psychology may well involve a symbiotic relationship between human cognitive and emotional capabilities and AI's computational efficiency, leading to enriched learning experiences and enhanced professional training. This evolving landscape calls for continuous research, development, and adaptation in educational methodologies to fully realize the potential of AI in shaping the future of education.

7. Conclusion

The integration of artificial intelligence into the educational landscape, particularly in the field of psychology, represents a paradigm shift in how education is delivered and experienced. Our study has illuminated AI's potential to revolutionize traditional educational practices, offering innovative, individualized, and efficient learning experiences. However, it also underscores AI's limitations in areas such as creativity, critical thinking, and emotional intelligence, aspects where human cognitive abilities still hold an edge.

The comparative analysis of essays written by psychology students and AI chatbots like Claude 2.1 and ChatGPT 4 has revealed distinct differences in creativity, depth of thought, and emotional expression. This underscores the unique contributions that human insight brings to the educational process, contributions that AI currently cannot replicate.

Despite these limitations, AI's role in augmenting the educational process cannot be understated. Its ability to handle routine tasks, provide instantaneous feedback, and offer a vast repository of information makes it an invaluable tool in an educational setting. This integration, however, necessitates a re-evaluation of educational methodologies and the development of new pedagogical strategies that balance AI's computational prowess with the nuanced understanding and emotional depth of human instructors.

Moreover, the emergence of roles such as prompt engineers, AI user facilitators, and AI facilitators reflects the growing complexity and interdependence of human-AI interactions in educational contexts. These roles highlight the necessity for educators and students alike to develop a deep understanding of AI capabilities and limitations, ensuring that AI tools are used effectively and ethically.

In conclusion, the future of education, particularly in psychology, lies in a synergistic relationship between human and artificial intelligence. This partnership promises to enrich learning experiences, foster innovation, and prepare students for a rapidly evolving technological landscape. Continuous research and adaptation in educational methodologies are essential to fully realize AI's potential in education, ensuring that it complements rather than supplants the human elements that are central to the learning process.

Abstract. Humanity's transition to sustainable development requires society to have a culture of decision-making that takes into account the long-term perspective of interaction with complex systems that demonstrate a non-linear response to impacts. Modern school education does not teach to make such decisions, which may be one of the reasons why modern schooling is in crisis. To provide useful experience for real-life decision-making, the authors propose including interaction with simulation models in education. In this work, we talk about the experience of independently creating and using such a model in the educational process. The authors proposed a model that teaches how to find optimal ways of using fish stocks in several interconnected water areas. In honor of the experience of the Republic of Palau popularized by David Attenborough, this model is named Palau model. The dynamics of such a system are counterintuitive, where restrictions on fishing ultimately lead to an increase in fish catches. The work describes the logic behind the Palau model calculations and discusses its implementation using the R language that facilitates the study of its properties. In the 2021 pedagogical experiment, the model was implemented using Google Sheets for 10th and 11th-grade high school students. Despite the lack of experimental data, the experiment showed the admissibility of using such models in the real educational process. The authors consider the development and testing of similar educational tools to be promising.

1. Why should humanity move to a way of decision-making that ensures sustainable development?

Sustainable development is a way of effective interaction with the surrounding world today, which will not eliminate the possibility of such interaction in the future [1]. The social, ecological and economic foundations of sustainable development cannot be properly implemented without the creation of education system that will teach people to effectively improve these areas of life in the long term. In our opinion, education is a key link for all pillars of sustainable development and should be given special importance.

Ensuring humanity's transition to sustainable development requires changes in the decision-making algorithms concerning the interaction of people and their groups with the environment. The way humanity has been making decisions throughout its history is not conducive to the sustainability transition. Is it possible to hope for a change over time? If so, what do we need to do to make this change happen?

In democratic countries, the decision-making mechanism of the authorities is heavily influenced by the mood of the voters. This influence often leads to the prioritization of "quick fixes" over sustainable solutions. In such cases, voters tend to support actions that will improve their immediate conditions, rather than those that address long-term sustainability. Authoritarian countries are focused on ensuring the stability of the regime at the moment before the priority of ensuring the stability of relations with the environment in the long term. In such conditions, hopes for coordinated changes in the course of action are unrealistic.

So, how can we help society make decisions that are adequate to achieve a sustainable state? Our solution is to create conditions under which citizens gain experience in making long-term decisions. Where can such experience come from? First of all, it should be provided by the education system. We believe that professionals planning society's transition to sustainable development should contribute to the restructuring of school education. Students should learn problem-solving skills that can be scaled and developed to contribute to humanity's transition to a sustainable state.

A study of the history of such ideas development in the scientific and pedagogical literature would require separate work. Therefore, it is important to note that the described requirements for the simulation model developed and tested by the article's authors are based not on the ideas expressed in the literature, but on our pedagogical experience.

2. Education system crisis and its disconnection from real life

We believe that the modern school system in Ukraine and many other countries is currently facing a major crisis. The COVID-19 pandemic has posed a significant challenge for the education system as it has shifted many students from full-time to distance learning. The full-scale invasion of the Russian Federation has become a much more powerful destructive factor, causing many students to become internal and external migrants and leading to the closure or destruction of many educational institutions. Strangely enough, in many cases, these processes have given new meaning to the continuation of the educational process: the main thing is that it continues despite the terrible obstacles. However, assessments of the effectiveness of education, such as the Program for International Student Assessment (PISA) [2], show that its quality is declining.

Despite the current problems, it should be noted that the substantive crisis in Ukrainian education began much earlier, even before the COVID-19 pandemic. Students were losing their understanding of why they should learn, and teachers were losing their understanding of why they should teach. We believe this is a consequence of the disconnect between typical school activities and the requirements that life has placed on a school graduate.

Success in life is a culmination of productive interactions between an individual and their surrounding systems, which include oneself, potential partners, social structures, organizations, working tasks, and the environment. To equip students with the necessary skills to tackle important life tasks, modern schools rely on traditional educational approaches such as examples, tests, questions, and occasionally "creative" works within a certain canon (table 1).

School tasks and life challenges are very different. School tasks and life challenges are two distinct domains. It is possible that individuals who excel in both areas possess a natural aptitude for problem-solving, and did not acquire it solely through academic preparation. Some people may be successful in solving problems in a certain area, but not in others, because they have not been trained in systems thinking...

3. Changing the nature of learning approaches

The organization of learning activities at school is largely explained by historical reasons. Comenius's classroom lesson system proved to be surprisingly effective for its time. At the same time, many features that ensured its success are now a thing of the past. Teachers are no longer the only source of knowledge and learning materials are no longer limited to printed books and lost their emotional value. Today's students are developing in a much more complex environment that offers a variety of alternative sources of information.

Table 1. Features of traditional learning tasks and target systems in real life.

Feature	Traditional learning	Target system in life
Complexity: the number of causal chains that determine system behavior	Simple: for understanding, it is enough to trace a single cause-and-effect chain	Complex: behavior is determined by the interaction of several causal chains
Correspondence of the causes that determine the system behavior to the branches of science	One-field: issues related to one academic subject are considered	Interdisciplinary, not limited by our usual division of sciences and academic subjects
The completeness of information about the important system properties	Full information (which is usually given in the terms of the assignment)	Incomplete information; we have to make assumptions about important aspects
Determinism: whether the initial conditions completely determine the outcome	Deterministic: the conditions of the problem uniquely determine its only correct answer	Non-deterministic (stochastic): conditions determine the probability distribution of possible outcomes
Dependence of the system's response on the nature of the impact on it	Linear: the change in the system is proportional to the effect on it (there will be more water in the pool if more water is poured into it)	Non-linear, often threshold or paradoxical, counterintuitive: the response of the system can even be oppositely directed relative to the influence on it
Emotional involvement in solving the task	Relative detachment: tasks are performed to obtain external approval or reinforce the self-image	Life involvement: the success of solving life problems is the success of the person

For instance, a student who is not interested in traditional classroom learning may be more engaged in interactive computer games. Finding solutions to problems posed by such games also involves effective interaction with classmates and other people.

In our opinion, one of the best solutions for the effective restructuring of school lessons is the widespread introduction of individual and group work with interactive digital models into school activities. These models' tasks should be closer to the properties of the target systems in life (table 1), rather than traditional learning tasks.

To ensure such an evolutionary change, certain point changes should be selected that can become positive examples of future-oriented changes. Let's look at one such example.

4. Two types of approaches: traditional and modeling

Let's look at the described difference with an example, starting with a traditional learning task.

Suppose a modern trawler can catch and process 120 tons of fish per day. Then, will one such ship suffice to meet the annual consumption of 20 kilograms of sea fish per capita for the entire population of Ukraine (which is estimated at 40 million)?

The biggest drawback of this task is its reliance on linear logic, where the response to human actions is always the same: more fishing – more catch. But we live in a world that works according to other laws, and often catching more means getting less! This example is not the worst. It is clear how the task is related to life (not a bad option in terms of engagement). The task has so-called "Interdisciplinary connections" – going beyond one field. However, it is still a simple deterministic linear system that includes all the information necessary for the solution. If a trawler catches 120 tons per day, it will catch 3,600 tons in a month...

This logic leads to a planetary crisis caused by the depletion of fish stocks. In 'A Life on Our Planet' [3], David Attenborough highlights the experience of the Republic of Palau, where fishing is one of the main industries. A complete ban on fishing in certain waters of this island nation has increased the total fish catch. Fish reproduce in protected areas, settle in the surrounding waters and, ensure a stable fishery. Let's discuss the following task.

There are several bays along the perimeter of the island where commercial fish live. The number of fish is affected by various factors such as:

- *fish reproduction, which is dependent on its population size;*
- *environmental restrictions in bays (availability of food, etc.);*
- *movement between bays (fish migrate to neighboring bays if there is a free environment there);*
- *human fishing activities.*

How exactly to fish on such an island? Fishing can be allowed in all bays or only in some of them. If fishing is allowed, it can be carried out in different parts of the fish stocks. The question is which option would result in the largest annual catch in the long run.

The system of replenishing and utilizing fish stocks is complex and depends on the interaction of reproduction, dispersal, and catch. It requires a multidisciplinary description, and many of its characteristics are only approximately estimated. Its long-term future also requires further research.

The dynamics of such a system are paradoxical and counterintuitive: fishing restrictions ultimately lead to an increase in fish catch, which can be difficult to understand.

Due to the counterintuitive behavior of such systems, people who are not trained to interact with them constantly make mistakes that are much more dangerous than mistakes in solving linear school examples.

What could be easier than using not tasks like an example about a trawler at school, but tasks like fishing in Palau... But how to build such tasks, how to work with them? Such work requires a change in the very nature of educational activity!

Let's say we have created a simulation model that visualizes the dynamics of fish reproduction, settlement, and catch in a region. This is a program that can work both online and offline on a computer, tablet, or smartphone. This model can be used in demonstration, interactive, and research modes.

Let's define a water area in the model that is divided into sites. Fish can live and reproduce in these sites if there are sufficient resources; they can also move to neighboring sites. Reproduction depends on the number of sires and available resources. Fish are caught by fishing vessels; the catch depends on the number of fish in the site. The user sets the number of fishing vessels and sites with fishing. The task is to maximize the catch in the long run.

In the demonstration mode, the teacher can show how to interact with the model (but you can also allow the student to figure out how it works interactively).

In the interactive mode, the student sets a certain solution to a learning problem. The model then calculates all the consequences of this solution. The student receives the result of the model's work, along with the dynamics of fish production from the model, and then attempts to improve the previous solution. The work should resemble a game with excitement maintained on the principles of both a puzzle (we know it can be done, but how?) and competition (who found the best solution – you or someone else?).

The complexity of a model can be associated with an increase in the number of cause-and-effect chains that affect the outcome:

- homogeneity and heterogeneity of available resources across different sites;
- the impact of random fluctuations like hurricanes on the model's behavior;
- changing resource consumption, size, and fecundity of fish with age over time;
- different fishing methods, with different degrees of success for fish of different ages;
- economics: changes in the price of fish depending on the catch and accounting for fishing costs;
- differences in commercial fish species (less valuable planktonic fish and more valuable predators that feed on them), etc.

5. Comparison of the work nature with tasks of different types

The interactive use of models has the benefits of both traditional learning and learning through daily life (table 2).

The "higher" level of model use – the research mode – should be associated with the possibility of changing the model itself. Students will then fully understand the model when they can "disassemble" it and "reassemble" it.

The software implementation of a model is essentially a practical embodiment of a conceptual model, which can be defined as a set of input parameters (initial conditions and the solution provided by the user), along with calculated parameters and the relationships between them (formulas and conditions for their application). This set ensures the calculation of the final results. The research mode involves the analysis of exactly which relationships between parameters determine the characteristic behavior of the system. How to ensure model transparency for such analysis? Two options are possible:

(i) the same software implementation of the model can be used for demonstration, interactive, and research modes – in this case, the user has access to the "insides";

(ii) the research mode is provided by a different implementation, for example, an interactive model made in spreadsheets (no visualization, but the calculation mechanism is clearly understood).

6. How can modeling tasks be effectively implemented in schools?

Ecology, as a science of interactions, provides excellent opportunities for modeling target systems that students will encounter in real life.

To overcome the crisis of school education with the help of simulation, it is necessary to define the desired result, and then identify the steps required to achieve it. For us, the desired state of a school is one in which students are successfully taught to solve problems that are important to their fate. Graduates of this school can manage complex non-deterministic systems in conditions of information scarcity, are not afraid of the counterintuitive reaction of such systems, and know how to learn from the process. Students of such a school understand why they are studying, and teachers know how to teach such (!) students to solve such (!) problems... Achieving this ideal requires significant resources and time investment, but it is possible through the widespread use of simulation models.

Table 2. Comparison of different ways of learning.

	Traditional learning tasks	Interactive work with models	Adapting to the environment in the course of life
Task setting	The task is set by the teacher, determining the next stage of complexity of the educational work	The teacher directs the student to work with the model; the further result of the work is determined by the interaction with the model	The task is set by the process of human interaction with the environment (with his/her life)
Tasks sequence	Usually a predetermined sequence of tasks proposed by the teacher	The sequence of tasks can be ensured by gradually complicating the models	Often there is no sequence; we are surrounded by unpredictable tasks of varying complexity
Necessary foundation	Usually textual explanations: teacher's narration or textbook; own student's experience in solving previous problems is also important	Use of a model in demonstration mode or own practice with interactive use of simpler models	Sometimes it is known how others solved similar problems/learning during previous experiences or during the solution itself
Motivation	The student solves problems to fulfill the teacher's instructions; motivation is mostly external	The student follows the teacher's instructions and is stimulated by the excitement of "fighting" the model or competing with others	The person is involved in the process; sometimes evading the decision for fear of making a mistake
Evidence of success	Often, the student cannot distinguish between correct and incorrect solutions and must wait for the final grade	Success or failure of the model is quickly apparent; one can learn from the process	In most cases, the success or failure of the effort is obvious; one makes trials and errors and learns through this process
Repeated solution attempts when failing	Failed tasks can sometimes be attempted again	In case of failure, work with the model can be repeated until victory, taking into account the experience gained	Fixing a failed solution is often difficult or impossible
Result evaluation	The result of the work is evaluated by the teacher according to his/her criteria	Both the model itself and the teacher can evaluate the solution	Life itself evaluates a person's success

An intermediate step may be to create and use a set of models that can support a specific section of existing educational courses or even a new small course. What kind of school courses might we be talking about? In Ukraine, such courses are the following:

- integrated courses in biology and geography;
- a special course on modeling ecological systems;
- integrated natural science courses, including the course "Natural Sciences. Past, Present and Possible Future of Humanity and the Biosphere" [4], etc.

7. Description of the Conceptual Palau model

The implementation of simulation modelling in the school education system should start with relatively simple models. One of these models, created personally by the authors of this article, is described below.

Let's consider a territory consisting of several linearly connected areas (each bordering the other two); assume that they are connected in a ring. To visualize such an arrangement, let's take the example of an island with coastal waters divided between six bays. Each "bay" has a certain number of fish. If the number of fish is less than the carrying capacity of the environment (the number that can exist in this area), they can reproduce and increase their number. If neighboring areas are filled to different proportions of their capacity, a certain number of fish move from the more filled area to the less filled.

The fish stocks of this "island" can be exploited. Fishing can take place in certain areas. The pattern of use (the relative location of the areas where fishing is carried out) and the intensity of fishing (the proportion of fish stocks that are removed at each step of the model) are determined by the user.

The main task that can be solved with this model is maximizing fish catch in the long run.

The described model can be characterized by the following main parameters:

- n is the number of areas corresponding to the bays along the island's perimeter that form a ring; in this particular example $n = 6$;
- K is the habitat capacity (Verhulst parameter) – the number of fish for which there is enough resource on the site; the capacity of different sites may be different or, as in the examples considered, the same;
- r is biotic potential (Malthus' parameter) – a measure of the fish stock's ability to reproduce; the proportion by which the number of fish increases for each step of the model if they do not feel the limitation of the number of resources they need;
- m (mobility) is a measure of fish ability to move between neighboring areas; movement should be calculated based on the m measure and the difference between the occupancy of fish in neighboring areas;
- u (use) – the intensity of use of the areas where fishing is carried out, the share of fish stocks that are removed at each step of the model;
- *pattern* – relative location of areas where fishing takes place.

How to characterize the pattern of site use is not an easy question. In the case of six sites with the same environmental capacity, we can specify 13 options for the relative location of protected and exploited areas.

In general, the pattern of use of 6 identical plots can be explained by the diagram (figure 1).

The scheme (figure 1 A) shows 6 sites with possible transitions between them.

The number of fish in the i-th site (N^i), as schematically shown for site #1, increases proportionally to r, but this growth is limited by the capacity of the environment K according

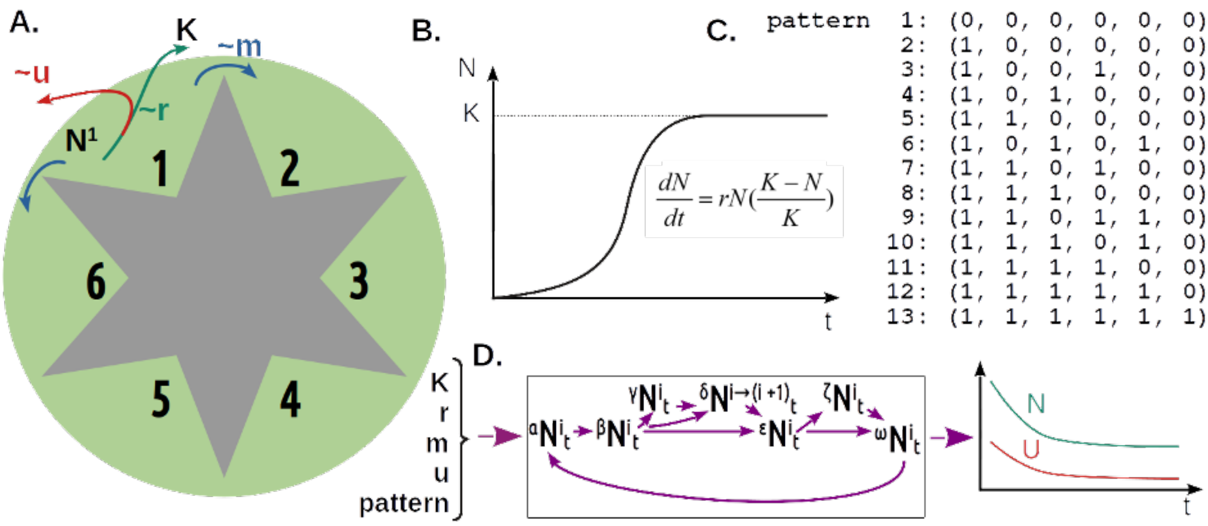

Figure 1. Scheme of the Palau model.

to the logistic model (shown next to it, figure 1 B). A decrease in the fish amount reduces the catch (if its pattern involves the use of the corresponding site); this catch is proportional to u.

If K is the same at all 6 sites, there are 13 different patterns of their use (figure 1 C): *pattern* 2 (one site is exploited) equally corresponds to cases where any of the 6 sites are exploited (because they are the same); *pattern* 1 corresponds to the absence of exploitation, and *pattern* 13 corresponds to the simultaneous use of all sites.

The main logic of the model is presented visually (figure 1 D). The set of input parameters determines the main calculations. At each cycle of the model work, the number of fish at each site is recalculated – from alpha numbers, ${}^{\alpha}_{t}N^{i}$, to omega numbers, ${}^{\omega}_{t}N^{i}$. The index i in these notations corresponds to the site sequence number, and t to the cycle of the model work. The output is presented as dynamics of fish amounts at each site (and the dynamics of the total number, N), as well as the dynamics of catch (total catch, U).

As will be explained below, the meaning of the stages of population recalculation is as follows:

- alpha numbers (${}^{\alpha}_{t}N^{i}$), the initial numbers of fish at each cycle;
- beta number (${}^{\beta}_{t}N^{i}$), the number of fish after reproduction;
- gamma number (${}^{\gamma}_{t}N^{i}$), the number of fish that would be achieved in case of their complete redistribution between sites i and $i+1$;
- delta numbers (${}^{\delta}_{t}N^{i\to(i+1)}$), the number of fish moving from site i to site $i+1$;
- epsilon numbers (${}^{\epsilon}_{t}N^{i}$), the number of fish in the sites after the relocation;
- zeta numbers (${}^{\zeta}_{t}N^{i}$), the number of fish caught from the site;
- omega numbers (${}^{\omega}_{t}N^{i}$), the final number of fish at each cycle (after capture).

8. Properties of the Palau model

We developed a system and created the Palau model in the R environment to study its properties. The R language script, which includes detailed explanations, is freely available on the Internet [5]. We implemented a variant with six identical sections that considers the combination of patterns of site use (the relative location of protected and fished bays) and fishing intensity in those areas open to exploitation, given a rate of reproduction (r) and mobility (m). The model calculates the dynamics of fish stocks and catches during 200 cycles (conditional years) for each selected combination of parameters. During this time, the system enters a stationary state, where fish stocks and catches become stable. The success of the exploitation of reserves is determined by the average total catch (for all exploited areas) during the last 20 cycles (from 181 to 200 cycles of model operation). The results obtained from the model can be viewed both numerically and on a 3D diagram (figure 2).

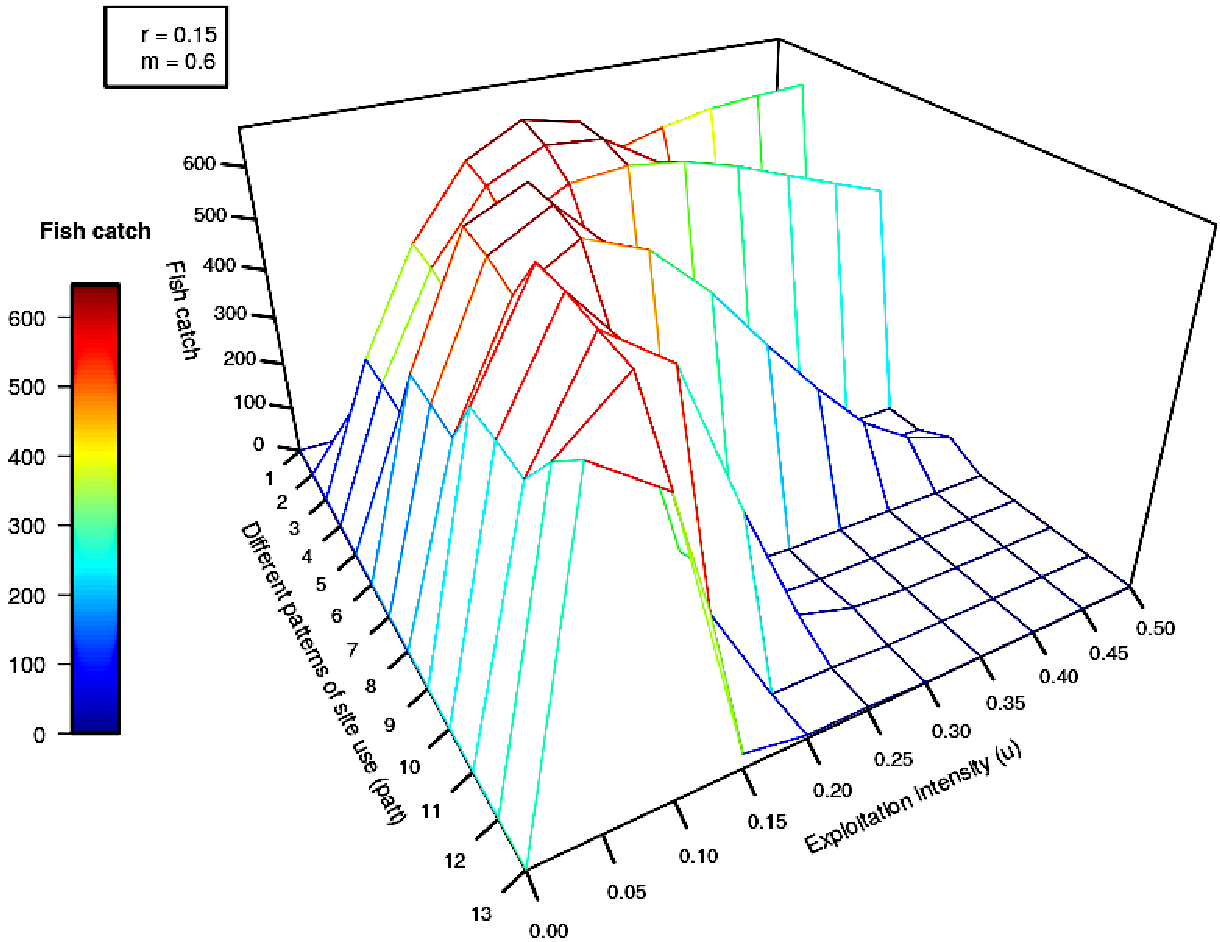

Figure 2. Results of visualizing the average catches for different patterns of area use and levels of exploitation, for a chosen value of fish reproduction and migration rates. The X-axis reflects the different degree of exploitation of the area – from a complete prohibition of fishing to catching half of the fish present in the area. The Y-axis shows catch volumes (for ease of understanding, the numerical values correspond to the color scale shown on the side). The Z-axis shows the beginning of each of the 13 patterns of site exploitation discussed.

In figure 2 shows several characteristic features of the model. In general, the model shows a more efficient use of fish stocks in the presence of protected areas, particularly in the case of relatively intensive fishing with exploitation. An increase in catch in response to increased exploitation occurs only when protected areas surround exploited areas, under the condition of high mobility of fish stocks. Even the presence of individual protected areas does not protect fish stocks from depletion in case of high intensity of exploitation. This is a consequence of the cessation of the reproduction of fish in case of a decrease in their number below the critical limit.

The optimal operating method depends on the interaction of several factors and their interaction is relatively unpredictable. To optimize the operating mode of a system, it's necessary to experiment with it and observe how it reacts to different settings.

The model we created in R is similar to real life in several ways. We believe that non-"survey" models, like the one we built, are more effective when working with schoolchildren. It is better to start with models that respond dynamically after a specific mode of operation is selected. Schoolchildren can study the properties of such a system based on the results of a series of attempts. "Review" models can be useful at a later stage to integrate the acquired experience.

9. Testing the concept in the school learning process

In 2021, we conducted a pedagogical experiment to test a new model in the educational process. We analyzed the work of 85 students in the 10th and 11th grades of the Public institution "Kharkiv University Lyceum of Kharkiv City Council Kharkiv region". This educational institution started to implement the experimental integrated course of natural sciences "Past, Present and Possible Future of Humanity" according to the program [4].

The lessons were held in two blocks: "A. Scientific Method and Natural Sciences" for 10th graders and "M. Agriculture as a Source of Substances for Humanity" for 11th graders. Both blocks used mixed types of lessons that involved interactive teaching approaches. Two different methods were used for teaching – traditional and interactive. Students taught in alternative ways took a common test after the lesson. The test was related to the topic covered but did not contain elements that were directly related to the material considered in the traditional or interactive form.

The students in each class were divided into two groups randomly by picking a candy of one of two colors from an opaque bag. The students who were taught within the traditional approach were assigned to read the learning materials in the form of text with bar charts, illustrations, and videos by following the link [6]. On the other hand, students who worked with the interactive model were given links to instructions on how to use the model [7] and how to implement the model using Google Sheets.

The knowledge gained in the course of studying this topic was tested using a test using Google Forms. The test included reproductive, competency, and general erudition tasks. Statistical analysis of the results was done using non-parametric Mann-Whitney and ANOVA comparisons.

The analysis of the final test results revealed that 11th-grade students performed better than 10th-grade students. However, no significant difference was found in the distribution of final test results between the traditional and interactive learning methods. Nevertheless, a statistically insignificant trend was observed, indicating that the use of interactive learning methods led to a slight decrease in academic achievement of less prepared students, while more prepared students showed a certain improvement.

Unfortunately, the model testing was interrupted due to the Russian Federation's attack on the Kharkiv region, which resulted in the disruption of educational institutions' work. Despite this, it was possible to establish that the use of simulation models instead of traditional teaching methods did not negatively affect the students' performance but is promising for future improvements. Therefore, it can be concluded that the use of simulation models in the educational process is acceptable.

10. Prospects for further research

Even though the experimental study of the Palau Model was disrupted by intense hostilities resulting from the aggression of the Russian Federation, the authors believe that it is extremely important to create, test, and implement similar models in the educational process. However, the application of the approach described in this paper is constrained not only by technical problems. To integrate promising forms of education into the educational process, it is necessary to restructure it. This restructuring should form the basis of ensuring sustainable development, starting from the school desk.

Acknowledgments

The authors are grateful to the administration of the Kharkiv University Lyceum of Kharkiv City Council Kharkiv region, for supporting the possibility of conducting a pedagogical experiment with the proposed model. Student Yaroslav Tsehelnyk and teacher Andrii Liashenko participated in the experiment. The authors express their sincere gratitude to them.

Abstract. One of Ukraine's Sustainable Development Goals is to ensure inclusive and equitable quality education and to promote lifelong learning opportunities for all citizens. Therefore, it is important to develop the professional skills and pedagogical competence of teachers to prepare future generations to achieve the Sustainable Development Goals through education. In particular, through the digitalization of education. The purpose of this article is to highlight the state of use of digital technologies and innovative approaches by teachers of Kryvyi Rih district in the context of blended learning in the context of sustainable development of society. The problems of development and use of video materials and interactive tools, virtual simulations, workshops and laboratories in teaching are considered. The issue of using game technologies for learning is highlighted. The use of platforms for collaboration and exchange of views between students and the use of e-learning systems is analysed.

1. Introduction

Today, digitalization is seen as an important driver of socio-economic development [1, 2]. The educational system, determining the social profile of the country's future, plays an important role in society. In particular, as a factor in eliminating inequality among citizens. One of the Sustainable Development Goals of Ukraine, as stated in the Presidential Decree [3], is to ensure inclusive and equitable quality education and to promote lifelong learning opportunities for all citizens [4].

Preparing generations to meet the Sustainable Development Goals is a major challenge. The use of cloud technologies [5–11], augmented reality [12–24], the development of tools for collecting and analyzing Big Data, 3D printing, etc. are changing both various sectors of the economy and society as a whole. This requires the training of a teacher who is motivated and able to participate in the creation of a new school based on the widespread use of digital technologies, cooperation and mutual understanding between all participants in the educational process.

Therefore, a modern teacher should be focused on professional and personal growth throughout his or her teaching career. Education for sustainable development is lifelong and includes all levels and categories of education and training. This includes formal education, including secondary and higher education, as well as retraining and re-qualification. In non-formal education, self-education, including for people of retirement age, is the mainstay.

In the context of the unstable security situation in Ukraine, a significant number of higher and secondary education institutions have been forced to switch to online or blended learning. This has become a serious challenge for many participants in the educational process. Many studies show significant educational losses caused by the inability to fully conduct classes. The difficulties of transitioning to online learning are especially noted by future teachers who are undergoing internships in educational institutions. This has revealed serious shortcomings in the pedagogical integration of ICTs, raising awareness of the need to develop digital competencies for each of the participants in the educational process.

The appropriate use of digital technologies in education will help make the learning process effective, accessible and motivating for students. It will help to ensure that the Sustainable Development Goals are met.

2. Theoretical background

Sustainable development is development that meets the requirements of the present without compromising the ability of future generations to meet their own needs. Fedulova [25] characterizes the global trends in the development and implementation of digital technologies to achieve the goals of sustainable development in the context of digitalization of the economy and society, and identifies key tasks in this area for Ukrainian science and public policy. The author identifies the following trends: 1) the complex impact of Industry 4.0 technologies on the achievement of the Sustainable Development Goals; 2) digital technologies as a driver of a new stage of sustainable development and opening of new markets, which concerns the activities of large corporations; 3) the intensification of international organizations in the transfer of digitalization policy.

García-Hernández et al. [26] note that adequate use of ICT is necessary to promote educational practices that contribute to sustainable development. The systematization of research in this area is seen as an opportunity to contribute to existing theories and practices related to the use of ICT and the development of the Sustainable Development Goals. According to the challenges, the authors identify innovative proposals that can be used to address sustainable development issues. In particular, the development of sustainable technological tools can be ensured through the creation of virtual tools or courses for quality education, and e-learning strategies need to be improved to ensure equitable and quality education.

Jeong and González-Gómez [27] consider mathematics education as a cornerstone for sustainable development. However, the problems of sustainable development are related to the typical issues of ecology and economy in the educational sphere. The authors note that, under the influence of modern ICT, changes in pedagogy lead to significant contradictions in teaching/learning mathematics. This study attempts to classify and investigate the criteria of mathematics education using the method of multi-criteria decision analysis/testing laboratory and fuzzy decision evaluation in the context of a flipped e-learning system.

Hilty and Huber [28] investigate the motivation of ICT students to study specific topics in the field of sustainable development.

Al-Rahmi et al. [29] highlight the problems of usng ICT for sustainable development of education. The authors analyze the factors that influence the intention to use ICT in education and their satisfaction with this use.

Serhiienko [30] defines that the tasks of education for sustainable development are reorientation of existing curricula towards social, economic, environmental knowledge and perspectives; formation of experience and values necessary for sustainable development; training of personnel in the interests of transition to sustainable development and further development of education for sustainable development.

The problems of digitalization of education are reflected in the work by Dziabenko et al. [31]. Among the tools of digital technologies, the authors distinguish tools for communication, collaboration, content creation, work organization, search, video and audio, and mobile applications. Educational trends include, in particular, practice-oriented learning, competence development, personalization, STEAM education, and entrepreneurship development. The authors of the study note that the most popular pedagogical technologies are research-based learning through the use of ICT, blended learning, maker education, formative assessment, integrated learning and inclusive education technologies.

Kartashova et al. highlight the technology of digital twins for blended learning in educational institutions [32]. This will provide free access to educational resources and networking for students.

Kuzminska et al. [33] study the problems of forming digital competence of students and teachers in Ukraine. In particular, measurement, analysis, and development prospects.

Mintii [34] notes that today, blended learning is characterized by studies that consider practical experience of implementation. The leading approaches to the organization of blended learning are highlighted: by the method of combination, by ICT tools, by appropriate pedagogical technologies.

The studies discussed above actualize the issue of forming professional skills and pedagogical competence of teachers to ensure the Sustainable Development Goals of society through education. There is a lack of research that would systematize innovative proposals that contribute to solving the problems of sustainable development of education. This is especially true for inclusive education and education in an unstable security situation.

3. Methodology

During 2021-2023, we monitored the use of digital technologies by mathematics and computer science teachers during their internships in educational institutions of the Kryvyi Rih district in a blended learning environment. We also conducted a survey on the use of online tools by math teachers during their professional development courses. Almost ninety teachers answered the questionnaire about the use of digital technologies during this period.

As part of the teacher training courses, we invited experienced math teachers to share their practice of using digital technologies in blended learning. At the same time, invited guests and experts took part in discussions, answered questions from students to expand their knowledge and improve their skills in using online tools.

The purpose of this article is to highlight the state of use of digital technologies and innovative approaches by teachers of Kryvyi Rih district in the context of blended learning in the context of sustainable development of society.

4. Results

Blended learning involves traditional classroom training with online learning; online learning with the possibility of contact with a teacher; simulation with structured courses; on-the-job training with some informal classes; management coaching with distance learning activities [35]. In Ukraine, various blended learning models are currently being implemented that allow for the most appropriate combination of group learning with independent study, small group work, technology integration, and a combination of face-to-face, synchronous, and asynchronous distance learning. It is important to ensure personalization of learning, take into account the individual needs of each participant in the learning process, and promote their high expectations of the learning process. The organization of blended learning requires careful selection of learning content, the use of modern technologies, and the creation of an effective learning environment.

4.1. Use of video materials and interactive tools

To provide asynchronous learning, teachers/lecturers widely use video lessons created by themselves or selected from the Internet. By creating video lessons, they can demonstrate appropriate teaching methods and solving typical problems. Among the most popular platforms and tools that are most often used, YouTube [36] is the most popular. 100 % of respondents use the lessons they find that are useful. 37 persons (43.0 %) said that they periodically create or upload their own lessons to YouTube.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012013 doi:10.1088/1755-1315/1415/1/012013

This is due to the possibility of providing easy access to video lessons for students, using the platform's video editor to add explanations, animations, and other elements. Very often, teachers/lecturers record live online lessons in Zoom (42 persons, 48.8 %), Google Meet (12 persons, 14 %)), or Microsoft Teams, which can be used for later viewing. In this case, they use the functions of the on-screen part and annotations to explain various concepts in detail. Teachers who do not record lessons in a blended learning environment mentioned the following reasons: fewer students participate in the lesson if the recording is made public later. Some students are embarrassed to know that their answers are being recorded and will be made public, even within the classroom. Recording impairs access to the network for some students, especially in rural areas, areas with significant destruction due to war, etc.

For future teachers to be able to freely create video lessons that are understandable to students, they need to prepare them in advance by completing similar tasks.

Some students noted that they used the Khan Academy platform (17 persons, 19.7 %), which has a built-in video editor and other tools, to create video lessons and study subjects. Teachers often used the Geogebra [37] dynamic math system to create video lessons, including interactive demonstrations and graphs (32 persons, 37.2 %). The teachers interviewed noted that Camtasia and Screencast-O-Matic, although they have free versions, were not used to record the screen and edit the video, add tips, animations, and sound.

Teachers widely use virtual whiteboards, such as Jamboard (63.1 %), Clever Maths (27.4 %), and Zoom Whiteboard (79.8 %), to prepare and deliver online lessons (see figure 1). Some teachers reported positive experiences with Miro (6.0 %), One Note (9.5 %) and Idroo (20.2 %) virtual whiteboards (figure 1). As practice has shown, a particularly high learning effect is achieved if participants in the learning process write synchronously on the board using a graphic tablet, special styluses, etc. Even if there is a multimedia whiteboard in the classroom, it is better to use virtual whiteboard software to ensure online collaboration. Virtual whiteboards in education can be used to simplify teaching, make explanations more accessible, and engage students in collaboration by providing different levels of access. It is convenient to use a virtual whiteboard to create concept maps or diagrams to visualize the connections between different topics.

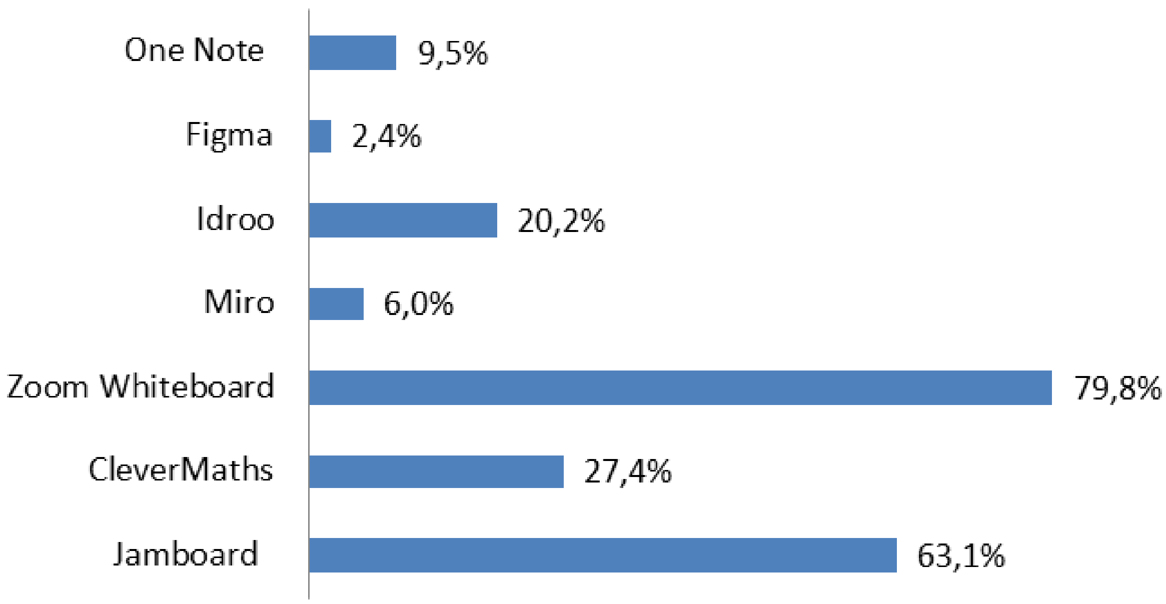

Figure 1. Statistics on the use of virtual whiteboards by math teachers in blended learning.

Padlet, an online collaboration tool, is widely used (40.7 %). Using Padlet, students create, add and discuss various tasks. The use of these interactive tools can make it easier for students to learn new things, giving them the opportunity to master the materials more efficiently.

From our own experience of training future mathematics teachers, we can note that an increase in the level of methodological competence can be achieved if online lessons are developed by a group of students using one textbook. Then students, discussing their own lessons with colleagues, will realize the importance of ensuring continuity, implementing intra- and interdisciplinary connections. The developed lessons, along with other selected visualizations, were placed in an e-learning course on the Moodle platform.

4.2. Use of virtual simulations, workshops and laboratories

Teaching mathematics in the context of sustainable development of society is relevant in the context of STEM education, successful mastery of future IT specialties, etc. [38–40] Simulations [41–44] and virtual laboratories [45, 46] provide students with the opportunity to experiment, learn, and visualize natural and mathematical concepts. Such tools are especially useful when implementing STEM approaches in education. Among the popular platforms, we note PhET Interactive Simulations and GoLab (Global Online Science Labs for Inquiry Learning), which have an interactive and intuitive interface and provide a large number of free simulations in physics, chemistry, biology and mathematics, including game elements. The study considers the scientific and theoretical underpinnings of immersive technologies in mathematics teaching, as well as methods for using the AR-Book application [47].

Using these platforms, you can personalize the educational trajectory of each student. Participants in the educational process will choose a convenient time and pace for studying the material.

Before using a particular simulation, the teacher/educator should establish the purpose of the application, using leading questions to encourage students to think critically about it. Körtesi et al. [48] focus on learning and teaching mathematics and analyze the role and usefulness of ICT tools in education, such as computer algebra systems and dynamic geometry systems in the implementation of active and innovative teaching methodologies related to sustainable STEAM education.

Among the specialized programs and tools for teaching mathematics, Ukrainian teachers most often use the visual and interactive platform GeoGebra (32 persons, 37.2 %), specialized in geometry, algebra, trigonometry, and calculus, to study specific mathematical topics. Geogebra has not only interactive geometric object designers, but also virtual laboratories for learning algebra, geometry, statistics, and other areas of mathematics. A much smaller share uses Wolfram Mathematica (9 persons, 10.5 %), GRAN educational and methodological complex (12 persons, 14.0 %) and SageMath (6 persons, 7.0 %). Desmos is widely used by math teachers in their teaching practice (41 people, 47.7 %). The results of the survey are presented (figure 2).

4.3. Game technologies for learning

Gaming platforms are a convenient tool for creating educational games [49] aimed at consolidating math knowledge. It is an effective way to engage students and make learning fun. Pertegal-Felices et al. [50] compare the impact of the Kahoot tool on the training of teachers and students of computer engineering for sustainable development of society. To ensure quality education, the authors make proposals for gamification using ICT to increase the likelihood of success and sustainability of educational institutions.

LearningApps as a multifunctional platform is used to create interactive exercises. It is very popular among domestic teachers/lecturers because it is easy to use, allows you to quickly create different types of exercises for active learning and testing the level of students. The WordWall application is similar to the interactive environment of LearningApps, but has more templates

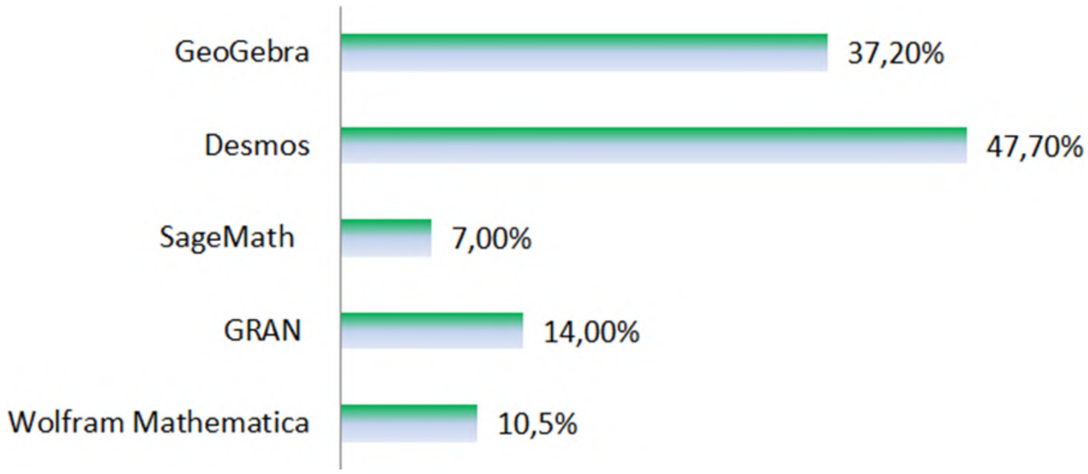

Figure 2. Statistics on the use of specialized programs and tools in teaching mathematics.

and functions. WordWall interactive exercises can be played on any web-based device, such as a computer, tablet, phone, or interactive whiteboard.

Kahoot allows you to create quizzes and question-and-answer games that can be used to test knowledge on various math topics and for formative assessment [51]. Quizizz is similar to Kahoot, allowing you to create question and answer games, but with a greater emphasis on the independent pace of students. It is advisable to combine surveys and the use of a smartphone with the online application Mentimeter.

53 teachers (61.6 %) reported using LearningApps exercises, 17 (19.8 %) – WordWall, 14 (16.3 %) – Kahoot, 6 teachers (7.0 %) – Mentimeter.

The following platforms are practically not used by Ukrainian teachers. Prodigy offers an online game that combines math tasks and adventure gameplay. The tool uses adaptive learning. Math Playground contains a variety of educational games, tasks, and puzzles to help students consolidate their math knowledge. Coolmath Games offers a large selection of math games that promote logical thinking and problem solving. Hooda Math offers a number of educational games focused on different sections of math.

Graphics and gamification can play a key role in creating an engaging and effective learning experience in education [52]. They help to create a stimulating environment in which learners are motivated to acquire new knowledge. This happens through the visualization of abstractions, gamification of tasks, and the use of games with a logical load. Appropriate gamification ensures personalization of learning by adapting content and tasks to the individual needs of students. Instant feedback is important, allowing students to see the results of their actions and improve their skills.

4.4. Using collaboration and idea sharing platforms

Among a number of free collaboration and idea-sharing platforms that can be used in education, Google Workspace and Microsoft Teams are popular among teachers/educators. Google Drive, Google Docs, Google Sheets, and other Google Workspace tools allow you to create, edit, and collaborate on documents and spreadsheets in real time. More than half of the teachers surveyed said that Google Meet is their preferred tool for online lessons (63 persons, 73.3 %).

Zoom is a video conferencing platform that allows teachers and students to communicate and conduct online lessons. In secondary education, teachers say they use the free version (71 persons, 82.6 %).

Platforms such as Slack, Discord, Trello, Asana allow students and teachers to work together, exchange ideas, create joint projects, and provide a user-friendly interface for real-time or asynchronous collaboration. However, these resources are not yet used by the teachers surveyed.

Organizing open discussions and interactions through online forums and discussion platforms can greatly enrich the learning process. For this purpose, it is advisable to create thematic forums, highlighting thematic sections or topics according to the sections of mathematics, so that learners can more easily find and discuss specific issues. It is important to promote the activity of participants by encouraging them to comment, add to and express their own opinions. It is advisable to establish a reward or rating system for active participants. The teacher should maintain an open dialog. In particular, to engage students in discussion by asking somewhat provocative questions, questions that are of interest, will stimulate their thinking and analysis. It is also worth considering delegating roles, such as moderator, to help organize and support discussions. Interactive online tools such as commenting, rating, or collapsing threads for easy navigation should be used. It is important to promote constructive communication and respect for the ideas of other participants.

Allow forum participants to add graphics, videos or other multimedia to better define their issues or illustrate solutions. It is advisable to promote collective problem-solving, stimulate discussion and exchange of different approaches to solving problems. The use of these strategies will facilitate active interaction and joint learning among participants through online forums and discussion platforms.

4.5. Use of e-learning systems

The models of blended learning that are currently used in the training of future teachers and in the professional development of existing teachers also differ due to the use of learning support systems such as Moodle, Google Classroom, and others. Open courses hosted on MOOC platforms are increasingly being used for training. The use of e-learning platforms can greatly facilitate the organization of materials, assignments and tests in training. Moodle is an open platform for creating e-courses. The advantages of using the platform and new opportunities are described by Mintii et al. [53]. Educators can download materials, create assignments and tests, and use forums for discussions. Although the e-learning system is recommended for higher education institutions and schools, we have not seen any reports in the questionnaire about the use of Moodle in secondary education institutions.

Most secondary education institutions use Google Classroom as an integrated part of Google Workspace, where teachers can create classes, add assignments, materials, and tests (71 persons, 82.6 %) .

Education departments and a large number of Kryvyi Rih schools cooperate with HUMAN, a Ukrainian ed-tech company that develops and implements products for the digitalization of the Ukrainian educational process, taking into account different levels of logistics and digital literacy in educational institutions. HUMAN provides comprehensive digitalization of educational institutions by consolidating tools for organizing the educational process, communication and analytics in a single system. As a result, the institution receives tools for full-time and distance learning, as well as transparent statistics of the educational process.

Canvas is an e-learning platform that allows you to create courses, assignments, tests, and communicate with students. According to respondents, Canvas is increasingly being used in educational institutions.

Some teachers said that they use the ability to create classes in GeoGebra as an interactive platform as an auxiliary tool. Teachers also mentioned creating courses using social media. The national educational platform Vseosvita (over 3.5 million registered users) provides teachers with a library of teaching materials, tools for designing lessons, tests, web quests, and the ability to keep electronic journals. 63 people (73.3 %) regularly use the materials of the Vseosvita educational platform, and 52 teachers (60.5 %) use the materials of the Na Urok educational platform.

When choosing a platform, it is important to take into account the needs and capabilities of students, as well as to determine which one best suits the teaching methods. Each of these platforms has its own advantages and opportunities for creating an effective learning environment. Therefore, future teachers should develop methodological competencies in the process of training to use these and potentially possible e-learning platforms in teaching students.

Tracking the progress of students and providing feedback through assessment systems should be an effective way to develop them and improve the quality of education. Let's consider strategies and tools that can be used for this purpose. It is advisable to use electronic platforms to create tasks and tests. For example, Google Forms, Moodle, or other learning management systems. Collecting data from such tasks can automate assessment and allow you to analyze the results. At the same time, use the functions of automated report generation, which can provide an overall picture of the progress of students. Such reports can include average scores, time spent on tasks, and other metrics. It is important to define clear evaluation criteria and use rubrics to assess different aspects of the work. This will allow students to better understand what is expected of them and provide specific feedback.

It is advisable to introduce different types of assessment to evaluate the quality of students' abilities and achievements, instead of limiting them to numerical grades. It is extremely important to take into account the individual characteristics of students when determining progress, to apply individualized tasks and assessments for each student. It is important to use reminder and task tracking systems to ensure that students are able to plan their time and complete their work on time. Thanks to these strategies and tools, it is possible not only to effectively track the progress of students, but also to provide them with constructive feedback for further development.

5. Conclusions

The successful use of digital technologies in education will ensure the achievement of the Sustainable Development Goals.

Blended learning, which combines traditional methods and digital technologies, can significantly improve the training of students by promoting the development of their skills and new teaching methods. This will contribute to the achievement of the Sustainable Development Goals. For the effective implementation of blended learning in training, it is advisable to integrate open online resources for the study of individual disciplines. Creating and completing interactive exercises and tasks is best organized through special platforms.

It is advisable to systematize virtual lectures and webinars, where experts can present new teaching methods or demonstrate the use of digital tools in teaching. It is important to ensure that students work practically with digital tools. It is necessary to use remote collaboration functions so that students can work together to solve tasks and solve problems. Creating online communities to discuss important topics, share ideas and resources will help build teamwork skills. In particular, through the use of forums, social networks or specialized platforms. To do this, you can provide students with feedback on their work through online platforms, taking into account both quantitative indicators and qualitative comments. This can apply to individual assignments or collective projects.

The use of adaptive technologies to individualize learning will help provide students with materials and tasks according to their needs and level of knowledge [54–56]. Blended learning allows students to acquire traditional knowledge while simultaneously becoming familiar with modern teaching methods and digital tools. It is also important to provide sufficient support and training for teachers to successfully implement these approaches. Maximizing the potential of artificial intelligence technologies in education and increasing public trust in them requires more detailed work.

In the future, in the context of ensuring the achievement of the Sustainable Development Goals, it is advisable to explore the prospects for realizing the potential of artificial intelligence technologies in education and increasing public trust in them.

Abstract. The article highlights the practical experience of implementing digital educational hubs to support civic education (CE) to ensure sustainable development. The role of the digital educational hub as a modern tool of the digital educational environment was determined. The digital educational hub is a multi-functional digital educational environment with electronic resources, tools, technologies and educational materials where organisational and pedagogical conditions are created for the acquisition of knowledge, the development of students' competencies and the effective accumulation of intellectual potential, which contributes to professional development and the implementation of innovations in practice. The purpose of this article is to investigate how digital educational hubs support civic education at school, how teachers and school leaders can use the resources of the hubs, and how teachers in Ukraine and other countries are supported in using digital tools for teaching civic education subjects, which are important for the professional development of teachers, including the development of their digital skills. The experience of using digital educational hubs supporting CE at schools in Ukraine and European countries (Belgium, Canada, Netherlands) is described. The practical significance of the digital educational hub, as a component of the digital educational environment, is to support and implement innovations in school education that contribute to the development of the personality of a modern citizen, an active member of the digital society. The novelty of the research: online learning and remote forms of communication are the most popular in education today. For teaching civic education, there is a combination of active forms of learning with the use of digital means and resources, which are actively offered by digital educational hubs. Highlighting the best practices of such use is important both for the professional development of teachers and for the diversification and activation of students' civic education. The practical significance based on the experience of European countries, forms and approaches to the use of digital educational tools for teaching civic education has been identified. Methods of using digital hubs to support civic education at school need further research.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012014 doi:10.1088/1755-1315/1415/1/012014

1. Introduction

The development of science and technology is transforming, developing and improving old and creating new forms of organisation of human life, optimising and modernising them. Globalization and integration processes in modern society transform education and require the joint efforts of all educators, which leads to the renewal of approaches to the organization of education processes and, in turn, to the creation of a technologically saturated educational environment. International Telecommunication Union (ITU) and the United Nations Development Program (UNDP) adopted the Sustainable Development Goal (SDG) Digital Acceleration Agenda stating that "Digital technologies have a powerful multiplier effect, both positive and negative, and so it is vital to ensure that their use minimises any increase, entrenchment, or exacerbation of inequality, especially as very real gender, location, and broader digital and data divides exist. Intentionally inclusive approaches to digital development – which place people and the protection of human rights at the centre – are vital in ensuring that the risks of digital transformation are proactively addressed and that no one is left behind" [1]. An important factor that influenced the emergence of digital educational hubs as a centre for learning was not only strategies aimed at the digitisation of education and science in the world but also the circumstances in which the world educational community found itself due to a significant period of the COVID-19 quarantine, limited access to educational institutions and resources. According to the latest data of the international PISA study conducted in 2022 compared to 2018, mean performance fell by ten score points in reading and by almost 15 score points in mathematics, which is equivalent to three-quarters of a year's worth of learning. The decline in mathematics performance is three times greater than any previous consecutive change. One in four 15-year-olds is now considered a low performer in mathematics, reading, and science on average across OECD countries. This means they can struggle to do tasks such as using basic algorithms or interpreting simple texts. This trend is more characteristic of 18 OECD countries and economies, where more than 60% of 15-year-olds are falling behind [2].

This indicates the loss of stability and consistency in education systems and calls for finding effective solutions for equal access of students and teachers to educational services, among which digital technologies are considered important today. On the positive side, according to PISA 2022, on average in OECD countries, about three-quarters of students are confident in the use of various technologies, including learning management systems, school learning platforms and video communication applications [2]. At the same time according to UNESCO, 45% of national curricula frameworks of 100 countries did not refer to climate change; 40% of teachers are confident teaching cognitive dimensions but only 20% can explain well how to take action. This shows that the digital environment is important for students, which is the digital solution that ensures stability and access to learning and the involvement of students in the educational process [3]. It is obvious that today environmental education, as a harmonious part of civic education, contributes to pedagogical and social mobilisation strategies, which, based on the development of scientific, civic social and emotional competencies, strengthens the harmonious relations between children and youth in society and contributes to its sustainable development.

The Global Education 2030 Agenda UNESCO, as the United Nations specialised agency for education, is entrusted to lead and coordinate the Education 2030 Agenda, which is part of a global movement to eradicate poverty through 17 Sustainable Development Goals by 2030. Education, essential to achieve all of these goals, has a dedicated Goal 4, which aims to "ensure inclusive and equitable quality education and promote lifelong learning opportunities for all" [4]. In this context, the Education 2030 Framework for Action guides the implementation of this ambitious goal and commitment [5].

One of the elements of the information and digital educational environment is the digital educational hub. The tools and the instruments of digital educational hubs can support any educational field, in particular the sphere of civic education (CE). The use of digital educational

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012014 doi:10.1088/1755-1315/1415/1/012014

hubs aimed at specific topics is a new practice today. In education, this practice demonstrates the need for students and teachers to combine informational and educational resources to achieve pedagogical goals. Therefore, the study of the best educational experience of using digital educational hubs for the implementation of civic education is important and can be applied to the further development of digital education. Active citizens need political and civic foresight so that they can become constructive agents of change that can effectively contribute to building a new society of the future in harmony with nature. New technologies and science can help in this regard, as well as in more efficient use of resources. We will focus on modern digital educational hubs aimed at civic education and the formation of students' key civic competence.

2. Literature review

An important issue that is considered today by the educational community and many authors is the issue of education for sustainable development in the future. It is about the fact that education for a sustainable future is needed today more than ever before. Education for sustainable development needs to be strengthened given the current social economic and cultural context. It should be community-oriented, with knowledge and observance of natural laws, sociological imagination, and political insight to make it more suitable to meet the challenges of the 21st century [6]. Research is also devoted to what are the key problems in school, and higher and professional education from the perspective of sustainable development. Of great interest are the works on how it is possible to link sustainable development and learning, economic and moral interdependence of people and nature, management, assessment and evaluation of learning and globalisation [7]. Modern researchers claim that digital technologies today are an integral part of the educational process and provide significant benefits for teachers and students. They provide access to a significant amount of information and various bodies of knowledge and also facilitate direct communication, which is not limited in space and time. Scientists are also investigating how modern digital technologies, such as gamification, contribute to the development of skills and behaviour in the context of sustainable development [8]. Researchers emphasise the role of ICT, which they play in the human capacity development for sustainable development through the revision of competency-based education and training, in particular, it provides the opportunity to transition to sustainable economies, environments and societies by equipping persons with skills, knowledge and attitudes that motivates the adoption of sustainable lifestyles [9]. Ukrainian researchers examine contemporary problems in education related to sustainable development [10]. A group of scientists considers the issue of sustainable development through the prism of challenges and opportunities of sustainability in various domains [11].

The studies of Ukrainian scientists are dedicated to the justification of the theoretical and methodological foundations of digital humanistic pedagogy [12]. Scientists emphasise that modern educational processes in physical and virtual space, where ICT is used, are interconnected. The applied research is devoted to the problem of building an information and digital educational environment was carried out by a group of scientists, considering the design and use of a cloud-oriented educational environment [13–16]; technologies for using network resources in the educational process and synthetic learning environment [17]. A significant part of the studies is devoted to the development of information and communication/digital competence and modelling of the modern digital educational environment [18]. The experience of European countries related to the creation and use of the information and digital educational environment was also highlighted by Ukrainian researchers [19]. The peculiarities of the development of civic education in the digital educational environment are considered in the works of a group of scientists. The aspects, that are revealed are the following: the development of a computer-oriented educational environment for multicultural education of students in the countries of the European Union [20]; the use of digital learning tools in the professional activities of teachers to ensure sustainable development and democratisation of education in European countries [11,21].

Conceptual approaches to civic education are highlighted in the works of foreign authors [22]. According to Bîrzéa [22], civic education is aimed at fostering democratic citizenship; it is a set of practices and types of activities aimed at improving the preparation of youth and adults for active participation in democratic life through the realisation of their rights and responsibilities in society.

The issue of the creation, implementation and development of educational hubs as an innovative component of the educational environment in higher education institutions is highlighted by Bondar et al. [23]; the place of the hub in modelling processes of internationalisation of higher education was studied by Hrynkevich and Lutchyn [24]; problems of so-called hub schools and the role of educational hubs in the process of the future teachers training studied by Ozminska [25]; Fedulova defines the ICT component and features of innovation and technological hubs [26]; Knight write about international educational hubs and gave analysis of 10 education hubs in Asia, Africa and the Arab stated of the Persian Gulf region [27]; the problem of the school as a hub of educational and public space was investigated in the works [28, 29].

However, the issue of creating, using and developing digital educational hubs to support and promote civic education as an element of the information and digital learning environment has not been sufficiently researched.

3. Research results

In today's world, the free use of ICT plays an important role, which affects the acquisition of life skills, as well as the ability for effective cooperation and communication, which ensure the identification of a conscious and active citizenship position, as well as the implementation of the idea of digital citizenship. This is also reflected in the social component of the concept of sustainable development. Sustainable Development Goal (SDG) Digital Acceleration Agenda emphasise: "National digital transformation must be a whole-of-society effort – including leveraging the catalytic power of a whole-of-government approach, the digital talents and expertise of the private sector, and most crucially the credibility and expertise of civil society" [30].

The requirements of the modern digital society activate a renewed vision and innovative approaches to the organisation of human activity and education in particular. Innovations in the early 2000s became a new model of organising professional activities, in particular, co-working, collective offices, and hubs. The concept of a hub is widely used in the transport industry and the field of ICT, it namely means a centre of activity, attention or a central node of a network. In a broad sense, a modern hub is a centre where various resources are collected, cooperation and communication are carried out, experience is gained, training and education are held, and new ideas are accumulated, the implementation of which requires the involvement and unification of like-minded people, the use of resources and tools for the intellectual development. Activities carried out in today's technologically oriented world occur both in real and virtual space. According to the place of deployment, the hub can be: real, created based on a physical object (premises); virtual, which is placed online on special means (servers); combined, which combines the features of both real and virtual hubs. Thus, the hub is a network of partners and uses the capabilities of educational and scientific institutions, their resource base and scientific achievements, a kind of "innovative and technological hub" as "a new stage in the comprehensive use of opportunities and resources organisations, as well as companies to create joint products and provide services through the implementation of technology-dominant projects" [26]. N. Bondar, V. Gubenya, I. Pidtilok, and L. Sharan describe the hub activities in the working space and note that seminars and training, creative and musical meetings, the functioning of the library and cross-booking can be a part of the hub working processes [23]. Researcher J. Knight considers the hub to be an educational innovation in the field of higher education and identifies three types of hubs: student hub, hub talents and knowledge/innovation hub [27]. Hrynkevich and Lutchyn highlight the role of the educational hub as an innovative form of institutionalisation of rapprochement processes, and integration of national educational systems and their institutions into the global educational environment [24]. Based on the above-mentioned opinions, the digital educational hub can be characterised as a multi-functional component of the educational space with the use of ICT. It can be created to unite and concentrate digital educational resources, tools, and technologies. The hub should provide organisational and pedagogical conditions for the acquisition of knowledge, the formation and development of competencies, the implementation of cooperation and communication of participants in the educational process (students, teachers, heads of educational institutions, students, post-graduate and doctoral students, scientists, parents, public organisations and all interested persons). It is organised to support learning, the development of ideas and the exchange of experiences, acquiring connections with like-minded people and their associations. This contributes to the creation of innovations and their implementation in education, project activities, professional and personal self-development and self-improvement. Educational hubs are aimed at collaboration in any educational field, in particular, civic education. This educational space provides an opportunity to efficiently and quickly accumulate intellectual potential for solving urgent problems, and discussion of acute issues related to theoretical and practical aspects of civic education.

Sustainable Development Goal (SDG) Digital Acceleration Agenda (International Telecommunication Union (ITU) and the United Nations Development Program (UNDP) UNICEF) showcase 34 digital solutions, two for each SDG, highlighting the power and potential of digital. There are Learning Passport (mobile online and offline learning platform) and Atingi (online learning platform)/ Digital solutions for the training of teachers for the 4th SDG Goal. Also, Digital Education Hubs and digitally supported Regional Training Centres can increase the number of teachers who are considered qualified according to national standards. Globally, around one teacher in seven does not have this level of qualification, risking sub-par educational outcomes for their students. For example, Mobile Innovation Hub: Platforms for Tomorrow is an accelerator program to support local and digital innovation ecosystems by facilitating investment, helping to build start-ups and delivering training.

A good example of a thematic digital educational hub is the Dutch project Club of Hubs "Digital Calendar Blocks" (`https://cultuursnack.nu/`, Arnhem, the Netherlands). The hub unites all participants in the educational process, as well as museums, libraries, archives, etc. Tools for creating and using educational materials on smart boards and tablets in the form of calendars on a certain topic are offered on the hub's free digital platform. Members of the hubs club can create their own digital calendars, share experiences, and use the resources of other hubs. Most digital calendar topics can be used to teach history, geography, languages, media literacy, biology, and technology. They also contain topics of civic education. CE is implemented in the Netherlands across all subjects. For example, the themes "Helderland memories – 75 years of freedom" and "Battle of Arnhem" are dedicated to the events of the Second World War and the liberation of the Netherlands from fascism. The cities of the Netherlands are told by the calendars "Eindhoven", "Valkenswaard", "View of Arnhem", "Digital block calendar South Holland", and "Breda, 2019 view". These calendars contain interesting facts related to a certain city of the Netherlands and have photos in thematic blocks. Each block can be accompanied by meaningful text, dates of events, questions for discussions, and topics for research. The space of the digital educational hub can be developed and integrated into the digital educational environment of the educational institution (school, teaching office, higher education institution, extracurricular education institution, etc.). The educational digital hub for CE supports the school subject "People and Society", it was created in the educational environment of the leading Flemish publishing house "Die Keure" (`https://www.diekeure.be/educatief/hub/`),

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012014 doi:10.1088/1755-1315/1415/1/012014

which takes active participation in the process of education development in Belgium. The functioning of the Digital Education Hub of Flanders is aimed at such important aspects of CE as the formation and development of civic, communicative and ICT competencies, as well as competencies related to financial literacy, cooperation, etc. The publishing house has created an original methodology for teaching subject "Man and Society" in a secondary school in the Dutch-speaking part of Belgium. The teacher can work based on the modular method. Six thematic electronic journals are offered for working with students. Six modules can be used in any sequence. E-zine topics include elements of civic education, including Life, Nutrition and Health, Back to Business: Entrepreneurship and Charity, Game On Gaming and Social Media, Passage: Travel and Nature, "Grinta: sport" and "Fear of Public Speaking: music, cinema and theatre". The publishing house created an online educational platform "POLPO" (`https://www.polpo.be/`) for teachers. Educators can use resources and tools to create their learning designs, apply a differentiated approach to teaching, and evaluate both students and themselves. An educational hub can function both by itself and as part of a network of hubs. The network can be deployed purposefully, and hubs can join the network themselves, attracting new members. The national network of multimedia education in the Netherlands "Filmeducatie" (`https://www.filmeducatie.nl`) supports citizenship education. "Filmeducatie" launched a project to create a National Network of Multimedia Hubs in Education in 2019. The project is gaining popularity and the network of hubs is expanding. Pupils, students of pedagogical institutions of higher education, teachers and lecturers from universities, parents, and civil society organisations can cooperate in hubs. Everyone can collaborate, propose ideas, get involved in projects, use resources, educational materials, video lessons and lectures, attend educational and cultural events, school performances, museums, libraries, etc. Digital educational hubs offer professional development courses for teachers. Teachers can remotely develop civic and digital competencies, learn new methods and forms of work, and use multimedia tools and ICT in professional activities. "From critical viewers and media creators to creative conscious citizens" is the mission of the Film HUB Gelderland hub. For the 75-th anniversary of the commemoration of the end of the Second World War, celebrated in the Netherlands in 2020 at the national level, a package of lessons "75 years of Freedom – War and Freedom in Pictures" has been created for teachers in the digital education hub "Beeldung". Teachers of civic education and teachers of other subjects who implement it in their lessons can use educational materials, show films and discuss with students the topic of war, human rights, democratic values and freedoms. Conceptually, the construction of the hubs of the National Network of Multimedia in Education of the Netherlands "Filmeducatie" is maintained in a single key, which is reflected on the Internet pages: an interactive map of the province is divided into municipalities and contains info-graphics that offer information about current events that take place in the field of film and media education, offers of cinemas, festivals, events in cultural centres, libraries, organisations and institutions of the province. The teacher can select the necessary resources for working with students using filters. This allows you to search by level of education: primary, secondary and senior, as well as by type of event, and type of activity. Information about educational platforms, cultural and educational coordination centres, schools that have joined the hub, etc. are collected in digital educational hubs. Teachers who have joined the work in the hub post their web pages, pages on social networks, and blogs. The hubs' web pages offer news, interesting facts, articles, issue newsletters and much more. You can also join the hub via the pages of social networks Facebook, LinkedIn and Instagram.

The creation and deployment of educational hubs is also inherent in Ukrainian education, which is associated with the impact on the educational environment of such factors as the rapid development and penetration of digital technologies into educational processes, the need to switch to remote forms of education for schoolchildren during the COVID-19 pandemic, and limiting access to school infrastructure in wartime.

In 2020, the Ministry of Digital Transformation of Ukraine initiated the creation of a network of digital educational hubs across the country. These hubs were established in libraries and other public places and were equipped with computers with Internet access. Such an initiative was carried out with the aim of providing an opportunity for everyone to come and learn how to use digital tools and resources and acquire digital skills. Also, for the organisation of training, UNDP and Sweden over the past three years supported the Ministry of Digital Transformation of Ukraine in building a network of hubs, as well as training their coordinators and users.

The number of Ukrainian educational hubs is growing every year. Among them are: "Osvitoria Hub", Kyiv (`https://hub.osvitoria.org`), "Spalah", a network of educational hubs (`https://spalah.com.ua`), "HUB School", Vinnytsia (`https://hubschool.com.ua`), "World School Hub", a network of licensed international schools in Ukraine (`https://worldschool.com.ua/`), international network "Impact Hub" (`https://impacthub.odessa.ua`), "Long Hub", Dovge, Transcarpathia, independent educational corporation "TeachHUB" (`https://teach-hub.com/`), "Kid's hub" network of the public organization "Crimean Diaspora", "Education HUB" (`https://edhub.com.ua/`) and many others are currently operating in the Ukrainian educational space. "Educational Hub of the City of Kyiv" is a powerful tool of the Ukrainian information and digital educational environment (`https://eduhub.in.ua`). This hub has a resource base that works in the format of blended learning, provides training and testing for the development of soft skills, promotes lifelong education and supports sustainable development. Meetings with successful and well-known Ukrainian political and cultural personalities are held on the grounds of the "Club of Prominent People" of the "Educational Hub of the City of Kyiv", intellectual games championships are held, professional orientation events and much more are organized. The implementation of civic education is carried out by the "Learning Hubs" network, which involves 40 schools in Zakarpattia, Donetsk and Luhansk regions. One of the initiatives is the educational project "Active Citizens". The project gathered active young people to create changes on the ground. Creating conditions for interaction and cooperation of teachers, professional mastery groups are held in the hub. As the members of the Network note, partnerships and cooperation contributed to its creation. Uniting hubs into a network allows coordination of joint actions, helps to strengthen organisational potential, helps to join efforts for the implementation of ideas and projects, to learn and exchange experience. An educational hub can function both independently and as part of a network of hubs. A network of hubs can be deployed purposefully, and independent hubs can join the network and attract new members to it.

Educational institutions train teachers, carry out teacher training and are involved in the process of creating hubs. Thus, the All-Ukrainian Educational Hub of Pedagogical Innovations of the New Ukrainian School was created based on the Cherkasy Regional Institute of Postgraduate Education of Educators of the Cherkasy Regional Council in 2020. It became the basic centre for the accumulation and distribution of the author's methods, technologies, models of the educational process and management activities, innovative methods and forms of work, and professional development of teachers.

"Skills Hub" of the Pavlo Tychyna Uman State Pedagogical University is an example of the implementation of CE and its elements. Participants learn "soft skills" at workshops and seminars, learn teamwork skills, and time management (optimal organisation of time to solve current tasks) and develop civic competence. Pupils and students are offered to create and make speeches in the format of "TED Talks" – a project of the US non-profit organisation "TED Conferences" (`https://www.ted.com/`). The project has been spreading "ideas that will change the world" since 2006. A collection of audio and video files of the best speeches, which can be accessed for free, is available on the Internet. Since 2017, civics education has been fully implemented in programs for grades 5-9. This approach requires training of teachers, providing them with high-quality educational materials and free access to them. Today, few educational environments are aimed at forming the civic competence of teachers and students. The website of the "New Age" project of the All-Ukrainian Association of Teachers of History and Social Sciences "3D-Democracy" – "Citizen's Workshop" (https://citizen.in.ua/about.php) and the educational platform "We Live in Democracy" (https://living-democracy.com.ua/) are actively working.

The educational platform "Living in Democracy" (https://living-democracy.com.ua/), launched as part of the Swiss-Ukrainian project "Development of Civic Competences in Ukraine – DOCCU" with the assistance of the Government of the Swiss Confederation, offers resources of the Council of Europe with education for democratic citizenship to conduct lessons and events on the topics of democracy, human rights and civic participation. The web pages of the platform contain educational materials, legal documents, video materials, illustrated cards about children's rights, and several Council of Europe manuals, in Ukrainian translation, including: "Teaching democracy", "Growing in democracy", "Living in democracy", "We take participation in democracy", "Exploring children's rights" and "Teaching democracy". Pupils, parents, teachers and school leaders can find useful information on social welfare issues, learn, develop and improve themselves. The digital educational hub, as already mentioned, is an environment for joint educational activities. The current state of ICT development offers a wide variety of tools to make the hub full of ICT, which will make access to it open and provide an opportunity to more fully realise its functions. The hub can be created for a separate subject, topic, project or educational direction. The resources posted on the website of the 3D-Democracy project "Citizen's Workshop" (https://citizen.in.ua/about.php) are aimed at supporting students and teachers of civic education. The educational platform "Living in Democracy" (http://www.living-democracy.com.ua), launched as part of the Swiss-Ukrainian project "Development of Civic Competences in Ukraine – DOCCU" with the assistance of the Government of the Swiss Confederation, offers resources of the Council of Europe with education for democratic citizenship to conduct lessons and events on the topics of democracy, human rights and civic participation. The web pages of the platform contain educational materials, legal documents, video materials, illustrated cards about children's rights, and several Council of Europe manuals, in Ukrainian translation, including: "Teaching Democracy", "Growing in democracy", "Living in Democracy", "We take participation in democracy", "Exploring children's rights" and "Teaching democracy". Pupils, parents, teachers and school leaders can find useful information on social welfare issues, learn, develop and improve themselves. The digital educational hub, as already mentioned, is an environment for joint educational activities. The current state of ICT development offers a wide variety of tools to make the hub full of ICT, which will make access to it open and provide an opportunity to more fully realise its functions. The hub can be created for a separate subject, topic, project or educational direction. The resources posted on the website of the 3D-Democracy project "Citizen's Workshop" (https://citizen.in.ua/about.php) are aimed at supporting students and teachers of civic education.

After reviewing the existing experience we propose to create digital educational hubs to support civic education based on educational institutions, which can serve as a component in the digital educational environment and contribute to the achievement of the goals of sustainable development. The digital educational hub, as already mentioned, is an environment for joint educational activities. The current state of ICT development offers a wide variety of tools that allow for open access to the hub and more fully implement the hub's functions. The hub can be created for a subject, topic, project or educational topic. Figure 1 presents the author's vision of a digital resource hub to support CE. Therefore, a digital resource hub for civic education may include the following resources: manuals and methodical recommendations on CE; bank of ideas and innovations; online networks with CE (domestic and international); access to participation in CE projects; student initiatives and SE portfolios; portfolio of teachers who teach civic education or implement its elements in their lessons; questionnaires, tests and monitoring tools; platforms for communication and exchange of experiences among colleagues, students, and parents.

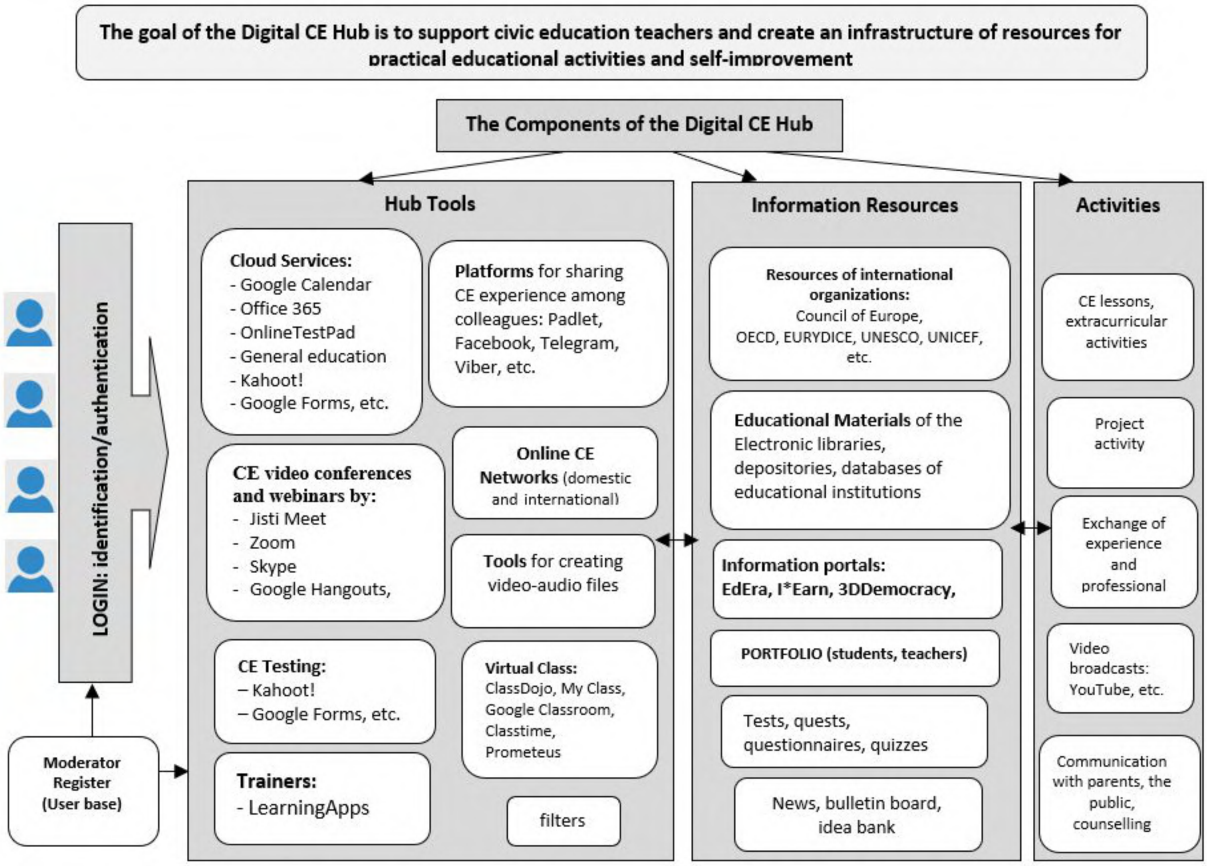

Figure 1. The vision of the digital hub for civic education (CE) support in schools.

Therefore, a digital hub for civic education (CE) may include the following elements: 1) conceptual and strategic documents on CE issues: legislative documents and concepts in the field of general secondary education, educational standards, strategies for implementing CE in the education system in Ukraine, international declarations and conventions in the field of human rights protection, relevant recommendations of the Council of Europe, UNESCO, UNICEF, UN and other international institutions working in the field of human rights protection and civic education; 2) CE manuals and methodological recommendations (domestic and international developments for the implementation of civic education, standards and framework approaches, curricula and thematic modules, references to the legislative framework of Ukraine on the protection of human rights and international documents, declarations and conventions in the field of human rights protection); 3) references to the online CE networks (domestic and international): a list and links to networks offering informational materials, and educational resources for improving the qualifications of teachers in the field of civic education; 4) access to participation in CE projects: descriptions and links to civic education projects implemented in Ukraine and abroad, eg. The Democratic School Project (European Wergeland Center, Oslo, Norway); 3-D Democracy project (Nova Doba Association) etc.; 5) references to the student initiatives and portfolio: description of student research, projects, examples and results of competitive student works, including works submitted to thematic Olympiads, creative works, and festivals; 6) banks of surveys and monitoring tools: questionnaires and data, tasks, quests, test tasks and examples; 7)links to the platforms for sharing experiences among colleagues, students, and parents; links to professional pages on social networks Facebook, Linked In, and Instagram, web pages, portals, platforms and resources for sharing experiences, blogs, YouTube channels, other digital resources of professional communities on CE issues; 8) bank of ideas and innovations for further implementation and development of CE in school: project proposals, methodical developments, scenarios of CE events; 9) electronic libraries and databases: links to libraries, and depositories, including state institutions, research organisations, museums, cultural centres, and public organisations (domestic and international).

Technical support of the digital educational hub for the implementation of CE should include a set of services aimed at ensuring the reliable, safe and secure functioning of equipment and services of the network, computing and engineering infrastructure of the environment.

Creative teachers should be supported in creating and using digital educational hubs to solve civic education problems. This activity can contribute to their professional and personal development. It is also important to consider the possibilities of civil society organisations offering civic education programs and projects for students and teachers.

Association of Innovative and Digital Education in Ukraine provides support and psychosocial assistance services for children and youth with the financial support of UNICEF in Ukraine. The Project Digital Learning Centers (SPILNO DLC) involves 16 digital learning centers in the communities of Mykolaiv, Odesa and Kherson regions, which will provide catch-up education for students, life lessons on the most popular modern skills of the 21st century related to the Civic Education topics, as well as career guidance, various training and remedial programs, psychosocial support and training for 30 thousand students from 7 regions, as well as teacher training and psychosocial support for teachers and school psychologists (`https://www.aide.one/en/projects`). Training courses for teachers, dedicated to subjects related to civic education, such as “Media Literate Resistance: Building Reasoned Dialogues” and “Media Literate Resistance: Communicating on Equal Terms” have been developed for teachers within the framework of the project “Study and Distinguish” with the support of IREX on the SPILNO platform (`https://eduhub.in.ua/category-course/onlayn-kurs-mediagramotniy-sprotiv`).

The importance of research and surveys of teachers and students that highlight the experience of civic education in different countries should also be emphasized. This is important for highlighting the best practices of teaching civic education and developing own methods, models and approaches to support civic education, including through digital educational hubs.

Digital educational hubs to support civic education are a relatively new phenomenon in education and this is related both to the significant quarantine period when teachers were forced to teach online, and to the development of technology and the transition to new technological solutions in education, and most importantly, the need to provide access to resources and training for teachers and students.

The best-known international research is the International Civic and Political Education Survey (ICCS), which is conducted every five years and assesses the knowledge, skills and attitudes of 8th-grade students in civic education (`https://www.iea.nl/research/iccs`); The Program for International Student Assessment (PISA), which is conducted every three years, includes a citizenship education module that assesses the knowledge and skills of 15-year-old students (`https://www.oecd.org/pisa/`); The European Values Study (EVS), conducted every nine years, examines the values and attitudes of citizens in various European countries, including issues related to citizenship education (`https://www.europeanvaluesstudy.eu/`).

Digital civic education hubs are important tools for disseminating knowledge about civil rights, democracy, social justice, and other aspects of civil society. These hubs provide access to learning materials, interactive resources, information sources and communities for acquiring citizenship knowledge and skills.

Having analysed the support of civic education through digital educational hubs and taking into account that civic education and education for democratic citizenship in different countries can be considered as an integrated course, a framework, or a program, certain approaches to the implementation of this direction should be singled out: a) at the political level: support for digital civic education hubs can be implemented through the initiation of programs, including cooperation programs with international organisations, such as UNICEF, UNDP, the Council of Europe, and the international technical assistance programs. Governments can develop national strategies and frameworks that recognise the importance of understanding the role of citizenship education from regional and national perspectives; b) in the classroom: civic education can be taught as an integral part of existing subjects – from geography to social studies, using the resources of digital educational hubs and projects containing civic education topics; implement school projects and create digital school communities for civic education; teachers can incorporate materials that build awareness of civic values. For instance, in Geography and Social Sciences, pupils can learn about countries and their political systems. Teachers can also assign students a group digital project where they will have to devise a campaign to address civic knowledge in their local community; c) at the level of professional development of teachers: use the opportunities for professional development in the use of digital educational resources, in particular from CE, as well as other subjects to acquire digital skills and master new methods, practices and methods of learning; d) at the level of civil society and out of class activities: to engage the capabilities of public organisations, including the created digital hubs to engage teachers and students in communication and learning about civic education and with the civic society, the initiation of educational activities for a broad interested public on issues of civic education.

4. Conclusions

Having conducted an overview of the existing experience of the use of digital educational hubs in the field of civic education conclusions and recommendations can be useful. Civic education is an important part of sustainable education and development allover the world. Turning to the issues of civic education and education for sustainable development, it should be noted that Ukrainian school programs do not provide separate subjects from these topics, and Civic Education as a separate subject is studied for only one year in the 10th grade. Sustainable development as a concept remains insufficiently mastered by the teachers, who are focused on teaching subjects and testing students' acquired knowledge. Cross-cutting skills and abilities (soft skills), which should be the result of education for sustainable development and the formation of competencies for democratic citizenship, are very important in the process of assessment of the students' achievements.

The latest changes in the shift to the distance and blended mode of learning proved the effectiveness and usefulness of effective digital technologies when teaching CE in schools. It refers to the wide and open access to CE information resources, widening the possibilities to communicate without borders, and to obtain knowledge at any time and place etc.

The author's vision of a digital resource hub to support civic education is presented in the main components (digital tools resources and activities) that are aimed at the support of civic education teachers to create and use an infrastructure of resources for practical educational activities and self-improvement. It is worth paying attention to such recommendations regarding its components as a bank of ideas and innovations for further implementation in the educational process; digital platforms for communication and tools for evaluation and questionnaires; hub pages in social networks, blogs and sites of teachers conducting training, seminars, lectures, workshops.

A digital civic education hub can be created based on a general secondary education institution, an out-of-school education institution, a post-graduate education institution, a civil society organisation, a scientific institution, or be a part of the regional educational authorities and professional teachers' associations. It is important to provide the tools of the digital educational hub with free access and adjustment of the organisation of distance learning and the opportunity to join the educational process for all those interested, regardless of their location and time. The functioning of the digital educational hub should be focused on the development of civic competence and, at the same time, digital competence through the integration of elements of online learning and the use of digital tools for the dissemination of civic education. The digital educational hub for civic education is an element of the information and digital educational environment, modernises and strengthens it, ensuring the development of civic and digital competence of participants in the educational process; digital educational hubs can be used to create thematic, branch, subject, etc. educational environments; creation of a network of digital educational hubs on issues of civic education will contribute to ensuring the quality of education in general. As stated in Goal 4 "Quality Education" of the Concept of Sustainable Development [30], education is "one of the most powerful and proven means of sustainable development" and plays an important role in the formation of a citizen and the development of a civil society built on the principles of democracy.

It was also explored that digital education hubs offer different support for the implementation of citizenship education. This includes the placement of educational materials, project activities, professional communities for teachers and thematic communities for students, resources and links for familiarization, exchange of experience.

Since civic education is an integrated direction in the school curriculum, it is worth paying attention to such important aspects as continuous professional development of teachers regarding the use of digital tools for social science subjects, motivation and involvement of teachers in professional communities, joint learning and exchange of experiences, psychological support of teachers. It is also important to work outside the classroom with students, involve civil society in the implementation of student projects, create opportunities for dialogue and exchange of opinions. Equally important is the technical support of digital educational programs and their popularization among parents and school leaders.

The conducted research does not exhaust the interest in finding better opportunities for Ukrainian teachers and students regarding the development and use of digital educational hubs for civic education. Ukrainian students and teachers need to get acquainted with the experience of foreign countries, to implement the best practices of using digital tools for civic education.

Therefore, further research is needed to study the forms and methods of using digital educational hubs for teaching school subjects in different countries, in particular civic education, monitoring the activity of students in such hubs, and studying the interests of students for further education and expanding the range of opportunities for students and providing them with open access to educational opportunities regardless of location and current situation in the country.

The perspectives of further research also can be realised in the field of ensuring scientific and methodological support of digital sustainable education in schools; teachers' professional development in the field of the use of ICT for CE teaching; monitoring of the influence of digital technologies and in particular the use of educational hubs on the results of students' achievements.

A digital educational hub for civic education, where the teacher has free access to electronic resources, online tools for the development of educational materials, evaluation, testing, surveys, involvement in online platforms for education, professional development, communication and exchange of experience, etc. at any time and in any place, can contribute to the solution of the problems that have deepened the educational gaps caused by the military aggression of the Russian Federation against Ukraine.

Abstract. This scientific paper is devoted to clarifying the relationship between artificial intelligence (AI), the modern labor market, and Education for sustainable development. Within this study, the authors concentrate their efforts on the following directions: (1) exploring the existing educational approaches and techniques, the knowledge of which helps minimize the possible negative consequences associated with the implementation of AI into the labor market; (2) analyzing Ukrainian and Slovak students' points of views, that were obtained by surveying, on AI technologies and their potential effects on the labor market; (3) providing substantiation regarding the need of using the pedagogical strategies, particularly, (a-b) the implementation of AI-related technologies in the professional cycle disciplines, (c) assigning tasks that require AI technologies to exploit, (d) exploiting AI technologies as the source of improving the information infrastructure in HEIs. While formulating these pedagogical strategies, the authors comprised possible consequences (a negative effect of AI on the labor market, risks of applying AI in all spheres of human activity, a negative attitude of students toward AI) of AI application and the planned results. The authors considered the five dimensions of sustainability (technical, social, environmental, user, and economic) and presented them in the format of the Sustainability Awareness Diagram (SAD). The visualization of the effects that may result from the use of pedagogical strategies for Education for Sustainable Features is suggested. Each planned result is put in the SAD, assuming their influence (immediate, enabling, structural) on Sustainable Features. In overall, the proposed strategies aim to reduce the potential negative impacts of AI on the functioning of the labor market and instill a positive attitude toward AI technologies in university youth. The findings comprise the multifaceted and dynamic relationships between AI, the modern labor market, and Education for sustainable development. Results also reveal that AI technologies significantly impact the labor market by influencing job roles and skill requirements. Correspondingly, Education for sustainable development is vital in preparing young people to be aware of the evolving demands of the labor market impacted by AI, promoting skills that align with both technological improvements and sustainable practices.

1. Introduction

Today, science engages in further scientific explorations of the questions related to AI and its effect on life. We look at some of these questions through the lens of this research. How has AI affected the labor market? And what are the forecasts for the impact of AI? What research reveals matters? Is a sustainable future at risk? These concerns are in our field of view. This study delves into the reality of AI being a part of life. It is worth noting that the day-to-day goal of the Sustainable Futures concept and the Sustainable Development Goals is to ensure sustainable development that satisfies the needs of today's life without compromising the knowledge of future generations to meet their needs. Nowadays, the world faces many challenges that hinder the development of Sustainable Futures [1]. Let us mention that the published report by the World Economic Forum, "Future Focus 2025: Pathways for Progress from the Network of Global Future Councils 2020–2022" [2], concerns detail the global challenges and offers considerations on how to confront them in terms of the Sustainable Futures concept. Among others, we focus on the following essential information and pay attention while reading the document: challenges within the economy (righting the economic course, the impact of extreme wealth inequality, a self-perpetuating system), challenges and the environment (climate change, air pollution, water scarcity, natural resources depletion), challenges and society (government action and corporate governance, access to education, health care, and opportunities, protecting vulnerable populations), challenges and technology (concerns about AI capabilities).

Moreover, according to the World Economic Forum, one of the new areas of concern facing our world is the development of artificial intelligence (AI), especially regarding its impact on the labor market [3]. The development of AI raises concerns about replacing human labor and automating work tasks, which will lead to the loss of jobs. Companies' expectations from employees are also changing: more and more vacancies require AI competencies. AI and Machine Learning Specialists top the list of fast-growing jobs [4]. Approximately 75% of companies surveyed said they plan to adopt AI technologies over the next five years, and this situation is projected to lead to losses in administrative positions as well as traditional security, factory, and sales positions by 2027. According to the report "Generative AI and the Future of Work in America", in the United States, by 2030, it will be possible to automate everyday activities that account for up to 30% of working hours. This trend will be accelerated by generative AI, office support, customer service, and food service employment, which could continue to decline [5]. Employment Outlook, a review of new evidence on the influence of AI on the labor market, emphasizes the significant uncertainty surrounding the current and especially future impact of AI on the labor market [6].

Solutions to these issues are proposed in politics, law, and business. In particular, Del Pero and Verhagen [7] point out that most countries primarily rely on soft law for AI-specific matters. Still, several countries are developing new AI-specific legislative proposals applicable to AI in the workplace. The report [3] raises questions that need to be addressed at the level of companies and business leaders, policymakers, and individuals as workers, consumers, and citizens. In particular, the extent to which people should be concerned about the emergence of generative AI and how workers and consumers can balance the convenience of generative AI with its impact on their workplaces. At the same time, the attitudes of students as future workers in a rapidly changing society towards AI technologies and the role of higher education institutions in addressing the impact of AI technologies on the labor market in terms of sustainable development education still need to be studied.

2. Literature review

Do the points of intersection between AI, the labor market, and education for sustainable development exist? This question became the topic of discussion for researchers, citizens, and university students. In line with the theme of this research, we present the literature analysis on the risks of introducing AI into the spheres of human activity. The study also involves the exploration of scientists' opinions on this matter. Moreover, we delve into the educational sphere and look at it through the prism of sustainable development. In the research process, we were motivated by the following question: Is there any experience through education that can solve the problem of AI's influence on the labor market?

To answer these questions, we focused on the scientific works on the risks of using AI in human activity related to the labor market. In this regard, we note that the wide use of AI can lead to large-scale unemployment in the future [8]. Furthermore, AI has the potential to deepen the gap between developed and developing countries, as well as raise the demand for specialists with extraordinary talents, lead to job loss or drive down wages of less-qualified staff, dwindling tax revenues, and this shift has negative consequences on the labor market in general [9]. Salaries or wages could decline for workers involved in smaller amounts of less work due to automation [7]. Moreover, using AI leads to the emergence of new forms of video surveillance camera systems in workplaces. Also, increased workplace automation leads to adapting to the changes, leading to further labor market opportunities. Automation of workplaces can also lead to the loss of jobs by individuals [10]. Overall, the risks of introducing AI into areas of human activity are closely linked to the labor market, affecting employment opportunities and dividing the labor between humans and AI technologies depending upon where each excels.

To minimize these risks, scientists are constantly seeking solutions. Well-thought-out strategies, approaches, and tactics related to AI can minimize negative consequences [9].

Researchers Hassel and Ozkiziltan emphasize that the direct risks inflicted by AI workplace tools can be addressed by proactive regulation. They also point out that the recent EU Artificial Intelligence Act and the Proposal for a Directive on improving working conditions in platform work are two initiatives that are important in addressing the impact of AI technology on the labor market [10]. Also, the General Data Protection Regulation (GDPR) deters unauthorized proliferation of surveillance equipment at work. The GDPR requires companies to obtain employees' consent for using workplace surveillance tools and the data obtained from them. Under this body of rules, companies must obtain the Works Council's approval to launch and use workplace surveillance tools [11]. Addressing and mitigating the discrimination-related risks and challenges arising from using algorithms in labor markets requires dialogue and collaboration among policy-makers, employers and worker representatives, and computer and data scientists. This will help to build an "ecosystem of trust", providing "citizens the confidence to take up AI applications and give companies and public organizations the legal certainty to innovate using AI" [12].

The European Parliament, in its report on a comprehensive European industrial policy on artificial intelligence and robotics [13], partially addressed the indirect risks associated with AI-driven automation. In the document, besides the importance of revising and refashioning labor market policies, social security schemes, and taxation, attention is drawn to the extent of revising and refashioning training and education programs.

European Parliament urges Member States to focus on retraining workers in the industries most affected by the automation of tasks; stresses that new education programs should focus on developing the skills of workers so that they can seize job opportunities within the new jobs created by AI; encourages the development of digital literacy programs in schools, the development of apprenticeships and vocational training priorities to help workers adapt to technological changes.

Therefore, we consider it reasonable, based on studying the attitude of students regarding the impact of AI technologies on the labor market and their future professional activities, to propose pedagogical strategies to reduce the adverse effects of AI on the labor market and the negative attitude of future specialists to AI technologies.

3. Materials and methods

3.1. Methods, data collection tools and procedures

The study is a descriptive (description of the experience of using AI in education for sustainable development), qualitative (literature analysis), and quantitative (questionnaire) study. Within the research, the authors explore the experience of scientists who concentrated on and then summarized their scientific findings concerning the impact of AI on the labor market through education. The authors considered the above-mentioned scientific findings, considering the experience of scientists in solving the issues related to the influence of AI on the labor market through education, modeling an educational approach, and the method of diagrams.

The research also became possible thanks to the application of the Method for Sustainability Design [14]. The authors analyzed the data from the survey conducted at non-linguistic higher schools. The authors surveyed students in Ukraine (Bogdan Khmelnitsky Melitopol State Pedagogical University) and Slovakia (University of Economics in Bratislava, University College Prague) during the fall semester of 2023 and January 2024. We compiled survey data from 24 November 2023 to 15 January 2024. Data collection involved an online survey in Google Forms comprised of 4 questions (Appendix A). When compiling the questionnaire, we used the recent scientific research findings of Dakakni and Safa [15]. Participants, 138 young people, are bachelor's students of non-linguistic higher education institutions – first year students (76.8%), second year students (8%), third year students (4.3%), and a four year student; first year students at the master's program, and a second year student at the master's program (9.4%).

3.2. The aim, objectives, and the research questions of the study

Our scientific research aims to delineate the points of intersection between AI, the modern labor market, and education for sustainable development.

We stated the following research questions (RQ):

RQ 1. Are there educational practices to reduce the risks of introducing AI into human activities for sustainable development?

RQ 2. What are students' attitudes to AI technologies and their impact on the labor market?

RQ 3. What pedagogical strategies can be offered to education for sustainable development to reduce the possible negative consequence that AI can bring to the labor market and the negative attitude of today's students, who are future professionals, toward AI technologies?

To answer these questions, we set the following objectives:

- to analyze the risks of implementation of AI into the spheres of human activity and the proposals of scientists to reduce them in the aspect of education for sustainable development;
- based on the surveying results with views of students from different universities (Bogdan Khmelnytskyi Melitopol State Pedagogical University, University of Economics in Bratislava, University College Prague) and countries (Ukraine, Slovakia), to study the attitude toward AI technologies and their impact on the labor market;
- to propose pedagogical strategies to reduce the possible negative consequences of implementing AI technology in the labor market and the negative attitude of students, who are future labor market specialists, toward AI technologies for sustainable development.

4. Results

4.1. Descriptive findings from the online survey

In line with the second research question, "What is the students' attitude towards AI technologies and their impact on the labor market?", students' answers to the proposed questions were considered (Appendix A and Appendix B).

The analysis of students' answers to the Q1 of the questionnaire – "When applying for a job among hundreds of applicants, I would prefer that humans conduct the screening and selection process to avoid unfairness and error" – shows that 53.6% of respondents are concerned and aware of equity disparities among people and the loss of jobs instigated by AI; 20.3% of respondents are not worried about equity disparities; among people and the loss of employment initiated by AI; 26.1% – are concerned about AI ability to feel, which may render it capable of doing things on its own-likely destructive, aggressive behaviors.

In response to question Q2 of whether humanity is likely to worry about AI taking over jobs, evidence and students' perceptions reveal their concerns. 65.2% of respondents answered that they are concerned about the possibility of displacing jobs because AI will do the work. Note that the range of implications in the economy results in an adaptation of the workforce to the existing situation; AI in the labor market makes young people consider ethical dimensions, accepting the new reality of the nature of employment in the age of AI. However, 22.5% – do not worry that AI will take over human jobs, and 12.3% think AI has garnered a sense of malaise and distrust.

The opinions on the third question – Q3. What do you think about AI and equity issues in terms of machines replacing jobs? – are divided. Young people worry that AI will substitute human beings. Students (40.6% of respondents) adhere to this point of view. Though many students are not concerned about AI and that it can replace people, such a view is shared by 28.3%.

The intersection of AI and privacy notions has become a severe and life-threatening point in contemporary scientific discussion. The deployment of AI technologies raises concerns about data security, surveillance, and the potential loss of personal privacy. Noticing a slight and delicate balance between the transformative power of AI and protecting individuals' privacy poses complex and tricky challenges for officials, technicians, scientists, and society at large. On the Q4. Are you concerned about AI privacy issues? Opinions are distributed as follows: 30.4% think that there are privacy policies on every social media platform; 31.2% have never really thought about privacy concerns; 27.5% have heard about privacy issues all the time but for them getting the job done is more important; only 10.9% have no worries about AI and privacy.

As we can see from the conducted questionnaire, students have shown concerns about AI and the modern labor market, so we need to reduce their anxieties and fears. How? We propose applying the pedagogical strategies to students' university training to answer this question.

4.2. The pedagogical strategies targeted to teaching students at universities to tolerantly perceive the possible adverse effects of AI on the labor market and efficiently alleviate the risk of the hypothetical negative consequences of AI technologies

To equip students with relevant knowledge to tolerantly perceive the possible adverse effects of AI on the labor market and to mitigate the potential negative consequences of using AI technologies (figure 1/the possible consequences), we propose the pedagogical strategies, to be more precise, the instructional strategies (note: according to Dick et al. [16], instructional strategy is used to cover the various aspects of organizing the content, stating learning activities, and determining how to deliver the content and activities) for education for sustainable development.

The schematic representation of the pedagogical strategies targeted at teaching young people at universities to perceive the possible adverse effects of AI on the labor market tolerantly and efficiently alleviate the risk of the hypothetical negative consequences of AI technologies is presented (figure 1).

It is based on the belief that future specialists should be prepared to immerse themselves in the reality of AI technologies. The pedagogical strategies involve using AI-generated content in lessons and AI technologies to improve higher education institutions' information infrastructure.

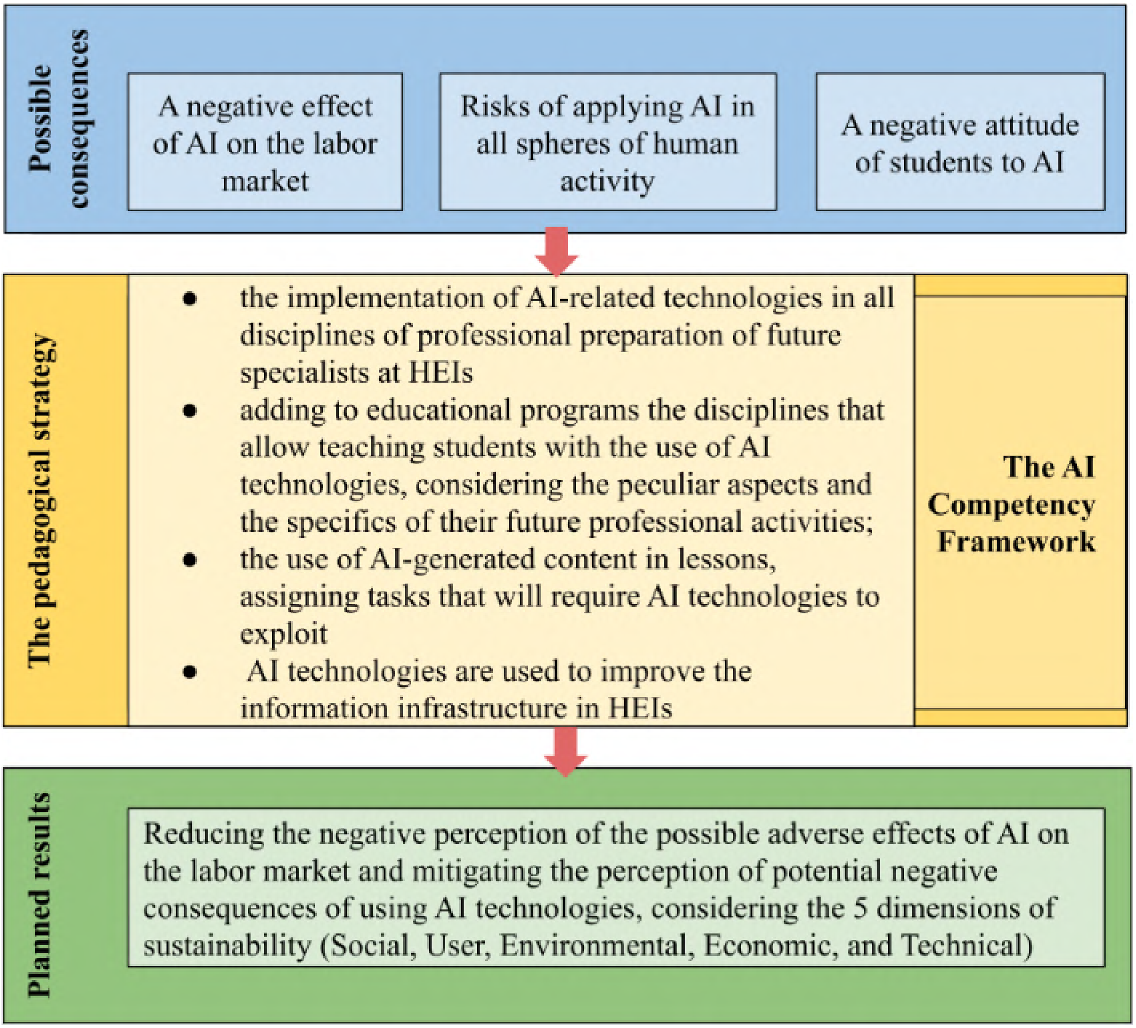

Figure 1. The schematic representation of the pedagogical strategies applicable to the training process to help students tolerantly perceive the possible adverse effects of AI on the labor market and mitigate the perception of the potential negative consequences of using AI technologies.

The pedagogical strategies aim to help cope with the negative consequences of using AI technologies (figure 1/the pedagogical strategy).

Its design involves:

- the implementation of AI-related technologies in all disciplines of professional preparation of future specialists at higher education institutions (HEIs);
- adding to educational programs the disciplines that allow teaching students with the use of AI technologies, considering the peculiar aspects and the specifics of their future professional activities;
- the use of AI-generated content in lessons, assigning tasks that will require AI technologies to exploit;
- AI technologies are used to improve the information infrastructure in HEIs (e.g., distance learning systems, decision-making systems, forecasting systems).

Depending on the university's capabilities, pedagogues can choose the ways of immersing students in AI technologies. However, they can only achieve a comprehensive and sustainable result using these methods simultaneously.

We propose the pedagogical strategies rely on the recommendations of the Artificial Intelligence Competency Framework for higher education institutions [17], even though the AI competency framework is situated in the Montreal AI context; instead, it determines the standard set of competencies required by AI practitioners. This AI competency framework aims to outline the core competencies (knowledge, skills, and abilities) needed by AI practitioners in the technical, business, and human domains. With ethics being integral to the AI field and the work of AI practitioners, ethical competencies have been integrated into the technical, business, and human domains. This competency framework is a tool for various educational roles, including educators, program developers, and prior learning coordinators involved in the program development process from inception to implementation. This framework has more than 70 competencies, which are understood to be the primary knowledge, skills, and abilities required by AI practitioners. In introducing the proposed approach for students of different specialties, selecting those most suitable for a particular specialty from this list of competencies is advisable. For example, it is appropriate for IT professionals to direct their professional training to mastering competencies, which are listed in the “Technical Domain” of the AI Competency Framework.

The authors formulated the planned results that can be achieved when higher education institutions and pedagogues meet the conditions of applying the pedagogical strategies, which reduces the perception that AI harms the labor market and mitigates the negative attitude of young people toward AI technologies. The authors considered the aspects of sustainable development while formulating the planned results (figure 1/planned results). These aspects are considered within the current study, well-thought-out, and matched with the Sustainability Awareness Diagram (SAD) [18]. As a result, the authors complete the diagram entitled “Visualization of the effects that may result from the use of the pedagogical strategies for Education for Sustainable Futures” (figure 2).

We propose the pedagogical strategy, to be more precise, the instructional strategy (note: according to Dick et al. [16], instructional strategy is used to cover the various aspects of organizing the content, stating learning activities, and determining how to deliver the content and activities).

The planned results of applying the pedagogical strategy (figure 1) at the higher education institutions are detailed and presented in table 1.

As mentioned above, each of the five dimensions of sustainability is divided into three levels of impact [18]: immediate – caused by the direct function of the system or its development; enabling – arising from the application of a system over time; structural – referring to persistent changes that can be observed at the macro level. The authors present the visualized version of the effects that may result from using the pedagogical strategies for Education for Sustainable Futures. The authors used the format of the Sustainability Awareness Diagram (SAD) (figure 2).

The authors put each planned result in the SAD, considering their influence (immediate, enabling, structural) on Sustainable Futures.

5. Conclusions

To sum up, it is essential to mention that according to this study, there needs to be more educational practices to reduce the risks of introducing AI into human activity for sustainable development. Such tasks are mostly solved at the legal or state level and by organizations dealing with humankind’s environmental and economic problems. Because of this, a survey conducted among students of non-linguistics universities in two countries testifies to students’ awareness of the disproportion between people and their concern about the loss of jobs because of AI. Many students worry that AI will replace someone (40.6%). Therefore, we

Table 1. Planned results of the implementation of the pedagogical strategy, considering the five dimensions of sustainability.

The dimensions of sustainability	The sustainability of the results
Social	**Education and Social Exchange (EaSE)** The improvement of skills to use AI technology in future professional activities. Contributing to the understanding of AI technology and the ethical aspects of its use in professional activities
User	**Personal experience of using AI in professional activities and everyday life (PEuAI)** Improving the level of professional competence in the AI sphere and the ability to use the knowledge of AI effectively in day-to-day life **Empowering users (EU)** Increasing access to information with the use of AI technologies for lifelong learning **Psychological stability (PS)** Increasing the level of psychological resilience and reducing social tension due to increased confidence in a sustainable future thanks to awareness about AI technologies and their use in professional work
Environmental	**Sustainable Enterprise Management (SEM)** Promoting sustainable development of specialist professional competence to allow sustainable management in enterprises and maintain workers' high professional qualifications **Sustainable Business Practices (SBP)** Promoting sustainable business practices in the enterprise, based on constant innovations and changes that significantly differ from traditional business methods **Sustainable Resource Management (SRM)** Promoting sustainable management of a resource such as a human resource. Thanks to AI technology, employees will be more satisfied, calm, and stress-free because AI will do part of the work, and therefore, they can do more creative tasks, which brings them more pleasure
Economic	**Cost-effectiveness for enterprises (CEE)** Promoting the effective practical work of employees. Saving money that is no longer spent on their training, as they will know how to get knowledge and learn using AI. Therefore, it will increase the profitability of the enterprise **Economic Impact (EI)** The impact on the country's economy through the enterprise's profitability growth
Technical	**Technical safety issue (TSI)** Compliance with the General Data Protection Regulation (EU GDPR) and data protection and confidentiality principles will be a priority during future specialists' training and professional activities

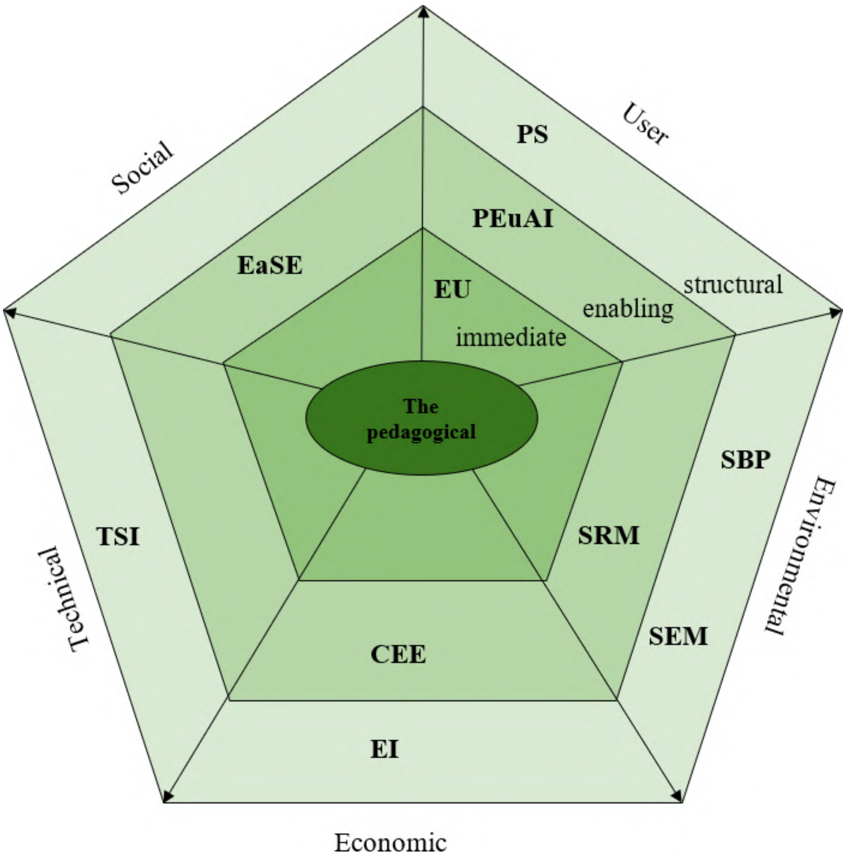

Figure 2. Visualization of the effects that may result from the use of the pedagogical strategies for Education for Sustainable Futures.

have developed the pedagogical strategies to teach university students to perceive the possible adverse effects of AI on the labor market tolerantly and efficiently alleviate the risk of the hypothetical negative consequences of AI technologies. The pedagogical strategies merely start from possible consequences (a negative impact of IT on the labor market, risks of applying IT in all spheres of human activity, a negative attitude of students to AI), offering the solution (the pedagogical strategies) at the level of higher education institutions, taking into consideration the AI Competency Framework, focuses on results aimed at Reducing the negative impact of AI on the labor market and the negative attitude of future specialists to AI technologies for five dimensions of sustainability (Social, User, Environmental, Economic, Technical).

The scientific article explores the intricate interplay between AI technologies, the labor market, and education for sustainable development. The authors investigate the common ground among these factors; the research delves into the multifaceted impacts of AI implementation on employment dynamics, emphasizing the need for the pedagogical strategies that align with principles of sustainable development. The article critically analyzes the challenges and opportunities within the nexus of AI, the labor market changes, and sustainable education, offering ideas for pedagogues that help to find the path to teach students to navigate the everchanging technology landscape, support the employees, whose work can never be replaced by automation, to foster both technological advancement and well-being of society.

Appendix A. Questionnaire

The survey was compiled using the research finding of Dakakni and Safa [15].

AI and equity

Q1. When applying for a job among hundreds of applicants, I would prefer that the screening and selection process be conducted by humans to avoid unfairness and error?
Response options
- I am concerned and aware of equity disparities among people and the loss of jobs instigated by AI (I am aware of a dark side of AI as concerns about bias and inequity)
- I am not concerned with equity disparities among people and the loss of jobs instigated by AI
- I am concerned about AI's ability to feel, which may render it capable of doing things on its own-likely destructive, aggressive behaviors

Q2. Do you think humanity is likely to worry about AI taking over jobs?
Response options
- Yes, I do. AI has garnered a sense of malaise and distrust
- Yes, I do. I am concerned about the possibility of AI technology displacing jobs and labor
- No, I do not

Q3. What do you think about AI and equity issues in terms of machines replacing jobs?
Response options
- I do not have any concerns about AI replacing people or equity issues. I feel technology creates jobs in another form for people
- I worry that AI will substitute human being, but I cannot deny the fact that it is very helpful
- I am against AI taking over jobs. Honestly, I am afraid of this happening in the future
- I do not think AI separates people, but it could become a threat because people have detected feelings in the answers of AI, so it is closer to a human that you interact with. It can start doing things on its own. Now, that is scary

AI and Privacy

Q4. Are you concerned about AI privacy issues?
Response options
- No, I have no worries about AI and privacy
- I have never really thought about privacy concerns. This is not something I stop to think about
- Yes, I hear about privacy issues all the time, but to me getting the job done is more important

- I think there are privacy policies on every social media platform; just do not go into the dark web because there are no agencies that can protect you from hackers and people using the dark web for illegal causes. I think, the rest is safe

Abstract. Despite the ongoing hostilities in Ukraine, the country has begun its recovery process. The renovation should be in line with the principles of energy efficiency and decarbonisation, with an emphasis on the use of renewable energy sources. The study aims to identify the most suitable locations for establishing solar power stations in the Ivano-Frankivsk region using GIS software. It also provides a cartographic model showing the suitability of different areas for local communities, providing valuable information for potential investors. The calculation process was carried out using QGIS, incorporating environmental, technical and economic factors, and resulted in the development of a conclusive suitability map. The primary assessment of photovoltaic potential was conducted for communities within the Ivano-Frankivsk region. The areas with the most promising potential, estimated to be over 50 MW, were ranked according to their suitability for solar plants.

1. Introduction

Decarbonisation involves decreasing carbon dioxide and methane, which are responsible for the greenhouse effect, output per unit of electricity generated [1]. As the global community intensifies its commitment to combat climate change and transition towards sustainable energy sources, the imperative for effective decarbonization and energy stability becomes increasingly pronounced. In this context, renewable energy, particularly solar power, emerges as a pivotal player in fostering a cleaner and more resilient energy landscape [2]. Ukraine aims to achieve decarbonization as part of its commitment to combat climate change and meet international obligations by reducing greenhouse gas emissions [3, 4]. Meanwhile, Russia's war against Ukraine continues, causing significant damage to infrastructure, housing, and natural habitats in Ukraine. Rebuilding the affected areas will inevitably lead to increased emissions from construction activities and the operation of new businesses. While solar energy is a crucial component of the decarbonization effort, a comprehensive approach to addressing climate change involves a combination of renewable energy sources, energy efficiency measures, and changes in consumption patterns [5–8].

Additionally, the integration of energy storage technologies and smart grid systems enhances the reliability and effectiveness of solar power in the overall energy landscape [9, 10]. It is important to realise that the Russian aggression has caused not only significant destruction and damage to energy infrastructure, but also environmental damage that can be described as ecocide. These environmental impacts include changes in the quality of the air over the territory of Ukraine. In the years following the military invasion, there was a significant increase in aerosol pollution [11,12]. Although major pollutants in the air have decreased overall, methane pollution, that significantly contributes to the greenhouse effect, is increasing in Ukraine [13], as confirmed by the results of satellite monitoring by the Sentinel-5 Precursor mission (figure 1).

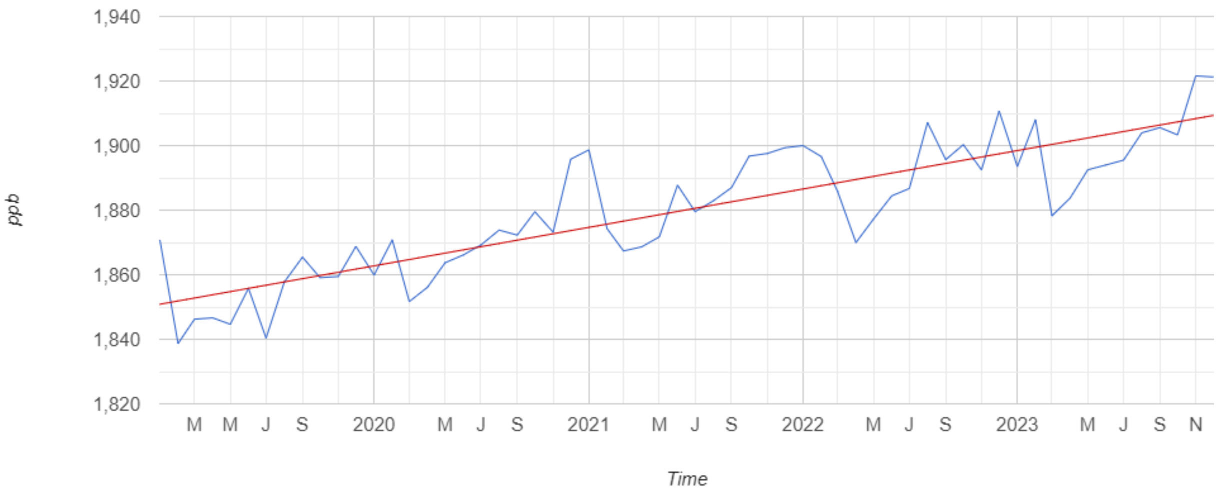

Figure 1. Monthly average density of methane (CH_4) over Ukraine from 2019 to 2023.

Furthermore, the eastern and southern regions of Ukraine, which have the highest solar potential, suffered the greatest losses. This includes damage to solar plants. In contrast, the western regions have lower solar potential due to geographical factors. Therefore, it is crucial to plan and allocate suitable sites for solar plants [14–17].

Geographic information systems (GIS) are the most effective tools for geospatial planning [18]. Most GIS-based studies on site suitability utilize multi-criteria analysis. This method is well-suited for complex issues involving multiple spatial criteria that often have differing units [15,19]. Common techniques within multicriteria analysis include the Analytical Hierarchy Process (AHP), Boolean logic, Weighted Linear Combination (WLC), fuzzy logic, etc. [20]. The Analytical Hierarchical Process (AHP) and Boolean Logic, which have been repeatedly tested to assess the solar potential of different areas around the world [19,21–24], were used in the research to assess the suitability of installing solar plants within the boundaries of local communities.

This article embarks on a comprehensive geoinformation assessment of solar plant potential in the Ivano-Frankivsk region, delving into the intricacies of harnessing solar energy to drive local decarbonization initiatives and fortify energy stability.

The Ivano-Frankivsk region faces an energy deficit, with rising electricity consumption. To enhance Ukraine's energy independence and address depleting fossil fuel reserves, especially given the region's focus on tourism, it's recommended to expand renewable energy use while improving efficiency. Currently, solar energy contributes 1.3% to the region's electricity production, covering about 10% of the population's energy needs [14].

The aim of this research is to analyze spatial suitability to solar plants building and create a cartographic model that visualizes the general suitability of the territorial communities.

In the subsequent sections, we will delve into the key aspects of the geoinformation assessment, presenting results and recommendations to catalyze the realization of a sustainable, decarbonized, and energy-stable future for the Ivano-Frankivsk region.

2. Data and methodology

When planning the installation of a solar power plant, it is essential to consider a range of environmental, technical, and economic factors that impact the solar potential of a territory. Each of these factors plays a crucial role in determining the feasibility, efficiency, and sustainability of the solar project.

In our study, we consider the spatial factors that determine the feasibility or impracticability of siting solar power plants, which have been identified as determinants in a number of publications [25–27]. Environmental factors include climatic (radiation and temperature), geomorphological (altitude, slope, aspect) and land cover. Socio-economic factors include the building, transport network and administrative boundaries of local communities, as well as regulatory restrictions on the siting of alternative energy facilities. An important technological factor is the availability of the electrical network and the possibility of connecting new objects to it. Geoinformation assessment of solar plant potential in the Ivano-Frankivsk region is a multifaceted process that involves considering various factors and environmental constraints regarding site selection and energy yield optimization (figure 2).

Figure 2. Methodology of the research.

Datasets, which were downloaded to assess the optimal placements for solar plants within the region, include region and community administrative boundaries, roads, hydrographic network, forests and parks provided by Research Institute of Geodesy and Cartography (Ukraine) (`https://gki.com.ua/`), electricity distribution and buildings data provided by Open Street Map (`https://www.openstreetmap.org/map`), land using data provided by Copernicus Global Land Service (`https://lcviewer.vito.be`); digital elevation model from EarthExplorer (`https://www.earthexplorer.usgs.gov`), solar radiation data provided by SolarGIS (`https://solargis.com/`) and average temperature data from WorldClim (`https://www.worldclim.org`).

The geoinformation approach combines geographical data with advanced technologies. It was applied with QGIS 3.32 using following steps and tools:

- data collection and geodatabase creation;
- data processing (transformation, clipping and rescaling layers);
- buffering, Boolean selection, overlay, Analytical Hierarchy Process;
- creating evaluation and constraint maps;
- combining maps – creation suitability map;
- zonal statistic – assessing administrative areas photovoltaic potential;
- thematic cartography and visualisation.

These tools provide a comprehensive understanding of the region's solar energy potential and aid in making informed decisions [28–31].

To prepare the downloaded data for AHP analysis and site selection algorithms, the following steps were completed: converting data to the single coordinate system, clipping vector and raster layers for analysis, creating buffer zones, and converting vector data to raster format. This process resulted in constraint maps indicating suitability of areas for solar power plants, with 0 representing unsuitable areas and 1 representing suitable areas, used for Boolean analysis. The next phase involved generating a slope map from digital elevation model (DEM) and further clipping raster data. It was important to standardize the varied units of raster layers (e.g., solar irradiation, slope, distance from power lines, temperature) to a uniform scale using linear scaling, which normalizes data across a common numerical range. This standardization facilitates accurate weighting and comparison in AHP analysis. The Boolean logic algorithm transforms the data from each raster map into binary form, using 0 and 1 (representing false and true, respectively). Consequently, areas deemed completely unsuitable are assigned a value of 0, while areas considered suitable are given a value of 1.

The process of combining maps to create a suitability map involves merging multiple raster layers that have been assigned binary values indicating suitability (0 for unsuitable, 1 for suitable). This integrated map highlights regions based on their overall appropriateness for specific uses, such as site selection for solar photovoltaic power plants. Each layer's information contributes to a composite view that assists decision-makers in identifying optimal locations. Zonal statistics is a spatial analysis technique used to evaluate the potential for photovoltaic energy within specified administrative areas. By applying this method, we can calculate statistics like the mean values of raster cells within each zone. The final results are visualised using a thematic map in GIS.

3. Results and discussion

By conducting a thorough geoinformation assessment, suitable locations for solar plant development in the Ivano-Frankivsk region were identified. Generally, areas with slope up to 3°, solar radiation more than $1100kWhm^-2$ per year, distance from the power lines up to 1000 m and average temperature in July between 25°C and 15°C, were evaluated as the most suitable for the construction of solar plants [14, 32].

The photovoltaic potential of the territories was estimated based on the expected land capacity of 0.003-0.004 ha/kW [8, 33] and the territorial communities were categorized into six groups based on their photovoltaic potential (figure 3).

For communities with the highest potential (above 25 MW), the areas were estimated with an equal interval classification method according to the following five categories:

- the most suitable areas;
- high suitability;
- moderate suitability;
- low suitability;
- not suitable at all.
- zonal statistic – assessing administrative areas photovoltaic potential;
- thematic cartography and visualisation.

The results are shown in table 1.

There are two major limitations in this study that could be addressed in future research. First, the study focused on large-scale assessment and did not take into account small-scale photovoltaic installations that could be situated on private properties, rooftops, or facades of individual buildings [34–37]. Second, access to information resources with spatial data, including the Public Cadastral Map, is currently limited due to the restrictions of martial law in Ukraine. Therefore, it is not possible to compare the compliance of identified sites suitable for solar plant location with plots designated as 'lands for industry, transport, communications, energy, defence and other purposes'.

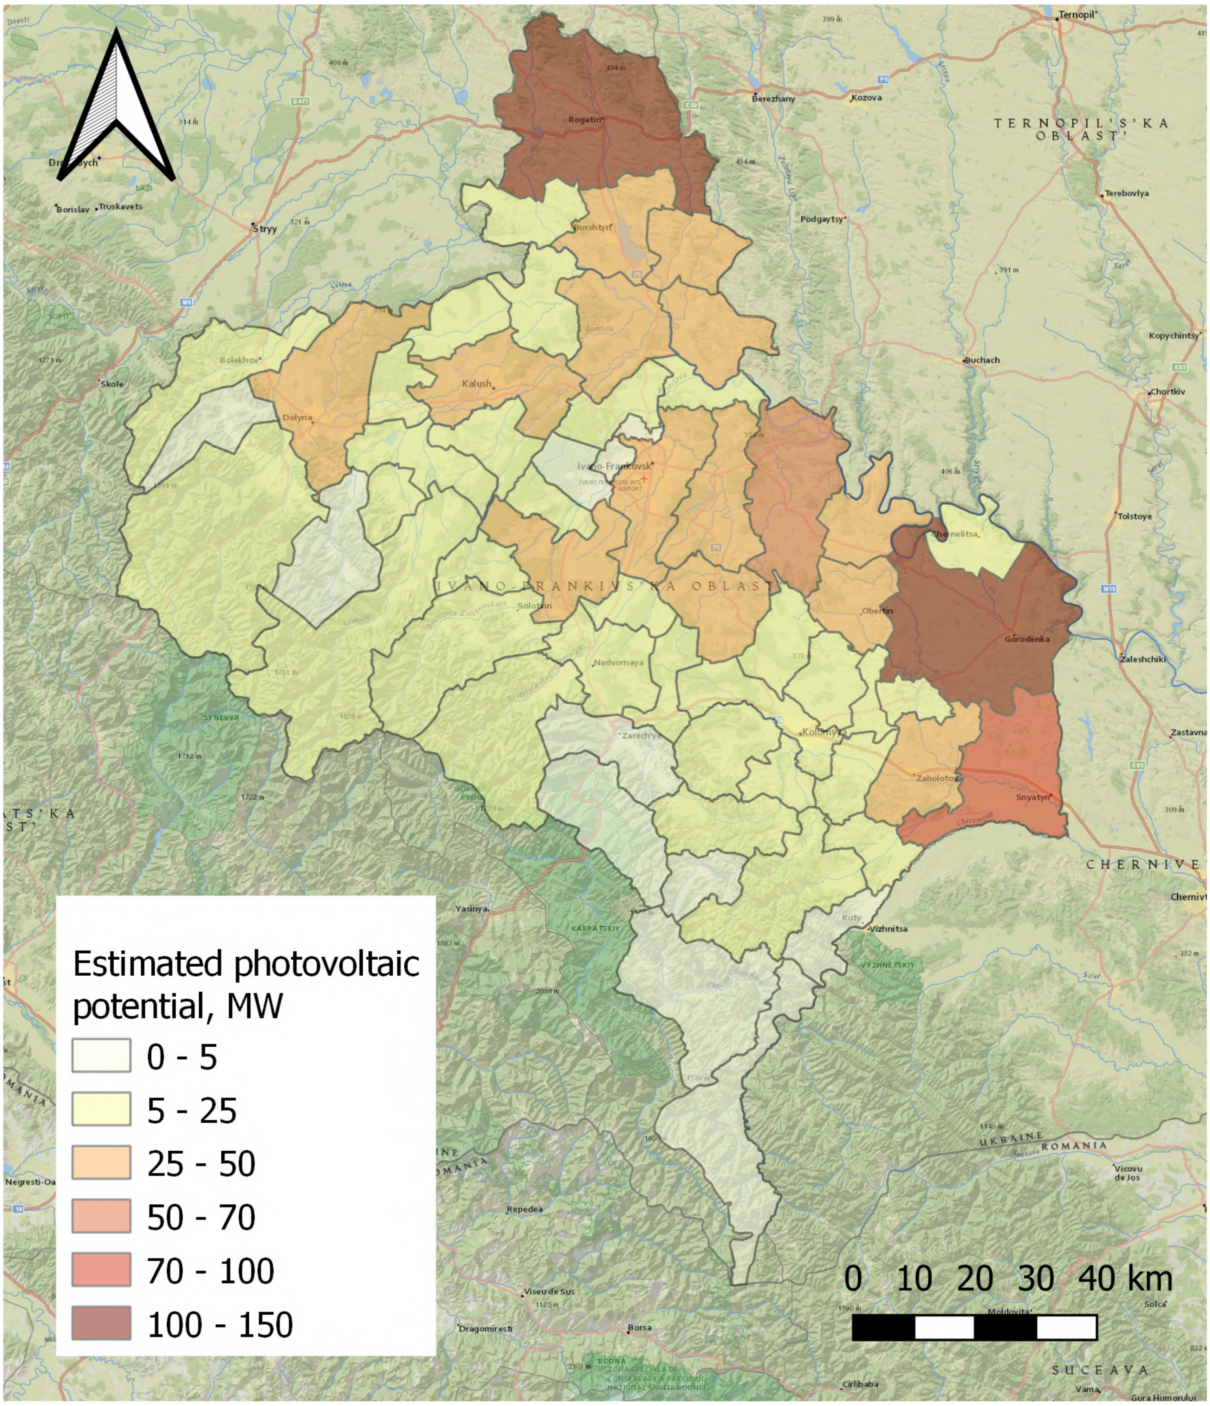

Figure 3. Photovoltaic potential of the communities within Ivano-Frankivsk region.

4. Conclusions

The sustainable reconstruction of Ukraine's energy system faces obstacles due to the ongoing war, widespread destruction, a substantial dependence on fossil fuels, and hindered advancements toward climate goals. The loss of solar energy capacities in the south of Ukraine makes it necessary to focus on the western regions, the solar potential of which is significantly lower due to natural factors. Therefore, geoinformation systems, which allow for an effective and

Table 1. Communities with the highest photovoltaic potential.

Community	The most suitable areas, km^2	High suitability, km^2	Moderate suitability, km^2	Low suitability, km^2	Unsuitable areas, km^2
Horodenkivska	105	144	69	11	295
Rohatynska	70	114.5	55.5	17.5	390.5
Snyatynska	84	71	19.5	2	177.5
Tlumatska	48.5	61.5	22.5	6	220.5
Ivano-Frankivska	67	38	6.5	0.5	149

comprehensive assessment of the potential for placing solar energy facilities, are an indispensable tool for spatial planning at both the regional and local levels. The creation of assessment cartographic models of solar potential at the local communities' scale will make it possible to create cadastres of solar potential in the future to improve land management in the Ivano-Frankivsk region. The study identified the territorial communities with the highest potential for the installation of solar power plants, namely Horodenkivska, Rohatynska and Snyatynska. The territorial communities with the lowest potential are those with a high level of urbanisation and located in mountainous areas. Obviously, for these communities it is worth considering the possibility of installing solar panels on individual buildings. As the future development of the research is considered the development of an integration roadmap for integrating solar power into the existing energy framework of the region. This plan will address technical, economic, and regulatory aspects, ensuring that the transition to solar energy is smooth and sustainable. It will also include strategies for scaling up solar energy production, integrating it with other forms of renewable energy, and possibly achieving sustainability and energy independence.

Abstract. One of the important problems preventing the increase in energy efficiency of biogas reactors is the use of heating elements operating in the free-convective mode of heat exchange. In addition to the large heat exchange areas, and the correspondingly reduced useful volume of the reactor, the use of free convective heat exchangers leads to the formation of stagnation zones, stratification of the medium, hypocooling of the lower zones of the reactor, overheating of the upper zones. The intensification of the heat exchange between the heating element and the substrate will allow to reduce the area of the heat exchange devices in the reactor, activate the thermostabilizing processes and reduce the cost of the reactor construction. Based on the results of the analysis of the influence of the fluid oscillation created by the movement of the activator plate on the intensity of heat transfer from the heating wall to the water and the substrate, the choice of the determining temperature of the liquid and the temperature of the wall with different methods of organizing convection is substantiated.

1. Introduction

The profitability of biogas plants is inversely proportional to the energy consumption for heating the reactor. Microbiological features of the anaerobic fermentation process require compliance with the limits of temperature regimes and temperature stabilization, uniform heating of the environment, absence of hypothermic and overheating zones.

In paper [1] is investigated the phenomena of biogas production and mass transfer for individual anaerobic granules in a microreactor.

A thorough examination of biogas production performance in both submerged and external Anaerobic Membrane Bioreactors featuring polymeric and ceramic membranes is conducted by Tomczak et al. [2]. The study places particular emphasis on analyzing the influence of temperature and hydraulic retention time on biogas yield. Additionally, detailed descriptions of strategies to mitigate fouling are provided.

In [3] is formed a neural network model of the investment process of biogas production, which allows to increase the efficiency of the management decision-making process on the feasibility of investing in biogas plants.

Terziev, Zlateva and Ivanov [4] considers enhancing the fermentation process in the digester for biogas production, obtained from animal and plant waste substrates.

Pilarski et al. [5] analyze energy conversion in an active biogas plant as an open thermodynamic system.

Abanades et al. [6] provide a brief overview of some safety rules and proposed policies based on world regulations. The effect of these regulations and policies on marketing and promoting biogas is highlighted for different countries.

In the course of anaerobic fermentation of biomass, it is necessary to observe certain limits of temperature regimes [7–14]:

- psychrophilic – substrate temperature up to 20°C, fluctuations ± 3...4°C;
- mesophilic – substrate temperature 35°C, fluctuations ± 2.8°C;
- thermophilic – substrate temperature 55°C, fluctuations ± 0.3°C.

At the same time, the speed of movement of the substrate under the conditions of the optimal fermentation process should not exceed 0.7 m/s. The expansion of the development of biogas plants requires a reduction in their capital and operating costs.

One of the important problems preventing the increase in energy efficiency of biogas reactors is the use of heating elements operating in the free-convective mode of heat exchange. In addition to the large heat exchange areas, and the correspondingly reduced useful volume of the reactor, the use of free convective heat exchangers leads to the formation of stagnation zones, stratification of the medium, hypocooling of the lower zones of the reactor, overheating of the upper zones. The intensification of the heat exchange between the heating element and the substrate will allow to reduce the area of the heat exchange devices in the reactor, activate the thermostabilizing processes and reduce the cost of the reactor construction.

2. Results and discussion

In literary sources, the following methods of intensification of free-convective heat exchange under the conditions of external washing of the surface are of interest [7, 11–14]:

1) the formation of a forced flow near the heating surface due to the installation of vertical limiting walls;
2) increasing the heat exchange surface by finning, which can both increase and decrease the intensity of heat exchange;
3) local and massive bubbling of the heat exchange surface by biogas jets, while the intensity of heat exchange increases by 1.5...2.0 times;
4) vibration of the heat exchange surface, which increases the intensity of heat transfer for water up to 20 times, but it is undesirable due to structural complications of the heat supply and vibration drive systems;
5) vibration of the environment, acoustic methods, the maximum achievable intensification of heat exchange 2...4 times.

The method based on the vibration of the environment is the most suitable for the conditions of the biogas plant, since, in addition to the intensification of heat transfer, additional mixing takes place. Also, among the most effective methods of increasing the intensity of heat exchange when liquid flows around bodies is the vibration of the environment, which provides, under optimal conditions, an increase in the intensity of heat exchange by 2-4 times compared to free convection. The high intensity of heat exchange during the vibration of the medium and the relatively small consumption of power for its implementation, the simplicity and flexibility of managing this process – all this provides the advantages of vibration activation in relation to other ways of intensifying heat exchange in liquids and gases. These advantages have led to a fairly widespread of vibration activation in modern technology. Washing surfaces with liquid waves is used in power engineering, metallurgy, chemical technology, air conditioning systems, and other fields of technology.

Oscillation of the liquid with the help of a pulsator-valve, a crank mechanism, etc. allows to create of artificial turbulence in the area of the heat exchange surface, which will destroy the viscous wall layer, intensive washing of the heating wall and intensification of heat exchange. For small and medium-sized reactors, one of the effective mechanisms for stirring is the engine-driven crank-rod stirrer. Consider the movement of the crank mechanism, which was used as a pulsation exciter in the biogas reactor (figure 1). Let's assume that the mechanism activates the activator plate, which is placed above the heat exchanger and performs oscillating movements above it. The plate can be both solid and perforated, its shape determines the hydraulic resistance of the medium – the substrate.

The equation of motion of the activator plate can be found by solving the Lagrange equation:

$$\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial T}{\partial \phi}\right) - \frac{\partial T}{\partial \phi} = Q\phi, \tag{1}$$

The total kinetic energy of the system is defined as the sum of the kinetic energies of the movement of the components of the crank-connecting mechanism – the flywheel, the crank and the activator plate:

$$T = T_1 + T_2 + T_3, \tag{2}$$

To determine the kinetic energies of the components of the system, we write down the kinematic relations between the elements.

Having entered the coordinate system, as shown in figure 1, we write down the kinematic relations between the components of the activator mechanism and the velocity equation, provided that the instantaneous center of velocity is point P_2.

$$KA = r \cdot \sin(\phi) - \epsilon, \tag{3}$$

$$KB = \sqrt{l^2 - (\sin(\phi) - \epsilon)^2}. \tag{4}$$

$$\left\{ \begin{array}{r} Y_B = r \cdot \cos(\phi) + KB \\ X_B = \epsilon \end{array} \right\} \tag{5}$$

$$\left\{ \begin{array}{r} X_c = \epsilon + \frac{\mathrm{K}A}{2} = \epsilon + (r \cdot \sin(\phi) - \epsilon)/2 \\ Y_c = r \cdot \cos(\phi) + \frac{\mathrm{K}B}{2} = r \cdot \cos(\phi) + 0.5 \cdot \sqrt{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)} \end{array} \right\} \tag{6}$$

$$\left\{ \begin{array}{r} V_B = \dot{Y}_B = \dot{\epsilon} * r * \sin(\phi) + \frac{-(r * \sin(\phi) - \epsilon) \cdot r \cdot \cos(\phi) \cdot \dot{\phi}}{\sqrt{l^2 - (r \cdot \sin(\phi) - \epsilon)^2}} \\ V_C = \sqrt{\dot{X}_c^2 + \dot{Y}_c^2} = -\sqrt{\frac{r^2 \cdot \dot{\phi}^2 \cdot \cos^2(\phi)}{4} + \left| -r \cdot \dot{\phi} \cdot sin(\phi) - \frac{\dot{\phi} \cdot r \cdot cos(\phi) \cdot (r \cdot sin(\phi) - \epsilon)^2}{\sqrt{l^2 - (r \cdot \sin(\phi) - \epsilon)^2}} \right|} \end{array} \right\} \tag{7}$$

The distance h_2, which will be covered by the center of mass of the link PK – point C, during the movement of the mechanism, is determined according to the equation:

$$h_2 = r + \sqrt{l^2 - \epsilon^2}/2 - \left(r \cdot \cos(\phi) + \sqrt{l^2 - 0.5 \cdot (r \cdot \sin(\phi) - \epsilon)^2}\right), \tag{8}$$

The distance h_3 passed by point B during movement of the mechanism is determined from the equation:

$$h_3 = r + \sqrt{l^2 - \epsilon^2} - \left(r \cdot \cos(\phi) + \sqrt{l^2 - (r \cdot \sin(\phi) - \epsilon)^2}\right), \tag{9}$$

Let's find the equation describing the value of the generalized force Qϕ:

$$Q_\phi = \frac{\delta A}{\delta \phi}. \tag{10}$$

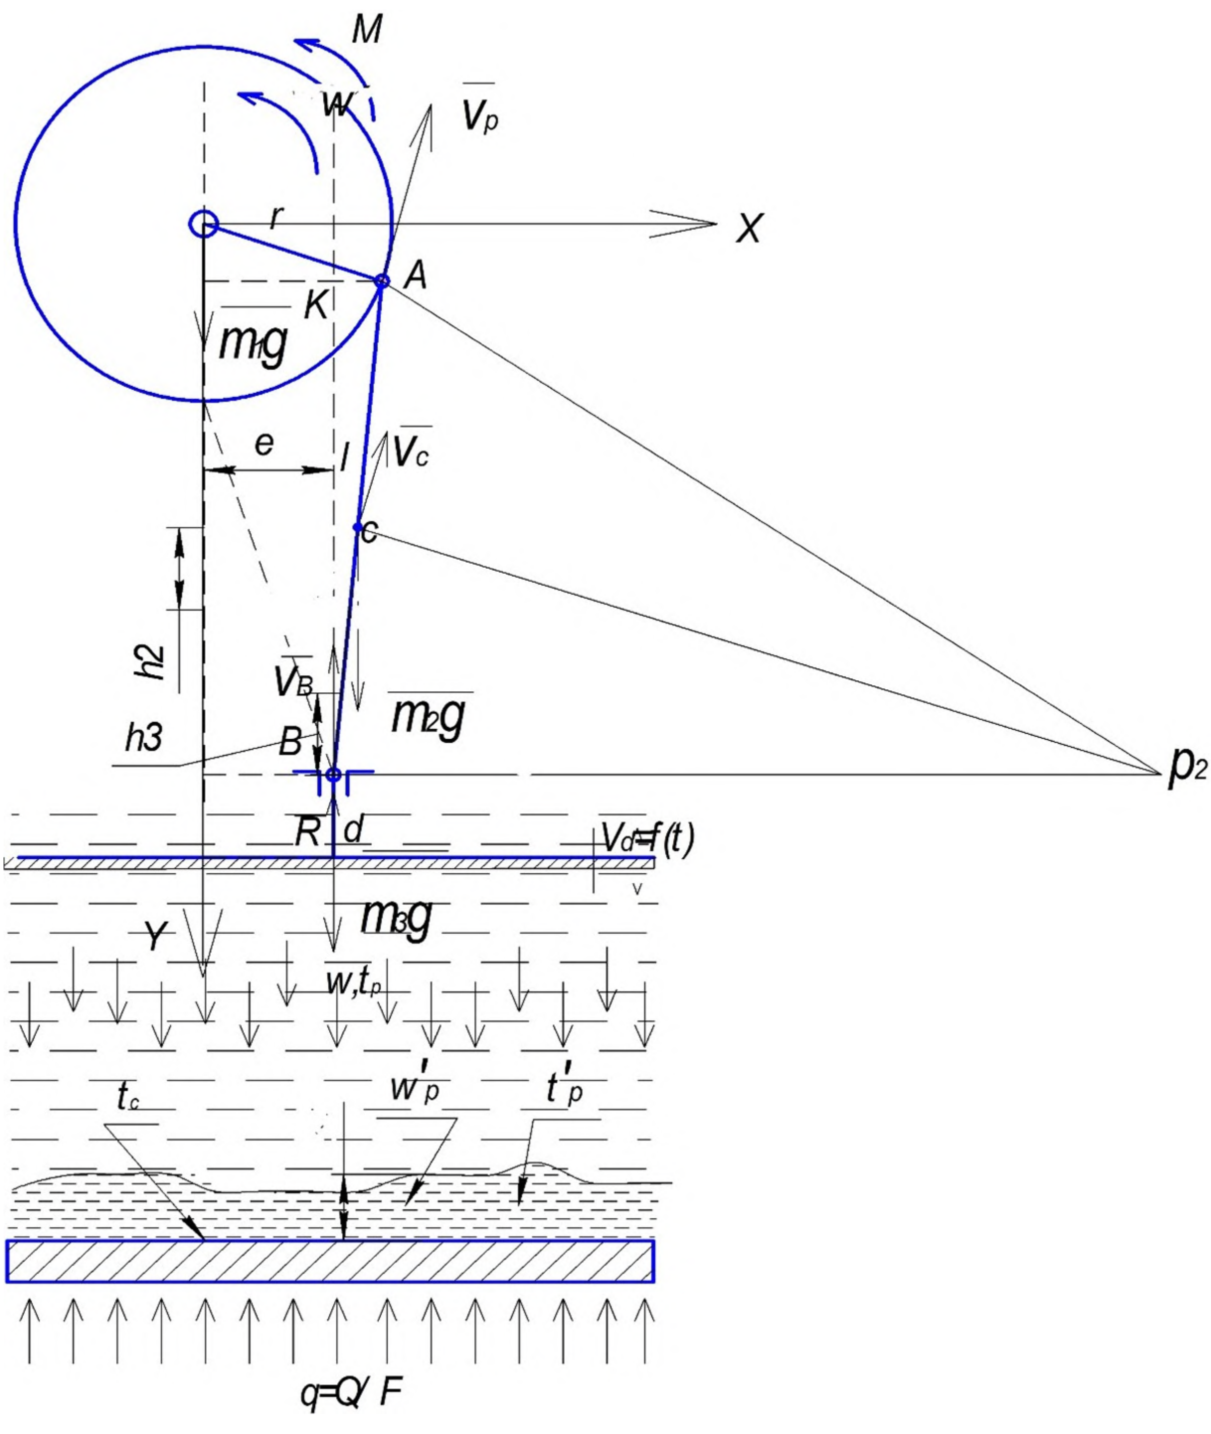

Figure 1. Dynamic diagram of the movement of the working organ of the bioreactor with an activator plate.

The total work of the forces acting on this activator mechanism consists of the work of the weight of the crank link – A_m2g weight forces of the slider $-A_m3g$; work moment of forces, which sets the activator in motion – A_M; the work of the resistance force of the movement medium of the activator plate is A_R.

$$A = A_m2g + A_m3g + A_M + A_R \tag{11}$$

Let's find the meaning of these works:

$$A_m 2g = -m_2 \cdot g \cdot \left[r \cdot (1 - \cos(\phi)) + \frac{\sqrt{(l^2 - \epsilon^2) - \sqrt{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)}}}{2} \right] \tag{12}$$

$$A_m 3g = -m_2 \cdot g \cdot \left[r \cdot (1 - \cos(\phi)) + \sqrt{(l^2 - \epsilon^2)} - \sqrt{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)} \right] \tag{13}$$

$$A_M = M \cdot \phi \tag{14}$$

We write down the resistance force of the movement medium of the activator plate in the form:

$$R = C \cdot S \cdot \frac{\rho \cdot Wmax^2}{2} \tag{15}$$

where C is the experimental coefficient [15], which depends on the aspect ratio of the plate; $Wmax$ is the maximum permissible speed of movement of the substrate ($Wmax = 0.7$ m/s). Using the value of the resistance of the medium in the form (15) allows us to take into account only the technologically maximum permissible value of the speed of movement of the substrate, thus simplifying the engineering solution of equation (1).

$$A_R = -0.245 \cdot m_3 \cdot \rho \cdot C \cdot S \cdot \left(r + \sqrt{(l^2 - \epsilon^2)} - (1 \cdot \cos(\phi) + \sqrt{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)} \right) \tag{16}$$

Then the expression for finding the generalized force will have the form:

$$\begin{aligned} Q = M - m_2 \cdot g \cdot \left(r \cdot \sin(\phi) + \frac{\cos(\phi) \cdot (r \cdot \sin(\phi) - \epsilon)}{2 \cdot \sqrt{l^2 - (r \cdot \sin(\phi) - \epsilon)^2}} \right) - m_3 g \cdot \\ -m_3 g \cdot \left[r \cdot \sin(\phi) + \frac{r \cdot \cos(\phi) \cdot (r \cdot \sin(\phi) - \epsilon)}{2 \cdot \sqrt{l^2 - (r \cdot \sin(\phi) - \epsilon)^2}} \right] - \\ -0.245 \cdot m_3 \cdot \rho \cdot C \cdot S \cdot \left(r + \sqrt{(l^2 - \epsilon^2)} - (r \cdot \cos(\phi) + \sqrt{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)} \right) \end{aligned} \tag{17}$$

The kinetic energy of the system is the sum of the kinetic energies of the component links. Taking into account the peculiarities of the movement of each of the components, we will write down the equation for determining the kinetic energies of the links of the oscillatory activator:

$$T = T_1 + T_2 + T_3 \tag{18}$$

The kinetic energy of the first body is rotational motion:

$$T_1 = \frac{J \cdot \dot{\phi}^2}{2} = \frac{m_1 \cdot r^2 \cdot \dot{\phi}^2}{4} \tag{19}$$

The kinetic energy of the second body is plane-parallel motion:

$$\begin{aligned} T_2 = \dot{\phi} \cdot r^2 \cdot m_2 \cdot 0.5 \left[\left[\frac{\left[r \cdot \cos(\phi) + \sqrt{[l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \cdot \tan(\phi) - \epsilon \right]^2}{l^2 - (r \cdot \sin(\phi) - \epsilon)^2} \right] + \right. \\ +0.25 \cdot l^2 - \left[r \cdot \cos(\phi) + \sqrt{[l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \cdot \tan(\phi) - \epsilon \right] \cdot \\ \left. \cdot (r \cdot \sin(\phi) - \epsilon) + \frac{l^2}{12 \cdot [l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \right] \end{aligned} \tag{20}$$

The kinetic energy of the third body is translational motion

$$T_3 = \phi^2 \cdot r^2 \cdot \left[\frac{m_3 \left[(r-\epsilon)\cos(\phi) + \left[l^2 - (r \cdot \sin(\phi) - \epsilon)^2 \right]^2 \right]}{2 \cdot (\cos(\phi))^2 \cdot [l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \right] \tag{21}$$

The expression for determining the kinetic energy will look like this:

$$\begin{aligned} T = \phi^2 \cdot r^2 \cdot \Bigg[& 0.25 m_1 + \frac{m_3 \left[(r-\epsilon)\cos(\phi) + \left[l^2 - (r \cdot \sin(\phi) - \epsilon)^2 \right] \right]^2}{2 \cdot (\cos(\phi))^2 \cdot [l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} + \\ & + m_2 \cdot 0.5 \left[\left[\frac{r \cdot \cos(\phi) + \sqrt{[l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \cdot \tan(\phi) - \epsilon^2}{(l^2 - (r \cdot \sin(\phi) - \epsilon)^2)} \right] + \right. \\ & + 0.25 \cdot l^2 - \left[r \cdot \cos(\phi) + \sqrt{[l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \cdot \tan(\phi) - \epsilon \right] \cdot \\ & \left. \cdot (r \cdot \sin(\phi) - \epsilon) + \frac{l^2}{12 \cdot [l^2 - (r \cdot \sin(\phi) - \epsilon)^2]} \right] \Bigg] \end{aligned} \tag{22}$$

The partial derivative of the kinetic energy along the angle of rotation:

$$\begin{aligned} \frac{\delta T}{\delta \phi} = (& m_3^2 \cdot \frac{\left[(r-e) \cdot \cos(\phi) + l^2 - (r \cdot \sin(\phi) - e)^2 \right]}{\cos(\phi)^2 \cdot [l^2 - (r \cdot \sin(\phi) - e)^2]} \cdot \\ & \cdot [(-r-e) \cdot \sin(\phi) - 2(r \cdot \sin(\phi) - e) \cdot r \cdot \cos(\phi)] + \\ & + m_3^2 \cdot \frac{\left[(r-e) \cdot \cos(\phi) + l^2 - (r \cdot \sin(\phi) - e)^2 \right]^2}{\cos(\phi)^3 \cdot [l^2 - (r \cdot \sin(\phi) - e)^2])} \cdot \sin(\phi) + \\ & + m_3^2 \cdot \frac{\left[(r-e) \cdot \cos(\phi) + l^2 - (r \cdot \sin(\phi) - e)^2 \right]^2}{\cos(\phi) \cdot [l^2 - (r \cdot \sin(\phi) - e)^2]} \cdot (r \cdot \sin(\phi) - e) \cdot r + \\ & + 0.5 \cdot m_2 \cdot \Bigg[2 \cdot \frac{[r \cdot \cos(\phi) + [l^2 - (r \cdot \sin(\phi) - e)^2]^1/2 \cdot \tan(\phi) - e]}{l^2 - (r \cdot \sin(\phi) - e)^2} \cdot \\ & \cdot [-r \cdot \sin(\phi) - \frac{1}{[l^2 - (r \cdot \sin(\phi) - e)^2)]^1/2} \cdot \tan(\phi) \cdot (r \cdot \sin(\phi) - e) \cdot \\ & \cdot r \cdot \cos(\phi) + [l^2 - (r \cdot \sin(\phi) - e)^2]^1/2 \cdot (1 + \tan(\phi)^2] + \\ + 2 \cdot & \frac{[r \cdot \cos(\phi) + [l^2 - (r \cdot \sin(\phi) - e)^2]^1/2 \cdot \tan(\phi) - e]^2}{l^2 - (r \cdot \sin(\phi) - e)^2} \cdot (r \cdot \sin(\phi) - e) \cdot r \cdot \cos(\phi) - \\ & - [-r \cdot \sin(\phi) - \frac{1}{[l^2 - (r \cdot \sin(\phi) - e)^2)]^1/2} \cdot \tan(\phi) \cdot (r \cdot \sin(\phi) - e) \cdot \\ & \cdot r \cdot \cos(\phi) + [l^2 - (r \cdot \sin(\phi) - e)^2]^1/2 \cdot (1 + \tan(\phi)^2] \cdot (r \cdot \sin(\phi) - e) - \\ & - [r \cdot \cos(\phi) + [l^2 - (r \cdot \sin(\phi) - e)^2]^1/2 \cdot \tan(\phi) - e] \cdot r \cdot \cos(\phi) + \\ & + \frac{l^2}{[12 l^2 - 12(r \cdot \sin(\phi) - e)^2)]^2} \cdot (r \cdot \sin(\phi) - e) \cdot r \cdot \cos(\phi) \Bigg] \cdot \phi^2 \cdot r^2 \end{aligned} \tag{23}$$

In (22), we denote the expression in parentheses by "D", then the time derivative:

$$\frac{d}{dt} \left(\frac{\delta T}{\delta \dot{\phi}} \right) = 2 \cdot \ddot{\phi} \cdot r^2 \cdot D \tag{24}$$

The Lagrange equation (1) will be written in the form:

$$2 \cdot \ddot{\phi} \cdot r^2 \cdot D - \frac{\delta T}{\delta \phi} = Q_\phi, \tag{25}$$

where $\delta T/\delta\phi$ and Q_ϕ are determined from equations (23) and (17), respectively. Let's turn the resulting nonlinear differential equation into a system of linear differential equations of the first order by substitution:

$$\begin{bmatrix} \ddot{\phi} = \dot{z} \\ \dot{\phi} = z \end{bmatrix} \tag{26}$$

We will solve this system using the Runge–Kutta numerical method and obtain a solution in the form of values of the function $\omega = f(\varphi)$. Using the solution of system (26), it is possible to determine the value of the speed of the activator plate. The liquid under the action of the plate also begins to make oscillatory movements and washes the heat exchange surface. A wall layer is located around the heat exchange surface, in which heat is transferred mainly due to thermal conductivity (figure 2).

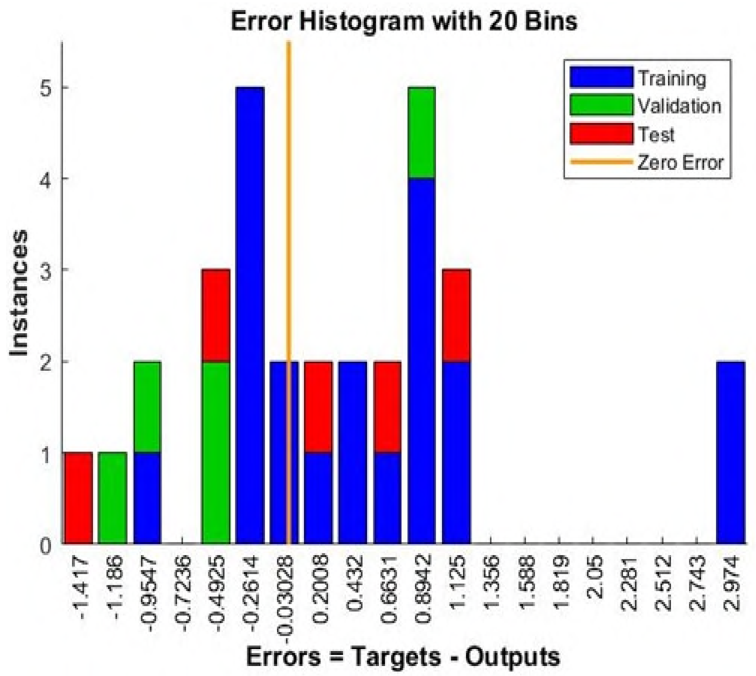

Figure 2. Thermal and hydrodynamic situations around the heat exchange surface according to the hypothesis of Reynolds and Prandtl.

According to the Fourier equation, we write that the heat flow q is determined:

$$q = \lambda \cdot \frac{t'_p - t_c}{\delta'_t} \tag{27}$$

where δ'_t is the thickness of the thermal layer; t'_p is the temperature of the liquid in the wall layer.

According to Kays, Crawford and Weigand [16], and Bergman et al. [17] the thickness of the viscous wall hydrodynamic δ' and thermal δ'_t layers is determined from the dependencies:

$$\delta' \approx 12 \frac{\nu}{\sqrt{s/\rho}} \tag{28}$$

$$\delta'_t \approx 12\frac{\nu Pr^{-0.33}}{\sqrt{s/\rho}} \tag{29}$$

The thermophysical properties of the substrate are determined from equations [7]:

$$\rho = 1000 + 2.4 \cdot c; \tag{30}$$

$$c_p = c_{dry} \cdot c + c_w \cdot (1 - c); \tag{31}$$

$$\mu = \mu_w \cdot \left[1 + 10 \cdot \left(\frac{10 \cdot (c-2)}{(11 - \beta_u \cdot c)} + c\right)\right], \tag{32}$$

where c is the content of dry matter, 2–15%; c_{dry} - heat capacity of the dry substance of the substrate; c_w – heat capacity of water; μ_w is the viscosity of water at a certain temperature; β_u is a coefficient that depends on the type of waste and is 0.7 ... 0.75 for cattle and β_u =0.6...0.7 for pigs.

According to Newton's equation, the value of the tangential stress is defined as:

$$s = \mu_w \frac{w'}{\delta'} = \mu_w \cdot \left[1 + 10 \cdot \left(\frac{10 \cdot (c-2)}{(11 - \beta_u \cdot c)} + c\right)\right] \cdot \frac{w'}{\delta'}, \tag{33}$$

where w' is the speed of movement of substrate particles that have entered the wall layer.

According to the Reynolds theory, supplemented by Prandtl hypothesis, the fluid flow washing over the heat exchange surface and having an average speed w, falling into the wall layer, slows down and acquires a speed w'. The temperature of the liquid inside the flow is t_p, the temperature of the liquid inside the wall layer is t'_p. According to the law of conservation of momentum, the force of motion resistance will have the form:

$$S = G' \cdot (w - w'), \tag{34}$$

where G' is the amount of liquid that entered the wall layer per unit of time. The amount of heat transferred by the liquid G' will be determined according to the expression:

$$Q = G' \cdot c_p \cdot (t_p - t'_p) \tag{35}$$

Then, given that S $= s \cdot F$ and Q$= q \cdot F$, we get:

$$q = c_p \cdot s \cdot \frac{t_p - t'_p}{w - w'} \tag{36}$$

From equations (29) and (33), the velocity in the wall layer w$'$ is determined:

$$w' = 12\sqrt{s/\rho} \tag{37}$$

Temperature gradients are determined from equations (27) and (35).

$$t'_p - t_c = q \cdot \delta'_t/\lambda \tag{38}$$

$$t_p - t'_p = \frac{q \cdot (w - w')}{c_p \cdot s} \tag{39}$$

Adding expressions (38) and (39), we get:

$$t_p - t_c = \frac{q \cdot (w - w')}{c_p \cdot s} + q \cdot \delta'_t/\lambda \tag{40}$$

Let's transform equation (40), taking into account that

$$\alpha = \frac{q}{t_c - t_p}$$

$$\alpha = \left[\frac{w - 12\sqrt{s/\rho}}{c_p \cdot s} + \frac{12\upsilon}{\lambda\sqrt{s/\rho}} \right]^{-1} \tag{41}$$

The values of isobaric heat capacity, density, and viscosity can be determined using equations (30), (31), (32).

The speed of fluid movement w is determined from the solution of system (26), assuming that the fluid moves to the heat exchange surface at the speed of movement of the activator plate. In the criterion form, equation is written as:

$$Nu = \frac{d}{\lambda} \left[\frac{w - 12\sqrt{s/\rho}}{c_p \cdot s} + \frac{12\upsilon}{\lambda\sqrt{s/\rho}} \right]^{-1} \tag{42}$$

The value of the tangential stress s during vibration washing of a single cylindrical surface is currently unknown. In the first approximation, it is possible to take the value of the tangential stress determined for the turbulent washing of the plate, transforming it as follows:

$$s = 0.037 \cdot \rho \cdot \frac{(w_A)^2}{2} \cdot (w_a \cdot d/2 \cdot \upsilon)^{-0.2} \tag{43}$$

Thus, equation (42) makes it possible to determine the value of the Nusselt criterion during oscillatory washing of the heat-exchange cylindrical surface in bioreactors for the utilization of organic waste of agricultural enterprises.

Based on the results of the analysis of the developed mathematical model, it has been found that in the range of measurements, the obtained value of the increase in the coefficient of heat transfer from the horizontal heating tubular element to the water exceeds the value for free convection by an average of 1.5...2.8 times. Both medium fluctuations and heat flow have a significant influence on the intensification of heat exchange. Moreover, an increase in the frequency of oscillations affects the increase in the coefficient of heat transfer from the horizontal cylinder to the water more significantly than an increase in the amplitude by an average of 15–25%. After analyzing equation (43), the surface of the influence of the arguments included in this equation – R_e and P_r – on the value of the function – the Nusselt criterion (figure 3) was constructed.

The proposed mathematical model calculates the heat exchange processes in biogas reactors under vibration activation of the substrate heating process from the tubular heat exchange element. Based on the parameters of the heat exchange subsystem of the reactor: the heat exchange area, the frequency and amplitude of oscillations, the temperature of the coolant, the thermophysical properties of the substrate, choosing one of the three fermentation temperature regimes, it is possible to determine the heat exchange coefficient from the surface of the heater to the substrate, calculate the amount of heat transferred, carry out design calculations of the heat exchange process. In addition to activating heat exchange processes in the substrate environment, temperature fields are equalized, and warming is more uniform.

Due to the activation of the heat exchange, a reduction in the mass of the heat exchange process for the $V = 3$ m^3 reactor was achieved by 18% a decrease in the cost of the reactor by 7% due to a lower cost of the heat exchange process (while taking into account the increase in the price of the reactor due to the vibration activator), an increase in the yield of biogas due to thermal stabilization by 12...14% compared to the free convective heating process. The results were obtained at a model reactor and as a result of implementation in a small farm in the Vinnytsia region.

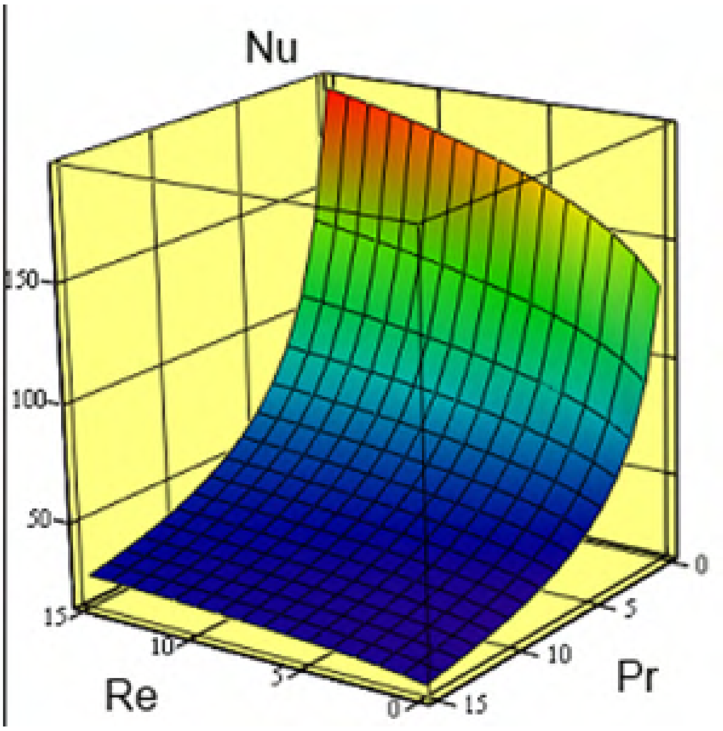

Figure 3. The surface of the influence of the Reynolds and Prandtl criteria on the value of the Nusselt criterion during vibration activation of heat exchange.

3. Conclusions

The law of motion of the activator plate has been found by solving Lagrange's differential equation. Based on the laws of thermal conductivity, convective heat and mass transfer, and conservation of momentum, a criterion equation has been developed that describes the heat exchange processes between the heating element and the substrate during oscillatory washing of the heater wall.

The mathematical model was checked for adequacy by comparing the obtained results with the results of experimental studies. For this, several experimental data were collected. Based on the comparison of two samples using the Student's criterion, the model was evaluated, errors were calculated, and a t-test was performed. It was determined that the t value does not exceed the critical value for the given degrees of freedom and the significance level of 0.05. That is, the developed mathematical model is adequate.

Based on the results of the analysis of the influence of the fluid oscillation created by the movement of the activator plate on the intensity of heat transfer from the heating wall to the water and the substrate, the choice of the determining temperature of the liquid and the temperature of the wall with different methods of organizing convection is substantiated. It has been found that the oscillation of the medium by the activator plate intensifies the free convective heat transfer in the aqueous medium by 1.5...3.0 times, in the $C = 8\%$ suspension by 1.3...2.5 times. Thus, the use of an activator plate to intensify heat exchange in bioreactors allows thermostabilization and intensification of the biogas production process and saves material resources by reducing the area of heat exchange devices.

Abstract. Traditional biological wastewater treatment systems are unable to completely remove biogenic substances due to the lack of the necessary amount of substrate, the specifics of the technological scheme, and only the involvement of raw sediment and partially excess sludge in the biological process (continued aeration) can solve the specified problem. The use of psychrophilic anaerobic displacement reactors with an expanded layer of sludge (EGSB-reactors) and subsequent stages of biological treatment will allow to achieve of deep purification of wastewater from carbon, nitrogen and phosphorus in purified water and significantly reduce the volume of extracted sediments and their morphology. Therefore, the aim of our work was the development of a method of municipal wastewater treatment using facilities with a lower material capacity, with lower energy consumption for deep biological removal of carbon, nitrogen and phosphorus compounds. Systematic investigations of the technologies, reactor designs, and processes for anaerobic treatment of low-concentration effluents in psychrophilic conditions calculations were carried out at the Kaniv wastewater treatment plant. Based on this, a model-concept of treatment facilities was developed. Design work was completed for the reconstruction of the Kaniv wastewater treatment plant, where two EGSB psychrophilic reactors, converted from the existing two-tier clarifiers, were put into operation.

1. Introduction

Pollution of rivers with untreated sewage, which are sources of drinking water, and significant areas adjacent to treatment plants with waste from cleaning (sediment) is an urgent problem today [1–4]. For example, the annual environmental damage caused to the environment by inefficiently working facilities with a capacity of 1.0 thousand m^3/day (Hadyach, Poltava region – 2020-2021) is estimated at UAH 8.0 million, excluding additional costs to water intakes located downstream, to bring drinking water to the requirements of Sanitary rules and norms [5]. There are more than a hundred such structures in Ukraine. No one has calculated the losses from the global pollution of large and medium-sized rivers by discharges of untreated or insufficiently treated sewage from small cities and towns in Ukraine, but, in our opinion, they are extremely large if all the consequences are taken into account.

Most of the municipal sewage treatment plants in small towns and villages have long been physically worn out and require significant restoration work or new construction [6]. Also, the existing technologies for wastewater treatment and sediment disposal are morally outdated and do not meet modern requirements for the removal of organic carbon, nitrogen, phosphorus and waste management; as a result of aridization of the climate – blooming of ponds, pollution of underground sources of drinking water, deterioration of atmospheric air quality [7,8]. The well-known methods of removing excess nitrogen compounds are ensuring the modes of nitrification of ammonium by autotrophic producers and denitrification of nitrites and nitrates by heterotrophic reductants to molecular nitrogen [9, 10]. To remove phosphorus compounds in practice, chemical methods (reagents) and biological methods are used both due to the selection of special heterotrophic phosphorus-accumulating organisms (FAO) and without FAO [11]. The disadvantage of known systems for the removal of biogenic elements is their significant energy and resource consumption with insufficient efficiency of biological purification, especially from phosphorus compounds [11–14].

The task we set for ourselves was to develop a method of municipal sewage treatment using structures with a lower material capacity, with lower consumption of energy carriers for deep biological removal of carbon, nitrogen and phosphorus compounds.

2. Materials and methods

The Kaniv wastewater treatment plant (WWTP) was chosen as the basic experimental site.

Laboratory control of the operation of sewage treatment plants – measurement of pollution indicators – was carried out according to the approved methods of the State Committee of Ukraine on matters of housing and utilities [15]:

- Methodology for measuring the mass concentration of petroleum products – Governing normative document (GND) 01-05-2002.
- Methodology for measuring the mass concentration of iron – GND 02-05-2002.
- Methodology for measuring the mass concentration of suspended substances – GND 03-05-2002.
- Methodology for measuring the mass concentration of ammonium nitrogen – GND 04-05-2002.
- Methodology for measuring biological oxygen demand (BOD)– GND 05-05-2002.
- Methodology for measuring the mass concentration of nitrates – GND 06-05-2002.
- Methodology for measuring the mass concentration of nitrites – GND 07-05-2002.
- Methodology for measuring settling substances – GND 08-05-2002.
- Methodology for measuring the mass concentration of orthophosphates – GND 09-05-2002.
- Methodology for measuring permanganate oxidizability – GND 10-05-2002.
- Methodology for measuring of sediment density – GND 11-05-2002.
- Methodology for measuring of anionic synthetic surfactants – GND 12-05-2002.
- Methodology for measuring of dissolved oxygen – GND 13-05-2002.
- Methodology for measuring the mass concentration of chlorides – GND 14-05-2002.
- Methodology for measuring mass concentration of sulfates – GND 15-05-2002.
- Methodology for measuring of chemical oxygen demand (COD)– GND 16-05-2002.
- Methodology for measuring of ash content and hygroscopic moisture of sediments – GND 19-05-2002.
- Methodology for measuring sediment moisture – GND 20-05-2002.
- Methodology for measuring total nitrogen – GND 23-05-2002.
- Methodology for measuring total phosphorus – GND 26-05-2002.

Ensuring the reliability of the determination of measurements according to the necessary indicators of pollution was carried out by the employees of the Institute through control checks. Also, the following approaches and calculations were used for express analytical assessment of organic pollution reduction:

- Biochemical consumption of oxygen during five days (BCO_5) = 0.875·BCO_{20} = 0.75·COC, where BCO_5 – biochemical consumption of oxygen during five days, BCO_{20} – biochemical consumption of oxygen during twenty days, COC – chemical oxygen consumption [16].
- Effect of sewage treatment on sand traps: for SS – 3-5 %; BCO – to 5 %, SS – suspended substances [17].
- COC (B) = 0.67·ASS; COC (B) – COC of active biomass [18].
- Cs = SS of anaerobic sludge, where Cs – sludge concentration [18].

For approximate calculations – COC (SS of raw sediment) = 0.98·SS according to [18] and COC = (BCO_{20} dark – BCO_{20} illumin.)/0.86 = 40.69 g/people·day, and SSsedim. = 40 g/people·day.

Lighting curves were obtained experimentally (according to [16, 19]).

Ultrasonic scanning of the reactor volumes and sludge sampling were carried out once a week during the maximum inflow of wastewater to the facilities and in the absence of wastewater. The break between the inflow of sewage to the sewage treatment plant (between measurements) was 15-20 minutes. Scanning was carried out with the Ease 245DS echo sounder, which has a depth scale displayed on the monitor, which allows continuous determination of the height of the silt. By changing the sensitivity of the device, the required effect of recognition of the silt layer was achieved. Checking the reliability of the device readings was determined by immersing the control board to a depth of 4 m from the water surface.

To determine the concentrations of sludge, its ash content and index, sludge from the expanded layer was taken by a submerged membrane pump of low productivity (domestic pump “Strumok”). The pump pumped out samples from different heights of the expanded layer.

The qualitative and quantitative composition of the formed gases was determined by the gas chromatography method. Gas chromatographic analysis of inorganic gases (H_2, CO, CO_2) and methane was carried out on a chromatograph Chrom-5 (Czech Republic) with a detector for measuring the thermal conductivity of gases. For the analysis of light gases, stainless steel 1.5 m long and 3 mm internal diameter, filled with a sorbent: activated charcoal of the SKT brand with a fraction of 0.25–0.50 mm, impregnated with a 10 % $NiSO_4$ solution. The carrier gas is argon, the flow rate of which was 20 ml per min. The temperature of the columns thermostat and the detector is 100 ^oC, the evaporator temperature – 120 ^oC, and the detector current – 40 mA. Hydrogen analysis was carried out on a glass chromatographic column with a length of 1.5 m and an internal diameter of 3 mm, filled with pre-fired CaA zeolite with a fraction of 0.25–0.50 mm. The carrier gas is argon, the flow rate of which was 30 ml per min. Analysis temperature – 60 ^oC, evaporator temperature – 120 ^oC, detector current – 80 mA. The gas sample was introduced into the chromatographic column through a calibrated loop using a dosing tap. The sample volume was 0.37 ml. Analysis of organic reaction products was carried out on a chromatograph “Agilent Technologies 7890A” (Agilent, USA) which was equipped with a flame ionization detector and using a DB-624 UI quartz capillary column with a length of 60 m and an internal diameter of 0.32 mm in a combined temperature regime (isothermal – 10 minutes at 40 °C, then programming the temperature from 40 to 250 ^oC at a speed of 5 degrees per min. Samples were introduced into the column with a microsyringe with a capacity of 1.0 μl. Processing of the analysis results was carried out according to the areas of chromatographic peaks by the method of internal normalization using calibration coefficients.

3. Results and discussion

Systematic research was preceded by significant work on the study of technologies, reactor designs, and calculations of processes for anaerobic treatment of low-concentration effluents in psychrophilic conditions. Taking into account the economic situation in the communal economy of Ukraine, climatic conditions and the human factor, the existing projects and results of the operation of classical and experimental treatment facilities for small cities and settlements, as well as local treatment systems at individual enterprises, were rethought. Based on this, a model-concept of treatment facilities was developed, which provides for the following:

- replacement of primary clarifiers with anaerobic EGSB-reactors with an expanded layer of granular sludge;
- use for the aerobic stage of cleaning facilities with features of aerofilters with easy loading and aeration tanks-settlements;
- provision of conditions for constant removal of partially destroyed organic matter from the EGSB reactor to the next stage of purification;
- ensuring discharge of excess sludge from the aerobic treatment stage into the EGSB-reactor;
- application (based on the characteristics of the effluents) of the oxidation channel for additional purification of wastewater from nitrogen-containing compounds (nitrification);
- application (based on effluent characteristics) of a baffled anaerobic reactor (ABR) for effluent denitrification;
- the use of highly loaded sludge sites;
- application of jet aeration using submersible sludge pumps for deeper saturation of sludge with oxygen directly in the aerator.

The specified model-concept was applied during the implementation of design works for the reconstruction of Kaniv WWTP, where two EGSB psychrophilic reactors, converted from the existing two-tier clarifiers, were put into operation. The reactors were started without inoculant (a special biological preparation) and under a full hydraulic load, which was about 4 thousand m^3/day (of which almost 1.5 thousand m^3/day is the effluent of a local cheese factory). The formation of a trophic chain of anaerobes was assumed due to the introduction of microbial flora and fauna at the rate of 1 m^3 per 1000 m^3 of effluent. From the completion of the process of formation of the "working bacterial population" of the reactors to the first discharge of anaerobic surplus sludge from the EGSB reactors, six months passed, and the sludge discharged to the site had a moisture content of 90-92%. Over the next two weeks, it became air-dry and suitable for removal and transport.

The main task of the research, which would provide an understanding of the effective functioning of the creation of a wastewater treatment system, was to establish the characteristics of psychrophilic reactors for the treatment of households or equated to them wastewaters:

- volumetric load on the structure;
- load on sludge;
- the rate of removal of organic matter in an anaerobic reactor;
- total sludge increase;
- sludge concentration in the reactor;
- values of sludge expansion and sludge concentration limits;
- ashiness of silt and emerging crust;
- depth of destruction of suspended substances and excess sludge;
- sludge index.

The specified characteristics were determined by:

- carrying out laboratory control of wastewater treatment processes and destruction of settled organic suspended substances and excess sludge;
- organization of ultrasonic scanning of the volumes of anaerobic reactor structures in order to study the change in the height of the sludge to study its growth and the retention time of the biomass in the reactor;
- sampling sludge from the expanded layer during the recommended [18] of biomass retention time in the reactor and determination of concentrations, ash content and sludge age;
- analysis of daily (once a day), weekly (once a week) and average monthly indicators of pollution and sludge characteristics.

Sampling for laboratory analyses of pollution was carried out during the period of the maximum flow of sewage to treatment facilities, and for sludge – during the flow and in the absence of wastewater.

As an example, table 1 shows the results of laboratory-technological control of wastewater treatment in anaerobic psychrophilic reactors reduced to average monthly indicators.

Table 1: Results of laboratory-technological control of wastewater treatment in anaerobic psychrophilic reactors.

Wastewater characteristics	Control period in 2018			
	August	September	October	November
1. Inflow of sewage per day, m^3/day	3450	3510	3580	3690

clearly defined elevations or depressions. The phase boundary (sludge-water) was traced at the same level, which indicates the levelling of the fluid velocity field and the same distribution of the nutrient substrate in the active sludge layer. The active sludge layer itself should obviously start from a height of 0.85-2.6 m, depending on the retention time of the biomass, counting from the time of discharge of excess sludge. Here, 0.85 m is the height to which sand particles can be hydrotransported, and 2.6 m is the level of compacted biomass (in 60 days) in the volume of 50-60 m^3 discharged from the reactor. During compaction of sludge, its concentration increases in proportion to the decrease in volume and reaches 80-100 kg/m^3 in the lower part of the reactor (depending on the time of compaction).

The specified height of the lighting zone (at least 1.0 m) does not need to be changed. Removal of biomass with a concentration (SS) of 81-83 g/m^3 during the control period ensures the necessary operation mode of the next stage of aerobic treatment and is within the recommended limits for anaerobic reactors [18].

Unloading (volumes) of fermented excess anaerobic sludge (without worsening the biodegradation of organic substances) should correspond to the volume of biomass growth in a compacted state (by 200 %): so when it is unloaded once a month – 25-28 m^3; when unloaded once every two months – 50-56 m^3. When the time between sludge discharges increases (2 months or more), its average mineralization (of discharged sludge) increases – from 62 to 70 % (according to analyses of sludge at sludge sites). One of the explanations for the mineralization of biomass can be an increase in the share of inert carriers – sand particles in the sludge mass, which are classified in the lower part of the reactor due to the greater mass of their particles with correspondingly smaller sizes. The discharged sludge needs further study, namely, the determination of the nature of active biomass carriers and the remaining active biomass in it.

According to the research results, the amount of ash (mineralization) of the crust floating on the water surface of the reactor is in the range of 52-55 %.

The obtained depth of decomposition (removal) of organic substances in psychrophilic anaerobic reactors with an upward flow of liquid was:

- for organic pollutants of various natures (SS and dissolved) (1167/2462)·100 % – 47.4 %, where 2462 kg/day – all average daily organic substances (SO and dissolved) at the entrance of the reactors during the observation period, 1167 kg/day – all organic substances removed from the reactors per day;
- for unloaded excess sludge – 40 %;
- for a pop-up crust – 35 %.

The study of the sludge index showed that the anaerobic sludge formed during the purification of household wastewater has a value of J = 18-81 cm^3/g. It settles quickly, especially the sludge of the lower and middle part of the expanded layer (J = 18-31 cm^3/g), which, with correct calculations of the upward liquid flow rates, will ensure hydraulic retention of the biomass in the reactor in the expanded layer. The analysis of the pH of wastewater and the pH of water in the reactors indicates a balanced passage of the process within the range of pH from 6.55 (deviations in previous periods) to 7.97 without loss of the oxidizing capacity of the facilities. That is, within the specified limits, in a psychrophilic anaerobic reactor with an upward flow of liquid, biomass inhibition did not occur and it remains active in the pH range of 6.55-7.97.

The maximum decrease in temperature (monthly average) was observed up to 14 ^{o}C (results of previous periods). However, this decrease does not affect the oxidizing power of the buildings. First of all, because changes in temperature (especially temperature) and pH of the liquid reactor did not occur instantaneously but increased (according to the control results), this probably allowed the attached microorganisms to adapt to environmental changes and not lose activity. As for the pH, the buffering of the volumes of the medium of the reactors (system) smooths out volley discharges of acidified effluents of the local dairy plant (non-regular status at this enterprise).

Extraction of both suspended solids trapped in sand pits and sand (aeration of sand pits) and their removal to anaerobic reactors will only improve the physical and sanitary-epidemic

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012018 doi:10.1088/1755-1315/1415/1/012018

condition of the unloaded sand. It will dehydrate faster and be safer to release into the environment.

The re-fermented excess sludge discharged from the reactors (control period and previous ones) after 20-60 days (depending on the season) is already suitable for mechanized removal from the sites. Also, due to the rapid dehydration of sludge, its further decomposition and atmospheric air pollution do not occur (ash content does not increase). The dry sludge residue is a safe product and can be used in urban improvement, as an organic additive in land planning, etc. In traditional WWTP technologies, up to 30 cubic meters of excess sludge and sediments are removed from every 1,000 cubic meters of sewage effluent every day. For their dewatering, it is necessary to have at least 0.5 ha of sludge disposal sites (clause 6.388 [19]) in the case of the Kaniv – 2.0 ha. In our case, during unloading – 113 m^3 of sludge (humidity 92%) once every two months; the required area of the disposal sites is only 0.12 ha.

The specified characteristics that can be recommended for research and design organizations for process calculations or psychrophilic anaerobic reactors for domestic wastewater treatment with simultaneous treatment of raw sediments (perhaps also sludge) are summarized in table 4. It's important to note that these characteristics may need further clarification when dealing with anaerobic reactors and excess sludge from the aerobic purification stage.

Table 4. Summary table of obtained characteristics.

№	Parameters	Recommended value	Comparison[a]
1	The maximum speed of the upward flow, m/h	1.5	1.0
2	Maximum expansion of sludge volume, %	100	–
3	Sludge concentration in the reactor by SS, kg/m^3	25	25
4	Sludge concentration in the reactor for ashless sludge substance (ASS), kg/m^3	17.5	19
5	Volume load on the structure, kgCOD/m^3·day	0.94	1-4
6	Coefficient of biomass growth, kgASS/kgCOD	0.076	0.1-0.2
7	Sludge loading, kgCOD/kgASS·day	0.51	0.7-1.5[b] 0.1-0.3[c]
8	kgCOD/ kgCODB	0.2	0.3-0.7[b] 0.05-0.15[c]
9	Permissible limit of pH	6-8	5-8,5
10	Permissible wastewater temperatures, °C	≥14	≥15

[a] – characteristics are determined in the temperature range of 15-25 °C for industrial psychrophilic EGSB reactors;
[b] – for easily soluble organic substances;
[c] – for (SS) hardly soluble organic substances.

During the operation of sewage treatment plants using anaerobic fermentation at the first stage of wastewater treatment in a psychrophilic reactor, a significant amount of gas is released, which can be attributed to biogas by its origin. We have collected it in a sealed container and analyzed it. The results of the analysis are presented in table 5.

Table 5 shows that the obtained biogas contains, on average, about 75 % of organic gases – mainly methane, and about 25 % of organic ones – mainly carbon dioxide.

Based on the above research, we proposed a new municipal wastewater treatment technology "Biokonveier". The main advantage of our technology, in comparison with those introduced in the 20th century, is the guaranteed obtaining of standard indicators of purified wastewater: SS –

Table 5. Gas chromatographic analysis of biogas composition.

Gas	Sample 1, %	Sample 2, %
H_2	1.0	1.1
CO	0.2	0.3
CO_2	23.5	25.1
H_2S	0.01	0.01
Inorganic	**24.71**	**26.51**
CH_4	74.79	72.99
C_2	0.3	0.3
C_3	0.2	0.2
Organic	75.29	73.49

15 mg/dm^3; COD – 40 mg/dm^3; BCO_{20} –15 mg/dm^3; BCO_5 – 12 mg/dm^3; total nitrogen – 12mg/dm3; total phosphorus – 1.5 mg/dm^3.

In the case of increased requirements for discharge into a reservoir with a slight dilution of wastewater, further treatment of wastewater using sand self-washing filters or filters with liquid microfiltration is provided: SS – 10 mg/dm^3; COD – 28 mg/dm^3; BCO_{20} – 10 mg/dm^3; BCO_5 – 8 mg/dm^3; total nitrogen – 12 mg/dm^3; total phosphorus – 1.5 mg/dm^3.

Biological treatment facilities "Biokonveier" consist of:

- a special anaerobic section – from an anaerobic psychrophilic reactor with an expanded layer of sludge, where the anaerobic stage of sewage treatment, destruction of raw sediment and preparation of the nutrient substrate for the next stages of purification, selection of phosphorus-accumulating microorganisms, removal of retained phosphorus with excess sludge takes place;
- a special section where aerobic and anoxic processes periodically take place – ARS- aeration tank, which works with a change of aerobic and anoxic regimes and where the stages of destruction of carbon compounds, nitrification and denitrification of nitrogen, removal of orthophosphates from the solution take place;
- aerobic section (post aeration tank), where the stages of oxygen saturation of the mixture of wastewater and activated aerobic sludge take place, final oxidation of possible residues of wastewater pollution, removal of molecular nitrogen into the atmosphere, removal of excess sludge from the technological process;
- settling tank, where wastewater and activated sludge are separated in anoxic conditions, sludge compaction is required, compacted sludge is diverted to the ARS aeration tank (60-100% recirculation);
- adagulation anoxic compactor of surplus sludge of anaerobic and aerobic stages of sewage treatment, where contact coagulation (compaction) of sludge is carried out in anoxic conditions to exclude nitrates from entering the anaerobic reactor (at the head of the structure) with sludge water;
- equipment for the preparation and dosing of dephosphatization reagents, in the case of cleaning a mixture of domestic and industrial wastewater, for example – effluents from dairies, which have an increased content of phosphorus compounds.

"Biokonveier" facilities for the carbon, nitrogen and phosphorus compounds removal are schematically shown in figure 1 and figure 2. Figure 1 shows the ARS-aeration tank of periodic action, which works under aeration conditions – carbon oxidation and nitrification of ammonium nitrogen, removal of orthophosphates, and figure 2 – in conditions of denitrification, removal of carbon compounds when aeration of the ARS-aeration tank is turned off.

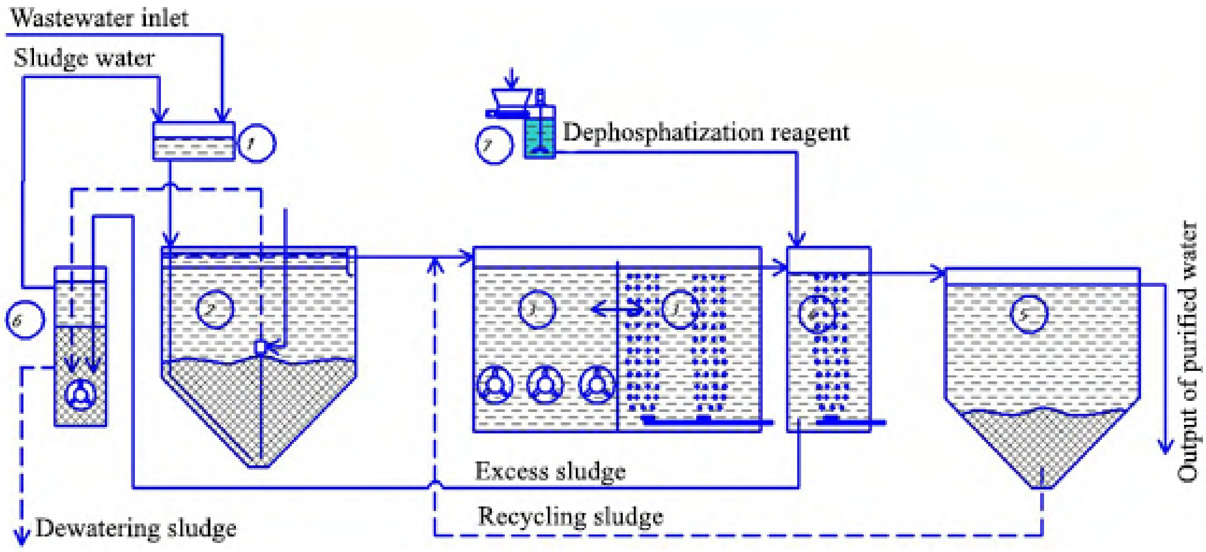

Figure 1. Block diagram of excess carbon, nitrogen and phosphorus from municipal or equivalent effluents removal: 1 – receiving capacity; 2 – anaerobic psychrophilic reactor; 3 – ARS – aeration tank periodic inspection; 4 – post-aeration tank; 5 – settling tank; 6 – adagulation anoxic sludge sealer; 7 – dephosphatization equipment. Conditions for a mixture of wastewater treatment and sludge: anaerobic – the first stage of wastewater treatment; aerobic – the second stage of wastewater treatment; aerobic – the third stage of wastewater treatment.

Facilities for biological treatment of sewage from carbon, nitrogen and phosphorus compounds (figure 1, figure 2) have receiving capacity (1), anaerobic psychrophilic reactor with an expanded layer of sludge (2), ARS-aeration tank periodic inspection (3), post aeration tank (4), settling tank (5), adagulation anoxic sludge sealer (6), equipment for introducing dephosphatization reagents (7).

The anaerobic psychrophilic reactor in the lower part has a distribution system for the supply of sewage, a pipeline for the removal of excess sludge, and, if necessary, can be equipped with a cap for collecting biogas. Treated effluents under anaerobic conditions together with removed anaerobic sludge (no more than 85-100 mg/dm^3) are constantly diverted from the upper part of the reactor to the ARS-aeration tank. In the last one, an aeration system is installed, which is protected from water ingress when the air is turned off, and flow generators ensure the movement of a mixture of sludge and wastewater to prevent the fall of suspended particles (sludge) when the air is turned off, when the section is switched to the denitrification mode, to ensure high-quality mixing of effluents coming from the anaerobic reactor with the liquid of the pool, for internal recirculation of the mixture (up to 100%). From the upper part of the ARS-aeration tank, liquid in calculated volumes constantly flows into the post-aeration tank. The last one is also equipped with a protected aeration system and reagents for dephosphatization, including ferrous iron, which needs oxidation, and can be fed into its capacity as needed. From the lower part of this section, excess sludge is also constantly diverted for compaction, from the upper part – treated sewage with sludge for separation in the settling tank. If necessary, a polymer nozzle can be loaded into the upper part of the sump to improve water purification. The settling tank is also equipped with a system for the permanent removal of compacted activated sludge of the required concentration. Surplus sludge from the post-aeration tank is sent to the

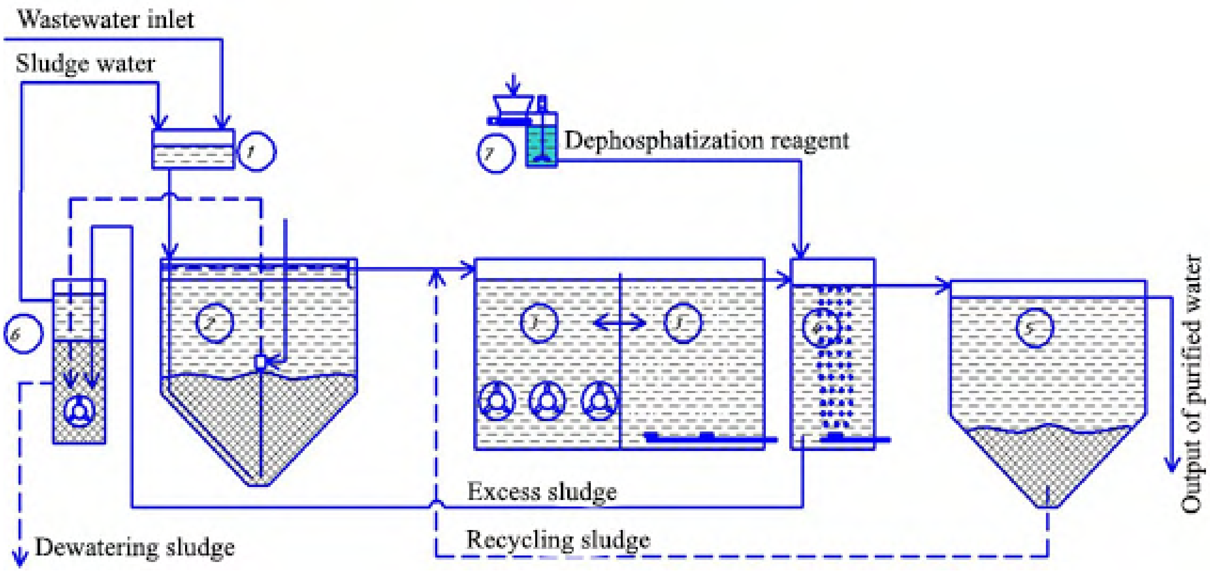

Figure 2. Block diagram of excess carbon, nitrogen and phosphorus from municipal or equivalent effluents removal: 1 – receiving capacity; 2 – anaerobic psychrophilic reactor; 3 – ARS – aeration tank periodic inspection; 4 – post-aeration tank; 5 – settling tank; 6 – adagulation anoxic sludge sealer; 7 – dephosphatization equipment. Conditions for a mixture of wastewater treatment and sludge: anaerobic – the first stage of wastewater treatment; anoxic – the second stage of wastewater treatment; aerobic – the third stage of wastewater treatment.

lower part of the adagulation anoxic sealer, where it is periodically mechanically mixed with the well-structured sludge of the anaerobic reactor (the flakes are compact, integral, there are granular forms) the particles of which have much larger linear dimensions. As a result of contact coagulation, silt particles thicken (compaction). After settling and separating the mixture, the sludge water is pumped into the receiving tank of the anaerobic reactor, and the compacted sludge is sent for dewatering [20].

The feature of the “Biokonveier” station is receiving purified wastewater and safe waste. In addition, the minimal amount of discharged sediments puts our proposed biotechnology in an exceptional position compared to existing facilities for domestic sewage or similar effluent treatment. The development of the “Biokonveier” station with a capacity of 1.0 to 15.0 thousand m^3/day with the use of sediments and sludge active processing is an example of the introduction of biotechnologies with modern hardware implementation.

The “Biokonveier” station is made of a single closed block (figure 3). In the underground part, sewage treatment removed biomass and excess microorganism’s destruction, which purified water, takes place. Various technological equipment, control and management systems, administrative and household and warehouse premises are located in the above-ground part. Emission gases released from process tanks are cleaned and disinfected before being released into the atmosphere. Air conditioning is provided in administrative and domestic premises, and ventilation is necessary in production areas to create a safe atmosphere.

The output of biogas ($CH_4 + CO_2$) produced in anaerobic fermentation is determined by COD removal in an anaerobic reactor, as well as chromatographically:

$$1\text{kg COD} \rightarrow 0.35\ \text{m}^3\ \text{CH}_4 + 0.188\ \text{m}^3\ \text{CO}_2,$$

where the CH_4 content in the gas mixture is 65-70%.

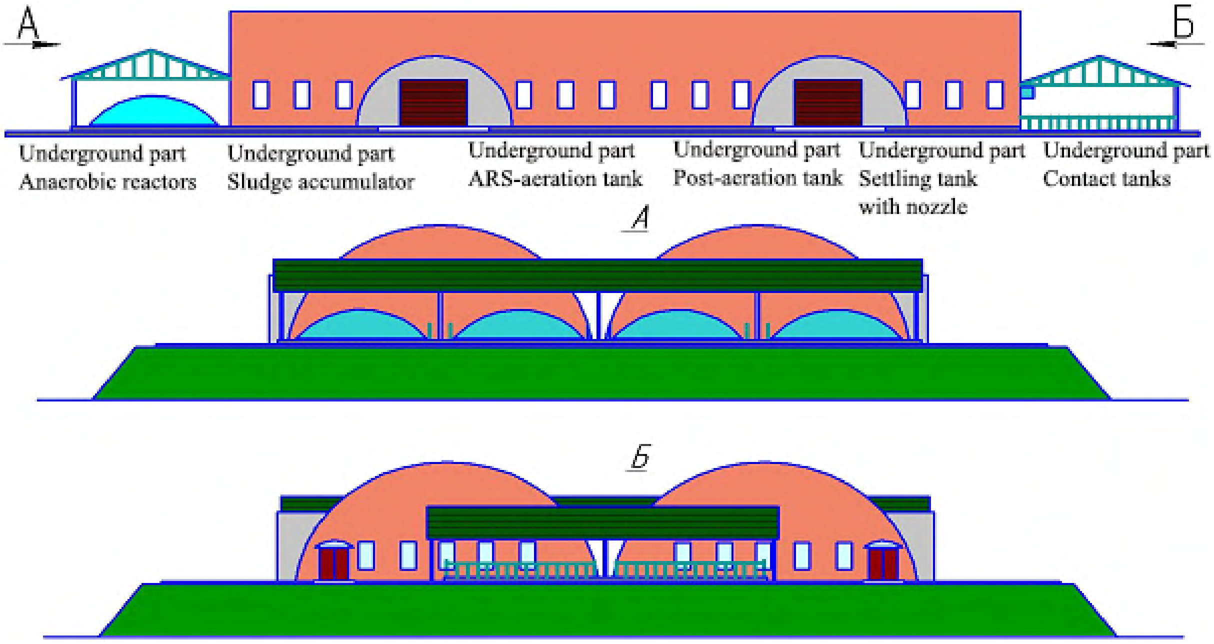

Figure 3. Industrial design of the "Biokonveier" station with a 10,000 m^3/day capacity.

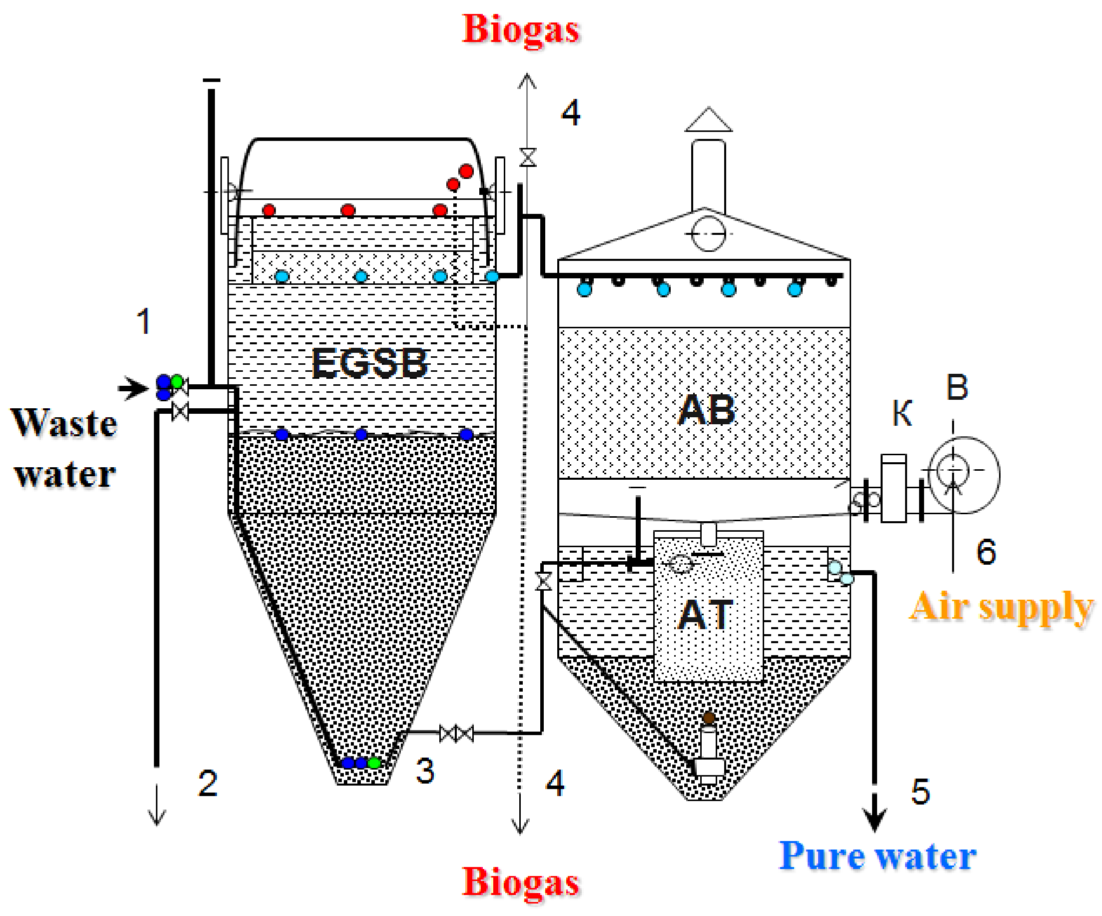
As a result of the use of energy-saving equipment, modern aeration systems, effective management of technological processes in real-time modes, and the use of biogas, electricity consumption at the "Biokonveier" stations will be only 0.2 to 0.4 kWh per m^3 of treated wastewater [20].

The proposed model-concept was successfully used during the design works for the reconstruction of the Kaniv WWTP. Two EGSB psychrophilic reactors, which were converted from existing two-tier sedimentation tanks, were put into operation. This new technology only required 0.5 ha of land for depositing the sediments produced, while the traditional method required 2.0 ha of sludge sites. However, the practical results from several years of operating the sludge sites showed that only 0.12 ha were used. Furthermore, a one-time dose of discharge of excess sludge from the reactors was determined to be 50 m^3 per half month. It is important to note that the significant rate of dehydration of sediments during the process did not result in their decomposition, which could have caused environmental pollution. The sediments were further cleaned in aerobic conditions using reconstructed aerofilters and secondary sedimentation tanks that were converted into aero-settling tanks with jet aeration.

The long-term operation of the anaerobic reactor, created based on the primary sedimentation tank, and the obtained positive results of wastewater treatment confirm the perspective of using the selected approach in the technological schemes of urban sewage treatment.

The analysis of the experimental results obtained in the field led to the unequivocal conclusion that the implementation of the developed approach, where the first stage is the anaerobic treatment of wastewater in psychrophilic conditions, provides, first of all, a significant (by 4-5 times) reduction in the dry matter of sludge with good water-releasing properties, high ash content and stability, which means a reduction in the area of sludge sites. This, in turn, ensures the unloading and improvement of the operation of the aeration tank with insignificant capital costs for the reconstruction of the existing Kaniv WWTP and their modernization with an increase in the capacity of the facilities. An important positive is that conversion of existing WWTP facilities (primary clarifiers, two-tier clarifiers, etc.) into EGSB reactors is possible by the organizations that operate these facilities. In addition, the complex of conducted research and accumulated operational experience created the necessary prerequisites for the development of low-cost WWTP projects for new construction with specific electricity consumption of no more than 0.2-0.5 kWh/m^3 of treated sewage, with the possibility of manufacturing in factory conditions relatively cheap compact cleaning plants. The system's resistance to various hydraulic and organic regimes, and, therefore, the absence of sewage averaging facilities, makes the technological scheme of anaerobic-aerobic treatment even more compact with a reduction in the area under treatment facilities, which is especially important for enterprises with individual treatment facilities. Combining in the main technological line the biological processes of low-temperature anaerobic decomposition and aerobic oxidation of the organic component of sewage, deep processing of sediment and excess sludge under anaerobic conditions in the EGSB-reactor, as well as the use of biofilters combined with aeration tank-settlers, which are practically equivalent components of aerobic part, makes it possible to fully decentralize sewage treatment with the prospect of complete automation and remote control of the treatment process. Inclusion in the technological scheme of the biogas production process will allow the WWTP to provide



● - Waste water; ● - Anaerobic purified water; ● - Biogas (CH_4, CO_2); ● - Aerobically purified water; ○ - Air aeration; ○ - Pure water; ● - Excess sludge.

Figure 4. Complete scheme of combined facilities for biological wastewater treatment: EGSB – anaerobic EGSB reactor; AB – anaerobic biofilter; AT – aeration tank-settler; B – fan; K – air heater; 1 – supply of sewage for treatment; 2 – removal of excess sludge; 3 – recirculation line; 4 – biogas outlet; 5 – purified water outlet; 6 – air supply.

its own heat needs (heating, hot water supply, etc.).

Figure 4 shows a complete scheme of combined facilities for biological wastewater treatment and processing of raw sediments and sludge.

Nowadays, only the anaerobic part of the water purification process works successfully, effectively fulfilling its function. The clarified water is then purified on artificial bioplates to meet the existing standards for discharge into the Dnipro River.

4. Conclusion

The process of biodegradation of organic impurities in reactors, the actual loading of flow-through psychrophilic reactors in terms of organic substances, the amount of biomass growth, and the biomass biodegradation rate were studied. The output of biogas obtained in a psychrophilic flow reactor and its composition were determined. A model-concept of treatment facilities has been developed. The technology of municipal sewage deep cleaning from biogenic elements "Biokonveier" is proposed. Anaerobic treatment of wastewater in psychrophilic conditions provides a 4-5-fold reduction in dry matter of sludge with good water-releasing properties, a reduction in the area of sludge sites by an order of magnitude and allows for the creation of inexpensive projects of municipal sewage treatment plants for new construction with a specific electricity consumption of no more than 0, 2-0.5 kWh/m^3 of treated sewage. Systematic studies of the process of anaerobic wastewater treatment at Kaneva sewage treatment facilities allow for the development of recommendations and calculation methods for the design of anaerobic psychrophilic flow reactors for the treatment of municipal sewage effluents or a mixture of municipal and industrial effluents with a BOD of up to 2.0 g/dm^3. At the same time, use them as combined structures for partial destruction of the organic component of sewage and mineralization of sediment and excess sludge from the aerobic treatment stage, obtaining biogas to meet the energy needs of the treatment plant site. Also, justify the expediency of replacing in cities and villages of Ukraine anaerobic psychrophilic flow reactors of primary settling tanks in sewage discharge treatment schemes.

Abstract. One of the main development programs of each country is the control and utilization of industrial waste since the sustainable development of this industry is accompanied by the greatest environmental pollution. Iron ore beneficiation byproducts are artificial quartz-iron mineral mixtures that are fed into sludge ponds that form the so-called tailings ponds in the form of pulp. Tailings ponds occupy more and more territory every year and have a significant negative impact on the environment. At the same time, industrial waste from iron ore enrichment, the so-called tailings, is used as a fine aggregate in concrete mixtures to replace quartz and construction sand. Studies show that a 40% replacement of quartz sand with fine iron ore dressing waste is optimal for the manufacture of concrete mixtures without any adverse effect on strength and durability properties. The paper considers the stress-strain state of beams in the second group of limit states made of concrete mixtures at 100% replacement of quartz sand with fine plant protection products waste. The percentage of reinforcement of beam sections of all series and the class of concrete were assumed to be the same for samples of all series. The results of experimental tests showed almost comparable results of crack resistance of beams reinforced with metal reinforcement and with hybrid reinforcement. At a load of 70% of the destructive capacity, BM and BMD beams do not exceed the maximum permissible width of normal crack opening, and BMBD beams do not exceed the maximum permissible width of 60%.

1. Introduction

One of the strategic sectors of Ukraine's economy is the mining and metals sector, whose sustainable development provides the largest tax payments to the budget, stimulates the growth of other sectors of Ukraine's economy, and provides more than 200,000 jobs [1]. At the same time, the development of this industry is accompanied by the largest environmental pollution, as by-products are an integral part of each production stage.

Iron ore enrichment by-products are overburden and host rocks from ore mining and by-products of their enrichment. The beneficiation by-product makes up 40-60% of the beneficiation material and is a non-cohesive material consisting of sharp-angled rough grains – an artificial quartz-iron mineral mixture that is less homogeneous than quartz sand in terms of both particle size distribution and chemical composition. Waste from iron ore beneficiation in the form of pulp is removed through pipelines to sludge ponds, which form the so-called tailings ponds.

Today, there are about 465 tailing dumps in Ukraine, which contain more than 6 billion tons of waste from various industries and, occupying large areas (over 7,600 hectares in Kryvyi Rih alone [1]), have a significant negative impact on the environment:

- flooding of adjacent territories;
- groundwater pollution;
- acting as a powerful source of dust generation due to the drying of the upper part of the beaches.

At the same time, according to the State Statistics Service of Ukraine, the volume of iron ore enrichment is not sustainable and increases every year (figure 1), which leads to an even greater accumulation of industrial waste in tailings ponds.

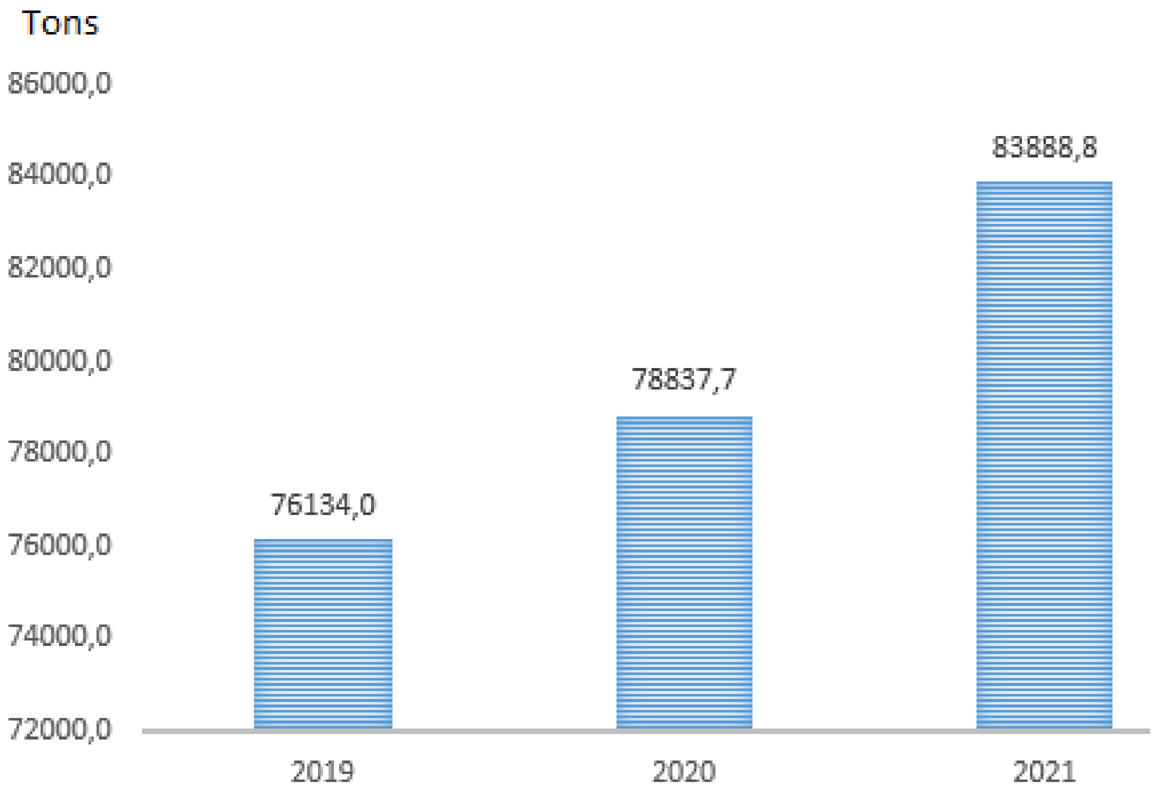

Figure 1. Production of non-agglomerated iron ore and concentrate (gross production).

At the same time, industrial waste from iron ore beneficiation, the so-called tailings, is used as a secondary raw material for the production of construction materials:

- in construction mortars, as fine aggregates in heavy and extra heavy concrete;
- for the construction of artificial foundations for roads, buildings, structures, backfills, etc.

However, there is no publicly available static data on the volume of plant protection products waste utilization or their use in the construction industry.

In the production of concrete mixtures, it is plant protection products waste that is a full-fledged alternative to quartz sand, which is a versatile natural material used in various industries: glass, chemical (including for filtration), construction (concrete mixtures, plaster, etc.) and metallurgy (molding sands for metal casting).

Quartz frac sand is extracted by open pit mining or by dredging from natural deposits in floodplains of rivers and lakes. Deposits of construction sand are located almost all over Ukraine, but river sand is the most popular on the market as it contains a minimum amount of pollutants.

According to open sources of information on construction sand production in the country:

- about 650 deposits are officially registered and only 230 are officially under development. However, according to indirect unofficial sources, the total number of construction sand deposits is up to 900;
- in 2017-2020, the production of construction sand amounted to 13.7-15.5 million tons per year, according to the data provided on the state website "Data Portal of the Extractive Industry of Ukraine". At the same time, according to indirect unofficial sources, the total annual production reaches up to 25-35 million tons per year;
- construction sand production, according to the State Statistics Service of Ukraine [2], almost doubled in 2021 compared to 2014 (figure 2) and amounted to 19.2 million tons.

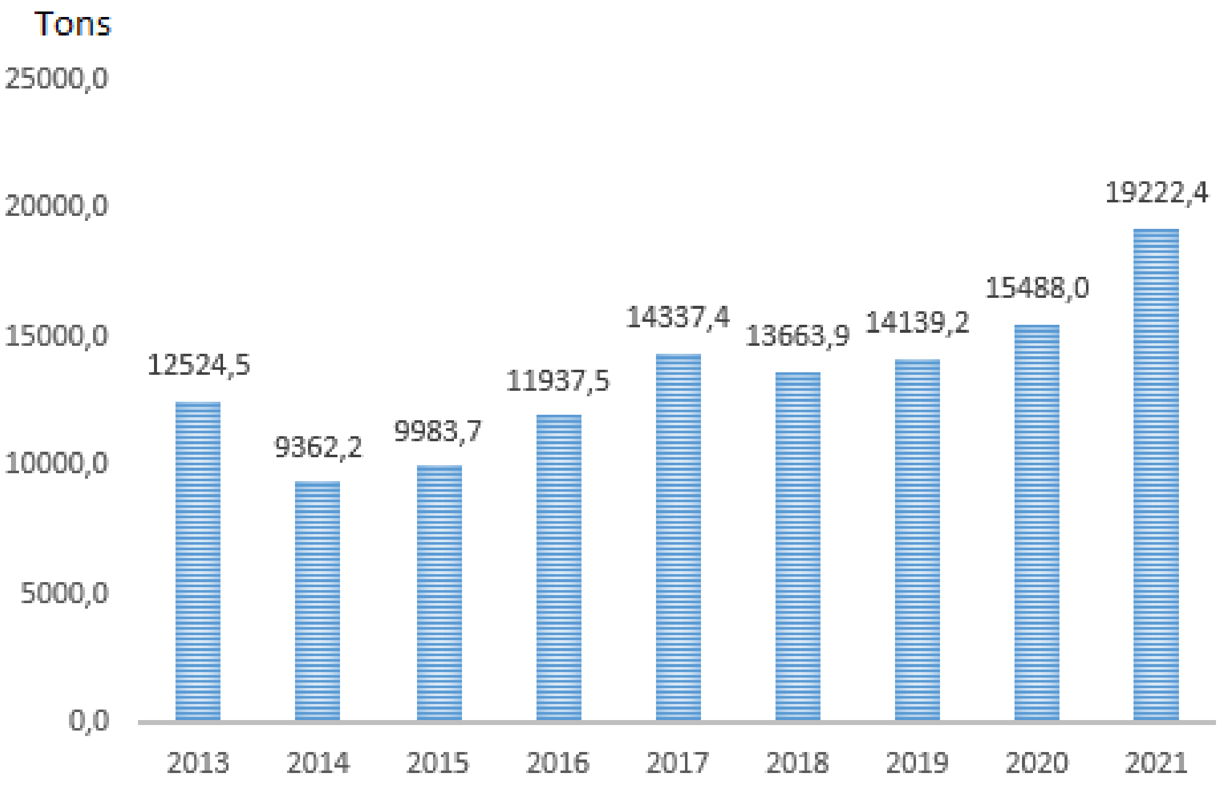

Figure 2. Construction sands, such as clay, kaolin, feldspar (except for flint and metal-bearing sands) (gross production).

It should be noted that the extraction of construction sand from natural deposits in the floodplains of rivers and lakes leads to:

- changes in the bottom landscape, which forms the so-called stagnant zones where aquatic life lacks oxygen and water quality is significantly reduced;
- soil erosion and salinization of aquifers.

Moreover, in a new report of the United Nations Environment Program of 2022 [3], it is proposed to recognize sand as a strategic resource at the international level due to the fact that its volumes are rapidly decreasing and its extraction is accompanied by negative environmental impact.

In view of this, the wider use of small waste of plant protection products, pulp, instead of construction sand, for the manufacture of reinforced concrete structures, on the one hand, will reduce the amount of iron ore beneficiation waste entering tailings, and on the other hand, will reduce the demand for construction sand. This will also reduce the cost of manufacturing such structures.

In recent years, fiber-reinforced polymers (FRP) have been increasingly used in the manufacture of reinforced concrete structures to reduce costs and take certain advantages. This is due to certain advantages of composite reinforcement (FRP) over metal reinforcement: higher tensile strength, high resistance to aggressive environments (does not corrode), low thermal conductivity, dielectricity, non-magnetism, and relatively low weight. At the same time, composite reinforcement has not only advantages but also disadvantages, the main one being a lower elastic modulus compared to metal reinforcement, which negatively affects the rigidity of structures [4].

Within the country, carbon fiber-reinforced polymers (CFRP) and aramid-fiber-reinforced polymers (ARFP) are of limited use due to their high cost, while basalt fiber-reinforced polymer (BFRP) and glass fiber-reinforced polymer (GFRP) are comparable in price and in some cases lower than metal reinforcement. Further research into the performance of BFRP and GFRP in reinforced concrete structures led to the development and publication in 2012 of relevant regulations for the design and manufacture of structures using this composite reinforcement. However, the use of basalt fiber reinforcement polymer (BFRP) is more promising than glass fiber reinforced polymer (GFRP) due to better mechanical and operational properties (elastic modulus, deformability, resistance to alkaline environment) [5, 6].

2. Literature review

Experimental studies of the possibility of using small plant protection products waste from slurry pits as fine aggregate in the production of concrete mixtures date back to the 1960s. In 1982, a collection of works was published, which analyzed and summarized the results of the physical and mechanical performance of both concrete mixtures and reinforced concrete structures made with fine aggregates from plant protection products waste, and compared them with traditional concrete on quartz sand [7]:

(i) comparison of concrete mixtures:

- concrete composition can be determined by well-known methods;
- the strength of the concrete mixture is 11.8% higher;
- stiffness and water resistance of the concrete mixture are higher;
- equal corrosion resistance;
- reduced mobility, which is solved by the use of appropriate plasticizers.

(ii) comparison of reinforced concrete structures:

- the load-bearing capacity of off-center compression racks under short-term load is 20-25% higher;
- the experimental values of beam deflections are lower by 24.6%;
- the same deflection in the slabs was recorded under the action of a bending moment, which was 28.3% higher than in the slabs of the same series made of concrete on quartz sand. The performance of slabs made of concrete with plant protection products waste exceeds the calculated values: strength – by 20-28%; stiffness – by 40-45%, deformability is lower by 37-40% and 33-34%.

However, it was only in the 1990s, with the publication of the relevant regulations, that the widespread use of fine plant protection products waste as fine aggregate in concrete mixtures became possible in construction. At the same time, the results of further studies of concrete mixtures indicate certain reservations about the complete replacement of quartz sand with small waste plant protection products in concrete mixtures.

Thus, in work [8], the physical and chemical properties of concrete were investigated both in the form of a mixture and at different times after hardening. For the study, concrete mixtures were made with partial replacement of quartz sand with small waste of plant protection products – 10%, 20%, 30%, 40%, and 50%. General studies have shown that, depending on the physical and chemical composition of small waste plant protection products, the replacement of up to 40% is optimal for the manufacture of concrete mixtures without any harmful effects on the strength and durability properties. At a replacement rate of 50% or more, it is recommended to add plasticizers due to a decrease in concrete strength.

In the work [9], similar studies were conducted and similar test results were obtained – the replacement of 40% of quartz sand with fine plant protection products in concrete mixtures gives the maximum compressive strength compared to a mixture of quartz sand or in mixtures in which plant protection products are introduced in other proportions.

Experimental studies were conducted for M20 concrete with the replacement of sand by 10%, 20%, 30%, 40%, 60%, 80% and 100% of small waste plant protection products [10]. The maximum increase in compressive strength was obtained at 40% sand replacement. Also, it was found that the strength of reinforced concrete beams working in bending is also maximum at 40% sand replacement.

And the results presented in the work [11] showed somewhat different results of testing concrete mixtures with 100% replacement of quartz sand with fine plant protection products waste. The strength of concrete cubes of the T100 series made using the small waste of plant protection products, is 3.3% higher than the control series of T0 cubes made of quartz sand.

This difference in the results obtained by scientists from different countries is explained by the unstable and heterogeneous composition of fine iron ore waste due to the specifics of the technological processes of iron ore beneficiation at individual enterprises, as well as the regular modernization of their equipment. Therefore, the tailing dumps of each enterprise require separate studies to clarify the chemical and physical and mechanical properties of the tailings for the possibility of their further widespread use in the construction industry.

The results of experimental studies conducted by various scientists indicate that there are no restrictions on the use of BFRP reinforcement in reinforced concrete structures working in bending, made of concrete mixtures on quartz, construction, and sand [5, 6, 12, 13]. As for the structures reinforced with BFRP made of concrete mixtures containing small waste of plant protection products, such information is either absent or very limited.

The lack of experimental studies of the performance of bending structures reinforced with basalt plastic reinforcement made of concrete with fine aggregate of plant protection products hinders the updating of regulatory documents and the increase in demand for concrete made from fine plant protection products instead of quartz sand.

In this regard, the company has previously:

- developed a program for experimental testing of beams;
- prototypes of beams were manufactured;
- experimental tests of the beams were conducted;
- analysis of the stress-strain state of the prototypes of the beams according to the first group of the limit state [14].

Below are the crack resistance values of the test specimens of beams reinforced with both metal and basalt-plastic reinforcement. The comparison of indicators was carried out according to the criterion of different compositions of the concrete mixture of the beam samples: concrete on quartz sand and concrete with complete replacement of quartz sand with plant protection products waste.

3. Results

The experimental test program provided for the manufacture of 6 series of prototypes of concrete reinforced beams, three beams in each series table 1.

Table 1. Experimental test program.

Beam series	Reinforcement of the tensile zone	Reinforcement mark
BM	2ø12	Metal
BMD	2ø12	Metal
BB	2ø12	BFRP
BBD	2ø12	BFRP
BMB	2ø8,2ø8	Metal, BFRP
BMBD	2ø8,2ø8	Metal, BFRP

In accordance with the current requirements, the prototypes of all series were reinforced. The scheme of reinforcement of beam samples is shown in [14]. The reinforcement of the specimens was intended to achieve the destruction of the beams of the control series due to the destruction of the stretched reinforcement. To allow for a correct comparison of test results, the percentage of reinforcement of beam sections of all series and the concrete class were assumed to be the same for specimens of all series. The BM series, made of concrete on quartz sand, was taken as the control series of beams.

For the reinforcement of the specimens, metal (A400) and basalt-plastic (BFRP) reinforcement provided by the manufacturer of composite reinforcement, Technobasalt-Invest LLC, Ukraine, was used. The mechanical characteristics of the reinforcement are shown in [14].

For concreting, concrete of class C25/30 was used, which was produced at a concrete-mixing plant. Beams of the BM, BB, and BMB series were made of concrete mix with quartz sand as a fine aggregate, and beams of the BMD, BBD, and BMBD series were made of concrete with 100% replacement of quartz sand with small plant protection products waste. The latter is a fractionated quartz-iron mineral mixture with a density of 1,500-1,600 kg/m^3. The composition of concrete mixtures is shown in table 2.

Table 2. Composition of concrete mixes per 1 m^3.

Composition	Units of measurement	On industrial waste	On river sand
Cement	kg	380	380
Pulp	kg	750	0
Sand	kg	0	720
Gravel	kg	1200	1200
Water	1	180	180
Additives (Relaxon)	1	20	20

Short-term tests of the beams were carried out on a hydraulic press P-125 according to the scheme of a single-span free-lying beam. The diagram of the stand and the stand itself for testing experimental samples of beams in bending are shown in [14].

In the process of crack development in the tensile zones of concrete, three stages are distinguished: the appearance of cracks when they are still invisible; the appearance of cracks when they become visible with a microscope; and the opening of cracks to the maximum possible values. For elements with a normal reinforcement content, the last two stages are mainly considered: crack initiation and crack opening.

Based on the results of the experimental tests of the beams, table 3 shows the information on the cracking forces of the beams.

Table 3. Experimental cracking forces of the beams.

Beam series	Average destructive load, kN	Force determ., mm	Force of cracking, kN
BM	70.22*	50.0	39.24
BMD	75.87*	50.0	34.30
BB	100.88	70.0	14.22
BBD	96.06	70.0	17.33
BMB	96.06 (45.13*)	70.0	26.16
BMBD	99.24 (49.70*)	70.0	32.70

* Specified force corresponding to the beginning of yielding of metal reinforcement.

The results obtained, summarized in table 3, indicate that the moment of cracking in the beams of the BBD and BMBD series occurred at a load that was 21.9% and 25.0% higher than that of the BB and BMB series, respectively, and in the BMD series beams – 12.6% lower than that of the BM series. The moment of cracking for beams of the BB and BBD series occurred at more than half the load compared to the control series of BM beams.

The figures (figure 3, figure 4, figure 5) shows the graphs of the "load – crack opening width" dependence separately for the series with the same reinforcement.

The tendency to increase the width of the normal crack opening of beams under load made of concrete on fine plant protection products waste shows almost comparable results with the series of beams made of concrete on quartz sand. The overall performance of the beams of all series under load showed a direct dependence on the type of reinforcement used in the tensile zone.

Beams reinforced with metal, BM, and BMD series, showed typical performance as for beams with traditional reinforcement. The first normal cracks appeared in the pure bending zone at a load of 0.3-0.4 of the destructive load. Further increase of the load led to the appearance of new normal cracks and an increase of their width. Thus, for the BM and BMD beam series, the width of the crack opening at 5.0 t and 7.0 t is the same, and in other cases the difference ranges from -20.0% to 23.5%. The beginning of reinforcement yield was recorded at a load of 0.9 of the destructive load, which caused the destruction of the beams with the compression of the concrete of the compressed zone.

The beams with basalt-plastic reinforcement of the BB and BBD series showed the largest values of the width of normal cracks, which is explained by the lower elastic modulus of the BFRP reinforcement itself. At a level of 0.1-0.2 of the destructive load, the first normal cracks appeared, and at the destructive load of 0.5-0.6, inclined cracks began to appear. A uniform location of cracks was noted, with a step of 100-150 mm, along the length of the beam. Figure 4 shows an almost linear dependence of the increase in the values of the width of normal cracks with increasing load, which is typical for beams with composite reinforcement due to the lack of yield properties of the latter. The crack opening widths of the BBD series beams showed larger values compared to the BB series beams at all stages of loading, and the difference ranged from

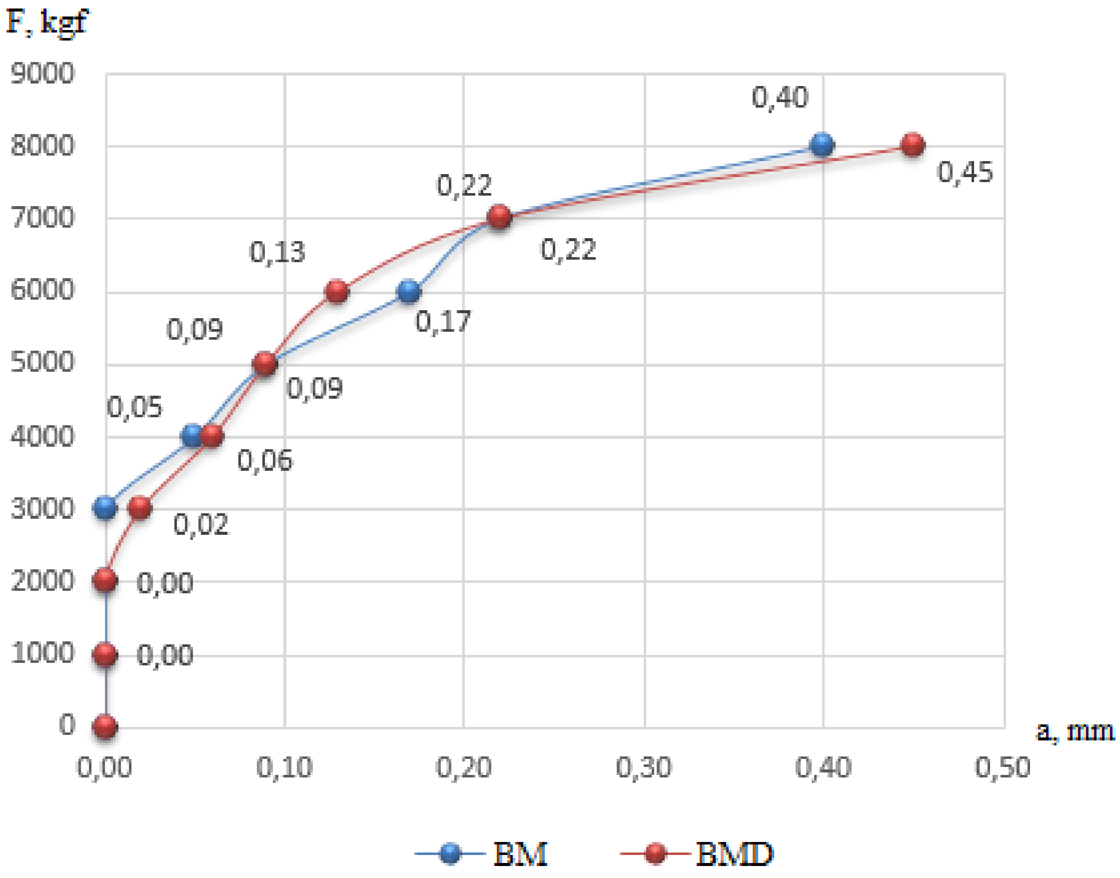

Figure 3. Graph of dependence F – a of BM and BMD beams.

-47.1% to -11.5%. The destruction of the beams occurred due to the crushing of the concrete of the compressed zone. No rupture or slippage of the BFRP reinforcement rods was observed.

The development of normal cracks in beams with hybrid, metal, and basalt-plastic reinforcement, of the BMB and BMBD series can be divided into two stages – before and after the onset of metal reinforcement yielding. At a level of 0.2-0.3 of the destructive load, the first normal cracks began to appear. Up to a level of 0.4...0.5 of the destructive load, the performance of the beams was similar to the BM and BMD series beams, which is explained by the predominant influence of metal reinforcement. After the appearance of reinforcement fluidity, basalt-plastic reinforcement begins to exert the main resistance to load. The behavior of the beams becomes similar to that of the BB and BBD series – the number and width of cracks increases. The destruction of the beams occurred due to the compression of the concrete of the compressed zone with the simultaneous complete or partial rupture of the BFRP reinforcement fibers. It should be noted that in the case of a series of BMBD beams made of concrete on fine plant protection products waste, the crack opening width was smaller at all stages of loading compared to a series of BMB beams.

For further analysis of the obtained values of the widths of the normal crack opening of the experimental beams and the limit values according to current standards, table 4 was compiled.

Since the test specimens of beams of all series do not contain tension reinforcement, reinforced concrete beams must meet the category of requirements for crack resistance 3c, which is limited only by the limit value of the calculated crack opening width of 0.3 mm in accordance with clause

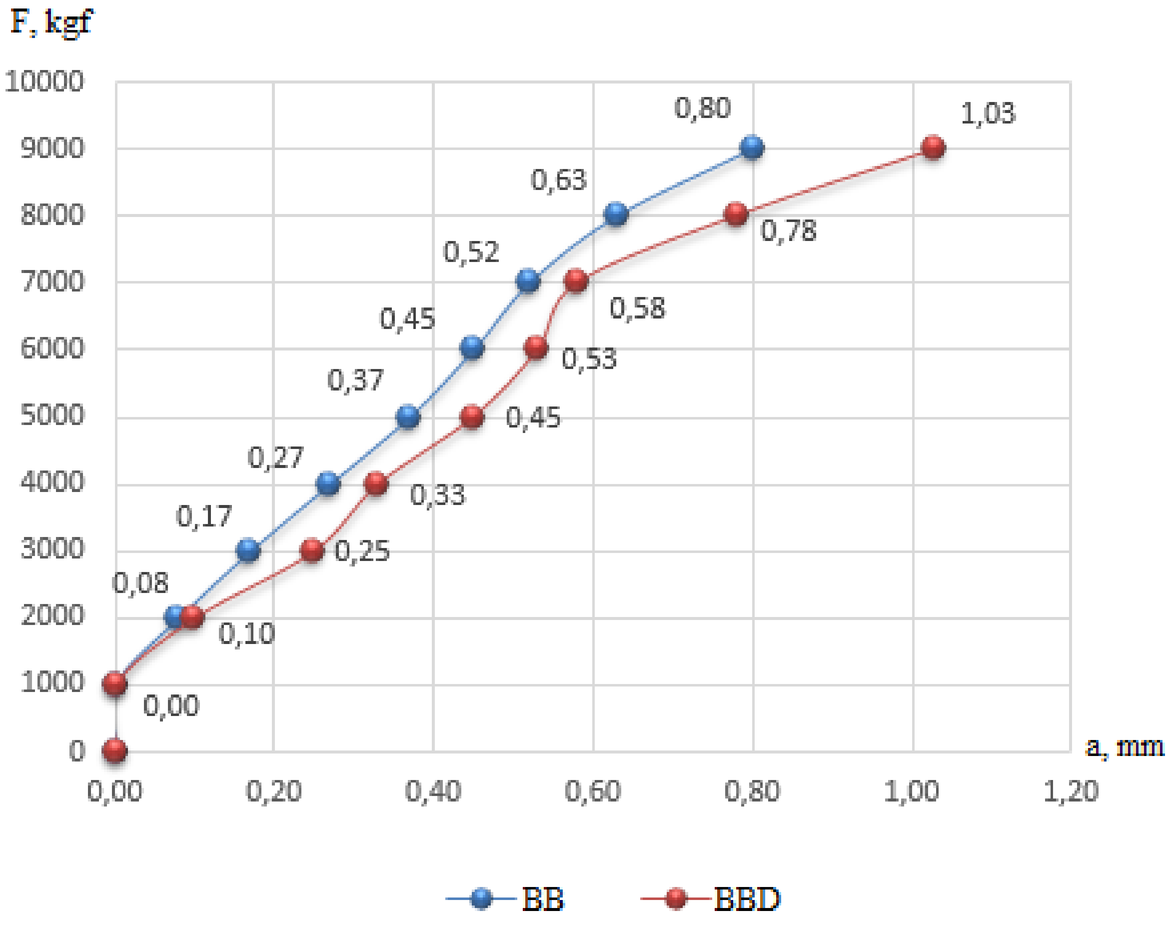

Figure 4. Graph of dependence F – a of BB and BBD beams.

Table 4. Average experimental values of the width of opening of normal cracks in the test beams.

Beam series	Force determ., kH	Average crack width, mm	Permissible value, mm
BM	50.0	0.09	0.3
BMD	50.0	0.09	0.3
BB	70.0	0.52	0.3
BBD	70.0	0.58	0.3
BMB	70.0	0.38	0.3
BMBD	70.0	0.35	0.3

3.95 [15]. Less stringent requirements for the maximum crack opening width are imposed when using basalt-plastic reinforcement in structures, which is explained by the material's resistance to aggressive environments. Thus, according to table G.4 [16], basalt-plastic reinforcement belongs to Group IV, in which the crack opening width due to corrosion conditions in accordance with Annex D [16] is not standardized. According to clause 5.2.4 of the norms [17], the maximum width of crack opening in concrete elements with basalt-plastic reinforcement should be determined taking into account aesthetic and psychological requirements and should not

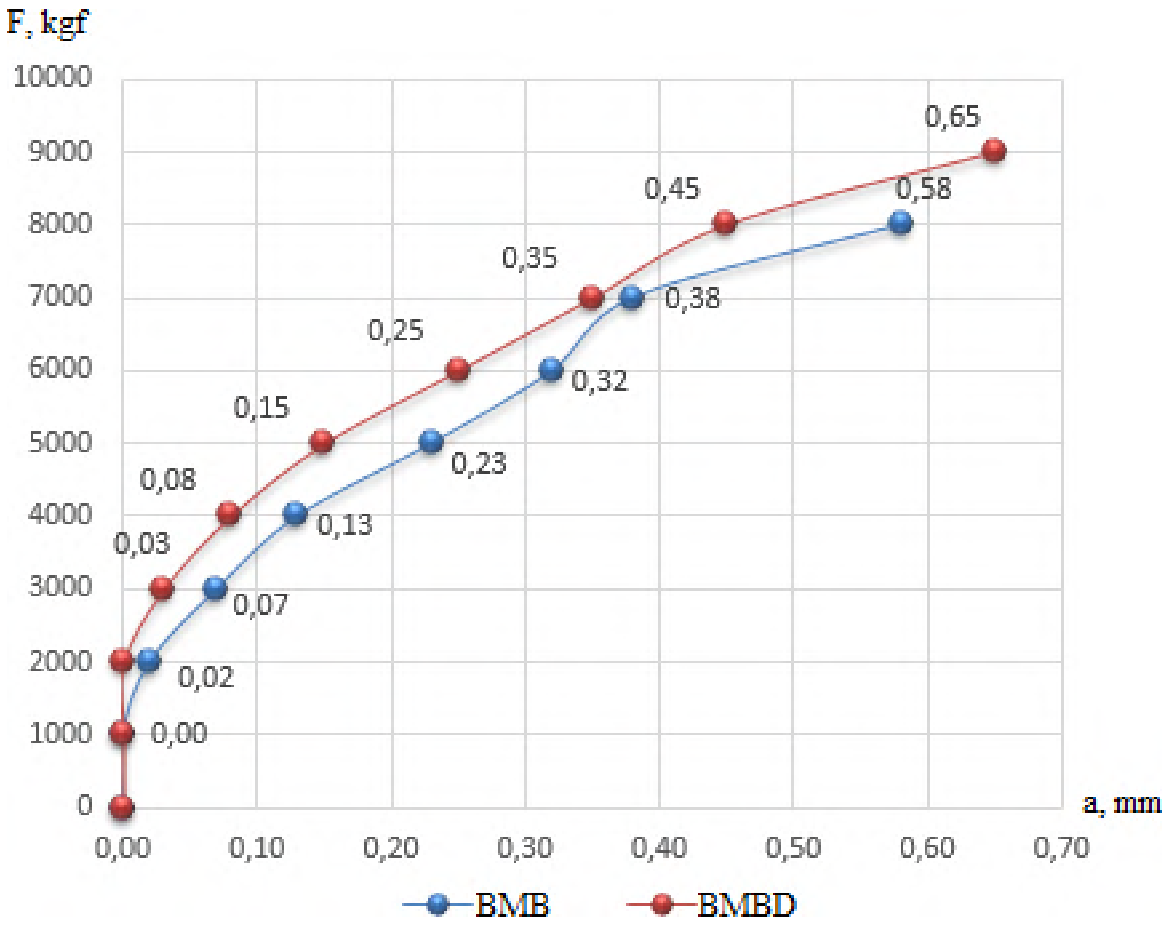

Figure 5. Graph of dependence of F – a of BMB and BMBD beams.

exceed 0.4 mm if the requirements for an acceptable appearance are established, and 0.8 mm in other cases. Since the series of BM beams with metal reinforcement in the tensile zone is taken as a control one for comparing the stress-strain state with beams of other series, for correct further analysis, we take the maximum permissible value of the crack opening width of 0.3 mm in accordance with [15].

The values of the width of the normal crack opening of the experimental beams given in table 4 indicate that 100% replacement of quartz sand with the small waste of plant protection products in the manufacture of concrete mixtures for reinforced concrete structures led to such results:

- BMD series beams have the same value of normal crack opening width as the control BM series beams – 0.09 mm, and do not exceed the maximum permissible value of 0.3 mm;
- beams of the BBD series reinforced with basalt-plastic reinforcement showed a larger value of the width of normal crack opening by 11.5% than the BB series, and exceeded the maximum permissible value by 93%;
- beams with hybrid reinforcement of the BMBD series showed a smaller value of the width of normal crack opening than the BMD series, by 7.9%, and exceeded the maximum permissible width by 16.7%. It should be noted that at a level of 60% of the destructive load, beams with hybrid reinforcement of the BMBD series had a normal crack opening width less than the maximum permissible width.

4. Conclusions

Studies of the use of small plant protection products waste in concrete mixtures for the manufacture of reinforced concrete structures show the following:

- there is no systematic control of annual volumes of plant protection products waste utilization;
- plant protection products waste has a chemically unstable and heterogeneous particle size distribution at each individual enterprise and requires additional research;
- the time period between experimental studies and publication of regulatory documents can be more than 10 years, which slows down scientific and technological progress;
- beams made of concrete on fine plant protection products waste showed comparable development of normal cracks with beams made of concrete on quartz sand under load;
- beams of BM and BMD series showed the same value of normal crack opening width – 0.9 mm, and beams of BMBD series, even less than the BMD series by 7.9%;
- at 70% of the destructive load, beams of BM and BMD series do not exceed the maximum permissible width of the normal crack opening, and beams of BMBD series do not exceed the maximum permissible width of 60%;
- there are no precautions regarding the use of concrete mixtures with 100% replacement of quartz sand with small waste of plant protection products for the manufacture of structures working in bending with metal, basalt-plastic reinforcement and hybrid reinforcement with metal and basalt-plastic reinforcement at the same time. The crack opening widths for all cases of reinforcement have similar values, regardless of the concrete composition. The difference does not exceed 11%, which is within the calculation error for this type of problem.

Abstract. Composite preparations were created for foliar feeding of winter wheat using obtained silica nanosols and lignin fugate after coals carbonization. Both laboratory and vegetative studies have confirmed the effectiveness of created preparations for foliar treatments of Cubus winter wheat (*Triticum aestivum L.*). When applied, the preparations enhanced the moisture-holding capacity of leaves, photosynthetic processes of the leaf apparatus, and biosynthesis of organic matter, compared to the control group. Additionally, the studied compositions increased the content of endogenous antioxidants, such as carotenoids in plants, and reliably contributed to the reduction of peroxidation processes in cell membrane lipids. Their use could increase the drought resistance of wheat plants.

1. Introduction

Many scientists have studied the nature of silicon in rice waste due to its various applications. The properties of ash formed from the husks depend on the burning method and thus determine possible applications in the future. Rice production waste contains high levels of silica (SiO_2) and other macro- and microelements, making it a promising source of silicon-containing preparations. These preparations, containing active silicon, have a significant effect on plant growth and development, increasing yield, product quality, and resistance to various stressors. This field is actively developing, with synthetic silicon-containing preparations being created for seed priming and foliar feeding of plants [1–6].

Previously, rice husk ash was obtained, which served as a starting material for the silica nanosols creation [7].

The industrial synthesis of silicic acid sols involves several methods, including neutralization of soluble silicates with acids, ion exchange, peptization of freshly formed silicic acid gels, electrodialysis, hydrolysis of silicon alkyl derivatives, dissolution of elemental silicon, and dispersion of fumed silica. Among these methods, the ion exchange method was first patented by Berdom [8] and has several modifications known in the literature. The main stages of synthesizing silica hydrosols with dense particles include such stages as: preparing the silicic acid solution, synthesizing the "seed" sol, particle growth, sol concentration, and changing the particle surface.

The amorphous structure of silicic acid sols remains intact for a long time, even when prepared through different methods. However, due to the development of stresses, the primary amorphous particles break down into many small crystalline particles that subsequently grow, aggregate, and form structures as the sol ages further. Amorphous silica (AS) has a lower degree of polymerization than quartz, which means that the differences in structure are only quantitative and not qualitative. One of the methods that can regulate the aggregative stability of sols and the adsorption capacity of the surface of silica particles is through adsorption modification of the surface. Modified sols synthesis significantly expands the potential applications of colloidal silica. The adsorption patterns of metal cations on silica at different pH and temperature have been studied in several works [8–10], and the process can be carried out in both acidic and alkaline environments. A technological process has been developed for obtaining concentrated and stable silica sols [11], which are stabilized with ammonium hydroxide. The amorphous silica use affects the phosphorus, calcium, potassium, and magnesium absorption and accumulation by plants [12]. It is known that AS strengthens the resistance of bread grains to various fungal diseases and can be used as an insecticide against corresponding insects. AS absorbs lipids from the cuticle of insects, leading to rapid dehydration of their bodies. Hydrophobic silica is more effective in this regard than hydrophilic silica. Silica aerogel, which is partially organophilic due to its preparation method, can inhibit the activity of weevils and grain weevils in granaries at a concentration of 0.05%. It has a longer protective effect compared to chemical insecticides and is non-toxic to animals and humans [12, 13].

The use of foliar sprays containing silicon compounds is a relatively new technique. Silicates were first used for spraying leaves in 1990 while spraying with stabilized silicic acid was introduced in 2003. Recently, spraying with silica nanoparticles has also been introduced. Silicates are effective as pesticides, while spraying with stabilized silicic acid has a positive effect on growth and yield, and also helps protect plants from stress. When silicon is absorbed by plant roots from the soil solution, it reaches a maximum of only 1-5% of the available number of forms. However, when vegetative plants are sprayed with an aqueous solution of silicon, the absorption level by the leaves is 30-40%. Therefore, the most effective way to use silicon-containing compounds is to treat vegetative plants with their aqueous solutions through foliar spraying [14].

Researchers have carried out experiments to determine the most effective sources of silicon (Si) for foliar application. It has been suggested that stabilized silicic acid is a promising compound for this purpose. The literature provides convincing evidence that certain cell wall components can cause SiO_2 deposition. Combining soil application and foliar spraying is an effective method for enhancing Si uptake by plants [14, 15].

Some authors have investigated that $Si(OH)_4$ (hereinafter referred to as Si for simplicity) acts as a “tonic agent”, priming plants, i.e. preparing protective reactions, which are then fully deployed at the onset of stress [16]. For example, salinity stress affects more than 800 million hectares worldwide – up to a third of all agricultural land and almost half of all irrigated land, which produces about a third of the world’s food. Drought stress, which shares many features with salinity stress, is even more widespread and destructive to agricultural production, especially in arid and semi-arid regions, which account for approximately 30% of the world’s land area. Both problems are predicted to be exacerbated by anthropogenic climate change [17]. There is a lot of evidence that silicon can improve the strength of cell walls and provide mechanical support to certain types of plants, specifically monocots and pteridophytes. However, less is known about how it affects dicots. Silicon can enhance suberization, lignification, and differentiation, resulting in improved structural stability. This is due to the binding of Si to the hemicellulose of the cell wall, which is especially useful during water deficiency [18]. Moreover, biosilification in plants involves the polymerization of silicic acid within the apoplast, which creates a barrier of amorphous silica. This barrier can help protect against both biotic and abiotic stresses by preventing pathogen infection and the penetration of toxic elements, such as Al, Cd, and Na [13, 19–21].

Si plays a vital role in reducing the transport of Na^+ to the shoots in the roots of salt-sensitive wheat. This happens because Si increases the binding of Na^+ to the cell wall in the root. Si can also regulate water transport by enhancing the accumulation of osmolytes which can affect the osmotic potential of cells. In addition, Si can reduce oxidative stress and membrane damage which can lead to an increase in root hydraulic conductance. Recent research has explored the concept of "seed priming" where exposure of seeds to Si for a few hours can strengthen plants against future stress events. Although studies have mostly focused on the resistance to biotic stress, seed priming has shown promise in conferring resistance to abiotic stress such as drought and salinity [22, 23]. In such studies, a decrease in proline, malondialdehyde (MDA), and Na^+ content was observed in seedlings treated with Si. However, more research is needed to understand the underlying mechanisms of Si's effects on seed priming [23].

The purpose of our work was to investigate the effect of foliar spraying with silicon-containing solutions on the growth and post-stress recovery of winter wheat under conditions of simulated moderate soil drought.

2. Materials and methods

2.1. The method of obtaining silica nanosols

Dispersion was carried out in an aqueous medium with a molar ratio of H_2O: SiO_2 = 1:0.047. The rotation speed of the disperser rotor was 15,000–20,000 rpm (Homogenizer, DAIHAN Scientific – Co.LTD, Korea). The ultrasound frequency used was 35 kHz, and the treatment lasted for 3 hours. White suspensions were obtained, from which large particles were removed by centrifugation. By varying the ratio of components, dispersions with a mass concentration of SiO_2 ranging from 1.13 to 10.63% can be obtained.

The surface morphology was investigated with atomic force microscope (AFM) NT-206 (Company with double liability "Microtestmachines", Belarus) equipped with standard sonde CSC37 and rigidity of console 0.3-0.6 N/m. The scan was run in a contact static mode at 10 mcm/s with a step of 0.3 nm.

2.2. Methodology of vegetation experiments

Determination of the effectiveness of created nanosols for foliar spraying of Cubus winter wheat plants was carried out in vegetation experiments. The experimental scheme is provided in the tables in the following section.

The vegetation experiment followed an established research methodology [24]. To prevent infections, 60% ethyl alcohol was used to treat wheat seeds for 15 minutes, followed by thorough washing with distilled water. The treated seeds were then germinated for one day at 26 ^oC in Petri dishes on moist filter paper with 50 seeds per cup. The sprouted grains were then planted in the soil. Winter wheat plants of the Cubus variety were grown in 5 kg vegetation pots filled with dark grey podzolic soil. The soil had an average content of macronutrients such as nitrogen, phosphorus, and potassium. Soil moisture in vegetation vessels was kept at 60% of its full moisture capacity and the plants were watered using Arnon-Hoagland solution. To create soil drought, watering was stopped for 18-day-old plants until the moisture content of the substrate was reduced by half. The air temperature during the experiment was maintained at 28–32 ^oC. Plants were grown under a light installation with a light intensity of 690 $\mu mol/(m^2{\cdot}s)$ and a photoperiod of 16/8 h (day/night). The experiment lasted for 58 days and was repeated 5 times. Phenological observations of the wheat plants were carried out during the experiment, and the impact of foliar spraying on their growth and development was also determined.

The thermogravimetric method was used to determine the mass fraction of dry matter in the plant material [24].

To determine the water-holding capacity index of leaves using A. Arland's method, the raw leaves were weighed using electronic scales. The mass of the leaves was then measured at 2, 4, 6, and 24 hours after the start of the experiment, along with the mass of dry leaves [25]. The experiment was repeated four times.

2.3. Determination of chlorophylls

In 58-day-old plants, the content of chlorophyll a, b and the total content of carotenoids were determined according to the Welburn method [26]. Dimethyl sulfoxide (DMSO) was used as a pigment solvent, which has some advantages over other solvents. Extraction of pigments was carried out for hours at a temperature of 67 °C in a thermostat. Spectrophotometric measurement of the optical density of solutions was carried out at wavelengths 665, and 649 (red region of the spectrum) and 480 nm (violet region). DMSO was used as a control.

The content of pigments was calculated according to the formulas:

$$C_a = 12.19 \cdot A \cdot 665\text{–}3.45 \cdot A \cdot 649, \quad (1)$$

$$C_b = 21.99 \cdot A \cdot 649\text{–}5.32 \cdot A \cdot 665, \quad (2)$$

$$C_{car} = (1000 \cdot A \cdot 480 \ --2.14 \cdot C_a \ --70.1 \cdot C_b)/220, \quad (3)$$

where C is the concentration of the corresponding pigment in the extract, μg/ml; A is the optical density measured at the appropriate wavelength for the chlorophyll a, b and carotenoids (car) determination.

To determine the concentration in mg of pigments per gram of crude substance, the following formula was used, taking into account the extract's dilution (C_p):

$$C_p = C \cdot 10 \cdot 3/(0.1 \cdot 1000 \cdot 0.5), \quad (4)$$

where C is the concentration of the corresponding pigment in the extract, μg/ml; 10 – extract volume, ml; 3 – volume of diluted extract, ml; 0.1 – weight of chopped raw leaves, g; 0.5 – volume of extract used for dilution, ml; 1000 – const (for recalculations of measurement units).

The amount of pigments (P) in mg per 1 g of dry matter of leaves was determined by the formula:

$$P = C_p/B, \quad (5)$$

where B is the content of dry matter, %.

The content of malondialdehyde (MA) in plant leaves was determined by the photocolorimetric method using thiobarbituric acid [27].

The experimental results were processed by the variational statistics method using the Student's test [28]. Average arithmetic values were presented in tables. Statistical data was analyzed with Microsoft Excel.

3. Results and discussion

3.1. Characteristics of obtained silica nanosols

Silica nanoparticles were obtained using two methods: high-speed dispersion with ultrasound processing (mechanical method) and nanosol synthesis by hydrolysis of tetraethoxysilane. It's important to note that silica particles tend to aggregate in a liquid medium to form agglomerates. Moreover, as the particle volume decreases, the effect of agglomeration becomes more pronounced due to the size effect. For instance, if the particle size is 10.3, 10.2, and 10 nm, the share of the interface increases from 0.3 to 3 and 30%, respectively. Therefore, dispersing silica into a sol consisting of discrete particles is quite challenging. High-speed dispersion damages the skeletal structure that is formed by silanol groups (Si–OH). Ultrasound treatment is more effective in this regard, as it creates cavitation shock waves that can break down large particles.

The synthetic method involves hydrolyzing tetraethoxysilane in an acidic environment (aqueous ethanol pH 1.5-2) at a temperature of 42 °C for 2 hours. This ripens the nanosol, which is then diluted with water at a ratio of 1:8. The solution is then treated with alkaline reagents or anionites. The concentration of the nanosol is 10.1%. To estimate the size of the obtained particles, a comparative AFM of the samples was carried out.

In figure 1(a), you can see a 2D image of a sample's surface obtained through high-speed dispersion with ultrasound processing. The scan size of the image is 4.9 μm x 3.8 μm, and there is a section line marked as 1-2. The surface roughness of the sample is Ra = 6.6 nm which is shown in figure 1(b). Additionally, the cross-section analysis of section 1-2 (figure 1(c)) reveals that the surface on this cross-section is made up of particles having a size of 8.1, 6.4, and 8.7 nm.

In figure 2(a) a 2D image with a scan size of 2.4 μm x 2.3 μm is shown. This image displays the surface of the nanosol, which was obtained by hydrolyzing tetraethoxysilane. The cross-section

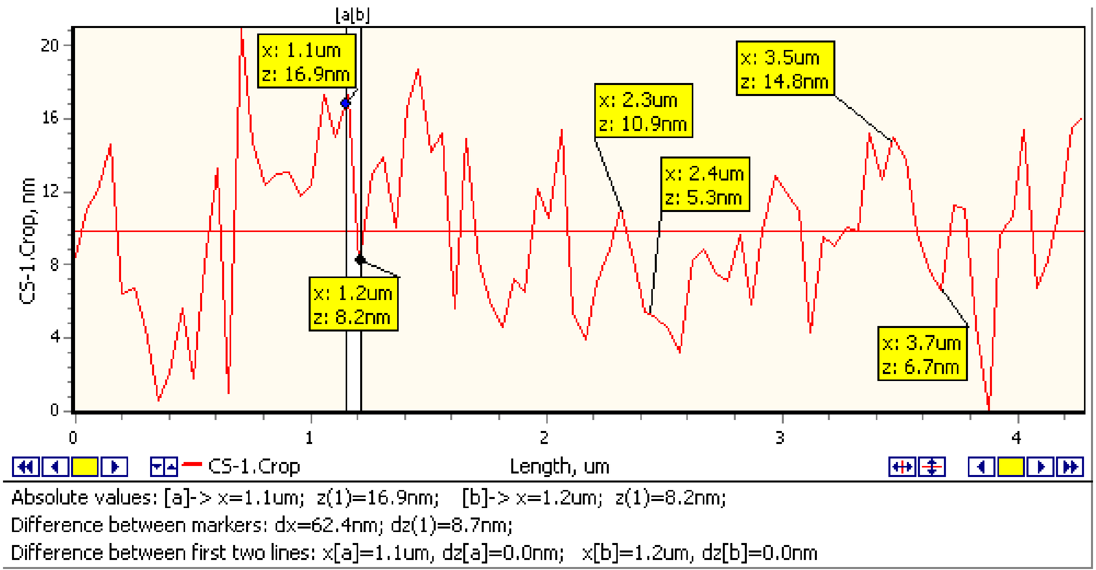
(b)



(c)

Figure 1. 2D (a) and 3D (b) images of the surface of the sample obtained by high-speed dispersion with ultrasound processing with shown cross-section line 1–2 and the profile of the last one (c).

line 1-2 is also visible in the figure 2(a). The surface roughness is minimal at $Ra = 0.5$ nm, as shown in figure 2(b). A closer analysis of the cross-section profile 1-2, as seen in figure 2(c), reveals that the surface is formed by particles particles with sizes ranging from 0.3-0.8 nm.

After analyzing the AFM data of two nanoparticles samples, it can be concluded that larger and more aggregated nanoparticles are formed in the case of dispersion. On the other hand, nanosol obtained by the hydrolytic method is made up of smaller particles with sizes an order of magnitude smaller than those in the case of dispersion. These smaller particles are less aggregated and more discrete.

The obtained nanosols were used to create biologically active composites with metal salts, humates and lignohumates (LH).

3.2. Study of the effectiveness of the use of Si-nanosols for foliar treatments of winter wheat
Foliage is an important indicator characterizing the growth processes of plants, which in the future directly affects the yield. The process of photosynthesis and, accordingly, the formation of organic substances, which is the basis of productivity, depends on the leaf's formation and development.

Determination of the created products' anti-stress effect based on silica nanosols, a potassium silicate (lignin centrate) solution for foliar treatments, was carried out in a vegetative experiment with winter wheat of the Cubus variety. In the vegetation experiment, soil moisture deficiency was simulated three times (soil moisture was maintained at the (30±5)% level of the total soil moisture content for two weeks).

Based on the analysis of the results presented in table 1, it was found that treated plants did not differ in biomass when compared to plants grown under favourable conditions. When modelling under regulated conditions of soil moisture deficit at the level of (30±5)% of the total moisture content in the tillering phase, the experimental wheat plants reliably differed from the control ones in terms of productivity. The mass of the ground part of 100 plants in the experiment had a range of 10.6 g (in the control group) to 12.15 g (when using the composition with potassium dihydrogen phosphate) after three treatments of plants with compositions based on silica nanosols. Other versions of the experiment demonstrated an increase in the mass of the ground part by 10-12%. On the other hand, the weight of the roots of the experimental wheat plants (2.9–3.01 g) was almost no different from the control (2.9 g). The treatment of plants with Si-LH, Si-KH_2PO_4, and Si-nanosol resulted in the highest values of root mass (3.0-3.01 g). Essentially, foliar fertilization with Si-containing compositions led to a slight increase in the processes of organic matter synthesis and nutrient translocation in plants, even under insufficient moisture in the conditions of the vegetation experiment.

It should be noted that in the experiment, the aqueous solutions application of the studied compositions through foliar feeding resulted in an improvement in the linear dimensions of wheat plants, including the length of their roots and above-ground parts. In particular, treating the leaves thrice with nanosol solutions stimulated the growth of the above-ground parts of the plants. Compared to the control, an increase in the length of the leaves by 6-7 cm was observed in the variant using nanosol Si-HA (humic acids) + ME (microelements) and Si-LH. The addition of potassium humate with biogenic ME and LH to the composition of Si-nanosol

Table 1. The effect of foliar fertilization with silicon-containing compounds on the biometric parameters of experimental plants and the bioproductivity of 58-day-old plants of winter wheat of the Cubus variety in a vegetation experiment.

likely contributed to the stimulation of growth processes in the experimental plants of Cubus winter wheat.

A mandatory condition for the growth and development of plants, resistance to the influence of adverse environmental factors is their ability to maintain a certain level of water balance. Plants react to moisture deficit with a complex response, which includes perception of stressor action, initiation of signal transduction pathways and physiological and biochemical changes in the cell. Under the influence of drought, the formation of reactive oxygen species increases in chloroplasts and mitochondria. Therefore, exogenous influences inducing the antioxidant system are considered methods of increasing the drought resistance of plants. Even with a slight stress on the water balance of plants caused by drought, the normal course of metabolic processes is disturbed, as a result of which the productivity of plants decreases [29].

The water-holding capacity was studied according to the method of A. Arland, which is based on the calculation of the rate of water loss during the withering of the shoot by weighing it at regular intervals. The obtained data on the change in shoot weight characterize the level of water-holding capacity.

Statistically probable indicators of the water-holding capacity of winter wheat leaves of the Cubus variety under the influence of foliars (after 2, 4, 6, 24 h) in the tillering phase are given in table 2. Two hours after cutting the leaves of experimental plants of the variants, where foliar spraying with certain solutions was carried out, lost 14.5–21% less water compared to the control. Similar results were also obtained after 4 and 6 hours. Thus, water loss decreased by 15–21% compared to the control, where spraying was carried out with water. The amount of water lost by the leaves of plants of the control variant was greater by 20 and 21% compared to the indicators in the variant where a solution of nanosol with potassium dihydrogen phosphate was used three times. Obviously, more osmotically active substances accumulated in the leaves of plants of the specified variant due to foliar fertilization. It is worth noting that the composition of the two test solutions contains potassium (in variants 6 and 9), which is an osmotically active cation [30, 31] and provides reliable moisture-retaining protection, which affected the indicators of moisture loss in the vegetation experiment with winter wheat of the Cubus variety. After 24 h, the leaves lost a significant amount of water and the probable difference between the control and the experimental variant was not determined. The analysis of the obtained indicators shows that under the influence of solutions for foliar treatments, the leaves of experimental plants of winter wheat lost less water compared to the control.

According to leading physiologists, the content of photosynthesis pigments (PP) in plants can be a more informative indicator of the toxicity of seed or leaf treatments. table 3 shows the

^{a} – the difference is probable compared to the control at $p \leq 0.05$.

results of determining the effect of foliar treatments of Cubus wheat with the studied compounds based on silica nanosols on the content of chlorophyll, total carotenoids and malondialdehyde (MDA) in the leaves of 58-day-old plants. The data in this table show that the PP content in the experiment varied depending on the options for foliar treatment of plants. Thus, the use of Si-containing preparations in the experiment contributed to the accumulation of a larger (by 5–7.5%) amount of chlorophyll in plant leaves compared to the control. The greatest increase in the content of chlorophyll a was observed in the version using potassium dihydrogen phosphate or copper-ammonia complex. More significantly, the fertilization variants affected the formation of chlorophyll b. Its content increased by 8–14% compared to the control, and the greatest effect was noted in the option with three times the use of compositions with potassium dihydrogen phosphate and copper-ammonia complex – an increase of 12.7 and 14% respectively.

Table 3. The effect of foliar fertilization on the water-holding capacity of winter wheat leaves of the Cubus variety (amount of water lost in %) in the tillering phase, M±m, $n = 12$.

	Research options	Chlorophyll content, mg/100 plants			Total carotenoids content, mg/100 plants	MDA content, nmol/g of raw leaf mass
		a	b	a+b		
1	Control	53.1±1.7	15.8±0.4	68.9±2.1	8.2±0.3	79.9±3.4
2	SiO_2-nanosol, 0.006 (%)	54.4±1.7	15.1±0.5	69.5±2.2	8.7±0.4	71.1±3.9
3	SiO_2-HA, 0.006 (%)	55.0±1.8	16.9±0.6	74.9±2.4	8.9±0.5	72.0±3.8
4	SiO_2-LH, 0.006 (%)	55.8±1.8	17.1±0.3	72.9±2.1	9.2±0.4	69.5±3.7
5	SiO_2-HA+ME, 0.006 (%)	54.1±1.7	16.6±0.7	70.7±2.4	9.1±0.3	70.3±3.8

8	$K_2SiO_{3centrate}$, 0.006 (%)	54.8±1.7	15.9±0.6	70.7±2.3	9.1±0.3	71.0±3.7

This also affected the indicator of the sum of chlorophylls (a+b) – an increase of 8–11% compared to the control. Variants of foliar fertilization with compositions based on silica nanosols with potassium dihydrogen phosphate or a copper-ammonia complex provided the greatest increase in the amount of chlorophyll – by 11%. It should be noted that the treatment of plants with the created compositions significantly contributed to the increase in the biosynthesis of endogenous antioxidants – general carotenoids. The highest content of carotenoids in leaves was observed with the use of foliar nanosols with potassium dihydrogen phosphate and with Cu-NH_3 – an increase compared to the control by 16 and 20%, respectively. With the use of lignin fugat, the content of carotenoids exceeded the reference values by 11%. The introduction of humic and lignohumic components into the composition of the nanosol provided an increase in the indicator by 9–11%. Obviously, the change in the number of carotenoids in our experiments was associated with a lower sensitivity of the enzymes of their synthesis to the components of the preparations, as well as with the active role of the specified pigments in the neutralization of reactive oxygen species (ROS).

By increasing the content of endogenous antioxidants – carotenoids in plants, the studied compositions contributed to a 12-17.5% decrease in the formation of MDA in plant leaves – an intermediate product of lipid peroxidation, mainly lipids of cell membranes. A decrease in the content of MDA in the leaves of experimental plants of winter wheat was more significantly observed in the version using Si-Cu-NH_3 – by 17.5% and with Si-potassium dihydrogen phosphate – by 17%. The use of aqueous solutions of lignin centrate and silica nanosol led to a decrease in the MDA index by only 11%.

Quantitative changes in lipid peroxidation in the experiment indicate that foliar fertilization of winter wheat of the Cubus variety with Si-containing solutions has a stress-protective effect on plants that were grown in conditions of insufficient moisture supply. This can probably be explained by the initial non-specific reaction of the variety to stress (insufficient moisture supply) due to the passive adaptation of the plant.

The results of the vegetative experiment allow us to state that the created compositions based on silica nanosols exhibit antioxidant properties – they ensure a decrease in the content of malondialdehyde in the leaves of plants – an intermediate product of the undesirable peroxidation process of lipids, mainly lipids of cell membranes, which negatively affects the functioning of cell membranes and, probably, on growth processes. The use of Si-containing compounds for foliar feeding helps to increase the activity of the photosynthetic apparatus, and by reliably increasing the content of total carotenoids in the leaves, exogenously strengthens the antioxidant system of plants, which is important for increasing the resistance of plants to stresses. Thus, they increase the resistance of plants against such stress as insufficient moisture supply.

According to the integral evaluation of the obtained results, spraying of vegetative plants of winter wheat (three times) with preparations based on silica nanosols and lignin fugate did not cause burns on the leaves of winter wheat plants of the Cubus variety and provided protection of plants from the negative impact of stressful growing conditions – insufficient moisture supply.

4. Conclusion

The analysis of the obtained results of the vegetation experiment gives reason to conclude that the compositions of silica nanosols with lignohumates, potassium dihydrogen phosphate, and copper-ammonia complex are effective for carrying out foliar spraying in conditions of insufficient moisture supply of plants. The use of these compositions for foliar feeding of Cubus wheat activates the work of the photosynthetic apparatus of plants, suppresses the processes of peroxidation of lipids of cell membranes, and provides higher indicators of water-holding capacity. Thus, under stressful conditions of winter wheat plant growth and development, three-fold foliar treatment with products created based on silica nanosols ensures a reduction in the negative effect of the stress effect of adverse environmental factors.

Abstract. The article is devoted to the urgent problem of utilisation of red mud (RM) – a by-product of bauxite ore processing in the process of aluminium production. The acuteness of the problem is increased by the negative influence of red mud on the environment due to its high alkalinity of its pulp (pH = 9-12) and fine dispersibility. The article characterises the main properties of RM, reveals the essence of the most effective method of its storage today – dry stacking. Due to the presence of high content of iron oxide and such metals as Al, Ti, Y, Ce, etc. in the composition of RM, it is a valuable complex man-made raw material. The analysis of modern technologies of RM processing has shown that the important tasks in its utilisation are the processes of dehydration and disinfection. The first one is most successfully solved by using filter presses, the second one – by adding lime to the sludge washing system. Technologies for extraction of valuable components from RM can be divided into two groups – pyro- and hydrometallurgical. The most promising solution to the problem of effective integrated waste-free processing of RM is a rational combination of these two processes.

1. Production and storage, composition and properties of red mud

Red mud, sometimes called bauxite residue, is a by-product of alumina production, the main product of which, alumina, obtained from the processing of bauxite ore using the Bayer hydrometallurgical process, serves as a raw material for the production of aluminium. Global production of this valuable metal, which is widely used in many industries, is continuously increasing. In 2022, global aluminium production rose by 2.2 % to 69 million tonnes. Aluminium production is expected to grow at an average annual rate of 6.1 % until 2029 [1]. The largest consumers of refined aluminium are East Asian countries, where aluminium consumption increased from 7.1 million metric tonnes to over 40 million metric tonnes in 15 years (2005 – 2020). The world's largest consumer of refined aluminium is China.

The increase in aluminium production is accompanied by an increase in alumina production (figure 1) and its by-product red mud, which yields about 1.2 tonnes per tone of alumina produced [2] and can range from 900 to 1500 kg/t [3]. The specific yield of red mud depends on the quality of feedstock and the perfection of alumina processing technology. The higher they are, the lower the yield of the by-product – sludge.

The world production of red mud in 2017 was $\sim$ 150 million tonnes, and its total reserves worldwide are estimated by different data from 2.7 to 4 billion tonnes [3–5].

Due to the current lack of effective technologies for mud processing, in most cases it is simply stored in isolated areas – mud storages – tanks with a height of 30 – 50 metres. They occupy

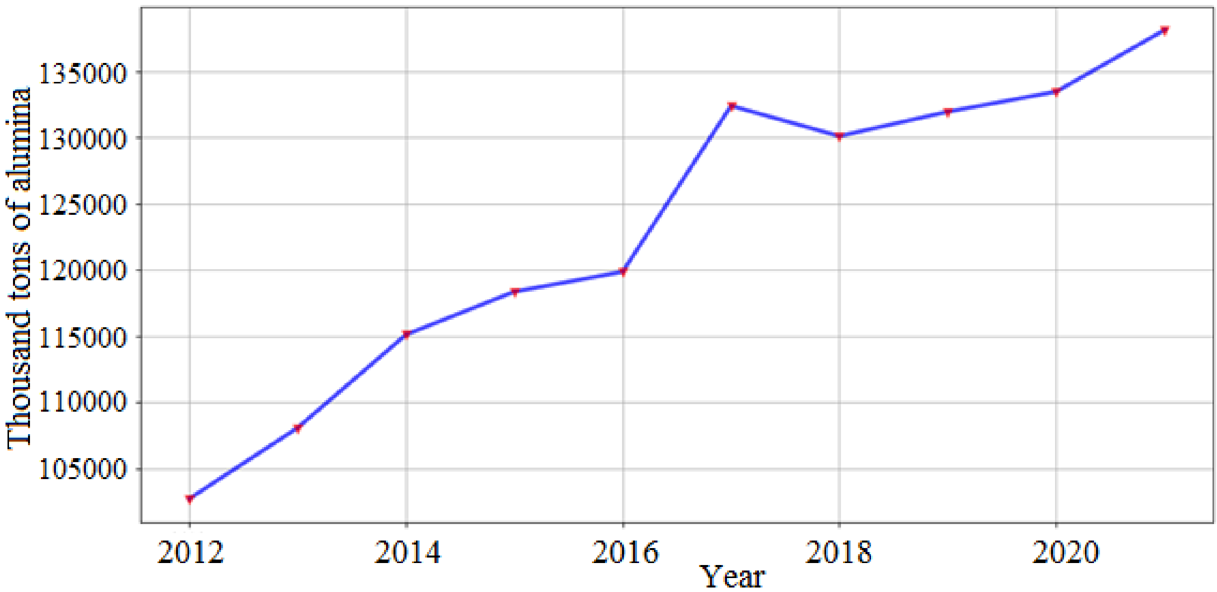

Figure 1. Global alumina production in 2012-2021.

10-50 hectares of land area and contain tens of millions of tonnes of mud [3]. Construction of new mud storages and maintenance of old ones requires large expenses. In addition, mud storages serve as a source of environmental pollution (including due to the risk of mud storages rupture, as it happened in Hungary in 2010 (figure 2) [3]), and the lands on which mud storages are arranged are removed from useful land use.

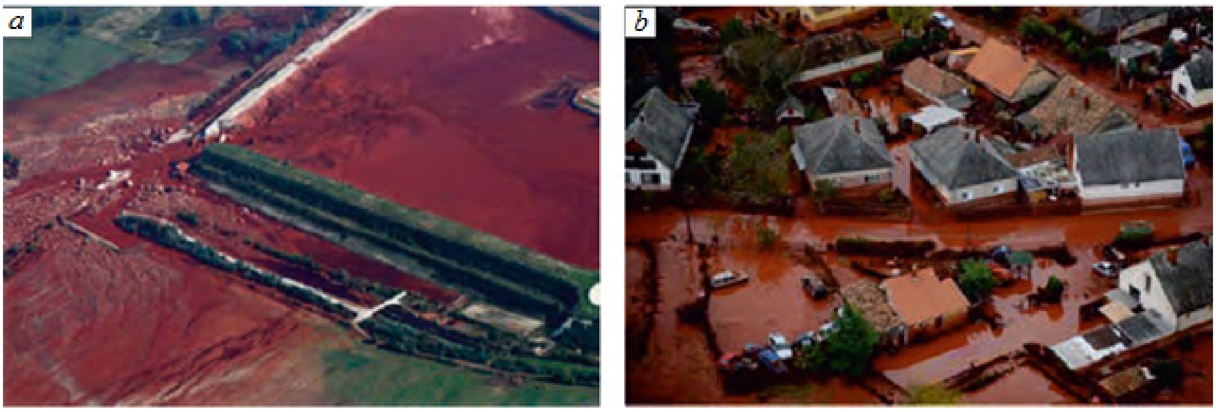

Figure 2. Environmental disaster in Hungary: (*a*) breach of the red mud storage dam; (*b*) flooding of Kolontar village with mud.

A specific Guide to the Sustainable Management of Bauxite Residues [2] has been developed, which explains the life cycle of stored red mud and, based on relevant case studies, shows how stakeholders can play an active role in its sustainable management.

Alumina refineries around the world are experiencing difficulties in the storage and utilisation of red mud. Dry stacking is currently one of the most popular methods of red mud disposal. This method is a safer and more stable disposal of red mud with lower land costs compared to the creation of sludge storage facilities. When using the dry stacking method, covering the discharged red mud reduces the risk of environmental contamination. Among eighty four alumina refineries worldwide, seven refineries discharge red mud into the sea due to insufficient alumina [5].

Red mud is a residue of bauxite leaching with $NaOH$ solution, therefore its Na_2O content can be up to 12.36 %. The chemical composition of the sludge varies considerably depending on the composition of the initial bauxite and leaching parameters. The content of the main components of red mud from different plants (and approximate average value) is as follows, %: 6.8 – 65.7 (41) Fe_2O_3; 2.12 – 33 (17) Al_2O_3; 0.6 – 23.8 (10) SiO_2; 0.19 – 46 (9) CaO; 2.5 – 22.6 (9) TiO_2; 0 – 12.36 (5) Na_2O; 1 – 30 (10) moisture, volatile, rare earth metals (REM). The red mud contains significant amounts of La, Ce, Pr, Nd and other REM, the total content of which is in the range of 506 – 2500 g/t, including 90 – 110 g/t Sc_2O_3 [3].

The phase composition of red mud from different plants also varies greatly. The most typical minerals are hematite (present in the amount from 7 to 29 % practically in all sludges), goethite, betite, gibbsite, anatase, rutile, ilmenite, perovskite, quartz, as well as complex aluminosilicates such as sodalite, cancrinite and kaolinite [3].

The particle size of red mud is very small and ranges from 0.1 to 200 microns [3] with an average particle size of less than 10 microns and density of 3.0 – 3.8 g/cm^3. Specific surface of particles is in the range of 10 – 25 m^2/g and depends mainly on the temperature of processing of initial raw material [4].

Another characteristic of red mud, which makes its utilisation difficult, is the high alkalinity (pH 10-12) of its pulp due to its sodium content, which makes it corrosive [4].

2. Preparation for use and main directions of red mud utilisation

An important place in the technology of utilisation and possible recycling of red mud is occupied by the dewatering operation, which provides not only effective storage of sludge, but also its shipment to the consumer, as well as preparation for subsequent recycling processes. Several methods of sludge dewatering can be distinguished, which have different degrees of applicability (figure 3) [3].

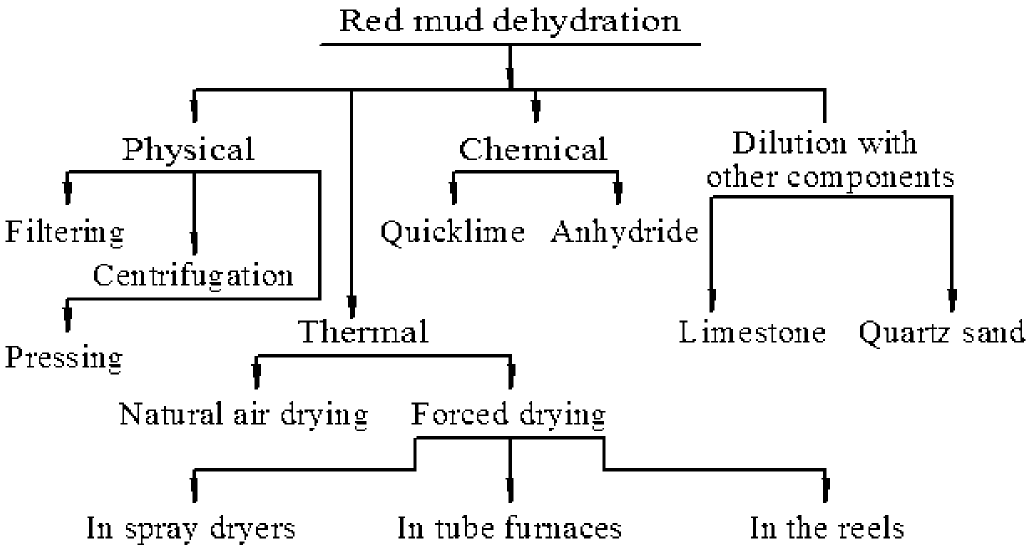

Figure 3. Methods of red mud dewatering.

The most effective way of dewatering is filtering, which, due to the possibilities of modern equipment, allows to obtain sludge with low moisture content. Preparation of red mud using belt filter press FRAKM-25 allows to receive a cake with humidity about 25 %, which has the required transportability properties. Positive results of tests on a pilot plant with a capacity of 20 thousand tonnes/year (figure 4) served as a basis for the construction of a shipping complex designed for the full capacity of the alumina refinery [6]. The experience of operation of the complex of red mud dewatering by filter presses with a capacity of 500 – 700 thousand tonnes/year has shown that this method is optimal for today [3].

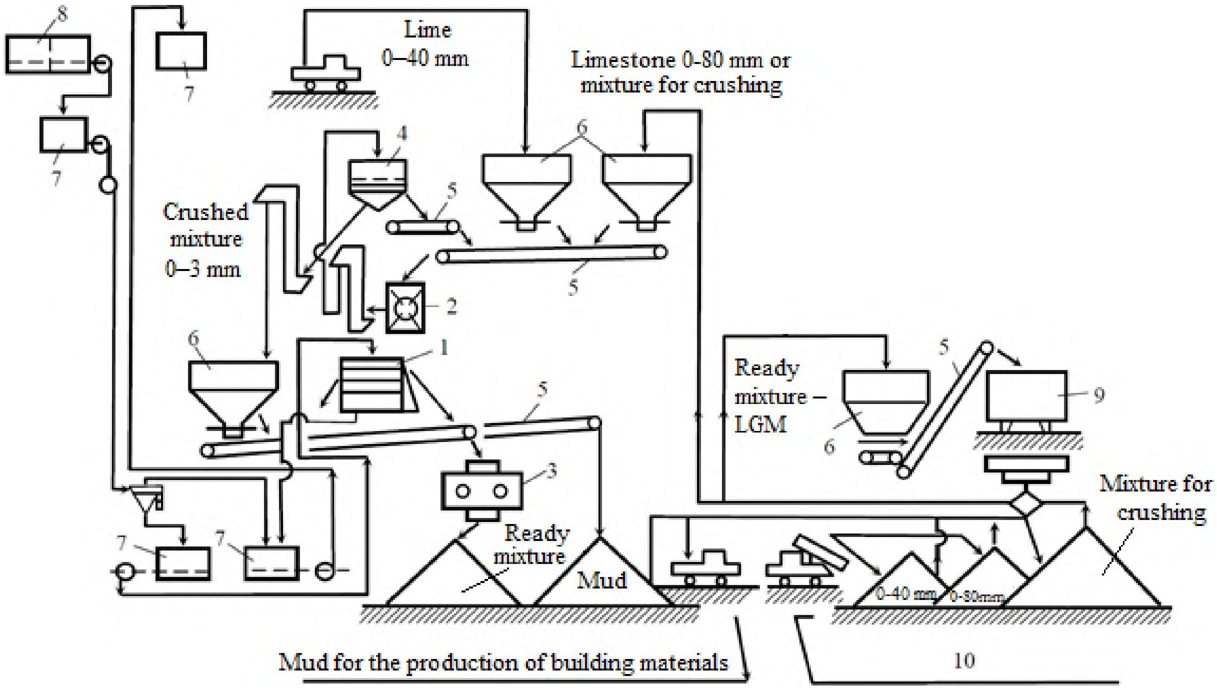

Figure 4. Apparatus-technological scheme of pilot plant for production of transportable commercial red sludge with capacity of more than 20 thousand tonnes per year: *1* – filter-press; *2* – crusher; *3* – mixer; *4* – screen; *5* – conveyors; *6 – 8* – alumina shop washer; *9* – railway wagon; *10* – stack.

Experimental studies of drying kinetics after filter press of mud of Greek origin using thin-layer modeling have established the values of effective moisture diffusion in the temperature range 50-250 $^{\circ}C$, as well as the value of activation energy of drying of red mud equal to 28.133 kJ/mol [7].

Depending on the composition and physicochemical properties of mud, various methods of its neutralization and processing are used: chemical, physicochemical, thermal and their combinations [8].

The most common technologies for regeneration of alkali from red mud back to the Bayer process are methods of its removal by adding lime to the washing system or after it. It is known that the addition of lime to the slurry, which includes slightly alkaline wash water, can remove 70 – 80 % of alkali [3]. Studies of alkali regeneration from red sludge by adding lime allowed to establish the optimal parameters of the process: temperature 80 – 95 $^{\circ}C$; L:S from 3:1 to 8:1; dosage of lime 1.5 – 4.0 mol per 1 mol Na_2O sludge and duration of treatment 1.5 - 3.0 hours [3]. In the process of testing the red mud containing, %: 13.36 Al_2O_3; 45.52 Fe_2O_3; 2.8 Na_2O, after washing in a stirrer at L:S = 3:1 and temperature 90 $^{\circ}C$ for two hours was mixed with lime at the rate of 3 mol CaO_{act} per 1 mol Na_2O sludge at the duration of treatment 1,5 - 3,0 hours. The obtained weak alkaline solution was directed to the Bayer process of the main alumina production.

Neutralization of red mud by removal of alkaline film is possible with the help of aqueous hydrochloric acid solution [9]. As a result of the acid reagent, the mass fraction of water-soluble components in the heterogeneous system decreases, while the average particle size increases from 1.6 to 2.0 μm and specific surface area from 23.7 to 25.7 m^2/g as a result of adhesive interaction. The ratio between particle size fractions of red mud practically does not change.

Due to its rich material composition, red mud should be considered not only as a by-product of alumina production, but also as a secondary technogenic raw material requiring complex processing to obtain marketable products. Calculations have shown that red mud contains 44 % of chemical exergy of bauxite and is produced at a mass ratio of (2-3):1 to metallic aluminium. The relatively high exergy embodied in red mud is due to the significant amount of residual minerals (hematite, anatase, quartz) originally present in bauxite [4].

The most common methods of sludge utilisation are thermal. Fire treatment allows complete neutralization of combustible components of sludge with obtaining harmless combustion products and ash residues consisting of metals and their oxides. Along with direct incineration, thermal methods are often a part of complex technologies of sludge neutralization and utilisation. In these technologies, thermal treatment either precedes or follows a physicochemical or chemical process for the extraction of valuable components from the sludge. Such complex methods extract iron from sludge, recover catalysts containing nickel, palladium, platinum, copper, tellurium and other valuable metals, as well as extract these metals from spent catalysts [8].

For firing of red mud, drum furnaces with countercurrent thermal treatment system are used. For the same purposes cyclone furnaces with upper gas outlet are used, calcination in which provides complete neutralization of sludge due to combustion of toxic organic substances and capture of valuable mineral products [8].

The hydrometallurgical process for the extraction of alumina and sodium oxide from red mud is used in the calcification-carbonisation method (CCM), which was proposed to increase the scale of integrated sludge recycling [10]. First, the alkali in the red mud is removed by adding lime, then the calcined residue (including hydrogranate) is decomposed with carbon dioxide, finally, the carbonised residue is decomposed with aqueous alkali at low temperature and a new structure of red mud based on $CaSiO_3$ and $CaCO_3$ is obtained.

In many works, such as [11–13], pyrometallurgical methods with the production of pig iron (ferrosilicon) and alumina slags are characterised as the most efficient. A distinctive feature of pyrometallurgical methods is their multistage nature.

A waste-free process of red mud processing (figure 5) was proposed, which includes obtaining carbon-containing pellets from sludge and semi-coke, their reducing roasting using a rotary hearth furnace, smelting of the reduced pellets in an electric arc furnace to produce metal and desulphurising flux [12]. This process combines the methods of alumina and steel industry, which can not only solve the problem of red mud processing in alumina refinery, but also help steel mills to reduce the production cost.

One of the variants of complex processing of red mud is its reductive smelting in a mixture with limestone in an electric furnace to produce pig iron and alumina-calcium slag. The alumina-calcium slag can be processed into alumina and cement.

Another use of red mud is to use it directly as an additive in the production of various products. There are solutions to use red mud in the production of cement, bricks, ceramics, fire-resistant concrete, foundry-moulding mixtures, sewer pipes, glass fibre, for soil consolidation in road construction, as a coagulant for wastewater treatment, as the main component of a complex binder for mine workings and for other purposes. Nevertheless, so far few of these proposals have received practical use in life [8].

For example, Bayer sludges are plastic due to their aluminous-iron composition and high dispersibility, so in mixtures with clays they can be used in the production of ceramic products. The optimal composition of silicate bricks is as follows, % (by weight): sand – 76.2; bauxite

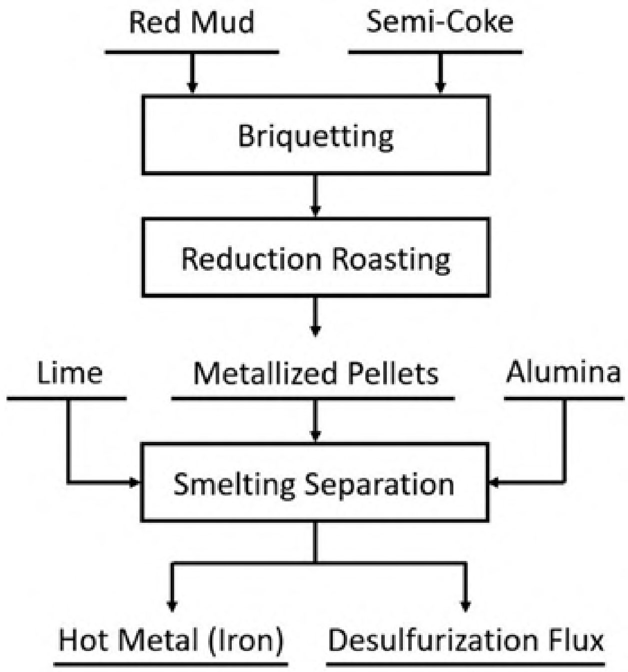

Figure 5. New process of red mud processing.

sludge – 18.8; lime – 5. Bayer sludge can also be considered as a raw material source for the production of complex iron-aluminium containing coagulant. The production of such a coagulant is based on sulfuric acid decomposition of bauxite sludge to form a mixture of trivalent iron sulfate and aluminium sulfate [14].

The possibility of using red sludge in the form of a slurry with the ratio L:S about 5:1 for purification of industrial waste gases from sulphur compounds and as a modifying additive used in the technology of slag granulation has been established [15,16]. Studies of sorption properties of red mud showed its high absorption capacity in relation to sulphur compounds, which is due to the ratio of calcium, magnesium and aluminium oxides to silicon oxide, so it can be an alternative to expensive lime and limestone. The proposed technology has a great advantage over other granulation methods using calcium oxide and calcium hydroxide. The addition of red mus is not only a desulphuriser, but also serves as a valuable component for slag processing with further application in the construction industry.

Among various methods of using red mud, its potential as a catalyst for various chemical processes has proved to be very successful. The presence of many valuable metals in red mud, in particular iron, makes it a suitable catalyst for energy production by such processes as pyrolysis, hydrotreating, transesterification and H_2 production from biomass and other raw materials (figure 6) [17].

At the same time catalyst on the basis of red mud can be prepared by various methods: acid treatment, saturation with active metals, calcinations, oxide reduction, etc.

A special problem hindering the introduction of red mud processing technologies is its increased radioactivity inherited from bauxite and caused by the presence mainly of thorium and to a lesser extent uranium. The methods of extraction of radioactive metals from red mud offered today are not economically efficient, and the most promising are complex technologies of red mud processing, allowing to extract rare, rare-earth and radioactive metals simultaneously [18].

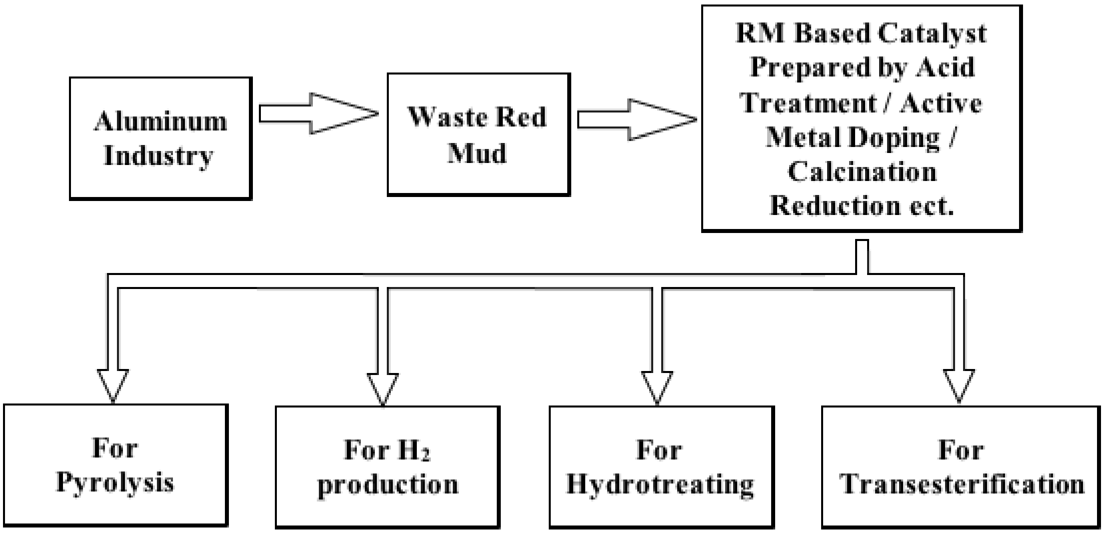

Figure 6. Scheme of possible directions and methods of using red mud as a catalyst for energy production by means of chemical rocesses.

3. Metallurgical orientation of red mud processing

The increased content of iron, aluminium and titanium oxides makes red muds attractive for extraction of these metals. It is established that as a result of red sludge recycling it is possible to obtain pig iron, aluminium, concentrates of rare metals.

As a result of technological modeling the technological (figure 7) and apparatus schemes of joint leaching of red mud and oily rolled scale were proposed [19]. A distinctive feature of the technological scheme, which increases the efficiency of solvent utilisation, is a closed water cycle with compensation of moisture losses with sludge and spent filtrate. The primary treatment of scale is proposed to be carried out at the place of its receipt, and the secondary (together with red mud) – at the enterprise processing bauxite. The technological scheme, in addition to those presented in fig. 7, includes the following operations: treatment of oily scale with industrial water at the ratio of solid to liquid 1:(45) and temperature $90 - 100$ $°C$; sedimentation of the pulp with drainage of the upper oil layer and subsequent activation of the pulp; oil utilisation by dewatering and filtration; processing of the pulp with separation of the washed dewatered scale in a centrifuge; transportation of scale for joint processing with red mud; introduction of washed scale into the reactor with mixing with red mud at the mass ratio of scale and mud in the mixture corresponding to the requirements of the subsequent processing of the solid filtration product, i.e. blast furnace process [9].

As a result of stepwise leaching of the main valuable components of red mud – iron and aluminium oxides – using hydrochloric acid, the following results were obtained [20]. At the stage of pre-leaching under optimised conditions using HCl (0.2 M) at room temperature for 2 hours, 89 % of calcium contained in the red mud was removed. For selective removal of solid silica, the residue was treated with concentrated HCl (3.0 M, l/s 20 mL/g) at 95 $°C$, resulting in dissolution of iron and aluminium content with up to 90 % efficiency. After Fe^{3+} and Al^{3+} precipitation, they were characterised by FT-IR, BET, EDS, XRD, SEM and TEM monographs, confirming the formation of nanoscale alpha hematite (α-Fe_2O_3) and mesoporous gamma-aluminium oxide (γ-Al_2O_3). Consequently, inexpensive red mud was converted into very valuable nanoscale metal oxides using simple, sustainable techniques and cheap reagents. Moreover, this method generates the least amount of waste in the leaching process and all reagents can be recycled for further use, making this method promising.

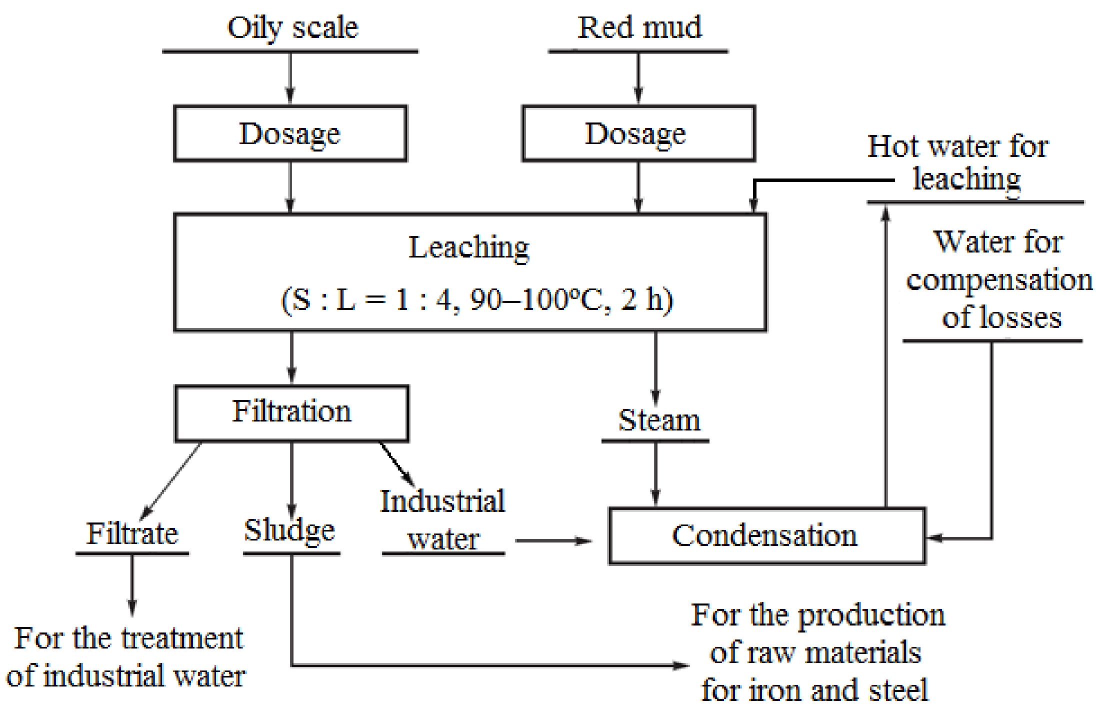

Figure 7. Technological scheme of joint processing of red mud and oily rolling scale.

The parameters of the process of carbothermal reduction of charge containing red mud and charcoal during microwave treatment have been scientifically substantiated [21]. The obtained results of experimental studies allow us to conclude about the intensifying effect of microwave heating on phase transitions from hematite to reduced iron, while providing the coarseness and uniformity of iron grains in the volume of samples is much greater than that of agglomerates obtained by conventional technology of reduction at the same temperature. The new approach to red mud processing under the influence of microwave heating creates prerequisites for creation of red mud processing technology for obtaining high-strength pelletised iron ore products with reduced iron content up to 85 %, which can become an alternative charge material for ferrous metallurgy.

4. Conclusions

Red mud is an unavoidable by-product of the Bayer aluminium production process. Due to the growth of aluminium production, the annual production of red mud in the world is continuously increasing, reaching 160 million tonnes in 2023.

Due to the lack of effective technology for processing red mud, its unclaimed mass is stored in special storages, which occupy large areas of the earth's surface, taking them out of economic use. World reserves of red mud amount to about 4 billion tonnes.

Due to its large production volume, excellent dispersibility and high alkalinity, red mud is capable of damaging the environment by polluting soil, water and atmosphere, threatening to destroy the sludge storage dam, causing an ecological disaster.

At the same time, due to the presence in the sludge of a significant proportion of iron, aluminium, titanium, as well as alloying and rare-earth metals, it should be considered as complex ore technogenic raw materials.

The optimal technology of sludge dewatering is based on the use of filter presses. This allows organizing its dry storage in a closed warehouse, which provides a reduction of the occupied space and safer storage conditions compared to sludge storages.

The most common way to regenerate alkali in the Bayer process is by adding lime to the slurry before or after the washing system, which allows 70 to 80 per cent of the alkali to be released.

Thermal methods of red mud treatment, which are carried out in drum or cyclone furnaces, in many cases are combined with physical-chemical or chemical processes of extraction of valuable components from the sludge.

Typical pyrometallurgical methods of red mud processing are three-stage waste-free processes, including production of carbon-containing pellets, their reduction roasting and smelting of reduced pellets in an electric arc furnace to produce metal and desulphurising flux.

A hydrometallurgical process for the extraction of alumina and sodium oxide from red mud allowing increasing the scale of integrated sludge recycling is used in the calcification-carbonisation method, which results in a new material structure based on $CaSiO_3$ and $CaCO_3$.

As a result of technological modeling, technological closed water intake schemes and apparatus schemes for hydrometallurgical sludge processing were developed.

Co-leaching of red mud and oily rolled scale is proposed.

The technology of step-by-step leaching of the main valuable components of red mud – iron and aluminium oxides – with the use of hydrochloric acid is proposed, which allows obtaining nanosized alpha-hematite (α-Fe_2O_3) and mesoporous gamma-aluminium oxide (γ-Al_2O_3). The advantage of this method of obtaining valuable nanoscale metal oxides is the use of simple, sustainable technologies and cheap reagents, as well as the generation of minimal waste in the leaching process.

Known proposals for the use of red mud in construction (production of cement, bricks, ceramics, fire-resistant concrete, glass fibre, for strengthening soils in the construction of roadbeds), in obtaining coagulant for energy generation and wastewater treatment, as the main component of complex binder for laying mine workings, complex raw materials for the extraction of rare earth, rare and radioactive metals.

The best prospect for large-scale industrial implementation is a complex project of waste-free processing of red mud, which provides for the first stage of pyrometallurgical extraction of thermodynamically recoverable metals, and the second stage – hydrometallurgical extraction of the remaining metals from the slag, with the subsequent direction of the final solid materials in the construction industry.

Abstract. The purpose of the research in this article is to reveal modern approaches in the development of the intelligent transport city's networks, as a component of the social infrastructure of the modern city. The research carried out by the authors in this direction is relevant in the field regarding the improvement and attractiveness of a modern, digital city. In particular, the authors in the article examine the so-called "sleeping" districts with multi-story buildings. The authors suggest the creation of a high-speed bus transportation system to improve the services provided by public transport. The article uses the ArcGIS geoinformation system and built a geodatabase. These two components together allow you to visualize results for a visual presentation of information and qualitative analysis. The authors use such proprietary developments in the article that it is possible to model various variants of the transport network. The authors conducted research on the example of Kramatorsk, a city of regional importance in the Donetsk region. The article develops and proposes a sequence of stages in the development of a geodatabase and a transport network of high-speed bus transportation. The further direction of research may be related to the accounting of a large number of factors. The authors carried out the work with the help of the ArcGis geoinformation system and the developed geodatabase with the necessary layers and attribute information. The article develops a system of high-speed bus transportation in the city of Kramatorsk with promising routes. Such development will allow further improvement of the social infrastructure of other cities. The principle of preliminary modeling using the developed geodatabase used by the authors will be effective for solving issues related to social infrastructure, so it can be applied to solve similar problems in any city. Thus, the authors' intellectual analysis of geostatic models of public transport movement on the territory of the city made it possible to find zones and classify them depending on the pedestrian accessibility to stops and compare them with existing transport routes. With the help of geostatistics methods, the article transforms data from a discrete to a continuous form of representation.

1. Problem statement

Ground urban transport is one of the main elements of urban development, it provides transportation of the population, uninterrupted transportation of food, clothing, and medicines, connection of the people with hospitals, and many more functions. Became especially noticeable in large cities during the so-called "blackout" when ground urban transport was carried out

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012022 doi:10.1088/1755-1315/1415/1/012022

precisely due to the clear coordination of ground transport.

In peacetime, and especially in wartime, the development of motor vehicles relates to the growth of the urban population and the service of its needs. And during emergencies, the use of motor vehicles should allow people to save time for trips due to the rational distribution of routes around the city. City public passenger transport carries a huge number of passengers every day. The stable operation of this sector of the economy provides about 85% of trips in urban and suburban areas. And during the "blackout", even 100% of the city's transportation was provided by city ground transport. Thus, ground urban transport is important in the infrastructure of a modern city.

But not all areas of large cities are sufficiently covered by a transport network of routes that could satisfy all the needs of the people. Thus, the task of developing or redistributing new land transport routes in a modern city arises. Necessary to connect distant parts of the city and the centre. That is, it is using innovative developments in the modelling of transport systems and the development of transport routes, which can provide city residents with greater informativeness and safety, as well as qualitatively increase the level of interaction of traffic participants in comparison with conventional transport systems.

2. Literature review

Currently, the technology of automated vehicles, that is, the intellectualization of the transport system, deserves the attention of researchers as one of the means of increasing the efficiency of high-speed bus systems. But there are some problems with such a solution. Such a modern intelligent transport system opens up unprecedented opportunities for solving problems of improving public [1–3]. The research suggests using cloud-based technologies to track a vehicle's presence on the road and adjust its speed. This structure proposed by the researchers is being field tested in the city of Sejeon in South Korea, where there are various traffic conditions such as bus stops, overpasses, underground tunnels, intersections, and pedestrian crossings. The qualities of the proposed system are compared with different types of control scenarios, and field test results show that the proposed system improves public service in various aspects, including driving safety, driving comfort, and energy efficiency [4].

It is also necessary to pay attention to the harmful emissions of carbon monoxide by bus engines. A paper for the Mumbai metropolitan region (India) suggests the use of several bus infrastructure modernization scenarios to reduce aggregate carbon dioxide emissions. The evaluation of the effectiveness of the scenarios is based on three levels of impact, i.e. conservative, moderate, and aggressive. The results show that the modernization of the bus infrastructure to a greater extent contributes to the reduction of emissions of harmful substances. The study emphasizes the priority development of high-speed bus transportation in urban planning [5].

The commercial appeal of high-speed buses is one of the most influential parameters. In the literature, many factors affect the speed of movement of buses between stops. Much research has been devoted to the study of commercial bus speed prediction. One study examines this problem using the example of Thessaloniki, Greece. The researchers developed models based on data from 10 lines of the bus network. The data included several characteristics such as the time the bus was on the road, passenger flow, bus stop location, bus stop infrastructure, etc. After that, the researchers determine the effect of the independent variables on the speed of the bus. The distance between bus stops is determined by the researchers as an important indicator of the model. The researchers found that a distance of more than 450 meters between two stops has a positive effect on the speed of the bus. Passenger waiting time for the vehicle was also an important parameter in the simulation. The researchers established that the increase in the number of traffic lights and turns on the section of the route negatively affects the speed of the buses. But the researchers did not predict the relationship between the total passenger flow and the speed of the buses [6].

Researchers pay great attention to the division of traffic lanes into lanes reserved for high-speed buses. That is, it is necessary to quantify the improvement of the quality of such transportation by high-speed bus, compared to transportation by ordinary buses. For this, the researchers suggest using an approach based on Global Positioning System (GPS) data. The speed of the line, obtained from GPS data, gives an idea of the spatiotemporal variability of the buses, and provides the necessary statistics. Studies show that a network of high-speed buses provides higher speeds with less variability compared to regular buses. However, increasing the speed of traffic in densely populated urban areas during peak hours is possible only if a separate traffic lane is allocated. Research also shows the usefulness of using GPS data recorded by vehicles to identify traffic hotspots in the city [7, 8].

In some publications, attention is paid to such a phenomenon of the transport network as excessive loading of vehicles. It reduces the quality of public service, shortens the social distance of bus passengers, and thus increases the rate of spread of epidemics, such as the coronavirus disease. In the post-pandemic era, one of the main tasks of municipal departments is to ensure sustainable city bus service. This will balance the convenience and safety of the trip for bus passengers, reduce passenger crowding, and smooth out the imbalance when boarding and disembarking passengers. A correctly calculated interval between stops can effectively reduce passenger flow during bus transportation. Thus, the appropriate design of the service network can help the administrative institutions of the city to minimize the spread of the virus, while guaranteeing the quality of transport services in the post-pandemic era [9].

A fairly common problem of the transport network is the grouping of buses at a bus stop. Solving this problem can lead to a shorter average waiting time for passengers, to less congestion of buses at bus stops. Improving the delay of waiting for a bus at a bus stop can be solved due to the timely notification of drivers in real-time mode [10].

3. Results

The authors chose the transport structure of the city of Kramatorsk as the object of the study. The total length of transport roads in the city is 347.7 km. Transportation in the city is provided by 22 bus routes, 3 tram, and 6 trolleybus routes. That is, all public transport is ground. A significant problem for citizens is the low level of pedestrian accessibility to public transport stops. In addition, the researchers observed duplication of transport routes in the city.

To solve existing problems, it was decided to introduce a system of high-speed bus transportation. Such a solution to the problem by the authors implies a comprehensive reform of the transport infrastructure in the city. For this, it is necessary to make a geo-informational analysis of the city's transport infrastructure, based on data on the population's accessibility to transport infrastructure facilities public transport stops [11]. This will allow researchers to identify weaknesses in the formation of the passenger transportation network that exists today. The authors developed a geodatabase in the ArcGIS software product [12–14]. As a result of the research, the authors created the following classes of spatial data:

- linear to represent the axis lines of transport routes (Buses, Trams, Trolleybuses);
- point to represent the population living in the relevant districts of the city (Naselennia);
- polygonal for representing transport stops (Stops).

To analyse the transport infrastructure of the city, vectorization of all active public transport routes and stops was performed (figure 1). Based on statistics on the population of the city of Kramatorsk as of July 1, 2021, the "Population" layer was created, considering the uneven distribution of the population depending on the type of development of the residential area of the city (high-rise buildings in new districts and one- and two-story buildings in the private sector) (figure 2).

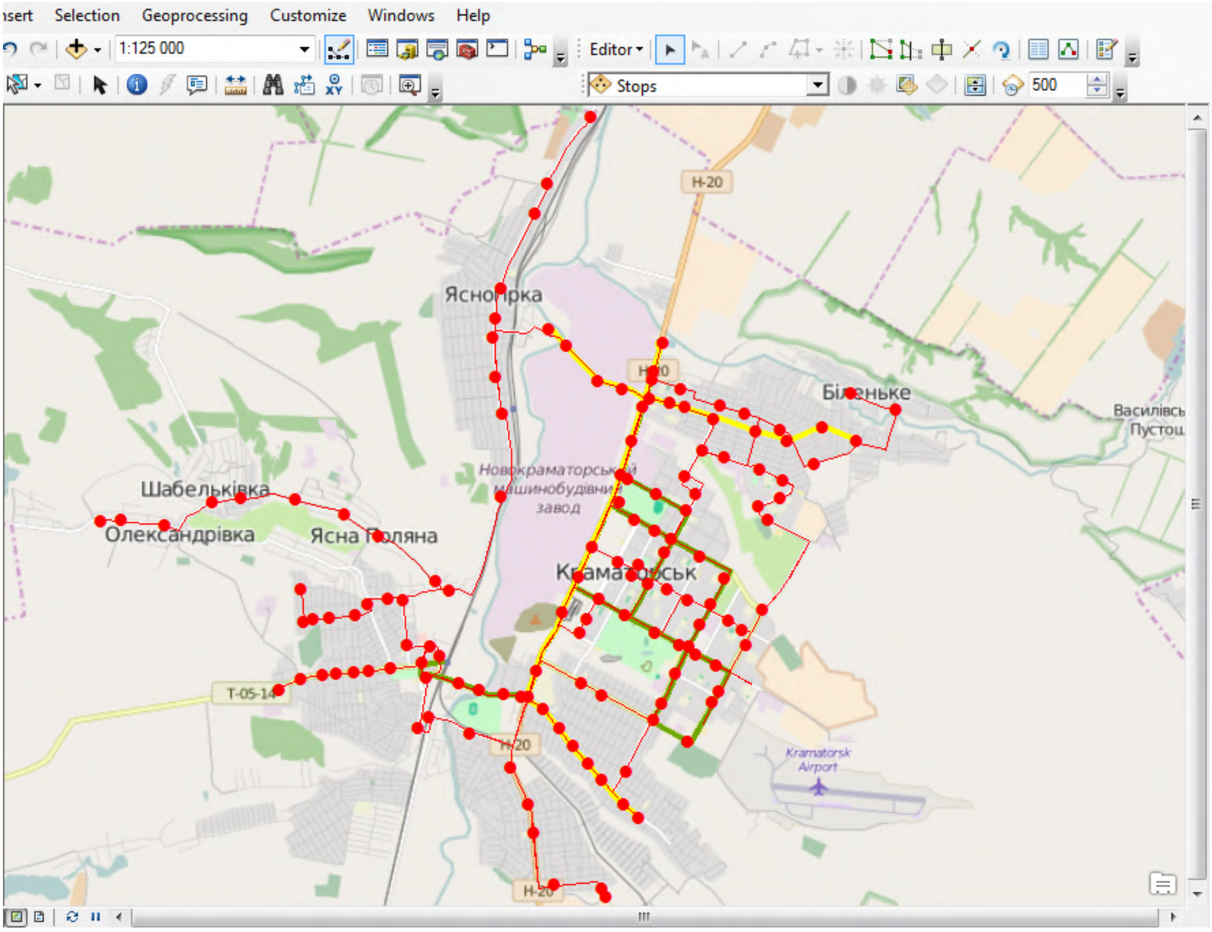

Figure 1. A network of transport routes and public transport stops.

One of the main indicators characterizing the level of public transport service is the availability of public transport stops. It is usually expressed in the range of walking approaches. Normative requirements require not to exceed a range of more than 500 m.

With the help of the ArcGis geoinformation system and the Buffer tool, the level of accessibility to public transport stops was visualized on pre-created layers (figure 3).

By analysing the attribute tables of the created geodatabase for the “Population” and “Population in the buffer” layers, information was obtained for specific areas regarding the total area of residential buildings in the area in km^2 and the area included in the 500-meter walking distance to stops. Thus, the following formula can be used to calculate the percentage of the urban population that has walking access to public transport stops:

$$D_{stops} = \frac{H_{buffer} \times 100\%}{H_{general}} \quad (1)$$

where D_{stops} is the percentage of the population that has pedestrian access to public transport stops; H_{buffer} – the area of the territory of the district (quarter), which is included in the buffer zone of pedestrian accessibility to public transport stops; $H_{general}$ – the total area of the territory of the district (quarter).

Thus, it was established that the level of pedestrian accessibility to public transport stops is extremely low:

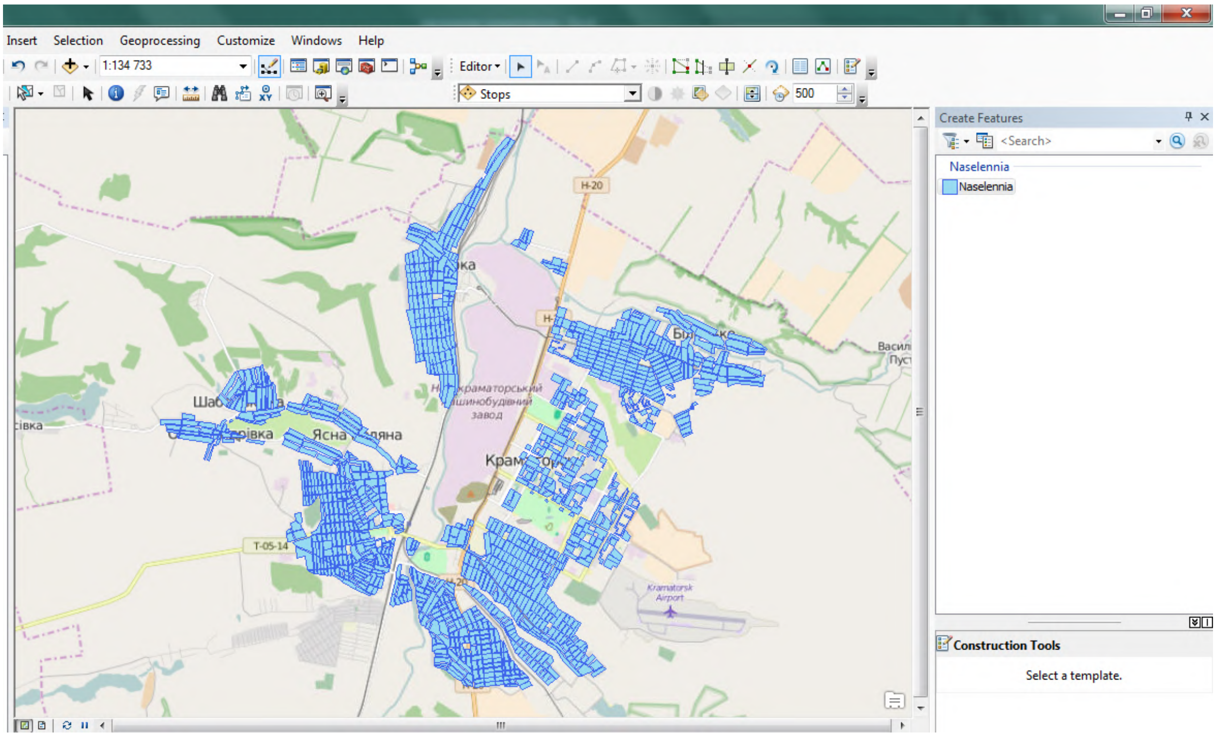

Figure 2. View of the "Naselennia" polygonal layer.

- 0-40% – 9 districts;
- 40-60% – 5 districts;
- 60-80% – 8 districts;
- 80-100% – 1 district.

As a result of the calculations, the authors determined the level of pedestrian accessibility to public transport stops in the city of Kramatorsk, which is 42.06%.

The authors determine that the introduction of a high-speed bus transportation system in the city will be able to solve such problems. Moreover, the implementation of the high-speed bus transportation system does not require additional land acquisition and the arrangement of specially allocated traffic lanes [15, 16]. The following steps must be taken to develop and implement such a modern transportation system.

The first step in the implementation of the authors' strategy should be the creation of the concept of trunk routes (figure 4). Separate traffic lanes for public transport should be organized on the main routes in the city that will connect transport hubs. To implement this task, two lanes are sufficient – one in each direction. But the right to use these lanes should be reserved exclusively for buses of the high-speed transportation system, in extreme cases, cars of the city's emergency service (police, ambulance, rescue service) may use them. To monitor the state of technical means on the route, where traffic is organized along dedicated lanes, it is mandatory to use electronic systems. Data from each bus, including from the on-board diagnostics system and from the terminal that registers tickets, are transmitted to the control room through communication means, where they are processed for further use. For priority passage through the intersection, buses must be equipped with devices that affect the traffic lights for accelerated activation of the traffic light signal, which allows movement in the direction of the bus. Traffic lights, in turn, must be equipped with receivers of such signals.

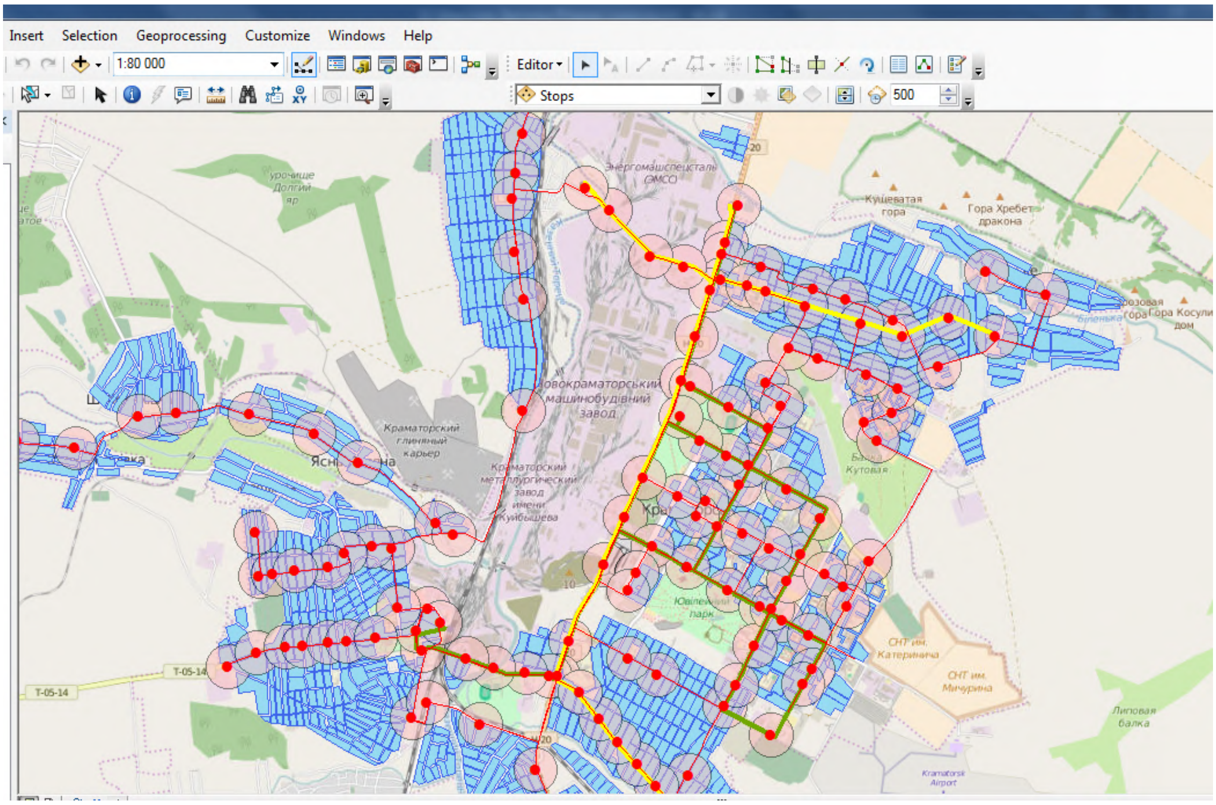

Figure 3. Buffer zones around stops along the network of transport routes.

The second step is the implementation of transport interchanges in the city. That is the introduction of a separate complex in which passengers transfer from one type of transport to another conveniently and quickly. At the same time, passenger flows during transfers are orderly, with convenient navigation. Such nodes should become the basis of the city's new transport system and will be equipped with taxi stands, bicycle parking lots, and car parking lots. To provide the passenger with data on the schedule of city transport in real-time, the deployment of a modern automated dispatching control system is required. Universal accessibility to interchange nodes will allow all people to use the advantages of public transport. To ensure fast delivery of passengers to transport hubs, the authors suggested introducing regional local routes (highlighted in green in figure 4).

The system developed in the article provides pedestrian accessibility to public transport stops by 72.53%, which is 30.74% higher than the existing one today. Such a system is basic and must still undergo several discussions with the participation of experts and community representatives in case of its practical implementation.

The use of trunk routes and transport interchanges proposed by the authors in this concept meets the modern needs of public transport in the city. This concept, proposed by the authors, is advisable to use in cities with a large population and the availability of only ground transport. The concept proposed by the authors will consider the interests of various population groups in the modern city.

4. Conclusions

The key contributions and findings of this research are:

1. A geodatabase was created with the necessary object classes to analyze indicators for

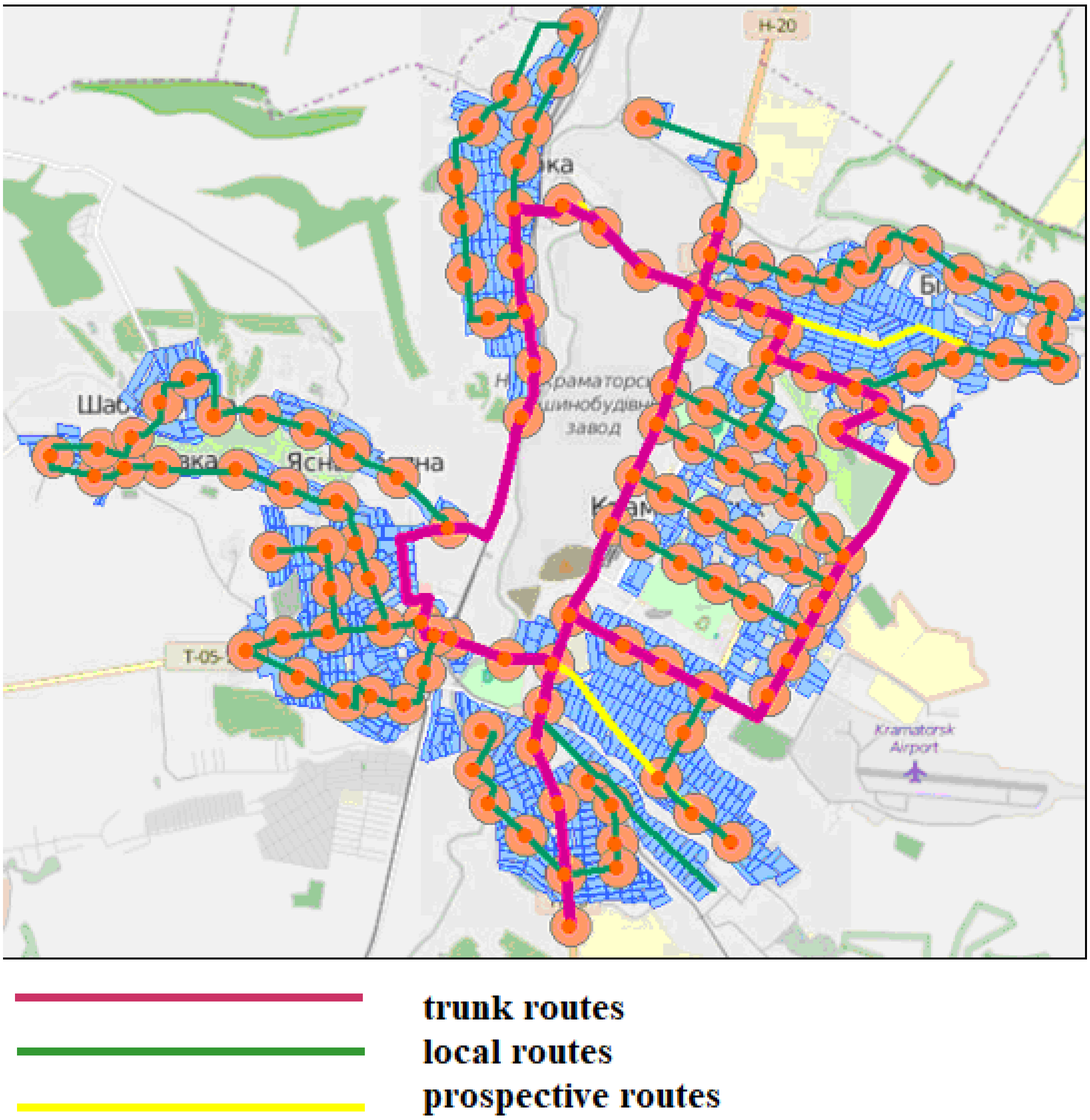

Figure 4. A system of high-speed bus transportation in Kramatorsk has been developed.

improving the city's social infrastructure, with a focus on the public transport system.

2. GIS analysis was performed to evaluate the current degree of pedestrian accessibility to public transport stops in Kramatorsk.
3. Using the ArcGIS software, an improved system of high-speed bus transportation routes was designed for the city.
4. The proposed high-speed bus system increases the population's pedestrian accessibility to public transport stops by 30.74% compared to the existing network.

The methods demonstrated in this research, leveraging geo-information technologies and GIS-based route optimization, offer significant practical value for transport planning. The results enable data-driven decision making when creating new public transport routes, and the visual outputs facilitate rapid analysis of residents' access to bus stops. While applied here to the city of Kramatorsk, the approach can be adapted to improve transport infrastructure and urban mobility in other cities facing similar challenges.

Abstract. Trolleybuses, as an integral component of city infrastructure, play a pivotal role in sustainable urban transportation. This paper emphasizes their pivotal role in public transit, highlighting the need for advancements in monitoring and management. Recognizing the need for advancements in monitoring and management, the study advocates for the creation of a comprehensive trolleybus automated monitoring system. This system represents a critical step forward in enhancing the efficiency, reliability, and overall performance of trolleybus networks. By seamlessly integrating real-time monitoring, data analytics, and automation technologies, such systems not only facilitate proactive maintenance but also enables informed decision-making for urban planners and transit authorities. The proposed automated monitoring system aims to optimize trolleybus operations, minimize downtime, and contribute to the sustainable evolution of urban transportation. As cities worldwide strive for smarter and more efficient public transit solutions, the implementation of automated trolleybus monitoring systems emerges as a vital and strategic investment in the future of urban mobility and of sustainable infrastructure of the cities.

1. Introduction

The comfort of living in a particular city largely depends on its transportation infrastructure. The quality and expansiveness of roads, the presence of an adequate number of stops, as well as the quantity and technical condition of transportation, determine the efficiency of residents' mobility and impact their overall quality of life.

Trolleybuses play a crucial role in providing fast, environmentally friendly, and convenient transportation for city residents [1]. One of the main advantages of trolleybuses is their environmental friendliness. Trolleybuses are eco-friendly because they operate using electric power. This feature helps reduce emissions of harmful substances, contributing to the fight against environmental pollution and making trolleybuses a significant tool in urban sustainable development strategies [2]. It is also worth noting that a modern and comprehensive trolleybus system can contribute to reducing car traffic, decreasing congestion, and improving air quality in the city. A well-developed trolleybus network significantly facilitates the daily commuting of residents.

In the 21st century, automation stands out as the primary tool for enhancing any system. Automation in public transportation opens up new perspectives for improving the efficiency and reliability of transportation systems [3].

An automated trolleybus fleet management system is an integrated set of software and hardware tools designed to automate the monitoring and control of trolleybus operations. The system may include elements for monitoring the technical condition of trolleybuses, automated route planning, driver performance monitoring, as well as remote monitoring and diagnostics [4].

Unfortunately, there's currently no specialized system for monitoring trolleybuses and generating technical reports. When considering online monitoring and effectively managing sensor data, SCADA systems might seem like the obvious choice. However, they're unsuitable for our needs due to several drawbacks. SCADA systems are complex and costly to implement, lack scalability, and are heavily reliant on infrastructure. Moreover, they offer limited flexibility in sensor selection and are not equipped with technical reporting functionalities. Thus, the development of a specialized automated monitoring system for trolleybus fleets is timely and essential.

The advantages of implementing an automated trolleybus fleet management system are evident [5–8]. It allows engineers to quickly respond to technical malfunctions of trolleybuses and ensures control over electricity consumption, leading to resource savings and a reduction in operational costs.

The creation of automated systems for trolleybus fleets in cities not only helps improve the comfort and accessibility of public transportation but also contributes to the overall goal of making cities more sustainable and livable [9–11]. That is why the development of such systems is a priority today.

2. Subject area

The subject of research in this work is the system for monitoring the technical condition of the trolleybus.

The trolleybus is a complex assembly of electrical, pneumatic, electronic, and mechanical components necessary to ensure the reliable operation of this type of urban electric transport. The primary components of the trolleybus system include the electric motor, contact network, accumulator, and control system.

The generalized diagram of the trolleybus is shown in figure 1.

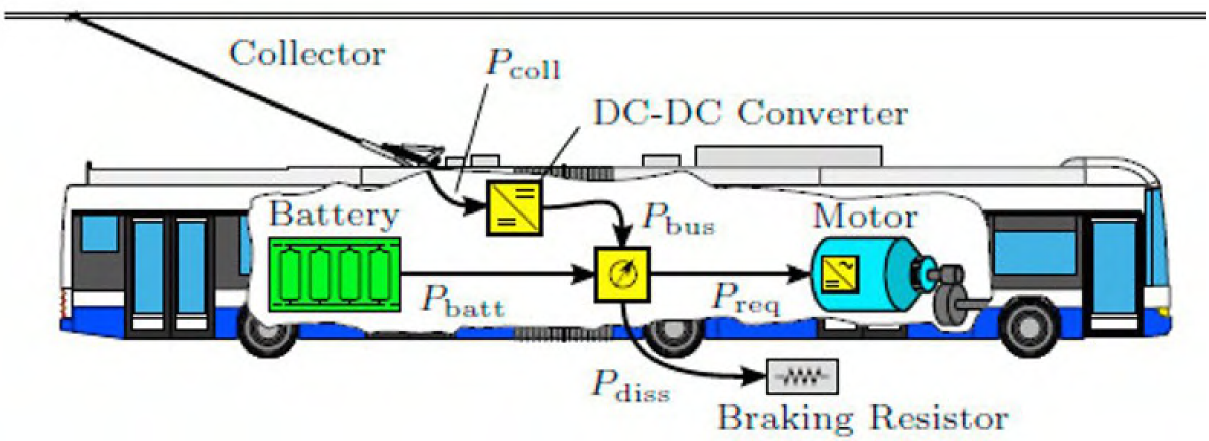

Figure 1. Trolleybus diagram.

The electric motor is the main component of the trolleybus responsible for propelling the vehicle. The electric motor operates on electrical energy supplied by the power supply system. Typically, alternating current electric motors are used [12].

The electric current to the electric motor is supplied through the contact network. The contact network is a system of wires or conductors positioned along the trolleybus route. A pantograph (collector) located on the roof of the trolleybus maintains contact with the power lines, ensuring the transfer of electrical energy from the lines to the trolleybus.

To store electrical energy for times when there are no power lines or for shorter routes outside areas without such lines, the trolleybus is equipped with an accumulator battery [13]. It consists of battery blocks, which, in turn, are made up of cells where electrical charge is stored.

The control system is responsible for coordinating the operation of the electric motor and the accumulator battery, ensuring optimal vehicle operation and efficient use of electrical energy. The control system includes controllers, sensors, and other electronic devices that regulate the current supplied to the electric motor and monitor the charge and discharge of the batteries.

Trolleybus fleet personnel must continuously monitor the technical condition of trolleybuses. Tracking such battery parameters as cell voltage, voltage drop across the block, voltage drop between all blocks, block temperature, and overall temperature differential is crucial for safety, efficiency, and the longevity of the battery system and electric motor. Cell voltage and voltage drop monitoring helps ensure an even distribution of charge among cells, enhancing battery efficiency. A high voltage drop may indicate faults in the battery that can reduce performance. Regular monitoring of block temperatures and temperature differentials helps prevent overheating, which typically leads to reduced battery life. Maintaining optimal conditions contributes to the long and efficient use of battery packs. Therefore, monitoring these specific parameters is a key element in ensuring the safety, longevity, and efficiency of battery systems in trolleybus systems.

Without the existence of an automated monitoring system in the operation of the trolleybus fleet all these parameters need to be tracked manually. To obtain data from the sensors of all trolleybuses in the fleet, each of them needs to be inspected. This process consumes a significant amount of time. Another significant drawback of such an approach is the inability to obtain data when technical expert is not near the trolleybus. Additionally, there is the risk of data loss if, for some reason, technical expert fails to record it (e.g., forgot to document the sensors data into a technical report).

3. Solution

The battery cell data collection is done primarily using the specialized voltage sensors installed on these cells. The data from the sensors are transmitted to a dedicated controller (modem), whose main function is to collect, aggregate, and structure such data. The modem can transmit data using internet protocols to other sources for data collection and processing. The collected data can be stored for further analysis and identification of prolonged or systemic issues.

The obtained from the sensors data is handled by a specialized visualization and notification system. This system enables operators to track the voltage on each cell in real-time. Additionally, the system can send notifications in case of anomalies or deviations from specified parameters.

The integration with the management system can become a crucial part of the monitoring system. This integration could enable the automatic implementation of measures in case voltage-related issues arise.

Monitoring the voltage of battery cells allows for maintaining the electric motor in an optimal operating mode, ensuring reliable and safe operation of the vehicle.

It's worth noting that in any governmental structure, there is a need for creating and storing data in a formalized format, such as technical reports. Generating technical reports on the state of a trolleybus is an essential part of its maintenance and determining its operational condition. These reports can be used to document identified issues, plan repair work, and ensure the safety of operation. Technical reports typically include the following information: trolleybus vehicle number, technical inspection data, information about systems and components, data from the diagnosis of electronic components, a description of identified faults and defects, a list of recommendations for routine maintenance and repair work, and the signature of the person who has prepared the technical report.

Technical reports creation helps to systematize information about the condition of the trolleybus, simplifies work planning and ensures efficient and safe operation of the trolleybus.

The automated monitoring system was created for the trolleybus fleet in the city of Dnipro as the result of commercial government order.

The generalized structure of the automated system is provided in figure 2.

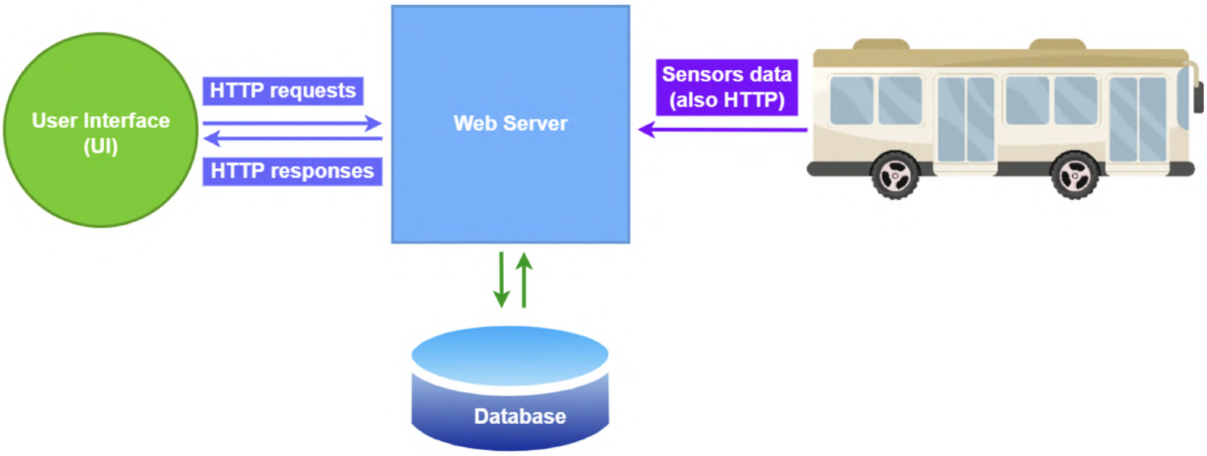

Figure 2. The monitoring system diagram.

The system consists of three main components that communicate with each other using the HTTPS protocol: web interface, web server, and a multitude of trolleybuses in the trolleybus fleet with installed controllers and sensors.

The web interface is presented as a regular website on the Internet, essentially serving as the terminal for interacting with the monitoring system. The primary advantage of such a web interface is its accessibility: trolleybus operators can access it from any device with internet connectivity (phone, tablet, desktop computer, etc.). The user interface layout has been constructed using dynamic elements, making the web interface responsive, meaning it displays equally well on screens of any size.

The web server is a key component of the monitoring system, containing all the business logic. The web server operates as a REST API service, meaning it can receive and respond to HTTP requests. The web server receives data from sensors, as well as information inputted by the user through the web interface. All incoming information is processed and structured into a format convenient for the server, and then it can be accessed by system users through the web interface. The web server stores the received information in a database.

The Teltonika TRB145 controller is installed on each trolleybus in the fleet and serves for processing and transmitting data from the trolleybus to the monitoring system. It's worth noting that the monitoring system created is entirely independent of the modem installed on the trolleybus. The data is received by the server through an HTTP request. For the server it doesn't matter which modem is used to send the data. Therefore, if the technical specialists of the trolleybus fleet decide to replace the modems on the trolleybuses, the end user of the system will not be aware of it and no changes to the system's source code will be necessary. The operators will only need to configure the new controllers for data transmission to the system server.

The development of the automated monitoring system utilized state-of-the-art web development technologies. The user interface was created using the React framework and the Typescript programming language. The web server was developed using the ASP.NET Core framework and the C# programming language. The MySQL relational database management system (RDBMS) was used for working with the database.

The main functions of the system include:

- real-time display of voltage data on accumulator batteries cells. The system provides users with the ability to view real-time data on the voltage of accumulator batteries cells in trolleybuses. This allows trolleybus operators to track the technical condition of each trolleybus and respond promptly to any anomalies;
- fault tracking. The fault tracking subsystem helps record faults and mark them as repaired. Users also have access to the history of faults for each trolleybus in the fleet. On the main page of the web interface, users can quickly identify which trolleybuses are faulty, operational, or have minor damage with each represented by different colors based on the severity of the fault;
- management of technical condition reports for trolleybuses. The system facilitates the creation, viewing, editing, and export to PDF of technical condition reports for trolleybuses covering five different types. Functionality for searching and sorting these reports is also implemented. During the creation of technical reports users can upload data from the sensors to populate relevant fields.

For the end user, the monitoring system is presented as a set of user interface screens, including:

- authentication screen;
- main dashboard screen;
- trolleybus menu screen;
- technical status screen;
- technical reports screen;
- technical report creation screen;
- technical report viewing screen;
- technical report PDF export screen;
- administrator panel.

The authentication screen (figure 3) serves as the entry point to the system. Upon successful authentication users are automatically redirected to the main screen of the system.

The main screen essentially serves as an interactive panel displaying the trolleybuses belonging to the trolleybus fleet. The icons representing trolleybuses are colored according to their current technical status, allowing operators to quickly assess the situation with the trolleybuses in the fleet. By clicking on a specific icon, the user is directed to a trolleybus menu page which contains more detailed information about that particular trolleybus (figure 4).

The trolleybus menu (figure 5) is divided into three main blocks. The first block displays information from the battery sensors collected for the current day. The second block provides a brief overview of the trolleybus's technical condition and includes a button redirecting the user to the technical status page. The third block shows a concise summary of technical reports generated during inspections, also featuring a button redirecting the user to the full page with technical reports.

Technical status screen (figure 6) presents information regarding the current technical condition of the trolleybus. Two tables are displayed on this screen: one for registering trolleybus

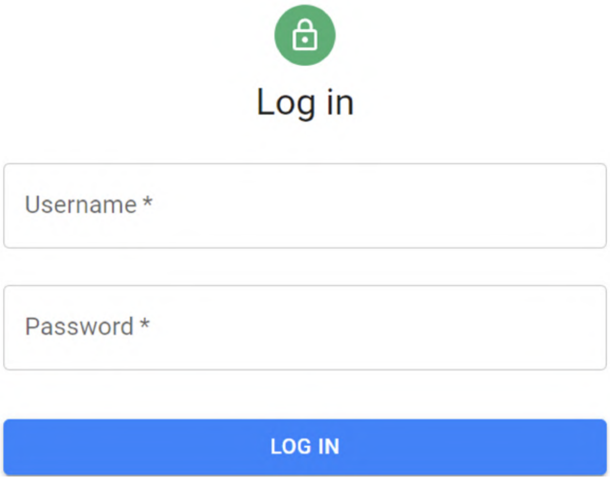

Figure 3. Authentication screen.

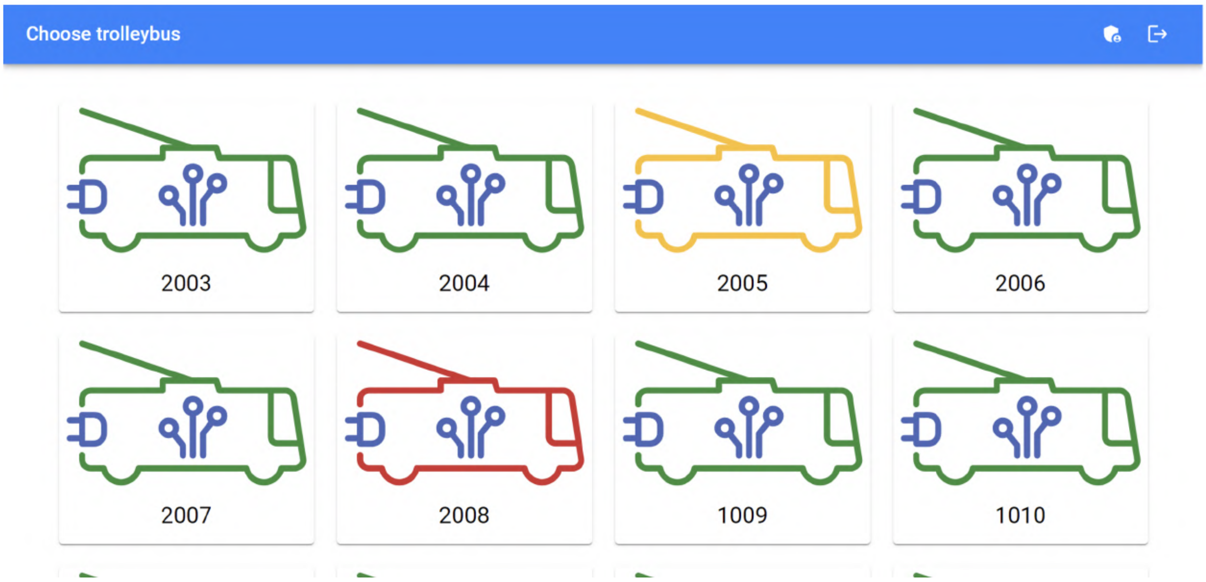

Figure 4. Main screen.

damages, and the other containing data about the trolleybus repair history. The user can manage trolleybus damages and repairs directly on this screen.

Technical reports screen (figure 7) displays a table of technical reports for the selected trolleybus. Users can sort the technical reports by creation date and type. Additionally, the screen features a button redirecting the user to the technical report creation form. If a user clicks on a specific technical report in the table, they will be redirected to a page containing the content of that particular technical report.

Technical report creation screen (figure 8) includes a technical report creation form. It's important to note that the form contains different fields depending on the selected type of technical report. At the end of the form, there is a button for creating the technical report. The form includes user input validation to ensure that the data sent to the web server is in the expected format. It is crucial to highlight that some technical reports should include information from batteries sensors and the technical report creation form allows the user to upload sensors

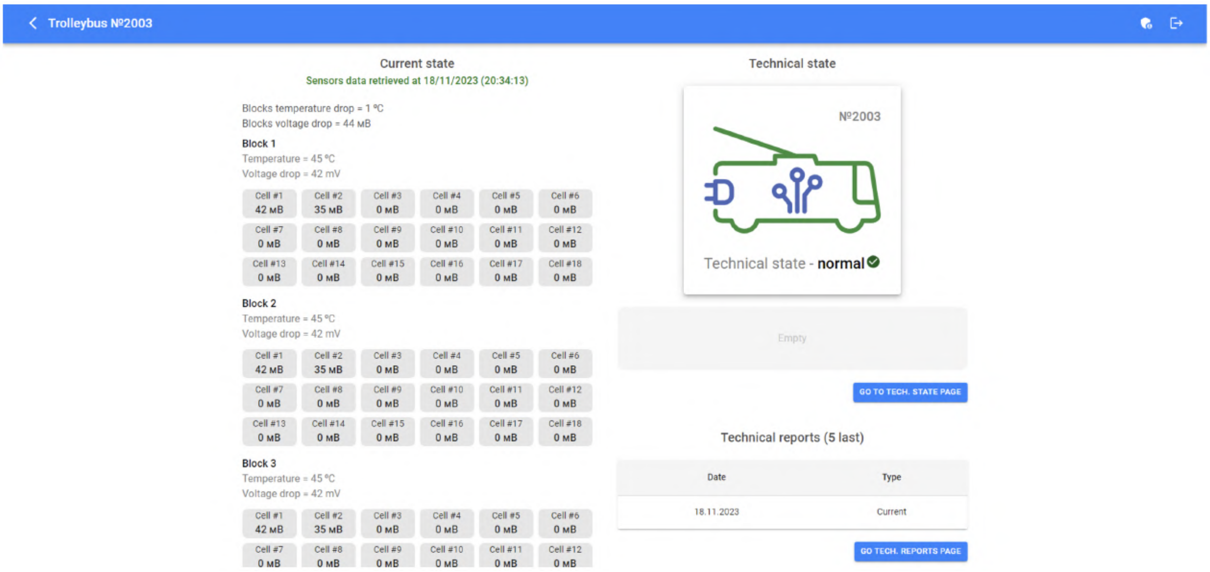

Figure 5. Trolleybus menu screen.

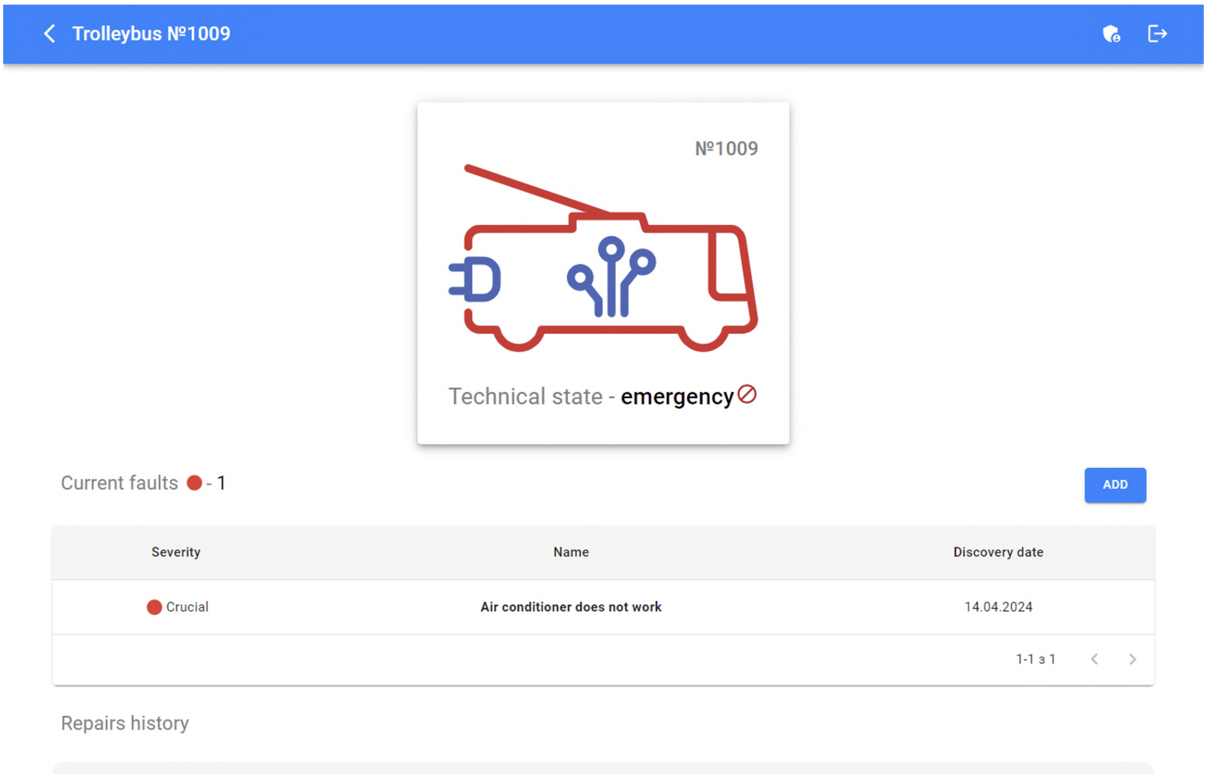

Figure 6. Technical status screen.

data to the form.

Technical report viewing screen and technical report PDF export screen are presented in figures 9 and 10.

Both screens display the created technical report. PDF export screen additionally offer the

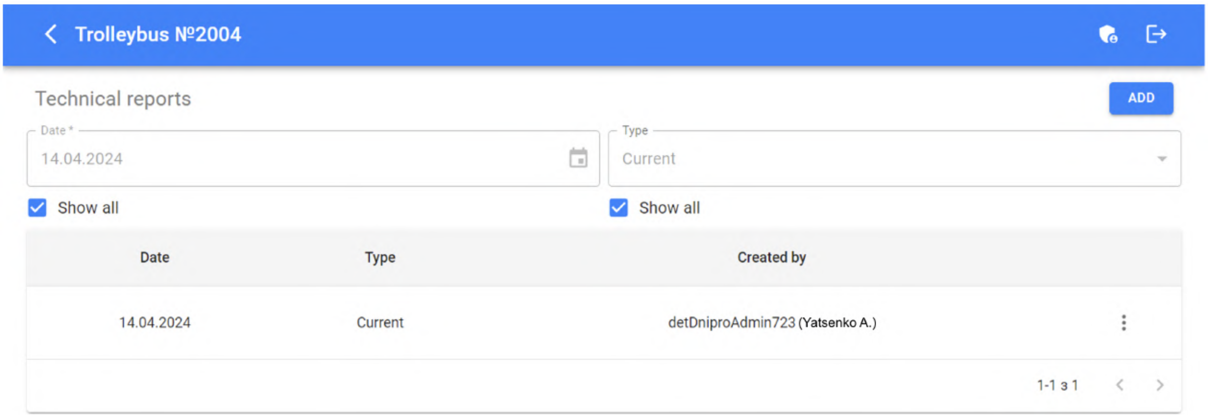

Figure 7. Technical reports screen.

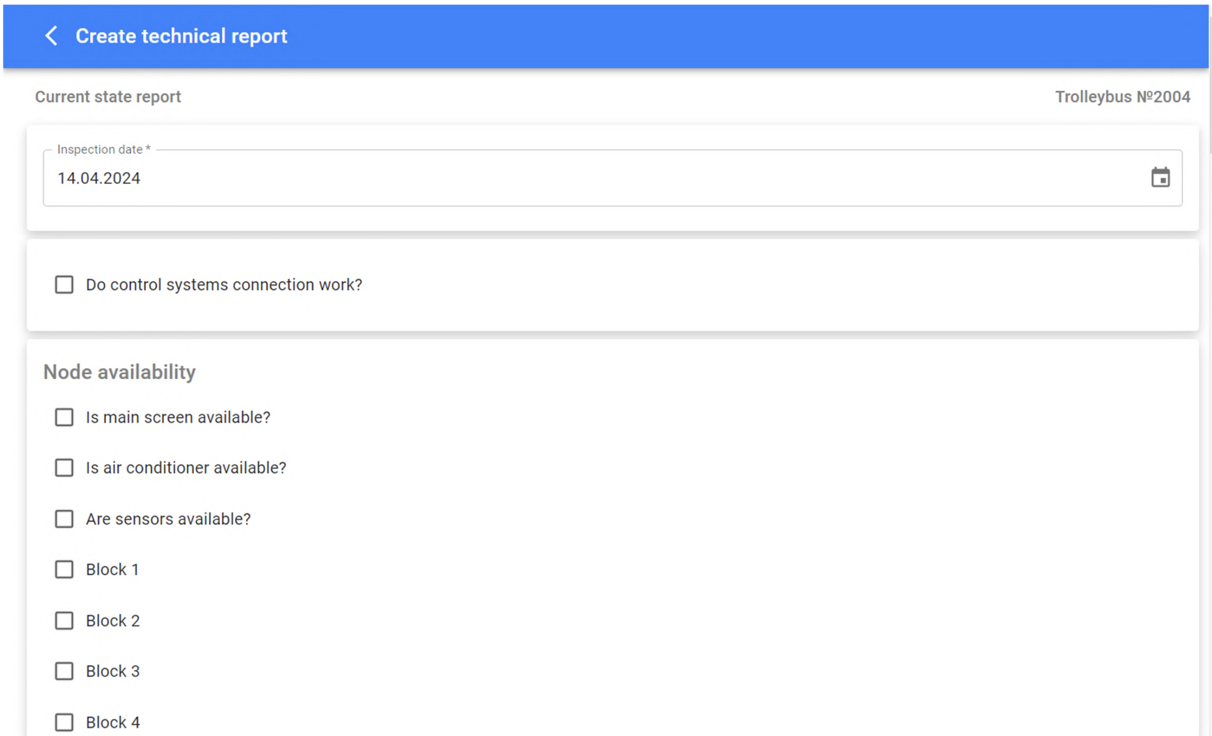

Figure 8. Technical report creation screen.

user the option to download the technical report in PDF format.

Administrator panel (figure 11) essentially serves as the control panel for the system. It contains information about system users and features functionality for managing their accounts.

There are three user roles in the system:

- Administrator (creation, deletion, and editing of user data in the system, management of technical reports, management of trolleybus malfunctions);
- Writer (ability to view and modify data);
- Reader (ability to only view data).

Significant attention was devoted to securing the developed system from external influence

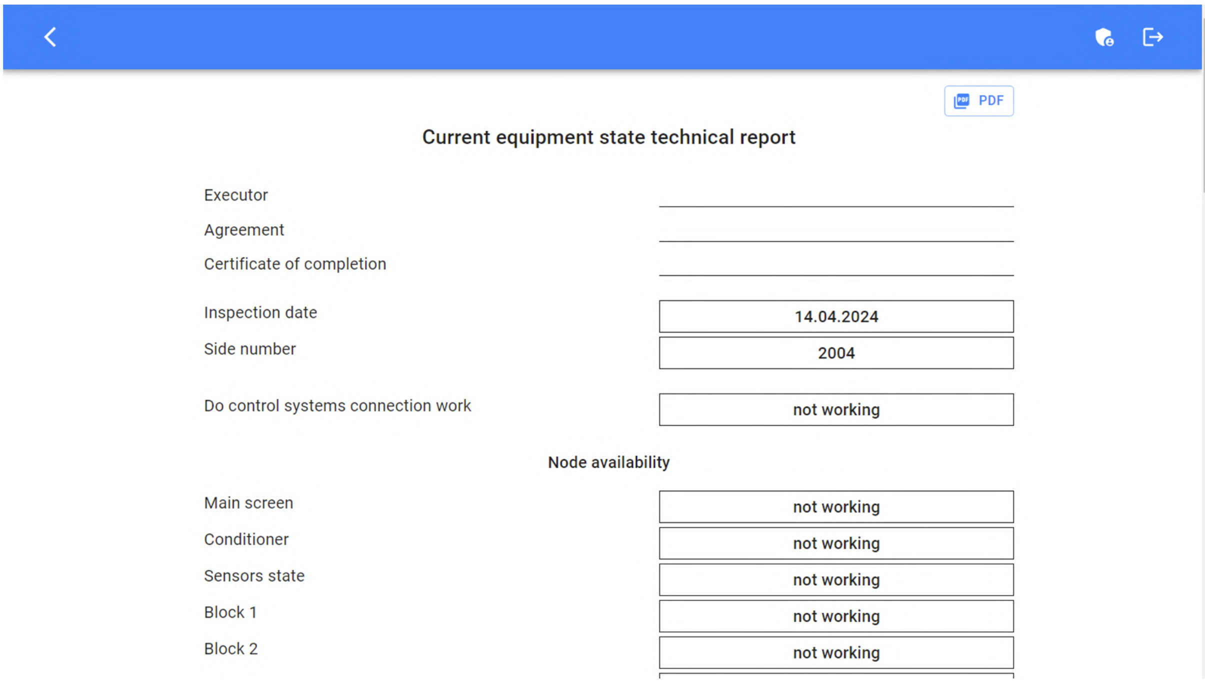

Figure 9. Technical report viewing screen.

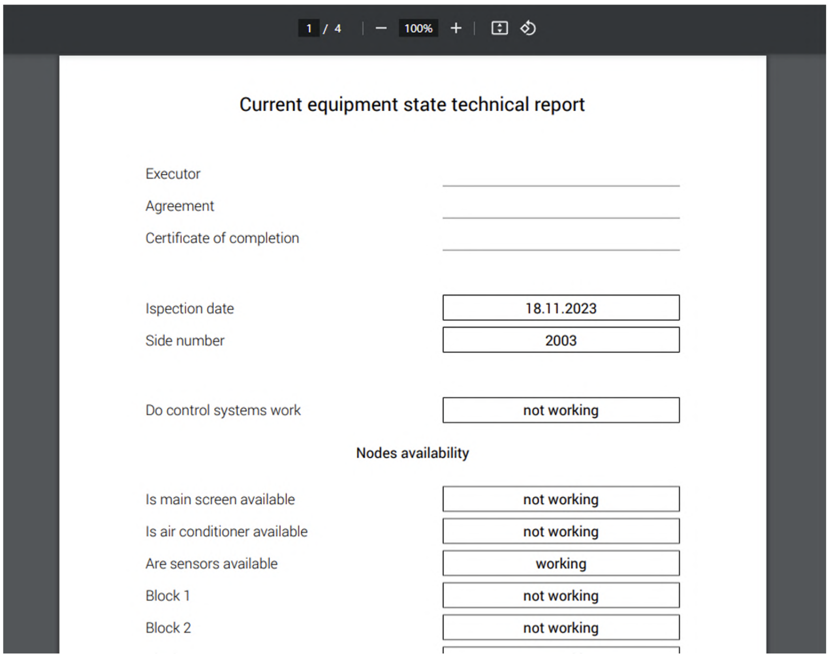

Figure 10. Technical report PDF export screen.

and unauthorized access. The authentication and authorization module, implemented using JWT tokens, allows restrict the access to the system. Access to the web interface of the system is only possible through the HTTPS protocol, ensuring encryption of all interaction traffic. The controller installed in each trolleybus in the fleet sends sensor data and the request body contains a secret token known only to the monitoring system and the controller itself, providing assurance

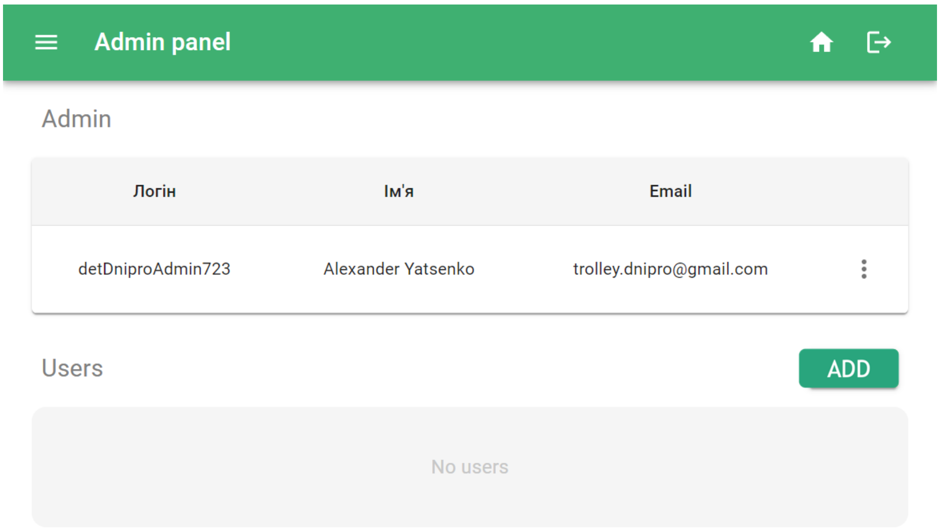

Figure 11. Administrator panel.

against data tampering. It is also worth noting that the development was carried out with an understanding of most modern web system vulnerabilities, such as SQL injections, XSS, and CSRF attacks.

The created system offers significant advantages compared to the situation where such a system is not available to the trolleybus fleet:

- rapid creation of technical status reports for each trolleybus, made possible through an intuitive interactive interface and the ability to receive real-time sensor readings (manual creation of a technical report previously took about 20 minutes, whereas with the system, it now takes 30 seconds);
- reduced number of manual errors in the automated generation of technical reports;
- efficient management of technical reports with quick access;
- export of technical reports to PDF format;
- consolidation of all technical information about each trolleybus in one centralized location;
- capability to record and manage damages to trolleybuses;
- real-time access to sensors data;
- continuous collection of sensors data, enabling future analysis;
- interactive tracking of the technical status of trolleybuses.

These advantages contribute to a streamlined and efficient process for managing and maintaining the trolleybus fleet, offering real-time insights, reducing manual effort, and improving overall data accuracy and accessibility.

4. Conclusions

The developed system represents the first step in optimizing the operation of the entire trolleybus fleet. Currently, the system includes only the functionality of monitoring the state of the battery, registering and tracking malfunctions, and generating technical reports. However, the list of functions will continue to expand as the development progresses.

Application is available on any mobile or computer device, the only requirement is Internet connection. System is designed for the Dnipro's trolleybus fleet needs (Ukraine), but can be used in any other city. The program logic is completely decoupled from the sensors used so it provides a lot of flexibility when we are talking about infrastructure needed. The application of such a system significantly enhances the quality and productivity of employees' work.

Abstract. The paper examines a promising component for the energy sector – development of gas reserves and gas production, taking into account the peculiarities of mining-geological and mining-technical conditions of the Western Donbas deposits (Ukraine). Two components of the solution to this issue are analyzed: the texture and physical-mechanical properties of weakly metamorphosed rocks and the use of high-performance complexes, reuse of extraction drifts with resource-saving technologies for their maintenance. Based on multivariate computational experiments, schemes have been developed to determine parameters for the location of outgassing wells. Three basic methodological provisions based on the conducted analytical research performed by the finite element method have been substantiated. Calculations, which are the basis for the methodology of selecting outgassing well location parameters, have been conducted. Experimental measurements conducted at six extraction sites of two mines confirm that the outgassing coefficient according to the recommended parameters exceeds that corresponding to the existing outgassing well location schemes in mines (the range of relative increase in the outgassing coefficient is from 19 % to 123 %). In addition, a significant influence (up to 35 – 60 %) has been revealed of the coal-overlaying formation texture, the well gradient angle (20 – 30 %), and the drilling step of outgassing wells (30 – 40 %). It has been found that an increase in the longwall face advance velocity improves the gas trapping efficiency by 25 – 40 %, leading to a decrease in the methane flow into adjacent mine workings and substantiates an opportunity to accelerate the longwall face advance.

1. Introduction

Modern conditions of foreign and domestic political situation require a comprehensive and integrated development of a long-term plan for the energy component of the country's revival [1, 2].

In terms of Ukraine's energy independence, the development of gas deposits and gas production is a topical issue for the coal industry [3–5].

The conducted research, of course, proves that methane reserves in Ukrainian coal deposits are many times higher than natural gas reserves. Thus, industrial development should be directed towards the inextricable link between coal mining and gas extraction. That is, these two components have common tendencies to change [6, 7]. But there is a constraint on the operation of modern highly mechanized complexes, since the gas release process limits the rate of coal mining in terms of gas factor.

Therefore, an urgent task arises to resolve these contradictions. Scientific and practical experience has been gained in this regard [8–13]. However, a number of issues remain that relate to the specifics of the mining-geological and mining-technical conditions for mining the Western Donbas deposits (Ukraine) [14–19]. The peculiarities of mining these deposits consist in the occurrence of weakly metamorphosed rocks, that is, it is necessary to take into account in the calculations the differences in their texture and physical-mechanical properties [20–25]. On the other hand, there is a mining-technical component, which consists in the use of high-performance complexes, the repeated use of extraction drifts with resource-saving technologies for their maintenance and modern underground transport [26–31].

Thus, substantiating the site outgassing parameters for highly-stressed longwall faces in the Western Donbas mines has a significant impact on increasing coal production, which is currently the main factor in Ukraine.

Thus, the work [32] concludes that the gas release intensity from undermined coal-overlaying formation is directly related to its shear parameters. This makes it possible to reasonably select appropriate routes for site outgassing wells relative to the Western Donbas conditions (figure 1).

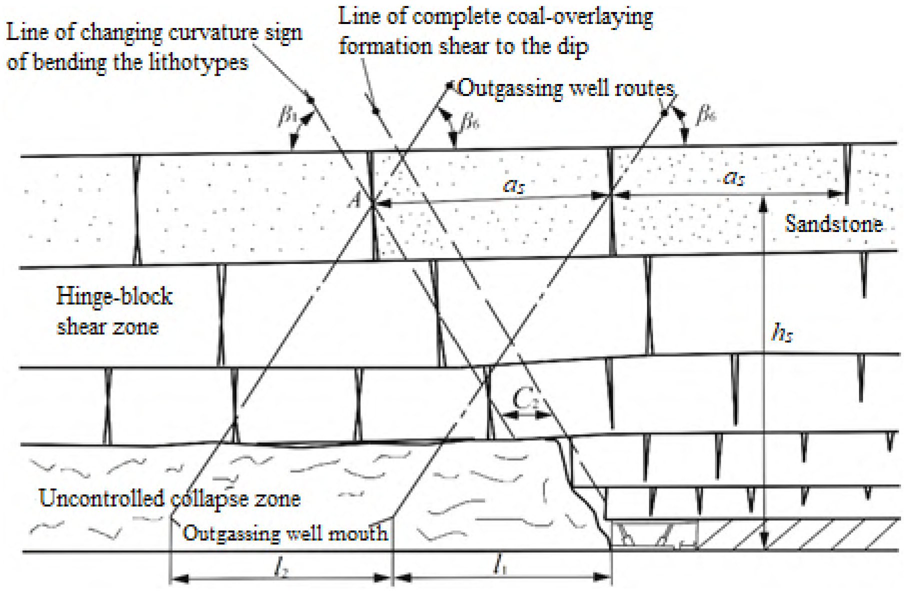

Figure 1. Scheme for determining the outgassing well location parameters to the dip of the coal seam.

Thus, a methodology has been developed for selecting the outgassing well location parameters based on the finite element method results.

The issue of scientific substantiation of the shear mechanism of the coal-overlaying formation of weakly metamorphosed rocks has been studied in the works [33, 34] for determining zones of maximum stratification and fracturing in the area of stoping operations. It is proposed to consider the shear mechanism in a spatial setting [32]. The next research step is modeling of the adjacent mass using the finite element method (FEM) [35–39] to determine the parameters of the zones of maximum stratification and fracturing. The computational model includes: a part of the rock mass ahead the longwall face and on the side of the virgin coal stratum, the mined-out space behind the longwall face, an extraction drift and the longwall face itself with a simulator of powered support. During the calculations, the texture of the coal-overlaying formation and generalized (throughout the main roof height) mechanical properties of its lithotypes, as well as the depth of the longwall face location, are changed.

Based on the conducted multivariate computational experiments, the dependences of changes in the coordinates of zones of maximum stratification and fracturing under fluctuations of the main geomechanical factors have been obtained. Regression equations have also been obtained to determine the gradient angle of the line of changing curvature sign of the main roof rock layers bending behind the longwall face and the distance of the maximum bending of the rock layers in the frontal bearing pressure zone ahead the longwall face. The methods of correlation-dispersion analysis are used to determine the dependences [40–43].

The second research component using a computational experiment is to determine the influence of the stoping face advance velocity.

2. Methodology for selecting the outgassing well location parameters based on the finite element method results

The methodology is formed based on the results of the analysis of stress-strain-state (SSS) calculations of the coal-bearing mass surrounding the longwall face end zone; these studies are performed by conducting a series of computational experiments based on the FEM, and the recommendations and conclusions provided will be adjusted based on the results of mine experiments [44–46].

The initial data for the calculation are information about the depth H of stoping operations, the texture and mechanical properties of coal-overlaying formation rocks, the planned longwall face advance velocity V_l, the layout of the equipment for drilling site outgassing wells [47–49]. The listed information is obtained from the mining-geological prediction for mining the extraction site, the longwall face passport and the passport for draining-out of gases.

Calculation of rational parameters for the location of outgassing wells has the following sequence.

1. The gradient angles of the lines of changing curvature sign of the lithotypes bending to the dip β_1 and along the strike β_3 of the coal seam are determined.
   Predominantly thin- and medium-bedded texture:
   - high mechanical properties:
     1) mudstone $\sigma_{compr} = 20 - 25$ MPa, $\sigma_{tens} = 1.5 - 2.5$ MPa, $E = (1.0 - 1.5) \cdot 10^4$ MPa;
     2) siltstone $\sigma_{compr} = 20 - 30$ MPa, $\sigma_{tens} = 2.5 - 3.0$ MPa, $E = (1.5 - 2.5) \cdot 10^4$ MPa;
     3) sandstone $\sigma_{compr} = 25 - 40$ MPa, $\sigma_{tens} = 3.0 - 4.0$ MPa, $E = (2.5 - 4.0) \cdot 10^4$ MPa.

$$\beta_1 = K_{V_l}(136.3 - 133.3H^{-0.15}); \quad (1)$$

$$\beta_3 = N_{V_l}(62.8 + 0.033H); \quad (2)$$

   - low mechanical properties

$$\beta_1 = K_{V_l}(175.8 - 242.5H^{-0.15}); \quad (3)$$

$$\beta_3 = N_{V_l}(56.6 + 0.036H). \quad (4)$$

   Predominantly thick- and medium-bedded texture:
   - high mechanical properties

$$\beta_1 = K_{V_l}(169.3 - 262.5H^{-0.18}); \quad (5)$$

$$\beta_3 = N_{V_l}(52.3 + 0.041H); \quad (6)$$

- low mechanical properties:
  1) mudstone $\sigma_{compr} = 5 - 10$ MPa, $\sigma_{tens} = 0.5 - 1.0$ MPa, $E = (0.2 - 0.3)\cdot 10^4$ MPa;
  2) siltstone $\sigma_{compr} = 8 - 15$ MPa, $\sigma_{tens} = 1.0 - 1.5$ MPa, $E = (0.4 - 0.6)\cdot 10^4$ MPa;
  3) sandstone $\sigma_{compr} = 15 - 20$ MPa, $\sigma_{tens} = 1.5 - 2.0$ MPa, $E = (0.8 - 2.0)\cdot 10^4$ MPa.

$$\beta_1 = K_{V_l}(56.9 + 0.039H); \tag{7}$$

$$\beta_3 = N_{V_l}(53.2 + 0.023H); \tag{8}$$

where

$$K_{V_l} = 1.14 - 0.028V_l; \tag{9}$$

$$N_{V_l} = 1.31 - 0.062V_l. \tag{10}$$

In equations (1) – (8), the depth H is substituted in meters, and the angles β_1 and β_3 are calculated in degrees; in equations (9) and (10), the longwall face advance velocity V_l is measured in m/day.
In the case of mining-geological conditions of averaged texture or averaged mechanical properties of the coal-overlaying formation lithotypes, the averaged value between the two limit calculations is also taken.

2. The distance value a_s of the maximum bending of sandstones in the bottom hole zone is calculated, which is also equal to the sandstone block length in the hinged-block displacement zone.
   With a height of sandstone occurrence (from the coal seam bottom) of $h_s \geq 12 - 15$ m and its thickness of $m_s \leq 2 - 3$ m:
   - for conditions of high mechanical properties

$$a_s = c_{Vl}\left[3.2 + 0.27(\tfrac{H}{100})^{2.06}\right] \tag{11}$$

   - for conditions of low mechanical properties

$$a_s = c_{Vl}\left[5.6 + 0.54(\tfrac{H}{100})^{1.92}\right] \tag{12}$$

   With a height of sandstone occurrence of $h_s \leq 10$ m and its thickness of $m_s \geq 6 - 8$ m:
   - for conditions of high mechanical properties

$$a_s = c_{Vl}\left[1.5 + 0.25(\tfrac{H}{100})^{1.77}\right] \tag{13}$$

   - for conditions of low mechanical properties

$$a_s = c_{Vl}\left[4.2 + 0.43(\tfrac{H}{100})^{1.45}\right] \tag{14}$$

   where $c_{Vl} = 1.22 - 0.044V_l$.
   In equations (11) – (14), the value a_s is calculated in meters.
3. The outgassing well route gradient angle β_4 along the strike of the coal seam is determined from

$$\beta_4 = \arctan\frac{h_s}{h_s\cot\beta_3 + C_1 + W_{pr} + W_{eq}} \tag{15}$$

   where h_s – the height of sandstone occurrence from the coal seam bottom; C_1 – the distance between the line of complete coal-overlaying formation shear and the line of changing curvature sign of its lithotypes bending along the strike of the coal seam; typically $C_1 = 2.0 - 3.0$ m; W_{pr} – the width of the extraction drift protection system; it is determined by the passport for mining the extraction site; typically $W_{pr} = 0.8 - 1.5$ m for the Western Donbas conditions; W_{eq} – the distance of the drilling equipment location from the drift working wall.

4. The outgassing well turning angle β_5 in the direction to the coal seam rise is determined from
$$\beta_5 = \arctan \frac{C_1 + W_{pr} + W_{eq}}{h_s \cot \beta_1 + C_2 + L_{eq}} \tag{16}$$
where C_2 – the distance between the line of complete coal-overlaying formation shear and the line of changing curvature sign of its lithotypes bending to the dip of the coal seam; typically $C_2 = 2.0 - 3.0$ m for the Western Donbas conditions; L_{eq} – the distance of the drilling equipment location from the well mouth is determined according to the passport for draining-out of gases at the extraction site.
5. The outgassing well gradient angle β_6 to the coal seam stratification plane is determined from
$$\beta_6 = \arctan \frac{h_s \sin \beta_5}{C_1 + W_{pr} + W_{eq}} \tag{17}$$
6. The distance of the first well from the fence of the powered support sections L_1 and the distance L_2 between the mouths of the next wells are calculated from
$$L_1 = h_s \cot \beta_1 + C_2; \tag{18}$$
$$L_2 = a_s; \tag{19}$$
7. The well length L_w is determined by the formula
$$L_w = \frac{H_m}{\sin \beta_6} + \Delta_{ov}; \tag{20}$$
where H_m – height (from the coal seam bottom) of occurrence of methane-saturated lithotypes in the coal seam main roof; it is determined according to the mining-geological prediction for the extraction site; Δ_{ov} – well overdrill length; typically $\Delta_{ov} = 2.0 - 3.0$ m.

Thus, the developed methodology makes it possible to substantiate the appropriate parameters for site outgassing well routes based on determining the patterns of influence of geomechanical-technological parameters on the coal-overlaying formation shear indices in the Western Donbas conditions.

The methodology for determining the appropriate coordinates for drilling outgassing wells is based on the conditions, criteria and a set of obtained dependences, some of which will undergo experimental testing, discussed in the next section.

3. Mine research on the relationship between site outgassing efficiency and geomechanical-technological parameters of high-velocity mining of coal seams

3.1. Research methods

Mine research has three objectives. Firstly, it is aimed to test the objectivity and reliability of the results of analytical developments and methodological provisions regarding for calculating rational site outgassing parameters, which ultimately makes it possible to increase the productivity of stoping operations. Secondly, based on the results of mine tests, it is possible to make some adjustments to the site outgassing technology parameters towards their optimal values. Thirdly, a real basis is formed for substantiating the range of expedient stoping face advance velocities according to the "gas factor", and within this recommended range of V_l it will be necessary to improve coal mining technology operations in the Western Donbas conditions.

The principle of optimizing the site outgassing technology parameters is to experimentally determine such its values at which maximum methane trapping from coal-overlaying formation rocks will be achieved. Then the gas entry into the longwall face working space and the extraction

 doi:10.1088/1755-1315/1415/1/012024

drifts will be minimal and, accordingly, it is possible to increase their advance velocity, which is identical to an increase in the coal-mining productivity.

The number of experimentally studied variable parameters can be reduced and the necessary information about the patterns of gas release and outgassing processes can be obtained, which are criterion factors for choosing rational parameters for the site outgassing technology in the Western Donbas mines.

3.2. Algorithm for conducting mine experiments

General methodological provisions have been implemented in the developed algorithm for conducting mine experiments, which consists of the following stages.

The first stage is testing the reliability and degree of influence of geomechanical factors, which is conducted analytically by determining a number of patterns when modeling in the FEM.

A criterion has been proposed that can be called “relative site outgassing”, which determines the level of methane gas trapping in relation to the entire volume of methane released at the extraction site. There is already such a parameter in the technical documentation – the outgassing coefficient K_{out}, which is measured in relative values. This parameter does not depend on the conditions of mining the coal seams, and it is widely used in the practice of conducting mining operations and makes it possible to compare the efficiency of selected outgassing parameters for different extraction sites. But it is still necessary to specify which parameter of K_{out} to choose in the network of mine workings, depending on the coordinates of its measurement. In our opinion, the most informative will be the parameters measured outside the longwall face in the extraction drifts near the main preparatory workings. Under such conditions, it is possible to assess the methane inflow and the degree of outgassing throughout the entire extraction site.

Another studied technological parameter is the stoping face advance velocity V_l. It also varies at the selected extraction sites. But at the first stage this does not matter, since by measuring gas flow rate and calculating the coefficient K_{out}, a “base” is created for further comparison with the same parameter K_{out} for other geomechanical-technological factors and parameters. The algorithm for comparison is as follows:

- the “basic” parameters K_{out} are recorded for specific geomechanical factors (longwall face location depth, texture and mechanical properties of the coal-overlaying formation rocks) and technological parameters (longwall face advance velocity V_l, outgassing well location scheme);
- using the developed methodology based on FEM modeling, rational parameters for outgassing well location schemes at all extraction sites, selected for experimental research, are determined;
- for these rational parameters, the volumes of gas release and gas trapping are measured and the outgassing coefficient K^r_{out} is calculated;
- values K_{out} and K^r_{out} are compared and the following conclusions are drawn. If the values K_{out} and K^r_{out} are approximately the same (the difference is up to several percent), and the outgassing well location parameters differ significantly from the “basic” ones, then the main conclusion can be drawn about the inappropriate use of the proposed methodology. If, with approximately the same parameters for outgassing well location schemes, we have a significant difference (10 – 15 % or more) in the values of K_{out} and K^r_{out}, then this indicates the inadequacy and unreliability of the proposed methodology. If the rational parameters for outgassing well location differ significantly from the “basic” ones, and the values of K^r_{out} are significantly higher than K_{out}, then we conclude that it is advisable to use the developed methodology.

This general conclusion is the essence of the first stage of mine research: it substantiates the feasibility of using the methodology, but does not answer the question of the degree of its reliability.

The second stage is assessing the degree of correspondence of the influence patterns of geomechanical factors, obtained analytically and experimentally in mine research. Here the main purpose is to test the reliability of the dependences obtained in previous sections during the FEM modeling of the shear processes in the coal-overlaying formation rocks behind the longwall face. At the same time, it should be noted that there is an indirect method for assessing the reliability of the analytical research results, since it is not possible to "directly" experimentally record such parameters as: gradient angles of the lines of changing curvature sign of the lithotypes bending in the coal-overlaying formation to the dip β_1 and along the strike β_3, the distance a_s (from the stoping face plane) of the zone of the maximum bending stresses acting in the rock mass.

Three main geomechanical factors (the longwall face depth, the texture and mechanical properties of the coal-overlaying formation rocks) have been identified, the influence of each of which is studied experimentally in the following way. A fairly wide range of variations in the depth H of the longwall face location is provided by studies at six extraction sites of two mines: 501, 503, 962 and 1124 longwall faces of the Heroiv Kosmosu mine, as well as 885 and 1043 longwall faces of the Zakhidno-Donbaska mine. In addition, there is a certain change in H at the extraction sites during their mining to the coal seam rise. With regard to variations in the texture and mechanical properties of the coal-overlaying formation rocks, they usually occur within a certain range at each extraction site (figure 2). And since six of them are studied at two mines, the range of variation of these geomechanical factors is quite representative (figure 3).

Thus, an experimental research into the patterns of influence of geomechanical factors on the site outgassing technology efficiency of extraction panels has been provided.

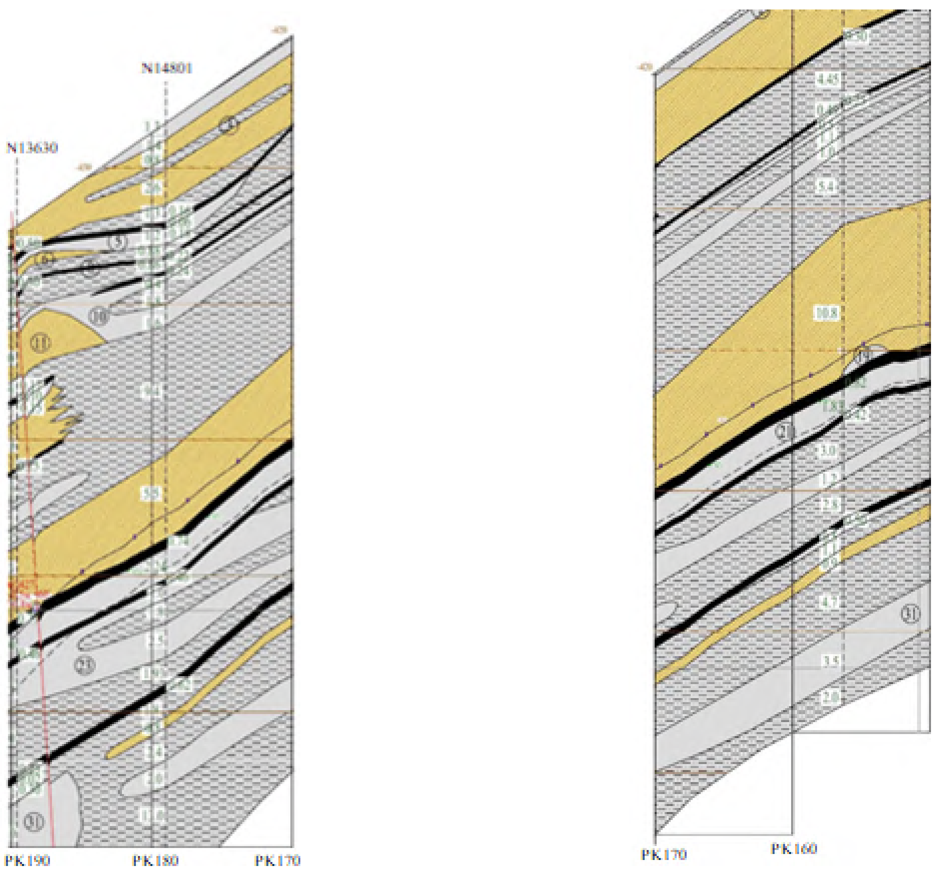
The third experimental research stage involves studying the influence of a number of technological parameters on the outgassing process efficiency, among which three main ones are: longwall face advance velocity V_l, gradient angle β_6 of outgassing wells to the coal seam stratification plane, the step l_2 of drilling wells along the extraction drift, that is the distance between the mouths of adjacent wells.

As a result, the developed methodological provisions and the algorithm for conducting mine experiments will allow to achieve the purpose set – a comprehensive assessment of the adequacy and reliability of recommendations for determining the rational parameters of site outgassing technology at the Western Donbas mines.

4. General assessment of the objectivity of recommendations on selecting the site outgassing technology parameters

According to the developed methodological provisions and a well-founded algorithm for conducting mine research, their results are presented sequentially, starting with the first stage regarding the assessment of the rationality degree of the recommendations on selecting the site outgassing technology parameters, developed on the basis of analytical research on the processes of the coal-overlaying formation shear into the mined-out space behind the longwall face using the FEM. The methodology of the first mine research stage involves the calculation of site outgassing technology parameters according to the recommended methodology, followed by a comparison of the outgassing coefficient K_{out}^r with its value K_{out} based on the available parameters, used at extraction sites according to their passport for draining-out of gases. The main purpose of this research is to assess the influence of geomechanical factors while testing recommendations in different mining-geological conditions. For this purpose, six extraction sites in two Western Donbas mines have been selected.

The mine research first stage results are shown in figure 4 in a somewhat limited form; the main reason is to provide a more informative look to the graphs $K_{out}^r(H)$ and $K_{out}(H)$ for



(a) (b)

Figure 2. Fragments of the mining-geological section along the extraction site of the 501 longwall face of the Heroiv Kosmosu mine: (a) – predominantly medium-bedded texture; (b) – predominantly thick-bedded texture.

individual extraction sites (501 and 503 longwall faces of the Heroiv Kosmosu mine, as well as 1043 longwall face of the Zakhidno-Donbaska mine).

Thus, from the comparative analysis, the main tendency is consistently observed (for different mining-geological conditions): the outgassing coefficient according to the recommended parameters K_{out}^r exceeds the corresponding value of K_{out} for the existing parameters of outgassing well location schemes. For example, for 1043 extraction site of the Zakhidno-Donbaska mine, the difference in coefficients K_{out}^r and K_{out} ranges within 0.143 – 0.280, that is 29 – 74 % in relative units. That is, if to adhere to the proposed recommendations, then it becomes possible to increase the load on the longwall face by 29 – 74 % according to the so-called “gas factor”.

Regarding two extraction sites (501 and 503 longwall faces) at the Heroiv Kosmosu mine, there is also an excess of K_{out}^r over K_{out} (figure 4), which in relative units has a significant value: 31 – 123 % for 501 extraction site; 23 – 85 % for 503 extraction site. Of course, in the provided ranges of fluctuations, the maximum values of the ratios K_{out}^r and K_{out} should be considered as unit – they do not characterize their real difference, but an increase in the outgassing coefficient by 20 – 30 % is quite possible, and this contributes to a significant increase in the extraction site productivity in terms of the “gas factor”.

At different ratios of geomechanical factors, there is a tendency for the outgassing coefficient

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012024 doi:10.1088/1755-1315/1415/1/012024

Figure 3. Fragments of the mining-geological section along the extraction site of the 1043 longwall face of the Zakhidno-Donbaska mine: (a) – predominantly medium-bedded texture; (b) – predominantly thick-bedded textureе.

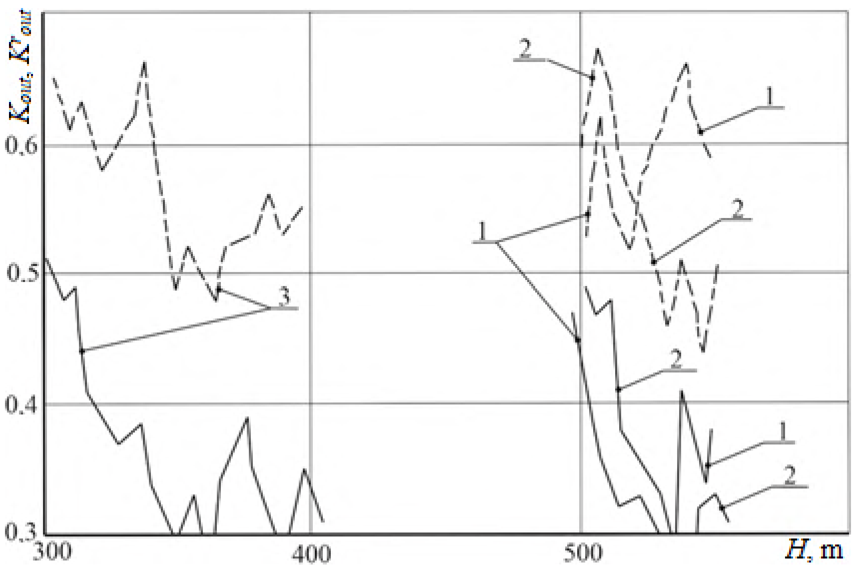

Figure 4. To a comparative analysis of existing and recommended parameters of site outgassing schemes: 501 (1) and 503 (2) longwall faces of the Heroiv Kosmosu mine and 1043 (3) longwall face of the Zakhidno-Donbaska mine.

to decrease with increasing longwall face depth H; this tendency is noted at all extraction sites, both with the existing schemes for outgassing well location, and at the majority of experimental sites with the recommended outgassing parameters.

Summarizing the results of the first experimental research stage, it is possible to confidently speak about the feasibility of subsequent, more deterministic stages of mine experiments of site outgassing technology according to the recommended parameters for the outgassing well location.

5. Influence of geomechanical factors on site outgassing parameters

The main purpose of the second research stage is to determine the tendencies in the influence of geomechanical factors (the longwall face location depth H, texture and mechanical properties of the coal-overlaying formation rocks) on the site outgassing efficiency, as well as to study the differences in its performance with the existing and recommended parameters for outgassing well location schemes.

The results of recording the gas release and gas trapping volumes, as well as the subsequent calculation of outgassing coefficients K^r_{out} and K_{out}, are graphically shown in figure 5 and figure 6.

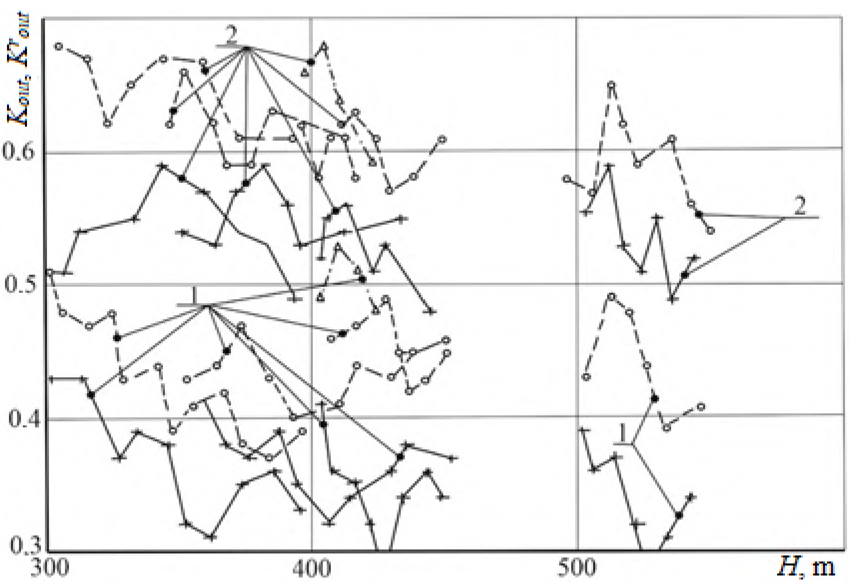

Figure 5. Patterns of texture influence on the effectiveness of existing (1) and recommended (2) site outgassing schemes: predominantly thick-bedded texture; predominantly medium-bedded texture; predominantly thin-bedded texture.

Then, study the tendencies of the influence of the coal-overlaying formation rock texture, which is divided into three groups: predominantly thin-bedded, predominantly medium-bedded, and predominantly thick-bedded. Such a division is capable of covering almost all coal mass texture types observed in the Western Donbas, and a clear identification of the lithotype thickness according to the existing classification (thin, medium and thick) is practically impossible, because it is not found in the geological mass structure. It should also be noted that the graphs in figure 5 have gaps (along the coordinate H), which separate parameters K^r_{out} and K_{out} for different extraction sites.

There is a steady tendency for outgassing coefficients to be exceeded at more stratified roof than at less stratified roof, regardless of the selected parameters for outgassing well location schemes. For example, for the 503 extraction site of the Heroiv Kosmosu mine, two types of textures are distinguished: predominantly medium-bedded texture and predominantly thick-bedded texture. When comparing the coefficients K^r_{out} and K_{out}, it is noted that for a

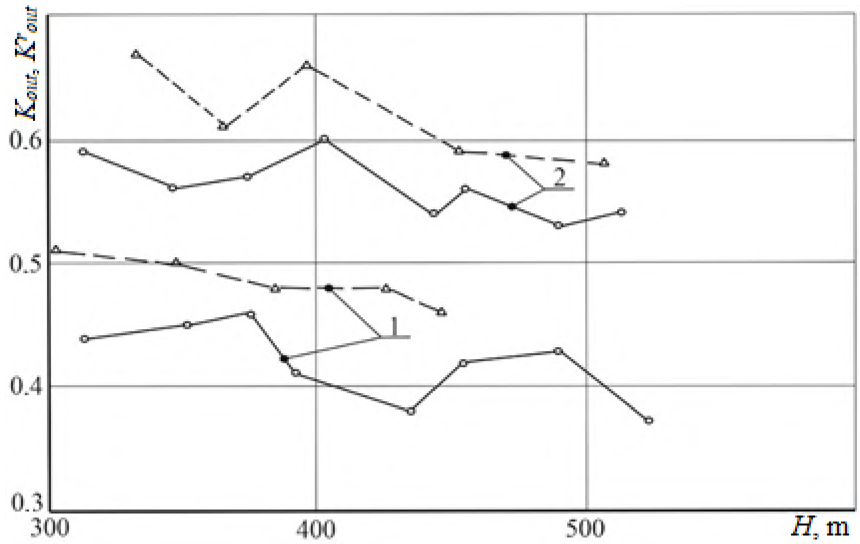

Figure 6. Patterns of influence of mechanical properties of coal-overlaying formation rocks on the effectiveness of existing (1) and recommended (2) site outgassing schemes: low and averaged mechanical properties.

predominantly medium-bedded texture the coefficient K^r_{out} is higher by 1 – 25 %, and for a predominantly thick-bedded texture the coefficient K_{out} is exceeded by 10 – 63 %. Similar tenedencies are observed for other extraction sites: 962 longwall face of the Heroiv Kosmosu mine – there is an excess of 6 – 24 % for K^r_{out} and 11 – 55 % for K_{out}; for 1043 longwall face of the Zakhidno-Donbaska mine, the corresponding ranges are equal to 14 – 37 % – K^r_{out} and 3 – 34 % – K_{out}; for 885 longwall face of the Zakhidno-Donbaska mine, the following excesses are: 2 – 19 % – K^r_{out} and 6 – 27 % – K_{out}.

The predominantly thin-bedded texture of the coal-overlaying formation rocks has been identified only in separate sections of the 962 extraction panel. When comparing predominantly thin-bedded and predominantly thick-bedded textures, an excess of the coefficient K^r_{out} by 13 – 30 % and K_{out} by 20 – 71 % has been obtained.

The main conclusion from the above results is this: the texture of coal-overlaying formation rocks has a significant influence on the outgassing efficiency, regardless of other geomechanical-technological factors; therefore, the type of texture should be taken into account when choosing parameters for site outgassing well location schemes.

Another main task of the second research stage is to determine the tendencies of influence of mechanical properties of coal-overlaying formation rocks on the site outgassing efficiency according to the criterion of comparison of coefficients K^r_{out} and K_{out} with different strength characteristics of lithotypes.

Figure 6 shows plotted graphs of the change in outgassing coefficients K^r_{out} and K_{out} for two variants of the generalized strength characteristics of coal-overlaying formation rocks (reduced and averaged) according to the depth coordinate H of the longwall face location. It should be noted here that the number of areas with approximately the same texture, but different mechanical properties, is very limited. Therefore, the influence of the mechanical properties of lithotypes can only be observed at the level of tendencies in changes in K^r_{out} and K_{out}, but this information also has some benefit in terms of the evidence base for the feasibility of using the developed recommendations.

From the experimental data analysis, the moderate influence of the generalized strength characteristics of coal-overlaying formation rocks can be clearly seen, which can be given in quantitative terms on the following examples: with the recommended parameters for site outgassing well location schemes, the outgassing coefficient K^r_{out} is higher by 5 – 17 % for predominantly reduced mechanical properties than in the case of their predominantly averaged values; relative to the existing parameters for outgassing well location schemes, the excess of K_{out} is by 4 – 24 %.

The final conclusion is as follows – despite the moderate influence of the mechanical properties of coal-overlaying formation rocks, this geomechanical factor should also be taken into account when substantiating the parameters for site outgassing technology, since the final multifactorial influence of geomechanical factors consists of the total effect of each of them. And the existence of such an influence once again confirms that the outgassing coefficient K^r_{out} according to the recommended parameters for outgassing well location schemes exceeds the existing ones by 24 – 38 % with reduced mechanical properties and by 25 – 49 % with the averaged mechanical properties of coal-overlaying formation rocks.

6. Influence of technological factors on site outgassing parameters

At the preliminary experimental research stages, a significant influence (on the site outgassing efficiency) of geomechanical factors has been revealed. However, the identified patterns together with technological factors differ from each other for different extraction panels examined in terms of fixing gas release and gas trapping with subsequent calculation of outgassing coefficients K^r_{out} and K_{out}. Now it is the turn of the third experimental research stage, the purpose of which is to determine the level of influence of the technological parameters of the site outgassing process, among which three main ones were identified earlier: the longwall face advance velocity V_l, the gradient angle β_6 (to the coal seam stratification plane) of the outgassing wells, and the step l_2 of drilling them along the extraction drift.

The results of gas release and gas trapping measurements are given in figure 7 in the form of dependency graphs of the coefficients K^r_{out} and K_{out} on the longwall face advance velocity V_l. These graphs illustrate data only for individual extraction sites. Thus, for 501 longwall face, there is an increase in outgassing coefficients with an increase in its advance velocity V_l: the outgassing coefficient K^r_{out} according to the recommended schemes for outgassing well location increases up to 34 % in the range of $5.2 \leq V_l \leq 8.7$ m/day; the outgassing coefficient K_{out} with existing technological parameters increases up to 71 % in the range of $5.1 \leq V_l \leq 8.5$ m/day. Similar tendencies have been observed for other extraction sites: 503 longwall face – up to 15 % (5.0 – 6.1 m/day) and up to 33 % (4.9 – 6.1 m/day), respectively; 962 longwall face – up to 47 % (5.9 – 8.2 m/day) and up to 36 % (6.0 – 7.6 m/day); 1043 longwall face – up to 18 % (4.7 – 7.1 m/day) and up to 24 % (4.8 – 6.9 m/day).

The main conclusion from the above data is that an increase in the longwall face advance velocity V_l (by an average of 30 – 45 %) contributes to an increase in the gas trapping efficiency by an average of 25 – 40 % under various mining-geological conditions of mining the Western Donbas coal seams. In other words, tendencies in the same direction of increasing the coal mining productivity have been identified: the growth of V_l leads to a decrease in the methane inflow into the adjacent mine workings (when using site outgassing technology), and this, in turn, substantiates the possibility of accelerating the longwall face advance. This main conclusion is confirmed by another experimentally determined fact – with the recommended schemes for outgassing well location, the outgassing coefficient increases (relative to that with existing parameters) in the ranges of 9 – 46 % (501 longwall face), 20 – 56 % (503 longwall face), 13 – 27 % (962 longwall face), 10 – 28 % (1043 longwall face). Thus, there is a potential to increase the coal mining productivity by "gas factor", and it may become secondary to other structural and technological factors in the operation of highly-stressed longwall faces.

The next technological factor influencing the outgassing efficiency (based on the FEM modeling results) is positioned as the gradient angle β_6 to the coal seam stratification plane

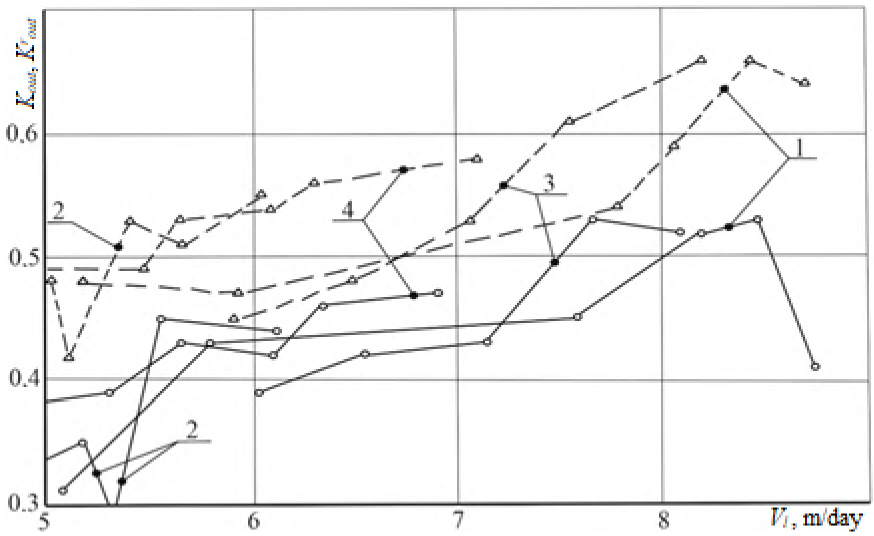

Figure 7. Patterns of influence of the longwall face advance velocity V_l on the effectiveness of existing and recommended parameters of site outgassing schemes: 501 (1), 503 (2) and 962 (3) longwall faces of the Heroiv Kosmosu mine; 1043 (4) longwall face of the Zakhidno-Donbaska mine.

of the outgassing wells. For each extraction site (from the list of those studied), three values of K_{out} have been determined at different gradient angles β_6 in the variation range of $43^{\text{o}} \leq \beta_6 \leq 68^{\text{o}}$.

The research results in the form of dependency graphs K_{out} (β_6) are shown in figure 8, from which it is clear that the tendencies of the angle β_6 influence are somewhat ambiguous. For example, for extraction sites No. 501, 503 and 962 of the Heroiv Kosmosu mine, there is an increase in value of K_{out} with increasing outgassing well gradient angle β_6, and this increase occurs over the entire range of β_6 changes. But the gradient of the increase in K_{out} decreases with growth of β_6, which indicates an approach to a certain maximum, that is, in our research, to a rational value of β_6. The existence of such a value is indicated by the dependency graphs K_{out} (β_6) for other extraction sites: No. 1124 of the Heroiv Kosmosu mine and No. 885 and No.1043 of the Zakhidno-Donbaska mine. The maximum of K_{out} is clearly observed here, but with the only three experimental points on the graphs, it is impossible to determine the reliability of the rational values of outgassing well gradient angle β_6. What can be stated for sure is the significance of β_6 influence; the difference between K_{out} values for different β_6 values is: 36 % for 501 longwall face, 29 % for 503 longwall face, 17 % for 962 longwall face, 56 % for 1124 longwall face of the Heroiv Kosmosu mine and 20 % for 885 longwall face and 24 % for 1043 longwall face of the Zakhidno-Donbaska mine.

The outgassing coefficient K_{out} measurement and calculation results are shown graphically in figure 9 for each studied extraction site separately. As expected, there is an increase in K_{out} with a decrease in l_2 at all extraction sites: by 26 % for 501 longwall face, by 47 % for 503 longwall face, by 26 % for 962 longwall face and by 40 % for 1124 longwall face of the Heroiv Kosmosu mine; by 51 % for 885 longwall face and by 31 % for 1043 longwall face of the Zakhidno-Donbaska mine. This level of influence (by an average of 30 – 40 %) should be taken into account when substantiating the appropriate parameters for site outgassing technology. Also, taking into account the identified tendencies, it can be recommended to limit the rational step l_2 values to an interval of $9 \leq l_2 \leq 13$ m, where the outgassing coefficient K_{out} has increased values (figure 9).

Summarizing the experimental research results, it can be argued that they, based on

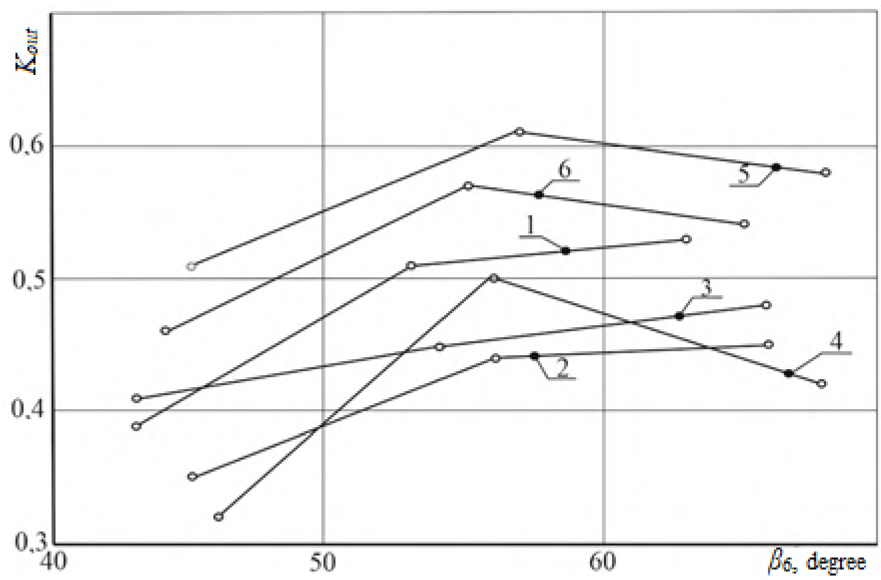

Figure 8. Patterns of influence of the gradient angle β_6 (to the coal seam stratification plane) of outgassing wells on the outgassing efficiency: 501 (1), 503 (2), 962 (3) and 1124 (4) longwall faces of the Heroiv Kosmosu mine; 885 (5) and 1043 (6) longwall faces of the Zakhidno-Donbaska mine.

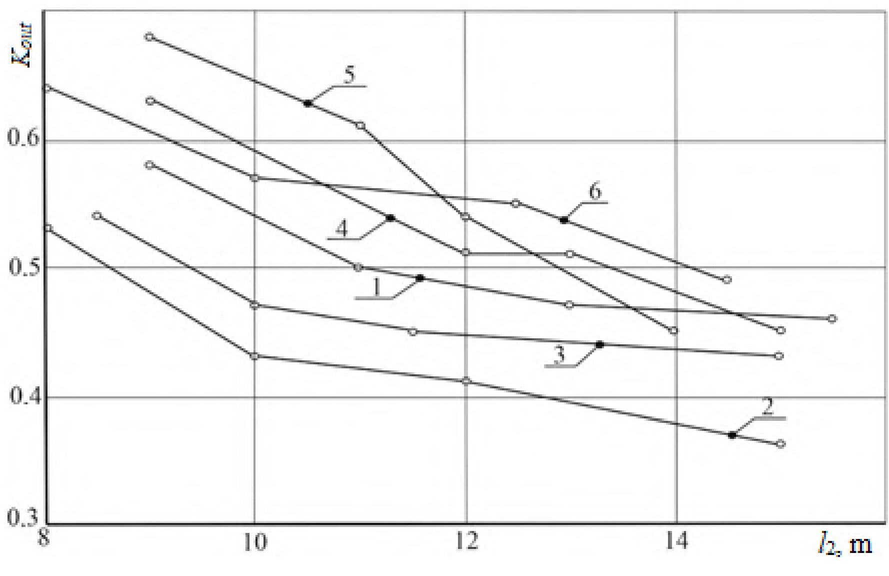

Figure 9. Patterns of influence of the step l_2 of drilling wells on the outgassing efficiency: 501 (1), 503 (2), 962 (3) and 1124 (4) longwall faces of the Heroiv Kosmosu mine; 885 (5) and 1043 (6) longwall faces of the Zakhidno-Donbaska mine.

indirect parameters (outgassing coefficient), confirm the general tendencies in the influence of geomechanical-technological factors on the site outgassing efficiency during high-velocity mining of coal seams in the Western Donbas mines. The feasibility of using the proposed recommendations (based on the FEM modeling results) for the selection of site outgassing parameters, which will allow an average of a third increase in the productivity of stoping faces using the so-called "gas factor", has also been confirmed.

7. Methodology for selecting site outgassing parameters

The algorithm for calculating the parameters for site outgassing well location is described in detail earlier, and now some clarifications are given based on the experimental research results, since the study of the outgassing process at six extraction sites of two mines has not revealed fundamental differences with the FEM modeling results [50, 51].

The calculation is performed on the basis of mining-geological prediction data (depth of stoping operations, texture and mechanical properties of coal-overlaying formation rocks), the longwall face passport (planned indicators of its advance, schemes for placing equipment at the end longwall face sections) and the passport for draining-out of gases (scheme for placing drilling equipment). This information is the initial data, based on which the following sequence of calculations is accepted.

1. The outgassing well route gradient angle β_4 along the strike of the coal seam is calculated by the formula $\beta_4 = \arctan \frac{h_s}{h_s \cot \beta_3 + C_1 + W_{pr} + Weq}$ and the outgassing well turning angle in the direction to the coal seam rise is calculated by the formula $\beta_5 = \arctan \frac{C_1 + Wpr + Weq}{h_s \cot \beta_1 + C_2 + L_{eq}}$ To do this, it is necessary to calculate intermediate parameters using the formulas (1) – (10).
2. The outgassing well route gradient angle β_6 to the coal seam stratification plane is determined by the formula $\beta_6 = \arctan \frac{h_s \sin \beta_5}{C_1 + W_{pr} + Weq}$. It is preferable for the calculated value of β_6 to fall within the experimentally determined rational range $55^{\circ} \leq \beta_6 \leq 65^{\circ}$; then the reliability of our recommendations increases.
3. The step l_2 of drilling outgassing wells is calculated by the formula $L_2 = a_s$; before this, it is necessary to calculate the intermediate parameter a_s using the formulas (11) – (15). To increase the reliability of recommendations for choosing the l_2 value, it is preferable that it be in the range of $9 \leq l_2 \leq 13$ m.
4. The time for drilling the next well is determined provided that the distance of its mouth from the fencing of the powered support approaches the value l_1 determined by the formula $L_1 = h_s \cot \beta_1 + C_2$.
5. The outgassing well length l_w is determined by the formula $L_w = \frac{H_m}{\sin \beta_6} + \Delta_{ov}$. However, at the longwall face advance velocities of $V_l \geq 7$ m/day, the well length can be reduced by 25 – 40 %, since the coal-overlaying formation stratification height is limited.
6. The calculation parameters for outgassing well location schemes are tested for 20 – 30 m of the extraction drift length. If necessary, well drilling parameters are adjusted.

8. Conclusions

A complex of mine instrumental observations of gas release and gas trapping processes in the site outgassing technology allowed to obtain multifactorial information on the influence of geomechanical-technological factors on them, conduct a comparative analysis of the analytical and experimental research results. This eventually contributed to the development of a methodology for selecting rational parameters for outgassing well location schemes for highly productive mining of the Western Donbas coal seams.

A new methodology has been developed, which differs from the existing ones by taking into account the multifactorial geomechanical-technological factors of outgassing the extraction sites. Three main methodological provisions have been substantiated on the basis of performed FEM analytical research. They are included in the newly created algorithm for conducting mine experiments, consisting of three interconnected stages: general verification of the reliability of recommendations generated analytically using FEM; assessing the objectivity of the patterns of influence of geomechanical factors on the site outgassing process; studying the influence of a number of its technological parameters on the outgassing process efficiency.

At the general experimental assessment stage of the objectivity of recommendations, the main tendency is consistently visible (for various mining-geological conditions): the outgassing coefficient according to the recommended parameters is higher than that corresponding to outgassing well location schemes existing in mines. The objectivity of this conclusion is confirmed by experimental measurements at six extraction sites of two mines – the range of relative increase in the outgassing coefficient ranges from 19 % to 123 %.

There is a significant influence (up to 35 – 60 %) of the coal-overlaying formation texture on the outgassing coefficient; this influence is independent of other geomechanical-technological factors of mining the Western Donbas coal seams.

It has been experimentally determined that an increase in the longwall face advance velocity V_l (by an average of 30 – 45 %) contributes to an increase in the gas trapping efficiency by an average of 25 – 40 % in various mining-geological conditions of mining the Western Donbas coal seams. That is, the tendencies in the same direction of increasing the coal mining productivity have been identified: the growth of V_l leads to a decrease in the methane inflow into the adjacent mine workings, and this, in turn, substantiates the possibility of accelerating the longwall face advance.

The influence of the well gradient angle β_6 on the outgassing coefficient is by an average of 20 – 30 % under different mining-geological conditions of mining the Western Donbas coal seams.

The step of drilling l_2 of outgassing wells along the extraction drift has an average level of 30 – 40 % influence on the outgassing coefficient; therefore, the parameter l_2 should be taken into account when substantiating the technological factors of site outgassing technology. Based on the experimental research results, a step l_2 in the range of $9 \leq l_2 \leq 13$ m is recommended, where K_{out} has increased values.

Abstract. The article discusses aspects of geometrization of mineral deposits. Particular attention is paid to the geometrization of mineral reserves. Various geometrization methods allow one to obtain ambiguous results, depending on the geological structure and spatial location of mineral deposits. Various options for estimating mineral reserves are considered and the method for optimal estimate is described. The method makes it possible to estimate reserves of mineral deposits of a complex configuration, find the most probable strike line of such deposits and clarify their contour. The method is based on choosing the optimal direction of vertical cross-sections and the distance between them. The influence of the shape of a mineral deposit on the accuracy and completeness of reserve estimate was considered. The experiments were carried out theoretically and practically in various mining and geological conditions. A more accurate estimate of mineral reserves is made using geostatistical and heuristic methods developed by the authors of the study. The described methodology for geometrization and estimate of mineral reserves was applied at mining enterprises in Ukraine and gave effective and accurate results. This made it possible to increase the efficiency of mining planning and the rationality of the mining enterprise.

1. Introduction

The operation of a mining enterprise is entirely dependent on the efficiency of mining [1]. Various methods for estimating mineral deposits are aimed at determining the properties of minerals and rock masses. Geometrization of mineral deposits ensures the completeness of the estimate of mineral deposits [2, 3].

Technological properties of rocks are an important aspect of the geometrization of mineral deposits [4]. The methods for such geometrization are determined by the composition and properties of the rock mass [5]. In this case, it is important to take into account all interacting factors affecting the efficiency of mining [6].

Improving the technology of mining and the extraction of mineral resources requires a comprehensive mining-geometric estimate of geological and technological objects. Increasing the efficiency of mining operations is based on comprehensive information obtained by geometrization methods [7, 8].

A large number of studies are aimed at determining the state of the massif and changes in its state during mining operations [9]. Such studies can be based on determining the geophysical parameters of the rock mass, the mineralogical composition of minerals, as well as the technological properties of rocks [10].

The sustainable development of the mining industry is based on increasing efficiency and mining operations [11]. During mining operations, it is necessary to comply with environmental protection requirements. Achieving high results is closely related to an integrated approach to the geometrization of mineral deposits [12]. The issues of geometrization of deposits in complex mining and geological conditions are especially relevant.

Objective planning of mining operations [13] and productive work of a mining enterprise is based on a clear understanding of the geometric position of the mineral resource and mine workings [14,15]. Long-term and current planning of the work of a mining enterprise is an urgent task of mining production.

The creation of promising and effective systems for the mining of mineral deposits widely uses mining-geometric methods for estimating technological processes and their impact on the rock mass, providing comprehensive monitoring of mining operations [16, 17].

Various conditions for the mining of mineral deposits can be systematized by taking into account and monitoring the mining and geometric parameters of individual sections of the mineral deposit [18]. The result of geometrization in this case will be a clear idea of the quality and quantity of minerals in different areas of the deposit [19].

Prospects for the development of methods for mining iron ore deposits are especially important in modern conditions [20]. The method for geometrization of iron ore deposits is very relevant at all stages of a mining enterprise and covers a wide range of studies [21]. Rationalization of the work of a mining enterprise and the use of subsoil is achieved through a mining-geometric estimate of the deposit [22].

One of the most interesting areas of geometrization of mineral deposits is the estimate of their reserves [23]. Integrated use of mineral deposits is an integral part of mining. Research aimed at the most rational use of deposit resources is the most important direction in geometrization of mineral deposits [24].

Geostatistical and heuristic methods for estimating mineral reserves are one of the most promising areas of research [25, 26]. These methods are accurate, easy to use, and easy to modify [27, 28].

Thus, the study is devoted to the methodology for geometrization of mineral deposits using geoinformation systems. Much attention is paid to the geometrization of mineral deposits of a complex configuration, as well as the selection and modification of the optimal method for their geometrization in various mining and geological conditions.

2. Methods

The existing methods of geometrization are based on the idea of placing indicators of a mineral deposit in the form of a geochemical field, which can be described by some function of the coordinates of a point in space $P=f(x,y)$ or $P=f(x,y,z)$ [29]. There is an assumption that the function P satisfies the conditions of finiteness, uniqueness, continuity and smoothness. In subsurface geometry, the method of isolines is used as one of the main methods of depicting surfaces of topographical order [30].

Depending on the degree of exploration of the deposit, the exploration network may use regular testing, irregular testing, and continuous testing. The implementation of the isoline method depends on the parameters of the geological exploration network and the characteristics of the variability of the deposit indicators. The main methods for constructing isolines include:

the method of invariant lines and slopes; polyhedron method; method of profiles; statistical and geostatistical methods; reverse distance methods, etc. Their logical analysis for the purpose of formalization made it possible to single out the following main computational, graphic and heuristic procedures for geometrizing the deposit. These include the following procedures: mining geometric analysis of the initial data and the choice of a specific method of graphic modeling or their combination; conversion of initial data into an induced network; construction of isolines in a linear approximation followed by smoothing; creating a graphic image.

As a result of the mining and geometric analysis of geological data, the general regularities of the location of the indicator in the subsoil are established. At this stage, the invariant lines and slopes of the depicted surface are outlined, the boundaries of the geometrization areas are determined. It is this stage that is the most difficult to formalize for the use of geographic information systems.

The results of studying the variability of the indicator provide additional data for mining and geometric analysis. If the invariant lines are close to straight lines, then when studying variability, the main directions of anisotropy approximately coincide or are perpendicular to the invariant lines. Quantitative estimates of the parameters of variability are used to determine the height of the section of the isolines.

The choice of the method for construction of isolines is determined by the results of mining and geometric analysis and studies of variability. Polygon, invariant lines, and slope methods are commonly used to construct structural plans with an irregular scout network. Since qualitative indicators usually contain a significant part of a random component, the statistical window method or its modification is used to display their properties. The size of the smoothing window can be determined based on the height of the section of the isolines.

The transformation of the original data into a regular rectangular or square network is carried out using analytical models of the placement of indicators or smoothing methods, including methods of optimal statistical interpolation.

Thus, regardless of which data network is used (triangular or rectangular), the isoline coordinates are determined at the first stage using interpolation on the edges of the network along two adjacent nodes. After that, the broken isolines are smoothed out, that is, a nonlinear approximation of the depicted surface is performed.

For volumes that correspond to sample sizes, Krige developed a method for estimating the content at a given point by averaging the content at the nearest sample points with weights that decrease with increasing distance from the point. This method was called kriging [31]. To use kriging, it is necessary to estimate the variogram, which is a correlation function, from the test data. The accuracy of the calculation of mineral reserves depends on the correct estimation of this function. In this regard, the issues of changing these functions depending on the geometry of the samples, the orientation of the sampling lines in relation to the ore body, etc. There are empirical formulas to account for the effect of sample geometry on the appearance of these functions, but the effectiveness of their use remains controversial. However, this issue significantly affects the solution of kriging problems. In a more general form, it can be stated as the study of the type of these functions and content histograms depending on the change of the volume within which the content is evaluated. There is no definite solution to these issues, and the mentioned problems remain unresolved to this day. However, the ideas listed above served as a prerequisite for the development of technologies for building mathematical models of deposits.

The mathematical model of the deposit is a basic element of the method for estimating conditions and counting reserves, because it is used to geometrize reserves and build blocks, find the optimal position of contours of mining, calculate mineral reserves, etc. The mathematical model of the deposit, when solving many tasks of technical and economic substantiation of conditions and calculation of reserves, replaces the base of primary data of exploratory testing, on the basis of which the tasks of calculating mineral reserves are solved.

Most of the listed operations in graphic modeling are quite easily formalized, with the exception of a number of heuristic procedures. So, for example, for the selection of invariant lines and slopes, as well as for the triangulation of geological exploration networks, additional geological information must be used.

The analysis of logical connections between computational, graphic and heuristic procedures determines the principle of building mathematical support for the tasks of graphic modeling of the deposit. Mathematical support of automated geometrization contains programs of three levels: basic, functional and applied. The division of mathematical support into levels corresponds to the degree of detail of the displayed graphic information.

Basic programs allow construction of the simplest geometric elements.

Functional programs are developed taking into account the content of applied tasks. Functional mathematical support for graphic modeling tasks includes: construction of coordinate grids with coordinates along the perimeter of the grid; construction of test plans with plotting of wells, their names, content of components; construction of the main elements of mining plans; coordinate transformation (affine, functional, etc.); design of graphic documents; drawing graphs of functions that are given analytically in an explicit form and parametrically; drawing graphs of functions, which are given in the form of a table, using various interpolation methods.

Applied graphic modeling programs provide drawing of isoline plans by various methods, geological sections with isolines of quality indicators, plans of mining works, block diagrams, three-dimensional images of surfaces of topographical order, models of mining and geological objects in axonometric projections. Given the fact that different methods of graphic modeling contain identical interpolation procedures (transformation of coordinates, smoothing of isolines, signing of isolines), the most rational principle of forming a package of application programs is modular.

In figure 1, as an example of performed geometrization presents the graphical result of geometrization of the deposit, which is mined by the Slavyansky chalk-lime plant quarry. The combination of mining-geometric methods used makes it possible to geometrize a mineral deposit and build a digital model of a mineral deposit.

Modeling and evaluation based on a multidimensional heuristic forecasting algorithm based on the use of a polynomial of arbitrary degree developed by the authors has a number of advantages over existing one-dimensional and multidimensional methods. The accuracy of modeling and the efficiency of using available geological information are significantly increased through the quantitative expression of either previously unknown or known qualitative genetic relationships between indicators [32].

The algorithm in general can be depicted in the form of a block diagram (figure 2).

The flowchart is a generalized illustration of the sequence of operation of the algorithms included in the multidimensional heuristic forecasting algorithm. It can be seen that the algorithm as a whole has a cyclic structure. The cycles are organized in such a way that when they are repeated, the forecast function becomes more complex, its accuracy and adequacy to the real pattern of placement of the forecast indicator increases. The criterion for stopping the algorithm can be the absence of an increase in the accuracy of the predictive function at the next iteration, or the achievement of the specified accuracy.

Using this method, you can identify almost any known functional dependence. Although the method does not use trigonometric functions, any of them can be represented as a power series and calculated with a given accuracy. An example of this is the Maclaurin series expansion of the function of sine, cosine, natural logarithm, etc. If within the considered mineral deposit there is an intermittent pattern of distribution of the predicted indicator, then the principle of conditional division by zero is used. In this case, the function is assigned an optimally fixed value. This method was first used to create this algorithm. This method is the first to consider

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012025 doi:10.1088/1755-1315/1415/1/012025

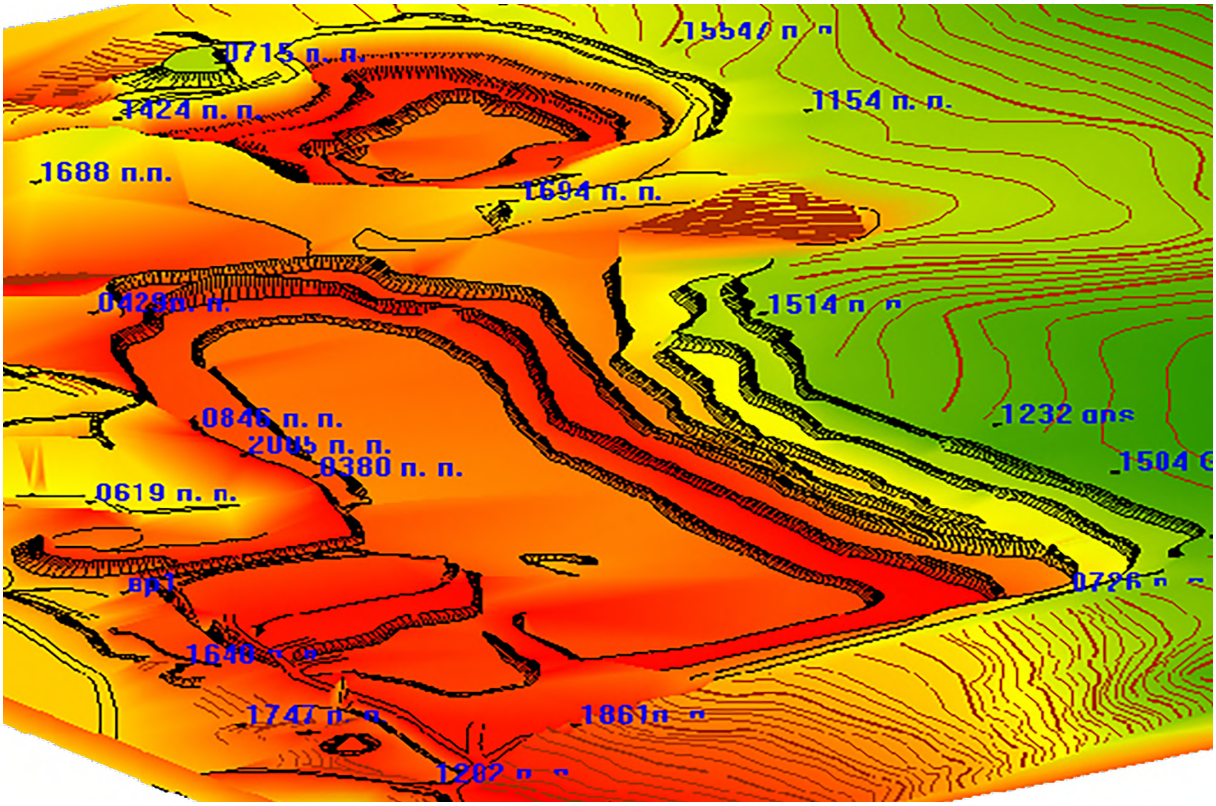

Figure 1. Digital graphic model of the Slavyansky chalk-lime plant quarry.

a mathematical method for determining the sensitivity of numerical coefficients, which makes it possible to quickly estimate the gradient of a function change and, therefore, the ability to select the coefficient to which the function is most sensitive. This is a simplified functional model of empirical evaluation. The algorithm for grouping data according to deviation criteria for constructing individual forecast functions is also considered for the first time in this method.

3. Results and discussion

The methodology of geometrization developed by the authors of the study is a set of methods that ensure obtaining the most complete and objective estimate of geological and mining-technological indicators of mining operations. The use of geoinformation systems such as Micromine, K-Mine, Surfer, AutoCad provides an efficient automated process of deposit geometrization based on promising and accurate mathematical methods implemented in these systems. The most significant is the geometrization and estimate of mineral reserves. The efficiency of the mining enterprise depends entirely on the accuracy and completeness of the estimate of the deposit's reserves.

Geometrization of reserves of minerals of a complex configuration requires modernization and refinement of the methodology for estimating reserves in complex areas of the deposit. Methods for geometrization of mineral deposits of a complex configuration are an integral part of the methodology for geometrization of the deposit. This method was applied at the mining enterprises of Ukraine. For example, consider a deposit of a complex configuration, which is mined by the "YUZHNIY GOK" quarry.

There are several problematic issues in the method of parallel vertical cross-sections, which is quite common in production. It is necessary to pay attention to the impossibility of calculating

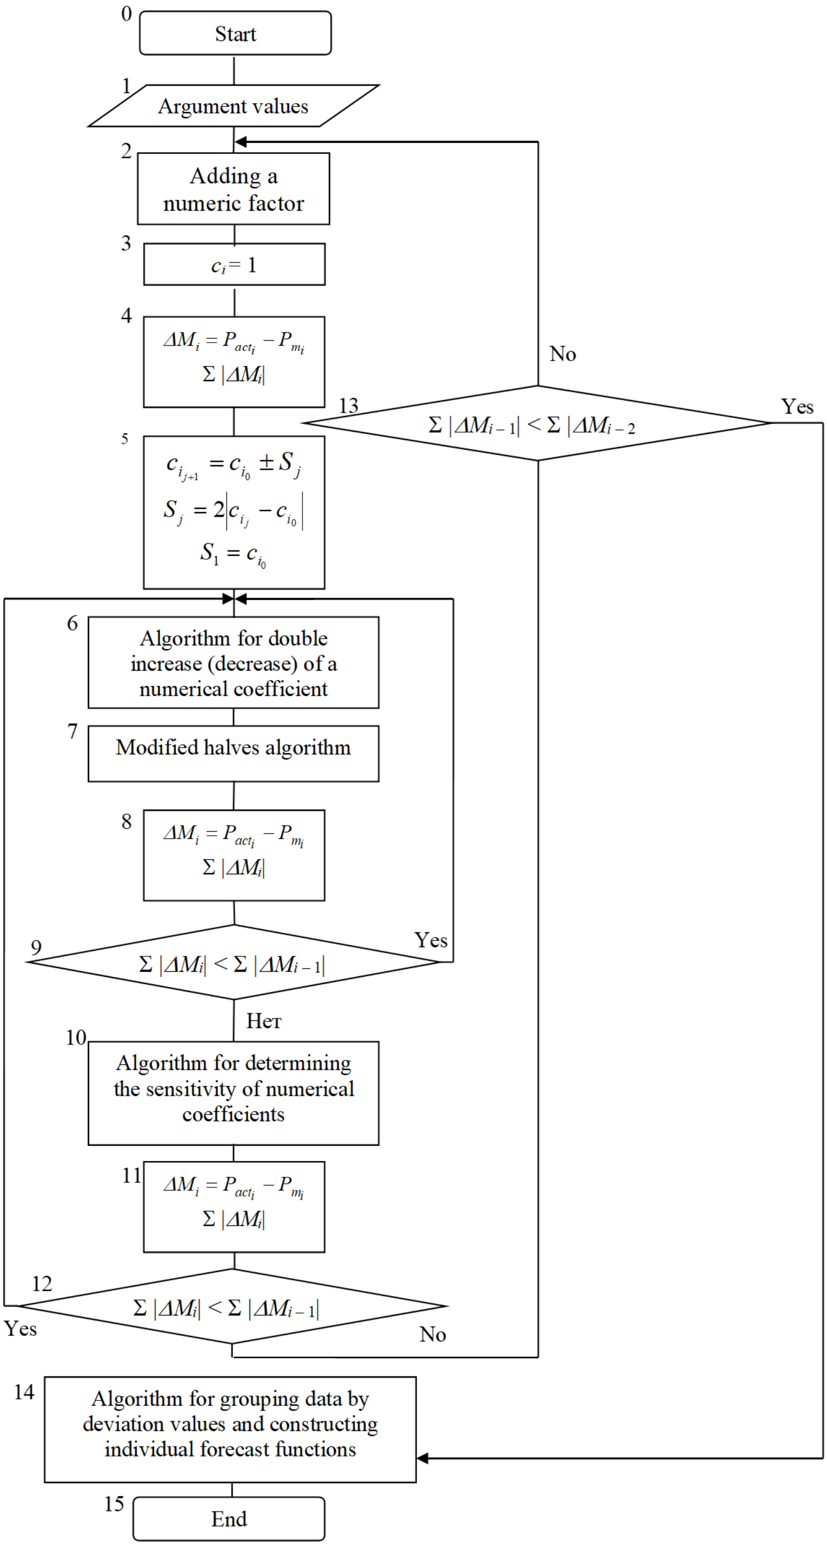

Figure 2. Multidimensional heuristic forecasting method: $\triangle M$ – the deviation of the modeled function; S – the intermediate value of the simulated function; c – the modeled indicator.

the volumes in the extractable blocks of a complex configuration. It is impossible to optimally locate the mineral deposit strike line, perpendicular to which cross-sections are built, without violating the condition of their parallelism. The optimal directions of the location of fragments of the mineral deposit strike line in separate parts of the block do not lie on the same straight line. The use of one line, under the condition of fixed distances between cross-sections, leads to an increase in counting errors.

A known situation is when the planned position of the mineral deposit strike line is clearly established. According to such an arrangement of cross-sections, it is convenient to calculate the volumes of several figures with the possibility of their constant accumulation. It is possible to perform different counting options, for example, at different time intervals. However, due to this, variants with a significant loss of accuracy are possible. The error mainly occurs in cases where the blocks or their parts are not located across the cross-sections, but along or at an angle close to it. At the same time, significant changes in the configuration of the contours of the calculated block are possible between cross-sections, and the total volume of the part of the block between adjacent cross-sections can be calculated with an unacceptable error.

One way to solve this problem is to add intermediate cross-sections to reduce the distance between the cross-sections. Thanks to this, the error is reduced.

There is an assumption about the existence of the optimal direction of the arrangement of cross-sections in the method of parallel vertical cross-sections when the distance between adjacent cross-sections is reduced to the required level. It is possible to find the optimal distance between the cross-sections and the optimal direction of the cross-sections, at which the volume of mineral in the block will be maximum. This will mean that the cross-sections cover the area of the block as much as possible. This will also make it possible to more accurately outline mineral deposits. In this case, you can get more accurate results of the interpolation of the conventional contact line.

To study the change in volume from the angle of rotation of the planned position of the cross-sections and the distance between them, an experimental block was modeled. Through the center of gravity of the block in the XY plane and parallel to the X axis in the conventional coordinate system, the probable mineral deposit strike line was drawn, perpendicular to which cross-sections were separately constructed after 20 meters. Based on them, the volume was calculated, in the form of a report, which consisted of a table with calculations (table 1) and constructed cross-sections on the appropriate scale (figure 3), for the possibility of checking the obtained results.

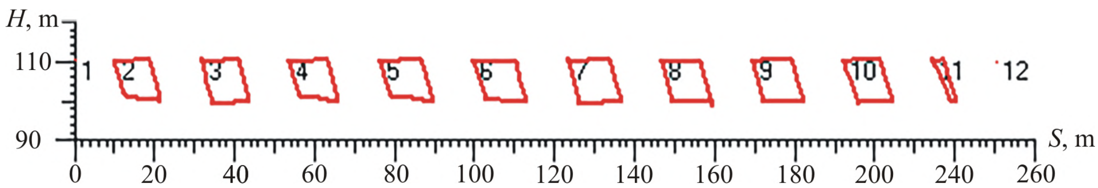

Figure 3. Vertical cross-sections for volume calculation, the distance between which is 20 m: S – the distance along the mineral deposit strike line, m; H – the vertical distance, m.

The next step is to calculate the volume of this block relative to the Y axis. The results obtained from the report according to the previously described template were compared with the previous ones. The volume was calculated in the direction where the angle of the plan position of the cross-sections is equal to the average angle of the two previous angles. Analyzing the results of the previous calculations, the rotation of the cross-section line in the plan is continued in such a way that the cross-section line turns clockwise relative to the center of gravity by one degree, and the calculations are repeated. The process is repeated until the line is rotated 180°.

Table 1. Calculation of volumes by the method of parallel vertical cross-sections with a distance between cross-sections of 20 m.

Section number	Area, m^2	Section number	Area, m^2	Distance, m	Volume, m^3
1	0.00	2	201.77	16.87	1134.39
2	201.77	3	247.67	20.00	4486.61
3	247.67	4	223.37	20.00	4708.27
4	223.37	5	237.70	20.00	4609.96
5	237.70	6	256.99	20.00	4945.66
6	256.99	7	279.48	20.00	5363.07
7	279.48	8	256.65	20.00	5359.62
8	256.65	9	266.57	20.00	5231.91
9	266.57	10	236.68	20.00	5029.62
10	236.68	11	40.71	20.00	2503.68
11	40.71	12	0.00	6.82	92.51
Total volume. m^3:					43465.31

In this way, you can consider all possible calculation options (figure 4).

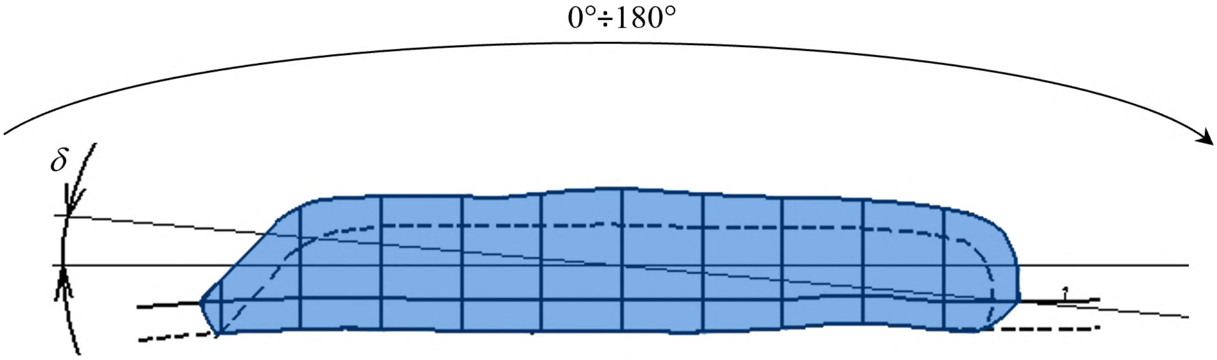

Figure 4. Simulated experimental block: δ – the angle of rotation of the cross-section line, which varies from 0 to 180 degrees. The experimental block is indicated in blue.

First, the volumes were calculated at a distance between cross-sections of 20 m. To check the assumption described above, the distances between cross-sections are reduced. In the same way, preliminary calculations are performed for distances between cross-sections of 10 m, 5 m, 2 m and 1 m.

Further reduction of the distances did not result in significant differences at these volumes. The dependence study is completed at a distance between cross-sections of 1 m.

For each stage of the calculation, a report containing a table containing data on the numbers of cross-sections, their areas, and the volumes between two cross-sections was generated. Based on these data, graphs of dependencies were constructed, which indicate that the angle of rotation of the cross-sections ceases to play a significant role when the distances between the cross-sections are reduced to the optimal value. For example, for the selected block, it is advisable to use a distance between cross-sections equal to one meter. You can make sure of this visually by looking at the combined graph of the dependence of the volume of the block on the angle of the cross-sections strike line of at different values of the distance between the cross-sections (figure 5). Line 20, which corresponds to the dependence at distances between cross-sections of 20 m, has the largest error of the volume and is not acceptable for the use of an arbitrary angle. The following lines corresponding to distances of 10 m, 5 m and 2 m are also inadmissible. However, there is a tendency to straighten the line at the mark of the true volume. Lines 1 and 2 almost do not differ from each other and have almost the same volume value for all variants of the angle of rotation, which confirms the assumption. However, it is line 1 that has the smallest deviation from the real volume, and therefore the distance between the cross-sections, which is equal to one meter, can be used for an arbitrary plan angle of the location of the cross-sections.

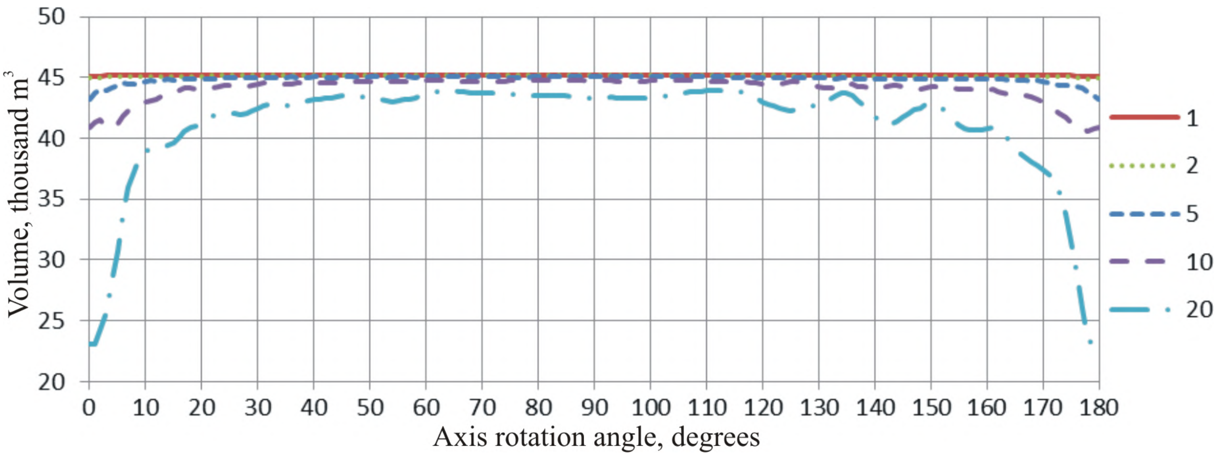

Figure 5. Graph of the dependence of the volume of the block on the angle of the cross-sections strike line at different values of the distance between the sections: 1 – the dependence at a distance of 1 meter; 2 – the dependence at a distance of 2 meters; 5 – the dependence at a distance of 5 meters; 10 – the dependence at a distance of 10 meters; 20 – the dependence at a distance of 20 meters.

To find out the influence of different configurations of mineral deposits on the accuracy of volume calculation, three configurations of blocks at different horizons were chosen: a flat elongated block, a block with a sharply rounded configuration, and an intermediate variant (figure 6). For each of the blocks, the volume was found at different values of the distance between the cross-sections and different values of the angle of the cross-sections strike line.

The results of estimating the reserves of the direct configuration block did not significantly differ from the results of estimating the reserves of the previous block, which was created to study the dependence of the volume on the influence of the planned location of the cross-sections and the distances between them. Therefore, let's dwell in more detail on the round and convex block configurations.

For the round configuration of the block, according to the previously described method, the results were also obtained, which were tabulated for the purpose of the subsequent comparison of similar data and their statistical analysis to estimate the accuracy of the conducted studies. Similar actions were performed for the block with the convex configuration. To compare the results obtained by different block configurations, the following graphs were constructed (figure 7, figure 8).

4. Conclusions

Thus, the described method makes it possible to estimate and outline deposits with a complex nature of mineral placement. This is realized by choosing the optimal direction of construction of cross-sections, in which the maximum amount of minerals falls into the plane of the cross-sections. At the same time, the optimal distance between cross-sections depends on the quality

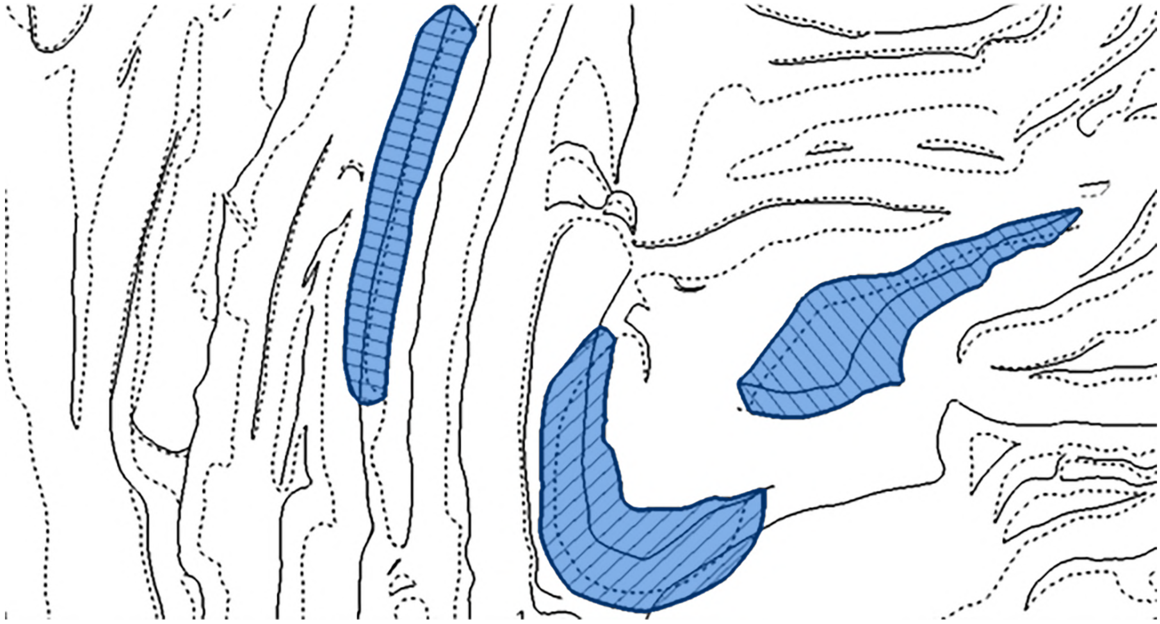

Figure 6. Blocks of various configurations with cross-sections for volume calculation. Experimental blocks are indicated in blue.

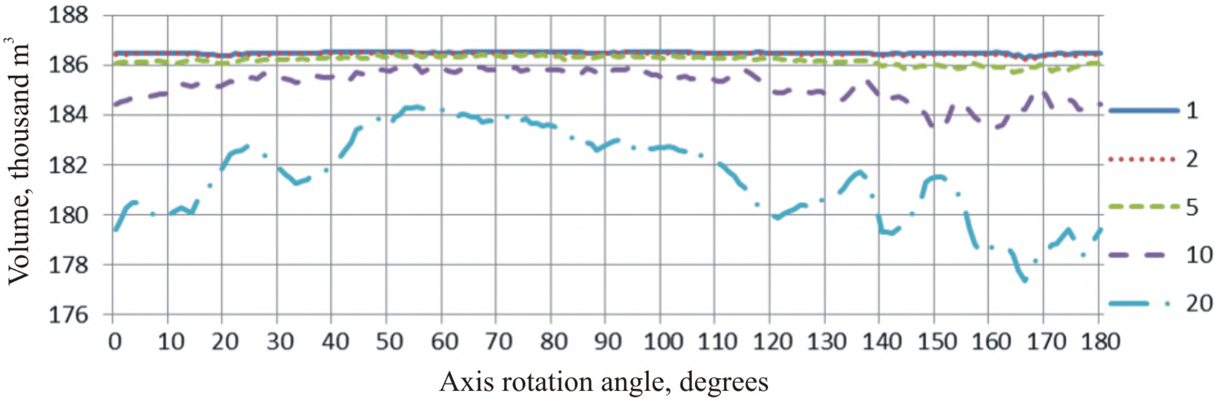

Figure 7. Graph of the dependence of the volume of the block of the circular configuration on the angle of the cross-sections strike line at different values of the distance between the cross-sections.

of geological information, which is the basis of the geometrization of the mineral deposit. The quality of geological information can be estimated using geostatistical methods, which include the kriging method. The methodology of geometrization, developed by the authors of the work, widely uses geoinformation systems, which implement geostatistical methods for geological information estimate. The multidimensional heuristic method for mineral deposit estimate developed by the authors makes it possible to construct functional dependencies of the placement of indicators of a mineral deposit. In general, the set of methods included in the methodology increases the accuracy of the estimation of mineral reserves, and makes it possible to estimate the reserves of a mineral deposit with an error 6 – 8%.

This makes it possible to increase the efficiency of planning of mining operations and the rationality of the operation of the mining enterprise.

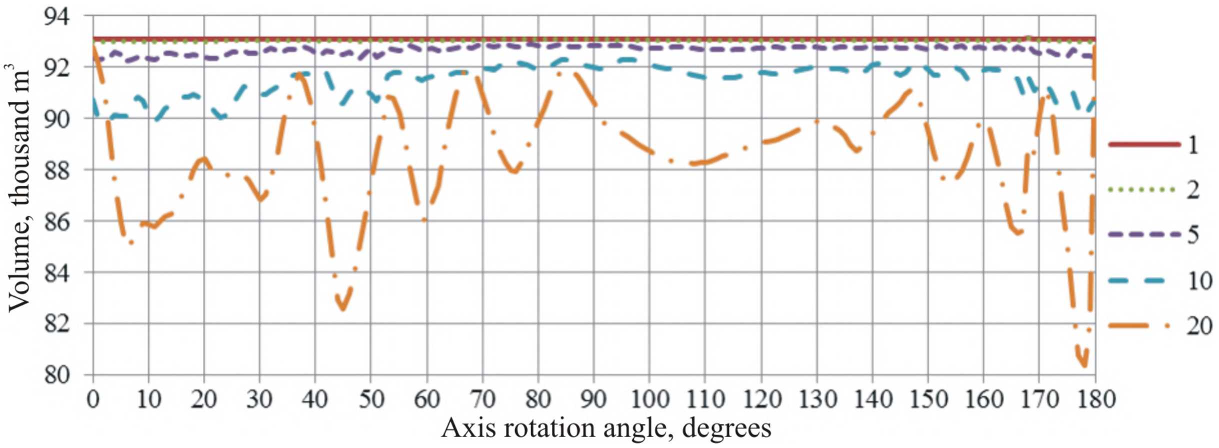

Figure 8. Graph of the dependence of the volume of the block of the elongated configuration on the angle of the cross-sections strike line at different values of the distance between the cross-sections.

The further direction of research consists in the development of methods that are included in the methodology for geometrization of mineral deposits, and increasing its accuracy and universality. The most promising areas of development are geostatistical and heuristic methods for mineral deposit estimate.

Abstract. The floor heave is one of the most acute issues of underground mine roadways stability problem. With an increase in mine depth, the floor heave becomes more dramatic. Analysis shows that rock bolts reinforcement is the most advanced and worldwide method of floor heave control. The current mine roadway support systems in Ukraine usually do not provide measures to floor heave control. As a result, floor heave values exceed 0.7-1.0 m, which leads to disruption of transport chains and failure of ventilation regime. In this paper, for the typical conditions of coal mines located in Pokrovsky, Dobropilsky districts and Western Donbass, stress-strain evolution in roadway's bottom before and after excavation face was studied. Ansys code was used to analyze the evolution of stress and strain in immediate floor of roadway before and after excavation face. It was found that rocks in immediate floor undergo cyclic loading and alternating strains. Before and after excavation face a zone of increased stress and a stress relief zone are formed respectively. Thus, in the immediate floor behind the excavation face cracks are formed and structurally defects are branched. This initiates the origin of floor heave process. The control of the immediate floor delamination after excavation face can be ensured by a timely installation of rock bolts in the excavation face with their inclination to roadway face. The most appropriate bolt inclination coincides with the contour of the stress concentration zone, which can be determined from the results of numerical modeling.

1. Introduction

The post-war reconstruction of Ukraine will undoubtedly require a powerful energy and metallurgical growth. Therefore, it is most likely that the roadmap for the transformation of the Ukrainian coal industry will be adjusted, at least in the near future. The current shortage of energy carriers in the country, caused by Russia's military aggression, shelling of critical energy infrastructure, insufficient gas and oil resources, and the European energy crisis, can only be overcomed by increasing coal production. Thus, despite the global trend of decarbonization, increasing the productivity of coal production in wartime and the period of post-war recovery is an urgent task of the Ukrainian energy industry.

In order to ensure the rhythmic operation of coal mines, it is necessary to solve the issue of mine ventilation, organization of main and auxiliary transport in a timely manner. The permissible methane or flammable gas concentrations in the coal mine, the rhythm of mine roadway preparing and coal mining directly depends on the mine roadways state.

Among the issues of underground mine roadways stability , the most acute today is the issue of floor heave control. About 70-80% of mine roadways in Ukraine are repaired due to dramatic floor heave [1]. Same repairing rate is noted by researchers from other countries [2]. With an increase in mine depth, the problem of roadway floor stability becomes even more urgent. The current methods of excavation and supporting of mine roadway in Ukraine usually do not provide floor support system, or additional measures to control the floor deformation and failure. This leads to the disruption of transport chains, the reduction of the cross-section of the mine roadway and, accordingly, the failure of ventilation regimes. The floor heave control is carried out primarily by floor digging method. The floor heave problem is typical not only for the mine roadways. This phenomenon is observed during the tunnel construction, civil engineering in mountains, construction of another underground objects [3, 4].

Currently, many scholars have conducted extensive research on the floor-heave mechanism through in-situ monitoring, laboratory tests, physical and numerical simulation. The results indicated that the floor heave is mainly related to factors such as in-situ stress field, rock mass type, water inflow, and mine roadways support design. Faria Santos and Bieniawski [5] summarize main floor heave mechanism, including bearing capacity failure, buckling, and swelling (figure 1).

Bearing capacity failure of floor rock happens when the vertical stress that transmitted from roadways sidewall to floor, exceeds the load-bearing capacity of rock mass in immediate floor [6]. Swelling is observed as a result of exposure of clay-rich materials, such as mudstone, claystone, and shale, to moisture [5]. Buckling usually occurs where the rock mass of immediate floor is stronger than the strata underneath. Buckling is typically observed where the high horizontal stress initiates floor layer moving [7]. Anyway, a significant cause of floor heaves is alters of the natural equilibrium state and stress redistribution in the surrounding rock [8, 9]. There is the reason why the main efforts of scholars in recent years have been directed to the stress and strain study of the surrounding rock. Usually such studies are carried out by numerical simulation.

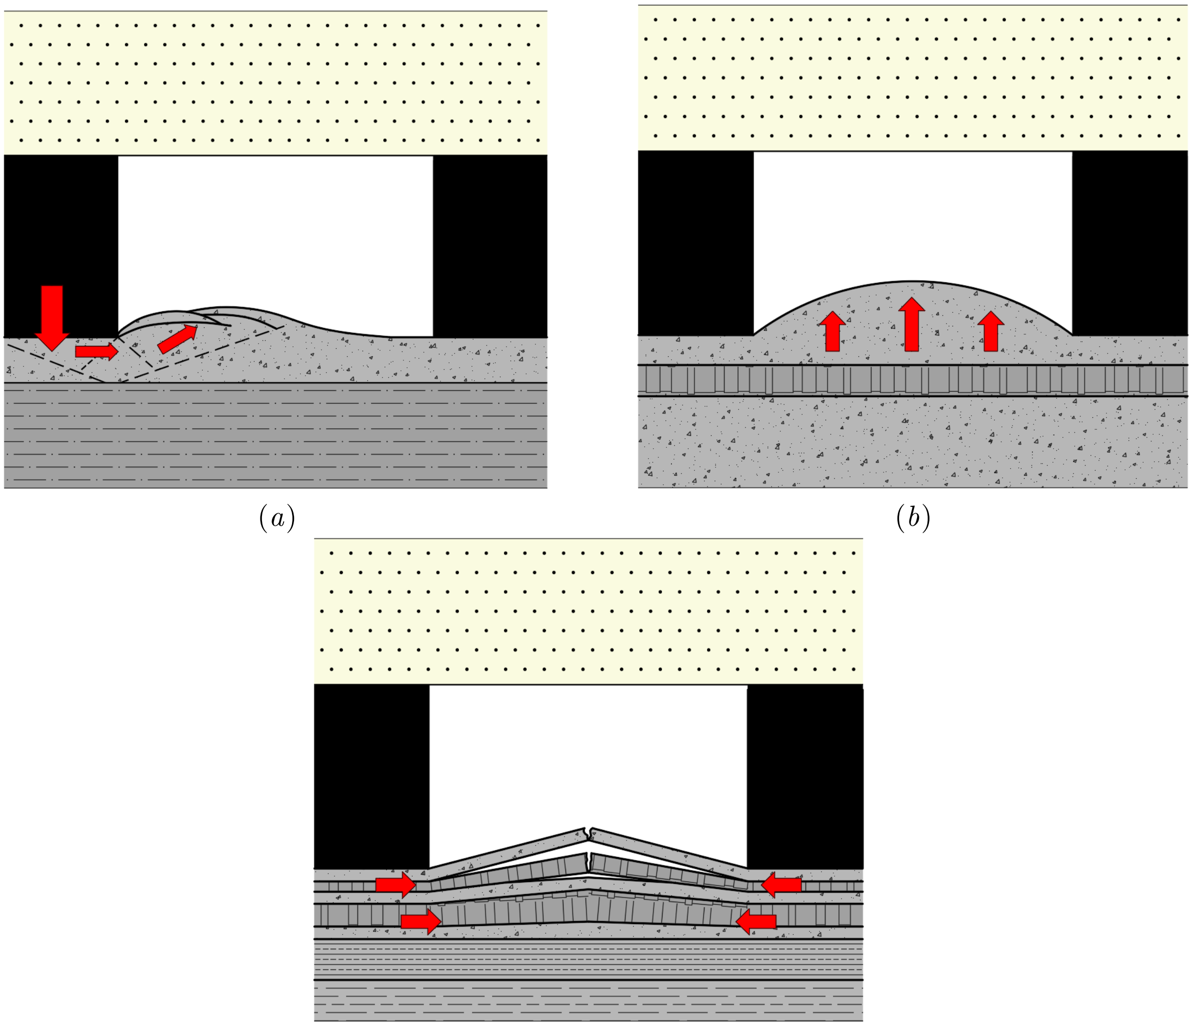
Zhao et al. [10] presented the simulation results of the U-shaped steel closed support that is able to control the floor heave of roadways. The numerical simulation was conducted using the finite difference software FLAC3D.

Liu et al. [11] analised floor stress distribution law after mining in the surrounding rock, that was verified by FLAC3D numerical simulation. Zhou et al. [12] put forward three support optimization schemes, simulated the support effect of each scheme, and finally determined the best support optimization scheme. In this paper, the analysis of the distribution plastic area, stress nephogram, and displacement field simulation results in surrounding rock was proposed by using FLAC3D. Małkowski, Ostrowski and Stasica [13] used a Phase 2 program for numerical simulations of two-dimensional deformation of roadway floor heave in dry and waterlogged conditions. Qi et al. [14], and Zhang et al. [15] simulated the failure mechanism of soft rock roadway by UDEC.

Sakhno and Sakhno [16] used ANSYS code to simulate the floor heave control by the rock bolts reinforcement technology.

Usually, during such studies, the stress-strain field in surrounding rocks in the cross section of mine roadway is analyzed. At the same time, the change in the stress field immediately after the equilibrium state alter before and after excavation is not taken into account. Nevertheless, the previous research overlooked the evolution of stress-strain state in surrounding rock under the excavation redistribution stress. This phenomenon is also not taken into account during analysis of the effectiveness of floor heave control methods.

Floor heave control methods are mainly related to inverted arch construction, floor concrete beam or circular closed support construction [17, 18], cutting stress relief slot in the floor or wall of roadway [19, 20], and reinforcing of immediate floor [21, 22]. Rock bolts reinforcement is the most advanced and worldwide method of floor heave control [23].



(a) *(b)* *(c)*

Figure 1. Floor heave mechanisms: (a) bearing capacity failure, (b) swelling, (c) buckling.

In this paper, for the typical conditions of coal mines located in Pokrovsky, Dobropilsky districts and Western Donbass, stress and strain evolution in immediate floor before and after excavation face was studied. This study provides a characteristic of the underground roadway excavation influence on stress-strain state of immediate floor and its delamination. This paper proposes floor support method based on rock bolts installation in the stress concentration zone before the excavation face.

2. Engineering background

The analysis of geological maps and the current state of the coal industry shows that mines of Pokrovsky, Dobropilsky districts and Western Donbas are the most perspective for the development of coal mining. Mines located in the occupied territory require extremely large investments, which is not advisable when the mine fund is worn out by 80-90%. In the current balance of coal production in Ukraine: 65% is the production of coal by the mines of the DTEK company (located in Western Donbas and Dobropilsky district), 23% is the production of PRJSC Pokrovske Colliery (Pokrovsky district), 8% of coal production is provided by mines located in state ownership, and only 4% – other non-state owned mine.

The geological information and mining plans were used to analyse the distribution rate of different strength layers in the floor strata. This information included such data: the lithologia, depth of development and strength of the rocks. In terms of lithology, the Middle Carboniferous formations are mainly composed of sandy-clay rocks. The uniaxial compressive strength (UCS) indicators of rocks are presented in the table 1, where min UCS, max UCS, aver UCS – minimum, maximum and average uniaxial compressive strength respectively, MPa; ΔUCS – mean quadratic value of uniaxial compressive strength respectively, MPa; Δ – coefficient of variation, %.

Table 1. UCS of rocks.

min UCS	max UCS	aver UCS	Δ UCS	Δ, %	Rock type
7.4	57.8	27.8	10.2	36.9	Mudstone
23.4	57.0	32.9	15.3	35.7	Siltstone
41.8	138.6	75.3	25.3	29.5	Sandstone
38.1	193.0	107.0	45.8	42.7	Limestone

The first layer of immediate floor was represented by:

- siltstones in 73% of cases at an average thickness 5.8 m,
- sandstones – 13% at an average thickness 8.3 m,
- mudstones – 9.3% at an average thickness 2.2 m,
- limestones – 4.7% at an average thickness 3.4 m.

The highstrength rocks (with a UCS more than 60 MPa) in the first and second layer of floor strata was observed in 16% of cases with accuracy within the limits of statistical reliability. The analysis indicated that 74% of the coal seams floor was composed by layered siltstones and argillites. Based on the generalization of geological information, a strata histogram was constructed, which characterizes typical conditions for Pokrovsky, Dobropilsky districts and Western Donbass. The strata histogram is illustrated in figure 2.

According to existing ideas, in the absence of water inflows, buckling is the most likely mechanism of floor heave.

3. Methods

The 3D numerical simulation by ANSYS code was performed to analyze the stress-strain distributions in surrounding rock before and after excavation face. This approach made it possible to analyze the evolution of stresses around the roadway in two mutually perpendicular sections (in the longitudinal and cross sections). The simulated rock mass corresponded to the strata histogram presented in figure 2.

To simulate the behavior of rock mass, the Drucker–Prager model was used. Parameters of deformation model such as: Young's modulus, Poisson's ratio, cohesion, angle of internal friction were established in accordance with the methodology proposed by Sakhno, Molodetskyi and Sakhno [23]. Mechanical parameters of rock mass are presented in table 2.

The principle of force superposition was used. The model is axisymmetric, so half of the cross-section of the mine roadway was simulated. The model was 60m long, 60m wide, and 100m high. A 5.2×3.8m arch shape roadway was modeled. The numerical model is shown in figure 3. The load-bearing capacity of the U-shaped steel support (310kN, type KSHPU-17.7) was simulated by applying external pressure to roadway contour.

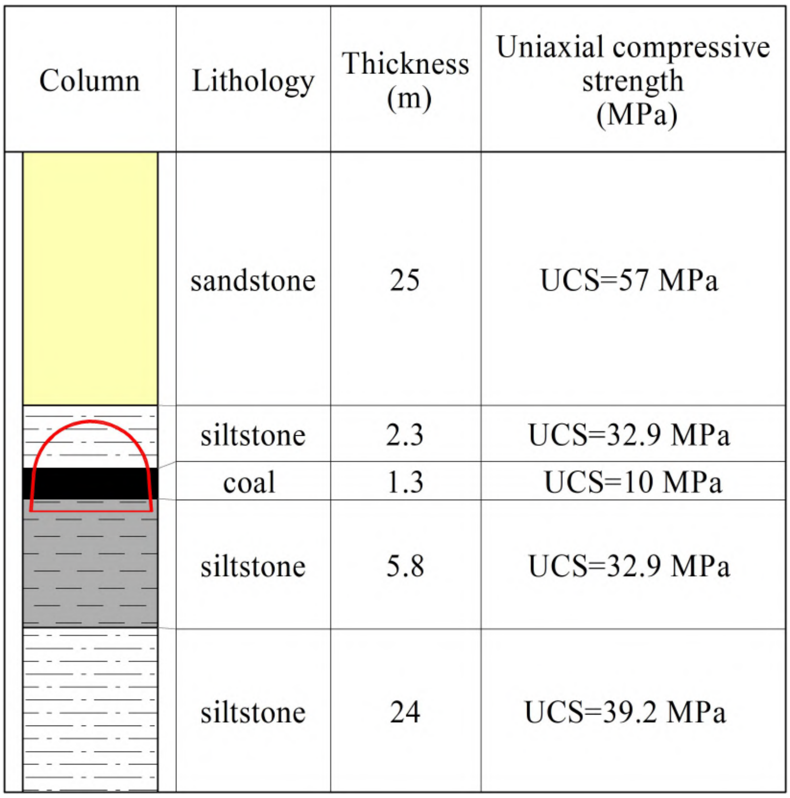


Figure 2. The strata histogram.

The maximum principal stress theory was used as the yield criterion. A vertical pressure of 22.5MPa, that equivalent to overburden stress at a 900m depth, was applied on the top of the model.

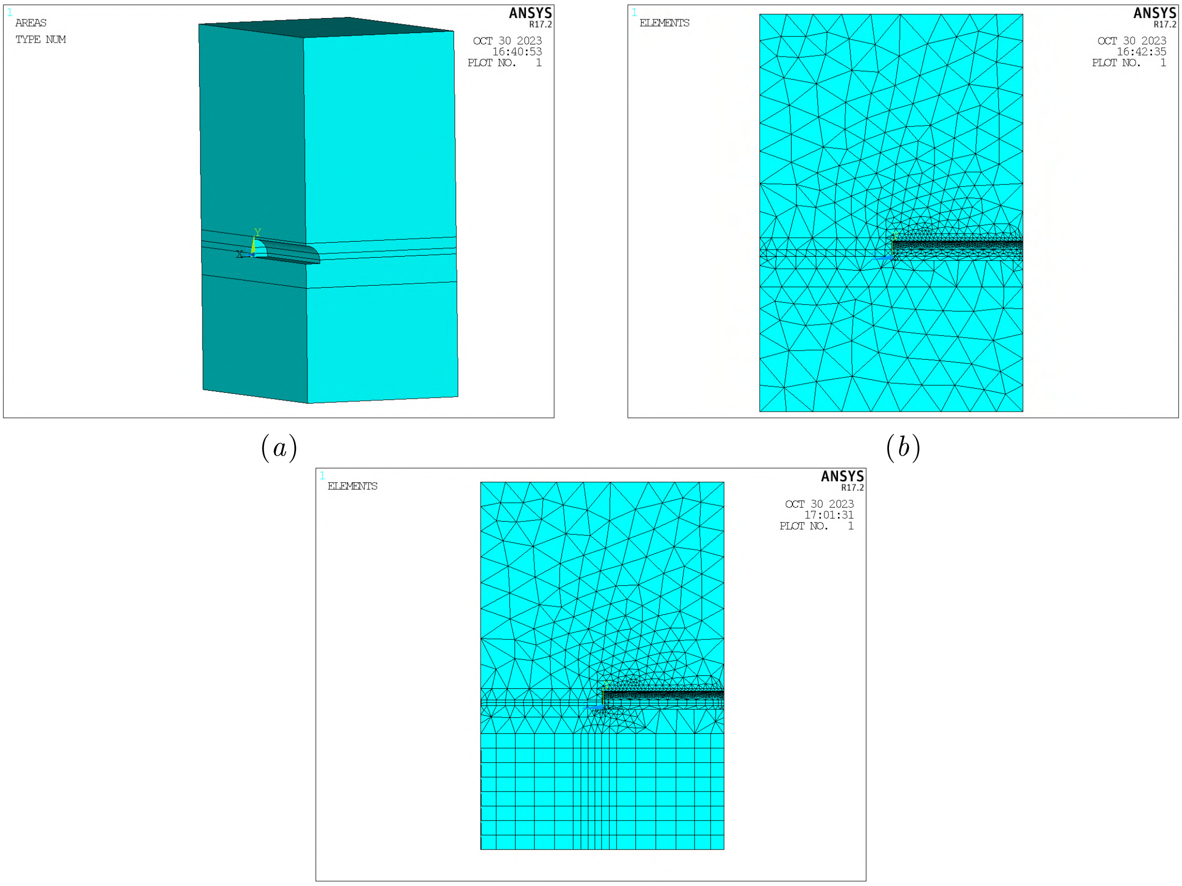
The size of the finite element was refined (figure 3b, c). Near the mine roadway contour, the size of the finite element was minimal, since high accuracy is important there. On the contour of the model the stress field is uniform, so the finite elements size was maximal. This is traditional practice in numerical simulation.

4. Results

The maximum principal stress and strains distributions in the surrounding rock are shown in figure 4.

Table 2. Rock mass parameters for numerical simulation.

	Density, kg/m^3	Elastic modulus, GPa	Poisson's ratio	Cohesion, MPa	Angle of internal, deg	Dilatancy angle, deg
Main roof	2400	6.12	0.3	5	32	32
Immediate roof	2300	2.20	0.3	6.3	30	30
Coal	1300	1.1	0.25	2.6	26	26
Immediate floor	2300	2.2	0.3	6.3	30	30
Main roof	2300	3,6	0.3	5,35	30	30



(*a*) (*b*)

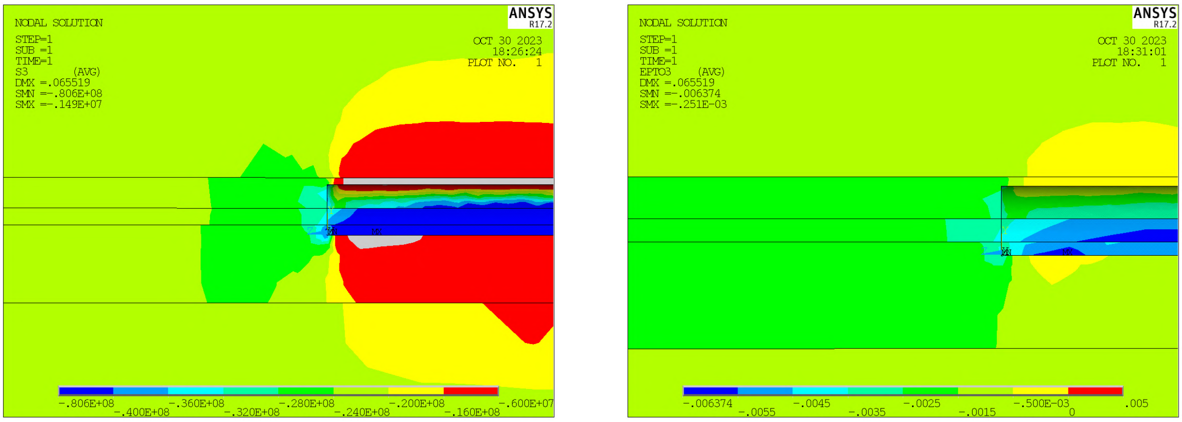
Figure 4. Distributions of maximal principal stresses (a), and maximal principal strains (b) in the surrounding rock.

Analysis of the simulation results (figure 4a) shows that a zone of increased stress is formed before the excavation face, which includes the immediate roof and immediate floor. It is clear, that in this zone, the lithological stresses (determined by gravitation) increase. The rock mass there is compressed. The same conclusion can be drawn from analyzing the strain distribution (figure 4b). At a distance of 1.5-2.0 m from roadway bottom contour, a zone of reduced stresses appears. This zone is marked in red colour in figure 4a. The size and the magnitude of stresses in this zone increase with an increasing of the distance from the excavation face. The maximum tensile stress that occurs in the roadway floor is 3.9 MPa. It exceeds the rock tensile strength.

The minimal principal stress and strains distributions in the surrounding rock are shown in figure 5.

Since the minimal principal stresses are compressive, analyzing the patterns of their distribution, it is possible to estimate the size of stress concentration zone.

This zone is formed before the excavation face. Its maximum depth before face is more than double the height of the roadway. The entire layer of the immediate floor is included into this



(a) (b)

Figure 5. Distributions of minimal principal stresses (a), and maximal principal strains (b) in the surrounding rock.

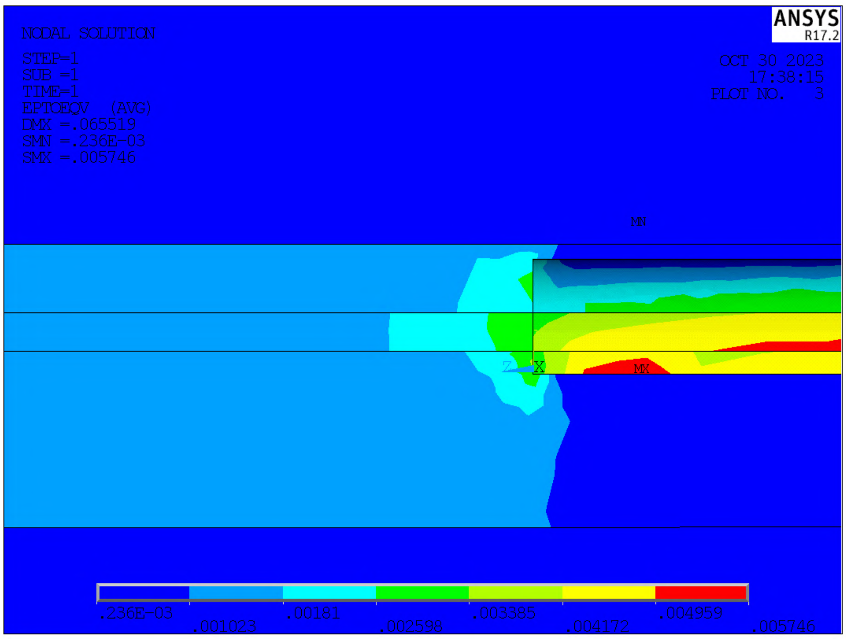


Figure 6. Distributions of equivalent strains in the surrounding rock.

zone. The rocks are compressed there by stresses 25-35 percent higher than the lithological stress. This conclusion is confirmed by the results of minimum principal strain pattern analysis (figure 5b). The zone of reduced stresses is formed in the immediate floor in distance of 1.5-2.0m below the roadway bottom.

The analysis of equivalent strain distribution (figure 6) shows the general characteristic of the deformation state of surrounding rock. In the zone of influence of the excavation face, strain fluctuation is the highest.

A quantitative assessment of stress variation was obtained by analysing of stress graphs along profile lines in immediate floor. As an example figure 7 shows the graph of the minimum principal stresses variation, that was built along a profile line oriented in the immediate floor (0.25m below the bottom) along the roadway axis (figure 7a). The profile line (stress path) is marked with dots in figure 7a. The section 8m before the excavation face and 2.0m behind it is taken into account.

The following conclusions were obtained after analyzing the stress graph (figure 7b):

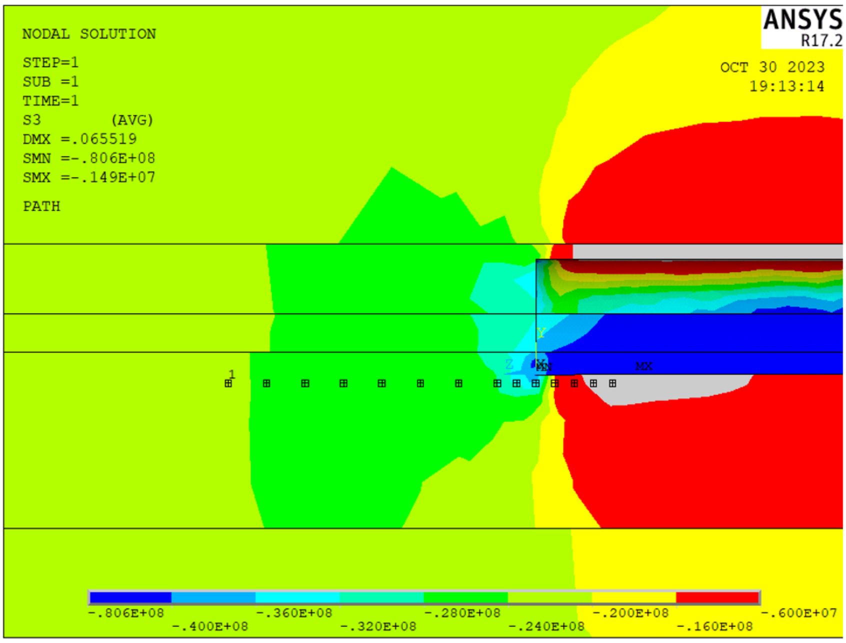
(i) at a distance more than 8 m before the excavation face, the stress field corresponds to the overburden stress (approximately 23.8 MPa);
(ii) the face influence zone begins at a distance of 8.0 m before it. There stress increase from 23.8 to 37.2 MPa, which corresponds to its increase of 56%;
(iii) the stress relief zone in roadway bottom appears immediately under the excavation face surface. There stress decreases rapidly. At a distance of 2.0 m behind the excavation face at a depth of 0.25 m in immediate floor, the stress are 3.8 MPa. Therefore stress reduce rate is 84% relative to the initial stress field and 90% relative to the maximum stress concentration. Thus the rocks in immediate floor are loaded cyclically. At the same time, the sign of the loading-unloading stresses changes.

After that, 4 profile lines were built to analyse stress-strain variation in depth of immediate floor. Profile lines were oriented in the immediate floor along the roadway axis at a distance of 0.25, 0.5, 0.75, 1.0 m from the roadway bottom. The length of the profile lines was 3.0 m before excavation face and 2.0 m after it. figure 8 shows graphs of the minimal principal stresses variation along profile lines. The position of the profile lines is shown in figure 8.

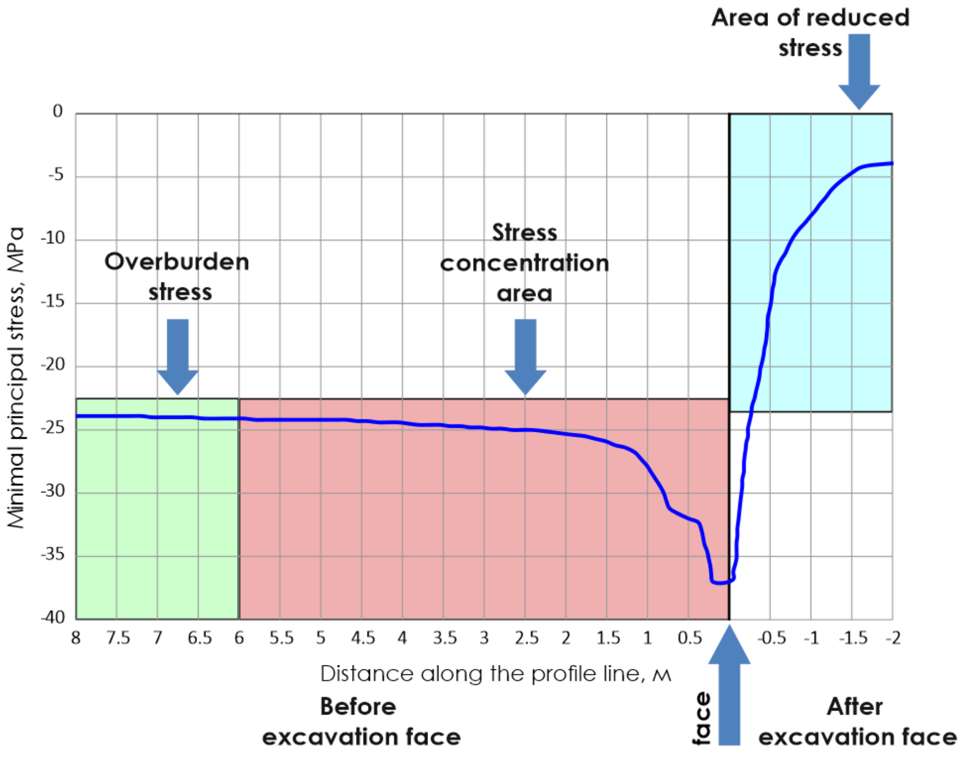
The analysis of the minimal principal stresses variation (figure 8) shows that the stress concentration zone before excavation face in the immediate floor is limited by a depth of 1.0 m. In addition, the magnitude of the stresses before the excavation face decreases with a depth. Similar conclusions can be drawn for the section of immediate floor behind excavation face. The increase of the distance from the roadway bottom leads to a decrease of the stress relief zone. For example, at a depth of 1.0 m from roadway bottom, the stresses in immediate floor at a distance of 2.0 m after excavation face are 7.35 MPa, which corresponds to their decrease of 70%.

Figure 9 shows graphs of the equivalent strain variation along profile lines in the immediate floor along the roadway axis at a distance of 0.25, 0.5, 0.75, 1.0 m from the roadway bottom.

Graphs in figure 9 show changes in the deformation type (compression-tension) in the immediate floor before and after the excavation face. This confirms the stress analysis results. Similar conclusions can be drawn also about the size of the roadway influence zone before and after excavation face. The magnitude and fluctuations of the strain also decrease with depth. For example, at a depth of 0.25 m from roadway bottom, the strain in immediate floor increases by 60% in the stress concentration zone before excavation face and decreases by 87% in the stress relief zone after it. At a depth of 1.0 m, the corresponding percentage are 9%, 77%. The conclusion regarding the sign change of stresses and strains in immediate floor before and after excavation face is confirmed.



(*a*)



(*b*)

Figure 7. Profile line in pattern of minimal principal stresses (a) graph of the minimal principal stresses variation (b).

Thus, it was established that in the immediate floor in the influence zone of excavation face at the initial stage of the roadway life cycle, compressive stresses first increase by more than 50% in the stress concentration zone, after that they decrease by more than 80% in the stress

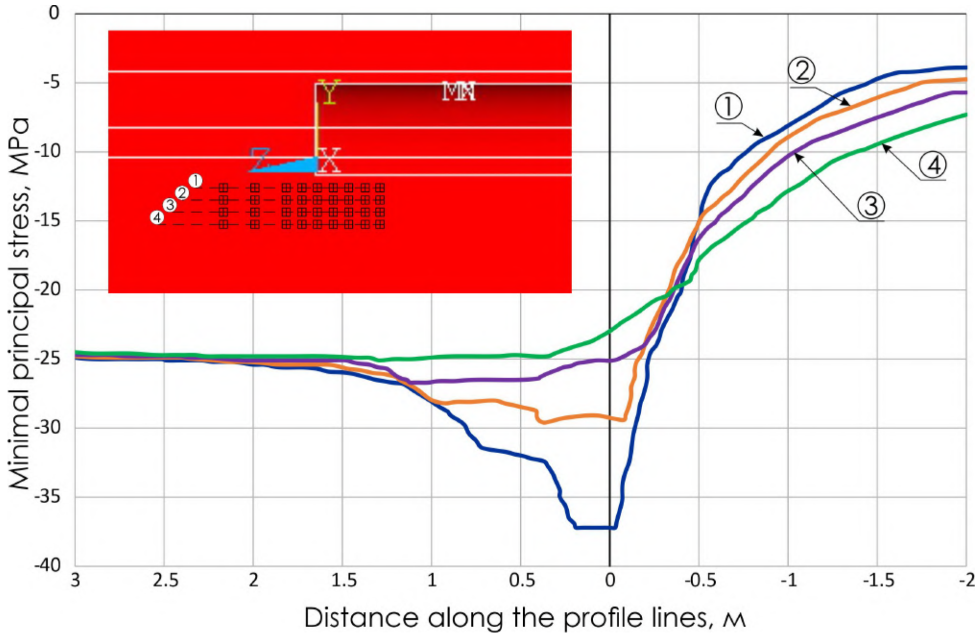


Figure 8. Graphs of the minimal principal stresses variation along profile lines in immediate floor at a distance of: (1) 0.25m, (2) 0.5m, (3) 0.75m, (4) 1.0 m from the roadway bottom respectively.

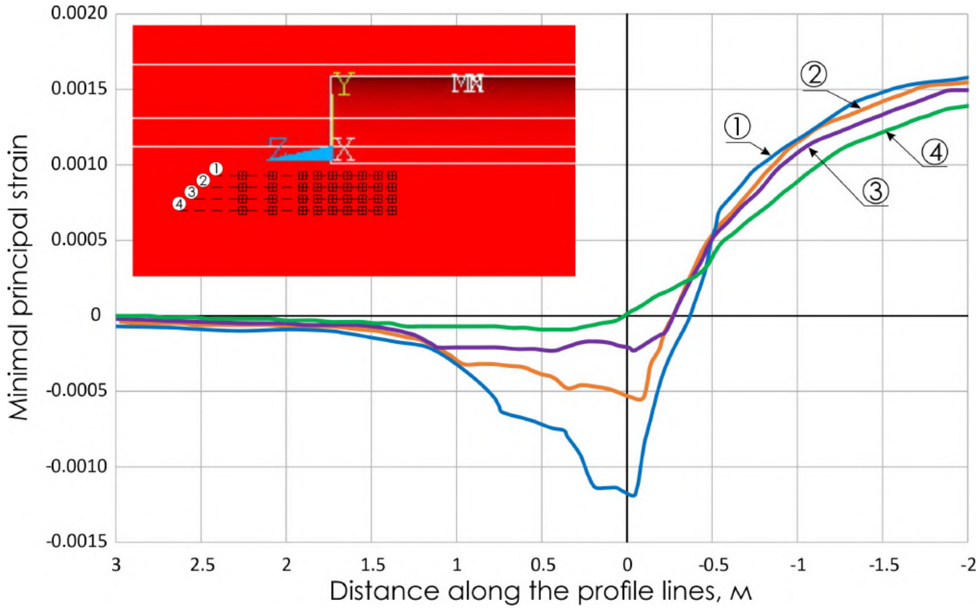

Figure 9. Graphs of the equivalent strain variation along profile lines in immediate floor at a distance of: (1) 0.25m, (2) 0.5m, (3) 0.75m, (4) 1.0 m from the roadway bottom respectively.

relief zone. In this case, the rocks undergo cyclic loading and alternating strains.

5. Discussion

It is known that cyclic loading of rocks leads to a significant decrease in their strength even after the first loading cycle.

Burdine [24], Brown and Hudson [25] first found that cyclically loaded rocks would fail in a limited number of cycles under the condition that the maximum cyclic loading is less than the uniaxial compressive strength of rocks.

Brown and Hudson [25] first illustrated the residual failure locus, and researchers further pointed out that there is a fatigue failure law for rocks. The terminal fatigue strain of rocks is approximately equal to the post-peak monotonic strain [26–28]. In most experiments, the irreversible strain develops a three-stage mode. In the initial stage, the axial strain rapidly develops owing to the closure of pre-existing voids or cracks in rocks. Rocks under cyclic stress usually characterized by low fatigue life.

For soft rocks, the deformation modulus increases during the first few cycles due to closure

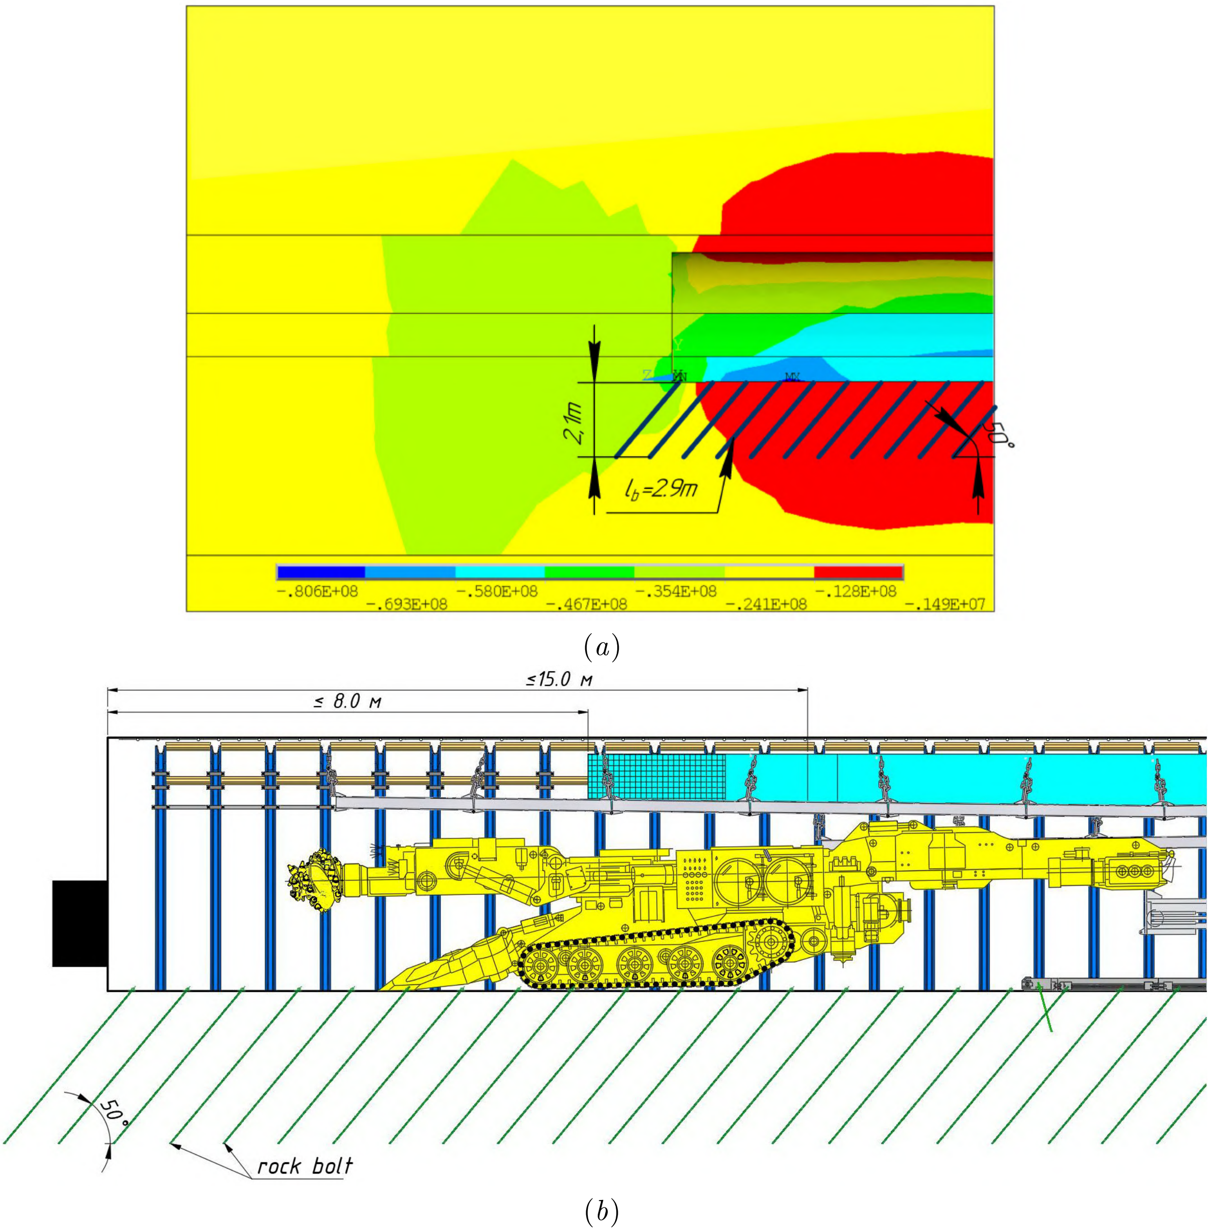

Figure 10. Scheme for determining the rock bolt inclination based on the numerical simulation results (a), floor support scheme during the roadway excavation (b).

of voids and hardening of specimens. For cyclic triaxial compression tests, the irreversible volumetric strain is one of the key quantities related to the dilatancy effects of rocks [29].

Liu and He [30] show that the irreversible volumetric strain is positive in first few cycles and then becomes negative, indicating that the rock specimen is first contracted and then dilated until fatigue failure. The irreversible volumetric strain at the dilatancy point increases with an increasing of confining pressure.

Miao et al. [31] found that cyclic disturbances result to numerous tensile cracks and crack branching. Wang et al. [32] found that the microfracturing processes and accumulation of damage that occurs during cyclic fatigue loading can cause rock failure.

Summarizing the above, it can be concluded that in the immediate floor behind the excavation face in the stress relief zone, cracks are formed in the floor strata and existing structurally defects are branched, interlayer contacts are opened and delamination occurs. This creates a negative impact on the roadway stability in its next life period. In addition it is the origin of floor heave process.

The fracture of rocks can be prevented by artificially restraining the delamination of the immediate floor after excavation face. Rock bolts installed with an inclination to roadway face were proposed for this. However, this method will be effective only if the bolts are installed in a timely manner rapidly in the excavation face. Thus, the rocks will be reinforced in the stress concentration zone, and their subsequent delamination in the stress relief zone will be controlled by rock bolts.

The rock bolt inclination is advisable to determine from the stress pattern in immediate floor. The most appropriate bolt inclination coincides with the contour of the stress concentration zone. Research on the optimal support scheme and floor reinforcement length for rock bolts is proposed by Sakhno and Sakhno [16]. The example of determining the bolt inclination by a graphical method for the simulation results presented above is shown in figure 10a. The proposed technology of mine roadway excavation and floor support is presented in figure 10b. The figure shows rock bolts with standard length of 2.9 m used in Ukrainian mines.

6. Conclusions

This paper presents the numerical simulation results of underground roadway excavation impact on the origin floor heave. In this study, deep mining roadway of coal mines located in Pokrovsky, Dobropilsky districts and Western Donbass was considered as the research subject. Based on the results of this investigation, the following conclusions can be drawn:

1. The numerical analysis shows that in immediate floor before roadway's excavation face a zone of increased stress is formed. Maximal comressive stress in this zone increases the lithological stress by more then 50%. The stress relief zone in immediate floor after excavation face appears. The stress there is less than the lithological stress and maximum stress by more than 80% and 90% respectively. Thus the rocks in immediate floor are loaded cyclically. This is confirmed by alternating strains in the area of face excavation impact.
2. An analysis of the literature indicates that cyclically loaded rocks would fail in a limited number of cycles under the condition that the maximum cyclic loading is less than the uniaxial compressive strength of rocks. Thus, in the immediate floor behind the excavation face cracks are formed and structurally defects are branched. This creates a negative impact on the roadway stability and origin of floor heave process.
3. Rock bolts support of roadway floor was proposed for restraining the delamination of the immediate floor after excavation face. In this case, bolts installation in a timely manner in the excavation face with inclination to roadway face was proposed. The most appropriate bolt inclination coincides with the contour of the stress concentration zone. Further research

will be aimed at studying the influence of rock bolts installed immediately in the roadway face on the stress-strain evolution in the roadway floor.

Abstract. This study delves into the importance of ensuring the necessary degree of rock crushing in open pit mining technology and its profound impact on extraction, loading operations, and overall production processes. The degree of rock crushing significantly influences excavation and transportation costs, making it a pivotal factor in determining the total cost of mining operations. Traditionally, empirical formulas have been used to establish the dependence of granulometric composition of blasted rocks on rock properties and technological factors. However, this study emphasizes the need for a multifactorial model to predict rock crushing quality, incorporating characteristics of rock massifs, explosives, and specific costs. By doing so, it aims to enhance the efficiency of open-pit mining technology and evaluate the investment attractiveness of deposit development at the pre-project stage. The study also explores the use of linear regression analysis and non-linear search methods to determine the parameters for predictive calculations of blasting quality. The research offers valuable insights into optimizing blasting approaches and minimizing operational costs in open-cast mining operations, thereby contributing to the sustainable development of mineral deposits.

1. Introduction

Ensuring the required degree of crushing of rocks is one of the main problems in open pit mining technology. The necessary degree of crushing has a significant effect on the extraction and loading operations, and accordingly on all technological processes in the open pit. If rock crushing is of insufficient quality, the content of oversized pieces increases, the excavation process is complicated, the duration of non-productive time spent on selecting and removing oversized pieces increases, and the costs of transportation and mechanical crushing increase. This leads to a decrease in the productivity of the extraction and loading and transport equipment, increases their downtime during the shift, as well as the costs of repair and maintenance of excavators.

In this regard, the definition of piecemealness is of great importance, since this information is a tool that allows to connect all production processes, to balance them in the direction of minimizing the total cost.

Until recently, there was no alternative to the empirical formulas. These formulas very roughly established the dependence of the granulometric composition of the blasted rocks on the physical properties of the rocks and technological factors.

The study of the influence of various natural and technological factors on the size of the average piece of the blasted rock mass, and therefore on the intensity of crushing, is relevant today. An important factor is establishing the dependence of the granulometric composition of the blasted mining rocks on the physical properties of the rocks and explosives.

Therefore, in order to further improve the efficiency of open-pit mining technology, it is necessary to solve the urgent task of creating a multifactorial model for determining the quality of rock crushing, for example, in the form of the size of the average piece from the characteristics of the massif of rocks, used explosives and their specific costs. And, accordingly, determining the quality of future rock crushing is an important factor for aggregated forecasting of the cost of mining operations. In turn, the solution of this task will help to evaluate the investment attractiveness of deposit development at the pre-project stage.

2. Literature review

Formulas for calculating the parameters of the location of charges from the properties of the mass of rocks and explosives prevail in the literature [1–3]. Leng et al. [4] proposes to carry out drilling and blasting works according to a checkerboard scheme of commutation of charges with a combination of wells with a diameter of 138 and 200 mm, which will ensure the proper quality of rock crushing, provided that the specific consumption of explosives is constant.

Dhekne, Pradhan and Jade [5] describe a method of modeling artificial neural networks for predicting the number of oversized pieces formed as a result of blasting wells of different diameters. It was established that the decrease in the number of oversizes occurred due to the increase in the diameter of the well.

Li et al. [6] consider the problems of low explosion energy utilization rate due to the use of inappropriate blasting materials during blasting. The method of development and testing of a self-inflating material is presented. As a result of field tests, it was established that the quality of rock crushing using a self-inflating hammer improves compared to a hammer made of drill bits.

Based on the Kuz-Ram model, a simulator for predicting rock crushing quality using the Monte-Carlo method was developed by Morin and Ficarazzo [7]. This tool allows you to predict the outcome of blasting, taking into account various factors, such as the properties of rocks and explosives, as well as blasting patterns. The authors believe that the use of Monte-Carlo simulation will improve the efficiency of blasting operations and optimize the economic performance of open-pit mining operations.

In the paper [8], research was carried out on the optimization of blasting parameters using a deep neural network. A model was created for the conditions of the Skhidniy open-pit to establish the relationship between blasting parameters and rock fragmentation and their forecasting. It was established that the neural network, optimized with the help of a genetic algorithm and numerical simulation, has the highest accuracy in predicting the result of blasting operations.

Most textbooks, reference books and articles are dominated by formulas for calculating the parameters of the location of charges from the properties of the mass of rocks and explosives [5,9,10]. At the same time, it is believed that a rational grinding quality will be achieved [11–13], but specific indicators of this quality are not given. There are not enough mathematical formulas in which the characteristics of rocks, explosives and the result of the explosion would be connected at the same time. In works [14,15] the mathematical formula (1) of V. A. Kuznetsov is proposed:

$$d_c = 0.1 \times \left(\frac{(d_e \times \gamma)^{0.5} \times (f \times d)^{0.33}}{q} \right) \le d_e \tag{1}$$

where f is the strength coefficient of rocks according to M. M. Protodeaconov; d_e – the average block size in the array, m; γ – volumetric weight of the rock, t/m^3; d – charge diameter, m; q – specific consumption of explosives, kg/m^3;

Taking into account the specific characteristics of explosives could increase the accuracy of this calculation approach, but their use is not envisaged here.

If we analyze the factor characteristics in the formula of V. A. Kuznetsov, we rightly note that the most influential of them is the specific consumption of explosive, since it is in the first degree. Other factors have a degree much less than one and are mainly the properties of rocks, and even the diameter of the blast hole. There are no properties of explosive, which is probably explained by the fact that the creation of the formula was preceded by many years of work in the conditions of the use of granular explosive, and the accumulated material served as an irreplaceable foundation for this mathematical expression. Attempts to use the given formula in practice show that it is valid for super-strong hard-rock rocks. It should be noted that the formula serves as the basis for creating a classification of explosiveness in the form of a mathematical expression, the main product of which is the size of the average piece, and the detailing is not strictly limited to categories [16–19]. In addition, it can be adapted to the conditions of any specific production and, thus, unlike previously created classifications, it gives a specific answer for deterministic work conditions [20].

Perehudov [21] obtained an empirical formula for calculating the size of the average piece in the blasted rock depending on the specific consumption of the explosive substance q, the volume of the rock detonated by one blast hole charge Q and the strength of the rock f:

$$d_{av} = \beta \times \left(\frac{Q^{1-a}}{q^a}\right) \times \sqrt{\frac{f}{\rho}}, \tag{2}$$

where a, β are empirical coefficients.

Taking into account dependence (2), Perehudov [21] obtained an analytical expression for determining the rational value of the specific consumption of explosive in the following form:

$$q = \beta \times \left(\sqrt{\frac{100 \times f}{\rho}} \times \frac{Q^{1-a}}{d_{av}}\right)^{\frac{1}{a}}. \tag{3}$$

This expression was obtained for the mining and geological conditions of the Pershotravnevy and Hannivsky open-pits of PJSC "Northern Mining and Processing Plant".

Let's consider the peculiarities of the impact on the quality of rock crushing of cracking indicators and physical and mechanical properties of rocks [3, 4, 8, 22].

The influence of fracturing as the main factor in the explosive destruction of a massif of rocks was studied by Yuanjuan [23], Johansson [24], Esen et al. [25]. The results of their research showed, that in general this influence manifests itself in two ways. For this reason, fracturing largely determines, especially in the zone of poorly regulated crushing, the chunkiness and shape of the pieces of the blasted mining mass [26].

V. K. Rubtsov was one of the first who use the blockiness value of the massif to estimate its explosiveness [27]. He also additionally proposed to evaluate the fracturing (explosiveness) of the massif by the content of large fractions in it (0.3, 0.7 and 1.0 m).

However, this characteristic is essentially superfluous, since the fractional composition and the average size of individual units in rock massifs are functionally related. This is confirmed by the research by Wang and Konietzky [28], who showed that the average diameter of individual particles calculated from the fractional composition of individual particles determined as a result of field measurements in the massif coincides with the value of the average distance between cracks.

Based on the results of research by V. K. Rubtsov, a unified classification of rocks by the degree of fracture of rocks for open-pits was developed [27]. It includes 5 categories of rocks that differ in the average diameter of individuals: I – up to 0.1; II – 0.1-0.5; III – 0.5-1.0; IV – 1.0-1.5; V – more than 1.5 m.

A number of laboratory studies, as well as the experience of blasting work in open-pits, determined that maximum crushing of rocks and a flat surface of the slopes are achieved in the case when the chipping is carried out perpendicular to the main system of steeply and subvertically falling cracks (usually layered), that is, perpendicular to the long edge individualities [29]. The most unfavorable situation is when the blasting is carried out at an angle of 45° to the main system of such cracks, while along with the unsatisfactory crushing of the rocks, cuts are formed in the back of the massif along the cracks. Also, horizontal arrangement of cracks of the main system, perpendicular to the axis of blast hole charges, is unfavorable from the point of view of the quality of explosive destruction of the massif [30].

Thus, when carrying out in-situ studies of rock fissures in quarries for the purpose of studying their explosiveness, it is necessary to document the orientation of the cracks, the size and shape of individual parts. The main indicator of fissuring, which is included in the absolute majority of formulas for calculating the specific consumption of explosives and by which classes (categories) of rocks are distinguished by fissuring, is the average size of the elementary structural block (natural separation).

To solve the question of the influence of various factors and characteristics of explosives on the diameter of the average piece in the blasted mining rocks, it is necessary to perform a statistical analysis of experimental data, which will allow obtaining mathematical relationships between these factors and the quality of crushing.

3. Results

In the blasted rock mass after the explosion, pieces of different sizes are formed. The analysis of the results of the explosions indicate that there is a correlation between the sizes of rock pieces after the explosion, the properties of the rock mass and the explosives used for the explosions. Analytically, such a dependence can be written in the form:

$$\bar{d} = f(\bar{D}, f, q, Q, \Delta), \tag{4}$$

where $\bar{d}$ – average size of rock pieces after the explosion, m; $\bar{D}$ – the average size of the block in the rock massif, m; f – rock strength coefficient according to M.M. Protodiakonov; q – specific consumption of explosives, kg/m^3; Q – explosion energy of explosives, kJ/kg; Δ – charging density, kg/m^3.

At the first step of finding dependence (4), we select its structure. Taking into account the characteristics of the explosion and the results of the experiments, we conclude that it is appropriate to choose the structure of formula (4) in multiplicative form:

$$\bar{d} = K \times \bar{D}^{a_1} \times q^{a_2} \times Q^{a_3} \times \Delta^{a_4}, \tag{5}$$

where $K = a + b \times f$; a, b, a_i $(i = 1, \ldots, 4)$ – numerical parameters.

At the second step of finding the dependence (4), we will find the values of the parameters, a, b, a_i $(i = 1, \ldots, 5)$ according to the results of experiments.

First, to simplify the analysis of the obtained results, it is natural to reduce formula (4) to a dimensionless form:

$$d = K \times D^{a_1} \times q^{a_2} \times Q^{a_3} \times \Delta^{a_4}, \tag{6}$$

where $d = \frac{\bar{d}}{d_0}$, $D = \frac{\bar{D}}{D_0}$, $f = \frac{f}{f_0}$, $q = \frac{q}{q_0}$, $Q = \frac{Q}{Q_0}$, $\Delta = \frac{\Delta}{\Delta_0}, K = a \times (1 + c \times f)$, $c = \frac{b}{a}$.

Value $d_0, D_0, f_0, q_0, Q_0, \Delta_0$ can be called basic, have meaningful units of measurement, and are determined by analyzing the statistical results of experiments. To facilitate finding parameter values a, b, a_i $(i = 1, \ldots, 5)$ prologarithm (3), which will give:

$$\ln d = \ln(1 + c \times f) + \ln a + a_1 \ln D + a_2 \ln q + a_3 \ln Q + a_4 \ln \Delta, \tag{7}$$

Taking into account the peculiarities of the occurrence of parameters in (7) for the purpose of applying linear regression analysis, it is advisable to transform (7) into the form:

$$y = a_0 + \sum_{i=1}^{4} a_i \cdot x_i, \tag{8}$$

where $y = \ln\left(\frac{d}{1+c\times f}\right)$, $a_0 = \ln a$, $x_1 = \ln D$, $x_2 = \ln q$, $x_3 = \ln Q$, $x_4 = \ln \Delta$.

Parameters $a, a_i (i = 1, \ldots, 5)$ we will find with the help of linear regression analysis, but to find the value of c, and, therefore, b, it is necessary to use non-linear search methods. In the future, we add the sum of the squares of the deviations of the values obtained as a result of experiments from those calculated according to formula (8) and get:

$$F(a_0, a_1, a_2, a_3, a_4, c) = \sum_{k=1}^{n} \left(y_k - a_0 - \sum_{i=1}^{4} a_i \cdot x_{ik} \right)^2, \tag{9}$$

where $y_k = \ln\left(\frac{d_k}{1+c\times f_k}\right)$, $x_{1k} = \ln D_k$, $x_{2k} = \ln q_k$, $x_{3k} = \ln Q_k$, $x_{4k} = \ln \Delta_k$, $d_k = \frac{\bar{d}_k}{d_0}$, $D_k = \frac{\bar{D}_k}{D_0}$, $f_k = \frac{\bar{f}_k}{f_0}$, $q_k = \frac{\bar{q}_k}{q_0}$, $Q_k = \frac{\bar{Q}_k}{Q_0}$, $\Delta_k = \frac{\bar{\Delta}_k}{\Delta_0}$.

Thus, the task of finding parameter values is reduced to the minimization of function (7).

$$F(a_0, a_1, a_2, a_3, a_4, c) \to \min_{a_0, a_1, a_2, a_3, a_4, c}. \tag{10}$$

Taking into account the structure of function (10), the algorithm of conditional minimization of this function is implemented, taking into account the parameter c according to the parameters $a_i (i = 0, \ldots, 4)$. The parameter c is chosen in such a way as to minimize (9), but with explosives hiding the physical meaning of the parameters being sought. We emphasize that the parameters $a_i (i = 1, \ldots, 4)$ indicate the rate of relative change in the average size of a piece of rock $\bar{d}$ from the relative change of values $\bar{D}, q, Q$ and Δ, respectively. Indeed, calculating the partial derivatives, we have:

$$\frac{\partial \bar{d}}{\partial \bar{D}} \times \frac{\bar{D}}{\bar{d}} = a_1, \quad \frac{\partial \bar{d}}{\partial q} \times \frac{q}{\bar{d}} = a_2, \quad \frac{\partial \bar{d}}{\partial Q} \times \frac{Q}{\bar{d}} = a_3, \quad \frac{\partial \bar{d}}{\partial \Delta} \times \frac{\Delta}{\bar{d}} = a_4. \tag{11}$$

At the same time, the rate of relative change in the average size of a piece of rock $\bar{d}$ from the relative change in size f has a more complex form, which is caused by the requirement of physical content, and is calculated by the formula:

$$\frac{\partial \bar{d}}{\partial f} \times \frac{f}{\bar{d}} = \frac{c \times f}{1 + c \times f}. \tag{12}$$

Expressions (11) and (12) make it possible to determine the limits on these values, which would correspond to the physical content of the found parameters.

Parameters found $c, a_i (i = 0, \ldots, 4)$ we will check their significance using statistical methods, in particular, testing the hypothesis that they are not equal to zero. For this, we will use the Student distribution. First, we calculate the parameter statistics a_i:

$$t_i = \frac{|a_i|}{s_{a_i}}, \tag{13}$$

where s_{a_i} – the standard deviation of the parameter a_i.

Next, according to the selected level of significance α and the number of degrees of freedom k according to the Student's distribution table, we find $t_{\alpha,k}$. If $t_i \geq t_{\alpha,k}$ is fulfilled, it is considered to be at the level of significance α that the parameter is $a_i \neq 0$. To check the adequacy of the found formula to the results of the experiments, we will use dispersion analysis, for which we will check the significance of the multiple correlation coefficient using the Fisher test, calculating statistics:

$$F = \frac{(n-l-1)}{l} \times \frac{r^2_{y.x_1x_2\ldots x_l}}{1 - r^2_{y.x_1x_2\ldots x_l}}, \tag{14}$$

where n – sample size, l – number of independent variables, $r_{y.x_1x_2\ldots x_l}$ – multiple correlation coefficient.

Next, according to the Fisher distribution table for the selected level of significance α, we find the value $F_\alpha(l, n-l-1)$. If there is an inequality $F > F_\alpha(l, n-l-1)$, then with probability $1-\alpha$ it can be stated that there is a dependence between y and variables $x_1, x_2, \ldots, x_l$. The results of series of experimental explosions in open-pits are summarized in table 1.

Table 1. The results of experimental explosions on the study of the size of pieces of rock from the properties of the rock mass and explosives.

Table 2 summarizes the coded values of the results of the experiments according to formula (6). We present the basic values of the quantities according to one of the experiments: $d_0 = 0.25$ m, $D_0 = 1$ m, $f_0 = 14$, $q_0 = 1.195\,\text{kg/m}^3$, $Q_0 = 3220\,\text{kJ/kg}$, $\Delta_0 = 1210\,\text{kg/m}^3$.

After logarithmizing the coded results of experiments on the size of rock pieces from the properties of the rock mass and explosives, we get an array of numbers for statistical processing of which it is advisable to use the "LINEAR" function, which is part of the "Function Master" of the Microsoft Excel program. The results of such calculations are shown in table 3. The last column of table 3 shows the values of the final error when the experimental results are approximated by the function (8).

19	1.456	1.6	1.428571	1.307113	1	1

Table 3. Results of finding the minimum of function (6) by parameter c.

c	a_0	a_1	a_2	a_3	a_4	S_{fin}
0.7	-0.526	0.658	-0.344	-0.645	0.392	$1.28 \cdot 10^{-3}$
0.8	-0.585	0.661	-0.409	-0.661	0.369	$9.23 \cdot 10^{-4}$
0.9	-0.643	0.657	-0.453	-0.724	0.288	$8.90 \cdot 10^{-4}$
1	-0.692	0.662	-0.489	-0.687	0.334	$9.30 \cdot 10^{-4}$
1.1	-0.742	0.662	-0.513	-0.697	0.32	$1.06 \cdot 10^{-3}$
1.2	-0.789	0.661	-0.528	-0.706	0.308	$1.19 \cdot 10^{-3}$

The analysis of table 3 allows us to conclude that the optimal value is the $c_{\text{opt}} = 0.9$. Thus, the optimal values of the parameters have been established: $a_0 = -0.643$, $a_1 = 0.657$, $a_2 = -0.453$, $a_3 = -0.724$, $a_4 = 0.288$, $c = 0.9$.

To check the significance of the found parameters, we will use the Student's criterion. According to the calculations, the standard deviations for the found parameter values are as follows: $s_{a_0} = 0.002038$, $s_{a_1} = 0.00696$, $s_{a_2} = 0.0148$, $s_{a_3} = 0.0876$, $s_{a_4} = 0.112$.

We calculate the value of statistics according to formula (12): $t_0 = \frac{|a_0|}{s_{a_0}} = \frac{0.0643}{0.002038} = 31.55$, $t_1 = \frac{|a_1|}{s_{a_1}} = \frac{0.657}{0.00696} = 94.4$, $t_2 = \frac{|a_2|}{s_{a_2}} = \frac{0.453}{0.0148} = 30.61$, $t_3 = \frac{|a_3|}{s_{a_3}} = \frac{0.724}{0.0876} = 8.26$, $t_4 = \frac{|a_4|}{s_{a_4}} = \frac{0.288}{0.112} = 2.57$.

Using the Student's distribution table, we find the critical value for the level of significance $\alpha = 0.01$ and the number of degrees of freedom $k = 25$, $t_{0.01;25} = 2.787$. Given that $t_i > t_{0.01;25}$

Table 4. Calculation of the average size of a piece in the crushed rocks mass by an explosion depending on the specific consumption of the explosive substance.

f	D_{av}, m	$0.8q$	$0.9q$	q	$1.1q$	$1.2q$	$0.8d_{\text{av}}$	$0.9d_{\text{av}}$	d_{av}	$1.1d_{\text{av}}$	$1.2d_{\text{av}}$
6	0.2	0.51	0.57	0.63	0.69	0.75	0.06	0.06	0.05	0.04	0.04
8	0.4	0.62	0.71	0.78	0.85	0.93	0.11	0.1	0.09	0.08	0.07
10	0.6	0.74	0.84	0.93	1.02	1.11	0.15	0.13	0.12	0.11	0.1
12	0.8	0.85	0.95	1.06	1.16	1.27	0.19	0.17	0.15	0.14	0.13
14	1.0	0.95	1.07	1.19	1.30	1.42	0.23	0.21	0.19	0.17	0.15
16	1.2	1.06	1.18	1.32	1.45	1.58	0.27	0.24	0.22	0.20	0.18
18	1.4	1.15	1.29	1.44	1.58	1.72	0.32	0.28	0.25	0.23	0.21
20	1.6	1.25	1.40	1.56	1.71	1.87	0.36	0.32	0.28	0.26	0.24

($i = 0, \ldots, 4$), we conclude that the found values of the parameters are significant at the level of $\alpha = 0.01$.

Adequacy of the found formula to the results of experiments is checked by the significance of the multiple correlation coefficient using the Fisher test. We calculate statistics according to formula (13), using the result of calculating the multiple correlation coefficient $r^2_{y.x_1x_2\ldots x_5} = 0.999$.

Using the Fisher distribution table with equal significance $\alpha = 0.01$ and the number of degrees of freedom $k_1 = 6$ and $k_1 = 24$, we find $F_{0.01}(6, 24) = 3.67$. Considering that $F > F_{0.01}(6, 24)$, we conclude that with probability $1 - \alpha = 0.99$ there is a dependence between y and variables $x_1, x_2, \ldots, x_5$.

Thus, formula (6) takes the form:

$$\frac{\bar{d}}{0.25} = (0.526 + 0.473 \times f) \times \left(\frac{\bar{D}}{1}\right)^{0.657} \times \left(\frac{q}{1.195}\right)^{-0.453} \times \left(\frac{Q}{3220}\right)^{-0.724} \times \left(\frac{\Delta}{1210}\right)^{0.288} \tag{15}$$

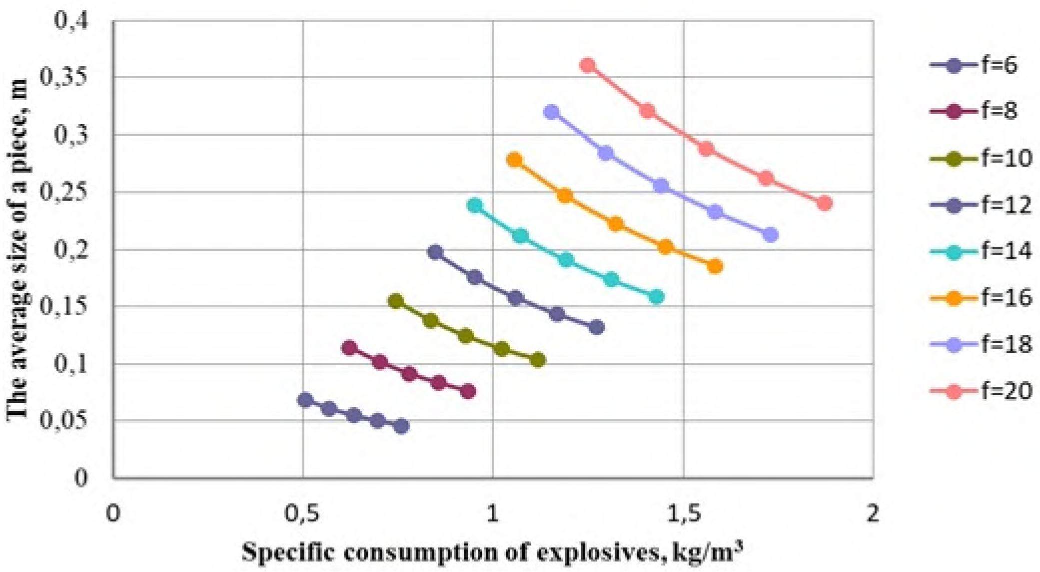

Figure 1. Graphs of the dependence of the size of the average piece on the specific consumption of explosives.

This formula makes it possible to obtain dependences of the size of the average piece in a specific rock that is in the classification [31] or between the boundaries of its categories.

Let's calculate the value of the size of the average piece for rocks with different strength f according to the scale of M. M. Protodyakonov, based on the above-mentioned classification of rocks by blasting in table 4. As one of the main factors, we take the specific consumption of the explosive substance. We take the explosion energy Q and charge density Δ as 3220 kJ/kg and 1210 kg/m^3 (anemix-70), respectively. The average distance between the cracks D_{av} is taken according to the classification. Let's calculate its value by 20 and 10% in the direction of growth and 10 and 20% in the direction of decrease from the reference value of the specific consumption given in the classification.

In figure 1 shows the dependence of the average piece size on the specific consumption of explosives for different rock strengths, which makes it possible to predict the quality of rock crushing at the design stage of mass explosions in open-pits with different properties.

On the basis of the classification of rocks by blasting, we will establish the dependence of the expected size of the average piece in the collapse on the blockiness of the massif. To do this, we

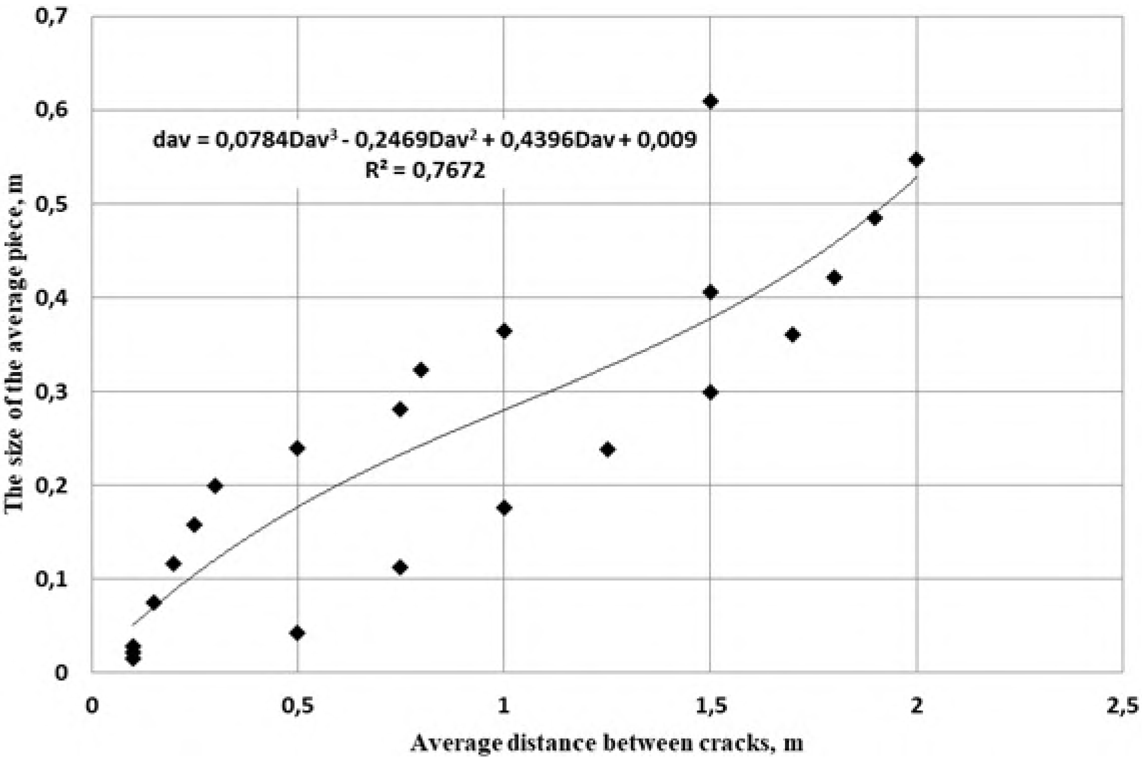

Figure 2. Graph of the dependence of the size of the average piece on the average distance between cracks in the massif of rocks.

will use the classification data and form a data array (table 5) and visualize it in figure 2.

With the help of regression-correlation analysis, the dependence with the largest correlation ratio was obtained, which is described by a polynomial of the third degree.

4. Conclusions

A general formula was obtained for calculating the average size of a piece of blasted rocks depending on the properties of the rocks, their blockiness, the used explosives and its specific consumption. The specified formula can be used to calculate the average size of a piece of rock with any physical properties and various blasting conditions. Also, with the help of regression-correlation analysis, the dependence of the expected size of the average piece of crushed blasted rocks on the blockiness of the rocks was established.

The results of scientific research can be used for large-scale forecasting of the cost of extracting a mineral. Also, the application of the proposed approach will help to assess the investment attractiveness of deposit development at the pre-project stage.

Abstract. The article presents a toolkit of manage balanced functioning of the fuel and energy complex with the aim of improving the system of state support for coal mines and harmonizing the interests of the enterprise, national interests, and interests of product consumers. To solve the problem, a comprehensive approach was used, which includes the assessment of the investment attractiveness of the enterprise, the determination of the production potential, and the determination of the possibility of transition to the break-even mode. The process of planning ways of saving the industrial potential of coal-producing regions can be considered as a reflection of a multidimensional space (initial and design values) into a one-dimensional (the amount of investment funds). The reduced task to the selection of the smallest number of factors that would most adequately reflect the internal potential of mine in terms of economic added value – as a result of the interaction factors of economic activity of coal mine. The scientific novelty lies in the fact that the formed matrix model of the commercial coal products balance is aimed at avoiding an imbalance in the sectoral coal market and significantly reducing unjustified costs both on the part of the state and on the part of mining enterprises due to the optimization of planned and forecast indicators. The practical significance lies in conducting an actual assessment of coal enterprises state of Ukraine and determining break-even limits, which made it possible to formulate recommendations for attracting volumes of financial resources.

1. Introduction

The energy industry of Ukraine directly depends on the coal industry, as basis of the country's industrial development [1, 2]. It is based on the principles of energy saving and effective use of all available energy resources [3]. Despite the recent world trends of decarbonization [4–7], the coal industry in Ukraine is the main, core, city-forming one and, despite the decline in prestige, remains one of the main industrial branch.

One of the main directions of the task implementation of improving the reliable operation of coal mines is not only improvement of coal mining technology [8] and develop workings, but also the development of a tool for managing and planning the production potential of coal mining enterprises.

Amosha, Shemiakina and Ponomarenko [9], Cherevatskiy and Volchin [10] developed practical recommendations to substantiate the rational level of production for unprofitable mines of the Central District of Donbas, and the degree of intensity of use of fixed capacities was also determined. In addition, these approaches allow not only to develop recommendations, but also to make long-term forecasts. Therefore, in order to stabilize the state of the industry, it is necessary to conduct an analysis of the balance between labor resources, involved capital and the final level of production – the application of existing criteria generally accepted in the world economy allows solving the problems of effective development of mineral deposits. The logic of these assumptions is explained by the presence of rational design area [9], that is, regardless of the mining and geological conditions of the deposit and the existing technical and economic indicators, there is always a set of parameters that allow to reach the break-even level, that is, to choose a rational format of life activity [11].

Nieć [12] states that in order to increase production efficiency, it is necessary to balance the flows of input and output resources depending on the production scenario. On the basis of a retrospective analysis of the state of the industry, Li et al. [13] made an assumption that currently the industry cannot be brought out of a crisis state without attracting investment. At the same time, further delay will lead to stagnation, the transition from "stable decline" to the uncontrolled curtailment of production capacities, so it is necessary to develop mechanisms for assessing the expediency of supporting coal mines [14].

Numerous scientific studies are devoted to the problems of the functioning of the coal industry in the conditions of the formation of a market economy. In particular, ways of increasing the efficiency of the industry management system [15], innovative and investment mechanisms [16], means of reducing the unprofitability of state mines [17], etc. were considered. On the basis of the research results, it is possible to form a general scheme of the economic mechanism for supporting the capacity of coal industry enterprises, one of the components of which is the budget subsidy subsystem. In the studies of Ukraine economists, a mechanism was developed for quantitative assessment of the condition of each mine from the point of view of investment attractiveness. The impracticality of mass closure of mines without appropriate social means has also been proven.

However, in modern conditions, along with the study of certain aspects of coal mining, the study of the mechanism of revitalization of the potential of the industry, disrupted by the instability in the eastern regions of Donbas, is of particular relevance. One of the priority measures today is the normalization of the price policy in relation to competition with natural gas, the identification of objects of investment, in order to ensure the expanded reproduction of the potential of the coal industry. Some aspects of this problem are outlined in this paper.

Based on the above, the purpose of this work is to develop a tool for management and planning of the fuel and energy complex, taking into account the production potential of coal mining enterprises of Ukraine.

2. Results and discussion

To solve the problem, a complex approach is applied, which is based on the implementation of the neoclassical production function in the form of the Solow model for the analysis of the state in the coal mining industry, as well as the assessment of the economic reliability coefficient for the development of a tool for the management and planning of the energy complex, taking into account the production potential of coal mining enterprises of Ukraine.

The efficiency of the operation of the enterprise can be estimated by the ratio of incoming flows (capital) and outgoing (level of production) resources, while the innovative component plays a significant role. Analysis of the relationships between resource flows allows choosing optimal scenarios.

The relationship between the balance models of all levels of management is especially important, regardless of the "planned" or "market" orientation of coal mining enterprises.

The formed matrix model of commercial coal products balance is aimed at avoiding an imbalance in the sectoral coal market and significantly reducing unjustified costs both on the part of the state and on the part of mining enterprises due to the optimization of planned and forecast indicators.

It has been proven [18] that coal remains virtually the only available and relatively reliable energy source in Ukraine. In particular, in the Energy Strategy of Ukraine for the period until 2030, the country's coal industry, despite the difficult geological conditions, outdated material and technical base and growing unprofitability, is recognized as the foundation of the domestic energy industry. But the presence of 5-7 billion tons of economic reserves, which lie in extremely difficult conditions, is not yet a reason for optimism. In Europe, mines with layers occurrence and production conditions approaching Ukrainian ones have long been closed. That is why it is necessary to improve the budget policy management system to reduce the level of unprofitability of state mines, methods of targeted investment to support the capacity of enterprises depending on their rating, the state of mining industry, the quality and volume of remaining reserves.

Without the liberalization of the coal market, it is quite difficult to establish a system of supporting the capacity of the mining fund, since the cost of production is significantly higher than the market price. An exception can be only vertically integrated companies that receive the main profit not from mined coal, but from the result of its use – electricity or metal [19]. As you know, the main problem of improving the structure of the mine fund of the industry has not been solved due to untimely and insufficient financing of support for each ton of the installed mine capacity. In addition, until now, a clear concept of regulating the productive flows of coal mines in terms of the sale of finished coal products has not been created. In the new conditions of the formation of the economy of Ukraine through integration into the world community, the level of unprofitability of coal enterprises due to price management, the excess of the cost price over the price and the amount of subsidies should correspond to the following expression [20,21]:

$$\mathbf{F} = P + S + G \to \min \tag{1}$$

where: P – sale price of mined coal; S – the need to subsidize 1 ton; G – subsidy opportunities of the mine owner.

Since all terms in expression (1) are positive, minimizing the sum means minimizing each term. The minimization of the first term P is equivalent to the reduction of prices to the minimum permissible value. The minimization of the second term S means the maximum satisfaction of subsidy applications associated with the excess of cost over price. In particular, if all subsidy applications are fulfilled, then the term S acquires its minimum value equal to zero. The minimization of the third term G leads to a decrease in the amount of subsidies. At the same time, all components in expression (1) are independent and their minimization realizes opposite tendencies. Indeed, the decrease of the first term P, i.e. the price of products, is accompanied by an increase in the amount of subsidies and the underfulfillment of subsidy applications, therefore, an increase in the terms S and G. A decrease in the second term S means the maximum fulfillment of subsidy applications, which leads to an increase in the amount of subsidies to the price, i.e. an increase in the terms P and G. A decrease in the third term G – the amount of subsidies – is accompanied by a worse satisfaction of subsidy applications, which causes an increase in the price. The comparative value of the coefficients of the objective function should reflect the balance of the influence of these opposing tendencies.

Such a mechanism is designed to prevent the spread of a vicious system – the greater the losses of the mine, the more subsidies from the state. In other words, it allows to determine the mine's potential of production. At the same time, in the management system of the mine's potential, the interests of the enterprise, national interests, and the interests of product consumers are coordinated. When modeling such a system, the interest of the enterprise is expressed in the target function, and the national interest is expressed in the system of restrictions on the production and sale of certain grades of coal.

Unfortunately, the old economic system of attracting and distributing additional resources from above depending on the change in the level of planned indicators has been preserved in the coal industry. Such a balance model, by itself, is inert to prices. At any price (planned, calculated, optimal, market), its calculation parameters do not change. This made it possible to use estimated prices (including planned ones), so inter-industry proportions were not supported by prices, but artificially, for example, by the planned distribution system. For such a system, prices always remain an external element. At the level of local production systems, the imbalance of different types of prices (figure 1), the presence of the division of the industry into "conditional-planned" and market, leads to the existence of a certain number of producers of commodity products, whose local optima (interests) come into conflict with the global optimum (nationwide interest)

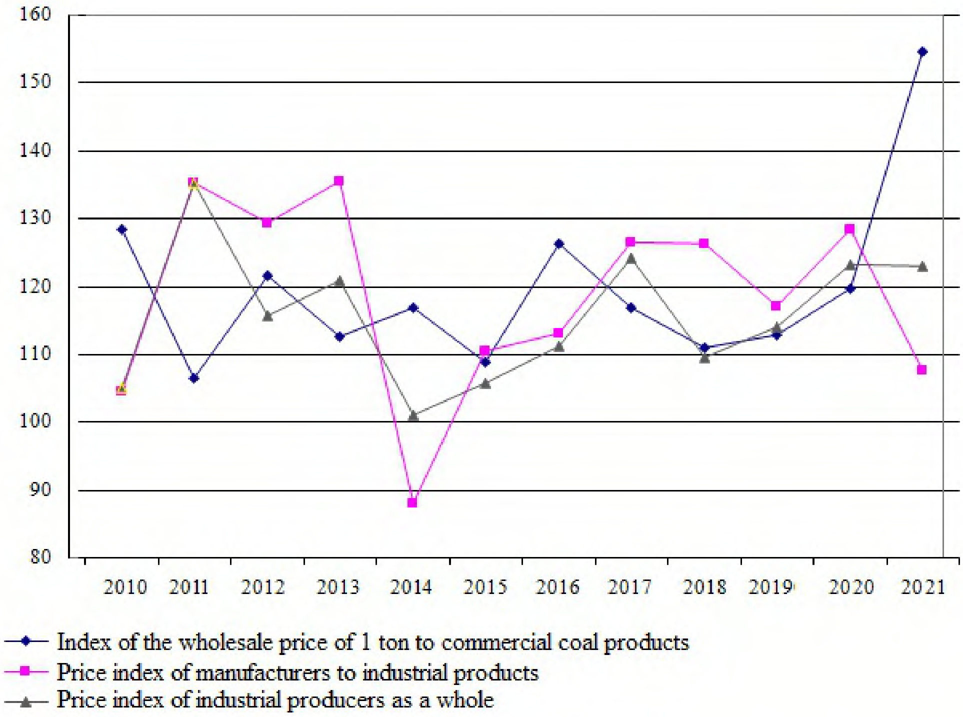

Figure 1. Imbalance of price indicators of producers of commercial coal product.

Thus, ratio (1) is economically interpreted as follows: the optimal volume of production at an individual enterprise based on its orientation to market prices is achieved when marginal variable costs are equal to market prices. If prices do not change, these production volumes provide the maximum profit for the enterprise. That is, it is once again confirmed that it is the market prices that are the regulator of the balanced development of the coal enterprise. The matrix models of the balance of commercial coal products formed on the basis of this are aimed at avoiding imbalances in the sectoral coal market and significantly reducing unjustified costs both on the part of the state and on the part of unprofitable coal mines due to the optimization of planned and forecast indicators. Therefore, when drawing up a carbon balance, the existence of such phenomena should be taken into account. Of course, it is necessary to fight them at the legislative level, but, as practice shows, on currently this struggle is not effective. Therefore, the first necessary step for the formation of an optimal balance model is the determination of all participants in the coal market, the actual volumes of coal production, as well as the schemes according to which it is distributed for consumption [22, 23].

The basis for determining the quantitative indicators of production and consumption of commodity products of enterprises of a separate industry is the forecast balance (matrix) model (figure 2), which includes the final output of all production units of the industry (II quadrant), costs of its production (I quadrant) and total income (III quadrant), which includes the sum of wages and net income of all enterprises in the industry. Quadrant IV of the balance is located at the intersection of the final output columns and the income rows, and it reflects the final distribution and use of the total income of the industry. At the same time, the term "final" refers to products that enter the sphere of production into the sphere of final use – for consumption, accumulation, and export.

Manufacturers	Consumers				Final production	Gross production
	1	2	…	In total		
1.	x_{11}	x_{12}	…	x_{1n}	Y_1	X_1
2.	x_{21}		$\boxed{\mathrm{I}}$		$\boxed{\mathrm{II}}$	X_2
…	x_{n1}	x_{n1}	…	x_{nm}		X_3
In total	$\Sigma\ \ \Sigma x_{ij}$					
Import					Y_n	… X_n
Pay	V_1	V_2	…	V_n	V_k	
Net profit			$\boxed{\mathrm{III}}$		$\boxed{\mathrm{VI}}$	
	m_1	m_2	…	m_n	m_k	
Gross production	X_1	X_2	…	X_n		X

Figure 2. Typical balanced (matrix) model.

Such a model was named the main task of production planning and allows the process of optimization calculations and analysis of optimal solutions to be divided into three stages:

(i) finding the best production methods and minimum labor costs for a given vector of final products based on the model;
(ii) determination of the volume and structure of the variable part of the final product (it is possible to use different criteria and maximization conditions);
(iii) calculation of a balanced production plan that ensures the production of all final products with limited resources.

Under these conditions, it is reasonable to use the upper and lower limits of the mine capacity and variable consumer demand. The essence of the approach is as follows. The specified values D_i^{min} and D_i^{max}, which correspond to the lower and upper limits of the production capacity of the mines. Values $b_j (j = 1, 2, \ldots, n)$ determine the probable volumes of consumption of finished coal products in the j–th points, C_{ij} – revenue from the sale of 1 ton of products, taking into account fluctuations in the level of prices, demand and the amount of budget subsidies; X_{ij} – number of units of products delivered from the mine (factory) from point i to point j. It is necessary to find a nomenclature of placement of production capacities in a specific coal mining region so that the economic potential of the mines does not decrease.

Mathematical formulation of the problem. Find the set Xij to maximize the functional F

$$\mathbf{D}_i^{min} \leq D_i^{max} (i = 1, 2, ...m) \tag{2}$$

$$\sum_{i=1}^{m} X_{ij} \neq b_j (j = 1, 2, ...m) \tag{3}$$

$$\sum_{i=1}^{m} D_i^{min} = \sum_{j=1}^{n} b_j \geq D_i^{max} \tag{4}$$

$$\mathbf{F} = \sum_{i=1}^{m} \sum_{j=1}^{n} CijXij \to \max \tag{5}$$

We consider it expedient to solve this expression as an open optimization model with limited bandwidths of suppliers (mines) and stochastic values of the parameter C_{ij}. Moreover, determining the optimal values of the sought production volumes X_j is not the main task. More important are the answers to the questions about the impact on the efficiency of the mine of each of the resources used, as well as the technical and economic parameters that form the potential of the enterprise in terms of prices and reducing the degree of unprofitability. It should be emphasized once again that the degree of utilization of production resources of mines is so inefficient that the shadow price of these resources cannot in any way correspond to their real value, as laid down in the duality limit theorems [24].

If we assume that the coefficients in the expression for the objective function are random values, then the values of all controlled variables X_j are determined in the absence of information about what values the parameters of the functional C_j will actually take. Such a situation in real conditions occurs when solving the task of planning the operation of mines, when future sales prices, which depend on poorly predictable changes in demand and the future cost of materials and energy at the time of developing the plan, are strictly unknown.

The obtained results do not contradict numerous studies in this field. Therefore, the developed tool for management and planning of the fuel and energy complex, taking into account the production potential of coal mining enterprises of Ukraine, is appropriate.

3. Conclusions

Until now, the approach to the quantitative description and consideration of socio-political factors, strategy and tactics of economic activity in the coal industry is implemented within the traditional scheme of inter-industry balance. In particular, in macroeconomic models, the variables characterizing the economic activity of the state are usually classified as exogenous, and the scenario blocks that form a set of exogenous variables are postulated or justified by political hypotheses.

The degree of unprofitability and the level of unprofitable state subsidization mines should be determined in such a way that the minimization of the price of coal products is built in parallel with the maximum satisfaction of subsidy applications for the tariff agreement and the excess of the cost price over the price. This achieves an appropriate balance of prices depending on the priority of mines in terms of coal quality and the level of economic reliability of the enterprise.

The relationship between the balance models of all levels of management is especially important, regardless of the “planned” or “market” orientation of coal mining enterprises. The formed matrix model of the balance of commercial coal products is aimed at avoiding an imbalance in the sectoral coal market and significantly reducing unjustified costs both on the part of the state and on the part of mining enterprises due to the optimization of planned and forecast indicators.

Abstract. In recent years, there has been a development and popularization of conducting mine surveys through remote methods. This is a result of the continuous development of the mining industry, where projects are becoming increasingly complex. Therefore, the application of remote surveying is expected to grow rapidly in the coming years. In the future, UAV (Unmanned Aerial Vehicle) technology, satellite imagery, and LiDAR surveying can completely transform the measurement life cycle in mining enterprises. The conducted research helped justify the best instruments for mine surveying and the software for processing field results, which were used in practical experiments. Measurements of mining volumes were carried out using the selected instruments and software, and the results obtained were compared with the reference values. The conducted work allowed for the evaluation of the possibility of using UAVs for mine surveying and determining the optimal choice of instruments and software for conducting such activities.

1. Introduction

Currently, aerial surveying is the most cost-effective and relevant method for geodetic monitoring of large territories. Unmanned technologies have firmly established themselves as tools for engineering tasks in the field of geodesy. The evolution of constructive innovations, reduction in size and form changes, and varying equipment configurations have led to the classification of Unmanned Aerial Vehicles (UAVs) [1]. Diverse measurement methods have emerged depending on the type of task execution. The evolution of UAV usage has touched nearly all areas of engineering, from measuring linear objects to dendrological studies of forest masses. Consequently, the widespread adoption of unmanned technology, particularly in geodesy, could not bypass mine surveying.

Mine surveying equipment for mining operations is a labour-intensive process requiring highly qualified personnel, expensive equipment, and specialized software. During open-pit mining, various mine surveying tasks need to be addressed, including monitoring work progress and mapping assessments of mining volumes and dumps. Unmanned technologies are indispensable for capturing various types of mining activities. They allow mine surveying tasks to be performed with minimal fieldwork costs, although specific skills and knowledge are required for the post-processing of acquired data.

In the future, UAV, satellite, and LiDAR surveying technologies will be capable of completely transforming the measurement life cycle in mining enterprises. Photo and video materials, along with 3D models created based on them, enable the determination of production scale, tracking and conducting measurement work, monitoring the progress of work, and updating information in real time.

Utilizing unmanned aerial vehicles to address geodetic tasks will allow for a broader range of tasks to be completed in shorter periods with less risk for the operators. Many urgent geodetic tasks exist today, but they often require excessive time. This can be associated with the volume of work or the inaccessibility of the object. Using UAVs during field topographic-geodetic research significantly reduces the time and cost of such work.

One of the main drawbacks of remote sensing is the influence of weather conditions and the presence of restrictive objects near the shooting area. However, these issues can be mitigated. For example, shooting can be conducted during weather conditions that minimally affect the process, and limits for shooting can be established for each device. Based on the above, it can be concluded that by considering all factors affecting the shooting process, optimal conditions for conducting the surveys can be selected.

Considering the above, the application of UAVs will increase the efficiency of mine surveying. Therefore, our research focuses on determining the feasibility of using UAVs for mine surveying and selecting optimal equipment and software for these tasks.

The research holds significant value in modernising the process of conducting mine surveying through open methods. Just a few years ago, the most effective way to obtain contours and terrain data was through the use of digital photogrammetric stations (DPS). These systems automated the processes of internal and external image orientation and the creation of digital terrain models.

Today, software solutions such as Pix4D, Reality Capture, Photoscan, and others are designed to generate three-dimensional models using photogrammetric methods efficiently. These programs have become particularly popular with the advent of accessible UAVs, allowing for rapid and effective aerial surveying.

Implementing this innovation significantly accelerates and enhances the safety of the mine surveying process. To achieve the best results, selecting suitable instruments for surveying and software for processing is essential, ensuring the highest accuracy in the results. Considering those as mentioned earlier, it was decided to conduct this research.

The research aims to study the feasibility of using UAVs for mine surveying and determine the instrumentation and software for fieldwork processing that can provide more accurate results.

2. Theoretical background

In recent years, the need for terrain information in many industries has no longer been satisfied solely by the use of topographic maps in analogue and digital formats. Detailed information about objects' spatial position and heights is required to address various engineering tasks.

Cartographic materials, aerial and satellite images, and field survey data serve as sources for modelling digital terrain models [2]. Andreev and Zhilin stated that UAV aerial surveying offers numerous advantages compared to obtaining data through satellite imagery and piloted atmospheric aircraft. The key prerequisites for these advantages include the operational acquisition of aerial images, the ability to capture images from low altitudes, and the capability to operate in emergency zones without risking the lives and health of pilots [3].

Using UAVs in mining has two main advantages. Firstly, it is the time it takes to perform fieldwork and the ability to conduct remote operations. Secondly, UAVs equipped with various types of sensors can quickly survey an area, both in emergency situations and when detecting potential hazards [4].

Li and Choi classified the applications of drones in the mining industry, including open-pit mining and underground and abandoned mines, as shown in table 1 [5]. One method of surveying using UAVs involves the use of additional equipment such as Light Detection and Ranging (LiDAR). The technology of conducting surveys with this device is described in the work of Staroverov and Gaykin. The operation principle of the LiDAR system is similar to radar. LiDAR emits laser beams that reflect off the ground objects. The instrument measures the time intervals between the emission and return of the signal, determining the length of the path travelled by the beams [6].

Table 1. Applications of UAVs in mining [5].

Open-pit mining	Underground mine	Abandoned mines
• Mine surveying • 3D mapping • Slope stability • Construction monitoring • Asset management	• Geotechnical characterization • Rock size distribution • Gas detection • Mine rescue	• Settlement monitoring • Reclamation • Landscape mapping • Gas storage detection • Acid drainage monitoring

Jarahizade and Salehi conducted a comparison of software for processing UAV data. Specifically, they evaluated the use of Agisoft Metashape, Pix4d, and DJI Terra for processing drone-based forest mapping. According to their research, specific software is recommended for achieving certain results [7].

Niederhaeuser et al. conducted a study comparing five sensors and four different software packages for modelling vegetation cover. Their findings revealed that Agisoft and MicMac were the most suitable for their tasks [8].

Berber, Munjy, and Lopez noted that the most popular programs for image processing are Agisoft Metashape and Pix4d [9].

3. Methods

The main research methods include literature analysis, factor analysis, analysis of instruments for performing surveying using UAVs, and analysis of software used in processing field materials. The theoretical part of the work involves studying works related to UAV-based surveying and processing of results in open-pit mining.

To assess the readiness level of surveying services and determine the economic feasibility of using remote surveying equipment, a comparative analysis method was used.

The study employed a systems analysis to evaluate the technical component in the field of surveying and explore ways to improve surveying using UAVs.

The research focuses on the method of economic and practical analysis, modern UAVs for surveying, and software for processing materials obtained after the survey. The factor and situational analysis methods were also used to address potential issues and factors influencing the development of the study.

As of today, obtaining data on the performance of surveying software related to UAV-based surveying is impossible because it requires detailed testing and evaluation. Therefore, the main methods for researching software include analyzing works related to surveying and comparing their functionality. For investigating software, the analysis method was used to explore options for survey processing, the possibility of an automated processing system, and the ability to create a 3D model.

These methods served as the basis for selecting, researching, and comparing instruments for remote surveying and software for processing field results.

Using digital and mathematical modeling methods, the obtained results were processed, allowing for the assessment of the qualitative characteristics of conducting surveying. The data obtained demonstrate the feasibility of introducing innovations into the surveying system, enhancing the productivity and safety of the conducted work. The analytical research in this work shows that the proposed surveying methods contribute to the effective execution of surveying.

Utilizing the mentioned methods, a survey of the mined area of the enterprise was conducted using UAVs. The survey results were processed, and the volumes of the work areas were calculated. A comparison of results obtained using different instruments and software was performed. Based on this comparison, the feasibility of using UAVs for surveying was determined, and the optimal choice of instruments and software for conducting surveying was justified.

4. Results

Modern remote measurement methods allow for obtaining high-quality and objective information about objects and processes on Earth's surface. They are widely applied in various fields, including the oil and gas industry.

Geometrization of deposits is the process of creating digital models of deposit objects used for planning and conducting geological exploration works and deposit development. The use of modern remote measurement methods for the geometrization of deposits allows for:

- Reducing costs for geological exploration.
- Increasing the accuracy and reliability of geological models.
- Expanding the possibilities of geological exploration works.

One of the keys to successful measurements at a mining enterprise is a well-chosen method of measurement execution. Analyzing the purpose and goal of the measurements, determining the final vision of the results, and considering the locality, dimensions, deposit conditions, peculiarities, and financial expenses, it is essential to choose the method of measurement execution.

Today, there are many means of remote measurements. In this work, the main remote methods suitable for the geometrization of deposits were considered, such as:

- Aerial photography.
- 3D scanning (LiDAR).
- Electromagnetic survey.

Each of the methods for conducting remote measurements has functional differences from one another. Therefore, when choosing a specific method for surveying, it is necessary to compare the data of different methods. Several popular methods for remote surface surveying were considered for research, and their advantages and disadvantages were investigated. The list of main advantages and disadvantages is provided in table 2.

According to the data in table 2, it is evident that each method has its own advantages and disadvantages. By comparing the surveying methods, we can conclude that the most significant drawback among the mentioned ones is the limited spatial resolution, which affects the final model and the accuracy of the measurements conducted. This limitation is associated with the Electro Reconnaissance method. Since precision is of great importance in cadastral surveys, the choice for further practical research in this work was Aero-photography and 3D scanning (LIDAR).

Table 2. Comparison of remote measurement methods.

Technology	Aerial photography	3D scanning (LIDAR)	Electrical reconnaissance
Advantages	• Speed; • Clarity of shooting; • Safety of filming	• High accuracy and resolution; • Wide range of measurements; • Ability to collect data; in real-time; • Ability to collect data over long distances.	• Speed; • Availability; • Ability to collect various data
Disadvantages	• Dependence on weather conditions	• Limitation of weather; conditions; • A device for transportation during shooting	• Dependence on weather conditions; • High costs • Limited resolution

With the growing interest in aerial photography using UAVs, the number of announcements from modern digital photogrammetric systems developers about introducing special algorithms and sets of functions for working with geodata in their software products is increasing.

Among the well-known photogrammetric systems, some of the most prominent software products include:

- AgiSoft Metashape;
- Drone Mapper;
- Pix4D.

Each of the presented products for UAV data processing has certain differences, making it challenging to choose specific software. The most popular software for surface survey processing was investigated during the research, and their main advantages and disadvantages were identified. The key pros and cons of each of the mentioned software products are presented in table 3.

Comparing the software based on table 3, it can be concluded that, in general, all products are similar in their characteristics. The comparison revealed a significant drawback in the Drone Mapper software, namely, a limited number of images for processing. The advantages of AgiSoft Metashape and Pix4D include a simple and convenient survey processing interface. Thus, for the research on cadastral survey processing, AgiSoft Metashape and Pix4D are chosen.

In modern conditions, where speed and accuracy in obtaining information are crucial, manual volume calculation methods do not meet the requirements of modern companies. Therefore, modern methods, such as Agisoft Metashape software, are applied. After constructing a digital terrain model with the necessary quality and accuracy, volume calculations can be initiated.

One advantage of Agisoft Metashape software is that volume calculation can be performed directly in the program without using third-party applications. This saves time since there is no need to export the model. The volume calculation principle is similar in both programs and is carried out automatically. To determine the volume, it is necessary to outline the contour of the required figure.

To assess the effectiveness of using UAVs for cadastral surveying, the volume of worked-out rock mass at the Leznikivskyi granite deposit was calculated. The measured contour is shown in figure 1.

Table 3. Comparison of software for processing survey results using UAVs (unmanned aerial vehicles).

Software	AgiSoft Metashape	Drone Mapper	Pix4D
Advantages	• Simple interface; • Automatic recognition of landmarks function; • Survey lity to adjust processing factors of the survey; • Export capability to various file formats;	• Two tabs during operation: "Results" and "Tasks and Processes"; • Informative interface; • Optimized software operation	• Convenient interface; • Automated survey processing; • Support for personal cloud service
Disadvantages	• Lack of prior automatic configuration	• Processing of surveys without coordinate reference is not possible; • Maximum scale 1:2000; • There are limitations on the number of images	• Limited user impact on processing; • Imperfect manual editing; • Georeferencing to landmarks with low accuracy

Figure 1. Contours of the research areas.

During the research, surveying of the worked-out rock mass of the enterprise was performed using each of the proposed devices (Aero-photography and 3D scanning (LIDAR)). After

fieldwork, data processing was carried out using the selected software (AgiSoft Metashape and Pix4D), meaning each survey was processed in both programs.

To assess the accuracy of volume calculations obtained from processing data of aerial photography with UAV and LIDAR, it is necessary to compare the results with the reference values indicated in the table (table 4). The reference value chosen is the volume of the worked-out rock mass obtained based on the execution of the theodolite survey.

According to the data in table 4, we can conclude that the obtained values are quite close. Based on the results in table 4, the error (in %) from the reference value was calculated and is presented in table 5.

Based on table 5, we can conclude that all four variants of cadastral surveying can be recommended. Since the maximum error is 3.4 percent, which is an acceptable value, and

Table 6. Average error values for different calculation methods.

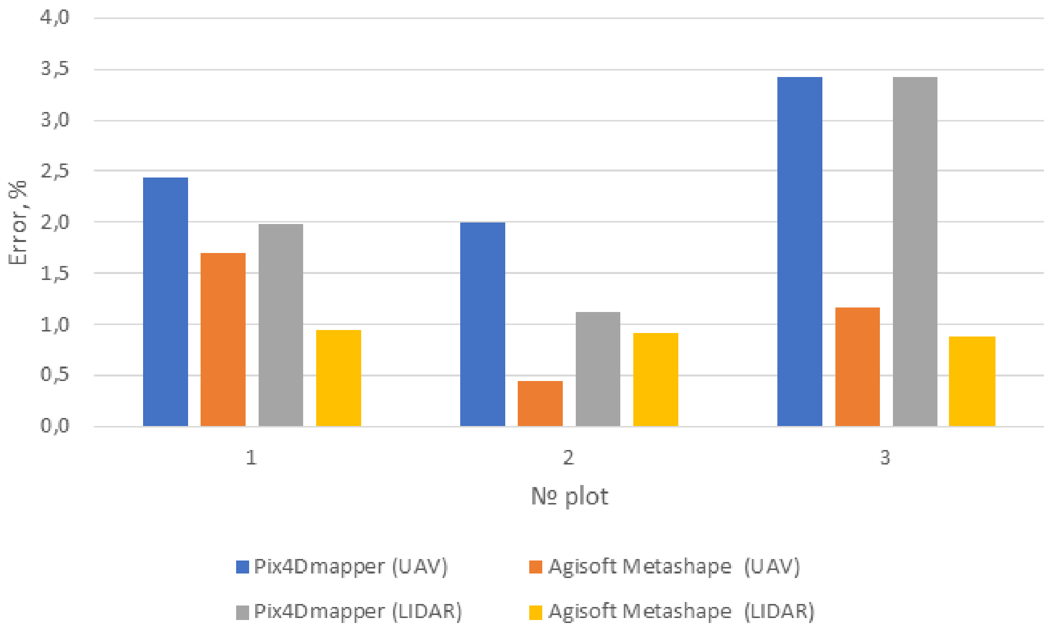

Figure 2. Comparison of errors.

the maximum error does not exceed 15 percent [10].

The table data is used to compare errors by plots and calculation methods, as depicted in figure 2.

Based on figure 2, we can conclude that the smallest error occurs when surveying with LIDAR and processing the data with Agisoft Metashape. Considering this, we recommend conducting cadastral surveying with this combination of equipment and software.

Using the results from table 5, the calculation of average values for each variant and the range of deviations for each variant were performed, as presented in table 6 and table 7, respectively.

Due to the data in table 6 and table 7, graphs were constructed, which are depicted in figure 3 and figure 4, respectively.

By analysing the graphs, it can be concluded that the smallest average error and the smallest range of deviations occur when using LIDAR for cadastral surveying, and the data processing is done with Agisoft Metashape. Next, in terms of accuracy, is the option of using UAV for cadastral surveying and data processing with Agisoft Metashape.

The discrepancies in volume measurements obtained using different surveying instruments are much smaller than when using different software. Considering the above, it can be concluded that the choice of the surveying instrument has a lesser impact on accuracy than the choice of software. Considering this, we recommend conducting cadastral surveying using the specified combination of equipment and software.

5. Conclusion

The research compared various surveying instruments for remote sensing and software for processing field data. As a result, the optimal combination of using LIDAR for cadastral surveying and processing data with Agisoft Metashape was selected.

A comparison of the volumes of mined material using four proposed surveying and field data processing schemes to the reference value obtained through theodolite surveying and processing in Civil 3D was conducted. The results of this comparison show that all proposed variants are acceptable, as the maximum deviation from the reference value is 3.4 %, within the acceptable

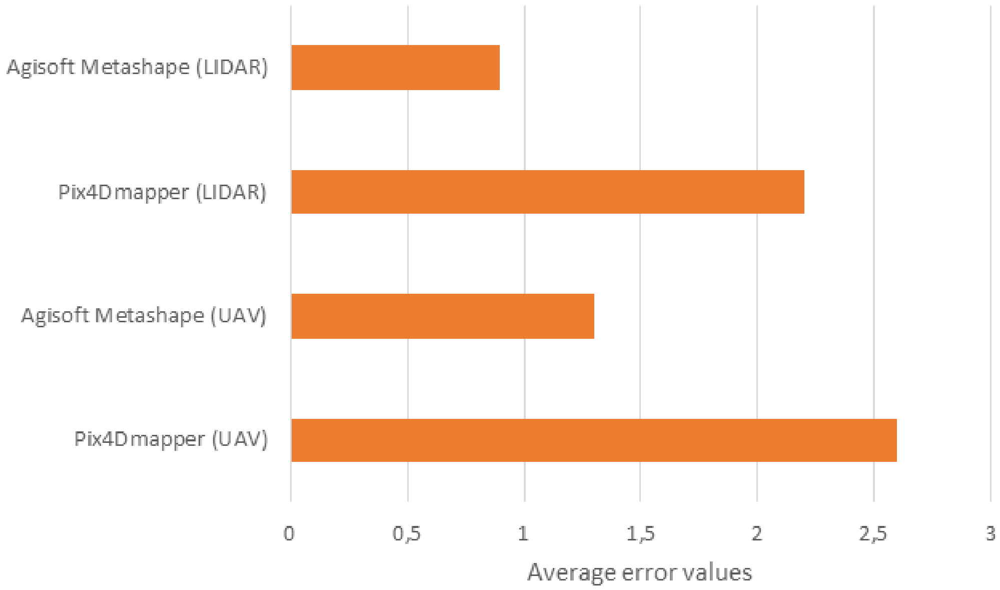

Figure 3. Average error values for different calculation methods.

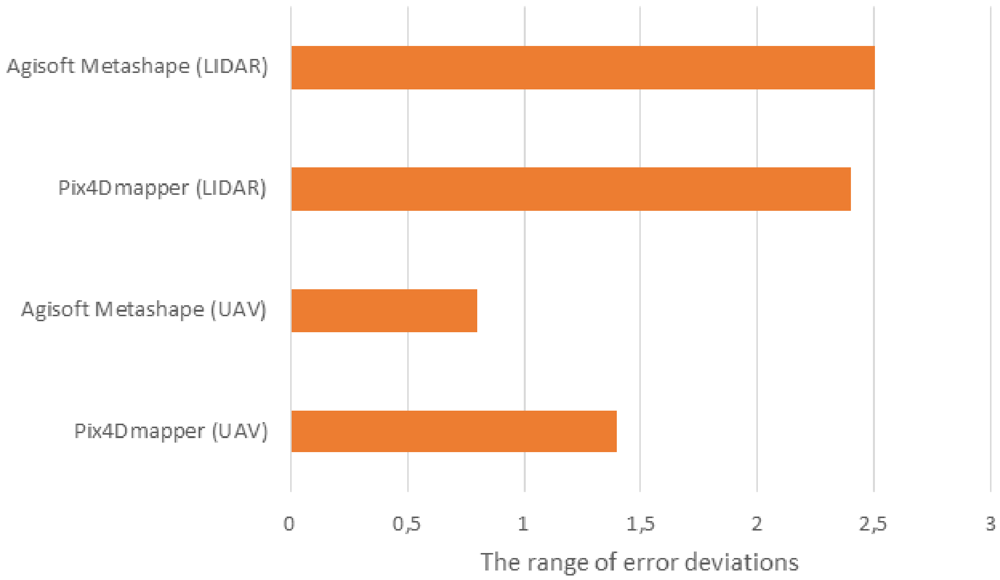

Figure 4. Range of error deviations for different calculation methods.

error limit of 15 % for volumes up to 20,000 m^3 [10]. Since the smallest measurement error occurs when surveying with LIDAR and processing the data with Agisoft Metashape, this surveying method is the most accurate.

To enhance the efficiency of cadastral surveying, it is recommended to conduct the survey using UAV, utilising LIDAR for surveying and Agisoft Metashape for data processing. Implementing this surveying approach will provide the necessary accuracy, efficiency, and safety in conducting the work.

Abstract. The article examines the problem of the occurrence and spread of fires in mines caused by the increased emission of methane and coal dust. The method of mining space isolation with the help of fire-prevention stopping, reducing the oxygen concentration and creating an inert medium, was studied. It has been experimentally established that thermal action on coal without air access causes the formation of combustible gases such as methane, carbon monoxide, hydrogen and unsaturated hydrocarbons. The peculiarities of the formation of a multicomponent gas mixture in the temperature range from 400 to 900^{0}C were determined. High temperature causes a gas phase yield rise, which leads to an increase in its heat of combustion according to a quadratic dependence. It was found that the methane yield increases up to 600^{0}C , and then its decrease in the gas mixture is observed due to decomposition into hydrogen and atomic carbon at temperatures above 700^{0}C . High values of combustion heat of gases are determined by methane at temperatures up to 800^{0}C , after which the influence of hydrogen rises with high temperatures. The obtained data of the gas mixtures combustion heat make it possible to establish the qualitative and quantitative parameters of the thermal process occurring in the isolated mining space. This can be used to calculate the heat balance of the mining medium and to simulate the thermodynamic processes occurring during mining fires.

1. Introduction

The coal industry of Ukraine plays an important role in providing the country with energy resources and raw materials for industry, especially during a wartime. Currently, there is a very urgent need for coal as the main source of energy in war conditions due to the versatility of coal combustion technologies at thermal power plants. Here are the main advantages:

- flexibility in responding to consumer needs (the operation of coal thermal power plants allows for prompt response to changes in electricity production needs, which during military actions can be critical for ensuring the energy supply of whole country);
- independence from external factors (coals make it possible to reduce dependence on foreign suppliers of nuclear fuel or raw materials for renewable energy sources);
- simpleness of operation and availability (coal thermal power plants are relatively easy to operate and require less time to restore a fast power supply, and the modularity of such stations will allow them to be deployed at the local level and provide power supply even due to obstacles in the transportation of energy carriers, caused by military actions).

Despite the problems caused by the war, the stable operation of coal mines continues. By 2014, there were 145 mines in Donetsk coal basin. Due to the hybrid aggression of the Russian Federation and the occupation of a part of Donetsk region, 96 mines remained in the non-government controlled area, and 49 in the government-controlled area [1]. Currently, 21 mines operate in the Donetsk region, including 15 state-owned ones [2, 3].

In 2022, state-owned coal mining enterprises mined 173 thousand tons of coal, and this figure decreased over a prolonged period. However, in January 2024, the production amounted to 178 thousand tons, in February – 197 thousand tons, and by the end of March, the production reached 221 thousand tons, which is 24 % more than in January [4].

These statistical data indicate the relevance and importance of coal mining and processing in Ukraine for the stable generation of electricity in thermal power plants. However, these processes are associated with numerous risks to the lives and health of miners, because in coal mines the working conditions are characterized by a significant number of hazardous factors. These include methane emissions, the stressed state of the coal-rock mass, presence of closed space, limited access of air, water and the presence of electrical equipment. [5]. Under certain circumstances, all of this can lead to explosions and fires. In addition to all this, coal mining at great depths is complicated by difficult mining geological and technical conditions, which include gas content, the degree of self-ignition of coal, the explosiveness of coal dust and the ability of coal to form dust. Because of this, the danger of emergency situations with serious consequences in the technological process of mining of mineral deposits in underground conditions increases, which poses a threat to the life and health of miners [6].

Every year, numerous accidents occur at coal enterprises, which can be caused by rock collapses, sudden coal and gas outbursts, explosions of coal dust-air mixtures and underground fires. In the period from 2016 to 2018, an increasing number of accidents and emergency situations were observed in Ukrainian mines, which emphasizes the threat to the safety of miners and the stability of coal production. The main conclusions from the analysis are given below [7]:

- the total number of accidents and emergency situations almost doubled, from 18 cases in 2016 to 37 in 2018; this indicates the difficult state of coal mining conditions;
- the total number of accidents and emergency situations almost doubled, from 18 cases in 2016 to 37 in 2018; this indicates the difficult state of coal mining conditions;
- despite the stable number of general accidents, there is an increase in the number of underground fires and exogenous accidents, which indicates the problems of fire control and it prevention;
- the number of evacuated persons increased from 1,918 persons in 2016 to 3,244 persons in 2018, which indicates the seriousness of accidents and the need to improve rescue operations;
- the duration of accidents liquidation and emergency situations increased significantly from 1094 hours in 2016 to 3748.7 hours in 2018, which indicates the complexity and duration of liquidation works;
- enterprises suffered losses that increased from UAH 61,280,000 in 2016 to UAH 77,693,000 in 2018, this can have a serious impact on the financial condition of mining companies.

2. Problem statement

In general, the occurrence of fires of both endogenous (caused by self-ignition of coal) and exogenous (caused by external heat impulses) nature in worked-out area has become more frequent. Huge difficulties arise with the elimination of the fire consequences in mines, where coal mining is carried out at the same time. In such conditions, it is not always possible to extinguish an endogenous fire by direct attack. The elimination of such fires can take tens of years and complicate mining processes [8].

In terms of caused damage, fires with methane and coal dust ignition are mostly catastrophic. They are the most destructive, complicated and long-lasting in terms of their elimination. They are also accompanied by significant human victims, lead to large material losses and damage underground communications and equipment. In recent 10 years, there have been 13 such accidents in which 5 or more people were injured, 9 of them were directly related to the explosion of methane and coal dust. This indicates about violation of safety regulations, insufficient financing of coal mines, and a low level of implementation of new, modern, safe coal mining technologies

Any underground fire, regardless of the cause of its occurrence and the type of combustible material, is accompanied by complex physical and chemical processes that lead to a change in the composition of the mine atmosphere in general, as well as in the area of flame flashing. In coal mines, the composition of the mine atmosphere is constantly monitored. Any deviations in its composition from permissible values can characterize various processes occurring in mining tunnels. Therefore, a violation of the gas regime in such tunnels can lead to the formation of dangerous explosive mixtures, when there is an intensive yield of methane from natural and man-made cracks.

The application of existing solutions for the prevention and spread of fires in underground tunnels is complicated by the problem of the air-tightness of the isolated space and the management of the parameters of the mine atmosphere in it. To accelerate the extinguishing of underground fires, the method of mine space isolation is used by constructing of fire-prevention stopping, which contributes to the further reduction of oxygen concentration and the formation of an inert medium around the ignition point. It can happen in different ways: by thermochemical processes with oxygen absorption, injecting of inert gases into the mine tunnel, filling of the mine space with recirculating combustion products.

All of this can be further complicated by the shutdown of the main ventilation fan due to rocket and artillery shelling and the lack of electricity. For example, as a result of a projectile hitting, a coal mine lost power, and ventilation of the mine tunnels was maintained through natural draft. Meanwhile, initial signs of a fire were detected in the extraction area, leading to the decision to isolate part of the mine. Due to the complex mining-geological and security conditions in the conflict-affected region, standard methods for determining the development of fires are not feasible. Therefore, there is a need to determine the quantitative and qualitative indicators of fire gases based on their volume and combustion heat in conditions of limited mine space and oxygen-free medium to prevent the development of endogenous fires.

3. Related work

It is well known that in the conditions of a limited space of a coal mine and an oxygen-free medium, the determination of quantity and quality indicators of fire gases is a key aspect for preventing the development of endogenous fires. Significant results were obtained when studying the composition of combustion products in isolated mine spaces, which were reflected in [9–14]. The search for the causes of explosions in coal industry and the development of ways to prevent endogenous fires in deep mines were carried out by Bulat, Minieiev and Smolanov [15], Pashkovskyi [16], Gluzberg [17]. In these works, the basic physical conditions of coal oxidation were formulated and a theoretical interpretation of this mechanism was presented.

The analysis of existing works has shown that thermal impact on mine medium can take place both in an oxygen-free environment and with the use of oxidizers. These processes primarily involve the decomposition of the organic matter, the recombination of the splitting products and the formation of thermodynamically stable final substances: the solid residue, the liquid products and the gas phase. The physical essence of the thermal process of coal is as follows. According to the Fuks-Krevelen pyrolysis theory [18] the process can be accurately described as a sequence of chemical reactions, involving the decomposition of organic matter occurred in the adjacent layer and in the outer surface of the particles.

Physical-chemical transformations begin to appear at temperatures of about 500^0C. However, at 350^0C constitution moisture and adsorbed carbon gases, such us carbon dioxide, methane, air component were released. Consequently, organic matter decomposition does not occur, but likely, certain changes in its internal structure transpire. At temperatures greater than 450^0C a certain quantity of water vapor and carbon dioxide are evolved, that is a result of complicated chemical reactions, involving, in general, in the external polar groups. In the temperature range of 500-600^0C processes of coal structure decomposition are increased. The intensive emission of water vapor, carbon dioxide, some amounts of hydrogen sulfide and organic compounds of sulfur are occurred. At this stage, the oxygen content in the coal-contained material is markedly reduced. However, in this temperature range weak chemical bonds are splitting. Profound changes in the internal structure of the organic matter have not been observed yet. At temperatures above 600^0C the organic matter are intensively decomposed with the formation of free and unstable substance groups. Occurred recombination processes were developed in two directions: formation of condensed products characterized by a high content of carbon and low content of hydrogen; formation of liquid and gaseous products enriched with hydrogen. Deep decomposition of organic matter and emission of liquid products are completed generally at a temperature of about 800^0C. These processes are accompanied by releasing of hydrogen, methane, carbon monoxide and nitrogen. During further temperature heating the yield of methane, nitrogen, oxygen, carbon dioxide were not observed, however, the hydrogen and carbon monoxide were formed in significant quantities. In conclusion, it is necessary to identify the following options of thermal process of coal decomposition:

- low-temperature thermal process (600-800^0C), at which the maximum yield of the liquid phase and the solid residue, as well as the minimum yield of the gas phase with high calorific value;
- medium-temperature thermal process (800-1000^0C), in which there is an increase in the yield of the gas phase with a decrease in its heat of combustion and a decrease in the yield of liquid products and solid residue.

However, the insufficient amount of experimental research did not allow to investigate the processes in isolated space during thermochemical reactions of oxidation due to the difficulty of sampling fire gases in mining and geological conditions [19].

So, the goal of the study is to produce further information regarding the following question: what kind of gas should be produced during coal combustion in isolated space to identify signs of underground fire development.

4. Methods

Therefore, in order to solve this problem, there were carried out an investigation, which made it possible to establish experimentally a quantitative and qualitative parameters of coal combustion products [20]. As a matter of fact, carbon, oxygen and hydrogen, which are part of the molecular composition of coal, turned into methane, carbon monoxide and water vapor. The degree of such transformations was determined by the rate of chemical reactions according to the Arrhenius law [21].

Low grade sapropel coal, which is mined in the Lviv-Volyn coal basin, was chosen as the material for the study of the influence of the combustion process on the quantitative and qualitative indicators of fire gases. The results of technical and elemental analysis data of coal samples are listed in table 1.

The table 1 shows data on the content of carbon C, hydrogen H, nitrogen N, oxygen O, the total amount of sulfur S_{total}, moisture W, ash content per dry mass $A_d$and the yield of

Table 1. Results of elemental and technical analysis of coal and rock samples.

Material	Structural composition, %							
	C	H	N	O	S_{total}	W	A_d	V_{daf}
Sapropel coal sample 1	34.8	2.5	0.7	3.2	0.3	1.8	56.7	52.2
Sapropel coal sample 2	36.8	2.8	0.9	3.4	0.8	1.2	54.1	59.9

volatile substances per dry ash-free mass V_{daf} in the organic matter of the above mentioned coal material.

The essence of the experimental method was to heat a certain mass of coal to a temperature from 400 to 900°C without access of air with obtaining a solid residue and collecting gaseous and vaporous products formed in the thermal process.

The scheme of the laboratory installation is shown in figure 1.

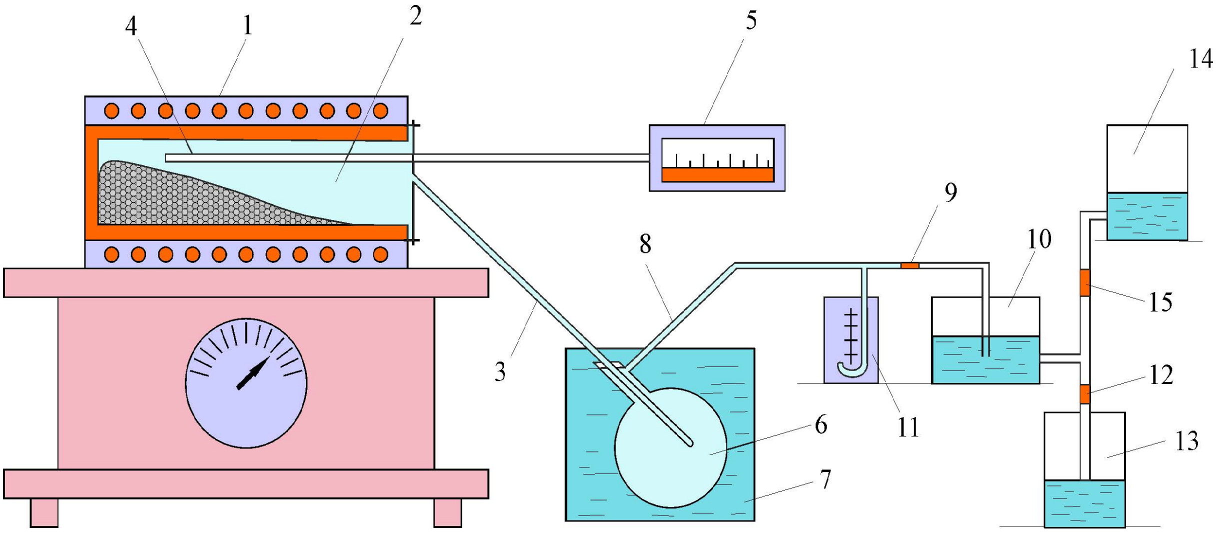

Figure 1. The scheme of the laboratory installation for the study of coal combustion processes: 1 – electric furnace, 2 – retort, 3 – volatile outlet tube, 4 – thermocouple, 5 – galvanometer, 6 – receiving flask, 7 – vessel with a cooling liquid, 8 – gas outlet tube, 9 – valve, 10 – gasometer, 11 – U-shaped manometer, 12 – valve, 13 – water measuring cylinder; 14 – leveling vessel; 15 – valve.

At furnace 1, a retort 2 is installed, where some amount of coal material was placed. The retort was a thick-walled cylindrical container made of heat-resistant steel, which consists of a removable cover and a special volatile outlet tube 3 with a thermocouple 4. The temperature in the furnace was recorded using a thermocouple and a galvanometer 5. A receiving flask 6, placed in a vessel 7 with a cooling liquid, is connected to the gas outlet tube 8. The pressure, at which the thermal process took place, was measured by a water U-shaped manometer 11, and was maintained by pouring water in a metered manner into the water measuring cylinder 13. The measuring system is regulated with the help of leveling vessel 14 and valves 9, 12 and 15.

The yield of reaction products was determined as follows. A sample of the carbon-contained material was poured into the retort 2, closed with a lid, which was tightened with bolts for sealing, and heated, observing a certain regime of temperature rise. Liquid products, released by heating of the sample, were condensed in the receiving flask 6, and the gases, passing through the outlet tube of the flask 8, entered the gasometer 10 for further analysis. The amount of gas phase was determined indirectly by subtracting the weight of liquid products and solid residue from the weight of the initial sample.

The non-condensed part of the volatile substances was directed through the gas outlet tube 8 to determine their chemical composition. For this purpose, a special apparatus was used, in which there were seven identical absorption vessels filled with a bundle of glass tubes to increase the contact surface of the analyzed gas with the following reagents:

- solution of caustic potash for absorption carbon dioxide CO_2 and hydrogen sulfide H_2S;
- solution of potassium bromide, saturated with liquid bromine, for absorption of unsaturated hydrocarbons C_nH_m;
- alkaline solution of pyrogallol to absorb oxygen O_2;
- ammonia solution of copper semichloride for absorption carbon monoxide CO;
- solution of sulfuric acid for absorption from the analyzed gas of ammonia vapors formed in the gas after passing through an ammonia solution of copper semichloride;
- table salt solution, which serves as a receiver for gas when burning hydrogen H_2;
- solution of caustic potash, which serves as a receiver for gas and absorption of carbon dioxide CO_2 during the combustion of methane CH_4.

Nitrogen N_2 was measured in a pre-cooled installation after burning methane CH_4 and hydrogen H_2.

So, according to the provided information, the laboratory installation could carry out an analysis and determine the quantitative content of the following components of the gas phase: carbon dioxide CO_2 and hydrogen sulfide H_2S (simultaneously), unsaturated hydrocarbons C_nH_m, oxygen O_2, carbon monoxide CO, hydrogen H_2, methane CH_4 and nitrogen N_2.

5. Results and discussion

It should be mentioned, that at this stage of complex investigations about the influence of quantitative and qualitative indicators on the fire gases combustion, only experimental data for one average statistical sample were given. Four temperature intervals for four gases were used to construct the graphs, which contributed to better visualization and mathematical processing of the obtained data.

The gas mixture included hydrogen H_2, carbon monoxide CO, methane CH_4 and unsaturated hydrocarbons C_nH_m. The results of the experimental researches are presented in figure 2.

The researches have established the following important parameters of gas mixtures during coal combustion in oxygen-free medium:

- at a temperature of 400^0C, CO was released the most
- at a temperature of 600^0C, H_2 was released the most;
- at a temperature of 800^0C, H_2 was released the most;
- at a temperature of 900^0C, H_2 was released the most.

Calculating the heat of combustion, the following assumptions were made. Firstly, due to the small content of carbon disulfide, this gas was not taken into account. Secondly, the combustion of the gas mixture took place under normal conditions (the amount of oxygen in the air is 21.8%).

The calculating results of the heat of gas mixture's components combustion and their percentage in relation to the amount of methane depending on the temperature are presented in figure 3 and figure 4.

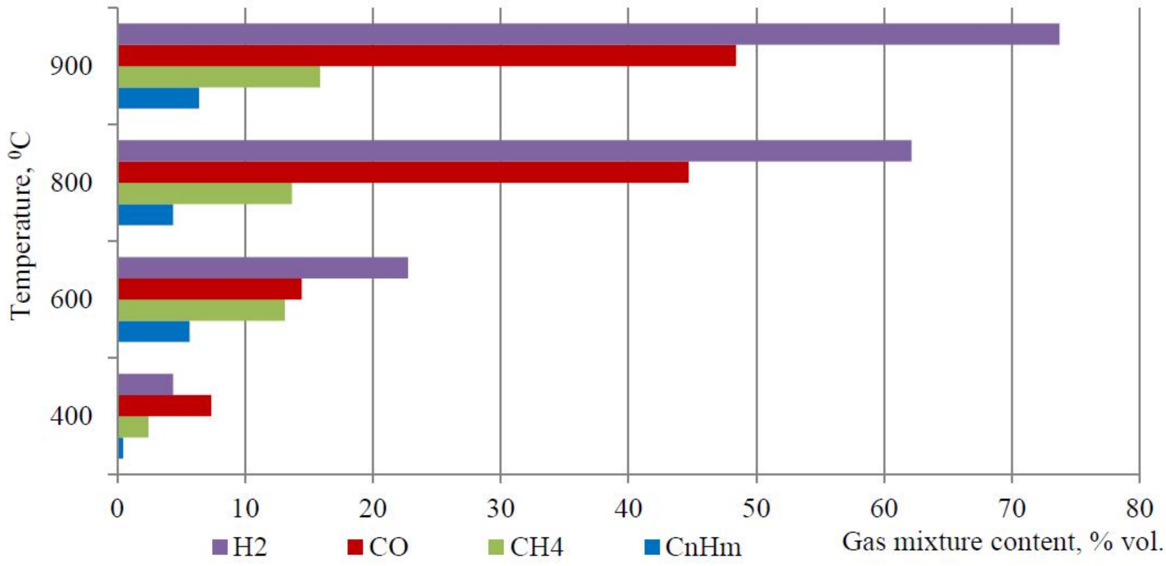

Figure 2. Yield of combustible gases depending on process temperature.

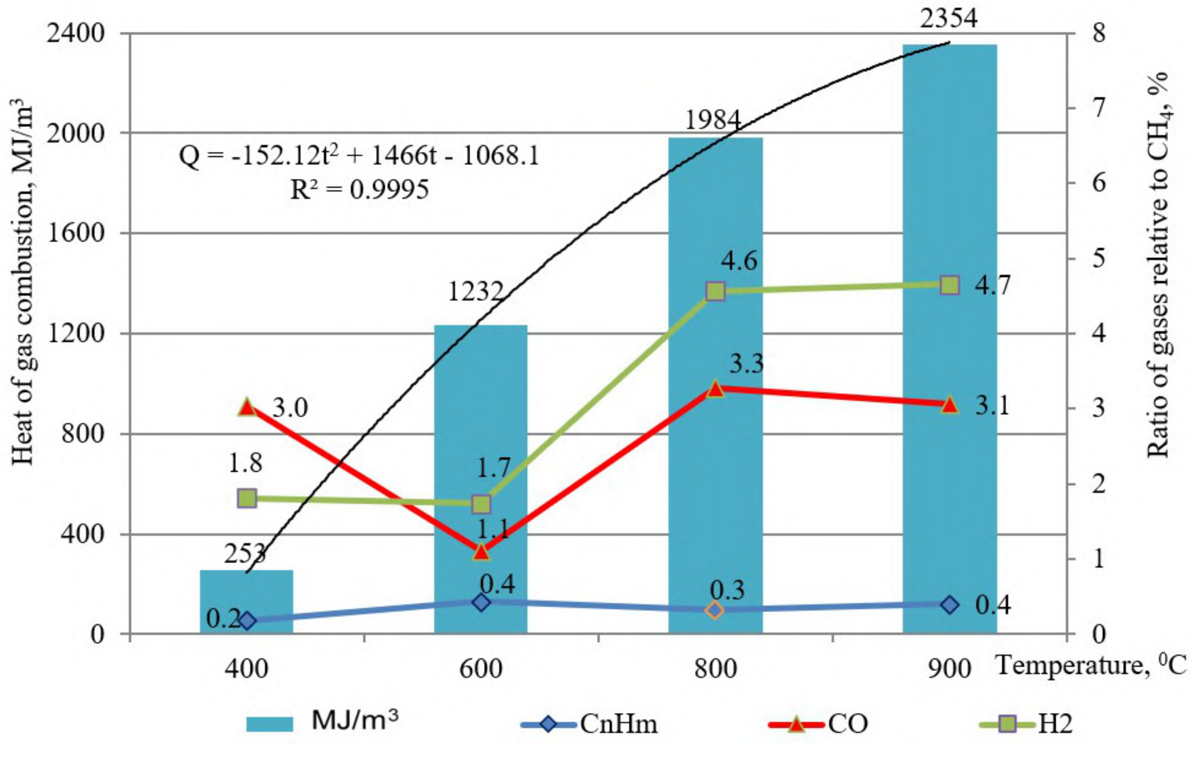

Figure 3. The ratio of combustible components and heat of gas mixture combustion in relation to the amount of methane depending on the process temperature.

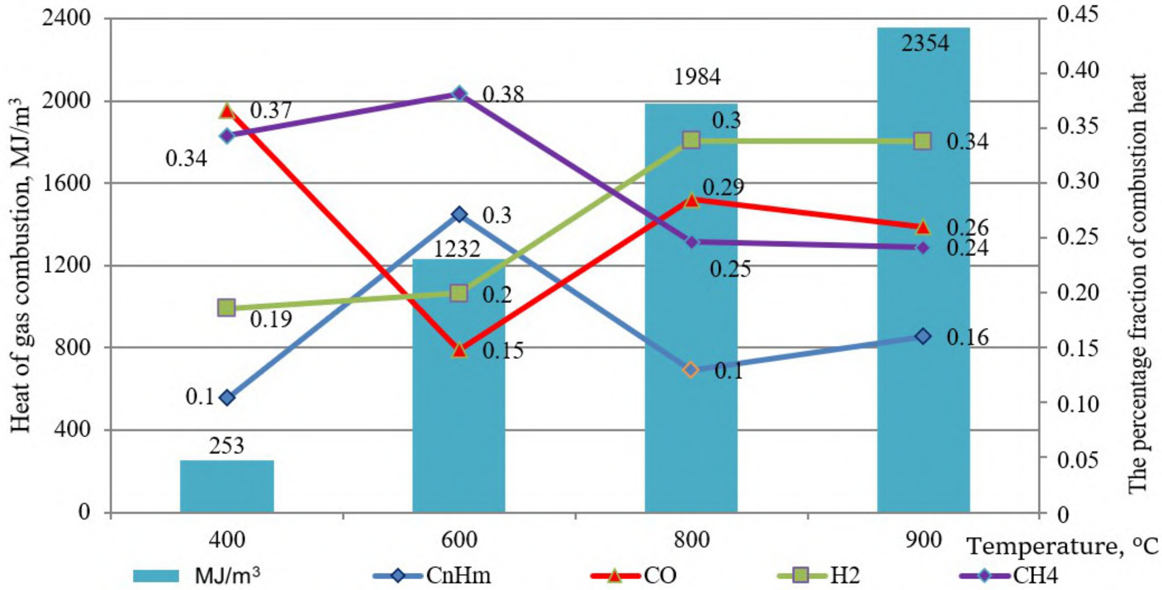

Figure 4. Dependence of the calculated combustion heat of the percentage fraction of each gas on the process temperature.

According to figure 3, the following conclusions can be given. In the temperature range from 400 to 900^{0}C with the increasing of temperature increases the gas mixture yield, and, as a result, the heat of its combustion according to the quadratic dependence

$$Q = -152.12 \cdot t^2 + 1466 \cdot t - 1068.1$$

with the coefficient of determination $R^2 = 0.9995$.

At a temperature of 400^{0}C, three times the release of carbon monoxide and twice the release of hydrogen compared to methane were observed. At a temperature of 600^{0}C, two times more hydrogen was released compared to methane, and the amount of carbon monoxide was formed as much as methane, and the heat of combustion of this mixture increased 6 times due to the large amount of methane. At a temperature of 800^{0}C, five times the release of hydrogen and three times the release of carbon monoxide compared to methane were observed, and the heat of combustion of this mixture increased by 1.6 times due to the large amount of hydrogen and carbon monoxide. At a temperature of 900^{0}C, five times the release of hydrogen and three times the release of carbon monoxide compared to methane were observed, and the heat of combustion of this mixture increased by 1.2 times due to the large amount of hydrogen and carbon monoxide.

According to the conducted researches (figure 4), at a temperature of 400^{0}C, methane (34%) and carbon monoxide (37 %) contribute the biggest fraction the heat of gas mixture combustion, at a temperature of 600^{0}C – methane (38 %) and unsaturated hydrocarbons (30%), at a temperature of 800^{0}C – hydrogen (30 %), carbon monoxide (29 %), methane (25 %), at a temperature of 900^{0}C – hydrogen (34 %), carbon monoxide (26 %), methane (24 %). In figure 4, let's consider the main heat-generating gases. At temperatures of 400^{0}C, as well as 800^{0}C and 900^{0}C, the percentage ratio of methane and carbon monoxide is practically the same. At a temperature of 600^{0}C, the percentage ratio of methane and carbon monoxide is 2 to 1.

6. Conclusions

So, the obtained statistical data indicate the relevance and importance of coal mining and processing in Ukraine for the stable generation of electricity in thermal power plants. However, these processes are associated with numerous risks to the lives and health of miners, because in coal mines the working conditions are characterized by a significant number of hazardous factors. These include methane emissions, the stressed state of the coal-rock mass, presence of closed space, limited access of air, water and the presence of electrical equipment.

In general, the occurrence of fires of both endogenous (caused by self-ignition of coal) and exogenous (caused by external heat impulses) nature in worked-out area has become more frequent. Huge difficulties arise with the elimination of the fire consequences in mines, where coal mining is carried out at the same time. In such conditions, it is not always possible to extinguish an endogenous fire by direct attack. The elimination of such fires can take tens of years and complicate mining processes.

The analysis of existing works has shown that thermal impact on mine medium can take place both in an oxygen-free environment and with the use of oxidizers. These processes primarily involve the decomposition of the organic matter, the recombination of the splitting products and the formation of thermodynamically stable final substances: the solid residue, the liquid products and the gas phase. As a matter of fact, carbon, oxygen and hydrogen, which are part of the molecular composition of coal, turned into methane, carbon monoxide and water vapor. The degree of such transformations was determined by the rate of chemical reactions according to the Arrhenius law.

The following combustible gases are formed during thermal action on coal in air-free medium: methane, carbon monoxide, hydrogen and unsaturated hydrocarbons.

It was found that in the temperature range from 400 to 900^0C with the increasing of temperature increases the gas mixture yield, and, as a result, the heat of its combustion according to the quadratic dependence $Q = -152.12 \cdot t^2 + 1466 \cdot t - 1068.1$ with the coefficient of determination $R^2 = 0.9995$.

Methane yield increases up to a temperature of 600^0C, then its content in the gas mixture decreases. This can be explained by the decomposition of methane into hydrogen and carbon at temperatures above 700^0C. This process helps to raise the amount of hydrogen in this temperature range.

High values of combustion heat of the gas mixture in the temperature range from 400 to 600^0C are achieved due to methane. When the temperature increases, the heat of combustion due to hydrogen and carbon monoxide raises.

Obtained values of combustion heat of gas mixtures made it possible to establish qualitative and quantitative parameters of the thermal process. These data will be used in the future for the calculation of the thermal balance of the mine medium and modeling of thermodynamic processes arising as a result of mine fires in the isolated space.

Abstract. The purpose of the research is to increase the efficiency of work on monitoring deformation processes and shear in the areas of influence of mining activity. The research methodology is based on the analysis of instrumental observations of the objects negatively affected by mining activities. As a result of the research, special attention was focused on the use of innovative instruments for instrumental measurements and software processing the data. The scientific novelty of the obtained results consists in using a comprehensive modern digital and satellite methods for performing instrumental observations on profile line reps, which makes it possible to obtain a more complete feature of the deformation process and information about the current state of the ground surface and other objects located in the research area, which makes it possible to increase the accuracy of the prediction for a certain period of time and quickly verify the dimensions of the displacement zone and its spreading limits. The practical significance of the research is that its results will contribute to ensuring the safe operation of the deposit and the development of more effective measures to protect the environment and mitigate the negative impact of mining activities on the area and buildings located in the zone of their influence. The studies have shown that the automated method of comparing point clouds to sinkhole areas obtained from two digital models can produce significant errors. These errors, when determining the spatial position of points, can reach 10-15 meters. In the case of a "manual" set of picket points, the errors do not exceed 0.1-0.2 m, but the time of data processing increases significantly, i.e., increasing the accuracy of determining the desired values requires a decrease in the efficiency of this process.

1. Introduction

The objects of mining enterprises in Kryvyi Rih are characterized by difficult mining conditions. There may be several mining sites in one area, and a deposit is developed by several mining companies simultaneously. Because of this, the harmful influence on a particular structure can be determined only by the displacement vector. One of the important tasks of the surveying team of a mining enterprise is to ensure the protection of buildings and structures from the negative impact of mining activities [1]. The use of only classical or modern methods of performing surveying monitoring of the displacement process doesn't always allow obtaining complete information about the process and solving this scientific and practical task at the appropriate level [2–5]. Only the complex use of these methods gives the best effect.

At the Kolachevsky mine, when studying the process of surface displacement in the area affected by underground mining activities, to ensure the safe operation of buildings and structures, a comprehensive method is used, which includes: the method of profile lines

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012031 doi:10.1088/1755-1315/1415/1/012031

with linear-angle measurements; satellite method with the determination of the coordinates of points using GNSS equipment; ground photogrammetric survey; RTK survey of new cracks and terraces; aerial survey for a comprehensive survey of the displacement zone and adjacent territories [6–8]. Based on practical experience, it can be argued that only such a comprehensive approach can ensure informed decision-making on the protection of structures and the environment [9–14].

2. Choosing a methodology for performing deformation studies

Additional profile lines were laid in the sinkhole area by specialists from the Department of Surveying at Kryvyi Rih National University in 2010. Systematic aerial surveys of the sinkhole and adjacent territories for their comprehensive survey have been implemented since 2019 [6–8], and systematic ground stereotopographic surveys since 2018.

Satellite methods have been implemented at mining enterprises in Kryvyi Rih since 2007, but were of limited use until 2017. Since 2017, monitoring of landslide and deformation processes using new technologies has been carried out on an ongoing basis. A comprehensive monitoring method was introduced with the intensification of landslide processes in 2017-2021, which resulted in: an increase in the landslide area and the process beyond the design limit; an increase in the actual size of the hazardous landslide zone on the hanging side.

Before the 2010 collapse, the observation station at the top of the mine consisted of 32 ground benchmark, which are metal pins 1500-1800 mm long and 25-30 mm in diameter. In addition, the observation station included 20 wall benchmark, which were installed in the middle XX century. After the collapse in 2010, the Kryvbasproject State Enterprise developed a project for additional profile lines, taking into account the current situation.

When developing a deposit of ore or non-metallic mineral resources, for which the displacement processes have not yet been fully defined or sectoral regulations have not yet been developed, measures to protect structures and the environment should be carried out on the basis of recommendations of a specialized research organization, such as, for example, Research and Development Mining Institute of Kru=yvyi Rih National University (KNU). Therefore, the recommendations of Research and Development Mining Institute KNU additionally includes the location of profile lines in the area of the kindergarten, boiler room, and other buildings and structures, with a frequency of observations of 4 times a year.

Recommendations for the safe exploitation of structures and improvement of surveying monitoring in 2023 at the Kolachevsky mine were provided by the Department of Surveying and Geodesy of the State Enterprise "Ukrrudprom". According to the recommendations and requirements of the instruction, the intervals between the benchmark are approximately 20 meters, but sometimes, due to the presence of underground utilities and the impossibility of laying benchmark in the private sector, etc.

It is known that the leveling benchmark profile lines is carried out according to the class III leveling method, in one direction by closed ranges or closed passages or hanging passages in the forward and reverse directions [15]. The leveling is performed with a high-precision level (Zeiss Ni2 level is used for leveling on the mine territory). At the same time, the permissible misalignment in closed and double drifts did not exceed 10 mm $\sqrt{L}$, where L is the length of the drift in km (figure 1).

The lengths of the intervals between benchmark were measured using a Sokkia SET630R electronic total station with a standard deviation of 2 mm in the forward and reverse directions. The centering of the reflector is performed using a bipod. This measurement technique allows obtaining the length of the intervals between the benchmark with a relative accuracy of no more than 1:10 000.

Earlier, when studying the landslide process using observation stations, linear measurements and geometric leveling were used, but later it turned out that this wasn't always enough to

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012031 doi:10.1088/1755-1315/1415/1/012031

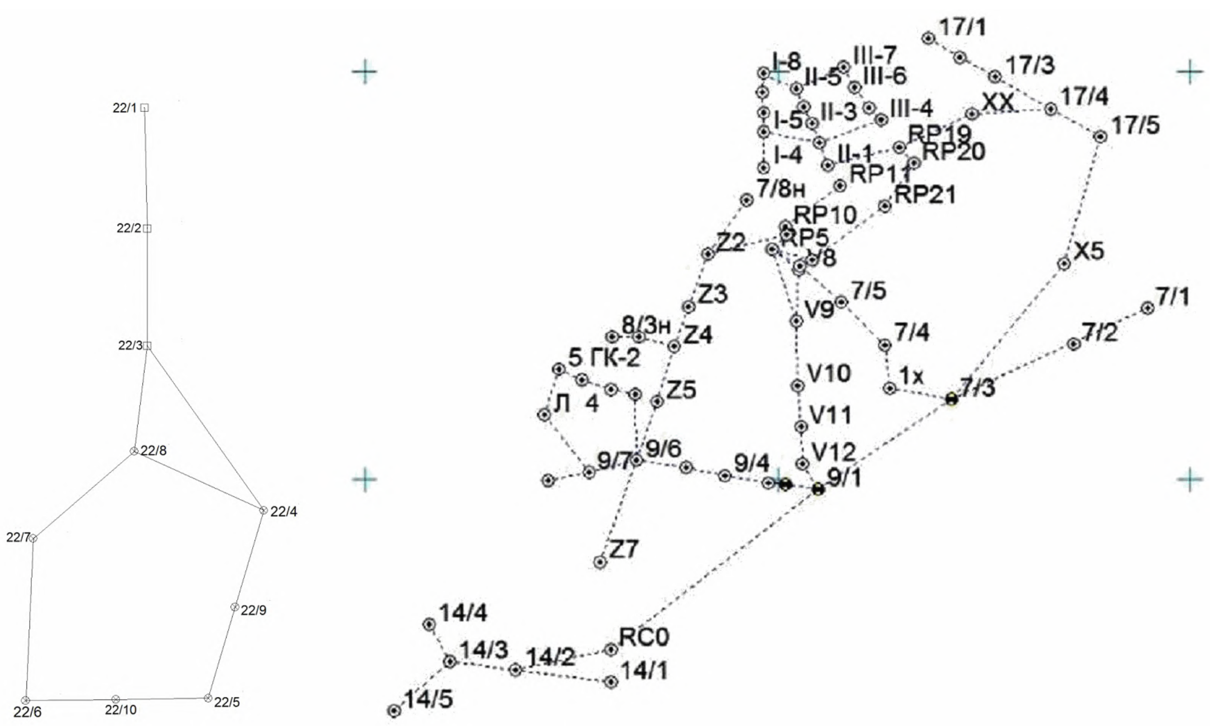

Figure 1. Schemes of leveling moves kindergarten area and industrial area.

obtain a complete characterization of the displacement process. Therefore, in order to obtain more complete information, the coordination of profile line benchmark using GPS observations was introduced.

To link the initial references, three class 1 triangulation points were used (Dubova Balka, Brato-Semenivka, Tovsta), which are located at distances of 7 to 10 kilometers from the Kolachevsky Mine. At these points, work was done to study their condition and determine their coordinates. These points are important for the enterprise, as they were taken as the starting points when creating the mine's coordinate system. Their coordinates were determined using GPS, with the duration of observations at the station being two hours. As a result of this work, their coordinates were determined with an accuracy of 3 mm and 6 mm in plan and height, respectively. Thanks to these measurements, the coordinates of the original benchmarks and changes in their position over a period of more than 60 years have been updated. To perform these works, 4 Top-con Hiper+ receivers and one Topcon HiperPro were used. In terms of accuracy class, they correspond to high-precision devices with an accuracy deterioration of 0.5 mm per kilometer in the planned and elevation positions. Figure 2 illustrates the scheme of binding to triangulation points.

High-precision satellite monitoring are used to monitor the position of 19 benchmarks, 5 of which are located mine's territory (figure 3). When performing measurements on the benchmarks, the static mode is used with a measurement recording interval of 5 seconds. At the same time, the time of standing on the benchmark is from 30 to 60 minutes, and the cutoff angle is 13 degrees. A prerequisite for high-precision measurements using GPS is to ensure minimal influence of error sources or, if possible, their exclusion. It is known that the accuracy of measurements is affected by the characteristics of spacecraft, such as the geometry of satellites, etc. Reducing the recording interval to 1 second of measurement doesn't affect the accuracy of coordinate determination, but it does increase the file size by 3-5.

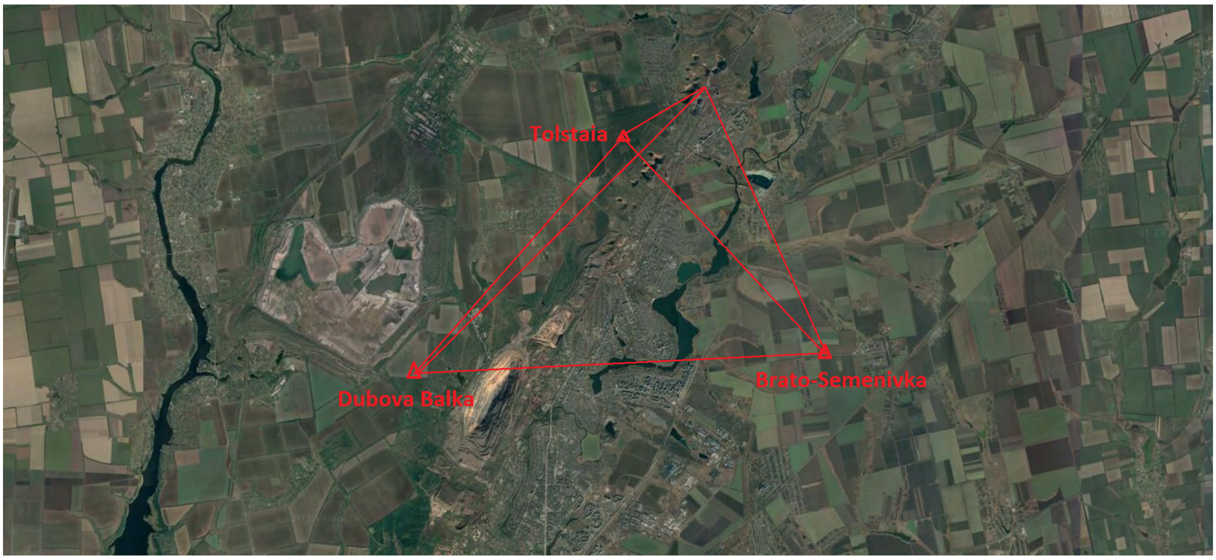

Figure 2. Scheme of linking to triangulation points.

This scheme to locate the benchmarks allowed us to make the determinations on the respective profile lines more accurately.

3. Analyzing the research results

Based on the results of the research, the following results were obtained:

- using the method of observation stations, the marks of the references were obtained based on the leveling data, and the results of linear and angular measurements
- the location in plan benchmarks and the distance between them;
- the results of instrumental surveys made it possible to refine the design data of the project organizations and make adjustments to the project decisions;
- the information obtained on the current technical and geomechanical state of the ground surface and other objects located in the study area allows us to provide a short-term prediction for a particular period;
- the results of the work allow us to clarify the parameters of the displacement zone and its location;
- the effective use of modern satellite methods in conducting instrumental measurements on profile line benchmarks has been proven.

It is known, the analysis of deformation values obtained at the points of location of the benchmarks and characterizing the deformation processes of the earth's surface and individual buildings is performed to analyze the state of the ground surface and buildings located on it. The analysis is carried out taking into account the values of critical deformations characterizing the process and used to determine the boundaries of the zone of dangerous influence of underground works and shear angles. It is known that the values of critical deformations are as follows:

- curvature k $-0.2 \cdot 10^{-3}(1/m)$;
- inclination i $-4.0 \cdot 10^{-3}$;
- horizontal tension-compression ε $-2.0 \cdot 10^{-3}$.

Figure 3. Schematic of the location rappers, the position determined by the satellite method.

Depending on the conditions of the research, different methods are used, including traditional ones: linear-angular measurements, notches, etc. In order to study the impact of mining on the building and its territory, 12 soil and 10 wall replicas were laid on the territory of the kindergarten (figure 4).

The chosen methodology for monitoring deformations makes it possible to determine the horizontal and vertical displacements benches, in accordance with DSTU B V.2.1-30:2014, according to the II class of measurement accuracy.

To reduce the risks to the safe exploitation of buildings and structures, an additional photogrammetric control method is performed.

At the same time, the ground survey is carried out with a digital camera from high points of the location, and the aerial survey is carried out from an unmanned aerial vehicle.

In figure 5, the area studied by aerial survey is circled in green, and the area studied by ground digital survey is circled in red. For aerial surveys, the SENSEFLY EBEE unmanned aerial vehicle is used, and for ground stereo surveys, a Canon EOS 6D Mark II camera and a Topcon Hiper Plus satellite receiver. The aerial survey covers almost the entire territory of the

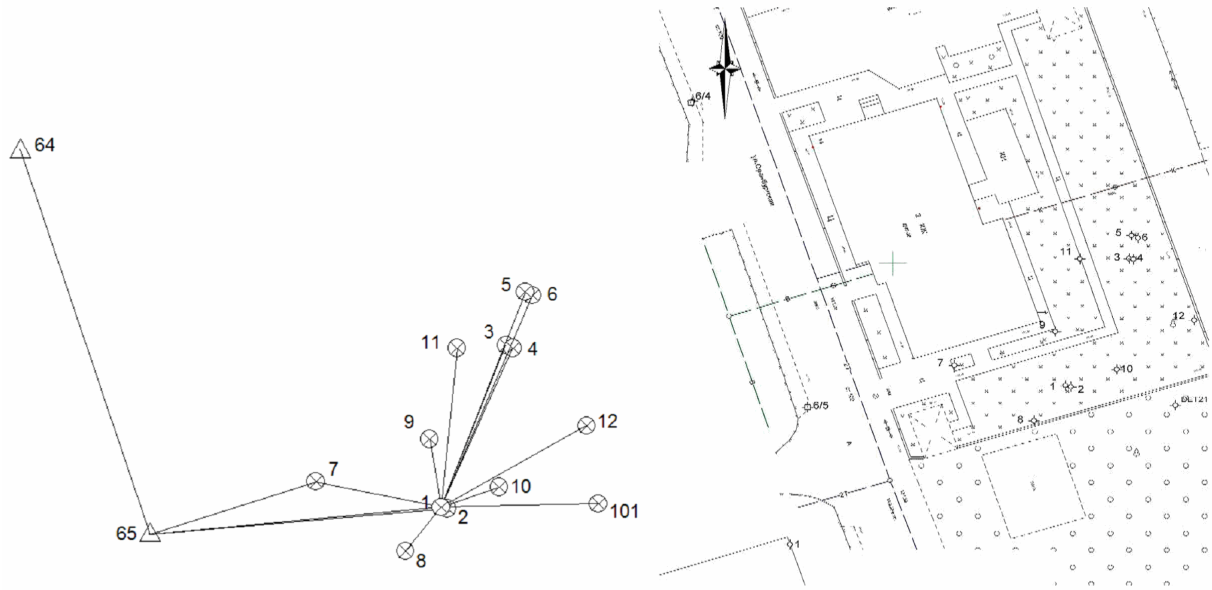

Figure 4. The location of the observation station's benches on the territory of the kindergarten.

mine's mining allotment.

Aerial photography is effective remotely monitoring areas that are dangerous for humans, such as landslide zones [16–19]. However, with a sufficiently high efficiency of photogrammetric remote methods, there are disadvantages, which consist in the impossibility of detailed marking and coordination in the landslide zones, the presence of vegetation and significant elevation differences, which complicates the survey process.

It is proved, automated method of comparing point clouds obtained for two digital models can have significant errors, and differences in determining the positions of points that can reach 10-15 meters [20]. Therefore, after the primary processing and determination of image orientation elements, further processing is performed in Delta/Digitals software.

In the case of setting pickets and other points along the upper and lower borders using a stereoscope, the mark in the "manual" mode can be brought closer to the ground surface, which, unlike the automatic mode of creating and comparing point clouds, will not allow building surfaces on the tops of trees and vegetation, which are false.

The methods of automatic detection and "surface level selection" for such objects don't work because of the complex terrain and significant elevation fluctuations. Manual pickets take much more time when performing cameral work, but provide an accuracy of 0.1-0.2 m, rather than 10-15 m, as with automatic. Figure 6 shows the distribution of deformation values in the experimental area in millimeters by color.

4. Features of digital surveying

Ground stereotyping is performed by a Canon EOS 6D Mark II digital camera with a set of lenses [21–23]: Canon EF 50mm 1:1.8II, Canon Lens EF 50mm 1:1.4 and Sigma 85mm 1:1.4 DG HSM. If you need to get more detailed images, you can use the Phoenix AF 2x teleconverter, which is inserted between the camera and the lens and doubles the focal length of the lens, which allows you to zoom in on a larger scale, bringing the subject much closer. However, the disadvantage of using a Tele-converter is that the focusing time is almost three times longer.

Figure 7 shows images of the slope of the embankment area with the remains of the building, obtained with lenses with focal lengths of 500 mm and 50 mm, respectively. The 500 mm

Figure 5. Location ground and aerial surveys.

MTO 500 lens was used in conjunction with the Canon 1200D. When switching to a full-frame camera, the Canon EOS 6D Mark II, work with the MTO 500 is impossible due to hardware incompatibility.

Based on the results surface survey, a comparative analysis of the two surfaces constructed from the images was performed and a color image to distribute the deformation values researching areas during the period between surveys was created (figure 8).

The color image of deformations, as shown in figure 8, allows you to visually assess the condition of a surface or object and helps to make timely decisions on taking the necessary measures to protect the environment and buildings and structures [22–24].

In 2022, the “Methodology for inspecting landslide zones by color display of deformation values” by O. V. Dolgikh, under the agreement between Kryvyi Rih National University and the Private Joint Stock Company “Central Iron Ore Enrichment Works”, was put into production and showed its effectiveness in studying deformations in difficult and dangerous conditions.

The survey is performed using a special application that combines a digital camera and a Topcon HiperPro satellite receiver (figure 9) [24].

The research results are presented in tabular and graphical form. The tables, in accordance with the requirements of the instruction [25–27], show the estimated values of vertical and horizontal deformations, subsidence slump for different time periods: from the date of the beginning of measurements or from the last measurements. The graphical display of the

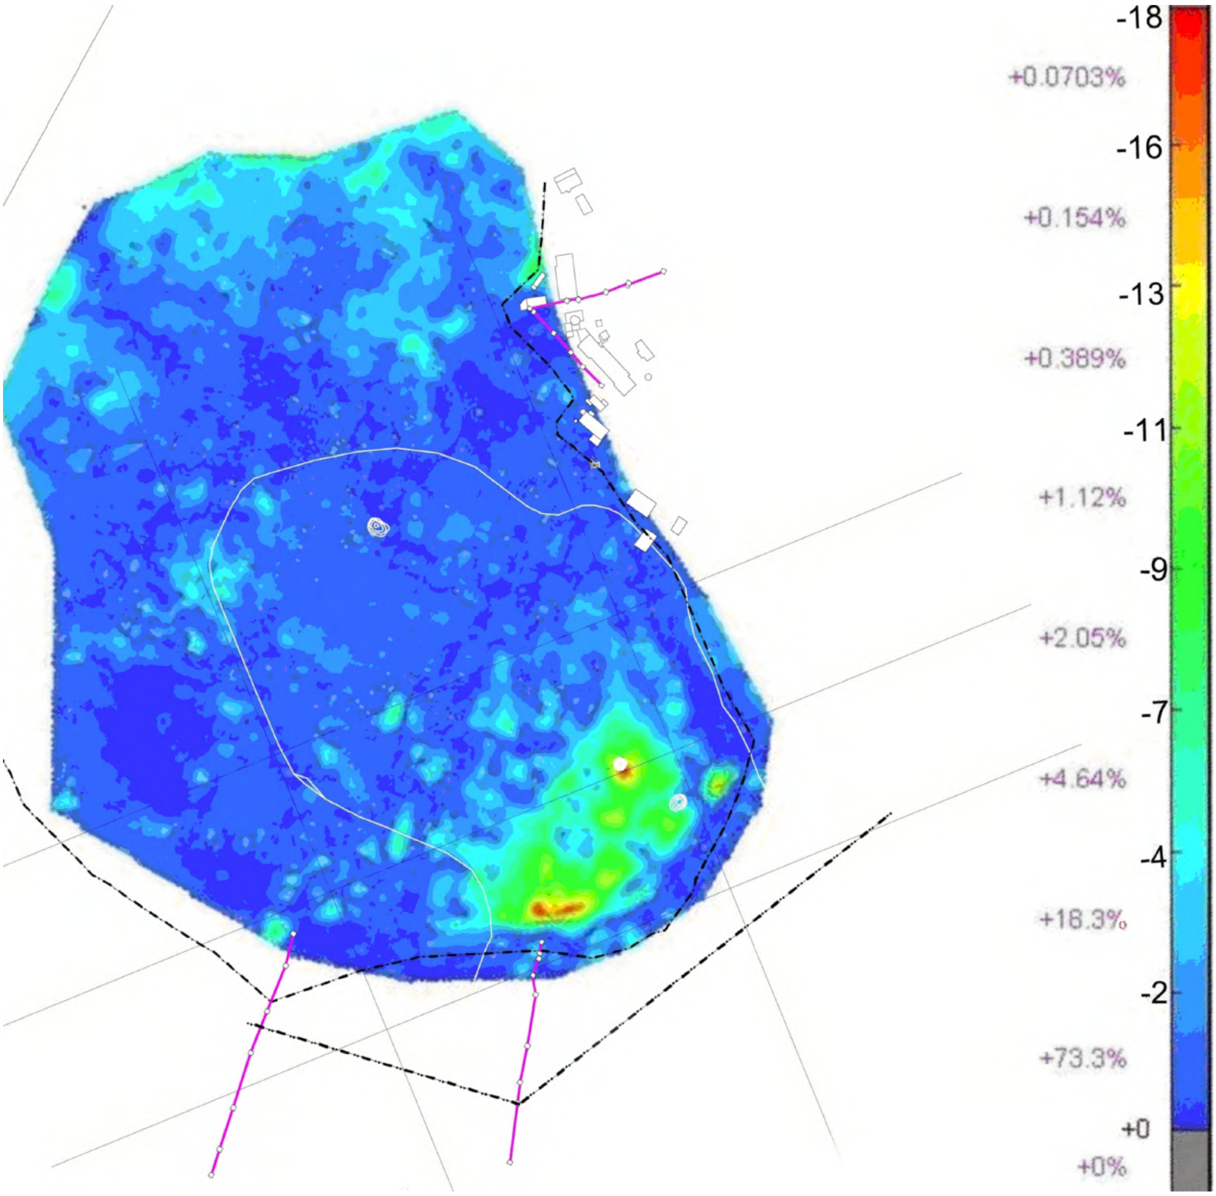

Figure 6. The results researching of the surface condition based on the data of aerial photography.

deformation values allows us to visually present the results of the monitoring (figure 10).

The research made it possible to determine the values of deformations on the benches of the profile lines observation station and, taking into account the planned mining activities, to predict the further state of the landscape and objects.

Figure 10 is a graph of subsidence of benchmarks 15, 19 and 20 for the measurements period from 2012 to 2023.

The research made it possible to determine the values of deformations benchmarks of the profile lines of the observation station and, taking into account planned mining activities, to predict the further state of the area and objects. The results of a comprehensive study of the landslide and deformation process, using satellite methods and photogrammetric methods using aerial and ground surveys, made it possible to more reasonably determine the number of voids

filled, to obtain a complete characterization of the study area, which allows to improve the safety of buildings and structures located in areas affected by underground mining operations. Based on the analysis of the instrumental measurements performed in the study area, it was found that the actual size of the landslide hazard zone in 2023 does not exceed the design one, and the deformation processes are attenuated on the profile lines of the hanging face of the deposit.

5. Conclusion

The research negative influence mining activities on the environment is an urgent problem throughout the entire life of a mineral deposit. The use of the most modern technologies in performing instrumental measurements and processing the data obtained allows to increase the efficiency of these works, which affects the reliability of the forecast of the future state of the area and objects. The studies have proven the advantage of digital imaging of objects and the daytime surface in conditions where it is dangerous for a person to be on them. The use of satellite technologies allows obtaining a more complete analysis of the deformation process in conditions where simple distance measurements and leveling doesn't provide complete information about the process. The important goal of the surveying service of a mining enterprise is researching the impact of mining activities on the environment, which today requires further research to improve it [19].

Acknowledgments

The authors are grateful to the administration of the Private Joint Stock Company "Central Iron Ore Enrichment Works" for the opportunity to carry out the research at its objects.

Abstract. In the course of experimental studies, the method of operational setting of the parameters of mass crystallization of gas hydrate in reservoir systems that have not reached a state of equilibrium is substantiated. The technique is implemented by setting the process parameters at the moment of visual identification of the solid phase of the gas hydrate on the interphase surface of the gas bubble or the place of its exit from the liquid. The requirements for the construction of the reactor unit of the laboratory installation for the implementation of this technique are substantiated. A laboratory installation has been developed and implemented. The results of test studies are presented and the features of identification of the solid phase of gas hydrate at the moment of the beginning of its mass crystallization are demonstrated. The proposed method allows you to quickly obtain objective information about the possible behavior of this system in the case of intensive changes in parameters in non-equilibrium conditions.

1. Introduction

The course of any technological process requires control of its parameters. This is especially true for the oil and gas industry. As is well known, the production of hydrocarbons is accompanied by the formation of undesirable solid clathrate structures – gas hydrates [1, 2]. In this regard, there is a need for constant and operational monitoring of hydrate formation parameters in production and product preparation systems (where there are thermobaric conditions favorable for this) [3].

Along with that, the thermobaric parameters of a significant part of the technological chain of extraction and preparation of hydrocarbons lie in a narrow range of equilibrium conditions of hydrate formation. Moreover, system parameters can change constantly and quite dynamically. However, even their slight fluctuation can stimulate the formation of gas hydrate, its dissociation, and further – repeated hydrate formation [1, 4]. Based on this, these processes definitely need constant support in the form of operational monitoring of their parameters. However, the considerable duration of laboratory setting of parameters of hydrate formation according to traditional methods [5] often does not allow to do it quickly enough. In addition, in order to effectively control the technological process, it is necessary to have means of operational prediction of the behavior of the system at any point of the technological chain. However, classical methods provide for fixing the equilibrium parameters of hydrate formation at the moment when the system reaches equilibrium [5, 6]. At the same time, in most cases, the speed of fluid flow in technological lines and the dynamics of changes in its parameters in no way allow the system to reach an equilibrium state. Therefore, it is important to promptly predict the behavior of the system under the condition that it is guaranteed to be in an unbalanced state and will not be able to reach it during the time of movement along the technological line.

Thus, the goal of the work is to develop a methodology (and appropriate equipment) for quickly setting the parameters of mass crystallization of gas hydrate in reservoir systems that have not reached a state of equilibrium, as well as to substantiate the design of a laboratory installation for its implementation.

2. Features of formation of gas hydrates

Gas hydrates are non-stoichiometric crystalline compounds that are formed at relatively low temperatures and a certain pressure [1].

There are three main stages of phase transitions associated with the formation of gas hydrates: nucleation, growth, and agglomeration [1, 7]. The formation of gas hydrate is a phase transition of the first kind, which begins with hydrate nuclei (crystal nuclei) [8]. The process of hydrate nucleation is preceded by a time interval during which the "water – gas" system is in a metastable state, which is called the induction period. This time is necessary for the formation of a certain amount of the hydrate phase or absorption of the hydrate-forming gas. In this process, hydrated shells and clumps of particles (their aggregates) grow and decompose. Nuclei must reach a critical radius before further growth becomes thermodynamically advantageous [9]. The formation of embryos is stochastic and not yet fully explored. Stochastic behavior increases with decreasing sample volume [10] and system supercooling [11].

The process of gas hydrate formation is surface-contact. Experiments [12] and simulations [13] show that, due to the low solubility of hydrocarbons in water, the formation of nuclei mainly occurs at the interphase boundary, where both hydrate components are present.

Nucleation can be induced through crystal nuclei or can occur spontaneously through random molecular interactions [14]. In the case of spontaneous nucleation, the energy barrier (Gibbs energy, Δ G) must be over come for the formation of critical nuclei. The probability of this will increase with the growth of the driving force of the phase transition [15]. This driving force is determined primarily by the degree of supercooling (Δ T). However, in the case of gas hydrates, it also depends on pressure, temperature, gas composition and degree of supersaturation [1]. At a given pressure, the driving force of the process is the supercooling temperature, which is the main characteristic of the hydrate system and can affect the induction time [1, 9].

The rate of nucleation depends significantly on the thermal history of the system. This phenomenon is called the memory effect [16]. A solution that previously contained hydrate or ice and was kept at a low temperature shortens the time of nucleation [16]. However, when the dissociation temperature was higher than 25 $^{\circ}C$, the memory effect disappeared [17]. This fact is explained by the fact that water has a kind of structural memory and the crystal structure that existed before the melting of ice or hydrate remains as structural elements in liquid water. These structures combine again in the presence of gas molecules and form critical hydrate nuclei [1, 2].

After reaching the critical size of the nuclei, the stage of mass crystallization follows. Crystal growth occurs by diffusion and inclusion of blocks on the critical surface of the nucleus. This stage is spontaneous and is accompanied by a sharp increase in gas consumption [1, 2].

As in the case of nucleation, the main site of hydrate growth is the interfacial surface. Under static conditions, the hydrate spreads and occupies the entire free surface of the "water – gas" contact, forming a hydrate film on it. Further hydrate growth is determined by the diffusion of water and gas to the front of hydrate formation through the hydrate crust [1, 2].

In the case of mechanical interaction of crystals, their agglomeration is possible – a stage of phase transition resulting in the formation of hydrated plugs [2].

3. Methods of setting hydrate formation parameters

Despite the achievements in the study of the properties of gas hydrates, significant practical experience in their prevention, scientific innovations and technical improvements, the problem of combating such complications remains relevant. Therefore, reliable and economical hydrate management strategies have become an urgent need for safe and reliable oil and gas production. Important components of these strategies are the development of methods to detect early signs of hydrate formation to give operators sufficient time to take appropriate measures to prevent hydrate formation.

In recent years, new technologies have emerged to provide the necessary information to field operators to understand how thermodynamically close the system is to hydrate formation conditions, known as gas hydrate early warning and monitoring systems. It is believed that various analytical methods together with experimental simulations from large-scale to micro-scale will play an important role and provide strong support for future research on gas hydrates [18].

In general, the equilibrium of the hydrate phase in the presence of pure water or solution can be predicted relatively accurately with existing software. Existing models for predicting the phase equilibrium of hydrates are mainly proposed based on the Van der Waals and Platteu model [19]. However, a large amount of experimental data is still needed to validate the models. In particular, the predictions of some models are very sensitive to experimental data.

There are several experimental methods for determining the parameters of gas hydrate phase equilibrium, for example, the visual control method, the graphical method, as well as a number of the latest technologies that require special equipment [5]. An observation method is also used, which requires a transparent reactor and is only suitable for solution systems. The graphic method is the main one. It is divided into isothermal, isobaric and isochoric (consists in keeping one of the three parameters constant) [5]. Among them, due to its simplicity, the isochoric or T-cycle method is widely used [20]. In this method, the temperature of the system is gradually reduced, ensuring the formation of hydrate, which is detected by the pressure drop in the vessel and/or by visual observation. After the hydrate is formed, it is dissociated by heating. On the corresponding "pressure – temperature" diagram, the intersection of the cooling and heating paths is considered as a point of thermodynamic equilibrium [6]. The conditions for the formation of hydrates have a greater degree of dispersion compared to the conditions for dissociation. Therefore, it is advisable to fix the hydrate equilibrium at the stage of dissociation. Two methods of heating are used: continuous (with a rate of about 0.2 K/h) [6] and stepwise [21] (for example, with a step of 0.5 K and a duration of 4-8 hours). Thus, the determination of only one equilibrium value of gas hydrate dissociation takes 24-48 hours.

Since measuring a wide range of equilibrium thermobaric parameters and concentrations is a time-consuming and expensive process, it is possible, as mentioned above, to use reliable models [22] or software for their prediction.

However, when the system contains gaseous mixtures or an aqueous solution of organic inhibitors, some methods are imperfect, which requires more accurate experimental data [22]. Moreover, simulations may not predict metastable states occurring under certain thermodynamic conditions that may be common in hydrate reservoirs [23]. Therefore, experimental determination of hydrate formation parameters is still relevant.

4. Justification of the need for operational control of gas hydrate mass crystallization parameters for systems in non-equilibrium conditions

The result of the manifestation of the water memory effect is a significant discrepancy in the results of experimental studies. However, based on the analysis of technological processes, the maximum temperature of part of the production wells and most of the intervals of the well product preparation lines does not exceed 18-20 $°C$, that is, much lower than the temperature of the destruction of the structures that determine its memory (about 30 $°C$ [17]). In addition, in addition to water, well products include dispersed solid phase impurities of various nature (gas hydrate crystallization centers). Thus, the induction period, with repeated hydrate formation, in such a system will be absent or its duration will be insignificant.

Given that reservoir systems are constantly in a non-equilibrium state after production, in the laboratory determination of the probability of the formation of a solid phase of gas hydrate there is no need (or it will be a mistake) to wait long before fixing the result.

In addition, taking into account the intensive change of thermobaric parameters of real systems, in order to reduce the duration of their laboratory research (process modeling), it is advisable to provide an increase in the speed of their change by 1-2 orders of magnitude (for example, up to 0.1-0.3 $°C/\mathrm{min}$).

At the same time, the investigated parameters that must be taken into account for controlling the technological process should be the thermobaric parameters of repeated mass crystallization of the gas hydrate and the duration of its delay, as well as the parameters and rate of gas hydrate dissociation.

As is known, one of the conditions for the formation of gas hydrate is the presence of a condensed phase of water [1]. At the same time, its composition may contain a significant amount of microcrystals of gas hydrate. But their presence in the reservoir system does not harm the process until a certain point. So in the work [24, 25] the parameters are substantiated and the possibility of pumping and movement through the pipeline without complications of gas hydrate suspension in water is demonstrated.

But after some time, crystals may thicken through their growth and/or coagulation, or their dissociation (but mainly preservation of elements of hydrate structures that provide (so-called) memory properties of water). The process is accelerated by changing thermobaric conditions. At the same time, it is important to set the parameters of the process at the moment of the beginning of the consolidation of gas hydrate crystals (the stage of their massive growth).

Thus, for the effective control of a number of oil and gas production processes, it is important to quickly (in the order of minutes) laboratory determination of mass crystallization parameters of gas hydrate nuclei in reservoir systems under non-equilibrium conditions.

5. Justification of the principle scheme of the laboratory installation

5.1. Optical system

Currently, a wide variety of phenomena and processes can be studied using microscopy methods combined with image capture and processing technologies. This technology allows detecting earlier stages of processes. Therefore, the thermobaric parameters recorded at the moment of visual identification of gas-hydrate structures will be sufficiently accurate even when using budget laboratory equipment. Therefore, it is advisable to use the method of visual control of the sample as the main source of information in the research methodology of the mass crystallization process of gas hydrate.

The use of a microscope in the optical system of a laboratory setup involves the study of a small object or reactor volume. Based on this, the reactor of the laboratory installation can be of minimum size. Also, obtaining a high-quality image of objects requires their high-quality lighting. In this case, the light sources must be placed in such a way that transparent and colorless hydrate crystals "appear" as clearly as possible on the obtained images.

5.2. Mixing system

Intensification of hydrate formation involves the creation of maximum "gas – liquid" interphase contact. For this purpose, reactors are equipped with devices for mixing. The use of a small-volume rector requires analysis and optimization of the mixing system. For example, effective contacting of phases can be achieved in the process of intensive gas bubbling through a liquid layer.

When bubbling, gas bubbles are pushed to the surface. Moving through the liquid layer, they cause its turbulent mixing, and therefore relatively developed interphase interaction. At the exit from the liquid, the bubble overcomes the interaction forces of the surface layer at the interfacial contact, causing a short-term disturbance.

In addition, the very process of bubble growth (and therefore the area of interfacial contact) at the opening of the bubbling device is actually a process of mixing on the scale of the liquid surrounding the bubble.

Thus, the periodic process of bubble nucleation, its growth, detachment after reaching a critical size, movement through a layer of liquid and disturbance at the moment of breakthrough of the "liquid – gas" contact can be considered as a process of mixing the local volume of liquid in the reactor with a mini-mixer of the bubbling type.

At the same time, the composition of the gas phase in the reactor will change during the formation or dissociation of the gas hydrate. In the work [26] shows a monotonous change in gas composition during each operation. Therefore, the advantage of bubbling mixing (if the gas is supplied from outside and not circulated in the system) is that each bubble is a portion of gas whose composition has not undergone previous changes as a result of selective dissolution or hydrate formation.

Therefore, in the design of the laboratory installation, it is advisable to provide:

- small volume reactor;
- an optical system based on a microscope;
- a device for bubbling mixing of reactor contents.

Therefore, when using bubbling mixing, the most informative objects for recording the signs of mass crystallization will be gas bubbles and the liquid surface in the zone of their exit. Considering the focal length of the microscope, the object must be in close proximity to the transparent window of the reactor. Since gas hydrate crystals can form both on the bubble and on the surface of the liquid in the reactor, the entire picture of the process must be in the field of view of the microscope. Therefore, it is advisable to place the reactor in such a way that the plane of contact "liquid – gas" is roughly half a transparent window. (In the version of the rector of a cylindrical shape with an end viewing window - orient in a position close to horizontal.)

Structurally, slow gas bubbling and the possibility of visual control of the processes on the surface of the bubbles and the place of their exit are proposed to be implemented with the help of a single capillary immersed in the liquid near the viewing window. For improve observation of the bubble, it is suggested to place the capillary below the liquid level in the reactor at an angle of 20-30 ° to the horizontal. In addition, close the lower opening of the capillary and cut an oval on the side (figure 1). A bubble that stays on the opening of the capillary for a certain time is formed as a result of the ultra-sensitive balancing of the surface tension forces, the pressure of the liquid column and the gas pressure in the capillary with minimal gas supply.

The fact of the appearance of the solid phase of the gas hydrate is proposed to be recorded in this microvolume (which is approximately 3-5 ml). For such a volume, this method of mixing will be sufficient to quickly approach the concentration of gas molecules in the liquid to equilibrium. According to previous studies, the intensity of bubbling to saturate the liquid with gas is assumed to be within 0.5-3 bubbles per minute.

In the design of the reactor of the laboratory installation, it is also advisable to provide an auxiliary rotary mixer for mixing the entire sample. For example, without interfering with the research, control the effectiveness of microbubble by periodically turning it on. At the same time, the stirrer blades must effectively bubble gas bubbles into the liquid and disperse them. In the course of previous studies, the best result (recorded by increasing the temperature and

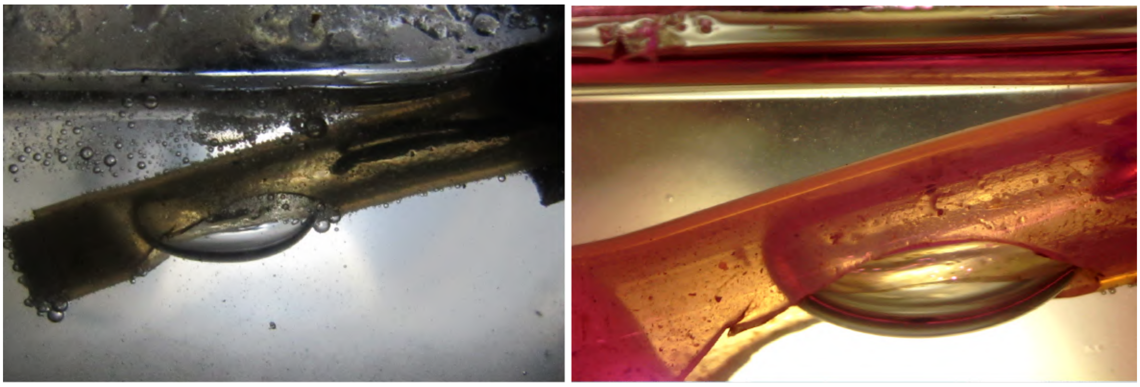

Figure 1. The formation of a gas bubble at the opening of a capillary immersed in a liquid (photo by the authors in the process of research).

Figure 2. Rotor of a mechanical stirrer.

decreasing the pressure in the reactor) was noted for the design of the mixer rotor shown in figure 2 in the horizontal arrangement of its axis.

In this position, the stirrer blades move part of the way in the gas phase during rotation. Then they plunge into the liquid, cutting its surface, and capture a certain volume of gas. Next, this gas is dispersed to the size of microbubbles. At the exit from the liquid, the agitator blades pick up part of the liquid and disperse it. As a result, almost immediately after turning on the stirrer, the sample under study turns into a foamy mass that fills the entire volume of the reactor (figure 3). This allows for 3-5 seconds of operation of the rotary mixer to bring the system as close to equilibrium as possible.

5.3. Improvement of the pressure and temperature control system

During the tests of the laboratory installation, a significant sensitivity of the capillary system to the pressure drop between the reactor and the gas supply line was recorded. So, for example, after cutting off the reactor volume with a valve located along the inlet line at a distance of 15 cm and the stirrer running for 2 s, the active release of bubbles from the capillary was recorded. At the same time, the phase shift of mixing and the release of bubbles occurred within 1 s. After repeated turning on of the stirrer, bubbles did not appear. The reason for equalizing the pressure between the reactor volume and the capillary line was stimulation of the dissolution of gas molecules in the undersaturated liquid. In another case, 1.5 min after the start of the stage of intensive heating of the sample (heating inertia was observed), the liquid began to rise

a *b* *c*

Figure 3. The position of the rotor of the stirrer in the reactor (a) and the appearance of the test sample during the operation of the stirrer (b) and after its stop (c) (photo by the authors during the research).

through the capillary. Therefore, in addition to the function of a bubbling device, a capillary immersed in a liquid can be periodically used as a super-sensitive differential manometer during research to assess the pressure change between the reactor and the gas input line.

For increase the sensitivity of this differential pressure gauge on the gas supply line, it is advisable to sequentially place a fine adjustment valve and a buffer tank (receiver) with a volume of 30-50 ml. After overlapping the input and output lines, a system of two containers is formed, connected to each other by a capillary line with a hydraulic valve of the liquid layer. As a result, any decrease in pressure in the reactor (as a result of temperature decrease, gas dissolution or hydrate formation) will be accompanied by the release of bubbles at a rate proportional to the intensity of the process.

In the course of preliminary testing of this system, it was established the need to experimentally select a certain level of thermal insulation of the buffer tank: more intensive gas cooling in it compared to the reactor leads to liquid being pushed from the reactor into the tank, and excess thermal insulation leads to too intense bubbling of gas during the research process.

For increase the sensitivity, it is advisable to place the temperature sensor in the liquid phase as close as possible to the capillary system, but distance it on a heat-insulating support from the metal body of the reactor.

At the same time, at the moment of mass crystallization of gas hydrate in the reactor, its minimum amount is formed. This practically makes it impossible to fix the temperature anomaly of this endothermic process.

5.4. Identification of signs of the solid hydrate phase on the interfacial surface

As is known, the process of hydrate formation occurs most intensively at the interphase boundary and is visually manifested after a certain induction period from the moment of mass crystallization in the form of a hydrate film. Visually, this process is fixed by the transformation of the mirror surface of the interphase boundary into a matte one. In addition, in the course of research, it was established that the most effective sign of the formation of microcrystals of gas hydrate on the surface of the bubbles is the distortion of the reflection of the light source on it. The dynamics of the mass crystallization initiation process is illustrated in figure 4.

As can be seen in figure 4, b and figure 4, c, no other visual signs of the beginning of the process of hydrate formation (mass crystallization) are observed, except for the distortion of the reflection of light sources on the surface of the bubbles. At this stage, it is extremely difficult

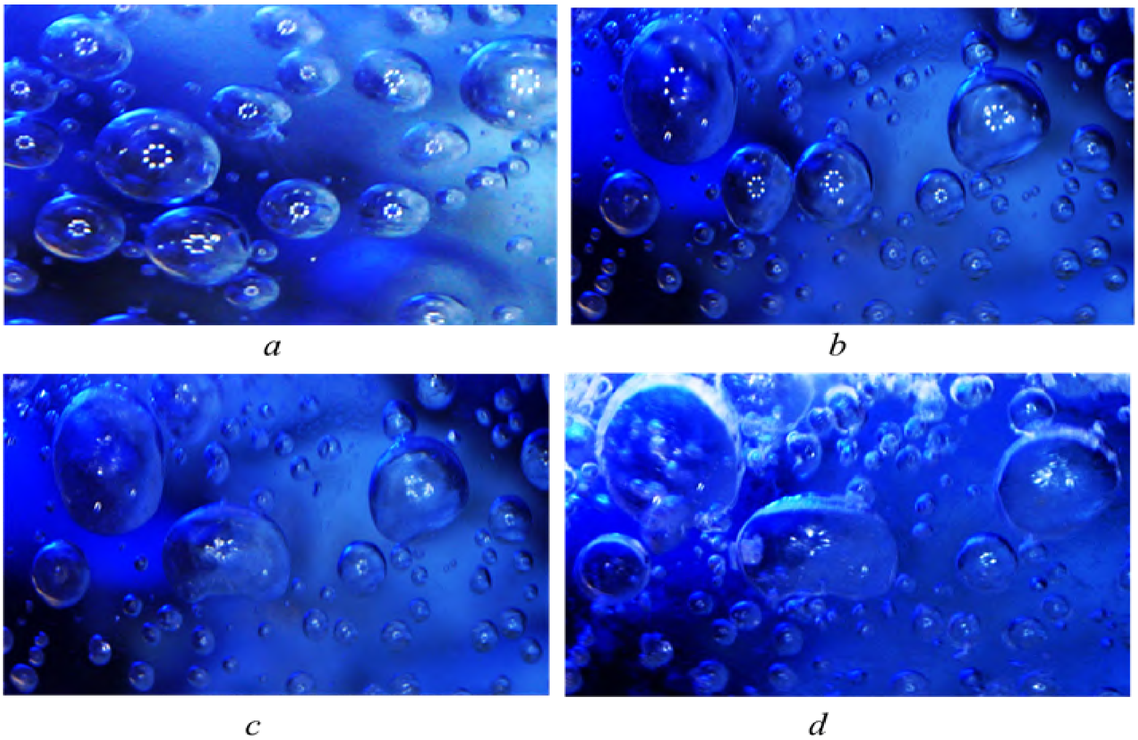

Figure 4. Dynamics of distortion of reflections of point light sources on the surface of gas bubbles as a result of the formation of a film of gas hydrate crystals (photo by authors in the process of research): a – the reflection is clear, without distortions; b – the first visual signs of reflection distortion (formation of a gas hydrate solid phase); c – significant reflection distortion (mass crystallization); d – the surface of the bubble becomes matte due to the formation of a thick crust of gas hydrate.

to record the change in thermobaric parameters in the reactor.

6. Design features of the laboratory installation

Taking into account the above, it is possible to formulate the following basic requirements for the design of the reactor unit of the laboratory installation for the implementation of the method of setting the parameters of the start of mass gas hydrate crystallization:

1) the shape of the reactor is cylindrical, the ratio of its diameter to length is within 1x2.5-3.5, the diameter of the reactor is within 45-65 mm;
2) the position of the reactor is horizontal or close to horizontal (it is necessary to provide for the possibility of adjusting the angle of inclination of the rector);
3) the presence of a rotary mixer whose shaft axis coincides with the axis of the reactor;
4) the level of optimal filling of the reactor with liquid relative to the viewing window is within 50-60 %;
5) the presence of a fine adjustment valve on the gas input line to the reactor with a flow rate starting from 1 bubble per 3 minutes;
6) placement of the capillary system: a transparent capillary with an inner diameter of 2.5 mm is placed in the liquid at an angle of 20-25° to the horizontal;

7) the following research objects should be within the visual range of the optical system at the focal distance: a gas bubble at the opening of the capillary, a part of the surface of the liquid in the reactor where the bubble breaks through to the surface, and a layer of liquid between the opening on the capillary and its surface. Taking into account the possible different light transmittance of the investigated systems, the thickness of the glass of the observation window and the limited focal length of the microscope of the optical system, the capillary must be placed at a minimum distance from the observation window, and it should be oriented in such a way that the trajectory of the bubble after separation is between the capillary and the glass. Thus, the hole on the capillary should be 15-20 mm below the axis of the reactor, but at least 5 mm from the reactor body and 4-6 mm from the viewing window. Based on the thickness of the transparent window of the reactor and the size of the controlled zone, the level of magnification by the optical system will be in the range of 70-120;
8) to obtain a high-quality image, it is necessary to place a light source behind the investigated object. A variant of such a source for an opaque reactor, in the form of a system of an external light source and a cylindrical crystal with a hemispherical end for scattering light, mounted in a through hole in its wall, is presented in figure 5;
9) from the outside of the reactor at a minimum distance from the axis of the microscope lens, it is necessary to place an auxiliary light source, but in such a way that the reflection from it on the surface of the window does not distort the image figure 6;
10) place an intermediate heat-insulated container with a volume of 0.5-1.5 reactor volumes along the gas supply line between the shut-off valve and the reactor.

Taking into account the requirements for the design of the reactor unit of the installation for the implementation of the methodology for setting the parameters of mass gas hydrate crystallization, a laboratory installation was developed and manufactured, the diagram of which is presented in figure 7. In figure 8 a photo of the reactor unit of the installation and its elements is presented.

7. Preliminary experiments

In the course of research, it was established that the most favorable conditions for the beginning of mass crystallization (appearance of visual signs of the solid phase) occur in the zone of exit of the bubble to the surface of the liquid (figure 9, a), along the perimeter of the capillary opening (figure 9, b) and in the lower "pocket" of the capillary (figure 9, c). In the first case, the most active mixing takes place in this area, in the second and third – cyclic wetting of the capillary walls 1 (figure 7) with a water film, that is, the formation of a new interfacial contact surface. At

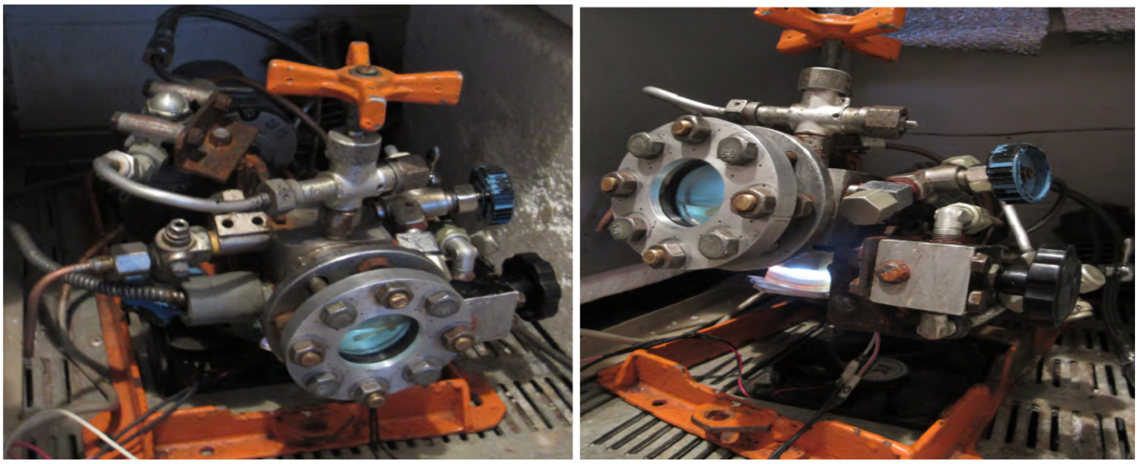

Figure 8. Photo of the laboratory installation (photo of the authors in the process of research).

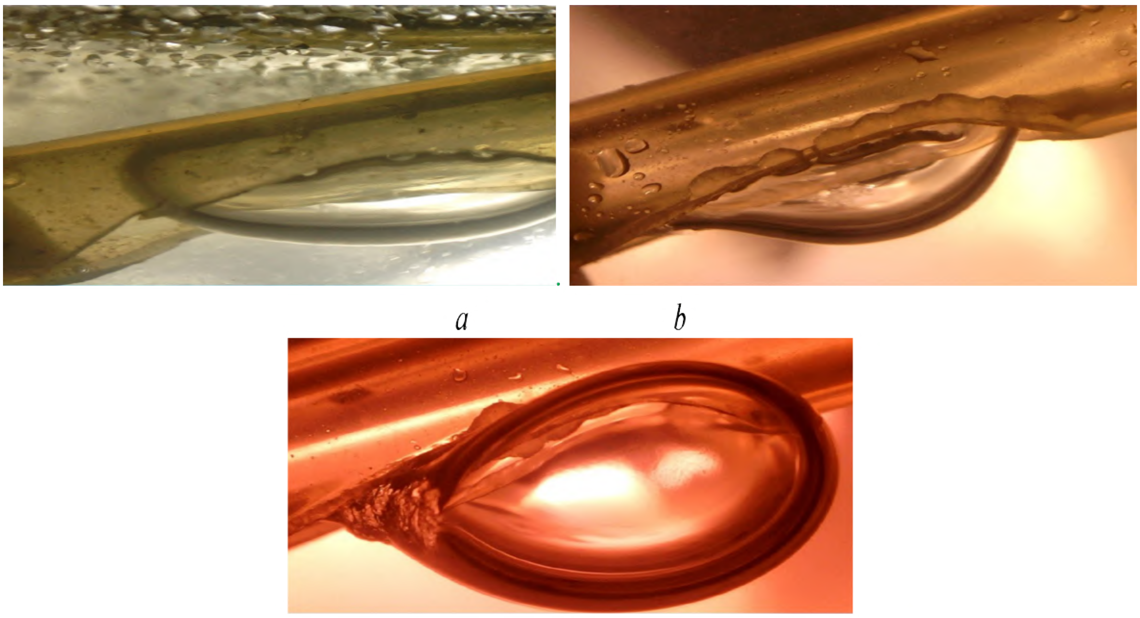
the same time, most often the first signs of the solid phase of the hydrate were recorded in the zone of bubbles breaking through to the surface. This is explained by the fact that, in addition to gradual bubbling mixing, the surface of the liquid in the reactor 8 (figure 7) is constantly in contact with the gas. Its molecules can be dissolved in water all the time, while the surface of the bubble exists for a relatively short time.

Thus, according to the methodology, the appearance of one of these signs is identified as the investigated moment of the beginning of mass gas hydrate crystallization under these thermobaric conditions.

The essence of the technique consists in the preliminary creation of a model of the well



a *b*

c

Figure 9. Typical signs of the beginning of mass crystallization of gas hydrate: a – in the zone of bubble breakthrough on the liquid surface; b – along the perimeter of the hole in the capillary; c – in the lower "pocket" of the capillary (photo of the authors in the process of research).

production, which has the memory of hydrate structures or the seeds of hydrate formation remain in its composition. For this purpose, at least part of the water of the studied sample is preliminarily incorporated into the composition of the gas hydrate. Next, the hydrate is dissociated as a result of a simultaneous decrease in pressure and increase in temperature. Moreover, dissociation is carried out to a level that would ensure the preservation of part of the hydrate structures and/or crystallization seeds and/or water structures that determine its hydrate memory in water.

After that, the prepared sample is subjected to gradual cooling with simultaneous gas supply to compensate for the pressure drop as a result of cooling. The gas is supplied through the capillary by the control zone. A marker of repeated hydrate formation is the formation of signs of the solid phase of the hydrate, which are visually visible at a magnification of 70-120 times. At the moment of their appearance, the corresponding thermobaric parameters are fixed.

8. Methodology

8.1. Preparatory operations

A sample is fed into the reactor 9 and vacuumed for 30 min with periodic inclusion of the stirrer 10 (figure 7). After that, the test gas is fed into the reactor. The pressure is increased to 6.0 MPa and the stirrer 10 is turned on for 10 s. After waiting for 10 minutes, the gas is released. Then the pressure is raised again to 6.0 MPa and immediately begin intensive cooling of the reactor to a temperature of 1-2 $^{\circ}C$ to achieve significant supercooling of the system. For accelerate the dissolution of the gas, every 2-3 minutes, turn on the stirrer 10 for 2-3 seconds. After the beginning of hydrate formation, the process of periodic inclusion occurs until the disappearance of the sign of gravitational water between the hydrate crystals. After that, the gas hydrate is melted. For this, the heating element 24 is turned on and the thermally insulated chamber 7 is partially depressurized. The maximum temperature to which we use sample heating in this operation and in all subsequent gas hydrate dissociation operations during the research is 16 $^{\circ}C$.

When a temperature of 9.0 $^{\circ}C$ is reached (taking into account the inertia of heating), the pressure in the reactor is reduced to atmospheric by opening valve 11 within 15-20 seconds. (The pressure in this and the following operations is reduced gradually, because when the gas is suddenly discharged, due to the small size of the reactor and its horizontal location, the liquid is removed through the fitting). After waiting for 20 seconds, valve 11 is closed. For guaranteed dissociation of the gyrate, the reactor is kept for 15 minutes until a temperature of 16 $^{\circ}C$ is reached. In further operations, the amount of hydrate will be minimal, so this exposure time will be reduced to 3 minutes.

8.2. Experiment

Before starting each repetition of the experiment, the temperature rises intensively (at a rate of 0.5 $^{\circ}C$/min) to 9 $^{\circ}C$. After that, the pressure in the reactor 9 (figure 7) decreases to atmospheric within 15-20 seconds. After holding for 20 seconds, valve 11 is closed and held for 3 minutes. An additional task of such degassing is to prevent the gradual accumulation during each repetition of C_{2+} components in the liquid phase, and therefore the associated error.

After that, depending on the repetition of the experiment, the pressure is raised to a level ranging from 1.0 to 5.5 MPa, which is approximately 0.8-1 MPa lower than the crystallization pressure. This interval is determined by the minimum temperature in the reactor during research, which for non-inhibited systems to prevent the formation of ice and the occurrence of an error in the identification of gas hydrate should not be lower than 0.5 $^{\circ}C$, as well as the maximum permissible for this reactor (7.0 MPa).

Immediately with the increase in pressure, cooling begins at a rate of 0.2 $^{\circ}C$/min. The gas input line in front of buffer tank 18, which remains connected to the reactor 9 (figure 7) through the hydraulic valve of capillary 1, is closed (valves 13 and 14 are closed and valve 19 is opened).

After that, the stirrer 10 is turned on and the process of saturation of the sample with gas is controlled by the intensity of the leakage of bubbles through the capillary 1.

By this time, the temperature in the reactor will rise to 14-15 $°C$. After reaching a temperature of 16 $°C$, a pressure of 1.0 MPa is set on the reducer 15 of the gas source 16, which is higher than the estimated one for possible gas hydrate crystallization, and the fine-tuning valve 19 is set to supply gas through the capillary 1 with an intensity of about 3 bubbles per minute. This gas supply rate compensates for the pressure drop associated with reactor cooling and slightly exceeds it. Therefore, by the time mass crystallization of the hydrate begins, the pressure in the reactor 9 will be higher than the initial one by 0.3-0.8 MPa.

When the temperature of the sample is reached, which is approximately 2-4 $°C$ higher than the mass crystallization temperature of the gas hydrate, the procedure for saturating the liquid with gas is repeated (turning on the stirrer 10 for 3-4 s). The intensity of bubbling drops to approximately two bubbles per minute. Further observation continues until the moment of fixation of signs of mass crystallization.

Immediately after that, the heating element 24 is turned on, and the above-described preparation procedure for the next repetition of the experiment continues. The results of testing the methodology on sample natural gas of a typical composition are presented in figure 10, figure 11, figure 12.

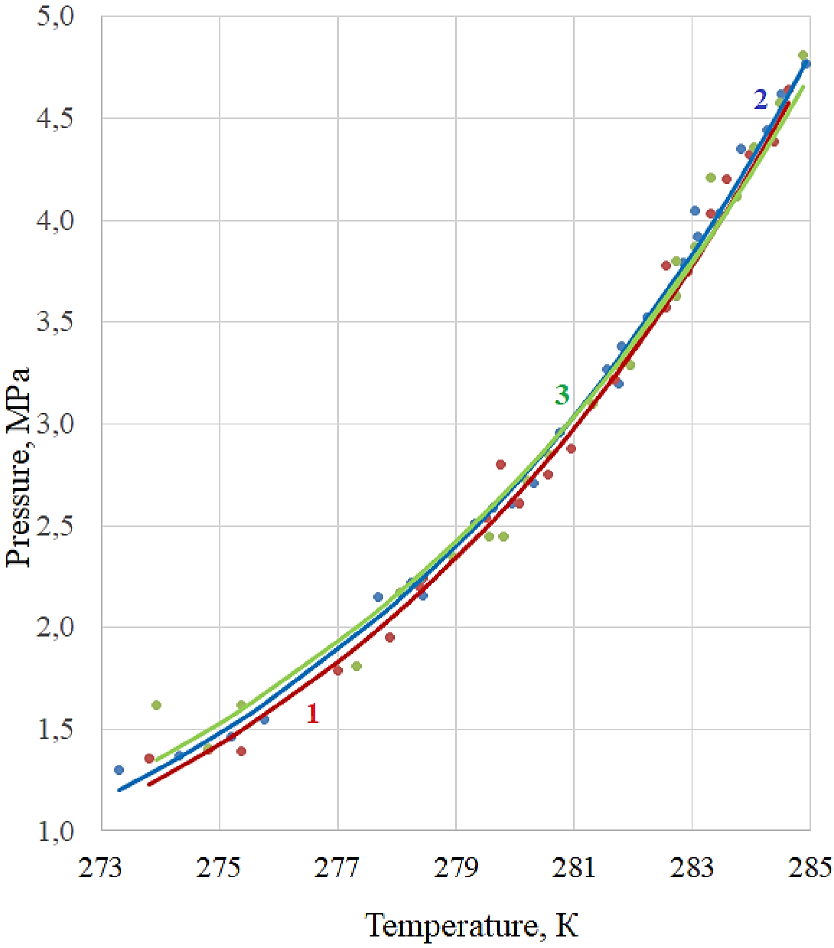


Figure 10. Results of experimental studies to establish the parameters of gas hydrate recrystallization in the studied sample: experiments 1-3.

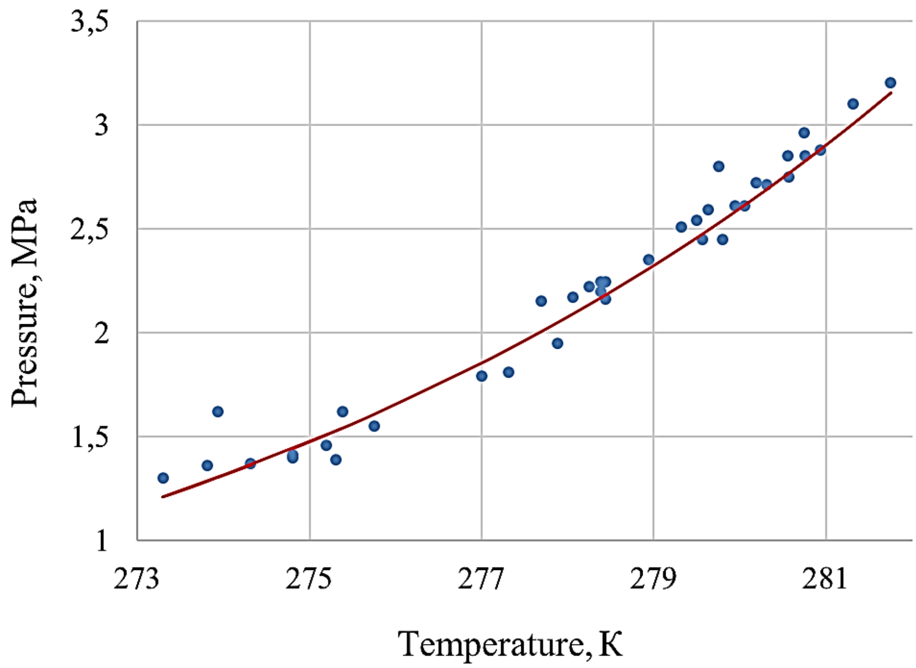

Figure 11. Approximated empirical curve of mass crystallization parameters of gas hydrate in the studied sample.

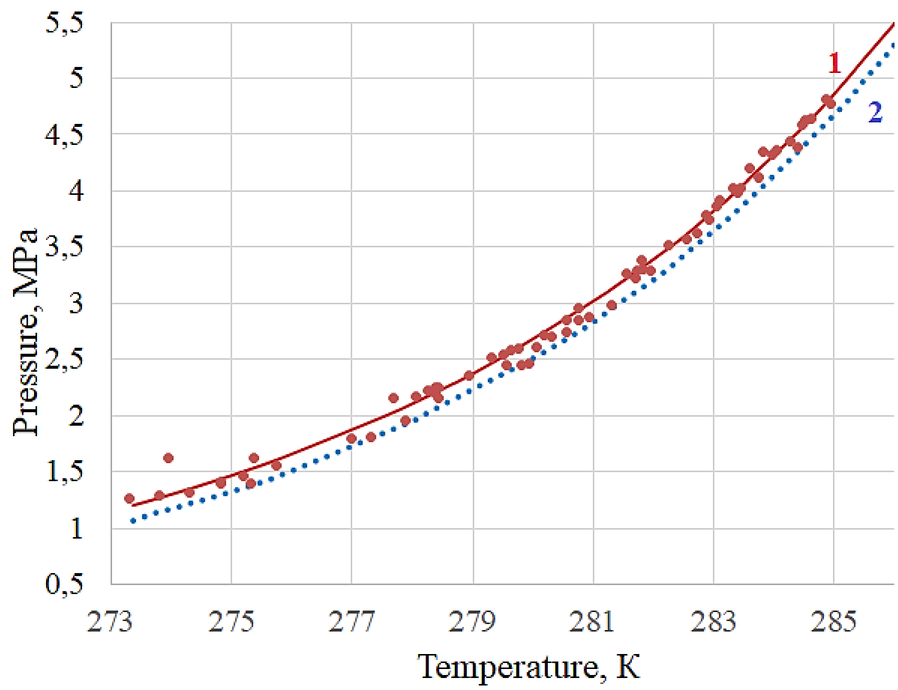

Figure 12. Comparison of the obtained experimental dependence of the mass crystallization parameters of the gas hydrate in the studied sample (1) and the equilibrium curve of hydrate formation for the given gas composition, obtained according to the Barrer-Stewart equation (2).

9. Conclusions

The method of operational setting of the mass crystallization parameters of gas hydrate in reservoir systems by visual identification of the appearance of a solid phase on the interfacial surface (on the surface of a gas bubble or at the place of its exit from the liquid during the process of increasing the pressure in the reactor and decreasing the temperature of the sample) has been theoretically justified and experimentally confirmed.

A laboratory installation was developed and implemented for the implementation of the technique of operative setting of the parameters of mass crystallization of gas hydrate in reservoir systems.

The given experimental data were obtained in less than 9 hours of the research cycle, which is almost an order of magnitude faster than the traditional methods of determining the equilibrium parameters of hydrate formation of the system.

The developed technique, first of all, makes it possible to evaluate systems that have a memory of hydrate structures. However, preliminary transfer of part of the water of the studied sample through the gas hydrate form, to give it the properties of hydrate structures, makes it possible to estimate the parameters of hydrate formation of any reservoir system.

The industrial application of this technique will allow obtaining additional important information for the prevention of gas hydrate complications. In many cases, this may be the basis for clarifying the consumption norms of hydrate formation inhibitors and the zones of their introduction into the technological line. In the course of further research, it is planned to develop samples of equipment for the implementation of this technique at industrial facilities.

Abstract. The article presents the results of a study of the process of transporting grain from the territory of Ukraine in global supply chains. In order to study the negative impact of the transport sector, a simulation model of the existing logistics system was developed, namely, using only road transport. The model was developed using Java SE technology based on the agent-based and discrete-event principles. As a result of a series of experiments based on the grain supply chain through the Mykolaiv commercial port, it was found that the actual CO_2 emission rates per unit of transport work are 12.8 kg per tonne and 32.9 kg per 1000 tonne-km.

1. Introduction

Sustainable transport is a key factor in sustainable development. Due to the significant role and, accordingly, the impact of transport on sustainable development goals, the achievement of the Agenda and the Paris Agreement on climate change is ensured or hindered. Unlike sectors such as energy and water supply, which rely on SDGs to track sector performance, transport does not have a specific SDG. Nevertheless, transport has important socio-economic importance, contributes to economic and social development and is the basis of public welfare.

Modern transport and logistics (TL) systems are in a state of constant change, adapting to the external environment, taking into account new challenges and implementing the achievements of scientific and technical progress, but from the standpoint of sustainable development, these changes are not enough to ensure a full transition to sustainable transport. At the same time, achievements and results in this area create unique opportunities for rethinking passenger and cargo transportation systems and finding sustainable solutions to accelerate transformation processes on a fundamentally new basis.

Sustainable transport means the provision of TL services and the use of infrastructure for the mobility of people and goods, promoting economic and social development for the benefit of present and future generations in a safe, accessible, efficient and resilient manner, minimizing carbon emissions and other emissions and environmental impact. The process of transition of TL systems requires the use of an integrated approach, which is based on the awareness of positive impacts and the avoidance or mitigation of negative consequences.

Meanwhile, analysts say that freight volumes will continue to grow. It is expected that road freight traffic will grow by about 40% by 2030 and 80% by 2050 [1]. This directs transport policy towards reducing road transport and using less polluting and more energy-efficient types of vehicles. While we fully agree with the need for this kind of transformation, we emphasise that technological factors, in particular the application of sound approaches to multimodal transport planning, can have a significant impact on the sustainable operation of transport lines. According to the EU transport policy, along with internalisation of external costs, more targeted investments in physical infrastructure, direct support for intermodal transport, and better use of information are key types of actions to support greater use of multimodal solutions [2], which require appropriate methodological support.

2. Problem description and method

Due to the fact that multimodal transportations are complex TL systems with a significant number of objects, technological processes and random variables, and, accordingly, certain events are difficult and sometimes impossible to predict, the simulation modelling methodology is used for their planning. Simulation modelling, thanks to its powerful mathematical apparatus, allows covering a significant number of TL parameters of the multimodal transport system, reflecting the dynamics of processes and taking into account uncertainty.

Simulation modelling (SM) methods are used in operations research to support decision-making. Modern SM research can include the development of models using a specific modelling technique (discrete event modelling, agent-based modelling) or hybrid modelling (interdisciplinary and combined) [3]. Discrete event simulation (DES) is the process of codifying the behavior of a complex system as an ordered sequence of defined events that occur at a certain point in time and indicate a change in the system state [4]. Agent-based modelling (ABM) explores the behavior of autonomous agents, the interaction between agents and the environment, as well as the impact of behavior on the most complex aspects and adaptation of the system as a whole [5–7]. Each of these approaches has a rather long history of development. Meanwhile, the hybrid modelling approach (HS), which is based on the use of interdisciplinary approaches at different stages of modelling or combines two or more methods, including discrete event modelling, system dynamics and agent-based modelling (combined modelling), has experienced an almost exponential increase in popularity over the past decades [8, 9].

Researchers offer a number of important contributions that present simulation modelling methods as tools for solving various issues related to the development of TL systems of multimodal transport. Approaches are being developed to classify this contribution in the context of identifying the most researched areas, established trends and promising areas of research [10]. At the same time, it is argued that despite the exponential growth of academic literature, there is a gap for empirical research on the numerous drivers, barriers, theories, moderators, intermediaries and methods related to supply chain sustainability [11]. It is even noted that due to the growing sustainability concerns, simulation models have become limited in minimizing, for example, CO_2 emissions during transportation planning, as they are not goal-oriented as optimization models [12].

The analysis of individual publications allowed us to summarize the following observations on the methodological features of a number of studies. Carlos Henrique et al. [13] presents an approach to modelling and optimizing planning to minimize carbon emissions in grain logistics export chains while meeting demand requirements. The results show the possibility of reducing emissions, but the data and therefore the conclusions are limited to railways. Matsiuk et al. [14] presents agent-based simulation models that allow for a comprehensive assessment of the performance of complex queuing systems. However, in these studies, the probability of technological failure is considered to be a complex indicator, rather than technological indicators, such as service time. In [15] delivery speed is considered from the perspective of the entire supply chain based on a simulation model and data that combines information from line operators and customers to analyze how they influence decision-making in maritime supply chains. Katsman et al. [16] considers a multifactor queuing system. Using an analytical model of the system states, the authors determine the performance indicators of a complex, multifactor queuing system. However, this approach has certain limitations for use in the study of complex supply chains. Studies have shown that the impact of speed can be small in terms of total supply chain costs, but quite significant in terms of carbon emissions. Mazaraki et al. [17] presents a simulation model of grain delivery by rail and water transport, and although the process is multiphase, it does not take into account the use of road transport as a means of transporting grain from production sites to railway stations.

Based on the hypothesis put forward and taking into account the results of generalization of the latest methodological tools, the purpose of this study is to determine the optimal parameters of the process of grain supply by road to Ukrainian seaports. To achieve this goal, it is planned to:

- to develop a network simulation model of grain delivery by a centralized fleet of vehicles from production sites to grain terminals of seaports;
- to study the conditions of sustainable functioning of the transport and technological line "production points – road transport system – sea trade port";
- based on the optimal technical and operational characteristics of the grain supply chain, to determine the specific CO_2 emissions per unit of transport work.

3. Results and discussion

The complete turnover of the vehicle in the grain supply chain structure will be equal to:

$$Q_{to} = t_{waitL.} + t_{l.} + t_{moveToSeaPort.} + t_{waitUnl.} + t_{Unl.} + t_{moveToBack.} \tag{1}$$

where $t_{waitL.}$ is the time spent waiting for the loading operation, hours; $t_{l.}$ is the time spent on loading grain, hours; $t_{moveToSeaPort.}$ is the time spent on moving the vehicle to the seaport terminal, hours; $t_{waitUnl.}$ is the time spent waiting for the unloading operation, hours; $t_{Unl.}$ is the time spent on unloading, hours; $t_{moveToBack.}$ is the time spent on moving the vehicle from the sea terminal to the point of the next loading, hours.

More generally, expression (1) can be represented as:

$$Q_{truck} = \sum t_{t.w.o.} + \sum t_{exec.} \tag{2}$$

where $\sum t_{t.w.o.}$ is the total waiting time for operations. This element can be interpreted as unproductive vehicle downtime, hours; $\sum t_{exec.}$ is the total executional time of operations. This element can be interpreted as the time of vehicle use, hours.

Then the vehicle utilization rate will be defined as:

$$\upsilon_{truck} = \frac{\sum t_{exec.}}{\sum t_{t.w.o.} + \sum t_{exec.}} \tag{3}$$

At the same time, grain delivery time significantly depends on the efficiency of the vehicle fleet and, for network processes, is a derivative of a set of transport and technological parameters. Taking into account that the delivery time should be as short as possible, subject to the rational use of production resources, we obtain the following optimization model:

$$t_{deliv} = f(k_{grain}, N_{truck}, N_{elev}, \{M_1 : M_k\}) + f(m_{truck}, N_{truck}, \{M_1 : M_k\}, N_{elevseaPort}) \to min. \tag{4}$$

with restrictions:

$$f(n) = \begin{cases} z_r < r_{truck} < z_f, \\ m_{truck} = 1, 2, 3...M_{truck}, \\ N_{truck}, N_{elev}, m_{truck}, N_{truck}, \{M_1 : M_k\}, N_{elev.seaport} > 0. \end{cases}$$

where k_{grain} is the average intensity of formation of grain cargo mass, tonnes/year; N_{truck} – estimated fleet of trucks, units; $N_{elev}, N_{elev.seaport}$ – the estimated required capacity of elevators at the primary point of grain accumulation and elevators at the seaport, tonnes; $\{M_1 : M_k\}$ – the multiplication of possible routes of grain delivery by road on the grain supply network; z_r is the rational limit of vehicle fleet utilization; z_f is the limit of reliability of the vehicle fleet.

Since the objective function of the optimization model is presented in implicit terms, its implementation will be carried out through computer simulation.

The simulation model is a computer model that simulates the process of transporting grain from the places of its production – the primary storage network – to the terminals of sea grain ports.

The model was developed using a hybrid approach based on two basic principles of simulation modelling: agent-based and discrete-event modelling [18]. The agent-based principle allows for the full application of system factor analysis, as the agent model is a multi-element system operating in a single development environment based on the main agent. The discrete-event principle allows you to simulate a technological process of any complexity in detail. In this case, this tool is used to simulate the full technological turnover of a vehicle – a truck.

The model was implemented on the example of the Mykolaiv Commercial Port and the region of attraction to it – Mykolaiv, Kirovohrad, Dnipro, Zaporizhzhia and Kherson regions in the GIS

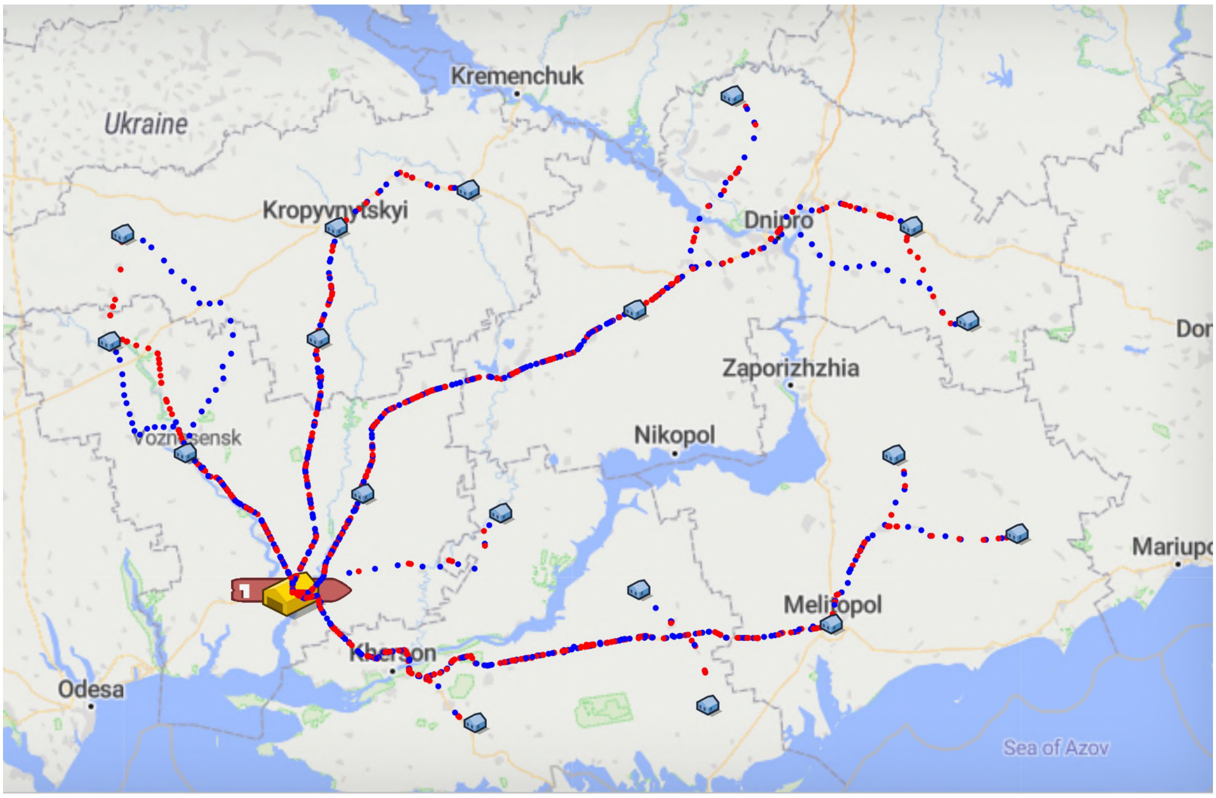

Figure 1. General view of the presentation of the simulation model.

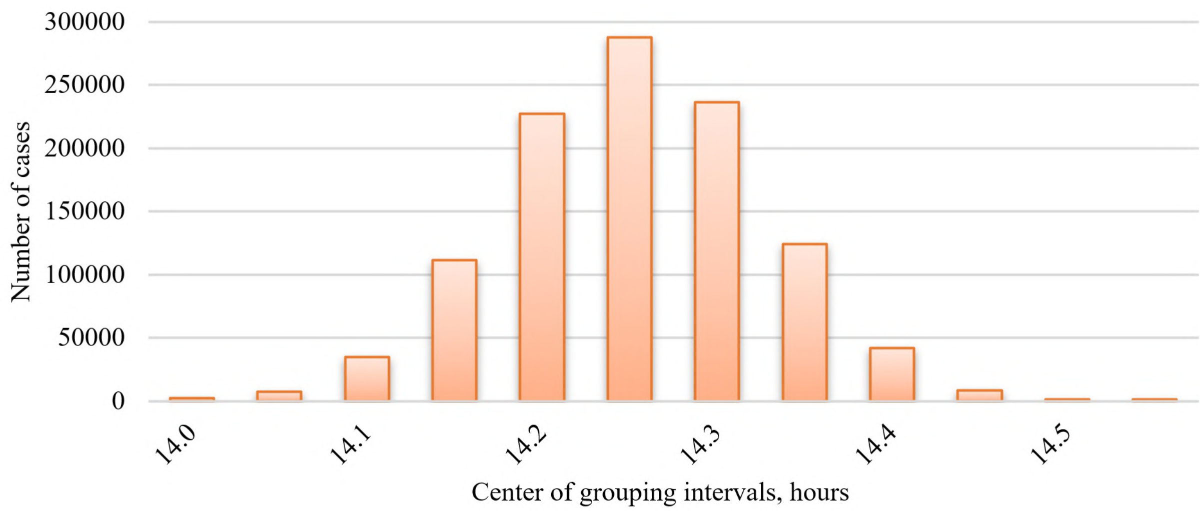

Figure 2. Probability density of grain delivery time distribution at optimal sizes of the fleet of vehicles (trucks and ships).

spatial environment of a real map of road routes using the Java SE technology and compiler. Initial data and grain production volumes were taken in accordance with official statistics for these regions for the 2021-2022 marketing year, totaling 14.5 million tonnes.

The general view of the model presentation is shown in figure 1.

According to the modelling results, the regularity of formation of the average level of vehicle fleet utilization (load factor) depending on the number of trucks involved in the transportation process has been established (figure 2). It has been experimentally established that the optimal level of vehicle fleet utilization of 51% is achieved at 2300 units. At a load factor of 47% of the bulk carrier fleet, the average time spent by a tonne of cargo in the transport system is 14.2 hours and has an almost perfect normal law distribution density with parameters $M(x) = 14.22$ hours and $s(x) = 0.113$ hours.

CO_2 emissions per unit of transport work (one ton-km) and one transported ton of cargo were determined (table 1).

Table 1. Experimental results.

Indicator	Indicator value
Average delivery time, hours	14.3
The average distance of the cargo route, km	391
We need a fleet of trucks (carrying capacity 20 tons)	2300
The coefficient of utilization of the car park	$p = 0.55$
Average costs of diesel. fuel for the delivery of 1 ton of cargo by land, l.	4.21
Average costs of diesel. of fuel per 1000 ton-km, l	5.34
CO_2 emissions for the transportation of a ton of cargo over land, kg	12.8
CO_2 emissions per 1000 ton-km, kg	32.9

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012033 doi:10.1088/1755-1315/1415/1/012033

4. Conclusions

A network simulation model of grain delivery by a centralized fleet of cars from production sites to grain terminals of sea trade ports has been developed, which, unlike the existing ones, takes into account the time spent waiting for loading / unloading and simulates the full cycle of car turnover under centralized control. It has been established that the sustainable functioning of the transport and technological line of grain – the level of use of vehicle fleets within the range of 50–60% in the conditions of Ukraine – is achieved with the size of the fleet of trucks (with a carrying capacity of 20 tons) of 2,300 units for every 14.5 tons of grain. On the basis of the defined technical and operational indicators, the actual norms of CO_2 emissions per unit of transport work were established: 12.8 kg per ton and 32.9 kg per 1000 ton-km of grain transported over land.

Abstract. Under present-day conditions in the development of the transport market, organizing the transportation of dangerous goods by rail is an urgent task, considering the specific properties of the impact of dangerous goods on technical devices, human health, and the environment. The number of parameters influencing the safety of the transportation process is quite large, therefore, programs for the safe and sustainable development of railway transport must involve protection from all possible sources of danger. The strategy for sustainable development of railway transport should be based on improving regulatory and technical documentation, developing safe technology for eliminating the consequences of emergencies, developing network computer technologies, and improving vehicles and transportation technology. Since the transportation of dangerous goods represents a significant share of the total transportation of goods, including railway transport, the research outlined in the presented work is aimed at solving some aspects of this strategy, which as a result forms a strategic approach to the sustainable development of railway transport when organizing the transportation of dangerous goods. In this paper, considering modern conditions for the development of railway transport, it is proposed to comprehensively implement the assigned task with a new approach by introducing a system of operational control during the transportation and temporary storage of dangerous goods and applying the developed method for the optimal distribution of empty cars among cargo checkpoints in the organization of the transportation process.

1. Introduction

Transportation of dangerous goods is an activity associated with the movement of dangerous goods from the place of their production or storage to their destination, with the preparation of freight, containers, vehicles, and crew, acceptance of freight, freight operations, and short-term storage of goods at all stages of movement [1–3].

Transportation of dangerous goods, including railway transport, is a necessary task in the context of sustainable development of transport, since ensuring the sustainable organization of such transportation will maintain the health of personnel and the population, exclude negative impacts on the environment, and take all necessary actions to prevent the occurrence of an emergency [4–6]. On the one hand, this direction corresponds to Sustainable Development Goal No. 9 “Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovations”, and on the other hand, it satisfies the provisions and Sustainable Development Goal No. 11 “Make cities inclusive, safe, resilient and sustainable”, No. 12 “Ensure sustainable consumption and production patterns”, No. 13 “Take urgent measures to combat climate change and its impacts” [7].

These provisions characterize the implementation of the environmental component in the concept of sustainable development. At the same time, the research presented in this work is also aimed at optimizing the organization in the transportation of dangerous goods by optimally allocating empty cars through freight points. This will ensure economic stability, which is confirmed by the results of the research. Thus, the relevance of the chosen research topic is due to the desire for a balanced development of the economic and environmental components in the concept of sustainable development through the implementation of the proposed strategic approach to organizing the transportation of dangerous goods by railway in Ukraine.

Since the transportation of dangerous goods by railway is a specific type of transportation, with regard to the potential danger of transporting goods, the unconditional implementation of all preventive measures aimed at warning the occurrence of emergencies when organizing the transportation of dangerous goods, including by railway, is required from all entities in the transportation process [8–10].

Confirmation of the relevance and need to formalize a strategic approach to sustainable railway development in organizing the transportation of dangerous goods is statistical data on the number of dangerous goods transported in 2018-2022, as well as the number of accidents, transport events and emergencies that occurred in Ukraine during the transportation of dangerous goods for the same period [11]. These data are presented in tabular and graphical forms (table 1, table 2, figure 1). The materials provide statistical data under the classification of dangerous goods (classification by class, category, and packaging group) in line with State Standards of Ukraine (SSU) 4500-3 “Dangerous goods. Classification” depending on the type and degree of their potential danger according to indicators and criteria [12].

Data from table 1 and figure 1 show that the highest rates of dangerous goods transportation in Ukraine were in 2019 and 2020. In 2022, we see a rapid decline in the volume of railway transport, also due to certain problems in logistics.

A significant proportion of chemically hazardous facilities are concentrated on the territory of Ukraine, as well as a significant number of fire-hazardous facilities, which are usually located next to railway tracks or have their private tracks. At the above potentially hazardous facilities, large quantities of hazardous substances are extracted, processed, transported, stored, and consumed, which in any case require further safe transportation [13–15].

Considering the above, in modern conditions, it is especially relevant to review the current technology for transporting dangerous goods, including in bulk, along the Ukrainian railway network, and to find ways to improve it to prevent the occurrence of emergencies, which increased in the period from 2018 to 2022 by 22 percent (table 2).

It should also be noted that complex European integration processes relating to Ukraine and its transport system [16–18], different levels of economic development, and the characteristics of the productive and consumer specialization in the EU countries and Ukraine will lead to the fact that the volume of transport of dangerous goods in Ukraine and beyond will steadily increase [19]. This requires the search for effective tools to optimize the organization of dangerous goods transportation by railway in Ukraine.

The work is devoted to formalizing a strategic approach to organizing the transportation of dangerous goods by introducing a system of operational control during transportation, temporary storage of dangerous goods, and formalizing the optimal allocation of empty cars

Table 1. Percentage ratio in the number of dangerous goods transported following the class of dangerous goods from 2018 to 2022.

Danger class	2018	2019	2020	2021	2022
Class 1 Explosive Materials	15.89	10.88	10.52	9.35	10.16
Class 2 Gases	23.20	16.08	15.35	16.23	17.71
Class 3 Highly flammable liquids	10.39	18.07	20.73	18.04	16.32
Class 4.1 Inflammable solid	4.81	4.88	6.64	7.21	10.17
Class 4.2 Substances capable of self-ignition	8.36	7.12	6.92	6.07	5.87
Class 4.3 Substances that emit flammable gases interacting with water	3.38	3.67	3.36	2.23	3.46
Class 5.1 Oxidizing substances	7.06	10.57	7.93	9.36	8.92
Class 5.2 Organic peroxides	12.72	6.56	7.02	8.01	10.49
Class 6.1 Toxic substances	3.86	1.72	5.36	4.02	1.72
Class 6.2 Infectious substances	0.00	$1 \cdot 10^{-6}$	$1 \cdot 10^{-5}$	0.00	0.00
Class 7 Radioactive Materials	0.00	$1 \cdot 10^{-6}$	$2 \cdot 10^{-6}$	0.00	$4 \cdot 10^{-6}$
Class 8 Corrosive Substances	4.51	6.22	9.67	10.84	3.50
Class 9 Other hazardous substances	5.80	14.23	6.50	8.65	11.66
In total	100.00	100.00	100.00	100.00	100.00

Table 2. Number of transport events with dangerous goods.

Number of	2018	2019	2020	2021	2022
Transport events	130	141	147	154	161
Lost	29	17	11	6	8
Injured	9	7	11	6	4

among freight points to ensure the implementation of the concept of sustainable development of railway transport in Ukraine.

2. The operational control system for the transportation and temporary storage of dangerous goods

An analysis of transport events related to the transportation of dangerous goods [11] shows that the so-called "human factor" remains decisive in the issue of ensuring safety [20–22]. In modern conditions, it can and should be assessed even at the stage of admission to work with dangerous goods by introducing a unified system of professional training, qualified selection, and certification of personnel whose activities are directly linked to dangerous goods.

In solving this problem, an important role is assigned to the audit apparatus, its professional selection, and advanced training.

Railway transport is equipped with automation facilities at a fairly high level. At the same time, research is aimed at reducing the number of technical equipment failures and personnel errors. The developed multi-level system for controlling and ensuring the safety of train traffic allows, in addition to performing direct control and safety tasks, to detect potentially dangerous situations. In this case, the dispatch apparatus (assistant station masters, train dispatchers) is given a corresponding signal, and the priority for processing information that comes from the control and monitoring object is set. The system also provides for the development of predicting

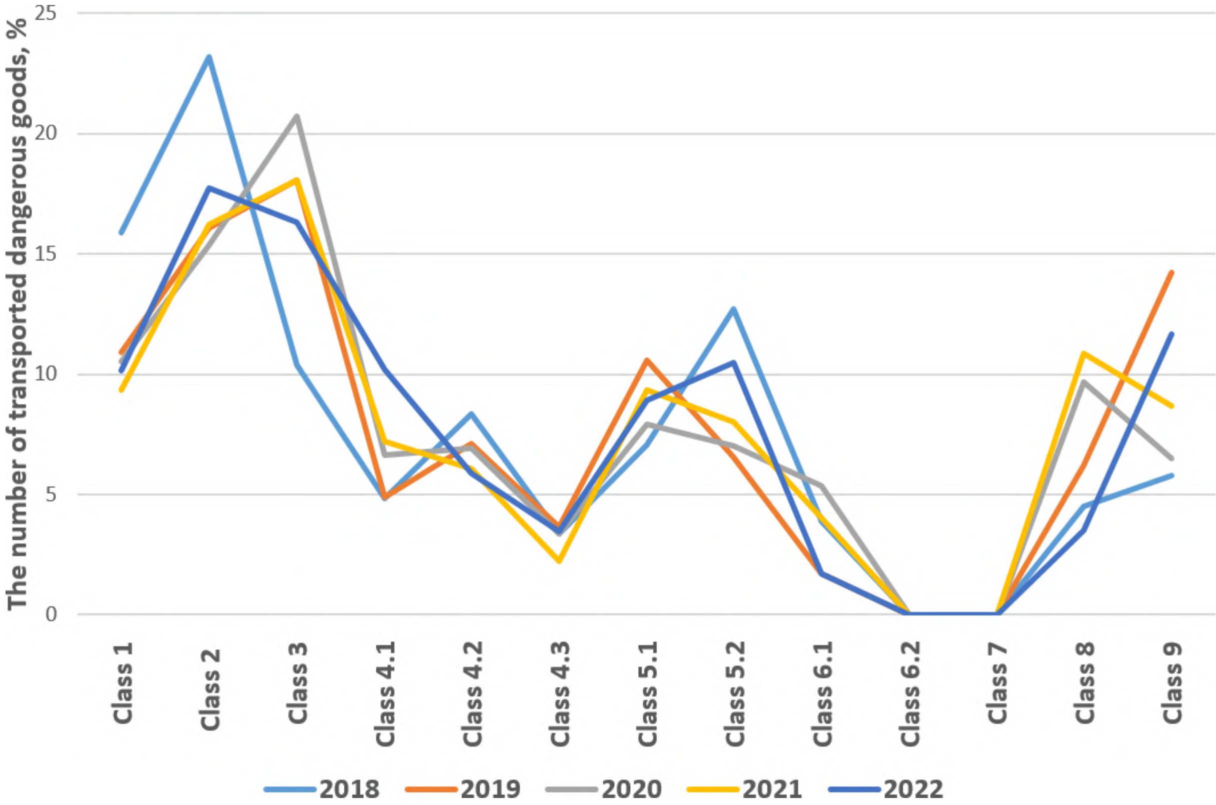

Figure 1. The number of transported dangerous goods in 2018-2022, in percentages.

the development of the situation in the event of accidents or emergencies and the development of model options for switching on backup control subsystems and ensuring the safety of train traffic.

In general, the implementation of the system involves reducing, and in some cases eliminating, the influence of the human factor on the safety of train traffic. To do this, erroneous actions of the dispatch apparatus and incorrect operation of devices in the event of a dangerous failure or unauthorized interference in their operation are blocked.

Environmental control points at border checkpoints play an important role when organizing the international transport of dangerous goods.

One of the main problems when transporting dangerous goods, including in bulk, is the insufficient level of reliability of rolling stock. An analysis of recent accidents associated with the transportation of bulk dangerous goods shows that in several cases rolling stock with an extended service life was used (for example, shippers have the majority of such specialized tanks). The tanks used do not have technical means to reduce the evaporation of petroleum products, casings to protect drain devices from impacts on the ground, and the boiler body is structurally unable to withstand an impact on the ground when there is a tank derailment. New generation tanks having a reinforced boiler body are practically not being introduced. The railway management is taking the initiative to renew the tank fleet. In light of this, it would make more sense to incentivize shippers of dangerous goods to upgrade their cars. In addition, it is necessary to tighten control when accepting bulk dangerous goods for transportation from the shipper, especially paying attention to the following points:

- control of the technical condition of tanks, including control of non-interference in their design without agreement with the manufacturer;

- monitoring compliance with the conditions for loading goods into cars following established rules and instructions for tanks;
- control of correct completion of transportation documents, availability of necessary permits and licenses;
- control of compliance with the rules of escort and security.

When organizing the transportation of dangerous goods in bulk, it is necessary to monitor compliance with the transportation conditions provided for by the rules. For this aim, using modern automation tools, it is proposed to develop and equip tanks with technical means that reduce the evaporation of petroleum products during transportation in tanks. In addition, it is possible to install sensors that monitor and signal the state of dangerous goods during transportation. Information about deviations in the state of the control object is immediately transmitted to the provided levels of automated systems and the staff makes a prompt decision on further actions.

As a rule, the onset of a destructive process with dangerous freight (seepage, leakage, evaporation, etc.) begins with a slight depressurization of the container and can subsequently result in a significant negative impact on the environment, both during transportation and temporary storage of dangerous goods at the transfer station.

Moreover, if depressurization occurs along the way, then the dangerous freight can leave a trail of tens or even hundreds of kilometers long during the time from the beginning of the depressurization process until the moment it is detected. Therefore, it is very important to define the beginning of an emergency as soon as possible and begin to neutralize its consequences.

Creating a system to prevent transport incidents when transporting dangerous goods will undoubtedly reduce environmental and economic damage.

The operational control system for the transportation and temporary storage of dangerous goods includes a set of technical systems, devices, and measures to monitor the condition and location of dangerous goods, determine the onset of emergency (pre-emergency) situations and accidents, process information and transfer it to dispatch control centers for developing solutions to prevent emergencies, localize and neutralize the consequences of accidents.

The system for operational monitoring of the condition of transported and stored dangerous goods includes the following technical subsystems and devices:

(i) subsystems for monitoring the technical condition of containers for the transportation of dangerous goods and the condition of them themselves to determine their release into the environment using sensors;
(ii) subsystems for collecting information from control sensors, processing it, and transmitting it to a repeater installed on the locomotive;
(iii) subsystems for transmitting information from the locomotive (train, car, warehouse) to train dispatchers and processing it.

To determine the economic efficiency of implementing an operational control system during the transportation and temporary storage of dangerous goods, research is needed to define the resulting economic damage that causes costs for:

(i) liquidation of the accident and its consequences and restoration of traffic;
(ii) compensation for damage to the environment (including to the population) – fines and compensation;
(iii) losses from the cessation of the transportation process during the liquidation of the accident (including damage to vehicles);
(iv) possible payments for freight insurance.

Determining such average costs will allow us to evaluate the effectiveness of implementing the system, and organizational and technical solutions for eliminating accidents and their consequences.

Sensors control for monitoring the condition of dangerous goods can be made in the form of sensors that can not only signal the occurrence of leaks of substances, but also indicate their locations (by using an additional substance that can change the colour), and also allow them to be quantitatively assessed. Monitoring sensors together with the unit of a primary information collection must meet the technical requirements. In addition, they must have protection systems against dynamic loads, vibration, external damage, exposure to aggressive substances, and unauthorized penetration.

The placement and fastening of sensors and the primary information unit on special tanks must be permanent and have connectors for connecting the information transmission system.

The issue of reducing the threat of an emergency with dangerous goods transported in bulk through the territory of Ukraine plays an important role since accidents accompanied by spills of hazardous liquids lead to significant environmental damage to the environment.

In this regard, it is rational to develop and implement technology to eliminate the consequences of transport accidents with dangerous goods. In addition, it is possible to develop a methodology and determine environmentally acceptable routes for dangerous goods to reduce the risk of an emergency.

Considering that more than 90 percent of liquid freight consists of petroleum products, great attention must be paid to improving the organization of their transportation. The achievements of scientists make it possible to optimize the car flows of petroleum products. In this case, important conditions are the routing of their transportation and the organization of empty tank car flows.

Routing of railcar flows of petroleum products is a particularly effective measure for mass export transportation to seaports, which allows for reducing freight delivery times and speeding up the turnover of railcars.

Also, one of the sources of reducing costs and car turnover is the rational allocation of empty tanks for loading. At the same time, it is taken into account that in the case of loading a freight similar to the dumped one into a tank, there is no need for hot working of the tanks (cold working is sufficient), and this can significantly reduce the downtime of tanks at loading stations and the costs associated with processing.

The rational allocation of empty tanks for loading consists in increasing the degree of conformity of the structure of tanks arriving for loading, according to the names of the dumped and filled petroleum products. This is possible by increasing the depth of information that is transmitted to loading stations about the names of dumped petroleum products from tanks arriving at their address in empty tank trains, and about the use of this information when distributing empty tanks for loading. The depth of information means the availability of the necessary information not about one composition of empty tanks for filling, but about 2...3 or more. Thus, with an increase in information to three trains, the proportion of tanks sent for loading of petroleum products similar to the dumped one increases by 2.5...3 times compared to the availability of information about only one train. Accordingly, a reduction in costs for washing and steaming operations is achieved and the turnover of tanks is accelerated.

The depth of required information can be increased by using modern information technologies. It is necessary that the dispatch apparatus make a timely decision on the assignment of trains of empty tanks to one or another loading station and that the necessary information is transmitted to them in advance to enable the rational allocation of tanks for loading.

Thus, the allocation of empty cars is a key and rather complex management task. The authors propose an optimal solution to the problem of distributing empty cars on freight points as one of the methods for optimizing the organization of transportation of dangerous goods by railways.

3. The description of the mathematical apparatus

Problems of the type under consideration can be divided into two groups depending on how fully all the factors associated with finding the optimal option for allocating empty cars are considered:

(i) optimization is done only from the viewpoint of the best use of the capacity of cars, and the costs associated with the movement of empty cars between freight points are not taken into consideration;

(ii) optimization of the process in the allocation of empty cars is carried out according to the criterion of overall operating costs associated with the supply of cars to freight points and with the transportation of goods by railways.

Ignoring the costs of supplying empty cars can be justified only if they do not differ significantly from each other or are insignificant in their absolute value.

In its simplest form, the problem of allocating different-type cars to freight points depending on the static load was formulated by A. B. Kaplan. In mathematical formulation, this problem is written as follows:

$$R^* = y_{ij}^{min} \sum_{i=1}^{n} \sum_{j=1}^{m} y_{ij}, \tag{1}$$

if

$$y_{ij} \geq 0, i = 1, 2, \ldots, n; j = 1, 2, \ldots, m, \tag{2}$$

$$\begin{cases} \sum\limits_{i=1}^{n} y_{ij} P_{ij} = Q_j; \\ \sum\limits_{j=1}^{m} y_{ij} \leq n_i. \end{cases} \tag{3}$$

The main goal of drawing up an optimal allocation plan is to minimize the number of empty cars y_{ij}, required to transport a given amount of freight Q_j, if restrictions are imposed on the number of cars (3). In this case, at each freight point, there is only one type of freight j, the statistical load of which P_{ij} when transported in cars of the i-th type is given, and the costs of supplying empty cars are neglected. The sources of empty cars arriving at the freight points at the station are both unloading points and cars arriving from neighbouring stations.

The task of the type under consideration should be formulated differently if there is a shortage of empty cars:

$$R^* = y_{ij}^{max} \sum_{i=1}^{n} \sum_{j=1}^{m} y_{ij} P_{ij}, \tag{4}$$

if

$$y_{ij} \geq 0, i = 1, 2, \ldots, n; j = 1, 2, \ldots, m, \tag{5}$$

$$\sum_{j=1}^{m} y_{ij} = n_i; \tag{6}$$

$$\sum_{i=1}^{n} y_{ij} P_{ij} \leq Q_j. \tag{7}$$

In this formulation, the optimization problem lies in finding such y_{ij}, that would maximize the linear form (4), representing the amount of freight loaded into n_i of delivered cars. At first

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012034 doi:10.1088/1755-1315/1415/1/012034

sight, the optimal choice for distributing empty cars that mostly satisfies the requirements for the best use of capacity and tonnage is one in which only cars of one type are delivered to freight points.

However, with a significant number of freight points and a lack of empty cars of the "optimal" type, constructing such a distribution plan using heuristic methods seems impossible, and then the problem posed can only be solved using linear programming methods since functionals (1) and (4) and restrictions (3), (6) and (7) are linear.

4. Results

Let us consider a numerical example for conditions when there is a shortage of empty cars at the station. At two freight points there are freights in the amount of $Q_1 = 540$ tons and $Q_2 = 620$ tons, the volumetric weight of the freight is $y_1 = 0.3$ tons/m^3 and $y_2 = 0.75$ tons/m^3.

The station has three types of covered cars with the following characteristics for cars of the first type $P_1 = 62$ tons, $V_1 = 107$ m^3 in the amount of $n_1 = 8$, for cars of the second type $P_2 = 62$ tons, $V_2 = 120$ m^3 in the amount of 12 and for the third type of cars $P_3 = 62$ tons, $V_3 = 90$ m^3 in the amount of 6. The static loads of the cars are as follows: $P_{11} = 32$ tons, $P_{12} = 62$ tons, $P_{21} = 36$ tons, $P_{22} = 62$ tons, $P_{31} = 27$ tons, $P_{32} = 62$ tons.

The condition is set – to ensure the loading of all freights with a volumetric weight of $y_1 = 0.3$ tons/m^3. We will substitute the initial data of the task into expressions (4) — (7) and after transformations we obtain

$$R = 32y_{11} + 62y_{12} + 36y_{21} + 62y_{22} + 27y_{31} + 62y_{32} \tag{8}$$

or

$$R_1 = 1.2y_{11} + 2.3y_{12} + 1.3y_{21} + 2.3y_{22} + y_{31} + 2.3y_{32}, \tag{9}$$

$$y_{ij} \geq 0 \ (i = 1, 2, 3; j = 1, 2), \tag{10}$$

$$\begin{cases} y_{11} + y_{12} = 8; \\ y_{21} + y_{22} = 12; \\ y_{31} + y_{32} = 6. \end{cases} \tag{11}$$

$$\begin{cases} 32y_{11} + 36y_{21} + 27y_{31} = 540; \\ 1.2y_{11} + 1.3y_{21} + y_{31} = 20; \\ 62y_{12} + 62y_{22} + 62y_{32} \leq 620. \end{cases} \tag{12}$$

$$y_{12} + y_{22} + y_{32} \leq 10. \tag{13}$$

Let us exclude from expressions (9), (11) and (13) variables y_{12}, y_{22}, y_{31}, y_{32} and after simplification we obtain

$$R_2 = 0.46y_{11} + 0.7y_{21}; \tag{14}$$

$$y_{11,21} \geq 0; \tag{15}$$

$$0.2y_{11} + 0.3y_{21} \leq 4. \tag{16}$$

Condition $1.2y_{11} = 1.3y_{21} \leq 20$ is less strong than (16).

From conditions (11) it implies

$$\begin{cases} y_{11} \leq 8; \\ y_{21} = 12. \end{cases} \tag{17}$$

The task is to find such y_{11} and y_{21}, that would maximize the linear form (14). Since the task has been reduced to determining two variables, it can be solved graphically (figure 2). The search direction is shown by an arrow going from the origin of coordinates, since according to the condition it is necessary to maximize the functional (16), which grows with increasing

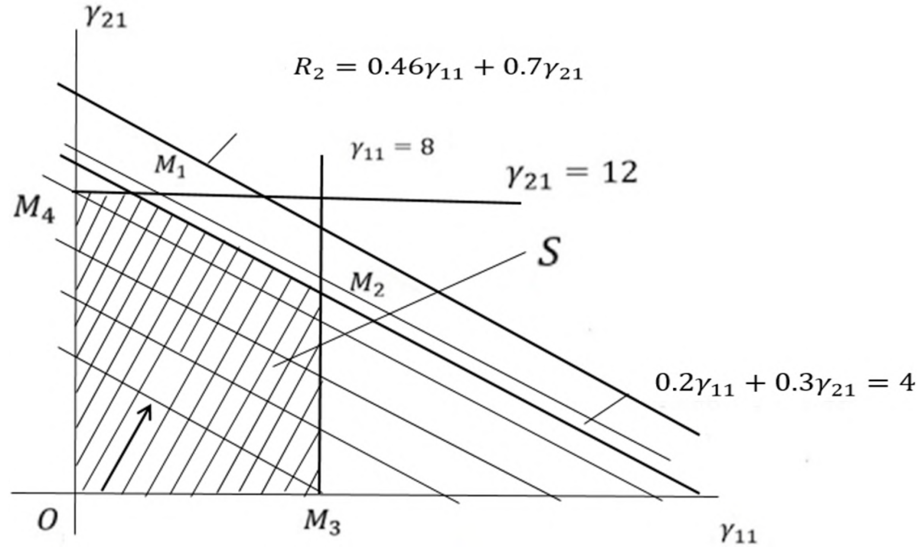

Figure 2. Graphical method for searching for the optimal option in allocating empty cars according to the criterion of maximum static load.

y_{11} and y_{12}. The desired solution should be sought in the area S, bounded by polygon $M_1M_2M_3OM_4$. Apparently, the coordinates of points M_1 and M_2 (that are farthest from the origin of coordinates) will correspond to the optimal solution.

Solving equations $0.2y_{11} + 0.3y_{21} = 4$ and $y_{11} = 8$, together, we determine the coordinates of point $M_2 : y_{11} = 8, y_{21} = 8$. As a result of the joint solution of the equations $0.2y_{11} + 0.3y_{31} = 4$ and $y_{21} = 12$ we obtain the coordinates of point $M_1 : y_{21} = 12, y_{11} = 2$. To establish the optimal solution, we substitute the coordinates of the points M_1 and M_2 into expression (14) and as result we have $R_2(M_2) = 9.28, R_2(M_1) = 9.32$. Thus, the coordinates of point $M_1 : y^*_{21} = 12$ and $y^*_{11} = 2$ are the optimal solution. Using equitation (11) and (12), we calculate the remaining components of the optimal solution: $y^*_{12} = 6,\ y^*_{22} = 0,\ y^*_{31} = 2,\ y^*_{32} = 4$. For this solution, the value of the functional will be equal to $R = 1100 tons$ and the balance of unshipped freight will be $(540 + 620) - 1100 = 60$ (tons).

The proposed method for finding the optimal option in distributing empty cars according to the criterion of maximum static load is a distinctive option for solving the problem of distributing empty cars in railway transport in comparison with currently existing methods. For example, in [23], the optimization model for the problem of distributing empty freight cars at a railway site is characterized as a combination of the flow task with minimum cost with the task of selecting a vehicle route. In paper [24], the problem of distribution of empty cars in the Chinese railway system takes into consideration the requirements of timeliness of demand for empty cars. Based on this a spatiotemporal network is created to describe the process of distributing the empty cars, where, in terms of the types of cars and network capacity, an integer programming model is proposed, allowing to minimize the total costs in the distribution process. In line with the obtained results, the authors of [24] concluded that many train routes must be scheduled to guarantee the timely delivery of empty cars to the station. Thus, the proposed method for finding the optimal option for distributing empty cars according to the criterion of the maximum static load is a relevant tool for supporting operational decision-making on the rational distribution of empty cars, which is recommended to be used to optimize the transportation process in railway transport in general, and when organizing the transportation of dangerous goods particularly.

5. Conclusions

Thus, due to the increasing attention of the world community to the global problems of humanity and the strategy for creating equitable and dynamic economic growth, sustainable transport is becoming one of the most important areas of further development. Sustainable transport has a positive impact on the environmental, social and economic stability of society.

Based on the research, we can conclude that the realization of the proposed strategic approach in optimizing the transportation of dangerous goods, which is determined by the implementation of an operational control system for the transportation and temporary storage of dangerous goods and the realization of the optimum allocation of empty cars among freight points, will ensure:

- improving transportation technology, increasing the level of their implementation, and ensuring the prevention of emergencies with dangerous goods during transportation on the Ukrainian railway network;
- realization of the “National Transport Strategy of Ukraine for the period of up to 2030” by solving the problem of increasing the level of safety in transport by introducing a system of operational control during the transportation and temporary storage of dangerous goods in order to ensure a high level of safety during the transportation of dangerous goods;
- compliance with the principles;
- realizing the concept of sustainable development, since the goal of the research corresponds to the three goals of sustainable development in concordance with the official document of the UN General Assembly “Transforming Our World: The 2030 Agenda for Sustainable Development” (goals 9, 11-13 [7]).

It is also worth noting that the need for the modern development of railway transport and technological systems in a single transport space, the development and implementation of effective transportation process management systems require the creation of new and adjustment of existing methods for the distribution of freight and car flows [23, 24]. Therefore, with a view to optimizing the transportation process in railway transport in general, and when organizing the transportation of dangerous goods in particular, the use of the proposed method for finding the optimal option for distributing empty cars according to the criterion of maximum static load is a relevant tool for supporting operational decision-making, which will provide a solution to the important operational task of rational distribution of empty cars among cargo points.

Abstract. Safe and reliable air transportation plays a significant role in modern society by facilitating connection, communication, and economic activity, which has been growing steadily for recent decades. Ensuring a safe, reliable, and efficient operation of the air transportation network is a central challenge in assuring smooth progress in modern and future aviation. This research addresses the problem of human-caused issues in aerial transportation by proposing, substantiating, validating, and designing automated flight situation advisory systems that can provide critical input to the crew in the cases of unexpected and challenging flight situations. It was shown that a proper design and use of these systems could be instrumental in managing flight situations and could eliminate or mitigate a significant fraction of human-cause faults and emergencies. It would expected that such an advisory system can become a proactive and cost-effective tool to improve safety and reliability in the operation of air traffic networks of today and tomorrow. The study's main result is to assess the importance of factors influencing the development of recommendations by the advisory system.

1. Introduction

Air transportation plays an important role in the life of modern society. This conclusion is confirmed by the data of the International Air Transport Association [1], which established that over the past two years, there has been an increase in air transportation of passengers and cargo in the world, which is associated with the lifting of restrictions imposed during the onset of the COVID-19 pandemic.

In addition, air transport is an effective means of facilitating the solutions to social and international challenges such as humanitarian and military aid delivery, evacuation of victims of natural disasters, diplomatic visits, development of commercial and social projects, and others.

As the role and critical nature of air transportation has been increasing steadily, more attention is being paid to improving the quality of the aircraft and their safe, reliable and efficient use. Current trends in air transport development are aimed at reducing air emissions and noise level of aircraft engines, developing optimal strategies in route formation to reduce the cost of transportation, studying different flight and approach/landing scenarios, improving the quality of pilot training, studying technological and behavioral strategies aimed at solving the needs of both the carriers and the passengers.

Improving the safety and efficiency of air transport utilization is also influenced by the study of air catastrophes, not the least, examination, investigation, determination and the elimination of their causes. Many aircraft faults and failures leading to serious accidents are not so much of technical origin but rather can be related to incorrect decisions and actions, improper crew activities and other human-caused issues. Thus, according to ICAO estimates, the human factor can account for about 80% of all air accidents [2].

Thus, ensuring the correctness of the crew's actions in difficult flight conditions can be an essential challenge in the pursuit of safe and efficient air transportation. One of the possible solutions for an accident-free operation of air transport can be the creation of Automated Onboard Assistants (AOA), such as advisory expert systems that could assist in both finding and executing the solutions to complex flight situations based on the characteristics, the prognosis of the flight situation and provide the crew effective with effective solutions for specific developing flight situations [3]. The basis for analyzing the current state of the aircraft can be based not only on the information from the diagnostic systems of the craft but also integral indicators of the route progression, which ensures a smooth and reliable flight.

The purpose of the research is to design and create effective onboard advisory expert systems that analyze real factors that determine flight safety, which will ensure the rapid implementation of such systems on an aircraft in the interests of developing sustainable and acceptable air transport.

2. Related work

The main idea of air transport advisory systems is based on the construction of reliable and productive onboard computer systems developed in the interests of space, air, and ground vehicles.

Würfel et al. [3] proposed the nearest approach to the definition of an onboard expert system for applications in manned aviation. The described system is represented by a two-level hierarchical knowledge base, the first level of which activates the problem adequate to the actual situation, whereas the second level solves the tasks of forecasting the development of the situation using the mechanisms such as a range of alternative solutions, product rules, and precedent decisions based on optimization problem.

A multi-factor hierarchical model for assessing the level of air transport safety based on an accurate assessment of the current state was developed by Bugayko et al. [4]. The model consist of 7 components and 29 indicators and evaluates economic, technological, social, and environmental that can influence a developing flight situation.

Studies of the properties of different types of motors to reduce environmental pollution were attempted in [5,6]. To this end, Eberle and Helmolt [5] studied variants of construction of electric energy storage sources of automobile engines based on accumulator batteries and hydrogen with the use of fuel cells for energy conversion. Jiménez-Crisóstomo, Rubio-Andrada and Celemín-Pedroche [6] studied the difficulties of transition to non-carbon energy paradigms in aviation technology.

New variants and principles of construction of onboard computers and their software were studied in [7, 8]. Fayyaz and Vladimirova [7] proposed the design of a satellite fault-tolerant distributed onboard computer (FTD-OBC), in which an adaptive middle-ware block was used to automatically migrate executing tasks from a faulty node to other nodes in a case of failure. Lüdtke et al. [9] presented a concept of an onboard computer for next-generation systems that address future requirements. This concept assumes a distributed reconfigurable onboard computer structure that utilizes off-the-shelf commercially available high-performance hardware components.

Lund et al. [10] studied a related approach involving the use of off-the-shelf performance software components in onboard computers. They considered middle-ware components that implement additional functions for modern space application computer hardware. Software updates for satellite systems onboard computers combined with cold, hot and Kim et al. [11] proposed warm redundancy, based on stochastic networks. Leppinen et al. described the development experience, design, initial flight test results, and lessons learned of the Linux-based Aalto-1 spacecraft flight computer [12].

Kato et al. [13] proposed an open source software project profile of Autoware that provides a set of control modules including localization, detection, prediction, scheduling, and control, enabling autonomous embedded vehicle computer systems. The study focuses on the performance of Autoware on ARM-based embedded computing cores and Tegra-based embedded graphics processing units (GPUs).

Kemmerer and Labelle [8] studied an onboard computer that collects standardized data for efficient disaster outbreak management, and improved competitiveness was presented. Brewer et al. [14] compared performance models obtained using data processing techniques to evaluate their equivalence. Problems and challenges in reliable and uninterrupted operation of networks of aerial vehicles based on protocols of distributed situation-aware intelligent decision systems were discussed in Shmelova et al. [15].

Gudmundsson et al. [16] formulated a concept of sustainable development in the context of transportation planning, management, and decision-making. The first part of the concept involves the development of indicators and a framework for measuring sustainable development in the transportation sector. In the second part, the authors analyze the actual planning and decision-making in transport agencies under different management conditions.

The impact of transportation in the context of human values is based on the put-forward quality of life indicators studied by Steg and Gifford [17] considered the evaluation of possible consequences of such a policy. They established a tendency to favor the use of transportation facilities by obtaining short-term benefits at the expense of long-term losses of society. Daley [18] formulated the criteria for the efficient use of air transportation contributing to sustainable societal development.

The analysis of the earlier studies shows that there is a need to develop effective onboard recommendation systems that ensure smooth and sustainable long-term operation of air transport in complex, uncertain, conflict, and other challenging situations in the operation of an aircraft.

3. Characteristics and criteria in uninterrupted operation

Even though air transportation safety has been improving, the absolute number of conflict situations has been increasing as well. The recognition that air flight professionals operate in complex rapidly evolving environments, additionally influenced by individual human factors came in the early 1990s [2]. Understanding the complexity of aircraft control leads to the need to increase trust in the automated means of detection and analysis of the situation and to use its recommendations to ensure the safety and uninterrupted character of the air transport mission.

Continuity of operation is defined by a set of indicators that affect the airplane's performance as a whole. These are reliability, safety, timing, and accuracy indicators of air transport operations [19].

The loss of air transportation service L, including those due to aircraft equipment failures in flight, can serve as an indicator of air transport usability by an organization. An element of this indicator can be aircraft reliability, which is characterized by the probability of failure-free operation of the aircraft within a specified time interval or by the operating time per failure.

Air transport safety S is a complex indicator that can be defined as the integral safety performance of various flight support services. For example, one of the indicators of air transport safety is the number of passengers injured in accidents. The output data can be information about the operating organization, which is usually represented by diagrams or graphs.

Uninterruptible is characterized by the disruption of the air transport schedule, delays T in cargo delivery, and passenger's arrival at the final destination. Possible causes of interruptions in the service can be external factors, such as weather conditions, efficiency of airfield support services, quality of pre-flight maintenance, technical condition of the aircraft, etc.

Technical errors E of the control system operation, which can be caused by external factors or failures of its elements; can account for up to 30 % of all service interruptions.

Next, one can introduce the integral indicator of uninterrupted operation of air transport that can be presented in the form:

$$I = \alpha L + \beta S + \gamma T + \delta E, \tag{1}$$

where α, β, γ, and δ is the scale (weight) coefficients satisfying $\alpha+\beta+\gamma+\delta = 1$, $\alpha > \beta > \gamma > \delta$.

The introduced indicator is of a multi-plane type, as it indicates that a trouble-free operation of air transport depends not only on the technical condition of the aircraft but also on the effective interaction of various services at all stages and in all phases of flight preparation and execution. Nevertheless, they can be assessed by the onboard recommendation system, which will strive to minimize the integral indicator of uninterruptible (1) during an active flight mission.

4. The structure of an onboard automated advisory system

The main requirements for the onboard-automated advisory system are based on the analysis of the current flight situation whereby the decisions are made on the accumulated knowledge in the order defined by the relevant recommendations and instructions [20]. The expert knowledge contained in the system is distributed across the following domains:

- recommendations of the actions in the current flight situation are made based on a detailed analysis of the external environment and the internal state of the craft;
- the crews can request a recommendation from the advisory system at any moment of the flight, whereas the situations of uncertainty, conflict and/or emergency have the highest priority compared to the others and can be initiated by the system automatically upon detection, without an explicit request from the crew;
- the order of actions in an advisory on actual flight situations is based on the rules formed based on previously accumulated experience taking into account the activities of the crew, the final decision is made by the flight professional with the sufficient level of expertise, experience, and authority;
- can accumulate, process, and incorporate new knowledge about actions in both already-known and novel situations.

The structure of the proposed system is shown in figure 1.

To realize these requirements, the onboard advisory system must receive information about the external environment and the current state of the craft from its own and external measuring devices such as sensors, indicators, and similar. These data are collected, analyzed, combined by categories, classified by priority, and based on the available rules and the knowledge incorporated in the system, a recommendation for the course of action is produced to the crew for execution. Thus, the onboard recommendation system should include the following subsystems:

- sensory, including its sensors and means of obtaining information from the outside world;
- data collection and analysis;
- categorization and prioritization;
- rules and knowledge base;
- decision-making and preparation of human-friendly recommendations to the crew, including specific control commands.

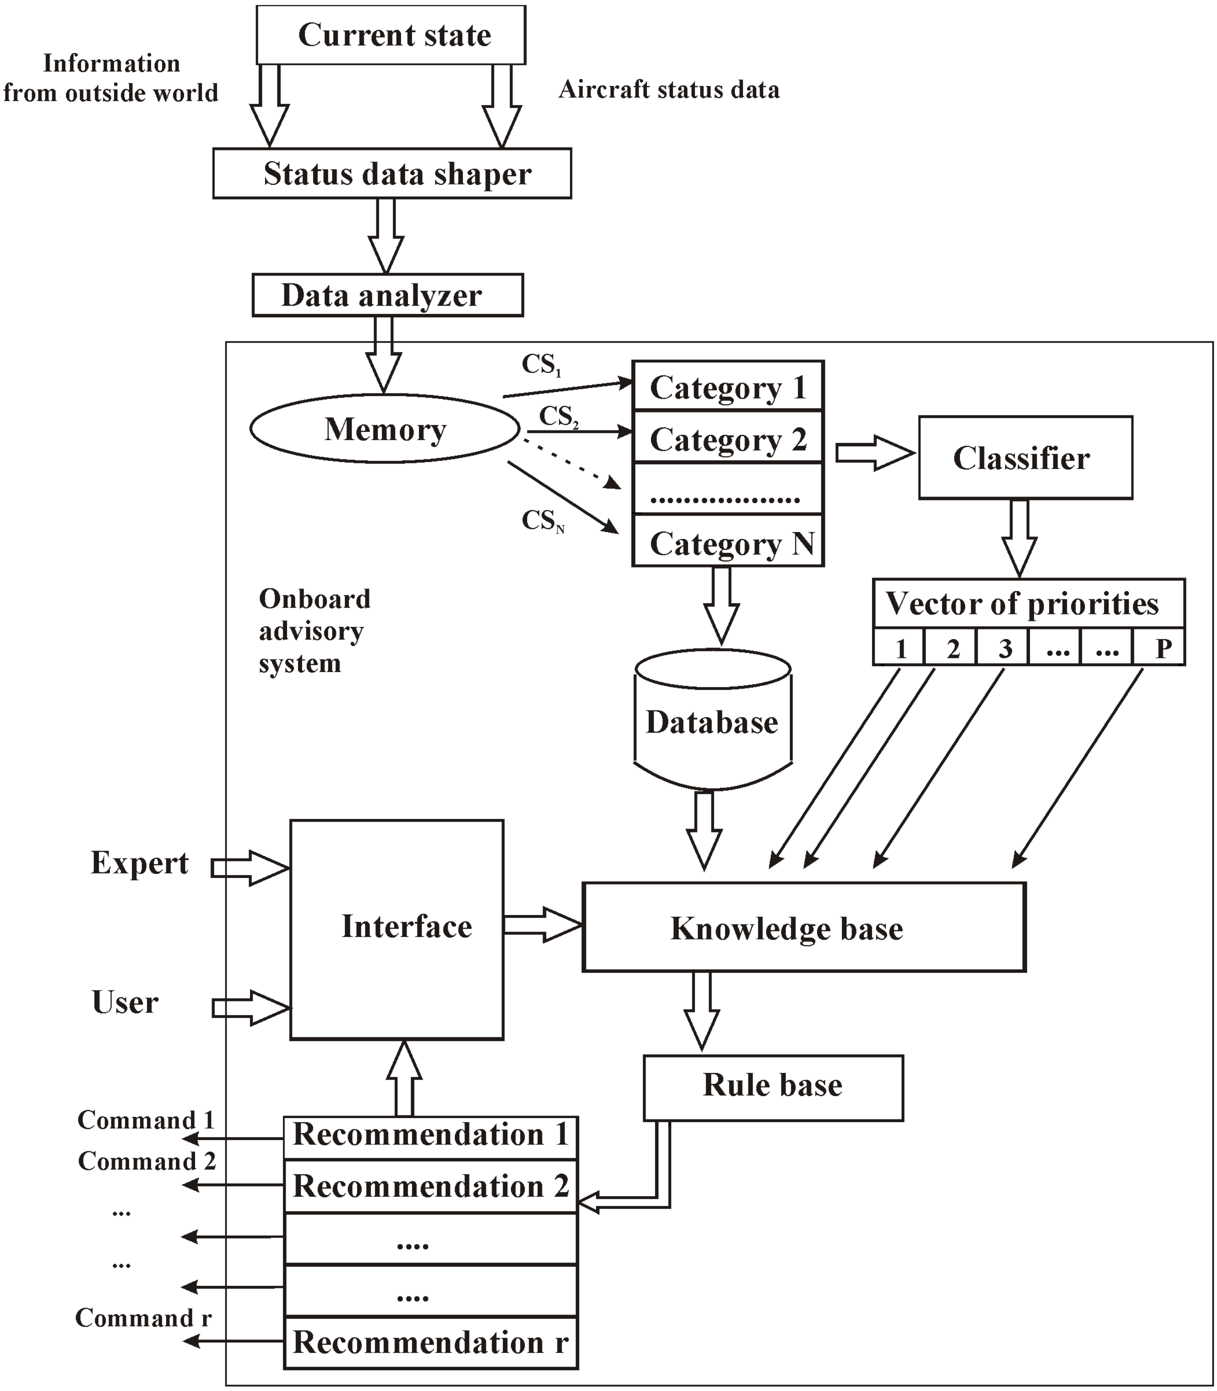

Figure 1. A general structure of an on-board flight advisory system.

5. Formalization of a functional aerial mission

The operation session consists of detailed organization and planning of the flight route. Planning a flight route requires careful study and correct selection of the parameter vector $X = (x_1, x_2, ..., x_n)^T$. Typical flight parameters are:

- *Departure and destination airports*
  In this stage, the flight planner selects a route that is specifically designed for each runway

and specific airport. In this case, it should take into account the aircraft's tracking from take-off to the start of the climb and between the last fixed point and the initial approach point.

- *Approximate takeoff weight*
  Based on the statistical information on the payload on the route, the takeoff weight is used to either be measured directly or estimated for the calculation of fuel consumption. If the flight plan is for a new route, using the maximum operational takeoff weight can be a good guess in this respect.
- *Air temperature range*
  Changes in air temperature in flight have a significant effect on engine fuel consumption.
- *Flight route*
  The route from origin to destination can be carefully selected using Jeppesen en-route charts, Skyvector [19, 20], or another application, taking into account, for example, the presence of a suitable airport on the route for landing in the event of an emergency, the presence of a noticeable obstacle in case of engine failure, etc.

When executing a route, typical flight situations are possible, comprising the vector $d = (d_1, d_2, \ldots, d_p)^T$. For example, in the case of a normal flight, deviation from the route, failure of one of the important flight support systems, etc.

The onboard advisory system calculates the numerical value of the priority of a typical situation, based on data received from various types of sensors. Based on the results of determining the priority of the situation, recommendations and actions of the crew, as well as commands to the autopilot, are formed that correspond to the specific situation. The priority values are normalized and are in the interval $P \in [0, 1]$, where the situation with the highest priority has a value of one, and the situation with a priority equal to 0 does not affect the execution of the flight mission.

A qualitative scale and a corresponding quantitative scale of priorities are introduced, for example, such as is presented in table 1.

Table 1. Priority scale.

Number	1	2	3	4	5	6
Priority, P	higher	high	middle	noticeable	low	not noticeable
P, value	1-0.9	0.7-0.8	0.5-0.6	0.3-0.4	0.1-0.2	less 0.1

The priority of a typical situation is calculated using the formula

$$P = \sum_{i=1}^{n} \alpha_i x_i, \tag{2}$$

In formula (2) x_i is data from sensors, it is assumed that these data are in the intervals

$$\underline{x_i} \leq x_i \leq \overline{x_i}, \tag{3}$$

where $\underline{x_i}$ and $\overline{x_i}$ are the lower and upper limits of sensor data measurement, and α_i are the coefficients that satisfy the data in table 1 and to be determined, taking into account the limitation imposed on them

$$\sum_{i=1}^{n} \alpha_i = 1, \tag{4}$$

where n is the number of sensors.

By using formula (2), sensor data is preliminary normalized following the expression

$$x_i^* = \frac{\overline{x_i} - x_i}{\overline{x_i} - \underline{x_i}}, \tag{5}$$

where x_i is the current value of the ith sensor, x_i^* is the current normalized value of the ith sensor. In the case of negative values of the parameters in (5), the absolute values of the measured quantities should be taken.

When sensor data makes an opposing contribution to (2), they should be divided into two groups to ensure an equal contribution between the measurement data. In this case, (2) should be applied in the form [21, 22].

6. Illustrative example

For the onboard system under consideration, a limited set of generalized factors are introduced that characterize the external situation, technical condition, pilot condition, and route change. It is assumed that their values change in relative units and are within the limits $x_i \in [0, 1]$. In this case, the worst values of the state indicators of the pilot and the aircraft are assessed by the highest values, i.e. take the value 0, and the best ones are rated 1, and the indicators of the external situation and route changes are vice versa, i.e. the worst value is 1, and the best corresponds to 0, the presence or absence of change.

Factor designations: x_1 are the values of the external situation indicator, EF, x_2 are the values of the technical condition indicator, TC, x_3 are the values of the pilot's condition indicator, FC, x_4 are the values of the route change indicator, RR.

The coefficients α_i from (2) are found by analytic hierarchy process, while two preference matrices are introduced for positive and negative views on priorities, in each of which the highest ratings are given to the technical condition and condition of the pilot about the factors of changing the route and the external situation, which allows us to obtain weighting coefficients:

$$\alpha_1 = 0.063, \alpha_2 = 0.384, \alpha_3 = 0.45, \alpha_4 = 0.102, \tag{6}$$

The obtained coefficient values correspond to the priority values given in table 1. The calculations carried out confirm the assumptions made.

A comparative diagram obtained based on calculations using formula (2) with weighting coefficients (6) is presented in figure 2, where the calculation was carried out for changes in each factor $xi \in [0, 1]$ and the values of other factors $x_j \neq x_i, x_j = 1$, allows us to establish the importance of priorities.

Figure 2 confirms the priority of the human factor and the technical condition factor compared to other factors when making decisions in an onboard recommendation system, all other things being equal.

7. The directions for implementation of onboard advisory systems

Design and implementation of onboard flight situation advisory systems comprises these areas and components:

- *Collection and processing of case data*
  Collection, and verification of flight situation data, and its processing into a compressed informative format that can be used in the rule/decision engine.
- *Design, implementation, and verification of the rule/decision logic and engine*
  Expert rules are formalized, defined, implemented, and verified with sample flight-situation data.

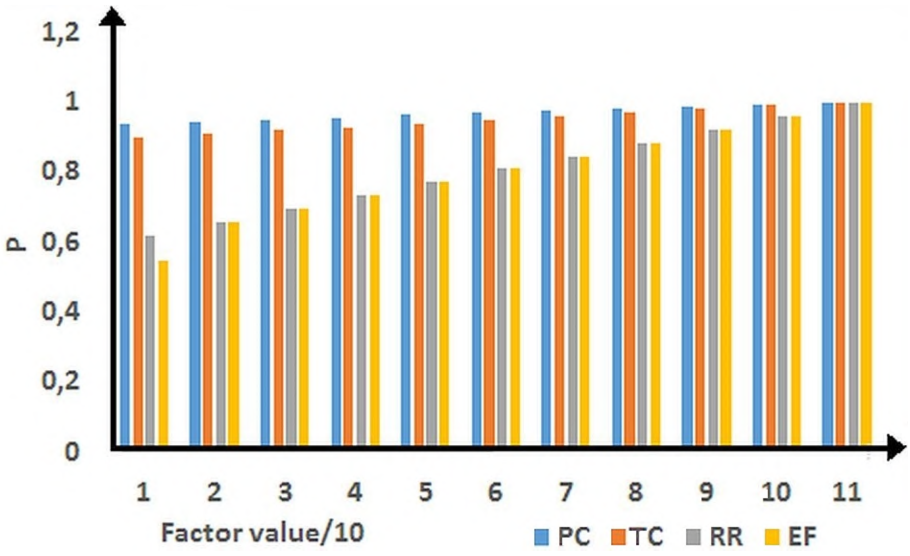

Figure 2. Comparative chart of relative importance of priorities.

- *Comprehensive verification of the rule/decision engine with validation of both actual and simulated data. Correction of faults and errors*
- *Optimization of the system's operational characteristics*
- *Optionally, incorporation of generalization methods, such as supervised and unsupervised learning with flight situation data*
- *Comprehensive end-to-end verification of the system in actual operation*

8. Conclusions

An important distinguishing feature of a modern aircraft can be a presence of an automated onboard flight analysis and recommendation system. The formation of recommendations is based on an integrated view of the data arriving from the environment and the internal technical state of the aircraft. These data are grouped according to the determined bundle of attributes, among which priorities are determined. For each attribute, recommendations are formed, and the actions of both the crew and the aircraft control systems are determined. In this case, as studies show, the aircraft's technical and the pilot's physical conditions are of the highest significance.

Several approaches to prioritizing the evaluation of a real-time situation were proposed, described, and analyzed. In the future generations of such systems, current techniques for modeling and analysis with uncertainty can be applied to situation assessment along the directions outlined in this work. In the view of the authors, equipping modern aircraft with such advisory systems has the potential to significantly improve the quality and reliability of individual aircraft operations as well as aerial operational networks overall.

Future research is focused on studying the problem of integrating the advisory system into the global air network and analyzing its practical value.

Abstract. The article presents the results of a research on the efficiency of multimodal grain transportation from Ukraine in the global supply chains. The research was conducted on the basis of the developed simulation model. Unlike existing ones the presented model takes into account the stochastic nature of the main technological operations and delays at the intersection point of different modes of transport. Using the developed simulation models, the process of transporting grains in global supply chains from Ukraine through the Mykolaiv Commercial Port was simulated. It was experimentally determined that the environmental impact of the multimodal route is significantly lower. CO_2 emissions per ton of transported grains were 1 kg, which is almost 90 percent lower than when transported by the existing method.

1. Introduction

The main objectives of the European Green Deal are sustainable development and reduction of environmental pollution [1] to transform the EU economy into a circular economy by 2030 and achieve climate neutrality by 2050 [2]. Environmental legislation applies to various sectors, including transportation, one of the most important of which is road transport. In the EU transport market and road transport companies dominate in terms of the number of vehicles and traffic volumes [3] and at the same time it is road transport that has the largest negative impact on the environment causing more than 70 percent of all transport emissions [4].

As a result, effective incentives to reduce CO_2 emissions, improve air quality and ensure carbon neutrality in order to achieve sustainable development goals are primarily focused on road transportation. The Green Deal's policy to encourage the shift from road to rail and water transport, aimed at reducing fuel consumption, minimizing emissions of pollutants, reducing traffic intensity, and preventing road congestion, was adopted by the European Commission many years ago.

One of the policy instruments that the Commission emphasised to achieve this goal was the restructuring of the railway sectors of the Member States. The restructuring of the railway sector included market liberalisation and the creation of conditions for the development of competition between operators, primarily by creating opportunities for the emergence of new companies involved in the ownership of a fleet of wagons and locomotives and the operation of rolling stock. According to researchers, this solution is, at first glance, the least obvious political choice among the alternatives, including the Pigovian pricing system or infrastructure subsidies [5].

At the same time, the current EU transport policy aims to promote multimodal and combined transport in the Member States and third countries [6] as one of the leading means of reducing the environmental impact of transport and reducing CO_2 emissions by 20 percent by 2030 [7].

Meanwhile, the advantages of rail transport in terms of lower environmental impact compared to road transport are balanced by significant disadvantages for the shipper due to low average delivery speed, capacity and reliability [8]. At the same time, in the water transport, speed is directly correlated with the amount of fuel consumed, which is the main source of greenhouse gases. Fuel consumption per unit is a cubic function of speed, meaning that if speed increases by 10 percent, consumption will increase by 33.1 percent. As a result, higher speeds, while reducing transport time, lead to higher CO_2 emissions and increased transport costs [9]. However, currently, there are no effective tools for assessing and forecasting CO_2 emission volumes specifically for mixed (multimodal) transportation in recommendations and methodologies.

2. Problem description and method

Multimodal and combined transport as a coordinated system of several modes of transport is widely mentioned in transport policy is the subject of academic research and is used in practice to address environmental issues and overcome dependence on road transport. Multimodal transportation is defined as the transport of goods carried out by a sequence of at least two different ways [10], traditionally by road, rail and water transport [11]. Intermodal transport is a type of multimodal supply chain that involves the movement of goods in one cargo unit or vehicle and is not processed during a change of mode [12]. Multimodal transport activities, such as loading, transportation and transshipment operations, require a large amount of resources, determination of optimal route plans and cost control [13].

Route planning for multimodal transport has been studied by numerous researchers, and solutions primarily included optimization based on various criteria groups. These criteria include cost, time, safety, risk, environmental impact (CO_2 emissions), demand, and customer preferences [11, 14–18]. Inland water transport has been positioned as a priority in logistic chains due to its higher economic efficiency and lower pollutant emissions, making it more competitive [11,18]. However, the vast majority of studies have focused on multimodal transport without inland water transport, specifically involving road and rail transport [19], international port-rail transport, port-road inland transport, combined ship-road-rail transport [20] modal shift from road to sea transport [21], port infrastructure development as a multimodal logistics center based on container transport parameters [22].

The above underscores that there is a need for integrated decision support tools to optimize and solve the problems of sustainability of multimodal supply chains using road, rail and water transport.

The purpose of the research is, through experimental simulation, to provide a forecast of CO_2 emissions volumes in the multimodal grain supply chain. To achieve this goal, it is planned to:

(i) to develop a mathematical (simulation) model of multimodal grain transportation involving road, rail and water transport;

(ii) develop a methodology for assessing the negative impact of the transport sector in multimodal grain transportation.

The research focuses on the transportation of grain cargo due to the fact that Ukraine is a key player in the global food market. In the period from March 2022 to December 2023 were exported 41.6 million tonnes of corn and 24.7 million tonnes of wheat. Out of the total volume of cargo were crossed the border through ports: 73.3 million of tonnes and 18.7 million tonnes were exported by rail, and 7.4 million tonnes by road [23].

3. Results and discussion

The delivery time of bulk goods, essentially from origin points to seaport terminals, by rail and road transport, can be formalized as follows:

$$Q_{deliv} = t_{truck} + t_{rail}, \tag{1}$$

where t_{truck} is the time spent by cargo mass in the road transport subsystem, hours; t_{rail} is the time spent by the cargo mass in the railway transportation subsystem, hours.

However, each element of the expression (1) consists of two main components: the waiting time for technological operations and the time for performing technological operations (illustrated for road transport).

$$t_{truck} = t_{wait.} + t_{work.oper.}, \tag{2}$$

where $t_{wait.}$ is the total time spent by the cargo mass and vehicle on the idle time while waiting for technological operations, hours; $t_{work.oper.}$ is the total time spent by the vehicle to perform technological operations, hours.

At the same time, each of the elements of expression (1) represents a combination of two large components – time for waiting for technological operations and time for performing technological operations (using the example of road transport):

$$t_{deliv} = \sum t_{wait.} + \sum t_{work.oper.} \rightarrow \min, \tag{3}$$

with restrictions:

$$\begin{cases} \zeta_{truck} \leq \zeta_f, \\ \zeta_{truck} \leq \zeta_r, \\ \zeta_{rail} \leq \zeta_f, \\ \zeta_{rail} \leq \zeta_r, \\ n_{truck}, n_{rail}, n_{bulk} = 1, 2, 3, ...N, \end{cases} \tag{4}$$

where $\sum t_{wait.}$ is the total time spent waiting for operations in the transportation process on the entire multimodal grain supply chain, hours; $\sum t_{work.oper.}$ is the total time spent on operations in the process of transportation on the entire multimodal grain supply chain, hours; ζ_{truck}, ζ_{rail} is utilization rates of use of the fleet of trucks and railway rolling stock; ζ_f is the limit level of technological failure resistance of elements of transport systems; ζ_r is the limit level of technological rationality (expediency) in the use of elements of transport systems; $n_{truck}, n_{rail}, n_{bulk}$ are the need for rolling stock: trucks, railway routes, bulk carriers, units.

Given that most of the presented elements of the optimization model and its constraints are implicit functions of complex multi-phase processes in mass service systems under stochastic flows one of the few methods for studying could be simulation (computer modeling).

The carrier model was developed on the basis of the agent-based approach since the entire multimodal process represents a combination of independent subsystems involved in one process – the grain supply chain.

Then the following processes and phenomena will act as agents of such model (table 1).

The model was implemented using the Java SE libraries in the AnyLogic University Researcher using the example of the most typical grain supply chain from the central regions

Table 1. Agents of the simulation model of the multimodal route.

The name of model agents	Function of the model agents
Automotive subsystem	Modeling the turnover of trucks on the network. Simulation of technological processes of loading / unloading, waiting for operations, movement
Railway subsystem	Modeling the turnover of railway routes on the network. Simulation of technological processes of loading / unloading, waiting for operations, movement
Water subsystem	Modeling the turnover of cargo ships – bulkers within the global supply chain. Simulation of technological processes of loading / unloading, waiting for operations in ports, traffic
Warrant	Simulation of the preparation of an information message about the availability of a ready-to-ship consignment. This type of agent is essentially the same for all transport subsystems. The difference is that it is generated by the model under different conditions. The main condition for the generation of the message: the actual presence of a ready-to-ship grain cargo in sizes that meet the technical standards for loading, respectively, into a truck, a railway dispatch route, a bulk carrier
Cargo model	A unit of cargo generated as a random requirement in the simulation process. For this model, one ton of grain is accepted as a cargo module

of Ukraine through the Mykolaiv seaport. This freight flow is one of the key components for Ukraine's agricultural sector and continues to operate even during periods of constant shelling due to military aggression from the Russian Federation. Agent-based and discrete methods in simulating multimodal transportation have been extensively discussed in our previous studies [24].

The following results were obtained during experimental modeling (table 2).

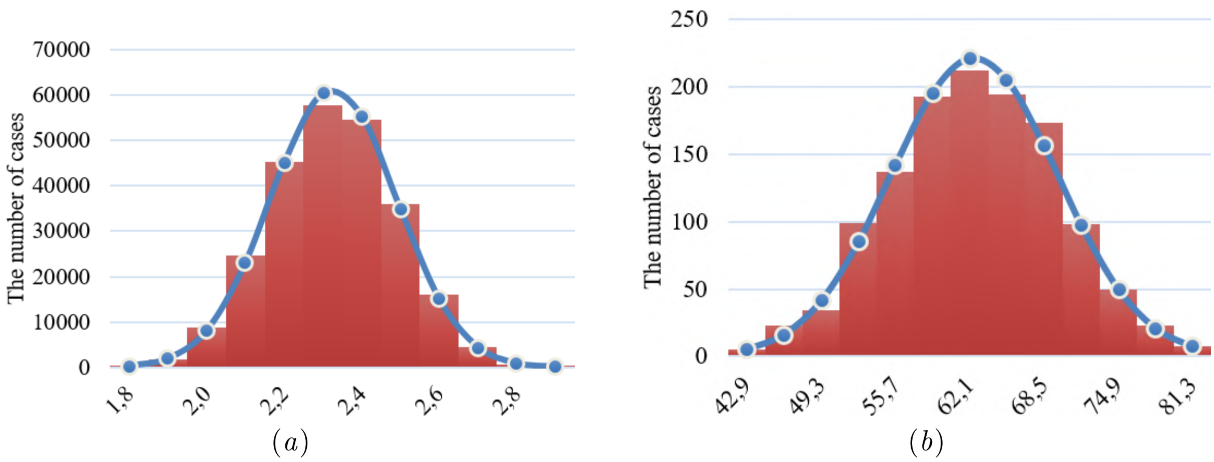

Figure 1. Experimental results. Normal density distribution of dwell time for cargo mass in the truck (a) and railway (b) transportation subsystems.

Table 2. Results of experimental modeling.

Parameter	Value	Note
Output data		
Volume of grain transportation, thousands of tons per year	1000	
Points of origin and primary concentration of cargo (the distance to the destinations was automatically calculated using GIS technology (with an accuracy of 100 meters))	Velika Viska; Alexandria; Tyshkivka; Bobrynets	
Point of departure from Ukraine	Mykolaiv Sea Port	
Received data		
Automotive transport system:		At the technical
coefficient of use of rolling stock	72 percent	loading rate
the need for rolling stock	18	of 20 tons
Railway transport system:		At the technical
coefficient of use of rolling stock	59 percent	loading rate
need for rolling stock (railway routes)	3	of 4,000 tons

Table 3. Carbon footprint levels per unit of transport work.

Indicator	Only by road (existing option)	Multimodal route (road and rail)	Difference, percent
emissions for transportation of a ton of cargo by land, kg*	12.8	1	- -92.0
emissions per 1000 ton-km, kg*	32.81	2.64	-92.0

* Under the assumption of using "clean" CO_2 emissions-free electricity.

The dwell time of one ton of cargo in the transportation subsystems follows a normal distribution, indicating sufficient resilience of the transportation process (figure 1).

The actual carbon footprint levels per unit of transport work were as follows (table 3).

4. Conclusions

An agent-based simulation model of multimodal transportation of grains involving truck, rail and water transport has been developed. Unlike existing models, the presented model maximally considers the stochastic nature of performing key technological operations.

Based on the developed simulation models, the process of transporting grains in global supply chains from Ukraine through the Mykolaiv Trade Port was simulated. As a result, it was established that the environmental impact of the multimodal route is significantly lower. CO_2 emissions per ton of transported grains amounted to 1 kg, which is nearly 90 percent lower than in the existing transportation method.

Abstract. Currently, Ukrainian rural communities experience the devastating impact of war, which increases the difficulties of economic and social growth in sparsely urbanized areas. The military escalation has put on standby the processes of social infrastructure modernization, creation of peaceful jobs, expansion of local production and the development of local culture, forcing Ukrainians to focus on such problems, as increasing the stability of settlements, preserving the lives and health of their residents, and saving critical infrastructure. At the same time, preparing for the post-war reconstruction of the country, experts have to think about ways to develop recovery strategies and about further sustainable development of all regions of Ukraine. This study presents an analysis of the urban-planning and environmental challenges faced by the Pirnovo community on its way towards a sustainable future and offers ways of transforming the architectural environment in order to improve the quality of life of the local population and preserve the ecological and cultural heritage. The research methodology includes analysis of current community issues and unrealized opportunities, spatial modeling of comprehensive territorial development, development of proposals for gentrification of existing settlements, improvement of the environment through innovative technologies. The proposed comprehensive development plan allows for considering alternative options for utilizing the recreational potential of the territory, methods of modernizing the cultural and household services system for the population, and ways to achieve environmental balance. Our version of the general plan for Pirnovo focuses on necessary land management changes, development of social infrastructure, and improvement of the quality of living environment without destruction of the natural. The detailed plan of the central part of Pirnovo demonstrates possible approaches to reconstruction and creation of modern public spaces. The research offers new ways to address existing problems in specific areas that can help other settlements and rural territorial communities achieve sustainable development.

1. Introduction

Today, the development of strategies for sustainable development of specific regions [1] is becoming a priority requirement of administrative reform aimed at solving pressing problems of the rural population of Ukraine. The most important among them are the creation of additional jobs, the transformation of an outdated social infrastructure, the introduction of new technologies for local production, protection and restoration of natural environment and local culture. And during the post-war reconstruction period in Ukraine the relevance of these intentions will only grow.

A large number of international and state documents are devoted to the problems of sustainable development [2–4]. The research considered urban aspects of sustainable development [5], issues of administrative and territorial reform of Ukraine [6], problems of using the recreational potential of local settlement systems [7], approaches to preserving the traditional nature of planning and construction of historical architectural environment [8], options, creation of possible tourist and recreational facilities in rural areas and rural settlements [9], the basics of reconstruction of the central villages of the primary settlement system [10], principles of reforming the social infrastructure of the village [11], the problem of creating children's medical institutions network in Ukraine [12] and approaches to solving the issues of architectural organization of innovation parks [13]. Researchers paid much less attention to the problems of sustainable development of specific territories and communities, and the creation of a comfortable living environment for the inhabitants.

At the same time, the analysis of foreign experience proves how important the aspect of sustainable development is in the creation of residential units that will meet modern ecological, social and architectural requirements and challenges. It is necessary to support the implementation of programs and projects aimed at achieving sustainable development of rural areas. A significant number of such projects have already been implemented and proven to be a positive contribution to the achievement of sustainable development goals.

Thus, in 1991, at the initiative of the European Union, a program named LEADER was developed with funding periods to support the development of rural areas, with the aim of revitalizing rural areas and creating jobs. The program of activities is aimed at small, cohesive areas of communities. Local actors develop the concept of local development strategies, and the public and private sectors mobilize all available skills and resources to implement the strategy. LEADER is guided by the principles of innovation – the introduction of new ideas and methods, and integration between economic, social, cultural and environmental factors [14]. The program is not going to be any less relevant in the future, neither. Now all rural areas of the EU are able to use the program. The local population, organizations and institutions are trained at the local, regional, national and European levels. Cooperation between the participants of the program for the exchange of experience is also developing. This program is designed not only for building development strategies, but also achieves serious results in the practical implementation of these strategies [15].

The ReGen Villages project is a group of 100 energy-positive houses situated on 1.5 hectares on the outskirts of Amsterdam. The project offers an environmentally friendly alternative to city life. State-of-the-art technologies and business methods are combined here. For example, vertical farming and aquaponics. The concept has seven components that will make each home completely self-sufficient: House, greenhouse, aquaponics, seasonal garden, animal husbandry, solar panels, water storage. home, greenhouse, aquaponic, seasonal garden, livestock, solar cell, water storage. The settlement is self-sufficient and sustainable and meets almost all 17 UN Sustainable Development Goals [16].

The Crystal Waters Permaculture Village in Australia – the world's first permaculture village – was founded in 1984. The community has more than 250 residents, being a unique and sustainable village. The houses use solar energy and collect rainwater. The village is located next to a wildlife reserve in the scenic Conondale Valley, so on the way you can see kangaroos, wallabies and other wildlife species that coexist beautifully with the residents. The settlement is based on permaculture principles and offers a wide range of activities: an organic wood-fired bakery, monthly markets, music events, Friday movies, permaculture and sustainable living classes, the community includes a Crystal Waters eco-park, with camping sites [17].

Since 2016, the Rural Habitability program has been operating in Chile, improving the lives of the rural population. Rural life in Chile was unfortunately characterized by poor quality, overcrowded houses, lack of electricity, efficient heating and sanitary conditions. So, the Chilean government announced the Emergency Housing Plan. The program provides funding and technical support to people in rural communities. New energy-efficient houses are being built, existing houses are being improved. Special attention is paid to vulnerable groups, indigenous people and households headed by women. Thanks to the program, it was possible to reduce the migration of the rural population to large cities, which is of serious importance for the Chilean economy [18].

This study is devoted to a local territory in the suburbs of the capital of Ukraine that belongs to the Pirnovo territorial community. Among the acute problems of the Pirnovo community are seasonal fluctuations in population, lack of jobs, chaotic development of settlements, destruction of reserves, lack of waste sorting and a recycling system. However, the area has a favorable location and has significant recreational potential.

The purpose of this study is to analyze the strengths and weaknesses, opportunities and threats, risks and challenges to be considered in forecasting urban development of Pirnovo community in Kyiv region, as well as in the theoretical justification and development of project proposals for restructuring and renovation. Architectural environment of the administrative center of the community – the village of Pirnovo, aimed at improving the quality of life of the local population.

2. Methodology

Identification of the peculiarities of historical development and the current state of the territory, which today belongs to the Pirnovo community, in this study was carried out using the methods of historical analysis and field survey. Historical analysis involved examining archival documents, historical maps, and scholarly literature to trace the evolution of the territory from ancient times to the present. Field surveys were conducted to assess the current state of settlements, infrastructure, and natural resources within the community.

Methods of SWOT analysis and structural-logical modeling were used to analyze current problems and unrealized opportunities of the community. The SWOT analysis identified the Strengths, Weaknesses, Opportunities, and Threats facing the Pirnovo community, providing a comprehensive assessment of its internal and external factors. Structural-logical modeling was employed to visualize the relationships between these factors and to develop a conceptual model of sustainable community development.

Methods of spatial-territorial and project-planning modeling, as well as experimental design were used to form project proposals for adjusting the integrated development of the community, restructuring existing settlements and improving their architectural environment. Spatial-territorial modeling involved creating digital maps and 3D models of the community's territory to analyze land use patterns, infrastructure networks, and ecological systems. Project-planning modeling was used to generate alternative scenarios for the functional zoning and spatial organization of settlements based on the principles of sustainable development.

Experimental design techniques were applied to test and refine these scenarios through participatory workshops with community stakeholders. The resulting project proposals were visualized using a combination of 2D drawings, 3D renderings, and physical models to effectively communicate the vision for the community's sustainable future to decision-makers and the general public.

3. Results

3.1. Peculiarities in historical development of present-day Pirnovo community

The Pirnovo community is located in the northern part of the Kyiv region and is part of the Vyshhorod district. The community consists of ten villages: Novosilky, Lebedivka, Nyzhnia Dubechnya, Vyshya Dubechnya, Voropaev, Zhukin, Rovzhi, Bodenki, Suvid, and the territorial center of Pirnovo, located 28 km northeast of Vyshhorod and 48 km from Kyiv.

The total area of the community is 72760 hectares with a population of 6233 thousand people as of 2021 [19]. Most of the territory has a gentle relief. The Desna River flows through the north-eastern part of the territory, and the Kyiv Reservoir is located in its north-western part.

The beginning of digest of the area currently remains unclear. In the lands between the villages of Suvid, Zhukin and Voropaev, cultural heritage monuments related to the Bronze Age, Kievan Rus' and the late Middle Ages were found. There is a legend about the founding of the village of Pirnovo by ancient Russian princes, who stopped at this place and "feasted" ("to feast" in Russian: "pirovat"), which suggests that this ancient Slavic word is where the name of the village Pirnovo is derived from.

It isn't just the legend hat testifies to the stops of the princes on this terrain, but also the study of the lower Desna terrains, during which five differently dated sites of the Bronze Age were found near the village of Zhukin and between the villages of Zhukin and Voropaev. In the chronicles "Teachings of Volodymyr Monomakh" the Kyivan prince recalls that during his reign in Chernihiv he had to ride more than 100 times back to Kyiv to the summons of his father, the Grand Duke of Kyiv Vsevolod Yaroslavych, and that he rode "from morning to evening" [20]. Archaeological explorations have made it possible to specify the prince's route along the Desna. Along his route he passed a number of settlements and villages, where replacement horses were kept, without which such a high-speed journey would hardly have been possible. The location of modern settlements of the Pirnovo community coincides with the location of the settlements on the Monomakh's "Chernihiv – Kyiv" route [21].

In the time of the Russian Empire, the contemporary community's lands were part of the Oster County of the Chernihiv Province. According to county documents, Russians, Belarusians, Germans, Poles and Bashkirs lived here. During the October Revolution, confrontations between various social groups began in these territories as well. With the advent of Bolshevist power, wealthy citizens were repressed. In later Soviet times however, cultural and educational activities were actively carried out.

The village of Pirnovo itself is very young. The first written mention of it is contained in the "List of settlements of Kyiv districts" and dates back to 1926. Then this area was called Pirno tract. In 1926, a country settlement appeared there. During the temporary Nazi occupation in the village of Pirnovo were located resorts of the National Socialists.

The Germans began to develop the village. During their stay on the territory, a number of facilities was built: a water tower (which still serves as the village's calling card), administrative buildings, a prison and a hospital building. Facilities built during the National Socialist era are still in use.

The consequences of the Second World War were mass graves and lost settlements. Entire villages such as Zhukin, Voropaev, Suvid, Novosilky and Nyzhnia Dubechnia were destroyed by fire at the hands of criminal groups. Such gangs' intimidated locals, organized sabotage, and banned dialogue between the local residents and Soviet officials. These events are evidenced by the scientific works of Philip Warren on Nazi occupation security in Eastern Europe and Soviet Russia in the period from 1942 to 1945 [22].

In the postwar years, due to the large number of people with injuries after the war, the medical industry was actively developing. Professionals and the entire Union were distributed among hospitals, outpatient departments and tuberculosis dispensaries. In 1957 a hospital was opened in Pirnovo. Intensive resettlement of residents began – people returned from the war, from camps, or simply came here from other places due to complete destruction of their own homes, villages and towns.

In the 1950s, the area was connected to the grid. Electrification has given rise to the development of industrial facilities, collective farms, cultural, educational and health facilities. A new state system is formed, the Pirnovo district appears. Pirnovo is becoming a district center, infrastructure is developing. In addition, there is a butter factory, school, kindergarten, cinema, house of culture, market, road department, military enlistment office, open-air summer cinemas, Dynamo Stadium, a number of recreation centers, shops, own bakery, poultry farm, lemonade factory, TV studio, forestry, hunting, post office, a large number of cafes, river port, airfield direction Zhulyany – Pirnovo, a bus station and the Pirnovo Ornithological Reserve.

Pirnovo doesn't just become the district center, but also a tourist magnet. The village includes several recreation centers: "Rozdollya", "Slavutich", "Desna" (exit to the second beach of the sleeve), "Voskhod", "Druzhba", and "Chaika". In the direction from the center of Pirnovo towards Desna, near the ornithological reserve there are recreation centers "Leleka" and "Dynamo" (near the football field). The architectural and planning structure of the village on the peninsula is formed mainly along the old transport routes: from the ferry to the land routes that connected the route Chernihiv – Vyshgorod – Kyiv. The main planning axis extends perpendicularly from the regional highway R-69 Kyiv – Chernihiv towards the forest and continues up to the Desna.

The accents in the composition of the village are the territories of recreation centers, while the rest of the buildings are ordinary and clearly structured on a hippodame grid. The features of the village's landscape and spacial structure is due to landscape and recreational factors. In the 1970s, the population density during the holiday season was very high, as tourists came from all over the Soviet Union to admire the picturesque banks of the Desna and enjoy their holiday.

Other villages of the Pirnovo district were characterized by another sphere of activity: collective farms and other agricultural structures were located in these territories. For instance, the village of Nyzhnia Dubechnya was engaged in cattle breeding, there was a dairy farm, Zhukin is famous for beekeeping, the village of Novosilky was famous for apple orchards, and Voropaev – for machine building. Accordingly, the planning structure of these settlements is very different from the district center, with more chaotic buildings, manor-type dwellings at a great distance from each other and are hectares of fertile land between them.

In the 90's production stopped completely, there was a change of owners and officials, and a total redistribution of land. The area has stopped providing quality tourist services, although ever since people have still been coming here for vacation, mostly from Kiev and surrounding areas.

Unfortunately, the beginning of the 21st century for the village of Pirnovo was marked by complete anarchy and decline. The sale of about 5 hectares (more than half) of the gray heron ornithological reserve has led to the destruction of centuries-old oaks and pines, the destruction of its ecosystem. Although bird nesting has declined significantly, the gray heron is still returning to the reduced reserve. During this period, the territories of collective farms fell into disrepair, a significant part of agricultural land was illegally taken away from residents, and there was an illegal change in the purpose of land.

In 2014, a master plan was developed with. Pirnovo, who ignores the legal and planning restrictions of the territory [23]. In 2020, the master plan of Pirnovo was declared invalid by a court and in gross violation of the laws of territorial planning [24].

3.2. Analysis of the modern use of the community's territories

In order to assess the current problems and the potential for further development of the area, we studied some aspects of economic, social and cultural life of the Pirnovo community, as well as the convenience of transport links and available resources of the nature reserve fund.

BUDGET-FORMING ENTERPRISES : INDUSTRIAL AND AGRO-INDUSTRIAL ENTERPRISES	
1. ROVZHI	HUNTING AND FISHING BASE: «NEPTUN», «EBIS»
2. SUVID	WOODWORKING
3. BODENKI	MEDICAL AND OBSTETRIC STATION
4. ZHUKIN	GROWING CEREALS & MEAT PRODUCTION «AGROMARS COMPLEX»

(b)

Figure 1. Budget-forming enterprises of the Pirnovo territorial community: a) industrial and agro-industrial enterprises, b) recreation centers.

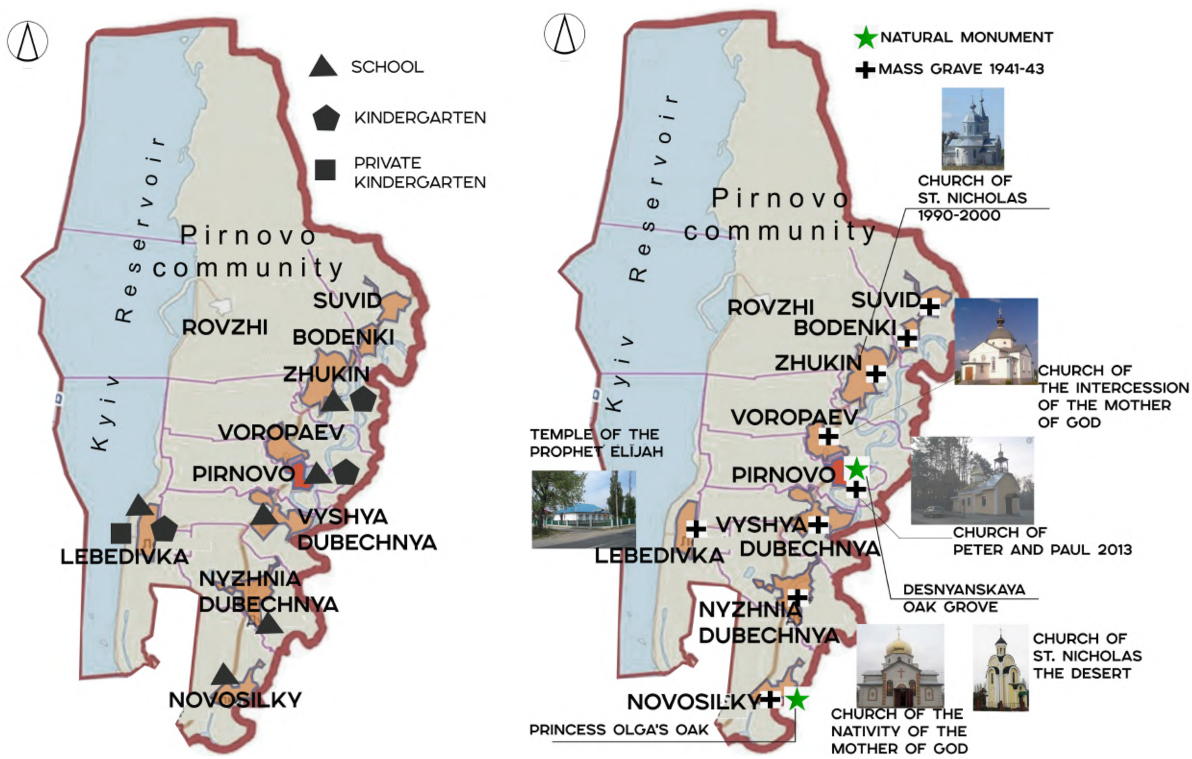
Thus, figure 1a shows the most powerful productions, which are “Vyshchedubechanske forestry”, “Agromars Complex”, farms for growing fruits and vegetables, berries and grapes.

Another powerful budget-generating source of the community is the area’s recreational resource. Figure 1b shows the number of recreation centers in different localities. It turned out that the village of Pirnovo, the community center, has the largest number of territories set aside for recreation.

Figure 2a shows the institutions of preschool and secondary general education. As can be seen, there are 9 educational institutions on the territory of the community, mostly state ones, but there is also one private preschool institution.

Figure 2b shows sites of historical and cultural value. Unfortunately, there are no monuments left in this area that would have a protected status. There are only monuments of local significance, namely: monumental art at the Common Graves, the monument to I. P. Pavlov on the territory of the hospital in the village of Pirnovo. There are also religious buildings, in particular, six churches of the Orthodox rite.

Socio-demographic analysis of the population showed that the area is inhabited by Ukrainians, Russians, Jews, Georgians and Armenians. According to official data, the number of people registered in the territory is 6764. However, there is a problem of counting the real population, because the territory of the community is inhabited not only by villagers but also by urban citizens. There are a large number of private country houses, cottage villages, wealthy residences and health resorts. As a result, a large number of vacationers come here during the holiday season. This provision is evidenced by the cadastral map of Ukraine, master plans of villages, and personal experiments to monitor capacity. Also, the events of recent years related to the



(*a*) (*b*)

Figure 2. Some aspects of social and cultural life of the Pirnovo community: a) educational institutions, b) historical and cultural monuments and religious buildings.

coronavirus epidemic have shown that the population of Kyiv is rapidly moving to suburban settlements. This is possible due to the small distance from all settlements of the Pirnovo community to the capital of Ukraine.

The analysis of the nature reserve fund confirmed the significant recreational potential of the analyzed area. The community includes the ornithological reserve "Zhuravlyny" and the reserve of the gray heron "Pirnovoskyi", the landscape reserve "Dniprovsko-Desnyanskyi" and "Chernynskyi" (figure 3). As of 2016, the Kyiv Reservoir was included in the "Emerald Network", a large area of which was included in the Pirnovo community. The Emerald Network is an area that contains rare and very valuable plant and animal habitats [25]. To date, the Emerald Network at the level of Ukrainian legislation exists in a contradictory state, although information about it can already be obtained in free access on the cadastral map [26].

Documents certifying the priority of the resort and tourist-focused of development of the studied community have recently been prepared. In particular, the decision of the Kyiv Regional Administration of October 15, 2020 "On official approval of the recognition of natural areas of the Pirnovo community as a resort area of local importance" [27] provides for further development of tourism development programs, health resorts, specifically in this area, within Pirnovoska communities. Such a project is funded by the state and creates an attractive investment climate.

Another encouraging signal is the discussion of an action plan for the development of medical tourism in the Kyiv region. This is noted by KODA and the Association of Medical Tourism in Ukraine. Due to the fact that a large number of resorts and medical institutions are located in the region, it became possible to develop medical and tourist activities on the territory [28]. Such projects contribute to the popularization of the region and the development of rural areas. This will help reduce unemployment in the country. New jobs, in turn, will keep people from looking for a better life abroad.

The analysis showed that over the past ten years there has been a revival of the economy of the Pirnovo community, and the interest of investors in the development of the territory is growing. At the same time, in order to move to a qualitatively new level of development and completely restore the community after the decline, it is necessary to use the hidden opportunities of this area, open it and make it attractive to investors by developing and diversifying the economic complex, involvement in the economic turnover of the resource potential of all settlements of the community. The opportunity for sustainable development of the Pirnovo community can be ensured through significant reserves of forest resources, promising development of tourism and recreation, and the use of innovative recycling technologies.

3.3. Proposals for restructuring the territory of the Pirnovo community

Proposals for community development are based on five resource-oriented subsystems: "Population", "Infrastructure", "Production", "Nature" and "Heritage".

Subsystem "Population" is among the leading ones and determines the parameters and organization of other subsystems. The infrastructure subsystem includes housing, social, and engineering and transport components. The subsystem "Production" unites the workplaces of the population. The subsystem "Nature", on the one hand, is the basis of the rural region, and on the other – establishes the resort and tourist direction of its development. A special role belongs to the subsystem "Heritage", which determines the individuality of the formation of spatial planning structure of the rural community (figure 4).

In order to obtain an expanded description of the Pirnovo community, a SWOT analysis was carried out which revealed the internal and external factors of land development that belong to it. The internal factors influencing the state of the territories include strengths and weaknesses. Strengths of the area are transport accessibility, a complex of water bodies (Kyiv Sea, Desna River, lakes); attractive landscape and recreational areas, biodiversity. Weaknesses of the area are neglected territory, lack of tourist infrastructure, unsatisfactory state of social, transport,

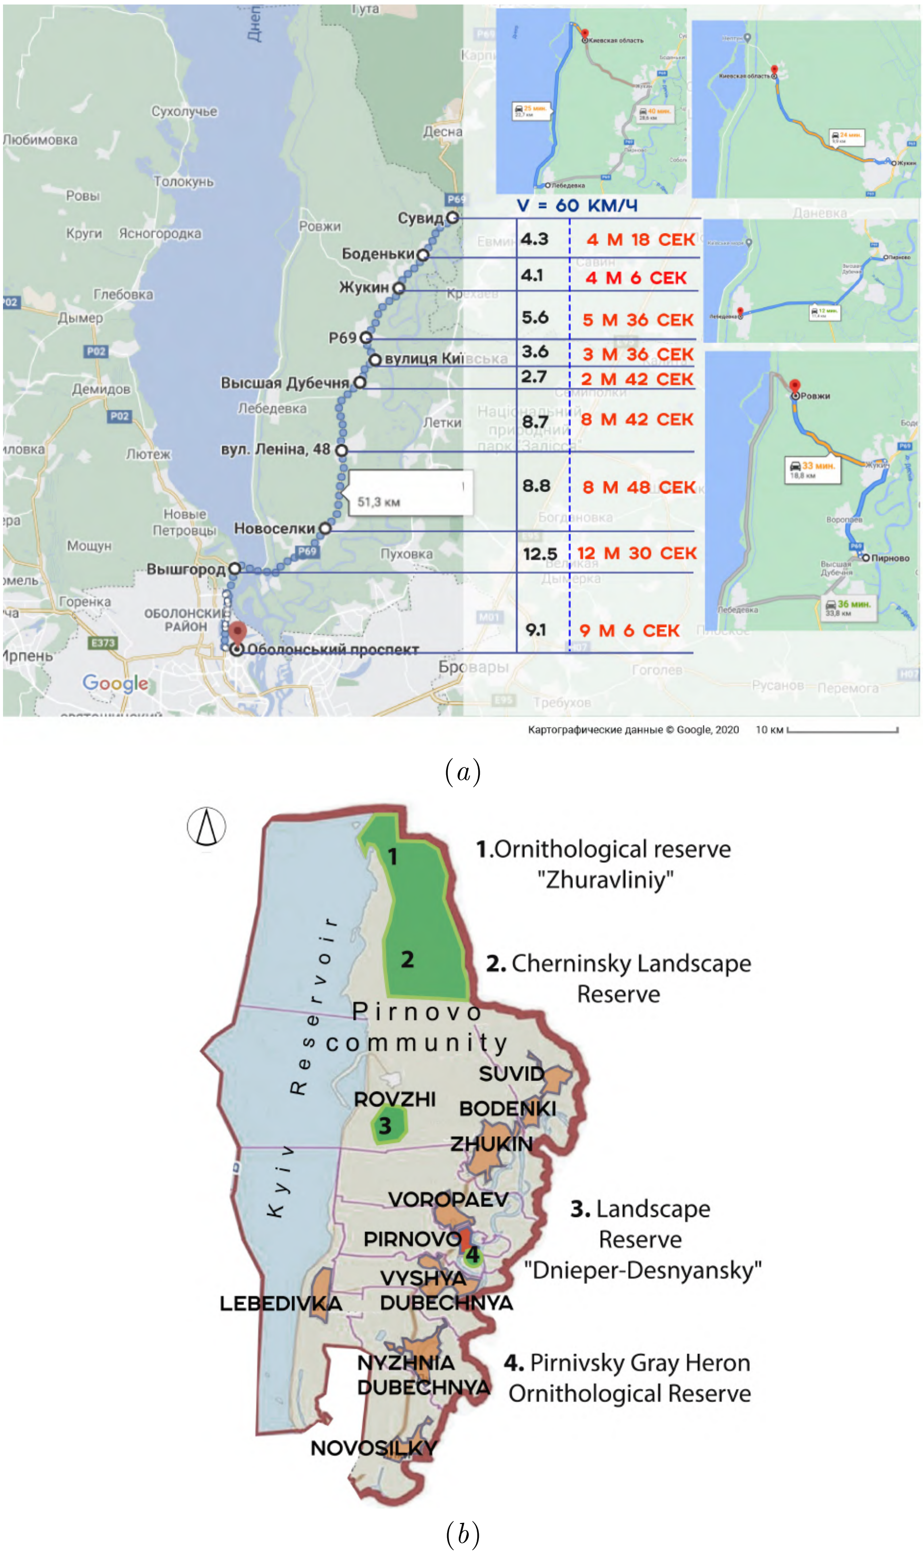


Figure 3. Analysis of transport connections and nature reserve fund of the Pirnovo community: (a) written in red is the time of movement by motor transport between settlements, (b) areas of the nature reserve fund.

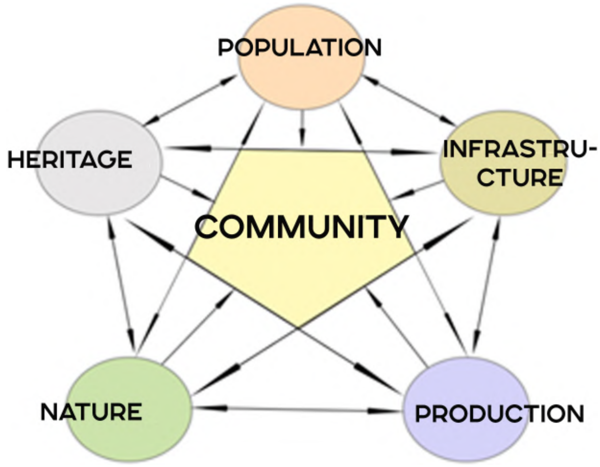

Figure 4. Five resource-oriented subsystems for the development of the Pirnovoska community.

and engineering infrastructure.

External factors include potential opportunities and threats to the stable development of the analyzed areas. Opportunities – revival of nature reserves, interest in tourism development (festivals, fairs), rational use of recreation areas (development of a network of rehabilitation facilities for persons affected by the war), introduction and promotion of advanced technologies of agro-industrial production, craft technologies, IT technologies and recycling technologies, providing of decent conditions for temporary residence of internally displaced persons and increasing the attractiveness of areas by improving the quality of life of locals. Threats – the devastating consequences of the war, manifested in the constant killing and maiming of people, the destruction of residential buildings, public buildings, industrial enterprises, engineering and transport infrastructure, the contamination of agricultural lands, recreational areas and water bodies with harmful substances and explosive objects, changes in the demographic structure of the population, interruptions in the provision of electricity and many other challenges that multiplied the pre-war troubles, including: the impact of the pandemic, unstable situation in the country, lack of sufficient funding, instability of the legislative sphere, destruction of green spaces, as well as lack of initiative of a large part of residents.

The conducted analysis suggested the basic features for the model of sustainable development of the Pirnovo community, which will help transform the weaknesses into strengths, and threats into opportunities (figure 5). The compiled model highlights the key functional and planning elements of the community and sets out proposals for the formation of new types of entrepreneurial activity. The main functional areas include residential, production(working), recreational and communal storage areas, as well as areas of hotel industry and retail. The production(working) zone is supposed to include budget-generating enterprises of touristic, recreational, medical, wellness, economic and industrial nature, the formation of which should contribute to achieving the main objectives of sustainable development of the Pirnovo community and the territory belonging to it.

The proposed model allowed to determine the priority areas of activity of local residents and became the basis for drawing up a comprehensive plan for spatial development of the Pirnovo community with specific proposals for the reorganization of rural areas (figure 6). This plan was developed on the basis of a comprehensive assessment of areas, taking into account the cadastral map, current planning restrictions, existing transport infrastructure and landscape plan of community areas. The complex plan of spatial development of the Pirnovo community includes drawings of general plans of settlements with existing buildings, and adjacent territories

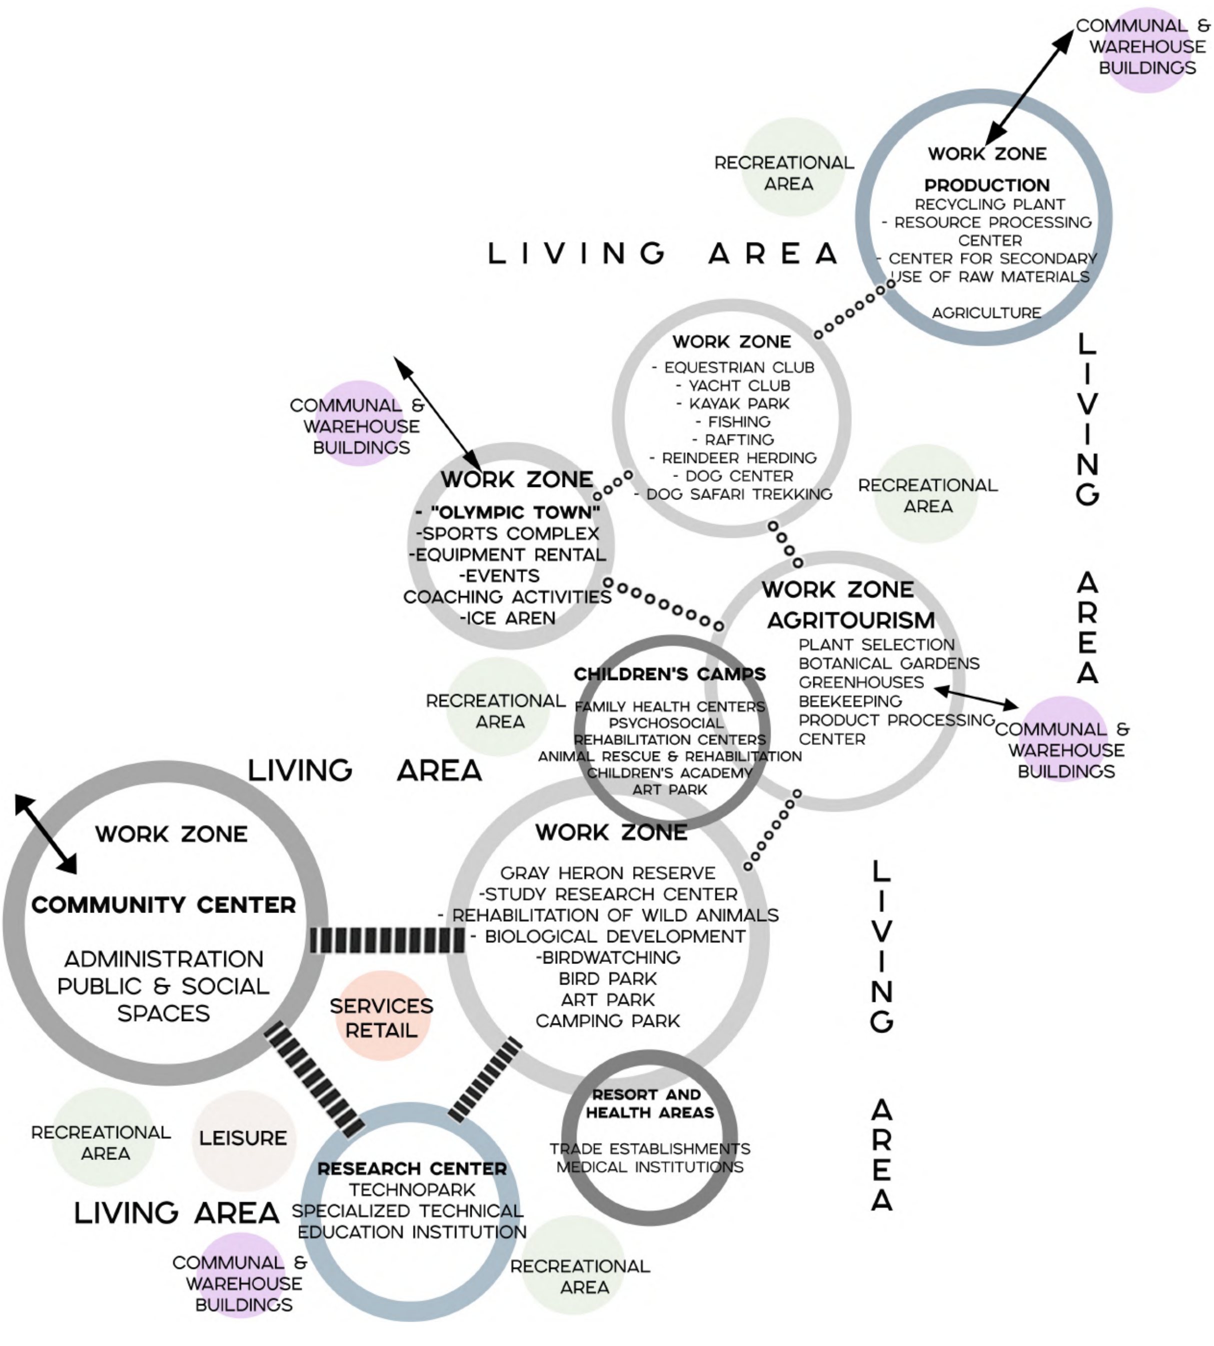

Figure 5. Model of sustainable development of the Pirnovo community.

of the community, separately defined areas of reserves. New ideas for the development of the existing resettlement system include the separation of the “working zone” of each settlement. The list of budget-generating enterprises included in these territorial and spatial elements is determined by the availability of the best conditions for their development in their locations.

In particular, in the western part of the community it is proposed to support sports and recreation. To do this, from the side of the Kyiv Reservoir, south of the village of Lebedivka to create an “Olympic Town” with a sports complex for events and training in ice sports, north of the village of Lebedivka appropriate to organize a yacht club, a kayak park and rafting routes. In

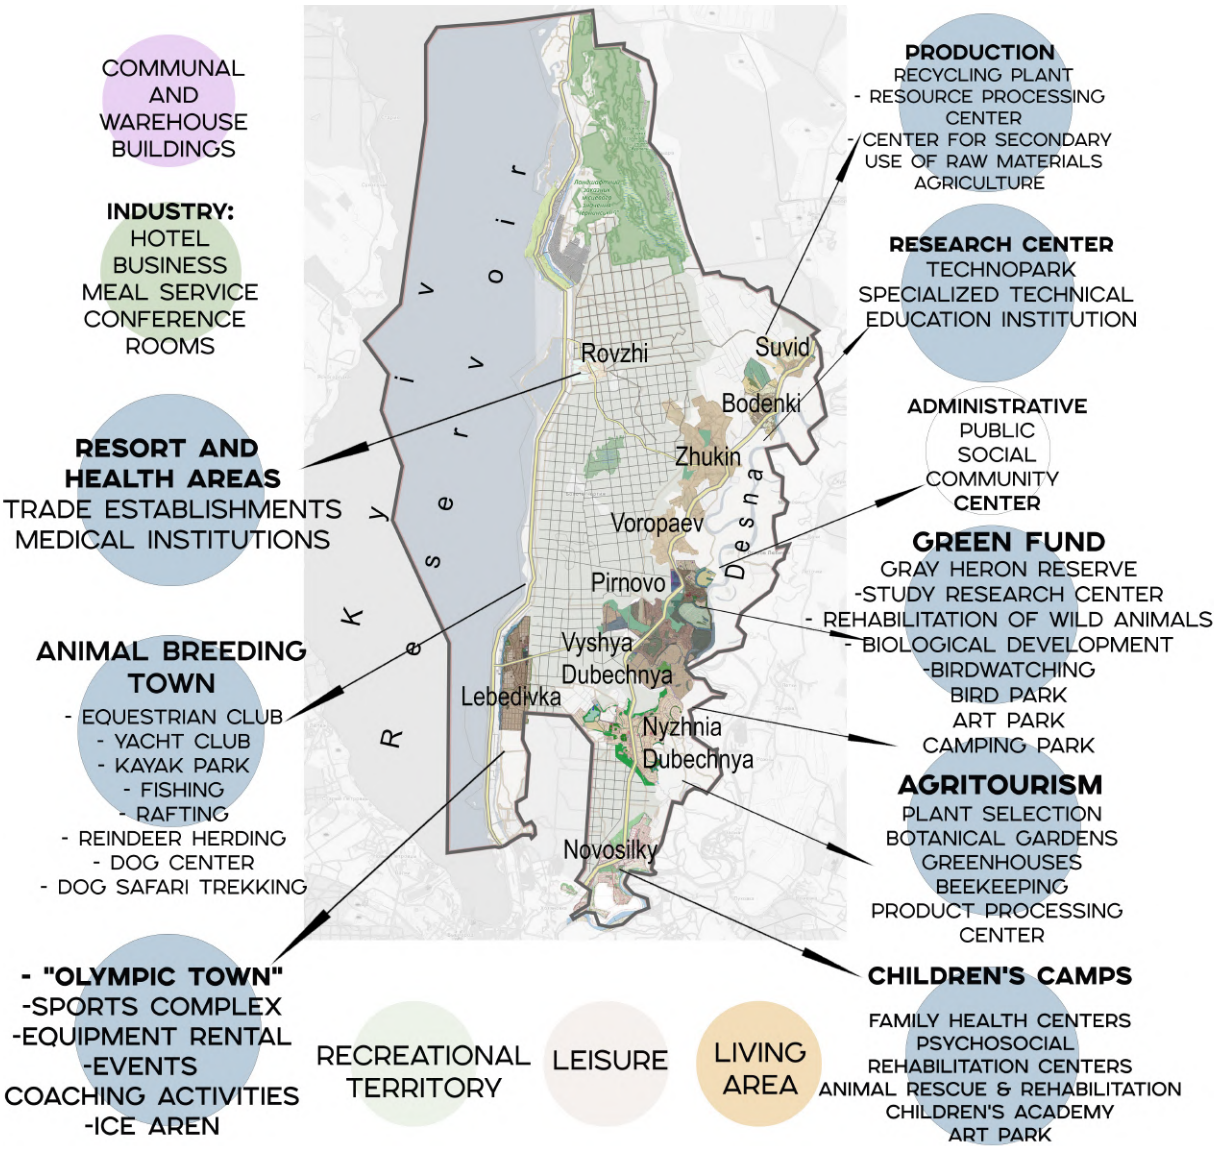

Figure 6. Comprehensive plan of spatial development of Pirnovo territorial community of Kyiv region.

the village of Rovzhi, it is proposed to build a “Retreat Town”, which will include health resorts, medical facilities, tour organization and touring facilities. The eastern part of the community – the village of Vyshya Dubechnya – might be turned into an “Agrotourism town” with complexes of plant selection, a botanical garden, greenhouses, apiaries and centers of processing of agricultural products. In the southern part of the community – the village of Novosilky, it is planned to create a “Family Town” with children’s camps, family health and psychosocial rehabilitation centers, animal rescue and rehabilitation centers, a children’s academy and an art park. The village of Zhukin is supposed to become an “Animal Breeding Town” with equestrian club complexes, fishing ponds, reindeer herding grounds, a dog training center, a dog breeding facility for service and sports purposes, as well as dog safari trekking routes. The village of Voropaev should be equipped with a “Technopark”, which will include a research center and a specialized technical education institution. In the northern part of the community – near the village of Suvid – it is proposed to locate a "Center of production activities" with a waste sorting station, waste processing plant, enterprise for processing resources and recycling, as well as a center for automation and robotics of agriculture. Finally, it is proposed to turn the village of Pirnovo into the center point of the community – the "Community's Green Fund", which will include a restored ornithological "Gray Heron Reserve", wildlife rehabilitation centers, wildlife research and biological development, birdwatching centers, a bird park , an art park, and a camping park. Tourists accompanied by a guide will be able to visit the Chernynsky and Zhuravlyny Reserves, which are located in the very north of the community.

The next step on the way towards sustainable development of the Pirnovo territorial community should be to determine the necessary measures for the transformation of individual settlements. The peculiarities of this stage can be shown by drawing out a clear strategy for the main settlement of the community, the village of Pirnovo. To provide a sustainable development strategy of Pirnovo it is necessary to define the requirements for the transformation of the settlement and the formation of a model of its harmonious organization with further development of the project of territorial and spatial development of the village, with specific proposals, restoration of favorable hydrological regime and sanitary condition of the Desna and general improvement of ecological conditions of the territory.

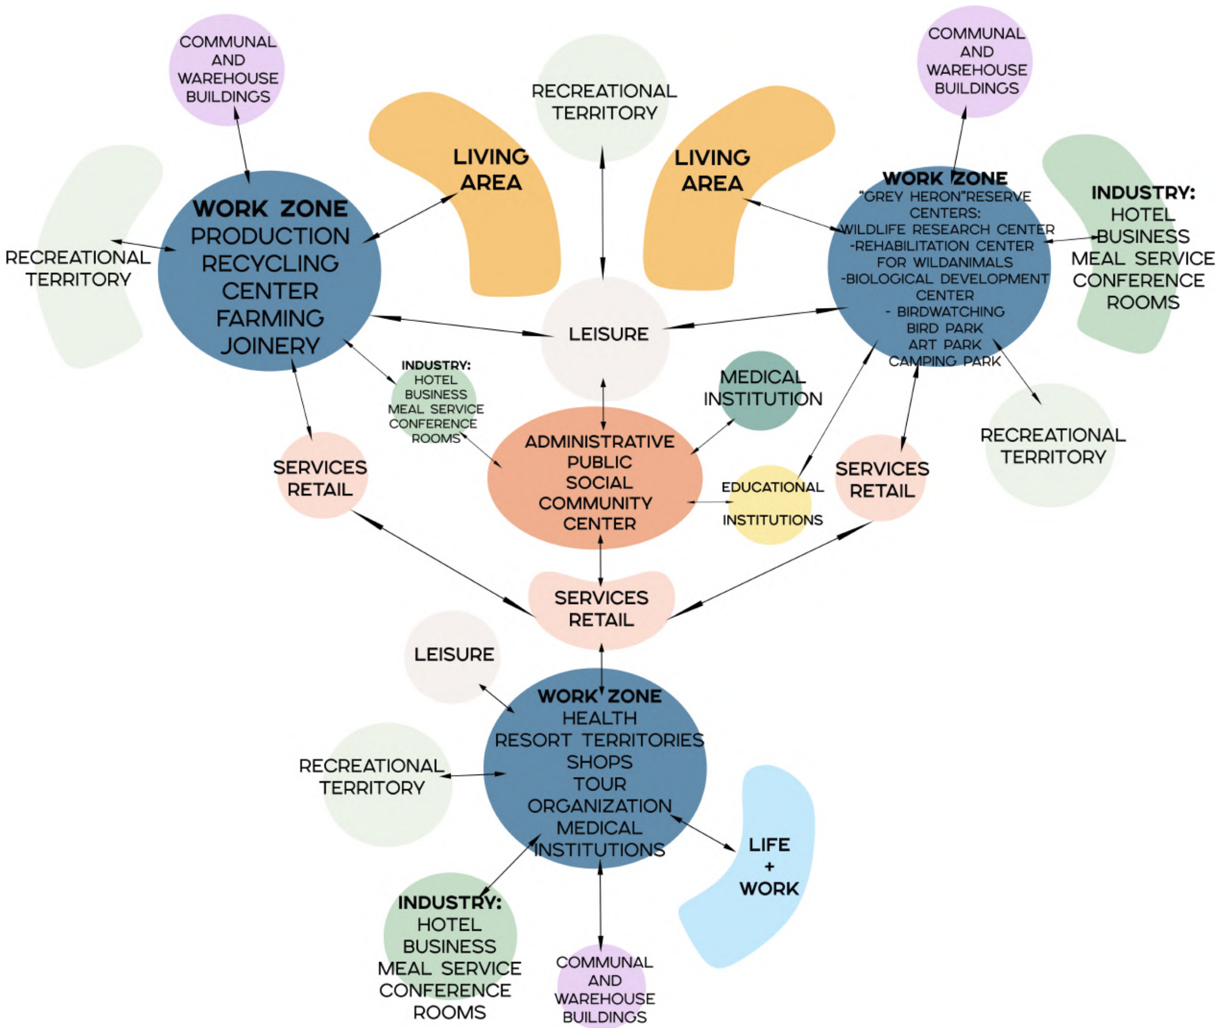

Figure 7. The model of sustainable development of the village of Pirnovo, Kyiv region.

The model of sustainable development of Pirnovo clarifies the composition and location of the village's main functional areas, as well as the presence of the necessary planning links between them (figure 7).

Based on the proposed model, an alternative master plan for the village of Pirnovo was developed, which, unlike the existing one [23], which has actually never been officially approved, takes into account land ownership, functional purpose of land according to land cadastre, and current state building codes in Ukraine (figure 8).

At the final stage of their work, the architect must record their ideas on the formation of the village's imagery and the restoration of its aesthetic appeal. In this study, we drew attention to the need to reconstruct the central part of the village. The artistic concept of the settlement's architectural environment transformation was to develop a comfortable, modern community center which will meet the goals of sustainable development that will not harm the natural

Figure 8. Materials master plan of the village of Pirnovo, Kyiv region scheme of cultural and household services (left), scheme of planning decision (right).

Figure 9. Reconstruction project of the Shevchenko Boulevard in Pirnovo, Kyiv region.

environment (figure 9).

The project provides for a clear functional zoning, development of the historically formed central planning axis of the village, and filling it with all the functions that the community needs. Staying in this area will allow to implement a variety of scenarios of human behavior in the architectural environment. The territory will be visited by residents of different ages, employees of nearby public services and tourists.

Different groups of the population will find here convenient and interesting areas for recreation and active leisure. Implementation of proposals for the reconstruction of the central part of the village of Pirnovo involves a number of special measures for engineering preparation of the territory (vertical planning, lowering the groundwater level, compliance with sanitary gaps, flood protection, etc.). Reconstruction of existing buildings and construction of new ones involves the use of modern energy efficient technologies. Improvement of renovated public spaces should be carried out using recycled materials.

4. Conclusions

Based on historical and SWOT analysis, structural-logical territorial-spatial and project-planning models have been developedin order to implement the principles of sustainable development of Pirnovo territorial community by monitoring urban planning, public service system, organization of engineering and transport infrastructure, and other less mobile groups, environmental protection, as well as the preservation of immovable cultural heritage sites and archeological monuments and the traditional nature of the environment of settlements.

The results of the analysis and modeling were used in the process of experimental design of the Comprehensive Spatial Development Plan of the Pirnovo Territorial Community of Kyiv Oblast, the General Plan of its administrative center – the village of Pirnovo, and the Detailed Plan of the territory of the central part of this settlement. These proposals are aimed at the primary post-war recovery steps of the studied territory and the achievement of quite realistic goals considering its sustainable development, related to the balanced economic and social growth of the territorial community, the reproduction of ecological balance and the further development of local culture.

The proposed comprehensive approach in the post-war period can be applied in other regions of Ukraine and become the basis for managing their functioning and recovery, taking into account the tasks of sustainable development for settlements and communities. This will increase the effectiveness of activities related to the implementation of the state‘s strategic goals, as well as solving local problems – planning rural areas, improving the quality of the architectural environment of settlements, a harmonious combination of artificial and natural surroundings, which will contribute to overcoming the destructive consequences of war and the further development of the capital region.

Abstract. Metamorphic processes in natural conditions reached a certain stage of the original organic matter transformation at temperatures no more than 650 °C. Analyzes of the coal physical and chemical characteristics are carried out at higher temperatures. Thermal decomposition processes determine the properties of coals during their further transformation, which is important for establishing their consumer properties. The quantitative and qualitative composition of the formed volatiles is not directly related to the fluids, previously removed from coal seams in natural conditions. The thermal decomposition products of coals are the result of a new stage in the initial organic matter transformation. It is shown that the method for determining the yield of volatile substances on a ash-free dry mass when establishing technological properties does not reflect the state of coal seams in natural conditions. Analysis of the results indicates that at present there are no methods for complete the coal sample demineralization. Obtaining an accurate value for the yield of volatile substances per ash-free dry organic mass leads to an overestimation of this indicator. Significant differences in the balances between the metamorphic processes occurring in coal seams and during the thermal decomposition of coal are caused by different conditions for their determination. The products assignment of thermal decomposition processes to a ash-free dry organic mass according to industrial classifications doesn't allow to use of their consumer properties indicators to characterize the hazardous properties of coal seams in natural conditions. It is proposed to develop the basic principles of the methodology for predicting the hazardous properties of coal seams based on the deviation of the content of organic matter main components, including moisture and sulfur, from their average indicators.

1. Introduction

Metamorphic changes in fossil coals proceeded mainly under the influence of temperatures and pressures that developed in the earth's crust as a geological processes result [1]. They boil down to enrichment of organic matter with carbon and depletion of other components. The chemical composition of coal largely determines the hazardous properties of coal seams: gas content, outburst hazard, spontaneous combustion, coal dust explosiveness and other negative phenomena. To clarify the mechanism and conditions of their occurrence, it is necessary, at least, to know the changes in the initial composition of fossil coals under the influence of these factors.

Most researchers recognize that of all the factors of metamorphism, temperature has the greatest influence [2, 3] Knowing the transformation temperature of an initial organic mass and a composition of a resulting substance, one can judge the ongoing chemical transformations of fossil coals. Based on the experiments, it was concluded that the temperature boundary between the formation of brown and hard coals is in the range of 300-325℃. The transition from coal to anthracite is possible at least at 500 ℃. Anthracite formation took place at a temperature of 500-650 ℃ [4].

The transformation of an original organic matter of fossil coals consists in increasing the carbon content (possibly up to 100 %) and reducing other components to practically zero. This trend in compositional changes with an increase in the degree of metamorphism is confirmed by the results of coals analysis from different basins [5]. The change in an elemental composition of the initial organic matter is one of the main characteristics of the metamorphic processes manifestation. The principles of determining an metamorphic transformations degree of coals by the elemental composition of organic matter are not observed in the regulatory framework [6–8], regulating the safety of mining operations. As the main indicator of metamorphic transformations of coal seams, the release of volatile substances on dry ashless organic fuel mass during a coal thermal decomposition without air access is taken (V^{daf}). This indicator and some others were borrowed, without proper scientific justification, from industrial classifications used in different periods [6].

Metamorphic processes in natural conditions reached a certain stage of the original organic matter transformation at temperatures no more than 650℃. Thermal decomposition according to the requirements [9] is carried out at 900℃for 7 min. In the first case, an organic matter during a certain geological period was in a certain pressure and temperature regime. As a result, the coal raised to the surface is characterized by a mineral association, which is inherent in conditions of high temperatures and pressures. Its stability and safety is largely determined by the previous transformation conditions. In the second, this association undergoes a change at higher temperatures. Thermal decomposition processes determine the coals properties during their further transformation, which is important for establishing their consumer properties. The quantitative and qualitative composition of the formed volatiles is not directly related to the fluids previously removed from coal seams in natural conditions. The products of coal thermal decomposition are the result of a new stage in the transformation of an initial organic matter. An example of the different stages of coal conversion, raised to the surface, are the methods for determining their suitability for producing coke and semicoke [10]. Different temperature regimes in this case determine the formation of different products of thermal decomposition, the quantitative and qualitative composition of volatile substances. (V^{daf}). This proves that coals metamorphism and their thermal decomposition are different forms of organic matter transformation, and the resulting chemical compounds differ significantly in qualitative and quantitative compositions. For this reason, the hazardous properties of coal seamsmust be predicted by indicators whose values are directly a consequence of the impact of metamorphic processes, and not the result of thermal decomposition of already converted coal.

Volatile matter yield is widely used to characterize the technological properties of coal. For these purposes, it is customary to determine V^{daf} on a dry ashless mass. This is important for calculating the yield of coke oven gas and chemical products during coking coal. Volatiles are formed from organic matter and mineral impurities. Their total amount released during thermal destruction of coals largely depends on their ash content: the higher it is, the more distorted the V^{daf} value. With an increase in ash content, the proportion of volatiles matters from mineral components increases and organic matter, to which V^{daf} belongs, decreases. Due to the lack of complete demineralization methods, the exact V^{daf} value cannot be determined in a laboratory way [4, 10, 11], and the conversion of volatile substances to organic matter leads to an overestimation of the indicator. The existing method for determining V^{daf} only approximately characterizes the behavior of the coals organic mass during thermal destruction and is completely unacceptable at a high ash content of the sample [12]. In addition, the V^{daf}

composition does not take into account the presence of moisture in the original coal samples, which has a significant effect on the condition of coal seams during mining operations.

The above facts indicate that the V^{daf} indicator was developed only to establish the consumer properties of coals and it does not characterize the degree of seams transformation at different stages of their metamorphism. Its use to determine the hazardous properties of coal seams is not sufficiently scientifically substantiated. In this regard, there is a need to improve the regulatory framework in terms of ensuring the safety of mining operations. Research in this direction is relevant, since the reduction of accidents and injuries in coal mines largely depends on their results.

Purpose of the study is to establish a set of basic indicators of the degree of metamorphic transformations of coal seams, which determine the manifestation of their dangerous properties during mining operations.

2. Results

Research methodology was developed based on the results of an analysis of currently known indicators of the degree of metamorphism of coals and scientific justification for their possible use to characterize the hazardous properties of coal seams.

Most indicators of fossil coals are designed to reliably establish their calorific value and coking capacity. For these purposes, at different times, the indicators of coking capacity (K), the yield of volatile matters (V^{daf}), the carbon content in organic matter (C_0), the presence of analytical moisture (W^a) and brand identity (M) were used. Each of these indicators characterizes one of the many aspects of the metamorphic processes of the original organic matter transformation. To varying degrees, they are mutually correlated with each other, which do not exclude some duplication in assessing the technological properties of coals. The effectiveness of using this indicators set for assessing the consumer properties of coal is beyond doubt. This is confirmed by the constant improvement of industrial classifications. Now, the classification of coals by their genetic and process parameters [7] is the most perfect. In addition to V^{daf}, R^0, V_v^{daf}, $lg\rho$, and y, it uses 6 more classificatory parameters are applied. The main of them is an average reflectance of vitrinite. As distinct from V^{daf}, R^0, V_v^{daf}, $lg\rho$, and y, the limits of its alterations are established for the whole range of metamorphism series of fossil coals as per their ranking.

It is not possible to improve the regulatory framework for the safe mining of coal seams, in which the yield of volatile during the coal thermal decomposition (V^{daf}) is used as the main indicator, for several reasons. The main one is the thermal decomposition of coals, in essence, is a modern artificial stage in the continuation of the coals transformation that occurred in earlier geological periods. The method for determining V^{daf} on a dry ashless mass does not take into account the influence of the presence of moisture and mineral impurities on the actual chemical-physical state of coal seams.

The need to establish an indicators set of the degree of coal seams conversion is dictated by the lack of consensus on the use of individual indicators in solving engineering problems. In most cases, some indicator that is not directly related to the coal seams transformation is assigned an absolute role in establishing the stages of metamorphism. A priori, one indicator can characterize only one side of the change in composition or properties during metamorphic processes.

Conventional coal grades, established for their industrial use according to the V^{daf} indicator, are taken as a criterion for general metamorphism in determining the dust-generating capacity of coal seams [6, 13]. Similarly, the strength properties of coals [14] and the propensity of seams to outburst hazard [15, 16] are assessed by their brand identity.

The danger of anthracites spontaneous combustion is made dependent on the logarithm of the specific electrical resistance. In another case [6], the propensity of seams to spontaneous combustion was determined by the interrelated V^{daf} and coal grades (M). In addition to them, a carbonation indicator has been introduced. It partially takes into account the change in the composition of organic matter with an increase in the carbon elemental content (C_0) and a decrease in hydrogen (H_0) and oxygen (O_0). Vdaf parameter adequately describes orders of bituminous coals, but there are some uncertainties in determination of boundaries between grades and sub-grades. For example, for coals of 1G grade, 1GV sub-grade, no upper parameter value has been determined. For this case, $V^{daf} = 38\%$ and more. Such an approach to determine V^{daf} alteration boundaries is kept for many ranks, grades, sub-grades, and classes. During development of coals classification by manifestation of their hazardous characteristics, it is desirable for this disadvantage to be eliminated. Advantage of V^{daf} parameter for its application for any purposes consists in its sufficient previous study in part of correlation relationship with other parameters. Ultimately, coals of all grades from D to T were assigned to the group of increased endogenous hazard. Coal of the same grades from D to T fell into the category of coal seams, where endogenous fires were absent. This once again indicates the absence of a direct connection between V^{daf} and M indicators with the manifestation of hazardous properties of coal seams. The values of the volatile matters yield can differ significantly for different mines due to the heterogeneous petrographic composition of the organic mass [2]. To clarify the consumer properties of coal, this requires an individual determination for each mine formation, taking into account changes in coalification indicators. The same approach is required to establish the hazardous properties of coal seams, but using a different set of classification indicators.

The problem of establishing a indicators set for predicting the hazardous properties of coal seams appeared as a result of copying without scientific substantiation of industrial classification methods for determining the stages of coal metamorphism (grades). At all stages of improving industrial classifications, the main criterion for the distribution of coals by consumer properties has been and remains to this day the yield of coke to organic matter (K). According to this indicator, 10 stages of coal metamorphic transformations were initially conventionally established. The classification diagram developed later [6] was based on the coals distribution by their sintering capacity into 4 groups. Weakly caking coals were determined by the values of V^{daf} and C_0, caking ones were classified using V^{daf} and the thickness of the plastic layer (y), weakly caking coals were grouped according to V^{daf} and tar yield (T^{daf}_{sk}), and the gradation of non-caking coal and anthracites was made according to the specific gravity (K_d) of organic matter and mechanical copra strength (P_c). In the case under consideration, different pairs of main indicators were selected to characterize different degrees of one consumer property manifestation. In addition, the oxygen content in organic matter (O_0) and the higher heat of combustion for the wet ash-free state of the organic matter (Q^{af}_s) were taken into account. Subsequently, using the values of V^{daf}, y, Q^{af}_s and maximum moisture capacity (W^{af}_{max}),the coal was divided according to their technological qualities into 10 grades (D, G, GZh, Zh, KZh, K, K2, OS, SS, T) and six stages of metamorphism. The discrepancy between the grades and the number of stages is due to the fact that the transitional grades (GZh, KZh, OS and SS) were determined simultaneously by two stages of metamorphism. After improvement, the modern industrial classification [8] divides all fossil coals using 10 indicators into eighteen grades, including brown coal and anthracite. In addition to establishing the brand identity, a gradation was made into groups, subgroups, classes, categories, types and subtypes. A total of 86 varieties of fossil coal have been identified. Correspondence to these varieties of the same number of stages of metamorphic transformations of formations has not yet been made. The solution to this problem is not a priority for establishing the consumer properties of coal. In contrast to industrial classifications, determining the conformity of individual stages of metamorphic transformations of coal seams is a primary task for improving the regulatory framework for the safe conduct of mining operations. The division into 10 stages of metamorphism of formations according to the yield of coke [6] has remained practically unchanged to date. Their number coincides with the number of originally established brands. This allows, as a first approximation,

to compare the grades of coal with the corresponding stages of metamorphic transformations of coal seams (table 1). Developed on the analysis results basis of the currently known indicators of the coal metamorphism degree and the scientific substantiation of their possible application for characterizing the hazardous properties of coal seams.

The yield of coke to organic matter uniquely determines the removal of fluids (V_k^a) at each stage of a formation transformation. The average value of coke ($\bar{K}$) corresponds to the amount of removed fluids ($\bar{V_k^a}$), based on the condition of their total 100% content in the dry ashless organic mass of the mine formation:

$$\bar{V_k^a} = 100 - \bar{K}, \%$$

In this case $\bar{V_k^a}$, in addition to gaseous products, the composition includes coal tar, pyrogenetic moisture, crude benzene and other products of formations metamorphic transformations. Significant changes are also observed in the elemental composition of organic matter (figure 1).

According to the one-sided direction of the processes of metamorphism, with their intensification, an increase in the content of carbon ($\bar{C_0}$) and a decrease in hydrogen ($\bar{H_0}$), nitrogen ($\bar{N_0}$), sulfur ($\bar{S_0}$) and oxygen ($\bar{O_0}$) occur. The reduction of individual components in the organic mass at different stages of metamorphism occurred with different intensity. Their total amount (figure 1b) is strictly controlled by the carbon content (figure 1a), based on the ratio:

$$\sum \bar{H_0}, \bar{N_0}, \bar{S_0}, \bar{O_0} = 100 - \bar{C_0}, \%$$

Equation represents the total elemental balance of dry ashless matter at different stages of fossil coals conversion. It does not take into account the change in moisture in the original sample $\bar{W^a}$ (figure 1b), a as well as the ratio between coke $\bar{K}$ (dry residue) and fluids $\bar{V_k^a}$ removed from the layers. The moisture influence on the manifestation of the hazardous properties of coal seams is beyond doubt [13]. The fraction of fluids removed from the layers $\bar{V_k^a}$ exceeds the yield of volatiles $V^{\bar{d}af}$ per dry ashless mass.

Significant differences in the balances between the ongoing metamorphic processes in coal seams and during the thermal decomposition of coal are caused by different methods of their determination. The assignment of the thermal decomposition processes products to a dry ashless

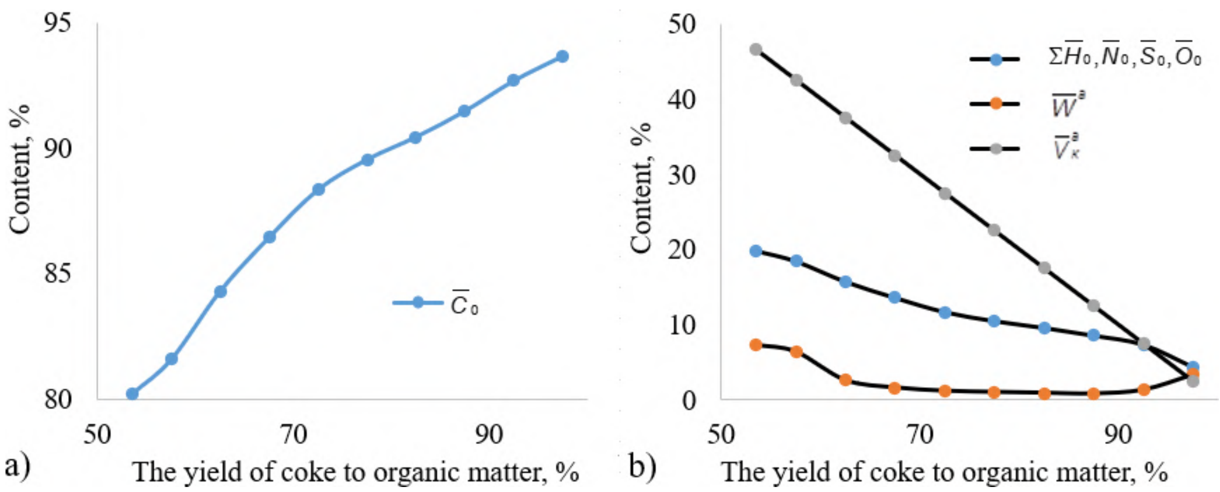

Figure 1. Dependence of the organic matter content and volatiles removal from the layers on the yield of coke to organic matter.

mass according to industrial classifications does not allow the use of their consumer properties indicators for characterizing coal seamsin natural conditions. The hazardous properties of coal seams cannot be directly determined by the yield of coke to organic matter. According to the K value, the stages of coals metamorphic transformations were initially only approximately determined. At different stages of metamorphism, the composition of organic matter, almost 100% (table 1), is determined by the sum of the components $(H_0, N_0, S_0, O_0, C_0)$.

The relationship between them in the process of metamorphic transformations does not remain constant. Only an increase in the elemental content of carbon in organic matter occurs unambiguously $\bar{C_0}$ (figure 1). Other indicators of the degree of metamorphic transformations $(\sum \bar{H_0}, \bar{N_0}, \bar{S_0}, \bar{O_0}; \bar{V_k^a}; \bar{W^a})$ vary according to different dependences. The manifestation of the hazardous properties of coal seams is largely determined by the elemental composition of organic matter. For this reason, the methodology for their prediction should be based, to a large extent, taking into account changes in the elemental composition of organic matter. Its main constituent at the stages of coal and anthracite formation is carbon. Its content increases in the range from 70 to almost 100%. When the carbon content is less than 93%, the sum of the remaining components of organic matter $(\sum \bar{H_0}, \bar{N_0}, \bar{S_0}, \bar{O_0})$ decreases according to a linear inverse proportional relationship (figure 2).

A linear inversely proportional decrease in the total of organic matter components with an increase in carbon content indicates the predominant mechanical removal of fluids at the early and middle stages of layers metamorphism and an insignificant amount of formation of new chemical compounds with the participation of carbon. At values $\bar{C_0} > 93\%$ the dependence $\sum \bar{H_0}$,$\bar{N_0}$,$\bar{S_0}$,$\bar{O_0}$ from inversely proportional to nonlinear, which indicates the possibility of the formation of new chemical compounds under the influence of elevated temperatures and pressures.

Other indicators of metamorphic transformations of formations – removal of fluids $\bar{V_k^a}$ and the content of analytical moisture $\bar{W^a}$ also depend on the carbon content in organic matter. This gives rise to the value together with the individual content of other organic matter components H_0, N_0, S_0, O_0, C_0 and moisture, to be considered the main indicators affecting the safety of mining operations. The dependence of the fluids removal $\bar{V_k^a}$ at different layer stages differs significantly from the yield of volatiles $V^{\bar{d}af}$ during the thermal decomposition of coal. The difference between and at the early and middle stages of layer transformation $(\bar{C_0} \approx 70 \div 90\%)$

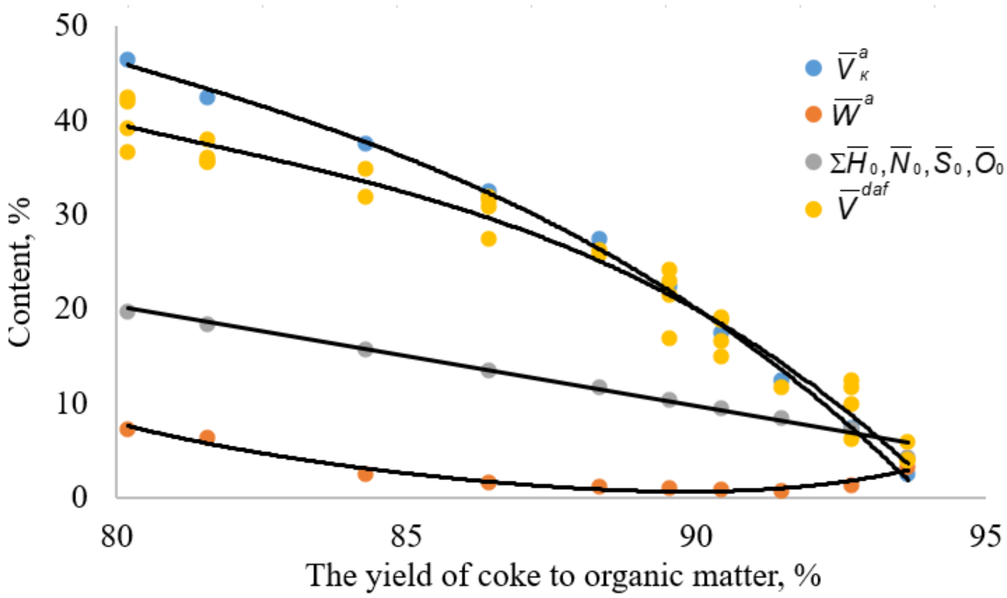

Figure 2. Dependence of the average indicators of seams metamorphism and the yield of volatile substances from organic matter due to coal thermal decomposition on the average carbon content in organic matter.

is due to the removal of moisture and coal tar from them along with gaseous products. The determination procedure V^{daf} takes into account only the total yield of gaseous products. The coincidence at values $> 90\%$ indicates the predominant removal of gaseous fluids from the layers.

The values of the indicators and are determined on the basis of the average composition of the Donets basin coals. They are in full agreement with the results of the coals analysis carried out for different deposits [3, 12, 13], which indicates the sufficient reliability of the obtained results.

It is proposed by methods for predicting the hazardous properties of each mine layer to establish individual deviations of the organic matter components and moisture from their average values for the stage of metamorphic transformations under consideration. The stage of transformation is determined by the carbon content in organic matter. A significant deviation of any organic matter component ($\bar{H}_0$,$\bar{N}_0$,$\bar{S}_0$,$\bar{O}_0$,$\bar{W}^a$) from its average values causes a redistribution of their individual content in the elemental organic matter composition. This, in turn, determines the individual characteristics of the hazardous properties manifestation of coal seams during mining operations. If necessary, an additional analysis is made for anomalous composition of mineral impurities.

3. Conclusions

The studies carried out made it possible to establish the features of the metamorphic transformations stages and their differences from the processes of coals thermal decomposition, to develop a methodology for predicting the hazardous properties of coal seamsto improve the regulatory framework. Its main provisions are based on the following principles:

- intensification of layers metamorphic transformations is associated with a one-sided increase in the carbon content in organic matter and a change in the content of other components (hydrogen, nitrogen, sulfur, oxygen, moisture);
- one of the main factors determining the manifestation of the hazardous properties of mines is the elemental composition of the original organic mass and the degree of its transformation

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012038 doi:10.1088/1755-1315/1415/1/012038

during geological processes;

- metamorphic transformations of brown coal seams occurred at temperatures up to 300-325°C, stone – at a temperature of 325-500°C. Achievement of the anthracite stage corresponded to a temperature of 500-650°C;
- the final conversion cycle of the original organic matter consists in achieving the elemental carbon content close to 100% and approaching zero of the sum of the content of the remaining components;
- the temperature of coals thermal decomposition without air access (900°C) when establishing their technological properties significantly exceeds the temperature of metamorphic transformation of seams (300-650°C). This allows us to consider the products of thermal decomposition as the next stage of coal transformation, which is not related to the appearance of hazardous properties of coal seams;
- there are currently no methods of complete demineralization of the coal sample. Obtaining an accurate value for the yield of volatile substances per dry ashless organic mass leads to an overestimation of this indicator. The error increases with the increase in the proportion of the mineral component. When the carbon content is less than 93%, the sum of the remaining components of organic matter ($\sum \bar{H}_0,\bar{N}_0,\bar{S}_0,\bar{O}_0$) decreases according to a linear inverse proportional relationship;
- the method for determining the yield of volatile substances on a dry ash-free mass when establishing technological properties does not reflect the state of coal seams in natural conditions;
- the method for determining the yield of volatile substances on a dry ash-free mass when establishing technological properties does not reflect the state of coal seams in natural conditions;
- the basic principles of the methodology for predicting the hazardous properties of mines are proposed to be developed based on the deviation of the content of the organic matter main components, including moisture and sulfur, from their average indicators.

Abstract. The need for worker safety in the coal mining industry is critical because workers in this industry are exposed to a number of hazards and risks. Accidents occurring in the technogenic sphere of the coal industry cause significant damage to the state economy. Loss of production, repair and restoration of infrastructure, compensation to victims, damage to the environment require significant financial outlays. Therefore, it is important to take all necessary measures to prevent accidents and minimize their consequences. The purpose of the work is to identify the zones of manifestation of hazards and forecasting the risks of emergencies, as well as to develop a set of technical and organizational measures to prevent accidents and incidents during production work. The importance of the study lies in the development of recommendations for identifying the main risk factors in coal mines cleaning faces, the creation of a set of technical and organizational measures to quantify the risk of emergencies, as well as improving the level of safety of the main working processes in planning safe mining operations. Ensuring safety of coal industry workers is an integral part of successful and efficient operation of this industry.

1. Introduction

Accidents and industrial injuries that occur in the technogenic sphere of the coal industry are a source of enormous damage to society and the state as a whole. Development and implementation of measures to ensure efficiency the functioning of systems for preventing and eliminating accidents in longwalls seems to be difficult in conditions of insufficient knowledge of the patterns of man-made hazards, the occurrence of emergency situations and the causes leading to them. This is especially noticeable in the absence of a systematic analysis of risk factors and effective methods for predicting the level of safety at such stages as design and organization of production [1]. The development of risk assessment methods is the most important condition for forecasting man-made hazards, the occurrence of emergency situations, their consequences, and damage assessment. This will allow us to identify effective measures to prevent accidents and injuries at the planning stage of mining operations. To reduce the likelihood of man-made emergency situations at coal mining enterprises, taking into account the requirements of legislation in the field of labor protection, it is necessary to develop and implement a set of organizational and technical measures [2]. They should be aimed at predicting and assessing risk factors, improving the occupational safety and mining safety management system, taking into account the concept of acceptable risk, and revealing the basic patterns of formation of the preconditions for negative events depending on the technical level of production and mining and geological conditions. Most of the mines are located in the territory not controlled by Ukraine (67), 2 more mines are not operating, 33 are operating (but only 4 are considered profitable). That is, about 30 mines are modern enterprises, and more than half of the mines operate without reconstruction, have complex ventilation networks and multi-stage underground transport. In the total fleet of operating downhole equipment, the share of mechanized mining complexes and road headers of a new technical level is only 2%. In general, the industrial and production assets of coal mining enterprises are worn out by an average of 65% [1, 2].

Increasing the level of safety of mining operations in the working faces of coal mines is also associated with improving methods for predicting places of possible emergency situations based on the analysis of geomechanical and gas-dynamic phenomena, such as rock bursts, sudden outbursts of coal and gas, increased rock pressure, roof collapse, caused by the morphology of deposits coal [3]. Therefore, at present, in order to maintain the required level of labor protection and industrial safety, scientific research on the development of a set of technical and organizational measures to predict emergency situations in the working faces of coal mines and assess their consequences can objectively be qualified as relevant.

The purpose of the work is to establish the influence of a complex of mining-geological and technological factors on the formation of the preconditions for emergency situations to identify dangerous zones of hazard manifestations and predict the risks of emergency situations and to develop a set of technical and organizational measures to prevent accidents and injuries during mining operations [4]. This consists of implementing a systematic approach to object-oriented assessment of the risk of emergency situations during cleaning operations in coal mines, taking into account the geodynamic manifestations of rock pressure to predict high-risk zones. The main provisions of which are:

- the methodology for assessing and predicting identification of man-made hazards, risks of occurrence and dynamics of emergency situations, and their consequences is based on a comprehensive accounting of the ranks of risk factors for the conditions of a particular mine;
- ranking of the main risk factors influencing the likelihood of emergency situations is based on the methodological principles of retrospective analysis of the dynamics and consequences of man-made hazards in the working faces of coal mines [5];
- reliable forecasting and effective monitoring of man-made emergency situations, on the basis of which effective protective measures are developed in dangerous zones of manifestations of geomechanical processes, is ensured by implementing the electromechanical analogy method for quickly determining the location of dangerous zones of the coal-bearing massif and assessing their values [6];
- the use of the electromechanical analogy method based on an algorithm for operational prediction of the location of emergency zones allows us to objectify the opology of the workings network of the excavation site and the direction of mining its reserves, taking into account the geomechanical factor.

To date, the Ukrainian coal industry has not solved the problem of predicting the location of man-made emergency situations in the working faces of coal mines. the problem, a significant reduction in the level of occupational morbidity of workers at coal enterprises, is an urgent and priority task [7, 8]. Existing comprehensive assessments of the hazard level require clarification and additional research into mining operations with various equipment options.

In this regard, the following tasks were set and solved:

- analysis and evaluation of the main patterns, reasons for the manifestation of hazardous factors in the working faces of coal mines;
- ranking of the main risk factors that shape the accident rate and industrial injuries in coal mines;
- research of existing methods necessary for the development of measures for operational forecasting and monitoring of safe cleaning work in coal mines;
- development of an algorithm for electromechanical modeling methods for determining and assessing the values of the horizontal components of the stressed part of the coal massif and their trajectories;
- development of methods for assessing and forecasting man-made hazards, risks of occurrence and dynamics of emergency situations, their consequences, and possible damage.

2. Results and discussion

The study and processing of an array of statistical data on the manifestation of man-made hazards revealed the main groups of risk factors influencing the occurrence of emergency situations [9,10]. The ranking of the main risk factors was carried out on the basis of determining the specific gravity of the groups (f) as the ratio of each of them to the total number of manifestations of hazards over a given period of time. As a result, several thousand cases of industrial risk were analyzed, more than thirty enterprises and organizations were studied. The spread of basic data on the share of risk factors (standard deviation) for various geological and mining conditions did not exceed 10% (table 1, figure 1). Based on the results of the study of the main risk factors, it was possible to find out that the greatest number of manifestations of man-made hazards are associated with gas-dynamic, hydrodynamic and, mainly, geodynamic phenomena. Now in this area there is a significant lag in the development of new effective measures for the operational forecasting of emergency situations associated with the uncontrolled growth of the stressed state of the mountain range. An assessment of the magnitudes and directions of action of deformations and stresses in the presence of blockiness of the massif can be performed using methods of mathematical modeling of the stressed state of a coal seam, the distinctive feature of which is the efficiency and clarity of the solution process.

Analysis of the modeling results indicates that the manifestation of geodynamic phenomena in the marginal parts of the mountain range associated with the stressed state of the coal seam depends mainly on the tectonics of the deposit. It was found that the system of tectonic faults makes the most significant contribution to the nature of the stress state of flat and inclined coal seams [11]. Therefore, one should expect dynamic phenomena of rock pressure in the immediate vicinity of the fault plane at the moment when the maximum stress state of the massif is reached. During the movement of cleaning work in the roof of the fault plane, the stress state of both the edge of the formation and the fault plane itself is summed up. Mathematical modeling methods have been known for quite a long time and not only in Ukraine, its application has been carried out for the conditions of many ore deposits and is described in methodological manuals. In mines in England and Germany, modeling methods are integrated into management systems labor protection [12]. The use of this method in domestic mines to predict the risk of accidents and injuries would improve the level of industrial safety and labor protection. Therefore, the result of further research based on the integration of electrographic modeling into the system of mine services was the development of an algorithm for operational forecasting of the location of man-made emergency situations (figure 2).

This algorithm includes determining the location and assessing the values of the horizontal components of tectonic stresses, their trajectories for the conditions of the mining site of a mine based on electrographic modeling [13]. The algorithm also includes a retrospective analysis of

Table 1. Grouping the main risk indicators.

Group	Risk	Risk factors	f, units
Group 1	Natural action	Tectonics, blockiness, disturbances, depth, gas hazard, impact hazard, emissions hazard, explosion hazard, dust pollution, fire hazard, hydrohazard.	0.30
Group 2	Monitoring array and lava (availability)	Numerical sediment recording; application of the optical-imaging method of georadar location; seismic tomography; reservoir mapping; Internet; phone; presence of geo-, hydro-, micro-, vibraphones; communication-information system	0.23
Group 3	Equipment	Technical readiness coefficient; firm; operating time; wear; computer control of a mine or site; degassing	0.17
Group 4	Constructive factors	Visors; aprons; screw; protection from gas, rock bursts, sudden outbursts of coal and gas, collapses, flashes, overturns; ergonomics; telecontrol, remote, infrared control.	0,11
Group 5	Technological factors	Rear sights; roof management; speed; lava length; drilling; meeting angles; direction of faces; passport.	0.09

man-made hazards and risk factors at a given facility, and determination of their specific weights. The final stage is an assessment and forecast of the risks of emergency situations and damage from them. The result of the research is the development of measures for the safe conduct of cleaning work, the main task which choose the direction of lava movement depending on the values of the horizontal components of tectonic stresses and their trajectories.

In professional risk assessments, risk typically combines the likelihood of an event occurring with the impact it would produce, as well as the circumstances surrounding the occurrence of that event.

Assessment and forecast of risks of emergency situations and damage from them as the final stage of the algorithm for operational forecasting of the location of emergency situations is carried out using a specially developed methodology.

$$\lambda = \sum_{i=1}^{7} fN, \tag{1}$$

where λ is the average expected number of accidents (frequency, risk), accidents/million tons per year; f is probability of risk factor occurrence (specific gravity) according to mine data (figure 1,

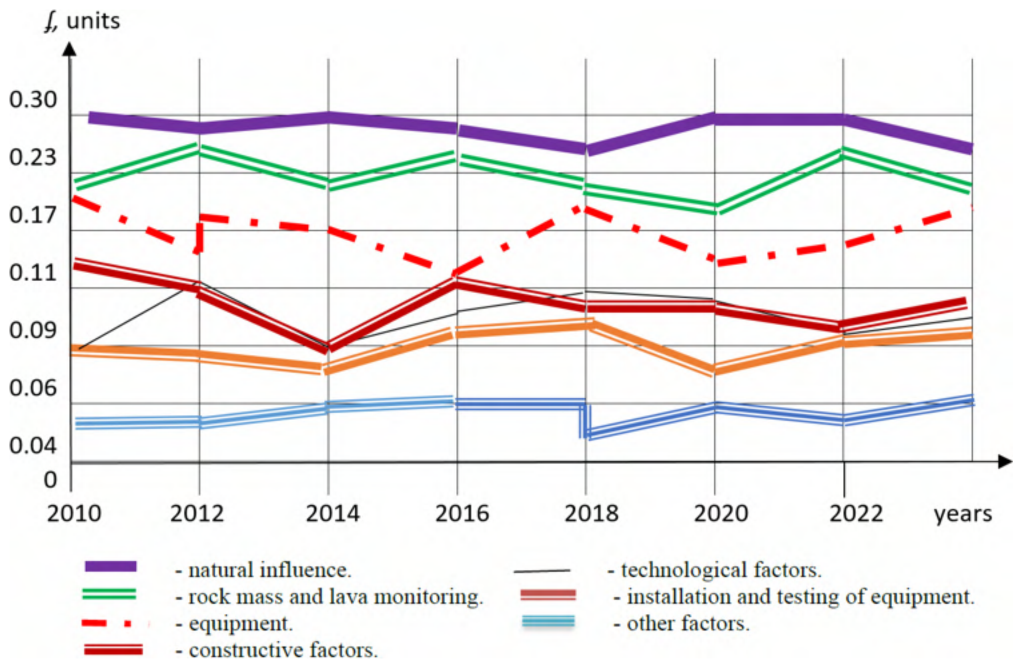

Figure 1. Dynamics of man-made hazards in mine working faces.

table 1), units; N is accident statistics, number of pieces/million tons per year.

When calculating the average expected number of accidents data should be used retrospective analysis of man-made hazards and accident rates injuries at this mine. Further, for clarity, this method presents results of calculations based on data from the coal industry as a whole (table 2).

Table 2. Average expected number of accidents during an emergency.

Emergency situations from an accident	Quantity, N pieces/million tons year	Group	Factor share, f, units	Frequency, λ accidents/million tons per year
1 Violation of the pelegas regime, spinning, heaving	350	1	0.3	35
2 Blowouts	30	2	0.2	6.0
3 Collapse	10	3	0.2	2.0
4 Rock bumps	5	1	0.3	1.5
5 Explosions of methane, dust	2	1	0.3	0.6
6 Rock pressure, disturbances, flooding, pulp breakthroughs	8	5	0.1	0.8
7 Fires	1	1	0.3	0.3
Sum, Σ				46.2

Calculation of the expected risk of technical downtime accidents were carried out according to the formula obtained from formula 1.

$$R_d = \lambda \sum_{k=1}^{2} \sum_{i=1}^{7} f_{1k} T_{1k}, \tag{2}$$

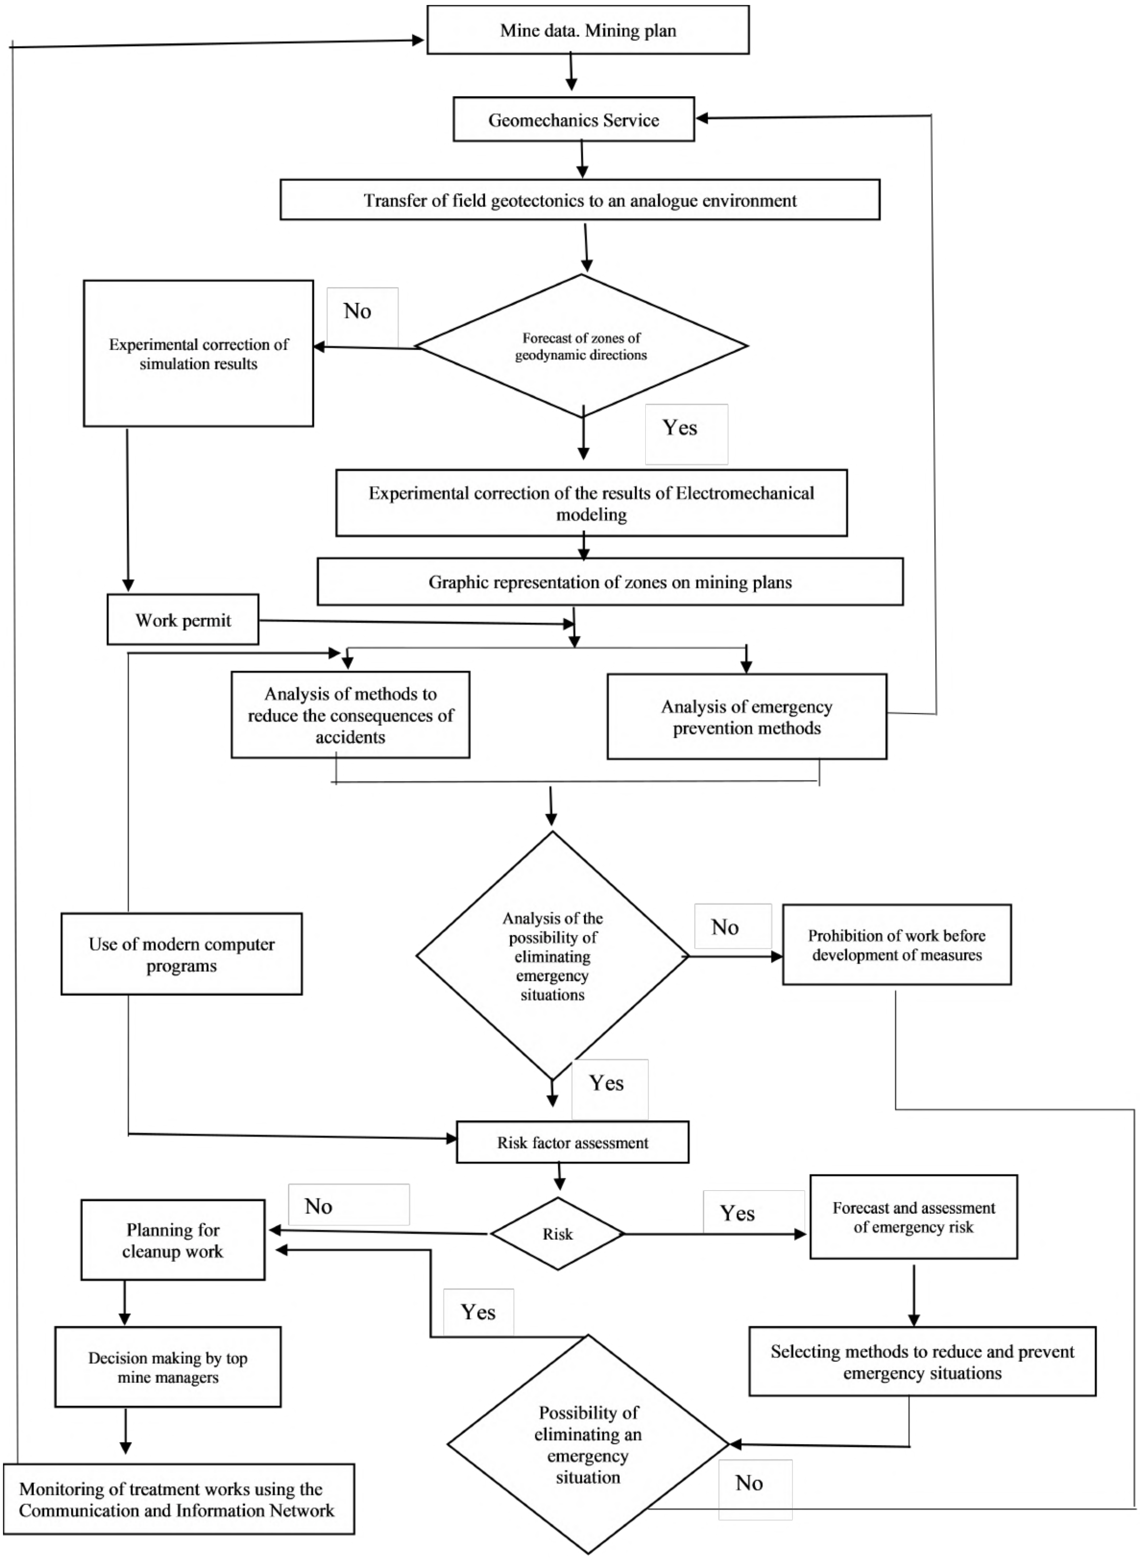

Figure 2. Scheme of the algorithm for operational forecasting of the location of emergency situations.

where R_d is the expected risk of downtime, av./million tons per year; λ (frequency) or accident risk for a given mine (formula 1); f_{1k} is share of downtime or external environmental factors, as well as from stoppages during rescue operations, units; T_{1k} is stop time during rescue operations, days.

The algorithm for calculating accidents during downtime of a mechanized longwall in coal mines is presented in figure 3.

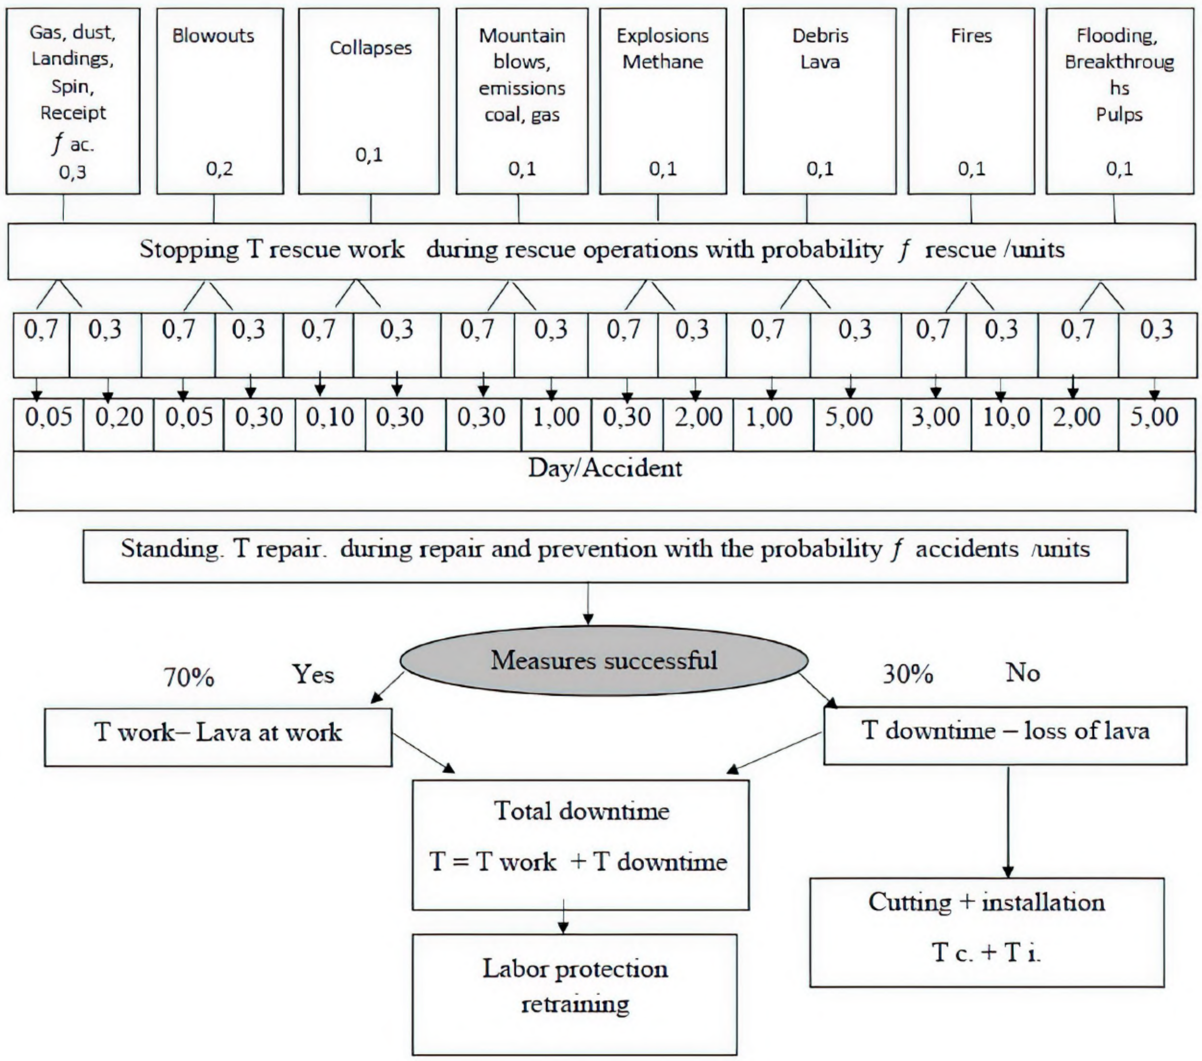

Figure 3. Downtime during emergencies with probability f accidents/units; T rescue work – time during rescue operations, day; T repair – time for repair and prevention, days; T work – operating time of the lava, days; T downtime – lava downtime, days; $Tc.$, $Ti.$ – time of cutting and installation of lava, days; T – total downtime, days.

By transforming formula 1, we calculate the risk of death injuries during coal seam mining man/longwall year).

$$R_f = \sum_{i=1}^{7} fN_s, \tag{3}$$

where R_f – risk of fatal injuries, person/year; f – share occurrence of a negative event, units;

N_s – statistics of fatal injuries for a given mine, person/million tons per year.

Safety conditions for working in the longwall

$$R_a \leqslant R_f, \tag{4}$$

where R_a and R_f are, respectively, the actual and permissible risk levels of emergency situations in the event of accidents.

Damage from the implementation of negative events (calculated damage)

$$D_c = \sum R_f, \tag{5}$$

where is D_c the damage caused to the mine by fatally injured people, c.u./person victims; R_f – the risk of fatally injured, person/lava per year.

The level of risk of an accident at the mining site, taking into account the downtime of the longwall from emergency situations, based on retrospective analysis of accident rates at coal mines is

$$R_a = \lambda T, \tag{6}$$

where R_a – risk level of longwall downtime due to accidents, day/longwall year; λ – average expected number of accidents (frequency), accidents/million tons per year; T – longwall downtime due to accidents, days/year.

Research has made it possible to create a cost chart for monitoring and measures to reduce risk factors in working faces of coal mines (figure 4).

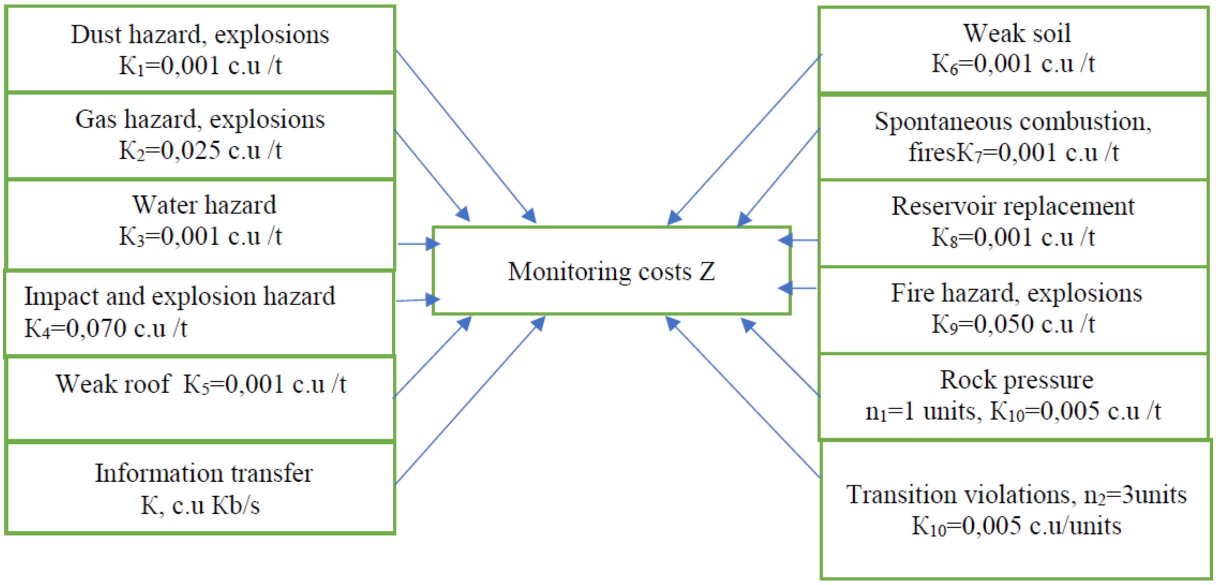

Figure 4. Scheme of costs for monitoring and measures to reduce risk factors coefficients $K_1 - K_9$ specific costs per ton of coal, $K_{10} - K_{11}$ specific costs to overcome negative factors, c.u/units.

Conditions for the economic efficiency of the project and the costs of monitoring and activities in the longwall for the conditions of this mine

$$Z = (K_1 + ... + K_9 + K_{10}n_1 + K_{11}n_2)P, \tag{7}$$

where Z is the cost of monitoring and safe measures, c.u.; $K_1 - -K_9$ specific cost coefficients per ton of coal, c.u./t; $K_{10} - -K_{11}$ specific cost coefficients to overcome negative factors, c.u./pcs.; $n_1 - -n_2$ – units of risk factors; P – load on lava per year.

Preventing man-made emergencies in the working faces of coal mines, increasing production efficiency, safe mining operations and, as a consequence, minimizing occupational injuries depend on the development, improvement and implementation of integrated occupational safety management systems [14, 15]. In order to systematically achieve a high level and constantly use the potential of modernization, the future implementation of the concept of the occupational safety and health management system, it is necessary to use the developed algorithm for operational forecasting of the location of emergency situations. In order to more effectively manage hazardous mine processes, significantly reduce occupational injuries and improve occupational safety, as the experience of the leading countries of the world shows, it is necessary to involve independent contracting commercial organizations that have licenses to carry out specialized mining operations, such as ventilation, degassing, control of dust and gas conditions, hydro, gas, geodynamic phenomena, excavation and cleaning work [16, 17]. A radical measure to prevent man-made emergency situations is the choice by the geomechanics service of the direction of movement of cleaning work relative to the trajectories of the horizontal components of tectonic stresses based on a forecasting algorithm emergency situations. Thus, using the developed algorithm for operational forecasting, data from mathematical modeling of the mining and geological conditions of the mine, as well as the specific weights of risk factors, it is possible to forecast, monitor and assess man-made hazards, risks of emergency situations, their dynamics and consequences, as well as assess damage from them.

3. Conclusions

The main conclusions are as follows:

1. Conducted studies of natural and man-made hazards, basic patterns, reasons for the manifestation of hazardous factors in the working faces of coal mines made it possible to identify seven groups of risk factors, such as natural exposure, rock mass and longwall monitoring; equipment, design factors; technological factors, installation and testing of equipment, other factors.
2. Groups of risk factors are ranked in accordance with the specific weight of influence on the occurrence of man-made emergency situations.
3. An algorithm has been developed for the mine service to quickly predict the location of man-made emergency situations, which includes the method of electromechanical analogy and a methodology for predicting and assessing the risks of accidents in the working faces of coal mines.
4. A methodology has been developed for assessing and forecasting the risks of emergency situations, their dynamics and consequences, technical downtime, fatal injuries, loss of a mechanized complex, damage from longwall downtime in an environmental accident.
5. Based on the methodology for assessing and forecasting the risks of emergency situations, quantitative values of possible damage from the manifestation of man-made hazards during underground coal mining were obtained.
6. A set of organizational measures and recommendations has been developed to ensure the safe conduct of underground coal mining, based on the results of forecasting and monitoring of geodynamic manifestations processes that provide a reasonable choice of the direction of movement of preparatory and cleaning work, taking into account the values and vectors of the horizontal components of the stressed part of the surrounding massif.

Based on the research, the problem of developing a set of technical and organizational measures for forecasting man-made hazards, risks of occurrence and dynamics of emergency

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012039 doi:10.1088/1755-1315/1415/1/012039

situations, their consequences and assessing damage in the working faces of coal mines, which is of significant importance for the coal industry, was solved.

Abstract. Tailings ponds and sludge storage facilities do not currently meet modern standards that regulate the requirements for operational safety, reliability, stability and durability. The research considers new constructive solutions for retaining walls with increased shear resistance due to passive soil resistance. Schemes and designs of tailings dams are analyzed. A comparative analysis is carried out using recommended methods to determine the safety factor for the design slip curves. The regularities of the influence of multilayer nonlinearly deformed backfill and external loads are established and new principles for determining the horizontal pressure on the retaining wall are formulated. The development of new design solutions for retaining walls and calculation methods for determining the lateral pressure of multilayer backfill is an urgent scientific task. Consideration of the influence of a multilayer nonlinearly deformed massif under external loading allows formulating new principles for determining the horizontal pressure on the retaining wall.

1. Introduction

Accumulation of a significant amount of industrial waste is associated with the development of the mining and metallurgical industry in Kryvyi Rih. The volumes and areas of production sludge and concentration tailings have grown considerably over the long term of operation. This negatively affects the state of technological and environmental safety and worsens the environmental situation in the adjacent areas [1–5].

Tailings ponds and sludge storage facilities do not currently meet modern standards that regulate the requirements for operational safety, reliability, stability and durability as they were designed in the last century [6, 7].

Application of retaining walls is proposed to prevent or avoid the negative engineering conditions of dams and embankments.

In the practice of designing retaining walls, no engineering method has been developed that takes into account the multilayer nature of the foundation in the presence of surface loads. The existing methods of H.K. Klein and other authors cannot be used because each layer of heterogeneous backfill, when taking into account the weight of the soil, has its own most unfavourable slope angle of the sliding planes, and the patterns of pressure distribution in the massif caused by different types of payloads have not yet been found. Therefore, even the simplest superposition method, which allows summarizing the pressure caused by the soil and the loads on the surface, remains technically unfeasible for multilayer soil.

Current engineering practice assumes that loads outside the traditional prism of failure do not affect the retaining wall, but this is not true and can lead to accidents.

The development of new design solutions for retaining walls and calculation methods for determining the lateral pressure of multilayer backfill is an urgent scientific task.

2. Research objectives

The aim of the research is to ensure the stability of tailings dams by using the proposed prefabricated retaining walls with increased shear resistance during the multilayer backfill build-up and operation of the structure.

To achieve this, the following tasks should be solved:

- to conduct an analytical review of the schemes and designs of tailings dams;
- to conduct a comparative analysis using the recommended methods to determine the safety factor for the calculated sliding curves;
- to develop a new design of the retaining wall to ensure the stability of the enclosing dams;
- to formulate new principles for determining the horizontal pressure on the retaining wall, considering the multilayer backfill and the load on the surface.

3. Results

In recent years, significant experience has been gained in the operation of storage facilities and the construction of dams and embankments made of waste and overburden.

Any type of storage capacity, except for pit and basin ones, requires the construction of enclosing dams or embankments that are washed from waste materials or filled with overburden or local soils. Depending on the technical conditions, enclosing dams or embankments can be built to their full height at once or in stages.

All existing storage facilities are divided into two types depending on the type of structures:

- dammed (filling) facilities, in which enclosing structures are erected at once to the full height or in stages;
- gradual construction storage facilities, in which a primary dam of low height is first constructed to arrange backwash, and then the storage facility is increased in height by gradually constructing secondary dams;
- damless facilities, which exclude the construction of both the embankment and the primary dam.

Depending on the terrain, the following types of storage facilities are distinguished:

- ravine dams located in ravines or gullies blocked by a dam;
- plain facilities arranged on flat ground and dammed around the entire perimeter. The operational advantage of a plain storage facility is that there is no need to discharge natural runoff and build expensive spillway structures for this purpose;
- ravine and plain facilities built on plains crossed by ravines, which are blocked by a dam, and the plain is dammed;
- floodplain facilities located on river floodplains and dammed on two or three sides, depending on the terrain;
- slope dams arranged in areas and enclosed by dams on three sides and the slope itself on the fourth;

- pit storage facilities located in dead pits, and waste can be stored without building a dam;
- basin storage facilities located in basins, where waste can be stored without a dam or a low-height dam is required.

The type of enclosing dams for the storage facility is determined depending on the availability of certain soils in the immediate construction area, the construction method, engineering, geological and hydrological conditions of dam foundations, and the capacity of the concentration plant at the mining and concentration works.

The same soils can be used to construct enclosing dams as for the construction of water retention dams and embankments, as well as waste discharged by concentration plants.

There are two ways to fill a storage facility: from the dam or the embankment to the banks and from the bank to the dam or embankment, and in the case of a plain storage facility, the dam is filled by pools. Three methods of waste inwash into in dams and embankments are recommended – trestle, zenithal and trestleless.

To construct dams and embankments, overburden and waste from concentration plants, as well as various local construction materials should be used as much as possible, specifically sand, clay soils, crushed stone, gravel, stone, etc. Soils for dam construction should meet the requirements of the standard for the design of dams made of soil materials [8].

The Mining and Concentration Plant ArcelorMittal Kryvyi Rih is an operating iron ore mining and concentration facility located in the southern part of Kryvyi Rih.

Tailings are stored alternately in Obiednane and Myroliubivka tailings ponds, which are located to the south and southeast of the central industrial site, respectively.

The operation of Myroliubivka tailings pond with a build-up layer up to the level of the 135 m and above is distinguished by an alternating block system of construction and pool washing.

First of all, the cells of the southern block (№ 6, 7-8, 9-10, and 11) are built and washed out. The northern block includes pools 1-2, 3-4, and 5. These pools are built and washed out in the second turn, and the duration of the construction of the northern block of pools is determined by the time of washing out the southern block of pools.

The Additional Compartment pool is also washed out, but its washing out period does not depend on the washing out of other blocks.

The main focus of the inspection was on the most hazardous area of the tailings pond, namely the area between S38 and S41. It required reconstruction as a result of lost stability, negligent operation and increased moisture of soils.

The design of the general tailings dam is a combined one, consisting of embanked secondary belt dams and an "washed in retaining prism" made of tailings.

The Myrolyubivka tailings pond is classified as a capital class 1 facility in terms of its capacity, overall height and degree of responsibility.

Structurally, Myroliubivka tailings facility currently consists of a primary loam dam from the crest level of 102.5 m and secondary dams are being built up at 108.5 m, 115.0 m, 120.0 m, 125.0 m, 130.0 m and 135.0 m levels. The entire perimeter of the tailings pond was previously filled with downstream surcharge: for the most part the tailing pond up to the level of 103.0 m, in the vicinity of spillway 3 – up to the level of 111.0 m.

The primary dam is constructed of loam with a retaining prism and rock overburden support. At 108.5m, 115.0 m and 120.0 m, the dams are structurally a rock prism with a tailings face. Modern man-made (rock-fill and hydraulic) formations, namely waste dumps, raise of dams, roads, sludge in tailings ponds, etc. play a significant role in the geological structure of the area. The thickness of these formations is often measured in tens of meters.

Myroliubivka tailings pond is located on Velyka Krokva gully, its slopes and adjacent areas. Velyka Krokva gully flows into Hrushevata gully.

The area around tailings ponds is built up with technological facilities and communications. Temporary man-made (rock-fill and hydraulic) formations, such as waste dumps, walls of embankments and dams, roads, sludge in tailings ponds, etc., play a significant role in the geological structure of the area. These formations are often tens of meters high.

Beneath the man-made formations in the tailings pond area under investigation are Quaternary accumulations represented by alluvial-deluvial loams, less often clays (containing organic matter), a loess-like thickness of yellow-brown and pale sandy loams, two levels of dark brown (slightly humus), red-brown loams and clays in the gullies.

The thickness of Quaternary accumulations is highly variable and reaches 20.0-23.0 m in some places. These formations are underlain by Neogene sediments of the Pontic and Sarmatian levels. Below are the Paleogene deposits, which are based on weathered crystalline rocks of the Paleozoic-Cenozoic period.

The depth of groundwaters and Quaternary sediments occurence varies widely from 0.5-1.0 m to 10-15 m. In the tailings ponds, these groundwaters are of a pressure nature. In some places, the pressure reaches tens of meters.

The waters are highly mineralized and hard, ranging from slightly aggressive to highly aggressive towards concrete.

To control the quality of the washed in tailings, the Geotechnical Control Service (GCS) took 185 samples in 23 boreholes (figure 1) on the beaches at the dike at the 140.0 m level. The monitoring time of the control and measuring equipment (CME):

- at the dam crest elevation of 140 m, 12 cycles were performed between January and December;
- at the dam crest elevation of 135 m, 1 cycle was conducted in August;
- at the 130-meter crest elevation ("Additional Compartment"), 7 cycles were conducted between January and August;
- at the 130-meter dam crest elevation, 1 cycle was conducted in September;
- at the 125-meter dam crest elevation, 1 cycle was conducted in October;
- at the 120-meter crest elevation, 1 cycle was conducted in October;
- at the 115-meter crest elevation, 1 cycle was conducted in October.

The laboratory studies determine granulometric composition of tailings.

Based on the results of CME instrumental inspections and a comparison with the previous year's results, we can conclude that there is a uniform increase in subsidence. This is due to intensive beach erosion and active construction of 140.0 m dikes.

Along the perimeter of the tailings pond, 14 CME dam site are installed on the dike from the at the crest level of 140.0 m, and 6 CME sites – in the area of the Additional Compartment at 130.0 m. Based on the results of the measurements, graphs of subsidence are built (figure 2, figure 3, figure 4, figure 5).

To monitor the depression curve, water levels are measured quarterly in piezometers (figure 6) installed on the dams at 115.0 m, 120.0 m, 125.0 m, 130.0 m and 135.0 m crest levels.

A system of drainage devices is installed to improve the reliability of the dike operation to reduce the level of the depression curve, prevent its release onto the downstream slopes and avoid pollution of surface and groundwater.

Calculations aim to assess the tailings pond condition, ensure regulatory stability during the increase of the enclosing dams to the 140.0 m level of the tailings pond and propose additional measures to ensure the required reliability during operation.

The reliability of a storage facility is understood as a complex property that consists in its ability to perform the functions of a waste storage tank under specified operational, structural, and environmental safety indicators during the estimated period of time.

Strength and stability of modern hydraulic facilities are assessed by the limit state method, according to which all the initial design values, which are random in nature, are represented by

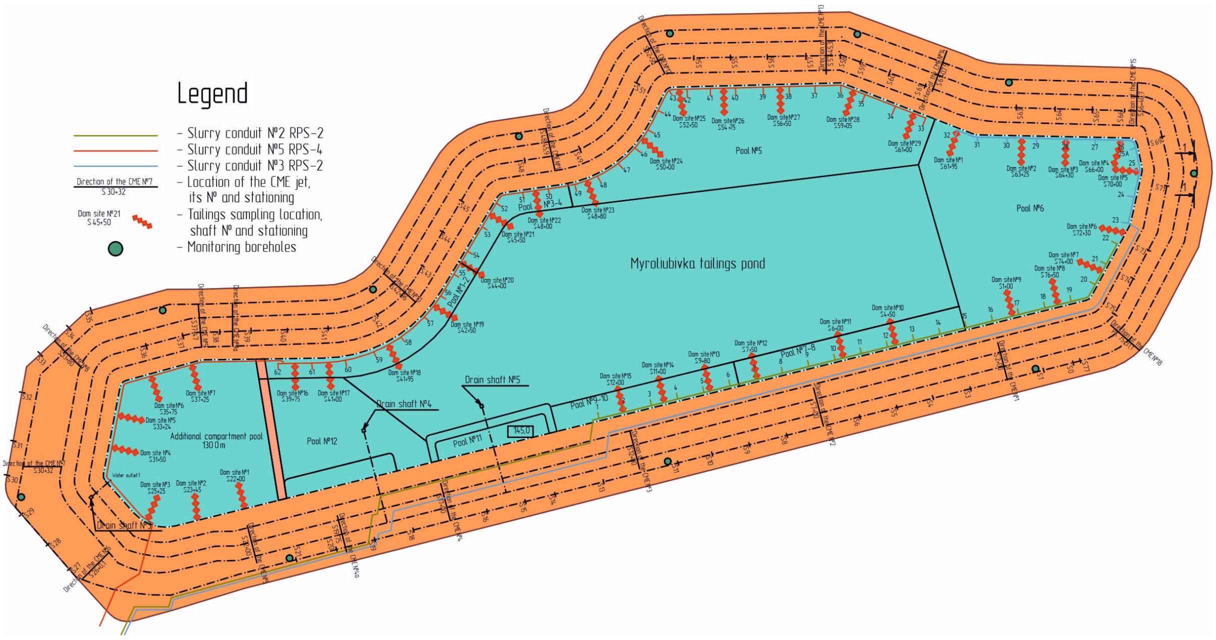

Figure 1. Tailings sampling plan for Myroliubivka tailings storage facility.

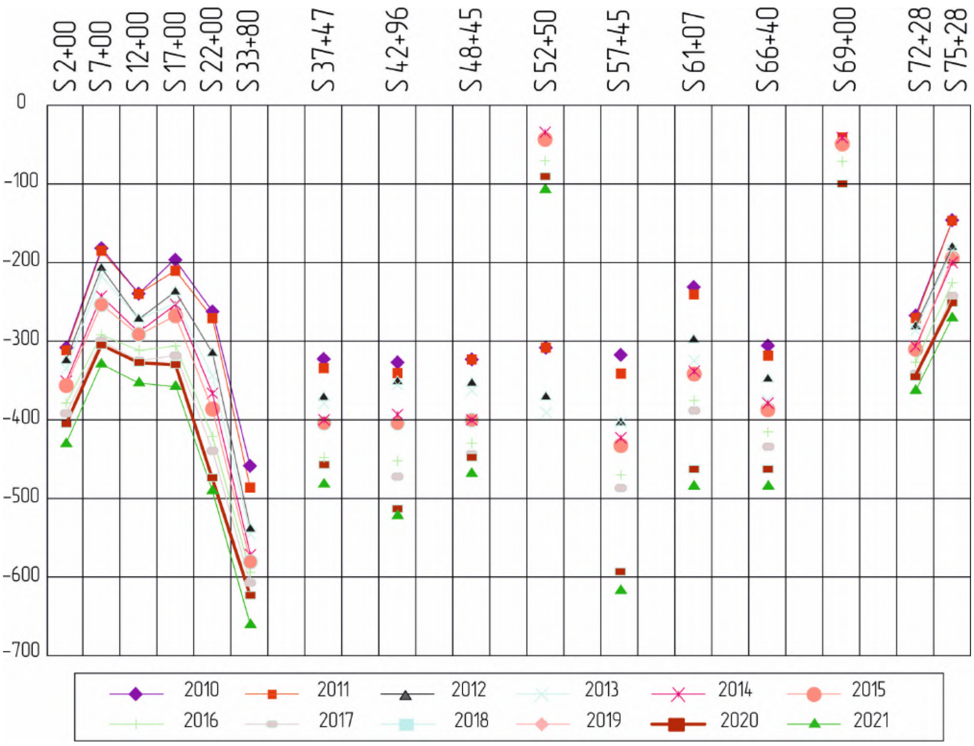

Figure 2. Subsidence diagram CME by the 120 m dike overflow levels.

some deterministic values, and the impact of this variability on structure reliability is taken into account by relevant coefficients regulated by the standards.

In the case of storage facilities, it is very difficult to consider all the randomness and uncertainties using deterministic coefficients.

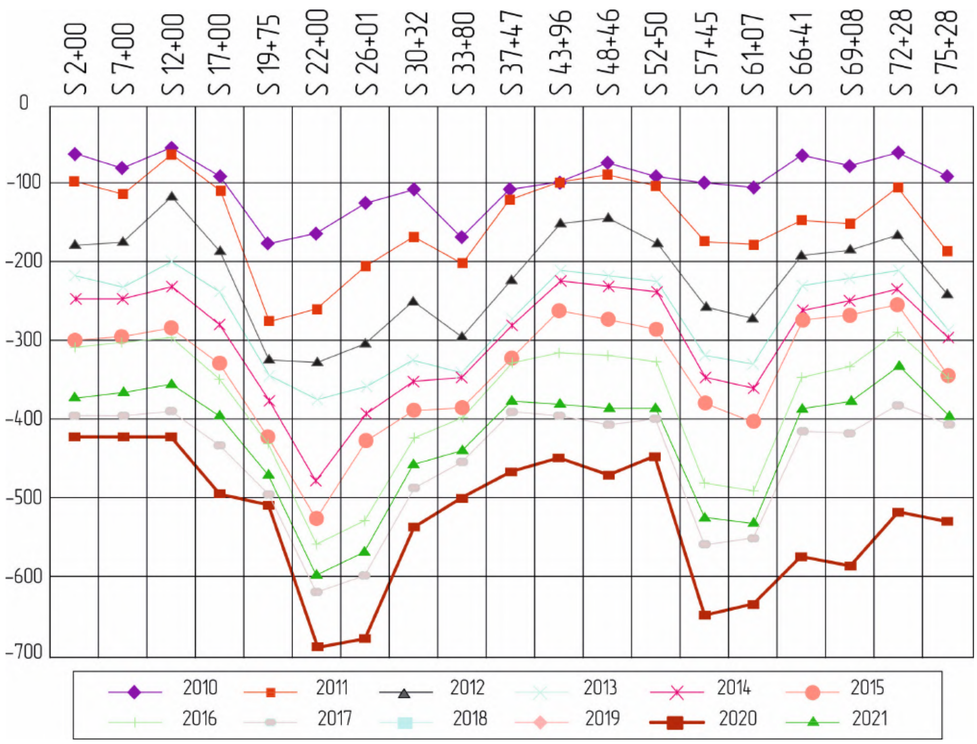

Figure 3. Subsidence diagram CME by the 125 m dike overflow levels.

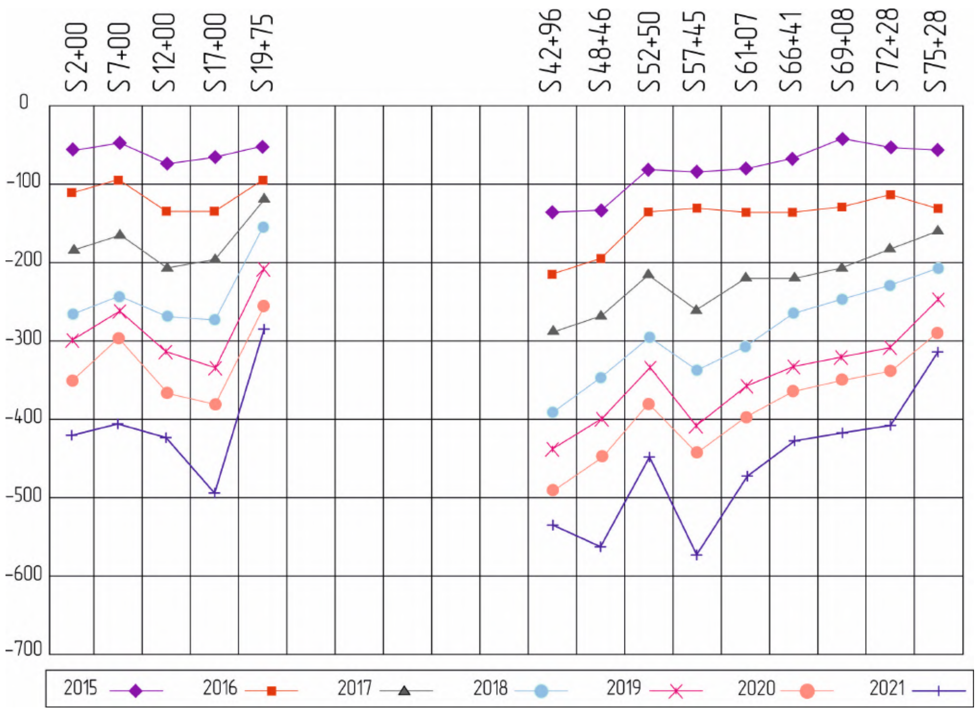

Figure 4. Subsidence diagram CME by the 130 m dike overflow levels.

As a rule, pressure structures of storage facilities are embankments of a complex layered structure, the soils and materials of which are characterised by significant variability of

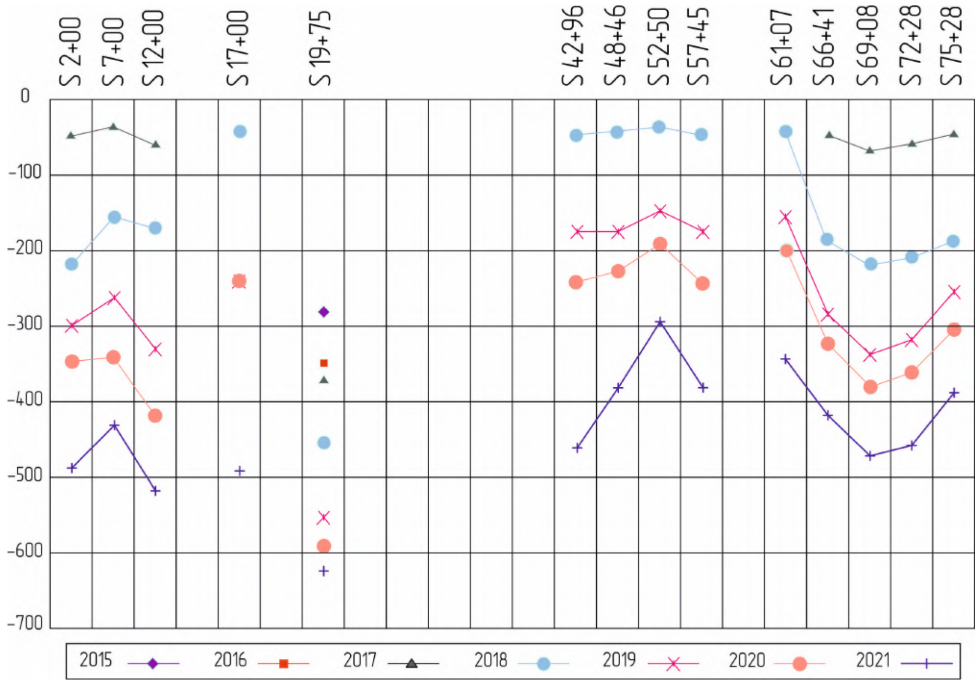

Figure 5. Subsidence diagram CME by the 135 m dike overflow levels.

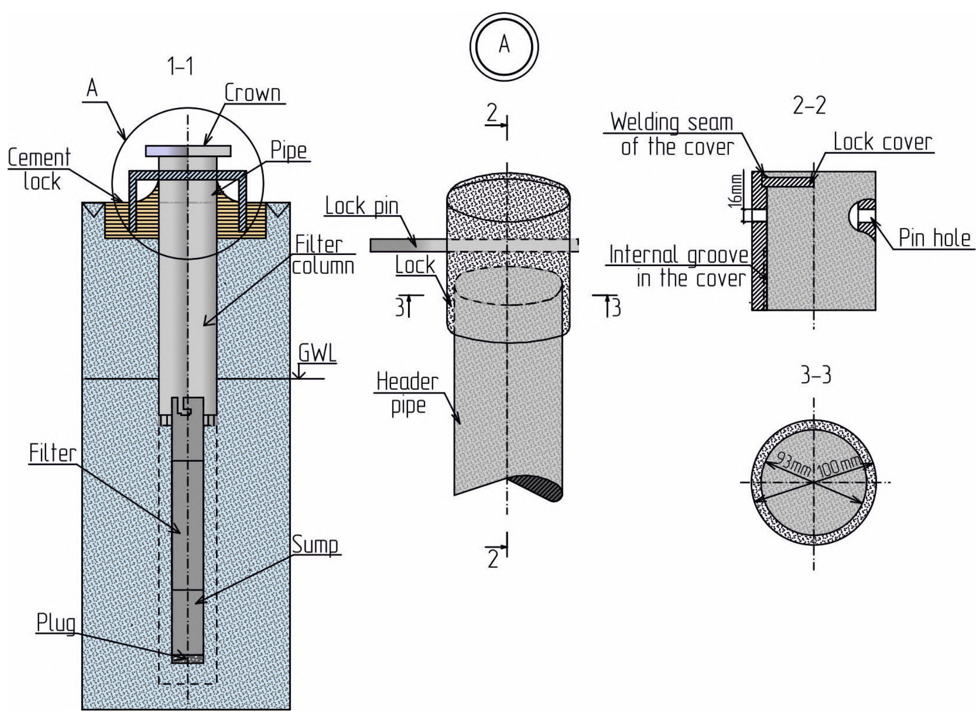

Figure 6. Design of observation boreholes.

characteristics, including time variability. In addition, the specificity of the storage facility is a change in their main technological parameters (elevation, impact area, etc.) during their service life, which, taking into account other factors and features mentioned above, introduces significant uncertainty into each of the indicators characterising the facilities' condition.

Considering that the designed tailings pond is a hydraulic structure, the material for which is the waste (tailings) stored in it, the reliability of the structure and the possibility of emergency situations depend on the quality of tailings alluviation and compliance with the specified design parameters (both physical and technological).

The following design case was considered for the stability of the downstream slope of Myroliubivka tailings pond (for all cross-sections): no water in the downstream, normal retaining level (NRL) in the upstream is assumed to be at its maximum position, and the dam body is considered to have installed filtration for the maximum design water level.

The following design cases are considered in determining the stability of the hydraulic dam in the vicinity of spillway 4:

- for the downstream slope – the main load combination; a dam with the 135.0 m crest, normal retaining level in the upstream, and filtration installed in the dam body;
- for the upstream slope, the construction period is designed: the main protection dam and the dams of the pools with the 135.0 m crest (at the end of washing out the last layer of the pools). The water level of the clarification pond (in the pool) is at 134.3m, the level of sludging the upstream slope with tailings is 133.75m), and filtration is installed in the dam body. At the base of the hydraulic dam, the tailings pond is washed out up to 121.6 m; the water level is at 122.5 m.

In determining the dam stability in the vicinity of spillway structure 3, the following design case is considered. As for the main load combination, the dam has a 125.0 m crest, a normal retaining level (123.5 m) in the upstream, and filtration in the dam body.

The dam stability is calculated by two programmes: the computer aided design system for ground hydraulic structures and the KZU86K programme developed by specialists of the VIOGEM Institute (the All-Russian Research Institute for Mineral Deposits Drainage, Protection of Engineering Structures from Flooding, Special Mining Works, Geomechanics, Geophysics, Hydrotechnics, Geology and Mine Surveying).

The computer-aided design system for soil hydraulic structures (CAD SHS) is designed to solve a number of problems in designing dams, dikes, upland ditches, sludge ponds, tailings dams and other structures [8].

The Terzaghi method provides lower safety factors for gentle slopes (1:2 or more), with a difference of 10...20%. The averaged slopes of Myrolubivka tailings pond are much gentler.

The desire to take into account all equilibrium conditions in the shear scheme leads to the emergence of such methods as the Mozhevytynov method (method of inclined interaction forces) and the finite element method (FEM).

The Terzaghi-Chuhaiev calculation method gives results intermediate between the Terzaghi and Chuhaiev methods. In accordance with the regulatory literature, the methods adopted in this study are allowed to be used in calculations.

All the described calculation methods refer to the case of a plane problem, i.e. it is assumed that no resistance forces occur along the lateral parts of a single slip or retaining prism along the front of the structure. In reality, slope failures are usually local and have a closed contour in plan view. Taking into account the spatial extent of sliding for conditions that are not variable along the length (front) of the structure leads to an increase in stability coefficients, and therefore, in these cases, solutions of the plane problem are usually used, which are included in the "stability margin".

The software allows performing stability calculations using the following methods:

- Terzaghi weight pressure method;
- Mozhevytynov method of inclined interaction forces, recommended by the standard;
- FEM (the finite element method).

The programme also allows performing filtration calculations necessary for calculating slope stability.

Filtration calculations determine the following parameters of the filtration flow:

- position of the filtration flow surface (depression surface);
- filtration water flow through the body of the structure and its foundation;
- pressure gradients of the filtration flow in the body and base of the structure at the boundaries of soils and media.

Filtration calculations are performed in accordance with the following regulatory documents.

Filtration calculations are performed using the FEM method based on the methodological recommendations for calculating the safety factor of slopes with a circular-cylindrical sliding surface using the KZU86K programme.

The programme allows defining a set of design slip curves (with safety factors) in a given slope range. This makes it possible to define both "general" and "local" slip curves.

Tasks solved by the programme include:

- determining the safety factor of the slope of the soil massif assuming arbitrary and circular-cylindrical sliding surfaces under static and seismic conditions, taking into account possible concentrated loads and pore pressure;
- determining all force characteristics for the selected sliding section (active and reactive forces on the covering footwall, column weights, distribution of filtration forces, etc.;
- solving the inverse problem (at a given stability factor of 1, it is determined by the strength of the slope soil property).

To obtain the desired result, a calculation algorithm is developed:

- select design materials for the construction of design diameters;
- draw geological sections on cross-sections;
- analyse the results of geological data and selected design characteristics;
- encode initial data for calculation for all cross-sections and interpret the geological data;
- enter the information into the calculation software;
- perform primary calculations using 4 methods (ITU, Mozhevytynov, Terzaghi, and Terzaghi-Chuhaiev) and 2 programs (CAD SHS, KZU86K) for all the dam sites (for the "general" curve and "local" curves);
- select the contours of additional loading of the downstream slope with intermediate calculations;
- analyse the results obtained.

The results of stability calculations are expressed as slip curves on the cross sections of Station (S) 39+00 (upstream and downstream slope) (figure 7, figure 8).

The results of calculations of the stability of the downstream dam slopes, with the selection of minimum safety factors determined for the "general" curve, are shown on the design sections.

The minimum safety factors of the "general"/"local" curve for the main combination of loads in the calculation of the stability of the lower slopes of dams are as follows:

- for S 8+50 according to the methodology: Mozhevytynova (1.501 / 1.568), FEM (1.522 / 1.423), Terzaghi (1.417 / 1.45), Terzaghi-Chuhaieva (1.53 / 1.58);
- for S 19+00 (upper) by methods: Mozhevytynova (1.638 / –), FEM (1.474 / –), Terzaghi (1.231 / –), Terzaghi-Chuhaieva (– / –);

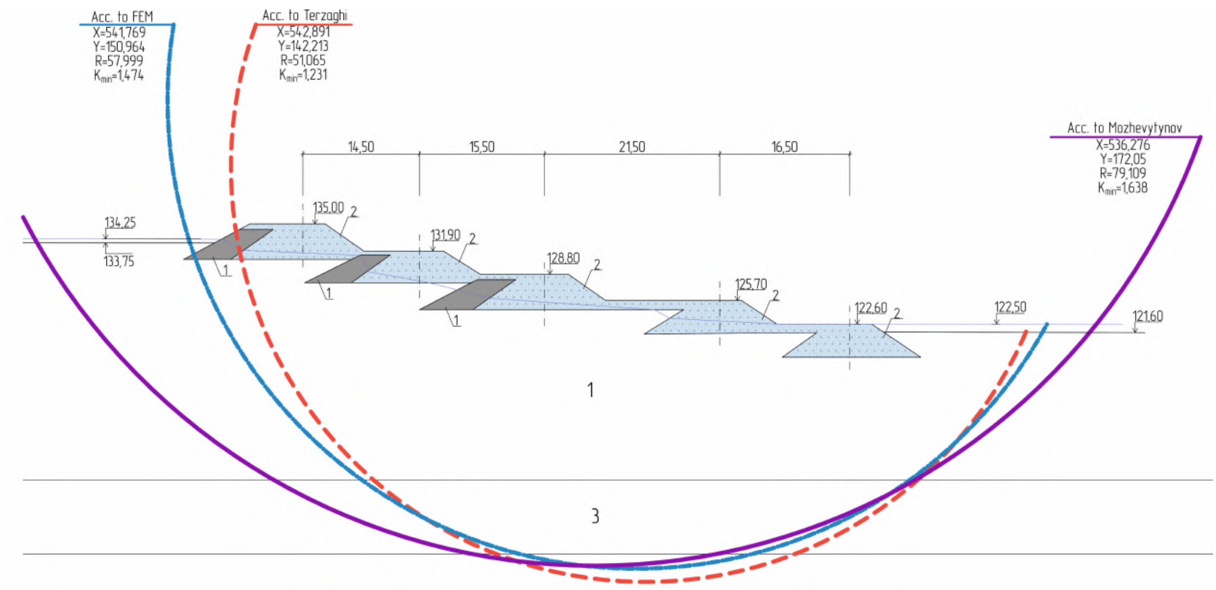

Figure 7. Results of stability calculations (upstream slope of the S 39+00 cross section): 1 – silt washed-in tailings; 2 – rocky overburden; 3 – loam washed-in tailings.

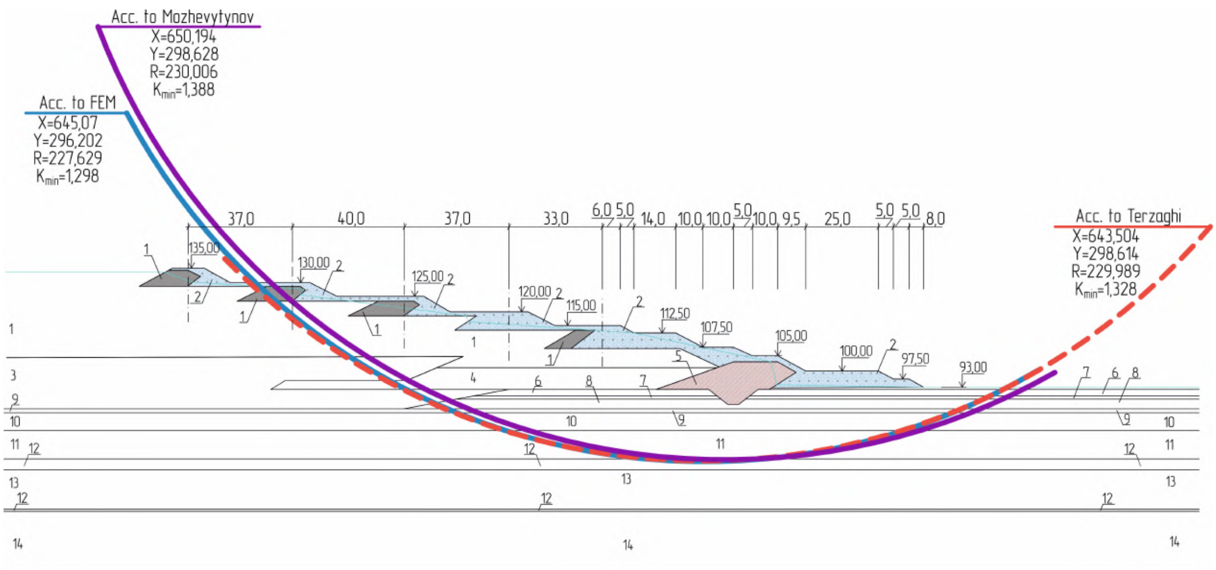

Figure 8. Results of stability calculations (downstream slope of the S 39+00 cross section): 1 – silt washed-in tailings; 2 – rocky overburden; 3 – loam washed-in tailings; 4 – small washed-in tailings; 5 – filled soil – clay in the body; 6 – loess, heavy, silt, red-brown loam; 7 – hidden soil, silt heavy loam; 8 – loess, heavy, silt, yellow-brown loam; 9 – hidden soil, heavy loam; 10 – heavy, red-brown loam; 11 – light, silt, ocher-red clay; 12 – heavy, silt, green-gray clay; 13 – fine sand with a layer of loamy sand and loam; 14 – light, green-gray, light gray clay.

- for S 19+00 (lower) by methods: Mozhevytynova (1.388 / –), FEM (1.298 / –), Terzaghi (1.328 / –), Terzaghi-Chuhaieva (– / –);
- for S 24+25 by methods: Mozhevytynova (1.5 / 1.488), FEM (1.471 / 1.484), Terzaghi (1.437 / 1.411), Terzaghi-Chuhaieva (1.49 / 1.42);

- for S 27+50 by methods: Mozhevytynova (1.265 / 1.048), FEM (1.208 / 1.166), Terzaghi (1.143 / 1.055), Terzaghi-Chuhaieva (1.26 / 1.27);
- for S 31+00 by methods: Mozhevytynova (1.366 / 1.551), FEM (1.335 / 1.527), Terzaghi (1.313 / 1.44), Terzaghi-Chuhaieva (1.37 / 1.58);
- for S 33+80 by methods: Mozhevytynova (1.785 / 1.618), FEM (1.871 / 1.630), Terzaghi (1.722 / 1.503), Terzaghi-Chuhaieva (1.71 / 1.38);
- for S 34+60 by methods: Mozhevytynova (1.637 / 1.003), FEM (1.601 / 0.98), Terzaghi (1.576 / 0.888), Terzaghi-Chuhaieva (1.66 / 1.08);
- for S 42+96.6 by methods: Mozhevytynova (1.553 / 1.444), FEM (1.494 / 1.561), Terzaghi (1.501 / 1.53), Terzaghi-Chuhaieva (1.52 / 1.51);
- for S 51+60 by methods: Mozhevytynova (1.742 / 1.218), FEM (1.726 / 1.25), Terzaghi (1.667 / 1.08), Terzaghi-Chuhaieva (1.55 / 1.53);
- for S 55+25 by methods: Mozhevytynova (1.477 / 1.626), FEM (1.427 / 1.585), Terzaghi (1.428 / 1.487), Terzaghi-Chuhaieva (1.53 / 1.46);
- for S 61+07.5 by methods: Mozhevytynova (1.554 / 1.505), FEM (1.498 / 1.475), Terzaghi (1.462 / 1.445), Terzaghi-Chuhaieva (1.49 / 1.5);
- for S 69+02.2 by methods: Mozhevytynova (1.471 / 1.49), FEM (1.561 / 1.645), Terzaghi (1.437 / 1.433), Terzaghi-Chuhaieva (1.62 / 1.65);
- for S 72+60 by methods: Mozhevytynova (1.622 / 1.738), FEM (1.62 / 1.753), Terzaghi (1.565 / 1.582), Terzaghi-Chuhaieva (1.62 / 1.52).

In calculations of the stability of the downstream dam slopes of dams, the position of the depression curve (the position of the filtration flow surface) is taken on the basis of CAD SHS-based filtration calculations.

A comparative analysis of the calculation results of the stability of the downstream slopes shows comparatively close values of the obtained coefficients and the correctness of the choice of calculation methods as the most commonly used in practice.

Analysis of the actual condition of hydraulic structures, taking into account the calculations performed, drawing the following conclusions about Myroliubivka tailings storage facility:

- The reliability of the downstream slope of the tailings dam at Myroliubivka tailings storage facility is assessed in accordance with regulatory requirements;
- Most calculated cross-sections, according to all the methods used to calculate the downstream slope, have a safety factor (both for general and local stability) that is higher than the minimum required by the standard;
- For certain cross-sections, minimum safety factors determined are less than the required standard values. For these sections, additional measures to ensure standard stability are required;
- According to the standard, Kryvyi Rih is classified as an area with a seismic intensity of 6 points. Soil conditions at Myroliubivka tailings pond are classified as category III. At the same time, the overall seismicity of the area is 6 points and it does not fall within the seismicity standard. On this basis, no seismic stability checks are performed at this stage of work.

Recommended measures include:

- All hydraulic structures of Myroliubivka tailings facility should be subjected to constant monitoring of the dam condition, compliance with design requirements for tailings allocation technology, the degree of wear of pipelines (especially those passing through dams and in the vicinity of hydraulic structures), and compliance with design water levels in the tailings facility;

- To ensure the required reliability of the tailings facility, it is proposed to construct a special type of retaining wall in the area with the lowest safety factor for the period of dam operation [9, 10].

The proposed prefabricated block-type retaining wall (figure 9, figure 10) consists of a foundation slab and a vertical element presented in the form of concrete or reinforced concrete blocks mounted on top of each other, the front face of each of them is made straight, and the back face is in the form of a structural surface of pyramids. The foundation slab of the retaining wall is equipped with piles located directly under the base of the foundation slab.

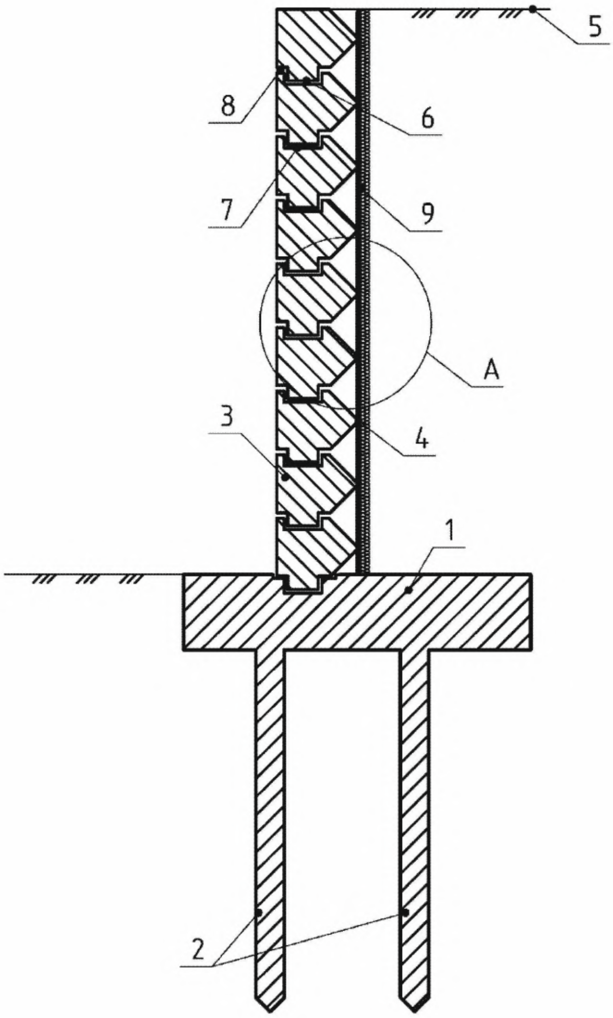

Figure 9. Prefabricated block type retaining wall: 1 – foundation slab; 2 – piles; 3 – blocks; 4 – surface in the form of pyramids; 5 – soil; 6 – spikes; 7 – groove; 8 – high-strength solution; 9 – two sheets of flexible, resilient material.

To prevent premature filling of the cavities, two flexible separating sheets of elastic and pliable material made of a biodegradable polymer are placed on the back surface of the vertical element.

The proposed prefabricated block-type retaining wall consists of a foundation slab 1 with piles 2 and a vertical element made of blocks 3 stacked one on top of the other. The vertical element includes front and back faces. The front face of blocks 3 is rectilinear, and the back face is in the form of a structural surface, which is a protruding pyramid 4 from the side of retained

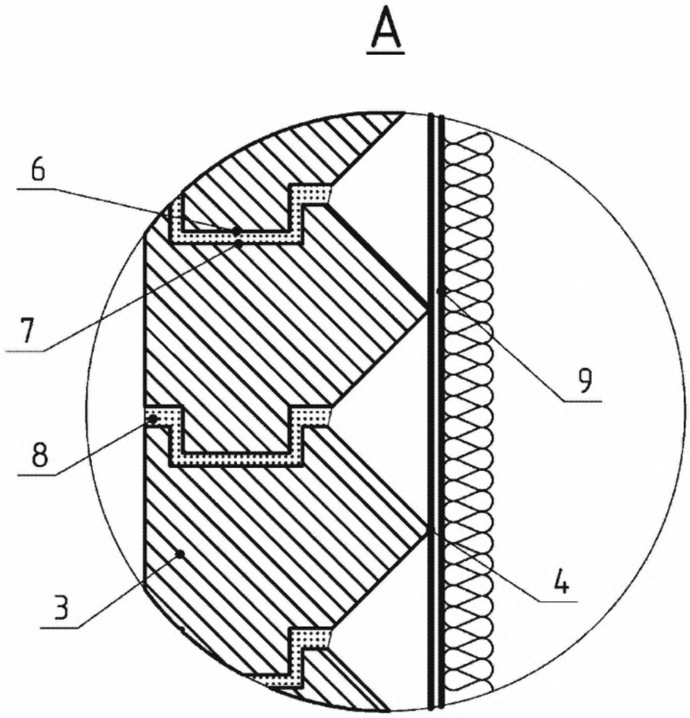

Figure 10. Node A: 3 – blocks; 4 – surface in the form of pyramids; 6 – spikes; 7 – groove; 8 – high-strength solution; 9 – two sheets of flexible, resilient material.

soil 5. The blocks are mounted one on top of the other and interconnected by spikes 6 that fit into grooves 7 on high-strength mortar 8. On the back face of the vertical element, there are two sheets of flexible, resilient material 9 made of biodegradable polymer.

To connect the vertical element consisting of blocks 3 to main slab 1, a block with a straight front face, a pyramidal back face, spike 6 on the lower surface and groove 7 on the upper surface is used. The main components of the vertical element are blocks with a straight front face, a pyramidal back face, groove 7 on the upper surface and spike 6 on the lower surface. The vertical element is completed with a block with a rectilinear front face, a pyramidal back face and spike 6 on the lower surface.

Stability of the retaining wall is ensured by piles 2, spikes 6 and grooves 7 of blocks 3. Blocks 3 can be connected with high-strength mortar 8. The surface in the form of pyramids 4 of blocks 3 in contact with soil 5 significantly reduces the horizontal pressure of soil 5, redistributing it along the height of the retaining wall. The effect increases with active shear of soil 5.

The back surface of the vertical element has two sheets of resilient material 9. Sheets 9 are arranged in two rows and uniformly compact the backfill soil, with the first sheet serving as an anti-friction coating to reduce friction forces. The sheets are made of modern materials that are completely decomposed by microorganisms under aerobic or anaerobic conditions into carbon dioxide, methane, water, biomass and inorganic compounds.

The polymer decomposition period depends on the length and structure of the polymer chain, which in turn makes it possible to select the required polymer composition to perform the tasks set throughout the entire service life of the block retaining wall. Reduction of the polymer chains leads to a loss of mechanical properties (strength, tensile strength, bending strength). Therefore, the sheets of elastic-responsive material 9 are selected as follows: the first sheet from the retaining wall is thinner, but with longer polymer chains, the second sheet is thicker, but with shorter polymer chains, so that the first sheet will perform the function of an antifriction coating for a longer time, and the second sheet will absorb and redistribute the forces from horizontal movement of the soil by decomposing faster than the first one.

This structure is able to withstand significant shear loads and forces from horizontal ground displacement for an even longer period of time, which extends its service life.

The proposed prefabricated block-type retaining wall can be used to stabilize unstable slopes, while the foundation slab, piles and blocks of the vertical element can be unified.

The block-type prefabricated retaining wall can withstand significant shear forces arising from the operation of unstable slopes, as well as horizontal ground movements during excavation.

The proposed structure can be used to stabilize unstable slopes, while the foundation slab, piles and vertical element blocks can be unified. It is highly reliable when operating in a critical situation of an unforeseen emergency increase in the shear force load. The installation of this structure will provide additional stability of the hazardous area of the tailings pond and will guarantee the reliability and operational longevity of the tailings pond (figure 11, figure 12, figure 13).

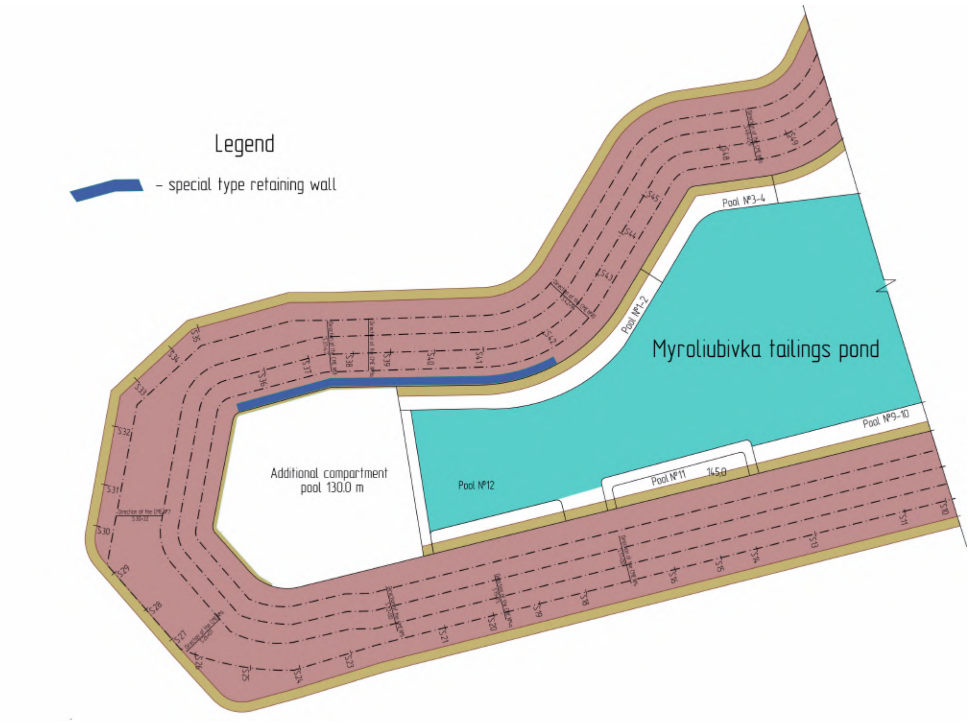

Figure 11. Retaining wall area.

The paper analyses experimental and theoretical studies of distribution of sliding planes in multilayer backfill of retaining walls in the absence and presence of different strip loads on this surface. These studies indicate that horizontal shear of the entire wall or any of its upper parts leads to the formation of a single shear plane under not only complex but also concentrated loads on multilayer backfill. Moreover, this effect does not depend on the sequence of layers with different physical and mechanical characteristics φ and γ along the backfill depth.

Adoption of a single sliding plane for each depth of the retaining wall allows presenting a calculation scheme for determining the horizontal pressure (figure 14) and formulate new principles for determining the horizontal pressure on the retaining wall, taking into account the multilayer backfill and the load on the surface in accordance with the standard [11].

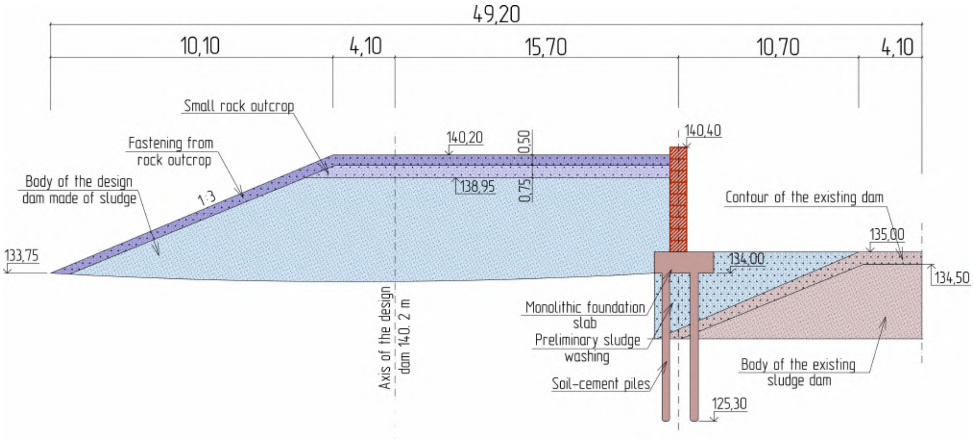

Figure 12. Installation of a prefabricated retaining wall.

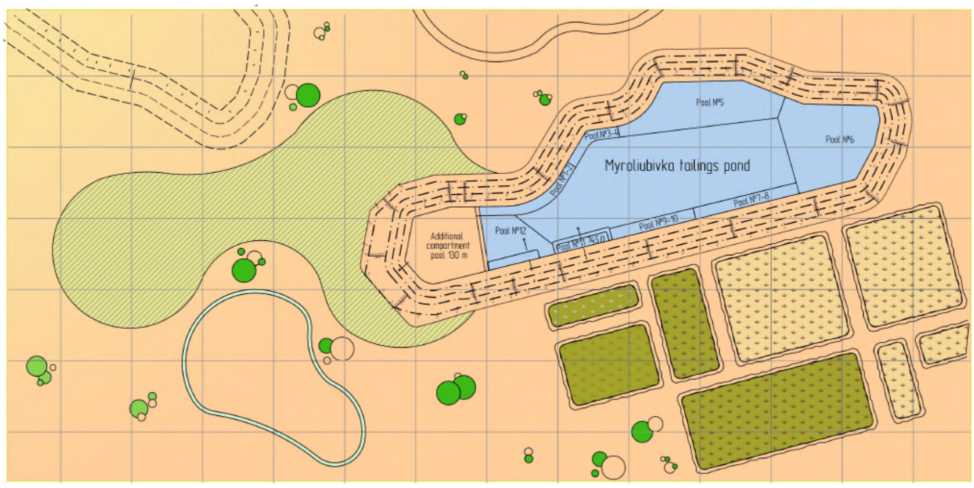

Figure 13. Flooding area in case of a potential failure.

4. Conclusions

Myroliubivka tailings pond is an engineering structure of the first category of responsibility and currently requires new approaches, as well as changes in technology to ensure its stability during long service life.

Available calculation methods based on the theory of linearly deformed media do not fully meet the operating conditions.

Therefore, consideration of the influence of a multilayer nonlinearly deformed massif under external loading allows formulating new principles for determining the horizontal pressure on the retaining wall, namely:

- the mass of sowing between the wall and the shear plane is divided into separate prisms resting within each layer hi on the collapse plane;
- the prisms are divided by vertical planes extending from the intersection of the collapse area with the boundaries of the soil layers to the backfill surface (in areas of loaded surface) or to the footwall of the local load;
- part of the distributed load located on any prism is summed with the weight of this prism, i.e. included in the value Gi;

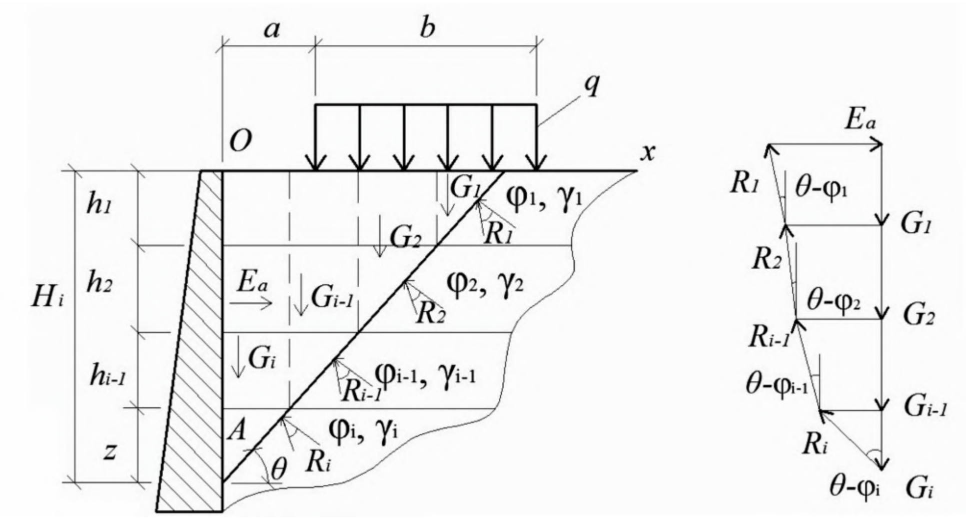

Figure 14. Design diagram of a retaining wall with multilayer backfill and surface load.

- interaction of prisms along vertical planes is not taken into account;
- each depth has its own collapse area, the position of which does not depend on the total wall depth Hmax.

Application of a special type of retaining wall allows obtaining an economic effect due to both the design solution and the extension of the service life.

The effectiveness of the existing system for protecting the aquatic environment (primarily groundwater) from pollution by the Mirolyubovskoye tailings dump in the area under consideration is estimated at 87 percent.

Abstract. The article presents the retrospective analysis of the territorial organization of the settlement of Kryvyi Rih territory on the basis of a detailed study of topographic maps of various historical periods, namely, the Map of the Polish-Lithuanian Commonwealth, the Special Map of the Western Part of the Russian Empire by F. Schubert, Three-mile military topographic map of the Russian Empire, the Maps of the Office of Military Topographers of the Red Army, the Maps of the German Army, Topo maps of the US Army and Maps of the General Staff of the USSR Armed Forces. The research is based on the authors' method of retrospective modeling of the historical settlement of the region using historical topographic maps of various time periods and their complex analysis by means of GIS. The results of the research constitute the model of the territorial organization of the settlement process in Kryvyi Rih region. The model represents the historical population resettlement in the studied region and indicates the spatiotemporal changes of the following indexes: the nature and number of settlement locations, the size of settlements, number and density of the population, the ratio of rural and urban populations, etc. The obtained cartographic materials and demographic indicators of resettlement at various times make a significant contribution to the historical and geographical research of the region.

1. Introduction

1.1. The problem statement

The multifaceted studies of geographical landscapes stipulate special attention to the retrospective research featured by spatio-temporal combinations. As Langton [1] noted, instead of simply comparing isolated systems in equilibrium, i.e. performing so-called "synchronistic analysis", researchers must be able to study processes retrospectively by "slicing successive series of synchronous images of systems" through time.

The study of landscape dynamics is extremely important for determining the anthropogenic impact on the transformation of technogenically disturbed geosystems. Kryvyi Rih constitutes a vivid example of such an anthropogenically disturbed geosystem, as for more than 130 years, it has been excessively mined and minerals (iron ores) have been processed in extremely large volumes.

Within the scope of this publication, we consider Kryvyi Rih region as a conditional territorial unit of geographic zoning, which boundaries coincide with the borders of the Kryvyi Rih natural and economic district [2].

The territorial organization models of the settlement process in a respective region reflects the experience of interaction in the human-nature system. The above-mentioned models are formed in the process of historical resettlement of the population in a certain territory and are characterized by spatio-temporal changes, such as: the totality and size of settlements, the number and density of the population, the share of the rural and urban population. Retrospective studies of the territorial organization of a settlement can reveal the cause-and-effect relations between geodemographic and anthropogenic processes, and therefore, implement a scientifically based policy of socio-economic development of the territory.

Retrospective studies are grounded on the spatial multitemporal and attributive materials to form a wide information field. Therefore, GIS technologies enable a quick and high-quality analysis of spatial and temporal changes in territories. The advert of a new type of GIS (historical-landscape) makes it now possible to visualize a clear picture of the development of territories in different historical periods. So, "cross-cutting" historical-landscape analysis explores the territory, the dynamics of its landscape and economic activity with the subsequent compilation of a number of maps, different in chronology [3].

1.2. Theoretical background

The extensive analysis of the scientific literature has established the following three research directions:

1) scientific investigations of the system of population resettlement analysis;
2) retrospective studies of regional settlement systems of individual territories;
3) historical and geographical works on the process of formation of settlements within Kryvyi Rih area.

The population resettlement system is presented in many general-theoretical and regional-practical works of Langton [1], Denysyk et al. [4], Dzhaman [5], Illiash and Tkach [6], Topchiiev [7] and Boudeville [8]. The authors mostly characterize various aspects of the functioning of territorial structures, models of spatial arrangement of settlements, resettlement and migration of the population, etc.

The retrospective studies on the regional population settlement systems [9–17] focus on identification of the features of the historical settlement of territories depending on their socio-economic development. The focal point of these publications is both various regions and different approaches to delineating the historical retrospective.

The formation of settlements within the territorial structure of Kryvyi Rih is described in a number of historical and geographical studies [18–25]. The above-mentioned works substantiate historical stages of the development of the region on the basis of archival sources, as well as present accounting and statistical materials of individual settlements.

The analysis of scientific research has established significant achievements in the study of population displacement in its historical retrospect, but also revealed certain gaps concerning such important aspects as the identification of spatio-temporal changes in the displacement of the population of Kryvyi Rih region and the anthropogenic activity impact caused by centuries-long extraction of useful fossils.

1.3. The objective of the article

The purpose of the publication is to reconstruct the anthropogenic effect on the transformation of natural landscapes by means of a retrospective analysis of the process of territorial organization of Kryvyi Rih settlement.

The primary purpose comprises three following research tasks:

1) to determine the chronological limits of the formation of settlement landscapes on historical maps of Kryvyi Rih at various times;
2) to develop a methodology for modeling the historical settlement of Kryvyi Rih territory;
3) to conduct a retrospective analysis of the settlement process of Kryvyi Rih territory using GIS.

2. Methods

2.1. Factual research material

The retrospective research admittedly uses two main sources of information which reflect the state of the territory in a certain period of time: various historical texts (primary sources and historiography) and cartographic materials of different times.

This publication uses a number of historical text materials that reflect the development of Kryvyi Rih area. However, we note that these sources provide unsystematic and episodical accounts of the settlement of the territory of the studied region and mostly without spatial visualization. The analyzed material sometimes manifest significant content contradictions, which require further determination of the validity of the presented spatio-temporal data.

Cartographic materials of the studied territory are represented by a number of historical maps created over three centuries of topographic research. The main ones are: Map of the Polish-Lithuanian Commonwealth, Special map of the Western part of the Russian Empire by F. Schubert, Three-mile military topographic map of the Russian Empire, the Maps of the Office of Military Topographers of the Red Army, the Maps of the German Army, Topo maps of the US Army and Maps of the General Staff of the USSR Armed Forces. We utilized these maps as primary tools for assessing the anthropogenic transformation of the territory, because they recorded all environmental changes.

The presented scientific research is the extension of the team study of co-authors [26], which evaluates and compares different temporal cartographic materials in view of their accuracy and reliability. In particular, different temporal topographic maps of Kryvyi Rih area are considered as an information resource for retrospective studies. We also carry out the additional research which determines the chronological intervals of correspondence of the data applied to cartographic works, and thus to select reliable cartographic material (table 1). Meanwhile, the study of historical maps of Kryvyi Rih arises a number of challenges, such as: map poor-quality depiction (crumpled and worn sheets, unclear printing, etc.); different mapping and nomenclature of maps cause variation of location of the research area in different sources (on one or several sheets); on most maps, the legend is missing or presented in a very simplified version; maps differ significantly in terms of their mathematical basis (scale, longitude, cartographic projection, length measurement system, etc.); the maps differ significantly in toponymy (for example, the modern name of the village *Sofiivka* has undergone the following changes since its foundation to the present day: *Sofievka, Sofievo-Geikivka, Sofievo, Valove*). The described difficulties significantly complicated the analysis of spatial indicators of different time cartographic works.

2.2. Research methodology

Establishing the historical process of settlement of Kryvyi Rih territory requires to determine the time of origin and location of settlements within the region, and to characterize their demographic indicators at different times (population of settlements, number of yards, etc.).

The specified methodology supposes to analyze the cartographic works of various times and to determine the nature of the settlement placement using a system of conventional signs. However, as established earlier [26], the date of publication of most maps of Kryvyi Rih region does not correspond to the time of topographic surveys. Predominantly the basis of the studied maps were older cartographic materials with changes and clarifications with the period of inconsistency ranging from 10 to 30 years, or even longer. Therefore, with a view to accurately determine the spatio-temporal characteristics of the studied objects marked on the maps, we exploit a comparative analysis of the information given in various historical sources.

For example, figure 1 shows a diagram illustrating the quantitative changes of the yards in the Kryvyi Rih settlement at the end of the 18th century – the end of the 19th century. The plotted data on the number of yards in Kryvyi Rih, obtained from the Special Map of the Western part of the Russian Empire by F. Schubert, created in 1849, shows 460 yards. Yet the updated Three-mile military topographic map of the Russian Empire, corrected on the results of the 1888 survey, there are 770 yards. So, we can conclude that the data visualized on the Schubert map correspond to 1810, and on the Three-mile map to 1882.

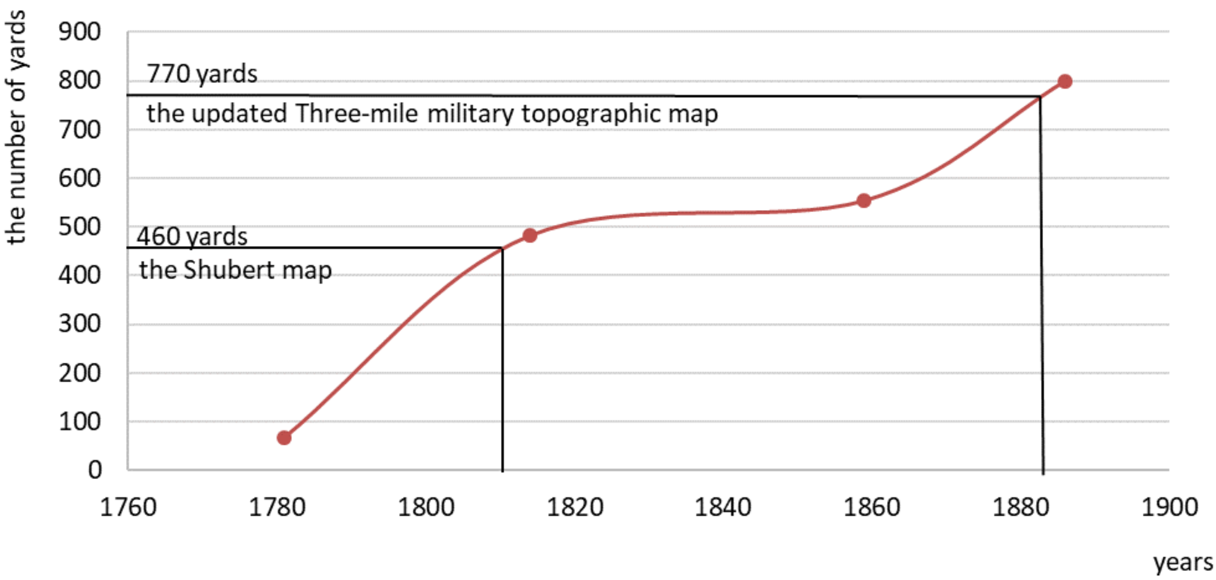

Figure 1. Diagram of changes in the number of yards in Kryvyi Rih from the end of the 18th to the end of the 19th century.

We make similar diagrams for other "cross-cutting" settlements (Lozuvatka, Nedayvoda, Shiroke, etc.), which help determine the temporal intervals of correspondence of the data plotted on these maps (table 1).

Analogically, the population of Kryvyi Rih city on the map of the General Staff of the USSR Armed Forces, created in 1990, corresponds to the time range of 1985-1987 (figure 2).

The most obvious findings to emerge from the analysis of different time maps of Kryvyi Rih are as following:

1. The map, identified by historical sources as the map of the Polish-Lithuanian Commonwealth, dated the end of the 17th century, is an exact copy of F. Schubert's Special Map of the Western Part of the Russian Empire with designations of settlements in Polish and the use of specific conventional signs. In order to use it in our research as cartographic basis of the end of the 18th century period, we performed some corrections to remove objects belonging to another time interval.
2. The tactical map of the German army, created in 1942, is used to analyze the settlement of Kryvyi Rih in the 1st half of the 20th century. It was built on the basis of the Map of the Office of Military Topographers of the Red Army (1930) and the Map of the General

* - detailed characteristics of the maps (year of creation, scale, projection, average relative error, etc. [26]

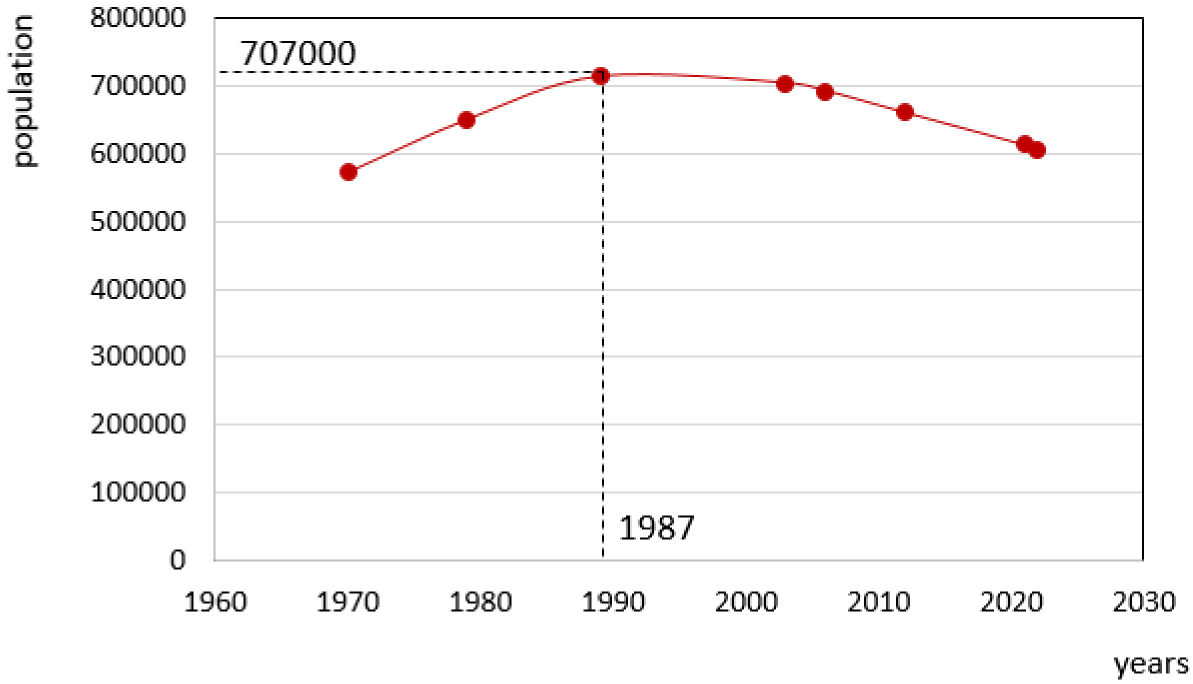

Figure 2. Chart of population changes in the city of Kryvyi Rih from 1970 to 2021.

Staff of the Red Army (1931) without reconnaissance. As a result, it did not reflect the changes occurred in the region for more than 10 years of active settlement. For example, the Karachuniv reservoir, which construction started in 1932, is not marked on the map. Accordingly, that map of the German army contains information from the 30s of the 20th century (table 1). Beyond that, the lack of accounting and statistical data for the stated period made it impossible to quantitatively analyze the features of the settlement of the population in the region.

The retrospective analysis enables to consider the facts depicted on these maps in accordance with certain periods of the region's development.

Quantitative characteristics of various temporal indicators of the studied territory demonstrates almost the absence of systematic and full-flegged information about the specifics of the population settlement of Kryvyi Rih area in certain periods of time, despite a significant number of historical documents.

We pay special attention to conflicting data present in various historical materials regarding the population (both of the region in general and of individual settlements) in different periods of the settlement of Kryvyi Rih area. To fill the identified gaps, we additionally study historical documents in order to establish the correlation between the number of yards and their population on the territory of residence. However, the calculations do not take into account the indicators of large settlements, such as Kryvyi Rih, Lozuvatka, etc., since the historical and statistical information about them is quite detailed. The result of the data obtained on the basis of the analysis of accounting and statistical information is the linear diagram presented in figure 3.

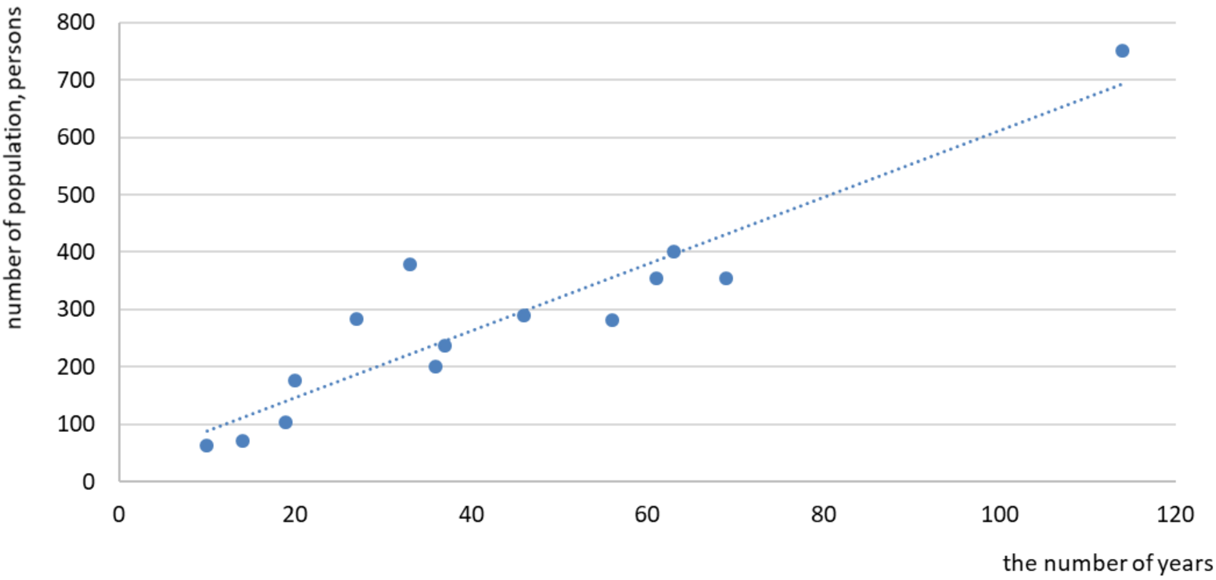

Figure 3. The relationship between the number of yards and the population of the villages of Kryvyi Rih area at the beginning of the XIX century.

The diagram shows the close correlation between the number of yards and their population on the territory of residence according to the pairwise correlation coefficient is +0.89. So, the number of yards in Kryvyi Rih area allows to calculate with a high degree of reliability spatio-temporal indicators of the population for all analyzed time segments. A spot check of the obtained results based on historical materials confirms their accuracy, since the error did not exceed 5% for settlements with up to 100 yards.

The peculiarities of the processing of spatial and attributive data of various time periods by means of GIS technologies deserve particular characterization. Topographic maps of the region at various times were used as basic spatial materials for the geo-informational analysis of the territory of Kryvorizhzhia (table 1).

At the first stage, we "stitch" the map sheets, since the entire territory of Kryvyi Rih is placed on two sheets (e.g., the map of the German army) and four sheets (e.g., the updated Three-Mile military topographic map of the Russian Empire).

At the second stage, the raster image of the maps is linked to the free access GIS – QuantumGIS. This stage challenge is connected with binding to one modern topographic basis, since all cartographic materials differ significantly in their mathematical basis.

Particularly, on the Map of the General Staff of the USSR Armed Forces (scale 1:100000), binding of sheets was carried out by an array of registration points (from 20 to 45) depending on the scale and projection of historical maps, as well as their location on the base map. We use as registration points the points marking the settlements of the region and the elements of the relief of the area. Despite the large number of registration points, we make coordinate correction of the points on the retrospective maps during the binding. The resulting error ultimately ranges from a few tens of meters on the Map of the German Army to 200 meters on the Special Map of the Western Part of the Russian Empire by F. Schubert. Taking into account the low accuracy of old maps and the specifics of their mathematical basis, the obtained results should be considered sufficient for the historical and landscape analysis of the territory.

At the third stage, we make vectorization of the locations of settlements on all historical maps and fill in the corresponding attributive tables with established statistical demographic indicators (number of yards, population size, sex-age ratio, etc.). As a result, the primary retrostructural GIS model of Kryvyi Rih area was formed.

Geoinformational analysis of primary layers includes interpolation by the method of inverse distance weighting (IDW), construction of heat maps (estimation of core density), drawing of isolines, application of cartodiogram method, etc. [27–29]. Overall, a common workspace of more than 40 maps were created, which serve as a basis for the analysis and substantiation of the study conclusions.

3. Research results

Despite the tendency of a settlement system to sustainability resulting from the relative stability of the historical framework of the settlement network [11], it undergoes some dynamic changes during its development (new settlements appear, the old ones disappear, changes in their size, status, etc.). Therefore, throughout each historical stage a region forms its own settlement system, which reflects the local natural-geographic and socio-economic features of the development of the region (figure 4, figure 5).

The resettlement of Kryvyi Rih area actually began in the middle of the 16th century, when the territory became part of the territory of the Zaporizhzhia Nizovy Host, where it remained until 1775, the end of the Zaporizhzhia Army existence. At that time, there were about 10 winter camps with a population of at least 120 people within the boundaries of modern Kryvyi Rih area [25].

After the extermination of the Zaporozhian domains, the region was declared the property of the royal treasury. Part of the Zaporizhzhia people moved to a settled way of life in the newly created villages. However, active settlement of Kryvyi Rih area was observed since 1771, when the government of Tsarist Russia began distributing land to officers, former Cossack foremen, Russian, Ukrainian and Polish landowners. Thus, General Rakhmanov founded the village of Rakhmanivka, and Cornet Gdantsev founded the village of Gdantsivka. The founders resettled in the villages their serfs from other settlements in Russia and Ukraine. In addition, a significant share of state lands was sold to peasants and freed serfs [21]. This is the way how the settlement system of the region was formed at the end of the 18th century.

The analysis of the map of the Polish-Lithuanian Commonwealth (with the correction of the territorial distribution of settlements at the end of the 18th century) by means of the heat map method demonstrates the linear nature of the spatial distribution of settlements without the formation of concentration nodes (figure 4A). The increase in the density of settlements near Kryvyi Rih is exceptional. The settlements are quite distant from each other: the average distance between them is 7.9 km (figure 6), the total number of settlements in this period is 25 (figure 7), and the density of settlements was 1 per 152 km^2 of the area.

The linear nature of settlement is due to the localization of all settlements along the riverbeds of the Ingulets, Saksagan, Kamianka and Bokova rivers (figure 8). So, we can conclude that the

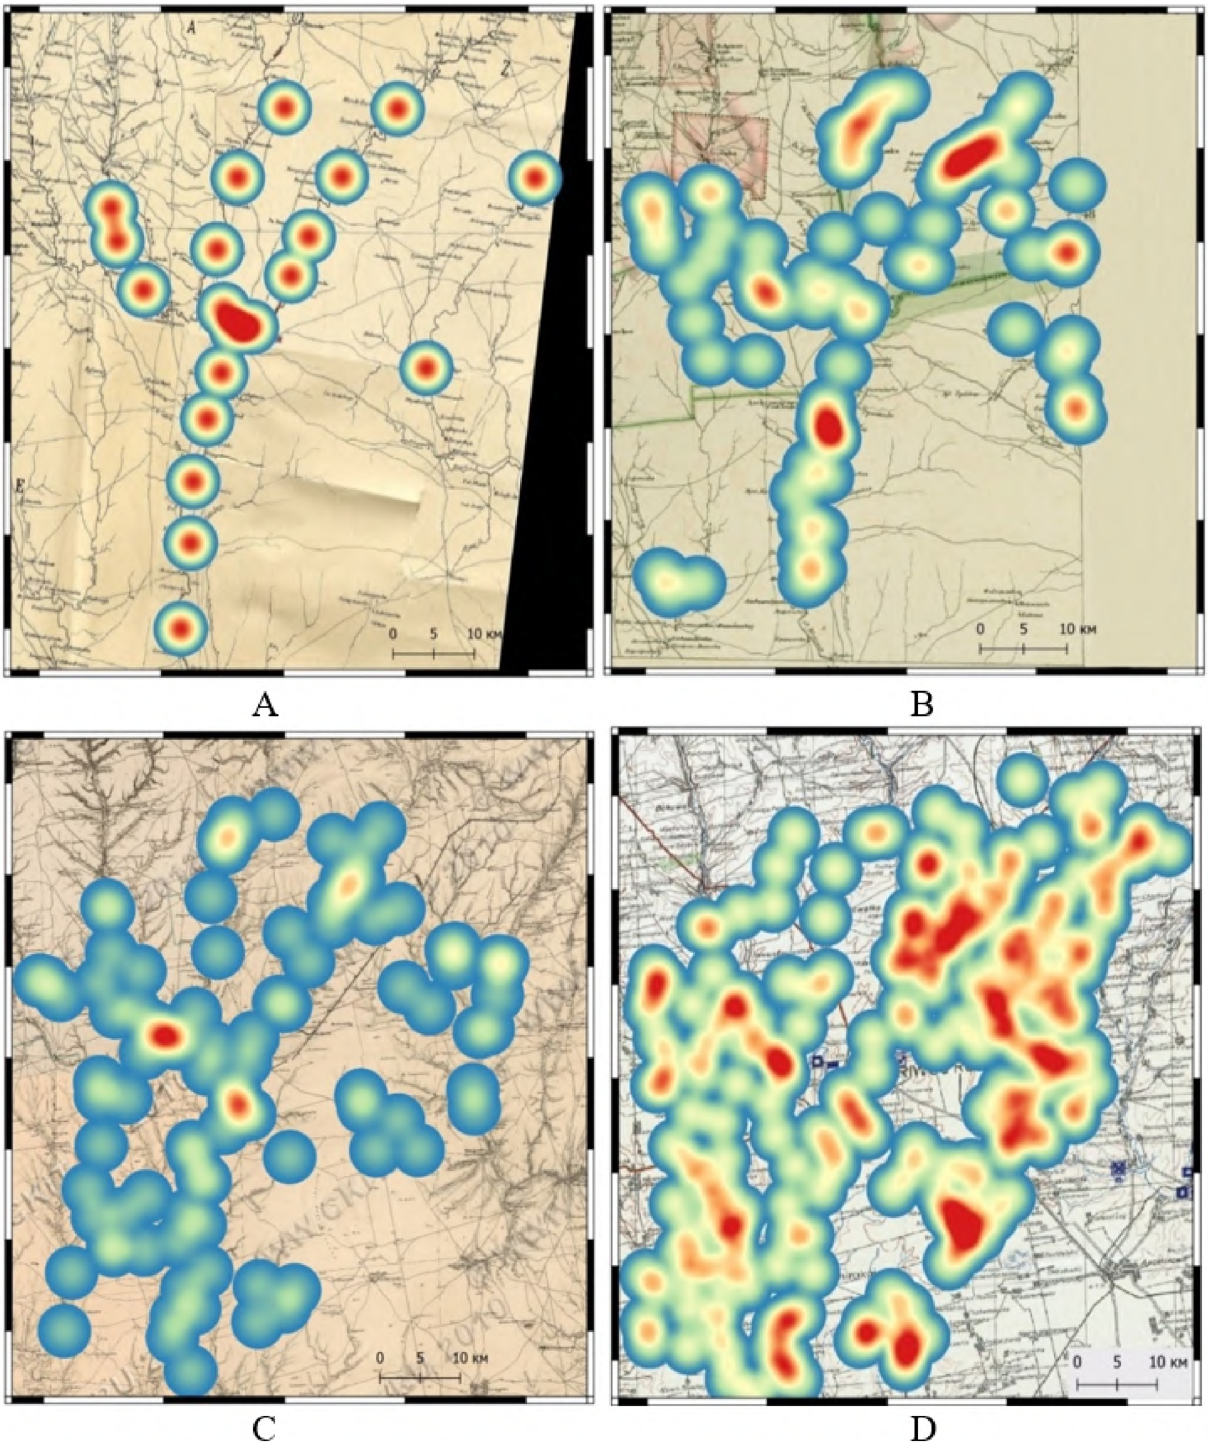

Figure 4. Thermal maps of the location of settlements in Kryvyi Rih area in different historical periods *(A – map of the Polish-Lithuanian Commonwealth; B – Special map of the Western part of the Russian Empire by F. Schubert; C – Updated three-mile military Topographical map of the Russian Empire; D – Map of the German army).*

natural factors, primarily the proximity of the river network, prevailed during the formation of a peculiar settlement structure at the end of the 18th century, as people chose fertile lands near

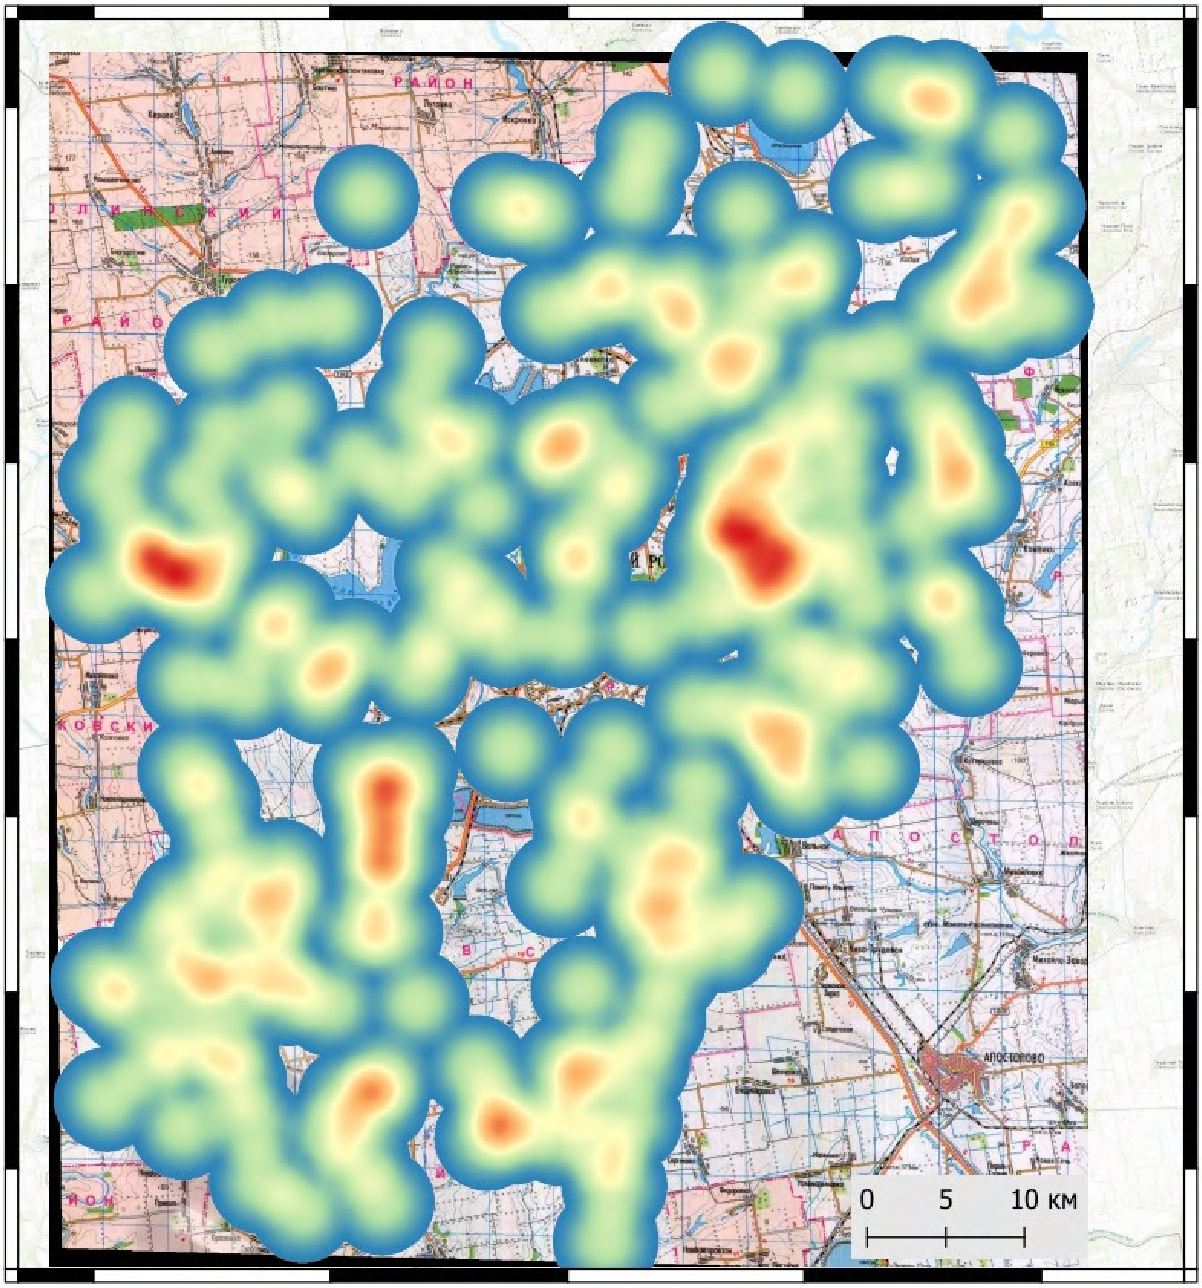

Figure 5. Map of the General Staff of the USSR Armed Forces.

rivers for settlement.

Quantitative composition of the population of Kryvyi Rih area at the end of the 18th century (figure 9A) shows the formation of two centers of development: Kryvyi Rih – in the center of the region and Lozuvatka – in the north. Their population significantly exceeds the one in other settlements. Thus, 762 people lived in Kryvyi Rih, and 353 in Lozovatka, the average population in other settlements was 30 people, which is visualized on the heat map (figure 9). The map demonstrates the uniform distribution of the population at that time, apart from the village of Zelene with the minimum number of people (7 people), and the village of Sofiivka with the maximum (67 people).

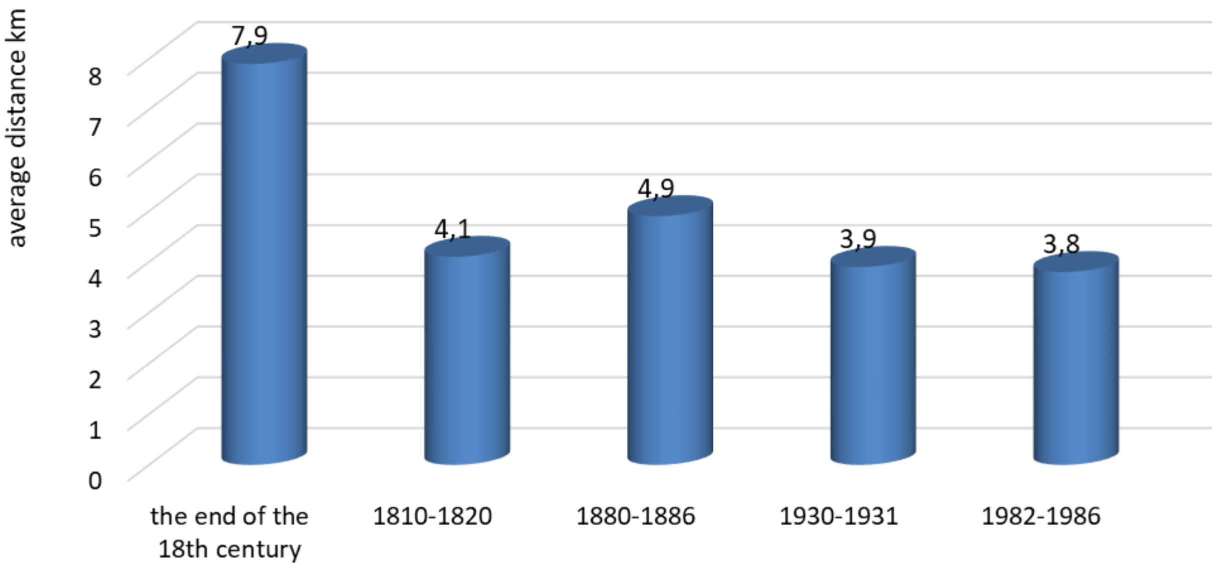

Figure 6. Change in average distances between settlements in Kryvyi Rih in different periods of settlement.

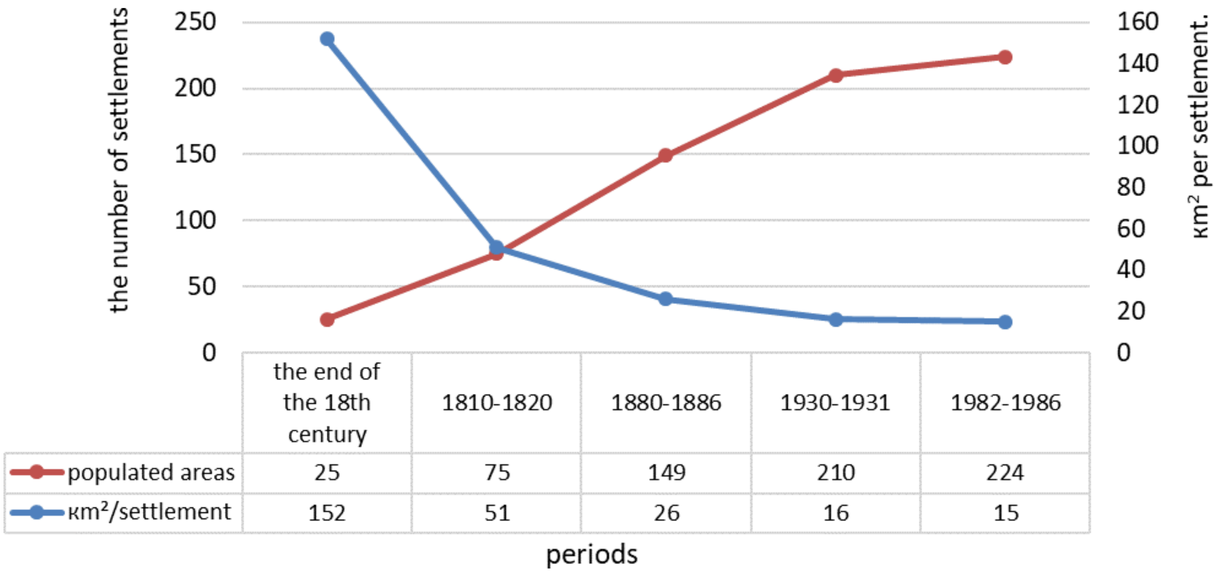

Figure 7. Changes in the number of settlements in Kryvyi Rih and the density of their location during the settlement of the territory.

We should remark that due to the lack of data on the population of Kryvyi Rih area at the end of the 18th century – the 1st half of XIX century, the calculations are based on the probable share of the population of 8 volosts, which later formed the Kryvorizky district. Thus, in 1785, the population was 1.7 thousand people [30]. The population of Kryvyi Rih area was presumably 1,671 people, according to the results of the calculation of the number of yards in the settlements of the region at the end of the 18th century (1780–1790). So, the indicators are correlated, which proves the reliability of the obtained calculations. At that time, the population density was 0.44 people per km^2 (figure 10).

At the beginning of the 19th century the number of settlements in Kryvyi Rih area increased

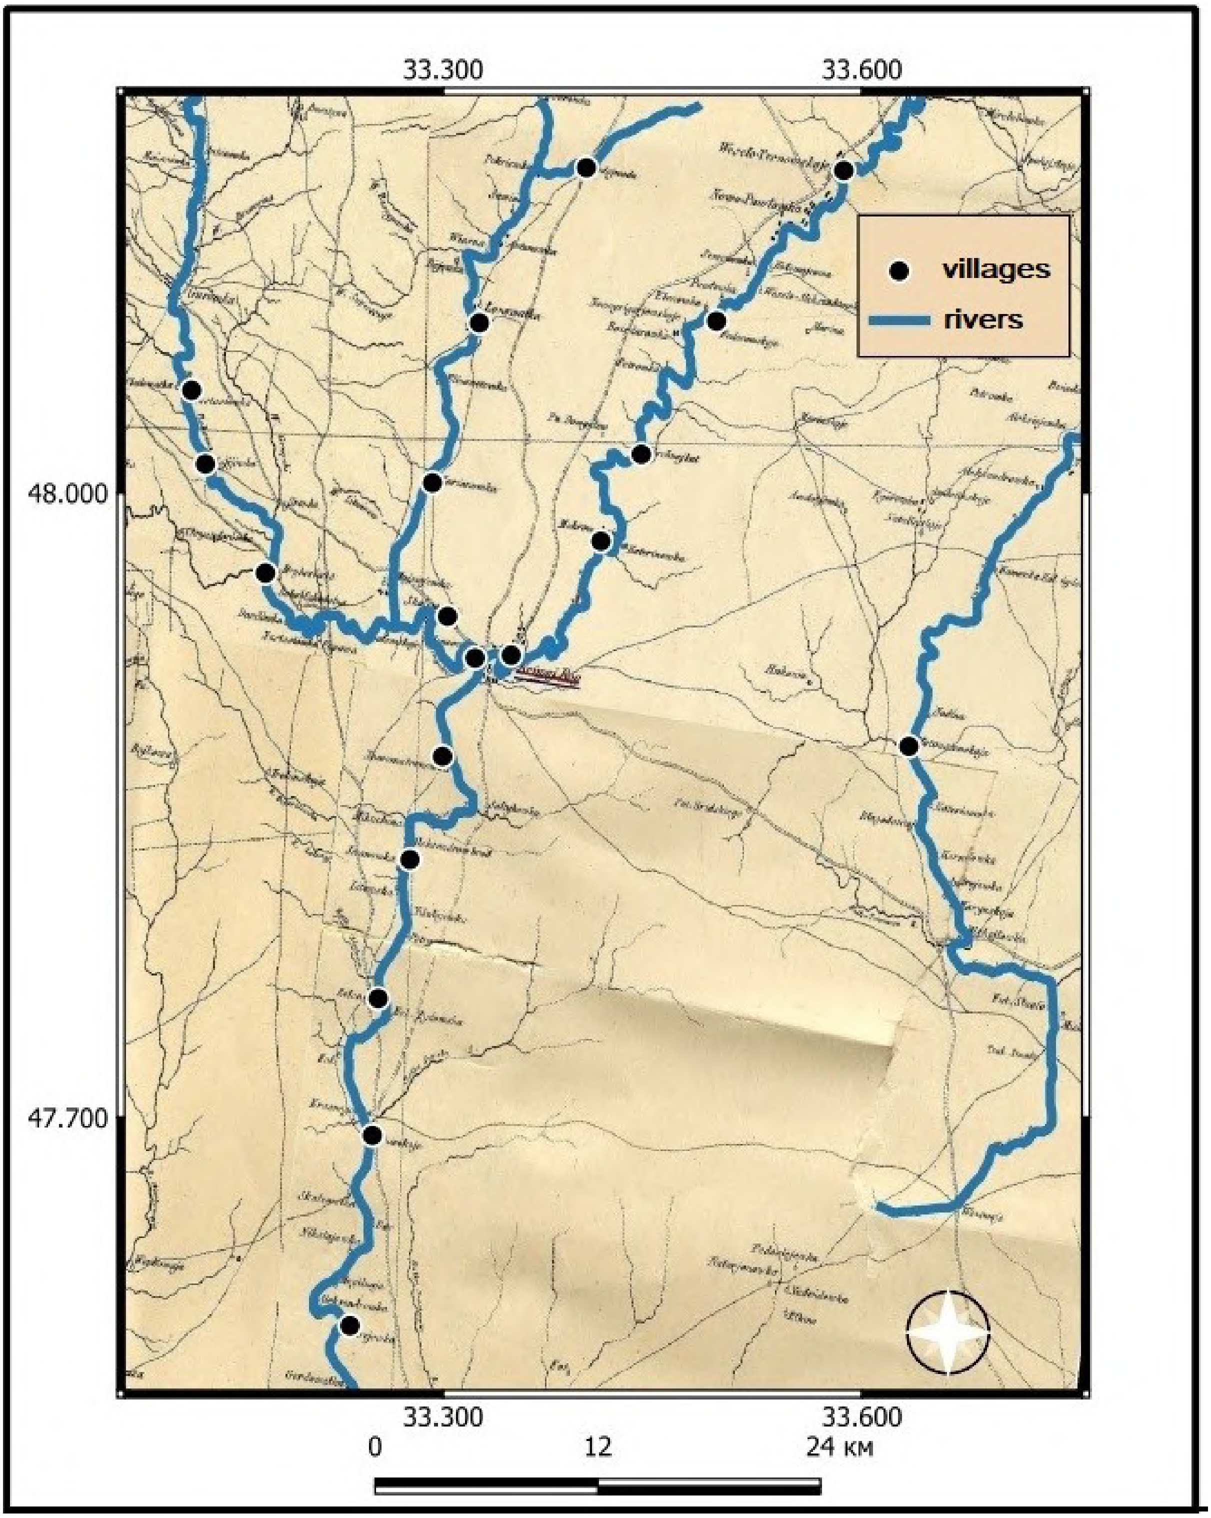

Figure 8. Localization of Kryvyi Rih settlements along riverbeds at the end of the 18th century (based on the Map of the Commonwealth of Nations).

almost threefold. According to the information provided on the Special Map of the Western Part of the Russian Empire by F. Schubert, the total number of settlements in the studied region

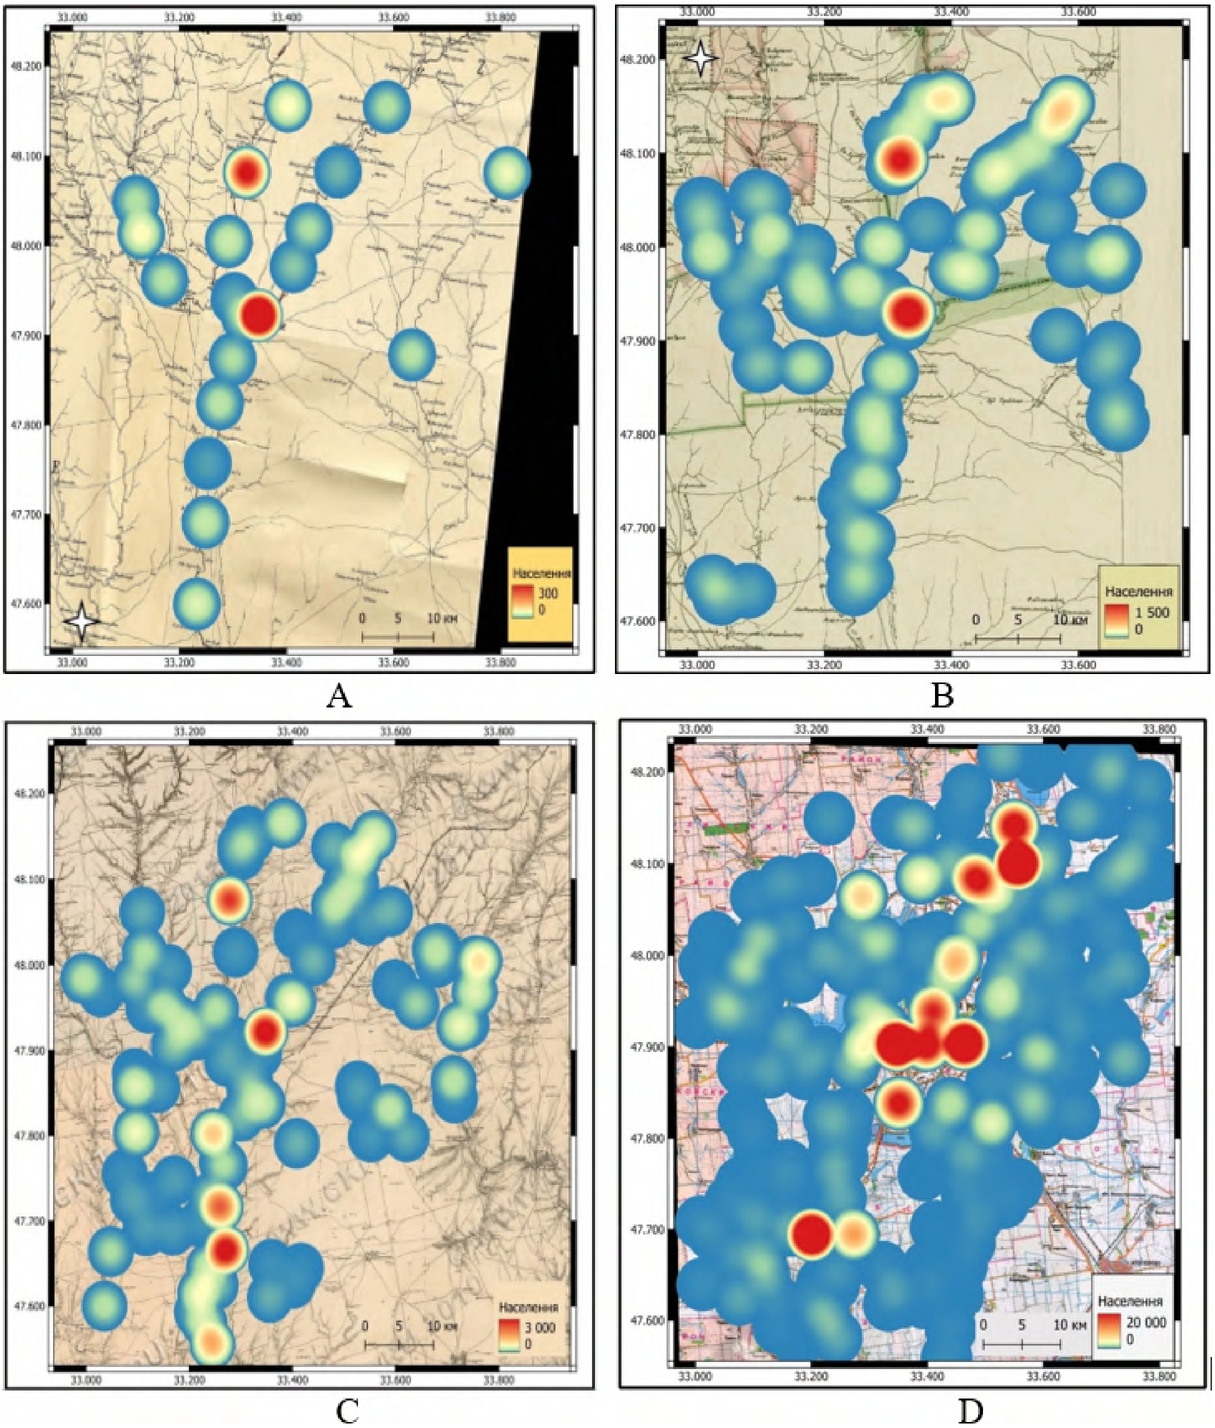

Figure 9. Heat maps of the population density of Kryvyi Rih in different historical periods of settlement of the region:*(A – Map of the Polish-Lithuanian Commonwealth; B – Special map of the Western part of the Russian Empire by F. Schubert; B – Updated three-mile Military Topographical Map of the Russian Empire; G – Map of the General Staff of the USSR Armed Forces).*

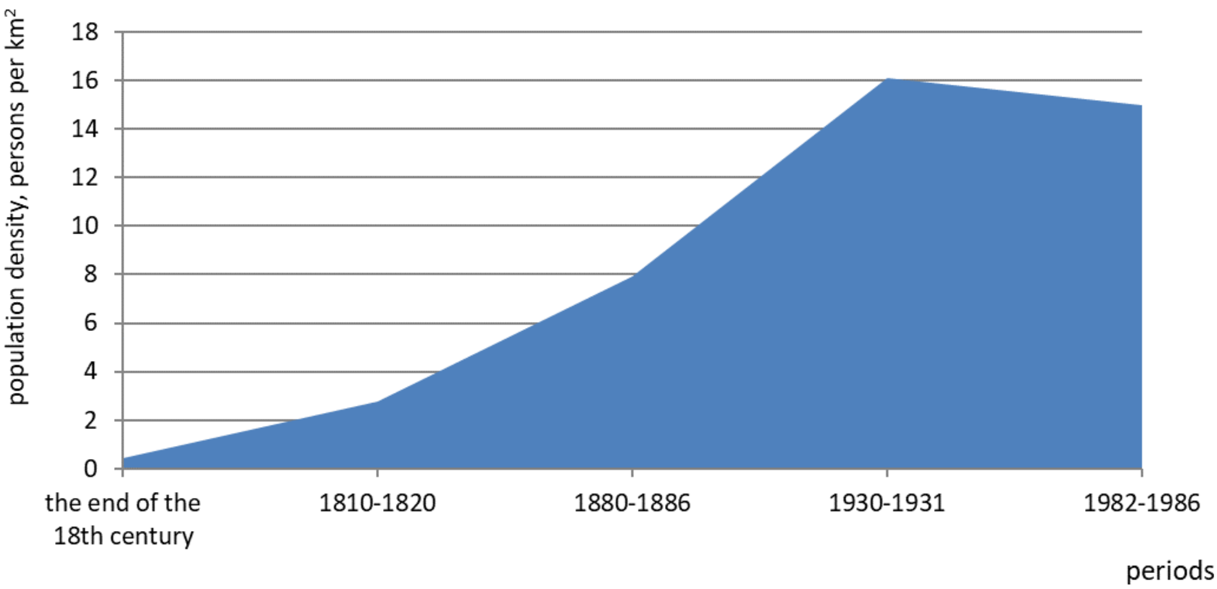

Figure 10. Dynamics of the population density of Kryvyi Rih area during the settlement of the territory.

was 75 (figure 7); the density is 1 settlement per 51 km^2 of the total territory, and the average distance between settlements is 4.1 km (figure 6).

The emergence of new settlements in the region is connected with the resettlement of a significant number of serfs from different parts of the Russian Empire, and is also the result of the anti-Semitic policy of the government of Alexander I, when Jews were expelled from Moscow, Petersburg and other cities. They founded the first Jewish agricultural colony of Ingulets. Later, their number grew to 7 [22].

The settlement structure of the region at that time almost did not change. New settlements gravitated to riverbeds of the Ingulets, the Saksagani, the Kamianka, and the Bokova, people also settled down near the Bokovenka and the Verbova rivers. Therefore, in Kryviy Rih area of that period there was a clear localization of settlements near the river valley landscapes.

The second focal factor together with the natural one that had a significant impact on the settlement of the population was the ethnic factor. Thus, certain systems of farming and land ownership specificity in Jewish colonies and their interrelation, contributed to the formation of some ethnonodes in the south and east of the region.

Overall, Kryvyi Rih territory at the beginning of the 19th century is characteristic of six areas with an increased density of settlements (figure 4B), the largest ones were the newly formed settlements along the Saksagan River in the north of the district (the settlements of Novo-Pavlovka, Bozhedarovka, Fedorovskoe, Semenovka), as well as in the south, along the Ingulets River (villages Aleksandrov Dar, Ivanovka, Nikolaevka, Petrovka, etc.). Here and further, the names of the settlements correspond to the names given on the historical maps.

At that time, the population of Kryvyi Rih also increased significantly: 10,455 people lived in the region. Generally, the spatial structure of quantitative indicators of population settlement has not changed. There remained two centers of development – the villages of Kryvyi Rih and Lozuvatka with a fairly even distribution of population density in the region (figure 9B). In the meantime, we can observe an increase in demographic indicators: 2,300 people lived in Kryvyi Rih, 1,590 in Lozuvatka. The average population in other villages increased to 90, and the population density was 2.75 people per km^2 (figure 10).

At the end of the 19th century the number of settlements in Kryvyi Rih area doubled to 149, and the density was 1 settlement per 26 km^2 of the total territory (figure 7). We can explain such an increase in the number of settlements due to their location on vacant land between previously built settlements (figure 4C). It resulted in a transition from a linear structure of settlement of the region to a linear-planar one, increasing the average distance between settlements to 4.9 km compared to the indicators of 1810–1820 (4.1 km) (figure 6).

The increase in the number of settlements on vacant land led to a more uniform structure of their density (figure 9C). We note only two areas with a higher concentration: one in the center of the region (near Kryvyi Rih), the other in the west (in the meanders of the Bokovenka river). The concentration of settlements Vladimirovka, Popovka, Khrushchevka, Bohoblagodatnaya and others in the meanders of the Bokovenka river is connected with the fertility of the land and proximity to water. Yet, an economic core was gradually forming around Kryvyi Rih.

From the middle of the 19th century Kryvyi Rih turned into a significant agricultural and trade center of Southern Ukraine, which made it a town of the Kherson province in 1860 [25]. Since then, the development of Kryvyi Rih was affected by its growing economic role. The rapid socio-economic development of the region impacted the population growth. So, 3,644 people lived in Kryvyi Rih in 1859; 4,023 people in 1880; 15,859 people in 1890, and at the end of the 19th century 35,000 people already lived on the territory that is part of the city nowadays [18]. The reason for such a dramatic Kryvyi Rih population increase was the discovery of large reserves of iron ore in Kryvyi Rih, and hard coal in Donbas, which created the prerequisites for the development of a metallurgical base. In 1897 the Kryvyi Rih iron ore district placed first in ore extraction in the Russian Empire, and in 1900, 79 mines operated there. Thus, Kryvyi Rih became a powerful labor market, which caused mechanical movement of the population to the city from its outskirts and nearby settlements. The construction of the Catherine railway in 1884 boosted the development of Kryvyi Rih as well, connecting the city with the industrial regions of Dnipro and Donbass [22].

The transformation of Kryvyi Rih into a big economic center entirely effected the location and functioning of virtually all settlements of Kryvyi Rih area. Firstly, the territorial organization of the population changed: a set of processes or actions that regulate the interrelation between the population location and production, interconnection and subordination. The changes in the nature of settlement near Kryvyi Rih after the construction of the Hdantsivka ironworks in 1890–1892 can serve as an example. Peasants from nearby settlements were used to work at the plant. Consequently, at the end of the 19th century Hdantsivka absorbed several small settlements: Katerynivka, Likhman's farm, Tychy Prytulok, Tsareva Mogyla, and others [23]. Most of the mines were opened on the lands of landowners or leased lands of peasants. Thus, the Galkovsky (Artema) mine was opened in 1888 on the lands of the Galkovsky landowners, the Rostkovsky mine was founded in 1886 – on the land of the landlady M. Rostkovskaya, the Veseloivanivskyi mine was founded in 1898 on the leased lands of Veseloivanivka villagers, the Boyky mine was founded in 1899 on the agricultural lands of Kryvyi Rih villagers.

In general, in 1880–1886, the population of Kryvyi Rih area made up almost 30,000 inhabitants (figure 11). Compared to the beginning of the 19th century, the third population center in the south of the region (the colony of Ingulets and the village of Shiroke) came into being making the main changes in the spatial structure of quantitative indicators of population displacement (figure 9C). If we do not count the population of these settlements, the average resident number of other settlements of the region increased to 118, and the population density was 7.8 people per one km^2 (figure 10).

It is worth noting that the rural settlement network significantly changed its role in the general system of settlement of the region, since at that time it acquired a secondary role in the economic development of Kryvyi Rih area, which consequently altered its functions and ecological-reproductive load. Virtually, a gradual transition from natural to economic factors of settlement structure formation took place at that time.

	the end of the 18th century	1810-1820	1880-1886	1930-1931	1982-1986
Kryvyi Rih	762	2300	4023	195000	713059
Kryvyi Rih area	1671	10455	29789	240800	756559

Figure 11. Changes in the population in Kryvyi Rih and Kryvyi Rih area in different periods of settlement.

The analyses of the nature of settlement of Kryvyi Rih area in the period between the beginning of the 20th century and before the Second World War is challenging as there is almost no necessary factual material. We can explain the lack of high-quality cartographic materials of that period by the changes in the administration of the region (Kryvorizka Volost, Kryvorizka County, Kryvorizka District), the low level of population accounting by settlements, especially after the Bolsheviks seized power in 1917.

Therefore, we analyze the Map of the German Army to study the nature of resettlement in Kryvyi Rih area not taking into account the spatial indicators of the population. Population data are correlated since 1930.

Factually, the settlement structure of the Kryvyi Rih settlements was finally formed by that time. The active process of resettlement of peasants during the period of the Stolypin reform (1906), and mostly the abolition of landlord land ownership by the Decree on Land (November 8, 1917) with the subsequent distribution of allotments among peasants, contributed to the active development of almost the entire territory of the region.

By 1930 the number of settlements had increased to 210 making a fairly uniform planar structure of settlement in the region (figure 4D). The density of settlements was 1 settlement per 16 km^2, the average distance between settlements decreased to 3.9 km. The total population of Kryvyi Rih at that time was 240,800 people, of which 195,000 lived in Kryvyi Rih. Excluding the population of Kryvyi Rih, Lozuvatka, and Shiroki, the average number of inhabitants of the villages increased to 199 people, and the population density was 16 people per km^2 (figure 10).

According to the Map of the General Staff of the USSR Armed Forces, the number of settlements (224) in Kryvyi Rih area in 1982–1986 hardly changed compared to 210 in 1930. However, judging by historical materials two mutually opposite processes in the settlement of the region occurred in that period: a significant increase in the number of settlements until the middle of the 20th century, which later began to decrease. The gradual increase in the number of settlements is quite understandable: Kryvyi Rih area has fertile soils and a favorable geographical position combined with the irrigation system in the region which contributes to the development of a rural settlement network.

The process of physical disappearance of settlements in the region was partially noted even before the Second World War. The settlements Karachunivka, Moiseivka, Khrushchevka, Bogoblagodatne, Hannivka vanished as they fell into the zone of flooding by the Karachuniv reservoir (works on the construction of the Karachuniv dam began in 1932). Similar processes occurred during the creation of the Iskrivskyi, Kresivskyi, Southern and other reservoirs. However, settlements faded away more massively in the 1970s. If we analyze the graph of changes in the number of settlements in Kryvyi Rih area (figure 7), we can say that at certain times their number reached 240–250 settlements. The decrease in the number of settlements during the growth of urban agglomeration is a fairly common trend throughout the post-Soviet space, which is due to a number of reasons.

Firstly, Kryvyi Rih absorbed nearby settlements. Thus, in 1960–1970, the city of Ingulets, the villages of Rakhmanivka, Zaliznychne, Suvorovo, Kalinina, Zelene, Terny, R. Luxemburg, Novoivanivka, Gleyevatka, etc. were subordinated to the Kryvyi Rih City Council [25]. Therefore, the city of Kryvyi Rih is an agglomeration created by separate villages and working villages built near the facilities of the metallurgical industry (mines and factories). The city territory is a united industrial landscape and urban development complex; which shape follows the configuration of the Kryvyi Rih geological structure with iron ore deposits.

Secondly, the rural population outflew significantly to Kryvyi Rih. The lack of employment in villages distant from the economic core of Kryvyi Rih causes their disappearance (for example, the village of Kateryno-Natalivka, which actually does not exist nowadays).

Thirdly, the villages are administratively cancelled because of their ineffectiveness or location in the zone of potential risk. For example, the village of Shyroke was divided into two villages: Hryhorivka (Grygoro-Hrygorivka) and Shyroke until 1934; due to the construction of the Dnipro-Kryvyi Rih canal, residents from the surrounding villages of Hrushivka, Kuta, and Maryanskoye were resettled in the village of Pershe Maia (name on the map).

The settlement structure of Kryvyi Rih remained unchanged for a long time: evenly planar (figure 5) (with the density of 1 settlement on average – per 15 km^2, the average distance between settlements is 3.8 km).

The total population of Kryvyi Rih area in the period 1982–1986 increased significantly (756,559 people), which is caused by a dramatic increase in the population of Kryvyi Rih city (up to 713,059 people). The number of the rural population simultaneously decreased by 2,300 people (up to 43,500) compared to 1930. The population density consequently decreased to 15.1 people per km^2 (figure 10).

We display the identified trend of changes in the quantitative composition of the population of the region in the structure of the heat map of the population density of Kryvyi Rih area of the specified period (figure 9D). The map demonstrates that the linear zone of the city territory stands out clearly as the area of maximum population density among the low indicators of the rural settlement network emphasizing the role of Kryvyi Rih as the economic core of this region. Due to the specificity of the urban planning structure of Kryvyi Rih, the quantitative indicators of the population are displayed in the form of indicators of its individual components (former villages, towns, working villages, and micro districts)

After the analysis of changes in the population of the "cross-cutting" settlements of the region (figure 12), we divide them into three groups according to the dynamics of changes:

- the first group is characterized by a sharp increase in the number of the population in the second half of 20th century (histograms with clear distinct right-sided asymmetry): the city of Kryvyi Rih, the town of Radushnoe, the villages of Stepove, Poltavka, etc., as well as settlements located near Kryvyi Rih, which are under its high economic influence;

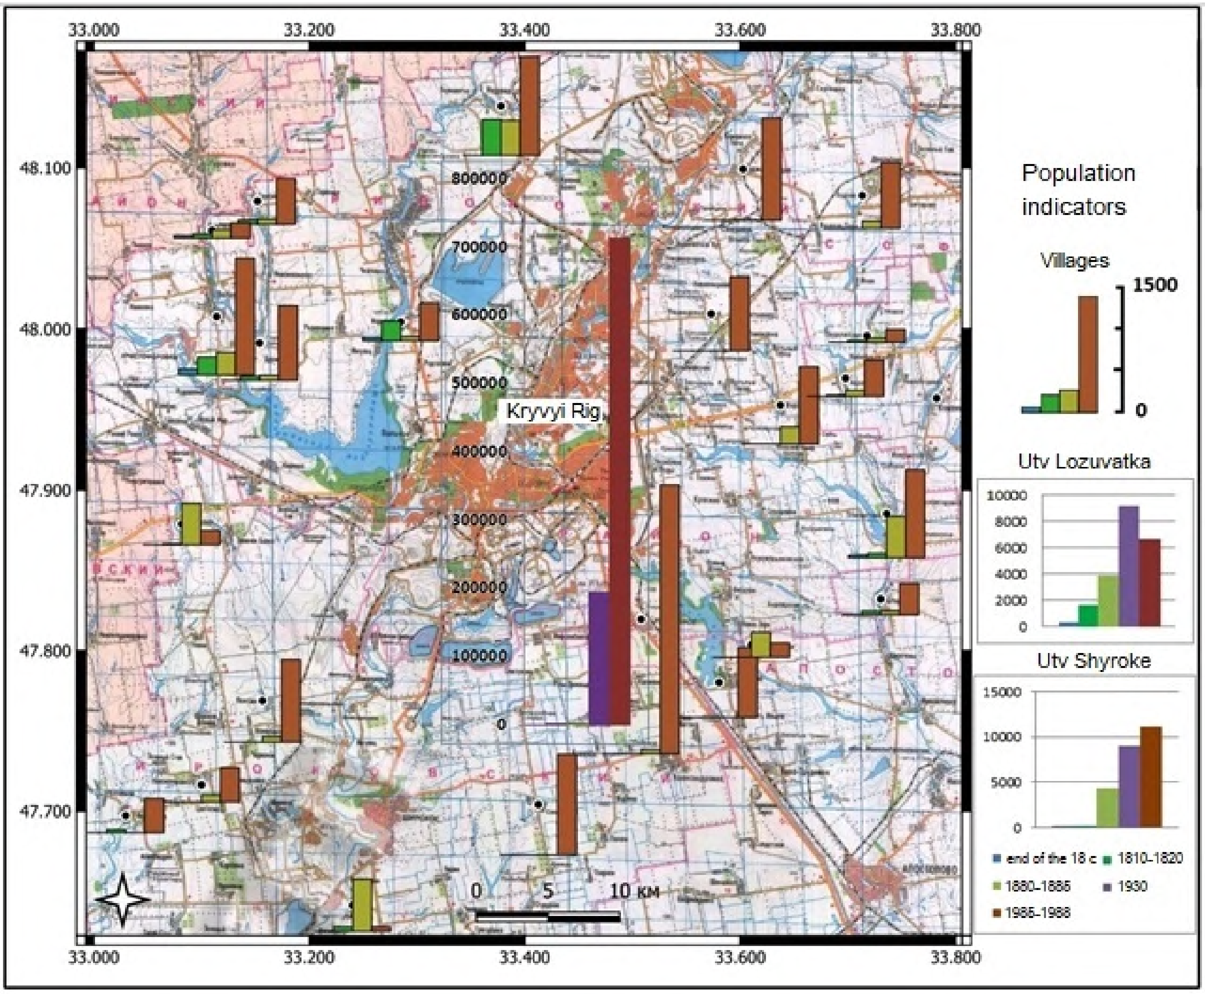

Figure 12. Histograms of changes in the population of "cross-cutting" settlements of Kryvyi Rih (histograms of the city of Kryvyi Rih, Shiroke township and Lozuvatka township are built on separate scales).

- the second group illustrates the regular statistical distribution of the population indicator (histograms with bilateral asymmetry): Shirokoye township, Novokurske, Novo-Kovno, Makarovka and others. These settlements are characterized by regressive processes in the population size. These settlements mostly used to be Jewish agricultural colonies or were under their economic influence before the Second World War;
- the third group comprises settlements with a stable dynamic development of demographic indicators (histograms with smooth right-sided asymmetry). This includes the villages of Valovoye, Anastasovka, Zlatoustovka, etc., which are distant from Kryvyi Rih, so the city economic influence is insignificant.

4. Conclusion

The retrospective analysis of the territorial organization of the settlement of Kryvyi Rih area leads to the following conclusions:

1) the model of the territorial organization of the Kryvyi Rih settlement process was formed during the historical resettlement of the population in the region and is determined by the

spatio-temporal changes of the following indicators: the nature and number of settlements, settlement size, number and density of the population, the ratio of the rural and urban population, etc.;

2) a methodology for retrospective modeling of the historical settlement of Kryvyi Rih area is developed using historical topographic maps and adopting GIS;
3) natural factors, particularly the dominance of the location of the river network in the area, were the main factors in the formation of the original settlement structure of Kryvyi Rih area from the beginning of settlement to the end of the 19th century;
4) the resettlement of the population in Kryvyi Rih during the 19th century was also determined by the ethnic factor connected with the advert and development of Jewish agricultural colonies. The farming systems and peculiarities of land ownership in Jewish colonies caused the formation of separate ethnonodes in the south and east of the region;
5) the settlement of Kryvyi Rih area witnessed a transition from a linear (in the middle of the 19th century) settlement structure of the region to a linear-planar (at the beginning of the 20th century) and planar (in the 30s of the 20th century);
6) the end of the 19th century is marked by a change in the role of the rural settlement network in the general settlement system of the region caused by a gradual transition from natural factors of settlement structure formation to economic ones; at the beginning of the 20th century Kryvyi Rih becomes the economic core of the region development;
7) the analysis of temporal changes in the number of the population of "cross-cutting" settlements of the region prompts their division into three groups depending on the dynamics of changes and Kryvyi Rih economic effect on their development;
8) the findings of study are indicators of population settlement in different time periods of the development of the region: the number of people in settlements; population density in the region; average distance between settlements, etc.; these indicators present a significant contribution to the historical and geographical research of the region.

We envision the prospects for further research in the retrospective study of changes in the natural landscapes of Kryvyi Rih.

Abstract. The COVID-19 pandemic has its own geography, reflected in the spatio-temporal model of its regional evolution, with uneven and spatially differentiated worldwide spread. The global nature of the coronavirus pandemic makes it impossible to study its evolution in a single country in isolation from global realities. Comparison of the dynamics of growth in the number of detected cases of coronavirus infection in the world and Ukraine shows that the pandemic is wave-like, but the amplitude, period and length of the variations barely match. Each of the waves of the pandemic in the world and Ukraine had its own characteristics in the spatial and temporal differentiation of the disease parameters, which was determined by various and multidirectional factors. Based on the results of the geospatial analysis, a zoogeographical map of Ukraine's zoning according to the epidemiological course of the COVID-19 pandemic was constructed, which reflects the spatial differentiation of the pandemic parameters, which is associated with various and multidirectional factors that determine the course of the epidemic, the main ones being: population density and spatial mobility, as well as the peculiarities of regional governance.

1. Introduction

The COVID-19 pandemic will go down in the history of humanity as one of the most important events of the first quarter of the 21st century [1]. It has caused unprecedented consequences in the political and socio-economic spheres of all countries of the world without exception [2, 3]. Thus, according to the WHO, the total number of deaths in the world directly or indirectly related to the COVID-19 pandemic (excess mortality) amounted to at least 20 million people, and the IMF estimated the global economic losses since the beginning of the COVID-19 pandemic at $3.7 trillion.

As a result, the scientific community is widely interested in addressing all aspects of the pandemic [4–6]. Researchers and geographers do not stand aside. While epidemiologists, virologists, and physicians were developing drugs, vaccines, and medical solutions, geographers around the world were studying the relationship between the pandemic outbreak and geographic space. This was facilitated by the availability of various geospatial analysis techniques using GIS to map and monitor the spread of various diseases, including infectious ones [7–11].

The beginning of research in this area is associated with the creation of various online and mobile GIS and mapping dashboards and applications (e.g: *Johns Hopkins University Center for Systems Science and Engineering dashboard; World Health Organization dashboard; HealthMap: analyzing and mapping unofficial sources on the Internet*, etc.) to track the coronavirus epidemic. Some of these dashboards and apps received near real-time data updates [12]. Communication through dashboards based on interactive maps provided unlimited access to information about the spread of the virus both globally and in specific regions and metropolitan areas. At this stage, online dashboards were an important source of information, but GIS methods were more focused on visualizing the development of the COVID pandemic.

After the spread of the pandemic, which provided a statistical sample, studies using geospatial analysis methods appeared. As rightly noted by Helbich, Mute Browning and Kwan [13], the use of geographical principles related to spatial and temporal units of analysis helps to make fruitful progress in COVID-19 research. Technically, geospatial methods for analyzing the spread of diseases are classified into three categories: disease mapping, exposure mapping, and spatial epidemiological modeling [14]. Research on the spread of COVID-19 has been conducted in all of these areas [12, 15–17].

The most common spatial methods used were clustering, hotspot analysis, spatio-temporal scan statistics, and regression modeling. The researchers used a wide range of spatial and statistical software.

It is important to note that the various geospatial methods used by researchers (e.g., spatial autocorrelation [18], or spatio-temporal autocorrelation [19], etc.) aim to explain the dynamics of the pandemic and develop a scientific forecast of its spread. Spatio-temporal mapping of confirmed cases is correlated with geographic factors such as climate, population density, population composition, travel patterns, and others.

For example, Helbich, Mute Browning and Kwan [13] found that COVID-19 is positively correlated with temperature and humidity, but also that these factors alone are not sufficient to predict infection rates. A study by Briz-Redón and Serrano-Aroca [20] demonstrated a high spatial correlation (+0.85) between population density and infection rates, while Sannigrahi et al. [21] added that, in addition to population size, income (-0.68) and poverty (+0.69) have a high correlation with infection rates. In general, GIS technologies have demonstrated high efficiency in creating geoforecasts of the pandemic spread [11, 15].

In addition to global studies, most countries affected by the pandemic have conducted research on the spread of the disease at the regional level. It should be noted that most of the published studies focus on the countries most affected by COVID-19: China [22, 23], North Korea [18]; the United States [24, 25], Brazil [26–28], Italy [29–31], Spain [20], Portugal [32], Germany [10], etc. Most spatial epidemiological studies were conducted during the first months of the epidemic. This made it possible to identify the factors influencing the spread of the pandemic at the regional level and to predict the epicenters of the disease in the near future.

Geospatial studies of COVID-19 in Ukraine are rather limited. As in global research, studies of the spread of the coronavirus began with the creation of interactive maps. Thus, with the increase in the number of confirmed cases, *the Main Situation Center of Ukraine* (under the National Security and Defense Council of Ukraine) created an electronic map of the spread of COVID-19 infection in the world and in Ukraine. The map was updated daily with statistics on laboratory-confirmed cases; the number of patients; the number of recovered patients; the number of deaths, etc.

Experts of the World Data Center for Geoinformatics and Sustainable Development created an interactive thematic panel *WDC-Ukraine COVID-19 Dashboard* to track and forecast the spread of COVID-19 in Ukraine. The service provided data for Ukraine as a whole and by region on the number of laboratory-confirmed COVID-19 cases, deaths, and recovered patients. The information was presented in the form of maps, charts, and counters.

The aforementioned studies are limited to the geospatial analysis of the spread of COVID-19 in Ukraine. As an exception, there are some works in which the authors demonstrate cartographic materials on the pandemic. Most studies of COVID-19 in Ukraine are related to the impact of the pandemic on various aspects of the country's socio-economic life: the crime situation [33], the labor market [34], the economy [35], etc.

Thus, there is no doubt that geoinformation monitoring of the COVID-19 pandemic is a unique tool for studying the peculiarities of the spatial development of the disease, which provides the scientific community and practitioners with a wide range of benefits. Its use allows developing territorial forecast models of the pandemic, creating various medical and cartographic materials (maps of epidemiological burden, medical and geographic forecast, epidemic foci, etc.)

Such research should be conducted at all regional levels, so studying the geography of the coronavirus pandemic in Ukraine is a relevant and crucial task. However, given the fact that the global nature of the COVID-19 pandemic makes it impossible to study its development in a single country apart from global realities. The purpose of the research is to conduct a geospatial analysis of the spread of COVID-19 in Ukraine and the world, identifying similarities and differences.

2. Methods

The work is based on the synthesis of monitoring and geoinformation approaches to the study of the new coronavirus infection. The main parameters of geoinformation monitoring include a variety of data sources and visualization of the dynamics of the processes under study. The statistical basis of the study is the materials from the official websites of global and Ukrainian organizations: World Health Organization, Johns Hopkins University, UNICEF, Ministry of Health of Ukraine, etc.

The Quantum GIS geoinformation application was used as a geoinformation platform. The geospatial analysis was carried out using the methods of cartodiagrams and choropleths with the number of quintile classifications according to the number of research objects. The network analysis was based on the interpolation of spatial-attribute data using the inverse distance weighting (IDW) method.

3. Results and discussion

The COVID-19 coronavirus pandemic has been going on for over three years. During this time, it has spread to almost all countries of the world, with more than 765 million cases of infection recorded, according to official data, and the disease has taken millions of lives, leading to a global economic recession and other crisis phenomena in the socio-economic life of our planet.

COVID-19 was first reported in December 2019 in Wuhan, China, and has spread around the world. It is caused by the SARS-CoV-2 virus, a coronavirus discovered in 2019. The rapid spread of the virus from Wuhan around the world is attributed to the city's well-established air links with almost all continents, but primarily with Asian countries. Thus, in early January 2020, the virus spread to Asia's neighboring countries: Japan, South Korea, Taiwan, Thailand, and Vietnam. As soon as the virus entered these countries through the airline network, it began to spread exponentially from these territories and by the end of January it had reached the United States, Germany, Russia, France, Canada, Italy, and Spain. These are the countries that had the largest number of business, trade, and transportation contacts with China and with each other.

Thus, in the first month of 2020, COVID-19 was detected in 26 countries, and in February – in another 36 countries in Southwest Asia and Latin America In March, the pandemic already

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012042 doi:10.1088/1755-1315/1415/1/012042

covered 150 countries, and by early April – almost the entire world. According to WHO, the number of confirmed cases has exceeded one million.

In Ukraine, the first case of COVID-19 coronavirus infection was confirmed on March 3, 2020. The patient arrived in Chernivtsi from Italy, where he had been traveling from February 21 to 26. Later, cases of infection were detected in Khmelnytskyi, Odesa, Donetsk, Kharkiv, Zaporizhia, Kherson, and Vinnytsia regions.

Epidemiologists call the first patients people who returned from foreign trips, where they could have caught COVID-19. For example, patients in the eastern regions returned from Egypt and Europe, particularly France. In the western regions – from Austria, Hungary, and Italy. In the southern regions - from the United Arab Emirates, Egypt, the United States, and European countries (figure 1). Due to personal contacts with infected people, COVID-19, as a respiratory disease, spread rapidly across the country.

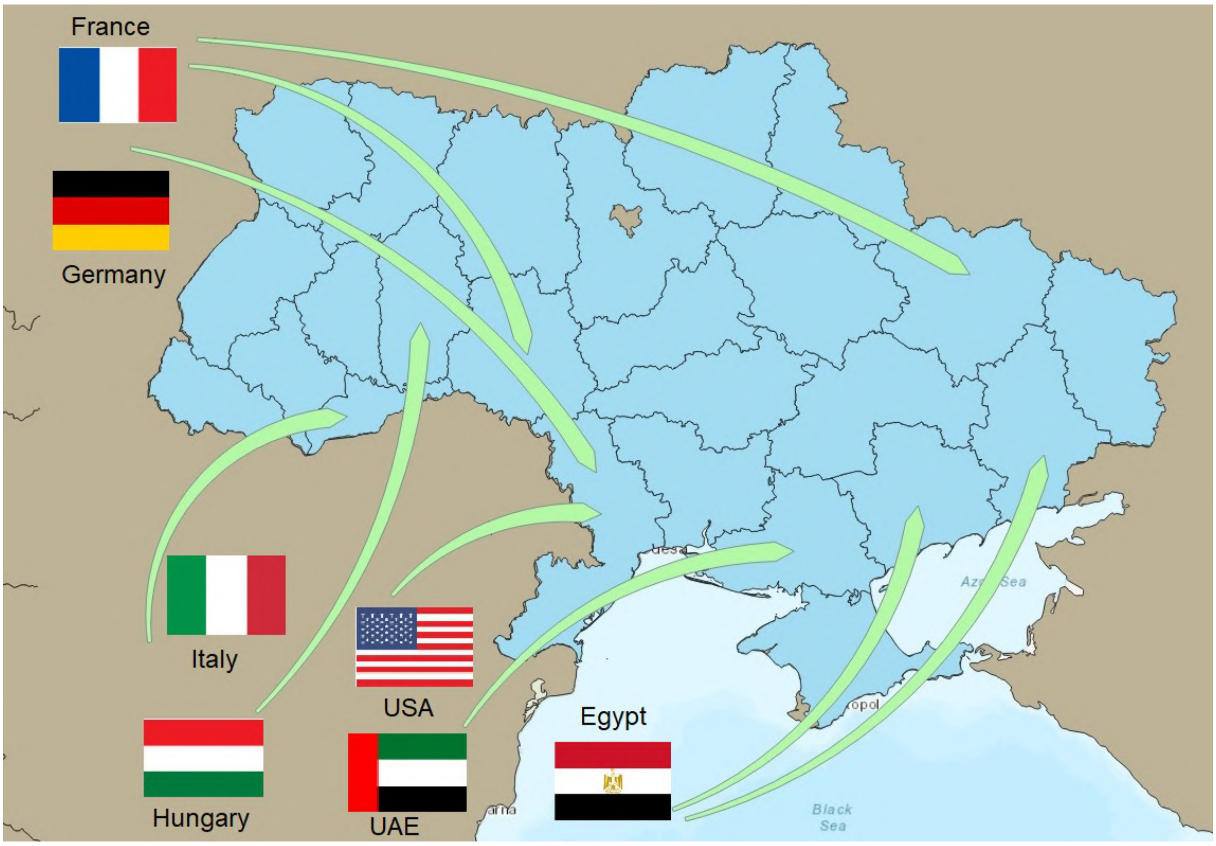

Figure 1. The geography of the first cases of COVID-19 in Ukraine.

Thus, the mechanism of the virus infection in Ukraine is similar to the global one – from the primary source through the chain of contacts with the infected. However, due to the lack of direct flights to Wuhan (China), Ukraine "received" the virus after its long transit through other countries almost two months later than countries in Asia, Europe, and America.

This temporal discrepancy has been observed throughout the pandemic. This conclusion is best illustrated in figure 2, which shows the temporal correlation between the waves of disease development in the world and Ukraine.

From this graph, we can identify four waves in the development of the disease both globally and in Ukraine. The first wave of pandemics was the longest, with a global start in July 2020 and an end in February 2021, with a peak in December 2020-January 2021. In Ukraine, this

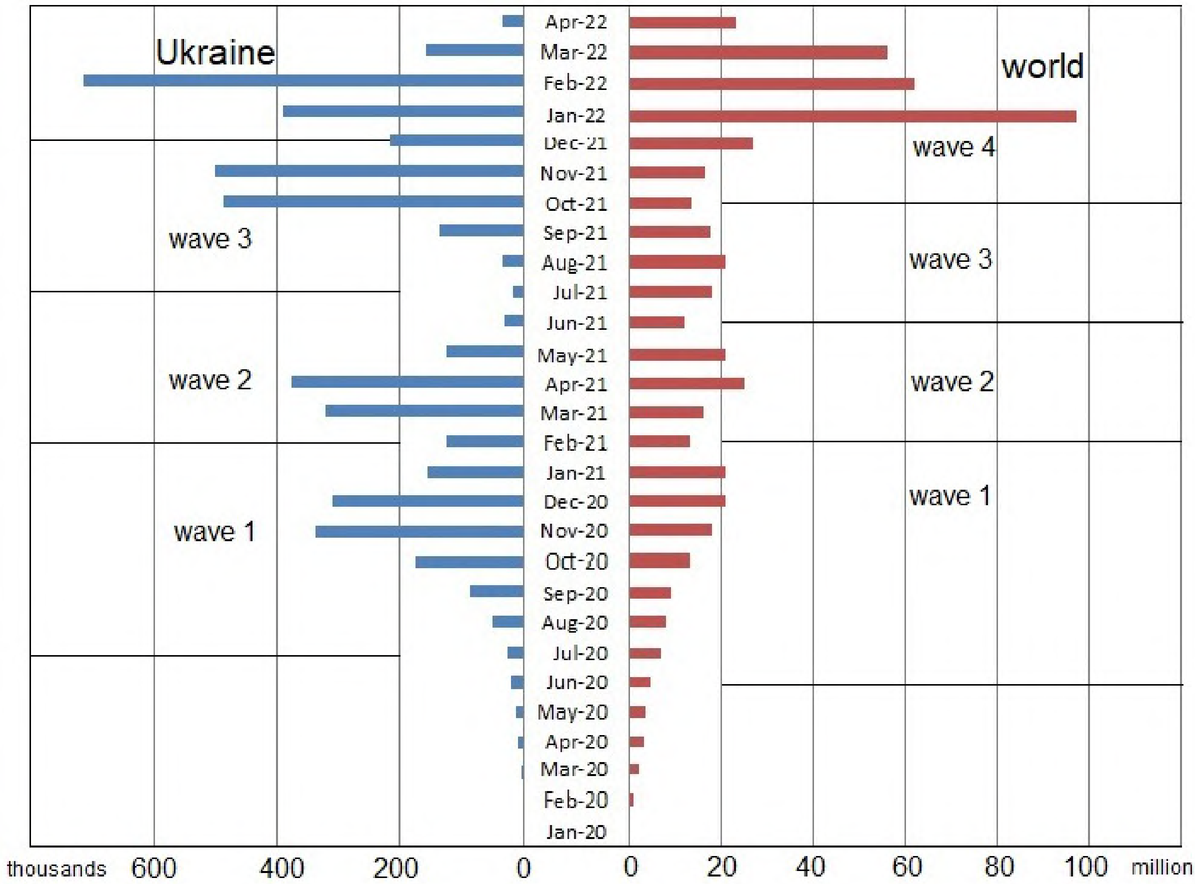

Figure 2. The epidemiological profile of COVID-19 during the pandemic in Ukraine and the world.

wave began one month late (July 2020), but due to the active spread of the virus across the country, the peak of the disease was observed a month earlier – in November 2020.

An analysis of choropleth maps of the spread of coronavirus in the world has revealed that the largest number of COVID-19 cases at the beginning of the first wave occurred in countries located in the subtropical monsoon climate belt and its northern bands. These are: Turkey (165 thousand cases), Iran (155 thousand), Italy (233 thousand), Spain (240 thousand), etc. It can be concluded that at the early stage of the pandemic, the climatic factor (high temperature and humidity) created a favorable basis for the spread of the pandemic, which was exacerbated by the development of tourist flows in these regions.

At the peak of the first wave, the epicenter of the disease shifted from East Asia to North America and Western Europe. As a result, the countries with the largest populations in this belt are already leaders in terms of the number of infections: The United States (26.5 million), Brazil (9.2 million), France (3.2 million), and India (1.4 million). Thus, population density is still a major factor in the pandemic.

It is important to note that while at the beginning of the first wave in Europe, mainly Western and Central European countries and, in particular, megacities were affected, later on, the epicenter shifted to Eastern Europe.

Due to the long period of the pandemic as well as the lack of sufficient vaccines, when the total number of confirmed cases worldwide was nearly 117 million, the first wave had the highest number of deaths at 2.66 million [36].

The lack of a vaccine, as well as the ineffectiveness of the lockdown, contributed to the active spread of coronavirus in Ukraine. Thus, while at the end of April 2020, about 10 thousand people were infected in the country, by the end of November, more than 700 thousand cases were recorded, of which more than 12,000 died (mortality rate of 1.7%). The average daily number of infected people was 12 thousand, with 250 deaths.

By region, the total number of cases during the peak period ranged from 5,500 in Kirovohrad region to more than 56,000 in Kharkiv region (as of 11/28/20). The highest infection rates were observed in the most populated regions: Odesa (47 thousand), Dnipro (40 thousand), Kyiv (39 thousand) regions, etc. At the same time, most (80%) of the detected cases of infection were recorded in the megacities of these regions.

Nevertheless, it is worth noting the higher than average rates in the western sparsely populated regions: Rivne (31 thousand), Chernivtsi (34 thousand), Ivano-Frankivsk (38 thousand), etc. In the diagram of the relationship between population and the number of coronavirus cases in the regions of Ukraine during the first wave of the pandemic (figure 3), the western regions are localized separately, demonstrating the absence of such a relationship. This indicates that in the early stages of the pandemic in Ukraine, the carriers of the coronavirus – Ukrainian workers from European countries – played a major role in the spread of the coronavirus, who began arriving end masse in the western regions of the country after the announcement of lockdowns in Europe. The deviation from the general trends in two regions – Donetsk and Luhansk – is noteworthy. This can be explained by the lack of correct data on the population of the regions after Russia annexed parts of these regions in 2014.

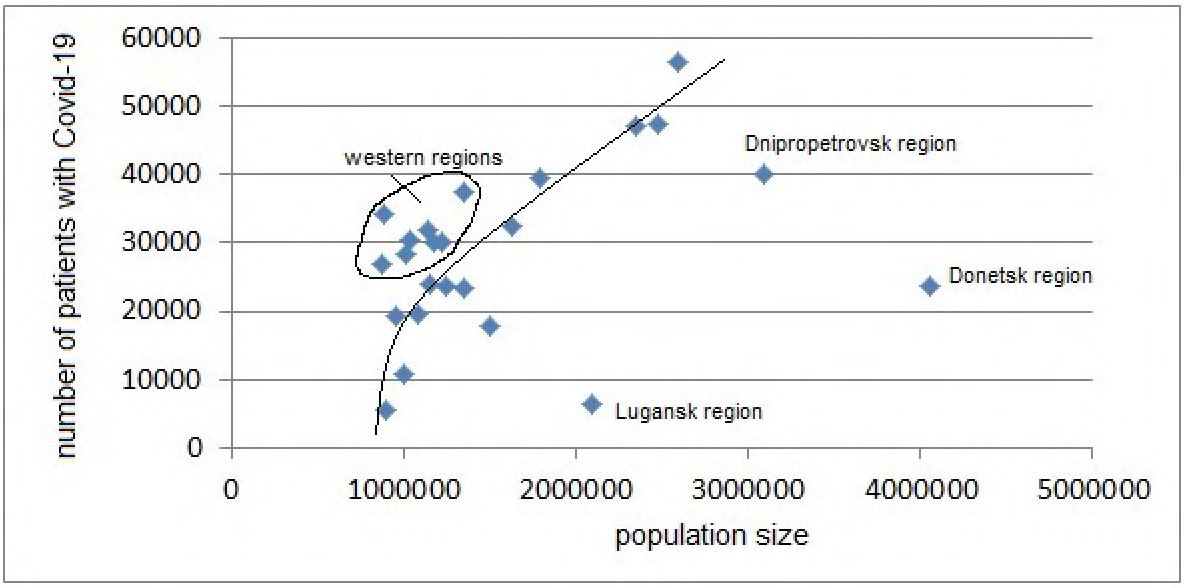

Figure 3. The relationship between the number of population and the number of diseases caused by coronavirus infection in the regions of Ukraine during the first wave of the pandemic.

Similar trends in the beginning of the epidemic were established during geospatial studies of the H1N1 influenza pandemic in Ukraine in October-December 2009 [35]. The western regions of the country also played the role of centers of disease spread.

The second global wave of the pandemic was observed from March 2021 to June 2021, with a peak in April 2021 (figure 2). It was caused by the emergence of a new coronavirus mutation, the beta strain, which was called the British strain. As of mid-May 2021, 163 million cases of coronavirus infection were reported worldwide. The British strain first affected European countries and then spread to North and South America.

At this stage of the pandemic, a general model of spatial differentiation of the spread of the COVID-19 virus in the world was formed, which remained until the end of the pandemic (figure 4). Therefore, the choropleth maps of the spread of coronavirus in the world, based on the indicators of subsequent waves of pandemics, do not differ significantly. The only difference was in the absolute number of people infected: it increased significantly from one wave to the next.

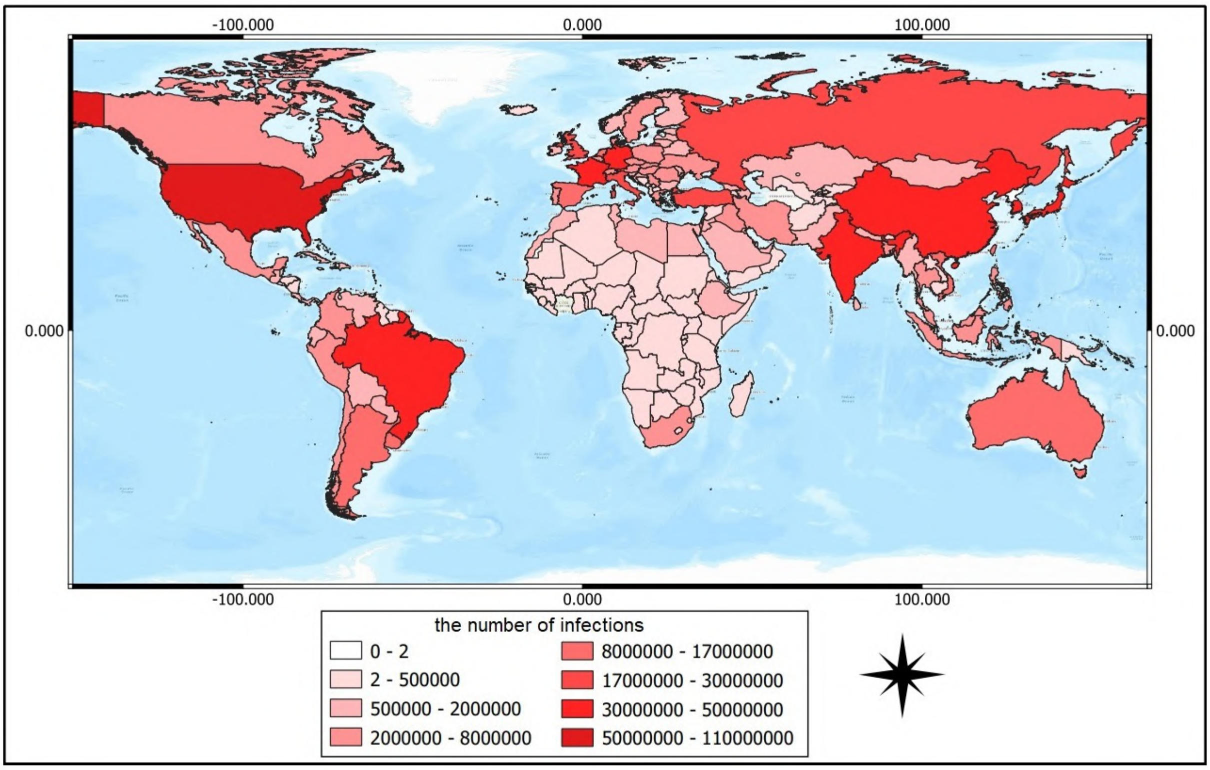

Figure 4. Horopleth map of the distribution of the number of detected cases of COVID-19 infection in the world at the end of the pandemic (data as of March 9, 2023).

As a result, the United States (33 million), India (30 million), and Brazil (18 million) remained the leaders in the number of COVID-19 cases, but the number of cases in Europe increased rapidly: France (5.6 million), Turkey (5.3 million), the United Kingdom (4.5 million), and Italy (4.2 million). In total, almost 47 million confirmed cases of infection were recorded in Europe during the peak of the second wave, despite the strict measures taken by the governments of these countries to contain the spread of the pandemic.

In total, during the second wave, almost 70 million confirmed cases were identified worldwide, with 1.33 million deaths [8].

The second wave of the pandemic in Ukraine was almost synchronized with the global one: it started in March 2021, ended in July 2021, and peaked in April 2021. It was more powerful than the first one, both in terms of the number of cases and the number of deaths.

During the second wave, almost 1 million people were infected in Ukraine, and during its peak period, two million people were infected, with more than 16 thousand daily laboratory-confirmed cases. Up to 400 people died of coronavirus every day in the country.

Such an exponential increase in the number of new infections during the second wave is due to the delay in the vaccination campaign compared to most European countries and its very slow pace. Vaccination became widespread in Ukraine only in late summer 2021. As a result of the diffusion of the virus during the second wave, the top five regions in terms of the number of cases were formed (as of May 1, 21): Kharkiv (137103), Odesa (134410), Lviv (130217), Dnipro (122704), and Kyiv (119241) regions. In fact, their "leadership" remained until the end of the pandemic (figure 5).

This is explained by the largest population of the respective regions and large metropolitan areas. High population density, as an indirect indicator of social contacts, was the main factor in the spatial differentiation of pandemic indicators at this stage.

The lowest number of infected persons was recorded in (data as of May 1, 21): Kirovohrad (18489), Luhansk (23644), and Kherson (31498) regions, which are the regions farthest from the disease centers and have low population density.

The third global wave of pandemic lasted from the beginning of July 2021 and ended in October 2022 (peak in August 2021). Researchers attribute it to the emergence of a new strain of coronavirus, Delta.

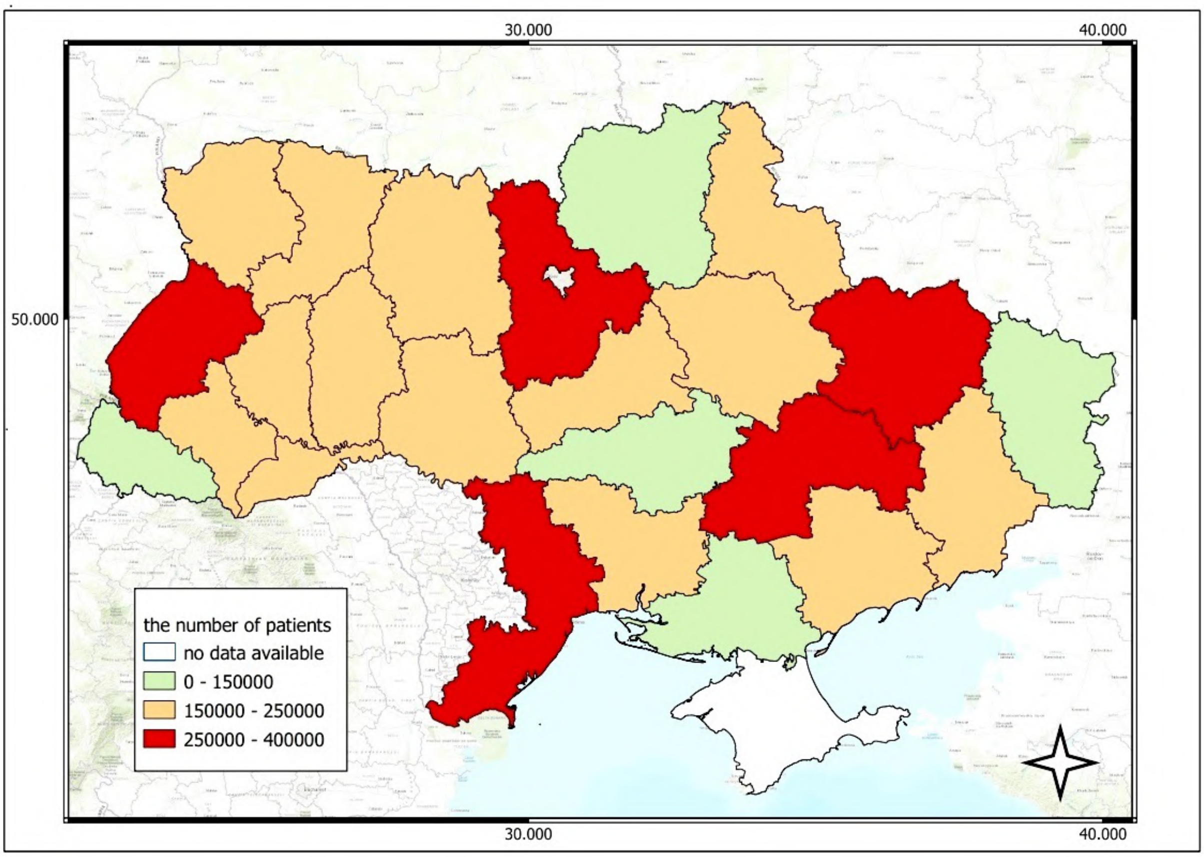

Figure 5. Horopleth map of the distribution of the number of detected cases of COVID-19 infection in the Ukraine at the end of the pandemic (data as of March 9, 2023).

According to the National Academy of Sciences of Ukraine, the Delta strain is 1.6 times more infectious and 2.26 times more likely to lead to hospitalization, but does not cause a significant increase in mortality. Over the course of several months, it gradually becomes dominant, displacing other coronavirus strains.

Mass vaccination against COVID-19 and restrictive measures in countries around the world served as deterrents to the significant spread of the virus, so the number of confirmed cases of infection during the third global wave was the lowest at 65 million. Global mortality rates were also the lowest, amounting to about one million deaths. Despite the fact that the spread of Delta began in India, it spread most widely in the United States, Brazil, European countries (UK, Portugal), and Russia. Therefore, the number of infected people at the peak of the wave (as of September 1, 23) increased in the United States to 40 million, Brazil to 21 million, the United Kingdom to 6.8 million, and so on.

The Delta strain entered Ukraine only at the end of June 2021, so the third wave began a month later than the global wave (beginning in August 2021, ending in December 2021), and the peak shifted by almost two months (late October – early December 2021).

The country's healthcare system could barely cope with the high epidemiological burden caused by the Delta strain. During the relatively short period of the third wave, 1.23 million people were infected in Ukraine, and almost 43,000 died.

The overall picture of the virus spread at this stage is broadly similar to the previous period. The most populated regions are leading in terms of infection rate (as of December 1, 21): Kharkiv (235914), Odesa (228750), Lviv (210153), Dnipro (233290) and Kyiv (147887) regions. Zaporizhia (172575) and Donetsk (155732) regions are close to them. The lowest figures were recorded in Kirovograd region (29854).

In general, a characteristic feature of this wave is the spread of the disease from the center to the periphery, not only across the country as a whole, but also within regions. Thus, at this stage, the number of patients in rural areas of Ukraine has increased significantly. The fourth global wave of morbidity lasted from the beginning of November 2021 and ended in April 2022 (peak in January 2022). It is associated with a new dominant strain, Omicron. This strain is highly contagious compared to previous coronavirus mutations, but the course of the disease after infection is mild. As a result, the number of confirmed cases during the fourth wave was the highest at more than 240 million, but the mortality rate was one of the lowest (1.13 million).

Similar trends have been established for the incidence rates of the fourth wave of the pandemic in Ukraine. It took place a month later compared to the global wave (beginning in December 2021, decline in April 2022, peak in February 2022). More than 1.38 million people were infected, with 12.5 thousand deaths.

The geographical distribution of confirmed cases and deaths has hardly changed. At the end of the pandemic, according to WHO, the five countries most affected by coronavirus infection were: The United States (109 million cases), India (45 million), France (40 million), Germany (38 million), and Brazil (38 million). If we analyze the quantitative composition of the thirty countries with the highest incidence rates, most of them are from Europe (12) and Asia (10). In terms of the absolute number of cases, the countries with the largest populations are leading the way. Only African countries are absent from this ranking. It is worth noting that, for the most part, regional patterns of the pandemic, both at the country level and at a larger scale, are almost identical. In general, they correspond to pandemic waves and differ only in the intensity of the pandemic indicators, and may also shift in time depending on the region's exposure to the pandemic wave.

The development of the pandemic in Ukraine is an example of this. Thus, the spatial differentiation of the number of detected cases of COVID-19 infection in Ukraine at the end of the pandemic (figure 6) generally corresponds to the distribution of the population by regions of the country in the pre-war period: the regions with the largest population have the highest number of cases (Dnipropetrovsk region – 372339 infected; Odesa – 356835; Kharkiv – 322502, etc.) and, accordingly, the regions with the smallest population have the fewest cases (Kirovohrad region – 59243 infected; Kherson region – 110926; Zakarpattia region – 130309, etc.) At the same time, the nature of the histograms showing the temporal change in the number of confirmed cases of infection is almost identical for all regions of Ukraine and differs only in absolute terms of the pandemic.

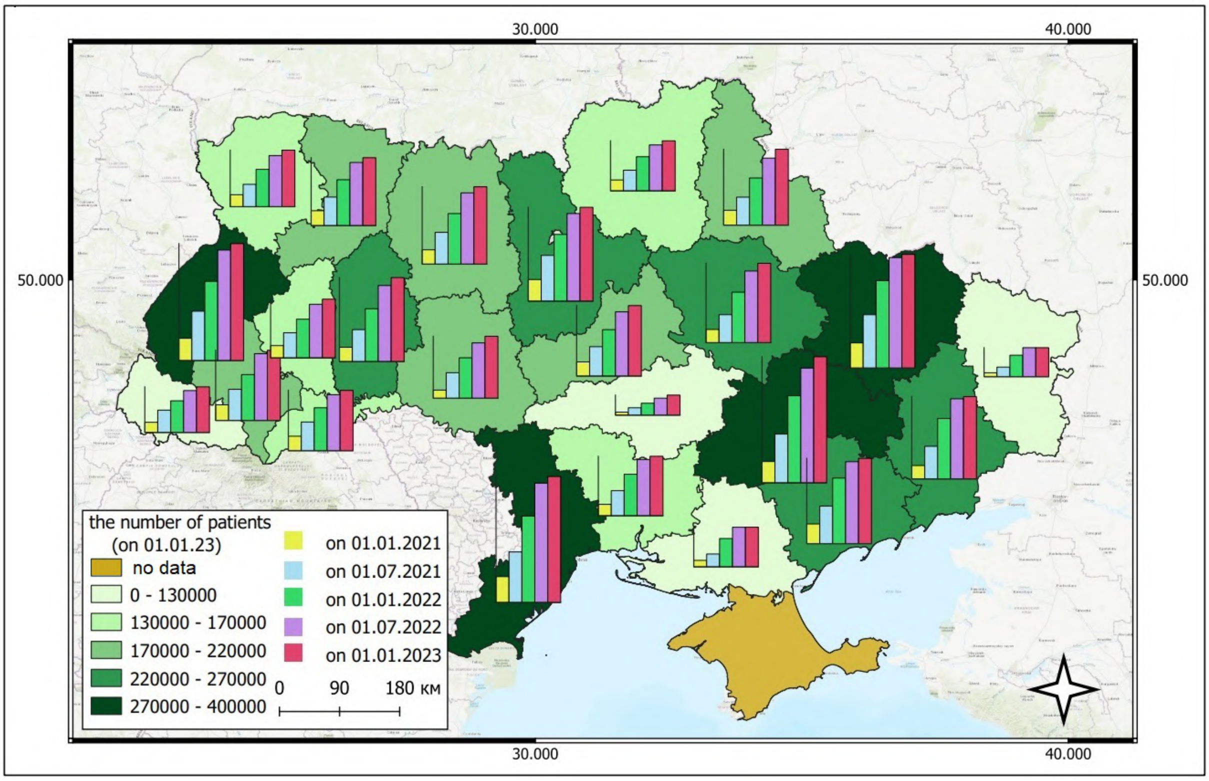

Figure 6. Spatial and temporal change in the number of confirmed cases of infection with COVID-19 in Ukraine.

However, it should be noted that since February 24, 2022, Ukraine has experienced very active processes of migration from the war zones due to Russia's military aggression. Also, part of the country's territory was and is under occupation. Therefore, if we analyze the map of the distribution of the number of detected cases of COVID-19 infection to the number of people (according to the data as of February 24, 22) in the regions of Ukraine (figure 7), we can clearly see the zonal distribution of this indicator: its value increases in the directions of south → north and east → west. This spatial differentiation is explained by migration processes. The number of people and, accordingly, the number of COVID-19 cases in the northern and western regions has increased significantly due to migration from the frontline areas in the south and east of Ukraine.

The main consequence of the coronavirus is a sharp increase in global mortality. According to the WHO, at least 7 million people have died during the coronavirus pandemic. However, as most pandemic researchers suggest, the real number of deaths could be three times higher than the official estimates, amounting to about 20 million people.

The choropleth map of coronavirus deaths actually duplicates the map of the spread of the infection in the world (figure 4). The main reason for this is the close correlation between the total number of infected and deaths. The correlation coefficient is +0.88, but there are exceptions. For example, in France and Germany, the number of deaths is lower than the average model indicators by less than 200 thousand people, and in North Korea and Japan by almost 300 thousand people. At the same time, in Russia, these figures are 100 thousand deaths

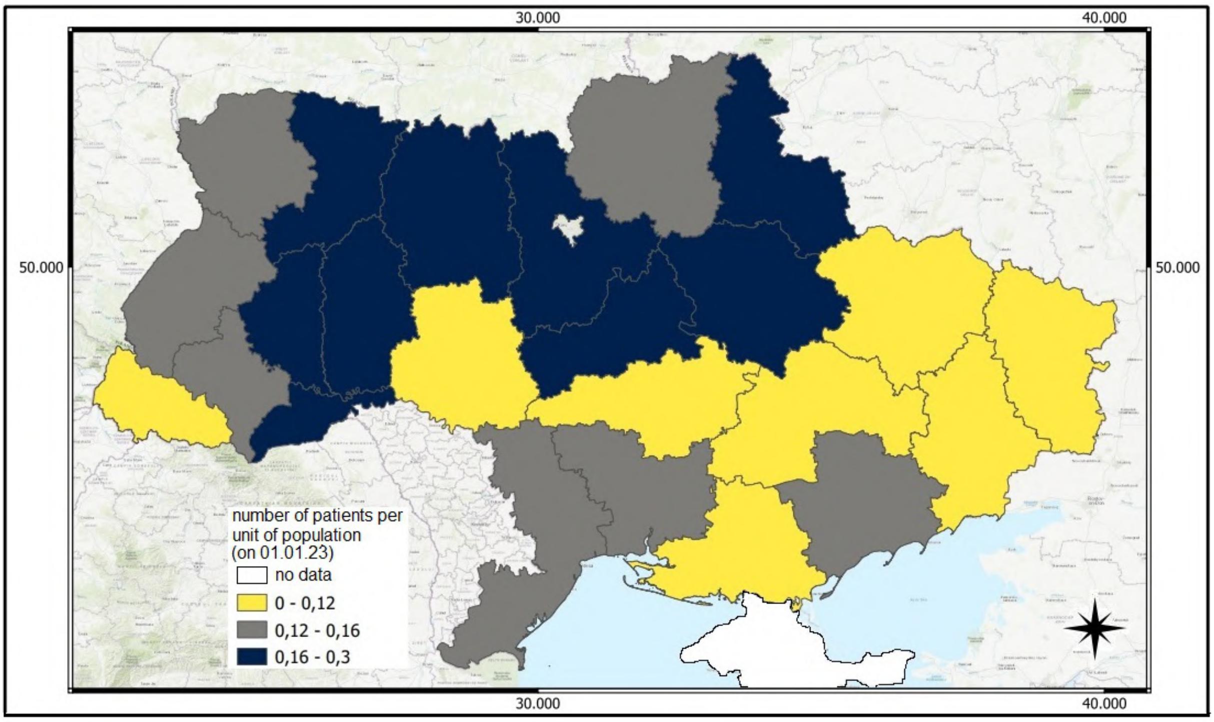

Figure 7. Horopleth map of the distribution of the number of detected cases of infection with COVID-19 by the number of the population in Ukraine at the end of the pandemic (data as of March 9, 2023).

higher than the average, and in Mexico and Peru, they are almost 200 thousand deaths higher. This demonstrates the different levels of healthcare systems in these countries.

The map showing the spatial differentiation of mortality from COVID-19 looks radically different (figure 8). This indicator shows the number of deaths from the coronavirus relative to the total number of patients from the pandemic for each country. In fact, this indicator demonstrates the effectiveness and accessibility of the social security and health care system in countries around the world.

The average death rate from coronavirus in the world was 0.99%. Most countries in Africa and Latin America have the highest mortality rates. Anti-leaders: Peru – 4.92%, Mexico – 4.37%, Yemen – 18.07%, Sudan 7.89%, Egypt – 4.77%, Liberia – 3.65%, Ecuador – 3.37%, etc. With low and very low rates of total COVID-19 cases, almost one in twenty people who contracted the coronavirus died on average in these countries. This illustrates the inability of the healthcare system in these countries to cope with such an epidemiological burden.

For comparison, the mortality rate in South Korea is 0.1%, Qatar – 0.15%, Japan – 0.22%, Denmark – 0.28%, etc. These countries have developed social security and health care systems that have coped with the epidemic even during the peak stages of overload due to the pandemic.

In Ukraine, there is also a high correlation between the number of detected cases of COVID-19 infection (figure 5) and the number of deaths from the disease: the regions with the highest number of cases have the highest number of deaths. For example, out of the 112478 deaths from coronavirus in Ukraine as of 29.06.23, 9.1% (10187 deaths) were recorded in Dnipropetrovsk region, 6.6% (7404 deaths) in Kharkiv region, 6.2% (6931 deaths) in Lviv region, and 5.5% (6206 deaths) in Odesa region. Accordingly, the lowest rates were recorded in Kirovohrad (1936 deaths, 1.7%) and Ternopil (2482 deaths, 2.2%) regions.

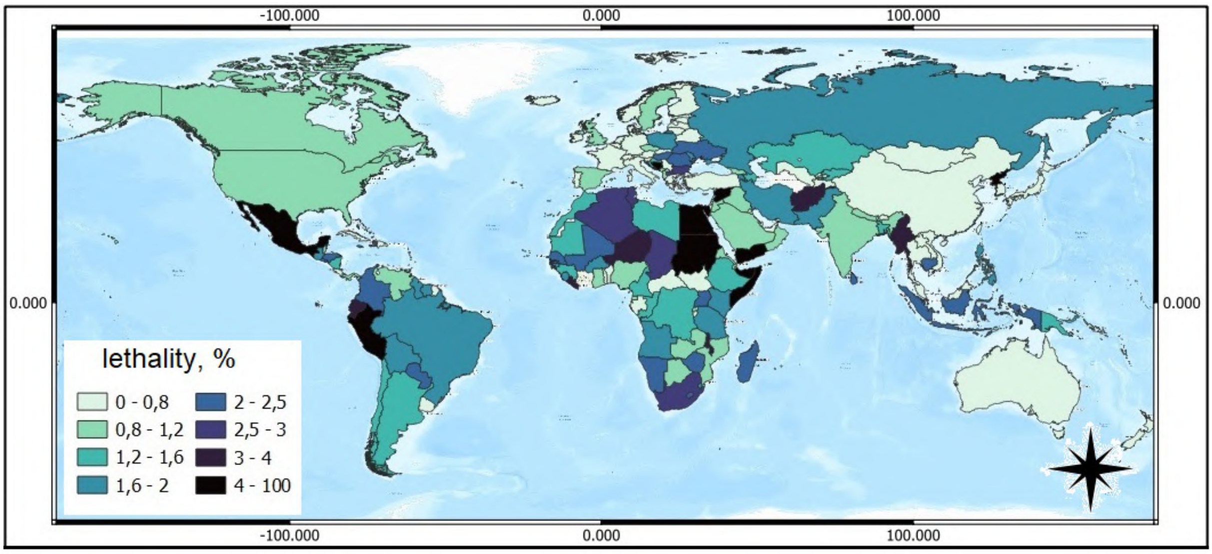

Figure 8. Horopleth map of the distribution of the lethality rate from COVID-19 in the world at the end of the pandemic (data as of March 9, 2023).

As of 29.06.2023, the coronavirus mortality rate in Ukraine averaged 2.02%, which is more than twice the global rate (0.99%). The highest mortality rate from coronavirus was recorded in Kirovohrad (3.27%), Luhansk (2.98%), Dnipro (2.74%), and Kherson (2.65%) regions. The lowest rates were recorded in Rivne (1.37%), Ternopil (1.47%), and Volyn (1.57%) regions. As a result, there is a pronounced spatial differentiation of COVID-19 mortality rates on the map of Ukraine (figure 9): the southeastern and eastern parts of the country have the highest mortality rates (over 2.3%), and the northern and northwestern parts have the lowest (less than 1.7%). The rest of Ukraine has average rates.

Ukraine is characterized by a correlation between the number of infected people and COVID-19 deaths by region (correlation coefficient +0.85): mortality in the regions increases in direct proportion to the number of infected people. However, there are regions where this relationship is significantly disrupted. For example, mortality in Zaporizhia region is almost 2000 people higher than the average correlation, in Donetsk region – 1800 people, in Dnipropetrovsk and Kirovohrad regions – 1000 people, etc. At the same time, in Odesa region, the mortality rate is more than 2000 people lower than the calculated one. This demonstrates the different capacity of the health care system in the country's regions.

According to the quantitative characteristics of the two main indicators of the epidemiological course of the COVID-19 pandemic (the number of detected cases and mortality), all regions of Ukraine (except for the temporarily occupied territory of the Autonomous Republic of Crimea) can be divided into four groups (figure 10):

Group I (Zakarpattia, Chernihiv, Kirovohrad, Kherson, and Luhansk region) – regions with the lowest number of patients with coronavirus infection (less than 150000 people) but with an above-average mortality rate (< 2%). With their low population density, these regions have demonstrated difficulties in the healthcare system's ability to withstand such an epidemiological burden.

Group II (Sumy and Cherkasy region and most regions in the western part of Ukraine: Volyn, Rivne, Zhytomyr, Ivano-Frankivsk, etc.) – have the lowest mortality rate (> 2%) with average numbers of detected cases (< 150000; > 250000). These are the regions with the best epidemiological situation of the pandemic.

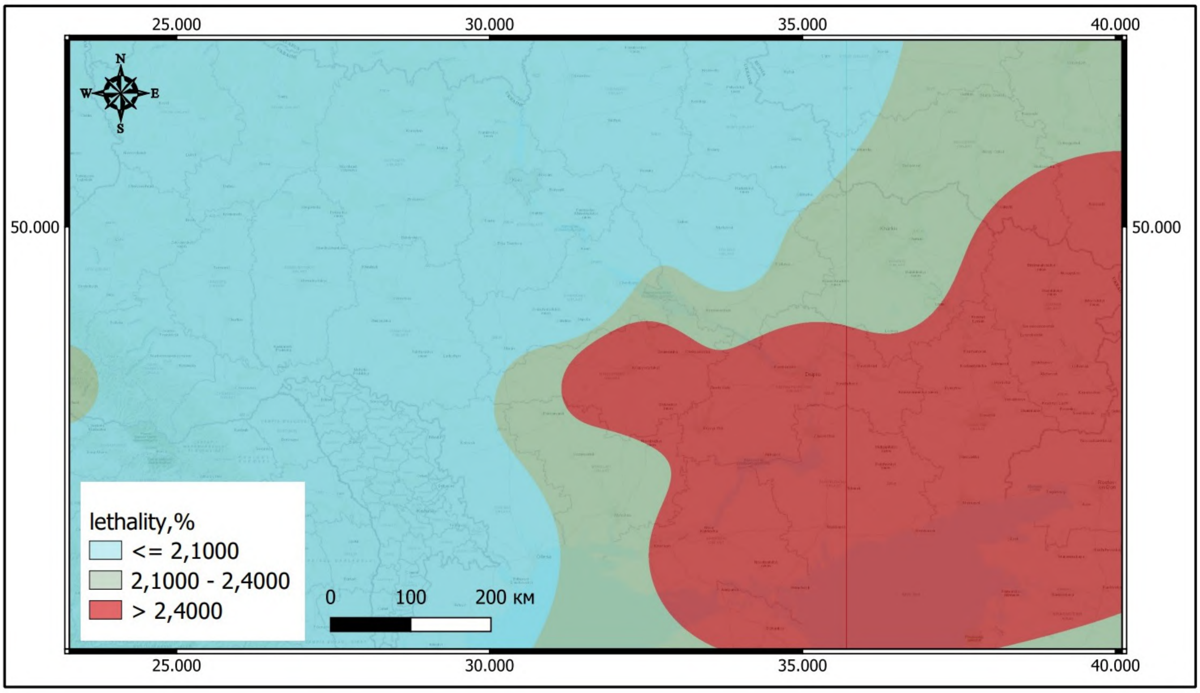

Figure 9. Map of spatial analysis of changes in the indicator of lethality to COVID-19 in Ukraine, based on the use of the incremental method (IDM).

Group III (Chernivtsi, Vinnytsia, Mykolaiv, Poltava, Zaporizhia and Donetsk regions) – characterized by mortality rates above 2%, with an average number of detected cases (< 150000; > 250000).

Group IV (Kharkiv, Dnipro, Kyiv, and Lviv regions) – regions with the highest mortality (< 2%) and morbidity (< 250000) in Ukraine. These are the regions with the highest population density and, accordingly, the most difficult epidemiological situation.

The course of the pandemic in Odesa region should be noted separately. With the largest number of detected cases (almost 360000), the mortality rate in the region was recorded at 1.74%. This can be explained by the most favorable climatic and environmental conditions in the region.

Based on the results of the geospatial analysis, a zoogeographical map of Ukraine's zoning according to the epidemiological course of the COVID-19 pandemic was constructed (figure 11), which reflects the spatial differentiation of the pandemic parameters, which is associated with various and multidirectional factors that determine the course of the epidemic, the main ones being:

A. *Population density.* Regions with the highest population have the highest morbidity and mortality rates.

B. *Spatial mobility of the population.* External and internal migration of the population has had a significant impact on the spread of the disease.

C. *Peculiarities of regional management.* The development of the epidemiological situation was largely determined by the quality of management decisions made by regional and city authorities (the state of the health care system, the behavior of the population during the lockdown, holding mass events, etc.)

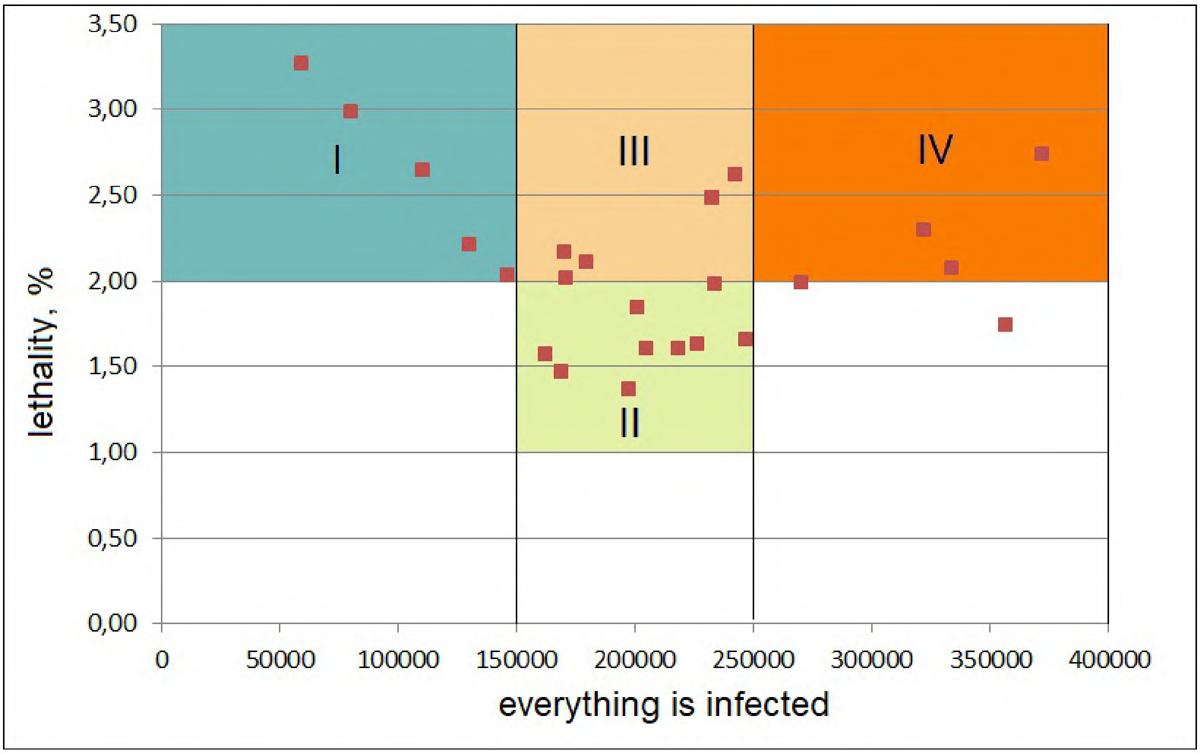

Figure 10. Classification of regions of Ukraine based on indicators of epidemiological transition of the COVID-19 pandemic.

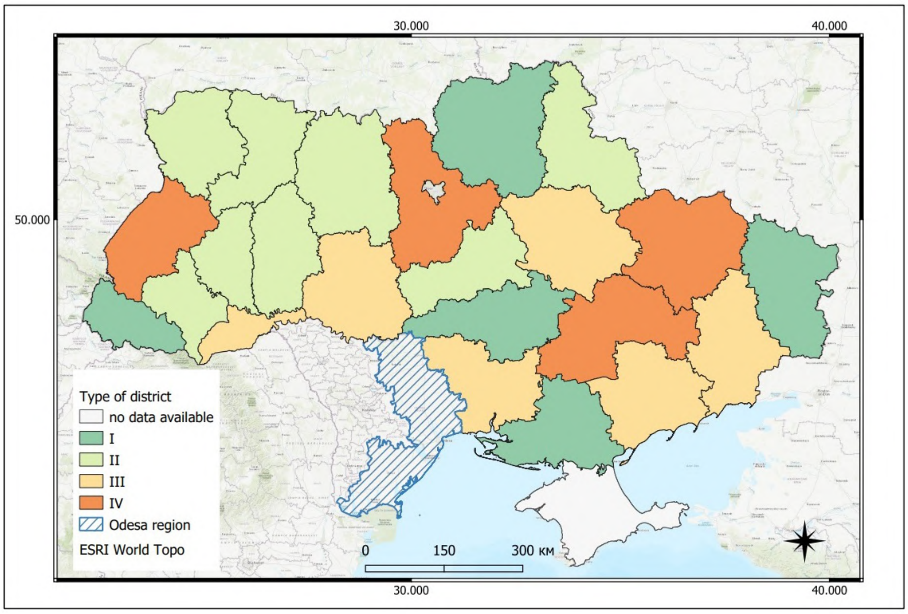

Figure 11. Map of the zoning of Ukraine according to the epidemiological course of the COVID-19 pandemic (classification indicators for each group are shown in figure 10).

4. Conclusions

The study of the geography of the COVID 19 pandemic in Ukraine and the world has led to the following conclusions:

1. The COVID-19 pandemic has its own geography, which is manifested in the spatial and temporal model of regional development.
2. The global nature of the coronavirus pandemic makes it impossible to study its development in a single country in isolation from global realities. Comparison of the dynamics of growth in the number of detected cases of coronavirus infection in the world and Ukraine shows that the pandemic is wave-like, but the amplitude, period, and length do not coincide in most cases. However, the genesis of these waves is the same.
3. Each of the waves of the pandemic in Ukraine had its own characteristics:
   - during the first wave, carriers of the coronavirus – Ukrainian workers from European countries – played a major role in the spread of the disease, who began arriving in big amountsin the western regions of the country after the announcement of lockdowns in Europe;
   - high population density in a number of regions, as an indirect indicator of social contacts, was the main factor in the spatial differentiation of pandemic indicators during the second wave;
   - a characteristic feature of the third wave is the spread of the disease from the center to the periphery, not only across the country as a whole, but also within regions; it is associated with the spread of the Delta strain and is characterized by high rates of disease, without a significant increase in mortality;
   - the fourth wave was distinguished from the previous ones by a very rapid rise and rapid decline, it is associated with the Omicron strain; its peculiarity is the highest incidence rate with the lowest mortality rate.
4. Significant spatial and temporal differentiation of the pandemic parameters is associated with diverse and multidirectional factors that determine the course of the epidemic and the spatial differentiation of its indicators.

Abstract. The development and digitalisation of modern society have created the necessary preconditions for the emergence of new hobbies and sports. Esports has become an integral part of society and is officially recognised at the state level in several countries, including Ukraine. That is why the question arises of the emergence of esports arenas as a new type of architectural typology of public buildings and structures. This publication is devoted to studying the peculiarities of functional zoning of esports arenas, considering the concept of sustainable development of the territory. The article analyses existing esports arenas, computer clubs in the world and Ukraine, and approaches to the organisation and functioning of esports championships. The needs of players and spectators for creating a comfortable space and convenient functional planning of esports arenas are investigated, considering the concept of sustainable development of territories. The proposed solutions are analytical and conceptual, requiring a detailed development of constructive, architectural and design solutions, considering the current standards for public buildings and structures.

1. Introduction

Rapidly developing modern technologies provide unlimited opportunities for finding new solutions and innovations in developing Ukrainian architecture. Recently, eSports, which improves and trains mental and physical skills, has gained momentum, being a mass spectacle with innovative technical aspects and information technologies. The digitalisation of society and the development of information technology have led to the need for entirely new facilities, such as an esports arena. When designing and building such facilities, it is necessary to use the main provisions of sustainable development of territories based on the unity of economic, social and environmental components of the concept to meet the modern needs of humanity and protect the interests of future generations.

An analysis of the competition procedure, requirements for technical equipment and facilities, the current state of buildings and facilities used for esports championships, and the constant growth in demand and the number of teams revealed the inadequacy of existing facilities, such as concert halls and sports stadiums, and created the prerequisites for a functional zoning study for the design and construction of an esports arena that would meet the modern needs of society, taking into account the requirements of sustainable development of territories.

There are few newly created and operating esports facilities in the world. At the same time, a significant number of facilities are currently in the process of planning, modernisation, development and implementation. The volumetric and spatial structure and functional zoning solutions for existing and future esports facilities are insufficient in Ukraine and, therefore, require careful analysis and research as a new type of public facility.

Esports facilities are an innovation in architecture. Until recently, architectural objects such as an esports arena (cyber arena) did not exist but were implemented as an option for expanding and modernising such facilities as computer clubs. However, more is needed for modern technologies and championships. Publications and research on zoning cyber arenas exist in related fields, including information technology, computer networks, cybersecurity, and sports. Therefore, it is relevant to find new scientific solutions and construction and architecture technologies for implementing such technologically innovative structures, considering the concept of sustainable development of territories.

Therefore, the purpose of this publication is to study the peculiarities of functional zoning of esports arenas by analysing existing esports arenas, computer clubs in the world and Ukraine, approaches to the holding and functioning of esports championships, and the needs of players and spectators to create a comfortable space and convenient functional planning, taking into account the concept of sustainable development of territories.

2. Theoretical background

Today, esports is developing rapidly, requiring new training and competition areas. Many countries worldwide pay attention to esports and create cyber arenas for training and competitions [1–4]. In Ukraine, many computer clubs and cyber arenas, including international ones, serve as training grounds and venues for competitions.

An esports arena is a multifunctional building with special requirements for functional planning. The physical dimensions of such a facility and functional zoning are determined based on the location and are related to the requirements of the concept of sustainable development of territories.

Given the rapid development of the digitalisation of society and the development of information technology, it can be stated that modern architecture is characterised by a continuous process of creating new types of architectural objects, the vast majority of which have a short life cycle [5]. Buravchenko and Barmashina [5] presented a new paradigm of architectural topology, the essence of which is the use of three "alternative to traditional typologies of the latest directions of the methodology of forming architectural objects" [5], namely the use of the parametric (scenario) method, the methodology of analysing types of architectural environment and typological differentiation. When designing this kind of building, it is necessary to explore the possibilities of its multifunctional purpose (formation of a multivalent space).

Creating a multivalent public space surrounded by mono-functional enterprises integrated with an esports arena, taking into account the concept of sustainable development, is significant scientific research in the field of the architectural environment [6–9]. Buravchenko [6] presents approaches to creating a universal methodology for designing multivalent public spaces with cyclical function changes. The author conducts a study of urban space optimisation with the aim of optimising and functional zoning for each specific period of the year and predicting its use for the interests of different communities.

Considering the conceptual provisions of Ukraine's Sustainable Development Goals [7] implies compliance with specific requirements for developing new territories. Among them are the preservation of the environment and natural resources and the creation of social benefits. When developing design solutions, it is necessary to consider the achievements of modern science and technology, information technology, the level of informatisation of society, and the architectural environment [8, 9].

Architectural solutions for the design of esports arenas are developing quite rapidly, particularly in Asia, the USA, and Europe. Dorosheno and Titova [10] presents a study on identifying an esports arena's architectural components and briefly describes architectural planning.

3. Results

Computer technology has reached a new level in technical fields and the gaming industry. As computer games became more accessible, Internet clubs emerged, allowing several gamers to play simultaneously online. These clubs also began hosting gaming competitions, bringing spectators and participants together. As the alternative universe gained more and more popularity among young people, gamers began to find venues for tournaments, as there was not enough space in online clubs.

The events currently taking place in Ukraine hurt the architecture of cities and villages. The destruction of buildings, architectural monuments, and other structures negatively impacts the architectural environment and requires the development of restoration, reconstruction, and development projects. Ukraine currently needs many vital resources but will need even more after the war ends. Resources are needed to rebuild cities, infrastructure, and many other economically important factors.

A multifunctional complex combines the necessary buildings and structures into one whole, minimising the time spent moving from one place to another. This is especially important in a large city, creating a single cultural, sports, and recreational centre for the community.

Esports facilities are an innovation in architecture. Until recently, architectural objects such as esports (cyber arena) did not exist, but they were implemented to expand and modernise facilities such as computer clubs. However, more is needed for modern technologies and championships.

The following aspects should be taken into account when designing a multifunctional complex with a cyber arena:

- location: analyse where the complex will be located;
- functional content: analyse the needs of the city's population;
- planning: to create planning solutions based on the analysis of the needs of cyber competitors, spectators, and requirements for competitions and training;
- integration: to determine the type of facilities, their number and purpose, methods and technologies for combining several structures and buildings into a single complex;
- safety: to provide civilians with quickly accessible and comfortable shelters, as well as to make them accessible to people with limited mobility;
- sustainability requirements: to provide an environmentally friendly, comfortable to use and favourable for development and living environment with architectural and design solutions;
- environmental safety: selecting materials for construction, design, and finishing that are environmentally friendly, durable, and high-quality.

We will analyse foreign and domestic design experience to implement the design of a multifunctional complex with a cyber arena.

An essential aspect of the recovery is public facilities where people can develop, do their own business, work, and relax, which is considered a whole life. It is worth noting that many people who have been forced to leave the territory of Ukraine and live abroad should return to Ukraine. To do this, it is necessary to create comfortable living and development conditions, considering the modern needs of young people. An analysis of the latest youth trends and preferences shows the diversity of their interests, among which eSports occupies a special place. Therefore, building a modern multifunctional complex with a cyber arena is essential.

Let us analyse the experience designing and implementing esports facilities worldwide and in Ukraine. To begin with, let us look at Blizzard Arena Los Angeles (Burbank, California, USA), which was included in the ranking of the world's best cyber arenas, the interior of which is shown in figure 1. It was here that Overwatch League tournaments were held. The arena was quite famous, but at the same time, its main drawback was the small capacity of the spectators; only 450 people could attend the match, although thousands of online viewers gathered during the broadcast of the tournaments. The area of the arena is 6875 m^2, and the central stage area is 1000 m^2. In the centre of the stage, a 13,000-pixel wide LED screen was installed to show the game's events, with an LED halo above the stage showing the progress of the upload during each round of Overwatch. The audience's proximity to the centre stage and a vast skybox was a unique feature. Given the specifics of holding esports games, matches and tournaments and the need to broadcast them, an essential aspect of the design is the support area (control rooms, sound rooms, communication rooms, server rooms, and observation rooms).

Figure 1. Interior of Blizzard Arena Los Angeles [4].

In 2010, one of the first esports arenas in the world was opened in Ukraine, which became the impetus for the massive construction of similar arenas around the planet, the interior of which

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012043 doi:10.1088/1755-1315/1415/1/012043

is shown in figure 2. This arena can accommodate about 3000 spectators, which generally meets the needs of the audience. The building of the Kyivsport Arena consists of:

- entrance area;
- a corridor leading to the main hall;
- main hall with an area of 1500 m^2;
- gambling shops;
- A commentary booth is located in the hall.

This arena had a dual purpose: it was used as a computer club and a venue for gaming championships. The main hall was mainly equipped as a gaming club, based on individual computer seats, and there was also a screen for broadcasts with a small number of seats for spectators. For large-scale championships, the main hall was arranged in such a way as to create the most comfortable conditions for participants and spectators, reducing the number of computer seats. A significant drawback of this arrangement is the players' need for more sound insulation. One solution to this problem was using sound-absorbing headphones, which only partially satisfied the teams.

Figure 2. Interior of the Kyiv Esports Arena [4].

Arlington Esports Stadium (figure 3) is the first full-fledged esports arena that meets all the needs of both gamers and spectators. It was opened in 2018 in the state of Texas.

It is divided into functional areas according to their purpose and includes

- team area
- lounge area for teams
- training rooms
- media zone
- area for communication with fans

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012043 doi:10.1088/1755-1315/1415/1/012043

Figure 3. Interior of the Arlington Esports Stadium [4].

- shop area
- gamer gallery
- auditorium
- production area
- VIP area
- zone for content creation
- technical zone

An essential factor of the competition is the availability of an individual recreation area for participants and guests. That is why the advantage of Arlington Esports Stadium is its location next to the sports complex and hotel.

Spodek Arena is an arena that serves as a hockey stadium and is currently used for esports tournaments in Katowice. It has a capacity of 11-12 thousand spectators, but 2017 at the Intel Extreme Masters Grand Final, it accommodated about 170 thousand spectators. The interior of the arena is shown in figure 4.

One of the most widespread cyber arenas located in Las Vegas is Esports Arena Las Vegas (figure 5). Its area is more than 9000 m^2, and the interior is shown in figure 5 and figure 6. This multi-level arena has a competition area, a zone for daily tournaments, modern broadcast and production studios, VIP rooms and telescopic seats. The arena also features the interactive zone “History of Gaming Dome”. It includes retro games and a gaming platform.

With the opening of Esports Arena Las Vegas, a new standard of professional sound in the gaming industry has been set, which delights gamers and their fans. Shops are located on the territory.

Gaming seats, broadcast stands, and retail outlets are located in the central hall of this area.

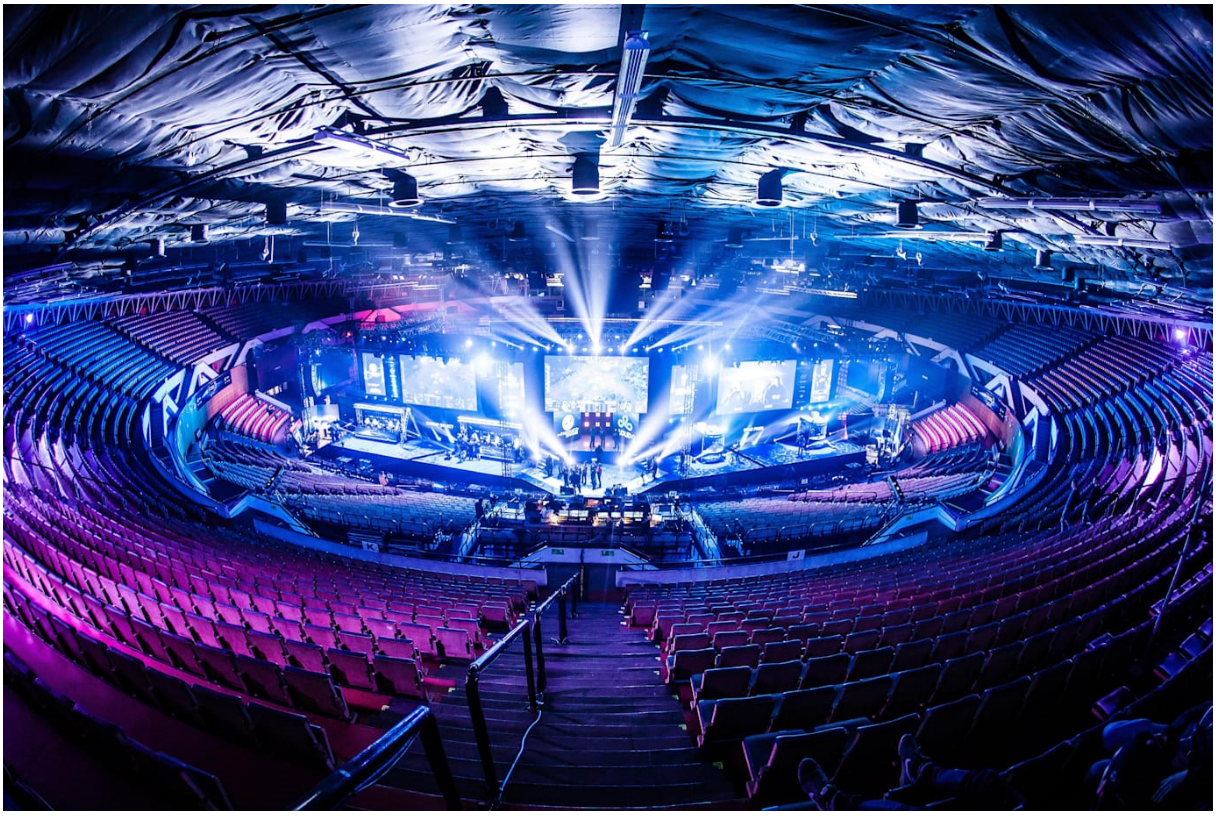

Figure 4. Spodek Arena interior [4].

Such a high demand in this area demonstrates the relevance of this problem and the prospects for developing esports as an independent area of architecture and design, which requires streamlining regulations and standards for the design and construction of facilities in this area.

Visitors to esports arenas are divided into the following groups: regular, unique visitors, and athletes. The regular attendance group includes employees of the complex and visitors who come regularly, regardless of the championships. Unique visitors are those who come to the championships and festivals. Esportsmen can come to championships and festivals or stay and train seasonally.

As a result of the study, we identify the main functional areas for a cyber arena, namely:

- The main arena, including the stands, stage, and commentary room. The tribune should be divided into two parts. Each team consists of 5 people: one coach and one technical support. The team should sit facing the audience.
- Training centre (often used for qualifying tournaments).
- Rooms for players (boot camps) must be soundproofed and equipped with climate control, but it is not mandatory to have window structures. Since a boot camp is designed for one team (7-8 people), an esports complex needs two.
- The lounge area is a recreation area that should be located near the players' room and can sometimes be included in the boot camp.
- Common areas.

Common areas include:

- Shops.

Figure 5. Esports Arena Las Vegas [11].

- A place for photo shoots.
- Dining room.
- Marketing area.
- Technical rooms: central server room; room of system administrators, engineers and programmers who serve them; media centre (video broadcasts); server room with special equipment; sound and light department.
- Lobby.
- Wardrobe.
- Storage rooms.
- Administrative premises.
- Bathroom for visitors.
- Bathroom for players.
- Changing rooms for teams.
- Medical rooms.
- Cafe area.
- Halls for special physical training.

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012043 doi:10.1088/1755-1315/1415/1/012043

Figure 6. Esports Arena Las Vegas [11].

Given the need for a constant power supply, it is essential to consider alternative ways of connecting to the electricity supply. As a rule, teams rent separate apartments or hotels for accommodation, install computers, and connect high-speed Internet. When designing an esports complex, it is worth considering a hotel as a complex component. It is also mandatory to have a psychologist's office. An analysis of the approaches to constructing the world's famous cyber arenas has identified several functional features of buildings and structures and the need to consider Ukraine's Sustainable Development Goals when designing them. This study will serve as a basis for further design of esports arenas.

The main goals in designing cyberspace are:

1. To create a comfortable environment, taking into account the needs of athletes, athletes, spectators, visitors, and staff, paying attention to internal and external features, as well as design elements of the architectural environment.
2. The design of this building should be open and bright, and adaptable to changes in the

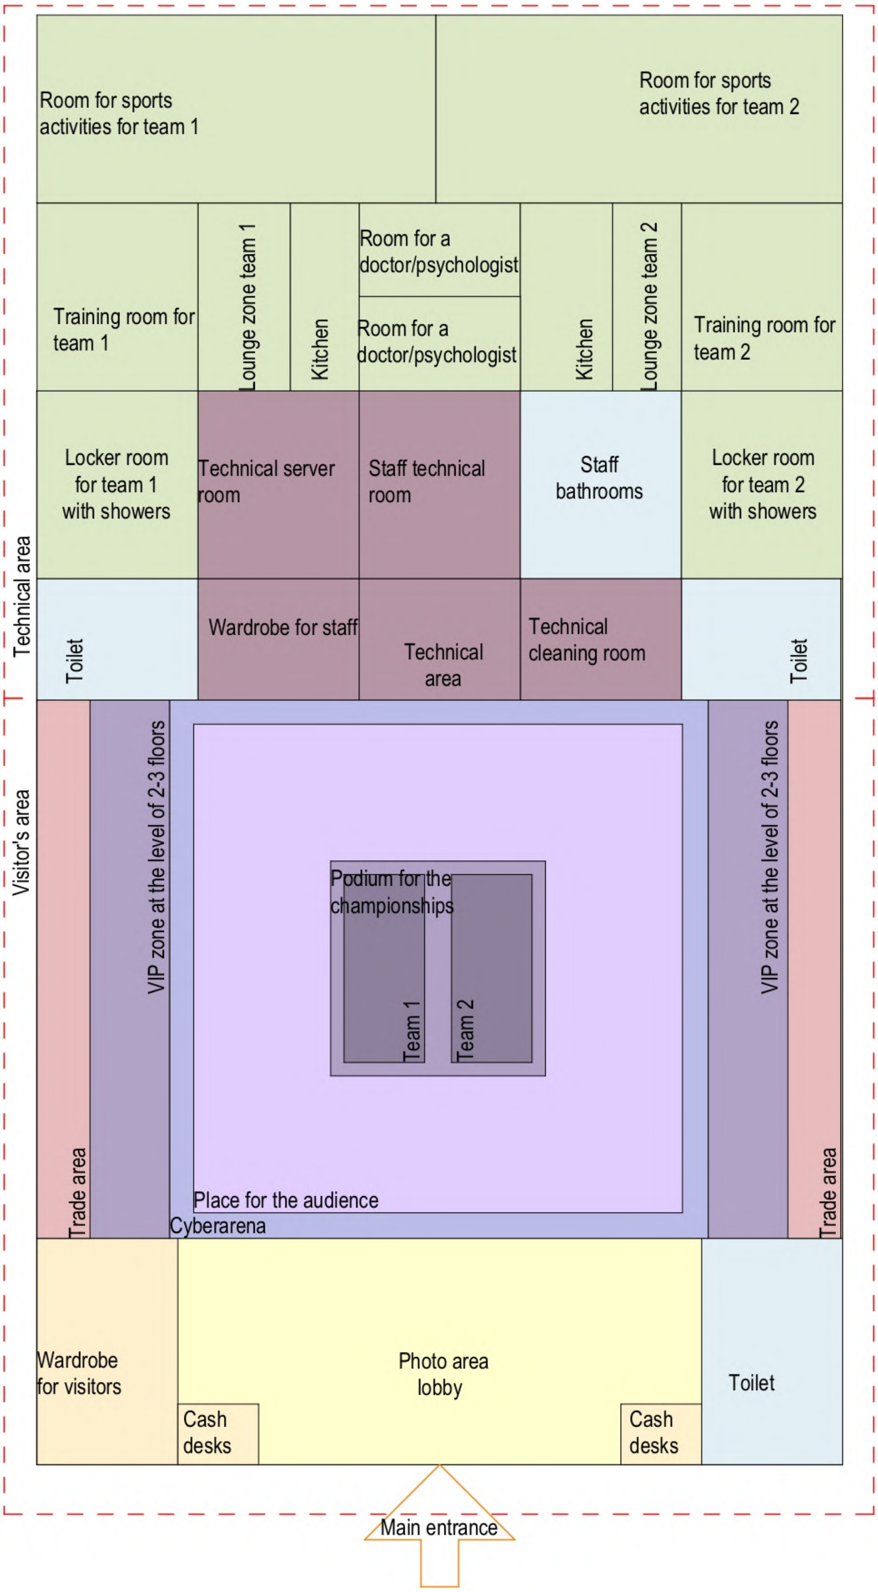

Figure 7. Scheme of functional zoning of the cyber arena (option 1).

functional purpose of the building.

3. Provide a vast visual space for a large number of people to stay together, as well as separate rooms for VIP areas.
4. It is also necessary to provide a zone of greenery in order to provide a comfortable environment for visitors and reduce the emotional stress of players.
5. The arena, training rooms and the room for teams to participate in the tournament should be soundproofed to ensure fair play.
6. It is necessary to think about a certain tendency to change the configuration of the arena for premises for various purposes.
7. It is necessary to provide a full-fledged place of residence for participants of championships

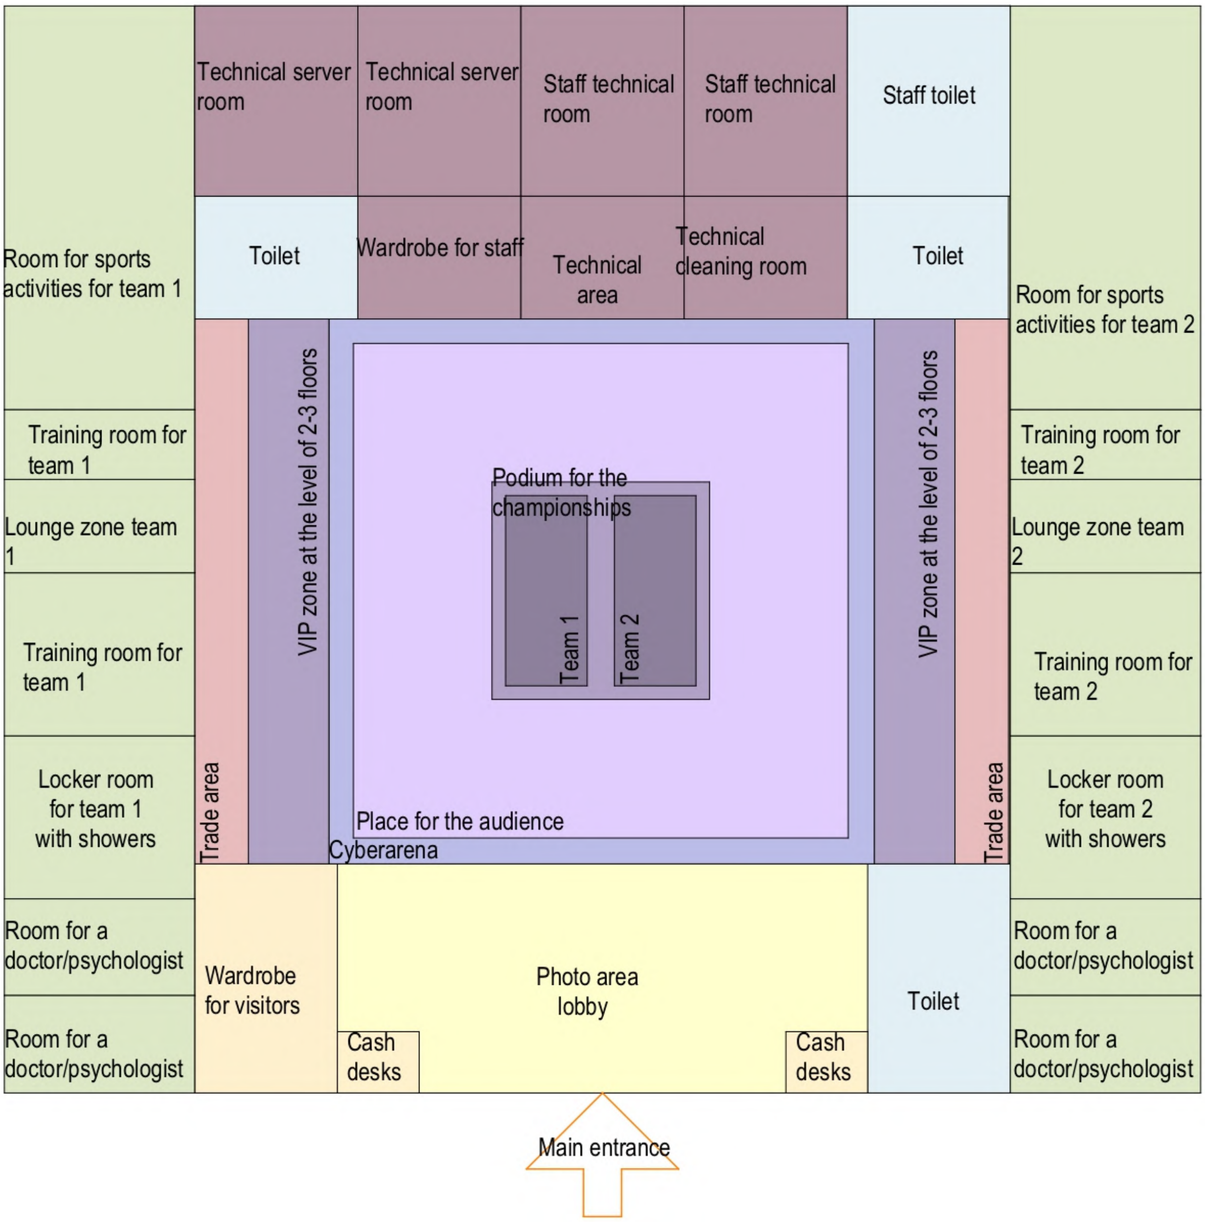

Figure 8. Scheme of functional zoning of the cyber arena (option 2).

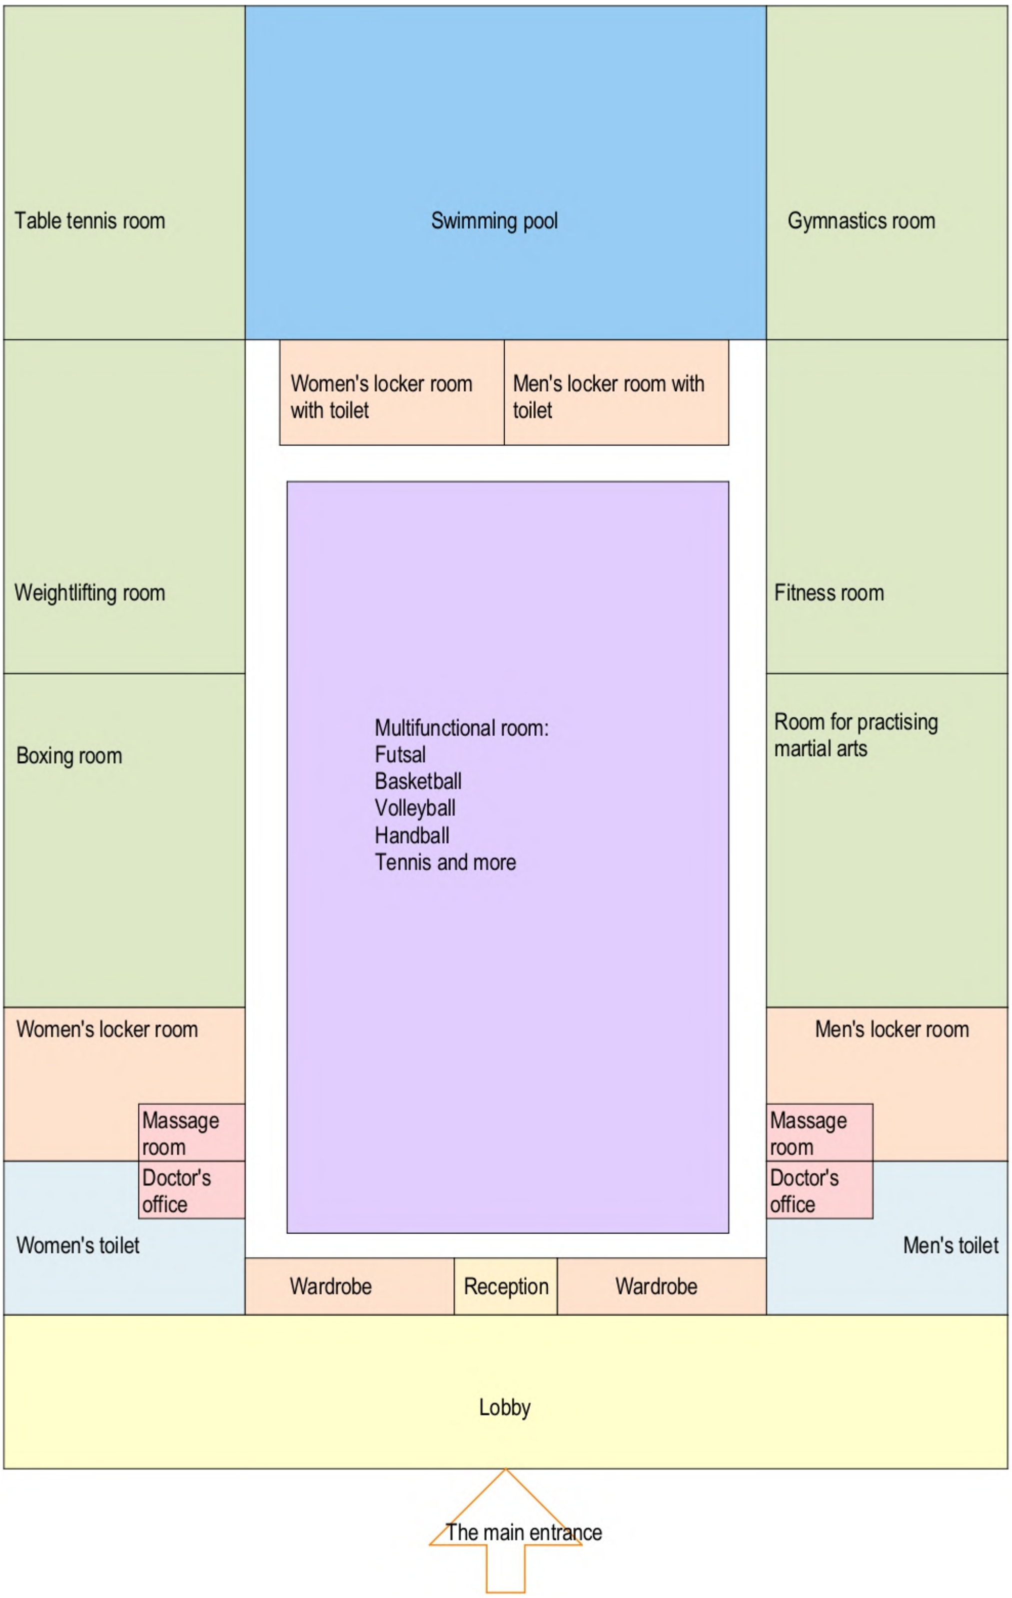

Figure 9. Functional zoning scheme of a sports complex with a multifunctional hall.

of various profiles, including esports.

8. Develop the necessary number of technical premises to ensure the functioning of the arena.
9. It is necessary to provide for the broadcast of events at the arena in the premises located inside and outside the arena and in the complex's parking area.

Taking into account the results of the analysis, current requirements, and identified features, three variants of the functional zoning scheme of the cyber arena were developed (figure 7, figure 8).

In the future, these schemes will be used as conceptual ones. We are developing a functional zoning scheme for a sports complex with a multifunctional hall for further research to find the optimal design solution, figure 9.

4. Discussions

The proposed solutions are analytical and conceptual, requiring more detail. In particular, the following issues require attention:

- researching approaches to the functional zoning of the interior and exterior of the esports arena;
- development of structural and electrical solutions taking into account the current level of science and technology;
- research of methods, algorithms, information and telecommunication technologies in order to create modern technical equipment for esports arenas for improvement;
- ensuring the protection of information for the proper functioning of such facilities;
- research of the processes of developing a master plan;
- development of a heating and ventilation scheme with the use of modern materials, approaches, and energy-efficient energy sources;
- conducting a feasibility study to optimise capital and operating costs.

5. Conclusions

Esports has become an integral part of our lives, directly influencing the development of other industries, especially architecture. The esports complex project's main objective is to meet society's needs and provide the most comfortable conditions for competitions and leisure. These are all prerequisites for the emergence of a new division in architecture in the field of esports.

Having analysed the specifics of esports competitions, we can identify the following functional features: the presence of a screen, which is the basis of any cyber arena and should be located without blind spots. Given the duration of the championship, there is a need for recreational areas for both visitors and players. Special attention should also be paid to the player's mental and physical health (one game lasts up to 12 hours). At professional competitions, players are isolated from spectators, so there is a need for additional rooms or acoustic booths.

To ensure the technical side of the esports complex, it is necessary to equip the building with server rooms, high-speed Internet and alternative power supply. It is also necessary to consider electrical outlets and a WIFI network for visitors.

Abstract. The production of vegetable and melon crops is one of the most labour-intensive branches of agricultural production. Production volumes depend not only on growing conditions, but also on the quality of seed material. A resource-saving method of extracting cucumber and melon seeds and a separator that allows its implementation are presented. The design feature of the separator is a combination of vibration and inertial modes. The use of a separator, which has a combination of the mentioned modes in the technological process, allows to significantly improve the quality of separation of seeds from the peel and pulp. Thus, at the next stage, when washing the seeds, it is possible to reduce the amount of water, using the technology of a complete closed cycle of cleaning for reuse. The scheme of the technological process of cucumber and melon seed separation, which is used to implement a resource-saving method, is presented. The main factors and optimization criteria were determined, according to which the quality assessment of the technological process of cucumber and melon seeds separation was carried out using the proposed constructive solution. The ranges of the optimal combination of independent factors are determined. Using a resource-saving method of extracting cucumber and melon seeds allows to significantly reduce water consumption when washing seeds and achieve an improvement in the quality of the technological process.

1. Introduction

The production of seed material of melon and vegetable crops is one of the most important problems that have arisen in the field of processing agricultural products. In the southern part of Ukraine, there were specialized farms for the production of seeds of vegetable crops. The volume of this production of cucumber and melon seeds was significant and provided seed material to almost all farms of Ukraine. Thus, the development of seed production of vegetable and melon crops, such as cucumber and melon, will provide an opportunity to provide the economy of Ukraine with seed material. High-quality seed material is one of the conditions for increasing productivity and reducing the cost of cultivated products, and well-organized seed separation in farms increases the production crops by 20 ... 25%.

Enhancing the sustainability of the food system begins with boosting food production [1]. Moreover, it is crucial to offer the theoretical underpinnings of the corporate interaction management technique [2]. Practitioners interested in learning more about various water engineering models and approaches, as well as their real-world applications and case studies, can find valuable information in economy of water in technological processes [3]. There are presented and discussed is the evolution of the key accomplishments in water-saving engineering solutions, with a focus on the key technologies [4]. Ukraine is among the top producers and exporters of agricultural production in the world, and expanding production and the economy can both benefit from market integration between Ukraine and the EU [5–7]. For the environmentally friendly production of agricultural production, it is crucial to optimise the technological processes [8]. Farmers may decrease their carbon footprint, cut greenhouse gas emissions, and boost sustainable productivity through climate-smart agriculture [9]. Melon selection process, which prioritizes quality, plays an important role in obtaining a quality product. A technique that uses the relationship between parameters to provide descriptions and actions in determining melon quality is used to describe, extract, and share semantic information [10]. The possibility of short-wave near-infrared spectroscopy for fruit classification issues is examined in the research. When fruit categorization automation is needed, an LED-based device with 770 nm, 840 nm, 910 nm, and 960 nm range LEDs can be employed [11].

The production of seeds of vegetable and melon crops in Ukraine is carried out in the conditions of agricultural enterprises and farms. The obtained seeds of above mentioned crops today do not meet the needs of agriculture, and this leads to the need to purchase seed material. Separation of seeds is carried out mainly on separators of the mechanical type: inertial, rotary or roller. It has found limited use in the seed production of vegetable crops. Flotation separation is practically not used due to high water consumption and significant material capacity of technological equipment. Pneumoseparation is energy-intensive and time-consuming when converting separators from one culture to another. Inertial and rotary separators have approximately the same productivity and quality indicators of the technological process. The use of one or another type of rotary separators is related to the specifics of obtaining seeds of the crop, the volume of its production and the technical security of the farm.

Due to the lack of special equipment, machines not designed for this purpose are often used in labor-intensive seed production processes, which in turn leads to large product losses. The efficiency of production processes of seed separation and finishing is very low. The main reason for this situation is the lack of scientific research to substantiate the principle of action, structural parameters and kinematic modes of machines and their working bodies. Information is often contradictory. This state is largely due to the lack of generalizing theoretical and experimental studies of the processes of separation and finishing of seeds, which, accordingly, affected the development of machines and technological lines.

An analytical summary of all the components of the complete cycle of cultivation and processing was produced, ranging from a detailed investigation of the characteristics of melon cultivation to studies on enhancing technologies to produce high-quality seeds. Erniati et al. [12], for instance, investigated melanoculture and the ideal conditions for producing material of superior quality. The growing parameters received special attention in this study, which monitored plant age, leaf area, plant height, relative humidity, air temperature, and radiometric solar intensity to forecast these parameters for the next two days.

Research on growing melon and vegetable crops as well as useful methods for extracting seeds has received a lot of interest. To satisfy the demands of contemporary agriculture, high-quality vegetable and melon crop seeds are necessary to cut expenses and do away with the necessity to buy them from outside producers [13]. Wahyudi et al. [14] focused on yield estimation of novel hybrid watermelon cultivars. It has been demonstrated that producing melon seeds within an agricultural business can boost output and revenue for growers of the fruit. An essential part of a plant breeding programme is the examination and selection of seeds. Kale et al. [15] investigated the impact of the mechanical and technological characteristics of vegetable and melon seeds on the ensuing seed quality, whereas Fayzullaev et al. [16] showcased the creation of a machine for planting vegetable and melon crops. Tests have demonstrated that the created machine satisfies all performance requirements and carries out the designated technological procedure with reliability.

According to Tlevlessova et al. [17], the shift from large-scale farming to small-scale home

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012044 doi:10.1088/1755-1315/1415/1/012044

growing has necessitated the introduction of cutting-edge scientific research and technology in order to produce high-quality seeds. The authors underlined that the shift in production from large agricultural operations to small private farms, which today account for over 90% of the total, is one of the major issues facing industrial melon seeds production. Simultaneously, small producers receive additional revenue from the transfer of output to the private sector, which could be their sole source of income. Private farms are more suited to the particulars of market interactions, as evidenced by the current state of affairs. A study was undertaken by Osuji et al. [18] to compare the processes of manual and mechanised seed separation for melon and vegetable crops. Using a press machine and a mechanical melon peeler, the seeds were peeled both manually and mechanically. It was determined how effective these devices were at extracting seeds. Out of all the automated procedures, the proposed design was the most productive. The cleaned seeds were assessed using technological and mechanical criteria. The results of the study demonstrated how important it is to select an appropriate variety, seed separator, and packing material in order to produce vegetable and melon seeds with optimal efficiency and quality. Kuchakorn et al.'s experiment from 2021 effectively separates ripe from unripe watermelons. The study focused on employing specialised equipment to determine fruit ripeness and if it was suitable for additional seed extraction [19]. The impact of native and germinated melon seeds on product quality is investigated in the paper [20].

Nascimento [21] pointed out that improving and preparing seeds can be a useful way to boost melon crops' survival rate. Particularly in cold climates, primed seeds perform better during germination. The author talks about a few factors of seed preparation and how they affect the germination and yield production of melon seeds [21]. Mazuela and Urrestarazu conducted experiments on improving the growing environment for vegetable crops in the context of studying the full cycle of vegetable and melon crops cultivation and seed production [22]. They noted that there is a need to increase the number of producers of vegetable and melon seeds. Getting hold of high-quality seeds contributes to higher yields, and grafting technology works wonders in lowering seed damage and yield losses. Lee et al. examined the topic of automating machines for cultivating vegetable crops [23]. The physical characteristics of vegetable crops have also been studied [24]. Thus, an essential component of the fields of food production and agricultural technology is the study of the physical characteristics of vegetable and melon crops and the methods used to measure them.

It is necessary to summarize the available experience in the development of machines for the complex mechanization of obtaining seeds of vegetable and melon crops, and on the basis of it to outline the main ways of developing and creating technological equipment. This will allow to increase the volume of production of seed material, will lead to a reduction of its losses in the process of production, storage and sale and ultimately will provide Ukraine with high-quality seeds. However, the creation of modern machines for the separation of seeds and technological lines that meet the requirements of modern production and belong to complex technical systems requires a deeper study of the interaction of working bodies with the processed product, the laws of the technological processes they perform, the dynamics and conditions of their operation. This task can be solved by conducting extensive theoretical and experimental studies of systematization and analysis of the achieved level of technical solutions. Thus, theoretical and experimental researches that allow to create modern, high-performance equipment for obtaining seeds of vegetable and melon crops are relevant and have an important national economic significance.

The aim of the article is to present the resource-saving method of extracting cucumber and melon seeds.

2. Methods

The methodology is based on the specific conditions for conducting experiments with the development and manufacture of the vegetable and melon seeds separator. To distinguish regular changes from random indicators, statistical methods of research and mathematical processing are applied [25]. For each experiment, 25..30 kg of crushed seed mass was selected, which was weighed, and the value of the selected weight was recorded in the log of laboratory and field observations. The main optimization criteria used to assess the quality of the technological process were: damaging of seeds (DS), purity of seeds (PS) and loss of seeds (LS). Their values must meet the following requirements:

- the amount of seed damaging should not exceed 5%;
- the value of seed purity should strive for the maximum level;
- losses should tend to the minimum value.

Before starting the experimental studies, the factors affecting the process were selected and the limits of their variation were indicated. In the initial stage of studying any object using the theory of experiment planning, it is necessary to conduct an a priory ranking of factors, which is performed by the method of expert evaluation (figure 1).

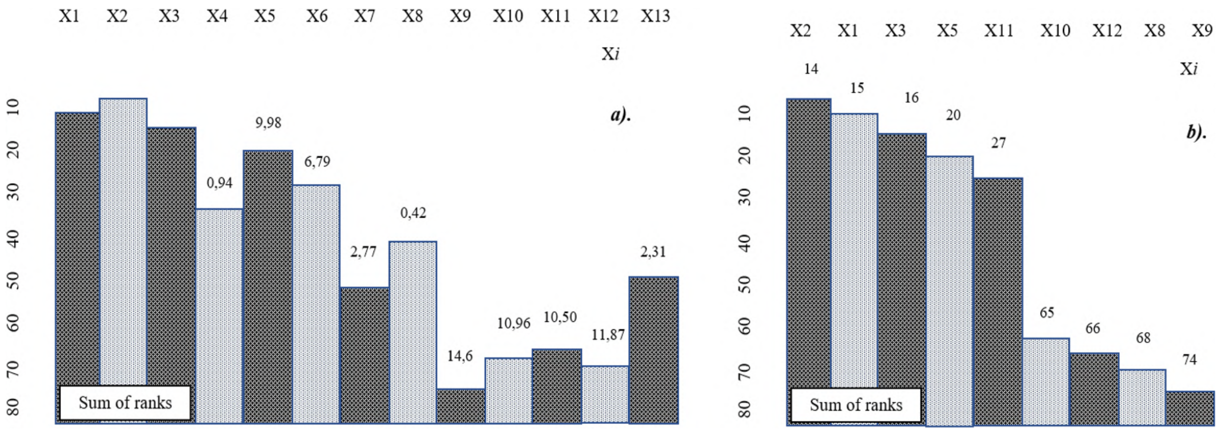

Figure 1. Ranking chart of factors affecting the quality of work A) to statistical assessment of the significance of factors; B) after ranking and determining insignificant factors.

There are the following factors:

X_1 – the angle of inclination of the sieve;
X_2 – frequency of sieve oscillations;
X_3 – amplitude of oscillations;
X_4 – level of mass supply for separation;
X_5 – the angle of application of driving force;
X_6 – the length of the sieve;
X_7 – sieve material;
X_8 – moisture of crushed mass;
X_9 – presence of cascades on the sieve surface;
X_{10} – coefficient of the live section of the sieve;
X_{11} – sizes of particles entering the separation;
X_{12} – shape of sieve holes;

X_{13} – the nature of the supply of crushed mass.

The amount of mass supplied to the separation (X_4) does not depend on the design of the device and is regulated by the initial requirements for development. The material of the sieve (X_7) and the moisture content of the separated mass cannot be changed in the process of experimental research and operation of the technological equipment. The first indicator is embedded in the design of the separator, and the second depends on the conditions before crushing. The method of supplying the crushed mass to the sieve cannot have a significant effect on the injury of the seeds, because the seeds have a high resistance to the perception of static and shock loads. After the analysis of the importance and waste of insignificant factors, the diagram of ranks was built until their value decreases in proportion to the degree of influence of one or another factor on the quality of the technological process. Rank level values are placed against the background of the chart columns. The analysis of the results of the expert assessment and their statistical processing allows us to conclude that the factors X_1, X_2, X_3, X_5, X_6 have the greatest influence on the progress and quality of the technological process. Factors $X_9 - X_{12}$ can be rejected and excluded during further research using the theory of experimental planning.

The levels of setting of independent variables (factors) and the range of their variation adopted during the experiments are given in the table 1.

Table 1. Levels and range of variation factors.

Factors	Levels of variation			Interval of variation	Dimension
	-1	0	+1		
X_1	-15	0	15	15	degree
X_2	100	300	500	200	1/s
X_3	10	30	50	20	mm
X_5	10	20	30	10	degree
X_6	1.0	1.5	2.0	0.5	m

In accordance with the experimental plan, an assessment of the dependence of technological process indicators on the frequency of vibrations of the sieve, the angle of its inclination, the amplitude of oscillations, the angle of addition of forced oscillations and the length of the separating surface, which have the greatest influence on the quality of the separator, was carried out. Repeatability of experiments for each of the optimization criteria – three times. In each line of the plan, the average value of DS, LS and PS was calculated. Experimental studies were carried out on seeds of cucumber (variety 'Konkurent') and melon (variety 'Ukrainka'). After statistical processing of experimental data, mathematical models describing the technological process were obtained.

3. Resource-saving method of extracting cucumber and melon seeds

There are presented the resource-saving method of extracting cucumber and melon seeds. It can be realized by the modernized construction of the cucumber and melon seeds separator the feature of which is the use of a two-screen sieve system. In the given system, the upper sieve separates the peel, and the lower sieve separates the seeds and pulp; the pulp and juice will be the by-product of the second sieve. The sieve, which performs an inertial movement, helps to extract the seeds associated with the peel. The technological scheme of extracting cucumber and melon seeds with experimental separator excludes stage of rubbing seeds that can prevent its damaging. The resource-saving method of extracting cucumber and melon seeds can help to reduce the amount of water needed for further washing of the seeds.

The separator is a system consisting of two sieves. With the help of the upper sieve, the coarse fraction of the crushed peel is separated, while the lower sieve separates the seeds. Other

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012044 doi:10.1088/1755-1315/1415/1/012044

fractions fall into the tray, namely pulp, pulp particles and juice. In order to reduce the loss of seeds in the peel fraction, it is advisable to use the mode of the inertial separator. Carrying out additional friction of the material against the edges of the holes in the peel fraction reduces the seed content. The mode of the vibrating conveyor for the second sieve is used to increase the passage of pulp through the sieve openings. There is presented the structural scheme of the cucumber and melon seed separator designed for cleaning seeds from pulp and crushed peel particles (figure 2). The technological process is as follows: the fruits are loaded with a special conveyor into the hopper 2 of the grinding chamber 3. Crushed by drums 4; 5 mass enters the sieve 10. The dimensions of the cells of the upper sieve for cucumber 5x15 mm. On its surface, the crushed peel (over-sieve product) is removed from the technological zone. Seeds, pulp and small pieces of peel equal in size to the seeds (product of grating) fall on the surface of the sieve of the second sieve 11 with the size of the holes. Seeds with impurities on its surface are fed for further cleaning, and pulp, juice and other small impurities fall into the tray and from it into pump 4.

The following adjustments are provided in the separating device:

- the rotation frequency of the cranks and, therefore, the frequency of the sieves oscillations was changed by V-belt variators 19; 20;
- the angle of inclination of the grating was changed by adjusting the length of hinged suspensions of sieves 12; 13;
- to change the length of the working part of the separating part of the sieve, partitions were installed along the movement of the technological product.

There are presented technological schemes of extracting cucumber and melon seeds with basic and experimental separator (figure 3). The second scheme excludes stage of rubbing seeds that can prevent its damaging and allows to significantly reduce water consumption when washing seeds and achieve an improvement in the quality of the technological process.

4. Results

In the course of the research:

- the factors that have the greatest influence on the quality of the technological process and are most amenable to regulation have been identified;
- an experimental setup with variable gratings and the ability to adjust the main parameters is presented;
- experimentally investigated the dependence of seed purity (PS), its losses (LS) and damaging (DS) on the frequency and amplitude of vibrations of the sieve, the angle of inclination of the sieve and the angle of application of the vibration force, as well as the length of the working zone of the separator.

The frequency of sieve vibrations, the amplitude of sieve vibrations and the length of the sieve have the greatest impact on the quality of the technological process. This is evidenced by the largest value of the coefficients for these factors in the regression equations. By equating to zero the value of the angle of inclination of the sieve and the angle of application of the force, the regression equations have the form:

$$PS = 65.519 + 2.802X_2^2 + 1.852X_3^2 + 6.507X_2 + 3.573X_6 - 0.645X_2X_3 + 1.572X_2X_6 + 1.209X_3X_6 \quad (1)$$

$$DS = 4.252 + 1.788X_2^2 + 1.522X_3^2 + 2.155X_6^2 + +0.387X_3 + 1.487X_6 - 0.987X_2X_6 \quad (2)$$

$$LS = 6.013 + 0.993X_2^2 - 0.907X_6^2 - 1.38X_3 - 1.948X_6 + 0.493X_2X_3 \quad (3)$$

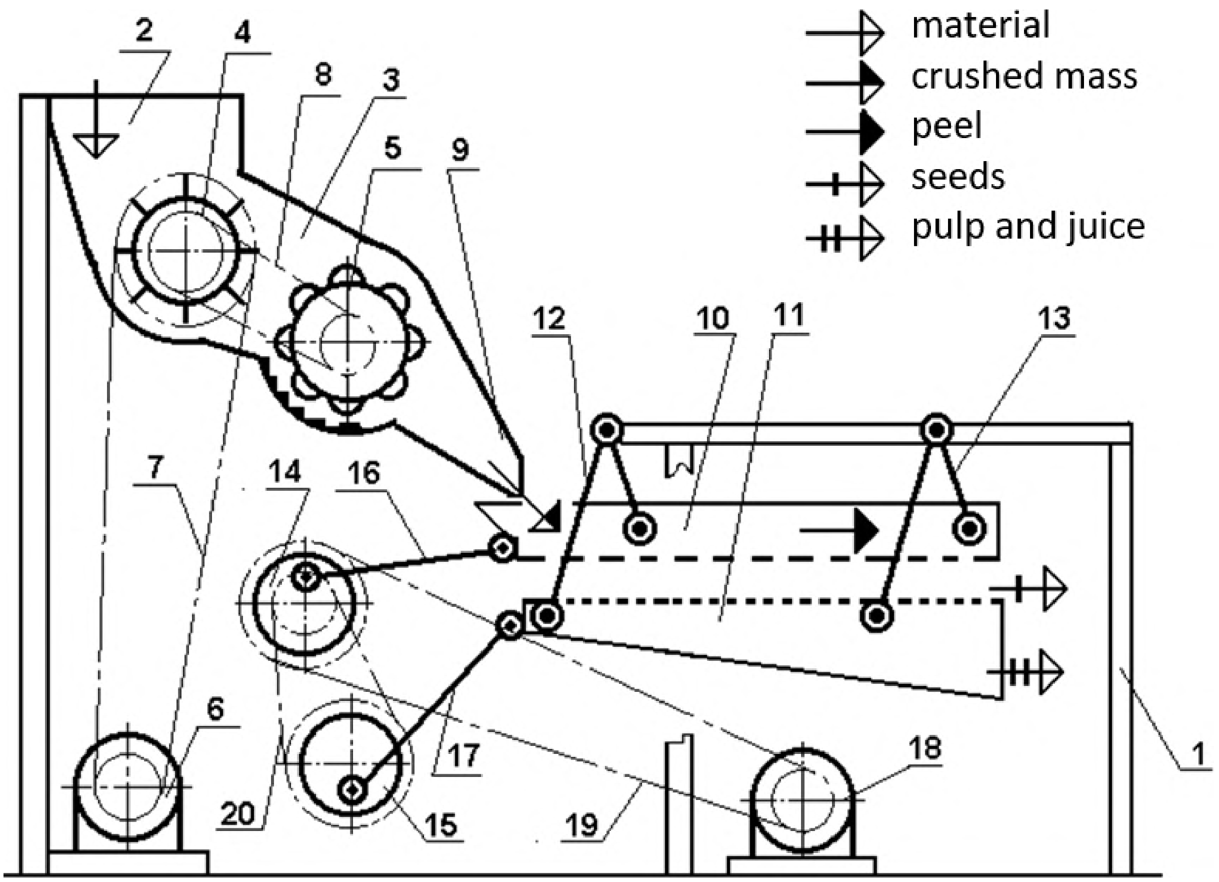

Figure 2. The scheme of the prototype of the cucumber and melon seed separator (1 – frame; 2 – receiving hopper; 3 – grinding chamber; 4 – grinding drum; 5 – wiping drum; 6 – electric motor; 7 – V-belt transmission; 8 – V-belt variator; 9 – tray; 10, 11 – the last grates; 12, 13 – sieves; 14, 15 – crank and connecting rod mechanisms; 16, 17 – hinged rods; 18 – electric motor; 19 – V-belt transmission; 20 – V-belt variator).

However, these equations are also not subject to canonical transformation, because they have an “extra” factor. It is equated $X_6 = -1$, after which the regression equations transform:

$$PS = 61.946 + 2.802X_2^2 + 1.852X_3^2 + +4.935X_2 + 1.209X_3 - 0.645X_2X_3 \quad (4)$$

$$DS = 4.929 + 1.788X_2^2 + 1.522X_3^2 + 0.987X_2 + 0.387X_3 \quad (5)$$

$$LS = 6.954 + 0.993X_2^2 - 1.384X_3 + 0.493X_2X_3 \quad (6)$$

Two-dimensional intersections of the response surfaces are presented.Having successively fixed both at the +1 level, and having performed calculations similar to the above, it is obtained the regression equation in the usual form with a new mutual combination of factors. When $X_2 = +1$, the regression equation takes the form (figure 4).

When setting the length of the sieve at the minimum level, it is impossible to achieve seed purity of more than 72%. The zone of optimal combination of factors is limited by the arcs of the HP curves; LS and DS intersecting at points I; II: III. At the same time, seed purity is within 71-72%; damaging will be less than 6%, and losses will not exceed 7%. For the vibration frequency of this technological mode is 24.3-36.25 (1/s), and the amplitude is 34-46 (mm). If the seed purity indicator drops to 71%, and losses to 8%, the range of permissible variation of

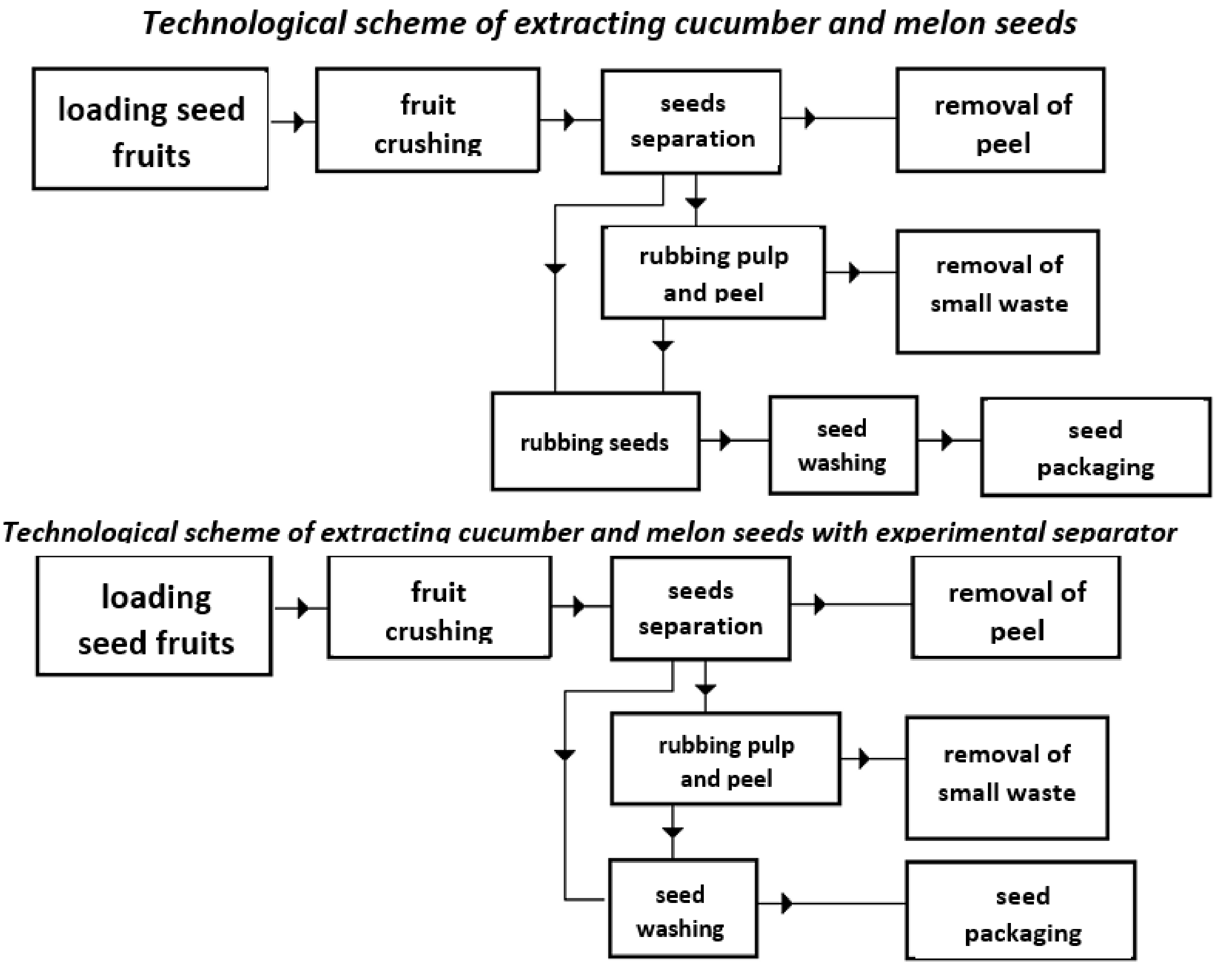

Figure 3. Technological schemes of extracting cucumber and melon seeds with basic and experimental separator.

kinematic modes (the figure is limited by points IV, V, VI) will be: for frequency – 24.3-45.0 (1/s); for an amplitude of 25-42 (mm).

Two-dimensional intersections of the response surfaces are shown in figure 5. Having successively fixed both at the +1 level, and having performed calculations similar to the above, it is obtained the regression equation in the usual form with a new mutual combination of factors.

When $X_2 = +1$, the regression equation takes the following form.

The analysis of the results of the experiment, the graphic interpretation indicates an increase in the indicators of the technological process when the frequency of oscillations is fixed at the maximum level. It was possible to achieve damage of seeds less than 4% with their purity more than 75% and losses in the range of 6-7% (the figure is limited to points I, II and III). The amplitude of oscillations is in the range of 24-32 mm, and the length of the working part is 1.51-1.625 m. In case of deterioration of damaging indicators to 5%, it is possible to achieve seed purity of more than 77.5% and losses do not exceed 6% (the figure is limited by points IV, V and VI). Independent factors can lie in the range: amplitude – 25-40 mm; sieve length – 1.75-1.825 m for a frequency of oscillations of 24.0-42.0 (1/s), for an amplitude of 24-48 mm.

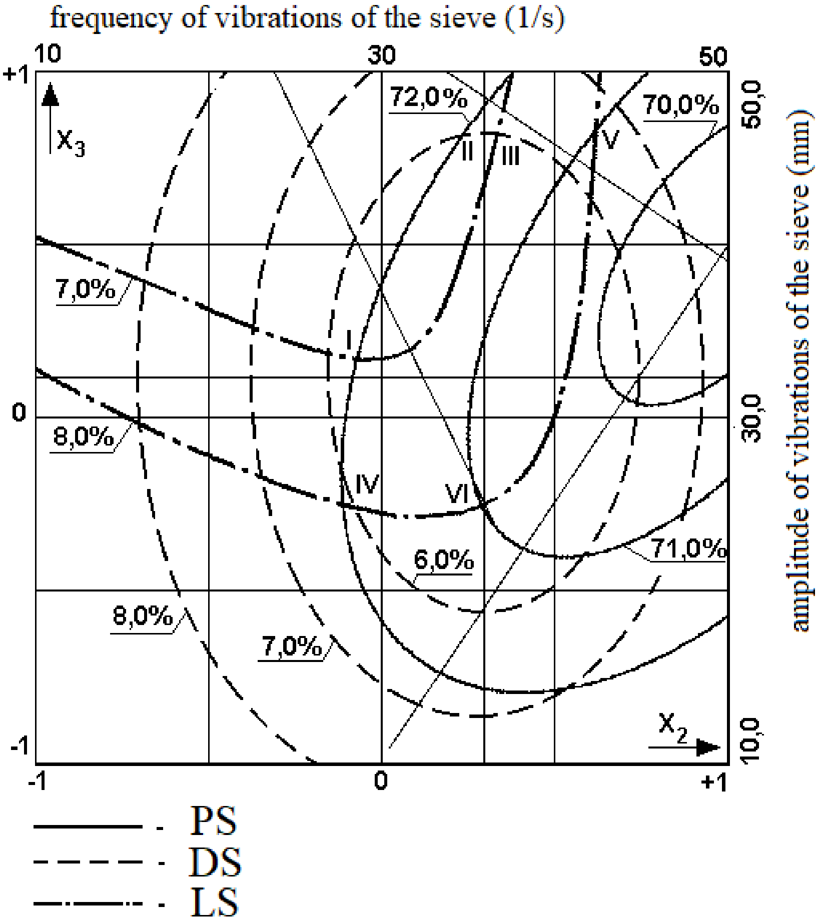

Figure 4. Two-dimensional intersections of response surfaces at $X_1 = 0; X_6 = -1; X_5 = 0$.

$$PS = 74.825 + 1.852X_3^2 - 0.645X_3 + +5.145X_6 + 1.209X_3X_6 \quad (7)$$

$$DS = 6.040 + 1.522 + X_3^2 + 2.155X_6^2 + 0.387 + +X_3 + 0.491X_6 \quad (8)$$

$$LS = 7.006 - 0.907X_6^2 - 0.891X_3 - 1.948X_6 \quad (9)$$

When $X_3 = +1$:

$$PS = 67.371 + 2.802X_2^2 + 5.865X_2 + +4.776X_6 + 1.572X_2X_6 \quad (10)$$

$$DS = 6.144 + 1.788X_2^2 + 2.155X_6^2 + 1.478X_6 - -0.987X_2X_6 \quad (11)$$

$$LS = 4.625 + 0.993X_2^2 - 0.907X_6^2 + 0.493X_2 - 1.948X_6 \quad (12)$$

Two-dimensional intersections of the response surfaces for the considered cases are shown in figure 6.

Analyzing the last graphic dependence, it can be concluded that in order to achieve the values of quality indicators of the technological process, which are comparable to the two previously considered options, it is necessary that the frequency of vibrations is 9.0-42.0 (1/s), and the length of the working part of the sieve is 1.2-1.6 m. The given combination of factors corresponds to the figure bounded by points II; III; IV, limited by the curves PS = 70%, DS = 6% and LS = 8%.

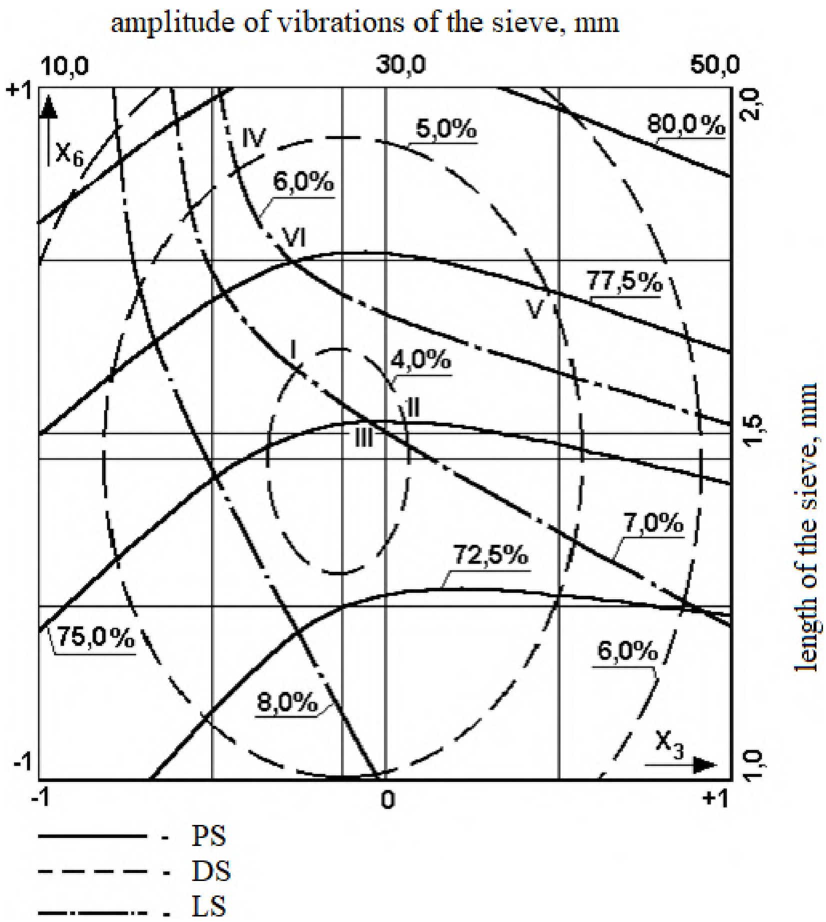

Figure 5. Two-dimensional intersections of response surfaces at $X_1 = 0; X_2 = +1; X_5 = 0$.

There are analyzed the graphical interpretation of the results of the experiment. Considering the constructed lines of “equal output”, can be concluded that the task of optimizing the main kinematic modes and design parameters is contradictory. An increase in any of the investigated factors: frequency of oscillations, amplitude of oscillations and length of the sieve leads to an improvement in the indicators of seed purity (PS) and their losses (LS), but to a certain extent worsens the indicators of damaging (DS).

5. Discussion

With the increase in the average annual air temperature on the planet and the aridity of the climate, their areas have a tendency to progressively expand. In the southern regions of Ukraine, zones of harmful agriculture are created due to the increased concentration of salts in the soil, which also suppresses natural flora and limits cultural diversity. The main reproductive organ of plants, the seed, is a unique product of evolution with a variety of morphological, physiological and biological characteristics, including different adaptability. Therefore, obtaining high-quality seeds and reducing resource costs for the technological process is an important task [26].

A lot of procedures in the technological processes are currently completed by people. Because of this, a big number of melon farms need a big amount of funding and human resources. Additionally, workers can measure the fertiliser solution incorrectly or fail to prepare the water and fertiliser solution needed for each planting step. The entire melon plant may be impacted by this and suffer harm as a result. Furthermore, low- to middle-class farmers who cannot

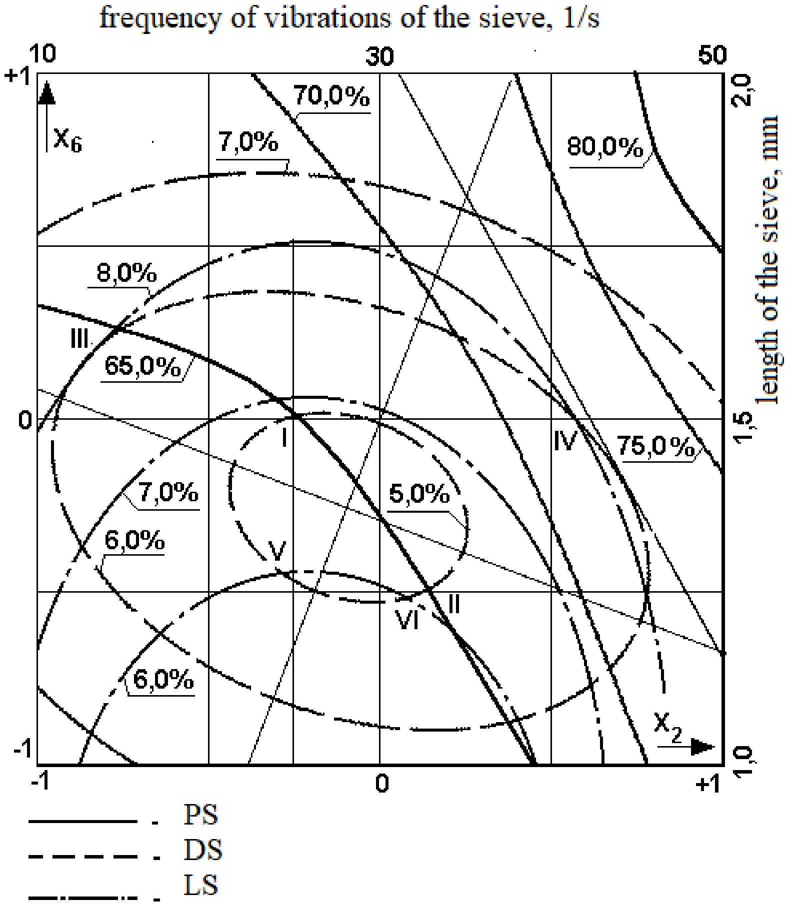

Figure 6. Two-dimensional intersections of response surfaces at $X_1 = 0; X_3 = +1; X_5 = 0$.

afford to make large investments in sophisticated machinery operate the majority of small and medium-sized melon fields [27].

A scientific notion of microwave energy's influence on grain crop growth rate under significant chemical reactant reduction was developed through systematic joint experiments conducted in both laboratory and field settings. A technique for treating vegetable crops' seeds that guarantees development rate has been devised; this is crucial for greenhouse vegetable farming. The findings that the microwave treatment increased the germination rate of melon seeds from 10% to 83% are interesting from a practical standpoint [28].

Energy-efficient agricultural equipment of low-productivity enterprises, according to its design, allows to use a simple technological scheme and reduce energy and resource costs for the technological process in the context of use in sustainable food systems [29].

From the analysis of previously conducted studies, it was established that determining the optimal relationship between the structural and kinematic parameters of separating devices of any type is a rather difficult task. In order to reduce the volume of experimental research, reduce the number of adjustments of the laboratory installation, the number of its working organs, as well as to obtain objective information about the dependence of seed injury, their purity and the amount of losses from the simultaneous change of several kinematic modes. Industrial machine models built for intricate production process automation and mechanisation are necessary for the growth of vegetable and melon seed production. Enhancing and growing the seed production sector will contribute to ensuring that agricultural production has access to seeds produced on-site, which will cut costs and boost industrial productivity. If growers of vegetables and melons generate their own seeds, they can lower the cost of producing these crops.

Vegetable and melon seeds are commonly separated using vibrating machinery. Chen and Yan [30] present their investigation on simulating crop sieving at varying vibration amplitudes, frequencies, and angles. The findings indicate that the sieving efficiency is not significantly affected by the vibration direction's angle of departure. The sieving efficiency rises and subsequently falls as other factors are taken into account. With an amplitude of 4 mm, a vibration frequency of 13 Hz, a sieve angle of 8°, and a vibration direction angle (angle between the vibration line and the Z-axis) of 0°, the optimal combination of sieving parameters was discovered after analysing the data. As in the case of the suggested design solution, the combination of vibration and inertial motion has a favourable impact on the quantitative and qualitative markers of seed separation [30].

The practical use of imbalanced vibration drives in adjustable drives of vibrating sieves has been investigated [31]. Both the operation of vibrating screens in the so-called "superresonant" mode and frequency control of the exciting force of the vibration motors are necessary for synchronous operation. The most significant experimental findings that were acquired under actual working settings are presented in this paper together with an experiment to ascertain the amplitude-frequency characteristics of vibrating screens. The authors' design strategy, which maximises design and operating parameters through the use of graphs, allows for a decrease in losses and an increase in seed yield [31].

For the goal of sorting seeds, Kaliniewicz et al. [32] assessed the correlations between the primary physical characteristics of seeds from a chosen species. Five species' seeds were examined for physical characteristics, and correlation and regression analysis were used to establish whether these features were interrelated. Sorting seeds using a sieve with two or more screens is recommended. The study highlights the necessity of technology tools for farms to process agricultural produce after harvest, with vibration machines being especially useful in this regard. By using the suggested design approach, high-quality seed separation is ensured by additional work in the inertial mode in addition to the use of vibrating machine properties [32].

The best values for the design and operational parameters of seed separators can be found by simulating the technology of processing the seed mass of vegetable and melon crops [33]. The researchers offered a solution to the seed characteristic prediction challenge. The final material's purity and seed loss were the optimisation criteria. On the other hand, compared to vibrating equipment, the pressurising machine employed in the experiment produced less-quality seed separation. Furthermore, the proposed study of the movement of the technological mass of vegetable and melon seeds allows for the optimal operating modes of the separator to be chosen using the suggested graphs, whereas the mathematical modelling of the technological process is time-consuming, only allows for modelling a specific sample of varieties of vegetable and melon crops, and does not allow for the prediction of the results [33]. As demonstrated by the experimental data gathered based on the mechanical and technological characteristics of the chosen samples, the combination of inertial and vibration motion of the sieves is the benefit of utilising the suggested design solution for the separator. It is possible to reduce the amount of water needed for seed washing and improve the level of the technological operation by using a resource-saving method of extracting cucumber and melon seeds.

6. Conclusion

The lack of modern, highly productive equipment does not allow to fully realize the possibilities in providing agriculture with its own seeds of cucumber and melon. The purchase of seeds leads to additional expenses, reduces the productivity of open ground melon cultivation due to the fact that not all varieties are regionalized. There are studies on the substantiation of the design parameters and kinematic modes of seed separators from the crushed peel and pulp obtained in the process of crushing seed fruits. The conducted theoretical justification applies only to sieve-type separators with a horizontal sieve with reciprocating movement and constant pressure of particles of crushed mass on the surface of the sieve.

Using the proposed method of extracting cucumber and melon seeds allows to lower the amount of water used for seed washing and raise the standard of the technological procedure. The feature of the proposed design solution of the separator of the melon and cucumber seeds is that the upper screen operating in the mode of an inertial separator and the lower screen operating in the mode of a vibrating separator that promotes better separation of seeds. The upper screen separates the coarse fraction of the crushed peel, while the lower screen separates the seeds. The remaining fractions, such as pulp, pulp particles and juice, fall into the tray. To reduce seed losses in the peel fraction, it is advisable to use the inertial separator mode. Additional friction of the material against the edges of the holes in the peel fraction reduces the seed content. The mode of the vibrating conveyor for the second sieve is used to increase the passage of the pulp through the sieve holes.

Factors affecting the quality of the technological process of the proposed solution of the cucumber and melon separator were identified: the angle of inclination of the sieve surface, the frequency of oscillations of the sieve, the amplitude of its oscillations, the angle of application of the vibration force and the length of the sieve. The following optimization criteria were chosen: purity of seeds, the extent of their damage and the level of seed losses. The factors that have the greatest influence on the quality of the technological process have been established: the frequency of vibrations of the screen, the amplitude of vibrations and the length of the working surface of the sieve. At the same time, the ranges of variation of independent factors made it possible to ensure modes of both inertial separation and vibration separation. The ranges of the optimal combination of independent factors are as follows: in case of seed injury 4-6%, purity 70-75%, losses are within 6-7%, a necessary condition is the frequency of oscillations 9.0-42.0 (1/s), the amplitude oscillations of 24-32 mm, and the length of the working part sieve 1.2-1.6 m. In the vibroseparation mode (oscillation frequency more than 30 (1/s); amplitude more than 35 mm (with an angle of application of the vibration force of 10°) seed damage does not exceed 5%, and their frequency is within 70...71%. At the same time in the inertial mode separator, seed loss at the level of 5-6% is achieved. Prospects for further research are recommendations on the design schemes of separator, its kinematic modes, which allows to intensify the process of cleaning freshly separated wet seeds from organic impurities.

Abstract. The application of ARDL modeling at the macroeconomic level for the analytical description and analysis of dependencies of production productivity in the grain industry on natural-climatic, technical-technological and marketing factors is studied. It is determined that the construction of the production function for the agrarian sector determines the consideration of internal and external factors of the organization of production and the conditions for its conduct. Another difficult point is the asynchrony of the dynamics of prices for grain and production resources, which necessitates bringing the indicators of costs and output to a comparable form, which determines the artificiality of comparison and non-stationarity of the dynamic series included in the model. It has been proven that the means of overcoming these obstacles is the application of the dependent lag autoregressive model (ARDL). The non-equivalence of the influence of individual factors on the dynamics of yield has been established. In particular, the p-value at the level of one percent has the payback of costs for the production of soft wheat grain in the reporting year, its first and third lag, as well as the second and third lag of payback of costs for the production of durum wheat. At the same time, there is an alternation of the sign of regressors, due to a decrease in prices in years of excess grain production and their increase in lean years. Likewise, the value of the unit cost regressor is also negative, while their lags according to the AIC criterion were not included. The prerequisite for this is the industrial nature of the technologies used. Thus, with an average yield of about 70 c/ha, the variation of the latter over the 29 years of the study did not exceed 7%, and therefore the increase in unit costs, and, accordingly, the yield, but does not provide a simultaneous increase in income due to a decrease in prices. In view of this, a negative value is logical cost regressor. Under such conditions, further study of the prerequisites should be aimed at studying the behavior of lag values of costs and the impact on their formation of a common European policy of regulating the productivity of agricultural production.

1. Introduction

Regression modelling is traditionally used to evaluate the efficiency, planning and forecasting of agricultural production. Multiple regression, discriminant, factor, cluster and logistic regression analysis, and principal component analysis are widely used in modelling the performance of the agricultural sector. Unfortunately, the accuracy of forecasts is sometimes significantly affected by the multicollinearity of indicators, their autocorrelation in certain years, and extreme structural shifts. These factors can reduce the adequacy of regression models and their parameters obtained using the least squares method (*OLS - Ordinary Least Squares*) [1]. At the same time, since the results of production in crop production are influenced by a significant number of interrelated factors with their inherent multicollinearity, it is advisable to use other approaches, in particular, an autoregressive model with a distributed lag (*ARDL – Autoregressive Distributed Lags*).

This model is a traditional OLS regression in which the independent variables are the lags of the factor variables and the outcome variable [2]. The ARDL, known for several decades, began to be widely used to study the cointegration of economic indicators after the publication of the works of Pesaran and Shin [3, 4]. Cointegration is defined as the property of several non-stationary (integrated) dynamic series to have some stationary linear combination [5]. Cointegration is inherent in many economic indicators, and its manifestation is that despite the random (poorly predictable) nature of simultaneous changes, there is a long-term relationship between them that causes common, interrelated fluctuations. In fact, we are talking about the Error Correction Model (ECM) – when short-term changes are corrected depending on the degree of deviation from the long-term trend.

The works of Engle and Granger [6], Johansen and Juselius [7], Saikkonen and Lütkepohl [8] are devoted to cointegration methods, but the advantage of ARDL is the possibility of including non-stationary variables in the model [9]. This model is based on a single equation, which allows the use of a sufficient number of lags [10]. At the same time, the number of estimated parameters decreases [3], and therefore ARDL is more reliable for samples of 30-80 observations [11–13], while Johansen's cointegration test requires at least 100 observations [14]. The ARDL method reflects the delayed effect of the aftereffect of the factor (x) and dependent (y) variables, as it includes their lags, which are taken into account in serial correlation [9]. In this case, the dynamic error correction model (ECM) can be derived from the ARDL using a linear transformation [15], which allows integrating short-term dynamics with long-term equilibrium without losing long-term information.

Therefore, taking into account the growth in demand for food products, research and development of methodical approaches to modeling macro- and microeconomic processes in the agricultural industry using ARDL-modeling is of particular importance.

2. Theoretical background

The use of dynamic models to describe the relationship between indicators of economic processes is based on the assumption of the presence of a long-term equilibrium relationship in changes in these indicators. A dynamic model is characterized by a dynamic relationship between the behavior of a variable at a current point in time, which may have an impact on it or on other variables in future periods, and these effects are usually inertial in nature [16]. The most common approach to the formalization of dynamic relationships is to use the resulting indicator as an independent lag variable simultaneously with the variables that characterize the process in the current period:

$$y_t = f(y_{t-1}, x_t), \tag{1}$$

where y_t and x_t are the values of the dependent and independent variables in the current period, y_{t-1} is the value of y in the previous period.

If the variable y is a function of the current and past values of the independent variable x, then it is a dynamic model with a distributed lag, in which the influence of the independent variable (x) on the dependent variable (y) can be traced in dynamics. The influence of the dynamics of the factor variable can be traced both at the present moment and in the future, and therefore the consequences of today's management decisions can affect the results of production both in the current, and in subsequent periods. For example, the hereditary effect of fertilizers has been observed for several years, and therefore managers are interested not only in the impact of changes in costs on the yield of the product, but also in the time during which the hereditary effect will be prevented. In view of this, it is expedient to introduce into the production function the values of the factor variable for several previous periods (lags):

$$y_t = f\left(x_t, x_{t-1}, x_{t-2}, \dots x_{t-k}\right), \tag{2}$$

where x_{t-1} and x_{t-2} are the values of the variable for the two periods (lags).

After combining (1) and (2), we get a dynamic model with lag variables (x) and (y):

$$y_t = f\left(y_{t-1}, x_t, x_{t-1}, x_{t-2}\right). \tag{3}$$

It is a distributed lag autoregression (ARDL), i.e. an extension (2). It is generally accepted that a change in one economic variable can affect another with a certain delay, as a result of which these changes do not occur instantaneously, but over several periods. So, we have a distributed model with infinite lag, in which autoregression (AR) characterizes the effect of its lags on the resulting function, and the component (DL) of the reflection is the lagging effect x. It can be described as follows:

$$y_t = \vartheta + \alpha_0 y_{t-1} + \ldots + \alpha_p y_{t-p} + \beta_0 x_t + \beta_1 x_{t-1} + \ldots + \beta_q x_{t-q} + e_t, \tag{4}$$

where p is the number of lags for y (lag order for y) and q is the number of lags for x (lag order for x).

Or in a more concise form of ARDL:

$$y_t = \vartheta + \sum_{i=1}^{p} \alpha_i y_{t-1} + \sum_{i=1}^{q} \beta_i x_{t-1} + e_t, \tag{5}$$

It assumes the presence of one explanatory variable, but if their number increases, ARDL (p, q_1, q_2, ..., q_k) will look like this:

$$y_t = \vartheta + \sum_{i=1}^{p} \alpha_i y_{t-1} + \sum_{i=1}^{q1} \beta_i x_{1t-1} + \sum_{i=1}^{qk} \beta_i x_{kt-1} + e_t, \tag{6}$$

This model is used to solve the sequential correlation problem to produce a transformed model with uncorrelated errors.

In turn, Pesaran et al. [4] proved that the error-corrected ARDL model looks like this:

$$\begin{gathered}\Delta y_t = \alpha_0 + \sum_{i=1}^{p} \alpha_{1i} \Delta y_{t-i} + \sum_{i=1}^{q1} \alpha_{2i} \Delta x_{1t-i} + \ldots + \\ + \sum_{i=1}^{qk} \alpha_{(k+1)i} \Delta x_{kt-i} + \beta_1 y_{t-1} + \beta_2 x_{1t-1} \ldots + \beta_{k+1} x_{kt-1} + \varepsilon_t,\end{gathered} \tag{7}$$

where β_i (i=1, 2, ..., k+1) is the corresponding long-term relation, while the parameter α_i (i=1, 2, ..., k+1) is the short-term dynamic coefficient of the underlying ARDL model.

The main areas of application of ARDL are forecasting and multiplicative analysis [16]. Both are tools of economic policy and operational management, since forecasting economic variables is a key issue for economists, and multiplicative analysis evaluates the effect on the behavior of one independent variable of others and the time limits of their influence.

3. Literature review

Issues of cost efficiency are usually studied through the prism of production functions of production of socially significant products. It should be noted the works devoted to the study of production functions, in particular pray, which focus on determining the forms of the production function adequate to economic processes [9, 17–23]. Attention is drawn to studies in which production functions are used to assess productivity, returns to scale and price in industry, trade and international economic relations [20, 24–32]. A significant number of works are devoted to the development of methods for assessing multi-product production functions [28, 33–36].

A whole direction of macroeconomic research, starting with the work of Hall [37], is devoted to the uncertainty of product prices. At the same time, most studies, highlighting the instrumental features of OLS functions, leave out the dynamic aspects of modeling at the level of an economic entity. For example, a number of publications are devoted to dynamic ARDL-modeling the relationship between macro-financial and macroeconomic indicators. Thus, Ghavam Masoodi and Tashkini [38] uses his study of the long-term relationship between the inflation rate and its factors. Tian and Ma [39] examines the relationship between the exchange rate and the stock market. Chaudhry et al. [40] examines the relationship between foreign exchange reserves and inflation rates in Pakistan. Chou and Tseng [41] analyzes the relationship between oil price volatility and inflation in Taiwan.

Some authors are trying to expand the ARDL toolkit. Thus, Alimi [42] investigated the relationship between inflation and interest rates in Nigeria and the degree to which the Fisher effect is fulfilled. He applied ARDL testing and vector error correction (VECM), and tested the stability of the function using CUSUM and CUSUMSQ. Hove and Tursoy [43] established a long-term relationship between stock prices and domestic interest rates in Turkey's financial markets. The study relied on the ARDL and the Vector Autoregressive Cointegration. Equations based on the modified least squares method (FMOLS), dynamic least squares method (DOLS), and regression (CCR) were applied to test long-term elasticity. Moawad [44] used ARDL to investigate the relationship between financial sector development and economic growth in France and Malaysia.

ARDL at the microeconomic level was applied by Blundell and Bond [19], who focused on the application of ARDL models for panel data. The focus was on single-equation models with dynamic autoregression and explanatory variables that are endogenous (not strictly exogenous), as well as estimates of the Generalized Method of Moments (GMM). The paper considers a simple autoregressive model for the rate of investment and the main production function for an industrial enterprise. At the same time, Chandio et al. [45] applied ARDL modeling to analyze production processes in agricultural formations. It investigated the impact of support prices on wheat production in Pakistan in 1971-2016. and confirmed their positive long-term impact, as well as fertilizer application, on wheat production using.

Therefore, today there is a need to deepen research on the possibilities of using ARDL for modeling at the level of agricultural enterprises, to improve approaches to the interpretation of the essence of lags of factor and resultant indicators, in particular, the use of this approach in forecasting the results of crop production.

4. Purpose, data and methodology of the study

The aim of the article is to highlight the results of the study of the use of ARDL modeling at the macroeconomic level for the analytical description and analysis of dependencies of production productivity in the grain industry on natural-climatic, technical-technological and marketing factors.

The basic production function is a model that describes the relationship between the accumulation of resources, their consumption and output:

$$y_t = f\left(x_{t1},\ x_{t2,} \ldots x_{tk}\right), \tag{8}$$

where y_t and x_{t1}, x_{t2}, x_{tk} are the values of the resulting feature and its regressors in the period t.

For the production of wheat grain, the outputs are output in physical or cost terms, and the inputs are consumed resources (resource potential), operating costs, or both. At the same time, the most important of them is soil fertility. But its inclusion in the model is problematic given the complex nature of the concept, and reduction to an economic equivalent causes a number of assumptions, which complicates the model itself and reduces the quality of the forecast. The analysis of publications shows an increase in attention to the economic assessment of land resource potential and its impact on production results. Unfortunately, the instrumental aspects of its process are not addressed.

The proposed approach is based on the assumption that the resource potential in conjunction with the production technology are components of the production potential of the agricultural sector, the efficiency of which is characterized by the culture of agriculture. At the same time, it is directly reflected in the yield for several periods preceding the reporting one, which determines its use in the autoregressive production function (AR).

Another disadvantage of agrarian production functions is the mutual correlation of certain types of costs, due to their synchronous growth as technology becomes more complex. In addition, traditional production functions almost do not take into account the aftereffect of fertilizers, in particular phosphate fertilizers, and the application of organic fertilizers has a positive effect on soil fertility, which causes mutual correlation of fertility indicators and the costs of their increase and complicates the formalization of the production function. At the same time, due to the aerobiological nature of the not always strictly functional, but nevertheless tangible relationship between production costs and output to overcome the problem of multicollinearity, a multifactor cointegration ARDL model can be applied, which will allow to assess the degree and speed of formation of the multiplier effect and correction of market failures through the prism of changes in the level of unit costs.

At the same time, a prerequisite for modeling is the feedback of input output, i.e. indicators of technological and economic efficiency on costs. In market conditions, such a factor is the price. At the same time, if its individual value is an assessment of the manufacturer's competitive position, then the average value is a factor in adjusting unit costs, which causes an increase (decrease) in productivity in the next period. Therefore, on a par with the lag values of yield and costs to ARDL It is advisable for the model to include sales price lags.

4.1. Inventory statistics

Turning to the results of the study, it should be noted that given the inflationary nature of prices for purchased resources, the inclusion of costs per unit of crops without pre-treatment leads to erroneous conclusions, and therefore the dynamics of costs was brought to a comparable type. Due to the conditions of the war, the possibilities of its implementation according to the data of Ukrainian agricultural formations are limited, and therefore the indicators of EU farms were used. In particular, data on the unit costs of wheat grain production at constant prices in 2010 of French agricultural formations are available on the Eurostat (ESS) website.

The European practice of statistical accounting provides for the independent accumulation of data on prices for durum and soft wheat grains, which is due to the different functional purposes of the products. Unfortunately, the inclusion of both prices in the model causes a deterioration in its quality due to the integration of their dynamic series at level $I(2)$ as a result of structural changes caused by the reform of the EU Common Agricultural Policy during the study period. In view of this, the dynamic price series were has been replaced by derivative indicators of payback of costs for the production of soft and durum wheat, which are reliable determinants of the costs of the current period.

Thus, the model included indicators of yield (YLD), production costs in constant prices (UVC), payback of costs for production and marketing of soft wheat *(PLSW)* and durum varieties ($PLDW$). Descriptive statistics of these dynamic series (table 1) and their graphical interpretation (figure 1) show a tendency to increase the return on costs for the production of durum wheat grain and the stationarity of other series. At the same time, against the background of a high variation in the indicator of costs in constant prices and their payback during the production of durum wheat grain, for yield and cost recovery, the production of soft wheat grain is moderate, which positively characterizes the common agricultural policy of the EU countries, which does not allow a crisis of overproduction.

Table 1. Basic inventory statistics (based on `https://ec.europa.eu/eurostat` data).

Variable	Abbreviation	Average	Standard deviation	Max	Min
Wheat yield, c/ha	YLD	68.8207	4.7951	74.9858	56.2021
Production costs per 1 ha of wheat crops, EUR*	UVC	11.0859	1.4916	15.2066	8.5323
Recoupment of costs for the production and sale of wheat grain					
soft varieties	$PLSW$	0.9094	0.0705	1.0464	0.7933
durum grades	$PLDW$	1.2320	0.1627	1.5387	0.9321

* in constant 2010 prices.

Attention should be paid to the positive correlation between each pair of independent variables. In particular, there is a low value for production costs and profitability of production and marketing of durum wheat, moderate profitability for production costs and profitability for the production and sale of soft wheat, and profitability for the sale of durum and soft wheat. The results of correlation analysis indicate the absence of multicollinearity between the independent variables, since all correlation coefficients are less than 0.8 (table 2).

Table 2. Correlation matrix of independent variables (based on `https://ec.europa.eu/eurostat` data).

	UVC	$PLSW$	$PLDW$
UVC	1.0000	0.2855	0.0203
$PLSW$	0.2855	1.0000	0.4651
$PLDW$	0.0203	0.4651	1.000

The next step was to check the rows for stationarity. A series is considered to be stationary if the mean, variance, and structure do not change during the study period. The stationarity test proposed by Dickey and Fuller [46] is based on the fact that the nonstationary series (X) is integrated in the d-order and has as many unit roots as many times as it needs to be differentiated

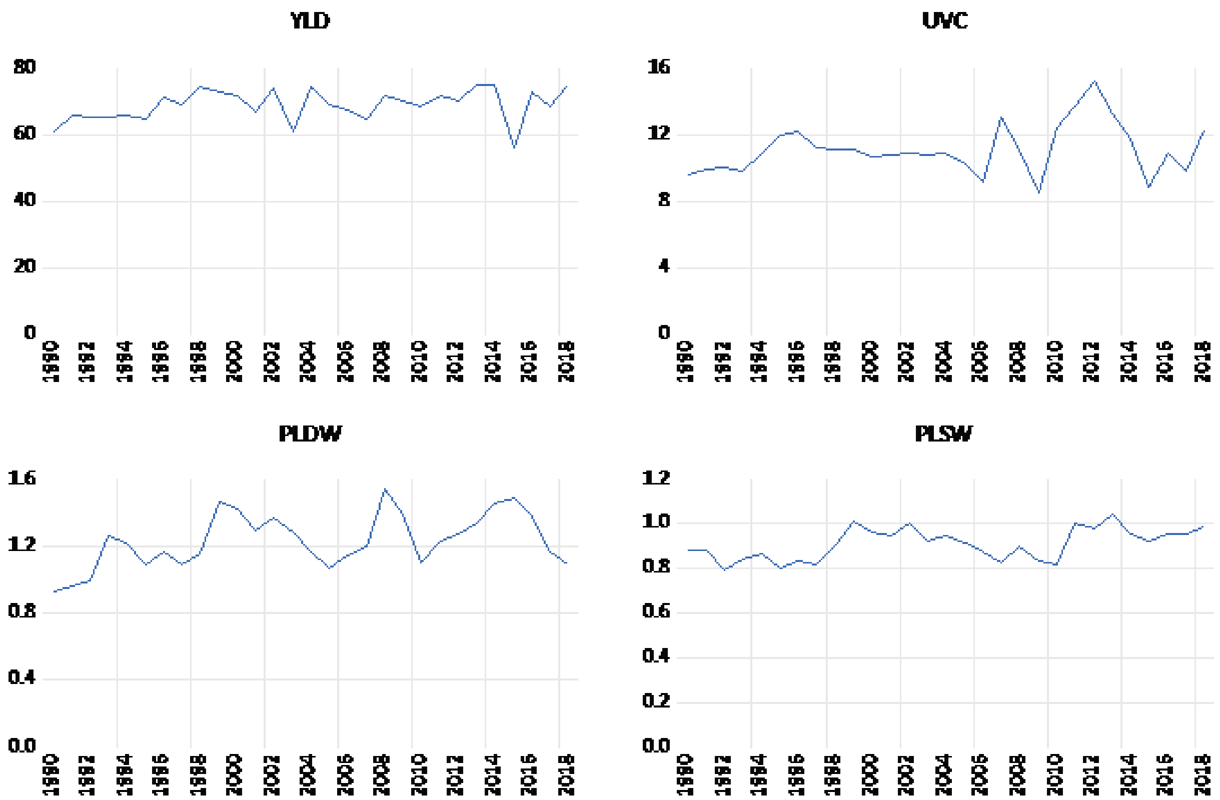

Figure 1. Dynamics of dependent and independent variables in 1990-2018 (based on `https://ec.europa.eu/eurostat` data).

to become stationary. Null hypothesis (*H0)* of the Dickie-Fuller test (*DF*) is the assumption that "the series has a unit root" versus the alternative hypothesis (*H1*) that it is stationary. The *DF* test assumes the presence of "white noise", so the autocorrelation of the dependent variable, which causes the autocorrelation of the error (ε) and the unreliability of the DF test. The ADF test for the variables included in the model showed that the dynamic series of yield and profitability of durum wheat are stationary at the *I(0)* level. On the other hand, the series of production costs per 1 ha of wheat crops and the profitability of sales of soft wheat varieties are integrated in the first order *I(1)* (table 3).

Table 3. Dickie-Fuller advanced test results (ADF) (based on `https://ec.europa.eu/eurostat` data).

Variable	Level of integration
YLD	*I(0)*
UVC	*I(1)*
PLSW	*I(1)*
PLDW	*1(0)*

5. Evaluation and specification

The specification of the proposed ARDL model is based on its canonical form, based on the results of research by Pesaran et al. [4]:

$$\Delta YLD_t = \alpha_0 + \sum_{i=1}^{p} \alpha_{1i} \Delta YLD_{t-i} + \sum_{i=1}^{q1} \alpha_{2i} \Delta UVC_{t-i} + \sum_{i=1}^{q2} \alpha_{3i} \Delta PLSW_{t-i} +$$

$$+ \sum_{i=1}^{q3} \alpha_{4i} \Delta PLDW_{t-i} + \beta_1 YLD_{t-1} + \beta_2 UVC_{t-1} + \beta_3 PLSW_{t-1} + \beta_4 PLDW_{t-1} + \varepsilon_t). \quad (9)$$

In the context of the existence of a long-term relationship, a conditional autoregressive model with a distributed lag is formed, which will allow estimating the coefficient of the long-term relationship:

$$\Delta YLD_t = \alpha_0 + \sum_{i=1}^{p} \alpha_i YLD_{t-i} + \sum_{i=1}^{q1} \beta_i UVC_{t-i} + \sum_{i=1}^{q2} \theta_i PLSW_{t-i} + \sum_{i=1}^{q3} \gamma_i PLDW_{t-i} + u_t \quad (10)$$

In this case, the long-term equation is as follows:

$$YLD_t = a_0 + b_1 UVC_t + b_2 PLSW_t + b_3 PLDW_t + u_t \quad (11)$$

Thus, the long-term parameters in (11) can be obtained using OLS (10):

$$\overline{a}_0 = \frac{\alpha_0}{\left(1 - \sum_{i=1}^{p} \overline{\alpha}_i\right)}; \overline{b}_1 = \frac{\sum_{i=0}^{q1} \overline{\beta}_i}{\left(1 - \sum_{i=1}^{p} \overline{\alpha}_i\right)}$$

$$\overline{b}_2 = \frac{\sum_{i=0}^{q2} \overline{\theta}_i}{\left(1 - \sum_{i=1}^{p} \overline{\alpha}_i\right)}; \overline{b}_3 = \frac{\sum_{i=0}^{q3} \overline{\gamma}_i}{\left(1 - \sum_{i=1}^{p} \overline{\alpha}_i\right)}. \quad (12)$$

The second step of limit testing is to evaluate the conditional ECM, which is defined by the equation:

$$\Delta YLD_t = \alpha_0 + \sum_{i=1}^{p} \alpha_{1i} \Delta YLD_{t-i} + \sum_{i=1}^{q1} \alpha_{2i} \Delta UVC_{t-i} +$$

$$+ \sum_{i=1}^{q2} \alpha_{3i} \Delta PLSW_{t-i} + \sum_{i=1}^{q3} \alpha_{4i} \Delta PLDW_{t-i} + \upsilon ECT + \varepsilon_t, \quad (13)$$

where ECT is the error correction term, which indicates the rate of correction of the parameter, ECT shows how much of the disequilibrium is being corrected, i.e., to what extent any disequilibrium in the previous period is corrected in the current period.

6. Empirical results

During the analysis of the initial data in the EViews 12 software environment, the ARDL model with the lowest AIC value with a three-year yield lag, four-year lags of payback of costs for the production of durum and soft wheat grain was chosen as the baseline. On the other hand,

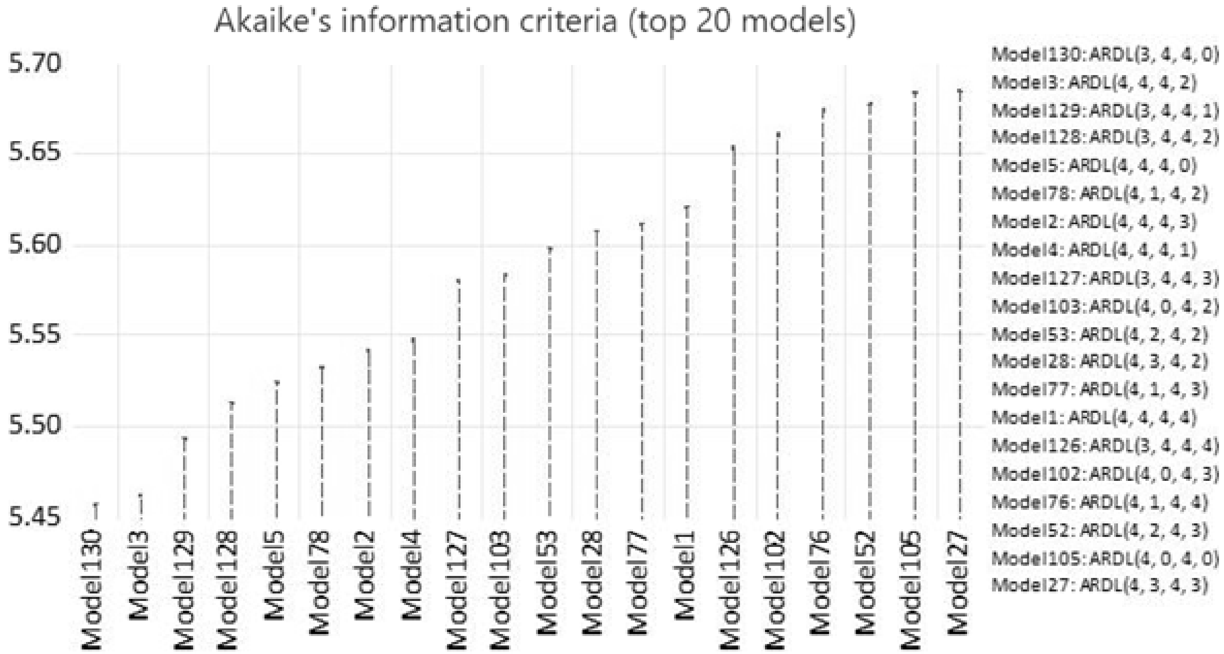

Figure 2. Summary graph of model selection (based on `https://ec.europa.eu/eurostat` data).

according to the chosen criterion of information similarity, the inclusion of lags of production costs per unit of crops in constant prices in 2010 is inexpedient, which requires additional research (figure 2).

The results of the simulation indicate discrepancies in the influence of lags of individual variables on the dynamics of yield (table 4).

In particular, the p-value at the level of 1% had the fourth lag of payback of costs for the production of durum and soft wheat, as well as the constant (α_0). The significance at the level of up to 5% was the first lag of yield and the second lag of payback costly production of durum wheat. In turn, the current costs per unit of crops at constant prices in 2010, the second and third lags of yield. The first and third lags of payback of costs for the production of durum wheat grain, the second and third fourth lags of cost recovery for the production of soft wheat grain were significant at the level of 10%. On the other hand, the indicators of payback of costs for the production of soft wheat grain in the reporting year and its first lag are not significant.

6.1. Bound test

The next step was the limit test for the presence of a long-term connection. It was found that the value of the F-statistic exceeds the upper limit for *I(0)*, based on this, it should be noted that there is a long-term relationship at the significance levels of 1%, 5% and 10% (table 5).

In view of this, an error correction model (ECM) was formed, which allows to assess which part of the disequilibrium is corrected, that is, how much the disequilibrium of the previous period is corrected in the current one (table 6).

It is recognized that a positive ECT coefficient indicates a recession, and a negative ECT indicates convergence. If it is equal to one, then during the period 100% of the deviation is corrected and the adjustment is instantaneous and complete, if ECT = 0.5, then 50% of the adjustment occurs in each period (year). ECT = 0 indicates that no adjustment occurs and it cannot be said that there is a long-term relationship. For the analyzed ECT model is negative

and is highly significant, indicating convergence. Therefore, it can be argued that 246.6% of the short-term to long-term adjustment occurs in less than four months.

7. Evaluation of model reliability

Subsequently, the assumptions about the stability of the model were checked and the characteristics of the residues were diagnosed. In particular, the cumulative residue test (CUSUM-test) by Brown, Durbin and Evans [47] showed that the evaluated model satisfies the stability condition, since there is no root lying beyond the significance level (figure 3).

The absence of consistent correlation of residues was verified using the LM test, and the hypothesis of the absence of heteroscedasticity was rejected at a significance level of 5% (table 7).

At the same time, the null hypothesis about the absence of a sequential correlation does not deviate at the level of 0.05, which indicates the absence of a sequential correlation in the

Breusch Pagan Godfrey test for heteroscedasticity	0.562511	0.8423

residuals of the model. In addition, there is no heteroscedasticity in the residues (that is, the variance is constant), as indicated by the Breusch Pagan Godfrey test.

To check the normality of the residues, the Jarque-Bera test (JB) was used (figure 4). His null hypothesis is that the residues are normally distributed. Given the graphical interpretation and the p-value, the probability at the level of 66.2% should be stated that the residuals are normal, so the null hypothesis is proven.

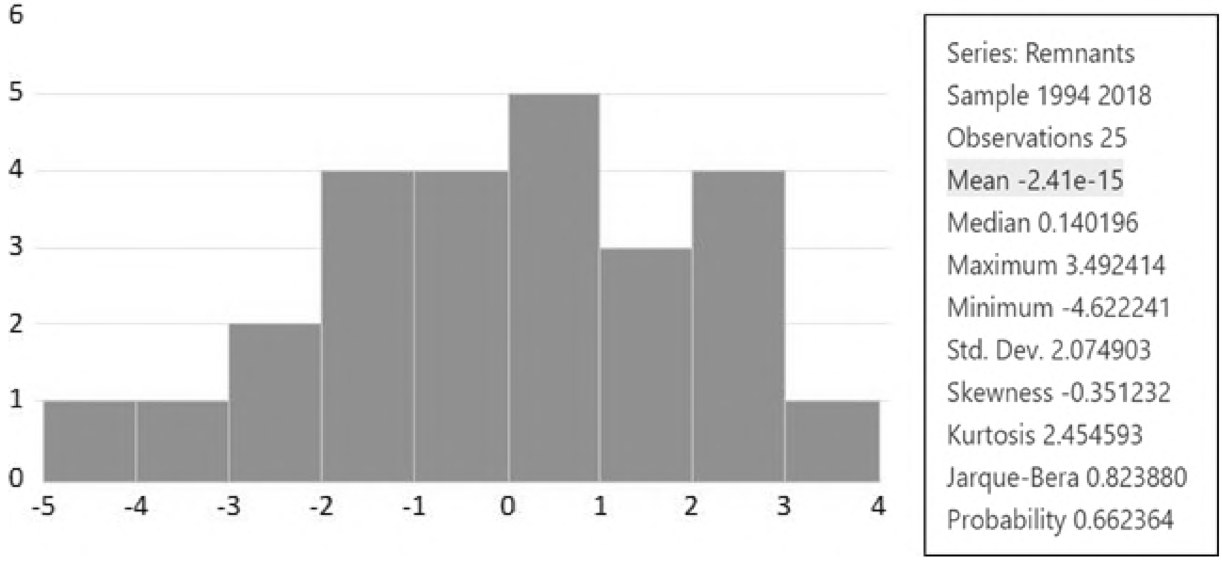

Figure 4. Normality diagram and Jarque-Bera test (based on `https://ec.europa.eu/eurostat` data).

8. Conclusions

1. Construction of the production function for the agricultural sector, in particular the grain sector, determines the consideration of internal and external factors of the organization of production and the conditions of its conduct. Unfortunately, this process involves a number of obstacles. Thus, taking into account the impact of land fertility on the basis of the bonitet score or economic valuation determines its correlation with other operating costs of the current and previous years, which distorts the results of modeling. Another difficult point is the non-synchronicity of the dynamics of grain prices and production resources, which necessitates bringing the indicators of costs and output to a comparable form, which determines the artificiality of comparison and non-stationarity of the dynamic series included in the model. One option to overcome these obstacles is to use a dependent lag autoregressive model (ARDL).
2. The variables of the wheat yield model were the indicator of operating costs at constant prices in 2010 and the payback of costs for the production of wheat grain for 1990-2018, as well as the lag values of the yield in the years preceding the reporting year, which made it possible to take into account the efficiency of using the production potential of the grain industry. Structural gaps in the dynamics of prices for purchased resources and wheat grain in the domestic Ukrainian market in 1990-2018, which led to its non-stationarity and prompted the construction of a model based on the indicators of farms in France for the same period. This made it possible to assess the conditions for the formation of costs and revenues of grain producers in the EU countries, on the eve of the accession of Ukraine and its grain industry to it.
3. The formed ARDL model is characterized by a high level of reliability, as evidenced by tests for the absence of sequential correlation and the absence of heteroscedasticity, as well as the Jarque-Bera test for the normality of the distribution of residues. The error correction model showed that the value of the ECT coefficient is negative, and the adjustment from short-term to long-term occurs in less than four months.
4. Modeling showed the non-equivalence of the influence of individual factors on the dynamics of yield. In particular, the p-value at the level of one percent has the payback of costs for

the production of soft wheat grain varieties of the reporting year, its first and third lag, as well as the second and third lag of recoupment of costs for the production of durum wheat. At the same time, there is an alternation of the sign of regressors, due to a decrease in prices in the years of excess grain production and their increase in lean years. The value of the unit cost regressor is also negative, while their lags according to the AIC criterion were not included. The prerequisite for this is the industrial nature of the technologies used. Thus, with an average yield of about 70 c/ha, the variation of the latter over the 29 years of the study did not exceed 7%, and therefore the increase in unit costs, and, accordingly, the yield, but does not provide a simultaneous increase in income due to a decrease in prices. In view of this, a negative value is logical cost regressor. Under such conditions, further study of the prerequisites should be aimed at studying the behavior of lag values of costs and the impact on their formation of a common European policy of regulating the productivity of agricultural production.

Abstract. Experimental studies have been carried out to determine time for opening and closing of spray in Lechler ST 110-02 and IDK 120-02 nozzels for the combined spraying working body (CWB). The spray nozzles have been filmed by digital video camera. We received the results of opening time for nozzles and calculated the arithmetic mean, average square deviation (standard), and coefficient of variation by average square deviation. The opening time(arithmetic mean) for Lechler ST 110-02 flat nozzle 0,235 s. The opening time for Lechler IDK 120-02 injection sprays nozzle 0,435 s. The average value of the closing for spray in Lechler ST 110-02 is 0.04 s, and the Lechler IDK 120-02 nozzle is 0.08 s. The transient time for switching from the ST 110-02 nozzle to the IDK 120-02 nozzle should be 0.395 s, and the switching from the IDK 120-02 nozzle to the ST 110-02 nozzle should be 0.155 s.

1. Introduction

The intensification of agricultural production and the widespread introduction of mechanized technologies for growing field crops require the rational use of chemical plant protection products. A significant variety of soil and climatic conditions, meteorological factors, contamination of fields with many types of weeds, a large set of cultivated plants and many other factors necessitate the introduction of modern plant protection machines, especially the ability to adjust such important parameters as working fluid consumption and dispersion during the work process.

Many scientists have been studied technological processes and working bodies for chemical plant protection:

- flow and pressure regulation for agricultural sprayers using solenoid valves [1];
- comprehensive model of pesticide spray drift with an assessment in vineyards [2];
- flow, spray pattern, and droplet spectra characteristics of an electronically actuated variable-orifice nozzle [3];
- effect of nozzle type and pressure on spray droplet characteristics [4];
- machine protection equipment, describing its characteristics, process flow charts, settings, and methods of use [5];
- improvement of dispersion for pesticide spraying [6];
- substantiation of parameters of the pneumohydraulic system for dosing and supply of working fluid in sprayers [7];
- jet pump for direct supply of pesticides to the sprayer discharge communication [8].

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012046 doi:10.1088/1755-1315/1415/1/012046

The analysis of the well-known authors works have been showed that we don't have the research of time for opening and closing of spray in flat and injector studies have been carried out to determine time for opening and closing of spray in flat and injector nozzles of the combined spraying working body (CWB).

2. Materials and methods

The research was being conducted at the National University of Life and Environmental Sciences of Ukraine at the Department of Agricultural Machinery and System Engineering named after Academician P. M. Vasylenko in 2021-2023.

The main factor that affects on the speed of the droplet departure from the spray nozzle, and therefore the time for opening and closing of spray in flat and injector nozzles, it is the pressure in the spray manifold.

Since it is impossible to record the time of opening and closing of the spraying plume using a stopwatch and visual organs, we decided to film it using a Panasonic NV-GS75 digital video camera, which allows you to take 25 frames per second.

The experimental sprayer OP 2000-2 has being transported to the test site. A cardan shaft have been attached to the sprayer pump and connected to the PTO of the MTZ-82 tractor. The tractor PTO speed was 540 rpm.

The pressure in the manifold was being monitored using a WIKAI EN837-1 manometer [9]. Since the sprayers operate at a pressure 0.2 to 0.5 MPa, the tests have been conducted at the average pressure 0.35 MPa.

The Panasonic NV-GS75 digital video camera have been mounted on a Continent TRIPOD A2 tripod. The installation height of the video camera was 1 meter above the ground and 1.5 meters to the CWB. The video camera was set to a shutter speed of 1/500 second, an aperture of $D = 8$ to ensure the highest clarity, and a 10x optical zoom. The shooting has been carried out in triplicate, on three sections of the boom, each type of sprayer have been filmed separately (figure 1).

After the research, the camera has been connected using a FireWire connector to the PC based on an Athlon 2800+ processor. The video has been processed using the Motion DV STUDIO 5.3E program, where the time for opening and closing of spray in flat and injector nozzles for the CWB has been calculated (figure 2).

The research data has been processed according to the method of statistical processing for empirical data and have been evaluated by the arithmetic mean time of opening and closing for the spray nozzle of the combined spraying working body.

The arithmetic mean value the time of opening and closing for the spray nozzle has been determined by the following equation [10]:

$$X = \frac{\sum x_i}{N}, \tag{1}$$

where the X – time for opening or closing of spray nozzles, second; N – the number of experiments.

The dispersion had been calculated by the following equation [10]:

$$\sigma^2 = \frac{\sum (x_i - X)^2}{N - 1} \tag{2}$$

The average square deviation (standard) had been calculated by the following equation [10]:

$$\sigma = \sqrt{\sigma^2} \tag{3}$$

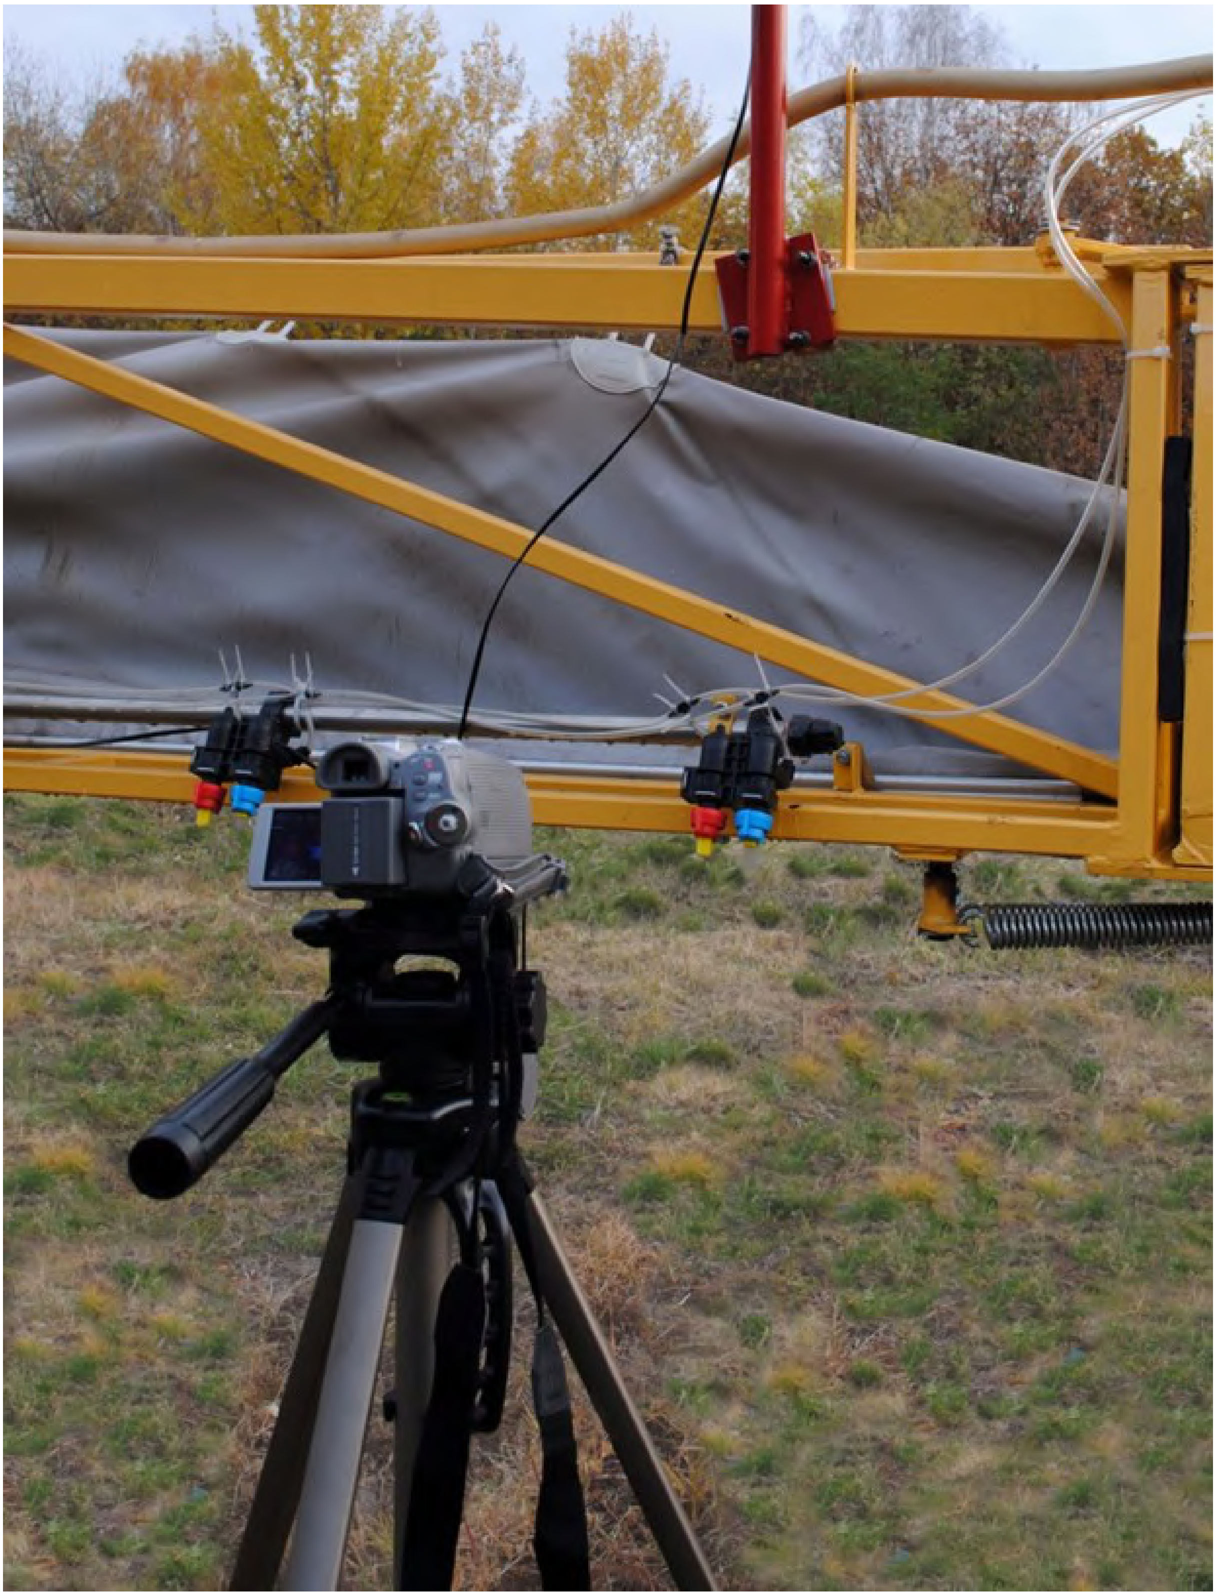

Figure 1. Filming of opening and closing of spray in flat and injector nozzles.

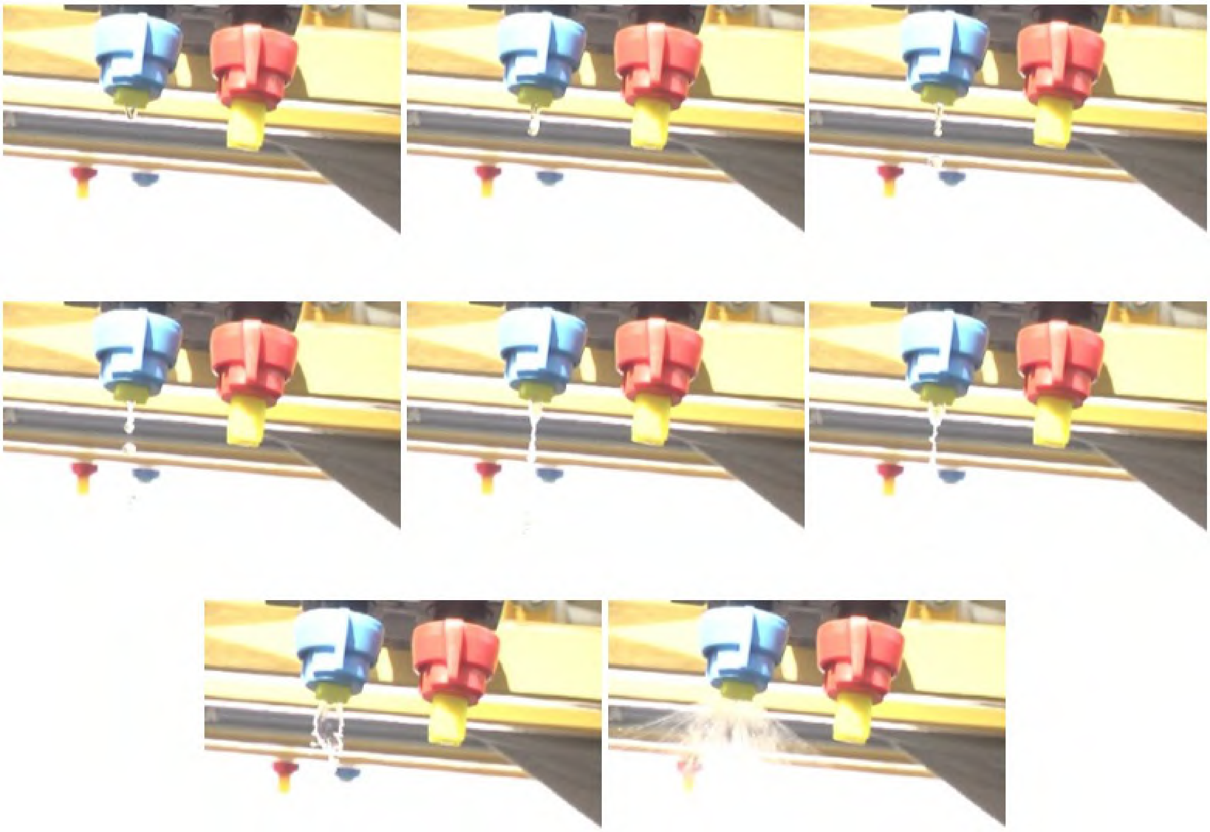

Figure 2. Opening of the Lechler ST 110-02 spray nozzle (photo interval – 0.04 s).

The coefficient of variation by average square deviation had been calculated by the following equation [10]:

$$V = \frac{\sigma}{X} * 100\%. \quad (4)$$

3. Results and discussion

The results of the data (arithmetic means from three sections, three repetitions) you can see in figure 3 and figure 4.

The arithmetic mean has been determined with help of equation (1). Calculations have been performed using Microsoft Office Excel software.

The results of calculations for arithmetic mean, average square deviation (standard), and

Table 1. Results of calculations for experimental studies.

Opening time, seconds	Arithmetic mean	Dispersion	Average square deviation (standard)	Coefficient of variation
Lechler ST 110-02 flat nozzle	0.235	0.002	0.045	19.17
Lechler IDK 120-02 injection spray nozzle	0.435	0.005	0.068	15.55

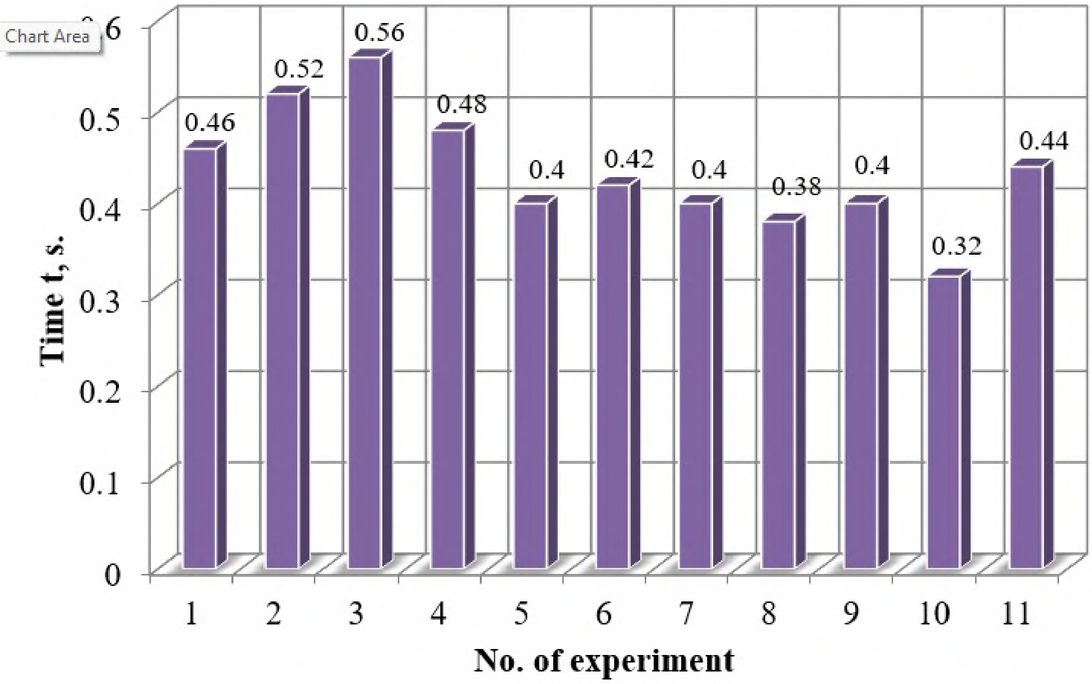

Figure 3. The opening time for Lechler IDK 120-02 injection spray nozzle.

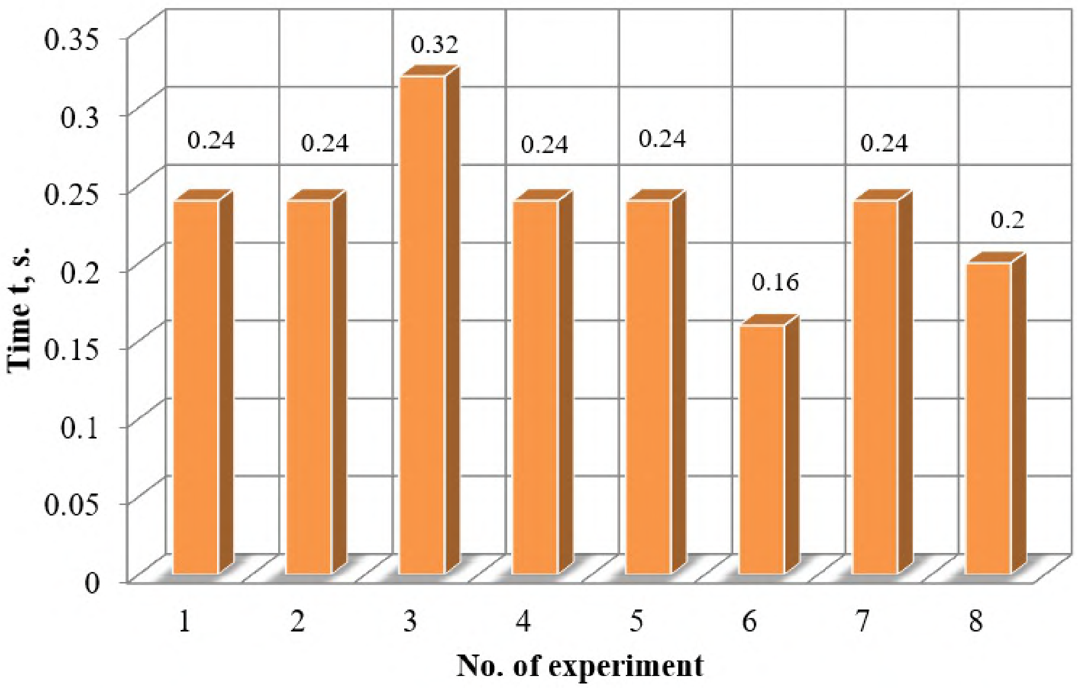

Figure 4. The opening time for Lechler ST 110-02 flat nozzle.

coefficient of variation by average square deviation you can see in table 1 (calculations have been performed using equations (1)-(4)).

The average value of the closing of spray in Lechler ST 110-02 is 0.04 s, and the Lechler IDK 120-02 nozzle is 0.08 s.

4. Conclusions

The opening time(arithmetic mean) for Lechler ST 110-02 flat nozzle 0.235 s. The opening time for Lechler IDK 120-02 injection spray nozzle 0.435 s. The average value of the closing for spray in Lechler ST 110-02 is 0.04 s, and the Lechler IDK 120-02 nozzle is 0.08 s. The transient time for switching from the ST 110-02 nozzle to the IDK 120-02 nozzle should be 0.395 s, and the switching from the IDK 120-02 nozzle to the ST 110-02 nozzle should be 0.155 s.

Abstract. Plant-based dairy alternatives have been gaining popularity recently in developing nations, but only a little is known about the consumer perception of these goods. This study aims to analyze the key determinants that affect millet milk consumption in India. An online survey was conducted with a sample of 178 people belonging to different age groups and educational backgrounds. Binary logistic regression was used in the study to analyze the factors that will significantly contribute to the consumption of millet milk. The results suggested that veganism and ethical concerns significantly affected decision-making. In addition, the educational background of the people was also significant but negatively correlated in influencing the consumption of plant-based dairy alternatives. The study aligns with SDG 12: Sustainable Consumption and Production, SDG 13: Climate Action, and SDG 3: Good Health and Well-being, contributing valuable insights for fostering sustainable dietary patterns and environmentally conscious consumer behavior. To promote millet milk in the Indian market, the stakeholders can customize their marketing strategies and emphasize ethical concerns and veganism.

1. Introduction

Milk and milk products are an integral part of the Indian diet and are one of the most accepted sources of nutrition. They are usually sourced from cows, goats, and buffalos and serve as regular human food. Nevertheless, the number of people experiencing lactose intolerance has extensively ramped up. This rise in the lactose-intolerant population focuses on the need and scope for seeking alternatives to dairy milk [1]. The non-dairy milk alternatives are sourced from plant sources such as cereals, legumes, nuts, seeds, pseudo-cereals, and so on [2]. This plant-based milk is a juice derived from plant extracts and water, resembling the colour of bovine milk, but has a different taste.

Plant-based alternatives have higher calcium, potassium, and vitamin content and lower amounts of fat, sugar, and saturated fat content when compared with regular bovine milk. Cereal-based milk is now majorly developed from oats, rice, etc.; millet is a new addition to this category. Being high in protein and low in calories, it is an ideal replacement for dairy, especially in the current scenario where high nutrition and low calorie is preferred. The high fiber content of millet makes digestion slow, prolonging the body's energy supply [3]. Although they are superior to other cereals, their utilization as food, especially as a milk alternative, is minimal. Millets are extensively cultivated in India and they are known to thrive well in all soil types with less maintenance and less water, making them a sustainable crop that has the potential to meet the food security needs of our country [4]. Therefore, it is an ideal crop to be used as a dairy replacement through value addition. The immense potentialities that millet milk and its dehydrated products possess could also be utilized in developing novel food products at the therapeutic end [5]. Therefore, this study aims to analyze the millet milk market in India.

In this context, the study is involved in identifying what are the crucial factors involved in the purchase of millet milk. The primary motivation for conducting this study is the growing popularity of plant-based diets and the trend towards veganism and sustainability. This study aims to investigate the aspects that influence the uptake of millet milk, such as its nutritional value, personal taste preferences, environmental concerns, animal welfare ethics, age demographics, and the influence of education on people's dietary decisions. The study aims to offer insights into the developing market dynamics of plant-based dairy substitutes, especially millet milk, in response to shifting consumer habits and health-conscious trends by examining these variables. The study directly tackles the objective of encouraging sustainable consumption (SDG-12), good health and well-being (SDG-3), and climate action (SDG-13) by analyzing the determinants of millet milk consumption in the context of plant-based dairy substitutes. The research's conclusions can help promote environmentally friendly purchasing behaviour and sustainable eating habits.

2. Literature review

Over the past few years, the idea of veganism, which originated predominantly in the Western world, has gracefully found its way into Southeast Asian homes. Alongside the well-known soy and almond milk choices, other alternatives, such as oats, cashews, peas, and hemp milk, have also placed their foot in the Indian markets. Millet milk is a new addition to this family.

Plant-based milk presents an acquired taste distinct from the familiar fresh cow's milk that Indians have traditionally grown up with, and this is a newer concept in India [6, 7].

Millet is the sixth most important cereal in the world and is considered a rich source of energy, protein, and minerals [7]. Unprocessed millet milk contains 9.17 percent protein, three times more than dairy milk, and 0.68 percent fat, 1.7 times less than dairy milk [8]. They also contain significant aggregates of carbohydrates (60-70 percent), dietary fibers (2-7 percent), and minerals, especially calcium, iron, zinc, and iodine [9]. In addition to this, some components present in millet, such as phytates, phenol, and tannins, provide anti-aging benefits. The high amount of bioactive and antioxidant compounds and low levels of saturated fats in millet help maintain positive health by preventing the onset of non-communicable diseases like obesity, cardiovascular disease [10], inflammatory disease, and diabetes mellitus [11]. Dietary fiber and micronutrients in millet help maintain health and prevent type-2 diabetes, breast cancer, and heart diseases [12]. They match nearly all the most prominent global health food trends, including being a superfood, ancient grain, gluten-free, low glycemic index, high in antioxidants, and suitable for managing weight [13]. When considering these factors, and due to numerous other water-soluble nutrients, millets are a good source for developing plant-based milk substitutes.

There has been a significant increase in consumer interest in natural and healthy foods, especially since the COVID-19 pandemic. The rise in millet consumption can be ascribed to increased health awareness. People are turning to a millet-based diet to improve and rant up their immunity levels and to have a healthy lifestyle, recognizing food as a medicine [14]. In India, many entrepreneurs and food companies have shown interest in using millet lately after understanding its nutritional benefits in various modern products, including flour in pancakes, pasta, and noodles. Popped, flaked, and puffed millet variants are used in snack bars and as breakfast cereals [15, 16].

An investigation into the connection between the attributes of dairy-alternative drinks and consumers' propensity to buy shows that nutrient-related health characteristics, such as calories, protein, fat, and vitamins, matter to them [17]. Besides nutritional benefits, the product's taste was another crucial factor influencing plant-based beverage purchases. Taste preference plays a significant role in buying milk, leading to the hypothesis that it is inversely related to purchasing plant-based milk [18]. This assumption is based on the understanding that individuals who prioritize taste in their choice of milk might be less inclined to opt for plant-based alternatives. Millet milk has attracted the attention of lactose-intolerant and vegan consumers today. According to Good Food Institute India (GFII), the market for these plant-based dairies is still driven by lactose intolerance, ramped-up demand for vegan food options, and climate change. The increase in dietary restrictions and growing adoption of veganism, a dietary style of consumers, is predicted to positively influence the consumption of plant-based milk dairy [19,20]. This assumption is based on the knowledge that people who follow particular dietary guidelines and preferences, such as veganism or lactose intolerance, are likely to influence the growing acceptance of plant-based milk substitutes like millet milk.

Environmental concerns might be another factor driving individuals to choose plant-based dairy substitutes in addition to their benefits to health, affordability, and flavor [19]. Furthermore, people who view animal welfare as a critical consideration when choosing foods view plant-based dairy alternatives as more ethical [20]. Therefore, environmental and ethical concerns about animals positively influence consumers' perception of plant-based dairy alternatives [19]. Along with plant-based dairy substitutes' objective nutritional qualities, what customers think about this product category also matters, which is why this study focuses on understanding the factors that lead to the purchase of millet milk.

Young individuals are more liberal in consuming plant-based milk [21]. Therefore, age is expected to have a negative influence. It is claimed that younger and middle-aged individuals are expected to be more curious and open to trying new items in the market than older individuals. This anticipation is anchored in the fact that younger and middle-aged groups frequently demonstrate greater openness to innovative experiences and innovations. Thus, it was expected to influence the choice of plant-based beverages positively. Education gives people the information and analytical abilities they need to choose healthier foods [22]. Therefore, it is expected to affect Individuals' nutritional choices positively. It is assumed that in this particular setting, people with greater levels of education are more likely to prioritize nutrition, which will positively impact their total dietary choices.

3. Methodology

3.1. Methods and procedures

The study is designed as a quantitative study to gain insights into the relatively unexplored phenomenon of millet milk consumption among consumers in India. While millet milk and its products offer numerous health, environmental, and ethical advantages compared to traditional bovine dairy, it is essential to understand the factors that drive consumers to purchase.

Data regarding the current market size and growth trends of plant-based non-dairy in India was collected through secondary sources such as existing studies, industry publications, research firms, and other reliable sources. This will help to understand the demand for existing plant-based, non-dairy beverages in India.

More participants will participate in a survey online rather than in a traditional one-to-one setting [23]. Hence, an online mode was adopted in this scenario. A structured survey was prepared in Questionpro for primary data collection. It was distributed to all potential participants from November to December 2023 to understand the consumer perception of millet milk across India. The questions were tailored explicitly to analyze and understand the fundamental driving forces and barriers in consumers' minds.

The survey was distributed through various online and social media channels to reach a broad audience across India. Efforts were made to target individuals from urban, suburban, and rural areas to ensure geographic diversity. This study has recorded 178 opinions from 6 questions to understand the market acceptance and challenges of millet milk in India. The survey predominantly concentrated on individuals aged 20 and above as they have higher chances of being employed and will have their own opinions on the food items they consume. Most respondents (about 90 percent) from the sample were over 20 years old and above. 50.54 percent of the respondents said that they had consumed plant-based milk earlier. Regarding gender, females comprised almost 53.51 percent of the sample, while males contributed the remaining 46.49 percent. Nearly 9.19 percent of the individuals surveyed only had senior secondary education as their educational qualification, and 32.97 percent had completed undergraduate degrees. While 46.49 percent of the individuals had post-graduate and 11.35 percent had doctorate qualifications. In total, 90.8 percent of individuals qualified for undergraduate and above degrees.

The transcriptions of the questionnaire were moved to Excel format and analyzed using the Statistical Package for Social Sciences (SPSS). At First, a cleaning process was performed to guarantee its completeness and validity. This procedure examined logical inconsistencies, outliers, and missing numbers. The values of the means and standard deviations of the variables were generated to prevent these data issues. Based on these values, no missing values were found, but some outliers were discovered. The outliers were handled by substituting them with the mean values of each variable.

This study utilized binary logistic regression to identify the significant factors that influenced the consumers' purchase decision of millet milk. A binary logistic regression is a kind of regression model where the dependent variable is a categorical dichotomy that can have just two values, one or zero [24].

3.2. Model specification and variable description

Since the likelihood of customers' replies was a binary decision, the binary logistic regression model was employed for the study. The dependent variable measured the consumers' choice regarding plant-based dairy alternatives (either consumed or never consumed). In contrast, independent variables were derived from the consumer's demographics, such as age, gender, educational background, and veganism. Characteristic variables influencing a consumer's purchase include dietary restrictions, curiosity to try a new item, taste preferences, ethical concerns, and environmental factors. These variables included in the study were consistent with the literature. The age of the individuals represents the age of the consumers in years, and the education of the individuals was measured in the years of schooling under two categories: graduation and above and below graduation. Finally, bivariate correlation analysis was conducted to test the correlation between the factors that led to the purchase of millet milk.

4. Results and analysis

4.1. Descriptive analysis

The dietary style of individuals was recorded as vegan or non-vegan. Among the transcripts, almost 87.91 percent of the individuals surveyed were identified as either vegetarians or omnivores, while only 12.09 percent were vegans. This breakdown is essential for comprehending the market segment that is either open to or interested in embracing plant-based milk substitutes like millet milk. Among the factors influencing individuals' milk purchases, the main motivator was tasting preference, followed by considerations for nutrition, the environment, and the ethical treatment of animals. It is essential to comprehend these impacting elements to address customer preferences and customize marketing methods properly.

Table 1. Variable definition, unit of measurement, and expected signs.

Variable code	Variable name	Measurement	Expected signs
Dependent variable			
cnsptn	Consumption of Millet Milk	1 if yes, 0 if otherwise	
Independent variables			
Age	Age of Individuals	Number of Years	−
Gen	Gender of the Individuals	1 if Male, 0 if Female	
Edu	Education of the Individuals	Years of Schooling	+
Vegan	Dietary Style of Individuals	1 if yes, 0 if otherwise	+
Curi	Curiosity to try new items	On a scale of 1-7	+
Nutri	Nutritional content of milk	On a scale of 1-7	+
Diet	Dietary Restrictions of Individuals	On a scale of 1-7	+
Envi	Environmental Concerns	On a scale of 1-7	+
Taste	Taste Preferences	On a scale of 1-7	−
Ethical	Ethical Considerations	On a scale of 1-7	+

4.2. Factors affecting millet milk consumption: Binary logistic regression analysis

This study used binary logistic regression analysis to determine the parameters impacting plant-based milk consumption in India. The estimated variables are shown in Table 2. The explanatory variables in the model's estimated coefficients (B), standard error (S.E.), significance value (sig.), and odds ratios were displayed in the table. If all other predictors are identical, the coefficients (B values) estimate the changing likelihood of the dependent variable for a unit change in the related predictor [25]. The sign of the coefficient values indicates the explanatory variable's direction of impact. The model was very significant (P-value of 0.000) in predicting consumers' millet milk choices.

The explanatory factors significantly influencing millet milk consumption were veganism, educational background, and ethical treatment. However, age, gender, nutritional factors, environmental concerns, taste preferences, nutritional content, curiosity, and dietary restrictions (like lactose intolerance) were not statistically significant. Also, the signs of the estimated coefficients of some independent variables aligned with the prior expectations; however, others were contrary to expectations.

The variable 'veganism' was found to influence the purchase of millet milk in India significantly. The beta coefficient of this variable was 1.614, with an associated P-value of 0.010. The effect of this dietary culture on the purchase turned out to be positive, as expected. Similarly, the ethical concerns about animals significantly influenced the purchase with a beta coefficient value of 0.333 and an associated P-value of 0.015. This variable had a positive influence. This explains that the more ethical concerns individuals have towards animals, the greater their chances to shift towards a plant-based dairy. This result was well aligned with the previous study, which concluded that people with an ethical concern towards animals are more likely to turn to millet milk [19].

The variable 'educational background,' although significant, demonstrated a negative effect on the consumption of millet milk. This finding did not support the previous results, which report that education will have a positive influence [22]. The reason for the above could stem from individuals being reluctant to break with their long-standing cultural custom of drinking cow milk. Despite being informed about the advantages of plant-based milk, people may exhibit reluctance to embrace dietary choices that align with their well-established traditions. One possible explanation for this resistance to switching to healthier options is a reluctance to deviate from cultural norms and practices [26]. As stated, though people know the nutritional benefits, none of this intellectual knowledge is reflected in their eating habits. Similarly, even nutritional content did not significantly influence the purchase. This could be because consumers prioritize taste and texture above nutrition. These results align with the previous study, which states that consumers of cow milk need to have 1-2 percent fat content in their milk and perceive it as a staple food [27].

Table 2. Binary logistic regression results in identifying the factors influencing the consumption of millet milk in India.

Variable	B	S.E	Sig.	Exp (B)
Age	0.008	0.17	0.645	1.008
Gen	0.199	0.340	0.558	1.220

Other factors, such as environmental concerns, curiosity to try a new item, and taste preferences, had a non-significant effect on the purchase of millet milk. This result did not support previous studies, which concluded that the above factors would positively influence the purchase of millet milk [19, 28]. Remarkably, those concerned about the environment only sometimes chose plant-based dairy substitutes over conventional cow's milk. This confirms that individuals only sometimes express ecologically conscious consumer behaviour [28]. The study also found no statistically significant influence of milk's taste on customers' selection of millet milk. This supports the findings that full-fat dairy milk was preferred over plant-based dairy alternatives [29]. These results imply that although various factors influence consumer decisions, tastes, curiosity, and environmental concerns do not significantly impact the preference for millet milk over traditional options. Overall, the binary logistic regression has yielded insights into the critical factors that affected millet milk intake in India. Of all their demographic characteristics, only the veganism of the customers' diet was the most significant factor influencing their buying choice. Animal ethics also has a significant role to play in the purchasing process.

5. Conclusion and recommendations

The study reveals several key insights with implications for companies and stakeholders promoting millet milk in India. Veganism has been found to influence the consumption of millet milk significantly, indicating that those who follow a vegan diet are more likely to choose plant-based alternatives. Consistent with earlier studies, the study indicated a favourable association between the decision to use millet milk and ethical concerns regarding animals. People who cared deeply about animal welfare as an ethical issue were more likely to select plant-based dairy alternatives.

Surprisingly, individuals with greater educational backgrounds negatively influenced millet milk intake, even though their effect was statistically significant. This might be explained by cultural inertia, a phenomenon in which dietary changes are resisted despite knowledge of the advantages of plant-based alternatives due to ingrained customs and behaviours. These findings showcase the context-dependent nature of consumer behaviour in the adoption of millet milk. The non-significant influence of environmental concerns, curiosity, taste preference, nutritional content, age, gender, and dietary restrictions underscores the need for a more comprehensive understanding of the diverse elements in shaping consumer preferences for plant-based milk alternatives.

Given that veganism has a major impact on the consumption of millet milk, businesses should focus their marketing efforts on this expanding vegan market. To attract this customer niche, it may be useful to highlight the plant-based character of millet milk and its compliance with ethical and animal welfare issues.

Conversely, the negative effect of educational background on millet milk intake suggests that awareness initiatives focusing on the health advantages of millet milk need to be revised. Companies need to acknowledge the cultural and traditional aspects of dairy consumption, including the standing tradition of consuming cow's milk. Strategies must be devised to address and potentially overcome these cultural barriers, emphasizing the health benefits without directly challenging cultural norms. Despite the non-significant influence of nutritional content, there is room for educating consumers on the health benefits of millet milk. Providing consumers with clear information about the benefits can help bridge the gap between consumption and awareness.

Overall, the study emphasizes the importance of understanding the factors affecting the intake of millet milk. This study adds unique insights into the dynamics of sustainable choices in the food sector (SDG-12), climate action (SDG-13), and good health and well-being (SDG-3), shedding light on the intricate interaction of ethical concerns, dietary preferences, and educational variables in determining the consumption patterns of millet milk in the Indian market. To effectively promote millet milk in the Indian market, companies and stakeholders should customize their promotional activities to emphasize ethical issues, target specific customer categories like vegetarians, and overcome cultural hurdles. Furthermore, realizing that environmental concerns and taste preferences are not the main motivators helps improve marketing techniques. More research is advised to explore these areas in greater detail. The omission of price as a factor in our study was due to the early stage of the millet milk market in India, where awareness about pricing dynamics is currently limited among consumers. The study acknowledges the significance of price in shaping consumer behavior and consumption patterns. Incorporating price or the relationship between household income and the affordability of millet milk in future studies will enrich the understanding of the dynamics surrounding millet milk consumption. Additionally, future studies can include factors influenced by varying socio-economic contexts by examining consumption preferences across different demographic segments, including rural and urban populations. Knowing the subtle aspects influencing consumer decisions can help the millet milk industry improve its marketing tactics and product development initiatives.

Abstract. The main acceleration of climatic changes is considered to be the main consequences of existing anthropogenic influences and transformations in the wood ecosystems of the Steppe Dnipro industrial areas. Now, the preparation of science-based programs for the restoration and development of artificial tree plantations, which can increase the stability and diversity of forest ecosystems in the steppe zone under these conditions, is very important. However, artificial tree and shrub plantations are formed according to certain natural laws. It is necessary and urgent to study the current state of phytodiversity to ensure the effective protection of biodiversity, and implement nature conservation management on this basis, including the expansion of the areas of nature reserves. The purpose of this research work was to assess changes in the structure of the Dnipro Steppe woody ecosystems using the example of dust-protection and water-protection sanitary plantations. Modern biodiversity, formed in the natural ecotopes of the Steppe Dnipro region of Ukraine, is quite specific, primarily due to the combination of natural and anthropogenic landscapes in these territories. Depending on the ecological location territory conditions, taking into account the vitality indicators of the plantations, the further development of woody ecosystems according to the vectors of progress or regression is possible. Hence, there is an urgent need to study the biometric indicators of the Kryvyi Rih district's woody ecosystems under different growth conditions. The work carried out will become the basis for the development of the main directions of preservation and reproduction of phytodiversity in the woody ecosystems of the territory, which will make it possible to plan the necessary vectors for the protection and restoration of biological diversity of artificial trees and shrub plantations of the Kryvyi Rih districts. identifying the features of local guarantee of rare species from various protection lists. It will also contribute to the provision of ecosystem services by natural, spontaneous and artificial woody plantations of the Middle Dnipro region. The received recommendations form the basis of complex measures to preserve and restore the stable state of artificial tree plantations of the Kryvyi Rih district, located on the steep slopes of mine dumps and rafter-beam systems near the rivers and water reservoirs of the Dnipro Steppe.

1. Introduction

Acceleration of industrial and technical greenhouse gas emissions and disruption of the energy balance of the atmosphere, which is characteristic of powerful industrial regions in Ukraine, are considered the main causes of the existing climate changes [1–4]. Now the emergence and manifestation of catastrophic degradation phenomena, such as the development of the desertification process in the southern and Ukraine southeastern regions, are also associated with military operations and pyrokinetic effects and chemical pollution in the cycle of nutrients in the Dnipro Steppe natural and artificial woody ecosystems. The analysis of the main multi-year ecological consequences of global climate violation such as warming, as well as changes in the conditions of growth and development of tree ecosystems determines the further direction of work on acclimatization and introduction of woody plant species. Identification of new woody introduced taxons, the invasion of which has already occurred or may occur in the near future in Ukraine is an important area of ecological and botanical research. When studying the impact of climate change on woody and shrub plants used in landscaping and agriculture, it is also necessary to take into account the characteristics of nutrition with soil microelements and moistening with underground and above-ground water resources [5–12].

In the Ukrainian steppe territory the spatio-temporal transformation of the woody ecosystems structure is associated with changes in the water ecosystems of the Azov Sea and the Kakhov reservoir, the destruction of which in 2023 led to an ecological disaster of a regional scale. At the local level, the state of tree ecosystems will depend on the river ecosystems of the Dnipro region, such as Saksagan, Ingulets, Kamianka, Bazavluk, Samara, etc.

Under these conditions, scientifically based restoration and preservation of woody ecosystems in the conditions of the steppe zone is important. However, artificial woody and shrub plantations form according to certain natural orders [1, 2, 6, 13–16]. Depending on the ecological conditions of theterritory location and the complex of viability indicators of woody ecosystems, their further development is possible according to the vectors of progress or regression. Hence, there is an urgent need to study the biometric indicators of woody ecosystems in Kryvyi Rih district under different growth conditions.

Sustainable forest management (SFM) is currently widely recognized as the main goal of forest policy and practice in leading European countries [17–19]. RRegional processes for the development and implementation of SFM criteria and indicators are ongoing worldwide. In continental Europe, a set of 35 pan-European indicators has been endorsed by the Ministerial Conference for the Protection of Forests in Europe (MCPFE) to measure progress towards SFM in 44 countries in the region [18, 20, 21]. The importance of studying various aspects of modern phytodiversity as an essential element of preserving woody ecosystems for the development of a national ecological network in the pan-European network system is also an applied direction for the natural environment restoration as a result of ecocide caused by military actions in Ukraine. For this purpose, it is necessary to investigate various characteristics of natural and spontaneously formed woody plant cover. Given the ecological specificity of the Middle Dnipro and the Forest-Steppe zone in Ukraine, a detailed analysis of natural and artificially formed woody plantations on man-made landscape formations, in raft-beam systems of rivers and reservoirs, as well as in floodplain woody ecosystems is required.

A lot of studies (e.g., [11, 17, 19–22]) discusses European approaches to the concept and requirements for a classification of woody ecosystem vitality that is more ecologically substantiated and suitable for MCPFE revealing. In Europe a unified approach to the of tree ecosystems classification implemented as part of the MCPFE monitoring process and its analysis, is reported to be resulted in a proposed European forest types scheme structured into a reasonably large number of classes, which improves the specificity of indicators.

In the experts works on the protection and preservation of Ukrainian woody ecosystems, the features of forest ecosystems, the distribution of tree species and the ecological conditions of their

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012048 doi:10.1088/1755-1315/1415/1/012048

growth are given. According to forest management data, the area covered by forest vegetation is 251341.3 hectares [23,24]. On the Middle Dnipro region territory the distribution of the forest plots area on edatopes, natural and artificially formed forests on the Dnipro steeps, in rafter-beam systems and in the floodplain of the Dnipro River and the Forest Steppe of Ukraine is as follows: trophotopes – subory (78083.2 ha, 31.07 %), conifers (77232.6 ha, 30.73 %), thickets (72520.6 ha, 28.85 %) and boreal forests (23504.9 ha, 9.35 %). hygrotopes – fresh conditions (183792.4 ha, 73.13 %), dry (34938.5 ha, 13.90 %), wet (19038.7 ha, 7.57 %), crude (11401.1 ha, 4.54 %), moist (1896.0 ha, 0.75 %) and very dry conditions (274.6 ha, 0.11 %) [23–25].

Up day, the tendency to intensive use of forest resources caused by the desire of forest industry enterprises to obtain high profits dictated by the market increases in the Kryvyi Rih district. On the other hand, currently the forestry land area amounts to 9,086 hectares, of which 6,500 hectares are forest land. On the main part of these lands, only the natural regeneration of the forest is taking place, while an recent years afforestation has been carried out on area of only 2 hectares.

The change in the vital state of woody ecosystems depends on several environmental factors – abiotic, biotic and anthropogenic. However, it is always possible to single out complex of key factors that have the greatest impact on tree regeneration, drying and waste, invasive introduction of aggressive tree species, etc. Factors regulating the population density of woody ecosystems are divided into density-dependent and density-independent factors. Homeostasis of the tree ecosystems population is defined as the ability to maintain a certain number (density) and self-regeneration of the dominant species of tree vegetation in Kryvyi Rih district. A significant period of forest resources reproduction limits the possibilities of their use, especially in the unfavourable conditions of the steppe climate and constant anthropogenic load. Such specificity of woody plantations requires constant monitoring of relevant changes in the species composition and vital state at the tree in ecosystems. This demands the improvement of the forest management system, the creation of environmental protection infrastructure governance, and the development of a financial and economic system of targeted financing of the forest protection industry [3, 6, 18, 22, 26, 27].

The work aim is evaluating the changes in the structure of forest ecosystems using the example of dust-protection and water-protection sanitary woody plantations, analyze the vital state of artificial woody plantations and the stability of the dominant tree layers representatives, caused by the stress factors of anthropogenic load industrial-residential nature and the region arid climate for further improvement of the forest resource management system and governance of nature protection activities in the ecological conditions of the Dnipro Steppe in Kryvyi Rih industrial district.

2. Methodology

Kryvyi Rih District is a territorial division of the land of geographical zoning in Ukraine. The district is located in the south-east of the Central part of Ukraine. More than 90 % of its area is administratively located in the southwestern and western parts of the Dnipropetrovsk region. Only in the north-west of the district, it borders the Kirovohrad region, in the south – with the Mykolaiv and Kherson regions. Geographic coordinates of the study area are from 48°19′ to 47°28′ south latitude, from 32°58′ to 33°47′ west longitude. The area of the territory research district is 4.1 thousand km^2, which is equal to 0.67 % of the entire area of Ukraine. The length from north to south is 96 km, and from east to west is 62 km. The research areas are located in the basin of the middle course of the Ingulets River and its tributary, and partly in the east of the Kamianka River, which flows into the Dnipro River. According to the geological and metallurgical zoning of Ukraine, the territory of the Kryvyi Rih District corresponds to the territory of the Kryvyi Rih Iron Ore Basin (Kryvbas). Its subsoil contains unique iron ore deposits, which led to the construction of reach mining and industrial plants in this region.

These industrial enterprises dominate the structure of the region's economy in terms of the volume of manufactured products [1, 23, 24].

Woody ecosystems that are in favourable ecological conditions in relation to the city of Kryvyi Rih are represented by the natural stands of the Hurivka village forest (3 sites with natural and artificial tree vegetation are located in the floodplain of the Bokovenka River and on the territory of forestry); Valove village forest (woody ecosystems in the vicinity of the village Valove, 3 sites with natural and artificial tree vegetation are located in the floodplain of the Bokova River, Kryvyi Rih district, Dnipropetrovsk region); Tarasivka village forest (forest massif in the vicinity of the village Tarasivka, 3 plots of natural and artificial origin Sofiivka district, Dnipropetrovsk region). They were formed with the dominance of oak trees (Quercus robur L.), the estimated age of which is 180–80 years.

Forest ecosystems growing in relatively moist conditions and formed as sanitary water-protective tree ecosystems in the territories of the city of Kryvyi Rih are presented: Arboretum "Veseli Terny" (5 plots located in the northern part of Kryvyi Rih, floodplain of the Saksagan River); Water protection plants of the Karachuny woter Reservoir (5 sites located in the southwestern part of Kryvyi Rih, floodplain of the Ingulets River); Water, noise and dust protection plantations of the "Artem-1" mine tract (3 sites located in the central part of Kryvyi Rih, floodplain of the Saksagan River); dendrological park "Dovhyntsivskyi" (11 plots located in the eastern part of the Kryvyi Rih city, floodplain of the Saksagan River). It should be noted that Kryvyi Rih forest phytocenoses function in relatively not favourable ecological conditions. Forest ecosystems of water protection woody plantations are of both natural and artificial origin, aged 120-40 years; woody ecosystems of the Dovhyntsivyi Arboretum (2 plots) and the water protection plantations of the Karachunivyi Reservoir (5 plots) belong to the zone with unfavourable ecological conditions for the growth and development of woody plants. They are formed with the participation of Quercus robur L., Fraxinus excelsior L., Robinia pseudoacacia L, Quercus rubra L., Tilia cordata L., Pinus sylvestris L.. All woody plantations of this ecological zone are of exclusively artificial origin and were created approximately 50-80 years ago.

Sanitary dust-protection and noise-protection woody plantations are of artificial origin, 90-60 years old and located in the zone of unfavourable ecological conditions, represented by tree plantations of the urban and sanitary-protective woody belts (6 plots, tract of Dnipropetrovsk highway, "Kiltse Kosiora", the territory of "Arcelor Mittal Kryvyi Rih"). The woody plantations are dominated by Quercus robur L., Fraxinus excelsior L., Acer negundo L., and occasionally Ulmus laevis L.. It should also be noted that the edaphic conditions are characterized by a low level of moisture (except for the plantations of plot 1 due to flooding with technical waters of "ArcelorMittal Kryvyi Rih") and very significant aerogenic pollution due to the closeness of their territory to the city's mining and metallurgical enterprises.

During the research, cartographic materials from Internet resources GoogleMaps and lk.ukrforest.com were used. The analysis of the typological structure of forests was carried out according to the methods of the Ukrainian school of forest typology [1, 23, 24, 28–30]. Data analysis was carried out using MS Excel 2010 software.

The woody ecosystem's vitality was investigated and measured by such indicators of wood as the area of tree plantations, stock of wood, age structure of wood, distribution of diameters of tree trunks, presence of dryness, composition of tree species and consequences of harmful effects of environmental agents [1, 28–30].

Arithmetic average indicators of the vitality of the tree stand are considered by specialists to be the main characteristics of the statistical population of all taxa in the areas reflecting the level, in order to determine the fluctuation of variations in plant diversity. This statistical indicator in our studies took into account not only the visual averaged indicators of woody and shrub ecosystems, but also the characteristics of each individual plant on the site. A total of 39 key stationary research sites were worked out and measurements were made of 1.939 tree plants. Calculations of the vital state of tree and shrub ecosystems in accordance with ecological conditions were calculated on the statistical indicators of the arithmetic mean (M), taking into account the absolute error of the mean (m), the coefficient of variation (V) according to the number indicators [1, 28–30].

The obtained materials and results were processed by the method of variable statistics at the level of significance P>0.05 [13, 14, 29–31].

3. Results and discussion

The climate of the steppe zone is moderately continental. The annual radiation balance varies from 4100 (in the north) to 5320 Mj/m^2 (in the south). Thanks to this, the steppe zone has the largest thermal resources. Average annual air temperatures change from the northeast to the southwest from +7.5 to +11 °C. Average temperatures in July increase in the southern direction from +21.5 to +23 °C. Annual precipitation decreases from 450 mm (in the north) to 350 mm (in the south). A characteristic feature of steppe landscapes is high evaporation (from 700 to 1000 mm). According to climate studies, over the past 5 years, an increase in annual temperature by 0.6 ± 0.20 C/100 years and a slight increase in annual precipitation (5–7 % per 100 years) have been noted in Ukraine. The scientific works of climatologists also investigate the peculiarities of the transformation of seasonal changes in the climatic boundaries of the territories of Ukraine in terms of temperature and atmospheric precipitation [5, 12, 23, 24, 32].The Kryvyi Rih climatic conditions reflect the changes in the climate of the Dnipro Steppe and Ukraine as a whole. Plant ecosystems clearly respond to global changes in temperature regimes. In general, natural and artificial forest ecosystems are the most powerful factor in stabilizing the functional organization of natural ecosystems and strengthening their resistance against anthropogenic influence and regional climate changes. Forest ecosystems are able to significantly reduce the harmful anthropogenic impact on climate change in the region.

The steppe zone on the territory of Ukraine is relatively young. There is an opinion that the front of the steppes was an ancient forest-steppe zone. The relief of the Ukrainian steppes is flat, but heterogeneous. Due to insufficient humidification of the atmosphere, the density of the river network is insignificant: 0.08-0.05 km/km^2. Runoff is formed due to melted snow water. In the woody ecosystems of the territory of the Middle Dnipro region, which includes natural and artificially formed woody ecosystems on the Dnipro steeps, in the rafter-beam systems and on the floodplain of the Dnipro River in the Forest Steppe of Ukraine, experts distinguish 62 types of forest, among which fresh oak-primary forests predominate subir (68319.9 ha, 27.18 %) and hornbeam forest (32871.8 ha, 13.08 %), slightly smaller areas are occupied by fresh pine forest (17568.3 ha, 6.99 %), hornbeam-oak-pine forest (16952.2 ha, 6.74 %), maple-linden forest (15144.4 ha, 6.03 %), hornbeam- pine (13775.4 ha, 5.48 %) and hornbeam (9334.3 ha, 3.71 %) forest stands, as well as dry maple-linden oak forest (12810.9 ha, 5.10 %). The species composition of forest-forming species is quite diverse and is represented by 71 species of woody and shrubby plants. [25]. The main forest-forming species are Pinus sylvestris (116592.9 ha, 46.39 %) and Quercus robur (60049.7 ha, 23.89 %). Robinia pseudoacacia (26406.0 ha, 10.51 %), Alnus glutinosa (11391.7 ha, 4.53 %) and Fraxinus excelsior (7835.5 ha, 3.12 %) occupy somewhat smaller areas. All other species occupy small areas [25]. Identifying all the diversity of the forest ecosystem, both natural spontaneous overgrowth and artificially planted woody plantations, will provide an opportunity for specialists to plan directions for preservation, reproduction and protection of phytodiversity. Separately, experts note the importance of establishing the number of sozophyte species included in various protection lists. Another direction of research is the provision of balanced ecosystem services of a recreational and educational nature for the preservation and reproduction of woody plantations in the Middle Dnipro region [12, 22, 25].

Steppe landscapes in Ukraine territory were formed in a hot climate with a negative moisture balance. Studies of the current state of biodiversity of woody ecosystems in the territory of the Middle Dnipro Forest-Steppe of Ukraine, including in the Emerald Network, the forest typological structure of the ecosystems of the Middle Dnipro and the typological characteristics of hardwood stands of the Left Bank Forest Steppe are considered in the works of Ukrainian forest scientists [25, 33].

One of the most important characteristics of any ecosystem is its stability. The main parameters of a sustainable ecosystem are the constancy of the species composition, the closed cycle of substances and relatively constant bioproductivity [2, 6, 13–17]. The leading biological and dendrometric characteristics of artificial woody plantations have a clear environmental stipulation. In the Ukraine steppe zone indicators of the artificial woody plantations viability indicate a lack of moisture in the soil and an increased level of atmospheric pollution: pollutants constantly accumulated on the surface of leaves and the surface of the soil are significant ecological negative factors for all components of the ecosystem [4, 34].

Within the vast European forest territory, the values of the main vital indicators of tree ecosystems of artificial and natural origin show a significant range of variations due to changing natural conditions and anthropogenic influence. Taking into account such variability, it is very difficult to understand the correlations of indicators of the woody plantation's vitality, if they are separated from their ecological local origin [6, 17, 20, 21].

The implementation of the seven main pan-European indicators for the assessment of woody stands approved by the MCPFE for SFM, improves the process of monitoring the tree ecosystems state in monitoring studies of forest ecosystems. Among these seven main generally accepted indicators are: the area of woody plantations, wood stock, tree age structure, distribution of tree trunk diameters, presence of tree dry matter, composition of tree species, harmful agents, degree of adaptation and naturalization of woody ecosystems. Permanent monitoring of forest vital activity indicators requires obtaining national data by types of forest plantations of natural, naturalized and artificial origin [17, 19–21].

Structural organization of the forest stand. Taking into account that the basis of forest ecosystems is the soil cover of Kryvyi Rih district, which is represented by ordinary and southern chernozem with a high level of fertility. We classified soils under woody plantations as ordinary and southern chernozems; meadow chernozem soils; soils, which are less favourable for the growth and development of woody plant species, were classified as "dry" and "fresh"; "wet" and "moist" soils are also found in the region [1, 28].

The analysis of dendrometric characteristics showed that their optimal level is observed in the natural ecosystems of Hurivka village forest, Tarasivka village forest and woody ecosystems of the Volove village forest surrounding village's Volove. These woody plantations and natural forest ecosystems are in the most favourable ecological conditions for growth. The aforementioned ecosystems are characterized by a fully formed vertical structure of the tree stand. Thus, the natural density of the I-III tiers of tree and shrub plantations was 1175-1200 pcs./ha, their average height was from 14.9 to 19.7 and grew up to 22.5 m (I tier, 2020), the trunk diameter from 16.4 to 41.9 cm grew to 20.8 – 44.2 cm (I tier, 2020), the stock of trunk wood was from 383 up to 560 m^3/ha, the sum of cross-sectional areas 46 m^2/ha. The ratio between the I, II and III tiers of tree and shrub plantations is: 1.0:0.89:0.53 according to the averaged height indicators and 1.0:0.51:0.23 according to the averaged indicators of the trunk diameter. The dynamics of these indicators of tree vitality are calculated from 2015 to 2020. In general, indicators of the current state of the natural phytocenosis of the Hurivka village forest are optimal and can serve as a control in further research (table 1).

In the territories of the city of Kryvyi Rih ecosystems of sanitary water protection artificial woody plantation are characterized by a partially formed vertical tree structure, in some places there are no III tier shrubs or there is an insignificant amount of undergrowth. These ecosystems are located in the relatively favourable ecological conditions of Kryvyi Rih and are formed by

Table 1. Indicators of the woody plantation's structural organization.

Name of ecosystem	Density (trees/plot)	Density (trees/ha)	Height (m)	Diameter (cm)
Woody plantations in the Hurivka village	48.01±0.03	1200.03±0.03	19.71±0.13	18.11±0.04
Woody plantations in the Valove village	47.01±0.03	1175.01±0.03	14.87±0.18	16.42±0.01
Woody plantations in the Tarasivka village	45.01±0.02	1180.01±0.02	17.02±0.15	17.51±0.06
Arboretum "Veseli Terny"	90.02±1.18	2250.01±1.18	15.98±0.21	28.70±0.41
"Artem 1" mine Water-resistant woody plants	77.03±1.13	1925.0±1.131	17.18±0.24	26.87±0.43

"Arcelor Mittal KR" dust-proof woody plantings	170.01±1.48	4250.03±1.48	9.95±0.22	9.77±0.51
Arithmetic average indicators	162.61	4070.53	14.90	17.84

the dominant I-II tier of representatives of the species Quercus robur L., Fraxinus excelsior L., Ulmus laevis Pall. In addition, invasive plants Acer negundo L., Acer campestre L., Populus alba L., Acer platanoides L., Ulmus glabra Hudson, Morus nigra L., Salix fragilis L., Acer tataricum L. are also present in the III tier of these ecosystems. The woody ecosystems of the Dovhyntsiv Arboretum and the Karachuniv Reservoir belong to the zone with relatively unfavorable ecological conditions for the growth and development of woody plants. It should be emphasized that the vertical structure of these forest phytocenoses is not formed, with poorly developed II and III tiers, as well as a practically absent shrub tier. The herbaceous layer was also insufficiently pronounced at all monitoring sites. In the studied artificial woody and shrub plantations with a sufficient level of moisture and relatively favorable ecological conditions, the average density of plantations of the I, II and III tiers is 1925-13050 pcs./ha, the height was from 11.3 m to 16.0 m (I tier, 2015) and grew up to 18.3 m (1st tier, 2020), trunk diameter – from 12.1 cm to 39.6 cm (1st tier, 2015) grew to 41.7 (I tier, 2020). At the same time, the stock of wood in plantations ranged from 993 to 1912 m^3/ha, and the sum of cross-section areas was 32-36 m^2/ha. The ratio between the I, II and 3rd tiers of tree and shrub plantations is different from the control: according to the average indicators of the height of the trees it is 1.0:0.85:0.31 and according to the average indicators of the diameters of the tree trunks – 1.0:0.6:0,23 (for 2015-2020).

In sanitary dust-absorbing and noise-reducing tree and shrub plantations, the vertical structure of the woody ecosystems in these areas is determined by the well-formed I and II tiers and the underdeveloped III tier, as well as the practically absent shrub tier. There is almost no grass layer in the areas. In the studied artificial woody plantations located in dust-protection sanitary zones of the city with insufficient levels of moisture and unfavorable ecological conditions, the density of plantations of the I-III tiers is from 1500 to 4250 pcs./ha, height from

10.1 to 16.5 m (I tier, 2015) grew to 17.8 m (I tier, 2020), trunk diameter from 9.8 to 39.7 cm (I tier, 2015) grew to 41.5 cm (I tier, 2020), the stock of wood is from 380 to 813 m^3/ha, the sum of cross-section areas is 28 m^2/ha. The ratio between the I, II and III tiers is significantly different from the control, in particular, according to the average values of tree height, it is 1.0:0.88:0.6, and according to the average values of tree trunk diameters, it is 1.0:0.7:0.13 (for 2015-2020, figure 1).

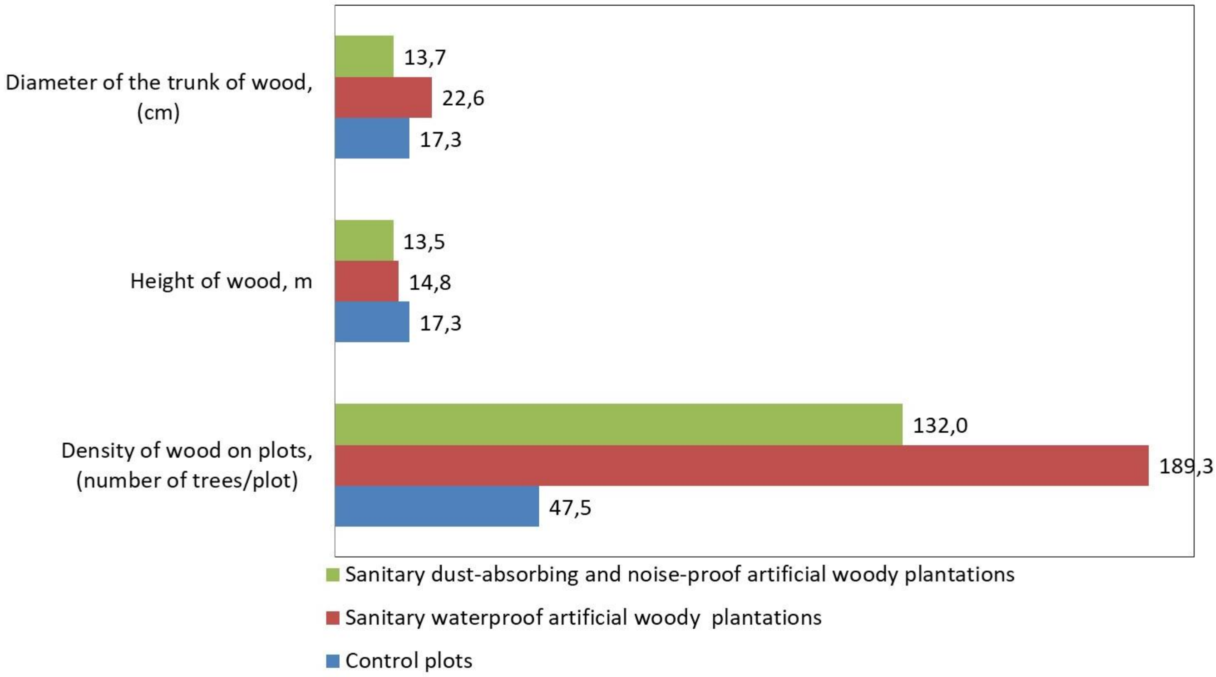

Figure 1. The average value of indicators of the structural organization of the state of trees (I-III tier) in the experimental plots.

Since 2021, access to the territories of research plots and sites has been partially or completely restricted due to military operations within the district or for security purposes. Thus, woody ecosystems were in relative isolation for 2-3 years.

In the territory of the Kryvyi Rih district factors regulating the density of tree and shrub populations of artificial and natural origin can be divided into dependent and independent of the density of tree plantations. Density-dependent factors including biotic factors transform with changes in the density of tree stands during their growth [4, 7, 35]. The study of the dynamics of the number of plants, taking into account pan-European indicators, for Sustainable Forest Management, improves the process of monitoring the state of tree ecosystems on the territory of the Dnipro Steppe. Thus, the investigation of seven main indicators can realize a comprehensive assessment of woody vitality to identify the key factors of the influence of the external environment on the homeostasis of an individual plant and the stability of the all ecosystem.

4. Conclusions

Therefore, the majority of tree ecosystems support the homeostasis of the population of dominant tree species, i.e. preserve the average number (the density is equal to 4070.50 trees per hectare) of artificial plantations of KKryvyi Rih district. Fluctuations in the number of woody and shrubby plants depend on a number of environmental factors – the speed of tree recovery, drying and removal, invasions of aggressive species, for example, such as Acer negundo L., Robinia pseudoacacia L., Acer campestre L., Populus nigra L..

The highest density of artificial tree plantations is noted on the territory of the Dovhytsivo Arboretum (13050.00 trees/ha) and the Karachuniv waterproofing tree plantations (10025.00 trees/ha), which is due to a complex of factors such as a good location in the terrain and a sufficient level of moisture. But the average indicators of height (14.83±0.24m) are not marked by an advantage compared to natural conditionally control plots. In each of the research plots, key influencing factors can be identified, such as the type of soil, insolation, moisture, temperature, the resistance of species to pests, distance from sources of industrial emissions, etc.

Such factors determine the direction of the further development of an individual woody plant and affect the growth of wood, the level of die-off, invasions of aggressive tree species, and changes in the species composition of the ecosystem.

It is also necessary to pay attention to the relatively high-density indicators of artificial forest plantations “Arcelor Mittal KR” 4250.00 trees/ha and “Kilce Kosiora” 4150.00 trees/ha due to the settlement of the III-rd tier. This tree layer consists of aggressive invasive species. However, these plantations are characterized by the smallest height (13.51±0.24m).

In perspective for order to assess the effects of abiotic factors, taking into account global features, it is necessary to develop regional scenarios of gradual changes in climatic conditions that will affect the tree ecosystems of Kryvyi Rih district locally and Steppe Dnipro regionally, namely temperature and precipitation fluctuations on this territory in Ukraine until 2050.

Abstract. This article discusses the use of machine learning methods in the QGIS software package to create a geographic information database of forest growth. The authors explore the possibilities of applying machine learning algorithms to analyse satellite images of different resolutions and geospatial data to determine the growth of forest resources. The authors consider classification and forecasting methods and their advantages in the context of creating a database for tracking and managing forest resources. The research results confirm the effectiveness of using machine learning in QGIS for accurate and automated analysis of the dynamics of changes in forest cover, which can serve as a basis for decision-making in the field of forestry and protection of natural resource potential.

1. Introduction

At the current stage of technology development, space-based forest observation is becoming an increasingly attractive area of scientific research. This approach allows obtaining meaningful information about the condition of ecosystems, identifying the dynamics of their development and responding to potential threats in a timely manner. In this context, our study is aimed at analysing the Slobozhanskyi National Nature Park in Kharkiv region, which represents a complex territorial structure. It is important to analyse the effectiveness of satellite imagery in identifying and classifying tree species in this region.

As part of the study, we have selected block 1 of the park and will use high-quality satellite imagery to determine the optimal time to recognise different tree species in the area. To achieve this goal, we plan to use machine learning methods, which will allow us to systematically analyse and classify the data using the QGIS OrfeoToolbox provider plug-in.

It is important to note that the quality and volume of input data, as well as the choice of the optimal learning method, can significantly affect the results of our study. Therefore, our study will include an analysis of qualitative and quantitative data parameters, as well as a comparative analysis of different machine learning methods' effectiveness.

2. Literature review

The use of machine learning algorithms to analyse satellite imagery and geospatial data allows for more accurate and comprehensive data on forest growth, which can be useful for effective forest management and decision-making in the field of forestry in particular and the entire ecosystem of the region as a whole [1].

Loiola et al. [2] considered the use of machine learning algorithms to classify forest types. Optimisation of the forest management process is looking for alternatives that make data collection possible. One of these alternatives is spectroradiometry, which consists of measuring the spectral response, having as a product the target response in different wavelength ranges.

Bychkov and Popova [3] investigated the possibility of using Forest Landscape Models (FLM) to predict forest change at the landscape level. FLM initialisation usually requires detailed data on tree species and age; hence, in the absence of forest inventory data, it is very difficult to collect initial data for FLM. In this study, the authors propose a method of combining open source data, including remote sensing data, to address the lack of initial data and describe the initialisation of the LANDIS-II model.

Scientists [3,4] considered one of the most important principles of the natural reserves effective use, in particular functional zoning. The main task to be solved in the functional zoning of the territory is to study the peculiarities of the spatial distribution of natural complexes and anthropogenic pressure. Suska et al. [4] offer a promising scheme of functional zoning of the Homilsha Woods National Nature Park. When planning the functional zoning of the NNP territory and establishing the boundaries of functional zones, the priority criterion was to preserve the phytocoenotic diversity of vegetation, especially the presence and distribution of typical and rare plant groups listed in the Green Book of Ukraine.

Grinand et al. [5] conducted a multi-temporal analysis of Madagascar's dry forests. The area of lost forests was estimated from 2000 to 2010 using remote sensing methods and open source software (QGIS).

Bhunia et al. [6] investigates and tests the use of open geospatial data and software for collecting real-time remote sensing data for forestry management, and notes the high prospects of this area of information acquisition and analysis. It is noted that products such as QGIS (free and open source) have eliminated the need for licensing and data acquisition, which was a significant barrier to wider participation in mapping, tracking and modelling of forest resources for local authorities. At the same time, it is noted that there is a need to provide special access to high-resolution remote sensing data for conservationists, scientists and researchers in the field of environmental management.

Rao et al. [7] analysed the feasibility of using remote sensing and GIS to create input data for the preparation and implementation of a number of forestry activities, followed by the use of geospatial databases in sustainable forest management. It has been demonstrated that the generation of forest type maps; treatment maps; stock maps; boundary updates, separation of felling rows and groups, and assessment of site suitability for silvicultural practices and soil and moisture conservation can be achieved quickly and with much greater accuracy than other traditional methods.

Digital technologies are used not only to monitor forest resources but also water resources. You can use methods developed for the study of other objects. For example, digital water quality monitoring is an important part of modern efforts to conserve and manage water resources. It involves the use of a variety of technologies, such as sensors, satellite sensing, geographic information systems and other digital tools, to collect, process and analyse water quality data [8]

3. Methodology

The study was conducted on the territory of the Slobozhansky National Nature Park. The location of quarters and boundaries of different tree species can be seen in figure 1. The data is

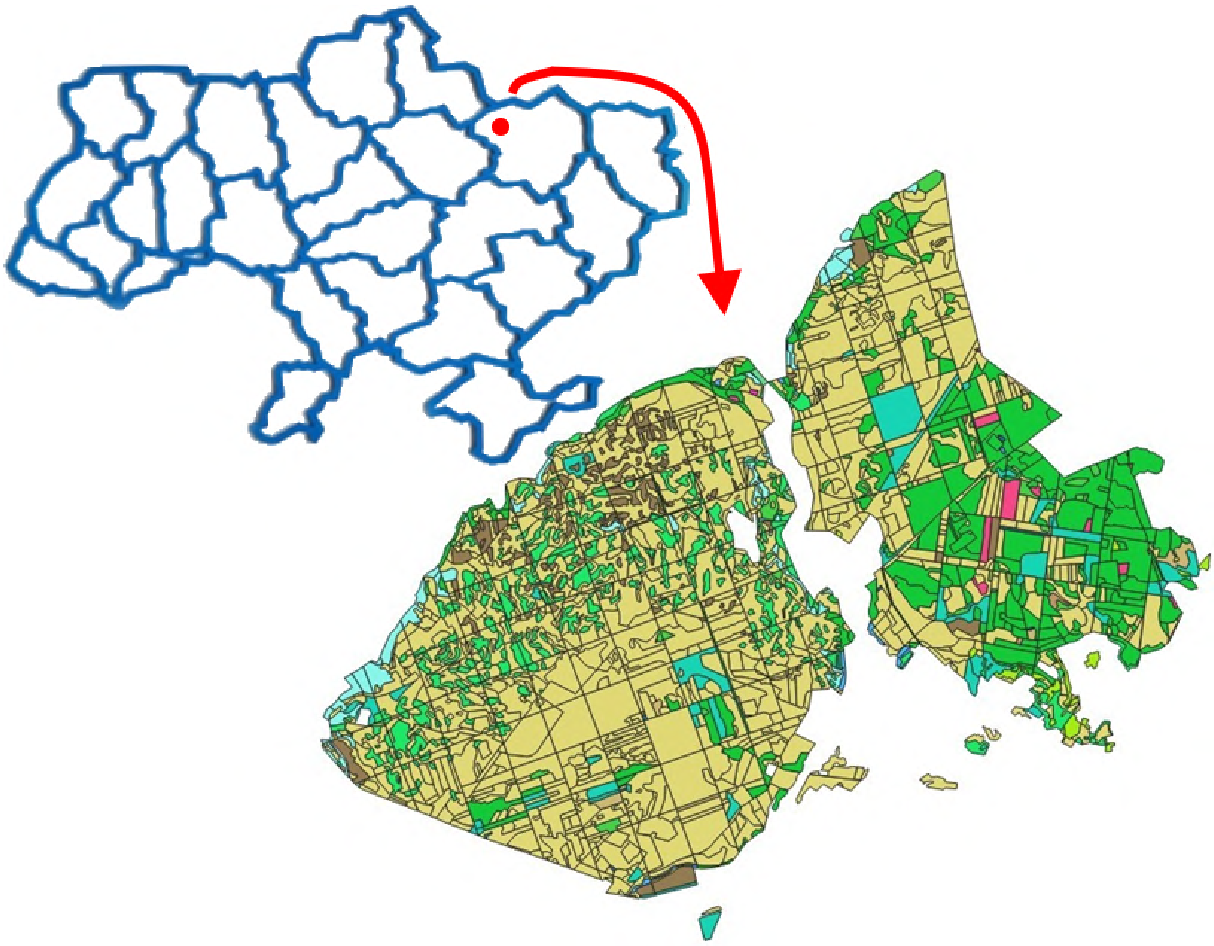

Figure 1. Slobozhanskyi National Nature Park, vector view.

presented in vector form using the QGIS software. The park is located in Kharkiv region near the town of Krasnokutsk.

Figure 1 shows that the territory of the National Park has a variegated structure, which makes it difficult to identify forest cover. According to the data, the park is divided into 127 quarters. For our experiment, we selected information about quarter 1, which is shown in figure 2. We downloaded three high-resolution satellite images from open sources for different years and months. This will allow to identify the time period most suitable for recognising tree species.

As you can see from figure 2, the satellite images differ, and this is especially evident in the 2018 image of April, when the trees are still without leaves. The exact tree species in the park is indicated in the semantic information (parameters) in the vector layer of the database. For quarter 1, figure 2 shows the following tree species: Scots pine (red areas), common oak (blue areas) and hanging birch (green areas).

Nowadays, the use of satellite imagery to study forests is becoming increasingly common. Thanks to the latest technologies and satellite data collection systems, we are able to study the state of forests in detail, detect changes in their cover and respond to threats to their ecosystems in a timely manner. However, the success of these studies depends heavily on the quality and relevance of the input data used.

One of the key aspects of using satellite imagery for forestry research is to determine the

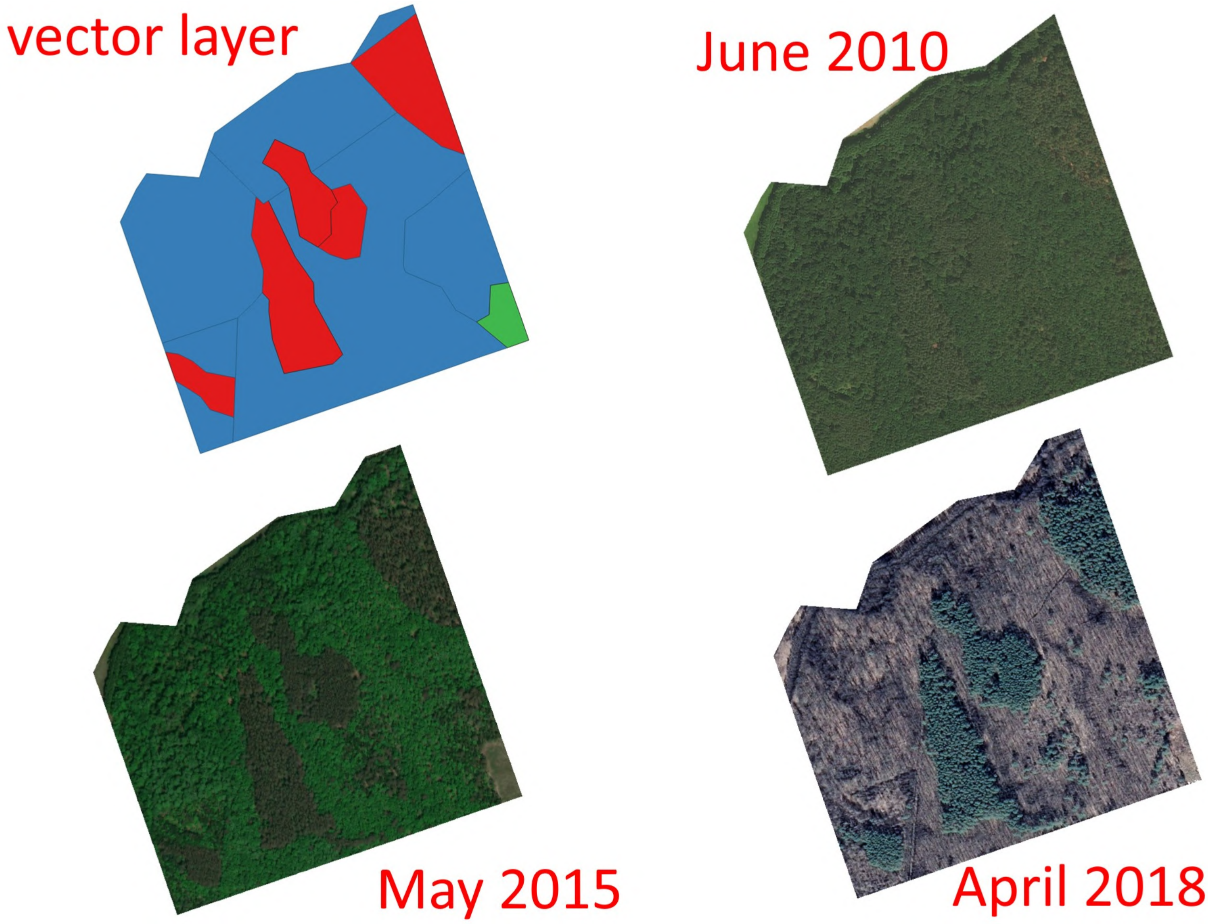

Figure 2. Quarter 1 of the Slobozhanskyi National Nature Park.

exact geolocation and characteristics of forest areas. For this purpose, it is necessary to have access to high-quality satellite images that provide sufficiently detailed information on the relief, vegetation types, soil conditions and other parameters. An important condition is also the ability to obtain up-to-date data at regular intervals, which will allow detecting the dynamics of changes in forest ecosystems.

Moreover, processing and analysis of satellite imagery is an important step in working with it. In order to achieve the best results, it is necessary to use specialised software that allows to perform a qualitative analysis of the data obtained. An important condition is also the proper expertise and qualifications of the specialist involved in processing and interpreting the images.

However, even with high quality satellite imagery and the right software, the success of our research depends to a large extent on the input data we use. Inaccurate or outdated data can lead to inaccurate results and even cause serious errors in conclusions [9]. Therefore, an important prerequisite for the successful use of satellite imagery for forest research is to consider the relevance importance and the input data quality. This means not only selecting the right data sources and collection tools, but also thoroughly checking them for accuracy and relevance.

The next stage of the study is to perform machine learning to recognise different breeds using the QGIS OrfeoToolbox provider plug-in. This free software product allows you to apply methods such as Boost classifier, Decision Tree classifier, Normal Bayes classifier, Random forests classifier, KNN classifier, Shark Random forests classifier, Shark kmeans classifier.

Before choosing a machine learning method, you need to clearly define the problem statement.

What kind of data do you need to solve this problem? What are the characteristics of this data (size, type, quality, etc.)? It is important to determine whether you have enough objects to train the model or whether you will need to collect additional data. Depending on what kind of task you want to solve (classification, regression, clustering, etc.), you should choose the appropriate machine learning method. For example, methods based on decision trees, neural networks or support vector machines may be suitable for classification [10]. It's important to understand how the model works and how decisions are made, so you should choose a machine learning method that provides a clear interpretation of the results.

To start training, you need to specify a sample image with a known class. The sample size (the number of objects in the training set) can affect the choice of machine learning method. For example, deep learning methods may be suitable for large amounts of data, while classical statistical methods may be effective for small samples. In our study, we performed machine learning on three types of data: three plots of 314 m^2 each, three plots of 1256 m^2 each, six plots of 628 m^2 each. This way, we will check how the number and area of training areas affects the efficiency of image classification. Given that we have three images, three learning approaches, and seven methods, we obtained 63 classification results.

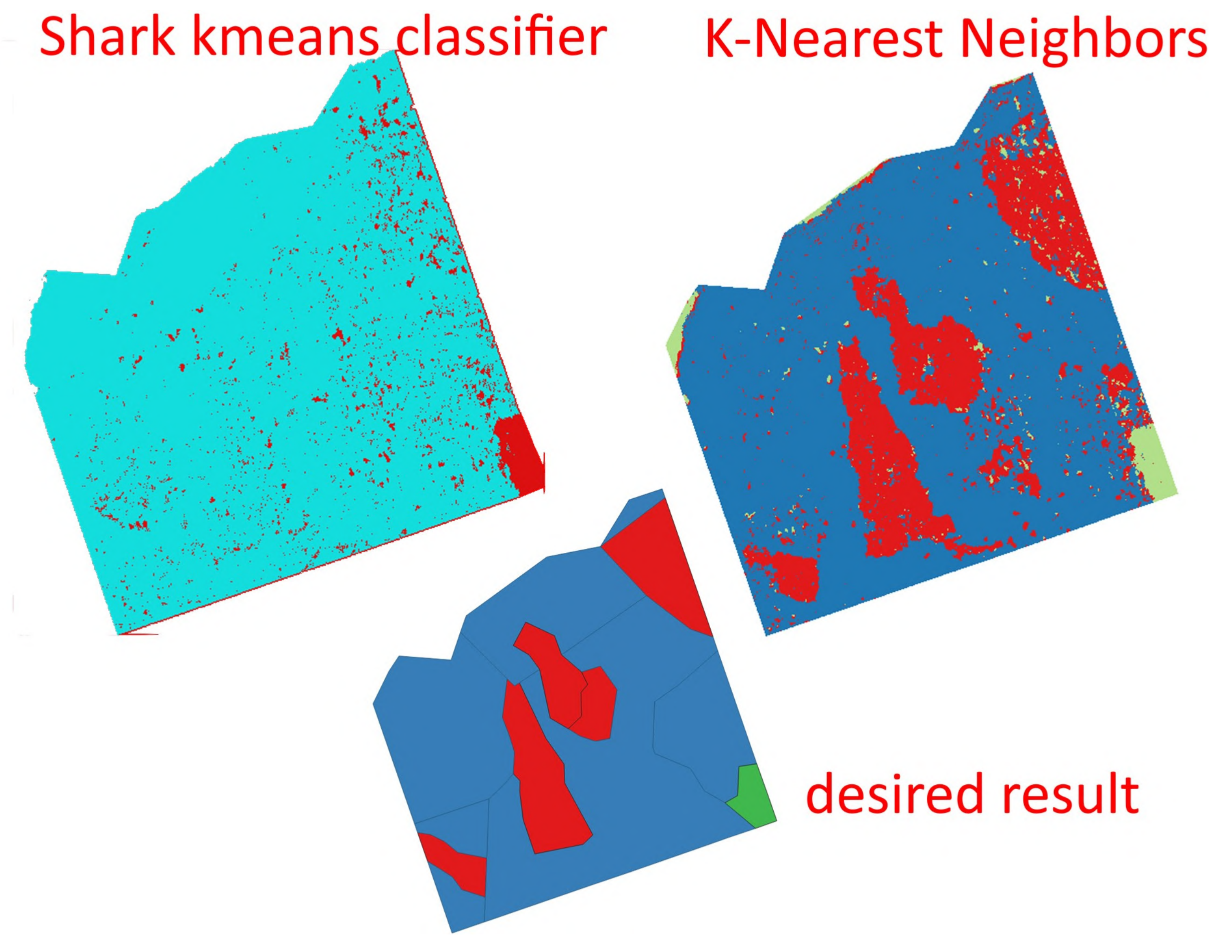

Figure 3. Comparing the results of different machine learning methods.

4. Results

The K-Nearest Neighbours method proved to be the most effective. The algorithm caches all training samples and predicts the response for a new sample by analysing a certain number (K) of the sample's nearest neighbours using voting, calculating a weighted sum, etc. This method is sometimes referred to as "learning by example" because it looks for a feature vector with a known response that is closest to the given vector for prediction.

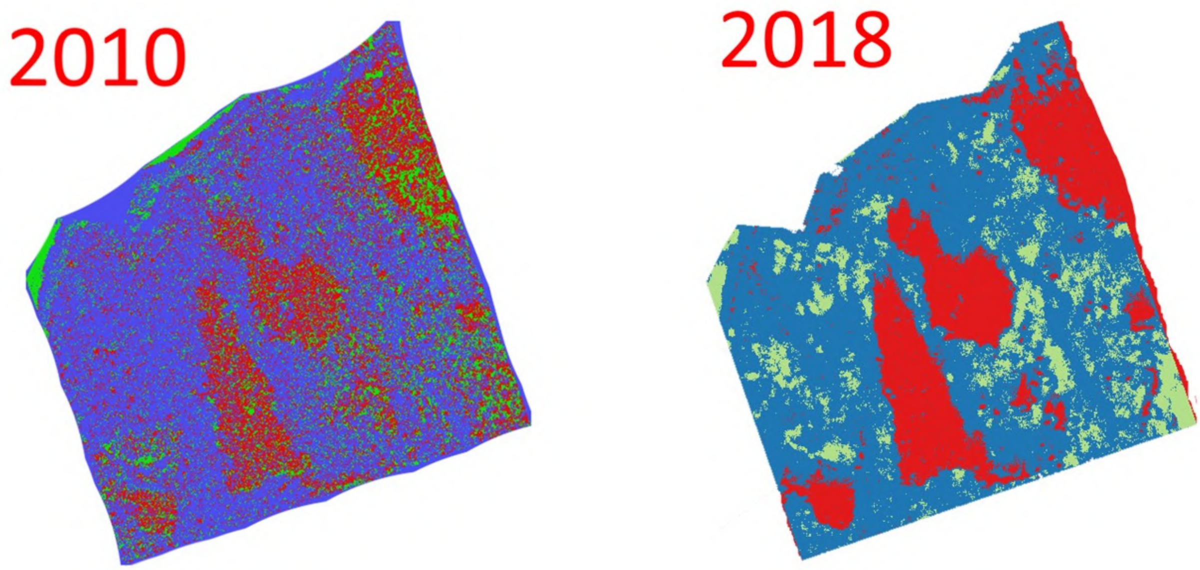

Figure 4. Comparison of satellite image classification results for different years and seasons.

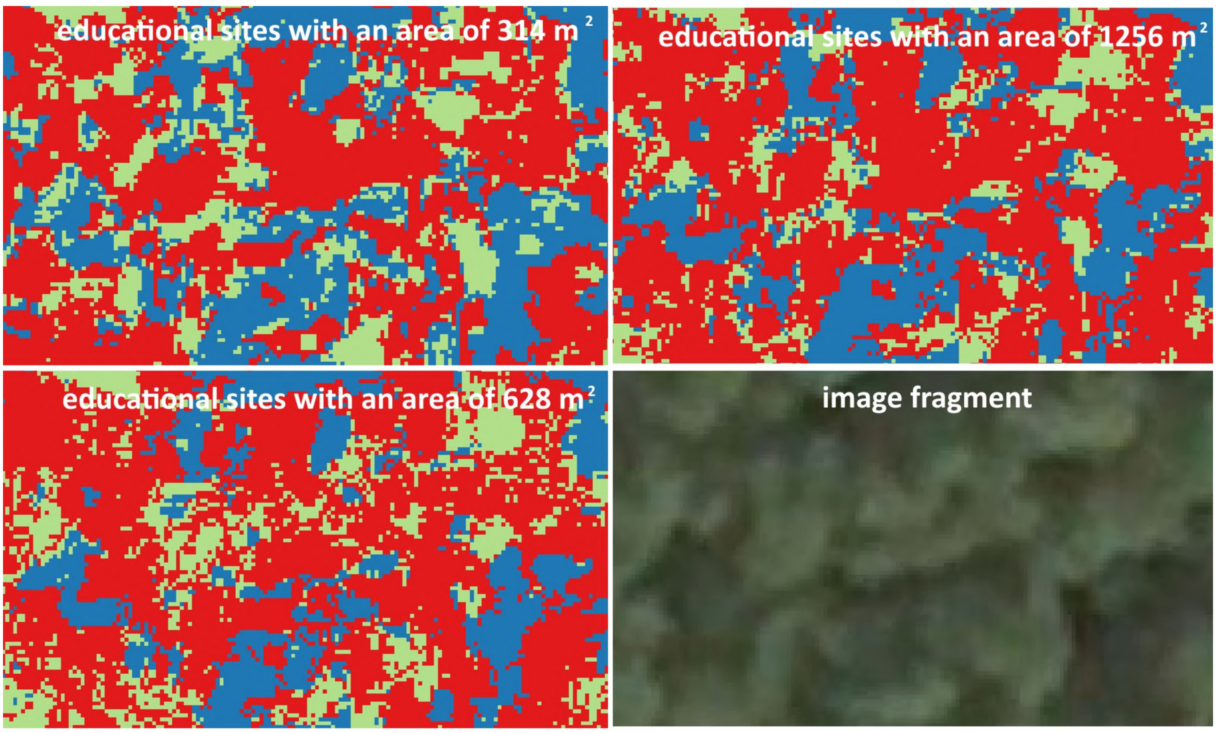

Figure 5. Visualisation of different approaches on the same image and with the same method.

An example of comparing the results of the K-Nearest Neighbours machine learning method with the Shark [11] k-means classifier method can be seen in figure 3. The same satellite image was used and the same training domain was used.

Figure 3 shows that K-Nearest Neighbours allows us to obtain a qualification result much better than from the same satellite image using other methods.

If we compare different images classified by the same method, we can see that the season of image acquisition is very important. Figure 4 shows the classification results for quarter 1.

As it is seen from figure 4, the date of image acquisition affects the efficiency of image interpretation. Depending on the type of tree species, the date of image acquisition should be selected. The information obtained should then be recorded in a single database. GIS software allows to combine and analyse different types of spatial data from different sources.

Not only does the resolution and time of acquisition (season) affect the quality of the classification, but also the amount and type of training the software receives to classify the image. Three different approaches on the same image and using the same method can be seen in figure 5.

Image classification is highly dependent on the selection of samples (objects) for machine learning. As it is seen from figure 5, the same fragment can be classified with different efficiency.

5. Conclusions

The use of machine learning to classify satellite images of forest resources allows to create and maintain up-to-date databases. Among a wide range of machine learning methods, you need to choose the one that will be most effective for identifying certain tree species. Combinations of methods may be used. Satellite imagery should correspond to the period when different tree species are very distinct and not blend into the background. It is necessary to take into account that trees look different in different seasons, i.e. biological features of the vegetation cover should be taken into account. Another condition for effective forest classification is the selection of the data amount to create a classification model (the learning program). There are no universal recommendations for this task. It is necessary to select an effective option in terms of area and fine contour by gradual approximations. The use of artificial intelligence in the form of machine learning allows the classification of satellite data, thereby ensuring the functioning of forest databases.

Thus, artificial intelligence in geographic information systems has great potential for solving complex tasks of analysing and processing geospatial data. At the same time, for the successful application of these technologies, it is necessary to address the issues of security, confidentiality and data availability. Taking these aspects into account, artificial intelligence in GIS can become a powerful tool for the development of various industries that use geospatial data.

Abstract. The study is aimed at analysing the conditions and prospects of the nature reserve fund development of the Kharkiv region in order to develop recommendations for optimising the management and conservation of natural resources in the sustainable development context. The nature reserve fund is an important component of the sustainable development model, contributing to the conservation of biodiversity, maintaining the sustainability of natural ecosystems, environmental education and recreation. The article examines the problem of slowing down the formation pace of new territories and objects of the nature reserve fund (NRF) in Kharkiv region and in Ukraine as a whole, which is a consequence of the current socio-economic situation. The authors of the article believe that to solve this problem, it is necessary to amend the current legislation, in particular, to simplify the procedures for creating new NRF objects and to introduce economic measures to encourage land users and landowners to create such objects. It is noted that the existing protected area rate in Kharkiv region, although exceeding the average rate in Ukraine, is still lower than in neighbouring European countries. The problematic issues are compounded by the lack of a clear strategy for the development of protected areas and the lack of the management system coordination at the state and regional levels. To solve these problems, it is necessary to ensure the implementation of a set of measures, such as the creation of a scientifically based network of protected areas and objects and a system of balanced nature management. The article offers a set of measures to intensify the processes aimed at achieving Goal 15 in Ukraine, in particular, to intensify the work of local authorities to create new territories and objects of the nature reserve fund.

1. Introduction

Sustainable development is currently one of the most important challenges for humanity. The essence of "sustainable development" is to maximize economic and social benefits from the development of the national economy system while protecting the environment and ensuring the long-term reproduction of natural resources. In the economic sense, sustainable development means not only the growth of the national economy and an increase in per capita income, but also the improvement of all elements of social security. Sustainable development should be accompanied by the necessary structural changes in the environmental, economic and social spheres.

The term "sustainable development" was coined at the United Nations Conference on Environment and Development, where it was defined as the development of society that meets current needs without compromising future generations [1]. Since the 1990s, sustainable economic development has involved significant organizational and managerial efforts to achieve the 17 global goals and 169 targets of the new 2030 Action Plan, which came into force on January 1, 2016. The growing transboundary environmental impact and other negative consequences of human activity indicate the need to strengthen international dialogue on security issues and implement a unified global strategy in the process of transition to the principles of sustainable development.

The sustainable development model is based on three components: economy, environment and society [2–4]. The axiom of this model is that one component cannot develop without taking into account the others. For example, if only the economy is developed without paying attention to the ecosystem, an ecological catastrophe may occur, which will call into question the very existence of humans. On the other hand, uniform development of the economy, but without taking into account society, can lead to poverty and unemployment of a large share of the population, which will eventually lead to a demographic and economic crisis.

The nature reserve fund is an important component that contributes to the conservation of biodiversity, the sustainability of natural ecosystems, environmental education and recreation [5]. Currently, the world and Ukraine are actively implementing reforms in two key aspects: expanding the area of protected areas and expanding their functions and tasks. The main emphasis is on the transition from simple species conservation and limiting human interference in wildlife to establishing methods of coexistence between humans and nature, rational exploitation of natural resources, and sustainable development of territories and communities. The study is aimed at analysing the condition and prospects of the nature reserve fund of the Kharkiv region in order to develop recommendations for optimizing the management and conservation of natural resources.

2. Literature review

The issue of sustainable development strategies as the basis for the future quality of life of society was considered by Guerra et al. [6]. The analysis of socio-economic indicators in the context of sustainable development has been studied by Çağlar and Gürler [7] and Deveci et al. [8].

Deveci et al. [8] examined the importance of seventeen Sustainable Development Goals (SDGs) using a decision-making approach based on rough sets. This new approach consists of three consecutive stages, namely a questionnaire (survey), data analysis, and SDG classification. First, a survey is conducted to obtain responses from international experts from different countries. Each participant offers to assess the importance of each SDG. Second, an analysis is conducted to identify groups of participants who respond in the same way and to identify the views of academia and non-governmental organizations. The degree of importance of each SDG for sustainable development is determined using a new decision-making approach, including the Ordinal Priority Approach (OPA), based on approximate data sets.

The issues of the consequences of the implementation of the sustainable development goals are described by Bansal, Singh and Nangia [9] and Del-Aguila-Arcentales et al. [10]. The results of the study [9] identify the most influential articles and sources on the topic based on their publication, citation, and importance to the smart grid; in addition, the study sheds light on the intellectual structure of the subject (thematic analysis), which is supported by the main clusters focused on "environmental impact", "economic and social impact", "technological innovation and digitalization", and "circular economy". In [10], a partial technical analysis was conducted using a structural equation using the least squares method. It was found that social SDGs (0.796) and environmental SDGs (0.196) had a positive impact on economic SDGs.

In the article by Lacka and Brzezicki [11], the development of European countries in the context of global strategic planning is studied. Taking into account the sequential nature of the stages, a combined analysis of eco-efficiency, eco-innovation and sustainable development goals

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012050 doi:10.1088/1755-1315/1415/1/012050

was conducted. The analysis was conducted for 27 EU countries in 2017–2019. The study used the SBM dynamic network and the Malmquist dynamic divisional index. The results of the study show that EU countries achieve relatively higher performance results in eco-innovation and SDGs than in eco-efficiency.

The experience of Poland's development in the context of the implementation of the SDGs is considered by Kasztelan [12]. The paper presents the results of assessing the implementation of the national sustainable development goals of Poland from 2010 to 2019. For this purpose, a synthetic index (National Sustainability Index) was developed using taxonomic methods. The study sought answers to the following questions: What is the overall level of Poland's achievement of sustainable development goals? What were the dynamics of changes in the relevant years? Which goals will require special attention and action in the coming years? Given the possible range of NSI, there has been a significant improvement in the achievement of the national sustainable development goals in Poland in the years under review. Nevertheless, some areas still require interventions at the decision-making level, which will further balance the paths of economic growth and development in Poland.

A number of Ukrainian researchers have examined the current problems of sustainable development of the country [13–15]. In particular, Rybak et al. [16] provides an example of bringing the territory of a biosphere reserve in line with international requirements for biosphere reserves; identifies the main areas of activity aimed at interaction between the administration of the Carpathian Biosphere Reserve and local communities and develops recommendations for the implementation of measures to ensure the creation of a transit zone of a biosphere reserve in Ukraine.

Riabtsova [17] discusses the general principles of nature management applicable to all subjects of law, as well as specific principles relating only to the use of natural resources in the field of economic law. The general principles include rational use of nature, the emergence of the right to use natural resources from the right of ownership, targeted use of natural resources, sustainability of the right to use nature, ecosystem considerations, integrated use of nature and free use of nature. Special principles of nature management, which are specific to economic entities, should include payment for special use of nature, restriction of nature use, licensing of nature use and greening of production, ensuring a balance between economic, social and environmental interests.

The article [18] is one of the first attempts to fill the existing gaps in the issue of the war's impact on protected areas. The article identifies trends in the development, current status and problems of the objects of the nature reserve fund of Ukraine in the context of Russia's unjustified full-scale military aggression, and provides an approximate calculation of the damage caused by hostilities.

Radchenko et al. [19] analyses the issue of forming a strategy for the development of the state through the prism of the state environmental safety, preservation of its natural capital in the process of forming and implementing the state environmental policy. The basic ecological, economic, and social principles of preserving the natural capital of Ukraine are considered. The possibilities of development of the ecological network of Ukraine are investigated and a comprehensive knowledge base for natural capital management is shown.

3. Results and discussion

Nature conservation and environmental protection are recognized as one of Ukraine's priorities in the context of European integration. The main structural element of the national territorial system of natural objects is the territories and objects of the nature reserve fund. They have been set aside for their unique environmental, scientific, aesthetic, recreational and other values in order to preserve the diversity of landscapes, the gene pool of animals and plants, maintain ecological balance and conduct background monitoring of the environment.

In the national legislation, the concept of "sustainable development" was first used in the Resolution of the Verkhovna Rada of Ukraine "On the Main Directions of the State Policy of Ukraine in the Field of Environmental Protection, Use of Natural Resources and Ensuring Environmental Safety" [20]. Section V "Main stages of implementation of the main directions of the state policy of Ukraine in the field of environmental protection, use of natural resources and ensuring environmental safety" states that "it is planned to create a system of state management of the use of natural resources, regulation of technogenic impact on the environment as a basis for managing sustainable development of society". One of the main tasks of this stage is "proper coordination of the rational use of natural and socio-economic potential, taking into account environmental factors on the basis of sustainable development".

One of the main objectives of the European Green Deal is to preserve and restore ecosystems and biodiversity. The EU is actively implementing transformational policies in this area, having already adopted the EU Biodiversity Strategy 2030 and the New EU Forestry Strategy 2030. The EU's goal is to cover at least 20 % of the EU's land and marine areas with nature restoration measures by 2030 and to restore all ecosystems in need by 2050.

Since 2015, when the UN adopted the 2030 Agenda and 17 Sustainable Development Goals [21], Ukraine's progress in their implementation has been uneven, with serious problems in achieving the vast majority of the SDGs. The implementation of the tasks to ensure the protection of ecosystems and biodiversity (SDG 15) has partially stopped (table 1)

Table 1. Dynamics of changes in the components of the Sustainable Development Goals Index of Ukraine, 2015–2021.

Goals	2015	2021	Growth rate 2021–2015, %	Goals	2015	2021	Growth rate 2021–2015, %
Goal 1	99.5	99.8	0.34	Goal 10	99.5	99.5	0.00
Goal 2	63.0	64.1	1.78	Goal 11	74.5	75.5	1.35
Goal 3	66.7	76.8	15.14	Goal 12	88.6	88.1	-0.53
Goal 4	80.9	80.2	-0.93	Goal 13	90.1	89.3	-0.86
Goal 5	64.4	67.7	5.15	Goal 14	64.8	73.4	13.21
Goal 6	79.0	78.8	-0.19	Goal 15	63.7	63.7	0.10
Goal 7	68.1	69.7	2.32	Goal 16	62.6	66.5	6.25
Goal 8	70.8	71.2	0.54	Goal 17	76.3	73.4	-3.76
Goal 9	23.0	49.3	113.95				

Russia's aggression against Ukraine has created numerous indirect challenges to its path to sustainable development, but it has not led to a halt to its aspirations for European integration and sustainable development. For example, the need for high-quality and timely data for effective decision-making has increased. However, today there are serious difficulties in collecting and processing economic and financial statistics, in particular in the context of the 2030 Agenda and assessing progress towards the SDGs. An important indirect impact is that military operations significantly distribute the government's organizational resources and impede coordination of actions under the 2030 Agenda. Even amid the war, Ukraine, which became a candidate for EU membership on June 23, 2022, has taken the first steps in this direction. In particular, it was decided to establish an Office for the Implementation of the Sustainable Development Goals. This office will be responsible for organizing the development and implementation of a mechanism for incorporating the SDGs into national and regional policies, strategies, and planning processes.

Assessments by international organizations and experts agree that the war and related economic problems have had a negative impact on sustainable development indicators across the entire list of SDGs in Ukraine. One of the central topics for discussion in the expert community is to identify the interrelationships between the various goals, targets and indicators within the 2030 Agenda. No country can achieve sustainable development without peace. Thus, Ukraine's regression in achieving the 16th SDG "Peace, Justice and Strong Institutions" is evidenced by the Global Peace Index, which decreased by 16 % in 2022 to 153rd place in the ranking (in 2021 it was ranked 143rd), demonstrating the worst dynamics among the 163 countries surveyed [23,24].

The implementation of the policy aimed at protecting and restoring terrestrial ecosystems, including the preservation and expansion of the territories of the nature reserve fund in Ukraine, has brought about certain positive changes, but unfortunately has not allowed for the dynamics necessary to approach the targets on the horizon until 2020. In particular y the area of territories and objects of the nature reserve fund in Ukraine increased (from 3803.13 thousand hectares in 2015 to 4173.2 thousand hectares in 2022) and the share of the area of territories and objects of the nature reserve fund in the total territory of the country (from 6.3 % to 6.76 %, respectively). However, such rates do not allow to achieve the target benchmarks – 6276.9 thousand hectares and 10.4 %, respectively. Due to the signing by the President of Ukraine of 15 decrees on the creation/expansion of territories and objects of the nature reserve fund, as well as other decisions at the national and local levels, the area of the nature reserve fund was increased by approximately 279 thousand hectares, or 0.36 % of the territory of Ukraine [25] (figure 1).

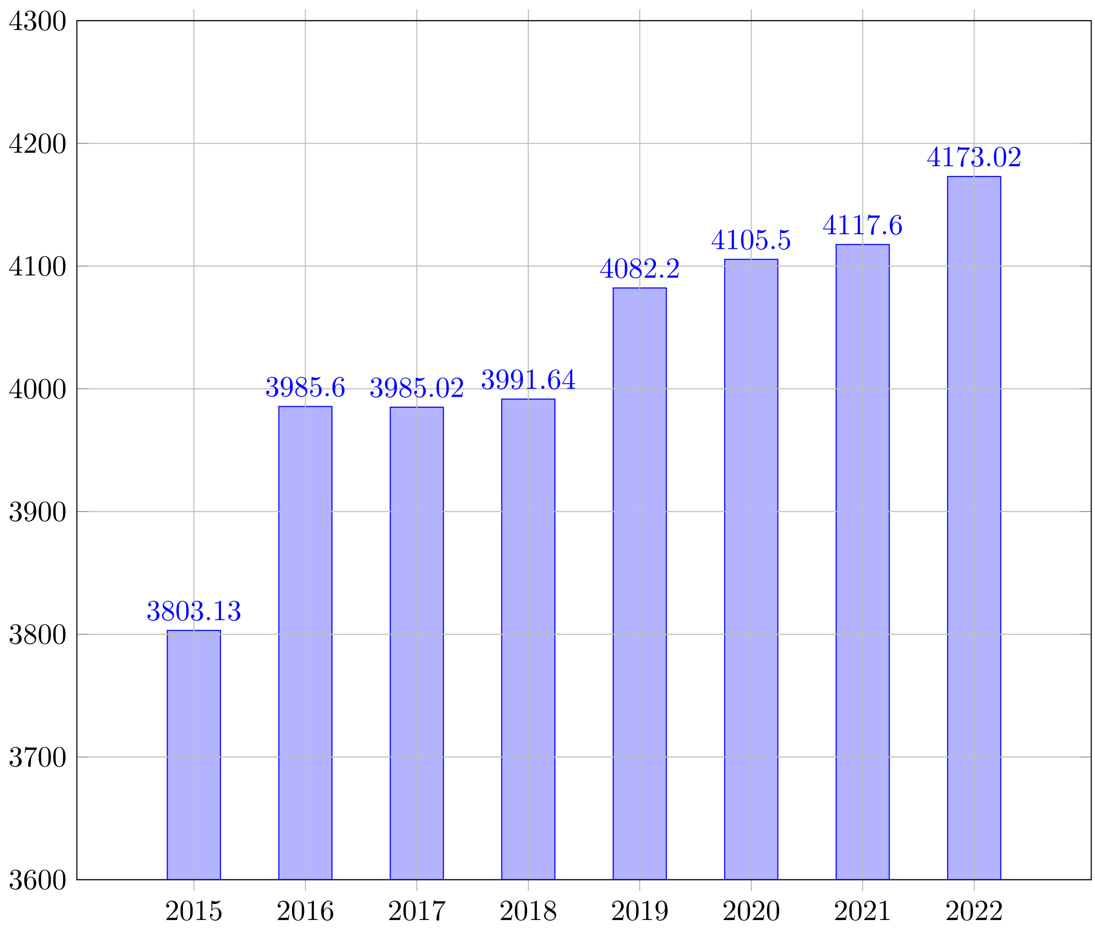

Figure 1. Area of territories and objects of the natural reserve fund, thousands of hectares [24].

One of the key current problems in the field of nature reserves funds (NRF) in Ukraine is the lack of clearly defined boundaries of nature reserves at the regional level and the unresolved issue of their introduction into nature, despite the existence of relevant decisions of the President of Ukraine and the Verkhovna Rada of Ukraine. The main reason for this is the lack of funding for the development of relevant land management projects, since the boundaries of NRF territories are determined only after the allocation of funds for their introduction into nature, i.e. after the creation of NRF territories, and not at the stage of their formation.

As of January 1, 2023, the nature reserve fund of Kharkiv region includes 247 protected areas, with a total area of 74.877 thousand hectares. Out of the total number, 13 nature reserve sites are of national importance and 234 are of local importance. The proportion of the area of the nature reserve fund in the area of the administrative unit is 2.4 %, which is one of the smallest in Ukraine, second only to Vinnytsia region [26].

According to Ukrainian legislation, as defined in the Law “On the Nature Reserve Fund of Ukraine” [25], there are two main categories of protected areas: natural and those created artificially in the form of collection and park objects. Natural territories include nature reserves, biosphere reserves, national nature parks, regional landscape parks, nature reserves, natural monuments, and protected tracts. On the other hand, artificially created objects include botanical gardens, dendrological parks, zoological parks, and parks-monuments of landscape art (table 2).

Analysing the dynamics of the structure of the region’s nature reserve fund from 2019 to 2022, we note an increase in the number of local nature reserves by 1 unit in 2021. During this period, at the initiative of the regional state administration, there were attempts to expand the lands of the region’s nature reserve fund, but no final decisions were made. We estimate that if measures had been taken to include the territory in the region’s nature reserve fund, which is 71450.5 hectares, the percentage of the actual area of the NRF to the area of the administrative unit would have been 4.65 versus the actual 2.4. Thus, as of 2022, the structure of the lands of the nature reserve fund of the Kharkiv region is shown in figure 2, where the national value is 28 %, local value is 72 %.

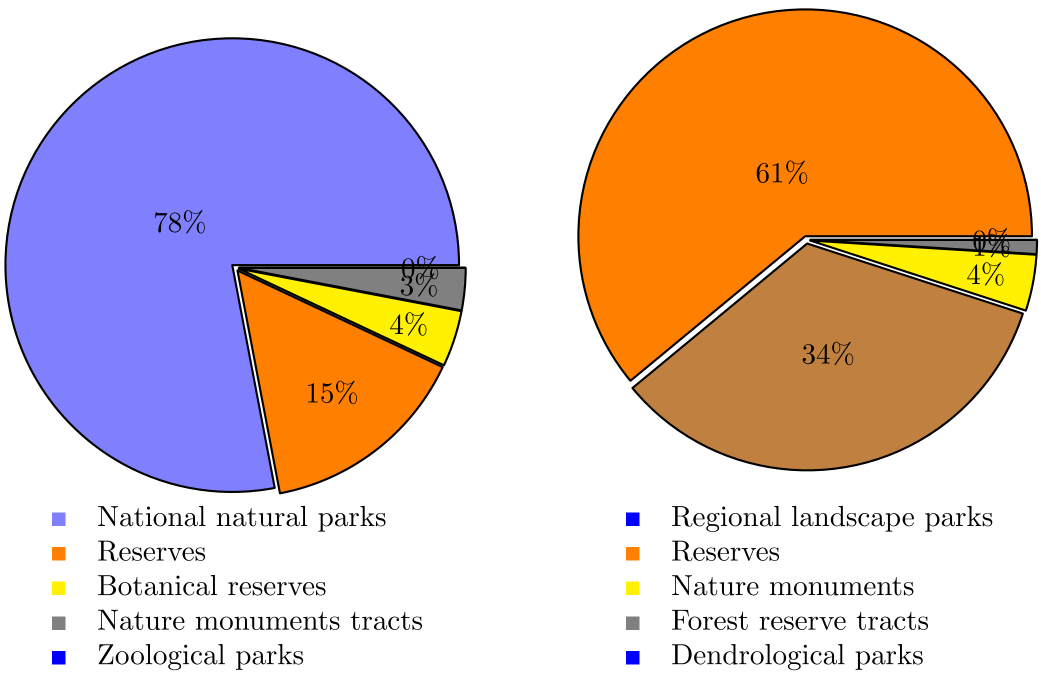

Figure 2. NFR structure in Kharkiv region as of 2022 [24].

Actual NFR area		74 843.56		74 843.56		74 877.06		74 877.06
% of the actual area of NFR areas from the area of administrative units		*2.38*		*2.38*		*2.4*		*2.4*

The fact that the State Strategy for Regional Development until 2020 [27] stipulates that the amount of land in the nature reserve fund of Kharkiv region should be 282.735 hectares at the beginning of 2020, which is equivalent to 9 % of the total area of the region, indicates a low level of measures to increase the percentage of the region's territory reserved (figure 3). In other words, the percentage of territories allocated for the reserve fund does not meet the planned indicators.

Thus, there are certain difficulties in the process of creating new and expanding existing protected areas in Kharkiv region. Due to restrictions on the use of natural resources, the work on the formation of NRF is delayed. Most stakeholders, such as local governments, forestry

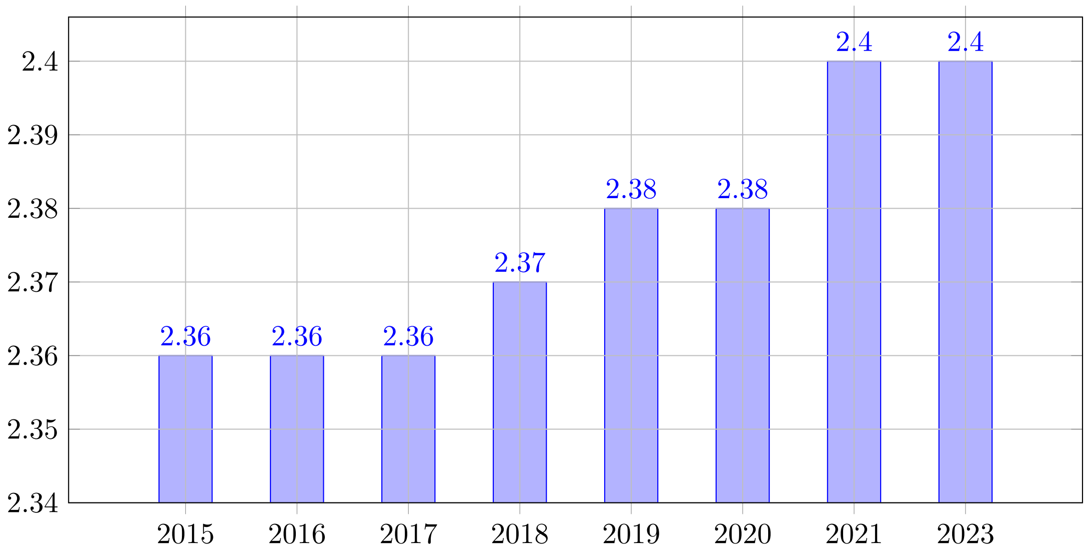

Figure 3. Dynamics of changes in the area of the nature reserve fund in Kharkiv region, % [24, 27].

enterprises, landowners and land users, do not agree to the creation of new or expansion of existing protected areas in the region. They justify their position with restrictions on nature management, restrictions on visiting the territory during certain periods of the year, restrictions on the activities of users of hunting grounds, as well as a ban on grazing and other aspects defined by the current legislation for protected areas. Ukrainian legislation in this area needs to be revised and adapted to European standards, especially with regard to taking into account the interests of landowners and land users in the process of including their land plots in the nature reserve fund.

There are certain disproportions and problems of nature management in the region's NRFs. In particular, the protected status of administrative districts is very uneven, with differences between them reaching dozens of times. Although after the administrative-territorial reform, the percentage of protected areas for new districts increased significantly, the percentage of protected areas in territorial communities remained at the level before the reform.

The perspective directions of development of the nature reserve fund of Kharkiv region can be represented by the following structural and logical scheme (figure 4). This logical structure can serve as a basis for the development and implementation of the strategy for the development of the nature reserve fund of the Kharkiv region.

One of the promising areas for increasing the area of land in the nature reserve fund of Kharkiv region may be at the expense of territories reserved for the creation of new or expansion of existing nature reserve objects, creation of ecological corridors, and land reclamation. In the current version of the ecological network of the Kharkiv region, only forest belts along the railways are included in the regional eco-corridors of artificial origin. In many districts of the Kharkiv region with moderately low levels of natural resources, it is forest belts with adjacent agricultural land that can optimize the structure of the adjacent territory. The design also fails to take into account that the proposed eco-corridors of natural origin of "local" significance do not ensure, first, the functioning of the region's ecological network as an integral system; second, a full-fledged connection between the biocenters of Kharkiv region and the biocenters of other regions (Poltava, Dnipro, Donetsk) [28].

Given the experience of Poland, it is the territories and objects of the nature reserve

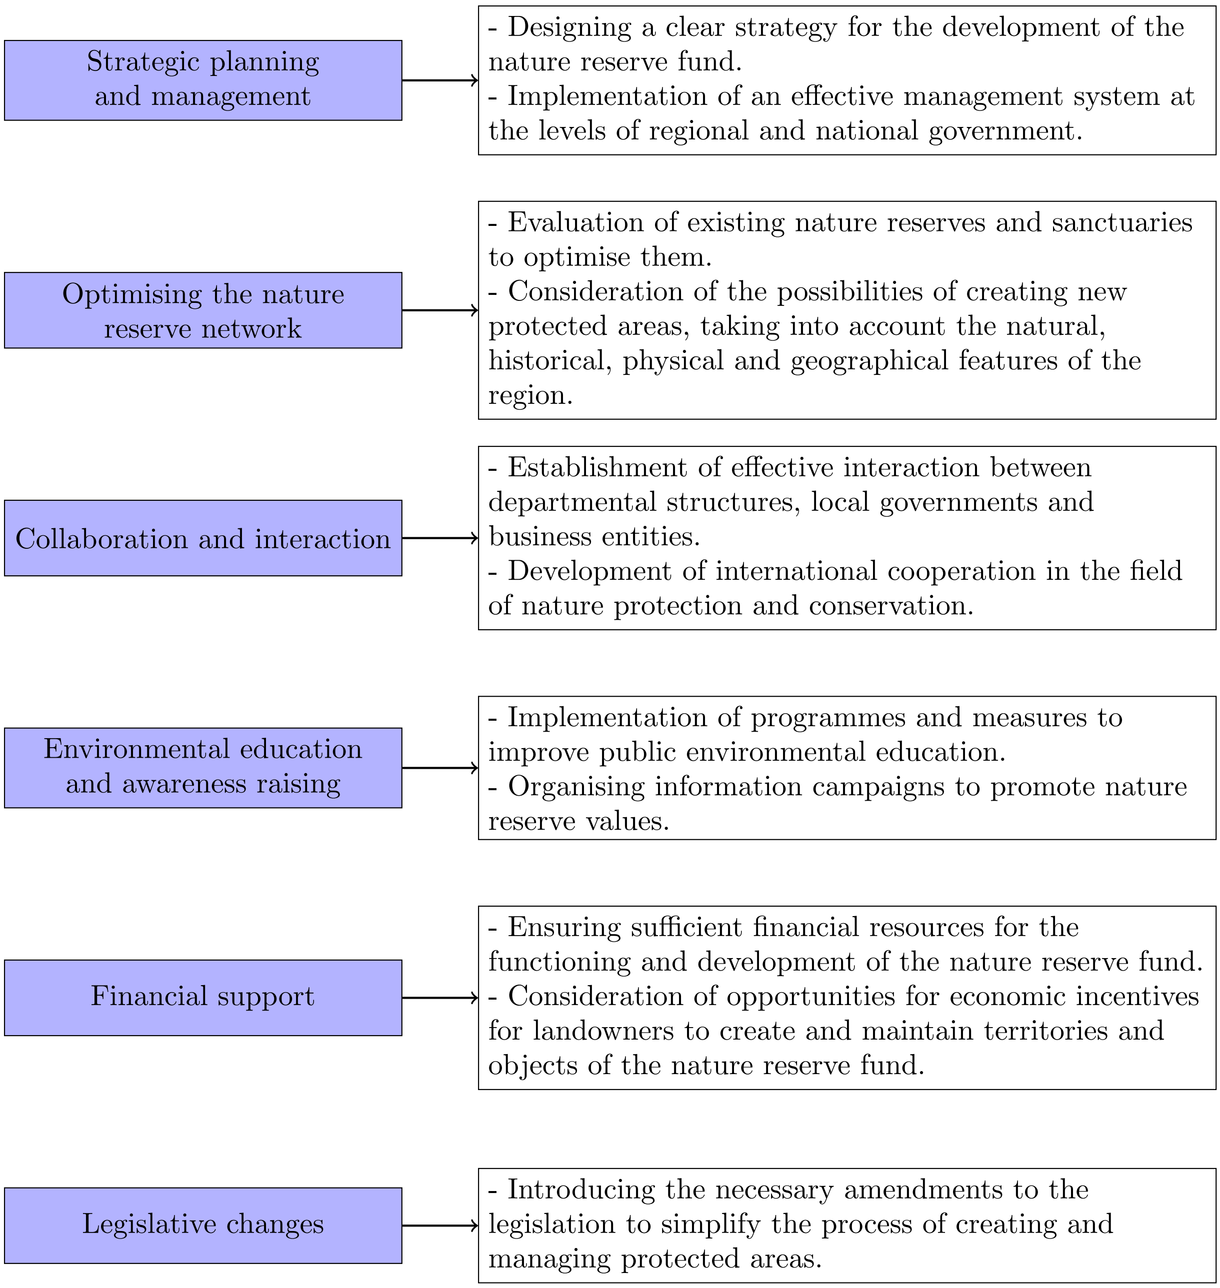

Figure 4. Structural and logical scheme of further development of the nature reserve fund of Kharkiv region.

fund that can disseminate information on their territories, in particular, within the areas of regulated recreation, on the existing ecological corridors that ensure migration of animals from this particular protected area. Each protected area that is a key territory should be assigned ecological corridors that connect the key territory with other areas in order to properly monitor the connecting areas for compliance with environmental legislation. It is also quite appropriate to work with local residents, explaining the benefits of the ecological network and the opportunities provided to local residents whose land plots are included in the ecological network [29]. In order to optimize the structure of the ecological network of the Kharkiv region, an additional category of ecological corridors can be identified, namely local ones, due to the boundaries of the beam and valley lands, where the vegetation has retained a relatively natural state and there is a limited anthropogenic load. Forest belts and watershed forests can become connecting areas between them, which makes it possible to promote the connection of existing ecological corridors.

For example, in the Krasnokutsk community of the Bohodukhiv district of the Kharkiv region, the inclusion of reserved areas in the lands of the community's ecological network will increase its area (the existing area of the nature reserve fund is 1091.6 hectares) and will amount to 11475.5 hectares, while the area of the nature reserve fund will be 1325.5 hectares, which will be

Table 3. The territories reserved for the next bequest of the Krasnokutsk community of Bohodukhiv district of Kharkiv region [24].

Name, category and type of territory	Estimated area, ha	Location	Characteristics
The hydrological reserve	6.9	Near Cherneshchyna village	The only forest lake of natural origin in the area. Habitat for rare species of aquatic flora
A complex natural monument	5.0	Near Horodne village	The beam is secured against collapse by brickwork terraces. A kind of acoustic effect is created
A complex natural monument	2.0	Parkhomivka forestry	Weymouth pine alley, 130 years old
General zoological reserve	33.0	Volodymyrivka forestry, 33	Habitat for rare species of animals: common burrowing owl, viviparous lizard, crested newt, Nikolsky's viper
Botanical reserve	20.0	Lavriki tract	Forested beam, a place of growth of medicinal plants rare for the region's flora
Botanical reserve	87.0	Near Moika and Kaplunivka villages	The upper reaches of the Khukhra River
Botanical reserve	80.0	Near Parkhomivka village	The upper reaches of the Kotelva River
Total	233.9		

Table 4. Areas to be protected as part of the ecological network of the Krasnokutsk community of Bohodukhiv district, Kharkiv region [24].

Name, category and type of territory	Estimated area, ha	Location	Characteristics
Slobozhansky National Nature Park	10000.0	Around Krasnokutsk town	The Merla River valley
Botanical reserve of local importance "Kapransky"	150.0	Near Kapranske village	A plot of meadows in the Merla River valley
Total	10150.0		

1.27 % (compared to the existing 1.05 %) of the total area of the community. The prospective territories of the nature reserve fund in the Krasnokutsk community of the Kharkiv region are shown in tables 3 and 4.

In modern conditions, the legislation defines the following stages of creation of the nature reserve fund territories (NRF):

1. Conducting a survey of the territory to identify objects requiring protection.
2. Preparation of a justification, including a description of the territory value (biological, historical, etc.).
3. Submission of the application to the responsible state authority (Ministry of Ecology in case of creation of territories of national importance, regional state administration in case of creation of territories of local importance).
4. Consideration and approval of the application by the responsible state body.
5. Approval of the application with the owners of land plots.
6. Development of the project for the formation of the territory.
7. Approval by the Cabinet of Ministers of Ukraine (the relevant commission of the regional council in case of creation of territories of local significance).
8. Signing of a Presidential Decree (for territories of national importance) or adoption of a decision by the regional council (in the case of territories of local importance).

As part of our study, we propose to supplement the stages of establishing nature reserve territories with the following recommendations.

At the stage of conducting a site survey to identify sites in need of protection, it is recommended to give preference to large and spatially coherent areas. It is also necessary to take into account the presence of several ecosystems in their natural state within the same site (e.g., river valley, steppe slopes, forest, etc.), which contributes to the increase of biodiversity in such a territory. The inclusion of reserved areas as objects of the nature reserve fund is an important step in expanding the nature reserve fund regime. Particular attention should be paid to the group of territories that were reserved in 1997 and still do not have the appropriate nature reserve status (table 5).

Table 5. The list of natural areas reserved for the creation of new or expansion of existing objects of the nature reserve fund (excerpt) [24].

Decision to reserve	Name of the territory/object offered to be created	Size, ha	Location
Decision of the Kharkiv Regional Council of the XIV session of the XXII convocation of 20.11.1997 “On reserving natural areas and objects for future conservation”	Ornithological reserve	328.0	Izium district (former Balakliya district) near Vilhuvatka village
	Soil reserve	50.0	Izyum district (former Balakliia district) near Petrivske village
	Paleontological reserve	96.6	Izium district (formerly Barvinkove) near the village of M.Garazhivka
	Botanical reserve	256.0	Izyum district (formerly Barvinkove) near Havrylivka village

IOP Conf. Series: Earth and Environmental Science **1415** (2024) 012050 doi:10.1088/1755-1315/1415/1/012050

To expand existing protected areas, it is recommended to conduct a study of areas bordering or adjacent to existing protected areas. This research should be carried out by biological scientists, especially employees of nature reserves, national parks, universities, research institutes and other relevant institutions, in order to determine the possibilities and necessity of expanding these areas.

Working with the local population and land users is one of the most difficult and crucial stages in the process of creating protected areas [30, 31]. This is due to the fact that there is a low level of public awareness of conservation issues, which can lead to a lack of understanding of the need for conservation and even active resistance to these processes. Therefore, it is necessary to disseminate information (in the form of oral communication, through booklets, information leaflets, presentations, mass media, etc.) among the local population, landowners and land users about the benefits and limitations that will arise when creating a territory or object of the nature reserve fund in order to form a positive attitude towards this process.

4. Conclusions

The slowdown in the formation of new territories and objects of the nature reserve fund in Kharkiv region and Ukraine as a whole is a consequence of the current socio-economic situation. This problem needs to be addressed at the state level by amending the current legislation. In particular, it is necessary to simplify the procedures for creating new nature reserve sites, especially in terms of coordination with local governments and executive authorities. It is also important to introduce economic measures to encourage land users and landowners to create territories and objects of the nature reserve fund on their lands. This may include effective economic incentives and budgeting at all levels for the purchase of land plots for further preservation as protected areas.

Although the existing protected area indicator in Kharkiv region, defined as the ratio of the area of land in the nature reserve fund to the total area of the region, exceeds the average indicator for Ukraine by 1.4 %, it is significantly lower than in neighboring European countries and below the European average. Taking into account the natural, historical, physical and geographical features of the region, the optimal reserve rate for the region today is considered to be at least 10 %.

The solution of problematic issues is complicated by the lack of a clear strategy for the development of nature reserves and the lack of the management system coordination at the national and regional levels. The nature reserve fund of the Kharkiv region is distributed among different departmental structures, local governments and various business entities, including private enterprises. All of this makes it impossible to create a proper vertical management structure that would ensure effective management and control over the formation and maintenance of the nature reserve fund in the region.

Despite the long period of formation of the modern network of NRF in Kharkiv region, the functioning of protected areas faces legislative, institutional, organizational, and financial problems. To solve them, it is necessary to ensure the implementation of measures to ensure appropriate conditions for the implementation of a unified state policy in the field of reserve development in Ukraine, to create a scientifically based network of NRF objects and form an ecological network on its basis as a component of the Pan-European Ecological Network, to ensure the development and implementation of scientific research and monitoring of ecosystems, to create a system of balanced nature management, environmental education and recreational use of their resources on the basis of protected areas and NRF objects.

In order to intensify the processes aimed at achieving Goal 15 in Ukraine, it is necessary to intensify the work of local authorities to create new territories and objects of the nature reserve fund; to promote the transition to organic agriculture to preserve/improve soil fertility and biodiversity, reduce land and water pollution (artificial pesticides/herbicides, etc.); to take measures to harmonize policies related to the use of natural resources and their conservation; to ensure effective management of territories and objects of the nature reserve fund of local and national importance, including increasing the amount of financial resources allocated for the conservation of the nature reserve fund; to intensify work on the implementation of the National Action Plan to Combat Land Degradation and Desertification, the Strategy and the implementation of tasks on the neutral level of land degradation; to ensure improvement of economic mechanisms to stimulate land protection and restoration of soil fertility; to ensure the regulation of the transformation of the country's land structure (reduction of arable land, increase of forest cover, restoration of hayfields and pastures, etc.) in the process of decentralization of power and transfer of land from state ownership to the ownership of united territorial communities.
